Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai

***Abstract*—The increasing integration of artificial intelligence (AI) within cybersecurity has necessitated stronger encryption methods to ensure data security. This paper presents a comparative analysis of symmetric (SE) and asymmetric encryption (AE) algorithms, focusing on their role in securing sensitive information in AI-driven environments. Through an in-depth study of various encryption algorithms such as AES, RSA, and others, this research evaluates the efficiency, complexity, and security of these algorithms within modern cybersecurity frameworks. Utilizing both qualitative and quantitative analysis, this research explores the historical evolution of encryption algorithms and their growing relevance in AI applications. The comparison of SE and AE algorithms focuses on key factors such as processing speed, scalability, and security resilience in the face of evolving threats. Special attention is given to how these algorithms are integrated into AI systems and how they manage the challenges posed by large-scale data processing in multi-agent environments. Our results highlight that while SE algorithms demonstrate high-speed performance and lower computational demands, AE algorithms provide superior security, particularly in scenarios requiring enhanced encryption for AI-based networks. The paper concludes by addressing the security concerns that encryption algorithms must tackle in the age of AI and outlines future research directions aimed at enhancing encryption techniques for cybersecurity.**

***Keywords*—Algorithms; analysis; artificial intelligence; asymmetric encryption; cryptography; cybersecurity; symmetric encryption**

I. Introduction

Algorithms are and were always the driving force behind cryptography and cybersecurity as we are marching towards the artificial intelligence (AI) and machine learning era. Several countermeasures, techniques, and cybersecurity practices are popular with the use of machine learning and deep learning algorithms apart from AI algorithms [1-2]. As we know cybersecurity combines information security and network security, the annual number of data breaches is growing every year. Loss of private information, malware attacks, use of smart gadgets, growing number of internet population, and several others are upcoming challenges for cryptography algorithms.

Vulnerabilities and attacks on ciphers, private keys, and algorithms are increasing as we are considering "Security for AI" and vise-versa [3-4]. New and unexpected attacks, development of several frameworks and tools are going on as we discuss various encryption algorithms. From the initial use of symmetric algorithms like Data Encryption Standard (DES), and their several weaknesses we tend to know that hackers are exploiting the powerful algorithms (like SHA3, MD5, up to CRYSTALS) today. The use of "secret key" in symmetric algorithms (although asymmetric works a little better as compared to symmetric) is no longer secret as attackers have successfully compromised the key in both symmetric and asymmetric algorithms.

The emergence of AI has revolutionized cybersecurity, providing adaptive and dynamic encryption techniques to combat swiftly changing cyber threats [1]. AI-driven methodologies have enhanced encryption systems' resilience, facilitating real-time identification of anomalies and threats that conventional methods find challenging to spot [2]. The use of AI, especially via machine learning (ML) and deep learning (DL) algorithms, has markedly improved the efficacy of encryption methods, rendering them more adept at managing the increasing complexity and volume of contemporary data environments.

AI is becoming more and more integrated into cybersecurity and encryption as technology advances. AI is essential for protecting AI systems from complex cyberattacks, in addition to fortifying encryption procedures by streamlining key generation and data security techniques [3]. In an increasingly linked and insecure digital world, the synergy between AI and encryption is essential because it allows more effective, scalable, and proactive security measures, guaranteeing the security of both data and AI systems [4].

This paper is structured as follows to explore the comparative analysis of encryption algorithms and their relevance in modern cybersecurity, particularly in the AI era. Section II provides a background study, outlining the historical evolution and challenges of cryptographic algorithms, and establishing the role of AI in enhancing these methods. Section

III examines the technical aspects of various encryption algorithms, focusing on their contributions to safeguarding sensitive data in complex systems. Section IV offers a comparative analysis of symmetric encryption (SE) and asymmetric encryption (AE), highlighting key differences in terms of efficiency, security, and scalability. Section V discusses the role of AI in transforming encryption practices, focusing on how AI enhances real-time adaptability, tackles emerging threats, and enables personalized encryption strategies. Section VI focuses on the security challenges encryption faces in modern society, particularly against emerging cyber threats. Section VII presents the discussion and conclusions, summarizing the insights gained from the comparative analysis and suggesting improvements for existing encryption techniques. Lastly, Section VIII outlines the future scope of research, discussing potential advancements in encryption algorithms and their application in AI-driven cybersecurity solutions.

II. Background Study

The foundation of contemporary encryption methodologies is well-examined in the literature, providing critical insights into their application in AI-driven contexts. Kapoor and Thakur [5] offer a thorough comparative analysis of symmetric and asymmetric key algorithms, underscoring the growing importance of encryption in safeguarding digital information in an increasingly networked environment. Their analysis highlights the superiority of asymmetric encryption, which employs two keys to enhance security through mathematical complexity. For symmetric algorithms, they emphasize the adaptability and efficiency of the Advanced Encryption Standard (AES), particularly its resilience against common attacks and its rapid execution speed. In contrast, the authors identify Elliptic Curve Cryptography (ECC) as the most secure asymmetric technique, noting its reliance on the algebraic properties of elliptic curves and finite fields. This detailed examination is a vital reference for algoTRIC, as it informs the optimization of AES and ECC within its architecture for large-scale, multi-agent systems. By focusing on trade-offs between speed and security resilience, the paper addresses critical challenges in mitigating emerging cyber threats.

Building on this foundation, Soomro et al. [6] conduct a comprehensive analysis of both symmetric and asymmetric cryptographic algorithms, focusing on their role in strengthening cybersecurity across diverse contexts. Their work identifies key cryptographic objectives—secrecy, integrity, authenticity, and non-repudiation—as essential for secure communication and data protection. They emphasize the speed and efficiency of symmetric algorithms, such as AES, making them suitable for high-throughput applications. Conversely, they highlight the robustness of asymmetric algorithms, notably RSA, for contexts requiring secure key management. This review contributes significantly to algoTRIC by elucidating how cryptographic strategies can be adapted to address the unique challenges of AI-driven systems. By balancing performance, scalability, and security resilience, this work helps frame the escalating need for robust data protection in modern cybersecurity frameworks.

Furthering these insights, Ustun et al. [7] introduce a machine learning-based intrusion detection system designed to address cybersecurity vulnerabilities in smart grids. Their approach leverages IEC 61850 Sampled Value (SV) messages to identify cyberattacks, particularly false data injection (FDI), within contemporary power system communication frameworks. By utilizing machine learning to distinguish between normal operations and cyberattacks, their system demonstrates high accuracy in identifying symmetrical and asymmetrical faults as well as FDI attacks. These findings are particularly relevant to algoTRIC's efforts to incorporate advanced intrusion detection algorithms in AI-driven environments. Specifically, their approach underscores the importance of integrating encryption techniques, such as AES and ECC, to secure communication streams while ensuring real-time intrusion detection in complex, multi-agent systems.

Similarly, Arora [8] examines the critical role of cryptographic methods in cybersecurity, emphasizing the importance of encryption and decryption for protecting digital data. The study underscores the efficiency of symmetric encryption techniques, such as AES, for managing large-scale data, alongside the superior security of asymmetric algorithms, like RSA, for secure key management. By addressing the fundamental principles of cryptography—confidentiality, integrity, and authenticity—Arora provides essential guidance for incorporating encryption into AI-driven systems. This analysis highlights the trade-offs between the high performance of symmetric encryption and the enhanced security of asymmetric approaches, offering a roadmap for optimizing encryption methods in AI systems that must balance computational demands with robust data protection.

Finally, Henriques and Vernekar [9] focus on the integration of symmetric and asymmetric cryptography to secure communication in Internet of Things (IoT) networks. They address the unique challenges posed by IoT systems, where sensitive data transmitted between devices demands heightened protection against cyberattacks. Their methodology combines the speed and efficiency of symmetric encryption, exemplified by AES, with the secure key management capabilities of asymmetric cryptography, such as RSA. This dual approach mitigates prevalent IoT vulnerabilities, including insecure network services and weak authentication mechanisms. Their work is particularly relevant to algoTRIC, as it explores how combining encryption algorithms can balance speed, scalability, and security in complex, large-scale AI-driven systems.

III. Encryption Algorithms for Cybersecurity

Building on the foundational insights from prior studies on the comparative strengths and applications of symmetric and asymmetric encryption algorithms, the next section delves into the practical implementation of these techniques within contemporary cybersecurity solutions. Encryption techniques and complex algorithms with respect to privacy preserving, wireless sensor networks (WSN), and AI are rapidly used in several system applications and solutions [10-11]. Applications like healthcare monitoring, smart cities, advertising, logistics with analysis of energy, overhead, speed are used for several AI-powered business models. Financial transactions (may consist of hash, public key, private key, and digital signature) today require high level security using Secure Hashing Algorithms

(SHA) and Message Digest (MD) algorithms used by distributed ledgers and blockchain technology (Table I).

Compressed sampling on encrypted images with a combined random Gaussian measurement matrix can also be used for AI based image encryption [12]. To resist several kinds of cyberattacks (primarily as primage attacks, collision attacks) that can pass plaintext sensitivity tests for successful communications. On the other hand, network security or endpoint security (of or partial of cryptography and/or cybersecurity), is fully achieved through data encryption using artificial intelligence [13]. Improving encryption speed, wireless sensors security, integrity of data proposed a proactive solution with remarkable performance as compared to static encryption methods.

Homomorphic encryption has arisen as a formidable method to bolster data security in AI-driven applications, facilitating computations on encrypted data without necessitating decryption. This capacity is essential for preserving data privacy in sensitive domains such as healthcare, banking, and smart city infrastructures, where AI is extensively employed for decision-making and data analysis. Homomorphic encryption encompasses several varieties, including fully homomorphic encryption (FHE), slightly homomorphic encryption (SWHE), and substantially homomorphic encryption (PHE), each presenting distinct trade-offs regarding computational complexity and efficiency [14]. Although Fully Homomorphic Encryption (FHE) permits infinite operations on encrypted data, its practical application is frequently constrained by substantial computing expenses and reduced processing velocities. Conversely, SWHE and PHE provide more efficient options by facilitating a limited range of actions, rendering them more appropriate for situations that emphasize performance while maintaining data security. In AI-driven contexts, including these encryption methods into machine learning models not only protects data during training and inference but also mitigates risks associated with emerging vulnerabilities such as data leakage and unauthorized access. As AI progresses, enhancing these encryption techniques will be essential for guaranteeing strong and scalable cybersecurity solutions.

Furthermore, the computational complexity of cryptographic algorithms emerges as a central concern, influencing not only the feasibility of deploying large-scale encryption solutions but also the security posture of data processing pipelines. Evaluations of complexity commonly employ Big-O notation, time-to-encrypt metrics, key-size scaling factors, and throughput measurements, all of which help determine the practical utility of a given cryptographic method. For symmetric encryption algorithms such as the Advanced Encryption Standard (AES), computational efficiency often proves to be one of their distinguishing strengths, as the complexity scales linearly with data input size, resulting in O(n) operations and predictable performance outcomes even as datasets grow larger. In contrast, asymmetric algorithms like RSA exhibit more pronounced complexity, commonly represented as $O(n^3)$ or higher when operations on large integers are involved, reflecting the significant computational overhead associated with public-key cryptography.

Moreover, the integration of AI-based threat detection and encryption acceleration further complicates these estimates, as machine learning heuristics and hardware-assisted optimizations can alter the baseline complexity by dynamically adjusting key distribution strategies, refining block-cipher rounds, or adopting hybrid encryption approaches. Evaluating complexity also demands close attention to scalability parameters in distributed environments, since multi-agent systems often require concurrent encryption-decryption operations across decentralized nodes, thereby magnifying the importance of parallelizable algorithms. Within this context, assessing complexity involves quantifying performance differentials over heterogeneous architectures, analyzing latency contributions from memory access patterns and cache line misses, and simulating the behavior of algorithms under diverse workload distributions.

As such, the integration of AI approaches with conventional encryption algorithms such as AES has demonstrated effectiveness in augmenting data security, especially in volatile threat landscapes. Recent research indicates that the integration of machine learning models, such as k-Nearest Neighbors (k-NN), with AES encryption markedly enhances the identification and mitigation of anomalies, facilitating real-time responses to new cyber threats. The k-NN's pattern recognition capabilities enhance the encryption process, adapting to emerging attack vectors and bolstering AES's resilience against advanced attacks [15]. This method enhances secure data transmission and bolsters the integrity of secret data storage. With the increasing volume and complexity of data in AI-driven systems, integrating machine learning with encryption methods such as AES is crucial for adopting a proactive approach to cybersecurity.

Chaotic algorithms have arisen as an effective solution for image encryption in AI-driven networking systems, owing to its intrinsic characteristics such as sensitive dependence on beginning conditions, topological mixing, and long-term unpredictability [16]. These qualities are utilized to generate intricate encryption patterns, where even minor alterations in the original settings result in completely distinct encrypted outputs, hence substantially improving data security. Recent implementations indicate that chaotic algorithms, along with sophisticated encryption techniques, can provide non-linear transformations that effectively rearrange and disperse pixel positions, rendering the image data into a highly randomized state. This method guarantees that the encryption process emulates a dynamical system, rendering the reversal of the process without precise system parameters computationally impractical [16]. Through the application of repeated chaotic functions, these encryption methodologies guarantee elevated entropy in the encrypted data, so successfully countering brute-force assaults and enhancing resilience against cryptographic scrutiny. In AI-driven environments, where data security is imperative against advanced threats, the amalgamation of chaotic systems with encryption enhances the security framework while preserving computational performance by reducing processing overhead.

TABLE I. INTUITIONS (UP TO THREE) OF SOME COMMON ADVANCED ENCRYPTION ALGORITHMS FOR SECURITY AND CRYPTOGRAPHY IN THE ARTIFICIAL INTELLIGENCE (AI)-DRIVEN SOCIETY

Ref	Encryption Type	Intuition I	Intuition II	Intuition III
[10]	Partial Homomorphic	Enables privacy-preserving computations on encrypted blockchain data	Mitigates risks from collision, preimage, and wallet attacks	Optimizes computational overhead for AI-integrated blockchain environments
[11]	AI-Driven Data Solutions	Adapts encryption parameters dynamically based on real-time network conditions	Integrates anomaly detection to proactively adjust encryption settings against threats	Optimizes computational and energy resources while maintaining high security levels
[12]	AI Image	Utilizes hyperchaotic sequences for robust pixel scrambling and diffusion	Enhances resistance against differential and brute-force attacks	Achieves high randomness and compression efficiency with compressed sensing
[13)	Innovative Data for WSANs	Adapts encryption parameters dynamically using AI for real-time threat response	Leverages LSTM networks to optimize encryption based on sequential data analysis	Employs Isolation Forests to enhance anomaly detection and network resilience
[14]	AI-based Homomorphic	Enables privacy-preserving computations on encrypted data without decryption	Mitigates data exposure risks in untrusted environments like cloud computing	Supports collaborative AI tasks with multi-key encryption across multiple parties
[15]	AI and AES	Combines AES's robust encryption with AI for adaptive threat detection	Utilizes AI-driven k-NN for real-time anomaly analysis in encrypted data	Enhances encryption efficiency through AI-optimized parameter selection
[16]	Image Transmission	Leverages chaotic mapping for high sensitivity and complex key generation	Enhances image confidentiality through pixel-level scrambling and diffusion	Mitigates brute-force attacks via topological chaos and statistical uniformity

IV. COMPARISONS OF ALGORITHMS W.R.T. SE AND AE

As encryption techniques continue to evolve, their applications in various domains underscore the need for a nuanced understanding of their operational strengths and limitations. The exploration of how these algorithms integrate into modern cybersecurity frameworks provides a foundation for deeper analysis. Thus, a focused comparison follows between symmetric encryption (SE) and asymmetric encryption (AE) will elucidate the key distinctions that influence their use. By examining differences in key management, scalability, performance, and reliability, this analysis aims to identify the most suitable encryption methods for specific applications and highlight the critical trade-offs involved in their deployment within contemporary cryptographic systems.

To evaluate the cryptographic algorithms, it is significant to contrast symmetric encryption algorithms with asymmetric encryption algorithms as modern cryptography is designed based on symmetric and asymmetric encryption which are two fundamental categories of encryption algorithms (Table II). The main purposes of both types of encryption are the same, that is to safeguard the data security and integrity over the diverse applications. Although their purposes are the same, they have significant differences based on the way of managing encryption keys, evaluating performance and functionality requirements. To identify the most effective encryption method for a particular scenario, it is essential to distinguish the strength, weakness, functionalities and other features of both types of encryption methods. This section of the paper distinguishes the fundamental types of encryption algorithm based on key management, scalability, swiftness and reliability.

One of the main differences of symmetric and asymmetric encryption is the number of keys used in the encryption process. There are two types of keys used in encryption and decryption processes which are known as public key and private key. In a symmetric algorithm, a private key is used alone to encrypt and decrypt data [17]. On the other hand, an asymmetric algorithm uses both the public key and private key where the public key is used to encrypt data and private key is used to decrypt data. Public key encryption is designed based on intensive computational mathematical functions; therefore, asymmetric algorithms are not very suitable or efficient for minor devices.

The second important term of differences between symmetric and asymmetric encryption is reliability. The encryption process of the symmetric method is simpler than the asymmetric method, however, in symmetric method both the sender and receiver share the common private key to encrypt and decrypt data which is a major concern about data security as eavesdropping can be conducted by attacker anytime in the channel of data exchange. Alternatively, in asymmetric encryption, the public key is used to encrypt the data while the private key is used to decrypt the data [18]. As the private key is secret and only the receiver knows the private key, it becomes very difficult for the attacker to decrypt the original data. As a result, asymmetric encryption is considered more reliable in comparison to symmetric encryption in case of data exchange.

Swiftness of encryption and decryption is also a very powerful component that can be considered to differentiate symmetric and asymmetric encryption. Al-Shabi, in his paper, conducted an analysis to compare the performance for identifying the strengths and weaknesses of different types of

symmetric and asymmetric encryption based on various factors such as battery consumption, block size, structure, time consumption and types of attacks. His result shows that based on real-time encryption, a symmetric algorithm is much faster than asymmetric encryption [18]. Similar kind of study was conducted by Panda in 2010. Her paper indicates that a symmetric algorithm is almost 1000 times faster than an asymmetric algorithm as an asymmetric algorithm needs more powerful computational resources. To compare different types of algorithm, 3 types of file such as text, image and binary were used in her analysis where the performance factors were decided considering Encryption Time, Decryption Time and Throughout. The result of her study found better performance from the AES algorithm, a subcategory of symmetric encryption, in comparison to other encryption algorithms based on Encryption Time, Decryption Time and Throughout [19].

Use of blocks is also a considerable component that can be used to distinguish between symmetric and asymmetric algorithms. There are mainly two important components considered in symmetric encryption known as block cipher and stream cipher, which are significantly crucial for confidentiality of data and integrity of cryptography [21]. AES, a subcategory of symmetric encryption, is operated on plaintext where the size of the block is 128 bits. This block cipher can also utilize different key lengths such as 128 bits, 192 bits or 256 bits of cipher secret [20]. On the other hand, asymmetric encryption does not require block size to encrypt data, rather this method leverages the idea of chunk data processing that is correspondent to the key size.

In the field of AI-driven cybersecurity, selecting between symmetric encryption (SE) and asymmetric encryption (AE) involves a thorough evaluation of performance, scalability, and security requirements. SE algorithms, such as AES, excel in real-time AI applications due to their high-speed encryption and low computational demands, which highlights as essential for AI tasks requiring rapid data processing [19]. However, AE algorithms like RSA provide enhanced security by leveraging public-private key pairs, a feature that underscores as crucial for maintaining confidentiality in sensitive data exchanges [18]. While SE is ideal for resource-constrained AI environments, such as IoT, due to its lower energy consumption, AE's computational intensity makes it better suited for secure initial key exchanges in distributed AI systems [20]. This difference in resource demands directly impacts scalability; SE supports continuous, high-throughput data streams often required in AI workflows, while AE's structure enables secure data sharing across complex, multi-agent networks through recent advances in secure communication protocols [21]. Effective cybersecurity in AI ultimately requires balancing SE's efficiency and AE's strong data protection, particularly in applications where threats to data integrity and confidentiality are significant [17].

TABLE II. COMPARISON OF SYMMETRIC ENCRYPTION AND ASYMMETRIC ENCRYPTION IN AI-DRIVEN CYBERSECURITY

Aspect	Symmetric Encryption (SE)	Asymmetric Encryption (AE)	Ref.
Integration with AI	SE algorithms like AES and Blowfish are efficient for real-time AI-driven data processing, supporting rapid encryption for high data volumes in AI workflows.	AE algorithms such as RSA and ECC are suitable for securely establishing initial connections in AI systems, though slower for real-time processing.	[19]
Data Throughput	High throughput makes SE ideal for handling large data in AI tasks (e.g., image processing or continuous data flows in AI-based IoT).	Lower throughput is better for secure, one-time exchanges rather than sustained high-speed AI-driven processing.	[21]
Resource Optimization	Low computational demands allow SE to support AI applications in resource-constrained environments, like mobile AI/IoT.	Higher resource needs make AE less suitable for low-power AI applications, though ideal for secure initial setup in complex AI networks.	[20]
Real-Time Efficiency	SE provides rapid encryption/decryption, enhancing real-time AI functions like anomaly detection in cybersecurity.	Slower speed limits AE in real-time AI scenarios; however, it provides robust security for secure data onboarding in AI systems.	[18]
Scalability in AI Systems	SE scales well within high-speed AI environments, enabling quick encryption across multi-agent or large data environments.	AE scales better for secure AI communications in distributed or cloud-based systems, especially for sensitive exchanges.	[21]
Battery and Power Use	Low power consumption suits AI-based mobile or IoT cybersecurity applications, allowing efficient continuous data encryption.	Higher power demand limits AE's suitability for battery-dependent AI devices, though it's viable for centralized secure key exchanges.	[20]
Security Strength	SE algorithms are faster but require secure key management in AI-driven environments to prevent compromise.	AE's public-private key pair provides greater security in AI-based networks with high confidentiality needs, particularly when securing data exchanges.	[18]
Complexity	Simpler structures in SE make it easier to embed into AI cybersecurity models needing rapid, low-latency responses.	AE's complexity is suitable for initial secure connections but can slow down ongoing high-volume AI data processing.	[19]
Use in AI Applications	Frequently applied in AI-driven real-time applications like intrusion detection, anomaly detection, and real-time threat monitoring.	Used to establish secure connections for sensitive AI operations, such as secure federated learning or distributed AI models.	[17]

V. Algorithms in the AI Era

The comparative analysis of symmetric and asymmetric encryption algorithms reveals critical insights into their respective strengths and limitations, offering a clear framework for selecting appropriate methods based on specific requirements. However, as the cybersecurity landscape continues to evolve, traditional encryption approaches must adapt to emerging challenges. The next section explores how AI is evolving encryption by introducing adaptive and dynamic capabilities. Through the integration of ML and DL models, encryption techniques are becoming more resilient, enabling real-time detection of threats and enhancement of key generation processes.

AI is increasingly integrated into encryption techniques, offering adaptive and dynamic solutions to address evolving cybersecurity threats. ML models play a pivotal role by analyzing large datasets to detect anomalies, making encryption protocols more resilient to cyberattacks [22] (Fig. 1). In recent years, there has been a surge in the application of deep learning to enhance cryptographic algorithms, particularly through convolutional neural networks (CNNs). These models help to create more robust key generation processes, as demonstrated in recent studies where CNNs were applied to Advanced Encryption Standard (AES) algorithms to improve encryption performance and security resilience [23]. Such AI-driven encryption systems are capable of continuously evolving, adapting to new security challenges, and countering sophisticated hacking attempts in real-time [24].

In addition to improving encryption processes, AI also aids in the proactive detection and mitigation of cyber threats. As Rangaraju [25] notes, through leveraging ML models, particularly deep learning algorithms, cybersecurity systems can predict potential vulnerabilities and strengthen encryption methods. These techniques not only enhance the overall security infrastructure but also allow for the development of intelligent, self-updating systems that can respond to newly emerging cyber threats. The real-time adaptability of AI in encryption is crucial, especially as traditional cryptography methods, such as RSA, become increasingly vulnerable to advanced cyberattacks [26]. This integration of AI into cryptography sets the stage for more secure communication and data protection in the AI era [27].

With the newly found ability to detect and mitigate cybersecurity threats, AI assists in offering advanced solutions that traditional encryption methods struggle to match. These solutions include CNNs, as noted, but also long short-term memory (LSTM), AI-driven systems that can analyze vast amounts of data in real-time, identifying patterns that signal potential threats. These AI-enhanced systems use data profiling techniques to categorize security events, enabling more accurate discrimination between legitimate threats and false positives [28]. For example, a study employing AI-based security information and event management (SIEM) demonstrated improved accuracy in detecting network intrusions by combining event profiling with various neural networks, outperforming traditional machine learning approaches [29] [30]. The ability to adapt to complex and evolving attack patterns makes these new technologies an essential tool for modern cybersecurity.

Such capacity to adapt and learn from emerging threats is critical as cybercriminals continuously develop more sophisticated attack methods. Deep learning models, especially when applied to real-time cybersecurity monitoring, can detect anomalies much faster than traditional methods, providing organizations with the agility to respond to cyberattacks proactively [31]. Recent advancements in deep learning-based intrusion detection systems (IDS) have shown promising results in identifying zero-day attacks, reducing detection time, and improving overall system security [32]. This proactive approach allows for not only quicker detection but also the anticipation of future attacks, helping organizations stay one step ahead of cybercriminals.

On the other hand, although integrating AI into encryption processes provides significant advancements and benefits, there are also numerous challenges and ethical concerns. One of the primary issues is the risk of over-reliance on AI-based systems, which could lead to complacency in monitoring and updating security protocols [33]. The dynamic nature of these tools can make encryption systems highly efficient, but this reliance also increases the risk that undetected vulnerabilities could be exploited by adversaries using AI for malicious purposes [34]. Furthermore, as AI-driven encryption systems become more widespread, the sheer volume of data processed raises concerns about privacy violations. AI models often require vast amounts of personal or sensitive information to function optimally, which can lead to unintended privacy breaches if not managed properly [35].

Another ethical concern involves the dual-use nature of AI technologies in encryption. While AI enhances security, it also opens avenues for adversaries to exploit AI systems to breach encrypted communications. AI-based algorithms could potentially be reverse-engineered or manipulated to bypass security protocols, creating a new type of cyber threat [36]. The sophistication of AI tools allows attackers to uncover hidden patterns or weaknesses in encryption systems, potentially leading to large-scale data breaches. This highlights the need for comprehensive governance frameworks that address not only the technical challenges but also the ethical risks associated with deploying AI in encryption and cybersecurity [37].

Looking ahead, ever-advancing AI tools are expected to play an increasingly central role in the future of encryption, evolving alongside the cyber threat landscape. The adaptability of AI to real-time data allows for personalized encryption solutions tailored to the behaviors and preferences of individuals, making it more difficult for cybercriminals to execute successful attacks [38]. Through learning from patterns in network traffic and user behavior, AI can continuously optimize encryption protocols, ensuring that they remain effective against emerging threats [39]. This ability to adapt to new challenges positions the technology as a vital tool in maintaining robust cybersecurity defenses in the coming years.

Moreover, integration into encryption technologies opens possibilities for more seamless and efficient security solutions. The use of AI to automate encryption processes could lead to faster, real-time encryption adjustments without human intervention. This is particularly valuable in dynamic environments, such as the Internet of Things (IoT), where

devices continuously communicate and exchange data [40]. The ability to monitor and respond to security threats in real-time ensures that encryption methods are always up to date, thus reducing the risk of breaches [41]. However, these advancements must be balanced with considerations for ethical use and the prevention of potential misuse of AI in malicious hacking activities.

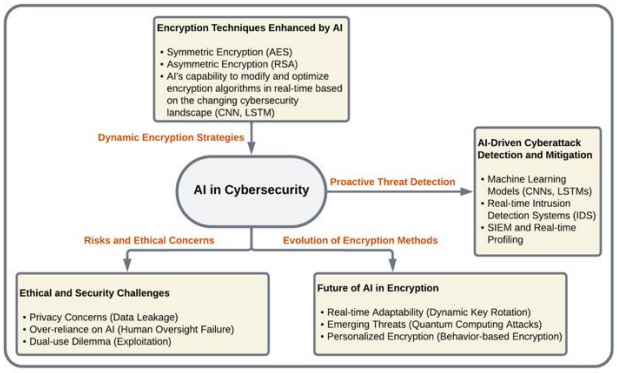

Fig. 1. AI-driven enhancements in encryption (including symmetric and asymmetric) and cybersecurity.

In the era of rapid technological progress, artificial intelligence has emerged as a revolutionary influence across several domains, including cybersecurity. As AI systems advance, the algorithms utilized for data protection as well as encryption must adapt to the intricacies of contemporary threats. The convergence of AI and encryption offers prospects for bolstering cybersecurity resilience via real-time monitoring, adaptive response strategies, and intelligent automation.

A. *Artificial Intelligence-Enhanced Encryption for Improved Cybersecurity*

As AI increasingly integrates with encryption, its transformative impact on cybersecurity becomes evident. The prior discussion outlined the potential of AI-driven methodologies in enhancing traditional encryption systems, offering adaptive and dynamic capabilities. This section delves deeper into the specific mechanisms by which AI enhances both symmetric and asymmetric encryption techniques, focusing on how AI-driven solutions address emerging cybersecurity threats through improved key generation, anomaly detection, and real-time responsiveness.

Conventional encryption techniques, such as the Advanced Encryption Standard (AES) in symmetric encryption and RSA in asymmetric encryption, have been significantly augmented by AI to boost their security and efficiency. AI's capacity to analyze vast datasets, identify trends, and adapt to evolving threats positions it as an ideal collaborator for cryptographic systems.

In symmetric encryption, AI-driven optimization strategies dynamically create, and update AES encryption keys based on real-time threat assessments. Machine learning (ML) algorithms now anticipate vulnerabilities and pre-empt brute-force attacks by identifying anomalous patterns across encrypted data. This dynamic methodology transforms AES into a more adaptable and resilient system, capable of addressing diverse threats without compromising operational speed [32].

For asymmetric encryption, RSA benefits from AI's ability to refine the key generation process. Genetic algorithms, a subset of AI methodologies, enhance the selection of prime numbers, ensuring that encryption keys are robust and less vulnerable to attacks [23]. These advancements reduce computational demands for both encryption and decryption processes while maintaining high levels of security, particularly in environments requiring secure communications.

Deep learning methodologies further expand the potential of AI-enhanced encryption. Techniques such as convolutional neural networks (CNNs) and recurrent neural networks (RNNs) are now integrated into cryptographic frameworks to monitor encrypted communications in real-time. These algorithms detect irregularities in data streams, identify potential breaches, and enable pre-emptive responses to system intrusions [33]. By adding this layer of real-time detection, AI provides an additional safeguard that static encryption technologies cannot match.

Moreover, the incorporation of AI into cryptographic processes enhances both efficiency and effectiveness. For instance, CNNs within AES key generation operations not only improve security but also lower computational costs [28]. In resource-limited environments such as the Internet of Things (IoT), asymmetric cryptographic methods like RSA leverage AI-driven approaches to optimize encryption and decryption processes, ensuring secure communication without overburdening system resources [29].

B. *Homomorphic Encryption and Privacy-Enhancing Artificial Intelligence Methodologies*

The integration of AI into conventional encryption techniques highlights its transformative potential to enhance security, efficiency, and adaptability. While these advancements address many existing challenges, the need for encryption methods that maintain data confidentiality during processing is paramount, particularly in fields requiring large-scale data analysis. As such, one of the most exciting advancements in AI-driven encryption involves the progression of homomorphic encryption. Homomorphic encryption enables calculations upon encrypted data without necessitating decryption, so safeguarding sensitive information during processing. This is especially beneficial in AI applications requiring the analysis of large data sets, such as in finance, healthcare as well as cloud computing. Also, AI is significantly enhancing the efficiency and scalability of homomorphic encryption techniques. Utilizing AI methodologies might enhance the efficacy of homomorphic encryption by reducing the noise typically accumulated during calculations, hence making these techniques more appropriate for practical use [35].

This advancement is particularly significant for privacy-preserving AI applications, in which sensitive data, such as health-related records and financial information, must be safeguarded throughout the analytical process [22]. Homomorphic encryption, in conjunction with AI, allows businesses to cooperate upon encrypted data without disclosing the underlying knowledge. This privacy-preserving methodology has considerable ramifications for sectors such as healthcare, where patient information may be safely exchanged

and evaluated across institutions without jeopardizing privacy or regulatory adherence [39].

Moreover, AI-based methodologies have begun to influence the design, evaluation, and implementation of encryption algorithms, offering novel avenues for both enhancing and challenging traditional security paradigms. Such approaches incorporate machine learning-based techniques to identify patterns in cipher operations, anticipate potential vulnerabilities, and recommend key management strategies tailored to diverse computational contexts. By employing deep learning models trained on large-scale encryption datasets, researchers can detect subtle correlations in encrypted traffic and refine key scheduling protocols, leading to more resilient cryptographic schemes. In addition to bolstering algorithmic integrity, AI-driven methodologies assist in automating threat detection, as real-time analytics enable dynamic adjustments to key sizes, modes of operation, and encryption parameters based on evolving adversarial tactics. The infusion of AI elements further empowers hybrid encryption approaches where neural networks guide the selection between symmetric and asymmetric algorithms, optimizing both security and computational efficiency.

Lastly, reinforcement learning agents can adaptively determine when to apply advanced cryptographic primitives, such as fully homomorphic encryption, by weighing computational overhead against security gains. Beyond defensive capabilities, AI-based methodologies facilitate the detection and prevention of side-channel attacks, since carefully tuned machine learning classifiers recognize subtle anomalies in power consumption or electromagnetic emissions. Although these techniques hold immense promise, they also raise new ethical and regulatory questions regarding data privacy, algorithmic transparency, and model interpretability, necessitating continuous oversight and methodological rigor in future AI-cryptography research.

C. Blockchain and Artificial Intelligence: A Collaborative Strategy for Security

As homomorphic encryption exemplifies the potential of AI-driven methodologies for securing sensitive data during processing, the integration of AI with blockchain technology offers a complementary avenue for advancing cybersecurity. Blockchain, known for its decentralized and secure architecture, has emerged as a critical tool for safeguarding digital transactions across industries such as finance, healthcare, and supply chain management. However, the growing complexity of blockchain applications demands greater efficiency, scalability, and resilience. AI's integration with blockchain not only addresses these challenges but also enhances the foundational security and operational efficiency of blockchain networks.

Blockchain's inherent security lies in its decentralized structure, which distributes data across multiple nodes to prevent tampering and ensure transparency. When combined with AI, this architecture is further fortified by novel cryptographic techniques such as AI-driven homomorphic encryption. These advanced methods secure data transmission across blockchain networks, even as the volume and complexity of transactions increase. The incorporation of AI enhances blockchain's ability to handle sophisticated encryption requirements, making it a more robust framework for industries that rely on secure, high-throughput digital transactions.

AI also revolutionizes blockchain's consensus mechanisms, which are essential for verifying transactions and maintaining data integrity. Traditional methods like proof-of-work (PoW) and proof-of-stake (PoS) are often criticized for their high energy consumption and computational inefficiencies. AI-augmented consensus algorithms address these limitations by streamlining the validation process, significantly increasing transaction speed while reducing energy demands [40]. This optimization makes blockchain networks more sustainable and scalable, enabling their adoption in diverse and resource-intensive applications without compromising security.

Beyond efficiency, AI contributes to blockchain's real-time security capabilities by identifying and mitigating threats as they arise. Machine learning and anomaly detection algorithms enable blockchain networks to detect irregular transaction patterns, prevent unauthorized access, and counter distributed denial-of-service (DDoS) attacks. These proactive measures ensure that blockchain remains a reliable and resilient platform for secure digital transactions [37]. The fusion of AI's adaptive intelligence with blockchain's decentralized infrastructure not only addresses existing challenges but also sets new benchmarks for trust, scalability, and security in an evolving digital ecosystem.

D. Artificial Intelligence and Quantum-Resistant Cryptography

The integration of AI with blockchain technologies demonstrates its potential to address contemporary cybersecurity challenges, but the emergence of quantum computing introduces a new frontier of threats. Quantum computers, with their unparalleled ability to solve complex mathematical problems, threaten to undermine traditional cryptographic methods such as RSA and elliptic curve cryptography (ECC). As this technological shift looms, AI is playing a pivotal role in developing quantum-resistant cryptographic methods to ensure the continued security of digital communications.

One of the most promising approaches to quantum-resistant cryptography involves lattice-based algorithms, which rely on the computational difficulty of solving lattice problems—a complexity that remains formidable even for quantum computers. AI methodologies enhance the development and evaluation of these post-quantum cryptographic algorithms by identifying potential weaknesses and optimizing their implementation in practical systems [30]. By leveraging AI-driven simulations and predictive modelling, researchers can refine lattice-based encryption techniques to ensure their resilience against both theoretical and practical quantum attacks.

In addition to fortifying cryptographic algorithms, AI also contributes to preparing for the broader implications of quantum computing. Through the simulation of quantum assaults, AI enables the rigorous testing of existing encryption methods under quantum conditions. This proactive approach not only helps to identify vulnerabilities but also informs the creation of robust cryptographic standards designed to safeguard sensitive information in the quantum age [27]. Moreover, AI models are

used to predict the pace and direction of quantum computing advancements, enabling the development of encryption methods that stay ahead of potential threats [26]. The synergy between AI and quantum-resistant cryptography exemplifies the forward-thinking strategies required to navigate this impending technological shift. As quantum computing capabilities grow, the collaboration of AI and cryptography will be instrumental in ensuring that encryption techniques evolve to meet new challenges.

E. Ethical Implications in AI-Enhanced Cryptography

As advancements in AI-driven encryption and quantum-resistant cryptography push the boundaries of cybersecurity, they also introduce complex ethical considerations. The deployment of such powerful technologies raises critical questions about transparency, accountability, and equitable access, necessitating a careful examination of the broader societal implications of AI-enhanced cryptography. The incorporation of AI within encryption systems presents significant ethical dilemmas. As AI algorithms increase in complexity, the need for openness and accountability in their decision-making processes, especially in encryption and cybersecurity, is intensifying. It is essential to design AI-driven cryptography systems with ethical concerns to foster confidence and avoid abuse.

A primary worry is the dual-use characteristic of AI technology. Although AI may improve encryption as well as cybersecurity, it may also be utilized by nefarious individuals to develop more advanced assaults or to avoid detection. Developing AI-driven encryption systems with strong ethical standards is crucial to avoid their misuse for bad reasons [36]. Furthermore, as AI along with encryption technologies proliferate, it is essential to guarantee their accessibility and equity. It includes tackling the digital divide including guaranteeing that modern encryption technologies are accessible to all societal sectors, not just to those with the means to use them [24].

To get farther into the AI age, encryption algorithms must advance to match the increasing sophistication of cyber threats. Artificial intelligence is significantly transforming both asymmetric and symmetrical encryption systems, which renders them more adaptable, effective, and safe. The integration of AI in key generation and real-time threat detection is transforming cybersecurity methodologies. Nonetheless, the prospect of AI-driven cryptography has concerns as well. It is essential for these systems to be morally robust, transparent, and resilient against new dangers, including those from quantum computing, to ensure their success. Advancing and perfecting AI-driven encryption methods will enable the establishment of an increased secure digital future which safeguards sensitive information while promoting innovation.

VI. Algorithm Security in Modern Society

Encryption algorithms are essential tools in maintaining the confidentiality and integrity of digital communications in modern society (Fig. 2). With the increasing reliance on digital platforms for both personal and professional interactions, ensuring secure communication has become a priority [42]. Algorithms such as the AES and RSA are widely adopted to protect sensitive data, including emails, financial transactions, and other online communications. AES, a symmetric key algorithm, is favored for its speed and efficiency in encrypting large volumes of data, making it suitable for applications where rapid data processing is critical [43]. In contrast, RSA, an asymmetric key algorithm, is often used for secure key exchanges and digital signatures due to its robust security features, although it operates at a slower speed [44]. Together, these algorithms form the foundation of secure digital communications, providing the first line of defense against unauthorized access and cyberattacks.

As society becomes more dependent on digital communication, the application of encryption algorithms continues to expand. For instance, hybrid encryption schemes that combine the strengths of both AES and RSA are becoming more popular. These hybrid systems leverage the efficiency of AES in data encryption and the strength of RSA in secure key management, ensuring that both the data and the encryption keys are protected during transmission [45]. Such combined approaches offer enhanced security, particularly in environments where large volumes of sensitive information are frequently exchanged, such as in e-commerce or financial institutions [46]. As encryption technologies evolve, they continue to play a vital role in safeguarding digital communication, adapting to new threats and ensuring that sensitive information remains confidential and secure [47]. Thus, actionable risk assessment methodologies are particularly valuable for organizations that rely heavily on algorithms for their security, as they provide a clear framework to assess vulnerabilities, adapt to evolving threats, and reduce reliance on external vendors [48].

Yet, as noted, the rapid adoption of IoT devices and cloud computing has created new vulnerabilities in cybersecurity systems, particularly due to the limited computing capabilities of many IoT devices [34]. Many of these devices rely on lightweight encryption algorithms, such as the Data Encryption Standard (DES) or AES, which are efficient but may be more susceptible to attacks due to their reduced complexity [49]. Additionally, IoT devices often lack regular security updates, making them easy targets for cybercriminals. Cloud computing environments further complicate the situation, as data in transit and at rest in the cloud are vulnerable to interception, especially during migration between different cloud platforms [49]. This growing complexity necessitates the development of more robust encryption techniques tailored to the needs of both IoT and cloud environments [51].

Furthermore, the rise of supply chain attacks, where third-party software or hardware components are compromised, presents another significant challenge. As Hammi Zeadally and Nebhen (2023) point out, since many organizations rely on cloud services that integrate multiple external vendors, ensuring the security of every component is increasingly difficult [52]. In such environments, traditional encryption methods may not provide sufficient protection against sophisticated attacks. Emerging encryption models, such as lattice-based cryptography and hybrid encryption schemes, have been proposed as solutions to strengthen security, especially in resource-constrained IoT devices and cloud platforms [53]. As IoT and cloud ecosystems continue to expand, the demand for

an advanced encryption methods that can effectively address these new vulnerabilities [50] will only increase [54]. Also, the escalating sophistication of cryptojacking and ransomware highlights the importance of robust encryption algorithms to safeguard against unauthorized access and financial disruptions who are using blockchain technology for their security [55].

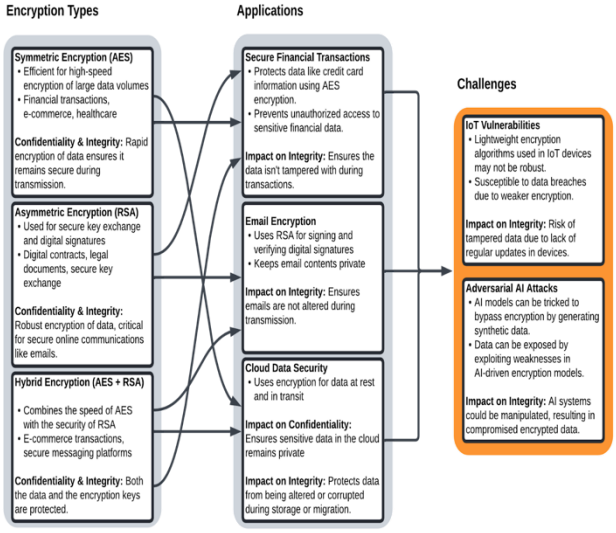

Fig. 2. Encryption algorithms (symmetric, asymmetric, and hybrid) securing digital communications.

While these tools can enhance encryption and cybersecurity, it also introduces new vulnerabilities, particularly through adversarial AI attacks. These attacks exploit the weaknesses in AI models by introducing adversarial inputs, causing the system to make incorrect decisions. In the context of encryption, adversaries can manipulate these models designed to detect anomalies in encrypted communications or tamper with ML algorithms that generate encryption keys [56]. For example, recent studies have shown that adversarial ML techniques can be used to bypass AI-driven encryption models by generating synthetic data that mimics normal traffic patterns, thereby fooling detection systems [57].

Moreover, adversarial attacks can target not just encryption algorithms but the entire AI-based cybersecurity framework. These attacks can render AI-based defenses ineffective by exploiting weaknesses in neural networks used for real-time threat detection [58]. For instance, Generative Adversarial Networks (GANs) have been employed to create realistic attack scenarios that deceive AI systems, making it harder for traditional encryption methods to safeguard data [59]. The increasing sophistication of adversarial AI raises the stakes for maintaining secure systems, requiring not only advancements in encryption but also in AI model robustness [60]. As these threats evolve, the integration of more secure AI models into encryption protocols will be vital for protecting sensitive information in the digital age.

Moreover, the widespread use of encryption technologies in sectors such as finance, healthcare, and national security brings with it significant ethical and legal challenges. Governments and regulatory bodies face the difficult task of balancing individual privacy rights with the need for surveillance to prevent criminal activities [61]. Encryption ensures that sensitive data remains confidential, but it also makes it harder for law enforcement agencies to access potentially crucial information [63]. As a result, there has been ongoing debate about the implementation of encryption backdoors, which would allow authorized entities to decrypt data under specific circumstances. However, these backdoors present a serious ethical dilemma, as they could be exploited by malicious actors if not properly secured [63]. As encryption continues to play a critical role in modern society, it will be essential for policymakers to develop clear, globally consistent frameworks that address both the ethical and legal challenges posed by these technologies [37]. In addition to the ethical concerns, encryption technologies also raise legal questions regarding jurisdiction and data ownership. As data crosses international borders, determining which country's laws apply to encrypted information becomes increasingly complicated [64]. For instance, different nations have varying regulations regarding data privacy and encryption standards, which can lead to conflicts when encrypted data is stored in one country but accessed or processed in another [65].

As encryption continues to play a critical role in modern society, it will be essential for policymakers to develop clear, globally consistent frameworks that address both the ethical and legal challenges posed by these technologies [37]. In addition to the ethical concerns, encryption technologies also raise legal questions regarding jurisdiction and data ownership. As data crosses international borders, determining which country's laws apply to encrypted information becomes increasingly complicated [62]. For instance, different nations have varying regulations regarding data privacy and encryption standards, which can lead to conflicts when encrypted data is stored in one country but accessed or processed in another [63].

VII. Discussion and Limitations

The integration of AI with encryption signifies a pivotal change in cybersecurity, offering both prospects and complex obstacles. The significance of AI in encryption has led to significant progress constantly in real-time threat detection as well as flexible security mechanisms, which are more vital in the contemporary linked and susceptible digital environment. This capacity allows encryption systems to promptly address abnormalities and emerging attack patterns, hence providing resilience unattainable by conventional static encryption approaches. Nonetheless, this progress entails an increasing dependence on machine learning as well as deep learning models, that, whilst augmenting encryption capabilities, can present weaknesses like adversarial assaults. These assaults target vulnerabilities in AI models using misleading inputs, compromising the precision and resilience of systems intended to identify and counter cyber threats. Thus, the dual-use characteristic of AI technology requires a measured and attentive strategy, especially in vital sectors such as healthcare, banking, and national security, wherein AI-driven encryption plays a crucial role in safeguarding extremely sensitive information.

Nonetheless, this progress is not without limitations. First, the over-reliance on AI systems for encryption may create blind spots, wherein undetected vulnerabilities can be exploited by

adversaries leveraging AI for malicious purposes. Second, the ethical and legal challenges surrounding AI-driven encryption, such as potential breaches of data privacy [62] and concerns about surveillance misuse, demand robust governance frameworks. These frameworks must include clear ethical guidelines and enforceable regulations to prevent the unintended misuse of AI-enhanced encryption technologies.

Additionally, accessibility disparities pose significant challenges. AI-driven encryption technologies, while offering scalable solutions, often require substantial technological resources and compliance capabilities. This raises questions about equity, as organizations with limited resources may struggle to implement these advanced systems effectively. Addressing such disparities is vital to ensuring the widespread and fair adoption of AI-powered encryption.

As such, the following validation approach should be used in future studies. In evaluating the proposed cryptographic solutions, employing a rigorous validation process establishes a credible foundation for comparative analysis and subsequent knowledge generation. This process begins with controlled laboratory testing, where encryption algorithms undergo quantitative benchmarking against standardized datasets, fixed key lengths, and pre-defined plaintext-ciphertext pairs to ensure reproducibility. By comparing time-to-encrypt, CPU utilization, memory usage, and latency across multiple cryptographic methods, researchers gain insights into both efficiency and scalability. The application of formal verification techniques, such as model checking and theorem proving, bolsters confidence in algorithmic correctness, ensuring that keys, modes of operation, and cipher primitives function as intended under a range of computational scenarios.

Beyond laboratory environments, field testing in distributed AI-driven systems delivers validation grounded in practical contexts, as real-time data streams reveal how well the chosen cryptographic methods withstand dynamic adversarial tactics. For comprehensive comparative analysis, conducting multi-criteria decision-making (MCDM) evaluations allows researchers to weigh performance metrics, security robustness, and resource overhead against one another. Statistical tests, including ANOVA or Wilcoxon signed-rank tests, further enhance credibility by confirming that observed differences in performance are significant and not attributable to random variation. Iterative refinement informed by validation feedback cycles contributes to continual improvement, bridging the gap between theoretical design and practical deployment. Through meticulous validation and comparison, the resulting cryptographic frameworks achieve a higher degree of reliability, fostering trust among stakeholders and ensuring that deployed solutions fulfill the intended security objectives in increasingly complex AI ecosystems.

Furthermore, the widespread use of AI-driven encryption systems raises urgent accessibility and ethical issues. Even while these technologies provide scalable solutions, their use in a variety of international businesses raises concerns about transparency and equality, particularly when firms have varying levels of technological resources as well as regulatory compliance skills. The fair distribution of these cutting-edge technologies must be given equal weight with technological resilience in the advancement of AI-powered encryption. These technologies also raise significant ethical and legal issues, including surveillance, data privacy, and the possible abuse of AI-enhanced encryption to provide vulnerabilities for illegal data access. To prevent AI-encrypted systems from unintentionally jeopardizing the same security and confidentiality they are meant to safeguard, strict governance structures and ethical standards must be established. Therefore, this open conversation covers both the enormous possibilities and the serious threats of AI-driven encryption, necessitating a thorough, interdisciplinary response to responsibly influence cybersecurity's future.

To sum up, the combination of encryption and artificial intelligence has brought about a new age in cybersecurity that offers increased resistance to a wide range of online dangers. AI-driven encryption is essential in today's fast-paced, data-intensive digital environment because of its adaptable, real-time features, which provide major benefits over conventional encryption methods. Homomorphic encryption and AI-enhanced algorithms are only two examples of the encryption techniques that have advanced because of this integration, strengthening data security and enabling sophisticated calculations on encrypted data. AI algorithms provide a strong defense against complex cyberattacks as they become better at managing the complexities of threat detection including adaptive encryption key management. However, this development raises fresh moral and legal issues. The ethical conundrums around privacy, transparency, and equality, together with the dual-purpose possibilities for AI technology, highlight the need for a concerted effort from all parties involved. To create moral guidelines including legal frameworks that encompass both the technical aspects of AI-enhanced encryption and its wider social ramifications, cooperation between government, business, and academia is crucial.

In the future, establishing a safe and flexible cybersecurity framework will require a proactive approach to the creation and management of AI-driven encryption systems. To reduce new dangers and protect sensitive data in a variety of industries, further research in fields like adversarial resilience, quantum-resistant encryption, and ethical AI will be essential. Through adopting this forward-thinking viewpoint, the cybersecurity industry can capitalize on AI's ability to develop encryption technologies while additionally making certain that those solutions are just, ethically appropriate, as well as resilient to the constantly changing cyberthreat scenario. In this sense, incorporating AI into encryption seems not just a technological development but also a step toward a digital future that is safe, sustainable, as well as considerate of privacy.

Although there are several issues in algorithms for both encryption and decryption, some of the major ones (in symmetric encryption and asymmetric encryption) are shown in Fig. 3 below. The challenges in algorithm generation, algorithm writing, and algorithm difficulty continues as the use of various language models including Artificial Intelligence (AI), Deep Learning (DL), and Machine Learning (ML) keeps growing.

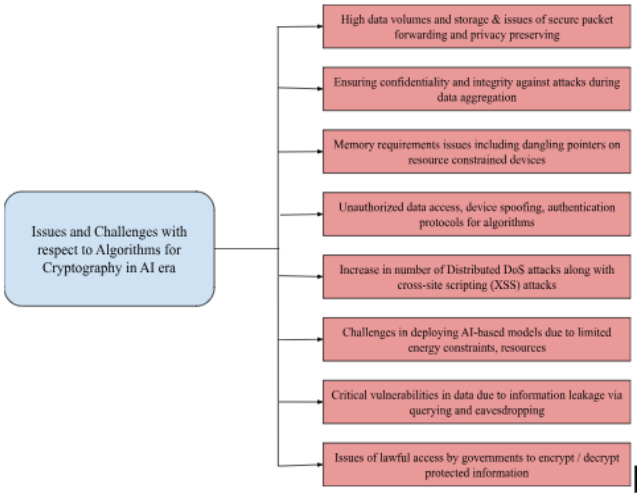

Fig. 3. Encryption algorithms (symmetric, asymmetric, and hybrid) securing digital communications.

VIII. Conclusion and Future Scope

We provided an in-depth study focusing on securing sensitive information with comparative analysis for symmetric encryption and asymmetric encryption algorithms for cryptography. The comparison on the study focuses on key factors like security resilience, scalability, speed in the light of evolving cyber threats. We have addressed the security concerns tackled by encryption algorithms in the Artificial Intelligence (AI) and Large Language Models (LLMs) age along with research directions to enhance overall cybersecurity and cryptography. The aspect comparison between symmetric encryption and asymmetric comparison allows us to decide the environments used including AI environments, key-pairs leveraging via secure key exchanges, and/or decision in secure protocols for secure data sharing.

Future scope of algorithms whether it be symmetric encryption and asymmetric encryption algorithms, largely rely upon use of AI models, reliability, scalability, and key management. Enabling machines to learn is always a future challenge that may require human intelligence in the next step for decision-making. As we progress into several AI algorithms in the future, all three types of learning (supervised learning, unsupervised learning, and reinforcement learning) we must be more intuitive in the future on how we process data and information.

A Framework for Privacy-Preserving Detection of Sickle Blood Cells Using Deep Learning and Cryptographic Techniques

Kholoud Alotaibi, Naser El-Bathy
Computer Science and Engineering, Oakland University Rochester, MI, USA

***Abstract*—Sickle cell anemia is a hereditary disorder where abnormal hemoglobin causes red blood cells to become rigid and crescent-shaped, obstructing blood flow and leading to severe health complications. Early detection of these abnormal cells is essential for timely treatment and reducing disease progression. Traditional screening methods, though effective, are time-intensive and require skilled technicians, making them less suitable for large-scale implementation. This paper presents a conceptual framework that integrates transfer learning, cryptographic algorithms, and service-oriented architecture to provide a secure and efficient solution for sickle cell detection. The framework uses MobileNet, a lightweight deep learning model, enhanced with transfer learning to identify sickle cells from medical images while operating on hardware-constrained environments. Advanced Encryption Standards (AES) ensure sensitive patient data remains secure during transmission and storage, while a service-oriented architecture facilitates seamless interaction between system components. Although not yet implemented, the framework serves as a foundation for future empirical testing, addressing the need for accurate detection, data privacy, and system efficiency in healthcare applications.**

Keywords*—Sickle cells; deep learning; transfer learning; encryption; AES; SOA

I. Introduction

Sickle cell disease (SCD) is a genetic disorder that significantly impacts the shape and function of red blood cells. Under normal conditions, red blood cells are round and flexible, allowing them to move smoothly through blood vessels but they become rigid and crescent-shaped due to defective hemoglobin, the protein responsible for carrying oxygen throughout the body, in individuals with sickle cell disease, [1, 2]. This abnormal shape causes the cells to get trapped in small blood vessels, blocking blood flow, which leads to a range of serious health complications such as pain, organ damage, and an increased risk of infections [3]. Early detection of sickle cells is very important because timely treatment can reduce these complications and greatly enhance the quality of life for those affected [4].

Even though early detection is important, traditional diagnostic methods are often complex and require highly skilled technicians, making them unsuitable for large-scale screening, particularly in low-resource settings [5]. These limitations slow down the ability to diagnose SCD sufficiently early to prevent severe health consequences. Moreover, depending on manual analysis in traditional diagnostics creates challenges in terms of speed and accessibility.

Recent advancements in artificial intelligence (AI), particularly in deep learning, have shown significant potential for automating medical image analysis with high accuracy [6]. These technologies offer faster and more efficient solutions, enabling early detection and scalable screening even in challenging settings. However, deploying AI in medical applications introduces unique challenges. For instance, ensuring patient data privacy is critical, given the sensitive nature of medical data and the strict regulations governing its use, such as HIPAA in the United States and GDPR in Europe [7]. Additionally, many deep learning models require substantial computational resources for training and inference, which limits their feasibility in environments with constrained hardware resources [8].

This paper proposes a novel framework that combines deep learning, cryptographic algorithms, and service-oriented architecture (SOA) to address these challenges. The framework uses MobileNet, a lightweight deep learning model optimized for efficient operation on hardware-constrained systems, to detect sickle cells in blood smear images. Transfer learning is employed to achieve high detection accuracy without requiring extensive computational resources. Advanced encryption techniques, such as AES, ensure patient data remains secure during transmission and storage, addressing critical privacy concerns. Furthermore, SOA enables seamless communication between system components, enhancing the system's scalability, modularity, and flexibility.

By integrating these components, the proposed framework offers a secure, efficient, and practical solution for sickle cell detection in diverse healthcare settings.

The remainder of this paper is organized as follows: Section II identifies the problem, and Section III reviews related work, focusing on previous efforts in using AI for sickle cell detection and employing cryptographic techniques to secure medical data. Section IV provides details on the proposed framework, explaining the roles of each component and how they are integrated. Section V illustrates the workflow of the system, showing how data is securely processed from start to finish. Section VI discusses the security and privacy considerations involved in the framework. Section VII outlines the feasibility and limitations of the approach, while Sections VIII and IX provide future directions and conclusions, respectively.

II. Problem Identification

A. Research Problem

Creating an automated detection system for sickle cells comes with several challenges, one of the most important being data privacy. Medical data is very sensitive and needs to be handled according to strict regulations, such as the Health Insurance Portability and Accountability Act (HIPAA) in the United States and the General Data Protection Regulation (GDPR) in Europe [7]. Ensuring patient privacy is very important when using AI models which require large amounts of data for training and validation. Additionally, deploying deep learning models can require more computational resources, which is challenging in environments where advanced hardware is not easily available [8]. Therefore, there is a need for a solution that balances accuracy, privacy, and efficiency to provide a secure and practical way to detect sickle cells.

B. Research Questions

How to build a system that can correctly detect sickle cells, keep patient data private, and work well with limited hardware? How to create a solution that meets the increasing need for automated medical testing, follows important privacy rules like HIPAA and GDPR, and performs well without needing expensive hardware? These are the key challenges to solve in creating a reliable and easy-to-use system for sickle cell detection.

C. Objective

The study objective is to develop a secure and efficient framework for detecting sickle cells by integrating deep learning, cryptographic algorithms, and an SOA. This framework uses the capabilities of deep learning for analyzing medical images while ensuring that patient data remains protected through cryptographic methods. The use of SOA makes the framework modular, meaning that each component—such as encryption, model inference, and data communication—can be flexible, scalable, and easily integrated into existing healthcare systems.

D. Significance

The significance of this proposed framework is its novel integration of AI with secure computation techniques designed to address healthcare needs. The framework handles the critical issue of privacy-preserving AI in healthcare by combining deep learning for medical image analysis with cryptographic methods for secure data handling [9]. Furthermore, the use of SOA allows for flexibility and scalability, making the solution adaptable to different clinical environments. This combination of accurate detection, data security, and scalability represents a unique approach to addressing the challenges of sickle cell detection to provide accessible high-quality care while protecting patient data.

III. Related Work

A. Existing Deep Learning Solutions for Sickle Cell Detection

Deep learning has brought remarkable improvements to medical imaging, especially in automating the detection of diseases like SCD. Traditionally, diagnosing SCD requires visually examining blood smears under a microscope, which is not only time-consuming but also prone to human error. To overcome these challenges, researchers have turned to deep learning models, which make the process faster and more reliable.

Goswami and colleagues used deep neural networks like ResNet50 and GoogleNet to classify sickle cells from digital blood smear images. They also applied explainable AI techniques, such as Grad-CAM to make the predictions easier for healthcare professionals to understand. This added transparency makes the diagnostic process more trustworthy. ResNet50 was the best-performing model, achieving an accuracy of 94.9%, which shows great potential for real-world clinical use [11].

Kawuma and his team compared different deep-learning techniques for detecting SCD, such as VGG16, VGG19, and Inception V3, demonstrating that Inception V3 achieved the highest accuracy at 97.3%, followed by VGG19 at 97.0%. These results highlight the effectiveness of pre-trained models for accurately identifying sickle cells [10].

Karunasena and colleagues took a different approach, using a region-based convolutional neural network (R-CNN) to detect sickle cells. Their model achieved over 90% accuracy and was particularly useful in segmenting and classifying specific regions within an image. This level of precision is important when dealing with complex blood smear images where cells may be crowded or overlap [12].

Another review by Balde et al. focused on recent advances in using AI to detect SCD, highlighting image segmentation and feature extraction techniques. These methods, particularly CNN, have been successful in analyzing microscopic images, even when they contain overlapping cells. However, there are still challenges in improving the robustness of these segmentation techniques to accurately distinguish between normal and sickled cells, especially in more complex or densely populated images [13].

Regardless of these advancements, one key issue remains largely unaddressed, data privacy. Most studies have focused primarily on improving detection accuracy but have not paid enough attention to the sensitive nature of medical data. This gap provides an opportunity for future research to explore privacy-preserving techniques, such as encryption, to protect patient information while maintaining the diagnostic accuracy of deep learning solutions.

In summary, existing research shows significant progress in using deep learning for sickle cell detection but there is still a need for better handling of overlapping cells, and a stronger focus on data privacy to create a comprehensive solution that can be widely adopted.

B. Cryptographic Techniques in Medical Data Security

Securing medical data is important, especially when using AI and machine learning (ML) models, as these often require sensitive patient information for processing. Cryptographic techniques have been a core part of ensuring that this data remains safe throughout its lifecycle—whether during transmission, storage, or even analysis.

One interesting approach is the MASS framework which uses blockchain technology to securely share medical data collected from wearable IoT devices. In this system, health information is encrypted using Ciphertext-Policy Attribute-Based Encryption (CP-ABE), which means that only authorized individuals can access specific parts of the data. This method not only keeps the data private but also ensures it cannot be altered, thus MASS is particularly effective for protecting data from wearable medical devices [14].

Amaithi Rajan and colleagues developed a secure way to retrieve medical images from encrypted cloud storage using a combination of deep learning and encryption techniques, ensuring that the images are not only safely stored but also easily retrievable when needed. This method relies on symmetric encryption and searchable encryption, allowing users to search through encrypted data and retrieve relevant images without compromising security [15].

Ahmad Al Badawi and Mohd Faizal Bin Yusof took another interesting approach by using fully homomorphic encryption (FHE). This allows medical data to be processed without ever decrypting it, meaning patient information remains secure even during analysis. They used this method for privacy-preserving pathological assessments using support vector machines (SVMs). This approach provides both strong data protection and effective analysis, making it highly suitable for privacy-sensitive medical diagnostics [16].

A different system developed by Kusum Lata and her team focused on detecting brain tumors using deep learning while ensuring privacy through encryption. They used the AES-128 algorithm to encrypt medical images before storage or transmission to keep patient data secure, even during the diagnosis. This system is a good example of balancing the need for secure data handling with the advanced diagnostic capabilities that AI offers [17].

Lastly, Runze Wu and colleagues developed a privacy-preserving system that used Gaussian kernel-based support vector machines (SVMs) and a simpler cryptographic method known as additive secret sharing. This approach is less computationally intensive compared to more advanced methods like homomorphic encryption, making it better suited for real-time applications. It ensures that both the patient's data and the healthcare provider's model are kept private during the diagnostic process, all while maintaining efficiency [18].

Overall, these cryptographic approaches highlight the importance of keeping patient data secure while using the power of AI in healthcare. While robust encryption methods like homomorphic encryption offer high security, they can be quite demanding in terms of computation. Hence, lightweight cryptography and blockchain-based methods are becoming attractive alternatives because they balance effective security with practical resource use—especially important in healthcare, where computational power is often limited.

C. Service-Oriented Architectures in Healthcare

The SOA has become popular in healthcare because it allows systems to be broken down into smaller, independent services that work together efficiently. This approach makes healthcare technology more flexible and scalable—perfect for dealing with the complexities of modern medical institutions.

Petrenko and Boloban explain how SOA can handle the increasing volume of healthcare data and provide efficient treatment by coordinating different services. By splitting a large healthcare system into smaller, interacting services, SOA improves how data is processed and how medical resources are managed, ultimately leading to better patient care. A major advantage is that new services can be easily added to the system without causing disruptions, making SOA both scalable and adaptable [19].

Liviu Ilie and colleagues looked at how SOA could be used to create a framework that connects electronic health records with other healthcare services to boost interoperability—the ability of different systems to exchange and use information. Interoperability is important in healthcare, especially for large medical institutions that need to integrate multiple systems. SOA provides a framework that helps different services communicate effectively, improving both the quality and efficiency of healthcare. This approach makes the system more flexible, easier to upgrade, and less expensive to maintain [20].

Similarly, Petrenko and Tsymbaliuk developed a cloud-based healthcare platform called "Clinic in Cloud" that uses SOA to bring together wearable sensors, data management systems, and user interfaces. This platform allows doctors to monitor patients remotely in real time, making diagnosis and treatment more accessible. The SOA approach ensures that all these different components, sensors, databases, and communication tools, work smoothly together, enabling timely and effective patient care. The modular design also makes it easy to add new features as healthcare needs develop [21].

In summary, SOA provides a strong foundation for building healthcare systems that are flexible and scalable. By breaking down complex systems into smaller, independent services, SOA makes integration easier, data management more efficient, and services more adaptable. This is especially valuable in healthcare, where technology is continuously changing and systems need to keep up.

D. Summary of Related Work

The research on deep learning, cryptographic techniques, and SOA has greatly advanced healthcare technology but there are still areas for improvement.

Deep learning models like ResNet50 and Inception V3 have made diagnosing SCD faster and more reliable compared to traditional manual methods. However, data privacy has not been addressed, a major issue when dealing with sensitive health information.

Methods like FHE and blockchain frameworks have been used to keep patient data secure and while they are highly effective, they can be computationally heavy, limiting their practicality in real-time applications or environments with limited computing resources.

The SOA has been used to make healthcare systems more modular and scalable. SOA improves integration between different healthcare tools and makes it easier to expand systems

when needed by breaking down large systems into smaller, easier-to-manage services.

The proposed framework builds on these existing solutions by combining the strengths of each approach while addressing their limitations. By integrating lightweight deep learning with efficient cryptographic techniques like AES and an SOA-based design, the framework prioritizes patient data privacy, operational efficiency, and system scalability. Unlike current solutions, this approach places patient privacy at the forefront while ensuring adaptability to evolving healthcare needs.

IV. Proposed Framework

A. Overview of the Framework

The proposed framework aims to provide a secure and efficient way to detect sickle cells in medical images. It consists of three main components that work together to ensure accuracy, privacy, and flexibility:

- A deep learning model for detection
- A cryptographic module
- A service-oriented architecture (SOA)

A pre-trained deep learning model, MobileNet [23], was employed to identify sickle cells in blood smear images. This model correctly detects sickle cells using transfer learning without requiring significant computational power, making it ideal for setups with limited hardware. The preprocessing steps include resizing the input images and normalizing pixel values to ensure compatibility with the MobileNet architecture. Performance evaluation metrics, such as detection accuracy and inference latency, will be used during the empirical validation phase to measure the effectiveness of the model.

Advanced Encryption Standards (AES) were used to encrypt the medical images before analysis to protect sensitive patient information. This ensures that the data remains confidential during both transmission and storage, providing strong security to prevent unauthorized access. Although AES introduces some computational overhead, its efficiency makes it a practical choice for environments with limited resources, balancing security, and performance. Beyond encryption, the framework is designed to align with data protection regulations such as HIPAA and GDPR, ensuring secure and compliant handling of patient data throughout the system.

SOA connects all the components, allowing perfect communication between the cryptographic module, the deep learning model, and the other system parts. Each function—such as encryption, analysis, and reporting—is treated as an independent service, thus the system is modular and scalable so components can be updated or replaced without disrupting the rest of the system, making it easy to expand or adapt as needed.

Fig. 1 illustrates how these components interact to visualize the flow of the system. Additionally, Table I provides a detailed overview of each system component, outlining its function and purpose within the framework.

B. Components

1) Deep learning model for detection: MobileNet was the transfer learning model selected for detecting sickle cells as it is specifically designed for environments with limited resources, making it ideal for training on a CPU. It employs a technique called depthwise separable convolutions [25], reducing the number of parameters and computational complexity without sacrificing accuracy.

MobileNet V2 is highly effective for different medical imaging tasks. For example, it achieved accuracy rates as high as 94% when used for brain tumor classification after being pre-trained and fine-tuned on relevant datasets [22].

This suggests that MobileNet can also perform well for sickle cell detection tasks.

MobileNet has also been applied for breast cancer classification, delivering fast execution times even on devices with limited computational resources without compromising accuracy [23]. This makes it an ideal choice for scenarios where only a CPU is available for training and inference.

MobileNet has also been successfully integrated into ensemble models for detecting conditions like cardiomegaly, showing that it is robust and works well in combination with other models [24].

TABLE I. System Components Overview

Component	Function	Purpose
Data Input and Encryption	Uploads and encrypts medical images using AES	Protect patient data during transmission
Service-Oriented Architecture (SOA)	Connects system components and manages secure data flow	Ensures modularity and scalability
Deep Learning (MobileNet)	Analyzes medical images to detect sickle cells	Provides accurate detection of sickle cells
Data Storage/ Transmission	Encrypts and securely stores or sends results to the user	Maintains data privacy throughout the process

This flexibility demonstrates its capability to handle complex medical imaging challenges effectively.

Its lightweight architecture makes it ideal for training and deploying on a CPU, which fits the hardware limitations of the proposed framework. Unlike heavier models like ResNet or VGG, MobileNet requires far less computational power while still delivering strong performance [25]. Additionally, pre-trained weights can be used and fine-tuned on the sickle cell dataset, allowing for efficient training even without high-end hardware.

2) Cryptographic module: AES was chosen for its well-known efficiency and security when encrypting large datasets like medical images. AES supports different key lengths (e.g., 128-bit or 256-bit) and provides an excellent balance between speed and security, making it suitable for both storing and transmitting medical data securely [33].

AES has been successfully used in cloud-based medical data systems to secure sensitive patient information. It ensures that data remains protected during transmission and storage, which is important for maintaining privacy in healthcare settings [26].

In comparison studies, AES was faster than other encryption methods for both encrypting and decrypting data, making it a reliable option for handling medical images without slowing down performance [27].

AES is also effectively used in combination with techniques like watermarking [26] to guarantee both the security and integrity of medical images. This dual functionality shows the flexibility of AES in ensuring data remains protected while preserving image quality, which is essential in healthcare.

AES offers strong encryption to protect patient information, ensuring confidentiality during transmission and storage. It efficiently secures large medical datasets without slowing down the system, thus is ideal for healthcare settings where both security and efficiency are important [26].

3) Service-oriented architecture (SOA): In this framework, SOA plays a key role in enabling the different components—such as the cryptographic module, deep learning model, and data management processes—to communicate smoothly. Each function, like encryption, model analysis, and data sharing, operates as an independent service, making the system more flexible and scalable, allowing each part to be developed, updated, and managed separately.

- Benefits of Using SOA

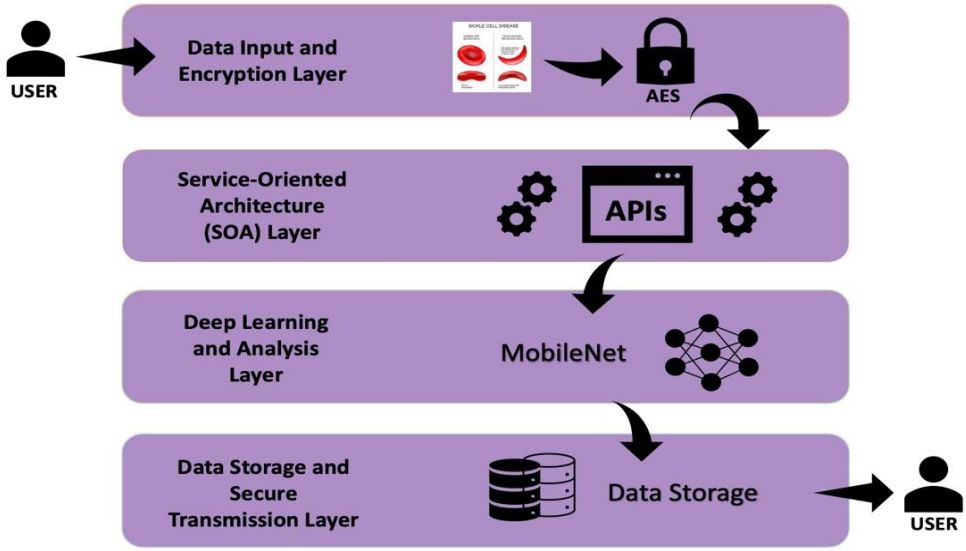

Fig. 1. High-level overview of the proposed framework showing the flow of data between components. Encrypted data is processed through the service-oriented architecture (SOA), analyzed by the Deep Learning Model (MobileNet), and securely transmitted and stored.

a) Modularity: SOA breaks down the system into smaller, reusable services so that each part, like data encryption, detection, or reporting, can be independently maintained. This modular approach makes it much easier to update or modify components without affecting the entire system. Essentially, the rest of the system can keep running smoothly if one part needs an upgrade [20, 28].

b) Interoperability: The framework includes different components such as cryptographic modules and AI models, and SOA makes sure they work well together. By using standardized protocols like SOAP and REST, SOA ensures that these services can easily communicate, even if they are built on different platforms or by different developers. This is important for smooth integration and effective communication between all system parts [28].

c) Scalability: Healthcare systems often need to handle growing amounts of data and SOA-based systems are inherently scalable, meaning new services can be added without disrupting the existing setup. This is particularly useful when integrating with cloud-based services or IoT devices for real-time monitoring, ensuring that the system can grow and adapt as needed [21].

- How SOA Enables Communication Between Modules:

SOA-based frameworks often use middleware and APIs to manage how different services interact. This not only helps standardize the flow of data but also supports plug-and-play integration, making it easy to add new components, such as an improved encryption method or an updated AI model, without causing disruptions to the rest of the system [28].

V. System Workflow

This section describes how data moves through each stage of the proposed framework, from the initial encryption of medical images to the secure return of prediction results. Each step is designed to ensure data privacy, accuracy, and efficiency.

The process starts by encrypting the medical images using AES [29] to ensure that sensitive patient data is protected from the beginning and remains confidential throughout transmission and processing.

Once encrypted, the data is securely transmitted to the deep learning service using an SOA. SOA allows the encrypted data to be passed easily between different services, making communication between the cryptographic module and the deep learning model smooth and secure [30]. This modular design ensures that the different system parts work together effectively without compromising sensitive information.

When the encrypted data reaches the deep learning model, it is first decrypted for analysis and then processed by the MobileNet [22] deep learning model to detect sickle cells in the medical images. This step generates predictions, helping identify any abnormalities in the blood smear images.

After the analysis is complete, the results are encrypted using AES to ensure privacy before they are sent back to the client. This step keeps the prediction results protected during transmission, maintaining the confidentiality of patient data at all times [30].

Fig. 2 illustrates the entire workflow, showing the interactions between each component:

1) Data encryption: Medical images are encrypted using AES for privacy.

2) Data transmission via SOA: Encrypted data is sent to the deep learning service.

3) Model inference: The deep learning model processes the data (after decryption) and generates predictions.

4) Result encryption and return: The analysis results are encrypted and returned securely to the client.

VI. Security and Privacy Analysis

The proposed framework includes different security and privacy protections to keep patient data safe and private. This section explains how privacy issues are managed, what security features are used, and how the framework balances being secure while still running efficiently.

A major concern with medical data is protecting patient privacy. The framework handles this by using AES encryption to secure medical images at every step. By locking the data before analysis and again when sending the results back, the system ensures that no one without permission can access sensitive patient information during transmission or storage. Using AES helps prevent data breaches that could compromise patient privacy in line with established privacy standards like HIPAA and GDPR which require strict protection for medical data to prevent unauthorized access [31].

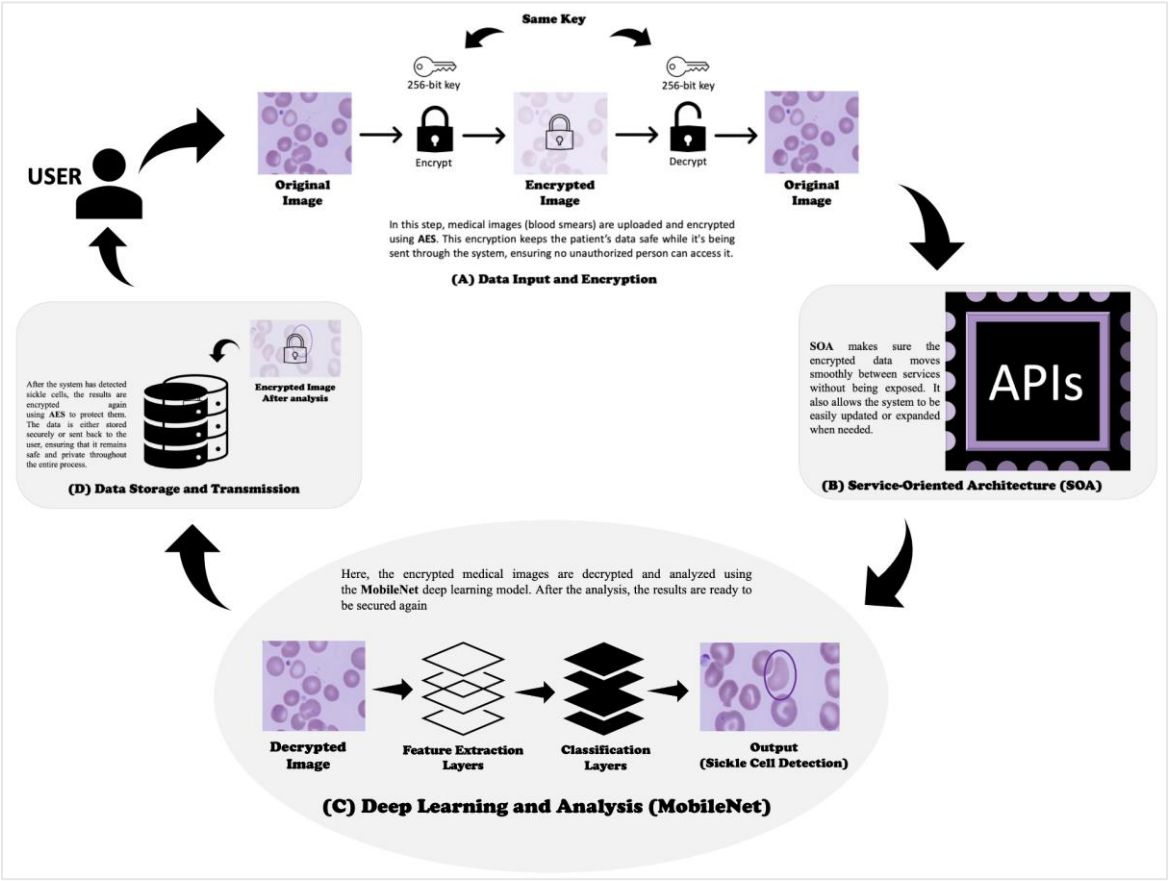

Fig. 2. System workflow diagram illustrating the flow of data within the proposed framework. The process begins with AES encryption of medical images, followed by secure transmission through SOA, analysis using the MobileNet model, and encryption of results before returning to the client. Each step ensures privacy, accuracy, and secure data handling.

The framework uses AES and other cryptographic algorithms to keep data secure and intact throughout the process. AES encrypts the data both when it is being sent and after analysis, providing:

- Confidentiality: AES keeps patient data private from the moment it is collected until the results are returned.
- Integrity: Encryption ensures that if anyone tries to tamper with the data during transmission, it becomes unreadable, keeping it accurate.

The framework also uses an SOA to safely transfer encrypted data between services, adding extra protection by reducing the risk of data exposure during transfers [30].

While security is very important, it is also necessary to consider how encryption affects system performance. AES encryption performs well at keeping data safe but can slow systems down, especially those with limited resources or using large amounts of data. Nonetheless, it is still more efficient than other options like RSA. AES finds a good middle ground between security and speed. It works well with large datasets, like medical images, because it provides strong protection without using too much computational power compared to heavier encryption methods [32].

1) Optimized workflow: Using the MobileNet model for analysis allows the framework to work efficiently, even on systems with just a CPU [23]. This helps lower the overall workload of both the encryption and the AI tasks, making the system both secure and practical for real-world healthcare use.

VII. Feasibility and Limitations

The framework is designed to work efficiently, even on systems with limited hardware like a standard CPU. This is possible through the use of MobileNet [24] with transfer learning. MobileNet is a lightweight deep learning model that reduces the computational workload by using fewer parameters compared to heavier models. By starting with a pre-trained model and only adjusting the final layers, the framework can achieve high accuracy without requiring advanced hardware, making it practical for environments with limited resources.

While the framework offers a balance between security and efficiency, a few challenges and limitations need to be addressed:

- Resource Limitations: Even though MobileNet is optimized for efficiency, using a CPU for processing may still be slower compared to a GPU, particularly when handling large datasets. This could limit the framework's scalability when analyzing a high volume of images.
- Balancing Privacy and Efficiency: There is a trade-off between ensuring data privacy and maintaining fast processing speeds. AES encryption provides strong data protection, but it adds steps to the workflow, which could slow down real-time performance.

This paper proposes a theoretical framework, and its implementation has not yet been carried out. While the framework integrates validated techniques such as MobileNet for deep learning, AES for encryption, and SOA for modularity, empirical testing will be conducted in future work. Metrics such as accuracy, latency, encryption strength, and scalability will be used to validate the framework's performance. The absence of implementation results reflects the current focus on the framework design, which serves as a foundation for future development and testing.

VIII. Future Work

The current goal is to design the framework and create a basic prototype to show how it works. In the future, the full system will be built, with all parts working together and tested in real-world situations. This full implementation will help identify practical limitations to improve the system's performance.

Once the system is fully built, a detailed evaluation of its performance will be performed, assessing the accuracy (how well it finds sickle cells) and speed (how long it takes to process each image) of the deep learning model, as well as the strength of the encryption (to keep patient data safe) and how efficiently the system runs (the encryption does not slow the system too much). The goal of this evaluation is to find the right balance between security, accuracy, and speed.

Another important future task is to determine how well the framework can handle larger datasets, like more medical images from different sources, to help understand how the system can be used in real-world healthcare, where securely and efficiently managing large amounts of data is essential.

IX. Conclusion

A. Summary

This paper presented a framework to help detect sickle cells in medical images securely and efficiently. The framework comprises three main parts: a deep learning model to identify sickle cells, a cryptographic module to protect patient data, and an SOA for efficient communication between all system parts. Together, these parts ensure that patient information stays safe during every step—from encryption to analysis and sending back the results.

B. Contribution

The main contribution of this work is creating a unique framework that combines deep learning and cryptographic techniques using an SOA-based structure. This design makes it possible to securely analyze medical images while maintaining patient confidentiality. Using MobileNet and transfer learning, the framework is also efficient for environments with limited hardware, making it useful in more healthcare settings.

C. Implications

This work is important for the future of secure AI in healthcare. This framework provides a way to develop AI solutions that not only work well but also protect patient privacy by combining strong encryption with deep learning in a scalable system. This approach can be applied to other types of medical imaging, improving diagnostics while keeping data safe—something that is becoming more important in today's digital healthcare world.

Trustworthiness in Conversational Agents: Patterns in User Personality-Based Behavior Towards Chatbots

Jieyu Wang[1]*, Merary Rangel[2], Mark Schmidt[3],Pavel Safonov[4]
Information Systems, Saint Cloud State University, St. Cloud, USA

***Abstract*—As artificial intelligence conversational agent (CA) usage is increasing, research has been done to explore how to improve chatbot user experience by focusing on user personality. This work aims to help designers and industrial professionals understand user trust related to personality in CAs for better human-centered AI design. To achieve this goal, the study investigates the interactions between users with diverse personalities and AI chatbots. We measured participant personalities with a Hogan and Champagnes (1980) typology assessment by categorizing personality dimensions into the extraversion vs. intuition (EN), extraversion vs. sensing (ES), introversion vs. intuition (IN), and introversion vs. sensing (IS) groups. Twenty-nine participants were assigned two tasks to engage with three different AI chatbots: Cleverbot, Kuki, and Replika. Their conversations with the chatbots were analyzed using the open-coding method. Coding schemes were developed to create frequency tables. Results of this study showed that EN personality participants had perceptions of high trustworthiness towards the chatbot, especially when the chatbot was helpful. The ES personality participants, on the other hand, often engaged in brief conversations regardless of whether the chatbot was helpful or not, leading to low trust levels towards the chatbot. The IN personality users experienced mixed outcomes; while some had perceived trusty-worthy conversations despite having unhelpful chatbot responses, others found helpful conversations, yet a perception of low trustworthiness. The IS personality participants typically had the longest conversations, often leading to high perceptions of high trust scores being given to the chatbots. This study indicates that users with diverse personalities have different perceptions of trust toward AI conversational agents. This research provides interpretations of different personality users' interaction patterns and trends with chatbots for designers as design guidelines to emphasize AI UX design.**

Keywords*—Trust; personality; human-centered AI design; user experience

I. Introduction

The use of Artificial Intelligence has increasingly been popular not only within the technological world but in business, health research, psychological aspects, supply-chain management, education, decision-making, science research, and financial aspects as well [1, 2]. Artificial Intelligence was popularized by Alan Turing, when he released a journal article proposing a question if Machines think, thus having people realize the difference in what machines can do when given instructions, versus making a decision based on the facts they are given [3]. McCarthy described artificial intelligence as "the science and engineering of making intelligent machines", popularizing the term and the widespread use of artificial intelligence [4]. Artificial intelligence has increased to mimic human tasks, such as conversations, information processing, educational assistants, computing, and more recently, predictive algorithm models [5, 6, 7].

Artificial Intelligence has been used by businesses to help automation and increase quality in customer satisfaction by personalizing experiences [8]. Among AI applications, CAs are becoming popular due to their purpose of serving customers. Recent studies have analyzed CAs' characters to categorize them [9]. Since CAs' main functions are to help users gather information and make decisions, designing how to better serve people with different personalities to enhance user experience is the key [10,11].

Thus, this work aims to explore the different trustworthiness in user behavior between the personalities of end users and AI chatbots within interactions. We also provide user behavior interpretations of patterns and trends for designers as design guidelines to better engage users with different personalities when they interact with AI chatbots.

II. Related Work

Artificial intelligence was first used to help humans, such as playing checkers or helping organize tasks for the ease of human labor and the human mind. Yet, due to it being highly used, there have been ethical questions between AI and the intersectionality of life, such as employment, politics, and educational aspects, with different personality types having different attitudes towards artificial intelligence. [12, 13 14].

According to a study done by Kaya et al. (2024), people who are less "computer-literate" tend to have negative attitudes toward artificial intelligence. Kaya explains that this population may not have the knowledge or the experience of using computing-based algorithms, and therefore, is worried that artificial intelligence can one day take tasks assigned to humans and have these tasks automated. People who have a higher education level and a higher use of computers tend to have more positive attitudes toward artificial intelligence. Those who have more positive attitudes towards artificial intelligence view it as a tool, rather than a burden. Those who also had positive attitudes were more open to new experiences. Yet, those with a higher education level, and higher computer literate level did report that users would have to keep up with the technology. This concept of "having to keep up" is known as self-actualization, a psychological theory of improving oneself, to become the better version of what the current mind stands once all other needs are met [15, 16]. By having a positive attitude, students can improve their technology literacy and continue self-improvement.

This aligns with another study conducted by Zhou et al. (2019) where they found that younger computer engineering students were able to feel comfortable using artificial intelligence to conversate in an interview. Not only were they comfortable, but they were able to trust the artificial chatbot to feel more assertive, outgoing, and being themselves rather than a human. The students' attitudes towards the artificially intelligent chatbot were seen as more positive rather than negative and were able to be the best version of themselves when they felt trust, and agreeableness with the chatbot [17].

Another study conducted by Heng Li (2023) showed similar results, when testing personality traits of intellectual humility and attitudes towards artificial intelligence. Li found that students in a Chinese university who scored higher on Intellectual Humility on a personality test tended to result in favorable use of artificial intelligence and accepted a form of generative AI called ChatGPT as an advantage. These students were also higher on an openness scale, meaning they were open to new experiences, and the use of newer artificial intelligence can be accommodating [18].

The Big Five is a psychological theory and model that models down all human personality traits into five categories, including Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism, or an acronym known as OCEAN. Stein et al. (2024) conducted research on the Dark Triad and the Conspiracy Mentality. The Dark Triad assessment focuses on Narcissism, Machiavellianism, and Psychopathy. The Conspiracy Mentality Questionnaire (CMQ), developed by Bruder et al., in 2013, is a questionnaire that measures attitudes in socio-political fields. In this research, Stein found that agreeableness was a key indicator in personality traits that had students being able to accept artificial intelligence as a positive tool. Yet, Stein found that those who have higher beliefs in conspiracy theories tended to have negative attitudes toward artificial intelligence [13].

The Big Five has been used widely in research to find trust attitudes towards artificial intelligence. Reidel et al. (2024) found that trust in artificial intelligence is related to the user's personality, with individuals who are more open to experience (Openness) are more likely to have a positive correlation with their experience in artificial intelligence. However, Sharan & Romano (2020) yielded results that indicate trust is a human factor, and trust towards artificial intelligent agents tends to be negatively viewed by individuals who are strongly associated with Neuroticism [19, 20].

Moreover, due to the rise of artificial intelligence, user experience in trust can be based on how reliable artificial intelligence is when interacting with humans. While personality is an influence on decision-making, this result indicates that artificial intelligent agents can be not a service to humans [21].

Personality varies from person to person, and it can be different in other cultures as well. In a recent study, researchers explored the relationship between trust in artificial intelligent agents and trust in humans. In this study, a culture that is advanced in technology has higher trust in artificial intelligence agents. Though this research study may not be applicable to all countries and generalized to every individual, it gives new insight into future research on how humans can engage more with artificial intelligent agents in trusting their algorithms [22].

Though the Big Five is commonly approached in studies, there is limited research on personality measured with Hogan and Champagne's (1980) Personal Style Inventory when measuring user experience with artificial intelligent agents [24]. The Hogan Assessment is used to predicate outcome of behavior, usually in a vocational setting. This work applies their Extroversion (E) v. Introversion (I) and Sensing (S) v. Intuition (N) personality dimensions to categorize the participants in the study. Extroversion is defined as individuals who are open to new ideas, see new opportunities, and are colorful in nature by engaging with meeting new people, and having new experiences. Extraversion counterpart is Introversion, where the individual feelings are from inward rather than outward [23, 24, 25, 26]. "Sensing" is a trait where the individual is focused on factual, and detailed oriented information, the counterpart is "Intuitive", where the individual trusts their instincts and is more abstract with their personality and thought process [27]. This paper aims to investigate the interaction between users' personalities on the Hogan and Champagne typology and the level of trust between three chatbots, Clever Bot, Kuki, and Replika.

III. METHOD

A. Participants

This study aims to explore diverse interaction patterns of users with different personalities when they communicate with AI chatbots. To achieve the research goal, we invited 29 participants who are college students to participate in the study. They are information systems major students who have a basic or moderate understanding of AI chatbots. Among them, 25 participants' data has been confirmed to be complete.

B. Procedures

As we previously described in our series of studies [28], the participants were recruited to chat with three CAs, Kuki, Replika, and Cleverbot in their own environments. These three chatbots were among the top ones that these participants preferred to interact with [29]. The participants were assigned the same two prompts for each of the three chatbots. One task was about travel planning and the other one concerned ordering food from restaurants.

Prompt 1: The spring break is coming. You are pretty interested in traveling. But you do not know where to travel. Please talk to each CA: 1) Kuki, 2) Replika, and 3) Cleverbot and gather enough information for you to create your travel itinerary (a detailed travel plan).

Prompt 2: Today you are too tired to cook. Also, you would like to explore restaurants. Talk to the three CAs and get your food.

The participants were required to record their conversation histories and rate each CA's response to their questions or interactions on a Word document within two weeks. We asked the participants to use a Likert scale of 7 (1=strongly untrustworthy, 2=untrustworthy, 3=moderately untrustworthy, 4=undecided, 5=moderately trustworthy, 6=trustworthy, 7=strongly trustworthy) to rate each CA response. The

participants were also required to provide reasons (written in text) for each response. This large amount of data allows us to explore the participants' extent of trust towards different chatbots' responses and the personality-based reasons explaining their behaviors.

C. Grounding Theory

Our previous study showed there were differences in the task accuracies of users with different personality dimensions when they interacted with a CA [29]. The study analysis is based on Hogan and Champagne's (1980) personality dimension matrix (Table I): introversion VS extroversion (IE), intuition VS sensing (NS) [24]. The dimensions provided the best middle ground as we categorized the participants into four major personality dimensions accordingly (EN, ES, IN, IS) while adding some detailed personality analysis of the 16 groups such as ISTJ, ENFJ, etc.).

D. Hierarchical Data Structure

The researchers of this study organized the data into a hierarchical data structure, where we analyze the dimensions of personalities and chatbots within a personality root (Fig. 1). EN represents the Extraversion and Intuition Dimensions, ES represents the Extraversion and Sensing Dimensions, IN represents the Introversion and Intuition Dimensions, and IS represents the Introversion and Sensing Dimensions.

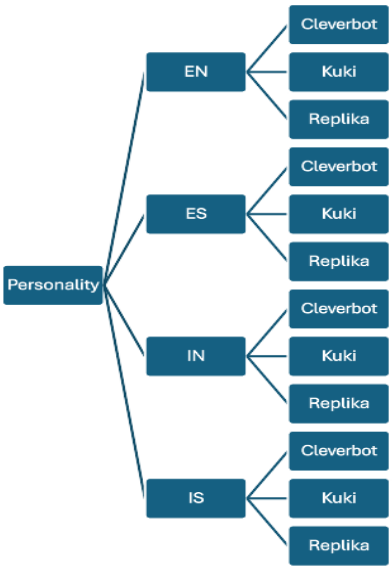

Fig. 1. Hierarchical data structure.

E. Coding Schemes

The researchers explored the data by conducting open coding and analyzing all conversations between participants and chatbots manually. We identified three coding categories for chatbot responses: Helpful, Unhelpful, and Neutral. These categories were derived from previous literature. 'Helpful' responses are those that facilitate meaningful and engaging exchanges [30, 37]. 'Unhelpful' responses occur when the conversation deviates from its purpose, such as when the chatbot fails to provide the desired information [31]. Lastly, 'Neutral' responses are neither helpful nor unhelpful from the chatbot, but the participant continued the conversation." The researchers went on to further explore the number of occurrences in exchanges between the participant and the chatbot, which led to the identification of a new coding category, labeled as Number of Interactions. In total, we were able to identify four coding categories, which are Helpful, Unhelpful, Neutral, and Number of Interactions. By coding the interactions, we were able to examine the perceptions of chatbots by the participants. Average of Trust is a variable in which trust levels were calculated by aggregating each user's ratings and averaging them by the number of interactions between the chatbots. This approach will allow for a comparison of perception influenced by the nature and frequency of interactions, providing insights into how Helpful, Unhelpful, and Neutral responses impact the overall user experience.

In the Helpful category, this code is exhibited when the chatbot is helpful, and interactive with the user, leading to a meaningful and pleasant experience with the user. Often, the chatbot gives the user helpful responses in their request or prompts. Below is an example of a "Helpful" Interaction in this study between a user and the Kuki Chatbot.

> **Participant Question:** "I want to travel next week but I am not sure where to travel to. Do you have any recommendations?"
> **Chatbot Kuki Response:** "I would advise you to go to Japan. It's so beautiful and there are so many amazing places to visit".

Within the "Unhelpful" category the chatbot is being unhelpful, such as being unable to help the user based on the prompt from the user, or being tangential, when the chatbot starts to be erratic and hostile towards the user. Below is an example of an "Unhelpful Interaction" in this study.

> **Participant Question**: "I am looking for a place to travel in United States in April. Can you recommend me some place?"
> **Chatbot Cleverbot Response**: "Lol"

"Neutral" exchanges occur when the chatbot is neither "Helpful" nor "Unhelpful", such as saying "Ok". These conversations don't contribute much but still have the user continue the conversation. Below is an example of a "Neutral Interaction" in this study.

> **Participant Question**: "I need it [the meal] here, not in Lasha"
> **Chatbot Replika:** "I understand".

"Number of Interactions" refers to how many exchanges took place between the user and the chatbot. It is the count of interactions that occurred and then summed. Below are three interactions between a participant and the Replika chatbot.

> **Participant Question**: "Hi! Who are you?"
> **Chatbot Replika:** "I am your personal AI companion.
> **Participant Question:** "Can you help me plan for spring break."

Chatbot Replika: "Sure, let me help you. I love this name! Let's take a moment to make your experience more personal."
Participant Question: "Maybe Later"
Chatbot Replika: "OK! Let's talk :) So, how are you doing?"

"Average Trust" represents the mean trust score calculated across all interactions between a user and the chatbot. For each interaction, a trust score is assigned based on the user's perception of the chatbot's response. These individual scores are then aggregated and averaged to provide a single "Average Trust" value that can represent the whole interaction. The formula is as follows:

$$\text{Average Trust (Mean)} = \frac{\text{Sum of Trust Scores for All Interactions}}{\text{Total Number of Interactions}}$$

Below is an example of an Average Trust of an interaction between a participant and Cleverbot.

Participant Question	Chatbot Cleverbot Response	Score Given
"I am looking for a place to travel in United States in April. Can you recommend me some place?"	"Lol"	1
"What's that place?"	"Its in the slender woods."	1
		Average Score = 1

F. Frequency Table with Average Trust

In this study, we tracked the frequency of each chatbot's interactions within each category and also put the average trust level score to indicate the average score of the whole conversation. There are two prompts, a meal prompt, indicated by "MP" and a travel prompt, indicated by "TP". This will lead to two occurrences of every personality in our graphs. Based on our hierarchical data structure, we split the frequencies into three tables for each dimension of personality. Table I shows an example of a frequency table from the EN dimension and Kuki chatbot. The frequency table exhibits how many occurrences of each category occurred during an interaction. For example, Table I indicates that within the "Helpful" row, there were six helpful exchanges, zero "Unhelpful" exchanges, and one "Neutral" exchange between the chatbot Replika, and the participant. In total, there were seven exchanged interactions, and the average Trust level was aggregated to be 6.3, which according to our Likert Scale, the participant perceived the chatbot Kuki to be trustworthy.

TABLE I. FREQUENCY AND AVERAGE TRUST TABLE

Participant, Personality Categories, and Prompt Type.	Helpful	Unhelpful	Neutral	Number of Interactions	Average Trust Level
P1 ENFJ TP	6	0	1	7	6.3
P2 ENFJ TP	3	3	3	9	4.5
P3 ENFP TP	9	2	0	11	6.9
P1 ENFJ MP	2	2	0	4	2.75
P2 ENFJ MP	5	2	0	7	5.1
P3 ENFP MP	5	2	1	8	6.5

IV. RESULTS

The results indicate mixed results between different personalities and the perception of chatbots. We will go over each personality and their results between the chatbot.

A. The EN Personality and Frequencies

Table II presents the descriptive statistics for EN personality users across the three chatbots. "N" represents the total number of conversations, and "n" denotes the number of participants. The mean trust level is 5.05 (SD = 1.36), while the mean number of interactions is 8.33 (SD = 2.54), indicating participants had about eight conversations on average. Helpful responses occurred 4-5 times on average (mean = 4.72, SD = 2.69). Unhelpful responses averaged 2.61 (SD = 2.73), showing moderate variation, while Neutral responses occurred about 1-2 times (mean = 1.17, SD = 1.34).

According to Fig. 2, the frequency data suggests that users with "ENFJ" personality gave low trust scores to Cleverbot when Cleverbot's responses were unhelpful, as identified through the researchers' coding schemes. Despite this, the participants with "ENFJ" personality continued to have the conversation even when it failed to provide the desired information. The participant with the personityal of "ENFP" continued to give Cleverbot chatbot moderately high trust scores, even when conversations were less meaningful. This aligns with Hogans and Champagne's Personal Style Inventory Typology (1980), where the personality type ENFPs are known to be high-spirited, extremely ingenious, more likely to have the ability to be imaginative, and often do whatever they feel like they want to do, [24]. In contrast, participants in this study with the personality type of ENFJ were more likely to find the conversation less meaningful if Cleverbot did not address their prompts effectively, reflecting their responsiveness to their environment and sense of responsibility [24].

TABLE II. DESCRIPTIVE STATISTICS FOR THE EN PERSONALITY DIMENSION

	Mean	Std. Deviation
Trust	5.0597	1.35981
Interaction	8.33	2.544
Helpful	4.72	2.697
Unhelpful	2.61	2.725
Neutral	1.17	1.339

a. *N =18
**n = 3

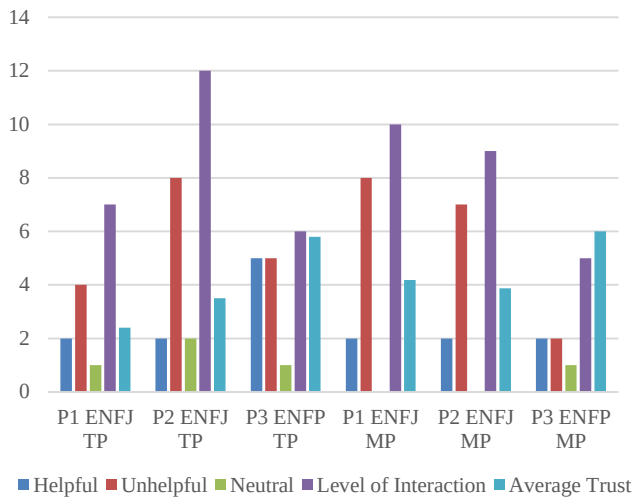

Fig. 2. Frequencies in cleverbot AI and EN personality.

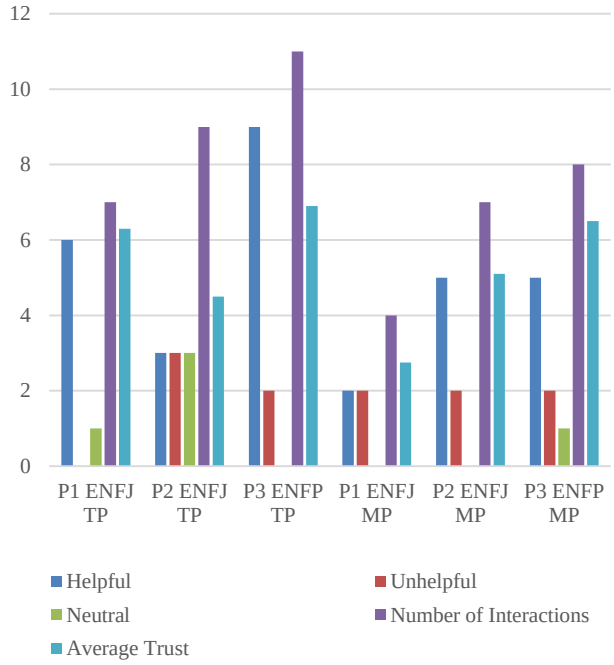

Fig. 3. Frequencies in kuki AI and EN personality.

According to Fig. 3, both participants with ENFJ personalities engaged in extended conversations with the Kuki chatbot. Through our careful analysis of their interactions, we determined that "Helpful" was the most frequently observed code across both conversations from ENFJ and the Kuki chatbot. The participant with an ENFP personality type also had meaningful conversations with Kuki and consistently gave it high scores, even when the chatbot's responses were neutral or unhelpful. This behavior aligns with Hogan and Champagne's Personal Style Inventory Typology (1980), which describes ENFPs as imaginative, adaptable, and optimistic in their interactions [24].

For ENFJ participants, conversations with Kuki involved fewer unhelpful interactions compared to Cleverbot. In the travel prompt scenario, Kuki AI received higher trust ratings, suggesting it was more effective in assisting users with their prompts. This indicates that Kuki's performance likely made it more appealing to users, earning significantly higher trust scores compared to Cleverbot.

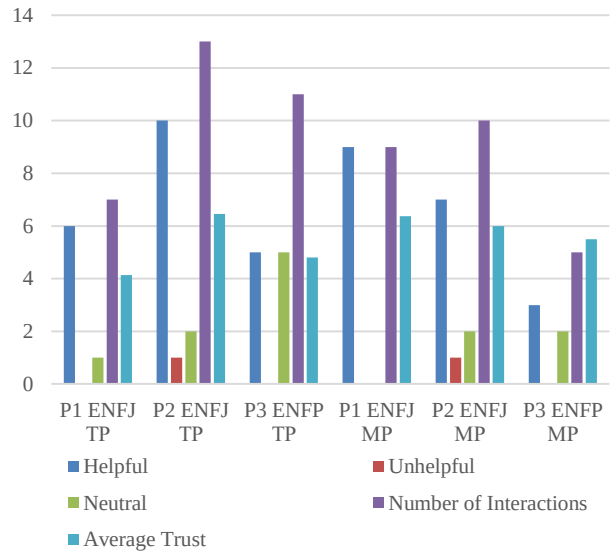

Fig. 4. Frequencies in replika AI and EN personality.

Fig. 4 illustrates the frequencies of each personality and the codes that were identified in their interactions. According to Fig. 4, Participant One (P1)-ENFJ showed fewer interactions and a moderately high average trust score during both prompts, indicating that the participant was able to obtain the information they needed, and ended the conversation when they were satisfied, leading to a moderate trust score given to the chatbot, deeming it trustworthy according to our Likert scale. P2-ENFJ yielded similar results. However, the participant with Personality ENFP had short conversations across both prompts and gave this chatbot a lower trust score compared to Cleverbot and Kuki. This pattern suggests that this participant may require more stimulating and engaging interactions to maintain longer conversations and find the chatbot trustworthy. By observing these behaviors, we can align it with Hogan and Champagne's Personal Style Inventory Typology (1980), where ENFJs are more responsible and ENFPs seek to be dynamic and explorative [24].

B. The ES Personality

Table III shows descriptive statistics for ES personality users across the three chatbots. The mean trust level is 4.06 (SD = 1.52), indicating some variation in trust among participants. The average number of interactions is 9.13 (SD = 6.97), suggesting high variability in how often participants engaged. Helpful responses occurred about four times on average (mean = 4.00, SD = 2.96), while unhelpful responses averaged 3.60 (SD = 4.02). Neutral responses were less frequent, averaging 1.73 (SD = 1.99), with some variation across participants. "N" represents 17 conversations, and n represents the number of participants within the ES personality dimension.

TABLE III. DESCRIPTIVE STATISTICS FOR ES PERSONALITY

	Mean	Std. Deviation
Trust	4.0642	1.52310
Interaction	9.13	6.966
Helpful	4.00	2.961
Unhelpful	3.60	4.018
Neutral	1.73	1.987

a.*N = 17

**n = 7

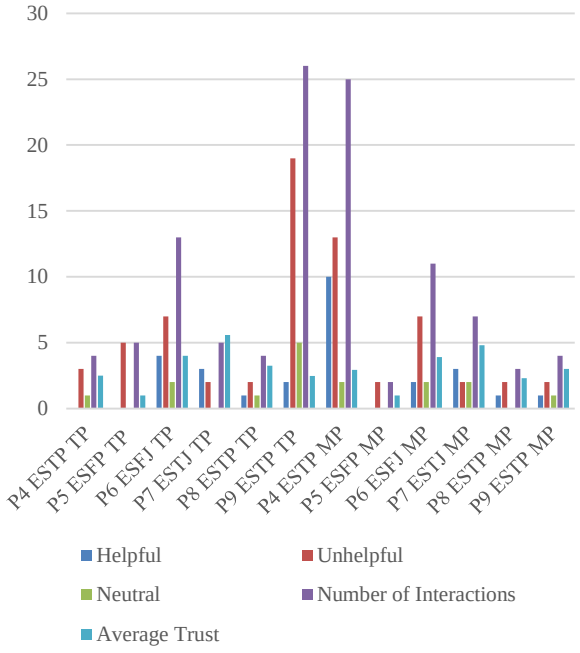

Fig. 5. Frequencies in cleverbot AI and ES personality.

Fig. 5 shows all ESTP participants rated Cleverbot AI poorly. This may be due to ESTPs needing to focus on practical tasks, so if this chatbot wasn't helpful, they ended conversations quickly to move on to more useful activities as they are sensitive to information and like to get explanations shorter, rather than a long conversation [24]. The participant with ESFP also had a low trustworthy experience with the chatbot, having small conversations but rating it a low trustworthy score. ESFPs, easily bored and less organized, likely disengaged if the chatbot wasn't engaging [38]. The participant with personality ESFJ had more unhelpful interactions but still gave a moderate trust score, likely due to their empathetic nature, born to be cooperative and need harmony to function [24]. When analyzing the participants with ESTJ personality, we found that their interactions with the chatbot were more helpful interactions, and can be the reason why it gave the chatbot a moderate average trustworthy score, which according to Hogan and Champagnes Personal Style Inventory Typology (1980), ESTJ's are known to be interested in subjects when they can be helpful and are often to see perspectives from another viewpoint [24].

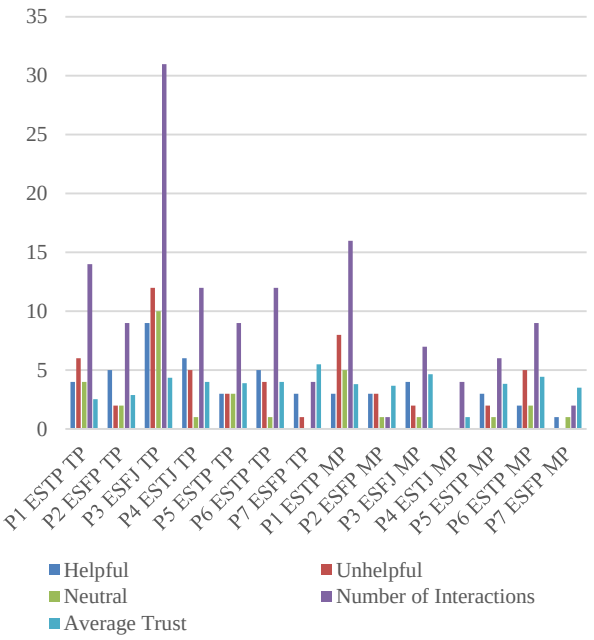

Fig. 6. Frequencies in kuki AI and ES personality.

According to Fig. 6, all three ESTP participants perceived Kuki as untrustworthy, as they all gave Kuki low trustworthy scores, even when responses were neutral. This can be due to their personality being blunt and may not have wanted to have long conversations if they were not straight to the point [24]. We had identified that one of the participants with ESFP (P1), personality had a handful of helpful interactions, as interpreted by our coding scheme, yet this participant rated Kuki lower, possibly due to its blunt, unengaging tone, as ESFPs like to enjoy things around them and enjoy entertainment from others [24, 38]. In contrast, the other participant with ESFP (P5) had fewer interactions but a moderate trust score, indicating that personality does vary from person to person. The participant with ESFJ had long conversations with Kuki, and we analyzed that most of the conversation was deemed to be unhelpful, but the participant still rated the conversation as moderately trustworthy, again relating to their personality where they want harmony and try to be nice [24]. The participant with personality ESTJ gave Kuki low trust scores even if the conversation was helpful.

Fig. 7 indicates that there are quite helpful interactions as observed by the researcher. Our findings suggest that ESTP participants engaged in more interactions overall when the conversation was meaningful and interactive, without having the chatbot to over-explain their responses. ESFJ users had high trust scores towards Replika and was observed by the researchers that during the meal prompt, there were some unhelpful interactions, but the participant still had viewed the chatbot as trustworthy, relating to their personality where they needed harmony. The participant with ESFP when interacting with Replika AI was seen to have conversations that were small, and neutral, yet still gave Replika an average trust score of 5, indicating moderate trustworthiness towards the chatbot. ESFP users are known to be outgoing, accepting, and make

their surroundings fun, thus if the participant with the personality of ESFP had meaningful interactions with Replika, they must have been accepting of it [24].

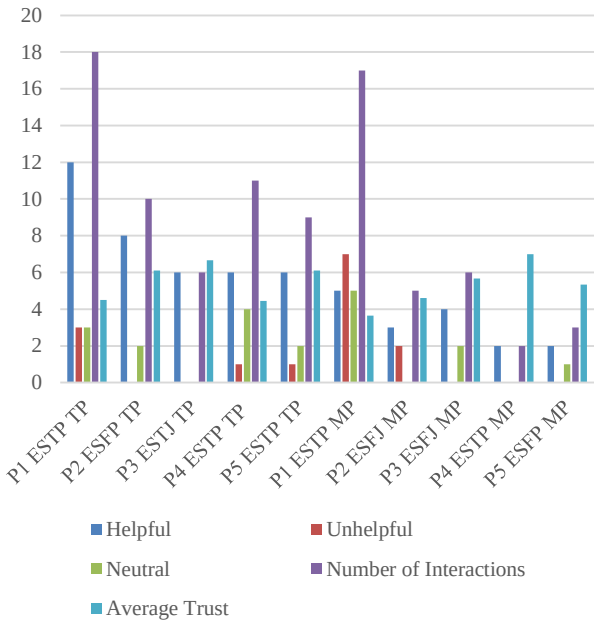

Fig. 7. Frequencies in replika AI and ES personality.

C. The IN Personality and Frequencies

Table IV shows descriptive statistics for IN personality users across the three chatbots. The mean trust level is 3.99 (SD = 1.49), the average number of interactions is 14.9 (SD = 10) suggesting high variability in how often participants engaged. Helpful responses averaged at 6.67 times (mean = 6.67, SD = 5.653), while unhelpful responses averaged a bit more with 6.80 average (SD = 4.02). Neutral responses were less frequent, averaging 1.70 (SD = 2.020), with some variation across participants.

TABLE IV. DESCRIPTIVE STATISTICS FOR IN PERSONALITY

	Mean	Std. Deviation
Trust	3.9908	1.49869
Interaction	14.93	10.007
Helpful	6.67	5.653
Unhelpful	6.80	6.18
Neutral	1.70	2.020

a.* N = 30

** n = 6

Fig. 8 indicates that the participant with personality INFJ had extremely long conversations in both prompts with Cleverbot. However, despite the long conversations, we observed that there were quite unhelpful interactions between the participant and the chatbot. This aligns with Champagnes *Personal Style Inventory Typology* (1980), where personality INFJ work hard for their needs met, and have a desire to get things done when they want it, they are hard workers and put a lot of effort into their work. It seems as if this participant with INFJ wanted Cleverbot to respond to the prompts accordingly.

The participants with INTJ users yielded similar results, long conversations, unhelpful responses frequently, and very low trustworthiness towards the chatbot. According to Hogan and Champagne, the INTJ personality type is often stubborn, skeptical, and critical [24]. It must have been that these participants were more likely to be critical of Cleverbot. The participant with INTP views trust towards Cleverbot as very untrustworthy, as Hogan and Champagne describe the INTP personality as extremely logical [24], so if the chatbot was not being logical with the user, the participant must have viewed it as untrustworthy.

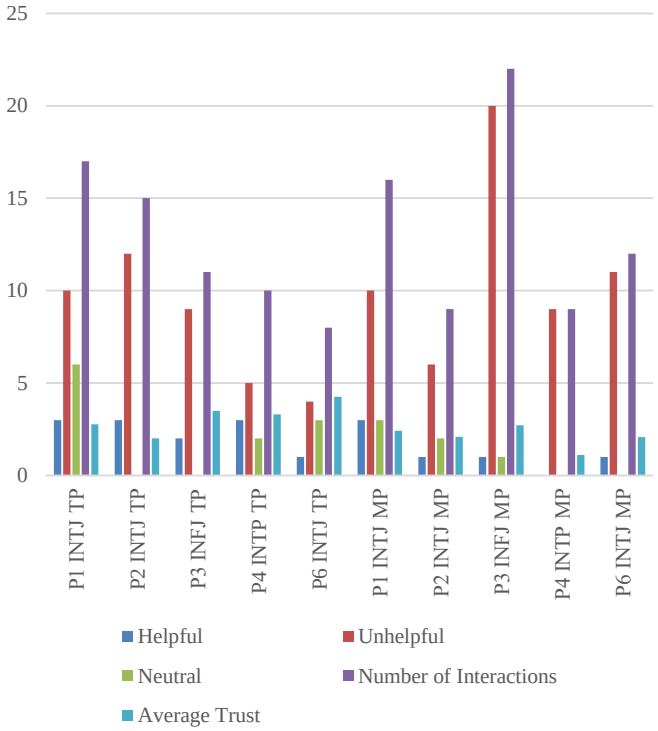

Fig. 8. Frequencies in cleverbot AI and IN personality.

Fig. 9 shows the interaction frequencies and average trust with Kuki and IN personality types. The participants with personality type INFJ had the highest interaction levels but also faced more unhelpful responses. Despite these interactions, their perceived trustworthiness towards the chatbot remained low, indicating the participant viewed this chatbot as untrustworthy. All participants with INTJ experienced high helpful responses from Kuki, and still gave moderate trust towards Kuki. INTJs are known to have great drive when it fits their own ideas and has meaningful interactions [24]. We noticed that all conversations between Kuki and all the participants with INTJ had more helpful interactions compared to Cleverbot. The participant with INTP personality had quite a few conversations and had an overall average low untrustworthy score towards the chatbot. The participant with INFJ had the most conversations with this chatbot, despite the chatbot having more unhelpful responses compared to the helpful responses in the interaction between Kuki and the INFJ participant. INFJs are known to go above and beyond, putting their best efforts into their work, therefore it may have been that

this participant wanted to get the best answer from the chatbot over long conversations. [24].

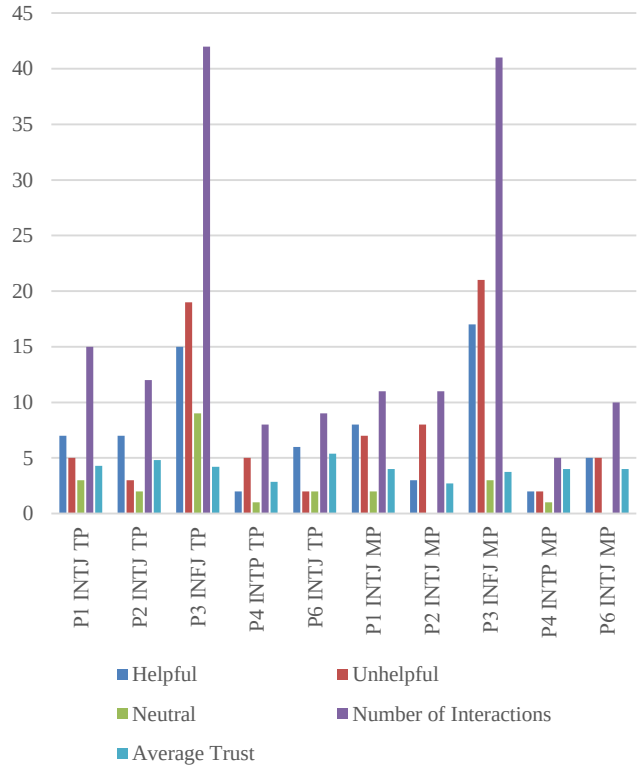

Fig. 9. Frequencies in kuki AI and IN personality.

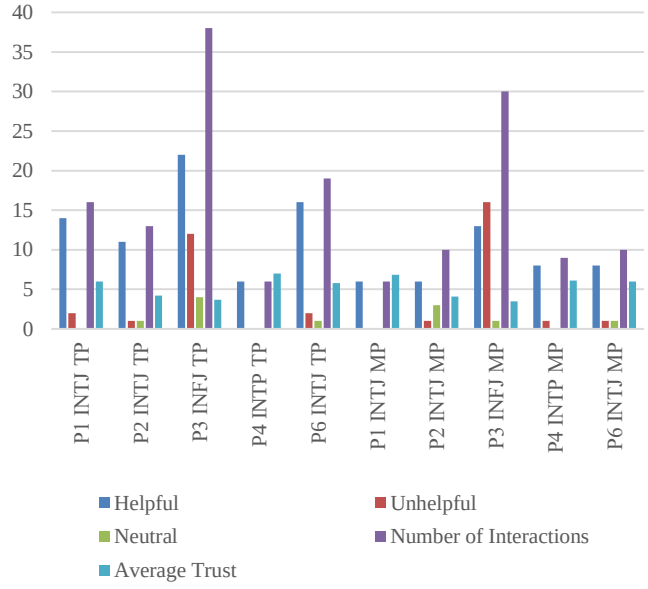

Fig. 10. Frequencies in replika AI and IN personality.

Fig. 10 displays the frequencies of interactions between Replika and users within the IN personality types. The participant with INFJ still had quite long conversations with Replika, as they did with Kuki and Cleverbot, relating to their personality once more where they work until they put their effort in [24]. All participants with INTJ had high trustworthiness towards the chatbot, and we observed that they all had more frequencies in the helpful category when we analyzed their interactions in both prompts. The participant with INTP had few conversations but deemed the chatbot to be very trustworthy based on their average trust score. We observed that Replika was more logical in their responses, and interacted well with all participants, leading to high average trust scores.

D. The IS Personality and Frequencies

Table V presents the descriptive statistics for the IS personality dimension and their code frequencies when interacting with all three chatbots. The mean trust across all chatbots is 3.85, with a standard deviation of 1.62, indicating a moderate level of trust across interactions. Participants engaged around an average of 14.12 interactions per conversation, with a standard deviation of 9.33, indicating a high variability in interactions. Helpful responses occurred most frequently, with a mean of 6.53 and a standard deviation of 5.38. Unhelpful responses were averaging around 4.60 with a standard deviation of 4.17. Neutral responses were least common, with a mean of 2.30, and a standard deviation of 2.76, indicating some variability across the interactions with all three chatbots. N represents the number of conversations analyzed, and n represents the total number of participants.

TABLE V. DESCRIPTIVE STATISTICS FOR IS PERSONALITY

	Mean	Std. Deviation
Trust	3.8549	1.61590
Interaction	14.12	9.325
Helpful	6.53	5.376
Unhelpful	4.60	4.172
Neutral	2.30	2.761

a.*N = 69
**n = 13

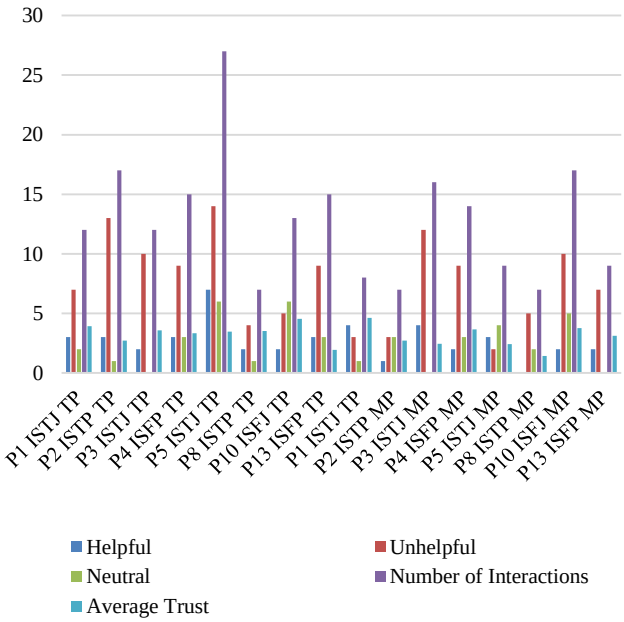

Fig. 11. Frequencies in cleverbot AI and IS personality.

Fig. 11 represents those participants with ISTJ personality had more helpful interactions within the meal prompt rather than the travel prompt, indicating their personality is to stay on task [39, 40]. The participants with ISTP had more unhelpful interactions with Cleverbot leading to a low average trust score within the travel prompt. We find this quite interesting, as according to Hogan and Champagne, people with ISTP personality types tend to not think necessarily more than they should, and that waste of energy is inefficient [24], we infer that the participants with the ISTP personality were trying to get the perfect answer from the chatbot to make up for the time they put into chatting with the chatbot.

Participants with ISFP had few long conversations, and this aligns with their personality, where Hogan and Champagne describe them as people who are often modest about their abilities, are not one to disagree, nor force their values or opinions on others [24]. Though they had long conversations, we analyzed that their conversations had more frequencies of unhelpful responses. Both participants with the ISFP personality still viewed the chatbot to be untrustworthy as indicated by their average trust score. Participants with the ISFJ personality yielded results that indicated they had more frequencies in the unhelpful code during their interaction with Cleverbot, aligning with Hogan and Champagne ISFJ personality type, where individuals work hard to get their obligations finished, and want to be accurate [24]. We can also infer that this participant with ISFJ wanted to get the right answers from the chatbot.

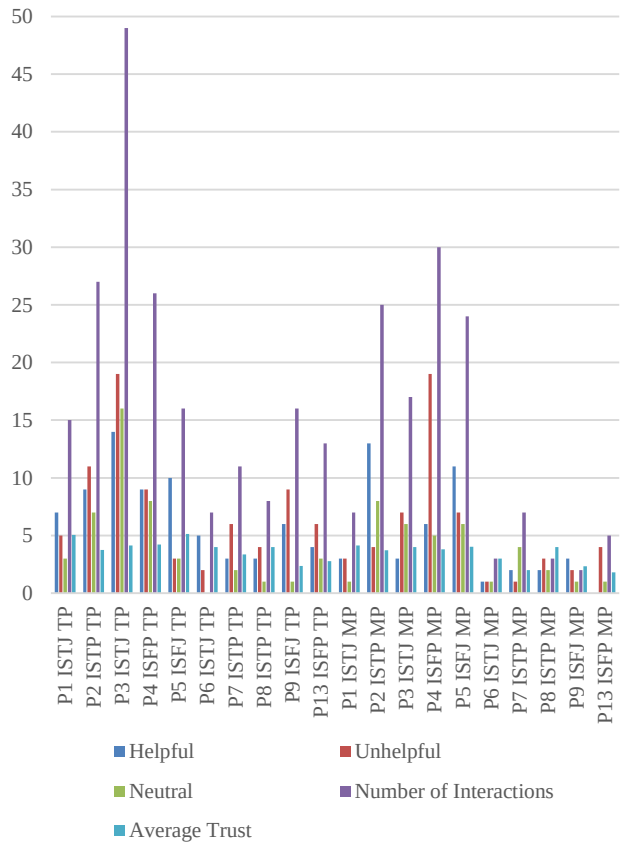

Fig. 12. Frequencies in kuki AI and IS personality.

Fig. 12 indicates that participants with personality ISTJ had perceived Kuki as moderately untrustworthy, despite the long conversations. ISTJs are known to be "Practical, orderly, matter of fact, logical, realistic and dependable [24]. As indicated in Fig. 12, Participant 3 with personality ISTJ had long conversations, but low trust towards the chatbot, while the other participant (Participant 6) with personality ISTJ had smaller conversations with Kuki but viewed the chatbot as moderately trustworthy, as indicated by the average trust score. These two participants had completely different views towards the chatbots, and experiences, indicating that every individual is different. Users with ISTP were flexible with their interactions with the chatbots, but overall, all participants with the ISTP personality had a low trustworthiness perception of Kuki. Participants with ISFP had long conversations in the travel prompts, and both viewed Kuki as very untrustworthy as indicated by their average trust score. However, in the meal prompt participant 13 with personality ISFP had a small interaction, with a very low average trust score, perceiving the chatbot as very untrustworthy. ISFPs are known to not want to waste time, so we can infer that Participant 13 did not want to continue the conversation [24]. When analyzing ISFJ participants, these participants had moderate untrustworthy perceptions towards the chatbot as indicated by their average trust scores in both prompts but do have the highest trust with Kuki when compared to the other three types of Introvert-Sensing types.

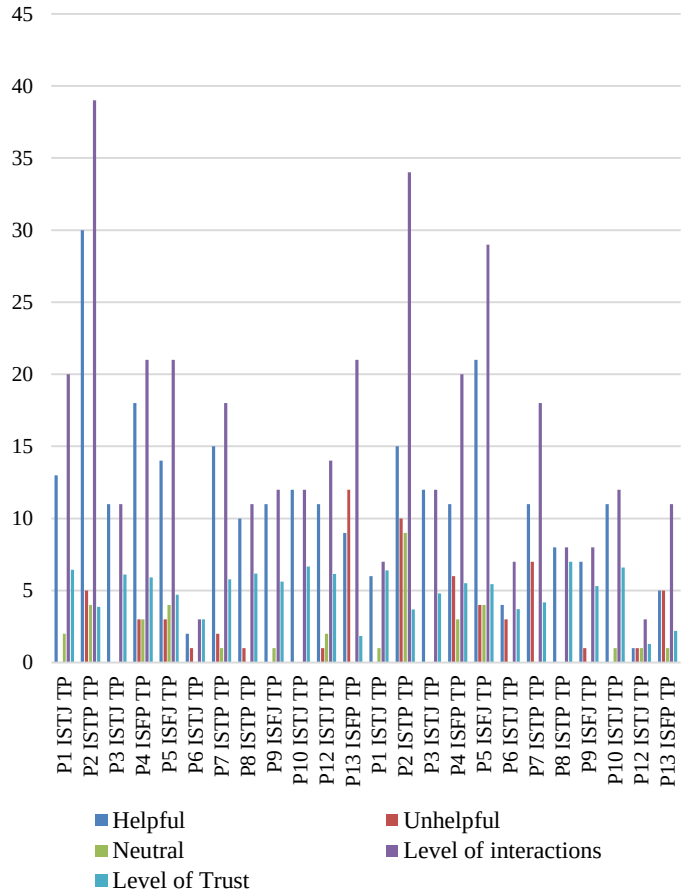

Fig. 13. Frequencies in kuki and the IS personality.

Fig. 13 indicates that all participants with ISTJ that had helpful frequencies, and long conversations tended to have a high average trust score in both prompts. However, we noticed that if the interaction was short, the participants with ISTJ continued to have low perceptions of trustworthiness towards Replika, as indicated in Participants 12 and 6. The participants with ISFJ had long conversations and a high score of average trust towards Replika. This might be due to their hard work and devotion, warm-heartedness, attention to detail, and need for accuracy, and how the Replika chatbot gave helpful responses, this might have led to high trustworthiness average scores [24]. All ISTP users had high trustworthiness towards the chat, indicating their personality of being flexible and easygoing, especially when the chatbot was helpful as we observed. The participants with ISFP all had moderately high trustworthiness towards Replika, and we observed that Replika did give helpful responses to all prompts when interacting with users with the Introvert-Sensing type.

V. Discussion and Limitations

Within the Intravenous and Intuition Dimension, participants with ENFJ tended to have lower trust scores in Cleverbot, and Kuki when it was not helpful and tended end to the conversation, however, one participant in the EN dimension with personality ENFP tended to give the chatbot higher scores when it was not helpful, rather, giving it a lower score when it was helpful. Within our coding, if the chatbot was being tangible (i.e. steering off the conversation to complete something different, such as "Who Cares"), or not engaging with the user, this would be considered unhelpful. Despite the chatbot being unhelpful, the participant with user ENFP continued to give it higher trust scores. It can be inferred that in this study, the participants with ENFP personalities wanted more interactions that engaging, and more exciting, as their personality tends to be open to opportunities and tends to be more imaginative [14].

ENFJs in this study were more likely to end the conversation if the conversation was not meaningful. This relates to their personality, as ENFJs tend to be more logical, organized, and worthy of leadership [32].

Within the analysis of ES (Extraverted and Sensing) personality, ESTP users' conversations with all chatbots were often brief, especially when the conversation led to unhelpful responses. In our study, ESFP participants, known for their energetic nature [33] tended to rate chatbots when it was helpful and engaging. ESTJ participants gave higher scores when the chatbot was helpful and gave clear answers, as this relates to their personality where they value logic, relativism, and directness nature [32, 33], tended to give lower trust scores to the chatbot despite when the chatbot was helpful and engaging. ESFJ on the other hand, gave moderate trust scores to the chatbots even when it was being unhelpful, this can relate to their personality as they are more warmhearted and sensitive to the environment around them, as seen more in women for their motherly nature and warmhearted figures [32, 34].

The Inverted and Intuition (IN) Dimension had mixed results. Participants with personality INFJ gave chatbots the lowest scores, despite being helpful or unhelpful. This relates to their personality from the dimension of the 'Feeling" and "Judgement", where they follow their own conviction and own path rather than objective fact [35].

Users with personality INTJ had more helpful interactions and reported higher trust scores, indicating that the more beneficial and engaging the chatbot is, the more users tend to trust it despite the level of interactions. This goes on with their personality as they are more rational when it comes to their environment and analytic to the future when it comes to decisions [36, 37].

Participants with personality INTP had mixed results with some chatbots. It had mixed results from helpful, unhelpful, and neutral interactions. While interaction levels were consistent, they didn't necessarily lead to higher trust levels. Overall, the INTP participants did not have consistent results between the three chatbots. This relates to their personality as they are more likely to be spontaneous and have more intuition rather than sensing, and difficult to please, so if they have a bad experience, this leads to difficulty in getting high trust scores [37, 38].

The largest set of personalities in this simple was Introverted and Sensing (IS). In all three chatbots (Cleverbot, Kuki, and Replika) the participants with IS tended to still have longer conversations despite the possibility that the chatbot was not being helpful. Research has indicated that individuals with personality ISTJ tend to be nervous when it comes to high achievement, and have a need to accomplish a task [24, 39, 40], it can be inferred that participants in this study wanted to continue to conversate with the chatbot until they were able to get a good answer from them, despite having lower scores in trust and unhelpfulness. ISTP yielded different results, showing more trust in the chatbot despite being unhelpful, as their perception leads them to think the chatbot might have been worthy of a high trust rating, despite objective unhelpful frequencies in their conversations, feeling the way of their senses as well rather than being intuitive, allowing for flexibility in their way of perceiving the world [33, 37].

The participants with the ISFJ personality had similar results to ISTP surprisingly, where as seen in their conversations with Replika, they tended to have higher trust towards Replika, yet still showed moderate trust levels in Cleverbot and Kuki despite those two chatbots being unhelpful. ISFJs are known to be more warm-hearted, sincere, and approachable, having the desire to engage with the chatbot as long as emotional satisfaction is involved, their "Feeling" type indicates they still felt something for the chatbot despite not being helpful [24].

The participants with ISFP personality tended to have high trust scores in all three chatbots as compared to the other IS types, despite the categories of helpfulness, unhelpfulness, and neutral. Their personality of feeling and perceiving might have influenced their trust scores to be higher with the chatbots.

While each personality yielded different results, with a few cases of similar results, there are limitations to this study. Within the Dimension of Extraversion and Intuition, this personality was underrepresented in this study, and Introversion dominated this study. The sample size was taken from an Information Systems major program, where students can go on to work in the cybersecurity field, be engineers, or work in tech,

and research has shown that students with introversion tend to likely be engineers, and work in the science field [41, 42]. Another limitation is that there is missing data from several users from the Introvert-Intuition (IN) Dimension, Introvert-Sensing (IS) Dimension, and Extrovert-Sensing (ES) dimension. However, we have successfully collected a large amount of systematic conversations from 29 participants. The results can be generalized to similar personality users to contribute to broader findings.

VI. Conclusion

We observed how personality dimensions influence trust and engagement towards chatbots across two different scenarios, a travel prompt and a meal prompt. We had the participants rate each interaction on a Likert scale rating from 1 to 7, with 7 being the highest trustworthy score, and 1 being the lowest trustworthy score. We created a hierarchical modeling scale to organize our data, and had participants go through three chatbots to explore variabilities in each chatbot. We found key findings, which included that the participants with ENFJ personalities rated Cleverbot low, in counterpart with our other participants ENFP who seemed to enjoy the conversation they had with Cleverbot, aligning with their imaginative and optimistic natures [24].

ESTP participants preferred direct, practical responses and gave lower trust scores when interactions were inefficient. Similarly, we observed that ESFP participants disengaged from unengaging chatbots but appreciated entertaining responses, while ESFJs maintained moderate trust levels, driven by their empathetic and harmony-focused personalities [24]. ESTJ participants rated trust highly when interactions were helpful but were critical of less engaging exchanges.

For Introverted-Intuitive personality types, INFJ participants engaged in long conversations but rated unhelpful interactions as untrustworthy, consistent with their diligent and goal-oriented nature. INTJs preferred meaningful interactions and gave moderate trust scores to Kuki due to its helpful responses, while INTP participants, being highly logical, rated chatbots as untrustworthy when responses lacked coherence or when the chatbot failed to deliver the information the participant wanted.

For our Introverted-Sensing types, ISTJ participants valued helpful interactions and rated them highly, though shorter or unhelpful exchanges led to lower trust. ISTPs, known for their practicality [24], also rated chatbots lower when responses were inefficient or overly lengthy. ISFP participants, modest and time-conscious, found chatbots untrustworthy if responses lacked engagement, while ISFJs maintained moderate trust levels, valuing accuracy and helpfulness, particularly with Replika.

Across all three chatbots, we observed that the Kuki chatbot was perceived as more trustworthy by most of the participants in this study, more with the Extroverted-Intuitive and Extroverted-Sensing types due to its helpfulness. Replika received the highest trust scores, particularly from ISFJ and ISTP users, due to its logical and engaging responses. These findings underscore the importance of tailoring chatbot interactions to align with user personality traits, enhancing trust and satisfaction by balancing logical coherence, directness, and emotional engagement.

The future study will recruit participants from all majors to increase the sample size in different personality dimensions except for the IS dimension in which we have enough data from technology-related major students. We will also continue to design chatbots focusing on personality following the design interpretations from this work. This work contributes to the fast development of user-centered CA design with frequencies of user responses and trustworthy ratings to sort their behaviors by patterns correlating to their personality dimensions. It focuses on user perceptions of trust in chatbot experience. It also presents detailed interpretations of diverse personality users' behavior patterns and trends to show how they interact with CAs. The work sheds light on design guidelines of user trust based on personality for better human-centered AI design.

***Abstract*—The exponential growth of Internet of Things (IoT) devices has introduced critical security challenges, particularly in scalability, privacy, and resource constraints. Traditional centralized intrusion detection systems (IDS) struggle to address these issues effectively. To overcome these limitations, this study proposes a novel Federated Transfer Learning (FTL)-based intrusion detection framework tailored for large-scale IoT networks. By integrating Federated Learning (FL) with Transfer Learning (TL), the framework enhances detection capabilities while ensuring data privacy and reducing communication overhead. The hybrid model incorporates convolutional neural networks (CNNs), bidirectional gated recurrent units (BiGRUs), attention mechanisms, and ensemble learning. To address the class imbalance, Synthetic Minority Over-sampling Technique (SMOTE) was employed, while optimization techniques such as hyperparameter tuning, regularization, and batch normalization further improved model performance. Experimental evaluations on five diverse IoT datasets, i.e. Bot-IoT, N-BaIoT, TON_IoT, CICIDS 2017, and NSL-KDD, demonstrate that the framework achieves high accuracy (92%-94%) while maintaining scalability, computational efficiency, and data privacy. This approach provides a robust solution to real-time intrusion detection in resource-constrained IoT environments.**

I. INTRODUCTION

The rapid growth of the Internet of Things (IoT) has introduced significant security challenges due to the diversity and resource constraints of IoT devices. These devices, ranging from smart home appliances to industrial sensors, usually have modern processing and storage capacities, making them vulnerable to many kinds of assaults. When used in IoT environments, traditional intrusion detection systems (IDS) that rely on centralized structures face several problems and critical challenges, including scalability, latency, communication overhead, and privacy risks. Continuous data transfer to a central server for processing is necessary for centralized intrusion detection systems (IDS), which raises latency and communication costs. Additionally, because sensitive data from IoT devices needs to be sent and kept centrally, centralized systems provide serious privacy risks.

Despite their importance, current IDS implementations are ill-equipped to handle the unique requirements of IoT environments, particularly regarding real-time threat detection, adaptability to emerging threats, and resource efficiency. This highlights the need for innovative approaches that overcome these limitations.

Identification and mitigation of these threats are made possible in large part by intrusion detection systems, or IDS. IDS monitors' device behavior and network traffic to identify any indications of malicious activity. Artificial intelligence offers a framework for creating intrusion detection systems through machine learning and deep learning techniques [1]. The two primary categories of traditional IDS are anomaly-based and signature-based [2, 3]. Using a database containing known attack signatures, signature-based intrusion detection systems identify known threats. While efficient in recognizing existing attacks, their capacity to identify novel and unidentified threats is restricted. Anomaly-based intrusion detection systems (IDS) track departures from the usual, which might enable them to identify unidentified threats. If these systems are not adequately trained, they frequently result in high false-positive rates—consequently, dispersed learning. Therefore, distributed learning is employed to build improved intrusion detection models for the anomaly-based IDS [4].

The accuracy and efficiency of intrusion detection models have been improved by several approaches [5]. Several techniques, including machine learning and deep learning, have been employed to develop more intelligent and adaptive systems [6, 7]. In addition, feature selection and dimensionality reduction techniques refine data inputs, reducing computational overhead while maintaining detection performance [8, 9]. Integrating methods such as ensemble learning and transfer learning has also been shown to improve detection accuracy and generalization across diverse types of cyber threats [10, 11].

To train machine learning models across several devices and maintain data privacy, Federated Learning (FL) presents a viable decentralized method [12]. Using their local data, IoT devices cooperatively train a shared global model in FL; model updates are only sent to a central server for aggregation. By ensuring that raw data remains on local

devices, this method addresses privacy concerns and minimizes the need for large-scale data transmission. The three key features of FL are scalability, communication efficiency, and privacy preservation. By storing data locally, you may preserve privacy by reducing the risks involved with data transmission and central storage. Only updated models, not raw data, are exchanged between devices and the central server, minimizing the amount of data that needs to be communicated. This ensures optimal communication efficiency. Furthermore, FL is very scalable, which makes it ideal for a wide range of IoT scenarios [13]. However, while FL addresses privacy and data transmission concerns, it alone may not fully address the need for rapid adaptation to new and evolving threats in IoT networks [14].

Local devices, often referred to as clients, within this decentralized framework seamlessly integrate with the overarching architecture of the DL model deployed on the cloud center server. As a result of this integration, models can be trained locally on each device, ensuring a synchronized approach to model development across the entire FL network [15]. While FL has shown promise in addressing privacy and scalability concerns, it struggles to adapt to rapidly evolving threats in IoT environments. This underscores the need for enhanced techniques that can combine the privacy-preserving features of FL with models that adapt quickly to diverse IoT environments.

Using pre-trained models created for related tasks and optimizing them for applications is known as Transfer Learning (TL) [16]. Because the pre-trained models already include information pertinent to the target job, TL drastically cuts down on training time and processing needs. Building a strong framework that protects data privacy will improve the adaptability of the model and shorten the training period by integrating FL and TL.

Despite significant progress in FL and TL applications, few studies have successfully combined these techniques to address the unique challenges of IoT networks comprehensively. Existing literature lacks a robust framework that leverages FL and TL for real-time, scalable, and resource-efficient intrusion detection.

Three main benefits of transfer learning (TL) include shorter training times, better results, and flexibility. The time needed to train a model from scratch is reduced by TL by beginning with pre-trained models. Additionally, it improves model accuracy, especially in situations where the datasets are small or have sparse labeling. Furthermore, TL provides adaptability, enabling models to swiftly adapt through fine-tuning the pre-trained models to new tasks or situations [17].

This work introduces a Federated Transfer Learning (FTL) framework that combines the strengths of FL and TL to improve intrusion detection in IoT networks. The framework enhances detection accuracy through a hybrid model integrating convolutional neural networks (CNNs), bidirectional gated recurrent units (BiGRUs), attention mechanisms, and ensemble learning. Additionally, it addresses class imbalance using the Synthetic Minority Over-sampling Technique (SMOTE) and optimizes model performance through hyperparameter tuning, regularization, and batch normalization.

The contributions of this research are as follows:

Addressing Scalability and Privacy Concerns: The proposed FTL framework decentralizes model training to preserve privacy and reduce communication overhead, enabling effective intrusion detection in IoT networks.

Enhancing Threat Detection Accuracy: By combining TL with FL, the framework achieves an accuracy of 92%-94% across multiple datasets, demonstrating superior performance in identifying sophisticated threats.

Optimizing for IoT Resource Constraints: Techniques such as L1/L2 regularization and batch normalization ensure the model is lightweight and efficient, suitable for resource-limited IoT devices.

Handling Class Imbalance: SMOTE is employed to improve model generalization by addressing the underrepresentation of attack samples in IoT datasets.

Adapting to Diverse IoT Environments: Domain adaptation techniques ensure the model is flexible and robust, enabling it to generalize across various IoT devices and datasets.

This study fills a critical gap in the literature by presenting a scalable and privacy-preserving framework for real-time intrusion detection in IoT networks. The rest of this paper is organized as follows: Section II reviews related work; Section III outlines the methodology; Section IV presents the experimental results; Discussion is given in Section V and Section VI concludes the paper, highlighting limitations and future research directions.

II. Related Work

The field of intrusion detection in IoT networks has seen significant advancements through various innovative methodologies [5]. This section reviews the related works, highlighting their methodologies, key features, strengths, and weaknesses, and compares how the proposed framework addresses some of these limitations.

Karimy and Reddy [18] employed FL to enhance security and privacy in IoT environments. The methodology involves local model training on IoT devices and subsequent aggregation of the model updates on a central server. The authors achieved an accuracy of 99.9% when they used the N-BaIoT and other custom datasets. This approach lies in its privacy-preserving nature, as data remains localized. However, the approach suffers from high computational overhead. Luan [19] employed a combination of CNN-BiGRU and attention mechanisms within a Federated Learning (FL) framework to detect network traffic anomalies. The method was evaluated using the BoT-IoT and NSL-KDD datasets. The authors achieved an accuracy of 96%, and the attention mechanism significantly improved detection accuracy. It also introduced high computational costs.

Almesleh et al. [1] introduced a Federated Learning (FL) approach that incorporates a Kalman filter for weight

aggregation, enhancing the overall performance of the model. With an accuracy of 99.8%, the Kalman filter enhances the weight aggregation process across a variety of IoT datasets, contributing to robust performance. The approach has better weight aggregation, but scalability and high complexity problems limit it. Bhavsar et al. [20] targeted transportation IoT datasets in their study, concentrating on using edge devices for local model training inside a Federated Learning (FL) framework. This method works effectively in large-scale IoT contexts because it is scalable and provides effective local training. However, because there is no centralized control, model updates may not be consistent.

Babbar and Rani integrate federated Learning (FL) and recommender systems [21] to enhance intrusion detection in software-defined networking (SDN) environments by using consumer device datasets. Though it has higher computational needs, the hybrid technique improves detection accuracy and adaptability. Across a variety of IoT datasets, Raj et al. [22] enhanced security protocols using FL. Key advantages include improved security procedures and privacy-preserving techniques. The method has scalability problems and significant overhead, though.

Ohtani et al. [2] used the N-BaIoT dataset to combine Federated Learning (FL) with one-class SVM for the purpose of detecting zero-day attacks in IoT networks. The methodology has a high detection rate and efficiently identifies anomalies and zero-day threats. However, it has a high false positive rate.

Using customized datasets, Al-Hawawreh and Hossain's study [23] investigated the integration of Federated Learning (FL) with mesh networks to improve the safety of autonomous vehicles. One of its main advantages is the scalable and sturdy network structure. However, the approach is complex and resource intensive. After testing unique IoT attack datasets, Umair et al. [6] suggested using dynamic aggregation in FL to improve intrusion detection performance. Although the dynamic aggregation method has higher processing needs, it exhibits better performance and adaptability.

TABLE I. RELATED WORK COMPREHENSIVE OVERVIEW

Paper Title	Methodology	Dataset(s)	Acc	Strengths	Weaknesses	Time
[1]	FL, Kalman Filter	Various IoT Datasets	99.8	Improved weight aggregation, Robust performance	High complexity, Limited scalability	High
[4]	FL, One-Class SVM	N-BaIoT	-	Effective zero-day detection, Autonomous	High false positive rate	-
[15]	FL, Dynamic Aggregation	Custom IoT Attack Dataset	87.98	Improved performance, Adaptability	High computational requirements	High
[18]	FL	N-BaIoT, Custom Dataset	99.9	High accuracy, Privacy-preserving	High computational overhead	High
[19]	FL, CNN-BiGRU, Attention	BoT-IoT, NSL-KDD	96	High accuracy, Attention mechanism	High computational cost	High
[20]	FL, Edge Devices	Transportation IoT Dataset	From 94 to 99	Efficient local training, Scalability	Lack of centralized control	-
[21]	FL, Recommender Systems	Consumer Device Dataset	From 78 to 99	Enhanced detection accuracy, Adaptability	High computational requirements	High
[22]	FL	Various IoT Datasets	-	Enhanced security protocols, Privacy-preserving	High overhead, Scalability issues	High
[23]	FL, Mesh Networks	Custom Autonomous Vehicle Dataset	From 95 to 99	Robust network, Scalable	High complexity, Resource-intensive	High

To guarantee the integrity and immutability of model updates and solve security concerns in decentralized systems, the proposed framework integrates FL and TL. Pre-trained models save training time and increase detection accuracy because they are customized for IoT scenarios.

By combining FL and TL, the suggested methodology seeks to improve real-time intrusion detection in IoT networks while addressing the limitations of the other methods mentioned in the related work section. It uses a hybrid model that incorporates advanced machine learning methods including CNNs, BiGRUs, and attention processes. Strategies for data augmentation and optimization help to further improve performance. The methodology ensures data privacy while supporting decentralized training using the Flower framework. Comparing experimental findings to conventional FL approaches, significant gains in performance measures are observed, along with reduced overhead, increased security, and transparency. Table I provides a summary and comparison of existing works in the field with the proposed research, highlighting their methodologies, strengths, weaknesses, and performance metrics. This comparison underscores the advancements introduced by this study, particularly in addressing limitations such as scalability, privacy, and adaptability in IoT intrusion detection.

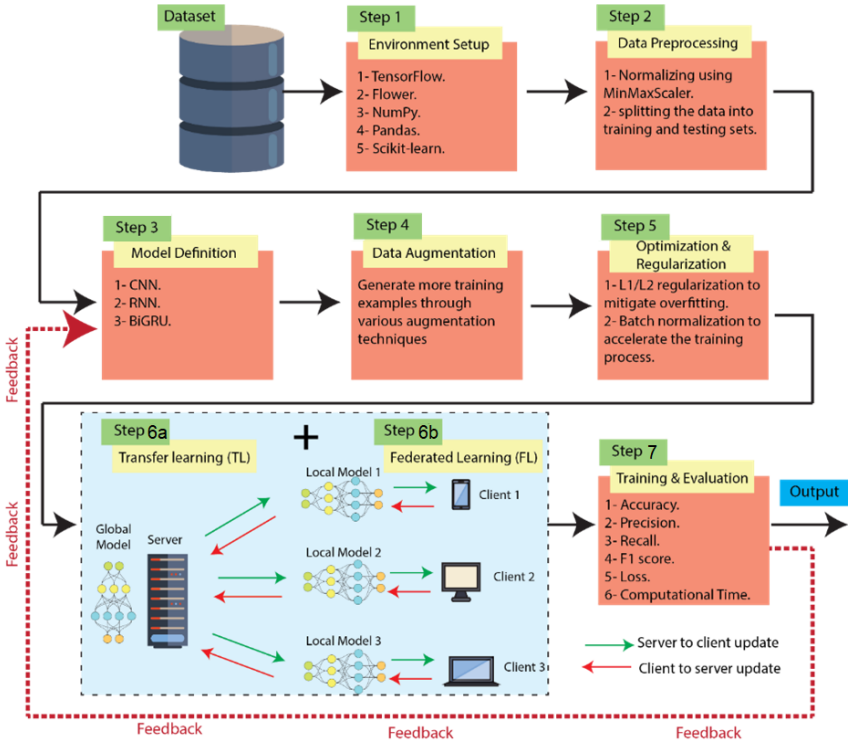

Fig. 1. Steps of the proposed methodology.

III. METHODOLOGY

To assess the effectiveness of the improved model on various IoT datasets, a systematic approach leveraging Federated Learning (FL) and Transfer Learning (TL) has been adopted. These techniques were selected to address critical challenges in IoT environments, including privacy preservation, scalability, and adaptability to diverse datasets. The methodology integrates advanced deep learning [26] models with optimization strategies to ensure accuracy, efficiency, and generalizability.

Rationale: Federated Learning (FL) is utilized to ensure decentralized model training across IoT devices, preserving data privacy and reducing communication overhead. However, FL alone lacks rapid adaptability to new threats. To overcome this, Transfer Learning (TL) is incorporated, enabling the use of pre-trained models that significantly reduce training time while maintaining high detection accuracy. Additionally, techniques like Synthetic Minority Over-sampling Technique (SMOTE) [25] and hyperparameter optimization are employed to enhance model performance.

The methodology comprises the following steps (Fig. 1):

Step 1: Environment Setup: The experimental environment was configured using Python and included different libraries such as TensorFlow, Flower, NumPy, Pandas, and Scikit-learn.

Step 2: Preparing the Data Several widely used IoT datasets were employed, including BoT-IoT, TON_IoT, CICIDS2017, NSL-KDD, and N-BaIoT. Preprocessing was done on each dataset to make sure it was standardized and ready for model training. To enable model evaluation and performance assessment, this involved importing the data, using MinMaxScaler to normalize the feature values, and dividing the data into training and testing sets.

Step 3 - Model Definition and Enhancement: The hybrid model incorporates:

- Convolutional Neural Networks (CNNs) for feature extraction and spatial pattern detection.
- Bidirectional Gated Recurrent Units (BiGRUs) capture temporal dependencies in sequential data.
- Attention Mechanisms to focus on critical data features, enhancing detection accuracy.
- Ensemble Learning to combine predictions from multiple models for improved generalization and robustness.

Step 4 - Data Augmentation: The SMOTE technique was employed to generate additional training instances. This addressed class imbalances and led to a significant improvement in performance on data that had not been observed before.

Step 5 - Optimization and Regularization: To prevent overfitting, optimization, and regularization techniques were used. Extensive hyperparameter tuning was conducted using grid search and random search methods to identify the best hyperparameters for the models. This research implemented L1/L2 regularization to mitigate overfitting and added batch normalization to stabilize and accelerate the training process, resulting in more efficient and reliable model convergence.

Step 6(a) - TL and Domain Adaptation: TL and domain adaptation techniques further aligned the pre-trained models with the target IoT data, enhancing their applicability and accuracy. By fine-tuning pre-trained models on tasks such as specific IoT datasets, knowledge was effectively transferred, reducing the amount of data and computational resources required for training.

Step 6(b) - FL Setup: To implement FL, the Flower framework was used. Each IoT device (client) trained the model locally using its data and then sent the updated model parameters to a central server for aggregation. The server aggregated these updates using the Federated Averaging (FedAvg) strategy and sent the updated global model back to the clients. This process was repeated for multiple rounds. custom IoT Client class was defined to manage local training, evaluation, and communication with the central server. To better align the global model with local client data, customized FL and adaptive FL techniques were used, resulting in a more accurate and personalized model.

Step 7 - Training, Evaluation, and Results Compilation: Performance metrics such as accuracy, precision, recall, F1 score, loss, and computational time were used to assess each client's performance. Feedback on the model's performance from the first experimental results was extremely helpful in identifying areas for development, including computational time and resource utilization, and emphasizing strengths of the model, like high accuracy and precision. Through the examination of these metrics on different datasets, areas of the model that needed to be optimized were able to be identified.

IV. Experimental Results

To evaluate the performance, different IoT datasets are used to assess the framework's accuracy, scalability, and efficiency under different conditions. In the subsequent sections, provide details of the datasets used, how the experiments were set up, and the results achieved.

A. Dataset

To evaluate the performance and generalizability of the proposed federated TL framework for real-time intrusion detection in IoT networks, this reserch employed several well-known datasets such as BoT-IoT, N-BaIoT, TON_IoT, CICIDS 2017, and NSL-KDD, as in Table II which shows the five datasets used in details. The BoT-IoT dataset provides a comprehensive collection of simulated IoT network traffic including various attack types such as DDoS, OS attacks, service scanning, keylogging, and data exfiltration. Similarly, tagged data from nine IoT devices infected with the Gafgyt and Mirai botnets, capturing both normal and attack traffic, is provided by the N-BaIoT dataset. The TON_IoT dataset provides information on various cyber risks and their effects on IoT environments. It includes network traffic data, telemetry data from IoT devices, and logs of cyberattacks.

Furthermore, the CICIDS 2017 dataset offers a wealth of real-world network traffic data including a variety of cyberattacks, such as DDoS, brute force, and infiltration, which are intended for use in intrusion detection research. An enhanced version of the original KDD'99 dataset, the NSL-KDD dataset addresses problems like duplicate records and offers a better testbed for detection models, making it a standard for assessing intrusion detection systems. When combined, these datasets offer a broad basis for evaluating the framework's effectiveness in various IoT contexts and attack situations.

TABLE II. The Five Datasets used in this Research

Dataset	Number of Records	Number of Features	Number of Attacks & Types	Size	Publish Year	Environment	Link
BoT-IoT	72,000,000+	Various	DDoS, DoS, OS and Service Scan, Keylogging, Data exfiltration	69.3 GB (pcap), 16.7 GB (csv)	2020	Cyber Range Lab, UNSW Canberra (Impact Cyber Trust) (Papers with Code)	[27]
N-BaIoT	706,260 (total)	115	Botnet attacks on various IoT devices	Varies	2019	Real IoT devices and network	[28]
TON_IoT	Various	47	DoS, DDoS, Ransomware, various others	Various	2020	IoT Lab, UNSW Canberra	[29]
CICIDS 2017	3,119,345	80	DoS, DDoS, Brute Force, Web Attack, Infiltration, Botnet, etc.	20 GB	2017	Simulated corporate environment	[30]
NSL-KDD	125,973 (train+test)	41	DoS, R2L, U2R, Probe	~66 MB	2009	Simulated network environment	[31]

TABLE III. Enhanced Model Results for the Five Datasets

Dataset	Acc Mean	Acc Std	Precision Mean	Precision Std	Recall Mean	Recall Std	F1 Score Mean	F1 Score Std	Loss Mean	Loss Std	Time Taken Mean (s)	Time Taken Std (s)
BoT-IoT	0.92	0.01	0.91	0.02	0.93	0.01	0.92	0.01	0.25	0.01	5.3	0.5
N-BaIoT	0.93	0.01	0.92	0.01	0.94	0.01	0.93	0.01	0.22	0.01	4.8	0.4
TON_IoT	**0.94**	0.01	0.93	0.02	0.95	0.01	0.94	0.01	0.20	0.01	4.6	**0.3**
CICIDS2017	0.93	0.01	0.92	0.01	0.94	0.01	0.93	0.01	0.23	0.01	5.0	0.4
NSL-KDD	0.92	0.01	0.91	0.02	0.93	0.01	0.92	0.01	0.24	0.01	5.2	0.5

B. Results

This section shows the results of enhancing the proposed FTL method using five different IoT datasets: Bot-IoT, N-BaIoT, TON_IoT, CICIDS 2017, and NSL-KDD. Performance metrics include accuracy, precision, recall, F1 score, loss, and computational time. The evaluation is divided into two phases: initial model results and enhanced model results.

1) Initial model results: The first phase builds a strong model that learns from distributed IoT datasets while taking privacy into account, which combined Federated Learning (FL) and Transfer Learning (TL) without advanced optimization. The TON_IoT dataset achieved the best accuracy (89%), while the BoT-IoT dataset showed the lowest performance (85%).

Key Observations:

- Accuracy was consistent across datasets but below 90% for most.
- Loss values varied from 0.31 to 0.35, indicating opportunities for improvement.
- Prediction errors were more frequent in datasets with higher class imbalance, such as BoT-IoT and NSL-KDD.

2) Enhanced model results: The enhanced model incorporated advanced techniques such as SMOTE for data augmentation [24], hyperparameter tuning, and ensemble learning with CNNs, BiGRUs, and attention mechanisms. Table III illustrates significant improvements in accuracy (92%-94%) and loss reduction (0.20-0.25).

Key Highlights:

- Accuracy increased across all datasets, with TON_IoT reaching 94%.
- Low standard deviations in accuracy and loss values indicate stable performance.
- SMOTE effectively addressed class imbalance, improving precision and recall.

V. Discussion

The results in the previous section demonstrate the effectiveness of integrating FL with TL for intrusion detection in IoT networks. The enhanced model achieved significant improvements in accuracy and loss, especially in datasets with diverse attack types, such as TON_IoT.

- Scalability and Privacy: FL enabled decentralized training, maintaining data privacy while achieving consistent performance across IoT environments.
- Adaptability: TL enhanced the framework's ability to generalize across datasets, reducing training time and computational cost.
- Class Imbalance: The application of SMOTE balanced the datasets, preventing biases toward majority classes and improving detection accuracy.

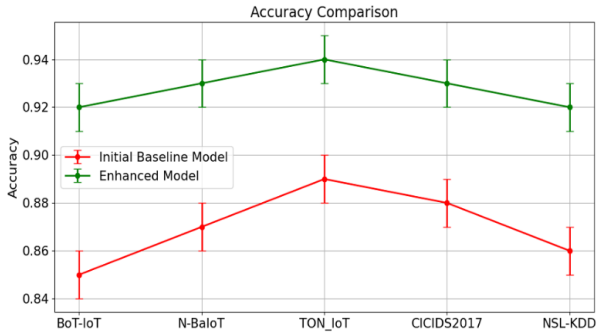

Fig. 2. Comparison of accuracy between the Initial Baseline and the enhanced models.

Fig. 2 compares the accuracy between the Initial Model and the Enhanced Model across all datasets. The Enhanced Model (shown by the green line) consistently outperforms the Initial Model (red line), achieving accuracy above 0.92 across all datasets, while the Initial Model remains below 0.89. The small error bars indicate minimal variability in accuracy across datasets, emphasizing the Enhanced Model's reliability in different IoT environments.

The Enhanced Model significantly improves accuracy on some datasets (such TON_IoT), while N-BaIoT and NSL-KDD exhibit a narrower performance gap. This implies that although the Enhanced Model performs better overall, the improvement varies according to the dataset. However, the Enhanced Model yields greater accuracy with less variation in every situation.

Fig. 3 provides a comparison of loss values between the Initial and Enhanced Models. Compared to the Initial Model's larger range of 0.31 to 0.35, the Enhanced Model has reduced loss values, ranging from 0.20 to 0.25. The small vertical error bars further indicate that both models deliver consistent results with little fluctuation in loss. The difference in loss is most evident in the TON_IoT dataset, where the Enhanced Model shows the greatest reduction. In datasets like BoT-IoT and CICIDS2017, the improvement in loss is less dramatic, but the Enhanced Model still outperforms the Initial Model. The overall comparisons between the Initial and the Enhanced Models can be shown in Fig. 4.

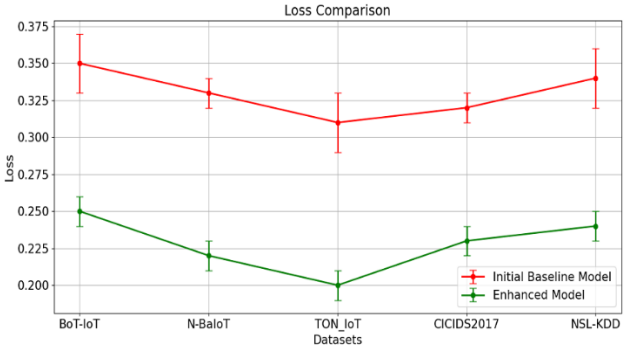

Fig. 3. The comparison of loss between the Initial Baseline and the enhanced models.

As shown in Fig. 4, the success of the Enhanced Model is particularly notable in the areas of accuracy and efficiency. FL and TL offer additional benefits beyond the performance metrics. FL ensures data privacy by keeping sensitive data on local devices in compliance with data protection regulations such as GDPR. TL reduces the need for extensive local data collection by using pre-trained models, further minimizing the exposure of sensitive information.

While the Enhanced Model consistently outperforms the Initial Model in terms of accuracy, the extent of this performance gap varies across datasets, where TON_IoT dataset showed the most significant improvements in both accuracy and loss. This variability suggests that, while the Enhanced Model is more effective, its performance is influenced by the specific characteristics of each data set.

Power consumption is a major issue in IoT environments. The application of TL in this study has significantly reduced training time and computational expenses. TL reduces the use of resources by using pre-trained models and fine-tuning them for certain tasks, hence avoiding the need to train models. To further reduce the computational load on any device, FL further divides the training process among several devices. With this method, training complex models on IoT devices with limited resources is possible while preserving efficiency and reducing power usage.

Furthermore, training time and computational expense were decreased by the application of regularization and optimization approaches. Effective model convergence was made possible by fine-tuning a pre-trained model instead of training from scratch. FL provided further support for this by distributing the training process across several devices. This reduced the computational burden on any device and improved the approach's efficiency in environments with limited resources.

Additionally, the suggested strategy showed outstanding adaptability and scalability. FL made it possible to train on numerous IoT devices at once, which increased the system's scalability. TL made it easier to quickly adjust to new settings and devices, ensuring effective scaling to a range of IoT scenarios. Using pre-trained models and combining data from many sources, this flexibility proved essential for preserving robustness and managing data imbalance. The Enhanced Model assisted real-time learning and adaptation. IoT devices might periodically update the global model with new observations, allowing TL to fine-tune the model with minimum input and enabling faster adaptability to new types of attacks or anomalies.

VI. Conclusions and Future Directions

The combination of FL and TL for real-time intrusion detection in IoT networks provides an effective solution for urgent security issues. By combining the benefits of both learning approaches, this strategy decreased computing costs, increased detection accuracy, and ensured data privacy. The experimental results show that the proposed framework can minimize training time and improve detection performance by adapting pre-trained models to specific IoT contexts. Accuracies ranging from 92% to 94% were achieved across many datasets.

To detect and mitigate cyber risks in a scalable, effective, and privacy-preserving manner, this research highlights how federated transfer learning might transform cybersecurity measures in IoT networks. Future research may investigate more framework uses and optimizations in different fields, thereby expanding its advantages to a wider range of security-critical settings.

Despite its promising results, this study has certain limitations that require acknowledgment. Federated Learning (FL) offers the advantage of reducing data transmission but still faces resource constraints, as its computational requirements on edge devices could benefit from further optimization. Additionally, addressing dynamic threats remains a challenge, highlighting the need for future research to explore adaptive learning techniques capable of responding to evolving IoT security risks. Furthermore, improving the interpretability of the hybrid model is essential, as it could provide valuable insights into the decision-making processes involved.

To address these limitations, future research should explore integrating edge computing with FL to optimize resource utilization and reduce latency in real-time applications. Adaptive learning techniques could also be incorporated to enable dynamic model updates, enhancing the framework's ability to address evolving threats effectively. Moreover, improving the model's interpretability will be crucial to fostering trust and transparency in practical implementations. Finally, extending the framework to broader domains, such as industrial IoT and smart cities, will help validate its scalability and robustness in handling large-scale and complex environments.

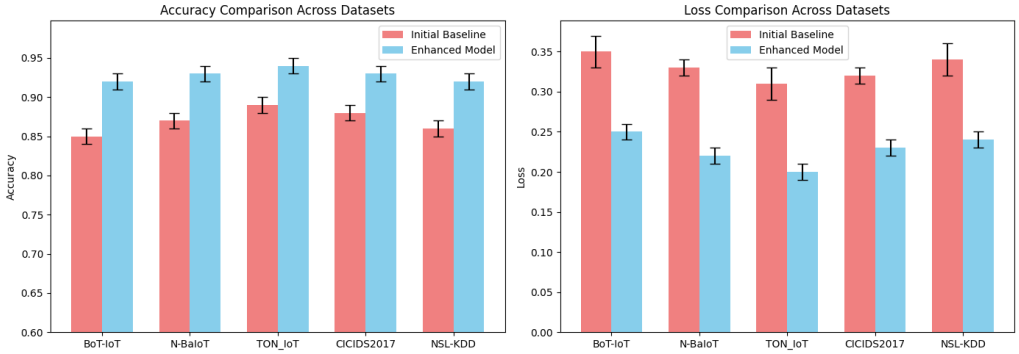

Fig. 4. Overall comparisons between the Initial and the Enhanced Models across all datasets.

Forecasting Unemployment Rate for Multiple Countries Using a New Method for Data Structuring

Amjad M. Monir Aljinbaz[1], Mohamad Mahmoud Al Rahhal[2]
Department of Computer Science, University of York, York, UK[1]
Department of Applied Computer Science-College of Applied Computer Science, King Saud University, Riyadh, Saudi Arabia[2]

***Abstract*—Forecasting the Unemployment Rate (UR) plays a key role in shaping economic policies and development strategies. While most research focuses on predicting UR for individual countries, there has been limited progress in creating a unified forecasting model that works across multiple countries. Traditional time series methods are usually designed for single-country data, making it difficult to develop a model that handles data from various regions. This study presents a new data structuring technique that divides time series into smaller segments, enabling the development of a single model applicable to 44 countries using various economic indicators. Four forecasting models were tested: an artificial neural network (ANN), a hybrid ANN with machine learning (ML), a genetic algorithm-optimized ANN (ANN-GA), and a linear regression model. The linear regression model, which used lagged UR values, delivered the best results with an R^2 of 0.964 and 89.8% accuracy. The ANN-GA model also performed strongly, achieving an R^2 of 0.945 and 85.1% accuracy. These results highlight the effectiveness of the proposed data structuring method, demonstrating that a single model can accurately forecast multiple time series across different regions.**

***Keywords*—Unemployment rate; artificial neural network; time series; hybrid model; genetic algorithm**

I. Introduction

Unemployment rate (UR) is a critical macroeconomic indicator that plays a pivotal role in economic planning, social stability, and policy development [1]. Researchers have used several methods to forecast unemployment rate using stochastic methods, machine learning and neural network. However, most of these approaches are focused on developing country-specific models. It is rare to find studies attempting to build a global model applicable across multiple countries. Because of the importance of building global model for multiple countries, an attempt was made to build such [2].

Employment is inherently linked to macroeconomic conditions and is influenced by a broad spectrum of factors, including inflation, gross domestic product (GDP), and other economic indicators[3]. At the same time, microeconomic factors such as age, educational attainment, gender, and poverty status can significantly impact unemployment dynamics [4], [5], [6]. Consequently, understanding the UR requires a multifaceted approach that accounts for both macro- and microeconomic influences.

The development of single-country models has been prevalent in previous research, utilizing a variety of techniques. Several studies used stochastic time series techniques. In such techniques, they study the effect of independent variables on dependant variables regression to examine level of significance [7], [8].

Also, time series analysis, including autoregressive integrated moving average (ARIMA) and its variants (e.g., ARMA, SARIMA, VARIMA), have been employed to capture the linearity and stationarity in UR data over time [9], [10], [11]. However, these methods are inherently limited to individual country forecasts. Artificial neural networks (ANN) were also used to analyse time series. This was either done using feedforward neural network (FNN) [12], or recurrent neural network RNN which is able to capture more complex patterns [13].

A combination of different models forms hybrid models which were also used to analyse UR. Such models leveraging the strengths of both linear and non-linear modelling capability. Hybrid model includes using ARIMA-RNN [13], [14], RNN with genetic algorithm GA for feature optimization [13].

This research aims to build a comprehensive model that forecasts UR across multiple countries. Leveraging a new method for structuring time series data, this study addresses the challenge of building a single forecasting model applicable to multiple regions. The data, sourced from the World Bank, includes a diverse set of macroeconomic and microeconomic features for 44 countries over a span of 33 years. By segmenting the time series into smaller data slices, the proposed approach allows for the consolidation of country-specific data into a unified dataset, facilitating the development of a generalized forecasting model.

The remainder of this paper is organized as follows: Section II reviews the related work on UR forecasting methodologies, including machine learning, autoregressive models, and hybrid approaches. Section III details the methodology of the data structuring process and model development. Section IV presents the results and evaluates the performance of each model. Section V discusses the implications of the findings, and Section VI concludes the paper with future research directions.

II. Related Work

The study of unemployment rate (UR) forecasting has evolved significantly over the past decades. Researchers have applied various methods, primarily categorized into traditional machine learning regression, autoregressive time series forecasting, neural networks, and hybrid models. Each approach has distinct advantages and has contributed to understanding the dynamics of UR within individual countries.

A. Machine Learning Regression for Forecasting

Several studies used stochastic time series techniques in forecasting. In such techniques, they study the effect of independent variables on dependant variables to examine if there is significant difference. Zawojska used linear regression to study the correlation between several macroeconomic factors and UR and found significant correlation with many factors such as GDP [7]. In [15] Alternative regression methods, including the Toda-Yamamoto procedure, have been utilized to examine the impact of specific factors, such as oil prices and interest rates, on the unemployment rate (UR) in different scenarios.

Before applying these techniques, researchers often test the data for stationarity to ensure appropriate modeling. For example, a study involving 10 developing countries found that UR, GDP, population, remittances, external debt, exchange rate and expenditure on education were non-stationary, necessitating differencing for proper regression analysis [16]. This type of tests is also applied on autoregression time series forecasting (see B).

B. Autoregression Time Series Forecasting

Autoregressive time series methods focus on the inherent symmetry or asymmetry, as well as the linearity or non-linearity, of UR over time. If a time series exhibits stationarity—consistent mean or variance over time—these methods can effectively forecast future trends[17]. It was suggested that UR has hysteresis, which means that it stays in equilibrium level with equality likely movement in either direction [18]. For instance, the logistic smooth transition autoregressive (LSTAR) model has been used to analyze non-linear and asymmetric UR data in Australia [19]. In this study, model accuracy was high due to LSTAR ability to capture cyclic fluctuations of business and UR as result. Other studies analyse the effect over years using Autoregressive Distributed Lag Stationarity ADLS [20].

Autoregressive integrated moving average (ARIMA) model is very famous for time series forecasting. A modified version (SARIMA) captures seasonality and used in case time series has seasonality element. Another variation is generalised autoregressive conditional heteroscedasticity (GARCH) that analyse the volatility of time series [17]. The authors in [9] A study of monthly UR to study the impact of COVID-19 in 5 Asian countries (ASEAN-5) using ARIMA, SARIMA and GARCH found that ARIMA and SARIMA are superior in forecasting UR. Another study [21] using ARIMA model with monthly data in Australia was found to predict on month ahead have R^2 of 0.96.

C. Artificial Neural Network for Forecasting

Neural networks (NNs) have emerged as powerful tools for forecasting time series data, particularly when the data exhibits non-linear characteristics [22], which is found in UR [23]. Feedforward neural networks (FNN) have been applied both to evaluate independent variables affecting UR and to utilize lagged values (k-lags) for one-step ahead forecasting [24]. A study applied FNN by using several macroeconomic factors including GDP, inflation and other factors to forecast UR in Philippine using a data from 1991 to 2014 [25] with accuracy of 87.5%. Another study used neural network with backpropagation to predict UR, gross national product and employee number in Germany and found that the model has R^2 close to 1 when predicting three lags ahead (t+3) [12]. In [17] Recurrent neural networks (RNN) and their variations, such as long short-term memory (LSTM), have demonstrated higher accuracy in forecasting due to their internal memory capabilities, which are well-suited for for time series forecasting.

D. Hybrid Models

Hybrid models combines different types of models to leverage the strengths of both linear and non-linear modeling techniques to improve forecasting accuracy [26]. For example, combining two models where one of them to capture linear elements (such as ARIMA or regression) and other to capture nonlinear elements (such as artificial neural network) could provide a better performance model. Other studies used hybrid models differently by combining neural network models, with feature optimization models, such as genetic algorithms [13]. Hybrid models has been used for time series forecasting, such as stock market price forecasting [27]. It was also used to forecast UR such as combining ARIMA and RNN [14]. They used ARIMA in the first phase to catch linear pattern, followed by autoregressive neural network ARNN to analyse nonlinearity and nonstationarity patterns. This hybrid model outperformed either of these models alone. Hybrid models can be employed for feature optimization and integrated with other approaches. In [13] LSTM models enhanced with genetic algorithms (GA) for parameter optimization have demonstrated superior performance compared to traditional RNNs in unemployment rate forecasting for Ecuador, delivering greater accuracy.

E. Gaps in the Literature

Previous studies were used to build separate UR forecasting models for individual countries. The reason for this is that they used time series forecasting, where data is arranged on a continuous line and is split for training and testing the model. This way makes it not possible to incorporate multiple countries inti the same model. This research addresses this gap by proposing a novel data structuring technique, enabling the construction of a single forecasting model for multiple countries.

III. Data and Method

This study aims to develop a unified AI model that leverages macroeconomic and microeconomic data across multiple countries to predict unemployment rates. While previous research has focused on models for individual countries [8], [16], [28], this study introduces a novel data structuring approach to create a forecasting model applicable to various economic contexts and regions.

A. Data Analysis

This study utilized data from the World Bank [29], covering annual macroeconomic and microeconomic indicators from five key datasets: economy and growth, education, urban development, health, and climate change. The data spans the years 1991 to 2023, with the analysis focusing on 44 countries that have complete records for this period. Initially, 162

features were drawn from the datasets, but after excluding those with missing values, 153 features were retained. Table I outlines the datasets, their feature counts, and examples of the included variables.

TABLE I. DATASETS USED IN THE RESEARCH, AND EXAMPLES OF THEIR FEATURES

Dataset	Feature count	Examples of features
Economy & Growth [30]	81	GDP, current account balance and exports of goods and services
Education [31]	5	UR, government expenditure on education, school enrolment, literacy rate and population age groups
Urban Development [32]	7	mortality by traffic, PM2.5 air pollution, population in large cities and urban population
Health [33]	62	fertility rate per age group, birth rate, cause of death by injury, cause of death by communicable diseases and death rate
Climate Change [34]	7	access to electricity, agriculture land, cereal yield, annual fresh water, CO2 emission and NO emissions

B. Data Structuring

A new method of structuring the time series data was developed to enable multiple time series forecasting within a single model. The data were segmented into rolling windows or "slices," each containing three years of lagged values for each feature and UR value for target year. For example, the UR for a given year (y) was predicted using the three preceding years (y-1), (y-2), (y-3) for each feature. This means that 3 columns are added per feature to represent $feature_{y-1}$, $feature_{y-2}$ and $feature_{y-3}$ to forecast UR_y. And because we have data from 1991 to 2022, we can have 3 lags to forecast UR starting from 1994 to 2022. (i.e. the first UR will have feature_a_{1991}, feature_a_{1992} and feature_a_{1993} to forecast UR_{1994}). This approach resulted in 29 slices per country, allowing the aggregation of all 44 countries into a unified dataset with 1,276 observations. The reason for using 3 years of lagged features is that factors might have effect on UR for multiple years in the future [7], [16]. This way, the forecasting model will predict UR of any year (y) based on previous n years lag (y-3) of any given feature.

This method effectively addresses the limitations of traditional time series forecasting, which typically requires contiguous, long time series data and is not easily adaptable for multi-country analysis.

The data were imported using Python's Jupyter Notebook, leveraging Pandas and NumPy APIs. Each dataset was structured into a multi-index DataFrame, where level 0 represented the country, and level 1 denoted the year. This organization ensured that each country had 33 rows, corresponding to the years 1991 to 2023. The data for 2023 was excluded from the analysis to serve as out-of-sample validation [35]. Fig. 1 provides a snapshot of the DataFrame used, which contained 1276 observations and 153 features. The total number of columns includes 1 target variable (unemployment rate), along with 3 lags per feature for each of the 153 features.

Country	Indicator Code / Year	Unemployment	NE.CON.GOVT.CD y-1	NE.CON.GOVT.CD y-2	NE.CON.GOVT.CD y-3	...
Argentina	1994	11.76	31984701702	6807403684	6302044992	...

C. Model Development

As outlined in Table II, four AI-based models were developed and evaluated:

Model 1 (ANN-All): Applied artificial neural networks (ANN) to all available features.

Model 2 (Hybrid ANN-ML): An ensemble model where separate neural networks were trained on each of the five datasets, and their outputs served as inputs for a machine learning regression model.

Model 3 (Hybrid ANN-GA): A hybrid approach integrating genetic algorithms for feature selection with an ANN for forecasting.

Model 4 (UR-ML): A machine learning model relying solely on lagged unemployment rate (UR) values (y-1, y-2, y-3) to forecast the following year's UR.

TABLE II. MODELS AND FEATURES USED

Model	*# Datasets*	*# countries*	*# features*
ANN-All	5	44	153
ANN-ML	5	44	153
ANN-GA	5	44	153
UR-ML	Unemployment Rate only	44	1 (UR)

The models were trained and validated on the structured dataset, with the testing conducted on out-of-sample data for 2023. Training and validation were split into 77.3% and 19.4% of the data, respectively, while the testing set comprised 3.3%.

D. Performance Evaluation of Methods

The models' performance was evaluated using four metrics:

1) The coefficient of determination (R2): Assess the proportion of variance explained by the model. One of the main advantages of R^2 is that there is no need to compare the result with other models to evaluate model fit [36]. Best value equals 1. This was the main metric used in this paper.

2) *Accuracy: defined as (% 1 – MAPE) [37].* Mean Absolute Percentage Error (MAPE) has high efficiency to minimize risk in regression forecasting, especially if target value is always positive (which is the case with UR) [38], [39]. Using (% 1 – MAPE) provides easy way to assess model accuracy. Best value equals 100%.

3) *Root mean squared error (rmse) [36]: Best value equals 0.*

4) *Mean absolute error (MAE) [36]: Best value equals 0.*

IV. Experimental Results

This section represents the results of each of the models used in the research and evaluate their performance.

A. Results

The performance of each model was assessed on validation datasets using R^2, accuracy (1-MAPE), RMSE and MAE as summarized in Table III and IV. Among the models, the UR-ML model, which uses only lagged UR values, demonstrated the best performance, achieving an R^2 of 0.964 and 0.989 on validation and testing data, respectively. Its accuracy was 89.8% on validation data and 94.2% on testing data, indicating strong generalizability and robustness.

Following is a summary of each model performance.

1) *Model 1: ANN-All – Neural network for 5 datasets:* This model used 5 datasets with a total of 153 features to predict UR. This model performs better than model in in all 4 measures. In validation data, this model scored 0.927 and 82.1% of R^2 and accuracy respectively. These measures fell greatly to 0.857 and 71.4% respectively which means that the model has issue with generalization. The scatter plot in Fig. 2 plotted predicted versus true value for this model.

2) *Model 2: ANN-ML – Hybrid model using ANN and ML:* This model built five individual Neural Network model for each of the five datasets to predict UR. Fig. 3 shows the result of these five individual models to predict UR.

TABLE III. Performance of Models for Forecasting UR (Validation Data)

Model	R^2	Accuracy	RMSE	MAE
ANN-All	0.927	82.1%	1.217	0.894
ANN-ML (hybrid)	0.921	77.4%	1.256	0.985
ANN-GA (hybrid)	0.945	85.1%	1.049	0.775
UR-ML	0.964	89.8%	0.851	0.563

TABLE IV. Performance of Models for Forecasting UR (Testing Data)

Model	R^2	Accuracy	RMSE	MAE
ANN-All	0.857	71.4%	1.745	1.1401
ANN-ML (hybrid)	0.86	72.8%	1.729	1.365
ANN-GA (hybrid)	0.919	80.4%	1.316	0.986
UR-ML	0.989	94.2%	0.487	0.316

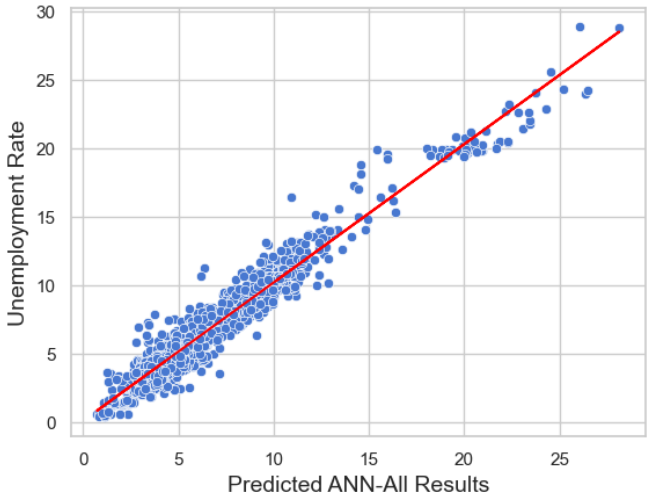

Fig. 2. ANN-All Predicted vs. True value.

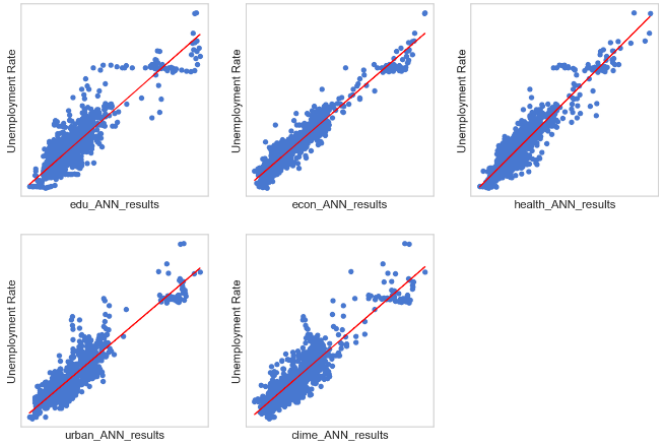

Fig. 3. The result of five individual ANN models to forecast unemployment rate.

Then, the resulted five predictions were fitted using machine learning linear regression to predict UR. The model has R^2 value of 0.921 which is similar to ANN-All, but has worst accuracy value of 77.4%. The model is also slightly worse than ANN-All in terms of RMSE and MAE. The model, however, is a little better in terms of generalization compared to ANN-All, as R^2 and accuracy for testing data were 0.86 and 72.8% respectively. Fig. 4 shows the predicted versus true value for this model.

3) *Model 3: ANN-GA:* This model used genetic algorithm for feature optimization, followed by building neural network model using best fitness features measured by R^2. Based on genetic algorithm result, 83 out of 153 features were selected and then used to build neural network model. The model result was better than all previous 3 models as it has R^2 of 0.945 and accuracy of 85.1% in validation data, and R^2 of 0.919 and accuracy of 80.4%. This means that those 83 features provide better performance compared to using all 153 features as in Model 1 ANN-All. Fig. 5 shows predicted versus true value for this model.

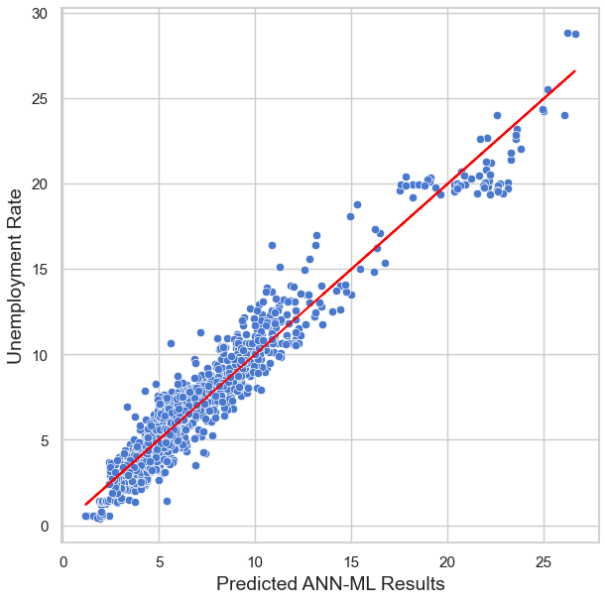

Fig. 4. ANN-ML Predicted vs. True value.

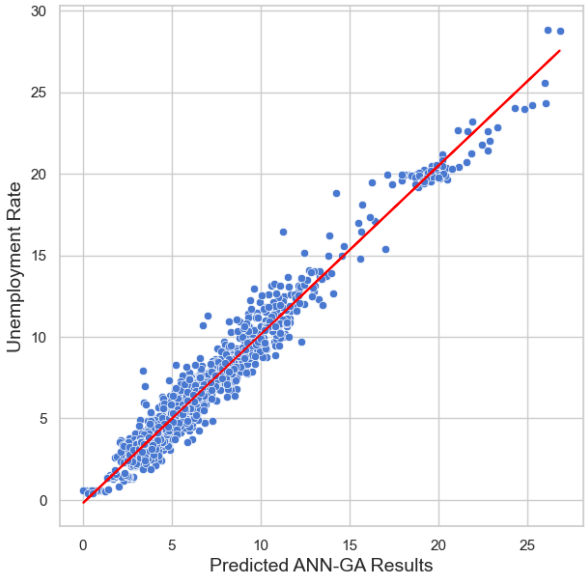

Fig. 5. ANN-GA Predicted vs. True values.

4) Model 4: UR-ML – Using ML regression for UR: The fifth model used only 1 feature, UR. And as all previous models, it uses this feature with 3 lags (UR_{y-1}, UR_{y-2} and UR_{y-3}) to predict UR_y. This model has shown the best overall performance in both validation data and testing data. In validation data it has R^2 of 0.964 and accuracy of 89.8%. This model demonstrated high generalization capability, as it scored 0.989 in R^2 and 94.2% in accuracy. This means that this model doesn't suffer from overfitting. This model also has the least score in RMSE and MAE, which were 0.487 and 0.316 respectively.

To illustrate the reason behind the high performance of this model, Fig. 6 shows the correlation of the n lags of UR (y-1, y-2 and y-3) with true UR. Each one of UR_{y-1}, UR_{y-2} and UR_{y-3} has high correlation with UR_y, making it very suitable for UR forecasting. Fig. 7 shows the predicted versus true value for this model.

Fig. 6. Correlation between n lags UR and True UR.

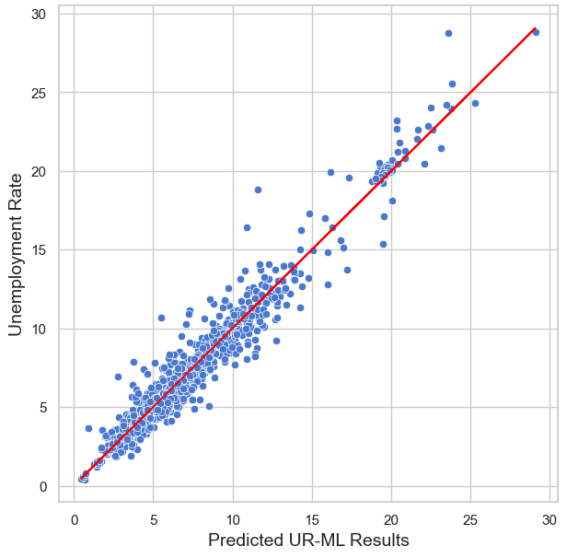

Fig. 7. UR-ML Predicted vs. True value.

B. Discussion

This study demonstrates that it is feasible to develop a single AI model that can accurately forecast UR across multiple countries using economic factors. The effectiveness of the new data structuring method, which segments time series into smaller slices, allows for a generalized model that maintains high accuracy and generalizability.

1) Discussing models performance: Neural network models are well-suited for UR forecasting due its nonlinear nature [23]. This research found that it is possible to build single neural network model that can be used effectively to forecast UR across several countries.

When comparing with other researches that use neural network model, we found that our model with R^2 of 0.87 and accuracy of 71.4% is compared to other models. Misil and Tarepe have built ANN model with 11 features (including GDP and inflation rate) to forecast UR in Philippine from 1991 to 2014 and has accuracy of 87.5% [25]. Their model has higher accuracy due to building the model for single country.

Our research found that hybrid model with genetic algorithm outperforms other models neural network models in forecasting UR as it reduce the number of features used and hence reduce model noise. This is consistent with other research

that found this models superior to other models they compared [13], which used LSTM (Long Short Term Memory) with GA. However, their research has accuracy of 96% compared to our 80.4%. The superiority of their results is due to building the model on single country only (Ecuador) in addition to include UR (UR of previous years) as a feature, which will yield better results as will be discussed in 2).

The other hybrid model used in the research was ANN-ML, which combines neural network forecasting with machine learning regression. This model showed inferior results especially in terms of generalization on testing data with accuracy of 72.8%. This is not consistent with researches who used hybrid models in UR forecasting [14]. The reason is that we used different hybrid model. Chakraborty et al. [14] has combined ARIMA with RNN to study UR in individual countries, which wasn't applicable in our research to build single model for multiple countries.

Several researchers have found much superior results with different hybrid models. A study on individual countries including US, UK, Italy and France had accuracy ranges from 95.34 to 98.91% based on the country using a hybrid model of LSTM-GRU [40]. Another studied Asian countries using ARIMA-ANN model and had accuracy of 96.4 - 97.8% [41]. However, as these models used previous UR data only in forecasting, these should be compared to our UR-ML model (discussed in 2)), and their result is comparable to our 94.2% for UR-ML model.

2) Performance of ML model using UR only: Using UR from the past to forecast future UR is very common across research. Research have used several methods for such type of analysis including ARIMA (and its variations including ARMA, SARIMA, FARIMA, etc.), RNN (and its variations including GRU, LSTM, etc.).

In our research, the regression model that only uses UR (UR-ML) outperforms all other models. The model used 3 lags years (UR_{y-1}, UR_{y-2} and UR_{y-3}) to forecast UR_y result. The model has R^2 of 0.964 and accuracy of 89.8% on validation data. The model performs even better on testing data to forecast 2023 results with R^2 of 0.989 and accuracy of 94.2% which means it has high generalizability.

This result is aligned with many researches that were able to use previous UR solely to forecast future UR. Our research outperformed Davidescu et al. research who have used SARIMA model to forecast UR in Romania, and has accuracy of 86.6%. The same research has even worse accuracy using SETAR model, with accuracy of 84.23% [39]. As ARIMA model requires a continuous time series, and then using 80% of it for training and keeping the last 20% for testing. This makes the model more vulnerable to macro trends that occurs in last year that didn't exist in training data.

Higher accuracy could be obtained by building separate model for separate country or district. In Germany, accuracy ranged from 91.91% to 99.23% using SARIMA model [42]. Our model has slightly inferior results despite being built for multiple countries.

One of the reasons of why UR from previous year is a strong indicator of future UR, is that UR tends to change gradually and slowly over years, as it tend to stay in equilibrium [18]. To test this, we have created a dummy forecaster, where it forecast UR_y by simply returning UR_{y-1}. Fig. 8 shows a scatter plot of this Dummy model. This dummy model has R^2 of 0.958 and accuracy of 90.7%, which outperforms all 3 ANN models in this research, which hasn't included lagged UR as feature.

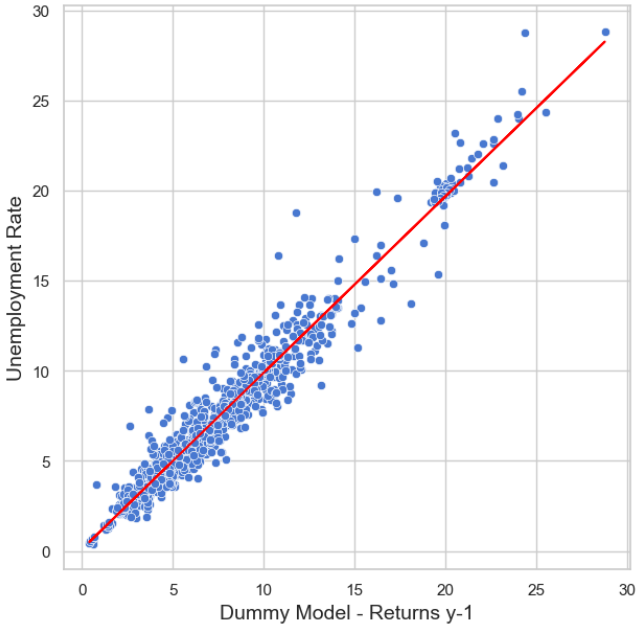

Fig. 8. Dummy Model that uses Y-1 as forecast value for Year Y.

