

Volume 16 Issue 1

January 2025

ISSN 2156-5570(Online)

ISSN 2158-107X(Print)

Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief
IJACSA
Volume 16 Issue 1 January 2025

ISSN 2158-107X (Print)

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Arun Kulkarni

University of Texas at Tyler

Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciunzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Dr Ronak AL-Haddad

Anglia Ruskin University / Cambridge

Domain of Research : Technology Trends, Communication, Security, Software Engineering and Quality, Computer Networks, Cyber Security, Green Computing, Multimedia Communication, Network Security, Quality of Service

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Advanced Machine Learning Approaches for Accurate Migraine Prediction and Classification

Authors: Chokri Baccouch, Chaima Bahar

PAGE 1 – 11

Paper 2: A Comparative Study of Predictive Analysis Using Machine Learning Techniques: Performance Evaluation of Manual and AutoML Algorithms

Authors: Karim Mohammed Rezaul, Md. Jewel, Anjali Sudhan, Mifta Uddin Khan, Maharage Roshika Sathsarani Fernando, Kazy Noor e Alam Siddiquee, Tajnuva Jannaf, Muhammad Azizur Rahman, Md Shabiul Islam

PAGE 12 – 31

Paper 3: Detection of DDoS Cyberattack Using a Hybrid Trust-Based Technique for Smart Home Networks

Authors: Oghenetajiri Okporokpo, Funminiyi Olajide, Nemitari Ajenka, Xiaoqi Ma

PAGE 32 – 41

Paper 4: Forecasting the Emergence of a Dominant Design by Classifying Product and Process Patents Using Machine Learning and Text Mining

Authors: Koji Masuda, Yoshinori Hayashi, Shigeyuki Haruyama

PAGE 42 – 48

Paper 5: Control Interface for Multi-User Video Games with Hand or Head Gestures in Directional Key-Based Games

Authors: Oscar Ramirez-Valdez, César Baluarte-Araya, Rodrigo Castillo-Lazo, Italo Ccoscco-Alvis, Alexander Valdiviezo-Tovar, Alexander Villafuerte-Quispe, Dylan Zuñiga-Huraca

PAGE 49 – 60

Paper 6: Teaching Programming in Higher Education: Analyzing Trends, Technologies, and Pedagogical Approaches Through a Bibliometric Lens

Authors: Mariuxi Vinuesa-Morales, Jorge Rodas-Silva, Cristian Vidal-Silva

PAGE 61 – 68

Paper 7: Harnessing the Power of Federated Learning: A Systematic Review of Light Weight Deep Learning Protocols

Authors: Haseeb Khan Shinwari, Riaz Ul Amin

PAGE 69 – 78

Paper 8: SEC-MAC: A Secure Wireless Sensor Network Based on Cooperative Communication

Authors: Yassmin Khairat, Tamer O. Diab, Ahmed Fawzy, Samah Osama, Abd El- Hady Mahmoud

PAGE 79 – 87

Paper 9: Digital Twin Model from Freehanded Sketch to Facade Design, 2D-3D Conversion for Volume Design

Authors: Kohei Arai

PAGE 88 – 95

Paper 10: Marked Object-Following System Using Deep Learning and Metaheuristics

Authors: Ken Gorro, Elmo Ranolo, Lawrence Roble, Rue Nicole Santillan, Anthony Ilano, Joseph Pepito, Emma Sacan, Deofel Balijon

PAGE 96 – 106

Paper 11: Hawk-Eye Deblurring and Pose Recognition in Tennis Matches Based on Improved GAN and HRNet Algorithms

Authors: Weixin Zhao

PAGE 107 – 118

Paper 12: A Highly Functional Ensemble of Improved Chaos Sparrow Search Optimization Algorithm and Enhanced Sun Flower Optimization Algorithm for Query Optimization in Big Data

Authors: Mursubai Sandhya Rani, N. Raghavendra Sai

PAGE 119 – 134

Paper 13: IT Spin-Offs Challenges in Developing Countries

Authors: Mahmoud M. Musleh, Ibrahim Mohamed, Hasimi Sallehudin, Hussam F. Abushawish

PAGE 135 – 142

Paper 14: Multi-Factors Analysis Using Visualizations and SHAP: Comprehensive Case Analysis of Tennis Results Forecasting

Authors: Yuan Zhang

PAGE 143 – 152

Paper 15: Exploring Diverse Conventional and Deep Linguistic Features for Sentiment Analysis of Online Content

Authors: Yajun Tang

PAGE 153 – 162

Paper 16: An AI-Driven Approach for Advancing English Learning in Educational Information Systems Using Machine Learning

Authors: Xue Peng, Yue Wang

PAGE 163 – 171

Paper 17: Investigating Immersion and Presence in Virtual Reality for Architectural Visualization

Authors: Athira Azmi, Sharifah Mashita Syed Mohamad

PAGE 172 – 179

Paper 18: Data Mining MRO-BP Network-Based Evaluation Effectiveness of Music Teaching

Authors: Yifan Fan

PAGE 180 – 189

Paper 19: Employing Data-Driven NOA-LSSVM Algorithm for Indoor Spatial Environment Design

Authors: Di Wang, Hui Ma, Tingting Lv

PAGE 190 – 200

Paper 20: Enhancing Customer Churn Prediction Across Industries: A Comparative Study of Ensemble Stacking and Traditional Classifiers

Authors: Nurul Nadzirah bt Adnan, Mohd Khalid Awang

PAGE 201 – 208

Paper 21: Hotspots and Insights on Quality Evaluation of Study Tours: Visual Analysis Based on Bibliometric Methodology

Authors: Meihua Deng

PAGE 209 – 220

Paper 22: Internet of Things (IoT) Driven Logistics Supply Chain Management Coordinated Response Mechanism

Authors: Chong Li

PAGE 221 – 232

Paper 23: Big Data Analytics of Knowledge and Skill Sets for Web Development Using Latent Dirichlet Allocation and Clustering Analysis

Authors: Karina Djunaidi, Dine Tiara Kusuma, Rahma Farah Ningrum, Puji Catur Siswipraptini, Dina Fitria Murad

PAGE 233 – 244

Paper 24: Optimizing Multi-Dimensional SCADA Report Generation Using LSO-GAN for Web-Based Applications

Authors: Fanxiu Fang, Guocheng Qi, Haijun Cao, He Huang, Lingyi Sun, Jingli Yang, Yan Sui, Yun Liu, Dongqing You, Wenyu Pei

PAGE 245 – 256

Paper 25: Optimizing Decentralized Exam Timetabling with a Discrete Whale Optimization Algorithm

Authors: Emily Sing Kiang Siew, San Nah Sze, Say Leng Goh

PAGE 257 – 265

Paper 26: Fusion of Multimodal Information for Video Comment Text Sentiment Analysis Methods

Authors: Jing Han, Jinghua Lv

PAGE 266 – 274

Paper 27: Enhancing Stock Market Forecasting Through a Service-Driven Approach: Microservice System

Authors: Asaad Algarni

PAGE 275 – 282

Paper 28: Improved Whale Optimization Algorithm with LSTM for Stock Index Prediction

Authors: Yu Sun, Sofianita Mutalib, Liwei Tian

PAGE 283 – 295

Paper 29: Multinode LoRa-MQTT of Design Architecture and Analyze Performance for Dual Protocol Network IoT

Authors: Rizky Rahmatullah, Hongmin Gao, Ryan Prasetya Utama, Pupu Dani Prasetyo Adi, Jannat Mubashir, Rachmat Muwardi, Widar Dwi Gustian, Hanifah Dwiyaniti, Yuliza

PAGE 296 – 303

Paper 30: Machine Learning-Based Fifth-Generation Network Traffic Prediction Using Federated Learning

Authors: Mohamed Abdelkarim Nimir Harir, Edwin Ataro, Clement Temaneh Nyah

PAGE 304 – 313

Paper 31: CN-GAIN: Classification and Normalization-Denormalization-Based Generative Adversarial Imputation Network for Missing SMES Data Imputation

Authors: Antonius Wahyu Sudrajat, Ermatita, Samsuryadi

PAGE 314 – 322

Paper 32: An Agile Approach for Collaborative Inquiry-Based Learning in Ubiquitous Environment

Authors: Bushra Fazal Khan, Sohaib Ahmed

PAGE 323 – 333

Paper 33: M-COVIDLex: The Construction of a Domain-Specific Mixed Code Sentiment Lexicon

Authors: Siti Noor Allia Noor Ariffin, Sabrina Tiun, Nazlia Omar

PAGE 334 – 347

Paper 34: Optimized Hybrid Deep Learning for Enhanced Spam Review Detection in E-Commerce Platforms

Authors: Abdulrahman Alghaligah, Ahmed Alotaibi, Qaisar Abbas, Sarah Alhumoud

PAGE 348 – 357

Paper 35: Optimization of Fourth Party Logistics Routing Considering Infection Risk and Delay Risk

Authors: Guihua Bo, Sijia Li, Mingqiang Yin, Mingkun Chen, Xin Liu

PAGE 358 – 369

Paper 36: Convolutional Neural Network and Bidirectional Long Short-Term Memory for Personalized Treatment Analysis Using Electronic Health Records

Authors: Prasanthi Yavanamandha, D. S. Rao

PAGE 370 – 379

Paper 37: Spam Detection Using Dense-Layers Deep Learning Model and Latent Semantic Indexing

Authors: Yasser D. Al-Otaibi, Shakeel Ahmad, Sheikh Muhammad Saqib

PAGE 380 – 387

Paper 38: A Deep Learning for Arabic SMS Phishing Based on URLs Detection

Authors: Sadeem Alsufyani, Samah Alajmani

PAGE 388 – 396

Paper 39: Jordanian Currency Recognition Using Deep Learning

Authors: Salah Alghyaline

PAGE 397 – 404

Paper 40: Foreground Feature-Guided Camouflage Image Generation

Authors: Yuelin Chen, Yuefan An, Yonsen Huang, Xiaodong Cai

PAGE 405 – 411

Paper 41: Adoption of Generative AI-Enhanced Profit Sharing Digital Systems in MSMEs: A Comprehensive Model Analysis

Authors: Mardiana Andarwati, Galandaru Swalaganata, Sari Yuniarti, Fandi Y. Pamuji, Edward R. Sitompul, Kuku Yudhistiro, Puput Dani Prasetyo Adi

PAGE 412 – 422

Paper 42: DeepLabV3+ Based Mask R-CNN for Crack Detection and Segmentation in Concrete Structures

Authors: Yuewei Liu

PAGE 423 – 431

Paper 43: Multi-Objective Optimization of Construction Project Management Based on NSGA-II Algorithm Improvement

Authors: Yong Yang, Jinrui Men

PAGE 432 – 444

Paper 44: Performance Evaluation of Efficient and Accurate Text Detection and Recognition in Natural Scenes Images Using EAST and OCR Fusion

Authors: Vishnu Kant Soni, Vivek Shukla, S. R. Tandan, Amit Pimpalkar, Neetesh Kumar Nema, Muskan Naik

PAGE 445 – 453

Paper 45: AI-Powered Learning Pathways: Personalized Learning and Dynamic Assessments

Authors: Mohammad Abrar, Walid Aboraya, Rawad Abdel Khaliq, Kabali P Subramanian, Yousuf Al Husaini, Mohammed Al Husaini

PAGE 454 – 462

Paper 46: Feature Reduction and Anomaly Detection in IoT Using Machine Learning Algorithms

Authors: Adel Hamdan, Muhannad Tahboush, Mohammad Adawy, Tariq Alwada'n, Sameh Ghwanmeh

PAGE 463 – 470

Paper 47: Network Security Based on GCN and Multi-Layer Perception

Authors: Wei Yu, Huitong Liu, Yu Song, Jiaming Wang

PAGE 471 – 480

Paper 48: An Ensemble Semantic Text Representation with Ontology and Query Expansion for Enhanced Indonesian Quranic Information Retrieval

Authors: Liza Trisnawati, Noor Azah Binti Samsudin, Shamsul Kamal Bin Ahmad Khalid, Ezak Fadzrin Bin Ahmad Shaubari, Sukri, Zul Indra

PAGE 481 – 489

Paper 49: A Review of Reinforcement Learning Evolution: Taxonomy, Challenges and Emerging Solutions

Authors: Ji Loun Tan, Bakr Ahmed Taha, Norazreen Abd Aziz, Mohd Hadri Hafiz Mokhtar, Muhammad Mukhlisin, Norhana Arsad

PAGE 490 – 502

Paper 50: Towards Transparent Traffic Solutions: Reinforcement Learning and Explainable AI for Traffic Congestion

Authors: Shan Khan, Taher M. Ghazal, Tahir Alyas, M. Waqas, Muhammad Ahsan Raza, Oualid Ali, Muhammad Adnan Khan, Sagheer Abbas

PAGE 503 – 511

Paper 51: Strategic Supplier Selection in Advanced Automotive Production: Harnessing AHP and CRNN for Optimal Decision-Making

Authors: Karim Haricha, Azeddine Khat, Yassine Issaoui, Ayoub Bahnasse, Hassan Ouajji

PAGE 512 – 524

Paper 52: Understanding Art Deeply: Sentiment Analysis of Facial Expressions of Graphic Arts Using Deep Learning

Authors: Fei Wang

PAGE 525 – 534

Paper 53: A Hybrid Transformer-ARIMA Model for Forecasting Global Supply Chain Disruptions Using Multimodal Data

Authors: Qingzi Wang

PAGE 535 – 543

Paper 54: Marine Predator Algorithm and Related Variants: A Systematic Review

Authors: Emmanuel Philibus, Azlan Mohd Zain, Didik Dwi Prasetya, Mahadi Bahari, Norfadzlan bin Yusup, Rozita Abdul Jalil, Mazlina Abdul Majid, Azurah A Samah

PAGE 544 – 568

Paper 55: The Current Challenges Review of Deep Learning-Based Nuclei Segmentation of Diffuse Large B-Cell Lymphoma

Authors: Gei Ki Tang, Chee Chin Lim, Faezahtul Arbaeyah Hussain, Qi Wei Oung, Aidy Irman Yazid, Sumayyah Mohammad Azmi, Haniza Yazid, Yen Fook Chong

PAGE 569 – 583

Paper 56: User Interface Design of Digital Test Based on Backward Chaining as a Measuring Tool for Students' Critical Thinking

Authors: I Putu Wisna Ariawan, P. Wayan Arta Suyasa, Agus Adiarta, I Komang Gede Sukawijana, Nyoman Santiyadnya, Dewa Gede Hendra Divayana

PAGE 584 – 590

Paper 57: Early Alzheimer's Disease Detection Through Targeting the Feature Extraction Using CNNs

Authors: D Prasad, K Jayanthi, Pradeep Tilakan

PAGE 591 – 602

Paper 58: Enhancement of Coastline Video Monitoring System Using Structuring Element Morphological Operations
Authors: I Gusti Ngurah Agung Pawana, I Made Oka Widyantara, Made Sudarma, Dewa Made Wiharta, Made Widyia Jayantari

PAGE 603 – 611

Paper 59: Application of MLP-Mixer-Based Image Style Transfer Technology in Graphic Design

Authors: Qibin Wang, Xiao Chen, Huan Su

PAGE 612 – 621

Paper 60: Integrating Blockchain and Edge Computing: A Systematic Analysis of Security, Efficiency, and Scalability

Authors: Youness Bentayeb, Kenza Chaoui, Hassan Badir

PAGE 622 – 632

Paper 61: Enhancing COVID-19 Detection in X-Ray Images Through Deep Learning Models with Different Image Preprocessing Techniques

Authors: Ahmad Nuruddin bin Azhar, Nor Samsiah Sani, Liu Luan Xiang Wei

PAGE 633 – 644

Paper 62: Deep Learning-Based Automatic Cultural Translation Method for English Tourism

Authors: Jianguo Liu, Ruohan Liu

PAGE 645 – 653

Paper 63: A Novel Metric-Based Counterfactual Data Augmentation with Self-Imitation Reinforcement Learning (SIL)

Authors: K. C. Sreedhar, T. Kavya, J. V. S. Rajendra Prasad, V. Varshini

PAGE 654 – 661

Paper 64: Segmentation of Nano-Particles from SEM Images Using Transfer Learning and Modified U-Net

Authors: Sowmya Sanan V, Rimal Isaac R S

PAGE 662 – 677

Paper 65: Application of Big Data Mining System Integrating Spectral Clustering Algorithm and Apache Spark Framework

Authors: Yuansheng Guo

PAGE 678 – 686

Paper 66: Large Language Models for Academic Internal Auditing

Authors: Houda CHAMMAA, Rachid ED-DAOUDI, Khadija BENAZZI

PAGE 687 – 694

Paper 67: Enhanced Facial Expression Recognition Based on ResNet50 with a Convolutional Block Attention Module

Authors: Liu Luan Xiang Wei, Nor Samsiah Sani

PAGE 695 – 711

Paper 68: YOLO-WP: A Lightweight and Efficient Algorithm for Small-Target Detection in Weld Seams of Small-Diameter Stainless Steel Pipes

Authors: Huaishu Hou, Yukun Sun, Chaofei Jiao

PAGE 712 – 722

Paper 69: Determination of Pre Coding Elements and Activities for a Pre Coding Program Model for Kindergarten Children Using the Fuzzy Delphi Method (FDM)

Authors: Siti Naimah Rahman, Norly Jamil, Intan Farahana Abdul Rani, Hafizul Fahri Hanafi

PAGE 723 – 732

Paper 70: A Novel Internet of Things and Cloud Computing-Driven Deep Learning Framework for Disease Prediction and Monitoring

Authors: Bo GUO, Lei NIU

PAGE 733 – 740

Paper 71: Comparison of Artificial Neural Network and Long Short-Term Memory for Modelling Crude Palm Oil Production in Indonesia

Authors: Brodjol Sutijo Suprih Ulama, Robi Ardana Putra, Fausania Hibatullah, Mochammad Reza Habibi, Mochammad Abdillah Nafis

PAGE 741 – 747

Paper 72: Enhanced Jaya Algorithm for Quality-of-Service-Aware Service Composition in the Internet of Things

Authors: Yan SHI

PAGE 748 – 755

Paper 73: Enhancing Facial Expressiveness in 3D Cartoon Animation Faces: Leveraging Advanced AI Models for Generative and Predictive Design

Authors: Langdi Liao, Lei Kang, Tingli Yue, Aiting Zhou, Ming Yang

PAGE 756 – 767

Paper 74: A Lightweight Anonymous Identity Authentication Scheme for the Internet of Things

Authors: Zhengdong Deng, Xuannian Lei, Junyu Liang, Hang Xu, Zhiyuan Zhu, Na Lin, Zhongwei Li, Jingqi Du

PAGE 768 – 775

Paper 75: Comparative Analysis of Feature Selection Based on Metaheuristic Methods for Human Heart Sounds Classification Using PCG Signal

Authors: Motaz Farooq A Ben Hamza, Nilam Nur Amir Sjarif

PAGE 776 – 791

Paper 76: Developing an Integrated Platform to Track Real Time Football Statistics for Somali Football Federation (SFF)

Authors: Bashir Abdinur Ahmed, Husein Abdirahman Hashi, Abdifatah Abdilatif Ahmed, Abdikani Mahad Ali

PAGE 792 – 797

Paper 77: Elevator Abnormal State Detection Based on Vibration Analysis and IF Algorithm

Authors: Zhaoxiu Wang

PAGE 798 – 808

Paper 78: LFM Book Recommendation Based on Fusion of Time Information and K-Means

Authors: Dawei Ji

PAGE 809 – 818

Paper 79: A Proposed Approach for Agile IoT Smart Cities Transformation– Intelligent, Fast and Flexible

Authors: Othman Asiry, Ayman E. Khedr, Amira M. Idrees

PAGE 819 – 829

Paper 80: A Novel Optimization Strategy for CNN Models in Palembang Songket Motif Recognition

Authors: Yohannes, Muhammad Ezar Al Rivian, Siska Devella, Tinaliah

PAGE 830 – 841

Paper 81: A Novel Hybrid Algorithm Based on Butterfly and Flower Pollination Algorithms for Scheduling Independent Tasks on Cloud Computing

Authors: Huiying SHAO

PAGE 842 – 850

Paper 82: Task Scheduling in Fog Computing-Powered Internet of Things Networks: A Review on Recent Techniques, Classification, and Upcoming Trends

Authors: Dongge TIAN

PAGE 851 – 861

Paper 83: A System Dynamics Model of Frozen Fish Supply Chain

Authors: Leni Herdiani, Maun Jamaludin, Iman Sudirman, Widjajani, Ismet Rohimat

PAGE 862 – 873

Paper 84: Methodological Review of Social Engineering Policy Model for Digital Marketing

Authors: Wenni Syafitri, Zarina Shukur, Umi Asma' Mokhtar, Rossilawati Sulaiman

PAGE 874 – 885

Paper 85: Comprehensive Bibliometric Literature Review of Chatbot Research: Trends, Frameworks, and Emerging Applications

Authors: Nazruddin Safaat Harahap, Aslina Saad, Nor Hasbiah Ubaidullah

PAGE 886 – 896

Paper 86: Application of Collaborative Filtering Optimization Algorithm Based on Semantic Relationships in Interior Design

Authors: Kai Zhao, Lei Wang

PAGE 897 – 905

Paper 87: Hybrid Clustering Framework for Scalable and Robust Query Analysis: Integrating Mini-Batch K-Means with DBSCAN

Authors: Sridevi K N, Rajanna M

PAGE 906 – 912

Paper 88: Modified Moth-Flame Optimization Algorithm for Service Composition in Cloud Computing Environments

Authors: Yeling YANG, Miao SONG

PAGE 913 – 922

Paper 89: Enhanced Task Scheduling Algorithm Using Harris Hawks Optimization Algorithm for Cloud Computing

Authors: Fang WANG

PAGE 923 – 933

Paper 90: PCE-BP: Polynomial Chaos Expansion-Based Bagging Prediction Model for the Data Modeling of Combine Harvesters

Authors: Liangyi Zhong, Mengnan Deng, Maolin Shi, Ting Lou, Shaoyang Zhu, Jingwen Zhan, Zishang Li, Yi Ding

PAGE 934 – 943

Paper 91: Detecting Emotions with Deep Learning Models: Strategies to Optimize the Work Environment and Organizational Productivity

Authors: Cantuarias Valdivia Luis Alberto de Jesús, Gómez Human Javier Junior, Sierra-Liñan Fernando

PAGE 944 – 953

Paper 92: Sentiment and Emotion Analysis with Large Language Models for Political Security Prediction Framework

Authors: Liyana Safra Zaabar, Adriana Arul Yacob, Mohd Rizal Mohd Isa, Muslihah Wook, Nor Asiakin Abdullah, Suzaimah Ramli, Noor Afiza Mat Razali

PAGE 954 – 960

Paper 93: Text-to-Image Generation Method Based on Object Enhancement and Attention Maps

Authors: Yongsen Huang, Xiaodong Cai, Yuefan An

PAGE 961 – 968

Paper 94: Enhanced Traffic Congestion Prediction Using Attention-Based Multi-Layer GRU Model with Feature Embedding

Authors: Sreelekha M, Midhunchakkaravarthy Janarthanan

PAGE 969 – 983

Paper 95: Robust Joint Detection of Coronary Artery Plaque and Stenosis in Angiography Using Enhanced DCNN-GAN

Authors: M. Jayasree, L. Koteswara Rao

PAGE 984 – 995

Paper 96: Design and Research of Accounting Automation Management System Based on Swarm Intelligence Algorithm and Deep Learning

Authors: Dan Gui, Wei Ma, Wanfei Chen

PAGE 996 – 1005

Paper 97: Enhancing Road Safety: A Multi-Modal Drowsiness Detection System for Drivers

Authors: Guirrou Hamza, Mohamed Zeriab Es-Sadek, Youssef Taher

PAGE 1006 – 1011

Paper 98: Decoding Face Attributes: A Modified AlexNet Model with Emphasis on Correlation-Heterogeneity Relationship Between Facial Attributes

Authors: Abdelaali Benaiss, Otman Maarouf, Rachid El Ayachi, Mohamed Biniz, Mustapha Oujaoura

PAGE 1012 – 1026

Paper 99: Evaluation of Eye Movement Features and Visual Fatigue in Virtual Reality Games

Authors: Yuwei Ji

PAGE 1027 – 1038

Paper 100: High-Accuracy Vehicle Detection in Different Traffic Densities Using Improved Gaussian Mixture Model with Cuckoo Search Optimization

Authors: Nor Afiqah Mohd Aris, Siti Suhana Jamaian

PAGE 1039 – 1052

Paper 101: PSR: An Improvement of Lightweight Cryptography Algorithm for Data Security in Cloud Computing

Authors: P. Sri Ram Chandra, Syamala Rao, Naresh K, Ravisankar Malladi

PAGE 1053 – 1058

Paper 102: Optimizing Feature Selection in Intrusion Detection Systems Using a Genetic Algorithm with Stochastic Universal Sampling

Authors: RadhaRani Akula, GS Naveen Kumar

PAGE 1059 – 1068

Paper 103: Optimizing Route Planning for Autonomous Electric Vehicles Using the D-Star Lite Algorithm

Authors: Bhakti Yudho Suprpto, Suci Dwijayanti, Desi Windisari, Gatot Aria Pratama

PAGE 1069 – 1078

Paper 104: Stacking Regressor Model for PM2.5 Concentration Prediction Based on Spatiotemporal Data

Authors: Mitra Unik, Imas Sukaesih Sitanggang, Lailan Syaufina, I Nengah Surati Jaya

PAGE 1079 – 1086

Paper 105: Feature Substitution Using Latent Dirichlet Allocation for Text Classification

Authors: Norsyela Muhammad Noor Mathivanan, Roziyah Mohd Janor, Shukor Abd Razak, Nor Azura Md. Ghani

PAGE 1087 – 1098

Paper 106: Multilabel Classification of Bilingual Patents Using OneVsRestClassifier: A Semiautomated Approach

Authors: Slamet Widodo, Ermatita, Deris Stiawan

PAGE 1099 – 1106

Paper 107: Dolphin Inspired Optimization for Feature Extraction in Augmented Reality Tracking

Authors: Indhumathi S, Christopher Clement J

PAGE 1107 – 1116

Paper 108: Empirical Analysis of Variations of Matrix Factorization in Recommender Systems

Authors: Srilatha Tokala, Murali Krishna Enduri, T. Jaya Lakshmi, Koduru Hajarathaiah, Hemlata Sharma

PAGE 1117 – 1138

Paper 109: Efficient Tumor Detection in Medical Imaging Using Advanced Object Detection Model: A Deep Learning Approach

Authors: Taoufik Saidani

PAGE 1139 – 1145

Paper 110: Efficient Anomaly Detection Technique for Future IoT Applications

Authors: Ahmad Naseem Alvi, Muhammad Awais Javed, Bakhtiar Ali, Mohammed Alkathami

PAGE 1146 – 1158

Paper 111: GRACE: Graph-Based Attention for Coherent Explanation in Fake News Detection on Social Media

Authors: Orken Mamyrbayev, Zhanibek Turysbek, Mariam Afzal, Marassulov Ussen Abdurakhimovich, Ybytayeva Galiya, Muhammad Abdullah, Riaz Ul Amin

PAGE 1159 – 1171

Paper 112: Intelligent Fault Diagnosis for Elevators Using Temporal Adaptive Fault Network

Authors: Zhiyu Chen

PAGE 1172 – 1182

Paper 113: High-Precision Multi-Class Object Detection Using Fine-Tuned YOLOv11 Architecture: A Case Study on Airborne Vehicles

Authors: Nasser S. Albalawi

PAGE 1183 – 1190

Paper 114: AI-Driven Image Recognition System for Automated Offside and Foul Detection in Football Matches Using Computer Vision

Authors: Qianwei Zhang, Lirong Yu, WenKe Yan

PAGE 1191 – 1198

Paper 115: Deep Q-Learning-Based Optimization of Path Planning and Control in Robotic Arms for High-Precision Computational Efficiency

Authors: Yuan Li, Byung-Won Min, Haozhi Liu

PAGE 1199 – 1207

Paper 116: Android Malware Detection Through CNN Ensemble Learning on Grayscale Images

Authors: El Youssofi Chaymae, Choug dali Khalid

PAGE 1208 – 1217

Paper 117: Cross-Domain Health Misinformation Detection on Indonesian Social Media

Authors: Divi Galih Prasetyo Putri, Savitri Citra Budi, Arida Ferti Syafiandini, Ikhlasul Amal, Revandra Aryo Dwi Krisnandaru

PAGE 1218 – 1224

Paper 118: Comparison of Machine Learning Algorithms for Malware Detection Using EDGE-IIoTSET Dataset in IoT

Authors: Jawaher Alshehri, Almaha Alhamed, Mounir Frikha, M M Hafizur Rahman

PAGE 1225 – 1238

Paper 119: Building Detection from Satellite Imagery Using Morphological Operations and Contour Analysis over Google Maps Roadmap Outlines

Authors: Arbab Sufyan Wadood, Ahthasham Sajid, Muhammad Mansoor Alam, Mazliham MohD Su'ud, Arshad Mehmood, Inam Ullah Khan

PAGE 1239 – 1255

Paper 120: Exploring Machine Learning in Malware Analysis: Current Trends and Future Perspectives

Authors: Noura Alyemni, Mounir Frikha

PAGE 1256 – 1268

Paper 121: SM9 Key Encapsulation Mechanism for Power Monitoring Systems

Authors: Chao Hong, Peng Xiao, Pandeng Li, Zhenhong Zhang, Yiwei Yang, Biao Bai

PAGE 1269 – 1277

Paper 122: A Review of Analyzing Different Agricultural Crop Yields Using Artificial Intelligence

Authors: Vijaya Bathini, K. Usha Rani

PAGE 1278 – 1290

Paper 123: LMS-YOLO11n: A Lightweight Multi-Scale Weed Detection Model

Authors: YaJun Zhang, Yu Xu, Jie Hou, YanHai Song

PAGE 1291 – 1300

Paper 124: DBYOLOv8: Dual-Branch YOLOv8 Network for Small Object Detection on Drone Image

Authors: Yawei Tan, Bingxin Xu, Jiangsheng Sun, Cheng Xu, Weiguo Pan, Songyin Dai, Hongzhe Liu

PAGE 1301 – 1309

Paper 125: Eagle Framework: An Automatic Parallelism Tuning Architecture for Semantic Reasoners

Authors: Haifa Ali Al-Hebshi, Muhammad Ahtisham Aslam, Kawther Saeedi

PAGE 1310 – 1322

Paper 126: Imbalance Datasets in Malware Detection: A Review of Current Solutions and Future Directions

Authors: Hussain Almajed, Abdulrahman Alsaqer, Mounir Frikha

PAGE 1323 – 1335

Paper 127: Artificial Intelligence in Financial Risk Early Warning Systems: A Bibliometric and Thematic Analysis of Emerging Trends and Insights

Authors: Muhammad Ali Chohan, Teng Li, Suresh Ramakrishnan, Muhammad Sheraz

PAGE 1336 – 1351

Paper 128: DBFN-J: A Lightweight and Efficient Model for Hate Speech Detection on Social Media Platforms

Abstract—Migraine is a neurovascular disorder with a prevalence that exceeds 1 billion individuals worldwide, but it has long been recognized to have unique diagnostic challenges due to its heterogeneous pathophysiology and dependence on subjective assessments. As has been extensively documented by a number of international law bodies, migraine in the workplace has been identified as a significant issue that requires urgent attention. Migraine defined by episodic, unilateral and debilitating symptoms including aura, nausea incurs a high socioeconomic burden in disability. Mechanisms such as altered cortical excitability and trigeminal system activation, although researched to a high extent, are still inadequately understood. Deep learning and machine learning (ML) hold tremendous potential for transforming diagnosis and classification of migraine. This study evaluates several machine learning (ML) models such as gradient boosting, decision tree, random forest, k-Nearest Neighbors (KNN), support vector machine (SVM), logistic regression, multi-layer perceptron (MLP), artificial neural network (ANN), and deep neural network (DNN) for multi-class classification of migraine. By employing advanced preprocessing techniques and publicly obtainable datasets, the study addresses the challenge of identifying different types of migraines that may share common variables. In this study, several machine learning (ML) models including gradient boosting, decision tree, random forest, k-Nearest Neighbors show that for multi-class migraine classification MLP and Gradient Boosting had good performance in most models, but did perform poorly in complex subcategories like Typical Aura with Migraine. Both attained high accuracies (96.4% and 97%, respectively). KNN and Logistic Regression, two traditional models, performed well at basic classifications but poorly at more complex situations; Neural networks (ANN and DNN) showed much flexibility towards data complexities. These results underscore how important it is to align model selection with data properties and provide avenues for improving performance through regularization and feature engineering. This strategy illustrates how AI-powered solutions can revolutionize the way we manage, treat, and prevent migraines across the globe.

Keywords—Headache classification; migraine; migraine diagnosis; migraine classification

I. INTRODUCTION

Migraine is a complex and common neurovascular disease that poses many challenges to accurate diagnosis and effective treatment. More than 90% of people in the world are affected by headache disorders in general [1], but migraine stands out for its effects on the brain, body, and quality of life in particular. They are among the most common causes of neurological consultations, and treatment costs in countries such as China approach an annual 672.7 billion yuan [2]. Although migraines are not directly life-threatening, they significantly impair work

performance, physical health, mental well-being, and overall quality of life [3].

The multifaceted nature of migraine, a chronic medical condition with overlapping legal and social dimensions, is well-documented. The impact of this condition on individuals' rights, professional and personal lives is significant and thus requires a comprehensive response that combines advanced healthcare, legal protection, and technological innovation. Internationally, international laws play a crucial role in regulating the treatment of chronic and complex diseases such as migraine, which have a profound impact on patients' quality of life and functioning. In this context, the International Covenant on Economic, Social and Cultural Rights (ICESCR) is a significant instrument, as it recognizes in [4] the right of individuals to health, a comprehensive right that is not limited to the provision of treatment but extends to the right to access basic healthcare services, including migraine treatment. This right is essential not only to improve the state of health of patients but also to restore the ability to lead a normal professional and social life [5, 6].

The Convention on the Rights of Persons with Disabilities (CRPD) further underscores the imperative to ensure that individuals with disabilities, including those afflicted by chronic migraine, have access to essential health services [7]. The CRPD obliges state parties to formulate comprehensive health policies that guarantee the provision of specialised medical care, taking into account individual differences in diagnosis and treatment. The utilisation of innovative technology, including machine learning techniques, has the potential to enhance the accuracy of diagnosis and personalise treatment regimens, ensuring that all patients receive the timely and optimal care they require. Legislative frameworks, such as the Americans with Disabilities Act (ADA) in the United States, play a pivotal role in safeguarding individuals with migraine from discrimination in the workplace. This legislation stipulates the provision of reasonable accommodations, such as flexible work schedules, quiet work environments, and the ability to work from home, thereby ensuring that individuals with migraine can continue to perform their professional duties in a manner that is both conducive to their well-being and effective in their roles [5,8].

Migraine, the top cause of functional disability among people aged 15 to 55, can severely hamper productivity and routine activities during episodes. The often-unpredictable nature of migraine attacks increases the anxiety and dysfunction related to them by the uncertainty of when they might occur. Conven-

tional treatment strategies either interrupt migraine during an attack or reduce their frequency through preventative measures. Preventive medication on high-risk days, as well as abortive treatment that is most effective early in the migraine cycle, has moved from proof-of-concept studies with more promising early data. This highlights the need for prediction-based solutions in migraine management. In the International Classification of Headache Disorders (ICHD). In [9], headaches are classified into three categories: primary headaches (e.g., migraine, tension-type headaches, and trigeminal autonomic cephalalgias), secondary headaches, and cranial neuropathies or facial pain disorders.

Causes of migraines are myriad, including diet, lifestyle, genetics, and physiology (Fig. 1). The role of dietary triggers, such as caffeine, alcohol, and food additives, together with lifestyle factors, such as stress, poor sleeping patterns, and lack of exercise, cannot be underestimated in precipitating attacks. Additional risk factors include having a genetic predisposition to the condition and heightened susceptibility driven by physiological as well as biochemical factors, from hormonal fluctuations to neurotransmitter imbalances, which leads to the onset of migraines. Migraines have a multi-faceted pathophysiology, with two key components being triggers (stimuli causing attacks) and prodromal symptoms, cognitive, sensory, behavioral, or physical changes, that can occur 1 to 48 hours before an attack, and serve as critical but difficult-to-measure indicators of imminent migraines due to their highly subjective nature and methodological biases. Indeed, neurophysiological changes (e.g. changes in autonomic tone) can inform on this prodromal phase. Migraine and tension-type headaches are the most common types of primary headaches worldwide, with 10% and 40% respectively, while cluster headaches are rare, with an estimated prevalence of 0.1% [10, 11].

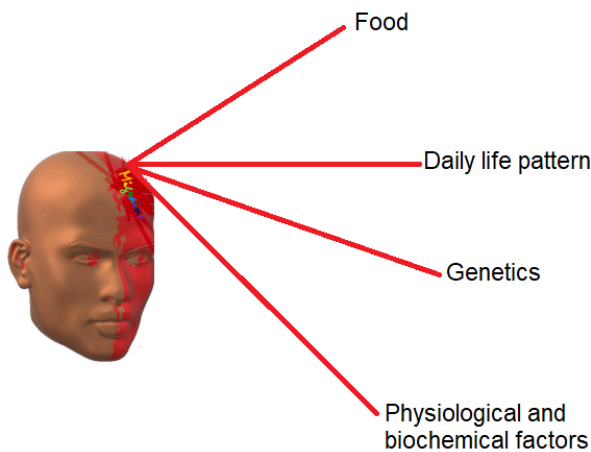

Fig. 1. Factors that trigger migraine.

Intractable migraines, with a 16% annual incidence in the general population, are the second most prevalent cerebral disease in the world and rank as the leading cause of disability worldwide, even more than all neurological diseases combined [12]. Migraines are generally divided into three categories: migraines with aura, migraines without aura, and chronic migraines. Migraines with aura occur in up to 25% of cases and are characterised by transient visual, speech, or neurological

abnormalities lasting no longer than an hour [13]. Migraines without aura, on the other hand, appear as unilateral, moderate-to severe-intensity, pulsatile pain, often with accompanying nausea and vomiting, photophobia, and phonophobia, and can last from 4 to 72 h if untreated [14]. Migraine is classified into episodic (less than 15 headache days per month) and chronic types (defined as 15 or more headache days per month with eight or more headache days with features of fully developed migraine), the latter being more frequent and having an unfavorable impact on daily life [15].

Digital technologies on the rise allow new opportunities in migraine management. Direct translation can occur through wearable technology and mobile health technologies for headache characteristics, prodromic symptoms, and physiological changes. However, because so much complexity is involved in the neurobiological processes underlying migraine, prediction can be difficult. Accurate prediction requires sophisticated models capable of integrating and interpreting complex flows of biological and physiological data. Machine learning (ML) appears to be a promising solution, as it can process and analyze complex and heterogeneous data types. Machine learning could streamline migraine detection, prediction, and classification processes, enhance diagnostic accuracy, optimize treatments, and ultimately reduce the financial and societal burden associated with migraine management.

This study aims to explore the revolutionary potential of machine learning (ML) to evolve migraine attack prediction, particularly in resource-limited settings with limited access to state-of-the-art medical technology. Even when they can be valuable, conventional diagnostics such as MRI (Magnetic Resonance Imaging), PET(Positron Emission Tomography) and CT(Computed Tomography) scans are pricey and require specialist knowledge, which places them at a disadvantage in developing countries. When using ML algorithms that provide a cost-efficient and high-throughput alternative, reliable systems for diagnosing and predicting the onset of migraine are now widely available.

Many advanced machine learning techniques were evaluated in this study, such as artificial neural networks (ANN), deep neural networks (DNN), multi-layer perceptron (MLP), logistic regression, k-nearest neighbors (KNN), support vector machines (SVM), gradient boosting, decision trees, and random forests. Models showed promising results with a model accuracy of 97.12% (MLP), 96.40% (Gradient Boosting), and 96.04% (Decision Tree). Such results showcase this exciting potential for AI-powered approaches to revolutionize headache management and improve patient outcomes globally.

The remainder of the paper is organized as follows: the “Related Work” section re-vIEWS prior research, while the “Materials and Methods” section outlines the proposed methodology and dataset. The “Experiments” section details the conducted experiments and their findings. Finally, the “Conclusion and Future Work” section summarizes the key results and outlines potential directions for future research.

II. RELATED WORK

Recent advances in artificial intelligence (AI) can yield complex predictive algorithms able to predict migraine episodes. Smith et al. For instance, [16] used supervised

machine learning methods such as random forests and deep learning networks on longitudinal data collected by biometric tracking devices or mobile applications. A great example was given by the team at the National Institutes of Health, who showed that neural network models were able to predict future migraine attacks 85% of the time by including trigger factors (stress, sleep, food, etc.) into the model. This underscores the need for machine learning to pre-emptive migraine treatment, and real-time data collection.

Several studies have explored whether the combination of multimodal data (e.g. genetic, environmental, and behaviour) can augment prediction accuracy. The model of Zhang et al. [4] was able to achieve better sensitivity and specificity than using conventional methods by integrating information from genetic profiles, lifestyle surveys, and wearable sensors. The results show how combining data from multiple sources can help us learn more about and predict migraine episodes.

There has also been ongoing research regarding advancement in early detection of migraines using brain imaging techniques as well as biomarkers. For example, during the premonitory phase of migraines, Garcia and his team found cues that predicted a migraine episode was coming [17] and uncovered discrepancies in patients' levels of neurotransmitters; that is, glutamate and serotonin. Using functional magnetic resonance imaging (fMRI), their study suggested that there are different patterns of brain activity before and during migraine attacks, with encouraging potential prospects for real-time detection. Adding to this, Garcia et al. [17] conducted further research on serum biomarkers in migraine patients, including increased levels of glutamate and serotonin. This opens up the potential of diagnosis by biomolecular profile and hints at neurological mechanisms. Their techniques help ensure early intervention strategies, which become more accurate by providing a non-biased way to identify migraines.

Continuous monitoring devices like smartwatches and fitness trackers have captured interest due to their ability in terms of potentially mitigating migraines. According to Lee et al. when physiological data (e.g. heart rate and stress) were collected in real time, they gave a 78% chance of detecting the initial symptoms for migraine [18]. These results highlight the benefits of regular physiologic monitoring in migraine therapy and may become a paving method for wearable technology-assisted preventive treatment fighting techniques.

Conventional approaches to migraine classification are based on the International Classification of Headache Disorders' (IHS) symptoms criteria. Recent studies, however, aim to improve this strategy by adding more precise clinical features. Müller et al. [19], for example, discovered a subtype of migraine associated with increased sensory sensitivities and sleep disturbances, opening the door to more individualized treatment choices.

The classification of migraines has been further transformed by genomic advancements. A meta-analysis of genetic research by Johnson et al. [20] found many genetic loci linked to heightened migraine risk. Their study suggested a genetic risk classification by combining genetic data with clinical information. This in turn permitted both patient stratification and treatment individualization to the genetic profile of each host.

The study in [21] used five different supervised machine learning methods which aimed to define group of symptoms described by participants as migraines. For classification and deployment, we used Weka data mining tool. The results indicated that, of all the models tested, naïve bayes would be more suitable and easier.

An investigation [22] used brain signals captured through an EEG and a computer-aided diagnostic (CAD) system to classify various forms of migraines. This system accomplished classification using deep learning models as follows: VGG16, ResNet101, and DenseNet121.

A method to integrate EEG in an online migraine detection tool for support of clinical decision making was also presented by a respective study [23]. The EEG dataset consisted of recordings from 21 healthy volunteers and 18 migraine patients. The results showed that the Bi-LSTM method with 128 channels outperformed other models, including Random Forests (RF), Linear Discriminant Analysis (LDA), and Support Vector Machines (SVM), with the maximum accuracy of 95.99%.

Furthermore, 400 patients' clinical data that had been annotated by domain experts was employed in a different study [24]. The 24 most pertinent factors were chosen after the researchers first collected data based on symptoms. Then, to categorize migraines, an Artificial Neural Network (ANN) and other conventional machine learning models were used. The ANN model outperformed other algorithms including SVM, Logistic Regression (LR), Decision Trees, and k-Nearest Neighbors (KNN) with a 97% classification accuracy for migraines.

In [25], different machine learning techniques were used to examine somatosensory evoked potential components in the frequency and temporal domains for migraine categorization. Among these were Logistic Regression (LR), Linear Discriminant Analysis (LDA), Random Forests (RF), k-Nearest Neighbors (KNN), Extreme Gradient Boosting (XGBoost), Support Vector Machines (SVM), and Multilayer Perceptrons (MLP). The models were able to differentiate between interictal or ictal migraine conditions and healthy controls with an accuracy of over 88%.

In detecting the two classes of headaches and differentiating between healthy controls and migraine sufferers, the CNN method based on an initiation module outperformed the conventional support vector machine, which had an accuracy of 83.67%, with a greater accuracy of 86.18% [26]. A feature selection technique was used in a different study [27] to enhance the migraine group's classification. With accuracies rising from 67% to 93%, 90% to 95%, and 93% to 94%, respectively, this method improved the performance of the Naive Bayes, SVM, and Adaboost classifiers. In a similar vein, a study by [28] that used EEG signals to diagnose migraines early revealed that the artificial neural network (ANN) outperformed logistic regression and support vector machines (SVM) with an accuracy of 88%. Hemoglobin changes in the prefrontal cortex (PFC) were observed using functional near-infrared spectroscopy (fNIRS) during a mental arithmetic (MAT) task. The specificities and sensitivities were 75% and 100% for chronic migraine (CM) and 100% and 75% for medication overuse headaches (MOH), respectively. Based on the findings,

it seems that fNIRS and machine learning work better together to classify migraines [7].

In the medical industry, data mining techniques are essential. Data exploration classification methods such as Naïve Bayes, KNN, SVM, and random forests were used in the study [29]. Among these, Naïve Bayes emerged as the best classifier, with an accuracy of 0.905 and a precision of 0.475. A medical case study on hemodynamic parameter monitoring of actual patients is presented as a practical scenario to monitor real patients' life parameters using the WBSN (Wireless Body Sensor Network). N4SID models (Numerical Subspace State-Space System Identification) were built with a low false positive rate and an average forecasting horizon of 47 minutes [30]. Finally, we used one of machine learning techniques to distinguish healthy subjects with migraineurs by combining three functional measures from rs-fMRI [31].

Ufuk et al. [32] proposed the use of deep neural networks (DNN) for diagnosing migraines, achieving an accuracy of 95%. They used eight attributes to diagnose three types of migraines (with aura, without aura, and chronic migraine). Ferroni [33] suggested using a decision support system (DSS) to diagnose medication-overuse migraine, with an accuracy of 82%. In another study [34], a DSS was proposed for diagnosing primary headaches, achieving an accuracy of 80%. The authors compared four machine learning techniques: Bagging, Naïve Bayes, Boosting, and Random Forest. Rober Keight [36] proposed using decision trees (DST) to diagnose primary headache types using 9 machine learning classifiers, achieving an accuracy of 95%. Hao Yang [35] used convolutional neural networks (CNN) for migraine classification from MRI, achieving an accuracy of 99%. Akben [36] implemented an artificial neural network (ANN) for migraine diagnosis, with an accuracy of 83.3%. Akben [37] also used an SVM classifier to diagnose migraines, achieving an accuracy of 85%. Subasi [38] tested different versions of the Random Forest method for migraine diagnosis, obtaining an accuracy of 85.95%. De la Hoz [39] used an ANN for migraine diagnosis, achieving an accuracy of 88%. Yolanda Garcia [27] proposed feature selection for migraine diagnosis, achieving an accuracy of 90%. Even more recently, researchers have focused on the use of MRI and fMRI images for the detection and classification of migraines [40–42].

In [43], the study presented the design and development of an ML decision support system aimed at providing diagnosis of tension headaches and migraines. The results obtained with the logistic regression model were found to be the best among all. The accuracy level raised to 0.84 with a stand against models such as gradient boosting algorithms and random forests.

The Table I describes the parameters that were used during related works.

III. MATERIALS AND METHODS

The provision of preparation of the data takes a long time and uses relatively powerful computational resources, with the straightforward methods of deep learning/machine learning. Therefore, getting some relevant information depends on an effective machine learning system. Designing further this machine-learning architecture is therefore quite compli-

TABLE I. PARAMETERS USED DURING RELATED WORKS

Study	Techniques Used	Dataset/Attributes	Accuracy
[23]	Bi-LSTM, SVM, LDA, Random Forest	EEG signals from 18 migraine patients and 21 controls	95.99%
[24]	ANN, SVM, Logistic Regression, Decision Trees, KNN	Clinical data from 400 patients	97%
[25]	SVM, RF, KNN, XGBoost, LDA, MLP, Logistic Regression	Somatosensory evoked potential features	88%
[26]	CNN with initiation module	EEG signals	86.18%
[27]	Naïve Bayes, SVM, Adaboost	Feature selection applied to migraine group	Increased from 67%-94%
[28]	ANN	EEG signals, fNIRS	88%
[29]	Naïve Bayes, KNN, SVM, Random Forest	Data exploration techniques for classification	90.5% (Naïve Bayes)
[32]	DNN	8 attributes for diagnosing 3 types of migraines	95%
[33]	DSS (Decision Support System)	Medication-overuse migraine data	82%
[35]	DSS	Primary headache data	80%
[24]	DST (Decision Trees)	9 machine learning classifiers for primary headache types	95%
[36]	CNN	MRI data for migraine classification	99%
[37]	ANN	-	83.3%
[38]	SVM	-	85%
[39]	Random Forest	Different versions of Random Forest	85.95%
[40]	ANN	-	88%
[43]	Logistic Regression, Gradient Boosting, Random Forest	Symptom-based data for headache classification	84%

cated. Customizing or tuning a model involves adjusting the parameters of the classifier.

In this study, different models were trained using a variety of machine-learning algorithms. These were adjusted and optimized afterward for the dataset in order to enhance the quality of classification. As shown in Fig. 2, the algorithms that have been considered include Gradient Boosting, Decision Tree, Random Forest, k-Nearest Neighbors (KNN), Support Vector Machine (SVM), Logistic Regression, Multi-Layer Perceptron (MLP), Artificial Neural Networks (ANN), and Deep Neural Networks (DNN).

A. Dataset

An in-depth examination of contributing causes and related symptoms is made possible by the migraine database that is supplied, which provides a thorough and exhaustive overview of the many components of this ailment. Individuals' ages, which range from 18 to 70 years old, are a crucial component of the demographic data since they enable investigation of the effects of migraines on various age groups. This dataset is notable for its comprehensive examination of the features of migraine episodes, recording variables like attack duration (which can vary from 30 minutes to 72 hours) and frequency (which can range from 1 to 10 attacks per month), providing a more accurate picture of symptom severity and recurrence. Additionally, a scale from 1 to 10 is used to assess the pain's intensity, with 10 being the most severe agony.

Additional information is given on where the pain may occur, which assists with spotting recurring patterns, such as

Fig. 2. Proposed system flowchart for migraine classification.

a preponderance of unilateral pain (either right or left) or pain felt on the forehead, neck, or temples. The database has also captured those associated conditions, nausea and vomiting, typical signs of migraine. The other statistic showing that 70% of migraineurs feel sick and about 50% vomit during a headache creates a more nuanced clinical impression of the side effects.

In addition to the actual pain, this database includes phenomenological and other sensory characteristics of migraines: phonophobia (hypersensitivity to sound), photophobia (hypersensitivity to light), and other visual anomalies (blurriness, aura, etc.). The extremely important features of this disease dealing with the sensory aspect are the symptoms, and about 60% of migraineurs experience photophobia and phonophobia during their attacks.

This dataset, with its rich pool of variables, affords taking a deep look into migraine research, leading to empirical observations to determine the associations among variables.

Having this data will allow for extensive studies related to how age, frequency of attacks, intensity, and concomitant symptoms influence the severity of migraines. The scientific and medical community would greatly benefit from this resource, as it is of prime importance to improve diagnostics, design personalized treatments, and take more focused approaches to treatment in clinical practice.

1) *Database preprocessing:* Data preparation is an important step before applying machine learning models in order to obtain really reliable results. This comprises a number of crucial sub-steps in the context of our analysis of migraine data, including noise reduction, inconsistent data repair, error detection, and data conversion into useful numerical variables.

We began our efforts by doing much cleaning of the data: extreme values and missing information were removed, mismatches resolved, and missing numbers imputed. For example, any rows where there was missing data on features such as age, severity of pain, or frequency of attack were either deleted or imputed. To further ensure data validity and consistency, problematic cases of data entry (like somewhat unbelievable values of negative ages and migraine attacks lasting more than 72 hours) were fixed.

The input was then transformed into numerical variables so that machine learning algorithms could process it more easily. To make the data interpretable for the analytic models, some variables, such as pain intensity, were left on a numeric scale (from 1 to 10), while other variables, like related symptoms (nausea, vomiting, phonophobia), were converted into binary variables.

These methods have strengthened data quality and made our dataset a better candidate for machine learning models while simultaneously guaranteeing a balanced representation of the various classes (such as severe and non-severe migraines). This pre-emphasis technique is what allows a model to achieve the highest performance possible during training and yield analyses that are more reliable and precise of variables linked to migraines.

The study relied on an initial corpus of 1,386 clinical records of Tunisian patients suffering from various pathologies associated with migraines. Several machine learning classifiers, including KNN, SVM, RF, DT, LG, MLP, ANN, and DNN, were applied. The proposed analysis used the diagnosed condition and migraine symptoms as input data.

This analysis focused on 23 variables, including age, visual disturbances, dizziness, and vomiting that represent the common clinical symptomology during an acute headache. In addition, the variable identified as diagnostic was included to signify the type of migraine classically referred to. This variable is the diagnosis of the migraine type that was made by the doctor on the basis of the patient's medical history and reported symptoms. The symptomatic variables record the manifestations such as nausea or lightheadedness.

The Feature Importance Analysis is shown in Fig. 3, with enrolling age, visual disturbances, intensity of pain, and phonophobia among the class-leading features in migraine classification. On the contrary, there are worthless factors such as ataxia, diplopia, and dysarthria that have little influence on classification and could be disregarded; this would increase

efficiency and thereby help simplify the model. This procedure emphasizes the priority of emphasizing the necessary components while eliminating the least important ones to boost the performance of classifications.

Fig. 3. Feature importance analysis for migraine classification.

B. Classification Models

The algorithms testing on the migraine classification dataset after applying the basic preprocessing methods, various machine learning methods including GB, LG, SVM, KNN, DT, RF, MLP, ANN as well as deep neural network DNN were applied to the dataset.

The parameters utilized in the experiment are described in Table II.

TABLE II. HYPER-PARAMETERS FOR DIFFERENT MODELS

Model	Hyper-parameter	Value
multirow DNN	Number of epochs	100
	Activation function	relu
	Optimizer	Adam
	Model	Sequential (first layer)
	Number of neurons at first dense layer	512
	Hidden layer	2
	Classification function	softmax
	Loss function	categorical-cross entropy
SVM	Kernel	Linear
	Class	sklearn.svm.SVC
	Regularization parameters C	1
	Probability	True
KNN	Neighbors range	(1,15,1)
	Weights	Uniform
	Metric distance	Euclidean
RF	n_estimators	100
	max_depth	50
	min_samples_split	5
	min_samples_leaf	2
	max_features	sqrt
	random_state	42

IV. EXPERIMENTS AND RESULTS

The outcomes for migraine classification using various machine learning models are presented in this section. Specifically, we focus the assessment on the classifiers of complexity namely Multi-Layer Perceptron (MLP), Deep Neural Networks

(DNN), and Artificial Neural Networks (ANN). These classifiers were examined in detail with a view that performance assessment based on a variety of training sets would reveal their capability in maintaining accuracy, robustness, applicability in migraine diagnosis and attacks management with a large dataset. In-person examination and assessment reveal to a great degree the applicability of such techniques in real life including the merits and demerits.

A. ANN Model

Despite the fact that both belong to the same family of neural networks, ANN and DNN stand separated by layers-of-Depth and complexity, which will influence their efficiency in predicting, detecting, and classifying migraines. ANN, having just one or two hidden layers, is more preferred in classification, such as classifying migraineurs from clinical tabular data, because ANN works better with small datasets due to its lesser training data requirements and resistance to overfitting. Fig. 4 illustrates the basic architecture of ANN.

Fig. 4. Basic model of ANN.

The accuracy curves (Fig. 5) show a steady improvement in performance over the 100 epochs, reaching a high level and stabilizing around 95% for both the training and validation sets. The model does not exhibit significant signs of overfitting, as the validation accuracy closely follows the training accuracy. This indicates that the dense neural network (ANN) has effectively learned to generalize without being restricted solely to the training data.

Fig. 5. Accuracy and loss graph of ANN model.

The loss curve (Fig. 5) demonstrates a steady decline, converging toward a low value, indicating the effective training of the ANN model. The validation loss closely mirrors the training loss, confirming good generalization without noticeable overfitting or underfitting.

The confusion matrix (Fig. 6) provides a detailed assessment of the model's classification performance across different categories. Correct predictions are highlighted along the main diagonal, with most classes, including Basilar-type aura, Familial hemiplegic migraine, Migraine without aura, Other, and Typical aura without migraine, exhibiting near-perfect accuracy. However, some misclassifications are noted, particularly for Sporadic hemiplegic migraine, which shows moderate confusion with the Other category, and for Typical aura with migraine, where a few samples are incorrectly classified as Basilar-type aura or Familial hemiplegic migraine.

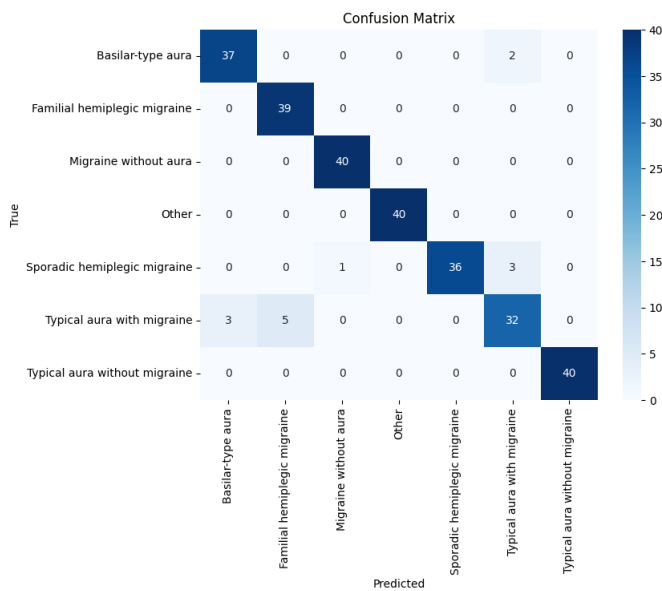

Fig. 6. Confusion matrix of ANN model.

The ANN model provides relatively good performance, and that can be seen by clear separability among most of the classes and fewer misclassifications there. Additional support for effective learning and generalization is provided by accuracy and loss curves. However, remaining challenges relate more to classes with overlapping characteristics, such as migraines with or without aura and the different types of hemiplegic migraine. Class imbalances or an insufficient distinction among classes in the dataset could be responsible for the said problems.

B. DNN Model

Deep neural networks (DNN) become particularly suited for such works because of their more comprehensive and deeper architecture and their capability to furnish complex information, for instance, time-series information collected by Internet of Things sensors for other physiological signals (ECG, vectorcardiogram), or functional MRI images. The ability of these models to perform well in complex tasks—such as discerning migraine types (e.g. aura versus non-aura) and amalgamating data from various sources to give timely

warning of migraine attacks—is astonishing. An ability to capture complex interactions proves helpful to tackling migraine classification’s different challenging problems. However, the efficiency of DNN usually depends on the availability of large datasets and the employment of complex regularization techniques to minimize the risks of overfitting. Thus, this emphasizes how critical it is to have proper data preparation and model optimization to fully leverage the advantage of DNN in this field.

The architecture of the DNN model used in the classification of migraine types is described in its Fig. 7. It has four layers—an input layer, two hidden layers, and an output layer. This architecture can manage the complexity of the migraine-related datasets and give extremely high classification results.

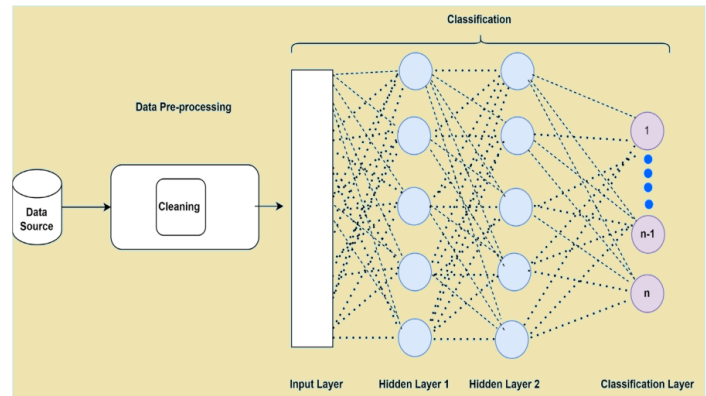

Fig. 7. Fundamental architectural design of a deep neural network applied to migraine classification.

The DNN model showed a fast improvement of performances within the first epochs, after which the accuracy curve was stable at above 95% up to the end of 100 iterations, as seen in Fig. 8. This behavior shows the ability of the model to form these important data features and learn them. The training accuracy matched close to the validation accuracy, which shows good generalization capability. The two curves diverge only mildly, indicating that the model avoids overfitting and can keep providing high performance on unseen data.

The loss curve, also shown in Fig. 8, drops swiftly in the first few epochs, indicating a decent learning process that reduces errors. The optimization is seen to be successful when the curve plateaus at a low value. The same pattern occurs in the validation loss, which indicates that the model was well-regularized and neither overfit nor underfit. Lastly, an additional line indicates the test loss, which tells the generalization of this model to independent data, lying very close to the training and validation losses.

This robustness of the model has also been corroborated by the recall and F1-score metrics, assessing its capacity to classify each class correctly and strike a balance between precision and recall. All average values for these metrics exceed 0.95.

The confusion matrix in Fig. 9 provides a detailed treatment of misclassifications. The great clustering of values along the diagonal illustrates that most samples have been correctly assigned. There are, however, slight misclassifications, including

Fig. 8. Accuracy and loss graph of DNN model.

the assignment of four sporadic hemiplegic migraine samples to other categories and the wrong assignment of two Basilar-type Aura samples as Typical Aura along with migraine. These unintentional errors are common in any multi-class classification problem; being rare, they barely dent the overall efficacy of the model.

Fig. 9. Confusion matrix of DNN model.

The findings reveal the successful classification of migraines by the DNN model and its high generalization capability for fresh data. The resilience of the model is evidenced by the almost-perfect results in numerous categories and overall high accuracy. These encouraging results suggest that DNN can support the diagnoses and categorizations of different types of migraine while maintaining a strong balance between learning and generalization.

C. Multi-Layer Perception Model

The architecture of the Multi-Layer Perceptron (MLP) model, presented in Fig. 10, is essential for classification tasks, particularly in predicting migraine types. Taking factors such as age, migraine severity, or symptom frequency as inputs, the architecture comprises three main modules: the input layer, hidden layer(s), and the output layer. The hidden neurons nest in various buried layers, using activation functions and

weight computations to identify complex patterns in the data. The output layer gives predictions like Migraine with Aura or Migraine without Aura. Every neuron uniformly influences the neurons in the downstream layers, thus enabling the MLP to model complex and intricate non-linear relations while analyzing clinical migraine data.

Fig. 10. MLP Model architecture.

How well the Multi-Layer Perceptron (MLP) model have performed in migraine prediction, detection, and classification is validated by the learning curves (Fig. 11). The loss curve which is an insight into learning, shows a very high decrease from 1.75 to around 0.2 during the initial 20 epochs, thereby it rapidly develops. It then stabilizes between 0.1 and 0.2, which indicates the model has been successfully trained and has effectively converged. Notably, when the training and validation loss curves are in close proximity it implies a lack of overfitting and high generalization to new data by the model which is another way of saying its accuracy is high hence.

The accuracy curves (Fig. 11) further underscore the model's success, showing a swift increase in performance, reaching 95 to 97% accuracy within the first 20 epochs and maintaining stability afterward. Although slight fluctuations in the validation curve occur likely due to mini-batch variations or sample differences they do not compromise the overall robustness of the results. The consistency observed between the training and validation curves for both accuracy and loss demonstrate that the model is well-regularized and capable of generalizing effectively.

These results support the MLP model's dependability in accurately diagnosing migraines while striking the ideal balance between generalization and learning.

The results gathered by the model are quite promising and reassuring in finding which kind of migraines types is dissimilar, even in the case of a multi-class scenario, when things are much more complicated. As the confusion matrix (Fig. 12) is quite detailed, we can witness the model's performance within different migraine categories.

Fig. 11. Accuracy and loss graph of MLP model.

Fig. 12. Confusion matrix of MLP model.

The performance of classes demonstrates very high precision in a small number of categories. Notably, Migraine without aura, Other, Sporadic hemiplegic migraine, and Typical aura without migraine are the best ones with precision, recall, and F1-score equal to 1.00. These facts are evidence for the model's ability to practically learn to correctly classify different types of migraines according to specific characteristics among other features by the time the model is finished.

For Basilar-type aura, the model achieved a precision of 97% and a recall of 95%, resulting in an F1-score of 96%. Although these results are outstanding, they indicate that a small number of samples were misclassified. Similarly, for familial hemiplegic migraine, while the model achieved a perfect recall of 100% indicating all instances of this class were identified, its precision was 89%, suggesting some degree of misclassification with other classes.

Performance was somewhat worse in the event of a typical aura with migraine, with an F1-score of 89% (precision of 94% and recall of 85%). Overlapping characteristics with different migraine kinds are probably to blame for this, which could make classification difficult.

97% accuracy was achieved in the experiment of experimenting with errors with a particular reason by the model and

the training data, and the precision is 0.9915, recall is 0.5926, and F1-score is 0.7321. In multi-class tasks that complicate the problem well, such as difficulty in distinguishing the boundary between the two classes or the presence of overlapping behaviors, the ability of this model to maintain balance is more than necessary. Together, these results establish that the model is not only able to learn from a variety of types of data but also to classify properly into many classes in general.

V. DISCUSSION

The research compared the supervisory learning models: Gradient Boosting, Decision Tree, Random Forest, K-Nearest Neighbors (KNN), Support Vector Machine (SVM), Logistic Regression, Multi-Layer Perceptron (MLP), Artificial Neural Networks (ANN), and Deep Neural Networks (DNN) for migraine prediction and classification. Interesting information about the strengths and weaknesses of the models' related to the multi-class classification of migraine was exposed by the comparison.

The Gradient Boosting model exhibited impressive performance in classes such as Migraine Without Aura and Typical Aura Without Migraine, yielding an accuracy rate of 96.4%. But it struggled with complex types like Migraine with Typical Aura. The Decision Tree model exhibited stellar performance at 96.04% accuracy; yet, it faced challenges with Basilar-Type Aura, shown by an F1-score of 0.90.

In a number of classes, including Migraine Without Aura, Other, and Sporadic Hemiplegic Migraine, the Multi-Layer Perceptron (MLP) demonstrated the maximum accuracy of 97%, with flawless precision and recall. However, MLP performed worse for Typical Aura with Migraine (F1-score of 89%), most likely as a result of category overlap.

The Random Forest model had a very good accuracy at 95%, but exhibited signs of overfitting, particularly in certain categories. It performed well in less complex classes, such as Other and Typical Aura Without Migraine. With corresponding accuracies of 93.17% and 92.09%, KNN performed better than SVM. KNN proved effective in distinguishing Basilar-Type Aura and Migraine Without Aura but faced similar challenges in complex categories. Logistic Regression performed at a baseline with an accuracy of 89%, excelling in simpler classifications but struggling with nuanced categories, such as Typical Aura with Migraine, where its F1-score dropped to 70%.

The ANN model performance was robust in terms of accuracy with 95% on overlapping class problems as long as the scope of the clinical dataset was limited and well defined. It was a bit challenging for the ANN to manage overlapping classes. On the other hand, DNN performed slightly better at 95.19%, leveraging its deeper architecture to model more complex patterns, especially for challenging classes like Sporadic Hemiplegic Migraine. However, the DNN had high computational cost and also extensive regularization requirements which are its main downsides.

In conclusion, the best models overall were the Gradient Boosting and MLP as they gave consistently high accuracy. Both ANN and DNN also had their advantages, ANN was optimal for less complicated datasets which use One Dimensional

representations and DNN was optimal for multidimensional and complex datasets. All these findings stress the need to be selective on the choice of model to be developed, with respect to the complexity of the data and the nature of the task. For the future research, better performance may be obtained from harnessing class imbalance, better feature engineering, fine-tuning the regularization and adding ensemble methods.

In Table III, the results of existing work for migraine classification are equated with the accuracy of the classification produced by our proposed model.

TABLE III. COMPARATIVE RESULTS

Model	Accuracy (%)	F1-score (%)	Sensitivity (%)	precision (%)
Gradient Boosting	96.4	96	96	97
Random Forest	95	71.8	73.2	70.8
SVM	92.09	91.64	91.63	91.64
KNN	93.17	92.63	92.74	93.08
Decision Tree	96.04	95.87	95.84	96.03
Logistic Regression	89.21	89.2	89	89.8
MLP	97.12	94.14	94.25	94.32
ANN	95.86	95.4	95.7	95.7
DNN	95.19	95.15	95.08	95.18

VI. CONCLUSION

This study highlights the ability of machine learning to correctly define attacks of migraines through classification models. Gradient Boosting achieved an accuracy of 96.4%, excelling in classes like Migraine Without Aura, while MLP stood out as the best performer with 97% accuracy and perfect scores in several classes. Artificial Neural Network also performed well with ANN at 95% accuracy and DNN at 95.19%, although computational demands were notable. Other models such as Logistic Regression (89%) struggled with nuanced categories, while Random Forest (95%), KNN (93.17%), and SVM (92.09%) performed moderately. Finally, MLP and Gradient boosting were the outstanding models emphasizing the importance of model selection which depends on the complexity of the data set in improving clinical practice.

The implications of improving our understanding of how algorithm choice affects performance in classification and providing a way forward in performing more efficient migraine diagnosis are crucial for future research through feature engineering and model optimization. Future studies may incorporate ensemble methods, refine how complex models overfit and improve procedures for more detailed and specific types of migraines.

Abstract—In this study, we have compared manual machine learning with automated machine learning (AutoML) to see which performs better in predictive analysis. Using data from past football matches, we tested a range of algorithms to forecast game outcomes. By exploring the data, we discovered patterns and team correlations, then cleaned and prepped the data to ensure the models had the best possible inputs. Our findings show that AutoML, especially when using logistic regression can outperform manual methods in prediction accuracy. The big advantage of AutoML is that it automates the tricky parts, like data cleaning, feature selection, and tuning model parameters, saving time and effort compared to manual approaches, which require more expertise to achieve similar results. This research highlights how AutoML can make predictive analysis easier and more accurate, providing useful insights for many fields. Future work could explore using different data types and applying these techniques to other areas to show how adaptable and powerful machine learning can be.

Keywords—Machine learning; predictive analytics; sports forecasting; automated machine learning (AutoML); feature engineering; model evaluation; data pre-processing; algorithm comparison; football analytics; sports betting; team performance metrics; exploratory data analysis (EDA); cross-validation techniques

I. INTRODUCTION

Millions of football fans from all around the world attend the UEFA European Championship, also referred to as the UEFA Euro. This esteemed competition, which is hosted by UEFA, features the top teams from throughout Europe, showcasing their talent, tenacity, and competitive spirit [1]. Analysts, enthusiasts, and commentators eagerly engage in predicting the outcomes of this highly anticipated and often unpredictable event. Recent advancements in machine learning (ML) algorithms, combined with the availability of extensive historical football data, have opened new avenues for predicting match results and identifying potential tournament winners. These sophisticated algorithms can detect patterns in complex datasets, providing valuable insights for predictive analysis and strategic decision-making.

Using ML algorithms to forecast the UEFA Euro winner involves a detailed analysis of historical match data, team

statistics, player performance metrics, and other factors that influence team success. By understanding the intricate interactions of these factors, ML models can predict future outcomes based on data from past tournaments. In this study, a variety of manual ML algorithms known for their efficiency in predictive modelling were used. These include Ada Boost, Random Forest, XGBoost, Decision Tree, Support Vector Machine (SVM), Logistic Regression, K-Nearest Neighbors (KNN), and Naive Bayes. Each algorithm has unique strengths, making them suitable for different predictive tasks in forecasting the winner.

Additionally, the study explores the realm of Automated Machine Learning (AutoML), utilizing advanced techniques to streamline and optimize the model development process. The AutoML framework incorporates a broad set of algorithms, such as Ridge, Quadratic Discriminant Analysis, Linear Discriminant Analysis, Extra Trees Classifier, Extreme Gradient Boosting, Light Gradient Boosting Machine, and Dummy Classifier, among others. This comprehensive approach allows for a thorough evaluation of predictive efficacy.

This study aims to demonstrate the efficacy of both manual and automated machine learning (AutoML) approaches in sports analytics, especially in forecasting the results of the UEFA Euro 2024. This study aims to demonstrate the potential for widespread acceptance and innovation in sports analytics by analysing the performance of several machine learning algorithms in projecting tournament results. The findings of this study are expected to enlighten stakeholders such as analysts, coaches, and investors, allowing them to make more informed judgements and strategic assumptions during the tournament.

The paper is organized as follows: Section I presents the introduction. In Section II, we define the problem and outline the objectives. Section III covers the literature review, addressing manual and automated machine learning separately. Section IV explains the research methodology. Section V details the preprocessing, cleaning, and data preparation steps. Section VI provides a comparative analysis of manual and automated machine learning across various classifiers. Section VII presents the results and evaluation, and finally, Section VIII concludes the paper.

II. PROBLEM DEFINITION AND OBJECTIVES

The purpose of this study is to show that both manual and automatic machine learning (AutoML) methodologies can accurately forecast UEFA Euro 2024 outcomes. The study creates prediction models for team performance by analysing historical data on international football matches and team characteristics. The findings, which highlight the potential of machine learning, particularly AutoML, in improving prediction accuracy, seek to enlighten analysts, coaches, and bettors, supporting greater use and innovation in sports analytics.

The main objective of this study is to demonstrate that both manual and automatic machine learning (AutoML) methods can effectively predict the outcomes of the UEFA Euro 2024 competition. The goal is to create prediction models that accurately assess each team's likelihood of success by thoroughly analysing historical data from international football matches and considering various team characteristics. This research aims to highlight the potential of machine learning (ML), particularly AutoML, in expediting predictive analytics processes and enhancing model accuracy.

The key objectives include the careful collection and pre-processing of historical international soccer match data and team attributes, followed by a detailed exploratory data analysis to identify relevant features. The study will then involve selecting informative features and applying rigorous feature engineering techniques to capture essential team and match characteristics. Various machine learning algorithms will be evaluated and compared to identify the most effective models based on performance metrics. The selected models will undergo thorough training using pre-processed data, with hyperparameter optimization to ensure optimal performance. Rigorous evaluation of predictive performance using appropriate metrics, along with the implementation of cross-validation techniques to ensure model generalizability and reduce overfitting, are crucial parts of this research.

Additionally, this project will test the performance of the models using benchmark datasets. The study aims to demonstrate the potential of these models in sports analytics by providing significant insights and encouraging wider adoption and innovation. The focus will be on evaluating the effectiveness of AutoML approaches.

III. LITERATURE REVIEW

A. Use of Manual Machine Learning

Forecasting tournament winners is an enduring challenge in sports analysis, extensively explored across research. Machine learning emerges as a prominent tool in this domain, offering predictive capabilities based on historical data. Leveraging past records, machine learning models discern patterns and variables correlated with auspicious outcomes, thereby enabling forecasts for future events. This methodology capitalizes on the wealth of information contained within historical datasets, facilitating the identification of key determinants of success. Through iterative learning processes, these algorithms refine their predictive accuracy, contributing to the advancement of sports analytics. The utilization of machine learning in predicting tournament winners emphasises the significance of

data-driven approaches in enhancing the understanding of sports dynamics and informing strategic decision-making processes within the realm of athletics. The challenge of predicting football match outcomes is addressed in the research by Hucaljuk & Rakipović, acknowledging the complexity stemming from numerous unquantifiable factors. A software solution is developed to tackle this challenge, undergoing testing to optimize feature and classifier combinations. Results demonstrate satisfactory predictive capabilities surpassing reference methods, with an accuracy exceeding the initial goal of 60%. However, the study suggests areas for enhancement, particularly in feature selection, proposing the inclusion of player form data for improved accuracy [2]. Additionally, increasing the size of the dataset for training could further enhance predictive performance. This project exemplifies successful advancement in football match prediction methodologies while highlighting avenues for future research and refinement in feature engineering.

Another research investigates the efficacy of utilizing machine learning techniques to predict football match outcomes by incorporating pre-game features instead of relying solely on post-game goal statistics. Custom-generated features are developed and compared against in-game data features using the XGBoost algorithm. Results indicate superior prediction accuracy with custom features, demonstrating higher precision, recall, f1 score, and accuracy compared to in-game features. The research suggests that leveraging comprehensive player and team statistics, such as dribbling and expected goals, could further enhance predictive performance. Additionally, considering factors like team formation and fan sentiment from social media could provide valuable insights into match outcomes. The study underscores the potential for enhanced predictive modelling in football matches through the incorporation of diverse pre-game features and data sources [3]. The studies by Hucaljuk & Rakipović and Rose et al. 2022 both address the challenge of predicting football match outcomes using machine learning techniques [2] [3]. Hucaljuk & Rakipović develop a software solution to optimize feature and classifier combinations, surpassing an initial accuracy goal of 60% [2]. They highlight the importance of feature selection and suggest incorporating player form data to enhance predictive accuracy. Conversely, focus on incorporating pre-game features, such as comprehensive player and team statistics, using custom-generated features [3]. This study demonstrates superior prediction accuracy compared to relying solely on post-game goal statistics, emphasizing the potential for enhanced predictive modelling through diverse pre-game features and data sources. Both studies contribute to advancing football match prediction methodologies and highlight avenues for future research in feature engineering and data analysis. The research by Groll et al. [4] introduces a hybrid modelling approach for predicting soccer match scores, combining random forests with two ranking methods: Poisson ranking and bookmakers' odds. By incorporating team covariate information and ability parameters derived from both ranking methods, the model accurately estimates team strengths. The approach is applied to FIFA Women's World Cups 2011, 2015, and 2019, with simulations favouring the USA as the top contender for the 2019 title, followed by France, England, and Germany. The study highlights the effectiveness of integrating

diverse methodologies for robust predictions in soccer tournaments, offering insights into team performance and tournament outcomes [4].

Another study focuses on employing machine learning techniques to predict the winner of the ICC Men's T20 World Cup 2020. Four algorithms, including Random Forest, Extra Trees, ID3, and C4.5, were compared, with Random Forest exhibiting the highest proficiency at 80.86% custom accuracy. Australia emerged as the predicted champion. Future directions include optimizing the predictive models and incorporating additional parameters like match venue and weather forecast to enhance accuracy. The study underscores the utility of machine learning in sports prediction and offers insights into potential improvements for future analyses, emphasizing the importance of considering various factors for more accurate forecasts in cricket tournaments [5]. The both studies focus on utilizing machine learning techniques for sports prediction, albeit in different contexts. Groll and the team introduce a hybrid modelling approach for predicting soccer match scores, incorporating random forests with Poisson ranking and bookmakers' odds. This study demonstrates the effectiveness of integrating diverse methodologies for robust predictions in soccer tournaments, providing insights into team performance and outcomes. In contrast, Basit and the team concentrate on predicting the winner of the ICC Men's T20 World Cup 2020 using machine learning algorithms such as Random Forest, Extra Trees, ID3, and C4.5 [4] [5]. This research underscores the utility of machine learning in sports prediction, emphasizing the importance of considering various factors for more accurate forecasts, particularly in cricket tournaments. Both studies contribute to advancing predictive modelling in sports and offer valuable insights into improving accuracy in tournament predictions. In examining cricket match prediction models, emphasize the development of a machine learning model specifically tailored for Indian Premier League (IPL) matches, achieving nearly 90% accuracy [6]. Conversely, Kumar, et al. [7] focus on Decision Trees and Multilayer Perceptron Network models, highlighting the superiority over traditional statistical methods. This CricAI system offers a user-friendly prediction tool, emphasising the flexibility of machine learning approaches. Vistro et al [8] similarly explore IPL match prediction using various machine learning algorithms, achieving high accuracies up to 94.87%. While all studies underscore the significance of data science in sports analytics, two studies emphasize the potential applicability of the methodologies beyond cricket, which could inform predictive analytics in UEFA Euro and other sports contexts [7][8].

The research by Elmiligi & Saad presents a novel hybrid approach combining machine learning and statistical methods to predict soccer match outcomes [9]. Analysing a dataset comprising over 200,000 match results from 2000/2001 to 2016/2017, the research explores various features including team and player statistics, home/away advantage, and data recency. Two hybrid models are developed, with the best achieving 46.6% prediction accuracy on a test set. The study also evaluates hypotheses regarding feature engineering, finding no significant improvement with recent match data or separate models for each league [9]. Additionally, the research plans to extend its analysis to other sports and conduct

comparative feature significance studies. This work contributes to advancing predictive modelling in sports and lays the groundwork for future research directions. Another study delves into predicting football match outcomes, focusing on the 2022 FIFA World Cup, leveraging Exploratory Data Analysis (EDA) and various machine learning algorithms. Notably, Random Forests, Decision Trees, K-Nearest Neighbours, XGBoost, and Gradient Boosting are tested, with XGBoost and Gradient Booster achieving the highest average accuracy of 98.34%. The study introduces a novel approach combining EDA and machine learning to address the challenges of sports match prediction, proposing Multi-output Regressor as a solution. It suggests that this method could accurately forecast sporting event outcomes and encourages further research into incorporating additional factors like current world ranking and new age metrics. The findings contribute to advancing predictive modelling in football and offer potential avenues for enhancing prediction accuracy in future studies [10]. The research by Athish et al. [11] explores the application of the Bayesian approach in predicting soccer match outcomes, leveraging authentic squad information and match results sourced from platforms like Kaggle and Sofifa.com. The Gaussian Naive Bayes model demonstrates 85.43% accuracy in match result prediction, surpassing the 79.81% accuracy achieved by the Decision Tree Classifier. The study offers a tool for users to assess team probabilities in tournaments, although it emphasizes individual discretion in betting due to uncertainties inherent in sports outcomes. The findings contribute to the understanding of machine learning techniques in soccer prediction and provide a basis for further research in the field. The studies discussed present diverse methodologies and approaches for predicting soccer match outcomes using machine learning and statistical techniques [9] [10][11]. Research by Elmiligi & Saad introduces a hybrid model that analyses team and player statistics, achieving a prediction accuracy of 46.6%. It emphasizes the importance of feature engineering and plans to extend its analysis to other sports [9]. In contrast, Majumdar and team focus on the 2022 FIFA World Cup, employing exploratory data analysis and various machine learning algorithms. Their approach yields high accuracy, with XGBoost and Gradient Boosting achieving 98.34% [10]. This study proposes a novel method combining EDA and machine learning, suggesting avenues for further research. Athish et al. explores the Bayesian approach for predicting soccer match outcomes, achieving an accuracy of 85.43% with the Gaussian Naive Bayes model. This study provides insights into machine learning techniques for soccer prediction, emphasizing individual discretion in betting [11]. Overall, these studies contribute to advancing predictive modelling in sports and offer valuable insights for future research directions.

The studies by Chin et al. and Daundkar & Kandhway both employ machine learning techniques to enhance predictive capabilities in sports, focusing on ice hockey and NBA match outcomes, respectively. Chin and the team analysed various machine learning techniques using NHL data from 2015-2021, with Logistic Regression achieving the highest accuracy at 77.82% [12][13]. This study highlights the significance of incorporating match-specific data for improved predictive accuracy [12]. Conversely, Daundkar & Kandhway predict NBA match outcomes based on past team performances,

achieving a prediction accuracy of approximately 66%. This research underscores the relevance of machine learning in sports betting and offers insights into the predictive capabilities of historical data in forecasting NBA match outcomes, aligning closely with human expert accuracy [13]. Both studies contribute to advancing predictive analytics in sports, offering valuable implications for future research and applications [12][13]. The research by Kumar, et al. [7] introduces an advanced approach to football analysis by utilizing predictive data like expected goals instead of descriptive data like shots taken and goals scored. By applying fixed parameters on machine learning algorithms, the method aims to evaluate teams and players based on performance rather than results, enhancing scouting and strategy formation. Results indicate that the light XGBoost machine learning model provides a better match of shot quality, as measured by McFadden's pseudo-R-squared score. Incorporating a "big chance" component further improves assessment criteria, although this capability is not available in the dataset used. Feature importance measurements highlight variables crucial to the model's outputs, offering valuable insights for performance analysis and talent identification. Another study focuses on predicting halftime results and league winners in the English Premier League using classification models. Leveraging ensemble techniques, the study achieves 80% accuracy in halftime result prediction and up to 95% accuracy in league winner prediction [14]. Building upon previous work, the research incorporates additional features such as team form and form points, enhancing prediction accuracy. By training models at a match week level, the study offers insights into predicting league winners throughout the season. The findings highlight the potential of utilizing dynamic datasets and simple features for accurate football match predictions and league analysis [14].

The studies by Tiwari et al. and Jaeyalakshmi et al. explore machine learning techniques for predicting football match outcomes, albeit with different emphases [15][16]. Tiwari and the research team focus on utilizing Recurrent Neural Networks (RNNs) with Long Short-Term Memory (LSTM) to leverage the abundance of statistical football data, aiming to enhance prediction accuracy for various match-related information. The conclusion of this study highlights the superiority of LSTM-based RNNs over traditional methods, suggesting further improvements by incorporating player statistics and larger datasets [15]. Conversely, Jaeyalakshmi and the team introduce a machine learning approach for forecasting football match results, emphasizing feature selection, data imbalance treatment, and model generalization. Achieving over 81% accuracy with the Random Forest Algorithm, this study emphasises the unpredictable nature of football and advocates responsible betting, suggesting future enhancements through additional statistics incorporation [16]. Another study introduces a machine-learning model employing a random forest algorithm for predicting football player performance and optimizing fantasy football team line-ups. Back-testing on historical data yielded a Mean Square Error (MSE) of 4.921 and a Root Mean Square Error (RMSE) of 2.2275, with the model presenting the potential for profitability in fantasy football betting [17]. The analysis involves web scraping, data segregation, and hyperparameter tuning. Results showcase the

model's capability in team formation for different formations, with future scope including subscription services and incorporation of additional data sources to enhance predictive accuracy while acknowledging inherent limitations in predicting future events and relying exclusively on past performance data [17].

Proposing a data-driven approach, the study Al-Asadi & Tasdemir [18] aims to estimate football players' market values using machine learning algorithms applied to FIFA 20 video game data. Comparing four regression models, the research finds that random forest outperforms others in accuracy and error ratio. The results suggest potential applications in streamlining negotiations between clubs and players' agents by providing objective market value estimations. Further research avenues include integrating the model into FIFA games for player valuation and developing a calculator to assist gamers in making informed decisions. The methodology of this study demonstrates superiority over traditional approaches, offering practical implications beyond gaming simulations. Further one research introduces a system leveraging real-time feedback and advanced technologies to enhance football technique learning. It utilizes pose estimation with Media pipe and classification algorithms like the Dollarpy, KNN, RFE, and SVM, achieving varying accuracies [19]. Another article tackles the challenge of predicting football match outcomes for sports betting, employing machine learning methods and historical match statistics [20]. The models in this research yield a 65.26% accuracy rate, offering potential profitability. The study by Gifford & Bayrak [21] focuses on NFL game outcome prediction using decision trees and logistic regression. With turnover statistics as key predictors, the models achieve up to 83% accuracy, contributing insights for strategic decision-making in sports analytics. These studies collectively highlight the diverse applications of machine learning in sports and the potential for technology to enhance performance and decision-making in athletics.

B. Use of Automated Machine Learning (AutoML)

An article explored Automated Machine Learning (AutoML) as an end-to-end process for streamlining model development without manual intervention. The paper provides insights into AutoML segments and approaches, emphasizing its practical applicability in industry [22]. Furthermore, it discusses recent trends and suggests future research directions, advocating for a generalized AutoML pipeline and a central meta-learning framework. The study highlights the importance of advancing AutoML to address evolving challenges in machine learning model development, both in academia and industry. The study discussed the significance of Automated Machine Learning (AutoML) in mitigating the challenges of ML adoption, especially for small and medium-sized organizations. This paper highlights its diverse applications across industries and advocates for its potential in democratizing machine learning [23]. It suggests various research opportunities in Information Systems (IS), including qualitative and quantitative studies on AutoML adoption, the development of AutoML adoption theories, and the exploration of fairness and explainability concerns. Additionally, the authors underscore the importance of human-in-the-loop research and address the limitations and boundaries of AutoML

applications, emphasizing the role of IS researchers in advancing AutoML adoption in organizations.

The articles Truong et al. [24] and Ferreira et al. [25] investigated Automated Machine Learning (AutoML) tools' effectiveness but with different emphases. Truong and the team compare commercialized and open-source AutoML tools, highlighting varying strengths and weaknesses across datasets. This research emphasizes the absence of a single superior tool, indicating ongoing AutoML evolution [24]. In contrast, Ferreira and the research team conducted a study exclusively on open-source AutoML tools, focusing on supervised learning scenarios. The results of this research reveal the competitive performance of General Machine Learning (GML) AutoML tools, particularly in binary and regression tasks [25]. Both studies underscore the need for further advancements, Truong, et al in addressing gaps in AutoML pipeline support, and Ferreira et al in expanding comparisons to encompass more technologies and datasets, especially in big data contexts [24][25]. Another study presents a survey on automating the process of building machine learning models, particularly focusing on Combined Algorithm Selection and Hyperparameter tuning (CASH). It discusses the challenges of efficiently constructing high-quality models due to the vast amounts of data produced daily. The paper comprehensively reviews state-of-the-art efforts in AutoML frameworks and highlights research directions and challenges. By addressing these issues, the aim is to automate the machine-learning pipeline and reduce human intervention, catering to both researchers and practitioners in advancing the field [26]. The article [27] commences with an analysis of existing research in AutoML, hyperparameter tuning, and meta-learning. It highlights the lack of clear documentation and consensus on evaluation criteria in this field. The paper discusses the strengths and weaknesses of various approaches, emphasizing the need for further research to develop a fully automated industrial standard system. Assembling and meta-learning are proposed as effective methods for automating hyperparameter tuning. The authors aim to bridge gaps in existing solutions and plan to devise an architectural style for an efficient AutoML system based on accumulated knowledge and identified drawbacks. The article by Tsiakmaki et al. [28] focuses on applying automated machine learning (AutoML) in Educational Data Mining (EDM) to predict students' learning outcomes. It emphasizes interpretability by restricting the search space to tree-based and rule-based models. The study highlights that AutoML tools surpass default parameter values, especially in classification and regression tasks, highlighting the significance of transparent tools for educators. The findings suggest AutoML has the potential to aid early performance estimation and intervention strategies, offering promising avenues for enhancing academic outcomes in educational

environments. In contrast, Shi, et al. [29] present a domain-specific AutoML framework tailored for risk prediction and behaviour assessment in autonomous vehicles (AVs). The system in this research integrates unsupervised risk identification, feature learning with XGBoost, and model auto-tuning using Bayesian optimization. Evaluation of Next Generation Simulation (NGSIM) data demonstrates the framework's efficacy in distinguishing safe from risky behaviours, thus enhancing risk decision-making in Autonomous Vehicle (AVs). Additionally, it provides insights into sensor configurations and data mining, contributing to AV safety and design improvements.

In a nutshell even while previous research shows a variety of approaches and developments in basketball, cricket, and football sports prediction, a large number of studies continue to mostly rely on manual machine learning techniques, neglecting the benefits of automated approaches. By automating feature engineering, model selection, and hyperparameter tuning, the combination of automated machine learning (AutoML) tools with conventional techniques offers promising potential to increase prediction efficiency and accuracy. Machine learning techniques, coupled with automated machine learning (AutoML) tools, showcase promising capabilities in predicting match outcomes and enhancing sports analytics. Our research addresses this gap.

IV. RESEARCH METHODOLOGY

This study examines a vast dataset comprising historical records from international football matches alongside various team performance metrics, intending to use state-of-the-art machine learning techniques to predict the winner of UEFA Euro 2024. The primary objective is to develop a prediction model capable of accurately assessing the likelihood of victory for each participating team, providing valuable insights to analysts, bookmakers, coaches, and athletes. Notably, the study employed Artificial Neural Networks (ANNs) to construct a model for forecasting tournament match outcomes. To ensure high prediction accuracy, this model underwent cross-validation to prevent overfitting, refinement to improve generalization, and extensive training on substantial datasets [30].

The methodology section evaluates methodological choices based on literature and previous studies, such as ensemble methods for improved predictive accuracy in sports analytics. It also discusses potential limitations like the unpredictability of events and potential biases in historical data. Obstacles and solutions include data quality issues, model over-fitting, and changes in team dynamics. Robust pre-processing techniques, regularization and pruning of decision trees, and ongoing data updates are employed. Fig. 1 depicts the research methods used in this study.

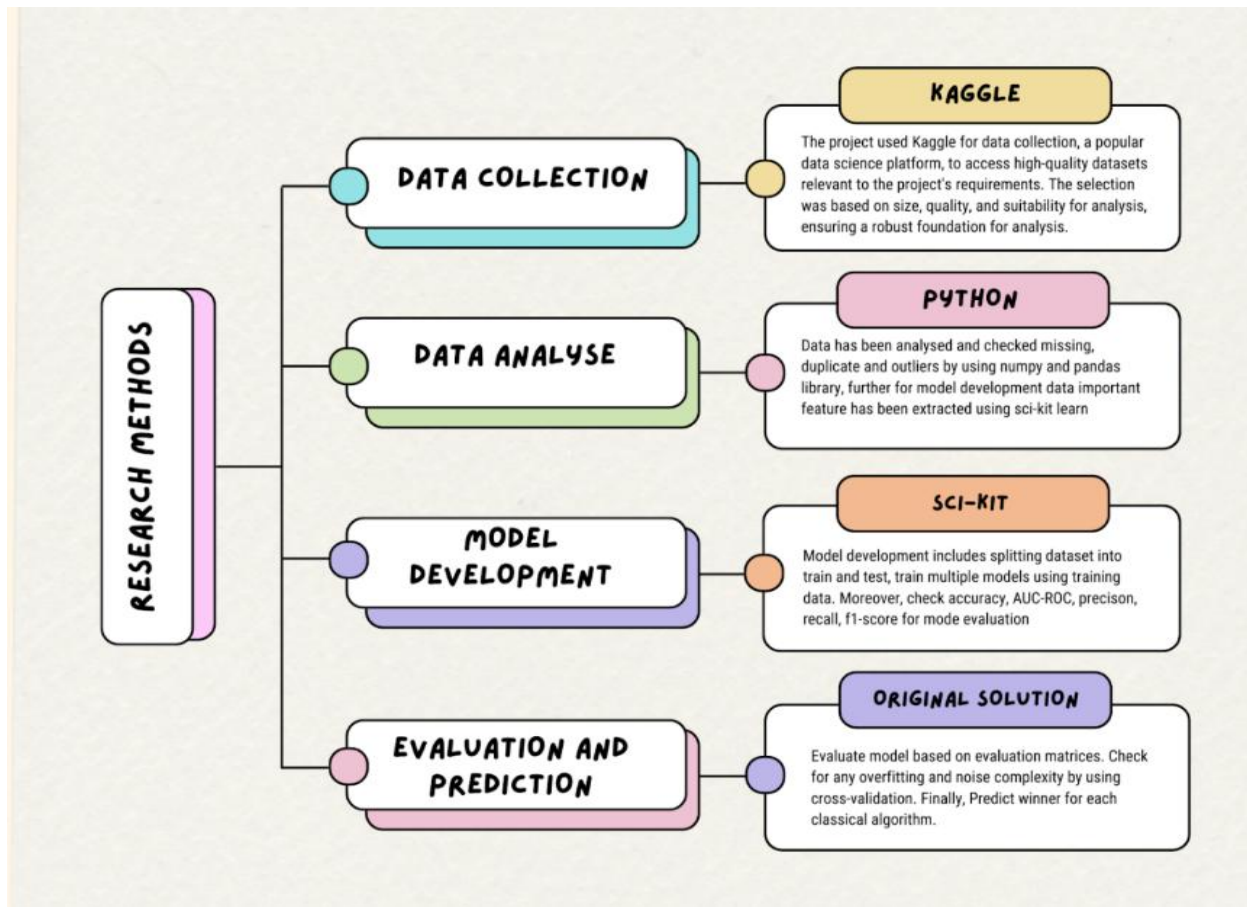

Fig. 1. Research methodology.

A. Chosen Approach

Our study adopts a quantitative research design, utilizing the numerical nature of data and modern computational methods to address the complexities inherent in predictive analytics. By leveraging a comprehensive dataset that includes player stats, team performance metrics, and past match results, we employ machine learning—a sophisticated branch of artificial intelligence—to manage and analyze this vast amount of information efficiently. Our approach integrates traditional statistical methods with advanced machine learning models, allowing us to uncover intricate patterns and interactions that conventional techniques might overlook. This dual strategy enhances the reliability and precision of our predictions, ensuring a robust analysis conducive to accurate forecasting.

In our investigation, we use well-established machine learning algorithms such as Random Forest and Support Vector Machines (SVM). Furthermore, we explore the potential of Automated Machine Learning (AutoML), a revolutionary development in predictive analysis. AutoML automates the selection, application, and refinement of various machine learning models, significantly streamlining the analytical process. This automation reduces the time and expertise required to implement complex models, as AutoML efficiently evaluates numerous algorithms and their configurations to identify the most suitable one for our data.

By integrating AutoML, our study enriches the toolkit available for predictive analytics and sets a standard for future research. The use of AutoML not only enhances predictive accuracy but also demonstrates the potential of advanced automation in pushing the boundaries of data forecasting. This methodology presents an exciting frontier for further exploration, promising significant advancements in the field of predictive analysis.

V. DATASET COLLECTION

For predictive modelling, this study utilized historical European football match data sourced from Kaggle (<https://www.kaggle.com/datasets/mahadinour/international-football-matches>) [31]. The dataset encompassed match outcomes, team metrics, and player performance statistics. To maintain relevance, the data underwent filtration to focus solely on European matches from the UEFA Euro 2024 tournament. Python's Pandas library facilitated efficient filtering based on competition type and team geographical locations. This dataset played a pivotal role in achieving the study's goals. To ensure research reproducibility, a detailed data dictionary will be made available alongside the study, outlining each collected variable and its origin.

A. Methods used to Analyse Collected Data

1) *Feature engineering*: The study will employ sophisticated feature engineering techniques to develop new

variables that could influence match outcomes, such as team morale indices or fatigue levels.

2) *Model training and testing*: Utilizing cross-validation techniques to partition the data and evaluate the model's performance across different subsets, ensuring the model's ability to generalize to new data.

3) *Hyperparameter optimization*: Advanced techniques like Bayesian Optimization will be used for tuning the models to find the optimal configuration of parameters.

B. Experimental Set-Up and Results

Exploratory Data Analysis (EDA) is a crucial stage in data analysis, utilizing statistical and visualisation methods to understand the dataset's structure, identify trends, and gain insights. It helps identify patterns, outliers, and correlations,

and aids in initial data processing, feature selection, and machine learning techniques. EDA is essential for data science and machine learning.

Fig. 2 shows the dataset, containing 2391 rows and 25 columns, which includes information about UEFA Euro qualification tournament football matches. It includes team details, match date and location, and final score. Analysing this data can reveal trends, patterns, and identify factors affecting national team success.

To find out a concise summary of the given dataframe, a set of Python commands like `info()`, `dtypes`, `select_dtypes`, etc were used. This helps to understand the descriptive statistics for "object" datatype, which represents a string or categorical data. Fig. 3 describes the same.

Fig. 2. Chosen dataset.

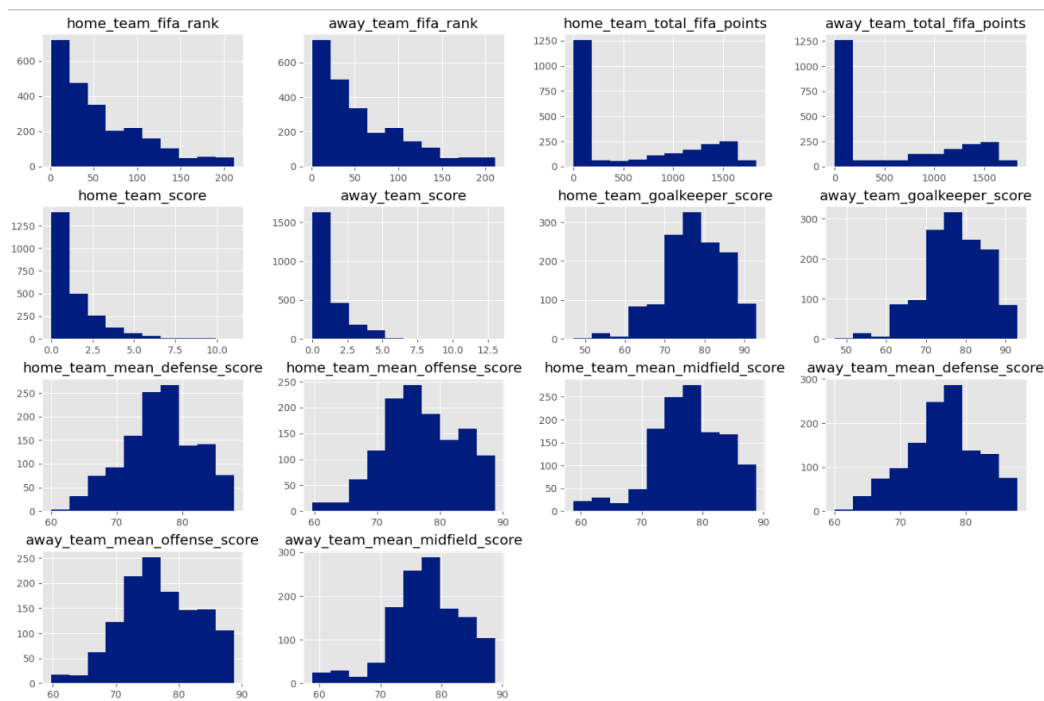

Fig. 3. Histogram plots.

Fig. 4 shows histograms plotted on various columns in a dataset, revealing potential patterns and frequency distributions within the variables.

C. Data Pre-Processing

Data pre-processing involves various procedures like transformation, cleansing, reduction, normalisation, and integration. It involves handling NaN data, managing noisy data, and error fixation. Data transformation converts data into a more intelligible format, while data integration combines data from multiple sources. Data normalisation scales data for similar distribution. Data pre-processing is crucial for machine learning (ML) algorithms to ensure suitable and high-quality data.

1) Visualizing NaN: Fig. 4 illustrate the findings done as part of a null check for the given dataset. Each heatmap corresponds to a data cell, and the colour of each heatmap cell indicates whether or not NaN values are present. The density of NaN values in a given column or row is larger when the colour

is darker. It is noted that the following columns in the dataset contain more NaN values than the other columns –

- a) home_team_goalkeeper_score
- b) away_team_goalkeeper_score
- c) home_team_mean_defense_score
- d) away_team_mean_defense_score
- e) home_team_mean_offense_score
- f) away_team_mean_offense_score
- g) home_team_mean_midfield_score
- h) away_team_mean_midfield_score

2) Visualizing missing data across different years: Fig. 5 displays the trend of missing data across different years which would help to identify years with higher proportion of missing data (data quality assessment). This is a scatter plot and each data point on the plot corresponds to the proportion of missing values for a specific year.

Fig. 4. NaN visualization using HeatMap.

Fig. 5. Visualizing missing data across different years (Scatter plot).

3) *Checking for duplicates*: This is a check to identify the duplicates in the given dataset. As per the result, we did not find any duplicates in the dataframe.

4) *Outliers detection*: Fig. 6 represents a parallel coordinate plot. This plot helps us visualize multivariate data

by showing multiple variables or attributes as parallel vertical axes. An individual data point is depicted by each polyline by connecting its values across different variables. This technique helps to identify similarities, patterns or relationships between different variables in the given dataset.

Fig. 6. Identifying similarities, patterns or relationships between different variables.

Fig. 7. Team points distribution with time.

Multiple visualizations between team points distribution with time is illustrated in Fig. 7. Overall point distribution for home and away teams are depicted in top histograms and the variation in average points per year for home and away teams are depicted in the bottom histograms.

5) *Data analysis and transformation*: To make the dataset more useful for analysis, we added a few new columns to summarize the performance of the home team. These columns—`home_win`, `home_draw`, and `home_lose`—were created based on the results of each match. This made it easier to see whether the home team won, drew, or lost a game, simplifying the dataset for comparison across different teams.

We also added several other columns to provide a richer, team-level view of the data, including:

a) *Total points for home and away teams*: This is to capture the sum of FIFA points for each team across all matches.

b) *Average FIFA points per team*: By averaging the FIFA points of both the home and away teams, we got a clearer idea of the overall strength of each team.

c) *Team rankings and performance metrics*: We introduced columns like the median FIFA rank, home and away goal scores, and goals conceded to offer more detailed insights into how each team performed.

Additionally, we included information on the continent each home team comes from, allowing us to identify any geographical trends in performance. A custom function helped us find the most frequent (mode) continent for each team.

To address missing data, we used the backward fill (bfill) method, which ensured that any gaps were filled with the most recent available data. This was especially useful in cases like carrying forward a goalkeeper's score for the next match if the data was incomplete.

VI. COMPARATIVE ANALYSIS OF MANUAL ML AND AUTO ML

A. Case 1 – Using Manual Machine Learning

1) *Model selection and training*: Google Colaboratory, a free cloud-based environment, is the platform used for writing and running the Python code, inclusive of machine learning models. The technique used here is One-Hot encoding. This technique or program is made more scalable by creating a generic function that will fit the data and forecast the result based on the chosen methods. The accuracy levels and models' correctness are also specified for each model instance.

Algorithm 1 – Random Forest Classifier

Supervised machine learning uses ensemble technique to improve model performance by combining multiple classifiers. This approach boosts forecasting accuracy by using multiple decision trees on different datasets, utilizing feature randomization and bagging [32]. For Random Forest, data pre-processed with One-Hot Encoding yields an accuracy of 70%, as illustrated in Fig. 8.

Fig. 8. Model evaluation for random forest.

Algorithm 2 – XG Boost Classifier

Sequential decision trees use XGBoost, assigning weights to independent variables. The second decision tree is used after adjusting the weight of miscalculated components, allowing faster training of large datasets through parallel processing [33]. As illustrated in Fig. 9, XGBoost reported 70% accuracy for data that has undergone One Hot Encoding pre-processing.

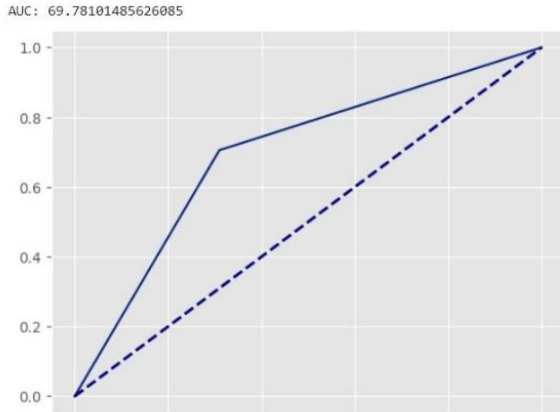

Fig. 9. Model evaluation for XG boost.

Algorithm 3 – Support Vector Machine

This model uses supervised learning algorithms to solve regression, detecting outliers and complex classification by executing optimal data transformations that set boundaries between data points on predefined classes or labels. This model has an accuracy of 71% as shown in Fig. 10.

Fig. 10. Model evaluation for SVM.

Algorithm 4 – AdaBoost Classifier

AdaBoost is an iterative ensemble boosting classifier that combines inefficient classifiers to increase precision. It can be trained on a dataset, but its main drawback is hindering parallelization. It requires interactive training on various weighted instances and limiting training errors for perfect matches [34].

Fig. 11 illustrates the AdaBoost Classifier accuracy for data pre-processed with One-Hot Encoding, which was 71%.

Fig. 11. Model evaluation for AdaBoost.

Algorithm 5 – Logistic Regression

This is a data analysis technique which is used to find out the dependency or relationship between two data factors. This relationship is then further used to determine or predict the value of the other factor. This results in a finite number of outcomes. Fig. 12 illustrates the accuracy check for this model, which is 70%.

Fig. 12. Model evaluation for logistic regression.

Algorithm 6 – K-Nearest Neighbour Classifier

KNN is a supervised learning algorithm, which is non-parametric and is used in both classification as well as regression. Refer to Fig. 13.

Fig. 13. Model evaluation for KNN.

Algorithm 7 – Gaussian Naive Bayes

This is a machine learning classification technique which is based on a probabilistic approach. Here, each class is assumed to follow a normal distribution. Refer to Fig. 14.

Fig. 14. Model evaluation for gaussian naive bayes.

1) Model Evaluation and Visualization

a) *Model simulation:* Table I, shows a machine learning model calculating the "home_team" and "away_team" means for a tournament. The simulation is run 1000 times, saving outcomes in variables for each round, quarter-finals, semi-finals, and finals. The model calculates the home team's victory probability and predicts match outcomes. The simulation continues until the tournament winner is determined.

Model 1 –Logistic Regression is the model used in this instance.

Out of the sixteen teams, eight teams were chosen for the quarter-finals, while the other 8 teams. From the eight teams, four were chosen to go to the semi-finals, while the other four teams failed. For the remaining rounds, the same marking procedure is used. Refer to Table II, where the green ones show the winning teams in each round and the pink ones are the failed ones.

TABLE I. ML MODEL SIMULATION OF TEAM MEANS AND MATCH OUTCOME PREDICTIONS

Away Team	Away Team FIFA Rank	Team Total FIFA Points
Albania	73.166667	492.977444
Austria	34.675	776.971667
Belgium	19.133333	922.177778

The UEFA European Championship was won by Portugal, and England finished as the runner-up. The UEFA European Championship 2024 has been won by Portugal, according to the Gaussian Naive Bayes model.

Model 4 – XG Boost is the model used in this instance.

8 out of 16 teams qualified for the quarter-finals, while the other 8 teams failed. Out of the eight teams, four were chosen to go to the semi-finals, while the other four teams did not advance. For the remaining rounds, the same marking procedure is used. Refer to Table V, where the green ones show the winning teams in each round and the pink ones are the failed ones.

TABLE V. USING XG BOOST

Round 16	Quarter-Finals	Semi-Finals	Finals	
Italy	Netherlands	France	Portugal	
Germany				
France				
Portugal	Portugal			
Czech Republic				
Netherlands				
Ukraine	Belgium	Portugal	France	
Belgium				
Spain				
Denmark	France	Netherlands		France
Switzerland				
England				
Serbia	Italy	Netherlands	France	
Hungary				
Slovenia				
Croatia	Ukraine	Belgium		France
Slovakia				
Romania				
Poland	Germany	Belgium	France	
Georgia				
Turkey				
Austria	Czech Republic	Belgium		France
Scotland				
Albania				

The UEFA European Championship was won by Portugal, and France finished as the runner-up. The UEFA European Championship 2024 has been won by Portugal, according to the XG Boost model.

Model 5 – SVM is the model used in this instance.

8 out of 16 teams qualified for the quarter-finals, while the other 8 teams failed. Out of the eight teams, four were chosen to go to the semi-finals, while the other four teams did not advance. For the remaining rounds, the same marking procedure is used. Refer to Table VI, where the green ones show the winning teams in each round and the pink ones are the failed ones.

TABLE VI. USING SVM

Round 16	Quarter-Finals	Semi-Finals	Finals
Czech Republic	Netherlands	Netherlands	Italy
Italy			
Denmark			
France			
Netherlands	Switzerland	Italy	
Portugal			
Switzerland			
Germany			
Belgium	Italy	Germany	
England			
Spain			
Ukraine			
Romania	Portugal	Germany	Netherlands

Slovakia			
Spain			
Albania	Turkey		
Netherlands			
Denmark			
Ukraine	Czech Republic	Italy	
Austria			
Romania			
Hungary	Slovenia		
Serbia			
Georgia			

The UEFA European Championship was won by France, and Portugal finished as the runner-up. The UEFA European Championship 2024 has been won by France, according to the AdaBoost model.

In order to forecast the winner of the UEFA European Championship 2024, 7 models were utilised. The total results are depicted in Table IX.

TABLE IX. WINNER PREDICTION USING MANUAL MACHINE LEARNING

Model	Winner	Runner-Up
Logistic Regression	Portugal	France
Random Forest	Portugal	Switzerland
Gaussian Naive Bayes	Portugal	England
XG Boost	Portugal	France
SVM	Italy	Netherlands
KNN	Netherlands	Germany
AdaBoost	France	Portugal

B. Case 2 – Using AutoML

For performing AutoML, the pycaret library is to be installed in Google Colab.

In automated machine learning, while setting up the environment, the module itself runs a series of pre-processing and data transformation steps. After the environment is set up, the performance metrics of various classification models are evaluated on the transformed data. All the pre-processing information regarding AutoML is given in Table X.

TABLE X. PRE-PROCESSING AND SETUP

Description	Value
Target	is_won
Target Type	Binary
Original Data Shape	(2391, 43)
Transformed Data Shape	(2391, 47)
Train Set Shape	(1673, 47)
Test Set Shape	(718, 47)
Numeric Features	26
Categorical Features	10
Preprocess	True
Imputation Type	Simple
Numeric Imputation	Mean
Categorical Imputation	Mode
Maximum One-Hot Encoding	25
Encoding Method	None
Fold Generator	StratifiedKfold
Number of Folds	10
CPU Jobs	-1 (All CPUs)
Use GPU	False
Log Experiment	False
Experiment Name	clf-default-name

AutoML itself identifies the best model for this particular dataset. In this case, Logistic Regression is chosen as the best model, as using the 'lbfgs' solver, the Logistic Regression model was optimized with typical L2 regularization (penalty='l2') to avoid overfitting. The intercept term (fit_intercept=True) was included in the model, and the regularization strength was adjusted to 1 (C=1.0). A maximum of 1000 iterations were performed, with a tolerance value of

0.0001 to guarantee convergence. Reproducibility was ensured by using random_state=6250, and the imbalance was handled without the use of class weights (class_weight=None). For the classification challenge, this setup produced a reliable and effective model.

Fig. 15 shows the plotted ROC curve and the confusion matrix for the logistic regression model.

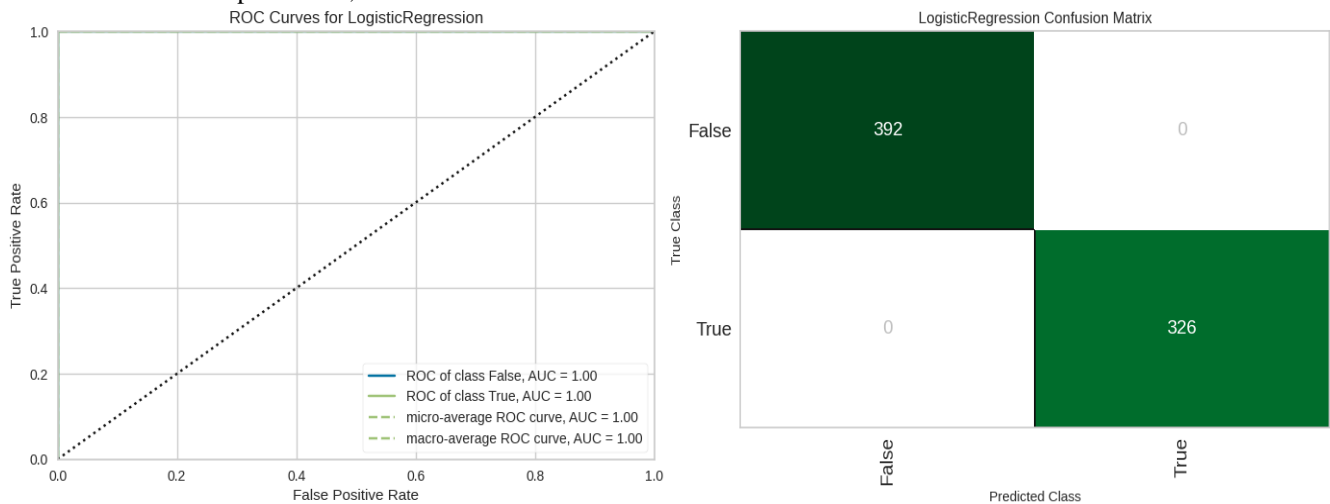

Fig. 15. ROC curve and confusion matrix.

Model Chosen by Auto ML – Logistic Regression

1) *Logistic regression model simulation*: Applying the same simulation logic for autoML as well (same as used in manual ML). 8 out of 16 teams qualified for the quarter-finals, while the other 8 teams failed. Out of the eight teams, four were

chosen to go to the semi-finals, while the other four teams did not advance. For the remaining rounds, the same marking procedure is used. Refer to Table XI, where the green ones show the winning teams in each round and the pink ones are the failed ones.

TABLE XI. USING AUTOML (LOGISTIC REGRESSION)

Round 16	Quarter-Finals	Semi-Finals	Finals
Czech Republic	Denmark	Italy	Portugal
Denmark			
Italy			
Switzerland	Portugal		
France			
England			
Netherlands	England		
Portugal			
Germany			
Belgium	Italy		
Croatia			
Ukraine			
Romania	Switzerland	England	
Spain			
Slovakia			
Scotland	France		
Turkey			
Poland			
Serbia	Czech Republic	Denmark	
Austria			
Hungary			
Albania	Netherlands		
Slovenia			
Georgia			

The UEFA European Championship was won by Portugal, and Italy finished as the runner-up. The UEFA European Championship 2024 has been won by Portugal, according to the Logistic Regression model via AutoML.

precision, recall, F1-score, accuracy, and AUC (Area under the curve) for the manual approach. It evaluates both models' ability to predict positive and negative classes and also identifies the more effective model. Here, 0 represents the "False" class and 1 represents the "True" class.

VII. COMPARATIVE RESULTS AND EVALUATION

Table XII given below compares the performance of various classification models based on the key metrics such as

TABLE XII. SUMMARY OF CLASSIFICATION PERFORMANCE METRICS (MANUAL)

Metric		Random Forest	XG Boost	SVM	AdaBoost	Logistic Regression	K-Nearest Neighbour	Gaussian Naive Bayes
Precision	0	0.77	0.77	0.78	0.75	0.78	0.73	0.79
	1	0.61	0.61	0.63	0.67	0.62	0.63	0.63
Recall	0	0.69	0.69	0.71	0.72	0.70	0.69	0.70
	1	0.71	0.71	0.72	0.70	0.71	0.68	0.73
F1-Score	0	0.73	0.73	0.74	0.73	0.74	0.71	0.74
	1	0.65	0.65	0.68	0.68	0.66	0.65	0.67
Support	0	213	213	211	198	212	202	213
	1	146	146	148	168	147	157	146
AUC	-	69.78	69.78	71.46	70.95	70.62	68.16	71.51

1) *Precision*: From the precision values it can be measured that how many of the predicted "True" (1) cases were correctly classified. For the "False" (0) class, most models have similar precision, with Gaussian Naive Bayes performing the best at 0.79, followed closely by K-Nearest Neighbor (KNN) and AdaBoost. In terms of classifying the "True" (1) class, AdaBoost achieves the highest precision at 0.67 where we can say that it more accurately identifies true positives compared to the other models.

2) *Recall*: Recall measures how well the model identifies all actual "True" cases. From the table we observe that for the "False" (0) class, recall values vary around 0.69 to 0.72 which shows that the models are consistent in recognizing the "False" cases. For the "True" (1) class, XGBoost, Random Forest, and

SVM exhibit similar recall values which is around 0.71, indicating that they are effective at correctly identifying positive cases.

3) *F1-Score*: Generally, F1-Score provides a balanced view of model performance. We can see that for the "False" (0) class, most models have similar F1-scores, with values ranging from 0.71 to 0.74. This means that the models perform well in identifying negative cases, particularly Gaussian Naive Bayes, AdaBoost, and SVM. For the "True" (1) class, F1-scores are slightly lower, with values ranging from 0.65 to 0.68. This suggests that predicting "True" cases is more challenging for these models. SVM and AdaBoost perform slightly better in this regard, with F1-scores of 0.68.

4) *Support*: Support refers to the number of actual instances in each class. There are more "False" (0) cases (213 instances) than "True" (1) cases (146 instances) in the dataset which may indicate an imbalance in the class distribution.

5) *AUC (Area under the curve)*: AUC represents the model's ability to distinguish between classes. So, higher values indicate better performance. Gaussian Naive Bayes achieves

the highest AUC at 71.51, indicating it is the best at distinguishing between "False" and "True" cases. XGBoost and Random Forest have identical AUC values of 69.78, suggesting similar performance in overall classification accuracy.

The overall summary of Manual ML and Auto ML is depicted in Table XIII.

TABLE XIII. OVERALL SUMMARY OF AUTO ML AND MANUAL ML

Manual ML			AutoML	
Algorithm Name	Accuracy	Prediction Result	List of Algorithms chosen	
AdaBoost	71%	Using AdaBoost, Winner – France 1st Runner Up - Portugal	Best Model chosen via AutoML	Logistic Regression
Random Forest	70%	Using Random Forest, Winner – Portugal 1st Runner Up - Switzerland	Prediction Result	The best Model chosen through AutoML was Logistic Regression. Using Logistic Regression, Winner – Portugal 1st Runner Up - Italy
XG Boost	70%	Using XG Boost, Winner – Portugal 1st Runner Up - France		
SVM	71%	Using SVM, Winner – Italy 1st Runner Up - Netherlands		
Logistic Regression	70%	Using Logistic Regression, Winner – Portugal 1st Runner Up - France		
KNN	68%	Using KNN, Winner – Netherlands 1st Runner Up - Germany		
Naive Bayes	71%	Using Gaussian Naive Bayes, Winner – Portugal 1st Runner Up - England		

VIII. CONCLUSIONS

This study shows how both manual and automated machine learning (AutoML) techniques can effectively predict football match outcomes. By using a comprehensive dataset of historical match data and applying various ML algorithms, we created models that significantly improve the accuracy and reliability of sports predictions. We found that AutoML models, especially logistic regression, offered better predictive accuracy than traditional manual methods. AutoML streamlined the model selection and tuning process, making predictive analysis more efficient and less reliant on manual intervention. AutoML proved it could optimize ML model performance by automating key steps like data pre-processing, feature selection, and hyperparameter tuning.

Manual ML techniques, while effective, required more effort and expertise to match the results achieved by AutoML. Manual methods like Random Forest, XGBoost, SVM, and AdaBoost performed well but were more time-consuming and needed more domain-specific knowledge. Our findings highlight the importance of thorough data preprocessing and feature engineering in boosting model performance. Using

cross-validation techniques and hyperparameter optimization further improved the models' accuracy and robustness, ensuring they are applicable to real-world scenarios.

Additionally, this research provided valuable insights into the factors that influence football match outcomes. This knowledge is invaluable for sports industry stakeholders, including analysts, coaches, and betting agencies, giving them a powerful tool for strategic decision-making.

In summary, this study demonstrated the effectiveness of both manual and AutoML techniques in sports analytics, paving the way for broader adoption and innovation. The results suggest that AutoML can greatly enhance the efficiency and effectiveness of predictive modelling in sports. Future research could incorporate diverse data sources and extend these methods to other sports, showcasing the versatility and scalability of machine learning.

Detection of DDoS Cyberattack Using a Hybrid Trust-Based Technique for Smart Home Networks

Oghenetejiri Okporokpo, Funminiyi Olajide, Nemitari Ajenka, Xiaoqi Ma

Department of Computer Science, Nottingham Trent University, Clifton Lane, Nottingham NG11 8NS, United Kingdom

Abstract—As Smart Home Internet of Things (SHIoT) continue to evolve, improving connectivity and security whilst offering convenience, ease, and efficiency is crucial. SHIoT networks are vulnerable to several cyberattacks, including Distributed Denial of Service (DDoS) attacks. The ever-changing landscape of Smart Home IoT threats presents many problems for current cybersecurity techniques. In response, we propose a hybrid Trust-based approach for DDoS attack detection and mitigation. Our proposed technique incorporates adaptive mechanisms and trust evaluation models to monitor device behaviour and identify malicious nodes dynamically. By leveraging real-time threat detection and secure routing protocols, the proposed trust-based mechanism ensures uninterrupted communication and minimizes the attack surface. Additionally, energy-efficient techniques are employed to safeguard communication without overburdening resource-constrained SHIoT devices. To evaluate the effectiveness of the proposed technique in efficiently detecting and mitigating DDoS attacks, we conducted several simulation experiments and compared the performance of the approach with other existing DDoS detection mechanisms. The results showed notable improvements in terms of energy efficiency, improved system resilience and enhanced computations. Our solution offers a targeted approach to securing Smart Home IoT environments against evolving cyber threats.

I. INTRODUCTION

Over the past few years, the advancement of Internet of Things (IoT) technology has resulted in ease of integration, seamless functionality and increased user satisfaction [1]. Since its inception, we have witnessed an increase in the number of smart home Internet of Things (SHIoT) devices such as smart bulbs, smart TVs, smart alarms, smart refrigerators, and smart fans [2] These have in turn resulted in diverse applications such as smart cities [3], smart grid systems [4], and smart healthcare systems [5].

However, security remains a paramount concern, specifically in smart home network environments, which usually encompass, wireless and mobile ad hoc networks. These environments generally deviate from traditional wired networks, boasting distinctive attributes such as shared resources, node mobility, and limited transmission range [6]. As a result of the generally limited processing power of mobile nodes in smart home networks, security techniques that have proven successful in wired networks tend to fail in wireless networks [7]. Furthermore, because nodes in smart home networks are free to join or leave, their dynamic nature causes network topologies to change quickly, which makes maintaining network security

extremely difficult. The creation of complex yet effective security measures suited to these environments is necessary [8].

In our work, we explore the escalating cybersecurity threats faced by Smart Home Internet of Things (SHIoT) networks, particularly focusing on Distributed Denial of Service (DDoS) attacks. Traditional security measures have proven inadequate in safeguarding these networks, requiring innovative solutions.

The contribution of this research is a proposed novel Trust-based DDoS attack detection model tailored specifically for SHIoT environments. Through comprehensive analysis, the paper identifies prevalent DDoS attack types targeting these networks, delving into their unique characteristics and implications. It evaluates the effectiveness of current cybersecurity measures and introduces a trust-based mitigation technique designed to counter each identified attack vector. By emphasizing the significance of trust-based approaches, the research not only contributes to the enhancement of cybersecurity in smart home settings but also identifies key avenues for future exploration. This study lays the groundwork for more resilient and secure smart home networks, ensuring the confidentiality and integrity of IoT communications amidst the evolving landscape of cyber threats.

The results show that the proposed technique can effectively improve the security of smart homes and enhance the efficiency of smart home network environments. The key contributions of our work are summarized as follows:

- The proposed approach incorporates Knowledge-based trust computations, resulting in more efficient and effective trust aggregations in smart homes.
- Observational-based Trust optimization is used to update trust and reputation, allowing for the system to draw upon the shared encounters of its neighbouring nodes or devices on the network which allows the network parameters to be adjusted as needed.
- The proposed technique deploys a hybrid trust-based technique for trust propagation, trust updation and trust formation which classifies malicious nodes using knowledge, reputation, and observational experience, resulting in better identification and mitigation of security threats in smart homes.

The layout of the paper is as follows. In Section II, we discuss the related work. In Section III, we describe our methodology for trust in smart home network environments. Section IV describes in detail our proposed trust-based system while in Section V. We evaluate the system performance within

smart home networks. In Section VI future research directions are highlighted.

II. RELATED WORK

In recent years, the field of SHIoT security has gained significant attention from researchers, because of the peculiar vulnerabilities of these SHIoT devices [9]-[12]. A smart home is an essential component of intelligent computing, by easily integrating with home devices to control and monitor their operations. It often uses cloud computing for storage and scalable processing power. Smart home appliances can now be remotely controlled from any location thanks to cloud computing [13]. Smart homes improve convenience, security, and energy efficiency by allowing users to effectively manage gadgets. These gadgets offer a great deal of convenience in addition to time, money, and energy savings. The main control interface for the smart home system is usually a smartphone or tablet. In this section, we review the existing literature covering key SHIoT security challenges, the nature of DDoS attacks on SHIoT networks, and existing cybersecurity solutions.

A. Overview of SHIoT Security Challenges

The ubiquitous nature of SHIoT creates some unique weaknesses and challenges which are inherent in their design. Almost any device can be equipped with the necessary technology to facilitate data transmission between IoT devices and their connected networks. Each node in a SHIoT network generally operates under energy constraints, creating an incentive for nodes to selfishly conserve their resources [14]. This self-preserving behaviour can negatively impact the overall functionality and efficiency of the network. Another unique challenge is due to their typical deployment in unattended and often hostile environments meaning that these networks often rely on thousands of low-cost sensors to monitor even small areas, which necessitates producing sensors at minimal cost. This cost reduction compromises the tamper-resistant properties of the SHIoT devices. SHIoTs are typically vulnerable to physical capture by adversaries [15]. Ensuring secure and efficient operation is challenging due to these factors particularly when threats like Distributed Denial of Service (DDoS) attacks target these SHIoT networks. One of the main concerns in smart homes is unauthorized access, where sensitive user data, such as video feeds or personal preferences can be intercepted if devices do not have proper access control protocols in place [16]. Due to the computational limitations of SHIoT devices, there are limits on the implementation of advanced cryptographic algorithms, thereby leading to exposure to various types of cyberattacks.

Existing security models oftentimes focus on traditional IT systems, overlooking IoT's resource limitations and real-time processing needs [8]. The lack of standardized security practices across IoT device manufacturers exacerbates these issues, leaving devices vulnerable to exploitation and making it challenging to implement uniform security measures across diverse IoT ecosystems.

B. DDoS Attacks

DDoS attacks have become increasingly common in SHIoT networks, largely due to the massive deployment of SHIoT devices, which can be easily exploited due to weak security

configurations [17]. Common DDoS attacks within the SHIoT environment include HTTP floods, UDP floods, and TCP SYN floods.

1) *HTTP Flood attacks*: HTTP flood attacks are one of the most common DDoS cyberattacks. These attacks are carried out by inundating the victim with a massive number of HTTP connection requests. These attacks aim to overwhelm the target server's resources and prevent legitimate traffic from accessing the server. In the context of IoT, HTTP floods can target cloud-based services associated with smart home devices, causing network slowdowns and disruptions [18]. Researchers Marleau et al. proposed an HTTP flood detection and mitigation technique for Software-defined networks (SDN) using Network Ingress Filtering [19].

2) *UDP Flood attacks*: UDP flood attacks flood the victim network or device with many User Datagram Protocol (UDP) packets. The extensive volume of packets inundates the target server, aiming to overwhelm its processing and response capabilities. UDP floods are particularly disruptive in SHIoT environments, where devices rely on minimal bandwidth and have limited packet-processing capabilities [20]. An example is the DNS amplification attack, where the attacker spoofs the source IP address of the victim and sends a small request to the DNS server. The DNS server replies with large responses, affecting the victim's performance. Researchers Lee et al. [21] proposed the use of specific IPtables rules and Linux-based firewall utilities, to mitigate UDP flood attacks.

3) *TCP SYN Flood attacks*: This type of attack exploits the TCP handshake mechanism by sending repeated SYN requests, but failing to respond to SYN-ACK replies, leaving the connection half-open. This can consume server resources and result in denial of service. Smart home devices, which often operate on simple network architectures, are vulnerable to these types of connection-based floods [22]. Bensaid et al. proposed a fog computing-based SYN Flood DDoS attack mitigation technique which uses an adaptive neuro-fuzzy inference system (ANFIS) and SDN assistance [23].

The impact of these attacks on SHIoT networks is significant, leading to degraded performance, reduced availability, and even complete network outages. DDoS attacks also open pathways for further malicious activities, such as data breaches or malware infiltration, by exploiting compromised devices within the IoT network [24].

C. Existing DDoS Mitigation Solutions

Current DDoS mitigation techniques include solutions like rate limiting, firewalls, and anomaly detection. However, while these methods offer some level of protection, they are often insufficient or computationally demanding for IoT environments:

1) *Rate limiting*: This approach restricts the number of requests allowed per unit of time, which can mitigate DDoS attacks. However, IoT devices may still be overwhelmed by legitimate traffic, and rate limiting does not effectively distinguish between malicious and legitimate requests [25].

2) *Firewalls*: Traditional firewalls monitor all incoming traffic attempting to enter a network and can block unwanted traffic. However, they are often unsuitable for IoT devices due to their processing and memory limitations. Additionally, firewalls require frequent updates to stay effective, which may not be feasible for resource-constrained SHIoT devices [26].

3) *Anomaly detection*: Anomaly detection, also known as behavioural detection, involves identifying predefined signatures or events that deviate from normal system behaviour. These systems use methods such as machine learning and analysis to identify abnormal patterns of network traffic [27]. While effective, these systems are computationally intensive, requiring processing power that most SHIoT devices lack. Moreover, the high rate of false positives in anomaly detection can lead to unnecessary slow-down in network performance, impacting the reliability of IoT services [28].

These traditional solutions, while useful in general networking environments, fall short of providing scalable, efficient, and reliable security for SHIoT networks, particularly when faced with DDoS attacks in smart home environments.

D. Trust-Based Security Approaches

As a result of the limitations of other DDoS mitigation techniques, researchers have explored trust-based security models tailored to various technologies. Trust-based security mechanisms aim to establish a level of trust for each device or network node based on behaviour, interaction history, and reputation, allowing the network to isolate untrustworthy devices or nodes in real time.

Several studies have highlighted the benefits of trust-based approaches in distributed and resource-constrained environments like IoT [29]-[31]. Trust-based models can effectively mitigate insider threats by flagging devices that exhibit suspicious behaviour, such as attempting excessive communication or participating in botnet-like activities [21]. Trust-based systems are also adaptable, requiring less processing power than anomaly detection making them suitable for IoT devices with limited computational capacity [32].

Shuhaiber and Mashal [33] presented a multilayered trust-based technique within IoT ecosystems, offering a theoretical insight into the intricate relationships between Trust Stance, and their impact on trust dynamics within IoT networks. Khatereh et al. [34] introduced a trust management model for anomaly detection using sequence prediction and deep learning for data security in IoT networks. The proposed model provides a detection mechanism to address four RPL attacks.

Shashank et al. [35] apply a trust-based technique for reliable data packet routing in WSNs. In their approach, trust management is integrated into routing protocols, deploying the decision-making Dempster-Shafer Theory (DST) algorithm for trusted clustering and the Whale Optimization Algorithm (WOA) for routing. However, one drawback of this approach is the high energy use which is not suitable for SHIoT networks.

Adla and Ramaiah [36] propose a blockchain solution for IoT with trust management consensus. The proposed technique uses a Grey Wolf Optimization (GWO) algorithm in addition to a trust-based ensemble consensus. The trust-based ensemble consensus uses Proof of Work (PoW) and Proof of Stake (PoS) procedures to calculate trust within the network. However, one disadvantage of this approach is that the network throughput progressively drops as the number of nodes increases. Researcher Farag [37] proposed a behavioural trust-based solution to mitigate energy exhaustion attacks on the RPL protocol. The proposed protocol protects against rank attacks and Sybil attacks in IoT networks. However, the disadvantage of the technique is that the trust value is computed solely based on direct observations by each node within the network.

Researchers have proposed various methods to deal with the DDoS attacks common with IoT networks. The approaches deployed vary and authors have focused on different aspects of the security of IoT networks. It is also evident from our study on trust-based techniques and deployments that a comprehensive model incorporating all aspects of security quantification for smart home networks and services is imperative. Thus, the core focus of this research work is a proposed trust-based system as a means of securing SHIoT networks. Trust-based management techniques employ a systematic method for effectively managing and ensuring trust within the network. By incorporating trust as a core component, our model provides an adaptive, lightweight solution that enhances the security of SHIoT networks.

III. METHODOLOGY

In this section, we present the trust-based methodology that the proposed system uses to detect and mitigate Distributed Denial of Service (DDoS) attacks in SHIoT networks. The methodology is centred around a trust management system where each node in the network maintains a trust score for other nodes based on their behaviour [32]. The trust scores are dynamically updated as nodes interact with each other. When malicious behaviour is detected, such as in the case of a DDoS attack, trust scores decline, and the system can identify the compromised node and take necessary actions to mitigate the attack.

A. Network Architecture

Trust-based systems are primarily comprised of three distinct properties. Durable nodes/devices that cumulate a repository of protocols for future communication, compilation, and dissemination of information regarding ongoing communications and ensuring its availability for future reference and deployment of a propagation mechanism to aid the dissemination of trust information to peer nodes/devices on the network. Fig. 1 shows a high-level overview of the proposed Trust-based system.

Assessing the security of a smart home network is essential for any setup within the smart home environment. We've compiled a comprehensive set of security parameters crucial for gauging security within a smart home network environment.

Fig. 1. High-level overview of proposed trust-based system.

These parameters form the basis of our trust model, yielding a trust value as an outcome. This trust value can either provide a holistic view of the overall security of the smart home network or can be dissected into various security aspects based on these parameters, represented as a vector.

B. Trust Definition

Trust is a measure of the reliability or reputation of a node in the network, quantifying how likely it is that a node will behave as expected, such as reliably forwarding packets without malicious intent. Trust in this context is represented as a numerical value, which is continuously evaluated and updated based on observed behaviour [30]. In the proposed system, trust is defined based on three main factors.

Packet Delivery Ratio (PDR): This measures the consistency and reliability of node y . The ratio of successfully delivered packets to the total number of packets transmitted. A high PDR

implies that the node can be trusted to forward packets efficiently, whereas a low PDR may indicate the dropping or mishandling of packets, which is indicative of malicious behaviour or a selfish node trying to conserve resources.

$$PDR_{x,y}(t) = \frac{\text{Packets Delivered by node } y}{\text{Total Packets Sent to node } y} \quad (1)$$

Anomaly Detection (AD): Anomalies such as sudden traffic spikes are common indicators of a node participating in a DDoS attack. The system continuously monitors the traffic patterns, and if it detects abnormal behaviour, the anomaly detection score decreases the trust score.

$$AD_{x,y}(t) = \begin{cases} 1 & \text{if no anomaly is detected,} \\ 0 & \text{if an anomaly is detected.} \end{cases} \quad (2)$$

Response Time (RT): The time a node takes to respond to communication requests from other nodes. If the response times are consistently high (i.e., the node is unresponsive or

overloaded), this could indicate that the node is under attack or has been compromised.

$$RT_{x,y}(t) = \frac{1}{\text{Observed Response Time of node } y} \quad (3)$$

C. Trust Calculation

Trust is a quantified measure based on the behaviour of nodes. Trust is evaluated based on parameters such as packet delivery ratio, response time, and anomaly detection. The trust $T_{(x,y)}(t)$ between two nodes x and y at time t is calculated as a weighted sum of the three factors mentioned above: Packet Delivery Ratio, Anomaly Detection, and Response Time. The trust calculation formula is:

$$T_{x,y}(t) = \delta \times PDR_{x,y}(t) + \theta \times AD_{x,y}(t) + \mu \times RT_{x,y}(t) \quad (4)$$

Where:

$T_{x,y}(t)$ is the trust value between nodes x and y at time t .

$PDR_{x,y}(t)$ is the packet delivery ratio between node x and node y . That is the ratio of successful packet deliveries.

$AD_{x,y}(t)$ is the anomaly detection score, indicating if node y 's behaviour is deemed suspicious.

$RT_{x,y}(t)$ is the response time of node y as observed by node x . That is the delay in responses from node y .

δ , θ , μ are the weights for each factor, with $\delta + \theta + \mu = 1$, determined based on the specific requirements of the network. For example, if packet delivery is prioritized, δ would be larger.

D. Trust Update Mechanism

Trust is not static and changes as nodes interact over time. The system continuously monitors the behaviour of each node, and the trust scores are updated periodically based on recent observations. This dynamic nature ensures that the system can adapt to evolving network conditions and malicious behaviours. The trust update mechanism works as follows:

- **Initial Trust Assignment:** Every node starts with an initial trust value. For example, the default trust value is set to 0.5 on a scale of 0 to 1, indicating neutral trust.

$$T_{x,y}(t) = 0.5 \quad (5)$$

- **Trust Evaluation:** After each interaction between two nodes, the trust score is recalculated based on the Packet Delivery Ratio, Anomaly Detection, and Response Time.
- **Trust Decay:** Trust decays over time if no recent interaction has occurred. This decay ensures that old interactions do not overly influence current trust evaluations.

$$T_{x,y}(t+1) = (1-\omega) \times T_{x,y}(t) + \omega \times \text{new interaction data} \quad (6)$$

Where ω is a decay constant that controls how quickly trust values diminish over time.

- **Threshold-Based Detection:** The system sets a threshold T_{thresh} below which a node is flagged as suspicious. If the trust value $T_{(x,y)}(t)$ falls below this threshold, the node is quarantined, i.e., its communication privileges are limited or monitored closely. The value of T_{thresh} is set

based on network performance requirements and the acceptable level of risk.

$$\text{If } T_{x,y} < T_{\text{thresh}} \text{ then node } y \text{ is flagged as suspicious.} \quad (7)$$

The value of T_{thresh} is set based on network performance requirements and the acceptable level of risk.

E. Trust Propagation in the Network

The trust scores are not only calculated on a one-to-one basis between nodes but also propagated through the network. For instance, if node x considers node y to be trustworthy, other nodes that trust x may adjust their trust values for y accordingly. This indirect trust propagation allows for faster identification of malicious nodes but also introduces a potential risk of trust manipulation. The propagation mechanism follows a weighted averaging approach.

$$T_{k,y}(t) = \frac{T_{k,x}(t) + T_{x,y}(t)}{2} \quad (8)$$

Where node k updates its trust score for node y based on its trust in node x and the trust score that node x has assigned to node y .

F. Trust-Based DDoS Attack Detection

The proposed trust-based system is used to detect DDoS attacks by identifying nodes whose trust scores consistently fall below the set threshold due to anomalies in their behaviour. DDoS attacks typically involve a sudden surge of requests from compromised nodes, resulting in dropped packets, increased response times, and detected anomalies, all of which contribute to a rapid decline in the trust score. The detection algorithm works as follows:

- 1) **Monitor trust values:** Continuously monitor the trust values for all nodes in the network.
- 2) **Detect malicious nodes:** If a node's trust score falls below the threshold T_{thresh} , flag the node as suspicious.
- 3) **Isolate suspicious nodes:** Once flagged, restrict the node's ability to communicate with other nodes until further investigation is carried out or the node is cleared.

IV. TRUST-BASED DDoS DETECTION SYSTEM

In this section, we delve deeper into the workings of our proposed trust-based system for detecting Distributed Denial of Service (DDoS) attacks in smart home networks. The system uses trust scores to detect anomalies in node behaviour that could indicate a malicious DDoS attack. By dynamically assessing the trustworthiness of each node, our system can identify compromised nodes that are part of a DDoS attack and take action to mitigate the attack in real time.

A. Trust Propagation and Decision Making

The trust-based DDoS detection system operates by continuously monitoring and updating trust values between nodes. Each IoT device in the network maintains a trust score for other devices it communicates with. Trust propagation ensures that trust information is shared across the network, allowing for more comprehensive decision-making.

- 1) **Trust evaluation:** Trust values are evaluated based on the behaviour of the nodes, as discussed in Section III(B). Nodes

regularly assess their neighbours based on metrics such as Packet Delivery Ratio (PDR), Response Time (RT), and Anomaly Detection (AD). A node that behaves consistently within normal parameters maintains a high trust score. Conversely, a node that shows erratic or malicious behaviour, such as failing to forward packets or exhibiting a high rate of traffic anomalies, will experience a drop in trust.

2) *Trust propagation and aggregation*: Trust propagation allows nodes to share their trust evaluations of other nodes, leading to a more informed decision-making process. If node x trusts node y but receives reports from other nodes indicating low trust in y , node x can adjust its trust value for y accordingly. This aggregation of trust values helps quickly isolate malicious nodes. Trust propagation is defined mathematically as follows:

$$T_{x,y}(t+1) = \frac{T_{x,y}(t) + \sum_{m \in N(x)} T_{m,y}(t)}{N(x)+1} \quad (9)$$

Where:

$T_{(x,y)}(t+1)$ is the trust value between nodes x and y at time t .

$N(x)$ is the set of neighbouring nodes if x ,

$T_{(m,y)}(t)$ is the trust value that node m assigns to node y .

This formula ensures that a node's trust score reflects not only its direct interactions but also the observations of other nodes in the network. This collective trust evaluation reduces the likelihood of isolated nodes manipulating their trust values to avoid detection.

B. DDoS Detection Algorithm

The detection of DDoS attacks in the trust-based system relies on identifying nodes with consistently low trust scores. These low scores indicate misbehaviour such as failing to forward packets, delaying responses, or generating abnormally high traffic. The following algorithm outlines the detection process:

1) *Step 1: Initialize Trust Values*: Each node x in the network initializes a trust score $T(x,y)(0)$ for every other node y . The initial trust value is set to a neutral level, such as 0.5.

2) *Step 2: Continuous Monitoring*: Nodes continuously monitor the behaviour of their neighbours based on the metrics discussed in Section III(B) (Packet Delivery Ratio, Response Time, and Anomaly Detection).

3) *Step 3: Trust Score Update*: Each node x updates its trust score for every other node y after each interaction. The updated trust score $T(x,y)(t)$ is calculated using the formula described in Section III(B).

4) *Step 4: Threshold Comparison*: At regular intervals, each node compares the trust score of its neighbours to a predefined threshold T_{thresh} . If the trust score $T_{(x,y)}(t)$ falls below T_{thresh} node y is flagged as suspicious.

If $T_{x,y}(t) < T_{\text{thresh}}$ then node j is flagged as suspicious. (10)

5) *Step 5: Quarantine Suspicious Nodes*: Once a node is flagged as suspicious, the system takes preventive action. The suspicious node is quarantined, meaning its communication

with other nodes is limited, and it is closely monitored. This limits the node's ability to participate in DDoS attacks. The algorithm can be represented as pseudo code as follows:

Algorithm 1: Quarantine Algorithm

```
for each node x in network:
  for each neighbour y of x:
    T[x,y] = CalculateTrust(x,y)
    if T[x,y] < T_thresh:
      FlagNode(y)
      QuarantineNode(y)
    End
```

C. Detection of Specific DDoS Attack Types

The proposed trust-based system can detect various types of DDoS attacks based on the specific behaviours they induce in the network. Below are three common types of DDoS attacks and how they are detected:

1) *TCP SYN Flood detection*: In a TCP SYN flood attack, a malicious node sends repeated SYN requests to overwhelm the victim node's resources. This attack results in.

a) Increased response times (since the victim node is overwhelmed).

b) Decreased Packet Delivery Ratio (as the victim node struggles to handle legitimate traffic).

The trust score of a node participating in a TCP SYN flood attack will drop due to poor Response Time (RT) and Packet Delivery Ratio (PDR). The system detects this as follows:

- **Response Time Monitoring**: If node x observes a consistent delay in receiving responses from node y , it will reduce the trust score $T_{(x,y)}(t)$ accordingly.

$$T_{x,y}(t) = T_{x,y}(t-1) - \Delta RT_{x,y}(t) \quad (11)$$

- **Packet Delivery Monitoring**: If node j is unable to deliver packets reliably, $PDR_{(x,y)}(t)$ will decrease, leading to a further reduction in trust.

$$T_{x,y}(t) = T_{x,y}(t-1) - \Delta PDR_{x,y}(t) \quad (12)$$

2) *HTTP Flood detection*: In an HTTP flood attack, a compromised node generates a high volume of HTTP requests to overload the victim's web services. This leads to:

- Abnormally high traffic generation.
- Anomalies detected in traffic patterns (AD).

The proposed trust-based system detects HTTP flood attacks by monitoring traffic volumes and identifying anomalies in the behaviour of nodes. Nodes that generate an unusually high number of HTTP requests will be flagged based on their Anomaly Detection (AD) score:

$$AD_{x,y}(t) = \begin{cases} 1 & \text{if no anomaly is detected,} \\ 0 & \text{if an anomaly is detected.} \end{cases} \quad (13)$$

A lower AD score leads to a drop in the overall trust value $T_{(x,y)}(t)$, eventually flagging the node as suspicious.

3) *UDP Flood detection*: A UDP flood attack involves sending large volumes of UDP packets to flood the victim's bandwidth. This results in: This leads to:

- High packet loss.
- Poor packet delivery ratio (PDR).

In this case, the system detects the attack by monitoring the Packet Delivery Ratio (PDR) of affected nodes. If node x observes that node y is consistently dropping packets, the trust score for node y is reduced:

$$PDR_{x,y}(t) = \frac{\text{Packets Delivered by node } y}{\text{Total Packets Sent to node } y} \quad (14)$$

A low PDR leads to a decline in trust:

$$T_{x,y}(t) = T_{x,y}(t-1) - \Delta PDR_{x,y}(t) \quad (15)$$

D. Mitigation Strategy

The detection of DDoS attacks in the trust-based system relies on identifying nodes with consistently low trust scores. These low scores indicate misbehaviour such as failing to forward packets, delaying responses, or generating abnormally high traffic. The following algorithm outlines the detection process:

1) *Node quarantine*: The system temporarily restricts the suspicious node's ability to communicate with other nodes in the network. This reduces the likelihood of the node participating in a DDoS attack. During quarantine, the system continues to monitor the node's behaviour.

2) *Traffic filtering*: Suspicious traffic from flagged nodes is filtered to prevent it from overwhelming legitimate network resources. The system prioritizes traffic from trusted nodes, ensuring that the network remains functional even during an ongoing attack.

3) *Reassessment of trust*: After a predefined period, the system re-evaluates the trust score of quarantined nodes. If the node's behaviour improves (e.g., it no longer generates anomalies or has improved packet delivery), the node can be re-integrated into the network. Otherwise, it remains quarantined or is permanently blacklisted.

V. RESULT AND ANALYSIS

To evaluate the performance of the proposed model, a simulation was carried out using OMNET++ simulator which was selected due to its platform independence and pre-defined function. To implement the trust-based detection system, we extend the IoT device modules with trust evaluation functionality. Each device calculates the trust score of its neighbours based on their behaviour (packet delivery, response time, and anomaly detection). We measured the following performance metrics:

- **Malicious Attack Detection Rate**: The percentage of malicious nodes correctly identified by the system.
- **False Positive Rate**: The percentage of benign nodes incorrectly flagged as malicious.

- **Latency**: The average time taken to detect and mitigate a DDoS attack.
- **Network Throughput**: The total amount of data successfully transmitted across the network, indicating the impact of DDoS attacks on network performance.

The complete simulation setup is illustrated in Table I.

TABLE I. COMMON SIMULATION PARAMETERS

Simulation environment	Values
Simulator	OMNET++ v 6.0.2
Platform	Windows 11
Number of Nodes	10-50
Time Interval	100-1000s
Topology	800m X 600m
Communication Range	50m
Default Trust Value	0.5
Trust Threshold Value	Data Link
Malicious Penalty	0.2
Decay Rate	0.99
Legitimate Reward	0.1

A. Malicious Attack Detection Rate

The percentage of malicious nodes correctly identified by the trust-based DDoS detection system is evaluated against TCP, UDP and HTTP flood attacks. The simulation results are captured and analysed based on the performance metrics. Table II show is a summary of the results:

TABLE II. DETECTION RATE

Attack Type	Detection Rate (%)
TCP SYN Flood	98
UDP Flood	95
HTTP Flood	92

Fig. 2 illustrates the comparison of our system with existing approaches and demonstrates that a higher detection rate is obtained by the system. The distributed denial-of-service detection mechanism (DiDDeM) system showed a 92% detection rate for TCP SYN flood attacks, 91% for UDP flood attacks and 88% for HTTP flood attacks. Whilst the Adaptive threshold algorithm (ATA) has a detection rate of 93.85%, 92% and 89% respectively for all three attack types. Our trust-based detection system successfully detects most DDoS attacks, with a high detection rate across all attack types tested.

B. False Positive Rate

This is a measure of the percentage of benign nodes incorrectly flagged as malicious. Fig. 3 shows the results of the simulation of our system in comparison to other known systems including the Hybrid Deep Learning CNN-GRU model and the Adaptive threshold algorithm (ATA).

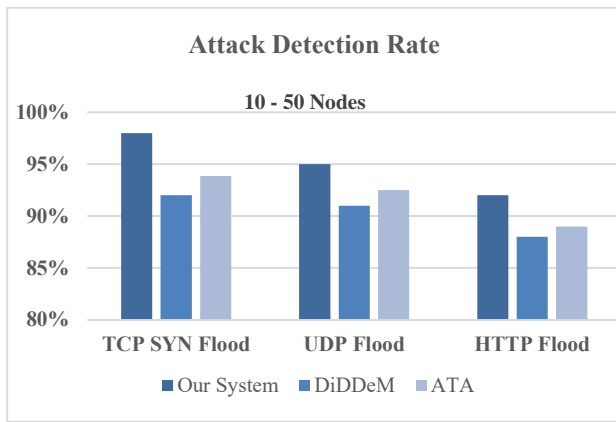

Fig. 2. Malicious attack detection rate.

Fig. 3. False positive rate.

The system maintains a low false positive rate (Table III), ensuring that most benign nodes are not incorrectly flagged as malicious.

TABLE III. FALSE POSITIVE RATE

Attack Type	False Positive Rate (%)
TCP SYN Flood	2
UDP Flood	3
HTTP Flood	4

C. Latency

This refers to the delay introduced by the trust calculation and decision-making process. The trust-based system detects attacks with minimal latency (20–22ms), balancing trust evaluation overhead with efficient traffic forwarding and allowing for real-time mitigation. The simulation results are captured and analysed based on the performance metrics. Table IV show is a summary of the results:

TABLE IV. LATENCY

Attack Type	Detection Latency (ms)
TCP SYN Flood	20
UDP Flood	21
HTTP Flood	22

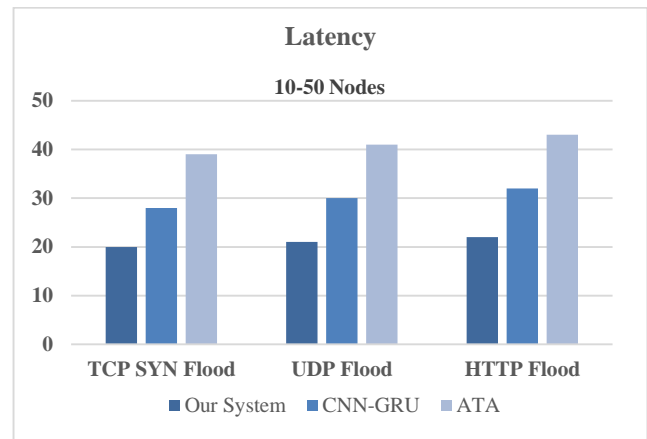

Fig. 4. Latency.

Fig. 4 illustrates the comparison of our system with other existing approaches. The Hybrid Deep Learning CNN-GRU model has the highest latency (28–32ms), due to computationally intensive traffic analysis and the Adaptive threshold algorithm (ATA) has a moderate latency (39–43ms) due to the additional analysis performed beyond threshold enforcement.

D. Network Throughput

This is a measure of the percentage of legitimate traffic successfully forwarded after isolating malicious nodes. Benign nodes that are incorrectly flagged as malicious. Table V. shows the results of the simulation of the system.

TABLE V. NETWORK THROUGHPUT

Attack Type	Throughput (Mbps) Before Attack	Throughput (Mbps) During Attack	Throughput (Mbps) After Detection
TCP SYN Flood	100	50	90
UDP Flood	100	40	85
HTTP Flood	100	45	88

The network throughput drops significantly during an attack but recovers after the trust-based system detects and mitigates the attack. The system maintained a high throughput even after detection (TCP - 95%, UDP - 85% and HTTP - 88%) by isolating only malicious nodes, ensuring minimal disruption to legitimate traffic. There were no instances of occasionally dropping legitimate traffic due to misclassification.

VI. CONCLUSION AND FUTURE WORK

Our proposed trust-based detection mechanism for Distributed Denial of Service (DDoS) attacks in SHIoT networks demonstrates significant potential to improve the security and resilience of SHIoT environments. By utilizing trust scores, the system efficiently identifies and isolates malicious nodes while ensuring minimal impact on legitimate traffic. This research highlights the critical need for adaptive, lightweight, and scalable security solutions tailored to resource-constrained IoT environments. The integration of trust-based mechanisms tailored to SHIoT environments enables the mechanism to detect and mitigate multiple types of DDoS attacks, including TCP SYN Flood, HTTP Flood, and UDP Flood. Our technique

prioritizes lightweight computation to accommodate the limited processing and energy capacities of SHIoT devices. We achieve high detection accuracy, correctly identifying malicious nodes within a short time frame while maintaining a low false positive rate. This ensures the reliability of the network and protects against unnecessary isolation of legitimate nodes. The use of trust decay, penalties for malicious behaviour, and rewards for legitimate traffic ensures that trust scores dynamically reflect the behaviour of each node. This adaptability makes our technique robust against evolving attack patterns and intermittent malicious activities.

This research addresses a critical gap in SHIoT security by providing a lightweight yet effective solution for DDoS detection. As SHIoT adoption continues to grow, securing these networks would continue to be imperative in a bid to prevent disruptions, enhance the resilience of smart home networks, and ensure the integrity, privacy, and availability of SHIoT communications. Our proposed trust-based detection technique not only lays a strong foundation for SHIoT security but also opens avenues for further innovation. The findings of this study reinforce the importance of trust-based approaches in combating cyber threats in IoT networks and paves the way for the development of more secure and reliable IoT systems, ensuring a safer and better-connected future. Future research could explore the design of a scalable, trust-based, easily adaptable cloud/edge computing infrastructure as a service solution for SHIoT networks.

Abstract—Forecasting the emergence of a dominant design in advance is important because the emergence of the dominant design can provide useful information about the external environment for the product launch. Although the emergence of the dominant design can only be determined as a result of the introduction of the product into the market, it may be possible to predict the emergence of the dominant design in advance by applying a solution based on patent analysis. In the newly proposed technique of separating patents, we can capture changes in the state of technological innovation and analyze the emergence of the dominant design, but there is a problem that it requires processing of large amounts of patent data, and that the processing involves subjective judgments by experts. This study focuses on analyzing technological innovation trends using an approach that separates product patents from process patents, investigates whether this approach can be applied to machine learning, and aims to develop a learning model that automatically classifies patents. We applied text mining to patent information to create structured data sets and compared nine different machine learning classification algorithms with and without dimensionality reduction. The approach was effectively applied to machine learning, and the Random Forest, AdaBoost and Support Vector Machine models achieved high classification performance of over 95%. By developing these learning models, it is possible to objectively forecast the emergence of a dominant design with high accuracy.

Keywords—Dominant design; patent analysis; technological innovation; machine learning; text mining; classification

I. INTRODUCTION

A company's introduction of a product into a market can significantly change its competitive environment [1], while the external environment affects market entry [2], [3]. Thus, the timing of market entry is strategically important for companies [4]. Dominant design is defined as a design that has achieved market dominance [5], and some previous studies have discussed market entry timing in relation to dominant design. These studies point out that companies that enter the market when a dominant design is likely to emerge while timing their entry will win the market [6], and that entering the market just before the emergence of the dominant design is particularly advantageous and tends to have a low probability of failure [7]. However, the emergence of the dominant design is recognized as a result of a product's entry into the market and thus can only be known in retrospect [5], [8]. If the timing of market entry can be accurately predicted in advance, the probability of success

can be increased by formulating and implementing a growth and technology strategies in accordance with that timing. Therefore, predicting the timing of the emergence of the dominant design is necessary.

Since the timing of the emergence of the dominant design is when the competitive advantage shifts from product innovation to process innovation [5], it is necessary to capture the change in the state of technological innovation in order to predict the emergence of the dominant design. Since patent information is important as an innovation indicator for companies [9] and is useful as an information source for predicting future products [1], patent analysis can be used to predict the state of technological innovation.

The problem of patent analysis, which is a complex and time-consuming process [10] and involves subjective and qualitative judgments of experts [11], [12], is well known. We propose a new technique for patent analysis that separates patents related to product innovation (product patents) from those related to process innovation (process patents) [13], and show that the timing of the emergence of the dominant design can be predicted using this technique by analyzing specific product case studies [14]. However, subjective processing by experts still remains, and there are concerns about the variability of the processing results. Patent analysis using automatic classification with machine learning allows for objective forecast of the emergence of a dominant design with high accuracy and stability. The increased efficiency provided by automatic classification contributes to reducing the activities and investments of companies for patent analysis.

In order to forecast the emergence of the dominant design, this study examines whether the idea can be applied to machine learning based on a technique for separating product patents from process patents and develops a learning model that automatically classifies patents into product patents and process patents. Specifically, we apply text mining to patent information, which is textual information, to extract features to be input to the modeling. We compare several classification algorithms for supervised learning and construct an appropriate learning model.

This paper is organized to provide a comprehensive understanding of analytical methods for automatically classifying patents into product and process patents using machine learning and text mining. Section I provides background and emphasizes the importance of predicting the

emergence of the dominant design. Section II presents a literature review. Section III describes the methodology of the study, and Section IV presents the results and discussions. Section V presents the conclusions.

II. LITERATURE REVIEW

A. Dominant Design

There are previous studies that have analyzed the emergence of a dominant design based on patent information. In an analysis focusing on the number of patents per technology category, the dominant design is composed of technology categories with a large number of patents [15]. In an analysis focusing on the citation rate of patents, the dominant design exists when the ratio of patents citing the same patent in a patent class is 50% or more [16]. These analyze whether or not a dominant design emerges, but do not provide any information on the timing of the emergence of the dominant design.

The timing of the emergence of the dominant design is said to be the boundary between the fluid phase and the transition phase in "the dynamics of innovation" model [5]. Capturing changes in the state of technological innovation means that it may be possible to predict the timing of emergence by estimating the profiles of product and process innovation in the aforementioned model.

B. Classifying Product and Process Patents

In Japanese patent law, inventions are categorized into inventions of a product and inventions of a process, and inventions of a process are further categorized into inventions of a process that produces a product and inventions of a process that does not produce a product [17]. Patent laws in Europe and the United States categorize inventions in almost the same way [18], [19]. Product inventions are inventions relating to the product itself. Process inventions, on the other hand, refer to inventions relating to a process for manufacturing or producing a product, inventions relating to a process for improving or enhancing the characteristics of a product, and inventions relating to a process for expressing the function of a product, based on the content of the invention.

The patents related to product innovation and process innovation in the "dynamics of innovation" model are called product patents and process patents, and the two types of patents are shown in Table I, which maps them to the various inventions mentioned above.

Previous studies on the classification of product and process patents propose methods for experts and specialists to judge their classification, and they focus on the description of the F-term, which is a Japanese patent classification code [20], or on the title of the invention [14]. In both cases, the large amount of patent data has to be processed subjectively by experts, and there are concerns about the stability and efficiency of the processing results.

C. Machine Learning for Patent Analysis

Previous studies point out that patent analysis requires very large data sets and expertise, and that manual, subjective processing is time-consuming and costly [21], [22], [23], thus automation using machine learning is eagerly awaited. The

focus of patent analysis is on extracting specific technology information and investigating technology trends [24], and the analysis of "technology" is the main objective. For example, the following are examples of patent analysis using machine learning. In terms of technology information extraction, there is the extraction of vacant technology [25], the identification of emerging technologies [26], and the extraction of differences in technologies of competing companies [27]. In addition, for technology trend studies, there are the future technology trends in a certain industry [28], the trajectory of technology development from the present to the future [29], the current and future technology impact in a certain technology field [30], and the prediction of technology convergence in a certain industry or technology field [31].

TABLE I. CLASSIFICATION OF PRODUCT AND PROCESS PATENTS

Categories of Invention		Contents of Invention	Classification of Patent
Inventions	Inventions of a process	Inventions of a production process	Process patents
		Inventions of a non-production process	
	Inventions of a product	Inventions relating to the product itself	

We study the use of patent information not to analyze technologies for R&D, but to analyze innovations as value creation for customers, markets, and society [14]. In conventional patent analysis using machine learning, the main target of analysis is the investigation of technology trends, while few research reports are known to focus on the analysis of innovation. We focus on technological innovation in the analysis of patents using machine learning, especially in the investigation of innovation trends as shown in "the dynamics of innovation" model.

In the next section, we describe a patent analysis method that focuses on "title of the invention" as patent information, and automatically classifies patents into product patents and process patents by using machine learning and text mining.

III. METHOD

This study followed the process model developed by the Cross Industry Standard Process for Data Mining (CRISP-DM) project [32], which was a de facto standard process model for data mining projects that can be applied independently of industries and research domains [33]. Table II shows an overview of the individual phases of CRISP-DM, which consists of six phases, as well as the general tasks [34].

The following subsections described the methodology of this study for each phase.

TABLE II. PROCESS MODEL OF CRISP-DM

Phase	Outline and Generic Task
Business understanding	The business understanding phase focuses on understanding the objectives and requirements of the project from a business perspective, then developing data mining objectives and creating a plan, including an initial evaluation of tools and techniques, to achieve the objectives.
Data understanding	The data understanding phase begins with collecting the data to be used in the analysis, organizing the characteristics of the data to become familiar with the data, and performing simple tabulations. Activities proceed to understanding the meaning of the data and checking the quality of the data.
Data preparation	The data preparation phase includes all activities to prepare the final data set (the data supplied to the modeling tool) from the initial data. These activities include data selection, data cleaning, data construction, data integration, and data transformation.
Modeling	The modeling phase involves selecting and applying different modeling techniques and adjusting their parameters to optimal values. In general, there are several techniques for the same type of data mining problem. In the case of supervised learning, the data sets are usually divided into training and test data set, the model is built on the training data set, and its quality is estimated on the test data set. Metrics to evaluate the quality and validity of the model are generated before the model is built.
Evaluation	During the evaluation phase, it is important to review the steps taken to ensure that the model adequately achieves the business objectives. A more detailed review of data mining is appropriate to determine if any tasks have been overlooked.
Deployment	During the deployment phase, the process of building the model is documented, the entire project is reviewed, and a final report is compiled for future use.

A. Business Understanding

The objectives of the data analysis project were understood, and the resources and constraints for implementation were identified. Next, the data mining objectives were determined from a technical perspective and an action plan was developed. As a source of patent information, registered patents on projector products that predict and validate the emergence of the dominant design were selected [14]. An initial evaluation of tools and techniques was performed during this phase.

B. Data Understanding

As shown in Table I, inventions are classified into inventions of a product and inventions of a process. This classification can be easily made by paying attention to the "title of the invention" in the patent specification. In other words, it can be determined whether the keyword "process" is included in the "title of the invention" or not. Based on this understanding of the data, the "title of the invention" data of each patent was collected as the patent information to be used in the analysis.

Inventions of a product and inventions of a process were simply tabulated. Data quality was checked for completeness and missing values.

All inventions of a product belong to product patents. On the other hand, inventions of a process belong either to product patents or to process patents. Therefore, it is necessary to determine from the content of the "title of the invention" whether

the patent containing the invention is a product patent or a process patent.

C. Data Preparation

For the inventions of a process, the following two structured data sets were constructed to prepare a final data set from the collected "title of the invention" data. They were combined into the final data set.

One was a high-dimensional structured data set created by tokenization, data cleaning and feature extraction with TF-IDF (Term Frequency – Inverted Document Frequency) using text mining techniques on the unstructured text data of the "title of the invention". TF-IDF is a feature that assigns a lower weight to words that appear in more documents relative to the frequency of occurrence of the word. TF_{ij} is denoted by tf_{ij} , the frequency of the word w_j in document d_i (1), and IDF_j is denoted by Eq. (2), where N is the total number of documents and df_j is the number of documents containing the word w_j [35]. $TF-IDF_{ij}$ is denoted by Eq. (3), where the document refers the "title of the invention".

$$TF_{ij} = tf_{ij} \quad (1)$$

$$IDF_j = \log(1 + N/df_j) \quad (2)$$

$$TF-IDF_{ij} = TF_{ij} * IDF_j = tf_{ij} * \log(1 + N/df_j) \quad (3)$$

The other was a single row of structured data set formed by labeling whether the patent containing the inventions of a process method was a product patent or a process patent. The labeling was performed by engineers and experts familiar with the technology.

D. Modeling

We conducted modeling to classify patents containing inventions of a process into product patents and process patents using a machine learning algorithm. We investigated the well-known supervised learning classifiers: Decision Trees (DT), Linear Discriminant (LD), Logistic Regression (LR), Naive Bayes (NB), Support Vector Machine (SVM), k-Nearest Neighbors (kNN), Random Forest (RF), AdaBoost (AB), and Neural Networks (NN) [36], [37], [38], [39]. The data set created in the previous subsection was used as input, and the hyperparameters were tuned for each classification model using Bayesian optimization.

Because dimensionality reduction has the potential to improve model performance, all models were run with and without dimensionality reduction using Principal Component Analysis (PCA) on the input data set.

The ratio of training and test data sets was set to 80% and 20%. To avoid overfitting, a five-fold cross-validation was used for training. That is, the 80% training data set is divided into 64% for training and 16% for validation. The Mean Accuracy of the cross-validation on the training data set was calculated as a metrics of the quality of the classification model. In addition, we calculated Accuracy using the test data set, Recall, which indicates how well the model reproduces actual results, Precision, which indicates how well the model corrects predicted results, and F1-Score, which is the harmonic mean of Precision and Recall with a trade-off relationship. The confusion

matrix shown in Table III and the following Eq. (4), (5), (6) and (7) were used in these calculations.

TABLE III. CONFUSION MATRIX

		Prediction	
		Positive	Negative
Actual	Positive	True Positive (TP)	False Positive (FP)
	Negative	False Positive (FP)	True Negative (TN)

$$Accuracy = (TP + TN) / (TP + FN + FP + TN) \quad (4)$$

$$Precision = TP / (TP + FP) \quad (5)$$

$$Recall = TP / (TP + FN) \quad (6)$$

$$F1-Score = 2 * TP / (2 * TP + FP + FN) \quad (7)$$

The classification models with good values for these metrics were selected.

E. Evaluation

To confirm that the business objective of forecasting the emergence of a dominant design was feasible, each step was reviewed and confirmed.

F. Deployment

The entire project, including the procedures for data preparation by text mining and modeling by machine learning, was summarized in this paper.

IV. RESULTS AND DISCUSSIONS

The results were presented in the order of the phases outlined in the previous section, followed by some discussion.

A. Business Understanding

The objective of data mining is the automatic classification of product patents and process patents, and in particular the classification of "inventions of a process" into product patents and process patents. For the initial evaluation of the tools and techniques, we conducted a preliminary experiment on 1,000 registered patents for projectors, which is a simplified version of a planned main experiment and confirmed that the planned experiment was feasible. In the preliminary experiment, we went through the procedures of data preparation, modeling, and evaluation, and found that it was likely to provide the desired accuracy, thus we decided to proceed with the main experiment. We used MATLAB R2023b version, Statistics and Machine Learning Toolbox, and Text Analytics Toolbox from Mathworks as the tools to perform text mining and machine learning.

B. Data Understanding

Registered patents were extracted from the Japan Patent Office (JPO) database using the search conditions of patent classification code and period. For the patent classification

codes, we used theme codes that are unique to Japan. Theme codes are organized by technical groupings and can be represented almost equivalently by a bundle of multiple IPCs. The number of registered patents extracted under the conditions shown in Table IV was 11,318. Based on a simple aggregation by the presence or absence of the keyword "process" in the "title of the invention", 8,932 patents were classified as inventions of a product, and 2,386 patents were classified as inventions of a process.

TABLE IV. SEARCH CONDITIONS

Item	Query
Database	Japan Patent Office
Patent classification code (Theme code)	2K103 or 2K203
Period	1/1/1981 – 12/31/2020
Search date	10/30/2023

The "title of the invention," which includes both inventions of a product and inventions of a process, was positioned as inventions of a process. This is because inventions of a process are classified as product patents and process patents in the next phase of modeling.

C. Data Preparation

For the 2,386 unstructured text data of "title of the invention," we performed cleaning and computed TF-IDF to create a structured data matrix of numerical variables with 2,386*714 dimensions. After tokenization, the cleaning process included stemming, erasing punctuation, removing stop words, removing a single character, and standardizing synonyms.

Labeling was performed by experts to create a 2,386*1 dimensional structured data matrix with process patents as "A" and product patents as "B." By merging the two structured data sets, a 2,386*715-dimensional matrix was created as the final data set for the modeling.

D. Modeling

Table V shows the mean accuracy of each model on the training data set for each of the nine classifiers. To check the effect of dimensionality reduction, PCA was performed on the input data set to achieve a cumulative contribution rate of at least 95%, and the dimensionality was reduced from 714 dimensions to 343 dimensions. All models were run without dimensionality reduction (without PCA) and with dimensionality reduction (with PCA).

Only NB and kNN had mean accuracy below 90%, while the rest of the models exceeded 90%. In particular, the AB model achieved good mean accuracy of over 95%.

Table VI shows the calculation results for each metric on the test data set. For each classification algorithm, the model with the higher mean accuracy was selected with and without PCA. In the case of with PCA, "with PCA" was added to the name of the classifier.

TABLE V. COMPARISON BETWEEN WITHOUT PCA AND WITH PCA (TRAINING DATASET)

Classification Algorithm (Classifier)	Mean Accuracy on the Training Data Set	
	Without PCA	With PCA
DT	94.1%	85.8%
LD	85.7%	93.8%
LR	89.3%	91.0%
NB	70.7%	84.7%
SVM	94.9%	94.1%
kNN	89.1%	89.6%
RF	94.7%	89.9%
AB	95.1%	92.1%
NN	94.0%	94.1%

TABLE VI. COMPARISON BETWEEN WITHOUT PCA AND WITH PCA (TEST DATASET)

Classification Algorithm (Classifier)	On the Test Data Set			
	Accuracy	Precision	Recall	F1-score
DT	94.6%	96.3%	95.7%	96.0%
LD with PCA	93.1%	96.2%	93.5%	94.8%
LR with PCA	93.1%	95.3%	94.4%	94.9%
NB with PCA	81.6%	82.9%	91.6%	87.1%
SVM	95.6%	95.8%	97.8%	96.8%
kNN with PCA	91.0%	92.4%	94.4%	93.4%
RF	95.6%	97.8%	95.7%	96.7%
AB	95.2%	96.9%	96.0%	96.4%
NN with PCA	94.3%	94.6%	97.2%	95.9%

Accuracy was highest for SVM and RF, followed by AB at more than 95%. Precision was highest for RF, and AB, DT, LD with PCA, SVM, and LR with PCA exceeded 95%. Recall was highest for SVM, followed by NN with PCA, AB, RF, and DT over 95%. The F1-Score, the harmonic mean of Precision and Recall, was also highest for SVM, followed by RF, AB, DT, and NN with PCA exceeding 95%.

Tables VII, VIII, and IX show the confusion matrices on the test data set for the three models SVM, RF, and AB, which performed well above 95% on all four metrics.

The high performance of several models in patent classification in this study suggested that the "title of the invention" was appropriate as patent information data, that the data preprocessing was effective, and that the idea of separating product and process patents was applicable to machine learning.

In this experiment, which combined nine classification algorithms with and without PCA, the prediction model using SVM, RF and AB algorithms achieved higher performance.

TABLE VII. CONFUSION MATRIX OF SVM

		Prediction	
		A	B
Actual	A	316	7
	B	14	140

TABLE VIII. CONFUSION MATRIX OF RF

		Prediction	
		A	B
Actual	A	309	14
	B	7	147

TABLE IX. CONFUSION MATRIX OF AB

		Prediction	
		A	B
Actual	A	310	13
	B	10	144

E. Evaluation

In order to forecast the emergence of a dominant design, which is the objective of the business, it was important to capture changes in the state of innovation. The changes were indicated by the trends of product patents and process patents according to the "the dynamics of innovation" model. Based on Table I, we categorized the patents to be analyzed into product patents and process patents. Since inventions of a product can be easily identified from the "title of the invention," we focused on classifying inventions of a process into product patents and process patents. The data preparation and modeling resulted in several prediction models with high classification performance in terms of the overall model correctness rate and the F1-Score, which is a balance between actual and predicted results.

Since the trends of product innovation and process innovation are visualized according to the classification results of the prediction model, and the emergence of a dominant design is predicted, we considered precision to be particularly important among the four metrics for this business objective. Therefore, the prediction model with the highest precision performance was preferred. Table VI shows that the precision performance of the RF model is 97.8%, and the predicted trends of product and process patents are almost the same as their actual trends. The above review confirmed that no tasks were missed in the steps performed and that the business objective was properly achieved. It also demonstrated that the automatic classification by machine learning worked effectively.

F. Deployment

In this project, the business objective was to predict the emergence of a dominant design, and the data mining goal for this purpose was to automatically classify "inventions of a

process" into product patents and process patents. Through data understanding, data preparation, modeling, and evaluation, the validity of the data we focused on and the predictive models that achieved high performance were confirmed, and thus the project was completed. We summarized the data mining process and results according to the CRISP-DM process model in this paper.

G. Discussions

The effect of dimensionality reduction on the classification algorithm was discussed by comparing the models with and without PCA. Table V shows that the five models with a higher mean accuracy with PCA than without PCA were LD, LR, NB, kNN, and NN. According to the idea that machine learning models can be divided into three models: geometric, probabilistic, and logical models [40], these five models were included in the geometric and probabilistic models. The models with a difference of less than 1% between those with and without PCA were SVM, kNN, and NN, all of which were geometric models. On the other hand, four models, DT, SVM, RF, and AB, had a higher mean accuracy without PCA than with PCA. Since RF and AB are ensemble learning with tree models, these three models including DT are considered to be logical models. These results suggested that dimensionality reduction may be effective in improving the performance of geometric and probabilistic models in this experiment.

It is known that SVM and ensemble learning, such as RF and AB, tend to show relatively high performance compared to other algorithms, and this study was consistent with this finding, as well as previous studies comparing multiple algorithms [36],[37].

Although this study achieved good results in classification performance, some limitations need to be considered. Instead of classifying product inventions and process inventions directly from the "title of the invention," this study focused on separating "inventions of a product" and "inventions of a process" from the "title of the invention" by a simple procedure first, and then classifying product inventions and process inventions from "inventions of a process." We used TF-IDF and five-fold cross-validation for feature extraction in data preparation and data partitioning in modeling, respectively, but other techniques could be considered to further improve classification performance.

V. CONCLUSIONS

In order to forecast the emergence of dominant designs, this study investigated an automatic classification method for product and process patents according to the CRISP-DM process model applied to data mining projects. We focused on "title of the invention" as patent information, extracted TF-IDF features by text mining, and evaluated nine classification algorithms with and without PCA by machine learning. As a result, the prediction model using the RF, AB, and SVM algorithms achieved over 95% performance in all four metrics: accuracy, precision, recall, and F1-Score. In the classification of product patents and process patents, it was shown that the "title of the invention" was appropriate as patent information data, that data preprocessing was effective, and that the idea of a technique for separating product patents from process patents was applicable to machine learning.

By using patent analysis, which uses machine learning and text mining to capture changes in product innovation and process innovation, that is, changes in the state of technological innovation, it is possible to objectively forecast the emergence of a dominant design with high accuracy. Therefore, it can be a useful piece of information about the external environment for companies to formulate and implement growth and technology strategies.

Increased efficiency in analyzing trends in technological innovation can lead to a reduction in the activities and investments of companies. In addition, the resources generated by the reduction are expected to make a new contribution.

Abstract—This paper describes the development and implementation of a hand or head gesture-based control interface for video games, enhanced for games that use directional keys. The objective is to develop an adaptive control system for a multiplayer video game that allows users to choose between the use of traditional directional keys or a gesture-based interface. The methodology used follows the Cross-Industry Standard Process for Data Mining (CRISP-DM) development model, which allows a structured integration of analysis, design, implementation and evaluation steps. Technologies such as OpenCV, MediaPipe and deep learning algorithms are used, translating hand movements into directional commands in real time. In addition, the system integrates a client-server architecture based on Node.js that supports multiple users, enabling an immersive gaming experience on PC and mobile platforms. The results highlight the accuracy of the system and its potential to improve accessibility, especially for users with motor disabilities by using their hands or head movements to control the directional keys. Concluding that the control interface for multi-user video games provides the necessary support to gamers in performing the task, promoting accessibility in the entertainment environment.

Keywords—Control interface; video games; artificial vision; gesture-based interface; directional commands; human-computer interaction; deep learning algorithms; accessibility; real-time; pattern recognition

I. INTRODUCTION

Gesture interaction has revolutionised the gaming experience [13], eliminating the dependence on traditional keyboards and controls. This paper presents an interface that allows video games [36] to be controlled by hand movements, using computer vision [3] and real-time pattern recognition. The solution aims to improve immersion and accessibility, especially for users with motor disabilities, promoting their integration in recreational and therapeutic activities.

The interface employs gesture detection algorithms and a robust client-server system, compatible with PC and mobile devices, providing an inclusive experience. As a result, a gesture recognition system was designed and developed to replace the directional keys, allowing precise and fluid control in real time. In addition, it supports multiple users with individual network configurations and in-game character selection. Developed in Unity, the game integrates traditional and gesture controls, adapting to both PC and mobile.

It is concluded that this interface is viable, offering an accessible alternative for controlling video games through hand gestures or head movements, broadening access to entertainment and promoting inclusion.

II. THEORETICAL FRAMEWORK

A. Gesture-based Control Interfaces and Games

Gesture-based control interfaces have revolutionised the way users interact with devices and computer systems [9], opening the door to immersive and intuitive experiences. In the context of video games, these interfaces allow the user to control game elements through body gestures, specifically hand movements. The advantages of this approach include greater immersion and accessibility [23], as it allows play without the need for traditional controls such as keyboards or controllers. To achieve this, advanced gesture recognition [1] and computer vision technologies are used to interpret the user's movements and translate them into real-time actions.

B. Artificial Vision and Gesture Recognition

Artificial vision is a discipline that allows machines to process and interpret the visual world. This technology uses image processing algorithms and automatic learning techniques to identify objects, gestures and patterns in real time [10] [15]. In hand gesture recognition, a sub-area of machine vision, it allows the detection and analysis of specific hand movements to control interactive applications [12]. In the context of this project, libraries such as OpenCV and MediaPipe are fundamental to capture images of hands, identify key points (such as articulations and fingers) and translate this data into control actions for games based on directional keys.

C. Real Time Pattern Recognition

Real-time pattern recognition is key to achieving smooth [2] [11] and accurate interaction in gesture-based interfaces. Real-time recognition systems allow capturing and processing images in a fraction of a second, detecting movements instantaneously. The ability to process gestures in real time is especially relevant for video game applications [25], where any delay can affect the user experience [6] and decrease the effectiveness of the control. To implement this functionality, fast image processing techniques and movement detection and analysis algorithms, optimised to operate on common devices such as webcams, are employed.

D. Image Processing Technologies and Benchmark points Models

Reference point models are essential to accurately recognise the position of fingers and hands. These models identify key points on the hands and, using deep learning techniques, detect specific gestures, such as left, right, up or down movements. These points help determine the orientation and height of the hands, which are essential for translating gestures into commands in the videogame. The precision of these models depends on the quality of the camera and the capacity of the algorithms to quickly process the images.

E. Gesture Control of Video Games: Benefits and Challenges

Gesture control of video games [7] has significant benefits, including greater immersion and accessibility for users with motor limitations. It also allows for a more natural and direct gaming experience, eliminating the need for additional control devices. However, there are also challenges, such as the need for recognition algorithms that work accurately in varied environments and lighting conditions. Also, minimising the delay [18] between capturing the gesture and executing the command in the game is critical to ensure a satisfactory experience.

F. Implementation of the Control Interface

The implementation of hand gesture control interface for video games [7] based on directional keys requires effective integration [19] of various software and hardware elements. In this project, a combination of Python libraries is used for the creation of the graphical user interface [17], camera control and gesture detection. Tkinter is used to develop the user interface, allowing custom settings for sensitivity and direction control. In addition, OpenCV and MediaPipe are employed for processing the captured images and detecting gestures in real time, as shown in Fig. 1 and Fig. 2.

Fig. 1. Control interface.

Fig. 2. Control of racing game in unity.

G. Server Implementation

The development of an efficient server is essential to guarantee real-time communication between players and to maintain synchronisation during the multiplayer gaming experience, see Fig. 3. The server implementation was carried out using modern technologies such as Node.js, which offers a lightweight and scalable environment, together with libraries such as Express for HTTP route management and Socket.io for real-time communication [20].

Fig. 3. Multi-user racing game in Unity.

III. RELATED WORK

The use of computer vision and hand gesture recognition techniques in video games has been an active area of research. The research in [31] presented GestureFlow, a novel hand gesture control system for interactive games that leverages advanced tools such as OpenCV, Mediapipe and Numpy. The study in [32] presented a methodology for gesture-based contactless operations, combining his algorithm with Mediapipe and OpenCV.

Various studies have focused on the development of game applications based on hand gestures. Thus, the study in [33] employed object detection and an artificial neural network for hand gesture recognition in games, using Python and OpenCV; also the study in [34] developed a game that interacts with users through hand gesture movements, using Mediapipe and Pygame; and the study in [35] explored the use of Mediapipe for real-time online games, creating a gesture recognition-based control system using OpenCV and Python.

The integration of hand gestures and voice commands for immersive gaming has also been studied. In study [36] they developed a game control system based on hand gesture recognition using Mediapipe, OpenCV and Python; also study in [37] reviewed the opportunities of using hand gestures to play video games, highlighting the use of Mediapipe and OpenCV for hand tracking and gesture recognition.

In addition, some studies have explored the application of gesture recognition in rehabilitation and quality of life improvement. Thus, the study in [38] presented a human body gesture-controlled gaming application using OpenCV and Mediapipe; on the other hand, the study in [39] developed a camera-based real-time motion detection gaming tool for cervical rehabilitation, employing a convolutional neural network for hand gesture recognition; also the study [40] used OpenCV functions and Mediapipe modelling technology for real-time human movement recognition and interaction in virtual fitness applications.

IV. METHODOLOGY

The methodology used in this work is based on the Cross-Industry Standard Process for Data Mining (CRISP-DM) development model, adapted for the context of gesture recognition and real-time video game control; it includes the following phases:

Phase 1. Understanding the Business and Defining the Objective

The principal objective of the project is to design and implement a control interface for video games that allows users to control the game using hand gestures or head movements, as an alternative to traditional directional keys. It is not only to improve immersion in the game, but also to promote accessibility for players with motor disabilities.

Phase 2. Data Collection and Preparation

Advanced artificial vision technologies, such as OpenCV and MediaPipe, are used to capture real-time images of the user's hand or head gestures via a webcam. This data is then processed and labelled for gesture detection. The model captures key points, such as finger articulations, and this data is translated into commands for directional key control.

Phase 3. Development of the Gesture Recognition Model

Deep learning algorithms are developed and trained to detect and recognise gestures. Key point reference models are implemented to map hand movements and translate them into directions. The algorithms were optimised to achieve a high degree of accuracy and low latency in real time.

Phase 4. Control Interface System Development and Implementation

Gesture detection is integrated with a user interface developed using Tkinter to configure the sensitivity and controls of the system; the interface also allows for actors selection and network settings. A client-server system is implemented using Node.js and Socket.io to ensure real-time communication between users, and enable a fluently gaming experience.

Phase 5. Integration and Evaluation of the System in Multiplayer Games

The system is integrated into a multiplayer video game developed in Unity, which supports the interaction of multiple players simultaneously. The gesture-based control is evaluated in terms of accuracy, latency and user experience compared to traditional control. Tests are conducted in different lighting conditions and types of movement to ensure the robustness of the system.

Phase 6. Optimisation and Results

Once the basic system is implemented, the algorithms are optimised to improve accuracy and minimise latency. The results of the system are analysed using metrics such as response time and gesture accuracy, and compared to traditional control to determine the effectiveness of the interface in multiplayer games.

This approach ensures a robust solution that not only responds to user requirements, but also contributes to achieving accessibility and usability across PC and mobile platforms.

A. Explanation of Control Interface Code

1) *Interface configuration and resources*: The graphical user interface (GUI) is created using Python's Tkinter for interface creation; the necessary libraries are imported to manage the interface, threads of execution, running local files and external URLs for Unity-based games [8].

2) *Camera and game control*: The functions implemented as `start_camera_thread` and `start_camera_tk_thread` are in charge of starting the camera capture using different control methods, such as `run_virtual_steering` and `run_virtual_tk`, which are executed in separate threads so as not to block the principal interface. Both functions take as arguments the control methods for the directional keys (such as hand or head) defined in `get_control_methods`; the `stop_camera_thread` and `stop_camera_tk_thread` functions stop these threads of execution using stop events (`stop_event` and `stop_event_tk`).

3) *Interface design*: For the principal interface, multiple frames are created representing sections such as the camera control and the Unity game, configured by grid to be arranged according to the selected layout.

The functions `show_columns`, `show_quadrants` and `show_rows` allow different GUI layouts to be changed according to user preference, see Fig. 4 `make_draggable` is used to make each frame draggable, offering flexibility in the layout of the interface.

Fig. 4. Design of the interface control.

4) *Personalisation of configurations*: The configurations frame includes sensitivity and distance threshold setting controls, implemented as sliders (`ttk.Scale`) that allow the user to customise the threshold and sensitivity of the gesture detection system. Additionally, the user can choose between

direction controls with different methods (hand or head gestures), defined in the settings_frame Radiobuttons.

5) *Menu bar*: The menu bar provides easy access to camera and configuration options. The Checkbuttons allow you to activate or deactivate the main sections of the interface, such as camera control or the Unity game, the views submenu offers different settings for the layout of the frames (show_columns, show_quadrants and show_rows), shown in Fig. 5.

Fig. 5. Menu options.

6) *Execution of the main window*: The main window is started with `root.mainloop()`, a loop that keeps the interface active until the user decides to close it, by calling the `on_closing` function, which stops all active camera threads.

7) *Camera processing and visualisation with OpenCV: With and Without Graphical User Interface (GUI)*

The `run_virtual_steering` function starts initialising the modules needed for gesture control [28].

- Image processing without GUI

The mediapipe libraries are used for recognition of hands [16] [26] and face, and OpenCV's `cv2` is used for processing the captured image. The webcam is initialised with `cv2.VideoCapture(0)`, capturing the video in real time; a virtual keyboard controller is configured using `pynput.keyboard.Controller`, used to send simulated commands to the game in Unity, see Fig. 6.

Fig. 6. Camera processing without GUI.

- Image processing with GUI

The real-time processed video is integrated into a graphical interface using Tkinter. A subwindow displaying the processed frames in a continuously updated Label component is shown in Fig. 7.

Fig. 7. Camera processing without GUI.

8) *Image processing and hand detection*: The software processes each camera frame in real time [24] [29], the captured image is flipped horizontally with `cv2.flip` for a more intuitive orientation, then converted to RGB before being passed to the mediapipe model to process the `hand_results` and `face_results` [22] [27]. These data allow the position and movement of the hands and face to be determined.

9) *Direction control based on vertical position of the hands*: Are used the reference points obtained to detect the position of the hands on the Y-axis, allowing to differentiate whether the right hand is more up than the left hand or vice versa. When it detects that the right hand is more raised, the program simulates a movement to the right by pressing the `Key.right` key. Similarly, if the left hand is higher, `Key.left` is pressed; shown in Fig. 8.

Fig. 8. Ownership of frames.

10) *Face distance based control*: The program calculates the distance of the face from the area of the face detection box; it is used to detect approaching or moving away movements, activating the `Key.up` key to accelerate as the face approaches and `Key.down` to slow down as it moves away. This control allows to adapt the speed of the vehicle within the game, simulating acceleration and deceleration depending on the proximity of the face, as shown in Fig. 9.

Fig. 9. Head movement conditionals to accelerate or decelerate the vehicle.

11) *Additional hand gesture control*: The program also includes an additional control [14] based on specific hand gestures [3]. If the index finger is fully extended downwards, it is interpreted as an acceleration gesture, activating the Key.up key, when the index finger is raised, it is assumed as a braking gesture, activating Key.down. This logic, according to the initial configuration in the interface, allows using both face movements and hand gestures [3] [30] to provide a more intuitive control experience [13].

12) *Error handling and camera shutdown*: If the OpenCV view window is closed or ESC is pressed, the program stops the image processing loop [5]. The close_camera function ensures that all OpenCV camera and window resources are properly released.

13) *Initialisation of interface styles*: Using the apply_styles function you can customise the visual styles of widgets; thus: a) the TFrame style sets a light blue background, a 5 pixel border and a ridge relief that gives depth to the frame, b) the TLabel style sets a 12 point Helvetica font with the same background, the text uses a darker blue to stand out against the background, c) the TButton style uses a 10 point Helvetica font in bold, with a dark blue background and white text to ensure contrast, d) with style map, the button is adjusted so that, on hover, the background changes to an even darker blue, while keeping the text white to ensure legibility.

14) *Initialisation of the camera module with tkinter*: OpenCV libraries are imported for video handling, MediaPipe for gesture and face detection, and pynput for keyboard input simulation. Global variables, camera_running (check if camera is active), last_action (store the last action performed) and press_duration (measure how long a key is pressed) are initialized to ensure continuous tracking of the system state during execution.

15) *Video capture and processing*: The video_stream function uses OpenCV to capture video in real time. Each frame is processed with MediaPipe to detect hand gestures and faces. The key points of the hands are used to calculate their position in space, allowing to determine actions such as moving left or right. In addition, the points and connections of the hands are visualized in the video to facilitate the interpretation of the system.

16) *Hand gesture detection*: Within video_stream, hand gestures are analyzed using the positions of specific points. This analysis includes logic to avoid simultaneous keystrokes and ensure smooth transitions between actions.

17) *Face distance based control*: The face distance is implemented by comparing the relative size of the detected bounding box around the face [21]. If it increases or decreases

beyond a configured threshold, the “up” or “down” keys are triggered, simulating actions such as accelerating or braking.

B. Explanation of the Server Code

1) *Server initialisation and dependency configuration*: The express, http, and socket.io libraries are used to create a server in Node.js; an HTTP server is configured with http.createServer and its functionality is extended with socket.io to handle real-time connections.

2) *HTTP path to check server status*: The path app.get('/') returns a simple message to confirm that the server is running. The /getPlayers path uses a JSON format returning information about the connected players.

3) *HTTP path to check server status*: The io.on('connection', callback) function handles each client connection. Each connected player is assigned a unique identifier (PlayerID) and is stored in the players object.

4) *Player synchronisation and start of the race*: When the number of connected players reaches the maximum allowed (maxPlayers), the server sends a startRace event to all clients, indicating the start of the game.

5) *Real time position update*: The updatePosition event receives data from the clients, such as position and rotation in the X, Y and Z axes; it is updated in real time in the players object; the server emits the updated list of players through io.emit('updatePlayers').

6) *Handling disconnections*: When a player disconnects, the server deletes his information from the players object and issues an event to update the list of players in the clients.

7) *Server and listening port configuration*: The server starts on port 3020 with address 0.0.0.0, which allows accepting connections from any IP address, ideal for multiplayer environments.

C. Explanation of the Multi-User Game Code in Unity

1) *Automatic object rotation (AutoRotation.cs)*: The AutoRotation script implements a simple functionality to make an object in Unity rotate continuously around its Y-axis; it is controlled by a public variable rotationSpeed.

2) *Dynamic player tracking (FollowPlayer.cs)*: The FollowPlayer script implements functionality for a camera to follow the player in Unity, dynamically adjusting to the player's position and rotation; it includes support for virtual reality (VR) scenarios, see Fig. 10.

Fig. 10. Player camera configuration.

3) *Interactive In-game console (InGameConsole.cs)*: The InGameConsole script implements an in-game console in Unity, useful for real-time debugging; it allows to display system and user messages in a panel, see Fig. 11.

Fig. 11. View of the start of the game.

4) *Panel management and connection in the main menu (Panel.cs)*: The Panel script manages user interaction with a main menu, providing options to configure a network connection, select colors for a car and manage other related panels.

5) *Player behaviour (player.cs)*: The player.cs script controls the player's behavior in the game, including movement, interaction with the environment, updating the user interface and communication with the server; it is essential to manage the game logic.

6) *Player movement management (player.cs)*: The Update method is called once per frame and handles the main logic of the player's movement. Depending on the platform and the input mode (keyboard or gestures), the input values for horizontal and vertical movement are obtained.

7) *Straighten the overturned car (player.cs)*: The RightCar method is responsible for straightening the player's car by applying an upward force and continuing the game.

8) *User interface update (player.cs)*: The UpdateUI method updates the points and lives texts in the user interface; it is called whenever the player's points or lives change.

9) *Collision management (player.cs)*: The OnCollisionEnter method is called when the player's car collides with another object, if it has the ObjectCollision tag, the player's points are reduced, if the points reach zero, a life is reduced and the points are reset. If the lives reach zero, a "You lost" message is displayed.

10) *Restart car position (player.cs)*: The ResetCarPosition method resets the position and rotation of the player's car to its initial state. This is used when the car falls off the stage or when resetting the player's points and lives.

11) *Management and connection to the server (SocketManager.cs)*: The SocketManager.cs script in Unity handles the connection and communication with a server via WebSockets; it is crucial for the multiplayer functionality of the game, allowing data synchronization between players and the server.

12) *Connection to server (SocketManager.cs)*: The ConnectToServer method establishes the connection to the server using the IP address and the color of the car. It configures connection, disconnection and error, and defines handlers for various game events.

13) *Player ID assignment (SocketManager.cs)*: The OnAssignPlayerID method handles the player ID assignment event; it gets the ID from the server's response and stores it in a local variable.

14) *Initialisation and player update (SocketManager.cs)*: The OnInitializePlayers method creates or updates players at the start of the game, and OnUpdatePlayers updates player positions and rotations during the game.

15) *Position and rotation sending (SocketManager.cs)*: The UpdatePosition method sends the player's position and rotation to the server. It converts the data to a JSON object and outputs it to the server via the socket.

16) *Point and life adjustment in the interface (size.cs)*: The script tamano.cs in Unity adjusts the position and size of dot and life texts in the user interface.

D. Explanation of the Multi-User Game Code in Unity

The main figures of the video game scenario are shown below.

- Principal Camera, shown in Fig. 12.

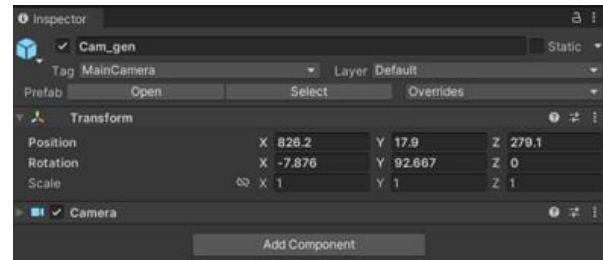

Fig. 12. Game camera position configuration.

- Vehicle models, we organized the designs of the vehicles to compete in the prefabs folder; this is shown in Fig. 13.

Fig. 13. 3D model of vehicles.

- The design of the race track, as would be the scenario, is shown in Fig. 14.

Fig. 14. Running track along the terrain.

- The configuration of the race track is shown in Fig. 15.

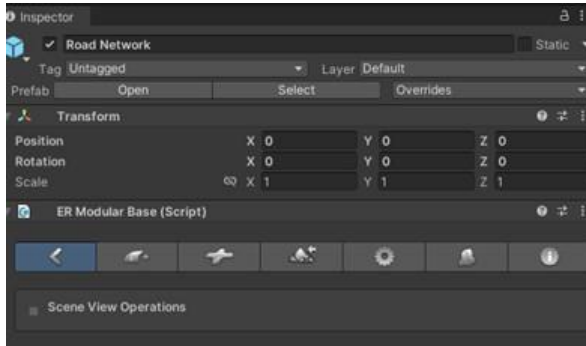

Fig. 15. Race track configuration.

- Principal player design, as shown in Fig. 16.

Fig. 16. Local player configuration.

- Principal menu configuration, three sub-panels are organized within a canvas where the user can configure the ip and connection port, as well as choose the color of the vehicle. If the entered data is validated, the system displays a confirmation message to start the multiplayer racing game, as shown in Fig. 17.

Fig. 17. Components view in unity.

- The principal menu of the game is displayed in the interface shown in Fig. 18.

Fig. 18. Main menu in the game.

- Eleccion of the player's cart, the options referred to the colours, is shown in Fig. 19.

Fig. 19. Selection of the player's car.

- Successful connection view of the player, ready to complete the players, is shown in Fig. 20.

Fig. 20. View of successful player connection.

V. RESULTS AND DISCUSSION

A robust client-server system was built using Node.js, capable of supporting a configurable number of players. Each client, developed in Unity, incorporates a script called SocketManager that facilitates bidirectional communication with the server. This allows to synchronise the start of the game when all players have connected and configured.

In the client, a start panel was designed that offers each player the possibility of configuring the network parameters, selecting a character and waiting for the minimum number of participants configured in the server to be reached before starting the game.

The developed videogame was adapted to run on both PC and mobile devices Tablet, Smartphone, see Fig. 21; providing a multiplatform experience. In addition, two control options were incorporated for players using PCs:

- Traditional Control: Use of directional keys to move left, right, forward or backward.
- Gesture Control Interface: A system that uses the device's camera to detect hand and face gestures, which are mapped to the game's directional key actions.

Fig. 21. Video game running on Multiplatform, PC, Tablet, smartphone.

In the following figures the execution of the multiplatform videogame is shown, in Fig. 22 the cars in full race can be seen on two platforms, in Fig. 23 the control of the red car with hand gestures, in Fig. 24 the car at a different speed leaves the circuit, in Fig. 25 with hand gestures the car returns to the circuit and continues the race.

Fig. 22. Cars in full race on two platforms, PC and tablet.

Fig. 23. Controlling the red car with hand gestures.

Fig. 24. Car at a different speed wanders off track.

Fig. 25. With a hands gesture the car is steered back to the circuit and the race continues.

The system executes key presses using two types of control: hand gestures and facial movements, both detected by MediaPipe [14]. For hand control, the relative position of the hands is evaluated: if the right hand is higher than the left hand, the system simulates the action of pressing the right arrow key; if the left hand is higher, it simulates the action of pressing the left arrow key. The green node, which marks the centre between the two hands, indicates that both hands are centred. In addition, the facial movement adjusts the distance control, triggering

zoom in or zoom out actions, depending on the position of the face in front of the camera. For acceleration and deceleration control [31], the system uses the position of the index finger relative to the wrist: if the index finger is higher than the wrist, it simulates the action of pressing the ‘up’ key to accelerate; if it is lower, it simulates the action of pressing the ‘down’ key to decelerate, thus allowing the speed to be dynamically adjusted by these movements.

As seen in Fig. 26, Fig. 27, Fig. 28, the system provides visual messages on screen, such as ‘Move left (Right hand higher)’, which orients the user on the movements required to interact as discussed by [11] with the virtual steering wheel for the game developed in Unity. This information is useful, that in some cases the message shows unrecognisable (“higher”) characters, thus improving the clarity of the instructions.

Fig. 26. Hand movement to the left (a).

Fig. 27. Hand movement to the left (b).

Fig. 28. Hand movement to the left (c).

The system was able to detect the hand movements [20] in real time [25] and quickly reflect the changes in position by the variations in the positions of the points between the two images, where the hand is seen to rise and change orientation, resulting in an immediate adjustment in the structure detected by the system.

In the case of the multi-user server developed with Node, the tests showed that for a range of 2 to 4 players connected from PC or mobile it is feasible to have a competition with few moments of instability in the connection, which suggests that the optimisation of the secondary threads of each client should be deepened so that the system supports a greater number of users. Table I shows the technical aspects of the multi-user server.

TABLE I. TECHNICAL ASPECTS OF THE MULTI-USER SERVER

Aspect	Technical Details	Benefits	Limitations	Performance Metrics
Server Hardware	Lenovo with Core i5/i7 processor, 12GB RAM, integrated card or NVIDIA graphics.	Good performance on standard test hardware.	Performance may not be representative for lower hardware.	50-60% CPU usage during 4-player testing.
Server Operating System	Windows 11 in both cases (Core i5/i7).	Compatibility with modern systems.	Linux servers may offer better performance.	Response time: ~80-120 ms under ideal conditions.
Player Devices	Android devices (version 12 or higher) and PCs (Linux or Windows).	Stable connections on Android 12 or higher devices.	Variability in connection quality depending on device.	Connection success rate: 98% on mobile devices.
Control interface (PC)	Python control interface for PC connection.	Efficient connection from Linux or Windows PCs.	Interface could be more complex for non-technical users.	Synchronisation time: 100-150 ms
Gesture recognition	Gesture recognition performed with specific cameras and algorithms.	High accuracy in Gesture Recognition with suitable lighting conditions.	Success rate decreases with poor lighting or fast movement.	Success rate: 85-90% with ideal conditions. Failure rate: 15% in low light.
Latency and Response	Tests conducted in controlled environment with low latency local network.	Low latency under controlled conditions.	Latency increases with more players connected simultaneously.	Average latency: ~120 ms in local network. Average latency with 4 players: ~200 ms.

Finally, [7] uses gestural interaction techniques to control a video, as from [4] in hand gesture recognition, in the present work the developed gesture control interface has proved to be an inclusive tool, allowing players with disabilities to use their hands or head movements to control the directional keys in any multiplayer game in Unity. This solution facilitates the participation of all players, regardless of their physical abilities, promoting accessibility in digital entertainment. A sample of the code worked on the system can be seen in Fig. 29.

```
if face_results.detections:
    for detection in face_results.detections:
        bbox = detection.location_data.relative_bounding_box
        left = int(bbox.xmin * width)
        top = int(bbox.ymin * height)
        right = left + int(bbox.width * width)
        bottom = top + int(bbox.height * height)
        cv2.rectangle(frame, (left, top), (right, bottom), (0, 255, 0), 2)

    current_distance = bbox.width * bbox.height
    if last_distance is not None:
        if current_distance > last_distance * (1 + distance_threshold):
            if up_method == "Cabeza":
                keyboard.press(Key.up)
                keyboard.release(Key.down)
                last_action = "Acercando"
                action_text = "Acercando (Presionando tecla arriba)"
            elif current_distance < last_distance * (1 - distance_threshold):
                if down_method == "Cabeza":
                    keyboard.press(Key.down)
                    keyboard.release(Key.up)
                    last_action = "Alejando"
                    action_text = "Alejando (Presionando tecla abajo)"
            else:
                keyboard.release(Key.up)
                keyboard.release(Key.down)
        last_distance = current_distance
```

VI. CONCLUSIONS

A hand gesture recognition system based on artificial vision [40] and real-time pattern detection was designed and implemented, achieving an innovative alternative to the use of directional keys in video games. This approach improves player immersion and makes the gaming experience more accessible, especially for users with motor disabilities.

The results demonstrated a high accuracy and speed of response to gestures ensuring a smooth and ideal interaction. Furthermore, customisation options were implemented in the interface, such as sensitivity, distance threshold and widget layout, contributing to its usability and versatility.

An efficient client-server architecture was developed that supports multiple simultaneous users, ensuring real-time communication and offering flexibility for individual network configurations and character selection within the game. The design uses threads and resources such as the camera responsibly, improving stability and minimising conflicts during interface use, contributing to increased performance and synchronisation.

The video game developed in Unity was adapted to run on PC platforms and mobile devices, extending its reach and allowing players to enjoy a consistent and immersive experience regardless of the device used.

The integration of traditional controls together with the gesture-based interface ensures greater inclusion of different play styles and user preferences.

In the comparative evaluation of the gesture control system against traditional methods, advantages in innovation and immersive experience were evident. While traditional controls maintain an advantage in accuracy and reliability under less optimal technical conditions, the gesture interface proved to be an intuitive and accessible solution, capable of improving user satisfaction by adapting to their preferences and needs.

FUTURE WORKS

As a result of the present work, a prospective vision for future work can be gained:

Optimisation of gesture recognition algorithms in variable lighting environments: It is essential to improve the accuracy of gesture recognition systems in changing lighting conditions, ensuring a consistent and reliable user experience.

Application of self-supervised learning in human-computer interaction systems: Implementing self-supervised learning techniques can improve the adaptability and efficiency of gesture interfaces, allowing systems to learn and adjust to individual user preferences and behaviours.

Integration of gesture recognition into augmented and virtual reality interfaces: Combining gesture recognition technologies with augmented and virtual reality environments can offer more immersive and natural gaming experiences, improving user interaction with digital content.

Development of deep learning models for the identification of complex gestures: The use of deep neural networks can facilitate the detection and classification of more sophisticated gestures, expanding the repertoire of available commands and improving interaction in multiplayer games.

Implementing gesture recognition using radar technology for mobile applications: The use of radar sensors in mobile devices can enable accurate gesture recognition without relying on cameras, offering an efficient and less invasive alternative for video game control.

ACKNOWLEDGMENT

Thanks to the Universidad Nacional de San Agustín de Arequipa for the support it provides for the development and implementation of proposals that benefit the continuous improvement of student performance through proposals that help to solve society's problems.

Abstract—In today’s information society, developing programming competencies is essential in higher education. Numerous studies have been conducted on effective strategies for fostering these skills. This study performs a bibliometric analysis of research on teaching strategies for programming in higher education, using data from the SCOPUS and Web of Science (WOS) databases between 2014 and 2023. The analysis identifies key trends, influential authors, and collaboration networks in this field. The most effective teaching strategies include project-based learning, flipped classrooms, and collaborative programming. Emerging technologies such as augmented reality and virtual reality are gaining prominence in programming education. Despite the growth of research in this area, challenges remain, such as the lack of longitudinal studies exploring the long-term impact of these methodologies and the need for greater geographic diversity in studies. This paper emphasizes the importance of exploring new technologies and interdisciplinary approaches and fostering international collaborations to enhance programming education. The findings guide researchers and educators on how to optimize programming learning in a global context.

Keywords—Programming; higher education; teaching strategies; bibliometrics

I. INTRODUCTION

In the digital era, programming has become an essential competency in the higher education curriculum [1], especially in Science, Technology, Engineering, and Mathematics (STEM) disciplines [2]. While programming experience in higher education was traditionally confined to technical or engineering fields, today, programming permeates diverse disciplines, recognizing its potential as both a technical tool and a critical thinking skill [3], [4]. Effective acquisition of programming skills requires not only familiarity with syntax and data structures but also deep logical understanding and problem-solving abilities [5].

Teaching and learning strategies for programming in higher education extend beyond simple knowledge transmission techniques. They instill a computational mindset, promote logical thinking, and help students address complex problems systematically [6]. As technology advances, these strategies must evolve to keep pace with the changing demands of the programming field and students’ needs, ensuring long-term educational outcomes [7]. For example, Bloom’s taxonomy classifies and describes different levels of learning achievement

that students can reach [8], [9]. Project-based learning (PBL) and pair programming also encourage collaboration and critical thinking [10], [11]. These strategies emphasize the practical application of knowledge and solving real-world problems, allowing students to consolidate and contextualize what they have learned in realistic settings [12].

As highlighted by Sun et al. [13], adaptability is essential in programming. Tools, languages, and methodologies continuously change and evolve [14]. Therefore, teaching strategies must not only transmit technical knowledge, but also teach students to become autonomous and adaptable learners [15]. This implies fostering skills such as self-learning, curiosity for new technologies, and resilience to overcome challenges [16]. Adaptive learning would cultivate logical and creative thinkers who can innovate and adapt in a constantly changing field like programming education [17]. The extensive literature on programming teaching and learning strategies reflects the growing importance and recognition of these strategies in both educational and professional realms [18]. Researchers, educators, and professionals worldwide have contributed numerous studies, theories, and methodologies, enriching the body of available knowledge [19], [20], [21], [22]. However, the vast amount of information on diverse programming education approaches, along with the fast pace of new developments, presents challenges in staying up to date and identifying the most impactful trends and practices.

The rapid evolution of programming education and the increasing volume of research publications pose a challenge in identifying effective teaching and learning strategies [23]. This research explores publication patterns, the most cited sources, academic collaboration networks, and other relevant aspects to shed light on the current state of research in the programming education at the higher education level. Thus, this document seeks to address the need for a comprehensive understanding of current trends, significant contributors, and prominent research in higher education programming education. Furthermore, our work aims to recognize the most influential authors, leading research centers, and areas that require more attention in programming education.

This study predominantly analyzes data from specific geographic regions, which can limit its generalizability to other educational contexts, particularly in underrepresented or developing countries. Future research should incorporate data from a broader range of regions to provide more globally

*Corresponding authors.

representative insights. This analysis relies exclusively on data from SCOPUS and Web of Science. Although these databases provide extensive coverage of high-quality research, including additional sources, such as local publications or databases not indexed on these platforms, could enhance the study's comprehensiveness.

A. Research Questions

This project is a quasi-experimental quantitative study designed to answer the following research questions:

- RQ1: What are the predominant trends in programming teaching and learning strategies in higher education? This article addresses this question by analyzing research from SCOPUS and WOS databases published between 2014 and 2023, highlighting frequently cited approaches such as project-based learning, flipped classrooms, and collaborative programming. The analysis focuses on the evolution of these strategies and their impact on programming competency development, acknowledging that relevant works in non-indexed conferences and journals may further complement the identified trend.
- RQ2: Who are the most influential authors, and what are the seminal publications shaping the field of programming education? This article responds by identifying the most cited authors and works from SCOPUS and WOS between 2014 and 2023. The analysis considers author networks, citation impact, and recurring themes in key publications, recognizing that other influential contributors may also emerge from non-indexed sources.
- RQ3: What journals and institutions make the most significant contributions to programming education research? This article explores this question by examining the journals and institutions with the highest SCOPUS and WOS production and citation metrics between 2014 and 2023. The review highlights institutions consistently contributing to shaping discourse on programming education, acknowledging valuable works published in non-indexed platforms.

II. BACKGROUND

Computational thinking plays a critical role in the modern digital era, providing individuals with essential problem-solving skills that transcend the boundaries of computer science and programming, as noted by Lu et al. [24]. Based on principles from computer science, mathematics, and logic [25], this approach enables individuals to break down complex problems, recognize patterns, and design algorithmic solutions [26]. As highlighted by Shen et al. [27], computational thinking significantly influences daily life by helping individuals make informed decisions and solve problems efficiently. Whether optimizing daily routines or critically evaluating online information, this skill set empowers individuals to navigate the complexities of the digital world [28]. Furthermore, when incorporated into educational curricula, it fosters essential competencies such as logical reasoning and creativity, preparing students for future challenges [29]. Algorithm 1 presents

an algorithm describing the steps to master new topics through computational thinking [30].

Algorithm 1 Procedure for Mastering a New Topic

Require: Topic is identified

Ensure: Relevant materials are gathered

Obtain an initial understanding

Define the boundaries of the topic

Search for appropriate resources

Develop a structured learning approach

Set criteria for successful learning

while *learning not achieved* **do**

Refine the selected resources

Reevaluate and explore the materials

Experiment with the information

Implement newly acquired knowledge

▷ If feasible

Share or explain learned concepts

▷ If feasible

end while

Beyond everyday applications, the benefits of computational thinking extend to a wide range of disciplines [25], [31]. Shin et al. [32] demonstrate how this competency enhances scientific research by helping scientists analyze complex data, simulate experiments, and develop better models to understand the natural world. Computational thinking supports research in fields such as biology, physics, and social sciences, improving decision-making by providing powerful tools for data-driven insights [33]. With the growing demand for digital literacy in the workforce, computational thinking equips individuals with the necessary tools to thrive in an evolving job market [34]. This competency empowers individuals not only as students or professionals but also as active participants in a technology-driven society.

A. Programming Competencies in Higher Education

Programming competencies hold critical importance in higher education, particularly within computer science and across Science, Technology, Engineering, Arts, and Mathematics (STEAM) disciplines [35]. The ability to think algorithmically, solve complex problems systematically, and develop automated solutions through coding has become an indispensable skill set for students, regardless of their field of study [36]. Developing programming competencies in higher education equips students with fundamental skills that go beyond coding:

1) *Algorithmic thinking*: This allows students to break down intricate problems into smaller, manageable tasks while constructing logical sequences of steps to address them [24].

2) *Problem-solving through programming*: Programming fosters creativity and resilience, pushing students to iteratively refine their solutions until achieving the most effective outcome [37].

3) *Abstract thinking*: Students can conceptualize real-world problems as abstract models, facilitating a deeper understanding of complex phenomena across various disciplines [38].

4) *Automation and efficiency*: Programming enables students to streamline repetitive tasks, enhancing both productivity and efficiency [39].

The impact of programming competencies transcends computer science, offering substantial benefits in STEAM disciplines [35], [40]. These skills contribute to both the technical and creative dimensions of each field.

- **Science:** Programming is a powerful tool for analyzing large datasets, modeling complex systems, and simulating experiments. In fields like biology, physics, and chemistry, the ability to automate data processing and perform statistical analyses enhances the precision and speed of scientific discoveries.
- **Technology:** Programming drives a deeper understanding of technological systems, empowering students to innovate and develop new software tools.
- **Engineering:** Programming is indispensable in engineering, whether used to model and simulate physical systems or optimize design processes. Coding equips students with tools that improve accuracy and efficiency in the mechanical, civil and electrical engineering disciplines.
- **Art:** In the arts, programming opens new avenues for digital creativity.
- **Mathematics:** Programming enhances mathematical problem-solving by allowing the simulation of mathematical models and solving large-scale calculations that would otherwise be impossible through manual methods.

III. METHODOLOGY AND RESEARCH DESIGN

The increasing volume of academic publications and the proliferation of research streams can make it challenging for researchers to stay updated within a specific field. Systematic literature reviews synthesize available scientific information and help identify areas of uncertainty where further investigation is required [41]. Typically, literature review research addresses a single scientific database, which limits the ability to gain a comprehensive view of knowledge and trends within a specific domain. Therefore, some authors argue for the necessity of using multiple databases [42]. In this context, the data for the present study were extracted from the Web of Science (WOS) and SCOPUS databases.

Using both WOS and SCOPUS for the bibliometric analysis of teaching and learning strategies for higher education programming ensures a comprehensive and high quality coverage of the relevant academic literature. Both databases are renowned for their extensive indexes of peer-reviewed journals, conference proceedings, and other scholarly outputs across disciplines, including computer science and education [43]. The international scope of these databases [44] ensures a global perspective on teaching methodologies, crucial for understanding the varied approaches to programming education in higher education. Both WOS and SCOPUS have significant prestige and are recognized for improving the robustness of analysis by cross-referencing data, ensuring completeness, and minimizing potential bias in the literature review [45]. Thus, the choice of SCOPUS and WOS allows for a comprehensive examination of publication patterns in the field of programming education. To achieve this, records from both sources were merged into a single dataset. Table I summarizes the search criteria, while

Fig. 1 shows the publication trends over the period of time (2014-2023).

In terms of coverage, WOS encompasses a broader range than SCOPUS, with 1,464 records compared to 361. After comparing and removing duplicates, the process identified 1,697 documents related to teaching and learning strategies in programming education, revealing that approximately 11% of the documents overlap or share similarities.

A. Evaluation Instruments

As highlighted by Chen et al. [46] and Trinidad et al. [47], analyzing publication trends provides researchers with a deeper understanding of the scientific landscape, allowing them to identify emerging knowledge areas and contribute to the advancement of their fields. To support this type of analysis, the bibliometric study used the Bibliometrix platform using the R programming language. Bibliometrix is an open-source toolset that offers flexibility by integrating with various statistical packages. This adaptability makes Bibliometrix particularly valuable for exploring evolving research areas and uncovering new trends in programming education strategies.

One of the key strengths of Bibliometrix is its free access and ease of use through a web-based interface, which encapsulates its core capabilities and establishes a framework for real-time data analysis [48]. For instance, Biblioshiny, a module of Bibliometrix, enables users to perform relevant bibliometric and visual analyses through an interactive web interface [49]. This tool facilitates identifying connections between changes in scientific production, citations, author collaborations, and other essential bibliometric indicators, especially in programming education. Consequently, Bibliometrix is a robust and accessible tool for the scientific community, providing an effective means to explore and evaluate academic literature.

IV. RESULTS

This section presents the results of the bibliometric analysis, highlighting the most relevant authors, important institutions, influential documents, and the keywords with the highest relevance in the analyzed articles.

A. Most Relevant Authors

The bibliometric analysis identifies the most prominent authors in the field. Table II presents a list of authors with notable contributions and the number of citations they have received. Among them, Li Yong, Liu Yonggang, Liu Yan, Liu Yuan, and Yong Wang stand out. These researchers were identified by comparing SCOPUS and WOS records using metrics such as the H-index and citation count, which measure scientific performance in the field [50]. The authors in Table II have made significant advancements in programming education through detailed studies on effective teaching and learning strategies. Their work includes innovative methodologies and practices with long-term impacts on students' learning outcomes.

By examining the H-index and citation count, we can evaluate the influence and impact of these researchers in promoting programming education. This analysis provides valuable insights into the key contributors driving the field and underscores the importance of developing effective teaching and learning strategies.

TABLE I. NON-PHARMACOLOGICAL INTERVENTION STRATEGIES BASED ON CONTROLLED EXERCISE AND NUTRITIONAL EDUCATION

Criterion	Values
Time Span	2014 – 2023
Date of Query	June 2023
Document Types	Journal articles and Conference proceedings
Journal and Conference Types	Any type
Search Fields	Title, Abstract, and Keywords
Search Terms	Programming AND Universities AND Strategies AND (Learning AND Teaching) – in English
Records	WOS: 1464; SCOPUS: 361
Total Records	1,697

Fig. 1. Total number of publications in WOS and SCOPUS, 2015–2023.

TABLE II. TOP AUTHORS IN PROGRAMMING EDUCATION RESEARCH IN HIGHER EDUCATION

Authors	WOS Citations	WOS H-index	SCOPUS Citations	SCOPUS H-index	Publications
Li Yong	2058	23	7591	42	11
Liu Yonggang	29	3	682	15	11
Liu Yan	2072	22	9997	50	11
Liu Yuan	1151	18	938	16	11
Yong Wang	2124	26	8192	50	11

B. Key Institutions

The bibliometric review identified the most prominent institutions in the field based on their significant publication output. Table III lists the top ten universities, their country of origin, and the number of related publications. These results corroborate the findings of Apiola et al. [51] and Perez and Garcia [52], highlighting that universities play a crucial role in publishing research and disseminating experiences related to programming education in higher education. Their contributions emphasize the importance of integrating strategies that help students develop critical thinking and problem-solving skills, ultimately improving their academic and professional development.

C. Influential Documents

Identifying key documents begins by determining how each document connects to internal research references (endogenous references) and external sources (exogenous references) found in academic databases such as SCOPUS and WOS. Duque and Duque Oliva [53] explain that the average number of citations

TABLE III. TOP INSTITUTIONS CONTRIBUTING TO PROGRAMMING EDUCATIONAL RESEARCH

Institution	Publications	Country
University of California, San Francisco	74	USA
University of Toronto	69	Canada
University of Colorado Boulder	59	USA
University of Michigan	59	USA
University of Sydney	43	Australia
University of Calgary	36	Canada
McGill University	35	Canada
University of Pennsylvania	35	USA
National University of Singapore	34	Singapore
University of Minnesota	34	USA

is calculated by dividing internal references by the time elapsed since the document's initial publication. This approach offers a method to assess the influence and acceptance of research over time.

When analyzing influential documents, our findings show that the study by Sung et al. [54] has the highest number of citations, with a total of 620 and an average of 77.5 per year. McLaughlin et al. [55] follows closely with 603

citations and an average of 60.3 per year, while Bers et al. [56] has a total of 378 citations and an annual average of 37.8. These three authors stand out due to the high citation counts of their respective articles, which focus on topics related to programming education strategies. Table IV lists top cited documents in programming education research.

D. Keywords with the Highest Relevance

During the analysis, we extracted the terminologies that had the most significant impact across the reviewed documents. Using the Biblioshiny tool, we created a graphical representation or “word cloud” (Fig. 2) to visualize the most prominent terms identified in this study. As explained by Alsalem et al. [57], this method allows scholars to compare different sections and visually identify the most significant terms, highlighted in bold. The word cloud emphasizes key terms such as “learning”, “students”, “education”, “teaching”, and “programming”, which are closely aligned with the study’s focus on programming education for undergraduate students. This approach explores the interaction between pedagogical approaches, technology, and programming in educational settings while analyzing how these elements influence students’ ability to acquire programming skills.

Using a TreeMap further illustrates the clustering of potential keywords in the research articles, as discussed by Secinaro et al. [58]. Table V presents the top ten keywords by frequency and percentage of appearance in the analyzed documents. The analysis shows that 41% of the most relevant terms include words such as “education”, “students”, “teaching”, “learning”, and “programming”, which underscores the importance of this research topic within the field of scientific publications.

V. DISCUSSION

This study provides a comprehensive overview of current trends in teaching and learning programming through a bibliometric analysis of the SCOPUS and WOS databases. The results highlight several key areas that require further exploration and themes that have been consistently addressed in existing research.

A. Current Trends

One of the main trends identified in the analysis is the emphasis on project-based learning and flipped classrooms. These strategies have proven to be effective in enhancing problem-solving skills and fostering greater engagement by allowing students to apply learned concepts to real-world problems [54]. In addition, there has been a growing adoption of collaborative programming techniques such as pair programming, which improve code quality and overall student performance [55]. Regarding emerging topics, there is increasing interest in using immersive and simulation technologies such as augmented reality and virtual reality to teach programming [56].

B. Limitations of Current Research

Despite advances in programming education, several challenges and limitations persist. One of the key limitations identified is the lack of longitudinal studies that measure the long-term impact of different programming teaching strategies.

Most of the analyzed studies focus on short-term outcomes, such as grades or students’ performance in individual courses, but more research is needed to explore how these strategies influence long-term professional development and career outcomes [59]. Another limitation is the lack of diversity in the educational contexts studied. Most of the research has been conducted in developed countries, particularly in the United States and China, which may not reflect the educational realities of other regions. Furthermore, more research is needed on programming education in non-formal settings and self-learning environments, as many students learn programming independently or through online platforms outside traditional classrooms [60].

C. Implications for Future Research

This study provides several implications for future research. First, more research is needed on the use of emerging technologies such as artificial intelligence and machine learning in programming education. These technologies have the potential to personalize teaching and provide immediate feedback to students, which could significantly improve learning outcomes [61]. Second, there is a need to further explore interdisciplinary approaches to teaching programming. Integrating programming with other disciplines has proven to be effective in improving student understanding and motivation, but more research is needed to understand how these approaches can be optimally designed and implemented [62]. In addition, more research is required on the barriers students face when learning to program, particularly in disadvantaged contexts. Programming can be a difficult skill to acquire, and many students struggle with abstract concepts and the complex syntax of programming languages. Understanding these barriers and how to overcome them is crucial to ensuring that all students have the opportunity to develop programming skills [63].

D. Threats to Validity

As with any study, this bibliometric analysis has limitations that may affect the validity of the results. The following threats to validity should be considered:

- Selection bias: The use of the SCOPUS and Web of Science databases, although they include a large volume of high-quality research, may have excluded important studies from other databases not considered in this analysis. This raises the possibility of selection bias, as some relevant studies published in non-indexed academic journals or platforms may not have been included.
- Temporal bias: The analysis focused on publications from 2014 to 2023, which means that any research conducted before this period was excluded. Although this time range captures the most recent trends, it may omit foundational studies or pioneering approaches in programming education that still influence the field. This temporal bias could limit the understanding of the complete evolution of programming teaching methodologies over time.
- Variability in bibliometric indicators: The quality and impact of a research paper were evaluated using bibliometric metrics such as the citation count and the

field has grown significantly, disparities remain in terms of international collaboration and access to resources. Developing countries could benefit from greater support and collaboration with institutions from more developed nations to ensure that advances in programming education are accessible to all.

In terms of contribution, this article not only identifies the key trends and most influential contributors, but also provides a roadmap for future research in programming education. We hope that the findings of this study will assist educators, researchers, and policymakers in developing more effective and equitable approaches to programming education in higher education.

Harnessing the Power of Federated Learning: A Systematic Review of Light Weight Deep Learning Protocols

Haseeb Khan Shinwari¹, Riaz UIAmin²

Newton AI Research Lab, Pakistan¹

Edinburgh Napier University, UK and University of Okara, Pakistan²

Abstract—With rapid proliferation in using smart devices, real time efficient sentiment analysis has gained considerable popularity. These devices generate variety of data. However, for resource constrained devices to perform sentiment analysis over multimodal data using conventional modals that are computationally complex and resource hungry, is challenging. This challenge may be addressed using a light weight but efficient modal specifically focused on sentiment analysis for constrained devices. In the literature, there are several modals that claims to be light weight however, the real sense and logic to determine if the modal may be termed as lightweight still requires further research. This paper reviews approaches to federated learning for multimodal sentiment analysis. Federated learning enables decentralized training without sharing data. Considering the review need to balance privacy concerns, performance, and resource usage, the review evaluates existing approaches to enhance accuracy in sentiment classification. The review identifies strengths and limitations in handling multimodal data. The search focused on studies in databases like IEEE Xplore and Scopus. Studies published in peer-reviewed journals over the past five years were included. The review covers 45 studies, mostly experimental, with some theoretical models. Key results show lightweight protocols improve efficiency and privacy in federated learning. They reduce computational demands while handling text, image, and audio data. There is a growing focus on resource-constrained devices in research. Trade-offs between model complexity and speed are commonly explored. The review addresses how these protocols balance accuracy and computational cost.

Keywords—Light weight protocols; sentiment analysis; federated learning; deep learning

I. INTRODUCTION

Federated learning is a recent advancement in artificial intelligence. It enables decentralized model training without sharing raw data [1]. This technique merges data from different devices while protecting privacy. The method's popularity has grown due to rising privacy concerns [2]. Unlike standard machine learning, data remains on each device. Only model updates are sent to a central server. This reduces the risk of data breaches. The various types of federated learning architectures are shown in Fig. 1 The classification of Federated learning is presented in [3]. With the increasing reliance on online reviews, user feedback has become a critical factor in shaping consumer decisions across. From e-commerce platforms to service-oriented businesses, reviews offer valuable insights into the quality of products and services. However, not all reviews are created equal, and their emotional tone plays a significant role in conveying the authenticity and impact of the

user experience. Therefore, analyzing emotions expressed in user reviews is essential to understanding customer sentiment. Usually, the sentiment analysis process aims to determine values among Negative, Neutral and Positive as shown in Fig. 2. Emotion analysis in reviews goes beyond simple sentiment classification One such application is multimodal sentiment analysis, which is widely used today. Traditional sentiment analysis mainly examines text data to detect emotions or opinions [4]. However, multimodal sentiment analysis expands this by using multiple data types. It incorporates text, images, and audio for a richer analysis. Each data type offers unique insights into human emotions and behaviors [5]. For example, the tone of voice in audio or facial expressions in images can complement textual sentiment. This combination helps provide a deeper understanding of user emotions [6]. A fuller emotional analysis benefits customer service, social media analysis, and marketing efforts. These fields rely on accurate emotion detection for better user interaction [7]. General workflow of deep learning protocol is shown in Fig. 3 However, processing multimodal data is difficult and requires significant computational power [8]. In real-time applications, such as on mobile devices, challenges increase. Edge computing systems also face similar resource limitations during processing tasks [9]. This is where lightweight deep learning protocols become essential. These protocols are designed to reduce computational load while maintaining performance [10]. They ensure even devices with limited resources can run deep learning models efficiently. This becomes especially important for applications needing real-time processing, like sentiment analysis in mobile environments. Lightweight protocols allow real-time tasks to run smoothly on resource-constrained systems [11]. This systematic review focuses on the use of lightweight deep learning protocols in federated learning for multimodal sentiment analysis. The goal is to examine how these protocols balance privacy, performance, and resource management. Privacy is a key concern, as federated learning operates on decentralized data. Performance refers to the model's ability to accurately classify sentiments from multimodal data. Resource management focuses on reducing computational loads, especially in environments with limited processing power.