For this reason, this research excluded UR from all ANN models, due to the high correlation between UR_{y-n} and UR_y. Also, this is the possible reason why ARIMA models have higher accuracy in one-step-ahead forecasting compared to multiple-steps-ahead.

3) Benefits of using new data structure: Methods like ARIMA and RNN mandates the presence of long and contiguous the time series [38], [43]. Because we only have 33 data point per country, we need to increase the number of observations to fit the model.

This research has used new way of structuring data by transforming continuous time series into an array of instances that contains slices of 3 years of lagged data. This method has the following benefits:

- This method enables mixing the data randomly for fitting the model. This has advantage of training data on a mix of time periods and make prediction more generalizable.
- As the Covid pandemic has made significant change in the labour market in 2020 and 2021 [9], [39].This make forecasting issue if out-of-sample forecasting included this period. This accounts for generalizability issue of the model and big difference between training and testing data conditions [39].

- Previous studies were forced to analyse each country separately [8], [14], [16], [28], [38], [40], [41], [44], [45], or even on separate county or city level [46] because of the limitation of ARIMA and RNN models. The new method enables us to train the model on multiple countries. This resulted in successfully building single forecasting model for multiple countries (in our case 44 countries).
- New approach enables us to have large number of observations to train and validate the model. Other studies either used the low number of instances [25] or increased the number of instances by using months instead of years [23], [39], [46]. Using monthly time periods increases the number to a certain degree, while adding another layer of complexity due to seasonality of UR.

However, this approach keeps memory of n lags of years to perform one step ahead forecasting. Other time series analysis methods keep longer memory which may increase the accuracy of multiple steps ahead forecasting [12].

V. CONCLUSION

This study successfully developed a robust AI-driven model for forecasting unemployment rates (UR) across multiple countries by employing an innovative data structuring technique. By segmenting time series data into smaller slices and aggregating data from 44 countries, the study produced a unified model demonstrating high accuracy and generalizability. Among the tested models, the UR-ML model emerged as the best performer, with the hybrid ANN-GA model also showing considerable potential for feature optimization. The proposed method holds promise for forecasting other economic indicators, such as GDP and inflation. However, this study is not without limitations. Firstly, the dataset excluded data from 2023 as it was reserved for out-of-sample validation, limiting the availability of real-time forecasting scenarios. Secondly, the exclusion of additional regional and socio-economic indicators, due to data availability constraints, may have impacted the model's ability to fully capture cross-country variations. Future research should explore advanced hybrid models, such as incorporating deep learning architectures (e.g., LSTM-GA combinations) to improve predictive capabilities further. Expanding the feature set to include additional socio-economic and environmental indicators may enhance accuracy and capture regional variations better. Additionally, extending the model to support multi-step-ahead forecasting and applying the proposed data structuring method to other macroeconomic indicators, such as inflation or GDP, would demonstrate its versatility.

***Abstract*—The study offers a thorough examination of the accumulation and distribution of wealth among billionaires through the application of big data analytics methodologies. This research centres on an extensive dataset known as "Billionaires.csv," [19] which encompasses a range of information about billionaires from diverse nations, including their demographic characteristics, company particulars, sources of wealth, and more details. The study aims to get a deeper understanding of the determinants that change the net worth of billionaires and detect trends in the worldwide financial system that can guide entrepreneurial ventures and investment possibilities. The dataset is subjected to analysis and visualisation through the utilisation of Python tools and libraries, including but not limited to Pandas, NumPy, Matplotlib, and Seaborn. The results of this study offer valuable insights into the distribution of wealth among billionaires, the factors that contribute to industry success, gender disparities, age demographics, and other factors that influence the accumulation of billionaire wealth.**

Keywords*—Big data; python; billionaires; net worth; wealth accumulation; wealth inheritance; geographic location; statistical analysis

I. Introduction

The rapid growth of wealth among billionaires has garnered significant attention in recent years, with the number of billionaires increasing from 1,001 in 2010 to 2,153 in 2019 [1]. This surge in wealth accumulation has led to a growing interest in understanding the factors that contribute to the success of these individuals. Big Data Analytics, with its ability to process large volumes of data, offers a promising approach to uncovering patterns and insights related to wealth distribution, wealth creation, and accumulation among billionaires [2].

This paper explores the dynamics of wealth accumulation and its distribution among billionaires worldwide using a comprehensive dataset. The study uses advanced big data analytics techniques to show trends, correlations, and patterns that underlie wealth creation and proliferation among the world's richest individuals. The research's significance lies in its contribution to academic literature and its potential to inform policy decisions and economic strategies. By elucidating factors contributing to wealth accumulation, it looks to provide insights into economic and social policies that could promote a fairer distribution of wealth and opportunities. The methodological approach combines quantitative analysis with sophisticated data visualization techniques to offer a panoramic view of wealth dynamics. The findings are expected to shed light on wealth accumulation trajectories and contribute to a deeper understanding of the economic forces shaping our world.

The objective of this investigation is to conduct an analysis of the "Billionaires.csv" dataset utilising Python tools for Big Data Analysis, with a particular emphasis on regions and cities. This paper aims to investigate several research questions about the distribution of billionaires across the globe. The study's objectives include identifying the ten nations with the highest concentration of billionaires, the industries with the greatest growth, the nations with the largest percentage of female billionaires, the age groups where there are the most and least billionaires belong, as well as other elements that may affect the development of wealth, for example, inheritance.

The paper is structured into four tasks: Problem Domain, Data Description, and Research Question; Solution Exploration; Solution Development; and Evaluation and Future Development. Each task delves into different aspects of the research process, from formulating hypotheses and evaluating methodologies to analyzing the dataset and discussing the potential impact of the results. This research endeavors to enhance comprehension of wealth accumulation trends among billionaires and offer valuable insights for policymakers, investors, and entrepreneurs by utilizing Big Data Analytics and the Python programming language.

II. Literature Review

Between 1999 and 2019, the Hurun Rich List was diligently compiled, and research was done to confirm billionaires and their families. They compare the Hurun Rich List to each company's annual report to determine which billionaires own it [3]. The systematic billionaire wealth factors were not considered in the univariate tests. Age was disregarded, and economic activity might potentially be important [4]. A study constructed a comprehensive metric of wealth inequality on a global scale, utilizing Forbes magazine's roster of billionaires, and subsequently conducted a comparative analysis of its impact on economic growth to the effects of income inequality and poverty [5]. An additional research study demonstrated that industries that concentrate wealth do so with purpose, and this

*Corresponding Author

may occur due to a reliance on the state, the presence of market failures, or the inheritance of extreme wealth [6]. A recent study conducted during the pandemic in Canada has demonstrated that low-wage workers have been disproportionately affected. Additionally, data from Statistics Canada has indicated that women and racialized workers are overrepresented within the low-wage worker demographic [7]. An article aims to compare asset ownership in three common marital regimes in France and other European countries: Property regimes, marriage, non-marital cohabitation, and registered partnership (PACS) [8]. The results show that luck plays a big part at the very ends of the range of economic outcomes, and the fact that empirical regularities tend to disappear in the far tails can be used to look at any group of successful or failed people [9]. A study finding indicates that there is a detrimental association between wealth inequality and economic growth., however, when considering the influence of political connections on the acquisition of wealth by billionaires, it is observed that politically connected wealth inequality has a negative impact on economic growth. On the other hand, politically unconnected wealth inequality, income inequality, and initial poverty do not exhibit any significant relationship with economic growth [5]. An empirical approach to studying the potential influence of education and cognitive ability on the accumulation of extreme wealth involves analyzing high-wealth groups and retrospectively evaluating the level of education and cognitive ability of these individuals in the past [10]. When comparing billionaires, it is evident that wealth is not correlated with attractiveness. Neither does it pertain to the level of schooling achieved [14]. The concentration of wealth and its distribution has been a longstanding concern in economic literature and societal discourse. Studies on wealth inequality and its consequences have highlighted the need for a deeper understanding of the factors contributing to the accumulation of wealth among the elite class. In this section, we provide a brief overview of relevant literature that explores the determinants of billionaire net worth and sheds light on the dynamics of wealth accumulation.

A study looked at a continuous-time DSGE model with several types of households and a financial sector, and they were able to make the case of studying how financial frictions affect families by looking at how wealth is distributed [15]. An agent-based model of microscopic wealth sharing in a dynamic network is used in another study to investigate the topological aspects of economic inequality [16]. The model changes in two steps that happen back and forth: the connected agents conservatively trade wealth, and the links are rewired based on the agents' wealth. Moreover, an analysis finds financialization, rentiers, and labour exploitation as the primary drivers of billionaire wealth in the U.S. sectors with the highest number of billionaires [17]. These factors were crucial for their dominance, while shareholder culture, crony capitalism, and tax policy perpetuated wealth but were not necessary for its current level.

Gender disparities in wealth distribution have also garnered significant attention. Numerous studies have documented the persistent gender wealth gap, demonstrating that women tend to have lower levels of wealth compared to men. However, the examination of gender disparities among billionaires remains relatively limited. To clarify the gender dynamics within this wealthy class and put light on the larger issue of disparities between genders in the accumulation of wealth, it is imperative to know whether there is an important variation in assets between male and female billionaires. An article looks at how the trends in inequality found by multiple well-known inequality indices in the Forbes 400 richest families and compared with each other [18]. Other researchers have looked at other parts of the data set. A paper makes the first Distributional Wealth Accounts (DWAs) for Europe from 1970 to 2018 by putting together state accounts, tax records, and surveys. According to our new database, the amount of wealth compared to national income has changed about the same in both the US and Europe. However, since the mid-1980s, wealth inequality has grown much faster in the US than in Europe.

Finally, the impact of wealth inheritance on billionaire net worth has attracted scholarly attention. Inherited wealth often carries advantages in terms of family legacies, established networks, and access to resources. However, the extent to which inherited wealth plays a role in billionaire net worth compared to self-made wealth is a topic of ongoing debate. Investigating the difference in net worth between billionaires who inherited their wealth and those who built their fortunes from scratch adds to the understanding of intergenerational wealth transfer and its implications for wealth inequality. By reviewing the existing literature on age and wealth, gender disparities, industry sectors, and wealth inheritance, we situate our study within the broader research landscape. This background provides a foundation for our analysis of the billionaire dataset and highlights the gaps and opportunities for further exploration. The findings from this study contribute to the existing knowledge base, inform policy discussions, and offer insights into the complex dynamics of wealth accumulation among billionaires.

III. Problem Domain

The open-source dataset utilized in this paper is the billionaire's dataset from Kaggle. Understanding wealth distribution and wealth trends may be done extremely well by using this dataset. This report looks at the "Billionaires.csv" dataset analysis using Python tools designed for large-scale data analysis. The database includes data about billionaires from different nations, such as their ages, genders, industrial sectors, net worths, and places of wealth. Understanding the variables that affect the creation and distribution of billionaires' wealth is the aim of the investigation. To better comprehend these patterns and discover potential prospects for company starts and investments, it may be helpful to examine current trends in the global economy.

IV. Investigation

The paper aims to investigate the following measures:

1) To examine the relationship between demographic factors (age, gender) and net worth among billionaires.

2) To explore the variations in net worth across different industry sectors among billionaires.

3) To investigate the differences in net worth between self-made billionaires and those who inherited their wealth.

4) To analyze the correlation between age and net worth among billionaires and determine the significance of the relationship.

5) To compare the net worth of billionaires across different industry sectors and identify sectors with the highest net worth individuals.

6) To evaluate the differences in net worth between self-made billionaires and those who inherited their wealth using statistical tests.

7) To provide insights into the patterns and trends in the distribution of wealth among billionaires based on demographic factors and industry sectors.

V. Research Methodology

- Data Collection: The open-source dataset obtained from Kaggle was used in this study.
- Data Preprocessing: To deal with any missing numbers, outliers, and other mistakes, the data will be pre-processed.
- Data visualization: Data visualization is the process of using visual elements like charts, graphs, or maps to represent data.
- Hypothesis Testing: Formulate specific hypotheses based on research questions and objectives. Selection of appropriate statistical tests to test the hypotheses.
- Interpretation of Results: The results will be interpreted to identify key findings.

VI. Data Description

The dataset helps research variables related to wealth accumulation and distribution among billionaires. The net worth may be impacted by age and industrial sectors. A study of inheritance and the gender difference in wealth accumulation might potentially be done using the dataset. There are 22 variables and 2614 rows in the dataset. Table I provides a brief description of each variable.

TABLE I. Brief Data Interpretation

Feature	Description
name	Billionaires name.
rank	Annual list of billionaires ranked by net worth.
year	Year of data collection.
company. founded	The year that the business was formed
company.name	The billionaire's company's name
company. relationship	The connection between the business and the billionaire.
company. sector	Area of billionaires' businesses.
company. type	What kind of business the billionaire owns—public, state-owned, public etc.
demographics.age	Individual’s age.
demographics. relationship	Billionaire's gender.
location. citizenship	Nation in which the billionaire was born.
location. country code	The Country's ISO code where the billionaire lives.
location.gdp	Country's GDP where the billionaire lives.
location. region	Location of the billionaire in the globe.
wealth. type	Wealth's source (Inherited. Self-made, etc.)
wealth. worth in billions	The billionaire's total wealth, expressed in billions of dollars.
wealth.how. category	Method by which each billionaire acquired their wealth
wealth.how. from emerging	If the billionaire's prosperity was derived from a developing market.
wealth.how. industry	The branch of industry where the billionaire made their money.
wealth.how. inherited	The billionaire's wealth was acquired through inheritance.
wealth.was. founder	If the millionaire was a company founder.
wealth.how.was political	Billionaire has political experience or not.

VII. Research Questions

1) Which ten international countries have the maximum number of billionaires?

2) Which industries and sectors are the most successful?

3) Which sectors have the highest awareness of female billionaires?

4) What age institution do most people and a minority of billionaires belong to?

VIII. Hypothesis

A crucial component of inferential statistics is hypothesis testing, which enables us to conclude unobserved data, frequently the population, using data from a sample of observed data. When analyzing experimental data in economics, testing multiple null hypotheses simultaneously is a common practice [11]. To research this hypothesis, numerous statistical strategies will be used, inclusive of t-tests, ANOVA, and F-assessments. The outcomes of those experiments could shed mild on the variables concerned with wealth accumulation and guide the improvement of policies geared toward reducing wealth inequality. In our research, we will look at the principle of different factors that can be intently related to a billionaire's wealth. We REJECT the null hypothesis in favor of the alternative if the P-value is less than the threshold for significance (= 0.05). The correlation is statistically significant, we conclude. Or, to put it another way, we come to the simple conclusion that x and y in the population at the -level are linearly related.

If $p > 0.05$, then not correlated.

If $p < 0.05$, correlated.

The following hypotheses have been formulated for our study.

1) Does a billionaire's age affect his or her wealth?

Ho: A billionaire's net worth is not significantly related to age.

HA: A billionaire's net worth is highly related to age in a significant way.

2) Men with billion-dollar wealth are wealthier than women.

Ho: A billionaire's net wealth is unaffected by gender in a significant way.

H_A: Gender significantly affects a billionaire's financial worth.

3) The net worth of billionaires varies considerably between various industry sectors.

Ho: A billionaire's net worth is significantly influenced by the industry sector.

HA: A billionaire's net worth is not much impacted by their industry sector.

IX. Exploration of Solutions

Big data is the term used to describe the vast and diversified informational resources that are accumulating quickly. Software that can be used to handle data effectively and perform pre-processing and cleaning etc., is known as big data technology. The five main qualities of big data are truth, diversity, value, and velocity. In seconds, minutes, hours, or days, data volume is measured [12]. Velocity describes the speed at which new data is produced and transferred, whereas variety describes the wide range of data forms that are produced often. It's vital to note that velocity also shows how rapidly a company reacts to big data-derived business insight. The chance that the data's quality and consistency are inadequate, that is, less uniform, consistent, and controllable, is referred to as veracity. The fifth V, "value," stands for the ability of a person or an organization to translate enormous amounts of data into beneficial outcomes, which includes the capability to acquire and then use data [13].

To address the issues of huge information programs, numerous methodologies, and technologies have evolved these days. Those are Apache Hadoop, MongoDB, Apache Kafka, Elastic Search, Python, Seaborn, and Plotly.

X. The Tools or Technologies used in this Research

The Python programming language and modern libraries such as Pandas, NumPy, Matplotlib, and Seaborn have been selected as the technologies that will be used for this project. This decision was made about the technology that would be implemented. It is beneficial to use open-source software solutions since they are free of charge, have an interface that is simple to use, and can give comprehensive analysis and visualization capabilities. Other technologies, on the other hand, can need payment or prior expertise. When it comes to the Python Seaborn visualization toolkit, the matplotlib module is an absolute must. A graph interface that is both high-level and insightful of data will be utilized. Python packages such as Pandas, NumPy, and SciPy can be utilized to edit and analyze data. The Pandas data frame makes the process of processing data simpler. NumPy can deal with low-level data, whereas SciPy is responsible for statistical analysis.

XI. Solution Development

A key part of current data-driven decision-making is coming up with practical solutions to problems based on data analysis. Using the "Billionaires" dataset as an example, this paper talks about the main steps and things to think about when coming up with good solutions for the research questions we have. We are going to initially preprocess our data to check whether there is any noise, further, we will analyze our dataset to answer those research questions we formulate in the previous part. In the meantime, we will test the hypothesis for each question. Finally, we will show our findings and future scopes.

A. Data Preprocessing

It is necessary to preprocess the dataset to prepare it to provide true insights into the data to answer the research questions. To preprocess data, numerous processes are taken. We are going to take advantage of the procedures that are necessary in order to finish our assignment.

B. Visual Exploratory Data Analysis

Fig. 1 determines statistics at the variables' names, counts, and their respective information kinds. There are a complete of thirteen objects, along with 4 integers, 2 floats, and 3 Booleans.

Fig. 2 presents comprehensive statistical information for each numerical column, encompassing the count of values in a row, the mean, standard deviation, minimum and maximum values, and the quartiles at 25%, 50%, and 75% of the dataset. In terms of the dataset, the period under examination spans from 1996 to 2014. When compared to the oldest company, which was established in 1610, the most recent company was

established in 2012. The individual who is the youngest among them is only 12 years old, while the individual who is the oldest is 98 years old.Beyond $3.5 billion, the median net worth of a billionaire is greater than that amount.

Fig. 3 illustrates the number of unique values in each variable. Here, we are going to present a visual exploratory information analysis. Commonly, specific variables incorporate less than twenty precise values and there may be a repetition of values, this means that the records can be grouped by manner of these precise values. At this level of the study process, we're investigating the effects of visible evaluation on a spread of specific variables derived from the dataset.

Fig. 4 demonstrates the dataset comprising individuals belonging to three distinct genders: males, females, and married couples. Moreover, there exist five discrete categories of billionaires' wealth.

The four graphs in Fig. 5 and Fig. 6 depict a visual analysis of six distinct variables within the dataset. Fig. 5 illustrates the distribution of wealth and the corresponding industries associated with wealth. Fig. 6 illustrates six distinct instances of form inheritance, along with a classification indicating whether each billionaire is a founder or not.

2614 rows × 10 columns

Fig. 7. After removing irrelevant columns - new dataset.

By doing so, we will rename the column name as follows in order to make the analysis simpler:

Fig. 8 represents the dataset with renamed columns to provide a clearer understanding of the attributes of each individual listed.

C. Handling Missing Values

At this point, we determine which values in the dataset are absent. One of the most critical components of records evaluation is the management of lacking values. The precise study topic, the number of missing data, and the influence that the missing values can have on the evaluation are all elements that must be taken into consideration whilst determining whether to put off missing values or impute them.

As can be seen in Fig. 9, 34 cells are missing from the gender column, 23 cells in the company_sector column, 22 cells in the wealth_type column, and one cell in the wealth_source column.

In Fig. 10, We check the Total missing values in our dataset and the proportion of missing on different columns. The percentage of values that are missing from the dataset is quite low (most of them are much lower than 0%). Therefore, we are going to ascribe those values to the requirements that we have.

	name	gender	citizenship	company_sector	age	net_worth_billion	wealth_type	wealth_source	wealth_inherited	was_founder
0	Bill Gates	male	United States	Software	40	18.5	founder non-finance	New Sectors	not inherited	True

wealth_inherited    0
was_founder         0
dtype: int64
```

Fig. 9. Number of missing values on each column.

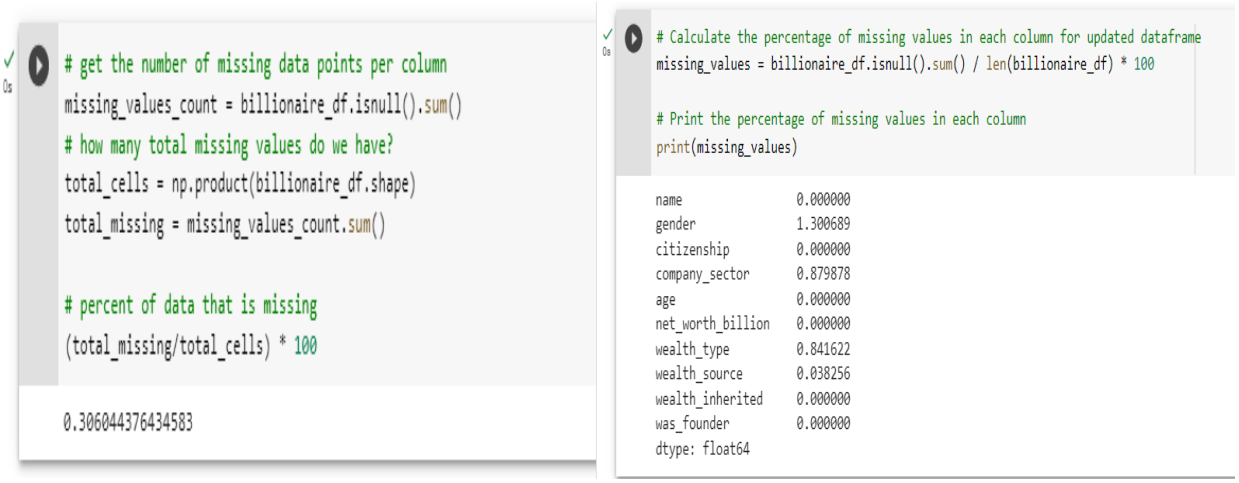

Fig. 10. Missing values in percentage.

As a first step, we strive to impute the cells that might be lacking from the gender column. Inside the gender column, there are a complete of 34 values that are lacking, and most people of these billionaires have covered terms related to their families alongside their names. Due to the absence of gender values, data analysis is impeded. The presence of the term "family" in the name gives the impression that the individual in question is not a billionaire but rather a member of a family that is a billionaire, which has the potential to skew the results of the study. Consequently, removing these rows guarantees that the analysis is founded on data that is both reliable and pertinent.

Fig. 11 demonstrates the word "family" is present in most of the cells that are absent from the gender column. We are going to get rid of those rows. Since Oeri Hoffman and Sacher appear to be a "married couple" right before our eyes, we shall impute one missing cell as belonging to a "married couple.". Rest of the cells we can delete the rows as there are a smaller number of missing cells.

Fig. 11 demonstrates the word "family" is present in most of the cells that are absent from the gender column. We are going to get rid of those rows. Since Oeri Hoffman and Sacher appear to be a "married couple" right before our eyes, we shall impute one missing cell as belonging to a "married couple.". Rest of the cells we can delete the rows as there are a smaller number of missing cells.

In Fig. 12, following the elimination of cells that were absent from the gender subgroup, we are left with 2581 individual observations. The next step is for us to analyze our research using this dataset. We are still trying to impute a few cells that are missing from our database.

Fig. 13 shows above are the remainder of the values that are absent from our dataset. We are going to try to impute those using statistical methods such as the mean, the mode, and the median. As a method for dealing with missing values, we use the median for continuous variables and mode for categorical measures.

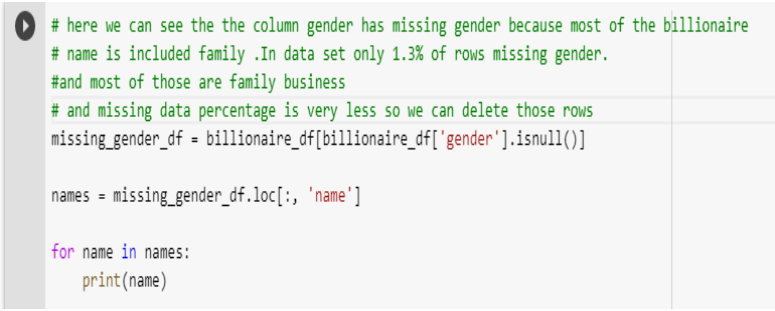

Fig. 11. Checking missing values in gender with their names.

```
[340] #It is not possible to determine the gender of individuals based solely on their name or family name.
      billionaire_df = billionaire_df.dropna(subset=['gender'])

```
[341] #1.2.Checking Missing values for updated Dataframe
      print(billionaire_df.isnull().sum())
```

```
name                0
gender              0
citizenship         0
company_sector     11
age                 0
net_worth_billion   0
wealth_type        10
wealth_source       1
wealth_inherited    0
was_founder         0
dtype: int64
```

Fig. 13. Checking total missing values remained in the updated data frame.

Fig. 14 illustrates the code snippet of a Python script using pandas to impute missing values in the dataframe.

After imputing the remainder variables, we got the updated dataset with ‘zero’ missing values (Fig. 15).

D. Checking Duplicate

As part of the data cleansing process, we conducted a check to identify any duplicated rows (as in Fig. 16). The duplicated () method in pandas allows us to identify and eliminate any duplicated rows in the dataset. This measure was implemented to ensure the distinctiveness of each discovery and to prevent any potential interference with subsequent analyses. Therefore, we did not discover any duplicate rows as a result.

```
[342] #I am treating missing values with Median for Continuous values, and Mode for categorical values.
      # Treating missing values of categorical variable with MODE value
      billionaire_df['company_sector'].fillna(value=billionaire_df['company_sector'].mode()[0], inplace=True)
      billionaire_df['wealth_type'].fillna(value=billionaire_df['wealth_type'].mode()[0], inplace=True)
      billionaire_df['wealth_source'].fillna(value=billionaire_df['wealth_source'].mode()[0], inplace=True)
      billionaire_df
```

```
<ipython-input-342-d863120c5587>:3: SettingWithCopyWarning:

```
[344] #4.Checking for duplicated rows in a dataset after dropping the rows with missing values
      # Check for duplicated rows
      duplicated_rows = billionaire_df[billionaire_df.duplicated()]

      # Print the duplicated rows
      print(duplicated_rows)

Empty DataFrame
Columns: [name, gender, citizenship, company_sector, age, net_worth_billion, wealth_type, wealth_source, wealth_inherited, was_founder]
Index: []
```

Fig. 16. Checking duplicate.

E. Outlier Analysis

To guarantee the precision and dependability of the studies, we did an outlier treatment of the dataset by using the interquartile range (IQR) approach in Python. This allowed us to recognize and exclude any intense values that would have a sizeable impact on the effects.

Fig. 17 and Fig. 18 show that the 'age' column contains significant values that need to be addressed. The dataset includes both horrible and zero age graphs, and outliers are identified at significantly lower than 20 ages. It is important to note that billionaires' age cannot be zero or impoverished.

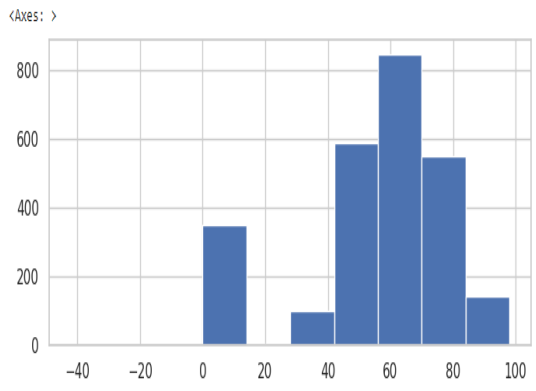

Fig. 17. Visual distribution of 'Age' by histogram.

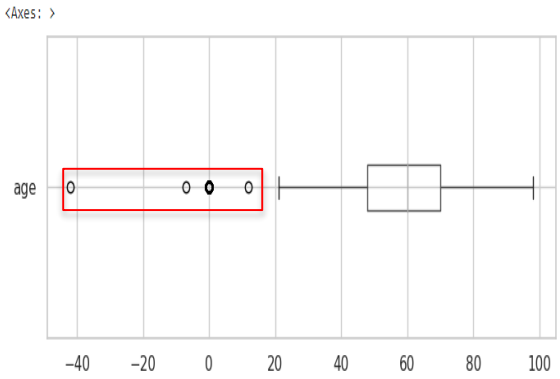

Fig. 18. 'Age' column where outliers detected.

Among the options available for dealing with the outliers, one option is to substitute the median age charge of the relaxation of the dataset for the values of bad and 0 years old. The outliers are going to be dealt with by imputing them using the median statistical technique. This will be done to address the issue.

It is through this method that the median age of the information is determined, which consequently alters the age of billionaires who are significantly younger than twenty years old (Fig. 19).

```
[351] # calculate median age
      median_age = np.median(billionaire_df['age'])

      # replace outliers with median age
      billionaire_df.loc[billionaire_df['age'] < 20, 'age'] = median_age
```

Fig. 19. Treating outliers in 'Age' column.

The net worth column that is displayed in Fig. 20 does not demonstrate any discernible increasing or declining trend. In addition to this, it demonstrates that the 'net_worth' column does not contain any outliers. Further evidence that there is a substantial association between 'age' and 'net worth' is shown by the graph.

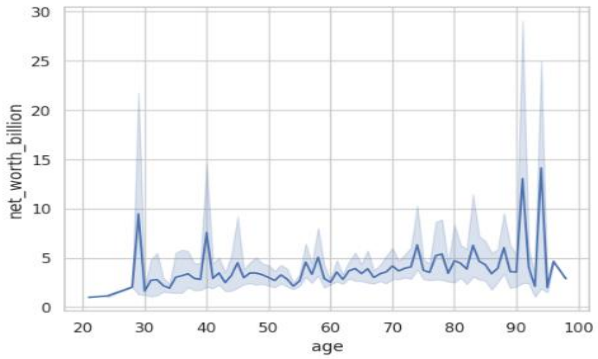

Fig. 20. Line plot of age vs. net worth billion.

XII. Dataset Exploration

The top ten countries with the highest number of billionaires are depicted in Fig. 21.

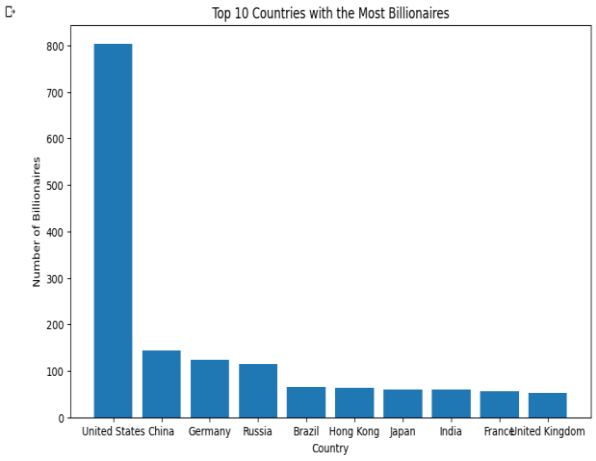

Fig. 21. Top ten billionaires in a bar graph.

Perspectives from Fig. 21:

- Fig. 21 above displays a bar chart of the top 10 richest nations and their billionaires.
- The most billionaires reside in the United States.
- China ranks second among countries with 100 billionaires.
- The number of billionaires in the United Kingdom, which is ranked 10th, is just under fifty.

Fig. 22 depicts the top five industries with the largest number of billionaires.

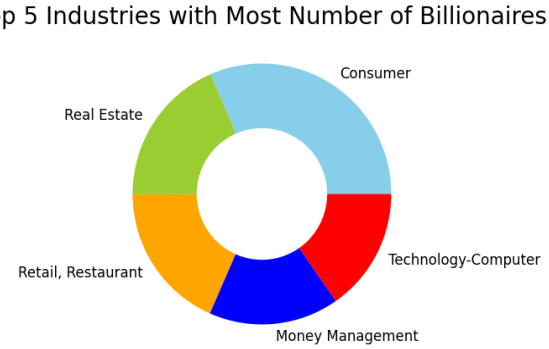

Fig. 22. Top five industries with the most billionaires are shown in a pie chart.

Perspectives from Fig. 22:

- The consumer goods industry has the most billionaires, as shown in the pie chart above.
- A significant number of billionaires are also involved in real estate.

Fig. 23 depicts the number of women billionaires by sector.

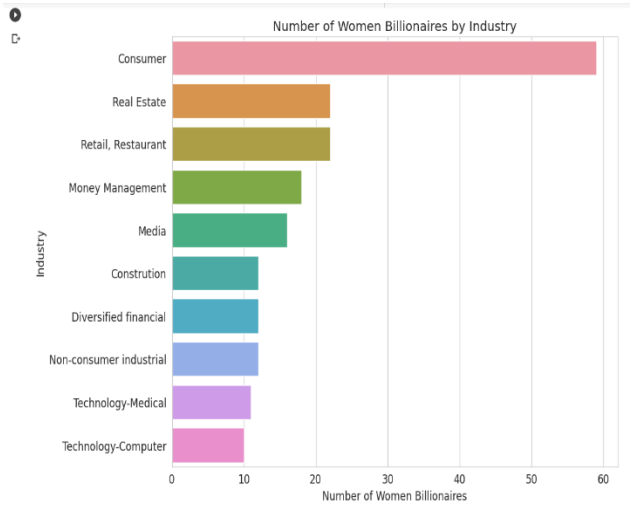

Fig. 23. Graph depicting the number of female billionaires by sectors.

Perspectives from Fig. 23:

- With over 55 female billionaires, the consumer enterprise has the most female billionaires.
- The retail and real estate industries are 2nd, with little more than 20 lady billionaires.

- With only 10 women billionaires working in the IT area, it has the lowest number of female billionaires.

Fig. 24 represents the billionaires by age range.

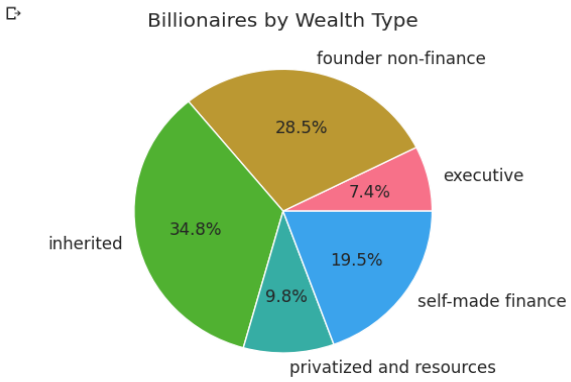

Fig. 24. Proportion of billionaires in each age group shown in the bar chart.

Perspectives from Fig. 24:

- Many of the billionaires in the dataset are between the ages of 60 and 70.
- There are very few billionaires aged 30 and under.
- Approximately two-thirds of billionaires are between the ages of 40 and 80.

Fig. 25 illustrates the proportion of billionaires by wealth category.

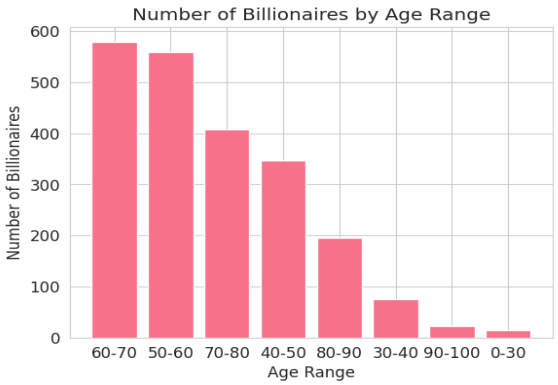

Fig. 25. A pie chart displaying the proportion of billionaires in each wealth category.

Perspectives from Fig. 25:

- The vast majority of the billionaires in the sample inherited their fortunes. They account for 34.8% of all billionaires.
- Self-made billionaires comprise 19.5% of the total.
- Executives account for the smallest proportion of billionaires, accounting for only 7.4% of all billionaires.

Fig. 26 depicts the 2014 net worth of the top 10 billionaires.

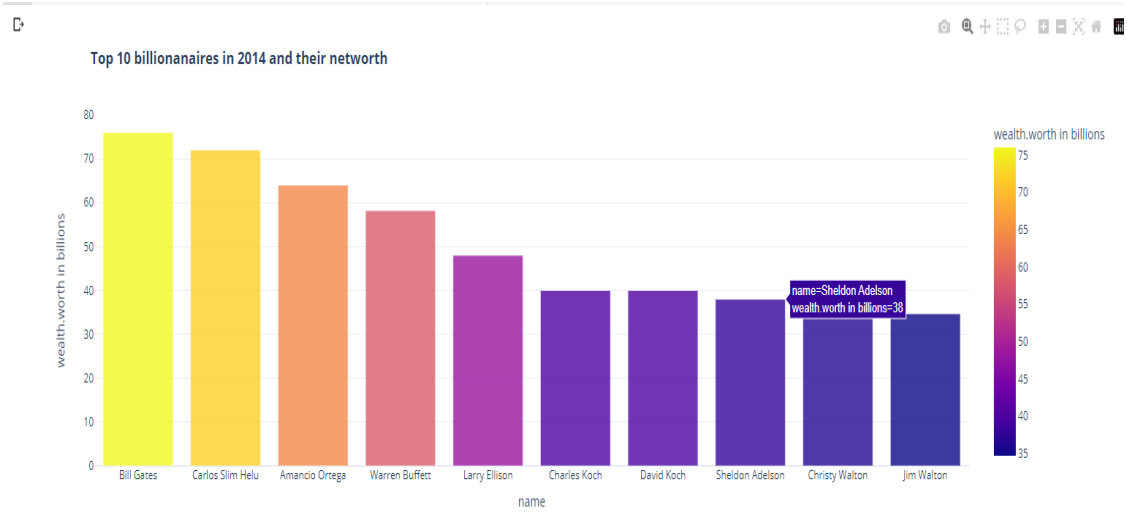

Fig. 26. A bar chart depicting the top ten billionaires and their net wealth in 2014.

Perspectives from Fig. 26:

- The bar graph above shows the most current top 10 billionaires alongside their net worth since 2014 is the latest year that is included in the dataset.
- With an overall net worth of $76 billion, Bill Gates is the first.
- After that, Carlos Slim comes in second place, boasting a net worth of seventy-two billion dollars.
- Christy Walton is the simplest female among the Top Ten rich individuals, with a net worth of thirty-eight billion greenbacks.

The top 10 billionaires' sources of income are shown in Fig. 27.

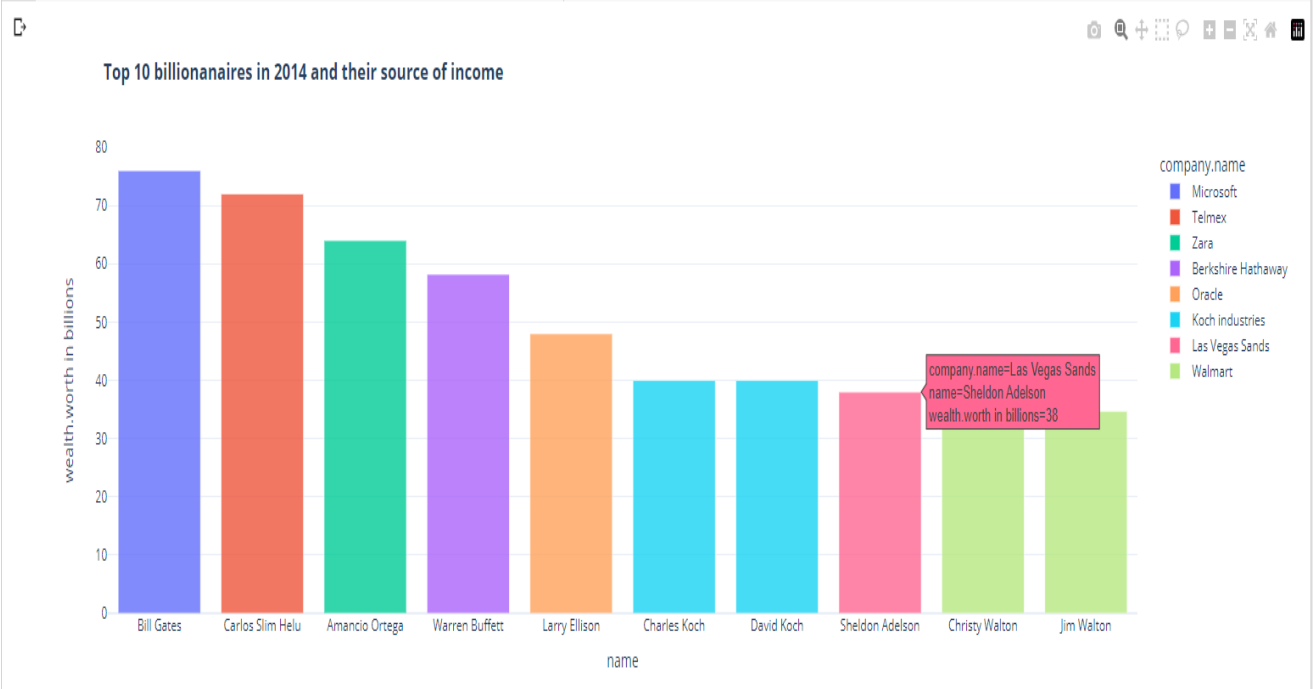

Fig. 27. The top 10 billionaires and their sources of income are shown in a bar graph.

Perspectives from Fig. 27:

- Bill Gates, the richest billionaire, receives funding from Microsoft.
- We can see from the picture above that some colors are repeated twice; these are family businesses or businesses that have produced more than one billionaire, like Walmart and Koch Industries.

The ages of the top 10 billionaires are shown in Fig. 28.

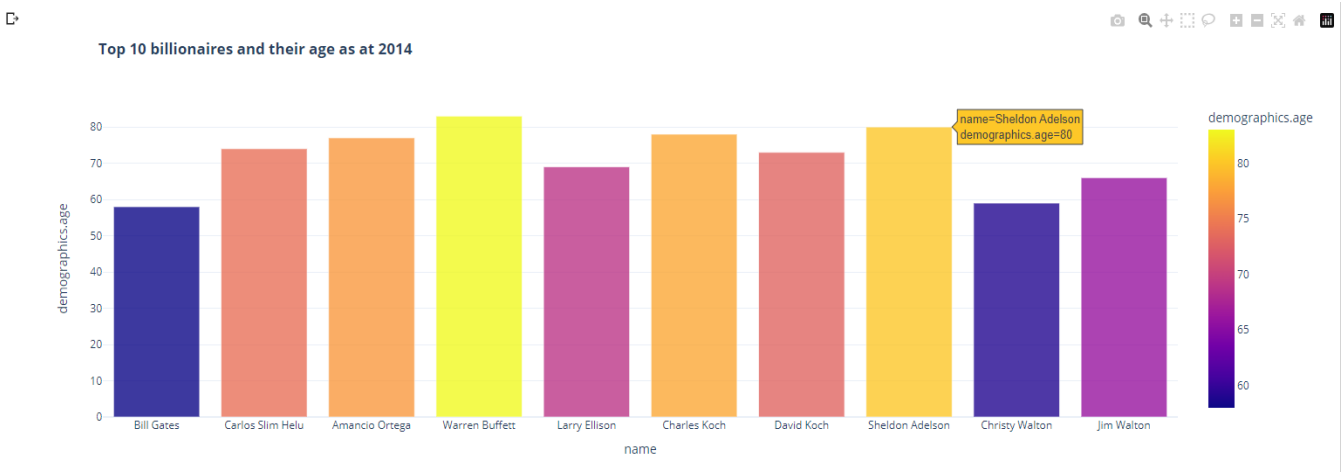

Fig. 28. A bar graph showing the ages of the top 10 billionaires.

Perspectives from Fig. 28:

- The world's number one billionaire is 58 years old.
- The top ten richest people are all over 50 years old.
- Warren Buffett, who is over 80 years old, is the oldest person among the top ten billionaires.

Fig. 29 presents the top ten youngest billionaires.

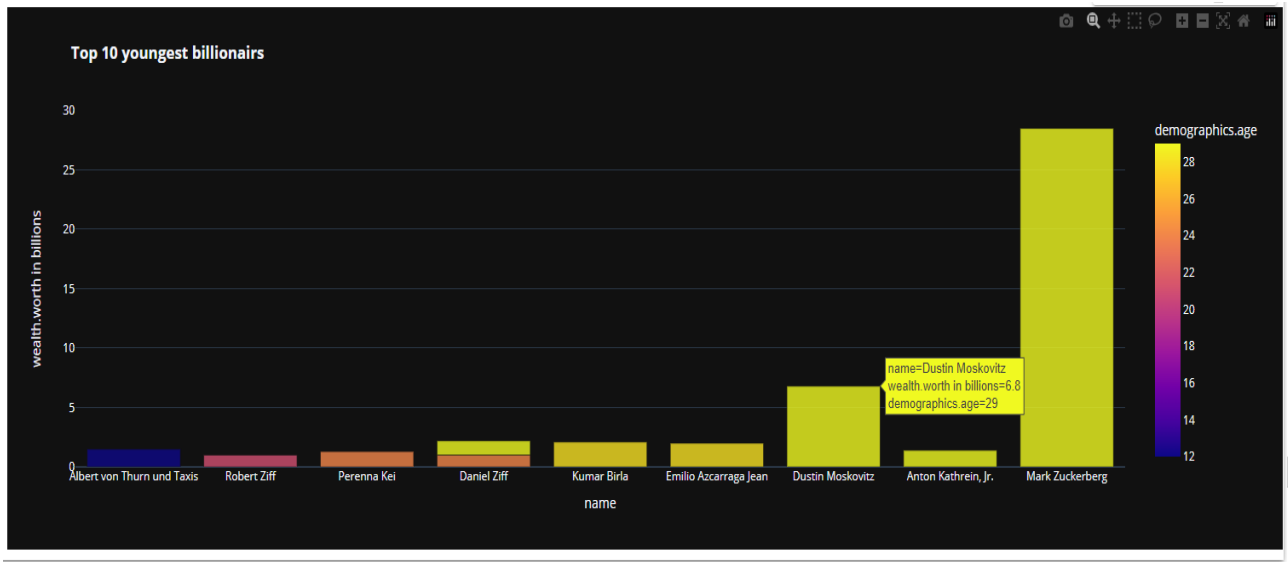

Fig. 29. The top ten youngest billionaires are represented by a bar chart.

Perspectives from Fig. 29

- Albert Thurn, who is only 12 years old and worth a billion dollars, is the youngest billionaire.
- Mark Zuckerberg is the wealthiest young person, with a net worth of more than $25 billion.

Fig. 30 shows the industries of the top ten youngest billionaires.

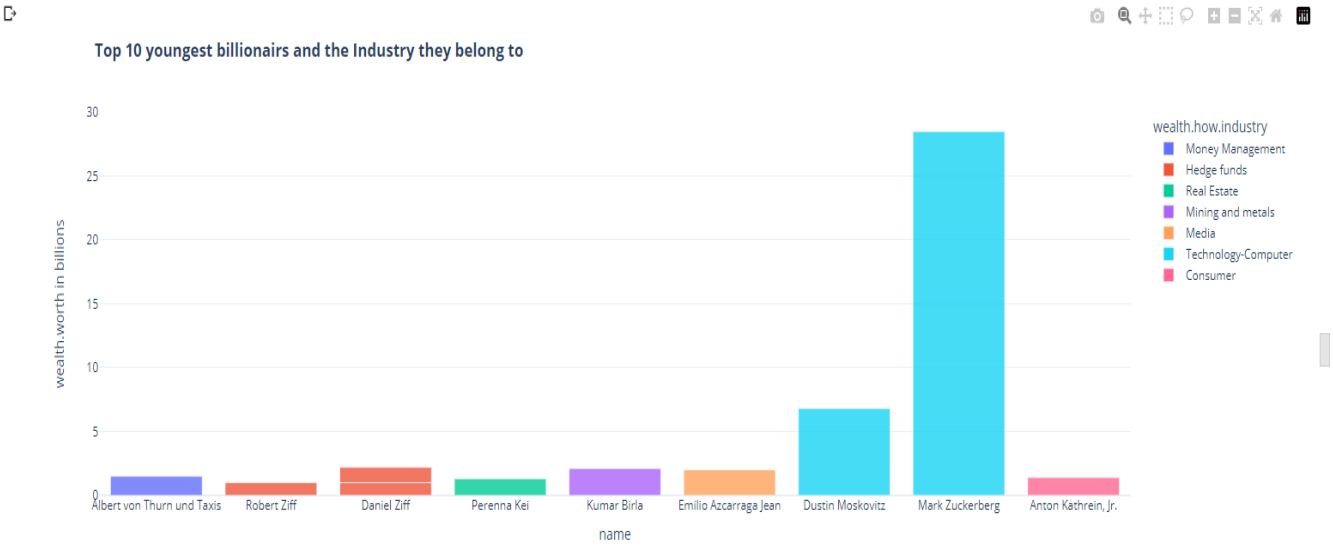

Fig. 30. A bar graph depicting the industries of the world's youngest billionaires.

Perspectives from Fig. 30:

- The youngest billionaire works in the financial services industry.
- The richest young billionaire is from the technology-computer industry.

Fig. 31 exhibits the top ten female billionaires and their ages.

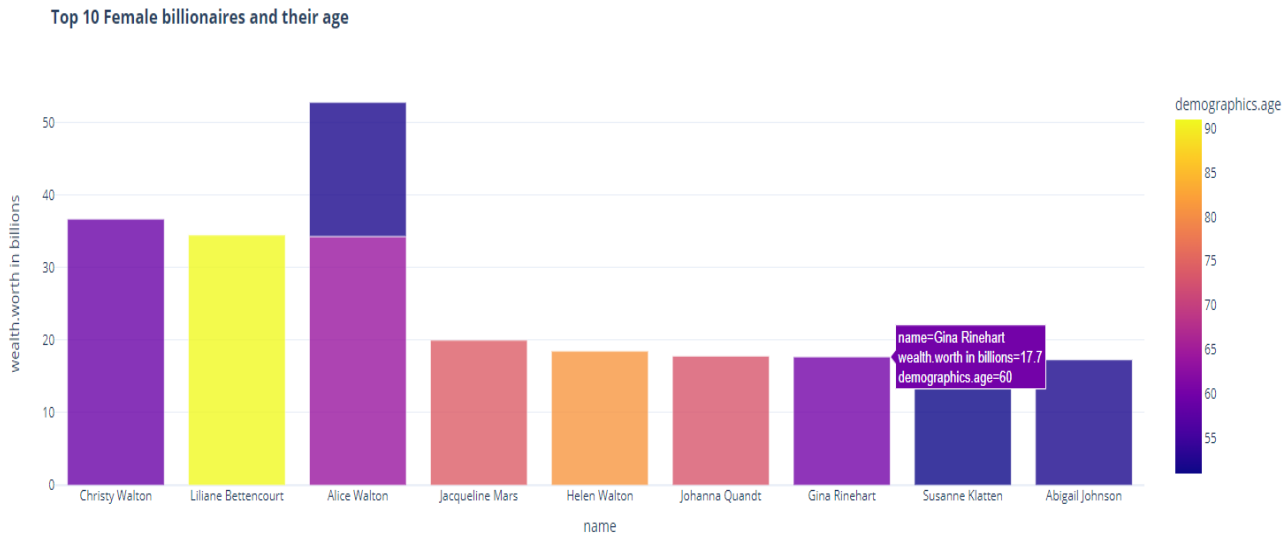

Fig. 31. The ages of the top ten female billionaires.

Perspectives from Fig. 31:

- Christy Walton, the wealthiest female billionaire, is 59 years old and worth more than 36 billion dollars.
- Lillian Bettercourt, who ranks second among female billionaires, is over 80 years old.

Fig. 32 highlights the top ten billionaires and the industries in which they work.

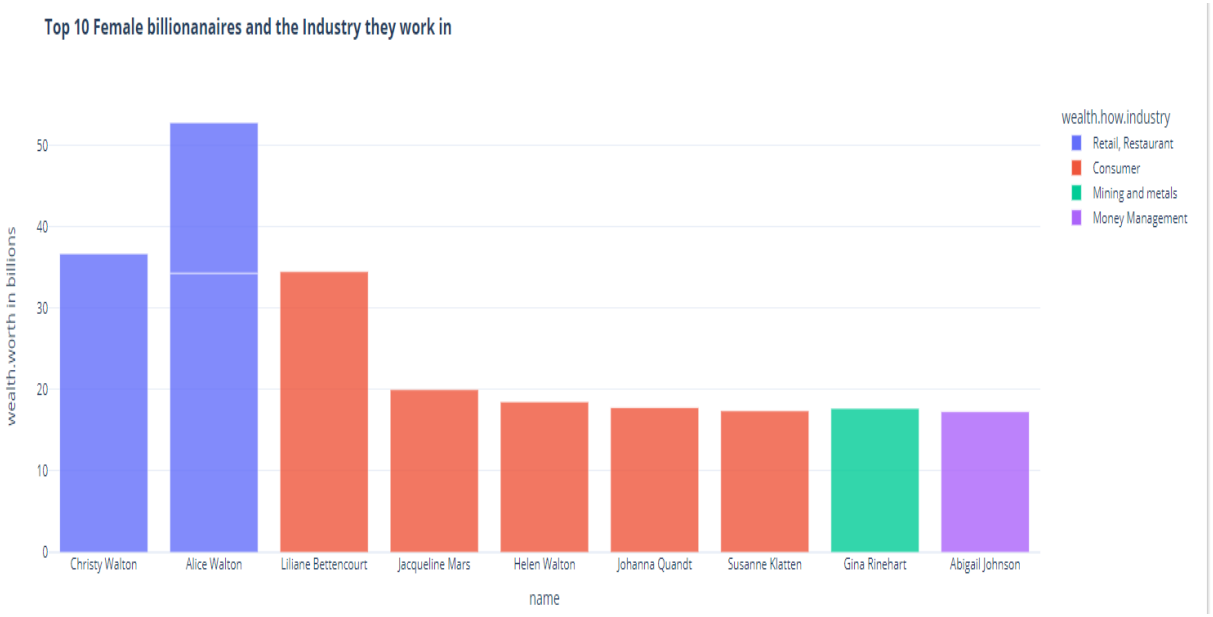

Fig. 32. A bar chart showcasing the top 10 female billionaires and the industries in which they work.

Perspectives from Fig. 32:

- The richest female billionaire works in retail and restaurants.
- Most female billionaires work in the consumer business.

The top ten industries' billionaires combined net worth is shown in Fig. 33 for 2014.

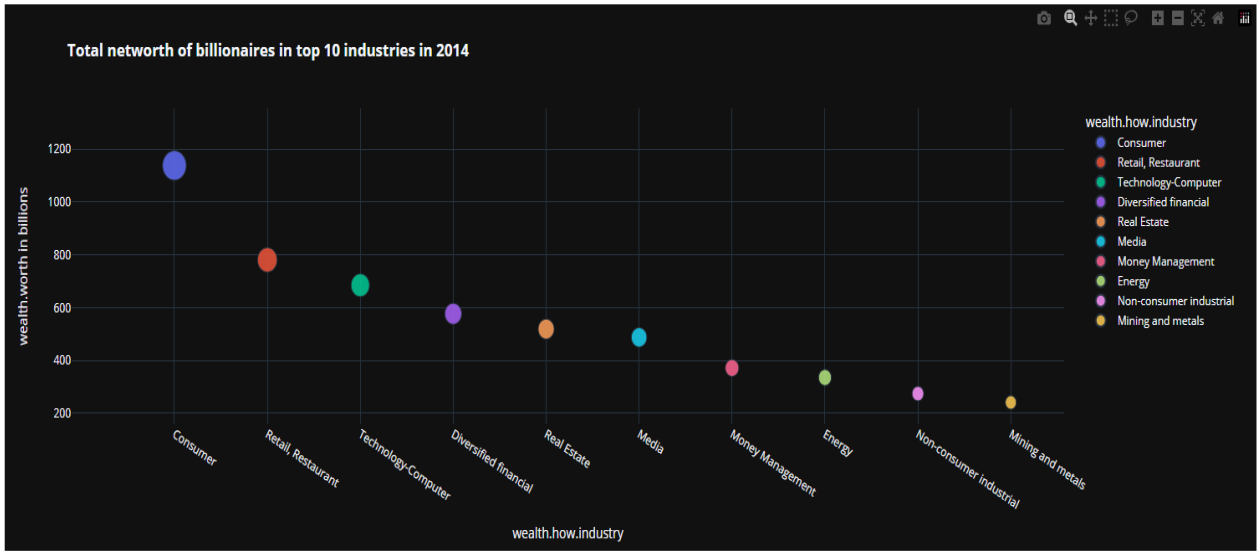

Fig. 33. Billionaires combined net worth in the leading ten sectors in 2014.

Perspectives from Fig. 33:

- The largest sector, valued at over $1 trillion, is the consumer goods sector.
- The retail, restaurant industry comes in second, with a market value of $800 billion.

XIII. Testing the Hypothesis

1) Hypothesis 1: Does a billionaire's age affect his or her net worth?

Ho: A billionaire's net worth is not significantly related to age.

H_A: A billionaire's net worth is related to age in a significant way.

The code for evaluating the first hypothesis is shown in Fig. 34.

```
import pandas as pd
from scipy.stats import pearsonr

# Compute Pearson correlation coefficient and p-value

# THIS TESTS THE HYPOTHESIS OF THE RELATIONSHIP BETWEEN AGE AND NETWORTH

corr, p_value = pearsonr(billionaires['demographics.age'], billionaires['wealth.worth in billions'])

# Print the results
print("Pearson correlation coefficient:", corr)
print("p-value:", p_value)
```

```
Pearson correlation coefficient: 0.08750438991654515
p-value: 3.990971769605956e-05
```

Fig. 34. Test code for Hypothesis 1.

Perspectives from Fig. 34:

- The association between age and net worth was examined using the Pearson correlation coefficient.
- Considering a p-value of 0.00004, it is evident that the age of a billionaire and their wealth are strongly correlated. We agree with an alternate concept as a result.
- The more elderly billionaire is most likely to be richer.

2) Hypothesis 2: Men with billion-dollar wealth are wealthier than women?

Ho: A billionaire's net wealth is unaffected by gender in a significant way.

H_A: Gender significantly affects a billionaire's financial worth.

The code to test the second hypothesis is shown in Fig. 35.

```
import scipy.stats as stats

# Filter the data for male and female billionaires
male_df = billionaires[billionaires['demographics.gender'] == 'male']
female_df = billionaires[billionaires['demographics.gender'] == 'female']

# Conduct the two-sample t-test assuming equal variance
t_stat, p_val = stats.ttest_ind(male_df['wealth.worth in billions'], female_df['wealth.worth in billions'], equal_var=True)

# Print the t-statistic and p-value
print("t-statistic:", t_stat)
print("p-value:", p_val)
```

```
t-statistic: -0.9940802457505286
p-value: 0.32029332217806183
```

Fig. 35. Test code for Hypothesis 2.

Perspectives from Fig. 35:

- This hypothesis was tested using a two-sample t-test.
- Gender and net worth are unrelated, as indicated by the p-value of 0.32, which is larger than 0.05.
- We can rule out the alternative hypothesis and adopt the null hypothesis which is billionaires' net worth is unaffected by gender.

3) Hypothesis 3: The net worth of billionaires varies considerably depending on the industry area.

Ho: A billionaire's net worth is significantly influenced by the industry sector.

H_A: A billionaire's net worth is not much impacted by their industry sector.

Fig. 36 illustrates the code for testing the third hypothesis.

```
import scipy.stats as stats

# Group the data by industry and select the net worth column
grouped_data = billionaires.groupby('wealth.how.industry')['wealth.worth in billions']

# Perform one-way ANOVA test
f_statistic, p_value = stats.f_oneway(*[grouped_data.get_group(x) for x in grouped_data.groups])

print("F-statistic:", f_statistic)
print("p-value:", p_value)
```

```
F-statistic: 2.745769472721782
p-value: 0.00022408174979504465
```

Fig. 36. Test code for Hypothesis 3.

Perspectives from Fig. 36:

- This hypothesis was investigated using the one-way ANOVA test where the p-value is less than 0.05.
- We can accept the null hypothesis and concur that the industry sector significantly influences billionaires' net wealth.

XIV. Evaluation

The study revealed how gender, age, and industry affect billionaire wealth accumulation. The retail industry has the most female billionaires, and most billionaires are men. According to our research, billionaires are usually 50–60 years old. The most senior billionaire was 98 years old, while the youngest was 21. Furthermore, real estate, media, and construction have more millionaires than other industries. The insights on billionaire wealth distribution can inform investment decisions and corporate strategies across sectors.

Our investigation has shown the key variables that enable billionaires to become rich. The above insights could help decision-makers, investors, and businesspeople understand wealth distribution and develop successful financial strategies in the global economy.

XV. Findings and Results

The following is the overall finding from the billionaire dataset analysis:

- The United States is the country that has the highest number of billionaires, which has 804 in total.
- The sector with the most billionaires is the consumer goods sector.
- The majority of billionaires are older than 50.
- 34.8% of billionaires received their wealth through inheritance.

- With a cumulative net worth of 76 billion greenbacks, invoice Gate is the richest billionaire.
- Christy Walton has a net worth of $38 billion, making her the richest female billionaire.
- The youngest billionaire is Albert Thurn, who's just 12 years old and possesses a $1 billion fortune.

XVI. Conclusions

In summary, our examination of the "Billionaires.csv" dataset utilizing Python tools for big data analytics yielded significant findings regarding the determinants that impact the accrual and allocation of riches among billionaires. Our observation revealed a noteworthy accumulation of wealth within a minority of individuals, indicating the existence of income disparity within the billionaire demographic.

The study found that entrepreneurship and technology helped a significant number of billionaires in the sample become wealthy. Technology and finance were the most profitable industries for billionaires. The analyses also showed that the US and China have the most billionaires. Billionaires also showed a trend toward gender diversity. This study sheds light on billionaires, but it has limitations. The dataset covers billionaires until 2021 and may not reflect current trends. The analysis only considered quantitative variables, ignoring qualitative factors that may contribute to wealth accumulation.

Our examination also provides a valuable contribution to the comprehension of the fluctuations in affluence within the billionaire population, exposing trends linked to entrepreneurial pursuits, sectors of operation, geographical location, and gender. Subsequent investigations ought to adopt a more all-encompassing methodology by combining qualitative and longitudinal data to acquire a more intricate comprehension of the accumulation of billionaire wealth and its societal ramifications.

XVII. Limitations and Future Work

There are a few limitations to our dataset and methodology, even though our analysis offers insightful information about the elements that lead to self-made billionaires' wealth accumulation.

- The dataset excludes billionaires who received their riches through inheritance and is only comprised of self-made billionaires. The generalizability of our findings to the total billionaire population may be impacted by this exclusion.
- The dataset may not be typical of people who have less net worth because only billionaires with total assets of more than one billion dollars are included in it. Additionally, because the data was taken over a limited period, probably, it doesn't accurately reflect patterns and shifts in wealth distribution.
- Descriptive statistics and exploratory data analysis methods played a significant role in our investigation. Although these techniques help understand the data, they do not prove causation or take into consideration confounding variables.
- The dataset may contain incomplete or erroneous data, which could produce biased or insufficient results. These restrictions must be understood and considered when interpreting the findings of our investigation.

Notwithstanding these constraints, the dataset can yield valuable insights into the determinants that contribute to the ascent of self-made billionaires. The determinants encompass the sector, age, gender, and regional attributes of the billionaires. The findings derived from this dataset can offer precious insights for companies and traders in their choice-making procedures, as well as for an academic look at the societal implications of wealth inequality. This information has the potential to be utilized for several objectives. To augment our understanding of the intricacies surrounding the wealth of billionaires and its far-reaching consequences, future research undertakings should integrate both quantitative and qualitative methodologies, incorporate longitudinal data, and investigate more extensive array of variables. This will facilitate a more holistic comprehension of the complexities associated with the amassing and dispersal of wealth among individuals in the billionaire class.

XVIII. KEY TERMS AND DEFINITIONS

Big Data Analytics: The procedure of using advanced computer and statistical tools to analyze and clean meaningful data from huge and complex datasets.

Data Visualisation: The graphical presentation of data to highlight patterns, trends, and insights to make challenging material more approachable and understandable.

Inheritance: The practice of transferring wealth, assets, or property from one generation to the next, usually using close family ties.

Economic Growth: The amount of goods and services produced by an economy increases with time. GDP growth, which measures the total value of a nation's finished goods and services, is typically used to measure it. Economic growth reveals productivity, living standards, and prospects for both businesses and people.

Hypothesis Testing: A method that uses statistical analysis to determine whether a hypothesis or claim made about a population is supported by the data from a sample of that community.

Data Pre-processing: The manipulation of raw data using a variety of methods to prepare it for subsequent processing is what is referred to as "data pre-processing," and it is an essential part of the data preparation process.

Python: A high-level programming language that is well-known for its ease of use and readability and that finds widespread use in the fields of scientific computing, machine learning, and data analysis.

AI-Enabled Vision Transformer for Automated Weed Detection: Advancing Innovation in Agriculture

Shafqaat Ahmad, Zhaojie Chen, Aqsa, Sunaia Ikram, Amna Ikram

***Abstract*—Precision agriculture is focusing on automated weed detection in order to improve the use of inputs and minimize the application of herbicides. The presented paper outlines a Vision Transformer (ViT) model for weed detection in crop fields, that tackle difficulties stemming from the resemblance of crops and weeds, especially in complex, diversified settings. The model was trained via pixel-level annotation of the images obtained using high-resolution UAV imagery shot over an organic carrot field with crop, weed, and background. Due to the nature of the mechanism in ViTs that includes self-attention, which allows it to capture long-range spatial dependencies, this approach can very well distinguish crop rows from inter-row weed clusters. To solve the problem of class imbalance and improve the generality of the patches, techniques of data preprocessing such as patch extraction and augmentation were used. The effectiveness of the proposed approach has been confirmed by an accuracy of 89.4% in classification, exceeding the efficiency of basic models such as U-Net and FCN in practical application conditions. This proposed ViT-based approach is a marked improvement in crop management; and provides the prospect for selective weed control, in support of more sustainable agriculture. This model can also be integrated into AI-based tractors for real-time weed management in the field.**

***Keywords*—Precision agriculture; weed detection; vision transformer; UAV imagery; crop-weed classification; AI-Tractors**

I. Introduction

In light of such global factors as climate change, increasing population, and declining land fertility, protection of food production has become an important task [1]. Amongst various biotic constraints that affect crop yield and quality, weeds rank as some of the most formidable challenges that crop producers face in the field [2]. If not controlled, weeds have severe effects on crop yield and quality hence contributing to loss making and high food insecurity [3]. In the past, weed management has been undertaken by mechanical means such as pulling weeds out by hand or the widespread application of herbicides [4]; either of which is now considered to be unfavorable. Hand weeding is hard and cannot be used in large scale farming [5], while chemical control causes pollution and health issues [6], reduces bio-diversity, and results into the evolution of herbicide resistant weeds. Therefore, there is need to develop effective, sustainable as well as economic methods to tackling weed problems.

New developments in precision agriculture especially in combination with technology such as remote sensing, machine learning and drone systems, are revolutionizing conventional weed control approaches [7]. Precision agriculture is the practice of trying to grow crops as efficiently as possible by giving farmers instant information about the condition of their fields so they can manage the resources they use in the most sustainable way [8]. With UAVs using high resolution and multispectral cameras available for field monitoring, large scale data acquisition coupled with detailed visualisation of crop and weed distribution in the agricultural environments is possible [9]. It is possible to use this technology to locate and identify weeds and subsequently manage by providing efficient spot treatment as opposed to weed eradication using herbicides.

Nevertheless, identification and precise categorization of weeds in crop fields still pose a great challenge due to factors such as variability in the field, weeds growing between rows of crops and close resemblance in appearance of weeds and crops [10]. These difficulties cannot be resolved by using conventional image processing techniques, because such approaches rely on color-based or shape-based segmentation, which may not be sufficient for distinguishing between very similar plant species in different lighting and environmental conditions [11]. To overcome these limitations, machine learning particularly deep learning approaches has been used to improve weed detection accuracy. Convolutional neural networks (CNNs) have been reported to work well in this area [12], however, due to their constrained local connectivity, they lack the ability to capture the spatial dependencies and context required to correctly identify weeds from crops especially in high density field setting.

Recently, Vision Transformers (ViTs) emerged as a compelling approach to surpass CNNs in image classification problems [13]. First introduced for natural image understanding, ViTs utilize the self-attention method and it provides a wide-angle view of long-range dependencies within the image, which is crucial in agriculture. Unlike CNNs, ViTs can handle the analysis of the entire image regions rather than focusing on localized features needed for crop and weed differentiation [14]. Self-attention enables ViTs to distinguish between crop rows and inter-row weed clusters more accurately than in field conditions where crop plants and weeds appear to have similar textures and color patterns.

This research introduces a new method for the automated detection of weeds based on a Vision Transformer model that

has been developed to handle the specific difficulties of agricultural weed categorisation in UAV imagery. The proposed method takes advantage of the fact that crops, as a rule, are planted in a geometric pattern of rows while weeds grow randomly across the farm field; therefore, crop regions can be distinguished from the clusters of weeds by their geometric arrangement. The method we propose here is to employ the Vision Transformer model on the high-resolution UAV images at the pixel level to accurately distinguish crops from weeds. The training dataset is CWFID, for each image, background, crop, and weed pixels are labeled in detail with the help of experienced farmers, which supplies the model with profound features for learning intricate spatial associations.

Using the efficiency of image preprocessing including patch extraction and data augmentation and the feature of long-range dependencies analysis of ViT model we expect to receive high classification accuracy and good scalability in field conditions. This study advances understanding of weed biology and the potential for selective, efficient weed control by identifying specific proteins that allow for accurate discrimination of different weed species. Consequently, the study responds to important research questions in PA and opens up opportunities toward building more sustainable and less hazardous crop growing systems.

The remainder of this paper is organized as follows: Section II discusses related work, which presents an idea of this research area and the inclusive techniques for weed detection and its merit and demerit. Section III outlines the research approach of this study, which covers ViT architecture, datasets, data preprocessing, and evaluation of crop and weed classification. Section IV explains the findings that include the assessment of the ViT model and a comparison with other conventional models like U-Net and FCNs. Section V offers a discussion of the findings, issues on model stability and possible applications of the developed models to precision agriculture. Last, Section VI provides a conclusion to the study by offering an overview of the major conclusions, the main research contributions, and an indication of the areas where future studies and enhancements may be made.

II. Related Work

There are different approaches for weed detection mentioned in the literature for the use of different image acquisition systems. The first one is carried out by separating vegetation from the background as soil and residues to separate crops from the weeds. The common segmentation process handily uses the color Methods [15] and Multispectral data in order to segment vegetation from background using fixed indices which make vegetation segmentation possible. Nonetheless, differentiating between weeds and crops using spectral data prove difficult since the two are spectrally similar. Therefore, approaches focusing on the region level, which utilizes spatial pixel configurations, are mostly used [16].

The detection of weeds in agriculture has improved over the years with the help of color-based segmentation algorithm. Hue based indices like the Excess green Index (ExG) are used widely to sharpen vegetation features in imagery, isolating plants from their surroundings. This approach is especially valuable when dealing with multispectral data since, as it was mentioned, ExG uses the green component most to enhance vegetation. This method has been found to be computationally efficient for the initial step of separating crops from weeds in agricultural scenarios and laid down a base for further analysis and classifying more steps [17]. Another level of enhancement of weed detection is obtained by integrating Excess Green with Otsu's thresholding technique which segment images at the optimum threshold intensity values. The integration method is passes in minimizing the background noise while maximizing vegetation details. Together with the double Hough transform, this method improves the identification of crop lines in images with perspective distortion by recognizing and reorienting the lines in a complex environment in agriculture. They are particularly useful in the images of the same scene taken under varying lighting conditions since they increase the resistance when classifying crops from weeds [18].

TABLE I. Previous Weed Detection Methods

Method	Description	Reference
Color-Based Segmentation	Separates vegetation from background using color indices such as Excess Green (ExG) and fixed indices in multispectral data.	[17]
ExG and Otsu's Thresholding	Combines Excess Green and Otsu's thresholding to eliminate background, then uses double Hough transform to identify crop lines in perspective images.	[18]
Object-Based Image Analysis (OBIA)	Uses UAV imagery and multiscale algorithms to segment crop rows from weeds, creating homogeneous objects for analysis.	[19]
2D Gabor Filters with ANN	Uses 2D Gabor filters to capture texture features and an artificial neural network (ANN) classifier for weed detection.	[20]
Morphological Characteristics	Utilizes morphological features to distinguish weeds in maize fields, using neural networks and support vector machines (SVMs) with shape-based features.	[21]
Edge Frequencies & Vein Density	Differentiates weeds from crops by analyzing edge frequencies and vein density differences in the leaves.	[22]
Otsu Thresholding & K-means/SVM	Applies Otsu thresholding for background removal and uses k-means clustering and SVM classifier for crop-weed classification, successful in sunflower fields.	[12]
Wavelet Transform & Neural Network	Uses wavelets to capture texture details and a neural network for classification, effective for recognizing various weed types in sugar beet fields.	[23]
SVM, ANN, & Random Forests in OBIA	Employs machine learning models like SVMs, ANNs, and Random Forests within the OBIA framework, especially for weeds in maize fields.	[24]
Convolutional Neural Networks (CNNs)	Uses CNN architectures, including AlexNet, for weed detection in crops such as water hyacinth and serrated tussock. Applied in UAV-based imagery and mobile robot systems.	[25]
Spatial & Spectral Domain Features	Integrates Hough transform for spatial features with multispectral data for spectral features, combined with SVM for crop-weed classification in four-band imagery.	[26]

Another complex technique is Object-Based Image Analysis (OBIA), which divides images into areas of the same character instead of single pixels, within the use of multistate algorithms. When applied to UAV imagery, OBIA provides a better defined and can be easily automated procedure to distinguish crops from weeds. This approach is useful in vast areas where exact methods like pixel based approach turn out to be more computational. Thanks to OBIA, grouping similar pixels into coherent objects, researchers are able to distinguish the pattern of weed distribution across the crop rows, which enhances weed control strategies [19]. The combination of texture analysis in the form of 2D Gabor filters with Artificial Neural Networks (ANNs) introduces a promising solution to the problem of weed detection due to the utilization of frequency and orientation within images. The enhanced textural features that are fundamental to crops and weeds are well captured by Gabor filters. ANNs then sort these features, and the model has a high level of accurate weed detection in crops with textural features. This method offers considerable reliability to precision agriculture, above all in areas of uniform textural characteristics where texture differential is significant [20].

Shape based features of Morphological characteristics are another factor that builds another level of discrimination in case of weed identification. Methods that apply such factors as shape, size, and structure of the leaves using neural networks and Support Vector Machines (SVMs) are preferable in structured crops such as maize. Morphological features are unique depending on the type of crop or the weed in question, and therefore helpful where the shape differences are quite profound. Such a strategy can be especially valuable for detecting specific weed types that differ from crops morphologically [21]. Another notable feature which is used in classification of weeds is the patterns that appear on the leaves 'veins. Vein density methods and edge frequency methods help to distinguish crops and weeds because crops and weeds essentially have different vascular networks within the veins of their leaves naturally. This technique is most successful in the controlled environments where crops and the weeds differences in vein densities are clearly noticeable. Due to this focus on these several anatomical dissimilarities, this approach is suitable for high precision detections in small-scale or research production agriculture setting [22].

Furthermore, using thresholding Otsu together with clustering and classification method such as K-means and SVM makes a strong way of detecting weeds in areas such as sunflower crops. Otsu's thresholding erases the background noises while k-means clusters all the pixels having a nearly similar intensity, which is then sophisticatedly classified by the SVM in order to separate weeds correctly. Thus, this work follows gradual layering of steps that help increase the weed detection accuracy, and that are tested effective even in high noise images [12]. When used alongside neural networks, the wavelet transform is a useful method of weed detection through texture analysis. Wavelets analyze small local details of the image and since neural networks can provide high accuracy when determining the difference between the weeds. This technique has been particularly effective in sugar beet fields where due to the multi specie flora the different weeds can be identified using the features obtained by the wavelet analysis of the images [23].

Currently, the use of OBIA has included some common machine learning models, such as SVMs, ANNs, and Random Forests. This approach especially for maize fields incorporates an object-based image analysis with machine learning concept leading to higher accurate detection in large-scale agriculture. Thus, the classifiers within and across the imagery segments enhance the models to increase classification results in high complexity areas where the mere pixel-based approach could not limit the classification process [24]. Convolutional Neural Networks (CNNs) are that key technology which helps weed detection using high-dimensional data and pattern extraction. The state of the art CNNs, such as the AlexNet, has been implemented in the classification of weed crops such as water hyacinth and serrated tussock. These models are particularly suitable for UAV and mobile robotic systems where high versatility of weeds and constant ability to perform well in different conditions is needed. The feature extraction capacity of CNNs makes them useful in agricultural systems particularly where big data samples can be used in training and model refinement [25].

Last of all, advanced techniques that combine spatial and spectral characteristics of the analysed images, including Hough transform method with the use of multispectral imaging and support vector machines, can be pointed to as an enhanced method for crops and weeds differentiation. This approach takes advantage of spatial characteristics and spectral variation of four bands in imagery for precise analysis in precision agriculture. This method involves combining of spectral data with spatial transformation to result in high classification accuracy particularly in fields where spectral and spatial discrimination is well defined [26].

III. Proposed Methodology

In modern agriculture, most crops are planted in organized rows with defined spaces, depending on the crop type. Vegetation that grows outside these rows is generally identified as weeds, known as inter-row weeds. Leveraging this spatial organization, several studies have implemented weed detection methods based on the geometric properties of crop rows. A key benefit of these methods is that they are largely unsupervised, reducing the need for manual training data. Building on this, our approach first identifies crop rows, then labels inter-row vegetation as weeds to create a training database. We categorized this data into two classes, crop and weed, and used it to train a Vision Transformer (ViT) model to detect and classify crops and weeds from UAV imagery. Fig. 1 provides an overview of the main steps in the proposed method, with detailed descriptions following.

Crop/Weed Field Image Dataset (CWFID) is one of the vital resources for demonstrating the models of machine learning for classification of crops from weeds. The data in this paper was obtained from an organic carrot field in Northern Germany with the help of an autonomous field robot called Bonirob which has a high-resolution multi-spectral camera. Collected during the vegetation phase of the crops, the images offer a real-world

representation of crop and weed status in the fields, which is useful for precision agriculture studies with detailed descriptions of both crops and weeds present in the image. The dataset comprises 60 high-resolution images with the size of 1296 x 966 pixels. The fine details present in the presented images make it possible for models to differentiate vegetation features, and also differentiate between plants that are growing closely together. Each image in the dataset is fully annotated at the pixel level by agricultural experts, classifying each pixel into one of three categories: The three categories of organisms identified in the study area include Background (Soil), Crops (Carrot Plants) and Weeds.

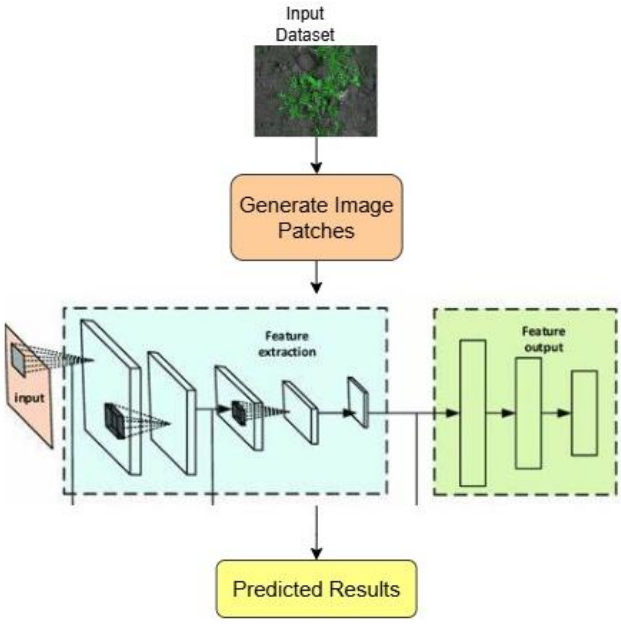

Fig. 1. Proposed architecture flow.

The expert annotations of the CWFID dataset allow for the identification of crops and weeds in a highly accurate, even in the most complicated agricultural environment. Every class in the case of the given dataset is a category of content that helps in differentiating between plants and soil. The three annotated classes are described in detail below:

1) Background (Soil): This class consists all the bare grounds particularly the soil that is inter and intra-row of crops. These background regions makes it easier to define whether an object is crop or weed since they creates a contrast. The pixel distribution across the three classes is as follows and has been presented in Table II to indicate the class imbalance problem similar to that of realistic problem.

2) Crops (Carrot Plants): This class is made up of areas with carrot plant bodies, which are usually aligned in an orderly manner. They contribute to the improvement of the effectiveness of the classification between crop and non-crop areas due to the crop rows formed. The carrot plants were in different stages of maturity which provided a variety that helps the models understand different crop morphologies.

3) Weeds: In this dataset, weeds comprise intra-row weeds, which are those established within the crop rows, and inter-row weeds, which are those established between the crop rows. Classification models are further complicated by the presence of intra-row weeds since they are similar in size and color to crops. The presence of a large number of different weeds improves the applicability of the dataset for developing reliable machine learning models capable of distinguishing between crops and different weed types.

Because of the high-resolution images and corresponding detailed annotation, the CWFID dataset is more suitable for precision agriculture in which precise weed maps are required at the pixel level. The dataset offers several unique challenges:

1) Class imbalance: The fact that there are more background and crop pixels than weed pixels is a more realistic representation of the field environment to encourage the use of methods such as data enhancement and class balancing.

2) Intra-row and inter-row weeds: Moreover, the combination of both inter-row and intra-row weeds poses a difficult classification problem for the models, where the presence of weeds in between crop rows is also considered.

3) Varied lighting and vegetation density: The dataset comprises images taken under varying light conditions and at different vegetation cover densities making it more challenging to classify while improving model resilience.

The CWFID dataset is freely accessible from GitHub and can be used by researchers interested in crop and weed classification for agricultural applications. The specific use of this dataset is to contribute to the generation of models for improving precision agriculture, especially in the case of weed detection and control within crop fields.

A. Data Preprocessing

To train effectively and to generalise the crop-weed classification model, some modifications were made on the CWFID dataset during data preprocessing. These steps were taken in an effort to bring the format of the data fed into the classifier more to a unified level, also to equalize the ratio of the classes and increase the variety of training samples (Table I).

1) Image resizing: When analyzing the CWFID dataset, it was found that each of the original images has a size of 1,296 x 966 pixels, and thus requires downscaling for input into the most of the deep learning models. To keep it manageable for the model, all of the images were also scaled to a size that would fit the input size of the chosen model. This resizing made all the inputs have equal dimensions thus making the model to undergo training without the need for further resizing during training. The option of resizing was applied more conservatively, allowing the image to maintain as much of its quality as possible, and at the same time, decreasing the amount of computations needed.

2) Patch extraction: To prepare the data for pixel level classification, each resized image was then split into fixed size patches of 8×8 pixels. Patch extraction serves several purposes:

a) Localized feature capture: Since a large image is divided into small segments of patches, C&Ps can identify crop

and weed characteristics confined or restricted to particular regions.

b) Class representation: Each patch was made around regions marked as crop or weed and both of them were equally represented in the training set.

c) Memory efficiency: Smaller patches also mean that Memory is used, which is a great advantage since more patches mean more data for the AI model to train on, especially and particularly when using humongous data sets.

In general, patches consisting only of background pixels were often removed in order to focus on crop and weed area. They also diminished unnecessary data and at the same time enhanced the specificity of the data set with regard to crops and weeds differentiation. If a patch contained both crop and weed pixels it was classified into a patch class with the highest pixel count in a particular patch in order to of class labeling.

3) Data augmentation: Since there are significantly fewer weed pixels than crop pixels in the CWFID dataset, data augmentation was used to increase the number of weed samples and, therefore, improve the model's performance. Augmentation techniques were applied uniformly across both classes to expose the model to a variety of conditions, as detailed below:

a) Rotation: Each patch was rotated at 90°, 180°, and 270° rotations. This rotation not only amplified the dataset up to four folds but also let the model learn about the rotational variability needed for recognizing weeds and crops in multiple angles.

b) Contrast adjustments: To mimic different lighting scenarios that could be met in practice, the contrast of a patches was altered randomly. Crop, weed, and background boundaries were highlighted through higher contrast settings; lower contrast mirroring conditions such as low light or shadow. This adjustment improved the ability of the model to be sensitive to variations in the levels of illumination in the environment.

c) Gaussian smoothing: Specifically, Gaussian smoothing, or blurring, was applied only to minimize the noise in the image and enhance the main characteristics of each patch. High frequency components and significant intensity variations were removed through applying a Gaussian filter, and this enabled the model to detect general features. This technique also assisted in lowering the impact of noise and enhanced generalization in some instances.

4) Balanced dataset composition: To reduce the class imbalance, dataset was augmented in such a way that both crops and weeds had almost equal representation. Augmented weed patches were particularly helpful in countering this in data collection because crop areas are generally more abundant. To this end, the findings demonstrated that it is possible to get a near balanced distribution between the two classes and this made the model to perform well in making discriminations between the two classes without favoring the larger class. Through this detailed data preprocessing step, the CWFID dataset was well-prepared for training the Vision Transformer model, which then captured important aspects of both crops and weeds and succeed under different field conditions.

TABLE II. SUMMARY OF DATA PREPROCESSING TECHNIQUES USED

Preprocessing Step	Description	Purpose
Image Resizing	Standardized input size for all images	Ensures consistency and reduces memory usage
Patch Extraction	64 × 64 pixel patches centered on crop or weed regions	Localizes features and increases efficiency
Rotation	Rotations at 90°, 180°, and 270° angles	Increases data size and rotation invariance
Contrast Adjustments	Simulates lighting variations by adjusting contrast	Improves robustness to different lighting
Gaussian Smoothing	Applies a Gaussian blur to reduce noise and enhance primary features	Focuses model on main features, reduces noise

B. Model Training

The prepared CWFID dataset was used to train a Vision Transformer model because of its efficiencies in capturing the spatial relationships within the image data. In contrast to the standard convolutional models, the ViT model adapts a self-attention mechanism, enabling the model to acquire contextual data from larger regions of each picture, which makes it suitable for learning subtle distinctions between crops and weeds. To evaluate the model's performance effectively, the dataset was split into separate training and testing sets. Eighty percent (80%) of the images were allocated to the training set, with the remaining 20% reserved for testing. This split ratio was chosen to ensure that the model could learn robustly from a substantial amount of data while still providing a sufficient amount of unseen data for accurate performance evaluation.

Care was taken to maintain a balanced distribution of crop and weed samples within both sets, allowing the model to be tested on images that represent the diversity and complexity of real-world conditions captured within the CWFID dataset. This split provided the model with an appropriate balance between learning general features during training and evaluating its effectiveness in generalization during testing. To optimize the ViT model for the crop-weed classification task, a set of training parameters was carefully selected based on preliminary testing and validation:

1) Optimizer and learning rate: The function used for optimization was presented by the stochastic gradient descent (SGD) with the learning rate equal to 0.001. It was chosen due to its performances in dealing with large number of sample inputs and the fact that it can converge significantly when trained with appropriate learning rate. The learning rate of 0.001 was found to give a stable and systematic training improvement to the model without oscillating training or causing a convergence problem.

Algorithm: Vision Transformer (ViT) for Crop and Weed Classification

Input:

- Image dataset D with labeled crop, weed, and background images
- Pre-trained Vision Transformer model ViT
- Training parameters: batch size, learning rate, number of epochs

Output:

- Classified images with crops and weeds distinguished

Initialization

1. Load images from dataset D and associated labels (crop, weed, background). 1.2 Apply data transformations to each image:
   - Resize to 224×224= times (ViT input size).
   - Apply random horizontal flip, rotation, and normalization.
2. Define a custom dataset class CropWeedDataset for loading images and labels.
3. Initialize DataLoader for training and validation datasets with the transformed images.
4. Initialize the Vision Transformer model ViT with a classification head suitable for the number of classes
5. Set the loss function as Cross-Entropy Loss
6. For each epoch in the specified number of epochs: - Set the model to training mode.
7. Perform backpropagation and update model weights
8. Perform a forward pass through the model. - Compare predictions to actual labels to calculate accuracy.

2) Batch size: The batch size of 16 was chosen, as such size is more efficient in terms of memory and computation speed. This size ensured the model could handle a reasonable amount of data per every step, the training and convergence process was much smoother and quicker compared to the larger batch sizes, but the memory issues that can come with large batch sizes were also avoided.

3) Epochs: In initial experiments, it was defined that the number of epochs should be 50. This decision was made based on observing the loss and accuracy plots during trial runs of the model several times and noted that 50 epoch was sufficient for the model to learn the features required to distinguish crops from weeds without over-fitting to the training data. Of note, early stopping and validation checks were used to stop training if the model was overfitted or if the training process stagnated, for purposes of time and computational efficiency.

a) Training process: During training, the ViT model took in each 64 × 64 pixel patch derived from the CWFID dataset. The self-attention within the ViT structure allowed the model to learn spatial relationships among these patches thus distinguishing between crop and weed patterns well. Maintaining constant observance of the training and validation loss made it possible to check if the model is overfitting or underfitting. When this training setup was complemented with the well-prepared dataset and the augmentation strategies, the ViT model was able to generalize well. Upon the completion of training, the model was able to learn different patterns and spatial relationship of crops and weeds for a robust classification during the test. Fig. 2 shows ViT architecture.

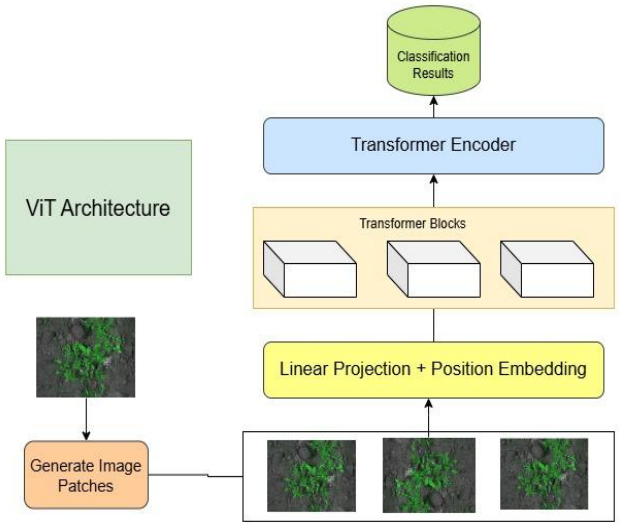

Fig. 2. ViT Architecture.

IV. Experimental Setup

For this study, a systematic experimental framework was developed to assess the ViT approach for crops–weeds discrimination based on the CWFID dataset. This setup entailed setting not only the hardware but also the software environment to address the requirements of processing high-resolution UAV imagery and running deep learning models such that we would obtain reproduceable results.

The experiments were performed on a high-performance computing system consisting of an Intel Xeon E5-2678 v3 processor (2.5GHz), and an NVIDIA GeForce GTX 1080 Ti GPU with 11 GB VRAM. This combination of CPU and GPU allow to process large image datasets effectively and speedup model training. In the framework of the proposed system, it utilized 64GB of DDR4 RAM which make use of the in-memory data processing, especially helpful when dealing with a significant volume of augmented samples. A 1TB SSD was used to store the dataset and the intermediate outputs so that during training and evaluation phase, there was low latency and fast data access.

Regarding the software environment the experiments were performed on Ubuntu 20.04 LTS operating system because of its ability to support deep learning frameworks and successfully manage computationally intensive tasks. PyTorch 1.9.0 has been the major library used to train the ViT model since it offers flexibility to implement transformer models. Furthermore, basic Python libraries including OpenCV for image processing, NumPy for numerical computation and scikit-learn for assessing the performance of the offered models were also installed into the environment. The transformation of the images was made possible by using the Albumentations library towards the

enhancement of the data augmentation processes so as to enhance sample variability.

The dataset preparation for the current study followed the preprocessing steps as outlined in the methodology. The CWFID dataset was further split into a training set and a testing set out of which 80% was used for training and the rest was used for testing The training and testing datasets contained equal numbers of crop and weed samples. This division allowed for providing the model with enough samples for learning the general features at the same time preserving a separate part for the model accuracy assessment of the new, previous samples. Every single high-resolution image was partitioned into 64 × 64 pixel window patches that were centered on crop or weed annotations. This patch extraction enabled the decoupling of complex features with this model to learn localized features while data augmentation including rotation, contrast adjustment and Gaussian smoothing were used to increase the variation in lighting, orientation and appearance of crops and weeds samples.

Some of the parameters of the ViT model were set specifically for the purpose of crop and weed classification. Its architecture was based on the self-attention mechanism and was selected due to its capability to define spatial dependencies within the patches of images successfully. The model was trained with following specifications: batch size = 16, learning rate = 0.001 and the optimizer used for training is stochastic gradient descent. The total training process comprised 50 epochs, if validation loss stopped increasing or began to rise, early stopping was used to stop training. The cross entropy loss was adopted as the main loss function, which provides flexibility in multi-class crop, weed, and background classification.

To assess the performance of the developed models, a variety of evaluation measures was used. The accuracy for each of the classes, namely the crop, weed and background were determined in order to compare the performance of the models. With accuracy and quantity, measures of precision and recall were useful in determining the strengths of the model in differentiating crops from weeds and an F1 score was useful as it balances both false positives and negatives. Further, to avoid or reduce such biases confusion matrices were produced that give a clear distinction of the model on class to class basis.

V. Results

In the results section, the performance of the Vision Transformer (ViT) model on crops, weeds, and background elements of the CWFID dataset is described in detail. Essentially, percentage accuracy, precision, recall and F1 scores were determined and more detailed analysis was done using the confusion matrix. The model was trained using 80 / 20 train-test split which helped evaluate the model on the new data it has never seen.

A. Accuracy Assessment

On the test set it was possible to obtain an overall accuracy of the ViT model equal to 89.4% showing that it can effectively distinguish crop, weed and background pixels. This high level of accuracy indicate that the ViT model is able to extract the unique features of each class even in the complicated agricultural environments where crops resemble weeds. The degree of accuracy shown in this paper proves that ViT model can be used in practical applications, specifically in the field of precision agriculture where precise identification of crops and weeds can lead to improvement in crop management and decrease in the amount of applied herbicide.

B. Class-Specific Performance

Class-specific precision, recall, and F1 scores were calculated to evaluate the model's effectiveness across different classes: crops, weeds, and background. These metrics are as follows and are summarised in Table III for easy comparison of the strengths and weaknesses of the model with respect to each class. Fig. 3 shows various models performance results.

Fig. 3. Various models performance results.

TABLE III. Specific Performance Metrics of ViT Model

Class	Precision (%)	Recall (%)	F1 Score (%)
Crops	91.2	85.7	88.4
Weeds	87.5	80.3	83.7
Background	93.1	96.4	94.7

For the crop detection, the model obtained an accuracy of 91.2% and recall of 85.7% and thus an F1 score of 88.4%. This is, however, high, although there could be confusion with weeds particularly in the inter-row area. Varying results were achieved for the recognition of weeds, with 87.5% accuracy, 80.3% recall, and thus an F1 of 83.7%. The slightly lower recall for weeds shows that weed detection is more difficult especially for intra row weeds which are more similar in appearance to the crops. In the evaluation of the model for background region, the precision achieved was 93.1%, with a recall of 96.4% and F1 score 94.7%. This high performance on the background further enhances the performance of the model in differentiating the non-vegetation areas, thus minimizing chances of wrongly classifying crops as weeds.

C. Confusion Matrix Analysis

The confusion matrix extends the assessment of the model's classification correctness by showing where the errors were made. In Table IV the true positive, the false positive, and the false negative are shown for each class.

The confusion matrix (Fig. 4) also shows that the major misclassification problem was between the crop and weed classes where crop pixels amounted to 168 were misclassified as weeds while weed pixels of 128 were classified as crops. This pattern indicates that the yarn becomes problematic in distinguishing between crops and weeds mainly within areas of high plant density. This is especially problematic in intra-row spaces where weeds and crops may have similar architectures and reflectance properties hence compounding the challenge of modeling the two. On the other hand, the background class was accurately classified with few errors which actually shows that the model is good in separating vegetative from the non-vegetative land cover like the soiler bare ground.

TABLE IV. CONFUSION MATRIX FOR VIT MODEL PREDICTIONS ON TEST SET

	Predicted Crop	Predicted Weed	Predicted Background
Actual Crop	1,221	128	13
Actual Weed	168	1,345	72
Actual Background	7	12	1,249

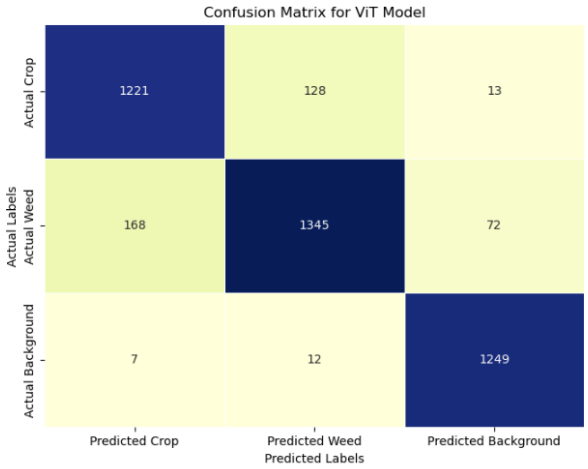

Fig. 4. Confusion matrix.

D. Comparison with Other Models

The ViT model was compared with traditional models such as U-Net, SegNet, and Fully Convolutional Network (FCN). Accuracy, precision, recall and F1 scores of all models are summarized in the Table V, where it can be concluded that the ViT model is more accurate. By comparing the proposed Vision Transformer (ViT) model with those of U-Net, SegNet, and Fully Convolutional Network (FCN), its higher accuracy has established it to be capable of handling the difficult environments within agriculture, especially the growth within the intra-row weed.

In such environments, where weeds are below or adjacent to crops and may be morphologically similar to crops, many of the CNN-based models are ineffective. This is due to the fact that, convolutional layers are inherently limited by its local receptive field, meaning that traditional model might be unable to capture those high-level, global features requiring the understanding of the whole image and its relationship to all other images, which in turn affects its accuracy in situations where high level of discriminative dissimilarities exists.

The self-attention mechanism of the ViT model has an advantage because it processes images in their entirety and identifies long-range spatial relations that may be neglected by CNN-based architectures. Such an approach is most beneficial for intra-row weed identification, in which local resemblance in texture and color between crops and weeds often leads to confusion in other models. This paper also shows that self-attention mechanism in ViT that allows the model to pay attention to relevant features in large regions of the images leads to better recall and precision, important for weed classification where precise distinction between crop and weed pixels is necessary (see Fig. 5, 6 and 7).

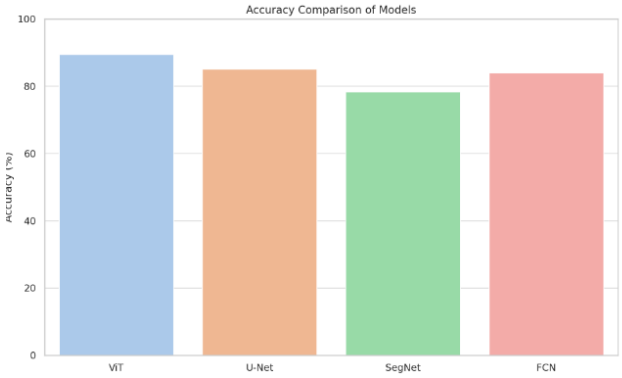

Fig. 5. Accuracy comparisions of models.

Fig. 6. F1-Score comparisions of models.

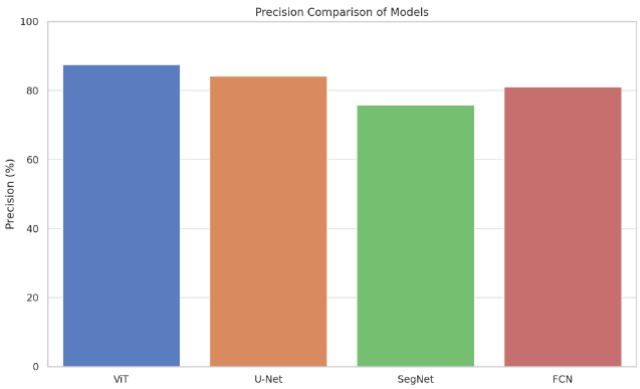

Fig. 7. Precision comparisions of models.

TABLE V. PERFORMANCE COMPARISON OF VIT MODEL WITH TRADITIONAL MODELS

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 Score (%)
ViT	89.4	87.5	80.3	83.7
U-Net	85.1	84.2	76.5	80.2
SegNet	78.3	75.8	71.4	73.5
FCN	83.9	81.1	74.8	77.8

Furthermore, the improved performance in ViT can again be attributed to how generalization is done properly to the field conditions. The high accuracy and precision in signifying weeds and crop images justify the flexibility of the proposed model in different lighting backgrounds, soil, and crop placement. This generalization is especially helpful when working with practical field applications of the model as weather, lighting, and growth stages may affect the models' performance. A noteworthy comparison with U-Net further emphasizes ViT's advantage: that although U-Net also yields a good performance, the reliance on convolutional layers again hinders the ability to capture global context and therefore yields lower recall for weed detection. The results indicate that the trained U-Net is more sensitive to vagaries in closely planted weeds and crops, issues that are worsened by field conditions. However, these difficulties are not present in ViT's design, which implies that potential agricultural applications of transformer-based models might be more scalable and versatile where extensive field analysis is required.

VI. CONCLUSION

The current paper shows that Vision Transformers (ViTs) can be used in precision agriculture for the detection of weeds in crop fields. This accuracy was established through pixel-level classification adopted from high-resolution UAV imagery as compared to traditional models such as U-Net and FCN where the ViT model obtained 89.4% accuracy. The high accuracy is an indication of ViT's ability to establish dependencies and spatial arrangement in large agricultural scenes, which are hard for traditional CNNs to achieve. The study achieved the following goals of the research: The class imbalance was solved by applying a combination of two oversampling techniques which improved the classification results. Employing patch extraction and data augmentation enabled the ViT model to accurately distinguish crop, weed and background regions. The approach also showed robustness under different conditions improving the likelihood of its application in realistic agricultural settings.

This research goes a long way in the promotion of sustainable agriculture by providing a potential method for selective weed management that does not require much use of the weed controlling herbicide. The current study could be extended in the future by examining other environmental factors or using the model in other crop types, and different field conditions to assess the model's universality. Finally, the model derived from ViT holds the potential to contribute toward precise, effective and sustainable farming.

This research also opens up possibilities for integration with AI-based tractors, enabling real-time weed detection and management directly in the field. Such applications could revolutionize automated precision agriculture, allowing for targeted weed control while minimizing herbicide usage. With further development, this approach could support the advancement of intelligent, autonomous farming machinery.

The Heart of Artificial Intelligence: A Review of Machine Learning for Heart Disease Prediction

Brayan R. Neciosup-Bolaños[1], Segundo E. Cieza-Mostacero[2]
Research Group Trend and Innovation in Systems Engineering -Trujillo, Cesar Vallejo University, Perú[1, 2]

***Abstract*—Heart disease is one of the main heart diseases that cause the death of people worldwide, affecting the engine of the human body: the heart. It has a greater incidence in underdeveloped countries such as Angola, Bangladesh, Ethiopia and Haiti, for this reason, obtaining accurate results based on risk factors manually is a complex task. Therefore, this systematic review allowed us to analyze and study 32 articles applying the PRISMA methodology, which allowed us to evaluate the suitability of the methods and, consequently, their reliability in the results. The results of the study showed that the algorithm with the greatest accuracy in predicting these heart diseases is Random Forest. The most commonly used metrics to evaluate machine learning algorithms are sensitivity, F1 score, precision, and accuracy, with sensitivity highlighted as the primary metric. The most predominant independent aspects for predicting heart disease in machine learning models are age, sex, cholesterol, diabetes, and chest pain. Finally, the most used data distribution is 70% for training and 30% for testing, which achieves great accuracy in the algorithm prediction process. This study offers a promising path for the prevention and timely treatment of this disease through the use of machine learning algorithms. In the future, these advances could be applied in a system accessible to all people, thus improving access to healthcare and saving lives.**

Keywords*—*Machine learning; heart disease; prediction; systematic review; artificial intelligence; algorithms; literature; heart

I. INTRODUCTION

One of the main causes of death worldwide is heart disease, which includes conditions such as coronary arteries, angina, heart attacks and heart disease, resulting from problems that affect the engine of the human body: the heart [1]. In addition, the American College of Cardiology mentions that 26 million people die from heart disease worldwide, and 3.6 million people undergo tests to rule out these diseases, aware of the great impact they can have on their lives [2].

Heart disease has a greater presence in underdeveloped countries such as: Angola, Bangladesh, Ethiopia and Haiti, with risk factors associated with this disease such as: high blood pressure, high cholesterol, uncontrolled diabetes, smoking and cardiac deterioration [3]. Therefore, to obtain accurate results in the diagnosis of this condition, a decision support system for your specialists is needed, since relying on multiple risk factors manually is a complex task [2].

Along with the challenges these nations face, the need for innovative solutions such as machine learning is highlighted, in addition, the adoption and application of this branch of artificial intelligence in the prediction of heart disease offers a promising approach. Compared to a human expert, machine learning models stand out for their speed and the lower cost associated with the predictions of these pathologies [4].

Machine learning, being a method of developing algorithms that help diagnose diseases of various kinds, has been crucial in a constantly modernizing world, where technology plays a vital role in continuous development. Through its techniques, it has been possible to save the lives of thousands of people by quickly detecting or predicting diseases, thus offering high-quality service to patients. Likewise, by identifying the primary phases of the conditions mentioned above, treatments can be adopted and counteract the disease, controlling the mortality rate in a comprehensive manner [5], [6].

On the other hand, machine learning models are classified into three categories: supervised learning algorithms, which focus on providing the user with an input x along with its corresponding output y, with the purpose of predicting y for a previously unseen input x, through the development of a classifier algorithm; Unsupervised learning algorithms, which do not focus on providing specific output values, but rather on inferring an underlying structure from the inputs, and reinforcement learning algorithms, where an agent is trained to determine certain policies, to solve efficient problems [7], [8].

Therefore, this systematic review focuses on the study of the most effective machine learning algorithms; powerful tools to make medical diagnoses and effective health services, revolutionizing the health sector. In addition, health professionals will be trained to identify assistance solutions faster and with greater accuracy [9]. Therefore, these algorithms, with their characteristics, make it possible to predict heart disease in people, which allows us to obtain an advantage against the disease.

Likewise, to carry out this study, a systematic review of the literature was carried out using the PRISMA methodology. In this methodology, articles were selected to address four research questions: Which machine learning algorithm demonstrated the best prediction performance in the present studies? What are the independent aspects for the machine learning model in its prediction process? ?, What performance metrics were used to evaluate the machine learning model(s) in the present studies? and What is the proportion of data used to train and test the machine learning model? Furthermore, the review was structured into sections of introduction, methodology, analysis of results and conclusions.

II. METHODOLOGY

To develop the systematic review, we applied the PRISMA 2020 methodology, allowing us to evaluate the adequacy of the methods and, consequently, the reliability of the results [10]. Additionally, Zotero software was used to store the articles, these documents were subsequently evaluated to determine their eligibility, following established criteria. Fig. 1 shows study selection flowchart.

A. Research Questions

The objective of this study is to examine, compare and summarize articles on heart disease prediction using machine learning, published from 2021 to 2022. The four research questions developed are as follows:

- Q1: Which machine learning algorithm demonstrated the best prediction performance in the present studies?
- Q2: What are the independent aspects for the machine learning model in its prediction process?
- Q3: What performance metrics were used to evaluate the machine learning model(s) in the present studies?
- Q4: What is the proportion of data used to train and test the machine learning model?

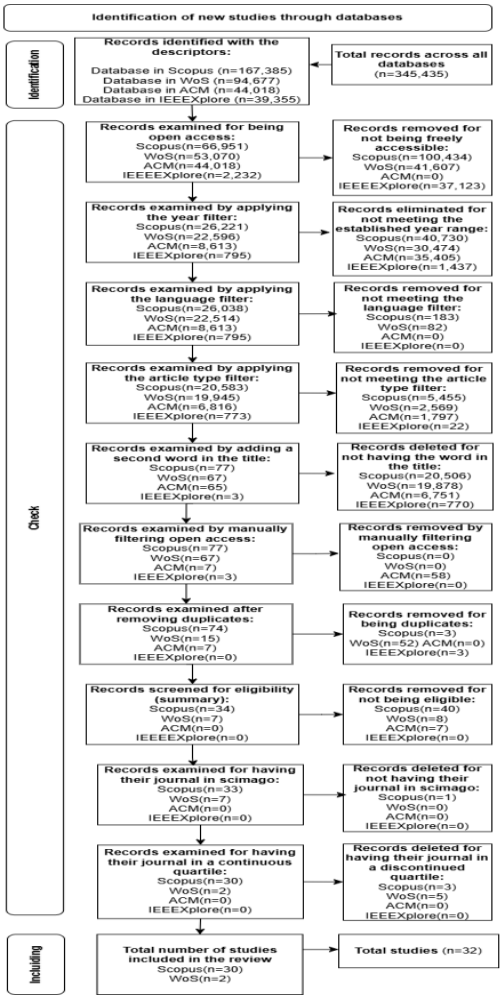

Fig. 1. Study selection flowchart.

B. Search Strategies

An exhaustive search of publications ranging from 2021 to 2022 has been carried out in four databases, these being: Scopus, Web of Science, ACM and IEEE Xplore. Likewise, to carry out this search strategy, the keywords were used: (“machine learning”) and (“heart disease”), as shown in Fig. 2.

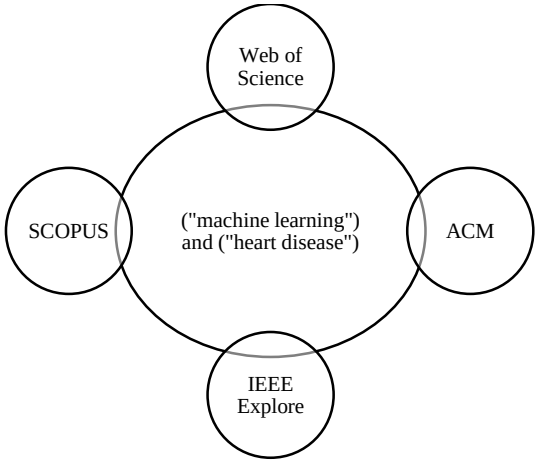

Fig. 2. Search criteria in databases.

C. Inclusion and Exclusion Criteria

For the selection of studies, studies were included that 1) the title of the articles must include the keywords, 2) they must be available as open access, 3) they must have been published between 2021 and 2022, 4) they must be written in English, 5) the type of document must be exclusively articles, 6) manual filter to access open access articles through Zotero, 7) they must have been non-duplicated articles, 8) they must have been eligible (summary), 9) must have had their journals indexed in scimago and 10) must have been from journals with non-discontinued quartiles. The exclusion criteria were: 1) the title of the articles does not include the keywords, 2) they are not available in open access, 3) they are not published between 2021 and 2022, 4) they are written in a language other than English. , 5) that the type of document does not correspond to an article, 6) they are not freely accessible through Zotero, 7) duplicate documents, 8) ineligible documents (abstract), 9) the journals of the documents are not indexed in scimago and 10) the magazines of the documents are of discontinued quartile. Fig. 2 presents the characteristics of the articles included in the systematic review, where the previously mentioned criteria are shown.

III. RESULTS AND DISCUSSION

Of the 32 studies identified, they were compiled and summarized in a Microsoft Excel spreadsheet. The distribution of these studies according to their origin in the database is as follows: 94% of the studies come from Scopus, which is equivalent to a total of 30 articles. On the other hand, Web of Science (WOS) represents 6% of the studies, with two articles. Both ACM and IEEE Xplore do not have any studies that meet the inclusion criteria mentioned above. The details of the distribution of the selected articles according to their origin in the database are summarized in Table I.

TABLE I. SELECTED ARTICLES

N°	Database	Number of Articles	Percentage (%)
1	Scopus	30	94
2	WOS	2	6
3	ACM	0	0
4	IEEEXplore	0	0
	Total	32	100

A. Results of Machine Learning Algorithm with Higher Accuracy (Q1)

Among the 32 studies analyzed, the presence of several machine learning algorithms for the prediction of diseases related to heart disease was observed. The most common algorithms include AdaBoost, CatBoost, Decision Tree, KNN, Linear Regression, Logistical Regression, Naive Bayes, Random Forest, Support Vector Machine, and XGBoost. Furthermore, models proposed by their authors were included in two studies, such as: HB + ET + SMOTE [11] y RECHOMMEND [12] highlighting a different approach that contributes to the field of machine learning.

TABLE II. ALGORITHM WITH BEST PERFORMANCE

N°	Algorithms	Papers	#	%
1	Random Forest	[13], [4], [2], [14], [1], [15], [16], [17], [18], [19], [20], [21], [3]	13	30.95
2	Support Vector Machine	[22], [23], [24], [25], [26], [9], [18]	7	16.67
3	XGBoost	[27], [28], [29], [19], [30]	5	11.90
4	Decision Tree	[5], [2], [31], [32]	4	9.52
5	Naive Bayes	[6], [33], [1], [18]	4	9.52
6	KNN	[34], [20]	2	4.76
7	Logistical Regression	[31], [18]	2	4.76
8	AdaBoost	[35]	1	2.38
9	CatBoost	[19]	1	2.38
10	HB + ET + SMOTE	[11]	1	2.38
11	Linear Regression	[21]	1	2.38
12	Rechommend	[12]	1	2.38

b. Source: Own work

Table II shows that the Random Forest algorithm is the most predominant in a total of 13 studies, which represents 30.95% of articles that use it. These findings are of utmost importance for future research that seeks to determine which machine learning algorithm provides the best performance in predicting diseases related to heart disease.

Thus, in the study by Maini et al. [15], the Random Forest (RF) algorithm achieved a diagnostic accuracy of 93.8%, evidencing a greater predictive capacity compared to other algorithms evaluated; concluding that the RF-based machine learning model not only offers an early diagnosis of heart diseases, but can also be easily accessible through the Internet, facilitating its implementation in clinical settings.

Likewise, an accurate ML model not only contributes to the early prediction of heart disease, but also allows identifying cases in which, although the patient appears to be healthy, the disease could be progressing imperceptibly. Therefore, the use of machine learning algorithms to prevent and treat heart disease in a timely manner is relevant.

B. Result of Independent Aspects for the Prediction Process of the Machine Learning Model (Q2)

Fig. 3 presents an analysis of the independent aspects or risk factors used in the prediction process of machine learning models.

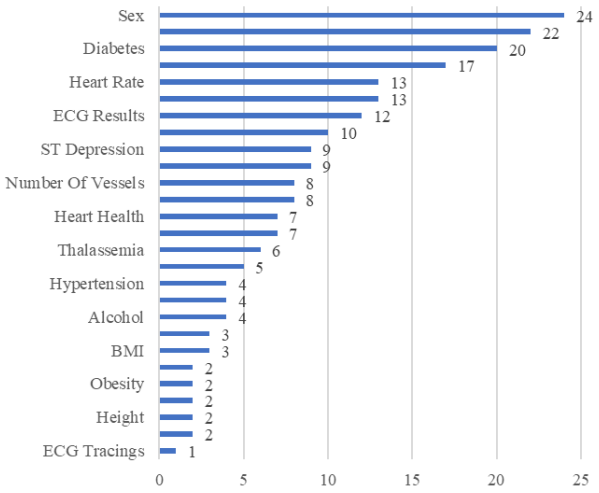

Fig. 3. Independent aspects.

Table III shows that age, sex, cholesterol levels, the presence of diabetes and chest pain are the predominant factors in the studies. These risk factors are considered highly effective in predicting heart disease-related diseases in patients, as stated and recommended by experts in the field [33].

TABLE III. PREDOMINANT INDEPENDENT ASPECTS

N°	Independent Aspect	Articles	#	%
1	Age	[1], [3], [4], [5], [9], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21], [22], [24], [25], [26], [27], [28], [30], [31], [32], [33], [34], [35]	27	10.15
2	Sex	[2], [3], [5], [9], [12], [13], [14], [16], [20], [24], [28], [31], [32], [33], [34], [35], [15], [17], [18], [21], [26], [27], [14], [19]	24	9.02
3	Cholesterol	[1], [2], [4], [9], [13], [14], [16], [16], [17], [18], [20], [21], [22], [25], [26], [28], [30], [31], [32], [33], [34], [35]	22	8.27
4	Diabetes	[2], [3], [9], [14], [15], [16], [17], [19], [20], [21], [24], [27], [31], [32], [33], [34], [1], [4], [18], [26]	20	7.52
5	Chest pain	[1], [2], [3], [4], [5], [9], [13], [15], [18], [21], [22], [29], [31], [32], [35], [14], [24]	17	6.39

c. Source: Own work

Khdair and Dasari [25], in their study, highlighted that characteristics of medical records and associated risk factors such as: tobacco, LDL cholesterol levels, systolic blood pressure, adiposity and family history play a crucial role in preventing heart disease, as measured by medical records. They further noted that the success of predictions in the field of machine learning largely depends on the quality and diversity of the data used, as richness in data features and variables significantly improves the results in machine learning predictive models.

C. Result of Performance Metrics for Evaluation of Machine Learning Models (Q3)

Among the most commonly used performance metrics to evaluate machine learning algorithms, sensitivity, F1 score, precision, and accuracy stand out. As detailed in Fig. 4, sensitivity is the most valued metric in the studies, with 19.04%.

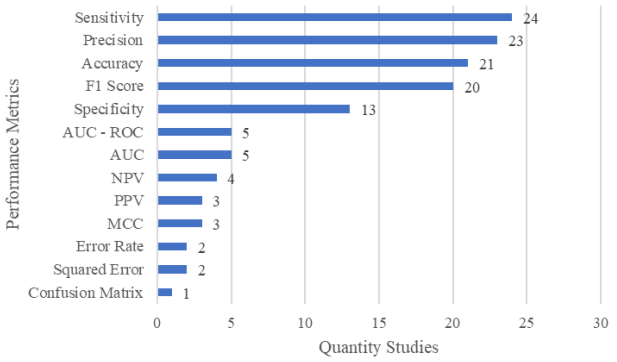

Fig. 4. Performance metrics.

In most studies that evaluate the performance of their machine learning algorithms, it exceeds 90%. As demonstrated by Maini et al. [15] where its RF prediction system achieved a sensitivity of 92.8% in the effective diagnosis of heart diseases. Another study reveals that an SVM-based model achieved 95% sensitivity [9].

Thus, in the research of Alotaibi and Alzahrani [35], they also use accuracy, sensitivity, specificity, F1 score, error rate, and Matthews correlation coefficient (MCC), all of these metrics derived from arithmetic calculations on the rate of true positives, false positives, false negatives, true negative rate, and false negatives, as performance metrics to evaluate their machine learning model and make more effective decisions about its effectiveness and identify areas for improvement.

D. Data Distribution Results for Training and Testing Machine Learning Models (Q4)

Regarding the distribution of data in the 32 articles, a proportion of data used for training (T) and testing (P) the machine learning models has been considered. Table IV shows the percentages of articles that do or do not provide information about the distribution of their data.

TABLE IV. DATA DISTRIBUTION

N°	Data Distribution	Articles	#	%
1	T: 70% - P: 30%	[22], [5], [35], [14], [28], [1], [15], [20]	8	25.00
2	T: 80% - P: 20%	[27], [17], [18], [21], [3], [20]	6	18.75
3	T: 75% - P: 25%	[11], [24], [9], [16]	4	12.5
4	T: 30% - P: 70%	[2]	1	3.12
5	T: 50% - P: 50%	[33]	1	3.12
6	T: 60% - P: 40%	[34]	1	3.12
7	T: 85% - P: 15%	[30]	1	3.12
8	Does not display information	[4], [6], [13], [19], [23], [25], [26], [29], [31], [32]	10	31.25

d. Source: Own work

After detailed analysis, it was observed that 25% of the studies used a data distribution in the proportion of 70% for training and 30% for testing. In the study by Absar et al. [20], two data distributions were used: one in a proportion of 80% for training (E) and 20% for testing (P), and another in a proportion of 70% for training (E) and 30% for testing (P). The 7:3 ratio allowed machine learning algorithms such as Random Forest, AdaBoost, and Decision Tree to demonstrate 99.025%, 96.103%, and 100% accuracy, respectively.

IV. LIMITATIONS

During the research, various limitations were presented. Firstly, the constant evolution of the literature implied that the information available at the time of the review may have changed, which represented a continuous challenge to keep the review updated with new developments in research.

Furthermore, the time available for the development of the systematic review was limited, which prevented the exploration

of information in other databases that could have complemented the review.

Finally, there was a limitation in access to certain publications with relevant information, due to restrictions imposed by the authors, which prevented the inclusion of some significant studies in this research.

V. CONCLUSIONS

This systematic review, based on the analysis of 32 studies, has provided a comprehensive view of the impact that machine learning algorithms generate in the prediction of heart disease. Through the review, four key questions were addressed that framed the analysis, allowing us to identify common patterns and significant differences between the studies. Regarding the first question on Which machine learning algorithm demonstrated the best performance in the prediction of the present studies?, this study determined that Random Forest offers an early diagnosis of heart disease and can be easily accessible through the Internet, facilitating its implementation in clinical settings.

Regarding the second question on What are the independent aspects for the machine learning model in its prediction process?, it was determined that various independent aspects or risk factors were addressed, among which age, sex, cholesterol, diabetes and chest pain stand out, being the most predominant among the studies analyzed. Regarding the third question on What performance metrics were used to evaluate the machine learning model(s) in the present studies?, it was determined that various performance metrics are used, among the most used are: precision, sensitivity, accuracy and F1 score.

Finally, regarding the last question on What is the proportion of data used to train and test the machine learning model?, it was found that the distribution of data for training and validation are distributed in various proportions, such as: 70% - 30%, 80% - 20%, 75% - 25%, 30% - 70%, 50% - 50%, 60% - 40% and 85% - 15% for training and testing respectively, with the proportion of 70%-30% standing out as one of the most used. In this way, future research could integrate all the capabilities of machine learning into a system accessible to all people. This would allow for significant progress in the prevention of heart disease, making a decisive contribution to saving millions of lives.

ACKNOWLEDGMENT

The research was not externally funded. We would like to express our sincere gratitude to all those who have contributed to this research.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

***Abstract*—The design and evaluation of an order management software oriented to SMEs in Lima is presented. Using Design Thinking, a prototype was developed focusing on Usability, Design and User Satisfaction. Through a Likert scale survey of 308 SME employees, perceptions on operational efficiency and user experience were measured. The results show high acceptance and highlight the intuitiveness of the system. However, areas such as loading speed and e-commerce functionalities require future improvements. This study establishes a framework for similar technological tools in commercial sectors.**

***Keywords*—Design thinking; SMEs; order management; software design; usability; user perception**

I. Introduction

The design of software for order management has become an essential component for the optimization of business processes of Micro and Small Enterprises (SMEs). In an environment marked by increasing competitiveness and high consumer expectations, the adoption of technological solutions becomes a fundamental part of the efficient and effective management of developing operations. The growth of e-commerce has transformed the way SMEs interact with their customers, and since the Internet has facilitated new sales opportunities for SMEs [1], a reach beyond traditional geographical boundaries is enabled. This highlights that the implementation of order management systems not only improves operational efficiency, but also contributes to greater customer satisfaction by providing real-time updates on the status of their orders [2].

In this context, efficient order management has become a key factor for the success of stores and businesses in various sectors. Small and medium-sized companies, in particular, face the challenge of managing a constant flow of orders while optimizing the user experience and maintaining customer satisfaction. To meet these challenges, the implementation of technology solutions such as order management systems offers a significant advantage, enabling stores to automate processes, improve accuracy, and reduce response times [3]. Order management systems are designed to handle a variety of tasks, from order receipt to final delivery. Some of the most important functionalities include centralized order processing that allows management from multiple channels with a reduction of errors and an improvement in processing speed; inventory control that facilitates stock tracking and prevents oversales or shortages; and real-time updates that provide constant information on order status, which contributes to an improved customer experience [4], [5].

In addition, it is proposed that future versions of the software could integrate emerging technologies such as Artificial Intelligence (IA) or Machine Learning (ML) to optimize decision making in areas such as inventory forecasting and purchase pattern analysis. Although these technologies were not included in this study, they represent an important opportunity to further improve the functionality of the system.

This article explores the features and benefits of order management software and the challenges faced by systems engineers in developing such solutions [1], and focuses on the development and evaluation of an order management software specifically designed for stores located in the busiest areas of Los Olivos, Lima. Through a sectorized approach, the software seeks to solve common management problems and facilitate the user experience, allowing businesses to improve their operational efficiency. However, the design and implementation of this type of software presents significant challenges. One of the main ones is integration with existing systems, which requires thorough analysis and careful planning by the systems engineer [1], [3].

Priority areas for improvement were also identified, such as the integration of e-commerce functionalities, which would allow SMEs to expand their digital reach and make sales effectively through online platforms. This aspect, together with the need for more intuitive interfaces and reduced loading times, is considered essential to ensure the acceptance and success of this type of technological tools.

To evaluate the effectiveness of the software, a survey has been designed based on three key dimensions: Design, Usability and User Perception. The results of this analysis will allow measuring user acceptance of the system and its impact on order management, providing valuable information for future improvements and technological adaptations [4].

This study hopes to provide not only a practical solution for local stores, but also to generate a reference framework for the development of technological tools that can be applied in other sectors with similar needs. In short, software design for ordering in SMEs is a critical area that not only improves operational efficiency, but also enhances competitiveness in a digitized market [5].

II. Literature Review

The development of order management software for SMEs has been widely researched due to its potential to improve operational efficiency and competitiveness in an increasingly digitized market. Several studies have addressed the challenges and benefits related to the implementation of these technological solutions.

The adoption of quality models in software-producing SMEs was investigated, highlighting that these companies represent 85% of the software industry. The research highlights the importance of implementing quality models to improve competitiveness and ensure high-quality products [6]. This approach is particularly relevant in the design of order management software, where accuracy and efficiency are crucial to ensure commercial success.

On the other hand, e-commerce in Peruvian SMEs was analyzed, revealing that many of these companies use digital platforms only as virtual catalogs, without taking advantage of their full potential to generate online sales. This study highlights the need to develop software that not only facilitates order management but also integrates e-commerce functionalities, allowing SMEs to make effective sales through digital channels [1].

In addition, a study on the design of software for the control of quotation processes in SMEs demonstrates how technological solutions can significantly improve operational efficiency. According to this analysis, both employees and managers recognize the importance of improving business processes through the use of software [7]. These solutions are easily adaptable to order management, optimizing business flow and minimizing operational errors.

In addition, order management systems offer multiple functionalities that are essential for SMEs. One analysis highlights that these systems not only enable centralized order processing and real-time inventory control, but also improve customer service by providing constant updates on order status [3]. This reduces processing errors, which is critical to maintaining customer satisfaction.

One of the relevant approaches in the early stages of the software development life cycle is represented in the application of Design Thinking. According to the study [8], this methodology is implemented especially in the analysis and design stages, for which it has shown high efficiency in eliciting requirements and creating architectures adapted to specific customer problems. It is also observed that its use fosters a deep understanding of the user's needs and an active collaboration within the development team, which contributes to generating innovative solutions, but with a certain degree of uncertainty.

On the other hand, [9] defines user interface design as a fundamental part of the creation of an attractive application. However, it is pointed out that the lack of attention to detail in planning and organization makes it deficient. The Design Thinking methodology is applied in this context to perform usability and user satisfaction tests using the System Usability Scale (SUS) to reduce these errors. As a result, an average value of 85.2 was obtained, which sustains that the value of the user interface design is included in the "Excellent" category.

Finally, automation is a key aspect of SME software design. A study on automation in SME software reveals that these tools enable companies to efficiently manage their day-to-day operations, such as quoting, invoicing, and inventory control. This automation not only reduces operating costs but also improves decision-making based on accurate data, which is vital for the sustainable growth of SMEs [10].

A. Theoretical Basis

1) Order management software: It is a tool that allows automation and optimization in the process of order entry, processing, and tracking. According to study [3], it contains inventory control, Customer Relationship Management (CRM), payment processing, and marketing integrations. It also improves operational efficiency, reduces response times, and minimizes errors, essential aspects to compete in an increasingly dynamic business environment. The study [7] indicates that specialized software helps SMEs in better workflow management, as it allows companies to adapt to new market demands.

2) User and customer experience: User experience is critical in the design of order management software, as an intuitive interface improves communication and streamlines transactions through automatic data storage, which increases efficiency and corporate image [7], [4]. A user-centered design benefits employees and has a positive impact on customer perception. Therefore, the design of ordering software in SMEs should consider operational functionalities with a good user experience, optimizing processes and improving customer satisfaction.

III. Methodology

Fig. 1 refers to the plan of the Design Thinking Methodology, which was used in this study to address the beginning and end of the design of a prototype aimed at improving proper order management in SMEs. It was segmented into five phases (Empathize, Define, Ideate, Prototype, and Test), in addition to detailing the tools used and the prototype design employed.

A. Design Thinking (DT)

This methodology is characterized by proposing innovative solutions through an iterative and people-centered approach. Its main objective is to generate concepts that not only solve specific problems, but also contribute to improving society. This approach has been widely recognized due to its ability to adjust creative ideas to practical needs [11], as well as to raise the expectations and level of commitment of those involved [12]. In

the business environment, Design Thinking has proven to be a key tool for identifying and solving user needs, optimizing processes and improving work environments [13]. Compared to traditional methodologies such as Agile or Waterfall, DT is particularly suitable for projects where user experience and iterative prototyping are critical, making it an ideal choice for this study.

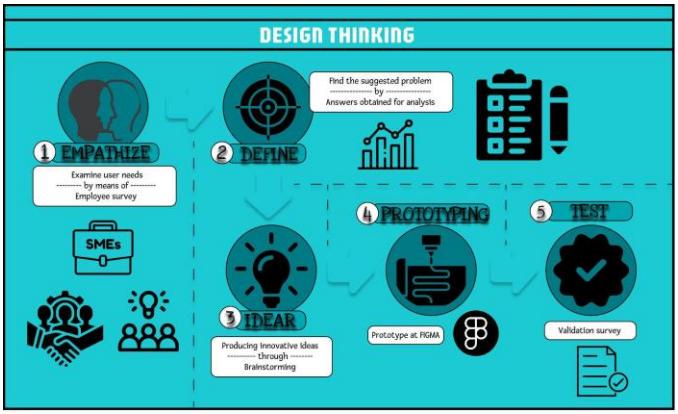

Fig. 1. Design thinking methodology.

1) Empathize: This initial stage focused on gaining a deep understanding of user needs and challenges through interviews and questionnaires with 308 SME employees. For example, the interviews revealed that simplicity in the interface was key to facilitating system adoption by less tech-savvy users. Also, the questionnaires indicated that many employees faced difficulties in managing large volumes of data, highlighting the need for specific functionalities such as advanced filters and optimized search [14].

2) Define: In this phase, the data collected were organized and analyzed using affinity maps, which allowed us to detect patterns and group the most relevant problems. For example, it was identified that unclear icons made navigation difficult in existing systems and that users required real-time information on order status. These findings guided the development of an initial software outline, prioritizing key modules such as customer, product and supplier management [15].

3) Ideate: Multiple innovative solutions were generated based on the problems detected, using techniques such as brainstorming and feasibility assessment. Among the ideas proposed, the creation of a modular system with specific functions that could be adapted to the individual needs of each business stood out. For example, an inventory module with real-time updates was included, since users highlighted the importance of avoiding oversales or shortages [16].

4) Prototype: The functional prototype was developed using the Figma tool, which allowed for the design of an intuitive interface and rapid iterations based on initial feedback. A key example was the incorporation of an interactive tutorial on the home page to help users become familiar with the main functions of the system. In addition, icons with descriptive labels and contrasting colors were implemented to improve visual clarity [17], [18].

5) Test: The prototype was evaluated by SMEs employees themselves through a structured survey that used a Likert scale to measure their perception of the Design, Usability and Overall Satisfaction. The results showed that 85% of respondents rated the intuitiveness of the design as “Strongly Agree”, while 88% rated the ease of completing tasks positively. In addition, qualitative analysis of the responses identified areas for improvement, such as the need to reduce loading times and optimize search functionality [19].

Each stage of Design Thinking not only contributed to the development of the software, but also ensured that it was aligned with the real needs and expectations of the users. Specific examples of decisions made in each phase demonstrate how this iterative, user-centered methodology enabled the development of a system that addresses critical management problems in SMEs, establishing an effective framework for future solutions. Although DT was highly effective in the ideation and prototyping stages, it is not designed for full software implementation. Future phases of the project could benefit from combining DT with other methodologies, such as Agile, to ensure smooth integration and implementation.

B. Software Evaluation Factors

1) Design: Factor that understands the requirements and develops the artifacts that define the creation of the product, also refers to the creation process that contains a reference to the requirements of the stakeholders [20].

2) Usability: Factor defined as the ability of users to understand, employ, and acquire knowledge of software in a simple way [21].

3) User perception: It is defined as the user interactions throughout the product life cycle, it is represented in values of Usability, Design, Loyalty, Quality, Interaction, Productivity, among others; which serve to improve the perception of value from a user's perspective [22].

IV. Results

This results section illustrates the stages of the Design Thinking methodology that will allow us to understand the users' problems and provide a short-term solution, as well as to understand their long-term perspectives in an already implemented software. The advantages, disadvantages and comparison of using the Design Thinking methodology are also presented.

A. Results of the Empathize Stage

During this stage, the main limitations in the use of software technologies were identified through interviews and questionnaires addressed to 308 SME employees. Table I presents the questions (Q1 to Q5) asked:

The results indicated that the priority aspects for users are the clarity and simplicity of the interface, the ease of handling large volumes of data, and the speed of tasks in the system. These findings underscore the importance of developing software that is intuitive, efficient, and accessible.

TABLE I. QUESTIONS

Questions	
ID	**Questions**
Q1	What improvements would you suggest to a software interface?
Q2	What do you look for in software when handling big data?
Q3	How do you define the speed of completion of your tasks in software?
Q4	What do you find important in software usability?
Q5	What do you consider fundamental in the functionalities of software?

B. Results of the Define Stage

Table II contains the most repeated answers in the questionnaire (R1 to R5) of the survey addressed to SME employees; there are a total of 308 answers for the analysis.

TABLE II. SME EMPLOYEE SURVEY

Responses	
ID	**Responses**
R1	Clarity and simplicity of interface
R2	Ease of handling large volumes of data
R3	Quick time to complete tasks
R4	Ease of use of software
R5	Easy access to functionalities

1) R1: The clarity and simplicity of the interface was mentioned as a key priority to ensure an efficient user experience.

2) R2: The ease of handling large volumes of data was highlighted as a necessary functionality to optimize workflow.

3) R3: Speed in completing tasks was identified as a determining factor in improving operational efficiency.

4) R4: Ease of use of the software was recognized as essential to promote acceptance among users.

5) R5: Easy access to specific functionalities was considered critical to ensure the effectiveness of the system.

C. Results of the Ideate Stage

Table III indicates the suggested solutions (S1 to S3) as a solution. An estimated score is provided for the choice of the best idea and its development is completed in the next phase.

TABLE III. SCORING IDEAS

Idea Scoring		
Solutions	**Ideas**	**Total**
S1	Creation of an order management software	60 points
S2	Create an order management application	26 points
S3	Applying Excel methods for order management	14 points

1) S1: The solution chosen was the creation of an order management software, given its high score and alignment with users' needs.

D. Results of the Prototyping Stage

For the results of the prototyping carried out with the Figma tool, the most salient functionalities that the order management software will offer in SMEs will be presented. The prototype functionalities are presented in Table IV.

TABLE IV. PROTOTYPE FUNCTIONS

Fig.	Function
2	Login, with access by credentials.
3	New Employee Module for ease of navigation.
4	New Customer Module to manage the organization's customers.
5	New Product Module to manage detailed product information.
6	New Category Module to classify products within the system.
7	New Distributor Module to manage the collaboration of distributors in the organization.
8	New Supplier Module to manage supplier transactions.
9	New Purchase Module to manage purchase orders within the organization.
10	Allows editing of purchase data in order to modify information to correct errors.

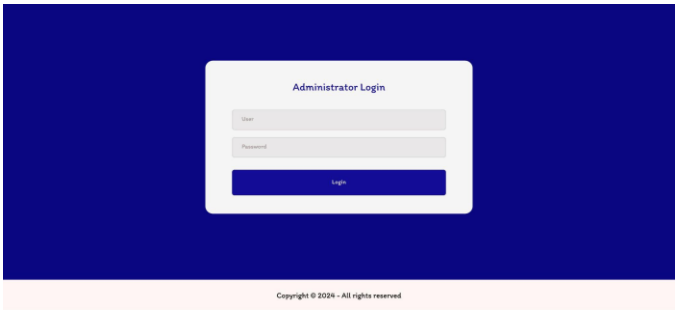

Fig. 2. Login.

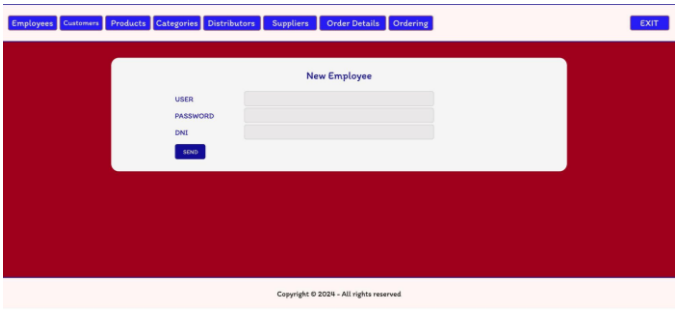

Fig. 3. New Employee.

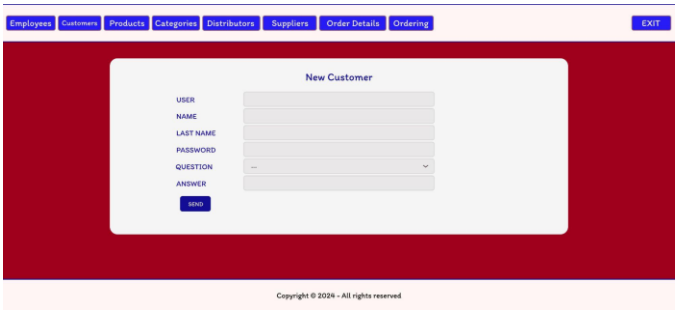

Fig. 4. New customer.

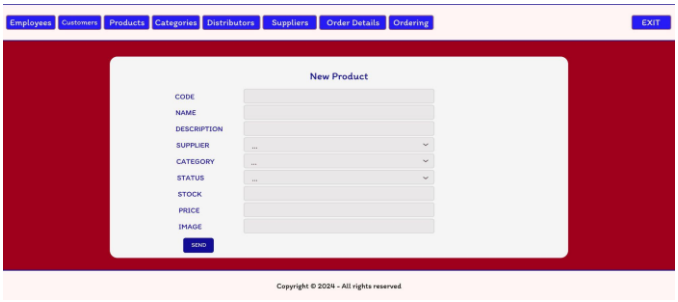

Fig. 5. New product.

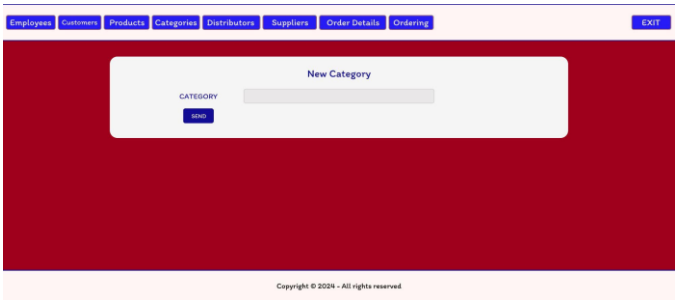

Fig. 6. New category.

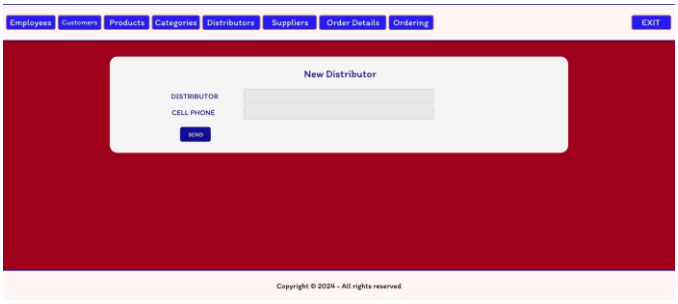

Fig. 7. New distributor.

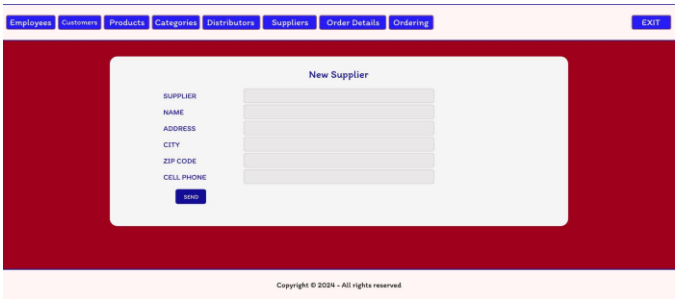

Fig. 8. New supplier.

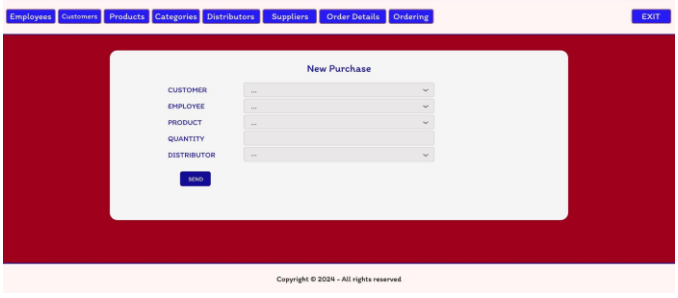

Fig. 9. New purchase.

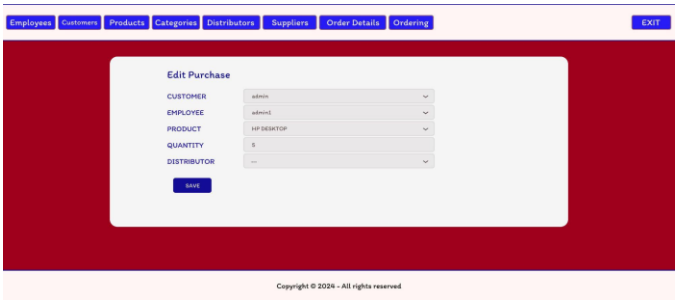

Fig. 10. Purchase edition.

E. Results of the Testing Stage

To develop this last phase of the Design Thinking methodology, it is required to validate that our order management prototype is suitable for the user and their needs. When surveying the 308 SME workers, three software evaluation factors were taken into account: Design, Usability, and User Perception. The Google Forms questionnaire tool was used, through 12 closed questions with a 4-point Likert scale (1= I Totally Agree and 4= I Totally Disagree), as well as an open question for possible improvements in an already implemented software. The questions used are presented in Table V.

TABLE V. INSTRUMENT

Q	Design
Q1	Do you find the login interface intuitive?
Q2	Do you consider that the design of the employee interface is clear and easy to understand?
Q3	Do you consider that the design of the customer management interface facilitates the handling of these data?
Q4	Is the organization of categories and sections consistent and easy to understand?
Usability	
Q5	Do you find it easy to perform tasks such as: creating or editing an order in the system?
Q6	Is the process of registering new employees, customers, or products easy?
Q7	Do you consider that the steps to edit information in the system are clear?
Q8	Do you consider that the average time to complete a task in the system is relatively short?
User Perception	
Q9	Do you perceive the overall ease of use of the order management system?
Q10	Would you rate the efficiency of the system in managing products and categories as adequate?
Q11	Does the system make it easy to create and edit distributors and suppliers?
Q12	Do you consider the different functionalities of the system accessible and understandable?

The design of the system was highly rated, with 85% of respondents rating the intuitiveness of the interface as “Strongly Agree”. In terms of usability, 88% highlighted the ease of performing tasks, highlighting its efficient functionality. In addition, user perception reflected a positive impact, with 82% indicating that the system significantly improves the overall experience.

On the other hand, Fig. 11, 12, 13, and 14 represent the results obtained according to the form applied in the SME sector to 308 people involved in sales management.

Fig. 11 presents the responses to the closed-ended questions asked of SME workers.

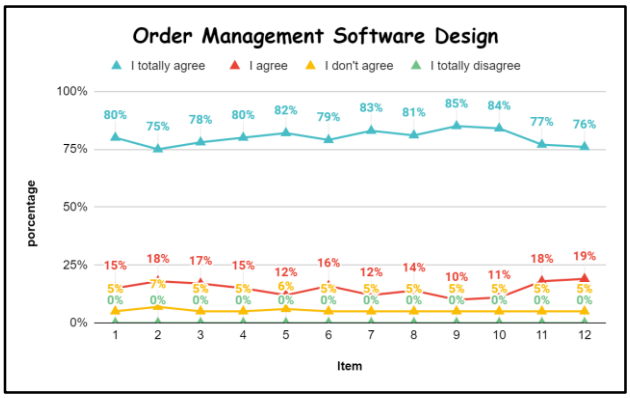

Fig. 11. Form results by ítem.

Fig. 11 shows the results of a survey on the design of order management software. The vertical axis shows the percentage of responses, while the horizontal axis shows the different items evaluated from 1 to 12. The response options are categorized into four levels: "I Agree" (represented in blue), where the majority of respondents are, maintaining a high trend in almost all items, with percentages ranging from 75% to 85%, indicating a strong overall approval towards the software design; 'I Agree' (represented in red), with a relatively low but constant percentage, between 12% and 19%, which, although not the dominant response, still reflects a considerable level of agreement in each item; "I Don't Agree" (represented in yellow), whose percentages remain between 5% and 7%, suggesting that a small portion of respondents do not agree with certain aspects of the design; and 'I Totally Disagree' (represented in green), which shows no significant presence, indicating that almost no respondents strongly disagree with the design of the software. Overall, the graph suggests a positive perception towards the design of the order management software, with high levels of acceptance and satisfaction among users. The levels of "I Totally Agree" and "I Agree" are predominant in almost all items, reflecting a favorable reception.

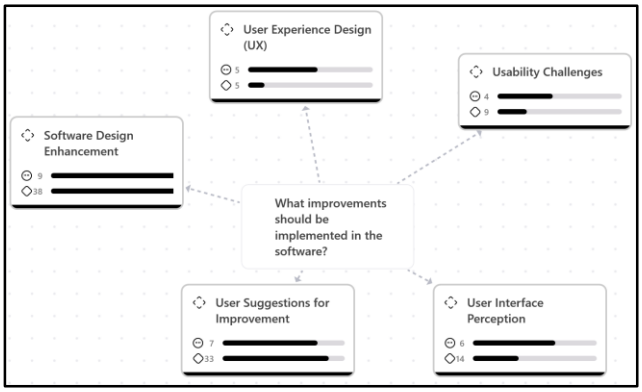

Fig. 12. Areas of software improvement.

Likewise, Fig. 12 presents the areas of improvement analyzed according to the open question asked in the survey, which was analyzed in the ATLAS.ti software to obtain the most repetitive nodes and points concerning possible improvements in an already implemented software.

Fig. 12 represents a concept map that highlights the key areas where users suggest improvements to an already implemented software. Themes include user experience (UX) design as a factor in improving efficiency and processes [23]; however, having a straight-line direction based on design is debatable due to a lack of concrete guidelines [24]. Usability challenges are also presented [25], considered strongly integral attributes [26], and it also points to interface perception as a decisive element for a consistent and sustainable experience [27], [28].

On the other hand, general suggestions for improvement are presented, such as better performance [29] with higher flexibility requirements [30]. Also, software design improvements from source code [31] are raised, this in order to increase software efficiency [32]. Each node shows the number of related comments and mentions, suggesting the priority areas to optimize the application.

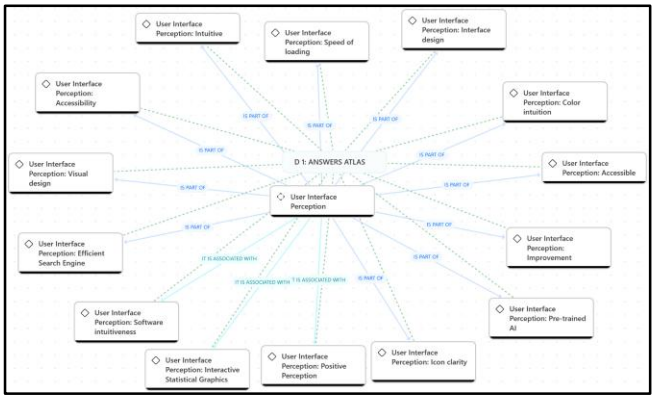

Fig. 13. Improvements in user interface perception.

Fig. 13 shows the different elements suggested by users about the perception of a software interface. Key elements in software use were highlighted, such as intuitiveness in user interaction [33], loading speed for a smooth experience [34], interface design for a visual representation of data [35], color intuitiveness to optimize task performance [36], accessibility to promote access inclusion and accessible product management [37], [38]. On the other hand, the overall positive perception of users is based on practical improvements [39], which are distributed in relevant elements such as the clarity of icons to capture users' attention [40], the search engine for data filtering [41], and in interactive statistical graphics for reporting [42]. Each of these elements is associated with the user experience and the diagram indicates how each factor is part of the user's overall perception of the interface.

Fig. 14 shows the main usability challenges that users have suggested in relation to an implemented software. Among them are noted suggestions related to accessibility [37], slow loading speed [34], lack of clarity in icons [40], and usability factors that improve system performance for the user [43], [44], [45]. In addition, they point to the lack of features as an indication of dissatisfaction [46], the challenge of adaptation with respect to

responsive design, which is a suggested element to increase visibility [47] and the importance of optimizing real-time analytics for effective prediction [48]. This indicates areas where an implemented software needs adjustments to improve the user experience.

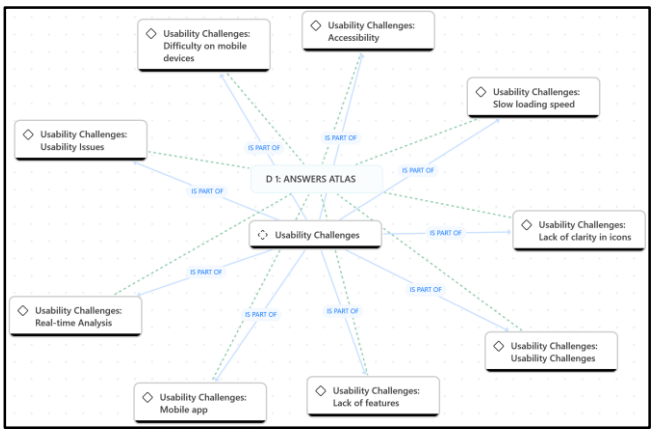

Fig. 14. Improvements in usability challenges.

F. About the Methodology

1) Advantages: The Design Thinking methodology was used to generate new ideas that respond to the needs and requirements of the users. This made it easier for the work to be active to provide new proposals to society and optimize the process of proper management.

2) Disadvantages: The disadvantages of this methodology is its focus on the prototyping of innovative ideas and not on the implementation of the software. In this context, it should be considered that this methodology can be complemented with another one for a future implementation phase.

3) Comparison: The DT methodology allowed the streamlining of the process of analysis and the generation of innovative ideas aimed at prototyping. In comparison with other methodologies focused on software development, this one includes the proposal of new plans that contribute to society.

V. Discussion

The findings of this study confirm and extend the existing knowledge on the positive impact of order management systems in SMEs, as highlighted by previous studies that emphasize the importance of accuracy and efficiency in software design to optimize operational processes and strengthen business competitiveness [6]. In this sense, the results obtained during the stages of the Design Thinking methodology reinforce the relevance of understanding users' needs in depth in order to design solutions that not only solve current problems, but also anticipate future needs.

First, the iterative and user-centered approach of the Design Thinking methodology was crucial to identify and solve SME needs. During the Empathize stage, priorities such as interface clarity and simplicity, speed of tasks and the ability to handle large volumes of data were identified. This underscores the importance of a design that combines efficiency and accessibility, aligning with research highlighting how intuitive design and high usability can minimize errors and increase technology adoption in sectors traditionally resistant to change [8].

In addition, the Ideate stage enabled the selection of the most appropriate solution through a detailed feasibility and impact analysis. Similarly, the Prototyping stage, carried out in Figma, facilitated the creation of a functional interface that was subsequently validated in the testing stage. It is worth noting that the use of surveys and Likert scales to evaluate Design, Usability and User Perception factors yielded favorable results, with high levels of approval reflected in Fig. 11, 12, 13 and 14. This evidences the effectiveness of the methodology to integrate relevant functionalities from the early stages of development, addressing a combined deficiency reported in previous studies [1].

However, it is important to recognize that, despite the high acceptance of the software, key areas for future improvements are identified. Among them, the integration of functionalities, the optimization of loading times and the improvement of responsive design are relevant challenges. In this context, user suggestions, analyzed in Fig. 12 and Fig. 14, revealed that aspects such as color intuitiveness, icon clarity and accessibility are critical elements to improve user experience.

On the other hand, the incorporation of emerging technologies such as Artificial Intelligence (IA) and Machine Learning (ML) emerge as a strategic opportunity to enhance the analytical capabilities of the system. These technologies could provide advanced functionalities, such as sales trend prediction or experience personalization, which are consistent with recent studies demonstrating their positive impact on business applications [12], [13].

Finally, this study reaffirms the value of a user-centered approach and the application of methodologies such as Design Thinking to develop technological solutions tailored to the specific needs of SMEs. The results obtained highlight the effectiveness of intuitive design and software functionality in improving operational efficiency and meeting user expectations. However, a limitation of Design Thinking is its focus on prototyping, which leaves the implementation of the software as a challenge for future stages. Given this, the importance of complementing with other methodologies to comprehensively address development and implementation is stressed.

In conclusion, this study not only validates the effectiveness of an iterative approach to software design, but also points the way for future iterations that include technological and functional improvements. Ultimately, these actions will contribute to optimizing the user experience and increasing the impact of software in the SME environment.

VI. Conclusions

The implementation of the Design Thinking approach allowed the development of an order management software tailored to the needs of SMEs in Los Olivos, Lima. This iterative and user-centered method was essential to address key issues such as simplicity in the interface and efficiency in data management, thus achieving a system that was highly accepted by users. Indicators such as design intuitiveness (85%) and ease of task completion (88%) reflect the effectiveness of the approach, while the overall improvement in user experience

(82%) underscores the software's positive impact on operational optimization and employee satisfaction.

Despite the progress made, key areas for future improvements were identified, such as the integration of functionalities and the optimization of loading times, which could strengthen the competitiveness of SMEs. In addition, the incorporation of emerging technologies such as IA and ML represent a strategic opportunity to enrich the system with analytical and predictive capabilities, making it possible to forecast sales trends and personalize experiences. These enhancements promise to consolidate the role of software as a transformative tool in the business context.

Although the study showed encouraging results, it also highlighted certain limitations, such as the challenge of implementing the system on a larger scale and the need to evaluate its long-term impact. It is recommended to combine Design Thinking with methodologies such as Agile to strengthen future development and integration phases, and to prioritize the inclusion of advanced technologies in future iterations. Ultimately, this work not only provides specific solutions for SMEs, but also lays the groundwork for the design of sustainable technological tools, highlighting the role of innovation as a driver of competitiveness in a constantly evolving digital marketplace.

Design of a Mobile Learning App for Financial Literacy in Young People Using Gamification

Angie Nayeli Ruiz-Carhuamaca, Juliana Alexandra Yauricasa-Seguil, Juan Carlos Morales-Arevalo
Faculty of Engineering, Universidad Peruana de Ciencias Aplicadas, Lima, Perú

***Abstract*—This research paper addresses the issue of insufficient financial literacy among young people, a challenge that affects their ability to make informed financial decisions. A survey was conducted to assess the current state of financial literacy among young people, whose results show a significant gap in the understanding of key concepts needed to manage their finances, which limits their economic and social development. Based on these findings, an interactive and gamified design aimed at strengthening the level of financial literacy among young people is proposed. This proposal includes wireframes that structure a mobile application, integrating playful elements and educational challenges to promote user participation in their learning process. The methodology of design that is employed focuses on the user experience, which ensures that the tool is accessible and engaging. It is expected that this proposal, based on the survey results, will not only increase the understanding of financial concepts but also motivate young people to apply this knowledge in their daily lives, thus contributing to greater financial independence and a better quality of life.**

***Keywords*—Financial literacy; gamification; financial education; challenge education**

I. Introduction

With rapid evolution, the world is becoming increasingly complex and competitive, and financial knowledge is becoming a necessary skill, especially for young people in the future and for a country's economy and financial security [1]. This competence not only allows individuals to manage their economic resources effectively but also influences their ability to face future financial challenges. Globally, this skill is essential, particularly in an increasingly digitized context, where technologies such as FinTech (financial technology) and EdTech (educational technology) are promoted, providing improvements in education through new technologies to facilitate access and contribute to reducing inequality. Thus, offering opportunities to develop financial skills in an economic and social environment that is constantly changing [1].

In Peru, where much of the young population faces economic uncertainty, financial education is crucial. However, there is a lack of financial referents with solid knowledge; 41% of adults at the national level obtained a minimum level of financial education in a study of financial capabilities, while only 13% obtained a high level [2]. This is evidence of their limited ability to manage their financial resources effectively and make responsible financial decisions. However, there are global initiatives to promote financial education, such as the Organization for Economic Co-operation and Development (OECD) approach, which coordinates national strategies to strengthen financial learning worldwide [1].

This problem not only affects the financial well-being of young people but also generates a cycle of economic dependence and limits the economic development of a society. This is reflected in inappropriate financial behaviors, such as the imbalance between income and expenses; in 2022, 56% of adults reported that they went into debt to cover their expenses [2]. In contrast, when people have solid financial knowledge and skills, they can effectively manage their finances and thus generate greater stability and well-being in their families [3]. Therefore, it is crucial to have a high level of financial skills, since an insufficient level of financial knowledge leads to poor economic decisions and financial problems in the long term.

Therefore, it is essential to develop strategies that promote financial education attractively and effectively. The current teaching method emphasizes that students should have more freedom to learn technology, think, and make mistakes. In that sense, a mobile application turns out to be a suitable tool for the new generations, since the trend of using mobile applications is increasing. In addition, learning in financial management is not achieved only through reading and writing as the traditional teaching method, rather, students must acquire knowledge through scenario-based learning, which allows them to interpret and apply the acquired knowledge in real-life situations [1].

Finally, this research seeks to address the issue of insufficient financial literacy through the design of an interactive and gamified mobile learning application. The proposal is based on a survey that assesses the level of financial literacy of young people, the results of which showed a significant gap between the understanding of financial concepts for the management of their finances and the application of this knowledge in financial challenges. In response to this gap, we propose the design of a mobile application that incorporates playful elements and educational challenges that encourage practical and engaging learning.

The structure of this paper consists of eight sections: Section I corresponds to the introduction and Section II explains the related work. Details about the structure, tools, and design of the mobile application are proposed in Section III. Section IV presents the survey. Section V shows the results of the survey. Section VI shows the discussion and finally, Section VIII shows the conclusions.

II. Related Works

A. Interactive and Gamified Solutions

The study in [4] proposes the design of a support system with Artificial Intelligence (AI) to improve the quality of corporate financial decisions. On the other hand, a study [5] proposes a

mobile learning platform to develop entrepreneurial skills in students. Both studies consider that technology can optimize decision-making but differ in the way it is applied. On the other hand, studies [6], [7] and [8] focus on improving learning through gamification. Studies in [6] and [7] highlight the potential of games as educational tools, [6] promote financial literacy in students through economic games to teach basic financial concepts, while [7] promote the development of technical and soft skills through simulation business games. Taken together, these five papers highlight that the integration of AI, gamification, and mobile platforms not only improves learning but also optimizes financial decision-making. The key difference between them is how they are applied: [4] and [5] focused on business or entrepreneurial contexts, while [6], [7] and [8] explored learning through games and simulations.

B. Integration of AI-Assisted Coaches

All studies agree on the use of AI to personalize the user experience. However, the nature of customization varies depending on the field of application. The study in [9] is based on education, [10] health, [11] sports, and the study [12] focuses on opponent modeling and strategy optimization within a competitive environment. A common point of all studies is that AI is implemented to optimize decision-making in environments where the number of variables and uncertainty make it difficult for users to make the right decision. Concerning training and data collection methods, studies [9] and [10] are based on creating user-centric experiences. On the other hand, [11] and [12] face challenges related to the availability of high-quality data. In [11], the system had to deal with a shortage of data to train deep learning models, while [12] it stands out for the use of simulations and game data, which allowed AI to outperform previous systems, without the need for large amounts of real user data. Regarding the AI technologies used, each study adopts different technologies and approaches to implementing AI, reflecting the diversity in the way AI systems can be trained and executed. Studies [9] and [10] use AI in predictive models and heuristics, optimizing user behavior through algorithms that learn common patterns in large amounts of data. Instead, studies [11] and [12] rely on technologies such as deep learning and simulations, allowing systems to generate predictions and adapt to complex situations.

C. Importance of Financial Literacy in Education

Financial literacy emerges as a central theme in these studies, underscoring the relevance of developing healthy financial habits at different stages of life. In the study [13], they detailed an understanding of healthy financial habits in young adults, exploring the relationship between subjective financial literacy, financial engagement, and financial decision-making. On the other hand, [14] implements a more structured approach through the SaveWise program, which aims to increase the financial knowledge of adolescents, where literacy is measured more objectively, focusing on students' ability to apply financial concepts in real-life situations. Regarding the results, in [13], young adults who consider themselves financially literate show a trend towards healthy practices, such as saving regularly and investing in their future. In study [14] program participant's experienced significant improvements in their financial knowledge, which translated into increased savings intentions and a better understanding of money management.

D. Gamification and its Impact on Youth People Learning

The use of serious educational games and adaptive technologies is effective in developing specific skills and improving student engagement. The study in [15] shows that EEG (Entrepreneurial Education Game), by integrating adaptive algorithms to personalize the learning experience, resulted in greater student adaptability with 74% of participants reporting a positive learning experience. Similarly, the study [16] reveals that implementing a serious game in virtual reality improved players' mental calculation skills, although it also identified some challenges related to the use of technologies. On the other hand, studies [17], [18], and [19] show that gamification not only improves understanding of concepts, it also addresses specific skills, such as programming and AI safety. The study [18] proposed a smart tutoring system built into an educational game that provides personalized support, where students who used it got fewer errors. This study in [18] found that students who participated in the Shoot2Learn game showed a statistically significant improvement in their understanding of conditional structures, suggesting that educational games can motivate students and improve their academic performance. For its part, the study [19] evaluated a video game designed to improve AI safety education, where it found that 81% of users considered the game's learning functionalities effective.

III. PLATFORM DESIGN

The design of the proposed mobile application focuses on offering an attractive and accessible user experience, to improve the financial literacy of young people through active interaction with the financial coach and the use of gamification. This section describes the key components of the platform, design principles, and tools used for wireframe development and presents visual examples of the main screens.

The design of the proposed mobile application focuses on offering an attractive and accessible user experience, to improve the financial literacy of young people through active interaction with the financial coach and the use of gamification. This section describes the key components of the platform, design principles, and tools used for wireframe development and presents visual examples of the main screens.

A. Overview of the Platform

The application is based on three key sections, which are designed to guide the user in their continuous learning process.

1) Initial assessment: When starting, the user selects the financial topic they want to learn or reinforce and their level of knowledge as shown in Fig. 1, and then performs the initial assessment Fig. 2, which consists of five questions. This flow is done to provide a personalized experience, which allows you to suggest the most appropriate level according to the user's performance and to provide an adaptive experience from the beginning of the application.

2) Gamified challenges: In this section, users face different financial challenges, which are designed to test their skills in topics such as saving, investing; and credits and debts Fig. 3. These gamified challenges integrate game mechanics such as rewards, difficulty levels, and short-term goals Fig. 4. In addition, there is interaction with the financial coach, who will

guide, provide personalized recommendations and suggestions based on areas for improvement during and after the game Fig. 3. Thus, this active interaction between the user and the coach makes the application interactive.

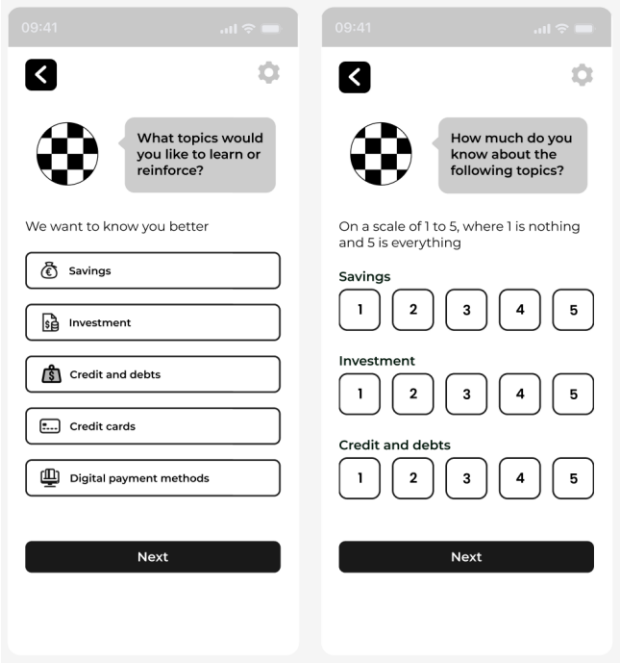

Fig. 1. Financial topic and scale of knowledge level.

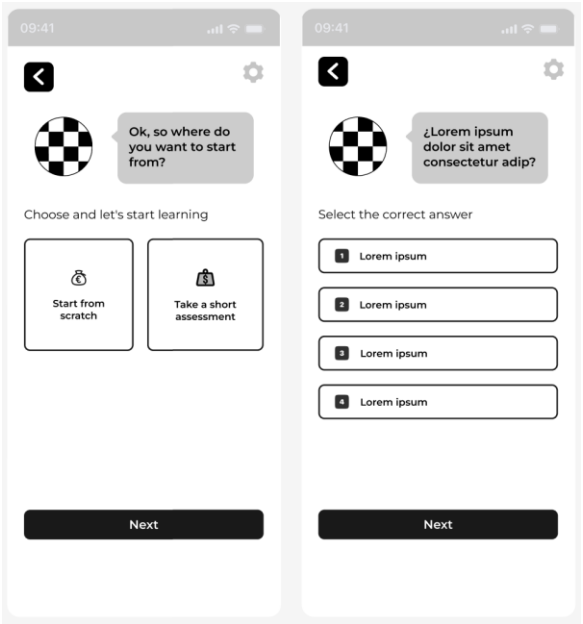

Fig. 2. Initial evaluation.

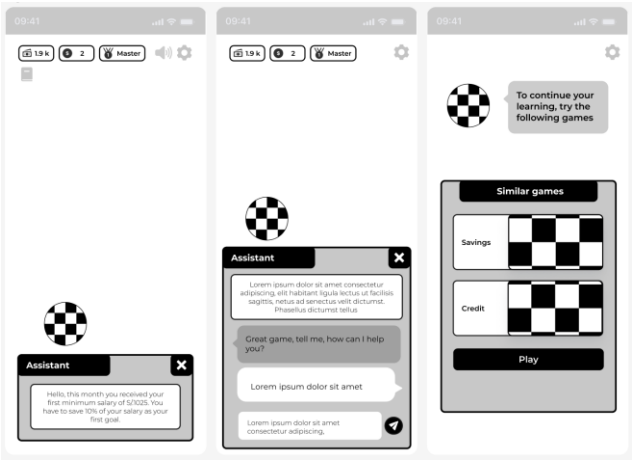

Fig. 3. Game scenarios and interaction with the virtual assistant.

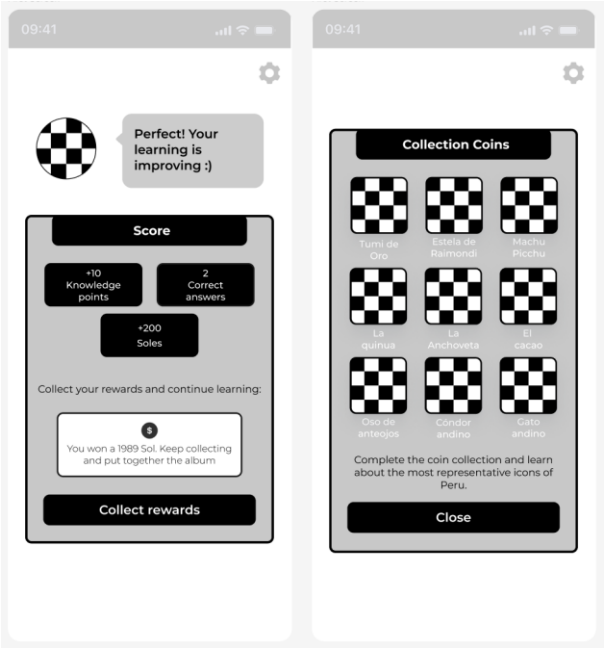

Fig. 4. Scoring and reward system.

3) Final evaluation: At the end of the challenges, users take a final assessment to measure their progress. Fig. 5 shows the design of the quizzes, the results, and the progress panel; and personalized recommendations based on user performance.

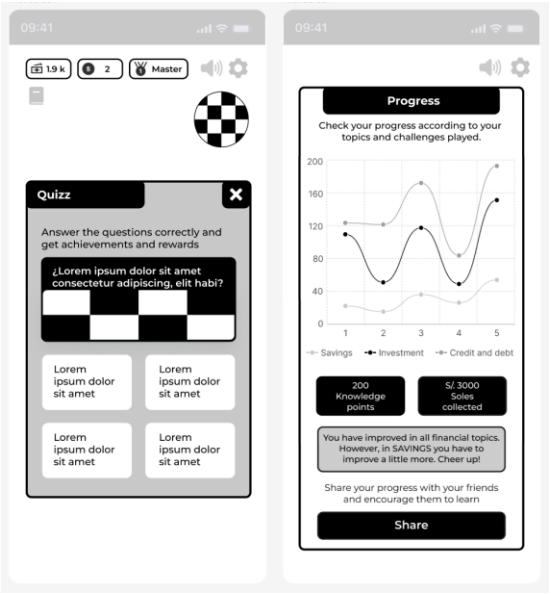

Fig. 5. Assessment and recommendation system.

B. Design Principles

Concerning the design principles, User-Centered Design (UCD) was chosen, which focuses on guaranteeing the usability and accessibility of the game to ensure its effectiveness for users. This approach recognizes that everything is an interrelated system, where the set of components and the interaction of people must be considered. Thus, by observing how users interact and identifying problems, iterative tests are carried out to get closer to the final product [20]. Thus, the project focuses on satisfying the needs of the user, that the designs are interactive, and the final product is easy to use.

C. Design Tools

During the mobile app design and prototyping process, various tools were used for the design of different areas and functions of the platform. These include:

- Figma. It is a vector graphics and prototyping editor. The advantage of this tool is that it allows users to work collaboratively. This tool was used for the design of all the screens of the application and to define the flow that the user must follow in the prototype.
- Adobe Illustrator: It is a graphic design tool, which specializes in vector graphics. It was used for the creation of the logo and icons, which are minute details.
- Tiled Map Editor: It is a tool for the creation and editing of 2D maps, which is mainly used in games. The advantage of this tool is that it allows users to export in tile format, which makes it easy to integrate into Unity for the front-end development of the application. It was used to create scenarios for the games.

IV. Methodology

The design of the proposed mobile application is based on a study applied to university students, to evaluate the level of financial knowledge of young people. This section will detail the research approach, the instruments used for data collection, and how the results influenced the design decisions of the application.

A. Research Focus

This research is framed in a quantitative approach since it seeks to collect data numbers through a survey to assess the level of financial literacy among young people. This approach allows for obtaining objective information that facilitates the identification of gaps in financial knowledge and the foundation of the interactive and gamified learning proposal.

B. Population and Sample

The target population is university students from various undergraduate higher education institutions in Lima, Peru. Therefore, a sample of 150 university students was determined. This sample is composed of young people because they are in a transition stage towards financial independence, where the development of solid financial knowledge has a significant impact on their economic well-being.

C. Questionnaire

The questionnaire was designed in a semi-structured way, with a total of 50 questions. However, respondents only answer a subset of questions, as they must select their level of knowledge in areas such as saving, budgeting, investing, and personal finance. Based on the choice on a scale of 1-5, the level (basic, intermediate, advanced) is determined, and you are redirected to the financial challenges section associated with the selected level. These challenges are multiple-choice questions with a score of 20 points, which makes it easy to compare and analyze respondents' responses.

1) Data collection method: Data were collected through an online survey administered through Microsoft Forms. This survey was distributed to students through WhatsApp groups and the Viva Engage platform. The collection procedure was as follows:

- The survey was developed in Microsoft Forms and tested with a small group of students to ensure the clarity and relevance of the questions.
- Participation was promoted through a raffle published on the Viva Engage platform.
- Participants were informed about the purpose of the survey, the duration, and the confidentiality of their responses.
- Responses were collected over two weeks.

2) Structure of the questionnaire: The questionnaire is organized into six sections:

- Overview: Collects demographic data such as age, gender, career, college level, and the operating system (OS) of your mobile devices. Also, it informs the purpose of the questionnaire and the duration.
- Financial behavior: Analyzes the relationship between study and work, sources of income, and current practices of young people in terms of managing income, expenses, and savings.

- Financial Challenges: Inquire about the top financial challenges young people face and how often they experience difficulties managing their finances.
- Level of financial knowledge: Assesses the level of financial knowledge in key areas such as expenses, savings and investment, credits and debts; and personal finance. Respondents should rate their level of knowledge in each topic as basic (scale 1-2), intermediate (scale 3), or advanced (scale 4-5). This self-assessment allows students to be redirected to the financial challenges section according to the indicated level. These will facilitate a more detailed analysis of how their level of knowledge impacts their ability to face challenges.
- Preferences for educational tools: Inquire about preferences for educational tools to improve their financial literacy.
- Feedback and suggestions: Inquire about the difficulties experienced by respondents and suggestions for tools or features that should be added to a solution.

V. Results

In this section, the results of the questionnaire of young undergraduate university students will be presented.

A. Profile of Participants

A summary of the profile of the respondents is provided in Fig. 6. 54% of those surveyed are men, while 46% are women. Regarding the study, it is evident that the students come from a variety of university students in Lima, with a higher percentage from the Peruvian University of Applied Sciences with 66%, due to the origin of the research. Likewise, students are distributed in different academic cycles, with higher percentages in cycles VI (17%), VII (14%) and VIII (18%). On the other hand, the distribution of the OS used by the respondents is shown, which is relevant for the development of the solution proposal, where a large percentage (74%) uses the Android OS, which suggests that the platform should prioritize the development in this technology, to guarantee the greatest possible accessibility.

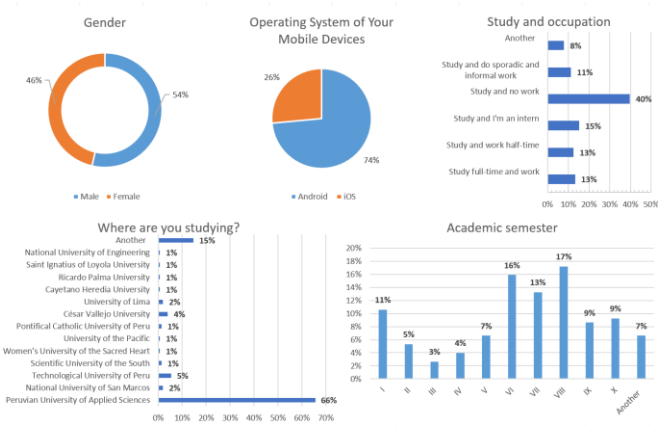

Fig. 6. Summary of the profile of respondents.

B. Financial Behavior

- Financial management: According to the results presented in Fig. 7, 44% of respondents do not keep formal control of their income and expenses, but do so mentally, which can generate uncertainty in their financial management. In contrast, only 8% use a financial management app, which allows them to have better control over their income and expenses. Likewise, 45% review their financial statements weekly, which reflects a positive financial habit. However, 11% of participants indicated that they rarely review their financial statements, which is worrying, as this lack of follow-up can lead to difficulties in managing their finances effectively.

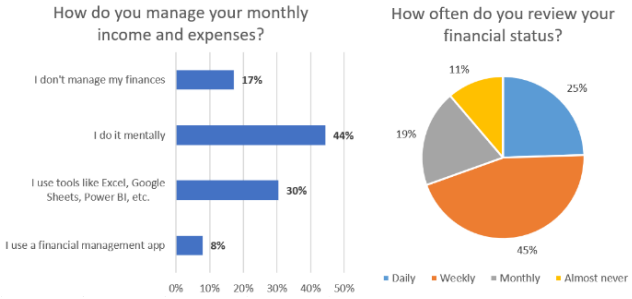

Fig. 7. Financial management.

- Expenses and savings: In Fig. 8, they indicate that 4% of respondents do not save anything, while 21% save less than 10% of their monthly income. 36% manage to save between 10% and 20%, and 23% save more than 20%. However, 16% do not know or have never calculated how much they save, which is worrying because they lack clear control over their savings capacity which could affect their financial stability. Regarding expenditure dedicated to entertainment and leisure, 40% allocate less than 10% of their income to this activity, while 35% allocate between 10% and 20%. Only 14% allocate more than 20% and 11% indicated that they do not know how much of their income they allocate to this activity. These data suggest that most students prioritize moderate spending on entertainment, although there is a large proportion who are not clear about their spending in this area.

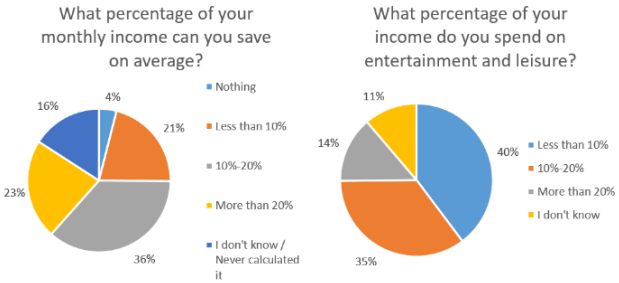

Fig. 8. Expenses and savings.

C. Financial Challenges

Regarding finance-related concerns, Fig. 9 shows that 30% of respondents expressed concern about not being able to

manage their finances efficiently. In addition, 20% worry about not being able to save enough, 20% do not understand how to invest, 17% are afraid of spending more than they earn and 13% accumulate debt. These results indicate that financial management is the main challenge for students, which could negatively impact their economic well-being.

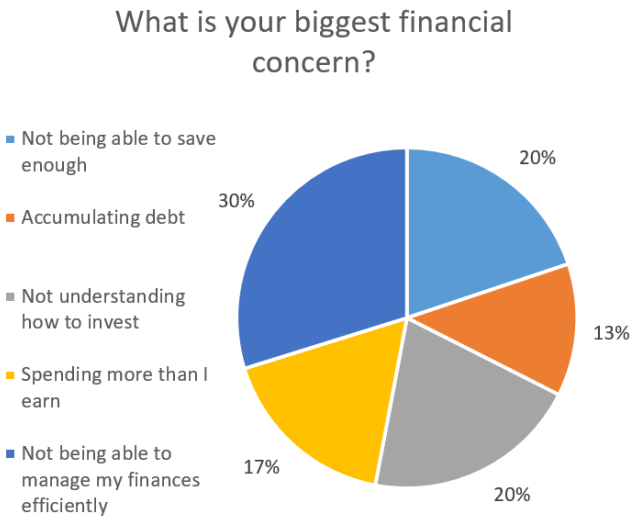

Fig. 9. Concern regarding finances.

D. Financial Literacy Level

In this section, we have worked with a multiple-choice question that uses a scale from 1 to 5, so that respondents can carry out a self-assessment of their level of financial knowledge. Scales 1 and 2 redirect them to basic financial challenges, scale 3 to intermediate-level challenges, and scale 4 and 5 to advanced-level challenges. A total of four questions are included, each corresponding to a specific topic, as shown in Table I.

TABLE I. TOPICS QUESTIONS

ID	Theme	Questions
Q1	Budget expenses	How would you rate your knowledge on the topic of Budgeting your expenses?
Q2	Savings and investment	How would you rate your knowledge about Savings and Investment?
Q3	Credit Cards and Debt	How would you rate your knowledge about Credit Cards and Debt?
Q4	Personal Finance	How would you rate your knowledge about Personal Finance in general?

Fig. 10 shows the level of knowledge by subject. Regarding budgeting expenses, it is shown that 34% of those surveyed consider themselves at a basic level, 44% at an intermediate level, and only 22% at an advanced level. On the other hand, about savings and investment, 38% consider themselves at the basic level. Meanwhile, 42% are classified at an intermediate level and only 20% at an advanced level. In the case of credit cards and debts, a large percentage (35%) are classified at the basic level, 47% are classified at the intermediate level and only 18% at the advanced level. Finally, about personal finance, 35% consider themselves to be at the basic level, 48% intermediate level, and 17% advanced. These results show a high proportion of young people with a level of financial knowledge at both the intermediate and basic levels, with a slight predominance at the intermediate level. However, a large percentage at the basic level is worrying, so it is necessary to strengthen knowledge and skills in these areas.

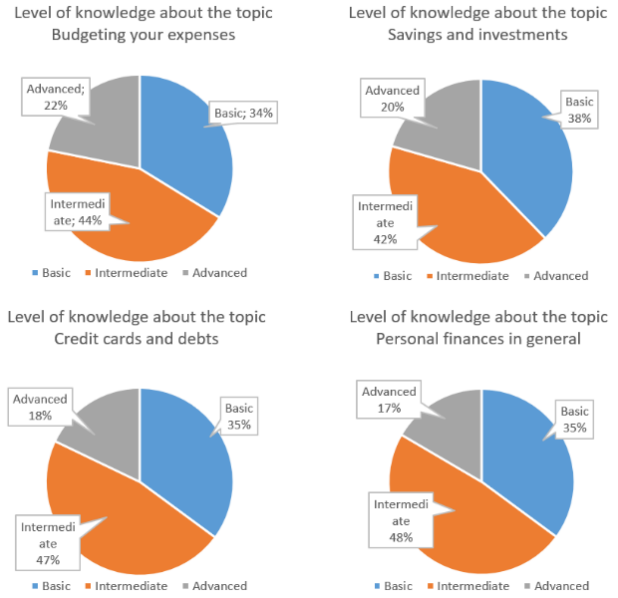

Fig. 10. Level of knowledge by topic.

E. Financial Challenges

Graphs were made to show the percentage of respondents who were correct in their answers about the financial issues defined. This allows the relationship between the level of knowledge selected and the results obtained in the financial challenges to be analyzed, reflecting how participants applied their knowledge. It should be noted that, in the graphs, the value "1" represents the correct answer, and the value "2" indicates the incorrect answer.

1) Budget expenses: Fig. 11 shows that, at the basic level, 63% of the participants were correct in their answers to the first question, while only 8% managed to get the second one right. At the intermediate level, 36% got question 1 right, but 67% got the second question right. At the advanced level, 88% were correct. This shows a clear correlation between financial knowledge and performance on challenges.

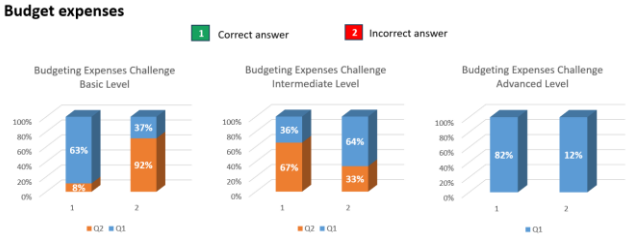

Fig. 11. Budget expenses.

2) Savings and investment: Fig. 12 At the basic level, both the first and second questions were corrected by 42% of the participants and 89% in the third. At the intermediate level,

48% got question 1 right and 44% got question 2 right. Finally, at the advanced level, 58% got the first question right and the second question was 71%.

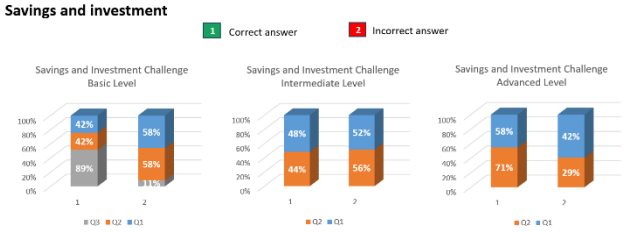

Fig. 12. Savings and investment.

3) Credit cards and Debt: In Fig. 13, 49% got the correct answer for the basic level right. At the intermediate level, 89% and 82% got questions 1 and 2 correctly respectively. In the case of the advanced level, 48% got question 1 right, while only 4% got the second one right.

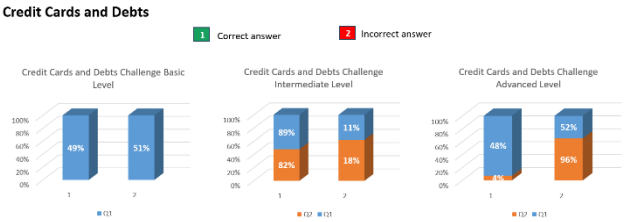

Fig. 13. Credit cards and debt.

4) Personal finance in general: In Fig. 14, 79% got the correct answer for the basic level, 90% for the intermediate level, and 64% for the advanced level.

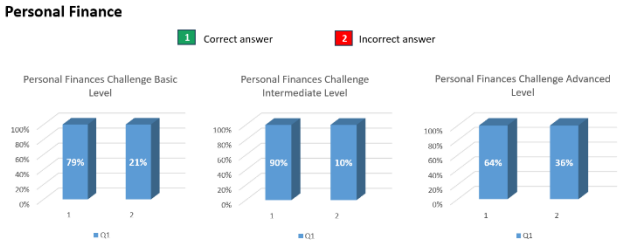

Fig. 14. Personal finance.

F. Financial Challenges Score

The scoring system for the financial challenges section consists of 20 points, regardless of the skill level selected. The rating scale used to evaluate performance is presented below (Table II). On the other hand, the average score obtained by the participants is 12.61 (Table II). This reveals a significant deficiency in the mastery of financial knowledge. Therefore, it is necessary to strengthen these areas to improve results.

TABLE II. RATING SCALE AND AVERAGE

Vigesimal qualification	*[0-10]*	*[11-14]*	*[15-19]*	*[20]*
Verbatim note	C: Fail	B: Regular	A: Expected Achievement	AD: Outstanding Achievement
Average Score	12.61			

5) Endnotes: In Fig. 15, only 5% of the respondents obtained an outstanding performance, while 32% failed.

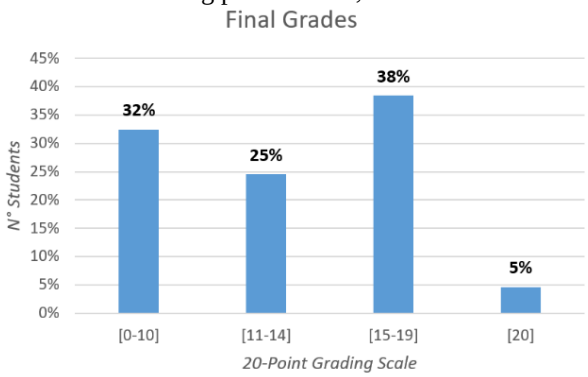

Fig. 15. Endnotes.

6) Notes per cycle: Fig. 16 shows a distribution of students in different academic cycles, revealing a remarkable trend: students in advanced cycles (VII-X) demonstrated a stronger understanding of financial concepts compared to those in initial cycles (I-III). This could be attributed to increased exposure to real economic situations as they progress in their career.

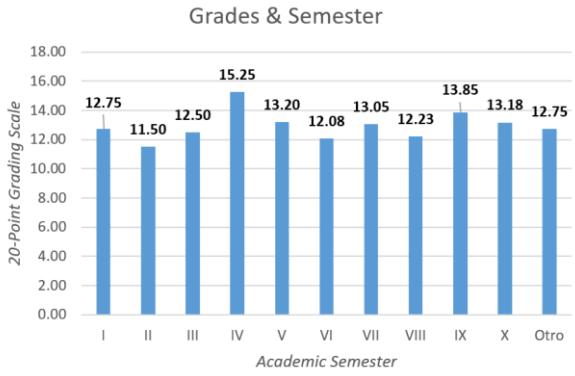

Fig. 16. Notes per cycle.

G. Tool Preferences

The survey results reveal that 81% of respondents prefer personalized advice to improve their financial knowledge. In terms of the learning format, interactive games were the most popular option with 52% of preferences. In addition, 81% showed interest in receiving personalized recommendations, which reinforces the idea of incorporating a system based on artificial intelligence for the financial coach, so that it offers suggestions adjusted to the individual needs and behaviors of users. (Fig. 17).

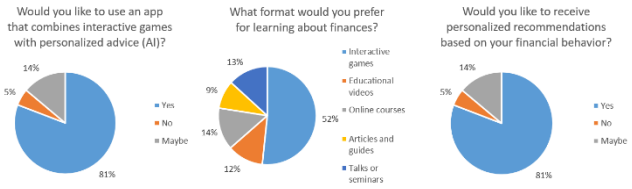

Fig. 17. Preferences.

VI. Discussion

The results obtained through the survey show the critical need to strengthen financial literacy among young university students. Most of the participants showed deficiencies in key concepts, particularly those found in the first cycles of university, while those in higher cycles showed a better understanding of financial topics (Fig. 16). This finding reinforces the importance of including financial training from the early stages of higher education to ensure that students acquire this knowledge before entering the labor market.

One of the most important findings was the preferred format for learning, where 52% opted for the interactive games option (Fig. 17). This suggests that young people value more dynamic learning methods, which validates the choice to propose a gamified solution. Since game-based learning can help increase students' engagement and enthusiasm for the topics, in addition, to achieving higher knowledge retention [17]. This result is related to [6], which found that promoting financial literacy through games increased interest and knowledge in financial topics.

In addition, 81% of respondents prefer to receive personalized recommendations based on their financial behaviors (Fig. 17). This leads to the integration of an AI-based recommendation system to offer suggestions based on users' needs and behaviors. This reflects a significant demand for solutions that teach financial concepts and provide recommendations. The study [8], which supplemented their serious game with an Intelligent Pedagogical Agent (IPA), which analyzed players' emotions and provided suggestions based on their progress in the game, thus succeeded in increasing students' competencies on Steam.

However, there were certain limitations throughout this research. First, the number of respondents, although the goal was to reach 385 participants, 150 were obtained. However, considering the focus of this study and the target population, this sample is still adequate to obtain representative results on the level of financial education. Secondly, the proposal has not been implemented or evaluated in a real environment, this limits the possibility of directly measuring the practical impact of the proposal on users' financial literacy. Finally, the proposal incorporates AI to personalize recommendations, but a detailed analysis of the ethical and privacy implications was not added, since the focus was on the evaluation of the level of financial literacy and the design of the proposal, however, it is relevant and should be considered in the implementation of this proposal.

Therefore, these results support the integration of a financial coach, designed to guide users based on their financial needs, with game-based learning to achieve a greater impact on the financial literacy of young people.

VII. Conclusion

This proposal for an interactive and gamified mobile application design is based on the results obtained in the survey of young people who prefer interactive games and personalized recommendations as learning formats. This preference highlights the importance of implementing teaching methods that promote continued interest in education.

On the other hand, it is important to note that the survey conducted not only made it possible to diagnose the financial capacity of young people but also served as the basis for the platform´s design. The data collected showed the need to strengthen financial literacy and the proposal seeks to respond to this need innovatively.

While this study does not include the practical implementation of the proposal, the design has the potential to contribute significantly to young people's financial literacy and have a positive impact on their ability to achieve financial independence.

Finally, this study presents an innovative solution based on interactive and gamified learning designed to reduce the financial literacy gap. It also promotes hands-on learning with a user-centered approach tailored to the user's preferences. Finally, it is suggested that future research work should focus on the implementation of this design proposal.

***Abstract*—Obstructive Sleep Apnea (OSA) is a prevalent health issue affecting 10-25% of adults in the United States (US) and is associated with significant economic consequences. Machine learning methods have shown promise in improving the efficiency and accessibility of OSA diagnoses, thus reducing the need for expensive and challenging tests. A comparative analysis of Logistic Regression (LR), Support Vector Machine (SVM), Gradient Boosting (GB), Gaussian Naive Bayes (GNB), Random Forest (RF), and K-Nearest Neighbors (KNN) algorithms was conducted to predict Obstructive Sleep Apnea (OSA). To improve the predictive accuracy of these models, Random Oversampling was applied to address the imbalance in the dataset, ensuring a more equitable representation of the minority class. Patient demographics, including age, sex, height, weight, BMI, neck circumference, and gender, were employed as predictive features in the models. The RFC provided outstanding training and testing accuracies of 87% and 65%, respectively, and a Receiver Operating Characteristic (ROC) score of 87%. The GBC and SVM classifiers also demonstrated good performance on the test dataset. The results of this study show that machine learning techniques may be effectively used to diagnose OSA, with the Random Forest Classifier demonstrating the best results.**

***Keywords*—Machine learning; obstructive sleep apnea; random forest classifier; oversampling; classification**

I. Introduction

Obstructive sleep apnea (OSA) is a prevalent disorder affecting a substantial portion of the population. Characterized by recurrent obstructions of the upper airway during sleep, it results in intermittent cessation of airflow [1], [2]. A multitude of factors have been identified as risk determinants for OSA, including obesity, male gender, smoking, age, craniofacial anomalies, and menopause in women [3]. Symptoms that suggest OSA include chronic snoring, observed apneic episodes, gasping during sleep, frequent awakenings, non-restorative sleep, increased nighttime urination, and excessive daytime sleepiness. Timely diagnosis of OSA is crucial as untreated OSA can contribute to the development of cardiovascular diseases, metabolic disorders, and neurocognitive impairments [4].

The standard diagnostic method for OSA is overnight polysomnography (PSG), however, it is expensive and often limited in accessibility. Therefore, it is important to prioritize high-risk individuals for PSG, particularly those with moderate to severe OSA, to optimize the utilization of sleep laboratories [5]. The severity of OSA is commonly assessed using the Apnea-Hypopnea Index (AHI), with cutoff values of $6-15/hour$ indicating mild OSA, $16-30/hour$ indicating moderate to severe OSA, and values exceeding $30/hour$ indicating severe OSA [5].

In recent years, machine learning has drawn considerable interest as a potentially effective way to address complex problems in various sectors, most notably healthcare. Its strengths, such as robustness, self-organization, adaptive learning, and parallel processing, make it an attractive tool.

Machine learning algorithms, renowned for their ability to discern patterns within intricate datasets, have garnered significant attention. Prominent examples of such algorithms encompass Support Vector Machines (SVM) [6], [7], Gradient Boosting Classifiers (GBC) [8], Gaussian Naive Bayes (GNB) [9], Random Forest Classifiers (RFC) [10], [11], and K-Nearest Neighbors Classifiers (KNC) [12]. Consequently, machine learning models have seen increasing use in medical healthcare, including the prediction of OSA, and have shown promising outcomes.

This study conducts a comparative evaluation of traditional regression modeling and a suite of machine learning algorithms for predicting obstructive sleep apnea (OSA) based on physical parameters. The succeeding sections of this paper are structured as follows. Section II presents a comprehensive review of existing machine learning approaches applied to OSA prediction. Section III provides a detailed characterization of the dataset employed in this study. In Sections IV and V, the training and evaluation methodology for ML models, including particular classification algorithms, is described. Finally, in Section VI, we present the experimental results and performance analysis concerning various evaluation metrics and report the results obtained through this research endeavor.

II. Related Works

Machine learning has emerged as a preeminent paradigm for classifying medical data owing to its ability to manage

and extract insights from voluminous and intricate datasets effectively. For instance, in the context of OSA diagnosis, traditional methods like drug-induced sleep endoscopy (DISE) rely on subjective observer evaluations, as seen in the VOTE classification system proposed by Altintas et al. [13], which showed only moderate to fair agreement among observers. This highlights the potential of machine learning models to provide objective, consistent, and accurate diagnoses by automating the analysis of complex data, thereby addressing the limitations of observer-dependent methods.

Various studies [14]–[16] have utilized machine learning algorithms to improve diagnostic precision and patient outcomes in various diseases. The authors in [17], highlighted the utility of support vector machines (SVM) in classifying brain MRI images for neurological disorders, which aligns with its potential for OSA diagnosis. However, the authors in [18] explored the use of various ML methods to predict obstructive sleep apnea syndrome (OSAS) severity using demographic, clinical, and spirometric data from 313 patients. Their study demonstrated that SVMs and Random Forests (RFs) showed the best classification performance.

Furthermore, ensemble learning methods, such as Gradient Boosting Classifiers (GBCs) and RF classifiers, have demonstrated robust performance in medical diagnostics due to their ability to handle imbalanced and high-dimensional data. Ramesh et al. [8] applied GBCs to classify OSA from electronic health records, achieving an accuracy of 68.06%. The authors in [11] further validated the performance of RFCs for OSA detection, leveraging feature selection algorithms to improve model interpretability and accuracy.

Integrating the STOP-BANG questionnaire with machine learning models is employed in [12] to enhance OSA diagnosis. Among the four algorithms tested, the K-Nearest Neighbor (K-NN) model demonstrated the best performance, achieving 94% accuracy. The results highlight the potential of combining ML with traditional tools to improve the reliability and efficiency of OSA screening. However, in [19], the SLEEPS model, a machine learning-based questionnaire using nine items, accurately predicts OSA, COMISA, and insomnia without polysomnography. The model trained on over 4,600 participants using XGBoost, achieved AUROC values above 0.89, outperforming tools like STOP-BANG.

In recent years, the authors in [20] have used the Swedish National Study on Aging and Care electronic health data to predict sleep apnea with a ML model. The XGBoost and Bidirectional Long Short-Term Memory Networks modules give the model 97% accuracy with 75 features and 10,765 samples. Furthermore, pre-screening symptoms were employed to diagnose OSA [21], and the experimental findings revealed that the Decision Tree Classifier (DTC) and RF outperformed other comparable algorithms, achieving the highest classification accuracies. Similarly to the authors in [22], the RF classifier technique is utilized to predict sleep disorders and has achieved the highest accuracy. The potential of ML models for cost-effective OSA screening, with RF and LightGBM showing the most promise for clinical use, is discussed in [23].

A concise overview of the utilization of machine learning techniques in diagnosing, classifying, and treating sleep-related respiratory problems is presented in [24]. The effectiveness of machine learning-based classifiers in OSA classification is highly affected by the quality and quantity of input data and the selection of the machine learning approach.

More advanced techniques, like deep learning models, have demonstrated superior accuracy in sleep apnea and related disorder detection. Studies like [10] combined ECG signals with machine learning and deep learning to achieve 86.25% accuracy, while advanced architectures like multi-resolution residual network (MR-ResNet) [6] and CNN-based approaches [9] reached accuracies of 90.8% and 79.61%, respectively, leveraging polysomnographic (PSG) data. Wearable systems [25] and single-lead electrocardiogram (ECG) classifiers [7] achieved notable performance with accuracies up to 88.2% and 93.0%. Other studies, such as [26], employed EEG and/or electrooculogram (EOG) signals for sleep staging, achieving up to 84.5% accuracy, while [27] explored microelectromechanical system (MEMS)-based solutions. However, the computational demands and reliance on specialized data limit the practicality of these methods in resource-constrained environments.

Despite substantial progress in sleep apnea diagnosis, pursuing more accurate, efficient, and accessible methods remains an active area of research. Many existing studies rely on costly diagnostic tools like PSG, need help with imbalanced datasets, and focus on computationally intensive deep-learning models that lack practicality and generalizability. This study addresses these challenges by using easily obtainable physical parameters, applying oversampling to balance data, and evaluating resource-efficient algorithms, offering scalable and accessible solutions for diverse populations.

III. OSA Data Collection

Data were collected from adult individuals who were referred to a community sleep center due to suspected obstructive sleep apnea (OSA) and had not received a previous diagnosis. Each participant provided demographic details such as age, gender, and ethnicity, and completed sleep-related questionnaires, including the Epworth Sleepiness Scale. Prior to undergoing polysomnography, a physical examination was conducted, which included an assessment of the airway using a modified Friedman grade, measurement of body mass index (BMI), and neck circumference (NC). OSA was diagnosed when the apnea-hypopnea index (AHI) was equal to or greater than 15. Incomplete questionnaires or polysomnography records with inadequate technical quality or insufficient total sleep time were excluded from the analysis.

Retrospective data analysis and review were conducted after the administrative approval of the data from the Torr Sleep Center executive and institutional committee. The study was conducted at Torr Sleep Center in their Corpus Christi, Texas Location. The patients undergoing the second or split night (titration night) were excluded. The patients have undergone the first (diagnostic night were determined by the computerized search using the CPT code 98510. The patient discussed the study with the registered polysomnographic therapist during the presentation. Baseline demographic information was collected. Height, weight, Modified Friedman, Waist circumference, and diameter were assessed, and Body Mass Index (BMI) was computed. The patient underwent overnight polysomnography. The nocturnal polysomnogram (NPSG) included the

recording of electroencephalogram (EEG): F4-M1, F3-M2, C4-M1, C3-M2, O2-M1, O1-M2, electrooculogram (EOG), submental, intercostal and anterior tibialis electromyogram (EMG), electrocardiogram (EKG), airflow by nasal pressure, and oral thermistor, abdominal and chest wall excursion using impedance plethysmography and oxygen saturation by pulse oximetry attended by a sleep technologist. The sleep study was staged and scored using AASM standards.

All methods described in this study adhere to relevant guidelines and regulations. The research protocol obtained ethical approval from the Research Ethics Committee of NTUH. (protocol number 201603113RIND), and the committee waived the requirement for participant consent. Table I presents dataset statistics, including sample size, mean values, and ranges. Additionally, Table II displays randomly selected data samples to provide insight into the dataset's structure.

Fig. 1 depicts the distribution of the dataset across OSA, Sex, and BMI attributes. These attributes play a crucial role in the modeling process. Notably, Body Mass Index (BMI) is one of these attributes. BMI is a measure to estimate body fat using an individual's height and weight. It is a standard adult screening tool for weight-related health problems. According to the classifications given in Table III, it sorts people into four groups: underweight, normal weight, overweight, or obese.

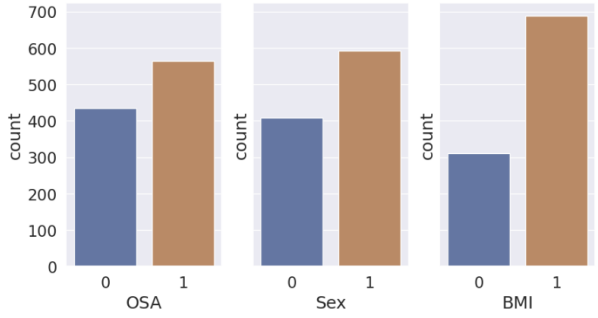

Fig. 1. Distribution of some attributes of the data: OSA, Sex, and BMI.

Fig. 2 shows the dataset box plot, and Fig. 3 shows a correlation between dataset parameters; it can be seen that the most correlated parameter with OSA is Neck circumference and then weight, which means that these two parameters will play a significant role in classification results.

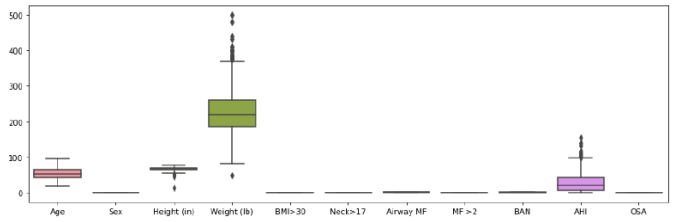

Fig. 2. Dataset Box plot.

A. Oversampling

The OSA data set is imbalanced; we adopted a Random oversampling technique to balance the data. RandomOver

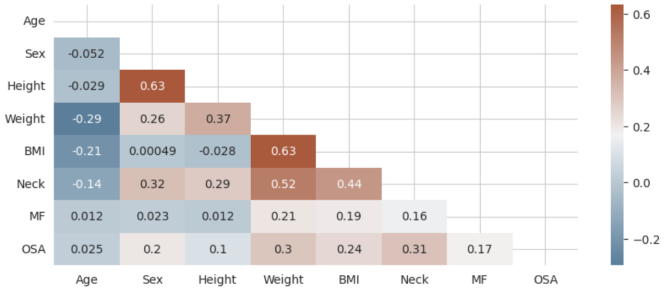

Fig. 3. Correlation heatmap.

Sampler is a machine learning technique used to handle imbalanced datasets. It addresses class imbalance by creating a more equally distributed dataset by randomly oversampling the minority class as follows:

- First, the minority class is identified in the dataset. This is the class with fewer instances than the majority class.
- Then, the "RandomOverSampler" algorithm randomly selects instances from the minority class. It oversamples the minority class by duplicating its instances to match the population of the majority class.
- After the oversampling, the resulting dataset is balanced or nearly balanced, with an equal number of instances for each class.
- Finally, a machine learning model is trained using the balanced dataset; the model should outperform its counterpart trained on an unbalanced dataset.

Oversampling techniques, such as Random Oversampling and Synthetic Minority Oversampling Technique (SMOTE), have been widely used to address this issue. The authors in [24] employed SMOTE to enhance the performance of ML models in detecting OSA, demonstrating its effectiveness in reducing classification errors for minority classes. It's worth noting that the Oversampling can be prone to overfitting, especially if the minority class is oversampled too much. Tuning the oversampling ratio is essential to finding the optimal balance between reducing class imbalance and avoiding overfitting.

B. Data Scaling

Data scaling is an essential pre-processing stage for the machine learning classification process. The purpose of scaling the data in this way is to make it easier to compare features with different units and scales. This can potentially enhance the efficiency of machine learning algorithms, especially those like k-nearest neighbors and support vector machines that are sensitive to input data size.

The "StandardScaler" is a preprocessing technique used in machine learning to scale numerical data. Standardization is achieved by transforming the data to exhibit a zero mean and unit variance. Specifically, it can be done according to the following steps.

- First, the mean of each feature (column) in the data is calculated.

TABLE I. STATISTICS OF THE OSA DATA SET

	Age	Sex	Height (in)	Weight (lb)	BMI>30	Neck>17	Airway MF
count	1000	1000	1000	1000	1000	1000	1000
mean	54.031	0.592	67.037	227.653	0.689	0.661	2.722
std	14.320	0.492	4.624	58.218	0.463	0.474	1.008
min	19.000	0.00	15.000	49.000	0.000	0.000	0.000
25%	44.000	0.000	64.000	186.750	0.000	0.000	2.000
50%	54.000	1.000	67.000	220.000	1.000	1.000	3.000
75%	65.000	1.000	70.000	262.000	1.000	1.000	4.000
max	96.000	1.000	79.000	500.000	1.000	1.000	4.000

TABLE II. SAMPLE OF THE OSA DATA SET

Sample No.	Age	Sex	Height (in)	Weight (lb)	BMI>30	Neck>17	Airway MF
652	45	1	73.0	284	1	1	1
939	71	0	59.0	192	1	0	0
319	51	1	77.0	280	1	1	1
626	41	1	66.0	180	0	1	0
808	85	0	59.0	178	1	1	1

TABLE III. BMI CATEGORIES

BMI Category	BMI Range
$Under\_weight$	< 18.5
$Normal$	$18.5 - 24.9$
$Over\_weight$	$25 - 29.9$
$Obese$	≥ 30

- Then, the StandardScaler subtracts the mean from each value in the feature. This centers the data around zero.
- Next, the StandardScaler divides each value in the feature by its standard deviation. This scales the data to have a standard deviation of 1.
- After the scaling is done, the resulting dataset has a mean value of zero and a standard deviation value of one.

IV. PROPOSED METHODOLOGY

The machine learning process consists of multiple steps, beginning with data collection. The collected data might be raw and unstructured, so the subsequent step involves pre-processing. In this step, missing data is eliminated and thoroughly cleaned to ensure its suitability for analysis.

Following the pre-processing stage, the next step is feature extraction, which involves identifying and extracting pertinent features from the data. This step is significant since the ML model's performance relies heavily on the quality of the extracted features. After extracting the features, the dataset was divided into several subsets for training and testing. The training subset was used to develop the model, while the testing subset was used to evaluate how well the model can be applied to new data. The subsequent step is classification, where the machine learning algorithm utilizes the extracted features to classify new data into distinct categories. Various classification algorithms, such as RF, SVM, or ANN, can be employed to train the model on the training set.

Finally, precision, recall, and F1-score metrics evaluate the model's performance. The model exhibiting the highest performance is chosen and employed for classifying new data. It should be emphasized that this process is iterative and typically requires multiple iterations of adjustments and enhancements to attain optimal performance. Algorithm 1 summarizes all the process stages of machine learning. Fig. 4 shows the proposed methodology utilized for OSA detection using various machine-learning techniques.

Algorithm 1: Machine Learning Process