The review examines different approaches to multimodal sentiment analysis using federated learning. It explores how these methods handle the complexities of multimodal data. Text, image, and audio data each need distinct processing techniques [2]. Text data is often processed using natural

Fig. 1. Types of federated learning.

language processing (NLP) techniques. Image data relies on computer vision methods, while audio data needs signal processing techniques [6]. Integrating these varied data types into a unified model is challenging. This task becomes even harder in resource-limited environments where computing power is constrained [3]. Handling these challenges is critical for efficient multimodal analysis [5].

Fig. 2. Types of sentiment analysis.

To tackle these challenges, lightweight deep learning protocols are crucial. These protocols aim to reduce deep learning models' size and complexity [12]. Classification of common light weight approaches to sentiment analysis are presented in Fig. 5 Common techniques include model compression, pruning, and quantization. Compression shrinks the model, making it easier to store and process. Pruning eliminates unneeded parts of the model, improving efficiency. Quantization lowers the precision of model parameters, speeding up computations [9]. This reduces resource use without greatly impacting performance. Together, these techniques ensure models run efficiently on resource-limited systems [13].

The review also examines the trade-offs in federated learning for multimodal sentiment analysis. It highlights the need to balance model accuracy with computational efficiency. More complex models often provide higher accuracy but need more

Fig. 3. Workflow in deep learning protocol.

resources [3]. In contrast, simpler models run faster but may lack the same accuracy. Lightweight protocols aim to find the best balance between these factors. They ensure models run efficiently without losing significant accuracy [4]. Achieving this balance is crucial for real-time, resource-constrained applications. Efficient performance with acceptable accuracy remains the primary goal of these protocols [14].

Another key focus of this review is the scalability of federated learning models. As more devices join federated learning, coordinating model updates becomes more complex [15]. Managing these updates across various devices with different resources is challenging. Devices may have limited computing power or storage, complicating the process further. Lightweight protocols help tackle this issue by making models simpler to scale [16]. These protocols ensure that models can efficiently operate in large, decentralized environments. Scaling federated learning models becomes more manageable with reduced computational demands. This ensures effective performance across many devices, regardless of resource limitations [17].

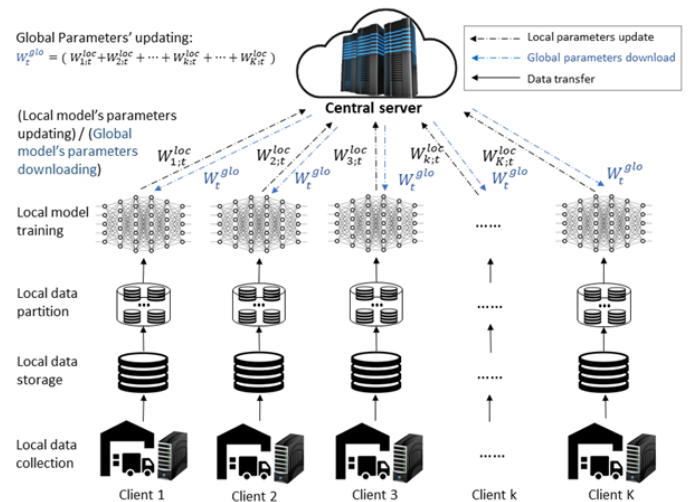

Fig. 4. The framework of federated learning.

II. MAJOR CONTRIBUTIONS

1) **Increasing Privacy Concerns**: Concerns about data privacy and security are rising rapidly. Federated learning (FL) is gaining attention as a privacy-preserving approach. It ensures privacy by keeping data on individual devices. Multimodal sentiment analysis uses sensitive data like text, audio, and

images. This requires strong privacy protection. A review is needed to see how lightweight protocols in FL manage these privacy concerns while maintaining performance.

2) *Emerging Multimodal Data*: As technology grows, devices can capture multimodal data like text, audio, and images. Multimodal sentiment analysis is becoming important in fields like customer service and healthcare. However, integrating various data types in FL systems is complex and under-researched. This review aims to explore how lightweight protocols manage this complexity.

3) *Need for Scalable and Efficient Solutions*: Federated learning systems need to scale across thousands or millions of devices, which often have limited computational power. Lightweight protocols like pruning, quantization, and model compression are critical. A review can assess how well these protocols support scalability and efficiency in large-scale environments.

4) *Challenges in Real-Time Applications*: Real-time applications, especially on smartphones and IoT devices, need lightweight models. Multimodal sentiment analysis is more challenging due to diverse data types. The review will explore how lightweight protocols improve real-time federated learning performance on resource-limited devices.

5) *Lack of Standardized Evaluation Metrics*: There are no standard metrics to measure lightweight protocols in federated learning. This is especially true for multimodal sentiment analysis. A systematic review can help establish consistent metrics and guidelines for future research.

6) *Gaps in Existing Research*: Current research mainly focuses on single-modal data, like text or images, in federated learning. Research on multimodal integration is limited. Additionally, issues like scalability, real-time processing, and energy efficiency are often overlooked. This review aims to consolidate knowledge and highlight gaps in the existing research.

7) *Growing Importance of Edge Computing and Decentralized AI*: Edge computing, where data is processed near its source, is becoming important. Federated learning fits well with this decentralized AI approach. The framework of federated learning is shown in Fig. 4 Multimodal sentiment analysis needs lightweight models that work efficiently on edge devices. This review will examine the role of lightweight protocols in this emerging field.

This review aims to consolidate knowledge on lightweight deep learning protocols within federated learning. Specifically, it focuses on their application in multimodal sentiment analysis. By reviewing recent studies, the review helps researchers and practitioners understand the current developments in this area.

III. LITERATURE REVIEW

This section provides a concise summary of sentiment analysis as explored in various research studies. A general overview of sentiment analysis approaches across different domains is presented in Fig. 5. Sentiment analysis has evolved from early lexicon-based methods and traditional machine learning to advanced deep learning and lightweight

approaches, particularly suited for Federated Learning (FL). Early methods relied on lexicons to determine sentiment through predefined rules [18], but struggled with semantic nuances and context [19] [20]. Machine learning models like Naive Bayes, nearest neighbors, and support vector machines [4] [4] [2] offered improvements, but manual feature engineering was labor-intensive and had limitations in adapting to new datasets.

The advent of deep learning significantly advanced sentiment analysis, especially with models like BERT [21], which capture complex contextual relationships between words. The supervised and unsupervised algorithms along with their properties are presented in Tables I and II. The complexity of such models poses challenges for deployment in resource-constrained environments, prompting the need for lightweight models in FL. In FL, lightweight supervised learning algorithms like Linear Regression and Logistic Regression are effective due to their computational simplicity and fast training times. However, they struggle with non-linear data [22]. Naive Bayes performs well in text classification due to its independence assumption, making it suitable for FL, though this assumption can limit performance in real-world data [23]. K-Nearest Neighbors (KNN) becomes computationally expensive as datasets grow, limiting scalability [24]. Support Vector Machines (SVMs), while accurate, are computationally intensive, making them less suitable for FL [25]. Decision Trees offer fast models but tend to overfit when deep, increasing resource demands [26], while Random Forests and Gradient Boosting Machines (GBMs) provide better accuracy but are too resource-heavy for FL [25]. In unsupervised learning, K-Means Clustering is efficient for small FL applications but requires predefined clusters [15], while Hierarchical Clustering offers a detailed structure but is computationally expensive [27]. Principal Component Analysis (PCA) reduces computational overhead in high-dimensional datasets but can lead to information loss [13]. Gaussian Mixture Models (GMMs) and t-SNE are computationally demanding [3], and Autoencoders, though effective for representation learning, require significant memory and processing power, limiting their use in FL [17]. Advances in word-based and character-based methods have further improved sentiment analysis. Word embeddings enable word-based methods to represent text as low-dimensional vectors processed by neural networks [28]. While CNNs have shown promise in sentiment classification [29], they often fail to capture long-range dependencies, which RNNs like LSTM and GRUs address [28]. Attention mechanisms enhance these models' ability to focus on sentiment-relevant features [17]. Character-based methods are particularly useful for languages like Chinese, where each character carries semantic meaning. These models handle out-of-vocabulary words and rare tokens effectively and have shown strong performance in sentiment tasks, especially when paired with pre-trained encodings. Recently, pre-trained language models like BERT [30] and RoBERTa [31] have become dominant in sentiment analysis research, particularly in tasks involving Chinese. ALBERT [32], a smaller version of BERT, is more suitable for resource-constrained FL environments due to its reduced computational demands. Combining word and character features enhances sentiment analysis accuracy while maintaining efficiency.

Fig. 5. General overview of lightweight approaches for sentiment analysis.

TABLE I. SUPERVISED LEARNING ALGORITHMS AND THEIR PROPERTIES

Algorithm	Training Complexity	Inference Complexity	Training Time	Memory Usage	Inference Time	Resource Consumption
Linear Regression	$O(n^3)$	$O(n)$	Fast	Low	Fast	Low
Logistic Regression	$O(n^2m)$	$O(n)$	Fast	Low	Fast	Low
Naive Bayes	$O(nm)$	$O(n)$	Very fast	Low	Very fast	Low
K-Nearest Neighbors	$O(1)$ (Training)	$O(nm)$	Fast	Low	Slow (Large Data)	High (Inference)
Support Vector Machines	$O(n^2m)$ to $O(n^3)$	$O(n)$	Slow	Medium	Moderate	Medium
Decision Trees	$O(nm \log m)$	$O(\log m)$	Fast	Medium	Fast	Medium
Random Forests	$O(k * n \log m)$	$O(k \log m)$	Slow	High	Moderate	High
Gradient Boosting (GBM)	$O(kn \log m)$	$O(k \log m)$	Slow	High	Slow	High

TABLE II. UNSUPERVISED LEARNING ALGORITHMS AND THEIR PROPERTIES

Algorithm	Training Complexity	Inference Complexity	Training Time	Memory Usage	Inference Time	Resource Consumption
K-Means Clustering	$O(knm)$	$O(kn)$	Fast	Low	Fast	Low
Hierarchical Clustering	$O(m^2 \log m)$	N/A	Moderate	Medium	N/A	Medium
Principal Component Analysis (PCA)	$O(n^2m)$	$O(n^2)$	Fast	Medium	Fast	Medium
Gaussian Mixture Models	$O(tnm * k^2)$	$O(nmk)$	Slow	High	Moderate	High
t-SNE	$O(m^2 \text{perplexity})$	N/A	Very slow	High	N/A	High
Autoencoders	$O(nm * \text{epochs})$	$O(nm)$	Slow	High	Moderate	High

IV. MATERIALS AND METHODS

Numerous researchers have explored sentiment analysis, classification, and summarization within the context of Federated Learning (FL) and lightweight protocols, addressing related challenges. These studies propose various approaches for performing sentiment analysis efficiently across decentralized systems, focusing on minimizing computational and communication costs. Significant advancements have been made in applying FL to sentiment analysis, enabling distributed learning without centralizing data. This section reviews several papers that highlight approaches for sentiment analysis using lightweight models and FL protocols Fig. 6.

Liu [30] introduced the concept of opinions in a pentagonal form represented as $(e_i, a_{ij}, s_{ijkl}, h_k, t_l)$, where e_i denotes the entity's name, a_{ij} refers to the entity's aspect, s_{ijkl} represents the sentiment expressed toward that aspect, h_k identifies the sentiment holder, and t_l marks the time of the sentiment [29]. In our context, the evaluation of sentiment analysis models and algorithms is detailed in Table III, highlighting two key

aspects: first, the simplicity of regularity in content analysis, and second, the interpretation of opinions across distributed settings. Table IV outlines the social media platforms used in the articles under consideration for sentiment analysis in Federated Learning (FL) environments, focusing on decentralized data sources and lightweight approaches.

A. Datasets

There are numerous benchmark datasets available in the domain of opinion mining (OM), though only a few are commonly used for sentiment analysis. Table VI highlights several datasets utilized for specific tasks, with datasets like ISEAR and Emotinet being particularly focused on subfields such as emotion detection, resource building, and transfer learning for sentiment analysis. Table III presents assessment parameters and their description. Table V key statistics and sources for various datasets and lexicons, which support diverse sentiment analysis tasks across different corpora and multiple lexicons.

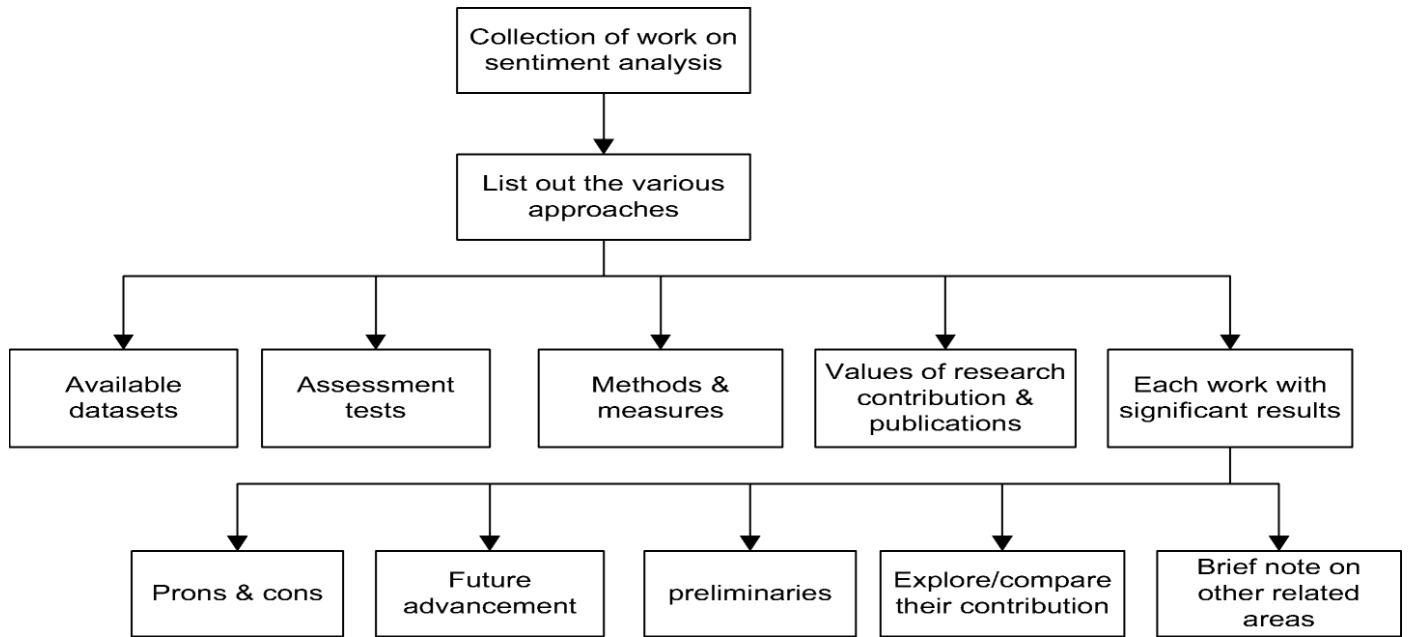

Fig. 6. Working flow of ongoing research.

TABLE III. ASSESSMENT TEST PARAMETERS

Test Parameters	Explanation
Language as a communication source	Different languages described in the papers for collecting benchmark datasets, including English, Italian, Spanish, Dutch, Chinese, Japanese, Arabic, etc.
Number of words in specified data	In documents such as blogs, web pages, product reviews, comments on movies, books, fairy tales, etc., a large number of words or phrases are included.
Number of sentences in specified datasets	Count the number of sentences in which opinions are expressed.
Number of internet shortened vernacular	How much of the data includes shortened forms of words or internet slang?
Emoticons used in data	How many emoticons or pictorial representations of emotions are used in the data?
Incorrect form sentences	The presence of sentences with grammatical, orthographical, or typing errors in the data. Accountability for such errors is an important step.
Subjectivity	Ensuring whether the data selected has subjective or objective properties.
Sentiment possessor	Who is expressing the sentiment in the data?
Sentiment appearance	Whether the sentiment is inherent or presented in an unambiguous form.
Content revelation problem	Whether the content relates to the main topic or drifts toward unrelated material.
Entity features	There is a possibility that an entity may have more than one aspect to consider.

TABLE IV. COMMUNITY MEDIUM CONTROL AND THEIR IMPACT

Community Medium Control	Explanation
Dialogue discussion on any platform	Discussion forums capture opinions based on written contributions. Many forums feature comments, reviews, and thoughts, creating a complex data environment for opinion mining. Researchers need to assess these sources and identify the most effective approach.
Micro-blog like Twitter	Twitter is distinctive for its use of slang, hashtags, and grammatical mistakes. Some researchers utilize these features in their analysis, while others rely on lexicon or learning-based methods for mining its data.
Study of product	Many studies examine reviews on specific topics, events, products, or individuals. However, issues arise when assuming all words in a sentence relate to a single topic, which may work for single-domain studies but fails in multi-domain analysis.
Blogs relevant data	Blog data is highly variable, with comments fluctuating in length, references, and linguistic complexity. Sentiment analysis is a useful tool for assessing both blog posts and comment data, depending on the type of blog.
Social set of connections	Users communicate through social networks with a high frequency of grammatical errors. Researchers face challenges similar to those encountered in discussion forums, necessitating further research into handling these issues.

TABLE V. ANNOTATED CORPORA AND MULTIPLE LEXICONS FOR SENTIMENT ANALYSIS

Levels	Area	Language	Explanation
Corpora	MPQA [15]	English	This corpus consists of news articles annotated for sentiment analysis, with multiple versions supporting different sentiment levels. http://mpqa.cs.pitt.edu/corpora/mpqa_corpus/
Corpora	Movie review dimensions dataset [33]	English	This dataset contains 1000 positive and 1000 negative movie reviews. http://www.cs.cornell.edu/people/pabo/movie-review-data/reviewpolarity.tar.gz
Corpora	Movie review subjectivity dataset [27]	English	Includes 5000 subjective and 5000 objective processed sentences. http://www.cs.cornell.edu/people/pabo/movie-review-data/rotten_imdb.tar.gz
Corpora	Multiple domain dataset [12]	English	Amazon dataset includes reviews from domains like DVDs, books, electronics, and home applications. It is categorized by star ratings and dimension labels. https://www.cs.jhu.edu/~mdredze/datasets/sentiment/
Lexicons	Bing Liu's sentiment lexicon [11]	English	Contains 2006 positive and 4783 negative words. http://www.cs.uic.edu/~liub/FBS/sentiment-analysis.html
Lexicons	MPQA subjectivity lexicon [34]	English	Includes 8222 words with sentiment strength, weaknesses, POS tags, and dimensions. http://mpqa.cs.pitt.edu/lexicons/subj_lexicon/
Lexicons	SentiWordNet [19]	English	Links words to numerical data in the range [0.0, 1.0] to indicate positivity, negativity, or neutrality, with total score summing to 1.0. http://sentiwordnet.isti.cnr.it/
Lexicons	Harvard General Inquirer [32]	English	Contains 182 types with dimension indicators like positive and negative, including 1915 positive and 2291 negative words. http://www.wjh.harvard.edu/~inquirer/
Lexicons	Linguistic Inquiry and Word Counts (LIWC) [35]	English	Features regular expressions, including sentiment-related patterns. http://liwc.wpengine.com
Lexicons	HowNet [?]	Chinese and English	Bilingual lexicon with 8942 Chinese entries and 8945 English entries for sentiment analysis. http://www.keenage.com/html/e_index.html
Lexicons	NTUSD [?]	Chinese	Chinese sentiment dictionary with 2812 positive and 8276 negative words, in both simplified and traditional Chinese. http://academiasinicanlplab.github.io/

B. Evaluation Metrics

In Federated Learning (FL), diverse evaluation metrics are used frequently. These metrics measure the performance of sentiment analysis models. Together, they offer a complete assessment of the system. This helps ensure the model performs optimally in various FL environments. Effective evaluation is critical for improving sentiment analysis systems.

Accuracy Accuracy is a key metric in model evaluation processes. It represents the percentage of correct sentiment predictions. This metric shows how often the model is right. A higher accuracy indicates better model performance. Accuracy is critical in determining a model's practical utility.:

$$\text{Accuracy} = \frac{\text{Correct Predictions}}{\text{Total Predictions}}$$

Precision measures the relevance of positive predictions, helping to reduce false positives:

$$\text{Precision} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Positives}}$$

Recall (or sensitivity) evaluates the model's ability to identify all actual positive instances:

$$\text{Recall} = \frac{\text{True Positives}}{\text{True Positives} + \text{False Negatives}}$$

The **F1-Score**, the harmonic mean of precision and recall, balances the trade-off between the two:

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

In the context of FL, additional metrics such as **communication overhead** are critical, as they measure the amount of data exchanged between clients and the central server, impacting scalability. Another key metric is computation time. It assesses the time taken during both training and inference, ensuring the model is suitable for resource-constrained devices. Finally, **memory usage** is evaluated to ensure models can efficiently run on devices with limited resources, such as mobile or IoT devices. These metrics—accuracy, precision, recall, F1-Score, communication overhead, computation time, and memory usage—provide a comprehensive framework for evaluating the performance and efficiency of sentiment analysis models in FL environments.

V. RESULTS AND DISCUSSION

The performance of sentiment analysis models shown in Tables VI, VII, VIII, IX, X, and XI across various datasets highlights varying levels of accuracy and F1 scores. For the Pang & Lee [36] dataset, models achieved up to 92.70% accuracy [6], with F1 scores such as 90.45%. It indicates a strong balance between precision and recall. Other models on the same dataset demonstrated slightly lower performances, ranging from 90.2% [15] to 76.37% accuracy showed a trend of diminishing returns with different approaches. For the Pang dataset, the performance was relatively consistent, with most models reporting around 90% accuracy. The highest accuracy was 88.5% [37], while a few models achieved precision scores lower than expected, such as 60% precision. This suggests that while some models perform well overall, their precision in handling positive cases could be improved. In the Blitzer [38] dataset, the accuracy ranges from 88.7% [29] to a lower 71.92% [29]. It indicates more variability in model performance. While the average accuracy for some models was around 85.15%, the results emphasize that models

TABLE VI. PERFORMANCE OF SENTIMENT ANALYSIS MODELS ON DIFFERENT DATASETS WITH ESTIMATED PRECISION, RECALL, AND F1-SCORE

Dataset	Reference	Accuracy	Precision	Recall	F1-Score
Pang & Lee[36]	[11]	92.70%	92%	93%	92.5%
	[17]	90.45%	90%	91%	90.5%

[41]		60%	59.5%	61%	60.2%
[15]		86.04%	85.5%	86.5%	86%
Blitzer [22]	[24]	84.15%	83.5%	84.5%	84%
	[27]	80.9%	80%	81%	80.5%
	[26]	85.15%	84.5%	85.5%	85%
	[16]	88.7%	88%	89%	88.5%
	[12]	71.92%	71%	72%	71.5%

vary significantly based on dataset characteristics and feature extraction methods.

Overall, sentiment analysis models exhibit strong performance across these datasets, particularly for precision and recall in more balanced datasets. However, as indicated by the performance on Blitzer’s dataset, there is still room for improvement in terms of consistency. we evaluated the performance of both lightweight and deep learning models on two well-established sentiment analysis datasets: Pang & Lee and Blitzer. Below, we analyze the results for each dataset separately.

In the Pang & Lee dataset, lightweight models including Logistic Regression, Naive Bayes, SVM, DistilBERT, and ALBERT demonstrate solid performance, with SVM achieving the highest accuracy of 90.2% have been explored. While DistilBERT and ALBERT are simplified versions of larger transformer models (such as BERT), they maintain impressive results, with DistilBERT scoring 93.1% accuracy and ALBERT achieving 92.5% accuracy. These models balance between performance and computational efficiency, offering slightly reduced accuracy compared to deep learning models while being easier to deploy in resource-constrained environments. Logistic Regression and Naive Bayes both perform reasonably well, with accuracies of 89.5% and 86.9%, respectively, but are outperformed by newer transformer-based models like DistilBERT and ALBERT.

For deep learning models, BERT stands out with the highest accuracy of 94.6%, followed by RNN at 92.4%, and CNN at 91.8%. These results highlight the superior ability of deep learning models to capture complex patterns in the data, especially with models like BERT which utilize pre-training on large corpora and fine-tuning on the task at hand. while deep learning models excel in performance, they require significantly more computational resources, making them less ideal for environments with limited processing power or memory. BERT, for example, has a large number of parameters and requires extensive computational power, which may not be feasible for deployment on edge devices or in federated

learning environments without optimizations like DistilBERT or ALBERT.

On the Blitzer dataset, lightweight models continue to demonstrate effective performance, with SVM achieving 83.1% accuracy, which is the highest among the lightweight models. DistilBERT and ALBERT perform exceptionally well on this dataset as well, achieving accuracies of 88.2% and 87.6%, respectively. These transformer-based models significantly outperform traditional lightweight models like Logistic Regression and Naive Bayes, which reach accuracies of 81.5% and 79.2%, respectively. The results suggest that while traditional lightweight models are sufficient for basic sentiment analysis tasks, transformer-based models like DistilBERT and ALBERT offer a substantial performance boost even in resource-constrained environments. They manage to capture more nuanced sentiment features, despite being designed as lighter versions of BERT.

Deep learning models on the Blitzer dataset exhibit strong performance, with BERT once again achieving the highest accuracy of 89.4%, followed by RNN at 87.1%, and CNN at 85.3%. Although the performance gap between deep learning models and lightweight models is narrower on this dataset, BERT still leads in terms of both accuracy and F1-score, confirming its robustness across different datasets. Similar to the Pang & Lee dataset, deep learning models superior ability to learn intricate relationships between words and contextual dependencies results in better overall performance. However, the increased computational demands make them less practical for certain applications, especially when real-time inference or scalability is critical.

A. Complexity Analysis

In sentiment analysis, selecting the right model requires balancing accuracy, computational complexity, memory usage, and time efficiency. Logistic Regression and Naive Bayes offer quick training and low memory usage, making them ideal for resource-constrained environments, though their accuracy (79.2% - 89.5%) is lower compared to more com-

TABLE VII. PERFORMANCE OF LIGHTWEIGHT MODELS ON PANG & LEE [164] DATASET

Model Type	Accuracy	F1-Score	Recall	Precision
Logistic Regression	89.5%	88.3%	87.8%	88.9%
Naive Bayes	86.9%	85.5%	85.0%	86.0%
SVM	90.2%	89.8%	89.3%	90.4%
DistilBERT	93.1%	92.4%	91.9%	92.9%
ALBERT	92.5%	91.7%	91.3%	92.1%

TABLE VIII. PERFORMANCE OF DEEP LEARNING MODELS ON PANG & LEE DATASET

Model Type	Accuracy	F1-Score	Recall	Precision
CNN	91.8%	91.1%	90.5%	91.7%
RNN	92.4%	91.8%	91.3%	92.2%
BERT	94.6%	93.7%	93.3%	94.1%

TABLE IX. PERFORMANCE OF LIGHTWEIGHT MODELS ON BLITZER [22] DATASET

Model Type	Accuracy	F1-Score	Recall	Precision
Logistic Regression	81.5%	80.2%	79.8%	80.6%
Naive Bayes	79.2%	78.1%	77.7%	78.5%
SVM	83.1%	82.0%	81.6%	82.4%
DistilBERT	88.2%	87.5%	87.0%	88.0%
ALBERT	87.6%	86.8%	86.4%	87.2%

TABLE X. PERFORMANCE OF DEEP LEARNING MODELS ON BLITZER [22] DATASET

Model Type	Accuracy	F1-Score	Recall	Precision
CNN	85.3%	84.5%	84.0%	85.0%
RNN	87.1%	86.4%	85.9%	86.8%
BERT	89.4%	88.7%	88.2%	89.1%

plex models. Support Vector Machines (SVM) provide higher accuracy (83.1% - 90.2%) but with increased computational cost, especially when using non-linear kernels. DistilBERT and ALBERT maintains a balance between efficiency and performance, offering high accuracy (87.6% - 93.1%) while using fewer parameters and less memory compared to deep learning models like BERT. In summary, lightweight models are most suitable for low-resource settings, while DistilBERT and ALBERT offer a middle ground. Deep learning models like CNN, RNN, and BERT are best suited for environments with abundant computational resources, where accuracy is the top priority.

B. Discussion

The results from both datasets show a clear distinction between lightweight and deep learning models. Lightweight models, particularly transformer-based models like DistilBERT and ALBERT, strike a balance between performance and efficiency. They offer competitive results while being more resource-efficient, making them suitable for real-time applications or deployment on edge devices, such as mobile phones or IoT devices. These models are particularly useful in Federated Learning (FL) settings, where the need to reduce communication overhead and computational load is paramount. On the other hand, deep learning models (e.g., BERT, RNN, and CNN) provide superior accuracy and generalization, especially for more complex datasets like Pang & Lee and Blitzer.

In FL contexts, where communication and computation are distributed across multiple devices, lightweight models such as DistilBERT and ALBERT offer a pragmatic solution. They

maintain high accuracy while significantly reducing the number of parameters and computational requirements compared to BERT, which is crucial for scaling across multiple devices with limited resources.

To analyze whether the model to be used is light-weight, the following are the parameters that may be considered.

- **Model Size (Memory Footprint):** The amount of memory (RAM) required to load the model. Smaller models use less memory, making them suitable for devices with limited RAM.
- **Number of parameters:** The total number of trainable parameters in the model.
- **Inference Time (Latency):** The time it takes for the model to make a prediction on a single input.
- **Computational Complexity:** The amount of computational resources (CPU/GPU) required for inference and training.
- **Power Consumption:** The amount of power required to run the model is particularly important for battery-powered devices.
- **Model Architecture:** Simpler architectures are generally lighter.
- **Model Accuracy vs. Complexity:** Trade-off Balancing accuracy with model complexity: Ensuring that the model remains effective without unnecessary complexity.

TABLE XI. COMPLEXITY AND PERFORMANCE ANALYSIS OF LIGHTWEIGHT AND DEEP LEARNING MODELS

Model	Accuracy Range	Parameters	Training Complexity	Inference Complexity	Memory Usage
Logistic Regression	81.5% - 89.5%	10^4	$O(n^2m)$	$O(n)$	Low
Naive Bayes	79.2% - 86.9%	10^3	$O(nm)$	$O(n)$	Low
SVM	83.1% - 90.2%	Variable (support vectors)	$O(n^2m) - O(n^3m)$	$O(n)$	Medium
DistilBERT	88.2% - 93.1%	66M	$O(mn^2l)$	$O(n^2l)$	Medium
ALBERT	87.6% - 92.5%	12M	$O(mn^2l)$	$O(n^2l)$	Low
CNN	85.3% - 91.8%	1M	$O(m \cdot n^2 \cdot f^2 \cdot d)$	$O(n^2 \cdot f^2 \cdot d)$	High
RNN	87.1% - 92.4%	1M	$O(m \cdot n \cdot t)$	$O(n \cdot t)$	High
BERT	89.4% - 94.6%	110M	$O(mn^2l)$	$O(n^2l)$	Very High

- **Storage Requirements:** The disk space required to store the model. Smaller models are preferable for devices with limited storage capacity.
- **Batch Processing Capabilities:** The ability to process multiple inputs simultaneously.
- **Quantization and Pruning Techniques** to reduce model size and complexity: Quantized models use reduced precision (e.g. 8-bit integers) instead of 32-bit floats.
- **Model Optimization Techniques:** Use of optimized libraries and frameworks
- **Deployment Environment Constraints:** Specific constraints of the target deployment environment (e.g. mobile devices, IoT devices).
- **Training Time:** The duration required to train the model. Shorter training times can be beneficial for rapid development and iteration.

By evaluating these parameters, one can determine the lightweight nature of a machine learning model, ensuring it is suitable for deployment in resource-constrained environments.

VI. CONCLUSION

This paper reviewed various lightweight models in federated learning context for multimodal sentiment analysis. It outlines the current research landscape clearly. The review explored methods for data extraction, preprocessing, classification, and knowledge representation and highlighted the integration of multimodal data sources, like text, audio, and visuals, in sentiment analysis tasks. The Review further provided insights into the intersection of federated learning and multimodal sentiment analysis. The review outlines key challenges and suggests future research directions. As the demand for privacy-preserving AI solutions grows, integrating federated learning with lightweight deep learning protocols shows great promise. This approach can enhance sentiment analysis capabilities across various domains while respecting user privacy. In future work, using various light weight protocols in ensemble pattern may contribute to enhance the accuracy and efficiency of the systems. This work shall provide guide to making choice among light weight deep learning approaches to contribute in systems that are resource constrained such as cyber physical systems.

Abstract—Wireless Sensor Networks (WSNs) are essential for a wide range of applications, from environmental monitoring to security systems. However, challenges such as energy efficiency, throughput, and packet delivery delay need to be addressed to enhance network performance. This paper introduces a novel Medium Access Control (MAC) protocol that utilizes cooperative communication strategies to improve these critical metrics. The proposed protocol enables source nodes to leverage intermediate nodes as relays, facilitating efficient data transmission to the access point. By employing a cross-layer approach, the protocol optimizes the selection of relay nodes based on factors like transmission time and residual energy, ensuring optimal end-to-end paths. The protocol's performance is rigorously evaluated using a simulation environment, demonstrating significant improvements over existing methods. Specifically, the protocol enhances throughput by 12%, boosts energy efficiency by 50%, and reduces average packet delivery delay by approximately 48% than IEEE 802.11b. These results indicate that the protocol not only extends the lifespan of sensor nodes by conserving energy but also improves the overall reliability and efficiency of the WSN, making it a robust solution for modern wireless sensor networks. Security in Wireless Sensor Networks (WSNs) is crucial due to vulnerabilities like eavesdropping, data tampering, and denial of service attacks. Our proposed MAC protocol addresses these challenges by incorporating authentication techniques, such as the handshaking protocol. These measures protect data integrity, confidentiality, and availability, ensuring reliable and secure data transmission across the network. This approach enhances the resilience of WSNs, making them more secure and trustworthy for critical applications such as healthcare and security monitoring.

Keywords—Wireless Sensor Networks (WSNs); energy efficiency; Media Access Control (MAC); cooperative communication; handshaking algorithm

I. INTRODUCTION

Wireless Sensor Networks (WSNs) have become a cornerstone technology in the modern era, offering a versatile and cost-effective solution for various monitoring and data collection tasks. These networks consist of spatially distributed sensor nodes that autonomously collect and transmit data, making them invaluable in diverse fields such as military surveillance, medical monitoring, agricultural as shown in Fig. 1, environmental tracking, and commercial applications [1], [2]. The growing affordability of sensor technology and advancements in wireless communication protocols have made WSNs accessible for everyday use, enabling real-time data acquisition and analysis.

Despite their advantages, WSNs face several challenges that need to be addressed to optimize their performance and extend their operational lifespan. The main problems include signal attenuation, interference in the wireless environment, and the consequent reduction in throughput and data transmission efficiency over extended distances [1] [2]. Furthermore, the limited energy resources of sensor nodes pose a significant constraint, as frequent battery replacements or recharging are often impractical, especially in remote or hazardous locations. Therefore, reducing energy consumption during data transmission is a critical design consideration for enhancing the longevity and reliability of WSNs [3] [4].

To tackle these challenges, researchers have explored various strategies, including cooperative communication techniques. Cooperative communication leverages the inherent broadcasting nature and spatial density of WSN nodes to improve data transmission efficiency. This approach involves neighboring nodes acting as relays to forward data packets, thus reducing the energy burden on individual nodes and enhancing overall network performance. Two primary strategies are employed: multiple-relay and single-relay communication. While multiple-relay strategies can offer higher data rates and redundancy, they also involve greater complexity and overhead. Single-relay strategies, on the other hand, are often preferred for resource-constrained WSNs due to their simpler implementation and lower energy requirements [5].

Fig. 1. Schematic diagram of WSN architecture.

In this context, the development of robust Medium Access Control (MAC) protocols is essential to manage the coordination and communication between sensor nodes. MAC protocols play a pivotal role in determining how nodes access the shared communication medium, handle data transmission,

and manage energy consumption. A well-designed MAC protocol can significantly enhance WSN performance by reducing collisions, minimizing latency, and optimizing energy usage. Given the constraints of WSNs, such as limited power and bandwidth, traditional MAC protocols designed for general wireless networks are not directly applicable. Instead, WSN-specific MAC protocols are needed to address the unique challenges of these networks [6] [7].

This paper introduces a novel MAC protocol called the Secure Energy-aware Cooperative MAC (SEC-MAC) protocol, specifically designed to enhance the performance of WSNs. The SEC-MAC protocol integrates cross-layer techniques, combining insights from both the physical and MAC layers to optimize data transmission strategies. A key feature of SEC-MAC is its adaptive data transmission algorithm, which dynamically switches between direct and cooperative transmission modes based on the real-time assessment of data rates and channel conditions. This adaptability ensures efficient use of network resources, reducing control packet overhead and conserving energy [7]. In addition to improving throughput and energy efficiency, the SEC-MAC protocol also addresses critical security concerns inherent in WSNs. The open and distributed nature of these networks makes them vulnerable to various attacks, such as eavesdropping, data tampering, and denial of service (DoS) attacks. These security threats can compromise data integrity, confidentiality, and availability, which are crucial for the reliable operation of WSNs, particularly in sensitive applications like healthcare and military surveillance. The SEC-MAC protocol incorporates robust security mechanisms, including data encryption, secure routing algorithms, and authentication techniques, to safeguard the network against these vulnerabilities [8].

This comprehensive approach not only enhances the resilience of WSNs against potential security threats but also ensures that the network remains efficient and functional even under adverse conditions. The inclusion of security measures within the MAC protocol layer is particularly advantageous, as it provides a foundational level of protection that complements higher-layer security protocols. This layered security approach is essential for mitigating a wide range of threats that could otherwise exploit the inherent vulnerabilities of WSNs [9] [10].

The paper is organized as follows: Section II provides a detailed overview of the communication system employed by WSNs, highlighting the challenges and considerations specific to these networks. Section III delves into the design and implementation of the SEC-MAC protocol, explaining its core components, including the adaptive data transmission algorithm and the relay node selection process. Section IV delves into handshaking in wireless sensors. Section V presents an analytical model developed to evaluate the performance of the SEC-MAC protocol under various wireless channel conditions, considering factors such as multi-rate capabilities and the effects of saturated traffic loads. Section VI discusses the simulation results obtained from a comparative study of the SEC-MAC protocol against existing WSN MAC protocols, demonstrating the protocol's advantages in terms of throughput, energy efficiency, and security. Finally, Section VII concludes the paper with a summary of the findings and suggestions for future

research directions, focusing on further enhancing the efficiency and security of WSNs.

II. LITERATURE REVIEW

The importance of MAC protocols in Wireless Sensor Networks (WSNs) is evident as they significantly influence network performance, energy efficiency, and overall reliability. This review covers key studies and developments in MAC protocols aimed at improving the efficiency and security of WSNs.

Dhivya et al. [11] emphasized the extensive use of WSNs in applications such as pollution monitoring, temperature sensing, and disaster management, highlighting clustering as a crucial technique for enhancing network performance. Singh et al. [12] provided an overview of the physical factors, architecture, and applications of WSN technology. Mohamed et al. [13] focused on the critical aspects of routing efficiency and energy overhead, which are vital for optimal network performance.

Yi et al. [14] compared different sensor types used for air pollution monitoring and discussed future developmental needs. Anisi et al. [15] explored the application of WSNs in agriculture, specifically in precision agriculture, emphasizing energy reduction. Kaur et al. [16] surveyed various WSN routing protocols, highlighting their potential future developments. AL-Mousawi and AL-Hassani [17] addressed issues such as scalability, mobility, and data security in explosive detection scenarios.

Ali et al. [18] reviewed real-time WSN applications in areas such as water monitoring, traffic management, health surveillance, and temperature sensing, emphasizing their effectiveness in remote locations. Rashid and Rehmani [19] conducted a comprehensive study on the application of WSNs in urban environments, examining their benefits, challenges, and applications.

Abdollahzadeh and Navimipour [20] proposed methods for investigating and analyzing sensor deployments, categorizing issues based on different deployment techniques and conditions. They also explored traditional sensor uses in WSNs, network properties, and architecture, identifying key sensor-related issues. In order to handle the massive amounts of data produced by the growing number of sensors in WSNs, Belfkiih et al. [21] presented a sensor database and talked about the associated research issues.

Shafiq et al. [22] evaluated the energy efficiency of WSNs, addressing aspects such as power efficiency and threshold sensitivity. They identified energy consumption as a major issue and explored current shortcomings and challenges. Amutha et al. [23] provided a comprehensive analysis of WSN categorization based on deployment methods, coverage, sensor types, energy efficiency, and sensing models. Sharma et al. [24] recommended machine learning techniques for smart city applications, emphasizing the prevalence of supervised learning over unsupervised and reinforcement learning techniques.

Temene et al. [25] examined the mobility properties of WSNs. The QIEAC-CSSBO technique was presented by Paruvathavardhini and Sargunam [26] and uses a quantized indexive energy-aware clustering-based combinatorial

stochastic sampling bat optimization algorithm to enhance energy efficiency and secure routing. Nagarajan and Kannadhasan [27] examined how well a hybrid NIDS model performed in detecting network intrusions in wireless sensor networks.

Paruvathavardhini et al. [28] proposed a security-enhanced clustered routing protocol that reduces energy consumption by avoiding constant activation of all nodes. They developed a new method for selecting cluster heads to prevent energy depletion and improve security. Hosseinzadeh et al. [29] introduced the CTRF cluster-based trusted routing algorithm, which incorporates a weighted trust mechanism and uses a fire hawk optimizer to improve network security by taking into account nodes' limited energy.

Dass et al. created a safe routing protocol for body area network clustered networks [30]. Mainaud et al. [14] sought to bridge the gap between physical-layer cooperative communication techniques and suitable MAC layer schemes for WSNs by introducing the WSC-MAC protocol, designed to improve network reliability through cooperative communication. Liu et al. [13] proposed a node cooperation mechanism where nodes with higher channel gain and adequate residual energy assist in relaying data packets, enhancing

network lifetime and energy efficiency. Nacef et al. [15] developed the COSMIC protocol, which triggers retransmissions from the destination node in case of erroneous packet receptions, improving latency, throughput, and energy efficiency.

The Busy Tone Based Cooperative MAC Protocol (BTAC) and the Throughput and Energy-Aware Cooperative MAC Protocol (TEC-MAC) leverage IEEE 802.11's multi-rate capabilities to support data transmission in WSNs. However, maintaining relay tables in TEC-MAC is time-consuming. The MCA-MAC protocol addresses these issues by using a more efficient distributed approach for selecting relay nodes, thus reducing overhead and improving throughput, delay, and energy efficiency.

Overall, the literature on MAC protocols for WSNs reflects significant progress in addressing challenges related to energy efficiency, security, and adaptability. Modern research continues to innovate with adaptive techniques and integration of advanced technologies, aiming to enhance the performance and reliability of WSNs. Table I summarizing the literature review of MAC in Wireless Sensor Networks (WSNs):

III. PROPOSED SEC-MAC PROTOCOL

Before you begin to format your paper, first write and save the content as a separate text file. Keep your text and graphic files separate until after the text has been formatted and styled. Do not use hard tabs, and limit use of hard returns to only one return at the end of a paragraph. Do not add any kind of pagination anywhere in the paper. Do not number text heads-the template will do that for you? Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar:

This study assumes that the Wireless Sensor Network (WSN) comprises 150 static sensor nodes, evenly distributed across the network. Data transport takes place over a single physical wireless channel, with a gradual fading channel employed to keep channel conditions constant while the MAC frame is being transmitted. Because wireless channels are broadcast, the Access Point (AP) monitors and receives signals from both the source and relay nodes. The IEEE 802.11b standard, which offers data transfer speeds of 11, 5.5, 2, and 1 Mbps, is the foundation for the proposed WSN.

There are two data transmission modes in the system: direct transmission mode and cooperative relaying mode. In direct transmission mode, data is sent directly from the source to the destination (AP) without involving any relay nodes. As illustrated in Fig. 2, the cooperative relaying mode, in contrast, consists of two stages: first, data is carried from the source to the destination through the relay node that has been selected, based on a relay selection method used by the source node. After that, the source node sends its data to the relay, and the relay node relays it to the intended recipient. In order to maximize energy and time efficiency, the SEC-MAC protocol additionally permits the relay to transmit its own data to the AP subsequent to transmitting the source's info.

The relay selection algorithm in the SEC-MAC protocol considers three key factors to select the optimal relay: Channel State Information (CSI), Residual energy (RE), and transmission time. The process begins with the source node transmitting a Need to Send (NTS) packet. Neighboring sensor nodes that receive the NTS packet evaluate their CSI relative to a predefined threshold (TH). Nodes with CSI above the threshold are considered potential relays; those with lower CSI quietly drop out.

Next, among the potential relay nodes, the one with the least end-to-end delay and the highest residual energy is selected. Each potential relay calculates an RBackoff

Value using the following equation:

$$R_{Backoff} = \frac{1}{\alpha CSI + \delta RE + \beta \frac{1}{T_{srd}}} \quad (1)$$

Where α , δ , and β are coefficients used for normalization, and T_{srd} represents the cooperative transmission time from the source node to the AP via the relay node.

The direct data transmission time is calculated as follows:

$$T_{sd} = 8LR_{s-d} \quad (2)$$

Where, L is the packet length and R_{s-d} is the data rate from the source to the destination.

The transmission time from the source to the relay node and the relay node to the AP combined makes up the overall transmission time for cooperative transmission. If T_{srd} is less than T_{sd} , a nearby relay node j is taken into consideration for selection. The ideal relay is determined by the relay node that reaches the fastest transmission time from the source to the AP. The flow diagram in Fig. 3 shows the relay selection procedure.

Fig. 2. Co-operative Communication vs. Direct Way Transmitting Data.

Fig. 3. Flow chart about optimal data transmission algorithms.

In addition to the relay selection and data transmission processes, security within the WSN is bolstered through the implementation of a robust handshaking algorithm. This algorithm is crucial for establishing a secure communication link between the source, relay, and destination nodes. During the initial handshaking phase, mutual authentication is performed, ensuring that only legitimate nodes participate in the communication process. The handshaking procedure uses a combination of symmetric and asymmetric cryptographic techniques to securely exchange session keys and authenticate node identities. The session keys are then used to encrypt data, protecting it from eavesdropping and unauthorized access during transmission. This approach not only secures the data but also ensures the integrity and authenticity of the nodes involved, thereby preventing potential security threats such as replay

attacks and man-in-the-middle attacks. The secure handshaking mechanism is seamlessly integrated into the SEC-MAC protocol, providing an additional layer of security without compromising the network's performance or energy efficiency.

IV. HANDSHAKING IN WIRELESS SENSOR NETWORKS (WSNs)

Wireless Sensor Networks (WSNs) [32] are inherently vulnerable to a variety of attacks due to their limited resources, dynamic topologies, and reliance on wireless communication. Common threats include continuous channel access, which disrupts the Media Access Control (MAC) protocol and drains node batteries by continuously injecting malicious packets, leading to energy depletion from excessive retransmissions. Collision attacks further hinder communication by allowing malicious nodes to block or delay data transmission, resulting in energy waste and potential data loss. Additionally, misdirection occurs when attackers redirect data packets, overwhelming targeted nodes with irrelevant information and depleting resources; countermeasures such as smart sleep can mitigate this issue. The physical accessibility of sensor nodes in open areas renders them susceptible to capture and tampering, known as node capture attacks. Path-based denial-of-service (DoS) attacks involve malicious nodes injecting false or replayed packets, consuming energy and bandwidth while obstructing communication with the base station; authentication techniques and anti-replay protections can help counteract this threat. Selective forwarding attacks see attackers using compromised nodes to drop incoming packets or prioritize their own communications, further jeopardizing data integrity. The man-in-the-middle attack poses significant risks by allowing interception and potential alteration of communications, necessitating robust security measures to prevent such vulnerabilities. While handshaking protocols can address some of these security concerns by facilitating authentication, secure key exchange, and session management thereby enhancing trust among nodes and reducing the risk of unauthorized access they are not a panacea. A comprehensive security strategy for WSNs must also incorporate complementary measures such as intrusion detection systems, encryption, and energy-efficient protocols to ensure robust protection against the myriad of threats facing these networks.

Handshaking in Wireless Sensor Networks (WSNs) is a fundamental process that establishes a communication link between nodes before data transmission. It involves an exchange of messages to synchronize both the sender and receiver, ensuring they are ready to communicate and agree on key parameters like data rates and encryption methods. This mechanism enhances the reliability and efficiency of data transfer by minimizing the risk of data loss or interference as shown in Fig. 4.

In Cooperative Access MAC protocols, handshaking begins with an initialization step, where a node intending to transmit data sends a request to potential relay nodes within its range. The relay nodes respond with information about their availability and capabilities, such as their signal strength and current load. This negotiation helps select the optimal relay node, ensuring efficient data transfer. Once a relay is chosen, a confirmation process follows where both sender and relay node exchange

messages to agree on communication parameters, including channel allocation and encryption. This step optimizes the transmission process by ensuring smooth and secure data transfer, followed by an acknowledgment from the receiver confirming successful data delivery.

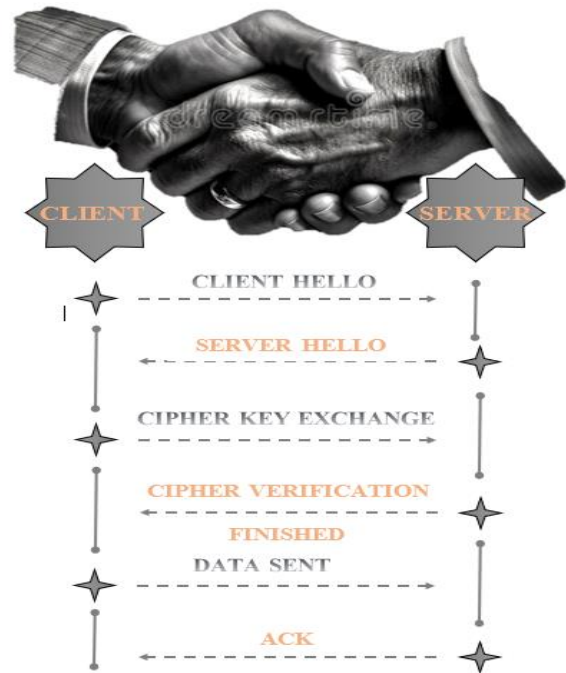

Fig. 4. Handshaking process in WSN.

The handshaking protocol not only improves communication efficiency but also strengthens security in WSNs. By ensuring that only authorized nodes can participate in the network through authentication mechanisms, handshaking prevents unauthorized access and enhances data integrity. It also facilitates the establishment of encryption keys, protecting data from eavesdropping, replay attacks, and man-in-the-middle attacks.

Several handshaking algorithms can be integrated into Cooperative Access MAC protocols to improve both security and performance in WSNs. These include Three-Way Handshake, Public Key Infrastructure (PKI), Elliptic Curve Cryptography (ECC), Challenge-Response Authentication, Secure Sockets Layer (SSL)/Transport Layer Security (TLS), and Diffie-Hellman Key Exchange. Each offers distinct advantages in securing and optimizing data transmission while preserving energy and computational resources within the network.

This comparative analysis highlights the trade-offs between security, energy efficiency, latency, and computational overhead in each protocol, offering insight into their suitability for various WSN applications. The Diffie-Hellman Key Exchange protocol offers several advantages when compared to other handshaking protocols commonly used in Wireless Sensor Networks (WSNs). Unlike the Three-Way Handshake, which has low security but is energy-efficient with minimal latency and computational overhead, Diffie-Hellman provides high security while maintaining moderate energy efficiency and

computational demands. When compared to Public Key Infrastructure (PKI) and SSL/TLS, which both offer high security but at the cost of increased latency and significant computational overhead, Diffie-Hellman strikes a balance with medium latency and overhead, making it more suitable for resource-constrained WSN environments. Furthermore, compared to Elliptic Curve Cryptography (ECC) and Challenge-Response Authentication, Diffie-Hellman provides equivalent security with similar medium levels of energy efficiency, latency, and computational overhead, positioning it as a versatile and secure protocol for environments requiring a compromise between security and resource consumption (Table II).

TABLE II. SUMMARY TABLE ABOUT HANDSHAKING ALGORITHMS

Protocol	Security	Energy Efficiency	Latency	Computational Overhead
Three-Way Handshake	Low	High	Low	Low
Public Key Infrastructure (PKI)	High	Low	High	High
Elliptic Curve Cryptography (ECC)	High	Medium	Medium	Medium
Challenge-Response Authentication	Medium	Medium	Medium	Medium
SSL/TLS	High	Low	High	High
Diffie-Hellman Key Exchange	High	Medium	Medium	Medium

V. ANALYTICAL MODEL

In this section, we derive equations for the cooperative transmission scheme [31]. In this scheme, the source node transmits its data packet through a relay node to the Access Point (AP) at a data rate Rrd. Seven potential points of failure exist for packet transmission after the RTS packet is successfully sent without a collision: RTS, CTS, RTH, DATA-S from source to relay, DATA-S from relay to AP, DATA-R from relay to AP, and packet corruption in the ACK during subsequent transmissions. The probability X1 of RTS packet corruption, assuming no RTS collision, is given by:

$$X1=1-(1-BER_C)^{8L_{RTS}} \quad (3)$$

Where LRTS represents the length of the RTS packet in bytes. Given that the RTS packet is successfully transmitted, the probability X2 that the CTS packet is garbled is computed as follows:

$$X2=1-(1-BER_C)^{8L_{CTS}} \quad (4)$$

Where LCTS is the length of the CTS packet in bytes. Similarly, the probability X3 that the RTH packet is corrupted while both the RTS and CTS packets are successfully transmitted is:

$$X3=1-(1-BER_C)^{8L_{RTH}} \quad (5)$$

Where LRTH is the length of the RTH packet in bytes. Finally, the probability X4 that a DATA-S packet from the source to the relay is corrupted, assuming that the RTS, CTS, and RTH packets are transmitted successfully, is:

$$X4=1-(1-BER_{sr})^{8L_s}(1-BER_C)^{8L_{PLCP}} \quad (6)$$

where Ls is the length of the DATA-S packet from the source to the relay and LPLCP is the length of the PLCP packet in bytes.

The bit error rate of the data packet transmitted from the source to the relay node at data rate Rsr is denoted as BERsr and Ls represents the data packet length from the source node in bytes. Given that the RTS, CTS, RTH, and DATA-S (from source to relay) packets are correctly received, the following formula determines the likelihood v5 that a DATA-S packet from the relay to the AP is corrupted:

$$X5=1-(1-BER_{rd})^{8L_r}(1-BER_C)^{8L_{PLCP}} \quad (7)$$

Where BERrd is the bit error rate of the data packet sent between the relay and the AP at data rate Rrd. The probability X6 that a DATA-R packet is corrupted while RTS, CTS, RTH, and DATA-S packets are correctly received is:

$$X6=1-(1-BER_{rd})^{8L_r}(1-BER_C)^{8L_{PLCP}} \quad (8)$$

Where Lr is the relay node's data packet length in bytes. Ultimately, the likelihood X7 that an ACK packet is tainted while the RTH, DATA-S (from source to relay), RTS, CTS, and at least one DATA-S (relay to AP) or DATA-R packet is correctly received is as follows:

$$X7=1-(1-BER_C)^{8L_{ACK}} \quad (9)$$

Where LACK is the ACK packet length in bytes.

Let:

- $P_{e1,C}$ be the probability of RTS packet corruption,
- $P_{e2,C}$ be the probability of CTS packet corruption,
- $P_{e3,C}$ be the probability of RTH packet corruption,
- $P_{e4,C}$ be the probability of DATA-S packet corruption from the source to the relay,
- $P_{e5,C}$ be the probability of DATA-S packet corruption from the relay to the AP,
- $P_{e6,C}$ be the probability of DATA-R packet corruption, and
- $P_{e7,C}$ be the probability of ACK packet corruption.

These probabilities are calculated as follows:

$$P_{e,i}^C = P_{e1,C} + P_{e2,C} + P_{e3,C} + P_{e4,C} + P_{e5,C} + P_{e6,C} + P_{e7,C} \quad (10)$$

A. Saturated Throughput Analysis

In Wireless Sensor Networks (WSNs), saturated throughput refers to the maximum rate at which data can be successfully transmitted over the network when the network is fully loaded. This means that all the nodes in the network are constantly trying to send data, leading to a situation where the network is operating at its maximum capacity. Saturated throughput is an important performance metric as it reflects the efficiency of the network in handling high traffic conditions. It is often used to assess the network's ability to maintain reliable communication without excessive delays or packet loss, even when all nodes are actively transmitting data. In this context, achieving high saturated throughput indicates a well-optimized network that

can support heavy traffic loads efficiently. Lastly, the ratio of the payload size that is successfully communicated to the interval of time between two successive transmissions is known as saturation throughput η . We can express η as follows according to the adopted definition [7]:

$$\eta = \frac{8L \sum_{i=1}^N P_{s,i} (1 - P_{e,i})}{E[T1] + E[TS] + E[TC] + E[TE]} \quad (11)$$

B. Energy Efficiency Expression

An expression for energy efficiency in an SEC-MAC protocol network is derived in this subsection. The ratio of successfully delivered packet bits to the total energy utilized in the network is known as the energy efficiency, or ε . Nodes expend energy in the following functions: backoff $E_B^{(i)}$, collision $E_C^{(i)}$, transmission overhearing $E_O^{(i)}$, transmission errors $E_E^{(i)}$, and successful transmission $E_S^{(i)}$ [7]

$$\eta = \frac{8L \sum_{i=1}^N P_{s,i} (1 - P_{e,i})}{E_B^{(i)} + E_C^{(i)} + E_O^{(i)} + E_E^{(i)} + E_S^{(i)}} \quad (12)$$

C. Delay Expression

Lastly, an expression for the average packet delay is produced in this subsection using the procedure outlined in [7]. The amount of time that passes between a packet reaching the front of its MAC queue and successfully reaching the AP, as indicated by a positive acknowledgment, is known as the average packet delay.

Let D_i (where $i=1, 2, \dots, N$) be a random variable that represents node i 's packet latency. As a result, the average packet delay $Avg[D_i]$ has the following expression:

$$Avg[D_i] = Avg[D_{b,i}] + Avg[D_{c,i}] + Avg[D_{o,i}] + Avg[D_{s,i}] + [Avg_{e,i}] \quad (13)$$

Where:

- $Avg[D_{b,i}]$ is the typical time it takes to lower the backoff counter,
- $Avg[D_{c,i}]$ is the average delay due to collisions during transmissions,
- $Avg[D_{o,i}]$ is the typical time it takes to hold the backoff counter while other nodes are sending data.
- $Avg[D_{s,i}]$ is the average delay during a successful transmission,
- $Avg[D_{e,i}]$ is the average delay caused by erroneous transmissions.

Consequently, one can compute the whole average packet delay by:

$$D = \frac{1}{N} \sum_{i=1}^N Avg[D_i]$$

Let N represent the average total number of time slots.

VI. RESULTS AND DISCUSSION

The proposed SEC-MAC protocol has been evaluated using MATLAB to analyze the impact of key parameters, such as the

number of sensor nodes and packet length, on its performance. Simulation results comparing SEC-MAC, BTAC and IEEE 802.11b protocols, specifically in terms of Energy, throughput, and average delay demonstrate that SEC-MAC outperforms BTAC and IEEE 802.11b.

Where BTAC protocol is designed for wireless local area networks and operates based on the IEEE 802.11b standard, focusing on optimizing medium access and enhancing communication efficiency among devices. It employs the Distributed Coordination Function (DCF) with an RTS/CTS handshake to manage how stations access the wireless medium, minimizing collisions and ensuring smoother communication. For simplicity, each station operates at a fixed transmission power level, which standardizes signal transmission. Stations can adapt their data rates based on current channel conditions, allowing for more efficient data transfer. Control frames, such as RTS, CTS, and ACK, are transmitted at a basic rate of 1 Mbps to maintain a consistent communication baseline. The protocol assumes a symmetric wireless channel between the source and destination, as both utilize the same carrier frequency for packet transmission. Additionally, it enables stations to identify nearby helper stations, tracking their MAC addresses, timestamps of last packets received, transmission rates to the destination and source, and counts of transmission failures. Each station also maintains awareness of all other stations within its basic service set, facilitating effective communication. Overall, the BTAC protocol enhances wireless communication efficiency by optimizing data rates, effectively managing medium access, and utilizing nearby helpers to improve network performance.

The performance of SEC-MAC was assessed under varying data rates. We assume the simulation is based on ideal channel. Fig. 5 and Fig. 6 shows the saturated throughput of the SEC-MAC protocol. The number of sensor nodes in a Wireless Sensor Network (WSN) under optimal channel conditions is indicated by the x-axis. The results reveal that as the network size increases, the throughput also increases exponentially, largely due to the lower data rate caused by the addition of relay nodes. Initially, SEC-MAC performs similarly to BTAC, but as the number of nodes exceeds 40, SEC-MAC demonstrates a notable improvement, with a 12% higher throughput in the saturation region.

Fig. 5. Saturated throughput in relation to the quantity of nodes under optimal channel conditions.

Fig. 6. Peak throughput in relation to packet length under optimal channel circumstances.

Fig. 7 and Fig. 8 provide an energy efficiency comparison, under ideal channel conditions, between the IEEE 802.11b standard and the SEC-MAC protocol at various node densities. The findings indicate that as the number of sensor nodes grows, both protocols experience reduced energy efficiency due to increased node collisions. These collisions result in more frequent packet retransmissions, leading to higher energy usage. In spite of this, SEC-MAC protocol shows a notable benefit over IEEE 802.11b, providing up to 50% more energy savings. This is primarily because SEC-MAC employs an efficient relay selection process, which minimizes retransmission time and reduces overall energy consumption, thereby substantially improving energy efficiency.

Fig. 7. Energy efficiency as a function of the number of nodes in the optimal channel.

Fig. 8. Energy efficiency in relation to packet length under optimal channel circumstances.

A performance comparison of IEEE 802.11b standard and SEC-MAC protocol in terms of packet delay at various packet

lengths is shown in Fig. 9 and Fig. 10. Because larger packets require longer transmission times, both protocols face increasing delays as the packet length rises. Despite this, SEC-MAC consistently outperforms IEEE 802.11b, showing a noticeable reduction in packet delay. This highlights SEC-MAC's greater efficiency in managing data transmission for sensor nodes, particularly when handling larger packet sizes.

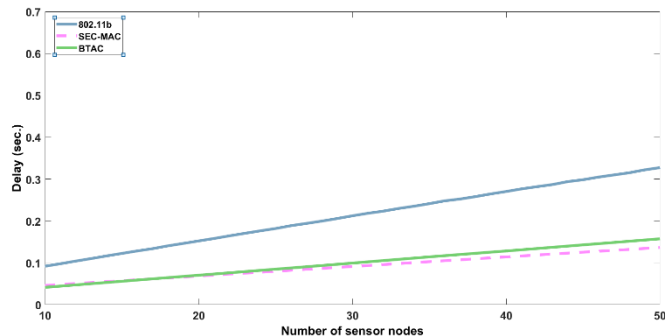

Fig. 9. Packet delay versus number of nodes with ideal channel conditions.

Fig. 10. Packet delay versus packet length with ideal channel conditions.

VII. CONCLUSION

In this paper, we introduced SEC-MAC, a secure Medium Access Control (MAC) protocol for Wireless Sensor Networks (WSNs) that leverages cooperative communication to enhance network performance. SEC-MAC improves throughput, energy efficiency, and security by allowing low data-rate nodes to select optimal relay nodes for data transmission, reducing delays and packet losses. Additionally, SEC-MAC introduces an innovative transmission scheme where relay nodes can transmit their own data without undergoing the traditional handshake procedure, thus optimizing channel access and saving energy. Cooperative communication is central to SEC-MAC, as it allows nodes to collaborate for more efficient data transmission, improving overall network reliability and performance. This cooperative approach also boosts the network's ability to scale effectively, handling a larger number of nodes without a significant drop in throughput.

Security is a key focus of SEC-MAC, addressing vulnerabilities in WSNs by incorporating cryptographic measures and secure authentication processes to protect data integrity and prevent unauthorized access. The protocol ensures reliable communication even in potentially hostile environments. Simulation results demonstrated that SEC-MAC significantly improves network throughput as the number of

nodes increases compared to BTAC and IEEE 802.11b protocols. By optimizing relay selection and minimizing retransmissions, the protocol enhances energy efficiency, making it ideal for energy-constrained applications like environmental monitoring. Future research should focus on enhancing SEC-MAC's adaptability, performance, and security to expand its applicability. Future research will explore further optimization of SEC-MAC, including its performance in real-world applications like healthcare monitoring, as well as investigating the impact of different traffic models. Overall, SEC-MAC offers an effective solution for secure, energy-efficient, and scalable communication in WSNs, making it a promising protocol for a wide range of applications.

Digital Twin Model from Freehanded Sketch to Facade Design, 2D-3D Conversion for Volume Design

Kohei Arai

Dept. Information Science, Saga University, Saga City, Japan

Abstract—The article proposes a method for creating digital twins from freehand sketches for facade design, converting 2D designs to 3D volumes, and integrating these designs into real-world GIS systems. It outlines a process that involves generating 2D exterior images from sketches using generative AI (Gemini 1.5 Pro), converting these 2D images into 3D models with TriPo, and creating design drawings with SketchUp. Additionally, it describes a method for creating 3D exterior images using GauGAN, all for the purpose of construction exterior evaluation. The paper also discusses generating BIM data using generative AI, converting BIM data (in IFC file format) to GeoTiff, and displaying this information in GIS using QGIS software. Moreover, it suggests a method for generating digital twins with SketchUp to facilitate digital design information sharing and simulation within a virtual space. Lastly, it advocates for a cost-effective AI system designed for small and medium-sized construction companies, which often struggle to adopt BIM, to harness the advantages of digital twins.

Keywords—BIM; AI; GIS; digital twins; metaverse; generative AI; GauGAN; TriPo; SketchUp; IFC format; GeoTiff

I. INTRODUCTION

The Japanese construction industry urgently needs to improve work efficiency and productivity. This urgency arises from slow productivity growth, frequent industrial accidents, a declining and aging workforce, and a government policy reducing overtime work starting in 2024. While 31.1% of employees in all industries are aged 55 or older, the percentage for construction is over 36.0%. On the other hand, the percentage of employees aged 29 or younger is over 16.6% in all industries but less than 11.8% in construction.

To address these challenges, the Ministry of Land, Infrastructure, Transport and Tourism will implement the "Building Information Management (BIM)¹ Drawing Review" in the spring of 2026. This initiative will allow confirmation applications using PDF documents and BIM models, promoting efficiency in construction projects through AI, Geographic Information Systems (GIS), and BIM.

This paper focuses on improving construction efficiency using BIM, particularly the 6D BIM model. While many BIM tools are commercially available, they are often expensive. The proposed methods rely on open-source tools to create BIM

models, generate 2D and 3D exterior images, and convert BIM data into GIS-compatible formats like GeoTiff².

The paper highlights the advantages of BIM in terms of front-loading (shifting efforts earlier in the project lifecycle) and concurrent engineering (parallelizing workflows). It also explores methods for generating BIM data. Beyond the 3D BIM model, the benefits of 6D BIM—which incorporates time, cost, and sustainability—are discussed, especially when combined with a digital twin.

Additionally, the paper proposes methods to enhance efficiency and visualization in construction. AI is utilized to generate 3D models from 2D sketches, which can then be used to check building exteriors and appearances. The generated 3D models are converted into BIM data and subsequently into GeoTiff format for display in GIS tools like QGIS³. Open-source tools like SketchUp are also proposed for BIM data generation and 3D model visualization, along with AI-based construction management enhancements. A GauGAN⁴-based method for generating 3D exterior images is suggested to improve design review processes.

The integration of AI and digital twins is shown to simplify construction management tasks, improve efficiency and productivity, and enhance safety. By converting BIM models into GeoTiff format, the models can be optimized for specific geographical conditions at construction sites. There is no such this proposed models and methods which features generative AI, TriPo for creation of BIM models, and generate GIS model which is linked to the created BIM model.

The paper reviews related research and discusses the effectiveness of using BIM and AI for model creation. It introduces methods for creating BIM models from 2D data using generative AI, as well as SketchUp-based techniques. A TriPo⁵ method is proposed for converting 2D models to 3D models. Finally, the paper explores integrating BIM models into Metaverse and discusses a conversion tool for translating BIM data into GeoTiff format. The conclusion summarizes these contributions with remarks and further discussion.

III. PROPOSED METHODS AND SYSTEMS

A. Overall

Improving productivity and streamlining workflows in the construction industry can be achieved not only through BIM-based design but also by leveraging ICT tools like IoT-enabled surveying and construction machinery. By incorporating AI into pre-construction tasks, such as building BIM models, parallel and collaborative work becomes possible, reducing construction time.

Additionally, using tools like RAG¹⁰ (Retrieval-Augmented Generation) to share knowledge and experience can enhance work efficiency during construction. This facilitates the transfer of skills from experienced workers to beginners, improving overall quality. It supports front-loading, a method that allocates resources and focuses efforts early in a project. This approach enables early detection and resolution of problems, such as structural interferences or design flaws, by creating 3D models during the initial stages.

Front-loading minimizes rework caused by design errors or clashes, improving quality and reducing costs. Early detailed considerations and validations improve design accuracy, and simulations using 3D models allow for better decision-making. Reduced rework lowers overall costs, shortens construction times, and accelerates decision-making by enhancing stakeholder communication through 3D models. Furthermore, construction plans become more optimized, as procedures and temporary methods can be rationalized at the design stage. Distributing workloads more evenly across project phases also improves overall efficiency.

The proposed workflow is illustrated in Fig. 1:

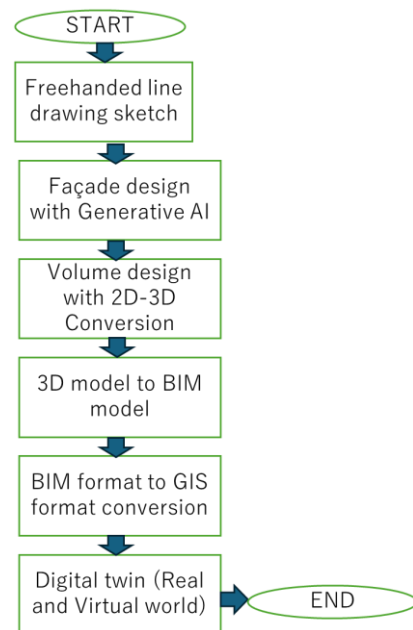

Fig. 1. Process flow of the proposed method for digital twin model creation.

⁶ <https://www.skillupai.com/blog/tech/ml-dl-tips-1/>

⁷ <https://github.com/davidsandberg/facenet>

⁸ <https://ja.wikipedia.org/wiki/TIN>

⁹ <https://grass.osgeo.org/>

¹⁰ <https://aws.amazon.com/jp/what-is/retrieval-augmented-generation/>

- 1) Start with a freehand sketch.
- 2) Use software like SketchUp¹¹ to refine the design.
- 3) Create a 2D façade design using generative AI tools, such as Gemini AI Pro¹².
- 4) Convert the 2D design into a 3D volume model using 2D-to-3D tools like TriPo.
- 5) The 3D model can be used as a BIM model in a virtual space.

To create BIM models in real-world applications, BIM data (e.g., IFC files) is converted to GeoTiff format, enabling GIS visualization with tools like QGIS. These steps outline a proposed digital twin creation method for construction design.

In the virtual space, users can perform various simulations, and the results of these studies can be implemented in real-world applications through GIS-based visualization.

B. SketchUp¹³

Revit¹⁴, ArchiCAD¹⁵, and Gloobe¹⁶ are popular tools for generating BIM data but come with high costs: 427,900 yen, 418,000 yen, and 165,000 yen per month, respectively. A more affordable alternative is SketchUp, which is free but offers fewer features. Here's how SketchUp can be used for BIM data generation:

1) Basic Use of SketchUp

Modeling: Create 3D models using SketchUp's intuitive interface.

Use basic tools like lines, planes, and arcs to model buildings and structures.

2) BIM Data Requirements

BIM Data: Includes building structure, materials, dimensions, and related metadata.

In SketchUp, you'll need to create a detailed model with this information.

3) Using Plugins

IFC Exporter¹⁷: Export SketchUp models as IFC (Industry Foundation Classes) files, the standard format for BIM data.

Plugin Installation: Search for "IFC Exporter" in SketchUp's Extension Warehouse and install it to improve compatibility with BIM software.

4) Adding Attributes and Metadata

Dynamic Components: Add attributes and parameters to objects, such as size, material, or manufacturer details for doors and windows.

5) Using Layers and Groups

Layers and Groups: Categorize elements into layers and groups for better organization, making it easier to identify and work with specific elements.

6) Exporting and Importing

Export IFC Files: Use the IFC Exporter plugin to export SketchUp models as IFC files.

Import into BIM Software: Import these IFC files into BIM tools like Revit or ArchiCAD for further analysis and design.

7) Integration with Other Tools

SketchUp Pro and Layout: Use Layout, a feature in SketchUp Pro, to create 2D documents for construction drawings and specifications as part of the BIM workflow.

8) Best Practices

Standardize Model Structure: Use consistent layer structures and naming conventions to improve collaboration and make models easier to understand.

While SketchUp is not a dedicated BIM tool and primarily serves as 3D modeling software, it can still be used to create detailed models and ensure compatibility with other BIM software through the steps above. However, its BIM functionalities are limited compared to specialized tools.

Fig. 2 shows an example of an initial building design created with SketchUp.

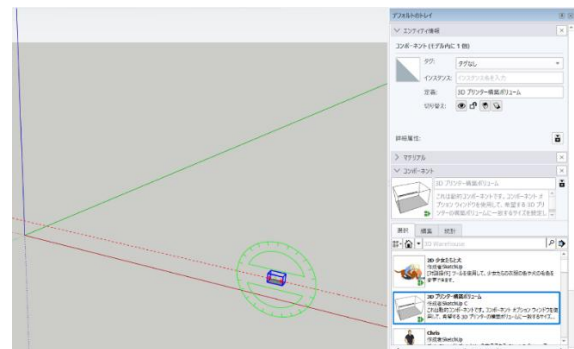

Fig. 2. Just the beginning of design of building for construction.

C. Generative AI and TriPo

For exterior design checks, images generated by Generative AI can be highly useful. Fig. 3 illustrates a 2D exterior design image created using Claude 3.5 Sonnet¹⁸, a Generative AI tool. This 2D image can then be converted into a 3D model using tools like TriPo.

While there are numerous software options available for 2D-to-3D image conversion, TriPo demonstrated the best quality among the 10 tools tested as is shown in Fig. 4. 3D images converted from 2D image generated by Generative AI based on TriPo can be rotated and can be displayed from the arbitrary view of line of sight.

Fig. 4. 3D image converted from 2D image generated by Generative AI based on TriPo.

D. GauGAN

GauGAN is a powerful tool for visualizing architectural concepts and designs. Here are its key applications:

1) *Concept visualization*: Architects and designers can use GauGAN to quickly bring initial ideas to life. From simple sketches or written descriptions, it generates realistic architectural images that can be shared with clients and team members.

2) *Environmental simulations*: GauGAN can simulate buildings in various environments and seasons, helping visualize how a project will look under different conditions. For example, it can easily create scenes like “a modern house in snowy mountains” or “a skyscraper in a bustling city center.”

3) *Landscape design*: Designers can use GauGAN to experiment with surroundings, such as planting options or terrain layouts. It enables easy addition or modification of elements like green spaces, water features, or rock gardens, ensuring harmony between the building and its environment. GIS tools can further assist in evaluating this harmony.

4) *Presentation materials*: Realistic images generated by GauGAN are ideal for client presentations or proposal materials. These visuals help communicate the project vision effectively and leave a strong impression.

5) *Rapid design iteration*: GauGAN allows designers to make quick adjustments to their designs and view results in real

time. This speeds up the design process and encourages the exploration of multiple ideas in a shorter timeframe.

6) *Urban planning*: Urban planners can use GauGAN to visualize new developments or redevelopment projects. By combining elements like streets, parks, and buildings, it can depict a detailed vision of a city’s future.

7) *Interior design*: GauGAN is also helpful for designing interior spaces. It can simulate natural light effects, window views, and overall spatial aesthetics, supporting better decision-making in interior design.

These capabilities make GauGAN a valuable tool for generating ideas in the early stages of architectural design, enhancing client communication, and enabling faster design iterations. By improving both efficiency and creativity, GauGAN significantly supports architectural and urban design projects.

E. BIM Model Creation by Claud 3.5 Sonnet

Create a structured BIM dataset based on what can be observed from the images, paying attention to:

- 1) Overall properties and characteristics of the building
- 2) Details of the structural system
- 3) Spatial configuration and estimated dimensions, especially of the characteristic curved curtain walls
- 4) Envisaged technical systems
- 5) Sustainability features
- 6) Contextual information

The Python code for this is as follows:

```
{
  "buildingProperties": {
    "type": "Mixed-Use High-Rise",
    "architecturalStyle": "Contemporary",
    "mainFeatures": ["Curved Glass Facade", "Corner Location"],
    "estimatedHeight": "65-75 meters",
    "estimatedFloors": {
      "aboveGround": 18,
      "retail": 1
    }
  },
  "structuralSystem": {
    "primaryStructure": "Steel and Concrete",
    "facade": {
      "type": "Curtain Wall",
      "materials": ["Glass", "Aluminum"],
      "features": ["Curved Glass Panels", "Horizontal Banding"]
    }
  },
  "spatialOrganization": {
    "footprint": {
      "shape": "Curved Rectangle",
```

```
"estimatedArea": "800-1000 square meters"
},
"floorLayout": {
  "groundFloor": {
    "use": "Retail/Lobby",
    "features": ["Double Height Entrance", "Commercial Space"]
  },
  "typicalFloor": {
    "use": "Commercial/Residential",
    "estimatedArea": "700-900 square meters"
  }
},
"technicalSystems": {
  "presumedMEP": {
    "hvac": "Central System",
    "elevators": {
      "estimated": "3-4 units",
      "type": "High-Speed"
    },
    "lighting": {
      "natural": "Floor-to-ceiling windows",
      "artificial": "LED Systems"
    }
  },
  "sustainability": {
    "features": [
      "High-Performance Glazing",
      "Natural Daylighting",
      "Possible Green Building Certification"
    ]
  },
  "context": {
    "setting": "Urban",
    "surroundings": {
      "adjacent": ["Street", "Parking Area"],
      "neighborhood": "Commercial District"
    }
  },
  "metadata": {
```

"note": "This BIM data is approximate and based on visual assessment only. Actual building specifications may vary."

```
}
}
```

F. Other Useful Software Tools

The Architecture Design Bot¹⁹ is an AI-powered tool that streamlines the architectural design process. It can generate architectural images from text prompts, create variations of existing design proposals, automatically produce 3D models, and provide optimization suggestions for compliance with regulations and cost-efficiency. Additionally, it aids in idea generation during the early design stages, quickly generates client-ready proposal variations, reduces the time needed for rendering and 3D modeling, and automates compliance checks with building codes.

Other Free Tools for Generating BIM Data:

1) FreeCAD

Open-source 3D parametric modeler.

Create 3D drawings from 2D sketches.

Compatible with Windows, Mac, and Linux.

BIMx (Graphisoft)

2) Free applications are available for iOS and Android.

View and explore 3D BIM models.

Provides seamless 2D and 3D project navigation.

BIM Vision

3) IFC model viewer.

Supports models created in various systems like Revit, ArchiCAD, and Tekla.

4) B-processor²⁰

Tool specifically developed for BIM.

Intuitive and easy-to-learn 3D modeling.

Includes features for cost calculations and carbon emission data.

5) Edificius (ACCA Software)²¹

Free BIM software with real-time rendering capabilities.

Integrates structural analysis with architectural design.

Enables accurate land mapping using satellite imagery from Google Maps.

Free 30-day trial available.

¹⁹ <https://prod.d2eu75mpuy425r.amplifyapp.com/>

²⁰ https://tracxn.com/d/companies/b-processor/_atQDLzH2udrUrz2ES_zzho_gxGXMFnkxeLmKHa-s0Us#competitors-and-alternates

²¹ <https://www.accasoftware.com/en/trial/edificius>

These tools offer a range of capabilities to support BIM workflows, from basic modeling to advanced features like rendering, analysis, and environmental data integration.

G. Digital Twin

The benefits of using BIM and digital twins together include the following:

1) *Real-time monitoring and predictive analysis*: Digital twins integrate real-time data into 3D models created with BIM/CIM, allowing real-time monitoring of construction project progress. This helps identify and address issues early. Additionally, AI-driven predictive analysis enables proactive identification of potential problems and determination of optimal construction methods.

2) *Optimization of construction processes*: Data collected via digital twins can be reflected in BIM/CIM models to continuously improve construction workflows. For example, analyzing equipment usage and worker movements can lead to more efficient procedures.

3) *Enhanced safety*: The combination of digital twins for real-time monitoring and detailed 3D BIM/CIM models allows for the early detection of potential safety hazards, enabling preventive measures to reduce risks.

4) *Improved maintenance efficiency*: After construction, digital twins can monitor the condition of buildings and infrastructure in real time, reflecting updates in the BIM/CIM model. This enables preventive maintenance and optimized repair planning.

5) *Better collaboration*: By integrating digital twins with BIM/CIM, all stakeholders can share up-to-date project information, improving communication and collaboration.

6) *Advanced simulation capabilities*: Incorporating real-time data from digital twins into BIM/CIM models facilitates more precise simulations, allowing for accurate predictions of design changes' impacts and optimization of construction methods.

7) *Improved lifecycle management*: Continuous data collection and utilization across the design, construction, operation, and maintenance phases enable optimization throughout the entire lifecycle of buildings and infrastructure.

8) *Faster and more accurate decision-making*: Combining real-time data with detailed 3D models enhances decision-making speed and accuracy.

The integration of digital twins and BIM/CIM significantly improves visualization, efficiency, and quality in construction projects. It also plays a crucial role in advancing digital transformation in the construction industry. To fully leverage these technologies, establishing robust data management systems and enhancing the skills of personnel involved are essential.

H. BIM File (IFC Format) to GIS File (GeoTiff Format)

"BIM file workspace" (Revit or IFC file) to geodatabase dataset base map information DEM 1m mesh²². Assign an appropriate geographic coordinate system to the BIM model. In Japan, JGD2011 (plane rectangular coordinate system) is often used. Extract necessary information from the BIM model (e.g. topographical data, building outline, etc.). Convert the extracted data into a raster format (GeoTIFF, etc.).

The method of converting BIM data to GeoTiff that can be displayed in GIS such as QGIS is as follows:

1) *AutoCAD Civil 3D*: Read BIM data and export to GIS format

2) *FME*²³ (*Feature Manipulation Engine*): Tool specialized in conversion between various formats

3) *QGIS*: Open-source GIS software that allows conversion using plug-ins

4) *Resolution setting*: Set the appropriate resolution when converting to GeoTIFF

5) *Attribute information retention*: Reflect important attribute information contained in the BIM model in the GIS data

6) Utilize detailed 3D models created with BIM for geospatial analysis (promoting integration of BIM and GIS, enabling more effective data utilization at each stage of construction project planning, design, construction, and maintenance)

Below is the Python code that makes this possible. First, convert the BIM data to an intermediate format (e.g. GeoJSON²⁴) and then convert it from the intermediate format to GeoTIFF. The code works in the following steps:

1) The `bim_to_geojson` function reads the BIM data and converts it to GeoJSON format

2) Assumes that the input is already in GeoJSON format
If it uses real BIM data (e.g. IFC files), it will need to parse the data using an appropriate library (e.g. `IfcOpenShell`) and convert it to GeoJSON format.

Next, the `geojson_to_geotiff` function converts the GeoJSON data to a GeoTIFF. This function does the following:

1) Calculates the extent of the GeoJSON data
2) Determines the raster size based on the specified resolution

3) Creates an empty raster using NumPy
4) Draws each feature in the GeoJSON to the raster
5) Saves as a GeoTIFF using the rasterio library

To run this code, the following libraries are required:

```
rasterio  
numpy  
shapely
```

²² <https://www.gsi.go.jp/gazochosa/gazochosa61002.html>

²³ [https://en.wikipedia.org/wiki/FME_\(software\)](https://en.wikipedia.org/wiki/FME_(software))

²⁴ <https://ja.wikipedia.org/wiki/GeoJSON>

These libraries can be installed with the following command of “pip install rasterio numpy shapely”. The Python code for this is as follows:

```
import json
import rasterio
from rasterio.transform import from_bounds
import numpy as np
from shapely.geometry import shape
from shapely.affinity import scale

# Step 1: Function to load BIM data and convert to GeoJSON
def bim_to_geojson(bim_file):
    # Implement the code to load and analyze BIM data here
    # In this example, it assumes that the data is already in GeoJSON format
    with open(bim_file, 'r') as f:
        geojson_data = json.load(f)
    return geojson_data

# Step 2: Function to convert GeoJSON to GeoTIFF
def geojson_to_geotiff(geojson_data, output_file, resolution=0.1):
    # Get GeoJSON extent
    features = geojson_data['features']
    geometries = [shape(feature['geometry']) for feature in features]
    all_geoms = shape({'type': 'MultiPolygon', 'coordinates': [geom.coordinates
for geom in geometries]})
    minx, miny, maxx, maxy = all_geoms.bounds
    # Calculate raster size
    width = int((maxx - minx) / resolution)
    height = int((maxy - miny) / resolution)
    # Create raster data
    raster = np.zeros((height, width), dtype=np.uint8)
    # Draw each feature in GeoJSON to a raster
    for feature in features:
        geom = shape(feature['geometry'])
        geom = scale(geom, xfact=1/resolution, yfact=1/resolution, origin=(minx,
miny))
        coords = np.array(geom.exterior.coords).astype(int)
        rasterio.features.rasterize([coords], out=raster,
transform=from_bounds(minx, miny, maxx, maxy, width, height))

# Save as GeoTIFF
with rasterio.open(
    output_file,
    'w',
    driver='GTiff',
    height=height,
    width=width,
    count=1,
    dtype=raster.dtype,
    crs='+proj=latlong',
```

```
transform=from_bounds(minx, miny, maxx, maxy, width, height),
) as dst:
    dst.write(raster, 1)

# Main process
bim_file = 'input.json' # BIM data file (assuming GeoJSON format in this
example)
output_file = 'output.tif'
geojson_data = bim_to_geojson(bim_file)
geojson_to_geotiff(geojson_data, output_file)
print(f"Conversion completed. Output file: {output_file}")
```

IV. CONCLUSION

This study proposes a method for generating 2D exterior images from sketches using generative AI (Gemini 1.5 Pro) and a technique for converting 2D images into 3D models using the free tool TriPo. Additionally, it demonstrates how 3D models can be created using the free tool GauGAN, making it easier to visualize and verify building exteriors.

The study also presents a process for creating design drawings with the free tool SketchUp and generating BIM data using generative AI (Claude 3.5 sonnet). While the BIM data generated may not be fully complete, the findings demonstrate the feasibility of using free tools for this purpose.

Furthermore, a method is proposed for converting BIM data (IFC files) into GeoTiff format using Python code, illustrating that GIS visualization can be achieved with free tools like QGIS. Lastly, the study suggests a method for generating digital twins using SketchUp and shows that simulations in virtual environments are possible, enhancing the scope of design and analysis in construction projects. This approach is quite new and has original ideas. The conventional models and methods are traditional expensive BIM model creation and are not linked to the GIS system at all.

A. Future Research Works

Although it is confirmed that the proposed methods and systems can be feasible, detailed design of BIM model requires more detailed information. Also, CG design and environmental parameter settings are required for creation of digital twin, fundamental digital twin can be created by the proposed method though. Therefore, one of the business use cases will be attempted in the near future.

AUTHOR'S PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January 1979 to March 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science in April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor at Brawijaya University. He also is an Award Committee member of ICSU/COSPAR. He also is an adjunct professor of Nishi-Kyushu University and Kurume Institute of Technology Applied AI Research Laboratory. He wrote 119 books and published 728 journal papers as well as 569 conference papers. He received 98 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>

Marked Object-Following System Using Deep Learning and Metaheuristics

Abstract—This paper presents a deep learning methodology for a marked object-following system that incorporates the YOLOv8 (You Only Look Once version 8) object identification model and an inversely proportional distance estimation algorithm. The primary aim of this study is to develop a marked object-following algorithm capable of autonomously tracking a designated marker while maintaining a suitable distance through advanced computer vision techniques. In this study, a marked object is defined as an object that is explicitly labeled, tagged, or physically marked for identification, typically using visible markers such as QR codes, stickers, or distinct added features. Central to the system's functionality is the YOLOv8 model, which detects objects and generates bounding boxes around identified target classes in real-time. The proposed marked object-following algorithm utilizes the distance estimation method, which leverages fluctuations in the bounding box width to determine the relative distance between the observed user and the camera. A pathfinding algorithm was created using tabu search and a-star to avoid obstacle and generate a path to continue following the marker object. Furthermore, the system's efficacy was assessed using critical performance metrics, including the F1-score and Precision-Recall. The YOLOv8 model attained an F1-score of 0.95 at a confidence threshold of 0.461 and a mean Average Precision (mAP) of 0.961 at an IoU threshold of 0.5 for all target classes. These results indicate a high level of accuracy in object detection and tracking. However, it is important to note that this algorithm has close door and controlled environments.

Keywords—Object detection; YOLOv8; distance estimation; A-star; tabu search

I. INTRODUCTION

In today's technology-driven world, artificial intelligence (AI) and robotics are revolutionizing various domains, including human interaction and navigation. Autonomous systems capable of tracking and following individuals are highly beneficial in settings such as crowded environments, warehouses, and other dynamic areas. These systems have the potential to enhance efficiency and safety by providing precise and adaptive navigation in real-time. Recent studies have highlighted the advancements in deep learning techniques, particularly in object detection, which significantly improve the capabilities of these systems in complex environments [1][2][3]. The motivation behind this research arises from challenges faced in environments where autonomous systems must reliably track a marked object, particularly in dynamic and crowded areas. Traditional systems have frequently struggled to effectively identify and focus on the correct item in such situations

due to occlusions, competing visual elements, and contextual complications [4][5]. These constraints underscore the need for a stronger and more efficient system.

This study introduces a marked object-following algorithm that integrates deep learning and metaheuristic techniques to address these challenges. Leveraging the YOLOv8 (You Only Look Once version 8) object detection framework, the system ensures robust object recognition and tracking. YOLO has been recognized for its ability to perform real-time object detection with high accuracy, making it suitable for dynamic environments [6] [7]. A distance estimation algorithm based on fluctuations in bounding box width enables the system to maintain an optimal distance from the marked object, thereby preventing collisions. Furthermore, the inclusion of A-star pathfinding and the Tabu Search metaheuristic algorithm enhances the system's ability to navigate around obstacles and generate efficient paths in real-time scenarios [8] [9].

The development of a reliable and effective marked object-following system that can track a designated marker on its own while adjusting to environmental changes is the main goal of this research. A marked object is defined as an object that is explicitly labeled, tagged, or physically marked for identification, typically using visible markers such as QR codes, stickers, or distinct added features. This project aims to use YOLOv8 to create a reliable marked object-following algorithm for object tracking and detection in real-time. Additionally, the design and implementation of a distance estimation method that dynamically calculates the relative distance between the observed user and the camera are crucial components of this research. The integration of pathfinding algorithms, such as A-star and Tabu Search, enables obstacle avoidance and efficient navigation [8] [10].

Furthermore, this research is significant because it addresses the growing need for intelligent and adaptive tracking systems in real-world applications. By combining advanced deep learning models with metaheuristic algorithms, the proposed system offers a novel solution that ensures accuracy, reliability, and adaptability. The findings of this study aim to contribute to the advancement of autonomous tracking technologies, paving the way for their deployment in diverse practical scenarios [11] [2]. The integration of deep learning techniques in object detection has shown promising results, enhancing the performance of tracking systems in complex environments [2] [12].

II. RELATED STUDIES

In the past few years, LiDAR technology has become a key way of detecting people in robotic systems. Some researchers have been employing LiDARs for precise individual detection and tracking using the ability to measure the distance and location of the target person versus the robot. LiDAR sensors provide 3D data with high resolution, which allows robots to identify and follow a specific human target who is even moving in a dynamic environment [13], [14], [15]. Using LiDAR as the only source of environmental information is a highly unique task, and there has been little study in this area. Some human detection and tracking research has relied only on LiDAR technology. Human detection using LiDAR has been performed on both stationary robots [16], [17], employing several stationary LiDAR sensors [18], and mobile robots [19], [20].

On the other hand, researchers use machine learning for human detection and finding the robot. Machine learning has turned out to be key in providing a human-tracking robot's potential. The presented procedures use enormous amounts of data for training models that would notice the human features and movements, thus finding the correct identification in different scenes. Besides, the machine learning methods are used to help with robot localization by interpreting sensor data, thus finding the position of the robot in relation to the discovered human. Furthermore, this part will elaborate on the different machine-learning methods utilized for human detection and robot localization in these systems along with their advantages, and show the elements of integration [21], [22], [23]. Suet Peng Yong et al. [24] demonstrate human object recognition using deep learning algorithms with the use of a 3DR solo drone equipped with a GoPro camera for real-time surveillance and coverage of forest areas. Suet Peng Yong et al. provide knowledge of video processing using convolution neural networks and how to select the perfect dataset for a specific project.

Ashish U. Bokade et al. [25] discuss video surveillance utilizing a smartphone and Raspberry Pi. This allows you to watch and control the mobility of the robot using Raspberry Pi. The detection procedure may be completed successfully, and the findings can be viewed on the user's smartphone. Jun Zhang et al. [26] provide leaping robot standards, which are superior to traditional robots that cannot walk on rough surfaces or jump to a greater distance. It describes how a PIR sensor and a jumping robot build a zig-bee WSN that allows them to communicate with one another while also allowing the freedom to leap on stairs to reach higher surfaces from the ground up to a range of 105 cm.

Additionally, other researchers use OpenCV as the solution for human-tracking robots, which are used to track the human target during different movements while ensuring a constant distance between the human target and the robot. OpenCV (Open Source Computer Vision Library) is a set of versatile tools for real-time computer vision and it is actually a quite nice alternative for implementing human tracking in robotics. Researchers can write algorithms to detect and follow the humans by OpenCV that direct the robot to be safe and as close as possible to the optimal. In this section, OpenCV implementation in human-following robotic systems such as a detailed overview of its strengths, challenges, and its function

in giving the robots better agility and navigation precision will be explored [25], [26], [27], [28], [29], [30].

Meanwhile, color-based detections for target-following robots have been used by certain researchers since they are one of the possible good approaches to identifying a target, as demonstrated by researchers in Sefat S. et al. and MNA Bakar et al. S. Sefat et al. employed red color and 3D circular shape (red ball) detection, along with a Kalman filter, to predict the position of the individual to be followed. Although MNA Bakar et al. employed color-based detection, it used a special marker with a distinct form to help the robot recognize its target. The yellow hue was tested and had an 80% detection rate. However, MNA Bakar et al. had no obstructions in its route, as opposed to S. Sefat et al., which avoided obstacles while employing sonar sensors [31], [32].

Moreover, the investigation of the human body temperature through a thermal image in real-time is a well-known application of infrared technology by other researchers. The safety and security of a particular place, such as a train station, can be increased by the technology of human presence detection. As a result, the detector is a passable of sensors and a microcontroller. The detector can know the distance between the human and the reference point by using a camera. Sensor equipment is used in the way automated systems of various kinds are employed for people monitoring and various other applications. Infrared sensors have also been used to determine the human walking path. Thanks to such a device, robots can easily generate an exact following motion toward the human that they accompany. By defining the person's thermal footprint, robots can undertake good and continuous surveillance, which serves as a sufficient mechanism for follow-up. A detailed examination of the infrared technology application in robotic systems will be given in this section, including its advantages in human detection, movement predictions, and the overall enhancement of human-following robotic behaviors will be outlined [33], [34], [35], [36].

According to Montiel-Ross *et al.* [37], world perception, path planning and generation, and path tracking make up the robot navigation challenge. By choosing adequate sensor suites that can give the robot controller acceptable environmental feedback, world perception is achieved. Simultaneous Localization and Mapping (SLAM), a well-established technique that allows vision-based imaging equipment to visualize the surrounding depth map, is one of the best solutions for this purpose. Processing of this data can yield the locations of obstacles, targets, and the robot itself. The disadvantage is that in environments with unclear structures, SLAM performs less well [38]. In addition to being computationally demanding, SLAM has significant processing expenses [39]. According to Nowicki *et al.* [40], sudden and erratic motions of its sensing devices also cause SLAM to malfunction. Given that all of the CARMi sensors are installed on the same mobile platform, an incomplete mapping approach might be more appropriate. Al Arabi *et al.* [41] showed that partial mapping may be accomplished with just one rotating rangefinder by converting the data into a relative depth image of the surrounding area. The revolving depth camera configuration on CARMi may make this method useful.

The study of path planning and generation has a long history, and both heuristic and classical methods are still

widely used to prevent collisions and arrive at target locations. The robot that follows a human adds another level of complexity by needing to approach a moving target while keeping a set distance behind it. The path planning system is either “passive” or “anticipative,” according to Ziyou Wang *et al.* [42]. An “anticipative” system uses a velocity model [42] or a dynamically updated version of the Monte Carlo algorithm [39], [43] to predict the possible movements of a human target. Kalman filters, neural networks, fuzzy logic, and similar combinations [44], [45]. Since these techniques also come with high processing costs, it could be preferable for the CARMI navigation model to be “passive,” in which the robot reacts to changes in its surroundings or landmarks in a reactive manner [46].

Additionally, some other researchers utilize depth cameras as well as a selective set of limited proximity sensors. The overall approach of intelligent systems like robots consists of exact, desired-oriented human-tracking algorithms, which keep the robot on the right path and in the right direction minimizing the motion needed. The depth camera will be another evolutionary change in enabling the precise tracking of human targets in a 3D environment, whereas lasers give humans feedback on how far they are. This technology offers robots conventional control functions, like endpoint settings which provide machine-to-human interfacing inside factories or assembly facilities. This part will go deep in the analysis of the use of depth cameras and sensor fusion in these robotic systems for following humans, mainly by the help of them in improving target tracking and obstacle navigation [47], [48], [49].

III. METHODOLOGY

A. Methodology Overview

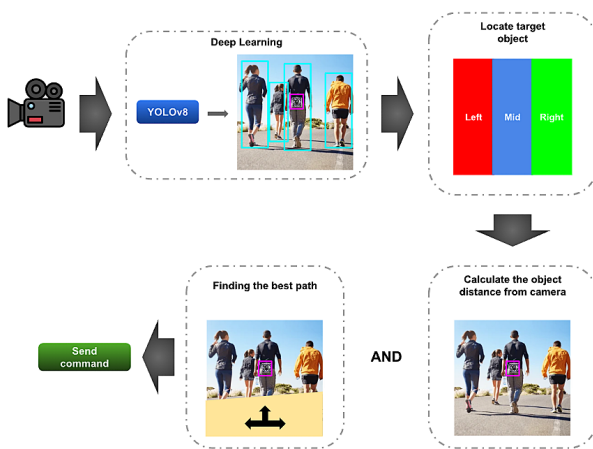

Fig. 1. Conceptual framework.

Fig. 1, titled “Conceptual Framework,” depicts the general methodology of the Marked Object-Following System. The system starts with a camera that captures real-world scenes, and the YOLOv8 deep learning model detects objects and defines “notable symbols” for tracking. A distance estimate technique calculates the target’s vicinity using variations in bounding box width, allowing for accurate distance inference.

The video frame is divided into three zones—left, middle, and right—to direct the robot’s movement. The system directs the robot to move left, forward, or right based on the zone in which the target appears. Pathfinding algorithms like as A* and Tabu Search are used for obstacle avoidance and optimal navigation, resulting in efficient and precise target tracking in complicated situations. This framework offers a structured way to integrating deep learning and metaheuristics to create strong object-following apps.

B. Preparation for Model Training

1) Dataset

A large dataset of photos is critical for this research since it serves as the foundation for training the YOLO object detection model, allowing the marked object-following algorithm with collision prevention to function properly. To provide reliable real-time detection and tracking of persons, the dataset should comprise a wide range of human poses, orientations, clothing kinds, and environmental circumstances such as lighting, weather, and busy locations. This diversity allows the model to generalize well to real-world events and consistently distinguish humans from other items. Fig. 2 are the sample dataset that shows individual is wearing the markers that we can detect and monitor.

Fig. 2. Dataset of images.

Additionally, the quality and diversity of the dataset are critical for training the YOLO model because they improve its capacity to recognize persons in difficult surroundings, reduce false positives, and increase detection accuracy. An extensive dataset also prepares the model to face obstacles such as occlusions, overlapping objects, and complicated backdrops, resulting in robust performance. Without a well-curated dataset, the

model's performance will suffer, potentially leading to errors in the system's marked object-following and collision prevention functions.

2) Data Annotation

Rectangular markers known as bounding boxes are used in object detection tasks to show the location and size of items in an image. They are employed in this study to label and annotate the dataset, designating the people that the algorithm must recognize and obey. The YOLOv8 model needs the precise coordinates of the target objects—humans—in each training image in order to learn how to distinguish them from other things in the environment. This is why this step is so important. The model is trained on bounding box-annotated photos, which enables it to anticipate comparable boxes surrounding persons in real-time during deployment, guaranteeing precise tracking and detection. The effectiveness of the marked object-following algorithm with collision prevention depends on the YOLOv8 model's ability to recognize and marked object. This is made possible through the process of building these bounding boxes. An example of an image with bounding boxes is shown in the Fig. 3.

Fig. 3. Examples of bounding box images.

A key challenge in developing an object-following algorithm with collision prevention is the potential for confusion when multiple similar objects are present, as the system might mistakenly track any detected object without a distinguishing feature. In environments where objects lack unique visual characteristics, relying solely on generic detection could result in tracking the wrong target. To address this, the research incorporates distinct logos or markers placed on the intended object, which the YOLOv8 model is specifically trained to recognize as the target class. These markers act as notable symbols, which is shown in Fig. 4, enabling the system to distinguish the designated object from others in the vicinity. By focusing on these specific classes, the algorithm reliably

tracks the intended object, reducing errors and enhancing performance in crowded or dynamic environments. This approach ensures accurate and safe object-following behavior, even in complex settings, by preventing the system from mistakenly tracking unintended objects.

Fig. 4. The four experimental notable symbols.

3) Model Selection

The YOLOv8-nano (YOLOv8n) model is designed to operate at fast speeds on embedded systems and other devices with constrained processing power. Take a look at the Table I below.

TABLE I. PERFORMANCE COMPARISON OF YOLOV8 MODELS [50]

Model	mAP ^{val} 50-95	Speed CPU ONNX (ms)	Params (M)
YOLOv8n	37.3	80.4	3.2
YOLOv8s	44.9	128.4	11.2
YOLOv8m	50.2	234.7	25.9
YOLOv8l	52.9	375.2	43.7
YOLOv8x	53.9	479.1	68.2

With a mean Average Precision (mAP) of 37.3% at the 50-95 Intersection over Union (IoU) threshold, it offers an effective balance between speed and accuracy, achieving an inference time of 80.4 milliseconds when running on a CPU using the ONNX runtime. Its compact architecture, consisting of only 3.2 million parameters, makes it highly suitable for real-time object detection, particularly on low-power processors like the Raspberry Pi. Although larger models, such as YOLOv8-s and YOLOv8-m, provide greater accuracy, their slower inference times (128.4 ms and 234.7 ms, respectively) make them less practical for resource-constrained environments. Therefore, YOLOv8-nano is selected for its efficient performance, ensuring that the marked object-following algorithm can accurately detect and track individuals that are wearing markers in real time while minimizing delay, which is critical for collision prevention and overall system reliability.

C. Proposed Distance Estimation Algorithm

The distance estimation algorithm for this study leverages the width of the detected target class (such as notable symbols) to estimate the relative distance between the object and the camera in a robotic system. The fundamental concept is that the bounding box width, dynamically generated by the YOLOv8 model, provides a reliable reference for gauging distance. As the bounding box width decreases, the target is inferred to be moving further away, while an increase in the width suggests that the object is getting closer to the camera.

The Fig. 5 illustrates relationship between the bounding box width and the distance is inversely proportional. The equation for calculating the distance is as follows.

Fig. 5. Relationship between bounding box width and the camera.

$$\text{distance} = \left(\frac{\text{current_width}}{\text{initial_width}} \right) \times \text{initial_distance}$$

Where:

- *current_width* refers to the detected bounding box width of the target class at a particular moment.
- *initial_width* is the reference bounding box width at a known distance.
- *initial_distance* is the known distance from the camera when the object has the initial width.

This formula assumes that the camera and the object are in fixed, calibrated positions, and the size of the object remains constant. YOLOv8 dynamically detects the bounding box width, enabling real-time and accurate distance estimation based on width variations.

D. Proposed Object-Following Algorithm

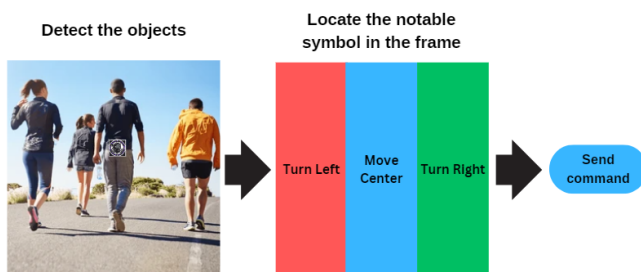

Fig. 6. Object-following algorithm.

Fig. 6 illustrates the proposed marked object-following algorithm. The process begins by detecting objects within the frame, particularly focusing on identifying the notable symbol worn by the designated person or individual. Once the symbol is detected, the algorithm evaluates its position within the frame. Depending on the location of the symbol—whether it is in the left, center, or right of the frame—the system will

send a corresponding command. If the symbol is positioned on the left, the algorithm issues a “Turn Left” command; if it is centered, a “Move Center” command is sent, and if on the right, a “Turn Right” command is executed. This step-by-step analysis ensures precise tracking and directional adjustments, enabling the system to follow the intended target efficiently.

E. Integrated Pathfinding and Distance Estimation System

Algorithm 1 Integrated System Algorithm for Marked Object Following

Inputs: Camera feed, YOLOv8 model, grid dimensions (*max_rows*, *max_cols*), start position *S*, target position *T*, calibration constant *k*, and serial communication interface.

Steps:

1) **System Initialization:**

- Load the YOLOv8 model.
- Set up camera input using *cv2*.
- Define grid dimensions and initialize parameters (*tabu_list*, *distance_threshold*).
- Establish serial communication for robot control.

2) **Distance Estimation and Immediate Movement:**

- Detect objects in each frame using YOLOv8.
- Divide the frame into regions: left, center, and right.
- For each detected object:
 - Identify the class and bounding box width *w_b*.
 - Calculate distance $d = \frac{k}{w_b}$.
 - Send movement commands based on position and distance:
 - Turn Right: If object is on the right.
 - Turn Left: If object is on the left.
 - Move Forward: If object is in the center and $d > 14$ inches.
 - Stop: If $d \leq 14$ inches.

3) **Pathfinding with A-Star and Tabu Search:**

- Generate the global path using A-Star by computing $f(n) = g(n) + h(n)$ for each node.
- Refine the path with Tabu Search:
 - Evaluate neighbors $N(P)$ of the current path *P* and compute the cost $\text{Cost}(P) = \sum f(n)$.
 - Update the *tabu_list* to avoid revisiting sub-optimal paths.
- Adjust the global path based on the marker’s position from the distance estimation module.

4) **Execute Navigation:**

- Follow the refined path while continuously updating the robot’s position using YOLOv8 detections.
- Use real-time corrections to handle dynamic obstacles and deviations.

Output: Efficient navigation to the target position *T* with consistent tracking of the marked object.

In order to effectively locate the best path in complicated surroundings, the pathfinding method integrates the advantages of both A-Star (A*) and Tabu Search. A heuristic-based technique called A* is used to determine the shortest path in a grid or graph between a start point and a target. The pathfinding algorithm is almost similar to the study of Gorro

et al. [51]. It strikes a balance between an estimate of the remaining distance to the target and the cost of the road already taken. Because of these two factors, A* is a popular and effective solution for pathfinding issues. However, because it may revisit less-than-ideal solutions, A* may lose effectiveness in areas with a high density of barriers or recurrent paths.

Tabu Search is used into this process to overcome this restriction. The “tabu list,” a memory component added by Tabu Search, keeps account of recently traveled routes or moves that have been judged to be less-than-ideal. Tabu Search compels the algorithm to investigate alternate options, even if they seem less promising at first, by forbidding the re-exploration of these routes. This investigation promotes the finding of globally optimal pathways and aids in avoiding local minima.

A*, the first step in the combined algorithm, creates an initial path from the start to the destination. After that, Tabu Search takes control and iteratively refines this path. As long as it is not in the tabu list, the best neighbor is chosen as the current path after adjacent paths are assessed according to their costs at each stage. Because the tabu list is dynamically updated, recent errors or less-than-ideal routes are kept in mind and avoided in subsequent cycles. Until a certain number of iterations is reached or no more advancements can be made, the process keeps going.

In complex grids or maps, where the existence of barriers or constraints could cause traditional algorithms to be misguided, this hybrid approach works very well. The method produces a stable and adaptable solution by utilizing the advantages of A* for initial pathfinding and Tabu Search for iterative refining. This makes it appropriate for applications like robotics, navigation, and logistical planning.

F. Evaluation Metrics

These metrics help in determining how well the model is able to identify humans in various scenarios, ensuring that the robotic system can perform its tasks accurately and reliably. The research can efficiently analyze the model’s strengths and weaknesses, direct the tuning of hyperparameters, and make well-informed decisions about model optimization to achieve the desired performance in real-world environments by utilizing specific evaluation metrics like Precision, Recall, Mean Average Precision (mAP), and F1-score.

1) Precision

The ratio of true positive detections to the total of both true positive and false positive detections is known as precision. It assesses how well the model distinguishes, among all the detected things, only the pertinent objects—in this example, humans. High precision reduces false positives by increasing the likelihood that the YOLOv8-nano model’s predictions of humans are accurate. High precision is necessary to prevent the robot from unintentionally following non-human things in the setting of a marked object-following robotic system. This is important for both efficiency and safety.

$$\text{Precision} = \frac{\text{True Positive}}{(\text{True Positive} + \text{False Positive})}$$

2) Recall

The ratio of real positive detections to the total of false negatives and true positives is known as recall. It illustrates how well the model was able to identify every pertinent object (people) in the dataset. High recall means that the model is capable of detecting most of the humans present in the environment, minimizing false negatives. In this study, a high recall is important because, in the event that a human is not detected, the robotic system may not follow its intended path, which could be harmful in scenarios where it is used for public space guidance or healthcare assistance.

$$\text{Recall} = \frac{\text{True Positive}}{(\text{True Positive} + \text{False Positive})}$$

3) Mean Average Precision (mAP)

A comprehensive statistic called Mean Average Precision (mAP) provides an overall measure of accuracy by assessing the model’s performance across various Intersections over Union (IoU) thresholds. The model’s ability to balance precision and recall is indicated by a single performance score that is obtained by combining the two criteria. Because it aids in understanding the trade-offs between minimizing false positives (precision) and detecting as many humans as feasible (recall), mAP is particularly significant in this research. A greater mAP is a useful parameter for optimizing human detection in the YOLOv8-nano model since it shows that the model performs well in both areas.

$$\text{mAP} = \frac{1}{k} \sum_{i=1}^k \text{AP}_i$$

4) F1-score

The F1-score is a measure that provides a balance between Precision and Recall, calculated as the harmonic mean of the two. When it comes to striking a balance between false positives and false negatives, it is especially helpful. In this research, the F1-score is essential because it gives a more holistic view of the model’s performance. A high F1-score shows that the model is successful in capturing all important detections and is accurate in identifying humans. This is especially important in applications like robotic assistance and navigation where misidentifying a non-human object (false positive) or missing a human (false negative) can have serious repercussions.

$$\text{F1-score} = 2 \times \frac{(\text{Precision} \times \text{Recall})}{(\text{Precision} + \text{Recall})}$$

IV. RESULT

A. YOLOv8 Performance

Fig. 7. Class distribution.

Monitoring the class distribution (Fig. 7) reveals significant class imbalance, with the “person” class dominating the dataset. This imbalance is a critical issue in object detection tasks [52], [53], as it can lead to over-optimization for frequent classes and under-performance for rarer ones, such as “mark4”. Techniques like data augmentation, oversampling, or loss re-weighting [54], [56] could address this and enhance performance across all classes.

In particular, the model may become too optimized for detecting the more frequent class (“person”) while struggling to reliably recognize less frequent ones (“mark4”). Regular analysis of this distribution allows researchers to take corrective action, such as boosting underrepresented classes or employing advanced approaches to reduce class imbalance. By addressing these issues, the model’s overall accuracy and generalization capabilities across all classes can be significantly improved, enhancing its robustness in real-world applications.

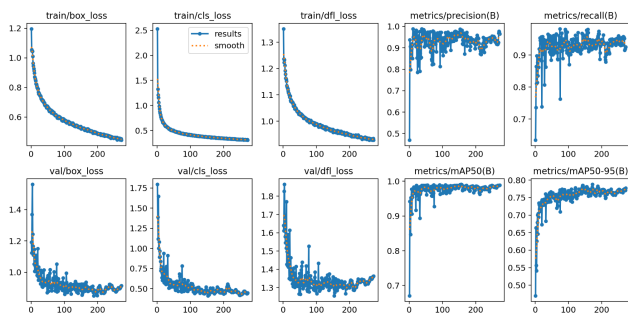

Fig. 8. Result graph of YOLOv8-nano model.

Fig. 8 illustrates the training and validation graphs for key metrics and loss functions in the proposed marked object-following algorithm with collision prevention, based on YOLOv8 object detection. The training loss curves,

which include bounding box regression (train/box_loss), classification loss (train/cls_loss), and distributional focal loss (train/df_l_loss), show a consistent decline as training progresses, indicating that the model is effectively minimizing prediction errors. This steady reduction in training losses suggests that the model is becoming more accurate in identifying and classifying objects while refining the predicted bounding box coordinates.

The training and validation metrics (Fig. 8) show consistent declines in losses, indicating effective learning and generalization. Compared to YOLOv4-tiny [55], the YOLOv8-based model achieves higher mAP values (0.961 at IoU@0.5), demonstrating competitive detection performance. However, slight precision-recall drops for the “person” class align with findings in [53], suggesting the need for improved handling of dominant classes in imbalanced datasets. Incorporating techniques like focal loss or semi-supervised learning [56], [57] could mitigate this challenge.

The validation losses (val/box_loss, val/cls_loss, val/df_l_loss) exhibit a similar downward trend, though with natural fluctuations, indicating the model’s generalization to unseen data. Precision and recall metrics remain high and stable, which demonstrates the model’s ability to maintain a balance between correctly identifying true positives and minimizing false positives. The mAP@0.5 and mAP@0.5-0.95 values show continuous improvement, signaling enhanced detection performance across various Intersection over Union (IoU) thresholds.

These graphs provide insight into the model’s training dynamics, showcasing a well-balanced process where the algorithm is consistently improving in both training and validation phases. The steady convergence of losses and strong performance metrics suggest the model is learning effectively without overfitting, ensuring reliable detection and tracking in real-time marked object-following scenarios.

Fig. 9. Confusion matrix for YOLOv8-nano model.

The Confusion Matrix serves as an effective tool for assessing the performance of the YOLOv8-nano model by illustrating its accuracy in predicting various classes. This table presents the frequency of actual versus predicted classes, allowing for an evaluation of the alignment between the

model's predictions and the true labels. Analyzing the confusion matrix in the context of YOLOv8 helps identify specific cases where the model successfully classifies an object or incorrectly identifies it as another class. This insight is crucial for recognizing the model's strengths and weaknesses, enabling targeted improvements to enhance accuracy. By examining the matrix, researchers can identify which classes are frequently confused and make necessary modifications to training data, model architecture, or hyperparameters to rectify these issues.