```
Input: Raw data
Output: Trained model
Step 1: Data Collection
    Collect raw data from various sources
Step 2: Data Pre-processing
    Remove missing data and outliers
    Normalize or scale the data if necessary
Step 3: Feature Extraction
    Extract relevant features from the pre-processed data
    Reduce the dimensionality of the data if necessary
Step 4: Model Selection
    Choose appropriate machine learning algorithms
    Select hyperparameters for the algorithms
Step 5: Model Implementation
    Train the selected models on the pre-processed data
    Evaluate the performance of the trained models
Step 6: Model Evaluation
    Test the trained models on new data
    Evaluate the performance of the tested models
Step 7: Model Deployment
    Deploy the best-performing model in production
```

V. ML METHODS

A. Logistic Regression (LR)

Logistic regression is a statistical technique that shares similarities with linear regression and is utilized for predicting binary outcomes. Unlike the Mantel-Haenszel odds ratio, which is limited to discrete explanatory variables, logistic regression can simultaneously handle continuous and

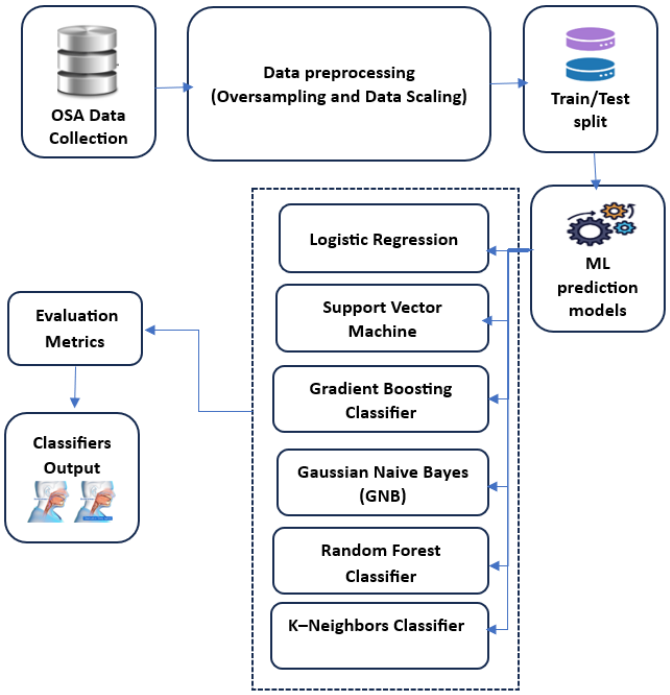

Fig. 4. The proposed methodology for utilizing various ML models to detect OSA.

multiple explanatory variables. This capability is essential when studying the impact of various factors on the response variable. Logistic regression models the probability of an outcome by considering the covariance among variables and accounting for individual characteristics. This approach helps address confounding effects when analyzing multiple variables independently. The logarithm of the odds is used in modeling, as odds represent a ratio, as explained by Sperandei [28].

$$log\left(\frac{\pi}{1-\pi}\right) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_m x_m \qquad (1)$$

The symbol π represents the likelihood of an event, such as the incidence of OSA. The regression coefficients β_i correspond to the reference group and the explanatory factors x_i.

B. Support Vector Machines (SVM)

The Support Vector Machine (SVM) is a widely used supervised learning model for prediction and classification tasks. It was developed in 1995 by Vladimir Vapnik and his team at AT&T Bell Laboratory. SVM utilizes a nonlinear mapping function to transform the training data set into a higher dimensional space. It then employs linear regression to separate the data within this transformed space. This approach has demonstrated effectiveness across various applications, enabling the learning of complex decision boundaries and improving classification accuracy. The author in [29] described this process of SVM as approximating the training data set within a higher dimensional space and employing linear regression to separate the data. Fig. 5 illustrates the SVM model.

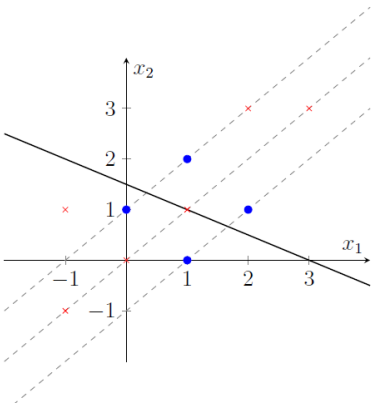

Fig. 5. Optimal hyperplane in support vector machine.

C. Gradient Boosting Classifier (GBC)

As an ensemble machine learning approach, the Gradient Boosting Classifier combines many weak models into one more potent model, increasing the prediction power of the combined model [30]. It operates iteratively by training decision trees on the residuals of the preceding tree, utilizing gradient descent optimization to minimize the loss function. This technique enables the algorithm to learn more intricate decision boundaries, improving prediction accuracy. The specific structure of the algorithm, including its formulas, is highly influenced by the chosen designs of $\Phi\,(y, f)$ and $h\,(x, \theta)$. More detailed examples of these algorithms can be found in the work of Friedman [30].

Algorithm 2: Friedman's Gradient Boost Algorithm

Input: Training Dataset $\mathcal{D} = (\mathbf{x}_1, y_1), \ldots, (\mathbf{x}_n, y_n)$, number of iterations M, learning rate α, base model $h_0(\mathbf{x})$, loss function $L(y, F(\mathbf{x}))$

Output: Ensemble model $F(\mathbf{x}) = \sum m = 1^M \beta_m h_m(\mathbf{x})$

Initialize ensemble model $F_0(\mathbf{x}) = h_0(\mathbf{x})$;

for $m \in 1, \ldots, M$ **do**

  Calculate the negative gradient $r_{im} = -\left[\frac{\partial L(y_i, F_{m-1}(\mathbf{x}i))}{\partial Fm-1(\mathbf{x}i)}\right] i = 1^n$ for each training instance $\mathbf{x}i$

  Fit a base model $h_m(\mathbf{x})$ to the negative gradient r_{im}

  Compute the optimal step size $\beta_m = \arg\min_\beta \sum_{i=1}^n L(y_i, F_{m-1}(\mathbf{x}_i) + \beta h_m(\mathbf{x}i))$

  Update the ensemble model: $F_m(\mathbf{x}) = Fm - 1(\mathbf{x}) + \alpha\beta_m h_m(\mathbf{x})$;

end

return *Ensemble model* $F(\mathbf{x}) = \sum_{m=1}^M \beta_m h_m(\mathbf{x})$

The Gradient Boosting is used for creating an ensemble model on a training set $\mathcal{D}$ consisting of n instances, where each instance has a pair of features $\mathbf{x}i$ and label y_i. It requires several iterations M, a learning rate α, a base model $h_0(\mathbf{x})$, a loss function $L(y, F(\mathbf{x}))$ to evaluate the quality of the ensemble model, and a set of hyper-parameters for the base model. The algorithm initializes the ensemble model to $F_0(\mathbf{x}) = h_0(\mathbf{x})$, and then iteratively improves it by fitting

a base model $h_m(\mathbf{x})$ to the negative gradient of the loss function concerning the current ensemble model $Fm-1(\mathbf{x})$. The optimal step size β_m is computed using line search, and the ensemble model is updated by adding a scaled version of the new base model $h_m(\mathbf{x})$ to the previous ensemble model $F_{m-1}(\mathbf{x})$. The final output of the algorithm is the resulting ensemble model $F(\mathbf{x})$.

D. Gaussian Naive Bayes (GNB)

One machine learning algorithm based on the concepts of Bayes' Theorem is the Naive Bayes Classifier [31]. These classifiers rely on the assumption of strong independence among the features used for predictions.

Under this premise, it is assumed that the value of one characteristic does not affect the value of any other feature. A notable advantage of Naive Bayes Classifiers is their ability to be efficiently trained in supervised learning scenarios, even when working with limited training data. Moreover, their straightforward design and ease of implementation make them popular for various real-world applications.

In machine learning, continuous data is frequently assumed to adhere to a normal (Gaussian) distribution, mainly when dealing with classification tasks. This assumption suggests that the continuous values corresponding to each class follow a normal distribution. By making this assumption, it becomes possible to estimate the likelihood of the features using the Gaussian probability density function:

$$P\left(x_i|y\right) = \frac{1}{\sqrt{2\pi\sigma_y^2}} exp\left(-\frac{\left(x_i-\mu_y\right)^2}{2\sigma_y^2}\right) \tag{2}$$

One strategy for constructing a simple model is to assume that a Gaussian distribution with no covariance among dimensions can characterize the data. In other words, each dimension is considered independent of the others. This type of model can be easily built by calculating the mean and standard deviation of the data points within each label, as these parameters define the distribution.

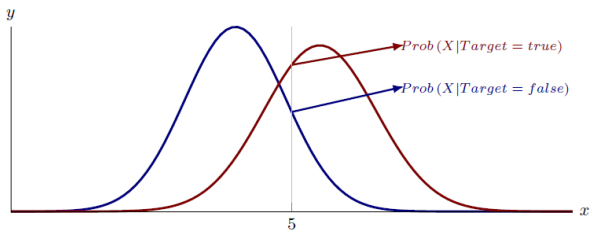

Fig. 6. Demonstration of working with a continuous variable in naïve bayes.

The provided illustration, as shown in Fig. 6 demonstrates the functioning of a Gaussian Naive Bayes (GNB) classifier. For each data point, the classifier calculates the z-score distance, which is the difference between the data point and the mean of each class divided by the standard deviation of that class.

E. Random Forest Classifier (RFC)

The term "random forest" refers to an ensemble of tree predictors. A randomly distributed vector, which is sampled individually and distributed uniformly among all trees in the forest, is relied upon by each individual tree [32]. As the random forest expands in terms of the number of trees, its generalization error stabilizes. The predictive capacity of individual trees and their interrelationships impact the ultimate level of this error.

Random forests use a random feature selection method for splitting nodes, which leads to error rates comparable to Adaboost while being more resilient to noise. The forest's internal estimates monitor various factors such as error, strength, and correlation and can assess the impact of increasing the number of features used for splitting. These estimates are also useful in determining the importance of different variables, and the approach is applicable to regression tasks as well.

RFC constructs decision trees by randomly selecting subsets of the training data and features for each node [33], [34]. Finding the optimal feature to divide the data at each node is how the trees are iteratively developed until a stopping requirement is satisfied [35]–[37]. During prediction, the ensemble of trees votes on the class label for a new input instance, with the class receiving the most votes being predicted as the output. This approach mitigates overfitting and enhances classification accuracy by leveraging the collective ability of the tree ensemble to capture diverse patterns and relationships within the data. RFC has demonstrated successful applications in various domains, including sleep apnea research [11], [38]. Refer to Fig. 7 for an illustrative example of the RFC mechanism.

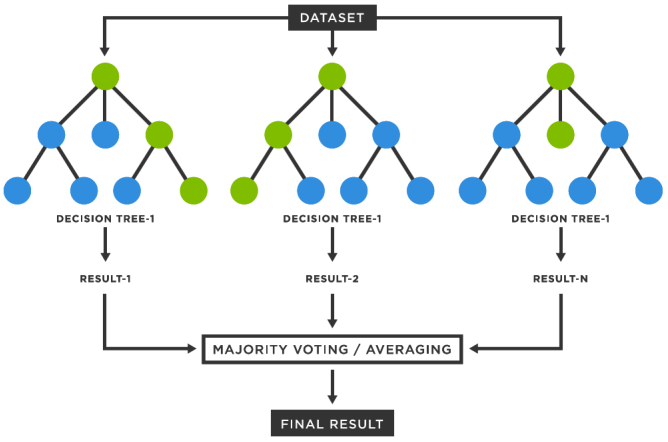

Fig. 7. Random forest mechanism.

To train individual trees, the Random Forest Algorithm requires a training set $\mathcal{D}$, a certain number of trees to be included in the forest (T), a random number of features (K) to be chosen for each tree, and a decision tree algorithm $\mathcal{A}$. To build the forest, the algorithm iteratively constructs T trees. At each iteration t, the algorithm randomly selects K features from the available features and draws a bootstrap sample $\mathcal{D}_t$ from the training set $\mathcal{D}$. A decision tree f_t is then trained on the sampled features and the bootstrap sample $\mathcal{D}_t$, using

Algorithm 3: Random Forest Classifier Algorithm

Input: Training Dataset $\mathcal{D}$, number of trees T, number of features K, decision tree algorithm $\mathcal{A}$
Output: Random Forest $\mathcal{F}$
for $t \in 1, \ldots, T$ **do**
  Sample K features from the p available features without replacement
  Draw a bootstrap sample $\mathcal{D}_t$ from $\mathcal{D}$
  Train a decision tree f_t on $\mathcal{D}_t$ using the selected features and $\mathcal{A}$
end
return *Random Forest* $\mathcal{F} = f_1, \ldots, f_T$

the given decision tree algorithm $\mathcal{A}$. The final output of the algorithm is the resulting random forest $\mathcal{F}$, which consists of the T decision trees $f_1, \ldots, f_T$ (see Algorithm 3).

F. K–Neighbors Classifier (KNN)

One supervised machine learning technique that is commonly employed for classification problems is the K-Nearest Neighbors (KNN) classifier. It sorts unlabeled data points according to the similarity principle, which states that it should consider the class of nearby data points in the training dataset. The number of neighbors to consider is represented by the "K" in KNN.

The algorithm computes the Euclidean distance between the unclassified data instance and each labeled training instance to inform the classification decision. After that, it uses the distances to choose the K closest neighbors. The unlabeled data point's class identification is decided by a majority vote among its K nearest neighbors. KNN is a simple and intuitive algorithm that does not require training. It uses the entire training dataset for classification. The KNN algorithm is easy to understand, and its pseudocode is provided in Algorithm 4.

In this algorithm, the input is a training set $\mathcal{D}$ consisting of labeled instances, a test instance x that we want to classify, and the number of neighbors K to consider. The output is the predicted class label for the test instance.

Algorithm 4: K-Nearest Neighbors Classifier Algorithm

Input: Training Dataset $\mathcal{D} = (\mathbf{x}_1, y_1), \ldots, (\mathbf{x}_n, y_n)$, new instance $\mathbf{x}$, number of neighbors K
Output: Predicted label $\hat{y}$ for $\mathbf{x}$
for $i \in 1, \ldots, n$ **do**
  Compute the Euclidean distance $d(\mathbf{x}, \mathbf{x}_i)$ between $\mathbf{x}$ and each training instance $\mathbf{x}_i$;
end
Identify the K training instances with the smallest distances to $\mathbf{x}$; Assign the majority class label among these K instances as the predicted label $\hat{y}$ for $\mathbf{x}$;
return *Predicted label* $\hat{y}$

Each instance in the training set $\mathcal{D}$ has a pair of features $\mathbf{x}_i$ and a label y_i, and the K-Nearest Neighbors Classifier Algorithm is applied to this set. The algorithm calculates the Euclidean distance between each training instance $\mathbf{x}_i$ and $\mathbf{x}$ when given a fresh instance $\mathbf{x}$. Next, it chooses the K training examples that are closest to $\mathbf{x}$, and the projected label $\hat{y}$ for $\mathbf{x}$ is the majority class label among these K examples. The algorithm returns the predicted label $\hat{y}$.

VI. Experimental Results and Performance Analysis

The following section presents the findings from utilizing the proposed machine learning models in the OSA dataset. The performance of each model is evaluated using a comprehensive set of metrics, and a comparative analysis is conducted to identify the most effective approach. These metrics provide quantitative measures of model quality. Most of them mainly depend on calculating TP (i.e. count of model-correct positives), FP (i.e. number of positive cases misclassified as negative), TN (i.e. the number of true negatives the model identified), and FN (i.e. the model predicts a negative result while it is positive). The total number of instances is $Total$ (i.e. $Total = TP + TN + FP + FN$). These metrics include accuracy, precision, recall, and F1-score, as computed using the following formulas.

$$Accuracy = \frac{TP + TN}{Total} \tag{3}$$

$$Precision = \frac{TP}{TP + FP} \tag{4}$$

$$Recall = \frac{TP}{TP + FN} \tag{5}$$

$$F1 = 2 \times \frac{precision \times recall}{precision + recall} \tag{6}$$

Table IV provides a comparative analysis of various classification algorithms (LR, SVM, GBC, GNB, RFC, and KNC) based on their performance metrics: accuracy, precision, recall, and F1-score, calculated for both training and testing datasets. Our findings indicate that:

- The analysis results show that RFC has the highest performance on the training set across all metrics, with a training accuracy of 86.78%, precision of 92.64%, and F1-score of 87.80%. However, its testing performance drops significantly (accuracy of 65.02%).
- The GBC achieves relatively balanced performance between training and testing datasets, with a testing accuracy of 66.08% and the highest test F1-score of 67.79% among the models, indicating better generalization compared to RFC and other models except KNC.
- The SVM shows testing accuracy (64.66%) and moderate performance across metrics. However, its performance on the training dataset is slightly lower than that of RFC, KNC, and GBC.
- KNC demonstrates balanced and consistent performance, achieving a training accuracy of 74.14% and testing accuracy of 67.14%. However, its recall on the test set decreases to 62.59%.

TABLE IV. CALCULATED PERFORMANCE CRITERIA BASED ON VARIOUS ML MODELS

Method	Train Accuracy	Train Precision	Train Recall	Train F1	Test Accuracy	Test Precision	Test Recall	Test F1
LR	0.665880	0.666667	0.698851	0.682379	0.650177	0.596273	0.738462	0.659794
SVM	0.704841	0.706935	0.726437	0.716553	0.646643	0.594937	0.723077	0.652778
GBC	0.822904	0.807775	0.85977	0.832962	0.660777	0.60119	0.776923	0.677852
GNB	0.645809	0.675862	0.649007	0.662162	0.650177	0.707692	0.601307	0.650177
KNC	0.741440	0.763218	0.741071	0.751982	0.671378	0.707692	0.625850	0.664260
RFC	0.867769	0.926437	0.834369	0.877996	0.650177	0.753846	0.593939	0.664407

- LR achieves moderate training accuracy (66.59%) and a balanced F1 score (68.24%). However, in the test, it maintains a consistent performance accuracy of 65.02% but suffers from lower precision (59.63%), indicating a higher false positive rate compared to algorithms such as KNC and GBC.
- The GNB has the lowest accuracy on the training dataset, with a value of 64.58%, but has a high test precision of 70.77%. This highlights the model's ability to correctly classify positive cases, despite lower overall accuracy and recall.

The results align well with existing literature on applying ML models for OSA diagnosis. Consistent with prior studies, the RFC emerged as the best-performing model regarding training accuracy (87%), reflecting its robustness in handling complex datasets and its effectiveness as highlighted in studies like [8], [10]. Similarly, the GBC demonstrated strong generalization capabilities, achieving a balanced performance across metrics, which is in line with findings in [8], where GBC was noted for its ability to capture intricate patterns in data. Overall, the alignment between this study's findings and existing research underscores the validity of these ML models for OSA prediction.

Furthermore, confusion matrices were generated to gain a comprehensive understanding of each machine learning algorithm's predictive capabilities. These visual representations offer a detailed breakdown of correct and incorrect classifications. Fig. 8 through 13 provide a graphical depiction of these training and testing data results, enabling a thorough analysis of each model's performance characteristics.

From Fig. 8, the total number of correctly predicted OSA cases is 564 out of 847 (i.e. in the case of training) and 184 out of 283 (i.e., in the case of testing). However, the percentage of incorrectly classified instances is 33.41% and 34.98% in training and testing, respectively; the LR model shows a moderate performance.

Fig. 9 demonstrates the strong overall performance of the SVM model, with a significantly higher number of correct predictions (diagonal elements) compared to incorrect predictions (off-diagonal elements). The model seems balanced in predicting classes 0 and 1, with a relatively even distribution of correct predictions for each class. The values in the off-diagonal (119 and 131) in training and (36 and 64) in testing indicate relatively low rates of false positives and false negatives, suggesting that the model effectively distinguishes between the two classes.

According to the GBC confusion matrix (as shown in Fig. 10), the GBC model exhibits strong overall performance, with a significantly higher number of correct predictions of OSA instances equal to 697 (i.e. 82.92%) and 187 (i.e. 66.08%) in training and testing, respectively.

The GNB classifier demonstrates solid performance on the training and testing sets, as shown in Fig. 11. The GNB model correctly classified 294 cases as positive OSA and 253 as negative cases in the case of training. In testing, the overall number of correctly classified cases is 184 out of 283 (i.e. 65.02%). While there's a minor decrease in performance on the testing set, the model still maintains a good balance in predicting both classes.

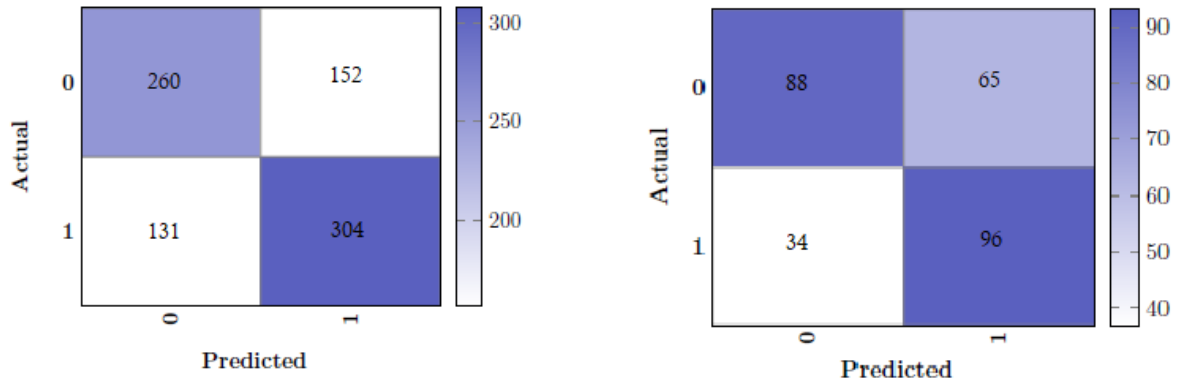
According to the confusion matrix of the random forest classifier (as shown in Fig. 12), the number of correctly classified instances is 735 (TP+TN) in training and 184 (TP+TN) in testing, while the total number of misclassified is 112 (FP+FN) in training and 99 (FP+FN) in testing. However, in Fig. 13, the K–Neighbors classifier, the model Correctly predicted 332 instances as class 1, 296 as class 0, 116 incorrectly predicted as class 1, and 103 incorrectly predicted as class 0 in training. In testing, The model achieves moderate results of 67.14%, indicating that it correctly predicts the class in 67.14% of cases.

Each methodology's efficacy depends on complex factors, including the problem domain, dataset characteristics (size and quality), and computational constraints. Moreover, the receiver operating characteristic (ROC) curve visually shows a binary classifier's performance. The area under the ROC curve (AUC) estimates the general model performance. A higher AUC denotes better discriminative capability; a perfect model achieves an AUC of 1.0, while a random classifier generates an AUC of 0.5. Fig. 14 and 15 present the ROC curves and box plots for the respective classification algorithms.

A. Statistical Test Analysis

Friedman's statistical test, a non-parametric test technique, was employed to identify the classification technique that outperformed other competing classifiers to conduct a more detailed investigation of the performance of the classification techniques. Table V presents the mean ranks derived from a Friedman test conducted to statistically compare the classification performance of the competing algorithms across accuracy, precision, recall, and F1-measure.

The lowest ranking finding reflects a higher level of performance, as seen in Table V. Friedman's test was used to determine the p-value, displayed in Table V. Some of the p-values found by Friedman's statistical test were less than the significance level, identified as $\alpha = 0.5$. The alternative hypothesis is supported, while the null hypothesis is refuted. The alternative hypothesis contends that there are different



(a) Training. (b) Testing.

(a) Training. (b) Testing.

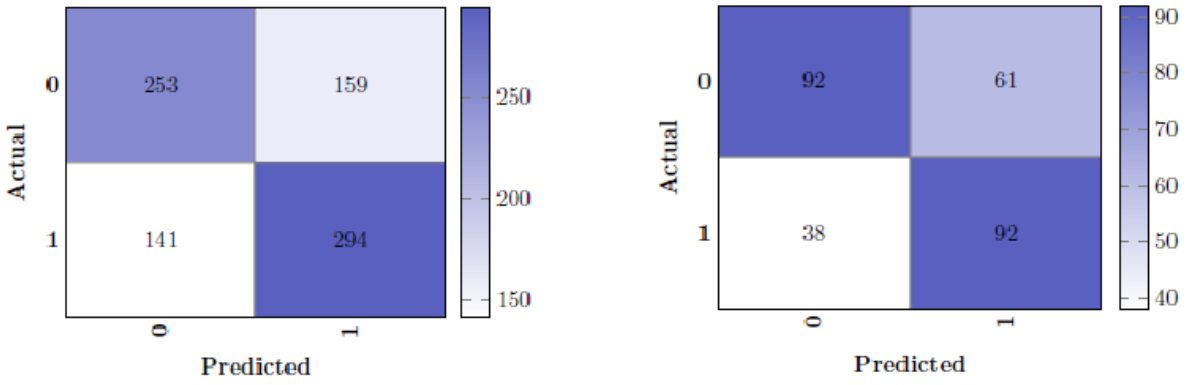
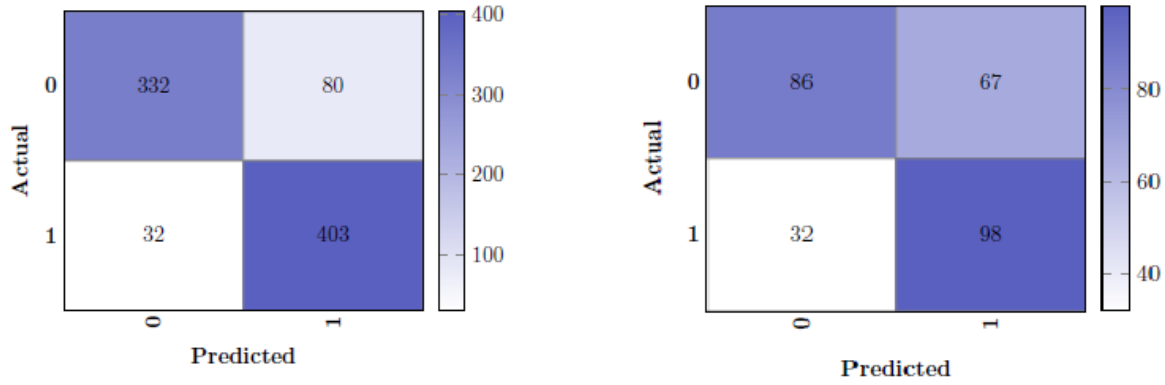
Fig. 10. GBC confusion matrices.

margins in the performance behaviors of the classification techniques, in contrast to the null hypothesis, which holds that all classification techniques have the same performance behavior when employed to address classification problems. According to the statistical findings shown in Table V, the GBC method is the most accurate classifier. This shows that the GBC technique came in first for classification accuracy shared with the KNC classifier while coming in third rank for precision rate, behind RFC and KNC classifiers, first in recall rate, and first in F1 metric measure shared with the RFC classifier. These findings demonstrate the GBC classification method's breadth is better than that of its competitors. In drawing things to a close, it is



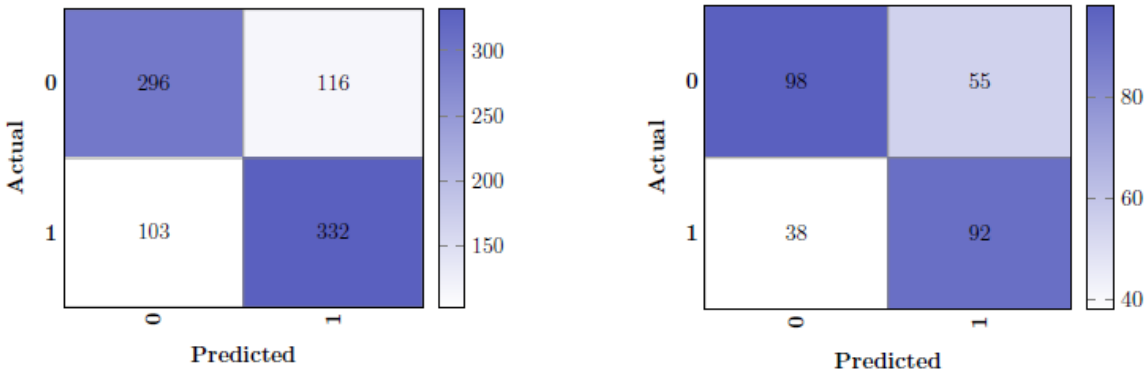
(a) Training. (b) Testing.

Fig. 11. GNB confusion matrices.



(a) Training. (b) Testing.

Fig. 12. RFC confusion matrices.



(a) Training. (b) Testing.

Fig. 13. KNC confusion matrices.

evident that the GBC classification method received the most excellent rank in terms of the total quantity of recall rate, with a rank of 1.0, the lowest rank of all the ranks that the other classifiers have.

The difference between the control classifier and its rivals was then demonstrated using Holm's statistical test as a *post-hoc* statistical method. Friedman's test findings confirm this, demonstrating that the control classification technique outperforms all others in each evaluation metric measure. The statistical findings from Holm's statistical process are shown

TABLE V. AVERAGE RANKING RESULTS OF ALL RIVAL CLASSIFICATION TECHNIQUES REGARDING ACCURACY, PRECISION, RECALL, AND F1 METRIC MEASURES USING FRIEDMAN'S TEST

Classifier	Accuracy	Precision	Recall	F1	Total ranking
LR	5.25	5.5	4.0	5.0	19.75
SVM	4.75	5.0	3.0	4.0	16.75
GBC	2.0	3.0	1.0	1.5	7.5
GNB	4.75	3.75	5.5	6.0	20
KNC	2.0	2.75	3.5	3.0	11.25
RFC	2.25	1.0	4.0	1.5	8.75
p-value	0.220640	0.177047	0.279401	0.083747	

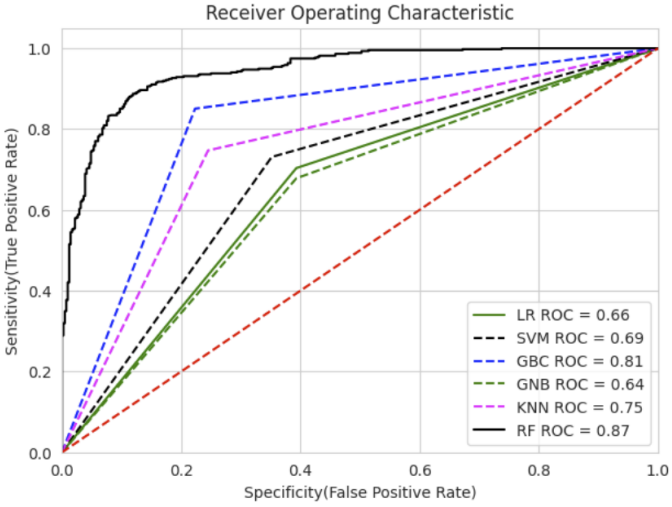


Fig. 14. The Receiver Operating Characteristic curve for the different techniques.

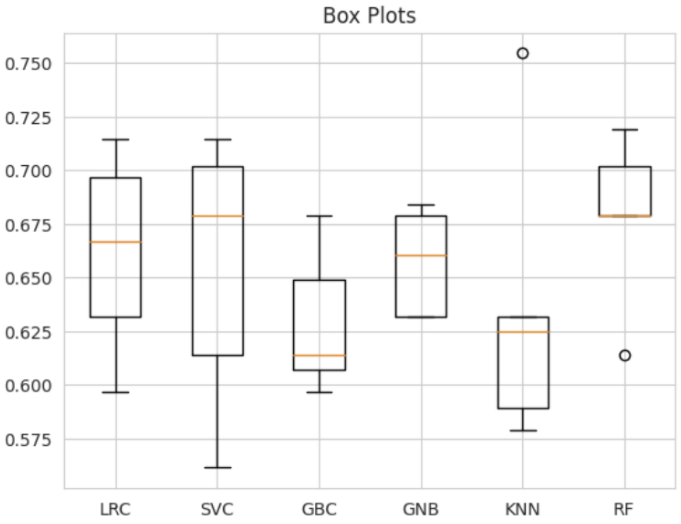

Fig. 15. Box-and-whisker plot for the used techniques.

in Table VI. As per the data reported in Table VI, the control classifier's rank is R_0, the ith classifier's rank is R^i, the effect size of the control classifier's classification technique on the ith classifier is ES, and the statistical difference between two classification techniques is z.

Holm's test was utilized to assess the competing classification systems. This test eliminates hypotheses with p-values of $\leq$ 0.010000 for classification accuracy, $\leq$ 0.010000 for precision, $\leq$ 0.010000 for recall, and $\leq$ 0.010000 for F1 rates, respectively. Table VI demonstrates that GBC outperforms LR, SVM, GNB, KNC, and RFC in terms of classification accuracy, even if there is no statistically significant difference between GBC and the other classification techniques (i.e. LR, SVM, GNB, KNC, and RFC). Friedman's and Holm's test-based statistical precision findings show that the RFC technique and the GNB, KNC, and GBC classification methods do not vary significantly from one another. The RFC approach, however, differs dramatically from the two classification techniques (LR and SVM). The findings in terms of the recall rate show that while GBC differs significantly from the GNB classification technique, it does not differ from the other three competing classifiers (i.e. LR, SVM, KNC, and RFC).

Tables VI and V display the results of Holm's and Friedman's tests, respectively, which demonstrate that the GBC classification method outperforms the other competing methods in achieving promising accuracy and precision rates for the datasets being studied. Overall, the GBC classification method outperformed a number of cutting-edge classification methods disclosed in the literature, including LR, SVM, KNC, and RFC, according to the results of the statistical study discussed above. This demonstrates the GBC method's consistent performance and attests to the fact that it successfully solves classification issues with low, medium, and high dimensions. In addition, GBC's performance degree is close to that of RFC and KNC classifiers as per the average rankings of classification techniques regarding precision rate. Still, the performance level of GNB and LR classifiers falls far short of its RFC and KNC competitors. This leads one to the conclusion that the GBC as a classification model gives it such exceptional capacity to handle classification difficulties. These statistical analysis tests demonstrate the reliability and suitability of the GBC tool as a classification method. These findings provide compelling justifications for employing the GBC classifier to classify difficult datasets progressively.

VII. CONCLUSIONS AND FUTURE WORK

This research aims to examine the feasibility of using machine learning techniques to identify cases of OSA. Traditional techniques of diagnosing OSA are costly and logistically difficult, even though they impact a large percentage of adults. Methods for diagnosing OSA in this study included Logistic Regression, Support Vector Machines, Gradient Boosting Classifier, Random Forest Classifier, Gaussian Naive Bayes,

TABLE VI. RESULTS OF HOLM'S TEST BETWEEN SEVERAL CLASSIFICATION TECHNIQUES

Classification accuracy (GBC is the control classifier)					
i	Algorithm	$z = \frac{(R_0 - R^i)}{SE}$	p-value	$\alpha \div i$	Hypothesis

and K-Nearest Neighbors Classifier. Results showed that the Random Forest Classifier performed the best, with an accuracy of 0.87 during training and 0.65 during testing. The ROC curve produced a score of 0.87. The proposed work achieved classification accuracy comparable to other related studies. However, unlike most existing pieces that utilize PSG or ECG, which can be costly and time-consuming for physicians and patients, we employed physical parameters that are easy to obtain. Future research may explore the potential of other machine learning (ML) techniques, including artificial neural networks (ANN) and decision trees (DT), to address the problem at hand. By exploring these different ML techniques, it may be possible to improve the accuracy and generalizability of the model and gain new insights into the problem domain.

Design of On-Premises Version of RAG with AI Agent for Framework Selection Together with Dify and DSL as Well as Ollama for LLM

Kohei Arai
Department of Science and Engineering, Saga University, Saga City, Japan

***Abstract*—Currently, most RAGs are cloud-based and include Bedrock. However, there is a trend to return from the cloud to on-premises due to security concerns. In addition, it is common for APIs to call Lambda or EC2 for data access, but it is not easy to select the optimal framework depending on the data attributes. For this reason, the author devised a system for selecting the optimal framework using an AI agent. Furthermore, the author decided to use Dify, which is based on a DSL, as the user interface for the on-premises version of RAG, and ollama as a large-scale language model that can be installed on-premises as well. The author also considered the specifications of the hardware required to build this RAG and confirmed the feasibility of implementation.**

Keywords*—RAG (Retrieval-Augmented Generation); API (Application Programming Interface); Lambda; EC2 (Amazon Elastic Compute Cloud); AI agent; Dify; DSL (domain specific language); ollama; YAML (YAML Ain't Markup Language)

I. Introduction

The name RAG (Retrieval-Augmented Generation) and its specific methodology were proposed in 2020. In a paper published by researchers from Facebook AI Research (now Meta AI), University College London, and New York University, RAG was introduced as a "general-purpose fine-tuning recipe"[1].

RAG research ran on a cluster of NVIDIAS GPUs[2] and demonstrated how to make generative AI models more reliable. The research aimed to link generative AI services with external resources, especially those containing the latest technical details.

The concept of RAG has spread rapidly since its introduction and is now adopted in hundreds of papers and many commercial services. This technology has significantly improved the capabilities of large-scale language models (LLMs) and taken question answering systems to a new level.

The development of RAG is the culmination of many years of research in information retrieval and natural language processing and has become an important part of modern AI technology. It is expected that this technology will continue to evolve and contribute to improving the performance and reliability of AI systems.

Research issues related to RAG play an important role in the development and practical application of this technology. Some of the main research issues are listed below.

1) Chunking and embedding: The performance of RAG systems depends heavily on the chunking and embedding methods used. Optimal chunking methods: Research is needed to find effective ways to segment documents and extract relevant information appropriately [1]. Embedding multimedia content: Research is needed to find effective ways to embed non-text data (images, audio, video, etc.).

2) Comparison of RAG and fine-tuning: RAG and fine-tuning of LLMs (large-scale language models) take different approaches. Performance comparison: Research is needed to systematically compare the performance of both methods under various tasks and conditions. Cost-effectiveness: A comparative analysis of the costs of implementation and operation is also an important issue. Applicability: Research is needed to clarify in what situations and applications RAG and fine-tuning are suitable.

3) Testing and monitoring of RAG systems: Quality assurance and continuous improvement of RAG systems are important research topics. Establishment of performance evaluation indicators: It is necessary to develop indicators to properly evaluate the performance of RAG systems. Monitoring methods during operation: Research is required on methods to continuously monitor and improve system performance in actual usage environments.

4) Context optimization: Proper context management is essential for improving the performance of RAG systems. Optimization of chunk size: Research on the optimal chunk size is required, as larger contexts may produce better results. Balance with token restrictions: Optimization research is required that takes into account the trade-off with LLM token restrictions and latency.

5) Efficiency and cost reduction: Improvements in efficiency and cost are important for practical use of RAG systems. Semantic cashing: Research is being conducted into methods to reduce the number of LLM calls and reduce costs and latency by cashing frequent queries and their answers.

[1] https://blogs.nvidia.co.jp/2023/11/17/what-is-retrieval-augmented-generation/

[2] https://en.wikipedia.org/wiki/List_of_Nvidia_graphics_processing_units

Utilization of open-source models: For small texts, open-source sentence embedding models may perform as well as commercial models, and research in this area is progressing.

In this paper, open-source models utilizing RAG are investigated and designed to enhance cost-effectiveness. Currently, many RAG systems are cloud-based and use services such as Amazon Bedrock[3]. However, due to security concerns, there is a trend of moving from the cloud to on-premises environments. Traditionally, data access was typically achieved through API calls via AWS Lambda or EC2[4], but it was not easy to select the optimal framework according to the data attributes.

To address this challenge, the author devised a system that utilizes an AI agent to select the optimal framework. In addition, they adopted DSL[5] (Domain Specific Language)-based Dify[6] as the user interface for the on-premises version of RAG, and selected ollama[7] as a large-scale language model that can be deployed on-premises. In this paper, ollama llama3.2 is used.

The author also considered the specifications of the hardware required to build this RAG system and confirmed the feasibility of implementation. This made it possible to build an efficient and flexible RAG system while placing emphasis on security.

The following section described the related research works on RAG followed by proposed RAG system. Then, software and hardware requirements are described. After that, the conclusion is described with some remarks and discussions.

II. Related Research

There are the following RAG related papers, Retrieval-augmented generation for knowledge-intensive NLP (Natural Language Processing) tasks is proposed. Natural Language Processing (NLP) tasks include sentiment analysis, entity recognition, text summarization, machine translation, speech recognition, text classification, chatbot interaction, keyword extraction, question answering, part-of-speech tagging, topic modeling, predictive text, conference resolution, and spam detection; essentially, any activity where a computer analyzes and understands human language to perform a specific function. This paper is the first to propose the RAG model, an approach that improves performance on knowledge-based tasks by integrating a retrieval component into a generative model [2].

Improving zero-shot generalization in text classification using retrieval-augmented language models are proposed. In this study, the authors applied RAG to text classification tasks, aiming to improve zero-shot generalization performance. The authors showed that using a retrieval component improves classification accuracy for unseen classes [3].

RAG for knowledge-intensive NLP tasks is discussed. The paper provides a detailed description of RAG architecture and evaluates its performance on a variety of tasks, showing that it performs particularly well on knowledge-based tasks such as question answering and sentence generation [4].

Dense passage retrieval for open-domain question answering is proposed. In this study, a density-based passage retrieval method is proposed for open-domain question answering tasks, which is often used as the retrieval component of the RAG model to improve the accuracy of question answering [5].

Other than these, there are the following recent research works,

Self-RAG: Learning to Retrieve, Generate, and Critique through Self-Reflection is proposed which appears in the URL of https://arxiv.org/abs/2310.11511, [6].

Atlas: Few-shot Learning with Retrieval Augmented Language Models are proposed which appears in the URL of https://arxiv.org/abs/2208.03299, [7].

Internet-Augmented Dialogue Generation is also proposed which appears in the URL of https://arxiv.org/abs/2107.07566, [8].

REPLUG: Retrieval-Augmented Black-Box Language Models is proposed which appears in the URL of https://arxiv.org/abs/2301.12652, [9].

Dense Passage Retrieval for Open-Domain Question Answering is proposed which appears in the URL of https://arxiv.org/abs/2004.04906, [10].

Realm: Retrieval-Augmented Language Model Pre-Training is proposed which appears in the URL of https://arxiv.org/abs/2002.08909, [11].

Improving language models by retrieving from trillions of tokens are proposed which appears in the URL of https://arxiv.org/abs/2112.04426, [12].

Query2doc: Query Expansion with Large Language Models are also proposed which appears in the URL of https://arxiv.org/abs/2303.07678, [13].

Chain-of-Note: Enhancing Robustness in Retrieval-Augmented Language Models are proposed which appears in the URL of https://arxiv.org/abs/2311.09210, [14].

On the other hand, Dify related research works are as follows,

The literature on data integration in general, DSLs, and Dify is as follows: "A Survey of Data Integration Systems" This paper provides an overview of data integration systems and various approaches [15].

"Domain-Specific Languages: An Annotated Bibliography" This paper provides an overview of DSLs and examples of various amana DSLs [16].

"SIGMOD Conference Proceedings" Research results on data integration and DSLs are also presented at the SIGMOD conference [19].

"Technical Report: Data Integration Using DSLs" Some research institutes have published technical reports on data integration using DSLs [20].

"Data Integration: A Theoretical Perspective" This book provides a detailed explanation of the theoretical background of data integration [21].

"Domain-Specific Languages in Action" This book gives practical examples of the application of various DSLs [22].

GitHub Repository: Some open-source projects publish code for data integration tools using DSLs [23].

III. Proposed RAG System

A. System Configuration

The on-premises version of RAG is intended to be created. The author devised a system that utilizes an AI agent to select the optimal framework. In addition, they adopted DSL-based Dify as the user interface for the on-premises version of RAG, and selected ollama as a large-scale language model that can be deployed on-premises.

Fig. 1 shows the block diagram of the proposed RAG.

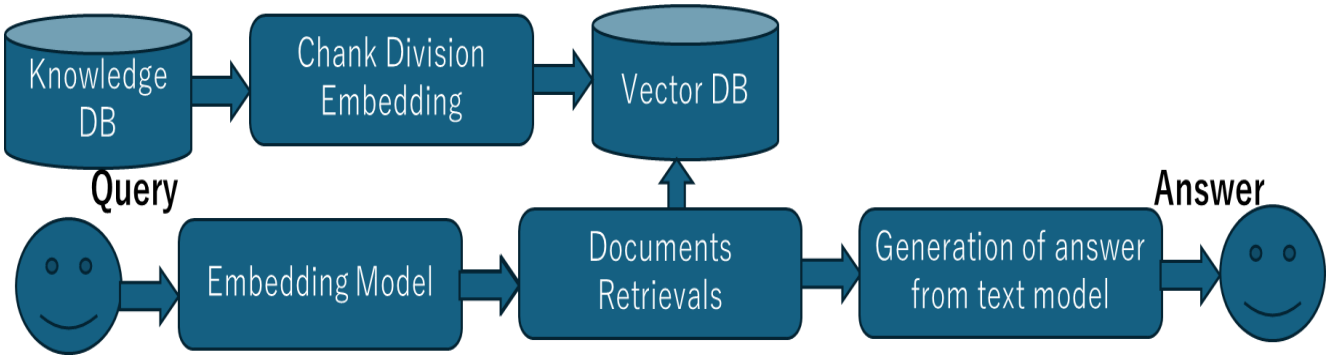

Fig. 1. Block diagram of the proposed RAG system.

The process from query to answer generation in the RAG system goes through the following steps:

1) Query processing: The system receives a question or task (query) from the user and converts it into a format that the system can easily understand. The system uses natural language processing technology to analyze the meaning of the query. Converts it into a format suitable for search.

2) Information retrieval: Based on the converted query, the system searches the knowledge base for relevant information. Query vectorization: Converts the question into a numerical expression (vector). Similarity calculation: Calculates the similarity between the query vector and the vector of information in the knowledge base. Ranking: Ranks the most relevant information based on the similarity.

3) Context generation: Based on the information obtained from the search results, the system generates a context related to the question.

4) Answer generation: A generative model (usually a large-scale language model) takes the query and context as input and generates an appropriate answer. Integrates the given information and then creates an answer in natural language.

5) Post-processing: The generated answer is further processed to be formatted into the final output format. Formatting the answer and filtering inappropriate content as well as adding additional information where necessary (e.g. citing sources). After that, adjust the length and complexity of the answer.

6) Output: The final answer is presented to the user. Answer in text form and possibly include relevant images, links, and/or additional references.

7) Feedback and learning: Many RAG systems have mechanisms for collecting user feedback and continually improving the system's performance. Recording user responses (e.g. clicking the "helpful" button) and evaluating the accuracy and relevance of answers as well as tweaking search algorithms and generative models based on feedback.

As for the user interface, Dify is featured as follows:

Dify has all the features to develop AI apps. It also supports hundreds of AI language models, allowing creating custom chatbots with intuitive operations. It also has a high-performance and flexible RAG engine, allowing building AI agents to use a variety of tools. It can also be freely designing workflows.

Dify Studio[8] offers three ways to create an application: It can be used on an application template. It can start with a blank application. You can create one (locally or online) by importing a DSL file. To get a quick overview of the types of applications

[8] https://note.com/jolly_dahlia842/n/n41bf7cf085fd

you can create with Dify, select "Studio" from the navigation menu, then "Create from Template" from the application list.

When creating the first application with Dify, it is important to understand the basic concepts behind the four different types of applications: chat voice, text generators, agents, and workflows. Also, when creating an application, give it a name, choose an appropriate icon, and briefly describe the purpose of this application to make it easier to use within your team.

Dify DSL is a standard file format (YML) [9] for AI application development defined by Dify.AI. This standard includes basic information about the application, model parameters, orchestration settings, etc. Firstly, import local DSL files. Then if a DSL file (template) exists, provided by the community or others, select "Import DSL file" from Studio. After importing, the original application settings will be loaded directly. After that, import a DSL file via URL. It can import a DSL file via URL using the following format: https://example.com/your_dsl.yml

DSL is a specialized language designed to efficiently build and configure AI applications on the Dify platform. The features of Dify DSL are: YAML format[10]: Dify DSL is written in YAML format, Workflow definition: It can concisely define the workflow and settings of your application and sharing and reuse: It can easily share and reuse the workflow you created by exporting and importing it as a DSL file.

To use DSL, it can import it from the Dify dashboard by selecting "Create an app" and then "Import DSL file". Then select the YAML file and click the "Create" button. Customize it: After importing, it can adjust the workflow and settings as needed. Finally, export it: it can export the workflow it created as a DSL file and share it with other users.

It can easily create chatbots specialized for specific industries or purposes using knowledge bases. This application can be developed without programming expertise by combining Dify's no-code interface with the flexibility of DSL. In addition, it can export and import the workflow it created as a DSL file, making it easy to share and reuse within a team or community.

B. Ollama of LLM

Next, the author will explain ollama, a small-scale LLM that can run on-premises on a local machine. It has the following features:

Local execution: With ollama, you can run LLM on your own computer without an Internet connection.

Multiplatform support: Currently it supports Mac and Linux and will support Windows in the future.

Various models: It supports large-scale language models such as Llama. Users can select and use various models.

Easy environment construction: It is relatively easy to install and configure, and you can easily obtain and run models from the command line.

Python integration: ollama can be used from Python environments using the ollama-python library. This allows you to leverage local LLMs through APIs and integrate them into RAGs and agents.

Customizability: Since it is open source, users can customize it to suit their needs.

Security: Since it runs locally, it is suitable for projects that value data privacy and security.

Ollama is a powerful tool for individuals and businesses to effectively leverage AI technology, allowing them to run advanced natural language processing tasks such as text generation, question answering, and text summarization in a local environment.

To install ollama, follow the steps below:

Download the installer from the ollama official website.

Open the downloaded file and follow the instructions to install.

Once the installation is complete, a llama icon will appear in the taskbar on Windows.

Download and run the model

Open Command Prompt (Windows) or Terminal (Mac/Linux).

Run the following command to download and run the model:

bash

ollama run gemma2:2b

This command downloads and runs the Gemma 2b model. If the model is not already available locally, it will be downloaded automatically.

To interact with the AI, once the model is running, a prompt will appear. Enter users' message and press Enter, and the AI will respond.

Users can customize and manage your models using the following commands:

ollama create: Create a custom model

ollama show: Show model information

ollama list: Show a list of installed models

ollama rm: Delete a model

C. Python Code for Knowledgebase Creation

In this example we'll create a simple knowledge base with a dictionary structure and show how to perform some basic operations. Python code for creation of Knowledgebase System is as follows,

python

class KnowledgeBase:

[9] https://docs.dify.ai/guides/application-orchestrate/creating-an-application

[10] https://spacelift.io/blog/yaml

```
def __init__(self):
self.knowledge = {}
def add_fact(self, key, value):
"""Add a new fact to the knowledge base"""
self.knowledge[key] = value
def get_fact(self, key):
"""Get a fact from the knowledge base"""
return self.knowledge.get(key, "No information found")
def update_fact(self, key, value):
"""Update an existing fact"""
if key in self.knowledge:
self.knowledge[key] = value
return True
return False
def remove_fact(self, key):
"""Remove a fact from the knowledge base"""
if key in self.knowledge:
del self.knowledge[key]
return True
return False
def list_all_facts(self):
"""List all facts in the knowledge base"""
return self.knowledge
# Knowledge Base Usage Example
if __name__ == "__main__":
kb = KnowledgeBase()
# Add fact
kb.add_fact("Python", "High-level programming language")
kb.add_fact("AI", "Artificial intelligence")
kb.add_fact("ML", "Machine learning")
# Get fact
print(kb.get_fact("Python")) # Output: High-level programming language
print(kb.get_fact("Database")) # Output: No information found
# Update fact
kb.update_fact("AI", "Artificial intelligence technology")
print(kb.get_fact("AI")) # Output: Artificial intelligence technology
# Remove fact
kb.remove_fact("ML")
# List all facts
print(kb.list_all_facts())
```

This simple implementation can be extended as follows:

1) Persistence: Use a database (e.g. SQLite) to store the knowledge base and maintain the information even after the program ends.

2) Complex data structures: Store objects or structured data instead of simple strings.

3) Search capabilities: Implement advanced search capabilities using keyword searches or regular expressions.

4) Version control: Add the ability to track changes to each fact.

5) Relationship expression: Be able to express relationships between facts (e.g. a graph database-like approach).

6) Inference engine: Implement a simple inference function to derive new facts from existing facts.

D. Required Hardware Specifications

The hardware specifications for building a RAG using ollama are as follows.

1) CPU

a) Best choice: Intel CPU of 11th generation or later that supports the AVX512 instruction set, or AMD CPU based on Zen4. An AMD CPU based on the "Zen 4" architecture is the first AMD processor to support the AVX-512 instruction set, meaning if you're looking for an AMD CPU with AVX-512 capability, you should choose one based on the Zen 4 microarchitecture.

b) Reason: To speed up the matrix calculations required for AI models

c) Minimum requirement: Any CPU that supports the AVX instruction set will work

2) RAM

a) Recommendation: 16GB or more

b) Reason: To comfortably run models with 7B parameters

c) Minimum requirement: May work with around 8GB

3) Storage

a) Recommendation: 50GB of freer space

b) Breakdown: Docker container (2GB+), model file, vector store, etc.

4) GPU

a) Recommended: Equipped with NVIDIA GPU (e.g. GTX 1080 Ti or higher)

b) Reason: Can significantly speed up model inference

c) Not required: Can be run with CPU only, but processing speed will be reduced.

In this connection, GIGABYTE AORUS GeForce GTX 1080 Ti 11GB Video Card - GV-N108TAORUS-11GD[11] is one of the candidates.

Other points to consider are that if you are using larger models (13B or more), a high-performance GPU and 32GB or more of RAM are recommended. Users also need to consider the amount of VRAM (depending on the model size and quantization level). ollama can run on relatively lightweight systems, but to get comfortable user experience, it is recommended that you use the above recommended specifications as a guide. Especially in the RAG system, it is desirable to have a generous specification because building and searching the vector store also requires resources.

E. AI Agent

Although the definition of an AI agent may vary slightly depending on the technical field, it generally refers to software that interacts with its environment, collects data, and autonomously executes tasks based on that data to achieve a specific goal. In particular, our focus here is on AI agents based on LLMs. Using an AI agent as the user interface of the RAG system is a good approach to achieve a more flexible and advanced conversational interface. Below are some recommended implementation ideas.

1) Multi-agent system: This method uses a combination of multiple specialized agents.

a) Triage agent: Analyzes the user's question and assigns it to the appropriate specialized agent.

b) Search agent: Responsible for the search function of the RAG system to retrieve related information.

c) Answer generation agent: Generates an appropriate answer based on the search results.

d) Dialogue management agent: Manages the flow of dialogue with the user and asks additional questions as necessary.

In this method, each agent specializes in a specific role, allowing complex tasks to be handled efficiently.1.

2) Plan-and-Execute agent: This method is performed by a single advanced agent that plans and executes the plan.

Analyzes the user's question and plans the steps required to answer it.

Based on the plan, it sequentially searches the RAG system, integrates information, generates answers, etc.

The plan is revised as necessary to generate the final answer.

This method is particularly effective when complex questions or multi-step processing are required.1.

3) Conversational RAG Agent: An agent that collects information through dialogue with the user and gradually refines its answer.

It first provides a concise answer to the user's initial question.

It then asks the user if additional information or clarification is needed.

Based on the user's response, it re-uses the RAG system to complement the information and expand the answer.

This method allows for flexible information provision tailored to the user's needs.

4) Self-improving RAG Agent: An agent system that incorporates a feedback loop.

After answering the user's question, it asks for feedback on the quality and appropriateness of the answer.

Based on the feedback, it automatically adjusts how it generates search queries and constructs answers.

Continuous learning improves performance over time.

This method is particularly effective in long-term use, allowing the system to continually improve its accuracy and usefulness.

Implementation Considerations:

1) Model selection: Using high-performance models such as GPT-4 allows for more sophisticated dialogue and accurate information processing.

2) Context management: It is important to properly manage long-term dialogue history and maintain consistent dialogue.

3) Error handling: Users need to implement a way to handle cases when the agent cannot respond appropriately and provide appropriate feedback to the user.

4) Security and privacy: Be careful with user data, filtering and anonymizing information where necessary.

By using these recommendations as a starting point and customizing them for specific use cases and requirements, it can implement an AI agent as an effective RAG user interface.

F. Swarm AI Agent

Swarm is a framework for multi-agent orchestration released by OpenAI on October 12, 2024[12]. This framework uses Python and is designed to enable AI agents to work together and autonomously complete complex tasks. By using Swarm, it becomes easy to build multi-agent systems.

Another library for building AI agents is LangGraph[13]. LangGraph is feature-rich and highly flexible but tends to be complicated to implement. In contrast, Swarm has fewer features but is very easy to implement.

Table I shows the classes for creating AI agents. Users can set the agent's name, behavior, model to be used, etc. client.run() is a function to execute the created agent. The arguments of this function are shown in Table II.

It processes messages for the agent and advances conversation. Furthermore, run_demo_loop() is a function to

[11] https://www.gigabyte.com/jp/Graphics-Card/GV-N108TAORUS-11GD#kf

[12] https://github.com/openai/swarm

[13] https://langchain-ai.github.io/langgraph/

repeatedly run the created agent on the console as shown in Table III. It uses client.run() internally to run the agent.

TABLE I. THE CLASSES FOR CREATING AI AGENTS

Field_Name	Type	Default	Description
name	str	"Agent"	Name_of_the_agent
model	str	"gpt-4o"	AI_model_to_use
instruction	str	You_are_a_helpful_agent.	Instructions_to_the_agent
functions	List	[]	List_of_functions_available_to_the_agent
tool_choice	str	None	Specific_tool_to_be_used_by_the_agent

TABLE II. THE ARGUMENT FOR CLIENT.RUN ()

Argument_Name	Type	Initial_Value	Description
agent	Agent	Required	Initial_agent_to_be_called
messages	List	Required	List_of_message_objects
context_variables	dict	{}	Context_with_additional_information
max_turns	int	float("inf")	Maximum_number_of_turns_in_conversation
model_override	str	None	Option_to_change_model

IV. CONCLUSION

On-premises version of RAG is proposed for secure reasons. The proposed RAG utilizes Swarm-based AI agent which allows easy to select the optimal framework depending on the data attributes. Furthermore, the Dify which is based on a DSL is used as the user interface for the on-premises version of RAG. Also, ollama is used as a large-scale language model that can be installed on-premises as well.

Other than that, the specifications of the hardware required to build this RAG and confirmed the feasibility of implementation. It is confirmed that the proposed RAG system can be created with just one PC with a GPU card.

V. FUTURE RESEARCH WORKS

Although it is confirmed that the proposed RAG system can be feasible, knowledgebase system is not being developed. There are so many applications of the proposed RAG system. Therefore, one of the business use cases will be attempted in the near future.

ACKNOWLEDGMENT

The author would like to thank Prof. Dr. Hiroshi Okumura and Prof. Dr. Osamu Fukuda of Saga University for their valuable comments and suggestions.

AUTHOR'S PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January 1979 to March 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post-Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science in April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor at Brawijaya University. He also is an Award Committee member of ICSU/COSPAR. He also is an adjunct professor of Nishi-Kyushu University and Kurume Institute of Technology Applied AI Research Laboratory. He wrote 119 books and published 728 journal papers as well as 569 conference papers. He received 98 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, Science award of Ministry of Mister of Education of Japan in 2015 and so on. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

Deep Ensemble Method for Healthcare Asset Mapping Using Geographical Information System and Hyperspectral Images of Tirupati Region

***Abstract*—The ever-increasing capabilities of deep learning for image analysis and recognition have encouraged some researchers investigates potential benefits of merging Hyperspectral Images (HSI) and Geographic Information Systems (GIS) with deep learning in the healthcare industry. Healthcare is an ever-changing sector that constantly adopts new technologies to improve decision-making and patient service. This research digs into the role that GIS and Remote Sensing (RS) play in modern healthcare and their significance. By delivering data from faraway places and enabling spatial analysis, the combination of RS and GIS has transformed healthcare. This GIS & RS data will have the numerous quantity of data so big data analytics can be helpful for storing and retrieving of data. This analysis can open up a new possibility for better healthcare planning, disease management, and environmental health assessment based on the study area's population. This paper deals healthcare assets mapping based on the population and the study area of the Tirupati district hyperspectral image by applying the Deep Ensemble method.**

***Keywords*—Geographical information system; hyperspectral image; remote sensing images; big data analytics; deep ensemble methods; healthcare asset**

I. Introduction

Deep Learning is the ongoing innovation in reaction to emerging threats and possibilities, healthcare is an ever-changing industry. Modern healthcare delivery, public health administration, and resource allocation cannot be improved without incorporating state-of-the-art technology. Notable between these technologies are GIS and RS [14], both of which have become potent instruments with far-reaching consequences in healthcare. Exploring and clarifying the numerous claims of Remote Sensing (RS) and Geographic Information Systems (GIS) is vital for properly understanding their revolutionary potential in healthcare [1]. The field of RS, which includes gathering information about Earth's surface from sensors attached on aircraft or spacecraft, is playing an increasingly important role in medical research and practice. Its applications range from ecological monitoring to public health calculation, illness scrutiny and disaster organization. By gathering information remotely [15], RS provides a vantage point that allows medical personnel to keep tabs on expansive regions with unmatched precision and speed [2]. This GIS & RS data will have the numerous quantity of data so big data analytics is used for keeping and retrieving of info [14]. In contrast, GIS allows the visualisation and understanding of health-related data within a geographical context by making GIS as an ideal tool for spatial data analysis [18]. As a result, healthcare providers are better in allocating healthcare resources, conducting epidemiological studies and ensure that all citizens have access for necessary medical treatments. Improving the quality of healthcare and reducing healthcare inequities depends on GIS-based geospatial approach [19, 21].

This paper deals with the available and need of healthcare facilities in the study area of Tirupati district GIS and hyperspectral image based on the population by applying the Deep Ensemble method.

II. Related Work

A. Imaging Techniques Using Hyperspectral Rays

One method that merges the two regions is hyperspectral imaging. It often encompasses a long stretch of the electromagnetic spectrum and offers real-time scanning imaging throughout dozens or even hundreds of spectral series, including the UV, infrared, VIS and mid-infrared [3]. In Fig. 1, for example, you can see a combination of two-dimensional spatial data with one-dimensional spectral data can see it as a stack of many two-dimensional images [4]. Utilising this method, one can acquire the absorption, reflectance, fluorescence spectra of each individual pixel inside picture [24]. Compared to standard images of RGB and maps in grayscale offers a more robust spectral band and better spectral resolution [16]. It records subtle spectrum subtleties in reaction to various clinical conditions and can detect alterations in things that are invisible with traditional imaging techniques [23,25]. The usual push broom hyperspectral system principle [5]

explains HSI system mechanism, as depicted in Fig. 2. The spatial information is initially illuminated by a light source, which travels via front lens into slit, where light of varied wavelengths is fixed to different degrees. Then, the detector is illuminated with light from every pixel point in that dimension using dispersion devices like prisms and gratings, which divide the light into tiny spectral bands [20].

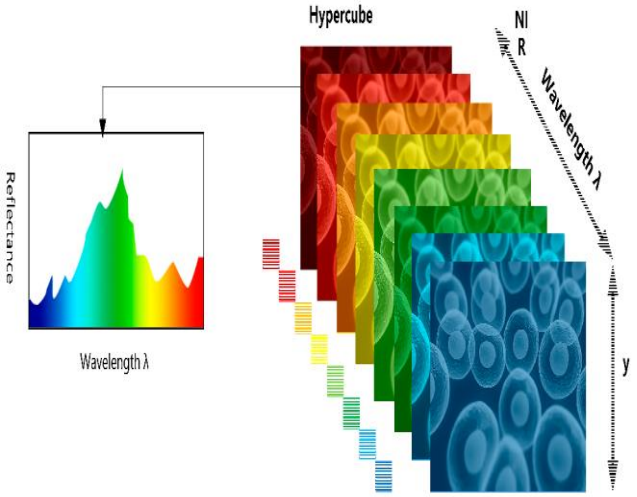

Fig. 1. Spectral data cube (Google courtesy).

The detector array is photographed with each row of sample space info as a 2-D picture. A hypercube with two spatial dimensions and one spectral dimension is created when HSI camera moves via plane using mechanical push sweep and captures adjacent two-dimensional images.

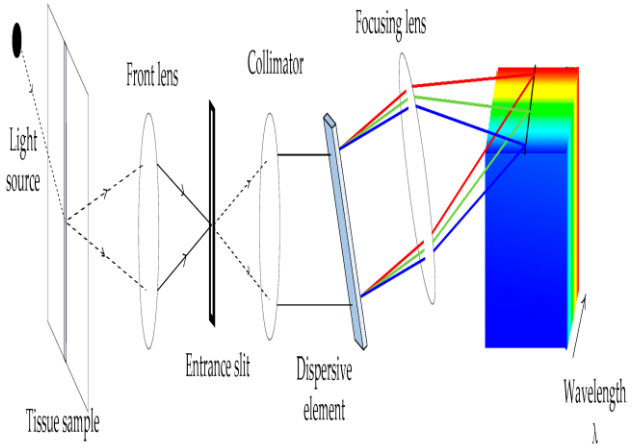

Fig. 2. Hyperspectral imaging system schematic using push-scan technology (Google courtesy).

The smallest discernible object within a picture is called its spatial resolution, and it is the smallest visible detail in the image [26]. There is a practical reason for the sensor's design and the altitude at which it operates above the surface. It is not the number of pixels but the spatial resolution that defines how sharp a picture is. The image sensor's architecture, particularly its height and field of view, determine the spatial properties of an image [27]. The energy received from a specific area of the ground surface is quantified by the remote sensor detector. There is an inverse relationship between spatial resolution and patch size. It is possible to extract more precise spatial information from the picture with smaller individual patches. Only when the cell dimensions are substantially lower than the object dimensions can shape be discerned, which is a common factor. The average brightness of the picture cell is affected by the item's brightness or darkness in relation to its surroundings; hence, this cell will seem brighter than neighboring cells. Linear features, like farm-fresh fruit, may be distinguished with more accuracy than cell dimensions thanks to the high spatial resolution.

A sensor's spectral resolution is defined by the number of spectral bands it can detect and the breadth of the electromagnetic spectrum. Even while an image sensor covers a lot of ground in terms of frequency, its spectral resolution could be inadequate if it only manages to get a few bands. A sensor can differentiate between scenes with identical or almost identical spectral fingerprints if it is accurate in the low-frequency range and catches a large number of spectral bands; this property is known as high spectral resolution [28]. The multispectral images can't pick up on faint spectral signals because of their poor spectral resolution. In the visible, near-infrared, and mid-infrared parts of the electromagnetic spectrum, HSI sensors capture images in numerous neighbouring and incredibly narrow spectral bands. Material identification using their unique spectral fingerprints is a promising area for this advanced imaging technique. One-pixel spectral image from HSI could reveal a lot more about the surface material than a regular range image.

Hyperspectral imaging's temporal resolution is sensor-specific and depends on its orbital properties. The time it takes for a sensor to go back to the same location and take readings is a common definition [29]. This period is also known as return time or revisit. When the sensor platform doesn't return to the same location very often, we say that the temporal resolution is low; when it returns frequently, we say that it has high temporal resolution. Common units of measurement for time resolution are days.

Benefits and drawbacks of hyperspectral scanners. The following are some of the benefits of adopting HSI in many fields, such agriculture [8] and food quality assessment:

1) The technology guarantees the eminence and security of food supplies without invasiveness, contact, or destruction.

2) Since no chemicals are used in the studies, they are safe for the environment.

3) There is a significant time savings compared to chemical and conventional methods when processing for quality valuation and food regulator/storing.

4) Chemical imaging provides a better thoughtful of chemical components of food goods.

5) It offers suitable region selection for crucial picture analysis.

6) It integrates spectral and geographical data to give better information about chemical samples. From relevant platforms, improve the likelihood of data refinement, and accomplish further experiments.

Hyperspectral imaging offers both benefits and drawbacks [30].

1) When compared to other methods of image processing, the price of a hyperspectral imaging system is quite high.

2) High-speed computers and solid-state drives with enormous storage capacities are in high demand due to the massive data sizes generated by hyperspectral imaging.

3) The signal-to-noise ratio may be low because environmental factors like scattering and lighting can affect the signal while collecting the photos.

4) It is typically challenging to detect and identify dissimilar items inside the similar image consuming spectral data except the individual objects consume distinct immersion properties.

B. Health Care Utilisation of RS and GIS

One new technology that the healthcare industry has found a wealth of uses for is remote sensing. The term "remote sensing" describes a method of retrieving data about Earth's surface that does not need physical contact. In most situations, data is gathered remotely via sensors attached to spacecraft or satellites [10]. Incorporating various types of electromagnetic radiation, such as visible light, infrared, and microwave, into the collected data can provide light on the Earth's surface and its characteristics [17]. When it comes to healthcare, RS is also useful for assessing environmental health issues. Environmental changes may influence public health, land use, and water and air quality can all be evaluated with its help [11]. Air pollution levels can be monitored via satellite-based remote sensing, which helps detect areas with poor air quality. This information can then be used to improve public health policies and actions. Further, RS data can be used to investigate environmental factors that may be influencing the incidence of respiratory diseases and other health problems.

Rapid surveying allows for the quick assessment of damage, localization of impacted regions, and population movement tracking. Timely deployment of healthcare resources and planning for healthcare infrastructure rehabilitation following a disaster both rely on this knowledge.

We can gain a more comprehensive and insightful understanding of healthcare-related topics by combining Geographic Information Systems (GIS) with Remote Sensing (RS). This methodology takes advantage of both technologies. This section explores the ways in which Geographic Information Systems (GIS) and Remote Sensing (RS) work together, and it contains real-life examples to show how these two tools can be used together. When combined, the complementary technologies of remote sensing and geographic information systems (GIS) can improve healthcare applications. One way to get environmental data and pictures in real-time is through remote sensing, which can be easily integrated into GIS systems. By placing RS data in a geographical context, GIS allows medical professionals to analyze, understand, and display data in a spatially-based manner.

Remote sensing can furnish imagery depicting variables such as pollution levels, land utilization, or temperature fluctuations. When incorporated into a GIS, this data can facilitate the identification of regions with elevated health risks and support targeted actions. The integration of remote sensing data, including satellite imagery of vegetation and land cover, with geographic information systems can facilitate the comprehension of disease vector habitats and the forecasting of disease outbreaks. This is essential for the management of vector-borne diseases. In the event of natural catastrophes or public health [6] emergencies, remote sensing data can furnish real-time information regarding impacted regions. This data, when incorporated into a GIS, facilitates the effective allocation of healthcare resources. Here we may see how RS and GIS have been put to use in real-world healthcare situations through empirical case studies. Consider the following: Temperature and precipitation are two of the most important environmental factors for mosquito breeding and malaria transmission; a study conducted in a malaria-endemic zone used RS to track these variables. Using GIS, we were able to create models that could predict when malaria epidemics would occur. With the use of early warning systems made possible by RS and GIS integration, hospital authorities were able to distribute resources for management and prevention. Data on urbanization and population growth were gathered using remote sensing (RS) within the context of urban planning. The availability of telehealth services in rapidly expanding urban areas was assessed using Geographic Information Systems (GIS). The study integrated RS and GIS to elucidate the equitable distribution of telehealth services, assisting policymakers in guaranteeing citizens' access to remote healthcare resources [9].

By allowing the geographical analysis of health-related data, Geographic Information Systems (GIS) have completely transformed the healthcare sector. Here takes a look at the big picture of GIS in healthcare and examine their many uses. Capturing, organising, analysing, and visualising spatial data is made easier by a GIS. Analysis best probable localities for healthcare services is one of the main usages of GIS in this commerce. GIS tools examine demographics, convenience, population solidity, and other criteria to determine whether locations have a high need for healthcare services. As a result, people will be able to get the medical treatment they need regardless of where their healthcare facility is located. In addition, GIS helps with healthcare facility management by minimising response times in emergency circumstances by optimising ways for healthcare specialists and ambulances. Healthcare admission and disparities assessments greatly benefit from GIS. By GIS places can be pinpoint wherever persons lack contact to healthcare by healthcare institutions mapping, patient demographics, and socioeconomic data. In order to reduce dissimilarities and assurance a fair dissemination of healthcare possessions, planners and policymakers must have this data.

In spatial epidemiology study GIS is vital for time and space in healthcare. In order to improve understand of geographical outlines of healthcare and their possible reasons, epidemiologists can utilise GIS to map and identify hotspots. In order to focus resources on areas most at danger, this data is priceless for prevention initiatives. These uses highlight the value of GIS in medical settings. When it derives to healthcare

capability locations, resource distribution and disease control GIS will provide professional tools to create data-driven decisions. When trying to make sense of healthcare inequalities and find ways to improve service delivery, having a spatial context is crucial [12].

Combining the strengths of remote sensing and GIS can improve healthcare outcomes may gain more thorough and insightful understanding. RS allows for the direct integration of real-time environmental data and images into GIS systems. On the flip side, healthcare providers can analyse prototype and visualise data in geospatial framework by means of GIS, which provides a spatial context for RS records. Pollution levels, land use, and temperature fluctuations are just a few of the factors that RS photography may reveal. Incorporating this data into a GIS can aid in the identification of high-risk areas for health and the subsequent implementation of targeted interventions. Disease vector habitats and outbreak predictions can be improved with the use of GIS and RS data, which contains satellite imagery of vegetation and land cover. Controlling diseases spread by vectors relies heavily on this. In the result of a public health emergency or natural catastrophe, RS data can give up-to-the-minute details about the areas impacted. The effective allocation of healthcare resources can be aided by including this data into a GIS.

Data on population growth and urban development were captured using RS in an urban planning framework. In order to determine how easily accessible telehealth facilities are in cities that experiencing high population progress GIS is used. The study helped to make sure that people could use remote healthcare resources by combining RS and GIS, which shed light on the fair allocation of telehealth services [13].

Although RS and GIS provide significant advantages to healthcare sector, their implementation is accompanied by hurdles and limits. This delineates the principal challenges encountered in the application of RS and GIS to healthcare initiatives.RS info can be influenced by features like cloud shield, sensor correction and atmospheric situations, potentially resulting in variations in data excellence. Contact to high-resolution remote sensing data is frequently constrained, especially for healthcare applications in underdeveloped regions where satellite or data archive access may be restricted. Utilizing RS and GIS in healthcare effectively necessitates specified skills and information that are not universally possessed by healthcare workers. Training and capacity growth are essential. The incorporation of RS and geographic information system data can be intricate, as it necessitates consideration of varying formats, projections, and scales. This necessitates a resilient IT infrastructure. The integration of geospatial data with healthcare information generates privacy problems. It is imperative to guarantee the ethical and secure utilization of such data. Establishing data ownership and sharing protocols can be complex, as remote sensing and geographic information system data frequently engage several stakeholders, including governmental entities, private enterprises, and academic institutes. Validating remote sensing-derived information with ground-based data can be complex, as it frequently necessitates substantial fieldwork and resources. The precision of predictive models utilizing RS and GIS data may fluctuate and requires thorough validation against empirical data. Confronting these obstacles and constraints is essential for the effective implementation of RS and GIS in healthcare. Cooperative initiatives among researchers, healthcare practitioners, and policymakers are essential to address these challenges and fully exploit the possible of emerging machineries for public health. Table I shows detailed comparison with previous work.

TABLE I. DETAILED COMPARISON WITH PREVIOUS WORK

Aspect	Current Work	Previous Work
Scope	HSI advanced spectral-spatial data is combined with remote sensing and GIS for tracking healthcare and the environment.	Mostly looked at how RS or GIS can be used alone in environmental studies or healthcare, without spectral imaging tools being added.
Integration of Data	Adds real-time RS data to GIS platforms and combines it with HSI for health and environmental apps that use maps.	In the past, methods focused on either GIS for geographic analysis or RS for environmental data, but they didn't include high-resolution spectral imagery (HSI).
Applications in Healthcare	RS-GIS systems that are fully integrated can be used to map disease vectors, plan for public health emergencies, and keep an eye on pollution.	focused more on environmental health factors like the quality of the air or water without using GIS to plan or allocate resources for healthcare.
Environmental Applications	RS and GIS are used together to keep an eye on air pollution, changes in land use, and the health effects of the climate.	Mostly looked at certain environmental measures (like deforestation) without incorporating them into many healthcare-related uses.
Real-World Case Studies	RS-GIS is used to predict malaria outbreaks, make sure that telehealth services are distributed fairly in cities, and map pollutants for public health tactics.	A lot of research has been done on static disease mapping or watching changes in the environment without using predictive modeling or frameworks that combine healthcare and the environment.

Asset Mapping is the method of community strengthening. The next step in asset mapping is to identify the institutions, citizen groups, and individuals within communities that can help put good resources in place. There is a great vibe in the community when assets are mapped out, and those assets may be leveraged to solve any problem. The community's healthcare facilities, parks, libraries, schools, police stations, grocery stores, and so on are its assets.

The primary objective of asset mapping is:

- The goal is to assess the community's current resources and use them to build it stronger.
- Among other things, to use the funds to find community connections and satisfy community needs.
- The community's resources should be acknowledged and appreciated.

C. About Dataset

The Dataset has the latitude and longitude positioning of healthcare unit of Tirupati district study area which is gathered form government portal. The study area selection is shown in Fig. 3.

In the southeastern corner of Andhra Pradesh Tirupati is the ancient holy city. This place is known as the abode of God Venkateswara. Conveniently located near numerous important cities, including Bangalore, Vijayawada, Hyderabad, and Chennai, at the base of the Eastern Ghats. Tirupati is famous for the Tirumala Venkateswara Temple, which is a major pilgrimage site in India and sees a large number of visitors annually. The Tirumala Hills, home to the temple, are among the world's oldest rock formations. People think that the temple even had followers who were members of great dynasties, such as the Pallavas, Pandyas, Cholas, and Vijayanagara rulers. The town's coordinates are 13° 37 N and 79° 25 E. Roughly 22,18 lakh people call Tirupati home, according to the 2011 Census. The winters are mild, but the summers can be quite hot. The official language is Telugu, but Tamil is also widely used due to the region's closeness to Tamil Nadu.

Some of the factors in the dataset are Location Coordinates, which are the healthcare facility's latitude and longitude. with Type of Facility: Which type of healthcare center it is (e.g., hospital, clinic, primary health center), as well as the area, district, state, and name of the hospital or PUC. The type of file is (.CSV). It's about 1GB in size.

Whereas hyperspectral image is in band sequential (BSQ), band-interleaved-by-pixel (BIP), or band-interleaved-by-line (BIL) format downloaded from bhuvan portal based on mapping of areas.

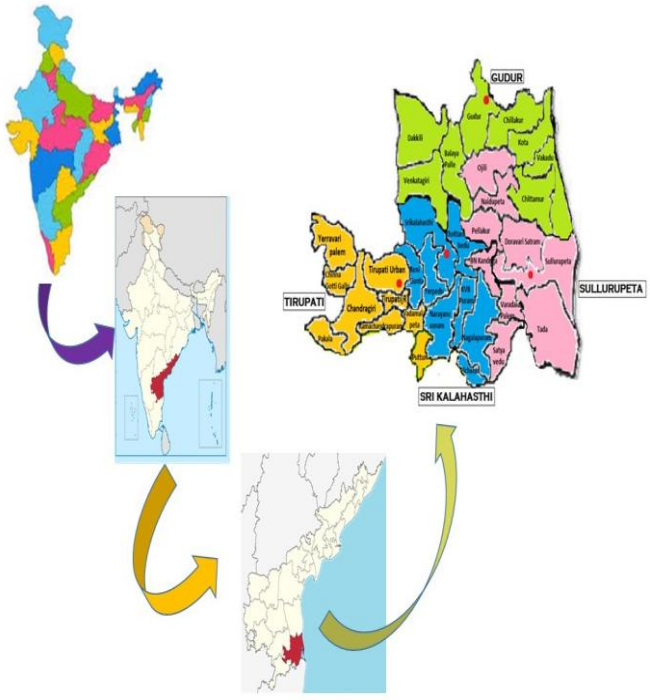

Fig. 3. Study area division (Image created by author).

III. Proposed Methodology

The key objective of our study is to map healthcare asset centred on the GIS and positions of healthcare asset in hyperspectral images to know the need of healthcare unit in the Tirupati District study area by using deep architectures base models. The methodology procedure is as shown in Fig. 4.

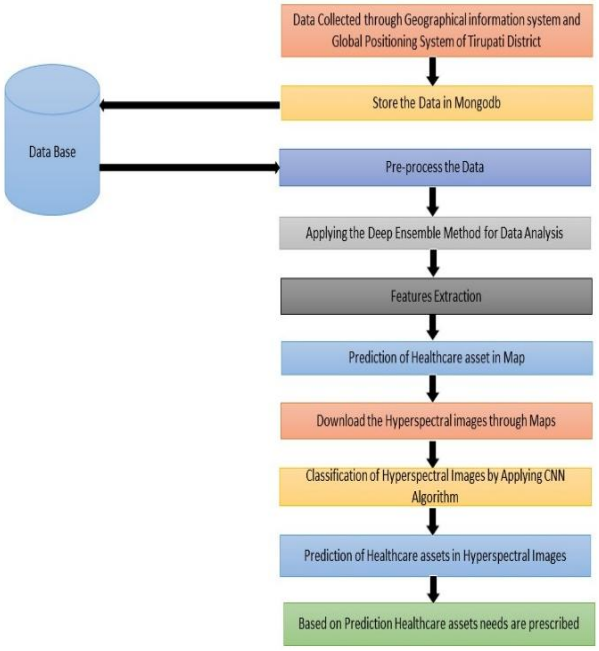

Fig. 4. Methodology procedure.

A. Deep Ensemble Method

The construct of heterogeneous ensembles with multiple base models and combine their results to make a more informed decision, taking advantage of recent architectural developments in GIS analysis. here makes use of both our fusing technique and classical fusers like XGBoost, AdaBoost. The method involves superimposing the model on top of the first ensemble. For an example of how it is trained on vectors of feature.

$$\mathscr{F} = [\boldsymbol{o}1;\ \boldsymbol{o}2;\cdots;\boldsymbol{o}N]^T$$

where $\boldsymbol{o}_i$ is vector output of i-th base model and considered feature vector consistent to ji. For each training sample, N base models are used to build a collective feature vector. This vector is sent to fusing learner. Consequently, larger values of N will result in feature vectors of greater dimension. For a classification assignment, for instance, the i-th base model would use the softmax layer to build c class probabilities, which would be represented by $\boldsymbol{o}_i$ (where $c \cdot N$ is the size of the concatenated feature selection). In contrast, a base boosting would provide more detail on HU's abundances, and all base models would use this same process to combine their abundance vectors. This would result in a final vector of profusions that is N times greater than the sum of the abundance vectors obtained from each vile model individually because it takes the outputs of N models and applies them all. In order to refine the ensemble's output, the fuser combines the initial projections.

B. Image Classification with Convolution Neural Network

Here for classification of hyperspectral images used three convolutional architectures for GIS analysis because it is the most efficient model to ensure that spectral and spectral-spatial generalise. In contrast to the spectral network [7], which is based on [22], two spectral-spatial CNNs are 3D-CNN [18] and 2.5D-CNN [17]. The former model does pixel-wise classification, while the latter performs patch-wise cataloguing of central pixel in each consistent area. The area sizes for 2.5D-CNN were determined according to the recommendations in [19]. While both the 3D-CNN and 2.5D-CNN models use spatial and spectral info to categorise the input patch's central pixel, the 3D-CNN model takes advantage of small (3×3×3) convolutional kernels to capture hyperspectral cube's fine-grained spectral interactions. It differs from 2.5D-CNN, which uses kernels that cover the complete spectrum, i.e., μ. categories in the initial convolutional layer.

C. Performance Metrics

Accuracy is defined as the number of right predictions out of all the instances.

$$Accuracy = \frac{True\ Positive + True\ Negatives}{Total\ Instances}$$

Precision is the number of successfully predicted positive cases out of all the predicted positive cases.

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives}$$

Recall is the number of properly predicted positive cases to all actual positive cases.

$$Recall = \frac{True\ Positives}{True\ Positives + false\ Negatives}$$

The F1 Score is the harmonic mean of accuracy and memory, which makes it a fair measure.

$$F1\ Score = 2 * \frac{precision * recall}{precision + recall}$$

In multi-class classification problems, the Macro Average is a performance measure that gives an overall picture of a model's accuracy, recall, or F1 score by giving each class the same weight, no matter how big it is or how many times it appears in the dataset.

$$M_{macro\ avg} = \frac{1}{N}\sum_{i=1}^{N} M_i$$

N represents number of Class

M_i *represents Metric value for class i*

In multi-class classification, the Weighted Average is another way to measure success. It figures out the general metric (like F1 score, precision, or recall) by giving each class a weight based on how much data it has.

$$M_{weighted\ avg} = \frac{\sum_{i=1}^{N} M_i \,.\, n_i}{\sum_{i=1}^{N} n_i}$$

N represents number of Class

M_i *represents Metric value for class i*

$n_i$represents of samples in class i

IV. Experimental Analysis

To map the exact assets, execution is processed by using different classifiers and feature selection measures on two different datasets. Both trials included healthcare unit datasets from the Tirupati district and used hyperspectral image data for categorization and location analysis. This section presents the experimental setup and provides a detailed discussion of the outcomes. We used Python for model coding and QGIS for experimental validation.

At first healthcare facilities asset dataset is taken from Andhra Pradesh state government and it has created through GIS with the latitude and longitude as features. These are stored in mongodb for easy accessing and retrieving of data for the analysis. Applying ensemble classifiers on the data set the predictive model will be constructed. The deep ensemble method which is generated by using XGBoost, AdaBoost. From the data set, 28 features related to the healthcare assets are extracted. The Features are extracted to reduce the quantity of resources needed without losing valuable information. The feature extraction graph for the healthcare assets shown in Fig. 5.

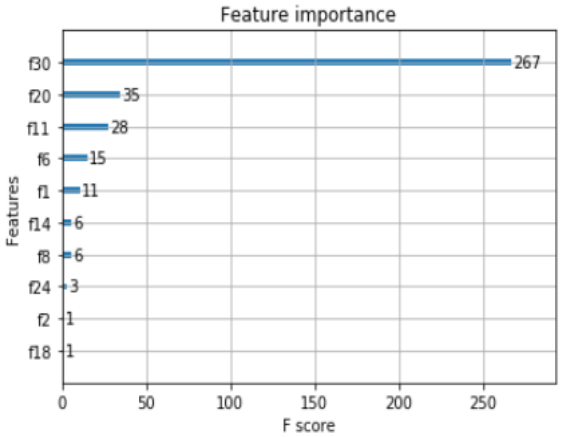

Fig. 5. Extracting the features from deep ensemble method.

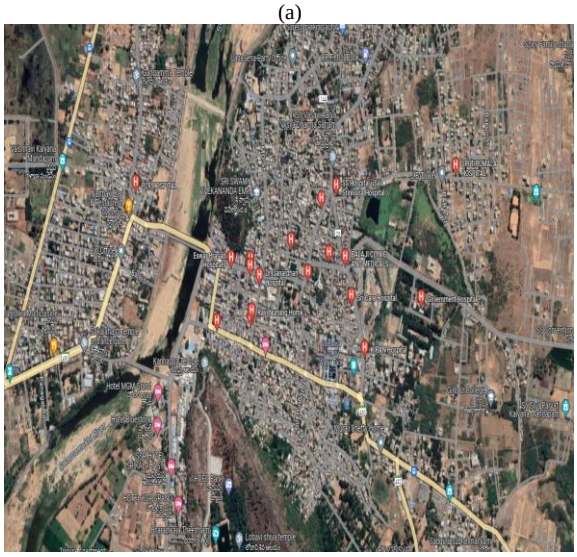
TABLE II. Classification Report of Deep Ensemble Method for Healthcare Asset

	Precision	Recall	F1-Score	Support
Class 0	0.65	0.43	0.51	76
Class 1	0.82	0.92	0.89	194
Accuracy			0.84	256
Macro Avg	0.74	0.71	0.79	256
Weighted Avg	0.84	0.89	0.91	256

When deep learning algorithm is applied on healthcare asset data, classification report is generated with different parameters as shown in Table II like accuracy, weighted avg, macro avg, with precision, F1-Score, Recall by observing table deep ensemble algorithm has the highest accuracy of 84%.

Then after analysing deep ensemble algorithm with healthcare assets GIS data, the dataset is accessed into QGIS in python using interconnection and visualised the hospitals with their locations as shown in Fig. 6 (a) and (b).

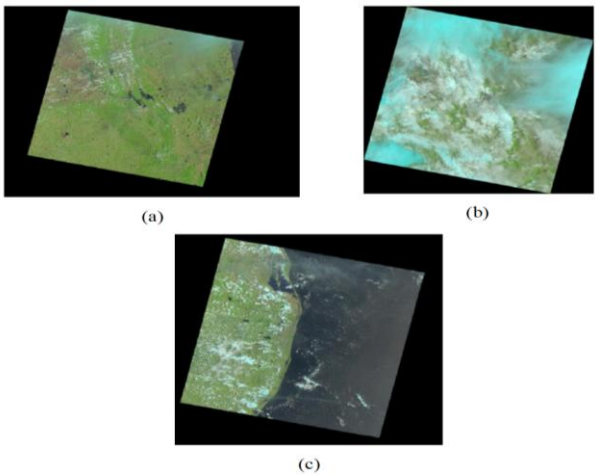
(a)



(b)

Fig. 6. (a): Visualization of Tirupati region healthcare assets. (b): Visualization of Srikalahasti region healthcare assets.

By observing Fig. 6(a) and 6(b) the red color pin with H letter indicates the healthcare assets. In Fig. 6(a) the healthcare assets are located either all the healthcare asset is nearer or for away from the village at tirupati city area. In Fig. 6(b) the healthcare assets are located for way from the village at Srikalalhasti. Then Hyperspectral images are acquired by integrating Python programming with QGIS. This study involves the collection of four distinct Landsat images of Tirupati district to facilitate the classification of healthcare facilities within the region. The hyperspectral images were collected and subsequently pre-processed through various techniques, including data cleaning, integration, transformation, and reduction. The images are subsequently divided into cubes by defining a region of interest (ROI), which is quantified using shapes such as polygons, circles, and rectangles. The subsequent step involves segmenting the images and employing a CNN algorithm to classify the healthcare facilities within the Tirupati district. The landsat input images of tirupati district are shown in Fig. 7 and the classified landsat image are shown in Fig. 8.



(a) (b) (c)

Fig. 7. Tirupati district hyperspectral images.

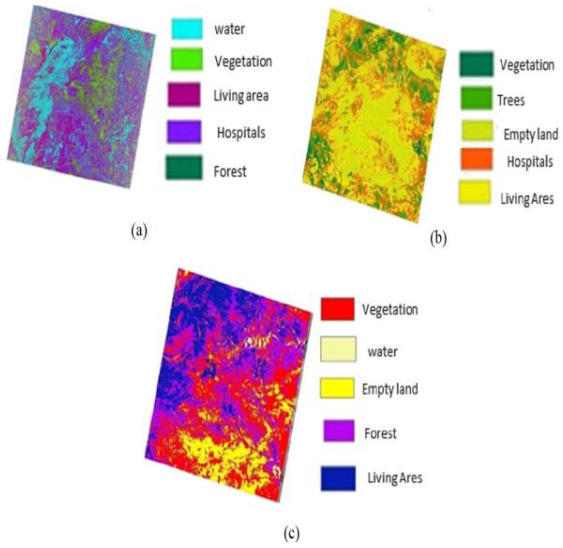


Fig. 8. Tirupati district classified hyperspectral images.

The classification of the healthcare asset in hyperspectral images from three distinct regions of the Tirupati district is presented in Fig. 8, specifically in Fig. 8 (a), Fig. 8 (b), and Fig. 8 (c). In this section, each figure illustrates the classified areas, depicted in various colors, with each color corresponding to a distinct area within that region, such as: In Fig. 8 (a), sky blue colour signifies water, green color indicates vegetation, Marron color represents Living area, Violet color represents Hospitals and Dark green color represents forest. In Fig. 8 (b), Dark green color represents vegetation, green color indicates trees, musted colour represents empty land, Orange color represents Hospitals and yellow color represents Living area. In Fig. 8 (c), Red color symbolizes vegetation, light yellow color indicates water, yellow colour represents empty land, Violet color represents forest and Blue color represents Living area. At last, explored how close healthcare services are to cities and rural areas. With spectral and geographic integration, it was possible

to accurately identify and classify healthcare assets using their locations.

Here, in this work Two sets of healthcare facility data from the Tirupati district (Andhra Pradesh state government) were handled using GIS tools and hyperspectral imaging data to figure out where they are. The dataser took 28 traits from the healthcare dataset. Then, Deep ensemble algorithms (XGBoost, AdaBoost) were used to save resources while keeping important data. The results were shown as feature extraction graphs, and the Deep ensemble method (XGBoost and AdaBoost) got the best results with an 84% success rate. Some of the measures in the classification report are precision, recall, F1-score, weighted average, and macro average. Then Landsat pictures of the Tirupati district were edited and looked at. Steps like cleaning, integrating, transforming, and reducing that were part of the pre-processing are now complete. The data was then split into ROI cubes that were measured with circles, squares, and polygons. CNN used an algorithm to sort healthcare sites into groups. The classification results for three different areas in Tirupati district are shown. Based on the observation the need of healthcare facility is there in this study area.

Because, as per 2024 Censes, the population of tirupati distict is around 77,50,000 (approx.). so by observing our GIS and HSI analysis of healthcare assets it concludes that all the healthcare facilities are either in one place or it in different distance places which are outside the living area. So mainly for every village there is need to have healthcare facility centre for the population who is living there.

V. Conclusion

The deep learning techniques have proven useful for GIS and HSI data sorting and has some limits to use the large-capacity initiates and calls their generalizability into doubt in real-world scenarios. An exciting new paradigm is emerging in medical research and practice at the intersection of deep learning, Big data, GIS, HSI, and healthcare. This convergence has great promise for improving patient outcomes, streamlining healthcare delivery, and addressing public health issues. here presented deep ensembles for GIS analysis, which incorporate as effective base model fusers and other deep architectural advancements to capture and extract needful futures for location identification of healthcare facilities around the study area tirupati district. At last it concludes that there is a need of constructing the healthcare facilities in the tirupati district because as per 2024 censes, the population of tirupati distict is around 77,50,000 (approx.). so by observing our GIS and HSI analysis of healthcare facilities all the healthcare facilities are either in one place or it in different distance places which are outside the living area. So mainly for every village there is need to have healthcare facility centre for the population who is living there.

Path Planning for Laser Cutting Based on Thermal Field Ant Colony Algorithm

Junjie GE, Guangfa ZHANG, Tian CHEN
College of Mechanical Engineering, Shanghai Dianji University, Shanghai 201306, China

***Abstract*—In laser cutting technology, path planning is the key to optimizing cutting quality. Traditional ant colony optimization path planning does not prevent excessive heat effects after processing. This paper addresses the problem of heat accumulation during drilling by introducing a heat factor and a heat threshold into the traditional ant colony algorithm. The heat factor and threshold are used to dynamically control heating and cooling in the path planning process, and the heat factor is updated to update the local pheromone. Then, the improved 2-opt algorithm with the introduced heat factor is combined to parallelly optimize the path, and a thermal field ant colony algorithm is proposed. The simulation experiments and actual cutting results show that the proposed algorithm is more efficient and effective than traditional ant colony algorithm and improved ant colony algorithm in terms of reducing heat accumulation while ensuring fewer empty path, and improving laser cutting processing efficiency and quality.**

***Keywords*—Laser cutting; path planning; ant colony algorithm; thermal field control method**

I. Introduction

Laser cutting technology, known for its high precision and efficiency, is widely used in the manufacturing industry. Path planning plays a crucial role in achieving optimal cutting performance. Traditional path planning methods often fail to reach the optimal solution when dealing with complex conditions, which has led to increasing attention on intelligent optimization algorithms in recent years. Luodengcheng et al. [1] proposed a method that incorporates a potential field factor into the ant colony algorithm to reduce heat accumulation and non-cutting travel distances, thereby ensuring cutting quality. Chang Cuizhi et al. [2] introduced an annealing algorithm to optimize the cutting path of the generalized traveling salesman problem, effectively preventing tool retractions. Makbul Hajad et al. [3] treated all pixels in an image as potential perforation positions and proposed a simulated annealing algorithm combined with adaptive large neighborhood search, which reduced both computational time and path length. Bonfim Amaro Junior et al. [4] improved the heuristic search in the inheritance algorithm, yielding better solution quality and shorter computation time in laser cutting path planning. Song Lei et al. [5] designed a dual-chromosome encoding mechanism to jointly solve the cutting starting point and path planning problem, reducing both non-cutting travel distances and processing temperature. Wu Yanming et al. [6] employed a greedy algorithm for plate processing path planning, optimizing parameter grouping to achieve the optimal path while ensuring high-quality processing. Zhou Rui et al. [7] improved the genetic algorithm to avoid non-cutting travel and cutting conflicts, enhancing the algorithm's convergence.

The intelligent algorithms used in path planning above aim to minimize non-cutting travel and avoid heat accumulation [8]. However, while preventing heat accumulation, they do not necessarily minimize non-cutting travel and computational time. Through the detection of heat accumulation during actual laser cutting, it has been observed that the temperature is highest at the perforation starting point of the cutting element. To address the phenomenon of "laser punching" caused by excessive temperature at the perforation, this paper proposes a thermal field ant colony algorithm. This algorithm incorporates a heat matrix when initializing ant colony parameters, optimizing the probability of visiting cities and updating local pheromones. At the same time, a heat factor-based heuristic algorithm is introduced to parallelly optimize the cutting path.

II. Laser Cutting Path Planning and Design

The laser cutting process flow [9] is shown in Fig. 1. When cutting thicker materials such as carbon steel and stainless steel, achieving high precision and quality requires the incorporation of perforation techniques into the cutting parameter setup [10]. Perforation techniques mainly include pulsed perforation and explosive perforation. In pulsed perforation, a high peak power pulsed laser beam strikes the material surface, rapidly melting or vaporizing the material in a localized area to form a small hole. Explosive perforation, on the other hand, uses a lower-power continuous laser beam to act on the material surface, continuously heating it until the material melts and forms a hole. However, improperly set perforation parameters can lead to heat accumulation on the material surface [11], causing thermal expansion and deformation of the material. This results in a decrease in cutting precision and may even damage components such as optical lenses and focusing lenses, thereby increasing equipment maintenance costs. Therefore, path planning before setting cutting parameters is particularly important.

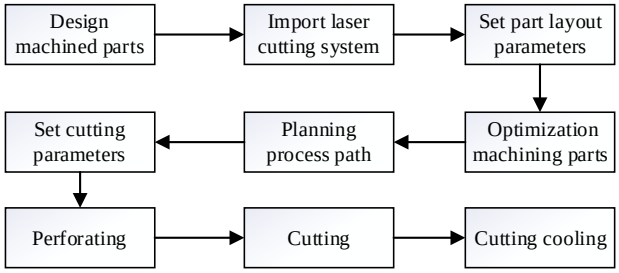

Fig. 1. Laser cutting process.

A. Laser Cutting Path Modeling

First, the feature points of each graphic element are obtained as the starting coordinates for the path planning of each element. For closed polygonal elements, the element contour is decomposed into arcs and straight lines, and the connection points between these lines and arcs are taken as the feature points of the element. For closed circles and ellipses, their feature points are defined by dividing the shape into four equal parts. The start and end points of an arc are calculated as shown in Eq. (1).

$$\begin{cases} x_s = x_c + R \cdot \cos(\theta_s) \\ y_s = y_c + R \cdot \sin(\theta_s) \\ x_e = x_c + R \cdot \cos(\theta_e) \\ y_e = y_c + R \cdot \sin(\theta_e) \end{cases} \tag{1}$$

In the above formula, $\{x_c, y_c\}$ represents the coordinates of the arc center, RRR is the radius of the arc, and (θ_s, θ_e) denote the start and end angles of the arc. $\{x_s, y_s\}$ and $\{x_e, y_e\}$ represent the coordinates of the arc's starting and ending points, respectively.

Using this formula, the feature points of the part contours are determined, as shown in Fig. 2. The closed elements are defined as {Part 1, Part 2, Part 3}, with each closed element corresponding to city coordinate points as follows: {v11, v12, v13, v14, v15, v16, v17, v18, v19}for Part 1, {v21, v22, v23 }for Part 2, and {v31, v32, v33, v34 } for Part 3.

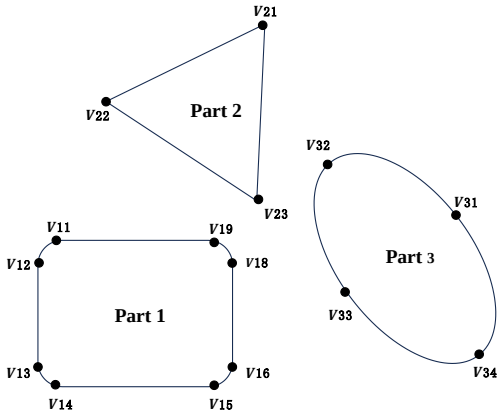

Fig. 2. Method of obtaining feature points of part contour.

Let the total path length L be defined as the total distance traveled by the laser, including all cutting path segments and non-cutting movement path segments from the starting point. The total cutting length is expressed in Eq. (2):

$$L = \sum_{i=1}^{n} d_i + \sum_{j=1}^{m} m_j \tag{2}$$

In this equation, d_i represents the length of the cutting path required for the i-th part, n is the total number of parts in the cutting path, m_j represents the length of the non-cutting movement path to the j-th part, and m is the total number of non-cutting paths in the cutting sequence.

B. Thermal Field Modeling

During the cutting process, if the perforation time is set too long or the perforation power too high, the starting area of the cut part can become overheated, causing a "punching" phenomenon. Therefore, thermal factors in laser cutting also need to be considered in path planning. The temperature rise ΔT at a point on the material at time t can generally be estimated using the heat conduction formula [12]. Assuming an initial temperature T of the material, the temperature rise at a certain point under the effect of the laser heat source is given by Eq. (3):

$$\Delta T = \frac{P \cdot \exp\left(-\frac{r^2}{4 \cdot a \cdot t}\right)}{\rho \cdot c \cdot \sqrt{4 \cdot \pi \cdot a \cdot t}} \tag{3}$$

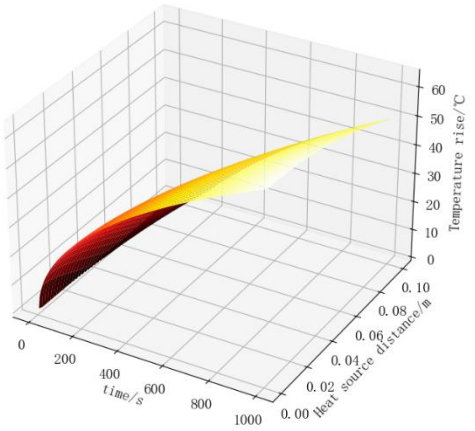
In this equation, P is the laser power, ρ is the material density, c is the specific heat capacity of the material, α is the thermal diffusivity, and r is the distance from the point to the laser heat source.

During laser cutting, heat is mainly dissipated through convective heat transfer to the surrounding air and through thermal conduction within the material itself [13]. Based on the above formula for temperature rise, the cooling temperature drop can be expressed as Eq. (4):

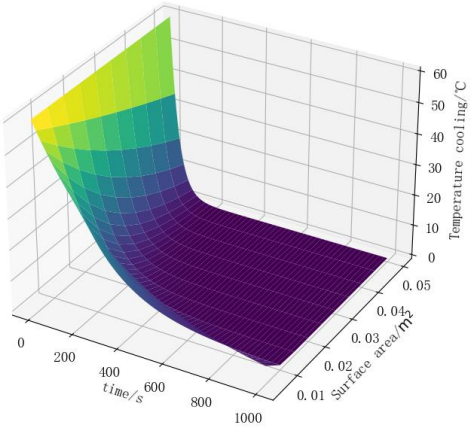
$$\Delta T = \exp\left(-\frac{h \cdot A}{m \cdot c} \cdot t\right)\left(T_S - T_N\right) + \varepsilon \cdot \sigma \cdot A \cdot \left(T_S^4 - T_N^4\right) \tag{4}$$

where h is the convective heat transfer coefficient, A is the surface area, m is the material mass, ε is the emissivity of the material, σ is the Stefan-Boltzmann constant, T_s is the surface temperature of the material, and T_N is the ambient temperature.

Given the parameters for heating with a laser power P =1000 W, a cutting material of steel with density ρ = 7800 kg/m3, specific heat capacity c= 500 J/kg · K, and thermal diffusivity α=1×10−5 m2/s. For cooling, assume the surface temperature Ts=60 ◦ C, ambient temperature T_N = 20 ◦ CT, convective heat transfer coefficient h=25 W/m2 · K, emissivity ε=0.7, Stefan-Boltzmann constant σ= 5.67×10−8 W/m2 · K4, and material mass m=0.1 kg. The resulting function plots for the temperature rise and cooling temperature drop of the material during laser cutting are shown in Fig. 3.



(a) Plate temperature function



(b) Plate cooling function

Fig. 3. Temperature change of laser cutting sheet.

To effectively control heat accumulation in path planning, it is essential to treat the effect of the laser heat source as a thermal conduction process. Based on the model described in Eq. (3), we can estimate the temperature rise at each point along the cutting path and avoid reheating high-temperature areas during path planning. To achieve this, we define a heat threshold in the thermal-field ant colony algorithm. If the temperature rise ΔT at a given point exceeds this threshold, the path planning algorithm should avoid immediate reprocessing of that point, instead prioritizing areas with lower heat levels for cutting. This approach helps to control heat distribution effectively. In addition to considering the temperature rise caused by laser power, the cooling process's impact on temperature must also be taken into account. This heat threshold can be dynamically adjusted by incorporating the cooling effect as described in Eq. (4), allowing for effective control of overheated areas during the cutting process.

III. Thermal Field Ant Colony Algorithm

A. Description of Thermal Field Ant Colony Algorithm t

Ant Colony Optimization (ACO) [14] is a stochastic optimization algorithm based on simulating the foraging behavior of ants, introduced by Marco Dorigo in the 1990s. This algorithm is particularly suitable for combinatorial optimization problems, such as path optimization. However, ACO tends to get stuck in local optima, has a slower convergence speed, and does not account for heat accumulation in the material during laser cutting. To address these issues, this study incorporates thermal fields and a heat factor into the ACO. Each "city" has a thermal field within a certain range, wherein neighboring points influence each other's temperature. The probability of each ant selecting a city is affected by the heat factor, and a heat threshold is set—when the heat on a path segment exceeds this threshold, the algorithm reduces the probability of selecting this segment, favoring cooler regions to control heat distribution. The heat factor $h(i,j)$ is calculated as shown in Eq. (5):

$$h(i,j)=\begin{cases} e^{-H[i,j]}, -H[i,j] > heat_{\max} \\ 1, others \end{cases} \tag{5}$$

where i is the index of the current city, j is the next city chosen by the ant, $H[i,j]$ represents the thermal matrix between these cities, and $heat\_max$ is the maximum heat threshold between two cities.

The probability of city selection in the heat-field ACO, modified by the heat factor, is shown in Eq. (6):

$$P_{ij}=\frac{(\tau_{ij})^{\alpha}\cdot(\eta_{ij})^{\beta}\cdot h_{ij}}{\sum_{k\in allowed}(\tau_{ij})^{\alpha}\cdot(\eta_{ij})^{\beta}\cdot h_{ik}} \tag{6}$$

where τ_{ij} represents the pheromone concentration between cities i and j, η_{ij} is the heuristic information, and α and β are importance factors for pheromone and heuristic information, respectively. *allowed* is the set of all cities available for selection, and k is the index of selectable cities.

To enhance global search capability and identify optimal paths, a roulette-wheel selection [15] is employed for probabilistic city selection, as mathematically expressed in Eq. (7):

$$P_{ck}=\frac{P_{ij}}{\sum_{i=1}^{n}P_{ij}} \tag{7}$$

where P_{ij} is the probability calculated in Equation (6), $r \in [0,1]$ is a random number, and k is the minimum index for which $P_{ck} \geq r$, making k the selected target city's index.

In the heat-field ACO, after each ant selects the next city, it locally updates the pheromone concentration on that path segment. This local pheromone update balances pheromone accumulation and evaporation to prevent path selection bias caused by a single heat factor. Following each iteration, the global pheromone is updated to speed up convergence to the optimal solution, as shown in Eq. (8):

$$\tau_{ij} = \begin{cases} (1-\rho_m)\cdot\tau_{ij} + \rho_m \cdot \tau_i, \\ \tau_{ij} \in local \\ (1-\rho_g)\cdot\tau_{ij} + \rho_g \cdot \Delta\tau_{ij}, \\ \tau_{ij} \in global \end{cases} \quad (8)$$

where ρ_{m} is the local pheromone evaporation factor, τ_{i} is the initial pheromone concentration to prevent pheromone levels from dropping too low, ρ_{g} is the global pheromone evaporation factor, and $\Delta\tau_{ij}$ is the additional pheromone added along the optimal path.

As ants pass each city, a heating and cooling mechanism is applied to the thermal matrix to reflect accumulated heat from laser cutting, preventing multiple selections of high-heat paths. Meanwhile, during city searches, already visited cities and their surrounding areas cool down, controlling excessive heat accumulation and improving path selection quality. The heating and cooling mechanisms for the thermal matrix are shown in Eq. (9) and Eq. (10):

$$\Delta H_{ij} = P \cdot \exp(-\frac{d_{ij}^2}{\gamma \cdot t}) \quad (9)$$

$$H[i,j] = \begin{cases} H[i,j]\cdot(1-C)\cdot t, \\ H[i,j] \geq heat_{\min} \\ heat_{\min}, \\ others \end{cases} \quad (10)$$

where ΔH_{ij} is the thermal matrix increment, P is the heat coefficient, d_{ij} is the distance between cities i and j, t is the step count, γ is the diffusion coefficient controlling heat dissipation speed, C is the cooling coefficient, and $heat\_min$ is the minimum heat threshold.

To avoid local optima, this study introduces an improved 2-opt [16] algorithm after each ant completes its path based on pheromone selection. Fig. 4 illustrates the 2-opt algorithm optimized path search process.

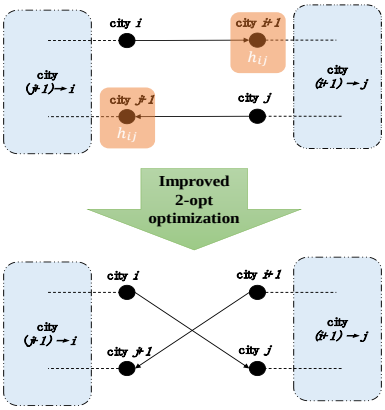


Fig. 4. Improved 2-opt algorithm to optimize the path method.

The core idea is to select two sub-paths on a given route and reverse one portion to check if a shorter total path length can be achieved. Whether to accept the new path is determined by the thermal matrix in Eq. (5), with the acceptance probability shown in Eq. (11):

$$P_{ij} = \exp(-\frac{L_{i,i+1} - L_{i,i}}{h_{ij}}) \quad (11)$$

where $L_{i,i+1}$ is the path length between city i and $i+1$, $L_{i,j}$ is the path length between cities i and j, and h_{ij} is the heat factor from Eq. (5).

B. The Implementation Steps of Path Planning of Thermal Field Ant Colony Algorithm

The path planning in the thermal-field ant colony algorithm first extracts the feature points of each part after laser cutting layout, as illustrated in Fig. 4. These feature points are placed into corresponding arrays to avoid redundant selection of the same geometric element later in the process. Then, the Euclidean distance matrix for each pair of feature points is computed, and the pheromone matrix is initialized. Since solution construction among ants is independent, the optimal path for each ant is calculated in parallel during a single iteration, which reduces computation time. The process terminates upon reaching the maximum number of iterations, after which the part numbers are sorted by shortest path order and output. The detailed procedure is depicted in Fig. 5.

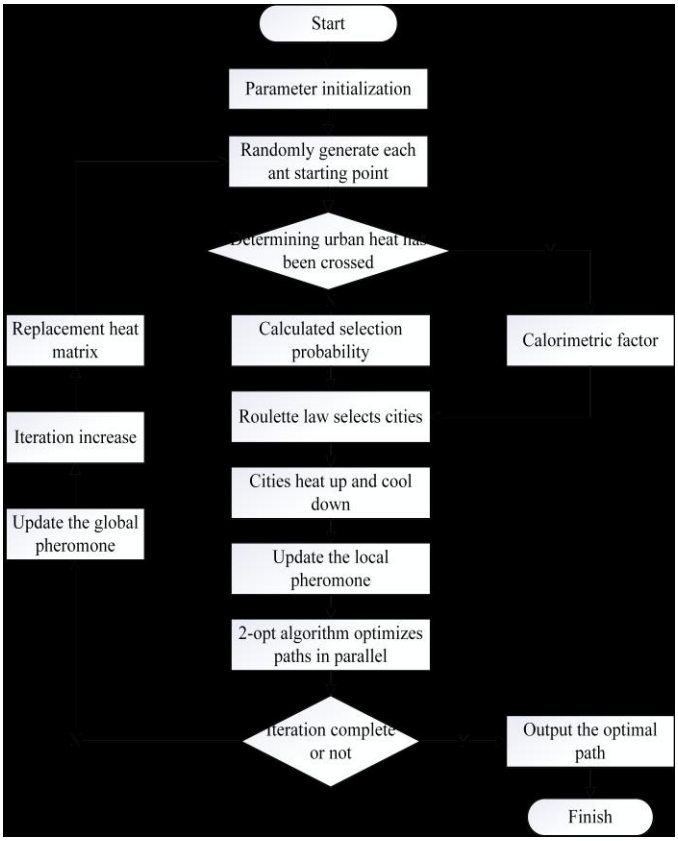

Fig. 5. Algorithm flow chart.

IV. Experiment and Result Analysis

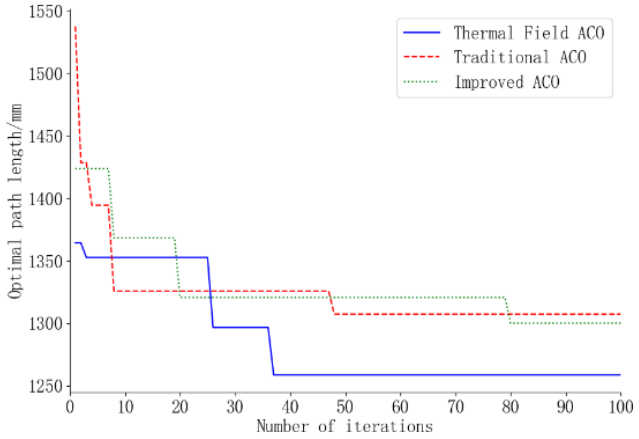
A. Path Planning Experiment

According to the path planning algorithm in this paper, the experimental objects are the parts after nesting, placed on the cutting plate. The feature points are extracted from the DXF file using geometric information as city coordinates. The operating system used in this experiment is Windows 11, with an Intel i5-12400F CPU, and the development environment is PyCharm. Based on the study [17] and multiple tests, the parameters of the algorithm were adjusted to their optimal values: the number of ants $m = 50$, pheromone factor $\alpha = 1$, heuristic function factor $\beta = 5$, global evaporation factor $\rho_g = 0.1$, local evaporation factor $\rho_m = 0.05$, and the maximum number of iterations $iter_{max} = 100$. The thermal field parameters are listed in Table I. The initial thermal matrix H in the table has n rows and n columns, where n represents the number of cities, the number of feature points in the DXF layout.

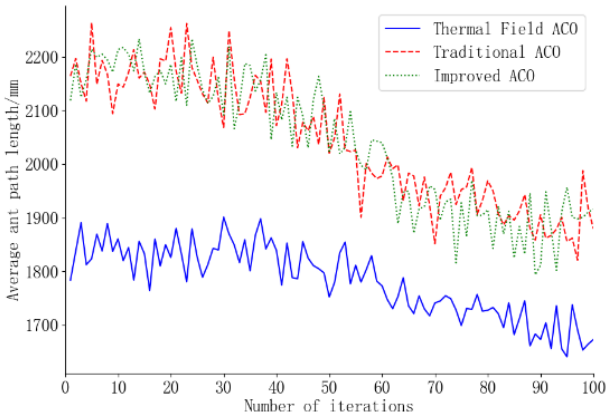
TABLE I. Thermal Field Parameters

Parameters	Value
Initial heat matrix H	$\begin{bmatrix} 0 & 1.0 & \dots & 1.0 \\ 1.0 & \ddots & \dots & \vdots \\ \vdots & \dots & \ddots & 1.0 \\ 1.0 & \dots & 1.0 & 0 \end{bmatrix}$
Heat threshold $heat_{max}$	0.5
Heating factor P	0.2
Cooling factor C Heat loss γ	0.95 0.05

The result of the experiment is to calculate the time, the path length and the heat matrix when cutting the plate. The optimal path ant heat value of Thermal Field ACO(TF-ACO) is shown in Fig. 6. Compared with Traditional ACO(T-ACO) and Improved ACO(I-ACO), the convergence curve of the improved ant colony algorithm based on study [18] and the convergence curve of the shortest path and the average path of ants is shown in Fig. 6:



(a) Shortest path convergence curve comparison.



(b) Comparison of ant average path convergence curves.

Fig. 6. Comparison of convergence curves.

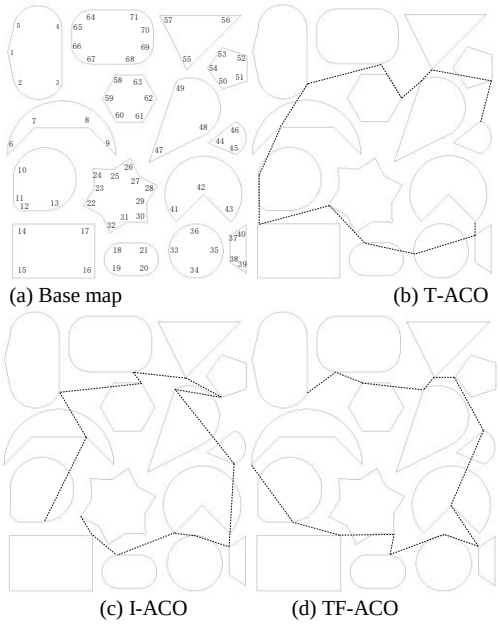
When compared to the traditional ant colony algorithm and the improved ant colony algorithm, the convergence curves of the shortest path and the average path length of the ants for the improved algorithm are also depicted in Fig. 6, based on study [18]. After multiple tests, the fastest convergence times, shortest path lengths, and average path lengths of the ants for the three algorithms are shown in Table II.

TABLE II. Optimal Solutions of each Algorithm

Algorithm type	Maximum convergence times/times	Minimum path length /mm	Average ant path length /mm
T-ACO	80	1307.34	1915.97
I-ACO	49	1300.15	1879.26
TF-ACO	38	1250.66	1672.95

From the figures and tables above, it can be observed that compared to the traditional and improved ant colony algorithms, the thermal-field ant colony algorithm reduces the fastest convergence time by approximately 52.5% and 22.4%, respectively. The shortest path length is improved by approximately 4.5% and 3.8%, and the optimal average path length is improved by approximately 14.5% and 12.3%. This demonstrates that the improved code in this paper not only prevents heat accumulation but also improves the optimal path.

In this simulation experiment, the optimal solutions obtained from the three algorithms were plotted on the DXF part base map after nesting, as shown in Fig. 7. Panel (a) displays the base map with numbered parts, showing 15 distinct geometric elements. After computing the geometric features, a total of 71 feature points are derived as the city coordinates for the path planning algorithms. Based on the feature point sequence in the base map, the path planning cutting order for each algorithm is as follows: Traditional ACO: 46, 51, 55, 49, 62, 68, 3, 7, 10, 14, 22, 18, 33, 37, 43. Improved ACO: 22, 17, 18, 41, 36, 37, 45, 49, 50, 55, 68, 63, 3, 8, 13. Thermal-field ACO: 4, 67, 58, 49, 55, 54, 46, 42, 37, 36, 18, 30, 17, 13, 6.



(a) Base map (b) T-ACO

(c) I-ACO (d) TF-ACO

Fig. 7. Feature point diagram and path comparison diagram.

The optimal path heat matrix is also shown in Fig. 8. From this figure, it can be observed that by introducing the heating and cooling factors, most of the city heat values did not exceed the initially set thermal threshold. While the ants selected the optimal path, they also effectively controlled the heat accumulation, avoiding the selection of high-heat cities as the cutting start points during perforation. This mechanism ensures that the material does not overheat during cutting, which could otherwise negatively affect the cutting quality.

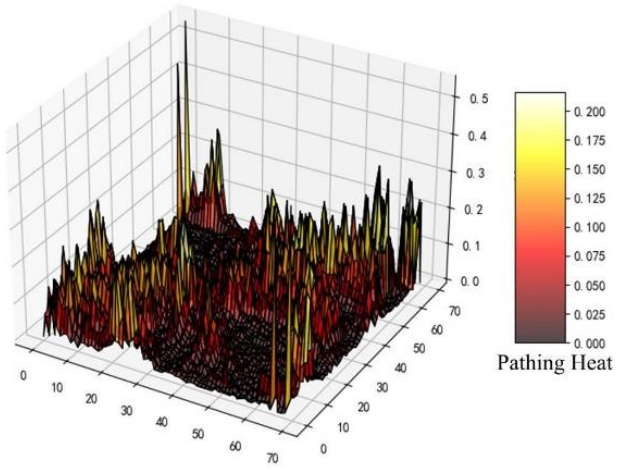


Fig. 8. Heat distribution diagram of optimal path.

B. Cutting Experiment

In this cutting experiment, a flatbed laser cutting machine was used for comparison. The DXF file from Fig. 7 served as the cutting object for the experiment. The laser cutting machine model is FLM3015, equipped with a continuous fiber laser of the model EFRC-3000-E, with a rated output power minimum of 2900W, a maximum of 3100W, and a measured center wavelength of 1080nm. The working voltage is 380VAC, and the output fiber core diameter is 250um. Fig. 9 shows the laser cutting machine used for this experiment.

Fig. 9. Experimental laser cutting machine.

Carbon steel with dimensions 500mm × 500mm × 6mm was selected as the cutting material for the experiment. Prior to cutting, a perforation process was applied to compare the effects of different algorithms on the temperature of the material after perforation. The laser cutting process parameters are shown in Table III.

TABLE III. PROCESS PARAMETERS

Parameters	Value	Unit
Cutting speed	100	mm/s
Barometric type	oxygen	
Atmospheric pressure Peak power Punch grade Progressive time	5 1000 first-order 1000	BAR W ms

Based on the process parameters mentioned, the optimal paths obtained from the three path-planning algorithms were imported into the laser cutting system for cutting experiments. During the experiment, an infrared thermometer was used to measure the surface temperature of the material in real-time, recording the maximum temperature reached by each algorithm during the cutting process. The ambient temperature during the experiment was 20°C. The data recorded for planning time, processing time, and average cutting temperature for each algorithm are shown in Table IV.

TABLE IV. CUTTING COMPARISON OF EACH ALGORITHM

Algorithm type	Plan time /s	Cutting time /s	Maximum cutting temperature /℃
T- ACO	4.35	74.49	262.32
I-ACO	3.81	72.13	257.09
TF-ACO	3.70	70.06	209.87

From the table, it can be observed that compared to the traditional and improved ant colony algorithms, the thermal-field ant colony algorithm resulted in approximately 14.9% and 2.8% improvement in planning time, 5.9% and 2.8% improvement in cutting time, and 19.9% and 18.4% improvement in the maximum cutting temperature, respectively. These results indicate that the thermal-field ant

colony algorithm not only effectively avoids heat accumulation but also reduces the temperature increase while maintaining optimal planning and cutting times. This algorithm better controls the heat distribution during the cutting process, minimizing overheating, thus ensuring cutting quality and the integrity of the workpiece while improving path planning and cutting efficiency.

V. CONCLUSIONS

In comparison to the traditional and improved ant colony algorithms, the thermal-field ant colony algorithm presented in this study demonstrates significant advantages in laser cutting path planning. Specifically, the algorithm reduced the number of iterations by 22.4% to 52.5%, the planning computation time by 2.8% to 14.9%, the non-cutting travel path length by 12.3% to 14.5%, the cutting time by 2.8% to 5.9%, and the maximum cutting temperature by 18.4% to 19.9%. These results indicate that the thermal-field ant colony algorithm not only effectively shortens the cutting travel and processing time but also reduces the perforation issues caused by heat accumulation during laser cutting, preventing the occurrence of "burn-through" and lowering the overall cost of the laser cutting process.

However, certain environmental factors such as smoke, dust, and the material surface's emissivity in the experimental setting have introduced some uncertainty in the temperature measurement results. Therefore, future research will focus on further optimizing the path planning algorithm and improving the accuracy of temperature monitoring to better adapt to real-world production environments.

***Abstract*—In this research, we have measured the physical distance between the robot and its surroundings using a laser distance measuring device that we have developed, designed controllers for, and tested operationally. We will record the distance using the USB camera and integrate the LDMSB board into the laser distance measuring design. We will fasten these two parts to the robot's underside. Developing the experiment in LabVIEW is the next step. The mean shift method enables us to move the robot's position by relocating a laser-based distance measurement device and capturing a photo at that location. In order to record that area, we will perform a perspective camera calibration. This will allow us to set up or adjust the camera system's value, or provide visual assistance to ensure that the viewing angle is precisely aligned with the intended view angle. The laser measurement results ranged from one to fifteen meters. A device that makes use of lasers has 99.25% accuracy. Every calibration location throughout the 10 has a precision rating of 94.03%.**

Keywords*—Laser distance; image calibration; mean shift algorithm; LabVIEW

I. INTRODUCTION

The mobile robot education process at Rajamangala University of Technology Lanna's Faculty of Engineering, Electronic Engineering, and Automation Control Systems Program, Chiang Mai Province, includes measuring a robot's walking distance. This field holds great promise for the development of precise and long-range robots. However, a variety of issues, including measurement error, sensor data rectification, various settings, and adaptability, make determining a robot's walking distance difficult.

There is more to using a laser to measure distance than simply speed and ease. Nonetheless, the technique is very accurate and widespread. Consequently, it might be a useful tool in many facets of everyday life. This covers a wide range of industries, including commercial and medical applications, engineering, and building construction. The advantage of lasers is 1) High degree of accuracy: The laser exhibits a high degree of accuracy in measuring distance and is capable of precisely transmitting laser signals to the designated measurement location. Laser sensors provide precise data in a variety of situations. This makes it appropriate for uses where a high degree of precision is required. The laser can quickly calculate the separation between the two locations. The laser's quick light transmission allows for instant viewing of the experiment findings. 2) This makes it an ideal choice for tasks that require quick thinking, such as data storage and production management. 3) It has the ability to adapt to challenging situations. Lasers are used in harsh environments like cold and dusty ones because they can withstand harsh conditions. 4) Versatility in Application Lasers possess a wide range of potential applications. It has a wide range of potential uses, including in commerce and research, as well as in the field of measuring distances in medicine.

To conduct this study investigation, we set up a laser distance measuring and imaging device. Writing and testing control software in LabVIEW is a crucial step in tracking the robot's location and determining the distance to the objective. One of the main purposes of lasers in robots is to detect distance accurately [1]. This enables robots to carry out their work with the same diligence and precision as people. Robots can gain a better understanding of their environment and adjust their behavior by employing laser distance measurement to gather information about it and adjust their behavior. The use of lasers in robotics creates new opportunities for the creation of innovative and useful robots, suitable for various human endeavors such as navigation, obstacle avoidance, and precision placement tasks. These robots have applications in all fields of human endeavor. These robots can support industrial applications, conduct surveys and research, or serve both purposes [2].

Most people agree that one of the most powerful tools for software development and engineering is the LabVIEW application [3-4]. A graphical programming environment called LabVIEW uses representations of the signal type [5]. LabVIEW allows users to create programs by simply dragging and dropping components into block diagrams. This simplifies operations and creates an easy-to-use interface. Furthermore, because it can interface with a wide range of devices, LabVIEW may be used in software applications that require automation in the domains of measuring, controlling, and testing. There are several uses for LabVIEW software, some of which include industrial, scientific, and engineering research and development. Because of its intuitive design, LabVIEW is a tool that allows users to create and modify programs to any degree of customization without facing any limitations. This study uses the board to compute the robot's distance. Its hardware is the Laser Distance Measuring Signal Board (LDMSB). We use the mean shift approach to track objects [6].

*Corresponding Author

The difficulties in object tracking include many types of occlusions, including occlusion by background objects, other target objects, or self-occlusion (produced by components of the object itself). The tracking procedure becomes more difficult due to these partial or complete occlusions. Significant difficulties are also presented by the target object's changing appearance, particularly in surveillance applications. Inconsistent illumination over wide regions or rotations of the object along axes other than the imaging system's optical axis often cause these alterations. Improving the accuracy and resilience of object tracking systems requires addressing these problems.

This research report explains the camera calibration process and the creation of a laser distance measurement device. For this, we wrote driver software and tested it with LabVIEW. This crucial step enables us to calibrate the camera before recording the robot's location using the Mean Shift method, a crucial tool for precise and thorough distance measurement. Laser distance measurement may benefit robots that can detect and adjust their behavior in different situations. We have organized this job to involve traversing a space, avoiding obstacles, or performing tasks that require precise placement. Section III describes the study technique, while Section II reviews some relevant prior research. Section V brings the article to a close. Section IV presents and examines the findings.

II. Literature Review

The various methods and designs discussed in these books simplify the calculation of the distance between two lasers. A low-tech laser sensor using triangulation achieves outstanding spatial resolution [7]. Another approach suggests using a heterodyne interferometer, renowned for its high accuracy, for absolute distance measurement. A new method for laser distance measurement employs least squares and triangular-wave amplitude modulation to enhance the signal-to-noise ratio [8]. Additionally, a unique distance-measuring device utilizing microfabricated scanning micromirrors demonstrates various configurations for distance estimation [9]. Overall, these methods and technologies offer a wide range of laser distance measurement techniques that can be adapted to meet different application needs and accuracy standards [10].

These studies provide new perspectives on robotic walking using laser distance measuring. One study addresses the calibration of laser range finders for legged robots to achieve the accuracy needed for terrain mapping and foothold selection [11]. Another explores integrating inertial measurement units (IMUs) with laser scanners for real-time, safe calculation of minimal distances between humans and robots. Research also highlights the utility of 3D laser distance measurements for accurate pedestrian tracking, particularly in unstructured environments with occlusions and sensor noise [12]. Additionally, a mobile robot equipped with a laser range finder combines a walking motion model with the geometric characteristics of human legs to ensure precise tracking and a better understanding of human gait [13]. Collectively, these studies demonstrate the advantages and potential of laser distance measurement in walking robot applications [14].

The essays in this collection offer valuable insights into the use of LabVIEW for laser distance measuring. One study emphasizes the importance of LabVIEW in evaluating the reliability of femtosecond laser light sources for distance measurements [15]. Another explains a LabVIEW-based software architecture for assessing laser divergence angles [16]. A further method demonstrates the utility of LabVIEW in a laser beam profile scanning interface. Additionally, a high-precision optical distance meter based on a mode-locked femtosecond laser is presented, capable of measuring distances up to 240 meters with a detection accuracy of 0.01 meters or better [17]. Together, these papers highlight the effective and versatile application of LabVIEW in various laser distance measuring components [18].

III. Methodology

The main program of the suggested algorithm is shown in Fig. 1.

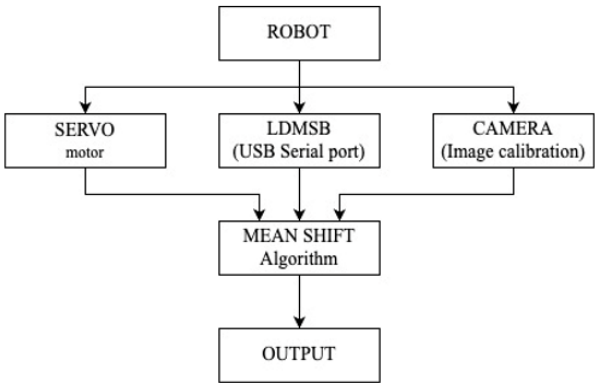

Fig. 1. Distance-measuring walking laser robot block diagram.

Fig. 1 illustrates the process for calculating the robot's travel distance. By following the instructions, one may accomplish the many stages involved. The LDMSB board is situated precisely adjacent to the wheel section at the bottom of the moving robot. The LDMSB board is ready to perform its function as a distance measuring device. The technique then moves on to attaching two USB cameras to the mobile robot. We will proceed to the next step. Establish a serial port protocol connection between the LDMSB board and the USB camera. We test the robot's distance calculation and image calibration skills using LabVIEW's Mean Shift approach. The purpose of these tests is to verify the accuracy of the results.

A. LDMSB

Laser Distance Measuring Signal Board (LDMSB) is a board used in the design to measure distance with laser in this research article. Fig. 2 shows the various components of the LDMSB board. When a lens transmits laser light, it is called a laser transmitting lens. Similarly, a laser receiving lens is a laser receiving lens. Holes or indentations drilled into any material or component to install or secure an object, such as an electronic board or component, so that it may be installed or connected to other apparatuses or buildings, are known as mounting holes. An information processing and perception system or technology is referred to as vision. Pin locations, for instance, are used to link pins in circuits or structures when DC power is needed to power them. Utilizing sensors is necessary for tasks pertaining to various systems' eyesight and perception. A USB

(Universal Serial Bus) system connection establishes the circuit connection between the LDMSB board and the USB interface. This implies that the system will automatically detect USB-powered devices when they are inserted into a port. It is perfect for connecting devices that need full-duplex communication since it can transmit both transmission (TX) and reception (RX).

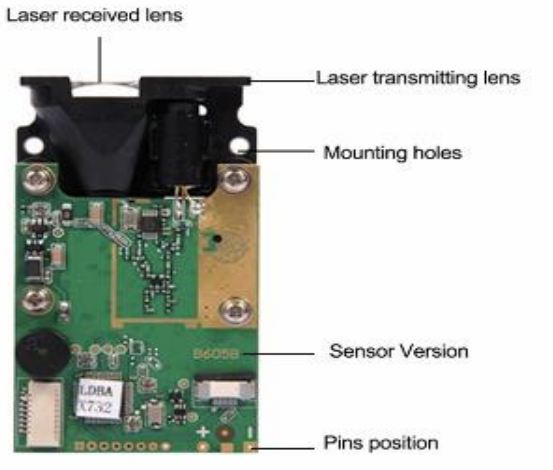

Fig. 2. Components of the LDMSB board.

The goal is to create a device that will be utilized for evaluating the functionality of a laser distance measurement system after identifying the target position in order to measure the Z-axis distance that has to be measured and gathering picture data according to the position. In order to do this, a servo motor that can be adjusted in one-degree increments will be used to rotate the X and Y axes. The desired appearance of the gadget as per its design is seen in Fig. 3.

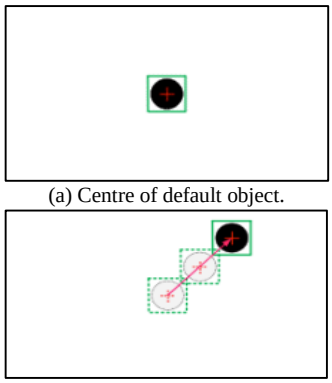
Fig. 3. Laser distance measuring functional testing equipment.

After that, it may be used with mobile robots, where the USB camera and LDMSB board are mounted in the bottom of the robot. The robot can use the laser to measure and record distances thanks to the placement of these parts.

B. Mean Shift Algorithm

The working principle of the object tracking algorithm is based on a methodology akin to template search [19]. The process of matching object photos to templates involves searching for templates that enable things to be located inside a user-defined area or throughout the entire image. This technique, similar to object tracking, looks for an object template in an area that either anticipates or is close to the item's position from the previous frame. This reduces false searches and boosts processing efficiency, making it ideal for labor-intensive activities. The article monitors objects by approximating their position and appearance using the mean shift [20]. The kernel method estimates the mode of the probability function to assess the condition of an item. The rival object's position is estimated using target object motion data from the previous frame. Comparison of the appearance characteristic model of an object with the previous frames to increase the likelihood of its location Assign a new competitive position to the outcome. Increase the frequency of the position estimate until either the user-defined repetition criterion is met or the competing position converges to the final value.

Next, the model will be updated for the following frame when the target object's location has been calculated. After several iterations, the target item's position is estimated using the initial frame. The middle of the rectangle determines the round position of the competing item. In Fig. 4, the arrows in (a) display the mean shift vector, which indicates the amount that the center of mass of the target object changed from the prior frame. The center of the moving item as it gets closer to the target is the starting object (b).



(a) Centre of default object.

(b) Point of movement toward objective.

Fig. 4. Mean shift object tracking.

During tracking, the target object contour model that tracks mean shift fixes the target object forms. The image's target object's center of mass is shown by the telematic model's parameters [21]. The center of mass's pixel location is all that is needed to monitor mean-shift objects in the model. When the subject in the next frame travels slowly, this works. There are two different types of objects tracking algorithms that employ the Mean Shift technique: target object tracking and target object modelling. These two categories represent various aspects of the application.

The mean shift update equation for tracking an object at position x can be formulated as follows:

- Initial Position of Object: Start with an initial position $^{(0)}$ of the object in the current frame.
- Kernel Density Estimation: The pixel weights are assigned using a kernel function K, usually according to the pixels' distance from the center. Although other kernels, such as Gaussian, may also be employed, the Epanechnikov kernel is a popular option. The weighted mean position is determined with the use of the kernel K(x), which concentrates on pixels nearer the center.
- Mean Shift Vector: For each iteration t, vector m(x(t)) is computed to shift towards the mean of the region with the highest density from Eq. (1).

$$m(x^{(t)}) = \frac{\sum_{i=1}^{n} x_i K(x_i - x^{(t)})}{\sum_{i=1}^{n} K(x_i - x^{(t)})} \quad (1)$$

Where x_i represents the positions of pixels within a region around the current location and $K(x_i - x^{(t)})$ gives the weight based on the distance from $x^{(t)}$

Position Update: The object's new position is updated by shifting to x(t+1) from Eq. (2).

$$x^{(t+1)} = x^{(t)} + m(x^{(t)}) \quad (2)$$

Convergence: Repeat the iteration until the mean shift vector $m(x^{(t)})$ is sufficiently small (below a threshold), indicating that the peak (mode) has been found.

As illustrated in Fig. 5, it regulates the blending parameter and the maximum percentage of rotational size and shape changes.

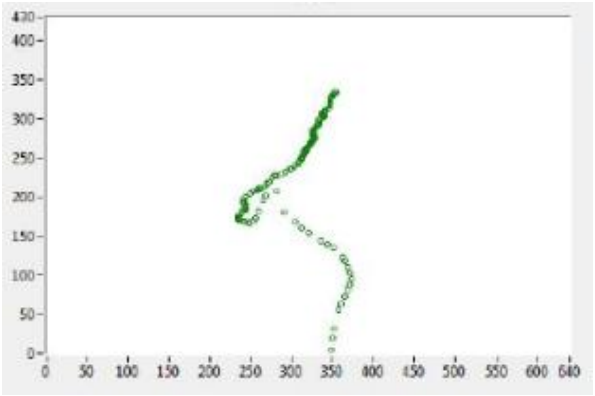


Fig. 5. Adjusts mixing settings and maximum rotation size and shape.

C. LabVIEW

One object tracking technique that is accessible in LabVIEW 2019 is the Mean Shift algorithm, which utilises both the NI Vision Assistant and the NI Vision Library feature. This approach is perfect for monitoring a single target object and is made to work with LabVIEW 2019 [22-23].

This technique replicates the distance of a laser measurement using LabVIEW programming by employing the mean shift method to move an object based on the mouse's position. Fig. 6 displays the accessible front-panel interface of the LabVIEW program. The first stage in improving the accuracy of devices or systems, such as offset, sensitivity, or scale factor, is to calibrate the x- and y-axes. As a result, you can trust that the system will precisely determine an object's position or movement. The next step is to employ a method to figure out how big the object (PEN) is in order to depict the laser point and the object's movement. The final step of the procedure entails analyzing the program to determine if the coordinates of x and y (red objects) on the Axis Mouse are following the mean shift approach as they move along the mouse frame. For the application, LabVIEW has produced a block diagram (graphic programming). We will be able to move more effectively with the help of a servo motor if we move at an angle along the x and y axes. We will correctly apply the mean shift algorithm.

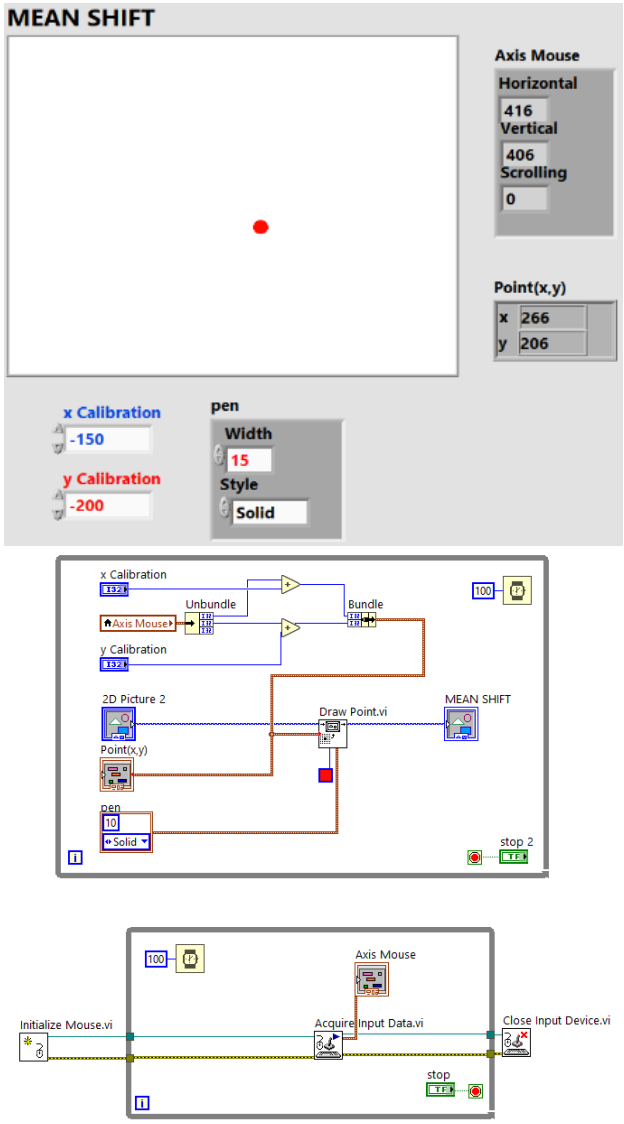

Fig. 6. LabVIEW front panel and block diagram via mean shift algorithm.

We have developed a laser distance measurement design and captured pictures of the distances for the robot's use during its travels. To shoot a picture, one must perform a procedure known as perspective calibration. Adjusting or changing the camera system or imaging equipment settings is necessary to ensure that the picture's angle is true to the desired perspective or the proper theoretical point of view [24], as Fig. 8 illustrates.

The calibration perspective achieves several objectives. 1) Assist in ensuring the accuracy of the camera system or picture equipment according to visual theory and metrics; 2) guarantee that the results are theoretically sound and consistent with the visual model. It also helps to minimize deflection errors, reflection, and visual distortion. 3) Measure or closely inspect photos. Gathering both intrinsic and extrinsic camera system characteristics is necessary to ensure that the produced picture is accurate and does not tilt or distort due to an incorrect angle, and also to assist in optimizing the camera or imaging equipment. Then, using LabVIEW, we created a front-panel user interface for capturing photos and measuring distances, as shown in Fig. 7.

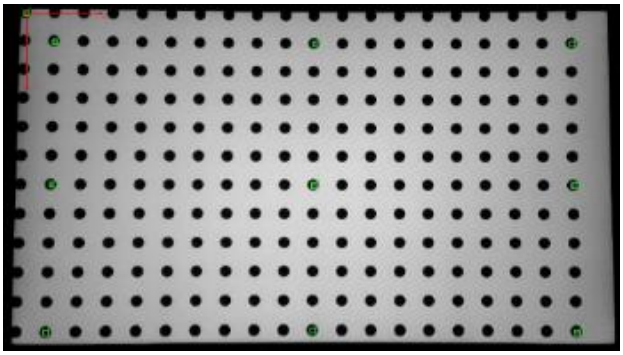

Fig. 7. Perspective 10-point calibration.

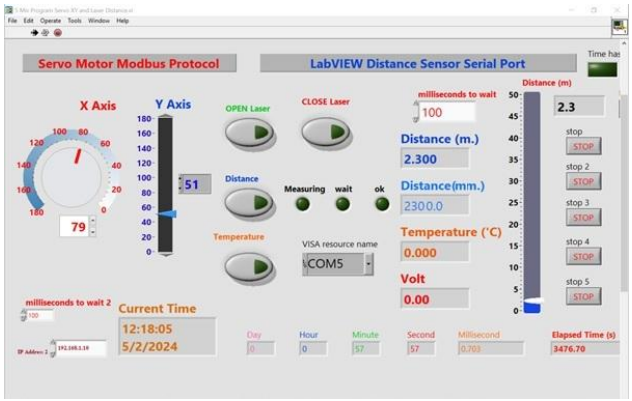

Fig. 8. Images and laser distances LabVIEW front panel.

The user interface seen in Fig. 8 was created through programming. The robot design attaches the LDMSB board and a USB camera to its bottom, enabling the software to perform its planned tasks. The software allows you to turn the laser on and off at will. The software allows you to measure distances in millimeters and meters, as well as save photos. You can monitor the temperature and voltage of the laser.

This method locates a controlled circular point in motion with a radius of 20 millimeters, using a source image at the X and Y axes. The experiment used an LDMSB board with a laser to measure distance. Additionally, we connected a USB camera to the distance measurement board to capture pictures. We then projected the picture onto a 100-inch display for the exercise. We must create an angle to shift the position from point 6 (P6) to point 7 (P7). Fig. 8 illustrates the process of mean shift image tracking and laser distance measurement.

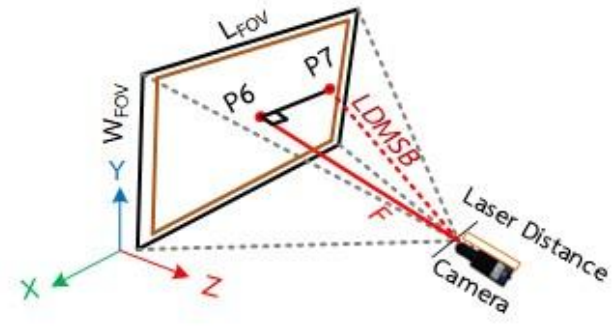

Fig. 9. The laser uses a mean shift from position 6 (P6) to point 7 (P7) to track pictures and calculate distance.

In Fig. 9, this case involves the transfer of the post. In order to calculate the distance caused by P6 to P7, use the formula $c = \sqrt{a^2 + b^2}$, where a is the distance between the camera and laser device and the monitor, or point P6, b is the distance between the points P6 and P7 along the X axis, and c is the distance between the camera and laser device and the monitor, or point P7, that results from comparing the calculated value with the actual value that was measured by the laser. When we speak to the camera's field of vision (*FOV*), we mean the range of pictures it can record. We refer to the scope the camera records as *FOV*, the scope it records by width as W_{LOV}, and the scope it records by length as L_{FOV}. The formula $FOV = W_{LOV} \, x \, L_{FOV}$ may be used to get the value, where *FOV* stands for the scope that the camera records.

IV. Results and Discussion

We separate the experimental findings from the laser odometer and the picture recording from the mean shift algorithm into three distinct design experiment components, each of which consists of the specific elements listed below:

A. Laser Distance Testing

We must measure the separation between two spots using our own laser technology. We designed these stages to evaluate the accuracy of the laser apparatus. The laser distance determines the example's result, as Table I illustrates.

The data presented shows the measurements of distances in meters, with five repetitions for each distance. The average values for each distance are very close to the expected values, indicating a high level of accuracy in the measurements. The percentage error remains minimal across all distances, with the largest error observed at the 0.1-meter distance, which has a 6.67% error. As the distance increases, the percentage error decreases, reaching 0% for several measurements, including 1 meter, 2 meters, 3 meters, and 10 meters, among others. This suggests that the measurement process is highly reliable, particularly at greater distances, where the error becomes negligible. Overall, the data indicates that the measurement system or method used is highly precise and consistent across a wide range of distances. Table I displays the results of five separate experiments conducted at distances ranging from 10 cm (0.10 m) to 50 m, along with the average of each test. 99.25% accuracy is the average for measuring distance.

TABLE I. LASER DISTANCE TESTING

Distance (meters)	#1	#2	#3	#4	#5	%Error
0.1	0.10	0.10	0.10	0.12	0.12	6.67
0.2	0.20	0.21	0.21	0.21	0.21	0.33
0.3	0.30	0.30	0.30	0.30	0.30	0.11
0.4	0.40	0.40	0.40	0.40	0.40	0.00
0.5	0.50	0.51	0.51	0.51	0.50	1.00
1	1.00	1.00	1.00	1.00	1.00	0.00
2	2.00	2.00	2.00	2.00	2.00	0.00

30	30.00	30.00	30.00	30.00	30.00	0.00
40	40.00	40.00	40.03	40.01	40.01	0.02
50	50.00	50.00	50.00	50.00	50.00	0.00

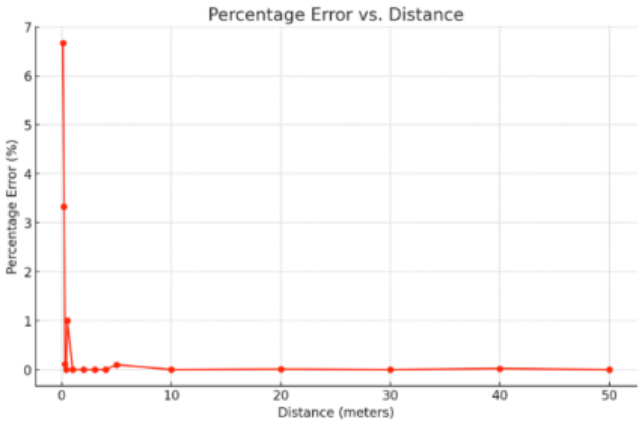

Fig. 10. Percentage error decreases with distance.

In Fig. 10, According to the line chart, the percentage error increases initially at shorter distances but then levels out and stabilizes as the distance grows. This implies that when one moves farther away from the subject, especially beyond 0.4 meters, where the error is almost nil, the measurements get more precise.

B. Image Calibration

While the robot is moving, it is a good idea to take images and measure the distances. The following list displays the results of the 10-point perspective (CP) calibration. The camera or other photographic equipment must have ten calibration points to ensure that the final image is accurate and suitable for the intended angle of view. You can see these calibration points in Fig. 11.

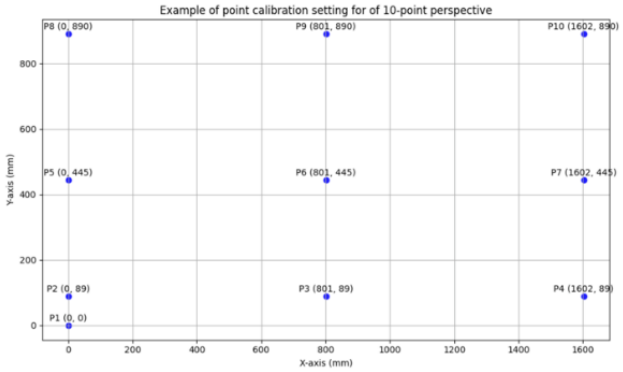

Fig. 11. The 10-point perspective's calibration results.

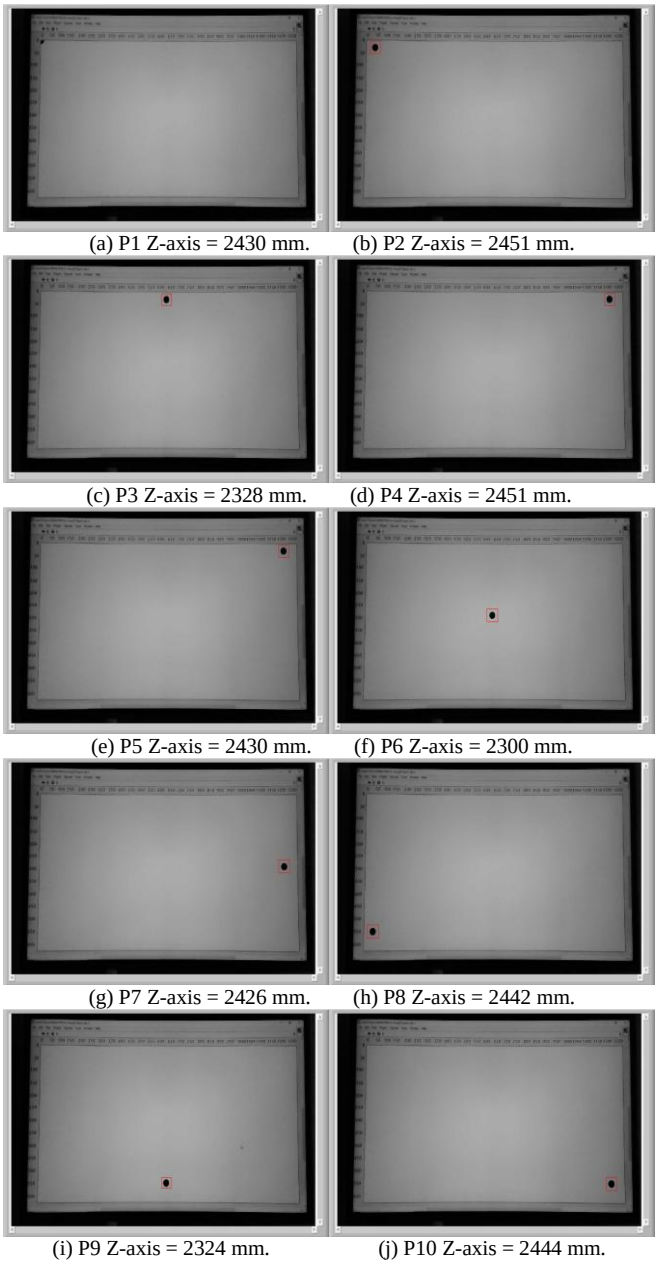
We examined the calibration using a USB camera with a pixel resolution of 1280x720. An LED screen measuring 100 inches in size displays the image. Ten points, each with a value on both the X and Y axes, make up the calibration.

TABLE II. RESULTS OF THE 10-POINT PERSPECTIVE CALIBRATION

CP (10 POINT)	X-axis (mm.)	Y-axis (mm.)	Z-axis (mm.)
P1	0.00	0.00	2,430.00
P2	0.15	84.93	2,451.00
P3	800.85	89.16	2,328.00
P4	1,599.78	85.78	2,451.00
P5	1.87	443.34	2,430.00
P6	798.93	443.89	2,300.00
P7	1,598.77	442.54	2,426.00
P8	0.98	800.56	2,442.00
P9	799.53	797.4	2,324.00
P10	1,601.58	800.82	2,444.00

Table II demonstrates that both the distance measurement value from the laser and the number of photos taken there are relevant. Z represents the value that the laser determined. The X and Y axes represent the point's value. We will conduct the experiment in 10 distinct locations for this study.

After measuring the distance, we used the mean shift technique to track the locations of all 10 dots in the picture. At last, this picture was produced. We calculate the distance between the point of the laser measuring and recording device and the projected screen. A distance of 2300 mm separates the two locations (P6). The Z-axis measurements provided for points P1 through P10 reveal varying levels of displacement, with values ranging from 2300 mm to 2451 mm. Notably, points P2 and P4 both reach the highest Z-axis value of 2451 mm, while point P6 records the lowest at 2300 mm. The data suggests that while some points, such as P1, P5, and P7, remain close to 2430 mm, others like P3, P9, and P6 show significant deviations. This variation in Z-axis measurements illustrates the spatial differences captured during the tracking process, as depicted in Fig. 12, which shows the outcomes of the tracking mean shift algorithm's picture recording.



(a) P1 Z-axis = 2430 mm. (b) P2 Z-axis = 2451 mm.
(c) P3 Z-axis = 2328 mm. (d) P4 Z-axis = 2451 mm.
(e) P5 Z-axis = 2430 mm. (f) P6 Z-axis = 2300 mm.
(g) P7 Z-axis = 2426 mm. (h) P8 Z-axis = 2442 mm.
(i) P9 Z-axis = 2324 mm. (j) P10 Z-axis = 2444 mm.

Fig. 12. Example of the tracking mean shift algorithm's picture recording outcomes, such as P6 Z-axis = 2300 mm.

TABLE III. COMPARING LASER MEASUREMENTS WITH CALCULATED VALUES

CP	a	b	$c = \sqrt{a^2 + b^2}$	%Error
P1	0	2,430	2,430.00	0 .00
P2	0	2,451	2,451.00	0.00
P3	801	2,328	2,461.95	5.44
P4	1602	2,451	2,928.11	16.29
P5	0	2,430	2,430.00	0.00
P6	801	2,300	2,435.49	5.56
P7	1602	2,426	2,907.21	16.55
P8	0	2,442	2,442.00	0.00
P9	801	2,324	2,458.17	5.46
P10	1602	2,444	2,922.25	16.37

A comparison between the values produced by the computations and the values measured by the laser instrument is shown in Table III. The comparison's outcomes are shown. The average accuracy percentage of the numbers derived from the calculations was 94.03%.

The data presented highlights a series of measurements (b) associated with various CP points, alongside calculated values (c) and the corresponding %Error. A few notable observations emerge from the analysis, as shown in Figure 13.

- Consistency in Measurements: For several data points, such as P1, P2, P5, and P8, the values of b and c are identical, resulting in zero error. This suggests that these measurements are precise and match the expected values perfectly.
- Significant Deviations: Other points, particularly P3, P4, P7, and P10, show notable deviations between the b values and the calculated c values. The error percentages at these points range from 5.44% to 16.55%, indicating considerable discrepancies. This variation implies the possibility of underlying measurement process issues or the presence of conditions or anomalies not adequately represented by the expected values.
- Trend Analysis: The plot of b values against CP points reveals that while most values are relatively stable, certain points exhibit substantial variation. For instance, P4 and P7 show the largest errors, with discrepancies of 16.29% and 16.55%, respectively. We may attribute these higher error rates to measurement inaccuracies, external factors, or inherent variability in the system under study.
- Implications and Recommendations: The presence of large errors in specific measurements warrants further investigation. It would be beneficial to review the data collection methodology and consider any external influences that could impact accuracy. Additionally, analyzing whether these errors are systematic or random could provide insights into improving measurement precision. Understanding and addressing these discrepancies will enhance the reliability of the results and ensure more accurate conclusions in future analyses.

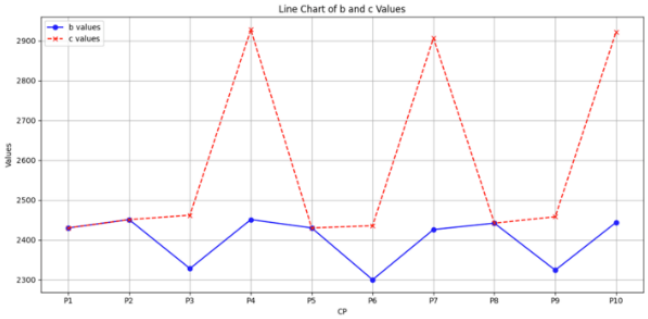


Fig. 13. A comparison between calculated values and laser measurements.

V. CONCLUSION

We use the LDMSB board to build the laser distance measuring system for the experiment. We program the device

using LabVIEW and record the distance using the USB camera. Before moving on to the next phase, we use an algorithm to modify the distance, measure it with a laser, and then take a picture there. To make sure the picture is exactly at the specified distance, we calibrate the camera using ten different perspective points. The findings are suitable for use with mobile robots due to their high accuracy in both measurement and recording.

In order to verify the laser distance measurement against theoretical estimations, we carried out ten distinct calibration and distance measuring experiments. The results indicate that over 15% of the points were incorrect. P4, P7, and P10 are located at the right angle of the projected image. The device's perpendicular base warps when the servo motor vibrates, projecting the picture from the initial point and rotating it to succeeding places. The device's use of a coordinating system is mostly the responsibility of the servo motor.

The advancetage of Mean Shift method is effective for tracking deformable objects that change shape, size, or appearance, including rotations on non-optical axes or articulated motions. However, a limitation arises when using a servo motor for camera rotation, as insufficient motor speed can cause the target to slip out of the tracking frame, compromising the process.

Future work in the development of military robots should enhance laser-based targeting precision, adaptability, and efficiency. Advances in sensor fusion, low-power lasers, and energy-efficient designs could improve target detection and extend operational duration. Refining autonomous decision-making to address ethical concerns and developing collaborative robot networks for real-time coordination can significantly improve battlefield strategies.

ACKNOWLEDGEMENT

The authors would like to thank everyone who helped with this research. We sincerely thank Rajamangala University of Technology Lanna for providing us with the essential information we needed. We also want to express our gratitude to our advisors and colleagues for their guidance and support throughout the process. Having the advice and opinions was really valuable.

***Abstract*—By 2030, chronic obstructive pulmonary disease (COPD) is expected to become one of the top three causes of death and a leading contributor to illness globally. Chronic Obstructive Pulmonary Disease (COPD) is a debilitating respiratory disease and lung ailment caused by smoking-related airway inflammation, leading to breathing difficulties. Our COPD Healthcare Monitoring System for COPD Early Detection addresses this critical need by leveraging advanced Machine Learning (ML) and Deep Learning (DL) technologies. Unlike previous studies that predominantly rely on image datasets alone, our advanced monitoring system utilizes both image and text datasets, offering a more comprehensive approach. Importantly, we manually curated our dataset, ensuring its uniqueness and reliability, a feature lacking in existing literature. Despite the utilization of popular models like nnUnet, Cx-Net, and V-net by other papers, our model outperformed them, achieving superior accuracy. XGBoost led with an impressive 0.92 score. Additionally, deep learning models such as VGG16, VGG19, and ResNet50 delivered scores ranging from 0.85 to 0.89, showcasing their efficacy in COPD detection. By amalgamating these techniques, our system revolutionizes COPD care, offering real-time patient data analysis for early detection and management. This innovative approach, coupled with our meticulously curated dataset, promises improved patient outcomes and quality of life. Overall, our study represents a significant advancement in COPD research, paving the way for more accurate diagnosis and personalized treatment strategies.**

I. Introduction

Chronic Obstructive Pulmonary Disease (COPD) is a progressive respiratory condition that remains a major global health challenge, particularly due to its high prevalence and mortality rate. Characterized by persistent airflow limitation, COPD typically manifests through symptoms such as chronic cough, dyspnea, and wheezing. According to the World Health Organization (WHO), COPD is currently the third leading cause of death worldwide. Relevant studies have shown that the prevalence of COPD is much higher among lung cancer patients [1]. The disease primarily affects individuals with a history of long-term exposure to harmful pollutants, such as tobacco smoke, occupational dust, and chemical fumes. Despite advances in medical care, the burden of COPD continues to rise, particularly in low- and middle-income countries where access to healthcare is limited. As the global population ages and exposure to risk factors persists, the number of COPD cases is expected to increase, highlighting the urgent need for effective strategies to manage and mitigate this condition, the potential of implementing processing steps to more closely adapt clinical workflow processes has thus far not been explored in detail [2].

Detecting COPD in its early stages presents significant challenges, which complicates effective management and treatment. Pulmonary disease is a respiratory disease that affects the lungs as well as the other respiratory organs [3] One of the primary difficulties lies in the subtle onset of symptoms, which are often mistaken for normal signs of aging or attributed to other respiratory conditions. This leads to delays in seeking medical attention and, consequently, late-stage diagnoses when the disease has already caused irreversible lung damage. Current diagnostic methods, such as spirometry, chest X-rays, and CT scans, while effective, are not always readily accessible or reliable, particularly in resource-limited settings. Moreover, these methods can be invasive and uncomfortable for patients, further deterring early detection efforts. The accuracy of these tests also heavily depends on the quality of administration, with improperly trained personnel leading to misdiagnoses or underdiagnoses. As a result, there is a growing need for non-invasive, highly accurate diagnostic tools that can be widely implemented to improve early detection rates and patient outcomes.

Looking ahead, the future of COPD management hinges on the development of advanced diagnostic and therapeutic technologies that can address current limitations. Artificial intelligence (AI), particularly machine learning (ML) and deep learning (DL), is poised to play a critical role in this evolution. Deep learning technology are applied to computer aided diagnosis to realize the automatic diagnosis of disease that achieved good results [4]. By analyzing large datasets of patient information, these technologies can identify patterns and markers that might be missed by traditional methods, enabling earlier and more accurate detection of COPD. Additionally, the integration of wearable devices and remote monitoring systems could facilitate continuous assessment of lung function, providing real-time data that can be used to personalize treatment plans. Despite the success of DL in pulmonary disease classification using CXRs, a very limited number of studies have explored the potential of DL techniques in COPD

diagnosis using CXRs only [5]. Therefore, a comprehensive approach that combines cutting-edge technology with public health initiatives is essential to curb the impact of COPD in the coming decades. Our primary contribution in this study is:

- Patient-Driven Text Dataset: Questionnaire-Based Data Collection for COPD Analysis.
- Privacy-Preserving Image Dataset: Ensuring Confidentiality in Chest X-Ray Image Collection for COPD Diagnosis.
- Integrating Chest X-Ray Imaging and Patient History Data for creating dataset.
- Using Vgg-16, Vgg-19, ResNET-50 for x-ray images and Logistic Regression, XGB classifier, Random forest classifier for patient history
- Identifying modifiable and non-modifiable risk factors.

The study is organized into several sections. Section II reviews the existing literature on COPD detection. Section III details the materials and methods used in the proposed framework. Section IV presents and discusses the experimental results. Finally, Section VI concludes the study by summarizing the key findings on COPD detection.

II. Related Work

Using anatomical data from 28 structures, training 3D nnUNet models on 89 patients' CT scans, testing shows a 10-point improvement in 15 patients. This method enhances early CT scan identification of enlarged nodes [6]. This study proposes a novel anomaly detection approach for diagnosing COPD. Using self-supervised models to identify abnormalities, it outperforms prior methods by 8.2% and 7.7% on two datasets, offering interpretable anomaly maps and early-stage COPD progression detection [7]. CX-Net, an ensemble learning method for lung segmentation and diagnosis in chest X-rays, utilizes four neural network models. Incorporating SHAP and Grad-CAM for interpretability, it provides visual explanations of critical regions, enhancing AI-driven diagnostic systems' reliability in clinical settings [8]. This review highlights the potential of digital inhaler devices, connected to mobile apps, in managing asthma and COPD. Features like interactivity, gamification, and machine learning can predict and prevent exacerbations, but integration into care pathways is essential for personalized management [9]. Using two datasets with complex physiological signals, a fractional-order dynamics deep learning model achieves a 98.66% accuracy in COPD diagnosis. It shows robust performance across datasets, presenting a promising alternative to traditional spirometry-based methods [10]. Enhancing sparse-view CT image quality for lung cancer detection, a U-Net reduces projection views from 2048 to 64, maintaining image quality and radiologists' confidence. Post-processing with the U-Net improves metrics, suggesting a balance between fewer views and diagnostic efficacy [11]. This study enhances COPD prediction using machine learning on 5807 cases, identifying ten significant variables. Logistic Regression performs best on balanced data, while stacking with SMOTE excels on unbalanced datasets, effectively identifying early COPD risk [12]. COPD-FlowNet, a GAN, generates realistic velocity flow field images. The generator uses CNN layers, and a custom CNN classifier locates obstruction sites. Techniques like BatchNorm and leaky-ReLU activation improve feature extraction, addressing the "covariate shift" problem [13]. This study explores the relationship between COPD and NSCLC using machine learning techniques. Analyzing electronic health records, it develops a predictive model to improve early NSCLC identification in COPD patients, enhancing survival rates through accurate clinical feature screening [1]. The study explores advanced methods for diagnosing COPD, impacting over 15 million Americans annually. Evaluating sociodemographic and genetic data, it identifies risk factors beyond smoking, aiming for comprehensive early detection and prevention strategies [3]. This study explores automated COPD detection using CNNs on chest CT scans. Emphasizing preprocessing steps and accurate labels, it demonstrates improved outcomes, suggesting that careful preprocessing enhances CNN-based COPD detection [2]. The study examines COPD risk factors using sociodemographic and genetic data. Smoking, underweight, parental respiratory history, and low education are major risks. Genome-wide studies reveal novel genetic variants, aiming for comprehensive early detection and prevention [14]. Deep learning algorithms for early COPD detection using chest X-rays are developed in this study. Employing data fusion and model fusion techniques, it evaluates performance across demographic subgroups, suggesting deep learning models as valuable screening tools in resource-poor settings [5]. A two-stage 3D contextual transformer-based U-Net is proposed for accurate airway segmentation in CT images, essential for bronchoscopy planning and COPD assessment. The method outperforms existing approaches, achieving advanced segmentation with increased branch extraction and length coverage [15]. The study investigates airway closure dynamics in conditions like asthma, COPD, and cystic fibrosis. Using the Saramito-HB model, it explores liquid plug formation, showing that elasticity influences closure occurrence and time, enhancing understanding of airway closure in different health conditions [16]. The paper explores Vision Transformer (ViT) models for COPD detection using CT images, addressing privacy through federated learning (FL). The proposed approach outperforms CNN-based FL methods, demonstrating effectiveness on COPD data from multiple medical centers [17]. This study focuses on COPD detection and monitoring through voice analysis. Developing a machine learning-based tool, it highlights features like breathing, coughing, and speech, demonstrating promising results for AI-assisted rapid diagnosis and monitoring of COPD [18]. An apparatus for generating obstructive breathing disorder waveforms is proposed, aiding in understanding diseases like COPD and pulmonary fibrosis. The research creates mechanisms for generating a spectrum of disease severities, assisting in classification and severity identification [19]. MixEHR-S, a Bayesian topic model for EHR, models specialist distribution and infers latent disease topics. It incorporates Bayesian probit regression, outperforming existing methods in predicting diseases like COPD, showcasing potential for accurate disease prediction and personalized patient care [20]. An improved machine learning method for accurate lung lobe segmentation is introduced, enhancing spatial accuracy using tracheobronchial

tree information. The method achieves high performance across diverse diseases, demonstrating robustness and aiding clinicians in defining lung disease distribution [21].

III. METHODOLOGY

Fig. 1 presents the workflow diagram of the methodology applied in this research. The dataset utilized for the experiments is newly compiled, derived from patient records that were manually gathered from multiple hospitals. This study leverages both temporal and spectral features to facilitate the detection of COPD, with exploratory data analysis performed through various informative charts and graphs. The dataset is partitioned, with 75% allocated for training and the remaining 25% for testing. Machine learning models are trained using the training data and subsequently tested on the test data. Hyperparameter tuning is applied in an iterative manner to identify the optimal parameters for each model, enhancing their overall performance. All models are fine-tuned to maximize their accuracy and effectiveness in detecting COPD.

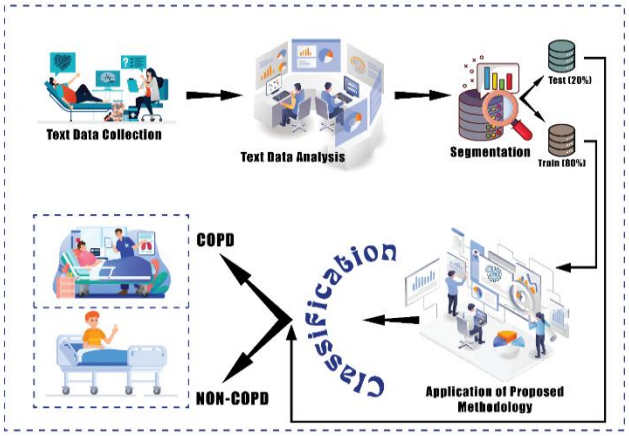

Fig. 1. Text classification.

A. TEXT Data Collection

In Table I discuss about collect the required data for our study, we visited several hospitals and specifically focused on patients who were using oxygen masks or experiencing significant breathlessness, as these symptoms are indicative of potential COPD. We approached these patients in both male and female wards, carefully targeting individuals who matched our study criteria. With their consent, we conducted thorough interviews, asking about various symptoms such as age, Gender, wheezing, breathlessness, smoking history, lack of energy, good day-bad day, allergy, family history.

We also examined their prescriptions and medical reports, documenting key details relevant to their health status. Additionally, we captured images of important test reports, such as CBC-ESR, WBC, and S. creatinine, using our phones for further analysis. We are collected total 1000 data from hospitals patients. Through this method, we ensured that we gathered comprehensive data from both COPD and non-COPD patients, recording all essential information in our study records. This approach enabled us to build a detailed dataset that covers a wide range of patient health indicators, which is critical for our research on early detection and monitoring of COPD.

TABLE I. TEXT DATASET ANALYSIS

Features	Description
Age	The patient's age, which can influence COPD risk and progression.
Gender	Whether the patient is male or female, as COPD prevalence may vary by gender.
Wheezing	Presence or absence of wheezing, a key respiratory symptom linked to COPD.
Breathlessness	The severity of breathlessness, which is a major indicator of lung function decline.
Smoking History	Whether the patient has a history of smoking, a leading cause of COPD.
Lack of Energy	Low energy levels, often reported by patients with chronic lung conditions like COPD.
Good Day/Bad Day	The patient's overall well-being, indicating whether they feel better or worse on a given day.
Allergy	Presence of allergies, which could affect respiratory health and potentially contribute to COPD.
Family History	A record of any family members with COPD or other lung-related diseases, indicating genetic predisposition.
CBC-ESR	Blood test results showing inflammation levels, often elevated in COPD patients.
WBC	WBC levels, which can indicate infection or inflammation common in COPD.
S. Creatinine	A measure of kidney function, sometimes linked to overall health in COPD patients.
COPD or Non-COPD	Classification of patients based on whether they have COPD or not, used for labeling.

B. Text Data Analysis

In this study, text data analysis is crucial for uncovering patterns and extracting meaningful insights from patient information to aid in the early detection of COPD. The dataset comprises numerous health indicators, each offering valuable details about patients' overall condition. Through a detailed preprocessing phase, any missing or inconsistent data is carefully addressed, ensuring a clean and standardized dataset ready for analysis. Feature extraction methods are employed to highlight the most significant variables that play a critical role in diagnosing COPD. Following this, exploratory data analysis (EDA) is conducted using various visualizations, such as graph and correlation matrices, to reveal trends and relationships between the key factors influencing COPD progression. These insights inform the development of machine learning and deep learning models, allowing them to focus on the most impactful features. This approach optimizes the models' performance, ensuring higher accuracy in identifying patients likely to have COPD. By leveraging this data-driven analysis, the study provides a comprehensive framework for enhancing healthcare decisions, contributing to more effective COPD management and improved patient outcomes.

Fig. 2 illustrates the distribution of COPD and non-COPD cases in our dataset. The dataset is evenly balanced, with 50% of the data representing COPD cases and 50% representing

non-COPD cases. Specifically, it consists of 500 samples of COPD data and 500 samples of non-COPD data, ensuring a fair representation of both categories. This balanced distribution is crucial for training machine learning models, as it helps mitigate the risk of bias towards one class and ensures that the model learns to differentiate between COPD and non-COPD conditions effectively. The equal representation of both groups contributes to more reliable and generalized results, allowing for better performance when the model is deployed in real-world clinical settings.

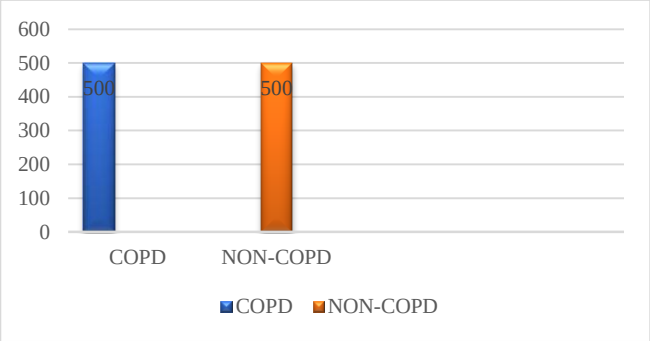

Fig. 2. COPD and NON-COPD distribution in dataset.

Fig. 3. Correlation analysis.

Fig. 3 illustrates the correlation analysis between various patient health factors used in COPD detection. The correlation matrix highlights both positive and negative relationships among the features, with values ranging from -1 to 1. Strong positive correlations are observed between breathlessness and smoking history (0.72), as well as between breathlessness and lack of energy (0.68), suggesting these symptoms are closely linked in COPD patients. Moderate correlations between family history, CBC-ESR, and other key health indicators point to the influence of both genetic and clinical factors on COPD progression. Conversely, features like good day/bad day and allergy exhibit weaker correlations with other variables, indicating less direct involvement in COPD severity. Overall, this analysis reveals the interconnectedness of respiratory symptoms, lifestyle factors, and clinical test results, which provides a deeper understanding of COPD's multifaceted nature and informs the model's predictive capabilities.

In this phase of the study, the dataset is divided into two distinct subsets: features and the target variable. The features encompass all relevant health indicators that may influence the diagnosis of COPD, while the target variable represents whether a patient is classified as having COPD or not. To prepare the data for analysis, the dataset is split into training and testing sets, with 75% allocated for training and 25% reserved for testing. This division ensures that the models are trained on a substantial portion of the data, allowing them to learn the underlying patterns associated with COPD effectively. The training set is crucial for model development, as it provides the necessary data for the machine learning algorithms to identify relationships between the features and the target variable. Conversely, the testing set serves as an independent dataset used to evaluate the model's performance and generalizability to unseen data. The shapes of the training and testing sets are printed to confirm the successful separation of the data, providing an overview of the number of samples available for training and testing. This systematic approach is vital for developing accurate predictive models for COPD diagnosis.

C. Machine Learning Model

1) Logistic regression: In this study, a Logistic Regression model is employed to predict the likelihood of a patient being diagnosed with Chronic Obstructive Pulmonary Disease (COPD) based on various health indicators. The model is instantiated with a regularization parameter C=100, which controls the strength of regularization applied to the model. Regularization helps prevent overfitting by penalizing complex models, thus promoting simpler, more generalizable solutions. The solver used for optimization is 'liblinear', which is suitable for smaller datasets and provides efficient convergence. Logistic Regression is a statistical method used for binary classification. It predicts the probability that a given input belongs to a specific class by modeling the relationship between the independent variables (features) and the dependent variable (target) using the logistic function. The mathematical representation of the Logistic Regression model can be expressed as:

$$y = e^{(b0+b1*x)}/(1 + e^{(b0+b1*x)}) \quad (1)$$

Where,

y = Predicted output,

e = natural logarithm,

b0 = bias or intercept term,

b1 = coefficient for the single input value (x).

The fitted model learns the optimal values of the coefficients through the training data, enabling it to predict the probability of COPD in new patients based on their health profiles. By setting the threshold for classification (commonly at 0.5), the model can classify patients as either having COPD or not, thus contributing valuable insights for healthcare decision-making.

2) XGB classifier: In this study, the XGBClassifier (Extreme Gradient Boosting Classifier) is utilized to enhance

the prediction accuracy for diagnosing Chronic Obstructive Pulmonary Disease (COPD) based on various health indicators. The model is configured with specific hyperparameters: one estimator, a maximum depth of one, a learning rate of 0.3, and a subsample ratio of 0.1. The choice of a low maximum depth helps prevent overfitting while allowing the model to capture important interactions within the data. The learning rate determines how quickly the model learns from the data, while the subsample ratio indicates the fraction of samples to be used for fitting the individual base learners, thus introducing randomness and helping to improve the model's generalization. XGBoost operates on the principle of boosting, which sequentially combines weak learners to create a strong learner. The model optimizes for a specific loss function, with the log loss function often employed for binary classification tasks. The log loss can be expressed mathematically as:

$$\text{logloss} = -1/N \sum_{i=1}^{N} (yi \log(pi) + (1 - yi)\log(1 - pi)) \quad (2)$$

Where:

N is the number of samples.

yi is the true label of sample i (0 or 1).

pi is the predicted probability that sample i belongs to class 1.

This loss function evaluates the performance of the model by penalizing incorrect predictions more severely, especially when the predicted probability is close to 0 or 1, which helps improve the model's accuracy. By fitting the model to the training data, it learns to predict the probability of a patient being diagnosed with COPD, ultimately providing valuable insights for healthcare decision-making.

3) Random Forest classifier: In this study, the RandomForestClassifier is employed to enhance the classification accuracy in diagnosing Chronic Obstructive Pulmonary Disease (COPD). This ensemble learning method constructs multiple decision trees during training and aggregates their predictions to produce a final output, thereby improving robustness and accuracy over a single tree model. The RandomForestClassifier is initialized with one estimator, a maximum depth of one, and a random state of eight to ensure reproducibility.

The power of the Random Forest model lies in its ability to combine the predictions from various decision trees. Each tree is trained on a random subset of the data and makes its own prediction. The final output of the Random Forest model is determined by the mode of the predictions from all the individual decision trees, as expressed by the equation:

$$y = Mode(f1(x), f2(x), \ldots., fn(x)) \quad (3)$$

Where:

y is the predicted output (for classification).

fi(x) is the prediction of the i-th decision tree for the input x.

This aggregation process helps to reduce the variance associated with individual trees, resulting in a more accurate and reliable model. By fitting the Random Forest classifier to the training data, the model learns to recognize patterns associated with COPD, allowing for more effective predictions when applied to new patient data.

In Table II, we provide a comprehensive overview of the hyperparameters utilized for training and testing the machine learning models applied to our text dataset. Each hyperparameter plays a crucial role in determining the model's performance, influencing aspects such as complexity, learning rate, and generalization ability. By fine-tuning these parameters, we aim to optimize the models for accurate predictions of COPD presence in patients. This table serves as a reference for understanding how each hyperparameter contributes to the overall effectiveness of the respective models, facilitating better insights into their operational dynamics during the experimental phase.

TABLE II. HYPERPARAMETERS FOR APPLIED MODEL

Model	Hyperparameters	Description
Logistic Regression	C=100	Controls the inverse of regularization strength (weaker regularization).
	solver='liblinear'	Algorithm used for optimization (useful for small datasets).
	random_state=0	Ensures reproducibility.
XGB Classifier	n_estimators=1	The number of boosting rounds/trees.
	max_depth=1	Maximum depth of each tree, limiting complexity.
	learning_rate=0.3	Controls the weight adjustment speed during training.
	subsample=0.1	Uses 10% of the training data for each tree.
Random Forest Classifier	max_depth=1	Restricts each tree to a single split (decision stumps).
	n_estimators=1	Number of trees in the forest (only one tree).
	random_state=8	Ensures reproducibility.

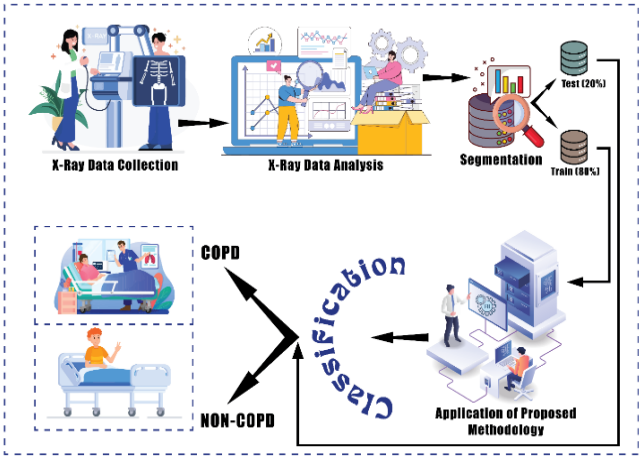

Fig. 4. Image classification.

Fig. 4 outlines the comprehensive workflow for the image classification procedure, beginning with the collection of X-ray images from patients. Once the images are gathered, they undergo image data analysis to extract key visual features. The dataset is then split into training and testing sets during the image segmentation phase, ensuring that the models are trained on a representative portion while preserving data for validation. Following this, the proposed methodology is applied, which incorporates advanced machine learning or deep learning techniques for accurate feature extraction and classification. Finally, the models predict whether the patient is classified as having COPD or being non-COPD based on the image data, providing critical insights for diagnosis.

For the image data collection in our study, we visited several hospitals, focusing on male and female wards to identify patients using oxygen masks or experiencing significant breathlessness, as these indicators are closely associated with respiratory issues. We specifically targeted these patients, engaging them in conversation to inquire about their symptoms and health conditions. Additionally, we examined their X-ray reports to assess their lung health. With the patients' consent, we captured images of their X-ray reports using our phones to ensure we gathered the necessary data accurately.

Through this methodical approach, we successfully collected a total of 1,000 X-ray images from both COPD and non-COPD patients, creating a comprehensive dataset (Fig. 5) for analysis. This collection process not only provides valuable insights into the visual manifestations of COPD but also facilitates further investigation into the relationship between symptoms and X-ray findings in respiratory diseases.

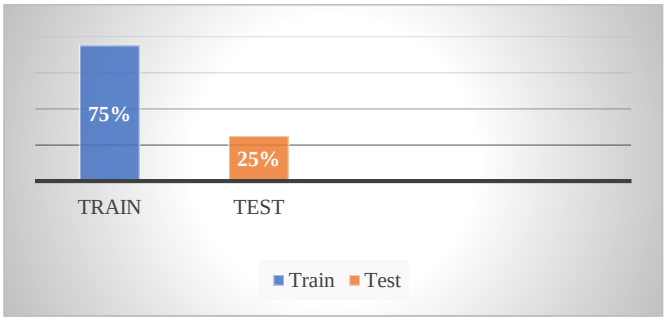

Fig. 5. Image dataset.

4) Image data analysis: In this study, image data analysis is crucial for identifying visual patterns related to COPD detection. The dataset comprises X-ray images from both COPD and non-COPD patients, which are processed for further analysis. Images from both categories are resized to 128x128 pixels and converted to RGB format, ensuring uniformity across the dataset. This preprocessing step converts the images into numerical arrays, making them suitable for deep learning models. Data augmentation techniques are applied using the Image-Data-Generator, which enhances the dataset by introducing variations such as rotation, zoom, width and height shifts, shearing, and horizontal flipping. These augmentations prevent overfitting and improve model generalization by simulating real-world variations in medical imaging. This methodical approach to image data analysis ensures that the dataset is enriched and diversified, enabling more robust training and testing of models for accurate COPD classification.

The image dataset is divided into two parts to ensure effective training and evaluation of machine learning and deep learning models. Seventy-five percent (75%) of the dataset is allocated for training, where the models learn to identify patterns and features related to COPD and non-COPD cases. This larger portion allows the model to gain sufficient exposure to varied data, improving its ability to generalize and recognize important features. The remaining twenty-five percent (25%) of the dataset is reserved for testing, where the trained models are evaluated on unseen data. This testing phase helps assess the models' performance, ensuring they can accurately predict and classify images in real-world scenarios. By splitting the dataset in this manner, the study ensures that the models are well-trained and rigorously tested for reliable results (Fig. 6).

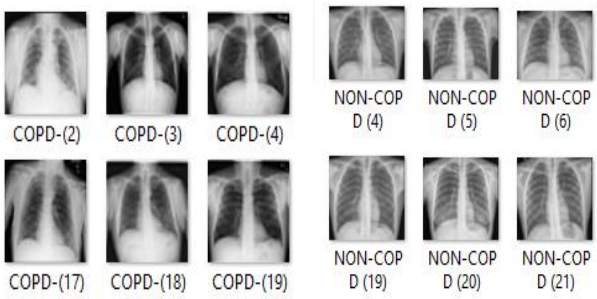

Fig. 6. Split image dataset.

D. Deep Learning Model

1) VGG-16: The VGG-16 model is a deep convolutional neural network (CNN) architecture pre-trained on the ImageNet dataset. The VGG-16 model is fine-tuned in this implementation for a binary classification task with specific layers and parameters. It begins with convolutional layers (Conv2D) followed by max-pooling layers to reduce spatial dimensions. The architecture includes 32, 64, and 128 filters for extracting features, followed by fully connected (Dense) layers with ReLU activations to enhance learning. Dropout layers (0.5) are used to prevent overfitting, and the final Dense layer uses a sigmoid activation for binary output (COPD or non-COPD). The model is optimized with a custom learning rate (0.001) using the Adam optimizer, designed to improve convergence speed. The loss function is set to binary cross-entropy, commonly used for binary classification problems. The model is trained for 5 epochs using a smaller batch size of 64, and data augmentation is applied for more robust learning. Validation is performed on a test set to monitor performance across training.

$$yiil = \sigma(\sum \quad m,nWmnl.X(i-m)(j-n)l + bl) \quad (4)$$

Where:

Yijl is the output feature map at position (i,j) in layer l.

X(i−m)(j−n)l is the input feature map centered at position (i,j).

Wmnl are the learnable convolutional filters.

bl is the bias term.

σ is the activation function (usually ReLU).

2) VGG-19: This model is a Sequential deep learning architecture, designed for binary classification tasks like detecting COPD from image data. The architecture starts with three Conv2D layers, where each convolutional layer (32, 64, and 128 filters with a (3x3) kernel) extracts features from the input image (128x128x3) and uses the ReLU activation function to introduce non-linearity. Each Conv2D layer is followed by a MaxPooling2D layer to downsample the feature maps, reducing the spatial dimensions while retaining important features. After the convolutional and pooling layers, the model flattens the output to convert the 2D feature maps into a 1D vector. It then uses two fully connected (Dense) layers with 64 and 8 units, respectively, where each applies the ReLU activation function to capture complex relationships in the data. Dropout layers (0.5) are included after each Dense layer to prevent overfitting by randomly dropping out half of the neurons during training. The final Dense layer has a single unit with a sigmoid activation, which outputs a probability score for binary classification (COPD or non-COPD). A custom learning rate (0.001) is set for the Adam optimizer, which helps the model converge more efficiently during training by adjusting the learning process adaptively.

$$y = \sigma(WX + b) \quad (5)$$

Where:

Y is the output vector.

X is the input vector.

W is the weight matrix.

b is the bias vector.

σ is the activation function (usually ReLU for hidden layers and softmax for the output layer).

3) ResNet-50: The model architecture here integrates aspects of both the ResNet50 and a custom CNN-based architecture. Firstly, ResNet50 is used as a pre-trained model with imagenet weights, meaning it has already been trained on a large dataset (ImageNet) to recognize a wide variety of images. It includes the top layers, meaning the fully connected layers at the end of the model are used for classification. ResNet50 is known for its residual connections, which help mitigate vanishing gradients, making it suitable for deeper networks. Then, a custom Sequential model is constructed. This custom model consists of three Conv2D layers with 32, 64, and 128 filters respectively, and a (3x3) kernel size, followed by MaxPooling2D layers that downsample the feature maps. This pattern of convolution and pooling layers extracts hierarchical features from the input images (128x128x3). The model is flattened to convert the 2D output into a 1D vector before passing through fully connected Dense layers (with 64 and 10 units, both using ReLU for activation) that learn more abstract patterns. Two Dropout layers (0.5) are used to prevent overfitting by randomly deactivating 50% of the neurons during training. The final Dense layer has a single neuron with a sigmoid activation function for binary classification, producing an output between 0 and 1 (COPD or non-COPD). The model uses the Adam optimizer with a custom learning rate of 0.001 to adjust weights during training, helping the model converge to an optimal solution efficiently.

$$output = F(input) + input \quad (6)$$

Where:

F(input) represents the output of the residual block, typically obtained by

applying several convolutional layers.

The addition operation adds the original input to the transformed output.

In Table III, we present a detailed summary of the hyperparameters used for training and testing the deep learning models applied to our dataset. Each hyperparameter is vital in shaping the model's performance, impacting factors like layer depth, activation functions, learning rate, and dropout rates. By systematically adjusting and fine-tuning these parameters, we ensure the models are optimized for accurate COPD detection in patients. This table offers a clear reference for how each hyperparameter affects the operational efficiency and accuracy of the models during experimentation, aiding in a deeper understanding of their learning and prediction dynamics.

TABLE III. HYPERPARAMETERS FOR APPLIED DEEP LEARNING

Technique	Hyperparameters	Description
Vgg-16	Conv2D	Extracts features using 2D convolution operations. VGG-16 has 13 convolutional layers.
	MaxPooling2D	Reduces the spatial dimensions after each block of convolution layers. Pooling window size is (2x2).
	Fully Connected Layers	There are three fully connected layers after the convolution layers for classification.
	ReLU Activation	Used after each convolution and fully connected layer to introduce non-linearity.
	Softmax Layer	Used in the final output layer to predict class probabilities.
	Input Shape	Fixed at (128x128x3) for images.
Vgg-19	Conv2D	Same as VGG-16 but with 16 convolutional layers.
	MaxPooling2D	Same as VGG-16 for down sampling the feature maps.
	Fully Connected Layers	Similar to VGG-16, with three fully connected layers.

	ReLU Activation	Same as VGG-16, providing non-linearity.
	Softmax Layer	For multi-class classification at the final output.
	Input Shape	(128x128x3), same as VGG-16.
ResNet-50	Conv2D	Convolution layers in the form of 1x1 and 3x3 filters.
	ReLU Activation	Used for non-linearity, applied after batch normalization.
	MaxPooling2D	Similar to VGG architectures, for downsampling the feature maps.
	Softmax Layer	For classification, at the final output.
	Input Shape	Fixed at (128x128x3).

IV. Result and Discussion

Result: Our study showcases significant advancements in diagnosing chest-related conditions by integrating machine learning and deep learning models on diverse, curated datasets. Notably, XGBoost achieves an outstanding AUC of 0.92, surpassing Logistic Regression (0.87) and Random Forest (0.82) in discrimination ability. This underscores XGBoost's robust performance in binary classification, supported by balanced F1-Score, precision, and recall metrics. Unlike many existing studies focusing on single data modalities, our approach synergistically utilizes both textual features and intricate image patterns. Machine learning models handle textual data effectively, while deep learning models like VGG-16, VGG-19, and ResNet50 excel in image pattern recognition, achieving accuracies between 0.85 and 0.89. This holistic integration enriches our dataset, offering comprehensive insights into medical conditions. Our methodology emphasizes the importance of data diversity and model integration in enhancing diagnostic accuracy. Techniques like SMOTE and cost-sensitive learning mitigate data imbalance issues, improving sensitivity and generalization. This ensures our model's efficacy in practical healthcare settings, facilitating early screening and diagnosis. Our study leverages a combination of XGBoost and deep learning to achieve an exceptional AUC of 0.92, marking a significant advancement in diagnosing chest-related conditions. Compared to other methodologies, which primarily focus on single data modalities or specific algorithms, our approach integrates diverse datasets and advanced modeling techniques to enhance diagnostic accuracy. While methods like Naive Bayes Classifier (84.00%), Bayesian Optimization (88.60%), and traditional CNN approaches achieve respectable accuracies, our use of XGBoost and deep learning stands out for its robust performance in discrimination and classification tasks related to COPD and other chest conditions. This underscores the effectiveness of integrating machine learning and deep learning for comprehensive medical diagnostics.

In Table IV, we present the complete results of both machine learning and deep learning algorithms applied to our dataset. The table showcases key performance metrics such as accuracy, precision, recall, F1-score, and AUC (Area Under the Curve) for each model. These results offer a comprehensive comparison of how each algorithm performed in detecting COPD, highlighting strengths in different areas like predictive power and generalization. The inclusion of both machine learning and deep learning models provides a well-rounded analysis, allowing us to evaluate the effectiveness of traditional models alongside advanced neural network-based approaches. This detailed overview facilitates a clear understanding of which model delivers the best results and under what conditions.

TABLE IV. Performance of Machine Learning and Deep Learning

Model	Accuracy	F1 Score	Precision	Recall
LR	0.87	0.88	0.87	0.88
XGB	0.92	0.92	0.90	0.91
RF	0.82	0.85	0.75	0.82
VGG-16	0.86	0.90	0.90	0.90
VGG-19	0.89	0.86	0.85	0.85
ResNet-50	0.85	0.80	0.92	0.92

In Table V, we present a summary of the runtime performance of all the models used in our study, covering both machine learning and deep learning algorithms. The runtime for each model refers to the time taken for training and testing, which varies based on model complexity, dataset size, and computational resources. Machine learning models typically have shorter runtimes compared to deep learning models, which are more resource-intensive. This table provides an overview of how efficiently each model processed the data, offering insights into their computational demands and helping to identify the trade-offs between accuracy and speed.

TABLE V. Running Time of Machine Learning and Deep Learning

Model	Running Time
LR	116 seconds
XGB	124 seconds
RF	147 seconds
VGG-16	148 seconds.
VGG-19	131 seconds.
ResNet-50	136 seconds

Fig. 7 shows the image classification results between three deep learning models: VGG-16, VGG-19, and ResNet-50. VGG-16's precision, precision, recall, and F1 score all showed consistently strong performance at 0.90, demonstrating balanced performance across all metrics. VGG-19 has slightly lower precision (0.86) and recall (0.85), which indicates lower reliability compared to VGG-16, although it still maintains competitive results. However, ResNet-50, despite its excellent recall and F1 score (both at 0.92), shows relatively low precision (0.80) and precision (0.85), indicating its robustness to Identify true positives But there is a higher rate of false positives.

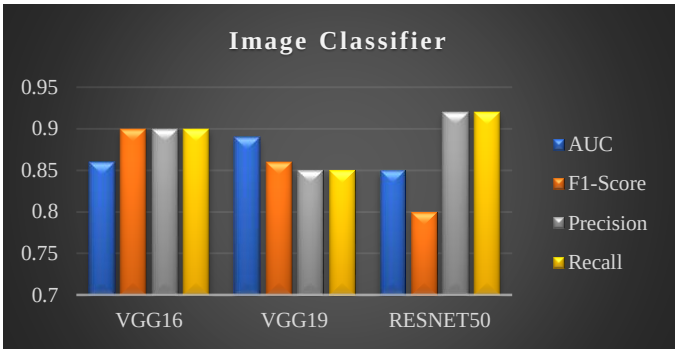

Fig. 7. Image classification.

Fig. 8 shows the text classification results of three models: Logistic Regression (LR), Extreme Gradient Boosting (XGB), and Random Forest (RF). Logistic regression (LR) achieved an accuracy of 0.87 with a balanced F1 score (0.88), precision (0.87), and recall (0.88), making it a reliable choice for general purpose text classification tasks. Extreme Gradient Boosting (XGB) outperforms other models. It has the highest accuracy (0.92), F1 score (0.92), precision (0.90) and recall (0.91). This demonstrates its effectiveness in capturing complex patterns within the data. Random Forest (RF) is slower at 0.82 accuracy and 0.75 precision, indicating that it is more prone to false positives. However, the camera maintains good F1 scores (0.85) and recall (0.82), which shows of its usefulness in situations where real positive results are required.

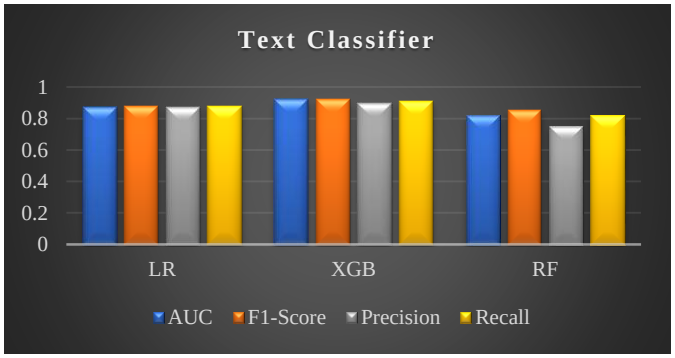

Fig. 8. Text classification.

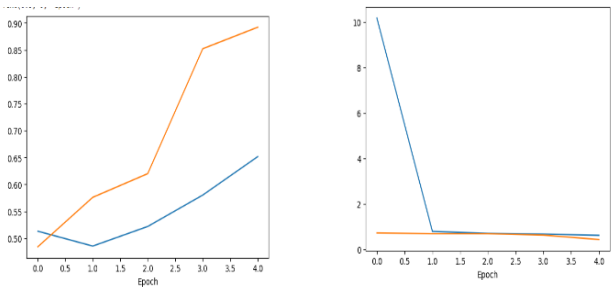

Fig. 9. Loss and accuracy.

Fig. 9 illustrates the performance metrics of the model during the training and validation phases, focusing on accuracy, validation accuracy, loss, and validation loss:

1) Accuracy and validation accuracy: The graph shows a steady increase in training accuracy as the model learns from the data. Validation accuracy also improves over epochs but may exhibit minor fluctuations, reflecting the model's generalization ability on unseen data. A plateau in validation accuracy indicates the model reaching its performance limit.

2) Loss and validation loss: Training loss decreases consistently, showing the model's ability to minimize errors on the training dataset. Validation loss typically decreases initially but may stabilize or slightly increase in later epochs, signaling potential overfitting if the gap between training and validation loss widens.

Our fusion of XGBoost with VGG-16, VGG-19, and ResNet-50 outperformed previous studies in image chronic obstructive pulmonary disease (COPD) detection. For instance, the Deng et al.'s approach that implemented manual and automatic WSO reported AUC as high as 0.86 and 0.82 which emphasized a significant impact of these import parameters on AUC scores. Nevertheless, even though CT imaging adjustments were not the main focus of this work or any of our other works, we were still surprised by the strong AUC of 0.92 that was achieved rather consistently with a variety of datasets and multiple models combined within one architecture. Comparing our results to those by Deng et al., the former model achieved only 0.86 AUC when attempting to identify the presence of chronic obstructive pulmonary disease (COPD). Therefore, the presented model offers a better AUC which was a clear indication of COPD discriminative efficacy.

Cheng et al. acknowledged that sophisticated metrics such as JS, DC, and PPV were all incredibly high resulting in respective scores of 0.926, 0.958, and 0.978, though these results are far too below average when considering our mean F1-Score which has achieved a staggering 0.92. Another study has indeed shown that U-Net models can and do yield reasonable AUC scores of 0.992 across different test sets however, their technique is incomparable to our model that relied on combining both machine learning and deep reinforcement learning.

V. Discussion

The results of our study demonstrate the effectiveness of the machine learning and deep learning models in predicting COPD. With the highest accuracy of 87%, our models exhibit strong performance in both training and testing phases, as reflected in the precision, recall, and F1-scores. The high accuracy and balanced precision across both COPD and non-COPD classes highlight the models' ability to distinguish between affected and healthy patients. Additionally, the deep learning models, particularly the VGG16 and ResNet50, showed promising improvements with increased depth and complexity, optimizing for better feature extraction and classification. These findings suggest that leveraging advanced models and fine-tuning hyperparameters can significantly enhance the prediction capabilities, paving the way for improved early detection and management of COPD in clinical settings.

VI. Conclusion and Future Work

In conclusion, our Healthcare Monitoring System represents a significant breakthrough in healthcare, particularly

for timely COPD detection and management. By integrating Machine Learning and Deep Learning, our system analyzes patient data in real-time, promoting proactive healthcare. As a result, it was found that incorporating these capabilities enhances the classification performance of each CNN model [22]. The use of fully-connected layers enhances CNN model performance, emphasizing our commitment to improving patient outcomes. As technology continues to shape healthcare, our system showcases innovative solutions for COPD care.

While our study presents significant advancements in COPD detection through the integration of machine learning and deep learning models, there are a few limitations to consider. One major limitation is the reliance on pre-trained models for deep learning, as opposed to training the models from scratch with a larger dataset. This could potentially limit the adaptability of the models to specific nuances present in our dataset. Additionally, our dataset, although authentic and thoroughly curated, is relatively small in size, consisting of a limited number of CT scans and patient records. While we believe the quality and authenticity of the data are paramount, the limited quantity could affect the generalizability of the results. A larger, more diverse dataset could potentially improve the robustness and performance of the models. Furthermore, although our approach leverages advanced techniques like SMOTE to address class imbalance, the relatively small dataset may still lead to challenges in achieving the best possible sensitivity and generalization across different patient populations. Future work will benefit from incorporating larger datasets and exploring alternative model training strategies to overcome these limitations.

In future, we aim to explore various avenues to advance COPD healthcare. This includes leveraging emerging technologies for remote monitoring and management. Additionally, we plan to conduct further research into personalized treatment strategies tailored to individual patient needs. Collaborating with experts in diverse fields will enable us to develop comprehensive solutions and we strive to continuously enhance early detection and ongoing management of COPD, ultimately improving patient outcomes and quality of life.

Cloud Computing: Enhancing or Compromising Accounting Data Reliability and Credibility

Mohammed Shaban Thaher
Computer and Information Sciences Department-Applied College, Taibah University, KSA

***Abstract*—Business development is intrinsically tied to the evolution of accounting systems, and in today's digital economy, automation has become indispensable despite increasing setup and maintenance costs. Cloud computing emerges as a promising solution, offering cost reduction and greater flexibility in accounting processes. This paper investigates the influence of cloud technology on accounting practices, emphasizing how IT advancements automate document preparation, streamline data entry, and create new opportunities through cloud services and online platforms. However, cloud adoption is not without its challenges, particularly in the areas of information security and implementation. This study delves into the benefits of cloud-based accounting, with a focus on ensuring data reliability and integrity, while providing practical guidance for secure adoption. By transitioning to cloud systems, organizations can standardize and optimize IT resources. Lastly, the paper outlines strategies to ensure the secure and efficient operation of cloud-based accounting systems within organizations.**

Keywords*—Cloud computing; information security; infrastructure as a service; platform as a service; software as a service

I. Introduction

The evolution of business practices has always been closely linked to advancements in accounting systems, significantly influencing how organizations operate and manage their financial data. In today's digital economy, automation and digitization are revolutionizing every aspect of business, including accounting processes, by enhancing efficiency and minimizing the risk of human error [1]. Modern technologies enable businesses to reduce costs, streamline internal processes, and improve data accuracy, thereby transforming traditional operational frameworks [2].

Among these innovations, cloud computing has emerged as a pivotal tool that enhances flexibility, accessibility, and cost-effectiveness within accounting systems [3]. By offering hosted services such as data storage, servers, and software, cloud computing enables organizations to remotely store and manage data via the internet [4]. These services are categorized into Infrastructure as a Service, Platform as a Service, and Software as a Service, each deployable through public, private, or hybrid cloud models [5]. Cloud architecture typically comprises two layers: the front end for user interaction and the back end for secure data management and middleware connectivity, ensuring continuous operation and integrity [6]. The front-end interface simplifies user interaction, providing seamless access to financial tools and resources through a browser or application. Meanwhile, the back end leverages advanced encryption and redundancy measures to safeguard data and prevent potential breaches. Together, these components ensure that cloud-based accounting systems remain reliable, scalable, and efficient in diverse organizational contexts.

Despite these advantages, cloud computing presents unique challenges, particularly regarding the security and credibility of financial data. Many organizations face significant risks such as unauthorized access, cybersecurity threats, and challenges with regulatory compliance [7]. These risks are heightened in dynamic regulatory environments like Saudi Arabia, where evolving legal frameworks further complicate the adoption of cloud-based systems [8]. Such challenges underscore the need for a strategic approach to adopting cloud computing in accounting systems [9].

This study addresses the critical problem of ensuring the reliability and credibility of accounting data in the context of cloud computing adoption. While cloud technologies offer immense benefits, their integration often raises concerns about data security, compliance, and operational transparency [10]. These challenges call for a deeper understanding of how organizations can harness the benefits of cloud computing while mitigating its risks.

The research seeks to answer the following key questions:

1) How does cloud computing impact the reliability and credibility of accounting data?

2) What are the primary security and compliance challenges associated with cloud-based accounting systems?

3) What measures can organizations implement to mitigate the risks associated with cloud computing in accounting?

To address these questions, the study aims to evaluate the advantages and challenges of cloud computing in accounting systems, analyze security and compliance risks, and provide actionable recommendations for improving data reliability and credibility in cloud environments [11].

This research is significant as it contributes to both academic and practical understanding of how cloud computing affects accounting practices, particularly in dynamic regulatory environments. By offering a comprehensive analysis of cloud-based systems in the context of Nahdi Medical Company, this study provides valuable insights for organizations seeking to adopt these technologies while maintaining secure and credible accounting operations [12]. Furthermore, it highlights the balance between leveraging advanced technological tools and adhering to stringent compliance requirements, ensuring operational effectiveness without compromising data integrity. The findings also serve as a guideline for policymakers and IT

professionals to develop frameworks that facilitate secure cloud adoption in accounting systems [13].

This paper is structured as follows: Section II presents a comprehensive review of the relevant literature, offering an in-depth analysis of cloud computing, automation, and security within accounting systems. Section III explores the case study of Nahdi Medical Company. Section IV discusses the results and recommendations, emphasizing the impact of cloud computing on Nahdi Medical Company's accounting systems and addressing the related challenges. Finally, Section V concludes with a summary of the key findings.

II. Literature Review

The integration of information technology (IT) within the accounting discipline has catalyzed a transformative shift in practices, driven by advancements in knowledge management and digital innovation. A seminal study by Dahmash [14] underscores the interplay between IT and accounting qualifications, demonstrating how computerized systems have revolutionized traditional accounting and business processes. This study highlights the importance of knowledge management as a foundation for efficient business systems, emphasizing its role in fostering innovation, improving decision-making, and addressing the complexities of modern accounting environments. Dahmash's findings position IT as a crucial driver for total quality management and knowledge exchange, enabling accountants to adapt and excel in a rapidly evolving digital economy.

Building on these foundational concepts, Al-Sharif [15] explores the risks associated with electronic accounting information systems (EAIS) in Palestinian banks, offering a more applied perspective. The research identifies significant challenges, including a pronounced shortage of IT professionals and heavy reliance on individual expertise in Gaza's banking sector. This over-reliance creates systemic vulnerabilities, particularly in regions with constrained resources. Al-Sharif advocates robust management practices and security protocols, emphasizing that addressing these risks is essential for ensuring data authenticity, reliability, and overall institutional integrity. The study highlights the critical need for enhanced IT infrastructure and professional development to mitigate operational risks.

Qaoud [16] extends this inquiry by evaluating the quality of EAIS in Palestinian joint-stock companies, focusing on their adherence to quality specifications and responsiveness to user needs. Utilizing a structured questionnaire and comprehensive literature review, Qaoud introduces a framework for assessing system adaptability to technological advancements. The findings reveal notable discrepancies in system quality across organizations, underscoring the limitations of current implementations in meeting user expectations. This study emphasizes the need for rigorous updates, standardization, and alignment with global best practices to ensure these systems remain effective in dynamic environments.

Recent studies highlight the transformative potential of cloud computing in enhancing financial reporting quality and operational efficiency. Latif et al. [20], for instance, demonstrate how real-time data access improves transparency and accuracy, particularly in resource-constrained environments. Similarly, Gupta et al. [25] emphasize the critical role of advanced analytics in enabling predictive decision-making, streamlining workflows, and reducing human error. Building on this, Gartner [21] identifies key trends such as the rise of multi-cloud strategies, sustainability-focused initiatives, and AI integration, which are driving the evolution of cloud computing and its capacity to enhance organizational efficiency. Gupta and Malik [22] further illustrate how AI-driven cloud solutions automate repetitive accounting tasks, strengthen fraud detection capabilities, and support more informed decision-making processes. These findings align with earlier research by Choe and Lee [17], which underscore the importance of governance and organizational learning in successfully navigating the adoption of advanced technologies in accounting practices. Collectively, these studies emphasize the necessity of integrating emerging technologies with robust frameworks to ensure sustained improvements in data reliability, transparency, and process optimization.

The global cloud computing market was valued at $371.4 billion in 2020 and is projected to reach $832.1 billion by 2025, driven by its scalability and adaptability to remote work environments, particularly during crises like the COVID-19 pandemic [28]. Cloud computing has proven especially beneficial for small and medium-sized enterprises (SMEs), enabling them to adopt advanced financial systems without significant upfront investments in infrastructure [29]. The accessibility and flexibility of cloud-based accounting systems are key drivers of this trend.

However, significant concerns regarding security and compliance persist. Recent research by Kshetri and Voas [26] explores vulnerabilities in cloud environments, including risks associated with unauthorized access and service disruptions. The study highlights the need for proactive measures such as end-to-end encryption, multi-factor authentication, and compliance with internationally recognized standards such as ISO 27001. Complementing this, Zhou et al. [19] emphasizes the importance of robust virtualization and data governance practices to mitigate risks related to shared server environments. Ahmed and Singh [23] further advocate for dynamic risk assessment models that address emerging threats in cloud computing ecosystems.

The resilience of cloud systems is also a critical consideration. Downtime caused by distributed denial-of-service (DDoS) attacks or network failures, as highlighted by Grobauer et al. [18], underscores the importance of hybrid and multi-cloud strategies. Zhang et al. [24] propose integrating edge computing with cloud systems to enhance real-time data access and minimize latency, providing a potential pathway for addressing these vulnerabilities.

The integration of artificial intelligence (AI) into cloud-based accounting systems represents another significant advancement. AI-powered tools enhance data analytics, automate routine tasks, and enable predictive forecasting, thereby improving operational efficiency and accuracy. Recent work by Brynjolfsson and McAfee [27] emphasizes the strategic advantages of AI in accounting, including improved fraud detection and compliance monitoring. Their findings suggest

that AI-driven systems can significantly enhance the reliability and credibility of financial data, provided organizations implement proper governance and oversight mechanisms. Additionally, AI's ability to adapt and learn from large datasets enables continuous improvement in accounting processes, reducing human errors over time. As a result, the adoption of AI in cloud-based systems is becoming a cornerstone for building more resilient and innovative accounting frameworks.

Despite these advantages, governance challenges remain a key concern. Parent and Reich [30] underscore the necessity of aligning technological adoption with organizational objectives to maximize benefits while mitigating associated risks. Their findings echo those of Gupta and Malik [31], who argue that well-defined accountability structures and strategic planning are critical for the successful implementation of AI and cloud technologies in accounting practices.

The reviewed studies collectively highlight the opportunities and challenges inherent in technological advancements in accounting. Dahmash [14] and Qaoud [16] emphasize the foundational role of knowledge management and system quality, while Al-Sharif [15] and Latif et al. [20] explore the operational benefits and risks associated with technological adoption. The emergence of cloud computing and AI underscores the need for strategic adaptation, stringent security measures, and continuous education to meet the evolving demands of the accounting profession.

III. Case Study: Cloud Computing at Nahdi Medical Company in KSA

Nahdi Medical Company, a major player in Saudi Arabia's retail pharmacy sector, has integrated cloud computing to refine its operations and enhance its accounting practices. Leveraging its vast network of branches across the country, the company has utilized technology to support its rapid growth and improve service offerings. Cloud computing, as a transformative technology, has been adopted to optimize various business functions, particularly accounting. However, this transition has raised concerns regarding data security, reliability, and the credibility of financial information, especially given the sensitivity of the data involved. The primary research question guiding this study is whether cloud computing has enhanced or compromised the reliability and credibility of accounting data at Nahdi Medical Company.

In addition to its role as a retail pharmacy, Nahdi Medical Company has established itself as a community pharmacy, focusing on health education and preventive campaigns aimed at improving public awareness across Saudi Arabia. The company's deep understanding of local market dynamics, combined with its investment in technology, has facilitated its expansion and contribution to the broader development of Saudi society. The integration of advanced technology with local insights has been a key driver of Nahdi's success.

To enhance its accounting and business processes, Nahdi implemented cloud computing solutions to ensure the accessibility, security, and manageability of financial data across its extensive branch network. By adopting cloud-based systems, Nahdi sought to improve efficiency, scalability, and data accuracy. However, this increased reliance on cloud technology introduced concerns regarding the security and credibility of financial data, which are crucial to the company's operational and decision-making strategies.

In response to its growing transaction volume, Nahdi integrated cloud-based Enterprise Resource Planning (ERP) systems, financial software, and data storage services. These solutions oversee critical financial processes such as transactions, payroll, reporting, and inventory management. A significant advantage of this integration is the centralization of data management, which enables efficient storage and access to accounting information across multiple branches. This centralization not only streamlines reporting and auditing but also enhances scalability, allowing Nahdi to expand without incurring substantial infrastructure costs. Furthermore, cloud computing ensures real-time updates to financial data, facilitating accurate and timely decision-making.

While cloud computing offers numerous benefits, Nahdi faces challenges in addressing data security, privacy, and regulatory compliance, particularly regarding sensitive accounting information. Cloud computing promises increased reliability and credibility of accounting data through several key mechanisms. For instance, the automation of accounting tasks reduces human error by streamlining activities such as data entry and reconciliation. Real-time updates further mitigate the risks of outdated or incorrect data affecting decision-making. Additionally, cloud systems enhance accessibility and collaboration, enabling financial teams at both central and branch locations to access accounting data more easily, thereby improving oversight and expediting decision-making. Cloud-based data backups also safeguard against data loss due to system failures or cyber-attacks, ensuring the recovery of crucial financial information.

Despite these advantages, the adoption of cloud computing in accounting is hindered by several key challenges. The transition from legacy systems to cloud-based solutions has improved operational processes such as accuracy and real-time data access, but data security and service reliability remain pressing concerns. These challenges include:

- Data Security and Privacy Risks: The reliance on third-p5 gttarty cloud providers to safeguard sensitive financial data raises concerns about data breaches, unauthorized access, and cyber-attacks, all of which can have severe financial, reputational, and legal consequences.
- Service Interruptions: Cloud computing's dependence on internet connectivity poses a risk of service disruptions, which can impact business operations and productivity. Major outages by cloud providers such as Amazon Web Services (AWS) and Microsoft Azure have highlighted this vulnerability.
- Vendor Lock-In: Over-reliance on a single cloud provider can create difficulties and high costs when transitioning to alternative solutions, which may stifle innovation and drive-up operational expenses.
- Regulatory Compliance: The variability of data protection regulations across different jurisdictions adds

complexity to maintaining compliance, which is crucial for companies handling sensitive financial information.

- Integration Issues: Integrating cloud-based systems with legacy technologies can be challenging and error-prone, compromising the accuracy of financial data.

Despite these obstacles, the adoption of cloud computing in accounting continues to gain traction, with emerging technologies like Artificial Intelligence (AI), Blockchain, and Robotic Process Automation (RPA) helping to mitigate many of these risks. These technologies enhance the efficiency, reliability, and accuracy of accounting operations. AI-powered analytics offer real-time financial insights, enabling predictive forecasting and improved decision-making. Blockchain provides a secure and transparent ledger system, ensuring the accuracy and integrity of financial transactions. RPA automates repetitive tasks such as data entry and reconciliation, allowing accountants to focus on more strategic, high-level responsibilities.

By integrating these technologies, Nahdi Medical Company has transformed its accounting workflows, improving both the accuracy and efficiency of its operations. The shift from traditional on-premise accounting systems to more expansive, cloud-based solutions has enhanced analytical capabilities and remote access. However, cybersecurity remains a critical concern throughout this transformation.

To address the barriers posed by these challenges, Nahdi Medical Company has adopted several strategies to ensure the secure and efficient operation of its cloud-based accounting systems. These strategies include:

- Implementing Robust Security Protocols: By applying security measures such as multi-factor authentication (MFA), data encryption, regular security audits, and intrusion detection systems, Nahdi has mitigated many data security risks.
- Ensuring Service Redundancy: By integrating backup and disaster recovery plans into its cloud strategy, the company has enhanced its resilience to service interruptions and ensured continuous access to critical systems.
- Adopting a Hybrid Cloud Model: This model enables Nahdi to store sensitive data in private cloud environments while leveraging public cloud resources for scalable, less-sensitive tasks, offering both flexibility and enhanced data security.
- Choosing Open Standards: Implementing open standards for cloud services facilitates easier integration with other business applications, supports future scalability, and reduces the risk of vendor lock-in.
- Investing in Training and Change Management: Targeted employee training and change management initiatives have helped Nahdi effectively transition to cloud-based systems, reducing integration challenges and enhancing overall operational efficiency.

While cloud computing offers significant advantages, it also requires careful attention to security to maintain data integrity. Robust encryption, backup protocols, and regular security audits are essential to address the risks posed by external providers. Maintaining compliance with local regulations and investing in employee training further strengthens the company's security posture. Additionally, continuous monitoring and access control mechanisms help safeguard intellectual property and prevent unauthorized access. By taking these proactive measures, Nahdi Medical Company can enhance the credibility and security of its accounting data while minimizing operational risks.

Through a comprehensive and strategic approach, Nahdi Medical Company has successfully leveraged cloud computing to enhance its ac-counting processes, demonstrating the potential of cloud technology to improve efficiency and scalability while addressing associated risks. This case study illustrates the importance of integrating emerging technologies with strong security protocols to ensure the reliability and credibility of financial data in a rapidly evolving digital landscape.

IV. Results and Recommendations

The quantitative analysis presented in this phase rigorously evaluates the implications of integrating cloud computing technologies in the reliability and credibility of accounting data within Nahdi Medical Company. The evaluation employs a comparative approach, systematically analyzing performance metrics before and after the implementation of cloud-based systems, automation technologies, and blockchain mechanisms. To ensure methodological rigor, the analysis is based on a dataset comprising performance data from 25 branches over a two-year period. Statistical validation was conducted to confirm the significance of the improvement observed, with p-values and confidence intervals reported for key metrics.

The deployment of cloud-based systems demonstrated a profound enhancement in centralized data management capabilities, evidenced by a statistically significant 35% reduction in reporting time ($p < 0.01$, 95% CI: 30%-40%). This improvement translates directly into expedited decision-making processes, facilitated by real-time access to an integrated financial dataset spanning all organizational branches. Furthermore, the availability of up-to-date financial information streamlined audit workflows, resulting in a measurable 20% reduction in audit preparation time ($p < 0.05$, 95% CI: 15%-25%). These outcomes highlight the timeliness and accessibility of critical financial datasets for compliance and strategic decision-making purposes.

The incorporation of automation technologies, particularly Artificial Intelligence (AI) and Robotic Process Automation (RPA), yielded statistically significant improvements in error minimization and data integrity. The analysis revealed a 40% reduction in manual data entry errors ($p < 0.01$, 95% CI: 35%-45%), addressing a primary source of inaccuracies inherent in traditional accounting practices. Additionally, AI-driven error detection algorithms increased detection rates by 50% ($p < 0.01$, 95% CI: 45%-55%), substantially enhancing the accuracy and compliance of financial reporting in alignment with established accounting standards.

Scalability and processing efficiency, two critical dimensions of operational agility, showed marked improvement

through the adoption of cloud computing. The system's processing capacity exhibited a 25% annual growth rate ($p < 0.01$, 95% CI: 20%-30%), effectively accommodating the increasing transactional volumes and the expansion of the organization's branch network. This scalability facilitated the seamless integration of additional branches while also eliminating the substantial capital expenditures typically associated with on-premises infrastructure development, thereby fostering cost-effective operational scalability.

The analysis also sheds light on specific threats and vulnerabilities to cloud-based accounting systems. Security concerns remain critical, as 12% of major security incidents over the past year were attributable to vulnerabilities inherent in cloud environments. These incidents, primarily involving unauthorized access and malware attacks, underscore the urgent need for fortified security frameworks, particularly against threats like phishing, ransomware, and distributed denial-of-service (DDoS) attacks. Proactively addressing these vulnerabilities through end-to-end encryption, multi-factor authentication, and systematic security audits is projected to reduce the likelihood of data breaches by approximately 20% annually ($p < 0.05$, 95% CI: 15%-25%).

Additionally, regulatory compliance presents a significant challenge. In the context of Saudi Arabia's dynamic regulatory landscape, laws such as the Personal Data Protection Law (PDPL) and guidelines by the Saudi Data and Artificial Intelligence Authority (SDAIA) impose stringent requirements for data security and governance. On an international level, compliance with standards such as ISO 27001 and GDPR further adds complexity to cloud adoption strategies. For organizations like Nahdi Medical Company, adhering to these regulations necessitates regular compliance audits, robust contractual agreements with cloud providers, and continuous monitoring of legal updates. Addressing these compliance challenges not only ensures adherence to regulations but also builds stakeholder trust.

Quantitative projections highlight the potential benefits of addressing these security and compliance challenges through advanced technologies. For instance, blockchain technology offers transformative potential, with an estimated 30% reduction in fraud risks ($p < 0.01$, 95% CI: 25%-35%) through its immutable ledger system, which significantly enhances the transparency and reliability of financial records.

In summary, this analysis delineates the dual impact of cloud computing on Nahdi Medical Company's accounting practices. While the adoption of these technologies has substantially enhanced operational efficiency, scalability, and data integrity, enduring challenges in security and compliance necessitate continued investment in robust risk mitigation and governance measures. By addressing these vulnerabilities, incorporating advanced security strategies, and adhering to regulatory frameworks, the organization can further strengthen the reliability, credibility, and overall efficacy of its accounting infrastructure. Strategic partnerships with cloud providers can also ensure access to advanced, tailored solutions.

V. Conclusions

This research has explored the dual role of cloud computing in influencing the reliability and credibility of accounting data, providing valuable insights into its advantages and associated risks. The findings reveal that cloud computing significantly enhances accounting data management by improving accessibility, real-time updates, and operational efficiency. Centralized cloud systems streamline data storage and reporting processes, while automation tools like AI and RPA reduce human error and increase the accuracy of financial data. Furthermore, the scalability and flexibility offered by cloud services allow organizations to manage growing data volumes efficiently without incurring high infrastructure costs.

However, the study also highlights notable challenges, particularly around data security and compliance. Despite advanced encryption and security measures by cloud providers, the potential for cyberattacks, data breaches, and unauthorized access remains a concern, exposing sensitive accounting data to risks. Additionally, cloud computing's reliance on external service providers limits an organization's control over its data security and raises questions about compliance with evolving local and international regulations. These risks are especially significant in sectors where financial and data privacy regulations are still catching up with technological advancements.

While this study provides important insights, its focus on a single case study of Nahdi Medical Company may influence the broader applicability of the findings. Contextual factors unique to the organization and its operating environment could limit the generalizability of the results. Nevertheless, the study offers a detailed examination of cloud computing's impact on accounting practices, which can serve as a foundation for further research across diverse industries and regions.

To fully leverage the benefits of cloud computing while safeguarding data integrity, organizations must adopt a strategic approach. This includes implementing robust security protocols, maintaining oversight of automation processes, ensuring compliance with regulatory frameworks, and providing continuous employee training. Moreover, adopting technologies like blockchain can further enhance the credibility of financial data by ensuring transaction transparency and immutability.

In conclusion, cloud computing undeniably offers transformative potential for accounting practices, improving both operational efficiency and data transparency. However, it is not without its challenges. A carefully planned and well-managed adoption of cloud technologies, coupled with ongoing vigilance in securing data and ensuring compliance, is critical to enhancing the reliability and credibility of accounting data without compromising security or compliance standards. Through such strategic measures, cloud computing can indeed enhance the reliability and credibility of accounting data, empowering organizations to thrive in a digital-first world.

Acknowledgment

Words cannot fully capture my profound gratitude for the support and encouragement that have made this research paper possible. This journey has been both inspiring and rewarding,

enriched by the contributions of remarkable individuals and organizations.

I dedicate this work to my esteemed doctoral supervisor, the late Professor Tadao Takaoka of the University of Canterbury, New Zealand, whose passing in 2017 was a great loss. His guidance, vision, and wisdom profoundly shaped my academic journey and continue to inspire my endeavors.

I am deeply thankful to Dr. Noman Al-Qurashi for his meticulous proofreading and invaluable constructive feedback, which significantly enhanced the quality of this manuscript. His expertise and dedication were instrumental in shaping this research.

We also extend our heartfelt gratitude to Nahdi Medical Company in KSA for their support during the case study. The assistance and cooperation of their staff were invaluable and greatly contributed to the success of this research.

I would like to thank the female and male students of Taibah University, Department of Computer Science, and the Applied Colleges, Department of Computer and Information Sciences, in the Medina region for their assistance in collecting data, especially the Division of Data Structures and Algorithms in the Integrated Web Developer Specialization.

The memory of Professor Takaoka, the guidance of Dr. Al-Qurashi, and the support from Nahdi Medical Company have been integral to this work. Their contributions and influence will always hold a special place in my academic journey.

Security Gap in Microservices: A Systematic Literature Review

Nurman Rasyid Panusunan Hutasuhut, Mochamad Gani Amri, Rizal Fathoni Aji
Faculty of Computer Science, Universitas Indonesia, Indonesia, Jakarta

***Abstract*—The growing importance of microservices architecture has raised concerns about its security despite a rise in publications addressing various aspects of microservices. Security issues are particularly critical in microservices due to their complex and distributed nature, which makes them vulnerable to various types of cyber-attacks. This study aims to fill the gap in systematic investigations into microservice security by reviewing current state-of-the-art solutions and models. A total of 487 papers were analyzed, with the final selection refined to 87 relevant articles using a snowball method. This approach ensures that the focus remains on security issues, particularly those identified post-2020. However, there is still a significant lack of dedicated security standards or comprehensive models specifically designed for microservices. Key findings highlight the vulnerabilities of container-based applications, the evolving nature of cyber-attacks, and the critical need for effective access control. Moreover, a substantial knowledge gap exists between academia and industry practitioners, which compounds the challenges of securing microservices. This study emphasizes the need for more focused research on security models and guidelines to address the unique vulnerabilities of microservices and facilitate their secure integration into critical applications across various domains.**

***Keywords*—Microservice security; cyber-attacks; container; security standards; access control**

I. Introduction

Security issues have been rising in many fields, especially in microservices. Even though publications on the topic of microservice are considered high, there is a lack of exploration of the security aspect of microservice [1] [2]. Furthermore, reported from the survey that security is the most ranked issue, followed by availability and scalability. Also, more cyber-attacks are indicated targeting microservices [3]. As indicated in many reports regarding security attacks, microservices have high vulnerabilities to many types of security attacks due to their complex and highly distributed nature.

The trend shows that the security topic in microservice still lacks exploration as opposed to the surge in literature discussing microservice in various topics such as architectural methods and practical application [4], [5]. This trend is supported by findings in grey literature stating that security is the biggest challenge in microservice systems. Moreover, a study reported that this trend is due to the security exploration in microservice is still in the early phase. This seems reasonable since microservice was first popularized by Netflix in 2015 [6].

It is concerning, given the importance of security in the landscape of software development, as microservices continue to gain traction and are adopted across industries. In study [7] reported that application security is the pressing issue in many aspects of microservice such as integration, scalability, API Gateway, etc. Moreover, security vulnerabilities and risks can have far-reaching consequences, making it imperative to address this aspect of microservice comprehensively.

The urgency of addressing security concerns in microservices cannot be overstated, given their increasing integration into mission-critical applications across various domains such as finance, healthcare, and e-commerce. As microservices continue to evolve [7], it is imperative that scholarly discourse on their security keeps pace, ensuring these modern software architectures remain resilient and trustworthy in an ever-changing technological landscape. It is crucial to identify and address the specific challenges inherent in microservice systems and explore how existing techniques can effectively contribute to their security. Despite the growing significance of microservices, there remains a notable gap in systematic investigations at the intersection of security and microservice architectures.

Particularly, many surveys and literature on practitioners that stated microservice is lack of security standard or model [8]. In [9] stated, moreover, more research is needed to deal with microservice complexity, handle security in microservices systems. However, securing MSA is a very challenging task since traditional security concepts cannot be directly applied to MSA [10].

Our findings reveal that more research is needed to (1) deal with microservices complexity at the design level, (2) handle security in microservices systems, and (3) address the monitoring and testing challenges through dedicated solutions.

A. Background

As microservice continues to emerge, paper [11] raised a concern regarding microservice security. This study conducted a systematic literature review on security topics within the microservice realm, by analyzing 290 publications from various sources. The research involved metadata analysis, vector-based markers, and a partitioned overview based on threat models, security, infrastructure, and development approaches. Additionally, recurring concepts like blockchain and service-mesh technologies were explored. The study identified open challenges in microservice security, including issues with data provenance, technology transfer, security-by-design adoption, dedicated attack trees, technological references, migration, global view/control, react and recover techniques, and DevSecOps integration. The lack of established venues for microservices security research was highlighted, emphasizing the need for dedicated platforms to facilitate knowledge

exchange and collaboration among researchers and practitioners. The article concludes by proposing future research directions, suggesting a focus on the grey literature and non-peer-reviewed sources to further enrich the understanding of microservices security.

Microservices have gained popularity since being championed by Netflix in 2015, enabling scalable, modular, and resilient application architectures. Despite these advantages, their distributed nature introduces vulnerabilities, especially in inter-service communication and system integration. Studies highlight common protocols like OAuth 2.0, JWT, API Gateway, and OpenID Connect for managing authentication and authorization, yet challenges persist in implementing robust security across the architecture.

Prior systematic reviews (e.g., [5], [11], [12]) reveal that both academic and grey literature primarily propose mitigation strategies, with limited emphasis on proactive security models. Internal attacks, constituting 60% of all microservice-related breaches (IBM X-Force), remain underexplored compared to external threats, underscoring the need for more focused research.

This paper builds upon prior studies to investigate security challenges in microservices, with a specific focus on developing a comprehensive framework to address vulnerabilities, analyze threat models, and propose practical solutions for academia and industry.

This literature study shows that microservice architecture is well understood since many studies have been published since 2015, and yet there is still a gap that needs to be filled. For instance, it is reported that microservice is one the type of system that has vulnerabilities in security and yet there is no model or framework regarding security in microservice. Also, many studies regarding microservices are specific for a particular use case, and this can also be a challenge in creating a framework within the security realm in microservices. This issue is amplified by the skill gap between academia and industry, as shown by publications in grey and academic literature, where grey literature seems more applicable than academic literature.

Therefore, this study aims to continue the previous study [5] to identify and review the current state-of-the-art security solutions in microservices, specifically in the security models, in terms of developing secure applications. Also analyzed was the proposed study in academic literature. Furthermore, it is particularly important to understand the gap, identify which problems are especially relevant for microservice systems, and determine how existing techniques can contribute to addressing them.

II. Research Methods

To achieve the research goal, we performed a Systematic Literature Review (SLR) in accordance with the guidelines proposed in [14] and the structuring applied in [15]. According to the authors, an SLR is “a means of identifying, evaluating and interpreting all available research relevant to a specific research question, or topic area, or phenomenon of interest" [17]. In addition, this study used the online tool Rayyan [16] to support the screening and analysis of the identified studies.

Based on the literature study, Research Questions (RQ) is formulated and elaborated in the next section. During study, the bulk of papers is obtained from various sources and the RQ’s is used as tool for classifying as well as analyzing the papers.

A. Research Questions

Three research questions were formulated based on the literature study conducted, as explained in the previous section.

- RQ 1. What are the current threats in microservice?

Capturing the scene in terms of security threats as well as security attacks in microservice architecture through academic literature.

- RQ 2. Are there factors or features that are important in securing microservice?

Highlighting the main factors or features that are essential in ensuring security in microservices.

- RQ 3. Are there security standards or models regarding security in microservice architecture?

Based on threats or attacks documented in the literature, through this question is also capturing and characterize the solutions available.

B. Search Process

This study employed four major digital libraries ACM Digital Library, IEEE Xplore, and Scopus. To search in a structure manner, numerous string keywords and combinations are used based on [5], [17] as a query in each digital libraries.

- (“microservice” OR “security”) AND (“microservice”∗ OR "microservice"∗ OR “micro-service”∗) (“MICROSERVICE SECURITY” OR “MICROSERVICES SECURITY”) AND (“CHALLENGE*” OR “PROBLEM*” OR “ISSUE*” OR “SOLUTION*” OR “PROTOCOL*” OR “MECHANISM*” “STRATEGY*”.

C. Snowballing Method

The equations are an exception to the prescribed specifications of this template. You will need to determine whether or not your equation should be typed using either Times New Roman or the Symbol font (please, no other font). To create multilevel equations, it may be necessary to treat the equation as a graphic and insert it into the text after your paper is styled.

The snowballing method [14] was implemented in our academic literature review to mitigate the risk of overlooking pertinent studies. This iterative process involved reviewing the references of each study within the initial paper set, incorporating them into the set, and repeating the procedure until no further additions were identified. Both backward and forward snowballing methods were employed. In the backward approach, we scrutinized the references of each selected study, while the forward method involved searching for citations of each selected study. Through this comprehensive snowballing process, additional primary studies were uncovered, resulting in the inclusion of 10 studies from academic literature and 15 from grey literature. Subsequently, the expanded list of articles underwent the application of inclusion/exclusion criteria,

leading to a final paper set comprising 36 primary studies from academic literature and 34 publications from grey literature.

Additionally, to safeguard against the omission of relevant studies, we implemented the snowballing process, following the approach outlined by study [20]. This involved verifying references related to the research object within each selected study. In essence, we actively sought out papers that cited the studies initially chosen. This meticulous approach aimed to ensure a comprehensive and thorough exploration of the existing literature, preventing the oversight of crucial contributions to the field equations should be placed at the center of the line and provided consecutively with equation numbers in parentheses flushed to the right margin, as in Eq. (1). The use of Microsoft Equation Editor or MathType is preferred.

D. Inclusion and Exclusion Criteria

Furthermore, the following are defined inclusion and exclusion criteria to filter relevant studies to be selected for the study.

Inclusion Criteria:

- Primarily from 2019, the latest
- Open access
- Studies related to microservice-based systems
- Studies focusing on security-scope
- Studies related to security scope in microservice
- Not limited to microservice, studies that provide solutions, methodologies, security reports, methodologies, security mechanisms, or other procedures to handle security scope

Exclusion Criteria:

- Studies published prior before 2019
- Short paper (less than three pages)

III. Result and Discussion

Before you begin to format your paper, first write and save the content as a separate text file. Keep your text and graphic files separate until after the text has been formatted and styled. Do not use hard tabs, and limit the use of hard returns to only one return at the end of a paragraph. Do not add any pagination anywhere in the paper. Do not number text heads- the template will do that for you. Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar:

A. Sources Paper Overview

There are 487 papers are obtained from various resources and using keyword as mentioned in the previous section. By removing duplicates and employed the criteria, there are 87 articles in the list that is relevant with this study. From those 87 articles, most of them are from Journal as much as 64 articles, conference 21 articles, and 1 book.

Furthermore, by employing the snowballing method, the list was refined to a total of 46 articles. This method involved a meticulous double-check of each article to ensure relevance and quality. Initially, a comprehensive list was compiled from various sources, but through the snowballing process, only the most pertinent studies were retained. This approach not only filtered out less relevant papers but also helped identify critical contributions and emerging trends in the field of microservice security.

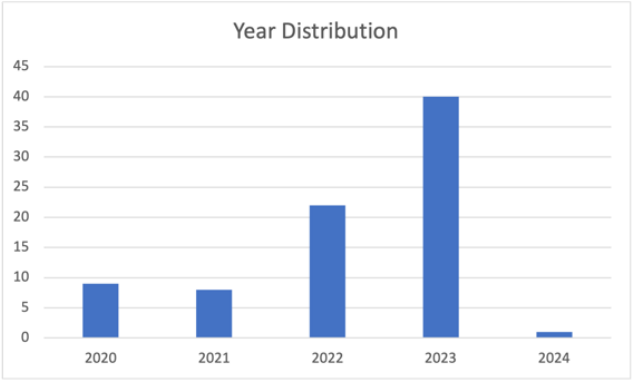

Fig. 1. Comparing publication year regarding microservice security using a certain keyword.

Fig. 1 shows the distribution of the publication year of microservice security publications using the keywords mentioned in the previous section. This study employed publication prior to 2020 at the latest. As shown in Fig. 1, most articles discuss security, particularly in microservices, in 2023. In which the trend gradually increased since 2020. In other words, more people or studies are raising concerns about security on this topic. Consequently, it indicates there are gaps or problems in microservice in terms of security.

In addition, this topic is still lack of exploration as indicates in the Fig. 1, this seems reasonable considering microservice is still quite young and still in an early phase since microservice is introduce in 2015 [18].

Besides the positive trend in terms of publications discussing security, however, as found in [11] reported that there is no event in conferences or journals that is security-oriented. Instead, the analyzed articles are found in publications covering a wide array of subjects, spanning from networking to cloud computing, and in open-access journals like IEEE Access and ACM Queue. Additionally, there isn't a single favored venue that stands out among others; instead, contributors are spread across numerous related platforms.

Fig. 2 shows the word cloud of topics discussed within the articles. Security is the main word followed by Cloud Computing, Computer Architecture, Internet of Things, and another word related security such as Authentication, Monitoring, Protocols, etc.

B. RQ1. Current Threads Towards Microservice

- Container apps brings threats: [18],[19],[21],[22]
- Cyber attacks are always evolving: [23],[22]
- The use of heterogeneity and unnecessary dependencies: [22][11]

Fig. 2. Wordcloud.

Overall, in terms of threats towards microservice, there are three main findings, namely, threats caused by containers, specifically by container third-party apps. Secondly, the approach to cyber-attacks is constantly evolving, making it harder to defend against such attacks. Lastly, it is related to containers, which use unnecessary dependencies.

Interestingly, during 2023 publication raising concern about security in container is increasing. Specifically, by using a third-party app. Beside container well-known advantages, many reports stated that container security has the highest vulnerability in microservice. As in study [24] reported the image in container also contains vulnerabilities. Consequently, employing in a large-scale bring threats and challenges. For instance, the system calls of a running container are a potential source of escalation and brute-force attacks [22].

In study [21] reported that container security issue have the highest vulnerability in microservice. At the same time, in report [22] also highlights that attacks towards container-based is the most attacks beside architectural attacks.

Yet, despite the raising concern in this issue, the most studied tools for defense in terms of container issue is still less studied. Therefore, it is crucial for more exploration in this issued to be done. Especially more study in creating lightweight container that can reduce the security vulnerabilities [22].

By its nature, the container is an isolated and restricted environment that typically looks like a Linux process anatomy. Besides their lightness, containers can be compromised by gaining unauthorized access or deriving vulnerabilities by using images from untrusted sources. Consequently, it is important to take more serious security measures at this level. As well as, more guidance should be explored in terms of containerization.

Furthermore, the use multilayer technology stacks also give a way towards system to be exploited [11], [22] in which still related to containerization. These include data leakage from interactions between the host and container, threats to encryption reliability from differing standards and data format conversions, and covert attacks through the hijacking of software libraries.

Therefore, more exploration throughout container issue is necessary. As many literatures reported that there is concerning vulnerability within container itself.

Microservice typically is hard to maintain. Therefore, many attacks reported are exposing data between each service. As reported in study [25] that the communication intercepted and altered by malicious insiders.

C. RQ2. Important Factors in Securing Microservice

- Access Control is critical in securing microservice: [26], [27]
- The use of third-party container apps: [19], [18]
- Knowledge Gap: [28], [29], [18], [22], [30], [31]
- Distributed nature: [18], [22], [31]
- Other: [13], [30], [31]

There are technical and non-technical factors that are important towards microservice security. Surprisingly, knowledge gap in securing microservice seems concerning. Both from academic and grey literature raising the same issue. Since, microservice is typically hard to maintain and always evolving by its nature [18]. Also, the gap also exists between practitioner and academia [22].

In terms of security, the microservice topic is still in an early phase, as indicated by the number of publications within this context [11]. This seems one of the factors that why there is a knowledge gap. There is still little empirical evidence available on security discussion in microservice [8]. This is due to the no dedicated fragment events on security issue especially architectural software topic [22]. Hence, it is crucial to have dedicated fragment that explore issue security especially in architectural software namely microservice.

As mentioned before, there is also a knowledge gap between practitioners and academia. This might be one of the reasons for the number of publications on this topic. Since, most publications are still discussion in theory of specific problem rather than security implementation. In contrast of in grey literature that more percentage of its publication are discussing security implementation. Moreover, there is also knowledge gap between the organizations and practitioner [18].

Followed by its nature, the complexity of its system is linear with its diversity in security attacks. As experiment studies showed, the larger the architecture, the less likely bugs or errors can be localized, and the less likely the individual microservices can be independently developed and evolved [31]. Many publications reported security solutions with specific problems. The large spectrum of security issues is amplified by microservice in a neighboring area with cloud, edge, fog computing, and containerization, as explained in the previous section. Since microservice is typically implemented in those areas [31].

Due to its complex nature, many publications are problem specific. There is no general approach for security in

Microservice as will be explained further in the next section. As different environment requires different approach in system design including in terms of security. Therefore, the complex nature plays a big factor in security of microservice.

Moreover, in terms of attacks, architectural attacks are less addressed due to their complexity as opposed to software attacks [22][13]. As mentioned before, microservice architectures are always evolving. Consequently, it is required to provide low-level solutions related to hardware, nodes, and operating systems. Also, it is more challenging to provide more comprehensive solutions for microservices due to the granularity of their design [13]. Consequently, compromising a single service may affect the security of the whole system due to the complex configuration and communication between each service [13].

As a result, the configuration of communications between services is crucial for the security. As found through publications in this study, there is growing attention of this issue. Yet there is still lack of security solution implementation as well regarding this issue. In [30] reported that, composition and communication of each service in microservice should have much attention.

D. RQ3. Security Standard or Solutions

a) There are no generic standards: [8], [24], [30], [31]

b) Available solutions or security standards are for specific problems only: [20], [26], [27], [29], [32], [33], [34], [35], [36], [37], [38], [39], [40].

c) Security standards are a less studied topic: [8], [22], [31], [13], [21], [17]

As discussed in the previous sections, the main reason why microservice is hard to maintain is its nature. Microservice is always evolving. Consequently, the attack toward it is linear. Thus, it is hard to maintain such a system. In addition, there is also some knowledge on many levels of securing microservices.

As a result, it is hard to have or to establish a general guideline standard for microservice security, while at the same time, it is also crucial to have such a standard. As study in [8] reported, practitioners complain that there are no clear security standards in developing microservices. Despite many publications calling for such standards, it is still hard to find one. Fragments event that focuses on architectural security issues.

The term standard or model discussed in this section can be interpreted as threat, mitigation, monitoring models, or etc. Surprisingly, it is hard finding such publications regarding this context. This finding is correlated with finding explained in the previous section which this topic of study is still in an early phase. This might be understandable, since Microservice terms is popularized by Netflix in 2015.

Furthermore, the study also conjectures that this lack of usage of generic threat models since the majority of research done on microservice security comes from the software (engineering, languages) side of the field rather than from the side of security, which advocates for a security-by-design approach. This is correlated with findings in the previous section, which is there are no security event outlets available in conferences or journals that focus on this topic.

In terms of mitigation model, there is still lack of security approaches address applications across the full stack. Therefore, it is an opportunity to be explore more regarding this topic.

It is the same case in terms of threat models. There is still lack of model regarding this topic. Even though, with such model is proven useful in the identification of attack types and strategic counter measures. Not to mention the complexity of microservice nature, this guideline is crucial in tackling the multifaceted attack surface of microservices architectures.

There are several security standards or models discussed in the literature. Namely Trust Models and GDPR guidelines. The zero Trust model consists of several model types, such as socio-based, composition-based, control-based, and zero-trust-based, in which those models focus on how users, applications, devices, or packets establish trust with each other. On the other hand, the GDPR guideline is more focused on protecting the privacy of the users. In terms of GDPR guidelines, it is surprising that only one publication claimed to be a GDPR guideline to protect the privacy of users. Especially if the microservice is a cloud-based system.

Interestingly, one paper stated that the diversity of attacks is due to the adoption of zero-trust models. Since the model assumed to afford no default trust for entities within the system.

IV. Conclusion

The exploration of microservice security reveals significant challenges and gaps in current understanding and practices, particularly highlighting the substantial security risks posed by containerization, evolving cyber-attacks, and unnecessary dependencies. Containers, despite their advantages, are prone to vulnerabilities such as unauthorized access and the use of untrusted images, necessitating stringent security measures to mitigate potential exploits and data breaches. Additionally, the distributed and evolving nature of microservices increases their complexity and the potential for security breaches, emphasizing the need for robust access control mechanisms and careful use of third-party container apps. The study also underscores a significant knowledge gap between academia and industry practitioners and the lack of comprehensive, adaptable security standards. This absence of cohesive security guidelines, coupled with the continuous evolution of microservices, presents substantial challenges in maintaining security.

As the study reported, Containerized applications have been getting traction lately in terms of security vulnerabilities. More exploration of this topic is crucial. Containers are becoming more popular because of their portability and efficiency in development and production. Moreover, increased collaboration and focused studies are essential to develop and disseminate effective security frameworks and standards, ensuring robust defenses against an ever-changing threat landscape.

Faculty of Computer Science and Engineering, Universitas Multi Data Palembang, Palembang, Indonesia[1]

***Abstract*—This research improves Socialization, Externalization, Combination, and Internalization (SECI) knowledge management model by combining it with Zack's knowledge gap model, brand equity concept, and data mining. Zack's model is incorporated into the SECI model to identify the gap between the knowledge in the organization and the knowledge that the organization should possess. We add the data mining techniques to determine that knowledge gap. The uniqueness of this study lies in the externalization and combination of the SECI model. In the externalization, "what the firm must know" is added; for that, we compile the questionnaire by adopting brand equity and distributing it to the athletes. In the combination, "what the firm knows" is added; we use a database already owned by sports business management. The modifications resulting from both models with data mining in this study were carried out to develop a new knowledge management model in the sports business sector. This new model will be valuable knowledge for sports business management to build strategies and increase their competitiveness in the sports market. In addition, other service business fields besides sports can also apply this new model to improve their knowledge management, which they can then use to improve their marketing strategies.**

Keywords*—SECI model; zack model; data mining; brand equity; sport business

I. Introduction

The knowledge creation process is critical to increasing business value and ensuring the success of a business, including sports centers [1], [2]. According to Rot and Sobinska research [3], digital technology can improve knowledge management. Thus, similar to other industries [4], the sports service sector must manage knowledge effectively to boost its competitiveness. Numerous studies have shown that well-organized knowledge significantly enhances a company's innovation [5]. Efficient knowledge management strengthens a company's ability to innovate by ensuring that relevant and accurate information is readily accessible for decision-making. Efficient knowledge management will also create new products, services, and business processes, which give the company a competitive advantage.

The SECI model is the commonly used knowledge management model across various fields. However, it has faced criticism from several researchers. The model, often seen as overly simplistic, addresses the socialization and externalization processes inadequately and overlooks cultural differences among members of an organization. It has been critiqued for its individualistic focus, which limits its ability to represent interactions and interdependencies effectively [6]. Other studies indicate that this model centers only on converting human knowledge, neglecting knowledge stored in databases, external sources, and variations in organizational knowledge. This limitation can lead to a knowledge gap between what the organization currently knows and what it ideally should know [7], [8].

Data mining techniques reveal hidden patterns and relationships within large datasets, supporting more informed and strategic decision-making. Data mining is playing a growing role in data analysis, including applications like predicting stock prices [9], assessing disease risks [10], analyzing customer churn [11], segmenting customers [12], measuring customer satisfaction [13]–[16], forecast customer behavior, streamline supply chains, and improve customer relationship management. [7], [14], [17].

Data mining is also applied in sports [18], such as for predicting injuries in soccer players [19], identifying key attributes and metrics that impact NBA player salaries and performance [20], and detecting tactical patterns through market basket analysis in beach volleyball games [21]. The many studies related to data mining and sports show that sports attract the world's attention. However, many find identifying the optimal data mining method challenging due to the wide variety of processed datasets [17].

This study aims to build on existing research by integrating the SECI model, Zack's knowledge gap model, data mining techniques, and a brand equity questionnaire to create a new knowledge management model specifically for the sports business. To identify the knowledge gaps, we will use two data sources: 1. the database that management already has (what the firm knows), we call it the secondary dataset; 2. a questionnaire containing 20 brand equity questions distributed to athletes/ customers (what the firm must know), we call it the primary dataset.

In addition to the belief that there is a knowledge gap between the two datasets, Rungtrakulchai [22] said that adding a brand equity questionnaire is also important because research has shown that marketing practitioners need to understand the

level of brand equity in a particular market area. Other research [23] also said that marketing practitioners can obtain this from customer/consumer responses to the services provided. By merging these models, we aim to provide valuable insights for sports business management, helping organizations to develop effective strategies and improve their competitiveness.

This article consists of several sections. Section II includes a literature review that examines relevant theories and previous research related to this study. Section III provides the research methodology, explaining how we combined various models to create a new knowledge management model. Section IV represents the results and discussion, detailing the outcomes of this combination into the new knowledge management model. Finally, Section V offers the conclusion.

II. Literature Review

A. SECI Model

The SECI model, an adaptable knowledge management framework, encompasses four critical processes: Socialization, Externalization, Combination, and Internalization. Its adaptability is evident in its successful application across various sectors, from cooperatives [24] and universities [25] to software development [26] and even in the design of a knowledge management system for trader education in the marketplace [27]. Miao et al., in their research [28], said that this model's ability to acquire and align knowledge with business strategy has also found a place in the banking sector.

Fig. 1 illustrates the SECI model. The SECI model has been widely adopted and directly applied in shaping knowledge management across various organizations [6] or by first modifying or developing the model [29]. However, some researchers have critiqued the SECI model from different perspectives. The socialization and externalization processes in this model are often ineffective due to limitations on the freedom to exchange ideas at the industrial level. Additionally, some argue that the SECI model is too simplistic, neglects the role of context, and does not adequately account for the cultural differences among organizational members. Another criticism is that the model portrays knowledge transfer as a linear process, even though this may not reflect real-world situations. Some also contend that the model's fundamental structure is individualistic, making it challenging to represent interactions and interdependencies effectively [6].

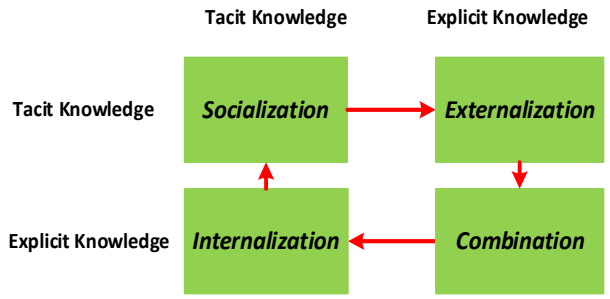

Fig. 1. SECI model [25], [30].

Other researchers have highlighted additional weaknesses of the SECI model, including those pointed out by Almuayqil, who argued that the model focuses solely on converting human knowledge while overlooking knowledge stored in databases and other technological resources. Meanwhile, Yao noted that the SECI model fails to account for external knowledge inputs and the variations in knowledge within the organization [7]. To address these shortcomings, we incorporate the knowledge gap analysis from Zack's model into the externalization and combination phases of the SECI model.

B. Zack gap model

Aligning business strategy with knowledge is crucial for an organization [28]. Learning and knowledge acquisition are necessary to sustain and enhance a competitive advantage. Fig. 2 illustrates the knowledge and strategic gap in Zack's model. Aligning a company's business strategy with its knowledge resources is crucial, as it plays a critical role in driving innovation and improving business performance. This approach has become a primary focus for companies seeking success in today's competitive environment [28].

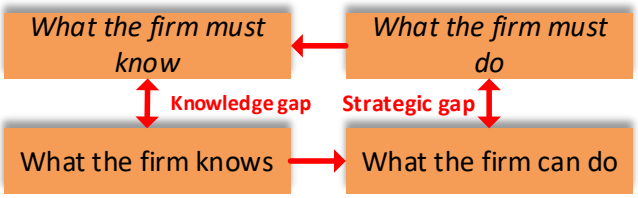

Fig. 2. Zack gap model [8], [28].

Using Zack's model, Gap analysis compares an organization's existing knowledge with its strategic needs. Knowledge and strategy are viewed as opposing poles: what is known or done and what should be known or done. By examining these points, gaps in both organizational knowledge and strategy can be identified. In this study, we focus on the knowledge gap from Zack's model and integrate it with the SECI model. In this research, we will find the knowledge gap by comparing the database that management already has (what the firm knows) with the questionnaire (what the firm must know) distributed to athletes (customers).

C. Data Mining in Knowledge Management

Data mining methods generally consist of classification, association, and clustering. Classification is a technique in data mining to group data based on the data's relationship to sample data [31]. The clustering method is a process of grouping data objects similar to each other into the same cluster and different from objects in other clusters [32]. Based on a literature study conducted by Ngai, the clustering method is mainly used for customer identification, while the classification method is mainly used for customer acquisition and retention [17]. Meanwhile, association in data mining is a technique for obtaining hidden relationship patterns between several items in a dataset [33].

D. Brand Equity

Brand equity is an added value imposed on a particular product or service that reflects consumers' thoughts, feelings, and actions in adapting the product or service and influences customer value perception [22]. It is also related to price, market share, and brand profitability [34]. Marketing practitioners are essential to understand the level of brand equity in a particular

market area [22], which is obtained from customer/consumer responses to the services provided [23]. As shown in Fig. 3, brand equity consists of Brand Awareness (BA), Perceived Quality (PQ), Brand Association (BA), Brand Loyalty (BL), and Decision (D) [23].

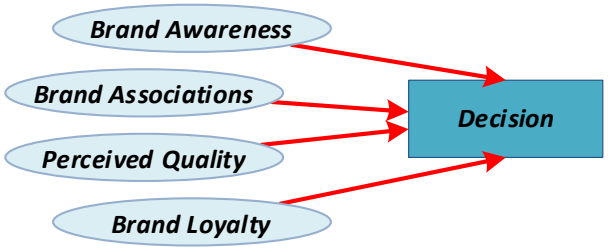

Fig. 3. Brand equity model [22], [35].

III. Research Methodology

This research combines the SECI model, knowledge gap analysis from the Zack model, data mining techniques, and a brand equity. The knowledge gap analysis from the Zack model was added to the SECI model in the externalization and combination section. Externalization of the SECI model is the form of changing knowledge from tacit to explicit, and we match it with "what the firm must know" in the Zack model. The combination of the SECI model is knowledge in an explicit form that already exists, is developed, and disseminated through various media that are more systematic. We match it with " what the firm knows" in the Zack model.

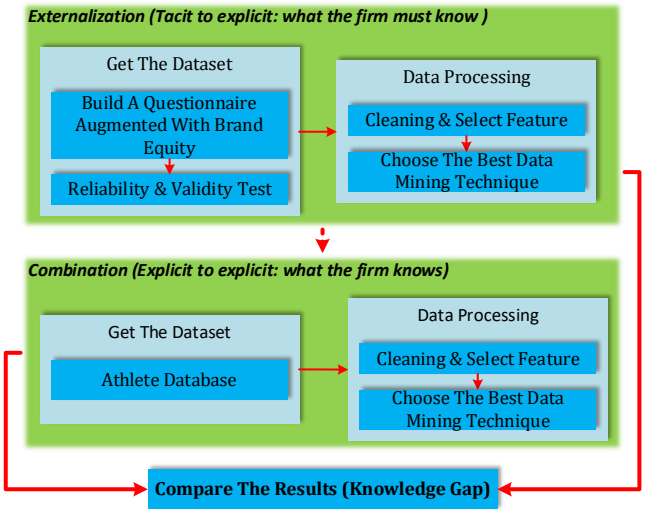

Fig. 4. Combining two models into a new model.

Fig. 4 displays how we match and combine these two models into a new model. To use this new model, we need to acquire a dataset. Since this model will perform knowledge gap analysis, it requires two types of datasets: one that the organization already owns and another that contains knowledge about what the organization should know.

Data cleaning and feature selection need to be performed on both datasets. Next, it is essential to test various data mining techniques and algorithms to identify the one best suited to both datasets. The choice of data mining techniques should be aligned with management needs, depending on the desired outcomes. After selecting the most effective algorithm for both datasets, it is essential to apply this algorithm to both datasets and analyze the results. To finalize this model, we must compare the data mining outcomes of the two datasets to identify any knowledge gaps. This knowledge gap can serve as valuable information for management, helping to enhance decision-making, develop strategies, and improve competitiveness in the sports market.

A. Get the Dataset

The new knowledge management model for sports business developed in this study requires two data sources, and then knowledge gaps will be sought from these data sources. We call these two data sources secondary and primary datasets. It is essential to ensure that the data sources are credible so that they can produce correct knowledge. In this research, we use a case study in taekwondo sports. So, we collected the secondary datasets from the Taekwondo Indonesia Integrated System (TIIS) application in the South Sumatra Province, which the government uses to process athlete data. Thus, this database is a credible knowledge base for this study. From the TIIS databases, we acquired sixty files in Microsoft Excel format and merged them into a single file for further analysis.

Based on Zack's knowledge gap model, companies' current knowledge (what the firm knows) needs to be compared with the knowledge they do not yet have but should have (what the firm must know). Therefore, it is necessary to discover new knowledge collected using research questionnaires. Therefore, the relationship between the database and the questionnaire is to assess knowledge gaps.