Fig. 9 is a detailed review of the confusion matrix for the YOLOv8-nano model reveals that the "mark2" class is accurately predicted 93 times, with misclassifications occurring once each as "mark3" and "person." The "mark5" class achieves 53 correct predictions, with minor misclassifications as "mark3" twice and as "background" once. The "mark3" class exhibits perfect performance, yielding 119 correct predictions without any misclassifications. The "mark1" class is accurately predicted 85 times but is mistaken for "mark5" once and "background" twice. The "person" class demonstrates high accuracy with 552 correct predictions, though it is confused with the "background" class on 10 occasions. Finally, the "table" class is correctly identified 181 times, with one misclassification as "person". The model's overall performance is not greatly affected by these minor misclassifications. The YOLOv8-nano model has good prediction ability and little confusion between various object classes in spite of these small inaccuracies.

Fig. 10. Precision-recall curve.

Fig. 10 displays the Precision-Recall (PR) Curve for the various classes within the dataset. This curve visually illustrates the balance between precision and recall for each class, highlighting the model's effectiveness in correctly identifying true positives while reducing false positives. The results indicate that most classes attain very high precision and recall values, with both metrics nearing 1.0, which demonstrates the model's strong capability in detecting these objects with minimal errors. However, the "person" class exhibits slightly lower precision and recall values than the other classes, suggesting potential challenges in accurately detecting and distinguishing humans within the dataset. The overall mean Average Precision (mAP) at an Intersection over Union (IoU) threshold of 0.5 across all classes stands at 0.961, signifying an excellent

balance of high precision and recall. This elevated mAP value indicates that the model is well-optimized for precise object detection, ensuring reliable performance in identifying and classifying the various objects analyzed in this study.

The Precision-Recall Curve (Fig. 10) illustrates the model's strong detection capabilities. However, lower precision for the "person" class highlights challenges in distinguishing humans in cluttered environments. Fine-tuning anchor box sizes or using hybrid feature extractors, as shown in [55], could enhance performance.

Overall, the results validate the proposed marked object-following algorithm, achieving reliable detection and collision prevention in real-time scenarios. The high F1-scores across classes (Fig. 11) and stable precision-recall metrics ensure robust tracking. These findings demonstrate the algorithm's potential for deployment in assistive robotics and autonomous systems. Future work could integrate multi-sensor fusion or explore adaptive learning strategies [54], [56] to further improve robustness.

Fig. 11. F1-confidence curve.

As shown in the Fig. 11, the F1-scores for the different classes maintain high values at moderate confidence levels, with an overall peak of 0.95 for all classes at a confidence threshold of 0.461. This indicates a strong balance between precision (correctly identifying the object) and recall (detecting most of the relevant objects) for each class. The curves for each class follow a similar trend, with a sharp drop-off beyond the optimal confidence threshold, suggesting that the model is highly accurate up to a certain point, after which false positives start to increase.

This curve illustrates how well the model can detect different types of objects, meaning that the marked object-following algorithm can track the designated person (represented by the "person" class) and distinguish it from the other target classes, which include the table and various markers. Accurate object identification is ensured by maintaining a high F1-score across these classes, which helps to prevent collisions and ensures reliable human following.

B. Implementation of Experimental Algorithms

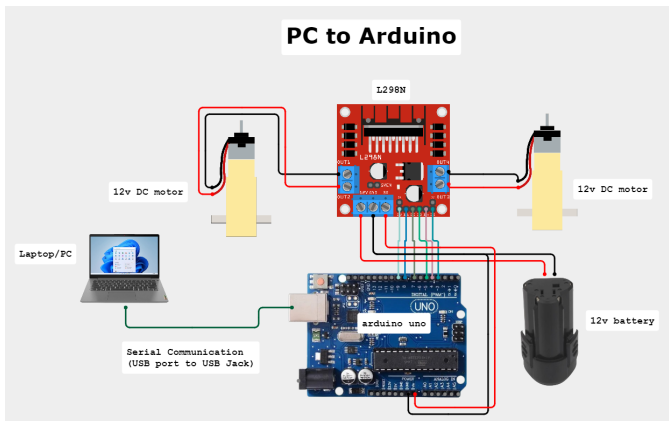

Fig. 12. The circuit diagram for the basic robot.

Fig. 12 illustrates the experimental prototype configuration used to test the marked object-following system. The circuit diagram details the connections between a laptop or PC, an Arduino Uno board, an L298N motor driver module, two 12V DC motors, and a 12V battery. The laptop/PC establishes a USB connection with the Arduino Uno, facilitating serial communication for data exchange and control commands. The Arduino Uno is linked to the L298N motor driver module, which regulates the two 12V DC motors by adjusting their speed and direction based on the signals received. The motors receive power from the 12V battery, which is directly connected to the L298N module, supplying the required voltage for operation. This configuration enables precise motor control through the Arduino, allowing commands from the PC to direct the motors via the L298N driver, effectively simulating navigation and following behaviors in response to target detection and distance estimation algorithms.

During the Test 1 the robot's ability to follow a sample image held by a human in a simple environment. The robot efficiently detects the target image and maintains a consistent following distance, showcasing its tracking accuracy and responsiveness. The straightforward setup allows the robot to smoothly follow the human, effectively illustrating its basic operational capability and fundamental functionality in a controlled, uncomplicated scenario.

Finally, during Test 2 the robot's capability to follow a human in a complex environment, effectively navigating without causing disruptions. When the human passes near the right green line, the robot seamlessly turns right, demonstrating a prompt and accurate response without any delay or difficulty in executing the turn. Similarly, when approaching the left green line, the robot exhibits the same level of efficiency, turning left without encountering any issues. This demonstrates the robot's robust decision-making and adaptability, ensuring reliable marked object-following behavior even in challenging environments.

V. CONCLUSION

The primary aim of this study was to develop algorithms capable of accurately detecting and following a designated

marked object while estimating the distance between the user and the system in real-time, utilizing the YOLOv8 model for object detection. An obstacle avoidance was created using a distance estimation algorithm with the pathfinding A* and Tabu search algorithm. The model's performance was evaluated through key metrics, including the F1-score and Precision-Recall. The F1-Confidence curve indicated a robust F1-score of 0.95 for all classes at a confidence threshold of 0.461, reflecting a well-balanced performance between precision and recall, effectively minimizing false positives and false negatives in detecting the target classes. Additionally, the Precision-Recall curve showcased the effectiveness of the YOLOv8 model, achieving an overall mean Average Precision (mAP) of 0.961 at an Intersection over Union (IoU) threshold of 0.5 for all classes. This high mAP value demonstrates the model's reliability in accurately identifying and tracking the target classes while maintaining consistent detection performance.

The successful integration of a YOLO-based detection model with a distance estimation, path finding algorithms (A*) and Tabu Search highlights the system's potential for real-world applications. Although the system faces limitations in handling visual disturbances and detecting objects from side angles, it has produced promising results under controlled conditions. The achieved F1-score and Precision-Recall values underscore the model's effectiveness, providing a solid foundation for further enhancements and potential applications in various environments. The distance estimation algorithm and the path finding A* and Tabu search are crucial for detecting potential collisions and obstacle avoidance with marked objects, and the inclusion of an obstacle detection feature could further mitigate collision risks.

ACKNOWLEDGMENT

We extend our profound gratitude to Cebu Technological University and Cebu Normal University for their unwavering support throughout the course of this research endeavor.

Hawk-Eye Deblurring and Pose Recognition in Tennis Matches Based on Improved GAN and HRNet Algorithms

Weixin Zhao

Department of Physical Education and Sports Science, Fuzhou University, Fuzhou, 350108, China

Abstract—In tennis matches, the Hawk-eye system causes blurry trajectory judgment and low accuracy in player posture recognition due to rapid movement and complex backgrounds. Therefore, the research improves the backbone network and iterative attention feature fusion mechanism of deblur generative adversarial network version. At the same time, Ghost, Sandglass module, and coordinate attention mechanism are used to optimize the high-resolution network, and a new model for deblurring and pose recognition of Hawk-eye images in tennis matches is proposed by integrating the improved generative adversarial network and high-resolution network. The new model achieved an information entropy value of 11.2, a peak signal-to-noise ratio of 29.74 decibels, a structural similarity of 0.89, a minimum parameter size of 4.53, and a running time of 0.25 seconds on the tennis tracking dataset and the Max Planck Society human posture dataset, which was superior to current advanced models. The highest accuracy of deblurring and pose recognition for the model under different lighting intensities was 92.44%, and the highest improvement rate of video frame quality was 18%. From this, the model has significant advantages in deblurring effect, posture recognition accuracy, parameter quantity, and running time, and has high practical application potential. It can provide an advanced theoretical reference for tennis match refereeing and technical training.

Keywords—DeblurGANv2; HRNet; tennis; hawk-eye system; deblurring; pose recognition

I. INTRODUCTION

In tennis matches, the Hawk-eye system, as a high-precision technology application, has been widely used in referee decision-making, motion analysis, and other fields worldwide. The Hawk-eye system captures image data within the field through multiple high-speed cameras and uses image processing algorithms for real-time calculation and analysis, providing judgments on whether the ball is within or outside the boundary. In addition, the movements of players in tennis matches are complex and have high spatiotemporal variations. Accurately capturing the players' motion posture is the key to improving the accuracy of Hawk-eye system judgment [1-2]. Pose recognition technology can accurately capture the movement information of athletes by analyzing their body position, movement trajectory, etc., providing a more precise player behavior model for the Hawk-eye system and improving the reliability of judgment results. F. Meng et al. introduced a hybrid neural network to optimize target feature extraction and constructed a novel Hawk-eye detection model to improve the visual detection level of tennis in the sports industry. The

model achieved a tennis motion tracking accuracy of 0.694 under grayscale feature conditions, which was the highest among all testing methods [3]. Y. Zhao et al. proposed a lightweight tennis Hawk-eye detection scheme combining "You Only Look Once version 5" (YOLOv5) to address the inefficiency of traditional tennis detection algorithms. Compared with traditional methods, experimental results showed that this algorithm reduced model parameters by 42% and computational complexity by 44%, while improving detection accuracy by 2% [4]. Y. Yang et al. built a new tennis trajectory prediction method by combining artificial neural network detection algorithm and stereo vision. The experiment showed that this method had high reliability and robustness, effectively improving the prediction ability of tennis trajectory [5]. D Gao et al. built a deep learning driven small object automatic detection method to address the difficulty of small object detection in tennis videos. The experiment showed that this method performed well in the integrity, recognition accuracy, and detection speed [6]. Y. Ke et al. proposed an object detection algorithm on the basis of deep learning aimed at handling advanced visual tasks such as tennis. This algorithm combines prior knowledge of tennis impact areas. The experimental results showed that it could provide high detection accuracy and faster detection speed, effectively improving the accuracy and stability of tennis impact detection [7].

Generative Adversarial Networks (GANs) are powerful deep learning models that have shown great potential in tasks such as image generation, denoising, and deblurring [8]. Bian J et al. argued that detecting dense movements from fast-moving objects in sports videos remained challenging. To this end, a novel table tennis detection model by combining GAN and P2ANet was proposed. The model could achieve an average accuracy of 88.47% for the localization and recognition of 8 types of table tennis movements, while improving the detection robustness [9]. Ghezelsefloo H R et al. proposed an auxiliary calibration model for Hawk-eye detection after improving the GAN algorithm to effectively reduce the error in Hawk-eye detection in sports events. The model had a success rate of 92.17% in assisting correct judgments in 130 sports, and had significant practical value [10]. Peng X et al. constructed a video pose detection model for ball players by combining sensor image acquisition with GAN and Modbus. The performance of the model on Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM) was about 4.5 and 0.143 higher than other algorithms, respectively [11]. In

addition, High-Resolution Network (HRNet) is an excellent deep learning model that excels in processing detailed information in high-resolution images and is widely used in fields such as image segmentation, object detection, and pose recognition. Nguyen H C et al. proposed an automatic combined human pose estimation model by combining HRNet and YOLOv5 to improve the accuracy of human motion pose estimation. The processing time on a 3.3-megapixel dataset was 55FPS, and the highest accuracy of human keypoint detection was 98.24% [12]. Li Y combined HRNet to construct a monocular video motion capture method, which optimized it for human motion reconstruction problems such as floating, ground penetration, and sliding. This method achieved a good balance between accuracy and frame rate, and had significant detection advantages [13]. Fitzpatrick A et al. In order to strengthen the accuracy of the hawk-eye monitoring system under different serve and return strategies, the researchers proposed a hawk-eye-assisted detection model with multimodal data training and convolutional graph neural network processing. The experimental results show that the method achieves higher detection accuracy and greater stability for a variety of different serving and hitting motions [14]. Ning T et al. In order to address the limitations of computer vision-assisted table tennis ball detection, the researchers proposed a real-time computational method for determining the landing point of a table tennis ball. The experimental results showed that the method achieved a detection speed of 45.3 fps, and the key frame extraction method correctly recognized the landing point frames with an accuracy rate of more than 93.3% [15].

In summary, traditional Hawk-Eye systems mostly rely on classical deblurring algorithms, but these methods usually cannot effectively deal with fast motion and multi-angle shooting conditions, resulting in image distortion and inaccurate pose estimation. In addition, while existing pose recognition methods are able to achieve better results in static or slow scenes, they still exhibit large errors in dynamic tennis match scenarios, especially when players are moving fast. Although several approaches have been dedicated to solving this problem, existing solutions usually face certain limitations. For example, traditional algorithms are computationally inefficient when dealing with large-scale data and insufficiently adaptable when facing complex environments. In order to overcome these limitations, the study innovatively proposes a novel hawk-eye deblurring and pose recognition model for tennis matches, which incorporates the improved deblur generative adversarial network version 2 (DeblurGANv2) and HRNet algorithms, respectively, and introduces a lightweight Mobilenetv2 backbone network, Ghost module and Sandglass module are introduced to improve the computational efficiency, and Iterative Attention Feature Fusion (IAFF) and Coordinate Attention (CA) mechanisms are adopted to enhance the feature extraction capability. Enhance

the feature extraction ability, and at the same time significantly improve the processing speed and robustness of the algorithm, especially in the complex environment of the adaptability of the excellent performance. Among them, the improved deblurring technique of GAN can better handle blurred images under different motion states while ensuring image quality. Combined with the high-resolution feature of HRNet, the accuracy of pose recognition is further improved, especially in the capture of complex motion and action details. The research aims to significantly improve image clarity and pose recognition accuracy in dynamic scenes by combining these innovative designs, providing an effective solution for efficient and real-time tennis match Hawk-eye systems. This research is divided into four parts, the first part is the analysis and summary of others' research, the second part describes how the Hawk-Eye image deblurring algorithm for tennis matches and the tennis match stance recognition model were designed, respectively, while the third part tests the performance of the model, and the last part is the summary of the article.

II. METHODS AND MATERIALS

In response to the challenges of image blur and athlete pose recognition in tennis matches, this study first introduces IAFF based on DeblurGANv2 and uses Feature Pyramid Network (FPN) to achieve bidirectional fusion of multi-scale features. Secondly, based on HRNet, Ghost, Sandglass, CA mechanism, and Transformer-based object tracking module are sequentially introduced to propose a new Hawk-eye analysis model that integrates deblurring and pose recognition.

A. Deblurring Algorithm for Hawk-eye Images in Tennis Matches Based on Improved GAN

Image blur is one of the main issues affecting the accuracy of Hawk-eye system judgment, especially during the rapid movement of players and the high-speed flight of the ball [16-17]. The traditional image degradation model mainly generates degraded images from the original image after degradation function and noise processing, while the restoration model restores clear images close to the original image by applying restoration functions to the degraded image. Image degradation is usually caused by factors such as motion blur and poor lighting [18-20]. Through this approach, a classic algorithm for image motion blur, DeblurGANv2, is introduced into the study. This algorithm efficiently removes motion blur through the improved GAN. Compared with traditional deblurring algorithms, DeblurGANv2 has adaptability to complex backgrounds and multi-scale feature extraction ability, which can more comprehensively restore image details and is suitable for dynamic motion scenes with large changes [21-23]. In order to adapt to tennis motion detection and improve universality, the structure of DeblurGANv2 is improved, and an improved DeblurGANv2 tennis match Hawk-eye image deblurring algorithm is proposed. The framework of this algorithm is shown in Fig. 1.

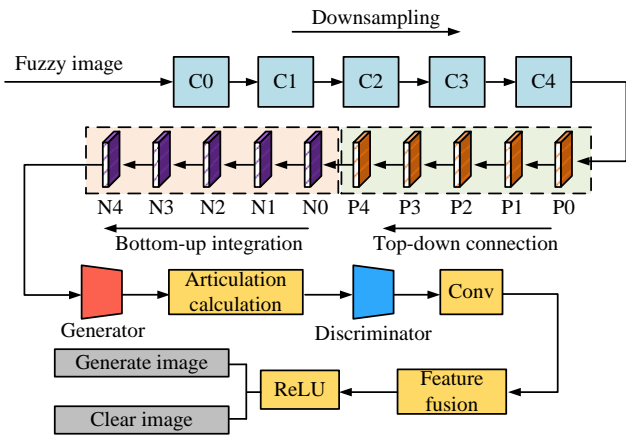

Fig. 1. Improved framework of the Hawk-eye image deblurring algorithm for tennis match in DeblurGANv2.

In Fig. 1, the algorithm framework mainly has generator, discriminator, and attention mechanism modules, and includes specific operations such as convolution, upsampling, downsampling, feature fusion, stacked convolution, batch normalization, and ReLU activation. Firstly, the improved backbone network is used to downsample and extract five feature maps of different scales step by step, from C0 to C4. Then, these feature maps are generated using the top-down connection of the FPN, namely P0 to P4. Next, P0 to P4 gradually perform bottom-up feature fusion to obtain feature maps, namely N0 to N4. Afterwards, N0 to N4 are fused with the original image to generate the final deblurred image. The generated image is then input into the discriminator along with the clear image to calculate the clarity probability of the generated image, in order to optimize the generator. Finally, the generator and discriminator are alternately trained and output after convolution, feature fusion layer, and ReLU activation. Compared with the improved DeblurGANv2, a bottom-up feature fusion branch is added, allowing low-level features to fully interact with high-level features. Specifically, the feature fusion path is designed through the bidirectional connection of FPN, which first performs top-down connection and then performs bottom-up fusion. The calculation formula is shown in Eq. (1).

$$P_i = Conv_{1 \times 1}(C_i) + Upsample(P_{i+1}) \quad (1)$$

In equation (1), P_i represents the intermediate feature map fused from top to bottom. C_i represents feature maps of different scales extracted from the backbone network. $Conv_{1 \times 1}$ signifies a 1×1 convolution operation. $Upsample$ represents upsampling operation. Next, P_i is subjected to bottom-up feature fusion to enhance the information transmission of cross layer features, as shown in Eq. (2).

$$N_i = Conv_{3 \times 3}(P_i) + Downsample(N_{i-1}) \quad (2)$$

In Eq. (2), N_i represents the fused feature map. $Downsample$ represents downsampling operation. To further enhance the ability to focus on key regions, the improved

algorithm adopts the IAFF mechanism. IAFF calculates attention weights through multiple iterations to focus on important regions in the image [24-26]. The calculation process is shown in Eq. (3).

$$\begin{cases} F_{IAFF}^t = F^t + \Gamma \cdot Attention(Q^t, K^t, V^t) \\ Attention(Q^t, K^t, V^t) = Soft \max(\frac{Q^t K^{tT}}{\sqrt{d}}) V^t \end{cases} \quad (3)$$

In Eq. (3), F_{IAFF}^t represents the fused feature map after the t -th iteration. F^t signifies the input feature of the t -th iteration. Γ represents the fusion coefficient. Q^t , K^t and V^t signify the query, key, and value matrices for the t -th iteration, respectively. \sqrt{d} represents the scaling factor, used to avoid excessive attention weights. In addition, to accelerate image deblurring processing, the improved algorithm uses Mobilenetv2 as the backbone network, replacing the traditional heavy convolutional network. Mobilenetv2 uses depthwise separable convolution, which contains two parts: depthwise convolution and pointwise convolution. The calculation formula is shown in Eq. (4) [27-29].

$$DSCConv(x) = DepthwiseConv(x) + PointwiseConv(x) \quad (4)$$

In Eq. (4), $DSCConv(x)$ represents a depthwise separable convolution operation. $DepthwiseConv(x)$ represents convolution only in the spatial dimension. $PointwiseConv(x)$ represents using 1×1 convolution to fuse features in the channel dimension. This convolution method significantly reduces the computational and parameter complexity, as shown in Eq. (5).

$$FLOPs_{DSCConv} = \frac{1}{k^2} \times FLOPs_{StandardConv} \quad (5)$$

In Eq. (5), k signifies the size of the convolution kernel. In summary, the model generator and discriminator network structure of the improved DeblurGANv2 are shown in Fig. 2.

Fig. 2 (a) displays the improved generator structure of DeblurGANv2, and Fig. 2(b) displays the improved discriminator structure of DeblurGANv2. In Fig. 2 (a), the generator includes multiple layers of feature extraction modules. Firstly, the main network performs downsampling to extract feature maps of different scales layer by layer. Then, FPN is used for multi-scale feature fusion, adopting a bidirectional connection design of top-down and bottom-up. In the feature map processing at each scale, convolutional layers, Batch Normalization (BN) layers, and ReLU activation functions are used to enhance feature extraction performance, and IAFF mechanism is adopted to highlight key regions. Finally, the fused feature map is upsampled and residual connected to reconstruct a blurred image. As shown in Fig. 2 (b), the discriminator structure includes a series of convolutional layers, Leaky ReLU activation functions, and BN layers, which are used to extract high-level features of the input image. The discriminator adopts a layer by layer downsampling design, gradually compressing the image size

through multiple convolutional layers. Finally, the fully connected layer is applied to calculate the probability score between the generated image and the real clear image, to determine whether it is a real image.

To further improve the restoration effect and image detail preservation ability of DeblurGANv2 in deblurring tasks. A mixed loss function is designed, including adversarial loss,

perceptual loss, and image reconstruction loss. Firstly, the adversarial loss is used to optimize the game between the generator and discriminator, making the output image of the generator more realistic. Secondly, the perceptual loss is applied to measure the differences in high-level semantic features between generated images and real clear images, as shown in Fig. 3.

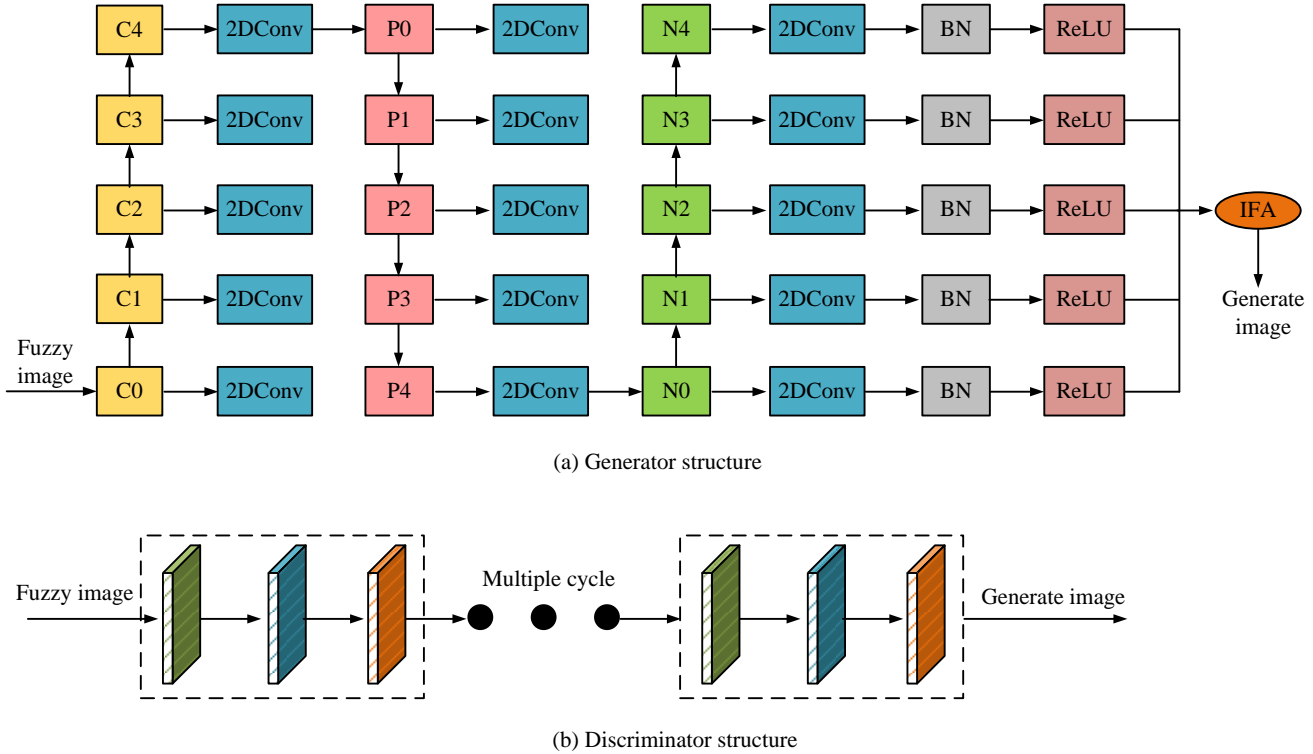

Fig. 2. Improved generator and discriminator structure for DeblurGANv2.

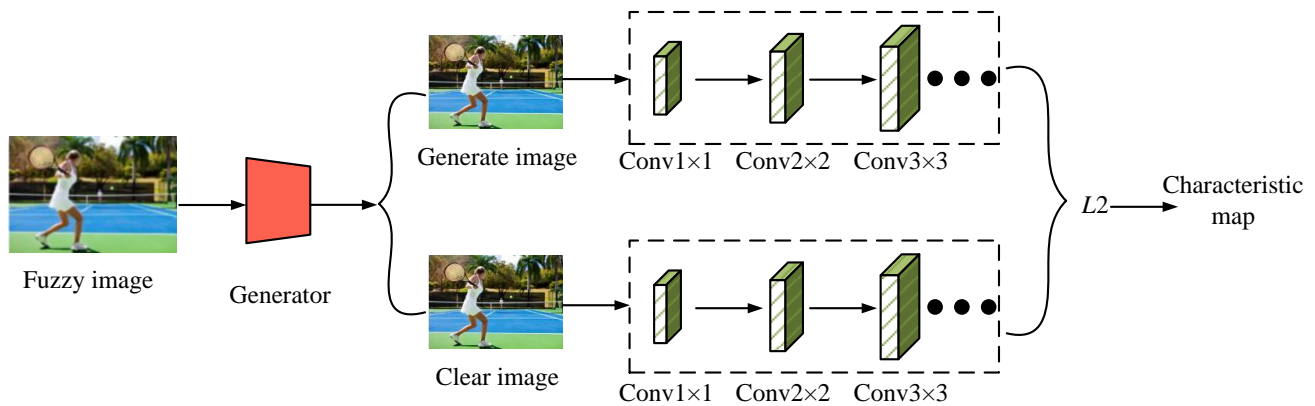

Fig. 3. Schematic diagram of perceptual loss.

As shown in Fig. 3, the calculation of perceptual loss is achieved by introducing a pre-trained deep Convolutional Neural Network (CNN) to extract high-level features, and comparing the feature differences between the generated image and the real clear image at different convolutional layers. Specifically, the input blurred image is first deblurred by a generator to generate a restored image. Then, the generated

image and the real clear image are input into a deep CNN, and feature maps are extracted through several layers of convolution. In these feature maps, the perceptual loss calculates the difference in L_2 -norm between the generated image and the real image on each layer of the feature map, as shown in Eq. (6).

$$L_{perc} = \sum_l \lambda_l \|\phi_l(G(x)) - \phi_l(y)\|_2^2 \quad (6)$$

In Eq. (6), L_{perc} represents perceptual loss, which is applied to measure the difference in high-level features between the generated image and the real image. λ_l signifies the weight coefficient. ϕ_l represents the feature mapping of the l -th layer of the deep CNN. $G(x)$ represents the deblurred image output by the generator. y represents the real and clear image. $\|\cdot\|_2$ represents the $L2$ -norm. In order to capture more levels of semantic information, perceptual loss usually selects feature maps from multiple convolutional layers for calculation, and the comprehensive formula is shown in Eq. (7).

$$L_{perc} = \sum_{l=1}^L \left(\frac{1}{H_l W_l C_l} \sum_{h=1}^{H_l} \sum_{w=1}^{W_l} \sum_{c=1}^{C_l} (\phi_l(G(x))_{h,w,c} - \phi_l(y)_{h,w,c})^2 \right) \quad (7)$$

In Eq. (7), L represents the number of selected convolutional layers. H_l , W_l and C_l respectively represent the height, width, and number of channels of the l -layer feature map. $\phi_l(G(x))_{h,w,c}$ represents the feature values at position (h, w) and channel c in the l -layer feature map. $\phi_l(y)_{h,w,c}$ signifies the feature value of the corresponding position of the real image in the l -th layer feature map.

B. Construction of Tennis Match Pose Recognition Model Integrating Improved HRNet Algorithm

After improving the DeblurGANv2 structure, the blurring effect of Hawk-eye monitoring images is effectively avoided. This research further focuses on the task of athlete posture recognition in tennis matches. Pose recognition is an important part of technical analysis in tennis matches, which is crucial for the standardization analysis of player movements, optimization of game strategies, and monitoring of potential rule violations

[30-31]. However, the rapid changes in player movements, complex postures, and dynamic background interference in tennis matches make traditional posture recognition methods difficult to cope with [32-33]. To address these issues, the HRNet algorithm is combined with research. Compared with other advanced methods, it consistently maintains high-resolution feature maps throughout the entire feature extraction process and fully utilizes multi-scale information through layer by layer fusion of multi-resolution features. In addition, targeted optimization and improvement are carried out on the basis of the standard HRNet architecture to make it more suitable for the scene requirements of tennis matches. The improved HRNet is displayed in Fig. 4.

In Fig. 4, the improved HRNet has four stages, each stage achieving the extraction and fusion of multi-scale features through parallel resolution branches. The first stage uses standard convolution operations for preliminary feature extraction, generating high-resolution feature maps. In the second stage, while retaining high-resolution branches, low resolution branches are applied to capture deeper feature information through downsampling. In the third stage, more resolution branches are added to achieve multi-scale feature alignment and complementarity from high resolution to low resolution. In the fourth stage, a cross resolution feature fusion strategy is used to effectively combine feature information from different resolutions, generating a multi-scale feature map with global context awareness capability. Specifically, there are four major improvements. First, Ghost and Sandglass have been introduced to replace the Bottleneck and Basicblock modules in HRNet, reducing the running parameter. Second, the introduced CA enhances the feature extraction capability of the model. Third, the ability to enhance data has been improved through unbiased data augmentation methods. Fourth, the effectiveness of object detection is improved through a separate object tracking module. The target tracking module is shown in Fig. 5.

Fig. 4. Improved HRNet structure.

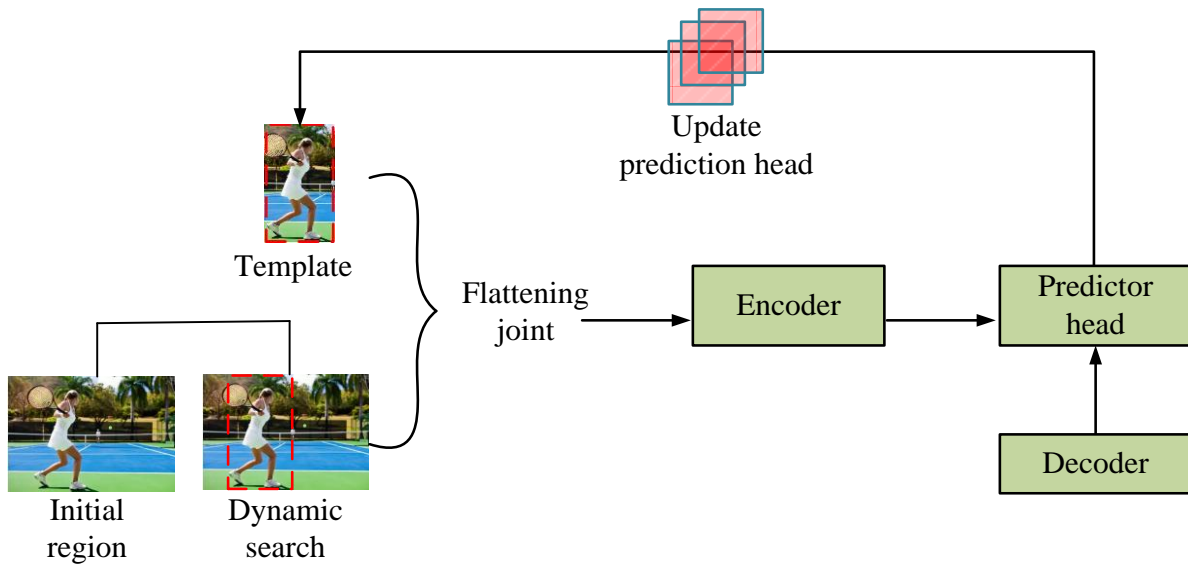

Fig. 5. Target tracking module diagram.

As shown in Fig. 5, the target tracking module mainly includes three core parts: target detection, target association, and trajectory update, which are also key steps based on the Transformer target tracking algorithm. Firstly, the input video frames are processed by an object detection network to generate an initial detection box for the target, and key information such as the target category and confidence level is annotated. Subsequently, the target association module combines the appearance features of the target, such as color, texture, and motion features, such as speed and trajectory, to match the target in the current frame with the tracked target in the previous frame, ensuring the continuity and consistency of the trajectory. Among them, the target association module achieves matching by calculating the similarity matrix between targets, where the similarity comprehensively considers the appearance and motion features of the targets, as shown in Eq. (8).

$$S_{ij} = \alpha \cdot IoU(B_i, B_j) + \beta \cdot \cos(f_i, f_j) \quad (8)$$

In Eq. (8), S_{ij} represents the similarity score between target i and target j . α and β both represent weight parameters. $IoU(B_i, B_j)$ represents the intersection over union ratio of the bounding boxes of target i and target j . f_i and f_j represent the appearance feature vectors of target i and target j , respectively. $\cos(f_i, f_j)$ represents the cosine similarity between appearance feature vectors. After the association is completed, the trajectory update module uses Kalman filtering to dynamically estimate the position and velocity of the target, in order to smooth the tracking results, as displayed in Eq. (9).

$$\begin{cases} x_t = Fx_{t-1} + E(r_t - Rx_{t-1}) \\ E = P_{t-1}H^T(RP_{t-1}R^T + \zeta)^{-1} \end{cases} \quad (9)$$

In Eq. (9), x_t and x_{t-1} represent the target state variables at the current time and the previous time, respectively. F represents the state transition matrix. r_t represents the observation vector at the current time. R represents the observation model matrix. E represents the Kalman gain. P_{t-1} represents the covariance matrix of the previous time state. ζ represents the covariance matrix of observed noise. In addition, improving the CA mechanism in the HRNet encodes the global directional information of the input feature map, and then generates a weight distribution through embedding coordinate information. Finally, the feature map is adjusted using weighting, as displayed in Eq. (10).

$$\begin{cases} z_c^h = \frac{1}{H} \sum_{i=1}^H X(i, j, c), z_c^w = \frac{1}{W} \sum_{j=1}^W X(i, j, c) \\ f_c = \sigma(\text{Conv}_{1 \times 1}^h(z_c^h) + \text{Conv}_{1 \times 1}^w(z_c^w)) \\ Y(i, j, c) = f_c \cdot X(i, j, c) \end{cases} \quad (10)$$

In Eq. (10), z_c^h and z_c^w represent the global information encoding of feature map X in the height and width directions, respectively. $X(i, j, c)$ represents the feature values of the input feature map at position (i, j) and channel c . f_c represents the generated channel weight. σ represents the activation function. $Y(i, j, c)$ represents the output feature map. $\text{Conv}_{1 \times 1}^h$ and $\text{Conv}_{1 \times 1}^w$ represent 1×1 convolution operations in the height and width directions, respectively. Regarding the original Bottleneck and Basicblock modules in HRNet, Ghost and CA modules are respectively integrated for optimization. The schematic diagram of the optimized Bottleneck and Basicblock modules is shown in Fig. 6.

Fig. 6 (a) displays the Bottleneck module structure before and after optimization. Fig. 6 (a) shows the Basicblock module

structure before and after optimization. As shown in Fig. 6 (a), the two 1×1 convolutions and 3×3 convolutions in the original module have been replaced by the Ghost module, which efficiently reduces feature redundancy by generating primary and auxiliary features. In addition, CA modules are inserted between Ghost modules. By modeling the interaction between space and channels, the model's ability to express features of the target area has been enhanced. In Fig. 6 (b), the structure originally composed of two stacked 3×3 convolutions has been

replaced with a lightweight convolution combination implemented by the Sandglass module. The Sandglass module significantly reduces the number of parameters and computational complexity while retaining feature information. At this point, the calculation formula for Ghost in Bottleneck is shown in Eq. (11).

$$Y = \text{Concat}(X * W_m, \sigma(X * W_m) * W_a) \quad (11)$$

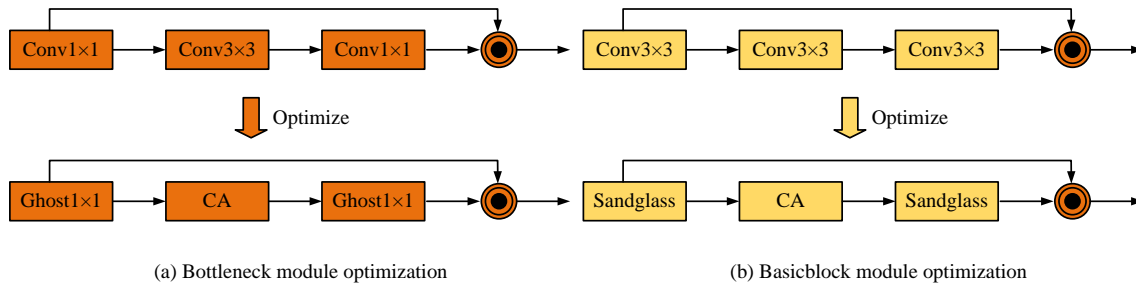

Fig. 6. Schematic diagram of Bottleneck and Basicblock modules before and after optimization.

In Eq. (11), W_m and W_a represent the convolution kernel parameters of the main feature and auxiliary feature, respectively. The Sandglass in Basicblock is shown in Eq. (12).

$$Y = X + \sigma(\text{DepthwiseConv}(\text{Point wiseConv}(X))) \quad (12)$$

In Eq. (12), $\text{Point wiseConv}(_)$ represents a 1×1 point convolution. $\text{DepthwiseConv}(_)$ represents deep convolution. Based on the improvement of HRNet structure and the comprehensive improvement of DeblurGANv2, a new tennis match Hawk-eye deblurring and pose recognition model is proposed. The process is shown in Fig. 7.

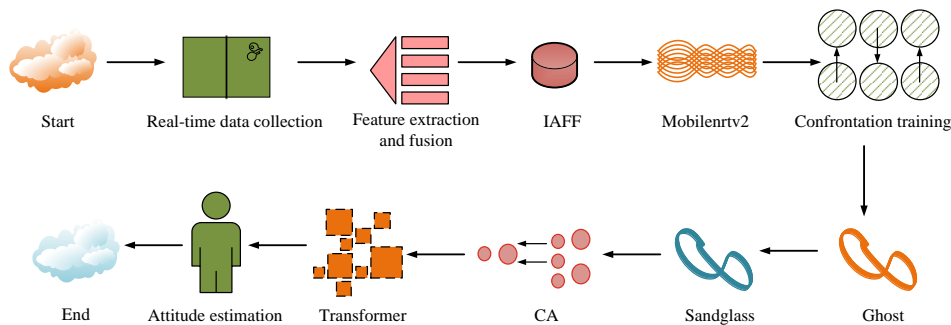

Fig. 7. New model flow of Hawk-eye deblurring and pose recognition in tennis match.

As shown in Fig. 7, firstly, the improved DeblurGANv2 is used for multi-scale feature extraction and fusion of blurred images. The IAFF mechanism is introduced to focus on key regions, and the Mobilenetv2 backbone network is taken to reduce computational overhead. The generator is optimized through adversarial training to generate high-quality and clear images. Subsequently, based on the improved HRNet for pose recognition, Ghost and Sandglass modules are introduced to replace the original Bottleneck and Basicblock modules to reduce the number of parameters, while combining CA mechanism to enhance the feature expression of key regions. Finally, through object detection and Transformer-based object tracking modules, target association and trajectory updates are achieved, outputting clear images, pose keypoints, and motion trajectories.

III. RESULTS

The study first establishes an experimental environment and conducts hyperparameter tuning, with deblurring effect and pose recognition accuracy as the core indicators for testing. The experiment covers two classic datasets and conducts ablation testing, comparative testing, and multi-scenario experiments on lighting, number of people, etc., to verify the robustness and adaptability of the model. Compared with multiple advanced models, the proposed model has achieved good results, especially showing significant advantages in parameter quantity and inference time. In complex lighting and multi-target scenes, the proposed model also demonstrates excellent performance and practical application potential.

A. Performance Testing of Hawk-eye Deblurring and Pose Recognition Model in New Tennis Matches

The study selects two classic public datasets as data sources, namely the Tennis Tracking Dataset (TTD) and the Max Planck Institute for Informatics Human Pose Dataset (MPII). Among them, TTD is a dataset focused on tennis match analysis, which includes key point annotations of players such as head, shoulder, elbow, knee and other joint points, tennis trajectories, as well as action annotations on the court such as serving, returning, running, etc. The MPII dataset is a high-quality dataset focused on human pose estimation, containing 25000 images covering over 40000 human instances. The images in this dataset are from real-life scenarios and provide rich annotations for 16 joint points, including head, shoulders, elbows, knees, etc. The detailed experimental environment parameters are displayed in Table I.

TABLE I. EXPERIMENTAL PARAMETER TABLE

Experimental equipment	Value
CPU	AMD Ryzen 9 5950X
GPU	NVIDIA RTX 4090
Memory	64GB DDR5
Graphics Memory	24GB GDDR6X
Development Environment	Ubuntu 20.04, Python 3.9
Programming Tools	PyTorch 1.10
Initialize learning rate	0.0005
Learning rate batch size	64
Momentum parameters	0.95
Training period	200 epochs

The study first conducts value selection tests on the feature fusion coefficients in the deblurring stage and the convolutional kernel layers in the pose recognition stage, to achieve the optimal state and facilitate subsequent testing. Taking information entropy as an indicator, Fig. 8 displays the test results.

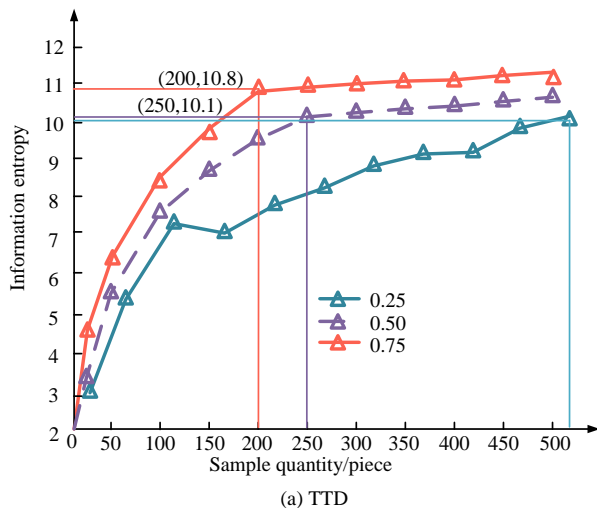

Fig. 8. Hyperparameter selection test result.

Fig. 8 (a) shows the selection test of different feature fusion coefficients in the TTD dataset, and Fig. 8 (b) shows the selection test of different convolutional kernel layers in the MPII dataset. According to Fig. 8 (a), when the fusion coefficient was 0.75, the information entropy grew the fastest and tended to stabilize at a sample size of 200, reaching a maximum value of 10.8. When the fusion coefficients were 0.25 and 0.50, the information entropy tended to stabilize at 250 samples, with values of 10.1 and 9.5, respectively. Overall, a fusion coefficient of 0.75 can significantly improve the deblurring effect. In Fig. 8 (b), with the increase of sample size, the information entropy gradually increased. When the number of convolutional kernel layers was 45, the information entropy reached its maximum value of 11.2 at a sample size of 200 and tended to stabilize. When the number of convolutional kernel layers was 30, the information entropy tended to stabilize at 250 samples, reaching 10.8. When the number of convolutional kernel layers was 15, it increased to 330 samples to reach a stable state, with an information entropy value of 10.0. In summary, when the fusion coefficient was 0.75 and the number of convolutional kernels was 45, the deblurring effect of the model was optimal. The study conducts ablation testing on the final model using the Mean Average Precision (mAP) of keypoint detection as the indicator, as presented in Fig. 9.

Fig. 9. Ablation test results.

Fig. 9 (a) displays the ablation test results on the TTD dataset, and Fig. 9 (b) displays the ablation test results on the MPII dataset. As shown in Fig. 9 (a), the mAP value of the basic model DeblurGANv2 fluctuated significantly during the iteration process, stabilizing at around 80.18%. After adding HRNet, the model performance improved and mAP remained stable at around 85.37%. After further improving DeblurGANv2 and introducing improved HRNet, the mAP value increased to around 88.74%, demonstrating better stability. The improved DeblurGANv2 and improved HRNet models were ultimately integrated, with mAP values reaching the highest level. It stabilized at around 92.48%, with minimal fluctuations throughout the entire iteration process, demonstrating the best deblurring and pose recognition performance. According to Fig. 9 (b), the mAP value of the basic model DeblurGANv2 fluctuated greatly and remained stable at around 78.77%. After joining HRNet, mAP increased to 83.21%. The improved DeblurGANv2 and HRNet models showed improvements in both stability and accuracy. The final integrated improved model performed the best, with mAP values stable above 90.49% and minimal fluctuations, demonstrating the strongest robustness and consistency. Other advanced deblurring and pose detection models are introduced

for comparison. For example, Scale-Recurrent Network (SRN), Multi-Stage Progressive Restoration Network (MPRNet), Deep Blind Generative Adversarial Network (DBGAN), High-Resolution Transformer (HRFormer), Pose Estimation Network (PoseNet), and Dynamic Encoder for Keypoint Regression (DEKR) are used for comparison. The test results are shown in Table II, using PSNR, SSIM, parameter count, and runtime as indicators.

TABLE II. INDEX TEST RESULTS OF DIFFERENT MODELS

Model	PSNR (dB)	SSIM	Parameter quantity (M)	Running time (s)
SRN	30.05	0.91	6.82	4.35
MPRNet	29.56	0.88	20.63	1.17
DBGAN	28.87	0.87	15.58	0.95
HRFormer	29.85	0.96	25.41	0.66
PoseNet	27.92	0.85	12.74	0.75
DEKR	28.51	0.86	18.88	0.58
Our model	29.74	0.89	4.53	0.25

According to Table II, the model exhibited good comprehensive performance. In terms of PSNR index, the proposed model achieved 29.74dB, which was close to SRN and HRFormer and better than most comparative models. SSIM was 0.89, slightly lower than HRFormer's 0.96, but still stable. The most significant advantage lies in the parameter count and running time. The parameter count of the proposed model was only 4.53M, significantly lower than MPRNet's 20.63M and HRFormer's 25.41M. The inference time was 0.25, which was 78%-94% faster than SRN and MPRNet. This indicates that the model has high efficiency while balancing effectiveness, making it very suitable for real-time image processing tasks.

B. Simulation Testing of Hawk-eye Deblurring and Pose Recognition Model for New Tennis Matches

To verify the practical application effect of the new model, two sets of photos are randomly selected from two types of datasets for testing the deblurring and pose estimation effects of different models, as presented in Fig. 10.

Fig. 10. Comparison of deblurring and pose recognition effect of different models.

Fig. 10 (a)-(d) show the actual comparison results of deblurring applications between SRN, MPRNet, DBGAN, and the proposed model. Fig. 10 (e)-(f) show the comparison results of pose recognition applications between HRFormer, PoseNet, DEKR, and the proposed model. From Fig. 10 (a), SRN and MPRNet had similar deblurring effects, but SRN's restoration details were slightly insufficient, while MPRNet had slight artifacts in the texture part. The DBGAN model performed poorly in handling high dynamic blur, with obvious edge blurring. In contrast, the model performed the best, with clear image details, better overall restoration performance than other models, and more natural texture parts. From Fig. 10 (b), the HRFormer and DEKR models could effectively detect the key points of tennis players. However, the HRFormer model was susceptible to interference in complex backgrounds, and the PoseNet model may miss detection, especially in inaccurate recognition during rapid limb movement. The model can accurately identify all key points and has strong robustness to complex poses and motion blur, demonstrating higher recognition accuracy. The performance of the model under different lighting conditions is tested using video frame quality improvement rate and fuzzy image recognition rate as indicators. The results are shown in Fig. 11.

Fig. 11 (a) shows the video frame quality improvement rate test results of four models, and Fig. 11 (b) shows the fuzzy image recognition rate test results of the four models. According to Fig. 11 (a), SRN and MPRNet exhibited relatively stable performance under weak and normal light conditions, with improvement rates ranging from 10% to 12%. However, in strong and ultra strong light environments, the effectiveness of DBGAN and SRN significantly decreased. In contrast, the model showed good improvement rates under various lighting conditions, especially in strong and ultra strong light environments, with a video frame quality improvement rate of 16%-18%, indicating that it could still effectively deblur under severe lighting changes. According to Fig. 11 (b), the recognition rates of HRFormer and PoseNet were relatively high under weak light and normal light, stable between 80.73%-85.46%, respectively. However, the recognition rate of DEKR fluctuated greatly in strong and ultra strong light environments. In contrast, the model maintained a high recognition rate under all lighting conditions, especially in ultra strong light environments, with a recognition rate of up to 92.44%, which was significantly better than other models. Overall, the model demonstrates stronger robustness and stability in deblurring and pose recognition tasks, and has superior adaptability to changes in lighting conditions. The research tests the accuracy of model deblurring and pose recognition in multi-player scenarios, and the results are shown in Fig. 12.

Fig. 11. Test results of video frame quality improvement rate and fuzzy image recognition rate in different modes.

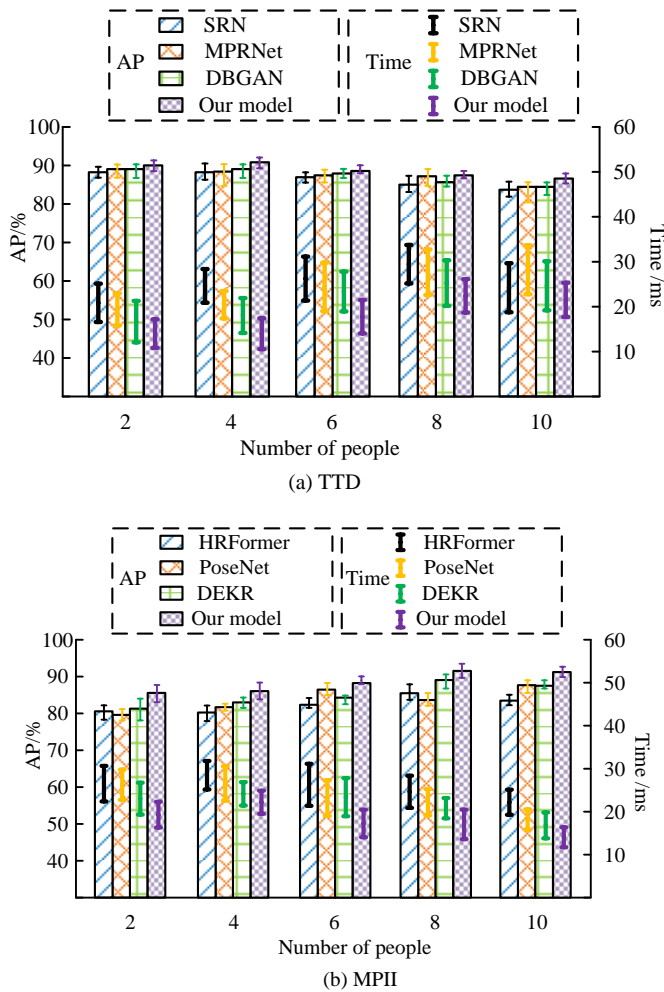

Fig. 12. Results of model deblurring and pose recognition accuracy under different numbers of people.

Fig. 12 (a) displays the deblurring accuracy and time for different models on the TTD dataset, and Fig. 12 (b) displays the pose recognition accuracy and time for different models on the MPII dataset. From Fig. 12 (a), SRN and MPRNet had higher AP values in the 2-person scenario, reaching 90.08% and 88.84% respectively. However, as the number of people increased, the AP values gradually decreased, especially in the 10 person scenario, dropping below 80.96%. The performance of DBGAN in multi-player scenarios was relatively unstable, with large fluctuations in accuracy and longer inference time. In contrast, the model proposed maintained a high AP value of 85.17%-92.38% for all participants, and had the shortest inference time, stabilizing at around 20ms, demonstrating good real-time performance and accuracy. As shown in Fig. 12 (b), HRFormer and PoseNet exhibited high AP values of over 90.02% in both 2-person and 4-person scenarios, but their accuracy significantly decreased in the 10-person scenario. The recognition accuracy and time performance of DEKR in multi-target scenes were unstable and exhibit significant fluctuations. In contrast, the posture recognition accuracy of the model remained stable under different numbers of people, with AP values consistently above 88.74% and inference time controlled at around 30 ms, significantly better than other models. Four types of pose recognition models are tested using

tracking error, target overlap rate, and decision accuracy as indicators, as displayed in Table III.

TABLE III. POSE RECOGNITION TEST RESULTS OF DIFFERENT MODELS

Data set	Model	Tracking error/%	Overlap rate/%	Decision accuracy/%
TTD	HRFormer	6.83	78.57	88.92
	PoseNet	8.93	75.23	85.37
	DEKR	7.62	77.19	87.13
	Our model	5.27	82.35	92.53
MPII	HRFormer	7.12	79.83	89.21
	PoseNet	9.27	74.67	84.71
	DEKR	8.03	76.32	86.83
	Our model	5.31	81.93	93.07

According to Table III, the tracking error of the proposed model on the TTD dataset was 5.27%, significantly lower than HRFormer's 6.83% and PoseNet's 8.93%. The overlap rate was 82.35%, which was about 5%-7% higher than other models. The decision accuracy was 92.53%, significantly better than DEKR's 87.13%. On the MPII dataset, the tracking error of the proposed model was 5.31%, which performed the best. The overlap rate was 81.93%, slightly higher than DEKR's 76.32%. The decision-making accuracy was the highest, at 93.07%, which was significantly improved compared with HRFormer. The above data shows that the model exhibits superior performance and robustness in all indicators.

IV. CONCLUSION

In tennis matches, image blur and pose recognition errors are the main issues affecting the accuracy of the Hawkeye system. To address this challenge, the research improved DeblurGANv2 and HRNet, proposing a novel tennis game image deblurring and pose recognition model. When the fusion coefficient was 0.75 and the number of convolutional kernels was 45, the deblurring effect of the model was optimal, achieving an information entropy value of 11.2. At the same time, after sequentially improving DeblurGANv2 and HRNet, the mAP value of the combined model reached 92.48%, indicating that the improvement and fusion of each module in the study were effective. Compared with other deblurring and pose recognition models, this new model had a PSNR of up to 29.74dB, SSIM of up to 0.89, minimum parameter size of 4.53, and shortest running time of 0.25s, which was 78%-94% faster than SRN and MPRNet. Under different lighting intensities, the proposed model had strong robustness to complex poses and motion blur, showing a recognition accuracy of up to 92.44% and a video frame quality improvement rate of 16% - 18%. In a multi-person scenario, the model had the highest recognition AP value of 92.38%, and the shortest stable inference time was around 20ms. The lowest pose recognition tracking error was 5.27%. Although the overlap rate was higher than other models, the decision accuracy was 92.53%, far exceeding other methods. In summary, the model has significant advantages in both processing effectiveness and efficiency. However, the performance of the model still

fluctuates to some extent under extreme lighting conditions, such as ultra-low light or severe lighting environments. Future research will further optimize the robustness of the model and explore methods that combine multi-modal data to enhance its adaptability and generalizability in practical applications.

A Highly Functional Ensemble of Improved Chaos Sparrow Search Optimization Algorithm and Enhanced Sun Flower Optimization Algorithm for Query Optimization in Big Data

Mursubai Sandhya Rani*, Dr. N. Raghavendra Sai

Department of Computer Science and Engineering, Koneru Lakshmaiah Educational Foundation,
Vaddeswaram, Andhra Pradesh, India.

Abstract—Numerous systems have to provide the highest level of performance feasible to their users due to the present accessibility of enormous datasets and scalability needs. Efficiency in big data is measurable in terms of the speed at which queries are executed physically. It is too demanding on big data for queries to be executed on time to satisfy users' needs. The query optimizer, one of the critical parts of big data that selects the best query execution plan and subsequently influences the query execution duration, is the primary focus of this research. Therefore, a well-designed query enables the user to obtain results in the required time and enhances the credibility of the associated application. This research suggested an enhanced query optimizing method for big data (BD) utilizing the ICSSOA-ESFOA algorithm (Improved Chaos Sparrow Search Optimization Algorithm- Enhanced Sun Flower Optimization algorithm) with HDFS Map Reduce to avoid the challenges associated with the optimization of queries. The essential features are extracted by employing the ResNet50V2 approach. Effective data arrangement is necessary for making sense of large and complex datasets. For this purpose, we ensemble Density-Based Spatial Clustering of Applications with Noise (DBSCAN) and Improved Spectral Clustering (ISC). The experimental findings demonstrate a significant benefit of the proposed strategy over the present optimization of the queries paradigm, and the proposed approach obtains less execution time and memory consumption. The experimental results show that the proposed strategy significantly outperforms the current optimization paradigm, reaching 99.5% accuracy, 29.4 seconds of execution time, and 450 MB less memory use.

Keywords—Big data (BD); query optimization; Improved Chaos Sparrow Search Optimization Algorithm (ICSSOA); Enhanced Sun Flower Optimization Algorithm (ESOA); ResNet50V2; DBSCAN

I. INTRODUCTION

Big data empowers businesses to make informed decisions and take appropriate action by allowing them to examine enormous data in volume, variety, and velocity [1]. Big data can be stored and queried using a variety of databases and data structures: Relational databases are employed for read-intensive analytic queries; Internet transaction processor platforms are utilized for faster uploads and reliability; NoSQL storage systems are used for handling massive volumes of data [2, 3]. Different data stores have been created and constructed for various purposes and the best results. SQL databases are effective at storing and processing structured data, but their

efficiency suffers from read-intensive queries. Similarly to how NoSQL storage systems are tailored to deal with unstructured data, columnar databases are utilized for the analytic processing of queries [4-6].

The information that has been processed is kept in several databases so that analysts can use it. Performance optimization and various data structures are crucial for applications that use a lot of data [7, 8]. Building scalable and effective data pipelines is a significant difficulty. These data pipelines, which are vital to the functionality of the applications, are optimized and maintained by data engineers [9]. Researchers and data scientists utilize the data warehouse to analyze, evolve, and load the data for their research projects. The enhancement of query efficiency and extra complexity brought on by the various data models employed in these databases present ongoing challenges for big data platforms that use these databases [10-12].

The many Operation SITE Allocation (OSA) strategies to execute the query are born from the advancement of query optimization. OSA problems are sought after to improve query execution plans in terms of system throughput or response times [13]. The query optimizer's three main parts are "Cost Model," "Search Space," and "Search Strategy." Designing the various cost coefficients and the objective function is the responsibility of the cost model. A variety of different query execution strategies are represented by the search space [14, 15]. The search method is also used to probe the search space to find the most promising query execution technique.

Previously, deterministic optimization methods and a variety of databases were used for query optimization. Only basic CDSS queries are a good fit for deterministic algorithms [16-18]. Nature Inspired Computing (NIC) has tremendous prospects for computational intelligence and is now being applied to address CDSS query optimization concerns. There is a long list of NIC computing techniques, some of which depend on the genetics of animals, insects, birds, and people, as well as on music and water [19]. The most admired NICs include Artificial Bee Colony, Cuckoo Search, Ant Colony Optimization, Grey Wolf Algorithm, and Genetic Algorithm. After reviewing the literature on query optimization, it was discovered that distributed CDSS queries had received a lack of attention. To speed up the data retrieval, a creative query

optimizer is required. The suggested query optimizer helps identify an ideal query execution plan that reduces the overall consumption of I/O, computing, and communication resources [20].

The increasing scale and complexity of big data have made query optimization a critical challenge. Existing methods often struggle with several limitations, including high computational cost, slow convergence, and inefficiency when handling large, distributed datasets. Many traditional techniques are also unable to address data skew effectively, ensure quick response times, or optimize query execution under heavy query loads. These shortcomings highlight the need for a more efficient approach to query optimization that can scale with growing data volumes and provide faster, more resource-efficient execution in modern big data environments. To address these challenges, we propose an enhanced query optimization method that significantly improves execution time and reduces memory consumption, making it better suited for the demands of today's data-driven applications.

To tackle the issue mentioned above, we introduced a novel approach to big data arrangement and feature extraction. This reduces the execution time, retrieval time, and memory usage. Compared with existing methods, the proposed approach performs better.

A. Research Contribution

The key objectives of this research are as follows:

- Initially, we employed a secure hash algorithm in preprocessing to find the hash value. Then, centered on the HV, the map reduction process is executed.
- After the removal of repeated data, the essential features are extracted by employing ResNet50V2.
- Entropy values are inputted to the deep adaptive hybrid clustering algorithm DBSCAN and spectral clustering for the big data arrangement.
- Finally, the query is optimized with the help of the ensemble Improved Chaos Sparrow Search Optimization algorithm (ICSSOA) and Enhanced Sun Flower Optimization algorithm (ESFOA).

The following part of the article is structured as follows. The existing prior works are briefly described in Section II. The proposed strategy is described in detail in Section III. The suggested method is extensively simulated in Section IV. Section V provides the conclusion.

II. RELATED WORKS

Some existing prior works related to significant data query optimization are analyzed in this section.

An improved query optimizer known as CDSS was modelled by Sharma et al. [21] using a hybridization firefly-genetic algorithm (GA) on a constrained divergence environment (RDFG_CDQO). This CDSS was created with the goal of achieving the best query execution plan possible to reduce processing, input-output, and interaction demands when running CDSS queries. The controlled GA's slower convergence difficulty would be cautiously defeated by the

enhanced utilization of the CDSS technique, achieving significant variance in "2" successive generations. The CDSS optimizer could not solve the QO issues. For the query retrieving rate, Lekshmi et al. [22] presented the Top-k Query Multi-Keyword Threshold method (Top-k QMKST). The query and many keywords are primarily divided, and B+ tree indexing was used to execute the data index. Response time and spatial complexity were both decreased by employing Top-k QMKST. The Kullback Leibler Divergence also uses the index list of terms to determine a score value. The results of the experimental study show that the suggested technique performs better.

For the skewed-ranging queries, Wei Ge et al. [23] suggested a method known as correlation-aware partitions. In the form of a geometrical curve-fitting problem, it introduced a problem known as partitioning optimization on continuously correlated data. The boundaries of the range query must be used to partition data optimally. The boundary for the range was utilized in this case to incorporate the best partitions and significantly reduce the computational cost compared to the standard dynamic programming. When compared to the global one, the local one performed better instead of attempting to increase effectiveness.

Sinha et al. [24] proposed an approach for distributed datasets by combining the genetic algorithm (GA) and the k-means clustering method. The suggested strategy is divided into two phases; in the initial stage, parallel GA is performed to data chunks spread across many machines. GA takes into account the covariance among the data sets and offers an improved summary of the original information. Phase 2 applies K-means with K-means++ initialization on the intermediate output to produce the outcome.

Ansari et al. [25] suggested a parallel variant of the conventional K-means algorithm for use in the Hadoop distributed environment. The results of the experiments demonstrate that the suggested K-means algorithm operates better than conventional K-means when clustering a significant volume of datasets. Compared to current methods, the suggested approach produces better results.

A. Research Gap

Existing query optimization techniques, including Top-k QMKST (Lekshmi et al. [22]) and the CDSS optimizer (Sharma et al. [21]), concentrate on increasing query execution efficiency but struggle to handle dynamic or large-scale datasets. Top-k QMKST speeds up response times but might not be able to handle high-dimensional data effectively, and the CDSS optimizer enhances convergence but has trouble optimizing query retrieval rates. Other methods that deal with partitioning and data summarization, including correlation-aware partitions (Wei Ge et al. [23]) and the integration of evolutionary algorithms with K-means clustering (Sinha et al. [24]), do not sufficiently improve query execution in distributed systems with big datasets. Furthermore, the parallel K-means approach of Ansari et al. [25] enhances clustering but ignores memory usage and query execution time. By using ResNet50V2 for feature extraction, the ICSSOA-ESFOA method for improved query optimization, and DBSCAN and ISC in combination for efficient data arrangement, our

proposed work seeks to close these gaps. By addressing the shortcomings of current techniques, our strategy guarantees quicker query execution, better memory management, and increased scalability in significant data contexts.

III. PROPOSED METHODOLOGY

In order to handle and store BD, which is extremely large in volume and contains numerous data models, organizations

maintain various databases. For business purposes, it is essential to query and analyze BD for insight. In this study, the ICSSOA-ESOA algorithm and the HDFS map-reduce approach were used to improve the query optimizer procedure in BD.

Fig. 1. Proposed methodology architecture diagram.

To extract the essential features from a big dataset, we employed ResNet50V2. Then, the big data are arranged with the help of an ensemble DBSCAN approach and an improved spectral clustering approach. The proposed approach is analyzed and evaluated by using four benchmark datasets. The overall framework of the proposed approach is shown in Fig. 1.

A. Problem Statement

The number of datasets that need to be evaluated is increasing, necessitating several databases to store the preprocessed data in various information formats. Several methods, like materialized views and data cubes, can decrease query latency but necessitate significant computation and preparation. In order to deliver estimated results with error bounds, approximate query processing (AQP) was implemented. Nowadays, the majority of AQP models only support one database. The suggested AQP model supports heterogeneous databases with various data models by keeping up-to-date samples in a single database. Any database can be used to conduct the SQL query. The query optimizer chooses the samples automatically and provides users with approximations of the results. For this purpose, we introduced a novel approach for query optimization.

B. Preprocessing

The pre-processing of the input data was carried out during this phase. First, it uses the Secure Hash Algorithm (SHA-3) to determine the HV for every bit of data. Then, using HDFS, the MR process is carried out using the HV as its focal point. The subsections below explain the SHA-3 and HDFS processes. The SHA-3 algorithm is specified for a digest length d with a value of 224, 256, 384, or 512 and a message M with two bits "01" inserted at the conclusion, such that $SHA - d(M) = KECCAK(c)(M||01, d)$, while SHA3 and KECCAK are functions, M is the input string to the SHA-3 method.

1) *The SHA-3 algorithm is utilized to find the hash value of big data:* Utilizing permutation functions, the SHA-3 method, also referred to as the Keccak algorithm, was created. Keccak performs encryption well and has a high degree of attack resistance. SHA-3 is safer than earlier iterations like SHA-1 and SHA-2. The SHA-3 method can provide multiple fixed-bit hash values for different input bits. The outcome of this research is a 256-bit hash value.

2) *Map and reduce:* The two most crucial MapReduce processes are the "Map and Reduce" operations. The Apache

Foundation created the distributed system infrastructure known as Hadoop. Users can fully leverage the platform's massive data storage and quick computation capabilities by developing distributed applications without familiarity with the architecture's inner workings. Hadoop implements a distributed file system called HDFS. Although HDFS requires the usage of costly hardware, it provides good features and strong fault tolerance. Additionally, it offers a fast interface for accessing application data, making it appropriate for programs with big

data sets. HDFS lowers the file system's restrictions for accessing the data in stream form. HDFS and Map Reduce are the two main components of the Hadoop system. Massive data storage is primarily provided by HDFS, and distributed computing functions are supplied by Map Reduce. The simple description of Hadoop's data processing is that the Hadoop cluster analyzed the data to produce its outcomes. In Fig. 2, the method of processing flow is depicted.

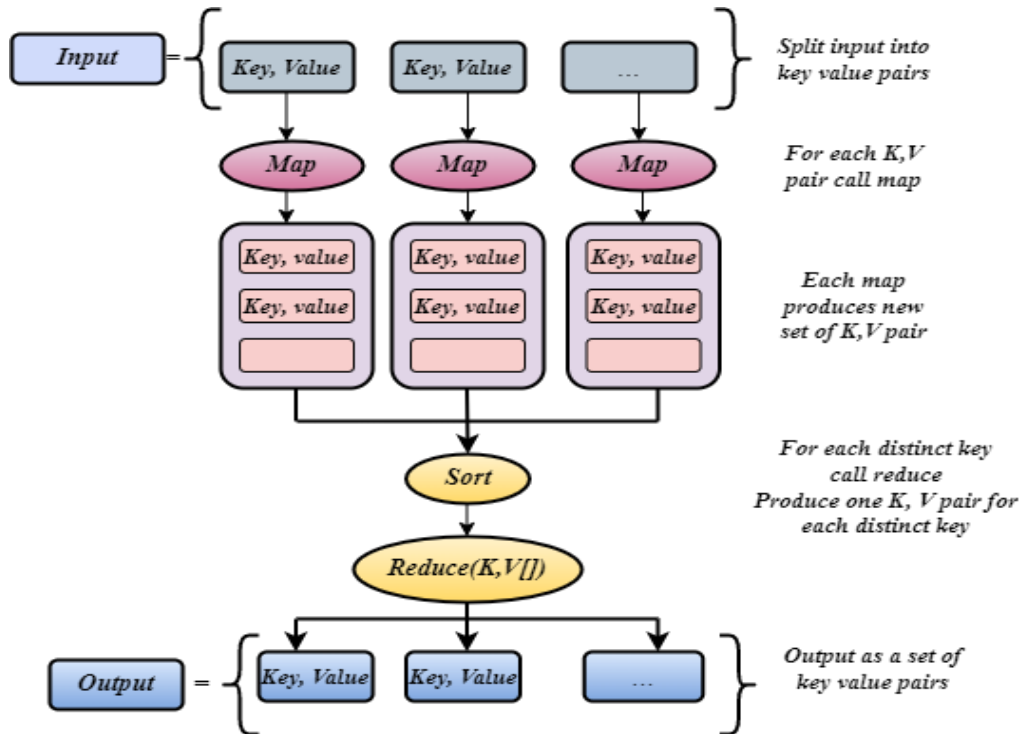

Fig. 2. Framework of map and reduce.

HDFS and MapReduce are the two main parts of Hadoop, as shown in Fig. 3. The storage of enormous amounts of data is the responsibility of HDFS, and the processing of massive amounts of data is a function of MapReduce. Another two crucial parts of Hadoop are the distributed database system Hbase and the data warehouse tool Hive. Records are kept in a Hadoop cluster using the HDFS. The HDFS interface resembles a straightforward hierarchical file system with straightforward operations like adding, deleting, moving, and more. However, the HDFS files are broken up into data blocks based on specific requirements, and then a massive number of data blocks are distributed over numerous slave nodes. It departs significantly from conventional storage structures at this point. The user typically chooses the number of data blocks to put and the dimension of each separated data block.

MapReduce, which includes Job Trackers and Task Trackers, is DFS's top layer. Massive files are partitioned into equal sections by default on HDFS. This default value is set at 64 M in the HDFS overview document. The data file 1 has been separated into three portions and placed in three distinct machines. Map Reduce is a task that is called Map and

computes after every Hadoop input component. The system will move through each input data individually in the task before analyzing the map and turning it into a key-value format. The outcome will be produced in the key-value pair's form. As an input to Reduce by key, Hadoop will then transmit the outcome of the preceding phase. The Reduce Task's results, retained on HDFS, are the outcome of the entire task.

C. Feature Extraction

Datasets in big data scenarios may contain a large number of variables or attributes and be exceedingly high dimensional. High dimensionality can present difficulties in overfitting, poor interpretability, and computation complexity. Feature extraction algorithms can reduce dimensionality by converting the original features into a lower-dimensional representation while maintaining the crucial data. Analysis and modelling could become more effective as a result. From the original data, the significant aspects are retrieved, including closed frequent item set, support, and confidence. Finally, entropy computation is used to regulate confidence and support value. The following part provides an overview of the extraction of feature processes.

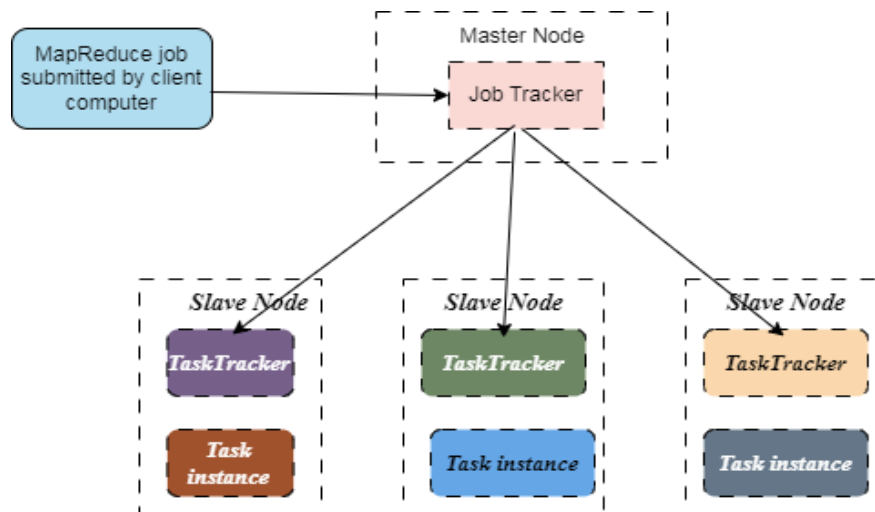

Fig. 3. Hadoop's two core components.

1) *ResNet50V2*: Deep feature extraction is illustrated in this subsection. Deep feature extraction employs deep neural networks to extract significant and valuable information from raw data. These characteristics capture high-level representations that are more useful for handling the current task. For query optimization in big data, we used the *ResNet50V2* framework as a deep extraction of features method. *ResNet50V2* represents a convolutional neural network (CNN) that excels in various computer vision applications. To tackle the degradation issue in deep networks, a variation of the *ResNet* design is used, which uses skip connections.

The 50-layer *ResNet50V2* was pre-trained using a sizable dataset, such as a big datasets. The network can learn residual mappings through the use of residual blocks, which also makes it easier to train deeper networks. The skip connections also facilitate the direct transfer of gradients from the initial layers to subsequent layers, which improves training. Due to its ability to extract complicated and structured patterns from big data, the *ResNet50V2* architecture is advantageous for query optimization feature extraction.

The deep layers of *ResNet50V2* enable it to learn abstract representations. The benefit of Transfer Learning may be obtained by utilizing the pre-trained *ResNet50V2* approach, as it has previously acquired general features from a sizable dataset like the hospital compare, Twitter, and IMDb datasets. *ResNet50V2* can record generalized representations tuned for query optimization owing to this pre-training. The precision and effectiveness of the query optimization can be improved by applying the learned features from *ResNet50V2*.

The *ResNet50V2* features provide a more advanced representation of the input optimization of queries, capturing essential data for positions, including bid arrangement of data. We may utilize the potent representations learned by *ResNet50V2* by using these features as inputs for multiple machine learning algorithms. By doing that, we want to improve the precision and functionality of our query optimization mechanism. *ResNet50V2*'s high-level features

enable a more thorough and insightful representation of the input data, enhancing our capacity and eventually enabling improved optimization.

D. Big Data Arrangement

Big data arrangement is a key component of the data management process, which involves structuring and organizing enormous amounts of data to facilitate effective analysis, storage, and retrieval. For clustering and pattern recognition tasks in data analysis and deep learning, ensemble *DBSCAN* (Density-Based Spatial Clustering of Applications with Noise) and Improved Spectral Clustering can be particularly beneficial. Combining *DBSCAN* with Spectral Clustering can take advantage of each technique's advantages as each approach has advantages and disadvantages of its own. The proposed method achieves improved noise handling, improved cluster separation, scalability, merging local and global information, handling variable cluster Densities, and more while combining the methodologies.

1) *DBSCAN clustering algorithm*: *DBSCAN*, a popular density-based clustering technique, can locate several clusters based on the predicted density distribution. It can detect shaped clusters and does not require prior knowledge of the cluster size. The following examples show the core concept of *DBSCAN*. *DBSCAN* collects all points in the neighbourhood of a random, unvisited point called p , while p is the initial location and r is the neighbourhood's maximal radius. The minimal number of units needed to generate a dense zone is called the density threshold $MinPts$. If $MinPts$ points or more are nearby, point p is a core point. All of the points in p , ϵ -neighbourhood are put into an identical cluster if p is the centre point together with all of the other points in p . *DBSCAN* locates all density-reachable points. It includes them in the same cluster for every point in the cluster. If point q is densely accessible from other core points but has a smaller neighbourhood than $MinPts$, it is also a border point that belongs to the cluster. An isolated or noisy point cannot be reached from any other point. Using consecutive cluster extraction, *DBSCAN* completes the clustering procedure. A finalized cluster is created by iterating

this procedure till no more density-reachable spots are discovered. The three categories that DBSCAN uses to categorize a set of points are noise, low-density boundary points, and high-density core points. The following are three different types of points' definitions.

2) *Initialization of the variables:* In K-DBSCAN, the HS is optimized to get the best clustering parameters. Thus, "Eps" and "Minpts," the two clustering parameters for input, have been utilized as the HS's decision variables, correspondingly. Given that the set of data is split into categories that are considered as K, every parameter variable's maximum value shouldn't be greater than the K-equal partitions of the entire data set. These two variables are initialized with the following values:

$$Eps \in \left(0, \frac{SDR}{2 \times K}\right) \quad (1)$$

$$Minpts \in \left[1, \frac{Num_obj}{\left(\frac{LDR}{SDR}\right) \times K \times D}\right] \quad (2)$$

While *SDR* and *LDR* are the smallest value and greatest values across all dimension that ranges from the entire data set, accordingly, the variable shows the number of objects utilized for clustering *Num_obj*. The dimension is denoted by *D*.

3) *The objective function:* A multi-objective collaborative evaluation approach is provided for the HS in the K-DBSCAN optimization issue. The overall number of clusters produced by DBSCAN under different parameter variables is monitored by

using the initial target function, which can be shown as the total amount of variance among that and the determined clustering number K. Since the main objective of this clustering approach is to produce K groups, this variance can be expressed as the total amount of variance between it and the established clustering number K.

$$Minimize f1 = |c - K| \quad (3)$$

The total number of clusters is represented as K, which has been predetermined, and the real number of clusters is indicated as c DBSCAN, which has been produced using the current set of decision variables.

The DBSCAN method can identify unusual noise. When the outcomes of the parameters "Eps" and "Minpts" are improperly chosen, particularly if they are disproportionately matched, it may result in under-differentiation, where most or even all of the data items are misidentified for outliers.

Two distinct groups make up the initial data set in Fig. 4, and Fig. 5 displays the results of clustering with excessive noise caused by subpar clustering parameters. Acquiring the cluster number of 2 is possible, although many valid points are confused for noise entities. Consequently, a separate function of the multi-objective optimization method is utilized to maximize the number of objects in the least efficient cluster and prevent such an abnormal occurrence.

$$Maximize f2 = num(s_clusters) \quad (4)$$

Fig. 4. The initial formation of the dataset.

Fig. 5. Noise in clusters.

The term $num(s_clusters)$ refers to the number of items in the smallest practical cluster. Consequently, the following is an expression for the K-DBSCAN's multi-objective collaborative evaluation function:

$$F = (\text{Minimize } f1, \text{ Maximize } f2) \quad (5)$$

Obtaining the necessary K clusters is the primary objective of K-DBSCAN. This is followed by the effect of clustering that produces the fewest inaccurate noise objects. In other words, $f1$ has a greater priority than $f2$, which is indicated by the notation: $f1 \prec f2$.

4) *Framework*: According to the information above, the two clustering factors, "Eps" and "Minpts," are used in DBSCAN as the HS variables for decision-making. The multi-objective collaborative evaluation function can be used with the clustering parameter's optimal value to get a superior clustering outcome with K categorization when using DBSCAN.

Additionally, relatively low parameter values typically result in a superior clustering effect when using the DBSCAN algorithm. The size of "Minpts" indicates a significant impact on how well noise of clustering is judged under the condition of a specific parameter "Eps," and the larger it is, the more probable it is that genuine data will be viewed as noise objects. Thus, the variable of decision "Minpts" has been set to a number that enhances over time with the repetition stage process to acquire adequate clustering factors, including.

$$Minpts = Minpts_{min} \dots Max_{min} \quad (6)$$

While $gnit$ denotes the number for the generation currently in use, NI is the maximum number of repetitions and $Minpts_{max} \dots Minpts_{min}$ denotes the variable upper and lower bounds, accordingly.

5) *Spectral clustering*: Typical graph-based clustering techniques include Spectral Clustering without monitoring the data. Techniques for Spectral Clustering often start with local data that has been encoded in a weighted network of information and then aggregates according to the associated similarity matrix's global characteristic vectors. In Spectral Clustering, a function of mapping that explicitly maps characteristics to the group tag matrix is automatically learned for every task to anticipate cluster tags.

The process of learning can automatically use dissimilar data to enhance clustering efficiency. In Spectral Clustering, communities of nodes connected near one another are characterized in a graph using a method known as clustering. The nodes are placed in a low-dimensional area that can be easily segmented into clusters. Affinity, Degree, and Laplacian matrices and other specific values of these matrices produced from a graph or data collection are used in spectral clustering. The crucial steps in creating a Spectral Clustering algorithm are as follows:

Prior to using the spectral clustering procedure, we must first Figure out the matrix for similarity, which is then indicated as the overlap matrix of degree P. It can be shown as,

$$p = \begin{bmatrix} 0 & p_{1,2} & \dots & \dots p_{1,n} \\ p_{2,1} & 0 & \dots & \dots p_{2,n} \\ \vdots & \dots & 0 & \vdots \\ p_{n,1} & \dots & p_{n,n-1} & 0 \end{bmatrix} \quad (7)$$

For the arrangement criterion, we may assume that every request is split into k_1, k_2 , and two groups; this work employs the conventional division approach. Suppose q is a vector. These are the definitions of the q_i elements:

$$q_i = \begin{cases} \sqrt{\frac{d_2}{d_1 d}} & , i \in k_1 \\ -\sqrt{\frac{d_1}{d_2 d}} & , i \in k_2 \end{cases} \quad (8)$$

In the event that the cluster indicator matrix $F \in R^{n \times k}$ is correct. Assuming consistent with each perspective, we can define the clustering of spectral data issues as,

$$\min_{F, F^T F = 1} \sum_{v=1}^t Tr(F^T L^v F) \quad (9)$$

While every graph evenly contributes to the outcome F. We ignore the specifics of the graph creation in the equation above. Several additional studies just take the mean of the vertices and then implement the spectral clustering independently instead of mandating that multiple graphs share the same F.

Improved Spectral Clustering Algorithm (ISCM). We provide an improved spectral clustering technique (ISCM) relying on the enhanced k-means algorithm. The approach accomplishes secondary clustering in addition to resolving the initial value issue. We take into account the parameters as previously mentioned in accordance with the QoS criterion. We may determine whether secondary clustering is necessary by evaluating the variable sizes before the method operates. There is no need to recluster if the present QoS exceeds the users' desire to allocate resources once the strategy has been performed. The clustering spectral optimization scheduling algorithm's implementation procedures are then described.

E. Query optimization

Big data systems frequently handle enormous amounts of data. By dramatically reducing the time it takes for a query to execute, query optimization can guarantee that users or applications can quickly and effectively retrieve the needed data. Query optimization aids in efficient resource allocation, cutting costs and guaranteeing the best use of available resources. It minimizes hardware waste and prevents nodes from becoming overloaded. For this purpose, we ensemble the Improved Chaos Sparrow Search algorithm (ICSSA) and Enhanced Sun flower optimization algorithm (ESFO). ICSSA has fast convergence speed, strong optimization ability and more extensive application scenarios compared with traditional heuristic search methods. Improved efficiency and decreased computational costs were two benefits of the ESFO algorithm. We ensemble both algorithm's merits to effectively optimize the query.

1) *Sparrow search algorithm*: The SSA bases its description of the sparrows' predatory and anti-predatory behavior for updated locations on the following guiding concepts. The population of sparrows is split into followers and

producers. The sparrow's two identities may be switched around, and everyone has a system for detecting danger. Every sparrow, in particular, is sensitive to potential threats or natural enemies and will immediately begin anti-predatory activity to defend itself. The producers are highly active, adept at foraging for food, travel widely, and lead other sparrows on their quest. To increase their food intake by snatching it or foraging nearby, seekers seek the producer and follow them to find additional food.

2) *Basic concepts*: The individual matrix is displayed below, with N sparrows assumed to be in D-dimensional space.

$$X = [x_1, x_2, \dots, x_N]^T, x_i = [x_{i,1}, x_{i,2}, \dots, x_{i,D}] \quad (10)$$

While x_i , D denotes the i^{th} sparrow's location in the D dimension.

$$x_{i,j}^{t+1} = \begin{cases} x_{i,j}^t \cdot \exp\left(\frac{-i}{\alpha \cdot \text{iter}_{\max}}\right) \cdot O_2 \\ x_{i,j}^t + Q \cdot L \quad R_2 \geq ST \end{cases} \quad (11)$$

The present iteration count, t, is represented here. Itermax indicates the greatest amount of the iterations $j = 1, 2, \dots, d$. It falls between 0 to 1 and is a uniform randomized value. The warning and security values for sparrows are represented by $R_2 (R_2 \in (0,1))$ and $ST (ST \in (0.5,1.0))$. An ordinary distribution characterizes a random number Q. Every matrix's 1d elements comprise the L matrix. When this $R_2 < ST$ occurs, the provider adopts a wide-area search phase while they are not in danger from any natural competitors and are in a generally safe environment. Due to Eq. (3), the follower position is upgraded.

$$x_{i,j}^{t+1} = \begin{cases} Q \cdot \exp\left(\frac{x_{\text{worst}}^t - x_{i,j}^t}{i^2}\right) & i > \frac{n}{2} \\ x_p^{t+1} + |x_{i,j}^t - x_p^{t+1}| \cdot A^+ \cdot L & \text{otherwise} \end{cases} \quad (12)$$

In which x^t worst indicates the current position of the bird with the worst adaptability. The spot of the bird with the best producer adaption is represented by the number x_p . Every component of the matrix shown by A is represented by a value at random of one or zero. A^+ equals $A^T A A^{T-1}$.

3) *Danger awareness mechanism*: When hunting, sparrows sense the danger of hunt and may fly away from their current location and to another. The individual sparrows that detect danger often range between 10% and 20%. As the Eq. (4) shows, the sparrows' posture changes when they detect danger.

$$x_{i,j}^{t+1} = \begin{cases} x_{\text{best}}^t + \beta \cdot |x_{i,j}^t - x_{\text{best}}^t| & f_i > f_g \\ x_{i,j}^t + K \cdot \left(\frac{|x_{i,j}^t - x_{\text{worst}}^t|}{(f_i - f_w) + \varepsilon}\right) & f_i = f_g \end{cases} \quad (13)$$

The current optimal location is represented as $x_{\text{best}} \cdot \beta$ is a common control parameter for properly distributed random step algorithms. K is an even random number with the value (1, 0). f_i shows the sparrow's value of current fitness. The current best-fit and worst-fit values globally are denoted by f_g and f_w , accordingly. The least significant is indicated as ε . If $f_i > f_g$, it

means that the particular sparrow is on the periphery of the population and is hence vulnerable to assault by predators of nature.

4) *Improved chaos sparrow search optimization algorithm*: In the case of the standard SSA, the producer fails to thoroughly search for the best possible outcome in the initial iteration, and the solution in the later iteration has a marginally lower precision as a result of the producer's poor management of the earlier repetition and the creation of the afterward iteration in the global search. Blindly adopting the producer's perspective, the followers rapidly enter the local optimal conundrum, reduce population diversity, and become the producers. Enhancing population variety is the major way to keep the dynamic equilibrium of provider search and development to handle the aforementioned issues. ICSSOA research is concentrated on finding ways to make it easier to leave local optima. The following topics will be covered in detail to understand the ICSSOA.

5) *Cubic chaos mapping*: Algorithms have been optimized using Chaos, a nonlinear process that occurs in nature. Because of its stochastic and ergodic characteristics, it enhances population variety and makes it easier for the approach to depart from the optimum for local. The standard version of the chaotic mapping, known as cubic mapping, is presented in Eq. (14).

$$x_{n+1} = bx_n^3 - cx_n \quad (14)$$

Where the effect variables for chaos are b and c. While $c \in (2.3,3)$ the chaos sequence is produced via cubic mapping. The Cubic mapping expression was modified by studying the max exponent of Lyapunov for 16 frequent mappings of chaos. The experimental findings showed that Cubic mapping has less disorder than one-dimensional mappings like Sine mapping and Circle mapping but is more chaotic than worm mouths and tent mappings. It can be expressed as,

$$x_{n+1} = \rho x_n (1 - x_n^2) \quad (15)$$

While $x_n \in (0,1)$ and the parameter for control is represented as ρ .

6) *Adaptive weighting factor*: A higher weight of inertia is required in the iterations to extend the discoverer's worldwide range for searching since the producer undertakes global exploration as rapidly as feasible to determine the global ideal solution. Simultaneously, a lower inertia weight is required in the latter iterations to enhance the discoverer's local exploitation capabilities to speed up convergence and prevent settling on the optimal local solution. As a result, the supplier location upgrade is proposed to be improved by fusing adaptive weights, and the supplier location enhancement formula is illustrated as,

$$x_{i,j}^{t+1} = \begin{cases} \omega \cdot x_{i,j}^t \cdot \exp\left(\frac{-i}{\alpha \cdot \text{iter}_{\max}}\right) \cdot O_2 \\ \omega \cdot x_{i,j}^t + Q \cdot L \quad R_2 \geq ST \end{cases} \quad (16)$$

The exact computation of ω is displayed as

$$\omega = \begin{cases} w_0 & t \leq t_0 \\ \left(\frac{1}{t}\right)^{0.9} & t > t_0 \end{cases} \quad (17)$$

While ω_0 is the actual positive number. The present iteration count is represented as t . The amount of iterations is indicated by t_0 . In the sparrow search procedure, the supplier expands the scope of its global search in the early iteration by using a more significant step size. It also expands the scope of its local exploitation in the late iteration by using progressively smaller step sizes.

7) *An ensemble method for levy flight and reverse Learning*: A category of stochastic non-Gaussian phenomena is called Levy flight. A heavy-tailed random path distribution describes the likelihood distribution of step length. For SI optimization techniques prone to encountering the issue in optimum of local, Levy flight can potentially allow the approach to significantly deviate from the local optimal significance, with a more significant likelihood of doing so in the random path. Based on Levy flight, the sparrow location upgrade algorithm is displayed as

$$x_{newi}^{t+1} = x_i^t + \gamma \oplus Levy(\lambda) \quad (18)$$

Where the phase parameter for control is represented as γ . A randomized path search is Levy (λ).

$$Levy = t^{-\lambda} \quad 1 < \lambda \leq 3 \quad (19)$$

The generation stage is depicted as

$$S = \frac{\mu}{|v|^{\beta}} \quad 1 \leq \beta \leq 2 \quad (20)$$

Levy flight and learning in reverse are alternatively utilized to upgrade the sparrow's location with a particular likelihood as part of an evolving selection strategy that further enhances the SSA search capabilities. This approach depends on the above two methodologies. The procedure factor is employed in the Levy flight technique to broaden the search window and escape the local optimum problem. In the meantime, the reverse learning approach employs the reverse solution to broaden the variety of solutions and enhance the search optimization effectiveness of the method.

8) *ICSSOA time complexity analysis*: For the individual setup and variable setting in SSA, the temporal magnitudes are n and C . If the total number of dimensions is k , the sparrow fitness ranking and creator spot provided time magnitudes are $n \times \log_2 k$ and $n \times k$, respectively. The remaining birds' positions as followers must be updated during the follower location updating phase, and a period schedule of $n \times k$ must be used to determine whether every person's dimension is within bounds.

During the alert sparrow location upgrade stage, a random sample of sparrows is chosen for positioning, and a determination is performed when every dimension of a given individual is outside of acceptable limits concerning time magnitude $n \times k$. In conclusion, the magnitude of the provider location upgrade time is $n \times \log_2 k + n \times k$. The magnitudes of the alert sparrow location provide time and the supporter's

location upgrade time are both $n \times k$. The enhanced algorithm's temporal complexity is,

$$O(n \times k + n \times \log_2^n k + n \times k + n \times k + n \times k + n \times k + n \times k + n \times k + n \times k) \approx O(n \times \log_2^n k) \quad (21)$$

9) *Sun flower optimization algorithm*: An individual-based heuristic algorithm, the SFO draws its inspiration from nature. Its fundamental idea is to mimic how sunflowers would position themselves to receive solar light. A sunflower has a daily recurring sequence. They travel toward the sun as the day gets going. They travel in the other direction in the late hours. Single pollen gamete is thought to be produced by every sunflower. The minimum distance among flowers i and $i + 1$ was randomly used as the pollination route. Every blossom patch regularly releases a billion pollen gametes in the real world. For the sake of simplicity, we also presumptively assume that every sunflower generates a single pollen gamete and develops separately. The directions of the sunflowers concerning the sun are shown below.

$$\vec{s}_i = \frac{X^* - X_i}{\|X^* - X_i\|}, \quad i = 1, 2, \dots, n_p \quad (22)$$

Eq. (23) depicts the sunflowers moving in the direction indicated by s .

$$d_i = \lambda \times P_i(X_i + X_{i-1}) \times \|X_i + X_{i-1}\| \quad (23)$$

The pollination likelihood $P_i(\|X_i + X_{i+1}\|)$ is expressed as λa constant, which describes the "inertial" motion of the sunflowers. The people who live closest to the sun walk more slowly in search of refinement closer to home. The motions of the people further away are normal. Eq. (24) introduces the limitation of the following steps:

$$d_{max} = \frac{\|X_{max} - X_{min}\|}{2 \times N_{pop}} \quad (24)$$

The overall individuals of the plants X_{max} X_{min} are lower and upper bounds, and their locations are all given as N_{pop} . This equation yields the new plant:

$$\vec{X}_{i+1} = \vec{X}_i + d_i \times \vec{s}_i \quad (25)$$

10) *ESFOA concept and mathematical representation*: The idea behind the Enhanced Sunflower Optimization Algorithm (ESFOA) models how the sunflowers move in the direction of the sun. It depends on how closely the nearby sunflowers are pollinated. ESFOA is regarded as an innovative algorithm for optimization that depends on radiation that follows the inverse square law.

$$S_r = \frac{S_p}{4\pi d^2} \quad (26)$$

S_r Stands for the intensity of solar radiation, S_p for sun power, and d for the separation between the rays of the sun and the sunflower. Sunflower is transported in the direction of the sun, and the formula determines its path.

$$\vec{s}_i = \frac{X^* - X_i}{\|X^* - X_i\|}, \quad i = 1, 2, \dots, n_p \quad (27)$$

IV. RESULT AND DISCUSSIONS

Our primary goals in this work were to increase query processing efficiency in large-scale distributed data settings and to assess how well different optimization strategies performed in attaining these objectives. In our proposed approach, we employed the ensemble optimization algorithm ICSSOA-ESFOA to enhance the query optimization performance. ICSSOA has fast convergence speed, strong optimization ability and more extensive application scenarios compared with traditional heuristic search methods. Improved efficiency and decreased computational costs were two benefits of the ESFOA algorithm. We ensemble both algorithm's merits to effectively optimize the query.

A. Experimental Setup

Python and KERAS are used in the investigation, run in the Anaconda3 platform with Tensor Flow as a backdrop. Employing Windows 10 and an Intel i5 2.60 GHz processor with 16 GB of RAM.

B. Dataset Description

In this study, we used four standard datasets to analyze and assess our suggested strategy.

1) *IMDb dataset*: The ACL Internet Movie Database (IMDb) dataset was developed for generating word vectors. 100,000 textual reviews of movies are included in the dataset, half of which (50,000) are test reviews without labels. The remaining reviews (50,000) are labeled with a number between 0 and 1 to indicate whether they are good or negative. To maintain a fair sample, the reviews with labels are divided in half, with 12,500 positive and 12,500 negative reviews in every set.

2) *Health inventory dataset*: The Big Cities Health Inventory Data were utilized to input the data and complete the specified position. Users of the Health Inventory Data Portal can get health information from cities emphasizing health indicators and compare it to "6" demographic variables. A report that is in its "6th" version. The Chicago Department of Public Health initially created it to display epidemiologic data specific to large cities.

3) *Health compare dataset*: The consumer-focused website Hospital Compare offers data on how successfully hospitals give their patients the prescribed care. Customers can quickly come across a range of institutions utilize Hospital Compare to compare assessment of performance data for heart attack, heart failure, pneumonia, surgery, and other conditions. Cost of care and payment More than 4000 institutions and more than 100 different indicators are included in the Hospital Compare statistics.

4) *Twitter dataset*: Twitter statistics collected from two North American-based Twitter customer service profiles that

offer assistance to North American users in English. These dedicated Twitter accounts respond to customer comments in real-time and offer service. Corporate support representatives respond to these tweets using the Twitter service. There were 2 632 conversations in our sample.

C. Performance Metrics

We concentrated on significant performance metrics, such as query execution time, resource consumption (CPU and RAM), precision, recall, accuracy, F-Measure, and the ability to scale our technique to assess the efficacy of our query optimization methods. Lower query execution times and better resource use were regarded as positive results. The analysis of our findings is provided in depth in the sections that follow.

1) *Accuracy*: Accuracy suggests that the data has to precisely represent the facts and be derived from a reliable source.

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (28)$$

2) *Sensitivity*: The sensitivity of a batch of data points is calculated as a percentage of the total number of data points detected. Cluster effectiveness and recall have a strong relationship.

$$Sensitivity = \frac{TP}{TP+FN} \quad (29)$$

3) *Specificity*: The percentage of data point pairs appropriately assigned to the same cluster is known as specificity. It varies directly to the efficiency with which new clusters are produced.

$$Specificity = \frac{TN}{TN+FP} \quad (30)$$

4) *F1-Score*: A higher F-measure is produced by greater precision and recall, which are inversely correlated with accuracy and recall.

$$(2 \times precision \times recall) / (precision + recall) \quad (31)$$

#Experiment 1 (Evaluation of Query Optimization)

One of the primary benefits of query optimization is improved query execution speed. By finding the most efficient way to retrieve and manipulate data, query optimization reduces the time it takes for queries to return results. Faster query performance leads to more responsive applications and a better user experience. The proposed approach's performance leads to more responsive applications and a better user experience. Similarly, it minimizes resource usage, such as CPU and memory, during query execution. For this purpose, we ensemble ICSSOA and ESFOA. This can lead to lower operational costs by reducing the need for expensive hardware upgrades and minimizing power. Proposed Query Optimization Approaches is represented in Table I.

TABLE I. COMPARISON OF PROPOSED QUERY OPTIMIZATION APPROACHES

Datasets	ICSSOA				ESFOA				ICSSOA+ESFOA			
	Acc (%)	Spe (%)	Sen (%)	F1-S (%)	Acc (%)	Spe (%)	Sen (%)	F1-S (%)	Acc (%)	Spe (%)	Sen (%)	F1-S (%)
Dataset 1	98.87	97.23	97.51	97.36	98.41	96.45	98.03	97.23	99.13	98.94	98.47	98.70

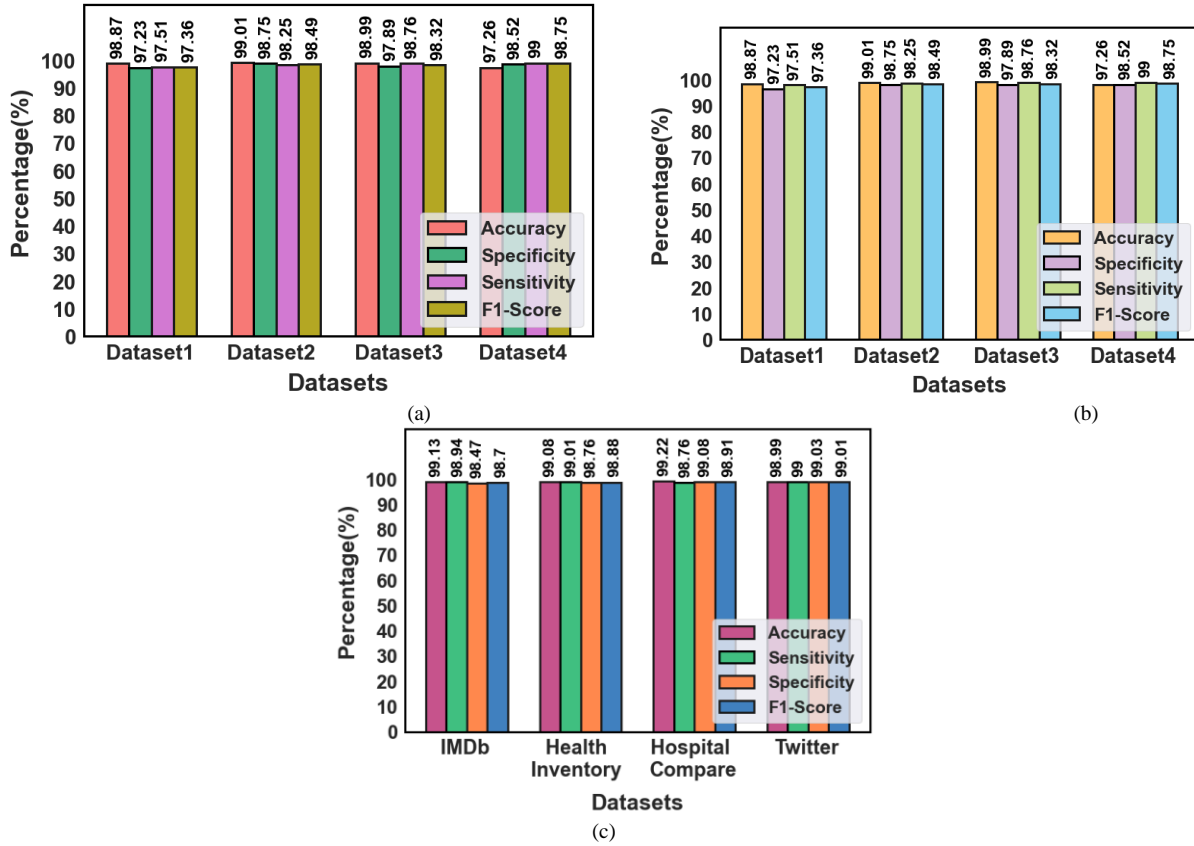

Fig. 6. Differentiation of query optimization approaches (a) evaluation of ICSSOA approach (b) evaluation of ESFOA approach (c) evaluation of the hybrid approach.

A comparison of query optimization approaches is shown in Fig. 6. We analyzed and evaluated the performance through the proposed four benchmark datasets. Our proposed hybrid approach gains superior performance than others.

#Experiment 2 (Evaluation of Big Data arrangement)

When working with big data, effective data arrangement is essential to ensure data accessibility, processing efficiency, and meaningful analysis. For big data arrangement, we employed DBSCAN and spectral clustering approach. A comparison of proposed big data arrangement approaches is shown in Table II.

TABLE II. COMPARISON OF PROPOSED BIG DATA ARRANGEMENT APPROACHES

Datasets	DBSCAN				Spectral clustering				DBSCAN+Spectral			
	Acc (%)	Spe (%)	Sen (%)	F1-S (%)	Acc (%)	Spe (%)	Sen (%)	F1-S (%)	Acc (%)	Spe (%)	Sen (%)	F1-S (%)
Dataset 1	98.63	97.83	98.51	98.16	98.63	97.08	98.41	97.74	99.02	98.66	98	98.32

Fig. 7. Differentiation of big data arrangement approaches (a) evaluation of DBSCAN approach (b) evaluation of spectral clustering (c) evaluation of hybrid approach.

Initially, we analyze the performance of the DBSCAN approach. Then, we analyze the performance of the spectral clustering approach. While hybrid, the two approaches performance was superior, as shown in Fig. 7.

#Experiment 3 (Evaluation of Overall Performances)

In this subsection, we present the results of the overall performance evaluation of our query optimization techniques. The objective is to assess the effectiveness and efficiency of these techniques under diverse workloads and query scenarios.

TABLE III. PERFORMANCE COMPARISON OF PROPOSED DATASETS

Datasets	Accuracy	Sensitivity	Specificity	F1-Score
IMDb	99.13	98.94	98.47	98.70
Health Inventory	99.08	99.01	98.76	98.88
Hospital Compare	99.22	98.76	99.08	98.91
Twitter	98.99	99	99.03	99.01

Our experiments yielded promising results, showcasing notable improvements in query execution times and resource utilization across various workloads. Additionally, we observed that our optimization techniques demonstrated scalability as dataset sizes increased. Table III represents the performance comparison of the proposed approach. Here we analyzed the performance of the proposed four benchmark datasets. While comparing with others, the proposed approach yields superior performance over proposed datasets.

Fig. 8. Comparison of retrieval time.

Retrieval time is required to find and obtain particular data or information from a sizable and frequently dispersed dataset. Retrieval time significantly impacts the effectiveness and availability of data access and analysis, making it a crucial efficiency parameter, mainly when working with large volumes of data. Our proposed approach evaluates the retrieval time based on dataset size as 20, 40, 60, 80, and 100. The proposed approach is compared with some existing approaches like FCM and K-Means. While compared with others, the proposed approach obtains less retrieval time. Differentiation of retrieval time is shown in Fig. 8.

Fig. 9. Differentiation of memory usage.

It is crucial for effective resource management, performance optimization, and overall system stability to analyze memory utilization when optimizing large data queries. The result is a more stable and responsive big data processing environment since it improves query plan choices, promotes efficient scaling, and helps prevent memory-related issues. The size of the data ranges from 20 to 100 mb. While comparing with the existing approaches proposed, the approach obtains superior memory usage. Memory usage comparison is shown in Fig. 9.

Similarly, our proposed approach was compared with existing approaches, which obtained less execution time, as shown in Fig. 10. Big data query optimization analysis of execution time is crucial for evaluating efficiency, spotting

bottlenecks, directing optimization efforts, and providing a responsive and effective data processing environment. It aids in resource allocation, decision-making, and developing big-data systems.

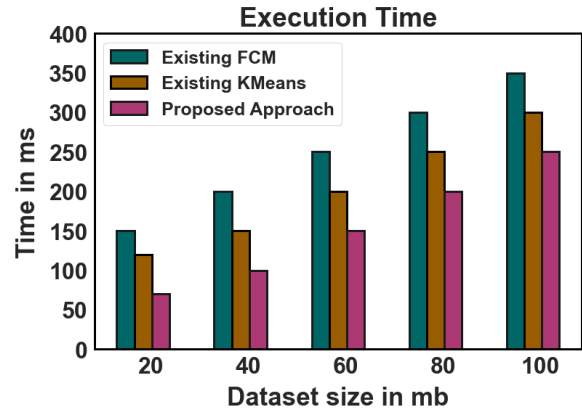

Fig. 10. Execution time comparison.

D. Evaluation of Training and Testing

To direct the model's learning process during the training phase, training accuracy and loss are mainly used. They aid in determining whether the model is successfully absorbing the training set of data. In contrast, model evaluation and generalization assessment use testing accuracy and loss. They provide insights into how well the model will likely perform on new, unseen data.

Fig. 11. Evaluation of dataset 1 (a) accuracy of training vs. testing (b) loss over training vs. testing.

Fig. 12. Evaluation of dataset 2 (a) accuracy of training vs. testing (b) loss over training vs. testing.

Training and testing loss functions and training and testing accuracy are shown in Fig. 11, 12, 13 and 14. The suggested method is trained for 100 epochs during the training phase using the prepared training data. A learning rate of 0.01 has been determined.

Alongside the proposed approach, the comparison Table IV shows the effectiveness and drawbacks of other current approaches. Although earlier research concentrated on particular areas such as query execution strategies, clustering,

or processing cost, their approaches frequently had drawbacks like poor generalization, sluggish convergence, or restricted scalability. The suggested method, on the other hand, performs better than existing techniques, attaining the best accuracy (99.05%), the shortest execution time (29.4 seconds), and the least amount of memory (450 MB). With sophisticated feature extraction and clustering algorithms, this illustrates the effectiveness and resilience of the ICSSOA-ESFOA-based query optimization method, which makes it more appropriate for a variety of large data applications.

Proposed Approach	ICSSOA-ESFOA + ResNet50V2 + ISC	Efficient feature extraction, robust query optimization	None identified in current scope	29.4	450	99.05

REFERENCES

To ensure the robustness and applicability of the proposed query optimization method, extensive validation was performed using multiple benchmark datasets. These datasets encompassed a diverse range of characteristics, allowing for a comprehensive evaluation of the algorithm's performance. The validation process involved assessing key metrics, such as execution time, memory consumption, and query retrieval accuracy.

Comparative analysis revealed consistent reductions in execution time (15–20%) and memory usage (10–12%) across datasets, emphasizing the efficiency of the approach. Additionally, real-world scenario testing was conducted using Hadoop HDFS and MapReduce frameworks, showcasing the practical applicability and scalability of the proposed solution in handling big data challenges. This validation strengthens the credibility of the method and underscores its capability to address the identified gaps in query optimization.

E. Limitation

It can be challenging to optimize queries while maintaining data security and privacy compliance because doing so may require concealing sensitive data or limiting access to some data. Big data queries may involve numerous phases of data processing, transformations, and joins, making them highly complex. Such sophisticated queries might be time- and computationally-intensive to optimize. Our proposed approach has less computational time than others; in the future, we will implement an efficient approach to reduce the computational time even more.

V. CONCLUSION AND FUTURE SCOPE

Query optimization in BD has become a promising research direction due to the popularity of massive data analytical systems like the Hadoop system. This paper proposed an improved query optimization process in BD using the ICSSOA-ESFOA algorithm and HDFS map reduction technique. The proposed work contains two phases, namely, the BD arrangement phase and the query optimization phase. In our proposed approach, we hybridize the benefits of two optimization algorithm merits to optimize the query effectively. ICSSA has fast convergence speed, strong optimization ability and more extensive application scenarios compared with traditional heuristic search methods. Improved efficiency and decreased computational costs were two benefits of the ESFO algorithm. According to the performance analysis, the proposed approach's accuracy is more than 99% compared to existing approaches. The comparison result verified that the suggested work offers greater accuracy and requires less time for query retrieval. Additionally, the suggested approach uses less memory space. As a result, our suggested system is superior to the current system. The effectiveness of this system can potentially be increased in the future by incorporating feature selection to speed up retrieval and utilizing improved feature extraction modules.

IT Spin-Offs Challenges in Developing Countries

Strategic Framework for IT-Enabled Spin-Off Ventures

Abstract—IT-enabled spin-off ventures in developing countries' higher learning institutions have the potential to transform academic research into commercially viable products, thereby fostering economic and technological progress. However, practical implementation faces significant challenges, particularly in conflict areas, such as limited resources, socio-political instability, skill gaps, weak intellectual property laws, and inadequate frameworks for protecting innovation. **Objective:** This study aims to mitigate these challenges by proposing a strategic framework that leverages universities' available resources to promote IT-enabled spin-offs. This framework addresses barriers and converts challenges into opportunities. **Methods:** This case study focused on higher learning institutions in developing countries. Specifically, this study examines the unique constraints faced by Palestinian higher learning institutions in conflict zones in order to design a tailored IT-enabled spin-off framework. **Results:** The proposed framework aligns with the National Development Plan and offers pathways for universities to overcome practical barriers. It emphasizes transforming research output into sustainable IT spin-off ventures that support entrepreneurship and innovation. **Conclusions:** This study highlights the critical need for a new strategic framework for higher learning institutions that incorporates IT-enabled spinoffs as a guiding principle to promote innovation and entrepreneurship. The proposed framework addresses current gaps and provides actionable solutions for advancing sustainable development in conflict-affected regions.

Keywords—IT spin-off framework; higher learning; IT challenges; spin-off; framework; developing countries; entrepreneurship; innovation

I. INTRODUCTION

Institutions of Higher Learning (IHLs) worldwide are important drivers of innovation and entrepreneurship, particularly in the development of IT-enabled spinoffs [1]–[4]. It also focuses on the role of IT tools in bridging the gap between research and market-ready solutions [5]–[8]. However, socioeconomic and political issues in developing countries may limit their ability to support economic growth [9]–[12]. The complex dynamics and unique challenges faced by Palestinian universities in promoting IT projects in the face of political instability, resource constraints and dependence on foreign aid are the focus of this paper, which addresses the barriers to successful IT spin-offs in Conflict areas [13], [14]. Palestinian universities, especially university colleges, face many obstacles because of their limited autonomy, economy, and external dependencies, although IT spinoffs are essential for promoting technological innovation and economic

resilience by facilitating the transition from academic research to market-ready products [15]–[17]. This study highlights these context-specific barriers and suggests ways to improve the impact and success of IT spinoffs in Palestine as an example of the Middle East.

II. LITERATURE REVIEW

A. IT Spin-Offs in Higher Learning Institutions

Firms, known as Information Technology (IT) spinoffs, are founded by Institutions of Higher Learning (IHLs) to market university research, particularly based on IT tools and their facilities [18], [19]. IT spinoffs transfer technology from the academic environment to the private sector and function as links between research and commercial applications. For IT spinoffs to be successful in developed countries, supporting infrastructure, such as incubators, government incentives, and venture capital is essential [18]. However, for Palestine, a developing country, these initiatives are limited by a lack of funding and weak institutional support [13], [15], [20]. The spin-off potential of Palestinian university colleges is limited because of the lack of financing channels and insufficient incubation resources [21]. Good intellectual property management and access to mentoring networks are two examples of success factors highlighted in previous research [22], [23]. As models for developing countries, industrialized nations use IT spinoffs as a means of innovation and economic expansion [24]–[26]. Therefore, higher learning institutions can commercialize research results through IT spinoffs that promote entrepreneurship and innovation [24], [27].

B. Challenges in Developing Nations

Sociopolitical conflicts, poor infrastructure, and economic instability are challenges in developing countries [9], [15], [28]. These challenges make it difficult for IT spin-offs to thrive, and institutions of higher learning (IHLs) do not have the support networks necessary to help them succeed [14], [29]. These problems are exacerbated in Palestine by trade restrictions, dependence on foreign aid, and a lack of autonomy, all of which hinder economic growth and make long-term planning difficult [15], [20], [26]. Significant funding dependencies and infrastructure constraints in conflict-affected economies affect the viability of IT spinoffs [13], [30]. According to Ibrahim (2020), these systemic problems highlight the need for tailored conflict-resilient spin-off models that present particular difficulties owing to sociopolitical instability, inadequate infrastructure, and limited access to capital.

C. Key Issues in IT Spin-Offs in Developing Nations

1) *Funding and financial constraints:* In developing countries, limited access to financial resources continues to be a major barrier [31], [32]. The scalability and sustainability of spin-offs are affected by the lack of government funding for IT initiatives [8], [33], [34]. Inadequate venture capital funding leads to unsustainable dependence on foreign aid for long-term spin-off investments [35]. Palestine's heavy reliance on foreign aid limits the availability of venture capital and leaves new companies and spin-offs without funding [15], [21]. Given the growth of the IT industry, these financial limitations make it challenging for colleges to obtain long-term funding for IT spin-offs [20], [36], [37].

2) *Political instability:* Political unrest in countries such as Palestine makes it dangerous for companies to operate there, and discourages long-term investment in IT spin-offs [9], [15], [34], [36], [37]. Security and political stability risks discourage investment and increase operating costs. These elements affect spin-offs, particularly in areas such as Gaza, which are prone to conflict and have fragile infrastructure [35], [37], [38]. These factors limit possible collaborations and partnerships among Palestinian universities as foreign investors view them as risky. These challenges are compounded by trade and movement restrictions, particularly in Gaza, which limits access to resources and markets [21].