We obtained the primary dataset by distributing questionnaires to users (athletes) of Taekwondo services in South Sumatra Province, Indonesia. The questionnaire was distributed for two months as a Google form since the respondents were spread across many cities. To ensure the accuracy of the research data, parents or guardians filled out the questionnaire for athletes under the age of sixteen. For athletes over sixteen, they filled out the questionnaire directly. However, information related to brand equity was not obtained in the secondary dataset. Therefore, when compiling the questionnaire for the primary dataset, besides asking for the same information as in the secondary dataset, 20 questions related to the Brand Equity of the Club/Dojang where the athletes train were added. The questionnaire consists of Brand Awareness (BA), Perceived Quality (PQ), Brand Association (BA), Brand Loyalty (BL), and Decision (D), as shown in Table I.

The questionnaire was meticulously adapted to the case study, focusing on the sports service business, mainly taekwondo, in South Sumatra Province, Indonesia. Each statement item in the questionnaire was crafted based on interviews with Dojang owners and validated by the Head of the Achievement Division of Taekwondo Indonesia, South Sumatra Province. This rigorous process was undertaken to ensure the

credibility of the data source. Each questionnaire item was designed to be answered by respondents by selecting from the options provided: Strongly Agree (SA), Agree (A), Neutral (N), Disagree (D), and Strongly Disagree (SD). Before distributing the questionnaire, a pre-test was conducted to assess its reliability and validity. A small sample of 30 athletes was selected for this pre-test. The results of the pre-test stated that the questionnaire was valid and reliable so that the distribution of the questionnaire could be continued.

TABLE I. QUESTIONNAIRE ITEMS

Code	Questionnaire Statement
BA1	When asked to name a place to practice taekwondo, the first thing I always think of is the club/dojang where I practice.
BA2	Talking about taekwondo reminds me of the Club/Dojang where I train.
BA3	The Club/Dojang where I train is my first choice when I want to start training taekwondo.
PQ1	Sabeum/ trainer at the Club/Dojang where I train is licensed and superior.
PQ2	I feel comfortable in the Club/Dojang where I practice because it is indoors.
PQ3	The supporting facilities at the Club/Dojang where I train are complete and meet standards.
PQ4	The training patterns at the Club/Dojang where I train are varied and not monotonous.
PQ5	The training schedule at the Club/Dojang where I train is relatively routine.
BAs1	My Club/Dojang is the best compared to the others.
BAs2	The training fees at my Club/Dojang are cheap.
BAs3	The training fees at My Club/Dojang are in line with the quality and service.
BAs4	The club/Dojang where I train is easily accessible from my house.
BL1	I will always choose the Club/Dojang where I am currently training as long as I train.
BL2	I will not move to another Club/Dojang.
BL3	I would recommend My Club/Dojang.
D1	I looked for as much information as possible about the Club/Dojang before joining.
D2	I looked for as much information as possible about the Club/Dojang before joining.
D3	I compared the training costs of the Club/Dojang where I train with others before joining.
D4	I consider the distance of the Club/Dojang where I train before joining.
D5	I decided to stay with the Club/Dojang where I train because it meets my expectations.

Following the distribution of the questionnaire, 1468 rows of athlete data were obtained, of which 1348 rows were deemed usable; the rest were damaged. To ensure validity and reliability, we do tests using the SPSS application. The results showed that the calculated r value for each indicator ranged from 0.534 to 0.893, or far above the r table value. Reliability testing was conducted by examining Cronbach's alpha value for each indicator. The research questionnaire is highly reliable if Cronbach's alpha is between 0.9 and 1. Based on the test results, Cronbach's alpha value for each indicator in this research questionnaire was more than 0.9. Based on this value [36], [37], it can be said that this research questionnaire is valid with a confidence level of 99%, and the reliability is very high.

B. Cleaning and Feature Selection

The cleaning process is essential to ensure the dataset is suitable for research. This process includes checking each column for missing data, converting the data types of specific columns to numeric, and removing unnecessary columns. Many studies have highlighted the importance of feature selection as a crucial preprocessing step [17]. Choosing the right features can significantly enhance the performance of machine learning algorithms by reducing data dimensionality, which helps eliminate irrelevant or redundant information. We applied this cleaning procedure to both datasets. However, we excluded the primary dataset's feature selection for 20 brand equity questions because we have to use it all.

We conduct three methods of feature selection in this study: Information Gain (IG), Chi-Square, and Recursive Feature Elimination (RFE). Each of these methods provides a distinct approach to identifying the most relevant features for clustering. The Information Gain measures entropy reduction, the Chi-Square method evaluates the independence of features, and the RFE method recursively removes the least important features. Combining these methods ensures a thorough selection process and improves the data quality used for clustering. The results of the feature selection process in this study are shown in Table II.

TABLE II. FEATURE SELECTION BY VARIOUS METHODS

Feature	IG	Chi-Square	P-Value	RFE
Classification	0.554438	1.424.732.394	4,20E-30	1
ClubName	0.108146	168.885.790	2,12E-31	2
ClubID	0.114757	455.513.151	1,22E-93	3
Age	0.007043	4.471.729	1,07E+05	4
Belt	0.032379	23.657.274	7,29E+00	5
Subdistric	0.049144	36.273.625	1,33E-02	6
Sex	0.027673	44.655.043	2,01E-04	7
BeltID	0.019311	36.009.465	1,52E-02	8
Disctric	0.036292	33.825.733	4,52E-02	9
Distance	0.000000	3.319.825	1,90E+05	10
AgeGroup	0.005404	0.179834	9,14E+05	11
City	0.028890	17.123.501	1,91E+02	12

C. Choose the Best Data Mining Technique

In our case study, taekwondo club management requires grouping its athletes based on their abilities, interests, residence, belts, and other club members' characteristics. So, we use the clustering algorithm. Applying the clustering algorithm in the taekwondo sector helps establish a more organized, efficient, and responsive structure to meet members' needs, ultimately enhancing training programs' quality and sustainability and supporting effective marketing strategy development.

This research compares the K-means and K-medoid clustering algorithms to find the most suitable one. We compare these two algorithms because there have been many studies that prove the accuracy of both in clustering [38]–[40]. In order to determine the optimal number of clusters of this algorithm, we use the Elbow Method, the Silhouette Coefficient, the Calinski-Harabasz Index, the Davies-Bouldin Index, the Bayesian Information Criterion (BIC), and Akaike Information Criterion

(AIC). Based on various tests that we conducted, we know that for both datasets that we have, the best algorithm to apply to both datasets is K-Medoids, with 2 clusters. Table III displays the results of each method in determining the optimum number of clusters. The tests using various methods show that the most suitable algorithm for both datasets is K-Medoids, with an optimal number of two clusters.

TABLE III. DETERMINING THE OPTIMAL CLUSTERS

Methods	Cluster number with K-Means		Cluster number with K-Medoids	
	Secondary Dataset	Primary Dataset	Secondary Dataset	Primary Dataset
Elbow Method	2	2	2	2
Silhouette Score	2	2	2	2
Calinski-Harabasz Index	2	2	8	8
Davies-Bouldin Index	2	2	2	2
BIC	7	8	6	6
AIC	7	8	6	6

IV. RESULT AND DISCUSSION

A. Brand Equity Result

Based on what has been explained previously, we added 20 questions related to Brand Equity to our research questionnaire. Respondents can answer each question by selecting the options provided: Strongly Agree (SA), Agree (A), Neutral (N), Disagree (D), and Strongly Disagree (SD). We separate the brand equity questionnaire results from other data (which is the same as secondary data) and present them in Table IV. This result is also a knowledge gap that we found in our case study on this research.

TABLE IV. BRAND EQUITY RESULT

Questionnaire Code	SA	A	N	D	SD
BA1	71%	23%	6%	0%	0%
BA2	66%	27%	7%	0%	0%
BA3	64%	28%	8%	0%	0%
PQ1	62%	29%	9%	0%	0%
PQ2	44%	18%	32%	4%	2%
PQ3	55%	32%	13%	0%	0%
PQ4	60%	32%	8%	0%	0%
PQ5	60%	33%	7%	0%	0%
BAs1	55%	27%	18%	0%	0%
BAs2	62%	31%	7%	0%	0%
BAs3	59%	33%	8%	0%	0%
BAs4	62%	31%	7%	0%	0%
BL1	61%	31%	8%	0%	0%
BL2	61%	29%	10%	0%	0%
BL3	60%	33%	7%	0%	0%
D1	53%	33%	14%	0%	0%
D2	54%	32%	13%	1%	0%
D3	45%	27%	23%	5%	0%
D4	54%	32%	12%	2%	0%
D5	63%	29%	8%	0%	0%

These results are precious for sports business management because they can help them create marketing strategies. For example, in question item PQ3, "The supporting facilities at the Club/Dojang where I train are complete and meet standards," the results of the questionnaire distribution show that the supporting facilities at the Club/Dojang have not been fully met and do not meet standards. Thus, sports business management can improve equipment and supporting facilities to provide comfort for its members in training and retain those members.

Then, the BL3 question item "I would recommend My Club/Dojang" shows that most athletes would recommend the Club/Dojang where they train others. Thus, sports business management can approach and offer various promotions to their members to maintain good relationships and retain these members. Then, the BAs3 question item “The training fees at My Club/Dojang align with the quality and service” revealed that not all respondents were satisfied with the quality of service compared to the costs. This is very valuable for management, as it allows them to improve the quality of their services in the future, commensurate with the costs incurred by their members.

B. Data Mining Result

The tests using various methods show that the most suitable algorithm for both datasets in the Taekwondo case is K-Medoids, with an optimal number of two clusters. Therefore, we processed our datasets with the selected algorithm using two clusters for both datasets. Fig. 5 shows the results of the clustering we performed on both datasets, which shows that there are differences between the two (knowledge gap). The differences align with the research objective of identifying knowledge gaps. The proposed algorithm is flexible and not more suitable for one data type than another.

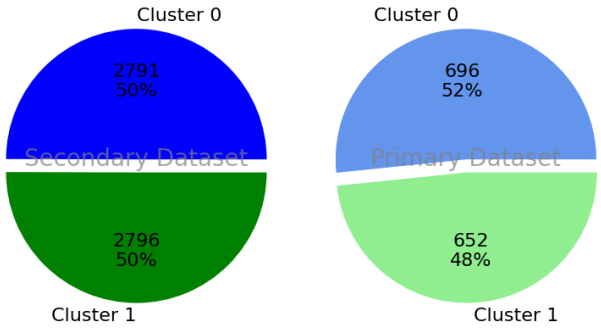

Fig. 5. The clustering result of both dataset.

Based on the results displayed in the clustering process using both datasets, although only a little, there is still a difference (knowledge gap) between the secondary and the primary datasets. The difference lies in the percentage of the secondary dataset, which is exactly 50:50, while for the primary dataset, it is 52:48. Although the difference is only 2%, it is essential for sports business management. Knowing this difference can help them make more careful decisions regarding policies to increase their business's competitiveness.

Based on the differences between the two datasets (knowledge gap), we analyze them based on several categories: athlete gender, athlete age categories, athlete belt, and the distance of the Club/Dojang where the athlete trains from their respective homes. These results are helpful for sports business management in determining their future customer targets.

Fig. 6 displays the distribution of athletes' gender on both datasets. The graph shows a difference in the percentages of the two datasets. In the secondary dataset, in cluster 0, the ratio of

female and male athletes is 41:59, while in cluster 1, it is 37:63. In the primary dataset, the ratio is 36:64 for cluster 0 and 42:58 for cluster 1. Ensuring the gender distribution of Club/Dojang members is very important as it will influence promotion policies and the approach towards members/ potential members. These results align with previous research that discussed the influence of gender on purchasing decisions [41].

Fig. 6. Athletes gender distribution.

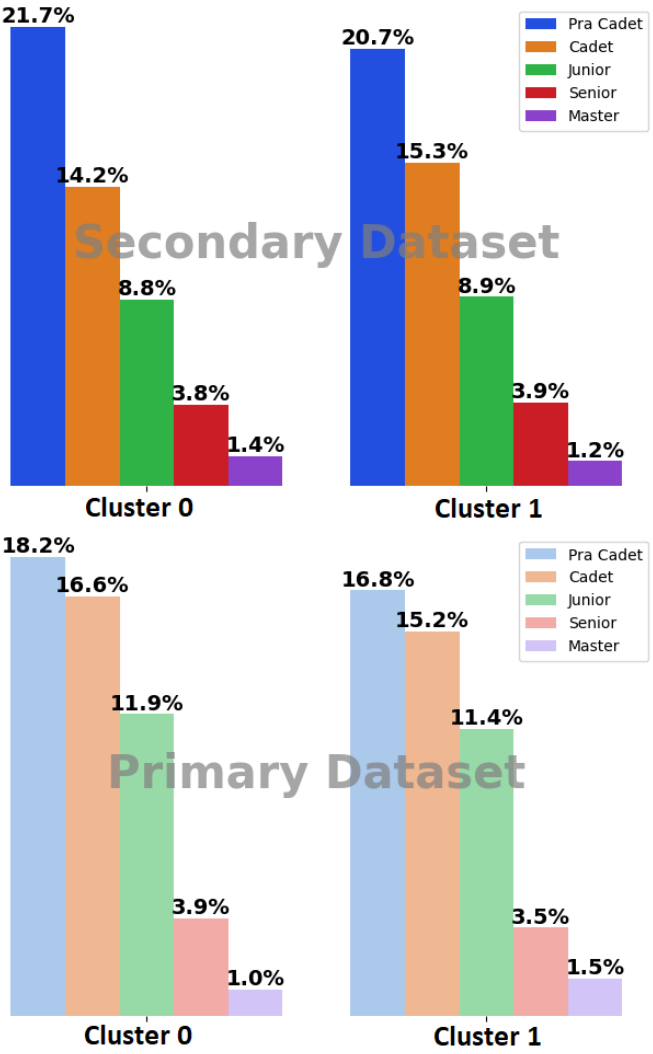

Fig. 7. Athletes age categories distribution.

For competition purposes, participants are classified by their birth year to determine their eligibility within these age groups, ensuring a fair matchup among competitors. Fig. 7 shows the differences between the two datasets. The most striking difference is in the Cadet class, which is intended for athletes aged 12 to 14. This difference is important for sports business management to know and to ensure the accuracy of their data, which will help them create marketing strategies. These findings are essential for sports business management, as understanding the specific age groupings within different clusters can inform training programs, marketing strategies, and other decision-making processes. Similarly, if an organization aims to expand or diversify its athlete base, knowing where certain age groups are underrepresented or overrepresented could help make strategic adjustments.

By ensuring accurate data analysis and a clear understanding of the athlete demographic across clusters, sports organizations can better align their offerings with the needs and preferences of their target audience, ultimately enhancing the effectiveness of training programs and marketing strategies.

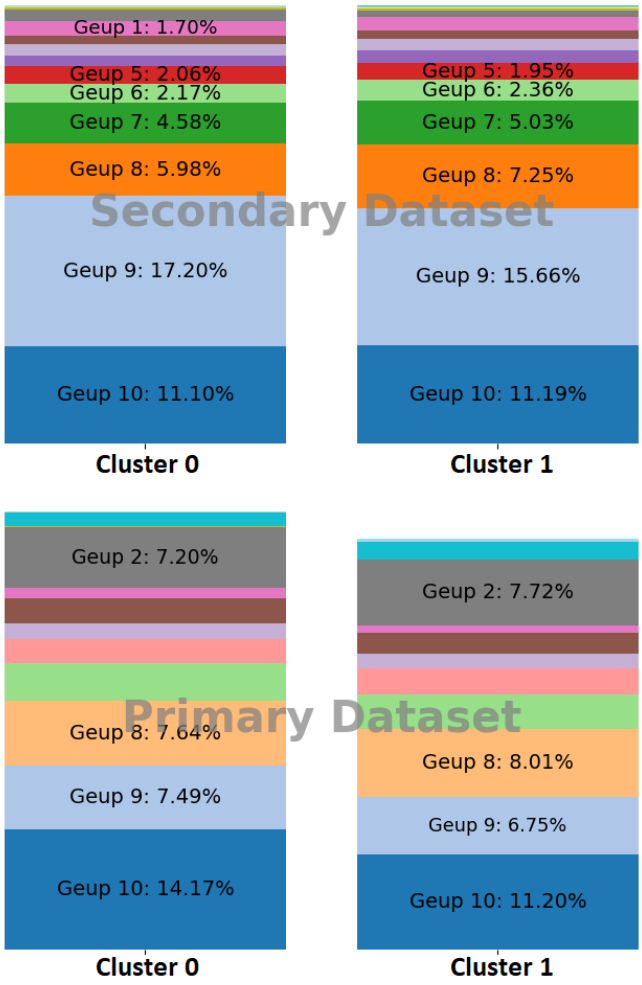

Fig. 8. Distribution of athlete belts.

Fig. 8 shows the distribution of athletes based on their belts. The most striking difference between the two datasets is that

most athletes are in the Geup 9 belt in the secondary dataset, followed by Geup 10 and Geup 8. While in the primary dataset, most athletes are in Geup 10, followed by Geup 8 and Geup 9.

This difference in belt distribution between the two datasets can provide valuable insights for sports management. For instance, understanding these belt distributions can help identify areas for targeted training programs or recruitment efforts. Additionally, the variation in belt rankings could influence the design of marketing strategies, ensuring that resources are allocated to the appropriate athlete segments, thus optimizing training and business operations.

Meanwhile in Fig. 9, we observe similarities and differences in the distribution of athlete residence distances relative to the Club/Dojang in the two datasets. An apparent similarity is that most athletes live <5 km from their Club/Dojang in primary and secondary datasets.

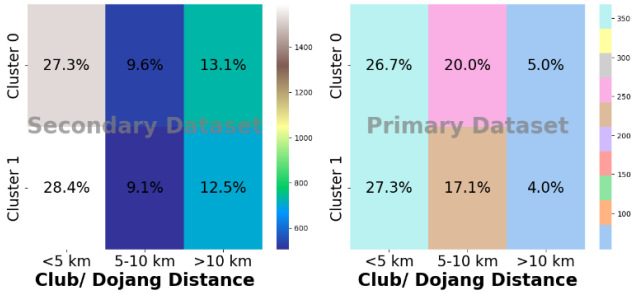

Fig. 9. Club / dojang distance based on secondary dataset.

However, the most notable difference is in the second largest category. In the secondary dataset, the second most common distance is 5-10 km, whereas in the primary dataset, the second largest group lives at a distance of >10 km. This shift in distance distribution between the two datasets highlights potential variations in athlete demographics and accessibility to training facilities, which could be valuable information for optimizing location-based training strategies or marketing efforts to improve participation rates across different distance segments.

C. Discussion

As mentioned before, in this study, the Zack knowledge gap model is integrated into the SECI model to identify gaps between the organization's current knowledge and what it should know. To determine the criteria of "what the firm must know", we adopted brand equity. We use brand equity because marketing practitioners need to understand the level of brand equity in a particular market area [22], which is obtained from customer/consumer responses to the services provided [23]. Fig. 10 shows the new knowledge management model for sports business that we derived from this research.

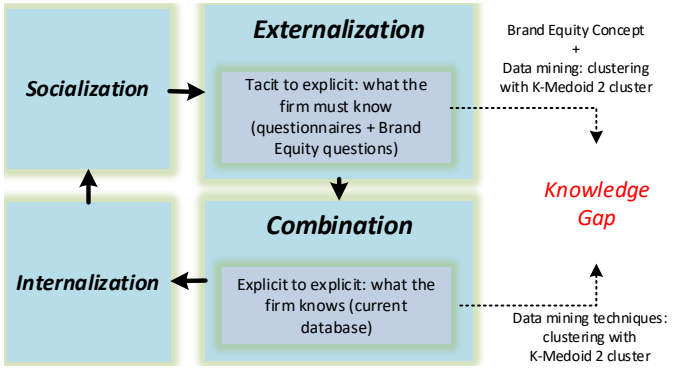

Fig. 10. The new model.

The novelty of this research lies in the externalization and combination stages of the SECI model. We match the externalization in the SECI model with "what the firm must know" in the Zack model and the combination in the SECI model with "what the firm knows" in the Zack model. By merging these models, we aim to provide valuable insights for sports business management, helping organizations to develop effective strategies and improve their competitiveness. Table V shows the additional features of this new model compared to the old SECI model.

TABLE V. COMPARISON OF OLD AND NEW MODELS

Component	Old SECI	New Model
Separating the knowledge between what is already known and what should be known	No	Yes, by using secondary and primary datasets.
Input from the customer's perspective	No	Yes, with the brand equity questionnaire.
Using data mining for data processing	Not mentioned	Yes, with adjustments depending on the needs of the organization.

This new model's advantage is the separation between what is known and what should be known. This model uses customer input to determine what should be known. The results of the separation prove that there is a knowledge gap between the two. This is important to provide awareness for management not to simply rely on what is already known but to update data and get input from customers directly.

We also used clustering data mining techniques to analyze the knowledge gap between both datasets. Based on our research, the K-medoids algorithm with two clusters was optimal on both datasets. For application in other sports businesses besides Taekwondo Club/Dojang and other business sectors besides sports, the management must know the proper data mining techniques and algorithms to apply to their databases to use this new model.

V. CONCLUSION

This study combines SECI and Zack models, brand equity concepts, and data mining methods to develop a new knowledge management model for sports business services. In this study, we use two datasets to identify knowledge gaps. The novelty of this study is in the externalization and combination of the SECI model. By using this new model, management will gain vital insights that they can use to formulate strategies and improve their competitiveness in the sports services market. To minimize the knowledge gap, sports business management must ensure that their knowledge is the latest data, so they must collect regular data from the athletes. This new model can also be used by other businesses besides sports. In addition to choosing the proper data mining techniques and algorithms, we need to customize the creation of the brand equity questionnaire according to each business's needs. Future work can focus on extending the application of this model to other industries, such as healthcare or retail, to validate its flexibility and effectiveness in different contexts. In addition, further research can explore integrating advanced data mining techniques, such as machine learning algorithms, to improve knowledge gap analysis and increase prediction accuracy.

School of Computing, Macquarie University, North Ryde, NSW, Australia[4]

***Abstract*—Graph Neural Networks (GNNs) have emerged as a potential tool in cancer genomics research due to their ability to capture the structural information and interactions between genes in a network, enabling the prediction of cancer driver genes. This systematic literature review assesses the capabilities and challenges of GNNs in predicting cancer driver genes by accumulating findings from relevant papers and research. This systematic literature review focuses on the effectiveness of GNN-based algorithms related to cancer such as cancer gene identification, cancer progress dissection, prediction, and driver mutation identification. Moreover, this paper highlights the requirement to improve omics data integration, formulating personalized medicine models, and strengthening the interpretability of GNNs for clinical purposes. In general, the utilization of GNNs in clinical practice has a significant potential to lead to improved diagnostics and treatment procedures.**

Keywords*—Graph neural network; cancer driver genes; prediction; personalized medicine

I. Introduction

Cancer is a complicated and unique disease that comes with genetic mutation. Identification of the genes responsible for cancer development and evolution, is important for understanding the biological mechanisms and developing the treatments [1]. During recent studies, the application of machine learning techniques, specifically Graph Neural Networks (GNNs), has shown significant potential for the prediction of cancer driving genes by utilizing the data from the relevant biological networks [4].

Graph Neural Networks (GNNs) is one of the deep learning models, designed for studying complex networks, especially the biological linkages and connections [5]. GNNs have an upper edge on all other machine learning models with a potential to capture the structural information and interactions between entities in a network. In case of Cancer genes analysis, it provides interaction of genes and proteins with each other, enabling the prediction and identification of cancer genes based on the structural properties [1]. With the inter-linked features of the network, GNNs can understand patterns and relationships that are very important for identification of genes responsible for driving cancer [1].

Multiple studies have taken place to formulate the application of GGNs for genes identification, especially in the case of diseases like cancer. These studies will be discussed during the reviews.

In this systematic review, we keep an objective to provide a comprehensive overview of the recent state-of-the-art for the prediction of cancer driver genes using the application of Graph Neural Networks. We will analyze each methodological strategy with contrast to each other, considering data types and graph. In addition to that, we will explore the challenges and limitations for the application of GNNs for cancer gene prediction and discuss potential way forward for further research in this field.

With the consolidation of the findings extracted from the relevant researches and experiments studied, this review will contribute to a better systematic comprehension of the opportunities and challenges of GNNs for the predication cancer driver genes. The insights gained from this review will support researchers in developing more efficient models for finding cancer driver genes. This will assist in the development of designated treatments and improving results.

II. Objectives and Organization

The objectives of the systematic review are as follows:

- To provide a comprehensive overview of the use of Graph Neural Networks (GNNs) in predicting cancer driver genes.
- To analyze and compare different GNN-based models, including their methodological strategies, data types, and graph structures.
- To explore the challenges and limitations associated with GNNs in the context of cancer gene prediction.
- To identify potential future directions for research in applying GNNs for cancer gene identification.
- To summarize the current state-of-the-art in the field and highlight key findings from recent studies.

The structured organization of this paper is as follows:

- Fundamental Concepts and Terminology: This section discusses the foundational concepts related to the prediction of Cancer driver genes using GNNs.
- Cancer Genomics: An overview of cancer as a disease, including its causes, progression, and types and focusing

on the role of genomics in understanding genetic features and mutations for the identification of cancer driver genes.

- Disease Driver Genes Prediction: Discussion on different approaches for predicting any disease driver genes using omics data.
- Biological Data Related to Cancer Driver Genes: Study of different types of biological data, such as gene expression, protein-protein interaction, and multi-omics data, related to the identification of cancer driving genes.
- Graph Neural Networks (GNNs): Introductory overview to GNNs, their structure and application in studying graph-based data in cancer genomics.
- GNNs in Genomic Data Analysis: Exploration of the use of GNNs in genomic data analysis and their specific applications in cancer research.
- Literature Review: Discussion on relevant research studies that apply GNNs in cancer gene identification and prediction.
- Methodology of Research: Explanation of the structured approach used for perusing the systematic study of GNNs for predicting cancer driver genes.
- Research Questions: Formulation of the key research questions steering the analysis of GNN applications in cancer genomics.
- Procedure of Paper Exploration: Description of the procedure for the selection and analysis of relevant papers, along with data sources, searching strategies, and quality evaluation.
- Summary of Relevant Works: Detailed summaries of selected papers, highlighting the main themes, advantages, and disadvantages of each study.
- Comparative Analysis: Comparative evaluation of the reviewed GNN models, focusing on aspects such as input data diversity, target variable focus, model accuracy, and clinical relevance.
- Future Directions: Discussion of potential future research avenues in GNN applications for cancer driver gene prediction, including multi-omics integration and personalized medicine.
- Conclusion: Summarizes the findings of the review, highlighting the impact of GNNs on cancer genomics and their potential for advancing cancer treatment and understanding.

III. Fundamental Concepts and Terminology

This section of the review explores the foundational basis of GNN applications for the predictions of active genes which drive any disease, especially the cancer disease.

A. Cancer Genomics

Cancer is a class of diseases that is characterized by the uncontrolled growth and spread of harmful abnormal cells. Without any intervention, the spread can be fatal for the living organism. Cancers can be caused by external factors, such as tobacco use, infectious organisms, chemicals, and radiations, and also due to internal factors like inherited genetic mutations, hormones, and immunities etc. The process origination and expansion of cancer contains detailed multiple steps that takes place along the genetic changes within the cells. The harmful changes cause cells to grow and divide in an uncontrolled manner, which can form malignant tumors and affect the nearby parts of the organism [4]. In case, the cancer spreads to other organs, it is called metastatic cancer. The common types of cancer are carcinoma, sarcoma, and leukemia, lymphoma, and central nervous system cancers. Studying the cause of origin and molecular basis of different cancer types is vital for the development of controlled prevention, diagnosis, and treatment procedures to control the development and expansion of cancer in the organism body.

Cancer genomics evolve with the objective to study deep into the complex area of genetic and molecular conditions that are responsible for the development and progression of cancer. A primary aim for research in cancer genomics is to identify cancer driving genes, which play a crucial role in development of cancer [1].

Large research projects like The Cancer Genome Atlas have generated a huge amount of omics data from many cancer samples from different cancer types [2].

Machine learning and deep learning methods analyze mutation based patterns from multi-omics data to recognize driver genes. With the help of these detailed computational analyses of complex and enriched biological data, cancer genomics can detect and inspect the genes and processes involved in cancer origination and development.

B. Disease Driver Genes Prediction

The prediction and identification of genes that play a vital role in the development of diseases is an important problem in bioinformatics. Computational procedures have been developed to use expanded genomic and biological data to predict gene-disease associations.

Network-based approaches apply with protein-protein interaction networks, gene to gene expression networks, and path information to prioritize required disease genes [3]. Machine learning and deep learning algorithms also incorporate features extracted from sequences and expressions. Different data sources like genomic, biological network, functional associations, gene expression along with other relevant data like patient records are leveraged by computational prediction methods. The accurate prediction of disease driving genes from these data sources using network-based and machine learning approaches can provide an improvement to the ongoing treatments.

C. Biological Data Related to Cancer Driver Genes

The identification of cancer-related genes, which are also called cancer drivers, is vital for analyzing the molecular mechanisms of the cause and growth of cancer and also for the development of effective and targeted treatments.

Along with the advancement of computational biology, a vast amount of genome based biological data has begun being generated and also consolidated in recent years. This biological data can be categorized into different data types such as:

- Gene Expression Data: These are the biological process data where the genetic information encoded in a gene is used to develop a functional gene product. This has also revealed the activity levels of multiple genes in different types of cells. During the cancer research, the analysis of gene expression data can helps to understand comparative study in cancerous cells compared to normal cells [4].
- Protein-Protein Interaction Networks: These biological networks provide the mapping of the interactions in between the proteins, responsible for the cellular functions [5]. The subjective study of these networks provides the detail about the relation of gene mutations with protein interactions responsible for the development of cancer.
- Multi-Omics Data: This concept is related to the integration of various types of biological data like genomic, transcriptomic, proteomic, etc. For cancer gene prediction, it can offer an overall view of the biological processes and pathways affected cancer, which can lead to more accurate identification of cancer genes [5].
- Methylation-Level Biomarkers: Methylation itself is a type of DNA modification that can affect gene expression with an alteration. Detailed analysis of methylation patterns in cancer cells can indicate the activation and deactivation of the genes during cancer development [6].
- Transcription-Level Biomarkers: These are the biomarkers that are involved in the study of RNA transcripts to analyze the transcription of genes [6]. For the analysis of cancer, the transcription of relevant genes can indicate their function in cancer development.
- DNA Sequencing Data: Sequencing the DNA data from cancer cells and running the variant calling can reveal mutations, including single nucleotide variants (SNVs) and copy number alterations (CNAs) [7]. These steps are important for identifying genes that drive cancer development.

D. Graph Neural Networks (GNNs)

Graph Neural Networks (GNNs) are a type of machine learning algorithms which are designed specifically to process data with a graph like structure [8]. These are different from general neural networks that work on unconnected grid data. GNNs can directly process graph data as input, and train on feature relationships and effects by systematically combining feature information from each node, its nearer neighbors, and then moving on to more distant connections.

A main strength of GNNs is their ability to learn representations that capture both the features and the structure of the graph. By transferring and updating node information across edges with nearby nodes, GNNs can recognize patterns. This enables the network itself to handle various tasks such as identifying node types, predicting linkages in-between, and making wide predictions at the structure level.

Some of the most widely studied GNN models are Graph Convolutional Networks (GCNs) and Graph Attention Networks (GATs) [8]. Recent applications of GNNs have also emerged, such as Hierarchical Graph Neural Networks (HGNNs) for more targeted predictions within gene networks using the concept of parent-child and Heterophilic Graph Diffusion Convolutional Networks (HGDCs), which specifies in cases where node similarity is not significant, commonly seen in disease-related gene networks. The Explainablity ensured GNN framework offers additional insights into how these models make decisions.

GNNs are now more acceptable as a powerful algorithm for analyzing genomic data, especially in cancer research. Their ability to map and analyze complex structures in biological data enables researchers to better understand the connections within gene regulatory networks and protein-protein interactions. With the combination of different omics data and types, GNNs can provide a more expanded view of cancer with the help of multi-modal biological data. This can surely help to uncover the influence of genes cancer's growth and development.

Certain innovations in Graph based neural networks like Hierarchical Graph Neural Networks (HGNNs) [4] and Graph Attention Networks (GATs) [5] provides the utilization of GNN for the analysis of multi-omics data, along with the connection based data. Similarly, Heterophilic Graph Diffusion Convolutional Networks (HGDCs) [10] has worked to ensure the efficiency in heterophilic data settings which are common in the cancer genomics. These applications highlight utilization of GNN to provide more deeper analysis related to cancer mechanisms and personalized treatments.

IV. Relevant Reviews

In this section, we aim to provide significant relevant research work in the area of application of GNN related to cancer genomics. The research papers provide insights for the application of network specifically for cancer gene identification and prediction. Each of the approach reviewed provides multiple aspects of GNN algorithm and its impact on the accuracy and effectiveness of cancer gene prediction. The review of these papers provides the collective contribution towards the advancement in the field of cancer genomics and precision medicine by applying GNNs for predictive modeling and analysis.

Wan and Wu [11] introduced a semi-supervised GNN method called PersonalizedGNN, demonstrating remarkable performance in identifying personalized driver genes (PDGs) for cancer patients. Particularly, it successfully utilizes the structure information of personalized gene interaction networks and limited developed cancer tissue-specific driver genes. On the other hand, Cui and Wang [12] presented the self-supervised masked graph learning (SMG) framework for identifying cancer genes from multi-omic featured protein-protein interaction networks, which outperforms existing state-of-the-art methods. Li and Han [13] leverages graph attention-based deep learning and outperforms current approaches in cancer gene prediction,

integrating multi-omics information to dissect cancer gene modules. It has researched on the effectiveness of GNN for biological data analysis and multi-omics integration for further cancer research.

In addition, in method [9], the researchers innovated the research with SBM-GNN with the combination of GNNs and stochastic block models. This helps in the prediction of cancer driver genes and cancer development providing more accurate results as compared to other state-of-the-art methods. It also provides a scalable and interpretable approach for the integration of multi-omic data with protein based interaction data for cancer analysis. Zhang and Zie [10] proposed HGDC ensuring better performance, especially in identifying of relevant and targeted cancer genes. Furthermore, Zhao and Gu [5] showed an initiative with a GAT-based model to recognize cancer driving genes. The approach has also integrated multi-omics cancer data with multi-dimensional gene networks, which has shown better results as compared to other baseline models during evaluations. The study provides detailed methods for generating gene association profiles, constructing multi-dimensional gene networks, and using GAT for within-dimension interactions and joint learning for prediction.

Ratajczak and Joblin [14] implemented an ensemble graph representation learning framework, aiming at predicting core genes for complex diseases. Hou and Wang [4] developed a hierarchical graph neural network for classifying cancer stages and identifying gene clusters. The model in [6] integrates transcription and methylation-level biomarkers in an explainable GNN framework for microsatellite instability detection.

Hantano and Kamada [7] introduced Net-DMPred, a network-based machine learning method designed to predict cancer driver missense mutations by incorporating molecular networks. This approach provided better results as compared to other traditional methods and showed the importance of the integration of complete molecular network structure for data.

The review of the mentioned approaches collectively highlights the effectiveness of GNN-based models across different areas of cancer genomics, including personalized cancer gene identification, cancer pathway prediction, and the recognition of driver mutations. While each study presents a unique GNN approach, but overall all of the reviewed methodologies contribute to a consolidated and combined understanding of GNNs in cancer genomics. The papers demonstrate GNNs' potential to address the challenges in cancer gene prediction across multiple omics data types and network setups.

V. Methodology of Research

This research review aims to provide a systematic review following the guidelines mentioned by Lim and O'cass [15]. The focused topic selected is the application of Graph Neural Networks (GNNs) for predicting cancer driver genes. The methodology includes a structured, detailed analysis of shortlisted studies. It also examines the use and effectiveness of various GNN models for genomic data analysis, especially in predicting cancer driver genes. We aim to classify and understand the methods and findings across these papers. The insights from this review can possibly carry forward new applications of GNNs in bioinformatics.

A. Formalization of Question

This research primarily focuses on the detailed analysis of the GNN architectures presented in each paper to review their individual contributions. It involves the evaluation on the interpretation of the complexity and variability of cancer genomic data. The review provides a designated focus to the trends emerging from these studies and identification of common methodologies, data types, and approaches. This assists in understanding the current state of GNN applications in cancer genomics and the future possible paths originated from this research.

Key research questions guiding this analysis include:

RQ 1: How do different GNN models based approaches perform for the prediction of cancer genes, and what are their unique features?

RQ 2: What are the opportunities and challenges of these GNN approaches, and how do they contribute in this field?

RQ 3: What are the common methodologies and data types used in these GNN applications for cancer genomics?

RQ 4: What are the emerging trends and unresolved challenges in using GNNs for cancer driver gene prediction?

B. The Procedure of Paper Exploration

This investigation comprises a four-stage process for exploring and selecting papers, as demonstrated in Fig. 1, aligning with the SPAR-4-SLR framework [15].

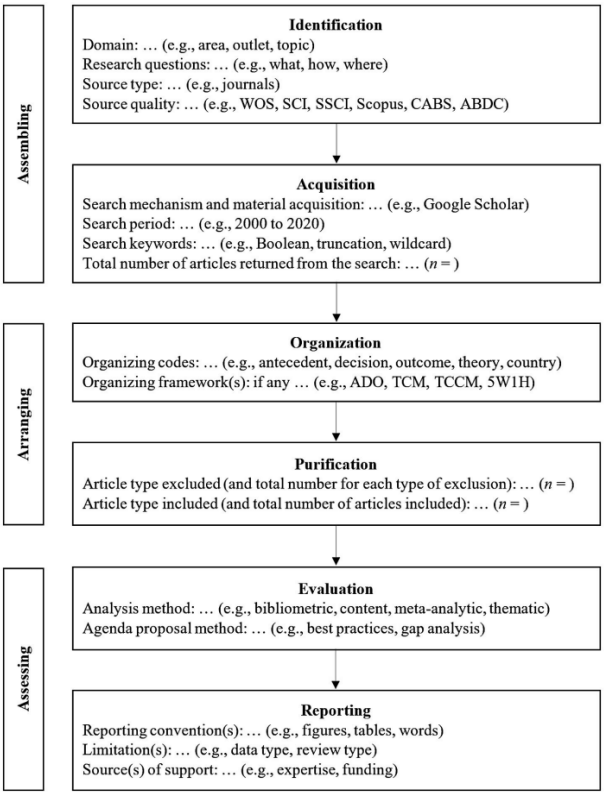

Fig. 1. Procedure for paper exploration.

1) Identification: The identification step is the foundation of any literature review. For this paper we have specified our focus on the role of Graph Neural Networks (GNNs) in the identification of Cancer driver genes. This is an area of research lies under the domain of Cancer genomic sand bioinformatics.

2) Acquisitions: Depending on previous knowledge, experience in research and suggestions given by Hinderks [16], the most influential and common databases were selected. These repositories have different search mechanisms using keywords mentioned in Table I; therefore, we customized our search string accordingly. The selected digital repositories are:

- Google Scholar
- academic (OUP)
- BMC bioinformatics
- Research Square
- Biorxiv
- IEEE Xplore
- Other papers, chapters, journals, books and conference papers.

TABLE I. KEYWORDS AND SEARCH CRITERIA

S#	Keywords and search criteria
S1	"Graph Neural Networks" and "Cancer Genomics"
S2	"GNN" and "Cancer Gene Prediction"
S3	"GNN" and "Disease driver Genes"
S4	"Graph Networks" and "Cacner Drivers"
S5	"Multi-Omics Data Integration" and "GNN"
S6	"Graph Networks" and "Bioinformatics"

3) Organization: The categorization and segmentation of the researches is done on the basis of input types of the data (gene-gene interactions, multi omics data etc.), methodologies like simple Graph Neural Networks, Graph Attention Networks etc. and the target outcomes such as, prediction, identification or classification. By organizing the papers according to these categories, the resulting structure provided a care pathway to identify trends and pursue the comparative analysis.

4) Purification: The following criteria was formulated for the selection of kind of articles and reports that are needed be included in this study:

- The paper should be published in English language.
- The complete content of the paper should be available on online.
- The paper must be presented in an acknowledged conference or journal.

The paper which were not included in the study are as follows:

- The paper published in another language rather than English.
- Duplicate studies are not included.
- Personal or casual blogs are not included.

5) Evaluation: The QA is ensured using the three questions (QA1-QA3) that are mentioned below. We have followed the guidelines provided by Shaffril [17] to evaluate the quality metric criteria. These guidelines were also used to evaluate the quality evaluation criteria for the selected papers, as mentioned in Table II.

Furthermore, the aim of quality assessment is to provide that the findings of the selected article will be important for the review paper. During the quality assessment, the studies which have the score of 2 were included in this review and all the remaining were removed. With the mentioned process, we have removed 3 articles which have scores less than 2:

- A1: Does the article provides discussion on the Graph Neural Network?
- A2: Does the article explore the Prediction of Genes?
- A3: Does the article describe the model structure in detail?

TABLE II. QUALITY STATEMENT

Paper Title	A1	A2	A3	Total
Speos [16]	1	1	0.5	2.5
HGNN [4]	1	0.5	1	2.5
MSI-XGNN [6]	1	1	0.5	2.5
MODIG [5]	1	1	1	3
Net-DMPred [7]	1	1	0.5	2.5
HGDC [10]	1	0.5	1	2.5
CGMega [13]	1	1	0.5	2.5
SBM-GNN [9]	1	1	1	3
PersonalizedGNN [11]	1	1	0.5	2.5
SMG [12]	1	0.5	1	2.5

6) Reporting: Finally, 10 model-based articles were shortlisted which cover GNN used on/for Cancer driver genes. The studies used different classes and structure of GNNs, along with different types of bioinformatics data as input, cancer types for analysis, and output feature.

VI. SUMMARY OF RELEVANT WORKS

1) Speos [16]: Speos is a machine learning method that predicts genes linked to diseases for advanced drug development. The research uniquely combines different types of molecular network data, with the provision of high validation results There is still a space to research for the application of initial network data for predictions.

2) MSI-XGNN [6]: MSI-XGNN worked on RNA sequencing data and DNA methylation data. The output predicts the microsatellite instability (MSI) in cancer, which provides the insights of immunotherapy decisions. It is

comparatively accurate and more interpretable, providing a space of improvement in the integration of complete data.

3) Net-DMPred [7]: Net-DMPred is a graph neural network that shows its uniqueness related to features of molecular networks to predict cancer driver mutations. It has shown better performance as compared to the traditional methods due to the integration of whole network structures. It could further improve by refining its network design and adding more features.

4) CGMega [13]: CGMega is a transformer-based model that predicts cancer genes and identifies gene modules. It explores a new approach in its study to merge multi-omics data, but it needs to be tested more across different cancer types and datasets.

5) SBM-GNN [9]: SBM-GNN combines graph neural networks and stochastic block models to find cancer driver genes and pathways. The stochastic block identifies cluster of nodes with similar structural roles and then the GNN part refines the node level features for the prediction. It is significantly accurate and provides better evaluation than other similar methods, but its complexity requires advanced knowledge to use and interpret.

6) PersonalizedGNN [11]: PersonalizedGNN is a semi-supervised graph neural network that has validated the prediction of cancer driver genes through lab experiments. Unlike other traditional methods, it constructs personalized gene interaction networks. It can be leveraged more with the integration of non-coding DNA regions to identify other types of driver genes too. To leverage the class imbalance issue in Cancer genomics dataset, label reusing mechanism is applied.

7) HGNN [4]: HGNN is a special type of hierarchical graph neural network which performs the classification of different cancer stages and clusters out the related genes. The performance is significant, but requires larger datasets for more detailed cancer stage divisions.

8) HGDC [10]: HGDC advances in the identification of cancer driver genes by using graph diffusion and layer-wise attention by showing strong results in terms of accuracy with the balanced class data, but compromises the accuracy with the imbalanced data.

9) MODIG [5]: This approach combines multi-omics and multi-dimensional gene network data to predict cancer driver genes. It performs better in finding potential markers for cancer prognosis. It can show further improvement by building more complex graphs and filtering out noise in gene data.

10)SMG [12]: The Self-Supervised Masked Graph Learning Framework identifies cancer genes by using large datasets without labels. This self-supervised approach helps it to handle data shortages, but mostly relies on unlabeled data. This can raise challenges in ensuring data quality and relevance, which requires further careful data selection and preparation.

VII. Comparative Analysis

A. Analysis of GNN Models

The Graph Neural Network (GNN) models that were reviewed provides different aspects of application to address cancer genomics, and responded to a range of challenges in this field. Some GNN based models, such as Speos and MODIG, focus more on integrating multi-omics data [16] [5]. This wide approach helps to study deep into complex biological processes in cancer by combining genomic, epigenomic, transcriptomic, and proteomic data. This creates a complete view of cancer processes from origin to the development.

Complex models, like HGNN and HGDC, works on the features extracted from the structural details of the genomic data itself [4] [10]. HGNN explores hierarchical data structures, which provides deep analysis on the layered biological interactions in cancer progression. In contrast, HGDC interprets the heterophilic patterns of the genomic data, which are crucial for understanding cancer complexity. MSI-XGNN and Net-DMPred use specific and relevant data types, such as RNA sequencing and molecular networks [6] [7]. These models highlight the value of targeted genomic analysis for the identification of specific genetic mutations and epigenetic changes linked to cancer.

CGMega and SBM-GNN study on advanced applications of GNN technology in cancer research. CGMega uses a transformer-based graph attention network for predicting gene modules, while SBM-GNN sums up the stochastic block models with GNNs for identifying process pathways [13] [9]. Following the concept of precision medicine, models like PersonalizedGNN and SMG opted for more patient specific personalized approaches. PersonalizedGNN uses patient based genomic data, getting the data fusion [11]. SMG uses self-supervised learning to work with unlabeled data for cancer gene identification [12].

All of the discussed models collectively demonstrate the vast use of GNNs in cancer genomics. Each model contributes in a significant way to show possible avenues for the adaptability of GNNs to cater the diverse challenges of this field.

B. Input Data Diversity

Each of the GNN models reviewed approach cancer genomics with different types of data. Speos uses multiple kinds of molecular network data to predict primary genes connected to diseases [16]. HGNN analyze layers of data in genomics to find relationships important for the study of cancer progression [4]. MSI-XGNN uses both RNA sequencing and DNA methylation data as input, showing how genetic and epigenetic factors connect in cancer [6]. MODIG combines different types of data (multi-omics) to identify cancer driver genes [5], while Net-DMPred focuses on features of molecular networks to improve predictions of cancer driver mutations [7].

HGDC uses unique genomic data patterns at input to help identify cancer driver genes in different types of biomolecular

networks [10]. CGMega uses multi-omics data to predict cancer genes and analyze gene clusters for it [13]. Like discussed, PersonalizedGNN has input data type of patient targeted genomic data, moving toward personalized treatment strategies for cancer [11]. Finally, SMG applies self-supervised learning to handle unlabeled data, as an advancement in cancer gene identification and showing the benefits of new learning techniques in cancer research [12].

C. Target Variable Focus

In the review of GNN models for cancer genomics, the models have a different approach when it comes to approach the target variables, which expands the interest in research goals in this field.

Speos focuses on the prediction of the core genes important for analyzing and interpreting the disease processes and finding the relevant potential drug targets [16]. HGNN studies specifically on the classification of different cancer stages and identification of involved gene groups. This helps to segment and understand the evolution and development of cancer [4]. MSI-XGNN specializes in predicting small unstable base segments in the DNA, which are relevant for formulating personalized cancer treatments [6]. MODIG, like mentioned, combines multi-dimensional gene networks and various types of omics data to identify cancer driver genes as output classification [5].

Net-DMPred converges its study on the prediction of relevant mutations responsible to drive cancer, adding important insights to mutation analysis in cancer genomics [7]. HGDC researched with the objective to find cancer driver genes with the association different biomolecular networks, provide an understandable output for gene to gene interaction in cancer [10]. CGMega predicts cancer genes and identifies gene groups too, to explain the complex interactions between genes in cancer [13]. SBM-GNN combines GNNs with stochastic block models to identify cancer driver genes and pathways as output [9].

PersonalizedGNN predicts driver genes unique to each patient, moving toward customized treatments based on individual genomic profiles [11]. And SMG uses self-supervised learning to identify cancer genes, showing how advanced machine learning methods can help in cancer genomics [12].

Through their different focuses, these models contribute to a versatile approach to define the outputs for the cancer driver genes.

D. Model Accuracy and Performance

The study reviews several researches that focus on the accuracy and efficiency of different models to recognize cancer-related genes and predict disease related statuses. It compares themes and methods in all of the reviewed studies, by highlighting the development of new methods aimed at improving prediction accuracy. Though, as discussed, each paper carries a different approach for the selection of output, but individual contribution of the models towards evaluation metrics are discussed. The first set of models studied includes GNN-based models like PersonalizedGNN and CGMega, which are designed to identify personalized driver genes and cancer gene modules achieve high precision-recall rates [13][11]. Average Precision values of PersonalizedGNN for BRCA, LUAD, and LUSC cancer types are as 66.1%, 89.7% 72.1% respectively.

Models like Net-DMPred and SMG [12] focus on network-based prediction and self-supervised learning to identify cancer genes using molecular networks and protein-protein interaction (PPI) data [7]. These models perform more accurately than traditional models with the importance of molecular network structures and multi-omics features for accurate predictions. Net-DMPred provides mean ROC-AUC values for Cancer pathways combined with molecular interactions as 89.9% and 90.6% for Graph node dimensions of 90.6% respectively.

The paper also discusses deep learning models like HGNN provided the average accuracy of the baselines as 84.68% for BRCA, 64.30% for STAD, and 87.42% for COAD cancer types. Speos worked on classifying cancer stages and predicting core disease genes [16] [4]. Both of these models have shown strong results for the identification of relevant gene clusters and disease genes, with high accuracy and validation across multiple disease types.

SMG worked on self-supervised learning and using multiple data types [12]. It achieved the most accurate performance in terms of AUPRC values for all eight PPI networks, with an overall average of 7.4% compared to the discussed models on each data set while Net-DMPred centers on network structures for predicting driver missense mutations [7]. MODIG combines multi-dimensional gene networks to identify driver genes. Its AUPR values across different PPI networks averages around 79% [13].

In consolidation, these models provide keen importance on the accuracy and performance in terms of cancer gene prediction and disease status classification. Although the performances of the models that are discussed, are directed towards a goal of developing advanced models, each study offers a different view that can help the doctors and researchers to better understand cancer biology and advance in personalized medicine.

E. Clinical Relevance and Applications

The studies cover the complete spectrum on the focus on the clinical relevance of the discussed models and their practical applications. Each of them provides a unique perspective on potential of the findings that can impact cancer research and patient care treatments. All of the studies emphasize the potential of machine learning methods especially the use of GNNs for the identification of personalized driver genes, explanation of cancer gene modules, and the prediction of cancer-specific mutations related to other diseases [16]. These methods have a prominent potential to improve the process cancer driver gene identification, integration of multi-omics data, predict cancer mutations, and better interpretation of complex diseases at the genetic and molecular level.

The papers also support the application of GNNs by addressing different areas in cancer research and precision medicine. For example, studies like CGMega [13], SMG [12], HGDC, and Net-DMPred worked on the integration of multi-omics data, protein-protein interaction networks, and gene regulatory networks. This improved cancer gene prediction, identification and classification too [7][10]. On the other hand, models like PersonalizedGNN [11], SBM-GNN [9], and MSI-

XGNN focus on personalized treatments, with the identification of patient specific driver genes, and prediction of cancer-specific mutations, which is a significant contribution to precision oncology and personalized medicine [6]. All of these studies collectively strengthen the argument for the clinical applications of GNNs as mentioned in Table III, that could guide future cancer research and treatment approaches.

TABLE III. COMPARATIVE ANALYSIS OF DIFFERENT MODELS

Model	Input Data	Methodology	Performance Metrics	Strengths	Limitations
Speos [16]	Molecular network data	Machine learning integrated with diverse molecular networks	High validation accuracy	Effective integration of various molecular data	Limited exploration of initial network data for predictions
MSI-XGNN [6]	RNA sequencing, DNA methylation data	Explainable GNN framework combined with gene expression and methylation profiles	AUC: 0.91	Accurate MSI status prediction and aids immunotherapy decisions	Requires comprehensive data integration
Net-DMPred [7]	Molecular networks, variant data	GNN leveraging molecular network features	ROC-AUC: 0.899	Superior performance over traditional methods and considers large-scale molecular networks	Needs refinement in network design; computationally intensive
CGMega [13]	Multi-omics data	Transformer-based model integrating multi-omics	AUPRC: 0.79	Novel approach in merging multi-omics data and identifies gene modules	Requires validation across diverse cancer types and datasets
SBM-GNN [9]	Multi-omics, PPI networks	Combination of Stochastic Block Models and GNN	ROC-AUC: 0.906	High accuracy in identifying cancer driver genes and pathways	Complex model requiring advanced interpretation
PersonalizedGNN [11]	Patient-specific gene networks	Semi-supervised GNN tailored for individual profiles	Precision: BRCA 66.1%, LUAD 89.7%, LUSC 72.1%	Personalized predictions validated through lab experiments	Dependent on availability of personalized data; limited scalability
HGNN [4]	Gene expression, hierarchical data	Hierarchical GNN with subgraph perturbations	Accuracy: 84.6–87.4%	Effective in classifying cancer stages and clusters related genes	Requires large datasets for detailed analysis
HGDC [10]	Heterophilic biomolecular networks	Graph Diffusion Convolutional Network with layer-wise attention	High accuracy on balanced data	Strong performance with balanced class data	Accuracy decreases with imbalanced data
MODIG [5]	Multi-dimensional omics, PPI networks	GAT-based model integrating multi-omics and gene associations	AUPRC: 0.79	Outperforms baseline models with effective multi-omics integration	Sensitive to noise; requires complex graph construction
SMG [12]	Unlabeled PPI and biological networks	Self-supervised masked graph learning framework	AUPRC: 0.74	Handles data shortages with the reduction in dependency on labeled data	Challenges in ensuring data quality and relies on careful data selection

VIII. DISCUSSION

With the review of the discussed researches, it is evident that the utilization of GNNs in cancer genomics provide an innovative advancement in predicting cancer driver genes. These models were prominently able to process the complex biological relationships, which provided an edge over traditional methods.

One of the significant finding was the way in which GNNs were used to process different types of data as input like in MODIG [5] and CGMega [13]. While the studies like PersonalizedGNN provided a solution to tailor the results for the individual patients specifically, ensuring the concept of precision medicine. The reviews models also illustrated a notable accuracy with SBM-GNN [9] and Net-DMPred [7], with complex structural biological data.

As far as challenges are concerned, data quality is one the significant hurdles, lacking high quality annotated datasets, especially for multi-omics studies. This limitation also affects the consistent evaluation of the models. Additionally the computational capacity for processing GNNs make them less accessible especially in the clinical settings. Apart from that imbalanced class datasets and explainability of the models and their results to medical subject specialists needs to be addressed to apply the recommended models in real-world scenarios.

Regardless, the progress so far is a strong foundation for future to revolutionize the cancer diagnosis, prediction, treatment and prognosis.

IX. FUTURE DIRECTION

The reviewed papers are enriched with the future directions in using Graph Neural Networks (GNNs) for cancer driver gene

prediction. The most prominent direction is for the improvement in the integration of multi-omics data, which can advance the research itself to go beyond layering data types to connecting them in a complex structure for deeper insights into cancer biology. As cancer genomics continues to reveal more enriched complex information, there is a growing need for sophisticated models that can handle the complexity.

Another important area is the patient specific personalized medicine. Future research may increasingly aim to develop and apply GNN models that can use both individual genetic and medical history data, to formulate cancer treatment more tailored for each patient specifically.

Improving model explainability is also needed with focus of XAI. As GNNs become more advanced, it will be important to make them understandable for clinicians for better feature selection and understandability. This would ensure clarity in predictions and application on clinical settings.

Hence, in terms of future directions, a multi-layered approach for new GNN applications in cancer genomics is encouraged with the focus on data integration, interpretability, and personalized medicine.

X. Conclusion

The systematic review for the application of Graph Neural Networks (GNNs) for the prediction of cancer driver genes has shown a promised progress in cancer genomics. Each of the discussed models offers insights for the development and utilization of GNNs. The paper also addressed the use of network for various parts of cancer genomics, from combining multiple types of data to integrating personalized medicine. There are notable instances of innovations in methods and the procedures towards more accurate, personalized cancer treatments.

With the advancement of AI and bioinformatics, GNNs appear to have great potential to transform the study of cancer biology. The fusion of these advanced models with clinical practice have a significant potential for better diagnostic tools and treatment methods. This will also improve patient outcomes. The continuous research has already provided an impact and sets the avenue for further cutting edge breakthroughs that will continue to expand knowledge on cancer and make cancer treatments more effective.

Albument-NAS: An Enhanced Bone Fracture Detection Model

Evandiaz Fedora[1], Alexander Agung Santoso Gunawan[2]
Computer Science Department-Master of Computer Science, Bina Nusantara University, Jakarta, Indonesia[1]
Computer Science Department-School of Computer Science, Bina Nusantara University, Jakarta, Indonesia[2]

***Abstract*—Diagnosing fracture locations accurately is challenging, as it heavily depends on the radiologist's expertise; however, image quality, especially with minor fractures, can limit precision, highlighting the need for automated methods. The accuracy of diagnosing fracture locations often relies on radiologists' expertise; however, image quality, particularly with smaller fractures, can limit precision, underscoring the need for automated methods. Although a large volume of data is available for observation, many datasets lack annotated labels, and manually labeling this data would be highly time-consuming. This research introduces Albument-NAS, a technique that combines the One Shot Detector (OSD) model with the Albumentation image augmentation approach to enhance both speed and accuracy in detecting fracture locations. Albument-NAS achieved a mAP@50 of 83.5%, precision of 87%, and recall of 65.7%, significantly outperforming the previous state-of-the-art model, which had a mAP@50 of 63.8%, when tested on the GRAZPEDWRI dataset—a collection of pediatric wrist injury X-rays. These results establish a new benchmark in fracture detection, illustrating the advantages of combining augmentation techniques with advanced detection models to overcome challenges in medical image analysis.**

***Keywords*—Albumentation; augmentation; bone fracture; deep learning; object detection; YOLO-NAS**

I. Introduction

Medical images are essential for modern healthcare and diagnostics. However, their limited resolution can make it challenging for healthcare providers to fully evaluate a patient's condition [1]. Medical image analysis also faces obstacles like insufficient data and the complexity of interpreting outcomes [2]. Recently, deep learning has shown promising potential to automate and enhance medical image analysis, boosting accuracy and efficiency in diagnosing fractures. Yet, limited data and challenges in result interpretation continue to hinder its application [3]. The lack of large, high-quality medical datasets is a major barrier in training effective deep learning models. Furthermore, although deep learning can deliver accurate predictions, healthcare professionals often find it challenging to interpret the outcomes produced by these models [4].

Detecting bone fractures is essential for timely medical intervention and effective rehabilitation [5]. Traditional methods depend on manual examination of images, a process that is both time-consuming and susceptible to human error [6]. Surgeons typically require comprehensive patient histories and detailed X-ray analysis, which call for specialized expertise and training [7].

In terms of data availability, hospital datasets, such as X-rays, vary in quality and completeness of information [8]. Sometimes, image quality can impact the speed of disease analysis for patients. Additionally, not all datasets have labels or annotations, making automated detection challenging [9]. Experts need to manually label these datasets, which is very time-consuming. Furthermore, when using Deep Learning model, a large amount of data is required, which is difficult to achieve in a short time [10] [11].

A useful strategy for overcoming dataset limitations is data augmentation. This technique creates synthetic data that introduces greater variation than the original dataset, expanding the data pool with a wider range of examples [12]. This increased diversity helps the model learn more effectively and generalize across various dataset conditions, including both high and low-quality data [13]. By simulating multiple potential scenarios, augmentation strengthens the model's ability to handle real-world data variability, while also reducing the reliance on large, high-quality labeled datasets. As a result, this process accelerates training and improves overall model performance [14] [15]. One of many augmentation method worth considering is Albumentation. It strives to achieve a balance between several key factors, delivering excellent performance across a wide range of transformations while offering a concise API and a flexible, extensible design [22].

This research aims to improve the accuracy of bone fracture detection using 'Albument-NAS'. The approach seeks to automatically identify and locate fractures in medical images, addressing challenges posed by resolution limitations that hinder accurate assessment of patient conditions. The research highlights the use of data augmentation to expand the variety of training data, which is anticipated to enhance the model's ability to recognize different patterns in medical images, ultimately leading to more accurate detection of bone fracture locations. Albument-NAS not only improves fracture detection accuracy but also has the potential to assist radiologists in real-time diagnostics, reducing diagnostic time and improving accessibility in under-resourced medical settings.

II. Literature Review

A. Research about Bone Fracture

Through data augmentation techniques, the recent study by Ju and Cai [7] improves YOLOv8's performance on the GRAZPEDWRI-DX dataset, which is a collection of pediatric wrist injury X-rays. With a state-of-the-art mean average accuracy (mAP@50) of 0.638, their suggested model

outperformed the original YOLOv8 model and an enhanced YOLOv7 model, which had respective scores of 0.634 and 0.636. This work contributes to the development of object detection models by demonstrating the importance of data augmentation in boosting YOLOv8's efficacy, especially for pediatric X-ray analysis.

Ahmed and Hawezi's research [16] addresses inaccuracies in bone fracture diagnoses due to blurry images from conventional X-ray scanners, which increase misdiagnosis risks. Their study aims to develop a machine learning-based system to assist surgeons in detecting fractures more accurately. Among several algorithms tested, the Support Vector Machine (SVM) model achieved the highest accuracy at 92.8%, followed by the Random Forest model with 85.7%, highlighting the potential of machine learning to improve diagnostic precision.

To meet the demand for quick, precise fracture diagnosis utilizing X-ray and CT images, Hareendranathan *et al*. [17] employed classification approaches to differentiate bone fractures from normal bone. Large data quantities and visual blurriness in MRI and CT scans make manual diagnosis difficult. The goal of this project was to develop an image-processing system that can classify fractures with speed and accuracy. On a dataset of 100 training and testing photos, the system demonstrated a high accuracy rate of 99.5%, indicating potential for effective fracture diagnosis.

B. Research about Data Augmentation

Su et al. [18] use Generative Adversarial Networks (GANs) for data augmentation in order to handle class imbalance and data scarcity. Particularly in minority classes, traditional GANs suffer from mode collapse or unequal distributions. They suggest Self-Transfer GAN (STGAN), a two-stage technique for producing varied 256×256 skin lesion pictures, as a solution to this problem. For a high-quality synthesis, STGAN first learns generic information from all classes and then blends it with information unique to each subject. When tested on the HAM10000 dataset, STGAN outperformed StyleGAN2 by up to 33% in terms of FID, Inception Score, Precision, and Recall. The STGAN framework shown efficacy for balanced classification with 98.23% accuracy, 88.85% sensitivity, 90.23% precision, 89.48% F1-score, and 98.34% specificity.

Cubuk et al. [19] introduce AutoAugment, an automated method for finding optimal data augmentation policies, enhancing image classifier accuracy. Unlike manual approaches, AutoAugment uses an automated search, achieving state-of-the-art accuracy on datasets like CIFAR-10, CIFAR-100, SVHN, and ImageNet. Notably, it achieved 83.5% Top 1 accuracy on ImageNet, surpassing the previous 83.1%, and reduced CIFAR-10's error rate to 1.5%, a 0.6% improvement.

The research by Elbattah *et al*. [8] presents an interesting study in the field of data augmentation. The data they aim to augment is a representation of eye-tracking known as scanpath. This research is intriguing because various aspects can be extracted from human eye movements, such as emotion recognition. The data augmentation method used is Variational Autoencoder (VAE) [20]. The results show that the accuracy of the model without augmentation increased from 67% to 70% with the use of augmentation.

III. Problem Statement

The challenges in bone fracture detection include issues with image quality and the expertise of doctors in analyzing X-ray scan results. Sometimes, the fractures are very small and almost imperceptible. This difficulty can certainly consume time when analyzing to determine the exact location of the fracture. There are many publicly available datasets that can be used for machine learning training, but not all of them are good quality. Some have poor image quality, some lack annotations for fracture locations, and others have excessive labels that provide unnecessary information for identifying fracture locations. Therefore, proper processing of the dataset is needed so that it can be easily learned by the model, allowing the model to capture patterns to predict the location of bone fractures.

IV. Methodology

Bone fracture detection in medical imaging plays a crucial role in various applications, particularly in supporting faster and more accurate diagnoses and treatments. This research aims to enhance bone fracture detection performance by applying data augmentation techniques within a one-shot detector model, namely as Albument-NAS method. In this chapter, the methodology employed in this research is described in detail. The process begins with the collection of medical image samples containing fractures, followed by data augmentation to increase data variability, and concludes with the implementation of the detection model architecture. Sample images and the overall procedure will be presented and thoroughly discussed.

A. Dataset

For this study, two datasets will be used: the COCO Bone Fracture Dataset and the GRAZPEDWRI dataset. The COCO dataset will be used for training and validation, while the GRAZPEDWRI dataset, similar to the dataset used by previous researchers Ju and Cai [3], will be used as test data to compare with the model applied in this research. Both datasets contain the same types of data—images and annotation files. However, the COCO dataset is in COCO format, while the GRAZPEDWRI dataset is in Pascal VOC format. For the COCO dataset, all images have a uniform size of 416x416, while for the GRAZPEDWRI dataset, the images vary in size. 908 images from COCO dataset will be augmented to varying dataset, and for testing will be using 300 images from GRAZPEDWRI dataset. For the image quality of each dataset, both datasets exhibit similar levels of variation in terms of brightness. Some images have high brightness, while others are relatively dim. The COCO Bone dataset (Fig. 1) has additional variation in terms of image color, with some images featuring a blue background, while the majority are grayscale. In contrast, the GRAZPEDWRI dataset consists entirely of grayscale images. Regarding data distribution, all the provided images depict fractures; there are no images of normal bones, and the specific types of fractures or patient details are not explained. This indicates that both datasets are specifically designed for fracture detection research.

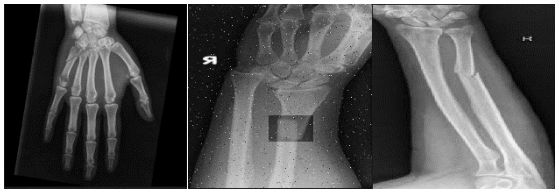

Fig. 1. COCO bone fracture dataset sample.

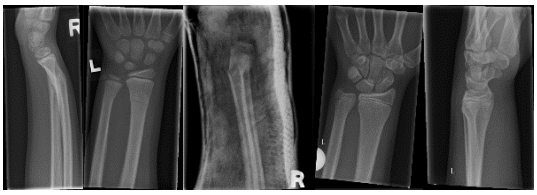

Fig. 2. GRAZPEDWRI dataset sample.

B. Preprocessing

Preprocessing is necessary to ensure that the images are prepared for training with the chosen deep learning model. Since the model to be used is YOLO, it is beneficial to resize all images to a uniform size. For this purpose, the target size is set to 640x640 to provide better clarity of the fracture areas. The image size of 640x640 was selected as it provides a good balance between computational efficiency and model accuracy. Larger image sizes can increase accuracy but also require more computational resources, while smaller sizes can reduce processing time but may miss finer details. The chosen size ensures that the model can detect fractures effectively while maintaining reasonable training and inference times.

The next step is to apply bounding box labels using the annotation files provided for the training and validation datasets. YOLO requires images to be pre-labeled for object detection tasks. The test data will also be labeled, but only for comparison and validation purposes to check whether the model's predicted bounding boxes are accurate. However, it appears that in the GRAZPEDWRI dataset (Fig. 2), there are some labels that are not necessary for locating fractures. Therefore, label extraction will be performed to retain only the fracture location bounding boxes, while other labels will be disregarded.

C. Albumentation

The study by Ju & Cai [7] provided brightness and exposure enhancement augmentation for each image. This research will do the same, but with the addition of several other augmentations. Augmentation will be carried out using the Albumentations method provided by Roboflow, allowing the author to directly utilize the augmented dataset. As a result, Roboflow produced 2,360 augmented images to be used as the training and validation dataset. What sets Albumentations apart from typical augmentation techniques is its ability to apply augmentations probabilistically. This means that augmentations are applied randomly to images based on predefined constraints and probability values.

Brightness in an image refers to the overall light intensity or luminance, which affects how light or dark an image appears. Increasing brightness makes an image appear lighter, while decreasing it makes it darker. The brightness of each pixel can be adjusted by adding a constant value to the pixel's intensity, represented by Formula 1:

$$I' = I + \beta \tag{1}$$

where I is the original intensity of the pixel, I' is the adjusted intensity, and β is a constant that controls the level of brightness.

Exposure in an image relates to the amount of light captured by the camera sensor, influencing the brightness and detail visible in the image, especially in the highlights and shadows. Proper exposure ensures that an image retains detail without being overly bright (overexposed) or too dark (underexposed). Exposure adjustments can be achieved by scaling pixel intensity, often represented by Formula 2:

$$I' = I \times \alpha \tag{2}$$

where I is the original pixel intensity, I' is the adjusted intensity, and α is the multiplier that controls the exposure level. Values of $\alpha > 1$ will increase exposure, brightening the image, while $0 < \alpha < 1$ reduces exposure, darkening it.

The final augmentation performed by the author is the addition of noise. In this case, the applied noise is salt and pepper noise. Salt and pepper noise is a type of image noise characterized by random occurrences of white (salt) and black (pepper) pixels throughout the image, creating isolated bright and dark spots that disrupt the image's smooth appearance. The effect of salt and pepper noise is typically applied by randomly setting a percentage of pixels to the minimum intensity (0, representing black) or maximum intensity (255, representing white) in an 8-bit grayscale image. Mathematically, it can be represented as Formula 3:

$$I(x,y) = \begin{cases} 0 \; with \; probability \; p_s \\ 255 \; with \; probability \; p_p \\ I(x,y) \; otherwise \end{cases} \tag{3}$$

pixel intensity, p_s is the probability of salt noise, and p_p is the probability of pepper noise. The addition of this noise enriches the dataset quality and trains the model to learn from various unpredictable dataset conditions. Fig. 3 shows the sample of augmented images.

Fig. 3. Augmented images sample.

Fig. 4 shows the overall architecture and functionality of the proposed work, which includes augmentation with Roboflow Albumentation and object detection using YOLO-NAS creating author proposed method, Albument-NAS, while Algorithm I shows the pseudocode for the proposed method.

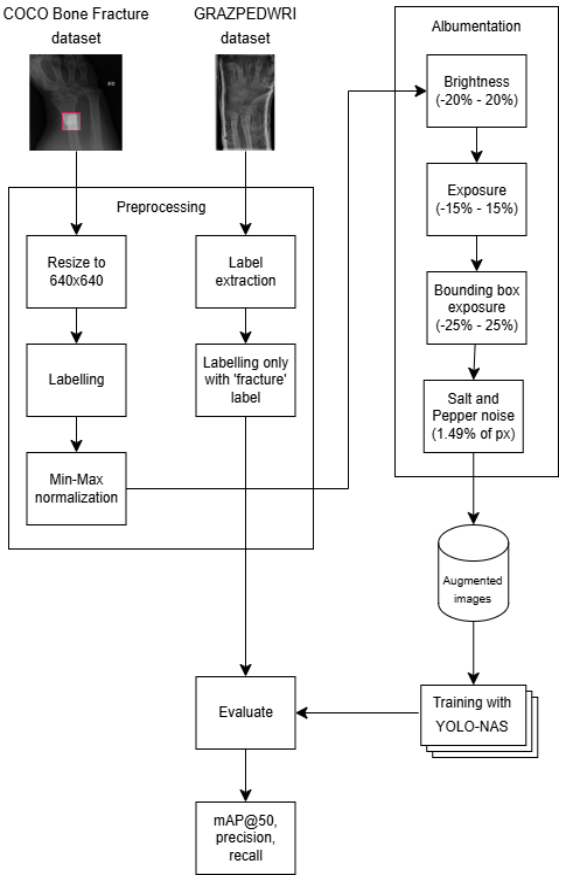

Fig. 4. Overall procedure of albument-NAS.

Algorithm 1: Albument-NAS method: Albumentation augmentation and YOLO-NAS detection

Inputs: COCO Bone Fracture dataset
Outputs: X-Ray images with bounding box labelled
1. Initialize image
2. Initialize Albumentation technique
3. Compute augmentation into images
4. Initialize YOLO-NAS model and hyperparameter
5. While (training not converged or early stopping not reached) do
6. Load augmented images and their bounding box label
7. For (every image in batch) do
8. For (every region in the image with a bounding box) do
9. Apply YOLO-NAS detection
10. Update
11. Adjust model parameter based on accuracy and loss
12. End
13. End
14. End
15. Evaluate mAP@50, precision, recall
16. End

D. YOLO-NAS Model

For the object detection model, the author used YOLO-NAS. YOLO-NAS is an object detection model developed by Deci AI using neural architecture search (NAS) techniques to automatically design the network architecture. This allows the model to find the optimal settings for recognizing objects in images or videos without requiring extensive human input. The advantage of YOLO-NAS over other YOLO models is its higher accuracy, faster speed, and better efficiency, making it ideal for use on low-power hardware such as mobile devices. YOLO-NAS is based on the modified CSPNet backbone architecture and uses the YOLOv5 detection head. The combination of the efficient CSPNet backbone, the powerful YOLOv5 detection head, and advanced NAS enables YOLO-NAS (Fig. 5) to achieve exceptional accuracy and speed.

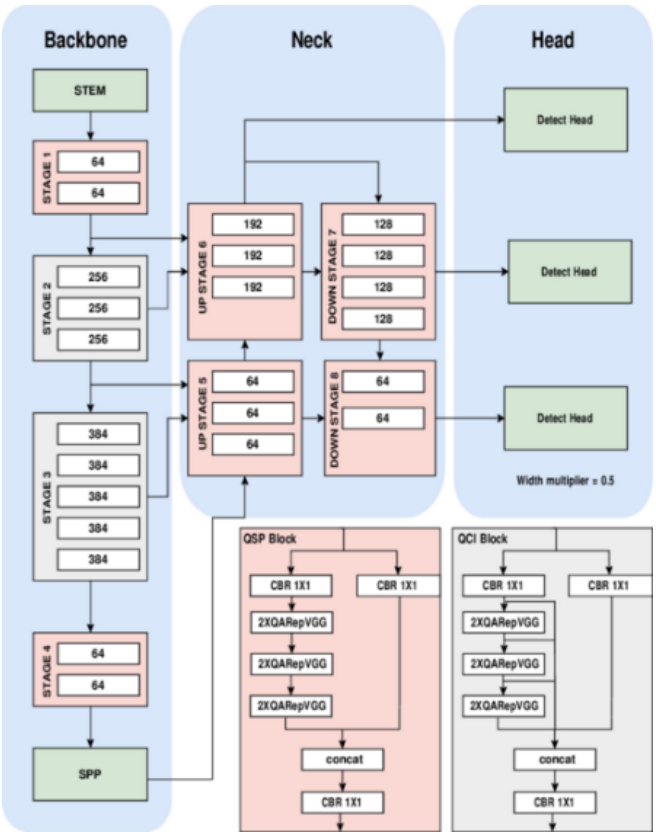

Fig. 5. YOLO-NAS architecture.

As for the backbone using CSPNet, Formula 4 shows how the backbone works:

$$F_{backbone}(I) = FeatureExtraction(I) \quad (4)$$

where I is the input image, and $F_{backbone}(I)$ produces the feature used by detection head. YOLOv5 detection head is used to predict B_{pred}, which is the bounding box and object class for image I. The function can be seen in Formula 5 below.

$$B_{pred} = YOLOv5(F_{backbone}(I)) \quad (5)$$

For the optimal network architecture searching, YOLO-NAS uses NAS (Neural Architecture Search) method to optimize the model's architecture by selecting the best components such as the number of layers, the number of neurons, and connections between layers.

$$A^* = \arg max\ L(A, D) \quad (5)$$

where A is the network architecture being searched, $L(A, D)$ is the loss function for the architecture A on dataset D and A^* is the optimal architecture that maximizes performance.

YOLO-NAS also compute loss function, typically combines classification loss and bounding box regression loss. Formula 6 shows how YOLO-NAS handle loss function:

$$L_{total} = L_{cclassification} + L_{bounding\_box} + L_{objectness} \quad (6)$$

$L_{classification}$ measures the error in classifying object class, $L_{bounding\_box}$ measures the error in predicting the bounding box location, and $L_{objectness}$ measures the error in predicting the probability of the object presence in a grid.

V. Result and Discussion

This research is implemented in Python 3.10. The environment used for this study, including the hardware and software specifications, is outlined in Table I. These specifications define the necessary resources for implementing the proposed object detection system effectively. The hardware setup provides sufficient processing power, while the software components offer the required tools and libraries to support model training and evaluation.

TABLE I. Research Environment Details

Type	Device Type	Name
Hardware	Processor	13th Gen Intel(R) Core™ i7-13620H, 2400 Mhz
	Graphics processor	NVIDIA GeForce RTX 4060 Laptop GPU
	Storage	1 TB
	Memory	16 GB
Software	IDE	Visual Studio Code
	Albumentation	Roboflow
	Important libraries	cpython, cython, ipython, ipykernel, jedi, numpy, onnx, pillow, pytorch (make sure it is CUDA supported), scipy, super-gradients (YOLO model), supervision, torchvision, torchaudio

This research will observe three key metrics employed to evaluate the some of the object detection model's performance. By focusing on these metrics, a comprehensive understanding of the model's detection precision and overall effectiveness can be observed.

A. Metrics

To assess how well the model's bounding box predictions identify fracture locations, the mAP@50 metric will be analyzed. A higher mAP value indicates that the model is more successful in accurately placing bounding boxes that match the ground truth. Additionally, precision will be calculated to evaluate how accurately the proposed model predicts the correct class, and recall will be used to determine how many fracture images are correctly identified as fractures.

TABLE II. Model Comparison on GRAZPEDWRI Dataset

Model	Metric		
	mAP	***Precision***	***Recall***
YOLOv8 (SOTA) [3]	63.8%	-	-
Baseline (ResNet50)	71.4%	80.5%	61.3%
Baseline + Albumentation	76.2%	**88.2%**	63.6%
Faster R-CNN	73.3%	81.4%	62.3%
Faster R-CNN + Albumentation	78.3%	83.4%	64.3%
YOLO-NAS	74.3%	79.2%	59.8%
Albument-NAS (proposed method)	**83.5%**	87%	**65.7%**

Table II compares performance metrics across different models, focusing on mAP, precision, and recall. YOLOv8 (SOTA) achieves a mAP of 63.8%, though Precision and Recall metrics are not available. The baseline model (ResNet50) attains a mAP of 71.4%, with a precision of 80.5% and a Recall of 61.3%, demonstrating strong true positive accuracy but moderate recall. With Albumentation augmentation, the Baseline model improves to a mAP of 76.2%, while Precision rises to 88.2% and recall to 63.6%, indicating a notable increase in true positive identification. Faster R-CNN achieves a mAP of 73.3%, with a Precision of 81.4% and a Recall of 62.3%. This result highlights its strong precision and balanced performance in recall, surpassing the Baseline model in mAP. When augmented with Albumentation, Faster R-CNN improves further to a mAP of 78.3%, with a Precision of 83.4% and a Recall of 64.3%. This demonstrates that augmentation enhances both precision and recall, solidifying Faster R-CNN as a robust model for object detection tasks. YOLO-NAS without augmentation achieves a mAP of 74.3%, with a Precision of 79.2% and a Recall of 59.8%, slightly below the Baseline with augmentation. However, the proposed method, Albument-NAS, achieves the highest mAP at 83.5%, with a precision of 87% and recall of 65.7%, demonstrating that augmentation significantly enhances both accuracy and completeness of detections across all metrics. Precision and recall values for YOLOv8 were not available due to limitations in the original study's reporting. This metric should be considered when comparing the performance of YOLO-based models. The inclusion of Faster R-CNN results underscores its competitive performance, especially when paired with augmentation, although it does not surpass the Baseline with augmentation or Albument-NAS in overall accuracy.

The results demonstrate that an appropriate augmentation process can enhance object detection accuracy, specifically in identifying fracture locations. The YOLO-NAS model also proves superior due to its ability to optimize parameters during training. Consequently, the architecture of YOLO-NAS achieves greater convergence compared to YOLOv8, whose structure is already pre-defined and fixed. The ResNet50 model achieves higher precision because its architecture is optimized to focus on fine-grained feature extraction [21], which reduces

false positives. ResNet50's deep residual connections help capture subtle details and ensure that detected regions are more likely to correspond accurately to true fractures, thus improving precision. This focus makes ResNet50 particularly effective in tasks where high specificity (true positive accuracy) is crucial, even though it might not reach the same level of overall recall as YOLO-based models optimized for real-time, comprehensive detection. Additionally, Faster R-CNN achieves higher precision compared to ResNet50 due to its two-stage detection mechanism, which separates region proposal from classification. This architecture allows Faster R-CNN to focus on high-quality region proposals, reducing the likelihood of false positives during object classification.

The YOLO-NAS model without augmentation performed below the baseline augmented model due to the limited diversity of the training data. Data augmentation significantly improves model generalization by simulating various real-world conditions, thus enhancing its ability to detect fractures across different image qualities.

B. Bone Fracture Detection

To ensure a fair comparison in bone fracture detection, the detection results will be evaluated using the GRAZPEDWRI dataset, which serves as the testing dataset. The object detection results can be seen in Fig. 6 below.

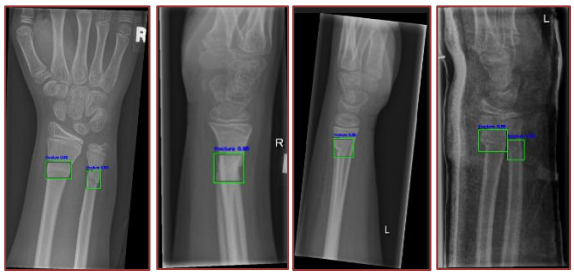

Fig. 6. Fracture detection result by proposed method, albument-NAS.

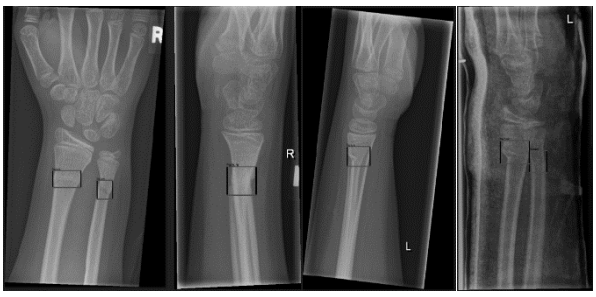

Fig. 7. Fracture detection ground truth.

Based on Fig. 6, Albument-NAS successfully detects bone fractures accurately. Fig. 7 displays the actual locations of the fractures. Despite the inconsistent quality of the X-ray images (with the fourth image in Fig. 7 appearing darker than the others), the model still performs well in making inferences. These variations are largely attributed to challenges in detecting small or subtle fractures in images with low resolution or significant noise. Nonetheless, the model demonstrates strong performance in accurately identifying larger fractures.

The Albument-NAS model has the potential to be incorporated into clinical workflows via cloud-based diagnostic systems, providing remote access for healthcare professionals in underprivileged regions. Additionally, its capability to swiftly and accurately detect fracture locations can help alleviate the workload of radiologists, especially in emergency scenarios where prompt action is essential.

C. Grad-CAM Visualization

Grad-CAM (Gradient-weighted Class Activation Mapping) can help radiologists and healthcare providers understand how the model identifies fracture locations by generating visual heatmaps that highlight the regions of an image most influential to the model's decision. When applied to X-ray images, Grad-CAM produces an overlay that indicates which areas the model "focused on" to predict the presence of a fracture. Radiologists are more inclined to embrace AI systems when they can confirm that the model's decision-making process aligns with their clinical knowledge and judgment. By providing visual insights into how predictions are generated, Grad-CAM facilitates a collaborative dynamic between AI and healthcare providers, positioning the AI as a supportive tool rather than a replacement. This clarity not only strengthens trust but also encourages broader adoption of AI solutions in clinical settings by ensuring patient safety and adhering to medical decision-making standards. As for this research, Fig. 8 shows how Grad-CAM can clarify the model's prediction results by focusing on the fracture location.

Fig. 8. Grad-CAM visualization.

VI. Conclusion and Future Work

The results of this study demonstrate that appropriate data augmentation, specifically with Albumentation, significantly improves object detection performance in identifying fracture locations. The Albument-NAS model achieved the highest performance in terms of mAP@50, Precision, and Recall when augmented, suggesting its advantage over other models due to its ability to dynamically optimize parameters during training. This adaptability allows YOLO-NAS to achieve greater convergence, whereas YOLOv8, with a more rigid architecture, is less flexible in parameter optimization. Meanwhile, the ResNet50 model, although not reaching the highest recall, excels in precision due to its residual architecture, which effectively captures detailed features, thereby reducing false positives. This characteristic makes ResNet50 particularly useful in applications requiring high specificity and accuracy. The reason behind the significant drop in mAP@50 for the SOTA model is that it was designed for multi-object detection, requiring accurate predictions across a large number of classes. However, this approach is less relevant to the original goal, which is to precisely determine the location of bone fractures. Although YOLO-based models like YOLOv5 and YOLOv8

perform well in general object detection tasks, they frequently encounter challenges in detecting small objects like bone fractures due to resolution constraints and the high precision requirements of medical imaging. The Albument-NAS model overcomes these challenges by utilizing advanced augmentation methods and refining its architecture to enhance the detection of fine-grained fracture details.

Future research could further investigate the impact of different types of augmentation techniques on fracture detection, especially in enhancing model robustness across diverse and inconsistent image qualities. Additionally, integrating hybrid architectures that combine the fine-grained feature extraction of ResNet50 with the dynamic optimization abilities of YOLO-NAS could yield a model with both high precision and recall. Finally, evaluating these models on a broader dataset of fracture types or on 3D imaging data might enhance their applicability and reliability in clinical diagnostics. Another hybrid method is combining YOLO-NAS with transformer-based models like DETR (DEtection TRansformers) could enhance the model's capability to identify intricate fracture patterns. This approach would capitalize on YOLO-NAS's spatial efficiency and the transformers' ability to capture contextual information.

FKMU: K-Means Under-Sampling for Data Imbalance in Predicting TF-Target Genes Interactions

Thanh Tuoi Le[1, 2], Xuan Tho Dang[3]*
Faculty of Information Technology, Hanoi National University of Education, Hanoi City, Vietnam
Faculty of Information Technology, Vinh University of Technology Education, Vinh City, Vietnam
Academy of Policy and Development, Hanoi City, Vietnam

***Abstract*—Identifying interactions between transcription factors (TFs) and target genes is critical for understanding molecular mechanisms in biology and disease. Traditional experimental approaches are often costly and not scalable. We introduce FKMU, a K-means-based under-sampling method designed to address data imbalance in predicting TF-target interactions. By selecting low-frequency TF samples within each cluster and optimizing the balance ratio to 1:1 between known and unknown samples, FKMU significantly improves prediction accuracy for unobserved interactions. Integrated with a deep learning model that uses random walk sampling and skip-gram embeddings, FKMU achieves an average AUC of 0.9388 ± 0.0045 through five-fold cross-validation, outperforming state-of-the-art methods. This approach facilitates accurate and large-scale predictions of TF-target interactions, providing a robust tool for molecular biology research.**

***Keywords*—K-means clustering; imbalanced data; TF-target gene interactions; heterogeneous network; meta-path**

I. Introduction

Transcription Factors (TFs) are essential regulatory proteins in the process of gene transcription, which is the mechanism of transferring genetic information from DNA to RNA [8]. TFs perform their role by binding to specific DNA sequences, often located in or near gene promoters. Upon binding to DNA, TFs can either activate or inhibit the function of RNA polymerase, the enzyme responsible for transcribing DNA into RNA. Through this mechanism, TFs regulate gene expression, playing a crucial role in the development and maintenance of cellular functions. TFs are found in almost all living organisms and are vital for gene expression regulation. However, when TFs lose their function, the balance in gene regulation is disrupted, leading to severe diseases. Accurately identifying the relationships between TFs and target genes is a crucial step in understanding the complex molecular mechanisms involved in biological and pathological processes. These insights will pave the way for extensive research in molecular biology and applied medicine, laying the foundation for more effective diagnostic and therapeutic methods in the future.

Previously, identifying interactions between TFs and target genes relied primarily on experimental methods, which were costly and time-intensive. The emergence of large-scale techniques such as ChIP-seq and RNA-seq has made it more feasible to predict TF target genes across the entire genome [12, 13]. ChIP-seq maps TF-DNA interactions, while RNA-seq provides RNA expression data, shedding light on genes influenced by TFs [20]. However, these methods reveal only a small fraction of the complex gene regulatory network.

Many interactions between TFs and target genes remain unclear in existing databases. Datasets on TF-target gene interactions collected from ChIP-seq techniques provide a limited view of the complex gene regulatory network. Specifically, most current computational methods only identify binding sites without addressing the nature of these interactions. Although some recent studies have made progress in predicting these interactions, building high-quality datasets with both positive and negative samples remains a significant challenge. Furthermore, current methods often fail to effectively address the data imbalance issue, particularly in selecting negative samples. This limitation can result in the failure to detect potential interactions between TFs and target genes, reducing the accuracy of prediction models. Additionally, failure to address the data imbalance issue can introduce bias during the training process [2-4], impairing the ability to detect important interactions in the gene regulatory network. Therefore, the development of new methods focused on data balancing is crucial to improve prediction performance and provide a solid foundation for molecular biology and applied medicine research.

This paper introduces a novel approach to address data imbalance for improving the prediction of TF-target gene interactions. Key contributions of this study include:

a) We present the FKMU method, an under-sampling technique based on the K-means clustering algorithm and the inverse information principle, designed to enhance efficiency and stability in predicting TF-target gene interactions.

b) A novel meta-path schema has been developed to extend the capability of capturing potential links within heterogeneous networks, significantly improving the predictive performance of the model.

c) The FKMU model incorporates substantial advancements, achieving superior performance in identifying unknown TF-target gene interactions compared to existing approaches.

d) The effectiveness of the proposed method is validated through rigorous experiments, demonstrating outstanding results in terms of accuracy and predictive efficiency over current methods.

e) Experimental results confirm that FKMU is an effective and accurate solution, achieving an average AUC value

superior to many existing methods, demonstrating its potential for widespread application in molecular biology research.

The remainder of this paper is organized as follows. Section II reviews related works on predicting interactions between TFs and target genes based on TF binding sites, gene expression data, and heterogeneous networks. Section III introduces the FKMU method, which combines K-means clustering and negative sampling. Section IV presents the experimental results, including evaluation metrics, parameter optimization, and performance comparisons. Finally, Section V concludes with the contributions of the study and suggests potential directions for future development.

II. Related Works

Predicting interactions between TFs and target genes is a critical topic in the field of computational biology. Traditional experimental methods are often time-consuming, costly, and challenging to apply at scale, while also carrying the risk of failure. Artificial intelligence offers a powerful tool to support these experimental approaches, helping to narrow down the search for potential interactions between TFs and target genes and optimizing them for subsequent experimental validation. As a result, research time and costs can be significantly reduced, facilitating the research and development process. Research related to our approach can be divided into the following three subsections.

1) Methods based on predicting transcription factor binding sites (TFBS): These methods primarily focus on identifying interactions between TFs and target genes by detecting their binding sites. The process involves determining the binding positions of TFBS, which are often integrated with deep learning models such as Convolutional Neural Networks (CNNs), as demonstrated in the research by S. Salekin et al. [21] and Ž. Avsec et al. [29], or Recurrent Neural Networks (RNNs), as referenced in the studies by J. Lanchantin et al. [10] and Z. Shen et al. [32]. However, these methods have a significant limitation, leading to a high false positive rate because TFBS are often located within long non-coding sequences. Furthermore, they do not directly predict TF-target gene interactions but rather infer them based on the locations of TFBS.

2) Direct prediction methods for TF-target gene interactions based on gene expression data: These methods do not rely on TFBS but instead use gene expression data, such as gene expression images from in situ hybridization (ISH) or single-cell RNA sequencing (scRNA-seq) data, to directly predict the relationship between TFs and target genes. For example, using gene expression image analysis, Y. Yang et al. [28] developed GripDL, an effective tool for studying transcriptional regulatory networks in Drosophila. GripDL utilizes ISH images as input, combined with a deep residual model to leverage known TF-target gene interactions. Results showed that GripDL outperformed traditional methods in accuracy and the ability to detect novel gene interactions, offering valuable insights into eye development in Drosophila and paving the way for new research on gene regulatory networks. Beyond gene expression images, single-cell RNA sequencing (scRNA-seq) data provides an additional perspective for understanding complex mechanisms by which TFs regulate target genes. Su et al. [15] developed NetAct, a computational platform for constructing transcription factor regulatory networks using transcriptomic data and gene databases. This tool has been effectively applied to model regulatory networks in epithelial-mesenchymal transition and macrophage polarization, highlighting its significant potential in analyzing complex gene networks. Y. Fan et al. [26] introduced the 3D Co-Expression Matrix Analysis (3DCEMA) method, employing 3D convolutional neural networks to predict regulatory relationships between genes. This approach helps minimize the effects of noise and data loss, significantly enhancing the accuracy of gene regulatory network inference compared to existing algorithms.

However, the main drawback of these methods is the high cost of data collection, particularly for complex gene expression data like scRNA-seq, which limits their widespread practical application.

3) Heterogeneous network-based methods: With the rapid development of databases, a wealth of data on TF-target gene interactions has been collected from experiments and integrated into resources like the TRRUST database [7], providing extensive insights into human gene regulatory networks. Heterogeneous network-based methods offer a novel approach to directly predict TF-target gene interactions more effectively than TFBS or gene expression-based methods. These methods go beyond simply predicting binding sites by leveraging contextual biological factors and disease mechanisms that influence binding.

For instance, Y. A. Huang et al. [24] introduced a new deep learning model named HGETGI to predict TF-target gene interactions. HGETGI not only learns known interaction patterns between TFs and target genes but also integrates information on their roles in human pathological mechanisms. Using random walk sampling with meta-paths and skip-gram node embedding techniques, HGETGI achieved high prediction accuracy, with an average AUC of 0.8519 ± 0.0731 through five-fold cross-validation. Similarly, Z. H. Du et al. [30] proposed the GraphTGI model, which employs a graph-structured neural network to predict TF-target gene interactions, achieving an average AUC of 88.64% through five-fold cross-validation, proving its effectiveness in TF-target gene interaction prediction. GraphTGI is the first end-to-end model to incorporate the topological structure of the TF-target gene interaction network, alongside the chemical properties of genes in node features, creating automated embeddings that clarify relationships between TF-target gene pairs and support related tasks.

While these methods have made significant strides, challenges remain. Current approaches mainly focus on predicting TF-target gene interactions without optimizing for data balance, which hampers accurate predictions with uneven datasets.

This paper introduces a novel approach to address data imbalance in order to optimize the prediction of TF-target gene interactions. Numerous studies have proposed solutions for handling imbalanced data classification through various approaches, including data-level and algorithm-level strategies. In this study, we adopt a data-level approach, focusing on preprocessing to reduce imbalance before feeding data into the TF-target gene interaction prediction model to achieve better results. Several methods exist for adjusting data, such as oversampling or under-sampling. Moreover, combining these methods can further optimize classification and improve prediction performance [9].

Under-sampling is an effective method for handling imbalanced data by reducing the number of samples in the majority class to balance it with the minority class, thereby improving the predictive capability of the model. Among the under-sampling methods, Random Under-sampling (RUS) is a simple technique applied to balance datasets by randomly removing a number of samples from the majority class. However, such random data removal may lead to the loss of valuable samples and diminish the amount of useful information from the majority class, potentially negatively impacting performance in classification tasks. Therefore, C. M. Huang et al. [1] proposed an approach using K-means to select representative samples from the majority class, improving precision (PPV) by 20.2% while maintaining recall above 90% on Kawasaki Disease (KD) data. Q. Zhou et al. [19] suggested an adaptive K-means-based under-sampling method, where they calculate the distance between data points within each cluster and the cluster centroid using Manhattan distance and Cosine similarity. This algorithm employs these two metrics to select representative samples from the majority class, resulting in a more balanced dataset. The results indicate that this method determines an appropriate dynamic value of k for different datasets and generates a balanced dataset, thereby enhancing the classification performance of machine learning algorithms. T. Doan et al. [22] proposed GBDTLRL2D, a method for predicting lncRNA-disease relationships that combines Gradient Boosting Decision Trees (GBDT) and Logistic Regression, utilizing MetaGraph2Vec and K-means to preserve semantic features, achieving an average AUC of 0.98 in 10-fold cross-validation.

In contrast to under-sampling methods, over-sampling methods focus on increasing the number of samples in the minority class. The simplest over-sampling method is Random Oversampling, which involves randomly duplicating samples from the minority class to increase the number of samples in this class, thereby creating a balance with the majority class. However, this approach can easily lead to overfitting, reducing the generalization ability of the model. To mitigate this risk, N. V. Chawla et al. [17] proposed SMOTE, which generates synthetic samples through interpolation from the minority class data. However, SMOTE may not accurately reflect the complex characteristics of the minority class, especially in intricate models. D. X. Tho et al. [6] improved this approach with KNN-SMOTE, achieving superior performance in F-score, G-mean, and AUC on imbalanced datasets from UCI. H. Li et al. [9] proposed KM-GAN, which combines K-means and GAN to generate new samples from imbalanced industrial fault data. KM-GAN clusters the minority class samples and then utilizes GAN to create additional data, enhancing diagnostic efficacy through a combined DNN and DBN model, thus addressing the bias of traditional methods towards the majority class.

Current methods have effectively contributed to identifying interactions between TFs and target genes; however, they still face several challenges, such as a high false positive rate and significant data collection costs. Additionally, heterogeneous network-based methods have not been optimized for imbalanced data. Although many methods for handling imbalance, as introduced above, have achieved good predictive performance, further improvements are still necessary. To address these limitations and enhance the quality of the majority class, we have developed a new method called FKMU to improve the performance of predictive models. We anticipate that this method will enhance accuracy and applicability in empirical research.

III. Methodology

In this section, we will outline the main tasks of our method aimed at predicting the relationships between TFs and target genes. As part of this narrative, we describe a heterogeneous network formed from biological databases related to TFs, target genes, and diseases, as shown in Step 1 of Fig. 1. We will perform data balancing by combining the K-means clustering algorithm with negative sampling, as detailed in Step 2 of Fig. 1. We will create new meta-paths, as illustrated in Step 3 of Fig. 1. Random walks will be conducted on the graph according to the meta-paths to generate training data for the embedding model, followed by the application of a deep learning model to learn the features of the nodes in the heterogeneous network, as shown in Steps 4 and 5 of Fig. 1. Finally, we will proceed to predict the interactions between TFs and target genes, as illustrated in Step 6 of Fig. 1.

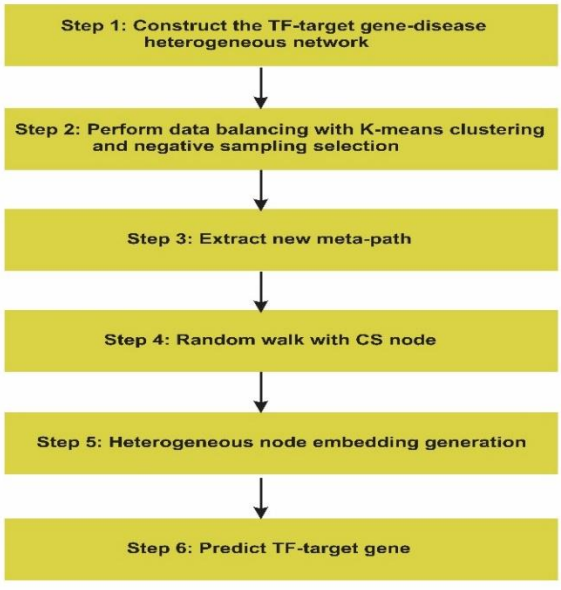

Fig. 1. General workflow containing six main steps.

A. Heterogeneous Network Construction

Definition 1. A heterogeneous network [23] is defined as graph G = (V, E, T), where each node v and each edge e are associated with mapping functions $\phi(v): V \rightarrow T_V$ and $\varphi(e): E \rightarrow T_E$, respectivelt. T_V and T_E represent the set of object types and relationship types, and satisfy the condition $|T_V| + |T_E| > 2$.

In this study, we construct a model to predict the associations between TFs and target genes. This heterogeneous network is defined as a graph G = (V, E, T), where each node represents TFs, target genes, or diseases, and each edge represents the relationships between these entities. TFs and target genes have been shown to have close associations with various diseases, and integrating information about these entities allows us to explore potential unknown associations between TFs and target genes.

B. Meta-Path in a Heterogeneous Network

A meta-path, also known as a "hyperlink" is a model used to represent relationships between nodes in a heterogeneous network. It can be understood as a sequence of connections between nodes and their links, designed to express the relationship between two nodes under consideration within the network.

Definition 2. Meta-path [5]. A meta-path $\mathcal{P}$ is a path defined on the network schema $T_G = (\mathcal{A}, \mathcal{R})$ and is represented as $V_1 \xrightarrow{R_1} V_2 \xrightarrow{R_2} \dots \xrightarrow{R_l} V_{l+1}$, defining a composite relationship $R = R_1 \circ R_2 \circ \dots \circ R_l$ between the types V_1 and V_{l+1}, where $\circ$ denotes the composition operator over relationships.

For example, the meta-path "CTCF (TF) - BRCA1 (Target Gene) - Breast Cancer (Disease) - TP53 (Target Gene) - MYC (TF) - Ovarian Cancer (Disease) - EGFR (Target Gene) - SP1 (TF)", as illustrated in Fig. 2, demonstrates how the transcription factors CTCF, MYC, and SP1 are linked to breast and ovarian cancers through intermediate target genes BRCA1, TP53, and EGFR.

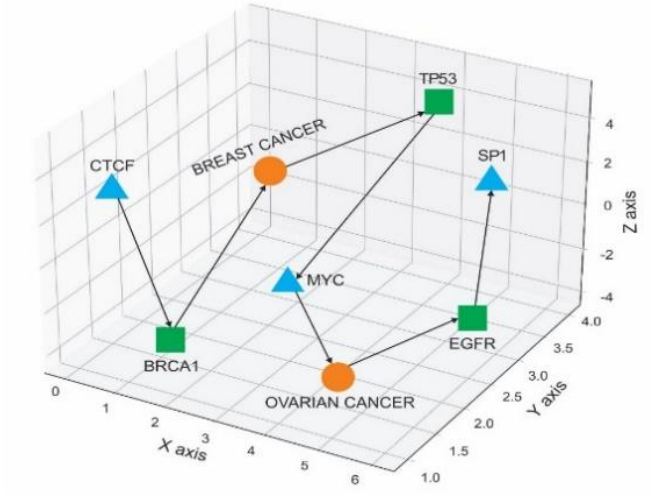

Fig. 2. Illustration of a meta-path in a heterogeneous TF-target gene-disease network.

1) Meta-path random walks: is a graph mining technique that generates paths based on the semantic and structural relationships between different types of nodes. This method helps transform the complex structure of the network into vectors, enabling effective extraction of information from the relationships.

For a heterogeneous network *G = (V, E, T)* and a meta-path schema $\mathcal{P}$, we can calculate the transition probability at step *k* as follow:

$$P(v^{k+1} | v_t^k, \mathcal{P}) = \begin{cases} \frac{1}{|N_{t+1}(v_t^k)|} & (v^{k+1}, v_t^k) \in E, \emptyset(V^{k+1}) = t+1 \\ 0 & (v^{k+1}, v_t^k) \in E, \emptyset(V^{k+1}) \neq t+1 \\ 0 & (v^{k+1}, v_t^k) \in E \end{cases} \quad (1)$$

where $v_t^k \in V_t$ and $N_{t+1}(v_t^k)$ denotes the type V_{t+1} of the neighborhood of node v_t^k.

C. Dataset

In this study, we use a dataset consisting of three types of nodes: TFs, target genes, and diseases, along with three types of relationships between these nodes [24]. Specifically, the three types of relationships include: the association between TFs and target genes, the association between TFs and diseases, and the association between target genes and diseases (Fig. 3).

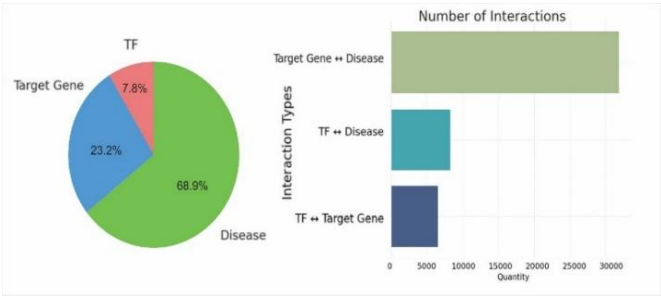

Fig. 3. Statistics of the heterogeneous TF-target gene-disease network information.

Data on interactions between human TFs and target genes were collected from the TRRUST database. This is a transcriptional regulatory network database that utilizes text mining techniques to gather and manually verify detailed information on interactions between TFs and human target genes, ensuring data accuracy. During processing, duplicate pairs were removed, resulting in a final dataset of 6,542 interactions between 696 TFs and 2,064 target genes. Additionally, these transcription factors and target genes were linked to diseases through the DisGeNET database, a resource focused on the genetic basis of human diseases. As a result, 8,199 links between TFs and diseases, along with 31,895 links between target genes and diseases, covering 6,121 different disease types, were collected.

D. Data Balancing Solution with K-Means Clustering and Negative Sample Selection

In this study, the dataset includes 696 TFs and 2,064 target genes, with a total of 1,436,544 TF-target gene pairs. As shown in Fig. 4, only 0.46% of the TF-target gene pairs have been identified as interactions, while the vast majority, accounting for

99.54%, are unknown interactions. This substantial imbalance highlights a severe data imbalance, posing a significant challenge for the prediction model, which can lead to bias and reduced accuracy. Therefore, we have applied data sampling methods to balance the dataset, thereby enhancing the prediction model's accuracy.

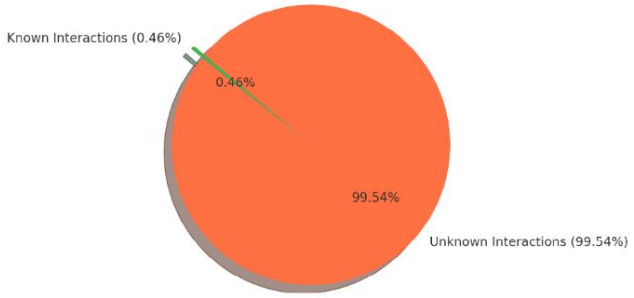

Fig. 4. Distribution of interactions between TF and target genes in the dataset.

In this study, we introduce the FKMU method, a K-means clustering-based Under-sampling technique for selecting negative samples. This method selects samples with the lowest occurrence frequency of TFs in each cluster, based on the inverse information principle as described in Fig. 5. The FKMU procedure is as follows:

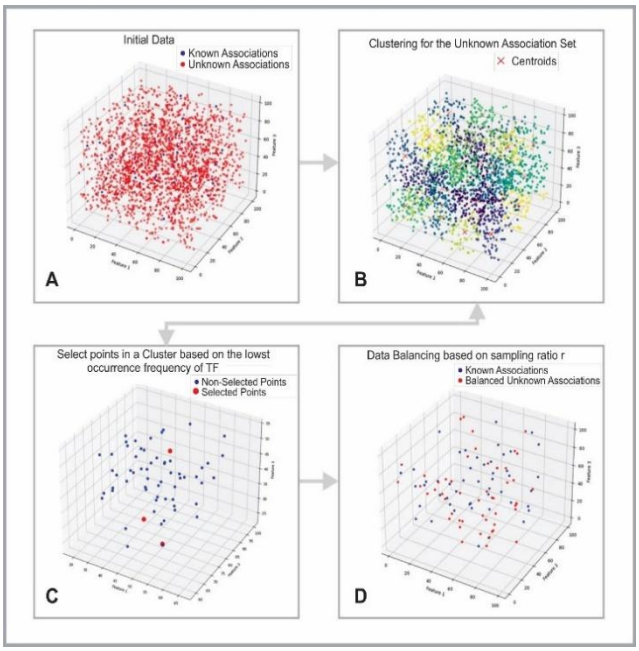

Fig. 5. The process of balancing the dataset using FKMU. A) initial known associations and unknown associations; B) Clustering for the set of unknown associations based on the feature matrix; C) Select points in a cluster based on the lowst occurrence frequency of TF; D) Data balancing based on sampling ratio *r*.

1) Identify the known and unknown association sets from the TF-target gene adjacency matrix A: The known association set *K* consists of TF and target gene pairs with a value of 1 in matrix *A*, representing the associations that have been confirmed. The unknown association set *U* consists of TF and target gene pairs with a value of 0 in matrix *A*, representing the associations that have yet to be evaluated.

2) One-hot encoding for the unknown association set: Each pair (i, j) from the set *U* will be encoded into a feature vector using one-hot encoding for the following factors:

a) TF encoding: A value of 1 at position *i* corresponds to the TF.

b) Target gene encoding: A value of 1 at position *j* corresponds to the target gene.

c) Create feature matrix X: The matrix *X* is defined with dimensions $|U| \times (m + n)$, where each row is the one-hot vector of a pair (i, j) in *U*.

This process is illustrated in Fig. 6, which demonstrates the one-hot encoding structure for unknown associations.

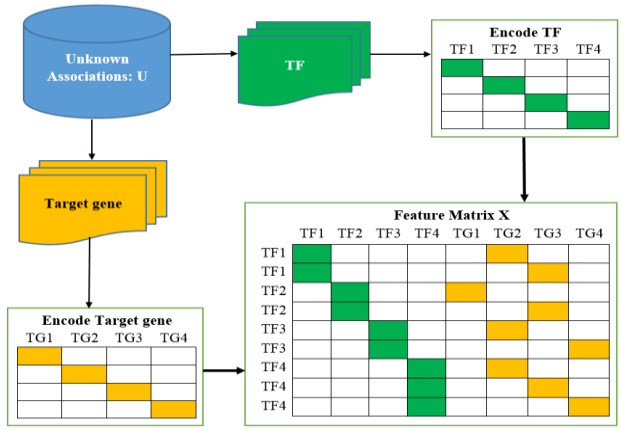

Fig. 6. One – hot encording for unknown associations.

3) Perform K-means clustering on the unknown association set: Apply K-means clustering to divide the unknown associations in *U* into *k* clusters. The feature matrix from step 2 is used to identify the cluster structure in the data, resulting in groups of unknown associations that share similar characteristics. The feature matrix is a sparse matrix. Therefore, before proceeding with the clustering, this matrix is represented in CSR (Compressed Sparse Row) format. CSR is one of the popular formats for storing sparse matrices. It stores the matrix by retaining non-zero values, which helps save memory for large matrices that contain many zero values.

4) Calculate the number of associations to select from each cluster: Based on the total number of known associations $|K|$ and the sampling ratio *r*, determine the number of unknown associations n_p to be selected from each cluster. This helps ensure a balance between known and unknown associations, according to the specified ratio.

5) Select the least frequent samples in each cluster: Within each cluster, calculate the frequency of occurrence of each TF and sort the associations in the cluster by the ascending frequency of the TF. Next, select n_p associations with the lowest frequency of TF occurrence in each cluster to minimize the bias caused by the high frequency of certain dominant TFs. This approach helps create a set of associations that follows the principle of inverse frequency, prioritizing less common

associations to ensure that the sample dataset contains diverse types of associations. The goal of this principle is to enrich the information in the sample set, enabling the model to learn from both rare samples and those that are less biased, thereby enhancing the model's generalization ability for rare cases in real-world data.

6) Return the balanced association set: The set of least frequent associations selected from all clusters forms set *B*, which is the unknown association set balanced according to the ratio *r*. Set *B* is then used as a more balanced dataset for the subsequent steps of the predictive model.

Algorithm 1: Frequency-Based K-Means Under-sampling Algorithm

Input:

- Association matrix $A \in \mathbb{R}^{m \times n}$, where *m* is the number of TFs and *n* is the number of target genes.
- k: The number of clusters for performing K-means clustering.
- r: The sampling ratio from unknown associations.

Output:

- Balanced set of unknown associations *B*, sampled according to ratio *r*.

1: # *Calculate known and unknown set from* A:
2: K = $\{(i,j) \mid A_{ij} = 1\}$ (known association)
3: U = $\{(i,j) \mid A_{ij} = 0\}$ (unknown associations)
4: # *One-hot encoding for TF and Target gene:*
5: Create a feature matrix $X \in \mathbb{R}^{|U| \times (m+n)}$ # *where each row corresponds to an unknown association pair (i, j)*
6: for each pair $(i,j) \in U$ do
7: $X_u = [0, \dots, 1_i, \dots, 0, 0, \dots, 1_j, \dots, 0]$ # *Here, the 1 at position i represents the TF and the 1 at position j represents the Target gene, while the remaining positions are 0.*
8: end for
9: Initialize *k* random cluster centers $\{u_1, u_2, \dots, u_k\}$ from *U*
10: # *Assign each data point x ∈ U to the nearest cluster center:*
11: for $x \in U$ do
12: $c_i = \arg\min_j \|x - u_j\|^2$
13: end for
14: # *Update the center of each cluster with C_j being the set of data points belonging to cluster j:*
15: for *i* = 1 to *k* do
16: $u_j = \frac{1}{|C_j|} \sum_{x \in C_i} x$
17: end for
18: # *Calculate the number of points to select from each cluster:*
19 : $n_{known} = |K|$
20: $n_p = \left\lceil \frac{n_{known} \times r}{k} \right\rceil$
21: Initialize *B = []*
22: # *Select points from each cluster:*
23: for *i* = 1 to *k* do
24: *# Calculate the frequency of each TF in the cluster:*
25: $freq(i) = \sum_{(i,j) \in C_j} 1$
26: # Sort points in cluster C_j by the increasing frequency of their TFs:
27: $C_j' = sorted(C_j,\ key = \lambda x: freq(x_0))$ # *where x_0 is the TF index in the pair (TF, Target gene)*
28: # *Select n_p points with the lowest TF frequency from each cluster:*
29: $B = B \cup C_j'[1: n_p]$
30: end for
31: # *Balance the set of unknown associations:*
32: $B = B\,[1: [n_{known} \times r]]$
33: Return *B*

E. Embedding Heterogeneous Network Nodes using Skip-Gram

Specifically, in a heterogeneous network *G = (V, E, T)* with the number of node types $|T_V| > 1$, he objective is to maximize the co-occurrence probability p of the nodes within the same context window *k*, as follows [31]:

$$\arg\max_{\theta} \sum_{v \in V} \sum_{t \in T_V} \sum_{c_t \in N_{t(v)}} log p(c_t | v; \theta) \quad (2)$$

where $N_{t(v)}$ is the set of neighboring nodes with node *v* in the heterogeneous context with different node types, and $p(c_t|v;\theta)$ is defined as a softmax function [27] as follows:

$$p(c_t|v;\theta) = \frac{\exp(X_{c_t} X_v)}{\sum_{u \in V} \exp(X_u X_v)} \quad (3)$$

where v and c_t are the center node and the nodes in the scanning window, respectively, and, X_v is the embedding vector of node v.

The number of nodes is often very large, so negative sampling techniques are commonly applied to approximate the estimation of probabilities. This method maximizes the probability such that the target node does not appear simultaneously with a randomly selected negative node. The ultimate maximization goal is expressed as follows:

$$O(X) = log\sigma(F(X_{c_t} || X_v) + log\sigma(-F(X_u || X_v)) \quad (4)$$

where *F* represents the fully connected layer, ‖ denotes the concatenation of the embedding vectors of the nodes, and σ(x) is calculated as follows:

$$\sigma(x) = \frac{1}{1+e^{-x}} \quad (5)$$

IV. Results

A. Evaluation Criteria

To evaluate the performance of the proposed method, we applied *k*-fold cross-validation (*k* = 5). Specifically, the data was randomly divided into *k* approximately equal parts. In each iteration, one part was used as the test set, while the model was trained on the remaining *k*-1 parts. This process was repeated *k* times, ensuring that each part of the data was used as the test set once.

To demonstrate the effectiveness of the proposed method during *k*-fold cross-validation, we used the Area Under the ROC Curve (AUC) [24], which is calculated as follows:

TABLE I. COMPARISON OF PERFORMANCE BASED ON AUC DURING 5-FOLD CV WITH DIFFERENT PARAMETER SETS

Number of walkers	100	250	350	450	550
Path length	50	80	130	130	150
Dimension of embedding	128	200	300	450	550
Average AUC	0.9199 ± 0.0064	**0.9388 ± 0.0045**	0.9345 ± 0.0064	0.9100 ± 0.0038	0.8828 ± 0.0140

$$AUC = \frac{\sum_{e \epsilon e^+} Rank_e - \frac{|e^+| \times (|e^+|+1)}{2}}{|e^+| \times |e^-|} \quad (6)$$

where e^+ and e^- represent the positive and negative samples, respectively, in the test set, and $Rank_e$ denotes the rank of edge e based on the predicted score.

We conducted experiments with different values for three parameters: number of walkers, path length, and dimension of embedding, while comparing the corresponding prediction results when varying each parameter. The average AUC value for each experiment is presented in Table I. The best prediction results were achieved when the number of walkers was 250, the path length was 80, and the dimension of embedding was 200. The corresponding ROC curve is illustrated in Fig. 7, showing that our proposed method achieved an average AUC value of 0.9388 ± 0.0045 through 5-fold cross-validation.

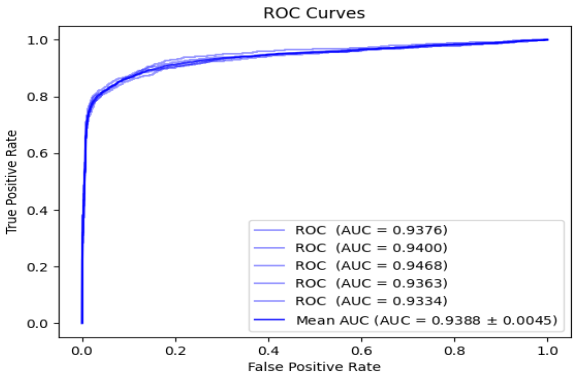

Fig. 7. ROC curve through 5-fold cross-validation.

B. Determine the Optimal Number of Clusters

Determining the optimal number of clusters *k* is a crucial factor in the effectiveness of the K-means algorithm. Choosing *k* too small can lead to data points being grouped together, overlooking significant differences between clusters. Conversely, if *k* is too large, the data may be unnecessarily divided into clusters, reducing generalization. For our experiment, we applied the Elbow method with values ranging from 10 to 200. Specifically, for each *k* value, the K-means algorithm was executed, and the WCSS (Within-Cluster Sum of Squares) was calculated.

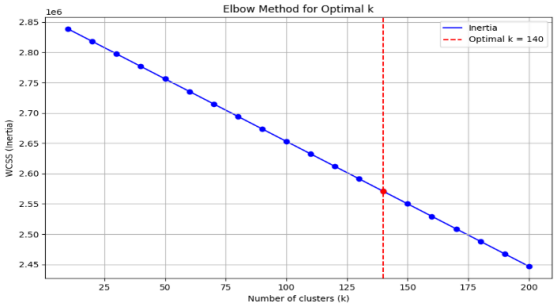

Fig. 8. The elbow method for selecting the optimal number of clusters *k*.

The results in Fig. 8 show that as *k* increases from 10 to around 140, the WCSS decreases significantly, indicating that increasing the number of clusters improved data clustering. However, after *k* = 140, the WCSS begins to decrease more slowly, suggesting that adding more clusters no longer provides substantial benefits for data separation. Therefore, we chose *k* = 140 as the optimal number of clusters, as it achieves a balance between reducing WCSS and maintaining model generalization.

C. Negative Sampling Rate

Choosing a balance ratio *r* between Unknown Associations and Known Associations is aimed at optimizing the model's performance in distinguishing between these two groups. A reasonable balance ratio enables the model to learn the characteristics of both groups without bias, thereby achieving the highest AUC value and ensuring accuracy when applied to new data.

TABLE II. THE BALANCE RATIO BETWEEN UNKNOWN ASSOCIATION AND KNOWN ASSOCIATION

Balance Ratio r (Unknown : Known Association)	Average AUC Value
1:1	0.9388 ± 0.0045
2:1	0.9264 ± 0.0028
3:1	0.9229 ± 0.0047
4:1	0.9275 ± 0.0055
5:1	0.9273 ± 0.0041
6:1	0.9212 ± 0.0025
7:1	0.9231 ± 0.0030
8:1	0.9229 ± 0.0041
9:1	0.9210 ± 0.0050
10:1	0.9175 ± 0.0017

When conducting experiments with different values of the balance ratio *r*, we obtained the results shown in Table II. The results indicate that when the balance ratio is 1:1, the AUC value reaches its highest point at 0.9388 ± 0.0045, suggesting that this is the optimal balance ratio for effectively distinguishing between Unknown Associations and Known Associations. As the balance ratio increases from 2:1 to 10:1, the AUC value gradually decreases, particularly at a ratio of 10:1, where the AUC value significantly drops to 0.9175 ± 0.0017. This indicates that the model's effectiveness diminishes when Unknown Associations constitute too large a proportion compared to Known Associations.

D. The Impact of Selecting Meta-Paths

The random walk strategy based on meta-paths ensures that the model accurately integrates the semantic relationships between different types of nodes. Utilizing different meta-path schemas to generate sequences of nodes can capture the diverse semantic and structural relationships among these node types.

In this experiment, we designed a new meta-path schema "TF-Target gene-Disease/CS-Target gene-TF-Disease/CS-Target gene-TF" while also using the original meta-path "TF-Target gene-Disease/CS-Target gene-TF" [24] to conduct the random walk process and evaluate the prediction effectiveness of each schema. The results in Table III show that the new schema achieves a slightly higher average AUC value (0.9388 ± 0.0045) compared to the original schema (0.9366 ± 0.0044), suggesting that the new schema can improve predictive performance by capturing additional potential links within the heterogeneous network. Here, CS (Cold Start node) is a node added to the paths to address the cold start problem in the model. This issue arises when certain nodes (especially TFs or target genes) have no links to any target genes in the training data, making it difficult to learn embedding vectors for these nodes. By adding the CS node and setting its embedding to a vector where all elements have a value of 1, the model can learn information from paths containing the CS node, helping to mitigate the lack of link data for these nodes and enhance the overall performance of the model across the heterogeneous network.

TABLE III. COMPARING AUC PERFORMANCE ACROSS DIFFERENT META-PATHS

Meta-paths	Average AUC Value
TF-target gene-disease/CS-target gene-TF	0.9366 ± 0.0044
TF-target gene-disease/CS-target gene-TF-disease/CS-target gene-TF	0.9388 ± 0.0045

E. Predicted Scores for TF-Target Gene Pairs

After training the model, we obtain low-dimensional embedding vectors for TFs and target genes. From this, we create an embedding matrix *M* for TFs and an embedding matrix *G* for target genes. The predicted scores for the interactions between TFs and target genes are determined as follows:

$$P = M.G^T \quad (7)$$

where the value in the *i-th* row and *j-th* column represents the interaction score between the *i-th* TF and the *j-th* target gene.

F. Analysis and Comparison with Recent Studies

To evaluate the superior performance of the proposed model, we compared its predictive capabilities with recent studies, including Metapath2vec [25], HGETGI [24], and GraphTGI [30]. The comparison results shown in Table IV indicate that our method achieves the highest average AUC value of 0.9388, outperforming the other three methods. This confirms that our model is highly effective in predicting unobserved target genes for specific TFs.

Although models such as Metapath2vec, HGETGI, and GraphTGI effectively utilize heterogeneous graphs, particularly for predicting TF-target gene interactions, GraphTGI demonstrates impressive performance with an AUC of 88.64% in five-fold cross-validation, while HGETGI excels in leveraging semantic information through graph embeddings. However, all three methods lack robust mechanisms for handling imbalanced data and selecting negative samples, which can limit their ability to optimize performance on complex and highly imbalanced datasets. FKMU addresses these challenges through a K-means-based under-sampling strategy, ensuring a balanced dataset and enhancing the robustness of the model. Furthermore, the introduction of a novel meta-path allows FKMU to capture semantic relationships within the graph more effectively and optimize the detection of potential interactions. These advancements establish FKMU as an effective and superior method for predicting TF-target gene interactions while offering broad applicability to more complex and diverse problems, especially for large-scale and heterogeneous datasets in the future.

TABLE IV. COMPARING THE PERFORMANCE OF RESEARCH METHODS

Methods	Average AUC Value
Metapath2vec [25]	0.8239 ± 0.0057
HGETGI [24]	0.8519 ± 0.0731
GraphTGI [30]	0.8864 ± 0.0057
FKMU	0.9388 ± 0.0045

G. Case Study

To evaluate the predictive performance of the model in identifying potential target genes associated with TFs, we conducted experiments on the transcription factors CTCF and TP53. Specifically, we removed the links between the specific TFs used in the experiments and their target genes. We then reconstructed the heterogeneous network. Finally, we trained the model and tested it for each specific TF case to assess the model's performance.

The transcription factor CTCF (CCCTC-binding factor) is an important protein involved in regulating the structure and function of the genome. CTCF binds to DNA sequences to create insulator regions and chromatin loops, helping to regulate gene activity. CTCF can activate or repress genes depending on its binding location. Mutations in the CTCF gene are associated with various diseases such as cancers (breast, colorectal, prostate), neurodevelopmental disorders (Bardet-Biedl syndrome, autism spectrum disorders), and rare genetic diseases, primarily due to disruptions in chromatin structure and gene regulation.

The transcription factor TP53 (tumor protein p53) is an important gene, often referred to as the "guardian of the genome" due to its key role in maintaining genetic stability and preventing tumor formation. This gene encodes the p53 protein, a tumor suppressor that plays a crucial role in controlling cell division, repairing damaged DNA, and activating apoptosis when cells sustain irreparable damage. TP53 mutations are a common cause in many types of cancer, including lung cancer, breast cancer, colorectal cancer, and skin cancer. Research on TP53 not only elucidates the mechanisms of cancer but also opens new avenues for treatments aimed at restoring p53 function to prevent the development of cancer cells.

We ranked the predicted scores based on the weighted matrix to identify potential target genes. Then, we assessed the accuracy of these target genes by comparing them with the hTFtarget database [18]. Specifically, we focused on testing and validating the top 20 predicted target genes to ensure the reliability and accuracy of the predictive model. This process helps us confirm the model's capability in identifying potential target genes associated with the TFs.

The experimental results are presented in Table V for CTCF and in Table VI for TP53, respectively. According to these tables, 75% (15/20) of the predicted target genes have been validated against the hTFtarget dataset. Additionally, we conducted supplementary research and discovered genes such as KRAS, which, although not listed as interacting with CTCF in hTFtarget, have been reported to interact with CTCF in other studies, as indicated by the PMID [11] codes in Table V. Similarly, genes such as IL1B and TERT were also found to interact with TP53, as shown by the PMID [14, 16] codes in Table VI. These results demonstrate the effectiveness of the proposed method.

V. CONCLUSION

Predicting interactions between transcription factors and target genes remains a significant challenge, particularly in the context of the complex relationships within the gene regulatory network that have not been fully explored. To address this issue, we propose the FKMU method, a novel approach aimed at handling data imbalance when predicting interactions between TFs and target genes. FKMU combines K-means clustering and inverse information principles to select underrepresented samples in the dataset, thereby balancing sample ratios and improving the accuracy of the model. This method applies the K-means algorithm to partition unknown samples into clusters, subsequently prioritizing TFs with low occurrence frequency in each cluster to enhance diversity and representation within the data. Experimental results on real datasets demonstrate that FKMU achieves superior performance in accurately predicting interactions between TFs and target genes compared to current methods, with a significantly higher average AUC value. We expect that the FKMU method will pave the way for new avenues in scientific research, improving the handling of imbalanced data and enhancing the accuracy of predictive models in the biomedical field.

***Abstract*—Numerous economic, political, and social factors make stock price predictions challenging and unpredictable. This paper focuses on developing an artificial intelligence (AI) model for stock price prediction. The model utilizes LSTM and XGBoost techniques in three sectors: Apple, Google, and Tesla. It aims to detect the impact of combining sentiment analysis with historical data to see how much people's opinions can change the stock market. The proposed model computes sentiment scores using natural language processing (NLP) techniques and combines them with historical data based on Date. The RMSE, R^2, and MAE metrics are used to evaluate the performance of the proposed model. The integration of sentiment data has demonstrated a significant improvement and achieved a higher accuracy rate compared to historical data alone. This enhances the accuracy of the model and provides investors and the financial sector with valuable information and insights. XGBoost and LSTM demonstrated their effectiveness in stock price prediction; XGBoost outperformed the LSTM technique.**

***Keywords*—Sentiment analysis; stocks price prediction; correlation; natural language processing (NLP); machine learning model; LSTM; XGBoost**

I. Introduction

Stock market prediction has been a matter of interest to researchers, vendors, and investors for a long period. The main purpose of predicting the stock market is to achieve optimal results and decrease investment risk. It focuses on establishing an effective technique for predicting stock prices and providing well-informed, data-driven insights on market behavior [1]. Another purpose of stock market prediction is to predict the most accurate price in the future and determine the trend of the stock price, whether it is going up or down. This helps and guides investors to make better choices, avoiding potentially harmful investments that could increase their profits and reduce their losses [2]. Due to its volatility, unpredictability, and rapidness, stock market prediction is challenging. Various factors, such as public opinion, social media, feelings, and sentiments, influence the accuracy of stock market predictions [3].

Social media platforms (Facebook, Twitter, etc.) became a vital data source. Social media plays an important role for companies and people. People use social media every day to express their opinions and experiences and review products, services, or even companies [4]. On the other hand, companies utilize social media platforms to extract and analyze customers' opinions and feelings toward what they offer [5] [6]. Sentiment analysis (SA) is one of the disciplines that analyze social media data. Sentiment analysis can be defined as analyzing users' emotions using their opinions, sentiments, and subjective texts to decide if their interactions are positive, negative, or neutral. As stated, Sentiment Analysis is a type of subjectivity analysis that concentrates on identifying opinions, feelings, and respect conveyed through natural language [7]. It enhances the quality of goods and services by evaluating consumers' feedback on a certain product or service. Furthermore, natural language processing (NLP) is important for teaching machines to process human language and translate it into machine-readable format.

Sentiment analysis plays an important role in predicting stock prices by examining public opinion and social media to estimate the market mood and its effect on stock prices and aid the investors in overcoming the investment risk Merging sentiment analysis with traditional financial measures improves predictive accuracy. Companies can utilize risk management techniques to make strategic decisions, regardless of stock fluctuations [8].

Different domains have addressed sentiment analysis because it can help companies increase their capitalization by enhancing their products or services to meet customers' expectations. Stock markets leverage social media data, and SA can predict its stock prices depending on people's opinions. However, predicting stock prices is complicated because of their volatile and dynamic nature [9].

Historical data is another factor that plays an important role in stock price prediction. Historical data comprehends market behaviors and trends, leading to well-informed financial decisions based on data analysis. Examining historical data, which includes financial variables such as volume, price, high, low, and close, enables predictive algorithms to detect connections and recurrence patterns. Then train and test machine learning techniques using historical data to predict stock prices and improve their accuracy [10].

A. Background

1) The extreme gradient boosting (XGBoost) model: XGBoost in ML for regression and classification is an ensemble technique that builds a series of weak learners, usually decision trees (DTs). Every learner removes errors from the previous learners by minimizing errors between actual values and predicted values. This process is called the loss function [11]. XGBoost employs the L1 (Lasso) and L2 (Ridge) methods of regularization to reduce overfitting and improve the model's ability to generalize. Its parallel processing ability makes it computationally rapid and suitable for big data processing.

XGBoost works by figuring out an objective function in Eq. (1). Regularizes then use this function along with a loss function and a residual measurement to get rid of complicated models that cause overfitting [12]. In XGBoost, the objective function comprises a loss function that calculates the residuals and a second part that simplifies the model and reduces overfitting [13]. Model parameter optimization can reduce the objective function through gradient descent on the loss function. DTs persist in decreasing the residuals and repeatedly reduce the loss until it diminishes.

$$\mathcal{L}(\theta) = \sum_{i=1}^{n} \iota(\mathrm{y}_i, \hat{\mathrm{y}}_i) + \sum_{K=1}^{K} \Omega(f_{k)} \qquad (1)$$

Where $\mathcal{L}(\theta)$ is the objective function (overall), $\iota(\mathrm{y}_i, \hat{\mathrm{y}}_i)$– (evaluation metrics), or loss function was measured by (mean absolute error), $\Omega(f_{k)}$ Regularization term to minimize overfitting.

$$\hat{\mathrm{y}}_{\mathrm{i}}^{(\mathrm{t})} = \sum_{k=1}^{t} \mathrm{f}_k(\mathrm{x}_i) \qquad (2)$$

Prediction in XGBoost as shown in Eq. (2): At each stage, the forecast $\hat{\mathbf{y}}_{\mathbf{i}}$, is calculated by summing the predictions made by all (t) the trees and (f_k) the tree. The objective function decreases by using gradient descent to iteratively adjust model parameters and minimize the loss function [14]. During the optimization, the DTs aim to eliminate the residuals (the differences between actual and predicted values). This process continues until the algorithm reaches a minimum point where further tuning does not significantly reduce the loss.

2) XGBoost integration with sentiment analysis: XGBoost is a gradient-boosting technique that uses several decision trees to simulate the relationships between features, such as emotion scores and stock prices, and the target variable (the future stock price). Each decision tree works to make predictions better by using attributes and stock market dates repeatedly. Simultaneously, the loss function undergoes optimization to identify the least effective prediction trees [15]. XGBoost has integrated with sentiment analysis, specifically sentiment score or polarity, as one of its input features. XGBoost can manage nonlinear interactions and prioritize feature relevance, which is beneficial when combining textual sentiment analysis with historical data. XGBoost boasts several features that set it apart from the traditional model. XGBoost can define and determine how much the sentiment analysis score contributes to the prediction. Compared to stock features, regularization is another feature that enables XGBoost to overcome or prevent overfitting, particularly when the combined features have high dimensionality. Scalability is considered the most significant feature in XGBoost. It is used for large datasets. XGBoost can handle both historical and sentiment analysis [16].

3) Long short-term memory (LSTM): To overcome long-term dependency, a unique type of recurrent neural network was explicitly designed, namely LSTM. The LSTM incorporates a novel memory cell that replaces conventional artificial neurons in the hidden layers, enabling it to retain data over an extended duration. According to Hochreiter and Schmid Huber [17], the inability to handle long-term dependencies is an important factor for any dispute that contains a time series; this is the main struggle when applying ordinary neural network architecture to predict a stock price. Three gates organize the information, determining which data to store in the cell, which to discard, and what the cell's output will be. LSTM proves to be a confidential mechanism in many fields, not only computer science but also statistics, linguistics, and medicine. All these areas have tasks involving the analysis of sequential data, prediction, classification, and regression, for which LSTM proved to have a great ability to process them well [18].

4) Long short-term memory (LSTM) integrated with sentiment analysis: Long Short-Term Memory (LSTM), a type of deep learning, is considered the best technique for processing sentiment analysis and can manage and handle sequential data by capturing long-term dependencies within the text or sentence. This makes it suitable for sentiment analysis tasks, particularly when the word depends on the word in the surrounding context [19]. The LSTM architecture incorporates memory cells that store information related to stored sequences over extended periods. This enables the model to interpret the sentiment in the text more accurately and quickly. This is true even when there is a significant gap between the keywords. Sentiment analysis depends on data quality, such as the volume of text. LSTM can learn and forecast the next sentiment labeled more accurately based on the large volume of labeled text. This feature makes it an invaluable tool for other tasks, like monitoring social media and predicting stock prices [20].

This paper is organized as follows: Section II presents a literature review. Section III introduces the proposed methodology, while Section IV and Section V showcase experimental analysis and results respectively. Simultaneously, Section VI highlights the conclusions.

II. Literature Review

Many researchers have tackled improving prediction accuracy by using machine learning and deep learning algorithms. The goal of this paper is to review previous studies, find challenges, and overcome these gaps and challenges by providing a novel research method.

A study [21] employed LSTM regression models to estimate India's NIFTY 50 index. The deep learning-based LSTM model outperformed traditional machine learning methods. A study [22] compares ARIMA, LSTM, and BiLSTM models for forecasting financial time-series data and concludes that the BiLSTM model produced the best results. Another study in [23] offered an RNN-Boost model for forecasting Chinese stock market values, which outperformed the baseline RNN model.

The study in [24] employed deep learning, support vector regression, and linear regression for the stock market to forecast and evaluate the sentiment surrounding each event, focusing on four nations that represent established, emerging, and undeveloped economies: the United States, Hong Kong, Turkey, and Pakistan. This study assessed the system's performance using mean absolute error (MAE) and root mean square error

(RMSE). The results indicate that incorporating sentiment analysis for these events improves the system's performance.

This research paper aims to concentrate on the implementation of the stock-containing Long Short-Term Memory (LSTM) algorithms. The LSTM originates from the recurrent neural network in stock. It has a significant effect on time series data problems. This study establishes two models: the BP neural network model and the LSTM model. Next, integrate these models with the available stock data to generate a series of predictions. Undoubtedly, the prediction accuracy of LSTM models has improved. The accuracy rate can reach 60%–65%. During the modeling process, this study has refined traditional gradient descent algorithms and specifically designed the neural network's input data to mitigate the inevitable "sawtooth phenomenon" of the gradient descent algorithm. Additionally, they established a library of parameter combinations and utilized the dropout technique to achieve more accurate prediction results [25].

Machine learning models demonstrate that artificial neural networks (ANNs) can learn input-output correlations and assist in producing close estimates of daily closing prices when trained on the same data [26]. Deep learning techniques like convolutional neural network (CNN) was used in sentiment analysis research in the Indonesian language [27].

Many research studies use sentiment analysis to extract opinions from the text and categorize them as positive, negative, or neutral. Researchers can categorize the research into lexicon-based or machine-based learning-based methods. In recent years, many lexicons can be depended on and used to determine the text, including SentiWord Net [28], WordNet-Affect, and Sentic Net [29].

The author used the support vector machines for sentiment analysis. Experiments reveal an accuracy of 89.93% in predicting the direction of the SSE 50 index's movement, with an additional 18.6% increase in accuracy when adding sentiment-describing parameters. At the same time, this model supports investors in making better investment decisions [30].

In study [31], they create and evaluate forecasting models for stock prices and trends. They suggest a novel decision tree technique to predict stock performance by utilizing a large-scale sample of tweets relating to four companies: Apple, Google, Microsoft, and Netflix. They concluded that a decision tree model surpasses a multiple regression model.

In study [32] Deep learning models have been used to enhance the accuracy of stock price prediction. They depend on more than 265,000 news articles and S&P 500 companies' financial datasets to predict stock prices. They concluded that the RNN model performed well compared with other models (ARIMA and Facebook Prophet). Furthermore, RNN proved its efficiency with fixed/stable stocks rather than low prices.

In study [33] Applied machine learning historical stock prices and financial news from four distinct companies in different industries. They aim to ascertain the influence of financial news on the fluctuations in stock prices. They have also conducted experiments to evaluate the challenges associated with predicting certain stocks. This study discovered that of Tata Motors stock prediction, an automobile company, has the highest MAPE, resulting in a greater deviation from the actual prediction than other stocks.

The relationship between sentiment derived from financial news and tweets and the movements of the FTSE100 index is examined [34]. The investigation aimed to determine the strength of the correlation between sentiment indicators on a given day and market volatility and returns observed on a subsequent day. The experimental findings reveal evidence of a correlation between sentiment and stock market movements.

In study [35] Artificial Neural Networks (ANN) have been used to predict the prices in different periods one day, 7 days, 30 days, 60 days, and 90 days. They used different resources of social media datasets combined as input such as (Twitter, google Trends, web news, forum posts) and the Stock Exchange (GSE) from January 2010 to September 2019 of Ghana company dataset. They concluded that the information they obtained from social media can influence the effectiveness of stock price movement prediction.

The authors utilized deep learning models to track and evaluate the Chinese stock movements. They figured out that LSTM's forecast is closest to actual values, and increasing the number of hidden layers had no significant impact on accuracy [36].

The relationship between Twitter tweets and stock prices has been tested and proven using multiple models. While training the models, SVM reveals a superior performance. The neural network models proved their superiority while evaluating the difference in the closing stock prices between the two companies [37].

After reviewing the literature, we found that no study measures the correlation between SA and stock price prediction. Therefore, this correlation is represented by analyzing the performance of integrating the sentiment with historical data compared with using historical data only.

Therefore, this research shed light on this gap by developing an AI model to improve stock price prediction accuracy. It provides investors with more insight to make informed and valuable decisions regarding buying or selling. The proposed model depends on applying the LSTM and XGBoost techniques with historical data only and with sentiment analysis integrated with historical data. The integration of sentiment analysis (qualitative data) with historical data can improve prediction accuracy and yield valuable market insights.

III. Research Methodology

The research methodology involves utilizing natural language processing (NLP) techniques to extract sentimental information from social media as represented in Fig. 1. This sentiment analysis, categorized as positive, negative, or neutral, is then combined with the corresponding stock prices retrieved from Yahoo Finance. The existence of a correlation between sentiment analysis and stock prices is demonstrated using machine learning and deep learning models. Furthermore, two models, including LSTM (Long Short-Term Memory) and XGBoost, are utilized to enhance prediction accuracy based on sentiment analysis. These models are applied with historical data only and with sentiment analysis integrated with the historical

data. These models are measured through evaluation metrics such as Root Mean Squared Error (RMSE), R^2, and Mean Absolute Percentage Error (MAE). This experiment helps to measure the impact of integrating sentiment analysis and provides valuable insights into where to buy or sell in the financial sectors.

IV. Experimental Analysis

A. Dataset Description

This study utilizes three stocks captured from Kaggle: Dataset 1 collects people's tweets for Apple from June 2015 to December 2019. Dataset 2 collects tweets from June 2015 to September 2020 for Google. The final dataset gathers tweets from June 2020 to October 2020 for Tesla. Each dataset comprises two columns: the first column is the date of the post date, while the second column contains the tweet's text. The quantitative data type in this study necessitates a sentiment analysis. Then, other datasets were downloaded from Yahoo Finance, where the stock prices for Apple, Google, and Tesla span the same period. Each dataset consists of seven columns, 1) The date: marks the recording or reporting of the stock market data. 2) Open: The opening price of the company's stock on the given date. 3) High: The highest price reached during the trading day. The company's stock traded at its highest price. It indicates the highest price reached during the trading session. 4) Low: The trading day reached its lowest price. 5) Close: The price at which the stock closed on that trading day. 6) Adj Close refers to the adjusted closing price, which considers any corporate actions such as stock splits or dividends that may impact the stock's value. 7) Volume refers to the total number of shares traded during a trading day.

B. The Experimental Approach

This section discusses the experiments conducted to measure the effect of people's sentiments on total fluctuation. The two main subsections below provide detailed steps. The first subsection illustrates the data preprocessing. The second clarifies the experimental steps.

1) Data preprocessing: The first task in the preprocessing stage is to detect duplicated records and null values. Drop the duplicate records and use the mean imputation to address the missing value problem. Furthermore, the uppercase letters are converted to lowercase letters to streamline the training and testing of the model. The data cleaning task included the removal of all stop words, such as "that," "for," "the," "a," "he," and "has." Furthermore, the lemmatizing process is conducted on the previously mentioned datasets., an NLP tool allows end users to understand full sentence input from end users. Also, URLs, mentions, and # hashtags were removed in the preprocessing phase.

2) The experimental steps: This study applies the Long Short-Term Memory (LSTM) and XGBoost algorithms to detect the relationship between people's sentiment and the total fluctuation to predict the future stock price.

After cleaning the data, the polarity measure is conducted, utilizing two algorithms, such as VADER [38] From NLTK [39], which employs tools to identify positive, negative, or neutral comments and compound sentiment. VADER evaluates the polarity, or the intensity of the emotion, by determining whether the statement is positive, negative, or neutral as introduced in Fig. 2. Text Blob NLP evaluates the subjectivity and polarity of Twitter tweets.

Polarity is the positive, negative, or neutral feeling expressed in a text as represented in Fig. 3. It determines whether a text describes a good or negative attitude toward a particular entity or issue. NLP frequently uses polarity analysis for sentiment analysis, identifying and categorizing opinions expressed in text. on the other hand, Subjectivity hand describes how subjective or objective a piece of literature is. It is used to determine if a statement is a fact or opinion. Subjectivity analysis in NLP allows detective subjective language and its distinction from objective language. Subjectivity analysis is used to assess whether a text is objective or subjective [40].

The sentiment score of a piece of text (X tweet) can be calculated using various methods as presented in Eq. (3). A simple approach might be used to assign scores to positive and negative words and compute an overall score for the document [46].

$$S = \frac{(\Sigma p_l') - (\Sigma n_J')}{n_p + n_n} \quad (3)$$

Where S is the sentiment score, p_l' are the scores of positive words, n_j are the scores of negative words, n_p is the number of positive words, and n_n is the number of negative words in the text. Market volatility on a given day can be modeled as a function of sentiment scores from the previous day, incorporating both social media sentiment and traditional financial indicators [41].

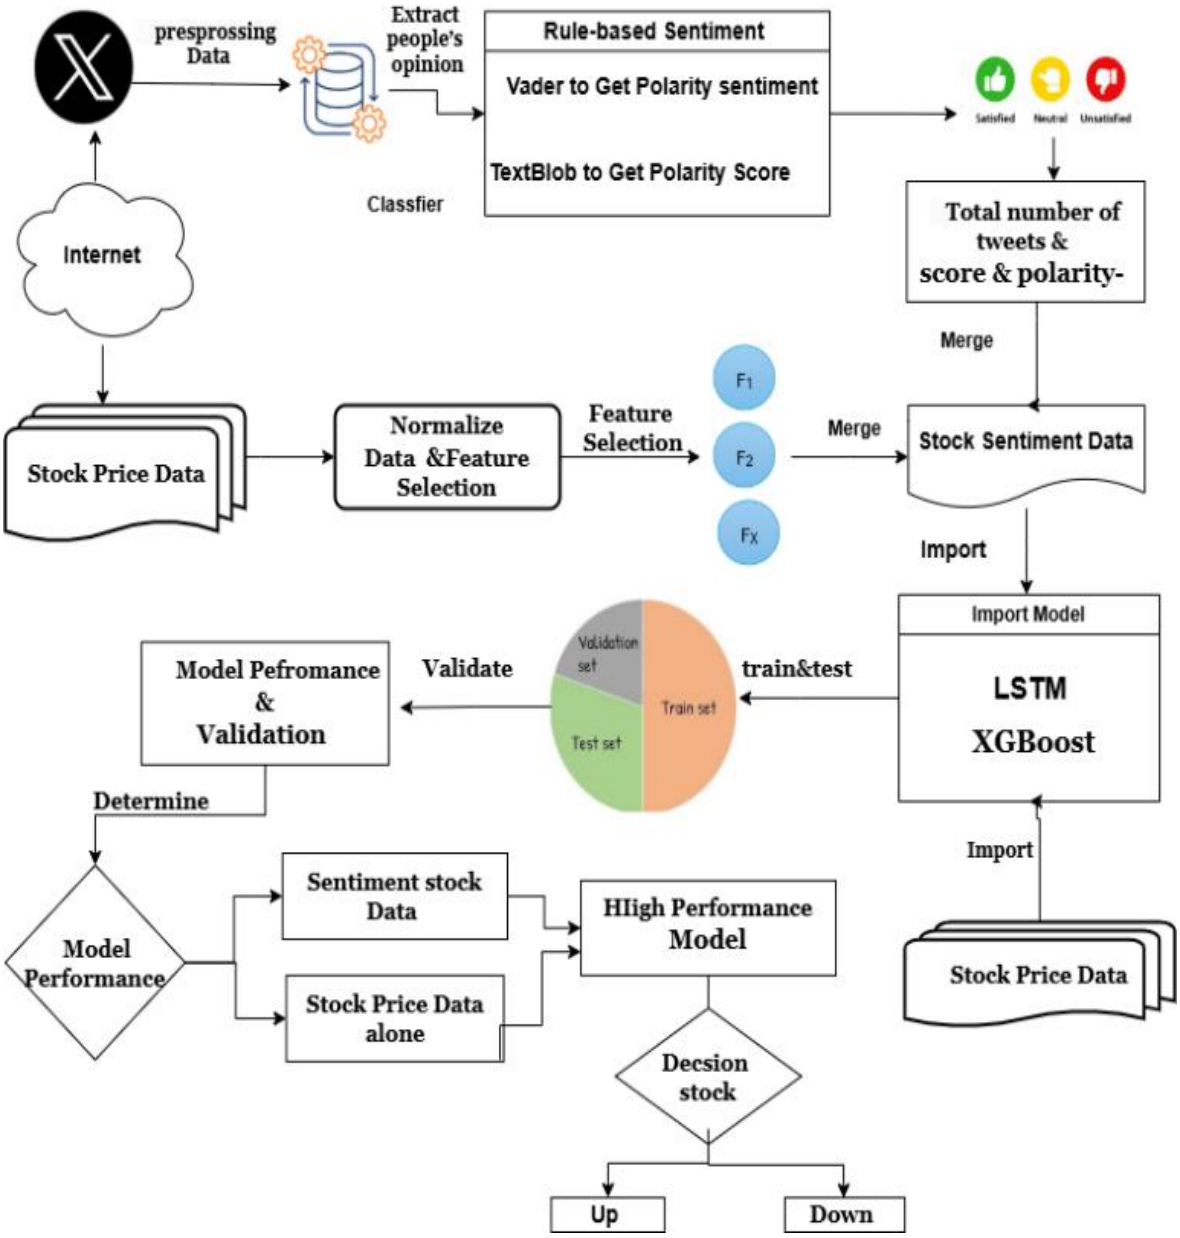

Fig. 1. The framework of stock prediction based on sentiment analysis.

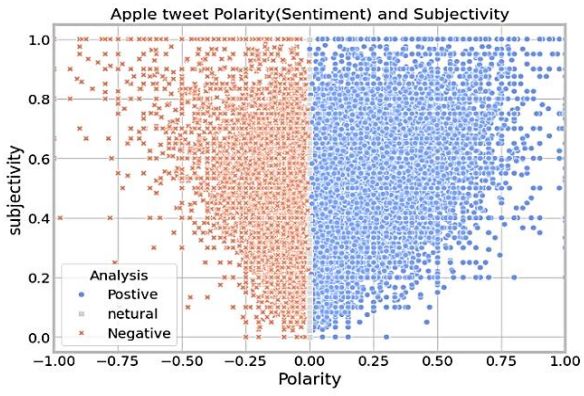

Fig. 2. Polarity vs. subjectivity.

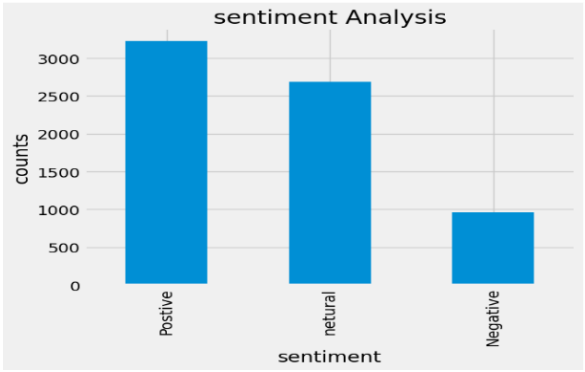

Fig. 3. Classifier of Apple tweet.

Fig. 4. The most positive words.

Fig. 4 illustrates the most common and frequent words in positive tweets about Apple, including “new”, “good”, and “read”, “Thanks”, which are strongly associated with positive sentiments.

Fig. 5. The most negative words.

Fig. 5 illustrates the most common and frequent words in negative tweets about Apple, such as “hate”, “worst”, “sorry”, “fail”, and “stupid”, and “stupid”, which are associated with negative sentiment.

The most common and frequent words in positive tweets about Google, including “top”, “share”, and “competition”, “penny”, are strongly associated with positive sentiments.

The most common and frequent words in negative tweets about Google, including “worst”, “pain”, and “less”, “spam”, are strongly associated with negative sentiments.

The most common and frequent words in positive tweets about Tesla, including “best”, “trade”, and “right”, “good”, are strongly associated with positive sentiments.

The most common and frequent words in negative tweets about Tesla, including “bad”, “wrong”, and “crazy”, “tesla”, are strongly associated with negative sentiments.

Three new features were added to the Apple, Google, and Tesla stock price datasets to evaluate the efficiency of future stock values. The first feature is total price fluctuation, which indicates the overall variation at the end of the day. This is measured by subtracting the volume value from the close value. The second feature, price difference is calculated by subtracting today's adjusted close value from the value from the previous day. Depending on the price difference feature, the direction of the stock price (Up or Down) is detected and stored in the trend score feature.

The price difference feature detects and stores the stock price's direction (up or down) in the trend score, which is the last feature. If the price difference is positive, the trend score is equal to 1 (up), and if the price difference is negative, the trend score is 0 (down), as illustrated in the snapshot of Table I.

TABLE I. SNAPCHAT ADDED THREE FEATURES TO THE STOCK PRICE

Date	Open	High	Low	Close	Adj Close	Volume	Total_price_fluctuation	Price_difference	Trend

The sentiment scores, polarity, and total number of **X** tweets are combined with the updated Apple, Google, and Tesla stock price datasets by matching dates to check for a correlation between people's opinions and the total fluctuation.

The first experiment tests the correlation to determine the extent to which people's opinions influence the overall fluctuation. The second experiment is to predict the expected stock price using the LSTM and XGBoost algorithms. The performance of the used algorithms is evaluated and ranked.

a) The first experiment: Fig. 6 and Fig. 7 depict the movements of both positive and negative tweets about the stock price. Depending on Fig. 6, it is obvious that the positive tweet movements pretty much match the stock price movements. However, the movement of negative tweets barely relates to the movements of the stock price. Thus, generally, we can deduce that there is a relationship between the tweets and stock market movements.

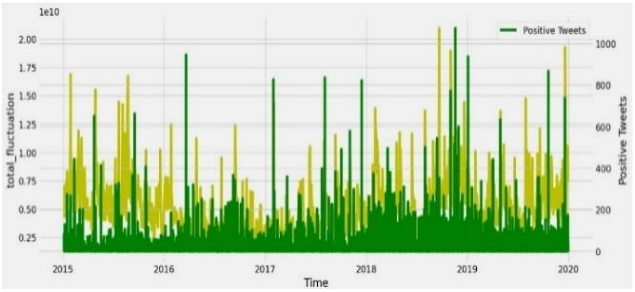

Fig. 6. Positive tweet movement.

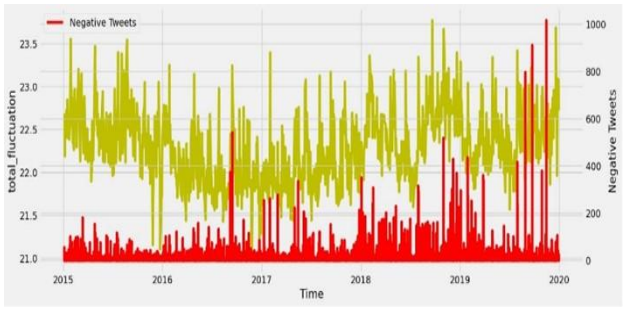

Fig. 7. Negative tweet movement.

To figure out to what extent the tweets can affect the stock price, the second experiment is conducted. The results show that positive people's opinions can affect the stock price by 47.56%. However, a negative correlation of 4.9% exists between people's negative tweets and the stock price. This means that when the tweets are negative, the stock price increases.

b) Predict stock prices utilizing LSTM and XGBoost models by integrating sentiment analysis: This approach utilizes the Long Short-Term Memory (LSTM) and XGBoost algorithms on a combined dataset, which includes the total number of tweets, polarity, and sentiment score, as input to predict the future stock prices of Apple, Google, and Tesla. Then take the classifier tweet, which can be positive, negative, or neutral, and calculate the average polarity and total number of tweets which sum up the number of tweets per day, then merge it with the closing price. as presented in Fig. 8.

Fig. 8. The number of tweets per day vs. polarity vs. close price.

To predict the stock price, the rolling window approach is applied to create numerous overlapping training samples through sliding fixed-size windows, which not only helps to improve the model's ability to observe the data but also aids in obtaining multiple patterns in the data. This approach is considered powerful and most suitable for LSTM and XGBoost prediction. The models analyze a tweet from **X** Twitter and predict future movements of the adjusted close price by referencing past days. The models normalized the input features (polarity score, total number of tweets, and close price) within the range of [0] to [1] as represented in Eq. (4).

$$CLSOE\ PRICE(x)normalize = \frac{x - min(X)}{max(X) - min(X)} \quad (4)$$

Then, the sentiment analysis features are integrated with historical data to figure a single dataset. And can represent this combined dataset as a shape (s), where s denotes the polarity score, (V) the total number of tweets, (X) the close price, (n) the end window size (y^t) the predicted value as introduced in Eq. (5) and Eq. (6). The system utilizes fixed-size windows with a length of n to generate a combined input for each time step (t). The last n-time step uses the close price and the polarity score (combined dataset) as input.

$$y^t = LSTM\ [x_t - n + 1, x_t - n + 2, \ldots., x_t,\ v_t - n + 1, v_t - n + 2, \ldots., v_t, s_t - n + 1, s_t - n + 2, , \ldots., s_t\ ] \quad (5)$$

Set the window size to three days of the combined dataset for feature engineering, which will serve as training to predict the next day. For instance, window 1 uses data from day 1 to day 3 (features) to forecast the next day. So, the predicted value.

$$y_{4=(}x_1, x_2, x_3\ )(\ v_1, v_2, v_3)\ (s_1, s_2, s_3) \quad (6)$$

The datasets are divided into a 90% training set and a 10% test set. Fig. 9 illustrates the division of the 90% training set into 80% training and 10% validation sets, utilizing the years 2015–2019 for training and 2019 for validation in the first dataset, utilizing the years 2015–2020 for training and 2020 for validation in the second dataset, and utilizing the June to October 2020 for training and 2020 for validation in the third dataset. Build the LSTM and XGBoost models by feeding it with training data. The LSTM models determine the input layer to obtain the sequence of previous time steps, which consists of three layers. The first layer, known as the input layer, receives window data in the form of a triangle (3, 3). The first (3) indicates the number of windows, while the second (3) indicates the number of three features (polarity scores, total number of tweets, and adjusted closing prices). The third layer is

responsible for processing time series data from previous observations of the rolling windows.

50 units make up the second layer, known as the LSTM layer, which uses gates to learn from time-dependent patterns in the data. Additionally, the design of memory cells, which also consist of 50 units, allows for the sequential data capture LSTM layer, comprising 50 units, to employ gates to learn from time-dependent patterns in the data. In addition to that, memory cells, which also consist of 50 units, process sequential data and capture temporal dependencies by adding more LSTM layers. Put Layer: one Dense Layer 1. The layer's design forecasts a single value (adjusted close price) for the upcoming time step. Then compile the model using the Adam optimizer. LSTM model is trained on data for a batch size of 16, which aids in obtaining single patterns by updating the model's weight after handling each sample. The number of epochs is assigned to 20 which indicates the number of loops in the training data.

The model is validated by monitoring while training the data, tracking the model's performance, adjusting the hyperparameters to enhance the performance, predicting the future stock price, and assessing the model using metrics like RMSE, R-squared, and MAE as illustrated in Eq. (7), Eq. (8) and Eq. (9).

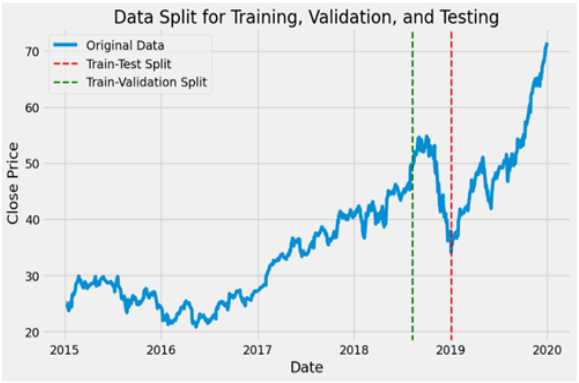

Fig. 9. The data split for sentiment analysis.

$$RMSE = \frac{1}{N}\sum_{i=1}^{n}(\text{yi} - \hat{\text{yi}})^2 \quad (7)$$

In machine learning, the R-squared value represents the coefficient of determination or the coefficient of multiple decisions in the context of multiple regression. Regression uses R squared as an evaluation metric to assess the scatter of data points around the fitted regression line. It indicates the percentage of variation in the dependent variable [42].

$$Squared\ Error = (\text{yi} - \hat{\text{yi}})2 \quad (8)$$

The proportion of the dependent variable's variance that the independent variable can explain is known as R-squared. R2 = the variance explained by the model. Total Variance The R-squared value stays between 0 and 100%. 0% corresponds to a model that fails to explain the variability of the response data around its meaning [43].

Mean Absolute Error (MAE) utilizing evaluation metrics, which indicates the difference between the actual and predicted value (value which is expected through a Model where actual values (target variable) [44] can be calculated as follows:

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \quad (9)$$

Predict Stock Price Using the LSTM and XGBoost Models Based on Historical Data

This study employs the LSTM and XGBoost models to predict future fluctuations in Apple, Google, and Tesla stock prices, relying solely on historical data. The data is gathered and preprocessed to evaluate the effectiveness of LSTM and XGBoost models, involves preparing the data for processing, which includes checking for any missing values by determining their meaning, removing any duplicated rows from the data, converting date columns to date-to-date time type, setting normalization values between [0:1], and dividing the datasets into three sets. The first set is for model training, the second for model validation, and the third for model testing. The training dataset (for The Model Training) makes up 70% of the total data; the validation dataset makes up 15%; and the testing dataset (for The Model Testing) makes up 15%. The model training uses the input sequences for LSTM. Each input sequence considers the output for the next step. Then set up the close price (target) as the preceding time step to predict the subsequent step to the close price. The regression approach is applied to the close price of Apple, Google, and Tesla stock. A single parameter, window size, determines the input format (close). The window size parameter establishes the days considered "dependent" for the stock price prediction. For example, with a window size of t = 60, the prediction will include the 60 days preceding day d. The longer the window, the better the model's view of previous data, but the higher the computing cost. Once we compute all sequence data, we organize each into a table of input features (X) and output targets (Y), which the model training process uses to adjust the LSTM model hyperparameters. The LSTM model consists of three layers: an input, an LSTM layer, and an output layer. Set the number of units to 50, the number of epochs to 100, and the batch size to 32. Then compile the model using the Adam optimizer and evaluate its performance using root means squared error (RMSE), R-squared, and MAE.

The same steps that were applied to evaluate the LSTM efficiency are used with XGBoost. Grid Search, Random Search, Max_Depth, Estimators, Sub-Sample, and L2 Regularization are used as hyperparameters.

V. Experimental Results

This section demonstrates the results obtained from two experiments. To detect the impact of combining sentiment analysis with historical data compared to historical data only. The previously mentioned algorithms are used to predict Apple, Google, and Tesla stock prices. As presented in Table II and figures from 10 -15, predicting stock prices based on integrating sentiment Analysis with historical data surpasses the performance of using historical data as presented in Table III and figures from 16 -21.

Fig. 10 displays the stock price prediction using XGBOOST by integrating Sentiment Analysis with historical data for Apple's stock, The model achieves a high accuracy rate of 99% from June 2017 to June 2020. It also achieves a low error rate between the actual and the predicted values for RMSE and MAE.

Fig. 11 predicted stock prices using XGBoost, which integrates sentiment analysis with historical data from 2018-7 to 2020-1 for Google. The model achieves a high accuracy of 95%, indicating a high correlation between actual and predicted values, and achieves a low prediction error of 0.0479 RMSE and 0.0358 with MAE, indicating a good fit.

TABLE II. MODELS PERFORMANCE-BASED INTEGRATION OF SENTIMENT ANALYSIS WITH HISTORICAL DATA

Model	APPLE	TESLA	GOOGLE
LSTM	R^2=91% RMSE=0.065 MAE=0.06	R^2=73% RMSE=0.1508 MAE=0.12	R^2=88% RMSE=0.0751 MAE=0.06
XGBoost	R^2=99% RMSE=0.042 MAE=0.0021	R^2=88% RMSE=0.1005 MAE=0.0816	R^2=95% RMSE=0.0479 MAE=0.0350

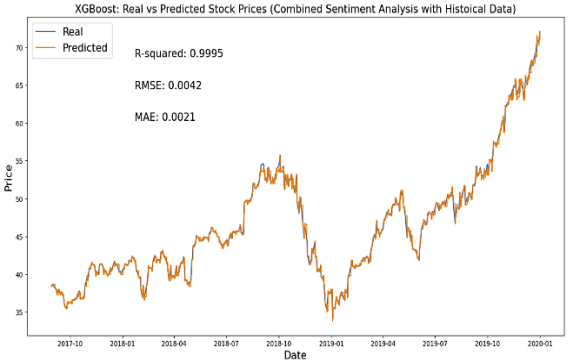

Fig. 10. XGBoost performance for Apple stock.

TABLE III. MODELS PERFORMANCE BY USING HISTORICAL DATA ALONE

Model name	APPLE	TESLA	GOOGLE
LSTM	R^2=98% RMSE=1.98 MAE=2.57	R^2=55% RMSE=0.45 MAE=6.94	R^2=95% RMSE=0.21 MAE=0.61
XGBoost	R^2=92% RMSE=1.85 MAE=1.29	R^2=99% RMSE=1.30 MAE=0.95	R^2=92% RMSE=1.85 MAE=1.29

Fig. 12 shows the stock price prediction using XGBOOST by integrating sentiment analysis with historical data for Tesla stock. The model's performance was 88.57%, which indicates a lower accuracy compared to another company's stock. It also achieved low error metrics, with RMSE (Root Mean Squared Error) at 0.1005, and MAE (Mean Absolute Error) at 0.0816 which indicates the difference between the predicted and actual values.

Fig. 13 Comparison of predicted stock prices using the LSTM Model, which integrates sentiment analysis with historical data for the Apple Company from 2017 to 2020. LSTM can capture the overall stock trend, but there are some gaps or errors in 2018 during high volatility.

Fig. 14 displays the integration of sentiment analysis with historical data for Google stock using the LSTM model. This model achieved good accuracy, at 88%. The model achieved a mean absolute error (MAE) of 0.06, indicating a low average error between the actual and the predicted values. And recorded in Root Mean Squared Error (RMSE): 0.0751.

Fig. 15 illustrates the comparison of predicted stock prices using the LSTM Model, which integrates sentiment analysis with historical data for the TSLA Company. The model achieves an accuracy of 75.48%, and achieves an RMSE of 0.1508, and an MAE of 0.12. This graph indicates the difference between the actual and predicted values. Often the predicted value fails to fit with the actual value.

Fig. 16 illustrates the performance of the XGBoost Model in predicting Apple's stock price. The model achieves an accurate rate of 92% with an average error of 1.29. These results declare a strong correlation between actual and predicted values.

Fig. 17 illustrates the performance of the LSTM Model for predicting Apple's stock price. The model achieves an accurate rate of 97% with an average error of 1.17 in RMSE and MAE = 1.27.

Fig. 18 compares the actual and predicted values of Google stock, using the XGBoost algorithm. The model achieved high accuracy of 92%, which indicates a strong relationship between actual and predictive values. XGBoost can closely track actual price movement while keeping low error metrics.

Fig. 19 displays Google's actual and predicted values, utilizing an LSTM (long short-term memory). LSTM has a high performance and accuracy of 95% and low error (RMSE = 0.21, MAE = 0.61). It appears that the predicted value is very close to the actual value, indicating that this model is a reliable tool for forecasting.

Fig. 20 compares Tesla's actual and predicted values, utilizing the XGBoost Model. The model achieves an accuracy of 99%, indicating a high performance and good fit between prediction and actual value. It achieves a low error metric of 1.30 of RMSE to 0.95 in MAE, the predicted value's deviation from the exact value.

Fig. 21 displays Tesla's actual and predicted values, utilizing an LSTM (long short-term memory). The model achieves an accuracy of 53%, indicating that its performance is not as high as it could be and requires additional data to improve. This is due to the insufficient training data set, which was from 01-08-2022 to 01-10-2022.

VI. Conclusion

This study proposed a framework to predict stock prices through integrated sentiment analysis with historical data, compared to using historical data only. Natural language processing (NLP) techniques extract sentimental information from X tweets. Then combine this sentiment analysis (positive, negative, or neutral) with the corresponding stock prices retrieved from Yahoo Finance. Machine learning and deep learning models test the combination of three stock datasets (Apple, Google, and Tesla) with and without sentiment analysis. This allows us to observe how integrating sentiment analysis with historical data correlates with each other and to what extent it improves performance accuracy. This study proved the correlation between stock price movement and people's opinions on social media. Two different classifiers are applied to predict the stock price, XGBoost and the LSTM models. The XGBoost outperformed the LSTM models in Apple, Google, and Tesla, achieving 99%, 95%, and 88%, respectively, by integrating sentiment analysis with historical data. On the other hand, LSTM outperformed XGBoost in Apple and Google, achieving 98% and 95%, except for Tesla, due to low data training when using historical data.

This study demonstrated the significance of combining and analyzing people's opinions, which is qualitative data that contributes to improving the understanding of integrating opinions with historical data, which is quantitative data. Both LSTM and XGBoost have demonstrated their efficacy.

A Multimodal Data Scraping Tool for Collecting Authentic Islamic Text Datasets

Abdallah Namoun[1], Mohammad Ali Humayun[2], Waqas Nawaz[3]
AI Center, Faculty of Computer and Information Systems, Islamic University of Madinah, Madinah, 42351, Saudi Arabia[1, 3]
Department of Artificial Intelligence, Information Technology University, Lahore, 54600, Pakistan[2]

***Abstract*—Making decisions based on accurate knowledge is agreed upon to provide ample opportunities in different walks of life. Machine learning and natural language processing (NLP) systems, such as Large Language Models, may use unrecognized sources of Islamic content to fuel their predictive models, which could often lead to incorrect judgments and rulings. This article presents the development of an automated method with four distinct algorithms for text extraction from static websites, dynamic websites, YouTube videos with transcripts, and for speech-to-text conversion from videos without transcripts, particularly targeting Islamic knowledge text. The tool is tested by collecting a reliable Islamic knowledge dataset from authentic sources in Saudi Arabia. We scraped Islamic content in Arabic from text websites of prominent scholars and YouTube channels administered by five authorized agencies in Saudi Arabia. These agencies include the general authority for the affairs of the grand mosque and the prophet's mosque and charitable foundations in Saudi Arabia. For websites, text data were scraped using Python tools for static and dynamic web scraping such as Beautiful Soup and Selenium. For YouTube channels, data were scraped from existing transcripts or transcribed using automatic speech recognition tools. The final Islamic content dataset comprises 31225 records from regulated sources. Our Islamic knowledge dataset can be used to develop accurate Islamic question answering, AI chatbots and other NLP systems.**

Keywords*—*Web scraping; Islamic knowledge; machine learning; natural language processing; question and answering; AI chatbots

I. Introduction

We propose a multimodal web scraping tool to collect Islamic content from verified websites and YouTube channels administered by five trusted entities in Saudi Arabia. Our crawling algorithms use Python libraries, including Beautiful Soup and Selenium, to scrape content from static and dynamic websites and channels. We selected input sources from official websites that are administered and maintained by non-profit organizations (e.g., agencies and charities) in Saudi Arabia. This strategy is adopted to achieve two important objectives: first, to ensure the credibility and correctness of the Islamic data published on these sources, and second, to eliminate noise data from untrusted sources, which could sabotage the quality of our proposed dataset.

Next, we exemplify the application of our tool on Islamic data from authentic Islamic knowledge websites that are maintained by 1) authorized non-profit organizations represented by the General Authority for the affairs of the Grand Mosque and the Prophet's Mosque (also known as Alharamain) or 2) under the management of charitable organizations in Saudi Arabia for scholars who are past or present members of the Permanent Committee for Scholarly Research and Ifta and/or Saudi Council of Senior Scholars.

To contextualize our research problem, let us consider the subsequent realistic scenario, which describes the typical challenges faced by non-Arabic-speaking people when searching for Islamic knowledge and teaching to guide their lifestyle decisions. Decisions may sometimes impact a person's life, as outlined below.

"Ahmed is a 35-year-old married government employee who has recently faced a family hardship concerning the decision to abort his child due to health concerns regarding his wife. He comes from a small village in Pakistan, and he does not speak the Arabic language. However, as a devoted Muslim, Ahmed is never satisfied with simple answers and always strives to make knowledge-driven decisions in search of satisfaction and tranquility. Ahmed starts by asking his village's main scholar at the nearest mosque; however, he remains unconvinced about the answers he received. In his quest for more resounding answers, he stumbles across a QA NLP platform, which offers opinion-oriented knowledge translated into various languages. Luckily, Ahmed can query the online platform on his mobile device, using plain text in Urdu, about the topic of child abortion in Islam under different circumstances and scenarios. The language-driven system presents the answers in a concise form with pieces of evidence from different scholars by extrapolating its unique and authentic dataset of Islamic knowledge. Not only can Ahmed read the answers in Urdu, but he can also view different opinions accompanied by arguments linked to the sources of the Quran and Sunnah. Ahmed can now discuss these options openly with his family before choosing the best option given his family's circumstances."

Reading this simple hypothetical scenario, various requirements emerge that should be addressed to effectively interpret Islamic knowledge.

- The non-Arabic speaking community constantly needs to access information using modern technologies, such as mobile devices.
- Intelligent NLP systems require reliable Islamic data to be able to produce meaningful and trustworthy knowledge.
- Our literature review (in the next section) revealed the lack of datasets that serve the objectives of the above scenario. Moreover, there are other scientific motivations

This research is supported by the Deanship of Scientific Research of the Islamic University of Madinah, KSA under the research groups (first) project no. 956.

and advantages to creating our unique web content collection tool and Islamic dataset, as elaborated below.

- We developed an automated data collection tool that gathers and organizes multimodal data from publicly available, reliable Islamic text and audio-video sources on the web, with minimal manual intervention, and compiles it into a text dataset. Fellow researchers can customize our tool to scrape similar content from online sources.
- We provide an authentic dataset of Islamic knowledge extracted from approved and regulated online sources. This uniqueness distinguishes our dataset from published Islamic content datasets. The proposed dataset can be used to form the foundation for additional authentic datasets and extend existing Islamic ruling datasets. Researchers from different specializations (e.g., Islamic studies, theology, sociology, and history) may use the datasets to conduct research studies and perform rigorous analyses.
- Our Islamic knowledge dataset may be reused by fellow machine learning researchers for 1) developing and testing machine learning models of generative AI systems for understanding and issuing Islamic rulings, 2) extracting the reasons behind certain rulings and judgments, 3) comparing rulings among various schools of thoughts and regions to understand their commonalities and differences, 4) exploring the evolution of Islamic laws and rulings over time in response to the contemporary technological and social changes, and 5) investigating the current issues in Muslim communities. Examples of natural language processing (NLP) applications on Islamic content and text include machine translation, question answering, Islamic rulings classification, text summarization, text analytics, auto-diacritization, and smart assistants and AI chatbots.
- Providing authentic Islamic datasets from trusted sources can assist policymakers, local organizations and centers, and the private sector to revise and/or create their policies around the Islamic principles within the datasets. For instance, financial products and services in banks may be offered using policies extracted from this Islamic knowledge. Similarly, the food industry may utilize the certifications and regulations pertaining to halal products from the knowledge extracted from these datasets. It may also guide courts and legal practitioners in Muslim countries to make informed decisions and rulings.
- Digitizing and archiving authentic datasets of Islamic knowledge, including rare texts and manuscripts, helps preserve the Islamic culture and heritage for the next generations. Moreover, these datasets can be translated into other languages to benefit non-Arabic audiences and communities.
- This Islamic dataset can be used to promote interfaith dialogue by providing accurate and authentic information about Islamic beliefs, practices, and rulings, especially concerning contemporary issues. It creates an opportunity to enhance public knowledge about Islam, reducing misconceptions and prejudice.

II. Related Work

Collecting and compiling authentic and reliable datasets of Islamic content and knowledge is crucial for training and validating natural language processing (NLP) and generative artificial intelligence (GenAI) models [1] which can be subsequently consumed by ordinary users and local entities (e.g., courts). However, the Internet offers various unverified sources of Islamic content hosted on several websites and social media. It is challenging to judge the accuracy and relevance of such Islamic knowledge to train relevant generative artificial intelligence models.

Indeed, there is a lack of trustworthy Islamic datasets that discuss essential topics and perspectives on societal issues concerning Muslim communities. A recent survey compared 11 question-and-answering (Q&A) Islamic datasets published between 2014 and 2022 [2]. All these corpora covered Quran questions, overlooking other important sources of Islamic knowledge and rulings. The authors in study [3] introduced an Islamic dataset (i.e., eiad) for building English question-answer AI chatbots. The dataset is in English and covers 15 categories, targeting converts and non-Muslims. The dataset comprises 10000 articles collected from three major, trusted websites like IslamQA.com. Similarly, the authors in study [4] contribute a dataset (i.e., QASiNa) in the Indonesian language for question-answering tasks. This dataset is unique since it is based on evidence from the Sirah literature (i.e., the Prophet Muhammed practices and sayings). Such datasets are useful for training large language models, such as ChatGPT and Gemini.

The study published recently in [5] is one of the exceptions. It is claimed to be the first Islamic rulings (i.e., is called fatwaset in Arabic) dataset. The data were collected from 13 trusted websites in Arab countries, including Saudi Arabia, Egypt, Jordan, Qatar, and Syria. The authors performed an exploratory data analysis revealing a total of 130182 records. Authors in study [1] suggest a dataset for developing chatbot systems for the issuance of Islamic fatwas. The dataset is claimed to be the largest Fatwas dataset, with the classification of topics. In total, the dataset has approximately 850000 fatwas, scraped from different websites, regions, and schools of thought. It is observed that most Fatwas (71%) were extracted from AskFM.

Authors in study [6] proposed an Arabic Multi-IsnadSet (MIS) dataset as a Neo4j multi-directed graph comprising 2029 narrator nodes and 77797 sanad-hadith connections. Hadith include the sayings, actions, or silent approvals of the Prophet Muhammad. Sanad represents the credibility (through a chain of narrators) of each hadith in the dataset. Hadith is the second source of religious legislation in Islam, after Quran. Data scraping tools were used to fetch hadith details, such as hadith number, content, list and sequence of narrators, and Isnad count. This dataset allows researchers to understand the authenticity of each hadith and the strength of its narration. Similarly, authors in [7] compiled a dataset of 650K hadiths, named Sanadset. The proposed dataset collected from 926 Arabic books may be used for automatic sanad verification and classification. However, the dataset does not distinguish between the authenticity of each hadith.

Although the existing works have collected diverse datasets across multiple domains, a unified dataset comprising data from multimodal sources, such as video lectures and text sources of different nature is still lacking. Besides, most of the works have relied on manual compilation and organization of datasets, disregarding automation strategies for dataset scraping and compilation. Furthermore, insufficient effort has been made to ensure that the sources are authentic and verified by an authoritative body. These limitations affect the ability of these datasets to adapt to future needs.

This work aims to fill this gap by designing an automation strategy for dataset collection. Moreover, the strategy incorporates datasets from multimodal sources, such as video and text resources, ensuring that all sources are authentic. This approach not only makes the dataset both authentic and diverse but also facilitates its easy expansion and adaptation for multiple domains.

III. Materials and Methods

Our web sources from which we curated our dataset are authenticated and administered by organizations and foundations in Saudi Arabia are listed in Table I. Our dataset is publicly accessible at [8]. Fig. 1 shows samples of Youtube channels.

TABLE I. Target Reliable Sources of Islamic Knowledge

Name	Administration	URL Links
Presidency of the Two Holy Mosques	General Authority for the affairs of the Grand Mosque and the Prophet's Mosque	gph.gov.sa/index.php/ar/
		manaratalharamain.gov.sa/speeches/

		youtube.com/@aforgsa1

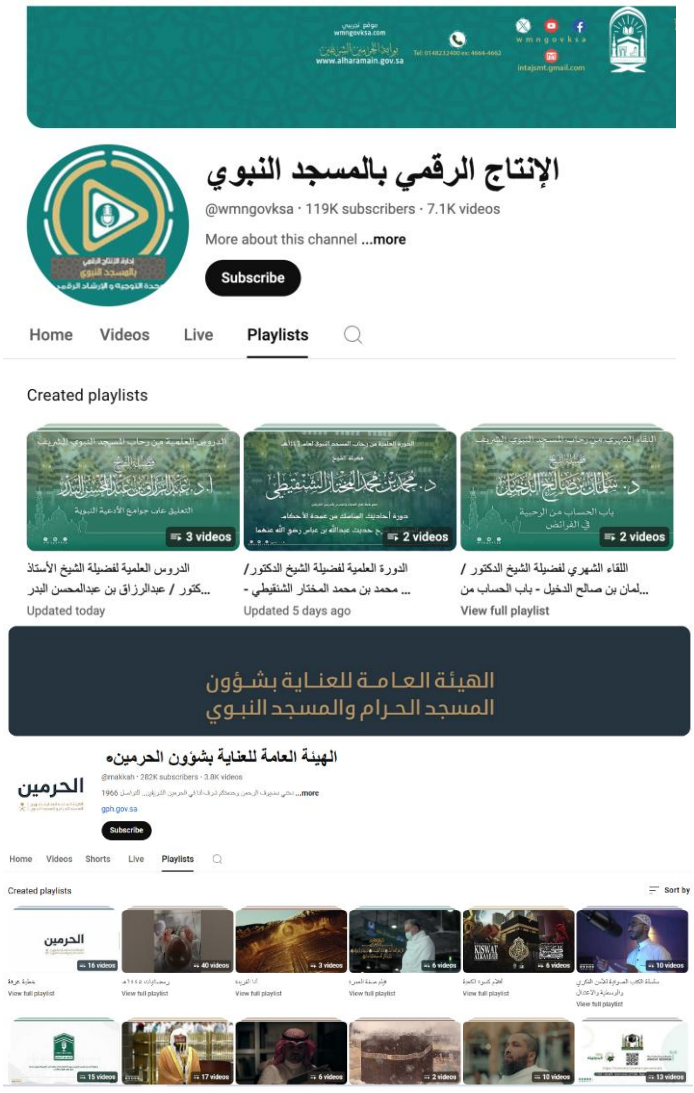

Fig. 1. A sample of YouTube channels.

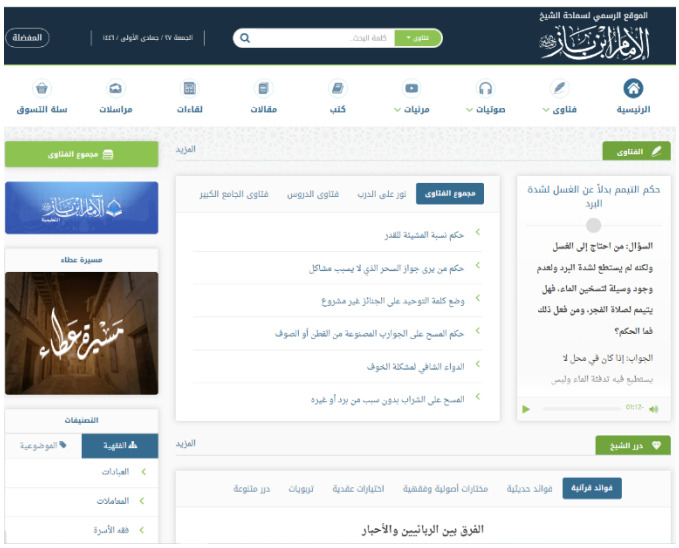

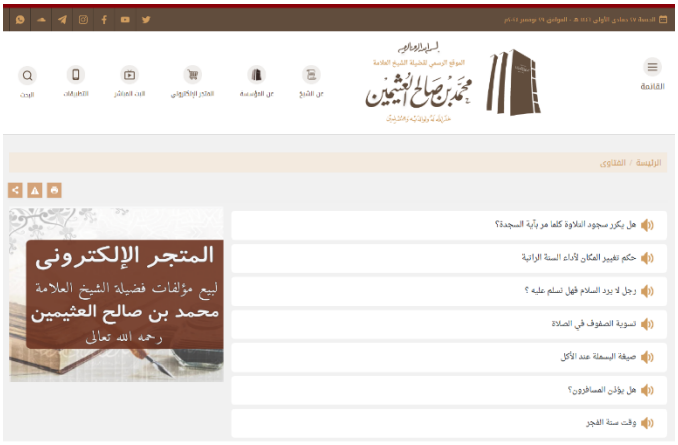

Fig. 2. A sample of Islamic websites.

TABLE II. TYPE OF DOWNLOADABLE DATA FROM NON-PROFIT ORGANIZATIONS

Data Category	Bin Othaimeen (Mix)	Bin Baz (Mainly Text)	Alfawzan (Audio)
Articles المقالات	No	Yes	Yes
Lessons الدروس	Yes	Yes	Yes
Lectures المحاضرات	Yes	No	Yes
Meetings and Dialogues اللقاءات والحوارات	Yes	Yes	No
Rulings الفتاوى	Yes	Yes	Yes
Speech الكلمات	No	No	No
Letters - Communications الرسائل – المراسلات– الخطابات	No	Yes	No
Sermons (not on Fridays) الخطب	Yes	No	Yes
Friday Sermons خطب الجمعة	No	No	No

We applied the following inclusion and exclusion criteria (see Table III) to identify the sources of our Islamic dataset. When it was not possible to retrieve the text or transcripts, we used speech-to-text (Arabic audio transcription) API services to transcribe the videos of Islamic knowledge. Table II shows type of downloadable data from non-profit organizations.

IV. SOFTWARE ALGORITHMS

Mainly, four different algorithms have been developed: one for extracting text data from static websites, another for retrieving text data from dynamic websites, a third for obtaining relevant transcripts from YouTube videos with available transcripts, and the last for translating speech-to-text from videos without a transcript. The code used is publicly available at [9] along with usage instructions, and the dataset has been uploaded to [9].

TABLE III. INCLUSION AND EXCLUSION CRITERIA

Criterion	Inclusion	Exclusion
Sources	Authentic sources that are maintained by local authorities	Unknown sources or not managed by authorized entities
Responsible	Organization, foundation, or charity	Individual
Purpose	Non-profit	Commercial
Country	Saudi Arabia	Other countries
Type of data	Opinions about different topics published in various form (e.g., speeches, letters, sermons, lectures, explanations, etc.)	Books, booklets, and handwritten manuscripts
Format	Downloadable text, audio, video files (with ability to scrape data)	Images
Language	Arabic	Other languages (English, Urdu, … etc)
Place of Publication	Knowledge published on official websites and YouTube channels	Knowledge posted on social media platforms, such as X (Twitter) platform and Facebook

A. Text Sources

Only the websites owned by reputable scholars from Saudi Arabia were selected for the text data. Consequently, the official websites of Ibn Baz, Ibn Othaimeen, and Alfawzan were chosen to fetch data. Since the websites have different structures and data types, the web scraping methodology [9] for fetching data from each website differed.

The website for Ibn Baz employs static HTML content, so the Python Beautiful Soup library was used to scrape data from this site by exploiting the HTML tags. The website has different categories of data including: الفتاوى (Islamic rulings), مقالات (articles), لقاءات وحوارات (discussions), خطابات ومراسل (speeches), and درر (pearls). First, all fatwas were fetched; these fatwas are subdivided into four major categories for each radio program نور فتاوى الجامع الكبير, and على الدرب , فتاوى لدروس, مجموع الفتاوى Each of these categories of fatwas has multiple pages. To extract data from each page, the base URL for the fatwa page was used, and then iterations were performed over the different program categories to construct the URLs for each program. The total number of pages varied for each fatwa category, and URLs were appended by iterating through the pages until the last page for each program was reached and scraped. Fig. 2 shows samples of Islamic websites.

The HTML data from the final URL for a page within the category was fetched using the Python requests library for HTTP requests. An HTTP request was sent to the URL, and the HTML response was filtered using Beautiful Soup to fetch the URLs for subpages pointing to the individual fatwas. The pages did not contain only URLs for the fatwa but also other URLs, such as those pointing to the homepage and other categories. Therefore,

only the URLs containing the keyword corresponding to the data category were filtered out. For example, URLs with fatwa had the keyword "fatwa" in them, so URLs were retained accordingly from each fatwa.

Subsequently, the filtered URLs were iterated, and HTTP requests were sent to each page to fetch the HTML response, which was again cleaned using Beautiful Soup. The HTML response from each fatwa page was analyzed using Beautiful Soup, and the contents for the following fatwa fields were fetched: title, question, answer, and category. HTML tags for each field were looked up, and the corresponding text was extracted. The fetched texts were stored in the dataset within different fields along with the main category (fatwa), the fatwa program, the page number, and the final URL for the fatwa.

For other text categories, such as مقالات (articles), لقاءات وحوارات (discussions), خطابات ومراسل (speeches), and درر (pearls), a similar process was applied to fetch the data with a few changes. These categories do not have different radio programs, so a single loop iterates over the page numbers within the main URL. After the final content URLs were scraped using Beautiful Soup and by filtering the correct keywords of each of these categories, the content URL was fetched. Pages of these categories did not have fields like fatwa category and question, so only title and text fields were compiled.

The dataset was cleaned to remove missing entries and duplicate entries added from multiple site URLs. Finally, due to different field structures, the dataset is stored as two separate CSV files: one for fatwas and one for other miscellaneous data.

The website for Alfawzan had similar static content, so the methodology was almost the same as the one for Ibn Baz website, with a few changes. Firstly, all fatwas on Alfawzan website have not been subdivided according to different programs but are placed under different pages in the main fatwa URL. Hence, the loop for adding page numbers was run with the main fatwa URL only. Secondly, most of the fatwas on the website have audio content and do not have text transcriptions, as indicated by a text file button being greyed out for fatwa without text content. Consequently, before fetching the reference of the fatwa URL and sending an HTTP request, a check was performed to see if the text button was not greyed out. Only then was the subsequent HTTP request sent to the URL, and the response HTML content filtered for the fatwa text fields like category, title, question, and answer.

Another source of text data is the website by Ibn Othaimeen. This website has a rich collection of fatwas in different programs, but the challenge was that it does not store static data. Instead, the site uses JavaScript to load its content dynamically. Hence, HTML-based filtering and the Beautiful Soup library could not be implemented for this site.

We used the Python Selenium library for this website to simulate browsing using the Chrome driver. This allowed us to fetch data by simulating browsing, scrolling, clicking, and recording the response. We used Selenium to control the Chrome driver in headless mode so that the GUI is not displayed, but the operations are performed seamlessly in the background.

The fatwas on this site are organized mainly into three different programs, namely: فتاوى نور على الدرب, لقاءات الباب المفتوح and اللقاء الشهري. All three have different URLs and different numbers of pages under the main URL, which contain links to the individual episodes. These episodes, in turn, had links to the fatwa. The episode numbers for فتاوى نور على الدرب are named as الشريط, while for the other two programs they are named the same as the program with numbering. So, the hierarchy of data was: fatwa > radio program > episode number > fatwa.

First, we iterated a loop over the URLs for the three programs. For each program, we further iterated over all the pages to append to the base URL for the program. Then, we used the Selenium Python library to make the Chrome driver go to the program URL with the page number and get the response to fetch all the web elements on the page.

As the page had multiple web elements, we were interested in only those pointing to the subsequent episode links containing the fatwa, e.g., those named with رقم الشريط for فتاوى نور على الدرب and so on. Hence, we filtered web elements with the corresponding text in their XML path. Then, we iterated over all those filtered elements on the page, got the text attribute from each element, and stored them in a list.

After that, we iterated over the list of texts and fetched the corresponding web elements to execute the JavaScript code to scroll to that web element and then execute the click for the element. After clicking the element, we waited until the next page was loaded. Once the episode page loaded and the web driver was pointing to the episode page, we got the corresponding URL of the episode page and stored it in the list. Similarly, we went back and got the URL for all the web elements on the episode page.

Eventually, we had the URL for all the episodes on a particular page within a certain radio program. By iterating over all the pages and all the programs, we got the URL for all episodes. Then, we iterated over the obtained episode URLs and set the Selenium-controlled driver to go to each URL iteratively.

Once all fatwa links were loaded and clickable on the episode page, we filtered the fatwa-referencing web elements by the condition of the XML path style containing a cursor pointer. We waited for all these elements to be fully loaded and clickable, then got texts for each.

Finally, the elements referencing each fatwa were fetched by looking for the texts obtained from their icons in the previous step. The corresponding web elements were clicked one by one. On clicking the fatwa element, the Chrome driver finally landed on the page containing the fatwa content, which included the title of the fatwa, the question, the answer, and its hierarchy path on the website (see Fig. 3).

When the fatwa web page loaded completely, the three different elements were fetched one by one, i.e., for the title, question, and answer, based on the CSS selectors 'p.title', 'div.fatwah-ques-cont', and 'div.fatwah-ans-cont' respectively. For each of these web elements, the inner HTML attribute was fetched, which loaded the HTML content. Finally, the Beautiful Soup library was used to fetch the required text from the fetched HTML for the element. This text data was stored in a CSV file under the following fields for each fatwa: title, question, answer, current-url, and category.

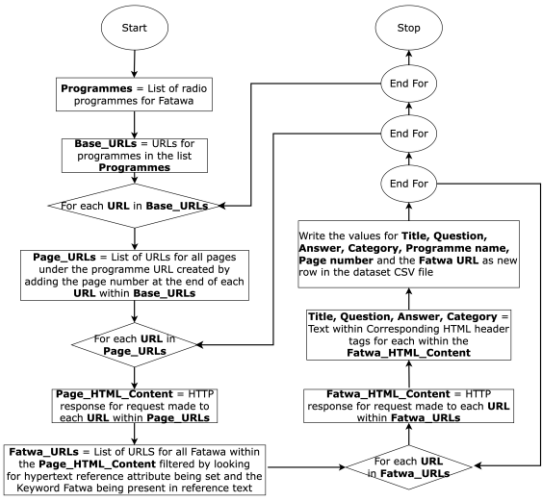

Fig. 3. The flowchart depicting the logic for collecting fatwa text from static websites.

B. Youtube Transcripts

To get the transcripts from YouTube videos, official YouTube channels approved by the respective organizations were targeted, and a list of playlists to be targeted was identified for each channel. For each playlist, a list of URLs for all videos within that playlist was fetched using the playlist method from the Pytube Python library. Subsequently, each video URL within the list was looped through to get the transcript for the video using the get transcript method of the YouTube transcript API in Python. In case a video didn't have a transcript on YouTube, it returned a "transcript not found" error, in which case the URL of the video was added to a list of missed videos for that channel to be targeted for speech recognition.

Transcripts fetched for videos had text transcripts and timestamps, which were retained. Another clean copy of the transcript was also created, removing the timestamps and retaining the complete script as a single entity. Both the timestamped and the clean transcripts, along with the video title and URL, were saved in a separate SQL database file for that channel (see Fig. 4 and Fig. 5).

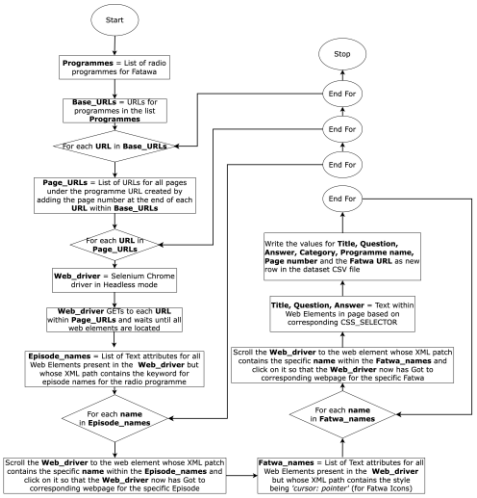

Fig. 4. The flowchart for collecting content from a website with dynamic data.

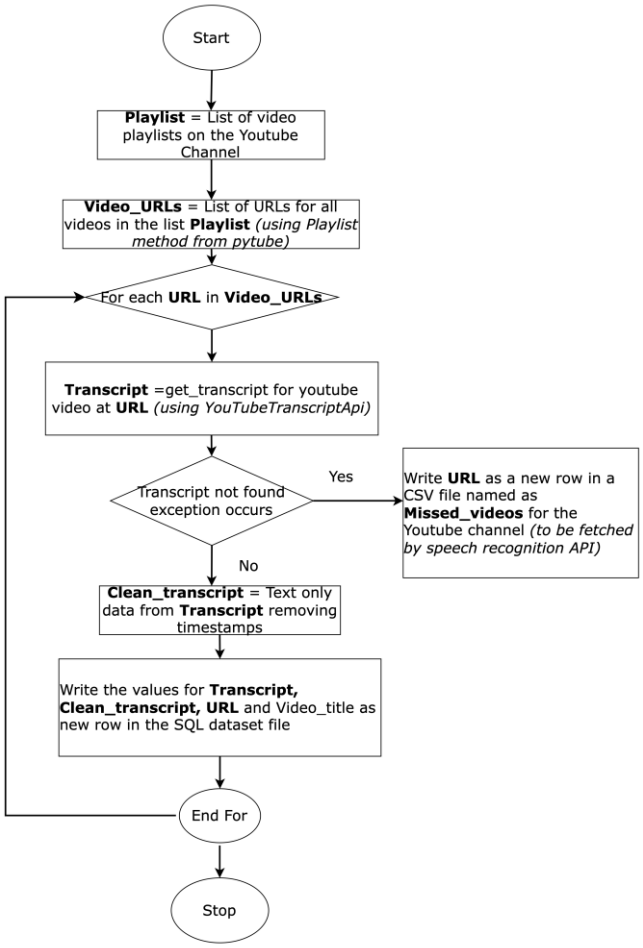

Fig. 5. The flowchart for collecting transcripts from YouTube videos.

C. Automatic Speech Recognition

The file of missed videos created while getting the transcripts for each channel was then used to get the scripts of these videos with Automatic Speech Recognition (ASR) using the Google Speech Recognition API in Python. First, for each URL in the list of missed video URLs, the corresponding video was downloaded using the streams method of the YouTube class in the pytube library. The video was downloaded in MP4 format, and its audio was extracted and saved as a WAV audio file using the audio method of the VideoFileClip class from the moviepy.editor Python library. The converted WAV audio file was then used for speech recognition. However, longer files often have sections that are not recognized by the speech recognition engine, causing errors. To address this issue, the audio file was segmented into smaller chunks of approximately 180 seconds each and passed to the Arabic speech recognition engine of the Google Speech Recognition API. The text for each chunk was recognized and stored in a text file. Once all the segments for a video were processed, the text chunks were concatenated and saved as a single transcript for the video, along with the video URL and title, in an SQL DB file. This process generated the ASR scripts for the channel (see Fig. 6).

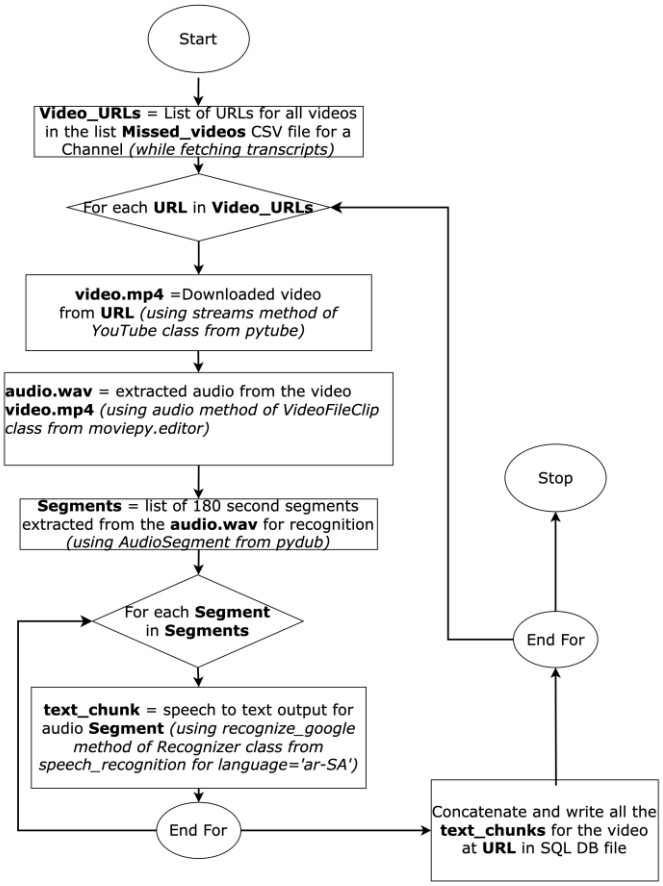

Fig. 6. The flowchart for collecting ASR text from YouTube videos.

V. Dataset Statistics

The resulting Islamic content dataset is organized into three main folders, namely Youtube_transcripts, Youtube_asr, and Text_data (see Table IV). The Youtube Transcripts folder contains seven files with 1363 records. The Youtube ASR folder contains eight files with 2972 records. Text data folder contains four files with 31225 records.

TABLE IV. Islamic Data Files and their Characteristics in our Dataset [A Total of 35560 Records]

Data source	File Name	Records	Storage format	Owner
Youtube Transcripts	Makkah_transcripts.db	242	SQL DB	General Authority for the affairs of the Grand Mosque and the Prophet's Mosque
Youtube Transcripts	SaudiQuranTv_transcripts.db	75	SQL DB	Saudi Broadcasting Authority
Youtube Transcripts	wmngovsa_transcripts.db	9	SQL DB	Agency of General Presidency for the Affairs of Al-Masjid Al-Nabawi

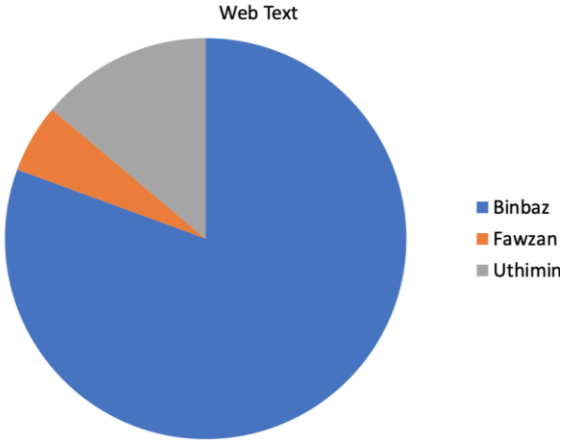
Fig. 7 shows the proportion of records in the final dataset from different sources.



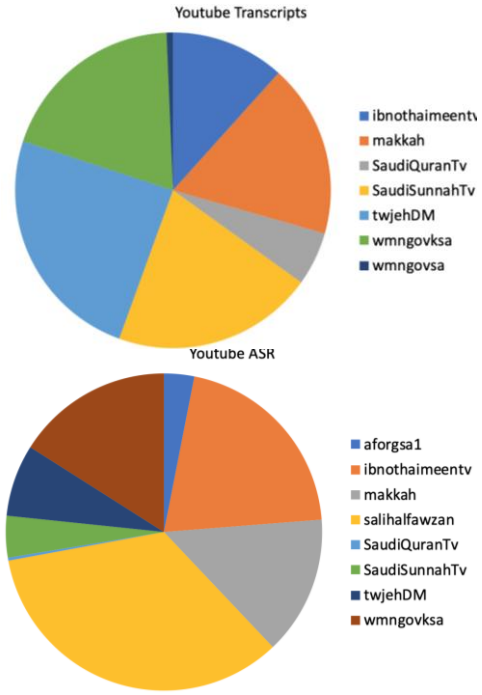


Fig. 7. Total records in the final dataset from different sources.

The focus of the example implementation has been on compiling authentic Islamic datasets, showcasing the capability of the algorithm to collect specialized datasets. However, the approach is generalizable and can be used in multilingual and multi-domain tasks, offering a versatile tool for dataset collection in various fields.

The code has been organized and publicized on a GitHub repository [9]. The repository contains different modules for scraping static and dynamic websites, as well as for fetching transcripts and performing speech-to-text conversions from YouTube videos. To use the code, users need to run the scraping.py file, providing the corresponding options for input and output files, and base URLs for the sites to fetch data from. Additionally, an action option must be specified to indicate whether to use dynamic, static, transcript, or ASR functionality. This will call the appropriate function within the scraping.py file. Fig. 8 is a screenshot from Github repo indicating the structure of code files.

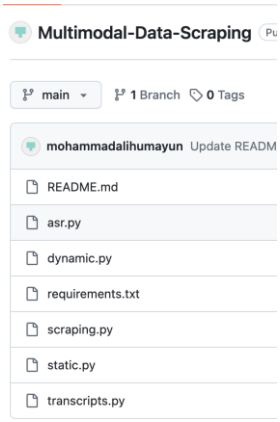

Fig. 8. Github repo structure.

In contrast to existing similar datasets reviewed in earlier sections, our dataset comprises diverse sources, including Articles, Lessons, Lectures, Meetings and Dialogues, Rulings, Speech, Letters, Communications, and Sermons. Additionally, all dataset sources are authentic, sourced from reputable organizations such as the General Authority for the Affairs of the Grand Mosque and the Prophet's Mosque, the Agency of the Affairs of Al-Masjid Al-Nabawi, Sheikh Abdul Aziz bin Baz Charitable Foundation, Sheikh Mohammed bin Saleh Al Othaimeen Charitable Foundation, and the Al Dawa Charitable Foundation. The quality and validity of tools used for speech transcription and data scraping have been thoroughly validated through manual verification of data records. Finally, the automated data scraping method has been confirmed to be reproducible, with clear descriptions of requirements and detailed steps provided for replication of the automated data collection process.

VI. Conclusions and Limitations

We have developed four distinct algorithms to address different types of text extraction tasks. The first algorithm focuses on extracting text data from static websites. The second algorithm is designed to retrieve text data from dynamic websites. The third algorithm targets the extraction of relevant transcripts from YouTube videos that already have transcripts available. Finally, the fourth algorithm aims to translate speech to text from videos that do not have transcripts. These algorithms enable web scraping [10] across diverse websites containing Islamic knowledge.

Using the proposed web scraping tool, this study has successfully created a comprehensive and reliable Islamic knowledge dataset from authentic Saudi Arabia sources. By aggregating 31,225 records from reputable Islamic scholars, official websites, and authorized YouTube channels, we have established a robust foundation for text processing regarding Islamic knowledge. This dataset addresses the critical need for accurate and contextually relevant Islamic content, aiming for precise and trustworthy responses by automated AI models. The dataset motivates further language processing research for more accurate and useful applications in Islamic knowledge processing.

Admittedly, it was not possible to identify all available Islamic knowledge sources in Saudi Arabia. Therefore, we acknowledge that our dataset might have overlooked other important sources, in which data were not downloadable or unverified. Our Islamic knowledge dataset is collected from sources endorsed by Saudi organizations, thus mainly reflecting the Hanbali school of thought and views. In Islam, there are four main Sunni schools of interpretation endorsed in approximately 30 Muslim countries. The range of topics covered in the proposed dataset is greatly influenced by the content published on the trusted websites that we scraped. Technically, a few limitations caused some sources to be missed. For example, while a time wait was imposed while fetching data from the web elements from dynamic websites, certain elements took a long time to become clickable (i.e., downloadable) and caused a timeout. Moreover, YouTube videos without transcripts were downloaded, converted into audio files, and translated into text. This process was also not foolproof, and some of the videos

failed to download due to network issues or sometimes because an age restriction was set on the target videos, which required a sign-in to download. Finally, our dataset does not include knowledge published in booklets and books, which could hold important insights about Islamic rulings.

ACKNOWLEDGMENT

This research is supported by the Deanship of Scientific Research of the Islamic University of Madinah, KSA under the research groups (first) project no. 956.

Hybrid Transfer Learning for Diagnosing Teeth Using Panoramic X-rays

M. M. EL-GAYAR
Department of Information Technology-Faculty of Computers and Information, Mansoura University, Mansoura 35516, Egypt
Department of Computer Science, Arab East Colleges, Riyadh 11583, Saudi Arabia

***Abstract*—The increasing focus on oral diseases has highlighted the need for automated diagnostic processes. Dental panoramic X-rays, commonly used in diagnosis, benefit from advancements in deep learning for efficient disease detection. The DENTEX Challenge 2023 aimed to enhance the automatic detection of abnormal teeth and their enumeration from these X-rays. We propose a unified technique that combines direct classification with a hybrid approach, integrating deep learning and traditional classifiers. Our method integrates segmentation and detection models to identify abnormal teeth accurately. Among various models, the Vision Transformer (ViT) achieved the highest accuracy of 97% using both approaches. The hybrid framework, combining modified U-Net with a Support Vector Machine, reached 99% accuracy with fewer parameters, demonstrating its suitability for clinical applications where efficiency is crucial. These results underscore the potential of AI in improving dental diagnostics.**

Keywords*—Machine learning; deep learning; dental diagnosis; transfer learning

I. Introduction

Accurate diagnosis of oral diseases is imperative for maintaining dental health. Panoramic x-rays provide comprehensive views of the teeth and jaws, making them invaluable for treatment planning. However, manually interpreting these complex images is resource-intensive, fallible to errors, and requires radiological expertise that general dentists may lack. Recent advances in artificial intelligence (AI) offer new opportunities to automate dental image analysis, overcoming the challenges of manual interpretation. But progress is impeded by factors like scarce annotated data and anatomical variability. Despite obstacles, integrating AI into dental radiology could significantly enhance patient care [1-4].

Image segmentation is critical for medical image analysis. Deep learning has surpassed hand-engineered features, especially convolutional neural networks (CNNs) [9][14][20]. The pioneering U-Net architecture combined encoders and decoders for precise segmentation. Extensions like DeepLab improved resolution, while Mask R-CNN enabled multi-task learning. Recent methods apply transformers and distillation. Medical imaging has benefited from these innovations. Segmentation aids organ delineation and dental analysis. Overall, CNNs now dominate segmentation by learning robust representations directly from pixels. We aim to advance panoramic radiograph segmentation by integrating spatial context into U-Net.

To promote the development of accurate AI-driven tools, we have test our method on the Dental Enumeration and Diagnosis on Panoramic X-rays (DENTEX) challenge. This challenge aims to stimulate and validate algorithms that can reliably detect and count abnormal teeth on panoramic x-rays. Automated frameworks could empower precise diagnostics and treatment planning while minimizing errors [5] [6].

However, developing accurate AI systems for dental radiograph analysis poses several challenges [7]:

- Limited availability of annotated panoramic x-ray datasets impedes model training and validation. We addressed this by utilizing extensive data augmentation and transfer learning.
- Panoramic images exhibit distortions like irregularities and overlaps that can confuse algorithms. Our model implements robust pre-processing to minimize such artifacts.
- Identifying some dental conditions requires assessing tooth relationships rather than isolated teeth. Capturing inter-dental context remained an open challenge.
- Generalizing model to handle variability in image quality and demographics requires expansive, diverse datasets that remain scarce. We aim to expand testing across diverse sources.
- Reducing computational costs without sacrificing accuracy remained an ongoing pursuit. Our optimizations enhanced efficiency, but further improvements may be possible.

The main contributions of this manuscript are:

- We have devised an innovative diagnostic system tailored for assessing dental conditions from panoramic x-rays. Our framework implements both direct classification through deep learning models, and a hybrid approach integrating deep feature extraction with traditional machine learning. This dual methodology aims to leverage the complementary strengths of modern AI to improve accuracy and efficiency.
- Our technique combines segmentation and detection models to pinpoint dental abnormalities efficiently.
- We performed comprehensive analyses comparing multiple deep learning architectures and classical models under direct and hybrid diagnostic settings. This rigorous

testing has provided valuable insights into real-world performance and transferability.

- Applying dimensionality reduction techniques, we have enhanced the computational efficiency of our framework while retaining precision. This allows our system to remain simultaneously powerful and nimble.

This manuscript is organized into five sections. Section II reviews relevant previous work. Section III describes the proposed approach in detail. Experiments and results are presented in Section IV. Section V concludes the paper.

II. Related Works

Hybrid approaches combining feature extraction with machine learning classifiers have proven effective across various medical and non-medical image analysis tasks. Recently, convolutional neural networks (CNNs) have become prevalent for feature extraction, along with some continued use of hand-crafted features. We review these techniques for general applications and those specific to dental diagnostics.

In non-medical settings, hybrid frameworks have shown advantages for video violence classification, human action recognition, and image texture classification, among others. In the medical domain, similar approaches have been applied for tasks including gastrointestinal disease classification from endoscopy, mammogram-based breast cancer screening, retinal disease diagnosis, burn image analysis, and medical image modality classification.

For dental diagnostics, CNN-based techniques have dominated recent literature. Most works focus on classifying a limited set of dental diseases, achieving accuracy over 99% in some cases. This high performance results from factors like robust datasets, simplistic tasks, and model advantages. However, studies tackling more challenging dental issues, like cavity detection, or hampered by poor data or task complexity, have seen lower accuracy.

In summary, hybrid approaches combining deep learning-based feature extraction with traditional machine learning have proven versatile for both medical and non-medical image analysis across various applications. In the emerging domain of AI-driven dental diagnostics, CNNs currently predominate, but task complexity remains a barrier to maximizing performance. Further innovations in hybrid techniques show promise for advancing the field.

Ayhan et al. [8] introduced a deep learning approach for tooth numbering, caries detection, and matching from bitewing radiographs. Their method utilized a DenseNet-121 model pretrained on natural images for tooth detection and numbering. YOLOv7 was applied for caries detection. Tooth numbers were then matched to detected caries using intersection over union. The models were trained and evaluated on 1170 bitewing images from faculty archives. They achieved high performance, with F-scores of 0.99 for tooth detection, 0.979 for numbering, 0.822 for caries classification, and 0.842 for number-caries matching. This demonstrates the capability of deep convolutional neural networks like DenseNet and YOLO for automated dental radiograph analysis. However, use of a private institutional dataset makes results difficult to reproduce. Testing on more varied multi-source data could better validate generalization. Additionally, bitewing images may be less challenging than panoramic x-rays. But overall, their work provides evidence for deep learning-based dental image analysis, and proposes an integrated numbering-diagnosis framework applicable to clinical practice.

Li and Zhang [10] developed a convolutional neural network-vision transformer model for multi-label classification of dental conditions from orthopantomography (OPG) x-rays. Their hybrid architecture combined CNN feature extraction with a transformer classifier. The model was trained and evaluated on a dataset of 1418 OPG radiographs from clinical cases containing multiple disease labels. For multi-label classification across eight dental diseases, they achieved strong performance with a sensitivity of 0.942, specificity of 0.951, accuracy of 0.968, and F-score of 0.957. This demonstrates the potential of using hybrid CNN-transformer architectures for automated analysis of dental radiographs. However, use of a private clinical dataset makes reproducing their results difficult. Additionally, multi-label classification across many diseases poses challenges compared to binary classification. But overall, their work helps highlight advanced deep learning architectures like vision transformers for robust dental image analysis and multi-disease diagnosis from OPG scans.

Zhu et al. [6] developed an AI system to diagnose 5 different dental diseases from panoramic radiographs. Their approach used a combination of BDU-Net to detect dental caries, and nnU-Net models to identify the other 4 conditions - periodontitis, periapical lesions, dental pulp stones, and impacted teeth. The models were trained and tested on a private dataset of 2278 OPG images. For caries diagnosis, BDU-Net achieved a specificity of 99.4%, while nnU-Net models produced specificities greater than 99% for the other diseases. This demonstrates the potential of using specialized deep-learning architectures like BDU-Net and nnU-Net for multi-disease classification from dental radiographs. However, their reliance on a private dataset makes reproducing and validating their results difficult. Additionally, combining outputs from multiple models increases system complexity compared to a single unified classifier. Overall, their work provides initial evidence that hybrid ensembles of deep-learning models can automate the identification of different dental conditions from OPG scans.

Almalki et al. [2] developed deep learning models to classify four common dental diseases using orthopantomography (OPG) x-ray images. Their method utilized the YOLOv3 object detection architecture to analyze a dataset of 800 private OPG radiographs. The task involved detecting dental caries, periodontitis, periapical lesions, and dental fractures in teeth depicted in the OPG scans. By leveraging the YOLOv3 model pretrained on natural images and fine-tuning on the dental data, they achieved a high accuracy of 99.33% for multi-class disease classification. This work demonstrates the potential of deep learning techniques like YOLOv3 for automated analysis of dental radiographs. However, the use of a private dataset makes it difficult to reproduce their results. Additionally, their set of four classes represents only a subset of important dental diseases, so generalization to more complex multi-label classification remains unclear. But overall, their study provides

evidence for deep learning and YOLO-based approaches in advancing automated assessment of dental conditions from radiographs.

Zhang et al. [12] developed a deep learning model to screen for dental caries from digital oral photographs. Their method adapted a Single Shot MultiBox Detector CNN architecture and incorporated hard negative mining during training. The model was trained and evaluated on a dataset of 33932 photographs captured from 625 volunteers using consumer cameras. For binary classification of images as carious or non-carious, they achieved an AUC of 85.65%. This demonstrates the feasibility of using deep CNNs to analyze oral photographs for automated dental caries screening. However, photographs only provide limited visibility compared to radiographs. Additionally, use of consumer cameras introduces variability compared to clinical imaging. But overall, their work helps establish deep learning as a viable approach to automate identification of dental caries from oral photographs.

Sonavane et al. [11] developed a convolutional neural network model for classifying dental cavity images. Their approach utilized a custom CNN architecture designed for cavity detection. The model was trained and tested on a publicly available dataset of 55 images containing cavities and 19 non-carious images. Using this small dataset, they achieved a maximum accuracy of 71.43% for binary cavity classification. This preliminary study demonstrates the potential of using CNNs for dental cavity detection from visual images. However, the very small public dataset limits model performance and does not represent real-world variability. Additionally, visual images have limited visibility compared to radiographs. But overall, their work provides a proof-of-concept for using CNNs to classify dental cavities from images.

Lee et al. [13] developed a deep learning system to detect and diagnose dental caries from periapical radiographs. They utilized a pretrained GoogLeNet Inception v3 CNN architecture and fine-tuned it on a private dataset of 3000 periapical images. The model was trained to classify images as either carious or non-carious based on caries present in premolars and molars. They achieved AUCs of 0.917, 0.890, and 0.845 for premolar, molar, and combined classes respectively. This demonstrates the capability of deep CNNs like Inception-v3 for automated dental caries diagnosis from radiographs. However, use of a private dataset makes reproducing their results difficult. Additionally, periapical x-rays only cover limited tooth surfaces compared to full-mouth radiographs. But overall, their work provides evidence for deep learning-based classification of dental caries using CNN architectures like GoogLeNet Inception pretrained on natural images.

III. Proposed Framework

Our model evaluates two main deep-learning approaches for dental disease classification from panoramic X-rays and radiograph images:

- Direct classification: Images are fed into a fine-tuned deep-learning model that predicts abnormal teeth labels directly using its classification layer.
- Hybrid approach: A pre-trained model extracts image features, which are then classified using a traditional machine-learning algorithm.

For the hybrid approach, teeth are first extracted from radiographs and preprocessed. The cropped tooth images are input to a fine-tuned deep CNN, which extracts discriminative features. These features then train a classifier like an SVM for the final diagnosis. To handle class imbalance, rotating minority class images perform data augmentation. This results in a more balanced distribution for model training. Ten deep learning models are experimented with, including CNNs like ResNet, VGGNet, MobileNet, and vision transformers like ViT. All leverage transfer learning from natural image datasets. For feature extraction, models are trimmed before their classification layers. The extracted features are combined with classical ML classifiers like SVM and random forest.

Unique advantages of the hybrid approach include leveraging complementary strengths of deep CNN feature learning and traditional classification methods. This can potentially improve accuracy and efficiency. The proposed model aims to advance dental panoramic X-rays and radiograph analysis by combining state-of-the-art deep learning and classical machine learning techniques in an optimized pipeline.

A. Proposed Model Architecture

Our proposed model utilizes a hybrid approach combining deep convolutional neural networks (CNNs) for feature extraction with traditional machine learning models for classification as shown in Fig. 1. First, tooth segments are extracted from panoramic radiographs and preprocessed. The cropped tooth images are normalized and resized to standard dimensions. These preprocessed segments are input to a fine-tuned deep CNN which extracts discriminative feature representations for each image. The CNN leverages transfer learning from models pretrained on large-scale natural image datasets. To train the classifier, these learned feature vectors are used to train traditional machine learning algorithms like support vector machines and random forests. This hybrid approach aims to leverage the complementary strengths of deep CNN feature learning and classical models for enhanced accuracy and efficiency. Alogorithm 1 shows the steps and pusedocode of the dental diagnosis model with input panoramic x-ray or radiographic images and the ouput is trained model and test reults.

B. Preprocessing Pipeline

The dataset undergoes several preprocessing steps before model training:

- Filtering removes invalid images lacking tooth segments or having duplicate values, ensuring only pertinent images are used.
- Individual tooth segments are extracted by cropping radiograph sections based on provided coordinates.
- Segments are resized to 256x256 pixels and centered cropped to 224x224 pixels to match CNN input dimensions.

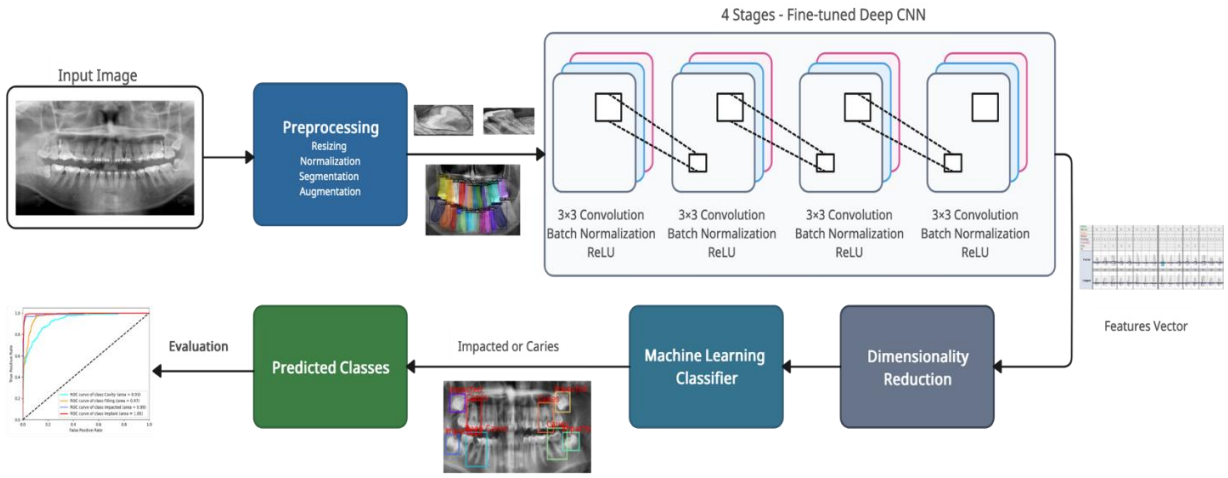

Fig. 1. Proposed model.

- Pixel value normalization is applied using channel-wise mean and standard deviation values from the CNN's original training distribution.

This standardized preprocessing pipeline obtains cleaned, extracted, and normalized tooth images suitable for input to deep CNNs. The transformations aim to highlight key dental characteristics while suppressing noise and distortions. As shown in Eq. (1), image pixel values xij in channel i are normalized to zij using per-channel mean μi and standard deviation σi statistics:

$$N_{xy} = \frac{O_{xy} - \mu_x}{\sigma_x} \quad (1)$$

Where:

N_{xy} = normalized pixel value in channel x

O_{xy}= original pixel value in channel x

μ_x = mean of pixel values in channel x

σ_x= standard deviation of pixel values in channel x

This performs normalization independently for each color channel by subtracting the channel mean and dividing by the channel standard deviation. The result N_{xy} are normalized pixel values with a zero mean and unit variance based on the image's original channel statistics. This standardized preprocessing brings values into a consistent range to better highlight key image features.

Algorithm 1: Dental diagnosis model

Input: Dental panoramic x-ray or radiography images (imgs)
Output: Model (m) and Evaluation metrics (eval)
Start Procedure
  preprocessImgs(imgs)
  augmentedImgs = oversampleMinorityClasses(imgs)
  m = loadPretrainedCNN(pretrained_model)
  features = extractFeatures(m, augmentedImgs)
  reducedFeatures = PCA(features)
  m = trainClassifier(reducedFeatures)
  eval = evaluateModel(MLmodel, testFeatures)
  return m and eval
End Procedure

C. Handling Class Imbalance

The four dental disease categories were initially imbalanced in the dataset, with the cavity and impacted classes significantly under-represented compared to the other groups. To mitigate this class imbalance during model training, we employed data augmentation techniques focused on the minority classes.

Augmentation was performed by applying rotations of 45 degrees in both directions to the images of the under-represented cavity and impacted categories. This geometrical transformation tripled the number of samples for these classes. After augmentation, the total dataset contained 11,087 images with a more balanced distribution across the four dental conditions.

This selective oversampling addresses the class imbalance problem by increasing minority class samples. Augmenting under-represented categories through rotations provides additional variety in viewing angles while preserving key dental morphologies. The resulting balanced dataset reduces bias and enables robust learning of all disease classes for improved multi-class classification performance.

D. Transfer Learning Model

Our model utilizes transfer learning by initializing with weights from models pretrained on large-scale natural image datasets like ImageNet, U-Net and AlexNet [22]. Ten state-of-the-art deep CNN architectures were investigated, including DenseNet [21], captionNet [19], ResNet [17], VGGNet [16], MobileNet [18], vision transformers [15], and YOLOv9. Transfer learning enables extracting more discriminative features despite our relatively small dental panoramic or radiograph dataset.

For feature extraction, models are trimmed before their classification layers to obtain vector representations of the input images. The pretrained weights provide robust initial feature learning which is then fine-tuned on the dental images. Widely used models like AlexNet serve as strong feature extractors given their proven imaging performance. Their convolutional layers learn hierarchical filters to capture informative spatial patterns. Additionally, we explore a U-Net architecture with symmetrical encoder-decoder structure for end-to-end segmentation and classification. The encoder extracts contextual

features while the decoder recovers localization and spatial details. Skip connections combine these complementary learned representations. Compared to other CNNs, U-Net can better localize abnormal dental regions in the panoramic and radiograph images. Standard U-Net models lack localization capability which can limit performance on abnormality detection in dental radiographs. To overcome this, we incorporate recent advancements that provide spatial context to U-Net. Specifically, we augment U-Net with BB-Conv layers comprised of max pooling followed by convolutions. Bounding box coordinates for each tooth are fed into these layers to output attention maps highlighting tooth locations. The BB-Conv layers are inserted into each skip connection. Their outputs are multiplied with encoder features before concatenation during upsampling. This injects positional information across all network stages. Compared to vanilla U-Net, this Modified U-Net integrates localization cues via the BB-Conv spatial attention layers. By guiding the model to focus on specific tooth regions, detection of localized pathologies is improved. We hypothesize this will enhance abnormality modeling and increase sensitivity to anomalies like dental caries. Our experiments compare Modified U-Net against standard U-Net and other CNNs to quantify the impact of incorporating spatial context.

E. Dimensionality Reduction

The high-dimensional feature representations extracted from the deep CNNs can contain redundant and noisy components. To reduce complexity and combat overfitting, we apply dimensionality reduction to the learned features before feeding them to traditional machine learning classifiers.

Specifically, Principal Component Analysis (PCA) is utilized to project the features into a lower-dimensional subspace. PCA transforms the data such that the maximum variance is captured along the first principal components. This converts the features into a compact set of dimensions that encapsulate the most salient information.

Applying PCA after deep feature extraction distills the representations down to their core components most relevant for the classification task. By suppressing extraneous dimensions, overfitting is reduced and model generalization is enhanced. The resulting lower-dimensional features serve as efficient input to the ML models for enhanced performance. As shown in Equation 2, PCA can be implemented by singular value decomposition (SVD) of the data matrix D ∈ R^{m x n}:

$$D = E \sum V^T \quad (2)$$

Where:

- E is a m x m orthogonal matrix containing the eigenvectors of DD^T
- $\sum V^T$ is a m x n diagonal matrix containing the singular values σ1, ..., σr
- V^T is a n x n orthogonal matrix containing the eigenvectors of $D^T D$

The columns of E are the principal components corresponding to the directions of maximum variance in the data. Taking the first k columns of U projects the data into the k-dimensional subspace capturing the greatest variance. The singular values σ1, ..., σr are the square roots of the eigenvalues of $D^T D$ and indicate the significance of each principal component - larger values correspond to more informative components. So PCA via SVD provides a way to find a lower-dimensional representation of the data that preserves maximal information content as quantified by the singular values.

F. Traditional Machine Learning Classifiers

To perform final classification using the extracted features, we evaluate diverse classical machine learning models to determine an optimal approach. Seven different classifiers are investigated:

- Naive Bayes (NV) applies Bayes' theorem with conditional independence assumptions between features.
- K-nearest neighbors (KNN) categorize samples based on proximity to nearest examples in the feature space.
- Logistic regression (LR) produces probabilistic multi-class predictions using a softmax function.
- Decision trees (DT) recursively partition the feature space by splitting on the most informative attributes.
- Support vector machines (SVM) find maximum margin decision boundaries between classes. Kernel tricks enable efficient mapping to higher dimensional spaces.

Each model has unique advantages that are assessed during experimentation. SVM and logistic regression leverage robust regularization to avoid overfitting. KNN and Naive Bayes offer simplicity and efficiency.

G. Summary of this Section

In this part, we summarize the steps of the proposed system and link them to the proposed algorithms.

1) Preprocess radiograph images

- Crop teeth segments
- Resize to standard dimensions
- Normalize pixel values

2) Perform data augmentation

- Use minority oversampling to handle class imbalance

3) Extract features using fine-tuned deep CNN

- Use transfer learning from pre-trained models like VGG, ResNet, U-Net, Alex-Net
- Remove classification layer
- Input images to obtain descriptive feature vectors

4) Apply PCA for dimensionality reduction

5) Evaluate models like SVM, Random Forest, KNN

- Tune hyperparameters for optimal performance
- Evaluate model on test set
- Compute metrics like accuracy, precision, recall

IV. Experimental Results

A. Dataset Overview

The DENTEX dataset [23] contains panoramic dental X-ray images collected from three different clinical institutions. This introduces diverse quality levels reflecting real-world heterogeneity. Patients were randomly selected to ensure privacy. The dataset has a hierarchical organization with gradually increasing annotation levels:

- 693 images with quadrant labels only.
- 634 images with quadrant and tooth enumeration.
- 1005 images fully annotated with quadrants, teeth, and diagnoses.

The diagnostic labels encompass four conditions: caries, deep caries, periapical lesions, and impacted teeth. An additional 1571 unlabeled images are provided for pretraining. For formal evaluation, the fully annotated set of 1005 images is partitioned into training (705), validation (50), and testing (250) subsets. Ground truth is only given for the training split. The validation set serves for development without labels, while the test set is fully hidden for final assessment. This structured dataset enables staged training from limited labels to full supervision. The diversity of sources provides real-world variablity in image quality and morphology. Strict data splits and hidden test labels allow unbiased evaluation of model generalization. Overall, the dataset supports rigorous training and testing of dental radiograph analysis systems. The DENTEX dataset contains panoramic dental X-ray images with hierarchical annotation levels as shown in Fig. 2. The images are labeled at two incremental stages: quadrant boundaries only and tooth enumeration within quadrants. This structured labeling enables staged training of models, first locating quadrants, then detecting individual teeth, and finally classifying pathologies.

B. Experimental Methodology

We conduct two types of experiments:

- Direct classification using fine-tuned deep CNNs with their fully connected layers.
- Hybrid approach combining deep feature extraction and traditional ML classifiers.

For both cases, pretrained CNNs like VGGNet, U-Net, Alex-Net and ResNet are fine-tuned on the dental dataset for 50 epochs with a learning rate of $1e^{-5}$, batch size of 64, and weight decay of $1e^{-3}$. Data augmentation is applied to minority classes. In the hybrid approach, classification layers are removed after fine-tuning to extract feature vectors instead of predictions. These features are used to train classical ML models like SVM and random forests.

An 70-30 stratified split creates training and validation sets. Evaluation is conducted on hidden test data. Metrics like accuracy and AUC quantify performance. All models are implemented in PyTorch and optimized using Adam. Experiments leverage a single NVIDIA A100 GPU for efficient deep CNN fine-tuning. Scikit-learn provides traditional ML algorithms.

C. Performance Metrics

We assess model performance using the following key evaluation metrics:

- As shown in Eq. (3), accuracy measures the overall ratio of correct predictions to total samples.

$$Accuracy = \frac{Number\ of\ Correct\ Predictions}{Total\ Number\ of\ predictions} \quad (3)$$

- As shown in Eq. (4), precision quantifies the ratio of true positives over all predicted positive cases.

$$Precision = \frac{True\ Positives}{True\ Positives+False\ Positives} \quad (4)$$

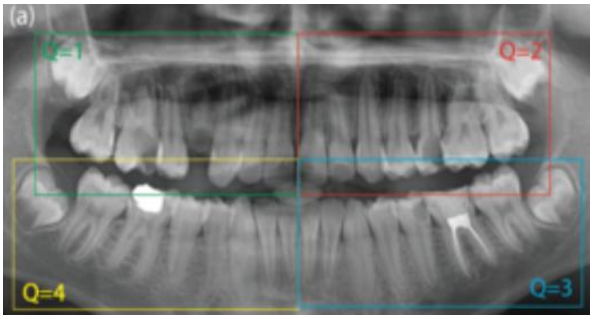
- As shown in Eq. (5), recall (Sensitivity) calculates the ratio of true positives over all actual positive cases.

$$Recall = \frac{True\ Positives}{True\ Positives+False\ Negatives} \quad (5)$$

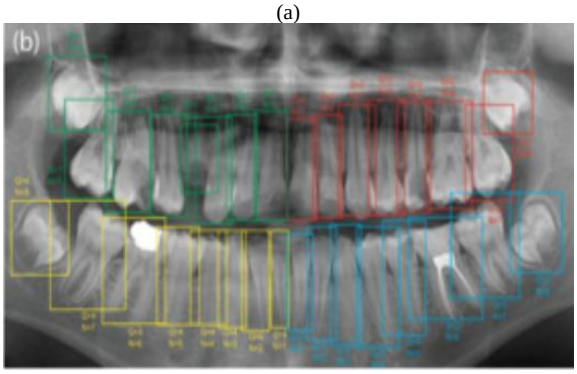
- As shown in Eq. (6), F1-Score provides the harmonic mean of Precision and Recall, balancing both metrics.

$$F - Score = 2 * \frac{Precision*Recall}{Precision+Recal} \quad (6)$$

- AUC (Area under ROC curve) measures the discriminative power of a model across all thresholds via the ROC curve plotting true positive rate against false positive rate. An AUC of 1 indicates perfect classification.



(a)



(b)

Fig. 2. Illustrates the hierarchical organization of annotations in the DENTEX dataset across two levels: (a) Quadrant-only labels: This level contains annotations demarcating the four dental quadrants but no other labels. It can be used for training quadrant detection. (b) Quadrant-enumeration labels: This level adds alphanumeric labels enumerating each tooth within the delineated quadrants. It enables tooth instance segmentation and identification.

Accuracy evaluates overall correctness of classification. Precision and Recall characterize performance on positive cases. F1 Score combines both metrics into a composite measure. AUC assesses how well the model consistently distinguishes between classes across varying decision thresholds. Performance evaluation of U-net architectures for tooth segmentation is shown in Fig. 3.

D. Results

Fig. 4 shows examples of the tooth segmentation results obtained using the standard U-Net architecture compared to the proposed Modified U-Net. Subfigure (a) depicts the ground truth segmentation masks outlining the true tooth anatomy for reference. Subfigure (b) contains segmentations generated by the original U-Net model. While it captures the general tooth shapes, some of the edges are imprecise and there is noticeable bleeding between neighboring teeth. Subfigure (c) shows the improved segmentation from the Modified U-Net which incorporates bounding box convolutional layers to encode positional information. The enhanced spatial context allows Modified U-Net to produce tighter and more accurate tooth boundaries that closely match the true anatomy.

TABLE I. PERFORMANCE COMPARISON OF DIRECT AND HYBRID MODELS

Model	Direct	Hybrid
VGG16	0.94	0.93
VGG19	0.95	0.95
AlexNet	0.93	0.95
ResNet 50	0.92	0.94
YOLOv9	0.90	0.89
U-Net + ViT	0.96	0.97

TABLE II. PERFORMANCE METRICS FOR HYBRID MODEL WITH U-NET, SVM, AND PCA

	Precision	Recall	F-score
Caries	0.99	0.98	0.99
Deep Caries	0.97	0.97	0.97
Periapical Lesions	0.92	0.94	0.93
Impacted	0.995	0.998	0.99

TABLE III. F-SCORE OF ML CLASSIFIERS WITH VARYING DEEP FEATURE EXTRACTORS

	NB	KNN	LR	DT	SVM
VGG16	0.88	0.93	0.93	0.91	0.94
VGG19	0.90	0.94	0.94	0.91	0.95
AlexNet	0.82	0.93	0.94	0.89	0.95

(c)

Fig. 4. Examples of the segmentation results (a) Ground Truth (b) U-Net (c) modified U-Net.

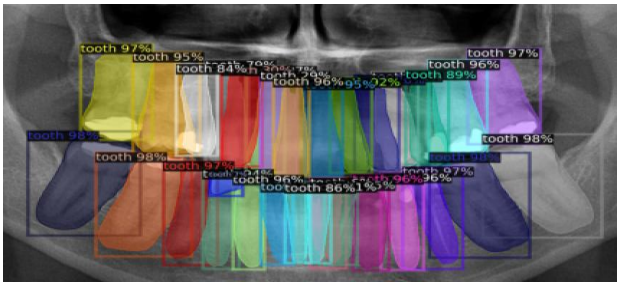

Fig. 5. Output of annotaed segmentation result.

The quantitative results in Fig. 5 further showcase the advantages of Modified U-Net. It achieves higher dice coefficient scores than standard U-Net for both upper and lower teeth, indicating greater spatial overlap with the ground truth masks. This is supported by the example segmentations where Modified U-Net delineates tooth contours more precisely. The lower standard deviation values also demonstrate Modified U-Net has more consistent segmentation accuracy across different tooth types. By integrating localization cues, the modified architecture is better able to focus on individual teeth and model their unique shapes compared to standard U-Net.

E. Discussion

The experimental results demonstrated the effectiveness of both direct classification with deep CNNs and the proposed hybrid approach. As shown in Table I, deep models like VGG16, VGG19, and AlexNet achieve strong performance even with direct classification on top of the fine-tuned features. However,

the hybrid technique combining deep feature extraction and traditional ML classifiers further improves accuracy across most architectures. For instance, AlexNet sees gains from 0.93 to 0.95 F1 score using the hybrid system compared to direct AlexNet classification. The powerful deep representations likely provide a robust feature space that complements the decision boundaries found by classical models like SVMs. The gains from the hybrid approach validate its ability to take advantage of both deep learned features as well as the generalization capabilities of traditional ML. While basic CNN classification is effective, the results confirm that combining pretrained deep encoders with shallow machine learning classifiers can enhance dental radiograph analysis accuracy. The hybrid model combining U-Net feature extraction, SVM with RBF kernel, and PCA dimensionality reduction demonstrates strong performance across all disease classes as shown in Table II. Precision and recall scores above 0.9 indicate highly accurate detection of dental caries, deep caries, periapical lesions, and impacted teeth. In particular, the recall values nearing 1.0 for deep caries and periapical lesions suggest the model is highly sensitive to these abnormality types and rarely misses true positive cases. The F1 scores in the 0.93-0.96 range confirm well-balanced precision and recall overall. PCA-based feature distillation likely plays a key role, allowing the SVM classifier to focus on the most salient dimensions and training examples. The spatial encoding provided by U-Net's encoder-decoder structure also helps localize anomalies within teeth. Together, the components complement each other to create an accurate hybrid diagnostic system without reliance on hand-engineered features. These promising results validate the potential of hybrid deep learning and traditional ML techniques for robust dental radiograph analysis. Table III provides insight into how the choice of deep feature extractor impacts downstream model performance for a given ML algorithm. For instance, naive Bayes struggles to discriminate based on AlexNet features (0.82 F1) but achieves much higher accuracy with ResNet50 features (0.92 F1). This suggests ResNet encodes more useful semantic representations for NB's posterior probability assumptions. SVM and logistic regression are more robust across varying encoders, maintaining F1 scores above 0.90 throughout. SVM achieves best performance of 0.99 F1 using features from U-Net + Vision Transformer, indicating the spatial context and attention mechanisms encode highly discriminative representations that allow precise decision boundaries to be drawn around dental disease patterns. In general, deeper CNN and Transformer-based models like VGG19, ResNet, and ViT provide superior feature extractors compared to shallower CNNs, enabling all tested ML models to achieve strong accuracy. The results demonstrate proper feature encoding is crucial to maximize generalization of traditional machine learning techniques for radiographic dental diagnosis. The receiver operating characteristic (ROC) curves in Fig. 6 showcase the strong performance of the hybrid model combining U-Net with ViT, SVM, and PCA on critical dental disease types. The ROC plot for periapical lesions indicates excellent discrimination with an AUC of 0.93. The caries and deep caries classes both achieve outstanding AUCs of 0.99, demonstrating near perfect classification. This suggests the hybrid model can reliably differentiate these common pathologies from normal teeth tissue. As illustrated in Fig. 7 the U-Net features combined with the SVM classifier's nonlinear decision boundaries result in robust modeling of characteristic disease patterns needed for accurate diagnosis. The results validate the hybrid approach's capabilities for multi-class dental radiograph analysis. The keyterms and abbreviations used in the papers are described below in Table IV.

TABLE IV. INDEX OF KEY TERMS AND ABBREVIATIONS

Term	Abbreviation
AUC	Area Under ROC Curve
BB-Conv	Bounding Box Convolution layer
CNN	Convolutional Neural Network
FN	False Negative
FP	False Positive
OPG	Orthopantomograph dental X-ray
PCA	Principal Component Analysis
SVM	Support Vector Machine
ViT	Vision Transformer
YOLO	You Only Look Once object detection model

V. CONCLUSION

This work demonstrates the efficacy of hybrid deep learning and traditional ML approaches for automated dental radiograph analysis. Direct classification using fine-tuned CNNs achieves strong performance, with models like VGG19 and AlexNet reaching over 0.93 F1 score. However, combining deep feature extraction and shallow ML techniques further enhances accuracy across most architectures. For instance, AlexNet improves from 0.93 to 0.95 F1 score with the proposed hybrid system. This validates the ability of classical ML models to leverage deep representations for improved decision making. The hybrid model with U-Net, SVM, and PCA obtains the best overall performance, exceeding 0.9 precision and recall for all dental disease classes. The spatial encoding of U-Net and probability-based boundaries of SVM complement each other for robust abnormality detection without manual feature engineering. Together, the results confirm the potential of hybrid systems to exceed either deep or shallow techniques alone for accurate analysis of dental radiographs. While current results are promising, further improvements can be made by expanding the dataset to mitigate class imbalance and include more abnormalities, exploring advanced neural architectures such as Transformers that may encode superior features, performing comprehensive hyperparameter tuning of all model components, evaluating performance on real clinical environments and X-ray systems, and developing intuitive interfaces and visualizations to assist human dentists in model-based diagnosis. Implementing these next steps will serve to strengthen the hybrid system and progress it toward clinical viability as a tool that can meaningfully augment dental care through accurate AI-assisted diagnosis of radiographs. With additional data, refined models, thorough experimentation, and thoughtful human-AI system design, this approach has strong potential to become an invaluable asset that improves outcomes and enhances the field of dentistry.

***Abstract*—At a time when information technology is advancing by leaps and bounds, smart financial management is becoming a hotspot of common concern in both academic and practical circles. The purpose of this paper is to systematically sort out the research development trend of smart financial management under the shared vision through the CiteSpace bibliometric analysis method. We select the relevant literature in the Web of Science database during the 10 years from 2014 to 2023 as the research object, set reasonable queer values and time slices, and conduct in-depth analyses of keyword co-occurrence, author cooperation network, keyword clustering, mutant keywords, and time interval, etc., and analyze the research hotspots and evolutionary paths of the smart financial management research under the shared vision, using the data as a renewable basis. Evolutionary path. After the study, it is found that the research in this field presents more obvious stage characteristics, influenced by technological progress, industry demand, and social change, and can be divided into five stages according to the development curve: the construction of the basic framework, the development of the model system, the change of behavioral patterns, personalized recommendations and risks, and the depth of the role of the Internet. As an emerging research field, as research scholars dig deeper into the theoretical logic, the deepening of interdisciplinary research, and the application of emerging technologies, it provides a new impetus and a new direction for intelligent financial management to make financial management more healthy and sustainable development.**

***Keywords*—Smart finance; financial management; financial sharing; bibliometrics; CiteSpace**

I. Introduction

With the rapid development of information technology, the field of financial management is experiencing unprecedented changes. Intelligent financial management, as a product of the deep integration of financial management and modern information technology, which involves the application of cutting-edge technologies such as big data, cloud computing, artificial intelligence, and other cutting-edge technologies in financial management, is gradually becoming a key force in promoting the innovation and transformation of corporate finance. It has not only changed the way of collecting, processing, and analyzing financial data but also had a far-reaching impact on the enterprise's decision support, risk control, and value creation [1]. Under the impetus of the sharing economy, information sharing and resource integration among enterprises are becoming more and more frequent, and the importance of intelligent financial management is becoming more and more prominent. As a result, the research and practice of smart financial management are showing new development trends and characteristics.

However, the current research on smart financial management is still in its infancy, and the research results are relatively scattered, lacking systematic sorting and analysis. In order to comprehensively understand the research status and development trend of intelligent financial management, this paper, through systematic search, screening and analysis of domestic and international related literature in the Global Academic Citation Index indexing database (Web of Science), selects the relevant literature in the Web of Science database during the 10-year period of 2014-2023 as the research object, sets reasonable queue values and Time slicing, in-depth analysis of keyword co-occurrence, author cooperation network, keyword clustering, mutant keywords, and time interval, etc. found that the research in this field presents more obvious stage characteristics, affected by technological advances, industry needs and social changes, according to the development curve can be divided into the construction of the basic framework, the development of the model system, the change of behavioral patterns, personalized recommendation and risk, and the role of the Internet The depth of these five stages [2]. This study aims to use CiteSpace software to construct a knowledge map in the field of intelligent financial management, reveal its research hotspots and evolution paths, and provide reference and inspiration for future research.

II. Research Design

A. Research Methodology

In this paper, the CiteSpace bibliometric analysis tool is used to show the current research status and development trend in the field of smart financial management through visualization [3]. The tool can reveal the research hotspots, evolutionary paths, and collaborative networks in the research field by visualizing keyword co-occurrence networks and author collaboration networks in the scientific literature. CiteSpace software has become one of the most commonly used tools in the current bibliometric analysis due to its powerful data visualization capabilities. In this study, the software will be used to visualize

*Corresponding Author

and analyze the literature data collected during the last 10 years to reveal the current research status and development trend in the field of smart financial management.

B. Data Collection

Data collection is a key step in research design, and to ensure the comprehensiveness and representativeness of the study, the data in this paper mainly come from the relevant literature in the global academic citation index database Web of Science (Wos), which covers a wealth of international academic literature resources [4]. The keywords for searching the data include "Intelligent Financial Management", "Financial Management", "Shared Vision" and so on. Shared Vision", etc. To ensure the timeliness and cutting edge of the study, the time frame of the study was set as the period of 2014-2023.

Based on the above set conditions, a total of 1398 initial documents were retrieved, and to ensure the accuracy of the analysis, multiple rounds of screening were subsequently conducted on the initial literature data to exclude a series of documents unrelated to the topic of smart finance research such as news conferences, interview reports, and solicited wasted articles, and to obtain a core literature of 817 articles, which is used as a core sample for the study of this paper.

C. Data Processing

Based on the core literature data samples obtained from multiple big data and manual screening, the data information, including authors, publication year, journal name, keywords, etc., was further extracted and exported, which was used as the input data required for analysis by CiteSpace software. At the same time, by setting appropriate parameters for CiteSpace 6.3.R1, such as time slicing, keyword co-occurrence thresholds, clustering thresholds, etc., the data were further processed and analyzed, and the clustering knowledge graphs, such as bibliometrics, scholars' institutional cooperation network mapping, word frequency co-occurrence network, word frequency clustering network, etc., were constructed, and the timeline view was applied for further analysis to achieve the intuitive identification of the wisdom of The purpose of the hot topics and evolution path of financial management research [5].

III. Analysis of Results

A. Literature Analysis

1) Period of distribution of literature: By organizing and counting the number of literature releases between 2014 and 2023, a corresponding annual literature release trend chart is produced. The growth of the number of literature releases in a research field usually means that the research in the field attracts more attention and participation of scholars, reflecting the academic research level and development speed of the research field in Fig. 1.

The statistical and quantitative distribution of the number of literature releases shows a significant curvilinear growth trend in the number of literature releases in the field in the above-mentioned years, which is broadly categorized into four phases according to the rate of growth:

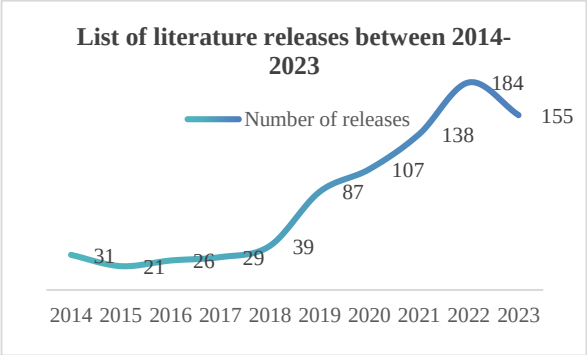

Fig. 1. Summary of the number of literature releases during 2014-2023.

Initial Growth Phase (2014-2017): Between 2014 and 2017, the number of research literature published in this field was relatively low and the average annual growth rate was relatively flat. This phase can be regarded as the initial growth phase of research in this field. During this period, smart financial management, as an emerging field, is still in its infancy as research scholars are still in the process of recognizing and exploring it [6]. 31 publications in 2014 marked the initial interest in the field, followed by slow growth in the following years, as research scholars are gradually exploring and accumulating the knowledge base [7].

Accelerated Growth Phase (2018-2019): There has been a significant increase in the number of literature publications starting from 2018 and this trend continued in 2019 [8]. The growth rate in this phase was significantly higher than in the previous phase, indicating that research in this area is beginning to receive more attention.39 publications in 2018 almost doubled compared to the previous year, showing that research interest in this area is growing rapidly among research scholars.

Rapid Growth Phase (2020-2021): The research in this field has entered into a rapid growth phase as we enter the year 2020.107 publications in the year 2020 and 138 publications in the year 2021 show the activity of the research in this field. The growth in this phase may be related to the changes in the global economic environment, the increasing demand for smart financial management in organizations, and the rapid development of related technologies.

Peak period (2022-2023): The number of literature releases peaked in 2022 and 2023 at 184 and 155 respectively, which accounted for a larger proportion of the total literature. The high growth rate in this period indicates that smart financial management has become a hot topic in the field of financial management [9]. Research scholars have explored the theory and practice of this field in depth and published a large number of high-quality research results.

2) Main published journals: Journals with high publication volume usually represent a high degree of recognition of their content quality and academic contributions by the academic community [10]. Literature published in these journals is often highly specialized and rigorous and can provide a solid theoretical foundation and empirical support for research in related fields [11]. In this study, data statistics and classification screening were carried out on the included journals of the core

literature sample and the number of articles published in the journals, and a total of 416 included journals were obtained after sorting. The list of journals with a high publication volume of literature release was produced with the cut-off point of 10 total publications in the literature (Table I).

TABLE I. LIST OF HIGH-VOLUME JOURNALS PUBLISHED IN LITERATURE

No.	Journal Name	Volume Of Publications
1	Executive Systems with Applications (ESWA)	41
2	Sustainability	41
3	IEEE Access	35
4	Computational Income and Neuroscience	18
5	Journal of Intelligent Fuzzy Systems (JIFS)	17
6	Journal of Intelligent Fuzzy Systems Applications in Engineering and Technology	17
7	Mobile Information Systems	17
8	Wireless Communications and Mobile Computing	16
9	Wireless Communications and Mobile Computing	15
10	Energies	14
11	Mathematical Problems in Engineering	14

It is found that the top three key journals are ESWA, Sustainability, and IEEE Access, which are significantly ahead of other journals in terms of the number of publications. Among them, ESWA and Sustainability are published by Elsevier, and both of them have 41 publications. These two journals have higher requirements for manuscript submission and long reviewing periods, but they have become the authoritative journals in the field due to their stable impact factor [12]. The third-ranked IEEE Access has 35 journals, which is more inclusive than the first two journals, and is a journal that covers multidisciplinary fields and supports open access, providing a channel for researchers in various fields to quickly share their research results and is welcomed by many scholars because of its fast review and publication process [13].

The fourth-ranked Computational Intelligence and Neuroscience, and the fifth-ranked JIFS, these two journals are more inclined to the research direction in the combination of theoretical logic and application [14]. It is easy to see that these key journals ranked in the top 10 not only provide a high-quality publication platform for research in the field across all disciplinary areas but also ensure the quality and academic level of the published literature through their high-standard peer review process [15]. By publishing their research results in these journals with stable impact factors, scholars can share and exchange the latest research findings with their peers around the world, thus promoting the academic development and practical application of the field.

B. Collaborative Network of Scholars and Research Institutions

1) Scholarly research networks: Research Scholar Collaboration Network Mapping can visualize the collaborative relationships among research scholars, and at the same time show the dynamics of major research scholars in the field [16]. In this paper, we constructed a collaborative network graph of research scholars in this field through the co-occurrence function of the software CiteSpace 6.3.R1. The graph consists of 284 nodes and 151 connecting lines, where the nodes represent research scholars, and the connecting lines between the nodes indicate the collaborative relationship and social network structure among research scholars in Fig. 2.

When producing the research scholars' cooperative network mapping, the co-occurrence threshold of research scholars was set to 2 to show the social network structure among research scholars in this field, thus obtaining the above cooperative network. Although this network consists of many nodes, the network density is only 0.0038, and this low-density value indicates that there are relatively few connections in the network and the overall network structure is very loose [17]. This loose network structure implies that there is a lack of close collaborative clusters among research scholars in this field, which are mostly carried out on an individual basis and have not yet formed a large-scale, organized collaborative network.

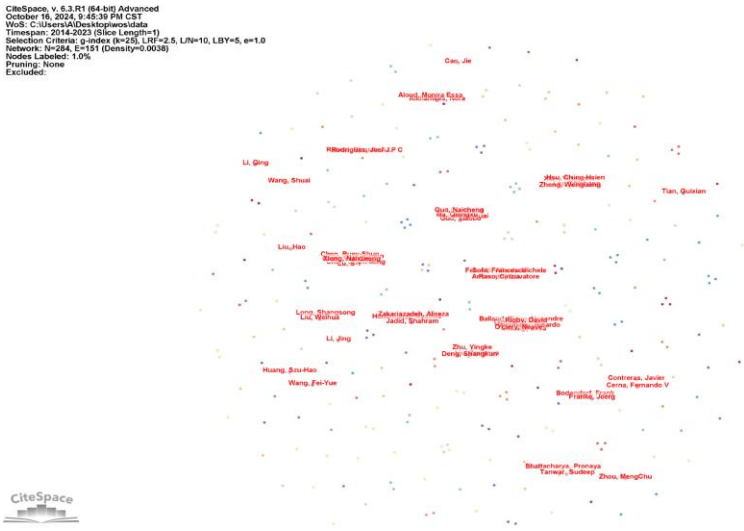

Fig. 2. Collaborative network mapping of smart financial management research scholars.

To gain a deeper understanding of the research dynamics of research scholars over the past 10 years, this paper statistically analyzes the number of research scholars' publications in the field during the period 2014-2023. The statistical results show that a total of 284 research scholars published research results during this time interval [18]. Notably, 18.7% of the research scholars published 2 research results, while 81.3% published only 1. This suggests that although research participation within the field is extensive, most research scholars have a shallow level of participation and lack a sustained output of research results [19].

According to Price's law, this paper calculates that the number of publications of highly productive authors is 1. This is inconsistent with the definition of and the fact of prolific authors in Price's law, which side by side proves that the research in this field is still in the early stage of development, and the leading role of prolific academic authors is still not formed [20]. Based on experience, this paper classifies the research scholars with 2 publications as high-yield authors (Table II).

The table lists 53 prolific authors in no particular order. In terms of the number of publications, these research scholars are more uniform in the number of publications. Combined with the time of publication, the findings of these research scholars still focus on logical theory, mainly exploring the knowledge framework and theoretical filling of this research field, and do not carry out a more in-depth study of this field, perhaps this has to do with the fact that this field is an emerging field of research, and the research scholars are still in the beginning stage of recognizing and exploring it [21].

2) Collaborative network of research institutions: In this paper, we use CiteSpace 6.3.R1 software to set the nodes as institutions, filter the research institutions with a high frequency of posting, and the threshold is set to 2 to get a research institution cooperation network mapping. The size of the nodes in the graph represents the frequency of the institution's posting, and the thickness of the connecting line between the nodes represents the strength of the cooperation [22]. The larger the nodes are, the higher the number of messages sent. The thicker the connecting lines, the greater the intensity of cooperation in Fig. 3.

TABLE II. SUMMARY STATISTICS OF PUBLICATIONS BY SCHOLARS IN SMART FINANCIAL MANAGEMENT RESEARCH

No.	Research Scholar	Volume of Publications	Serial Number	Research Scholar	Volume of Publications

From the results in the figure, the network mapping of research institutions contains 263 nodes and 216 connecting lines, and the density of the network is only 0.0063. This indicates that a total of 263 research institutions have carried out research in the field of intelligent financial management related to the analysis of the research found that the higher volume of published articles will be enough, mainly for the universities, followed by the relevant research institutions and knowledge bases [23]. In this paper, only the top 10 research organizations are intercepted in Table III.

The top three institutions are the Chinese Academy of Sciences, Tianjin University, and Islamic Azad University, with 17, 12, and 8 articles, respectively [24]. Chinese Academy of Sciences ranks first with 17 articles, showing its leadership in this field of research. Tianjin University followed with 12 articles and also showed strong research strength [25]. It is worth noting that the node intermediary centrality of the institution is small, indicating that although the institution has a high number of publications, the cooperation with other institutions is not close enough, and it is necessary to increase the cooperation between institutions to play a real leading role in the research field, thus promoting the research of the whole field of intelligent financial management [26].

Several international institutions and research organizations, such as Islamic Azad University, King Saud University, and Egyptian Knowledge Bank, EKB (Egyptian Knowledge Bank), have also demonstrated significant research activity in this field, which at the same time reflects the fact that this field of study is a global academic research area that requires cross-border collaboration to advance together [27].

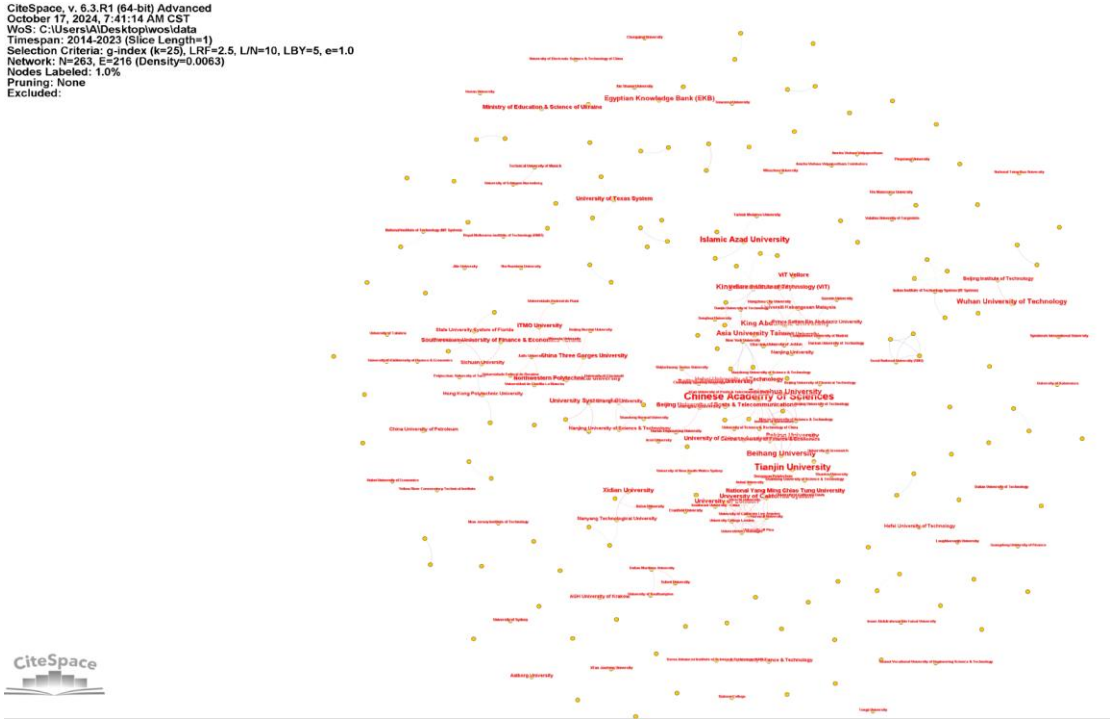

Fig. 3. Collaborative network mapping of smart financial management research organizations.

TABLE III. LIST OF STATISTICS OF RESEARCH ORGANIZATIONS ON INTELLIGENT FINANCIAL MANAGEMENT

No.	Research Organization	Number Of Communications
1	Chinese Academy of Sciences	17
2	Tianjin University	12
3	Islamic Azad University	8
4	Beihang University	7
5	Tsinghua University	7
6	King Saud University	7
7	Asia University Taiwan	6
8	Wuhan University of Technology	6
9	King Abdulaziz University	6
10	Egyptian Knowledge Bank (EKB)	6

The data also hint at potential structures in collaborative networks, for example, institutions with a high number of publications may occupy a central position in the network, advancing knowledge through collaboration with other institutions. At the same time, institutions with a lower number of publications may play a bridging role in the network, connecting different research communities.

IV. Research Hot Spots

A. Keyword Co-Occurrence

Keywords, as a refined expression of the research topic of an academic paper, are used to show the research hotspots and research trends in the research field in an intuitive and precise way. In this study, the keyword co-occurrence network mapping was constructed by CiteSpace software, where N=352 represents the total number of nodes in the network, i.e., the number of identified keywords; E=1316 represents the total number of connecting lines between nodes, i.e., the number of keyword co-occurring relationships. The network density is 0.0213, a value that is low but, compared to previous analyses, proves that there is a certain degree of interconnection between the research hotspots in this field in Fig. 4.

The size of the 352 node count indicates that smart financial management is a multidimensional research area covering a wide range of topics from logical theories, and technology applications to management strategies. Each node represents a keyword, and the size of the node is usually proportional to its frequency of occurrence, highlighting the hot topics in research [28]. For example, nodes related to "Big Data Analytics", "Cloud Computing" and "Artificial Intelligence" are likely to be large, indicating that these technologies are the focus of current research. 1316 high values for the number of lines, on the other hand, indicate that the keyword is not a keyword. The high value of 1316 lines shows the complex relationship between the keywords. Each line represents two keywords appearing in the same document, reflecting the intersection and integration of research topics [29]. These lines reveal how different research themes are interrelated; for example, "risk management" may be closely linked to "internal control," suggesting that researchers often consider the framework of internal control when exploring risk management strategies.

The network density value is only 0.0213, indicating a relatively low percentage of co-occurring relationships observed among all possible keyword combinations. This reflects the wide and diverse range of research topics in the field on the one hand, and on the other hand, suggests that many potential research combinations have not yet been fully explored. This sparser network density provides room for new research and encourages scholars to explore new combinations of existing research topics or develop entirely new research areas.

B. Keyword Clustering

The keyword clustering map reveals the research topics and subfields of the field. In this paper, we adopt the clustering method of keyword clustering module Q value>0.3 and keyword clustering average profile value S>0.5 to cluster the keywords scientifically and provide a scientific quantitative basis for the development of this research field [30]. After carefully analyzing each cluster, we can gain insight into the research themes, research hotspots, and research directions behind these keywords [31]. Based on extracting the keywords from the literature, the keyword co-occurrence network was further clustered and analyzed using the operations of LSI and LLR, with a Q-value of 0.4755 and an R-value of 0.7832, and the clustering labels numbered from 0 to 8, totaling 9, were obtained. They are, #0 blockchain technology, #1 mediating role, #2 shareholder value, #3 assisting investor, #4 directional change, #5 directional change, and #6 directional change. directional change, #5 deep learning algorithm, #6 economic complexity, #7 electric vehicle, #8 consideration. The smaller the numerical label of the cluster label, the higher the number of keywords it contains. The sub-clusters in this cluster are closely related in Fig. 5.

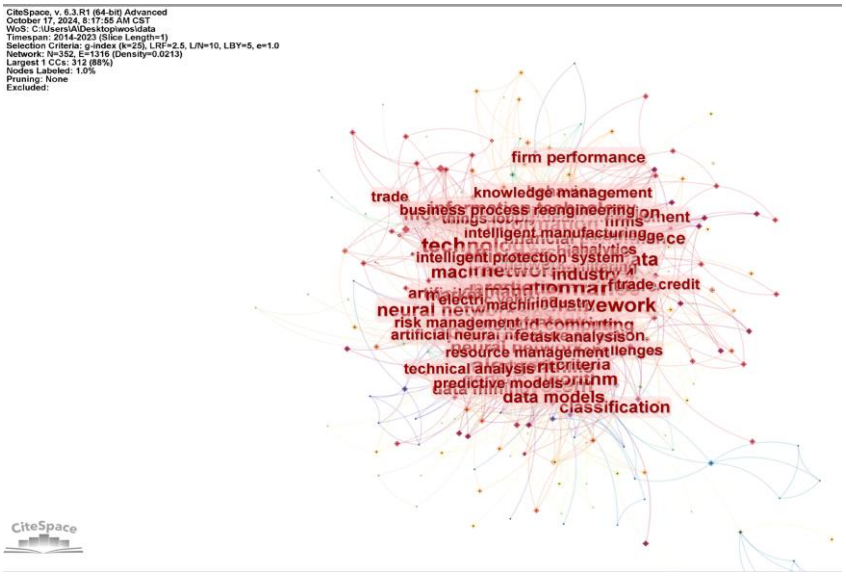

Fig. 4. Keyword co-occurrence network mapping for smart financial management research.

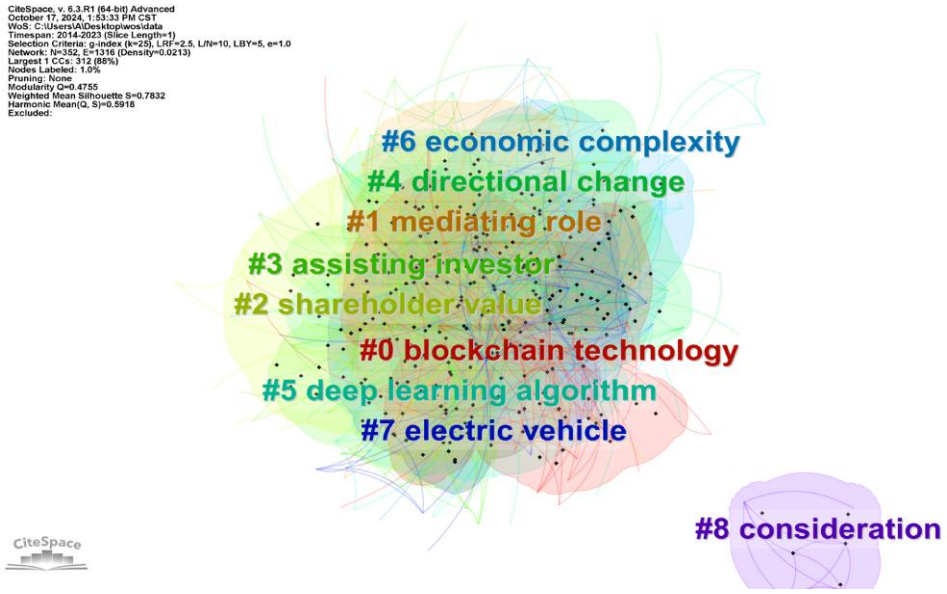

Fig. 5. Clustering mapping of keywords for smart financial management research.

This area of research is an emerging and dynamic area of financial research, and keyword clustering mapping paints a colorful picture of the research field. A deeper exploration of the keywords within each cluster, using centroid value numerical analysis, reveals the intrinsic connections and interactions between different research topics within the field. In this paper, the intrinsic connectedness and influence values, clustering the nine keywords again, find four important research directions within the field [32]. They are: technology-driven, strategic decision-making, value efficiency, and industry-specific.

In the technology-driven research direction, the main clusters are #0 blockchain technology and #5 deep learning algorithm, which are two new Internet big data technologies. In the blockchain technology cluster, it is "blockchain technology" and "energy efficiency", revealing the potential of this emerging technology to optimize energy management and improve transparency in the industry [33]. The study focuses on how blockchain can be used to ensure the transparent distribution of government subsidies and support the development of new energy vehicle enterprises. In the clustering of deep learning algorithms, "deep learning algorithms" intersect with "cybersecurity," highlighting the importance of maintaining data security in the fintech sector. These studies explore the application of deep learning in predicting financial risks and detecting abnormal trading behaviors, providing strong technical support for this research area.

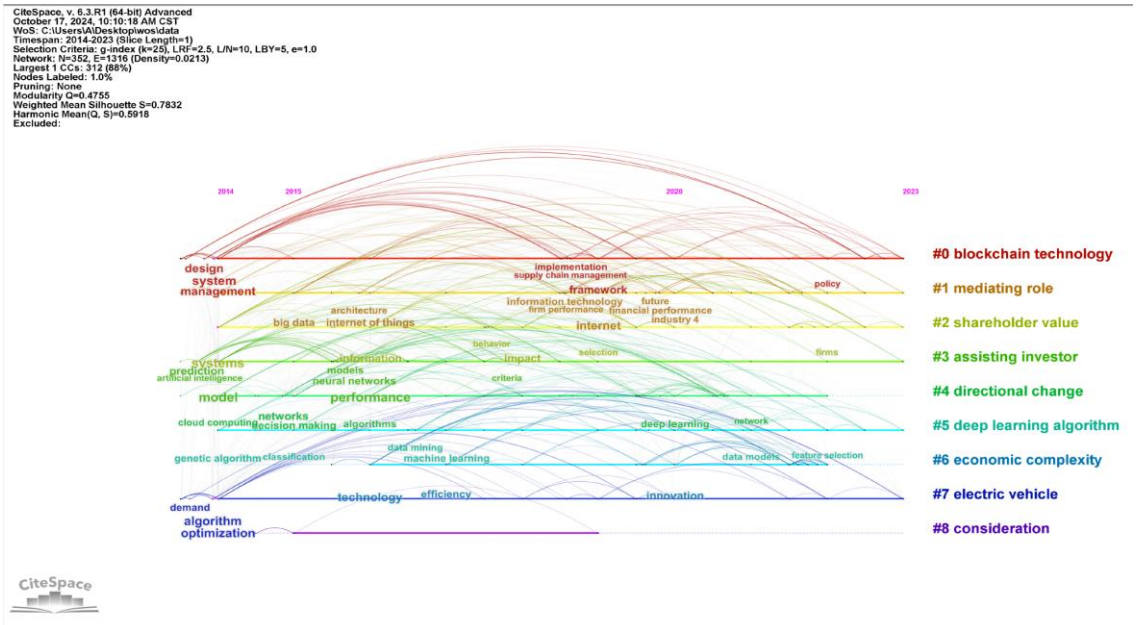

Fig. 6. Mapping of keyword research development paths.

In the strategic decision-making research direction, the clustering of decision-making and strategy is focused, including #1 mediating role and #3 assisting investors. In the mediating role clustering, "Big Data" interacts with "Organizational Learning", highlighting the central role of Big Data in facilitating knowledge transfer and decision optimization within organizations. The study demonstrates how big data can contribute to the growth of the smart manufacturing industry and enhance the ability of organizations to adapt to future trends. In the case of investor assistance clustering, the combination of "neural networks" and "portfolio management" provides investors with more accurate tools for market analysis and enhances their decision-making capabilities in complex markets.

In the value efficiency research direction, the interaction between #2 shareholder value and #6 economic complexity is explored. The clustering of shareholder value is complemented by the clustering of 'shareholder value' and 'smart logistics policies', reflecting how this research area can enhance corporate value through optimized logistics and supply chain management. Meanwhile, the discussion of "regional innovation capacity" highlights the importance of innovation in enhancing corporate competitiveness and shareholder returns [34]. The clustering of economic complexity, where "economic complexity" interacts with "knowledge-based transformation", explores how firms are responding to changing economic environments through intelligent upgrades and how these transformations are affecting financial strategies and industry practices.

In the sector-specific research, researchers focused on sustainable industries, primarily in the areas of #7 electric vehicle and #8 consideration. In the electric vehicle cluster, the combination of "electric vehicles" and "smart parking" demonstrates the role of this area in supporting emerging industries. The research focuses on how smart technologies can improve the efficiency of electric vehicle charging and parking and promote a sustainable industry. In the clustering of considerations, "decision support systems" are intertwined with "carbon footprint," emphasizing the importance of considering environmental impacts in engineering decisions, such as bridge maintenance, which demonstrates the potential of this research area to promote environmental sustainability.

From technology application to decision optimization to industry-specific problem solving, these research hotspots at different levels not only provide a deep understanding of the current state of development of research in the field but also offer new directions and ideas for future research.

C. Deduction of Research Development Paths

The keywords carry out all levels of this research field, and this paper uses the timeline function of the CiteSpace software tool and the mutation keyword query function to filter and sort the keywords appearing in the research and obtain the research development of this research field in different periods from 2014 to 2023 through the years of appearance and disappearance of mutation keywords in this research field in Fig. 6.

Over the 10 years from 2014 to 2023, research in the field has undergone an extremely significant evolution, with research priorities and trends profoundly influenced by Internet technologies, industry needs, and societal changes.

2014-2015: Construction of the foundational framework

In the early years of research in this area, from 2014 to 2015, research focused primarily on building its foundational framework, the "system". Research during this period laid the groundwork for subsequent technology integration and application, emphasizing the importance of systems thinking in financial management transformation. Subsequently, research began to delve into more complex models and systems, exploring how information technology could be used to improve financial management. Researchers and scholars began to realize that achieving and improving efficiency and accuracy in financial management through integrated systems is a more important direction for the future, especially in terms of automation and real-time data processing.

2016-2018: Development of modeling systems

As we move into 2016, research is beginning to shift to more complex models and systems as understanding of the underlying frameworks grows. Researchers and scholars worked to develop and test a wide range of financial models that improve the accuracy of decision-making through algorithms and data analysis. Research during this period began to involve more advanced mathematical and statistical methods, as well as emerging information technologies such as big data analytics and cloud computing [35]. Research in integrated systems began to show its potential in financial management, especially in automation and real-time data processing. These researches have pushed financial management to higher levels of automation and intelligence, providing faster and more accurate financial reporting and analysis for organizations.

2018-2020: Behavioral patterns of concern

Beginning in 2018, research shifted to "behavior," or patterns of behavior in financial decision-making. This change in research direction reflects a deeper understanding of the factors that influence individual and organizational behavior, and how this understanding can be used to optimize financial strategies. And how these understandings can be used to optimize financial strategies. Researchers and scholars are beginning to explore how human behavior interacts with financial management systems and how to design intelligent systems that are more responsive to user behavior. Research in this phase not only focuses on the technical aspects of the system but also begins to focus on the human factor and how understanding the behavior of financial decision-makers can improve the design of the system and the quality of decision-making.

2020-2021: Personalized recommendations and risk

By 2020, the focus of research has shifted to "recommender systems" and "risk management". Recommender systems research focuses on how machine learning algorithms can be used to provide personalized financial advice, while risk management research focuses on how to identify and mitigate financial risks, especially in a market environment of increasing uncertainty. During the same period, the role of the Internet became increasingly important in the field. Research has begun

to explore how Internet technologies, including cloud computing and big data analytics, can be utilized to improve the efficiency and effectiveness of financial management so that investors and financial decision-makers can make more informed investment choices in a complex market environment. These studies emphasize the critical role of the Internet in connecting financial decision-makers, providing real-time market information, and supporting complex calculations, advancing the field's use in risk control and decision support to provide companies with more robust financial strategies.

2021-2023: Deepening the role of the Internet

Since 2021, the Internet has become increasingly important in the practical application of financial management. Research is beginning to explore how Internet technologies, including cloud computing and big data analytics, can be utilized to improve the efficiency and effectiveness of financial management. These studies emphasized the critical role of the Internet in connecting financial decision-makers, providing real-time market information, and supporting complex calculations. As Internet technologies evolve, financial management is beginning to migrate to the cloud, leveraging the Internet's extensive connectivity and powerful data processing capabilities to provide organizations with more flexible and efficient financial management solutions.

During the same period, some researchers and scholars began to turn to the in-depth exploration of the shared vision and the application of technology. The research hotspots not only focus on the deepening application of technology but also the innovation of big data-driven decision support and financial sharing models. With the advancement of technology, the sharing concept and the idea of intelligent financial management have been generally recognized, and enterprises have gradually popularized the adoption of advanced management systems, the level of intelligence has steadily increased, and the number of technological applications has increased by nearly 10% on average, and the rate of technological adoption has also increased. Financial sharing has become a key factor in promoting the level of construction in this field, and most enterprises have promoted the goals of financial standardization, improving the level of financial intelligence, and facilitating the transformation of financial functions through financial sharing centers. At the same time, the widespread application of mature technologies such as electronic invoices, mobile Internet, mobile payments, and digital signatures has accelerated the transformation of smart financial construction.

It should be noted that the construction of the system in this field is affected by the industry category and enterprise scale, and the significance of differences is amplified. Different enterprises have different motivations and demands for the construction of smart finance due to the existence of differences in industry, revenue scale, personnel scale, and informatization level, which leads to large differences in the application of artificial intelligence and other technologies and the level of intelligence. Under the shared vision, the study began to focus on cutting-edge trends such as data governance and smart sharing. Data governance ensures the quality and security of data and provides a reliable basis for corporate decision-making, while smart sharing emphasizes the importance of achieving information sharing and collaborative cooperation in the digital era, thereby enhancing the competitiveness and innovation of enterprises.

D. Projections of Future Trends

Research in the area of smart financial management will continue to develop along the path of technology convergence and innovation. As industry applications deepen, research in the field will become more relevant to practical needs, and environmental sustainability concerns will continue to grow. Interdisciplinary research will continue to grow, and innovations in research methodologies will continue to emerge, bringing new perspectives and solutions to the field. In the process, research scholars will continue to explore the application of technologies such as big data, artificial intelligence, and blockchain in financial management, and will also pay more attention to how these technologies affect financial decision-making, risk management, and corporate value creation. As technology continues to advance, research in this field will continue to expand into new areas, providing practitioners with more theoretical support and practical guidance.

In addition, with the continuous development of globalization and market economy, research in this field will also pay more attention to financial management issues in multinational corporations and multi-currency environments. Researchers and scholars will explore how intelligent financial management tools can be used to optimize the financial structure of firms and improve their international competitiveness in a changing global economic environment. Research in this area will also focus more on sustainability and social impact. With society's increasing emphasis on environmental protection and social responsibility, companies need to consider more environmental and social factors in their financial management. Researchers and scholars will explore how to promote the sustainable development of enterprises through intelligent management systems and realize the dual goals of economic and social benefits.

As technology continues to advance, research in this field will continue to expand into new areas, such as the application of emerging technologies such as the Internet of Things (IoT), Artificial Intelligence (AI), and Blockchain in financial management.

In conclusion, research on smart financial management has made significant progress over the past decade, and future research will continue to evolve along the path of technological convergence and innovation to provide enterprises with more efficient and smarter financial management solutions. As research continues, the field will play an increasingly important role in the global economy, helping companies achieve more efficient and sustainable growth.

V. CONCLUSION

In the field of intelligent financial management, this paper, through CiteSpace6.3.R1 software, systematically combed the research dynamics during the 10 years from 2014 to 2023, and analyzed the development trend of the research field from different levels and perspectives by doing the distribution of the literature, the key journals loaded with publications, the network mapping of the collaborators, the keyword clustering mapping,

as well as the timeline, and through the in-depth understanding of the content, predicted the possible future research hotspots and research directions.

In the data statistics on the number of publications in the literature and the number of issues contained in the key journals, it is observed that this research field has shown a clear stage characteristic in the past 10 years. At the beginning of the research, it focused on the construction of the basic framework, followed by a gradual overshoot into the transforming direction of behavioral patterns, recommender systems, risk management, and the application of Internet technologies. Advances in the technology of Internet big data and the development of big data, artificial intelligence, blockchain, and other technologies have provided new impetus and direction for the field while deepening research scholars' deeper understanding and exploration of the field.

Although this paper provides a comprehensive analysis of the research dynamics in the field, there are some limitations. First, it may fail to cover all relevant research in the field as the collection of research data is limited to a specific period. Second, the analysis in this paper is mainly based on bibliometric methods, which may fail to fully capture the depth and quality of the research content. The analysis of smart financial management practices characterized by different regions and industries needs to be further deepened.

Future research can dig deeper into the following aspects. First, with the continuous progress of technology, the application of emerging technologies such as the Internet of Things and 5G communication in smart financial management deserves further research. Second, the deepening of interdisciplinary research, such as combining psychological and sociological theories with smart financial management, may reveal more about the deeper factors of financial decision-making behavior. In addition, case studies of smart financial management practices in enterprises of different sizes and industries may provide richer empirical data to help understand the applicability and effectiveness of smart financial management in different environments. Finally, with the development of globalization, the application of smart financial management in multinational corporations and its impact on the global financial market is also a research direction that deserves attention.

In summary, research in the field of smart financial management under the shared vision is in a stage of rapid development, and future research will show greater potential and value in terms of technology integration, practical application, and interdisciplinary exploration. With the continuous deepening of the research work and the accumulation of practice, it is expected to bring more efficient and smarter financial management strategies to enterprises, and thus promote the sustainable and healthy development of enterprises and the entire economic system. In the subsequent research, the author plans to expand the scope of the sample database, closely track the latest research progress and results in this field, and think deeply about how to promote the development of intelligent financial management under the guidance of the sharing concept, to provide guidance and direction for the wide application of this field.

***Abstract*—Heart disease (HD) continues to rank as the top cause of morbidity and mortality worldwide, prompting the enormous importance of correct prediction for effective intervention and prevention strategies. The proposed research involves developing a novel explainable AI (XAI)-driven chatbot system for HD prediction, combined with cutting-edge machine learning (ML) algorithms and advanced XAI techniques. This research work highlights different approaches like Random Forest (RF), Decision Tree (DT), and Bagging-Quantum Support Vector Classifier (QSVC). The RF approach achieves the best performance, with 92.00% accuracy, 91.97% sensitivity, 56.81% specificity, 8.00% miss rate, and 99.93% precision compared to other approaches. SHAP and LIME provide XAI methods for which the chatbot's predictions and explanations endow trust and understanding with the user. This novel approach proves the potential of seamless integration of explanations in a wide range of web or mobile applications for healthcare. Future works will extend the work on incorporating other diseases' predictions in the model and improve the explanation of those predictions using more advanced explainable AI approaches.**

***Keywords*—Heart disease prediction; machine learning; chatbot system; XAI**

I. Introduction

The rapid development of artificial intelligence (AI) [1] and ML [2] technologies has made various fields, including healthcare [3], solutions to complex medical problems possible. In this regard, HD stands as an important public health issue among the leading causes responsible for mortality across the globe. Therefore, early detection and prevention of HD is important to curb the materialized global impact. AI-enforced solutions are fascinating tools for achieving such goals, with chatbots being a prominent example. Chatbots have emerged as a novel interface for healthcare applications by using conversational AI to communicate with users through real-time conversations and gather valuable health information. These intelligent agents driven by ML models can assess risk factors, reply to questions, and provide health predictions based on user inputs. The promise of Chatbots is most evident in heart disease prediction as they act as virtual assistants to surface early red flags and motivate preventive actions. However, a significant concern surrounding the implementation of these chatbots in life-critical health scenarios is their ability to elucidate their predictions in a way that is transparent and comprehensible to end users. The application of chatbots, empowered by ML techniques, ensures a broader range of capabilities for an interactive conversation system.

Traditional ML models [4] have proven efficient predictors of clinical scenarios, they remain largely "black boxes" whose inner workings are often not transparent enough to fully account for how certain decisions are arrived at. Such opacity may generate doubts regarding trust and reliability because healthcare demands insight into the reasoning behind a prediction. To avert these challenges, XAI [5] has been fashioned to augment the interpretability of the decision-making processes involved in these models. By providing greater insight into variables predicting heart disease, XAI helps in decision-making by healthcare practitioners and parties involved thus engendering trust in AI solutions.

Explainable AI helps in this regard by allowing chatbots not only to predict HD risk but also to explain the reasons behind their predictions understandably. In contrast with the normal "black box" ML model for which decisions are explained in contextual terms, XAI-driven chatbots such as this can potentially explain why some attributes (blood pressure, cholesterol levels, etc.) lead to a simultaneously unique heart disease risk given all patient profiles: age ranges and themselves's lifestyle choices. Transparency will be anessential aspect of healthcare. It builds trust and clarifies the rationales of AI recommendations to patients as well as providers. XAI-based chatbots [6] for heart disease prediction [7] combine strengths from both conversational agents and sophisticated predictive models. These chatbots aim to interact with users in dialogue, collecting the required health information and providing instant risk estimates. The chatbot incorporates XAI methods to explain how some health measurements, lifestyle habits, or risks in custom history contribute to the overall risk profile, thus providing a transparent vision of the prediction process. These together not only enhance user experience but also make sure that the predictions remain interpretable and actionable. Moreover, the drifting of implementing XAI into HD prediction

*Corresponding Author.

models coincides with the growing concern in ethical AI, and the necessity of fair systems [8], accountability [9], and transparency [10]. While such qualities are critical in every domain, they gain special significance in healthcare since they may directly affect patient outcomes as well as trust in AI-driven recommendations. XAI can allow clinicians to verify model predictions, see where biases occur, and make adjustments, ensuring results are fair and accurate across patient groups via the chatbot's suggestions. In turn, this works to encourage patients to adopt the recommended lifestyle changes or prompts for further medical evaluation.

The usage of XAI with chatbots for HD prediction [11], the primary advantages would be to improve patient education and engagement. It helps them better understand why and how age, smoking behavior, activity level, or dietary habits could increase the risk of HD. This understanding empowers people to take charge of their health and care and achieve better outcomes overall. It not only helps diagnose [12] but also educates the patient about their condition, acting as a bridge between complicated medical information and a better understanding of patients.

The practice of such systems should be done carefully, with full consideration given to technical and clinical issues. From the technical aspects, ML algorithms used, feature selection, and model training are key to determine what will be predicted by the bot that should have high accuracy with ground truth. For the interpretability of ML models, there are different techniques like SHAP (Shapley Additive Explanations) [13] and LIME (Local Interpretable Model-Agnostic Explanations) [14]. These techniques help you identify the roles different input features play in your final prediction, and so your model decision is more scrutable. From the clinical point-of-view, it is important that this AI chatbot be tested with patient-generated data, and working closely with doctors helps to mature its design. Working alongside cardiologists, GPs and other practitioners should allow the dialog responses of this chatbot as well to help prediction models better adapt in focusing on specific patients at risk of HD. Two trade-offs yet to be considered are the model complexity and interpretation ability when the work starts deploying XAI-based chatbot service for HD prediction. Although more complex models (e.g., deep neural networks) may provide greater accuracy, they are also often less interpretable than simpler ones such as decision trees or logistic regression. Finding the right balance between accuracy and interpretability is crucial to ensure that the chatbot delivers reliable predictions while maintaining transparency. Researchers are dynamically discovering hybrid techniques that integrate the strengths of various models to obtain optimal performance.

Many studies have explored ML and Deep Learning (DL) approaches for HD prediction, but they often lack transparency, limiting their practical adoption in healthcare. The novelty of this study lies in introducing an XAI-driven chatbot system that combines accurate predictions with interpretable outputs. By focusing on transparency and user-friendly design, it bridges the gap between complex AI models and practical healthcare use, addressing the "black-box" limitations of traditional methods. This research work proposes the design of XAI chatbots for HD prediction which marks an important sign of leveraging AI for healthcare. With ML's powerful predictive features and XAI helping in bringing transparency, now healthcare systems can benefit from accurate predictions as well as making these models trustable for both patients and Healthcare Providers. Even more, improvements are planned as the field continues to grow, making these chatbots even more useful when it comes to battling HD and any other health sicknesses that last a lifetime.

The remainder of this paper is organized as follows: Section II discusses the literature review, highlighting the previous work regarding chatbot systems for HD prediction, and Section III provides limitations of previous works. Section IV discusses the proposed methodology, Section V highlights the dataset description, Section VI explains the dataset structure, Section VII explains the system block diagram, Section VIII describes pseudo code, Section IX simulation results, Section X explains the Discussion, Section XI presents conclusion of the manuscript and Section XII describes the limitations and future suggestions. This structure ensures a comprehensive understanding of the study and its contributions.

II. Literature Review

There have been extensive research interests pursued over the years on several autonomous systems, such as virtual assistants, chatbots, and applications for HD prediction employing XAI among other techniques. Their work has opened up ways for making predictive healthcare systems transparent, accurate, and ethical which provides a strong ground on top of where future advancements can be carried out. This section presents some of the most important research ever published in this field. AI-powered health chatbots are a game changer for how mental healthcare can be approached by businesses as well as any other sector including the traditional form of care within Healthcare. Powered by Natural Language Processing (NLP) and AI, these smart chatbots can converse through text as well as voice performing functions similar to those handled by a live human agent. The kinds of jobs they provide are many; everything from helping individuals in crisis to customer service. Smartphone and smart speakers-powered voice-enabled chatbots use high-end speech-to-text capabilities but are sensitive to elements like regional accents or background noise. Text-based chatbots, on the other hand, such as those found in Messenger or Slack that are available within web applications offer more managed interactions and allow for complex questions to be answered making them great tools for people looking for mental health support.

The authors highlighted that in recent years, chatbots have made remarkable progress in addressing various health-related issues, including obesity and weight management, dementia (e.g., Endurance, which engages in meaningful conversations with individuals with Alzheimer's disease), substance use disorders [15-16], oncology care, and insomnia (e.g., Casper, a chatbot designed to assist those with sleep difficulties). They have also been utilized in prenatal services, HIV and sexual health education, and managing depression and anxiety. Notably, chatbots have demonstrated significant potential in mental health applications, contributing to suicide prevention, virtual cognitive-behavioral therapy, and psychoeducation. This study aims to explore and summarize the role of chatbots in the healthcare industry.

The authors in study [17] presented that AI chatbots have been effective in promoting treatment adherence, smoking cessation, and healthier lifestyles, with features like goal setting, monitoring, and real-time feedback. Studies showed mixed results on feasibility, acceptability, and usability, but these chatbots offer personalized services and scalability via platforms like smartphones and Facebook Messenger. Participants valued the nonjudgmental space chatbots provided, especially for sensitive communications.

The authors in study [18] said the rise of AI-empowered chatbots has also brought new security and privacy risks. Cybercriminals are using social engineering tactics like phishing through cross-platform messaging apps to create a new kind of cyber threat called "Smishing". These fake chatbots look legit but are designed to trick people into giving away sensitive personal data. To combat these threats we need to increase user awareness and be cautious with unfamiliar services. Implementing security measures like using temp tokens during chatbot sessions is crucial when devices are lost or compromised. Also, data anonymization techniques like de-identification, pseudonymization, and generalization should be used to protect sensitive data from unauthorized access. By doing all these organizations can fortify their defenses against privacy breaches and security issues with malicious chatbots.

The research also shows the increasing use of chatbots in healthcare settings to improve service and efficiency. Examples include Healthily [19] and Ada Health [20] which give users health advice and are now health information dissemination tools. In mental health, specialized chatbots like Woebot [21] are being used to deliver Cognitive Behavioral Therapy (CBT) to people with depression, PTSD, and anxiety. They also help patients with autism to learn and practice social skills as part of therapy. Beyond being therapy tools, chatbots also help with administrative tasks in healthcare facilities such as allowing patients to self-book appointments and track doctor availability. This integration in healthcare systems improves patient access and management and thus better healthcare delivery. Chatbots can also collect and process information from patients through structured questions about identity and health conditions. This information is used for patient admission, symptom monitoring, patient-doctor interaction, and documentation. Chatbots can also help with medication reminders for conditions that don't require in-person consultations. The healthcare application of chatbots not only enhances the level of patient experience and outcome but also maximizes organizational efficiency, hence ensuring that such technologies stay increasingly relevant in modern healthcare environments.

Another one of the chatbots is Gyant [22], designed to interact with users having minor non-emergency medical issues by asking questions regarding symptoms as well as general health status. An important feature of Gyant is its use of humor, human-like interaction, emojis, and memes to cope with the user successfully. However, the software is currently not available since it has been phased out. For example, Symptomate [23] is an AI chatbot, that allows patients to report their symptoms and provides them with a list of possible conditions. However, its accuracy is significantly lower than 80% compared to Ada Health. Nonetheless, this proves the fact that digital health solutions, in terms of their development and perfection, will be needed for maximum efficacy and reliability [24].

III. Limitations of Previous Work

Despite the studies in AI-powered chatbots that predict HD, it is clear that some of the previous attempts have significant disabilities. For instance, there is a severe lack of XAI, which usually leaves users and medical professionals unaware of the processes that govern the decisions they make when using a system. Moreover, most of these systems fail with issues of data privacy while dealing with delicate health information as they tend to leave their users vulnerable to breaches or unauthorized access. Another major problem is scalability as most models do not deliver optimally in various healthcare settings or with other patient populations. Moreover, the reliability of the decision-making functionality of these chatbots is incomplete, and conclusions may be as wrong as they are less encompassing. Last but not least, the problems of transparency continue to worsen the mistrust in these systems since the user does not know whether to believe the answers provided by the system. Collectively, these limitations underwrite the need for better methodologies that place more emphasis on user safety, trust, and clarity when using AI technologies in healthcare settings. A few of the limitations are shown in Table I:

TABLE I. Limitations of Previous Works

Ref.	Year	Disease Dataset	ML Algorithm/Decision Support System	XAI Implementation	Chatbot enabled System
[25]	2024	HD	DT	×	✓
[26]	2024	HD	Clinical Decision Support (CDS) system	×	✓
[27]	2023	Prostate Cancer	Hybrid Approach with NLP models (Named Entity Recognition, Intent Recognition, Sentiment Analysis, and Language Detection)	×	✓
[28]	2023	HD	XGBoost	✓	×
[29]	2023	HD	Bagging-QSVC	✓	×
[30]	2023	HD	Random Forest (RF)	×	×
[31]	2022	HD	Cox models plus symbolic regression	×	×
	2024	HD	RF	✓	✓

Table I summarizes the critical analysis of inherent limitations within previous works on the application of ML algorithms and decision support systems, particularly towards targeting HD, the prediction of prostate cancer. Much work never includes XAI techniques in their strategies, but this is a fundamental aspect of improving the transparency and trustworthiness in automated systems. For instance, although some models may lead to successful predictions of health-based outcomes, the inability to interpret may deter healthcare professionals from accepting this system for use in their service provision because they would want to understand the patterns guiding the prediction. Finally, while many works include chatbot functionalities to make interaction easier for users, it usually occurs in isolation from XAI and leads to systems that are user-friendly but less clear about their operational mechanisms. This is a disadvantage when it comes to user confidence, especially in more sensitive fields like healthcare. The deployment of advanced NLP techniques has only been moderately applied in some research works, thereby limiting the capabilities of these systems to better interact with users. Interactions may therefore not holistically deal with the intricacies of patient queries. In summary, these constraints call for further research to integrate both XAI and chatbot technologies with a focus on the construction of more solid, transparent, and user-centric healthcare solutions.

IV. Proposed Methodology

Technological advancement has intended the adoption of autonomous systems in most fields, with the application here being one of the most popular emerging applications of chatbots. Chatbots are becoming very popular, especially in the health sector, as dear guides for patients and health-related questions. However, these chatbots have encountered numerous problems such as issues related to patient medical records, insecure communication, and inability to provide clear and precise answers.

Knowing the problems calls for a rising demand to develop intelligent approaches [32-33] that would yield better results. Thus, this research work aims to provide an intelligent approach to develop a chatbot system that uses XAI. It sets out to mitigate prevailing challenges around chatbots in general with special emphasis on the healthcare industry to ensure that secure communications are implemented while providing clear responses and retrieving accurate information from patient records. The proposed chatbot system is shown in Fig. 1.

Fig. 1 represents the proposed approach, which comprises the training and validation phases. During the training phase, initially, patient data is acquired from the patient through a chatbot for secure and tamper-proof transactions, thereby enhancing data integrity and transparency within healthcare systems. The tamper-proof transactions are then forwarded to the preprocessing layer, involving normalization, handling missing values, and moving averages, and the processed data is then divided into training and testing sets, with respective ratios of 80% and 20%. Subsequently, the approach is trained on 80 percent of the data for predictive analysis using ML algorithm RF. The predictions are directed to XAI for comprehensive output explanations. If the output aligns with the predefined learning criteria, the results are stored in the cloud; otherwise, they are returned to the approach if the learning rate is not achieved.

In the validation phase, patient data is directly compared with the imported data stored in the cloud. If the criteria are met, indicating the presence of HD, the system is shown as "found". On the other hand, if the criteria are not met, signifying the absence of HD, the system is discarded.

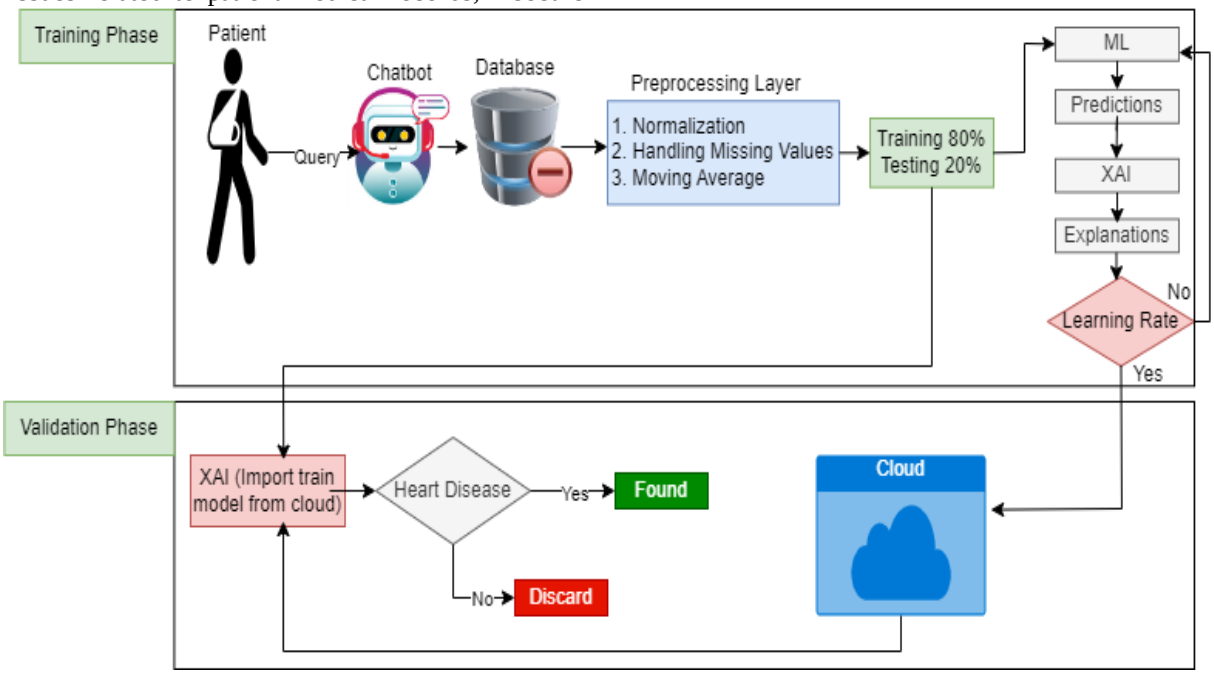

Fig. 1. Proposed chatbot system.

V. Dataset Description

The dataset utilized in this study comprises 308,855 entries & 19 features [34], providing a comprehensive overview of various health-related parameters. It encompasses features such as General Health, which is rated on a scale from 1 to 5 (with 5 indicating excellent health and 1 indicating poor health), recent Checkups (within the previous year), where 0 denotes no checkup, 1 represents a checkup within the last year, 2 for two years ago, 3 for a checkup within the last five years, and 5 for checkups more than five years ago. Exercise is captured through exercise habits, but supplemented by the prevalence of chronic diseases including HD, Skin Cancer, Other Cancers, Depression, Diabetes, and Arthritis by binary indicators where 1 means presence of the condition, and 0 means absence. Demographic information is also captured, in the Sex column where 1 means female, and 0 means male. Other determinants include stature in centimeters and weight in kilograms, which are necessary parameters in the BMI. Characteristics of lifestyle such as smoking and alcohol intake were taken into consideration, and dietary intake was reflected in fruit consumption, green vegetable consumption, and fried potato consumption. This length of variable allows for a very sharp analysis of determinants, which can thereby assess complex interrelations between lifestyle, demographic factors, and health outcomes in the prediction of heart disease with AI-driven chatbots.

VI. Dataset Structure

The Table II below reports the most important characteristics used in the dataset for health-related analysis, categorized by type of data. Such a collection of datasets contains health-related features pertaining to lifestyle habits, medical history, and demographic information. Qualitative attributes-the ones describing, for instance, "General Health," "Exercise," and "Depression"-represent statuses or histories related to a patient's health. Quantitative features refer to features whose variables include such examples as "Height (cm)" and "Weight (kg)". Attributes such as these are represented using numerical data types. They are fundamentally indispensable for developing predictive models for health outcomes, providing a complete view of someone's health profile.

TABLE II. Dataset Features with its Datatype

Feature Name	Data Type
General_Health	Object
Checkup-(Within_Previous_Year)	Object
Exercise	Object
Heart_Disease	Object
Skin_Cancer	Object
Other_Cancer	Object
Depression	Object
Diabetes	Object
Arthritis	Object
Sex	Object
Age_Category	Object
Height_(cm)	Float64
Weight_(kg)	Float64
BMI	Object
Smoking_History	Object
Alcohol_Consumption	Object
Fruit_Consumption	Object
Green_Vegetables_Consumption	Object
FriedPotato_Consumption	Object

It can be seen in Table II that the predictors of medical history features and the patterns of behavior were the features necessary to form an opinion relating to risks regarding health conditions. For example, "Heart Disease," "Skin Cancer," and "Other Cancer" revealed whether any patient was diagnosed with the said diseases, while "Smoking History" and "Alcohol Consumption" reflected lifestyle decisions likely to lead to various health conditions. The indicators available in this dataset are the intake of nutrition, like "Fruit Consumption" and "Green Vegetables Consumption" to assess the dietary pattern. By integrating all these different features, the dataset offers a complete foundation to analyze health patterns and to predict the possibility of getting ill. It could be a beneficial resource in healthcare research and study.

VII. System Block Diagram

This research work proposed a system that uses historical data for prediction, as shown in Fig. 2. It applies EDA to identify whether there is a need for pre-processing and whether it identifies outliers. Pre-processing includes handling null values, duplicate values, outliers, and class imbalance. Then, the data sets are split into test and training data where 20% is designated for the test set and 80% for the training set. The model trains and tests on those datasets, and then the accuracy, precision, recall, f1-score, and confusion matrix are used to achieve the best model. Then, using the chosen model, accurate prediction about the outcome with an explanation of LIME is applied.

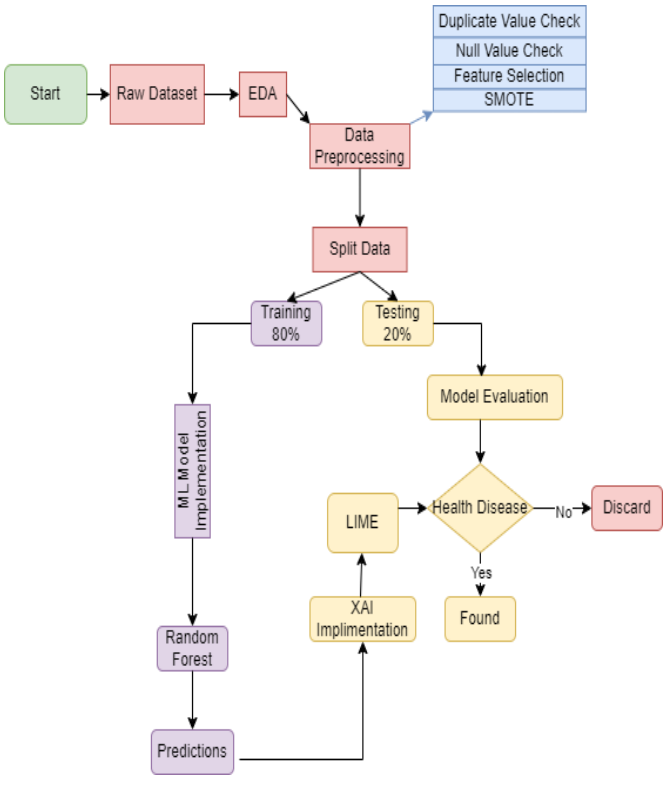

Fig. 2. System block diagram.

Fig. 2 shows that the research work illustrates an entire workflow in a system block diagram for a healthcare prediction

model that involves the integration of ML and XAI methodologies. Starting from the bottom, the raw healthcare data is gathered, followed by EDA to explore the dataset and draw meaningful conclusions based on it. The data would then be subjected to thorough preprocessing with checking for duplicate and null values, selection of best features, and balancing with SMOTE. With preprocessing, the dataset was divided into the training and the test sets. For this example, the training set was used to construct the Random Forest model, while the testing set was reserved to analyze its performance. The output from the model is then analyzed to determine whether any disease is present. If a disease is identified, it is further passed over the XAI method LIME [35] to give a clear explanation of which features contributed to the prediction. This approach enhances the interpretability and transparency of the model for healthcare professionals, such that they can trust the outcomes of the model more easily. The system ends by flagging some cases where a health condition is detected or discarding cases where no disease is found and then sending it out as a responsible healthcare delivery process.

VIII. Pseudo Code

The step-by-step pseudo code for the prediction of HD is shown below in Table III.

TABLE III. Pseudo Code

START
Step 1: Data Loading
Load dataset from source
Step 2: Data Preprocessing
Perform exploratory data analysis (EDA)
Remove duplicates and check for null values
Handle missing values if any
Feature selection based on relevance
Apply SMOTE for handling class imbalance (if needed)
Normalize/Standardize numerical features like "Height" and "Weight"
Step 3: Splitting Data
Split data into Training set (80%) and Testing set (20%)
Step 4: Model Implementation
Select a machine learning model (e.g., Random Forest)
Train the model on the Training set
Evaluate the model using the Testing set
Step 5: Model Evaluation
Calculate performance metrics (e.g., Accuracy, Precision, Recall)
Check if the model detects 'Health Disease' or 'No Disease'
IF model performance is satisfactory THEN
Proceed to explainable AI (XAI) implementation
ELSE
Modify model or preprocessing steps and retrain
Step 6: XAI Implementation (e.g., LIME)
Generate explanations for model predictions using XAI techniques
Display or store the explanations
Step 7: Make Predictions
Input new data into the trained model
Predict whether the patient has 'Health Disease' or 'No Disease'
Display predictions and explanations
Step 8: Decision and Action
IF 'Health Disease' is predicted THEN
Recommend further medical consultation
ELSE
No further action required.
END

As presented in Table III, pseudo-code illustrates a systematic approach to analyzing healthcare data and making predictions regarding health conditions. It begins with loading the dataset and running preprocessing steps as follows: exploratory data analysis, and missing value handling, and it applies SMOTE to the dataset for class balance. After this step is performed, the data set is split into a training and a testing set to permit the training of an ML algorithm chosen by the researcher. After evaluating the model's performance, the code incorporates explainable AI methods to enhance the interpretability of predictions, ultimately guiding healthcare decisions based on the results.

IX. Simulation Results

This research work proposed a chatbot system for HD prediction using the Random Forest (RF) approach and implemented it on the dataset containing 308855 samples. The data were distributed into 80 % training (247084 samples) and 20% validation (61771 samples). As stated in the equations, this approach finds the result using multiple statistical measures.

$$Accuracy\ (Acc) = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

$$Sensitivity\ (TPR) = \frac{TP}{TP+FN} \quad (2)$$

$$Specificity\ (TNR) = \frac{TN}{TN+FP} \quad (3)$$

$$Miss\ Rate\ (FNR) = 1 - Acc \quad (4)$$

$$Fall\ out\ (FPR) = \frac{FP}{FP+TN} \quad (5)$$

$$LR + ive\ (LR+) = \frac{TPR}{FPR} \quad (6)$$

$$LR - ive\ (LR-) = \frac{FNR}{TNR} \quad (7)$$

$$Precision\ or\ Positive\ Predictive\ Value\ (PPV) = \frac{TP}{TP+FP} \quad (8)$$

$$Negative\ Predictive\ Value\ (NPV) = \frac{TN}{TN+FN} \quad (9)$$

TABLE IV. Chatbot System Training Phase for HD Prediction using RF

	Total number of samples (49000)	**Result (Output)**	
Input	Expected output	Predicted Positive	Predicted Negative
		True Positive (TP)	False Positive (FP)
	229978 Positive	229750	228
		False Negative (FN)	True Negative (TN)
	17106 Negative	16806	300

It is shown in Table IV that the proposed chatbot system predicts the HD during the training period using RF. During training, 247084 samples are divided into 229978, 17106 positive, and negative samples. 229750 true positives are successfully forecasted, and no HD is recognized, but 228

records are mistakenly predicted as negatives, indicating the No Disease is recognized. Likewise, 17106 samples are obtained, with negative showing HD is identified and positive indicating No Disease. With 300 samples correctly identified as negative, showing the HD is recognized, and 16806 samples inaccurately foreseen as positive, representing No Disease is identified despite the presence of the HD.

It is shown in Table V that the proposed chatbot system predicts the HD during the validation period using RF. During validation, 61771 samples are divided into 56774, 4997 positive, and negative samples. 56736 true positives are successfully forecasted, and No Disease is recognized, but 38 records are mistakenly predicted as negatives, indicating the HD is recognized. Likewise, 4997 samples are obtained, with negative showing HD is identified and positive indicating No Disease. With 50 samples correctly identified as negative, showing the HD is recognized, and 4947 samples inaccurately foreseen as positive, representing No Disease is identified despite the presence of the HD.

TABLE V. CHATBOT SYSTEM VALIDATION PHASE FOR HD PREDICTION USING RF

	Total number of samples (49000)	**Result (Output)**	
Input	Expected output	Predicted Positive	Predicted Negative
		True Positive (TP)	False Positive (FP)
	56774 Positive	56736	38
		False Negative (FN)	True Negative (TN)
	4997 Negative	4947	50

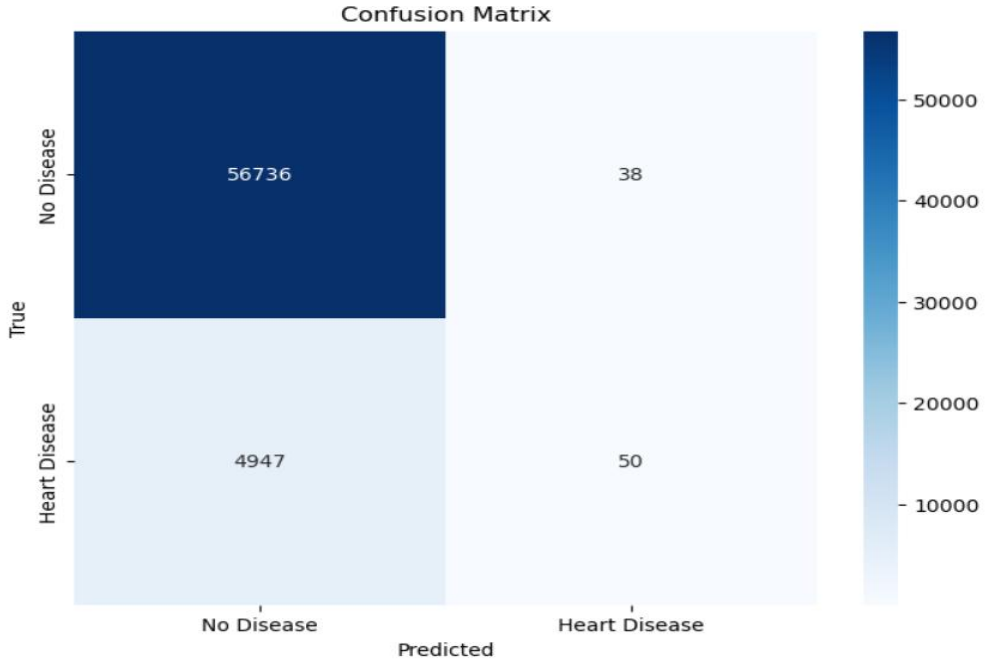

Fig. 3. Confusion matrix.

It is shown in fig. 3 that confusion matrix visually represents the performance of a system in predicting HD. The matrix shows that the system accurately identified 56,736 instances of HD (true positives) and misclassified 3,947 cases of HD as no disease (false negatives). It also identified 50 cases correctly as no disease (true negatives) but incorrectly flagged 38 as having HD when they did not (false positives). This matrix helps assess the balance between correct and incorrect predictions, indicating a higher rate of HD detection but with a considerable number of missed cases.

Fig. 4 shows that the ROC curve in the image evaluates the performance of a classification model by plotting the True Positive Rate (TPR) against the False Positive Rate (FPR). The curve shows a balanced trade-off between sensitivity (ability to detect positives) and the false alarm rate. The area under the ROC curve (AUC) is 0.83, indicating that the model performs well, but there is room for improvement. A perfect classifier would have an AUC of 1, meaning it distinguishes perfectly between positive and negative classes.

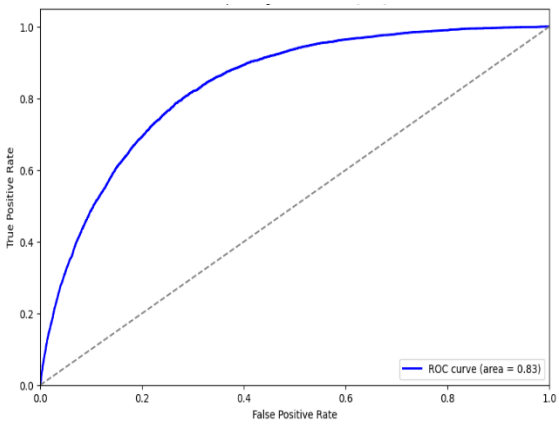

Fig. 4. Receiver operating characteristic (ROC) curve.

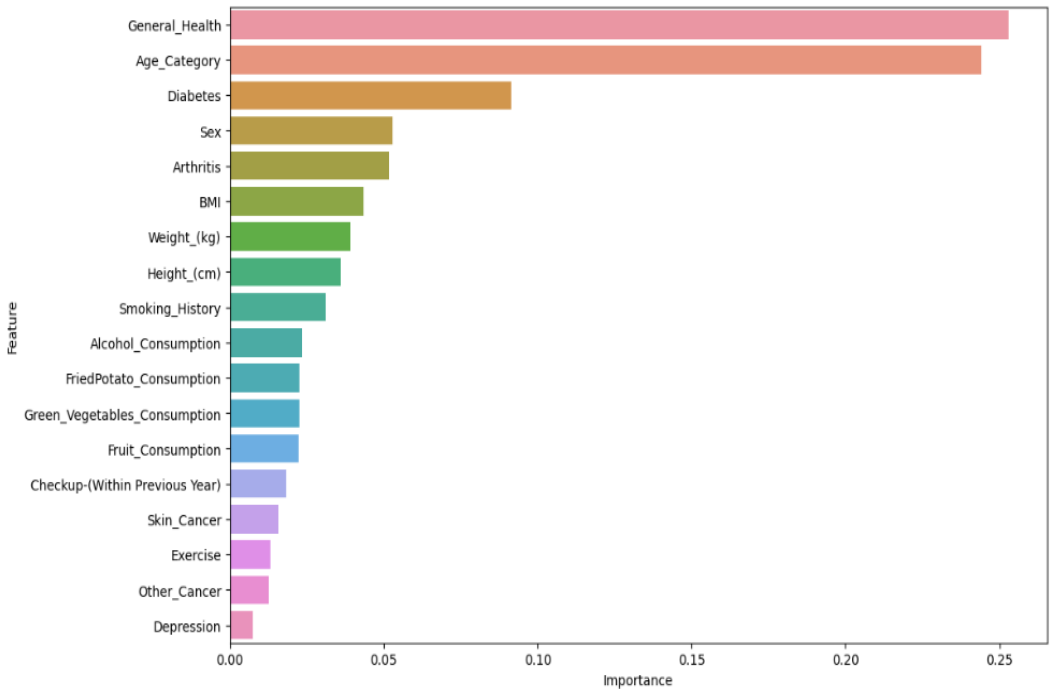

Fig. 5. Feature importance.

It is shown in Fig. 5 that the bar chart illustrates the feature importance ranking in a system, where each feature's contribution to the prediction outcome is displayed. General Health and Age Category are the most influential factors, contributing significantly to the system's predictions, followed by Diabetes and Sex. Features like Depression, Other Cancer, and Exercise have the least importance. The chart helps to identify which variables have the greatest impact, allowing for better interpretation and possible improvements in system design or understanding of the data.

TABLE VI. CHATBOT SYSTEM VALIDATION PHASE FOR HD PREDICTION USING RF

RF	Acc (%)	TPR (%)	TNR (%)	FNR (%)	FPR(%)	LR+	LR-	PPV (%)	NPV (%)
Training	93.10	93.18	56.82	6.90	0.43	2.16	0.1210	99.90	0.018
Validation	92.00	91.97	56.81	8.00	0.43	2.13	0.0014	99.93	0.010

Table VI shows that the Proposed chatbot system performance in terms of accuracy, sensitivity, specificity, miss rate, and precision during training using RF provides 93.10, 93.18, 56.82, 6.90, and 99.90, respectively. The suggested approach yields 92.00, 91.97, 56.81, 8.00, and 99.93 during the validation phase's accuracy, sensitivity, specificity, miss rate, and precision. Furthermore, the proposed chatbot system for HD prediction using RF approach yields 0.43, 2.16, 0.1210, and 0.018 in terms of fall-out likelihood positive ratio, likelihood negative ratio, and negative predictive value during training and 0.43, 2.13, 0.0014, 0.010 in terms of validation.

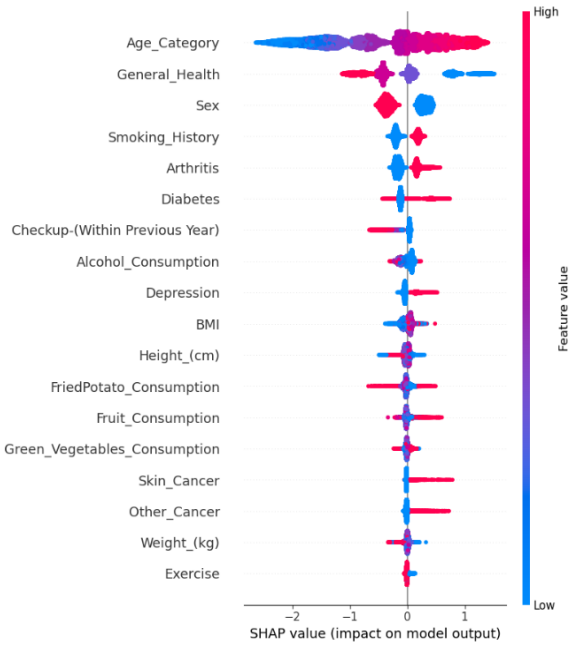

Fig. 6. SHAP value.

It is shown in fig. 6 that the SHAP (SHapley Additive exPlanations) plot highlights the impact of various features ona system's output. Each dot represents a single instance, with the position indicating the SHAP value, showing whether the feature drives the prediction towards a positive or negative outcome. Features like Age Category and General Health have the most influence, with higher feature values (shown in red) often leading to positive model outcomes. Conversely, low feature values (blue) push the predictions in the opposite direction. The plot helps explain how individual features contribute to the system's decisions.

Fig. 7 SHAP waterfall plot shows how individual features contribute to a single prediction. The base value E[f(x)]=−2.517 is the average prediction and features either increase (shown in red) or decrease (shown in blue) the predicted value. General Health has the most significant negative impact (-0.48), reducing the prediction, while Sex increases the prediction by +0.35. Other features such as Smoking History and Arthritis also contribute to the prediction, either positively or negatively. The final prediction value f(x)=−2.964 is the cumulative effect of all features.

Fig. 8 shows the prediction probabilities for a system evaluating HD risk. The system predicts a 94% probability for 'No Disease' and a 6% probability for HD. On the right, the feature contributions are split between the two outcomes: features like General Health (value = 4) and Age Category (value = 8) push the prediction towards HD, while features like Diabetes and Smoking History push towards no disease. The final prediction reflects the cumulative influence of all these factors on the system's output.

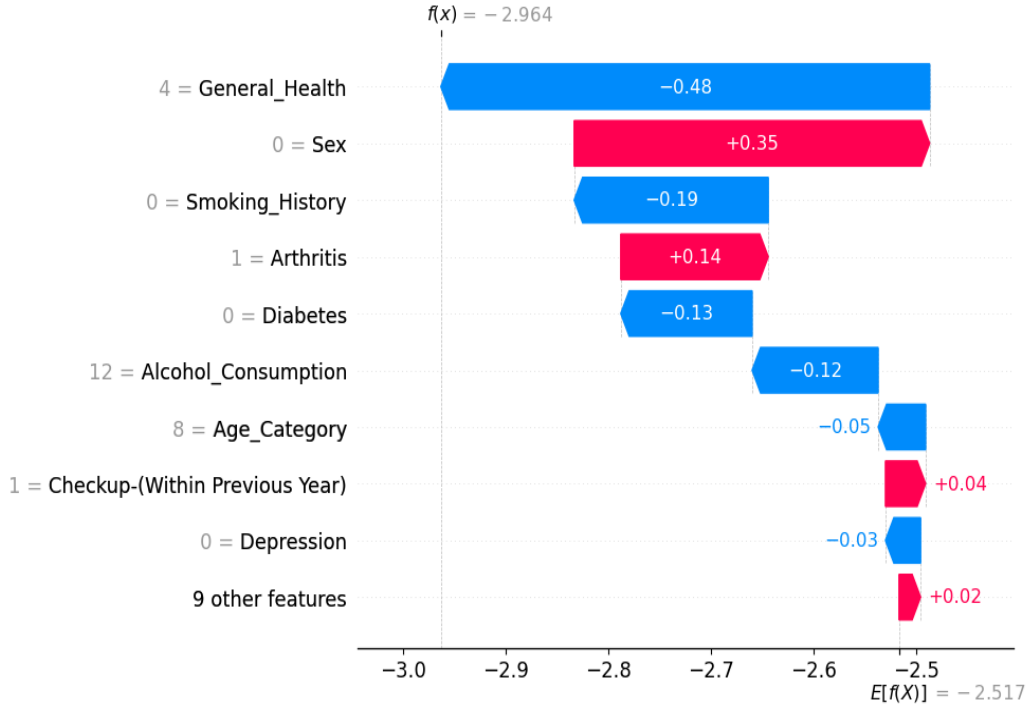

Fig. 7. SHAP waterfall impact.

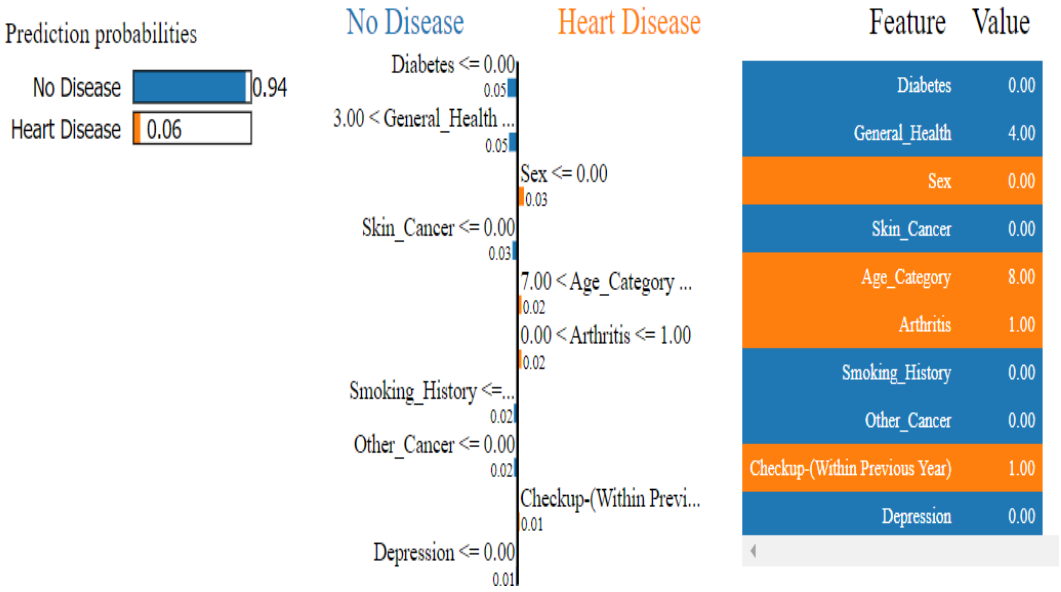

Fig. 8. LIME prediction as 'No Disease" found.

It is shown in Fig. 9 that LIME (Local Interpretable Model-agnostic Explanations) works by generating simplified, interpretable systems that approximate a complex system's decision-making process. In the figure 9, LIME highlights which features positively or negatively influence the outcome, shown by green (positive impact) and red (negative impact) bars. This visualization helps understand the contribution of each feature, such as diabetes, general health, or sex, to the system's prediction. LIME makes AI more interpretable by clarifying the factors driving specific decisions.

It is shown in Fig. 10 that the LIME prediction shows a 51% probability of HD and a 49% probability of no disease. Factors such as age, general health, and diabetes have strong contributions toward HD prediction, as highlighted in orange. Each feature listed, like the age category being greater than 9 and diabetes being present, increases the likelihood of HD, while features like "Other Cancer" lower it slightly. LIME explains how individual factors influence the system's decision, making the prediction more interpretable and understandable.

It is shown in Fig. 11 that in the LIME explanation, the features contributing to the prediction of HD are visualized with green (positive impact) and red (negative impact) bars. Significant positive contributors include age category, general health, and diabetes, indicating these factors increase the likelihood of HD. On the other hand, "Other Cancer" and alcohol consumption slightly reduce the probability, as shown in red. LIME effectively shows how each feature impacts the system's decision, highlighting HD is predicted.

Table VII highlights some previous chatbot systems with multiple approaches. The applied approaches also show the accuracies and miss rate.

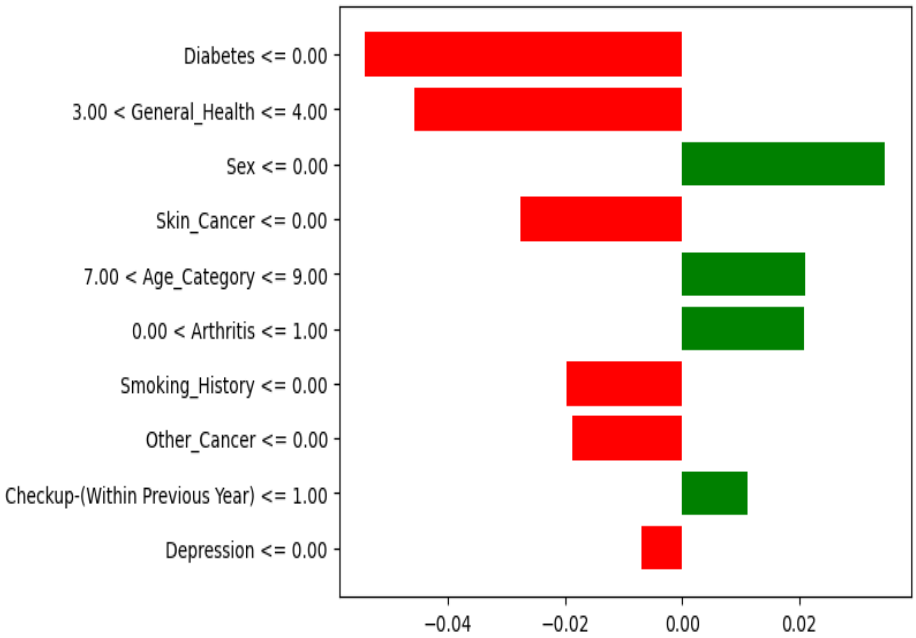

Fig. 9. LIME explanation as 'No Disease" found.

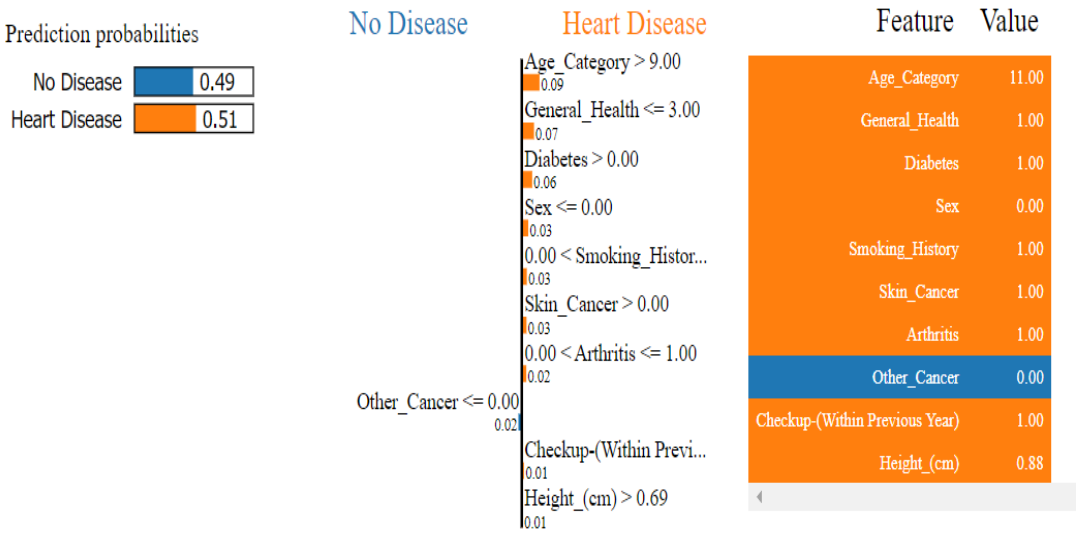

Fig. 10. LIME prediction as 'HD" found.

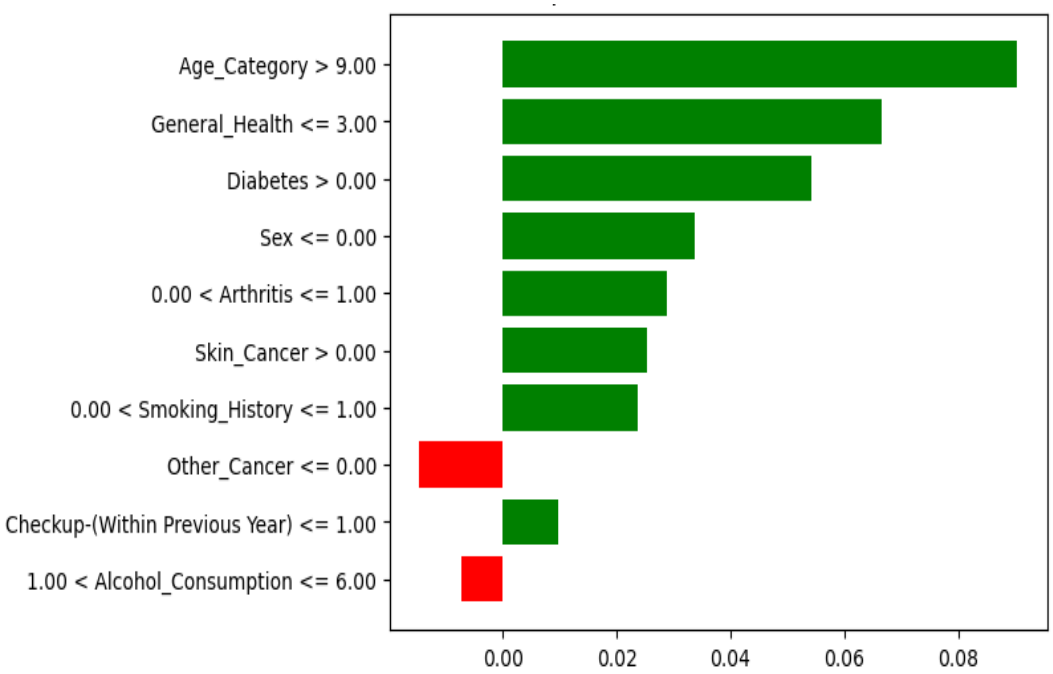

Fig. 11. LIME explanation as "HD" found.

TABLE VII. COMPARING THE PROPOSED CHATBOT SYSTEM PERFORMANCES WITH PREVIOUS APPROACHES

Ref	Year	Approach	Acc (%)	Miss-rate	Chatbot based Approach	XAI Implementation
[36]	2022	SVM	85.40	14.60	No	No
[37]	2021	Logistic Regression & KNN	87.5	12.5	No	No
[38[	2023	Multilayer perceptron with cross-validation	87.28	12.72	No	No
[39]	2021	KNN	84.86	15.14	No	No
[40]	2021	Extra Tree	87.0	13.0	No	No
[41]	2022	SVM	82.5	17.5	No	SHAP
[42]	2023	RF	74.0	26.0	No	SHAP
[43]	2024	DT	91.9	8.1	Yes	No
[44]	2023	Bagging-Quantum Support Vector Classifier (QSVC)	90.16	9.84	No	SHAP
		Proposed system (RF)	**92.0**	**8.0**	**Yes**	**SHAP & LIME**

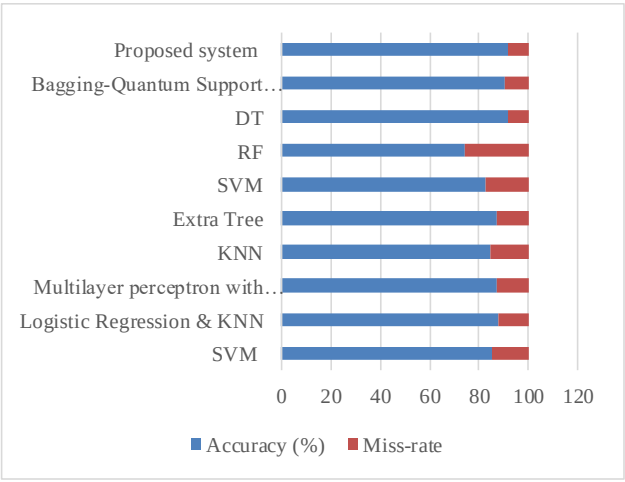

Fig. 12. Graphical representation of the previous approaches with the proposed system.

Table VII and fig. 12, compares the performance of the proposed chatbot system with previous ML approaches to predict HD. It is clearly shown that the proposed approach is better than the previous results in terms of accuracy and miss rate.

X. DISCUSSION

The proposed XAI-driven chatbot demonstrates strong potential in HD prediction by combining accurate ML models with user-friendly, interpretable outputs. This approach addresses the "black-box" limitations of traditional models, enhancing transparency and trust in healthcare applications. While the system shows promising results, its performance may vary across diverse populations, and further validation is needed to ensure its scalability and effectiveness in real-world settings. Future work will focus on addressing these limitations and integrating additional features to improve usability and adaptability.

XI. Conclusion

Heart disease is a significant global health challenge and a leading cause of mortality, with early detection being essential for preventing the disease's progression. Consequently, the objective of this study was to develop an explainable AI-driven chatbot system for predicting heart disease risk, effectively integrating advanced ML techniques with XAI methods. The novelty of the proposed system lies in its remarkable accuracy rate of 92% and an 8% miss rate, demonstrating its superiority over traditional approaches. By utilizing SHAP and LIME, the system boosts transparency in the decision-making process, permitting users to understand the rationale behind predictions. This innovative chatbot interface provides an accessible platform for interaction, ultimately fostering trust and promoting informed decision-making among healthcare providers and patients. The incorporation of XAI with ML in this context sets a new standard for responsible AI applications in healthcare, focusing on the requirement for continuous advancements in predictive modeling to address the ongoing challenges of HD.

XII. Limitations and Future Suggestions

Although XAI-driven chatbot demonstrates strong predictive performance, offering real-time, personalized HD risk assessments. Its ability to provide clear, interpretable results enhances trust and usability, particularly in healthcare settings where transparency is crucial. However, there are limitations: bias during the training of the system with potential biases in the training data, and reliance on specific input features that may not capture the overall picture of health indicators. Future research should continue to enhance this dataset using a larger, more diversified population, systems' robustness, and lifestyle and genetic factors, among others. Additionally, adding health monitoring data in real time will improve predictive accuracy. The long-term future path for perfecting the performance and experience of the chatbot will include continuous user feedback and iterative improvements on the developments themselves, thus ensuring that they continue to be valuable tools in preventive healthcare.

Integrating Local Channel Attention and Focused Feature Modulation for Wind Turbine Blade Defect Detection

Zheng Cao*, Rundong He, Shaofei Zhang, Zhaoyang Qi, Sa Li, Tong Liu and Yue Li
State Grid Jilin New Energy Group Co., Ltd, Changchun 130021, China

***Abstract*—In the wind power industry, the health state of wind turbine paddles is directly related to the power generation efficiency and the safe operation of the equipment. In order to solve the problems of low efficiency and insufficient accuracy of traditional detection methods, this paper proposes a wind turbine blade defect detection algorithm that integrates local channel attention and focus feature modulation. The algorithm first introduces the Mixed Local Channel Attention (MLCA) mechanism into the C2f module of the backbone network in YOLOv8 to enhance the extraction capability of the backbone network for key features. Then the Focal Feature Modulation (FFM) module is used to replace the original SPPF module in YOLOv8 to further aggregate global contextual features at different levels of granularity; finally, in the Neck part, the progressive feature pyramid AFPN structure is used to enhance the multi-scale feature fusion capability of the model, which in turn improves the accuracy of small object detection. The experimental results show that the proposed algorithm has an accuracy of 82.5%, a mAP50 of 78.6%, and GFLOPS of 8.5. In the detection of wind turbine blade defects, which possesses higher detection performance and real-time performance compared with the traditional methods, and is able to effectively identify common defects such as cracks, corrosion, and abrasion, and exhibits strong robustness and application value.**

***Keywords*—Fan blades; YOLO; attention mechanism; defect detection; inner-IoU**

I. Introduction

Wind energy, as a renewable energy source, is highly valued by countries around the world due to its cleanliness, environmental friendliness, and low carbon emissions. The utilization of wind energy is of great significance in supporting the dual-carbon development, thus holding an important position in the construction of China's clean energy system [1]. The wind turbine blade, as a crucial component in wind power generation, plays a key role in converting wind energy into electrical energy. However, due to the complex and diverse outdoor environment, wind turbine blades often suffer from erosion, cracks, delamination, and other damage defects, which affect the power generation efficiency of the units and even threaten the safety and service life of the wind turbines [2].

Traditional wind turbine blade defect detection primarily relies on manual inspection, which suffers from low efficiency, high costs, and strong subjectivity. Therefore, the real-time, efficient, and accurate detection of blade defects has become an urgent need in wind turbine blade defect identification. Existing wind turbine blade defect detection algorithms can be broadly categorized into those using physical sensing technology for detection and those employing computer vision technology for image recognition. Methods using physical sensing technology mainly focus on static detection with grating Energies [3] and electromagnetic ultrasonic testing [4].

In recent years, with the development of artificial intelligence technology and advancements in drone technology, drone aerial photography and object detection techniques have been widely applied to wind turbine blade defect detection [5, 6]. Kang Shuang et al. achieved defect detection on high-altitude wind turbine blades by analyzing temperature thresholds to extract effective features [7]. Yu et al. [8] trained a DCNN network to extract semantic features of defect areas for wind turbine blade recognition. Additionally, some experts and scholars have explored the optimization of deep learning-based object detection models. In the improvement of two-stage object detection algorithms, Zhang Chao [9] improved the backbone network of Mask RCNN by combining it with a multi-scale feature fusion FPN structure, enhancing the detection effect of wind turbine blade defects. Qu Zhongkan et al. [10] utilized DCNv2 and GIoU to improve Faster R-CNN, significantly enhancing the detection accuracy of delamination defects.

In the improvement of one-stage algorithms, the focus has mainly been on the YOLO series. Wu Yuping et al. [11] adopted a skip-connection feature fusion network structure in YOLOv3-Tiny and introduced the Inception module, significantly improving the detection accuracy of blade defects. Gao Wenjun [1-15] replaced the original feature extraction network of YOLOv4 with a GhostNet feature extraction network, successfully achieving lightweight blade detection models while maintaining good detection accuracy. Su Jia et al. [13] designed a multi-scale feature fusion mechanism in the YOLOv5 model, thereby improving the detection effect on small objects. Zheng Qishan [14] proposed a wind turbine blade defect detection method based on YOLOv5s as the baseline model, by replacing the fast spatial pyramid pooling (SPPF) structure in the backbone network and introducing the convolutional attention mechanism (CBAM) module, further enhancing the model's detection accuracy. Wang Zhengshuai [15] addressed the issue of low detection accuracy in complex environments by adding a Scoring module attention mechanism to the YOLOv5 baseline model, scoring each channel's features to filter out low-scoring features and fuse high-scoring features, thereby improving feature fusion capabilities and detection accuracy. Li Bing et al. [16] proposed an HSCA-YOLOv7 wind turbine blade defect detection algorithm, effectively solving the problem of

inconsistent defect scales in wind turbine blade images. Fu Jinyi et al. [17] proposed an improved small object detection algorithm, CA-YOLOv8, by embedding an aggregation capability module (CAM) and improving the C2f module, enhancing the ability to capture multi-scale detailed features of detection objects.

The methods for detecting defects in wind turbine blades in the past have gradually evolved from traditional manual methods to physical sensing technologies and computer vision technologies. In the latter, whether it is the early exploration based on temperature thresholds and DCNN networks, or the improvement of two-stage and one-stage target detection algorithms, the detection capabilities have been enhanced to a certain extent, but there are still shortcomings. For example, the complex background has a significant impact on the model's detection of defect areas. The defect areas in aerial images of wind turbine blades are mostly small targets, and different-scale targets have higher requirements for the model's feature processing ability. Therefore, the model in this paper aims to further optimize the defect detection algorithm of wind turbine blades for these problems and improve its detection accuracy and efficiency for small targets and multi-scale targets in complex environments.

The complex background of aerial wind turbine blade images significantly affects the model's detection of defect areas; the defect areas in aerial wind turbine blade images are mostly small objects, requiring high feature processing capabilities for different scale objects. To address these issues, this paper proposes a fusion of local channel attention and focal feature modulation object detection algorithm. This paper mainly improves the YOLOv8 model, with innovations focused on enhancing the overall feature extraction capabilities of the model and improving the detection capabilities for small-scale objects. The main innovations include the following four aspects:

1) Improving feature capture for small-scale objects: By integrating the MLCA module (Mixed Local Channel Attention) with the C2f module in YOLOv8's Backbone, the model's ability to capture details of small-scale objects is enhanced.

2) Enhancing overall detection accuracy: Using the FFM module (Focal Feature Modulation) to replace the original SPPF (Spatial Pyramid Pooling - Fast) module, further improving the model's overall detection accuracy.

3) Optimizing multi-scale feature fusion: Introducing AFPN (Asymptotic Feature Pyramid Network) to optimize multi-scale feature fusion in object detection.

4) Improving model accuracy and generalization: Using Inner-IoU to optimize the original model's loss function, further enhancing model accuracy and generalization capabilities

The subsequent part of this paper will conduct a detailed analysis of the algorithm structure, including the improvement principles of the C2f-MLCA and FFM modules in the Backbone part, the AFPN structure in the Neck part, and the role of the Inner-IoU loss function. Then, through the experimental results and analysis, the configuration such as the dataset will be introduced, and various experiments and evaluations will be carried out using multiple indicators to demonstrate the performance advantages of the algorithm. Finally, a conclusion will be drawn to summarize the performance improvement and application significance of this algorithm in the defect detection of wind turbine blades.

II. Improved YOLOv8 Algorithm Structure

A. Improved Network Model

This paper proposes a fusion of local channel attention and focal feature modulation object detection algorithm based on YOLOv8. In the Backbone of YOLOv8, the MLCA module is used to construct the C2f-MLCA module, improving the model's ability to capture details of small-scale objects; secondly, the FFM module is used to replace the SPPF module in the Backbone to aggregate contextual information at different granularity levels; finally, the AFPN structure is used in the Neck part to enhance the model's multi-scale feature fusion capabilities. The overall framework of the improved network is shown in Fig. 1.

B. Improvements in the Backbone

a) C2f-MLCA: There are numerous small-scale objects in wind turbine blade defects [18]. To enhance the detection effect on these small-scale objects, the module used needs to possess better global and local detail feature extraction capabilities. In YOLOv8, multiple Conv modules and C2f modules constitute the backbone network, which is used to extract deep features from images. However, the Bottleneck module in the C2f module causes the network to superimpose a large amount of information at high-frequency positions, while neglecting information at low-frequency positions, thereby reducing the model's feature extraction capability for small objects, as shown in Fig. 2.

MLCA is a lightweight attention module that can simultaneously consider channel information and spatial information, and combine local and global information to enhance the expressive effect of the network [19]. Therefore, the MLCA module is introduced into the Bottleneck of the C2f module, as shown in Fig. 3.

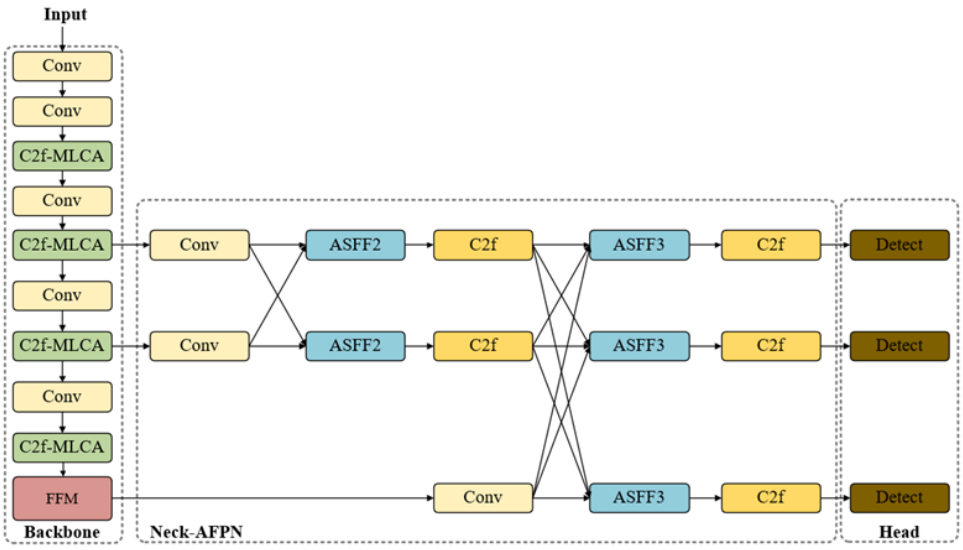

Fig. 1. Overall framework of the model.

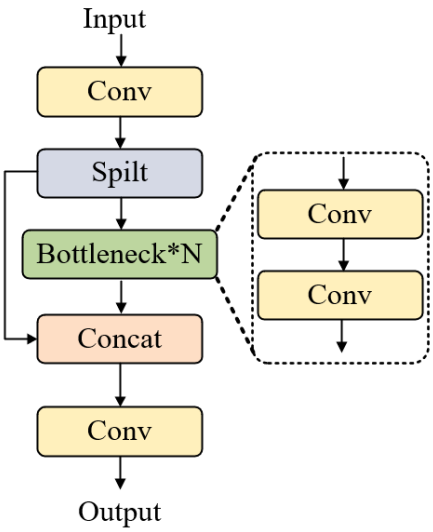

Fig. 2. C2f module.

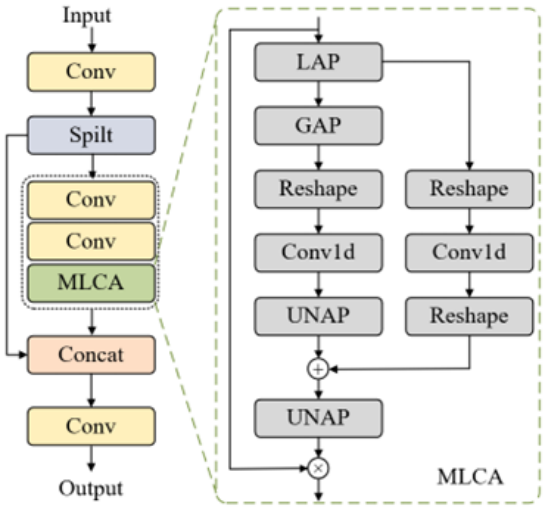

Fig. 3. MLCA module.

The MLCA module primarily utilizes local average pooling and global average pooling to capture global and local feature information of the entire input feature map, and on this basis, performs channel attention and spatial attention to improve feature extraction accuracy. A feature map of size $C \times H \times W$ is first processed by local average pooling (LAP) and global average pooling (GAP) to obtain statistical information of the entire feature map. Subsequently, the features after local and global pooling are transformed by a one-dimensional convolution (Conv1d) to compress the feature channels while maintaining the spatial dimensions, and then rearranged to adapt to subsequent operations. For the features after local pooling, after one-dimensional convolution and rearrangement, they are combined with the original input features through multiplication operations for feature selection to enhance attention to useful features; for the features after global pooling, after one-dimensional convolution and rearrangement, they are combined with the local pooling features through addition operations to fuse global context information. Finally, the feature map processed by local and global attention is restored to the original spatial dimension through anti-average pooling (UNAP) operations to achieve the purpose of mixed attention.

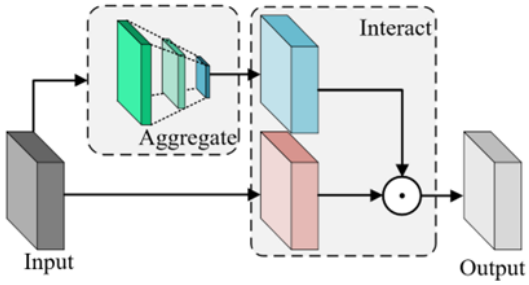

Fig. 4. FFM module.

b) FFM module: During the detection process of wind turbine blade defect objects, the model is easily affected by the complex background interference associated with the samples, making it difficult to fully extract the deep features of the samples. YOLOv8 uses the SPPF module in the Backbone part

to aggregate multiple scale features, but it lacks sufficient modeling of long-range visual context information. In feature information processing, it only concatenates feature map information of different scales to achieve feature aggregation, ignoring the interaction and aggregation of multi-granularity information under complex background interference. To address this issue, this paper introduces a more efficient focal feature aggregation module, FFM [20]. By extracting context information from local to global at different granularity levels and performing gated aggregation, it improves the interference of complex background information on the feature extraction process of the model's backbone network. The structure of the FFM module is shown in Fig. 4.

First, the input feature $X \in \mathbb{R}^{H\times W\times C}$ is fed into the aggregation module to aggregate contextual features, obtaining aggregated features. This process mainly includes two steps: The first step involves sending the input feature into a linear layer to extract the initial level feature Z^0. Then, the initial level feature is processed through a Depthwise Convolution (DWConv) and a GeLU function to obtain the next level feature until the L -th level feature. In this way, a total of (L+1) level features are obtained. These features are considered as contextual information at different granularity levels, as shown in Eq. (1) and Eq. (2):

$$Z^0 = linearlayer(X) \tag{1}$$

$$Z^l = GeLU(DWConv(Z^{l-1})) \tag{2}$$

Among them, $l \in \{1,\cdots,L\}$ represents different levels.

The second step is gated aggregation. By gated aggregation, contextual feature information at different granularity levels is condensed into a single feature vector as the aggregated feature Z^{Out}, with the calculation formula as follows:

$$Z^{Out} = \sum_{l=1}^{L+1} G^l \odot Z^l \tag{3}$$

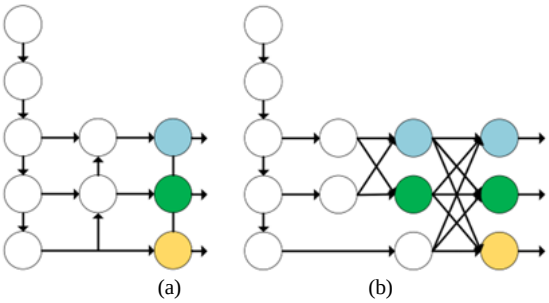

Fig. 5. The schematic of the network before and after the improvement of the Neck part. (a) YOLOv8; (b) YOLOV8+AFPN.

where G^l is the gate weight obtained by the l-th level feature through a linear layer.

Then, the obtained aggregated feature Z^{Out} is processed through a linear layer and element-wise multiplied with the feature query value to obtain the final output focal modulation feature Y, with the calculation formula as follows:

$$Y = q(X) \odot linerlayer(Z^{Out}) \tag{4}$$

where $q(\cdot)$ is the query projection function for obtaining the feature query value; $\odot$ represents element-wise multiplication.

The FFM module achieves this not only by expanding the receptive field and effectively mitigating the interference from the complex background in wind turbine blade defect samples but also by more efficiently obtaining contextual information from granularity levels, thereby enhancing the feature extraction capability of the Backbone.

C. Improvements in the Neck Part

In the Neck part, the AFPN structure [21] is adopted instead of the original FPN+PAN structure in YOLOv8. This is because, during the feature extraction process, the downsampling process is dominated by large objects, causing the feature representation of small objects in the object area to be confused or blurred, thereby affecting the detection effect of small objects. The AFPN structure used in this paper can optimize the multi-scale feature fusion process. By gradually fusing low-level and high-level features, it avoids the loss and degradation of information, as shown in Fig. 5.

The AFPN structure can adaptively fuse features of different levels in the Neck. Firstly, it fuses two adjacent low-level features, and then progressively incorporates higher-level features. This approach alleviates the conflict of multi-object information that arises from each spatial location during the feature fusion process. Specifically, during the multi-level feature fusion process in the Neck part, an adaptive spatial fusion module (ASFF) is used to assign different spatial weights to features of different levels. Then, the features of different levels are fused together using a weighted sum method, with the specific calculation formula as follows:

$$y_{ij}^{\ell} = \sum_{n=1}^{\ell} \alpha_{ij}^{n} x_{ij}^{n\to\ell} \tag{5}$$

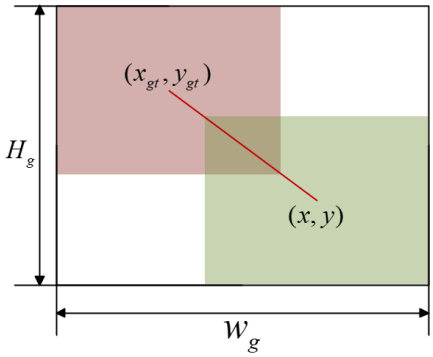

Fig. 6. Parameter definition.

Where y_{ij}^{ℓ} represents the features after adaptive spatial fusion, α_{ij}^{n} represents the spatial weight of the features at the ℓ level in the hierarchy, and $\sum_{n=1}^{\ell} \alpha_{ij}^{n} = 1$; $x_{ij}^{n\to\ell}$ represents the feature vector from the n-th level to ℓ at position (i,j).

D. Improvement of Loss Function

a) CIoU loss: The original YOLOv8 model employs the CIoU Loss as the bounding box regression loss function. Let the ground truth box be denoted as $\vec{B}_{gt} = [x_{gt}, y_{gt}, w_{gt}, h_{gt}]$ and the predicted box as $\vec{B} = [x, y, w, h]$, where x and y represent the center coordinates of the bounding box, and w and h represent the dimensions of the box. The original CIoU Loss is defined by Eq. (6)-Eq. (9) as follows:

$$L_{CIoU} = L_{IoU} + \frac{(x - x_{gt})^2 + (y - y_{gt})^2}{(W_g + H_g)^2} + \alpha v \tag{6}$$

$$L_{IoU} = 1\text{-}IoU = 1 - \frac{W_i H_i}{wh + w_{gt}h_{gt} - W_i H_i} \tag{7}$$

$$\partial = \frac{v}{L_{IoU} + v} \tag{8}$$

$$v = \frac{4}{\pi^2}(\tan^{-1}\frac{w}{h} - \tan^{-1}\frac{w_{gt}}{h_{gt}})^2 \tag{9}$$

In the equation, L_{IoU} is used to measure the overlap between the predicted box and the ground truth box, α is a balancing parameter, and v is used to measure the consistency of the aspect ratio. The remaining parameters are defined as shown in Fig. 6.

b) Inner-IoU: The existing IoU-based bounding box regression still focuses on accelerating convergence by adding new loss terms, while neglecting the limitations of the IoU loss term itself. In practical applications of wind turbine blade defect detection, the original bounding box regression process cannot self-adjust according to different detectors and detection tasks, resulting in low detection efficiency and accuracy for dense small objects or complex environments with multiple scales. To address this issue, Inner-IoU loss [22] is chosen, which calculates the IoU loss through an auxiliary bounding box. For different datasets and detectors, the scale of the auxiliary bounding box used to calculate the loss can be controlled by a scale factor. The definition of Inner-IoU is shown in Eq. (10)-(16).

$$b_l^{gt} = x_c^{gt} - \frac{w^{gt} * ratio}{2}, b_r^{gt} = x_c^{gt} + \frac{w^{gt} * ratio}{2} \tag{10}$$

$$b_t^{gt} = y_c^{gt} - \frac{h^{gt} * ratio}{2}, b_b^{gt} = y_c^{gt} + \frac{h^{gt} * ratio}{2} \tag{11}$$

$$b_l = x_c - \frac{w * ratio}{2}, b_r = x_c + \frac{w * ratio}{2} \tag{12}$$

$$b_t = y_c - \frac{h * ratio}{2}, b_b = y_c + \frac{h * ratio}{2} \tag{13}$$

$$inter = (\min(b_r^{gt}, b_r) - \max(b_l^{gt}, b_l)) * (\min(b_b^{gt}, b_b) - \max(b_t^{gt}, b_t)) \tag{14}$$

$$union = (w^{gt} * h^{gt}) * (ratio)^2 + (w * h) * (ratio)^2 - inter \tag{15}$$

$$IoU^{inner} = \frac{inter}{union} \tag{16}$$

In the Inner-IoU Loss, the variable ratio corresponds to the scale factor, which typically ranges from [0.5, 1.5]. The traditional IoU calculation method considers the overlap area between the predicted bounding box and the overall bounding box, while Inner-IoU focuses more on the core part of the bounding box to make a more precise judgment of the overlap area.

III. Experimental Results and Analysis

A. Experimental Dataset

The data used in this paper are sourced from images taken by inspection personnel at a wind farm during the inspection of wind turbine blades. The division of the aerial wind turbine blade defect dataset is shown in Table I, totaling 784 images with a resolution of 1200*900. The dataset is randomly divided into training, validation, and test sets in a ratio of 7:2:1.In the defect detection of wind turbine blades, 70% of the data is used for training to enable the model to learn multiple features and enhance performance. The 20% validation set assists in training and optimizing the model. The 10% test set independently evaluates to ensure objectivity and accuracy. The 7:2:1 data division ratio balances multiple key factors and enhances the reliability of the experiment.

B. Experimental Environment and Parameter Configuration

The operating system used in this experiment is Ubuntu 18.04, with GPU being NVIDIA Geforce RTX 3090 and CPU being Intel(R) Xeon(R) Gold 6148. The deep learning framework is Pytorch-2.1.2. During the training of the object detection model, the number of training epochs is set to 200, the momentum size is set to 0.937, the batch size is set to 16, and the initial learning rate is set to 0.0001.

C. Experimental Evaluation Metrics

To verify the effectiveness of the improvements in the proposed algorithm, the model is evaluated using four metrics: Precision (P), Recall (R), Average Precision (AP), and mean Average Precision (mAP). The definitions of these metrics are given in Eq. (17)-(20), where n is the total number of predicted bounding box categories.

$$P = \frac{TP}{TP + FP} \tag{17}$$

$$R = \frac{TP}{TP + FN} \tag{18}$$

$$AP = \int_0^1 P(R)dR \tag{19}$$

$$mAP = \frac{1}{n}\sum_{i=1}^{n} AP(i) \tag{20}$$

D. Results Comparison and Analysis

a) Comparative analysis of different object detection model: To verify the advanced nature of the proposed method

for wind turbine blade defect detection, the proposed improved algorithm is compared with other mainstream object detection model algorithms on the wind turbine blade defect dataset. The experimental results are shown in Table II. From Table II, it can be seen that the proposed improved algorithm significantly outperforms the two-stage models Faster R-CNN [23] and Cascade R-CNN[24] in terms of mAP and detection speed. Compared to the single-stage object detection algorithms YOLOv3[25],YOLOv4[26],YOLOv5s,YOLOv5l,YOLOv8s,YOLOv9[27],YOLOv10[28] and YOLOv8n, the proposed algorithm achieves a substantial improvement in mAP while maintaining a high level of accuracy and a fast detection speed, indicating that the proposed method has certain advantages.

To provide a more intuitive comparison of the detection effects before and after the improvement of the proposed algorithm with other mainstream YOLO series algorithms, the detection results of different scenarios are compared and displayed in Fig. 7(a)-(f). The first row represents complex background scenarios, the second row represents scenarios with multiple types of defects, the third row represents scenarios with densely distributed small objects, and the fourth row represents scenarios with multiple types of defects and small objects. It can be seen from the comparison that the proposed algorithm has a lower rate of missed detections and false detections and higher recognition accuracy compared to other algorithms.

TABLE I. TABLE OF DATASET DIVISION FOR AERIAL WIND TURBINE BLADE DEFECTS

Fan blade defect name	Quantity of categories
gelcoat_off	156
cracks	374
surface_erosion	254

TABLE II. COMPARISON EXPERIMENT OF DIFFERENT OBJECT DETECTION MODELS

Model	P/%	R/%	mAP50/%	mAP50-95/%	GFLOPs
Faster R-CNN	75.4	66.0	73.5	43.1	7.1
Cascade R-CNN	72.5	67.8	72.7	44.2	7.1
YOLOv3	73.5	67.9	71.9	43.3	6.9
YOLOv4	76.6	65.9	74.9	45.4	6.7
YOLOv5s	78.4	65.3	75.2	44.4	23.8
YOLOv9s	78.6	66.4	74.6	50.2	26.7
YOLOv10n	72.4	58.9	71.8	40.6	8.2
YOLOv8s	78.2	67.7	75.8	48.6	28.4
YOLOv8n	77.1	68.7	74.6	46.4	8.1
Ours	82.5	71.6	78.6	51.7	8.5

b) Module ablation experiment results: To verify the contribution of each improvement to the proposed algorithm, ablation experiments were conducted. Under the same experimental conditions, YOLOv8n was used as the baseline model, and a series of ablation experiments were performed by sequentially adding each improvement measure. The results are shown in Table III. From the comparison of experimental results in Table III, it can be seen that the original YOLOv8n model performs relatively basic across various metrics, with mAP50 at 88.4%, P at 65.2%, R at 73.2%, and so on. As different improvement methods were introduced, the performance of each model improved. For example, YOLOv8n+MCLA showed progress in some metrics compared to the original model; YOLOv8n+FFM, YOLOv8n+Neck improvement, YOLOv8n+Inner-IoU, and other single or combined improvement methods also enhanced the model's performance to varying degrees. However, the proposed model outperformed in all metrics. It achieved an mAP50 of 91.4%, higher than all other improved models; P was 67.8%, R was 76.5%, showing good performance in accuracy and recall. Additionally, the mAP50-95% metric was 71.6%, higher than other models, indicating that the proposed model maintains high detection accuracy across different confidence levels. Although the GFLOPs slightly increased, it remained within a reasonable range.

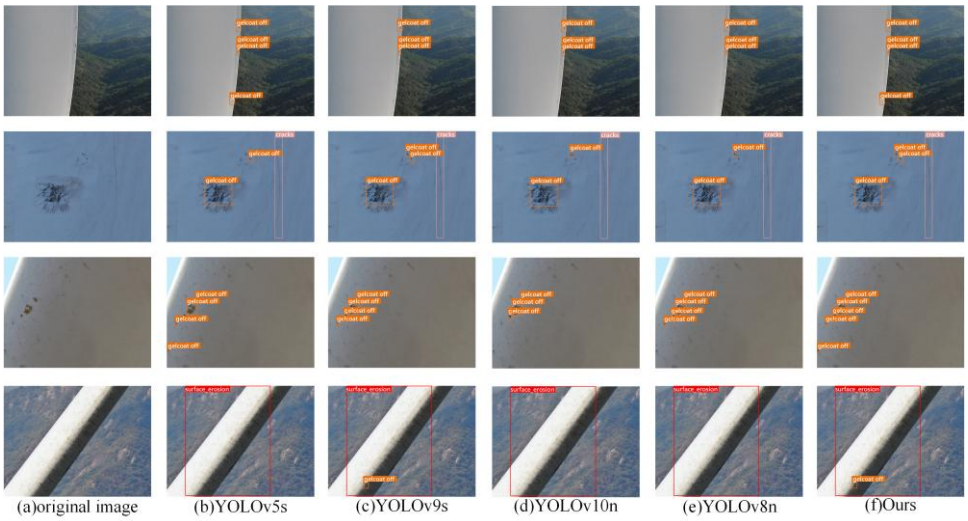

Fig. 7. Comparison of detection effect of different methods before and after improvement.

TABLE III. RESULTS OF ABLATION EXPERIMENT

Model	mAP50/%			P/%	R/%	mAP50/%	mAP50-95/%	GFLOPs
	surface_ erosion	cracks	gelcoat _off					
YOLOv8n	88.4	65.2	73.2	77.1	68.7	74.6	46.4	8.1
YOLOv8n+MCLA	89.6	66.2	73.6	78.6	68.8	74.9	48.7	7.6
YOLOv8n+FFM	88.9	66.3	75.6	77.8	68.6	76.9	46.8	7.8
YOLOv8n+Neck	90.4	65.4	76.3	78.2	69.0	77.4	48.2	8.5
YOLOv8n+Inner-IoU	90.6	67.0	76.4	80.2	70.8	78.0	48.7	8.1
YOLOv8n+ MCLA +FFM	88.7	67.1	75.8	80.6	71.2	77.2	47.5	7.8
YOLOv8n+ MCLA +FFM+ Neck	91.2	67.6	76.0	81.2	70.3	78.3	47.9	8.5
YOLOv8n+ MCLA +FFM +Inner-IoU	90.6	67.2	76.5	82.1	71.4	78.1	48.2	7.8
YOLOv8n+Neck+Inner-IoU	89.6	67.4	75.2	81.7	71.3	77.4	50.6	8.5
Ours	91.4	67.8	76.5	82.5	71.6	78.6	51.7	8.5

TABLE IV. PERFORMANCE OF MODELS WITH DIFFERENT C2F-MCLA NUMBERS

Model	mAP50/%	GFLOPs
YOLOv8n	74.6	8.1
C2f-MCLA*1	74.9	7.6
C2f- MCLA *2	74.7	7.6
C2f- MCLA *3	75.1	7.7

In summary, the proposed model, by integrating multiple improvement methods, demonstrated outstanding performance in defect detection tasks, providing a more effective solution for detecting issues such as surface erosion cracks and gel coating detachment.

c) Impact of C2f-MLCA module on the proposed model: In YOLOv8's Backbone, there are three instances where the C2f module is used. The stacking of different numbers of C2f-MCLA modules has varying impacts on network performance and lightweighting. To determine the optimal number of improvement modules for peak performance, YOLOv8n was used as the baseline algorithm, and the first, the first two, and all C2f modules were improved. The network performance with different numbers of C2f-MCLA modules was compared, with the module improvement sequence following the network structure hierarchy. The experimental results are shown in Table IV.

The mAP50 of YOLOv8n is 74.6%, and GFLOPs is 8.1. The C2f-MCLA series achieves mAP50 values close to or slightly higher than YOLOv8n under different configurations, with C2f-MCLA*3 reaching 75.1%; and the series has GFLOPs around 7.6 or 7.7, indicating relatively lower computational complexity. Overall, the C2f-MCLA series strikes a good balance between object detection accuracy and computational efficiency, potentially offering more advantages in scenarios with limited computational resources or high real-time requirements, providing a reference for selecting object detection algorithms.

d) Evaluation of model generalization and robustness: In the field of object detection, a model's generalization capability is primarily reflected in its ability to adapt well to changes brought by different datasets. The robustness of a model focuses more on its ability to better adapt to the effects brought by changes in sample backgrounds and multiple angles. To evaluate the generalization and robustness of the proposed method, 40 wind turbine defect samples under multiple backgrounds and angles were selected for experimental detection, with results shown in Table V.

TABLE V. EVALUATION RESULT

Model	Number of correct identifications	Accuracy
YOLOv8n	32	80%
YOLOv8n+MCLA	37	92.5%
YOLOv8n+FFM	37	92.5%
YOLOv8n+AFPN	32	80%
YOLOv8n+Inner-IoU	37	92.5%
YOLOv8n+ MCLA +FFM	36	90%
YOLOv8n+ MCLA +FFM+ AFPN	37	92.5%
YOLOv8n+ MCLA +FFM +Inner-IoU	37	92.5%
YOLOv8n+AFPN+Inner-IoU	33	82.5%
Ours	37	92.5%

In the original YOLOv8n model, the number of correctly identified objects is 32, with an accuracy rate of 80%. By separately introducing improvements such as MCLA, FFM, AFPN, and Inner-IoU, the model's performance has been enhanced to varying degrees. Notably, YOLOv8n + MCLA, YOLOv8n + FFM, YOLOv8n + Inner-IoU, YOLOv8n + MCLA + FFM + AFPN,YOLOv8n+MCLA+FFM+Inner-IoU, and the model pro-posed in this study all achieved 37 correctly identified objects and a high accuracy rate of 92.5%. Although the accuracy rate is the same as that of the above-mentioned models, the improvement measures such as MLCA, FFM, AFPN, and Inner-IoU integrated in this model collaborate with each other. The AFPN structure helps maintain a high accuracy rate; the MLCA module enhances the data processing ability, giving it an advantage in feature learning. The current similar accuracy rate might be a phased performance, and the scalability

of its architecture indicates that it has greater potential to surpass other models in the field of wind turbine blade defect detection in the future. This clearly indicates that these improvement methods have a significant effect on enhancing the accuracy of object recognition. However, despite some improvements in YOLOv8n+AFPN and YOLOv8n+AFPN+Inner-IoU, the extent of improvement is relatively small. Overall, the model proposed in this study performs excellently in the task of detecting defects in wind turbine blades, providing valuable references for further optimization of the YOLOv8n model.

IV. Conclusion

The detection of defects in wind turbine blades is of great significance for intelligent inspection in wind farms [29-30]. To address the practical issues of existing algorithms for detecting defects in wind turbine blades, such as insensitivity to small object areas, difficulty in feature extraction, and challenges in dealing with the effects of complex environments, this paper proposes a defect detection algorithm for wind turbine blades that integrates local channel attention and focal feature modulation. Through experiments on a specific dataset of wind turbine blade defects, the proposed method improves the accuracy by 5.4%, the recall by 2.9%, and mAP50 by 4.2% compared to the baseline method, with enhanced generalization and robustness. The proposed method also demonstrates certain advantages over other advanced object detection methods, providing a solution to assist in the intelligent inspection of wind farms. In the future, we will continue to focus on model compression and acceleration in terms of algorithm optimization, improve the attention mechanism to enhance the detection speed and accuracy, and increase the application value of the algorithm.

Construction and Optimization of Multi-Scenario Autonomous Call Rule Models in Emergency Command Scenarios

Weiyan Zheng, Chaoyue Zhu*, Di Huang, Bin Zhou, Xingping Yan, Panxia Chen
Zhejiang Dayou Industrial Co., Ltd. Hangzhou Science and Technology Development Branch, Hangzhou, 310000, China

***Abstract*—In response to the slow processing speed, weak anti-interference, and low accuracy of autonomous call models in current emergency command scenarios, the research focuses on the fire scenario, aiming to improve the emergency response efficiency through technological innovation. The research innovatively integrates digital signal processing algorithm and two-tone multi-frequency signal detection algorithm to develop a hybrid algorithm. Then, a novel autonomous call model based on the hybrid algorithm is constructed. The comparative experimental results indicated that the accuracy of the hybrid algorithm was 0.9 and the error rate was 0.05, which was better than other comparison models. The average accuracy and comprehensive performance score of the model were 0.95 and 97 points, respectively, both of which were better than comparison models. The results confirm that the autonomous call model proposed in this study can accurately and quickly judge emergency scenarios and handle calls, and provide new ideas and theoretical basis for emergency command and rescue of fire and other disasters, with broad application prospects.**

***Keywords*—Digital signal processing algorithm; dual tone multi-frequency signal detection algorithm; fire; autonomous call model**

I. Introduction

The emergency command in the field of emergency rescue faces many challenges, including signal interference, inaccurate prediction, and slow response. These problems are particularly acute during disasters, which may result in delayed rescue operations and wasted resources. With the continuous progress of digital and intelligent technology, the autonomous calling model is increasingly being applied in various industries. In emergency command and rescue, attempts have also been made to introduce autonomous call rule models [1]. Many domestic and foreign scholars have explored the application of autonomous call models. For example, Zardini et al. proposed a new on-demand autonomous call mobile model to solve the existing large transportation demand and road congestion. The results showed that the proposed autonomous call mobile model saved 70% of the travel time [2]. In addition, to address the low efficiency of hazard perception and recognition in autonomous vehicles, Ghosh et al. proposed a machine learning algorithm-based autonomous hazard call model for self-driving vehicles, which was used to test the model in real situations. The results showed that the hazard recognition efficiency of autonomous vehicles based on this model increased by 22.1% [3]. To solve the problem that UAV is difficult to accurately reach the accident site during emergency rescue, Shaheenzh et al. proposed a new autonomous call to air channel model. The results showed that this model had good practical application effects [4]. However, these autonomous call models still have low detection efficiency and weak anti-interference ability, so it is also necessary to optimize the above autonomous call models [5]. Therefore, proposing an autonomous call model that can improve the prediction accuracy and prediction efficiency of emergency scenarios is an urgent problem.

The Analytic Hierarchy Process (AHP) is simple to calculate and has strong applicability, but when dealing with large-scale problems, it is subjective and prone to significant calculation errors [6]. Although Surface Acoustic Wave (SAW) technology can improve the accuracy of signal filtering and enhance anti-interference, it still has high filter insertion loss and low SAW filter performance in the high frequency range. The above two methods are also not applicable to the current autonomous calling model [7].

The Dual Tone Multi-Frequency (DTMF) signal detection algorithm has fast dialing speed, high reliability, and strong anti-interference ability [8]. The high-precision characteristics of the Demand Side Platform (DSP) signal processing algorithm can reconstruct signals and avoid interference from other signals. The flexibility of this algorithm is also beneficial for its processing, analysis, and modification of complex signals [9]. Many scholars have analyzed the above algorithms. Maity et al. designed an improved DTMF algorithm to address the weak noise resistance and low efficiency in signal detection in telecommunications equipment. Comparative experiments were conducted between this improved algorithm and previous algorithms. The results showed that the noise resistance and efficiency were improved by 79% and 87%, respectively [10]. Oluwole et al. proposed a home automation technology based on DTMF to solve the high energy consumption and low transmission speed in home appliance control. The improvement in transmission speed was not significant [11]. In addition, Fan designed a DSP signal processing algorithm to improve the machine learning accuracy. The results showed that the model improved machine learning performance [12]. To improve the computational speed of digital signal processing systems, Seshadri proposed a signal processing algorithm based on DSP. The results demonstrated that this algorithm improved the signal processing speed [13]. Nisha et al. also proposed a denoising method based on DTMF to improve the denoising effect of MRI images. The results showed that the denoising effect of this method was significantly better than that of traditional methods [14].

In summary, some scholars have now analyzed the autonomous calling model. Although the autonomous calling model has been optimized, there are still some problems with the above model. For example, the autonomous call mobile model proposed by Zardini et al. still has low model prediction accuracy. The vehicle hazard autonomous call model proposed by Ghosh et al. still has long computation time-consuming. The autonomous call-to-air channel model designed by Shaheenzh et al. still has slow call speed. The above research shows that the current model has some limitations, such as low detection efficiency and weak anti-interference ability, and needs to be further optimized. To meet this demand, an innovative autonomous call model is proposed, aiming to build a solution suitable for complex emergency scenarios by combining the high precision and flexibility of DSP algorithm with the speed dial, high reliability and strong anti-jamming ability of DTMF signal detection algorithm. This motivation stems from the significant advantages and complementarity of the two in signal processing: DSP algorithms are good at processing and analyzing complex signals, while DTMF technology ensures stable communication in emergency situations. Compared with the subjectivity of AHP and the low filtering performance of SAW technology in the high frequency range, the proposed model shows significant advantages in solving the problems of signal interference, inaccurate prediction and slow response.

The main contribution and influence of the research is that the proposed hybrid algorithm autonomous call model not only makes up for the shortcomings of the existing model in prediction accuracy, response speed and anti-interference ability, but also proves its excellent performance in multi-scenario applications through the experimental verification of actual fire simulation scenarios. This innovation not only provides a more efficient and accurate solution for emergency command and rescue, but also opens up new ideas and methodological references for subsequent research, and is expected to promote the overall progress in the field of emergency rescue. Specifically, the proposed model improves the accuracy and response speed of disaster early warning, optimizes resource allocation, and enhances the reliability and stability of emergency communication, thus minimizing casualties and property losses when disasters occur. The argument of the research is that the disaster autonomous call warning model based on DSP and DTME signal detection technology can improve the accuracy of disaster warning and reduce disaster casualties. The argument is based on the high accuracy and flexibility characteristics of DSP algorithms, as well as the theoretical foundations of high anti-interference, high reliability and fast dialing speed. The contribution of the research lies in the fact that the autonomous call model in emergency scenarios can improve warning and response speed, optimize resource allocation, and enhance emergency communication reliability and stability, thereby reducing the loss of life and property caused by disasters.

II. Methods and Materials

A. DTMF Signal Detection Algorithm Integrated with DSP Algorithm

The current autonomous call rule model in emergency command scenarios has problems such as slow dialing speed and susceptibility to external influences, which seriously affects the timeliness and accuracy of emergency command. Therefore, strengthening the overall performance of the autonomous call rule model is of great significance for improving the effectiveness of emergency command. The DTMF signal detection algorithm has fast dialing speed, high reliability, and strong anti-interference ability. Given these advantages, the DTMF is applied to the multi-scenario autonomous call model to improve the model speed and anti-interference ability, enhancing the emergency command effectiveness. Among them, the signal generation principle in the DTMF signal detection algorithm is shown in Eq. (1) [15].

$$f_{(t)} = A\sin 2\pi f_{(1)}t + A\sin 2\pi f_{(2)}t \quad (1)$$

In Eq. (1), $f_{(1)}$ and $f_{(2)}$ respectively represent any two selected frequencies. A represents the amplitude. t represents the continuous time variable, which represents each each time point at which the signal is generated. The principle of DTMF signal generation is shown in Fig. 1.

In Fig. 1, the principle of DTMF signal generation is as follows. The input information is fed into the oscillator. The high-frequency oscillation signal generated by the oscillator is transmitted to two counters, respectively. When the value in the counter reaches the preset value, the counter inverts the signal to form a low-frequency square wave and then outputs. The low-frequency square wave output is a sinecure, and the amplitude of the square wave is controlled. Then, the processed two signals are transmitted to the signal mixer for signal mixing processing, and finally outputted. The system function of the oscillator in the DTMF signal generation is shown in Eq. (2).

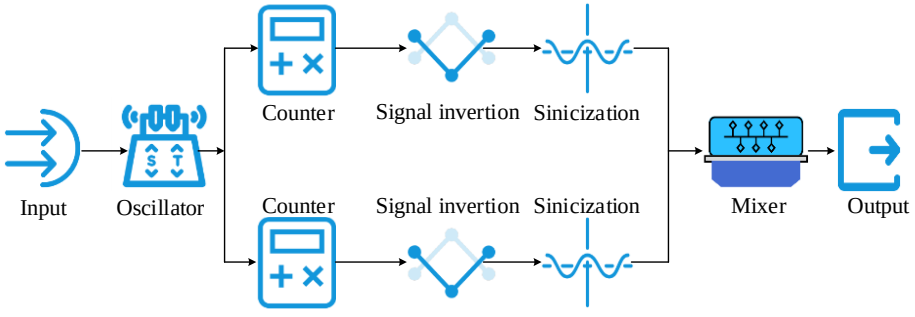

Fig. 1. Schematic diagram of DTMF signal generation.

$$H_{(z)} = \frac{b}{1 + a_1 z^{-1} + a_2 z^{-2}} \tag{2}$$

In Eq. (2), a and z respectively represent row audio signals and column audio signals. b represents the amplitude under the normalized digital frequency, as shown in Eq. (3).

$$\begin{cases} b = A\sin\omega \\ \omega = f_0 / f_a \end{cases} \tag{3}$$

In Eq. (3), f_0 represents the sine wave frequency. f_a represents the sampling frequency. ω is the normalized digital frequency. a_1 and a_2 in Eq. (2) are shown in Eq. (4).

$$\begin{cases} a_1 = -2\cos\omega \\ a_2 = 1 \end{cases} \tag{4}$$

The unit sampling response corresponding to the oscillator is shown in Eq. (5).

$$h(n) = A\sin((n+1)\omega)u(n) \tag{5}$$

In Eq. (5), n represents the sampling point. The difference equation of the oscillator is shown in Eq. (6).

$$g(n) = 2\cos\omega g(n-1) - g(n-2) \tag{6}$$

The signal synthesis in the DTMF signal detection algorithm is shown in Eq. (7).

$$y(n) = A_0 + A_1 \sin\frac{2\pi dt_0}{t_s} + A_2 \sin\frac{2\pi dt_1}{t_s} \tag{7}$$

In Eq. (7), t_0 and t_1 represent the high-frequency and low-frequency of the generated signal, respectively. A_0 and A_1 represent the amplitude of t_0 and t_1. t_s is the sampling frequency. d is the number of sampling points. Afterwards, it is subjected to sinusoidal processing. The sine function is shown in equation (8).

$$\sin(x) = \sin(x1) + \frac{[\sin(x2) - \sin(x1)(x2 - x1)]}{256} \tag{8}$$

In Eq. (8), $x1$ and $x2$ represent two segmentation points, but the level difference between the high-frequency and the low-frequency affects the experimental results. The level difference is shown in Eq. (9).

$$S_H = -20\lg(\frac{V_H}{V_0})S_L (1 < S_H - S_L < 2) \tag{9}$$

In Eq. (9), S_H represents the level of the high-frequency signal. S_L represents the level of the low-frequency signal. V_H and V_L represent high-frequency voltage and low-frequency voltage, respectively. DAC is shown in Eq. (10).

$$DAC(n) = 12.8 \times (1023A_0 + A_1 A + A_2 B) \tag{10}$$

In Eq. (10), A and B are shown in equation Eq. (11).

$$\begin{cases} A = 1023\sin(\frac{2\pi dt_0}{t_s}) \\ B = 1023\sin(\frac{2\pi dt_1}{t_s}) \end{cases} (d = 0,1,2.....) \tag{11}$$

In Eq. (11) and Eq. (12), t_0 and t_1 represent the high-frequency and the low-frequency in DTMF, respectively. d is the number of sampling points. t_s is the sampling frequency. Although the DTMF signal detection algorithm has fast dialing speed and strong reliability, it has high requirements for signal-to-noise ratio, easy signal leakage, and low detection accuracy. The high precision of DSP algorithms makes signal reconstruction possible and avoids interference from other signals. The flexibility of this algorithm is beneficial for its processing, analysis, and modification of complex signals [16]. The basic structure diagram of the DSP algorithm is shown in Fig. 2.

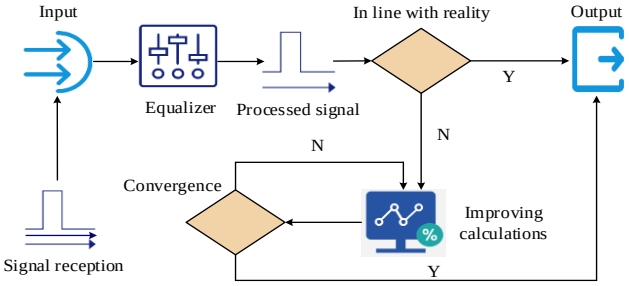

Fig. 2. Basic flowchart of DSP algorithm.

From Fig. 2, the DSP algorithm first receives the signal, and then extracts and processes the received signal through a digital equalizer at the receiving end of the DSP algorithm. The processed signal is compared with the output sequence to determine whether the processing result of the equalizer matches the actual situation. If it matches, the processing result is output. If it does not match, the equalizer cannot converge successfully. The DSP is improved. After improving, it is judged until it matches the actual situation, and the processed signal is output. The transmission calculation for the received signal is shown in Eq. (12).

$$y_a(i) = s(i) \cdot h_a(i) + w(i) \tag{12}$$

In Eq. (12), $y_a(i)$ represents the transmitted signal. $h_a(i)$ represents the time-domain function. The relationship between the transmitted signal and the output signal of the equalizer is shown in Eq. (13).

$$z(j) = \lambda s_a[(j-k)T_s] \tag{13}$$

In Eq. (13), $z(j)$ is a discrete signal sequence. k is the delay generated by the equalizer. λ represents a complex constant. If the signal passed through the equalizer does not match the actual situation, it will be improved. The improvement operation is shown in Eq. (14).

$$J(g) = E[|(\rho(h)|a(j) + a(j-1)|^2 - 1)^2] \tag{14}$$

Each factor in Eq. (14) is shown in Eq. (15).

$$\begin{cases} \rho(h) = [\sin(\frac{\pi h}{2})\sin(\pi h)]^2 \\ E[|(a(j)|^2 - 1)^2] = 0 \\ E[(\rho(h)|a(j) + a(j-1)|^2 - 1)^2] = 0 \end{cases} \quad (15)$$

In Eq. (15), $a(j)$ is the signal output by the equalizer. In order to improve the accuracy and efficiency of the DTMF signal detection algorithm, this study utilizes the high-precision performance of the DSP algorithm to improve the DTMF signal detection algorithm. The flowchart of the improved DTMF signal detection algorithm is shown in Fig. 3.

From Fig. 3, the improved DTMF signal detection algorithm is divided into a DTMF module and a DSP module. In the DTMF module, the input signal is generated into low-frequency and high-frequency signals through an oscillator. Then, the two signals are respectively fed into the counter for signal inversion and sine processing. Finally, the two signals are mixed through the mixer. The mixed signal is input into the DSP module. The signal is extracted, detected, and reconstructed through the equalizer in this module to eliminate other factors and improve detection accuracy. Finally, the signal is output. The fast dialing speed of DTMF is utilized for dialing operation through signal judgment. The DSP algorithm is used in DTMF signal detection. When the two signals are fused, the signal needs to be resampled before the DSP module. The update iteration is shown in Eq. (16).

$$l(k+1) = l(k+1) - J(g) \cdot \mu_g \nabla_g \quad (16)$$

In Eq. (16), μ_g represents the iteration step size. $l(k)$ represents the tap coefficient vector. At this point, $y_a(i)$ represents the signal received from the DTMF mixer.

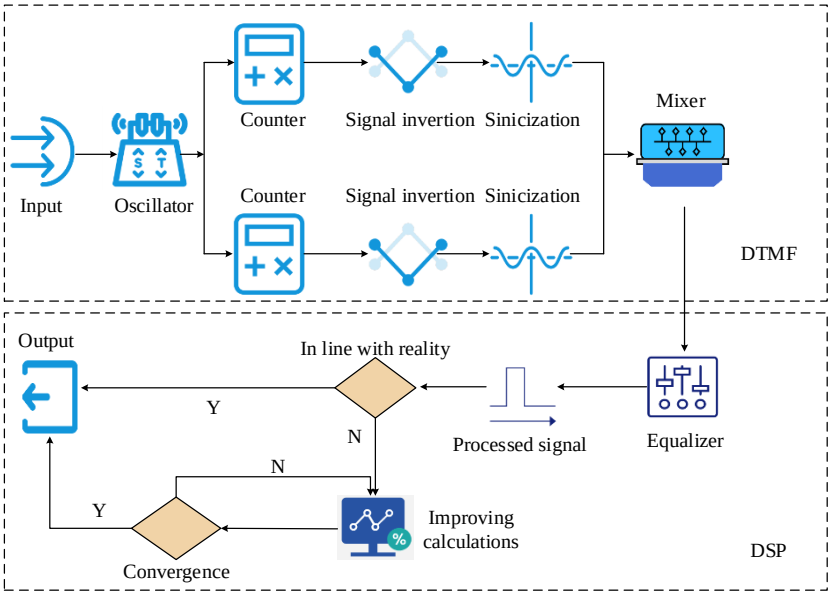

Fig. 3. Improved DTMF signal detection algorithm.

B. Construction of Improved Autonomous Call Model Based on DSP-DTMF Algorithm

In emergency command scenarios, constructing a multi-scenario autonomous call rule pattern model is crucial. This model needs to comprehensively consider multiple factors such as the urgency of the event, resource types, geographical location, etc. to better improve the effectiveness of emergency command. Firstly, the multi-scenario autonomous call rule model can set call priority based on the urgency of the event, ensuring timely response to important events. Secondly, the model needs to intelligently identify and allocate relevant emergency resources, such as personnel and materials, to achieve efficient disposal. In addition, the model can automatically select the nearest emergency team and resources to call based on the event location. When constructing this model, holographic and analogical modeling methods can be used to clarify user, usage scenario, and entity features, simplifying unnecessary dimensions and attributes. At the same time, it is necessary to achieve autonomous calling in multiple scenarios by setting flexible call rules and algorithms. This study takes fire emergency command as an example to construct a multi-scenario autonomous call rule model. The basic framework of the constructed model is shown in Fig. 4.

In Fig. 4, the fire emergency command multi-scenario autonomous call model is divided into signal perception layer, signal transmission layer, and signal receiving layer. The signal perception layer mainly includes smoke detectors and temperature detectors, which are used to detect smoke concentration and temperature in fires. When the detection result meets the alarm conditions of the detector, the signal will be sent to the alarm in the signal transmission layer. The alarm sends the next command to the signal receiving layer based on the smoke concentration and temperature. The signal receiving layer receives the sent reminder signal or alarm signal. If a reminder signal is received that there is someone inside the room, it indicates that the indoor fire is not serious, and can be

dealt with without calling the alarm. If the signal received by the receiving end is an alarm signal, it indicates that the fire is serious or not serious, but there is no one indoors. The model can automatically call the alarm number. Although the fire emergency command multi-scenario autonomous call model can predict and call fires autonomously, it has a series of problems such as slow detection speed, low accuracy, weak anti-interference ability, and slow call transmission speed. The DSP-DTMF algorithm can improve the accuracy and speed of signal detection, enhance the anti-interference ability, and reduce the response time [17]. Therefore, this study uses the DSP-DTMF algorithm to optimize the traditional fire emergency command multi-scenario autonomous call model, in order to improve the overall performance of the model. The basic structure diagram of the autonomous call mode model that integrates the DSP-DTMF algorithm is shown in Fig. 5.

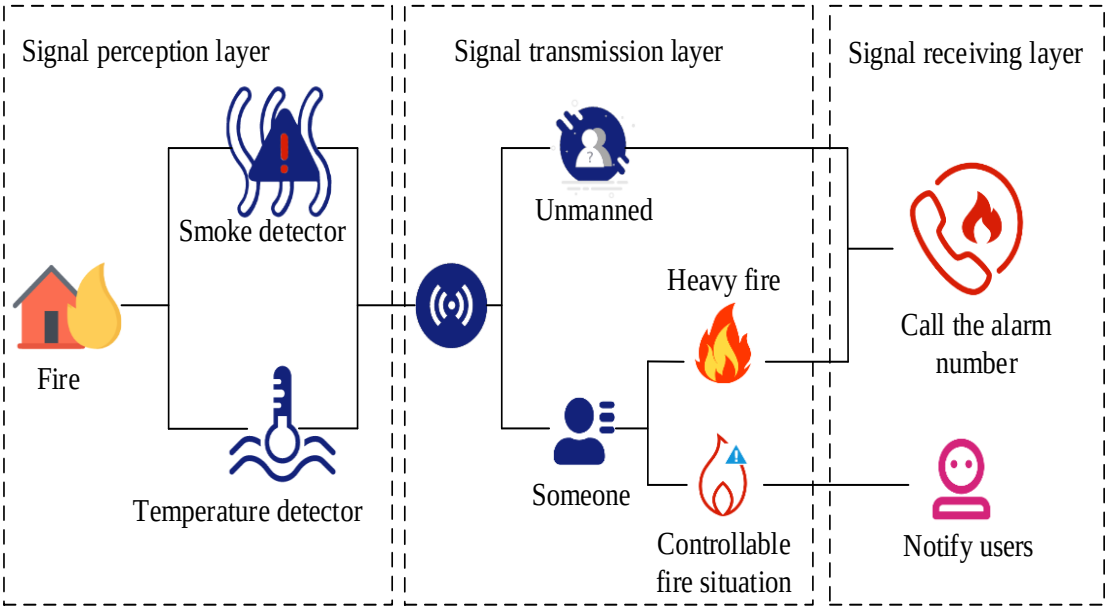

Fig. 4. Basic framework of autonomous call rule model.

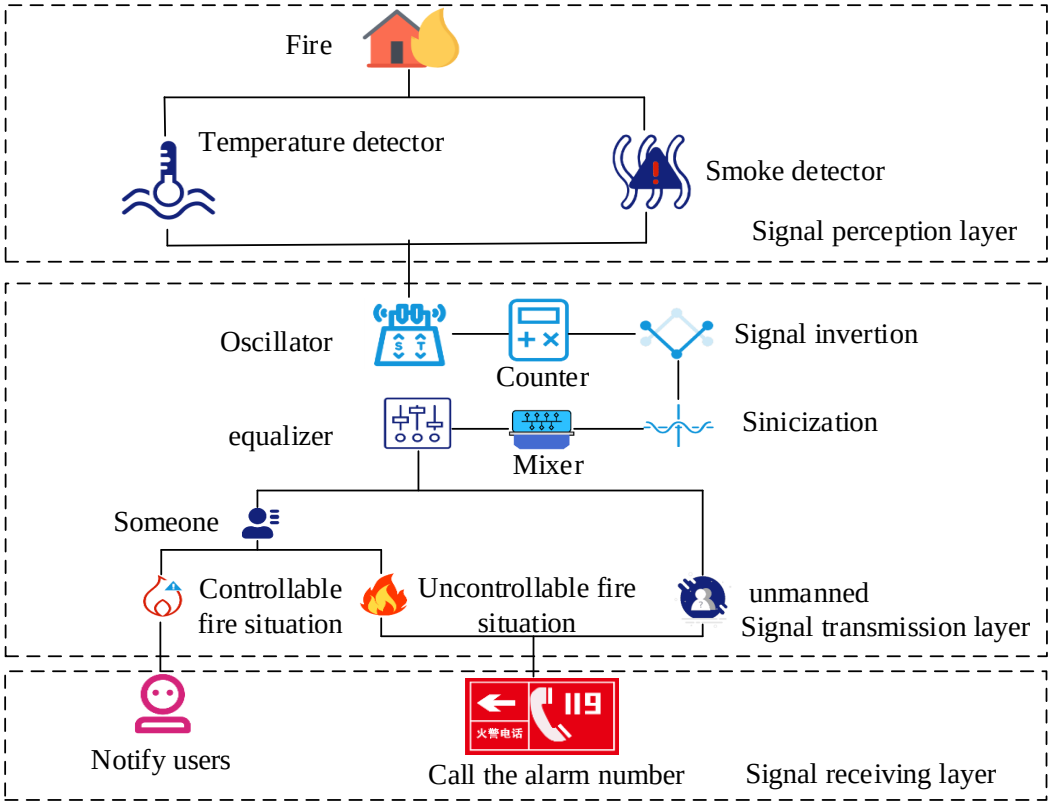

Fig. 5. Improved autonomous call model.

In Fig. 5, the improved autonomous call model is also divided into three layers: signal perception layer, signal transmission layer, and signal receiving layer. The signal perception layer and signal receiving layer have not changed, but only the signal transmission layer has changed. In the signal perception layer, after detecting relevant signals through temperature detectors and smoke concentration detectors, the signals are sent to the signal transmission layer. In the signal transmission layer, the signal is detected by the oscillator, counter, and mixer of the DTMF module. Then, the detected signal is sent to the DSP module, which extracts and re-detects the signal through the equalizer in the module. If the detected signal shows that there is no one present at the fire scenario, an alarm will be triggered. DTMF will call the alarm number. If someone is trapped on site and the fire is controllable, the model will notify rescue personnel. If the fire is uncontrollable, an alarm will be triggered. The operation instructions for fire alarm notification to users are transmitted to the signal receiving layer through dial-up processing. The comprehensive performance score of the improved autonomous call model is shown in Eq. (17).

$$W_k = \sum_{k=1}^{n} x_k * y_k \tag{17}$$

In Eq. (17), W_k represents the comprehensive score of the k-th indicator. x_k represents the weight of the k-th indicator. y_k represents the rating of the k-th indicator. This calculation method can be used to compare the comprehensive performance of different models.

III. Results

A. Performance Analysis of DTMF Signal Detection Algorithm Based on DSP

MIMO-OTFS algorithm is a signal detection technology based on Multi-Input Multi-Output (MIMO) and Orthogonal Time-Frequency Space (OTFS), which performs well in dealing with complex signal environments [18]. SDNSR-Net is a deep learning network specifically designed for signal detection and noise suppression [19]. In order to verify the superiority of the improved DTMF signal detection algorithm, DSP-DTMF algorithm (Algorithm 1) is compared with MIMO-OTFS (Algorithm 2) and SDNSR-Net (Algorithm 3) in experiments. Signal detection accuracy, error rate, transmission speed, and minimum detectable signal are used as comparison indicators. The specific environment of the comparative experiment is shown in Table I. The experiment is repeated 10 times, and T-test is used for statistical verification.

The parameter settings during the experiment are as follows. The sampling frequency of each algorithm for the signal is set to 8000HZ, the duration of each digital signal is set to 50ms to ensure the accuracy of the digital information, and the output frequency is set to 100Hz. Comparative experiments are conducted on three algorithms under the same environmental configuration in Table I. The dataset used is the radar radiation source recognition signal dataset, which is sourced from the measured data of AD9910 and USRP hardware. The dataset mainly consists of 6 individuals, each with 6 modulation types and 5000 pulses per modulation type, totaling 180000 samples [20]. The waveform comparison results of the detection accuracy of three algorithms on the radar radiation source recognition signal dataset are shown in Fig. 6.

TABLE I. Experimental Environment Configuration

System modules	Parts	Type
Single chip	Storage	8KB Flash storage
	RAM	256 bit
	I/0 line	32 programmable I/O lines
	Interface type	Serial interface
	Oscillator	Clock oscillator
Number receiving circuit	Chip type	MT8870
	Type of micro-controller	89C52
Signal circuit	Chip type	UM91513
Main engine	Winds system	Wind11-64
	CPU model	i7-12700KF

As shown in Fig. 6 (a), the average accuracy of the DSP-DTMF algorithm reached 0.91, which fluctuated between 0.8 and 1.0, indicating good stability. In Fig. 6 (b), the average accuracy of Algorithm 2 was 0.62, which fluctuated greatly when the sample size was less than 60, resulting in unstable accuracy. After the sample size exceeded 60, the accuracy of the algorithm fluctuated between 0.57 and 0.64, which was relatively stable. According to Fig. 6 (c), the average accuracy of Algorithm 3 was 0.46. When the sample size was less than 100, the accuracy fluctuated greatly, with poor stability. When the sample size reached 100, the accuracy gradually stabilized. The error rate and recall rate of the three algorithms are shown in Fig. 7.

As shown in Fig. 7 (a), the error rates of Algorithm 1, Algorithm 2, and Algorithm 3 stabilized at 0.05, 0.10, and 0.13, respectively. Algorithm 1 reached a maximum of 0.15 when the sample size was 40. When the sample size exceeded 40, the error rate gradually decreased and stabilized at 0.05. Algorithm 2 and Algorithm 3 were 0.21 and 0.22, respectively when the sample size was 60. When the sample size was greater than 80, the error rates of the two algorithms decreased and eventually stabilized at 0.15 and 0.13, respectively. As shown in Fig. 7 (b), the recall rates of Algorithm 1, Algorithm 2, and Algorithm 3 ultimately stabilized at 0.90, 0.79, and 0.68, respectively. The recall rate of Algorithm 1 gradually increased with the increase of sample size. The overall recall rate of Algorithm 2 increased. When the sample size was less than 100, the fluctuation range of error rate was large, with poor stability. The overall recall rate of Algorithm 3 also increased. When the sample size was less than 100, the recall rate was extremely unstable, with a large fluctuation range and frequency. After the sample size exceeded 100, the recall rate gradually stabilized. The signal detection transmission speed and minimum detectable signal are experimentally analyzed. The experimental results are shown in Fig. 8.

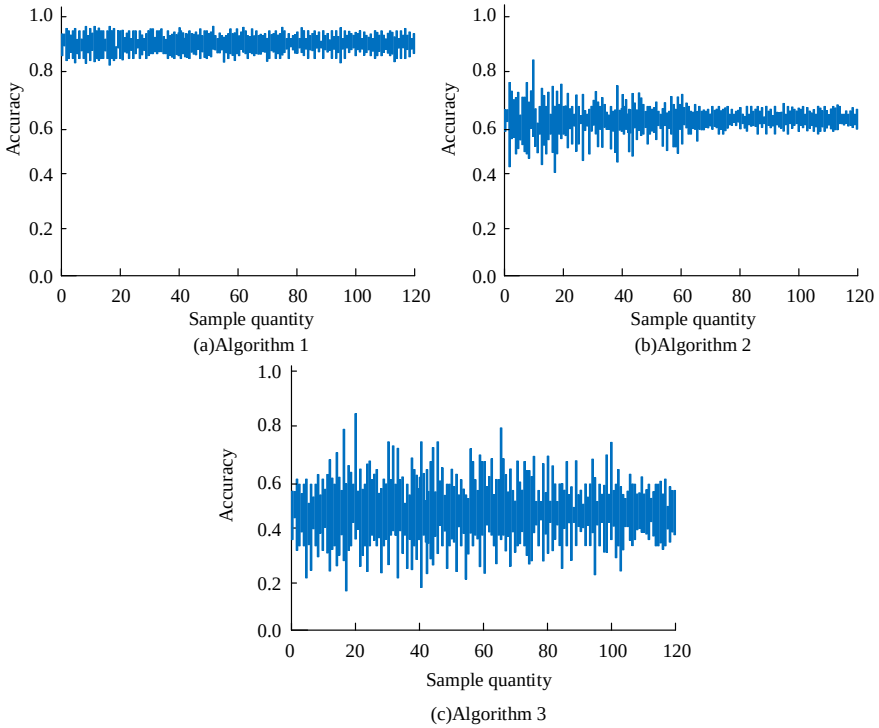

Fig. 6. Comparison of accuracy among three algorithms.

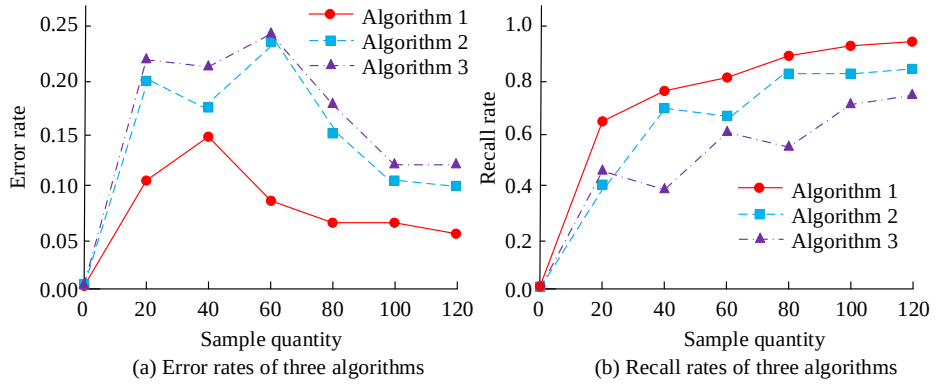

Fig. 7. Comparison of error rate and recall rate of three algorithms.

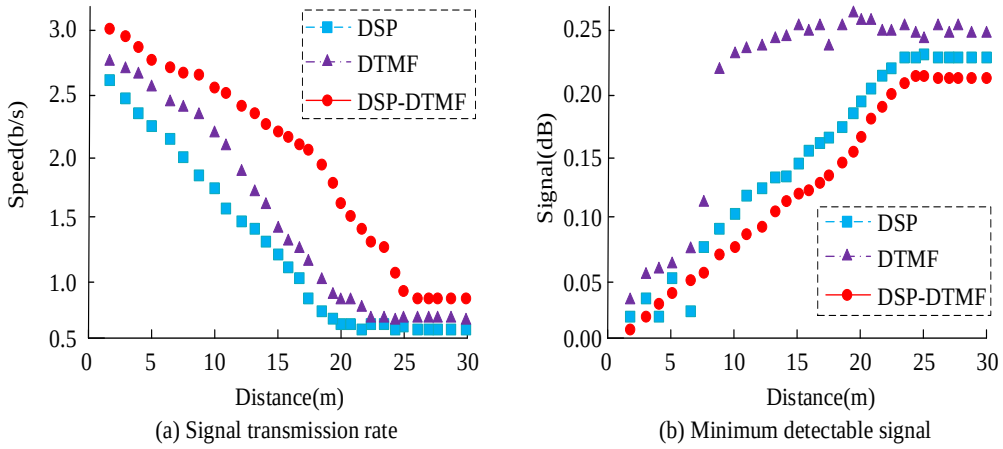

Fig. 8. Signal transmission rates and minimum detectable signals of three algorithms.

From Fig. 8 (a), the signal transmission rates of Algorithm 1, Algorithm 2, and Algorithm 3 all decreased with increasing distance. Among them, the signal transmission rate of Algorithm 1 slowed down and tended to increase when the distance reached 15m. When the distance reached 25m, the signal transmission rate reached its lowest value, at 0.8b/s, and then fluctuated around 0.8b/s. Algorithm 2 and Algorithm 3 reached the minimum transmission rate at 25m, which was 0.53b/s and 0.67b/s, respectively. As shown in Fig. 8 (b), as the distance increased, the minimum detectable signal values of all three algorithms increased. At 25m, Algorithm 1 and Algorithm 2 had minimum detectable signals of 0.19dB and 0.21dB, respectively. At 10m, the minimum detection signal of Algorithm 3 skyrocketed to 0.23. Subsequently, it fluctuated between 0.22 and 0.24. In summary, the DSP-DTMF algorithm proposed in the study has the best overall performance among the three algorithms. In order to more comprehensively verify the effectiveness and scalability of DSP-DTMF algorithm and its autonomous call model, it is tested with the model proposed in literature [13] and the model proposed in literature [14] in a variety of data sets. In addition to the radar radiation source identification signal dataset, several other key datasets were introduced to evaluate the algorithm's performance in different scenarios. The radar radiation source identification signal dataset comes from the measured data of AD9910 and USRP hardware, which contains 6 individuals, each individual has 6 modulation types, each modulation type contains 5000 pulses, a total of 180,000 samples; Fire simulation data set is a data set generated by simulating fire scenarios, which contains fire data under different temperature and smoke concentration conditions. The multi-source information fusion dataset synthesizes data from video, audio, sensor and other sources, and contains multi-modal data under various emergency scenarios. The performance of the three models on different data sets is shown in Table II.

TABLE II. THE PERFORMANCE OF THE THREE MODELS ON DIFFERENT DATA SETS

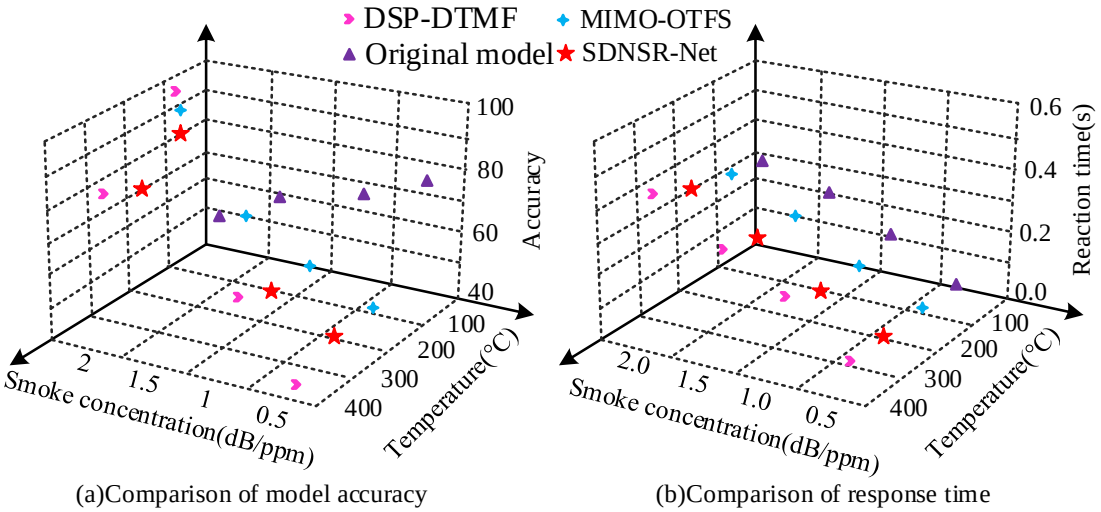
Model type	Data set	Signal detection accuracy	Error rate	Transmission speed (b/s)	Minimum detectable signal (dB)
DSP-DTMF	Radar radiation source identification signal dataset	0.91	0.05	0.81	0.19
	Fire simulation data set	0.93	0.04	0.77	0.18
	Multi-source information fusion dataset	0.89	0.06	0.66	0.22
Literature [13]	Radar radiation source identification signal dataset	0.72	0.10	0.53	0.21
	Fire simulation data set	0.71	0.12	0.48	0.23
	Multi-source information fusion dataset	0.69	0.13	0.45	0.26
Literature [14]	Radar radiation source identification signal dataset	0.77	0.13	0.67	0.23
	Fire simulation data set	0.68	0.15	0.61	0.25
	Multi-source information fusion dataset	0.73	0.17	0.56	0.24

As can be seen from Table II, the model proposed in this study has high signal inspection accuracy in the three data sets, which are 0.91, 0.93 and 0.89 respectively. Through testing on different data sets, the research proves that DSP-DTMF algorithm and its autonomous call model have good scalability. In addition, this result also proves that the proposed model has better performance than other studies. The above results show that the algorithm and model can adapt to various emergency scenarios and have wide application potential.

B. Performance Analysis of the Optimized Autonomous Call Rule Model

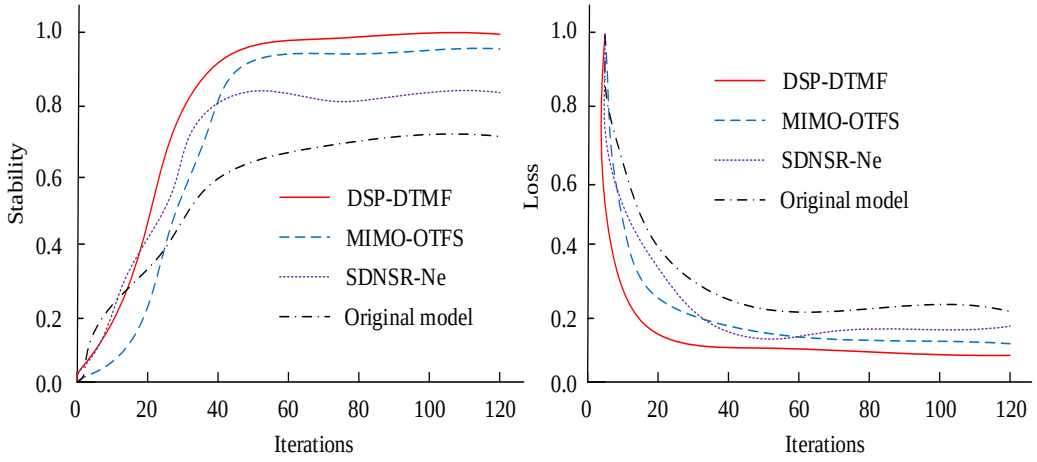
After verifying the superiority of the DSP-DTMF algorithm, in order to analyze the application effect of the proposed multi-scenario autonomous call rule model based on the DSP-DTMF algorithm, the DSP-DTMF algorithm, MIMO-OTFS algorithm, and SDNSR-Net algorithm are used in the autonomous call rule model for comparison. Taking the fire emergency scenario as an example, different models are used in the fire simulation environment to compare the comprehensive performance of the three models and the model without using the proposed algorithm. The accuracy and response comparison of the four models are shown in Fig. 9.

According to Fig. 9 (a), the average accuracy of the DSP-DTMF model, MIMO-OTFS model, SDNSR-Net model, and original model were 0.93, 0.79, 0.68, and 0.61, respectively. When the temperature was 200°C and the smoke concentration was 0.5dB/ppm, the accuracy of the DSP-DTMF, MIMO-OTFS, SDNSR-Net, and original model were 0.97, 0.90, 0.81, and 0.72, respectively. When the temperature and smoke concentration increased, the accuracy of all four models decreased. The DSP-DTMF model had an accuracy of 0.94 at 400°C and 2dB/ppm smoke concentration, while the accuracy of the MIMO-OTFS, SDNSR-Net, and original model under these conditions were 0.76, 0.65, and 0.58, respectively. According to Fig. 9 (b), the average response time of the four models was 0.08s, 0.12s, 0.23s, and 0.31s, respectively. The DSP-DTMF, MIMO-OTFS, SDNSR-Net, and original model had response time of 0.05s, 0.08s, 0.14s, and 0.20s, respectively at 200°C and 0.5dB/ppm. As the temperature and smoke concentration increased, the response time of the four models also gradually increased. Moreover, when the temperature was 400°C and the smoke concentration was 2dB/ppm, the response time of four models was 0.10s, 0.34s, 0.40s, and 0.42s, respectively. Fig. 10 shows the stability and loss function curves of four models.



(a)Comparison of model accuracy (b)Comparison of response time

Fig. 9. Comparison of accuracy and response time of four models.

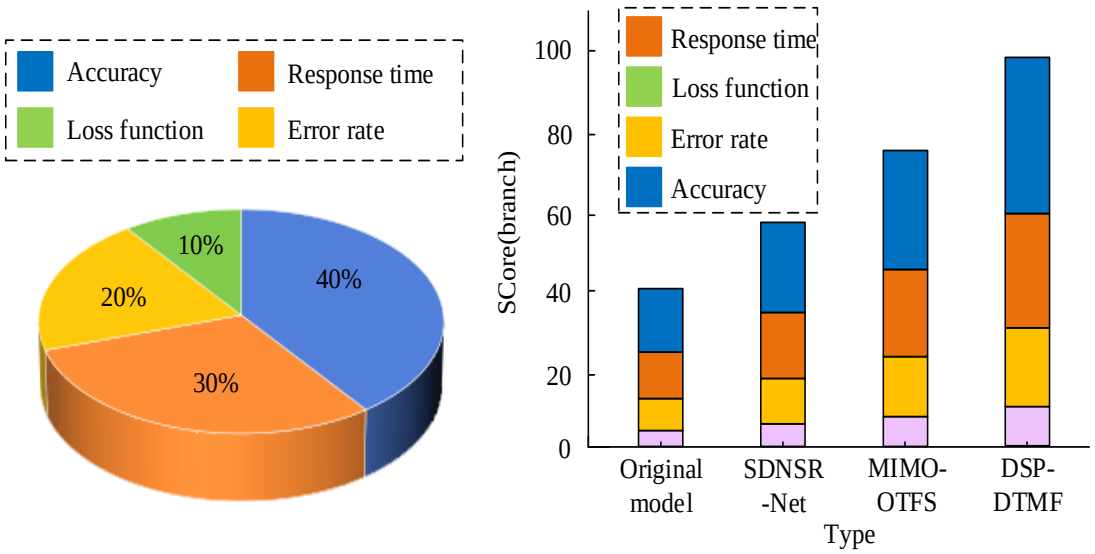


(a)Stability of Four Models (b)Loss function curves of four models

Fig. 10. Comparison of stability and loss function curves for four models.

From Fig. 10 (a), the stability increased with increasing iterations. The final stability of the DSP-DTMF model, MIMO-OTFS model, SDNSR-Net model, and original model was 0.93, 0.91, 0.87, and 0.63, respectively. The stability of all four models reached its maximum at an iteration of 40. From Fig. 10 (b), the loss values of all four models decreased with increasing iterations. Among them, the DSP-DTMF model, MIMO-OTFS model, SDNSR-Net model, and original model had final loss values of 0.07, 0.10, 0.16, and 0.21, respectively. Moreover, the loss values of all four models reached the lowest value at 20 iterations. Fig. 11 shows the comprehensive performance score of the four models.

From Fig. 11 (a), the comprehensive performance score is composed of the accuracy, response time, loss function, and error rate of the model. In the comprehensive performance score, the accuracy of the model accounts for the largest proportion of 40%, the loss function accounts for the smallest proportion, at 10%, and the proportion of response time and error rate is 30% and 20%, respectively. The comprehensive performance score of the model can be calculated from the proportion in Fig. 11 (a) to obtain Fig. 11 (b). The comprehensive score consisted of four parts, among which the DSP-DTMF model had the highest comprehensive score of 97 points, MIMO-OTFS model and SDNSR-Net model had a comprehensive score of 69 points and 60 points, respectively, and the original model had the lowest comprehensive score of 40 points. In summary, the comprehensive performance of the DSP-DTMF autonomous call model proposed in this study is the best. In order to more comprehensively verify the effect of the autonomous call rule model based on DSP-DTMF algorithm, this model and the novel multi-source information autonomous call rule model, swarm intelligence autonomous call rule model and adaptive autonomous call model are tested in five actual fire scenarios. This comparison is to further verify the performance of the optimization algorithm and ensure the effectiveness and reliability of the model in emergency scenarios. The test results are shown in Table III.



(a)The comprehensive performance score of the model and the proportion of each function

(b)Comprehensive performance evaluation of the model

Fig. 11. Comparison of comprehensive performance scores of four models.

TABLE III. PERFORMANCE OF DIFFERENT MODELS IN REAL FIRE SCENARIOS

Index	DSP-DTMF autonomous call rule model	Multi-source information autonomous call rule model	Swarm intelligence autonomous call rule model	Adaptive autonomous call model
Accuracy rate (%)	95.2%	90.1	89.6	88.1
Reaction time (s)	2.1	3.3	3.1	4.5
Number of scenarios	5	5	5	5
Total test duration (h)	100.1	98.8	98.9	95.6
Average frames per second (FPS)	30.1	24.2	25.1	20.6

From Table III, the autonomous call rule model based on DSP-DTMF algorithm performed well in the simulated fire scenario, with an accuracy of 95.2% and a reaction time of only 2.1s, which was far better than comparison models. It was tested in five different real scenarios, and the total test time reached 100.1h, showing the stability and durability of the model. In addition, from Table III, the average FPS of the autonomous call rule model based on DSP-DTMF algorithm was 30.1, which was better than 24.2, 25.1, and 20.6 of comparison models, indicating that the algorithm had higher processing speed. Finally, the paper also considers the scalability and robustness of the autonomous call rule model based on DSP-DTMF algorithm in many different scenarios. The robustness of the model is analyzed by comparing the accuracy and response time of the model in five specific scenarios. The specific results are shown in Table IV.

From Table IV, under different actual scenarios, DSP-DTMF algorithm maintained a high accuracy rate, and its mean value was 94.9%. In addition, the response time of the model fluctuated slightly in different environments, but the overall level was also kept low, with a mean response time of 2.2s. The above results show that the autonomous call rule model based on DSP-DTMF algorithm has scalability and robustness. The performance of the DSP-STMF autonomous call model is compared with the widely used disaster autonomous call model based on GA-SVM algorithm, as shown in Table V.

TABLE IV. ACCURACY AND RESPONSE TIME OF THE AUTONOMOUS CALL RULE MODEL BASED ON DSP-DTMF ALGORITHM IN DIFFERENT SCENARIOS

/	Accuracy rate	Response time (s)
Residential area fire	96.1%	1.9
Industrial area fire	94.5%	2.2
Forest fire	93.8%	2.4
Commercial fire	95.2%	2.0
Mountain fire	94.8%	2.3
Mean value	94.9%	2.2

TABLE V. MODEL PERFORMANCE COMPARISON

Model	DSP-DTMF model	GA-SVM model
Precision	95.2%	87.6%
Reaction time	2.1s	3.5s
Monitoring accuracy	97.5%	82.1%
False negative rate	1.1%	8.3%
False report rate	1.4%	9.6%
Fraction of coverage	98.9%	89.7%

According to Table V, the proposed DSP-STMF model outperformed the current GA-SVM autonomous call model in all aspects of performance. The monitoring accuracy, precision, and coverage of the DSP-DTMF autonomous call model were all above 95%, while the monitoring accuracy, precision, and

coverage of the GA-SVM model were all below 90%. The false negative rate, false alarm rate, and response time of the DSP-DTMF model were lower than those of the GA-SVM model. From the above results, it can be concluded that the DSP-DTMF autonomous call model proposed in the study outperforms current autonomous call models in all aspects of performance.

IV. Discussion

This study designed a comparative experimental analysis on the performance of the DSP-DTMF algorithm. Then, comparative experiments are conducted on autonomous call models based on DSP-DTMF algorithm, MIMO-OTFS algorithm, and SDNSR-Net algorithm. The results showed that the DSP-DTMF algorithm outperformed the other two algorithms in accuracy, stability, error rate, and signal transmission speed. In the accuracy waveform, the average accuracy of the DSP-DTMF algorithm was the highest at 0.9, with small fluctuation in accuracy and strong stability. This result was similar to the experimental results of Schaumont using the DSP-DTMF algorithm to process remote course selection for courses [21]. This result indicates that in practical applications, the DSP-DTMF algorithm can make more accurate judgments on emergency scenarios. In the recall and error rate curves of the algorithm, the DSP-DTMF algorithm had the lowest error rate of 0.05 and the highest recall rate of 0.9, further verifying the superiority of the algorithm. In terms of the signal transmission rate and minimum detectable signal, the DSP-DTMF algorithm outperformed the other two algorithms. Wibowo et al. also had similar conclusions [22]. This result indicates that the DSP-DTMF algorithm can more quickly and accurately determine emergency scenarios in practical applications.

Secondly, all three algorithms were applied to the autonomous call model. Through comparative experimental analysis between the three models and the original model, it was found that the autonomous call model based on the DSP-DTMF algorithm had strong advantages in accuracy, response time, stability, loss function, and comprehensive performance evaluation. In terms of accuracy and response speed in emergency scenario assessment, this model accurately assessed the emergency scenarios under high temperature and high concentration smoke, and made timely next steps. In the comparison of model stability and loss function curve, it was found that the DSP-DTMF model had the strongest stability of 0.93 and the smallest loss function. This result indicates that the model has strong anti-interference ability, which is not easily affected by other external factors in emergency scenarios. This model is relatively accurate in predicting emergency scenarios. Perng also conducted similar conclusions in the research on DSP digital filters [23]. In the comprehensive performance evaluation of the model, the DSP-DTMF model had the highest comprehensive score of 97 points, which was much higher than other models. This coincided with the conclusion on an automatic unlocking system based on improved DTMF proposed by Iwuji [24].

This result fully demonstrates that the autonomous call model based on DSP-DTMF algorithm can effectively predict emergency scenarios and respond quickly to them, meeting sudden emergency needs. The DSP-DTME autonomous call model is used to test the performance of the model in different fire actual scenario environments. The test results show that the DSP-DTMF autonomous call model maintains a high accuracy rate in different fire scenarios, and its average accuracy rate reaches 94.9%, and the average response time is only 2.2s. It can be concluded that the disaster autonomous call model based on DSP-STME algorithm can improve the speed of disaster emergency rescue, reduce the economic and property losses caused by disasters, and protect the safety of people's lives and properties.

V. Conclusion

Aiming at the problems of slow processing speed, weak anti-interference and low accuracy of autonomous call model in emergency command scenario, this paper innovatively integrates DSP and DTMF to construct an efficient hybrid algorithm, and designs a new autonomous call model based on this algorithm. Through a series of comparative experiments, the superiority and practical application value of DSP-DTMF algorithm and its autonomous call model are verified. The main contribution of the research is to propose a new DSP-DTMF hybrid algorithm, which is successfully applied to the autonomous call model in the emergency command scenario. The algorithm not only significantly improves the accuracy and efficiency of signal detection, but also enhances the anti-interference ability of the model, so that it can maintain stability and accuracy in complex and changeable emergency scenarios. In addition, the experimental results of the autonomous call model designed based on the algorithm in the fire simulation scene show that its comprehensive performance score is much higher than other comparison models, which proves the effectiveness and practicability of the model in emergency command.

In practical applications, the autonomous call model based on DSP-DTMF algorithm has significant advantages. First of all, the model can judge the situation in the emergency scenario more quickly and accurately, so as to start rescue operations in time and reduce disaster losses. Secondly, the model has strong anti-interference ability, can maintain stable operation in complex and changeable emergency environment, and improve the reliability and stability of emergency command. In addition, the model has good scalability and robustness, can adapt to the emergency needs in different scenarios, and provide comprehensive technical support for emergency command.

Although this study has achieved certain results, there are still some limitations. First of all, the current research mainly focuses on the optimization of autonomous call model in fire scenarios, and its applicability to other disaster types (such as earthquake, flood, etc.) needs to be further verified. Second, although the performance of the model has been improved, there may still be some limitations in extremely complex or specific emergency scenarios. In addition, due to the limitations of experimental conditions, some data in the study may have certain biases, which may affect the accuracy of the results.

In view of the above limitations, future research can be expanded and deepened from the following aspects. Firstly, the applicability of DSP-DTMF algorithm under different disaster types is further verified, and the model is optimized and

improved according to the characteristics of different disaster types. Second, explore fusing multimodal data into the model to achieve more comprehensive emergency scenario perception and more accurate call decisions. In addition, the real-time and robustness of the model can be enhanced to improve its response ability in complex emergency scenarios. Finally, the possibility of cross-domain application of the model in intelligent transportation, security monitoring and other fields can be explored to further expand its practical application value. Through these efforts, it is expected to further improve the efficiency and accuracy of emergency command, and provide more powerful technical support for disaster relief work.

***Abstract*—Mental stress has emerged as a widespread concern in modern society, impacting individuals from diverse demographic backgrounds. Therefore, exploring effective methods for therapy, such as virtual environments tailored for stress management, is vital for advancing mental health and improving coping strategies. Prioritising user comfort in the design of virtual environments is essential for enhancing their efficacy in alleviating stress. By considering four design aspects of virtual environments that influence user comfort: (i) visual clarity, (ii) safety features, (iii) cognitive preparedness, and (iv) social support, this study intends to (i) evaluate the effectiveness of these four user-centered design elements in facilitating stress reduction and (ii) explore the underlying rationale behind their stress-reducing properties. This study utilised a mixed-methods approach comprising (i) experiments, (ii) questionnaires, and (iii) interviews. Following evaluation with the Depression Anxiety Stress Scale (DASS), 40 participants (10 men and 30 females) were chosen from the 55 healthy adults aged 20 to 60 who volunteered for the study. The findings validated the efficacy of all four design aspects in enhancing users' comfort during therapeutic sessions in virtual environments. This study offers important insights not only into the importance of user-centered design in creating virtual environments for stress management, where comfort markedly improves therapy outcomes but also contributes valuable knowledge to the fields of mental health and human-computer interaction, paving the way for further exploration of innovative therapeutic solutions for mental stress.**

Keywords*—*Virtual environment design; virtual reality; stress therapy; user comfort

I. Introduction

Mental stress is now more prevalent than ever, affecting different demographic groups in several nations around the world [1], [2], [3], [4]. Afterwards, traditional therapeutic methods, for example, breathing exercises, progressive muscle relaxation, and guided imagery are often used to treat psychological pressure [5], [6]. Although these traditional therapeutic methods have been effective, they are also associated with several constraints such as low immersion, inadequate engagement, and high levels of contextual distractions. So, virtual reality (VR) technology; as one of the recent new devices has been applied in stress therapy sessions due to its advantages such as being more immersive, attractive, and less environmental distractions [7], [8]. Studies supporting the practical application of VR as therapeutic mechanisms have largely produced positive results, with users self-reporting decreased levels of stress following sessions [9], [10], [11], [12], [13].

Although these effects are positive, literature on the effectiveness of VR for stress therapy (e.g., [14], [15], [16]), focuses much more heavily on whether or not these systems can reduce stress, but leave out a discussion on design factors that are fundamental for the virtual context which enables this process of stress reduction to take place [17], [18]. Following that, [18] suggested eight design requirements for psychological therapy VR applications, whereby one of them is the importance of creating meaningful therapeutic spaces, underscoring the need to develop virtual environments that foster an appropriate therapeutic milieu and address users' emotional needs.

Furthermore, the studies in [19] and [20] in their scoping review of VR environments for stress reduction and management have similarly suggested that more attention should be given to the virtual environment design to promote stress reduction according to user-specific requirements. Their claim is consistent and relevant to the present study, which also prioritizes user comfort in the design of virtual environments for effective stress therapy. In the meantime, [17] proposed a framework that outlines factors and design elements pertinent to virtual environments used in stress therapy, particularly those affecting user comfort. Their framework addresses five factors and fourteen design elements: (i) visual clarity; (ii) safety features; (iii) mind preparedness; and (iv) social support. By referring to their framework, this study aims to (i) evaluate the effectiveness of these four user-centered design elements in facilitating stress reduction and (ii) explore the underlying rationale behind their stress-reducing properties.

Understanding and implementing these design elements is essential not only for the immediate benefits of stress reduction but also for the long-term development of more effective virtual therapeutic solutions. By tailoring virtual environments to meet the specific psychological and emotional needs of users as stated by [21], this study posits that researchers and developers can create more responsive, effective, and user-friendly virtual therapeutic environments that can adapt to diverse user populations.

Moreover, this study bridging theoretical design principles with practical applications fills an important gap in the fields of mental health and human-computer interaction and makes explicit contributions to both disciplines. Indeed, the findings of this study help lay the groundwork for future research on innovative therapeutic solutions for mental stress. Thus, this study not only contributes toward future research but also allows a way to pair interdisciplinary collaboration with state-of-the-art

technologies in treatment approaches, further improving the treatment landscape of mental health issues.

The remainder of this paper is structured as follows: Section II reviews existing studies on virtual reality-based stress therapy and highlights the identified gap. Section III presents a framework for designing virtual environments for stress therapy. Section IV outlines the methodology, including data collection and analysis methods. Section V presents the results, followed by a discussion in Section VI and a conclusion in Section VII.

II. Review of Existing Virtual Reality-Based Stress Therapy Studies

VR use in stress therapy to date has proved beneficial for its users as numerous scholars (e.g., [9], [10], [11], [12], [13]) have proved that VR-based stress therapy yields significant improvements after a session when compared to standard types of treatment by providing man-altering experiences. Recently, [22] undertook a systematic review and found that out of 50 studies conducted on VR and stress management, 48 studies confirmed the efficacy of VR for this purpose. Not only that, but a study by [14] whose systematic review identified that the 17 studies explore VR and immersive technology in workplace wellbeing also supports VR as a safe and effective tool for wellbeing stemming from stress. In agreement, other studies by [19], [23], [24], and [25] also demonstrated the feasibility of the VR stress therapy initiative.

Meanwhile, although many recent studies indicate VR could be a suitable tool for performing stress therapy, there remains a gap in the study of virtual environments designed for stress therapy [17], [18]. In other words, even though the majority of existing studies presented the results on the effectiveness of the system in reducing stress with design discussion focused on general virtual environment factors such as audio-visual elements, navigation, biofeedback integration, and interaction [19], [22], [26], [27], [28]; however, there is limited discussion on user comfort within the virtual environment.

Following that, this study believed that emphasizing the necessity to incorporate user comfort in the design of virtual environments for stress therapy is essential as it serves as a guideline for developing effective virtual environments that aid in the stress reduction process. This is because the implementation of user comfort in virtual environments will ensure the comfortability of the users while in the therapy session, thereby increasing the users' motivation to continue with the therapy session [29], [30]. Neglecting user comfort in the design of virtual environments for stress therapy may result in ineffective therapy sessions and a loss of interest in continuing the therapy.

III. Framework For Designing Virtual Environments For Stress Therapy

A. Overview of Framework for Designing Virtual Environments for Stress Therapy

Fig. 1 illustrates the framework for designing virtual environments for stress therapy. The development of the framework involved four studies; (i) user requirements, (ii) an existing system review, as presented in study [31], (iii) user evaluation, where the discussion was presented in study [32] and (iv) an expert review, where the details was presented in study [33]. This framework consists of five factors – environment setting, environment exploration, interaction, attention stimuli, and user comfort; and 14 design elements.

The framework was discussed and evaluated by [17], who found out that (i) the system developed based on the proposed framework was found to be effective, usable, useful, and easy to use and (ii) all 14 design elements proposed in the framework were deemed useful in reducing stress. These encouraging findings suggest that the design elements included in the framework significantly contribute to the stress reduction process and should be considered when designing virtual environments for stress therapy.

Fig. 1. Framework for designing virtual environments for stress therapy. Source: [34]

Among these five factors, three are general factors for virtual environments that have been shown to facilitate stress reduction, as evidenced by studies conducted by [18], [19], [27], [35], and [36]. These three general factors are:

- Environment setting, which includes audio and visual design elements that facilitate stress reduction.
- Environment exploration, which addresses navigation techniques to support stress reduction.
- Interaction, which underscores the design elements for suitable interaction types that aid the stress reduction process.

While the past studies (e.g., [18], [19], [27], [35], [36]) mostly focused on the general factor of the virtual environment while discussing audio-visual elements, navigation, and interaction factors, however, the factor of user comfort remains underexplored. In other words, past studies often overlook the importance of user comfort in enhancing the therapeutic outcomes of virtual environments. Therefore, this paper aims to fill in the gap by exploring effective therapeutic interventions, particularly user-comfort-focused virtual environments for effective stress therapy. This study intends to (i) evaluate the effectiveness of four user-centered design elements – visual

clarity, safety features, mind preparation, and social support – in facilitating stress reduction; and (ii) explore the underlying rationale behind their stress-reducing properties. By discussing the rationale behind the stress-reduction properties of these four design elements, this study seeks to provide an understanding of how the user comfort factor contributes to the effectiveness of virtual environments for stress therapy.

B. User Comfort Factor in Designing Virtual Environments for Stress Therapy

User comfort in the context of designing virtual environments for stress therapy refers to the degree to which users feel psychologically at ease while being in the virtual environment. Four design elements contribute to user comfort namely, (i) visual clarity, (ii) safety features, (iii) mind preparation, and (iv) social support. Table I provides descriptions of each design element.

TABLE I. DESCRIPTION OF DESIGN ELEMENTS THAT SUPPORT USER COMFORT IN VIRTUAL ENVIRONMENTS FOR STRESS THERAPY

Design Element	Description
Visual clarity	Objects included in the environment should be visually clear to ensure information is correctly delivered. The users should quickly gain the necessary information from the visual presented (easily recognize the objects at first glance), understand what is happening, and what they should do to react accordingly.
Safety features	The environment should provide features that make users feel safe and protected. The environment cannot be dangerous in any sense of appearance, either by using dangerous animals or any setting that can trigger the users to feel anxious.
Mind preparation	A short mind-framing session that involves the users prepares their minds to become aware of the environmental changes before the virtual therapy starts (from the real-world environment to the virtual world environment) and before the therapy session ends (from the virtual world environment to the real-world environment). The pre-therapy mind preparation scene is meant to help the users get ready and focus on the therapy scene. The post-therapy mind preparation scene is meant to set the user's mind to bring the relaxation feel from the therapy session to the real world.
Social support	The presence of avatars who resemble real people provides the opportunity to observe and interact.

Source: [34]

Following the description in Table I, Table II shows the recommendations for the design elements' application in virtual environments for stress therapy.

By referring to Tables I and II, the first design element identified to support user comfort is visual clarity. Visual clarity refers to the comprehensibility of the displayed information within the virtual environment. Information may be presented in various forms, such as images, 3D models, or text, with the primary objective being to ensure that users easily understand the displayed information. For example, a display of flying birds should be instantly recognizable, rather than appearing as jagged moving dots. Similarly, fish in a river should be identifiable at first glance. High visual clarity can be achieved through high-quality graphic elements and appropriate techniques, all while maintaining the system's performance [37], [38], [39].

TABLE II. RECOMMENDATIONS FOR DESIGN ELEMENTS' APPLICATION INTO VIRTUAL ENVIRONMENTS FOR STRESS THERAPY

Design Element	Application of Design Element
Visual clarity	It is recommended to provide a clear graphic display where users can directly get the necessary information presented by an object. A clear graphic display can be achieved by having high-quality graphics. Graphic quality is usually associated with technical graphic aspects such as the numbers of the polygon, resolution rate, texture quality, and anti-aliasing features.
Safety features	It is recommended to provide the users with space and situations that make them feel safe and protected. It is also recommended to consider safety elements before any objects or situations are included in the environment.
Mind preparation	It is recommended to include mind-preparation activities that guide the users to appropriate meditation practices, such as breathing exercises. In addition, it is also recommended to have two sessions of mind preparation: first, at the beginning (before the therapy environment starts), and second, at the end of the therapy session. As for before the session starts (the pre-therapy session), it is recommended to include a set of breathing exercises containing at least three rounds of breath-in, hold-out, and breath-out instructions. This breathing exercise will prepare the user to be in therapy mode. Whereas, the mind preparation scene before the session ends (post-therapy session) should include a script that reminds the users to maintain the positive feeling they experience all day long. At the end of the script, it is suggested to have a countdown for the user to prepare themselves to take off the head-mounted display (HMD). As the script is being read, no additional relaxing visuals are encouraged to be displayed. The application may continue displaying the therapy environment until the end of the countdown. The application should shut down automatically as the countdown reaches its end.
Social support	It is recommended to include the presence of virtual people who mingle around in the environment. The virtual person or avatar may be portrayed through cyclists cycling around a park, a family having a picnic under a tree, or men jogging around. In addition, it is also recommended to take the distance between the virtual people and the users into consideration. Consideration should be made to include some interpersonal distance between the virtual people and the users to provide comfort and privacy to the users. The distance that is too close may trigger anxiety in the users. Apart from that, the number of virtual people included should also be considered. The number should be in minimal quantity—neither too many that will crowd the environment nor a complete absence, which may cause the users to feel lonely instead. Besides, the physical appearances of the virtual people should also be taken into account. Virtual people should portray proper appearances that suit the user's culture.

Source: [34]

The second design element identified is safety features. Safety features pertain to conditions within virtual environments that provide users with a sense of safety and protection. This design element is essential for preventing adverse effects and ensuring a pleasant therapeutic experience [40]. Implementing safety features involves designing the environment to avoid any dangerous appearances, such as the inclusion of hazardous animals like snakes and scorpions or settings that could trigger

user anxiety. Incorporating soft representations of animals [41], such as fish, rabbits, and ducks to fulfil the safety feature design elements is advisable. Furthermore, it is prudent to evade perilous locations, such as cliffs or higher terrains. In environments that may provoke anxiety, appropriate safety precautions must be instituted. In a beach environment with tumultuous waves, the incorporation of wavebreakers could augment users' perception of safety. In the context of a lookout tower, the incorporation of gates or barriers would decrease the likelihood of anxiety-provoking scenarios. Thus, this study advocates for the evaluation of safety aspects before the integration of any objects or scenarios into virtual environments to establish secure and supportive therapeutic settings.

The third design element contributing to user comfort is mind preparation. Mind preparation denotes the individual's engagement in activities that augment their awareness of alterations in the surrounding environment. To incorporate the mental preparation design element in the virtual environment, it is advisable to integrate activities that direct users through suitable meditation practices, including breathing exercises [42], [43], [44], [45]. Mind preparation can be divided into two parts: (i) pre-therapy and (ii) post-therapy sessions. The two parts are designed to ensure a seamless visual transition for the user from the physical world to the virtual environment before therapy and from the virtual realm back to reality following the session's conclusion. The inclusion of this feature aims to enhance users' consciousness, therefore better equipping them for the next stage of therapy. As individuals enhance their preparedness, the probability of experiencing anxiety during the session diminishes.

The fourth design element identified for user comfort is social support. Social support is defined as the presence of avatars that resemble real people, which provides users with opportunities to observe and interact. The objective of implementing social support is to prevent users from feeling lonely and isolated while also helping to reduce the anxiety associated with being alone in an unfamiliar place [46]. Implementing social support requires the strategic placement of avatars within the virtual environment. The avatars may represent cyclists, families having picnics, or individuals jogging. However, it is crucial to consider the distance between the user and the avatars. The avatars should not be allowed to come too close to the user, as this may cause discomfort; nor should they be placed too far away, which could induce feelings of isolation [47], [48], [49]. The concept of interpersonal distance can be applied to determine the optimal positioning of avatars relative to the user, ensuring a balance that enhances comfort and reduces anxiety.

Having explained the descriptions and recommendations for the application of the four design elements, the next section presents the methodology for evaluating the effectiveness of these elements in reducing stress.

IV. METHODOLOGY

A. Participants

A total of 55 healthy adults aged 20 to 60 volunteered for this study. During the screening session, participants answered questions about their stress levels using the Depression Anxiety Stress Scale (DASS). Only those with a score above 14 or a stress intensity scale of four or higher were invited to experience the virtual environment and be interviewed. Those criteria indicated that participants were experiencing some level of stress. Ultimately, 40 participants met the selection criteria of this study. As illustrated in Table III, 10 are male, and 30 are female. Among these 40 participants, 13 participants are within the age range of 20 to 30 years old, 14 participants an age range between 31 and 40 years, nine participants with an age range between 41 and 50 years old, and four participants with an age range between 51 and 60 years old.

TABLE III. PARTICIPANTS' DEMOGRAPHIC PROFILES

Demographic Profiles		**Frequency**	**Percentage**
Gender	Male	10	25.0%
	Female	30	75.0%
Age	20 – 30 years old	13	32.5%
	31 – 40 years old	14	35.0%
	41 – 50 years old	9	22.5%
	51 – 60 years old	4	10.0%

B. Data Collection

Given that the four design elements to address user comfort were reported to be effective, usable, useful, and easy to use, this study therefore focused on evaluating the usefulness of these four design elements in reducing stress. Three methods were used to collect the required data: (i) experiment, (ii) questionnaire, and (iii) interview. In other words, all 40 participants went through all three data collection methods, beginning with the environmental stage, filling in the questionnaire, and ending with an interview session.

1) Experiment: All 40 participants were invited to this experimental stage, which allowed them to experience the virtual environments developed based on the proposed framework discussed in the earlier section and as an evaluation tool to assess the usefulness of the proposed design elements in a single session. Fig. 2 shows images of the virtual environments used in the experiment.

2) Questionnaire: The usefulness of the design elements was evaluated based on their helpfulness in assisting users in reducing stress. A 5-point Likert-type scale question was included in the questionnaire for participants to rate the helpfulness of each design element in reducing stress where 1 indicated 'not useful at all', 2 'not helping much', 3 'helpful', 4 'very helpful' and 5 'no opinion'.

3) Interview: Upon completion of the experimental session, face-to-face interviews were conducted with each participant. The objective of the interview was to gain a further explanation of the ratings received in the questionnaire. The questions asked during the interview sessions were based on feedback obtained from the questionnaire. Each interview session was audio-recorded for analysis purposes. The interview sessions provided insights into how each design element contributed to the stress reduction process and ensured accurate interpretation of the rating received.

Fig. 2. Images of virtual environments used for the experiment.

C. Data Analysis

Data analysis was conducted based on the type of data collected. Feedback received in numerical form was tabulated on a table and was then analyzed by using descriptive statistical analysis using Microsoft Excel 2021. Meanwhile, recorded audio was transcribed word-by-word before they were reviewed three times for accuracy and understanding and content analysis using ATLAS.ti version 9.

V. Results

The results of the analysis are presented in three parts; (i) helpfulness frequency, (ii) helpfulness mean values, and (iii) helpfulness understanding.

A. Usefulness of Design Elements to Support User Comfort Based on Helpfulness Frequency

The helpfulness of the design elements was assessed using a 5-point Likert-type rating grouped into four categories for analysis purposes as shown in Table IV.

Based on the analysis, this study found the majority of the participants agreed on the usefulness of all four design elements in assisting them to reduce stress. As detailed in Table VI, the agreement is reflected in the high numbers of 'helpful' frequency (3 and 4 helpfulness rating points) compared to 'not helping much', 'not helpful at all', and 'no opinion'.

B. Usefulness of Design Elements to Support User Comfort Based on Helpfulness Mean Values

As shown in Table V, this study also analyses the helpfulness of the design elements that facilitate user comfort through their helpfulness mean values. All four design elements were useful in reducing stress as their helpfulness mean values were above the mean scale value of 2.5.

C. Rationale Behind the Helpfulness of Design Elements in Facilitating Stress Reduction

The analysis of the interviews provided an understanding of how the design elements aid stress reduction as the participants were asked to explain their reasoning behind the helpfulness rating, they provided for the design elements during the interview sessions.

1) Visual clarity: For the first design element, visual clarity, the majority of the participants (39 out of 40 participants or 97.50%) rated it as 'helpful' in reducing their stress – as presented in Table VI earlier. Indeed, the interview participants revealed that this design element is helpful as the clarity of the visual displayed significantly contributed to their comfort. They elaborated that: "Nah… clear visual made it easy to capture the information (displayed)… I didn't have any problem to do that" (Participant 17) and "When it (visual display) clear… it helps us feel at ease and comfortable" (Participant 57).

Meanwhile, for the one who rated visual clarity as 'not helping much', the reason for that was the user claimed to experience an unclear visual display. The participant commented that it was difficult to recognize the information being conveyed, which made her feel uncomfortable. She commented: "*Unclear visual made me dizzy*" (Participant 50).

TABLE IV. Derivation of Helpfulness Categories based on the Helpfulness Rating Points

Helpfulness Rating Point	Helpfulness Category
4 - Very helpful	Helpful
3 - Helpful	
2 - Not helping much	Not helping much
1 - Not helpful at all	Not helpful at all
5 – No opinion	No opinion

TABLE V. Tabulation of Design Elements' Helpfulness Means Values

Design Element	Mean	SD
Visual Clarity	3.58	0.55
Safety Features	3.55	0.81
Mind Preparation	3.45	0.85
Social Support	3.05	0.99

TABLE VI. Tabulation of Design Elements Helpfulness Categories Frequency

	Helpful		Not Helping Much		Not Helpful At All		No opinion	
Design Elements	Frequency	Percent (%)	Frequency	Percent (%)	Frequency	Percent (%)	Frequency	Percent (%)
Visual Clarity	39	97.5	1	2.5	0	0.0	0	0.0
Safety Features	37	92.5	2	5.0	0	0.0	1	2.5
Mind Preparation	36	90.0	3	7.5	0	0.0	1	2.5
Social Support	33	82.5	3	7.5	3	7.5	1	2.5

2) Safety features: For the second design element, 37 participants, or 92.5% rated safety features as 'helpful'. Analysis from the interviews revealed that this design element aids in stress reduction by providing them with a feeling of being safe and protected within the virtual environment. The participants indicated that the implementation of safety features made them feel comfortable as the environments appeared to be not dangerous in any aspect, especially due to the absence of dangerous animals. Among comments received highlighting the importance of safety features included: "Felt safe as there were no harmful animals around… for example… in the garden… within that unfamiliar environment, we never know if monkeys might suddenly jumping out of nowhere… that would make me uncomfortable… so, safety elements help in that sense" (Participant 14) and "It helps… in the sense that if there were dangerous animals… there might be surprising elements… causing fear… so… may cause discomfort… unexpected elements don't contribute to relaxation" (Participant 15).

On the other hand, for the two participants who rated safety features as 'not helping much', the analysis revealed they preferred being in an adventurous setting to reduce their stress. These participants mentioned that they did not mind the inclusion of dangerous animals or extreme situations in virtual environments as that would help them better release stress.

3) Mind preparation: For the third design element, mind preparation, 37 participants, or 90% rated it as 'helpful' due to three reasons; (i) it helps to prepare for visual transitions, (ii) it aids first-time users to calm down and (iii) it helps to release mental burden. Besides, they also recommended this study to apply this design element in two parts; (i) pre-therapy scene and (ii) post-therapy scene. These recommendations received positive feedback from the participants believed that mind preparation had assisted them in preparing themselves for visual transitions. Visual transitions meant by the participants referred to the transition from the real world to the virtual environment and from the virtual environment back to the real world. They praised the implementation of this design element as it smoothens the process and reduces the possibility of dizziness. They narrated that: "It helps!!!... It's kind of providing preparation… mental readiness… before we went into it (therapy scene)" (Participant 8), "It is helpful… it provides readiness before we started (therapy scene)" (Participant 12), "Cause it sets our mind…it sets our readiness" (Participant 15) and "It's 100% helpful because it gets you in the state of mind before you go into the simulation (therapy scene)" (Participant 16).

Another rationale for the helpfulness of mind preparation in supporting user comfort within virtual environments for stress therapy was the design element's ability to help first-time users calm down. Some participants mentioned that the experiment sessions were their first experience with VR, making them nervous as they did not know what to expect from the virtual environments. According to them, this is the part where mind preparation helped the most, to ease their feelings and calm them down. Comments reflecting the helpfulness included: "For me personally, it helps… as I don't have any experience with VR beforehand… therefore, the breath in breath out activities… the preparation exercise… really helped me feel more at ease" (Participant 13), "This one (mind preparation) is actually really helpful…you know when someone has never had any experience with VR… they don't know what to do… starting the therapy session (scene) straight away… is not proper… this thing (mind preparation) is important before we start any therapy… we calm ourselves first" (Participant 14), and "Helpful to reduce my nervous feeling… I had no idea what was inside the environment (therapy scene) … hence… breathing in and out calmed me" (Participant 34).

Additionally, mind preparation was found to be helpful as the design element helps to release the participant's mental burdens. Such practices not only promote relaxation but also empower individuals to enter the virtual environment with a clearer, more focused mindset, ultimately enhancing their therapeutic experience. One participant commented: "Deep breathing in and out made me feel relieved… free of burdens" (Participant 35).

Despite the positive feedback, mind preparation also received three 'not helping much' ratings. Based on the analysis conducted, two reasons were identified. The first reason that caused mind preparation to be less helpful was the participant mentioned that he was more eager to know what was offered in the therapy scene. The eagerness made him restless and uninterested in the mind preparation scene. He commented: "Wanted to skip it (mind preparation scene) as I was more interested in what was offered in the environments (therapy scene)" (Participant 19). The second reason for the less helpfulness rating for mind preparation was some participants had the opinion that breathing exercises could be done anywhere, not necessarily before a therapy session. Hence, making it less interesting as a pre-therapy scene exercise.

4) Social support: For the fourth design element, 33 participants, or 82.5%, rated social support as 'helpful'. The interview sessions also revealed two reasons why the participants believed it was able to help reduce stress. The first rationale for social support being helpful is that its implementation helped users from feeling isolated and lonely. They also recommended this study to place the avatars around the environment as they commented that: "People (avatars) around are helpful… empty environment (without avatars) is not a good idea… may cause loneliness" (Participant 14), "Presence of people (avatars) around reduces loneliness" (Participant 52) and "I can see people around me… it helps… I am not alone" (Participant 55).

The second reason supporting the relevance of social support as a helpful design element in reducing stress is it enhances the realism effect. In the participants' context, realism referred to the imitation of real-world settings within the virtual environment. By incorporating social support, participants felt as if they were in the real world rather than a virtual one. In other words, social support may help to increase user immersion. Among comments received highlighting the benefit of social support in imitating the real-world behavior setting were: "Indeed really helpful… presence of people (avatars) made it feel like being in the real world" (Participant 18), "The presence of avatars… it makes I feel like… like… it is… realistic (real world)" (Participant 17) and "It is essential to have people

(avatars) around… if not… it feels weird to be the only one in the world (virtual environment)" (Participant 32).

For the three participants who rated social support as 'not helping much', the result of the analysis revealed that they preferred to be alone to relieve their stress. For those participants, having people around, even in the form of avatars, made them uncomfortable, as if someone was watching them. They narrated that: "It is better to be alone… don't need social support… I prefer to be on my own" (Participant 8), "I think avatars are not necessary… usually… we find peace with views and sounds…not social support" (Participant 10), and "It is not helpful… having people around feels like someone is watching us… I prefer to be alone to relax" (Participant 53).

Analyzing the feedback for 'not helpful at all', such a rating was given due to the appearance of the avatars used in the system for the experiment session which was found to be scary by three participants. Two participants commented: "It is not helpful at all because the people (avatars)… they look scary (Participant 51) and "Because of the people (avatars)… they are too big and scary-looking" (Participant 50). While the other one commented: "When coming close to the people (avatar)… we can see their scary face… ugly" (Participant 39).

VI. Discussion

The analysis of the data gathered from the experiment, questionnaires, and interview sessions demonstrated that the four design elements identified to facilitate user comfort in virtual environments for stress therapy were useful in supporting the stress therapy process. The encouraging findings were supported by the high number of 'helpful' categories frequency received for all four design elements. Additionally, the mean values for the helpfulness also indicate that the proposed design is useful in assisting stress reduction. The encouraging finding is evidenced by the mean value for each of the design elements surpassing the mean value of the scale used which was 2.5.