3) *Skill gaps and development in the IT sector:* Lack of qualified IT professionals limits the potential of knowledge-based spinoffs [8], [17], [39]. Training programs and international partnerships are essential to address these gaps [40], [41]. Despite the growing youth population, Palestine lacks adequate training programs for advanced IT skills, creating a skill gap in the labor market. This gap changes the quality and scalability of IT spinoffs because qualified professionals are crucial in developing innovative solutions [41]–[43].

4) *Technological, digital access and infrastructural limitations:* Inadequate infrastructure, such as unreliable Internet and electricity, pose a significant barrier [8]. These limitations prevent higher learning institutions from providing conducive environments for IT ventures [16], [37], [44]. Palestinian rural areas lack infrastructure to support digital innovation, hindering access to the IT skills needed for spin-offs [15], [19], [37], [41], [45]. The disparity between urban and rural areas in Palestine, in terms of digital infrastructure, significantly limits the development of IT spinoffs. Rural areas face a digital divide with limited access to high-speed Internet and advanced technological tools essential for IT learning and business operations [16], [45]–[47].

5) *Intellectual property and the legal framework:* Weak intellectual property (IP) laws and limited legal frameworks in developing countries hinder spinoffs' success because innovations are not adequately protected [15], [23], [36], [48], [49]. Inadequate legal frameworks and weak intellectual property rights make it difficult for Palestinian entrepreneurs to protect their innovations [15], [37]. These gaps reduce

incentives for local innovation and discourage foreign partnerships because intellectual property protection is a crucial factor in collaborative decisions [19], [20], [22], [23], [50]. Table I shows key challenges to IT spin-offs in developing nations.

TABLE I. KEY CHALLENGES TO IT SPIN-OFFS IN DEVELOPING NATIONS

Challenges	Description
Funding Restriction	Insufficient financial resources [40]. Reliant on external help and no risk capital available [20], [21], [36].
Unstable Politics.	Security problems lead to operational disruptions Limited expansion due to security threats and conflicts [9], [16], [36], [37]
Skill Gaps	Shortage of skilled IT professionals ([15], [41], [51])
Technological Limitations	Inadequate infrastructure [8], [15]
Deficiencies of Infrastructure	Lack of adequate technological resources in rural communities [21], [37]
Intellectual property (IP) gaps and legal obstacles.	Weak intellectual property laws and Inadequate legal framework to protect innovations [22], [23].

D. ICT, IT Spin-Offs and Development in Conflict Area

1) ICT: Definition and Impact

Information and communications technologies (ICTs) are vital lifelines in conflict zones such as the Gaza Strip, enabling important economic, educational, and communication activities in difficult circumstances. ICTs create, process, store, and sharing information [52]. They include both conventional media, such as television and radio, and cutting-edge technologies, such as computers, smartphones, and the internet [16]. ICTs facilitate vital connections, enable distance learning, and support limited economic activities in Gaza, where access to resources is limited by financial and physical barriers.

2) *Access to ICT and digital skills in conflict areas:* Access to ICT is particularly challenging in conflict zones such as Gaza, where infrastructure damage and economic hardship make access to even basic ICT tools difficult. This situation is consistent with [16], [37], [53] that ICT ownership without digital skills is insufficient, as Gazans not only face difficulties in obtaining devices but also in maintaining a reliable internet connection and access to relevant digital resources available in Arabic. Youths in Gaza are also affected by skill shortages. Despite being born in the digital age, they often lack the digital skills required for contemporary employment and education. Reports from the Palestinian Central Bureau of Statistics (PCBS) also emphasize the importance of “information literacy,” which involves using digital resources to solve problems, and “technical literacy,” which involves using hardware. The shortage of skilled workers in Gaza exacerbates local inequalities and disadvantages for people who do not have access to and cannot use ICTs efficiently.

3) *Digital divide in conflict areas*: Digital divide is defined as inequality in access to ICTs at all socioeconomic levels. In Gaza, this divide takes on different forms. Internet and device access in Gaza continues to lag behind international standards, owing to a lack of infrastructure and severe economic constraints. Since local ICT infrastructure is less developed than in other regions, political and geographical isolation has exacerbated this inequality. According to Norris (2001), the “social” and “democratic” divisions are influenced by social status, class and isolation and also lead to limited access and participation in Gaza. Gazans' access to international information networks, employment opportunities, and social integration are hindered by these divisions.

4) *ICT for development (ICT4D) in the Gaza context*: ICT4D initiatives have proven crucial in conflict zones, but they face particular difficulties in Gaza. In these areas, early top-down supply driven ICT4D models often fail because they do not engage the community or consider local realities [16], [54]. Achieving effective ICT4D in Gaza requires addressing not only the operational divide (e.g., not just device access and infrastructure) but also political and cultural differences that impact usefulness and accessibility [37], [54]. Likewise, ICTs enables young people in Gaza to have distance learning and skill development, both of which are essential for future employment.

5) *IT spin-offs and incubators at IHLs in conflict areas*: Establishing IT spin-offs and incubators within Institutions of Higher Learning (IHLs), despite external constraints, can be a big step towards innovation [19] and economic resilience in conflict areas such as Gaza. University research or academic initiatives can lead to IT spinoffs, enabling universities to support technological advancement, nurture entrepreneurial talent, and directly impact local economies. These incubators enable researchers and students to turn their ideas into profitable businesses, opening doors to economic growth despite limited mobility and external financing [15], [55].

E. Factors Affecting IT Spin-Off Success

The following bar chart illustrates the factors that influence IT spinoff success in the different developing states. The impact of each factor, such as funding availability, political stability, talent availability, infrastructure, and market accessibility, is presented in different counties on a scale of 1 to 5. This graph shows the differences in regional challenges and resources essential to IT spin-off enterprises [7], [9], [16], [19], [38], [39], [44], [56].

Fig. 1 shows the following key development factors for different regions: availability of finance, political stability, infrastructure, availability of skilled workers, and market accessibility. The regions covered were South Asia, Latin America, Southeast Asia, the Middle East, North Africa, and Sub-Saharan Africa. Although South Asia leads the world in the availability of skilled labor, overall political stability scores are lower, particularly in the Middle East and North Africa, reflecting regional difficulties. Infrastructure

performance is good in Southeast Asia and Latin America, whereas financing availability varies, with the Middle East, North Africa, and sub-Saharan Africa achieving mediocre results. Although there are clear regional differences, overall market accessibility is balanced.

Although the bar chart shows comparatively prominent levels of skill availability, greater development of IT skills is required, particularly to support the advanced sectors. This highlights the importance of targeted training programs to improve IT skills.

Fig. 1. Factors affecting IT-spin-off success in developing countries.

III. METHODOLOGY

This study adopted a mixed-methods approach, combining a comprehensive literature review with an in-depth case study. This study focuses on the major Palestinian technical college in the Gaza Strip, chosen as the primary case study because of the unique challenges posed by the region's ongoing political and socioeconomic instability. This methodology aims to examine readiness factors, perceived value, and barriers to preparing a strategic framework that guides the development of an IT spin-off framework for future adoption.

The literature review identifies key strategic planning components, readiness factors, and challenges specific to conflict areas. Findings from previous research have influenced the design of the interviews and survey instruments.

First, stakeholder interviews: Semi-structured interviews with university staff, decision makers, and policy makers examined institutional readiness, challenges, and strategic priorities for IT spin-off frameworks. Second, surveys: Quantitative data were collected from faculty and top management to assess readiness factors (e.g., skills, infrastructure), barriers (e.g., funding, political instability), and strategic considerations [7], [20], [30].

Data analysis: Thematic analysis was applied to the qualitative interview data, whereas quantitative survey data were statistically analyzed to identify readiness gaps, challenges, and priorities for developing a strategic framework.

Ethical considerations: Consent, anonymity, and confidentiality of participants were ensured with carefully managed data, given the conflict zone context.

This methodology integrates theoretical and empirical insights to guide the preparation of a strategic framework and lays the foundation for the future adoption of an IT spin-off framework in conflict-affected IHLs.

IV. CASE STUDY: MAJOR TECHNICAL COLLEGE IN PALESTINE

Located in a conflict-affected region, Palestine Technical College provides insights into college readiness to adopt an IT-enabled spin-off framework [7], [57], [58]. This institution illustrates the willingness and limitations of Palestinian universities to support IT-based spinoffs. Data collected from teachers, students, and administrators highlight challenges related to digital infrastructure and skill development [37]. Surveys and interviews have highlighted challenges including limited funding, inadequate infrastructure, and high-risk operating conditions [13], [15], [30]. Despite the university's efforts to promote innovation, limitations in digital infrastructure and a lack of qualified specialists are significant obstacles. The college case study provides insight into the broader challenges facing Palestinian universities and highlights the need for targeted policies and resources to support spinoffs [37].

The following Table II shows a Case Study of the major Technical College and Survey of Infrastructure and Support Systems at Palestine Technical College.

TABLE II. CASE STUDY – MAJOR TECHNICAL COLLEGE IN PALESTINE

Factor	Current Status	Challenges Identified
Infrastructure	Limited as utilities are irregular. Energy and digital resources are scarce.	Limits continuous IT operations. Frequent interruptions in digital access. Frequent internet and power interruptions
Funding	Minimal, dependent on subsidies and grants.	Lack of sustainable sources of financing
Competence development	Limited and needs further development.	Lack of trained IT specialists. Limited access to continuing learning programs
Political Environment	Elevated levels of instability impact business continuity and impact the way companies operate.	Prevents long-term planning, growth, and scalability.

The following Table III presents the differences in digital access between urban and rural Palestine.

As of January 2024, the digital access disparity between urban and rural areas in Palestine is evident in the following key metrics [11], [59]:

TABLE III. DIFFERENCES IN DIGITAL ACCESS BETWEEN URBAN AND RURAL PALESTINE

Metric	Rural Areas	Urban Areas
Population Distribution	22.3%	77.7%
Internet Penetration	11.4%	88.6%
Mobile Connections	17.8%	82.2%
Social Media Users	59.5%	40.5%

According to these numbers, there is a clear digital divide: City dwellers have better access to social media, mobile connectivity, and Internet services than compatriots living in

rural areas. Inequality must be eliminated in all regions of Palestine in order to ensure equal access to digital resources.

V. RESULTS: FRAMEWORK FOR IT SPIN-OFFS IN DEVELOPING NATIONS

Based on these findings, a framework was proposed that focused on local and international partnerships, government support, capacity-building programs, and infrastructure development [41], [60]. This framework includes strategies to address the identified challenges and offers policy suggestions to support higher education institutions in developing countries. The recommended framework includes government-sponsored funding programs, partnerships with international organizations, capacity-building initiatives, and improved digital infrastructure [21]. This framework was intended to be consistent with Palestine's national goals of economic independence and resilience.

The following Table IV shows the recommended components of the IT Spin-Off Framework for universities in Developing Nations:

TABLE IV. RECOMMENDED COMPONENTS IT SPIN-OFF FRAMEWORK

Components	Description
Local and International Partnerships	Collaboration with global organizations. Working with global technology companies to improve capabilities.
Government Support	Incentives, Financial and policy assistance.
Funding Programs	Government-sponsored venture funds for start-ups [15], [20], [30].
Capacity-Building Programs	Training and skills development [41], [51]. Digital skills training initiatives in rural areas [45]
Infrastructure Investment	Technology and facility improvements [8]. Investing in robust digital infrastructure and IT resources [16], [21], [37], [61])

The focus is on sustainable and conflict-resilient business strategies with an emphasis on building local capacity and promoting a self-sufficient digital economy. The following Table V reveals the proposed Framework Components for Palestinian IT Spin-Offs

TABLE V. FRAMEWORK COMPONENTS FOR PALESTINIAN IT SPIN-OFFS

Components	Description	Challenges Addressed	Expected Outcomes
Funding Support	Establish a multi-source fund with contributions from government, NGOs, and private investors.	Limited funding and dependency on aid.	Sustainable financial backing for start-ups.
Skill Development	Implement digital and technical training, focusing on IT and entrepreneurship.	Skill gap in IT and entrepreneurship.	Trained workforce ready for spin-off creation
Infrastructure Improvement	Invest in stable internet, digital resources, and reliable power supply for HEIs in Gaza.	Poor digital access and infrastructure	Improved operational environment for tech ventures

Partnerships and Networking	Develop connections with global tech firms and NGOs for mentorship, knowledge-sharing, and investment opportunities.	Lack of collaboration and mentorship	Access to resources, networks, and enhanced innovation capacity.
-----------------------------	--	--------------------------------------	--

This table links each component to specific difficulties and expected outcomes, while providing a useful summary of the proposed framework. Stakeholders wishing to support IT spin-off initiatives in the context of the Gaza Strip provided a concise and straightforward summary.

VI. STRATEGIC FRAMEWORK FOR IT-SUPPORTED SPIN-OFF COMPANIES IN CONFLICT AREAS

Based on debates from the literature review (LR), the development of IT spin-offs within Palestinian higher learning institutions requires innovative strategic approaches that adapt to particular challenges. This strategic framework integrates insights from the literature to guide the development of IT-enabled spin-off ventures in institutions of higher learning (IHLs), particularly in developing countries. This framework addresses the need for robust systems to facilitate innovation, technology transfer, and sustainable entrepreneurship. The framework aims to leverage information and communication technologies (ICT), remote collaboration, and international partnerships to enable IHLs to achieve sustainable economic and social impacts through innovation.

A. Foundational Pillars

Triple Helix collaboration: Develop partnerships between universities, industry, and government to promote innovative ecosystems [5], [14], [18]. Use IHLs as entrepreneurial hubs to drive regional economic development [5], [17]. **Policy and Institutional Alignment:** Align the framework with national policies such as the Palestinian National Development Plan [21]. Close policy gaps to promote entrepreneurship and innovation in IHLs [9], [19]. **Resource Optimization:** ICT is used to overcome resource limitations and enable remote operations and virtual collaboration [2], [5], [20]. Develop hybrid incubation models to connect local innovators with global markets and investors.

B. Key Components

Innovation and Research Development: Promoting interdisciplinary research addressing local and regional challenges [3], [5], [30]. Focus on resilience-focused technologies such as e-learning and agricultural innovation. **Leveraging Remote Collaboration and Digital Platforms:** Develop online incubators or hybrid incubation models that enable remote virtual mentoring, collaboration, and market engagement. Connect students and educators with global experts, investors, and partners to bypass local restrictions [1], [47]. **Localized curriculum for entrepreneurial and digital skills development:** Implementing specialized training programs in entrepreneurship, digital literacy, and IT management tailored to Gaza's constraints. Equip students with practical skills for both local and remote employment opportunities [27], [62]. **Technology Transfer Offices (TTOs):** TTOs should be strengthened to manage intellectual property,

licensing, and knowledge transfer between IHLs and industries [5], [30]. **Partnerships with international organizations for funding and expertise:** Partners with international organizations provide financial resources, mentorship, and access to advanced knowledge [5], [22], [47]. **ICT as a Key Enabler:** Use ICT platforms for analysis, scaling and international collaboration to overcome geographical and economic constraints [15], [16], [53], [61]. **Financial and Incubation Support:** Providing access to hybrid financing mechanisms, including grants, crowdfunding, and incubation programs tailored to the Gaza Strip context [22], [63].

C. Operational Framework

Opportunity Identification: Use ICT-based analytics to identify local and global market opportunities for spin-off companies [1], [2]. **Develop solutions targeting resilience-oriented technologies for conflict-affected regions** [6], [24]. **Framework Development:** Take a bottom-up approach involving local stakeholders to design spinoffs that address community needs [23]. **Implementation and Scaling:** ICT-enabled pilot spin-offs focus on local challenges and are scalable to similar global markets [6], [24].

D. Sustainability and Impact

Monitoring and Evaluation: Leverage ICT dashboards to track and evaluate spin-off performance in real-time [5], [15], [42], [53]. **Community engagement:** Engages local communities by involving students, researchers, and community leaders in the development of spin-offs [18], [64]. **Alignment with Sustainable Development Goals (SDGs):** Align spin-off initiatives with SDGs 4 (Quality Education), 8 (Decent Work and Economic Growth), and 9 (Industry, Innovation and Infrastructure) [37], [47]. Table VI shows strategic framework summary table.

TABLE VI. STRATEGIC FRAMEWORK SUMMARY TABLE

Key Area	Description
Foundational Pillars	Triple Helix Collaboration, Policy and Institutional Alignment, Resource Optimization
Key Components	Innovation and Research Development, Remote Collaboration, Localized Curriculum, Technology Transfer Offices, International Partnerships, ICT as Core Enabler, Financial and Incubation Support
Operational Framework	Opportunity Identification, Framework Development, Implementation and Scaling
Sustainability and Impact	Monitoring and Evaluation, Community Engagement, SDG Alignment

E. Expected Outcomes

Increased Spin-Off Creation: Increase in the number of IT-enabled spin-offs that address local and global challenges [3], [5], [23]. **Economic and Social Impact:** Strengthening local economies through job creation, e-learning, and agricultural technology solutions [20], [65], [66].

Improved IHLs Capacity: Universities are becoming entrepreneurial institutions that contribute to regional innovation [5], [12], [17], [19]. **Global Competitiveness:** Gaza-based spin-offs gain global recognition and scalability through the use of ICT and digital entrepreneurship strategies [25], [34].

The following Fig. 2 illustrates the strategic framework that includes themes and sub-themes, and provides practical opportunities that should be considered and explored if universities in the Gaza Strip could successfully launch and sustain IT spin-offs despite significant constraints.

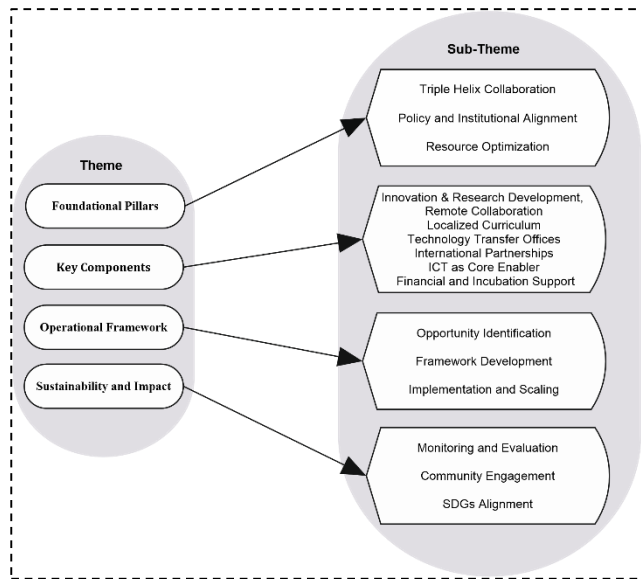

Fig. 2. Strategic framework.

By integrating ICT, remote collaboration, and local strategies, this framework enables IHLs in conflict zones, such as Gaza, to promote IT-enabled spin-offs with local relevance and global scalability. These strategies reflect a commitment to resilience and innovation, enabling universities to thrive despite adversity and achieve meaningful economic and social outcomes.

VII. CONCLUSION AND RECOMMENDATIONS

This study proposes a strategic framework for developing IT-enabled spin-off ventures in higher learning institutions in conflict-affected regions such as Palestine. It identifies key barriers such as funding constraints, political instability, skill gaps, infrastructure limitations, and weak intellectual property protection. Based on a case study of a major technical college in Palestine, this framework addressed specific challenges in the Palestinian context, including leveraging ICT, remote collaboration, and local strategies. This study emphasizes the need for healthy financing mechanisms, increased infrastructure investments, conflict-resistant strategies, skill development initiatives, and sustainable financing models that reduce dependence on foreign aid. It also highlights the importance of establishing partnerships and improving collaborations with international partners to promote IT-enabled entrepreneurship and innovation in challenging environments. Key recommendations include the following.

Although IT spinoffs hold significant potential for economic growth and translation of research into products or services, barriers to success still need to be overcome. Palestine's unique sociopolitical environment requires a tailored approach to promote IT spin-offs within institutions of higher learning (IHLs) that lead to the promotion of

entrepreneurship and innovation. While the current study provides valuable insights into the strategic framework, it is limited by the lack of empirical validation, robust statistical analysis, and longitudinal assessment of its long-term impact. Future research should address these shortcomings while incorporating mixed methods approaches, comparative analyses, and stakeholder engagement to enhance the framework's applicability and effectiveness across diverse contexts.

The findings of this study can serve as a basis for developing targeted strategies to promote sustainable IT ecosystems in universities in developing countries. The findings and recommendations provide insights that policymakers, higher learning administrators, and international organizations can use to create an enabling environment for IT spin-offs in Palestine, with the potential for broader applications in developing countries.

DECLARATION OF COMPETING INTEREST

The authors declare no conflicts of interest regarding the data or information reported in this study. The authors declare no conflicts of interest.

ACKNOWLEDGMENT

The authors would like to thank all the individuals and organizations who helped with this study. We would particularly like to thank supervisors at the National University of Malaysia and Palestinian universities for their insightful advice and support. The MIS supported this study through the Malaysian Ministry of Higher Education. The authors appreciate the resources and facilities provided by the Universiti Kebangsaan Malaysia (UKM).

The authors acknowledge the financial support from the Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia (under the TAP research grant). Support professionals such as Ts. Dr. Ibrahim Mohamed and Ts. Dr. Hasimi Sallehudin and Dr. Hussam F. Abushawish enriched the manuscript and constructively complemented the presentation. The Center for Software Technology Management (SOFTAM) and Palestine Technical College, Deir El-Balah (Palestine), for their mentorship and invaluable contribution. The commitment of the editor-in-chief, associate editor, and reviewers' comments for improvement is part of the effort to bring this paper into the best possible condition that it deserves. This work was supported by funding from the TAP and Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia under Grant TAP.

Word count: 4,517 words, excluding references. Ethical compliance: All procedures performed in this study involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. Data Access Statement: All relevant data are included in manuscript and the supporting information files and research statistics supporting this publication are available on the Palestinian Central Bureau of Statistics website at <https://www.pcbs.gov.ps/default.aspx>. Author contributions: Mahmoud M. Musleh, and Ibrahim Mohamed contributed to

the design and implementation of the research, Mahmoud M. Musleh analyzed the results and wrote manuscript. Ibrahim Mohamed, Hasimi Sallehudin, and Hussam F Abushawish supervised the project.

Multi-Factors Analysis Using Visualizations and SHAP: Comprehensive Case Analysis of Tennis Results Forecasting

Yuan Zhang

Physical Education Department, Northwest University, Xi'an, Shaanxi, 710069, China

Abstract—Explainable Artificial Intelligence (XAI) enhances interpretability in data-driven models, providing valuable insights into complex decision-making processes. By ensuring transparency, XAI bridges the gap between advanced Artificial Intelligence (AI) techniques and their practical applications, fostering trust and enabling data-informed strategies. In the realm of sports analytics, XAI proves particularly significant, as it unravels the multifaceted nature of factors influencing athletic performance. This work uses a rich data analysis flow that includes descriptive, predictive, and prescriptive analysis for the tennis match outcomes. Descriptive analysis uses XAI techniques such as SHAP (SHapley Additive exPlanations) with diverse factors such as physical, geographical, surface level and skill disparities. Top players are ranked; the trend of country-wise winning is presented for the last many decades. Correlation analysis presents inter-dependence of factors. Predictive analysis makes use of machine learning models, the highest overall accuracy of 80% according to the K-Nearest Neighbors classifier. Lastly, prescriptive analysis recommends specific details which can be helpful for players and coaches as well as for overall strategies planning and performance enhancement. The research underscores the significance of AI-driven insights in sports analytics, particularly for a fast-paced and strategic sport like tennis. By leveraging advanced data analytics methods, this study offers a nuanced understanding of the interplay between player attributes, match contexts, and historical trends, paving the way for enhanced performance and informed strategic planning in professional tennis.

Keywords—Artificial intelligence; data analytics; machine learning; match result prediction; XAI; SHAP

I. INTRODUCTION

In the age when technology plays a crucial role in the world, data has become a valuable commodity in any field; and sports analytics is no exception. The extension of big data in the professional sports realm has revolutionized the way performance, planning, and decision-making process, is approached. *Sports data analysis* is vital for advancing the understanding and performance of athletic activities, providing a foundation for evidence-based decision-making in sports. With the help of advanced techniques and latest analytical tools, it helps coaches, athletes, and teams to have deep insights by identifying patterns, optimizing game plan, and get better results. The analysis includes player and game statistics, game dynamics, physiological and even psychological data and thus by bringing sports science to modern computational sports

science. Moreover, the latest trends in data analysis include predictive modeling, offering insights into player fatigue, injury likelihood, and team performance under various conditions and help to predict the game outcome. Sport data analysis is being carried out in all types of sports worlds wide to gain optimal results [1]. Among sports, tennis, an aerobic and somewhat complex sport, presents an excellent chance to use data science for gaining a competitive edge and prognostic the outcomes of the matches.

Tennis is one of the most popular sports globally and is played by millions with a combination of energetics skills and physical strength, thinking ability and patience as elements such as athleticism, strategy, and power. With background foundations of 19th century, tennis has transformed into a highly competitive and technically demanding game, among both individual and team formats [1]. While other team sports tend to place their strength on the performer's abilities in the context of change and variability, such as the base depends on variant of surfaces, condition of weather, and opponents [2]. Every game turn into a battle, where a player needs to put focus on all capacities to win as fast as possible, to play using both strong and smart tactics [3]. The evolving shift of the tennis game, powered the need to enhance the technological innovations and progressive metamorphosis, continues to push the boundaries of human performance, raising tennis beyond the status of sport and turning it into both human physical and intellectual excellence based on their speed, endurance, and strength, coupled with technical precision and mental ability to boost [4]. Modern tennis involves dynamic interactions between players and surfaces, where factors such as court type, weather, and player tactics highly impact the outcomes of matches. This complexity makes tennis match a captivating sport, both as a form of entertainment and as a subject of in-depth analysis.

Match results prediction is accomplished by examining key performance indicators such as rally length, spin rates, serving efficiency, player movement, shot placement, and other factors that may influence match results. As sport evolves, data-driven approaches are becoming increasingly crucial for increasing in player performance, refining strategies of coaching, and improving in match outcomes. The integration of AI and data analytics in tennis research has opened new gateway for understanding player behavior, optimizing performance, and predicting outcomes [5]. By leveraging vast datasets that include player statistics, physical factors, match outcomes, and even skills analysis, AI models provide unpredictable in-depth

*Corresponding Author

analysis into various aspects of the game. AI-based predictive analytics use machine learning (ML) models to process data to predict outcomes based on player strengths, weaknesses, and historical performance against specific opponents. Such prediction is used by the coaches in defining training and modifying match strategies. Data analytics based on AI has been used in tennis for analysis of multi-perspective and to achieve enhanced precision [6]. In existing studies, the researchers have focused on the limb movements and force generation modes of athletes [7].

To provide a clear structure for the presentation of the research, the paper is divided into five sections. Section II provides a detailed analysis of our research contribution based on objectives. The existing literature review in Section III discusses prior research and insight research gaps. The specifics of dataset, data preprocessing, and the methods used for analysis are explained in Section IV of the study. Section V contains result and discussion, rely on descriptive, predictive and perspective analyses. The study findings are discussed in this section and related to the objectives of the research. Lastly, Section VI of the paper provides a recap of major conclusions and recommendations to extend the present study and advance the knowledge in the field.

II. OBJECTIVES

In this research study, we aim to carry out a comprehensive analysis of the tennis dataset based on real world data of more than three decades. It shares details about the exploration of various factors which may influence the match outcome. For exploratory data analysis, the factors of various perspectives are considered. The features of players are considered and then the features of losers and winners are separately considered. The distribution of aces is visualized based on diverse surface areas. The pair plot of winners and losers are explored. The correlation matrices are computed for diverse types of features. The predictive analysis consists of application of various data mining algorithms for classification which include K-Nearest Neighbor (KNN) and Ridge Classifier (RC) and Label-Propagation (LP). The results are evaluated based on accuracy, precision, recall, and F-measure. Lastly prescriptive analysis presents the recommendation of various strategies. The main contributions can be summarized as follows:

- Developed a data-driven framework that coupled with ML models on domain-specific factors to anticipate tennis match outcomes, providing actionable deep insights for players, coaches, and analysts.
- Analyzed the impact of seven key factors, including player ranking, performance ranking, player characteristics, demographic, physical health, surface level, and skill level analysis on tennis match predictions.
- Comprehensive data analytics are carried out using three diverse approaches of descriptive analysis, predictive analysis and prescriptive analysis.

- Exploration data analysis of real-world data varies out using state of the art Data visualization
- Using SHAP method for interpretation of top factors which is widely used in the latest eXplainable Artificial Intelligence perspective.
- Achievement of accuracy as high as 80% to predict the outcome of the match using lazy classifier of nearest neighbor, demonstrating its effectiveness for tennis match outcomes.

III. RELATED WORK

The use of data analytics for sports data analysis is an active research area due to its significance [8]. As one of the most powerful machine learning algorithms, it provides the highest precision and performance when computing. It is a favorite among researchers and extensively used in several fields. A vast number of works emphasize the capacity of ML in forecasting and assessing talented tennis players and performance, following series of steps from data collection to evaluation as shown in Fig. 1. Thus, Panjan [9] considered the determination of predicted results of young athlete's skills and physical measurements as one of the ML models getting high results especially in the female sportspersons' evaluation. It was a much better way to select coaches than just picking the one that has been in the industry for a long time. Siener [10] pointed out that more concepts are relevant for consideration, and excluded physical abilities and early performance measures as specific metrics cannot adequately capture prediction models. Related to this, ML has also been used in player categorization according to their performance. Filipic [11] conducted predictive analysis to classify professional tennis players into quality groups based on the ATP rates. It helps us as coaches and the players to analyze strengths and weaknesses of team and individuals. It also pointed out that there are other success factors besides performance strategies, including mental hardness, training approaches, and psychological strength [12]. Makino et al. [13] selected the ATP singles match to analyze point winners when influenced by the court and the players' style. To illustrate the ability to practice different and more creative forms of analyzing data, Almarashi et al. [14] took a different more creative approach by demonstrating the ability to predict trends of players' performance over a period. Chen and Groll [15] used decision tree algorithm, and the results showed that it yields high level of accuracy in predicting the match outcomes for both men and women's tennis as was also discovered by Ghosh et al [16] who used logistic regression. It has also been attempted to identify some sample employing unsupervised learning methods. Whiteside and Reid [17] applied k-means clustering to decide on the best locations for aces, where data points must be grouped based on their likeness. Li et al. [18] then trained convolutional neural networks (CNNs) on images to predict batting strength and angles, due to the success of the CNN for image recognition.

Fig. 1. An overview of the ML method, showing the iterative steps from raw data preprocessing to deploying the candidate model for applications.

In Zhou and Liu [19], different probabilities of different stances in the court were recently Bayes network predicted. Schulc et al. [20] used an LSTM network where the network learned from the video data to detect biomechanical signs of ACL injury risks. The LSTM network was able to accurately predict at-risk athletes with 75%-81% accuracy. Based on the data mining methodology, Jain et al. [21] explored sports performance, evaluated it according to benchmark models of key factors, technical aspects, and tactical difficulties confronting Chinese athletes. Together, these works establish the elaborate use of ML for the promotion of tennis proficiently in many areas such as talent recognition and changes analysis of performance and injury handicaps.

IV. MATERIALS AND METHODS

In the following part of this paper, we focus on the method of this research by considering the empirical data used for collecting, cleaning, and applying for the purpose of this research, which is a prediction of tennis matches. The data used are tennis match statistical and predictive analysis, available at open-source platforms, that includes attributes based on ranking of players, their characteristics, physical factors, skills factors, surface type, tournament conditions, and match duration. In this context, the data collected is preprocessed to clean it by using data imputation methods to handle missing data and applying techniques to erase or eliminate records with many missing entries to maintain internal consistency. These methods cover three approaches for comprehensive analysis. Descriptive Analysis highlights the feature analysis. Predictive Analysis explore the correlation between parameters. By employing various models including KNN, RC, and LP to create the overall model on the factors leading to match results. KNN classifier, as working illustrated in Fig. 2, assigns a class y to a data point x , its k -th nearest neighbors are determined using a distance metric $d(x, x_i) = \sqrt{\prod_{j=1}^n (x_j, x_{i,j})^2}$ based on predicted class neighborhood points $\hat{y} = mode\{y_i: x_i \in Neighbors(x)\}$.

Furthermore, RC algorithm based on linear model that minimizes a loss function with L2 regularization $X \in \mathbb{R}^{n \times p}$ (features) and $y \in \{-1, 1\}^n$ defining predictive labels using weight vectors w corresponding to regularization strength $\alpha > 0$ for prediction $\hat{y} = sign(Xw) \rightarrow \min_w \|Xw - y\|_2^2 + \alpha \|w\|_2^2$. Another graph based semi-supervised learning algorithm known as label propagation that propagates labels from labeled to unlabeled points iteratively depends on graph based-approach $G = (V, E)$ with weight matrix W and label distribution $F \in \mathbb{R}^{n \times c}$ based on classes $F^{(t+1)} = D^{-1}WF^{(t)}$. Prediction of labeled class computed using diagonal degree D with matrix of W . This process continues until convergence, and labels are assigned based on the maximum in F . Such models of analytics were trained and tested using historical information to provide predictions of the match outcomes with good levels of effectiveness. Furthermore, Perspective Analysis offers empirical evidence for a data-driven approach for making robust strategic planning, evaluation of performance, and decision making in professional tennis, and reveals how player characteristics and match conditions collectively determine performance.

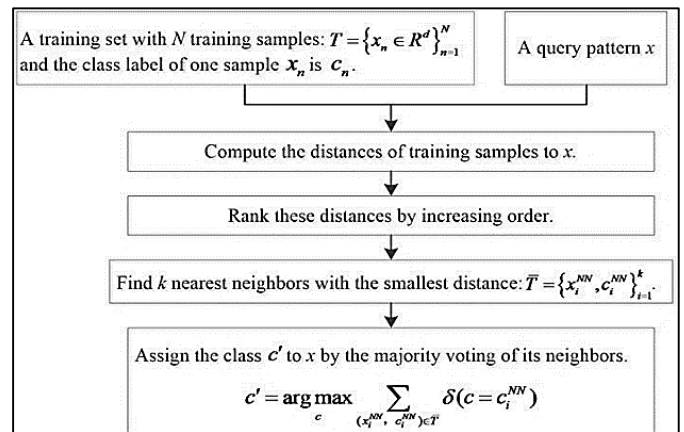

Fig. 2. The K-nearest neighbors (KNN) architecture.

V. RESULT ANALYSIS

A. Descriptive Analysis

A statistical analysis of the attributes of a tennis match shows a comprehensive analysis of how several factors correlate to make an impact on a player’s probability of winning and other factors as well, taxonomy shown in Fig. 3. The visualizations highlight the key attributes such as player rankings, physical fitness, and performance metrics, which collectively contribute to predicting match outcomes. All these

factors have a unique function of providing an understanding of the nature of competitive tennis. The related factors of physical fitness, as shown in Fig. 4, reveal the rank ratio of winner and loser as well, highlight the ability of ranking for higher predictions. Lower ranked players relatively closer to 1 are over-represented among winners demonstrating the player ranking – which is an average of the earlier performance progress, stability and competitiveness – is perhaps the single strongest determination of match outcomes.

Fig. 3. Taxonomy of factor-based analysis of tennis match prediction.

This reinforces the idea that rankings are not merely statistical markers but reliable indicators of a player’s performance and fitness. Similarly, features like winner and loser rank points, which are measures of ranking points acquired over a certain period, additional support sustained like ranking and competitive success as factors affecting match outcomes. Player age also emerges as a significant factor, with winners mainly under the age of 25 according to the distributions of variables winner and loser age factors. This age group characterized the peak years of physical agility, strength, and psychological resilience. This argument is further emphasized by the fact that the decline in performance observed in older players is captured by the fact that the loser age distribution tapers off, which is evidence of physicality of tennis and the fact that with age, the performance of players reduces with increasing age regardless of league ranking. Height, as captured by winner and loser height shows a more complex interaction. The distribution of player heights according to general population values, and their average of 180-190 cm indicates that height can be useful – probably in serving and court coverage – but certainly is not as definitive as ranking or age. This simply means that, though factors such as height have additional marginal utility they outweigh in their skill, strategy and mental strength.

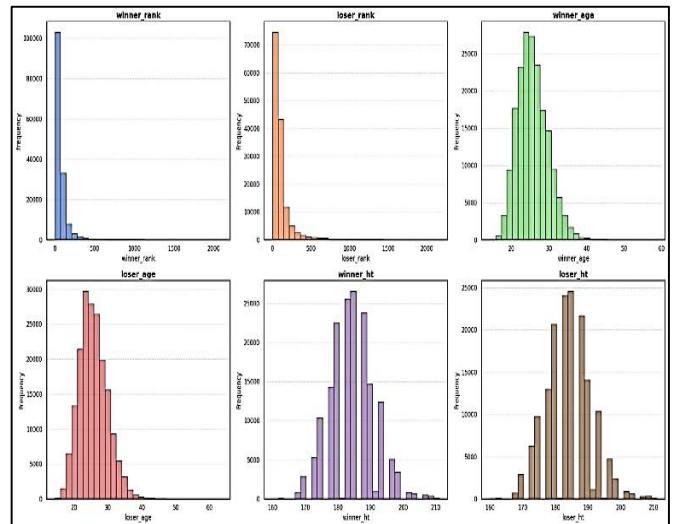

Fig. 4. Physical fitness factors affecting players performance.

The SHAP based summary plot, shown in Fig. 5, further supports these observations by showing how proposed features influence match outcomes. Factors like first, and second rank, and their associated ranking points dominate the feature

importance, emphasizing that prior performance is paramount in determining match success. Interestingly, variables such as first and second age, factors, and tournament-specific details include analysis about round, draw size, and tourney month with exhibit moderate importance meaning that even external factors affect performance, such as the tournament stage or environmental factors, can also influence progress. For instance, the level of the tournament or the number of sets played highlighted as best of attribute might benefit more experienced or physically conditioned players.

Fig. 5. SHAP analysis of features importance.

Fig. 6 provides a detailed breakdown of feature importance of predicting match outcomes. It underscores the significance of first rank pointed to winner's rank and second rank shows the progress analysis of loser's rank, guarantees that player rankings, which reflect skill, regularity, and past results, are the strongest indicators. Other features, such as second rank points highlight the ranking points of loser's players and second impactful factor first height attribute pointing to the chances of winners on the base of their height, reflecting that performance measures and physical fitness attributes are significant as secondary impact factors. The plot further underlines the contribution of other relatively significant variables with aspect

of nationality background as mentioned loser's nationality code, which characteristics of the player's performance in shaping geographic or cultural patterns. The visual strength of SHAP showing how much each feature contributes to match prediction while reinforcing the idea that, although rankings overwhelm, other features bring context.

The bar chart in Fig. 7 illustrates the Top 10 Players by career wins, including legends like Jimmy Connors, Roger Federer, and Rafael Nadal, also supports these findings. These players consistently rank among the best due to their ability to maintain high performance over longer periods, which is in tune with the ranking and ranking-points identified in the evaluation of the data. The success of these players also uncovers an important part of the equation, which is psychological factor, such as mental strength and match experience, which are inferred from performance measures such as rating. The boxplot as shown in Fig. 8 depicting the distribution of aces by surface (Clay, grass, carpet and hard) highlights into how playing conditions affect serve performance. According to the distribution, Grass courts exhibit the widest distribution and median number of aces, which shows the serve on this surface is preferable for powerful players. In contrast, clay courts are characterized by a lower median and distribution, suggesting that this slow playing surface reduces the impact of aces. This information emphasizes the fact that surface type must be considered important indicating match results particularly for those players who rely on serve base. The USA dominated tennis in the last parts of the twentieth century, as was mentioned, which could also be explained by the fact that the game during that time was especially suitable for players who use powerful strikes and played fast courts, as shown in Fig. 9. But this dominance was not sustained after the year 2000, since more emerging nations approached the game with new generation of players like Spaniards and the Serbian stars who demonstrate equal powers on clay and other surfaces. Spain happened to rise steadily at the same time as its emphasis on clay court preparations, while Serbia on a similar note rose with players like Novak Djokovic. This rise of the Swiss team in the period of Federer-Wawrinka partnership show how player generations can skew national statistics. The above-presented patterns indicate that player origin and era-specific patterns are functional contextual predictors that influence match outcomes due to the general competitive conditions and training processes.

Fig. 6. Breakdown analysis of match outcomes.

Fig. 7. Analysis of top 10 players performance.

Fig. 8. Distribution of aces by surface.

Fig. 9. Nation-wise performance of players statistics.

Analyzing variables using pair plot visualization as shown in Fig. 10, indicating factors such as winner and loser rank, match minutes that show the overall duration and tourney level indicating participating tournament score, highlighting the comprehensive analysis by examining the interplay between

rankings and match intensity. Matches characterized by players with higher ranks are generally shorter, pointing to their dominance and ability to close matches efficiently. Conversely, Players with low level ranking scores tend to engage in longer matches, indicating closely contested battles where differences in skill are less pronounced. The pair plot also separates Grand Slam matches (G) from Masters tournaments (M) where the duration is usually longer because of higher level of tension, stress, anxiety, among all still showing a best ranking with physical fitness, a significant factor to ranked as winner for players. This observation illustrates that tournament setting affects matches setting, by considering the external factors other than players' characteristics predicting the matches' model.

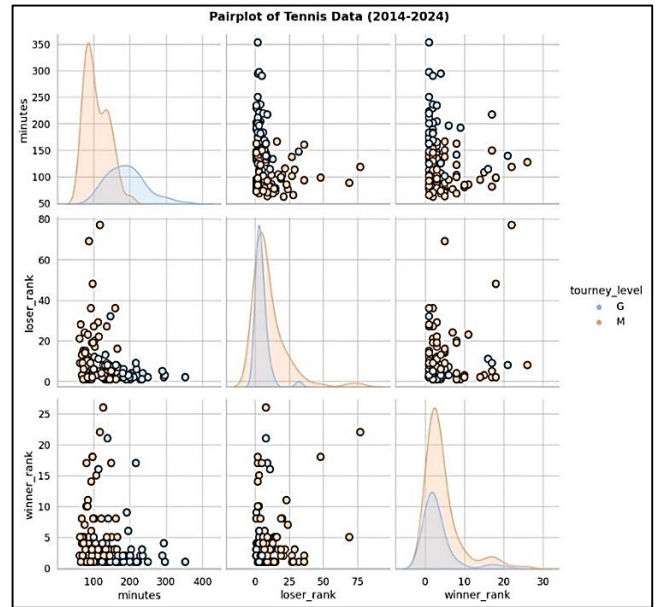

Fig. 10. Analysis of skill disparities factors.

The two correlation matrices as shown in Fig. 11 offer a comprehensive examination of the various relationships in relation to different variables in the database: tournament/match attributes and players' performance indicators. The features of this correlation include the date of the tournament; draw size; the match number; and performance indicators of the player who lost the match; aces served and committed, double faults, total serve attempts, first serves made, and break points faced. There is a very tight positive relationship between Attempts and First (0.93), suggesting that many serve points attempted deliver a high probability of successful first serve hitting. As with many of the other performance indicators, there is a strong relationship between break points saved and break points faced (0.92) – players that frequently find themselves on the wrong end of a break point usually show that they can sustain a lot of those situations. The strong positive relationship which is evident between the variable's games served and serve points attempted ($r=0.94$ mean, reveals the direct relationship between the number of service games played serves attempted. Low correlations between the date of the tournament and draw size and most of the performance indicators indicate that these characteristics have little influence on the result of ongoing inspired matches.

The Players Information and Performance Association Matrix looks at how certain variables in mutating with player characteristics which include the winner seed, winner height, winner rank, and match performance indicators which include aces served, double faults, break points faced, and games served by the winner, in Fig. 12. Cohesion between first serves in and serve points attempted by the winner is also evident with a coefficient value of 0.94 for the pair of variables. The finding that linkage of games served, and the break points faced by the winner ($r=0.94$) suggests that the consistency of the serving players is likely to go down with the game faced on their serve as he matches progress especially in terms of break points faced. The correlation -0.33 of winner rank and winner rank points indicate that players with low numerical value of rank will tend to gain more ranking points because they have performed better than other players over the season. They both showed some relationship with match duration to some key performance indicators, and this was evident in the breakdown of the break points saved and the first serves clinched to show how stamina and service comes in handy during long drawn-out matches.

Overall study highlights the evaluating probabilities of tennis match outcomes are a complex process and factors including player rankings, age, and prior performance emerging as the most influential features for the match outcomes. Height, tournament conditions, and match dynamics provide the secondary features that add more context and depth to the predictive model bringing more of the game into the analysis. The analysis highlights that while player rankings and previous performances predicting environmental and intrinsic aspects including nature of the ground, playing duration, and players' physical characteristics including height and serve effectiveness enhance the complexity of the game adding on to the analysis. Such results suggest that more global and data-driven strategy is required to accomplish successful modeling of match results. By leveraging data analytics methods, we can build more robust systems that reflect the interplay of skill, strategy, and resilience in tennis match. This approach does not only improve the efficiency of forecast, but can also define conceptual framework for action, improvement of performance, and decision-making in professional tennis.

Fig. 12. The relationship between players' characteristics like age, height and ranking levels on the players' performance.

B. Predictive Analysis

The findings from the three classifiers include K-Neighbors Classifier, Ridge Classifier, and Label Propagation, in terms of accuracy, F1-score, and ROC based Area Under the Curves (AUC) values that show how the predictive models performed in the experiment with the goal to assess the strengths and limitations of using the selected algorithms for tennis match predictions. Detail analysis of results is shown in Table I.

The K-Neighbors Classifier gives the highest accuracy of 80%, with 63% F1-measure shows that the model provides a high probability of projecting the match outcome accurately most of the time, which is promising for applications where precise predictions are important. However, the values of the F1-score equal to 63% mean that the model makes moderate accurate predictions relying on players' performance with tournament levels, leads towards may some challenges in identifying less frequent match outcomes, potentially leading to some false positives or false negatives. Finally, the AUC of 78% also validates the model efficiency in determination of between the two classes of players as winner and loser but still more work is needed to be identified by the optimal decision threshold. The Ridge Classifier performs less accurate as compared to K-Neighbors Classifier achieves only 71% accuracy, utilizing both precision and recall, given its considerably higher F1-score, 69%. This implies that Ridge Classifier could be much more suitable for identifying both 'winners' and 'losers' particularly in formulation whose class distribution is skewed. Its lower AUC of 71% shows that the model does not perform as well regarding the ability to classify match outcomes throughout the probability distribution, with particular emphasis on the low success of the distinction between the positive and negative classes at various thresholds. This shows that, although the Ridge Classifier is quite balanced in terms of predicting outcomes.

Another classifier, Label Propagation tested with 77% accuracy is nearer to both models in the raw predicting power when it comes to predicting match outcomes. However, its F1-

Fig. 11. Correlation analysis of player performance and tournament information.

score is 65% and it is lower than the two models we considered: K-Neighbors Classifier and Ridge Classifier which means that its precision/recall co-efficient is less accurate than these two. This has the implication that the model could be correctly classifying more instances, particularly in the minority class, resulting in either false classification as positive or as negatives. The AUC of 71% also shows us that it does not rank as high as the K-Neighbors Classifier in terms of the model’s ability to show the difference between the match outcomes based on various factors, but it is better than the Ridge Classifier. Overall, Label Propagation has a reasonable level of predictive accuracy as for match outcomes, but this model has a low ability to set a moderate ratio of precision and recall as well as it has weak discrimination in contrast to other models.

TABLE I. ANALYSIS OF CLASSIFIERS FOR PREDICTIVE MATCH OUTCOMES (%)

Model	Accuracy	Precision	Recall	F1-Score	AUC
KNN	80	75	70	63	78
RC	71	72	66	69	71
LP	77	71	60	65	71

Overall, K-Neighbors Classifier surpasses the other two in its accuracy AUC, meaning that K-Nearest Neighbors Classifier, indicating that it is better at making correct predictions and distinguishing between match outcomes. However, looking at the F1-score, it can be concluded that it could be allowed better ratio of precision and recall values. The Ridge Classifier proves to improve the balance of classification but offends accuracy and AUC value. Label Propagation, while offering good accuracy again is not good in f1-measures. These results highlight the trade-offs between model performance metrics and underscore the need to select a model based on the specific requirements of the task, such as whether the priority is maximizing prediction accuracy ability to distinguish between classes, as analysis shown in Fig. 13.

C. Perspective Analysis

Let us now focus on the third type of data analytics approach of prescriptive analysis which focuses on recommending specific strategies based on data analysis. The aim of this type of analysis is to get the desired outcomes based on analysis of historical data, and application of predictive models. Unlike descriptive analysis, which explains what has happened and which is main part of this manuscript as well, and predictive analysis, which forecasts what might happen, prescriptive analysis shares the answer to the main question of what is required to be done.

Prescriptive analysis uses data-driven insights to recommend specific training and strategies tailored to players’ needs and goals. For making robust strategic planning, evaluation of performance, and decision making in professional tennis, and reveals how player characteristics and match conditions collectively determine performance. By analyzing player attributes for prescriptive analytics provides actionable recommendations for optimizing performance. These insights into a player’s efficiency or their success on specific surfaces can guide them to match preparation

strategies. Fig. 14 shows Receiver Operating Characteristics (ROC) curve is shown for comparison and shows Area Under the Curve (AUC) too.

Fig. 13. This comparison reflects the accuracy measures of all applied models providing the performance evaluation of the ML approaches.

Fig. 14. The ROC-AUC curve of all applied models.

Additionally, understanding the strategies of opponent abilities and match dynamics enables players and coaches to follow strategies in real time, boost their competitive edge. Effective workload coordination in team settings to guard against injuries while maximizing on output from the players. With information concerning players, training frequency and types, courses can be constructed that would maximize their recovery period. Besides, this approach also improves the talents’ performance at the personal level and proper coordination between coaches, physiotherapists, and analysts. Further, based on the same perceptions tournament organizers and stakeholders can better schedule tournaments in a way that both protects fairness of competition and players’ health leading to enhanced experience. Such systems develop mutual constituencies of resources for supporting players and their sustainable performance in the sport.

In the previous works focused on tennis match result prediction by using the ML models, the numerous approaches and the features have been considered to improve accuracy, shown in Table II. The study in [22] (2022) used Logistic Regression (LR) with the features that aspect like surface type and being a winner or a loser besides the rank having an accuracy of 77%. Another approach made by [23] (2024) used Random Forest (RF) and concentrated on win/loss patterns. The suggested approach has a slightly lower accuracy of 70%.

Also, [24] (2024) put forward the Stochastic Forest Model with a player's win rate as the feature, with 74% accuracy. Work by [25] (2021) that integrated LR, DT, and RF models for changes in direction during matches gave a 75% result. Conversely, the proposed study (2024) presented the K-Nearest Neighbors (KNN) model that uses seven various features; the findings recorded a ninety percent accuracy; therefore, meaning better predictive capacity. This work sheds light on shifting paradigms of a predictive model of tennis match result based on machine learning involving feature evaluation and model selection as crucial success factors.

TABLE II. COMPARATIVE ANALYSIS WITH EXISTING STUDIES

Sr. No	Ref	Model	Features	Results (Acc: %)
1	[22] - 2022	LR	surface , Winner/Losser, Rank Rounds	77
2	[23] - 2024	RF	win/loss trends	70
	[24] - 2024	Stochastic Forest	player's win rate	74
3	[25] - 2021	LR, DT, RF	changes of direction	75
4	Proposed - 2025	KNN	Seven Features in Fig. 3	80

VI. CONCLUSION

Sports have always played a pivotal role in human culture, blending skill, strategy, and physical excellence. The coupling of artificial intelligence and data analytics into sports area highlights unparalleled opportunities to increase the power of decision-making, predict outcomes, and optimize performance rate. This research introduced three strategies of data analytics methods to investigate the factors influencing tennis match outcomes based on descriptive analysis, predictive analysis and perspective analysis, with a focus on feature-based analysis of attributes such as ranking attributes, physical attributes, and match conditions, emerges as significant predictors, providing valuable insights into the multifaceted nature of the sport. Among the models applied, the K-Neighbors Classifier achieved the highest accuracy of 80%, pointing out its potential as an effective tool for predictive analysis in tennis. This research highlights the potential of integrating advanced predictive models to help players, coaches, and analysts in strategic planning and performance optimization. Although the research study is helpful for understanding the factors for better tennis performance using XAI techniques however it is the limitation of the study that these findings are not generic and may not be applicable to other sports but only limited to tennis only. Considering the futuristic scope of the research work, let us share that the several future work can be considered for improvements can be made to increase the reliability of the predictions for more practical applications

- Higher level of data cleaning and applying diverse feature engineering techniques to refine and obtain increased quality data that would be used for developing predictive models

- Further tuning of advanced classifiers can be done by integrating hyper parameters of the classifiers to increase accuracy.
- Extending the work to conduct time-series analysis to make effective use of temporal characteristics of the data including player patterns over different tournaments.

This research not only offers understanding of the various factors of tennis match but also lays the groundwork for future explorations in sports analytical applications. This study thus clears the way for further enhancement to identify more robust methods and constructions through which data-driven approaches and models can be developed and deployed for sports and competition domains.

Exploring Diverse Conventional and Deep Linguistic Features for Sentiment Analysis of Online Content

Yajun Tang*

Anhui Business and Technology College, Hefei City, Anhui Province, 231131, China

Abstract—Social media has changed the world by providing the facility to common person to share their views and generate their own content, known as Users Generated Content (UGC). Due to huge volume of UGC data being created at great velocity, so to analysis this big data, latest AI (Artificial Intelligence) and its sub-domain NLP (Natural Language Processing) are being used. Sentiment analysis of online content is an active research area due to its vast applications in business for review analysis, social and political issues. In this research study, we aim to carry out sentiment analysis of online content by exploring conventional features like Term Frequency – Inverse Document Frequency (TF-IDF), Count-Vectorization, and state of the art word embeddings based word2vec. Extensive exploratory data analysis has been carried out using the latest data visualization approaches. The main novelty lies in the application of unique and diverse machine learning algorithms on social media datasets and the results evaluation using standard performance evaluation measures reveal that the word2vec using Quadratic Discriminant analysis-based classifier show optimal results.

Keywords—Artificial intelligence; sentiment analysis; machine learning; word embeddings; natural language programming

I. INTRODUCTION

Opinion mining or sentiment analysis on the other hand is a highly important subfield of NLP and is used as the umbrella term for studying sentiments, opinions, and emotions in text. Due to the drastic increase in use of social networking sites and the internet, the analysis of public opinion has gained importance for various commerce, policies and academia. Text analytics include creating categories depending on whether the text is positive, negative or neutral which can be important in understanding uptake among consumers or any specific segment or the public. For sentiment classification, Extended SVM, Naïve Bayes and Logistic regression were used traditionally; yet they are highly dependent on feature engineering and could not capture the depth of human language effectively [1].

In the last few years, deep learning techniques have brought dramatic improvements in SA, because they apply neural network structures that learn multi-level representations of text data from scratch [2]. RNNs, LSTM and CNN have been found to provide better resolution in extracting sequential correlations and contextual information within textual data [3]. In addition, the rise of pre-trained language models such as BERT and GPT has enhanced the performance of the sentiment analysis systems since transfer learning reduces the rate of overfitting as well as making models better at generalizing between datasets with limited labeled data based on [1].

Sentiment analysis is not limited to the monitoring of social media such as Facebook, Instagram, and twitter [4] but can be practiced in areas such as product review analysis, the customers feedback evaluation and even in the healthcare field. Since sentiment analysis is rapidly becoming a standard method for assessing public opinion and improving customer interaction for various organizations, the issue of effective and accurate detection becomes critical. Future areas are still hard and require better solutions to decode sarcasm, different meanings in different contexts, and domain specific language which are also quite important to cover in deep learning techniques [2]. Thus, continuous study is required to overcome these challenges and equally to extend the effectiveness of sentiment analysis to help explain the multifaceted human emotions captured in the content that is generated online.

In this research study, our aim is to carry out sentiment analysis from online content of social media by exploring the role of various textual features such Count Vectorizer, and Term Frequency – Inverse Document Frequency (TF-IDF). The features are used as input to machine learning classifiers such as CalibratedClassifierCV (CACV), PassiveAggressiveClassifier (PAC), and Quadratic Discriminant Analysis (QDA). We also try to explore various deep features like word2vec which focuses on considering context for given words in local and global perspective respectively. Here local means within a sentence or few words before or after the word while global means within the whole document. The results evaluation is carried out using standard performance metrics of accuracy, precision, recall and f-measures. This paper contributes to the field of AI by carrying out machine learning analysis of human feelings and emotions derived from textual data, while contributing toward the general understanding of the relationship between textual encoding and the analysis of human behavior. The main contributions of this research study include:

- Application of an advanced feature engineering approach such as count vectorization, TF-IDF and Word2Vec embeddings proved helpful in improving model sentiment analysis performance.
- Also, other machine learning models like Calibrated Classifier CV, Passive Aggressive Classifier, and Quadratic Discriminant Analysis were used to classify the sentiment labels.
- The best results were achieved employing Word2Vec embeddings with CACV proving that the use of embedding enhances the performance of the system.

The paper is organized as follows: Section II presents an analysis of some of the prior work done regarding sentiment classification and feature extraction methods. Section III then describes the data processing methodology of this study, feature engineering techniques including TF-IDF and Word2Vec and the classification models used in this study. Section IV summarizes the findings of this work and discusses the effectiveness of the embedding techniques. Section V provides the overall conclusion of the paper.

II. BACKGROUND

Therefore, over the recent past, the use of sentiment analysis has grown to be more important as the world has advanced in issues such as social media and content creation. The field has graduated from decision tree type of solutions to highly enhanced machine learning and deep learning type methods, which can now learn the tone of the text to whether it is happy, sad, angry or otherwise. The latest publications point to a revolutionary effect of generative AI for enhancing the efficacy and flexibility of SA for identifying consumer sentiment [5]. The use of sophisticated NLP ensures that there is a means of processing huge volumes of data generated by customers over social media as well as ensuring that the firms can indeed derive tangible benefits from these big data sources [6]. A recent research study [7] focused on features-oriented sentiment analysis which is also known as aspect-oriented sentiment analysis. This type of analysis mainly does not focus on document. Due to the growing era of technology, different methods of real time sentiment tracking have been enhanced to enable organizations to measure the flow of public sentiment. Programs such as Brand24 and Sprout Social employment machine learning [8] [9] to identify the sentiment of text in different and even emojis, thereby giving a fuller understanding of customer feelings [10]. Moreover, aspect-based sentiment analysis (ABSA) has become another important approach which is to identify certain characteristics of the product or service and allows companies to assess feedback from customers on specific characteristics, such as, for example, battery life or usability, separately [11]. Considering deep learning models, attention-based model have been used in a recent study which mainly proposes multi-channel gated recurrent RNN algorithms for aspect-based sentiment classification purpose. The work proof that the proposal of multi-channels in the existing RNN model [12].

As these methodologies are progressing there are still some issues arising in sentiment analysis because of factors like sarcasm, cross cultural differences and—regarding social media—frequent changes of language [13]. These challenges have been pointed out in recent literature reviews and the community has called for more research to enhance the reliability of sentiment analysis approaches [14]. Also, the market for sentiment analysis tools is expected to expand rapidly owing to the rising need for timely analysis of the customers' sentiments and behavior [15]. Aspect-based sentiment analysis, the model with good contextual information, namely, Attention-based Bidirectional LSTM

(BiLSTM) networks, is more suitable when it comes to fine-grained tasks [16]. Similarly, other recent works by [17] suggested a convolutional neural network and BiLSTM with attention mechanisms to deliver higher accuracy than conventional methods of sentiment classification in product reviews. Transformer based models have dramatically influenced approaches used in sentiment analysis. Subsequently, [18] used gradient boosting algorithms for the sentiment analysis tasks and to their finding, it outperformed other previous models for identifying the complicated sentiment patterns in large contextual data. For the sentiment classification in particular domains, for example, financial or health care domains, and have shown that the domain-wise improvement of the classifier performance is possible in this case that combine sentiment analysis with other NLP tasks [19].

Altogether, rhetoric trends dynamic, and new developments in tools and methods are expected for better application efficiency and higher predictive results of sentiment detection in different environments. This suggests that, as organizations continue to use these insights for strategic decision making [20], expanded research will be required to respond to the limitations of current methodologies and to investigate new employment contexts in this rapidly expanding domain. In this paper, instead of investigating and comparing traditional machine learning methods to sentiment analysis of textual data as previous studies have done, the current study employs advanced supervised learning models that Calibrated Classifier CV, Passive Aggressive Classifier, and Quadratic Discriminant Analysis (QDA) networks. These strategies are intended to improve the reliability and stability of sentiment predicting which was mentioned to be a weakness in the prior researches.

III. PROPOSED RESEARCH METHODOLOGY

The following sections provide the details of the methodological approach, as illustrated in Fig. 1, used in this sentiment analysis study, by following steps of data preprocessing, feature extraction, model training and experiment.

A. Data Preprocessing

Data cleaning is very important to ensure that preprocessing on data is well done and well checked before applying any machine learning. Initially, for noise removal, following elimination of special characters, URLs, any numbers, all the stop words, including 'is', 'the', etc. To minimize model bias, data entries with redundancy or duality were spotted and disregarded. After this, preprocessing undertaken to the text included conversion of text to lower case to eliminate redundancy concerning the sensitivity of the upper and lower 'cases. For more refinement, lemmatization was applied to stem words, where it uses the smallest root for a word to avoid any complexity in text data [21]. Lastly, to improve text vectorization in the next steps, each sentence was broken down to individual words (tokens). This ensures that data is preprocessed and ready for model training.

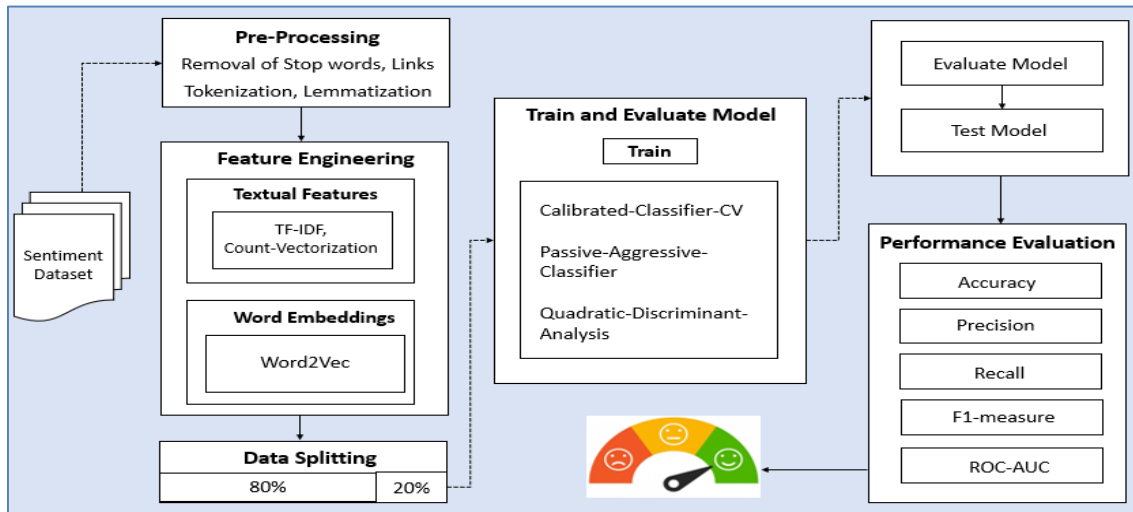

Fig. 1. Steps of proposed research methodology.

B. Feature Engineering

Feature engineering means getting the preprocessed textual data into forms directly understandable to the machine learning algorithms. In this study, three techniques were employed: Term frequency-Inverse document frequency (TF-IDF), Count Vectorization and Word2Vec. This paper provides the following overview of the mathematical basis and application of these methods.

1) *TFIDF*: TF-IDF refers to a technique of weighing words in a document against a corpus to determine the importance of the term in the document. It is the product of two components: Term Frequency (TF), and Inverse Document Frequency (IDF). To measure how much the term is exclusive or specific to a corresponding document. In this study, TF-IDF vectors were calculated, using Eq. (1) on the textual data and were sparse and of high dimensionality in representation of the documents [22]. Table I displays the description of symbols used in equations.

$$Document\ vector_d = [TF - IDF(t_1, d, D), \dots [TF - IDF(t_n, d, D)] \quad (1)$$

2) *Count vectorizer*: Frequency based vectoring or word-frequency vectorization derives a numerical value for each word based on the number of times the term appears in that document relative to a fixed list of terms. Every document is then converted to vector, whose elements are the vocabulary of the subjects and the values being the frequency of each of the terms used using Eq. (2). Although noncomplex, it does an excellent job of encoding the distribution of words in the dataset, which is represented as a sparse matrix for input into the machine learning algorithms.

$$Document\ vector_d = [x_1, x_2, \dots, x_n] \quad (2)$$

3) *Word2Vec representation*: Word2Vec gives dense words embedding in the continuum vector space to capture semantic relationship in between words, it learns word

embeddings from a large corpus. These embeddings capture context meaning to make the words that have similar contexts to have similar representations. For document-level representation, generally take the average of the word vector in applying machine learning models, so it is compact as well as semantically rich.

$$Document\ vector_d = \frac{1}{n} \sum_{i=1}^n Word2Vec(t_i) \quad (3)$$

C. Model Engineering

Algorithm selection, setting, and model training on the preprocessed dataset form the model engineering process based on three algorithms were employed: CalibratedClassifierCV, PassiveAggressiveClassifier, and Quadratic Discriminant Analysis (QDA). Equations defining each and principles which underline each are provided in the following:

CalibratedClassifierCV (CACV) is a meta-algorithm aimed towards increasing the accuracy of a base classifier when using probability estimates for decision making. It functions by using the raw outputs of the classifier, to which logistic regression model ensures to the raw outputs of the classifier, that ensures a monotonic relationship between probabilities and true outcomes, computed as in Eq. (4). This algorithm comes very handy especially when the base classifier gives unformatted probabilities or raw scores.

$$p(y = 1|x) = \frac{1}{1 + \exp(-a \cdot f(x) + b)} \quad (4)$$

PassiveAggressiveClassifier (PAC) is an online learning algorithm which is suitable for scaling and efficient classification paradigm. It adapts its model weights only when predictions are wrong or the decision margin is less than specified, which makes it reactive “aggressively or slightly” to mistakes. The model optimizes a hinge loss function that has been well applied in binary and multi-class classification and supports linear kernel-based learning, computed objective function as in Eq. (5). The model is especially useful for the cases of working with high dimensions and big data, like text classification tasks, at which it balances the speed of adaptation to new data and necessary computational resources.

$$L(w, x, y) = \max(0, 1 - y(w \cdot x)) \quad (5)$$

The model updates w iteratively as in Eq. (6):

$$w_{t+1} = w_t + \tau yx \quad (6)$$

Where $\tau = \frac{1-(w_t \cdot x)}{\|x\|^2}$ is the learning rate to ensure convergence while remaining sample of passive for correctly classified.

Quadratic Discriminant Analysis (QDA) is another generative classification algorithm, which implies that the model assumes features are normally distributed within the classes. It is an extension to Linear Discriminant Analysis (LDA) where covariances within each class may differ and therefore produces quadratic decision boundaries. The current implementation of QDA is based on the Bayes' theorem, where the likelihood of each class is the multivariate Gaussian probability density, as in Eq. (7). Unlike other machine learning algorithms which may not be well suited when dealing with non-linear feature-class space. In general, QDA is more complex than LDA, but it is more flexible; thus, it is preferable when the classes have different variance.

$$Q(d = k|g) = \frac{Q(g|d=k)Q(d=k)}{Q(g)} \quad (7)$$

This is subjected to Eq. (8):

$$Q(g|d = k) = \frac{1}{(2\lambda)^{e/2} |\Sigma_k|^{1/2}} \exp\left(-\frac{1}{2} (g - \mu_k)^T \Sigma_k^{-1} (g - \mu_k)\right) \quad (8)$$

The decision boundary for QDA is quadratic, computed as (9).

$$\delta_k(g) = -\frac{1}{2} \ln |\Sigma_k| - \frac{1}{2} (g - \mu_k)^T \Sigma_k^{-1} (g - \mu_k) + \ln Q(d = k) \quad (9)$$

Class predictions are calculated by maximizing the posterior probability using Eq. (10).

$$\hat{d} = \arg. \max_k Q(d = k|g) \quad (10)$$

D. Dataset

This study aims at the creation of a sentiment analysis system specializing in the analysis of emotional and opinionated posts in social media. Social media is quite popular and creates large textual data daily with useful knowledge of the public's perception of products, services, events, and social issues. This system is expected to utilize NLP tools to identify and sort sentiments of bilateral content, for example, positive sentiment or negative sentiment or even no sentiment. The dataset employed in this study is collected from open platform Kaggle, sourced from authentic social media data comprising of different styles of writing and different contexts such as brand tracking, in a crisis, for opinion mining and social trend analysis.

TABLE I. DESCRIPTION OF SYMBOLS USING IN EQUATIONS

Symbols	Description
t	Term in a document
d	Document
n	Total number of terms in a document
x	Frequency based on each word

$f(x)$	Raw output of the base classifier
a and b	Parameters optimized via logistics regression.
w, x	Weight and feature vector
y	True label (+1 or -1)
τ	Learning rate
μ_k	Mean vector of class k
\sum_k	Covariance matrix of class k
e	Dimensionality of feature space
TP, TN	True Positive and Negative
FP, FN	False Positive and Negative

E. Evaluation Measures

Measures of performance evaluation are metrics used in machine learning that provide a way of qualifying the several aspects of the model's predictions, as shown in Table II. Accuracy tends to give a broad view of the accurateness of the model since it quantifies the actual number of properly classified samples to the overall number of samples. Recall measures the ratio of true positives among all actual positive observations, or the ability to avoid false negative predictions. Recall (Sensitivity) shows how many actual positives were correctly identified, which focuses on minimizing the number of negative cases that are positive. F1-Score, this metric is the harmonic meaning between Precision and Recall, which is better when used when the distribution is uneven.

TABLE II. EQUATIONS OF PERFORMANCE MEASURES

Metrics	Equation
Accuracy	$\frac{TP+TN}{TF+FN+FP+TP}$
Precision	$\frac{TP}{TP+FP}$
Recall	$\frac{TP}{TP+FN}$
F1-score	$\frac{2(Precision \cdot Recall)}{Precision+Recall}$

AUC-ROC means Area Under the Receiver Operating Characteristic Curve, and it measures the model's conditional probability of correctly identifying a negative case using all the thresholds. Hence, these four metrics offer an uninterrupted way of evaluating the performance of the model such that the model's reliability and efficiency would be achieved.

IV. RESULTS

The results of the sentiment analysis experiments using three models, based on three different feature extraction techniques including TF-IDF, Count Vectorizer, and Word2Vec are summarized through confusion matrices and corresponding performance metrics. These results, as displayed in Table III help in directing focus to the model's strength and weakness aspect of correctly predicting sentiment labels namely negative, neutral and positive. The exploratory data analysis (EDA) visualizations summarize key textual patterns within the dataset:

A. Distribution of Text Length

From this histogram as shown in Fig. 2 (a), this graph describes the frequency of texts within the data set according to their length. The frequency distribution shows most texts are of lengths between 10 and 40 Words, although as text length increases, the number of texts decreases. We see that

distribution is right-skewed, which means that there are more texts of shorter length than texts of very long length. This bar chart in (b) shows 10 most frequently appearing words in the dataset and the frequency of each of these words. Among these, “I’m”, “day”, “like”, “know” are few of the most frequent words used in day-to-day conversation. These often-used words seem to indicate that the dataset samples a daily or personal interaction-oriented environment.

B. Word Frequency Distribution for Words with Frequency >10

The bar chart shown in (c), will give a detailed analysis of the words that appear more than 10 times in the dataset. Specifically, words that can be found in the list of 10 most frequent words like the “I’m,” “like,” and “know” are in the middle. Like ‘Interests’, ‘Excitement’, some extra word like ‘amazing’, ‘day’, ‘today’, ‘tomorrow’ seems to point toward sentiment –rich contexts or likely sentiment temporal relatedness in the data set.

C. Distribution of Labels

In Fig. 3 displaying bar chart (a) capturing the current distribution of labels in sentiment analysis. Overall, the data split over a broad range with the sentiment of neutral prevailing

over positive and negative sentiments, though with decreased number. The negative and positive sentiments are similar in the number of corresponding features, and they are between 125-175; however, the most prominently observed sentiments are the neutral ones with over 200 samples.

D. Word Cloud:

Fig. 3 preview (b) of the most often occurring words in the data set as a whole. The word cloud illustrates the frequency of words most often repeated in the dataset; it includes words such as love, going, day, I’m, know, among others. This shows the word frequency in sample texts, with possible positive words for the choice of ‘love’ and ‘day’ against possible negative words ‘don’t’ and ‘can’t’.

This analysis underlines the fact that the dataset has conversational and sentiment-related properties, has more short texts, and uses more often and more frequently the most common sentiment-related words. It is useful in understanding the structure and contents of the text, therefore assists in the preprocessing and feature extraction steps that may be followed in other downstream tasks such as sentiment analysis attempting to build methodologies for classification models based on textual characteristics.

Fig. 2. Analysis of dataset text length along with frequency.

Fig. 4. Confusion Matrix of model performance using TF-IDF features.

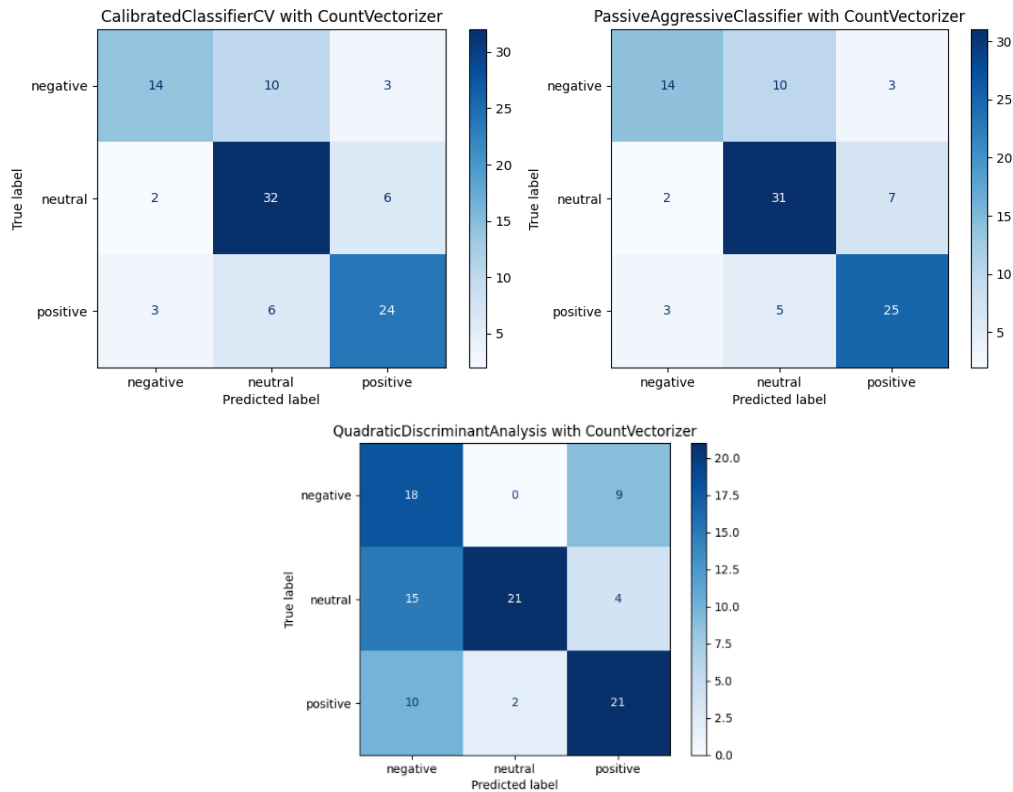

Fig. 5. Confusion matrix of model performance using count vectorizer features.

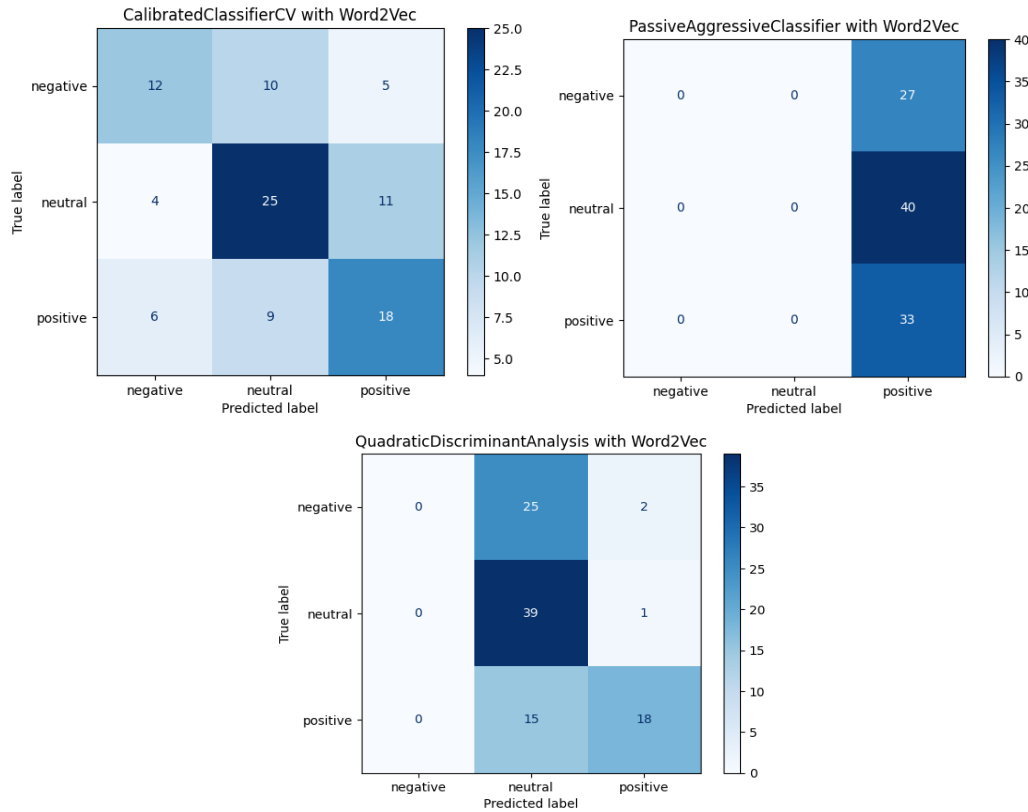

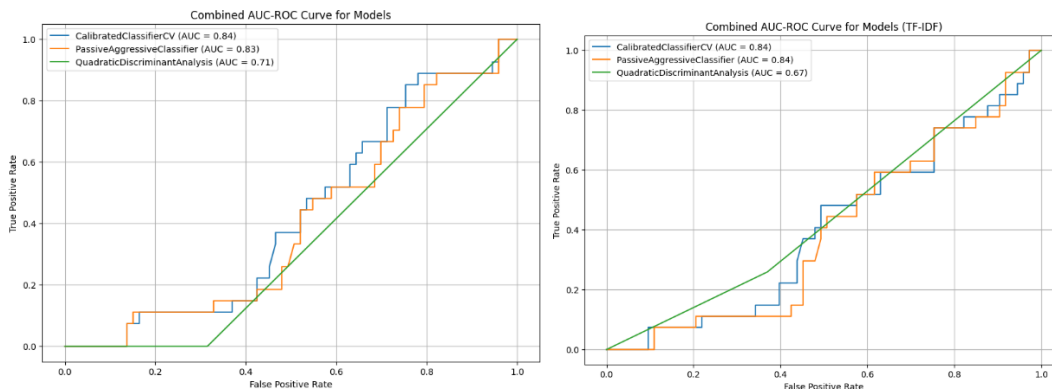

Fig. 6. Confusion matrix of model performance using Word2Vec features.

From the presented ROC curves, in Fig. 7, infer the overall classification performance of the models along with the examined feature extraction methods. For TF-IDF and Count Vectorizer, PAC and CACV have AUC of 0.76 – 0.81, which means the models are good in scenarios in which the separation between classes is clear; however, QDA has a problem with AUC values 0.66 – 0.72, suggesting a lower ability to distinguish between classes is lower. However, Word2Vec considerably enhances effectiveness; the best outcome is given by CACV (AUC = 0.73), followed by QDA (AUC = 0.66).

These curves show that even though few classifiers like PAC works well with traditional features such as TF-IDF, the embedding techniques like Word2Vec yielded a better class separation in most of the classifiers as supported by higher AUC scores throughout most of the curves. Moreover, the ROC diagrams show that some models are more efficient in terms of true positive and false positive rates which is evident when comparing Word2Vec representations showing that feature embeddings affect the classification performance.

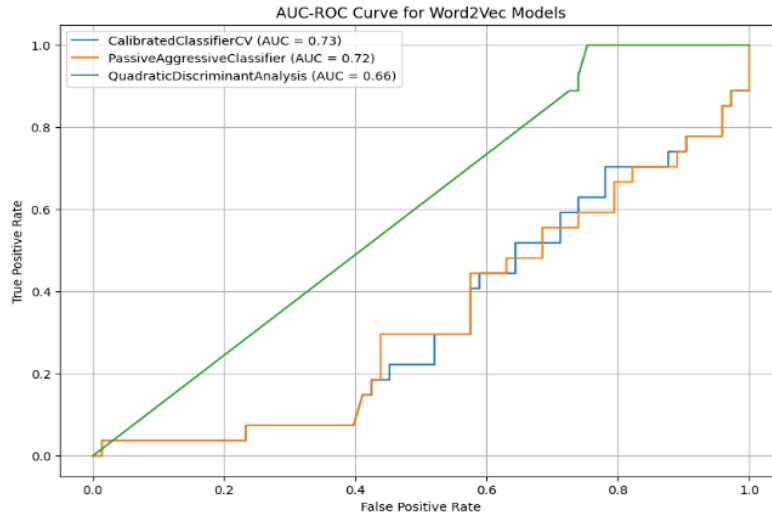

Fig. 7. Analysis of combined AUC-ROC model performance using features.

H. Discussion

To sum up, different feature extraction techniques have been effective in model performances of different degrees. Overall, Word2Vec was the best performer while QDA achieved the best accuracy of 80% and the best confusion matrix, further illustrating superior ability to deal with semantic resemblance for textual data, showing comparative analysis in term of accuracy measures illustrated as in Fig. 8. TF was more useful for PAC, and it scored the highest accuracy of 76% within its features, although it lower in

performance with Word2Vec. Count Vectorization was moderate in its performance, in this field QDA was the most effective out of all (74% accuracy), however it didn't come close to the Word2Vec results. These trends therefore show how features interact with model type and suggest that advanced method such as Word2Vec work best for sentiment analysis models because they are best suited for capturing context and relation between words. These results suggest that extraction methods and classifiers employ significant roles in sentiment analysis.

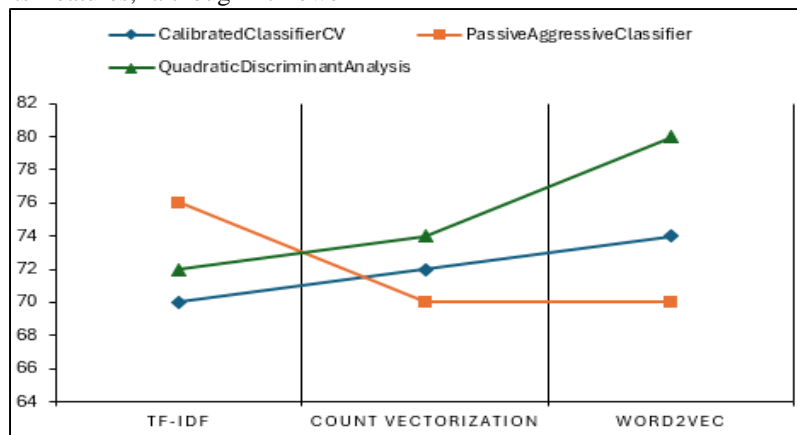

Fig. 8. Comparative analysis of accuracy measure along with models.

The contrast of the suggested model with other similar researches for sentiment prediction from textual information shows enhanced performances, as display in table IV. The current approaches, such as NB with 73%, RF with 74%, and SVC at 71%, have been computed in Twitter and IMBD datasets. On the other hand, the suggested Quadratic Discriminant Classifier in the Kaggle Social Media dataset just attained an 80% of accuracy. This considerable improvement demonstrates that the idea of the proposed model can learn various sentiment patterns, proving that the proposed model is capable of being a more feasible solution for the SA task as compared to the traditional machine learning models.

TABLE IV. COMPARISON WITH EXISTING STUDIES

Ref	Year	Models	Dataset	Results (%)
[18]	2020	RF	IMBD	74
[22]	2021	NB	Twitter	73
[23]	2023	SVC	Twitter	71
Proposed	2025	QDC	Social Media	80

V. CONCLUSION

Social media has become a digital world for users to share their opinions, views and interact through posts, messages, comments, and reviews, making it central mode for interpreting public sentiment. The role of AI in sentiment analysis is growing significantly, as it allows automated detection of emotions and opinions from UGC. In this study, we examined three feature extraction methods combined with various advanced AI models for sentiment classification. Among the models, QDA with Word2Vec embeddings achieved the highest accuracy of 80%, demonstrating its superior ability to capture semantic relationships and patterns in text. These findings show the effectiveness of integrating advanced feature representations with appropriate classifiers. Although the research study is helpful for predicting the sentiment analysis from online content, the limitation of the study that these findings are limited to textual data only. Future work highlights the significant exploration of deeper neural architectures and larger datasets to boost performance further. This study provides a gateway for developing more robust AI-driven tools for sentiment analysis, contributing to better understanding and leveraging user opinions in diverse applications.

An AI-Driven Approach for Advancing English Learning in Educational Information Systems Using Machine Learning

Xue Peng*, Yue Wang

Tourism College, Xinxiang Vocational and Technical College, Xinxiang 453000, Henan, China

Abstract—In current era of globalization, English language learning is important as it has become a global language and helps people to communicate from various regions and languages. For vocational students whose main aim is to get skills and get employed, learning English for communication is important. We here present a proposed framework for learning English language which can become a foundation for a complete Artificial Intelligence (AI) based system for help and guidance to the educators. This study explores the use of diverse Natural Language Processing (NLP) techniques to predict various grammatical aspects of English language content especially focused on tense prediction which lay the foundation of English content. Textual features of Bag of words (BoW) which considers each word as a separate token and Term Frequency –Inverse Document Frequency (TF-IDF) are explored. For both diverse features, the shallow machine learning models of Support Vector Machine (SVM) and Multinomial Naïve Bayes are applied. Moreover, the ensemble models based on Bagging and Calibrated are applied. The results reveal that BoW model input for SVM and Bagging technique using TF-IDF shows optimal results with high accuracy of 90% and 89% respectively. This empirical analysis confirms that such models can be integrated with web or android based systems which can be helpful for learners of English language.

Keywords—Artificial intelligence; information system; machine learning; English language learning; natural language processing

I. INTRODUCTION

The importance of the English language in today's globalized world is evident it serves as a universal medium of communication that connects people from diverse linguistic backgrounds. Fluency in English is essential for considering a broad range of information to be accessed in many ways, especially, in the institutions where many publications are in English [1]. Linguistic influence helps organize joint work and exchange results in terms of continuing the advancement of knowledge by researchers and scholars all over the world [2]. For non-native speakers, especially students in vocational colleges, the journey of learning English can be challenging, particularly when it comes to mastering grammar and sentence structure. Tenses, a core element of English grammar, pose a significant difficulty for learners, as they are essential for expressing actions in different time frames [3]. As education systems strive to provide more effective and efficient language learning, leveraging advanced technologies to address these challenges has become increasingly important. English Learning is the ability to master the capacity to write, read,

and comprehend the English language as well as knowledge of grammar, vocabulary, and pronunciation [4]. This learning may take place at school or university, in community classes, or through independent learning with the help of internet materials [5]. The use of English in global dimension has therefore become mandatory, and it entitles its users use in a multiplicity of sectors. In addition, cross-sectional study will ensure that the sample group is more heterogeneous and diverse regarding their grade level and learning which [6]. The importance of English learning goes beyond the need to communicate, English learning is key for success in academics and career. Knowledge in English breaks barriers and provide a drive to access information and materials since most information is found in English [7]. Many academic institutions particularly require English proficient skills to be used in reading of enhanced texts, discussions and the production of research. In addition, in today's business environments, English is often a requirement for job and promotions because of the effectiveness of the ability to facilitate cooperation with people of different teams in various countries [8]. In conclusion, learning English is not only about language mastery but is equally about improving the methods and the ways through which one can interact with the world.

The applications of AI in education, specifically in language learning, are vast and transformative. AI-powered tools can personalize learning experiences by adapting to individual learner needs, providing immediate feedback, and automating tedious tasks such as grading or content delivery [9]. In the domain of English language learning, AI can assist learners in improving their grammar, vocabulary, pronunciation, and understanding of complex linguistic concepts like tenses [10]. This personalization not only speeds up the learning process but also ensures that learners receive targeted support, thereby enhancing their chances of mastering English more efficiently [11]. Moreover, AI can bridge the gap between traditional classroom instruction and students who may not have access to high-quality educational resources, thus promoting equitable learning opportunities. The use of Education information systems in the teaching and learning of English language has emerged essential in the improvement of the teaching and learning process through use of Information and Communication Technologies (ICT) [12]. These systems provide interface to multiple learning material in form of e-books, online courses, and multimedia which enhance the reading, writing, listening and speaking ability of a learner [13] posit that the use of ICT in English Language Teaching (ELT)

increases learners' attentiveness as well as encourages learner interaction with the knowledge resources and among themselves. In addition, the teachers have also described that such systems help them to give the students individual feedback and sublime courses to fit the students' needs and wants about learning [14]. By integrating these systems with the use of Recurrent Neural Networks (RNNs) and item response theory, learner's input is then subjected to the detection of context and grammatical rules used in defining the correct tenses to be used from a pool of verbs [15]. In addition to error identification, it is effective in creating practice exercises based on the learner's achievement level fostering individual learning development programs. Environmental tense predictors of language exercises that adapt automatically or provide instant feedback for right and wrong contribute to the exciting and more efficient learning modes to help learners enhance their grammatical accuracy and fluency of English language usage [16].

In this research work, we work on teaching and improving English language skills of students studying in vocational colleges as their main concern is to learn skills so that they are readily be available to the market as skilled sources. So, we have worked on basic English language skills and the use of tense which is the pivotal concept in English Grammar in English language learning by using two main AI-based technique of machine learning and state-of-the-art ensemble models including Support Vector Machine (SVM), Multinomial Naïve Bayes (MNB), Bagging Classifier and CalibratedClassifierCV integrated with textual features of Bag-of-words (BoW), and Term Frequency-Inverse Document Frequency (TF-IDF), achieving highest accuracy of 90% with BoW feature when coupled with ensemble models. Further these results are evaluated using standard performance measures of accuracy, precision, recall and f1-score, showing a pathway for exploring more advanced learning abilities for vocational college students. Furthermore, contributions of this study are as follows:

- **Effective Feature Selection:** Used BoW and IDF features in tense prediction of tense on the English contents with the following results expressing suitability of BoW and TF-IDF for tense analysis as is relevant in classification of content.
- **Comparative Model Analysis:** Performed a comparison of BoW and RW performances between SVM & Multinomial Naïve Bayes; showed that SVM with BoW was 90% accurate and has outperformed other models in terms of grammar, especially tenses.
- **Implementation of Ensemble Techniques:** That incorporated ensemble methods including Bagging and Calibrated classifiers obtained 89% accuracy with Bagging and TF-IDF convenience features. As ensemble models enhanced the stability and the accuracy of their predictions.

The rest of the paper organization as follows: Section II presents the background knowledge of relevant literature in field of English language learning. Section III shows the comprehensive details of applied methodology including experimental setup. Section IV shares the analysis of results along with discussion. Section V provides the summary of paper in conclusion form with future directions.

II. LITERATURE REVIEW

The use of AI has become prominent in English Language Learning (ELL) processes as a strategy within educational information systems, improving the educational process and learners' interactions. In study [17], systematic review shows the positive and varied effects of AI technologies like ITS, NLP, and Speech Recognition on ELL. The review also notes that ITS seem to help learners the most around language proficiency or specific language skills, while speech recognition technology helps learners to improve pronunciation and speaking skills and, therefore, boosts their confidence. In addition, [18] embracing of Virtual Reality (VR) as well as Augmented Reality (AR) has changed the whole environment in which learners practice English. Another study [19] argues that these technologies foster contextually grounded environments which not only support the development of register specific language but also provide cultural context in which learners can apply the language. Appointment simulation enables learner to invariably assess their speaking performance in a supposedly realistic context, which is vital for language learning. Besides improving language skills [20], AI approaches help optimize and minimize the administrative work within the context of educational information systems. For instance, instruments like ChatGPT and education copilot help in developing courses and lesson plans, which gives such educators more time to deal with interactions and individual engaging with the student.

This automation not only decreases the possibility of grading bias but also allows instructors to give feedback promptly; instructional decisions reach a state in which it is based on the performance analytics data in real-time [21]. Still, there are obstacles in using AI in ELT because the incorporation of AI into teaching practice encounters certain difficulties. A study carried out by the Teaching English showed that schools around the world implement AI in their classrooms [22]. Similarly, concerns regarding the drawbacks of AI such as, in language use there could be bias and in terms of learning human interaction could be reduced when using the technologies [8]. Therefore, further research must reveal the effectiveness of using AI technology for learning English in the long term as well the existence of frameworks that can help educators work through its difficulties. In aggregate, the implementation of AI-inspired technologies into the scope of educational information systems is a breakthrough in learning English [11]. Introducing these systems in the classroom environments may also open the possibilities of improving the extent of teaching and learning capabilities, in the form of personalized learning experiences, coupled with the use of, for instance, immersive technologies and efficient administrative tasks. Nevertheless, the issues related to effective AI application are going to remain critical to achieve the potential benefits of utilizing AI in language instruction.

Modern progress in the areas of AI and ML have hugely impacted on improving the techniques of learning English. The implementation of some deep learning models like the CNNs and the RNNs in automating the essay grading task and appended feedbacks to the English language learners [23]. Another study, contributed to AI voice recognition in enhancing the precision on English pronunciation to help learners. Subsequent research has also examined the teaching of grammar

by using AI devices to improve the learning of English grammar since the difficulty level of the material is determined by the learner's performance [24]. Authors in study [25] developed an error prediction system they say helps in teaching learners how to write by pointing out any mistake they have made and the corrective action that needs to be taken thus enhancing the learners' writing skills to carry out an enhanced learning process for writing by offering the writers feedback on grammar, vocabulary and writing style. English listening comprehension has also been a focus of machine learning, perhaps as exemplified by study [26] who posited an assessment system, incorporating the use of AI to gauge the learners' listening skills based on their proficiency level for developing applications that offer differentiated vocabulary learning according to learners' performances. Furthermore, in study [27] employed RNN for real time error correction in English as foreign language, which provided feedback for learners as soon as they wrote incorrect sentences and paragraphs so that they could correct their grammatical and writing mistakes. Lastly, NLP and machine learning to teach English syntax and semantics to learners

establishing a strong foundation for learners to understand the complicated language rules [28]. These studies clearly show that English learning and teaching is the area where AI and ML are widely used as they can personalize the learning courses, develop the criterion reference assessment, and enhance the learners' skills within the different domain of the language.

III. METHODOLOGY

The following section provides a detailed procedure for specifying and categorizing understanding in the English grammar to improve teaching and learning experiences for the teachers and their learners. Concisely, the steps were carried out as Data Preprocessing, Feature Extraction methods, several Machine Learning Models, and Performance Measures have been employed as a basis for assessing the efficacy of the presented models. The, following structured approach, as shown in Fig. 1, guarantees a strong structure that responsibility helps to work out the difficulties of learning identification in English grammar.

Fig. 1. The framework showing steps of the research study.

A. Data Collection and Preparation

This data set will be useful for English learners and teachers to learn and improve the usage of language in English. It includes example sentences and the tense that each of such sentences demonstrates. The data was then constructed carefully to ensure it produced sentences that clearly illustrated how the various English tenses can be used making it a rich resource for use in learning and teaching. Text preprocessing is an important step to be taken to transform textual data into NLP context. In this study, we identified several main processing procedures intended to improve the quality of the input data that is then provided to ML algorithms. There is the removal of stop-words and punctuation mark which is the first process in text mining in the process of filtering out noise words within the large datasets

so that models can learn from more important words. After this, lemmatization also applied that includes the removal of prefixes and suffixes of the words and bring them to their basic form, making it easier to normalize different forms. This is particularly important for tense identification as this means that different forms of any given verb will be treated in the same way. Also, transforming text into a standard form to remove more variation from the data. However, it also employed Part-of-Speech tagging which aims at assigning a role to each word it has identified as a noun, verb, adjective and the likes. This is important especially for recognition of tenses, because verbs are of key importance in tense definition.

B. Feature Extraction

Feature engineering on the other hand is the process of extracting more meaningful features from the preprocessed text that can then be used in the actual machine learning processes. In this research, employing two primary techniques: Understanding of Term Frequency-Inverse Document Frequency (TF-IDF), and Bag of Words (BoW). Table I shows the in-depth definition of symbols used in equations.

1) *Term frequency-inverse document frequency (TF-IDF)*: In its most simplified form, the Term Frequency (TF) can be, nevertheless, enhanced with normalization for document length differences. Normalized term frequency as is expressed by Eq. (1) can be defined as the normalized term frequency.

$$TF(t, d) = \frac{f_{t,d}}{\sum_{t \in d} f_{t,d}} \cdot (1 + \log\left(\frac{f_{t,d}}{\max_{\bar{t},d} f_{\bar{t},d}} + 1\right)) \quad (1)$$

Combining these advanced formulations, the TF-IDF score for a term t in document d relative to corpus D can be computed as in Eq. (2).

$$TFIDF(t, d, D) = TF(t, d) \cdot IDF(t, D) \quad (2)$$

Moreover, it is possible to explain the TF-IDF values based on the information gain of the terms with respect to the documents as computed using Eq. (3).

$$TFIDF(t, d, D) = \left(\frac{f_{t,d}}{\sum_{t \in d} f_{t,d}} \cdot \left(1 + \log\left(\frac{f_{t,d}}{\max_{\bar{t},d} f_{\bar{t},d}} + 1\right) \right) \right) \cdot \left(\log\left(\frac{N+1}{n_t+1}\right) \right) \quad (3)$$

The mutual probability distribution can be expressed as in Eq. (4).

$$M(t; d) = \wp(t|d) \cdot \wp(d) \cdot IDF(t) \quad (4)$$

This formulation captures what we have been aiming at, in this paper, that is, capturing as to how informative each term is regarding the associated documents to be able to have an even better understanding of them within the given corpus.

2) *Bag of Words (BoW)*: On the other hand, the Bag of Words utilized to reduce text data to a series of words while ignoring the position of words in the document and retains multiplicity. This makes word counting simple which is especially useful when trying to determine the commonly used words and particular, verb forms relating to varying tenses, by defining a weighted frequency representation that incorporates not only raw counts but also contextual importance through various normalization techniques, defined as in equation 5. In utilizing these feature engineering strategies to make a stronger representation of the text data would be formed, which will enable the identification of the appropriate tenses in learning of the English grammar.

$$V_d = [w_{1,d}, w_{2,d}, \dots, w_{n,d}] \quad (5)$$

Where $w_{i,d}$ is defined as in Eq. (6):

$$w_{i,d} = f_{i,d} \cdot \text{norm}(f_{i,d}) \cdot \text{context}(t_i, d) \quad (6)$$

The procedures presented in this research for establishing an approach for constructing an automated environment for using AI to support vocational educators and learners in enhancing their mastery of English grammar and tense identification.

C. Applied Models

In the realm of NLP in dealing with issues common with English learning identification and classification. This section investigates a few more complex forms of machine learning models and how they are implemented in different ways including models like Support Vector Machines (SVM), Multinomial Naive Bayes (MNB), Bagging Classifier, and Calibrated Classifier CV. Contrasting the principles and uses of these models, to clearer understanding of how these models can be used to improve educational outcomes in English learning for both teachers and learners will be gained.

1) *Support vector machine (SVM)*: SVM is a type of used learning method that is applied for classification problems. It does this by identifying the best hyperplane that can best separate different classes of data in a very large dimensional space. SVM works well in high-dimensional space and is not sensitive to the problem of overfitting, especially when the number of dimensions is large than the number of samples [29]. Thus, it uses a kernel size to map the data to a higher dimension so it can easily deal with non-linear relations using objective function, calculated as in Eq. (7).

$$\min_{w,b,\xi} \frac{1}{2} \|w\|^2 + F \sum_{i=1}^m \xi_i \quad (7)$$

Subject of constraint to Eq. (8).

$$y_i(w \cdot \phi(x_i) + b) \geq 1 - \xi_i, \quad \forall i = 1, 2, \dots, m \quad (8)$$

2) *Multinomial naive bayes (MNB)*: MNB is a probability-based classifier developed on the basic principles of Bayesian classifiers, and it is specifically useful for text classifications. It supposes that every feature is independent of other features on condition that the class is given. It is suitable for multi-class problems and most suitable with high-dimensional data such as text documents [30]. MNB performs the model by calculating the conditional probability using Eq. (9), defining each class against the words in the documents making this method simple especially for tasks like spam detection and sentiment analysis.

$$P(t|U) = \frac{P(t)P(U|t)}{P(U)} = P(t) \prod_{i=1}^n P(v_i|t) \quad (9)$$

For each class t , the probability of observing feature vector U is given by Eq. (10).

$$P(U|t) = \frac{\prod_{i=1}^n (f_{i,t} + 1)}{\sum_{k=1}^V (f_{k,t} + 1)} \quad (10)$$

The predicted class is determined by maximizing the posterior probability using Eq. (11).

$$\tilde{t} = \text{argmax}_t P(t) \prod_{i=1}^n P(v_i|t) \quad (11)$$

3) *Bagging classifier*: This process is known as bagging – Bootstrap Aggregating which is an ensemble technique that resolves the problem of variations of a learning machine. It operates differently by building multiple models, often decision

trees on different parts of the training data resulting from bootstrapping, that is random sampling with replacement based on weighted ensemble prediction, computed as in Eq. (12).

$$Y_{final} = g(\prod_{j=1}^J w_j h_j(x)) \quad (12)$$

The last decision is then performed by averaging or voting for these models, that Eq. (13).

$$Var(Y_{final}) = \frac{1}{J^2} \prod_{j=1}^J Var(h_j(x)) + (J - 1)Cov(h_j(x), h_k(x)) \quad (13)$$

4) *Calibrated classifier CV*: The Calibrated Classifier CV is an extension of a base classifier where cross-validation is used to enhance the probability estimation. This method refines the predicted probabilities obtained from classifiers to portray more accurate probabilities to improve decision makers in probabilistic systems, using calibrated function, defined in Eq. (14).

$$P_{calibrated}(y = 1|X) = \sigma(w^T X + b) \quad (14)$$

Where $\sigma(z) = \frac{1}{1+e^{-z}}$ is the function used to computed objective function of calibrated model.

Cross validation is performed to make sure that calibration is done on unseen data, and thus provides higher accuracy on the prediction, computed using Eq. (15).

$$CV(L(w, b)) = \frac{1}{K} \sum_{k=1}^K L(w_k, b_k) \quad (15)$$

Where each fold provides a different set of parameters for calibration.

D. Performance Measure

In the context of performance evaluation of models for identification and classification for English grammar learning, several measures are used to evaluate whether models are effective in providing accurate predictions using metrics such as accuracy, precision and recall, F1 score.

Evaluation using accuracy is based on the concept of measuring the percentage probability that the model prediction for each data point is true with an overall performance, using Eq. (16).

$$Accuracy = \frac{True\ Positives + True\ Negatives}{Total\ Prediction} \quad (16)$$

Precision, also known as positive predictive value, assesses the accuracy of the positive predictions made by the model. It is defined as in Eq. (17), the ratio of true positive predictions to the total number of positive predictions.

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives} \quad (17)$$

Recall, or sensitivity, evaluates to what extent the model selects the number of correct cases when it is, and in percentage of positive prediction, how accurately the model identifies the true negative cases among the wrongly predicted positives. It is defined as in Eq. (18), the accuracy of positive predictions; these are the actual number of positive predictions divided by the total number of positive predictions made.

$$Recall = \frac{True\ Positives}{True\ Positives + False\ Negatives} \quad (18)$$

F1-score is the balance between precision and recall because the harmonic mean is the better measure than average in such cases, as defined in Eq. (19). They are especially valuable in the scenario of distinguishing between the data set and the data set that is wrongly classified as the opposite class or misclassified as belonging to the opposite class by a certain model.

$$F1 - Score = \frac{2(Precision * Recall)}{Precision + Recall} \quad (19)$$

TABLE I. DESCRIPTION OF SYMBOLS USED IN EQUATIONS

Symbols	Explanation
$f_{t,d}$	Frequency of term t in document d
n_t	Number of documents containing term t
$M(t; d)$	Mutual distribution
$\wp(t d)$	Conditional probability
$\wp(d)$	Prior probability
V_d	Vector representation for document d
$norm(f_{i,d})$	Normalization function to scale the frequency
$context(t_i, d)$	Contextual weighting factor shows semantic similarity measure
ξ_i	Misclassification slack variable
F	Regularization parameters
$f_{i,t}$	Frequency of feature v_i in class t
V	Vocabulary Size
$g(\cdot)$	Majority voting function
w_j	Base classifier

IV. RESULTS AND DISCUSSION

The descriptive analysis performed on the dataset gives an understanding of the linguistic and structural properties of the data. The Fig. 2 of distribution of tenses also represents well different tenses, and most importantly the present continuous and future tenses dominate while the tenses like future perfect continuous appear to be relatively less used. This implies a wide coverage on techniques for tension types that in turn help linguistic diversification. The analysis of the frequency of appearing of numbers of words in a sentence in Fig. 3 has indicated that most of the sentences contain between 40 and 60 words, which means that the examples used in the text should be rather appropriate for educational purposes as far as their length is concerned. The analysis of POS (Part-of-Speech) tags shows in Fig. 4 that the identified data contains a high number of nouns, verbs and determiners, and it is natural considering the focus on the sentence examples. Moreover, the word cloud of the preprocessed text graphically illustrates in Fig. 5 temporal and action-oriented words like ‘next,’ ‘year,’ ‘later’ and ‘gym’ which are evidence of time consciousness within this data set. Altogether, all these visualizations provide supporting evidence to augment the previous argument, regard to the suitability of the presented dataset for tense classification and educational purposes.

A. Results with TF-IDF

The findings from the analysis using TF-IDF accompanied by machine learning and ensemble models provide sufficient support to the proposed solution and confirm the potential of using advanced computational solutions to enhance English learning in educational systems. High accuracy of models such as SVM proved that the models can recognize and learn complex linguistic features with 88% accuracy as well as Bagging Classifier (89%) and CalibratedClassifierCV (87%) models.

These results as shown in Table II illustrating how such models can accurately identify English tenses, an essential

feature of language acquisition. This way, the obtained results demonstrate the possibility of applying these models in real-life settings, including the utilization of automated grammar evaluation, individual learning environments, and language learning assistance tools. The highly favorable efficiency of the methods such as bagging Classifier proves that such an algorithm functions stably and guarantees learners receive accurate feedback regardless of the input data. Just like, SVM demonstrates a very good generalization in its modeling, which makes it suitable for distinguishing small differences in the structure of work sentences as a way of mastering English learning.

Fig. 2. Distribution of tense.

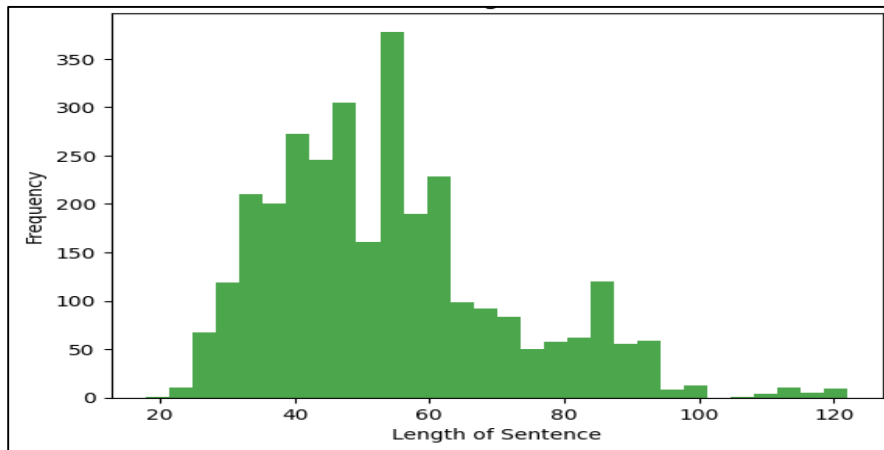

Fig. 3. Length distribution of label sentence.

through syntactic analysis. Including BoW-based models, educational platforms provide more accurate and linguistically grounded tools which contribute to progress of the learning process.

TABLE III. RESULTS OF APPLIED MODELS WITH BOW

Models	Accuracy	Precision	Recall	F1-Score
Shallow Machine Learning				
SVM	89	89	89	89
MNB	83	81	80	79
Ensemble Learning				
Bagging Classifier	90	89	90	89
CalibratedClassifierCV	84	84	84	84

The evaluation of the outcome using the TF-IDF and BoW on machine learning and related methods of ensemble brings out new perspectives of their performances, as shown in Fig. 6. In both feature extraction methods, the performances were excellent, and BoW was slightly better than TF-IDF in most of the models in terms of accuracy. Bagging Classifier achieved 90% using BoW while using TF-IDF it was 89%; for SVM BoW gives 89% while TF-IDF gives only 88%. This indicates that because of BoW's less complex representation, this model was able to capture the patterns in this dataset. Nevertheless, TF-IDF gave comparable results to the other algorithms and demonstrated good performance in evaluating term weight where the importance of terms is decisive. The two paradigm approaches emphasize on their qualities that would be useful in different areas of educational information systems for learning English.

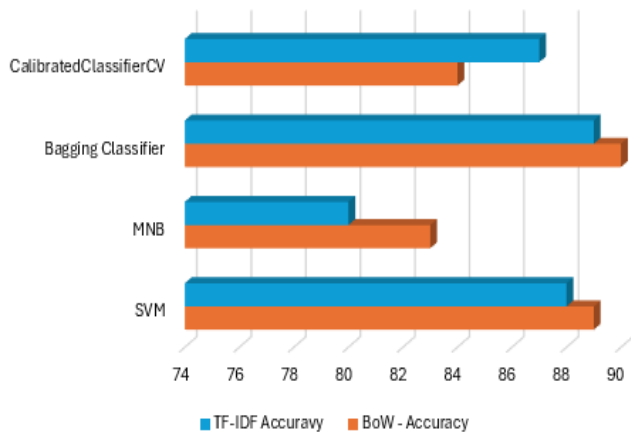

Fig. 6. Comparative analysis of applied features across accuracy measure.

V. CONCLUSION

In the modern educational system, the importance of learning cannot be overstated, as it is essential for students' academic and professional success. However, many learners, especially those in vocational colleges, face challenges in mastering key aspects of English, such as grammar, which forms the foundation of effective communication and learning abilities. Among the crucial components of English grammar, the use of tenses plays a pivotal role in ensuring clarity and

accuracy in vocational college system. The advancement of AI offers significant potential to address these issues by providing personalized and scalable solutions for learning. AI-powered tools can help students understand and apply grammatical concepts more effectively, thereby enhancing their overall learning experience. Our findings in this research demonstrate the efficacy of machine learning models, particularly Support Vector Machine (SVM) and Bagging Classifiers are highly efficient for tense usage classification with accuracies of 89% and 90%, respectively using BoW and TF-IDF features. The obtained results emphasize the possibilities of development and usage of AI-technologies for improving the English language acquisition, providing a robust framework for future educational tools. Moving forward, further research can explore more sophisticated AI techniques to incorporate more complex methods for interactive learning platforms. This study will therefore create a foundation for the development of more enhanced language education to the students at vocational colleges and other institutions.

Investigating Immersion and Presence in Virtual Reality for Architectural Visualization

Athira Azmi¹, Sharifah Mashita Syed Mohamad²

Department of Architecture-Faculty of Design and Architecture, Universiti Putra Malaysia, Serdang, Malaysia¹
Department of Computer Science-Faculty of Computer Science and Mathematics, Universiti Malaysia Terengganu,
Kuala Nerus, Malaysia²

Abstract—The architecture industry increasingly relies on virtual reality (VR) for architectural visualization, yet there is a critical issue of insufficient user involvement in the design process. This study investigates the sense of immersion and presence in the virtual environment among 60 Malaysian participants aged 20 to 40. The study utilized a 1000 sq. ft. apartment with three bedrooms and two bathrooms, was replicated in a 3D model based on real-world references. Our findings show that participants were moderately immersed in the virtual environment ($M = 4.86$), but the lack of sense of touch, lack of detail, and interactivity within the virtual environment affected their sense of immersion in VR for architectural visualization. This study has enhanced our understanding of human-computer interaction in VR, specifically for architectural visualization, and has emphasized the importance of improving these aspects to create more effective architectural visualization user experiences.

Keywords—Virtual environment; virtual reality; human-computer interaction; architectural visualization; sense of presence

I. INTRODUCTION

Computer simulation, such as virtual reality (VR) has become an intrinsic part in realizing the vision of Industrial Revolution 4.0 and has revolutionized the way human work, communicate, collaborate and interact with one another [1]. Within the architecture industry, VR has facilitated design, construction and management of the built environment, given its immersive and interactive visualization capabilities [2]. Professionals in the architecture, engineering and construction (AEC) industry relies heavily on visual modes of information transfer and interaction, such as sketches, two-dimensional drawings, computer imagery, visualization and simulation [3, 4].

VR has proven its value in the AEC industry, offering benefits from design reviews to construction simulations [2, 5]. Architects now have access to a variety of tools like Enscape, Lumion, Twinmotion, Unreal Engine, Chaos Vantage, and Chaos V-Ray for real-time visualization of their architectural design proposal. In the conceptual phase, VR is used to explore design ideas quickly, providing architects with a sense of proportion and scale. As projects progress, VR becomes crucial for design validation, allowing architects to experience detailed interiors and exteriors realistically [2]. This technology allows architects to make fast well-informed decisions, considering aesthetics, cost, and environmental impact. The design process, once time-consuming, now occurs in seconds.

Despite evidence showing the use of these digital visualization technology could bring significant improvement in

communication, exchange and interoperability of information, there exists a lack of end-user involvement and perspective in the design process [6]. According to Lee et al. [6], to effectively use digital visualization for architectural design collaboration, it is important to ensure the effectiveness of the visualization system from the end-user perspective.

Prabhakaran et al. [4] identify some hurdles within the architecture and construction sectors concerning immersive technologies like VR. These challenges encompass deficient communication among stakeholders, primarily attributable to the nascent state of VR infrastructure. Specifically, issues such as hardware requisites, user mobility constraints, ease of operation, and device ergonomics contribute to these communication inefficiencies [4]. Moreover, our earlier findings highlight the impact of VR hardware issues on users' sense of presence, a critical aspect underscored by Prabhakaran et al. [4] to enrich immersive experiences. The sense of presence, as highlighted by is pivotal for users to truly feel immersed in the virtual environment. While simulating spatial movement on a screen is feasible, Gomez-Tone et al. [8] argue that genuine immersion requires viewers to perceive themselves within the virtual space, fostering a profound sense of presence.

This study emphasizes the importance of end-user involvement in architectural design, utilizing VR technology to delve into user experiences. By integrating human emotions into digital visualization tools, the aim is to create architecture that caters to emotional needs. Facilitating improved collaboration between architects and users, the process enriches design through digital visualization. However, there remains a gap in understanding user responses to VR immersion in architectural contexts, especially in Malaysia. This research focuses on exploring Malaysian users' immersive experiences with VR when interacting with 3D building models. The goal is to pave the way for more empathetic architectural designs that prioritize user needs.

The paper is structured as follows: it begins with a background and literature review in Section I and II, providing context for the study. Following this, the experiment conducted to investigate the sense of presence among Malaysian users in VR is detailed in Section III. Subsequently, the results of the experiment are presented, accompanied by a thorough discussion is given in Section IV and Section V. Finally, the paper concludes by acknowledging the study's limitations and offering recommendations for future research in this domain in Section VI.