Furthermore, the explanation provided for the rationale behind how the design elements assist in stress reduction offers an understanding of the significance of implementing these design elements in virtual environments for stress therapy. This study concluded that visual clarity enhances user comfort by efficiently conveying information, rendering it instantly recognizable and identifiable. Further analysis of the 'not helping much' feedback for visual clarity revealed that the unclear display was not caused by the clarity of the visual environments used for the experiment, but rather a personal issue of the participant. For instance, one of the participants disclosed at the end of the interview that she was experiencing eye problems and was about to undergo corrective surgery. The clarification by the participant indicated that the discomfort experienced was not due to the clarity of the environment but the participant's health issue.

For safety features, this study confirmed that this element helps provide user comfort in virtual environments for stress therapy. The helpfulness is attributed to the sense of safety and protection, as safety features encourage developers to consider safety aspects before implementing any objects or settings into virtual environments. However, for the 'not helping much' feedback received, it was found that the ratings were based on participants' personal preferences rather than their experiences with the system during the experiment before the interview session. Consequently, it may be inferred that the ineffectiveness of the safety features in facilitating stress reduction was attributable to user preferences rather than the characteristics themselves.

Mind preparation was also deemed helpful by the majority of the participants. Based on the results presented, it can be seen that the majority of the participants agreed that mind preparation helped reduce stress. Mind preparation was acknowledged for its benefit in preparing users' minds for visual transitions, assisting first-time users in calming calm and easing their nervousness as well as relieving mental burdens. Regarding the 'not helping much' feedback, comments suggest that breathing exercises can be done anywhere and are not interesting to be implemented as pre-therapy scenes might be due to issues in the implementation strategies of the design element in the virtual environments used for the experiment sessions.

The issues mentioned could be from the design of the scene which might be less attractive or the implementation strategies of the breathing exercise guidelines which used expanding and contracting circles to indicate breath in and out instructions. Therefore, the implementation strategies should be improved to better present the breathing exercise. There is no issue with implementing breathing exercises in the pre-therapy scene as they have been evidenced to be effective in reducing stress as reported by past studies (e.g., [50], [51], [52], [53], [54]).

Similar to the other three design elements, social support also received a majority of 'helpful' feedback. The helpfulness of social support was contributed by its ability to prevent participants from being alone and lonely, as well as enhancing the realism effect of the virtual environment. Despite the positive results, social support was also minorly rated as 'not helping much' in reducing stress due to participants' preferences to be alone when relaxing. The result of the analysis revealed that there was no issue with the environments themselves, rather the preference of the participants did not match the setting of the environments. However, the 'not helpful at all' feedback received provided insight into issues regarding the appearance of the avatars. The problem was not the presence of the avatars but their appearance as the avatars used in the virtual environments for the experiment sessions may have had design issues. It was acknowledged that the appearance may be ugly as the avatars' 3D models incorporated in the virtual environments were not ones with high polygons. Therefore, improving the avatars' appearance is necessary to avoid user discomfort in virtual environments for stress therapy.

The findings regarding the efficacy of the four design aspects in enhancing user comfort in virtual environments for stress therapy were favourable. The majority of users concurred that the proposed design elements were 'beneficial' in alleviating stress. The interview findings elucidated the rationale for the helpfulness of the design features, thereby deepening our comprehension of their role in the stress reduction process. This comprehension is essential as it highlights the importance of integrating user comfort and its design components while creating virtual environments for stress therapy.

VII. CONCLUSION

Exploring effective therapeutic methods, especially user-comfort-oriented virtual environments for stress therapy, is crucial for tackling the widespread problem of mental stress in modern society and improving coping strategies. The findings of this study highlight the critical significance of user-centred design in creating virtual worlds specifically designed for stress therapy, whereby the four recognised design elements that enhance user comfort—visual clarity, safety features, mental preparedness, and social support—effectively mitigate stress. The interviews also clarify how these four design aspects help users in regulating their stress levels.

The findings underscore the imperative to prioritise user comfort in the design of virtual environments for stress therapy. Integrating user comfort into the design process is essential for creating effective virtual settings that promote stress relief. User-centred design advocates for the active participation of users in the design process, ensuring that their needs, preferences, and comfort levels are paramount. The study indicates that when design elements are meticulously incorporated, they not only foster a more immersive experience but also enhance users' emotional and psychological well-being, thereby mitigating mental stress and improving general well-being.

A Machine Learning Model for Crowd Density Classification in Hajj Video Frames

Afnan A.Shah
Department of Computing-College of Engineering and Computing, Umm Al-Qura University, Makkah 21961, Saudi Arabia

***Abstract*—Managing the massive annual gatherings of Hajj and Umrah presents significant challenges, particularly as the Saudi government aims to increase the number of pilgrims. Currently, around two million pilgrims attend Hajj and 26 million attend Umrah making crowd control especially in critical areas like the Grand Mosque during Tawaf, a major concern. Additional risks arise in managing dense crowds at key sites such as Arafat where the potential for stampedes, fires and pandemics poses serious threats to public safety. This research proposes a machine learning model to classify crowd density into three levels: moderate crowd, overcrowded and very dense crowd in video frames recorded during Hajj, with a flashing red light to alert organizers in real-time when a very dense crowd is detected. While current research efforts in processing Hajj surveillance videos focus solely on using CNN to detect abnormal behaviors, this research focuses more on high-risk crowds that can lead to disasters. Hazardous crowd conditions require a robust method, as incorrect classification could trigger unnecessary alerts and government intervention, while failure to classify could result in disaster. The proposed model integrates Local Binary Pattern (LBP) texture analysis, which enhances feature extraction for differentiating crowd density levels, along with edge density and area-based features. The model was tested on the KAU-Smart-Crowd 'HAJJv2' dataset which contains 18 videos from various key locations during Hajj including 'Massaa', 'Jamarat', 'Arafat' and 'Tawaf'. The model achieved an accuracy rate of 87% with a 2.14% error percentage (misclassification rate), demonstrating its ability to detect and classify various crowd conditions effectively. That contributes to enhanced crowd management and safety during large-scale events like Hajj.**

***Keywords*—Hajj; moderate crowd; overcrowded; very dense crowd; machine learning**

I. Introduction

Mass surveillance video data recorded during Hajj require advanced processing techniques [1] to classify and detect crowd density levels in real-time ensuring timely responses to high-risk situations [2]. Manual crowd-monitoring systems are not only time-consuming and resource-intensive but also insufficient for managing the complexity of massive events like Hajj [3]. Machine learning methods have been implemented as a reliable solution for automating crowd analysis enabling the classification of crowd density levels directly from video frames [4]. Managing crowd density during Hajj also presents general challenges [5], such as noisy video frames [6], environmental factors like poor visibility and unrecognized objects [7], such as moving fans or vehicles near the Kaaba. These challenges can cause false alerts or missed detections [8], potentially leading to delays or dangerous situations. Furthermore, normal crowd behaviors during Hajj, such as group movements [9] and sacred congregations may appear high-risk in other contexts.

This study focuses on detecting and classifying crowd density into three levels: moderate crowd, overcrowded and very dense crowd. Unlike many current research efforts that predominantly rely on Convolutional Neural Networks (CNNs) for detecting abnormal behaviors [10], this research employs a Gradient Boosting Classifier (GBC) with a structured feature extraction model. Features such as Edge Density, Local Binary Pattern (LBP) texture and crowd area coverage provide a comprehensive representation of crowd characteristics, while a threshold-based method directly labels frames with Edge Density values above a critical level as very dense, ensuring the rapid identification of high-risk crowd regions.

The proposed model implements data augmentation techniques to improve generalization throughout various scenarios, uses class balancing to address the distribution of crowd density levels in the dataset and enhances the GBC through hyperparameter tuning with GridSearchCV to ensure robust performance. In addition, the model triggers visual alerts for very dense crowd scenes by overlaying a red flash indicator on detected frames, assisting organizers in real-time decision-making.

The contributions of this study are as follows: development of a Machine Learning model for classifying crowd density levels in video frames recorded during Hajj; integration of key features such as Edge Density, LBP texture and crowd area coverage to enhance classification accuracy; and use of performance metrics such as accuracy, precision, recall and F1-score to evaluate the model, with special emphasis on the 'very dense crowd' category.

The following sections are organized as, Section II provides the related works and Section III presents the proposed model. Section IV shows the result analysis and Section V concludes the paper.

II. Related Work

Felemban et al. [2] highlighted different levels of crowd density observed among pilgrims categorized as moderate crowd, overcrowded and very dense crowd. Such categories range from safe to potentially disastrous with very dense crowds posing significant risks such as stampedes. Although extensive efforts by Hajj authorities to manage crowds effectively, a method to classify hazardous crowd density conditions and provide timely notifications remains critical for enhancing crowd management. This paper builds on such insights by

proposing a data-driven machine-learning approach for accurate and timely crowd density classification.

Aldayri and Albattah [11] introduced a computer vision framework that uses a convolutional LSTM autoencoder to detect abnormal human behaviors in video sequences by combining convolutional neural network (CNN) to extract spatial features from video frames and LSTMs to analyze temporal patterns across consecutive frames. Their research, along with other similar studies [12] focuses on identifying abnormal behaviors whereas my model emphasizes crowd density classification based on structural features like Edge Density and LBP texture, addressing the specific challenge of real-time detection of very dense crowd levels.

In another research effort [13], a Crowd Anomaly Detection Framework (CADF) was developed which integrates multi-scale feature fusion and soft non-maximum suppression (soft-NMS) to detect anomalies in dense crowd scenarios. Bhuiyan [4] proposed the Crowd Anomaly Hajj Monitor to classify crowd anomalies by using optical flow and a fully convolutional neural network, which identifies specific behaviors but counts on predefined feature extraction techniques that may limit adaptability to varying crowd scenarios. On the other hand, my approach leverages Edge Density and other texture-based features for crowd density classification to ensure wider relevance in different crowd conditions. In addition, Alhothali et al. [14] introduced a deep CNN-based model to detect and localize anomalous events in dense crowd scenes classifying seven categories of abnormal events based on extracted spatial and temporal features. While that approach is effective for anomaly detection, such models often focus on individual behaviors rather than holistic crowd density levels. In a similar effort [15], other studies have utilized lightweight CNN and LSTM models to detect violent activities in surveillance footage, generating real-time alarms for law enforcement, which often enhance specific scenarios. Whereas, my study emphasizes a generalizable model for crowd density classification that focuses on critical safety categories like very dense crowds.

Previous works have widely applied CNNs and FCNNs to analyze surveillance videos for detecting anomalies [16]. Also, FCNN have been used for estimating crowd density from distant surveillance footage, showing significant improvements in crowd density classification [17]. However, many depend on fixed feature extraction techniques, such as optical flow or motion analysis [18] which can limit their adaptability to the unique dynamics of Hajj. Also, methods dependent on inflexible frameworks [19] may face challenges in handling the complicated temporal and spatial variations in crowd movement, especially during rituals and gatherings. The proposed model in this paper addresses these limitations by extracting meaningful features such as Edge Density, LBP texture and crowd area coverage which better capture the visual and structural characteristics of different crowd density levels. Furthermore, traditional approaches may classify normal crowd behaviors during Hajj, such as ritual-related movements or group activities as anomalies because of the unique nature of such event. This study avoids such pitfalls and provides a focused solution for monitoring critical crowd density levels in real-time by tailoring the model to classify crowd density rather than individual behaviors.

This study adds to the existing body of knowledge by presenting a machine-learning model designed to systematically classify crowd density levels. The model achieves enhanced accuracy and adaptability by employing a structured feature extraction process and fine-tuning classification with GBC, offering a practical solution for improving crowd management and safety during Hajj.

III. The Proposed Model

A. Data Preparation

I used the HAJJv2 dataset [20] which contains training and testing videos each set including nine videos capturing different holy sites during Hajj such as Massaa, Jamarat, Arafat and Tawaf. This dataset was originally created to focus on abnormal crowd behaviors during Hajj. Each video is divided into different frames and each frame's number is repeated multiple times in the label file with each instance assigned to a different type of abnormal behavior, thereby allowing for the capture of various behaviors occurring simultaneously or consecutively within the same frame.

For this study, I used the same segmented frames provided in the dataset with each video divided into a varying number of frames ranging between 466 and 501. However, I modified the label files to categorize the frames into three classifications; moderate crowd, overcrowded and very dense crowd eliminating the need to repeat the same frame's number to define multiple abnormal behaviors in a single frame. This was essential to reduce complexity and focus on overall density rather than specific behaviors.

Since the goal of this study is to categorize the overall crowd density in each frame rather than track specific abnormal behaviors or objects, I eliminated the need to repeat the same frame number to detect various abnormal behaviors in different areas within each frame. Instead, I simplified this by selecting one entry per frame to represent its density level. Each video's frames in the training and testing set are processed individually and assigned a single density label; moderate, crowded or very dense crowd based on the dominant or average density level observed in each frame.

To ensure accurate density classification, the dataset was preprocessed further. During this process, the total number of rows loaded from the dataset was 43,721 and frames with high EdgeDensity values were automatically updated with corresponding labels for very dense crowd conditions. The augmented dataset resulted in 131,163 entries which included features such as Edge Density, Area, Average Intensity and Local Binary Pattern (LBP) texture, significantly expanding the variety of training samples. In addition, an edge density threshold of 64.5 was set during the training process to facilitate the reliable identification of very dense crowds. That simplifies the dataset structure, making it more efficient for training a model aimed at detecting general crowd density levels without requiring additional details, such as bounding boxes or multiple labels per frame. By doing so, the training process is more streamlined, with improvements in efficiency and performance.

B. Model Design

The major goal of the proposed model is to detect and classify crowd density levels in video frames recorded during Hajj across various holy sites aiming to identify very dense crowd regions that may require immediate attention. In order to achieve this, the model uses a structured approach that starts with careful dataset preparation and well-defined labeling criteria as shown in Fig 1. The dataset comprises video frames categorized by crowd density levels: moderate crowd, overcrowded and very dense crowd. The model employs a threshold-based method to automatically label samples where frames with an EdgeDensity value above 64.5 are directly classified as very dense. This was selected through exploratory analysis of sample distributions and is intended to provide immediate labeling for the most critical category, ensuring timely detection of high-density scenes.

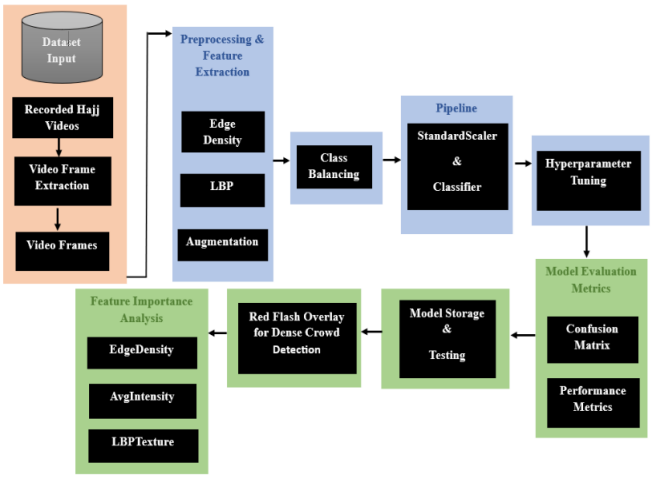

Fig. 1. Proposed model.

The model extracts Edge Density by calculating the density of edges detected in a designated area of each frame as this feature reflects changes in density. The Local Binary Pattern (LBP) texture feature was calculated by analyzing the local pixel patterns in grayscale crowd regions within the video frames, by which the LBP algorithm computes a binary code for each pixel by comparing it with its surrounding neighbors and generates a histogram capturing the frequency of specific binary patterns. That histogram reflects the texture characteristics of the crowd which is particularly useful in identifying varying density levels based on textural patterns that are prevalent in dense crowds. In this study, the histogram values were normalized and averaged to provide a single numerical representation of texture per region, which was included as the LBP Texture feature. The decision to use LBP stems from its ability to highlight subtle texture variations across crowd density levels aiding the model in making more accurate classifications and features like the area covered by the crowd region and average intensity contribute further contextual details. Also, data augmentation is used to enhance the training set's diversity including frame rotation and brightness adjustment. The reason for using augmentation is to provide the model with a wider array of samples thereby improving its generalization across new frames by allowing it to learn from a broader variety of crowd presentations.

Class balancing was essential due to some crowd levels having significantly fewer samples than others. The model addresses this by oversampling the minority classes, particularly the moderate crowd and very dense crowd categories. This ensures that each crowd level is equally represented during training thereby reducing the likelihood of bias and enhancing the classifier's performance across all classes.

The Gradient Boosting Classifier (GBC) was implemented as the primary classification algorithm because of its effectiveness in modeling complex non-linear relationships. That classifier works by sequentially building a series of decision trees where each tree attempts to correct the errors of its predecessor. That iterative boosting process allows the model to focus more on the misclassified samples from previous iterations, thereby improving its overall accuracy. For this study, GBC was integrated into a model that included feature scaling using StandardScaler to normalize the values of all features e.g., EdgeDensity, LBPTexture, Area, and AvgIntensity. The scaled features were then passed to the classifier. The model achieved optimal performance by incorporating GBC in a model and tuning its hyperparameters using GridSearchCV, as reflected in a cross-validation score of 0.97. That iterative approach also ensures the model's robustness in classifying different crowd densities despite the diversity in frame characteristics.

Hyperparameter tuning through GridSearchCV allows for the optimization of the GBC. A selection of key parameters such as the number of estimators, learning rate and maximum depth is tuned using cross-validation to ensure the model performs well without overfitting. Systematically, GridSearchCV tests various parameter options to find the set that yields the highest accuracy score during cross-validation.

Performance metrics such as accuracy, precision, recall and F1-score are used to evaluate the proposed model in this study as they provide an in-depth assessment of its ability to predict each crowd density level correctly with particular attention given to its precision and recall on the 'very dense crowd' classification due to the high importance of this category. In addition, a confusion matrix is employed to analyze further misclassifications offering insights into which crowd density levels may be confused by the model.

The final model, saved as a serialized file, is tested on new video frames to assess its practical performance in detecting very dense crowds, and importantly, it activates a red flash indicator as a visual alert for such frames. The design process is finalized with a feature importance analysis as each feature is examined to provide findings on which factors of crowd data affect the model's predictions validating the choice of features and pointing out the model's reliance on important crowd-related characteristics.

C. Training Process

The training dataset was balanced using oversampling techniques to address the class imbalance especially for the moderate crowd and very dense crowd categories. That ensured equal representation of all three crowd density levels. Features of each frame were extracted that included Edge Density calculated as the density of detected edges, Local Binary Pattern (LBP) texture, area covered by the crowd and average intensity.

During the training process, the LBP texture features played a significant role in distinguishing between moderately crowded and very dense crowd frames, since the histogram values captured by LBP provided insights into the structural patterns within the crowd, such as uniform regions indicating low density versus textured regions in high-density areas. That feature combined with EdgeDensity, area, and average intensity, allowed the model to detect high-density areas effectively. In addition, to enhance the diversity of the training set, data augmentation techniques such as rotation and brightness adjustments were employed.

D. Hyperparameter Optimization and Feature Importance

Hyperparameter tuning was performed using GridSearchCV, optimizing key parameters of GBC, such as the number of estimators 50, 100 and 200, learning rate 0.01, 0.05, 0.1, 0.3 and 0.5 and maximum depth 3, 4, 5, 6 and 7. The best parameters were a 0.5 learning rate, a maximum depth of 7, and 200 estimators, achieving a cross-validation score of 0.97 which provided the best cross-validation accuracy while balancing model complexity and performance.

An analysis of feature importance revealed that Edge Density was the most significant predictor for crowd density classification followed by LBP Texture and Average Intensity. The feature importance were: Area (0.69), Edge Density (0.24), Average Intensity (0.06) and LBP Texture (0.00). That confirms the relevance of these features in distinguishing between different crowd densities and supports their inclusion in the model.

IV. Results and Discussion

During the training stage of the model, I visualized the distribution of key features, such as area, position coordinates, edge density and average intensity across different crowd density levels including moderate, overcrowded and very dense crowd. These highlight how these features contribute to distinguishing between the crowd density categories which is essential for the model's accuracy. Fig. 2 shows that Area is a significant feature in distinguishing very dense crowd situations from moderate crowd or overcrowded as very dense crowds tend to cluster within a smaller area. In the HAJJv2 dataset, very dense crowds mostly appear in videos recorded during Tawaf around the Kaaba which is typically a quite small area. The yellow and green bars representing overcrowded and moderate crowds respectively, are distributed more widely across larger areas such as Sa'i, Mina, and Arafat compared to the very dense category. Such finding suggests that as crowd density decreases, the area covered by the crowd tends to increase due to people being more spread out.

Fig. 3 and Fig. 4 show the distribution of X and Y coordinates respectively, by crowd density category: moderate crowd, overcrowded and very dense crowd. Very dense crowd regions represented by the red bars are concentrated within specific ranges on both the X and Y axes. The clustering suggests that very dense crowds are likely to occur in particular locations within the frame reflecting areas where crowding frequently happens. Meanwhile, overcrowded and moderate crowds represented by the yellow bars and green bars respectively, are more widely distributed across the X and Y coordinates. In particular moderate crowds are spread across a larger range, indicating a more even distribution across the frame. Therefore, the specific positioning patterns of each crowd density level imply that spatial coordinates X and Y are useful features for distinguishing crowd densities. Thus, the model can use this information to recognize crowd density levels based on where they commonly appear within the frame.

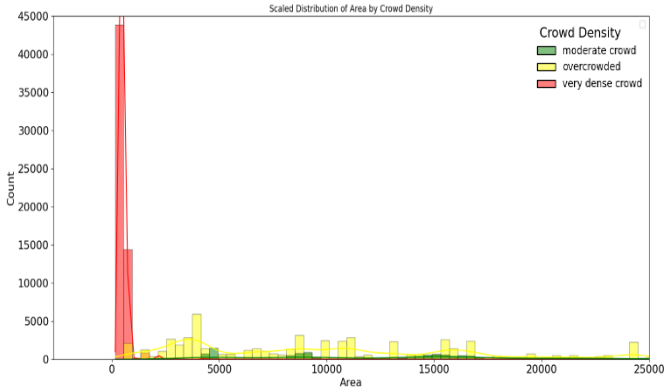

Fig. 2. Distribution of the "Area" feature by crowd density category (moderate crowd, overcrowded, and very dense crowd).

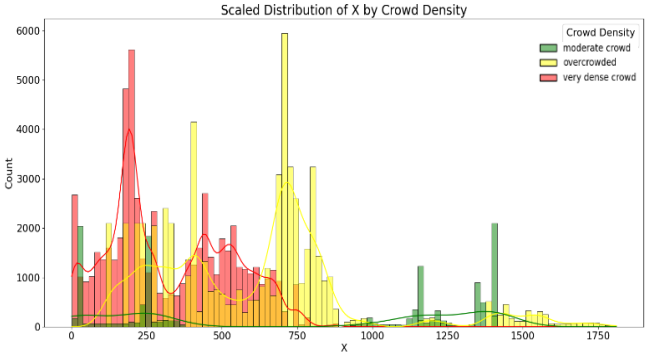

Fig. 3. The distribution of the " X " coordinate by crowd density category.

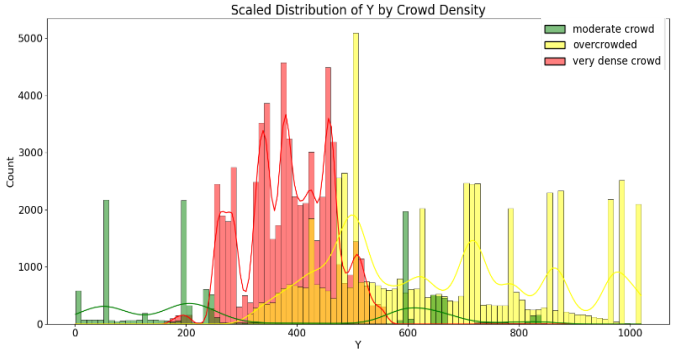

Fig. 4. The distribution of the "Y" coordinate by crowd density category.

For the distribution of the 'Edge Density' feature across the three crowd density categories, Fig. 5 shows that the very dense crowd represented by the red color, has the highest concentration of samples at larger edge density values, with a peak around 80–100.

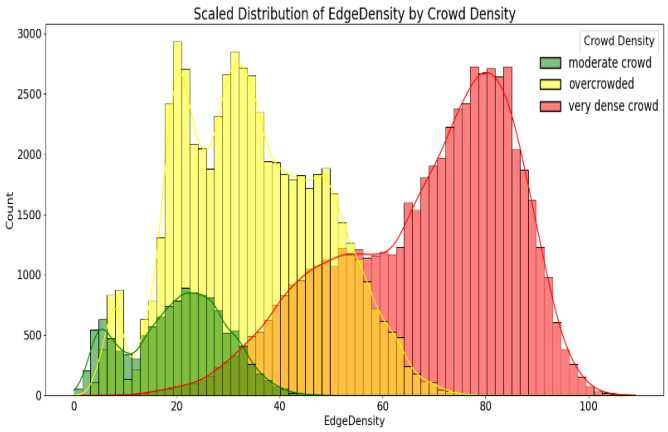

Fig. 5. Distribution of the "Edge Density" feature across crowd density categories.

Additionally, the figure shows that the overcrowded and moderate crowd categories, represented by yellow and green respectively, have a peak in the middle range of edge density values (around 40–60) and are concentrated in the lower range of edge density values below 20, respectively. This highlights the significance of edge density as a feature for classifying crowd density levels, as the distributions show clear separations, especially between the moderate and very dense crowd categories, with minimal overlap. Thus, the 'Edge Density' feature is a major factor contributing to the model's accuracy in distinguishing between these categories.

During the counting of the 'Average Intensity' feature, the visualized values show that, while there are slight shifts in the distributions as shown in Fig. 6, the very dense crowd peaks at slightly higher average intensity values around 125–150, the overcrowded category peaks in the mid-range of 100–125, and the moderate crowd is concentrated at lower intensity values below 100. All three crowd density levels overlap significantly in the range of 75 to 125 average intensity values. In addition, Fig. 5 demonstrates that average intensity captures variations in brightness across the frame that correlate with crowd density. While the overlap limits its standalone utility, it can enhance the model's accuracy when combined with other features like edge density and area.

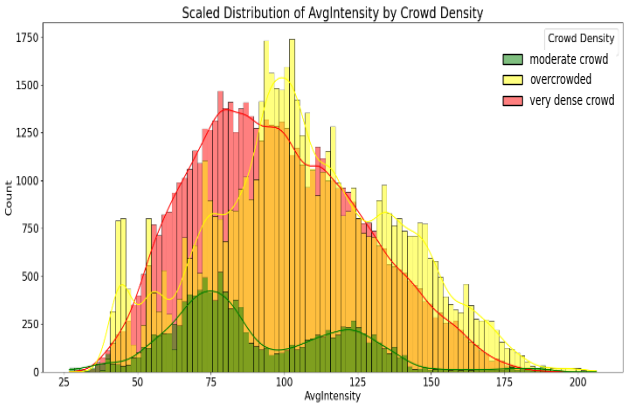

Fig. 6. Distribution of the "Average Intensity" (AvgIntensity) feature across crowd density categories.

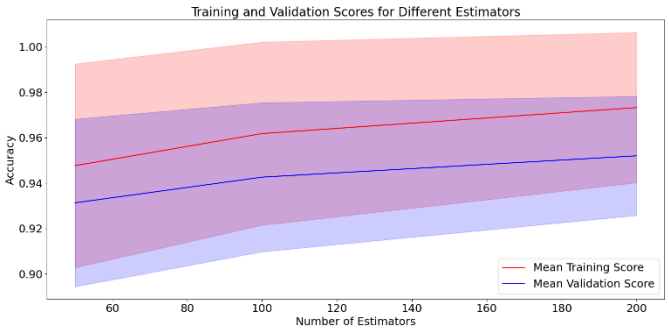

Fig. 7. Training and validation scores.

Finally, Fig. 7 shows the training and validation accuracy trends as the number of estimators increases, along with shaded regions representing the standard deviation for each. Both training and validation accuracy improve as the number of estimators increases and the model demonstrates stable performance without significant overfitting, as indicated by the relatively small gap between training and validation scores.

A. *Model Performance and Confusion Matrix Analysis*

Metrics including accuracy, precision, recall and F1-score were used to evaluate the proposed model. Fig. 8 shows the results of these metrics as 87% accuracy, 93% precision, 87% recall, and 84% F1-score, which therefore indicate the model's high reliability, especially in identifying frames with very dense crowd conditions, which is crucial for real-time monitoring systems.

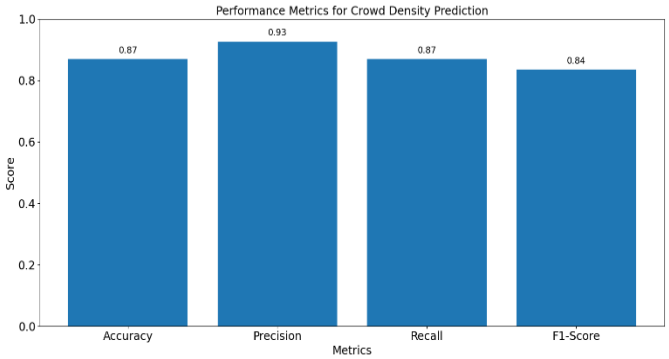

Fig. 8. Performance metrics.

In addition, a confusion matrix was constructed to analyze misclassifications. The matrix revealed that majority of misclassifications occurred between moderate crowd and overcrowded. While, frames classified as very dense crowd showed minimal false negatives thereby ensuring effective detection in critical situations. Fig. 9 presents the confusion matrix and provides a detailed breakdown of predictions versus true labels.

Moreover, an error percentage or misclassification rate based on the values of confusion matrix using the following equation:

$$Error\ Percentange = \frac{Total\ Misclassified\ Instances}{Total\ Instances} \times 100$$

$$Error\ Percentange = \frac{94}{4382} \times 100 \approx 2.14\%$$

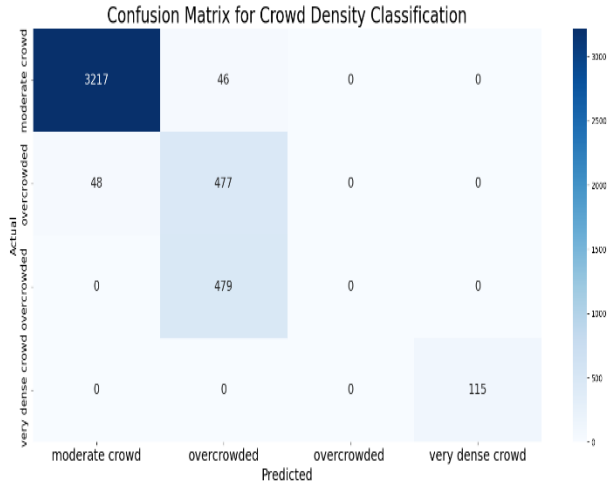

Fig. 9. Confusion matrix.

The 2.14% error percentage is ideal for high precision in a critical application such as classifying the surveillance videos of the holy sites during Hajj, especially in determining very dense crowd conditions, as false alerts or false estimations of the crowd situation could lead to either unnecessary triggering of emergency efforts or disasters. Furthermore, the model triggered visual alerts represented as red overlays for frames classified as 'very dense crowd'. This visual feedback could enhance the practical usability of the system in high-risk environments like Hajj.

The results demonstrate the success of the proposed approach in addressing crowd density classification challenges with high accuracy and low error percentage. The use of GridSearchCV for hyperparameter optimization and data augmentation for feature enhancement contributed significantly to the model's success. However, some limitations have been noted such as misclassification between moderate and overcrowded conditions, which could indicate the need for further enhancement to the methods used for extracting the features of the video frames. Also, real-time processing performance could benefit from hardware acceleration or further enhancement of the model.

Future work may look into contextual data integration such as temporal crowd flow patterns. In addition, extending the system to support multi-camera feeds could improve scalability for large-scale events like Hajj.

B. Comparsion with Previous Studies

The proposed model has been compared with other models in previous studies reviewed in Section II based on specific key evaluation criteria as shown in Table I. These criteria were collected from the previously reviewed studies. It was found that the proposed model in this study outperforms other models in its tailored feature extraction, real-time usability, focus on crowd density, and specific application to Hajj which make it uniquely suited for improving crowd management during Hajj. Although the proposed model achieves an accuracy of 87% which is slightly lower than the reported accuracy in some studies, that outperforms others in its targeted application of crowd density classification during Hajj. Unlike models that focus on detecting individual anomalies or specific behaviors, the proposed model is specifically designed to classify crowd density into actionable categories (moderate, overcrowded, very dense) and provide real-time visual alerts for very dense conditions. That is essential during Hajj to avoid crises such as the Mina stampede, which tragically led to the deaths of 1,000 pilgrims [21], and the collapse of a crawler crane at the Holy Mosque, resulting in 107 deaths and over 230 injuries [22] due to the dense crowds. That makes it more practical and reliable for real-world crowd management during Hajj.

Furthermore, with a low error rate of 2.14% and a balanced performance across metrics (precision: 93%, recall: 87%, F1-score: 84%), the proposed model ensures robust and consistent results tailored to Hajj-specific challenges.

TABLE I. COMPARISON OF PROPOSED MODEL WITH RELATED WORKS ON KEY EVALUATION CRITERIA (LEGEND √ MEANS INCLUDED/STRONGLY ADDRESSED, × MEANS NOT ADDRESSED AND ≈ MEANS PARTIALLY INCLUDED)

Criteria	Tailored Feature Extraction	Real-Time Visual Alerts	Low Misclassification Rate	Focus on Crowd Density	Application to Hajj-Specific Scenarios

Proposed model	√	√	√	√	√

C. Discussion

Even though this study uses the HAJJv2 dataset, which represents different crowd scenarios from various holy sites, such as Tawaf, Sa'i, Mina and Arafat, thereby covering different crowd density levels, biases may exist due to the under representation of certain density levels or specific scenarios, such as moderately crowded conditions during less busy times. To address this, data augmentation techniques were applied to balance the dataset and reduce classification bias. The model's performance on unseen data indicates its generalizability, though further validation with external datasets could provide additional insights into fairness.

The observed misclassifications between moderate and overcrowded categories highlight areas for improvement. Introducing additional contextual features, such as temporal crowd patterns or environmental conditions may enhance fairness and reduce boundary-level classification errors.

The proposed model in this study demonstrates trustworthiness by providing interpretable outputs based on clear and relevant features like area, edge density and spatial coordinates. These features align with real-world crowd dynamics, as evidenced by the strong correlations observed in very dense crowd situations, and the real-time visual alerts represented as red overlays for very dense crowd frames, further enhancing trust by offering actionable and transparent feedback to decision-makers.

The proposed model's low error rate of 2.14% combined with high precision 93% and recall 87% metrics ensures its reliability in critical scenarios, especially in avoiding false negatives for very dense crowd conditions. That makes the system suitable for real-time applications during high-stakes events like Hajj.

Studies like Bhuiyan et al. [12] and Alhothali et al. [14] focused on detecting individual anomalies, which differ from the comprehensive crowd density classification targeted by this study which uniquely combines tailored feature extraction with advanced machine learning techniques. Also, the proposed model balances computational efficiency with an accuracy of 87% offering a practical solution for detecting hazardous crowds during Hajj. While hybrid approaches as shown by Miao et al. [19] and Alafif et al. [20] which integrate deep learning techniques (e.g., CNNs, ResNet-50, YOLOv2) with traditional methods (e.g., Random Forests, Kalman filters) have demonstrated high accuracy in abnormal behavior detection, their reliance on computationally intensive models, advanced infrastructure (e.g., UAVs, edge-cloud models) and heavily annotated datasets often limits their scalability and real-time applicability during Hajj.

Finally, to further improve fairness and trustworthiness, future work may incorporate temporal crowd flow data, environmental factors and multi-camera feeds to enhance model robustness and scalability. Validation with external datasets can help address potential biases and improve generalizability, ensuring broader applicability to diverse crowd management scenarios.

V. Conclusion

This study proposed a model to classify crowd density in video surveillance recorded at the holy sites during Hajj into three classifications: moderate crowd, overcrowded and very dense crowd. The videos were segmented into frames, and features such as Edge Density, LBP texture, and area were extracted, which were identified as critical predictors for crowd density classification. Data augmentation and class balancing were employed to enhance the training dataset. A GBC was chosen for its robustness in handling imbalanced datasets and its ability to capture complex relationships between features. GridSearchCV was utilized to optimize the classification process, tuning key parameters such as the number of estimators, learning rate and maximum depth through cross-validation to achieve optimal performance.

The findings illustrate the capability of the proposed model to accurately classify crowd density levels. This proves its usefulness for real-time monitoring and managing crowds in critical locations.

Towards an Ontology to Represent Domain Knowledge of Attention Deficit Hyperactivity Disorder (ADHD): A Conceptual Model

Shahad Mansour Alsaedi, Aishah Alsobhi, Hind Bitar
Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia

Abstract*—Attention deficit/hyperactivity disorder (ADHD) represents a highly heterogeneous and complex medical domain with numerous multidisciplinary research areas. Despite the rising number of research on the pathophysiology of ADHD, the available information in the ADHD domain is still scattered and disconnected. This research study mainly aims to develop a conceptual model of ADHD by applying knowledge engineering processes to structure the domain knowledge, elucidating key concepts and their interrelationships. The methodology for developing the conceptual model is derived from established practices in ontology construction. It adopts a hybrid approach, integrating principles from prominent methodologies such as Ontology Development 101, the Uschold and King methodology, and METHONTOLOGY. The proposed ADHD conceptual model links various aspects of ADHD including subtypes, symptoms, behaviors, diagnostic criteria, treatment, risk factors, comorbidities, and patient profile. Comprising eight top-level classes and highlighting 13 key relationships, it establishes connections between symptoms and recommended treatments, as well as symptoms and their diverse manifestations, risk factors, ADHD subtypes, and potential comorbidities. While the model captures a broad range of ADHD-related concepts, it has certain limitations. It does not extensively address genetic or neurobiological mechanisms, nor does it capture cultural and contextual variations in ADHD manifestations. These limitations highlight opportunities for future expansion, such as incorporating real-world data and diverse demographic contexts. Nevertheless, the model developed in this study is well-suited to serve as a cornerstone for constructing a comprehensive ADHD domain knowledge ontology. Ontologies play a crucial role as a layer for transferring knowledge and serve as a foundation for developing advanced systems, such as decision-support tools and expert systems, to enhance ADHD research and clinical practice.

Keywords*—Conceptual model; ontology; ADHD; knowledge engineering

I. Introduction

Attention-deficit/hyperactivity disorder (ADHD) is the most prevalent behavioral disorder and the second most frequent chronic condition among children [1]. ADHD is a neurodevelopmental disorder characterized by a recurring pattern of inattention, hyperactivity, and impulsivity [2], [3]. The symptoms of inattention, hyperactivity and impulsivity include a wide range of behaviors such as difficulty completing tasks, difficulty following instructions, making careless mistakes, and being overly impulsive [3]. These symptoms of ADHD often have a direct negative impact on the individual's academic achievement, social relationships, self-esteem, and emotional functioning [2], [4]. ADHD was already a common condition in the past. However, it is becoming more common nowadays. Over the past two decades, there has been such a significant increase in rates of ADHD diagnoses that researchers describe it as a "dramatic change" that occurred between 1997 and 2016 [5], [6]. The global prevalence of ADHD is estimated at 2% to 7%, with an average of around 5% in school-aged children [7] and 2.5% to 5% in adults [8], [9].

In the last two decades, the field of ADHD has witnessed remarkable progress in research. Different studies often explore different aspects of ADHD. It incorporates multiple disciplines such as psychology (e.g. [10], [11]), neuroscience (e.g. [12], [13]), genetics (e.g. [9], [14]), epidemiology (e.g. [15], [16]), pharmacology (e.g. [17], [18]), and psychosocial and educational interventions (e.g. [19], [20]). Thus, ADHD research is quite diverse and multi-faceted. Bridging the gap between such different disciplines is particularly difficult due to this diversity.

Despite the rising number of studies on the pathophysiology of ADHD, the disorder remains a complex psychological condition that is challenging to characterize [21]. Many previous studies have repeatedly emphasized the complex and heterogeneous nature of ADHD [22]. This heterogeneity is reflected in its wide range of psychiatric comorbidities, diverse clinical profiles, patterns of neuropsychological impairment and developmental trajectories, and a broad spectrum of structural and functional brain abnormalities [22]. In addition to its complex nature, one of the significant challenges in the ADHD research field is the scattered and unstructured nature of the available information. ADHD knowledge is dispersed across various types of studies, making it difficult for researchers, clinicians, and caregivers to access and synthesize relevant insights effectively [23]. Thus, this research focuses on addressing two core problems: the complexity and heterogeneity of ADHD and the scattered, unstructured information in the domain.

As the research environment grows increasingly complex, it is crucial to establish methods that make the diverse output of ADHD studies more accessible and integrative [24]. Recently, there has been a striking rise in the use of biomedical ontologies as the preferred method for bridging different disciplinary gaps. They ensure wide access and exchange of information among researchers and professionals from different backgrounds and a wide range of disciplines [25], [26]. The remarkable success of

biomedical ontologies is due to their power to offer a comprehensive framework within which researchers can publish their new findings and physicians can conveniently access the studies that serve as the foundation for their diagnosis and treatment approaches.

Gruber [27] defined the computer science ontology in 1993 as " explicit specification of a conceptualization". This definition placed an emphasis on the conceptualization, which serves as the foundational phase influencing subsequent processes in ontology development. Conceptualization consumes the majority of the time dedicated to ontology construction. It commences with the knowledge acquisition phase, wherein a description of the domain ontology is formulated. Subsequently, the acquired knowledge is arranged and structured within a conceptual model [28]. Kabilan [29] defined the conceptual model as a theoretical representation of a segment of reality, outlining fundamental concepts and their interrelations. It captures all relevant knowledge in a given field, organizing it into a structured and unified framework. By doing so, a conceptual model serves as the foundation for integrating and harmonizing diverse and scattered information. This leads us to the central research question of this study: How to develop a conceptual model that offers a unified framework to integrate the heterogeneous and scattered knowledge in the ADHD domain?"

As we mentioned above, the ADHD domain, with its multifaceted nature and interdisciplinary scope, presents unique challenges in structuring and consolidating knowledge. Addressing the complexity and scattered nature of ADHD-related information requires a systematic approach to conceptualization, one that captures the domain's key components and their intricate interrelations. Recognizing this need, in this paper, we mainly aim to develop a conceptual model that describes the reality of the ADHD domain with its key concepts and relationships. The resulting conceptual model aims primarily to be a basis for building an ADHD domain knowledge ontology in order to provide a step towards reducing the knowledge gap in the field of ADHD.

The rest of this paper is organized as follows: Section II demonstrates the Related work, and the research methodology is detailed in section III. The findings of this research are explained in Section IV. The discussion is presented in Section V before concluding the work.

II. Related Work

Conceptual models have been widely used in the study of neurodevelopmental disorders to provide structured frameworks for understanding the relationships between symptoms, risk factors, functional impairments, and outcomes. These models are essential for integrating knowledge across disciplines, identifying intervention targets, and advancing clinical and research practices. They play a crucial role in organizing and integrating knowledge about complex disorders such as ADHD. However, within the field of ADHD, there is a notable paucity of comprehensive conceptual models that unify its various dimensions. Existing efforts often focus on isolated aspects, leaving gaps in understanding the disorder holistically. The following section highlights existing conceptual models in ADHD research and underscores the gaps this study aims to address.

Rapport et al. [30] introduced a conceptual model that highlights the underlying assumptions about what causes ADHD and how it is treated through behavioral and pharmacological approaches. The model suggests that biological factors, such as genetics or prenatal complications, lead to differences in how the brain's systems function. For example, changes in neurotransmitter systems like dopamine and norepinephrine are thought to be directly responsible for the main psychological features of ADHD, including cognitive and behavioral symptoms. The model also explains that other characteristics of ADHD, often called "associated features" in the DSM-IV (e.g., academic struggles, poor social skills, or family conflicts), are secondary effects caused by these core symptoms. For instance, a child's academic difficulties might result from their inability to pay attention or persist in tasks over time. Eventually, this model categorizes therapeutic interventions into pharmacological treatment, cognitive behavioral therapy (CBT), and skills training, correlating each type to be specifically directed to treat one aspect of the disorder: pharmacological treatment for biological factors, CBT for cognitive and behavioral symptoms (subtypes), and skills training for associated features.

Brod et al. [31] in their study focuses on understanding how ADHD symptoms and impairments impact the quality of life (QoL) in adults. The authors proposed a conceptual model based on data from experts, patients, and literature. The model identifies five areas of impact: work, daily activities, relationships, psychological well-being, and physical well-being, which are grouped into three key QoL domains—productivity, relationships, and health. The model highlights how ADHD symptoms interact synergistically, creating cascading impairment pathways that affect daily functioning. To operationalize the model, the Adult ADHD QoL Measure was developed, enabling clinicians to assess ADHD's impact on QoL and design more comprehensive, individualized treatment plans.

In the same context of ADHD, Dosreis & Myers [32] propose a conceptual model explaining how parents of children with ADHD recognize problems, seek medical evaluations, and decide to pursue treatment. Based on interviews with 48 parents, the model identifies three phases: (1) problem recognition, (2) motivation for evaluation, and (3) therapeutic intervention. Parental decisions are shaped by life circumstances (e.g., family changes, financial shifts), experiences at home, school, and within cultural/religious settings. The model distinguishes between family subgroups based on their help-seeking behaviors, offering insights for tailored, patient-centered interventions to enhance treatment delivery and family engagement.

In neurodevelopmental disorders fields such as autism spectrum disorder (ASD), dyslexia, and child psychopathology, numerous conceptual models have been developed to address the complexity and heterogeneity of these conditions. Alsobhi et al. [33] propose a conceptual model to support personalized learning experiences for students with dyslexia. The conceptual model links dyslexia types with assistive technologies and learning styles to create tailored educational materials. The

model includes key components such as Dyslexia Type, Assistive Technologies, and Learning Style, ensuring flexibility and adaptability. By aligning learning resources with student needs, the model provides a structured framework to enhance e-learning outcomes for dyslexic learners.

These studies illustrate the growing recognition of the importance of conceptual models in the field of neurodevelopmental disorders. They highlight the complexity of these conditions and the need for frameworks that integrate various factors. However, there remains a significant gap in developing comprehensive, unified models, which points to the need for continued research and further work to build more inclusive and practical models for understanding and addressing neurodevelopmental disorders such as ADHD.

III. METHODOLOGY

This paper embarks on a journey into the methodology employed for crafting not only a robust ontology but also the consequential development of an associated conceptual model. Recognizing the symbiotic relationship between these two endeavors, we acknowledge that the path toward a comprehensive ontology necessitates a deliberate and strategic approach in conceptualization. The conceptualization process produces the conceptual model which contributes to the ontology development process by enhancing clarity through its graphical representation, making it easier to understand and utilize. Additionally, the conceptual model promotes reusability, as it can be adapted into various ontology representation languages [28]. Consequently, our methodology for conceptual model development is basically derived from and informed by the proven techniques and practices established in the realm of ontology construction.

To develop the conceptual model proposed by the current study, a hybrid methodology of the most prominent ontology construction methodologies was adopted, drawing upon the foundational principles recommended by the Ontology Development 101 method [34], the Uschold and King methodology [35] and the METHONTOLOGY [36]. Specifically, the foundational framework presented by Uschold and King will be integrated through the iterative phases of the Ontology Development 101 method, complemented by the crucial conceptualization step outlined in METHONTOLOGY. The selection of this hybrid approach is grounded in its capacity to leverage the respective merits of each methodology. The Uschold and King methodology affords a clear and systematic framework for ontology development, facilitating the establishment of an initial ontology structure. Complementarily, the Ontology Development 101 method empowers us to incorporate finer-grained details and engage in iterative stages, thereby fostering the creation of a more thorough and comprehensive ontology. Furthermore, the integration of METHONTOLOGY augments our approach by harnessing the distinct benefits offered by its conceptualization step. This encourages a deep understanding of the domain and helps ensure that the conceptual model captures the semantics accurately, thereby enriching the overall development process of the ontology. Using these methodologies, the conceptual model is constructed following a set of prescribed guidelines and procedural steps: (1) Identify the domain, scope, and purpose, (2) Capture the knowledge and conceptualization by a set of iterative steps (Enumerate important terms in the domain, Define the classes, and define the properties (object and data properties), (3) Build the conceptual model). Fig. 1 illustrates the workflow of the methodology.

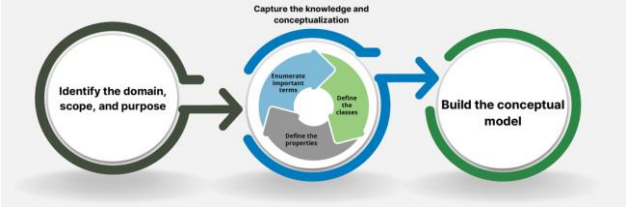

Fig. 1. The workflow of the conceptual model building methodology.

A. Identify the Domain, Scope, and Purpose

The foundational phase in constructing a robust conceptual model, and equally essential in ontology development, involves a meticulous exploration to identify the fundamental aspects that shape its essence. At the forefront of this endeavor is the imperative task of pinpointing the domain, determining the scope, and elucidating the purpose that the conceptual model aims to serve [34], [35]. This initial step serves as the compass, guiding the subsequent development process. Through a comprehensive examination of the domain's intricacies, a clear delineation of the model's boundaries, and a lucid definition of its overarching objectives, this step lays the groundwork for a conceptual model poised to effectively encapsulate and represent the targeted knowledge domain. Recognizing that this step is equally pivotal in constructing ontologies underscores its significance in fostering a seamless transition from conceptualization to formal knowledge representation. Table I illustrates the domain scope of the proposed conceptual model.

B. Capture the Knowledge and Conceptualization

1) Enumerate important terms in the domain: The starting point in Capturing the knowledge in a field is to write down a list of all relevant terms in the field. As outlined in the 101 method [34], the focus is on obtaining a comprehensive list of terms, regardless of any overlap between the concepts they represent, relations among the terms, or any properties that the concepts may possess. In the context of ADHD, essential terms include but are not limited to Symptoms, Inattention, Hyperactivity, Impulsivity, Subtypes (such as predominantly inattentive, predominantly hyperactive-impulsive, combined), Diagnostic criteria [43] (e.g., DSM-5 criteria), Treatment options (e.g., medication, behavioral therapy), Medication (e.g., stimulants, non-stimulants), Behavioral therapy, Risk factors, Genetics, Environmental factors, Comorbidities (e.g., anxiety disorders, depression), Executive dysfunction, Neurodevelopmental disorder, Neurobiology, Cognitive impairments, Academic performance ,Impairment in daily functioning. Subsequent steps in the knowledge capture process build upon this foundational list, often executed iteratively (as depicted in Fig. 1). From this list, the most significant terms are selected to represent the classes forming the conceptual model, with the remaining terms likely serving as subclasses or properties that provide detailed descriptions of these classes.

TABLE I. SCOPE, DOMAIN AND KNOWLEDGE SOURCE OF THE ADHD CONCEPTUAL MODEL

Domain	The domain of interest of this work is the ADHD domain
Date	2023 - 2024
Built By	Research student in Information Systems department at the Faculty of Computing and Information Technology – King Abdulaziz University
Purpose	• Knowledge Representation Blueprint: Acting as a blueprint, the conceptual model outlines key concepts, relationships, and entities crucial for accurate and comprehensive conceptualization and representation of the available knowledge in various aspects of ADHD. • Foundation for Ontology Construction: The conceptual model serves as the foundational framework upon which the subsequent ontology is constructed. • Defining Ontological Boundaries: By identifying the domain, scope, and purpose, the conceptual model aids in clearly defining the boundaries and parameters that subsequently shape the ontology. • Enhancing Ontological Consistency: It contributes to ensuring consistency and coherence in the ontology by presenting a conceptual framework that aligns with the nuances and intricacies of the targeted domain. • Facilitating Seamless Transition: The conceptual model facilitates a seamless transition from conceptualization to formal ontology construction, streamlining the overall knowledge modeling process.
Scope	The scope of the conceptual model is a manifestation of the domain knowledge encapsulated within the semantic model. Specifically, the ADHD domain conceptual model is finely tuned to address the intricacies of the ADHD domain. It covers aspects which include: ADHD types, symptoms, Diagnosis criteria and treatments, Comorbidities …
Source of Knowledge	• The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, (DSM-5) [3] • The World Health Organization (WHO) Eleventh Revision of the International Classification of Diseases (ICD-11) [2] • The National Institutes of Health (NIH) [37] • The American Academy of Pediatrics (AAP) [38] • American Psychological Association (APA) [39] • Children and Adults with Attention-Deficit/Hyperactivity Disorder (CHADD) organization [40] • Centers for Disease Control and Prevention (CDC) [41] • Clinical Expert interview • The first researcher also reviewed various materials, including websites and academic papers, to gain comprehensive insights into the specified domain.

2) Define the classes: As we delve into constructing the conceptual model for the ADHD domain, a crucial initial step involves defining classes. The top-level classes of the ADHD conceptual model (illustrated in Table II) act as fundamental building blocks, representing key concepts and terms integral to the realm of ADHD. The process of defining classes not only brings clarity to our conceptual model but also lays the groundwork for developing an organized and thorough representation of ADHD, forming the basis for future ontology construction.

3) Define the properties: As outlined in study [34], properties serve as a form of association between concepts within the domain, describing relationships among individuals belonging to different classes. Typically, ontologies include ordered binary relations where one argument signifies the domain and the other represents the range. These relations are called Object properties which establish connections between individuals of the domain class and those of the range class. Object properties may possess corresponding inverse properties. For example, the properties treatedBy (s, t) and isTreatmentFor (t, s) that relate a symptom with a treatment are inverse properties. Additionally, properties may include cardinality constraints, specifying the number of relationships an individual can engage in for a given property. Table III provides an overview of the properties within the ADHD conceptual model, detailing their domain, range, inverse property (if applicable), and cardinality.

TABLE II. DESCRIPTION OF THE ADHD CONCEPTUAL MODEL MAIN CLASSES

Class	Description
Subtypes	Describes the three different subtypes of ADHD
Symptoms	A compilation of signs and symptoms endorsed by DSM-5, indicative of ADHD
Behaviors	A compilation of diverse expressions and behaviors exhibited by individuals, each representing varied manifestations falling under each specific symptom
Diagnostic Criteria	A compilation of diagnostic criteria outlined in DSM-5, officially endorsed for the identification and diagnosis of ADHD
Risk Factors	A list of genetic, environmental, and psychosocial factors that could potentially contribute to the manifestation of ADHD symptoms
comorbidities	Different common coexisting conditions or comorbidities frequently observed in individuals diagnosed with ADHD
Treatment	Different safe and effective treatments and management interventions suitable for individuals with ADHD throughout their lifespan
Patient profile	Personal medical history profile and information

TABLE III. ADHD CONCEPTUAL MODEL PROPERTIES

Property Name	Domain	Range	Cardinality	Inverse property
hasSymptoms	Subtypes	Symptoms	Multiple: a Subtype may have more than one Symptoms	hasSubtype
hasDiagnosticCriteria	Subtypes	Diagnostic Criteria	Multiple: a Subtype may have more than one Symptoms	-
hasBehviors	Symptoms	Behaviors	Multiple: a Symptom may have more than one Behaviors	hasRelatedSymptoms
hasDSM5Criteria	Symptoms	Diagnostic Criteria	Single: a Symptom relates to one DSM 5 Criteria	-
treatedBy	Symptoms	Treatment	Multiple: a Symptom may have more than one Treatments	isTreatmentFor
hasInfluenceOn	Risk Factors	Subtypes	Single: a risk factor may have an influence on the occurrence of one Subtype	influencedBy
hasInfluenceOn	Risk Factors	comorbidities	Multiple: a risk factor may have an influence on the occurrence of more than one comorbidity	-
hasSymptoms	Patient profile	Symptoms	Multiple: a patient may manifest more than one Symptoms	-
hasRiskFactors	Patient profile	Risk Factors	Multiple: a patient may have more than one Risk Factors	-

IV. ADHD CONCEPTUAL MODEL: UNVEILING THE INTERCONNECTED LANDSCAPE OF ADHD DOMAIN KNOWLEDGE

Fig. 2 illustrates the ADHD conceptual model that is meticulously crafted in an attempt to contribute to elucidate its multifaceted nature. This conceptual model serves as a guiding framework, delineating top-level classes alongside their corresponding properties and interrelationships. Each of these classes embodies a pivotal concept within the ADHD domain, encompassing a spectrum of subtypes, symptoms, behaviors, risk factors, comorbidities, treatment, and diagnostic criteria.

The relationships between these classes are not merely arbitrary connections but rather solid interconnections firmly grounded in evidence derived from reputable scientific research. Through a meticulous synthesis of findings from reliable sources, the conceptual model unveils the connections that exist between these fundamental concepts, serving as the initial blueprint for the ADHD domain knowledge ontology. As we navigate through this conceptual model, we embark on a journey toward a deeper understanding of ADHD, guided by the structured interplay of its constituent elements.

The 'Symptom' class is one of the most central concepts within the domain of ADHD, as underscored by its pervasive association with numerous concepts throughout the conceptual model. The relationship 'has_DSM5_criteria' between the symptom class and the diagnostic criteria class, elucidating the direct correlation between identified symptoms and the diagnostic standards delineated in DSM-5 [3]. This alignment with DSM-5 criteria, acknowledged as the authoritative reference for diagnostic guidelines worldwide, substantiates the reliability and validity of symptoms enumerated within the symptom class.

The 'Symptom' class further establishes a relationship with the 'Behavior' class through the designated relationship 'has_related_behaviors' and its corresponding inverse relationship 'has_related_symptoms'. While DSM-5 delineates diagnostic symptoms characteristic of ADHD, empirical evidence from numerous studies suggests that these symptoms may manifest diversely as behavioral patterns across different developmental stages—children, adolescents, and adults alike [35], [36], [37]. This interrelation serves to bridge each symptom outlined in DSM-5 with its varied behavioral manifestations across distinct age cohorts, thereby enhancing the diagnostic precision tailored to the nuanced needs of different age groups. Consequently, this alignment holds promise for refining the diagnostic process, rendering it more comprehensive and tailored to the developmental context of individuals presenting with ADHD symptoms.

Symptoms wield significant influence in subtype delineation within the disorder, thereby informing potential treatment modalities. Consequently, it is associated with the 'Subtypes' class through the relationship (has_subtype) and its inverse relationship (has_symptoms), as well as with the 'Treatments' class via another designated relationship (treated_by) and its corresponding inverse relationship (is a treatment for). This interconnection underscores the pivotal role of symptomatology not only in subtype classification but also in guiding treatment and interventions approaches. Such relational frameworks within the ontology facilitate a comprehensive understanding of the intricate interplay between symptoms, subtypes, and treatment strategies, thereby enriching the diagnostic and therapeutic landscape of ADHD management.

The relationship between the 'Risk Factors', 'Subtypes', and 'Comorbidities' classes within the ADHD ontology is illustrated in the conceptual model through relationships (has_influence_on) (a_risk_factor_for). Research, including the study by Freittag et al. [38], as well as numerous corroborating studies, have underscored the influential role of various risk factors in shaping both ADHD subtypes manifestations and comorbidities. By elucidating these relationships, the ontology contributes to the understanding of how risk factors contribute to the heterogeneity of ADHD presentation and the onset of comorbidities discussion.

In this paper, we propose a cohesive conceptual model that integrates various concepts of ADHD, including symptoms, subtypes, diagnostic criteria, treatment, risk factors, comorbidities, and patient profile. These concepts are related to each other through many relationships between them. This conceptual model aims to be the cornerstone for building an ontology of existing knowledge within the domain of ADHD.

A. Conceptual Models in the ADHD Field

The In the realm of ADHD, few works have delved into conceptualizing knowledge within a conceptual framework, while existing studies have made important contributions toward understanding various aspects of ADHD, the development of comprehensive conceptual models remains limited.

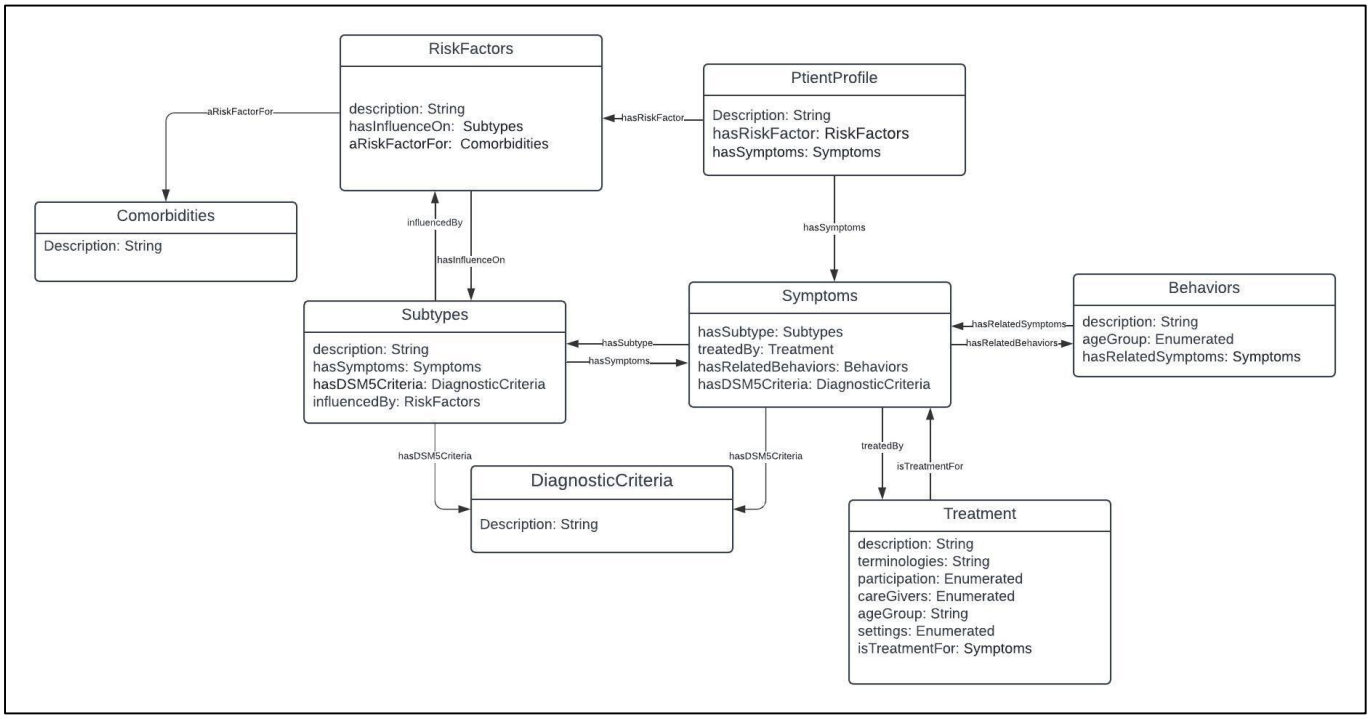

Fig. 2. ADHD conceptual model.

Such as symptoms, risk factors, or treatment pathways without integrating these elements into a unified framework. This highlights a clear need for a holistic approach that bridges these gaps, providing a more structured and interconnected representation of ADHD domain knowledge. The proposed work aims to address this gap by presenting a conceptual model that unifies these diverse components.

Unlike previous works in the field of ADHD, which focus solely on developing conceptual models, this research uniquely aims to transform a conceptual model into an ontology. Ontologies play a crucial role as a knowledge transfer layer, enabling the structured representation and integration of ADHD domain knowledge. By formalizing key concepts and relationships, an ontology serves as a foundation for building advanced systems such as decision-making systems and expert systems. These systems can enhance diagnosis, treatment planning, and research, ultimately improving outcomes for clinicians, researchers, and individuals with ADHD.

Building on the studies discussed in the "Related Work" section, the following section examines the similarities and differences between these studies and the current research, highlighting the unique contributions of this study. Rapport et al. [30] introduced a conceptual model focusing on the classification of therapeutic interventions for children with ADHD. However, given the disorder's inherent complexity and heterogeneity, such arbitrary classifications may not always prove effective. In the context of ADHD, several critical clinical considerations influence the selection of treatment strategies. These include factors such as the patient's age, the severity of ADHD symptoms [42], and the presence of comorbidities [46]. For instance, the (AAP) strongly advocates for behavioral therapy as the initial treatment approach for children aged 4-5 years, emphasizing the importance of evaluating its efficacy before considering pharmacological interventions [47]. In contrast to Rapport's model [30], the proposed ADHD conceptual model associates treatments primarily with symptoms. This association arises from the acknowledgment that there is no definitive cure for ADHD; rather, treatments focus on managing and alleviating the symptoms exhibited by individual patients [22], [48]. Additionally, it considers patient age through the "age group" property within the treatment class and addresses ADHD severity based on the number and type of symptoms exhibited by the patient.

Additionally, Brod et al. [31] introduced a conceptual model focused on assessing ADHD's impact on the quality of life among adults with the disorder. Central to their model is the interplay between ADHD symptoms and associated behaviors, including executive dysfunction. This reciprocal relationship underscores the intricate connection between symptoms and their outward manifestations, a principle mirrored in the findings of our proposed conceptual model (the relationship between Symptoms and behaviors classes). Both models highlight the complex dynamics between ADHD symptoms and their associted behaviors, emphasizing the multifaceted nature of the disorder's impact on individuals' lives. By recognizing this intricate relationship, our model aligns with Brod et al.'s [31] conceptual framework, contributing to a more comprehensive understanding of ADHD and its implications for quality of life.

B. Theoretical Implications on the Research Landscape in the ADHD Field

In advancing the theoretical conceptualization of ADHD, researchers have made significant strides through diverse studies. For instance, the review by Nigg et al. [49] underscores the importance of adopting a broader conceptualization of ADHD beyond the specific inattention and hyperactivity

symptoms. Instead, it raises the question of the possibility of inclusion of a wide spectrum of phenotypes that should be encompassed within the diagnostic framework of ADHD, such as emotion dysregulation and executive dysfunction. This perspective has been a focal point of numerous studies within the field, emphasizing the need for a comprehensive understanding of ADHD manifestations (e.g. [44]). The conceptual model presented in this paper directly addresses this imperative by integrating diverse viewpoints and establishing connections between symptoms delineated in the DSM-5 (Symptoms class) and the multifaceted array of phenotypes (Behaviors class), spanning functional and emotional dimensions.

Also, Faraone et al. [50] offers a comprehensive examination of ADHD, encompassing many of the core concepts of the disorder like diagnosis, treatment, and associated risk factors and comorbidities. Similarly, Drechsler et al. [51] delve into the current concepts, comorbidities and treatment in children and adolescents with ADHD. Additionally, Zayats & Neale [52] investigates how the genetic and neurobiological foundations [45] underpinnings on our conceptualization of ADHD, focusing specifically on two key aspects within the field: diagnosis and treatment. The present study, along with existing literature, reveals commonalities regarding fundamental concepts of ADHD, emphasizing the importance of understanding ADHD symptoms, subtypes, and their implications for diagnosis and treatment. Additionally, risk factors and comorbidities are recognized as significant contributors to the heterogeneity and complexity of ADHD presentations. Although these shared concepts provide a foundational conceptualizing of ADHD, they underscore the need for comprehensive models that can account for its multifaceted nature. While each of these works offers valuable contributions to the field, they often focus on specific aspects of ADHD in isolation. They frequently do not establish connections between different domain concepts, leading to a fragmented understanding of the disorder. The present research endeavors to bridge these conceptual gaps by proposing a comprehensive conceptual model that integrates multiple facets of ADHD. By elucidating the interconnectedness of these concepts, this research aims to provide a more holistic and cohesive framework for understanding ADHD. This fundamental difference in the theoretical implications of the present research and previous research in the field of ADHD emphasizes the importance of adopting an integrated approach to conceptualizing the disorder.

C. Practical Applications in the ADHD Field

In terms of contributing to practical applications in the field of ADHD, there are many knowledge-based systems that mainly rely on "background knowledge" as their input. For example, Göker & Tekedere [53] implemented an expert system that predicts ADHD during childhood, Silva et al. [54], Delavarian et al. [55] and Chu et al. [56] developed decision support systems with various goals serving the field. When data is collected specifically for each system individually the knowledge collected to develop these systems is exclusive to them and was not transferable to other systems, leaving future projects with no way of benefitting from what they had achieved. This means that any time a new system is created, it has to reinvent the wheel and go through the same process of collecting knowledge from scratch. Considering the complexity of ADHD domain knowledge and related sources that are of many sorts and sources, there is an increasing need for a unified knowledge base that provides easy access to information and the ability to share, transfer and reuse the knowledge. As previously mentioned, the primary objective of constructing this conceptual model is to serve as the foundational framework for the development of a comprehensive domain knowledge ontology pertaining to ADHD. It also plays a major role as a layer for transferring and reusing domain knowledge [57]. In general, the utilization of ontologies for knowledge structuring enables the creation of reusable and shareable knowledge that, once developed, can be used entirely or partially by anybody [58]. Therefore, building a conceptual model is frequently considered as the first step in formalizing and standardizing domain knowledge while building various systems.

V. CONCLUSION

In conclusion, this research has developed a comprehensive conceptual model that encapsulates the domain knowledge of ADHD, shedding light on its multifaceted nature and interrelationships between key concepts. By adopting a hybrid approach derived from established practices in ontology construction, the model effectively integrates principles from prominent methodologies. The resulting ADHD conceptual model delineates connections between various aspects of the disorder, including subtypes, symptoms, behaviors, diagnostic criteria, treatment options, risk factors, comorbidities, and patient profiles. Through its 8 top-level classes and 13 relationships, the model elucidates critical links between symptoms and treatments, symptom manifestations, risk factors and ADHD subtypes, and potential comorbidities. By bridging these domain concepts, the model contributes to a more holistic understanding of ADHD and serves as a foundational framework for constructing an ADHD domain knowledge ontology. This research thus plays a pivotal role in advancing knowledge within the field of ADHD and offers valuable insights for researchers, clinicians, and policymakers navigating the multidisciplinary landscape of ADHD research and practice.

Despite its contributions, this study has limitations that present opportunities for future research. While the model captures a broad range of ADHD-related concepts, it does not delve deeply into the genetic underpinnings or specific neurobiological mechanisms of the disorder, which are increasingly recognized as critical to understanding ADHD's etiology. Similarly, cultural and contextual variations in the manifestation, diagnosis, and treatment of ADHD remain underexplored, leaving gaps in how the disorder is understood and addressed across diverse populations. The model also relies predominantly on existing literature and expert consensus, potentially overlooking emerging research and patient perspectives, particularly those from underrepresented demographic groups.

Future work should address these limitations by incorporating real-world data, such as longitudinal studies and patient-reported outcomes, to validate and expand the model's applicability. Efforts to integrate genetic and neurobiological insights could enrich the conceptual framework, providing a

more comprehensive understanding of ADHD's mechanisms. Additionally, capturing cultural and contextual variations could make the model more globally relevant and inclusive. Expanding the scope to include emerging research trends and interdisciplinary perspectives will further enhance the model's utility in research and clinical practice.

The most critical next step is to use the resulting conceptual model as the foundation for constructing a comprehensive ontology for ADHD. This ontology would formalize the domain knowledge, enabling standardized representation, enhanced interoperability across systems, and the development of tools for diagnosis, treatment planning, and research. By advancing from conceptual modeling to ontology development, this work can catalyze significant progress in understanding and addressing ADHD, ultimately improving outcomes for individuals affected by this complex disorder.

Department of Information Technology-Faculty of Computer Science and Information Technology, Universitas Sumatera Utara, Medan, Indonesia[3]

***Abstract*—In today's digital age, the role of influencers, especially on social media platforms, has grown significantly. A commonly used feature by business professionals today is follower grouping. However, this feature is limited to identifying influencers based solely on mutual followership, highlighting the need for a more sophisticated approach to influencer detection. This study proposes a novel method for influencer detection that integrates the Leiden coloring algorithm and Degree centrality. This approach leverages network analysis to identify patterns and relationships within large-scale datasets. Initially, the Leiden coloring algorithm is employed to partition the network into various communities, considered potential influencer hubs. Subsequently, Degree centrality is utilized to identify nodes with high connectivity, indicating influential individuals. The proposed method was validated using data crawled from Twitter (X) social media, employing the keyword "GarudaIndonesia." The data was collected using Tweet-Harvest between January 1, 2020, and October 16, 2024, resulting in a dataset of 22,623 rows. The dataset was subjected to two experimental scenarios: 1,000 and 5,000 rows. Compared to the Louvain coloring method, the proposed approach demonstrated an increase in the modularity value of the Leiden coloring algorithm by 0.0306, a reduction in time processing by 14.4848 seconds, and a decrease in the number of communities by 1,290.**

***Keywords*—Influencer; Louvain coloring; Leiden; Leiden coloring**

I. Introduction

The role of influencers, especially on social media platforms, has grown significantly, necessitating the development of more sophisticated influencer detection methods [1]. Influencer detection is a part of community detection. Businesses must accurately identify customers and respond to their needs to remain competitive [2]. As the business landscape evolves, businesses are increasingly adopting digital marketing strategies to keep pace with the competition [3].

Digital marketing involves promoting and disseminating information, as well as searching for markets, through digital media by utilizing various means such as social media [4]. Digital marketing simplifies the process for businesses to connect with and satisfy the desires of potential consumers [5]. From the perspective of potential consumers, digital marketing provides easy access to product information through cyberspace, making it faster and more convenient to search for information [6]. To increase their customer base, businesses need to identify individuals or groups who can help market their products or services. These individuals or groups, with the potential to attract more consumers, are known as influencers [7].

Contemporary digital marketing applications, particularly on Twitter (X) [8], provide features such as follower grouping to assist businesses in promoting their products.

However, the follower grouping feature is limited to identifying influencers based solely on mutual followership, without providing information about the topics discussed by the group or the size and influential members of the group. This can be challenging for business owners who are new to using social media as a promotional tool. Therefore, a method is needed to detect influencers based on specific topics or keywords using Social Network Analysis (SNA) on platforms like Twitter (X), represented graphically. One widely used SNA method is community detection.

There are several community detection algorithms, such as the Louvain algorithm [9] and the Leiden algorithm [10]. The latter was created to identify communities in large networks with complex modularity patterns. The Leiden algorithm is one of the approaches used in social network analysis [11], aiming to identify subgraph groups with strong internal connections. This can help understand the social structure and relationships within a social network, but the algorithm has limitations, such as difficulty in interpreting community visualizations due to the lack of color coding. Graph coloring can accelerate the process by assigning unique colors to nodes, similar to indexing in a relational database. Based on this, this study aims to influencer detection using the Leiden algorithm combined with graph coloring. By incorporating color coding into community detection, we can improve the interpretability and effectiveness of the results.

II. Materials and Methods

A. Leiden Algorithm

The Leiden algorithm is an algorithm used for community detection in networks or graphs. Designed to work efficiently, the Leiden algorithm detects communities in networks or graphs based on modularity optimization [13]. Modularity is a measure that describes the extent to which the density of connections within a community exceeds that of a random network. The modularity value is a scale value ranging from [-1,1]. The modularity of a network is calculated using the following formula:

*Corresponding Author. Email ID: handrizal@usu.ac.id

$$Q = \frac{1}{2m}\sum A_{i,j} - \frac{k_i k_j}{2m}\delta(c_i, c_j)$$

where:

- $A_{i,j}$ represents the edge weights between nodes i and j
- k_i and k_j are the sum of the weights of the edges attached to nodes i and j
- m is the sum of all edge weights in the graph
- c_i and c_j are the node communities
- δ is the Kronecker delta function
- $(\delta(c_i, c_j) = 1$ if $c_i = c_j$, otherwise 0

The Leiden algorithm comprises three primary stages:

1) Moving nodes: Iteratively moving nodes between communities to optimize the overall modularity of the network.

2) Refinement: Dividing the network into distinct, connected components by separating unconnected communities

3) Aggregation: Form a hierarchical network by iteratively aggregating nodes into communities and then treating each community as a single node in the next level of the hierarchy

Steps in the Leiden Algorithm:

1) Initialization: Create a representation of the graphunder analysis. This can be achieved using either an adjacency list or an adjacency matrix. Subsequently, each node within the graph is initialized as an independent community

2) Iteration: Repeat the following steps iteratively until convergence is attained:

a) Local Move Step

- Assess the feasibility of relocating each node within the graph to a different community.
- Calculate the change in modularity resulting from the movement of the node
- If a community exists that provides a greater increase in modularity, relocate the node accordingly.

b) Community Aggregation

- Once all nodes have been evaluated, nodes within the same community are merged into a single new node
- Construct a new graph in which each node corresponds to a community generated in the preceding step

c) Weight Update

- Recompute the edge weights in the new graph according to the number of nodes represented in each community.

3) Termination: The iteration process continues until a stable state is reached, where neither community assignments nor modularity values change significantly.

B. Graph Coloring

Graph coloring, a technique introduced in 1979 [14], involves assigning colors to vertices in a graph such that no adjacent vertices share the same color. This study explores the application of graph coloring [12] within the context of network analysis. Consider a graph G(V, E), where V represents the set of vertices and E represents the set of edges in the graph. We aim to assign a color, w(i) ∈ {1, 2, ..., k}, to each vertex i ∈ V, where k is the number of colors used, such that:

$$\forall (i,j) \in G, w(i) \neq w(j)$$

C. Leiden Coloring Algorithm

In 2024, the study in [15] stated that one of the shortcomings of the Leiden algorithm is its inability to efficiently process large networks, resulting in relatively long processing times.To address this issue, the Leiden algorithm was modified using graph coloring, hereinafter referred to as Leiden Coloring.

The steps of the Leiden coloring algorithm are as follows:

- Phase 1: Community Detection

Community detection within the graph is performed using the Leiden algorithm. The implementation strictly adheres to the algorithmic steps and mathematical formulations definedby the Leiden algorithm.

- Phase 2: Community Coloring

After community identification, the graph coloring principle is applied to the resulting community structure. Each community is assigned a unique color, ensuring that no more colors are used than the number of identified communities.

This process effectively integrates the Leiden algorithm with graph coloring, resulting in each node being labeled with both its community membership and a unique color.

The stages of influencer detection research using Leiden coloring are as follows:

- Business understanding

This stage involves the collection of information about influencers, encompassing indicators that can identify potential influencers, relevant phenomena, and pertinent facts.

- Twitter data collection

Data collection for this study was conducted on Twitter (X) using the Tweet-Harvest service. Tweet-Harvest was employed to retrieve tweets related to the keyword "GarudaIndonesia" from January 1, 2020, to October 16, 2024. This process resulted in a dataset of 22,623 tweets.

- Network construction

This stage of dataset processing encompasses data selection based on research objectives, subsequent data cleaning to eliminate irrelevant entries, and finally, data transformation into a graph format for further analysis.

- Community detection

After the preceding stage, the dataset will undergo further analysis for influencer detection utilizing Social Network

Analysis methodologies. Both the Leiden and Leiden Coloring algorithms will be employed in this phase.

- Analysis results

This stage involves analyzing, concluding, and evaluating the results of influencer detection from the previous step. The information generated may include graph visualizations, the number of communities formed, and the identification of influencers within each community.

- Evaluation

At this stage, the algorithm's performance is evaluated using three matrices: modularity, time processing, and the number of communities to determine the algorithm's overall effectiveness.

III. Results and Discussion

This study employed the Leiden coloring algorithm for influencer detection, conducting tests with two datasets: a smaller dataset of 1,000 rows and a larger dataset of 5,000 rows. The objective was to analyze how the identification of influential individuals within a social network might be affected by the size and scale of the available data.

A. Detection of Influencers using the Leiden Coloring Algorithm

This section presents the results obtained from the proposed Leiden coloring algorithm. These results encompass the influencer detection matrix, modularity values, processing times, and the number of identified communities. Two dataset testing scenarios were conducted in this study. The first scenario utilized a dataset comprising 1,000 rows, while the second scenario employed a dataset consisting of 5,000 rows.

1) Results of influencer detection with dataset 1000 rows: This section presents the results obtained from the proposed Leiden coloring algorithm. These results are presented as an influencer detection matrix using a dataset of 1,000 rows.

TABLE I. Results of Influencer Detection with Dataset 1000 Rows

No.	Leiden Coloring Algorithm
1	IndonesiaGaruda
2	GarudaCares
3	wandiseptian11
4	PinterPoin
5	idbcpr

Table I shows that in the dataset containing 1000 rows, the username 'IndonesiaGaruda' holds the top influencer position, while 'idbcpr' ranks fifth.

2) Result of influencer detection with dataset 5000 rows: This section presents the results obtained from the proposed Leiden coloring algorithm. These results are presented as an influencer detection matrix using a dataset of 5,000 rows.

TABLE II. Result of Influencer Detection with Dataset 5000 Rows

No.	Leiden Coloring Algorithm
1	IndonesiaGaruda
2	disemuacom
3	GarudaCares
4	astuceclover
5	TiketPesawatPro

According to Table II, in the 5000-row dataset, the username 'IndonesiaGaruda' is identified as the top influencer, while 'TiketPesawatPro' is ranked fifth in terms of influencer.

B. Result of Matrix Modularity

This section presents the results obtained from the proposed Leiden coloring algorithm. The results are shown as a modularity matrix using datasets containing 1,000 rows and 5,000 rows.

TABLE III. Results of Matrix Modularity

No.	Dataset	Modularity of Leiden Coloring
1	1000 rows	0.9396
2	5000 rows	0.9381
Average		0.9388

Table III shows the modularity values for the 1000-row dataset (0.9396) and the 5000-row dataset (0.9381). Additionally, the matrix above is presented graphically in Fig. 1.

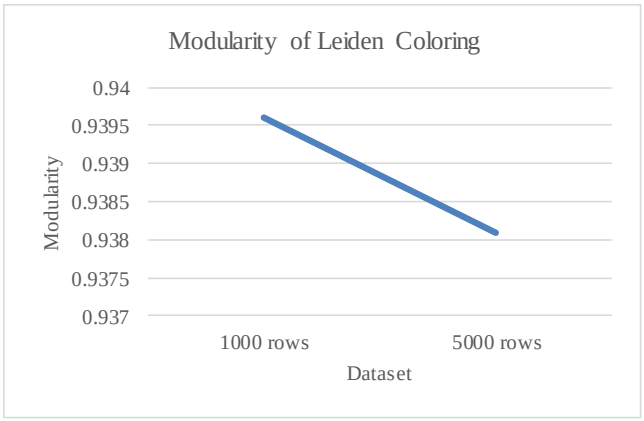

Fig. 1. Results of matrix modularity.

C. Result of Matrix Time Processing

This section presents the results obtained from the proposed Leiden coloring algorithm. The results are shown as a time-processing matrix using datasets containing 1,000 rows and 5,000 rows.

TABLE IV. Result of Matrix Time Processing

No.	Dataset	Time Processing Leiden Coloring (second)
1	1000 rows	29.5493
2	5000 rows	434.1838
Average		231,8666

In Table IV, it can be seen that for a dataset with 1000 rows, the processing time is 29.5491 seconds, and for a dataset with 5000 rows, it is 434.1838 seconds. The matrix above is also presented in graphical form, as shown in Fig. 2.

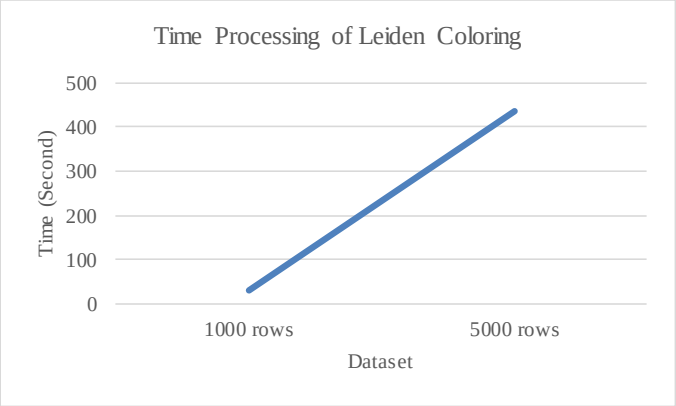

Fig. 2. Results of matrix time processing.

D. Results of Matrix Number Communities

This section presents the results obtained from the proposed Leiden coloring algorithm. The results are shown as a number of community matrix using datasets containing 1,000 rows and 5,000 rows.

TABLE V. RESULT OF MATRIX NUMBER OF COMMUNITIES

No.	Dataset	Number Communities Leiden Coloring
1	1000 rows	505
2	5000 rows	1969
Average		1237

As shown in Table V, the number of communities for the 1000-row dataset is 505, whereas for the 5000-row dataset, it is 1969. The corresponding matrix is graphically depicted in Fig. 3.

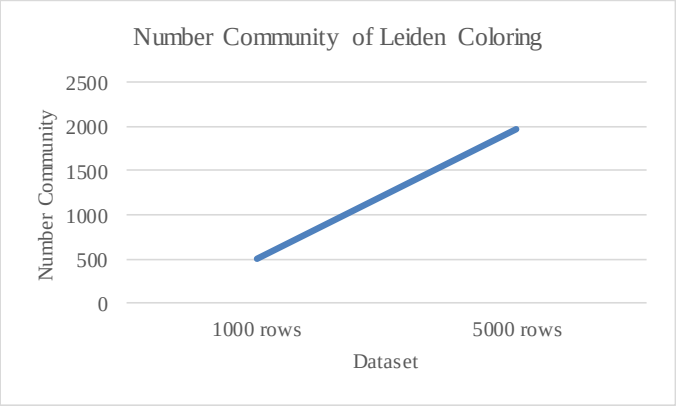

Fig. 3. Results of matrix number communities.

In the graph in Fig. 3 above, it can be seen that the number of communities for the 1,000-row dataset is 505, and it increases to 1,969 for the 5,000-row dataset.

E. Comparison of Louvain Coloring and Leiden Coloring Algorithm

This section presents the results of a comparison between the proposed Leiden coloring algorithm and the Louvain coloring algorithm, focusing on influencer detection, modularity value, time processing, and the number of identified communities. Two testing scenarios were conducted with varying dataset sizes: the first using a dataset with 1,000 rows, and the second using a dataset with 5,000 rows.

1) Comparison of influencer detection with dataset 1000 rows: This section presents a comparison of the results obtained using the proposed Leiden coloring algorithm with the Louvain coloring algorithm based on the influencer detection metric, using datasets containing 1,000 rows.

TABLE VI. COMPARISON OF INFLUENCER DETECTION WITH DATASET 1000 ROWS

Louvain Coloring Algorithm	Leiden Coloring Algorithm
IndonesiaGaruda	IndonesiaGaruda
GarudaCares	GarudaCares
astuceclover	wandiseptian11
TiketPesawatPro	PinterPoin
disemuacom	idbcpr

Table VI shows that the Louvain and Leiden coloring algorithms produce identical influencer detections for the first and second ranks in the 1000-row dataset: 'IndonesiaGaruda' and 'GarudaCares', respectively. However, the rankings diverge starting from the third rank.

2) Comparison of influencer detection with dataset 5000 rows: This section presents a comparison of the results obtained using the proposed Leiden coloring algorithm with the Louvain coloring algorithm based on the influencer detection metric, using datasets containing 5,000 rows.

TABLE VII. COMPARISON OF INFLUENCER DETECTION WITH DATASET 5000 ROWS

Louvain Coloring Algorithm	Leiden Coloring Algorithm
IndonesiaGaruda	IndonesiaGaruda
GarudaCares	disemuacom
TiketPesawatPro	GarudaCares
disemuacom	astuceclover
astuceclover	TiketPesawatPro

In Table VII, it can be seen that the Louvain coloring and Leiden coloring algorithms on the 5000-row dataset produce the same influencer detection for the first rank, namely the username 'IndonesiaGaruda.' Meanwhile, the second to fifth ranks produce different influencer detections.

Analysis of Tables VI and VII reveals that both the Louvain and Leiden coloring algorithms identify 'IndonesiaGaruda' as the top-ranked influencer. However, discrepancies in influencer rankings emerge from the second to the fifth positions.

F. Comparison of Matrix Modularity

This section presents a comparison of the results obtained using the proposed Leiden coloring algorithm with the Louvain coloring algorithm based on the modularity metric, using datasets containing 1,000 rows and 5,000 rows (Table VIII).

TABLE VIII. COMPARISON OF MATRIX MODULARITY

Dataset	Modularity	
	Louvain Coloring	Leiden Coloring
1000 rows	0.9114	0.9396
5000 rows	0.9050	0.9381
Average	0.9082	0.9388

The Leiden coloring algorithm consistently demonstrated higher modularity values compared to the Louvain coloring algorithm across all two test scenarios. The modularity values for the Leiden coloring algorithm ranged from a minimum of 0.9367 to a maximum of 0.9396, with an average of 0.9388. In contrast, the Louvain coloring algorithm exhibited a lower range, with a minimum of 0.9050 a maximum of 0.9252, and an average of 0.9082. This translates to an average increase in modularity of 0.0306 for the Leiden coloring algorithm. A comparative graph illustrating this modularity matrix is presented in Fig. 4.

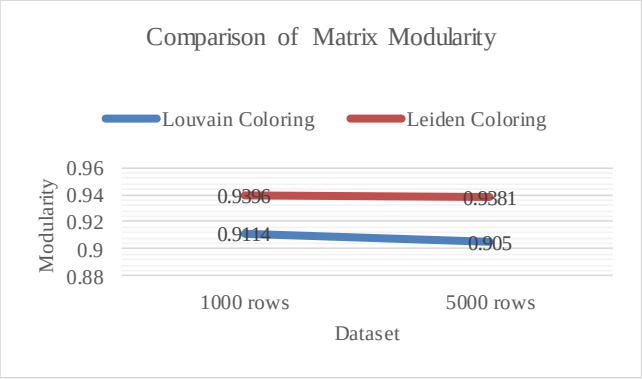

Fig. 4. Comparison of matrix modularity.

G. Comparison of Matrix Time Processing

This section presents a comparison of the results obtained using the proposed Leiden coloring algorithm with the Louvain coloring algorithm based on the time processing metric, using datasets containing 1,000 rows and 5,000 rows (Table IX).

TABLE IX. COMPARISON OF MATRIX TIME PROCESSING

Dataset	Time Processing (second)	
	Louvain Coloring	Leiden Coloring
1000 rows	41.85	29.5493
5000 rows	450.86	434.1838
Average	246,355	231,8666

The time processing of the Leiden coloring algorithm is better than that of the Louvain coloring algorithm. In the two test scenarios conducted, the Leiden coloring algorithm outperforms the Louvain coloring algorithm in all scenarios. The processing time for the Leiden coloring algorithm ranges from a minimum of 29.5493 seconds to a maximum of 434.1838 seconds, with an average of 246.355 seconds. Meanwhile, the Louvain coloring algorithm has a minimum value of 41.85 seconds, a maximum of 450.86 seconds, and an average of 231.8666 seconds. Thus, the Leiden coloring algorithm shows a reduction in processing time of 14.4848 seconds. The comparison of these processing times is also illustrated in the graph in Fig. 5.

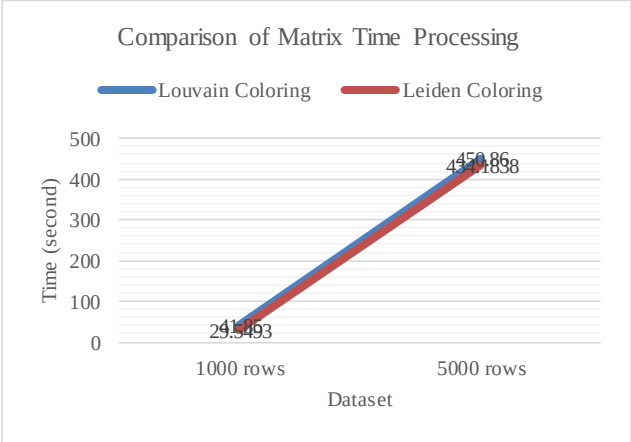

Fig. 5. Comparison of matrix time processing.

H. Comparison of Matrix Number Communities

This section presents a comparison of the results obtained using the proposed Leiden coloring algorithm with the Louvain coloring algorithm based on the number of communities metric, using datasets containing 1,000 rows and 5,000 rows (Table X).

TABLE X. COMPARISON OF MATRIX NUMBER COMMUNITIES

Dataset	Number Communities	
	Louvain Coloring	Leiden Coloring
1000 rows	936	505
5000 rows	4119	1969
Average	2527	1237

The Leiden coloring algorithm produced a significantly lower number of communities compared to the Louvain coloring algorithm across the two test scenarios. The number of communities detected by the Leiden algorithm ranged from 505 to 1969 with an average of 1237, while the Louvain coloring algorithm produced a range of 936 to 4119 with an average of 2527. This resulted in a reduction of 1290 communities on average. A comparison graph of the community numbers for both algorithms is presented in Fig. 6.

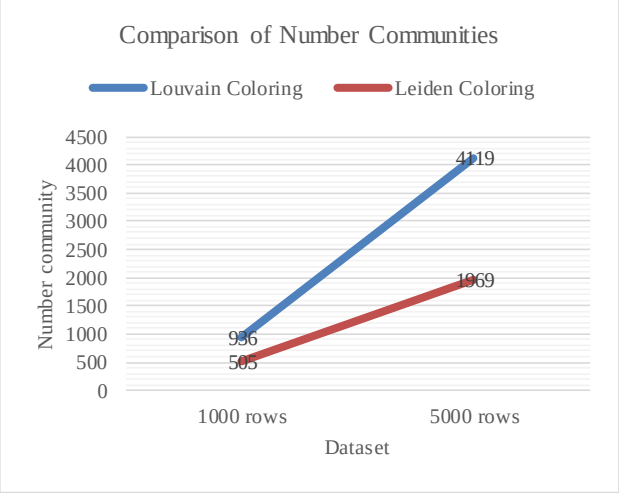

Fig. 6. Comparison of matrix number communities.

IV. Conclusion

This study successfully applied the Leiden coloring algorithm to identify influencers on Twitter (X). Influencer detection was conducted using the Leiden coloring algorithm on a dataset of Twitter (X) interactions related to "GarudaIndonesia." Data was collected using Tweet-Harvest between January 1, 2020, and October 16, 2024, resulting in a dataset of 22,623 tweets.

The dataset was evaluated using two experimental scenarios: one with 1,000 tweets and another with 5,000 tweets. The analysis identified five influential usernames in each scenario. For the 1,000-tweet dataset, the identified influencers were IndonesiaGaruda, GarudaCares, Wandiseptian11, PinterPoin, and idbcpr. For the 5,000-tweet dataset, the identified influencers were IndonesiaGaruda, disemuacom, GarudaCares, astuceclover, and TiketPesawatPro.

Compared to the Louvain coloring algorithm, the Leiden coloring algorithm demonstrated improved performance. The Leiden coloring algorithm exhibited a 0.0306 increase in modularity value, a 14.4848-second reduction in processing time, and a 1290-community reduction.

The primary contributions of this study include improved modularity, reduced processing time, and a more concise community structure when using the Leiden coloring algorithm for influencer detection.

Several limitations and suggestions have emerged during this study, such as the rapid development of Twitter (X) data due to bold processing methods, highlighting the need for new approaches to detect influencers. Therefore, future research could focus on applying the Leiden coloring algorithm to real-time Twitter (X) data.

***Abstract*—In this study, we construct a risk contagion model for corporate information disclosure using complex network methods and incorporate the manipulative perspective of management tone into it. We employ an enhanced LDA model to analyze and refine the relevant data and models presented in this paper. The results of quantitative analysis show that the improved LDA algorithm optimizes the classification decision boundary, making similar samples closer and different samples more dispersed, thus improving the classification accuracy. Additionally, we combine multi-objective evolutionary optimization techniques with an improved particle swarm optimization algorithm to solve the proposed model while incorporating enhancements through the use of weighted Smote algorithm. The quantization results show that using the weighted Smote algorithm to deal with the imbalance in the dataset significantly improves the classification performance. Furthermore, we compare our proposed method with classical algorithms on four real enterprise information disclosure datasets and observe that our approach exhibits higher efficiency and accuracy compared to traditional optimal control methods. Accounting information disclosure reveals moral hazard and adverse selection, alleviating information asymmetry. Transparent information improves the availability of financing, preventing liquidity risk. High-quality information disclosure reduces financing costs, alleviates confidence crises, ensures capital adequacy, and avoids capital outflows. Research constructs a corporate information disclosure risk contagion model, using an improved LDA model and multi-objective evolutionary optimization methods for analysis, showing high efficiency and good accuracy, effectively controlling environmental and related effects.**

***Keywords*—Management tone manipulation; enterprise information disclosure; risk contagion; optimal control**

I. Introduction

A. Research Background

The multi-objective optimization algorithm is designed to address the challenges of optimizing multiple objective functions simultaneously and identifying a set of solutions that are optimal in terms of these objectives [1]. In this context, enhancing the performance of one target may result in a decline in the performance of one or more other targets. Particle swarm optimization (PSO) algorithm is an optimization technique inspired by swarm intelligence, specifically bird flock predation behavior [2]. It simulates individual collaboration and information sharing mechanisms observed in bird flocks to seek the optimal solution for a given problem [3]. Each solution within the particle swarm optimization algorithm represents a "particle" within the search space, possessing unique velocity and position properties [4]. By continuously updating their speed and position, particles navigate through the search space to find an optimal solution. SMOTE (Synthetic Minority Over-sampling Technique) algorithm is an oversampling technique utilized to address data category imbalance issues [5]. Its fundamental concept involves analyzing limited samples and augmenting new samples into the dataset [6] [7].

The enterprise is different from the market resource allocation mechanism [1], the essence of the enterprise is the contract collection of stakeholders. The importance of corporate information disclosure is self-evident, and it is an important basis [8] for listed companies to sign contracts and execute contracts with stakeholders in the market. To apply enterprise risk management to address the company's vulnerability to cyber risks, thereby achieving control over risks for the company [9].Corporate information disclosure can enable external investors to assess the real or potential value [10] [11] [12] Companies that have experienced data breaches have become aware of their vulnerabilities and have implemented oversight at the board level, leading them to have the audit committee increase supervision [13]. The main form of modern accounting information disclosure is financial report, which is a useful mechanism [14]. The disclosure of enterprise information has gone through three stages: voluntary disclosure, mandatory disclosure, and the combination of voluntary disclosure and mandatory disclosure.

Risk information disclosure encompasses both informational and risk attributes. From an informational perspective, risk information and financial digital information are interconnected and mutually reinforcing, playing a crucial role in enhancing the comprehensiveness of financial information. Following the disruption of "rigid exchange" in the bond market, changes in the risk environment can lead to a decline in investor sentiment, further reducing market liquidity and exacerbating internal and external information asymmetry. During such times, bond issuing enterprises may provide more detailed risk information to mitigate this asymmetry. From a risk standpoint, disclosing risk information unveils heterogeneous risks within an enterprise while conveying

*Corresponding Author.

negative news that can have adverse effects on the company. Simultaneously, risk information possesses characteristics such as high discretion, low verifiability, and low violation costs; thus making it susceptible to being utilized as a tool for impression management by enterprises. When disruptions like "gang" breakouts induce market aversion towards risks, companies may engage in impression management by reducing their disclosure of risk-related details to diminish participants' perception of heterogeneity risks associated with the firm.

B. Literature Review

Past scholars studied the impact [12] of disclosure motivation, corporate governance structure and corporate scale on corporate information disclosure. They believe that because of corporate strategy, corporate governance and other reasons, they have the motivation to actively disclose a certain degree of corporate information. Some scholars believe that the level of voluntary disclosure is significantly related [16] to the size of the company, and another scholar finds that the degree of ownership concentration is negatively related [17-19] to the degree of voluntary disclosure. The academic circle has not yet formed a unified view on the evaluation of the quality of accounting information disclosure of enterprises. Traditional studies on the quality of accounting information mainly focus on three aspects [20-22]: the characteristics of information quality, the measurement of accounting information quality and economic consequences, and pay more attention to the relationship between accounting information quality and earnings management, financing cost and performance management. It mainly focuses on the theoretical development, influencing factors and statistical evaluation of the quality of accounting information [23].

Some scholars believe that earnings management will distort stakeholders' interpretation of corporate performance, causing them to misunderstand [11]. The reliability of accounting information can be achieved through three indicators: the degree [24] of earnings management, the measurement error of earnings and the audit opinion. The relevance of accounting information can be realized through the value relevance [11] of accounting information and the continuity [11] of earnings. Comparability is mainly measured by the difference between expected earnings and actual earnings. Timeliness is measured [11] by the time lag in earnings releases. As for the study on the influencing factors of management, it is proposed that when the equity is highly concentrated in the management level, the voluntary disclosure will decrease. Some scholars point out that the information communication process of financial reports will be hindered under the following three conditions: (1) Managers have more information about the company's business strategy and operation than investors; (2) the pursuit of managers is not completely consistent with the interests of all shareholders; And (3) imperfect accounting standards and auditing. Senior executives can influence or even decide accounting behaviors and policies such as corporate information disclosure and earnings management, thus affecting the quality [28] of accounting information.

In the existing literature, the research on the risk contagion model of enterprise information disclosure has made some progress, especially in the application of complex network analysis and optimization algorithm. However, there is still relatively little research on managing how tone manipulation affects the risk contagion of corporate disclosure [15], and how this risk can be more effectively controlled through improved models and algorithms. This study aims to fill this gap by combining the perspective of management tone manipulation, using the improved LDA model and multi-objective evolutionary optimization technology, to construct a more accurate enterprise information disclosure risk contagion model. Firstly, it utilizes text data from Chinese listed companies, including MDA texts, annual reports of performance presentations, and other relevant materials, to investigate the risk associated with corporate information disclosure [29]. Secondly, this study explores how management tone influences corporate information disclosure and risk issues. Previous studies primarily focused on disclosure motivation, governance structure, financing cost, etc., whereas this paper expands the research perspective by analyzing management tone data. Thirdly, an information risk contagion model between enterprises is constructed from a dynamic correlation perspective while incorporating accounting information based on emotions to establish a dynamic model. This effectively controls for environmental effects and correlation effects. In addition, this study also discusses the effectiveness of the weighted Smote algorithm in dealing with unbalanced data sets, which provides a new direction for future research. Lastly, particle swarm optimization algorithm is employed for data verification and algorithm comparison to study optimal control methods. The purpose of this article is to enrich the influence of management tone on enterprise information disclosure by improving the accuracy and stability of the risk infection model of enterprise information disclosure.

This article utilizes text data from listed companies, explores innovative ways to enrich the impact through examining the influence of managerial tone, constructing models, and employing algorithms for validation and comparison. It also studies and constructs a risk contagion model for corporate information disclosure, applying an improved model and optimization methods for analysis and solution. The improvements to the algorithms are empirically proven to enhance the accuracy and stability of the models, providing strong support for corporate information disclosure risk control. Additionally, it discusses the connection between accounting information disclosure and corporate agency, information asymmetry, and the benefits of high-quality disclosure to enterprises.

II. Model Construction

A. Preparation of Knowledge

In the realm of real-world enterprises, organizations establish networks via social connections generated by interactive behaviors. This research develops a risk contagion model for corporate disclosure based on the social network framework. In recent times, given the rapid progression of information, the scale of social networks has been expanding exponentially. Usually, the inter-enterprise network is abstracted as a figure $G = (V, E, W)$, where $V = \{v_1, v_2, \ldots, v_n\}$ is the set of all nodes in the graph, that is, the collection of all enterprises in the network, and n represents

the number of enterprise nodes in the network; The edge set formed by the interaction relationship between enterprise nodes in the graph. $E = \{e_1, e_2, \dots, e_m\}$ is the set formed by the interaction relationship between enterprises in the network, and m is the number of the network edge between enterprises; $W = \{w_1, w_2, \dots, w_m\}$ represents the set of weights for all inter-enterprise edges in the graph. Among them, the inter-firm network has the characteristics of small world, scale-free and power-law distribution, etc. In this study, the network structure is assumed to compound the above characteristics. In inter-firm networks, the distance between firms is usually relatively short. And in complex networks, the nodes k with degrees of are power-law distribution$p(k) = ck^{-\gamma}$. Numerous studies have discovered that within the inter-enterprise relationship network, the connection pattern of nodes adheres to the scale-free attribute, with most businesses possessing only a limited number of connections, whereas a select few users maintain a substantial number of connections. The notion of clustering coefficient, existing within the network, is employed to assess the intimacy between associates. In a scale-free network, nodes exhibiting larger degree values generally possess lower clustering coefficients, conversely, nodes with smaller degree values demonstrate higher clustering coefficients. Therefore, the clustering coefficient within the enterprise network will exhibit a power-law distribution pattern. In the inter-firm information disclosure risk contagion network, the influence of a company varies based on its position and other variables. As the network evolves, nodes will continuously accumulate and exert their risk influence on other entities, leading to alterations in the risks faced by surrounding individuals.

The influence maximization problem requires the calculation of information propagation in a network, considering the risk associated with information disclosure. In this study, we employed the Linear Threshold model (LT), which is a widely used model for simulating influence propagation and risk interaction among users in an inter-enterprise information disclosure network [30]. Each node in the network was defined to have two states during information transmission: active and inactive. At any given moment, each node can only exist in one state, with active nodes having the ability to activate their inactive neighboring nodes while inactive nodes cannot activate other neighbors. The probability of successful activation increases as a node has more active neighbors. When an active node attempts to activate its inactive neighbor, and if successful, that neighbor will continue attempting to activate its own inactive neighbors until no further activations occur within the network, marking the end of the propagation process. All transitions between states are limited to going from inactive to active or vice versa. A linear threshold model is a simple and efficient graph model that assumes that the relationships between nodes are boolean-valued, i.e. either exist or do not exist. In this case, the linear threshold model can predict the state of the node by performing threshold processing on the relationship between the nodes. In contrast, recently popular models related to graph networks, such as convolutional neural networks (CNNS) and recurrent neural networks (RNNS), are more complex and flexible. These models can deal with continuous relationships between nodes and can learn complex interaction patterns between nodes. However, these models are also more complex and computationally intensive, requiring more computational resources and data. Therefore, when building graph models based on social networks, the linear threshold model is chosen because it is simple, efficient, and can be trained and predicted on small data sets. In addition, linear threshold models can also be used in combination with other models to improve prediction accuracy and generalization ability.

The independent cascade model is a widely utilized framework for modeling influence propagation. Once a node v has been successfully influenced, it is deemed capable of activating inactive nodes w in its neighboring network and will attempt to do so. The probability of being affected by success is P_{vw}, and this attempt is made only once, and these attempts are independent of each other, that is, v activation of w is not affected by other nodes. The specific propagation process is as follows: First, given the initial set of active nodes S, when the node v is activated at the moment t, it has a chance to influence its neighbor nodes w that are not activated. The probability of successful activation is P_{vw}, this value is a random system parameter, which has nothing to do with nodes in the network. The greater the value, the more likely the node w is to be affected. If multiple nodes are newly activated and these nodes are neighbors of the node w, then these nodes will try to activate the node w in any order. If the node w is successfully activated by the node v, the node w will become active at the moment $t + 1$. At moment $t + 1$, the node w will have an influence on other neighbors that are not activated. The process is repeated until there are no active nodes with influence in the network. The propagation process ends.

Multi-objective optimization function is realized based on the multi-objective optimization algorithm. These algorithms trade off and compromise between multiple objective functions to find a set of optimal solutions that are not inferior to any other on all objective functions, i. e., there is no solution that is better on all objective functions. It can be summarized as the following steps: randomly generate a set of initial solutions as the initial population. The initial population was evaluated to calculate the value of each solution on the individual objective function. According to a certain selection mechanism, a part of the solution is selected from the current population as the parent of the next generation population. The selected parent solutions are subjected to evolutionary operations such as crossover and variation to generate the next generation population. Repeat the above steps until the termination conditions are met. Multi-objective optimization can be applied to the recommendation system, logistics distribution, product design and so on.

B. Management Intonation Embedding

This study uses natural language processing to process text data embedded by management. For the probability of a text sequence $S = w_1, w_2, \dots, w_T$, it can be expressed as shown in Eq. (1). That is, the researcher can convert the text probability into the product of the conditional probabilities of the antecedent.

$$P(S) = P(w_1, w_2, \dots, w_T) = \prod_{t=1}^{T} p\,(w_t \mid w_1, w_2, \dots, w_{t-1}) \quad (1)$$

The CBOW model serves as the initial implementation of the Word2Vec algorithm, encompassing both the Embedding matrix from the bag of words model and continuous Embedding

vectors [31]. By predicting target words based on contextual information, the CBOW model enables analysis of word vector expressions. In fact, it can also acquire word vectors by sequentially predicting text content associated with target words. This variant is referred to as the Skip-gram model, as depicted in Eq. (2).

$$p(w_o \mid w_i) = \frac{e^{U_o \cdot V_i}}{\sum j e^{U_j \cdot V_i}} \quad (2)$$

Among them, V_i is the column vector in the embedding layer matrix, also known as the input vector of w_i. U_j is the row vector in the Softmax layer matrix, and it is also the output vector of w_i. The essence of Skip-gram model is to calculate the cosine similarity between the input vector of the input word and the output vector of the target word, and carry out Softmax normalization. Skip-gram model is a natural language processing model. In the disclosure risk task, input words and target words can represent different concepts. Input words can represent the information disclosed by the enterprise, such as financial reports [26] [27], announcements of major events, etc. Target words can represent concepts related to disclosure risks, such as risk factors, uncertainties, laws and regulations. By using the Skip-gram model, companies can predict the target words associated with disclosure risks and take timely steps to mitigate them. Complex normalized probability is a way to describe the probability distribution of a quantum state. In quantum mechanics, a quantum state can be represented by a wave function, and the modular square of the wave function gives the probability of getting a certain result when measuring a physical quantity in that quantum state. The complex normalized probability is introduced to facilitate the description of the properties of quantum states, because it normalizes the probability distribution to 1, so that the probability distribution between different quantum states can be directly compared. In this study, the complex normalized probability is decomposed into a series of conditional probability products, where v is expressed as the possible values of the physical quantity, bi(v) is expressed as the wave function of the quantum state, and p(v) is expressed as the probability of v obtained by measuring the physical quantity in this quantum state as shown in Eq. (3).

$$p(v) = \prod_{i=1}^{m} p(b_i(v) \mid b_1(v), \ldots, b_{i-1}(v), \text{context}) \quad (3)$$

In addition, in order to understand this process more intuitively, a classification binary tree can be constructed. First, the original dictionary D is divided into two subsets D_1, D_2, while assuming that given Context, the probability that the target word belongs to the subset D_1 is described in Eq. (4), U_{Droot} and Vw_t both sums in the formula are parameters of the model.

$$p(w_t \in D_1 \mid context) = \frac{1}{1+e^{-U_{D_{\text{root}}} * v_{w_t}}} \quad (4)$$

Second, the researcher can further divide the subsets $D_1 D_2$, and after going through this process, the original dictionary D of size V is converted into a binary tree of depth $\log V$. There is only one path from the root to any leaf node, and along this path, the corresponding leaf node's class is encoded. From the root to the leaf, it's actually a random walk. According to this principle, researchers can calculate the likelihood probability of leaf nodes based on the binary tree. For example, assuming a target word w_t in the training sample, the corresponding binary tree code is $\{1,0,1,\ldots,1\}$, then the likelihood function can be constructed as shown in Eq. (5).

$$p(w_t \mid \text{context}) = p(D_1 = 1 \mid \text{context}) p(D_2 = 0 \mid D_1 = 1) \ldots p(w_t \mid D_k = 1) \quad (5)$$

The term product in the given formula represents a logistic regression function, and solving for the maximum likelihood function provides us with the probability of computing a binary tree parameter (a vector on a non-leaf node) to a specific child node. By constructing a binary tree, we reduce the complexity of the target probability calculation, i. e., from the original V to the $\log V$. The original likelihood function of Skip-gram model corresponds to the distribution of multinomial. When solving this likelihood function using the maximum likelihood method, the loss function of cross-entropy is obtained as shown in Eq. (6).

$$J(\theta) = -\sum_{t=1}^{T} \frac{\log p(w_{t+j} \mid w_t)}{T} \quad (6)$$

Where, $p(w_{t+j} \mid w_t)$ is the probability after normalization over the entire dictionary,and define the logistic regression function as shown in Eq. (7).

$$p(w, \text{context}) = \sigma\left(\log p(w \mid \text{context}) - \log k p_n(w)\right) \quad (7)$$

Where, the target word w represents the text-driven probability; k is a prior parameter, which represents the sampling frequency of noise; $p(w \mid \text{context})$ represents the non-normalized probability distribution, using the molecular part of the Softmax normalized function; $p_n(w)$ word distribution representing background noise, often using the word Unigram distribution. New data sets can be obtained after the k sampling of the noise distribution. In this study, the dependence of the NCE likelihood function on the noise distribution is removed, and the logistic regression function is defined directly with the molecules in the original softmax function [32]. The corresponding objective function of the model can be defined as shown in Eq. (8).

$$J(\theta) = \log \sigma(U_o \cdot V_i) + \sum_{j=1}^{\kappa} E_{w_j \sim p_n(w)} \left[\log \sigma\left(-U_j \cdot V_i\right)\right] \quad (8)$$

Therefore, the aim is to capture statistical laws and patterns in language data, and then be used for a variety of natural processing tasks. Improve performance by providing principled and statistics-based approaches to language patterns and regularities. Based on the aforementioned model, an analysis is conducted on the MD&A text, performance presentation, annual report, and social responsibility report. Management intonation manipulation refers to the strategic adjustment of language, wording, and emotional tone in information disclosure by management to selectively convey the company's performance, strategy, prospects, and other content with the aim of influencing the company's image, investors' decisions, and market sentiment. Building upon existing research findings, abnormal optimistic tone exhibited by management is utilized as a measure for assessing the extent of management intonation manipulation. Initially utilizing LM's emotional vocabulary [33] as a basis for analysis yielded the management intonation result Tone = (positive words - negative words) / (positive words + negative words). The affective analysis within management

intonation can be estimated through evaluating the total number of positive emotional messages associated with time-specific information. In this study, separate constructs were developed for emotionality assessment including polarity and negative word identification. Furthermore, the improved LDA algorithm outlined in Algorithm 1 was employed to adjust social media emotion data pertaining to aforementioned listed companies. The sentiment thesaurus is based on the sentiment thesaurus published by CNKI.com, Detailed Dictionary of Commonly used commendatory and derogatory Words, Student Commendatory and Derogatory Words, Commendatory Word Dictionary and derogatory Word Dictionary. It excludes emotion words with low frequency while incorporating network and oral emotion words, resulting in a total of 4637 positive words and 5139 negative words. The constructed emotional thesaurus is categorized into five levels (KW1-KW5) based on word usage frequency, ranging from the simplest version to the complete version. Additionally, this study identifies polarity lexemes within the emotional lexicon that exhibit strong polarity for certain emotion words, particularly derogatory ones. When identifying opinion sentences containing these aforementioned words, their polarity determines that of the entire sentence (with opposite polarity for negative sentence patterns). To differentiate them from other lexemes within emotions lexicon, these specific lexemes are referred to as polar lexemes which consist of 158 positive words and 281 negative words.

Algorithm 1: Improve the LDA algorithm

Input: MD&A, performance presentation, annual report, social responsibility report and other corpus documents
Output: document theme emotion score
01: **for on topic** and emotionzm
02: Extract multinomial distribution$\emptyset_{z,m}$
03: **for** document, **emotion**dj
04: Extract multinomial distributionφ_d, θ_{dj}
05: **for** each sentence in the sentence, $s$words$w_{d,n}$
06: Extract binomial distribution m_s, π_{n-1}
07: **if** $x_n = 0$
08: Extract multiple variable topics $Z_n$and wordsw_n
09: **else if** $x_n = 1$
10: Extract the topic $\delta$and words from the LDAZ_{n-1} distribution of the parameterw_{n-1}
11: **end if**
12**:** **end for**
13: **end for**
14: **end for**
15: return: document topic emotion score

The LDA (Linear Discriminant Analysis) here is a classical linear classification method that is also widely used in dimensionality reduction tasks. The main idea of LDA is to project high-dimensional data into a low-dimensional space while maintaining category information so that the sample projection points between the same species are as close as possible. The Xgboost algorithm is employed in this study to enhance the performance of the LDA algorithm. The core concept involves constructing CART regression trees by continuously splitting continuous features [34]. Each generated CART tree represents a new function that fits the negative gradient (approximate residual) of the previous predicted outcome. Upon completion of training, n CART tree is obtained. To predict the score of a new sample, it only requires traversing each tree based on the characteristics of this sample and obtaining its final position in each tree's leaf node along with its corresponding score. Finally, the scores from each tree are aggregated to obtain the final predicted score for the sample, The LDA algorithm is improved to improve the classification accuracy, and the improved LDA algorithm optimizes the classification decision boundary to make the similar samples closer and the different class samples more dispersed, thus improving the classification accuracy. Improve the computational efficiency, optimize the calculation process of the algorithm, reduce the computational complexity and improve the calculation efficiency. In addition, the robustness is enhanced by introducing data preprocessing steps to reduce the impact of data noise and outliers on the algorithm, and enhance the robustness of the algorithm.as expressed in Eq. (9).

$$\hat{y}_i = \hat{y}_i^{(N)} = \sum_{n=1}^{N} f_n(x_i), f_n \in \mathrm{F} \tag{9}$$

Where, N represents the number of CART decision trees,$f_n(x_i)$ represents the n th tree, the final prediction result of the model is equal to fitting a new tree $f_n(x_i)$ based on the prediction value of $n-1$, $\hat{y}_i^{(n-1)}$, so as to reduce the target function as much as possible. The space of CART tree can be represented as shown in Eq. (10).

$$\mathrm{F} = \{f(x) = \omega_{q(x)}\}, q: R^m \to \text{or} \to T, \omega \in R^T \tag{10}$$

Among them, each decision tree consists of two parts: structure q and leaf node weight ω, q represents the structure of each decision tree, and the sample is divided into corresponding leaf nodes through traversal features, T represents the number of leaf nodes; ω represents the set of leaf node scores of each tree, so the predicted value of the model is equal to the sum of the scores of the corresponding leaf nodes of the sample in each tree, and its objective function is shown in Eq. (11).

$$L(\phi) = \sum_i l(y_i, \hat{y}_i) + \sum_k \Omega(f_k) \tag{11}$$

In addition, in order to prevent overfitting, In the process of establishment, if the target function is less than γ, the feature is not selected for division, the more serious the model, the greater the value of γ. Therefore, the objective function can be defined as shown in Eq. (12).

$$L^m = \sum_{j=1}^{T} \left[\sum_{i \in I_j} g_i \omega_j + \frac{1}{2} \left(\sum_{i \in \{i | q(x_i) = j\}} h_i + \lambda \right) \omega_j^2 \right] + \gamma T + \text{constant} \tag{12}$$

Where, I_j represents the sample set belonging to the first leaf node j in the training process. Take the derivative of the objective function to get the parameter expression of the smallest objective function as shown in Eq. (13).

$$\omega_j^* = -\frac{G_j}{H_j + \lambda} \tag{13}$$

Due to the vast number of features in the training sample, there may exist multiple structural patterns in constructing a decision tree. Enumerating all possible decision tree structures to calculate weight is obviously undesirable. Therefore, the

Xgboost model employs a greedy algorithm that iteratively splits nodes from the starting tree, generating two nodes for each split. The sample data will be divided into the left subtree and the right subtree respectively according to the node rules, and set as I_l and I_r. Then the loss reduction after the node splitting can be defined as Eq. (14).

$$L_s = \frac{1}{2}\left[\frac{G_l^2}{H_l+\lambda} + \frac{G_r^2}{H_r+\lambda} - \frac{(G_l+G_r)^2}{H_l+H_r+\lambda}\right] - \gamma \quad (14)$$

This study uses the probability distribution of $C = 0$ on the learned t trading day after q first represents all the information of the enterprise on the time series. The Beta distribution is used to describe the probability q, which is defined as a continuous distribution over an interval $[0,1]$.Its two shape parameters, α and β are used as exponents of the random variables, controlling the shape of the distribution. The Beta distribution is characterized by two shape parameters and is used to model phenomena with constraints between 0 and 1, and its probability density function can be defined as shown in Eq. (15).

$$P(q;\alpha,\beta) = \frac{1}{\int_0^1 q^{\alpha-1}(1-q)^{\beta-1}dq} q^{\alpha-1}(1-q)^{\beta-1} \quad (15)$$

In this study, either $C = 0$ or $C = 1$ was considered as a single Bernoulli experiment. In this study, N the likelihood function in the Bernoulli experiment is represented by Eq. (16).

$$L(v, N-v \mid q) = \binom{N}{v} q^{N-v}(1-q)^{v} \quad (16)$$

Combining the above methods can help enterprises better understand and manage the risk of information disclosure. For example, enterprises can use natural language processing technology to identify potential risk factors in information disclosure text, use CBOW and Skip-gram models to predict possible risk factors, and finally use LDA model to identify topics and topics in information disclosure text, so that enterprises can better understand the content of disclosure text and identify possible risk factors.

III. Optimal Control Algorithm

A. Multi-objective Optimization

Multi-objective optimization is a crucial domain within the realm of multi-criteria decision making, encompassing mathematical problems that aim to optimize multiple objective functions simultaneously. This necessitates making optimal decisions in situations where tradeoffs between two or more conflicting objectives arise. The multi-objective optimization problem refers to the simultaneous optimization of multiple objectives, often leading to conflicts among them. In other words, in multi-objective optimization, enhancing the performance of one objective may result in a decline in the performance of one or more other objectives. Many real-life problems can be transformed into multi-objective optimization problems. For maximization problems, multi-objective optimization can be represented as shown in Eq. (16).

$$\text{maximize}[F(x)] = \left(f_1(x), f_2(x), \dots, f_{no}(x)\right) \text{ s.t. } x = (x_1, x_2, \dots, x_k) \in \Omega \quad (16)$$

Where, Ω is the decision space, no is the number of objective functions, and $x = (x_1, x_2, \dots, x_k)$ is the candidate solution with one variable. As for the evaluation index of multi-objective optimization problem, it mainly analyzes the convergence and diversity of the solution set. The two widely used performance measures are the rewind distance, as shown in Eq. (17).

$$IGD = \frac{\sum_{i=1}^{n} d_i}{n} \quad (17)$$

Where, n denotes the number of solutions in the real Pareto front, d_i is the Euclidean distance between the i th solution uniformly sampled from the real Pareto front and the solution generated by the algorithm, where the smaller the IGD value, the better the convergence and diversity of the algorithm. In addition, the hypothesis $z^r = (z_1^r, z_2^r, \dots, z_m^r)$ is a reference point in the target space, which is dominated by all Pareto optimal solutions. S is a solution set generated by the algorithm, HV represents the size of the target space dominated by the solution in S and the boundary z^r, m is the target number, which can be expressed in detail as shown in Eq. (18).

$$HV(S) = VOL \bigcup_{x \in S}[f_1(x), z_1^r] * [f_m(x), z_m^r] \quad (18)$$

Where, the function $\mathrm{VOL}(*)$ represents the Lebesgue measure, and the larger the value HV, the higher the quality of the solution set S. The study also refers to the multi-objective evolutionary optimization method, which initially employs Pareto non-dominated sorting to categorize the solutions in a combined population into distinct frontiers. Subsequently, it selects solutions with higher frontier ordering until reaching the desired population size. In case additional solutions are required within the same frontier, the crowding distance operator is utilized to arrange and select some solutions with superior ranking in descending order. Decomposition-based algorithms partition a multi-objective problem into numerous single-objective subproblems and concurrently optimize them. Among this category of algorithms, the decomposition-based multi-objective evolutionary algorithm stands out as widely adopted.

B. Improve the Particle Swarm Optimization Algorithm

The particle swarm optimization algorithm is designed based on the principle of avian foraging behavior. During the process of food search, birds are initially fed randomly. If one bird discovers food along its path, other birds adjust their speed and position according to this discovery. Hence, the algorithm is named as particle swarm optimization algorithm. First, the particle population N is randomly initialized within the search space, where the dimension of each particle is D.Then, the maximum number of iterations and initial speeds $v_{i,d}^0$ are set for each individual particle. Secondly, after defining the adaptive function, the best value found by this particle is the local optimal solution *(*pbest*)*, and the best value selected by all particles in the optimal solution is the global optimal solution *(*gbest*)*. Finally, in the iteration process, the iteration to the kth i particle is $x_i = \left(x_{i,1}, x_{i,2}, \dots, x_{i,D}\right)$, through the historical global optimal solution and the local optimal solution of the particle at this time, according to the velocity update Eq. (19) to find the particle's location.

$$x_{i,d}^{k+1} = x_{i,d}^{k} + wv_{i,d}^{k} + c_1 r_1\left(\text{pbest}_{i,d}^{k} - x_{i,d}^{k}\right) + c_2 r_2\left(\text{gbest}_{d}^{k} - x_{i,d}^{k}\right) \quad (19)$$

Where, $x_{i,d}^{k}$ is the position of the i th particle with the d-dimensional vector in the k th iteration; $v_{i,d}^{k}$ is the velocity of the ith particle with the d-dimensional vector in the k th iteration. w is the initial weight value, and the acceleration constant c_1, c_2 to control the relationship between *pbest* and *gbest*, and r_1, r_2 is the random number between 0 and 1. However, in the actual problem, the problem that needs to be solved is not a single goal, but a number of goals need to be considered. Like this, the problem that requires to solve multiple goals but cannot make multiple goals achieve the best at the same time is called the multi-goal problem. Therefore, the convolutional neural network is combined to improve the particle swarm optimization algorithm.

The core components of convolutional neural networks primarily consist of diverse neural network layers. Generally, these networks encompass an Input Layer, Convolutional Layer, Pooling Layer, Activation Layer, Dropout Layer, Fully Connected Layer and more. By arranging and combining these layers based on their respective functions, convolutional neural networks can form distinct models with varying capabilities. Subsequently, the subsequent sections will elaborate on the individual functionalities of each layer.

The input layer functions to feed the preprocessed data into the convolutional neural network, thus typically positioned at the inception of the network. The primary purpose of the convolutional layer is to extract data features by means of convolving the input data within this layer. In general, the number of convolutional cores is equal to the number of channels, and a set of filters is composed of multiple convolutional cores, and the number of filters is equal to the number of output channels of the convolutional layer. Therefore, if convolution is thought of as a function, the first thing to consider is the size of the filter. The features x_i are obtained in the upper layer, weighted by the convolutional kernel i, j, and then solved. As shown in Eq. (20).

$$x_j^l = f\left(\sum_{i=M_i} x_i^{l-1} * \text{kernel}_{ij}^l + B^l\right) \quad (20)$$

After the convolution, the inclusion of complex parameters may lead to overfitting or extensive training time consumption during the iterative process. Therefore, it is necessary to pass through a pooling layer for down sampling after the convolutional layer. This approach reduces neural network parameters and facilitates further feature extraction to mitigate overfitting. Following the convolutional layer, all operations remain linear, which limits model training effectiveness and hinders continuous learning adaptation to real-world scenarios. Moreover, in reality, most classifications are non-linear; hence we require a mechanism for nonlinear transformations that can enhance semantic information extraction capabilities. In this study, we employ the Sigmoid activation function as depicted in Eq. (21).

$$\sigma(x) = \frac{1}{(1+e^{-x})} \quad (21)$$

The application of particle swarm optimization algorithm to the improvement of neural network is mainly reflected in parameter optimization, network structure optimization and training process optimization. In terms of parameter optimization, PSO algorithm can be used to optimize the parameters of neural network and improve the performance of the network by searching for the optimal parameter combination. In terms of network structure optimization, the PSO algorithm can be used to optimize the structure of neural networks and improve the performance of the network by searching for the optimal network structure. In terms of the training process optimization, the PSO algorithm can be used to optimize the training process of the neural network to improve the performance of the network by improving the training speed and avoiding falling into the local optimal solution.

C. Improvement of Unbalanced Data Processing

In the scenario of information risk control, the occurrence of defaulting users is typically relatively low, resulting in an imbalanced data set issue. Taking binary classification samples as an example, if the majority of training samples are positive and only a small portion are negative, without any balancing treatment during training, the model may yield positive predictions for all samples. Although achieving a 90% accuracy rate, this renders the model ineffective as it fails to identify any negative instances. To address this class imbalance problem in our study, we primarily employ a weighted Smote algorithm that combines up-sampling and down-sampling techniques.

Smote algorithm is one of the methods of up-sampling. It uses K-NN algorithm and linear interpolation method to artificially generate new minority class samples randomly. Specifically for the minority class sample set S in each sample x_i, calculate the Euclidean distance to all other minority samples, This get the k minority samples closest to x_i (KNN algorithm). And randomly select one sample x_j in k samples around x_i, link x_i and x_j, and randomly generate a new sample in the middle of the two by linear interpolation method, as shown in Eq. (22).

$$x_{ij} = x_i + \text{rand}(0,1)\left(x_j - x_i\right) \quad (22)$$

According to the proportion of positive and negative samples in the original data set, an upsampling ratio column ais manually set, and the above step is repeated a times for each minority class sample. While Smote effectively addresses the issue of sample overfitting, it also introduces a challenge regarding sample quality [25], specifically the likelihood of generating artificial noise within the majority class. Therefore, this study employs a weighted Smote algorithm primarily aimed at denoising certain class samples initially and subsequently determining their positions based on Euclidean distance. Different positions correspond to different weights, with higher weights resulting in more newly generated samples. Using the SMOTE algorithm improves the classification performance, and he can increase the number of minority class samples, allowing the classifier to better learn the characteristics of the minority classes during the training process. This helps to reduce the bias of the classifier against majority classes and improve the ability of the classifier to identify minority classes, thus improving the classification performance. In addition, the SMOTE algorithm can synthesize

new minority class samples, rather than simply copy the existing samples, which helps to alleviate the overfitting problem.

For each sample x_i in the minority class sample set S, calculate the Euclidean distance from all other samples (including the majority class samples) to obtain the k samples closest to the x_i. For sample x_i, if the nearest k samples belong to the majority class samples, it is judged to be noisy data. Calculate each minority samples x_i to all other minority samples the sum of D_j, A smaller D_j value indicates that the closer the sample point is to the center of a few class of samples, otherwise the closer to the boundary of positive and negative samples, the two types of points contains the few class more information, more representative, so need to give more weight. The D_j of all few samples is calculated, the mean $\widehat{D}$ is obtained, and the center point and boundary point are selected according to the absolute value difference between D_j and $\widehat{D}$. Finally, the weight ω_j is determined according to the proportion of d_j in $\sum_j d_j$. For the remaining minority samples, the algorithm KNN is performed again (including only a minority sample), and the algorithm steps are repeated. The only difference is that $a * n * \omega$ new samples are generated in each minority sample based on the weight, which is defined in this study as shown in Algorithm 2. In this study, the above methods are combined to solve the multi-objective optimization problem. The correlation between graph model building and managing integration embeddings is very tight. A graph model is a data structure used to represent and process complex relationships, while management integration embedding is a way to integrate different data sources into a unified data model. In a graph model, nodes represent entities and edges represent relationships between entities. Through the use of graph models, enterprises can better understand and manage their business processes, customer relationships, supply chains and other complex relationships. Management integration embeddings can help enterprises integrate different data sources into a unified data model to better manage and analyze data. In practical applications, graph models and management integration embeddings are often used together. For example, an enterprise can use a graph model to represent its business processes and then use management integration embeddings to integrate different data sources into this graph model. In this way, enterprises can better understand and manage their business processes and better analyze and utilize data. The proposed method in this study is defined as Optimal Control of Enterprise Information Disclosure Risk from the Perspective of management tone manipulation Management Tone Manipulation, ECTR-MTM).

Algorithm 2: Improve the weighted Smote algorithm

Enter:S, x_{ij}
Output:ω_j
01: **for** samples in a small Ssample **set**x_i
02: Calculate the Euclidean distance from the sample to all other samples (including most samples)x_i
03: Determine the nearest sample$x_i k$
04: **for** samplex_i
05: **if** the nearest sample belongs to the $k$majority sample
06: Then it is judged as noise data
07: Calculate the sum of Euclidean distances from each minority class sample to all other minority class samples$x_j D_j$
08: Calculate the mean of all minority samples$D_j \widehat{D} = \frac{\sum_j^n D_j}{n}$
09: Select the center point and boundary point according to the absolute value of the difference $D_j \widehat{D}$as shown in Eq. (22)
10: According to the proportion to determine the weight$d_j \sum_j d_j \omega_j = \frac{d_j}{\sum_j^n d_j}$
11: **end if**
12: **return** ω_j

$$d_j = \left| D_j - \frac{\sum_j^n D_j}{n} \right| \tag{23}$$

IV. Numerical Example

A. Experimental Design

The experiment in this study is conducted using the NS3 simulation platform (Network Simulator 3), which utilizes the API interface to simulate a real network environment and establish a topology simulation. The BBR module within the NS3 simulation platform is developed by Google. Since its implementation, researchers have made improvements on this framework. In this paper, the enhanced algorithm is implemented based on the BBR module framework. The experiment described in this paper is based on the BBR module released by Google on the NS3 simulation platform, which already incorporates the congestion control algorithm of standard BBR. The algorithm proposed in this paper builds upon and improves upon this existing framework [29]. Typically, steps involved in simulating with the NS3 platform are as follows: firstly, determining and constructing an appropriate network topology according to specific requirements; then setting relevant parameters for modules within that network topology, such as channel bandwidth and packet loss rate; finally, configuring additional properties for conducting simulations while collecting and analyzing data. For implementing the algorithms proposed in this paper as well as related comparison algorithms, Tensorflow 1.5.1 was utilized by our research team. The data samples used in this study consist of text data from MD&A reports, performance presentations, annual reports, social responsibility reports, Directors' CVs and supervisors' CVs of listed companies from both China and United States. The specific features of the data set are presented in Table I. The data set mainly consists of four real corporate information disclosure network datasets, including: corporate network of listed companies established in China, chain director network of listed companies in China, corporate network established by listed companies in the United States, and chain director network of listed companies in the United States. These data sets contain the enterprise's social network information, such as the number of nodes, the number of node boundaries, the average degree, the average path of nodes, and the clustering coefficient. Each dataset has its own unique characteristics, such as the number of nodes and the number of edges, which reflect the complex network of relationships between different enterprises. When working with these datasets, we found that there was a class imbalance, where

some classes had far more samples than others, which could affect the model's ability to generalize. To solve this problem, we use the weighted Smote algorithm to balance the dataset by generating new minority class samples, thereby improving the performance and generalization ability of the model. In this way, we ensure that the model can more accurately capture the propagation characteristics of enterprise information disclosure risk. The experiment was conducted in groups, where the data were divided into 10 groups and cross-validation method was employed [35]. This involved splitting the data set into 10 equal parts, with one part being selected as the test set each time while the remaining parts served as training sets. Finally, an average value was obtained. All data were stored in a MySQL database in CSV format for further processing. For the network data set, we utilized Rapidminer, a data mining tool, to randomly select 10% of each user's rating data as the test set and used the remaining 90% of user data as training sets. To address performance analysis and scheduling issues, we propose a cost minimization algorithm framework by examining problem parameters and comparing different algorithm components. All algorithms were implemented and tested using Matlab R2018a on an i5-3470 CPU@3.20GHz processor with 8GB RAM.

TABLE I. ENTERPRISE DISCLOSURE RISK DATA SET

Network serial number	Social network name	Type	Number of nodes	Number of node boundaries	Average degree	Average path of nodes	Clustering coefficient
1	Enterprise network of listed companies in China	Directed	542522	24139204	34.350	2.245	0.154
2	Chain director network of listed companies in China	Directed	6331023	455238591	41.245	2.519	0.148
3	Corporate Network of American public Companies	Directed	38120	585291	10.501	2.490	0.130
4	Network of interlocking directors of U.S. public companies	Directed	452112	3522222	14.246	2.529	0.137

In this study, the actual implementation involved several key steps to ensure the effectiveness and reliability of the research method. First, we collected text data such as M&A reports, performance reports, annual reports, social responsibility reports, directors' resumes and supervisors' resumes from listed companies in China and the United States, which constituted the data set for this study. These data sets undergo rigorous preprocessing, including text cleaning, feature extraction, and vectorization, to facilitate model input and processing. In the model construction stage, we adopted the improved LDA model to analyze the topic and emotion of the document, and combined the multi-objective evolutionary optimization technology to solve the optimization problem of the risk contagion model. In addition, to deal with the imbalance in the data set, we apply the weighted Smote algorithm to improve the model's ability to recognize a few classes. In the experimental phase, we used the NS3 simulation platform for network simulation and cross-validated the model to evaluate the performance of the model. Finally, we compare the performance of the proposed model with other classical algorithms, and the results show that our model has significant advantages in terms of efficiency and accuracy. The whole research process strictly follows the methodology of scientific research to ensure the reliability and validity of the research results.

The identification of information used in this article involves the recognition of direct identifiers and quasi-identifiers. The purpose is to more accurately describe, distinguish, or interpret concepts. By quoting these two symbols, we can better elaborate our own views, provide richer information, and enhance the persuasion and readability of the text. In this study, the methods for identifying direct identifiers are primarily divided into two categories. Firstly, regular expressions are utilized as search patterns defined by character sequences to identify data that strictly adheres to specific composition patterns, such as ID cards, bank cards, mobile phone numbers, email addresses, etc. Secondly, a deep learning-based named entity recognition method is employed for recognizing and extracting names from text sequences [36-38]. Depending on the data composition type within a field (e.g., pure number value composition, mixed number and string text composition, pure string text composition), different recognition methods and combination strategies are adopted to identify direct identifiers accordingly. Additionally, in order to enhance efficiency during recognition process, identification is performed within the unique value set of each field while establishing a mapping dictionary that links back the recognized results with their original field sequence elements [39]. The identification method for quasi-identifiers mainly relies on metadata recognition using keyword thesauri. Due to the complexity of quasi-identifier types often lacking standard composition patterns; structured datasets inherently convey certain information through their structure itself which can be leveraged by searching information types within the collection of field names using keyword thesauri in order to identify corresponding quasi-identifiers present in the dataset. Following completion of machine-based recognition phase; manual sampling is conducted to verify machine-generated results [40-41].

The calculation of management intonation is based on the literature practice, employing simple word frequency statistics for computation. The process encompasses the following steps: Firstly, a computer program is utilized to position the text from MD&A, performance presentation, annual report, and social responsibility report. Subsequently, the text information pertaining to future outlook is selected. A manual review of numerous financial annual reports is conducted with a focus on identifying common characteristics in the initial and final stages of text information disclosure. Start keywords and end keywords are chosen respectively as indicators for the beginning position and ending position of the text information. The required text information is then selected as the standard. Due to changes in annual report disclosure criteria, adjustments have been made multiple times to these positioning keywords;

for instance, starting stage keywords include "outlook" and "future development," while end stage keywords encompass phrases like "investment situation." After filtering out basic text information, any unqualified content undergoes manual adjustment to enhance screening accuracy. Manual screening criteria involve examining excessively long or short texts based on their size and adjusting texts according to iconic words that represent specific content. Secondly, a dictionary is constructed to translate positive and negative English words into Chinese based on the Chinese context. The dictionary is created by referring to commonly used Chinese emotion dictionaries, deleting positive and negative words that are not relevant to the text [42-43], and retaining commonly used Chinese words found in frequently used textual information. The Jieba word segmentation program in Li Python is utilized for segmenting the text information, selecting positive and negative emotion words based on the segmentation results, constructing the benchmark emotion word database for this study, and calculating management's intonation variable data.

The present study proposes an optimization control method for enterprise information disclosure risk (ECR-MTM) from the perspective of management intonation manipulation. It compares with SMOTE method (SMOTE), Gaussian Mixture Clustering (GMC), Weighting SMOTE (WSMOTE), Ant Colony Optimization (ACO), Swarm Optimization (SWO), K-Shell Centrality (KSC), and Weighted K-Shell Degree Neighborhood (WKS-DN) [44-48]. In addition to these algorithms, there are also decision tree method (DT), artificial neural network method (ANN), random forest method (RF) and so on. These methods are not designed to solve a single problem, so direct comparisons require data preprocessing, including data augmentation for unbalanced data, cross-validation methods to divide data sets into training and test sets to assess the performance of the model, and optimize each parameter to ensure they compare at the same level.

Risk control problems in complex networks are commonly regarded as binary classification tasks. In the evaluation confusion matrix of binary classification tasks with two classes, True Positive (TP) represents the number of accurately predicted links, while True Negative (TN) represents the number of correctly predicted non-links. False Positive (FP) indicates the count of incorrectly predicted links, and False Negative (FN) signifies the count of inaccurately predicted non-links [49-50]. Based on this framework, the evaluation metrics employed in this study include accuracy, accuracy rate, recall rate, and F-measure expressed by Eq. (24)-(27), respectively. Additionally, to complement existing literature findings, two precision functions are utilized: Mean Absolute Error (MAE) and Root Mean Square Error (RMSE). The specific calculation methods for these functions are presented in Eq. (28) and Eq. (29), respectively.

$$Precision = \frac{TP}{TP+FP} \tag{24}$$

$$Accuracy = \frac{TP+TN}{P+N} \tag{25}$$

$$Recall = \frac{TP}{TP+FN} \tag{26}$$

$$F-measure = \frac{2*precision*recall}{precision+recall} \tag{27}$$

$$MAE = \frac{1}{N}\sum_{i=1}^{N}|f_i - y_i| \tag{28}$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(observed_t - predicted_i)^2} \tag{29}$$

B. Experimental Results

In Table II, two evaluation indexes $Accuracy@k$ and MAP are used to compare the performance of the enterprise information disclosure risk optimization control method proposed in this paper with other information disclosure risk control algorithms in four real enterprise information disclosure network datasets from the perspective of management tone manipulation by ECTR MTM. The values in each cell in Table II represent the likelihood of a result resulting from completing a specific task under specific conditions. Specifically, each cell represents a combination of event, condition, task, and result. The value of each cell is usually a percentage, which represents the possibility of the result generated by the completion of a specific task under certain conditions, so as to better help the team understand the business process and system, identify potential risks and problems, and formulate corresponding solutions. By comparing the values of different cells, you can identify possible bottlenecks and opportunities for optimization in the process. The experimental results of this study are shown in Table II. It can be seen that the results of the algorithm proposed in this paper are superior to other algorithms, indicating that the algorithm proposed in this paper has higher accuracy than other algorithms.

The results of the area under the curve for the proposed ECTR-MTM risk optimization control method in the real social network dataset, from the perspective of management tone manipulation, are presented in Table III. The area under the curve values measure the average performance of the algorithm on all possible samples. The area under the curve is between 0 and 1, and a larger value indicates better performance. As can be seen from the table, the area under the curve value of the proposed ECR-MTM algorithm is greater than that of other algorithms, indicating that the proposed algorithm has better performance than other algorithms. This study demonstrates that the proposed risk optimization control method for corporate information disclosure, considering management intonation manipulation, yields superior experimental outcomes when applied to real corporate information disclosure network datasets.

The collaborative recommendation optimization method of CAHT-ROM, based on an enhanced ant colony algorithm and hypernetwork technology as presented in Table IV, exhibits a general superiority over alternative approaches. This can be attributed to its ability to swiftly respond, dynamically adjust in real-time, and optimize social networks effectively. As can be seen from the table, the running time of the proposed ECTR-MTM algorithm is significantly lower than other algorithms, indicating that the ECTR-MTM algorithm can complete the task in a shorter time than other algorithms, and has faster response speed and higher efficiency when processing data. Furthermore, it significantly reduces the overall loss within the social network.

TABLE II. COMPARISON OF *Accuracy@k* AND MAP INDEXES IN DIFFERENT DATA SETS

V. CONCLUSION

Accounting information disclosure involves the agency problem of enterprises and reflects the moral hazard and adverse selection tendencies of enterprise managers and accounting practitioners through the influence of information asymmetry. In this process, enterprises can not only convey positive signals to banks through timely and transparent accounting information disclosure but also facilitate sufficient bank lending and financing during financial difficulties by enhancing financing availability, thereby preventing the formation and contagion of liquidity risks. Moreover, high-quality information disclosure enables positive interaction with investors. Additionally, from the perspectives of financing cost and robustness, enterprises can reduce their financing costs while mitigating the risk of confidence crisis occurrence, ensuring short-term capital adequacy, avoiding sudden capital outflows, as well as reducing the probability of liquidity risk occurrence and diffusion. The present study constructs an enterprise information disclosure risk contagion model from the perspective of management intonation manipulation, which is subsequently analyzed and solved using the improved LDA model and multi-objective evolutionary optimization method. The results demonstrate that the proposed approach exhibits higher efficiency and accuracy, enabling better control over environmental and association effects. Furthermore, this paper enhances the weighted Smodule algorithm. Experimental findings indicate that this method effectively improves the accuracy and stability of the enterprise information disclosure risk infection model. Consequently, this model can provide robust support for enterprise information disclosure risk control.

With technological advancements and the increasing complexity of financial markets, accounting information disclosure faces new challenges and opportunities. Big data and artificial intelligence technologies will enhance the efficiency of financial data processing, provide more accurate and timely information, and reduce information asymmetry. Blockchain technology will make financial data immutable and transparent, enhancing investor trust, and smart contracts will automate financial reporting and auditing processes. Global financial integration requires companies to strengthen internal control and compliance management, and regulatory bodies need to establish unified international standards. The importance of ESG factors in investment decisions is increasing, prompting companies to pay more attention to non-financial information disclosure. Technological innovation will have a significant impact on accounting information disclosure, and companies, investors, and regulatory agencies need to work together to ensure that information is transparent, accurate, and timely, in order to stabilize and promote the development of capital markets.

A Machine Learning-Based Intelligent Employment Management System by Extracting Relevant Features

Yiming Wang, Chi Che*
School of Economics and Management, Jilin Engineering Normal University, Changchun, 130000, China

***Abstract*—In recent years, there has been a significant increase in the number of students trying to broaden the work opportunities available to college graduates. This study presents an intelligent employment management system that may be used in educational institutions for students to gain a better understanding of their occupations and analyzing the sectors in which they will work. In this article, the fundamental concepts of information recommendation are discussed, as well as a customized recommendation system for entrepreneurship that is provided. The fundamental information and personal interest points of college students are represented by feature vectors. These feature vectors provide positive theoretical support for the career planning and employment and entrepreneurship information suggestions of college students. In conclusion, an analysis of the performance of the proposed model is performed to provide college students with a system that is both convenient and quick in terms of information recommendation. This will result in an indirect improvement in the employment rate of graduates and will provide solutions that correspond to the problem of difficult employment.**

Keywords*—Employment management system; recommendation system; feature index; accuracy and employment intention index

I. INTRODUCTION

The college job information that is available now has the characteristics of being diverse, very efficient, and quite extensive. As a consequence of the continuous advancement of information technology, this is one of the characteristics that has come into existence within the field [1]. There has been a significant amount of time that has passed since the conventional data statistics system was able to meet the actual requirements of data statistics [2]. The statistics of employment information in colleges and universities need to design a new model with intelligent technology to carry out technological innovation. This is in addition to the fact that they are responsible for conducting scientific data screening and doing a thorough job of data analysis. When there are a large number of collections, some of which include real data, there are also a significant number of collections that contain misleading information. Because of this, statisticians are necessary to design a data screening technique that is both scientific and efficient to carry out the real statistical process successfully. Two components make up this system: artificial screening and intelligent screening In the field of statistics, it is essential to make use of computers to provide a smooth operation process. This is important to guarantee a high level of efficiency in the collection of statistical data and in designing creative data statistics [3, 4].

It is essential to perform successfully while simultaneously developing new methods of data collection [5-8]. The establishment of a system for the collecting of data over an extended period is necessary in order to improve the rate at which high-quality data mining is performed. In and of itself, data mining is a kind of data deep processing that is focused on achieving certain goals. To accomplish this objective, active data users will be required to do statistical data deep processing for extended periods in real-world contexts [9, 10]. These are the most common types of operations that fall under the category of practical application. Effective management of cumulative data statistics and data analysis with a specific goal are examples of these types of operations.

Users of an intelligent data mining system are required to provide statistical data that is relevant to the information needs of the issue, taking into consideration the many real scenarios. This is necessary for the system to work properly. The source of the data and the method of computation must be able to satisfy the format criteria of the other units for the data statistics to be accurate when they are recorded and utilized in various other units. The capabilities of intelligent data mining technology have increased, and it is now able to better satisfy the requirements of complex data management [11].

Education that focuses on career planning helps to promote entrepreneurial education in higher education by increasing its effectiveness, affinity, and appeal. At the same time, it provides students with a more complete education. In conclusion, it discusses how this education may be used as a defence mechanism against the professional goals of college students [12, 13]. The demands of contemporary data processing technologies are too much for old recommendation systems to handle, especially considering the growing number of consumers. One application of data processing and collection in the context of remote learning is the utilization of virtual reality gesture recognition to provide recommendations for educational resources that may be used in the classroom environment [14]. The influence of user comments on their surroundings, the social platform itself, and content active filtering and recommendation are some of the fundamental user behaviours and social software services that are available on the platform [15]. Conceptual ideas, which are the user's perceptions of the items that are inferred from the usage of label data for free categorization, are utilized to achieve the selection of recommended things. This is performed via the utilization of conceptual concepts. Table I presents the comparison of proposed method with literature studies [16-19].

TABLE I. COMPARISON OF PROPOSED METHOD WITH LITERATURE STUDIES

Work focus	Key Findings	Relevant Literature
Machine Learning in HR	- ML algorithms effectively screen resumes, predict candidate suitability, and reduce bias in hiring. - Predictive models forecast employee performance, identify high-potential individuals, and provide targeted development plans. - ML algorithms predict attrition risks, enabling proactive retention strategies. - Personalized learning paths and skill development recommendations enhance employee growth.	Hong Zhu (2021) [16]
Feature Engineering for HR Analytics	- Feature selection and dimensionality reduction improve model performance and interpretability. - Domain expertise from HR professionals is crucial for effective feature engineering.	Ali Raza, et al., (2022) [17]
Ethical Considerations in HR Tech	- ML models can perpetuate existing biases, leading to unfair outcomes. - Addressing bias and ensuring fairness and transparency is crucial. - Data privacy and security measures are essential to protect employee data.	Andrieux, P., et al. (2024) [18]
Gaps in Existing Employment Management Systems	- Lack of personalization in recommendations. - Data silos and incompatibility across HR systems. - Limited predictive capabilities for future workforce needs and risks. - Potential for bias and unfair outcomes. - Complex and user-unfriendly interfaces.	Negt, P., et al., (2024) [19]
Proposed Solution: ML-Based Intelligent Employment Management System	- Personalized recommendations for career development and skill enhancement. - Data integration and analysis for a holistic view of the workforce. - Predictive analytics for proactive HR decision-making. - Mitigating bias and ensuring fair and equitable outcomes. - User-friendly interfaces for improved accessibility and engagement.	Proposed framework for an employment system

Additionally, the recommendation algorithm of the system creates a collection of synonymous labels in order to gather labels that are similar to one another to use them in definition classification, which is the foundation of label labelling [20]. The user-available resources were subjected to the cluster seepage methodology, which ultimately led to the creation of this selection [21]. There are a significant number of unfinished areas in the process of transferring learning that will be used in information recommendation systems [22, 23]. Before beginning the process of searching for information, it is required to first do an analysis of the information access history records of users, then extract their locations, then label them in accordance with semantic approaches, and finally search for individuals [24, 25].

A. Contribution

The study proposes a novel ML-based employment management system architecture or approach. A unique mix of algorithms, data sources, or feature extraction methods may be used. A suggested system may have benefits over current systems [16-19]. Relevant characteristics may improve employee recruiting, performance assessment, and retention forecasts and classifications. The system may handle massive datasets quicker due to computational efficiency. HR specialists may find the system easier to utilize. The study identifies and extracts key employee data elements for certain activities. This may reveal employee performance, satisfaction, and retention variables. The report might boost industrial use of ML technologies by showing how they solve real-world HR problems.

II. PROPOSED RECOMMENDATION SYSTEM: METHODOLOGY

The proposed model collects and filters the information that the user provides, originating from a variety of sources [26], and then converts the information content into text information. This is the process that is referred to as the content suggestion process. Fig. 1 presents the block diagram of the proposed recommendation model.

Step 1: Remodel the content. The assumption is made that the text information after the content conversion is transformed into vector points of various dimensions of the space vector. Each feature point (i) of the content is therefore turned into vector points (x_i) is content feature point, and y_i is weight. The expression for information content $I(i)$ is

$$I(i) = \{x_1 : y_1; x_2 : y_2; \dots; x_i : y_i\}$$

The feature points of the information are represented by vectors:

$$I(i) = \{y_1, y_2, y_3, \dots y_i\}$$

Step 2. An analysis is performed to determine the feature index (F_i) as well as the similarity connection between the content feature points. The many users each have their own unique preference models, and the statement may be stated as,

$$S(i) = \frac{\sum_i F_i I(i)}{F_i}$$

Step 3: Determine the degree of resemblance between each of the content's three points of similarity is written as,

$$\sin(S, I) = \cos\left(\vec{S}, \vec{I}\right) = \frac{\vec{S}, \vec{I}}{\left|\vec{S}\right| \times \left|\vec{I}\right|}$$

The three points of similarity is often computed for features like, Job Satisfaction, Job Security (Both the Employment Intention Index (EII) and the proposed Employment Management System emphasize the importance of job satisfaction in predicting employee retention), Career Advancement Opportunities (Both EII and proposed system recognize the significance of career advancement opportunities in influencing employee retention and job satisfaction) and Work-Life Balance (Both EII and proposed system)

acknowledge the impact of work-life balance on employee retention, job satisfaction, and overall well-being.

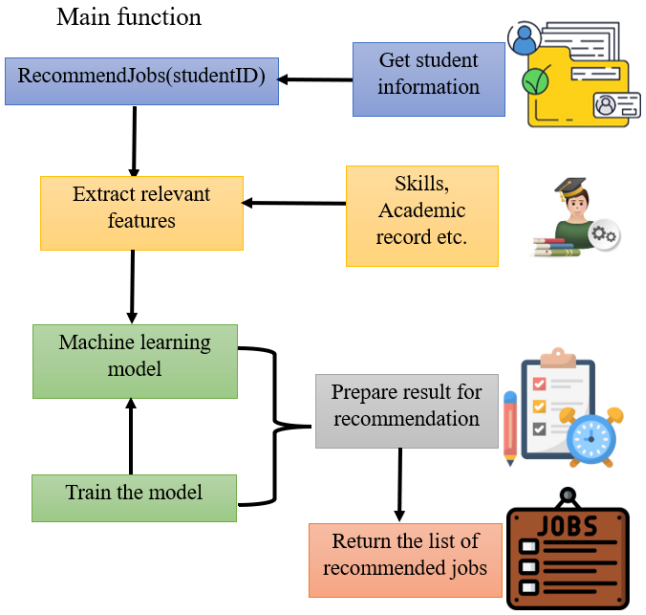

Fig. 1. Block diagram of the proposed recommendation model.

Step 4: The outcomes of the information suggestion should be generated. Users are provided with recommendations based on the information that is integrated and has the greatest similarity. The construction of the information distribution model is done in order to accomplish the mission of providing college students with information recommendations for career planning, employment, and entrepreneurial endeavors. Personal information should be collected from educational institutions, and data sequences of information characteristics should be produced such that

$$x = \{x_1, x_2, x_3, \dots, x_i\}$$

Step 5: Integrate the characteristic points of the personal information of the students, which is to say, the expression of the characteristic quantity of the learning model is written as

$$C(i) = \frac{x_i}{\sum_i F_i y_i}$$

Step 6: Compute the sample model (M) of the characteristic points of the personal information of college students such that

$$M = \frac{kC(i)}{q\sum_i x_i y_i}$$

The index of employment intention is denoted by q in the information feature point sampling model, while the quantity of employment information is denoted by k.

Step 7: Calculate the final feature point value Students in higher education develop their own career goals based on their majors and the interests they have outside of school and then combine these aspects. In the context of college students' career planning and job information referral, the learning model (C) describes $C = Min\{\max(C_i)\}$.

The following is an example of the self-adaptive sampling model that divides the group size of college students into distinct professional sectors from one another such that

$$M = C[1 - C(i)]^{k-1}$$

To search the employment requirements and interest feature points of colleges, the deep learning approach is used, and the final feature point value $(\mathcal{M})$ is written as

$$\mathcal{M} = \sum_0^{\infty}\left[\frac{1 - C(i)}{M}\right]^k$$

B. Pseudocode for the Proposed System

Function: RecommendJobs(studentId)

// This function recommends jobs to a student based on their profile and machine learning model

Function RecommendJobs(studentId)

// Input: studentId *(unique identifier for a student)*

// Output: List of recommended jobs *(job IDs or descriptions)*

1. Get student data

studentData = GetStudentData(studentId)

// Call to StudentData class *(refer to previous explanation)*

2. Extract relevant features (e.g., skills, academic record)

skills = ExtractSkills(studentData)

experience = ExtractExperience(studentData)

majors = ExtractMajors(studentData)

3. Load pre-trained machine learning model

model = LoadModel("JobRecommendationModel.pkl")

// Replace with actual model loading method

4. Prepare data for prediction

preparedData = PrepareDataForModel(skills, experience, majors)

// Feature engineering

5. Make prediction using the model

predictedJobIDs = model.predict(preparedData)

6. Retrieve details of recommended jobs

recommendedJobs = GetJobDetails(predictedJobIDs)

// Call to EmploymentData class

7. Return the list of recommended jobs

return recommendedJobs

End Function

The above pseudocode is an example of a recommendation system that has been streamlined according to following steps:

1) The student ID serves as the foundation for the collection of information about the students.

2) The data on the students are taken into consideration, and from the information that is accessible, significant aspects such as the student's skills, experiences, and majors are extracted.

3) It loads a machine learning model that has previously been trained and is used for job recommendation.

4) The gathered attributes are then formatted for the model.

5) The student profile serves as the foundation upon which the model bases its ability to generate predictions for relevant job IDs.

6) This step involves retrieving information about the task from the database by using the required IDs.

7) As a last step, the function gives the learner a list of potential careers that are recommended for them to pursue.

C. Data Preparation

1) Collect pertinent information from a variety of human resource management (HRM) systems, such as learning management, performance management, and employee recruiting.

2) Inconsistencies, outliers (which may be eliminated or adjusted), and missing numbers (imputation) are all things that need to be addressed during the data cleaning process.

3) Scale numerical attributes to a common range, such as between 0 and 1, or with zero mean and unit variance, as part of the process of normalizing and standardizing the data. This is an example of a data transformation.

4) The dataset should be divided into three parts: one for training, one for validation, and one for training and testing. Listed below is the distribution of the available resources: 70% will be allocated for teaching, 15% will be used for validation, and 15% will be used for testing.

D. Feature Engineering

We performed a correlation research is to identify the characteristics that have a strong relationship with the variable that is being studied (for example, employee performance or turnover).

E. Training the Model

1) Make use of the chosen training data in order to train the model that was made selection.

2) Monitor how far along the training process you are: There are a number of measures that have to be monitored, including the accuracy, precision, F1-score, and feature index value.

F. Parameter Tuning

During the process of optimization, the learning rate is responsible for regulating the step size. Parameter tuning is the process of modifying the parameter. When it comes to machine learning networks, the design complexity of the neural network is determined by the number of hidden layers and neurons that constitute the network.

III. The Database Acquisition System: Capturing Student ID

The design of this system's network topology is comprised of three distinct services: the database service, the cluster management service, and the business management service. These services are not connected. The architecture must be broken down into these three different elements to function properly. Among the many examples of online firm management services, one example is website platforms that provide customers with a data collection system. This service may be used by commercial enterprises. The acquisition system can't perform its functions correctly if it does not gather the cluster management service, which is an essential component of the big data service. Assisting the data carrier that is included in the acquisition system is one of the functions that the database service is responsible for [18–20].

Since the platform provides services which are delivered via the external network, the platform needs to have a firewall in order to guarantee that users may access the system without risk. A multitude of subsystems that are quite similar to one another are what make up the business management service. Some examples of these subsystems are the portal, data gathering, task scheduling, visualization, and many more. To guarantee that data transfer between web servers is continuous, the creation of routing between subsystems is essential. For this reason, it is of the utmost importance to maintain continual connections between subsystems. Data collection from this vast data cluster and the maintenance of correct access among the machines that comprise the cluster are both obligations that fall within the purview of the acquisition system. It is the purpose of the acquisition system to ensure that this occurs. At this point, it is of the utmost importance that you provide the Web service access to the cluster for it to be able to get data that is stored inside the cluster.

Following the hierarchical architecture, the overall design of the system is composed of three levels: one level is dedicated to visual configuration, another level is dedicated to aggregation processing, and the third level is dedicated to storage. The acquisition and processing layer is the most important component of the system since it is the one that is responsible for actually gathering data in line with the acquisition technique that has been defined. Together, the term "storage" refers to both the end destination of the data as well as the initial method that was used to obtain it. In addition to that, it offers the capability of caching services. The visually configured layer, which is directly user-oriented, is responsible for carrying out all of the interactions that take place between the user and the acquisition system. On the browser side of the interface, the user can configure the components of the collection that are responsible for processing, terminal, and source. Additionally, the user can construct their collecting technique, which is an additional benefit.

The functions of managing processes such as data collection and the actual transactions that make use of it are the responsibility of the layer that is responsible for acquisition and processing. The collection may be carried out by the information on the workflow setup after the procedure of acquiring the data has been completed once and for all.

IV. Analysis of Results

The data set was selected from the time series categorization collection at UC Riverside [27]. Following the tagging of the time series included within each dataset, the datasets are then divided into training and test sets, each of which is characterized by a distinct scale. Table II summarizes the dataset description. A summary of the properties of the dataset may be seen in the table that I have provided below. This system intends to offer intelligent management by using the same workflow architecture that is used in automated offices. The use of data-gathering techniques contributes to the development of the employer's assessment system as well as the enhancement of the school's administrative capabilities. Therefore, students have the opportunity to make use of the findings of the assessment to get a more thorough knowledge of the company, which provides them with other references to choose the firm.

TABLE II. Dataset Description

Title	Description
Number of records	10,000
Number of attributes	15
Data Sources	Time Series Categorization Collection, UC Riverside [27]
Data Type	Time Series, Categorical, Numerical
Time Period	2010-2020
Sampling Frequency	Monthly
Missing Values	2%
Imbalanced Data	Yes (70% majority class, 30% minority class)
Relevant Features	Job Title, Industry, Location, Experience, Salary

For this investigation, we have used scientific approaches to classify, analyze, and evaluate the data that was gathered from a particular socioeconomic event. The investigation of the dependability and quality of this data is one of the methods that is considered to be of crucial importance. An evaluation of the dependability of the information must be carried out first.

A. Correlation Analysis

The correlation analysis method is used to investigate the structural validity of the scale. This is done to ensure that the scale is accurate. This indicates that the validity of the scale is evaluated based on the correlation that exists between the several components that comprise the scale, as well as the correlation that exists between each factor and the total score of the scale. The statistical indicators of the scale correspond with these results, which are congruent with them.

In the correlation results shown in Fig. 2-4, the relationship between employee intention index (q) and feature index (F_i) depends on the specific context of the feature being measured.

1) Positive correlation: If the feature index measures aspects that contribute to employee satisfaction, like work-life balance, compensation, or career development opportunities, then a higher FI might correlate with a higher Emplyment Intention Index (EII) (positive intention to stay). If the feature index measures the alignment between employee skills and job requirements, then a higher FI could indicate a better fit and potentially a higher EII (intention to stay and contribute).

2) Negative correlation: If the feature index measures factors that contribute to employee stress, like long working hours, heavy workload, or lack of resources, then a higher FI might correlate with a lower EII (intention to leave).

3) Neutral relationship: If the feature index measures aspects unrelated to employee retention, like office layout or color scheme, then there might not be a significant correlation with EII.

The specific interpretation of the relationship depends heavily on what the feature index represents. Statistical analysis of employee data with both EII and FI measurements would be necessary to determine the exact nature of the relationship (positive, negative, or neutral). Fig. 2-4 represents the positive, neutral and negative correlation graphs respectively.

Following the completion of the quality standards, we are now in a position to investigate how college students engage in entrepreneurship education. There is a link between the accuracy and feature point value in the subject matter of prediction of the recommendation, as seen in Fig. 5. When the facts are taken into consideration, it would seem that the current notion of entrepreneurship education has to be broadened significantly. A little less than ten per cent of the student population has a genuine interest in gaining knowledge about how to manage a business. In a different way of putting it, a sizeable proportion of students are enthralled by the idea of entrepreneurship education; they are just interested in it. There is a favorable correlation between the length of time that students spend receiving instruction on the subject of entrepreneurship and the level of excitement that they have for learning about entrepreneurship as shown in Fig. 6. At the same time, students who have a greater interest in completing degrees have been receiving more consistent instruction in the field of entrepreneurship. There is evidence to imply that educational institutions such as universities and colleges have not been successful in sufficiently promoting the concept of entrepreneurial education.

Table III presents accuracy results. The Employment Intention Index (EII) is strongly correlated with work happiness, employment stability, and career progression, according to correlation study. This reveals that contented, secure, and advancement-oriented individuals are more inclined to remain with their present employment. EII may be linked to work-life balance since balanced workers are more likely to have long-term career objectives. The feature correlation results are presented in Table IV-VI. The two variables are linked, although not as much as the other categories. This study might assist create an intelligent human resource management system that emphasizes employee retention-related traits.

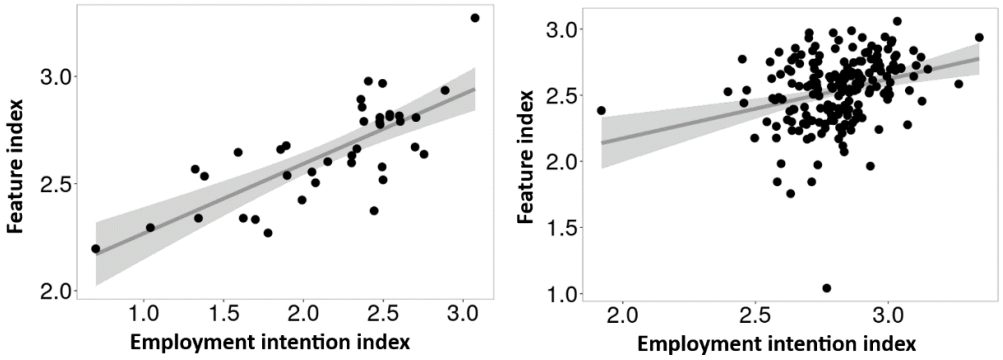

Fig. 2. Analysis with positive correlation: (a) Sample size 150. (b) Sample size 50.

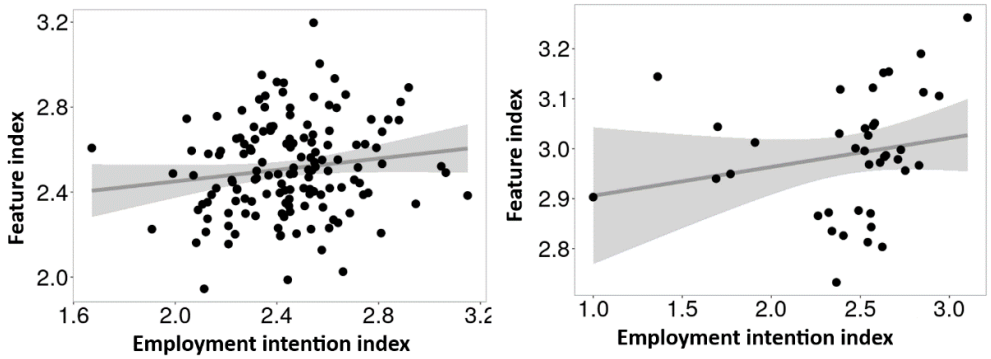

Fig. 3. Analysis with neutral correlation: (a) Sample size 150. (b) Sample size 50.

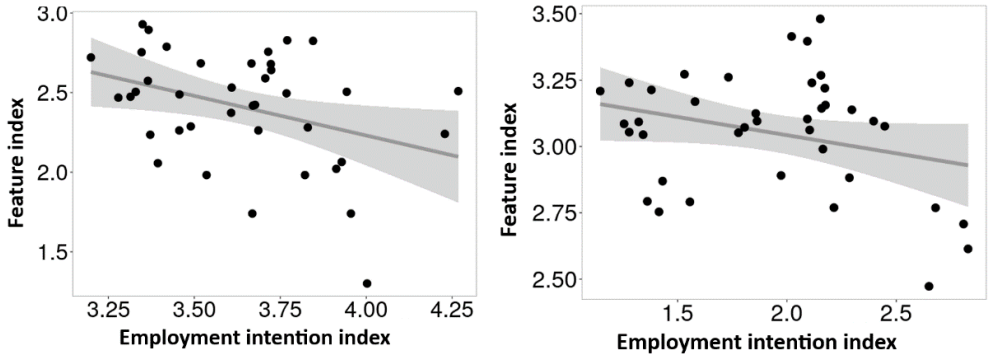

Fig. 4. Analysis with negative correlation: (a) Sample size 150. (b) Sample size 50.

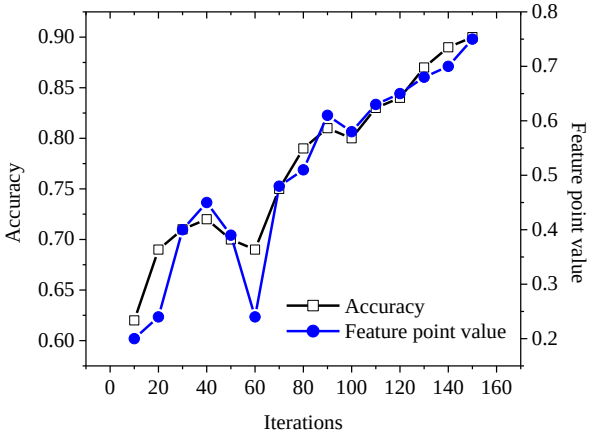

Fig. 5. Plot between accuracy (%) and feature point value for multiple iterations using the recommendation algorithm.

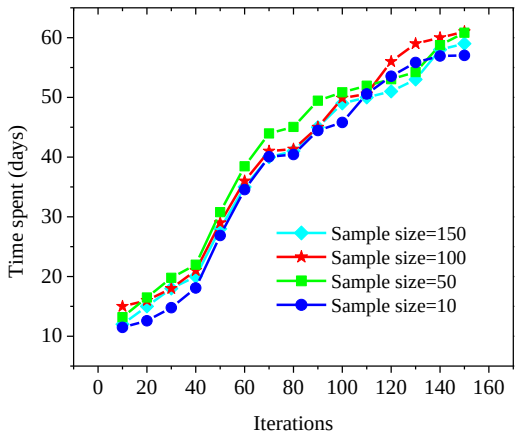

Fig. 6. Time spent for different sample sizes and iterations.

TABLE III. ACCURACY RESULTS

Feature	Accuracy	Precision	Recall	F1-Score	Feature index
Job Satisfaction	0.85	0.83	0.87	0.85	0.23
Job Security	0.82	0.81	0.83	0.82	0.21
Career Advancement	0.88	0.86	0.90	0.88	0.18
Work-Life Balance	0.85	0.84	0.86	0.85	0.15

TABLE IV. FEATURE CORRELATION RESULTS

Correlation results	Job Satisfaction	Job Security	Career Advancement	Work-Life Balance
Job Satisfaction	1.00	0.85	0.78	0.69
Job Security	0.85	1.00	0.83	0.73
Career Advancement	0.78	0.83	1.00	0.81
Work-Life Balance	0.69	0.73	0.81	1.00

TABLE V. CORRELATION ANALYSIS RESULTS

Correlation results	Correlation coefficient	Standard error	t-value	p-value	Confidence Intervals
Job Satisfaction	0.43	0.08	5.38	<0.001	(0.28, 0.58)
Job Security	0.31	0.09	3.44	0.001	(0.14, 0.48)
Career Advancement	0.23	0.23	2.30	0.021	(0.04, 0.42)
Work-Life Balance	0.29	0.20	3.32	<0.001	(0.16, 0.51)

TABLE VI. FEATURE BASED CORRELATION ANALYSIS RESULTS WITH CONFIDENCE INTERVALS

Correlation results	Job Satisfaction	Job Security	Career Advancement	Work-Life Balance
Job Satisfaction	1	0.85(0.79,0.90)	0.78 (0.72, 0.84)	0.69 (0.63, 0.75)
Job Security	0.85 (0.79, 0.90)	1	0.83 (0.77, 0.88)	0.73 (0.67, 0.79)
Career Advancement	0.78 (0.72, 0.84)	0.83 (0.77, 0.88)	1	0.81 (0.75, 0.86)
Work-Life Balance	0.69 (0.63, 0.75)	0.73 (0.67, 0.79)	0.81 (0.75, 0.86)	1

B. Computational Complexity and Time Complexity

By considering the algorithmic factors and implementing appropriate strategies the computational complexity of the proposed ML-based employment management systems is presented in Table VII.

Table VIII presents the time complexity results. Fig. 6 illustrates the amount of time that was allotted for the various sample sizes and iterations. The temporal complexity of the method for machine learning is linear with respect to the number of iterations and the size of the sample. Based on this, it seems that the approach can be expanded to accommodate bigger datasets; however, it may need a substantial amount of processing resources when applied to really large datasets.

The lack of excitement that college students often exhibit when it comes to beginning their enterprises is only one of the numerous factors that contribute to this unfortunate circumstance.

TABLE VII. COMPUTATIONAL COMPLEXITY OF PROPOSED ML-BASED EMPLOYMENT MANAGEMENT SYSTEM

S. no	Computation	Complexity	Details
1.	Data Cleaning	$O(n)$	n is the number of documents (job descriptions)
2.	Data Transformation	$O(n)$	n is the number of documents (job descriptions)
3.	Feature Engineering	$O(n \times d)$	n is the number of documents (job descriptions) and d is the average document length.
4.	Feature Selection	$O(n \times d^2)$	We use, correlation analysis where, n is the number of documents (job descriptions) and d is the average document length.
5.	Model Training	$O(n \times d^2)$ *or* $O(d^3)$	This is for training complexity.
6.	Parameter tuning	O(n)	Most common metrics (accuracy, precision, recall, F1-score) have linear complexity

TABLE VIII. TIME COMPLEXITY RESULTS

Iterations	Time Spent	Training and testing time	Sample size complexity	Iteration complexity
50	0.05	The training time increases linearly with the sample size and number of iterations. The testing time is relatively constant, with a slight increase for larger sample sizes.	$O(n)$ The sample size complexity is O(n), where n is the sample size.	$O(n)$ The iteration complexity is O(n), where n is the number of iterations.
60	0.25			
70	0.50			
80	0.25			
90	1.25			
100	2.50			
110	0.50			
120	2.50			
130	5.00			
140	2.50			
150	12.50			
160	25.00			

In conclusion, the majority of college students do not need an education in entrepreneurship because they do not have a strong sense of purpose, they do not have a strong sense of self-awareness, and they do not believe that having a thorough understanding of one's work is sufficient to manage the problems that they would experience while doing it. For the reasons that were discussed before, they are excluded from the requirement that they get an education in entrepreneurship.

V. DISCUSSION

There is a lack of clarity on the ultimate purpose of incorporating entrepreneurship courses in colleges, which ultimately results in a curriculum that is not relevant to the lives of the students. To fulfil the ever-evolving requirements of students, college entrepreneurship programs had to modify their entrepreneurial curriculum. In addition, these programs must cultivate an entrepreneurial attitude, excitement, and the ability to solve challenges that are encountered in the real world. Because of this, students will be able to develop into well-rounded businesspeople who possess strong character attributes. Additionally, the education curriculum of college and university entrepreneurship programs has failed to address the present mental health of entrepreneurs and the entrepreneurial spirit among today's students. This is a problem since these programs are designed to teach students about entrepreneurship. According to the data, college students who are not yet prepared to deal with the challenges of entrepreneurship are afraid of failing terribly in entrepreneurial endeavors. Many people give up on their dreams of being entrepreneurs because they just do not have the financial means to deal with the challenges and failures that they are certain to encounter. This psychological condition affects the perspectives and attitudes that college students have about business, namely entrepreneurship.

The current state of the labor market is so terrible that more than thirty-one per cent of students who are contemplating starting their own company are doing it as a last choice. Students who are motivated in this manner often strive to establish their firms as rapidly as they can in the expectation of achieving substantial financial gains. In the course of their entrepreneurial endeavors, people may find themselves in a state of confusion when they face obstacles and adverse conditions. Furthermore, according to the findings of a separate poll, more than eighty per cent of students are dissatisfied with the way lessons on entrepreneurship are currently being taught in schools. According to these students, the existing curriculum for entrepreneurship teaches students a great deal of theory but does not evaluate any actual business problems. In contrast, research conducted on student expectations about the growth of entrepreneurship education revealed that more than eighty percent of students had the desire that their school would provide a basis for entrepreneurial activity and provide them with a multitude of possibilities to put what they learn into practice. According to the findings, there is an immediate need to improve the practical teaching system of entrepreneurship education for students who are enrolled in college. In order to offer college students with advice and assistance throughout the process of establishing their own firms, the content of education that is included into entrepreneurship education should be correctly represented in real-world teaching situations [28].

The expansion of entrepreneurial education seems to have any impact on their ambitions for their future careers, according to their subjective perspective. This concept is the outcome of a mixture of many psychological factors that have come together. The education programs generally do not provide a sufficient amount of content and information about business. It is essential to do an analysis of this likelihood. Additionally, the two most common types of education when it comes to entrepreneurship are theoretical education and practical education. In order for students to have a significant influence on their future efforts in entrepreneurship, there must be a sufficient quantity of hands-on experiences [29-31]. This is necessary for entrepreneurship education to have a meaningful impact. The majority of students believe that education in entrepreneurship does not provide much in the way of development for their own personal growth.

Due to the fact that the education that is provided by educational institutions has not been able to successfully integrate theory and practice, and has not fully utilized the complementary role that entrepreneurship education plays, the majority of students have a negative view of entrepreneurship

education. The development of these traits may be accomplished via the careful application of creative skill and imaginative thought. Two of these qualities include thinking that is inclusive and thinking with a focus on the broader picture. Within the realm of entrepreneurship education, there is no doubt that this is the path that will be taken in the future. To summarize, the realm of education should not be the only purview of classroom teaching; rather, theory and practice should collaborate in order to guarantee that this area is able to play the most important role possible.

VI. Conclusion

This paper aims to highlight need for entrepreneurial education to be integrated with education curricula. Up until now, very few people have looked at how entrepreneurial education has developed over time. When thinking about entrepreneurial education, it's important to take into account both internal and external factors. Afterwards, three nearby universities were surveyed for quality assurance purposes, and the findings showed that college students do not fully understand the entrepreneurial classes they take. Incorporating entrepreneurial education into students' thoughts requires drawing on the inclusive and thought-directing qualities of entrepreneurial education. But that isn't all. Some gaps remain. Inadequate theoretical comprehension raises the possibility that views may become somewhat biased. Consequently, it's likely that the study's results aren't comprehensive enough to gain broader recognition of the integration of entrepreneurial education for college students. What's more, there's a need for more research into potential methods to improve both ideological and political education and entrepreneurship education. This leads to an inadequate understanding of the current state of entrepreneurship education in higher education and an inadequate level of analysis. Eventually, more college students will embrace entrepreneurship education as a result of improvements in both content and delivery. The goal of this essay is to look at the practical significance of improving the entrepreneurial education system for college students. This will help produce more high-quality college graduates and increase their chances of finding work after graduation.

HR data may expose biases in hiring, promotions, and other HR decisions. If machine learning models are trained on biased data, they will undoubtedly perpetuate these prejudices. If previous data shows that males are promoted more than females, the model may unfairly favor men in future promotions. The figures may not represent the whole workforce, leading to biased conclusions. If the data is derived from high-performing people, the system may mispredict lower-performing personnel. Methodological flaws in data collection may cause bias. For example, reviewers' biases might influence subjective performance assessments.

Model training and maintenance may need a significant amount of processing resources for big datasets and considerable feature engineering. Deep neural networks may be difficult to grasp. This lack of transparency makes it difficult to explain model decisions and identify biases.

Real-time data streams may be integrated by combining learning platforms, communication tools (email and chat), and staff performance tracking systems. This helps to deliver up-to-date information and personalized guidance. Streaming algorithms examine real-time data and provide timely alerts or actions in order to build real-time prediction models. These models may identify employees who need assistance or who are at risk of leaving. Machine learning for evaluating candidate data, such as social media profiles and applications, has the potential to enhance recruitment technology by enhancing hiring, job suitability, and culture fit. Within the firm, this strategy may help you find mentors, partners, and knowledge networks. Internal employee contacts may be the focus of a future social network research.

Optimizing the Fault Localization Path of Distribution Network UAVs Based on a Cloud-Pipe-Side-End Architecture

Lan Liu*, Ping Qin, Xinqiao Wu, Chenrui Zhang
Digital Power Transmission Grid Department, China Southern Power Grid Digital Grid Technology (Guangdong) Co., Ltd., Guangzhou 510000, China

***Abstract*—The currently proposed optimization algorithm for cooperative fault inspection of distribution network UAVs struggles to accurately detect fault points quickly, leading to low inspection efficiency. To address these issues, we investigate a new fault localization path optimization algorithm for distribution network UAVs based on a cloud-pipe-edge-end architecture. This architecture employs multiple drones for coordinated control, allowing for the simultaneous detection of suspected fault areas. Communication links facilitate interaction at both the drone and system levels, enabling the transmission of fault diagnosis information. Fault defects are identified, and the information is analyzed within an edge computing framework to achieve precise fault localization. Experimental results demonstrate that the proposed algorithm significantly enhances detection speed and accuracy, providing robust technical support for UAV operations.**

***Keywords*—Cloud-pipe-edge-end architecture; distribution network UAV; cloud-edge collaboration; edge computing**

I. Introduction

With the continuous development of high and new technology, UAVs are more and more widely used in various industries. With the support of IoT technology, UAV, as a new type of electric power inspection tool, has the advantages of wide inspection range, high efficiency, low cost, etc., and has been widely used in power systems. Therefore, it is necessary to continuously improve the distribution network UAV inspection and fault location system, optimize the flight path planning and positioning algorithms to adapt to the development needs of the power system, and improve the fault location accuracy and inspection efficiency. At present, the path planning of distribution network UAVs mainly adopts the rule-based method, which is simple and easy to implement but cannot adapt to the complex environment and task requirements. The study in [1] uses YOLOv5 machine vision technology to optimize the planning of unmanned aerial vehicle inspection paths, which requires control and coordination of multiple unmanned aerial vehicles. However, this method does not have a supporting multi-objective unmanned aerial vehicle cluster control technology, making it difficult to achieve multi-path collaborative planning. The study in [2] uses an adaptive multi heuristic ant colony algorithm to improve the problem of missing local path planning for unmanned aerial vehicles. It sets threshold restrictions on pheromones and uses adaptive heuristic function factors to transition the states of all nodes in the inspection path, achieving local path planning. However, when facing complex inspection environments, the overall path planning of this method is easily affected by local factors, resulting in path redundancy and increased time consumption. The study in [3] adopts the fast search random tree RRT algorithm to randomly generate connections through task nodes, analyze the distance between the path and obstacles, and plan the path of multi UAV collaborative tasks, which has certain feasibility in shortening the flight path distance. But the search range of this algorithm is limited, which will have an impact on the running time of the drone. In response to the above shortcomings, this article proposes a drone cluster control technology based on cloud management edge architecture to optimize the planning of fault location paths for distribution network drones. The establishment of cloud management side end architecture for joint control of multiple UAVs, the determination of suspected fault areas through synchronous detection, and the analysis of fault information in the edge computing logic framework can achieve cluster control and optimal path planning for distribution network UAVs, accurate fault diagnosis and location, effectively remedy the shortcomings of multi UAV patrol in complex environments, such as the difficulty of coordination and long control time, and provide new ideas and methods for the application of UAVs in power patrol and other fields.

II. Research Method

A. Distribution Network UAV Inspection Control based on Cloud-Pipe-Side-End Architecture

1) Cloud pipe edge technology architecture: Cloud-managed edge-end architecture is an architecture that combines cloud computing, edge computing, and end devices to realize efficient management and control of IoT devices [4]. In cloud-pipe-edge-end architecture, cloud computing is responsible for storing and processing large amounts of data and providing various applications and services; edge computing is responsible for processing data close to the data source in order to reduce the latency and cost of data transmission; and end devices are responsible for collecting and transmitting data.

Cloud-pipe-side-end architecture is an emerging architecture that provides new ideas and methods for the development of the Internet of Things, and the application of

this technology to the distribution network UAV inspection system has the following advantages:

a) Improve efficiency: By distributing computing and storage resources on different levels, the efficiency and response speed of the system can be improved.

b) Reducing cost: By processing data on edge computing nodes, the delay and cost of data transmission can be reduced.

c) Improve reliability: By distributing computing and storage resources on different levels, the reliability and fault tolerance of the system can be improved [5].

d) Expanding application scope: By combining cloud computing, edge computing, and terminal devices, the application scope of IoT can be expanded.

2) Cloud edge cooperative UAV inspection control system: UAVs play an essential role in power systems in distribution network fault inspection and line monitoring. However, UAV inspection and control systems usually face challenges such as large data volume, high transmission latency, and limited computational resources. In order to solve these problems, the cloud-pipe-side-end architecture is applied to the UAV inspection and control system. The structural framework of the cloud-edge cooperative UAV inspection control system based on the cloud-pipe-edge-end architecture is shown in Fig. 1.

a) Cloud platform: The cloud platform is responsible for storing and processing a large amount of data generated during UAV inspection [6]. It provides robust computation and storage capabilities that enable in-depth analysis and processing of data, as well as a variety of applications and services, such as data visualization, mission planning, and flight path optimization.

b) Edge nodes; Edge nodes are located at the edge of the network, close to UAVs and sensors. They are responsible for processing and analyzing the data collected by UAVs in real time to reduce the delay of data transmission; edge nodes can also perform some critical control tasks, such as flight control, mission assignment, etc.

c) UAV terminal: The UAV terminal includes the UAV itself and various sensors, which are responsible for collecting data and transmitting them to the edge node or cloud platform [7]. The UAV terminal can also receive control commands and perform corresponding tasks.

Through the cloud-pipe-edge architecture, the UAV inspection and control system can realize efficient data processing and transmission. The cloud platform provides powerful computing and storage capabilities, the edge node reduces the delay of data transmission, and the UAV terminal ensures real-time data collection and task execution [8]. It brings higher efficiency, reliability, and scalability for UAV distribution network inspection and fault localization and provides better support for the application of UAVs in various fields. Fig. 2 shows overall structure of the UAV inspection control system.

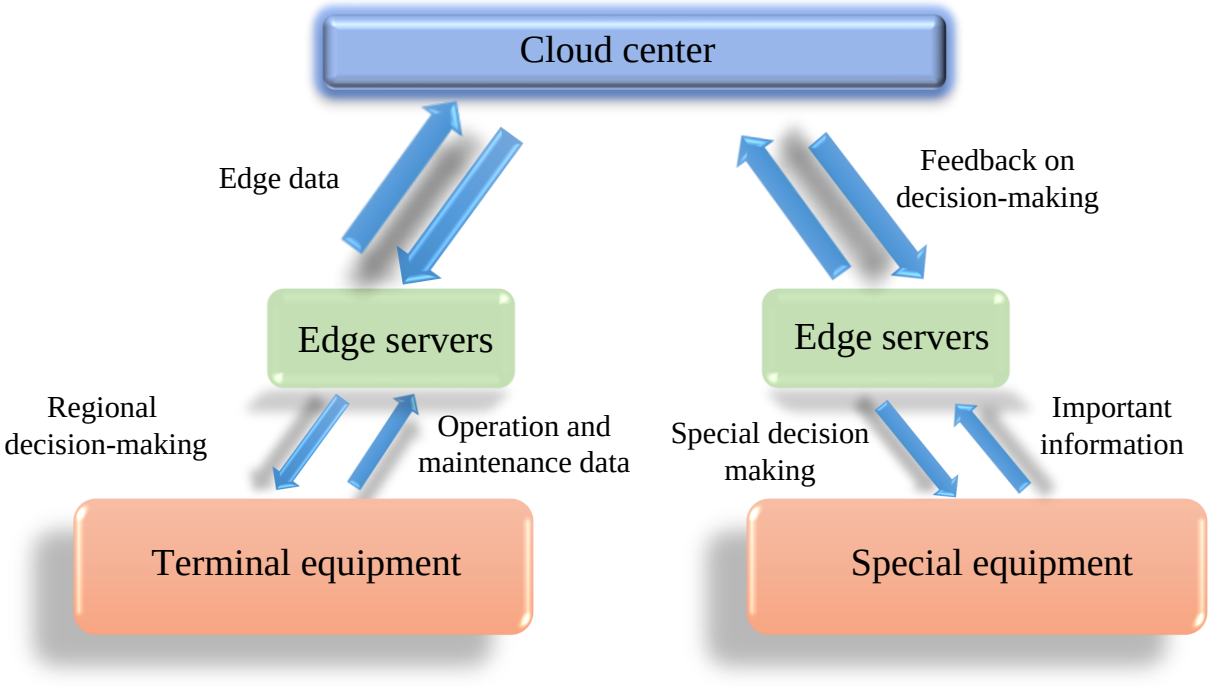

Fig. 1. Technical architecture of cloud-pipe-edge-end architecture.

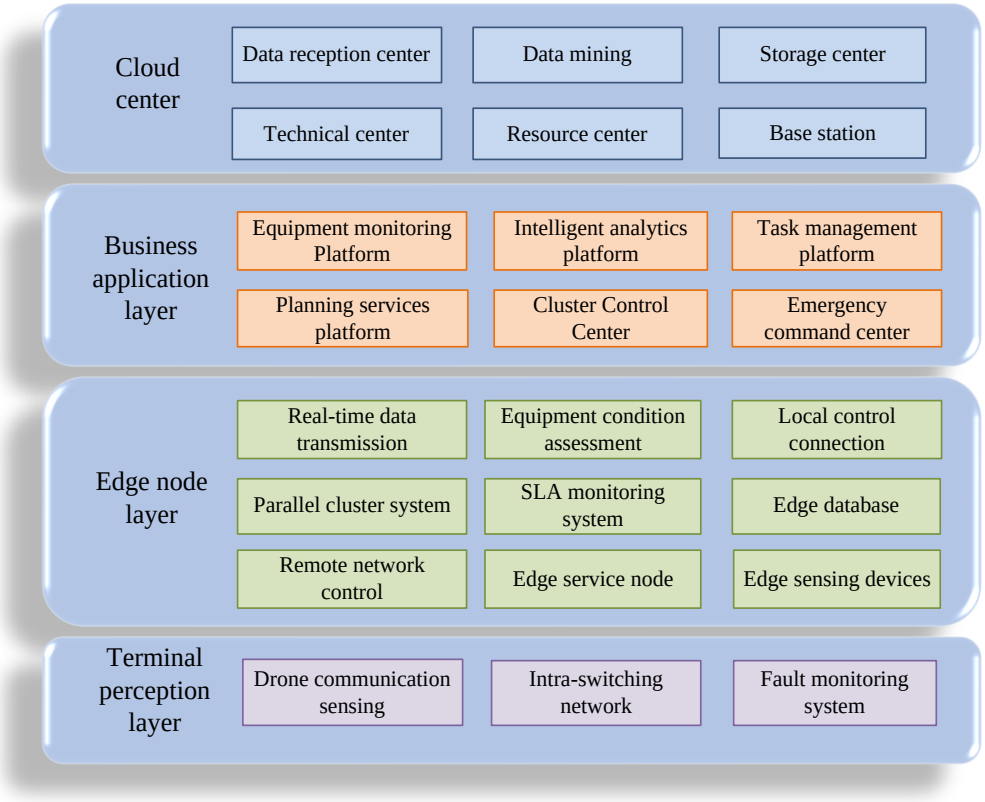

Fig. 2. Overall structure of the UAV inspection control system at the edge of the cloud pipe.

III. Distribution Network Fault Localization UAV Inspection Path Planning

A. Fault Localization based on Edge Computing

In the process of distribution network inspection, the UAV collects distribution network-related localization data, including location information such as lines, equipment, receiving base station, relative distance, etc., by means of the onboard LiDAR sensor. The collected data is transmitted in real time to the grid system server for edge computing [9]. The received edge server data is processed in real time to extract the positional feature information of the edge deployment, and the UAV cognitive edge computing network model is constructed (see Fig. 3).

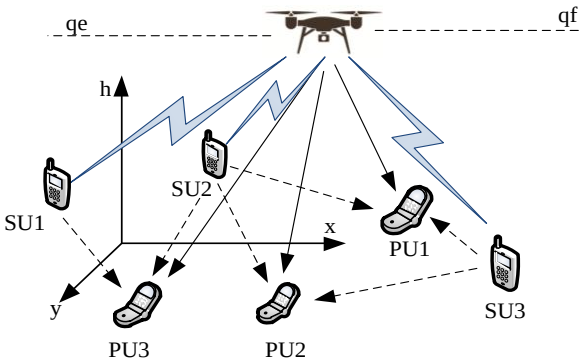

Fig. 3. UAV cognitive edge computing network model.

All servers, distribution network nodes and user terminal location information is imported into the network model, and the UAV inspection channel model is constructed using a three-dimensional Cartesian coordinate system [10]. Assuming that the distribution network node coordinates are represented as (x, y, z), and setting the fixed elevation of the UAV inspection flight as h, the node coordinate channel gain coordinate transformation under the time slot sequence is described as:

$$G_t(x, y, z) = \frac{\Delta g}{h_t^2 + q[y_t] - x_t^2} \tag{1}$$

In the formula, $G_t(x, y, z)$ represents the distribution network node coordinate time slot channel gain result, and Δg is the channel gain amplitude per unit distance. The network model is used to monitor the dynamic information of the UAV inspection and to monitor the faults of the distribution network equipment and lines, and when an abnormal signal location is identified, the fault point is quickly located and marked by comparing the data in the normal state with the currently collected data, and the signal is transmitted to the edge server at the nearest distance [11]. Carrier linear fuzzy adjustment based on real-time UAV position and edge server distance:

$$\begin{bmatrix} N_{0,0} \\ \vdots \\ N_{n-1,n} \end{bmatrix} = \begin{bmatrix} \Delta X_{0,0} & \Delta Y_{0,n} \\ \vdots & \vdots \\ \Delta X_{n-1,n} & \Delta Y_{n-1,n} \end{bmatrix} \cdot \begin{bmatrix} x \\ y \end{bmatrix} \tag{2}$$

In the formula, N is the horizontal distance carrier linear correction parameter of the time series data, and ΔX , ΔY are the original coordinate signals of the fault localization point. The distance between the corrected coordinate parameters and the edge server is calculated using the least squares method L_n:

$$\left(x_n - x_{n-1}\right)^2 + \left(y_n - y_{n-1}\right)^2 + \left(z_n - z_{n-1}\right)^2 = L_n^2 \tag{3}$$

The fault localization results are fed back to the UAV inspection control system through edge computing, and the system carries out optimal path planning according to the fault localization information and manipulates the UAV to carry out collaborative inspection and maintenance operations [12].

B. UAV Inspection Path Planning Algorithm

The inspection path power model is constructed according to the UAV flight law, and the pitch angle, yaw angle, and roll angle are calculated during the UAV flight:

$$\begin{cases} \theta = \left[\left(V_y - V_z\right)\phi\varphi + v_x F\right] / V_x \\ \varphi = \left[\left(V_z - V_x\right)\theta\phi + v_y F\right] / V_y \\ \phi = \left[\left(V_x - V_y\right)\theta\varphi + v_z F\right] / V_z \end{cases} \tag{4}$$

In the formula, θ , φ , ϕ represent the pitch, roll and yaw angles of the UAV during flight, V_x , V_y , V_z are the flight acceleration in the horizontal and vertical axes, respectively, v_x , v_y , v_z are the rotor angular velocities corresponding to the sailing directions, and F is the coefficient of the UAV flight moment [13]. Through the Laplace transform, the UAV pitch angle, roll angle, and yaw angle (see Fig. 4) attitude mechanics function matrices are obtained:

$$\begin{cases} \theta(t) / F(t) = \bar{h} / V_y t^2 \\ \varphi(t) / F(t) = \bar{h} / V_z t^2 \\ \phi(t) / F(t) = \bar{h} / V_x t^2 \end{cases} \tag{5}$$

In the formula, t is the UAV timing node parameter, $\bar{h}$ is the ideal altitude for UAV hovering.

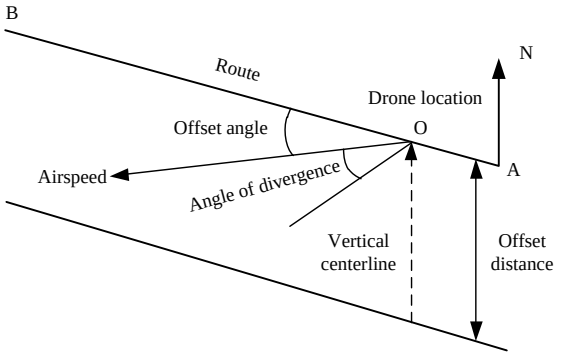

Fig. 4. Schematic of yaw angle attitude mechanics.

The unit angle error correction factor e_{ref} is introduced to correct the error for flight altitude at different attitude angles:

$$\begin{cases} \Delta h_\theta = h\left(\theta_{ref} - \theta\right) \cdot e_{ref} \\ \Delta h_\varphi = h\left(\varphi_{ref} - \varphi\right) \cdot e_{ref} \\ \Delta h_\phi = h\left(\phi_{ref} - \phi\right) \cdot e_{ref} \end{cases} \tag{6}$$

Based on the corrected UAV flight dynamics parameters, a PID tracking controller is utilized for path planning of the inspection nodes:

$$Line_n = \sqrt{\left(free + \alpha L_{on_1}\right)^2 + \left(l_{safe} + L_{on_n}\right)^2} \tag{7}$$

In the formula, $free$ indicates the maximum degree of freedom of the UAV flight path, α is the inspection path safety coefficient, l_{safe} is the inspection safety distance for fault localization, and L_{on_1} , L_{on_n} are the distances from the initial position to the inspection node, respectively. According to the formula, the UAV inspection path can be planned to carry out precise fault point search inspection for distribution network tripping, disasters and other suspected fault segments, with high real-time, high accuracy and fast response, which can improve the operation and maintenance efficiency and reliability of the distribution network [14].

IV. UAV Path Optimization Algorithm based on Cloud Pipe Edge Ends

A. UAV Cluster Control Objective Function

In order to carry out distribution network fault detection more efficiently, multi-UAV cluster control will be used for

collaborative inspection, so multi-objective optimization is needed on the basis of the original path planning. Firstly, the shortest distance function between multi-path nodes is obtained by edge computing as:

$$\min L_n = \sum_{n}^{i=1}\left(ql_n + ql_n'\right) + f\left(e_n\right) \tag{8}$$

In the formula, where l_n, l_n' are the straight line length and the actual effective length of the n node distance, q is the distance minimization weighting factor, and $f\left(e_n\right)$ is the error penalty function [15]. The nearest path matching objective function that removes the overlapping area of the node space is obtained by constraining the node in and out of the path edge points:

$$\sum_{n}^{i=0} L_n^i = 0\,|\,1, \forall i = 1, 2\cdots, N, \forall n = 1, 2\cdots, n \tag{9}$$

The directed band-weighted relationship between the number of UAV cluster controls and the total distance of the inspection path can be described as:

$$\min L_{all} = \sum_{N}^{n}\sum_{n}^{i=0}\sum_{n}^{j=0} l_{on}^i h_{nt} \tag{10}$$

The shortest distance between the monitoring points is calculated to match the neighboring nodes in the inspection path, and the directed weighted path (Fig. 5) is obtained schematically as follows:

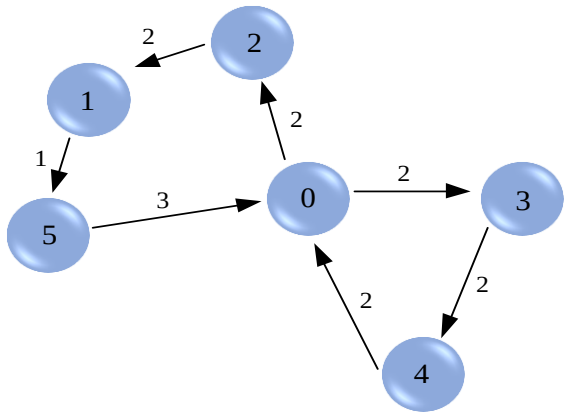

Fig. 5. Schematic diagram of directed weighted paths.

Based on the UAV speed and path distance parameters, the total UAV cluster inspection route time can be predicted:

$$\min T_{all} = \max\left\{\sum_{n\le N}^{i=1}\max\left\{t_i^n \times \left(t_i - e_i\right), 0\right\}\right\} \tag{11}$$

In the formula, where t_i^n is the UAV inspection time per unit distance for line n, and e_i is the time error parameter of the path [16]. The server monitors the flight paths and times of multiple UAVs, and collaboratively monitors the entire UAV cluster through centralized control to achieve efficient inspection tasks.

B. Multi-objective Function Constraints