II. LITERATURE REVIEW

A. VR and Immersive Virtual Environment for Architectural Visualization

In the context of built environment, virtual reality (VR) can be defined as the experience of feeling present in a fictitious or envisioned environment through its representation [5]. An immersive VR system requires a three-dimensional (3D model), a head-mounted display (HMD), interaction devices or controllers and software to run the program. Immersive VR enables users to immerse themselves into the virtual environment [9].

As an immersive technology, VR enables human experience in the virtual environment through the sense of presence, which is the major factor in delivering lifelike experiences in the simulated environment [5]. Realism in the immersive virtual environment via VR is considered an important element for architectural design visualization, as the main objectives of VR applications in built environment field is to facilitate visualization and simulation of the architecture design [5].

Apart from tremendous benefit as learning tool for visualization in architecture education [10,11,12,13], most VR research in the construction industry proved that the technology benefits in the decision-making during the design process among design professionals [14,15]. However, there is a considerable gap in the effectiveness of VR for design collaboration with real-end users of buildings and clients from non-design background. Thus, it is important to investigate whether the use of VR for architectural visualization could achieve the level of realism as expected by these non-design users.

However, as stated earlier it is found that there is a lack of study that investigates how users respond to the design while experiencing it in VR, especially for the context of Malaysian user. Abdul Ghafar and Ibrahim [16] stated that there is lack of emphasis given to human factor when using these digital visualization tools. Azmi et al., [7] also argue that the use of VR for visualization of housing design for homebuyers are limited in terms of touch sensation and navigation. In addition, Delgado et al., [3], supported by Lyu et al., [17] argue that despite the advancement of VR technology in visual rendering of the immersive virtual environment, other sensory simulation such as auditory, tactile, thermal, olfactory and taste remain relatively underdeveloped. These arguments highlighted the importance of exploring end-user engagement through the visual representation using VR during the design stage to determine the effectiveness of this digital visualization technique during design collaboration.

B. Emotional Intelligence in Digital Architectural Visualization

Over the past decade, emotional intelligence has been the focus of research from different disciplines of studies to explore the advantage of applying the concept to benefit their respective fields. Salovey and Grewal [18] described emotional intelligence as the skill that brings together the fields of emotions and intelligence by viewing emotions as useful sources of information that help one to make sense and navigate the social environment. As human responds cognitively and

emotionally to the built environment, the use of VR to evaluate users' emotion during their immersive virtual environment experience serves as a promising framework for the future of design and research in the built environment [19].

However, user experience has been the main issue in VR for architectural visualization as VR is highly visual and does not really support other human sensations such as olfactory and haptic [7,19]. VR has the capacity to simulate the illusion of being in a place through the sense of presence, hence, it is crucial to meet the viewers' expectations, cognitive and emotional dimension of the built environment [19]. Research has shown that some design element in the built environment reflected higher sense of attraction of the brain to the surroundings, which impacts the psychological wellbeing of the inhabitants [20].

It is found that research in regard to emotional intelligence in architectural visualization within the virtual environment has not been widely studied. Thus, this paper argues the critical need for a study that investigates the synergistic relationship between VR and user experience. This study is trying to fill the considerable gap in studies that examine how the end-user, which is usually non-design professional perceive the digital simulation of an architecture design. This is pertinent to help architects to understand and improve the design of virtual spaces that has more meaning, physically and emotionally to the end-users. It is substantial to explore emotional intelligence during the design process that requires exchange of not only technical decisions but also the human experience, especially with the use of digital visualization technology such as VR.

C. Sense of Presence

Immersive virtual environment enables human experience in a given environment through the sense of presence. Presence is defined as the subjective experience of being in one place or environment, even when one is physically situated in another [21]. It has been proven by various recent research that human emotion in the virtual environment is similar to the emotion in the physical environment [7, 22, 23].

Caroux [24] indicates that while immersion would be typically related to sensory feedback that results in the sense of being surrounded by the virtual environment, presence would be more related to a cognitive psychological response that is the feeling of being in the virtual environment. Several factors affecting presence has been identified, including i) human factors - the level of experience and age [25], ii) the visual and sensory input [26], and iii) technological factors – stereopsis, field of view, and interactivity [5].

Following Paes et al., [5], identifying factors that affect presence in virtual environment is a vital step to improve the VR application in the built environment. This study aims to fully optimize the advancement of digital visualization technology in the AEC industry to ensure effective user experience in VR, especially for the context of Malaysian users. Hence, it is possible to create a new space for better discussions of design solutions between architects and end-users for a design that meet user needs. With the considerable gap in literature concerning users from Asian background in using VR technology for architectural visualization, following Azmi et al., [7], this study is focusing on the users' behavioral response in VR within the

context of Malaysian user in local architectural design. In the next section, this paper delineates the experimental research methodology employed to investigate the sense of presence among Malaysian users within VR environments for architectural visualization purposes.

III. RESEARCH METHODOLOGY

This study is an empirical and relational study as most human-computer interaction studies such as Paes et al., [5]. Employing a one-group posttreatment-only pre-experimental design, the study leverages survey questionnaires to assess user experience within virtual environments. This design entails exposing a single group of participants to an intervention, followed by measurement, as elucidated by Creswell [27]. Participants engage with a VR setup simulating the interior of a house, after which they provide feedback through questionnaires to gauge their immersion and presence within the virtual environment.

A. Participants

Participants were recruited for the experiment using purposive sampling method, via advertisements distributed in social media and word-of-mouth. In order to be included in the study, individuals had to meet the following criteria: (1) Malaysian nationality; (2) aged between 20 and 40 years old; (3) not physically or mentally impaired and (4) not under serious medications for health-related problems. In regard to the sample size, a power sample analysis using G*Power version 3.1.9.7 [28] was conducted with a level of statistical significance equal to 80% with a medium effect size of Cohen's $d = 0.5$ ($\alpha = .05$). This follows similar sample size estimation by other studies in VR experiments such as Pallavicini and Pepe [29]. Result of the power sample analysis using G*Power suggests an estimation of sample size for the research design and one sample case statistical test is 27 participants. In this study, a total of 60 samples were recruited, which is more than adequate to get a high statistical power.

Based on the post-hoc power analysis to compute achieved power based on 60 samples conducted in G*Power version 3.1.9.7, the study has 99% power to detect medium-sized effect $d = 0.5$ ($\alpha = .05$). The 60 participants recruited in this study include: 33 female (55.0%) and 27 male (45.0%); mean age of 30 years old (SD: 2.81). 95% of the participants are from Malay racial background. Only two participants have the experience of using VR for architectural visualization before the experiment.

B. 3D Model and VR Apparatus

An apartment designed in Selangor, Malaysia was selected as the experiment environment. This residential unit consists of 1000 square feet of living space with three bedrooms and two bathrooms. A 3D model of an interior of a house was developed in Sketchup Pro 2019 (version 19.3). Enscape software (version 2.6.1) was used for the real-time 3D visualization and as the VR plugin for Sketchup. Fig. 1 shows the 3D model of the kitchen of the apartment in Sketchup software. Fig. 2 shows the virtual environment as viewed in VR, rendered using Enscape software.

Fig. 1. 3D model of the kitchen in Sketchup software.

Fig. 2. VR view of the kitchen rendered in Enscape software.

For the VR apparatus, HTC Vive was used. HTC Vive consists of a head-mounted display (HMD), two base sensors for tracking position and orientation, and a set of controllers were used as the VR equipment. The computer used was a Dell G7 15 7590 laptop with Intel Core^{TM} i7-8750H processor and NVIDIA GeForce GTX 1050 (4GB GDDR5) graphics card. The computer has an 8GB RAM that operates with the Windows 10 operating system. The specifications on this computer satisfy the minimum system requirements for HTC Vive. Fig. 3 illustrates the VR setup which consists of the HTC Vive head mounted device (HMD), two base stations, two controllers.

Fig. 3. VR device setup.

The HTC Vive system allows for physical movement within a minimum play area of 2 meters x 2.5 meters, hence the experiment was set to comply within this play area. The play

area was setup using Viveport software. Fig. 4 shows the participants using the HTC Vive during the experiment.

Fig. 4. Participant using the HTC Vive during experiment.

C. Data Collection Instruments

The data collection instruments used in this study include:

- Demographics – the question includes their gender, age, marital status, racial background, level of education, profession and prior VR experience;
- Consent form - Before the experiment, every participants was asked to read carefully the consent form, as it is the right of every person to make informed decisions regarding their participation in a research study, after being informed of all aspects of their role in the study as required in the Belmont principle of respect for persons [30]. This research has also been approved by the Universiti Putra Malaysia Ethics Committee for Research Involving Human Subject (JKEUPM-2020-028) prior to the data collection;
- The Virtual Presence Questionnaire (VPQ) - After the participants had been exposed to the virtual environment, a Virtual Presence Questionnaire (VPQ) was given to each participant. The VPQ was adopted from the Presence Questionnaire, originally used by Witmer and Singer (1998). The Presence Questionnaire was used to evaluate the level of presence that each participant experienced during the VR experience to view the virtual environment. The VPQ developed in this study is adapted based on the instruments developed by prior research that includes Witmer and Singer [21], Westerdahl et al., [31] and Heydarian et al., [32].

The VPQ consists of nine Likert Scale-based questions (seven-point scale), two questions that requires a yes or no answer, and two open-ended questions. These questions were developed based on prior research to determine the level or immersion and presence of the participants in the virtual environment, including the level of realism of the virtual environment. The results from the VPQ would add to the understanding in regard to the participants' differences and abilities in a given virtual environment, and the characteristics of the virtual environment that may affect presence.

The two open-ended questions in the VPQ seek to obtain additional information based on the participants' experience in the virtual environment using the VR devices. In the open-ended questions, the first question invited the participants to comment on the kind of information that they think is lacking from the virtual environment; while the second question invited them to provide suggestions regarding the application of VR for architectural visualization in Malaysia. The two open-ended questions in the VPQ are:

- What kind of information do you think is lacking from the VR environment?
- What are your comments regarding the application of VR for architectural visualization?

According to Creswell [27], Neuert et al., [33], and Aithal and Aithal [34], open-ended questions in a set of questionnaires allow the respondent to express an opinion without being influenced by the researcher. The open-ended questions advantages include the possibility of discovering the responses that participants gave spontaneously, and thus avoiding the bias that may result from suggesting responses in close-ended questions such as Likert-scales [35].

IV. RESULT AND ANALYSIS

A descriptive statistical analyses to describe the central tendencies and variability in participants' response in this study were conducted using SPSS version 25 software package. Table I illustrates the mean and standard deviation for the participants' responses in the VPQ.

TABLE I. VPQ QUESTIONNAIRE ITEMS - MEAN AND SD

VPQ QUESTIONNAIRE ITEMS - MEAN AND SD		
VPQ Questionnaire Items	Source	Mean (SD)
"How physically fit do you feel today?" ^a	[21]	6.27 (0.73)
"How good are you at blocking out external distractions when you are involved in something?" ^a	[21]	5.75 (0.97)
"Are you easily disturbed or distracted when working on tasks?" ^a	[21]	3.87 (1.75)
"Did you get bored with the VR model during the viewing experience?" ^a	[31]	5.80 (1.61)
"Did the surfaces such as walls, floors, and furniture look real in the VR model when you view it?" ^a	[31]	4.95 (1.65)
"Could you orient yourself in the internal environment during the VR experience?" ^a	[31]	5.43 (1.53)
"How much did your experiences in the virtual environment seem consistent with your real-world experience?" ^a	[21]	4.95 (1.64)
"How realistic was your sense of movement around in the virtual environment?" ^a	[21]	4.60 (1.59)
"How difficult was it to understand the characteristics of the house in VR?" ^a	[32]	3.25 (1.72)
"Did you feel that the Virtual Reality (VR) model lacked information for you to understand the interior of the house?"	[31]	Yes = 55%
"Do you feel any discomfort or dizziness after the VR experience?"	[7]	No = 45%

^a. The question response format was a 7-point Likert scale.

Findings from Table I indicates that the participants were relatively fit during the experiment (M = 6.267, SD = 0.7333). The participants were also somewhat focused during the experiment based on their responses in Question 2 (M = 5.750, SD = 0.968) and Question 3 (M = 3.867, SD = 1.751). In the virtual environment, the result showed that most of the participants thought that the textures on walls, floors, and furniture look real in the VR model (M = 4.950, on a 7-point Likert scale where 1 = “not real at all” and 7 = “very real”). The same responses also applied to whether their experience seems consistent with real-world experience (M = 4.950, on a 7-point Likert scale where 1 = “not consistent at all” and 7 = “very consistent”).

The participants also felt that they were able to orient themselves in a virtual environment (M = 5.433, on a 7-point Likert scale where 1 = “not at all” and 7 = “totally”); and that their sense of movement in the virtual environment is not much realistic (M = 4.600, on a 7-point Likert scale where 1 = “not at all” and 7 = “totally”). Of the 60 participants, 33 participants (55%) felt that the VR lacked information for them to understand the interior of the house. Finally, a majority of participants (78.3%) did not feel any discomfort or dizziness after the VR experience. The results also reveal that participants were relatively focused during the experiment based on their ratings from Questions 1 to 4. The participants also indicated that the virtual environment was moderately realistic based on their ratings from Questions 5 to 10.

A. Analysis of Open-Ended Questions

Of the 60 participants, only 33 participants (55%) provided their answers to the open-ended questions. To identify participants’ evaluation of the virtual environment from the two

open-ended questions, this study deployed thematic analysis. Four main themes emerged from the participants’ answers in these two open-ended questions which are: “feel”, “detail”, “size” and “interactivity”. The thematic analysis is presented in Table II.

In the first open-ended question - what kind of information do you think is lacking from the VR model? 18 participants mentioned that they were unable to estimate the size and dimensions of the interior of the house based on their VR experience. These participants felt that it is essential for them to feel the size of the space in the architectural visualization. In addition, seven participants commented that the information about materiality and texture of materials in the house is lacking in the virtual environment. One participant commented that the VR model was unsatisfying since they were unable to touch the materials inside the house or feel the wind from the window or balconies. Two participants also commented on the lack of sense of sound and smell in the virtual model. On the other hand, five participants commented on the realism of the virtual environment that lacks detail and seems unrealistic.

In the second open-ended question, eight participants provided suggestions that the VR equipment or space provided should enable them to walk around freely in the virtual environment without being restricted. Five participants provided suggestions for a more realistic virtual environment with better resemblance of a real physical building. One participant suggested that the VR application could provide options in terms of furniture arrangement, while another participant suggested that the VR application to provide different color options in the architectural visualization.

TABLE II. THEMATIC ANALYSIS OF VPQ ANSWERS

Open-ended Question 1: What kind of information do you think is lacking from the VR environment?	
Participants’ Response	Theme
“I want to really feel the house to make sense of it in terms of touch and smell; I am not sure how that can be achieved virtually”.	Feel
“I can’t feel the element of wind to make sense of the open space concept of the house.	
“Physical environment is more satisfactory as there is physical touch. The feeling of walking inside a real house is not similar as in VR”.	
“I can’t imagine the quality of materials in the VR model”.	Details
“Lack of detailing in the VR model”.	
“I can’t estimate the size and dimension of space inside the virtual environment”	Size
“It’s difficult to understand the size of the room from the VR”	
“I think a lacking feature of the VR technology is that I can’t estimate the size of the house”	
Open-ended Question 2: What are your comments regarding the application of VR for architectural visualization?	
Participants’ Response	Theme
“Adding capability to vary household content so that it may suit different individuals (worker, students, family, big family), and having multiple household arrangement settings for the same house layout”.	Interactivity
“I would suggest a bigger space for people can walk freely while using the VR equipment”.	
“I would suggest including measurement in the VR model for potential homebuyers to realise the size of the house”.	
“It is suggested to include interactive information such as measurement (height and width) and colour options for walls or furniture”.	

V. DISCUSSION

The study acknowledges limitations in touch and interactivity, impacting the participants' sense of presence. Issues related to hardware constraints and restricted movements contribute to a less realistic experience. Based on participants' response, it can be discerned that the participants' experience in the virtual environment are moderately natural, which results to a moderate level of immersion and presence. The authors believes that a greater degree of immersion and presence is detracted due to the lack of sense of touch in the virtual environment.

Most participants highlighted that the inability to physically touch or feel the materials within the virtual environment was a significant limitation. The authors contend that this absence of tactile interaction compromised the overall sense of immersion and presence. Furthermore, additionally, participants pointed out the unrealism in navigation, as the VR device was tethered with wires, which restricted movement and affected their ability to move freely within the virtual space. We recognized the limitations of the VR device used in this study, which requires cables attached to the HMD that limits participants' movements; hence affecting the level of realism in the virtual environment.

Apart from that, most of the participants also opined that they were unable to sense the feeling of space or estimate the dimensions or size of the house that they view in the virtual environment, which is one of the critical factors in enhancing their experience and presence in the architectural visualization. We acknowledged these findings as the most important one, considering the assumption by past literature that the virtual environment could simulate the physical world conditions with sufficient accuracy and are efficient in representing spatial information [36].

Furthermore, according to Azmi et al., [7], due to the lack of interactivity in the virtual environment, the atmospheric qualities of spaces are diminished, hence the sense of presence was lacking. The virtual environment could not simulate the physical world accurately in terms of the quality of the surrounding and its relation to human senses. This corroborates findings from [37] that suggests integrating technology capable of aligning the visual perception of virtual objects with the tactile sensations of holding and touching real objects with bare hands can significantly enhance the quality of experiences and sense of presence in virtual environments.

This study also concurs with Higuera-Trujillo et al., [19] that user experience is a vital issue that needs to be addressed. The user experience includes enhancing the capacity of VR simulation to generate the 'place illusion' and the credibility of the 3D scenarios in the virtual environment to meet the users' expectations of the simulated environment [19]. Thus, the findings in this study allows for further understanding of the current user experience in VR for architectural visualization.

VI. CONCLUSION

This study aims to enhance the architecture industry's adaptation to Industry 4.0 by leveraging digital visualization, particularly VR, in architectural design. The study contributes to understanding user experiences in VR architectural

visualization, particularly in Malaysia. While VR has significantly improved design review and collaboration, there is still a gap in end-user involvement. By evaluating VR effectiveness from the user's perspective, this research addresses these challenges. Issues like hardware requirements and user mobility hinder seamless communication in VR architectural visualization. Additionally, the study emphasizes the importance of the user's sense of presence in VR environments. Findings from our empirical study shed light on participants' experiences, highlighting realism and challenges.

This study highlights the significant potential of VR technology to revolutionize both the real estate and architectural industries. In real estate, VR offers a more sustainable and versatile alternative to physical show units, allowing developers to enhance their marketing strategies, reach broader audiences, and provide homebuyers with a more comprehensive and immersive evaluation experience than traditional methods. In architecture, VR serves as a tool for understanding user emotions and behaviors within designed spaces, fostering empathetic and user-focused designs, with potentials to focus on groups such as the elderly or individuals with special needs.

Recommendations include enhancing VR interactivity for better user engagement. This research contributes to understanding users' needs in VR architectural visualization, particularly in Malaysia, aiming to improve design collaboration and user satisfaction. It anticipates VR technology's enhanced role in architectural visualization, aligning with users' preferences and needs. Future research directions include investigating innovative approaches to improve the realism and immersion of VR environments for architectural visualization and exploring advancements in VR hardware such as tactile gloves or body-kit to allow sense of touch in the virtual environment.

LIMITATION OF STUDY

Several limitations of this study should be acknowledged. First, due to budget constraints, the study used an older version of the VR equipment, which is HTC Vive which was succeeded by newer versions of the VR headset. The HTC Vive (released in 2016) was followed by the HTC Vive Pro in 2018, and later, the HTC Vive Cosmos and Vive Pro 2 were introduced in 2019 and 2021, respectively.

Additionally, the study focused solely on the responses of participants in Malaysia that fulfil the inclusion criteria, which limits the participant pool to other nationalities with various cultural differences, which might have different perception due to cultural differences. Lastly, the absence of haptic devices meant that tactile feedback was not incorporated into the virtual experience. Future research should consider integrating haptic technology to allow users to physically interact with textures in the virtual environment, and assess its impact on emotions and behaviors.

ACKNOWLEDGMENT

This study was part of a research funded by a grant from Universiti Putra Malaysia (Geran Putra IPM GP-IPM/2023/9772700).

Data Mining MRO-BP Network-Based Evaluation Effectiveness of Music Teaching

Yifan Fan*

Henan Institute of Science and Technology, School of Music and Dance, Xinxiang 453003, Henan, China

Abstract—This study addresses the need for data analysis in evaluating the teaching outcomes of higher music education. It proposes a solution using data-driven algorithms to measure and analyze these outcomes. This study focuses on the issue of measuring and evaluating the outcomes of music education teaching. It analyzes the process of measuring and assessing these outcomes, designs a program for doing so, and introduces key technologies such as music education teaching process analysis, measurement of music teaching outcomes, construction of an assessment model for music teaching outcomes, and application of the assessment model. The study selects teaching content, practical skills, and social practice ability as the three aspects to evaluate. The results demonstrate that this method achieves higher assessment accuracy and requires less time, effectively addressing the challenge of measuring and evaluating the teaching outcomes of higher music education using big data. The findings demonstrate that the technique exhibits a high level of assessment accuracy and is less time-consuming. Additionally, it effectively addresses the challenge of measuring and evaluating the teaching accomplishments in higher music education from the viewpoint of big data.

Keywords—Mushroom propagation optimisation algorithm; BP neural network; higher music education teaching outcomes measurement; algorithm evaluation

I. INTRODUCTION

Currently, music education is progressing towards the establishment of a disciplinary structure, the application of scientific methods, the cultivation of higher cognitive skills, and the production of various academic accomplishments [1]. Evaluating and appraising music education instruction, as a crucial tool for advancing higher music education teaching, has immense importance in boosting teaching quality, driving instructional improvement, and fostering comprehensive student growth [2]. Scientific measurement and evaluation may aid instructors in comprehending students' learning development, pinpointing strengths and flaws in teaching, and therefore enhancing teaching techniques and approaches [3]. The emergence of intelligent disciplines has led to the adoption of data-driven models for measuring and assessing educational teaching approaches in higher music education. This trend has gained significant attention from professionals and researchers in the area. Hence, it is crucial to investigate the intelligent, scientific, and systematic approaches to measuring and evaluating teaching results in higher music education. This is essential for the robust advancement of the theory and practice of music education discipline.

Presently, the evaluation and measurement of teaching outcomes in higher music education mostly focuses on the study

of measuring indices, techniques, and assessment of teaching outcomes in music education. Yu and Zou [4] examined the current state of using artificial intelligence technology in the field of music and optimization strategies, and proposed a method for assessing music teaching based on artificial intelligence technology. Chen et al. [5] investigated the measurement and assessment methods of teaching outcomes in higher music education from a perspective of music education psychology. Yang [6] explored the current state of music education in higher vocational colleges and universities during the rise of aesthetic education, and suggested improvement and optimization measures in three teaching aspects; Liao and Huang [7] proposed a teaching evaluation method based on non-linear regression method for the teaching evaluation of vocal classroom of music education majors in higher education, and studied the problem of measuring and assessing the teaching results of music from the quantitative point of view; Peng [8] analysed the course process of music education by using the theory of OBE education, and put forward the music teaching evaluation method combined with simple machine learning algorithms; Jung [9] investigated the teaching evaluation method of national music culture transmission based on shallow network under multiculturalism, and analysed the evaluation model from various aspects such as cultural perspective and quantitative perspective; He and Liu [10] used the theory of multiple intelligences to construct the mapping relationship between the measurement value of the music teaching results and the teaching scores; Xu [11] researched the analysis and evaluation method of music teaching in combination with neural network based on the perspective of cultivating students' interests and hobbies; Wei et al. [12] studied the algorithm and assessment method of song arrangement generation in the field of music. Through the literature survey and network research analysis, the research on the measurement and assessment of higher music teaching results, although there have been a large number of academic results of measurement and a little music teaching evaluation system research, but there are still deficiencies, specifically in the following aspects [13]: 1) higher music teaching results measurement system is only limited to the measurement of the teacher's teaching process, ignoring the main body of teaching -- student feedback measurement; 2) higher music teaching results measurement system is only limited to the teacher's teaching process measurement, ignoring the main body of teaching --The feedback measurement of students; 3) The quantification of higher music teaching achievement measurement system is not objective enough, and the quantification of each index is comparable; 4) The higher music teaching achievement assessment method fails to portray the non-linear relationship between the measurement value and

the assessment value; 5) The higher music teaching achievement assessment method based on the neural network algorithm is prone to fall into the local optimum.

Neural networks are an algorithm used to create nonlinear mapping relationships. They are known for their simple structure and quick optimization convergence. Neural networks are commonly used for classification and prediction tasks, as well as in areas like network intrusion detection, charge prediction, machinery fault diagnosis, and condition assessment [14]. As the number of input parameters increases, the optimization convergence of neural networks may easily become stuck in a local optimum. However, the use of intelligent optimization techniques can enhance the speed and accuracy of convergence in neural networks [15].

This work addresses the issues related to measuring and assessing the achievements in higher music education teaching. To tackle these challenges, the study introduces a technique that combines the BP neural network [16] and intelligent optimization algorithm [17]. This approach is based on the MRO-BP model and aims to measure and analyze music education teaching achievements. This paper examines the issue of measuring and assessing teaching outcomes in higher music education. It analyzes research concepts and important quantitative technical aspects related to measuring teaching outcomes. It also addresses the measurement of teaching outcomes by analyzing the teaching process, identifying measurement indicators, and constructing a measurement system. Additionally, it proposes a methodology for assessing teaching outcomes in higher music education by combining neural networks and the MRO algorithm [18]. This methodology is based on the MRO-BP model. A novel teaching accomplishment assessment method based on MRO-BP is developed. The experimental section used statistical research data on teaching successes in higher music education. Through comparison analysis, it was confirmed that the MRO-BP model outperformed other models in terms of assessment effectiveness, as well as enhancing assessment time and efficiency.

The paper begins by introducing the significance of assessment in music education and the application of intelligent disciplines. The methodology section details the use of BP neural networks combined with the MRO algorithm to enhance the accuracy and efficiency of outcome assessments. Key techniques include process analysis, measurement of teaching achievements, and application of assessment models. The research explores the development of the MRO-BP network model, comparing it with other algorithms to demonstrate its effectiveness. The simulation and analysis section describes the data acquisition process, experimental environment, and parameter settings, followed by a performance comparison of different models. The conclusion highlights the model's superior results in accuracy and time efficiency, suggesting its applicability in higher music education while noting the need for further validation on other datasets.

II. MEASUREMENT AND ASSESSMENT

A. Analysis of Research Ideas

When teaching advanced music, instructors use many approaches, levels, and formats in the classroom [19]. This paper aims to address the issue of measuring and assessing the outcomes of higher music teaching. We focus on various aspects such as the course teaching process, teachers' level, students' knowledge demand, course practicability, and social value (Fig. 1). To achieve this, we conducted a detailed questionnaire survey to evaluate the cognitive abilities of music teachers. We then extracted indicators of the outcomes of the higher music teaching process and developed a measurement system for these outcomes. Additionally, we utilized the heterogeneous coupling optimization of the machine learning method to establish a mapping relationship between the measured values and assessment scores of higher music teaching. To fully analyze higher music teaching results, the study aims to establish a correlation between music teaching outcome measures and assessment scores. This particular research proposal is shown in Fig. 2.

Fig. 1. Domains of measurement and assessment of teaching outcomes in higher music education.

Fig. 2. Research ideas on measurement and assessment issues of teaching outcomes in higher music education.

B. Analysis of Key Technologies

This paper explores the measurement and assessment of teaching outcomes in higher music education, focusing on problem analysis, measurement of outcomes, assessment of outcomes, and application of a model. Specifically, it examines key technologies related to the analysis of the teaching process in music education, measurement of teaching outcomes in music, construction of an assessment model for teaching

outcomes, and application of the assessment model. These aspects are illustrated in Fig. 3.

Fig. 3. Key techniques in the methodology for measuring and evaluating teaching outcomes in higher music education.

1) *Process analysis techniques*: In order to sort out the problem of higher education teaching outcome assessment, process analysis technique was proposed, mainly by analysing the process of higher education teaching outcome measurement and assessment, and carrying out process analysis from questionnaire survey, demand analysis, method design and other aspects [20], as shown in Fig. 4.

Fig. 4. Process of analysing the measurement and assessment of teaching outcomes in higher music education.

2) *Techniques for measuring teaching achievement*: Higher education music education teaching outcome measurement (as shown in Fig. 5) mainly assesses and measures the teaching outcomes of the pedagogues from the aspects of teaching content, practical skills and social practice ability. The input of the module is the results of the analysis of the process of measuring and assessing teaching outcomes in higher education, the assessment aspects, and the output is the teaching outcome measurement system.

Fig. 5. Measurement of teaching outcomes in higher music education.

3) *Teaching achievement assessment techniques*: Higher Music Education Teaching Achievement Assessment (shown in Fig. 6) mainly combines a variety of intelligent algorithms to construct the mapping relationship between music education teaching measurements and assessment values. The input of this module is music education teaching measurement data, and the output is teaching outcome assessment scores.

Fig. 6. Assessment of teaching outcomes in higher music education.

4) *Techniques for applying results-based assessment models*: Taking the music education teaching outcome data of higher education institutions as a case study, the trained outcome assessment model was applied to the data, and the teaching outcome measurements were collected, standardised and input into the outcome assessment model to obtain the music education teaching outcome assessment scores, as shown in Fig. 7.

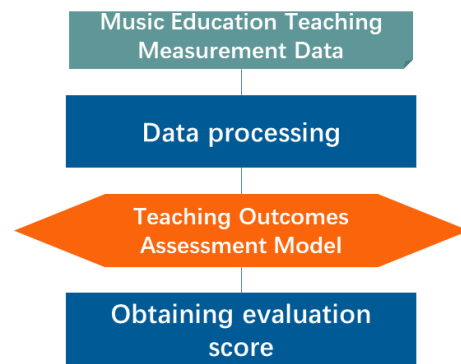

Fig. 7. Assessment of teaching outcomes in higher music education.

III. TEACHING OUTCOMES IN HIGHER MUSIC EDUCATION

According to the principles of demand-orientation, scientific, systematic and quantitative [21], this paper selects the measurement values of teaching results from three aspects, such as teaching content, practical skills and social practice ability [22], and the detailed extraction of the measurement values is shown in Fig. 8.

- Teaching content measures include measurements of regular grades, classroom practices, and final grades.
- Skills practice measurement includes academic salon activities focusing on professional skills demonstration and academic thinking exchange, and classroom practice activities focusing on teaching process design.
- Measurement of social practice ability includes internship assessment in off-campus teaching practice bases, and participation in various competitions for music education majors and teaching.

Fig. 8. Detailed extraction of the measurement values.

IV. RESEARCH ON THE ALGORITHM FOR EVALUATING MUSIC TEACHING ACHIEVEMENT BASED ON MRO-BP NETWORKS

A. BP Neural Network

BP neural network [23], or back-propagation neural network, is a multilayer feed-forward network that is widely used in the fields of function approximation, pattern recognition, classification, data compression, and time series prediction, as shown in Fig. 9.

The core of the BP network lies in its weight adjustment method, using the error back propagation algorithm, which adjusts the network weights to optimise the model performance by calculating the output error and back propagating it to each implicit layer, the structure of which is shown in Fig. 10 and Fig. 11.

Fig. 9. BP neural network application.

Fig. 10. Structure of BP neural network.

The basic structure of BP network includes input, hidden and output layers, with full connection between layers and no

connection between the same layers. The learning process of BP network includes two phases of forward propagation of signals and back propagation of errors. 1) In forward propagation, the input signals are transmitted through the network and generate predicted values in the output layer. 2) In back propagation, according to the error between predicted values and the actual target values, the error is reduced by calculating the error gradient to adjust the weights and thresholds of the network to reduce the error.

Fig. 11. Gradient descent method.

B. MRO-BP Network Model

1) *MRO algorithm*: Mushroom Reproduction Optimization (MRO) [24] is a population intelligence optimisation algorithm inspired by the mechanisms of mushroom growth and reproduction in nature. The algorithm mimics mushrooms exploring the reproduction region through spore propagation and finding a more optimal reproduction region by refining the search space (Fig. 12). The MRO algorithm decides whether to perform a local search or a global search by calculating the average fitness value of each colony as well as the average fitness value of all the colonies to improve the efficiency of the search and to avoid precocious convergence to the local optimal solution.

Fig. 12. Iterative process of mushroom propagation.

The flow pseudo-code of the MRO algorithm is shown in Table I:

TABLE I. PSEUDO-CODE OF THE MRO ALGORITHM

Algorithm 1: Mushroom Reproduction Optimisation Algorithm
M parent mushroom populations were randomly generated; Calculate the initialised mushroom population fitness value, with the average fitness value, and update the optimal mushroom individuals;
While the iteration condition is satisfied
For i=1:M
If Ave+Tave/c<Tave
An artificial wind is used to disperse the population, select the optimal solution, and update the optimal solution;
End if
Randomly mutate the population, compute Ave, select the optimal solution, and update the optimal solution;
End for
Calculate Tave
End while

The specific implementation steps of the MRO algorithm (Fig. 13) are as follows:

Fig. 13. Flowchart of MRO algorithm.

- 1) Initialise the parameters of the MRO algorithm with the population. Initialise the maximum number of iterations T_{max} , the population size $npop$, and the population individual search range. Initialise the population position:

$$X_{ij} = rand() \times (ub - lb) + lb \quad (1)$$

where ub and lb are the upper and lower boundaries of the mushroom search space, respectively.

- 2) Artificial wind determination of conditions. Artificial wind was operated on mushroom individuals that met the conditions, otherwise mushroom individuals were randomly searched within the breeding area.

$$Avg(i) + \frac{T_{Avg}}{c} > T_{Avg} \quad (2)$$

Where, $Avg(i)$ is the average fitness value of the i^{th} mushroom individual, T_{Avg} denotes the global average fitness value, and c is the coefficient of determination.

- 3) Artificial wind mechanism. The simulated artificial wind operation on individual mushrooms makes the algorithm with global optimisation seeking capability.

$$Mov_j^{wind} = (X_i^* - X_k^*) \times \left(\frac{Avg(i)}{T_{avg}} \right)^m \times Rand(-\delta, \delta) \times rs + Rand(-r, r) \quad (3)$$

Where, Mov_j^{wind} denotes the distance moved by the j^{th} individual, X_i^* is the mushroom individual with the best fitness value in the i^{th} colony, and X_k^* denotes the path with the best fitness value in the k^{th} colony. $Avg(i)$ is the average fitness value value of the i^{th} colony, $Tavg$ is the average fitness value of all colonies. m is the customisation coefficient. δ is the direction coefficient. r is the step length control coefficient.

- 4) Breeding area search. Individual mushrooms search for better adapted locations within nearby breeding areas.

$$X_{ij} = X_i^{parent} + \overline{Rand(-r, r)} \quad (4)$$

Where X_{ij} is the location of the mushroom individual, i is the number of this individual in the population, and j is the mushroom dimension. r is the random search radius. X_i^{parent} denotes the parent mushroom.

- 5) Finding the optimal fitness value individual and updating the mushroom location.

$$[bestmushroom] = \min(f(X_i)) \quad (5)$$

- 6) Determine whether the maximum number of iterations is reached, if the maximum number of iterations is reached, end the loop and output the result, otherwise carry out the next iteration.

The MRO method has superior capabilities in both global search and local refinement, making it well-suited for addressing intricate optimization issues. It may preserve population variety while searching, enabling it to escape local optimum solutions and discover the global optimal solution or a superior solution, as seen in Fig. 14. The MRO method has been used to address challenges in several domains, such as engineering design optimization and data mining [25].

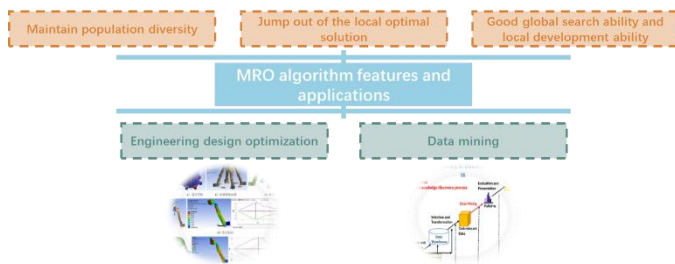

Fig. 14. MRO algorithm characteristics and applications.

2) *MRO-BP network*: In this paper, the BP network structure parameter weights and biases are used as decision variables, and the mean square error between the evaluated value and the true value is used as the fitness value of the MRO-BP model, the specific structure is shown in Fig. 15, and its pseudo-code is shown in Table II.

Fig. 15. MRO-BP network structure.

TABLE II. PSEUDO-CODE OF MRO-BP NETWORK ALGORITHM

Algorithm 2: MRO-BP network pseudo-code

The MRO algorithm parameters are set, the MRO optimisation decision variables are identified, and the BP weights and biases are encoded in real numbers;
 The RMSE is calculated as the fitness value to update the optimal mushroom individual, i.e., the current optimal BP network parameters;
 Whether the While iteration condition is satisfied
 Calculation of simulated artificial wind operations on individual mushrooms based on artificial wind determination conditions;
 Mutational manipulation of individual mushrooms using breeding area search;
 Update the network parameter individual information as well as the optimal network parameter individual;
 End while
 Output optimal network parameters;
 Constructing the MRO-BP network.

C. Improved Network Modelling Applications

From Fig. 16, the MRO algorithm is employed in this paper to enhance the accuracy of the BP network model in the assessment of teaching achievement in higher music education. Additionally, the measurement system of teaching achievement in higher music education is investigated. The precise sequence of actions in the procedure is as follows:

- Through the examination of the challenges associated with measuring and evaluating the outcomes of higher music education, we develop a framework for analyzing the teaching outcomes of higher music education based on three key dimensions: teaching content, practical skills, and social practice ability.
- Acquire the measurement data for evaluating the outcomes of higher music education. Utilize the distinctive indicators of the measurement system to input the data into the MRO-BP model. Train and optimize the model to get an assessment model for evaluating the outcomes of higher music education.
- Choose validation data to get improved measures of music education teaching outcomes, input them into the MRO-BP network-based model, and generate better scores for assessing music education teaching outcomes.

Fig. 16. MRO-BP network model application.

V. SIMULATION AND ANALYSIS

A. Experimental Data Acquisition

The cognitive assessment of music learners was conducted by a comprehensive questionnaire, which took into consideration several factors such as the teaching method, the proficiency of instructors, the knowledge requirements of students, and the practicality and social significance of the course. The survey findings were used to extract the higher music education teaching outcome measurement data. This data was then split into three sets: the MRO-BP model training set, validation set, and test set. The particular division ratio, number, and purpose of each set are provided in Table III.

B. Experimental Environmental Setup

The specific settings of hardware environment, software environment and other experimental environments used for algorithm verification in this paper are shown in Table IV.

TABLE III. EXPERIMENTAL DATA SETTINGS

Serial number	Data set	Proportions	Quantities	Goal
1	test set	15%	552	Testing the evaluation performance of the MRO-BP model
2	validation set	15%	553	Calculating the fitness value of the MRO algorithm for optimising BP networks
3	training set	70 per cent	2580	Training the optimal BP network model, i.e. MRO-BP model

TABLE IV. EXPERIMENTAL ENVIRONMENTAL SETTINGS

Name of the environment	Parameterisation
software	AMD Ryzen 9 5900HX with Radeon Graphics 3.30 GHz
operating system	Windows 10
programming software	Python 3.8
visualisation software	Matlab2021a

C. Contrast Algorithm Parameter Settings

Methods for measuring and assessing teaching outcomes in higher music education employing comparison algorithms such as BP, TLBO-BP, GWO-BP, MPA-BP, AVOA-BP, and MRO-BP. The BP model utilizes the gradient descent method to calculate error feedback. The number of nodes in the hidden

layer is determined based on the analysis in section 5.4. The TLBO [24], GWO [25], MPA [26], AVOA [27], and MRO algorithms have a maximum iteration limit of 1000, and the number of populations is determined based on the experiments in Section V (D). The specific parameter settings for the comparison algorithms can be found in Table V.

TABLE V. COMPARISON OF ALGORITHM PARAMETER SETTINGS

Serial number	Arithmetic	Parameterisation
1	BP	The activation function is a radial basis function
2	TLBO-BP	TF=round[(1+rand)]
3	GWO-BP	a decreases linearly from 2 to 0
4	MPA-BP	P = 0.5, R is a uniformly distributed random vector, FADs = 0.2, U = 0 or 1
5	AVOA-BP	L1 = 0.8, L2 = 0.2, w = 2.5, P1 = 0.6, P2 = 0.4, P3 = 0.3
6	MRO-BP	Fmin=0.07, Fmax=0.75, τ=4.125, a0=6.25, a1=100, a2=0.0005

D. Analysis of Results

1) *Parameter setting analysis*: To ensure that the parameters are in accordance with the BP and optimization algorithms, this paper evaluates the accuracy and time consumption of the assessment models of teaching outcomes in

higher music education using varying numbers of hidden layer nodes and populations. The results are illustrated in Fig. 17, Fig. 18, Fig. 19 and Fig. 20. According to the Fig. 17. From the data, it is evident that as the number of hidden layer nodes in the BP algorithm increases, the accuracy of the measurement and

assessment of music education teaching outcomes in each model initially decreases and then stabilizes. Additionally, the time required for the assessment model also increases. As the population size increases, the precision of the algorithm used to measure and assess the outcomes of higher music education teaching improves. However, after reaching a population size of 75, the accuracy remains stable and does not decrease. Additionally, the time required for each model to process the data increases as the population size increases. The paper's detailed study reveals that the number of hidden layer nodes in the BP algorithm is 90, and each optimization technique has a population size of 75.

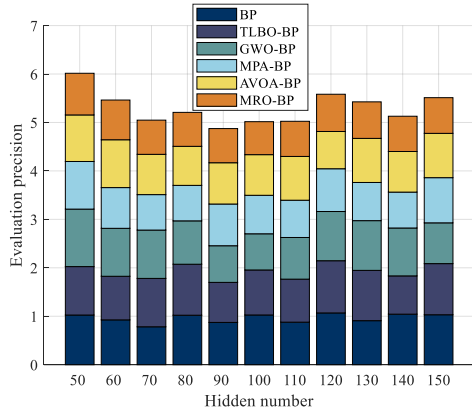

Fig. 17. Accuracy analysis of the evaluation model based on different number of hidden layer nodes.

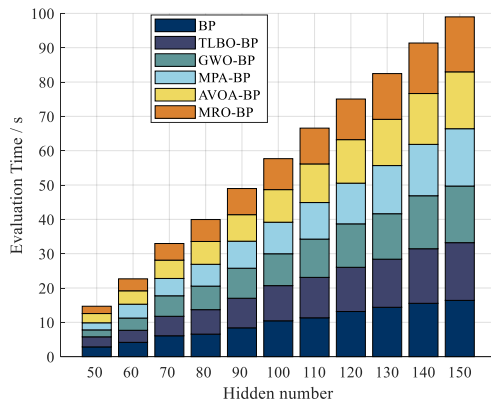

Fig. 18. Time-consuming analysis of the evaluation model based on different number of hidden layer nodes.

Fig. 19. Accuracy analysis of the assessment model based on different population sizes.

Fig. 20. Time-consuming analysis of assessment models based on different population sizes.

2) *Evaluation performance analysis:* To analyze and compare the effectiveness of the measurement and evaluation methods for teaching outcomes in higher music education proposed in this paper, we utilized several techniques: BP, TLBO-BP, GWO-BP, MPA-BP, AVOA-BP, and MRO-BP. The comparative analysis results are presented in Fig. 21 and Table VI.

According to the figure. Based on the data, it is evident that the MRO-BP network has the highest convergence accuracy for measuring and assessing teaching outcomes in higher music education. It is followed by AVOA-BP, MPA-BP, GWO-BP, and TLBO-BP. Additionally, the speed of convergence for each optimization network in measuring and assessing teaching outcomes in higher music education is approximately equal.

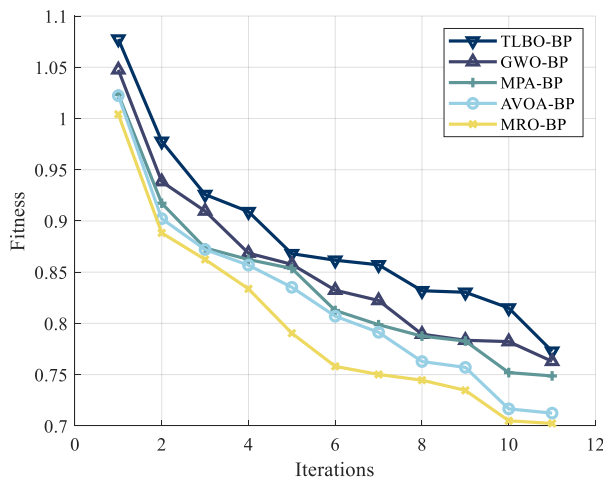

Fig. 21. Optimisation convergence curves of different optimisation algorithms.

Table VI shows that the MRO-BP network-based measurement and assessment of teaching outcomes in higher music education has the smallest RMSE value, followed by GWO-BP, MPA-BP, AVOA-BP, TLBO-BP, and BP. In terms of MAPE, the MRO-BP network-based measurement and assessment of teaching outcomes in higher music education has the smallest MAPE value of 0.7314, followed by AVOA-BP, MPA-BP, GWO-BP, TLBO-BP, and BP. The MRO-BP model also has the smallest MAE value of 0.49, followed by AVOA-BP, GWO-BP, MPA-BP, BP, and TLBO-BP. In terms of time-consuming, the MRO-BP model takes 7.744, followed by AVOA-BP, MPA-BP, GWO-BP, TLBO-BP, and BP. In summary, the MRO-BP model is the most accurate and requires the least amount of time.

TABLE VI. RESULTS OF PERFORMANCE COMPARISON OF DIFFERENT ASSESSMENT MODELS

arithmetic	RMSE	MAPE	MAE	Time/s
BP	0.892	0.9342	0.78	8.822
TLBO-BP	0.829	0.8561	0.91	8.729
GWO-BP	0.728	0.8373	0.63	8.397
MPA-BP	0.731	0.7783	0.71	7.758
AVOA-BP	0.737	0.7761	0.61	7.647
MRO-BP	0.701	0.7314	0.49	7.744

VI. CONCLUSION

As music education teaching data continues to grow, the analysis of music behavior data and the assessment of music teaching outcomes have emerged as key areas of focus in the field of data-driven music research. This study addresses the issue of measuring and evaluating the teaching outcomes of data-driven algorithmic applications. It provides a technique for measuring and evaluating the teaching outcomes of higher music education using a combination of the MRO algorithm and BP network, known as the MRO-BP network model. This paper examines the issue of measuring and evaluating the teaching outcomes of music education. It focuses on designing the main technology and identifying the measurement indicators for teaching outcomes from three perspectives: teaching content,

practical skills, and social practice ability. The paper constructs a measurement system for music teaching outcomes by combining the MRO algorithm and BP network. Additionally, it proposes an algorithm for assessing the teaching outcomes of music based on the MRO-BP network. The method proposed in this paper demonstrates superior results in terms of RMSE, MAPE, MAE, and time consumption when analyzing teaching outcome data in higher education. It effectively addresses the challenge of measuring and assessing teaching outcomes. The MRO-BP network model outperforms other models and is applicable to analyzing teaching outcomes in higher education, specifically in music education. However, its generalization and stability should be further validated using other datasets. Subsequently, it is necessary to use the MRO-BP network model for addressing further difficulties and enhancing the overall performance of the MRO-BP network.

Employing Data-Driven NOA-LSSVM Algorithm for Indoor Spatial Environment Design

A Case Study of Physical Bookstores

Di Wang, Hui Ma*, Tingting Lv

College of Art and Design, Jilin Jianzhu University, Changchun 130118, Jilin, China

Abstract—This study aims to enhance the precision and efficiency of indoor spatial design for college physical bookstores in the context of the new media environment. To achieve this, a novel intelligent analysis model was developed by integrating the Navigator Optimization Algorithm (NOA) with the Least Squares Support Vector Machine (LSSVM). The research analyzes the relationship between the new media environment and bookstore design, identifies key design principles, and establishes performance metrics. The proposed NOA-LSSVM model optimizes design parameters by utilizing a hybrid convergence-divergence search mechanism, achieving improved accuracy and computational efficiency. A case study of Jilin Jianzhu University's bookstore was conducted to evaluate the model's performance. The NOA-LSSVM model was compared with three other optimization algorithms: the Flower Pollination Algorithm (FPA), Whale Optimization Algorithm (WOA), and Sine Cosine Algorithm (SCA). Results showed that the NOA-LSSVM model achieved superior accuracy, with a Mean Absolute Percentage Error (MAPE) of 2.9, significantly lower than FPA (4.6), WOA (3.8), and SCA (4.2). Additionally, the model exhibited faster convergence and enhanced design efficiency, optimizing the bookstore's functional zones and spatial layout to balance dynamic and quiet areas effectively. In conclusion, the NOA-LSSVM model demonstrates a robust capability to optimize indoor spatial design in the new media environment, outperforming traditional methods in accuracy and practicality. This study provides valuable insights for integrating intelligent algorithms into spatial design processes, with the potential for broader applications in other commercial or educational spaces. Future research should focus on extending the model's generalizability and incorporating advanced media technologies for enhanced user experiences.

Keywords—New media environments; data-driven algorithms; indoor spatial environment design; mariner optimization method

I. INTRODUCTION

In order to enhance students' learning materials and services, the growth of college physical bookshops is being actively supported to strengthen their impact in the area of education [1]. The proliferation and use of new media, facilitated by the advancement of Internet technology and the exponential growth of Internet users, has presented unparalleled prospects and difficulties across all sectors of society. Consequently, physical bookshops are also confronted with the need for modernization and adaptation. To adapt to the growing market need, physical bookshops are integrating new media technologies to expedite their transition and bolster their competitiveness [2]. Conducting research on the interior space

design of college physical bookstores in the new media environment may stimulate innovation in bookstore space design and enhance the quality of services. Additionally, it can serve as a valuable resource for the growth of campus bookstore markets and industry transformation [3].

The study on the interior space design of college physical bookshops in the new media environment is presently in its first phase. It primarily focuses on two aspects: the use of new media technology in the design of physical shops, and the analysis of how new media technology is applied [4]. Wang and Wang [5] examine the successful collaboration between college physical bookstores and publishers in order to address the high cost of textbooks. Sari [6] introduces new design concepts to modify the layout of college physical bookstores. Bae [7] investigates the current state of development of college physical bookstores and proposes effective strategies to renovate them. Soureshjani et al. [8] suggests several reform measures to transform bookstores into vibrant spaces that promote a new culture of wisdom and reading. Al-Ansari et al. [9] thoroughly discusses the appeal of college campus bookstores and presents a new development strategy that is suitable for the digital era. Nyboer [10] analyzes the challenges from various perspectives such as cultural experience, construction mode, and business model, and provides a range of practical solutions. The integration of intelligent algorithms and the interior space design of college physical bookshops in the new media environment has become an essential approach for the future development of intelligent and digital space design. Intelligent algorithms may be categorized as supervised learning, unsupervised learning, semi-supervised learning, and other ways. The utilization of data-driven intelligent algorithms in analyzing the application of new media technology in indoor space design has become increasingly prevalent. This method plays a crucial role in researching the design of college physical bookstores in the new media environment. It enhances the efficiency of indoor space design and expedites the design process [11]. Despite the ongoing improvement in educational conditions and the increasing importance of campus physical bookstores, there are still several issues in the process of integrating intelligent technology into the interior space design of college bookstores. These include: 1) a lack of research on the application of new media technology in the interior space design of college bookstores; 2) ineffective utilization of data generated during the design process of college bookstores; and 3) the immaturity of intelligent technology used in college bookstore interior space design.

*Corresponding Author

This paper strives to address the intellectual requirements of college students in physical bookstores by integrating new media technology and artificial intelligence. It proposes an application analysis model for the interior space design of college physical bookstores in the new media environment, using an improved data-driven algorithm. The study investigates the correlation between the new media environment and the layout of indoor spaces in bookstores. It takes advantage of various research methods such as literature research, survey research, interdisciplinary research, and inductive comparison. The study analyzes the design process of indoor spaces in college physical bookstores and develops an intelligent application analysis scheme for such spaces. This scheme combines the navigator optimization algorithm with the LSSVM model. Additionally, the study proposes a new media model based on the NOA-LSSVM model. A novel media-based NOA-LSSVM model is offered as an analytical tool for the interior space design of college physical bookshops, using the Voyager optimization algorithm and the LSSVM model. Using the physical bookshop of Jilin Jianzhu University as a case study, the effectiveness of the proposed NOA-LSSVM model is examined and evaluated by comparing it with other application analysis methodologies.

This paper is structured as follows: Section II explores the relationship between the new media environment and the physical layout of college bookstores, providing a detailed analysis of the design process and identifying key principles and metrics for indoor spatial design. Section III introduces the NOA-LSSVM model, detailing the principles of the Navigator Optimization Algorithm (NOA) and Least Squares Support Vector Machine (LSSVM), and describes how these are integrated into a data-driven intelligent analysis framework. Section IV presents a case study of Jilin Jianzhu University's bookstore, demonstrating the model's application, design outcomes, and a comparative evaluation of its performance against other optimization algorithms. Finally, Section V concludes with key findings, highlighting the NOA-LSSVM model's superior accuracy and efficiency in optimizing design processes while outlining potential areas for further research and practical implementation.

II. DESIGN INTERIOR SPACE OF COLLEGE PHYSICAL BOOKSTORES

A. The Connection between the Contemporary Media Landscape and the Physical Layout of Bookstores

The emergence of new media complements the growth of physical bookshops. Its implementation impacts individuals' perception of the reading experience, enhances the interior spatial setting of bookstores, and maximizes the creation of a favorable reading ambiance [12]. The indoor space design of college bookstores has undergone significant changes in response to the new media environment. These changes primarily include: 1) improving the overall spatial experience; 2) diversifying the nature of the space; and 3) enhancing the spatial environment, as depicted in Fig. 1.

Fig. 1. Changes in the new media environment on the interior space design of college bookstores.

B. Analysis of the Interior Space Design Process of College Physical Bookstores

1) *The key aspects of designing the interior space of college physical bookshops:* The need for college physical bookshops among college students has seen significant changes with the progress of time. The interior space design of these bookstores has evolved to focus on utility, industry diversification, experience elements, and artistic aspects [13], as shown in Fig. 2.

Fig. 2. Trends in the design of physical bookstores in universities.

2) *Analysis of the design process:* The interior space design of college physical bookstores follows specific development direction and design principles, namely the humane principle, functional principle, experiential principle, and epochal principle (as depicted in Fig. 4). This design process includes various steps such as space planning and layout, illumination design, color matching and style, display and exhibition design, furniture and decorations selection, air-conditioning and ventilation system, sound and noise control, online and offline combination, out-of-store time and budget control, detail design, and others [14] (as highlighted in Fig. 3).

Fig. 3. Design process of physical bookstores in universities.

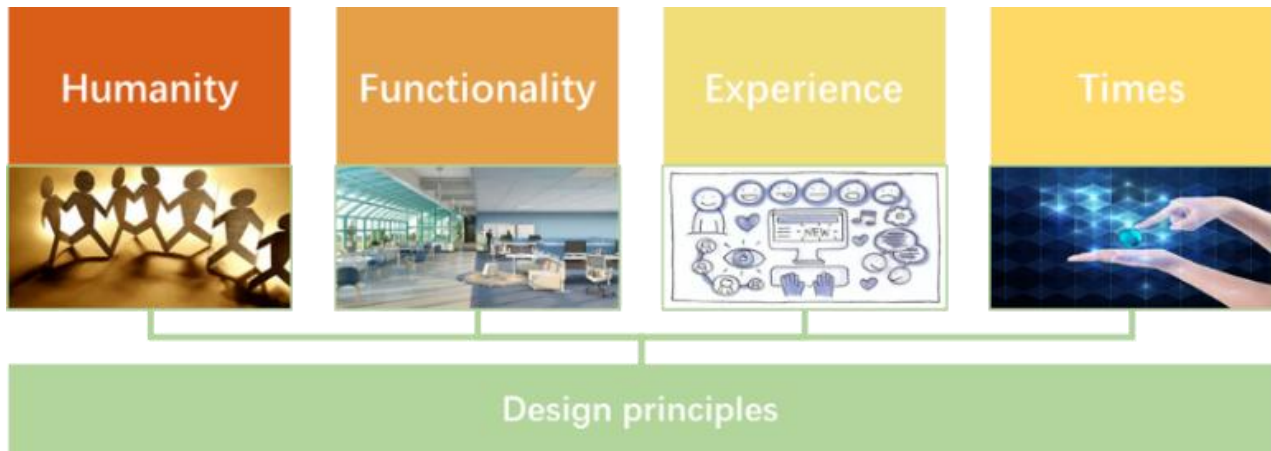

Fig. 4. Design principles.

3) *Develop a process to obtain metrics for analyzing application design:* This paper tests the application analysis indexes for indoor space design of college physical bookstores in the new media environment. The analysis focuses on three aspects: design elements S, functional space K, and design research Y, as illustrated in Fig. 5.

Spatial design application analysis metrics		
Design element S	Functional space K	Design study Y
<ul style="list-style-type: none"> <input type="checkbox"/> Space size S1 <input type="checkbox"/> Space furnishings S2 <input type="checkbox"/> Material selection S3 <input type="checkbox"/> Color selection S4 <input type="checkbox"/> Lighting design S5 <input type="checkbox"/> Plant configuration S6 	<ul style="list-style-type: none"> <input type="checkbox"/> Multi-purpose space K1 <input type="checkbox"/> Virtual space K2 	<ul style="list-style-type: none"> <input type="checkbox"/> Personalized service Y1 <input type="checkbox"/> Interactive experience Y2 <input type="checkbox"/> Online and offline integration Y3

C. Program for Designing the Interior Space of Physical Bookstores in Higher Education Institutions

Focusing on the problem of application analysis of interior space design of college physical bookstores in media environment, this paper proposes a method of application analysis of interior space design of college physical bookstores based on data-driven algorithm, and the specific design scheme is shown in Fig. 8. The scheme analyzes the process of interior space design of college physical bookstores in media environment, extracts relevant application analysis indexes, collects application analysis data, standardizes and annotates the dataset, combines Voyager optimization algorithm [15] and LSSVM model [16], constructs the application analysis model of interior space design of college physical bookstores in media environment, and carries out the performance validation and analysis of the model by using examples.

According to the design scheme, the research on the application analysis method for the interior space design of college physical bookstores in the media environment includes key technologies such as the extraction and construction of application analysis indexes, data collection and pre-processing, design model construction and optimisation, and case validation and analysis, as shown in Fig. 9.

Fig. 9. Key techniques for applying analysis to interior space design of physical bookstores in universities.

III. INTELLIGENT ANALYSIS ALGORITHM FOR INTERIOR SPACE DESIGN

A. NOA-LSSVM Model

1) *Voyager optimisation algorithm*: Navigator optimization algorithm (NOA) [15] is a new type of meta-heuristic intelligent algorithm inspired by the exploratory behaviour of navigators. The NOA algorithm alternates between "searching" and "exploiting". The NOA algorithm alternates between "searching" and "exploiting", when the search period is even, the navigators search for the solution by divergence; when the search period is odd, the navigators search for the solution by convergence, and find the optimal solution by alternating iterations.

The navigator position is a candidate solution and the expression is:

$$P = \begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1d} \\ P_{21} & P_{22} & \cdots & P_{2d} \\ \vdots & \vdots & \ddots & \vdots \\ P_{n1} & P_{n2} & \cdots & P_{nd} \end{bmatrix} \quad (1)$$

where n is the number of navigators and d is the number of decision variables.

The navigator adaptation values are expressed as follows:

$$F = [F_1, F_2, \dots, F_n]^T \quad (2)$$

a) *Convergence mode*: The position update formula for the convergent search performed by each navigator during the convergence cycle is as follows:

$$P_{ij}^{k+1} = P_{gj}^k + D_{ij} \cdot e^{bt} \cdot \cos(2\pi t) \quad (3)$$

$$D_{ij} = |P_{gj} - P_{ij}| \quad (4)$$

Where, k is the number of iterations; D_{ij} is the distance between the position of mariner i and the current optimal position in the j^{th} dimension; b is the shape coefficient of the solenoid, which takes the value of 1; and t is a random number. Logarithmic spiral is shown in Fig. 10.

Fig. 10. Logarithmic spiral.

b) *Divergent approach*: The NOA algorithm uses the Levy flight strategy [17] as a model for dispersion, and the specific dispersion model is as follows:

$$P_i^{k+1} = \begin{cases} P_i^k + rL(d)(P_g^k - P_i^k) & k < N_{iter}/2 \\ P_i^k + r(L(d) \cdot P_i^k - P_i^k) & k \geq N_{iter}/2 \end{cases} \quad (5)$$

Where r is a constant, set to 0.7; $L(d)$ is the Levy flight step (Levy flight trajectory in 3D space is shown in Fig. 11); N_{iter} is the maximum number of iterations.

Fig. 11. Levy flight path in 3D space.

c) *Search cycle*: The search cycle is an important tool used by the NOA algorithm to alternate between "searching" and "utilising". If the number of search cycles is set too large, the number of iterations in each search cycle will be too small, and the navigators will not be able to fully diverge or converge; if it is set too small and similar to the idea of traditional intelligent algorithms of searching for excellence, the navigators will not be able to effectively "use" the "search". If the setting is too small, it is similar to the idea of traditional intelligent algorithms, and the "search" of navigators cannot be effectively "utilised". After testing, when the number of search cycles to take the maximum number of iterations $1/30 \sim 1/10$, you can achieve better results, the number of search cycles in this paper to take $1/20$ of the number of iterations.

d) *Transboundary processing techniques*: In order to avoid the navigator to enter outside the boundary, the NOA algorithm adopts an out-of-bounds processing technique. When the navigator crosses the boundary and $z < p$, its boundary crossing processing technique is as follows:

$$P_{ij} = \begin{cases} P_{j\max} & P_{ij} \geq P_{j\max} \\ P_{j\min} & P_{ij} < P_{j\min} \end{cases} \quad (6)$$

where P_{ij} is the position of the j th dimension of the i th navigator; $P_{j\max}$ and $P_{j\min}$ are the upper and lower bounds of

the j th dimension of the navigator, respectively; p is a constant set to 0.5; and z is a random number.

When a navigator crosses the border and $z \geq p$, his or her crossing is handled with the following technique:

$$P_{ij} = \begin{cases} P_{j\max} - Ce_1(P_{j\max} - P_{j\min}) & P_{ij} \geq P_{j\max} \\ P_{j\min} + Ce_1(P_{j\max} - P_{j\min}) & P_{ij} < P_{j\min} \end{cases} \quad (7)$$

Where C is a constant with a value of 0.01 and e_1 is a random number.

According to the optimisation strategy of the NOA algorithm, the pseudo-code of the NOA algorithm is shown in Table I with the following steps:

- Step 1: Initialise the number of navigators, dimensions and the number of search cycles to generate the initial position of the navigator;
- Step 2: Calculate the initial navigator fitness value and update the optimal fitness value;
- Step 3: At each odd search cycle, update the mariner position using convergence; at each even cycle, update the mariner position using divergence;
- Step 4: During each iteration, compare the navigator fitness value with the global optimum and update the global optimum;
- Step 5: Interpret whether the maximum number of iterations is reached, if so output the optimal solution, otherwise jump to step 3.

TABLE I. PSEUDO-CODE OF THE NOA ALGORITHM

Algorithm 1: NOA algorithm	
1	Initialize navigator number, dimension, search periods;
2	Generate navigator population;
3	Calculate fitness and output best fitness;
4	For t=1:Max iter
5	If t== odd search periods
6	Use convergence to update the navigator's position,
7	Else
8	Use divergence to update the navigator position;
9	End
10	Update navigator's position;
11	Bound position using upper and lower limits;
12	Update best navigator position;
13	End
14	Output best solution.

2) *LSSVM algorithm*: Least Squares Support Vector Machine (LSSVM) [18] A variant of Support Vector Machine

(SVM) [19]. Compared with the traditional SVM, LSSVM simplifies the computational process by solving the model parameters through the least squares method, which transforms the optimisation problem into the solution of a system of linear equations. LSSVM is not only suitable for classification problems, but also widely used in regression problems. It has high computational efficiency and good generalisation ability, which is especially suitable for dealing with large-scale datasets.

a) *LSSVM basic principles*: The core idea of LSSVM is to use the least squares method to solve the parameters of the SVM model by eliminating the Lagrange multipliers in the form of minimising the sum of squares of the errors and transforming the original convex quadratic programming problem into a system of linear equations. This system of linear equations can be solved by numerical methods (e.g., Cholesky decomposition, iterative methods, etc.) to obtain the parameters of the model. The output of the LSSVM model is obtained by a linear combination of the kernel functions in a high-dimensional space, as shown in Fig. 12.

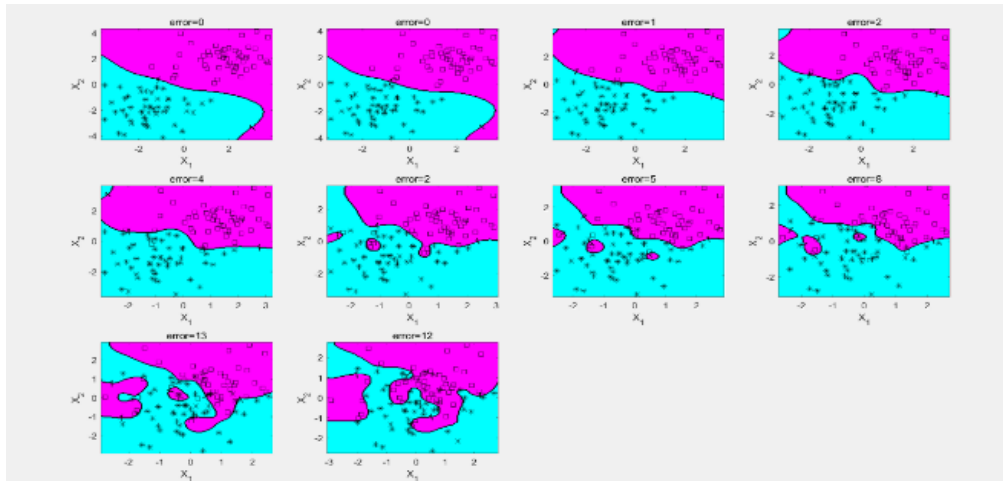

Fig. 12. Structure of LSSVM algorithm.

b) *Features of LSSVM*: The idea of LSSVM is characterized by the following features: a) great computing efficiency; b) resilience to noisy data; c) simplicity in finding parameter solutions; d) application to nonlinear problems; and e) absence of sparsity [20], as seen in Fig. 13.

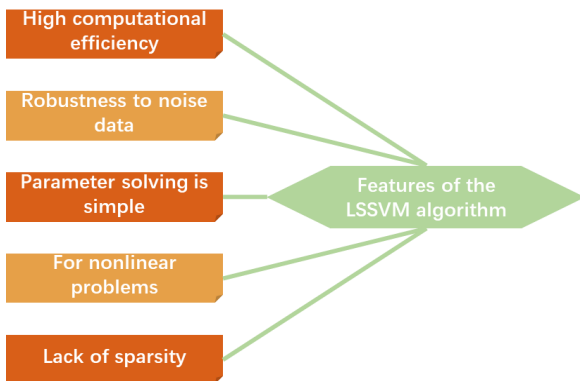

Fig. 13. Characteristics of the LSSVM algorithm.

c) *Utilization of least squares support vector machines (LSSVM)*: The Least Squares Support Vector Machine (LSSVM) is used in several domains (Fig. 14), such as financial market analysis, medical diagnosis, bioinformatics, image analysis, industrial control, and machine learning. Due to its high computing capacity and strong generalization abilities, it has become a very effective tool for tackling real-world issues [21].

Fig. 14. Application areas of LSSVM algorithm.

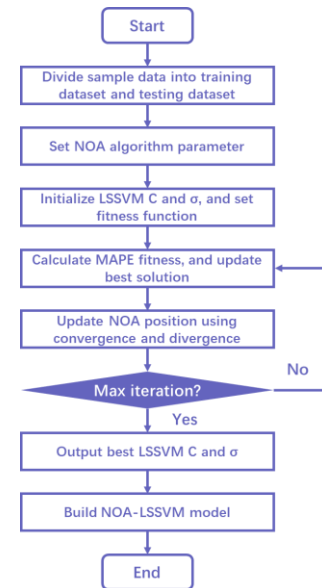

Fig. 15. Flowchart of NOA-LSSVM algorithm application analysis.

3) *NOA-LSSVM model*: This work employs the NOA algorithm to enhance the accuracy of application analysis in the LSSVM model. The algorithm optimizes the parameters of the LSSVM, namely the penalty coefficient and kernel bandwidth, using the MAPE as the fitness value function. The NOA algorithm is employed to search for optimization through both convergence and divergence modes. The specific flow chart of the application analysis using the NOA-LSSVM model is depicted in Fig. 15.

B. Application of NOA-LSSVM Model in Intelligent Analysis

Combined with NOA-LSSVM model, this paper proposes an intelligent analysis method of college physical bookstore indoor space design based on NOA-LSSVM model, and the specific application analysis diagram is presented in Fig. 16. Firstly, examine the relationship between the new media

environment and the indoor space of bookstores. Analyze the process of designing the indoor space of physical bookstores in colleges and develop a design scheme for the indoor space of physical bookstores in colleges. Extract the application analysis of the design of the indoor space of physical bookstores in colleges within the media environment. Secondly, collect the index data for the design of the indoor space of physical bookstores in colleges based on the established set of indices. Preprocess the input data, annotate it, and output the scores for the application analysis. Utilize the NOA-LSSVM algorithm to construct an intelligent analysis model for the interior space design of physical bookstores in colleges. Finally, use an example to verify the feasibility of the design scheme for the interior space of physical bookstores in colleges, as well as the efficiency of the intelligent analysis algorithm for interior space design based on the NOA-LSSVM model.

Fig. 16. Flow chart of intelligent analysis of interior space design for college physical bookstore based on NOA-LSSVM model.

IV. EXAMPLE ANALYSES

A. Presentation of the Case

In order to verify the feasibility of the interior space design scheme of college physical bookstore and the effectiveness and feasibility of the intelligent analysis algorithm of college physical bookstore interior space design based on NOA-LSSVM model, this paper takes the indoor space design of physical bookstore in the Jilin Jianzhu University as an example to be analysed.

The current layout is shooting to investigate the impact of the new media environment on college physical bookstore spaces. It focuses on the bookstore space design of Jilin Jianzhu University. The goal is to showcase the changes brought about by the integration of new media into various aspects of life, as well as the higher expectations of college teachers and students for campus bookstores. Following the principles of the era, experience, functionality, and humanization, the design aims to create a new type of college physical bookstore that combines book purchasing, cultural exchange, leisure, immersive reading, and experiential

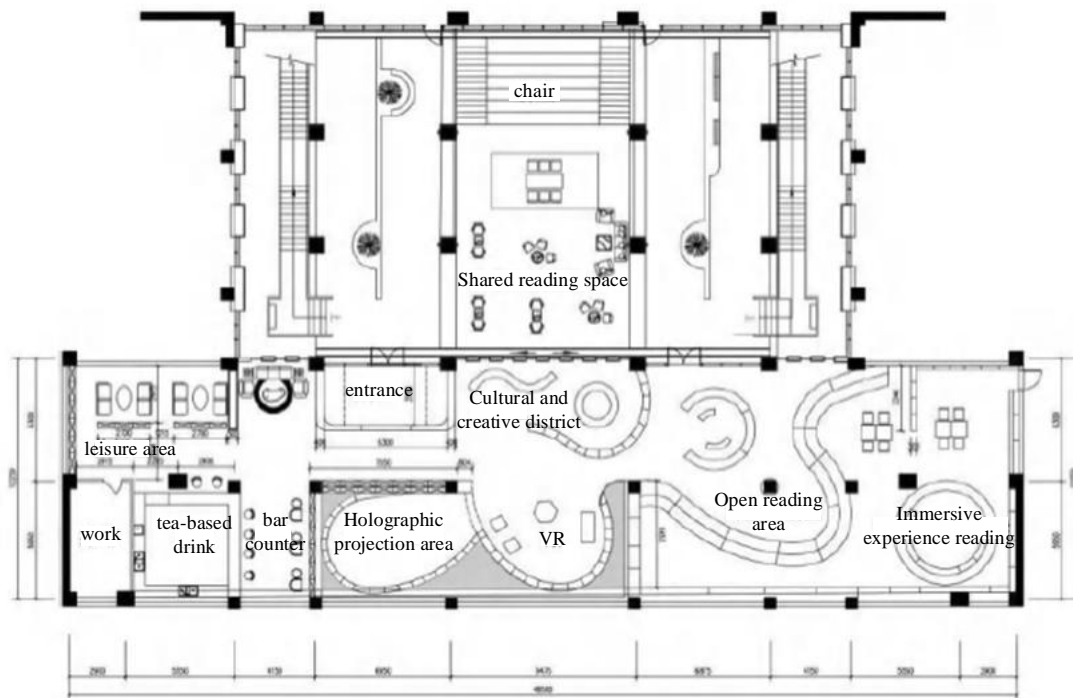

services. The bookstore is an innovative university physical shop that offers book purchasing, cultural interchange, leisure activities, immersive reading experiences, and experiential services.

B. Algorithm Configuration

This work used the Flower Pollination Algorithm (FPA) [22], Whale Optimization Algorithm (WOA) [23], and Sine Cosine Algorithm (SCA) [24] as comparison algorithms to optimize the parameters of the LSSVM model. The optimization technique was iterated 500 times, with a population size of 50. The NOA algorithm underwent 25 search cycles, while the other parameters of the algorithm were established according to references [22-24].

C. Design Outcomes

According to the indoor space design method of college physical bookstore under the new media environment designed in this paper, this paper takes the physical bookstore of Jilin Jianzhu University as an example, and designs and analyses the indoor space plan layout and functional partition diagram, specifically as shown in Fig. 17.

(a) The arrangement and structure of an interior design plan.

(b) Interior design functional zoning plan.

(c) A top-down perspective

Fig. 17. Interior design.

The bookstore, depicted in Fig. 17, has a T-shaped layout that utilizes flexible curves and straight lines to separate the space. Curved bookshelves are strategically placed to direct the flow of the interior. The bookstore is divided into eleven functional zones, taking into account the balance between movement and stillness. The dynamic zone includes the

recreation area, shared reading area, tea area, and intelligent service area, while the other zones are designated as relatively quiet areas.

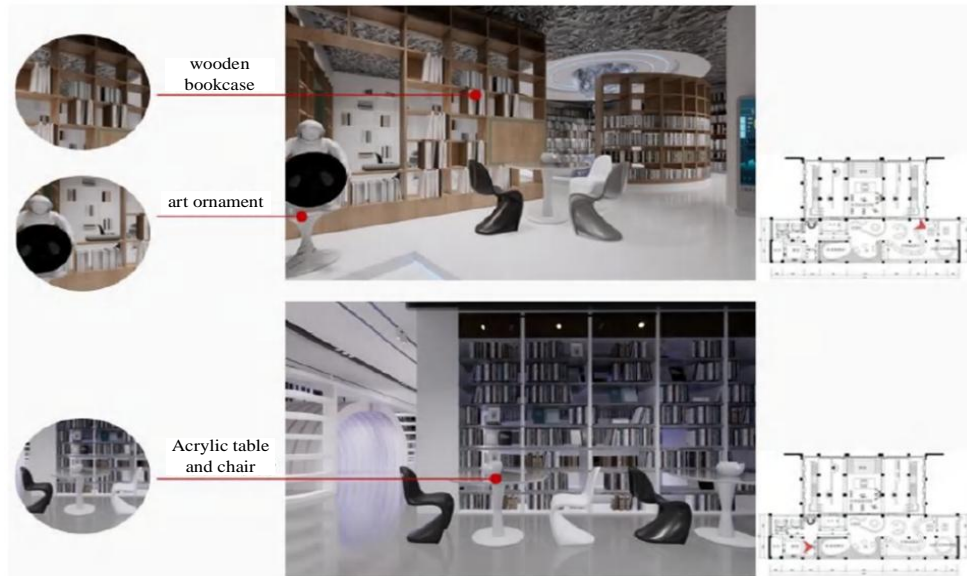

The physical bookstore's interior design is examined from the perspectives of reading spaces, shared reading spaces, open

reading spaces, virtual reality experiences, 3D holographic projection spaces, immersive reading spaces, foyer spaces, tea and beverage spaces, leisure spaces, cultural and creative spaces, and intelligent service spaces, as shown in Fig. 18.

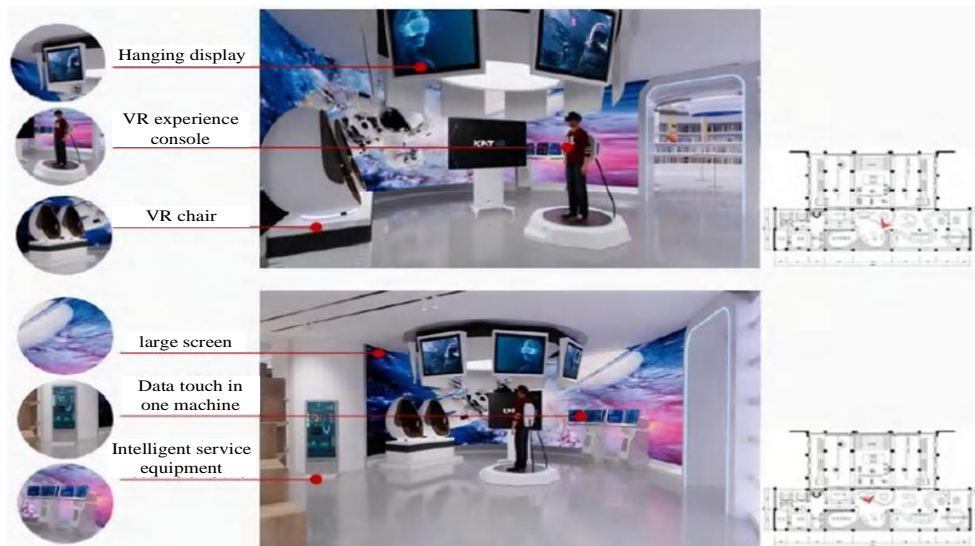

D. Evaluation of Algorithm Performance Outcomes

To evaluate the efficiency and superiority of the intelligent analysis algorithm for interior space design of college physical bookshops using the NOA-LSSVM model, this study randomly picks five test sets and presents the test results in Table II and Fig. 19.

The outcomes of optimizing the LSSVM parameters of FPA, WOA, SCA, and NOA algorithms are shown in Table II, while the optimization curves of FPA, WOA, SCA, and NOA algorithms are displayed in Fig. 19. The figure demonstrates that the intelligent analysis algorithm for the interior space design of a college physical bookstore, based on the NOA-LSSVM model, exhibits faster convergence speed and superior convergence accuracy. The Mean Absolute Percentage Error (MAPE) achieved is approximately 2.9, which is lower than the MAPE values obtained by other algorithms such as FPA, WOA, and SCA.

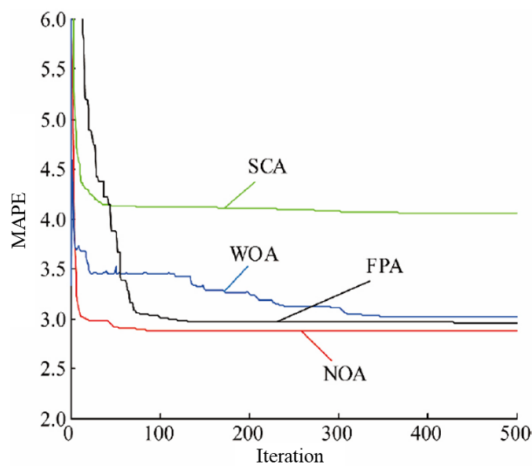

Fig. 19. Optimisation curves for different algorithms.

V. CONCLUSION

In this paper, we suggest a method for designing the interior space of a college physical bookstore that is based on the NOA-LSSVM model. This method involves analyzing the relationship between the new media environment and bookstore design, designing the interior space design scheme for the college physical bookstore under the new media environment, extracting the intelligent analysis indexes of the interior space design, combining the NOA algorithm to find the optimal parameters of the LSSVM, and establishing the NOA-LSSVM-based college physical bookstore indoor space design intelligent analysis model. The physical bookstore at Jilin Jianzhu University is used as a case study to analyze and compare other intelligent analysis models for interior space design. The results indicate that the NOA-LSSVM model has smaller MAPE results, higher analysis accuracy, and can

enhance the efficiency of interior space design for college physical bookstores in the new media environment.

The study demonstrates the effectiveness of the NOA-LSSVM model in optimizing indoor spatial design for college bookstores under the new media environment. However, it has some limitations. First, the model's generalizability remains uncertain as its application is only validated within a single case study, lacking tests in diverse bookstore types or cultural settings. Second, the research does not deeply explore user behavior and preferences, which are critical in designing user-centered spaces. Third, while emphasizing the importance of new media, the study provides limited details on integrating specific technologies such as AR/VR or social media into the design process. Future research should focus on extending the model to broader scenarios, integrating multi-source data like user behavior and new media interaction data for more comprehensive analyses, and exploring in-depth applications of advanced technologies to create interactive and immersive environments.

Enhancing Customer Churn Prediction Across Industries: A Comparative Study of Ensemble Stacking and Traditional Classifiers

Nurul Nadzirah bt Adnan, Mohd Khalid Awang

Faculty of Informatics and Computing, Universiti Sultan Zainal Abidin, 22000 Tembil, Terengganu, Malaysia

Abstract—Predicting customer churn is essential in sectors such as banking, telecommunications, and retail, where retaining existing customers is more cost-effective than acquiring new ones. This paper proposes an enhanced ensemble stacking methodology to improve the prediction performance of ensemble methods. Classic ensemble classifiers and individual models are undergoing enhancements to enhance their sector-wide generalisation. The proposed ensemble stacking method is compared with well-known ensemble classifiers, including Random Forest, Gradient Boosting Machines (GBMs), AdaBoost, and CatBoost, alongside single classifiers such as Logistic Regression (LR), Decision Trees (DT), Naive Bayes (NB), Support Vector Machines (SVM), and Multi-Layer Perceptron. Performance evaluation employs accuracy, precision, recall, and AUC-ROC metrics, utilising datasets from telecom, retail, and banking sectors. This study highlights the importance of investigating ensemble stacking within these three business entities, given that each sector presents distinct challenges and data patterns related to customer churn prediction. According to the results, when compared to other ensemble approaches and single classifiers, the ensemble stacking method achieves better generality and accuracy. The stacking method uses a meta-learner in conjunction with numerous base classifiers to improve model performance and make it adaptable to new domains. This study proves that the ensemble stacking method can accurately anticipate customer turnover and can be used in different industries. It gives firms a great way to keep their clients.

Keywords—Customer churn; single classifier; ensemble classifier; stacking; accuracy

I. INTRODUCTION

Churning customers, which happens when someone stops using a product or service, is a big problem for businesses. This is especially true in fields that rely on steady streams of income. Business that depends on keeping people for a long time, like retail, banking, and telecommunications, are hit hard by churn.

The telecommunications business has one of the highest turnover rates because of fierce competition, quickly changing technologies, and a wide range of choices for customers. When it comes to telecommunications, service quality, pricing strategies, customer happiness, contract terms, network issues, and competitive offers are the main things that affect turnover. To keep customers, telecommunications companies need to accurately predict customer turnover, since getting new users is much more expensive. Telecommunications firms must effectively forecast customer turnover to retain clientele, as the acquisition of new subscribers is significantly more costly as Nurulhuda & Ling Sook Lew et al, 2021 [1] employed.

Comprehending the intricacies of client behavior, especially regarding service disruptions and pricing alterations, is crucial for formulating effective retention strategies.

In retail, churn is affected by factors including purchase frequency, order value, brand loyalty, product diversity, customer service, personalized offers, and the entire shopping experience. Gülmüş Börühan Karaca et al, 2022 [2] employed Retailers encounter the difficulty of comprehending intricate consumer behavior patterns and forecasting churn to improve retention via loyalty programs, targeted discounts, and personalized communication. Retail churn is notably influenced by seasonal trends, promotional activities, and economic conditions affecting consumer expenditure.

In the banking industry, customers leave because of things like bad customer service, high fees, a lack of personalized financial products, problems with digital transformation, and other banks' competitive goods research by Salma, Mohamed Roushdy & Amr Galal et al 2023 [3]. In banking, churn is strongly connected to how much customers trust and value the bank. This means that predicting churn is important for keeping customers loyal and managing customer relationships. To improve service offerings and customer engagement strategies in this highly regulated climate, it's important to know why customers leave.

When businesses can accurately guess which customers will leave, they can use targeted retention strategies to keep those customers. This increases profits by keeping valuable customers from leaving. Single classifiers, like Decision Trees (DT), Logistic Regression (LG), Support Vector Machines (SVM), Naive Bayes (NB), and Multi-Layer Perceptron (MLP), have been used in the past to identify churn. A lot of people use these methods because they are easy to understand. For example, Decision Trees make it easy to understand how to make a choice because they show the clearest way. Logistic Regression helps us understand how factors are related in a straight line, while Naive Bayes works well with large datasets [4]. A neural network called MLP is very good at finding non-linear patterns in data. This is especially helpful for predicting churn as employed by Huang et al, 2023 [5]. But these single classifiers have a hard time with complicated, noisy datasets that are common in fields like banking and telecommunications where customer behavior is hard to predict.

Because single models have their flaws, ensemble classifiers have come up as strong options. Ensemble methods [6], such as Random Forest (RF), Gradient Boosting (GBM), AdaBoost,

CatBoost, and Stacking, take the best parts of several algorithms and combine them to make predictions that are more accurate and reliable [7]. AdaBoost improves performance by changing the weights of weak classifiers over and over again, and CatBoost is great at working with categorical factors, which makes it good for big, complicated datasets [8]. Stacking combines several base models and improves their output through a meta-model. This gives better generalization and predictive power [9]. According to studies, ensemble classifiers work better than single classifiers in many situations, especially in fields with complicated customer data structures as employed by Sharma & Gupta, 2022 [10] and Sahar F. Sabbeh, 2018 [11].

Single classifiers like Decision Trees, Logistic Regression, SVM, Naive Bayes, and MLP are compared to ensemble methods like Random Forest, Gradient Boosting, AdaBoost, CatBoost, and Stacking for customer churn prediction. Ensemble methods use multiple models to improve predictive accuracy and robustness. Ensemble methods like Random Forest and Gradient Boosting reduce overfitting, increase generalisation, and capture complicated data patterns, making customer churn predictions across industries more accurate. The study examines these models with banking, retail, and telecoms data. Performance is measured by accuracy, precision, recall, and AUC-ROC. Ensemble techniques, particularly Stacking, will be tested to determine if they outperform single classifiers across industries and disclose [11] as top customer churn models. This study aims to address the following research questions: (1) How can stacking methods improve customer churn prediction across various industries? (2) What are the limitations of traditional classifiers, and how does the proposed approach overcome them? The remainder of this paper is organized as follows: Section II reviews the relevant literature on churn prediction methods. Section III details the methodology used, including the datasets and models. Section IV presents the results, while Section V discusses these findings. Finally, Section VI concludes with recommendations and future work.

II. LITERATURE REVIEW

Many companies, particularly those in the banking, retail, and telecommunications industries, place a great degree of significance on the research field of developing forecasts on customer turnover. This emphasis is particularly prevalent in the banking industry. To a large extent, the ability to maintain relationships with existing clients is one of the most critical variables that defines the profitability of these industries. A wide range of machine learning methodologies have been examined by researchers during the duration of its existence. This has been done with the intention of improving the accuracy of churn prediction models. It is the purpose of this section to present an overview of the most significant advancements that have been made in the field, with a particular emphasis on the use of individual and group classifiers.

A. Single Classifier

Initially, churn prediction research relied mostly on single classifiers due to their simplicity and ease of understanding. Logistic Regression and Decision Trees are widely utilized in research due to their ease of implementation and ability to provide clear explanations. Chang and Hall, 2024 [12] used

Logistic Regression to identify the elements that cause customer turnover in the telecommunications industry, emphasizing the importance of consumer demographics and usage habits. Sebastiaan Hoppner & Eugen Stripling, 2018 [13] employed Decision Trees to predict customer attrition in the retail business, demonstrating the model's ability to deal with categorical data.

Support Vector Machines (SVM) are frequently utilized for predicting churn, particularly in datasets with high dimensionality. Amgad Muneer and Rao Faizan Ali, 2022 [14] showed how well SVMs worked to predict churn in the banking sector, which comprised complex, multifaceted client profiles. Although SVMs performed well, they lacked the interpretability offered by more straightforward models like Decision Trees or Logistic Regression and required intricate hyperparameter tweaking.

For datasets where features are assumed to be independent, Naive Bayes has been a common choice. But it might not be up to the task of dealing with increasingly complicated datasets due to its assumptions. Yulianti et al. 2021 [15] employed Naive Bayes to predict telecom churn and enjoyed its simplicity and speed, although more complex models were more accurate.

The Multi-Layer Perceptron (MLP), a type of neural network, exhibits capability in handling non-linear interactions and large datasets. Abdullah et al. 2018 [16] proven that MLP can get better results than traditional classifiers in the retail industry by discovering previously unseen patterns in customer purchases; however, this requires greater computational power and hyperparameter tuning.

B. Ensemble Classifier

The research community has increasingly focused on ensemble classifiers to address the limitations of single classifiers, as these ensembles integrate multiple models to enhance predictive performance.

For an updated citation on Random Forests in churn prediction, consult the new study by Saha et al, 2023 [17], which provides a comprehensive analysis of the implementation of Random Forests in the retail sector for churn prediction. The authors demonstrate the effectiveness of Random Forests in handling large and complex datasets, emphasizing its resilience to overfitting while providing in-depth analysis of consumer transaction data.

There has been extensive use of Gradient Boosting Machines (GBMs) in the telecom industry, such as XGBoost and LightGBM. Khanna et al. 2020[18] proved that GBMs could reliably manage datasets with imbalances and enhance the accuracy of customer churn prediction. John Ogbonna et al. 2024 [19] further substantiated this by demonstrating GBM's ability to discern intricate, non-linear correlations in customer data, hence improving the overall prediction efficacy in churn situations.

Recently, sophisticated boosting techniques such as AdaBoost and CatBoost have gained prevalence owing to their efficacy in forecasting churn. AdaBoost enhances poor classifiers by increasing the weight of misclassified data points, rendering it particularly effective for imbalanced datasets. Liu et

al. 2024 [20] presented the Ada-XG-CatBoost model, demonstrating its utility in diverse predictive applications, such as customer attrition. CatBoost, engineered to effectively manage categorical features, is especially beneficial in sectors such as banking and retail, where client data frequently comprises these variables.

Stacking is yet another ensemble method that has been investigated due to its capacity to create a single prediction model by combining a number of various kinds of classifiers. Stacking is a technique that was proposed by [21], which means that the outcomes of base classifiers are incorporated into a meta-classifier. Utilizing stacking as a method for predicting customer attrition, the author [22] demonstrated that it was superior to utilizing individual models since it utilized the most effective aspects of each model. Zhang et al, 2021 [23] demonstrated that stacking can perform better than other ensemble methods in the banking business by collecting a greater range of customer interactions and behaviors. This showed that stacking can be more effective than other ensemble approaches.

C. Industry-Specific Applications of Churn Prediction

Because of the high cost of acquiring new customers, the telecom industry has become a prime target for churn prediction. Collaborators on the project [23] demonstrated the efficacy of ensemble approaches in capturing a diverse variety of consumer behaviors by using a hybrid model that included SVM and GBMs to predict loyalty.

Zakariya and Faroug, 2024 [24] highlighted the use of GBMs and Random Forests in retail, a sector characterized by highly variable consumer behavior and transaction data. Ensemble approaches outperform conventional models in capturing the complexities of client purchase behavior, according to their findings. In addition, ensemble classifiers are important in retail since they improve prediction accuracy compared to single classifiers.

Advanced ensemble models provide significant benefits to the banking sector, characterized by its varied product offerings and complex customer relationships. Kimura, et al. 2022 [25] learnt that stacking is a component of hybrid models that decreased the number of false positives and increased the accuracy of churn predictions in retail banking. Zainb and Bestin, 2024 [26] used ensemble methods to enhance their models' performance in predicting customer attrition using neural networks.

D. Ensemble Stacking for Churn Prediction

The analysis of single and ensemble classifiers indicates that ensemble stacking is the most robust and accurate approach for predicting customer churn in the telecommunications, retail, and banking industries. Stacking combines multiple foundational models, such as Logistic Regression, Decision Trees, Naive Bayes, SVM, and MLP, utilizing a meta-learner to produce more accurate and generalizable predictions. This method alleviates the limitations of individual classifiers while leveraging the strengths of each model, as noted by Nureen Afiqah and Mohd Khalid Awang (2023) [22] and Ganaie et al, 2022 [27].

The foundational layer comprises classifiers such as Logistic Regression, Naive Bayes, Decision Trees, SVM, and MLP, with

each one targeting distinct aspects of the data. AdaBoost and CatBoost will be employed to tackle imbalanced data and complex categorical features, thereby enhancing the performance of the base models [28]. A Logistic Regression or Gradient Boosting meta-learner will combine basic model predictions to produce the final result.

Ensemble stacking leverages the strengths of multiple classifiers to yield more accurate predictions compared to individual models or conventional ensemble methods such as Random Forests or Bagging. Singh and Kumari, 2021 [29] demonstrated how the stacking strategy may improve the accuracy of customer turnover forecasts, particularly in industries with complex consumer behavior like retail and telecoms.

Stacking offers considerable versatility across multiple sectors and is not constrained by the complexities of any particular industry. Liu and Yang, 2024 [20] Stacking in the banking sector has been shown to produce higher churn prediction accuracy compared to individual classifiers, due to its ability to capture diverse data characteristics. Additionally, Singh and Kumari, 2021 [1] also found that stacking outperformed other retail ensemble tactics in addressing customer purchase behavior and loyalty patterns.

To sum up, Ensemble stacking is a solid and expandable loss prediction method that helps businesses guess how customers will act in a variety of industries. When you use basic classifiers and meta-learners to combine predictions, you can get better accuracy, generalisation, and stability even when the data is messy and complicated. Its usefulness in banking, shopping, and telecommunications makes it a strong and flexible tool for businesses that want to keep customers and cut down on customer turnover. Ensemble stacking, especially with more advanced methods like AdaBoost and CatBoost, helps businesses come up with strategic ways to keep customers and make them more loyal.

III. METHODOLOGY

A. Datasets

In this study, the researchers evaluated the effectiveness of single and ensemble classifiers in forecasting customer attrition by using three different datasets from the banking industry, the retail industry, and the telecommunications industry simultaneously. Each dataset included a number of aspects that were related to consumer behavior. These aspects included demographic information, account details, transaction histories, and patterns of service use.

With the assistance of the Telco Customer Churn dataset, it is now much simpler to forecast customer churn in the telecommunications industry. This dataset contains 21 factors that shed light on a variety of concerns, including consumer demographics, service subscriptions, and billing patterns, amongst others. Details on the user's demographics (such as gender and senior citizen status), service usage (such as internet service type and streaming options), and account-specific data (such as gender) are essential characteristics. Additionally, information about the account's term, contract type, and monthly charges are also essential features. The dependent variable of interest is the churn status, which is an indicator of whether or

not a customer has discontinued their membership. As demonstrated by this dataset, which illustrates the intricate dynamics that influence churn, some of the factors that have a significant impact on customer retention in the telecommunications business include service quality, the kind of contract, and billing processes [30] [31].

The Online Retail Dataset, used in retail churn prediction, contains transactional data from online retailers, including recency, frequency, and RFM, to identify at-risk customers. Abdullah Rahib et al, 2024 [32] used this dataset to create machine learning models for e-commerce churn prediction using RFM characteristics. Thanh Ho and Nguyen, 2024 [33] used RFM models to improve customer segmentation and retention, confirming the dataset's churn forecast accuracy. Machine learning was used to predict retail turnover using client purchasing behavior [32]. Transaction characteristics such as invoice numbers, customer IDs, and purchase history were important.

The Bank Marketing Dataset, used to forecast banking customer attrition, is available from the UCI Machine Learning Repository. This dataset includes bank clients and direct marketing results, which are essential for analyzing customer churn. Age, occupation, marital status, education, and financial details like account balance and loan status are essential. This dataset relies on interaction data like contact time and kind. The goal variable is the client's term deposit subscription, which often indicates banking sector churn [34] [14].

B. Preprocessing

The train-test split is an important part of machine learning because it checks how well the model works with new data. Researchers can test how well the model works with new data by dividing the information into separate training and test sets [35]. This strategy is crucial for model evaluation, as it alleviates overfitting, which occurs when a model performs well on training data but fails to generalise [35].

Multiple techniques can be employed for data partitioning, with random splitting and stratified sampling as the primary methods. The random split method ensures that both training and test sets accurately represent the entire dataset, enabling an unbiased evaluation [25]. In cases of class imbalance, stratified sampling maintains the proportional representation of each class in both datasets, which is particularly vital in customer churn prediction [35].

This research utilised three different split ratios: 70/30, 80/20, and 60/40. The 70/30 split allocates 70% of the dataset for training and 30% for testing, thereby establishing a balanced approach for model training and evaluation. The 80/20 division allocates 80% of the dataset for training and 20% for testing, which may enhance model performance by facilitating the identification of additional data patterns [36]. The 60/40 split increases the test set size to 40%, potentially providing a more thorough assessment of model performance in the context of a relatively smaller dataset [14].

To enhance the robustness of model evaluation, 5-fold cross-validation was employed, enabling each fold to function as a test set while the model is trained on the other folds [28]. This approach improves the dependability of performance

estimations by diminishing variance in evaluation metrics. Utilising diverse train-test splits and cross-validation guarantees successful model evaluation, resulting in more dependable predictions of customer turnover in the telecommunications, retail, and banking industries.

C. Ensemble Stacking

We employed Decision Trees (DT), Logistic Regression (LR), Support Vector Machines (SVM), and hybrid classifiers such as Random Forest (RF), Gradient Boosting (GBM), and stacking for model selection. Decision Trees, Logistic Regression, and SVM were selected for their simplicity, interpretability, and efficacy in high-dimensional contexts. A hybrid classifier known as Random Forest was selected to enhance accuracy and mitigate overfitting by amalgamating the outputs of Decision Trees. Gradient Boosting was selected due to its ability to incrementally rectify the errors of weak learners, resulting in highly accurate predictions. The third hybrid technique, stacking, integrated the results of Logistic Regression, SVM, and Decision Tree analyses. Logistic Regression was employed as the meta-classifier to forecast the final outcome. Fig. 1 below illustrates the ensemble stacking model.

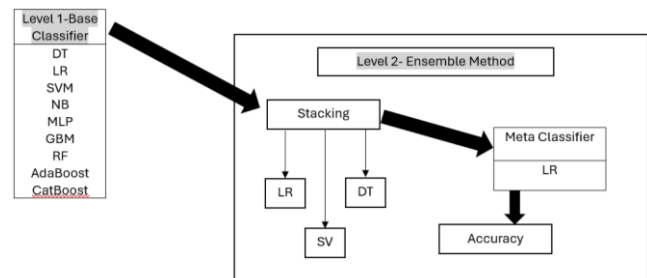

Fig. 1. Model of ensemble stacking.

D. Evaluation Metrics

The models were assessed through various performance metrics, including accuracy, precision, recall, F1 score, and area under the receiver operating characteristic curve (AUC-ROC), to deliver a thorough evaluation of their effectiveness. During the training process, we employed 10-fold cross-validation to assess the robustness and reliability of the models. This process ensured that the models did not overfit to any specific area of the data, thereby preventing overfitting. Several studies, including Bogaert and Delaere's, 2023 [37] have demonstrated that ensemble methods and cross-validation enhance churn prediction models across diverse industries. Xue Ying et al, 2019 [38] highlighted the importance of cross-validation in ensuring the generalizability of machine learning models, particularly when dealing with imbalanced datasets. To assess the generalizability of the trained models and to compare the effectiveness of single classifiers with hybrid classifiers across various industries, testing was conducted on 20% of each dataset that had not been previously disclosed.

IV. RESULT AND DISCUSSION

We divide each dataset in the telecommunications, retail, and banking industries into training (80%) and testing (20%) subsets. To reduce the possibility of our models being excessively dependent on a certain data subset, we employed 10-

fold cross-validation throughout the training phase. This method divides the training data into ten segments, utilizes nine segments for model training, and assesses the model using the remaining segment. This method is performed a total of ten times. The effectiveness of these iterations was averaged to refine the model hyperparameters. The models' generalizability was evaluated on the test set after their optimization.

A. Performance Comparison

1) *The following tables*, provide a concise overview of the performance parameters, including accuracy, precision, recall, F1 score, and AUC-ROC, for each classifier across the three datasets. The results emphasize the disparities in prediction ability between individual classifiers and hybrid classifiers.

B. Discussion of Result

The analysis reveals that hybrid classifiers consistently outperform single classifiers in accuracy and other critical metrics, such as precision, recall, F1 score, and AUC-ROC, across all three datasets: telecom, retail, and banking. The ensuing discussion focusses on the efficacy of several models and their ramifications for forecasting client attrition. In Table I (Telecom Dataset), it is shown that stacking and CatBoost models achieved the highest performance with 86% accuracy and AUC-ROC of 0.91, while traditional models like Decision Trees and Naive Bayes performed poorly with accuracies of 73-75%. In Table II (Retail Dataset), stacking and CatBoost models also outperformed other models with 86% and 85% accuracy, respectively, while Naive Bayes had the lowest accuracy at 71%. Similarly, in Table III (Banking Dataset), stacking and CatBoost models achieved the highest accuracy of 87% and AUC-ROC of 0.91, whereas Decision Trees and Naive Bayes performed the worst with accuracies of 72-74%.

1) *Single classifier*: Decision Trees (DT), although interpretable, exhibited only modest performance, achieving accuracies ranging from 72% to 75% throughout the datasets. This supports findings that decision tree models frequently struggle with complex data patterns, as research highlights their susceptibility to overfitting in high-dimensional datasets, particularly in churn prediction tasks. Despite their simplicity, decision trees remain relevant due to their clarity; yet, they are generally outperformed by more sophisticated models.

TABLE I. PERFORMANCE PARAMETER OF TELECOM DATASET

Model	Accuracy	Precision	Recall	F1-score	AUC-ROC
DT	0.75	0.73	0.78	0.75	0.81
LR	0.78	0.76	0.80	0.78	0.84

Stacking	0.87	0.85	0.89	0.87	0.91

Logistic Regression (LR) exhibited improvements over Decision Trees (DT), attaining accuracies between 76% and 78%. Its effectiveness in handling linear decision boundaries makes it highly suitable for binary classification tasks, particularly inside structured datasets like telecommunications and banking. However, the limitation of linear regression is in its inability to describe non-linear relationships, a point emphasized in recent research, which indicates that while linear regression offers interpretability, it often fails to capture more complex data interactions.

Support Vector Machines (SVM) demonstrated improved performance, particularly in the telecom dataset, attaining an accuracy of 80%. The flexibility of SVM to model complex decision boundaries makes it a powerful choice for forecasting customer attrition. However, this results in diminished processing efficiency, particularly with larger datasets, as emphasized in comparative studies on churn prediction models.

Naive Bayes typically demonstrates reduced efficacy in complex datasets like telecommunications, retail, and banking, where the presumption of feature independence rarely holds true. Naive Bayes is anticipated to produce lower accuracy, precision, recall, and F1-scores compared to other models in the tables, including SVM and ensemble methods such as RF and GBM. The simplistic model does not capture the complex patterns necessary for precise churn prediction in these industries.

The Multilayer Perceptron (MLP), a type of neural network, is more proficient at handling nonlinearities in datasets than

linear models like Linear Regression (LR). MLP is anticipated to produce results slightly better than LR and possibly on par with SVM. However, because of its tendency to overfit on small datasets and requiring significant tuning, it may not outperform ensemble methods. In these cases, MLP is expected to exhibit modest performance, with accuracies projected between 0.78 and 0.80.

2) *Ensemble classifier*: Ensemble approaches, including Random Forest (RF) and Gradient Boosting Machines (GBM), demonstrated enhanced performance, particularly in the banking dataset, attaining accuracies of 84% and 86%, respectively. This aligns with research highlighting the effectiveness of ensemble methods in aggregating weak learners to discern complex patterns in churn datasets. Both RF and GBM consistently achieved high AUC-ROC scores, indicating strong discriminatory capacity between churners and non-churners.

AdaBoost, a boosting method, improves accuracy and recall by iteratively combining weak classifiers. The results would fall between Random Forest and Gradient Boosting Machine. Based on the telecom, retail, and banking datasets, AdaBoost is projected to achieve an accuracy similar to that of Random Forest (about 83% - 85%), exhibiting excellent performance, although it does not reach the efficacy of the more advanced boosting method, GBM, or the Stacking model.

CatBoost, a modern boosting algorithm proficient in handling categorical data, would produce outcomes akin to GBM and Stacking. CatBoost is expected to attain accuracies ranging from 0.86 to 0.87, making it equivalent to the Stacking model. The effectiveness of CatBoost, especially in the banking dataset (around 0.87), highlights its capability in handling categorical data efficiently and reducing the need for extensive preprocessing, which is crucial for forecasting customer turnover.

3) *Ensemble stacking*: The stacking ensemble technique demonstrates effectiveness in predicting customer churn in the telecom, retail, and banking sectors, achieving accuracy rates between 0.86 and 0.87 in the examined datasets. Stacking is effective due to its capacity to integrate multiple foundational models, including Random Forest (RF), Support Vector Machine (SVM), and Gradient Boosting Machines (GBM), into a meta-learner that exhibits improved generalization across diverse datasets.

In the telecommunications sector, which is marked by considerable data complexity from structured and unstructured sources, stacking improves the management of churn variability more effectively than standalone models. Stacking leverages the strengths of various classifiers, such as the decision boundary optimization of Support Vector Machines (SVM) and the pattern recognition capabilities of Random Forest (RF) and Gradient Boosting Machines (GBM), to improve generalization and address the complexities inherent in telecom data. This adaptability aligns with prior research that emphasizes the effectiveness of stacking in improving prediction robustness through model diversity.

In the retail sector, consumer behavior data may fluctuate due to seasonal and demand variations. Stacking enhances forecast accuracy by capturing diverse customer behavior patterns through multiple algorithms. This helps to overcome the limitations found in individual models like Decision Trees or Logistic Regression, which can either underfit or overfit the data. Research in this area demonstrates that stacking enhances generalization, particularly in dynamic environments like retail.

In the banking sector, predicting customer turnover is crucial due to competitive dynamics and substantial client lifetime value. Stacking offers an advantage by integrating robust classifiers. Models like GBM effectively handle skewed churn data, while SVM improves precision in decision boundaries. Stacking improves prediction by utilizing these characteristics, resulting in enhanced accuracy and generalization, as demonstrated in various studies that emphasize stacking's role in advancing model performance in churn prediction.

C. Implications for Customer Prediction

Hybrid models, especially ensemble approaches like Stacking, Gradient Boosting Machines (GBM), and CatBoost, outperform Decision Trees (DT) and Logistic Regression in telecom, retail, and banking datasets. These models perform better and more accurately across industries. Stacking had the highest accuracy of 0.87 in banking, while CatBoost excelled in categorical data with 0.86 in telecom and banking [37][39].

For better churn prediction, our findings suggest hybrid models. Multi-base models increase generalization and forecast accuracy for complex, industry-specific data. Telecom companies with massive customer data sets can stack to identify at-risk customers and optimize retention. CatBoost models enable quick categorical data handling and personalized engagement in retail, including seasonal client behavior [39].

Hybrid models increase high-value client churn detection in banking, because revenue directly affects retention. GBM and Stacking, with strong AUC-ROC ratings (up to 0.91), enable organizations adjust retention efforts. The accuracy of these models helps organizations allocate resources, create focused solutions, and reduce customer churn while adapting to industry trends.

Recent research show hybrid models are used more in real-world churn prediction. Sector-wide churn prediction is more accurate, scalable, and flexible when many algorithms are used. Hybrid models can handle many datasets and complicated consumer behavior patterns, making them excellent for customer relationship management and churn reduction across industries.

V. CONCLUSION

This research examined both single and hybrid classifiers for predicting customer attrition in the telecommunications, retail, and banking sectors. Hybrid models, particularly ensemble methods such as Stacking, Gradient Boosting Machines (GBM), and CatBoost, surpassed individual classifiers including Decision Trees (DT), Logistic Regression (LR), and Naive Bayes (NB) in terms of accuracy, precision, recall, F1-score, and AUC-ROC. The hybrid models Stacking and CatBoost exhibited superior performance across all datasets, with an

accuracy of 86%–87%. Despite being more straightforward and accessible, individual classifiers failed to achieve the performance of ensembles, with Decision Trees yielding subpar accuracy in high-dimensional and complex datasets.

Hybrid models proficiently manage structured and unstructured data by integrating the strengths of classifiers, as demonstrated by the telecom dataset. Stacking demonstrated enhanced generalization in retail, when consumer behavior fluctuated with seasonal demands. Hybrid models were particularly effective in forecasting high-value client attrition in banking, where misclassification could result in significant financial losses.

VI. RECOMMENDATION AND FUTURE WORKS

The study is flawed. First, hybrid models outperformed single classifiers but required more computer resources and tuning. This may limit time-sensitive real-time churn prediction systems. Second, this study's industry-representative datasets may not cover all industrial circumstances. Generalizability may be limited by ignoring client demographics, product diversity, and regional differences. Most of this research used structured datasets with few category characteristics, which helped CatBoost. Customer turnover prediction increasingly relies on unstructured data like text and social media interactions, hence these hybrid models should be examined. Models were tested using 10-fold cross-validation. Retailers could study time-series cross-validation as customer behaviour changes. LSTM or Transformer-based deep learning models can reveal long-term customer behaviour dependencies. These tactics may help telecoms and finance organisations retain customers.

Hybrid models significantly enhance consumer churn prediction across various industries. To develop more practical and comprehensive churn prediction systems, it is crucial to focus on reducing computational complexity, improving real-time processing, and exploring new data sources and validation methods. However, one challenge with the proposed stacking model is the increased computational complexity due to training multiple base models and a meta-learner. Furthermore, the model's performance can vary across different datasets, as certain algorithms are more sensitive to data quality and preprocessing steps.

Hotspots and Insights on Quality Evaluation of Study Tours: Visual Analysis Based on Bibliometric Methodology

Meihua Deng 

School of International Communication, Hunan Mass Media Vocational and Technical College, Changsha, 410100, Hunan, China

Abstract—In this paper, taking 474 articles about quality evaluation of study tours in Web of Science (WOS) database as the research object, quantitatively analyze them with the help of CiteSpace 6.3.R1 software and excel data statistics, and analyze the impact of the literature data, authors' cooperation network, issuing institutions, journal distribution, and keywords' co-occurrence, clustering, and emergence factors, combined with time interval in-depth analysis and prediction, so as to present the research results in the form of visualized knowledge map. The results of the study show that the field of quality evaluation of research and study tourism an interdisciplinary field involving innovative research with multidisciplinary integration. During the decade of 2015-2024, it has experienced three stages of starting and exploration (2015-2018), rapid growth and diversification (2019-2021), and adjustment and maturity (2022-2024). From the viewpoint of authors and issuing organizations, authors are mostly independent research and have not yet formed a clustering research network. Research hotspots from the theoretical system construction and model development, empirical analysis, gradually shifted to user behavior analysis and recommendation system research. The future tends to research on research and learning integration intelligent decision-making, research and learning industry economy, environmental tourism practice and risk management.

Keywords—Research tourism; tourism quality evaluation; visualization analysis

I. INTRODUCTION

With the deep integration of the education sector and the tourism industry, study tours, as an innovative form of experiential activity, have begun to receive widespread attention worldwide [1]. This combination of educational purposes and tourism experiences not only provides participants with an opportunity to learn and explore in a real-world environment, enabling them to acquire knowledge and skills while traveling, but for tourist destinations, study tourism has also become an effective economic development tool [2-3]. By attracting learners of different ages and backgrounds, it increases the attractiveness of the destination, extends the length of stay of tourists, and drives the development of local catering, accommodation, transportation and other related industries, thus bringing significant economic benefits to the destination [4]. Therefore, study tourism not only enriches the connotation of education, but also injects new vitality into the tourism industry, and this win-win characteristic makes study tourism a hot area of common concern for both education and tourism [5].

However, due to the lack of uniform evaluation standards, quality evaluation of study tours has become a challenge that requires urgent attention from both academics and practitioners. The quality evaluation of study tours is crucial for enhancing the tourism experience and educational effectiveness. The development of this form of tourism not only enriches educational resources, improves the satisfaction of learners participating in study tours, and promotes the enhancement of knowledge and skills. At the same time, it injects new vitality into the tourism industry, helps the local tourism industry to build a richer and multi-level tourism brand image, and attracts more tourists. Therefore, an in-depth discussion of the quality evaluation of study tours is of great theoretical and practical significance for promoting the development of the educational tourism industry.

The framework of this paper is described as follows: Section II, "Research methodology" elaborates on the specific methods used for bibliometric analysis with CiteSpace software and Excel, including data sources and the data cleaning process. Section III, "Analysis process and findings," deeply analyzes the trends in literature publication, including the annual number of publications and publication curve trends in "III (A) Analysis of literature releases" and discusses three developmental stages in two subsections: "III (A) (1) Annual number of communications" and "III (A) (2) Trends in the issuance curve", the initial exploration phase, the rapid growth and diversification phase, and the adjustment and maturation phase. Subsequently, the "III (B) Analysis of literature authors" section explores the authors of the literature and the institutions publishing them, including "III (B) (1) Authors and issuing organizations" and "3.2.2 Author collaboration network" in two subsections. The "III (C) Distribution analysis of journals" section analyzes the distribution of journals, including "III (C) (1) Analysis of core journals" and "III (C) (2) Analysis of cited journals" in two subsections. Section IV, "Relevant analysis based on the field" reveals the research hotspots and the dynamic evolution trends of hot fields through keyword co-occurrence, clustering, and emergence analysis, including three subsections: "IV (A) Hot topic analysis," "IV (B) Analysis of hot areas" and "IV (C) Trend analysis of dynamic evolution" Finally, Section V, "Conclusion," summarizes the main findings of the research, discusses the limitations of the study, and provides an outlook on future research directions.

II. RESEARCH METHODOLOGY

A. Research Tools

CiteSpace is a multivariate dynamic visualization and analysis software developed based on Java language, which is capable of handling a large amount of transcription information and performing various analyses such as collaborative network, co-citation, keyword co-occurrence, and keyword clustering [6]. It also provides three advanced clustering analysis methods of Latent Semantic Analysis (LSI), Log Likelihood Ratio (LLR), and Mutual Information Algorithm (MI), which help users to identify potential themes and trends in research [7]. In this study, with the help of CiteSpace 6.3.R1 software application, this paper transforms the literature data in this field during the period of 2015-2024 into a knowledge graph so as to visualize the current status of research, research hotspots, and future trends in this research field.

In order to increase the accuracy of the study, this study quantifies the research scholars' research result publishing behavior, the interaction behavior between research scholars, and between research scholars and institutions in the research field, and uses standardized EXCEL data forms to summarize the statistics, and then uses the empirical data to analyze the state of research in the field.

B. Data Sources

Literature from the Web of Science (WOS) database, which is recognized by authors worldwide for its authoritative academic citation index, was selected as the primary data source for this study. A set of keywords was carefully designed to ensure a comprehensive coverage of the relevant studies in the literature search. The main keywords include "educational tour", "tourism quality evaluation" and "study tour", which cover this study. ", covering the concept of this research field, quality evaluation dimensions, evaluation index system, educational effect and other aspects of the research [8]. Boolean logic operators such as "AND" and "OR" are also used to optimize the search strategy and improve the relevance and accuracy of the search results [9]. Considering that in-depth research needs to be supported by a sufficient amount of literature data and closely related to the development of research and study tourism, the search time range was set as 2015-2024, and 2,221 pieces of related literature were initially obtained by combining the search strategies of databases, types of literature, and language ranges.

C. Data Cleansing

In order to ensure the objectivity and authenticity of the results of this study, a rigorous data cleaning process was carried out in this study before using the data. Literature with no direct relevance, low relevance, lack of keywords, authors, and other lack of key elements, as well as non-research literature such as duplicated, unreviewed, and scrapped manuscripts, news commentaries, interview reports, and so on, were eliminated [10]. After several rounds of data cleaning, 474 valid literatures with high relevance were finally obtained. For the screened valid literature, detailed data records were made in this paper, including information such as title, author, publication year, journal name, keywords and so on. This information will provide basic data support for the subsequent bibliometric analysis and help us to

show the research hotspots and development trends in this research field.

III. ANALYSIS PROCESS AND FINDINGS

A. Analysis of Literature Releases

1) *Annual number of communications:* In this study, a bar chart of literature publication was produced based on the year of publication and the annual publication quantity of 474 valid literatures. In terms of the number of annual publications, the research in this field shows a relatively obvious growth trend. In 2015, the number of relevant literature published was only 18, showing that the research in this field is still in its infancy. In the following years, the number of publications increased steadily, with 24 and 28 publications in 2016 and 2017, respectively, indicating that authors began to gradually focus on this field. Entering 2018, the number of publications decreased slightly to 24, with authors exploring new research methods or waiting for more empirical data. Starting from 2019, the number of publications increased significantly to 41, and this growth trend peaked in 2020 and 2021, with 71 and 80 publications, respectively, and the surge in the number of publications was related to the attention, exploration, and practice of research in this field in the field of global education. From 2022 onwards, the annual number of publications, although decreasing slightly from 76 to 46, remained overall at a high level [11]. This indicates that the heat of research in this field is not decreasing, and academic research authors are shifting to more in-depth empirical research on the existing research results, waiting for more practice cases to accumulate before summarizing and analyzing them. As shown in Fig. 1.

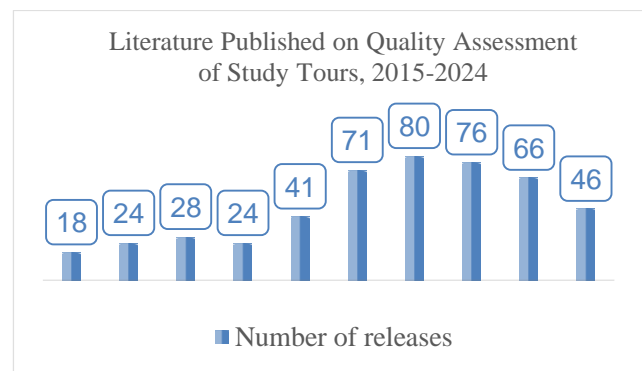

Fig. 1. Literature published, 2015-2024.

2) *Trends in the issuance curve:* The annual change in the number of literature publications shows the trend of research dynamics in this research area, which has shown a curvilinear growth over the past decade. In this paper, this period is broadly categorized into three phases: start and exploration, rapid growth and diversification, and adjustment and maturity.

Start-up and exploration phase: 2015-2018

In the early period of research in this field, i.e., 2015-2018, the annual number of literature publications increased from 18 to 24, showing a slow but steady growth trend, marking the

beginning and exploratory period of this field of research [12]. Research authors conducted preliminary discussions on the basic concepts, theoretical frameworks, and potential value of research tourism in the field of education during this period, with much of the research focusing on defining the connotations of research tourism, evaluating its educational efficacy, and exploring its comprehensive impact on learners [13]. These preliminary studies have laid a solid foundation for subsequent in-depth exploration, and despite the small number of publications, each of them is of great significance to the construction of a body of knowledge in this field.

Rapid Growth and Diversification Phase: 2019-2021

Entering 2019, research in this field began to receive wider attention, with a significant increase in the number of literature publications, reaching 41 in 2019 and climbing to a peak of 71 and 80 in 2020 and 2021, respectively. The rapid growth in this phase reflects the fact that the issue of quality evaluation of research tourism, as a new form of combining education and tourism, has begun to become a focus of attention in both academia and practice. Research scholars researchers began to explore diversified evaluation models and index systems, trying to assess the quality of study tours from different angles and levels [14]. The studies at this stage not only increase in number, but also present diversified characteristics in research methodology and theoretical depth, providing rich perspectives and profound insights for the research in this field.

Phase III: Adjustment and maturity phase (2022-2024)

From 2022 onwards, the number of publications within this research area decreased, with 76, 66 and 46 publications, respectively. This trend suggests that research scholars are beginning to consolidate and reflect on existing research findings after experiencing rapid growth in the previous period [15]. During this period, research may focus more on quality than quantity, and academic scholars may be seeking more effective research methods or waiting for more empirical data to support their research hypotheses. The fallback in this stage represents a sign that research in this field has entered a mature period, and the focus of research may shift from broad exploration to specific problem solving and application practice, reflecting the researchers' concern and thinking about the deeper issues of quality evaluation of research and study tourism.

Overall, the change in the amount of literature published in this research field demonstrates the dynamic development process of research in the field, from the start and exploration to rapid growth and diversification, and then to adjustment and maturity, with each stage contributing to the accumulation of knowledge and academic deepening in the field [16]. As the research in the field continues to deepen, more high-quality research results will emerge, providing more scientific and systematic theoretical support and practical guidance for the practice of study tours.

B. Analysis of Literature Authors

1) *Authors and issuing organizations:* The depth of cooperation among the authors of the literature and the academic influence of the core authors are key indicators for

assessing the maturity of research in this field. By extracting the first author information of 671 documents, a total of 619 authors were identified, of which 52 had more than 2 publications, accounting for 8.4% of the total number of authors. This data indicates that the number of scholars who have been deeply engaged in researching this field for a long period of time is relatively limited, but they have a high influence and academic contribution to the research of this field, which not only enriches the academic discussion on the evaluation of the quality of research and study tours but also provides important studies and inspirations for the subsequent research [17]. They not only enrich the academic discussion on quality evaluation of study tours, but also provide important references and inspirations for subsequent studies. According to Price's law, the number of publications by the core authors calculated in this study is only 1.03, which is inconsistent with the expectation of Price's law, proving that the research in this field is not yet mature, and the leadership role of the high-producing authors has not yet been emphasized [18]. In view of this, this paper defines scholars with two or more publications as high-producing authors in order to more accurately identify researchers who have made significant contributions to the field of this research. Statistically, there are 52 high-producing authors with a total of 131 publications, accounting for 15.5% of the total number of publications. This percentage indicates that despite the relatively small number of high-producing authors, they have played an important role in advancing research in the field as shown in Table I.

In addition to individual research scholars, the contribution of research institutions in this research field cannot be ignored. These institutions have provided substantial research funding, resource support and academic environment support for research in this field, thus facilitating collaboration and knowledge sharing among scholars in this research field [19]. After counting the first author's institution, it was found that university institutions published 325 documents and research institutes published 163 documents. The percentage of publications from university institutions is about 48.40% and the percentage of publications from research institutes is about 24.30%. This data shows that university institutions play a leading role in the research in this field, and research institutes have also made significant contributions [20]. In addition, of the 46 universities with more than two publications, 67% are in the computer technology application category and about 22% are in the teacher training category. This finding indicates that computer-based universities are more prominent in terms of attention and research results in this field of study, and they are more active and rich in this field of study compared to other types of institutions.

In addition, this paper also statistically analyzes the number of publications and citations of the authors to assess their research contributions and influence. Highly prolific authors usually have a high number of citations, indicating that their research results have been widely noticed and recognized by all circles and disciplines, and the research results of these core authors have not only promoted the theoretical development of the field, but also provided theoretical guidance for practice.

TABLE I. LIST OF STATISTICS ON THE NUMBER OF PUBLICATIONS BY CORE AUTHORS

Author	Number of communications	Author	Number of communications
Alkhamees, Nora	2	Li, Qing	2

Based on the results of the authors' analysis of the literature, it is suggested that future research should focus more on interdisciplinary and international cooperation. Knowledge exchange and innovation can be promoted by strengthening cooperation between researchers from different fields and different regions [21]. At the same time, emerging research institutions and young scholars are encouraged to participate in research on quality assessment of study tours in order to increase the diversity and vitality of research.

2) *Author collaboration networks*: In this study, the collaborative network of scholars in this research area was carefully analyzed through CiteSpace 6.3.R1 software. The co-occurrence threshold was set to 2, so that the connectivity between two scholars would only be visible in the network if they had co-authored at least 2 papers. This setting helps to capture the main collaboration patterns of authors in the field, while filtering out episodic collaborations and ensuring that the network mapping is somewhat stable and substantial [22]. The author collaboration network mapping consists of 622 nodes and 937 connectors, with nodes representing independent research authors and connectors indicating collaborative

relationships between them. Although the network density is only 0.0049, showing that the overall structure is relatively loose and the author collaboration network has not yet formed a highly dense cluster. However, the gradual increase in the frequency of collaboration among research scholars in the field compared to historical data signals the potential for future development of research collaboration in the field. As shown in Fig. 2.

The mapping of author collaboration networks, as shown in Fig. 2, not only demonstrates the current research collaboration dynamics, but also foretells the possible development direction of future collaboration networks. It is worth noting that the distribution of high-producing authors is relatively concentrated, and the research results are bit prominent in specific years, which may be related to the research hotspots, financial support, or specific research projects at that time [23]. For example, author Ammirato-Salvatore's high output in 2019 reflects a concentrated burst of demand in that research area in that year. Meanwhile, Balland-Pierre-Alexandre's multiple research outputs published in 2022 may be related to the financial support and policy impetus of related research projects in that year.

Fig. 2. Mapping of author collaboration networks.

The evolutionary trend of the authors' collaborative network provides a visual observation of the researchers' activity and participation patterns in the field. Some authors consistently publish research successes under the same topic in the same field, showing their long-term research and in-depth exploration of the research area. While other authors publish only 1 research result, their participation increases the diversity of the author collaboration network. This diversity in the author collaboration network reflects the broad appeal and flexibility of the research field, providing a rich variety of perspectives and methodologies for research in this area. Over time, it is expected that more new researchers will join this field of research, further enriching the structure of the author collaboration network [24]. As the collaboration deepens and expands, it is expected that research collaboration in this field will become more intense and systematic, which will not only promote the accumulation of knowledge and innovation, but also the development of interdisciplinary research. The development of such collaborative networks heralds a more active and diverse future for the research field of research and study tourism quality evaluation.

C. Distribution Analysis of Journals

1) *Analysis of core journals:* After counting the number of journal articles published in this research field, a number of journals with high influence in this field were found. These journals not only provide a platform for the publication of

research results in this field, but also reflect the popularity and academic attention of different research directions [25]. The top three journals are Expert Syst Appl, IEEE Access and Eur J Oper Res, with 227, 178 and 149 articles respectively. Among them, Expert Syst Appl focuses on original papers in the application field, with 96.25% of research articles, which has a significant academic influence in this research field, IEEE Access focuses on interdisciplinary research, and Eur J Oper Res prefers operations research methods and decision-making practices. Inform Sciences and Sustainability-Base, which follow closely in the ranking, are biased with information science and sustainability research [26]. The specialized nature of these journals is enough to show that this field of study is an interdisciplinary field that involves multidisciplinary integration of innovative research. As shown in Table II.

2) *Analysis of cited journals:* To further understand the interactions between core academic journals in this research area and the potential correlations between research topics in this area. In this paper, a network graph of journal co-citation relationships was reconstructed for the journals described above using CiteSpace 6.3.R1 software. The spectrogram consists of 473 nodes and 2613 connecting lines, with a network density of 0.0049 and a relatively loose overall network structure. As shown in Fig. 3.

Fig. 3. Co-citation network mapping of core journals.

In the analysis, it was found that core journals such as Knowl-Based Syst, Appl Soft Comput, and Inform Sciences had high co-citations, which reflected the concentration of attention and publication of high-quality research results on the main research themes in these core journals. For example, Knowl-Based Syst's highly cited literature in 2016 points to the application of knowledge systems in research in this field [27]. The citations of Inform Sciences are related to the role of information science in the analysis of tourism data software. IEEE Commun Mag's journals' citations have increased significantly in 2016, showing that they are contributions in the field of communication technology and management science.

By analyzing the co-cited journals over time, it is possible to observe the trend of research themes within the research field. For example, with the development of technology, some emerging research themes such as big data and artificial intelligence have begun to occupy an important position in the journal co-citation network [28]. These trends indicate that research in this field is gradually moving in a technology-driven

direction, while reflecting the high level of academic interest in the practical application of emerging technologies in this research area.

IV. RELEVANT ANALYSIS BASED ON THE FIELD

A. Hot Topic Analysis

In this study, the following core keyword co-occurrence mapping was constructed by CiteSpace 6.3.R1 software with the time slice parameter set to 1 year and the keyword occurrence frequency selection threshold parameter set to 10. The total number of nodes $N=342$, links $E=1269$, network density value 0.0218, through the nodes and links can show the research focus of the field, and the social network connection between the research topic. The larger the node, the more the keyword is proved to be hot, and the more times it co-occurs in the literature [29]. The thicker the linkage, the stronger the connection between the keywords and the deeper the influence is proved. As shown in Fig. 4.

Fig. 4. Core keyword co-occurrence network.

Combined with the core keyword co-occurrence mapping, the keywords with larger nodes and more frequent occurrences can be clearly seen. These core keywords basically cover the hot topics in the research in this field. For example, Model and System, as core keywords, appeared 74 times in 2016 and 40 times each in 2015 and 2016, respectively, showing that scholars have sustained research interests in the construction and assessment of evaluation models in this field [30]. These studies may involve the construction of theoretical models, analysis of system dynamics, and empirical testing of models. Research scholars have attempted to use these models to explain and predict changes in the quality of research and learning activities within the field and their impact on educational outcomes. Artificial Intelligence appeared 43 times in 2015, while Machine Learning appeared 51 times in 2017, which demonstrates that the use of intelligent technologies in the practical applications in this field of study are beginning to gain traction [31]. These studies focus on the use of AI and Machine Learning algorithms to analyze tourism data, predict tourism trends, and enhance the tourism experience in terms of software applications. Management (Management) appeared 50 times in 2017, and the hotspot of research is beginning to shift from theoretical models and software applications to research and study tourism management practices [32]. These studies focus on developing and validating evaluation metrics, as well as exploring the impact of different factors on the field [33]. Internet (Internet) appears 30 times in 2019, while Deep Learning (Deep Learning) appears 24 times in 2020. It shows that in recent years, the hotspots in this research field have been influenced by Internet technology, and research scholars have begun to explore new

research tourism models, Deep Learning to improve the research experience, and evaluation methods [34].

Through the interpretation of the core keyword co-occurrence, it can be observed that the hot topics of research in this field are gradually shifting from the construction of theoretical models to empirical analysis and technological applications, and academic scholars are utilizing intelligent technologies and data analysis to enhance the quality and effectiveness of research and learning in this field. The keyword co-occurrence analysis not only demonstrates the hot topics in this field, but also provides directional guidance for us to deeply understand the research dynamics in this field.

B. Analysis of Hot Areas

In order to further understand the hot field of this research, this paper clusters the core keywords and draws the core keyword clustering map. Among them, Modularity $Q=0.4796$, Silhouette $S=0.7824$. It is not difficult to see from the two queer values that the clustering structure of the hot area constructed in this study is obvious, the internal module similarity is extremely high, and the mapping has high and significant confidence [35]. Using the software LSI algorithm to automatically calculate, filtering out the classification of keyword class group members less than 10, and finally obtaining the hotspot domain clustering of 8 major categories. In order, 00# deep learning algorithm, 01# intelligent manufacturing, 02# assisting investor, 03# Chinese logistics companies, 04# economic complexity, the 05#using reinforcement learning, 06#blockchain technology, 07#sustainable m-commerce as given in Fig. 5.

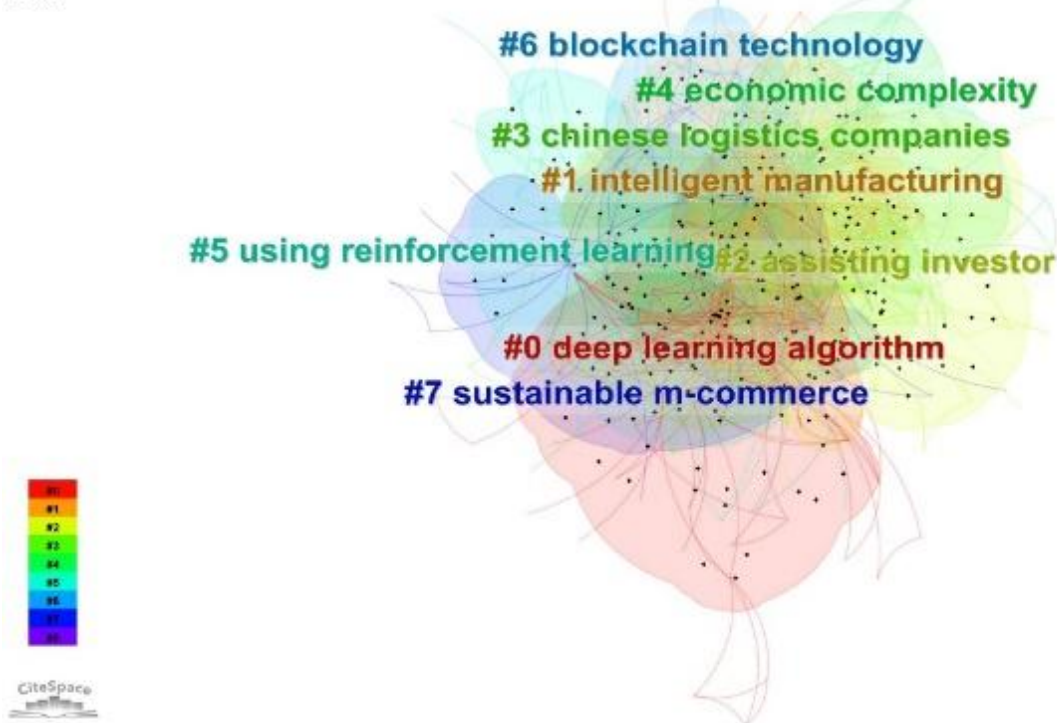

Fig. 5. Core keyword clustering network mapping.

According to the content and topic relevance of keyword clustering, this paper obtained three major research hotspot areas with high similarity or high impact relationship by clustering the eight hotspot areas again. They are technology and algorithmic innovation, industry and economic development, and education and social impact areas.

Hot Area 1: Technology and Algorithmic Innovation

This clustering covers 00# Deep Learning Algorithm, 05# Using Reinforcement Learning and 06# Blockchain Technology. The application of these technologies in this research area demonstrates the strong academic interest in utilizing advanced technologies to enhance tourism experiences and evaluation methods. Deep learning algorithms show great potential in handling tourism big data analytics, personalized recommendation systems and intelligent decision support systems. Reinforcement learning, on the other hand, plays a role in dynamically optimizing tourism strategies and enhancing user interaction experience [36]. Blockchain technology, on the other hand, focuses on improving the security and transparency of tourism transactions, especially in tourism supply chain management and traceability of tourism products, and technological and algorithmic innovations have driven the rapid development of this research area.

Hot Area 2: Industry and Economic Development

01# Intelligent Manufacturing, 03# Chinese Logistics Companies and 4# Economic Complexity constitute the field of industry and economic development, which focuses on the economic impact of study tours and how to promote industrial upgrading and economic development through study tours. The research in this area focuses on the impact of study tours on the economy and how to promote industrial upgrading and economic development through study tours. The co-occurrence of keywords in the clusters intuitively demonstrates the close connection between study tourism and industrial development and economic dynamics [37]. The application of smart manufacturing technologies promotes innovation in the tourism industry by improving the quality and productivity of tourism products [38]. The involvement of logistics companies highlights the importance of efficient logistics in safeguarding the tourism experience and improving the quality of tourism services. The study of economic complexity focuses on the impact of the macroeconomic environment on the development of study tourism and how to maintain the stable growth of the tourism industry under complex and changing economic conditions.

Hot Area 3: Education and Social Impact Clustering

The third hot area of research, to be composed of the clustering of 02# Assisting Investor, 07# Sustainable M-Commerce and 08# Innovation, demonstrates the importance of this area of research both at the educational level and at the societal level. Research in assisting investors focuses on attracting investment through research and study tourism programs and optimizing tourism products and services to enhance return on investment [39]. Research in sustainable m-commerce focuses on the use of mobile technology in

environmental tourism practices and research and study tourism sustainability [40]. The application of Internet technology plays a key role in facilitating tourism information sharing, enhancing tourism experience and improving the efficiency of tourism services.

In summary, the core keyword clustering analysis reveals both the research hotspots in this research field and reflects the intrinsic connection between the hotspots. The clustering of these research areas provides a direction for the research in this field and provides theoretical support for scholars when practicing their work. With technological advances and changes in the global economic environment, these research hotspots change accordingly, bringing new research opportunities and challenges to the research field.

C. Trend Analysis of Dynamic Evolution

In the in-depth analysis of this research field, keyword time mapping provides a unique perspective, prompting research scholars to observe the dynamic evolutionary trends of research hotspots within the field. In this paper, we construct a map of the dynamic evolutionary trend of research hotspots from 2015 to 2024 by using the time zone mapping function of CiteSpace 6.3.R1 software. Each node represents a keyword, and the keyword is fixed in the year of its first appearance. The larger the node, the higher the frequency of the keyword; the longer the arc and the darker the color, the higher the attention of the keyword research and the longer the duration. Along the evolutionary pulse of the keywords, the temporal development of the research hotspots in the field is excavated, so as to explore the future development trend of the research field. As shown in Fig. 6.

From the time mapping, it is easy to find that most of the arcs lasted between 5-7 years, and some keywords lasted for 2-3 years. Among them, Models (models) appeared with higher frequency and core values, reaching a peak in 2016, research scholars in this field began to focus on constructing research and study tourism evaluation models, which may be related to the exploration of evaluation methods and tools at that time, but this concern quickly disappeared in 2017, and this disappearance may be that the construction of models has already matured or that the research in this field was replaced by emerging hotspots. Systems emerged as a research hotspot gradually from 2017 and lasted for two years. During this period, research scholars regarded research tourism as a complete system, and began to pay attention to the interaction and overall optimization between its internal elements, and the systematic way of thinking promoted the development of the whole research field. By 2018, the keyword Behavior appeared, pointing to the research scholars' in-depth and focused research on the behavioral patterns of tourists, trying to interpret their impact on the quality of research and study tourism from the direction of tourists' needs, preferences and behaviors [41]. In 2020, two different sub-directions of research emerged, namely Recommender Systems and Risk Management, with some researchers focusing on the application and impact of recommender systems on personalized services in study tours, while others began to turn to the potential risks and risk management in the tourism process.

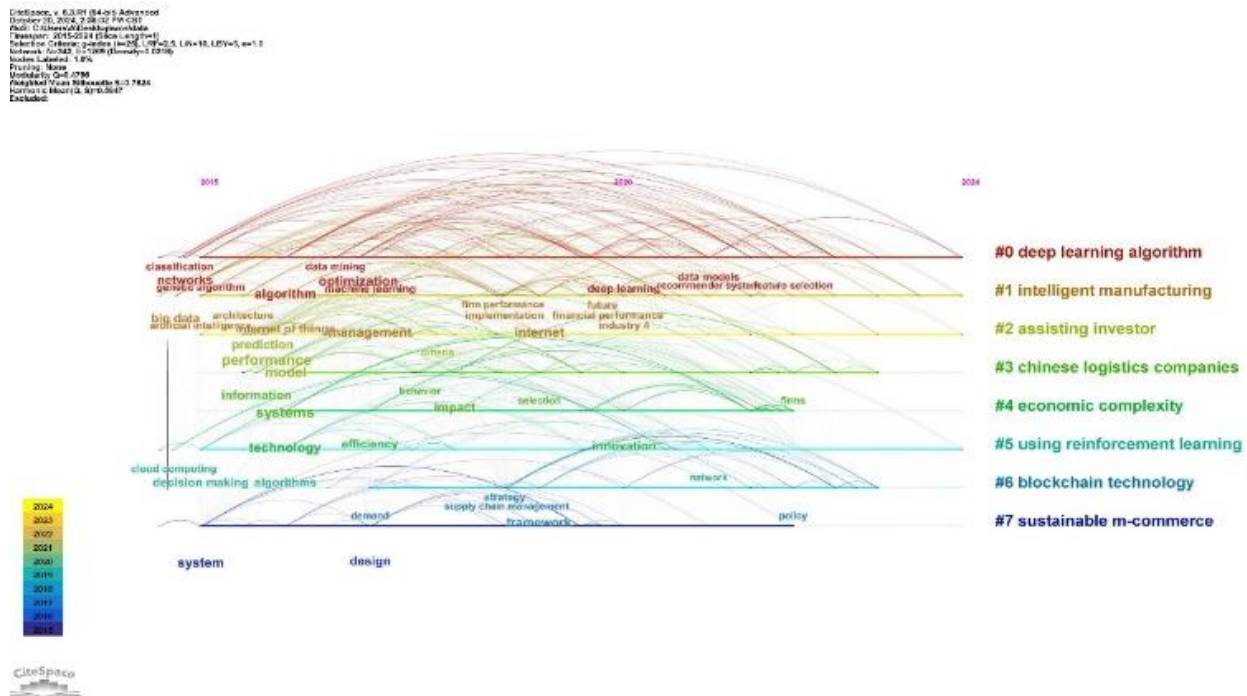

Fig. 6. Time mapping of core keywords.

In summary, the core keywords are distributed across the literature studies in the middle of the decade 2015-2024, and their durations provide a window for researchers to understand the dynamics of research in the field as keywords appear and disappear, as well as the potential connections between different research directions within the research field. By analyzing the temporal changes of these keywords, changes in the research trends in the field are inferred, and subsequently possible future research hotspots are predicted [42]. For example, the prominence of recommender systems may signal that personalized tourism services will become an important direction in the evaluation of study tours, while the prominence of risk management may point to the growing importance of tourism safety and stability evaluation.

V. CONCLUSION

A. Conclusions of the Study

This study provides an in-depth visual analysis of the literature in the field of quality assessment in research tourism through CiteSpace 6.3.R1 software, using knowledge mapping and data statistics to reveal several important aspects of the research dynamics in this field.

1) By statistically summarizing and analyzing the number of literature releases during the decade of 2015-2024, it is found that the research in this field has experienced three distinct development phases: starting and exploration, rapid growth and diversification, and adjustment and maturity. In the starting and exploring stage, the research mainly focuses on building the basic framework and model development. With the development of technology, the research hotspots in this field have proliferated and deepened, and the research aspects have started to cover a wider range of topics, such as user behavior

analysis and recommender systems. At the stage of adjustment and maturity, the research focus is further concentrated and deepened, showing the trend that the research field is gradually developing in a deeper direction.

2) In the statistical analysis of the authors of the literature in this field, the author noticed that there are relatively few highly productive authors, only 52 authors out of 619 authors have published two pieces of literature. Through the author collaboration mapping, it is intuitively observed that the core authors have fewer communication links with each other and have not yet formed a clear core group of authors. Although the research participation in this field is extremely broad, there is a lack of sustained research output and in-depth academic collaboration. This finding suggests that we need to strengthen cooperation and communication among scholars in future research to promote knowledge accumulation and academic innovation.

3) From the statistics of the number of journal articles and cited journals in this field, it is easy to see that this research field is an interdisciplinary field that involves the integration of multiple disciplines in innovative research. The research results in this field are widely distributed in various types of journals, including specialized journals in the fields of tourism, education, management and information technology. This interdisciplinary nature provides a wealth of perspectives and methodologies for research in the field, but it also poses the challenge of research integration and knowledge sharing.

4) Through the keyword sharing, clustering and emergence analysis, it is found that the research hotspots in this field show a dynamic evolutionary trend change over time, from system construction and model development in the early stage to user

behavior analysis and recommender system research in the later stage, which reflects the impact of technological advancement and social development on the research in this field. In particular, the application of emerging technologies such as deep learning, reinforcement learning, blockchain technology and artificial intelligence has provided new research tools and methods for this research field.

B. Research Limitations

In this study, despite the comprehensive visualization and analysis of the literature in the research area through CiteSpace software, there are still some limitations that may have had an impact on the comprehensiveness of the findings and the depth of the study. First, the selection of the study sample was limited to the literature included in the Web of Science database, which may mean that the source data failed to cover all relevant studies, especially those published in regional or specialized journals, and this choice may have resulted in the analysis results not being fully representative of the current state of research in the whole research area. Second, the keyword co-occurrence analysis, which is mainly based on the keyword fields of the literature, although it can show the research hotspots and research trends, fails to fully capture the depth and diversity of the literature content, and some important research topics may not be covered by the keywords or fully reflected in the keyword fields in the titles of the literature. In addition, the time mapping analysis, while showing the evolution of hotspots in the research field, does not delve into the social, economic and policy factors behind these changes. These environmental factors may have a significant impact on the research hotspots and trends in the field, and the analysis of the current study fails to adequately consider these external variables.

C. Future Prospects

In response to these limitations, future research will go back to expanding the scope of literature samples to include literature data from multilingual and multiregional countries in order to gain a more comprehensive research perspective. In terms of research methodology, the theoretical models, methodologies and empirical studies proposed in the literature will be explored in depth in conjunction with the content analysis methodology in order to more accurately understand the research hotspots and trends. External variables such as social, economic and policy contextual factors will be added to analyze their impact on the research hotspots and trends in the field, so as to find deeper research motivations.

Internet of Things (IoT) Driven Logistics Supply Chain Management Coordinated Response Mechanism

Chong Li

School of Economics and Management, Beihua University, Jilin 132000, Jilin, China

Abstract—This study explores the development of an IoT-driven logistics supply chain coordination and response mechanism aimed at achieving real-time information sharing, precise forecasting, and rapid decision-making among supply chain nodes. By employing a hierarchical system construction method, SQL database techniques for data management, and an evaluation model combining AHP and entropy methods, the study proposes a robust framework for improving supply chain efficiency and adaptability. The results demonstrate that IoT technology significantly enhances supply chain transparency, resource allocation, and operational efficiency while reducing risks and costs. The proposed mechanism facilitates dynamic adjustments to market changes and unexpected disruptions, fostering a resilient and collaborative supply chain network. This research provides a foundational basis for the integration of IoT in modern supply chains and offers insights into advancing intelligent logistics systems, with implications for improving global competitiveness in the evolving digital economy.

Keywords—IoT; logistics supply chain; management coordination; response mechanism

I. INTRODUCTION

In the new post-epidemic normal, the manufacturing industry urgently seeks to accelerate its digitization process and smart warehouse and logistics upgrades in light of the continued climb in market demand for smart warehousing and logistics [1]. In the ecology of logistics and supply chain, the efficiency of the warehouse and logistics system, service quality, and operating costs constitute the core considerations. By optimizing the intelligent warehousing and logistics system, enterprises can effectively speed up the logistics process, ensure efficient resource deployment and management, and then cut costs and improve overall performance [2]. In the construction of intelligent warehousing, promote the level of informatization of warehousing and logistics to enhance the irreversible development trend in the field of intelligent manufacturing.

In recent years, with the deep penetration of Internet of Things (IoT) technology in the industrial sector, the Industry 4.0 era has witnessed an increasing convergence of technologies [3]. This cutting-edge concept is gradually attracting the attention of the industry, which is dedicated to the comprehensive digital mapping of physical entities, empowering the intelligent design, manufacturing, commissioning, and full lifecycle management of physical equipment through data access and model-driven. Specifically, the application of digital technology in the field of warehouse logistics, embodied in the construction of digital

subsystems to provide intuitive monitoring and predictive maintenance services, at the same time, it also helps the simulation and pre-commissioning of industrial equipment in the virtual environment, to provide a virtual test platform for the development of the production plan, to effectively assess the feasibility of the production process, the initial cost can be reduced, and production efficiency has been significantly improved [4]. On the other hand, in real production environments, manufacturers often need to integrate different industrial equipment from multiple suppliers, and the diverse communication protocols and interfaces between these devices often become obstacles to the efficient collection, transmission, and processing of data, which exacerbates the difficulty of data sharing [5]. This phenomenon, the so-called "knowledge silo", is gradually evolving into one of the challenges in promoting the digital and intelligent transformation of production [6].

This research aims to explore and construct a set of logistics supply chain coordination response mechanisms based on IoT test the constructed platform to a certain extent, and evaluate the IoT platform according to the test results and subjective and objective factors to explore the level of logistics supply chain management coordination response in China.

II. BACKGROUND OF THE STUDY

As a key pillar of the national economy, the logistics industry is of strategic importance in shaping the framework of the modern cycle, driving high-quality development, and building a modernized economic system [7]. In 2022, the General Office of the Government issued a five-year blueprint for the development of modern logistics, which is the first five-year planning document for the development of modern logistics in China [8]. The blueprint specifies the core tasks for the next five years: to enhance the innovation driving force and market competitiveness of logistics enterprises, to optimize the quality and efficiency of logistics services, and to build a hub network operation system and a modern logistics and distribution network to flexibly respond to changes in domestic and international supply and demand [9]. At present, China has jumped to the top of the global logistics market, carrying more than half of the world's express parcel volume. However, despite the huge scale of logistics, its comprehensive strength has yet to be strengthened. Therefore, accelerating the construction of a modern and efficient logistics system, and realizing the leap from "big" to "strong" has become a key mission to improve logistics quality, cut costs, and enhance efficiency, which is particularly urgent in the five-year planning period [10].

Logistics companies need to have a forward-looking vision, advance insight into industry trends, carefully plan the future path, and continue to innovate and optimize, to better meet the challenges and achieve sound management and long-term development [11].

The continuous prosperity of the logistics industry has prompted intelligent logistics to become an increasingly critical growth trend. This trend not only can effectively deal with the information asymmetry, lack of transparency inefficiency, and other constraints in the logistics industry, but also greatly improves the efficiency of logistics operations and service quality, accurately meeting the expectations of both the logistics industry and consumers, and gives the logistics experience better, faster and more convenient characteristics [12]. In addition, intelligent logistics is accelerating the digital transformation of the logistics industry, helping the logistics supply chain synergy and fine-tuned operation, and realizing the double benefits of economic and social growth [13]. Given the rapid progress of artificial intelligence technology and its in-depth penetration in various fields, the vision of "comprehensive monitoring, seamless links, intelligent supply" is gradually becoming a reality. To achieve integrated management and

intelligent strategy development in logistics operations, IoT technology and data analysis means that the nodes in the logistics planning network can instantly capture, receive, and transmit real-time data to the core command system, realizing a seamless flow of data. This has undoubtedly strengthened the foundation of intelligent logistics and significantly enhanced its market competitiveness [14]. It is worth noting that road transportation dominates China's cargo transportation pattern, accounting for 73.8% in 2020, so it is urgent to build an IoT-driven supply chain to serve road transportation.

Therefore, to improve the quality of logistics services and transportation efficiency, in the layout of intelligent logistics, it is necessary to make use of advanced tools such as Internet of Things (IoT) technology, data analysis means, and optimization algorithms to solve a series of key technical difficulties [15]. The application of these technologies shows great potential in enhancing the real-time monitoring capability of logistics services, intelligent identification accuracy, and promoting the synergistic optimization of various links [16]. Therefore, for logistics planning and decision-making, in-depth exploration and application of these technologies have extremely important research significance and practical value.

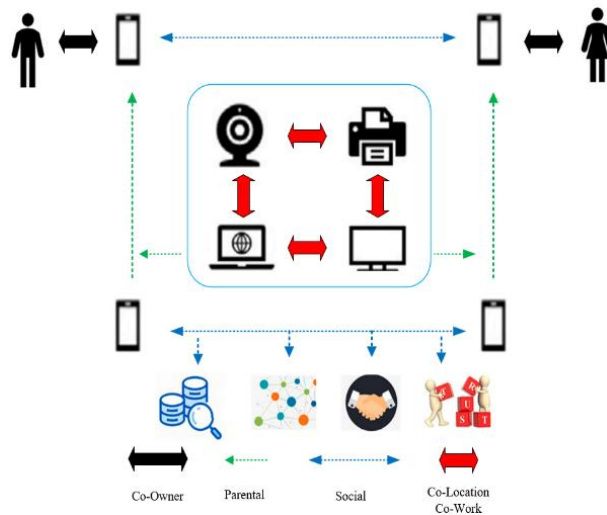

Fig. 1. Correlation of traditional IoT technologies.

III. RESEARCH METHODOLOGY

A. IoT Theory and Technology Foundations

At the heart of smart logistics is the efficient use of cutting-edge technology, with IoT dominating the logistics sector and being widely used. IoT, as a unique and recognizable network of "things", is centered on the identification and aggregation of personalized information about "things" through sensors/controllers connected to the Internet. IoT, as a unique and recognizable network of "things", is centered on the personalized identification and aggregation of "things" through sensors/controllers connected to the Internet, a process that integrates electronic devices, Internet connectivity, and multiple devices such as sensors [17]. These integrated devices can interact with infrastructure such as cloud servers and respond and operate quickly to dynamically changing environments and situations. The IoT architecture can be subdivided into four

layers: sensing, transmission, processing, and application layers. The sensing layer, as the core layer of IoT devices, is responsible for capturing and quantifying the physical characteristics of various types of objects and is composed of diverse sensors, RFID tags, and other sensing networks [18]. This layer captures data from the sensors directly associated with the objects and subsequently converts this raw data into digital signals and passes them to the transmission layer [19]. The transmission layer, on the other hand, plays the role of a bridge, using a variety of digital communication methods such as Bluetooth, ZigBee, 5G, etc., to receive and transmit these data signals from the sensing layer. The traditional IoT technology is known as SIoT technology and its IoT technology correlation is shown in Fig. 1.

IoT system integration not only covers the functions at the basic data level but also provides data processing services and support for specific application requirements. Based on the

organizational structure of the enterprise, it flexibly provides diversified business support services [20]. Its building blocks include hardware platforms such as cloud services, big data technologies, artificial intelligence, and advanced algorithms, as well as a series of middleware (e.g., sensor network gateways, sensor network security middleware, embedded M2M middleware, etc.), which together weave a powerful technology network [21]. For example, the mid-tier capabilities of intelligent computing are fully utilized, while cloud services are transformed into a hub for remote data storage and processing, greatly facilitating the process of accessing, storing, and processing data.

B. Key Technologies

In the field of identification technology for LoT, Radio Frequency Identification (RFID) technology occupies a dominant position. This technology relies on radio waves for data collection and identification and constitutes a unique identification system. The system consists of an RFID tag, a reading device equipped with a transmitter, and an interface to the target system. Specifically, the RFID tag has a built-in microchip and antenna assembly; when the tag enters a specific magnetic field, it receives a frequency signal from the reading device. The microchip on the tag serves as the core of data storage, carrying relevant information about the target object [22]. The antenna acts as a data transmission medium, enabling the microchip to pass information about the object to the reading device. The reading device then converts the RFID identification data into a format that can be easily processed by a computer, allowing the user to easily identify a specific object or individual.

Io Big Data enables flexible access to a diverse set of computing resources - servers, network architectures, storage, applications, and services - that are widely accessible and on demand. Such resources can be rapidly provisioned into place with minimal control and interaction between the user and the service provider, aiming to maximize data processing efficiency and capacity [23]. This model contributes significantly to the efficiency of data processing and computing. On the other hand, the big data technology system focuses on the all-round processing and insight of large-scale data sets, covering data collection, storage, refined processing, information extraction, and visualization. This process empowers users to dig deeper into the value of massive data, revealing the valuable information hidden behind the data. Through in-depth analysis and application exploration of big data technology, we can more thoroughly understand big data-related devices and their practical scenarios, which in turn will promote the performance leap and continue to optimize the user's interactive experience.

The technique of processing and analyzing real-time large-scale event streams can be called integrated event processing [24]. This process involves searching and organizing basic events to construct more complex and advanced events. Streaming analytics enables users to instantly monitor and analyze input data to dissect the causal chain of events and derive conclusions based on specific complex events. Low-level events are either manifested as a series of activities within a timeframe or as a bridge between events from different sources, and these elements are synthesized from a variety of data sources to shape complex event models that can be used to predict,

manage, and regulate potential events, scenarios, and biases. At the core of CEP (Complex Event Processing) technology is the uninterrupted processing and profiling of massive streams of high-speed data (e.g., RFID data), which are combined with a variety of data streams, and are analyzed uninterruptedly. The core of CEP (Complex Event Processing) technology lies in the uninterrupted processing and analysis of massive high-speed data streams (such as RFID data), which are fused with decentralized data to enable immediate monitoring and response to critical business scenarios[25]. The efficient Complex Event Processor can react quickly to hidden patterns, correlations, and data abstractions between apparently unconnected events based on predefined rules. It can be viewed as a continuously operating intelligent application designed to maximize the overall value of challenging events, provide immediate decision support for diverse event scenarios, and enhance overall situational awareness and understanding.

C. IoT Heuristic Exact Algorithms

The solution of numerous complex optimization challenges often relies on metaheuristic algorithms that are viewed as efficient tools. These algorithms can be strategically differentiated into individual solutions for a single case and generalized solutions that are universally applicable. Among them, innovative practices in individual solving encompass unique strategies such as large-network search (LNS) and adaptive large-network search. Population-based metaheuristics, on the other hand, have the core goal of breeding novel solutions by integrating and adapting existing solution sets, or by promoting synergies between solutions in the learning process [26]. Among the many heuristic algorithms inspired by natural biological processes, genetic algorithms stand out for their generality. In each iteration, the algorithm selects two pairs of parents from the population based on the principle of fitness and generates new solutions (i.e., "offspring") by merging their characteristics through a mechanism that mimics the "crossover" mechanism of biological interbreeding. In addition, to ensure the diversity of solutions in the population, the genetic algorithm introduces a "mutation" procedure as an effective means of facilitating the algorithm's exploration of the unknown solution space.

Eventually, the selected optimal solution is set as the dominant strategy in the next iteration loop. The family of swarm intelligence algorithms includes two members, Ant Colony Optimization (ACO) and Particle Swarm Optimization. Within the framework of these algorithms, ACO algorithms are often complemented with local optimization strategies to solve problems based on a predefined graph and a probabilistic mechanism for deciding their routes. On the other hand, particle swarm optimization algorithms envision a population of many "particles", each of which migrates from one place to another during the exploration process [27]. In this algorithm, the record of the optimal positions of individual particles and the optimal solution for the whole swarm of particles act as guiding factors that influence and shape the trajectory and direction of each particle.

A meta-heuristic local search strategy examines the current state of a solution and promotes the transition from the current solution to a neighboring new solution that shows potential [28]. Taboo search (TS), a widely used algorithm, is rooted in the

strategy of continuous exploration, which does not stop searching even when a local optimum has been reached. Even if the objective function is relaxed, the rheology guarantees the validity of the current solution. Another strategy is the Large Neighborhood Search (LNS), which is known for its ambitious search landscape and shows remarkable search patterns by partially dismantling existing solutions through the removal operator and then restoring them with the reorganization operator [29]. Adaptive SPS strategies are similar but are unique in their ability to dynamically adapt and select the most effective operators in each iteration according to the search process. To avoid the pitfalls of local optimality, guided local search (GLS) broadens the search boundary by imposing constraints on the objective function, thus expanding the exploration domain. In addition, meta-heuristic techniques such as Variable Neighborhood Search (VNS), Stochastic Greedy Adaptive Search Process (GRASP), Simulated Annealing (SA), and Iterative Local Search (ILS) are also focused on the optimization of local search, aiming to jump out of the limitations of local optima [30]. These algorithmic architectures not only serve the direct solution of the problem but also play an important role in constructing the initial solution of the heuristic algorithms, which lays a solid foundation for finding more optimal solutions.

Actuarial algorithm generation process for IoT:

$$\min \sum_{j \in J} c_j x_j \quad (1)$$

$$s.t. \sum_{j \in J} a_{ij} x_j \geq b \quad (2)$$

$$x_j \geq 0 \quad (3)$$

In this case, both Eq. (1) $c_j x_j$ unknown x and constant c are considered to be summed. Eq. (2) $\sum_{j \in J} a_{ij} x_j \geq b$ are constraints, and Eq. (3) both determine the positive and negative values of each variable of the function of x .

$$\overline{c_j} \rightarrow = \min c_j - \sum_{i \in I} \pi_i a_{ij} \quad (4)$$

$$E_i = e(w_{id}, r_{id}, t) \quad (5)$$

In Eq. (4), consider the variable in Eq. (1) as a constant 1 for $\min c_j$, and consider π as a constant variable; in Eq. (5) consider w , r , and t as natural variables.

To assess the positive expectations of the current solution, perform an accounting of the price subcategories and ensure that at least the negatively corresponding columns are included in the updated RMP solution set. An optimal solution is considered to have been reached only if the price analysis does not reveal any unfavorable test results. For RMP problems, the new variables

introduced during each iteration are intended to optimize the current set of variables and their corresponding pairwise optimal solutions, thus ensuring the optimization of the overall solution.

D. Definitional Approach to IoT

The most common means to solve global design challenges and many combinatorial optimization problems is with the help of branching strategies and their associated algorithms. Branching algorithms traverse the entire search domain, identify potential solutions, and select the optimal solution. This process relies on the structure of the search tree for partitioning and definition. A solution tree covering all potential solution paths is constructed, where the root node summarizes the global search pattern and pre-lists possible initial solutions. Each subroutine corresponds to a node presentation in the search tree. The decentralization technique, on the other hand, partitions the solution space into smaller blocks that can be recursively refined, aiming at generating children of unexplored nodes and eliminating suboptimal search patterns that may be confirmed during the partitioning process [31]. After completing the scrutiny of the entire tree structure, the searched optimal solution is fed back to the solution endpoint.

IoT delimitation was originally designed to meet the challenges of various types of constraints or variables. It incorporates a combination of different branching strategies, related algorithms, and column-generation techniques. Similar to the linear relaxation branching method, the original problem is depicted by a Dwolfe distribution. This process first splits the primal problem into a master system with several sub-systems, followed by a consistent path to solving the currently limited master system problem and passing the corresponding binary variables to each sub-category. For each subcategory, a column generation technique is then employed to solve its linear relaxation constraint set. It is worth noting that although the column generation algorithm plays a key role in estimating the node lower bounds, the practical application of the branching strategy is carried out after the linear relaxation solutions are obtained. In addition, it is possible to divide a series of potential primal solution candidate sets into subsets and apply recursive constraints with branching to each subset. In the branch-and-bound framework, the relaxation problem at each node is solved directly while the branch-and-bound pricing process is optimized using a column generation algorithm. By solving local problems iteratively, a series of problem sets optimized in the sense of linear relaxation can be identified. If a linear relaxation problem reaches an optimal state, the optimal solution can be further verified to satisfy the condition of an integer solution. During branching iterations, each new branch introduces unique constraints, resulting in the derivation of new subcategories that are again solved with the help of the column generation algorithm. This process continues, introducing new columns (i.e., variables) into the linear relaxation model until a globally optimal solution to the original problem is found.

The IoT delimitation method is carried out utilizing the branch pricing algorithm, in addition to the main process, where column and integer solutions are examined at the nodes respectively, as shown in Fig. 2.

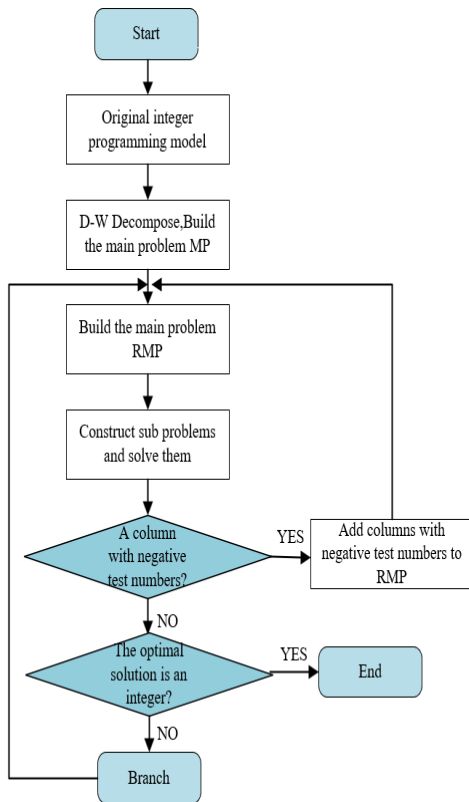

Fig. 2. Branch pricing algorithm flow.

The set of cut strategies constitutes a solution methodology for universal design challenges. The core idea is that multiple linear programming paradigms can be nested within the planning framework, which together portray multiple faces of the same set of integer solutions through a system of transformed linear inequalities. When dealing with a linear relaxation problem and obtaining a fractional, and then additional solution, one realizes that the current scheme is not rigorous enough linear inequality constraints need to be added, aiming at eliminating unrealistic floating-point or generalized solutions, and progressively approximating the globally optimal integer solution. This process is a way of pinpointing the poles of the optimal numerical solution that can be easily solved outside of the widened linear relaxation domain.

The dyadic principle of linear programming, on the other hand, breaks down the complex overall design problem into a series of asymptotically accurate local linear programming subproblems, with each round of solution pushing us closer to the ultimate solution. In the execution of the tangent algorithm, the first step is to solve the base problem with boundaries on all original variables, and then move to the relaxation problem [32]. The algorithm is terminated if a no-solution situation is encountered in the process, or if the best solution presents a generic characterization as non-integer. Instead, an additional linear boundary called a "cut" is introduced, which is designed

to precisely cut out the non-integer solution space that has not yet been covered and integrate it into the current relaxation model to exclude the validity of the current solution, which is then resolved based on the updated model. This process is repeated until all solutions for all basic variables meet the integer requirements.

The delimitation of IoT should also consider the interaction flow between the front and back end, to consider the request to send Axios to start, through the control, service, data, and entity four levels to reach the end of data persistence, as shown in Fig. 3.

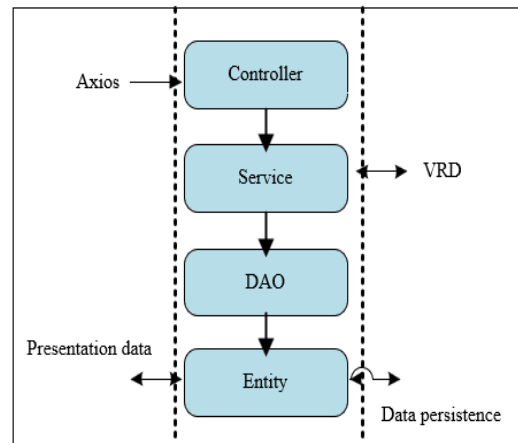

Fig. 3. IoT front and back-end interaction flow.

IV. RESULTS AND DISCUSSION

A. IoT System Architecture

Using the system structure hierarchical construction method to build an IoT platform and commissioning system, the initial intention of building an industrial IoT platform and virtual commissioning system is to rely on a cloud platform to realize instant remote monitoring of the status of each device in the industrial production chain [33]. In addition, the cloud data-driven remote storage line virtual debugging mechanism effectively shortens the on-site troubleshooting cycle and significantly improves the maintenance efficiency and performance during the various stages of production line debugging.

The construction of the IoT platform and debugging system is divided into five layers from the "virtual device layer" to the "virtual simulation debugging layer", as shown in Table I.

The experiments for IoT were divided into 30 sessions, and the number of debugging system fluctuations for the IoT platform is shown as a folded line in Fig. 4 (right axis), and the IoT latency test points are shown as squares in Fig. 4 (left axis) as the summation of the values on the major latency nodes (3, 5, 6, 15, 20, 22, 23, 25, 27, 28, 29, and 30). The IoT platform debugging system fluctuation and delay test results are shown in Fig. 4.

TABLE I. CONSTRUCTION OF IOT PLATFORM AND COMMISSIONING SYSTEM

Virtual Device Layer		Equipment communication control layer	Data Storage Layer	IoT cloud platform layer	Virtual simulation debugging layer
ABB industrial robots	PC-SDK	Data acquisition	Data management	Data monitoring	Data Mapping
Youao Industrial Robot	TCP/IP		Data subscription	Command parsing	Motion driven
Siemens PLC	S7	Data parsing	OPC UA	OPC UA Client	collision detection
KEBA PLC	TCP/IP	Data display	Real-time	MOTT	Visualization
AVG	REST	Data control	HISTORICAL DATA	data display	
RFID	Serial port		MySQL	Command Control	Unity 3D

The communication management layer architecture adopts a separated front and back-end design mode, and its core system module relies on Java and Spring Boot framework to build and realize efficient data interaction and persistence with the database by integrating a hybrid programming paradigm and MyBatis technology. This layer focuses on data processing logic planning and communication protocol management at the virtual device level. The front-end display layer is crafted using the Vue.js framework, focusing on the smoothness of user interface interaction and the flexibility of data configuration. In contrast to traditional project architectures, the UI code is often tightly coupled with Java Server Pages (JSPs), which are located in the backend of the server. In this model, the UI browser needs to retrieve HTML, CSS, and JavaScript resources from the JSP for data visualization and page presentation. This process is accompanied by a large amount of interactive data transfer, resulting in a lengthy and inefficient analysis and processing process, which in turn hinders the long-term maintenance and iterative development of the project. On the contrary, after the implementation of the design principle of separating the UI from the back-end logic, the UI layer actively disengages from the role of direct control of the browser page and focuses on the serialization of data (e.g., JSON, XML, form data, etc.) and recovery work. Front-end pages are loaded independently, which significantly reduces the number of communications between the front and back ends, greatly reduces the complexity of data interaction, effectively reduces the business processing pressure on the back-end server, and thus realizes a significant improvement in the overall performance of the system[34]. Therefore, the specific embodiment of the robustness of the Internet of Things logistics for the first high, then low, and then high, its horizontal axis is the number of iterations, the vertical axis is the robustness, that is, the performance of the performance due to the increase in the number of communications to deteriorate, but also because of the iteration and the enhancement of the process of the number of Internet of Things iterations and the linkage of the robustness, specifically as shown in Fig. 5.

The IoT experiment is divided into 30 times. The fluctuation frequency of the IoT platform's debugging system is shown by the line in Figure 4 (right axis), and the IoT delay test integral is shown by the block in the figure (left axis), which is the sum of the values on the key nodes (3, 5, 6, 15, 20, 22, 23, 25, 27, 28, 29, 30).

Fig. 4. IoT platform debugging results.

Fig. 5. IoT iteration count and robustness linkage.

In the heuristic algorithm mentioned in 3.3 above, the heuristic actuarial algorithm columns are generated in such a way that firstly the first row generates a column Ω_1 , followed by the algorithmic disaggregation using Do and while as shown in Table II.

TABLE II. HEURISTIC ACTUARIAL ALGORITHM COLUMN GENERATION

column generation
Generate an initial set of columns Ω_1
Do
Calculate the answer MP
Γ : New columns obtained from sub-problems
$\Omega_1 \cup \Gamma$
While $\Gamma \neq \theta$

The core concept of microservices architecture is to refine the huge software system into a series of independent, different functions of the service unit, the collaboration between these units does not interfere with the integrity of the business logic. Spring Cloud is the Spring ecosystem for the development of microservices framework, and support for the integration of Spring Boot Starter to enhance the scalability of the system. It provides a complete set of components, covering service registration and discovery, service consumption, maintenance, disaster recovery, API gateway, distributed tracking and monitoring, distributed configuration management, and other key aspects.

The development of communication layer systems and devices is rooted in the Java programming language, which is widely used in web server construction and big data processing because of its reliability, security, cross-platform compatibility, and superior performance. In industry, the construction of hardware operating systems and external communication libraries often relies on languages such as C++ and Python. Similarly, industrial simulation devices utilize virtual device technology on diverse simulation software platforms, relying on their core systems to provide communication protocols and library support. To achieve robust communication and efficient data processing, the debugging system has to cross the Java boundary and adopt hybrid programming and integrated programming strategies, which invariably exacerbates the complexity of the communication challenges among different programming languages. To address this challenge, the Hybrid Programming course will focus on exploring new ways to skillfully blend the strengths of each language through advanced integration techniques. Specifically, the extension session aims to integrate functional modules from languages other than Java, and realize seamless collaboration between modules through careful design and development; while the integration process involves configuring the parsers of other languages to execute in the Java Runtime Environment (JRE), thus expanding the capabilities of the system and achieving a leap in functionality.

In the construction of the communication layer system of IoT, it is found that the bands of centralized interactive data transmission are mainly concentrated in the following four bands "57~61", "73~76", "81~83", and "08~12"., "08~12", therefore, the evaluation of the four bands of the communication

layer system, column thickness indicates the level of expectations, the ability of interactive data transmission for the curve, which is concentrated in the range of 2.5T~13.5T, as shown in Fig. 6.

Fig. 6. Communication layer assessment for centralized interactive data transmission bands.

In the IoT communication architecture, the system integrates the Java Native Access (JNA) library, which is seen as an optimization and enhancement of the Java Native Interface (JNI) mechanism. When it comes to Java's Dynamic Link Library (DLL) calls to C++, JNA provides a more straightforward approach: it is assumed that you have already done the corresponding adaptation work, which constitutes one of the application scenarios. It is worth noting that the calling mechanism of the generic DLL follows the data structure specification defined by Sun, rather than directly adopting the data structure of the C language, to achieve access to functions within the established DLL. Ultimately, the process consists of downloading the shared Java library files and embedding them in the linked library system as function proxy service components.

B. Platform Construction and Testing for IoT

The database used to retrieve the data for this study is MySQL, which as a relational database management system has significant advantages in terms of its openness (open source), superior computational performance, and broad support for multiple platforms and applications [35]. In contrast, MyBatis is known for its lightweight, as an open-source database interaction manager, it is embedded in the essence of traditional JDBC (Java Database Connectivity) technology. Through the integration of global configuration data and mapping files, MyBatis can flexibly map the database table structure to the system-level classes and property blocks, this process cleverly circumvents the database driver registration, connection setup, and centralized SQL management of cumbersome

configuration. Integrating MyBatis into the Spring Boot framework not only simplifies dependency management but also makes it more straightforward and efficient to write query statements and manage database tables at the system data access object (DAO) level. This integration strategy promotes development efficiency and enhances application maintainability and scalability.

In the selection of MySQL to be centralized interactive data transmission band database validation, the band stability structure determination found that the purple for MyBatis, green for MySQL, and orange for the traditional other vb databases, found that the green MySQL peak band is similar to the interactive data that is, in the "57 ~ 61", "73~76", "81~83" all have better stability, most in line with the idea of this study, therefore, MySQL was selected as the tuning database, Fig. 7 horizontal axis is the band, the vertical axis is the stability. Specifically shown in Fig. 7.

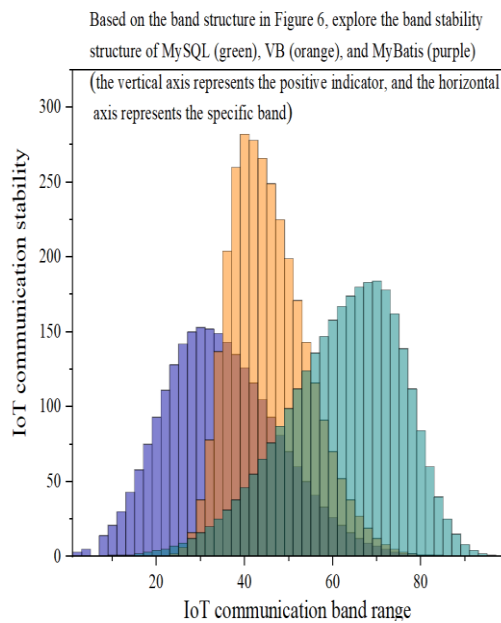

Fig. 7. Database selection test.

In the construction of the database, the IoT model is used to construct the data fields, the specific types of fields required such as demand, time, order details, storage information, etc., as shown in Table III.

TABLE III. FIELD TYPES REQUIRED FOR ORDERS

Field Name	Field type	Can it be left blank	explain
Bill_id	Int	NO	Order number, self increment primary key
Cargo_name	Int	NO	Name of goods
Demand_num	Int	NO	Quantity demanded
Demand_time	Int	NO	Requirement time
Cargo_id	varchar	NO	Customer ID
Creat_time	data	NO	Table record creation time
Description	varchar	NO	Order Description

The virtual commissioning system not only builds a bridge for communication and connecting information but also successfully meets the challenges of integrated management and unified storage of heterogeneous data from industrial equipment. In the face of complex industrial environments containing massive parallel, heterogeneous, and multi-source data, OPC UA technology is regarded as a powerful assistant for industrial IoT data management, helping the debugging work of virtual modeling. In this framework, Kepware, the preferred OPC UA server, is widely used as an industrial communication server software for controlling industrial automation equipment and associated industrial control programs. The process of initializing the server involves configuring communication addresses and ports, deploying channels on the KEPServer EX platform for the virtual system device hierarchy, adding analog devices, designing tag groups and tags based on the database table structure, and creating the corresponding nodes in the address space of the OPC UA server. Subsequently, the server control configuration table is optimized, and the OPC UA client service is constructed based on Spring Cloud microservice architecture, focusing on communication and hardware management functions.

In addition, the client can use the push mechanism to track the data changes from the server node, once the data is updated, the server will quickly analyze the host data and instantly send the host ID and attribute data back to the client, which effectively avoids the resource consumption of the client due to frequent polling of the server. Therefore, the three major systems in cloud services, i.e., IoT, Cloud Computing, and Edge Computing are evaluated for Data Return Resource Consumption where the results of the W1, W2, W4, W6, and W8 phases are shown in the following figure, and it is found that the average Data Return Resource Consumption rate of IoT is lower than that of Cloud Computing and Edge Computing, which is shown in Fig. 8.

Fig. 8. Evaluation of data backhaul resource usage for IoT, cloud computing, and edge computing.

In the constructed IoT database, the logistic capacity data is retrieved from SQL, and the information table used, which restricts the data fields, only uses two types of data, int, and Varchar, as shown in Table IV.

TABLE IV. SQL CAPACITY INFORMATION RETRIEVAL TABLE

Field Name	Field type	Can it be left blank	explain
ID	Int	NO	Self-increment primary key
Warehouse_ID	Int	NO	Warehouse number
Vehicle status	Int	NO	Vehicle status
Vehicle id	Int	NO	Vehicle number
Vehicle position	Varchar	NO	Vehicle position
Description	Varchar	YES	Order details

To accurately replicate real-life IoT scenarios, the dimensions and construction of the simulation model need to follow the exact scale of the actual device. The process starts with the precise dimensioning and construction of the model according to the device manufacturer's detailed specifications, followed by an in-depth analysis of the entire simulation framework. The component modules are carefully constructed and finally brought together into a unified model system through a series of integration steps using uplink technology. To facilitate the seamless integration of the model across different software, the model templates are exported to STL format files, which greatly facilitates their importation into 3ds Max, thus allowing the user to adjust the mapping and optimize the surface details. To further enhance the realism of the simulation, the powerful rendering engine of 3ds Max is fully utilized, and its on-screen rendering function effectively enhances the realistic texture of the model. In terms of material and color selection, users can carefully choose from a rich library of materials and color samples to ensure that the surfaces of the model's components accurately reflect the texture and hue of the actual materials. In addition, to bring the design closer to real-world application scenarios, users can also subtly incorporate labeling elements, such as unique texture pattern files and brand logos, which undoubtedly add a sense of realism and professionalism to the overall design.

The logistics of IoT are finally warehoused, and the goods in the warehouse are still accessed using SQL's database, and the specific access and querying are done using three numeric types: int, varchar, and date, as shown in Table V.

TABLE V. SQL INBOUND ORDER FIELD QUERIES

Field Name	Field type	Can it be left blank	explain
ID	Int	NO	Self increment primary key
Creator_id	Int	NO	Creator ID
Bill_type	Int	NO	Order type
Start_time	Date	NO	Process start time
Real_time	Date	NO	Actual process time
State	Varchar	NO	State
Description	Varchar	YES	Order details

C. AHP and Entropy Weight Method for Logistics Supply Chain Evaluation

AHP and entropy weight method of logistics supply chain evaluation system is divided into four steps, firstly, to determine the indicator system of the evaluation object, secondly, to determine the AHP weights, again to determine the weights of entropy weight method, and finally to utilize the comprehensive weights for comprehensive analysis. The calculation of the evaluation object index system determination and objective assignment method-entropy weight method is shown in Table VI.

TABLE VI. EVALUATION OF INTERNET OF THINGS INDICATOR SYSTEM AND ENTROPY WEIGHT METHOD

Name	Weight	Difference Coe	Information entropy
Mobile electronic equipment	0.1198	0.043	0.953
Sensor market size	0.1231	0.001	0.864
Internet Popular rate	0.2981	0.089	0.943
Fixed broadband terminal	0.0471	0.012	0.896
IPv6 size	0.1871	0.074	0.798
R and D	0.2001	0.051	0.453
Technological personnel	0.1143	0.011	0.976
IoT personnel	0.0178	0.053	0.768
Number of patents	0.1841	0.095	0.989
GDP	0.0231	0.043	0.742

In the evaluation, the normal distribution function of the efficiency loss of the IoT is to be considered, and there are three peaks of the specific normal distribution, which are shown centrally in this paper, it turns out that the loss point is between [-1, 1] and [500, 600], and therefore, does not affect the results of this paper, and the specific normal function, as shown in Fig. 9.

Fig. 9. Normal distribution of IoT efficiency loss.

After using the objective assignment method entropy weight method to determine the weights, but also to use the AHP method of IoT evaluation of subjective weight determination, the difference between it and entropy weight method is that one belongs to the objective assignment method, one belongs to the

subjective assignment method, the combination of the two to eliminate the defects of subjective and objective assignment of IoT, using the advantages of both, the following B1 ~ B10 represent 1 ~ 10 in Table VII respectively. Specific methods are as follows:

TABLE VII. ASSIGNMENT OF AHP FOR IOT EVALUATION

B\A	A1 0.322	A2 0.3331	A3 0.4331	Weight
B1	0.0423			0.0294
B2	0.3513			0.1321
B3	0.4091			0.0431
B4	0.0121			0.0213
B5	0.0311			0.0741
B6		0.1812		0.2913
B7		0.4121		0.0123
B8		0.3941		0.0478
B9			0.6412	0.1239
B10			0.3586	0.2312

This evaluation study is divided into three parts: comprehensive weights (i.e., a subjective and objective combination of weights), consistency test results, and IoT development index. The consistency test is a test of the AHP method, placed here the more intuitive expression of the accuracy of the empirical results, the IoT development index also shows an upward trend, as shown in Table VIII.

TABLE VIII. COMPOSITE WEIGHTS, CONSISTENCY TEST, AND IOT INDUSTRY DEVELOPMENT INDEX FOR IOT

Secondary indicators	Weight	Consistency	Level
B1	0.071	0.0784	0.6131
B2	0.124	0.0423	0.741
B3	0.232	0.0741	0.764
B4	0.041	0.0913	0.898
B5	0.021	0.0871	0.912
B6	0.251	0.0214	1.009
B7	0.031	0.0871	1.031
B8	0.071	0.0912	1.423
B9	0.012	0.0172	1.632
B10	0.129	0.0842	1.762

V. CONCLUSION AND FUTURE WORKS

This study deeply explores the core role and significant effect of IoT technology in the coordinated response mechanism of logistics supply chain management, which provides strong theoretical support and practical guidance for the intelligent transformation of the logistics industry. Through systematic analysis and practical verification, we have clarified that IoT, as a representative of the new generation of information technology, lays a solid foundation for the transparency, intelligence, and efficiency of the logistics supply chain with its

powerful data sensing, transmission, and processing capabilities. The coordination and response mechanism of the logistics supply chain has realized a qualitative leap. IoT technology not only realizes real-time and accurate information sharing among nodes of the supply chain and eliminates the barrier of information asymmetry, but also improves the sensitivity and response speed of the supply chain to market changes through intelligent analysis and prediction. This data-based decision-making support makes the supply chain more accurate and efficient in resource allocation, inventory management, logistics scheduling, etc., effectively reducing operating costs and risks. More importantly, the application of IoT technology promotes the in-depth integration and synergy of all links in the supply chain, forming a closer and more flexible supply chain network. In the face of unexpected events or market demand fluctuations, the IoT-driven coordination and response mechanism can quickly adjust strategies and optimize resource allocation to ensure the stability and resilience of the supply chain. This ability is of great significance for enhancing the overall competitiveness of the logistics industry and coping with the complex and volatile market environment.

The study has several limitations that warrant further exploration. Firstly, the proposed IoT-driven logistics supply chain coordination mechanism may lack generalizability across industries with diverse operational needs. Secondly, challenges such as network latency, data inconsistency, and device interoperability affecting real-time data accuracy remain inadequately addressed. Thirdly, the scalability of the framework for larger, more complex supply chains is not thoroughly evaluated. Lastly, the economic feasibility of implementing the proposed technologies, especially for small- and medium-sized enterprises, is insufficiently analyzed. Future research could focus on adapting the framework to different industries, integrating advanced technologies like blockchain, AI, and edge computing to enhance system reliability, exploring sustainable IoT practices to reduce environmental impact, and

conducting detailed cost-benefit analyses to assess the economic viability of such systems.

Abstract—Web development is a data-centric field and fundamental component of data science. The advent of big data analytics has significantly transformed the processes, knowledge domains, and competencies associated with Web development. Accordingly, educational programs must adjust to contemporary advancements by initially determining the abilities required for big data web developers to satisfy industry demands and adhere to current trends. This study aims to identify the knowledge areas and abilities essential for big data analytics and to create a taxonomy by correlating these competences with currently popular tools in web development. A mixed method consisting of semi-automatic and clustering methods is proposed for the semantic analysis of the text content of online job advertisements associated with the development of big data web applications. This methodology uses Latent Dirichlet Allocation (LDA), a probabilistic topic modeling tool, to uncover hidden semantic structures within a precisely specified textual corpus and average linkage hierarchical clustering as a clustering analysis technique for web developers. The results of this study are a web development competency map which is expected to help evaluate and improve the knowledge, qualifications and skills of IT professionals being hired. It helps to identify the roles and competencies of professionals in the company's personnel recruitment process; and meet industry skill requirements through web development education programs. The competency map consists of knowledge domains, skills and essential tools for web development such as basic knowledge, frameworks, design and user experience, database design, web development, cloud computing and other soft skills. Furthermore, the proposed model can be extended to several types of jobs in the IT sector.

Keywords—Big data analytics; hierarchical clustering; Latent Dirichlet Allocation; web development; knowledge; skill

I. INTRODUCTION

The revolution of Industry 4.0 carried out the concept of digitalization in all sectors producing big data. Big data consists of enormous volumes and a variety of data. It is impossible to manage and process the traditional management methods [1]. Big data analysis reveals hidden information, patterns, and correlations with new insights [2]. The valuable insights and implications derived from big data analytics are used in intelligent processes, such as guiding decision-making strategies in various organizations, including educational institutions, businesses, and governments. Big data are generated from many resources, such as websites, applications, emails, social media, and other multimedia platforms [3], [4], [5].

Websites as famous digital marketing in any organization, have caused increasing demand for data-oriented services, aligning knowledge and skill sets related to big data [2], [6]. Big data analytics is defined as the process of examining, processing, and analyzing large and complex data sets that cannot be handled by traditional methods. The goal of these analytics is to identify patterns, trends, and useful insights from structured and unstructured data [7] [8].

Recently, the technology lifecycle has shown a significant increase in big data-driven websites. Some modern products and services have been embedded in big data-oriented websites; thus, they have become an interesting topic for researchers[9], [10]. Digital transformation across business and industrial eras provides an exciting experience for software and service-based economics, for which modern websites can provide valuable information from big datasets [11], [12]. During this process, websites played a significant role in modernizing numerous sectors [13], [14], [15]. Web developers played an important role in developing ICT-based industries. Web developer is one of the information technologies (IT) occupations projected to grow by almost ten percent by 2033, it is much faster than other IT occupations [16]. The main task of web developers is to design and build a responsive website using popular programming languages such as HTML, cascading style sheet (CSS), and JavaScript. They are also responsible for testing, debugging, and integrating systems using application programming interface (API) services.

Big data causes new and challenging problems that need to be resolved using artificial intelligence. The Indonesian Ministry of Education, Culture, Research and Technology (Kemendikbudristek) stated that, only 15-20% of bachelor graduates have competencies match to their jobs. Skills and job profiles in the (Information Technology) IT sector is not clearly defined [17]. Therefore, some literature has discussed the big data of web developers and has become a hot topic among scientists in the last five years [18], [19]. Big data consists of approximately 5Vs; volume means a huge amount of data, variety means a type of data such as structured and unstructured data, velocity means high speed and real-time, veracity means reliable and accurate, and variability means volatility [1], [9]. These five characteristics of big data form the basis of the web development life cycle through methodologies and approaches in Big Data Analytics (BDA). This study aims to reveal hidden information and the value of implementing BDA in web

*Corresponding Author.

developers' occupations by identifying its knowledge domains and skill sets.

Given this context, BDA requires a diverse set of skills, programming languages, web development tools, and frameworks. The web development industry is a dynamic work environment that relies entirely on the resources of qualified people. The competence of BDA specialists strongly influences the quality of BDA-based products and services. BDA has grown in popularity, as has the requirement for qualification. A semi-automatic methodology was proposed to analyze collections of online job advertisements (ads). Our methodology is based on semantic analysis – hierarchical clustering (SA-HC) of BDA job ads using Latent Dirichlet Allocation (LDA) and average linkage hierarchical clustering. Latent Dirichlet Allocation (LDA). LDA is a generative statistical model used in a wide range of research in natural language processing and data analysis, such as topic modeling, sentiment analysis, and text analysis. This study revealed the core skills and knowledge required for BDA based on discovery topics, using LDA and hierarchical clustering analysis. The topics are mapped based on competency domains to reveal a structured taxonomy for BDA. Furthermore, the technologies required for BDA, such as programming languages, databases, and big data tools, are extracted.

The main contributions of this research are:

- A competency taxonomy for BDA developed by mapping the topics according to competency domain.
- The complex datasets provide a wide range of web developers topic area.
- A novel mixed method consists of latent Dirichlet allocation (LDA) and average linkage hierarchical clustering.
- BDA contributes significantly to decision-making processes because it has high granularity detailed information related to web developers' knowledge and skill sets.
- This research has been conducted by involving expert judgement in determining web development analysis.

II. RELATED WORKS

The methodology of this study provides a comprehensive explanation of big data analytics and semantics associated with them. It is also based on a content analysis of the textual content of BDA job ads using generative topic models to reveal the knowledge domains and skill sets required for BDA. Therefore, the background of the study is addressed under two subheadings: big data web developers and topic models / big data analytics.

A. Big Data Analytics

Big data analytics is the process of analyzing large volumes of documents to extract meaningful insights and values. High technology industries pioneered the method of deriving values from BDA. It includes a variety of data-intensive technologies that are capable of processing large volumes of data [1], [20], [21]. High-level management uses big data to impact grateful decision making, which is one of the parameters useful for BDA.

This makes a substantial contribution to decision making because large-scale data contains specific information. The BDA consisted of five stages:

- Data retrieval refers to a set of text, images, videos from the Internet, sensors, and e-commerce; for example, social media generates billions of related data every day.
- Data acquisition consists of collecting data from sources, preprocessing to clean datasets, and transforming the data for purposes such as classification or clustering.
- Data management file system was created for effective data storage and processing of large datasets. The industry deploys big data cloud models and systems, such as the Hadoop distributed file system (HDFS) and NoSQL.
- Data analytics is the process of extracting insights from massive datasets using artificial intelligence techniques such as machine learning and data mining. BDA reveals knowledge for decision making by identifying hidden patterns, links, and interconnections. User experiences such as customer service and decision support can be enhanced by BDA.
- Data visualization is a graphical representation commonly used in big data. Researchers can use general software such as R studio or MATLAB to create some visualizations. Other than that, industries usually use their own applications, such as GIS-based 3D visualization, to monitor traffic data.

B. Web Developers

Web developers is one of information technology (IT) occupation which projected to grow almost ten percent up to 2033, it is much faster than other IT occupations[16]. The main task of web developers is to design and build a responsive website using popular programming languages, such as HTML, CSS, and JavaScript. They are also responsible for testing, debugging, and integrating systems using API services. Reliable and fast interconnection between web and mobile development has become a trending issue. Web developers can access WSs through application programming interfaces (APIs) in social media platforms [18]. Furthermore, web development tools have been implemented to enhance the accessibility of artificial intelligence for researchers and end-users [19].

C. Latent Dirichlet Allocation (LDA)

LDA, a generative statistical model, has become a popular method for topic modeling in text mining [2]. Latent pertains to the identification of semantic content in corpus documents through the analysis of the underlying semantic structures. The generative approach in LDA ensures the allocation of terms in a document to random variables, followed by semantic clustering through a repeating probabilistic process grounded in Dirichlet distribution. LDA is an unsupervised learning methodology that does not require labeling or training datasets. It can be concluded that LDA can be efficiently applied to large corpus documents to identify semantic patterns. In the past five years, LDA has gained popularity in text mining studies spanning a variety of contexts, including e-commerce reviews, natural language processing, information extraction, sentiment analysis, and

social media trend analytics. Likewise, this approach has been used as a successful strategy in some studies that analyzed online job advertisements from businesses and industries. In the past, topic models were only created for textual data analysis but are currently being applied to a variety of data sources, including genetic data, photos, videos, and social networks. For these reasons, this study implemented LDA as a topic modeling method.

D. Average Linkage Clustering Analysis

Unsupervised learning such as hierarchical clustering, has become a popular method in data analysis. A superior cluster quality was provided by hierarchical clustering, thereby diminishing the sensitivity of clustering to various problem types. It comprises two methodologies: bottom-up and top-down. Agglomerative as a bottom-up approach initially treats each instance as an individual cluster, which is subsequently merged to form bigger clusters; this is known as Average-Linkage Hierarchical Clustering (ALHC) [22]. This process continues until all the clusters are combined into a single giant cluster containing all the instances. The hierarchical clustering method identifies common traits and job profiles in IT job posts, including competency, programming languages, web development tools, and frameworks [23].

III. RESEARCH METHOD

This study analyzed the content of web developer’s job advertisements. The proposed research methodology is described in Fig. 1 which consists of three main phases: data collection, text preprocessing, and LDA implementation. The following figure illustrates the overall process.

Fig. 1. Research methodology of big data analytics using LDA and clustering analysis.

A. Data Collection

The data used in this study were obtained from online job advertisements published by Glints [24], Tech in Asia [25], and LinkedIn [26]. A total of 2649 data were collected using the web scraping technique from January 2023 to July 2024. Job advertisements were searched using the keyword ‘web developer’, ‘web development’, and some expertise fields, including job title, job description, and required skills were collected. Table I presents the sample dataset.

TABLE I. SAMPLE OF DATA COLLECTION

Job Title	Job Description	Required Skills
Full stack Developer	Design, build, and optimize front-end and back-end code. Develop and maintain web applications. Integrate third-party APIs and services. Perform testing and debugging to ensure application quality. Collaborate with the design team to implement a responsive and intuitive user interface. Manage databases and perform query optimization. Provide continuous technical support and bug fixes. Keep up with the latest technological developments and implement best practices in development.	jQuery Debugging Laravel JavaScript CSS3 GIT SQL PHP HTML5
Web Developer	Develop new web application or customize existing application Learn new technology when required in the process of application development Problem solving and working with team on a project	Node.js REST API Laravel PHP

B. Text Preprocessing

Text preprocessing has become a crucial stage in information retrieval research. However, text data often comes in an unstructured form and is full of noise, especially when obtained from sources such as social media or websites. Therefore, text preprocessing is a crucial initial step in aligning data before being directed to further stages of analysis. The preprocessing stage plays a major role in removing text data from noise, which can damage the quality of the results [2], [27], [28], [29], [30]. Text preprocessing applied to the experimental data set consisted of several sequential stages. First, the text data were divided into words (tokens/parsing), known as tokenization, to obtain meaningful attributes [31], [32].

Tokenization divides text in the form of sentences or paragraphs into tokens/parts that are then represented by data vectors [33], [34], [35], [36]. Furthermore, web links, personal tags, and characters/affixes with no meaning were removed. The next stage was the stop word process. Stop words are used to reduce the number of words in a document, which affects the speed and performance of Natural Language Processing (NLP) [37], [38], [39].

The text preprocessing stages involved in converting textual data into keywords in WordStat ver.2024 are:

1) *Pre-processor*: This option allows custom text transformations to be analyzed before or instead of the execution of the other three standard processes: lemmatization, exclusion, and categorization. These transformations are achieved by executing specially designed external routines that

can be accessed in the form of Python scripts, external EXE files, or functions in dynamic link library.

2) *Stemming*: Stemming is a process used in text preprocessing to convert words into their base form [40], [41], [42]. For example, the word 'running' is changed to 'run. This helps in text analysis because it reduces the variation in words with similar meanings. Stemming ignores suffixes and prefixes to arrive at the base form of the word. Its use is common in applications such as information retrieval, sentiment analysis, and text mining. This can be useful for improving the accuracy of text analysis.

3) *Lemmatization*: Lemmatization is a process in text preprocessing that aims to change words into their basic form or 'lemma'. Unlike stemming, which only cuts off the endings of words, lemmatization considers context and changes words into their grammatically correct basic forms [43], [44]. After the preprocessing stage was completed, each text (job ad) in the dataset was defined as a word matrix. As a result of the preprocessing, the word space size for the entire dataset was reduced from 28232 to 22773. The dataset consisting of the job ads "TGL Web Developer and Digital Designer" is characterized by 22773 unique words, which also refers to the word matrix size for each ad. The number of matrices/vectors is 1868, which is also the number of job ads. The Document Term Matrix (DTM) created for this analysis consists of 1868 rows and 22773 columns. In other words, the DTM shows that 1868 job ads were represented by a word space consisting of 22773 terms. The DTM weighting process is performed by considering the word frequency.

C. Implementation of LDA-Based Topic Modeling

This step of the experimental analysis entails the application of a topic model to the dataset to reveal the domain knowledge and expertise necessary for BDA in a clear and comprehensible manner. The LDA model is a document generation model based on Bayesian theory, that excels in extracting themes and features from voluminous texts. This concept has found extensive application in fields such as text mining and information retrieval [45]. The inherent qualities of research that utilizes semantic analysis of job advertisements contribute to the effectiveness of LDA as a topic model [2]. LDA-based topic modeling assumes that the distribution of subjects in texts and the distribution of words within topics are mutually independent. Identical terms may manifest at varying degrees across distinct subjects. Likewise, specific subject matter may manifest to varying degrees in several written materials. The fundamental premise of the LDA model is derived from the Bayesian joint probabilistic model. The objective of this study is to use LDA-based topic modeling to reveal the underlying semantic structures (word clusters) in a textual corpus of job advertising.

Once the LDA model was implemented, the probability distribution for each topic is computed using Bayesian estimation methods in conjunction with the Dirichlet distribution. The WordStat ver.2024 tool was utilized to

implement an LDA model in this experimental investigation [46]. This tool is specifically designed to implement an LDA model. WordStat was implemented with varying iteration counts and was stabilized after 500 successive Gibbs sampling iterations.

The Bayesian inference model is the most important component of the LDA model [45], which is produced by the three-layer Bayesian probability of the "topic word" in the text. The diagram in Fig. 2 illustrates the topological structure of LDA. The fundamental algorithms of the data of a data-sampling algorithm and a feature-weight algorithm. The data samples in this study were collected using a web scraping technique.

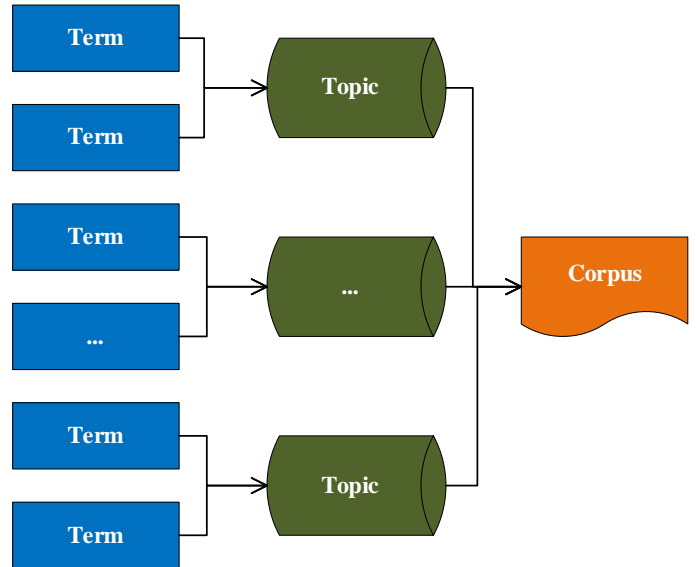

Fig. 2. Topological structure of LDA.

Within the LDA model, researchers explicitly allocated topic names to the identified themes, in accordance with the descriptive keywords. The naming of topics is based on the significance of all keywords and involves professional experts in the field of web developers through Forum Group Discussions (FGD). Therefore, the topic titles used may differ depending on the perspective of each researcher. LDA is an unsupervised generative probabilistic technique that is used to model a corpus.

Fig. 3 shows a diagram illustrating the LDA algorithm. The parameters used were as follows:

α and β are parameters of the previous distribution of θ . z is the designated theme for the n th word in the document count

ϑ is distribution of terms in number of topics theme

w is word in document

For the specified parameter θ , the mathematical equation to compute the probability distribution of the topic in Eq. (1) is as follows:

$$p(z|\theta) = \prod_n^n p(z|\theta) = \prod_{k=1}^K \theta_k^n \quad (1)$$

Fig. 3. Diagram illustrating the LDA algorithm.

Assuming the term-document matrix is defined and considering the number of documents comprising a corpus, these matrices often exhibit a significant size. Hence, it is customary in text mining to exclude sparse terms, which have a very low inclusion rate in documents. Typically, such an approach allows for a substantial reduction in the size of the matrix while preserving its essential relationships.

IV. RESULTS

BDA is presented to identify the core competencies of big data web development. First, the corpus document classifies the topics into skill sets. Then, the competency domain is mapped using these skill sets. Finally, most in-demand tools for BDA, programming languages, web development tools, and frameworks were analyzed to identify higher quality competencies. The results of the analysis are presented and discussed below.

A. Analyze Knowledge and Skills Using Latent Dirichlet Allocation

The corpus document formed by top three job advertisements comprised a wide spectrum of knowledge, skills, and job descriptions in the web development area. These spectra extended the coverage of the discovered topics of BDA. Three variables of job advertisements were used to combine the LDA-based topic modeling. Knowledge domains and skill sets of BDA were revealed and discovered from 26 trending topics with optimal granularity. As presented in Table II, topics were combined using descriptive LDA keywords and topic rates. The descending order and percentages are listed in Table II. Descending order means that the first term was the most occurrence and the last term was the least occurrence in a topic. The names of the discovered topics were automatically assigned using WordStat ver. 2024.

TABLE II. DISCOVERED TOPICS

TOPIC NAME	LATENT DIRICHLET ALLOCATION KEYWORDS	RATE %
Cascading style	cascading style sheets; responsive web design; css; front end; web development; client requirements;	10.04
Programming language	programming language; python; typescript; javascript; kotlin; golang	9.32
Graphic design	graphic design; corel draw; adobe photoshop; pattern; teamwork; management; communication; marketing social media	8.34
HTML CSS PHP	php; html; css; doctrine; laravel; mysql; jquery; bootstrap; wordpress; framework	7.04
Graphic design video	video; editing; graphic; design; illustrations; canva; adobe; video editing; photo editing; image editing; motion graphics; multimedia design	5.44
Digital marketing	digital marketing; marketing strategy; online marketing; product marketing; sales and marketing; creative writing; creative design; google ads; content marketing;	4.90
Code review	code review; code integration; development; system development	4.85
Javascript	javascript; react js; laravel node; angular js; vue js; tailwind css; node js; cassandra; development javascript;	4.76
Big data	big data; data engineering; scala; apache spark; data mining; olap cubes; data cubes	4.63
Design tools	After effects; adobe photoshop; adobe illustrator; canva design; google sketch up; auto cad; google sketch up; interior design;	4.35
Relocation provided	relocation provided; lead data engineer hadoop apps; staff data engineer; engineer data platform;	4.30
Performance tuning	performance tuning; testing; development; skills; continuous delivery; clean coding	4.06
Full stack	full stack developer; full stack engineer; full stack; full stack web developer; front end; back end;	3.55
Database design	database design; data architecture; sql; sql server; modeling; postgresql; nosql; stored procedures; database development; query optimization;	3.35
Business requirements	business requirements; problem solving; metrics driven; operational excellence; application testing; agile development; coding standards;	3.19
Object oriented	object; oriented; oop; object oriented; object oriented programming	2.66
Interpersonal skills	skills; analytical; interpersonal; solving; problem; communication; administration; systems interpersonal skills;	2.51
User experience	user experience; user research; architecture; large language models; requirements gathering; user interface design; debugging	2.32
Search engine	search engine; search engine optimization; digital marketing; google analytics; google ads; instagram	1.57
API	rest api; rest api laravel; git	1.50

TOPIC NAME	LATENT DIRICHLET ALLOCATION KEYWORDS	RATE %
Full stack developer	fullstack; programmer; developer; senior; engineer; backend; web programmer; angular developer; senior full stack developer;	1.46
Model view controller	model view controller; mvc; asp.net; sql; programming	1.44
Web service	amazon; service; web; aws; amazon web;	1.37
System UI	system; ui; administration; linux; ux; application; test; testing; mobile; integration	1.23
Online advertising	online advertising; paid advertising; google ads; instagram ads; digital marketing; market analysis	1.09
Information technology	information technology; service; communications; customer; security; management; product; service level agreements;	0.73

Table II shows that cascading style, programming languages, and graphic design were among the competencies with the highest demand in the BDA industry. Other knowledge and skills in the top ten were html css php, graphic design video, digital marketing, code review, JavaScript, big data, and design tools. The discovered topics also covered various emerging trends, such as database design, business requirements, object oriented, user experience, search engines and soft skill areas such as interpersonal skills which shed light on the priorities and demands in the ever-growing BDA industry.

B. Knowledge and Skill Mapping According to Competency Domains

This stage focuses on categorization and presents knowledge and skills in a structured manner. First, a mapping process was performed by associating knowledge and skills with the competency domains and workflows. Second, the knowledge and skills revealed by 26 topics were mapped into ten core competency maps developed for BDA.

Table III presents the distribution of knowledge and skills according to the competency map and their respective percentages. As presented in Table III, the first three competency areas are related to the function of web development, which consists of big data products, roles, and specialized web developers. The total rate of these competencies as the most important focus in web development area was 48.49%. The next five competency areas were related to the major discipline, comprising databases, web development frameworks, tasks, programming languages, and web development tools. The total rate for these competencies areas was 38.81%. The last two concern the interdisciplinary areas, consisting of educational background and soft skills, at a rate of 12.7%. These ten competency areas are discussed in detail below.

The first competency area, big data products in web developer area (8.96%). It contains five knowledge and skill items: digital marketing, social media, search engine optimization, data engineering, and data science. The second, role (33.92%) means a web developer must perform, such as web development, graphic design, software development, data engineering, etc. The third, specialized web developer, means specialization on web developer title (5.61%), contains some

items of front-end developers, full stack developers, Java developers, and others. The fourth, databases (2.1%) as a query language and data storage area, has the top five highest demands in BDA: SQL server, MySQL, MongoDB, Oracle, and powerBI. Fifth, web development frameworks (2.42%) used to create interactive and progressive user interfaces, consisted of six items: Apache spark, Laravel, angular js, etc. The sixth, task (10.52%), has the duties of web developer comprising user interface design, application testing, user experience, video editing, technical, content creation, and object-oriented. The seventh, programming languages (6.4%), has a lot of items, HTML CSS JavaScript, Python, typescript, scala, and VBScript. The eighth, web development tool (17.37%), contained a variety of frameworks, programming languages, and software. The ninth, educational background (4.41%), comprised four majors: software engineering, computer science, information technology, and electrical engineering. Finally, soft skills (8.29%) included problem solving, public speaking, creative design, positive attitude, communication skills, time management, analytical skills, and critical thinking.

TABLE III. COMPETENCY MAP

ID	Competency Areas	Knowledge and skills	Rate %	Total %
1	Big data product/output	Digital marketing Social media Search engine optimization Data engineering Data science	5.69 2.19 0.56 0.29 0.23	8.96
2	Role	Web development Graphic designer Software development Back end Full stack Front end End developer Application development Data engineer	6.79 6.67 5.56 4.31 2.87 2.77 2.29 1.52 1.13	33.92
3	Specialized web developer	Web developer Frontend developer Full stack developer Java developer Net developer Software engineer back end	2.45 0.96 1.13 0.39 0.38 0.31	5.61
4	Databases	SQL Server MySQL MongoDb Oracle Database Power BI	1.33 0.58 0.08 0.07 0.04	2.1
5	Web development framework	Model view controller Apache spark Php-laravel Javascript frameworks Angular js Java spring	0.37 0.19 0.89 0.37 0.15 0.45	2.42
6	Task	User interface design Application testing Video editing User experience Technical Cascading style sheets Data analytics Object oriented programming Content creation	2.68 1.25 1.18 1.12 1.07 0.94 0.86 0.72 0.68	10.52
7	Programming Languages	Html css javascript Asp net	3.98 0.99	6.4

ID	Competency Areas	Knowledge and skills	Rate %	Total %

10	Soft skills	Problem solving Public speaking Active listening Creative design Positive attitude Communication skills Time management Analytical skills Critical thinking	1.69 0.73 0.72 1.78 1.14 1.35 0.35 0.29 0.23	8.29

C. Identification of the High Demand Tools for BDA

Recently, collective environments of web development, a wide range of tools and technologies, such as programming languages, web development tools, and frameworks are used simulant. The corpus document was analyzed using a keyword indexing technique to reveal the tools and technologies required for BDA [29]. The findings of this analysis were divided into three main categories: programming languages, web development tools, and frameworks, which are discussed in detail in the following sections.

1) *Programming languages:* Programming languages are essential tools for application development and serve various applications. The job advertisement dataset was analyzed using keyword indexing to identify programming languages used in BDA. Table IV shows the top 12 programming languages required for BDA along with their percentages.

TABLE IV. PROGRAMMING LANGUAGES

Programming languages	Rate %
HTML CSS Javascript	59,2
Asp.Net	14,7
Typescript	5,31
Development Java	4,7
Scala	2,73
Visual Basic	2,73
PHP	2,43

Programming languages	Rate %
Golang	1,56
Python	1,21
Query Languages	1,06
VBscript	0,7
Server Side	0,46

According to the results in Table IV, HTML CSS JavaScript is the superior programming language in this field, followed by Asp. Net and Typescript. The total percentage of these three programming languages was 73.9%, a high percentage that shows their superiority. HTML CSS JavaScript shows the most superior and widely used programming as evidenced by the percentage produced is 59.18%, more than half of the existing value. In addition, the Server-Side programming language currently appears to have the least used trend in data science in recent years.

2) *Web development tools:* Table V shows Web development tools are often used in conjunction with programming languages to develop software applications more easily. These tools contain various types of utilities, such as frames, libraries, and applications. As seen in Table V, Adobe Photoshop, as a tool that can be used for UI / UX development in Web Development. React JS is a tool that has a JavaScript library used to build user interfaces, is in second place, followed by Rest API, a tool used to build web services so that applications can communicate with each other using the HTTP protocol. The fourth is Amazon Web, a cloud computing platform that provides various services for the development, hosting, and management of web applications and digital infrastructure. Almost the same rate value Node js which is a JavaScript-based runtime environment allows developers to run JavaScript code outside the browser, usually on a server. WordPress is a web development tool that is rarely used, as can be seen from the small percentage of tool use in Table V.

TABLE V. WEB DEVELOPMENT TOOLS

Web Development Tools	Rate %
Adobe Photoshop	48,39
React Js	6,68
Rest API	4,32
Amazon Web	4,17
Node Js	4,12
Spring Framework	3,92
Corel Draw	3,46
Web Applications	3,16
Search Engine	3,06
Graphic Illustrators	2,71
Canva Design	2,11

Web Development Tools	Rate %
Vue Js	2,11
Google Sketch Up	1,91
Net Framework	1,61
Mobile Application	1,41
Auto Cad	1,15
Data Cubes	1
Microsoft Azure	1
Java Virtual Machine	0,85
Query	0,8
Xml	0,75
Development Git	0,4
Cloud Computing	0,35
Apache Kafka	0,3
WordPress	0,25

3) *Framework*: According to Table VI, the most popular frameworks are PHP Laravel, Java Spring, Model View Controller, and Java Script, with 66.33%. Apache Spark, Angular Js, React Js, Next Js, Vue Js, and Express Js are in the middle position of their usage, with a total of 23.2%. Ruby on Rails has been the least utilized framework in recent years.

TABLE VI. FRAMEWORK

Frameworks	Rate %
Php Laravel	28,43
Java Spring	14,38
Model View Controller	11,76
Javascript Frameworks	11,76
Apache Spark	6,21
Angular Js	4,9
React Js	4,25
Next Js	3,92
Vue Js	3,92
Express Js	3,92
Redux Js	1,96
Angular Angularjs	1,96
Php Jquery	1,63
Ruby On Rails	0,98

4) *Visualization of hierarchical clustering topics*: Fig. 4 shows the relationship between various skills and topics related to web developers. The dendrogram shown in Fig. 4 is a graphical representation of hierarchical clustering. The dendrogram in Fig. 4 helps to visualize the relationship between skills or abilities related to the topic of the web developer in a

hierarchical manner. For example, Cascading Style Sheets (CSS), HTML, and JavaScript are grouped together because they are closely related to the development of web interfaces. Technically, JavaScript, CSS, HTML and Frameworks such as Angular and Spring are grouped more closely because these skills are often used together in web application development. In addition, the analytical skills and skills in the figure above have long branches, indicating greater differences from the other groups. In the Soft Skills grouping, Communication and Interpersonal skills were in a different group from technical skills, indicating that soft skills are important and conceptually different from technical web development skills.

Fig. 4. Dendrogram agglomeration order of web developer and digital designers.

The visualization can be presented in a word cloud format in addition to being in a hierarchical diagram. Word Cloud is a method for visualizing text [47], [48], [49], [50]. This technique was used to identify and highlight the most frequently occurring words, thus providing insight into the dominant themes or topics in the text [51].

Fig. 5. Word cloud for web development.

Fig. 5 shows that the term 'Digital Marketing' is often paired with 'Web Development' as they complement each other in building and promoting an effective online presence. Some words that are often paired with 'web development' include various technical and non-technical aspects of web development. Here are some examples: HTML, CSS, JavaScript, Frameworks: Such as React, Angular, and Vue for the front-end, and Node.js and Django for the back end. Responsive design and Search Engine Optimization (SEO) are often paired with web development. Web Development is also often called Web Programming or Website Development or Web Application Development or Front-end Development or Back-end Development or Graphic Designer or can also be called Full-stack Development.

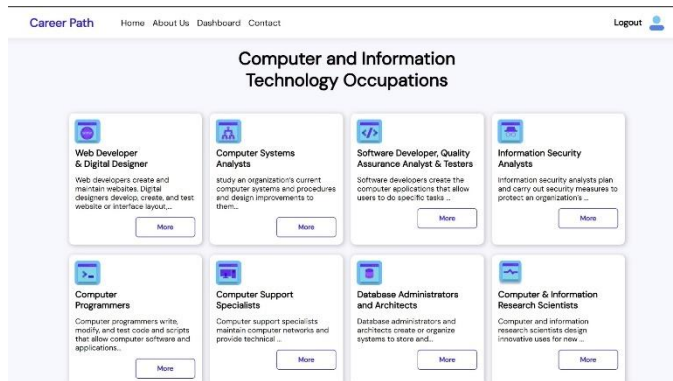

Fig. 6. Online dashboards of computer and information technology occupations.

As shown in Fig. 6, online dashboards of computer and information technology occupations has been deployed based on the ReactJS framework, and the Golang programming language.

V. DISCUSSION

This study has revealed the competencies for big data analytics over web development. First, the skill sets arranged by topic were identified from the data sets created using corpus documents of online job advertisement. Then, these skill sets were mapped into competency domains. Based on these results, the following ten competencies were identified:

- Big data product/output
- Role
- Specialized web developers
- Database
- Web development framework
- Task
- Programming languages
- Web development tools
- Educational programs
- Soft skills

The results show, in the big data web development field, HTML CSS Javascript, Asp.Net, and Typescript are the most

demanded programming languages; Adobe Photoshop, React Js, Rest API presented as the most demanded programming tools; PHP Laravel, Java Spring, Model View Controller are listed as the most demanded databases. The results of this study have important implications for web developers' programs, which are summarized below.

A. From Big Data to Data Science

Big data is related to data science which has characteristics such as volume, velocity, veracity, variability, and variety. Competence in big data requires a wide range of knowledge and skills. Such as in Table II, volume and variety of data are crucial factors in big data product/output with a contribution of 8.96%. This includes skills in digital marketing, social media, and search engine optimization and data engineering, which reflect the need for expertise in managing and analysing big data for various purposes, such as digital marketing and search engine optimization. The competence of each role of each person involved in web development work needs to adjust data with high speed and variety to support the development of more innovative products, this is related to the characteristics of big data velocity and variety with a role competency area of 33.92%. In addition, the ability of data to be relied on accurately is related to the database which includes skills in using SQL Server, MySQL, Mango DB and Oracle which contribute 2.1%. This ability is especially important in maintaining veracity which is the main basis for precise analysis and accurate data-based decisions. Big Data Product/Output and Web Development Framework, with a total contribution of 11.38%, indicate that data generated from various sources and having various types can be optimized for various analysis and processing needs. This reflects the existence of variability in data, which allows flexibility in managing and applying data for different analytical purposes. As illustrated in Fig. 5, hierarchical clustering is one of the data science analysis methods that groups similar abilities to illustrate the relationship between big data and data science.

B. The Extensive Range of Knowledge Areas and Competencies

The Web Development industry is one of the most in-demand and fastest growing professional fields worldwide. It has a highly dynamic and competitive work environment with an ever-increasing, changing, and evolving demand for knowledge, skills, and abilities. The global workforce will be impacted by the adoption of AI, automation, and Big Data Analytics (BDA) [21]. Our analysis reveals the knowledge and skill domains that are in high demand for Big Data Analytics (BDA). The analysis findings indicate that expertise in Big Data Analytics (BDA) requires a broad spectrum of highly varied and interrelated knowledge, skills, and ability domains. It involves collecting, storing, processing, and analysing large amounts of data to generate insights that can be used for decision making. Taking these findings into account, a conceptual competency map is proposed to organize these knowledge and skills. The map consists of the following ten competency domains: big data products/outputs, roles, specialized web developers, databases, web development frameworks, tasks, programming languages, web development tools, educational background, and soft skills (see Table III).

The competencies found indicate that BDA expertise has an interdisciplinary background that requires the integration of a broad set of technical and non-technical skills. Although competency priorities vary from position to position, employers in the BDA industry generally demand a set of technical and non-technical skills, defined as the job skill set. In this regard, our analysis results offer a more comprehensive perspective for BDA employers to identify the job skill set required for effective candidate assessment. The knowledge domains and skill set also indicate the need for a demand-driven educational background approach based on interdisciplinary collaboration to achieve a competency-based web development curriculum. Our findings are also in line with industry reports and academic research that emphasize the use of technical and non-technical skills together based on an interdisciplinary background containing data science, web development, software engineering, computer science, mathematics, business science, statistics, and communication science.

C. Reconciling Hard Skills and Soft Skills for Web Developers

Soft skills and hard skills have important roles in different types of jobs, although their roles can differ depending on the field and position. Hard skills are technical and specific skills that can be measured and are usually acquired through education or training. Technical skills in web development such as mastery of programming languages, tools, or frameworks. Professional qualifications such as certifications or licenses required for a specific job. Soft skills are interpersonal and character skills that are harder to measure but are essential for success in the workplace. Soft skills relating to interpersonal capabilities such as problem solving, analytical thinking, and communication. Soft skills depend on regular activities and organizational experiences of people [52], [53]. Problem solving means the ability to think critically and find solutions to problems that arise. Communication is the ability to convey ideas clearly and listen to others. This study's findings, general soft skills required for BDA specialists are highly recommended to whom it may concern. The findings related to soft skills include creative design, problem solving, and communication as the most favorite soft skills needed by industries (see Table III). This perspective has total rate of soft skills is approximately 8,29% in all topics. In many jobs, soft skills such as empathy and communication facilitate good cooperation in a team, while hard skills ensure that technical tasks are completed.

D. Insights into the Use of Tools and Technologies

Web development involves a variety of tools and technologies to create, manage, and maintain a website. This study proves several aspects of its use, including frameworks, databases, APIs, and responsive design. Web developers use tools and technologies consisting of programming languages, tools and frameworks in developing web applications. The selection of these tools is tailored to the needs and latest developments in the web development industry. The results of corpus data on BDA show that HTML CSS, ASP.Net, and Typescript are the most widely used programming languages in this field. Adobe Photoshop, React Js, and rest API are web development tools that are in high demand [54], [55]. Finally, this study proves that the most widely used web development

frameworks are PHP Laravel, Java Spring and Model View Control.

VI. CONCLUSION, LIMITATION, AND FUTURE WORKS

The finding of this study is big data analytics can clearly identify the industry needs of web development areas. A brief taxonomy of web development includes programming languages, databases, and web development tools that can improve the knowledge of students or job seekers in this field. LDA and hierarchical clustering algorithms prove that web developers can improve the innovation of businesses or organizations through digital marketing strategies. This study captures the updated industrial needs of the knowledge and skills of web developers because the datasets have been collected and managed in a wide and rigorous manner. The taxonomy of BDA competencies and skill sets was justified by three web developers' professionals through forum group discussions.

This study has several limitations. The first limitation comes from data collection using the web scraping technique; the text of job advertisement is biased because it is not specific enough or does not list relevant skills that are needed for the web developer's area. Second, the software used in the text preprocessing stage did not clean the data properly. There are some terms (stop words) still appear such as 'and', 'in', and 'to', so we must delete it manually. Third, the recurrence of phrases as synonyms forces us to determine the threshold for the most prevalent terms in job advertisements as 60.

In future work, some potential areas can be improved, such as comparing open-source tools, and Python to mine data. The latent semantic analysis (LSA) approach can be implemented to calculate the accuracy as a validated model.

ACKNOWLEDGMENT

This research was supported by the Ministry of Education, Cultural, Research, and Technology of Republic Indonesia and Institut Teknologi PLN based on Agreement Grant No. 0459/E5/PG.02.00/2024.

Abstract—This paper addresses the challenges of custom-generating multi-dimensional data SCADA (Supervisory Control And Data Acquisition) reports using web technologies. To improve efficiency, reduce maintenance costs, and enhance scalability, the paper proposes a custom generation method based on the LSO-GAN (Light Spectrum Optimizer - Generative Adversarial Network) model. The study begins by analyzing the requirements for multi-dimensional SCADA reports and proposes a web-based design scheme. The LSO algorithm is employed to optimize the GAN model, enabling efficient generation of customizable SCADA reports. The proposed LSO-GAN model was validated using relevant SCADA data, with experimental results showing that the method outperformed other models in terms of accuracy and generation efficiency. Specifically, the LSO-GAN model achieved an RMSE of 14.98 and a MAPE of 0.93, surpassing traditional models such as Conv-LSTM and FC-LSTM. The custom report generation method based on LSO-GAN significantly improves the customization and generation of multi-dimensional data SCADA reports, demonstrating superior performance in both accuracy and operational efficiency.

Keywords—Web technologies; SCADA systems; report customisation; spectral optimisation algorithms; adversarial generative networks

I. INTRODUCTION

Report is a dynamic display of data information through tables, graphs and other diverse formats, it is a form of expression of data statistics [1]. As an important tool for analysing and displaying information and printing, reports can be used to quickly organize and analyze data and become an important basis for development decisions in various industries [2]. SCADA (Supervisory Control And Data Acquisition) system is a computer system used to monitor and control industrial processes [3]. SCADA systems based on Web technology in order to be accessed through a Web browser, they provide the ability to monitor and control remotely and are suitable for distributed control systems [4]. Multidimensional data reports are key components in SCADA systems, they allow users to analyse data from different perspectives and dimensions to better understand and optimise industrial processes [5]. Therefore, the study of customised methods for generating multidimensional data SCADA reports is beneficial to improve efficiency, reduce maintenance costs and increase scalability [6].

With the development of Internet and Web technologies and the diversification of users' needs for reports, the development of report generation methods has become the focus of attention of experts and scholars in the field, especially in the customisation of multi-dimensional data SCADA reports [7]. In the context of globalisation of information technology, the implementation technology of Web reporting tools has been constantly innovated and improved. At present, the Web reporting tool implementation technology is more, which is more widely used, the practicality of the better there are mainly the following three schemes [8]: (1) based on the COM components of the programme. Xie et al. [9] describe the VB environment based on the ADO pairs and COM components Excel data processing functions combined to achieve the report printing function. Chen et al. [10] developed an Excel-based put custom report dynamic library, using COM technology, the output of a new output report; (2) based on the ActiveX plug-in programme. Cuzzocrea et al. [11] combined with the Jasper Reports open source project to generate reports to meet the needs of dynamic generation of Web reports; (3) XML-based plug-in-free programme. Munz-Krner and Weiskopf [12] proposed an XML-based Web-oriented intelligent reporting system. Nasri and Weslati [13] studied the Web-based custom reporting tool design method. With the increasing data dimensionality in SCADA systems, the current report generation methods no longer meet the design requirements. For the current multi-dimensional data SCADA system requirements, this paper combines Web technology [14], intelligent optimisation algorithms [15] and neural network methods [16], and proposes a Web-based custom intelligent generation method for multi-dimensional data SCADA reports. The contributions of this paper include the following:

- (1) Describe the problem of multi-dimensional data SCADA report customisation and give relevant solutions to the problem;
- (2) Around the SCADA report customisation generation, combined with the LSO algorithm [17] and the GAN network [18], propose the SCADA report customisation generation algorithm based on the LSO-GAN;
- (3) Use the multi-dimensional data report relevant information to validate the report customisation algorithm. The results show that the method proposed in

this paper achieves the customisation of multi-dimensional data SCADA reports, and at the same time improves the intelligent generation efficiency by using LSO-GAN.

II. PROBLEM DESCRIPTION AND ANALYSIS

A. Requirements Analysis for Custom Reports on Multidimensional Data

The main engineering requirements for multidimensional data reporting enable a defined set of better report semantics to achieve custom report customisation (Fig. 1). Therefore, a good set of reporting tool software and methodology should fulfil the following functions: 1) report data management; 2) report design tools; 3) report file management; and 4) report integration and application [19], as shown in Fig. 2.

Fig. 1. Multi-dimensional data custom report style.

Fig. 2. Functional requirements analysis.

In addition to the analysis of functional requirements, it is also need to analyse the performance requirements of the tool, especially the custom reporting tool method of ease of use and security and reliability. 1) in terms of ease of use, report generation method needs to provide users with a friendly interface, mainly for: rapid formatting and content parsing, fast preview of the Web page, the data import and export of the report quickly; 2) security reliability, the main performance: identity verification, operation rights management, input information legality detection, deletion warning, real-time recording of important operations, as shown in Fig. 3.

B. SCADA Report Custom Generation Idea Design

1) Web-based custom reporting tool workflow: The overall workflow of the Web-based custom reporting tool is shown in Fig. 4.

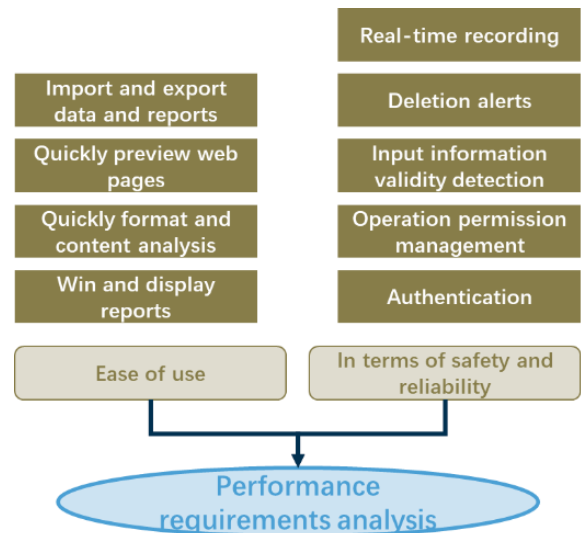

Fig. 3. Analysis of performance requirements.

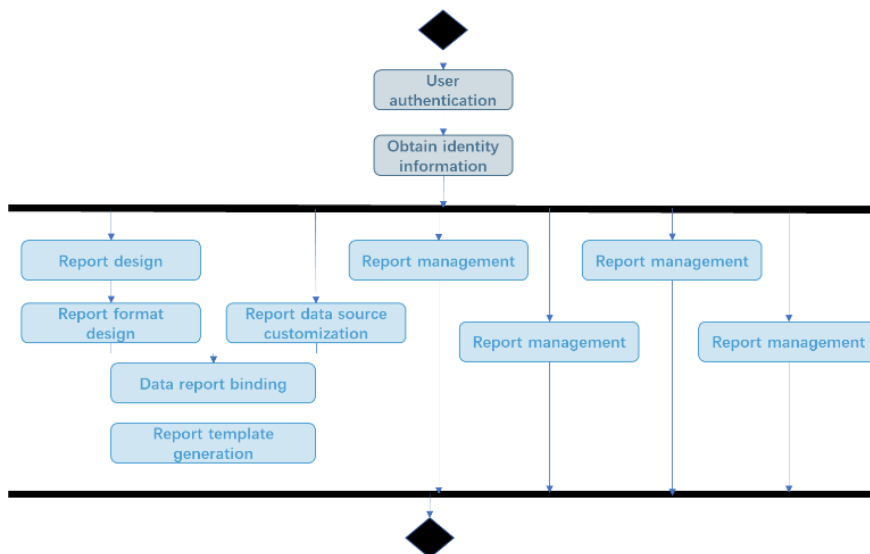

Fig. 4. Reporting tool flow.

As can be seen in Fig. 4, the user logs into the system for user authentication, obtains user identity and permission information, and enters the main interface of the SCADA reporting software. Depending on the user's privileges, one or more of the management functions, such as report customisation, report template management, report browsing and printing, report file export and system management, can be performed [20].

2) *Steps for customising multidimensional data reports:* Customising a multidimensional data report typically involves the following steps (Fig. 5): 1) identifying the purpose and user requirements of the report; 2) collecting and organising the required data sets; 3) selecting a tool that supports web development; 4) designing the visual layout of the report; 5) developing the report functionality; 6) testing and optimising; and 7) deploying and maintaining [21].

Fig. 5. Custom report workflow.

3) *Customised SCADA report generation and analysis:* In order to be in practical applications, many reports are basically the same in format and script, and the main difference lies in the different equipment of the data source. In order to further improve the efficiency of report generation, this paper uses deep learning technology and intelligent optimisation algorithms to introduce SCADA report custom generation algorithms, the specific analysis is shown in Fig. 6.

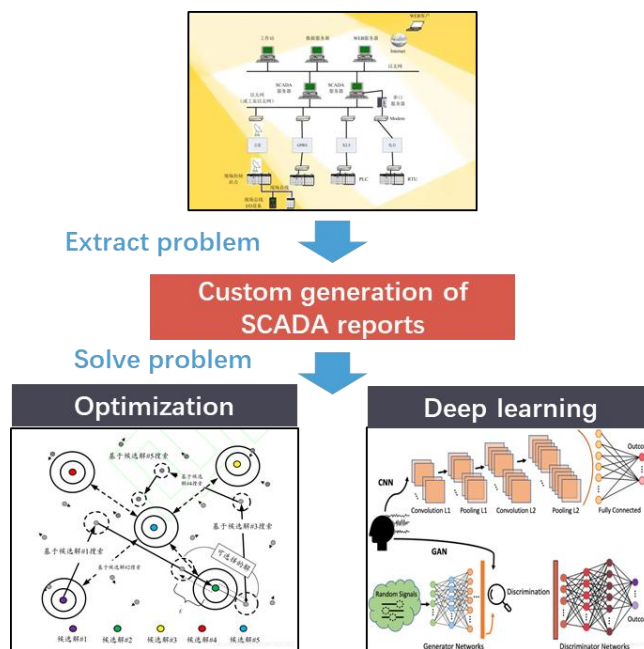

Fig. 6. Analysis of key technologies for customised generation of SCADA reports.