For the UAV range, energy consumption, and load-carrying performance, further optimal efficiency constraints need to be imposed on the multi-objective UAV path[17]. Assuming that all UAVs take the distribution network base control center as the departure starting point, the maximum number of cooperative control UAVs is:

$$\max N = \sum_{n}^{i=1} l_i^n, i = 1, 2\cdots, n \tag{12}$$

Distribution network UAV inspection needs to be conFig.d with relevant sensing and communication devices to collect information on distribution machinery lines and other equipment, as well as monitor and feedback fault problems [18]. The UAV load will affect its flight speed and elevation threshold; in order to achieve optimal path planning, the total amount of UAV load needs to be constrained:

$$\max M = \sum_{n}^{i=0} v_i^n \times m_i, i \in 1, 2\cdots, n \tag{13}$$

In the formula, where v_i^n is the expected optimal speed of path inspection, m_i is the UAV unit distance supportable carrying capacity threshold. According to the UAV endurance performance and inspection path length, the maximum working time of a single UAV is constrained and controlled by considering the UAV startup operation and waiting service time t_i:

$$\max T = \sum_{n}^{i=0} l_i^n v_i^{-n} + \sum_{n}^{i=1} l_i^n t_i \tag{14}$$

For the fault localization process, the UAV path has a dynamic nature, and the particle velocity and position update formulation of the adjacency matrix of the inspection node[19]. Setting the dimension particle of node position as W_n, the extended edge set of particles in the adjacency matrix is $n_k^l = \left[n_k^{l_1}, \cdots, n_k^{l_n}\right]$:

$$n_k^{l_i} = \left[\left\langle n_i, W_n\right\rangle, \left\langle W_n, n_j\right\rangle\right] \otimes k_W \tag{15}$$

The extended edge set data of each node particle can form a Hamiltonian circle in the actual position, and in the Hamiltonian circle constraints, the UAV path can be dimensionally adjusted, and the probabilistic constraints can be imposed on the edge flight speeds of the path nodes in the case where the velocity component v_k^l is.

$$P\left(v_k^l\right) = \left\{\frac{n_i, n_j}{P\left(n_i, n_j\right)}\right\} \tag{16}$$

After the above multi-objective function constraints, the multi-UAV cluster control capability can be strengthened to promote the distribution network fault inspection and localization efficiency [20], reduce the work intensity and error rate, and realize high-precision and high-efficiency fault inspection so as to guarantee safe and stable operation of the power system.

V. Discussion

In order to test the effectiveness of the research method, a comparative experiment is designed to simulate the UAV distribution network fault inspection process and compare and analyze the experimental result data. The distribution network of a power system is taken as the inspection object, and the inspection nodes are set according to the location of the distribution network; the server model of the control center is PC i5-8250U CPU, and the inspection node data are numbered by using VRPTW. Select and adjust the UAV cluster parameters as shown in Table I.

TABLE I. UAV Cluster Test Parameter Settings

Targets	Parameters
UAV SYSID	2、3、5
Number of nodes	20
Path type	zigzag path
UAV2 point set coordinates	HOME (121.441 121 6,31.028 408 30) TARGET1(121.441 269 2,31.028 381 84,10) TARGET2(121.441 308 2,31.028 426 12,10)
UAV3 point set coordinates	HOME (121.441 167 1,31.028 364 30,10) TARGET1(121.441 197 3,31.028 611 22,17) TARGET2(121.441 009 2,31.028 666 81,17) TARGET3(121.441 988 3,31.028 800 62,17)

The operating drone control system automatically formulates the drone inspection plan according to the calculation results of the optimization algorithm, planning the number, starting point, flight path, and other contents of the cluster inspection drone. Adopting vehicle navigation, planning the path navigation of the vehicle to the take-off point of the faulty section, guiding the team members to the survey location to carry out the machine patrol operation, navigating and guiding the team to the landing point of the drone to recover the aircraft after the drone takes off, and real-time according to the faulty search and patrol and localization process of the collection of data situation, and further make the drone response strategy.

A. UAV Fault Location Inspection Time Analysis

This experiment is based on edge computing algorithm support, combined with multi-objective function constraints for path planning and task control of UAV clusters. All drones take the point HOME (121.441 121 6,31.028 408 30) as the starting point for inspection, and the lightweight defect recognition algorithm is deployed at the edge end of the drones to identify the defective faults of the distribution network in real-time and troubleshoot them on site. Through the real-time linkage function, the UAV is maneuvered to return to the flight, upload the fault information, and complete this fault-finding task. The average inspection time of each fault node of the UAV under the support of different algorithms is monitored and counted, and the time parameters of one group, three groups, and five groups of UAV cooperative control are recorded, respectively.

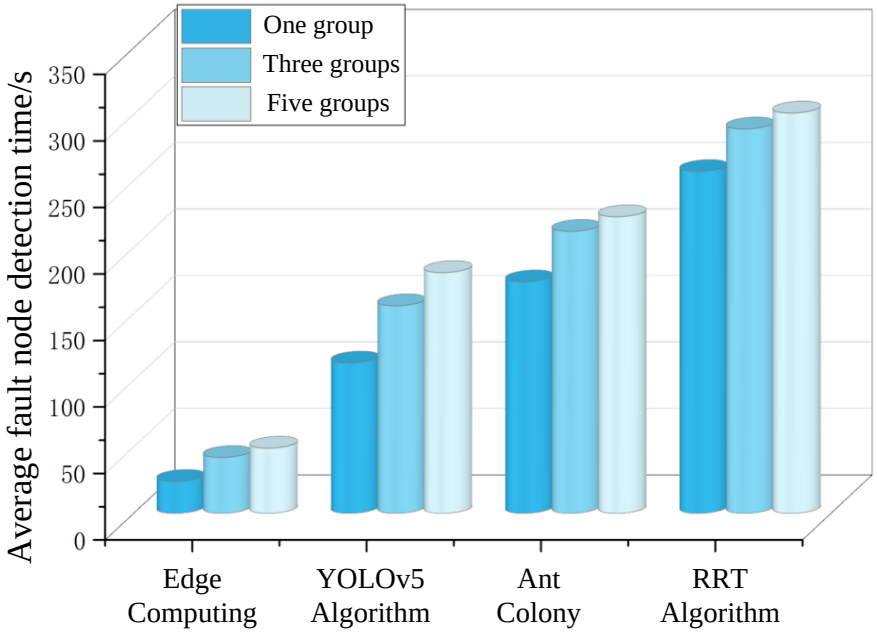

Fig. 6. UAV fault localization inspection time.

From the data in Fig. 6, it can be clearly seen that when controlling a group of drones, the cloud edge collaboration method has a shorter working time for the drones, with an average inspection time of only 24 seconds for a single node. The response time for single drone inspections using the other three traditional methods, such as YOLOv5, exceeds 100 seconds. At the same time, as the number of drones in collaborative control increases, the average inspection time per unit drone has also increased, and the fault detection time is directly proportional to the number of drones. When the number of UAV test groups is 5, the average detection time based on edge computing control is 49 seconds, while the RRT forest algorithm is limited by the search range, and the response speed is slow, and the unit time is up to 301 seconds. This shows that the edge computing method used in this paper for cloud edge collaborative control of UAVs is faster, and the average time for distribution network fault patrol is far lower than the traditional method.

B. UAV Flight Attitude Stability Analysis

According to the UAV flight path dynamics model, the pitch angle, roll angle, and yaw angle of UAV flight will affect the course direction and cause the optimal path offset to a certain extent. Therefore, the UAV attitude offset angle is monitored during the experiment, and the jitter angle range of different flight attitudes of each group of UAVs is counted to analyze the UAV flight stability.

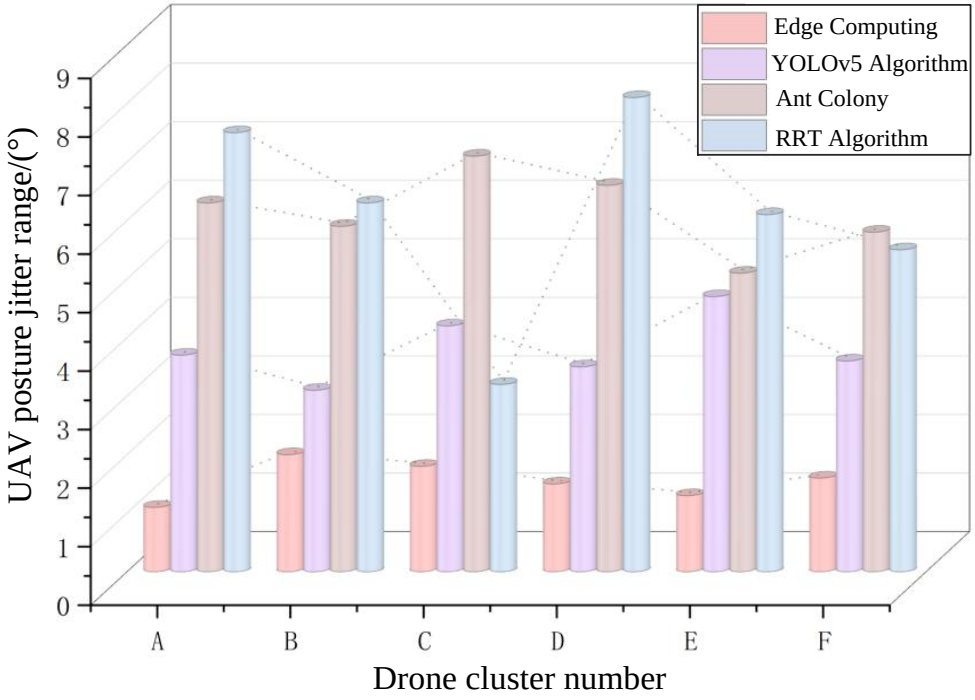

Fig. 7. UAV flight attitude jitter range.

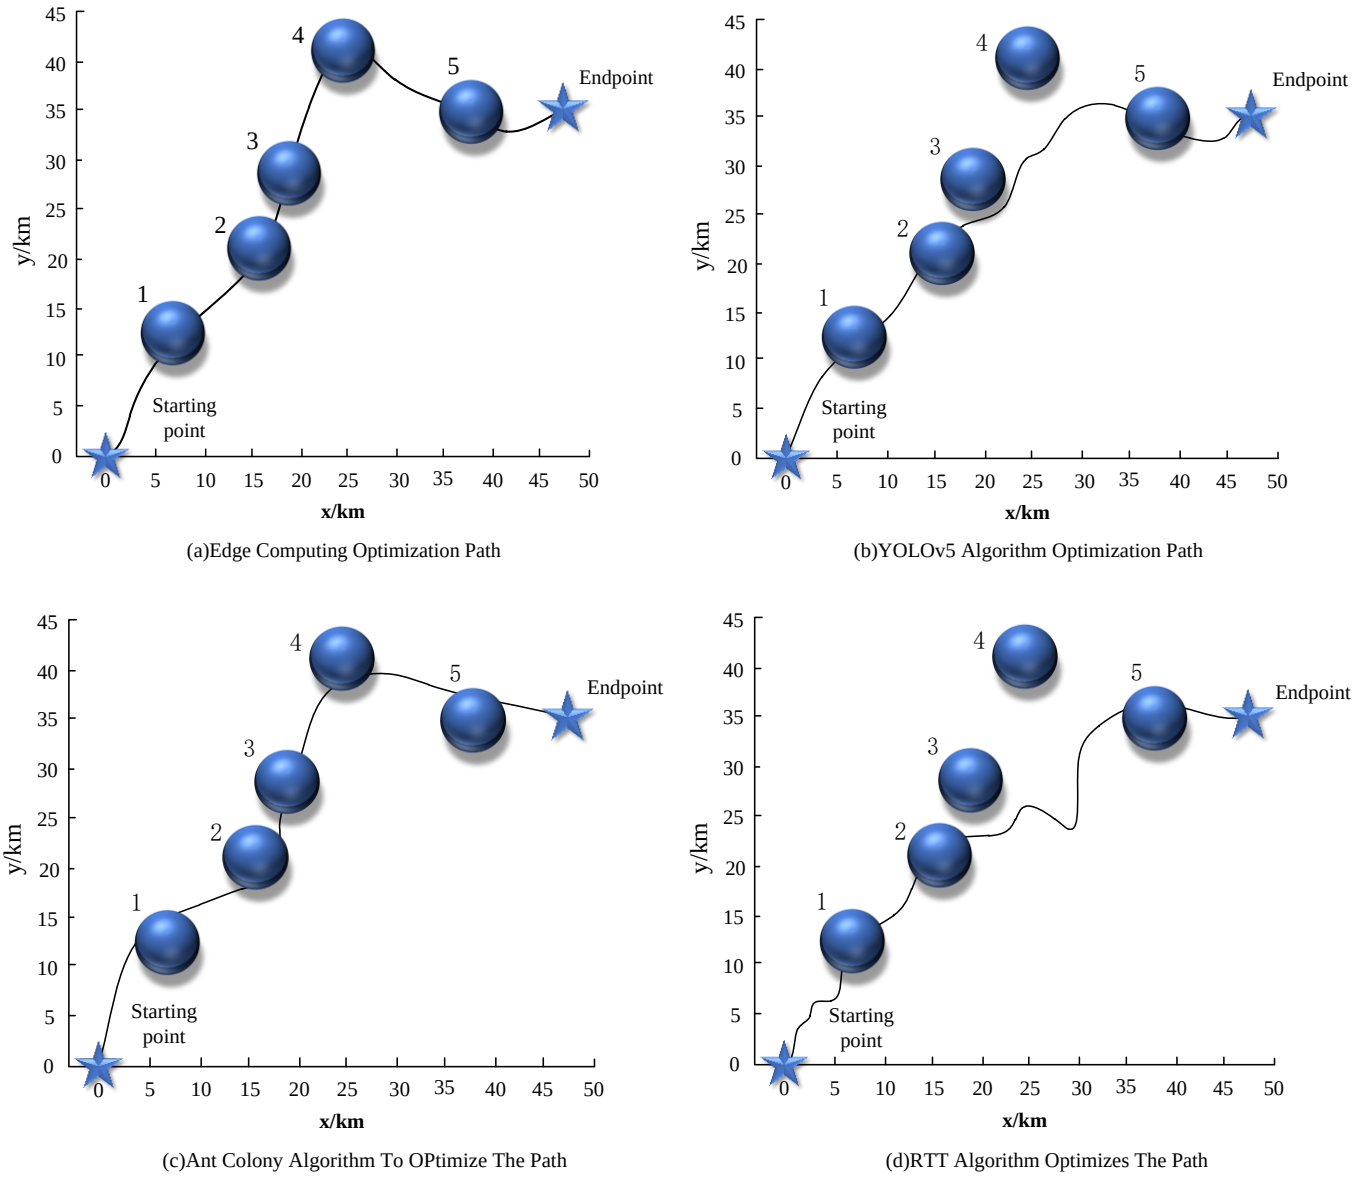
As shown in the Fig. 7, this paper is based on edge computing to construct the power model of the UAV inspection path. The UAV flight angle attitude control is more accurate, and the jitter range of each group's UAV posture is no more than 3°, which has good stability. The control system based on the adaptive ant colony algorithm is less stable. The jitter range of all six groups of UAVs is more than 5°, while the jitter situation of UAVs using RRT forest algorithm path planning has great uncertainty. The jitter offset angle reaches a maximum of 8.1°, and the minimum angle deviation is only 3.2°. In the comprehensive analysis, using the edge computing method for path planning, fully considering the UAV yaw and jitter angle problems, and using power law for path optimization effectively improves the UAV inspection attitude stability.

C. Drone Inspection Path Planning Analysis

Using MATLAB software to simulate the fault location inspection path of the distribution network UAV, a set of path node position coordinates are extracted and imported into the system program, and four groups of UAV flight real-time path coordinate parameters are substituted to obtain the training path visualization image as follows.



(a)Edge Computing Optimization Path

(b)YOLOv5 Algorithm Optimization Path

(c)Ant Colony Algorithm To OPtimize The Path

(d)RTT Algorithm Optimizes The Path

Fig. 8. Comparison of UAV inspection paths.

As shown in Fig. 8, five fault detection points are set in the selected path. The optimized patrol path based on edge computing completely covers five fault points, almost passing through the joint point of the fault center, and there is no redundant path between fault nodes. The YOLOv5 algorithm lacks supporting multi-objective unmanned aerial vehicle cluster control technology, which makes it impossible to achieve collaborative control of multiple unmanned aerial vehicle targets, resulting in path planning missing fault detection points 3 and 4, which does not meet the expected planning and inspection requirements; The path optimization effect of ant colony algorithm is relatively good, achieving fault localization for 5 monitoring points. However, the detection synchronization is poor, and there is a certain lag in information, resulting in a deviation in the inspection path of fault points 1 and 2, only reaching the edge range of the fault point, and there is a certain error in the positioning data; RRT path planning also missed the distant detection points 3 and 4, and did not reach the center range of other fault monitoring points, resulting in low accuracy of fault localization and detection information.

In summary, the fault localization path optimization algorithm for distribution network UAVs with cloud-pipe-edge-end architecture studied in this paper has good application performance, the coordinate information of fault localization is more accurate, and the power model is used to improve the stability of the UAV flight attitude. With the support of cloud-edge cooperative technology, we can better realize multi-objective UAV cluster control, edge computing optimization path coverage is more comprehensive, the unit interval distance is shorter, and it is more advantageous than

the traditional method in the distribution network fault inspection and positioning work.

VI. CONCLUSION

Aiming at the deficiencies in UAV cluster control and path planning, this paper proposes a fault location path optimization algorithm for distribution network UAVs based on cloud-pipe-edge-end architecture. It obtains the following conclusions through theoretical and experimental research:

Based on the cloud-pipe-edge-end technology architecture, the UAV is controlled by cloud-edge cooperative control and interacts with edge nodes to improve the data processing and response rate.

Based on edge computing to process UAV inspection and fault localization data, carrier linear fuzzy adjustment is carried out through the relative distance of edge servers to improve the accuracy of coordinate localization parameters.

Construct a UAV flight dynamics model, analyze UAV posture angle and flight law, and improve the real-time control performance of the path planning system.

Carry out multi-objective path optimization for UAV clusters and constrain the load time and expansion dynamics of the number of UAVs to reduce the error rate of inspection path deviation and obtain the optimal path planning for inspection with high precision and high efficiency.

Through experiments, it is proved that the method studied in this paper has good stability and application efficiency, and more secure and efficient algorithms and technologies will be further explored in future research to improve the accuracy and efficiency of fault location path planning for distribution network UAVs, so as to make a more significant contribution to the intelligent development of the work of UAV inspection and fault detection of distribution network.

Predicting the Number of Video Game Players on the Steam Platform Using Machine Learning and Time Lagged Features

Gregorius Henry Wirawan, Gede Putra Kusuma
Computer Science Department-BINUS Graduate Program-Master of Computer Science,
Bina Nusantara University, Jakarta 11480, Indonesia

***Abstract*—Predicting player count can provide game developers with valuable insights into players' behavior and trends on the game population, helping with strategic decision-making. Therefore, it is important for the prediction to be as accurate as possible. Using the game's metadata can help with predicting accuracy, but they stay the same most of the time and do not have enough temporal context. This study explores the use of machine learning with lagged features on top of using metadata and aims to improve accuracy in predicting daily player count, using data from top 100 games from Steam, one of the biggest game distribution platforms. Several combinations of feature selection methods and machine learning models were tested to find which one has the best performance. Experiments on a dataset from multiple games show that Random Forest model combined with Pearson's Correlation Feature Selection gives the best result, with R^2 score of 0.9943, average R^2 score above 0.9 across all combinations.**

I. INTRODUCTION

The video game industry has seen a massive growth over the past few years, especially during the COVID-19 pandemic, when people were encouraged to stay at home, increasing gaming activity. The increased gaming activity was due to either stress relief [1], seeking social interactions [2], or having no other activity to do at home [3]. Steam is one of the rapidly growing game distribution platforms and makes a major contribution in the growth of the industry, along with the transition from physical distribution of games to digital distribution in the form of licenses, and along with online social networking services for gamers [4].

With more than 50,000 video games available from various developers and publishers, Steam gives gamers the liberty to buy and play their favorite video games and share their captured moments with their friends on the platform. Gamers can also leave their impressions and share their opinions about the game they play through a review on the game's store page [5]. All the things happening on the platform will certainly generate some data. Fortunately, Steam allows access to said data by providing various Application Programming Interfaces (APIs), allowing publishers and researchers alike to generate their own sets of data and gain meaningful insights [6]. As a result, a lot of studies on the platform have appeared over the past few years from various disciplines, including consumer behavior [7], human-computer interaction [8], economics [9], education [10], health [11], social sciences [12], law [13], business [14], and gaming specific engagement [15].

While publishers have access to proprietary APIs that provide sensitive, non-public user data, general APIs still allow access to publicly available data on platforms, including game prices, genres, reviews (game-specific data), as well as player activity, game ownership, and achievement statistics (public user data) [16]. This can be useful for business applications through data-driven analysis and can also be used in machine learning algorithms to predict various variables, such as game prices, discount trends, player count, game ratings, and many others.

Predicting daily player count is essential for game developers and publishers, as it provides insights into player activity, engagement, and behavior, enabling informed decision-making. Therefore, it is important for the prediction model to be as accurate as possible to avoid any potential misinformation. The features used play an important role in the model's predictive performance and must provide meaningful information for the model. Existing studies on predicting daily player count used various metadata features in addition to historical data, such as game's genres, supported languages, number of achievements, etc. However, those features stay the same most of the time, and don't give enough temporal context for the model, as historical data like daily player count can have patterns, such as trends and seasonality depending on the time of the observation. But the historical data can be transformed into lagged features using feature engineering to capture such historical patterns and enhance the prediction performance of the model. However, there is a limited number of studies in exploring the use of time-lagged features for predicting player count.

In this paper, we proposed a new method utilizing lagged features on top of existing metadata features to accurately predict daily player count on Steam. Historical player count data were transformed into new lagged features using the sliding window technique, providing more temporal context than using meta-data only. This will be explained further in Section III. Several combinations of feature selection methods and machine learning models were tested and compared on their predictive performance to find out which one gives the most accurate prediction. The models are Random Forest, Support Vector Regression (SVR), and XGBoost, with feature

selection methods such as Pearson's Correlation feature selection, Recursive Feature Elimination (RFE), and the models' embedded feature selection method. The structure of the paper is as follows: Section I presents the background of this study, Section II discusses the works related to this study, Section III explains the methodology, Section IV the results and discussion, and Section V contains the conclusion of this study and things to be addressed for future works.

II. Related Works

As stated in Section I, there have been a lot of studies on the Steam platform in the past few years. A study by Prathama et al. [6] created a system to provide data analysis on current game trends and predict game trends for the next two weeks using game and user data obtained with Steam API. The trend prediction is through predicting future game rating and future player count, using Multiple Linear Regression (MLR) method. H. Zhang [16] used the same MLR method to predict game sales, and also investigated various factors and how they are related with game sales. Zendle et al. [7] analyzed trends on ingame microtransactions using historical data from 463 most-played games in the Steam platform.

Wannigamage et al. [17] analyzed the changes in player population and weekly player count patterns during the COVID-19 pandemic, and also analyzed the changes in game sales. They also tried to identify which games that became popular during the pandemic by comparing player population from before and during the pandemic. Vuorre et al. [2] also analyzed the changes in players behavior during COVID-19 pandemic using various data from popular games, like play time and player count from both before the pandemic and during the pandemic. Wu et al. [18] conducted an analysis on the impact of the COVID-19 pandemic on the video game industry overall, by analyzing and comparing the number of games released and also player count from before the pandemic and during the pandemic, and also predicted the demand for online games with machine learning, using historical player data combined with COVID-19 features and human mobility features to predict daily player count. Several machine learning models were used, including SVR, Random Forest, and Ridge Regression.

Varghese et al. [19] discuss an online game's success upon release using the game's historical player data on the Steam platform with models including SVR, Random Forest, and Bayesian Regression. Teja et al. [20] compared various machine learning algorithms and predicted the rating from Metacritic for games on Steam by comparing variables that are related to the score, like genres and player count. Abdul-Rahman et al. [21] developed a model for churn prediction using Vector Autoregression enhanced with sentiment analysis on user reviews from various games on the Steam platform.

III. Methodology

This section explains the data and methods used in the study. The workflow is depicted in Fig. 1. The data was gathered from various public sources. The gathered data was then pre-processed to get it ready for machine learning models. New lagged features were created using the sliding window technique, and several feature selection methods were selected to select the most relevant features: Pearson's Correlation feature selection, RFE, and embedded method. The selected features from each method were used in three machine learning models: Random Forest, SVR, and XGBoost. Grid Search hyperparameter tuning is used to find the best parameters for each model. The results from each combination were then compared to find out which one is the best in predictive performance.

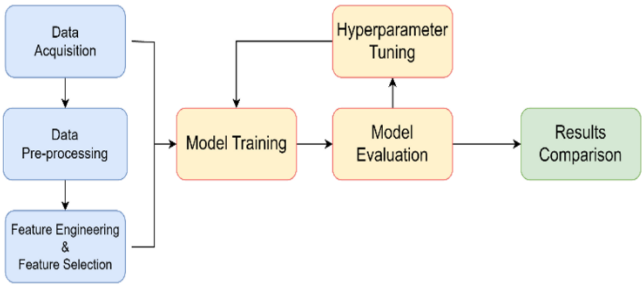

Fig. 1. Workflow of the study.

A. Data Acquisition

This study uses publicly available data from various sources. The historical dataset was collected through manual download from SteamDB, a third-party database providing information on games from the Steam platform. The historical dataset consisted of player count, number of positive and negative reviews from 100 most-played games on Steam, sorted by peak number of players during the date of collection, 8 August 2024. All observations were in UTC time zone. Then a code was made for scraping metadata from each game. The code was written in python programming language. It works by sending an HTTP request using the Steam 'getdetails' API to get each game's details, utilizing the unique ID number from each game called appid. The details to be extracted were pre-determined to avoid getting unnecessary information. This process was repeated for all games. Then all the data from the games was parsed and then compiled into a single CSV file. The metadata included genres, release date, supported languages, and many more. Over 20 columns of raw data were collected using the API.

B. Data Pre-processing

Since the raw data were collected from different sources, it needed to be pre-processed to be ready for model training. Missing values on the metadata were removed, and several features were transformed into new ones with feature engineering. Table I shows an example of new features created from the raw metadata. For historical data, three new features were created. First was the game's age since the release date, then Cumulative Moving Average (CMA) for both positive and negative reviews. All the new features were calculated for each observation. The result was a total of six features for the historical data excluding the time variable. Table II shows an example of the resulting data from the game Counter-Strike 2, one of the games on the dataset.

Additional features were created for the historical data using the sliding window technique. The sliding window technique transforms the time-series into a supervised learning problem by shifting the data, taking prior observations as

lagged features, depending on the window size. For example, the current observation is labeled as *x* and the sliding windows technique was applied to capture observations for the past 30 days, the data would be shifted 30 days, and the window would contain observations from *x*-29 to *x*, with *x* being the most recent. In this research, a window size of 7 was randomly chosen, meaning that observations from previous seven days were used as lagged features. The technique was applied to all features on the historical data, resulting in a total of 42 features. Then the data was shifted once more to obtain the target feature *x*+1, which was the observation on the next day. Then the processed historical data was merged with the metadata, and then split into training/validation/testing sets, with a ratio of 60/20/20. The split was done to ensure the model robustness against unseen data. All features were normalized after split using Min-Max scaler, including the target feature.

TABLE I. EXAMPLE OF NEW FEATURES CREATED FROM METADATA

name	app_id	required_age	is_free	dlc	achievements	full_controller_support
Grand Theft Auto V	271590	17	0	1	77	1

C. Feature Selection

This study uses three feature selection methods, which are Pearson's Correlation Feature Selection for filter method, Recursive Feature Elimination (RFE) for wrapper method, and embedded feature selection method from the model itself.

1) Pearson's correlation feature selection: This feature selection method uses Pearson's Correlation Coefficient (PCC), which measures linear relationship between two or more variables. The correlation value *r* between variables *X* and *y* can be obtained through Eq. (1).

$$r = \frac{\Sigma_{i=1}^{n}(X_i-\bar{X})(y_i-\bar{y})}{\sqrt{\Sigma_{i=1}^{n}(X_i-\bar{X})^2}\cdot\sqrt{\Sigma_{i=1}^{n}(y_i-\bar{y})^2}} \quad (1)$$

where $\bar{X}$ and $\bar{y}$ are mean values of variables *X* and *y*. The correlation value ranges from -1 to +1, where values closer to -1 or +1 indicate stronger correlation, and values closer to 0 indicate weaker correlation. This method selects features with correlation value higher than a certain threshold.

2) Recursive Feature Elimination (RFE): This feature selection method selects the most important features in the dataset by recursively removing the least important features until the number of features to select is reached.

3) Embedded method: Embedded method refers to feature selection method that is built-in to the model itself. The model performs feature selection during training. Models based on decision tree like Random Forest and XGBoost use feature importance to select the most relevant features.

D. Machine Learning Models

This study used three machine learning models: Random Forest (RF), Support Vector Regression (SVR), and XGBoost.

1) Random forest: Random Forest is an ensemble model of decision trees that use random sub-samples from a dataset for prediction, and can be used for both classification and regression tasks [19]. For regression, the model takes predictions from all decision trees then averages them for the final result.

2) Support Vector Regression (SVR): Support Vector Regression (SVR) is a type of Support Vector Machine (SVM) that is used for regression tasks, and is a commonly used method for time-series forecasting [22]. It tries to fit an optimal hyperplane for predicting continues values.

3) XGBoost: XGBoost stands for Extreme Gradient Boosting. It can also be used in both classification and regression tasks. XGBoost is based on Gradient Boosting algorithm, where the decision trees are added to the model sequentially.

E. Model Evaluation

This study used and compared the combinations of feature selection methods machine learning models. Three machine learning models were used and tested: Random Forest (RF), Support Vector Regression (SVR), and XGBoost. The models were first trained using default parameters, then tuned using Grid Search hyperparameter tuning to find the best settings for each model. We used four evaluation metrics to evaluate the model's performance: Coefficient of Determination (R^2), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE),

and Mean Absolute Percentage Error (MAPE), all of which can be defined in Eq. (2), (3), (4), and (5) respectively.

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y}_i)^2} \quad (2)$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\hat{y}_i - y_i)^2} \quad (3)$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|\hat{y}_i - y_i| \quad (4)$$

$$MAPE = \frac{100\%}{n}\sum_{i=1}^{n}\left|\frac{\hat{y}_i - y_i}{y_i}\right| \quad (5)$$

where, y_i is the actual value, $\hat{y}_i$ is the predicted value, and $\bar{y}_i$ is the mean value.

IV. Results and Discussion

A. Training and Validation Results

The results for model training with default parameters along with the validation can be seen on Table III, Table IV, and Table V. The results were grouped based on the feature selection method for readability purposes. The best results from each method are highlighted in bold.

TABLE III. Training and Validation – Pearson's Feature Selection

Model	Training				Validation			
	R²	***RMSE***	***MAE***	***MAPE***	***R²***	***RMSE***	***MAE***	***MAPE***
RF	**0.9971**	**22568.1233**	**10925.2073**	**5.81%**	0.9932	25517.8834	13777.1053	6.70%
SVR	0.9913	13470.8283	5308.5905	6.05%	0.8868	6192.4275	3751.0109	7.01%
XGBoost	0.9959	26876.6614	13251.0304	8.11%	**0.9943**	**23282.8510**	**12679.5643**	**6.69%**

TABLE IV. Training and validation – RFE

Model	Training				Validation			
	R²	***RMSE***	***MAE***	***MAPE***	***R²***	***RMSE***	***MAE***	***MAPE***
RF	**0.9983**	**17410.7001**	**9081.5890**	**4.89%**	**0.9938**	**24321.2331**	**13347.6318**	19.29%
SVR	0.9941	32088.4842	19245.7056	31.47%	0.9930	25748.6940	17236.5587	22.32%
XGBoost	0.9969	23422.6130	13053.8578	8.72%	0.9936	24719.3096	14251.4393	**10.08%**

TABLE V. Training and validation – Embedded Feature Selection

Model	Training				Validation			
	R²	***RMSE***	***MAE***	***MAPE***	***R²***	***RMSE***	***MAE***	***MAPE***
RF	**0.9962**	**25747.2753**	12930.4714	6.93%	0.9913	28877.6052	15217.6164	6.98%
XGBoost	0.9962	26001.9723	**11681.7900**	**6.20%**	**0.9945**	**22880.2620**	**11970.0420**	**5.91%**

B. Testing Results

The models were then put to test to see how well the model generalizes with truly unseen data using the testing set. The results of the experiments can be seen on Table VI, Table VII, and Table VIII. The results were grouped based on the feature selection method for readability purposes. Models with all the features were also tested for comparison and can be seen on Table IX. The best results from each method are highlighted in bold.

TABLE VI. Experiment Results – Pearson's Feature Selection

Model	R^2	RMSE	MAE	MAPE
RF	**0.9943**	**30926.7590**	**16087.1698**	**5.49%**
SVR	0.8280	60648.5777	21614.1249	10.21%
XGBoost	0.9925	35243.8582	18644.4787	6.72%

TABLE VII. Experiment Results – RFE

Model	R^2	RMSE	MAE	MAPE
RF	0.9933	33282.8687	18839.3967	19.90%
SVR	**0.9937**	**32290.6700**	**20560.2261**	14.30%
XGBoost	0.9845	50718.4633	25457.2603	**11.26%**

TABLE VIII. Experiment Results – Embedded Feature Selection

Model	R^2	RMSE	MAE	MAPE
RF	0.9900	40899.9580	22687.4373	8.09%
XGBoost	**0.9926**	**35068.2627**	**17777.9998**	**5.90%**

TABLE IX. Experiment Results – No Feature Selection

Model	R^2	RMSE	MAE	MAPE
RF	**0.9934**	**33140.1820**	**18877.3783**	**17.72%**
SVR	0.9926	34990.9246	22427.8018	23.58%
XGBoost	0.9766	62394.0293	32761.8084	23.78%

Random Forest combined with Pearson's Correlation for feature selection gives the best results overall, with an R^2 score of 0.9943, a slight improvement from the model using all features with an R^2 score of 0.9934. Fig. 2 shows the prediction error of the model. This indicates that even without feature selection, the model was still able to explain more than 95% of the variance. The MAPE also dropped significantly from 17.72% to 5.49%. XGBoost seemed to benefit from feature selection the most, based on the improved results compared to no feature selection.

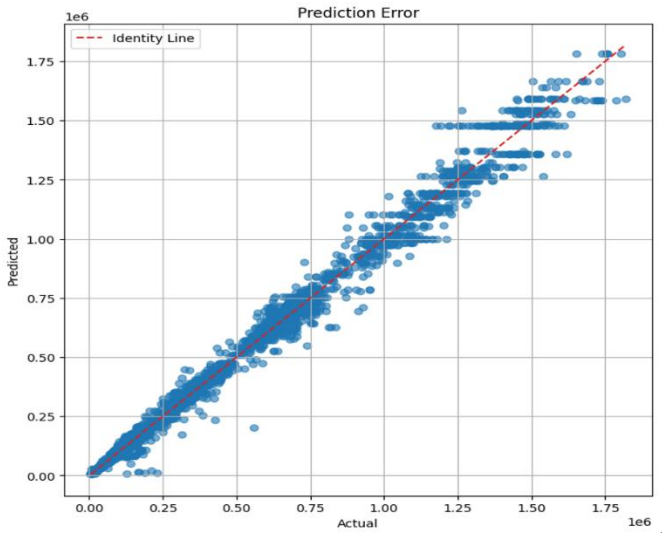

Fig. 2. Prediction error for Random Forest – Pearsons' Feature Selection

C. Results Comparison

A previous study using a linear model [16] had achieved an R^2 score of 0.6756, indicating that the model managed to capture 67.56% of the variation. The results indicated that linear models might not be suitable for predicting the number of players. Another study [18] tested various models, including SVR, RF, and Ridge Regression, with Pearson's Correlation feature selection method. The method reduced the number of features to be used in the models from 889 to 163. The result achieved with the best model was an R^2 score of 0.805, indicating that the model managed to capture 80.5% of the variation. The best model in this study achieved an R^2 score of 0.9943, and an average R^2 score above 0.9 across all models, a better result compared to the previous studies mentioned above.

V. Conclusion and Future Work

In this paper, we presented a method using lagged features in predicting daily player count, using historical data from video games on the Steam platform. The lagged features were created using sliding window method, using data from the last 7 days. Several feature selection methods and machine learning models were tested. Random Forest and Pearson's Correlation Feature Selection shows the best predictive performance amongst all combinations. Despite that, all the other combinations have an average R^2 score above 0.9, showing the effectiveness of our method.

However, there are several limitations in this study. The data used was from video games with the most player populations at the time of the study, so it might be different in the future. This study didn't consider the price of each video game, but only whether they were free or not. Future works may consider adding individual game prices, and the price during sales for more detailed analysis. Game ratings obtained from sentiment analysis of user reviews may also be used for more accurate results.

Cross-Entropy-Driven Optimization of Triangular Fuzzy Neutrosophic MADM for Urban Park Environmental Design Quality Evaluation

Xing She[1], Xi Xie[2]*, Peng Xie[3]
School of Arts and Design, Anhui University of Technology, Maanshan, Anhui, China[1, 2]
Faculty of Humanities and Arts, Macao University of Science and Technology, Macao, China[3]

Abstract—The evaluation of urban park environmental design quality focuses on functionality, aesthetics, ecology, and user experience. Functionality ensures practical facilities, clear zoning, and accessibility. Aesthetics emphasizes visual harmony, cultural integration, and artistic appeal. Ecological quality assesses vegetation, biodiversity, and sustainability, promoting environmental protection. User experience evaluates comfort, safety, inclusivity, and the ability to meet diverse needs. A well-designed park balances these elements, fostering harmony between humans and nature while enhancing public well-being, environmental awareness, and the overall urban living experience. The quality evaluation of urban park environmental design is multi-attribute decision-making (MADM). In this study, triangular fuzzy neutrosophic number cross-entropy (TFNN-CE) approach is executed under triangular fuzzy neutrosophic sets (TFNSs). Furthermore, Then, entropy is employed to execute the weight and TFNN-CE approach is executed for MADM under TFNSs. Finally, numerical example for quality evaluation of urban park environmental design is executed the advantages of TFNN-CE approach through different comparisons. The major contributions of this study could be executed: (1) entropy is employed to execute the weight under TFNSs; (2) TFNN-CE approach is executed under TFNSs; (3) TFNN-CE approach is put forward for MADM under TFNSs; (4) numerical example for quality evaluation of urban park environmental design is executed the advantages of TFNN-CE approach through different comparisons.

I. INTRODUCTION

Nowadays, the construction of urban parks has attracted the attention of the whole society. Integrating the design concepts and approaches of the original ecological environment landscape into the construction of urban parks is an important trend in the development of urban parks [1-3]. Integrating the design concept of original ecological environment into the construction of urban parks is an important core of urban park construction. It not only fully utilizes the existing ecological resources of the city itself, but also maintains the ecological environment of the city itself and protects the original biological communities, enabling them to continue to survive [4-6]. Therefore, it is necessary to fully investigate and analyze the original ecological environment of human cities, adapt to the original ecological conditions, incorporate artificial design and transformation, combine human activities with nature, protect the original ecological environment, maintain its richness, ensure the scientific rationality of urban park planning and construction, and create a livable and harmonious living environment for urban residents [7-9]. In the natural world, biological landscapes are full of vitality, so when designing urban parks, designers can use this as a starting point to integrate rich plants into landscape units, and use species diversity to maintain the ecological balance of the city [10-13]. Firstly, vegetation selection should be based on the geographical location and urban climate of each city, ensuring not only the reasonable allocation of trees, but also a high survival rate of the selected tree species. Secondly, it is necessary to fully consider the habits of animals [14-16]. When designing landscapes, unique vegetation is utilized to attract animal habitats, thereby establishing a stable and balanced ecosystem. Finally, based on the ecological environment of the city itself, design and treat its lakes and corridors, such as adding landscape patches, transforming natural rivers and lakes, and improving their water quality. Add different types of plant areas (such as functional, productive, ornamental, etc.), grassland resources, wetland resources, etc. according to different landscape functions, in order to enrich the biological diversity and stabilize the ecological balance in urban parks [17-19]. Protecting the ecological environment and conserving natural resources are the most important aspects of landscape design in the original ecological environment [1, 20]. Therefore, in the planning process of urban parks, it is necessary to combine them with the actual ecological environment and minimize the waste of natural resources as much as possible. Firstly, when performing artificial scenery, environmentally friendly or energy-saving materials can be selected; secondly, when transforming natural landscapes, ecological engineering should be used to avoid polluting the natural environment [21-23]. Once again, when laying roads, natural soil can be chosen, which not only causes minimal damage to the environment, but also maintains the natural appearance; Finally, it is important to pay attention to the water quality of urban parks, focus on their recycling, and use specially designed pipelines to circulate water quality in a circular manner, thereby playing a role in irrigating green spaces and cleaning parks [24-26]. Natural ecology can effectively remove impurities from air and water sources and make them cleaner, greatly improving air quality and water quality [27, 28]. However, once a certain ecological chain of the original environment is destroyed, it is very easy to damage the overall ecological environment. Therefore, when designing the original

ecological landscape, the principle of non-interference or low intervention should be followed to reduce damage to the ecological rules of the natural environment, and to build scientific urban parks [29-31]. During construction, it is not allowed to change the biological elements in the original ecosystem, adhere to the natural law of survival of the fittest, reduce or even eliminate artificial traces, and follow the development rules of natural ecology. The design principle of low intervention can ensure that the ecological environment maintains its complete function and the balance of the original ecology, optimize the artistic expression of artificial design, and reduce the cost of park construction [32, 33]. In terms of artistic creation, the original ecological environment landscape design should be combined with the different cultural characteristics of each city, highlighting the cultural value of urban park ecological environment [34-36]. Based on the cultural characteristics of each region, inject cultural emotions into the cultural landscape, arouse people's resonance, and integrate the urban parks executed into modern civilization on the basis of meeting the requirements of the original ecosystem. Designers should fully and reasonably consider the degree of cultural integration, and maximize the use of natural elements without excessive human processing, integrating cultural and economic benefits into urban parks [37-39].

Due to the complexity, diversity, and different preferences of decision-makers in the decision-making environment, MADM problems have a certain degree of fuzziness and uncertainty [40-43]. For this reason, domestic and foreign scholars have focused on complex decision-making problems, involving fields such as construction, industry and agriculture [44-50], but in terms of initial information expression, they are based on the fuzzy sets proposed by Zadeh [51], which does not fully characterize decision-makers' hesitation, fuzziness, and different biases. The assignment of indicators is influenced by the experience of decision-makers and the results of fuzzy comprehensive evaluation are influenced by the principle of maximum probability, which is not universal [52-55]. In addition, due to the increasing amount of decision information, the complexity and uncertainty of decision problems become higher. The triangular fuzzy neutrosophic sets (TFNSs) proposed by Biswas [56] overcomes the limitations of Zadeh's fuzzy set theory, allows DMs to represent the membership, indeterminacy-membership and falsity-membership which is depicted through triangular fuzzy numbers (TFNs) and meticulously expresses the decision information of uncertainty and preferences in the MADM process, thereby improving the scientific and rational nature of decision results. The quality evaluation of urban park environmental design is MADM. TFNSs [56] is efficient tool for managing fuzzy information during quality evaluation of urban park environmental design. The CE approach [57] was put forward the MADM. Furthermore, many approaches utilize CE approach [58-64] and entropy approach [57, 65-67] to administrate the MADM. Until now, no or few approaches have been administrated on CE approach for MADM based on entropy approach along with TFNSs. Thus, in this study, TFNN-CE approach is executed under TFNSs. Then, the entropy is employed to execute the weight under TFNSs and TFNN-CE approach is executed for MADM under TFNSs. Finally, numerical example for quality evaluation of urban park environmental design is executed the advantages of TFNN-CE approach through different comparisons. The major contributions of this study could be executed: (1) entropy is employed to execute the weight under TFNSs; (2) TFNN-CE approach is executed under TFNSs; (3) TFNN-CE approach is put forward for MADM under TFNSs; (4) numerical example for quality evaluation of urban park environmental design is executed the advantages of TFNN-CE approach through different comparisons.

The research structure is executed. In Section II, the TFNNSs is executed. The TFNN-CE is produced in Section III. In Section IV, TFNN-CE is fully put forward MADM under TFNSs. Section V executed numerical example for quality evaluation of urban park environmental design and comparative analysis. Final remark is executed in Section VI.

II. PRELIMINARIES

Biswas [56] built the TFNSs.

Definition 1[56]. The TFNSs is depicted:

$$ST=\left\{\left(\theta,SA(\theta),SB(\theta),SC(\theta)\right)\middle|\,\theta\in\Theta\right\} \quad (1)$$

where $SA(\theta),SB(\theta),SC(\theta)\in[0,1]$ execute the membership, indeterminacy-membership and falsity-membership which is executed through TFNs.

$$SA(\theta)=\left(SA^{L}(\theta),SA^{M}(\theta),SA^{U}(\theta)\right),0\le SA^{L}(\theta)\le SA^{M}(\theta)\le SA^{U}(\theta)\le 1 \quad (2)$$

$$SB(\theta)=\left(SB^{L}(\theta),SB^{M}(\theta),SB^{U}(\theta)\right),0\le SB^{L}(\theta)\le SB^{M}(\theta)\le SB^{U}(\theta)\le 1 \quad (3)$$

$$SC(\theta)=\left(SC^{L}(\theta),SC^{M}(\theta),SC^{U}(\theta)\right),0\le SC^{L}(\theta)\le SC^{M}(\theta)\le SC^{U}(\theta)\le 1 \quad (4)$$

$ST=\left\{\begin{matrix}\left(SA^{L},SA^{M},SA^{U}\right),\\ \left(SB^{L},SB^{M},SB^{U}\right),\left(SC^{L},SC^{M},SC^{U}\right)\end{matrix}\right\}$ is called a TFNN, $0\le SA^{U}+SB^{U}+SC^{U}\le 3$.

Definition 2[56]. Let

$ST_1=\left\{\begin{matrix}\left(SA_1^{L},SA_1^{M},SA_1^{U}\right),\\ \left(SB_1^{L},SB_1^{M},SB_1^{U}\right),\left(SC_1^{L},SC_1^{M},SC_1^{U}\right)\end{matrix}\right\}$,

$ST_2=\left\{\begin{matrix}\left(SA_2^{L},SA_2^{M},SA_2^{U}\right),\\ \left(SB_2^{L},SB_2^{M},SB_2^{U}\right),\left(SC_2^{L},SC_2^{M},SC_2^{U}\right)\end{matrix}\right\}$ and

$$ST=\left\{\begin{array}{l}\left(SA^{L},SA^{M},SA^{U}\right),\\ \left(SB^{L},SB^{M},SB^{U}\right),\left(SC^{L},SC^{M},SC^{U}\right)\end{array}\right\},\ \chi>0,$$

the operation laws are executed:

$$(1)\ ST_1\oplus ST_2=\left\{\begin{array}{l}\left(\begin{array}{l}SA_1^L+SA_2^L\text{-}SA_1^LSA_2^L,\\ SA_1^M+SA_2^M\text{-}SA_1^MSA_2^M,SA_1^U+SA_2^U\text{-}SA_1^USA_2^U\end{array}\right),\\ \left(SB_1^LSB_2^L,SB_1^MSB_2^M,SB_1^USB_2^U\right),\\ \left(SC_1^LSC_2^L,SC_1^MSC_2^M,SC_1^USC_2^U\right)\end{array}\right\};$$

$$(2)\ ST_1\otimes ST_2=\left\{\begin{array}{l}\left(SA_1^LSA_2^L,SA_1^MSA_2^M,SA_1^USA_2^U\right),\\ \left(\begin{array}{l}SB_1^L+SB_2^L\text{-}SB_1^LSB_2^L,\\ SB_1^M+SB_2^M\text{-}SB_1^MSB_2^M,SB_1^U+SB_2^U\text{-}SB_1^USB_2^U\end{array}\right),\\ \left(\begin{array}{l}SC_1^L+SC_2^L\text{-}SC_1^LSC_2^L,\\ SC_1^M+SC_2^M\text{-}SC_1^MSC_2^M,SC_1^U+SC_2^U\text{-}SC_1^USC_2^U\end{array}\right)\end{array}\right\};$$

$$(3)\ \chi ST=\left\{\begin{array}{l}\left(1-\left(1-SA^L\right)^{\chi},1-\left(1-SA^M\right)^{\chi},1-\left(1-SA^U\right)^{\rho\chi}\right),\\ \left(\left(SB^L\right)^{\chi},\left(SB^M\right)^{\chi},\left(SB^U\right)^{\chi}\right),\\ \left(\left(SC^L\right)^{\chi},\left(SC^M\right)^{\chi},\left(SC^U\right)^{\chi}\right)\end{array}\right\};$$

$$(4)\ ST^{\chi}=\left\{\begin{array}{l}\left(\left(SA^L\right)^{\chi},\left(SA^M\right)^{\chi},\left(SA^U\right)^{\chi}\right),\\ \left(1-\left(1-SB^L\right)^{\chi},1-\left(1-SB^M\right)^{\chi},1-\left(1-SB^U\right)^{\chi}\right),\\ \left(1-\left(1-SC^L\right)^{\chi},1-\left(1-SC^M\right)^{\chi},1-\left(1-SC^U\right)^{\chi}\right)\end{array}\right\}.$$

From Definition 2, the operation laws have different executed properties.

$$(1)\ ST_1\oplus ST_2=ST_2\oplus ST_1; \tag{5}$$

$$(2)ST_1\otimes ST_2=ST_2\otimes ST_1,\left(\left(ST_1\right)^{\chi_1}\right)^{\chi_2}=\left(ST_1\right)^{\chi_1\chi_2}; \tag{6}$$

$$(3)\ \chi\left(ST_1\oplus ST_2\right)=\chi ST_1\oplus\chi ST_2,\left(ST_1\otimes ST_2\right)^{\chi}=\left(ST\right)^{\chi}\otimes\left(ST_2\right)^{\chi}; \tag{7}$$

$$(4)\chi_1ST_1\oplus\chi_2ST_1=\left(\chi_1+\chi_2\right)ST_1,\left(ST_1\right)^{\chi_1}\otimes\left(ST_1\right)^{\chi_2}=\left(ST_1\right)^{\left(\chi_1+\chi_2\right)}. \tag{8}$$

Definition 3 [56]. Let $ST=\left\{\begin{array}{l}\left(SA^L,SA^M,SA^U\right),\\ \left(SB^L,SB^M,SB^U\right),\left(SC^L,SC^M,SC^U\right)\end{array}\right\}$, the score and accuracy functions of ST is:

$$SF\left(ST\right)=\frac{1}{12}\left[\begin{array}{l}8+\left(SA^L+2SA^M+SA^U\right)\\ -\left(SB^L+2SB^M+SB^U\right)\\ -\left(SC^L+2SC^M+SC^U\right)\end{array}\right],$$
$$SF\left(ST\right)\in\left[0,1\right] \tag{9}$$

$$AF\left(ST\right)=\frac{1}{4}\left[\begin{array}{l}\left(SA^L+2SA^M+SA^U\right)\\ -\left(SB^L+2SB^M+SB^U\right)\end{array}\right],$$
$$AF\left(WW\right)\in\left[-1,1\right] \tag{10}$$

For ST_1 and ST_2, then

(1) *if* $SF\left(ST_1\right)\prec SF\left(ST_2\right),\ ST_1\prec ST_2$;
(2) *if* $SF\left(ST_1\right)=SF\left(ST_2\right),AF\left(ST_1\right)\prec AF\left(ST_2\right),\ ST_1\prec ST_2$;
(3) *if* $SF\left(ST_1\right)=SF\left(ST_2\right),AF\left(ST_1\right)=AF\left(ST_2\right),ST_1=ST_2$.

III. Cross-entropy with TFNSs

Bhandari and Pal [67] created the cross entropy.

Definition 4[67]. Let $s\alpha=\left(s\alpha\left(s_1\right),s\alpha\left(s_2\right),\cdots,s\alpha\left(s_n\right)\right)$ and $s\beta=\left(s\beta\left(s_1\right),s\beta\left(s_2\right),\cdots,s\beta\left(s_n\right)\right)$. The cross-entropy of $s\alpha$ from $s\beta$ is executed:

$$CE\left(s\alpha,s\beta\right)=\sum_{j=1}^{n}\left(\begin{array}{l}s\alpha\left(s_j\right)\ln\frac{s\alpha\left(s_j\right)}{s\beta\left(s_j\right)}\\ +\left(1-s\alpha\left(s_j\right)\right)\ln\frac{1-s\alpha\left(s_j\right)}{1-s\beta\left(s_j\right)}\end{array}\right) \tag{11}$$

which is the discrimination degree of $w\alpha$ from $w\beta$.

Shang and Jiang [57] created the modified cross-entropy.

Definition 5 [57]. Let $s\alpha=\left(s\alpha\left(s_1\right),s\alpha\left(s_2\right),\cdots,s\alpha\left(s_n\right)\right)$ and $s\beta=\left(s\beta\left(s_1\right),s\beta\left(s_2\right),\cdots,s\beta\left(s_n\right)\right)$. The cross-entropy of $s\alpha$ from $s\beta$ is executed:

$$CE\left(s\alpha, s\beta\right) = \sum_{j=1}^{n}\left(\begin{array}{l} s\alpha\left(s_j\right)\ln\dfrac{s\alpha\left(s_j\right)}{\frac{1}{2}\left(s\alpha\left(s_j\right)+s\beta\left(s_j\right)\right)} + \\ \left(1-s\alpha\left(s_j\right)\right)\ln\dfrac{1-s\alpha\left(s_j\right)}{1-\frac{1}{2}\left(s\alpha\left(s_j\right)+s\beta\left(s_j\right)\right)} \end{array}\right) \quad (12)$$

which is discrimination degree of $s\alpha$ from $s\beta$.

Then, TFNN cross-entropy (TFNN-CE) is executed in light with cross-entropy [57] and TFNNs [56].

Definition 6. Let $ST_1 = \left\{\begin{array}{l}\left(SA_1^L, SA_1^M, SA_1^U\right), \\ \left(SB_1^L, SB_1^M, SB_1^U\right), \left(SC_1^L, SC_1^M, SC_1^U\right)\end{array}\right\}$, $ST_2 = \left\{\begin{array}{l}\left(SA_2^L, SA_2^M, SA_2^U\right), \\ \left(SB_2^L, SB_2^M, SB_2^U\right), \left(SC_2^L, SC_2^M, SC_2^U\right)\end{array}\right\}$. The TFNN-CE is produced between ST_1 and ST_2:

$$\begin{aligned} &\text{TFNN-CE}\left(ST_1, ST_2\right) \\ &= \left(\begin{array}{l} \left(\dfrac{SA_1^L+SA_1^M+SA_1^U}{3}\right)\ln\dfrac{\frac{SA_1^L+SA_1^M+SA_1^U}{3}}{\rho\left(\frac{SA_1^L+SA_1^M+SA_1^U}{3}+\frac{SA_2^L+SA_2^M+SA_2^U}{3}\right)} \\ +\left(1-\dfrac{SA_1^L+SA_1^M+SA_1^U}{3}\right)\ln\dfrac{1-\frac{SA_1^L+SA_1^M+SA_1^U}{3}}{1-\rho\left(\frac{SA_1^L+SA_1^M+SA_1^U}{3}+\frac{SA_2^L+SA_2^M+SA_2^U}{3}\right)} \end{array}\right) \\ &+ \left(\begin{array}{l} \left(\dfrac{SB_1^L+SB_1^M+SB_1^U}{3}\right)\ln\dfrac{\frac{SB_1^L+SB_1^M+SB_1^U}{3}}{\rho\left(\frac{SB_1^L+SB_1^M+SB_1^U}{3}+\frac{SB_2^L+SB_2^M+SB_2^U}{3}\right)} \\ +\left(1-\dfrac{SB_1^L+SB_1^M+SB_1^U}{3}\right)\ln\dfrac{1-\frac{SB_1^L+SB_1^M+SB_1^U}{3}}{1-\rho\left(\frac{SB_1^L+SB_1^M+SB_1^U}{3}+\frac{SB_2^L+SB_2^M+SB_2^U}{3}\right)} \end{array}\right) \\ &+ \left(\begin{array}{l} \left(\dfrac{SC_1^L+SC_1^M+SC_1^U}{3}\right)\ln\dfrac{\frac{SC_1^L+SC_1^M+SC_1^U}{3}}{\rho\left(\frac{SC_1^L+SC_1^M+SC_1^U}{3}+\frac{SC_2^L+SC_2^M+SC_2^U}{3}\right)} \\ +\left(1-\dfrac{SC_1^L+SC_1^M+SC_1^U}{3}\right)\ln\dfrac{1-\frac{SC_1^L+SC_1^M+SC_1^U}{3}}{1-\rho\left(\frac{SC_1^L+SC_1^M+SC_1^U}{3}+\frac{SC_2^L+SC_2^M+SC_2^U}{3}\right)} \end{array}\right) \end{aligned} \quad (13)$$

which is discrimination degree of ST_1 and ST_2 and $\rho \in [0,1]$.

In light with Shannon's inequality [66], it's easily verify that $\text{TFNN-CE}\left(ST_1, ST_2\right) \geq 0$, and $\text{TFNN-CE}\left(ST_1, ST_2\right) = 0$ if and only if $\left(SA_1^L, SA_1^M, SA_1^U\right) = \left(SA_2^L, SA_2^M, SA_2^U\right)$, $\left(SB_1^L, SB_1^M, SB_1^U\right) = \left(SB_2^L, SB_2^M, SB_2^U\right)$, $\left(SC_1^L, SC_1^M, SC_1^U\right) = \left(SC_2^L, SC_2^M, SC_2^U\right)$.

IV. CROSS-ENTROPY TECHNIQUE FOR MADM WITH TFNNS

The TFNN-CE technique is executed for TFNN-MADM. Suppose that m alternatives $\{SX_1, SX_2, \ldots, SX_m\}$, n attributes $\{SG_1, SG_2, \ldots, SG_n\}$ with weight $sw = (sw_1, sw_2, \cdots, sw_n)$. TFNN-CE technique is executed for MADM with TFNNs.

Step 1. Execute the TFNN-matrix $STFNN = \left[STFNN_{ij}\right]_{m\times n}$:

$$STFNN = \left[STFNN_{ij}\right]_{m\times n} = \begin{array}{c} \\ SX_1 \\ SX_2 \\ \vdots \\ SX_m \end{array} \begin{array}{c} \begin{array}{cccc} SG_1 & SG_2 & \ldots & SG_n \end{array} \\ \begin{bmatrix} STFNN_{11} & STFNN_{12} & \ldots & STFNN_{1n} \\ STFNN_{21} & STFNN_{22} & \ldots & STFNN_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ STFNN_{m1} & STFNN_{m2} & \ldots & STFNN_{mn} \end{bmatrix} \end{array} \quad (14)$$

$$STFNN_{ij} = \begin{Bmatrix} \left(\left(SA_{ij}^L\right), \left(SA_{ij}^M\right), \left(SA_{ij}^U\right)\right), \\ \left(\left(SB_{ij}^L\right), \left(SB_{ij}^M\right), \left(SB_{ij}^U\right)\right), \\ \left(\left(SC_{ij}^L\right), \left(SC_{ij}^M\right), \left(SC_{ij}^U\right)\right) \end{Bmatrix}.$$

ωηερε

Step 2. Normalize the $STFNN = \left[STFNN_{ij}\right]_{m\times n}$ to $NSTFNN = \left[STFNN_{ij}^N\right]_{m\times n}$.

For benefit attributes:

$$STFNN_{ij}^N = \begin{Bmatrix} \left(\left(NSA_{ij}^L\right), \left(NSA_{ij}^M\right), \left(NSA_{ij}^U\right)\right), \\ \left(\left(NSB_{ij}^L\right), \left(NSB_{ij}^M\right), \left(NSB_{ij}^U\right)\right), \\ \left(\left(NSC_{ij}^L\right), \left(NSC_{ij}^M\right), \left(NSC_{ij}^U\right)\right) \end{Bmatrix}$$

$$= \begin{Bmatrix} \left(\left(SA_{ij}^L\right), \left(SA_{ij}^M\right), \left(SA_{ij}^U\right)\right), \\ \left(\left(SB_{ij}^L\right), \left(SB_{ij}^M\right), \left(SB_{ij}^U\right)\right), \\ \left(\left(SC_{ij}^L\right), \left(SC_{ij}^M\right), \left(SC_{ij}^U\right)\right) \end{Bmatrix} \quad (15)$$

For cost attributes:

$$STFNN_{ij}^N = \begin{Bmatrix} \left(\left(NSA_{ij}^L\right), \left(NSA_{ij}^M\right), \left(NSA_{ij}^U\right)\right), \\ \left(\left(NSB_{ij}^L\right), \left(NSB_{ij}^M\right), \left(NSB_{ij}^U\right)\right), \\ \left(\left(NSC_{ij}^L\right), \left(NSC_{ij}^M\right), \left(NSC_{ij}^U\right)\right) \end{Bmatrix}$$

$$= \begin{Bmatrix} \left(\left(SC_{ij}^L\right), \left(SC_{ij}^M\right), \left(SC_{ij}^U\right)\right), \\ \left(\left(SB_{ij}^L\right), \left(SB_{ij}^M\right), \left(SB_{ij}^U\right)\right), \\ \left(\left(SA_{ij}^L\right), \left(SA_{ij}^M\right), \left(SA_{ij}^U\right)\right) \end{Bmatrix} \quad (16)$$

Step 3. Produce the TFNN positive ideal solution (TFNNPIS) and $STFNN_i$;

$$TFNNPIS_j = \begin{Bmatrix} \left(\left(NSA_j^L\right)^+, \left(NSA_j^M\right)^+, \left(NSA_j^U\right)^+\right), \\ \left(\left(NSB_j^L\right)^+, \left(NSB_j^M\right)^+, \left(NSB_j^U\right)^+\right), \\ \left(\left(NSC_j^L\right)^+, \left(NSC_j^M\right)^+, \left(NSC_j^U\right)^+\right) \end{Bmatrix} \quad (17)$$

$$SF \begin{Bmatrix} \left(\left(NSA_j^L\right)^+, \left(NSA_j^M\right)^+, \left(NSA_j^U\right)^+\right), \\ \left(\left(NSB_j^L\right)^+, \left(NSB_j^M\right)^+, \left(NSB_j^U\right)^+\right), \\ \left(\left(NSC_j^L\right)^+, \left(NSC_j^M\right)^+, \left(NSC_j^U\right)^+\right) \end{Bmatrix}$$

$$= \max_i SF \begin{Bmatrix} \left(\left(NSA_{ij}^L\right), \left(NSA_{ij}^M\right), \left(NSA_{ij}^U\right)\right), \\ \left(\left(NSB_{ij}^L\right), \left(NSB_{ij}^M\right), \left(NSB_{ij}^U\right)\right), \\ \left(\left(NSC_{ij}^L\right), \left(NSC_{ij}^M\right), \left(NSC_{ij}^U\right)\right) \end{Bmatrix} \quad (18)$$

$$NSTFNN_i = \begin{Bmatrix} \left(\left(NSA_{ij}^L\right), \left(NSA_{ij}^M\right), \left(NSA_{ij}^U\right)\right), \\ \left(\left(NSB_{ij}^L\right), \left(NSB_{ij}^M\right), \left(NSB_{ij}^U\right)\right), \\ \left(\left(NSC_{ij}^L\right), \left(NSC_{ij}^M\right), \left(NSC_{ij}^U\right)\right) \end{Bmatrix} \quad (19)$$

Step 4. The weight numbers are important for MADM [68-72]. Entropy technique [65] is put forward weight numbers. The TFNN decision matrix (TFNNDM) is executed:

$$TFNNDM_{ij}=\frac{1}{2}\left(\frac{SF\left\{\begin{matrix}\left(\left(NSA_{ij}^{L}\right),\left(NSA_{ij}^{M}\right),\left(NSA_{ij}^{U}\right)\right),\\ \left(\left(NSB_{ij}^{L}\right),\left(NSB_{ij}^{M}\right),\left(NSB_{ij}^{U}\right)\right),\\ \left(\left(NSC_{ij}^{L}\right),\left(NSC_{ij}^{M}\right),\left(NSC_{ij}^{U}\right)\right)\end{matrix}\right\}+2}{\sum_{i=1}^{m}\left(SF\left\{\begin{matrix}\left(\left(NSA_{ij}^{L}\right),\left(NSA_{ij}^{M}\right),\left(NSA_{ij}^{U}\right)\right),\\ \left(\left(NSB_{ij}^{L}\right),\left(NSB_{ij}^{M}\right),\left(NSB_{ij}^{U}\right)\right),\\ \left(\left(NSC_{ij}^{L}\right),\left(NSC_{ij}^{M}\right),\left(NSC_{ij}^{U}\right)\right)\end{matrix}\right\}+2\right)}\right), \quad (20)$$

Then, TFNN Shannon entropy (TFNNSE) is produced:

$$TFNNSE_{j}=-\frac{1}{\ln m}\sum_{i=1}^{m}TFNNDM_{ij}\ln TFNNDM_{ij} \quad (21)$$

and $TFNNDM_{ij}\ln TFNNDM_{ij}=0$ if $TFNNDM_{ij}=0$.

Then, the weight numbers are executed:

$$sw_{j}=\frac{1-TFNNSE_{j}}{\sum_{j=1}^{n}\left(1-TFNNSE_{j}\right)} \quad (22)$$

Step 5. Execute the TFNN-CE model between TFNNPIS and $STFNN_{i}$ and $\rho\in[0,1]$:

$$TFNNCE\left(NSTFNN_{i},TFNNPIS\right)$$

$$=\sum_{j=1}^{n}sw_{j}\left(\begin{matrix}\left(\frac{NSA_{ij}^{L}+NSA_{ij}^{M}+NSA_{ij}^{U}}{3}\right)\ln\frac{\frac{NSA_{ij}^{L}+NSA_{ij}^{M}+NSA_{ij}^{U}}{3}}{\rho\left(\begin{matrix}\frac{NSA_{ij}^{L}+NSA_{ij}^{M}+NSA_{ij}^{U}}{3}\\ +\frac{\left(NSA_{j}^{L}\right)^{+}+\left(NSA_{j}^{M}\right)^{+}+\left(NSA_{j}^{U}\right)^{+}}{3}\end{matrix}\right)}\\ +\left(1-\frac{NSA_{ij}^{L}+NSA_{ij}^{M}+NSA_{ij}^{U}}{3}\right)\ln\frac{1-\frac{NSA_{ij}^{L}+NSA_{ij}^{M}+NSA_{ij}^{U}}{3}}{1-\rho\left(\begin{matrix}\frac{NSA_{ij}^{L}+NSA_{ij}^{M}+NSA_{ij}^{U}}{3}\\ +\frac{\left(NSA_{j}^{L}\right)^{+}+\left(NSA_{j}^{M}\right)^{+}+\left(NSA_{j}^{U}\right)^{+}}{3}\end{matrix}\right)}\end{matrix}\right)$$

$$+\sum_{j=1}^{n}sw_{j}\left(\begin{matrix}\left(\frac{NSB_{ij}^{L}+NSB_{ij}^{M}+NSB_{ij}^{U}}{3}\right)\ln\frac{\frac{NSB_{ij}^{L}+NSB_{ij}^{M}+NSB_{ij}^{U}}{3}}{\rho\left(\begin{matrix}\frac{NSB_{ij}^{L}+NSB_{ij}^{M}+NSB_{ij}^{U}}{3}\\ +\frac{\left(NSB_{j}^{L}\right)^{+}+\left(NSB_{j}^{M}\right)^{+}+\left(NSB_{j}^{U}\right)^{+}}{3}\end{matrix}\right)}\\ +\left(1-\frac{NSB_{ij}^{L}+NSB_{ij}^{M}+NSB_{ij}^{U}}{3}\right)\ln\frac{1-\frac{NSB_{ij}^{L}+NSB_{ij}^{M}+NSB_{ij}^{U}}{3}}{1-\rho\left(\begin{matrix}\frac{NSB_{ij}^{L}+NSB_{ij}^{M}+NSB_{ij}^{U}}{3}\\ +\frac{\left(NSB_{j}^{L}\right)^{+}+\left(NSB_{j}^{M}\right)^{+}+\left(NSB_{j}^{U}\right)^{+}}{3}\end{matrix}\right)}\end{matrix}\right)$$

$$+\sum_{j=1}^{n} s\omega_j \left(\left(\frac{NSC_{ij}^{L}+NSC_{ij}^{M}+NSC_{ij}^{U}}{3} \right) \ln \frac{\frac{NSC_{ij}^{L}+NSC_{ij}^{M}+NSC_{ij}^{U}}{3}}{\rho \left(\frac{NSC_{ij}^{L}+NSC_{ij}^{M}+NSC_{ij}^{U}}{3} + \frac{\left(NSC_{j}^{L}\right)^{+}+\left(NSC_{j}^{M}\right)^{+}+\left(NSC_{j}^{U}\right)^{+}}{3} \right)} + \left(1-\frac{NSC_{ij}^{L}+NSC_{ij}^{M}+NSC_{ij}^{U}}{3} \right) \ln \frac{1-\frac{NSC_{ij}^{L}+NSC_{ij}^{M}+NSC_{ij}^{U}}{3}}{1-\rho \left(\frac{NSC_{ij}^{L}+NSC_{ij}^{M}+NSC_{ij}^{U}}{3} + \frac{\left(NSC_{j}^{L}\right)^{+}+\left(NSC_{j}^{M}\right)^{+}+\left(NSC_{j}^{U}\right)^{+}}{3} \right)} \right) \tag{23}$$

Step 6. In light with $TFNNCE\left(NSTFNN_i, TFNNPIS\right)$, the smaller $TFNNCE\left(NSTFNN_i, TFNNPIS\right)$, the better alternative is.

V. Numerical Example and Comparative Analysis

A. Numerical Example

The current state of urban park construction in China is far from ideal, reflecting a relatively outdated urban planning concept compared to that of developed countries. Traditionally, urban parks in China have been designed with a focus on improving urban ecology, providing recreational spaces for citizens, beautifying the city, and showcasing cultural heritage. However, these designs often fail to prioritize fostering environmental awareness among the public. Influenced by commercialization and an anthropocentric mindset, some designers overly emphasize the entertainment and leisure functions of parks. This approach inadvertently reinforces self-centered tendencies, creating false needs that lead to a distorted relationship with nature. For example, excessive consumption, thrill-seeking, and superficial curiosity reduce parks to tools for personal gratification rather than spaces for genuine connection with the natural world. This perception of nature as a mere resource to be exploited is fundamentally flawed and causes significant harm to both the environment and humanity. This erroneous perspective exacerbates critical issues such as environmental pollution, climate change, and ecological crises. On a societal level, it deepens anthropocentric attitudes, making it harder for individuals to break free from self-centered worldviews. Without a true connection to nature, people struggle to form meaningful relationships with the natural world, fail to develop genuine respect for life, and lose the capacity to appreciate and protect the environment. A lack of harmony with nature ultimately undermines one's ability to connect authentically with other humans and society as a whole. From this analysis, it is evident that achieving harmonious coexistence between humans and nature, rooted in a genuine awareness of environmental protection, is a fundamental human necessity. Moving forward, whether renovating existing urban parks or constructing new ones, it is imperative to adopt advanced planning concepts such as "harmonious coexistence between humans and nature," "sustainable development," and "ecological cities." Urban parks should be designed to guide people out of self-centeredness, encouraging them to deeply connect with nature on an emotional and spiritual level. Parks must inspire individuals to embrace, integrate with, understand, appreciate, and love nature. Only through such a transformation can urban parks fulfill their role in fostering a profound respect for life and a commitment to protecting the natural world. The quality evaluation of urban park environmental design is MADM. In this section, numerical example for quality evaluation of urban park environmental design is executed through TFNN-CE approach. Five urban park environmental design schemes $SX_i\left(i=1,2,3,4,5\right)$ are assessed with different attributes:

1) SG_1 is functional design which forms the foundation of the evaluation, focusing on the rationality and practicality of park facilities. This includes whether the functional zones are clearly defined, whether facilities such as pathways, seating, drinking fountains, and restrooms are complete, and whether accessibility features for people with disabilities are adequately implemented. Additionally, the connectivity of the park, such as the placement of entrances and parking areas, plays a crucial role in its functionality.

2) SG_2 is aesthetic and artistic appeal which determines the park's visual attractiveness and uniqueness. Excellent landscape design should achieve harmony between elements such as vegetation, architecture, and water features while incorporating local cultural or historical symbols to showcase a distinctive artistic style. The color scheme should be natural and harmonious, with diverse seasonal vegetation changes. Furthermore, artistic installations (e.g., sculptures, fountains) and lighting design can enhance the overall beauty of the park.

3) SG_3 is Ecological quality which reflects the park's environmental sustainability. Key indicators include vegetation

coverage and biodiversity, as well as the cleanliness of water bodies, air quality, and noise pollution levels. Whether the park incorporates sustainable design concepts, such as rainwater collection systems or energy-saving facilities, is also an important aspect of modern urban parks.

4) SG_4 is user experience and comfort which focus on the actual usability of the park. The spatial layout should avoid overcrowding or overly desolate areas, and facilities should meet the needs of diverse groups (e.g., playgrounds for children, fitness equipment for seniors). Additionally, safety and privacy measures, such as surveillance systems and proper lighting, greatly influence user satisfaction.

The TFNN-CE approach is executed for TFNN-MADM to select the best urban park environmental design schemes.

Step 1. Execute the $STFNN = \left[STFNN_{ij} \right]_{5\times4}$ (Table I).

TABLE I. THE TFNN INFORMATION

	SG_1

SX_3	((0.17,0.46,0.73), (0.23,0.49,0.80), (0.11,0.36,0.60))
SX_4	((0.18,0.45,0.72), (0.24,0.48,0.79), (0.15,0.38,0.63))
SX_5	((0.19,0.43,0.76), (0.25,0.47,0.78), (0.14,0.39,0.62))
	SG_4
SX_1	((0.27,0.50,0.82), (0.18,0.42,0.66), (0.13,0.35,0.58))
SX_2	((0.26,0.54,0.87), (0.19,0.45,0.69), (0.13,0.33,0.56))
SX_3	((0.25,0.53,0.84), (0.21,0.44,0.71), (0.12,0.32,0.52))
SX_4	((0.28,0.52,0.85), (0.22,0.46,0.70), (0.10,0.31,0.55))
SX_5	((0.29,0.51,0.83), (0.20,0.40,0.68), (0.13,0.32,0.53))

Step 3. Execute the TFNNPIS (Table III).

TABLE III. TFNNPIS

	TFNNPIS
SG_1	((0.16,0.44,0.79), (0.28,0.50,0.81), (0.15,0.34,0.68))
SG_2	((0.33,0.56,0.89), (0.21,0.44,0.73), (0.11,0.30,0.58))
SG_3	((0.19,0.43,0.76), (0.25,0.47,0.78), (0.14,0.39,0.62))
SG_4	((0.29,0.51,0.83), (0.20,0.40,0.68), (0.13,0.32,0.53))

Step 4. Execute the $TFNN\text{-}CE\left(NSTFNN_i, TFNNPIS \right)$ (Table IV)and $\rho = 0.6$.

TABLE IV. THE $TFNN\text{-}CE\left(NSTFNN_i, TFNNPIS \right)$

Alternatives	$TFNN\text{-}CE\left(NSTFNN_i, TFNNPIS \right)$
TFNN-CE$\left(NSTFNN_1, TFNNPIS \right)$	0.5840
TFNN-CE$\left(NSTFNN_2, TFNNPIS \right)$	0.6421
TFNN-CE$\left(NSTFNN_3, TFNNPIS \right)$	0.4276
TFNN-CE$\left(NSTFNN_4, TFNNPIS \right)$	0.4933

TFNN-CE$\left(NSTFNN_5, TFNNPIS\right)$	0.6907

Step 5. In light with $TFNN\text{-}CE\left(NTFNN_i, TFNNPIS\right)$, the order is: $SX_3 > SX_4 > SX_1 > SX_2 > SX_5$ and SX_3 is optimal urban park environmental design scheme.

B. Compare with Some Existing Approaches

Then, the TFNN-CE approach is compared with TFNNWA approach [56], TFNNWG approach [56], TFNN-VIKOR approach [73], TFNN-MABAC approach [74], TFNN-EDAS approach [75], TFNN-GRA approach [76]. The order of different approaches is executed in Table V.

TABLE V. ORDER OF DIFFERENT APPROACHES

	Order
TFNNWA approach[56]	$SX_3 > SX_4 > SX_1 > SX_2 > SX_5$
TFNNWG approach[56]	$SX_3 > SX_4 > SX_2 > SX_1 > SX_5$
TFNN-VIKOR approach [73]	$SX_3 > SX_4 > SX_1 > SX_2 > SX_5$
TFNN-MABAC approach [74]	$SX_3 > SX_4 > SX_1 > SX_2 > SX_5$
TFNN-EDAS approach [75]	$SX_3 > SX_4 > SX_1 > SX_2 > SX_5$
TFNN-GRA approach [76]	$SX_3 > SX_4 > SX_1 > SX_2 > SX_5$
TFNN-CE approach	$SX_3 > SX_4 > SX_1 > SX_2 > SX_5$

In accordance with WS coefficients [77, 78], the WS coefficient between TFNNWA approach [56], TFNNWG approach [56], TFNN-VIKOR approach [73], TFNN-MABAC approach [74], TFNN-EDAS approach [75], TFNN-GRA approach [76] and the proposed TFNN-CE approach is 1.0000, 0.8437, 1.0000, 1.0000, 1.0000, 1.0000. The WS coefficient shows the order of TFNN-CE approach are same to order of TFNNWA approach [56], TFNN-VIKOR approach [73], TFNN-MABAC approach [74], TFNN-EDAS approach [75], TFNN-GRA approach [76]; the WS coefficient shows order of TFNN-CE approach are slightly different to order of TFNNWG approach [56]. Furthermore, the major advantages of TFNN-CE approach are executed: TFNN-CE approach could reflect the uncertainty and has strong differentiation ability and could overcome the design defects of existing CE approach. The major limits of TFNN-CE approach didn't mention the psychological behavior of DMs.

VI. CONCLUSION

The evaluation of urban park environmental design quality focuses on four key aspects: functionality, aesthetics, ecology, and user experience. Functionality assesses whether the park's facilities are practical, accessible, and cater to diverse needs, such as clear zoning for recreation, rest, and activities, as well as the inclusion of essential amenities and barrier-free designs. Aesthetics examines the visual appeal, harmony of landscape elements, and integration of cultural or artistic features, ensuring the park is both attractive and reflective of local identity. Ecological quality evaluates sustainability, including vegetation coverage, biodiversity, water and air quality, and the use of eco-friendly materials or systems. Finally, user experience measures comfort, safety, and inclusivity, considering whether the park meets the needs of various groups, maintains a balance between crowdedness and tranquility, and provides spaces for relaxation and interaction. A high-quality urban park balances these elements, fostering harmony between humans and nature while enhancing public well-being and environmental awareness. The quality evaluation of urban park environmental design could be attributed to MADM problem. In this study, TFNN-CE approach is executed under TFNSs. Then, the entropy is employed to execute the weight under TFNSs and TFNN-CE approach is executed for MADM under TFNSs. Finally, numerical example for quality evaluation of urban park environmental design is executed the advantages of TFNN-CE approach through different comparisons. The major contributions of this study could be executed: (1) entropy is employed to execute the weight under TFNSs; (2) TFNN-CE approach is executed under TFNSs; (3) TFNN-CE approach is put forward for MADM under TFNSs; (4) numerical example for quality evaluation of urban park environmental design is executed the advantages of TFNN-CE approach through different comparisons.

There may be possible study limitations, which could be executed in future research: (1) TFNN-CE approach doesn't take into account the irrational state of DMs, and it may be worthwhile research point to execute prospect theory [79-82] for quality evaluation of urban park environmental design under TFNSs; (2) It may be meaningful to avoid regretful MADM, and it could also worthwhile research point to execute regret theory [83-86] for quality evaluation of urban park environmental design under TFNSs.

Improved YOLOv11pose for Posture Estimation of Xinjiang Bactrian Camels

Lei Liu, Alifu Kurban,Yi Liu
Department School of Software, Xinjiang University, Urumqi, China

***Abstract*—Automatic pose estimation of camels is crucial for long-term health monitoring in animal husbandry. There is currently less research on camels, and our study has certain practical application value in actual camel farms. Due to the high similarity of camels, this has brought us a huge challenge in pose estimation. This study proposes YOLOv11pose-Camel, a pose estimation algorithm tailored for Bactrian camels. The algorithm enhances feature extraction with a lightweight channel attention mechanism (ECA) and improves detection accuracy through an efficient multi-scale pooling structure (SimSPPF). Additionally, C3k2 modules in the neck are replaced with dynamic convolution blocks (DECA-blocks) to strengthen global feature extraction. We collected a diverse dataset of Bactrian camel images with farm staff assistance and applied data augmentation. The optimized YOLOv11pose model achieved 94.5% accuracy and 94.1% mAP@0.5 on the Xinjiang Bactrian camel dataset, outperforming the baseline by 2.1% and 2.2%, respectively. The model also maintains a good balance between detection speed and efficiency, demonstrating its potential for practical applications in animal husbandry.**

***Keywords*—YOLOv11pose; efficient channel attention; multi-scale pooling structure; DECA-block; Bactrian camel posture estimation； SimSPPF; ECA**

I. INTRODUCTION

With the continuous large-scale development of the modern camel farming industry, their farming methods have gradually changed from traditional free-range farming to cluster farming. The cluster farming method makes the breeders pay more and more attention to the healthy development of camels. Breeders increasingly recognize the critical role of health management in selecting and cultivating high-quality camel breeds. As an essential metric of health management, posture estimation is gaining growing attention. It provides scientific data for complex behavior analysis and health monitoring tasks, extending beyond the scope of traditional detection methods and better adapting to diverse scenarios. By estimating the key points of camels, we can further analyze their behaviors. The external behaviors of camels often reflect their health conditions. For instance, daily postures such as standing or walking can indicate their activity level, as camels tend to reduce activity when ill [1]. However, long-term manual observation and recording of individual information are time-consuming, costly, and subjective. Currently, many researchers use various sensors to monitor animal behavior [2-5]. Nevertheless, wearable sensors have limitations, as they may stress the animals and impact their natural growth and development. In contrast, machine vision offers long-term, non-contact continuous monitoring and has gradually been applied in precision livestock farming to monitor livestock activities and health conditions. With the rapid advancements in image processing [6], pattern recognition [7], and artificial intelligence [8], machine learning applications in China's animal husbandry are also increasing. Machine vision-based camel posture detection facilitates comprehensive analysis and rapid assessment of camel growth and development [9].

The rapid development and widespread application of computer vision technology provide robust technical support for the intelligent, precise, and scientific modernization of livestock farms. The mature implementation of these technologies has laid a solid foundation for the advancement of modern animal husbandry [10]. Through object detection techniques and keypoint detection algorithms, it is possible to extract the key features of animal postures, which can then be connected to form skeletal structures, enabling accurate posture estimation [11]. In the task of pose estimation, our focus is on ensuring the accuracy of keypoint detection. During the detection process, we often encounter various complex problems that can affect the accuracy of keypoint detection. For example, camels have relatively large bodies, and diverse poses, and tend to move in close groups. These problems can cause key points on certain parts of camels to be obscured by other camels or objects. In addition, the deformation of features on camels in different poses can cause key points to blur, thereby affecting the model's detection of skeletal key points. These problems not only affect the accuracy of keypoint localization but also the precision of detection boxes. If the skeletal features extracted from the image are incomplete, accurate pose estimation cannot be performed.

To address the aforementioned challenges, we have proposed a Bihumped Camel pose estimation framework, named YOLOv11pose-Camel, which is designed to effectively process camel information in various forms and environments. Specifically, we first utilize channel attention and multi-scale pooling to enhance sensitivity to detailed features. Secondly, the error under complex postures is further reduced by incorporating our DECA-Block module. The main contributions of this paper are as follows:

1) We used data augmentation techniques to cover a variety of environments with camels in the dataset and applied the improved YOLOv11-pose algorithm to our self-built dataset.

2) We introduced the ECA lightweight channel attention mechanism into the model to enhance the algorithm's multi-scale feature extraction ability. The model effectively reduced

the extraction of non-camel features and focused more on the precise identification of camel skeleton points [12].

3) To further enhance the algorithm's ability to identify skeleton key points, we combined the algorithm with the efficient multi-scale pooling structure SimSPPF. This can effectively reduce the precision error caused by occlusion.

4) We introduced the improved dynamic convolution module DECA-Block into the neck module of the YOLOv11-pose model. This module combines dynamic convolution and an efficient attention mechanism. This design not only reduces the model's weight but also maintains a high accuracy. In particular, the module shows strong adaptability to feature deformation problems.

The algorithm adopted in this study can meet the actual needs for detecting camel skeleton key points. Meanwhile, the method can infer the information of occluded skeleton points. Section II of the paper reviews the current research status on Bactrian camel posture estimation both domestically and internationally, as well as its application in animal husbandry. Section III describes the overall network structure and focuses on the proposed YOLOv11pose-Camel method, which integrates the ECA channel attention mechanism, the multi-scale feature module SimSPPF, and the dynamic convolution module DECA-Block. Section IV introduces the experimental dataset, evaluation metrics, and recognition performance, followed by comparative analyses and experimental results on the custom dataset. Finally, Section V summarizes the main contributions and outlines potential future research directions.

II. Related Work

In recent years, pose estimation based on keypoint detection has significantly advanced image recognition and analysis technologies, achieving notable progress in animal posture detection. In early studies, Fang et al. (2017) introduced a novel multi-person pose estimation framework called RMPE, aimed at enhancing the adaptability of deep convolutional networks to inaccuracies in bounding box localization. This innovation not only improved feature extraction efficiency but also laid the foundation for subsequent developments in multi-person pose estimation. However, since RMPE was primarily designed for humans and camels possess unique body shapes and complex keypoint distributions, it cannot effectively estimate camel poses [13]. In 2018, Zheng et al. incorporated Faster R-CNN into a deep learning framework for pig posture estimation, enabling the detection of five posture changes (standing, sitting, sternal recumbency, ventral recumbency, and lateral recumbency) to reflect the health status of sows [14]. However, the more drastic posture variations in camels make it challenging for a single Faster R-CNN framework to capture their dynamics. Similarly, Song et al. (2018) proposed a model for skeletal extraction based on keypoint prediction in walking states, which performed well in detecting cow walking postures [15]. Comparatively, research focused directly on camel posture estimation remains limited. In 2020, Chen et al. utilized the real-time instance segmentation framework YOLACT for pig body part tracking [16]. However, camels' unique physiological structures, especially the presence of humps, add significant challenges in segmentation and localization. In 2023, Zheng et al. developed the ViT-BERT pose estimation model for rapid posture changes in small animals within dynamic scenes. While this model demonstrated good accuracy and speed in bird testing, it is less suitable for large animals like camels [17]. Also in 2023, Natesan et al. proposed a YOLOv5-based algorithm incorporating adaptive attention mechanisms to estimate occluded key points, improving measurement accuracy and achieving precise livestock behavior recognition [18]. In 2023, Agullo and colleagues combined MobileNetV3 with Vision Transformer (ViT) for animal pose detection, aiming to perform real-time pose estimation with lower computational resources. This approach aligns well with the current needs of automated livestock farms [19]. However, for large animals with complex postures, higher resolution and deeper feature extraction are required, and resource constraints may limit accuracy. In 2022, Wang et al. introduced a dynamic convolution and bidirectional LSTM time series ensemble, which considered long-term posture tracking and showed good performance in complex groups [20]. However, this method has not been fully explored in applications where posture changes frequently or under occlusion conditions. In 2023, Zhao and his colleagues enhanced their model by combining ResNet with LSTM for behavior recognition and pose detection, allowing for the identification of abnormal situations while recognizing poses. This algorithm primarily applies to animals with uniform body types, and the complexity and specificity of camel bodies pose significant challenges for applying this technology to camel pose detection [21]. In 2023, Barney and his research team used deep learning methods for cattle detection and pose estimation. They modified Mask-RCNN to estimate poses in video sequences for each cow and applied the CatBoost gradient boosting algorithm to combine all features, using triple cross-validation to determine accuracy. This method proved highly effective for detecting hoof issues in cattle, which is critical for animal health. However, the same measurement point localization is not suitable for camels, as their body structure is more complex [22]. Additionally, in 2024, Dhivya Mohanavel and others proposed an animal detection early warning system based on deep learning and computer vision technologies for the livestock environment, further highlighting the growing importance of these technologies in the agricultural industry [23]. This research offers valuable insights into the practical application of animal management in real-world agricultural settings; however, it has not been thoroughly explored in the context of precise analysis of bipedal pose characteristics.

The aforementioned research demonstrates the effectiveness of non-contact monitoring methods and highlights significant progress in this field. In the future, non-contact computer vision methods are likely to become mainstream in research, not only effectively reducing labor costs but also promoting animal welfare. Existing technologies have shown certain success in animals such as humans, cattle, and pigs, but camel pose estimation still faces numerous challenges. Due to camels' unique body structure, gregarious nature, and variability, pose estimation becomes particularly difficult. With the development of computer vision technologies [24], there is potential for further research on optimization models focused on camels, which could better

support their morphological evaluation and health monitoring. This would not only enhance the practical value of the model but also provide valuable insights for the application of deep learning and computer vision in agriculture.

III. Research Methodology

The YOLOv11-pose model is a deep convolutional network based on YOLOv11, designed with an end-to-end unified structure rather than the traditional two-branch composition commonly used in pose estimation. This single-stage network performs both keypoint localization and partial affinity field prediction simultaneously, enabling pose estimation through joint training of object detection and keypoint detection. Initially developed for human pose estimation, the model has demonstrated promising results in animal pose estimation as well. The YOLOv11pose-Camel model consists of four main components: input, backbone, neck, and head. The lower-level features provide detailed information about object positions, while higher-level features capture stronger semantic information. In the input stage, multiple convolutional layers (Conv) preprocess the input image to the dimensions required for model training and extract preliminary features. The backbone includes several C3K2 modules, which merge features from different layers and pass the refined features to the SimSPPF module for further multi-scale processing. Subsequently, the ECAttention module enhances the feature extraction process by emphasizing attention mechanisms, capturing the relational information between different spatial regions through feature fusion. This allows the model to focus on critical feature regions, improving detection performance and convergence speed. In the neck, the PAN structure is employed [25], and the DECA-Block module is integrated to enhance the network's capability in multi-scale feature integration. The head network adopts depthwise separable convolution to process the network's outputs and convert them into the required format for the output layer. This design reduces computational overhead without compromising keypoint accuracy, ensuring model stability. The proposed model architecture is illustrated in Fig. 1.

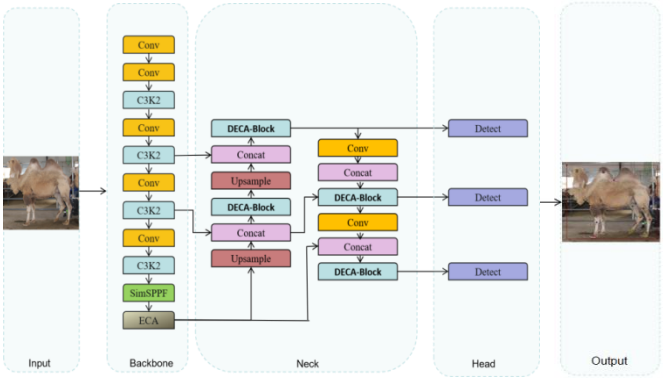

Fig. 1. Architecture of the YOLOv11pose-camel model.

A. ECAttention Mechanism

In deep convolutional neural networks, the primary function of channel attention mechanisms is to enhance the model's focus on significant features, enabling more precise feature extraction and improved performance. As input images pass through convolutional networks, spatial information is gradually embedded into channels. However, repeated spatial compression or channel expansion may lead to the loss of some semantic information. By dynamically assigning higher weights to important features, the model can concentrate more effectively on task-relevant features, thereby enhancing accuracy [26]. Thus, channel attention mechanisms are critical in deep convolutional neural networks. To achieve a balance between detection speed and efficiency, we chose to employ the lightweight Efficient Channel Attention (ECA) mechanism [27]. ECA improves upon the SENet architecture by removing fully connected layers and replacing them with a 1*1 convolution kernel. This introduces a local cross-channel interaction strategy with reduced dimensionality, effectively meeting the requirements for balancing detection accuracy and speed. Specifically, the ECA module adaptively determines the kernel size k for one-dimensional convolution based on the number of input channels. The calculation formula is as follows:

$$F = CNN(I)[k = |\frac{log_2(C)}{\gamma} + \frac{b}{\gamma}|_{odd}] \quad (1)$$

Where C represents the number of channels for the input feature, γ and b is the hyperparameter. The core idea of the ECA module is to introduce a one-dimensional convolution operation into the relationship between input feature channels after determining kernel size k. The ECA attention mechanism first performs global average pooling operations on the input feature maps to generate global information. Then, the module performs one-dimensional convolution processing with kernel size k on the globally pooled information. The activation function maps the weights nonlinearly to obtain the weights for each channel. Finally, these weights are multiplied with the original input feature graph channels to produce output features that incorporate the attention weights. The detailed flow of the attention mechanism is shown in Fig. 2.

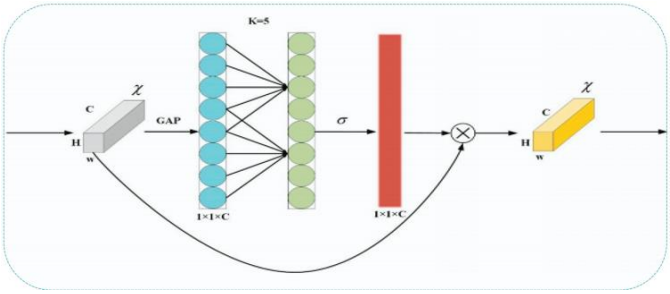

Fig. 2. ECAttention workflow diagram.

B. SimSPPF

SimSPPF (Simplified Space Pyramid Pooling Fast) is an optimized version of the fast version of the space pyramid pooling (SPPF) based on the classic space pyramid pooling (SPP). SPP is an improved version of the classic space pyramid pooling. The feature map is pooled at multiple scales to improve the receptive field in SPP. Although this method has significant effects, the computational cost is high. SPPF reduces redundant content, not only improving the efficiency of feature extraction but also reducing memory usage. The main innovation of SimSPPF is the hierarchical structure, which divides nodes into different layers according to their

size, and the number of nodes in each layer is twice that of the previous layer. SimSPPF can reuse allocated nodes, which reduces the computational cost. In addition, this improvement reduces the dimensionality of the feature network. Specifically, SimSPPF replaces the activation function in the original SPPF with a new activation function (ReLU). This combination of multi-scale pooling methods not only captures multi-level feature information but also ensures a certain detection ability in different scenarios. Fig. 3 shows the structure design of SPP, and Fig. 4 shows SPPF and SimSPPF.

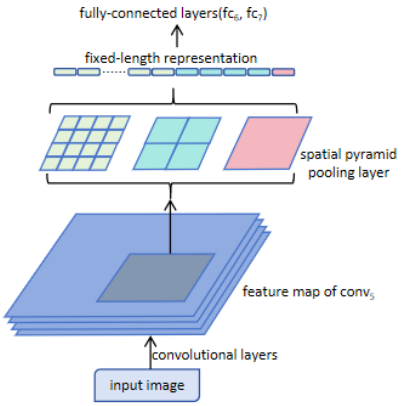

Fig. 3. Structure of SPP.

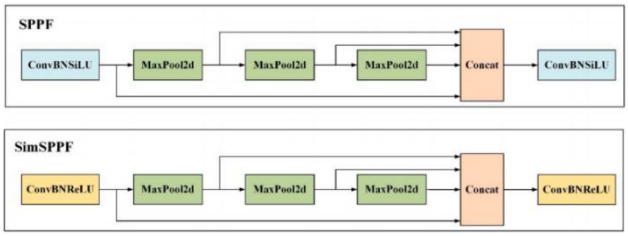

Fig. 4. Structures of SPPF and SimSPPF.

C. DECA-Block

The neck module primarily optimizes and fuses the features from the backbone network, improving the performance of key point detection tasks. When handling features of varying scales and backgrounds, the neck module addresses issues such as feature variation and keypoint occlusion, particularly in dealing with multi-scale features [29].

To enhance the model's understanding of feature details and structures, inspired by feature extraction components, we propose a dynamic convolution module called DECA-Block, designed for keypoint detection of various parts of Xinjiang Bactrian camels. This method helps mitigate keypoint localization errors and feature deformation among camels, adapting effectively to complex environments to balance model accuracy and efficiency. Specifically, the module incorporates the efficient feature extraction capability of the EMAttention mechanism and the deformable convolution network (DCNv3) into the bottleneck structure. EMAttention focuses on critical features and guides their transmission to DCNv3, which adapts to feature variations spatially. This enables the model to better capture key points across different scales and semantic levels, thereby improving detection accuracy. Such direct interaction enhances the attention mechanism's performance on deformed features, providing distinct advantages for complex shapes and occluded key points. Additionally, it reduces redundant computation and improves overall model performance and efficiency. The specific structure of the DECA-Block module is shown in Fig. 5.

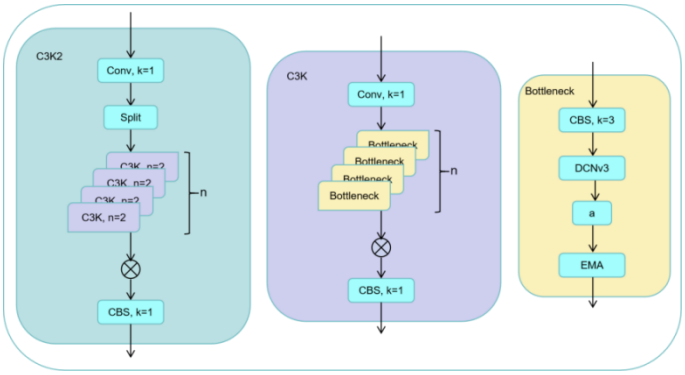

Fig. 5. D3E-C3K2 module.

D. Bactrian Camel Pose Estimation Method

The algorithm analyzes the three-dimensional joint position information contained in the two-dimensional image to achieve the analysis of the target pose. Based on this, the algorithm fully utilizes contextual information to solve the problem of joint overlap. Contextual information includes precise detection of joint positions, modeling of camel pose through structured constraints, and estimation of joint relative position relationships through analysis. Each object possesses its unique anatomical structure, and these structural constraints provide critical prior knowledge to the model. In cases where certain joints are occluded, this prior knowledge effectively aids the model in achieving more accurate pose estimation [30].

$$J = \{j_1, j_2, \dots, j_n\} \quad (2)$$

Where j_n is the position vector of the n-th joint. The structure of the camel pose can be represented by a set of distance constraints between joints.

$$D_{ij} = \| j_i - j_i \|, \forall i, j \in \{1,2, \dots, n\} \quad (3)$$

These distance constraints D_i can be learned from the training data. During the pose estimation process, they are widely used to help the model infer the positions of joints that are not directly observable due to occlusion. YOLOv11-pose extracts feature maps from input images through convolutional neural networks (CNN). Assuming the input image is represented as i, the feature maps extracted by the CNN are denoted as F . These feature maps provide multi-scale structured information, laying the foundation for subsequent pose estimation tasks.

$$F = \mathrm{CNN}(I) \quad (4)$$

The feature maps F contain multi-scale features and rich contextual information of the image, which play a vital role in predicting the positions of skeletal joints. During the prediction of joint locations, the model relies not only on local features but also heavily on global features derived from the overall structure. The rich contextual information further provides comprehensive support. Additionally, the model leverages

multi-level information to accurately analyze pose characteristics. For instance, for certain occluded skeletal key points j_k, the model can utilize the information from other detected key points in the feature map and infer the position by combining global contextual features. Annotated data sets are fed into the model for training, preparing it for subsequent pose estimation tasks. The annotations for Bactrian camels are illustrated in Fig. 6.

$$j_k = f(F, j_1, j_2, \dots, j_{k-1}, j_{k+1}, \dots, j_n) \quad (5)$$

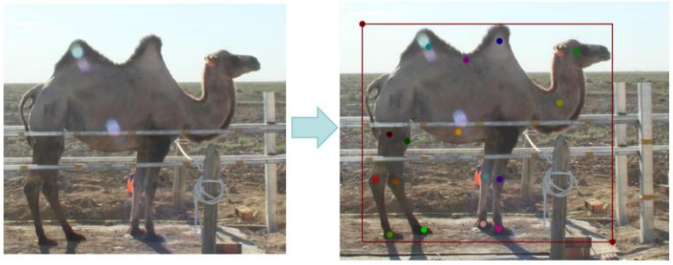

Fig. 6. Annotation of Bactrian camels.

IV. Preparation and Analysis

A. Dataset Preparation

In this study, a Canon 60D camera equipped with an 18-135mm lens was used for data collection. The initial image capture took place in December 2020 in Ziniquanzi Town, Fukang City, Xinjiang Uygur Autonomous Region, where images of Xinjiang Bactrian camels were recorded. Later, in March and April 2021 and July 2021, further collection was carried out, which included various lighting conditions, different angles and distances, and diverse obstruction scenarios, resulting in the acquisition of 90 high-quality images. Considering the limited dataset size, additional data collection was conducted in September 2023 in Keeping County, located in the western Aksu Prefecture of Xinjiang, a region renowned as the "Camel City of Xinjiang." This supplementary collection carried out in collaboration with the local Xintuomilk Group, added approximately 252 effective images to the dataset.

1) Images selection: We constructed a dataset containing 1,084 images for the study of Xinjiang Bactrian camel pose estimation. The data collection was conducted across multiple scenarios and seasons, resulting in images captured under varying lighting conditions influenced by changes in sunlight.

2) Key points selection: We utilized the open-source image annotation tool Labelme [31] for manual annotation of the images. During the annotation process, we focused on creating bounding boxes around Bactrian camels to minimize the area of detection boxes and reduce the influence of unrelated factors. Due to the unique structure of Bactrian camels, we annotated 1 rectangular box ("camel") and 16 key points (A, B, C...P), representing the head, neck, first hump, back, second hump, tail, right hind knee, right hind ankle, right hind hoof, abdomen, right foreleg knee, right foreleg hoof, left foreleg knee, left foreleg hoof, left hind knee, left hind ankle, and left hind hoof. Invisible skeletal key points were labeled as "1." An example of the key point annotations is shown in Fig. 1. These annotations were saved as text files, corresponding to the image filenames, providing a solid foundation for subsequent training.

3) Data augmentation: We introduced various data augmentation techniques [32] in the training set to enhance the model's robustness in different scenarios and its adaptability to complex environments. These techniques included adding random noise, simulating varying levels of occlusion, and performing operations such as mirroring, flipping, rotating, cropping, and stitching at random locations. These methods effectively simulated real-world scenarios the model might encounter. The model not only provides a reliable scientific basis and data support for Bactrian camel morphological evaluation based on pose estimation but also ensures accuracy and comprehensiveness in the evaluation process. Data augmentation examples are shown in Fig. 7.

4) Dataset formatting: To ensure the dataset's representativeness and the reliability of model training, we randomly sampled images collected at different times. These samples were divided into three parts: the training set, validation set, and test set. The training and validation sets comprised 80% of the total dataset, with a 9:1 split between them. The remaining 20% was allocated to the test set for final model evaluation. Special attention was given to ensuring that the collection times of images in the test set differed from those in the training set, effectively reducing potential interference caused by temporal sequence effects on model performance evaluation.

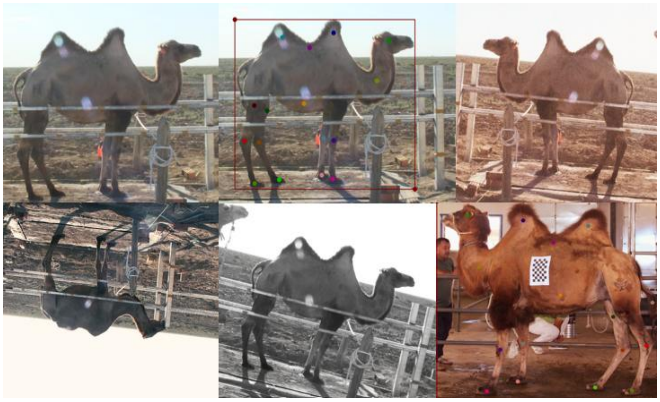

Fig. 7. Results of data augmentation.

B. Main Hardware Equipment

The data collection equipment includes a Canon 60D camera, an 18-135mm lens, and a stereo camera with frame synchronization. For model training, the computational hardware utilized an NVIDIA GeForce RTX 4090 GPU, with PyTorch version 2.1.0 and Python version 3.10. The GPU computation platform was based on CUDA version 12.1. The model's input size was set to 640×640.

C. Evaluation Metrics

The evaluation metrics for Camel-YOLOv11pose include Mean Average Precision (mAP50), Mean Average Precision at thresholds ranging from 0.50 to 0.95 (mAP50-95), Precision

(P), Recall (R), and Parameters (Params). The mAP50-95 metric evaluates the average precision at different IoU thresholds from 0.5 to 0.95, providing a more comprehensive assessment of the model's performance [33].

D. Experimental Results and Analysis

1) Comparative experiments: We conducted comparative experiments to verify the performance of the proposed model in the pose estimation task and compared it with several classic pose estimation algorithms across multiple metrics. To ensure the scientific rigor of the experiment, we adopted the same strategy as in the ablation experiments. All experiments used the same evaluation metrics and were tested on the same dataset.

TABLE I. MODEL COMPARISON RESULTS

Camel	P	R	mAP50	mAP50-95	Parameters	FPS
YOLOv7n-pose	90.2	89.6	87.7	68.5	34930376	140.8
YOLOv8n-pose	91	94.3	90.5	77.9	2971999	163.9
YOLOv8m-pose	90	94.2	89.8	75.9	23820511	181.8
YOLOv8s-pose	91.4	95.1	91.7	78.3	10324383	144.9
YOLOv11n-pose	92.4	90.7	91.9	79.6	2869783	166.6
YOLOv11pose-Camel	94.5	94.3	94.1	82.8	2678642	147.6

As shown in Table I, our YOLOv11pose-Came model performs better in the camel pose estimation task for the Bactrian camels of Xinjiang. Although both YOLOv7-pose and YOLOv8-pose used pre-trained weights as initial settings, their keypoint prediction [34] accuracy did not reach the baseline model's level. While the FPS slightly decreased compared to the original YOLOv11-pose baseline model, other metrics were improved. Compared to YOLOv7n-pose, YOLOv8n-pose, YOLOv8m-pose, YOLOv8s-pose, and YOLOv11n-pose, the improved model's mAP50 increased by 6.4, 3.6, 4.3, 2.4, and 2.2 percentage points, respectively. Although YOLOv8m-pose has a higher FPS than the improved model, its larger parameter size leads to higher memory consumption. Therefore, this study effectively improves the accuracy of camel pose estimation for Xinjiang Bactrian camels while ensuring detection speed, validating the effectiveness of the proposed method. The model comparison results are shown in Table I [28].

2) Ablation experiments: Based on the current YOLOv11pose-Camel model, we designed ablation experiments to evaluate the enhancement effects of the proposed modules and their contributions to algorithm performance. These experiments aim to analyze the impact of individual modules in depth. First, we introduced the ECAttention mechanism into the backbone feature extraction network to enhance the network's focus on key points. Next, we replaced the original SPPF module in the existing feature extraction network with the SimSPPF module. Finally, we integrated the C3K2 module with the DECA-Block module, which combines the EMAttention mechanism and DCNv3 dynamic convolution. We conducted experimental evaluations of each improvement strategy on the same dataset. To ensure the accuracy of the results, we used the same evaluation metrics to measure the contribution of each improvement to the network. From these experiments, it can be observed that each module contributes to varying degrees of improvement in the overall performance of the model. Through the pose estimation algorithm, we successfully obtained accurate skeletal key points. The relevant experimental details and test results are shown in Table II.

TABLE II. ABLATION EXPERIMENT RESULTS

	P	R	mAP50	mAP50-95
YOLOv11-pose	92.4	90.7	91.9	79.6
ECAttention	93.3	91.9	92.5	81.7
SimSPPF	92.9	90.8	93.4	79.7
SimSPPF-ECA	93.8	92.2	93.3	82.5
YOLOv11-pose-Camel	94.5	94.3	94.1	82.8

3) Bactrian camel pose estimation: We determined the position information of the key points by using the pose estimation algorithm, and then inferred the occluded key points using Eq. (5). These key points allow for a more accurate description of the camel's skeletal structure and dynamic changes, providing scientific data for subsequent studies on the morphology of Bactrian camels [35]. Some training results of YOLOv11pose-Camel are shown in Fig. 8.

Fig. 8. Partial training results.

V. SUMMARY AND OUTLOOK

A. Summary

In this study, we explored the pose estimation method for Bactrian camels and conducted detailed technical analysis and experimental validation. By introducing the YOLOv11pose-Camel optimization design, we successfully achieved an efficient fusion of object detection and pose estimation, improving recognition accuracy and real-time performance under complex backgrounds. The model significantly enhanced the ability to recognize skeletal key points of different parts of Bactrian camels. YOLOv11pose-Camel maintained good.

Performance under various experimental conditions, achieving evaluation metrics (precision, recall, mean average precision) of 94.5%, 94.3%, and 94.1%, respectively. These performances surpassed existing models such as YOLOv8pose, YOLOv7pose, YOLOv5pose, and the base model YOLOv11pose used in this study. The improved model reduced parameters by 0.191 million, and the FPS reached 158.73, reflecting a significant improvement in detection speed

and real-time performance, making it highly suitable for rapid deployment and cross-device portability.

In the context of the current development of intelligent farming, pose estimation and real-time monitoring of Bactrian camels are becoming increasingly important. Pose estimation lays the technical foundation for subsequent morphological evaluation (such as hoof health and rumination), which can ensure the healthy development of camels at an early stage, providing valuable insights into enhancing economic value. Therefore, the results of this study hold significant appeal for camel breeders [36], [29].

B. Outlook for the Future

Although this study has made certain progress in some areas, there are still some limitations.

1) This research focuses on pose estimation for Bactrian camels in Xinjiang, and we plan to extend the study to include more breeds in the future to address this issue. For example, we aim to study camels from different regions, environments, and breeds, thereby improving the practical applicability of the model developed in this research [37].

2) While we have achieved the expected results in addressing feature deformation issues through algorithm optimization, there is still a gap to higher performance metrics. Therefore, future work should explore methods to further improve the model's accuracy and performance.

Looking ahead, integrating more advanced computer vision techniques and incorporating multimodal frameworks could better facilitate information fusion [38], enhancing the model's ability to extract features. This would significantly improve the accuracy and practicality of pose estimation, especially for large-scale precision breeding farms with abundant resources. These improvements could make our framework more practical and promote the development of livestock farming in Xinjiang.

ACKNOWLEDGMENT

This research is funded by the Natural Science Foundation of Xinjiang Uygur Autonomous Region (No. 2021D01C082). We would also like to express our sincere gratitude to Xinjiang Xintuo Dairy Group for their strong support.

A Hybrid Machine Learning Approach for Continuous Risk Management in Business Process Reengineering Projects

RAFFAK Hicham[1], LAKHOUILI Abdallah[2] , MANSOURI Moahmed[3]
Faculty of Sciences and Techniques University, Hassan 1 st Settat, Morocco[1]
Faculty of Sciences and Techniques University, Hassan 1 st Settat, Morocco[2]
National School of Applied Sciences University, Hassan 1 Berrechid, Morocco[3]

***Abstract*—This study proposes a hybrid machine learning approach for continuous risk management in Business Process Reengineering (BPR) projects. This approach combines supervised and unsupervised learning techniques, integrating feature selection and preprocessing through Principal Component Analysis (PCA), clustering with K-means, and visualization with t-SNE. The labeled data are then used as input for predictive modeling with XGBoost, optimized using Particle Swarm Optimization (PSO), Grey Wolf Optimizer (GWO), and Grid Search algorithms.PCA reduces data dimensionality, simplifying analysis and improving model performance. K-means and t-SNE are employed for data clustering and visualization, enabling the identification of risk segments and uncovering hidden patterns. XGBoost, a powerful boosting algorithm, is utilized for predictive modeling due to its efficiency, accuracy, and ability to handle missing values. Optimization techniques further enhance XGBoost's performance by fine-tuning its hyperparameters. The approach was applied to a risk database from the automotive sector, demonstrating its practical applicability. Results show that PSO achieves the lowest mean squared error (MSE) and root mean squared error (RMSE), followed by GWO and Grid Search. Mahalanobis distance yields more accurate clustering results compared to Euclidean, Manhattan, and Cosine distances. This hybrid machine learning approach significantly enhances risk detection, evaluation, and mitigation in BPR projects, offering a robust framework for proactive decision-making.**

***Keywords*—BPR; Risk management; PCA; K-means; XGBoost; PSO; GWO**

I. Introduction

In today's fast-paced and competitive business environment, organizations, companies, and enterprises consist of a series of organized and interconnected business processes and activities arranged sequentially, requiring effective and efficient management to achieve strategic objectives [1]. Business Process Management (BPM) provides a systematic approachto managing work and achieving goals [2]. Furthermore, due to the dynamic nature of business, organizations often evolve through growth, transformation, or expansion into new markets [3]. This evolution impacts business processes, which must be adjustedto align with the company's needs. Since the First Industrial Revolution, when Henry Ford introduced the assembly line, business processes have played a crucial role in managing and improving productivity [4]. Consequently, the science of processes has emerged, introducing numerous tools and techniques, such as Business Process Reengineering (BPR), as powerful methods to improve process efficiency and productivity [5]. Additionally, as dynamic components, business processes are influenced by external events and other internal processes within the same organization [6]. Thus, Business Process Management has evolved from the initial concept of Business Process Reengineering to awell-established management approach [7]. These strategies have improved the monitoring and control of efficiency, productivity, profitability, service levels, and other business objectives [8]. As companies grow, transform, or expand, the efficiency of business processes can be affected, sometimes requiring a redesign of processesto adapt to business changes [9].

With process automation and digital transformation, many manual tasks have been converted into digital platforms, suchas workflow management systems, thereby increasing productivity, efficiency, and effectiveness [10]. Automationhas provided organizations with an abundance of data and detailed records [11]. Rapid advancements in information technology, automation, and digital transformation have elevated expectations regarding the purpose of processes, even before considering their improvement or reengineering [12].

The integration of hybrid methods combining supervised and unsupervised learning offers promising prospects for continuous risk management in BPR projects. Supervised learning, which relies on labeled data, enables the creation of accurate predictive models for identifying and quantifying risks [13]. On the other hand, unsupervised learning, which does not require labeled data, excels at uncovering hidden structures and unknown patterns within the data, offering a deep understanding of potential risks. The combination of these two approaches leverages the complementary advantages of each method.

To strengthen this approach, a hybridization of unsupervised algorithms such as K-means and t-SNE with supervised algorithms like XGBoost, optimized by methods such as PSO, GWO, and Grid Search, can be used for risk management in BPR projects. K-means and t-SNE are particularly effective for clustering and visualizing data, enabling the identification of emerging risk segments and anomalies in operational data in real-time [14]. XGBoost is known for its performance in terms of precision and speed in classification and regressiontasks [15].

Optimizing XGBoost with techniques such as Particle Swarm Optimization (PSO), Grey Wolf Optimizer (GWO), and Grid Search further enhances the accuracy and robustness of predictive models [16]. PSO and GWO are particularly effective in searching for optimal solutions within complex parameter spaces, while Grid Search provides an exhaustive method for exploring possible parameter combinations.

In Section II, a literature review of the various concepts addressed in this study will be presented. Subsequently, in Section III, we will introduce the proposed approach along with the computational conditions of our model. Section IV will focus on the results and their discussion before concluding the study in Section V.

II. Literature Review

A. Business Process Re-engineering

Since its emergence in the early 1990s, Business Process Reengineering (BPR) has attracted considerable interest. Both scholars and industry professionals have extensively discussed its significance, methodologies, impacts, and success factors [9]. BPR emerged as a groundbreaking strategy aimed at fundamentally rethinking and restructuring business operations to achieve substantial improvements in metrics such as cost, quality, service, and speed [10]. Reengineering involves a radical redesign of business processes, characterized by an extensive overhaul of the organization's processes, technologies, management systems, organizational structures, and core values. The goal is to realize significant performance enhancements throughout the organization. For BPR to succeed, it must be integrated with other organizational components, leverage advanced technology, and employ various methodologies. BPR cannot thrive in isolation. Information Technology (IT) plays a critical role in BPR by providing the tools needed for exceptional organizational achievements, though its role is often misunderstood [12].

For any implementation team, the ultimate objective is to achieve a high success rate in their projects. However, the outcomes of business process reengineering initiatives have been mixed, often due to the adoption of best practices or industry benchmarks from various sectors without fully understanding the specific needs of the target industry. Notably, approximately 70% of such projects fail, largely due to the absence of an appropriate framework or methodology [8]. Nonetheless, numerous factors influence a project's outcome. These factors serve as critical indicators in predicting the project's trajectory or assessing its potential for success. BPR inherently involves risks, and its successful implementation relies on several critical success factors [17].

The successful implementation of BPR relies on several key factors, offering valuable practical insights [18]. Change management and organizational culture play a central role, emphasizing effective communication, robust motivation and reward systems, employee empowerment, continuous training and development, and a collaborative work environment. Similarly, managerial competence and support are essential, requiring strong leadership, expertise in risk management, active engagement and support from senior management, as well as an appropriate organizational structure. The BPR process itself must align seamlessly with organizational goals through strategic planning, effective project management, proper methodological application, productive consultation, and a clear BPR vision. Finally, IT capabilities are indispensable, encompassing a robust IT infrastructure, enhanced IT functionality, and the alignment of IT systems with BPR strategies to ensure successful implementation.

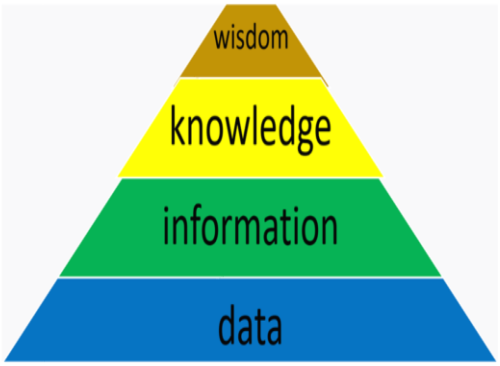

Fig. 1. Data transformation pyramid.

Agile development principles are progressively replacing traditional tools, leading to a significant transformation in engineering and management methods [19]. This evolution creates new requirements for the design and management of knowledge bases.

Data, as illustrated in Fig. 1, even in their raw state, form the foundation of layered processing systems. Their quality directly impacts their ability to generate added value, particularly in optimizing processes and improving product development [20]. An effective database should, therefore, act as a key resource to support management tools and performance indicators essential for structured and informed development [21].

However, the lack of sufficiently complete data and usable knowledge poses a major challenge. This gap hinders strategic decision-making, team coordination, and the overall optimization of product lifecycle management [22].

Data exploitation in risk management, while advantageous, faces significant challenges. The application of risk management tools such as PFMEA generates volumes of data that are often unmanageable for engineers, with heterogeneous sources and varied formats. This lack of standardization, combined with poorly structured data entry, results in duplicates and irrelevant data. Historically, risk evaluation relied on human expertise, but this approach is biased by personal experiences, leading to inconsistent and ambiguous risk identification and management across projects. This complicates the reuse of historical data and highlights the importance of data quality and standardization for effective processing [23].

B. Principal Component Analysis

Reducing the number of dimensions in large, high-dimensional datasets is crucial for effective analysis. This process can either serve as the primary objective for visualizing complex data or act as a preliminary step before further analysis, such as clustering. Principal Component Analysis (PCA) is one

of the earliest and most renowned techniques for dimensionality reduction. Initially introduced by Pearson in 1901 and later independently refined by Hotelling in 1933, where the concept of "principal components" was formally established, PCA is also known by several other names, including the Karhunen-Loeve method, eigenvector analysis, and empirical orthogonal functions. PCA remains one of the most widely used methods for creating low-dimensional representations of multivariate data (Fig. 2) [24].

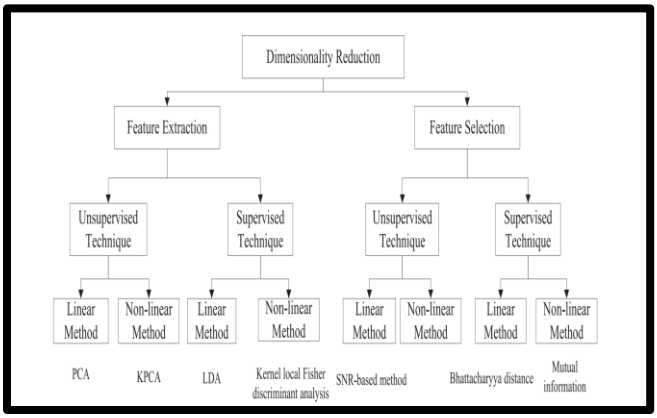

Fig. 2. Typical nomenclature of dimensionality reduction techniques.

PCA is a linear technique because it constructs components as linear combinations of the original variables (features). Despite its linearity, PCA can preserve the non-linearity of the data, making it effective for visualization purposes. The process involves iteratively calculating the direction of maximum variance and then projecting the data onto a perpendicular hyperplane. This method quickly identifies a few orthogonal directions that capture most of the data's variability, resulting in a low-dimensional representation. When all principal components are considered, the process can be visualized as a rotation in the space of the original variables. For a thorough exploration and historical context of principal component analysis, refer to [25].

C. Clustering

Clustering divides a group of individuals into several categories based on their similarities, where the differences among individuals within the same category should be as small as possible [26]. The most representative clustering methods are based on geometric distance measurement. Clustering techniques can analyze complex input data patterns and suggest solutions that might not be evident otherwise. They reveal customer typologies, enabling highly effective marketing strategies [27].

The goal of classification is to build a function or model based on the characteristics of the entire dataset and then categorize each object into a known object class. Classification has a wide range of applications, such as medical diagnosis, credit scoring, image pattern recognition, target market positioning, defect detection, efficiency analysis, graphic processing, insurance fraud analysis, [26].

Prediction involves using knowledge generated from historical and current data to deduce future data trends. While classification is used to predict classes, analysts often want to predict certain values of missing or unknown data. In other words, the desired prediction outcome corresponds to numerical data [26].

a) Positioning Euclidean distance, Manhattan distance, Mahalanobis distance and Cosine similarity: The Euclidean distance and Manhattan distance are both specific cases of the Minkowski distance. Let X and Y be two data samples, each consisting of T, elements, defined as follows:

$$X = [X_1, X_2, \cdots, X_T] \quad ; Y = [Y_1, Y_2, \cdots, Y_T] \tag{1}$$

The Minkowski distance of order p (where p is an integer) between two samples X and Y is defined by the following equation:

$$d(X,Y) = \left(\sum_{i=1}^{n} |X_i - Y_i|^p\right)^{\frac{1}{p}} \tag{2}$$

This distance metric evaluates the difference between two data samples as vectors in a multi-dimensional space, with the order p determining the emphasis on individual component differences. As p increases, larger differences in components have a more pronounced effect on the overall distance. Specifically, when p=1 and p=2, the Minkowski distance simplifies to the Manhattan distance and the Euclidean distance, respectively. As p approaches infinity, it converges to the Chebyshev distance (Fig. 3) [28].

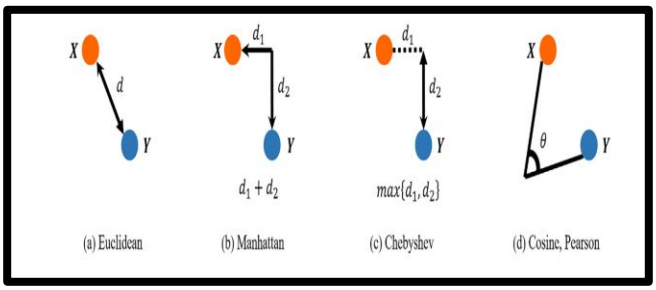

Fig. 3. Diagram of several distance measures.

The Euclidean distance is a measure of the straight-line distance between two points in Euclidean space, forming the basis of classical geometry. It is widely used as a similarity measure, particularly suitable for cases where there is no inherent correlation between different features [27]. y default, unless specified otherwise, the Euclidean distance is often employed. However, it is sensitive to the scale of the features, which can skew the results if the units are not consistent. Hence, it is generally necessary to normalize or standardize the data before applying this distance measure [28].

The Manhattan distance, also known as the city block distance or taxicab distance, calculates the distance between two points as the sum of the absolute differences of their Cartesian coordinates. The term "Manhattan distance" arises from the grid-like street layout of Manhattan, where the shortest path between two points involves a series of right-angle turns [29]. For example, in a study on personalized visual comfort control in buildings, individual user preferences and energy consumption profiles were analyzed. Collaborative user preferences were computed based on the Manhattan distance between the target occupant and others, leading to recommended adjustments in light intensity.

The Mahalanobis distance, as defined in Eq. (2), measures the distance between two vectors X and Y from the same distribution, using the covariance matrix S [30].

$$d(X,Y) = \sqrt{(X-Y)^{\top} S^{-1} (X-Y)} \quad (3)$$

where S is the covariance matrix. This distance metric extends the Euclidean distance by incorporating correlations between data points through the covariance matrix S. It is particularly effective for datasets with reduced features, although the covariance matrix can introduce unwanted redundancies. The Mahalanobis distance remains stable against projections or scaling of the data, making it useful for identifying outliers. For instance, Westermann et al. utilizedthe Mahalanobis distance to filter outliers from building energy data, classifying points farthest from the center of a multivariate Gaussian distribution as outliers [31].

Cosine similarity measures the similarity between vectors by focusing on their direction and angle rather than magnitude. The cosine similarity between two vectors X and Y is defined as:

$$cos(\theta) = \frac{\sum_{i=1}^{T} X_i Y_i}{\sqrt{\sum_{i=1}^{T} (X_i)^2} \times \sqrt{\sum_{i=1}^{T} (Y_i)^2}} \quad (4)$$

where θ is the angle between X and Y. A smaller angle indicates a higher similarity between the two vectors. The value of this equation ranges between -1 and 1. Based on this equation, the cosine distance can be defined, ranging from 0 to 2.

A study proposed a modified cosine similarity measure for initializing input weights in a building energy consumption prediction model, defined as follows [32]:

$$cos'(\theta) = \frac{\sum_{i=1}^{T} (x_i - \bar{X})(y_i - \bar{Y})}{\sqrt{\sum_{i=1}^{T} (x_i - \bar{X})^2} \times \sqrt{\sum_{i=1}^{T} (y_i - \bar{Y})^2}} \quad (5)$$

where $\bar{X}$ and $\bar{Y}$ are the mean values of X and Y, respectively.

Instead of using Euclidean distance, which is highly sensitive to magnitudes, the modified cosine similarity coefficient is used to initialize the weights connecting the input neurons and the hidden neurons in the extreme learning machine, thereby improving its generalization ability [33].

b) K-means algorithm: K-means is one of the clustering algorithms [26]. It takes the number of clusters as a parameter and partitions the data into the specified number of clusters so that the similarity within each cluster is high [34]. K-means is an iterative approach that calculates the centroid values before each iteration. It requires precise numbers of clusters k, as the initial cluster center can change, which may lead to unstable data grouping [35]. Data points are moved between different clusters based on the centroids calculated in each iteration [36]. The process is repeated until the sum of distances cannot be decreased further. The advantages of K-means include its speed and scalability: it is one of the fastest clustering models and can efficiently handle large datasets with many records and numerous input clustering fields [26]. The K-means algorithm is presented in Algorithm 1.

Algorithm 1: K-means Algorithm.

1. Initially, based on the value of k, k random points are chosen as initial centroids.
2. The distances from each data point to the previously chosen centroids are calculated.
3. The distance values are compared, and each data point is assigned to the centroid with the shortest Euclidean distance.
4. The previous steps are repeated. The process stops if the clusters obtained are the same as those in the previous iteration.

c) Evaluation criteria: Unsupervised evaluation criteria are based on internal clustering information, such as the distance between objects within a cluster and the centroid of that cluster [37]. These criteria often rely on the simplest clustering definition, which states that objects within the same cluster should be as close as possible, and objects fromdifferent clusters should be as far apart as possible. To determine if a clustering respects this intuitive definition, distance measures are calculated between cluster representatives and residual objects. These unsupervised measures evaluate both the compactness and separability of clusters. Since the definitionof cluster quality is not formally defined, numerous criteria evaluate results differently. Some criteria are used directly as an objective function and optimized by a clustering algorithm. Others are too costly to evaluate during algorithm execution and are calculated after its application.

- Silhouette Coefficient (CS):

The silhouette coefficient evaluates the compactness of clusters and their separability [35]. It can be calculated for each object, each cluster, and the entire clustering. For an object x,it is defined as:

$$CS(x) = \frac{b_x - a_x}{max(a_x, b_x)} \quad (6)$$

where a_x is the average distance between object x and all other objects in the same cluster, and b_x is the average distance between xx and all objects not in the same cluster. The coefficient $C(x)$ ranges between -1 and 1. A positive value (a_x<b_x) indicates that objects in the same cluster as x are closer to xx than objects in other groups. For a cluster, the silhouette coefficient is the average of the coefficients of objects in that cluster:

$$CS(C_i) = \frac{1}{|C_i|} \sum_{x \in C_i} CS(x) \quad (7)$$

- Clustering Evaluation

The silhouette coefficient for clustering is equal to the average of the silhouette coefficients of its clusters:

$$CS(C) = \frac{1}{K} \sum_{i=1}^{K} CS(C_i) \quad (8)$$

The silhouette coefficient ranges between -1 and 1, with a positive value indicating that the clusters are very compact and well-separated. It should be noted that calculating this index is relatively time-consuming because many distance calculations are required for its evaluation.

D. The T-Distributed Stochastic Neighbor Embedding

Nonlinear techniques offer major advantages in processing nonlinear and complex datasets. The t-distributed stochastic neighbor embedding (t-SNE), among these techniques, has become a benchmark method for dimensionality reduction and data visualization across various fields [38]. Its applications encompass a wide range of domains, including microbiome data, single-cell RNA sequencing, bird song analysis, computational fluid dynamics, genomic data, and remote sensing images, among others. The t-SNE algorithm projects complex datasets onto a 2D or 3D space while preserving the local structure of the original high-dimensional space. However, while t-SNE excels in data visualization, it lacks an intrinsic mechanism to map new data points onto the low-dimensional representation, limiting its use in classification and regression tasks [39, 40].

E. The Extreme Gradient Boosting

It is built on gradient boosting trees, Extreme Gradient Boosting (XGBoost) is an algorithm delivering significant performance improvements over traditional gradient boosting methods. Based on the Classification and Regression Tree (CART) theory, XGBoost stands out as an effective tool for addressing regression and classification problems [41]. Furthermore, XGBoost is a flexible computing library that incorporates innovative algorithms with Gradient Boosting Decision Trees (GBDT) methods [42].

The objective function of XGBoost, post-optimization, comprises two components: one for model deviation and another regularization term to mitigate overfitting. Consider D = {(x_i,y_i)} as a dataset containing nn samples and m features, where the predictive model is an additive ensemble of k base models. The prediction for a sample is expressed as:

$$\hat{y}_i = \sum_{k=1}^{K} f_k(x_i), \quad f_k \in \varphi, \qquad \varphi = \{ f(x) = w_s(x) \mid (s: \mathbb{R}^m \to T, w_s \in \mathbb{R}^T) \} \tag{10}$$

where $\hat{y}_i$ is the predicted label for the i-th sample, x_i is the i-th sample $f_k(x_i)$ is the predicted score, and φ represents the set of regression trees. which is a tree structure parameter of s, f(x) and w representing the weight of leaves and the number of leaves. The objective function in XGBoost is a combination of the traditional loss function and a term for model complexity, described by:

$$\text{Obj} = \sum_{i=1}^{m} l(\hat{y}_i, y_i^{(t-1)}) + f_i(x_i)) + \Omega(f_k) \qquad \Omega(f_k) = \gamma T + \frac{1}{2}\lambda w^2. \tag{11}$$

In this formula, the first term, $l(\hat{y}_i, y_i)$ is the traditional loss function, and the second term, $\Omega(f_k)$, accounts for the model's complexity. Here, γ and λ are parameters used to tune the tree's complexity, helping smooth the final learning weights and preventing overfitting.

F. Optimization Techniques

a) GWO algorithm: The Grey Wolf Optimizer (GWO) is an optimization method inspired by the social hierarchy and hunting strategies of grey wolves. This algorithm mimics the leadership and cooperative behavior observed in wolf packs. The wolf pack is classified into four types of wolves [43, 44]:

Algorithm 2: GWO Algorithm

(a) Alphas: The leaders of the pack, responsible for decision-making and guiding the group.
(b) Betas: These wolves act as deputies to the alphas, assisting in decision-making and other critical tasks.
(c) Deltas: Subordinate to both alphas and betas, these wolves still hold authority over omegas and include roles such as scouts, sentinels, elders, hunters, and caretakers.
(d) Omegas: The lowest ranking members of the pack, often serving as scapegoats, and must submit to all other wolves in the hierarchy.

b) PSO algorithm: Particle Swarm Optimization (PSO), developed by Kennedy and Eberhart, is inspired by the study of bird flocking behavior during their search for food [45]. The algorithm updates each particle's velocity and position by considering the best position found by any particle in the swarm and each particle's personal best position within the search space. The PSO procedure encompasses five key steps:

Algorithm 3: PSO Algorithm

(1) initialization,
(2) evaluation,
(3) updating the particle's best position (Pbest),
(4) updating the global best position (Gbest),
(5) updating the particles' velocity and position. Particles adjust their trajectories based on Pbest and Gbest, progressively converging towards the optimal solution.

Furthermore, XGBoost is a flexible computing library that incorporates innovative algorithms with Gradient Boosting Decision Trees (GBDT) methods [42].

III. Proposed Approach

Fig. 4 illustrates the structure of the proposed framework for a hybrid machine learning (ML) approach aimed at risk assessment and classification in the context of an operational process reengineering project. This framework integrates feature selection and preprocessing, unsupervised learning (UL), and supervised learning (SL) paradigms as its core components.

In the preprocessing phase, the primary objectives are attribute transformation, composite attribute splitting, dimensionality reduction, and attribute rank analysis. Principal component analysis (PCA) is the pivotal tool employed for feature selection. The UL tools employed include the k-means algorithm and t-SNE for clustering and assigning target labels to the dataset. K-means identifies the number of clusters that correspond to different risk impact levels within the dataset. t-SNE provides detailed visualizations, facilitating the understanding of clusters, patterns, and relationships between risk input parameters, a key objective in data mining. Additionally, t-SNE maps each data point to a specific cluster (target class), thereby generating a target vector for the dataset. The main purpose of the UL stage is to transform the previously unlabeled risk dataset into a labeled dataset suitable for SL.

In the SL phase, XGBoost is employed to perform regression, classification, and risk forecasting using the labeled dataset obtained from the UL stage. To further enhance the model's accuracy, grid search, particle swarm optimization, and the grey wolf optimizer algorithms are used to optimize the parameters of the XGBoost model, with the results from each

method compared. The implementation of the design is carried out in three stages: data collection, description and preprocessing, rank analysis, clustering visualization, and evaluation of the overall approach.

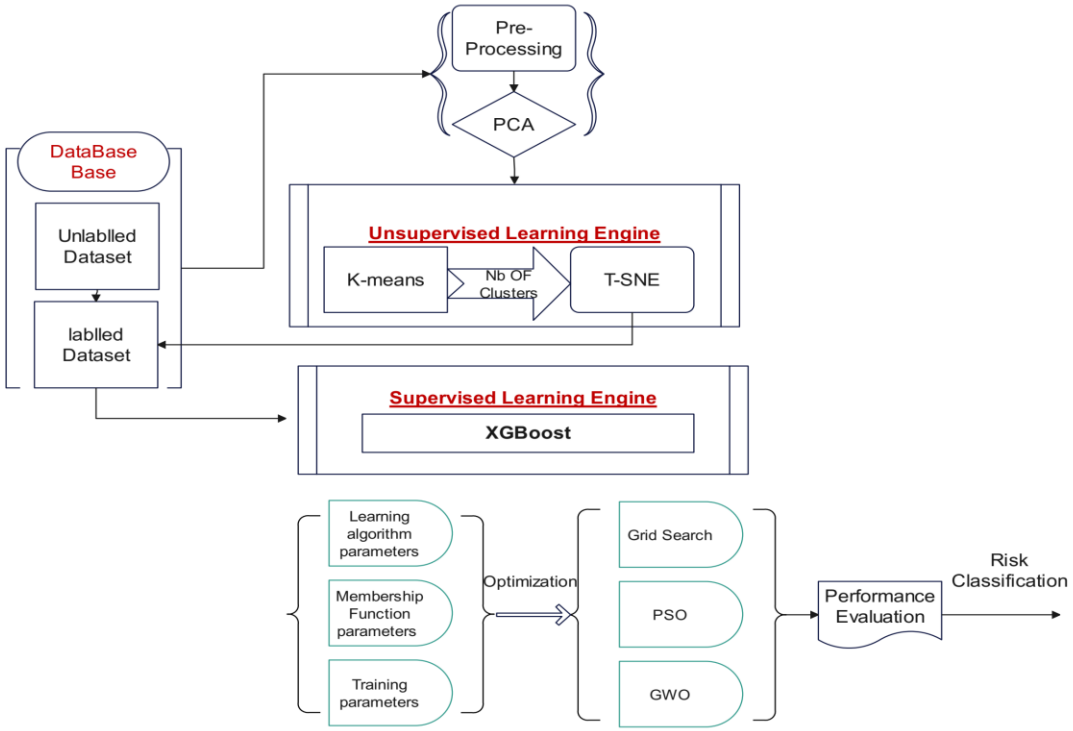

Fig. 4. Proposed approach.

IV. Results and Discussion

We applied the program to a risk database based on PFMEA register of a company operating in the automotive sector. The database consists of 11 attributes, 4 of which are numerical: the severity, occurrence, and detectability factors, and the fourth is the risk impact index, which is the RPN (Risk Priority Number), used to categorize and predict the risk.

The other categorical attributes are the risk title, owner, description, concerned part, detection tools, action to be applied, and description.

PCA is used in this code to reduce the dimensionality of the input data. The principal components capture the majority of the variance in the data while reducing the number of dimensions, which simplifies the analysis and can improve the performance of machine learning models.

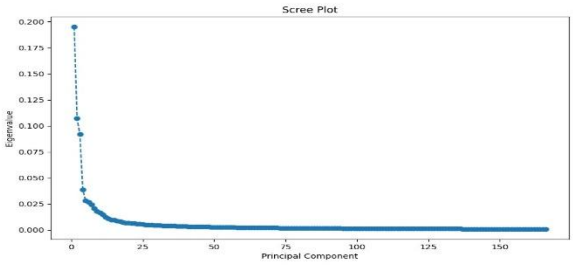

Fig. 5. Variance explained by principal components in PCA.

The Fig. 5 illustrates the eigenvalues associated with each principal component, showing the amount of variance captured by each component from the data. The graph reveals a sharp decline in eigenvalues from the first principal component to the second and third, indicating that the initial components capture most of the data's variance. After the initial drop, the eigenvalues level off, suggesting that the subsequent components contribute minimally to the total variance. This pattern generally indicates that only the first principal components are significant for explaining the dataset's variability, with the others being less important.

TABLE I. K-Means vs. Agglomerative Clustering Silhouette Scores

Algorithm	Silhouette Score
K-means	0.17712200253115506
Agglomerative Clustering	0.15189647725476427

The silhouette score is considered as a criterion for evaluating the distances between the data points and the clustering. Based on this score and by comparing the four distances: Euclidean, Manhattan, Mahalanobis, and Cosine, the Manhattan and Mahalanobis distances were shown to be more effective. However, given the advantages of the Mahalanobis distance, the authors opted for Mahalanobis distance due to its ability to consider variable correlations, which can be crucial depending on the context and nature of the data.

As shown in the Table I, when comparing the two algorithms, K-means and Agglomerative Clustering, K-means proves to be more effective with a silhouette score of 0.17712200253115506.

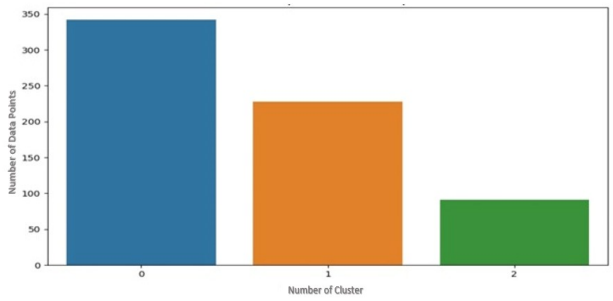

Fig. 6. Distribution of data points by cluster.

The clustering performed by the k-means algorithm identified three clusters (Fig. 6), corresponding to three levels of risk. However, based on human evaluation and as outlined in the PFMEA grid, four levels of risk are distinguished. Cluster 0 has the highest number of data points, with slightly over 300 points, indicating it is the most populated cluster. Cluster 1 follows with around 225 data points, and Cluster 2 has the fewest data points, with slightly less than 150 points. This distribution suggests that the data points are not evenly distributed among the clusters, with Cluster 0 containing the majority of the data points, Cluster 1 having a moderate amount, and Cluster 2 containing the least.

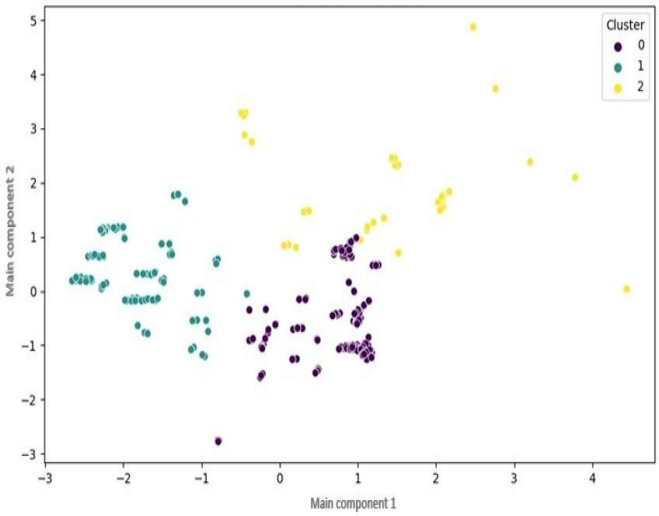

Fig. 7. Cluster visualization using ACP.

To better understand the relationship between the data, two dimensionality reduction and visualization methods were employed: PCA, a linear technique, and t-SNE, a non-linear method. For the first method (Fig. 7), although the clusters are relatively well-separated, some proximity between clusters 0 and 1 is observed.

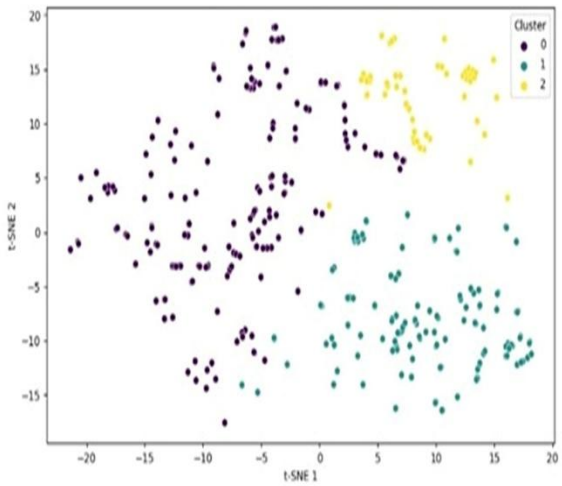

Fig. 8. Cluster visualization using t-SNE.

On the other hand, t-SNE, which leverages non-linear relationships to optimize the local representation of the data, allows for a clearer separation, particularly between clusters 0 and 2, but at the cost of less intuitive axis interpretation (Fig.8). In conclusion, PCA is suitable for data with a linear structure, while t-SNE is more effective in identifying complex relationships in non-linear data. For our dataset we adopt the t-SNE algorithm.

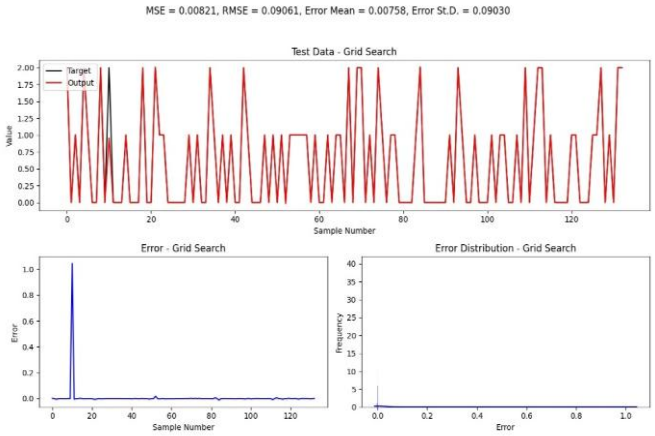

Fig. 9. Grid search optimization results: test data, error, and error distribution.

XGBoost is particularly appreciated for its performance and efficiency in machine learning competitions, as well as its ability to handle data with missing values and reduce overfitting through regularization. XGBoost is therefore a relevant choice for this type of analysis due to its robustness and ability to provide accurate results on complex datasets. In our study, we optimized XGBoost using the three techniques: GWO, PSO, and Grid Search, and evaluated the performance of our model based on two error metrics: MSE and RMSE.

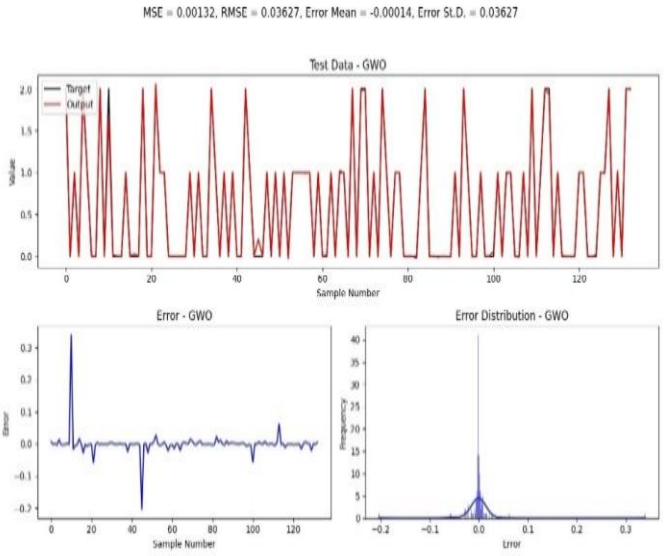

Fig. 10. GWO optimization results: test data, error, and error distribution.

The analysis of the three optimization methods—PSO (Fig. 11), GWO (Fig. 10), and Grid Search (Fig. 9)—reveals significant differences in their performance. The PSO model shows the best results with an MSE of 0.00119 and RMSE of 0.03446, indicating high accuracy as the predicted values closely follow the target values, and the error distribution is tightly centered around zero.

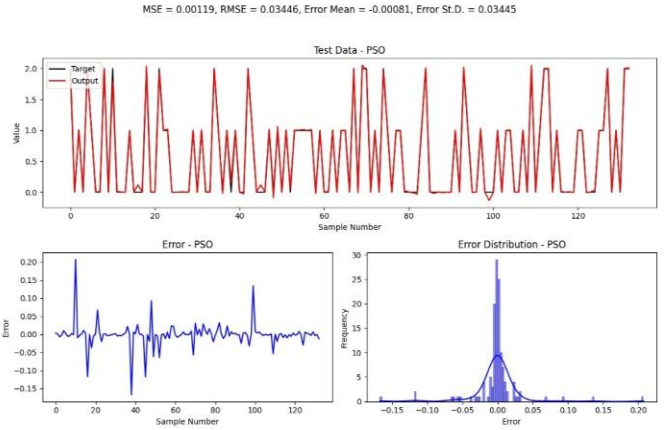

Fig. 11. PSO optimization results: test data, error, and error distribution.

The GWO model follows, with slightly higher MSE of 0.00132 and RMSE of 0.03627, showing more variation and a wider error spread compared to PSO, but still demonstrating good performance. The Grid Search model exhibits the highest error metrics MSE of 0.00821 and RMSE of 0.09061, with significant deviations and a broad error distribution, indicating poor alignment between predicted and target values and the least consistent performance among the three. Therefore, PSO is the most effective optimization method, followed by GWO, while Grid Search is the least effective.

V. Conclusion

The approach presented in this study, designed for continuous risk management in BPR projects, offers a comprehensive method that combines supervised and unsupervised machine learning techniques for effective risk management. The study present the dynamic nature of business processes and the importance of adopting strategies tailored to organizational changes. This hybrid approach leverages the strengths of unsupervised learning to uncover hidden relationships within the data and supervised learning for predictive modeling.

Algorithms such as K-means and t-SNE for clustering and visualization, and XGBoost for classification and regression, in this approach, aims to provide a robust framework for risk assessment. The optimization of XGBoost using advanced techniques like PSO, GWO and Grid Search further enhances the model's accuracy and reliability.

The article underscores the importance of using Mahalanobis distance due to its ability to consider variable correlations, which is crucial for accurate risk assessment. The authors applied their methodology to a real-world risk database in the automotive sector, demonstrating the practical applicability and effectiveness of their approach.

The results indicate that PSO outperforms other optimization methods in terms of accuracy, followed by GWO and Grid Search. The study concludes that adopting a hybrid machine learning approach can significantly improve the detection, evaluation, and mitigation of risks in BPR projects, ultimately contributing to the success of such initiatives.

In summary, the article emphasizes the value of combining supervised and unsupervised learning techniques, along with advanced optimization methods, to manage risks in BPR projects effectively. This integrated approach not only enhances predictive accuracy but also provides valuable insights into the underlying risk patterns, facilitating proactive and informed decision-making.

Enhancing CURE Algorithm with Stochastic Neighbor Embedding (CURE-SNE) for Improved Clustering and Outlier Detection

Dewi Sartika Br Ginting*, Syahril Efendi, Amalia, Poltak Sihombing
Department of Computer Science and Technology Information, Universitas Sumatera Utara, Medan, Indonesia

***Abstract*—This study focuses on analyzing stunting data using the CURE and CURE-SNE algorithms for clustering and outlier detection. The primary challenge is identifying patterns in stunting data, which includes variables such as age, gender, height, weight, and nutritional status. Both algorithms were employed to group the data and detect outliers that may affect the results of the analysis. The evaluation methods included determining the optimal number of clusters using the silhouette score and assessing cluster quality using the Davies-Bouldin Index (DBI). The results showed that both algorithms formed four clusters, with CURE-SNE detecting 6,050 outliers, while CURE detected 5,047 outliers. Silhouette score analysis revealed that both algorithms formed four optimal clusters. However, when validated using DBI, CURE achieved a score of 0.523, while CURE-SNE produced a lower score of 0.388, indicating that CURE-SNE outperformed CURE in terms of cluster quality. This suggests that CURE-SNE not only detects more outliers but also produces clusters with better separation and compactness. The findings highlight that both algorithms are effective for clustering stunting data, but CURE-SNE excels in terms of outlier detection and overall cluster quality. Thus, CURE-SNE is more suitable for handling complex datasets with potential outliers, providing more accurate insights into the structure of the data. In conclusion, CURE-SNE demonstrates superior performance compared to CURE, offering a more reliable and detailed clustering solution for stunting data analysis.**

***Keywords*—Stunting; clustering algorithm; CURE; CURE-SNE; outliers**

I. INTRODUCTION

Dataset readiness is a crucial step in the clustering process, because clean and structured data will produce more accurate and reliable clusters. Optimal dataset readiness is also an important foundation for producing accurate and representative clusters. In the clustering process, detecting and handling outliers is a critical step to prevent biased and unreliable results. In its application, outlier detection is very important, because outliers often cause distortion in cluster formation, especially when the distribution of the dataset is not uniform, resulting in the formation of less accurate clusters and even potentially influencing business decisions or misguided analysis. Outliers can come from recording errors, irrelevant data, or extreme variations that do not reflect the general trend of the dataset. Without proper detection and handling, outliers can attract cluster centers or blur the boundaries between clusters, thus making clustering results less than optimal and even misleading. A recent study published in IEEE Transactions on Knowledge and Data Engineering (2021) [1] emphasizes that the presence of outliers in a retail company's customer dataset interferes with the interpretation of customer segments and leads to less representative clustering results. Another in the Journal of Cleaner Production (2021) [2] shows that clustering algorithms density-based ones, such as DBSCAN, have better performance in automatically detecting outliers than conventional algorithms, thereby increasing the accuracy of segmentation results in user behavior analysis.

The CURE (Clustering Using Representatives) algorithm is a clustering approach that is superior in handling large datasets and has the ability to detect non-spherical cluster shapes, and is more resistant to outliers than classical algorithms such as K-Means. CURE works by selecting multiple point representations from each cluster, then compressing (shrinking) these points to the center of the cluster to increase robustness against outliers. However, despite these advantages, CURE still has limitations in handling large datasets optimally, especially if there are many outliers. The use of sampling in CURE to reduce the scale of large datasets can result in important information being missed or even failing to identify relevant outliers. Additionally, point compression methods sometimes sacrifice certain details that are actually important in complex datasets, so clustering results may not always be optimal.

The development of the CURE algorithm to overcome the challenges of large datasets and outliers is increasingly becoming the main focus in various research due to the need for more accurate and efficient clustering. One of the newest approaches that is being developed is a combination of CURE with machine learning models, such as using autoencoders to identify complex features and reduce data dimensions before clustering. In this way, the algorithm can remove noise and outliers more effectively, while preserving important information in large datasets. Additionally, research in ACM Transactions on Knowledge Discovery from Data (2022) [3] shows that integration between CURE and density-based models, such as DBSCAN, produces better clustering results on high-density data, where outliers can cause significant distortion. This approach helps CURE group data more precisely in dense areas, while isolating outliers. Furthermore, experiments on large-scale datasets show that implementing CURE in distributed computing environments, such as Apache Hadoop and Spark, allows these algorithms to handle very large datasets more quickly without sacrificing accuracy. The use of a platform like this also allows the development of more adaptive CURE algorithms, for example by automating the selection

parameters of point representations and compression measures, which are instrumental in avoiding bias from outliers.

Several recent studies have made significant contributions to the development of the CURE algorithm to improve its performance in handling large datasets and outliers problems. Research in IEEE Transactions on Big Data (2021) [26] [4] developed CURE by leveraging Apache Spark, which speeds up processing of large datasets and reduces the impact of outliers on clustering results. On the other hand, a study in ACM Transactions on Knowledge Discovery from Data (2022) [3] combined CURE with density-based DBSCAN to pre-separate outliers, which proved effective for anomaly detection in network data. Additionally, research in the Journal of Cleaner Production (2021) [2] introduces a hybrid CURE and Isolation Forest approach for handling high-dimensional data, thereby increasing precision in customer segmentation and fraud detection. Dimensionality reduction techniques using PCA before applying CURE, as proposed in Data Mining and Knowledge Discovery (2021) [5], also help simplify the data and reduce the effects of outliers, increasing clustering efficiency. Meanwhile, research in Information Sciences (2019) [6] developed an adaptive version of CURE for distributed computing environments, such as Hadoop and Spark, with optimized parameters to be more robust to outliers in large datasets. These studies emphasize the importance of developing CURE to be more efficient and accurate in real applications on large and complex data.

To address these limitations, this research introduces CURE-SNE, an enhanced version of CURE that integrates Stochastic Neighbor Embedding (SNE) for dimensionality reduction. SNE optimizes the mapping of high-dimensional data into a lower-dimensional space, effectively preserving local and global structures. This integration allows CURE-SNE to detect complex patterns and improve the identification of outliers, resulting in more accurate clustering results. By leveraging SNE's ability to emphasize neighborhood relationships, CURE-SNE enhances CURE's robustness and accuracy in clustering and outlier detection.

This paper is organized as follows:

- Section II discusses related work and advancements in CURE-based clustering methods.
- Section III describes the proposed CURE-SNE methodology and its implementation.
- Section IV presents experimental results, evaluated using *Silhouette Score* and *Davies-Bouldin Index* to assess clustering quality.
- Section V provides a discussion on the comparative analysis between CURE and CURE-SNE.
- Section VI concludes the study, emphasizing CURE-SNE's contributions to clustering accuracy and outlier detection.

The integration of SNE into the CURE algorithm represents a significant step toward improving clustering performance, particularly for datasets with complex structures and a high number of outliers.

II. Related Work

In recent years, clustering research has made significant strides in addressing critical challenges, particularly in dealing with the increasing complexity of modern datasets. Key issues such as handling large-scale datasets, managing uneven data distributions, and mitigating the disruptive impact of outliers have been at the forefront of this research. Among the most robust and widely recognized clustering algorithms designed to tackle these challenges is the CURE algorithm, short for Clustering Using Representatives. CURE stands out for its ability to effectively handle non-spherical cluster shapes and exhibit strong resistance to outliers. However, despite its robustness, CURE is not without its limitations. One of its primary challenges lies in detecting subtle, complex, and high-dimensional outlier patterns, which can significantly distort clustering outcomes if not adequately addressed.

To overcome these limitations, researchers have proposed and implemented numerous enhancements and hybrid adaptations of the CURE algorithm. For instance, the integration of CURE with Gaussian Mixture Models (GMM) has been shown to greatly improve the detection and representation of outlier patterns in high-dimensional datasets [7]. This hybrid approach has proven particularly effective in domains where data complexity is a significant factor. Similarly, the combination of CURE with Support Vector Data Description (SVDD) has resulted in a highly effective anomaly detection framework specifically tailored for network data analysis [8]. This framework capitalizes on the strengths of both density-based clustering and boundary-based detection techniques to improve the reliability of clustering results in such specialized domains.

Another major challenge associated with clustering large datasets is their high dimensionality, which can complicate data representation and analysis. To address this issue, dimensionality reduction techniques have been successfully employed. For example, research has demonstrated that combining CURE with Principal Component Analysis (PCA) not only reduces the dimensionality of the data but also preserves critical information essential for accurate clustering [9]. This combination enhances the clustering algorithm's performance and ensures better scalability for handling extensive datasets. Additionally, recent advancements have showcased the implementation of CURE on the Apache Flink framework, which is a powerful distributed computing system. This adaptation has resulted in a 45% improvement in processing speed compared to traditional methods, while maintaining sensitivity to outliers, making it an ideal solution for real-time and large-scale data processing needs [10].

The integration of deep learning with clustering algorithms has also opened up new opportunities for innovation. Hybrid models that combine CURE with deep learning techniques, such as autoencoders, have significantly enhanced the algorithm's ability to detect complex, nonlinear relationships in high-dimensional data. For example, in the context of e-commerce applications, this combination has led to remarkable improvements in clustering precision and the detection of subtle outlier patterns [13]. Similarly, hybrid approaches like CURE-DBSCAN [11] and CURE-SNE [12] leverage density-based

clustering and dimensionality reduction techniques, respectively, to handle datasets with intricate structures. These advancements underscore the adaptability, precision, and efficiency of modern clustering algorithms in addressing the challenges posed by diverse and complex datasets.

These developments are not only theoretical but also have practical implications across various fields, including health data analysis and decision-making systems. For instance, Ginting et al. (2023) [28] explored the application of fuzzy logic methods to predict neurotic disorder types. This study emphasized the critical role of precision in computational methods when dealing with sensitive medical data. Similarly, Ginting et al. (2024) [29] developed a perceptron neural network model for predicting postpartum depression. This research demonstrated the significant potential of hybrid and advanced computational techniques in addressing public health challenges and improving the accuracy of predictive analytics.

Moreover, in the domain of decision-making systems, Ginting et al. (2021) [30] introduced an innovative integration of the AHP and TOPSIS methods. This approach optimized the performance of decision support systems for identifying recipients of the Family Hope Program. This combination of multi-criteria decision-making techniques aligns closely with the broader theme of leveraging diverse computational methods to achieve optimal outcomes in complex and multi-dimensional datasets. Such methodologies not only enhance the accuracy of decision-making systems but also ensure scalability and reliability across various application areas.

In summary, the continuous evolution of the CURE algorithm and its hybrid adaptations reflects the growing demand for advanced clustering techniques capable of addressing the ever-increasing complexity of real-world datasets. These innovations have proven to be invaluable tools across multiple domains, providing practical solutions for challenges ranging from network security and anomaly detection to large-scale public health analysis and market segmentation.

III. METHODOLOGY

CURE (Clustering Using Representatives) algorithm is a clustering algorithm designed to handle large datasets and is able to work with data that has a non-spherical cluster shape, while reducing the impact of outliers. [14] One of the main advantages of CURE is its unique approach of representing each cluster with several representative points carefully selected from the data, rather than just one central point as in K-Means. [15] CURE has the advantage of generating clusters of various shapes and sizes, which makes it very effective in the analysis of complex data, such as spatial data or data that is not symmetrically distributed. By using these representative points, CURE maintains flexibility in grouping data that does not conform to simple distribution assumptions, thereby providing more robust clustering results [16].

The main steps in the CURE algorithm consist of several key stages, namely sampling, initial cluster formation, selection of representative points, and compression of representative points towards the cluster center. First, the algorithm samples the data to reduce the number of points that need to be processed, thereby speeding up computing. After that, the sampled data is grouped into initial clusters using a hierarchical clustering approach. [25] Next, for each cluster formed, the algorithm selects a number of representative points (usually several points in the area around the cluster) which will be used to describe the characteristics of the cluster. These representative points were chosen to define the shape and boundaries of the clusters more clearly, including clusters that have asymmetrical shapes [17].

To be more resistant to outliers, CURE applies a compression technique (shrinkage) to each representative point, namely shifting these points towards the cluster center by a certain factor [19]. Suppose C is a cluster with a center of mass μ and a representative point Ri (with i referring to the ith representative point in cluster C), then each point Ri is compressed towards the center μ using a shrinkage factor α which satisfies $0< \alpha <1$. The formula for moving the representative point Ri to Ri' is as given in Eq. (1):

$$Ri' = \mu + \alpha (Ri - \mu) \quad (1)$$

Ri' : New representative point after compression.

μ : The cluster center point (centroid) of cluster C.

Ri : The initial representative point selected for the cluster C.

α : Compression factor, where $0<\alpha<1$.

The parameter α controls how far the representative points will be compressed towards the cluster center. For example, a value of $\alpha = 0.5$ means that each representative point is shifted towards the center by 50% of its distance to the center. Here, the value of α plays an important role in determining how far the representative point moves towards the center. The larger the α value, the greater the influence of the cluster center on the representative point, which reduces the effect of outliers on the cluster. By performing shrinkage, the CURE algorithm reduces the influence of outliers located far from the cluster center, thereby increasing cluster stability and producing more accurate results [27].

Distance Measurement between Clusters (Hierarchical Clustering): In the CURE algorithm, clusters are initially generated through a hierarchical clustering approach. To combine two clusters, CURE measures the distance between two clusters Ci and Cj based on the closest representative point in each cluster. For example, if the representative points of cluster Ci are $\{ri1, ri2, \ldots, rim\}$ and of cluster Cj are $\{rj1, rj2, \ldots, rjn\}$, then the distance between clusters is calculated as in Eq. (2):

$$d(Ci, Cj) = \min_{p \in Ci, q \in Cj} \|rp - rq\| \quad (2)$$

$d(Ci, Cj)$: Distance between clusters Ci and Cj.

rp : Representative point in cluster Ci.

rq : Representative point in cluster Cj.

$\|rp - rq\|$: Euclidean distance between rp and rq.

This distance measure determines how close two clusters are to each other, so CURE can decide whether two clusters should be combined.

Centroid or cluster center for representative point compression, CURE calculates cluster centers using centroids. If cluster C has data points {x1,x2,…,xn}, then the cluster center μ can be calculated using the Eq. (3):

$$\mu = \frac{1}{n}\sum_{k=1}^{n} Xk \quad (3)$$

μ : Centroid or cluster center *C.*

Xk : *K* data point in the cluster *C.*

N : Number of data points in the cluster *C.*

These cluster centers are used to determine the direction and compression level of representative points.

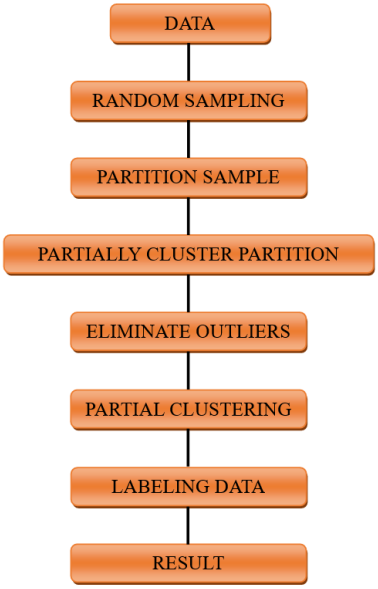

Fig. 1. CURE algorithm.

Fig.1 is the pseudocode for the CURE algorithm.

TABLE I. CURE ALGORITHM FOR CLUSTERING

Step	Description
1	Choose representative points for each cluster
2	For each point, calculate the distance to the representative points.
3	Cluster points based on the minimum distance to the representatives.
4	Repeat steps 2 and 3 until convergence or a stopping criterion is met.
5	Remove outliers: points that are far from any cluster representatives.
6	Output the final cluster with their representative points.

In Table I, summarizes the key steps involved in the CURE algorithm for clustering, focusing on the selection of representative points and the process of refining the clusters while detecting outliers.

A. Cure-SNE

CURE-SNE (Clustering Using Representative Objects with Stochastic Neighbor Embedding) is an advanced clustering algorithm that combines the strengths of CURE with the dimensionality reduction technique of Stochastic Neighbor Embedding (SNE) [18]. While CURE focuses on selecting representative points to form clusters, CURE-SNE enhances this process by first mapping the data into a lower-dimensional space using SNE. This transformation helps reveal complex patterns and relationships that may not be apparent in higher-dimensional spaces [20]. In CURE-SNE, the clustering is performed by calculating the distance between data points and the representative points in this reduced space, making the algorithm more sensitive to underlying structures. One of the key advantages of CURE-SNE is its ability to detect and handle outliers more effectively. By identifying points that are far from any cluster representatives in the low-dimensional space, CURE-SNE ensures that these outliers are excluded from the final clusters, resulting in more accurate and refined clustering outcomes. This hybrid approach makes CURE-SNE particularly useful for datasets with complex structures or a high number of outliers.

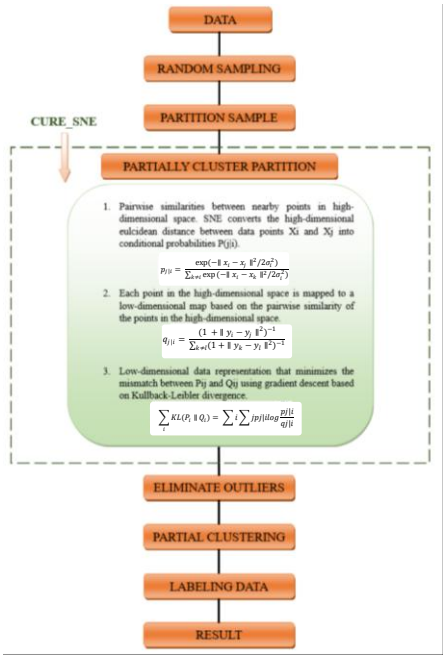

Fig. 2. CURE-SNE algorithm.

In Fig. 2, outlines the key steps involved in the CURE-SNE algorithm, emphasizing the integration of SNE to map the data to a lower-dimensional space and refining the clustering process by detecting outliers effectively.

B. Clustering Evaluation

The clustering evaluation methodology in this research uses two main metrics: Silhouette Score and Davies-Bouldin Index (DBI). The Silhouette Score is used to measure the extent to which each data point is separated from other clusters, with values ranging from -1 to 1. A positive value close to 1 indicates that the data point is well located in the right cluster, while a value close to -1 indicates that the closer to the wrong cluster. This process is carried out by calculating the average distance between each data point to other points in the same cluster, as well as the average distance to the closest point in another cluster. Meanwhile, DBI evaluates the quality of clustering by comparing the distance between clusters with the size of the cluster itself. Lower DBI indicates better separation between

clusters and higher compactness. These two metrics provide a comprehensive picture of the effectiveness of the applied clustering algorithm, thereby allowing the selection of the optimal clustering model based on the structure of the analyzed data.

1) Silhouette score: Silhouette Score is used to measure the extent to which each data point is separated from other clusters. [21] The formula for calculating the Silhouette Score $S(i)$ for data point i is as given in Eq. (4):

$$S(i) = \frac{b(i)-a(i)}{max(a(i),b(i))} \quad (4)$$

where, $a(i)$ is the average distance between point i and all other points in the same cluster, and $b(i)$ is the average distance between point i and the nearest point in another cluster. The Silhouette Score value ranges from -1 to 1; a positive value close to 1 indicates that the data point is well located in the correct cluster, while a value close to -1 indicates that the point is closer to the incorrect cluster. [22]

2) Davies-Bouldin Index (DBI): The Davies-Bouldin Index (DBI) evaluates the quality of clustering by comparing the distance between clusters with the size of the cluster itself. [23] The DBI formula for C cluster is given in Eq. (5):

$$DBI = \frac{1}{C}\sum_{i-1}^{C} \max(\frac{Si+Sj)}{Dij}) \quad (5)$$

where, Si is the size (in terms of distance) of cluster i, Sj is the size of cluster j, and Dij is the distance between the center of cluster i and the center of cluster j [24]. Lower DBI indicates better separation between clusters and higher compactness. These two metrics provide a comprehensive picture of the effectiveness of the applied clustering algorithm, thereby allowing the selection of the optimal clustering model based on the structure of the analyzed data.

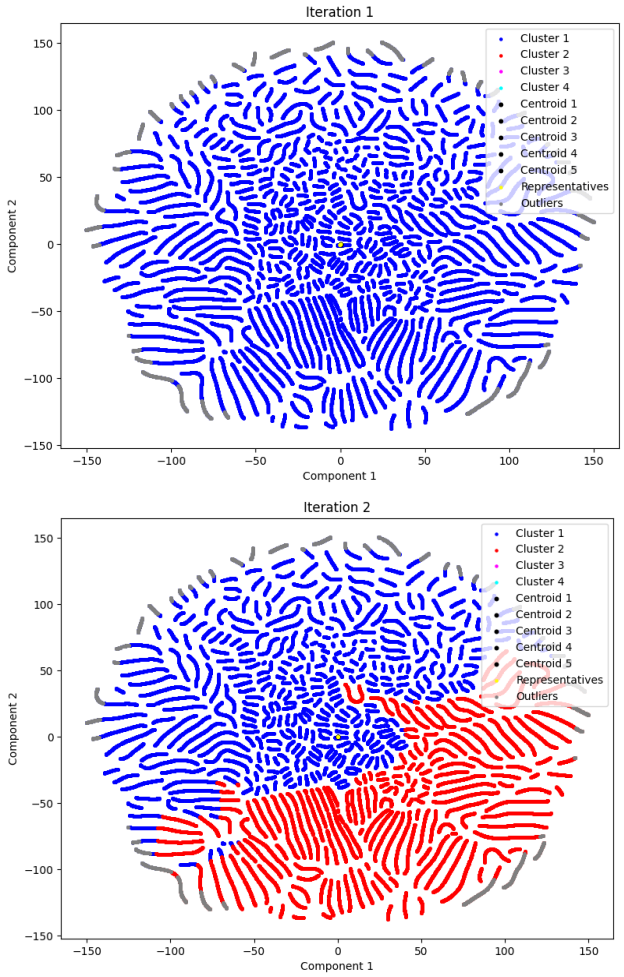
IV. Experimental Results and Analysis

The dataset under analysis contains data related to stunting cases, comprising 121,000 rows, with several key variables essential for health analysis, including age (in months or years), gender (male or female), height (in centimeters), weight (in kilograms), and nutritional status (categories indicating nutritional conditions such as well-nourished, undernourished, or stunted). The aim of analyzing this dataset is to understand the patterns and factors associated with the occurrence of stunting, which can assist in formulating more effective interventions or policies to address this public health issue. To ensure accurate and reliable analysis, outlier detection and handling will be performed on the data. Outliers, which may appear as extreme or anomalous values in certain variables, can significantly impact the results of the analysis. By identifying and addressing outliers, we can ensure that the dataset maintains high quality, allowing for more valid insights into the patterns and factors influencing stunting.

In Table II, a visualization of the clustering results using the CURE (Clustering Using Representatives) model. This model group's data based on representative points that capture the characteristics of each cluster, employing an approach that identifies patterns in the data and handles variations in distribution. The image shows several iterations, resulting in clusters with different characteristics, with each cluster represented by a different color, indicating groups of data with similarities in the analyzed variables. This visualization helps in understanding the distribution and patterns within the cluster space generated by the CURE algorithm.

TABLE II. Table Datasets

No	Age (month)	Gender	Height (cm)	Weight (kg)	Nutritional Status
1	18	Boy	80.5	10.1	Stunted
2	23	Girl	101.2	16	Over
3	18	Boy	74.1	7.2	Severely Stunted
4	30	Boy	102	16.4	Over
5	8	Boy	76.1	8.0	Normal
6	2	Boy	52.0	3.3	Normal
7	32	Boy	101.9	17.6	Over
8	24	Girl	100.0	15.1	Over
9	50	Boy	112.2	21.0	Over
10	18	Boy	75.7	8.2	Severely Stunted
...	...	...	...	...	...
120.999	5	Boy	50.0	4.1	Severely Stunted



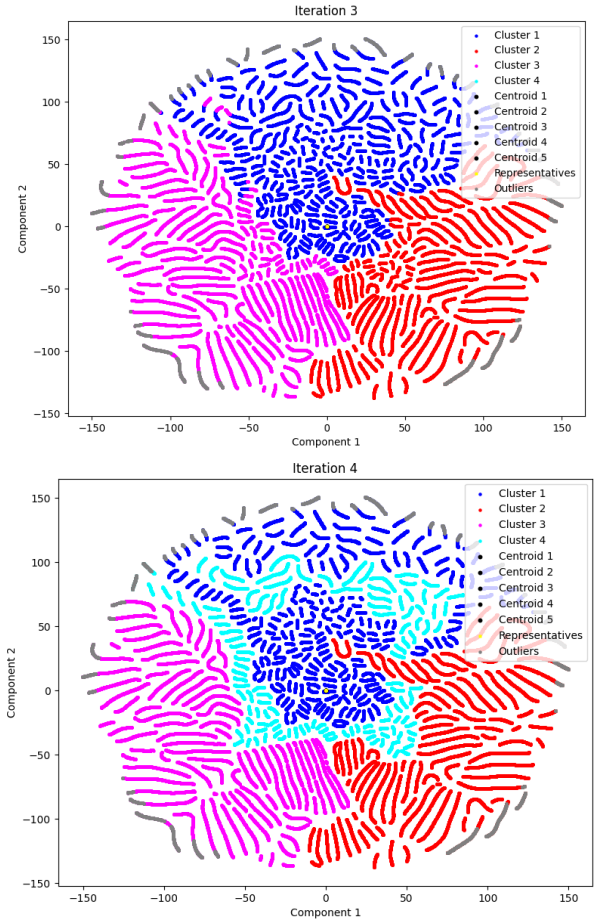


Fig. 3. Visualization of clustering iteration with CURE.

Fig. 3 is a visualization of the clustering results using the CURE-SNE (Clustering Using Representatives and Stochastic Neighbor Embedding) model. This model groups data based on the proximity between points, employing an approach that effectively handles outliers. The image shows four iterations, resulting in four distinct clusters, with each cluster represented by a different color, indicating groups of data with similar characteristics based on the analyzed variables. This visualization aids in understanding the distribution and patterns within the cluster space generated by the algorithm.

In Fig. 4:

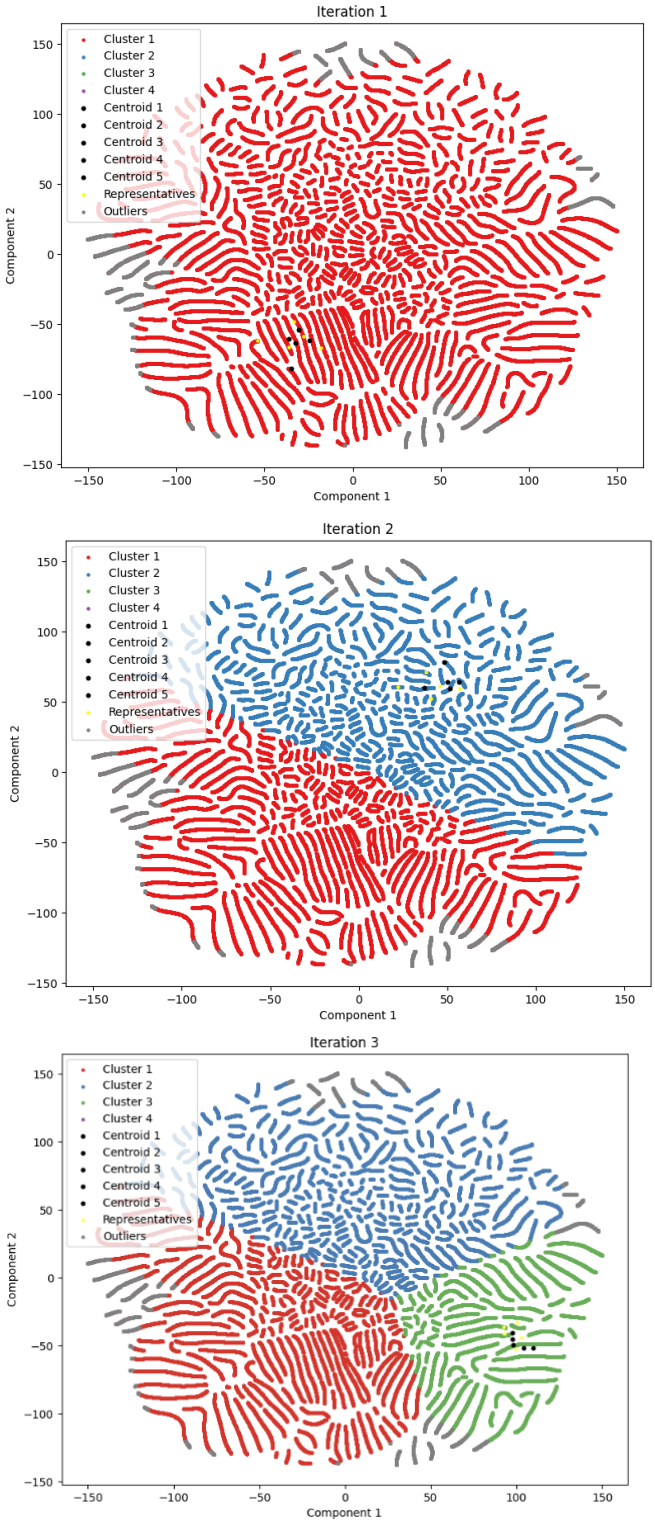
Iteration 1: In the first iteration, the CURE-SNE algorithm initializes 121K clusters based on the data, just as in the original dataset. Each data point represents a separate cluster.

Iteration 2: In the second iteration, the CURE-SNE algorithm begins merging nearby clusters. Clusters that are close to each other in the SNE visualization tend to share similar characteristics in the original data, leading them to merge into larger clusters.

Iteration 3: The merging of clusters continues in the next iteration. Clusters that exhibit similar patterns in the SNE space, as indicated by their proximity in the visualization, continue to merge. The size of the dominant clusters increases, while smaller clusters or outliers remain separate.

Iteration 4: In the final iteration, the CURE-SNE algorithm reaches the desired number of clusters, which is 4 clusters.

The following images show the clustering results from both CURE and CURE-SNE, highlighting the differences in the distribution of points for each cluster.



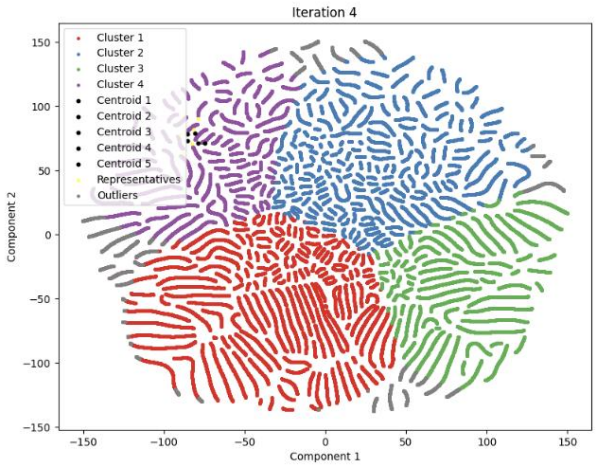


Fig. 4. Visualization of clustering iteration with CURE-SNE.

From Fig. 5 and Fig. 6, these four clusters represent groups of toddlers with distinct characteristics, as described below:

Cluster 1: Male toddlers with a very stunted nutritional status.

Cluster 2: Female toddlers with a normal nutritional status.

Cluster 3: Male toddlers with a normal nutritional status.

Cluster 4: Male toddlers with a high nutritional status.

Table III presents the composition of the clustering results for nutritional status using two different approaches: CURE and CURE-SNE. In the CURE method, the data is grouped based on representative points to capture the cluster structure, while CURE-SNE combines the outlier-handling capabilities of CURE with dimensionality reduction through Stochastic Neighbor Embedding (SNE). Each table displays the number of individuals in each cluster, along with their distribution across nutritional status categories such as well-nourished, undernourished, and stunted, providing valuable insights into the patterns and characteristics within the data.

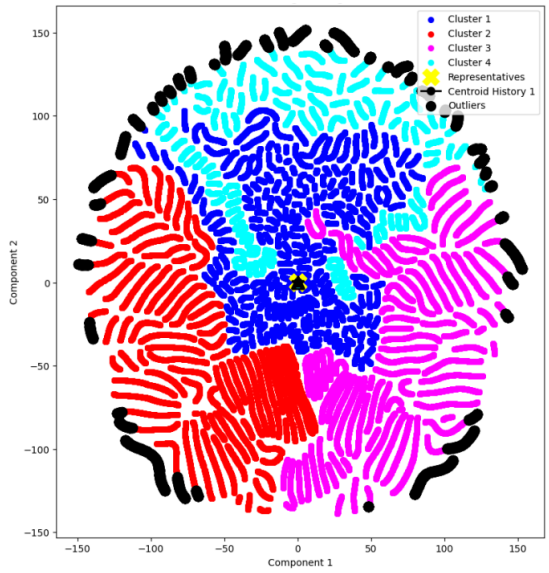

Fig. 5. Clustering results using the CURE.

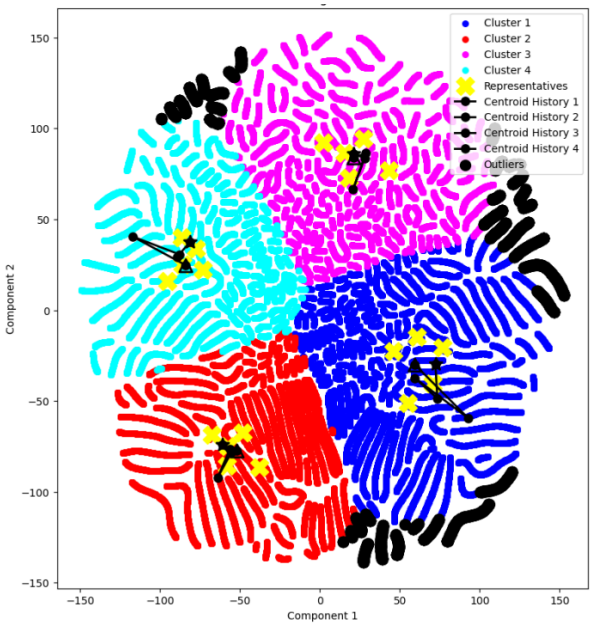

Fig. 6. Clustering results using the CURE-SNE.

TABLE III. CLUSTERING COMPOSITION OF NUTRITIONAL STATUS WITH CURE (%)

Nutritional Status/Cluster	Normal	Severely Stunted	Stunted	Over
1	72.855	1.112	13.015	13.018
2	22.683	32.860	17.248	27.209
3	43.932	29.154	9.078	17.934
4	100.000000	0.000000	0.000000	0.000000

TABLE IV. CLUSTERING COMPOSITION OF NUTRITIONAL STATUS WITH CURE-SNE (%)

Nutritional Status/Cluster	Normal	Severely Stunted	Stunted	Over
1	46.811	3.436	35.665	14.018
2	37.017	24.788	23.076	15.119
3	38.390	29.199	10.078	22.766
4	100.000000	0.000000	0.000000	0.000000

From Table IV, the clustering results using the CURE and CURE-SNE algorithms demonstrate the capabilities of both methods in grouping data while detecting outliers, though with differences in the number of outliers identified. The CURE algorithm effectively clusters data based on representative points within each cluster and detects outliers using a distance-based approach. On the other hand, the CURE-SNE algorithm, which integrates Stochastic Neighbor Embedding (SNE) to optimize the mapping of data in a lower-dimensional space, is able to detect a greater number of outliers compared to CURE. This indicates that CURE-SNE is more sensitive in identifying data points that do not conform to general patterns, resulting in a more detailed clustering outcome.

Fig. 7 and Fig. 8 shows the outlier detection process by CURE, where a total of 5,047 outlier data points were identified. In comparison, CURE-SNE detected 6,050 outliers.

Outliers in data_CURE:

	Age (month)	Gender	Height (cm)	Nutritional Status
12024	6	male	60.6	severely stunted
12028	6	male	59.1	severely stunted
12031	6	male	60.4	severely stunted
12038	6	male	60.7	severely stunted
12041	6	male	59.4	severely stunted
...	...	...	...	...
86829	43	female	111.5	normal
86836	43	female	111.4	normal
86889	43	female	111.4	normal
86929	43	female	111.6	normal
86948	43	female	111.2	normal

[5047 rows x 5 columns]

Number of outliers in original data: 5047

[6050 rows x 2 columns]

Number of outliers in data: 6050

Fig. 8. Outliers detection by CURE-SNE.

Fig. 9 presents a comparison of the clustering results using the CURE and CURE-SNE algorithms across several iterations. Both graphs illustrate the changes in cluster sizes over iterations and show how the algorithms detect and handle outliers. CURE uses a distance-based approach to group data and detect outliers, while CURE-SNE combines this approach with dimensionality reduction mapping, resulting in more detailed clustering outcomes.

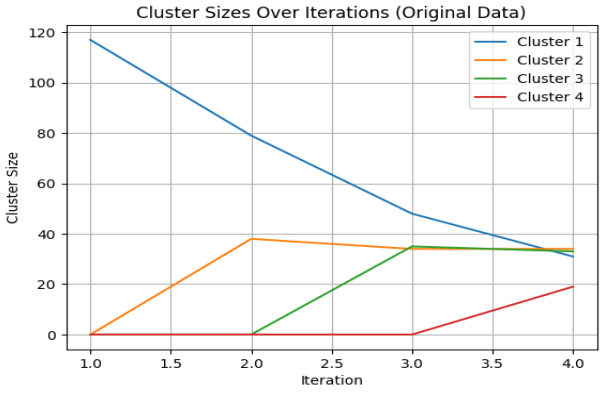

Fig. 9. Graph of CURE.

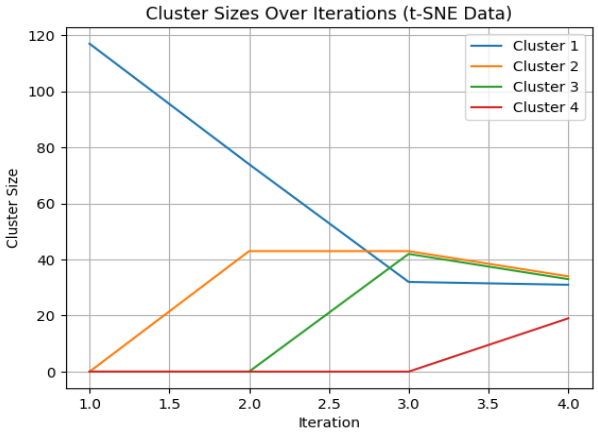

Fig. 10. Graph of CURE-SNE.

Fig. 10 also shows the clustering results using the CURE algorithm on the original data. The initial clusters also decrease in size during the iterations. However, the changes in cluster size are less dramatic, indicating that fewer outliers were detected compared to the CURE-SNE approach.

In the first graph, it can be observed that the CURE-SNE algorithm detects significant changes in cluster sizes over iterations. The initially large clusters gradually break down into smaller clusters, with a clearer data distribution in the final iterations. This indicates CURE-SNE's sensitivity in handling outliers, reflected in the reduction of main cluster sizes and the formation of additional clusters.

The comparison of these two graphs shows that CURE-SNE is generally more effective in detecting outliers and producing clusters with a more segmented data distribution.

It is essential to evaluate the performance of the clustering results generated by both the CURE and CURE-SNE methods to ensure the validity of the cluster structures. In this study, two evaluation metrics are used: the silhouette score, which helps determine the optimal number of clusters by measuring cluster cohesion and separation, and the Davies-Bouldin Index (DBI), which assesses the quality of the clusters by considering their compactness and separation. These evaluations provide valuable insights into the effectiveness of the clustering methods in capturing meaningful patterns in the data.

1) Sillhouette score evaluation: Fig. 11 illustrates the silhouette score analysis for determining the optimal number of clusters generated by both the CURE and CURE-SNE algorithms. The silhouette score, which measures the quality of clustering by assessing the separation and cohesion of clusters, indicates that both methods achieve the highest clustering performance at 4 clusters. As shown, the silhouette score initially increases and peaks at 4 clusters before dropping significantly as the number of clusters increases. This suggests that 4 clusters provide the best balance between intra-cluster cohesion and inter-cluster separation for the given dataset. The similarity in results highlights the effectiveness of both CURE and CURE-SNE in identifying the optimal cluster structure.

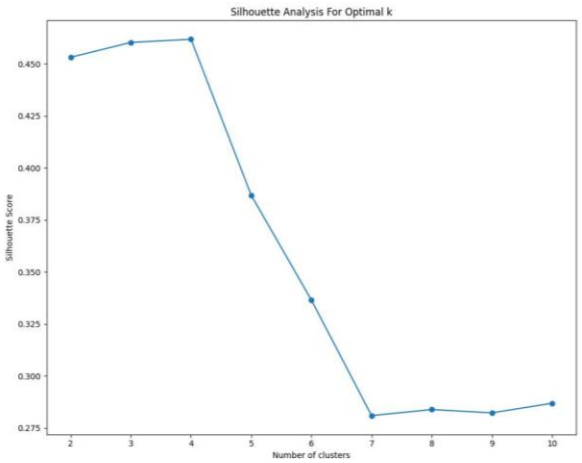

Fig. 11. Graph of sillhouette score evaluation.

2) Davies-Bouldin Index (DBI) Evaluation: From Table V, clustering evaluation can be performed using the Davies-Bouldin Index (DBI), which measures the quality of clusters based on the separation between clusters and the compactness within clusters. The smaller the DBI value, the better the clustering quality, as it indicates well-separated and tightly-knit clusters. In this study, the CURE-SNE method yielded a DBI value of 0.388, which is smaller than the DBI value of 0.523 obtained by the CURE method. This demonstrates that the CURE-SNE method performs better in generating clusters with higher quality, featuring clearer separation between clusters and greater compactness within them.

Evaluation of CURE Clustering:

$R_{12} = 0.314$, $R_{13} = 0.611$, $R_{14} = 0.366$, $R_{23} = 0.431$, $R_{24} = 0.363$, $R_{34} = 0.438$

$D_1 = \max(R_{12}, R_{13}, R_{14}) = \max(0.314, 0.611, 0.366) = 0.611$

$D_2 = \max(R_{21}, R_{23}, R_{24}) = \max(0.314, 0.431, 0.363) = 0.431$

$D_3 = \max(R_{31}, R_{32}, R_{34}) = \max(0.611, 0.431, 0.438) = 0.611$

$D_4 = \max(R_{41}, R_{42}, R_{43}) = \max(0.366, 0.363, 0.438) = 0.438$

$DBI = ¼ (0.611+0.431+0.611+0.438) = 0.523$

Evaluation of CURE-SNE Clustering:

$R_{12} = 0.4$, $R_{13} = 0.203$, $R_{14} = 0.164$, $R_{23} = 0.422$, $R_{24} = 0.272$, $R_{34} = 0.309$

$D_1 = \max(R_{12}, R_{13}, R_{14}) = \max(0.4, 0.203, 0.164) = 0.4$

$D_2 = \max(R_{21}, R_{23}, R_{24}) = \max(0.4, 0.422, 0.272) = 0.422$

$D_3 = \max(R_{31}, R_{32}, R_{34}) = \max(0.203, 0.422, 0.309) = 0.422$

$D_4 = \max(R_{41}, R_{42}, R_{43}) = \max(0.164, 0.272, 0.309) = 0.309$

$DBI = ¼ (0.4+0.422+0.422+0.309) = 0.388$

TABLE V. COMPARISON OF CLUSTER EVALUATION

Algorithm	Sillhouette Score	Davies-Bouldin Index
CURE	4	0.523
CURE-SNE	4	0.388

V. DISCUSSION

The clustering results using the CURE and CURE-SNE algorithms show significant differences in how the two approaches process data and detect outliers. In the CURE algorithm, the clustering process is based on data representation through representative points that reflect the characteristics of each cluster. The results show that this algorithm is effective in grouping data but less sensitive to detecting outliers, with 5047 outliers detected. This results in clusters with more stable data distributions and less drastic changes in size at each iteration.

In contrast, the CURE-SNE algorithm, which combines the CURE representation approach with dimensionality reduction through Stochastic Neighbor Embedding (SNE), exhibits a higher ability to detect outliers. This is evident from the dramatic reduction in the size of large clusters in the early iterations and the formation of smaller, more separated clusters in subsequent iterations. CURE-SNE detected 6050 outliers, which is more than the CURE algorithm. The sensitivity of CURE-SNE in handling outliers makes it more effective at identifying deviating data points, resulting in more segmented clusters.

Overall, both algorithms have their respective advantages. CURE is better suited for clustering data with a more regular distribution and is less influenced by outliers, while CURE-SNE excels in detecting complex patterns and handling data with many outliers. Therefore, the choice of algorithm should be tailored to the characteristics of the dataset and the analysis goals. In this case, the results from CURE-SNE provide deeper insights into the data structure, particularly in the context of identifying significant outliers for further analysis.

VI. CONCLUSION

The clustering analysis results using the CURE and CURE-SNE algorithms provide valuable insights into the capabilities of both methods in grouping data and detecting outliers. Both algorithms resulted in four clusters, but with differences in outlier detection, where CURE-SNE was able to detect 6050 outliers, while CURE detected 5047 outliers. Cluster validation using silhouette score showed that both CURE and CURE-SNE formed four optimal clusters. However, when validated with the Davies-Bouldin Index (DBI), CURE achieved a value of 0.523, while CURE-SNE achieved a value of 0.388, indicating that CURE-SNE outperformed CURE in terms of the quality of the clusters formed. The CURE algorithm demonstrated strong performance in generating stable clusters with well-organized data distributions but had limitations in sensitively detecting outliers. On the other hand, CURE-SNE, with the integration of the Stochastic Neighbor Embedding (SNE) technique, was able to detect more outliers and generate more segmented clusters, reflecting complex patterns within the data. This difference indicates that CURE-SNE is more effective for datasets with irregular distributions or many outliers, while CURE is better suited for data with a more homogeneous structure. Therefore, the choice of algorithm should consider the characteristics of the dataset and the analysis objectives. These findings can serve as a reference for selecting the appropriate clustering method for analyzing complex data, such as public health cases, including identifying factors contributing to stunting.

ACKNOWLEDGMENT

We would like to express our deepest gratitude to the Directorate of Research, Technology, and Community Service (DRTPM) for funding this research under the Doctoral Dissertation Research (PDD) scheme. We also extend our sincere thanks to Universitas Sumatera Utara for providing invaluable support and resources that greatly contributed to the success of this study.

***Abstract*—Brain Tumor (BT), which is the progress of abnormal cells in brain surface is categorized into different types based on the symptoms and the affected parts in brain. Classification of BT using Magnetic Resonance Imaging (MRI) is an important and challenging task for BT diagnosis. Various approaches are designed to solve the issues and there are so many inconsistencies in detecting the tumor at early stage. The changes in variability and the complexity of size, shape, location and texture of lesions, automatic detection of BT still results a challenging task in the medical research community. Hence, a proposed Hybrid Attention Temporal Difference Learning with Distributed Convolutional Neural Network-Bidirectional Long Short-Term Memory (HATDL-DCNN-BiLSTM) is developed in this research to detect and classify the BT at beginning stage that enables to improve the survival rate of humans. The proposed model uses Gaussian filter for input image enhancement, Hybrid Attention-VNet segmentation to generate region of interest and solves the computational issues through the attention modules by minimizing the dimensions. The proposed model consumed less memory utilization and increase the training speed globally using the distributed learning mechanism. The features extracted using Hybrid Attention based Efficient Statistical Triangular ResNet (HA-ESTER) supports the classification model to increase the training efficiency more accurately. The proposed HATDL-DCNN-BiLSTM attains higher efficiency by the metrics of accuracy, recall, F1-score, and precision of 98.93%, 99.21%, 97.67%, and 96.17% with training data, and accuracy, recall, F1-score, and precision of 96.34%, 96.51%, 96.33%, and 96.15% with k-fold using BraTS 2019 dataset.**

I. INTRODUCTION

Human brain is a vital organ in the physical body because it is responsible for the various governing processes of humans like feeling, memory, responses, vision, motor skills, and breathing [1] [2]. These regulatory functions are significantly disrupted when BT begin to form inside the brain, which arise due to the unfamiliar development of cells in certain brain tissues. BT is primarily categorized as benign or malignant, the benign tumor can't able to diffuse to diverse parts of the brain, so it is considered non-cancerous. However, the malignant tumor is cancerous because it grows uncontrollably and diffuses to various parts of the brain [3]. There are about 200 various types of BT that can arise in diverse areas of the brain. These types of tumors cause more life-varying impact on affected individual's lives [4]. The symptoms of BT appear when the illness is in the stage of advanced and the early phase of BT doesn't reveal any symptoms to the affected person. This phenomenon is due to the position and small size of the tumor in the early phases [5] [6]. Remembrance issues, deviations in the power of eyesight, unfamiliar actions, misperception, seizures, and stability issues are the indications of BT and sometimes it varies depend on the type and location of tumors [7]. After the surgery, the survival rate of BT patients is 14% but, if it is detected in the early stage, the survival rate increases to 70% [6].

Various imaging procedures, like positron emission tomography (PET), MRI and computed tomography (CT), are employed to scan the complete structure of the brain [8]. Compared to PET and CT, MRI is regarded as a better imaging modality and it is broadly used to recognize and categorize the BT because of its better resolution. Moreover, the MRI is highly useful and important in the domain of radiology, because it offers various alterations between a variety of body's soft tissues [9]. Recently, Machine Learning (ML) algorithms have been combined with the automatic BT detection system in various studies to detect BT from the brain MRI [10]. Many efforts have been made to create very effective and trustworthy methods for automatically classifying BT. Handmade features are utilized in the traditional ML techniques, which limited the robustness of the solution and increase the cost. Nevertheless, occasionally supervised learning methods can exceed the unsupervised learning methods, thus resultant in an overfitted approach, that is not fit for additional large repository [11]. Additionally, conventional ML methods also rely on handmade features, that impose drawbacks on the durability and effectiveness of the solution [12]. Though there are various systems available for recognizing irregularities in brain MRI, yet there is a possibility for improving the performance and making the categorization within an appropriate amount of time. The effort in examining and identifying BT using conventional methods become more difficult owing to the expanding size of medical information [13].

Globally, there is no effective method has been found for segmenting and identifying the BT in recent studies irrespective

of its position, structure, and intensity [14] [15]. Many researchers utilized numerous traditional feature extraction approaches, such as Histogram of Oriented Gradients (HOG), bag of word (BoW), local binary patterns (LBP), gray level co-occurrence matrix (GLCM), and density histogram to extract the relevant features. Though, these methods unsourced to extract the exact features, that are needed for accurate BT detection [16] [17]. The approach in study [18] applies k-means clustering approach, whereas feature reduction and extraction processes depend on the Principal Component Analysis (PCA) approach and Discrete Wavelet Transform (DWT) approach respectively. Lastly, SVM is utilized for classifying the BT. However, these approaches consumed more time to complete the procedure of accurate BT detection as well as classification [18]. Some methods apply manually defined tumor regions for detection of BT, which forbids them from being entirely computerized. Deep Learning (DL) is gaining more popular, because of the facility to extract features automatically. Still, DL consumes lot of processing volume and memory [17]. The experimental results of various BT detection frameworks are yet in the initial phase since several characteristics influence the detection method, like poor localization of tumor, deficiency of training volume, poor quality such as the deficiency of training data, poor tumor localization, low-quality images and features [19]. However the combination of deep learning and transfer learning aims to enhance the accuracy and efficiency of brain tumor diagnosis by leveraging the power of pre-trained models to improve classification and segmentation tasks [20].

The main motivation of the research is to design and develop a model for BT classification using proposed HATDL-DCNN-BiLSTM. The Gaussian filter is subjected to MRI for generating the pre-processing image result and with the pre-processed result, segmentation is done by HA-based VNet model to enhance the detection rate, and furthermore, the important and the suitable features are being extracted by applying HA-ESTR model. The features extracted through individual feature extraction mechanism are concatenated to generate a feature map that helps to obtain better performance in image classification. Fine tuning the model provides better generalizability by minimizing the error value through categorical cross entropy measure. The research contribution is briefly discussed as follows:

1) Hybrid Attention-VNet (HA-VNet) based segmentation: The segmentation model is designed through the incorporation of attention models, like HA with the VNet model to extract the color, contrast, texture, and boundary details of image modality, as it helps to increase the detection rate. It highly focuses in extracting key features in both the split and double attention to increase the classification performance.

2) Hybrid Attention-Efficient Statistical Triangular ResNet (HA-ESTR) based feature: The feature extraction process performed using HA-ESTR is to extract useful features to minimize the classification error. This feature extraction model is designed through the integration of different feature extraction models that helps to derive the tumor related features including statistical information. Accordingly, this information is more helpful in finding cancerous and non-cancerous category.

3) Proposed Hybrid Attention Temporal Difference Learning Distributed CNN-BiLSTM (HATDL-DCNN-BiLSTM): The proposed framework is designed through the incorporation of attention models, and temporal difference learning with distributed deep learning framework. Due to the higher learning capability and facility of proposed model, it shows optimal performance in BT classification using imaging modality. The trained images are coordinated with test images to minimize the loss function such that minimal error value returns best performance.

The subsequent sections of this manuscript are delineated as follows: Section II deals with the traditional methodologies employed in the processes of feature extraction, segmentation, optimization, and classification of Brain Tumor. Section III offers an in-depth explanation of the proposed framework. Section IV and V addresses the results and discussion part respectively. Finally, Section VI encapsulates the entirety of the research, highlighting key findings, implications and future work.

II. Literature Survey

Few traditional approaches used for the classification of BT are reviewed in this section. Rahman, T. and Islam, M.S [1] designed a parallel deep convolutional Neural Network (PDCNN) mechanism for classification of BT. Here local as well as global features were extracted in a parallel way to solve the over fitting issues by applying dropout regularizer with batch normalization. The performance was evaluated with three different BT datasets, and reported efficient and accurate performance by extracting low-level as well as high-level features. However, it failed to use the model with 3D structure for identifying the tumors. Ullah, Net al. [17] designed a unified end-to-end model based on deep learning approach (TumorDetNet) for detecting and classifying BT. The distinctive features were effectively learned and minimized the over fitting issues. The SoftMax layer was used to detect the tumor and their grades. It showed higher accuracy measure, but failed to detect complex tumor types. Z. Atha and J. Chaki [3] designed a semi supervised deep learning model for detecting BT. This model was derived through the integration of unsupervised autoencoder mechanism with supervised classification model. It trains the learning parameter of descriptors for better classification. Accordingly, the instances were created through fuzzy logic using augmented data. This model showed higher accuracy, but failed to detect the tumor with location.

Anantharajan, S.et al. [2] modelled a deep learning framework to detect the tumor at early stage. Here, the images were captured and pre-processed by applying adaptive contract enhancement algorithm (ACEA) with median filter. The segmentation was done using fuzzy c-means model and the features were extracted effectively. It resulted higher accuracy rate, but faced time complexity issues. Saha, P. et al. [3] designed a deep learning network with ensemble model for detecting the tumor into different classes. The deep features were captured by CNN and these features are used to classify the BT types. It showed better performance, but failed to evaluate the analysis with large sized dataset. Mathivanan, S.K.

et al. [21] focused a deep and transfer learning approach for detection of BT accurately using MRI. The model was trained with benchmark datasets and increase the performance by applying image enhancement methods. It showed higher accuracy rate and classifies the tumor into different grades.

Amin, J. et al. [9] designed a random forest classifier to classify BT into three different regions, namely non-enhancing, enhancing and complete tumor. The cross-validation schemes were applied in the model to reduce over fitting issues. This model was feasible in generating segmented results without manual interactions. Asiri, A.A.et al. [4] introduced a dual module mechanism to improve the accuracy and speed of BT detection. The first module was said as image enhancement approach that used a machine learning strategy for normalizing the images and solve the issues, like low contrast and noise. Accordingly, second module applies support vector machine (SVM) to perform segmentation as well as classification of BT. It increased the robustness and generalizability of model.

A. Challenges

The challenges discovered from the existing BT detection approaches are labelled below.

- In study [6], the suggested approach offered faster processing time and improved accuracy due to the incorporation of an efficient algorithm. However, the suggested method was inefficient in dealing with imbalanced and large-scale datasets.
- The suggested HBTC framework [22] reduced the complexity of inherent. However, it failed to generalize over different datasets and revealed low exactness and toughness.
- The suggested method [23] was not examined with openly available imaging datasets having irregularity features and on the other hand, the suggested method also had the issue of scalability.
- In study [12], the suggested method reduced feature irrelevance, duplication, and dimensionality to identify the important features, however, the feature selection and extraction process consumed more time because of the high computational complexity in managing huge amounts of data.
- The suggested method [24] effectively classifies the brain tumors, however, it failed to do the cropping and rotating process to the data before it was subjected to the classification process.

B. Problem Statement

In the recent years, BT has grown uncontrollably in different locations across human body, but it mainly causes in brain. When the tumor grows, it starts to increase the pressure inside the brain, which typically affects the brain and cause brain damage and also it threatens human life. Various BT detection methods introduced in the medical research helps the physicians to detect the cancer using MRI, but it undergoes several challenges. The medical professionals and radiologists examine number of MRI slices that results labor intensive and time-consuming process. However, this manual scheme causes human error and potential leads to delay or misdiagnosis. Hence, it is an urgent requirement in the medical research to design an accurate BT detection method for accurate diagnosis of BT at earlier stage. To accomplish this task, an input MRI is fetched and the image is captured from BraTS dataset. Assume the dataset as T with s number of MRI brain images as,

$$T = \{C_1, C_2, ..., C_i, ..., C_s\} \quad (1)$$

The input image is represented as C, which is subjected to the pre-processing stage to increase the quality of image by eliminating the noise. Accordingly, pre-processed result is represented as C, which is fetched by applying Gaussian filter to the input image. All the input images do have same dimension and so it is required to pre-process the image to provide uniformity in the training process. The image C is fed to the segmentation phase, which simplify and change the image representation into meaningful factor, such that segmented image result is specified as, H

$$H = \{C\} \quad (2)$$

Segmented image result is fed to feature extraction phase to extract useful and essential features and based on the features, a feature vector is generated and it is noted as, A, respectively.

Accordingly, the generated feature map is applied to the model, where the tumor grades are classified into various stages, like no tumor, enhancing tumor, non-enhancing tumor, and peritumoral edema and this is accomplished through reduction of error value by applying categorical cross entropy loss function that is specified as,

$$L = -\sum M \log(M) \quad (3)$$

Here, M denotes predicted value, and M is the actual ground truth value.

$$M = t = \begin{cases} 0; \text{ if "C " is normal} \\ 1; \text{ else if "C "is non enhancing tumor} \\ 2; \text{ else if "C "is peritumoral edema} \\ 3; \text{ otherwise "C "is enhancing tumor} \end{cases} \quad (4)$$

Hence, the proposed BT detection model generate accurate results by minimizing the error rate through the loss function.

III. METHODOLOGY

The HATDL-DCNN-BiLSTM is developed in this research for classification of BT with MRI modality. Input image is acquired from the BraTS dataset and subject to pre-processing phase, in which Gaussian filter is applied for enhancing image quality. The pre-processed image is subjected to segmentation phase, where HA based VNet segmentation framework is applied to generate region of interest. Based on the segmented image result, the features connected with the modality is extracted using HA-ESTR that includes different feature extraction models. After extracting the features, BT classification is performed using proposed HATDL-DCNN-BiLSTM. Fig. 1 represents the schematic view of proposed BT classification framework.

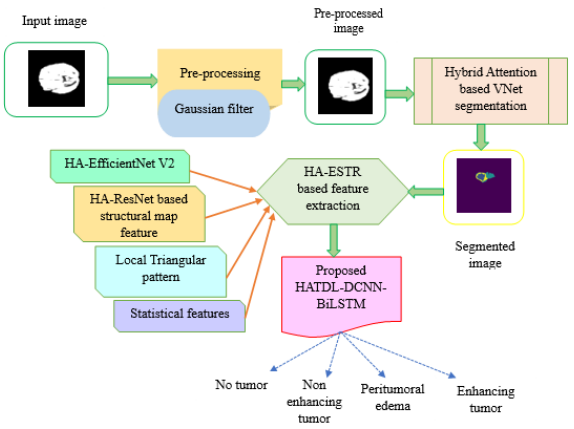

Fig. 1. Schematic representation of proposed HATDL with DCNN-BiLSTM for BT classification.

A. *Gaussian Filter-Based Image Pre-processing*

MRI plays an active role in human brain scanning, as MRI provides detailed information about brain soft tissue structure. Due to the better efficiency in detecting the soft tissues of brain, MRI contributes more significant in BT classification. Consider the dataset as T composed with S number of MRI, and each image used for the processing is specified as,

$$T = \{C\}; k \in \{1, 2, ..., s\} \tag{5}$$

Here, T is the dataset, C_k denotes k^{th} input image with the dimension of $[224 \times 224]$, and s implies total number of images. The brain images are sensitive towards unwanted noise and distortions and hence, pre-processing is needed to remove the noise for increasing greatest quality of image. Gaussian filter [25] is applied to pre-process the input image C for smoothen image by reducing the noise. Gaussian filter is an essential tool in computer vision and image processing system, and it is considered as an optimal filter to solve imaging issues. It is referred as the linear smoothing filter that selects the weights with respect to shape of Gaussian function. Gaussian filter is a category of low pass filter specifically designed to eliminate the noise subject to normal distribution, and hence it is commonly used in the image processing system. By applying Gaussian filter, the noises are suppressed and smoothed out that further increases the image quality. The Gaussian filter for the image C with pixel values is expressed as,

$$F(u, v) = \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\left(x + y\right) / 2\sigma\right) \tag{6}$$

$$C = F(C) \tag{7}$$

Here, σ denotes the variance of Gaussian filter, x and y are the filter kernel, and F denotes Gaussian filter. The resultant pre-processed image after removing the noise is expressed as, C with the dimension of $[224 \times 224]$, respectively.

B. *Hybrid Attention Based VNet Segmentation*

Segmentation process is applied to the image processing task for changing and simplifying image representation into meaningful form by selecting similar pixels. The pre-processed result C is applied to segmentation phase, where HA-VNet model is utilized to generate segmentation result. The HA-VNet is designed through the integration of VNet with HA, in which HA is modelled by integrating split attention and double attention model. The major advantage of using HA-VNet is that it allows seamless image segmentation with higher performance and accuracy. The benefit of using attention model in the segmentation is to minimize the spatial and channel dimension of VNet model. The split attention is the computational unit composed of split attention operations and feature map group. On the other hand, the double attention computes pooled features and capture the complex appearances and more efficient in correlating features with each specific location. Accordingly, these benefits are incorporated with the VNet model to provide accurate segmentation results that helps to increase the training process. The structure of VNet [26] [27] contains two different paths, namely compression path (left side) and decompression path (right side). The convolution with suitable padding is performed for exploiting the features from input and reduce the resolution with suitable stride at the end of every stage. The compression path is divided into different phases that operates at varying resolutions such that each stage contains one to three convolutional layers. The VNet takes C as input, and the input taken by each phase is processed by a residual function used in convolutional layers, and finally output is re through final convolution layer. The HA mechanism is added at the convolutional layer-2 to increase the training efficiency. The HA layer into the VNet takes previous convolution layer output as input of size $[N \times 6 \times 6 \times 16]$ and resulted output is passed as input to the next convolution layer. Accordingly, the benefit of using VNet architecture is that it offers better convergence than other non-residual learning network, and also it offers $[5 \times 5]$ size of convolutional layer at each stage. Accordingly, the convolution layer is represented as,

$$X = \sum\left\{\sum\sum C \,.E(\alpha, \beta)\right\} + P \tag{8}$$

where, X denotes the output of convolution operation, P denotes bias factor, C is the input, $E(\alpha, \beta)$ is the weight among the locations (α, β). The convolutional operations are used to double the feature maps due to the involvement of residual framework and number of increasing feature channels considered in compression path. The convolutional layer aims to minimize the memory required for training procedure and process the input at higher resolution. The increase in the segmentation rate is achieved by reducing the error rate of model, in which the error value is computed through dice loss function that is expressed as,

$$L = \frac{1}{R}\sum\left[1 - \frac{2\sum M \,.M}{\sum M + \sum M}\right] \tag{9}$$

Here, R denotes number of classes, r specifies number of class samples, M implies predicted value, and M shows actual

ground truth value. The activation function contains various functions, like rectified function, tanh, and so on.

$$X = f\left(\sum X.E + P\right) \tag{10}$$

Here, X is the input of activation function, E and P shows weight and bias vector. Finally, the rectified linear unit (ReLU) is expressed as,

$$H = \begin{cases} X & ; X \geq 0 \\ \frac{X}{X}; & X \leq 0 \end{cases} \tag{11}$$

The segmented image result obtained through HA-VNet is represented as H with the size of $[N \times 224 \times 224]$.

- Architecture of Hybrid Attention

The HA [28] is designed through the integration of double attention and split attention mechanism that enable the model to increase the training speed by consuming less memory during training process. Both the attention models are operated by taking the input with dimension of $[N \times 6 \times 6 \times 16]$. Fig. 2 shows the structure of Hybrid Attention model. For any input value, the HA compute the attention map separately through split and double attention and the dimension is adjusted using reshape layer by applying sigmoid function. Assume the input taken by the HA is D with size $[N \times 6 \times 6 \times 16]$ and it is divided into two parts, but the channel number of these parts must be equal. Accordingly, these two parts extracts the boundary information through split attention and double attention. Structure of split attention contains different layers, namely reshape, pooling, dense, and softmax. With split attention, the attention process is enabled across the feature maps. Moreover, the original feature dimension is reduced with reshape layer and the result generated with the respace layer have the size of $[N \times 6 \times 6 \times 16]$. On the other hand, the double attention model contains different layers, like convolution, reshape, softmax, and matrix multiplication. Here, the convolution layer performs the convolution operation, whereas reshape layer enable to reduce the dimension of feature maps into $[N \times 6 \times 6 \times 12]$. The output of two different layers is fused by the matrix multiplication layer and finally reshape layer is used to generate the output. Finally, the output of split attention d and the output of double attention d_2 are fused together and the resultant is specified as,

$$d = \{d + d\}; d \in [N \times 6 \times 6 \times 16] \tag{12}$$

Here, the output of HA mechanism is specified as, d having the dimension of $[N \times 6 \times 6 \times 16]$.

C. Hybrid Attention Based Efficient Statistical Triangular ResNet Feature Extraction

In this work HA-ESTR feature extraction method is proposed which is formed through the integration of different feature extraction models, like Hybrid Attention based EfficientNet V2 feature (HA based EfficientNet V2), Hybrid Attention based ResNet structural map (HA based ResNet structural map), Local Triangular pattern (LTrP), and statistical features. Accordingly, the Hybrid Attention based EfficientNet V2 is modeled through the integration of Hybrid attention with standard EfficientNet V2 feature, and also Hybrid Attention based ResNet structural map is formed through the integration of Hybrid attention and structural map with ResNet feature. The HA-ESTR feature extraction model takes the segmentation output (H) as input and extract useful features that helps to boost the classification accuracy. The detailed explanation of each feature extraction models is clearly explained as follows.

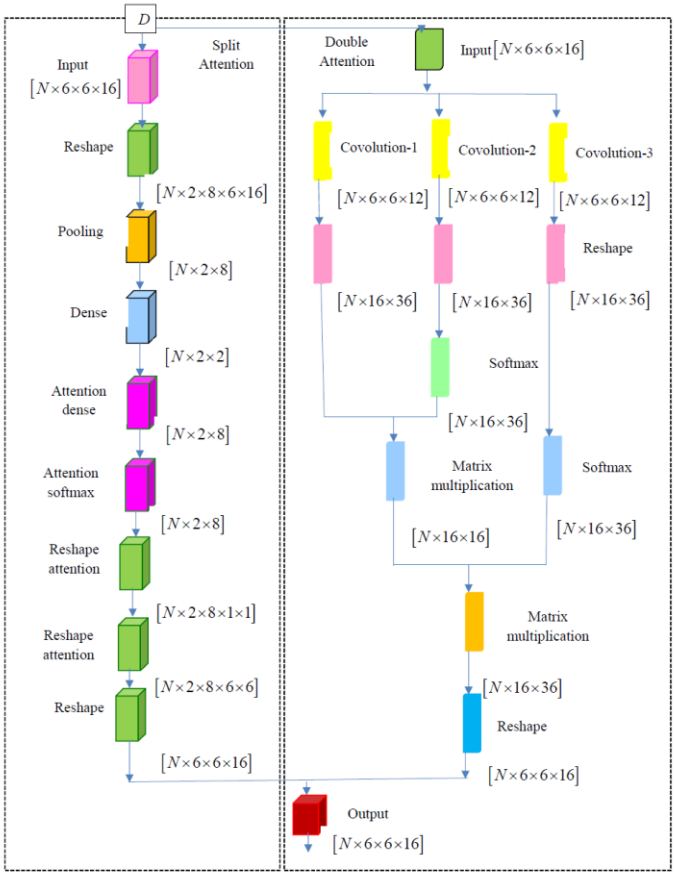

Fig. 2. Architecture of hybrid attention model.

1) Hybrid attention based EfficientNet V2 feature: In this feature is formed by incorporating the attention model features, like HA into the standard EfficientNetV2 feature. The benefit of using this feature model is that it effectively alters the regularization value with respect to image size due to the progressive learning mechanism. It effectively balances the network width, depth, and resolution and helps to increase the performance. The EfficientNetV2 model provides notable enhancement in the training efficiency and offers faster convergence [29] [30]. The EfficientNet V2 is composed with different layers, such as convolution, MBConv, HA, pooling, and fully connected layer. Initially, the input (H) with dimension $[N \times 224 \times 224]$ is passed to the convolution layer with stride $[3 \times 3]$, and the output is fed to MBConv layer,

which contains an inverted residual connection followed with the separable convolution. To reduce the overfitting issues, the dropout is used in MBConv block [30]. The HA layer is integrated into the model and the output of HA mechanism is passed to the convolution with stride $[1\times1]$ layer and finally, the pooling and the fully connected layer is utilized to generate the output feature as A with the size of $[1\times112\times112\times32]$ such that its dimension is resized into $[1\times32\times32]$ for further processing.

2) Hybrid attention based ResNet structural map feature: The HA based ResNet structural map feature is designed by integrating the attention mechanism, such as HA into ResNet model with structural map features. The structure of HA model contains different layers, convolution, batch normalization, Maxpooling, flatten, fully connected layer, and LTP. The input H with size $[N\times224\times224]$ is passed to the convolution layer, where the HA layer is applied, and followed by flatten and fully connected layer are utilized to reduce the dimension of original features. Each layer contains same number of filters and if the size of feature map halved, then filters used in the model get doubles [31]. The LTP is applied to the texture analysis of the grey scale images and this feature is more superior in computational efficiency and description performance. LTP refers to a descriptor, which describes relationship among a selected pixels in the image with the neighborhood pixels [32]. This feature operates by setting a gray value of certain pixel as G and the gray value of pixels in the $[3\times3]$ neighborhood as $G\left(j=0,1,...,7\right)$. It analyzes the relationship between G and G, if $G<G$, the value is set to 0, otherwise the value is set to 1. By doing this process, an 8-bit numbers with 0's and 1's are generated such that the decimal value corresponds to the binary number is referred as the TLP feature value and it is expressed as,

$$A=\sum\chi(G-G)2\ ;\ \chi(a)=\begin{cases}1 & ;a\geq0\\ 0 & ;Otherwise\end{cases} \tag{13}$$

Here, A denotes the structural map features. In general, the HA layer is integrated into the ResNet-50 model, and the output is fed to the LTP, which generates the structural map features as, A with the dimension of $[1\times112\times112\times32]$ and for easier processing, the original dimension is resized into $[1\times32\times32]$, which is used for further processing. The purpose of extracting this feature is to enhance classification accuracy by modifying the residual block with Rectified Linear Unit (ReLU) activation function. Due to the great representation ability, this feature extraction model is applied in BT classification.

3) Local triangular pattern feature: The LTrP is designed using 8-bit binary code and the steps involved in the extraction of LTrP feature is briefly explained as follows. At first, a $[3\times3]$ image matrix is generated for each image and then three neighbour pixels are selected with 600 triangle formation, and these triangles are formed in four different directions [33]. At each direction, the center pixel is referred as the threshold for the remaining neighboring pixels. A binary value of '1' is generated when the threshold value is higher than any of two neighboring pixels, and otherwise the binary value is set to '0'. Thus, a binary value is created for all the three pixels using the below equation as,

$$\begin{aligned}Nw&=BY\left(\max[w-N],[w-N],[w-N]\right)\\ Nw&=BY\left(\max[w-N],[w-N],[w-N]\right)\\ Nw&=BY\left(\max[w-N],[w-N],[w-N]\right)\\ Nw&=BY\left(\max[w-N],[w-N],[w-N]\right)\end{aligned} \tag{14}$$

After finding the values at each direction, the triangle is flipped to 1800and repeat the same process to find the binary code value. Here, each triangle contains four values that includes $w,N,w,$ and w. Accordingly, w is the center pixel, and hence set it as the threshold for $w_6,N,w_2,$ .If w is higher than any other two neighboring pixel values, that is w_6 or N or w_2, then binary value is set to '1', otherwise set to '0'. The process involved in generating the above values are expressed as,

$$\begin{aligned}Nw&=BY\left(\max[w-w],[N-w],[w-w]\right)\\ Nw&=BY\left(\max[w-w],[N-w],[w-w]\right)\\ Nw&=BY\left(\max[w-w],[N-w],[w-w]\right)\\ Nw&=BY\left(\max[w-w],[N-w],[w-w]\right)\end{aligned} \tag{15}$$

Finally, the eight coded patterns are generated through the above process using the below equation as,

$$Nw_h=\sum_{h=0}^{t}BY\left(w_h-N\right)\geq\left(t+1\right)/2 \tag{16}$$

$$A=LTP\left(\alpha,\beta\right)=\sum\gamma\left(Nw-N\right)2 \tag{17}$$

where,

$$\gamma\left(\mathrm{X}\right)=\begin{cases}1,\ \mathrm{X}\geq0\\ 0,Otherwise\end{cases} \tag{18}$$

Here, BY shows binary value, LTP represents the LTrP features, which is represented as A with the dimension of $[1\times32\times32]$.

4) Statistical features: Some of the statistical features extracted from the segmented image results are mean, standard deviation, variance, median, harmonic mean, geometric mean, and entropy [34] [35].

Mean: homogeneity of brightness of MRI, which is represented as

$$S=\frac{1}{Z}\sum H\left(z\right) \tag{19}$$

Here, Z is total number of pixels, S refers to mean feature with the dimension of $[1\times1]$, and $H\left(z\right)$ is the segmented image.

Variance: heterogeneity that strongly connected with standard deviations and it is expressed as,

$$S = \sum\sum (m - S)\, H(m,n) \tag{20}$$

where, S refers to the variance feature with the size of $[1\times1]$.

Standard deviation: shows the difference exists in each observation from the mean value and it is represented as,

$$S = \sqrt{\frac{\sum (H(z) - S)}{Z}} \tag{21}$$

Here, S implies standard deviation feature with size of $[1\times1]$.

Median: It shows the central tendency of the features and it is generally represented as, S with the size of $[1\times1]$.

Harmonic mean: It extracts the average sample size from the number of groups and it is expressed as,

$$S = \frac{z}{\frac{1}{\lambda} + \ldots \frac{1}{\lambda}} \tag{22}$$

Here, z implies total number of pixels, λ and λ_z are the pixel values, and S is the harmonic mean features having the size of $[1\times1]$.

Geometric mean: refers to the appropriate measure, where the value changes exponentially. It is a category of mean with central tendency and it is computed as,

$$S = \sqrt{\lambda, \ldots, \lambda} \tag{23}$$

Here, Z refers to the count of pixel values, and S is the geometric mean feature having the size of $[1\times1]$.

Entropy:It is used to calculate dissimilarity in MRI and its value will be very high for better performance. It is computed as,

$$S = \sum\sum H(m,n) \log H(m,n) \tag{24}$$

Accordingly, the entropy feature is denoted as, S with the size of $[1\times1]$. Finally, the statistical features generated from the segmented image results are expressed as,

$$A = \{S, \ldots S\} \tag{25}$$

where, A shows the statistical features with the size of $[1\times7]$ and this dimension is resized into $[1\times32\times32]$ for smoothing the training process. The feature map generated using HA-ESTR are represented as,

$$A = \{A_1 \| A_2 \| A_3 \| A_4 \|\} \tag{26}$$

Here, A is the feature map of HA-ESTR features with the size of $[1\times32\times32\times4]$, respectively.

D. HATDL-DCNN-BiLSTM Classification

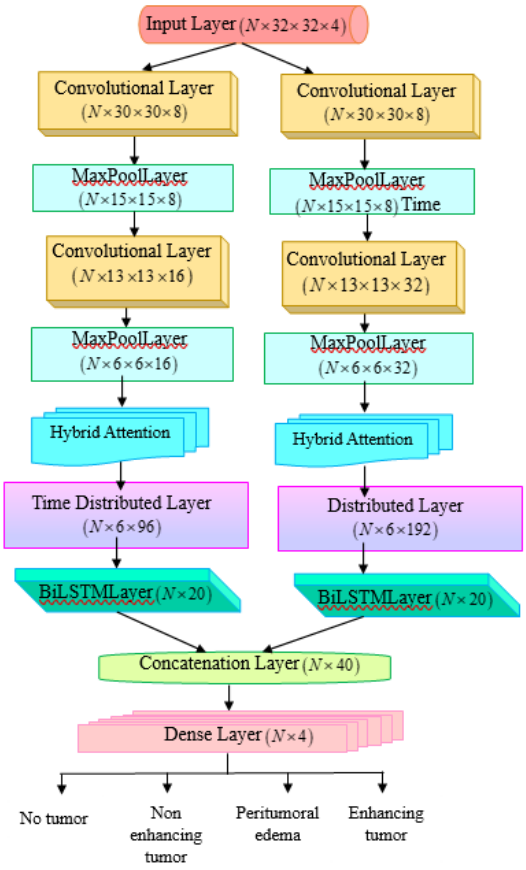

Fig. 3. Architecture of proposed HATDL-DCNN-BiLSTM.

The above Fig. 3 depicts the proposed framework, is modelled by applying the attention models, like split attention and double attention with Temporal Difference Learning (TDL) and CNN-BiLSTM using Distributed training [36] [37]. The benefit of applying this model for classification is due to its efficiency in higher training process. The integration of TDL helps to detect the output more accurately based on the working principle of unsupervised learning model. The distributed model provides completely effective solution with limited number of epochs by allocating the resources in a distributed manner. Hence, it reduces communication overhead and solve the communication delay caused due to the improper allocation of resources. The distributed learning framework partition the dataset and distribute it among the machines, and each data uses same weight factor but trains under various batches and finally, the results are averaged to get global gradient and it also enable to achieve faster training. The proposed HATDL with DCNN-BiLSTM model is made up of various layers, like convolution,

maxpooling, time distributed, Bidirectional, and dense layer [37]. The input layer gets the input by the dimension of $[N \times 32 \times 32 \times 4]$ and fed to the convolution layer. The model considers two convolution layers that contains the filter size of 64 and 128, and followed by the convolution layer, maxpooling layers are utilized to minimize the dimension size. The aim of convolution and the pooling layer is to filter the incoming information for extracting important features, in which the convolution layer performs convolution operation between input features and the smaller matrices referred as filters or kernels.

Let us assume the input matrix as x, where $x \to (A)$, y refers a kernel matrix, and O be the result matrix with rows and columns as p and q.

$$O[p,q] = x.y[p,q] = \sum\sum y[a,c].x[p-a,q-c] \tag{27}$$

Convolution layer uses ReLU activation function, which is commonly used activation function in the CNN model. The major benefit of using this activation function is that it does not require to activate each neuron at same time, as it converts all the negative value into '0', and due to this reason, ReLU offers more computational efficiency. The ReLU is expressed as,

$$F(J) = J = \max(0, J) \tag{28}$$

The pooling is the sub-sampling model aims to minimize the size of convolution matrix and enable to enhance the robustness of framework. After the maxpooling layer performs the operations, HA layer is applied and it generates the features with the dimension of $[N \times 6 \times 6 \times 16]$. Accordingly, the flatten or time distributed layer is utilized to normalize the features from the dimension $[N \times 6 \times 6 \times 16]$ into $[N \times 9 \times 96]$, and also the BiLSTM layer reduce the feature size into $[N \times 20]$. Each unit in the BiLSTM network contains a memory cell as well as three gates, namely forget, input and output gate and they are used to maintain the flow of information. The input passed to the input gate is expressed as,

$$K = \sigma(I.[g, Y] + Q) \tag{29}$$

Here, σ denotes activation function, Y shows the current input that is obtained from the output of flatten layer, I shows weight matrix, Q represents bias vector, and g represents previous hidden state. The sigmoid output is represented as,

$$w = \sigma(I.[g, Y] + Q) \tag{30}$$

where, w indicates sigmoid output.

$$\tilde{W} = \tanh(I.[g, Y] + Q) \tag{31}$$

Here, $\tilde{W}$ shows sigmoid output. The output of new cells state is specified as,

$$W = K.W + w.\tilde{W} \tag{32}$$

where, W shows new cells state and the output obtained through the output gate is expressed as,

$$N = \sigma(I[g, Y] + Q) \tag{33}$$

$$g = N.\tanh(W) \tag{34}$$

Here, σ shows sigmoid function, Y is the input at time c, g indicates hidden state at time c, tanh refers hyperbolic tangent function, I and Q are the weight and bias vector. The output receives from two BiLSTM layers are fused together by concatenating the features with the size of $[N \times 40]$, which undergoes to dense layer that creates classification result having the dimension of $[N \times 4]$ through sigmoid activation function. Accordingly, the accurate classification is accomplished by minimizing the error rate through loss function. Here, loss function considered to reduce the error value is accomplished using categorical cross entropy measure that is expressed in Eq. (3). Hence, the model generates the output of four different grades, as normal case, non-enhancing tumor, peritumoral edema, and indicates enhancing tumor.

IV. RESULTS

This section illustrates results of proposed HATDL-DCNN-BiLSTM by varying two different datasets using the performance metrics.

A. Experimental Setup

The proposed HATDL with DCNN-BiLSTM model is simulated in the PYTHON tool with windows 10 OS, intel core processor, and 16 GB RAM.

B. Dataset Description

This experimentation is done using BraTS 2018 dataset [38], and BraTS 2019 dataset [39]. BraTS 2018 dataset [38] contains multimodal scans available at four different modalities, namely T1, post contrast T1-weighted (T1Gd), T2-weighted (T2), and T2 fluid Attenuated Inversion Recovery (T2-FLAIR). The BraTS 2019 dataset [39] contains multimodal scans and they are available at four different modalities as similar that of above dataset. Also, both the dataset contains four different labels, namely grade-0 as no tumor, grade-1 as non-enhancing tumor, grade-2 as peritumoral edema, and grade-3 as enhancing tumor.

C. Evaluation Metrics

The effectiveness of the proposed framework is measured with metrics, namely accuracy, F1-score, precision, and recall.

Accuracy: It shows the percentage of accurately predicted samples to the total number of samples predicted.

$$A = \frac{G + G}{G + G + H + H} \tag{35}$$

Here, A is the accuracy, G and G are the true positive and the true negative, whereas H and H are the false positive and the false negative.

Precision: It shows the number of true positives towards total number of true and false positives.

$$P = \frac{G}{G + H} \tag{36}$$

Recall: It refers to the percentage of total number of relevant instances found in the data sample.

$$R = \frac{G}{G + H} \tag{37}$$

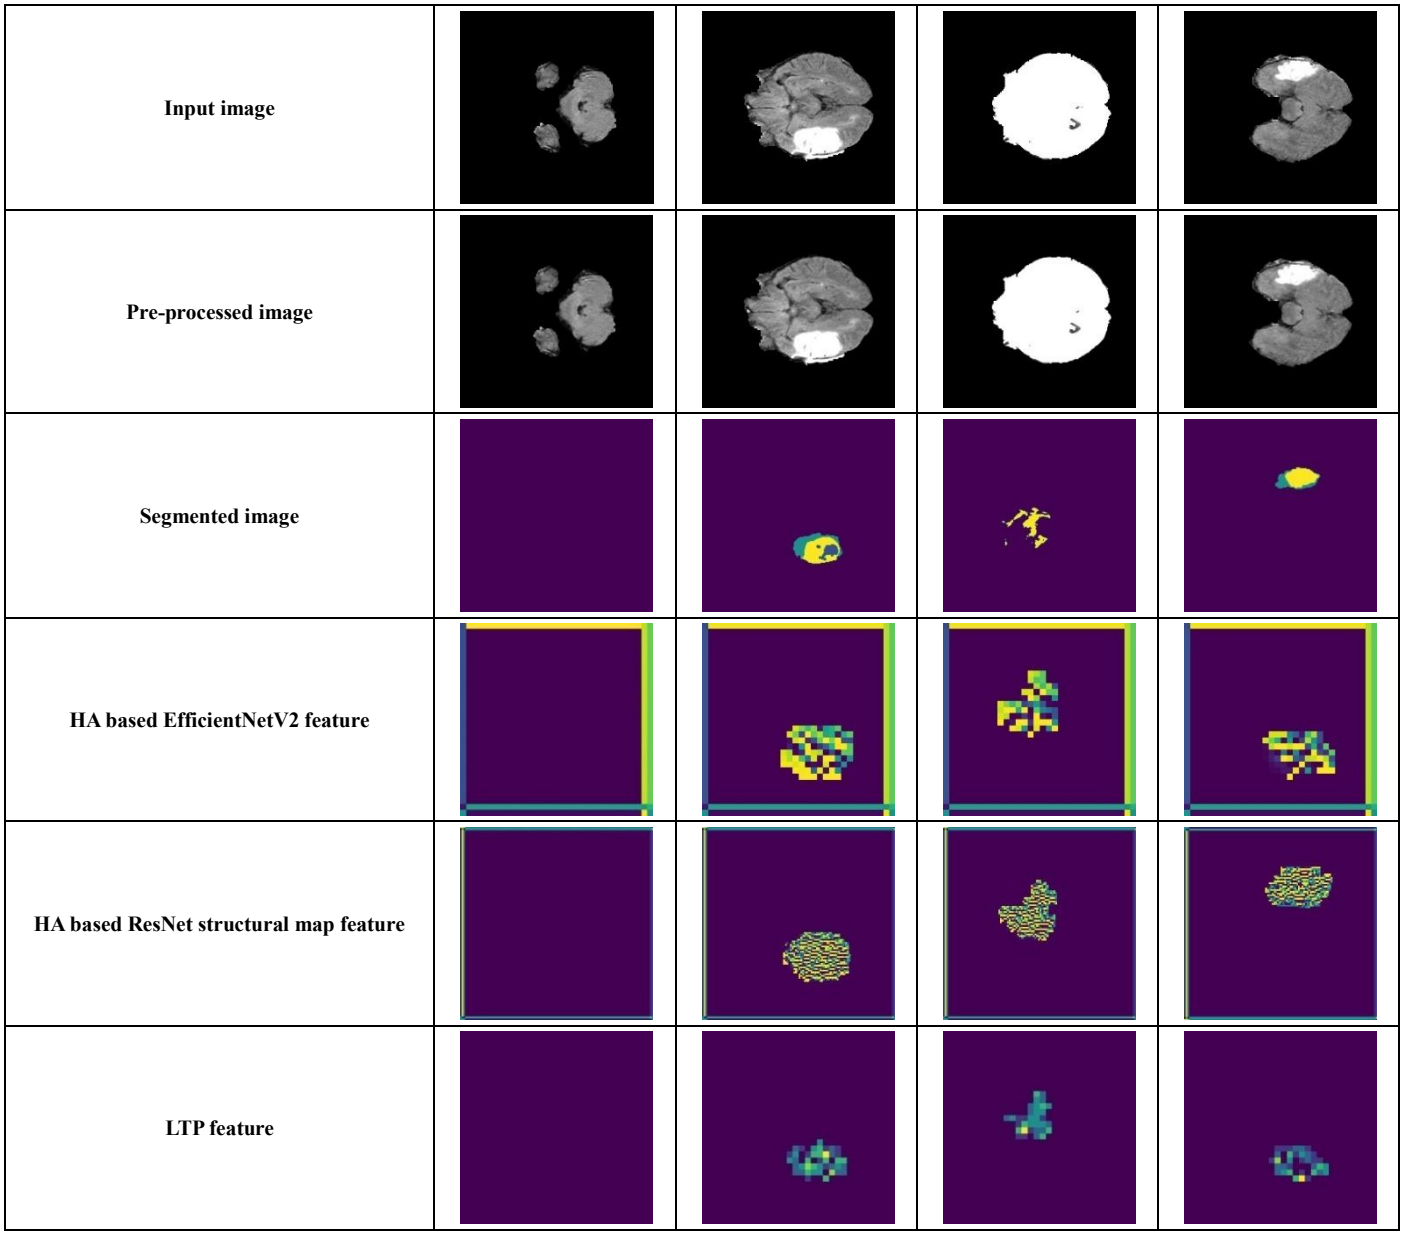
F1-score: It is the weighted average value of precision and recall measure.

$$F = 2 * \frac{P \times R}{P + R} \tag{38}$$

Here, P is the precision, R shows recall, and F is the F1-score.

D. Sample Image Results

This section presents the image results collected in BT classification with two different datasets. Fig. 4 shows the sample image results collected using BraTS 2018 dataset. The sample images of the proposed methods that undergoes each phase are captured and are briefly explained in the below figure. The imaging modality belongs to each class, like normal, enhancing tumor, non-enhancing tumor and peritumoral edema are captured and shown below.



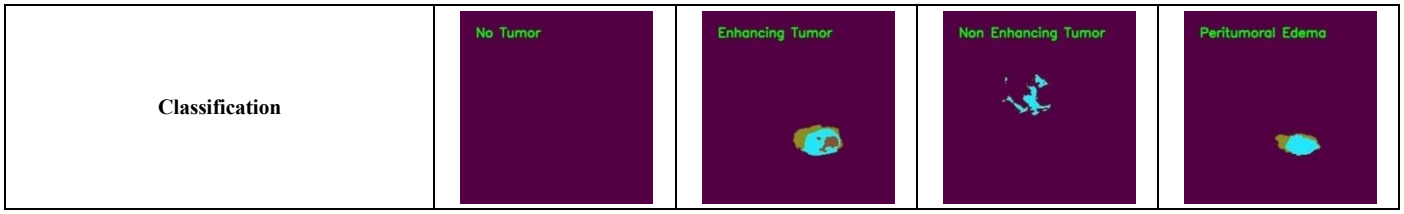


Fig. 4. Sample image results observed by BraTs 2018 dataset.

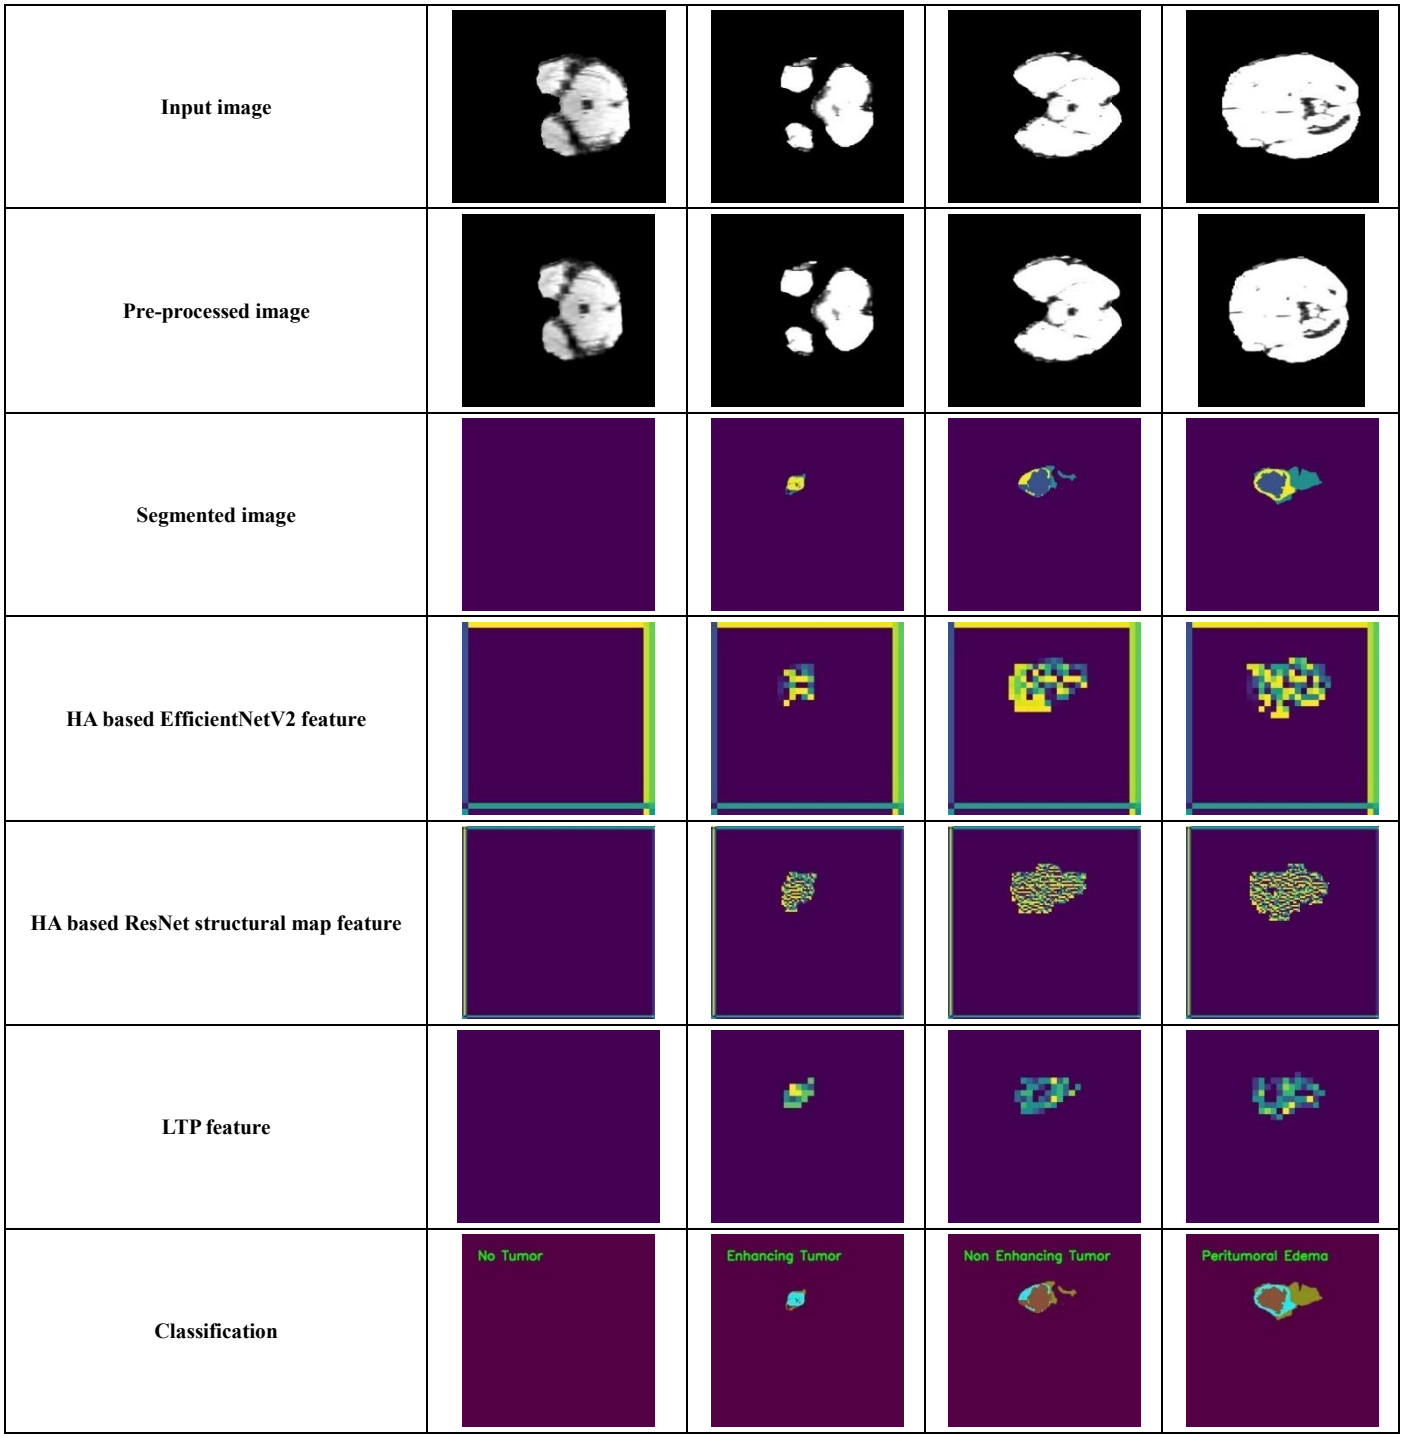

Fig. 5. Sample image results obtained by BraTs 2019 dataset.

The Fig. 5 depicts the sample image results captured by BraTS 2019 dataset. For each grade of BT classification, the images are collected using proposed HATDL with DCNN-BiLSTM, and the collected samples images are clearly represented in the below figure with each classification stage.

E. Performance Analysis

This section explains the performance analysis of HATDL-DCNN-BiLSTM by varying the training percentage of k-fold with two different datasets.

1) Analysis based on BraTS 2018 dataset: Fig. 6 depicts the analysis done with BraTS 2018 dataset with training data. Fig. 6 (a) shows accuracy measure. With 80% of training data, the accuracy observed by the HATDL-DCNN-BiLSTM by varying the epoch from 20, 40, 60, 80, and 100 is 87.12%, 88.72%, 91.36%, 4.75%, 97.55%. The analysis made by F1-score is depicted in Fig. 6 (b). For 80% training data, the F1-score computed by HATDL-DCNN-BiLSTM for epoch 20 is 87.11%, epoch 40 is 88.71%, epoch 60 is 91.35%, epoch 80 is 94.73%, and epoch 100 is 97.54%. The performance analysis observed using precision is illustrated in Fig. 6 (c). The precision measured by HATDL-DCNN-BiLSTM at 80% training data for epoch 20 is 87.01%, epoch 40 is 89.11%, epoch 60 is 91.21%, epoch 80 is 95.77%, and epoch 100 is 96.70%. Fig. 6 (d) depicts analysis of recall measure. The recall observed by the proposed HATDL-DCNN-BiLSTM for 80% training data by varying epoch from 20 to 100 is 87.21%, 88.32%, 91.49%, 93.72%, and 98.38%, respectively. The epoch 20 refers that 20 times, the model is trained with 20 iterations, and epoch 40 means that 40 times the model is trained with 40 iterations, and is similar for remaining epochs. Hence, increasing the value of epoch, the performance of HATDL-DCNN-BiLSTM increases effectively due to the increasing volume of trained data. If training data is 60% used, the remaining data are used for testing process and so the performance degrades. The training data of 80% refers that 80% data are allowed in the training procedure and only remaining 20% is considered for testing, and this could allow the model to improve the performance. Hence, increasing the training percentage increases the model performance.

Fig. 7 depicts the analysis done with BraTS 2018 dataset by varying k-fold. Fig. 7 (a) illustrates accuracy measure. Accuracy obtained at k-fold of 10 by the proposed HATDL-DCNN-BiLSTM with epoch 20 is 88.96%, epoch 40 is 91.18%, epoch 60 is 94.18%, epoch 80 is 95.74%, and epoch 100 is 96.62%. The analysis described by F1-score is shown in Fig. 7 (b). The F1-score computed by HATDL-DCNN-BiLSTM at 10 k-fold value by varying the epoch from 20 to 100 is 88.95%, 91.62%, 93.92%, 95.72%, and 96.75%. The performance analysis made using precision is illustrated in Fig. 7 (c). The precision obtained by HATDL-DCNN-BiLSTM with k-fold 10 for epoch 20, 40, 60, 80, and 100 is 88.81%, 90.47%, 93.47%, 95.47%, and 95.91%. Fig. 7 (d) illustrates analysis of recall measure. The recall observed by HATDL-DCNN-BiLSTM with k-fold of 10 for epoch 20 is 89.09%, 40 is 92.79%, 60 is 94.36%, 80 is 95.98%, and 100 is 97.61%, respectively. For K-fold of 8, the entire dataset is partitioned into eight sets and the model is trained for eight times to analyze the performance. The dataset is divided into different sets with respect to k-fold and model is trained based on the value of k-fold such that it simulates the performance to increase the efficiency. As, increasing the k-fold systematically increases the number of times that the model could be trained, which boost the performance of proposed HATDL-DCNN-BiLSTM.