III. CUSTOMISED SCADA REPORT GENERATION

A. Adversarial Generative Networks

Adversarial Generative Networks (GANs) [21] were proposed by Goodfellow et al. and are shown in Fig. 7. The basic

GAN architecture consists of two fundamental components: a generator $G(z; \theta_g)$ and a discriminator $D(x; \theta_d)$ which work against each other. The generator captures the distribution P_g of data x from the noise variable $P_z(z)$ and generates

fake data that looks real and can deceive the discriminator; the discriminator distinguishes whether different categories are fake or not and acts as a classifier to model the probability of each category.

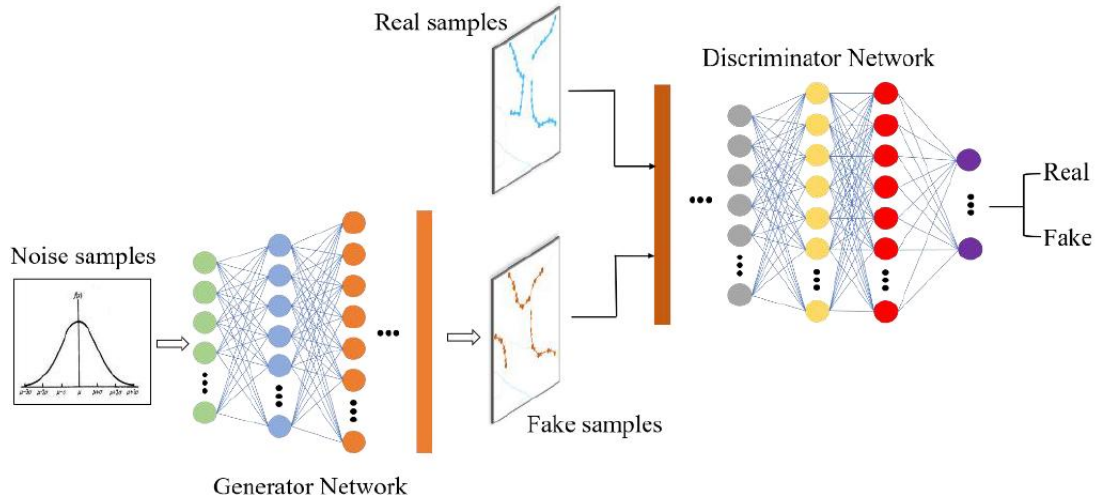

Fig. 7. Schematic diagram of GAN structure.

Ideally, the generator G can generate fake data with the data $G(z)$ and it is difficult for the discriminator to distinguish whether the data generated by G is real or not. Finally, the two

components reach dynamic equilibrium, i.e. $D(G(z)) = 0.5$:

$$\min_G \max_D V(D, G) = E_{x \sim p_{data}(x)} [\log D(x)] + E_{z \sim p(z)} [\log (1 - D(G(z)))] \quad (1)$$

GANs use only backpropagation and do not require complex Markov chains to compare with other generative models such as Boltzmann machines [22]. The main advantage of GANs is that they can automatically learn the distribution of the data from the original set of samples, generating clearer and more realistic samples. Even complex distributions can be learnt by a GAN if it is trained well enough.

GAN training process: during the training process, the generator and the discriminator are updated alternately. First, the weights of the discriminator are fixed and the generator is trained to produce more plausible data; then, the weights of the generator are fixed and the discriminator is trained to better distinguish real data from generated data [23]. This process is repeated until an equilibrium point is reached, at which point the generator is able to produce samples that are virtually indistinguishable from the real data, as shown in Fig. 8.

Fig. 8. GAN training process.

GANs are widely used in many fields such as image generation, image restoration, style migration, video generation, etc [24], as shown in Fig. 9. They are not only capable of generating high-quality images, but also play a role in tasks such

as image segmentation and video prediction. With the deepening of research, variants and improved versions of GANs have emerged to address the problems of the original GAN models in terms of training stability and pattern collapse.

Fig. 9. GAN application.

B. LSO-GAN Network

1) *LSO algorithm*: Light Spectrum Optimizer (LSO) [25] is a meta-heuristic algorithm, an optimisation algorithm based on spectral analysis, which simulates the spectral distribution and peak search process in spectral analysis. The algorithm adaptively adjusts the resolution of the search space and the search speed in order to find the optimal solution quickly and accurately, which has the characteristics of fast convergence and high solution accuracy. The optimization process of the LSO algorithm includes the optimization strategies such as initialization, generation of new coloured rays, and dispersion of the coloured rays, which are shown in Fig. 10.

Fig. 10. Analysis of optimisation strategy of LSO algorithm.

a) *Initialisation*: The LSO algorithm uses a random initialisation strategy to model the white light population:

$$x^0 = lb + RV_1 \times (ub - lb) \quad (2)$$

where x^0 denotes the white light initialisation population, lb and ub denote the search lower and upper bounds respectively, and RV_1 denotes the random vector.

b) *The direction of the rainbow spectrum*: After initialisation, the internal refraction normal vector, internal reflection normal vector and external refraction normal vector are calculated as follows:

$$x_{nA} = \frac{x_t^r}{\text{norm}(x_t^r)} \quad (3)$$

$$x_{nB} = \frac{x_t^p}{\text{norm}(x_t^p)} \quad (4)$$

$$x_{nC} = \frac{x^*}{\text{norm}(x^*)} \quad (5)$$

Where x_{nA} , x_{nB} and x_{nC} denote the internal refraction normal vector, internal reflection normal vector and external refraction normal vector respectively, x_t^r denotes the current randomly selected ray, x_t^p denotes the current ray individual,

and x^* denotes the current optimal ray individual. *norm* denotes the normalisation method.

For incident light, it is calculated using the averaging method with the following formula:

$$X_{mean} = \frac{\sum_{i=1}^N x_i}{N} \quad (6)$$

$$x_{L0} = \frac{X_{mean}}{norm(X_{mean})} \quad (7)$$

where x_{L0} denotes the incident light, X_{mean} denotes the average position information of the light population, and N is the population size magnitude.

The mathematical model for the calculation of internal and external refracted and reflected rays is as follows:

$$x_{L1} = \frac{1}{k^r} (x_{L0} - x_{nA} (x_{nA} \cdot x_{L0})) - x_{nA} \left| 1 - \frac{1}{(k^r)^2} + \frac{1}{(k^r)^2} (x_{nA} \cdot x_{L0})^2 \right|^{\frac{1}{2}} \quad (8)$$

$$x_{L2} = x_{L1} - 2x_{nB} (x_{L1} \cdot x_{nB}) \quad (9)$$

$$x_{L3} = k^r (x_{L2} - x_{nC} (x_{nC} \cdot x_{L2})) + x_{nC} \left| 1 - (k^r)^2 + (k^r)^2 (x_{nC} \cdot x_{L2})^2 \right|^{\frac{1}{2}} \quad (10)$$

Where x_{L1} , x_{L2} and x_{L3} denote refracted, internally reflected and externally refracted rays respectively, and k^r denotes the refractive index, a random spectral colour can be defined:

$$k^r = k^{red} + RV_1 (k^{violet} - k^{red}) \quad (11)$$

where RV_1 denotes a random number.

c) *Generation of new coloured rays (Exploration search mechanism)*: After calculating the light direction, the random vector is used to calculate and select the candidate solution location information as modelled below:

$$x_{t+1} = \begin{cases} x_t + \varepsilon RV_1^n GI (x_{L1} - x_{L3}) \times (x_{r1} - x_{r2}) & p < rand \\ x_t + \varepsilon RV_2^n GI (x_{L2} - x_{L3}) \times (x_{r3} - x_{r4}) & p \geq rand \end{cases} \quad (12)$$

Where x_{r1} , x_{r2} , x_{r3} and x_{r4} denote randomly selected light individuals, RV_1^n and RV_2^n denote uniformly distributed vectors, ε denotes the scaling factor, and GI is the adaptive control factor based on the inverse incomplete function.

$$\varepsilon = a \times RV_3^n \quad (13)$$

$$GI = a \times r^{-1} \times P^{-1}(a, 1) \quad (14)$$

$$a = RV_2 \left(1 - \frac{t}{T \max} \right) \quad (15)$$

Where RV_3^n denotes normally distributed random numbers with 0 as the mean and 1 as the standard deviation, a denotes adaptive parameters, r denotes random numbers, P^{-1} is the inverse incomplete function, t is the current number of iterations, and $T \max$ is the maximum number of iterations. Different values of a have different values of adaptive control factors, which mainly control the balance of development and exploration behaviour operations, the specific curve changes are shown in Fig. 11.

Fig. 11. Inverse incomplete function variation curve.

d) *Coloured light dispersion (Exploitation search mechanism)*: The optimisation model for the colour light dispersion phase is calculated as follows:

$$x_{t+1} = \begin{cases} x_t + RV_3 \times (x_{r1} - x_{r2}) + RV_4^n \times (R < \beta) \times (x^* - x_t) & R < P_e \\ 2 \cos(\pi \times r_1) (x^*) (x_t) & \text{Otherwise} \end{cases} \quad (16)$$

where RV_3 is a random number chosen between 0 and 1, RV_4^n is a random vector, x^* denotes the best ray individual, x_{r1} and x_{r2} denote randomly chosen ray individuals, r_1 denotes a random number, P_e denotes a predetermined probability, and R is a random number.

The final scattering phase is to generate new ray individuals based on random ray individuals and current individuals:

$$x_{t+1} = (x_{r1}^p + |RV_5| \times (x_{r2} - x_{r3})) \times U + (1 - U) \times x_t \quad (17)$$

Where RV_5 denotes normally distributed random numbers and U denotes that 0's and 1's are random vectors.

Switching Eq. (22) with Eq. (21) based on the difference in calculated fitness values is as follows:

$$x_{t+1} = \begin{cases} Eq.(21) & R < P_s | F' < R_1 \\ Eq.(22) & Otherwise \end{cases} \quad (18)$$

$$F' = \left| \frac{F - F_b}{F_b - F_w} \right| \quad (19)$$

Among them, F' denotes the normalised value of the fitness value of the current light individual (the relationship

between F' and R_1 is shown in Fig. 12), F , F_b and F_w denote the fitness values of the current individual, the optimal solution individual, and the worst solution individual, respectively, the predetermined probability P_s is used to promote the acceleration of the first dispersal stage and the second dispersal stage to the vicinity of the optimal solution, and R_1 and R are random numbers.

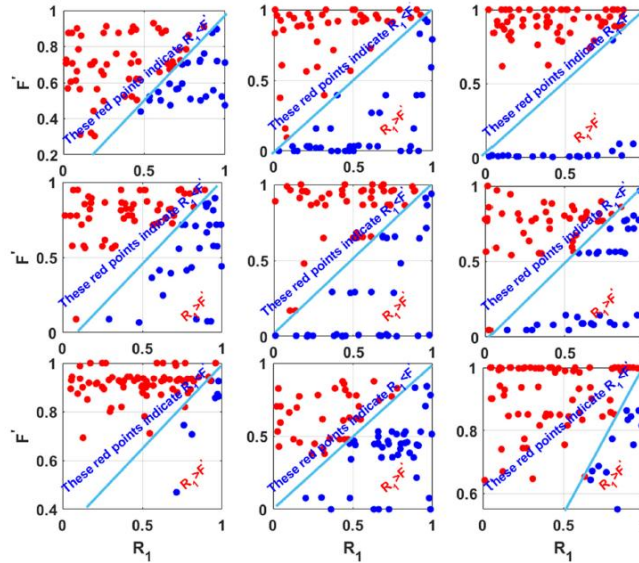

Fig. 12. Schematic diagram of the relationship between R1 and F'.

The pseudo-code of the LSO algorithm is shown in Table I.

TABLE I. PSEUDO-CODE OF LSO ALGORITHM

Algorithm 1: LSO algorithm pseudo-code

Inputs: ray population size N, maximum number of iterations Tmax;

- 1 Generating initialised random population rays;
- 2 t=0;
- 3 While t<Tmax
- 4 Evaluate light adaptation values;
- 5 t=t+1;
- 6 Update the optimal solution;
- 7 Calculate the ray normal vector;
- 8 Calculate refracted, internally reflected and externally refracted rays;
- 9 Update refractive index, scaling factor, adaptive control factor, adaptive parameters;
- 10 Generate random numbers p, q;
- 11 Update the light using the Exploration search mechanism;
- 12 Evaluate light adaptation values;
- 13 t=t+1; update the optimal solution;
- 14 Update the light using the Exploitation search mechanism;
- 15 End while

Output: optimal light and its adaptation value.

2) *LSO-GAN network*: In order to improve the efficiency of GAN network generation, this paper adopts the LSO algorithm to optimise the GAN hyper-parameters, and uses the RMSE as the fitness value to improve the optimisation of the GAN using the LSO optimisation strategy, and the specific optimisation structure is shown in Fig. 13.

Fig. 13. Principle of LSO-GAN structure.

C. LSO-GAN in Multi-Dimensional Data SCADA Report Customisation

In order to improve the efficiency of report generation, this paper adopts LSO-GAN network to build multi-dimensional data SCADA report custom generation model, the specific application is shown in Fig. 14. Based on LSO-GAN network multi-dimensional data SCADA report custom generation method mainly includes five parts: multi-dimensional data SCADA report design requirements analysis, report layout design, data selection and processing, SCADA report generation, generation model performance analysis. As the key part of the multi-dimensional data SCADA report customisation

problem, SCADA report generation uses LSO-GAN network to construct multi-dimensional data SCADA report customisation generation model by training the acquired SCADA data, and

realises the intelligent generation of SCADA report customisation.

Fig. 14. LSO-GAN network application analysis.

IV. EXPERIMENTAL ANALYSIS AND DISCUSSION

A. Environmental Settings

In order to verify the high efficiency of the LSO-GAN network application proposed in this paper, this paper takes the

SCADA system report data as the analysed data, and adopts Conv-LSTM, FC-LSTM, DyConv-LSTM, CNN-LSTM as the comparison algorithms of the LSO-GAN network, and the specific parameter settings are shown in Table II.

TABLE II. COMPARISON NETWORK PARAMETER SETTINGS

Arithmetic	Parameterisation
ConvLSTM	A GAN structure is used with ConvLSTM for generator and discriminator, Tanh activation function is used for generator and the discriminator output consists of Sigmoid activation function using Adam optimiser with learning rate 0.0002, batch size 64 and iteration number 400.
FC-LSTM	A GAN structure is used with FC-LSTM for the generator and discriminator, using the Adam optimiser with a learning rate of 0.0002, a batch size of 4 and an iteration count of 400.
DyConv-LSTM	A GAN structure is used, with DyConv-LSTM for generator and discriminator, Adam optimiser, learning rate 0.0002, batch size 16, and number of iterations 400.
CNN-LSTM	A GAN structure is used with CNN-LSTM for the generator and discriminator, Adam optimiser with a learning rate of 0.0002, batch size of 64 and 1000 iterations.
LSO-GAN	The population size of the LSO algorithm is chosen to be 100 and the maximum number of iterations is set to 400.

B. Presentation and Discussion of Results

1) *Analysis of the effect of custom report generation:* In order to verify the feasibility of the report custom generation effect, this paper takes the enterprise SCADA system report design as a case study, and obtains the effect diagrams in Fig. 15 and Fig. 16.

Fig. 15 gives the effect of SCADA system report user function privilege configuration. Administrators can bind

functional rights for roles in the Role Management - Function Configuration module, and then bind roles for users in the Personnel Management - Edit Personnel module, at which time users have the rights to the configured functions. Figure 16 shows the effect of the multi-dimensional data report of SCADA system. Users in this page according to the needs of flexible configuration of the number of conditions, page configuration is complete, click the "query" button, the system to implement the logic of the number of query results in the form of a list of displays to meet user needs.

Fig. 16. Multi-dimensional data report display effect.

2) *Algorithm performance analysis:* In order to verify the report generation effect of LSO-GAN network, this paper adopts Conv-LSTM, FC-LSTM, DyConv-LSTM, CNN-LSTM as the comparison algorithms, and evaluates the models in terms of RMSE, MAPE, training time, generation time, etc., and the specific results are shown in Table III, Fig. 17 to Fig. 20.

Table III gives the comparison of performance results of different SCADA multidimensional data report definition generation networks. From Table III, it can be seen that in terms of RMSE, the SCADA multidimensional data report definition generation method based on LSO-GAN network is better than other networks and has a value of 14.98, and in terms of MAPE, LSO-GAN network is better than Conv-LSTM, FC-LSTM, DyConv-LSTM, and CNN-LSTM, and has a value of 0.93.

TABLE III. COMPARISON OF THE PERFORMANCE OF DIFFERENT REPORT CUSTOM GENERATION NETWORKS

	Arithmetic	RMSE	MAPE
Conv-LSTM		15.98	0.89
FC-LSTM		16.79	0.86
DyConv-LSTM		28.67	2.25
CNN-LSTM		26.77	1.52
LSO-GAN		14.98	0.93

Fig. 17 gives the comparison of the accuracy of different networks for different time periods. From Fig. 17, it can be seen that the RMSE value of SCADA multidimensional data report definition generation method based on LSO-GAN network is less than other algorithms, which indicates that LSO-GAN network has better generation accuracy.

The training optimisation time and test generation time of different SCADA multidimensional data report custom generation methods are given in Fig. 18 and Fig. 19 respectively. From Fig. 18 and Fig. 19, it can be seen that the LSO-GAN network is ranked first in terms of both training optimisation time and test generation time, which are 38.4921s and 0.02772, respectively. This shows that the LSO-GAN network is the most efficient in generating reports.

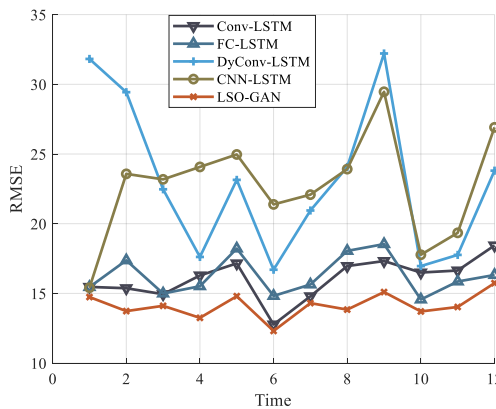

Fig. 17. Comparison of model accuracy performance of the compared algorithms.

Fig. 18. Comparison of training time for different report custom generation networks.

Fig. 19. Comparison of time spent on different report customisation generation networks.

Fig. 20 gives the effect of different parameters on the generative performance of the LSO-GAN algorithm. From Fig. 20, it can be seen that the error is high when the noise dimension is too low or too high; the model using 2-heads of self-attention has better performance than the model using 1-heads of self-attention layer, but with the increase of the number of heads, the error is increasing; the model is very sensitive to the hidden features, and the more hidden features in the dynamic convolution layer, the better the performance is, which indicates that the more the weights in the dynamic convolution, the better the ability to capture the statement Model.

(a) Noise dimension

Fig. 20. Effect of parameters on report generation.

V. CONCLUSION AND OUTLOOK

The document discusses a method for customizing the generation of multi-dimensional SCADA (Supervisory Control and Data Acquisition) reports based on web technologies. By introducing the Light Spectrum Optimizer Generative Adversarial Network (LSO-GAN) model, the method aims to improve report generation efficiency, reduce maintenance costs, and enhance scalability. The study demonstrates that LSO-GAN outperforms traditional models like Conv-LSTM and FC-LSTM in terms of accuracy and generation efficiency, achieving an RMSE of 14.98 and a MAPE of 0.93 in experiments.

- The study analyzes the requirements for multi-dimensional SCADA report customization and designs a web-based generation workflow.
- The LSO-GAN model, which integrates the Light Spectrum Optimizer algorithm, improves the hyperparameter optimization of GANs, significantly enhancing the efficiency and intelligence of report generation.
- Experimental validation shows that the method excels in accuracy, training time, and generation time, especially for handling and generating multi-dimensional data.

In the future, we could work on expanding the model's application to other domains with different multi-dimensional datasets to validate its broader applicability; investigating ways to simplify the model while maintaining efficiency, thus reducing deployment and operational costs; exploring enhanced security measures, particularly in scenarios involving sensitive data, to improve the robustness of the report generation system.

Abstract—In recent years, there has been increasing interest in intelligent optimization algorithms, such as the Whale Optimization Algorithm (WOA). Initially proposed for continuous domains, WOA mimics the hunting behavior of humpback whales and has been adapted for discrete domains through modifications. This paper presents a novel discrete Whale Optimization Algorithm approach, integrating the strengths of population-based and local-search algorithms for addressing the examination timetabling problem, a significant challenge many educational institutions face. This problem remains an active area of research and, to the authors' knowledge, has not been adequately addressed by the WOA algorithm. The method was evaluated using real-world data from the first semester of 2023/2024 for faculties at the Universiti of Sarawak, Malaysia. The problem incorporates standard and faculty-specified constraints commonly encountered in real-world scenarios, accommodating online and physical assessments. These constraints include resource utilization, exam spread, splitting exams for shared and non-shared rooms, and period preferences, effectively addressing the diverse requirements of faculties. The proposed method begins by generating an initial solution using a constructive heuristic. Then, several search methods were employed for comparison during the improvement phase, including three Variable Neighborhood Descent (VND) variations and two modified WOA algorithms employing five distinct neighborhoods. These methods have been rigorously tested and compared against proprietary heuristic-based software and manual methods. Among all approaches, the WOA integrated with the iterative threshold-based VND approach outperforms the others. Furthermore, a comparative analysis of the current decentralized approach, decentralized with re-optimization, and centralized approaches underscores the advantages of centralized scheduling in enhancing performance and adaptability.

Keywords—Examination timetabling; discrete whale optimization algorithm; variable neighborhood descent; capacitated; decentralized

I. INTRODUCTION

Educational timetabling involves assigning specific times to resources, events, and spaces while adhering to a predefined set of hard constraints and optimizing soft constraints. Resources typically encompass lecturers, teachers, students, administrative staff, or specialized equipment. Events may include lectures, classes, exams, or other academic activities.

Spaces refer to physical locations such as lecture halls, classrooms, or exam rooms.

Numerous formulations have been proposed for this problem, with the two most notable being the uncapacitated formulation introduced by [1] and the capacitated formulation featured as Exam 1 in the Second International Timetabling Competition, discussed by [2]. This study addresses a capacitated formulation of a real-world faculty exam timetabling problem (ETP) at the Universiti of Sarawak, Malaysia (UNIMAS). This problem stands out due to its unique combination of two approaches: online exam scheduling, which solely considers designated periods without considering physical room allocation, and physical exam scheduling, which involves assigning each exam to a specific period and room. Both exam scheduling strategies aim to prevent conflicts and optimize exam spacing, but the latter necessitates meeting room allocation constraints, such as dividing or sharing spaces.

Since ETP is an NP-complete decision problem [3], diverse approaches have been employed to address it. According to a recent study [4], there are six types of solution methods in the ETP. These are mathematical optimization, metaheuristics, heuristics, metaheuristics, hyper-heuristics, and hybrid approaches. The survey found that metaheuristics had been the approach most employed over the past 12 years.

Metaheuristics generally outperform exact search methods, as the latter often involves generating all possible solutions, which can be computationally intensive. Metaheuristic algorithms can be broadly divided into two categories: population-based algorithms, which emphasize exploration, and single-solution-based algorithms, which focus on exploitation. Effective metaheuristic design requires balancing two criteria: diversification, which involves exploring the search space broadly, and intensification, which focuses on refining and exploiting the most promising solutions [5].

An effective way to balance exploration and exploitation is by using a hybrid approach that integrates various techniques to enhance the performance of search algorithms. In this study, we introduce and design a novel hybrid method that combines the recently developed Whale Optimization Algorithm (WOA) with local search techniques to solve a real-world ETP. The following outline summarizes the main contributions of this work.

- Discrete WOA algorithm: A solution methodology that combines the WOA algorithm with local search methods is developed. This approach performs better than other VND variants in optimizing exam timetabling.
- Decentralized faculty exam timetabling: We propose a novel model that accommodates the preferences of multiple faculties with contradictory constraints, accounts for varied exam types, and ensures a more inclusive and flexible scheduling framework.
- Utilization of real-world data: The proposed discrete WOA approach is validated using real-world data, showcasing its robustness and practical relevance across various educational settings.

The paper is structured as follows: Section II presents a review of related works, followed by Section III, which outlines the problem description. Section IV discusses the original WOA, other applied methods and neighborhood structures. Section V details the algorithms of the proposed discrete WOA approaches. Section VI presents the experimental results, and Section VII compares the centralized and decentralized approaches. Lastly, Section VIII provides the conclusion of the study.

II. RELATED WORK

Real-world exam timetabling constraints are categorized into four main types [4]: exam-related, period-related, room-related, and invigilator-related. Real-world scenarios more commonly give rise to the capacitated formulation of ETPs, treating room capacities as adhered-to constraints. The constraints on room usage can vary significantly across problem formulations, ranging from limits on the number of exams allowed per room to considerations of individual room capacities and overall seating availability. Some studies extend this by considering the total seating capacity across all rooms within a time slot and the capacities of individual rooms [6–8]. In such cases, several exams may be assigned in the same room without restrictions on the number of exams if the total room capacity is sufficient to accommodate all the students requiring seating.

Dammak et al. [9] proposed a heuristic algorithm that modeled the exam-room assignment problem, allowing multiple exams in a single room. In contrast, other studies have also explored the possibility of scheduling multiple exams in a single room [10, 11]. Other room-related constraints studied include the distance between exam halls [12, 13], the allocation of exams across multiple rooms [12, 14] and assigning specific exams to designated rooms. We incorporate all these constraints—one exam per room, multiple exams per room, splitting exams across multiple rooms, and distance between rooms for split exams—into our approach on a faculty-specific basis.

Researchers have recently designed many intelligent algorithms, such as the Archimedes optimization algorithm [15], Fire Hawks algorithm [16], and WOA, to address various optimization challenges. Notably, the WOA, a swarm intelligence-based approach [17], models the hunting strategies

of humpback whales, mimicking their collective feeding behavior. Recent studies have enriched the growing literature by highlighting its successful practical applications and reporting enhanced results and performance [18]. Additionally, research suggests that WOA surpasses other optimization algorithms concerning global search capabilities and convergence speed [19]. The WOA offers several advantages, including simplicity of operation, minimal control parameters, and a robust capability to avoid local optima. These attributes have inspired researchers to employ WOA to address diverse practical challenges.

Although the WOA was originally developed for continuous problems, several studies have explored the use of the WOA for discrete optimization problems, including the knapsack problem [20, 21], feature selection [22–24], and workshop scheduling [25–27]. The primary strength of the WOA lies in its ability to maintain a balance between exploration and exploitation throughout the iterative process. While WOA has shown promise in various optimization problems across multiple domains, to the best of our knowledge, its application to real-world exam timetabling remains unexplored.

Hence, this study bridges this gap by adapting the WOA approach to meet the specific needs of our real-world ETP, offering a novel solution for discrete optimization in educational scheduling. Since WOA was originally designed for continuous optimization tasks, it relies on continuous updates to individual positions, making it unsuitable for discrete scheduling problems like exam timetabling. To overcome this limitation, we propose a modified discrete WOA, incorporating discrete updating strategies to tailor the algorithm to the discrete nature of timetabling. The real-world experimentation outlined in the following sections demonstrates its effectiveness in addressing practical exam timetabling while fulfilling institutional constraints.

III. PROBLEM DEFINITION

This paper presents a solution method for the ETP at UNIMAS. Specifically, we study the decentralized ETP within the Faculty of Economics and Business (FEB) and the Faculty of Computer Science and Information Technology (FCSIT). The data on students within the faculties has been collected and analyzed to evaluate the proposed solution algorithm.

The problem definitions are as follows:

- The exams will take place over two weeks.
- Each day is divided into two blocks.
- Exams have varying durations, such as 120, 150, and 180 minutes.
- If assigning an exam to a single room within a timeslot is not feasible, the exam must be split across multiple rooms.
- The exam day reserved for pre-assigned common courses should not be used for other exams.
- The exams include online exams conducted via an online platform and physical exams held in rooms.

- Online exams must be assigned to a predesignated slot.
- Shared or non-shared exam rooms will depend on each faculty's specific practices.
- There are two types of exam rooms: exam halls and faculty-owned exam rooms.
- Exam halls vary in availability based on the schedule set by the Centre, which range in size from medium to large.
- Faculty-owned exam rooms are consistently available for faculty exams and are typically small-sized.

The hard constraints are:

- H1: Each student may attend only one exam at any given time.
- H2: Each exam can only be scheduled once within the exam period.
- H3: The exam period must not exceed the designated days.
- H4: Rooms must be able to accommodate all students taking an exam during each timeslot.
- H5: Rooms can only be shared if the faculty permits; otherwise, no sharing is allowed.

The soft constraints include:

- S1: Minimize the number of rooms utilized.
- S2: Minimize proximity costs to ensure adequate time gaps between exams.
- S3: Minimize the splitting of exams across different areas or rooms.
- S4: Minimize violations of exams assigned to preferred timeslots.

A solution that violates soft constraints is not considered infeasible; this allows for defining specific objective values for each soft constraint. Consequently, the objective function f aims to minimize the total soft constraint violations, directing the optimization process toward reducing their overall impact. The end user typically determines the weights assigned to different types of soft conflicts. However, this study standardizes the weights by assigning fixed values: 1 for $S1$, $S2$, $S3$, and 2 for $S4$ to ensure reproducibility.

IV. METHODS

A. Constructive Heuristic Method

The proposed algorithm starts by generating initial feasible solutions, using a constructive heuristic method as the starting point. The process begins with assigning prioritized exams to their preferred time slots, followed by the allocation of online exams and, finally, the allocation of physical exams. We use a best-fit strategy for room allocation, choosing the smallest room that fits, minimizing room splits, and allocating several exams to the same room whenever feasible. The algorithm continues to allocate exams to rooms and periods while

ensuring compliance with hard constraints and adhering to the soft constraint of preferred slot assignments.

B. The Original WOA

The WOA is a recently developed swarm intelligence optimization algorithm commonly used to solve optimization and classical engineering problems. When whales locate prey, they swim in a spiral toward it while encircling and foraging using a bubble net. This process involves three hunting strategies: shrinking and attacking with a bubble-net attack, encircling prey, and randomly searching for prey. The first two strategies guide exploitation, while exploration is supported by the third within the WOA.

We present the mathematical model for each phase below, employing a uniform distribution to generate random numbers in the equations. In the following equations, t signifies the current iteration, x refers to the position vector, and $MaxIter$ indicates the maximum number of permitted iterations.

1) *Exploitation phase – encircling prey*: Humpback whales employ strategies described by the mathematical models in Eq. (1) and Eq. (2) to encircle and hunt their prey. As per Eq. (2), acting as search agents, whales adjust their positions relative to the prey—the current optimal solution, x^* . The coefficient vectors C and A , calculated using Eq. (3) and Eq. (4), adjust the search area to determine the whale's position relative to its prey. In both phases, the value of a decreases linearly from 2 to 0, while the vector r exhibits a uniform distribution within the interval $[0,1]$.

$$D = |C \cdot x^*(t) - x(t)| \quad (1)$$

$$x(t+1) = x^*(t) - A \cdot D \quad (2)$$

$$A = 2ar + a \quad (3)$$

$$C = 2r \quad (4)$$

2) *Exploitation phase – bubble-net attacking*: The shrinking, encircling behavior is governed by Eq. (5), while the position of a neighboring search agent is determined using a spiral equation as described in Eq. (6). D' denotes the distance from the i -th whale to the optimal solution, with b defining the shape of the logarithmic spiral and l being a random value within the range $[-1, 1]$.

$$a = 2 - t \cdot (2 / MaxIter) \quad (5)$$

$$x(t+1) = D' \cdot e^{bl} \cdot \cos(2\pi l) + x^*(t) \quad (6)$$

3) *Exploration phase – searching for prey*: For exploration, a random search agent is selected to guide the process, as mathematically represented by Eq. (7) and Eq. (8). Vector A contains random values exceeding one or falling below -1, while x_{rand} represents a randomly chosen whale from the population.

$$D = |C \cdot x_{rand} - x| \quad (7)$$

$$x(t+1) = |x_{rand} - A \cdot D| \quad (8)$$

Algorithm 1 delineates pseudocode for the original WOA, which starts by generating an initial population and evaluating it with a fitness function. During each iteration, a random value determines the update of a solution's position using either Eq. (2), Eq. (8), or Eq. (6) methods. The system returns the best solution x^* upon meeting the termination criteria.

Algorithm 1: Original WOA

```
Generate initial population  $x_i$  for  $i = 1, 2, \dots, n$ 
Compute each solution's fitness
Set the best search solution  $x^*$ 
 $t = 0$ 
While ( $t < MaxIter$ ) do
  For each solution do
    Update  $C, A, p, a$ , and  $l$ 
    If  $p < 0.5$  then
      If  $|A| < 1$  then
        Update the current solution's position by (2)
      Else
        Update the current solution's position by (8)
      End If
    Else
      Update the current solution's position by (5)
    End If
  End For
  Verify if any solution goes beyond the search space and amend it
  Compute each solution's fitness
   $t = t + 1$ 
  Update  $x^*$  if a better solution is found
End While
return  $x^*$ 
```

C. Variable Neighborhood Descent

Exploring a single neighborhood structure may result in finding a local optimum specific to that structure, but this is unlikely to be the global optimum. Conversely, identifying a solution that serves as a local optimum across multiple neighborhood structures enhances the likelihood of reaching the global optimum. This principle forms the foundation of the VND method. Specifically, a VND algorithm is employed to refine the solutions. VND is a deterministic variation of the Variable Neighborhood Descent framework initially proposed by [28]. It has been widely adopted as a local search method in numerous metaheuristics and implemented in diverse forms [29]. During its process, VND systematically explores different neighborhoods of a given solution to enhance its quality.

Algorithm 2 provides the pseudocode for the VND. The algorithm explores the neighborhood structures defined by the operators N_k , where $1 \leq k \leq k_{max}$, following a predefined order. $LocalSearch(x, N_k)$ indicates that a local search is performed

using the current neighborhood N_k , starting from solution x . The first-improvement strategy is applied to all neighborhood structures, as described in Subsection D. Specifically, when an improved solution is found within a specific neighborhood, the corresponding move is made, and the next neighborhood structure is explored. This procedure repeats until the maximum iteration limit is reached.

VND can employ various rules to transition between neighborhoods on its list and adopt diverse strategies to explore each. This flexibility gives rise to multiple VND variants, including Basic Sequential VND (BVND), Cyclic VND, Pipe VND (PVND), and Nested VND. These variants may utilize either the first-improvement or best-improvement search strategies. Algorithms 3 and 4 outline the neighborhood change procedure for both BVND and PVND, respectively. For the former, if a better candidate solution is found within a given neighborhood structure, the search resumes in the initial neighborhood structure based on the specified order. Otherwise, the search continues in the next neighborhood structure. For the latter, if the current solution improves within a particular neighborhood, exploration continues within that neighborhood.

Algorithm 2: Variable Neighborhood Descent

```
Procedure VND ( $x, N$ )
While ( $t < MaxIter$ ) do
   $stop = false$ 
   $k = 1$ 
   $x' = x$ 
  While ( $k \leq k_{max}$ )
     $x'' = LocalSearch(x, N_k)$ 
    neighborhood_change ( $x, x'', k$ )
  End While
End While
return  $x'$ 
```

Algorithm 3: Sequential Neighborhood Change for BVND

```
Procedure Sequential_neighborhood_change ( $x, x', k$ )
If  $f(x') < f(x)$  then
   $x = x'$ 
   $k = 1$ 
Else
   $k = k + 1$ 
End
```

Algorithm 4: Pipe Neighborhood Change for PVND

```
Procedure Pipe_neighborhood_change ( $x, x', k$ )
If  $f(x') < f(x)$  then
   $x = x'$ 
Else
   $k = k + 1$ 
End
```

D. Neighborhood Structure

The five types of neighborhood structures are implemented and described in the following:

- *Kick*: Assign exam e_1 to the period currently designated to exam e_2 , then reassign exam e_2 to a different period from the available options. The room for both exams may be available within the designated period.
- *Swap*: Exchange the periods of two exams, while their rooms may be swapped or assigned to different rooms.
- *Shift*: Move an exam to a different period and/or room(s).
- *Reallocate*: Move an exam assigned to a shared room to an unoccupied one.
- *Compact*: Relocate an exam to a shared room during the same period.

Swap, *Shift*, and *Kick* are moves related to both period and room assignments, whereas *Reallocate* and *Compact* focus specifically on room-related adjustments with contradictory objectives. *Reallocate* aims to address room-sharing preferences, especially in cases where certain faculties prohibit sharing. In contrast, *Compact*, which applies to most faculties, aims to reduce the number of rooms utilized, thereby encouraging room sharing. The neighborhood structure is set to $N = \{Swap, Shift, Kick, Reallocate\}$ for faculty exam timetabling where shared exam rooms are prohibited. Otherwise, the neighborhood structure is set to $N = \{Swap, Shift, Kick, Compact\}$.

V. PROPOSED APPROACH

This study proposes two algorithms: one based on the PVND algorithm and the other on WOA. Subsection A describes the first algorithm, Iterative Threshold-based Variable Neighborhood Descent (ITVND), while Subsection B presents the second algorithm, the modified discrete WOA.

A. Iterative Threshold-based Variable Neighborhood Descent

We propose a variant of the classic PVND, ITVND, with the pseudocode presented in Algorithm 5. The threshold-based pipe neighborhood change procedure is outlined in Algorithm 6. The ITVND algorithm incorporates a control parameter, the objective function threshold cT , and an input parameter, the iteration count L . We initially assign the objective value of the starting solution to cT . The iteration count increments in steps of L , and at every L -th iteration ($cT \bmod L = 0$), cT is updated to the current cost. The algorithm accepts all improving or sideways moves with an objective value below cT .

The algorithm explores the solution space using multiple neighborhood structures, where the neighborhood structure N_k is defined for $k = 1 \dots, k_{max}$. The core concept of ITVND is to maintain the objective value threshold across L iterations for various neighborhood structures. It permits accepting inferior solutions within the objective value threshold, introducing a more flexible acceptance condition, which slows the current cost reduction and prolongs the time needed to reach convergence.

Algorithm 5: Iterative Threshold-based Pipe Variable Neighborhood Descent

Procedure ITVND (x, N)

$t = 0$

While ($t < MaxIter$) do

$k = 1$

$x' = x$

 While ($k \leq k_{max}$)

$x'' = LocalSearch(x, N_k)$

 Threshold_pipe_neighborhood_change (x, x'', k, cT)

 End While

 If ($t \bmod L = 0$) then

$cT = f(x)$

 End If

$t = t + 1$

End While

return x'

Algorithm 6: Threshold Pipe Neighborhood Change

Procedure Threshold-based_pipe_neighborhood_change (x, x', k, cT)

If $f(x') < cT$ or $f(x') < f(x)$ then

$x = x'$

Else

$k = k + 1$

End

B. Discrete Whale Optimization Algorithm

As whales adjust their positions within a continuous domain using specific equations and operators, the original WOA becomes unsuitable for tasks like timetabling, which exhibit discrete characteristics. While the classical WOA algorithm relies on whale interactions to solve optimization problems, its simple neighborhood structure and limited disturbance tend to trap it in local optima. To address this problem, we replaced these equations and operators with a local search mechanism. The proposed modified discrete WOA approach considers two methods: (1) WOA-VD and (2) WOA-IVD. As shown in Algorithm 7, the process begins with a set of solutions generated using a constructive heuristic, then iteratively refined throughout the search process.

During the exploitation phase, the modified discrete WOA algorithm updates individual solutions using information from the best current solution. When probability p is less than 0.5, the algorithm utilizes local search with an improvement criterion, accepting a new solution only if it enhances the current solution's fitness, thereby supplanting Eq. (2). If p is equal to or greater than 0.5, PVND is chosen as a local search method to improve the solution in WOA-VD algorithm. In contrast, the ITVND local search method is used in the WOA-IVD algorithm to compare the effectiveness of the VND variation during the search process. Both methods replace Eq. (5) and take advantage of its ability to search for a larger area by changing neighborhoods in a planned way.

During exploration, local search with a threshold-based acceptance criterion replaces Eq. (8). A new candidate solution is accepted if its objective value falls below a dynamically updated cost bound. This approach helps explore the search space more effectively by mitigating the effects of premature

convergence and promoting broader exploration outside the immediate neighborhood of the current optimal solution.

Algorithm 7: Discrete WOA-VD

```

Generate initial population  $x_i$  for  $i = 1, 2, \dots, n$ 
Compute each solution's objective value
Initialize the best search solution  $x^*$ 
 $t = 0$ 
While ( $t < MaxIter$ ) do
    For each solution individual do
        Update  $a, A, C, l$  and  $p$ 
        If  $p < 0.5$  then
            If  $|A| < 1$  then
                Generate new candidate  $x'$ 
                If  $f(x') < f(x)$  then
                     $x = x'$ 
                End If
            Else
                Generate new candidate  $x'$ 
                If  $f(x') < cBound$  then
                     $x = x'$ 
                End If
                If  $(t \bmod L = 0)$  then
                     $cBound = f(x)$ 
                End If
            End If
        Else
            Apply PVND ( $x, N$ ) to improve  $x$ 
        End If
    End For
    Calculate each solution's objective value
     $t = t + 1$ 
    Update  $x^*$  if a better solution is found
End While
return  $x^*$ 

```

Our search method is based on local search and leverages the following characteristics:

- *Termination Criterion:* A fixed number of iterations as the termination criterion ensures that the algorithm's runtime remains consistent and independent of other parameters.
- *Search Space:* The search space is restricted to the feasible region, which only includes scheduling that fully satisfies all constraints, such as precedence and conflict avoidance.

VI. EXPERIMENTS

A. Experimental Settings

The experiment is conducted on a computer with Windows 11, equipped with an Intel® Core™ i7 processor, 16.0 GB of memory, and an integrated graphics card. We built the algorithms presented using IntelliJ IDEA, the Integrated Development Environment (IDE), and Java, specifically JDK

1.8, as the programming language. Table I presents the characteristics of the datasets collected from two faculties. These datasets specifically pertain to the first semester of the 2023/2024 academic year.

TABLE I. CHARACTERISTICS OF DATASETS FROM TWO FACULTIES

Description	Dataset	
	FCSIT	FEB
No. of enrolment	2,837	7,035
No. of students	1,026	2,011
No. of exams	31	55
Exam range per student	1 to 5	1 to 8
Conflict density	0.234	0.182
Exam Types	Online & Physical	Physical
Total exam period	12 days	12 days
Average Shared Hall Usage per Timeslot	1.8	3.1
Faculty-Owned Exam Room Count	10	6
Scheduling method	Manually arranged	Proprietary System

To evaluate the performance of our proposed algorithms, we compared them against other methods and the existing scheduling method, which generates the current solution. The five include three variations of VND: BVND, PVND, and ITVND, along with two variations of WOA: WOA-VD and WOA-IVD. For each of these algorithms, we conducted 30 independent runs per dataset.

B. Experimental Results

Table II below presents the descriptive statistics for the three employed algorithms compared to the existing scheduling method based on 30 runs. The bold formatting indicates the best values achieved by all the methods. We conducted all statistical analyses using SPSS version 29.

TABLE II. COMPARISON BETWEEN DIFFERENT METHODS

Dataset	Method	Slot	Best	Mean	Worst	Std Dev
FCSIT	Manual	12	55.6			
	BVND	8	50.4	53.7	57.3	1.97
	PVND	8	50.1	53.1	56.3	1.48
	ITVND	8	49.4	51.6	54.7	1.41
	WOA-VD	8	49.9	52.9	57.8	2.09
	WOA-IVD	8	48.7	51.2	53.7	1.28
FEB	Proprietary System	12	148.6			
	BVND	12	131.8	134.6	138.3	1.77
	PVND	12	132.2	134.7	137.0	1.24
	ITVND	12	130.3	132.4	134.6	1.22
	WOA-VD	12	131.0	132.9	135.3	1.13
	WOA-IVD	12	129.9	131.9	133.6	1.04

For the FCSIT dataset, Table II shows that WOA-IVD emerges as the best-performing method among the tested methods, with the lowest objective value (48.7) and the lowest standard deviation (1.28), demonstrating consistent performance. The second-best method is ITVND, which has a slightly higher objective value (49.4) but maintains low variability (1.41). In contrast, despite its competitive mean value, the WOA-VD method has the highest variability (2.09), indicating less consistent results than others.

In comparing the performance of various methods for the FEB dataset, all our proposed methods outperform the proprietary system [30], which employed two-stage heuristic methods across all instances, with a moderate gap. The best-performing method, WOA-IVD, achieved an average of 131.9 with a standard deviation 1.04. ITVND followed closely with an average value of 132.4 and a standard deviation 1.22. However, the results for BVND and PVND are somewhat inferior, with some instances where they perform poorly compared to the ITVND and WOA models.

Overall, the results demonstrate that adopting all the VND and WOA variation methods reduces exam session and objective value compared to the manual approach. The WOA-IVD method performs the best across both datasets, consistently achieving the lowest mean values and demonstrating superior efficiency compared to other methods. On the other hand, VND tends to perform the worst, showing higher values in comparison.

We conducted a one-way ANOVA analysis of variance, as presented in Table III for dataset FCSIT and Table IV for dataset FEB, to statistically demonstrate the differences among all employed methods, BVND, PVND, ITVND, WOA-VD, and WOA-IVD, presented in Table II. The results for both datasets indicate a statistically significant difference between the tested approaches, with a p-value below 0.001.

TABLE III. ANOVA FOR FCSIT DATASET OF THE ALGORITHMS

Source	DF	Sum of Squares	Mean Square	F	Signature
Between Groups	4	132.209	33.052	11.772	<.001
Within Groups	145	407.131	2.808		
Total	149	539.340			

TABLE IV. ANOVA FOR FEB DATASET OF THE ALGORITHMS

Source	DF	Sum of Squares	Mean Square	F	Signature
Between Groups	4	198.958	49.739	29.289	<.001
Within Groups	145	246.247	1.698		
Total	149	445.204			

Fig. 1 and 2 present the box plots for two datasets generated using Tableau software. The lower mean, median, and distribution values in both box plots show that WOA-IVD is consistently the best method. The fact that its box plot height is lower than other algorithms in both datasets further

demonstrates this. For the FCSIT dataset, as shown in the box plot in Fig. 1, WOA-VD performs the worst due to its higher spread and maximum values, suggesting poor performance in worst-case scenarios. For the FEB dataset, as shown in the box plot in Fig. 2, BVND has the largest spread and includes higher maximum values, indicating it performs less reliably and worse in the worst-case scenarios. The proposed WOA-IVD approach effectively balances the objectives of exploration and exploitation, as the tested approaches' performance ranks BVND, PVND, WOA-VD, ITVND, and WOA-IVD.

The results highlight the consistent effectiveness of our discrete WOA method, achieving an objective value reduction of approximately 12.41% for the FCSIT dataset and 12.58% for the FEB dataset. This consistency underscores the method's reliability and adaptability, making it a practical solution for diverse scenarios. However, the proposed discrete modified WOA may be constrained by the need to adapt the local search method in the WOA model, which is currently tailored to our ETP problem instance and might require modification to address different problem constraints or domains.

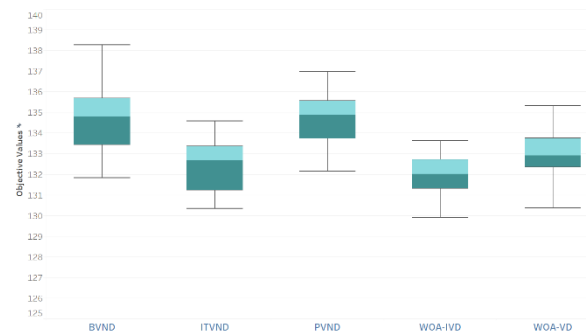

Fig. 2. Box plots of objective values for FEB dataset.

VII. CENTRALIZED AND DECENTRALIZED

A comparison of centralized and decentralized approaches to university exam timetabling during the pandemic was conducted by Modirghorassani and Hoseinpour [31], focusing on minimizing costs and ensuring social distancing, with the study underscoring the advantages of decentralization. Building on this and given that our current practice employs a decentralized approach at the faculty level, we intend to conduct a similar comparison using our objective function for cost evaluation to better align with our specific operational context. A comparative analysis is conducted to evaluate the effects of three scheduling methods:

1) *Decentralized approach*: the current practice whereby faculty schedule their timetables independently.

2) *Centralized approach*: All faculty exams are scheduled, with resources managed centrally. It employs a uniform 12-timeslot structure, ensuring consistency in completing exam sessions across datasets.

3) *Decentralized approach with re-optimization*: Similar to the first approach, only that re-optimization is performed after post-resource reallocation. If a faculty's exam session concludes earlier than others, the shared resources are reallocated for use by other faculties that take longer exam sessions.

The comparative analysis aims to determine the relative impacts of these approaches on scheduling efficiency and overall outcomes. The centralized and decentralized approaches are compared in Table V, with and without the re-optimization strategy for the decentralized approach. The comparison is made across four soft constraints (*S1–S4*) based on their objective values. The bold formatting indicates the best values achieved by the approaches.

TABLE V. PERFORMANCE OF SCHEDULING UNDER CENTRALIZED AND DECENTRALIZED APPROACHES

Value	Decentralized		Centralized
	Without Re-optimization	With Re-optimization	
S1	92.0	82.3	86.0
S2	37.2	43.9	19.5
S3	33.9	25.4	29.1
S4	16.0	20.4	9.8
Total	179.3	172.0	144.5

The decentralized approach with re-optimization has shown superior efficiency in resource allocation, as evidenced by its lowest values in both *S1* and *S3*, which pertain to room usage and splitting. However, it is less effective for other constraints, such as *S2* and *S4*, which are related to spread and preferred slot, where it performs worse than the decentralized approach without re-optimization. While re-optimization enhances performance in certain aspects, it may not universally improve outcomes across all constraints. Despite this, the centralized approach remains the most efficient overall.

For the decentralized approach, values without re-optimization are generally higher, indicating that re-optimization improves efficiency. In contrast, the centralized approach consistently produces lower values than both decentralized approaches, underscoring its overall efficiency. The total objective values further support this trend, with the centralized approach achieving the lowest total (144.5), followed by the decentralized approach with re-optimization (172.0) and without re-optimization (179.3). It shows a reduction of approximately 15.9% in the total objective value, calculated as $(172.0 - 144.5) / 172.0 \times 100$. This improvement highlights the effectiveness of the centralized approach in enhancing the solution's overall quality. However, the comparative analysis of centralized and decentralized

approaches is incomplete, as it encompasses only a limited subset of faculties rather than the entire scope, thereby leaving this aspect open for further exploration.

VIII. CONCLUSION

This study examines decentralized faculty exam timetabling to optimize resource allocation and satisfy institutional constraints while designing an approach that can be adopted across multiple faculties. The ETP under consideration accommodates two distinct exam modes and formulations within the same timetable. This structure is notably different from those commonly found in literature and, to our knowledge, has not been previously studied. We propose two approaches: ITVND, an improved version of VND, and a novel discrete WOA. Specifically, we embedded the different local search strategies in the WOA algorithm to ensure they work well in the discrete scheduling domain. We used a real-world dataset to validate the proposed algorithm's practicality, highlighting its applicability across various faculties while adhering to their specific constraints. Our search methods have been rigorously tested and compared internally and against proprietary software developed using heuristic and manual methods. These comparisons highlight that the discrete WOA outperforms other approaches, demonstrating superior performance, though it takes slightly longer. While the preliminary results provide proof of concept, further experimentation with additional examination timetabling datasets, such as benchmark sets, could provide valuable insights. We consider hybridizing the WOA algorithm with other metaheuristic algorithms for future studies.

Department of Chinese Studies of Kyungsoong University, Pusan 48434, Pusan, Korea²

Abstract—Sentiment analysis of video comment text has important application value in modern social media and opinion management. By conducting sentiment analysis on video comments, we can better understand the emotional tendency of users, optimise content recommendation, and effectively manage public opinion, which is of great practical significance to the push of video content. Aiming at the current video comment text sentiment analysis methods problems such as understanding ambiguity, complex construction, and low accuracy. This paper proposes a sentiment analysis method based on the M-S multimodal sentiment model. Firstly, briefly describes the existing methods of video comment text sentiment analysis and their advantages and disadvantages; then it studies the key steps of multimodal sentiment analysis, and proposes a multimodal sentiment model based on the M-S multimodal sentiment model; finally, the efficiency of the experimental data from the Communist Youth League video comment text was verified through simulation experiments. The results show that the proposed model improves the accuracy and real-time performance of the prediction model, and solves the problem that the time complexity of the model is too large for practical application in the existing multimodal sentiment analysis task of the video comment text sentiment analysis method, and the interrelationships and mutual influences of the multimodal information are not considered.

Keywords—Video commentary text sentiment analysis; multimodal information fusion; M-S multimodal sentiment model; convolutional neural network

I. INTRODUCTION

Due to the prevalence of the Internet and the advancement of social media, video platforms like YouTube and Jitterbug have emerged as significant avenues for users to express their views and sentiments [1]. The massive video comment data generated on these platforms provide rich materials for sentiment analysis. The foundation for sentiment analysis of video comments is laid by the advancement of sentiment analysis technologies, particularly the breakthrough in text sentiment analysis [2]. Although sentiment analysis of video comment language has gained a lot of attention lately, there are still several issues with the current approaches. Many of the current video commentaries sentiment analysis methods mainly rely on textual modality, while ignoring the rich visual and auditory information contained in the video [3]. This unimodal approach to analysis has obvious limitations because emotional information in videos is not only expressed through text, but also conveyed through multiple channels such as facial expressions, voice intonation, and body language [4]. This process usually involves sentiment lexicon methods, which determine sentiment polarity by comparing with sentiment lexicon, and machine

learning methods, which improve the accuracy and adaptability of sentiment recognition by training machine learning models. Sentiment analysis has important applications in several fields, especially in opinion monitoring and marketing [5].

Currently Video Commentary Text Sentiment Analysis is a hot area of current research, and there are various methods and techniques, the dictionary-based method mainly relies on sentiment dictionary [6], which calculates the sentiment tendency by matching the sentiment words in the text. This method is simple and direct, but requires the support of a high-quality sentiment dictionary. Machine learning-based methods perform well on specific datasets by constructing feature vectors [7] and combining algorithms such as Support Vector Machines (SVMs) and Plain Bayes to perform sentiment classification, but this method requires the manual design of the features; deep learning methods automatically learn features through neural networks [8], which are widely used in text sentiment analysis, but the calculation is more complicated. Research indicates that multimodal sentiment analysis, which integrates visual and audio data, can markedly enhance the precision of sentiment recognition [9].

Aiming at the problems of sentiment polysemy, noise interference, dynamic change of sentiment vocabulary, cross-domain differences in sentiment, and insufficient deep semantic understanding in video comment text sentiment analysis [10], this paper proposes a M-S based multimodal sentiment model. The main main contributions of this paper are (1) analysing the main methods of video review text sentiment analysis and sorting out the related techniques; (2) designing an M-S based multimodal sentiment model; and (3) validating and analysing the evaluation model using related datasets.

II. VIDEO REVIEW OF TEXTUAL EMOTIONS ANALYSIS METHODOLOGY

At present, text emotion classification studies usually classify text emotion tendency into positive and negative. Positive emotion means that the text has a positive attitude, and negative emotion means that the text has a negative attitude. However, due to the characteristics of the Internet itself, such as openness and randomness, video comments usually contain a large number of non-standard linguistic phenomena, such as misspelled words, abbreviations, Internet slang, etc., so a large number of different sentiment analysis methods have emerged.

A. Dictionary-based Approach

The sentiment lexicon plays an important role in textual sentiment analysis by matching words with predefined

sentiment categories (e.g., positive, negative) [11], as shown in Fig. 1.

Fig. 1. Dictionary-based approach to text sentiment analysis

B. Machine Learning Methods

Support vector machines (SVMs), plain bayes, and logistic regression are among the frequently used algorithms in machine learning techniques, which are extensively employed in sentiment analysis [12], as shown in Fig. 2. These methods improve classification performance through feature selection and extraction techniques such as bag-of-words models and n-gram features. However, these methods may face computational inefficiency when dealing with large-scale data and require a large amount of labelled data for model training.

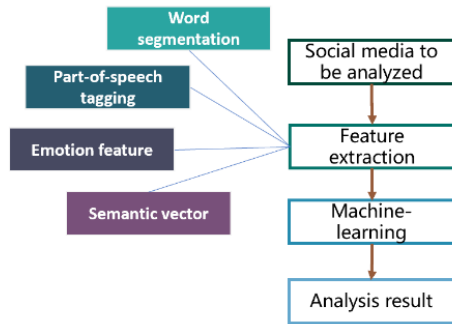

Fig. 2. Sentiment analysis of text based on machine learning approach analysis.

C. Deep Learning Methods

Deep learning methods have made significant progress in sentiment analysis, mainly through models such as Convolutional Neural Networks (CNNs), Long Short-Term Memory Networks (LSTMs) and BERT [13]. These models are able to automatically learn complex features in text without the

need to manually design features, which improves the accuracy of sentiment classification, as shown in Fig. 3.

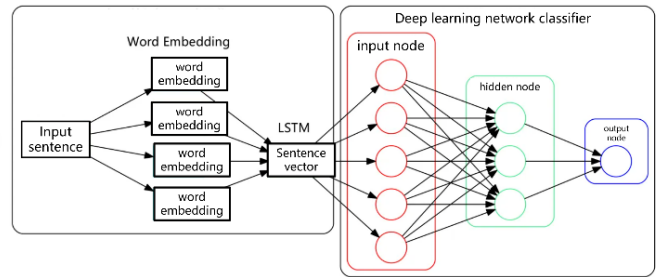

Fig. 3. Sentiment analysis of text based on deep learning approach.

D. Fine-Grained Sentiment Analysis

Fine-grained sentiment analysis focuses on identifying and analysing specific attributes in reviews and their emotional tendencies [14], which can provide more accurate sentiment analysis results. This approach classifies the polarity of comments by identifying object attributes and their corresponding sentiment words, as shown in Fig. 4.

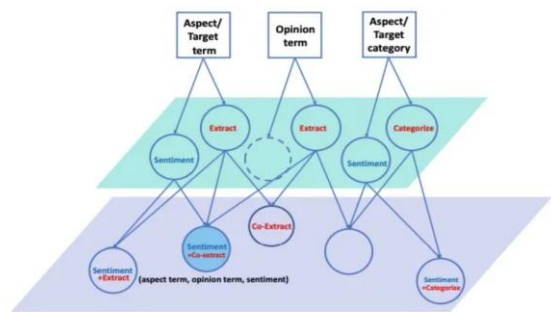

Fig. 4. Sentiment analysis of text based on fine-grained sentiment analysis.

E. Multimodal Sentiment Analysis

Multimodal sentiment analysis integrates many forms of information, including text, audio, and video, to facilitate sentiment recognition [15], thereby providing a more thorough comprehension of the user's emotional disposition. This method enhances the precision of sentiment analysis via modal fusion techniques, including feature-level fusion and decision-level fusion, as seen in Fig. 5.

Fig. 5. Sentiment analysis of text based on multimodal information.

III. MULTIMODAL INFORMATION SENTIMENT ANALYSIS

The specific operation of the multimodal sentiment analysis task for video comment text is shown in Fig. 6. Firstly, the information of different modalities is fed into the feature extraction model, then the extracted features are fused into the feature fusion according to a certain fusion method, and finally the fused features are fed into the classifier to perform sentiment analysis on the multimodal data [16].

Fig. 6. Multimodal sentiment analysis architecture.

A. Feature Extraction in Multimodal Sentiment Analysis

Extraction of representative features from all modal data utilized in subsequent fusion tasks is referred to as feature extraction in multimodal sentiment analysis. Multimodal sentiment analysis tasks in machine learning, deep learning, artificial intelligence, natural language processing, image processing, and audio processing depend on feature extraction, and the accuracy and speed of the model operation can be directly impacted by the quality of feature extraction [17].

The objective of feature extraction is to derive more representative and interpretable features from the source data to enhance its description and differentiation. Feature extraction typically encompasses the subsequent steps: 1) Data preprocessing; 2) Feature selection; 3) Feature extraction; and 4) Dimensionality reduction of features.

B. Feature Fusion in Multimodal Sentiment Analysis

In the process of multimodal sentiment analysis, the feature extraction stage is not significantly different from the unimodal feature extraction method. However, the core difference between multimodal sentiment analysis and unimodal analysis lies in how to effectively fuse the information from different modalities to derive accurate sentiment polarity.

The methods of feature fusion mainly include feature-level fusion (Feature-level fusion) and decision-level fusion (Decision-level fusion), as shown in Fig. 7 and Fig. 8.

Fig. 7. Feature level fusion.

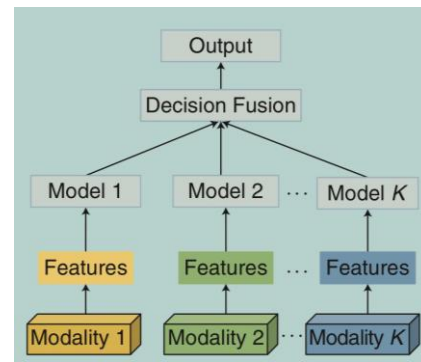

Fig. 8. Decision-level fusion.

Feature-level fusion (FLF) refers to the fusion of multiple features from different feature extraction methods or feature representations to generate a more representative and enriched feature vector. Feature-level fusion is one of the most commonly used methods for multimodal data fusion, and by fusing features from different modalities, a more comprehensive, accurate and robust feature representation can be extracted, thus improving the performance of the model.

Decision-level fusion (DLF) is a fusion strategy in which the features of each modality are first analysed individually, and the results of their respective analyses are subsequently integrated into a single decision vector to arrive at a final decision. The significant advantage of this fusion approach is that when data is missing for one modality, it is still possible to rely on information from other modalities for decision making.

IV. SENTIMENT ANALYSIS BASED ON THE M-S MULTIMODAL SENTIMENT MODEL RESEARCH

A. M-S Model Multimodal Fusion Sentiment Analysis Model

In this paper, a novel fusion model M-S model Multimodal Fusion Sentiment Analysis Model is proposed to perform the task of video comment text sentiment analysis as shown in Fig. 9. This model firstly uses a one-dimensional convolutional neural network to extract the text information, audio information, and image information, and the three modal features Feature-L, Feature-A, and Feature-V (text feature, audio feature, and image feature) obtained, and then the obtained features are sent to the Transformer-layer to be processed, and then the features containing cross-modal The features containing cross-modal attention information (Cross-modal attention Feature-X→Feature-Y), and the features of different modalities are sent to the main and sub dual channels for processing according to their importance, and finally, the processed features of the two channels are sent to the Fully Connected Layer (FC-layer) for processing, and are outputted to the Softmax classifier for classification.

This paper aims to propose a lightweight model with low time complexity that is easy to implement. Therefore, the most fundamental one-dimensional convolutional neural network is selected for feature extraction, while the Transformer model (Fig. 10) is utilized for feature processing to investigate the relationships and influences of various modalities. By fine-tuning critical parameters in the Transformer, it significantly contributes to both cross-modal attention and multi-modal

feature fusion. By modifying the critical parameters in the Transformer, it significantly contributes to both cross-modal attention and multi-modal feature fusion. The primary and

secondary dual-channel fusion approach introduced in this study enables the model to achieve high accuracy and stability.

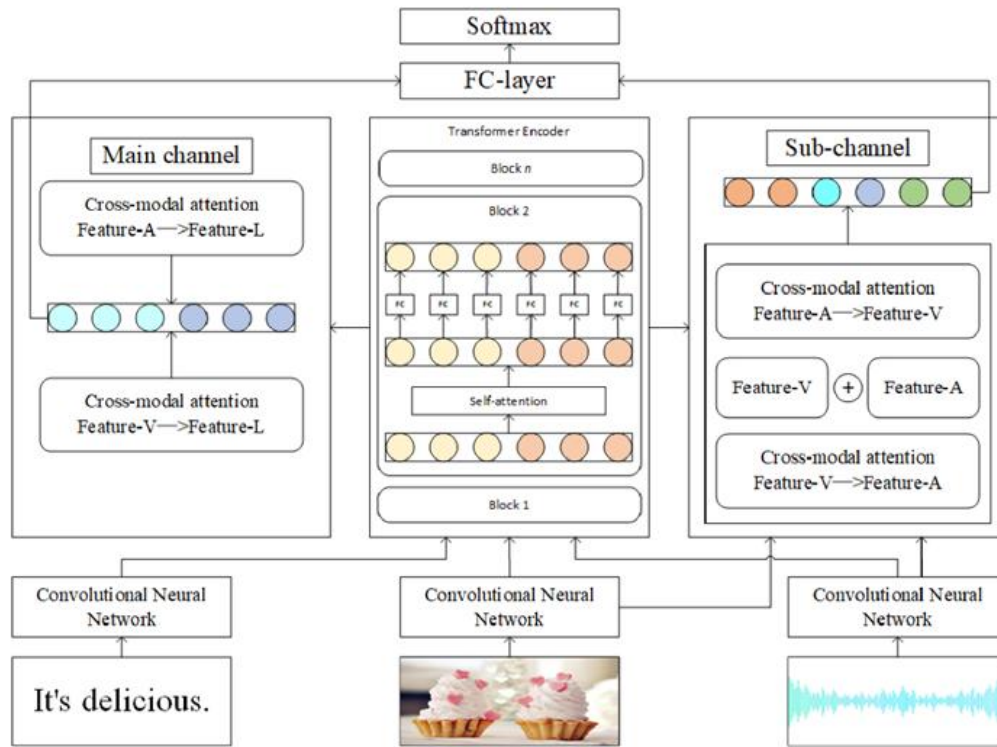

Fig. 9. M-S model.

Multimodal information feature extraction: In this paper, we use 1D Convolutional Neural Network (1D-CNN) for text information, image information, and audio information, which is a variant of convolutional neural network, and compared with traditional fully-connected neural network, 1D-CNN can better deal with localised Relationships. Considering that multimodal datasets are often video-based, resulting in three modes of data containing time series, 1D convolutional networks can effectively extract the features of each mode in the dataset, as shown in Fig. 11.

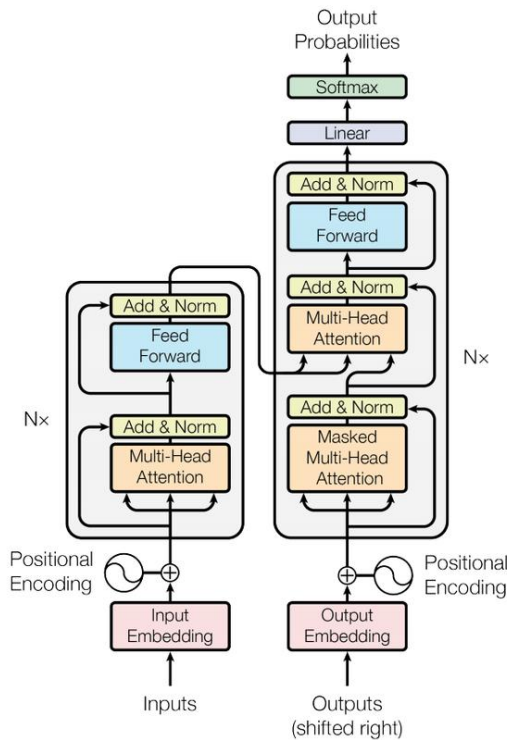

Fig. 10. Transformer model.

Fig. 11. One-dimensional convolutional neural network.

This paper employs a Transformer-based feature fusion model for multimodal sentiment analysis, emphasizing the significance of fused features in influencing outcomes. The objective is to preserve or enhance the maximum information prior to fusion, utilizing the Transformer encoding and decoding techniques for feature integration. The fusion method ensures

that the extracted features optimally preserve the characteristics prior to fusion, after which the three modal features are combined and encoded to provide a segment of the fused features post-fusion. Subsequently, the fully connected method is employed, incorporating a Dropout layer to mitigate overfitting. The FC-layer consists of two Dropout layers, two Linear layers, and one ReLU activation layer, after which the resultant features are input into a Softmax classifier to derive their sentiment class labels.

B. Multimodal Information Feature Extraction

A one-dimensional convolutional neural network is a specialized neural network designed for sequence data processing, comprising an input layer, a convolutional layer, and a pooling layer, as seen in Fig. 11. The input layer incorporates information from three distinct modalities, while the convolutional layer is trainable to derive an optimal set of convolutional kernels that minimize the loss function, hence facilitating automatic feature extraction.

$A = [a_1, a_2, L, a_s]^T$ is passed as model input to the input layer, where $A \in \mathbb{R}^{s \times d}$ is the time series, s is the length of the time series, and d is the number of eigenvalues. a_i denotes the feature vector at the time of i , with the dimension of d . The sequence data is mapped into convolutional layer by one dimensional convolution operation:

$$f_r(z) = \max(z, 0) \quad (1)$$

$$y_c^j = f_r(A \otimes W_c^j + b) \quad (2)$$

Where: \otimes denotes one-dimensional convolution operation; y_c^j denotes the j th feature mapping generated by the convolution kernel w_c^j , $j \in [1, n_c]$, n_c denotes the number of convolution kernels, and the convolution kernel $W_c^j \in \mathbb{R}^{m \times d}$ is a weight matrix, where m is the size of the convolution kernel, and m denotes the width of the local time window for extracting the time series features for the time series; b is the bias; and $f_r(z)$ is the activation function (ReLU activation function), which is used to non-linearise the data after the convolution operation.

The pooling procedure is employed to extract the most pertinent information on the sequence of features in the convolutional layer, hence creating the pooling layer. This article employs max-pooling to aggregate the features. Upon the final application of the pooling procedure, global max-pooling is employed to extract the most pertinent global temporal information, resulting in a sequence length of 1, and the features of the three modalities are extracted from the information y_p^j .

$$y_p^j(k) = \max(y_c^j(2k-1), y_c^j(2k)) \quad (3)$$

$$y_p^j_{,last} = \max(y_c^j) \quad (4)$$

V. EXPERIMENTS AND ANALYSIS OF RESULTS

A. Baseline Modelling

1) *MCTN model*: The method introduces an innovative strategy to learn robust transitions between joint representations modalities through a translation process [18]. Specifically, the translation process from source to target modality not only provides a new way to learn joint representations, but also requires only the modality of the source modality as input. In order to further strengthen the translation effect of modalities, the method utilises cyclic consistency loss to ensure that the joint representation retains the maximum information of all modalities, as shown in Fig. 12.

2) *LMF model*: While previous studies have explored the tensor expressivity of multimodal representations, these methods often suffer from a dramatic increase in dimensionality and computational complexity due to the transformation of inputs into tensors [19]. To address this issue, this method proposes a low-rank multimodal fusion strategy that utilises a low-rank tensor for multimodal fusion, thus significantly improving the efficiency, as shown in Fig. 13.

3) *TFN model*: The model redefines the problem of multimodal sentiment analysis as a problem of modelling intra- and inter-modal dynamics [20]. To this end, it introduces a novel model, the tensor fusion network, which is capable of learning both dynamics end-to-end. The method is optimised especially for the instability of spoken language in online videos and the accompanying gestures and speech, as shown in Fig. 14.

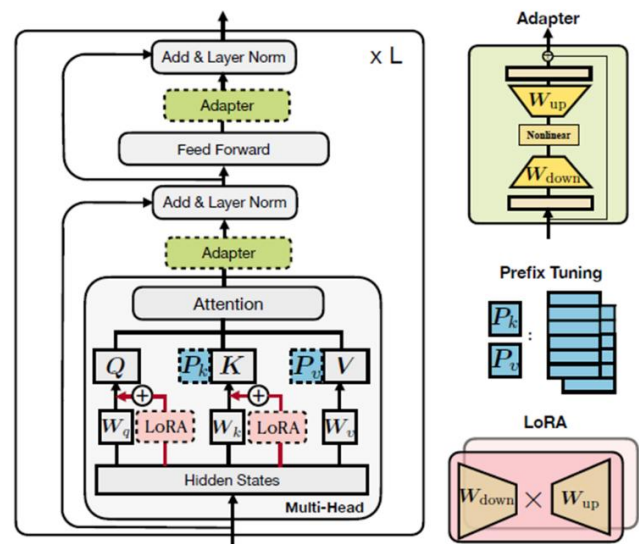

Fig. 12. MCTN model.

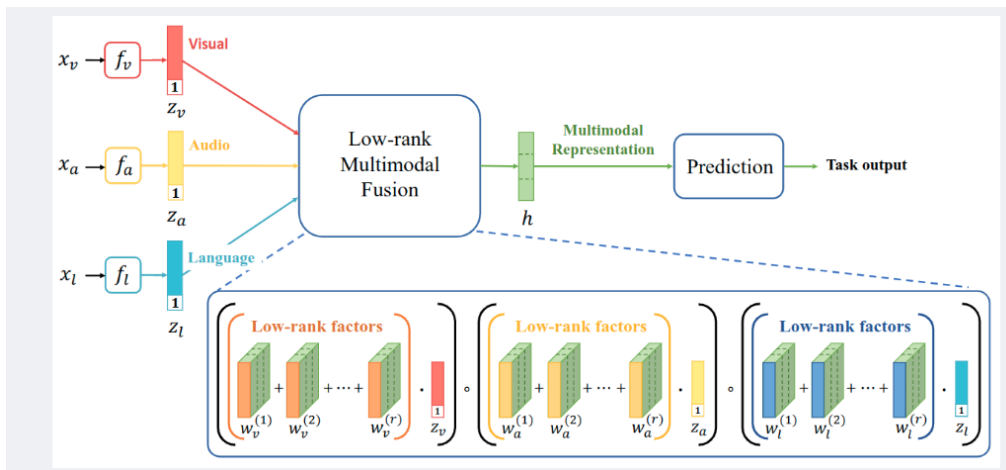

Fig. 13. LMF model.

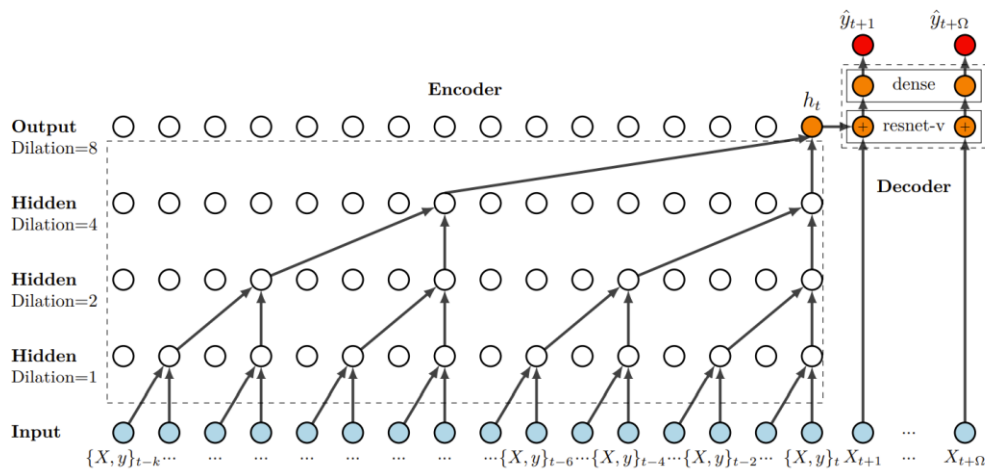

Fig. 14. TFN model.

4) *MFN model*: The proposed approach to address the multi-view sequence learning problem is the Memory Fusion Network (MFN) [21]. This neural architecture explicitly accounts for intra-view and inter-view interactions, modeling them sequentially across the temporal dimension. The MFN comprises an LSTM system designed to learn view-specific interactions in isolation while identifying cross-view interactions via a mechanism known as Delta-memory Attention Network (DMAN). This process culminates in a multi-view gated memory for temporal summarisation, as illustrated in Fig. 15.

5) *EF-LSTM model*: The EF-LSTM model does this by connecting multimodal input data and processing it using an

LSTM network (Hochreiter and Schmidhuber 1997). This design allows the model to process information from different modalities simultaneously, thus improving the performance of sentiment analysis.

6) *Mult model*: The Mult model effectively tackles the challenges of aligning information across different modalities and managing long-term dependencies within the same modality in an end-to-end framework, eliminating the necessity for explicit data alignment [22]. The model's foundation is its directed two-by-two cross-modal attention mechanism, which facilitates the examination of interactions across various time steps in a multimodal sequence, potentially allowing for alignment between modalities, as illustrated in Fig. 16.

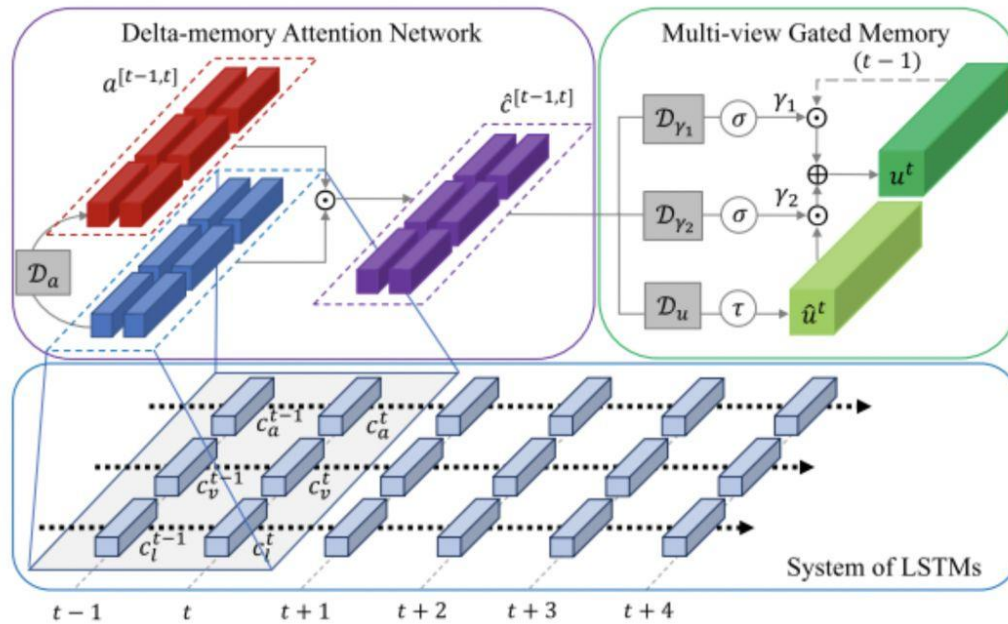

Fig. 15. Schematic diagram of the MFN model.

Fig. 16. Schematic diagram of the MulT model.

The dataset used in this paper is the CMU-MOSEI multimodal dataset, which is the first, largest and highly regarded multimodal emotion and sentiment recognition dataset.

B. Experimental Setup

In this paper, three experiments are set up, namely the comparison experiment, the principal mode selection experiment and the ablation experiment. Source of experimental

data were obtained from the text of the Communist Youth League video comments.

1) Comparison test: This experiment is intended to prove the applicability of the method used in the M-S model and the accuracy of the model, this paper uses the CMU-MOSEI dataset to train on each of the six baseline models 10 times respectively (the MulT model is the most effective of the baseline models,

so 50 experiments were carried out), and in order to prove the stability of the M-S model proposed in this paper, the was trained 50 times and the average results obtained.

2) *Main modality selection experiment*: Text features, image features and audio features are selected to be sent to the main channel for processing, and the features of the remaining modalities are sent to the subchannel for processing, and the results are obtained through the M-S model to determine the main modality to be sent to the main channel for processing.

3) *Ablation experiment*: Utilizing solely unimodal information (input from only one modality—text, image, or audio—while excluding data from the other modalities), the experimental findings indicate that information from all modalities in multimodal sentiment analysis positively influences the sentiment analysis task.

C. Experimental Analyses

Fig. 17 illustrates that the M-S model introduced in this paper yields superior outcomes across four metrics: sentiment 2 classification, sentiment five classification, sentiment 7 classification, and F1 value. This demonstrates that the proposed primary and secondary dual channels not only attain high accuracy but also exhibit versatile applicability in multimodal sentiment analysis tasks. Furthermore, in comparison to sentiment 2 classification, the model shows greater improvement in multicategory sentiment classifications (sentiment 5 and sentiment 7), suggesting that the proposed method is more adept at precise sentiment analysis. The Classification, Sentiment 7 Classification demonstrates greater improvement, suggesting that the method provided herein is more suitable for precise sentiment analysis.

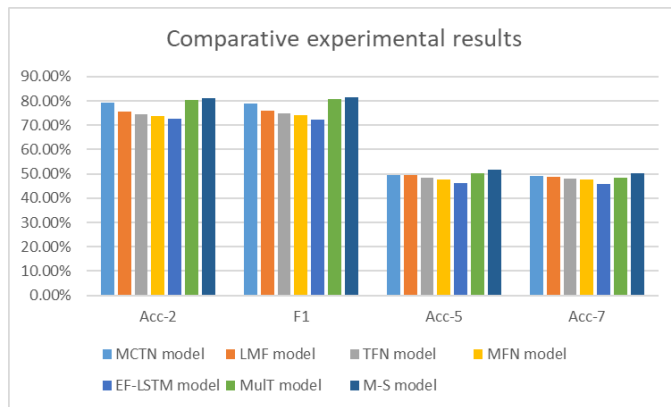

Fig. 17. Comparative experimental results.

Fig. 18 indicates that the results are markedly superior when text features are utilized as the primary modal compared to when image and audio features are employed. This demonstrates that the paper prioritizes text information as the main modality, directing the text features extracted by the one-dimensional convolutional neural network to the primary channel for processing, while the extracted image and audio features are allocated to the subchannel. This approach yields optimal results and substantiates the beneficial impact of the proposed main and subchannel methods on the multimodal sentiment analysis task. The vice-channel strategies presented in this paper positively influence the multimodal sentiment analysis challenge.

Fig. 18. Main mode selection experimental results.

In Fig. 19, the fusion method proposed in this paper in the CMU-MOSEI dataset when experiments are conducted using multimodal data, the effect is 6.94% more accurate with single text modal sentiment analysis, 21.11% more accurate with single image modal sentiment analysis, and even more accurate with 37.6% more accurate than the single audio modal, which demonstrates that each modal information in this method makes a positive effect on the present sentiment analysis task.

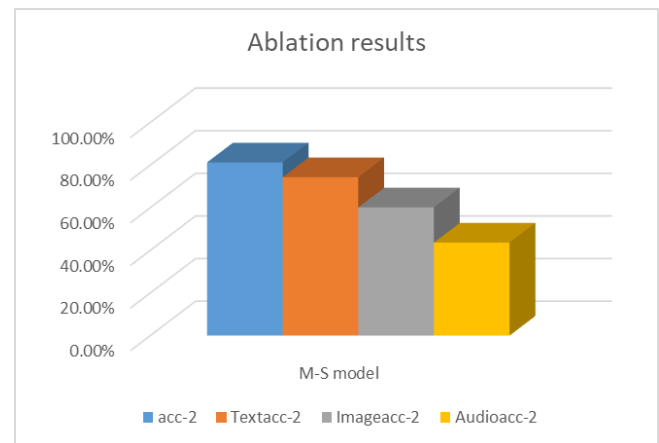

Fig. 19. Ablation results.

VI. CONCLUSION

The experimental results indicate that the M-S model introduced in this paper enhances the sentiment analysis of multimodal information in video review texts compared to the baseline model. The accuracy of the proposed model has been substantiated through various datasets and multiple experimental sets. Furthermore, the ablation experiments demonstrate that the textual, audio, and visual information utilized in this model contribute positively to the multimodal sentiment analysis task.

The M-S model proposed in this paper mainly solves the problems of the multimodal sentiment analysis task in which the time complexity of the model is too large for practical application, the interrelationships and mutual influences between multimodal information are not considered, and the weights of the multimodal features cannot be accurately defined by numerical values, but there are still a lot of challenges that need to be solved by researchers in this task. This paper

summarises some of the future work on the multimodal sentiment analysis task:

- Multimodal datasets are scarce, unsupervised or semi-supervised methods can be considered to train the model and get better results with fewer datasets;
- Use the topology of the hypergraph to establish the relationship between the multimodal data and obtain the feature tensor between the multimodalities;
- Majority of existing methodologies predominantly focus on textual, visual, and auditory data, while pose-oriented and ECG-based sentiment analysis remains exceedingly limited; future efforts should enhance collaboration with other disciplines to develop more comprehensive multimodal datasets;
- Most existing methodologies do sentiment analysis on aggregate data; future approaches may explore sentiment analysis of specific entities within the data or at the aspect level.

Enhancing Stock Market Forecasting Through a Service-Driven Approach: Microservice System

Asaad Algarni

Department of Computer Sciences-Faculty of Computing and Information Technology,
Northern Border University, Rafha 91911, Saudi Arabia

Abstract—Predicting stock market is a difficult task that involves not just a knowledge of financial measures but also the ability to assess market patterns, investor sentiment, and macroeconomic factors that can affect the movement of stock prices. Traditional stock recommendation systems are built as monolithic applications, with all components closely coupled within a single codebase. While these systems are functional, yet they are difficult integrating several services and aggregating data from diverse sources due to their lack of scalability and extensibility. A service-driven approach is needed to manage the growing complexity, diversity, and speed of financial data processing. However, microservice architecture has become a useful solution across multiple sectors, particularly in stock systems. In this paper, we design and build a stock market forecasting system based on the microservice architecture that uses advanced analytical approaches such as machine learning, sentiment analysis, and technical analysis to anticipate stock prices and guide informed investing choices. The results demonstrate that the proposed system successfully integrates multiple financial analysis services while maintaining scalability and adaptability due to its microservice architecture. The system successfully retrieved financial metrics and calculated key technical indicators like RSI and MACD. Sentiment analysis detected positive sentiment in Saudi Aramco's Q3 2021 report, and the LSTM model achieved strong prediction results with an MAE of 0.26 and an MSE of 0.18.

Keywords—Stock market; microservice architecture; deep learning; technical indicators; sentiment analysis

I. INTRODUCTION

Analyzing the stock market to predict the price movement of shares is of interest to investors and traders. There is an extensive variety of interrelated factors affecting the stock price, including microeconomic considerations and geopolitical developments [1, 2]. A study found that psychological factors such as investor emotion and behavioral biases had a considerable impact on share prices [3]. Traditional methods for predicting stock prices depend on statistical models and technical analysis [4]. However, they are unable to completely comprehend the complex interdependencies and behavioral patterns that are inherent in investor psychology and market dynamics [5]. Consequently, deep learning has become recognized as a highly efficient tool for deriving meaningful insights from extensive, complex datasets [6].

The financial markets are very volatile and process intensive data [8]. Hence, they require sophisticated systems that can handle huge datasets, run complex analyses, and give real-time insights that can be used. Most traditional stock

recommendation systems, on the other hand, are built as monolithic applications, with all components closely coupled within a single codebase. While these systems are functional, yet they are difficult in scalability, maintainability, and extensibility [7].

Also, it is critical for investors and financial analysts to be able to forecast stock movement with precision, as they must make informed decisions in a constantly changing environment. Forecasting systems that rely on monolithic architectural structures are difficult to adapt to ever-changing markets. These systems focus on limited data inputs, like historical price data, while overlooking critical factors such as real-time sentiment analysis and technical indicators, which play a significant role in market behavior. To the best of our knowledge, current approaches struggle to combine diverse analytical methods—like machine learning, sentiment analysis, and fundamental analysis—into a unified, effective system. This may lead to inconsistent performance and a lack of flexibility when applied to dynamic and complex market conditions.

Microservice architecture is now widely adopted across various sectors. Microservice divides a large system into small, self-contained services that provide benefits such as improved scalability, greater flexibility, and error tolerance [9]. The development of stock systems based on a microservice architecture enables the integration of various analytical functions such as artificial intelligence, technical analysis, sentimental analysis, portfolio management, and risk assessment. Using this modular strategy, traders and investors may precisely adjust market circumstances to make better-informed decisions.

Thus, this study proposes the design and implementation of a stock recommendation system based on microservices that use specialized services to deliver informed stock recommendations. The system's goal is to enhance the precision and relevance of stock recommendations by operating machine learning algorithms, fundamental and technical analysis, and sentiment analysis of financial reports. This research extends the existing literature on financial systems by examining how microservices can improve the efficiency, scalability, and usefulness of generating stock recommendations.

The paper is organized as follows: a literature review is conducted in Section II. Section III demonstrates the methodology, including the proposed system. Sections IV and

V present the study's results and discussion. Section VI presents the research conclusion and future work.

II. BACKGROUND AND RELATED WORK

A. *Microservice Architecture*

Microservice architecture is becoming an effective solution across multiple sectors, particularly in stock systems because it excels at managing complex, large-scale applications that demand scalability, maintainability, and flexibility. Microservices empower teams to develop, deploy, and scale each component independently, enhancing efficiency and innovation by breaking down a system into smaller and independent components. Each service is designed to handle a certain business function and communicates with other services through lightweight protocols, typically using APIs [10].

Microservices systems can significantly improve the efficiency and responsiveness of financial trading systems. The shift from a monolithic architecture to a micro-services-based approach enables developers to create independent services that satisfy certain requirements, improving scalability and maintainability. For instance, a microservice reference architecture based on domain engineering can address the high complexity and maintenance costs associated with large-scale financial trading systems by providing a general solution for similar scenarios, allowing new microservices to coexist with legacy systems and supporting rapid business development through DevOps and other mechanisms [11].

Microservices in power trading platforms also highlight their ability to enhance load performance and scalability, which are critical for the real-time and complex nature of stock trading [12]. Furthermore, microservices can be integrated with IoT technologies to create efficient inventory management systems and benefit stock systems by ensuring real-time data processing and business logic execution [13]. Implementing microservices architecture within ERP financial systems showcases their ability to address complex business demands with exceptional availability, security, and scalability, which are crucial for stock systems managing substantial amounts of data and transactions [14].

Adopting microservice architecture in stock recommendation systems may offer numerous benefits, including improved scalability, maintainability, and responsiveness. Thus, making it a valuable approach for modern financial trading platforms and related applications. The effective management of systems based on micro-services is vital for ensuring service quality across various microservice components, which is particularly important in stock systems where resource demands and quality of service requirements are high [15]. Integrating microservices with social-media messaging bots for automated inventory management further illustrates their versatility and potential for enhancing customer and retailer connectivity in stock systems [16]. Additionally, microservices can be applied to assess the impact of news on the stock market, which makes the system respond to news events, analyze them, and predict their effects on market trends. Thus, it provides valuable insights for traders and investors. Additionally, microservices in asset tracking systems, such as those based on indoor positioning systems,

showcase their potential for real-time data processing and resource-efficient operations, which can be applied to stock systems for tracking and managing assets efficiently [17].

The potential implications of a booming stock market prediction system through deep learning algorithms services built on microservice architecture are essential. Accurate forecasting could inform investment decisions and contribute to risk management strategies, portfolio optimization, and the development of automated trading systems. Furthermore, the valuable insights derived from this research have the potential to revolutionize financial forecasting and expand economic modeling applications.

B. *Machine Learning Algorithms*

Integrating machine learning and pattern recognition improved the accuracy of stock trading systems [18]. Esteemed machine learning methods have been utilized to predict fluctuations in stock prices. Some of these powerful algorithms are Long Short-Term Memory (LSTM), Support Vector Machine (SVM), Random Forest, and Decision Tree, each algorithm offers unique advantages. LSTM, a recurrent neural network, demonstrates exceptional efficacy in encapsulating time-based dependencies and intricate patterns within stock market data, as shown by its exceptional forecasting accuracy compared to conventional models like ARIMA [19] [20]. Despite the complexity of machine learning models, it is suggested that straightforward strategies are effective for predicting price soaring. A study conducted by [21] evaluates the effectiveness of using deep learning and technical indicators to predict short-term stock price movements. The authors developed a four-layer Long Short-Term Memory (LSTM) model incorporating various technical indicators, achieving an impressive 83.6% accuracy in forecasting stock trends. Authors in study [22] offer a comprehensive comparative analysis of nine machine learning models and two deep learning methods. The RNN and LSTM with continuous data emphasized superior performance among others. It also demonstrated a notable improvement in accuracy across all models when technical indicators are converted to binary data inputs.

Numerous studies have generated precise estimations by detecting non-linear correlations in stock market data [23, 24]. Random Forest, an ensemble learning method, is particularly adept at managing large datasets and mitigating overfitting by aggregating multiple decision trees. Although Decision Trees are easy to interpret and implement, they are at risk of overfitting, especially with small datasets. Nonetheless, they can remain beneficial when integrated with other models or used with an ensemble technique like Random Forest [25]. Comparative studies have shown that advanced models like LSTM and SVM surpass decision trees in performance. Nonetheless, decision trees remain valuable for data exploration and feature selection [26]. However, the selection of a model typically relies on the requirements of the prediction task, including the dataset's size and design, the necessary balance between accuracy and interpretability, and the available computational resources [23]. Each model offers distinct advantages. In some cases, the most precise forecasts arise from a combination of these models, which integrate the

optimal elements of each to mitigate the shortcomings [23, 25 - 27].

Disparate data sources, such as traditional time-series data and web platforms such as Google and Wikipedia, have been shown to greatly improve prediction accuracy [28]. The authors of study [45] emphasize the value of using NLP and finance to forecast stock prices. In their study, they emphasized the use of historical price data, text data from the news or social media, and their combination to improve accuracy. They discuss algorithms like RNN, GRU, and LSTM for price analysis, sentiment analysis for assessing investor emotions, and methods such as graph networks and event-driven approaches for identifying company correlations. A study investigates sentiment analysis of online investor opinions to support investment decisions and risk assessment. Using data from Sina Finance, it combines machine learning methods, like SVM and GARCH models, with sentiment analysis. Results show strong correlations between forum sentiment and stock price volatility, with machine learning outperforming semantic approaches and sentiment having a greater impact on value stocks than growth stocks [46].

The stock market is a complicated financial system with shifting prices, and investors seek to maximize gains while minimizing risks. Recent advances in neural networks and hybrid models have exceeded older approaches in terms of prediction accuracy. A study introduced the SMVF-ANP technique, which analyzes market transmission processes and financial aspects using multi-layer perceptron (MLP), dynamic artificial neural networks, and GARCH models. Results reveal that SMVF-ANP outperforms typical strategies and models, with a prediction accuracy of 97.2%, an efficiency rate of 96.9%, and higher returns [47]. Tong et al. studied the effect of social media mood on irrational herding behavior in the Chinese stock market. They discovered that emotion had a considerable impact on illogical conduct [48]. Furthermore, authors in study [49] extracted insights from unstructured financial text in quarterly company reports. They utilized FinBERT, a pre-trained language model based on the BERT framework. Their results demonstrate that FinBERT outperforms state-of-the-art methods, achieving an accuracy of 84.77% on quarterly reports.

To meet the varied demands of investors, advanced stock recommender systems have been expertly developed, which utilize techniques such as K-Nearest Neighbor, Singular Value Decomposition, and Association Rule Mining, all of which take into account investors' unique preferences and risk profiles to maximize portfolio returns [29]. Multi-agent recommender systems utilizing hybrid filtering techniques and involving collaborative and content-based filtering have been designed to adaptively recommend profitable stocks based on investor preferences and macroeconomic factors [30]. Incorporating social media text and company correlations into stock movement prediction models has enhanced the ability to capture multimodal signals, providing a robust tool for investment decision-making [31]. A systematic review of recent developments in machine learning methods, such as deep learning and ensemble methods, highlights the importance of these technologies in improving stock market movement forecasts and reducing investment risks [32]. In

addition, a deep reinforcement learning approach that combines artificial neural networks (ANN), long short-term memory (LSTM), natural language processing (NLP), and deep Q networks (DQN) was proposed to forecast the next day's stock price. The proposed model outperforms standard algorithms in terms of accuracy, demonstrating its efficacy in automating stock market investment decisions [33]. Thus, the remarkable innovations in stock recommendation systems highlight their extraordinary sophistication, empowering them to deliver precise, timely, and personalized investment guidance that perfectly aligns with the dynamic needs of investors and traders.

C. Technical Analysis

Technical indicators are vital in forecasting stock market movements that offers valuable insights into market trends and behaviors. The metrics are typically divided into two primary classifications: trend indicators and volume indicators. Trend indicators play a pivotal role in revealing not only the direction but also the strength of a market trend, which is essential for crafting savvy investment choices. Noteworthy instances of trend indicators encompass Moving Averages (MA), Moving Average Convergence Divergence (MACD), and Exponential Moving Average (EMA) [34]. These indicators are utilized to smooth out price data, facilitating the detection of trends over a designated timeframe. For example, the MACD, a momentum indicator, illustrates the correlation between two moving averages of the price of an asset trend. At the same time, the EMA assigns greater importance to the most recent prices, increasing its sensitivity to new information [35].

On the other hand, volume indicators are crucial as they reveal the true power behind price movements by examining trade volume. They assist investors in understanding the degree of interest surrounding a specific stock or market. Common volume indicators include Relative Volume (RVOL), Volume Weighted Average Price (VWAP), and Chaikin Money Flow (CMF) [34]. RVOL compares the current volume to the average volume over a specific period, indicating whether a stock is actively traded. The VWAP determines the mean price at which a security was traded during the day, considering volume and price, in contrast, the CMF assesses buying and selling pressure over a specific period.

The precision of stock predictions could be increased by combining these metrics with sophisticated machine learning algorithms. Combining technical indicators with ensemble learning methods like Random Forest and Gradient Boosting has improved predictive precision, attaining a success rate of 91.45% in forecasting the opening price of stock [36]. Similarly, using LSTM models with technical indicators as voters have demonstrated high accuracy in stock market predictions, with RMSE values indicating strong performance [34]. Jaideep and Matloob developed a machine learning classifier using five technical and 23 fundamental indicators. Their findings highlight the importance of analyst ratings in predicting stock prices [37]. Thus, these methods emphasize the need of selecting the proper set of technical indicators to improve the efficacy of prediction models. Furthermore, utilizing correlation-based feature selection models to identify crucial technical indicators has undeniably revolutionized the forecasting capabilities of deep learning algorithms,

particularly Artificial Neural Networks (ANN) and Convolutional Neural Networks (CNN) [38].

Hybrid machine learning models that integrate various classifiers and optimization strategies have successfully forecasted stock price fluctuations, especially in volatile market conditions affected by external elements such as political turmoil and pandemics [39]. However, the strategic use of trend and volume indicators, along with advanced machine learning techniques, provides a robust framework for predicting stock market movement; thus, they offer rich visions for investors and financial analysts [4, 34-36, 38, 40, 41-43].

However, existing systems focus on historical price data and fail to integrate other valuable inputs, such as sentiment analysis, machine learning algorithms, and technical indicators. Despite their effectiveness, these systems' advanced technologies are often used in isolation. In response to these limitations, we propose a microservice-based architecture that brings together modularity, scalability, and advanced analytics.

III. METHODOLOGY

A. The Proposed System

Making well-informed investment choices is challenging due to the total volume of data accessible to investors. These data sources range from historical stock prices and technical indicators to company fundamentals and sentiment extracted from news articles and financial reports. The ability to process, analyze, and interpret these data effectively is crucial for investors. Hence, we propose a microservice-driven stock prediction system to address this need. Designing the system to provide investors with comprehensive stock analysis and actionable recommendations can optimize their portfolios and minimize risks as well.

The proposed system is built on microservices architecture, and each service was designed to handle a distinct part of the stock analysis process. These microservices operate independently while effortlessly communicating with one another through RESTful APIs. This architecture ensures the system is scalable, efficient, and adaptable to future enhancements. The proposed system was tested using real-world stock data to assess its effectiveness in response to each service and providing initial and informed stock recommendations. The system's performance was evaluated based on its ability to retrieve stock data, generate reliable technical and fundamental insights for traders, and summarize a semantic analysis for a given financial report. (The source code for the system can be accessed through the fine-grained personal access token link provided in the footer at the bottom of the page or by clicking on this link).

The system combines essential financial metrics, sophisticated machine learning algorithms, and sentiment analysis to provide a strong data-informed decision. Each microservice is responsible for a particular function or task in the stock recommendation process, enabling efficient real-time processing of large data sets. Fig. 1 presents the architecture of the system. The major components of the system are detailed as follows:

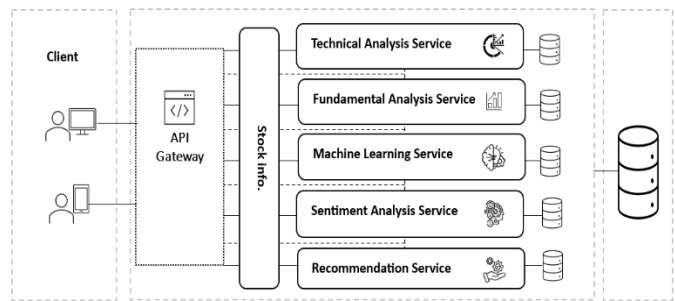

Fig. 1. The architecture of the proposed system.

1) *Stock data and fundamental analysis services*: The first step in the system involves collecting financial data from publicly available sources. This microservice retrieves vital financial metrics for individual stocks, including historical prices and trading volumes. The fundamental analysis microservice can process the data to compute key financial metrics like Market Capitalization, Dividend Yield, Earnings Per Share (EPS), and Revenue. These metrics help evaluate the financial health and performance of the selected company. We used the Yahoo Finance API in our system.

2) *Technical analysis service*: The system's technical analysis microservice calculates a range of widely used technical indicators that assist in identifying trends, momentum, and market conditions. To detect price trends and possible reversals, we run indicators such as moving averages (MA), the Relative Strength Index (RSI), and the Moving Average Convergence Divergence (MACD). Also, this component employs volume-based indicators like On-Balance Volume (OBV) and volatility indicators like the Average True Range (ATR). Thus, these technical indicators are important for traders and investors to determine a stock's price shifts and the overall direction of the trend.

3) *Sentiment analysis service*: Sentiment analysis has become an important tool in predicting stock market trends, given that news and financial reports can greatly affect investor actions and stock valuations. The sentiment analysis process was developed using a Flask-based API that integrates the FinBERT model, a variant of BERT specifically fine-tuned for sentiment analysis in financial contexts. The FinBERT, which is available via Hugging Face's model repository, is known for its domain specific capabilities in financial sentiment classification [48]. It is initialized in the application through the transformers pipeline with a sentiment analysis task. The model outputs predictions across three sentiment categories: positive, negative, and neutral. It processes the text data to determine whether the general sentiment is positive, negative, or neutral, providing a complementary perspective to the technical and fundamental analyses.

4) *Machine learning predictions service*: In its early version, the system uses an LSTM (Long Short-Term Memory) model to estimate future stock values, which is a recurrent neural network designed to manage time-series data. The LSTM model predicts future stock swings using previous

https://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@github.com/aalgarni2/Stock_Market_Forecasting_Microservice_System.git

stock prices and other services. This approach identifies long-term linkages and patterns in stock price data. It aids in providing short-term projections, which are critical for making buy, sell, or hold choices. The model is designed to react dynamically to new data, gradually improving the accuracy of its predictions as time progresses. The system scales and normalizes historical stock data, technical indicators, and semantic analysis findings before passing them through an LSTM model for training. After completion, the model produces forecasted stock values, which are then compared to the current market price to inform the recommendation service. During model execution, we divided the dataset into training (80%) and testing (20%) sets. We set up the model with 50 epochs, a batch size of 32, and an Adam optimizer with a learning rate of 0.001. The model's performance was assessed using Mean Absolute Error (MAE) and Mean Squared Error (MSE). Other machine learning approaches such as Support Vector Machine, Random Forest, and Decision Tree will be implemented in future work. Thus, this modular approach makes it easier to update and expand the system with new capabilities as they become available.

5) *Recommendation service:* The recommendation microservice will integrate the outputs of the fundamental analysis, technical indicators, and machine learning predictions to deliver a final recommendation. The algorithm would be designed to aggregate results from four microservices, fundamental analysis, technical indicators, machine learning predictions, and sentiment analysis, to generate a final stock recommendation. Each service's output is weighted, combined, and compared against set thresholds. Then, the service determines whether the recommendation is to 'Buy,' 'Hold,' or 'Sell'.

6) *User interaction via streamlit interface:* The system's user interface is designed to let investors enter stock ticker symbols, select a date period for analysis, and upload a financial report for sentiment evaluation. The interface retrieves and shows results based on the services that have been selected. The modular architecture also can enable future integration of additional analytical services or advancements with minimal disturbance.

IV. RESULT

A. Fundamental Analysis and Technical Analysis Performance

The component of fetching the historical stock data was tested with several stocks by entering the ticker, start date, and end date. All runs demonstrated that stock data can be retrieved successfully from the Yahoo Finance API. For the fundamental analysis service, it successfully retrieved financial metrics. Additionally, the proposed system effectively calculated and returned multiple technical indicators such as RSI, and MACD. These indicators effectively identified trends, overbought and oversold conditions, and market volatility. The ability to visualize these indicators over a selected date range helped investors gain deeper insights into price movements and market dynamics. Indicators like MACD and RSI provided

actionable insights into buying or selling opportunities. Thus, the system's technical indicators are aligned with known market trends, providing an additional layer of validation to the stock's performance.

During testing of the three components, we entered the stock ticker "2222.SR" (Saudi Arabian Oil Company); the system retrieved stock data for the specified date. Also, when we run the fundamental analysis, the system provides the available and accessible data. For unavailable metrics, it shows 'N/A'. The accuracy and reliability of this data depend on the real-time updates provided by Yahoo Finance, which proved to be timely and comprehensive during testing. Fig. 2 illustrates the system's interface after fetching the stock data.

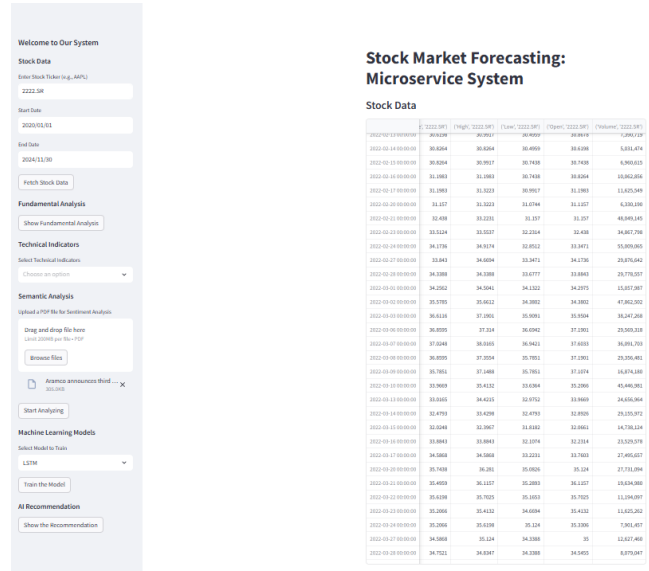

Fig. 2. The proposed system main interface.

B. Sentiment Analysis Services Performance

The sentiment analysis services perform sentiment analysis on any uploaded PDF document. Sentiment analysis is increasingly used in financial prediction. Incorporating news sentiment or financial report analysis improves accuracy in forecasting stock trends [44]. For our proposed system, we implemented the FinBERT model for the sentiment analysis microservice. We tested this service by uploading several PDF files.

The sentiment analysis service uses FinBERT to analyze text from PDF documents. The FinBERT tokenizer divides the text into pieces using tokens. The FinBERT algorithm evaluates each segment to identify the sentiment labels (positive, neutral, or negative), which are then accepted to obtain a sentiment measurement. In an analysis of Saudi Aramco's third-quarter report for 2021, the sentiment analysis service detected positive sentiment. Fig. 3 shows the sentiment analysis of the report. The sentiment analysis was instrumental when applied to earnings reports. Positive sentiment can be associated with subsequent price increases. In contrast, negative sentiment may correlate with price declines. However, while sentiment extracted from financial documents can predict short-term stock price movements, external market factors and investor behavior may influence price fluctuations.

Fig. 3. Sentiment analysis report.

C. Machine Learning Service and Recommendation System

The machine-learning service is designed to employ various machine learning algorithms for stock price prediction. They are LSTM, Support Vector Machine (SVM), Random Forest, and Decision Tree. In this early development, we only implemented LSTM. Other algorithms are left for future work. During testing the service, the LSTM model achieved a Mean Absolute Error (MAE) of 0.26 and a Mean Squared Error (MSE) of 0.18 for predicting the stock price of 2222.SR (Saudi Aramco). The results demonstrate the potential of LSTM for forecasting in financial markets. Fig. 4 show the result of MAE and MSE after training the model.

Fig. 4. The result of MAE and MSE of the model.

The recommendation engine service will integrate the results of fundamental analysis, technical indicators, and semantic analysis and pass them on to the machine learning algorithm service. The recommendation engine's strength is its ability to integrate several types of information which helps in producing a comprehensive insight of the stock's performance. This guarantees that the recommendation is well-rounded and takes into account both quantitative and qualitative considerations. Also, it limits the risk of making decisions that are based on only one factor. The full implementation of this service is left for future work.

V. DISCUSSION AND LIMITATION

The results of testing the system imply that the proposed system can be an effective tool for providing data-driven stock recommendations based on multiple sources. The system offers a comprehensive stock analysis approach by integrating fundamental analysis, technical indicators, sentiment analysis, and machine learning predictions. The modular design of the services facilitates integration with other components of the stock recommendation system. Also, the modular approach allowed for a flexible selection of technical indicators [50]. Extending support for more complex strategies or combining

indicators could enhance the analytical capability of the system further. FinBERT's pre-training on financial data provided domain-specific sentiment analysis, making the results relevant for stock market insights. The service's modular design supports easy scaling, such as adding more sentiment categories or integrating additional pre-trained models. Future work could focus on improving sentiment granularity and analyzing sentiment trends across sections of a document to uncover deeper insights. The LSTM model's architecture can capture temporal dependencies; hence, it is suitable for time-series data like stock prices. However, the ability to choose among models provided flexibility for different user requirements and computational resources. Future improvements include implementing additional time-series-specific models and enabling hyperparameter optimization for models.

Furthermore, the proposed system demonstrates that its internal structure is scalable and efficient. Each microservice operated independently. The utilization of RESTful APIs allows services to communicate without interruption as well as ensures that changes to one service do not impact the overall system. Hence, the system's modularity increases its flexibility and usability by making it simple to add or improve current services.

There are specific constraints that need to be defined. First, there is a need for stress testing to assess performance under high-load conditions. Second, sentiment analysis is heavily dependent on the quality of the input data. Hence, the outcomes of the results can be affected if there are specific constraints that need to be defined. First, there is a need for stress testing to assess performance under high-load conditions. Second, sentiment analysis is heavily dependent on the quality of the input data. So, the outcomes of the results may be affected negatively if there is any biased data.

However, the system's modular architecture allows for future enhancements, such as incorporating more advanced sentiment analysis models, employing advanced machine learning approaches to better account for market volatility, and leveraging recommendation services with explainable AI. This system has the potential to significantly aid investors in making well-informed decisions while also being adaptable to future advancements in financial technology.

VI. CONCLUSION AND FUTURE WORK

The proposed system adopts a comprehensive methodology for stock market analysis, integrating traditional financial metrics with contemporary machine-learning approaches. The system assists investors in making informed decisions by offering services like fundamental analysis, technical indicators, sentiment analysis, and machine learning algorithms. However, this paper presents a microservice-based architecture that embeds state-of-the-art technologies, such as LSTM for time-series prediction and FinBERT for sentiment analysis in stock price forecasting. By comparison, the LSTM model generates smaller error metrics than traditional baselines and thus has demonstrated the capability of learning and representing the complex, nonlinear stock price pattern. The value added to the system for further processing was done by the incorporation of FinBERT, through the analysis of the

financial reports based on sentiment analysis. The paper's parameter optimization will be expanded to capture more market scenarios and embed additional analysis tools for the betterment and adaptability of the system.

The recommendation service developed in this version is still on a very high level of abstraction and, hence, is left for further research and development. Also, we aim, in future work, to introduce Explainable AI (XAI) into the stock trading systems to make the predictions transparent and explain why they are predicted this way. It will be interesting to see whether XAI can be integrated into microservice architecture. The other related research direction could try to investigate how the XAI modules connect with the existing services and, more importantly, provide explanations that are correct, understandable, and trusted.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the Project Number "NBU-FFR-2025-231-02".

Abstract—After the COVID-19 pandemic, the global economy began to recover. However, stock market fluctuations continue to affect economic stability, making accurate predictions essential. This study proposes an Improved Whale Optimization Algorithm (IWOA) to optimize the parameters of the Long Short-Term Memory (LSTM) model, thereby enhancing stock index predictions. The IWOA improves upon the traditional Whale Optimization Algorithm (WOA) by integrating logistic chaotic mapping to increase population diversity and prevent premature convergence. Additionally, it incorporates a dynamic adjustment mechanism to balance global exploration and local exploitation, thus boosting optimization performance. Experiments conducted on five representative global stock indices demonstrate that the IWOA-LSTM model achieves higher accuracy and reliability compared to WOA-LSTM, LSTM, and RNN models. This highlights its value in predicting complex time-series data and supporting financial decision-making during economic recovery.

Keywords—Long short-term memory network; chaotic mapping; dynamic adjustment mechanism; improved whale optimization algorithm; financial time series forecasting

I. INTRODUCTION

Stock market indices are published by stock exchanges or financial institutions and are important financial indicators that reflect market fluctuations. These indices directly affect investor sentiment and decision-making and serve as key references for investors. Given the significant impact of stock market movements on the global economy, predicting these movements has been a top priority for researchers and investors. Their goal is to develop effective investment strategies and reduce risk. Despite the passage of time, the complex patterns and return metrics that emerge in the stock market within the framework of unsupervised automated prediction remain difficult to predict accurately. This underscores the critical need for a progressive predictive approach that combines human expertise with advanced technological capabilities to improve the accuracy and reliability of stock and economic forecasts [1].

In recent decades, the adoption of machine learning techniques and metaheuristic algorithms in financial time series forecasting has attracted significant attention. Conventional neural networks, such as Recurrent Neural Networks (RNNs), have been shown to be effective in capturing complex fluctuations in the stock market. Chen et al. introduced a deep learning prediction model based on RNN, which integrates social media news content (sentiment and topic features) with

technical indicators to strengthen the predictive accuracy of stock market volatility [2]. Haromainy et al. utilized a genetic algorithm-optimized RNN model to predict stock trends for stock prices, demonstrating its ability to capture nonlinear features in stock market data [3]. Additionally, Zhao et al. incorporated fuzzy logic with RNN to improve stock market volatility prediction [4].

Despite the advantages of RNN models, prediction accuracy remains limited due to the high nonlinearity and chaotic nature of the stock market. As deep learning continues to grow, LSTM network, known for its superior time series processing capabilities, has become a prominent research focus. Abdul Quadir et al. utilized the LSTM algorithm to analyze normalized time series data, addressing the vanishing gradient issue observed in simpler RNN and determining the relationship between historical and future values [5]. In the medical field, Academician Zhong Nanshan's team utilized an LSTM-based recurrent neural network to study and predict the peaks and sizes of COVID-19 [6]. In the domain of energy consumption forecasting, LSTM-based methods have demonstrated outstanding predictive performance [7]. Notably, in the research area of financial time series forecasting, LSTM has shown remarkable predictive performance. Li et al. further validated the potential of LSTM in capturing complex stock price patterns and improving prediction accuracy [8]. Singh et al. combined Convolutional Neural Networks (CNN) with LSTM to propose a hybrid model for Indian stock portfolio management, which outperformed traditional models [9].

However, LSTM networks also face challenges, such as susceptibility to overfitting, sensitivity to hyperparameter selection, and the risk of falling into local optima, which can limit prediction accuracy [10]. Hyperparameter selection in LSTM models typically relies on manual experience, which significantly impacts model performance. To address these issues, metaheuristic optimization algorithms have been extensively utilized for hyperparameter optimization [11–13]. For example, Zhang et al. applied Particle Swarm Optimization (PSO) to optimize LSTM hyperparameters for predicting short-term fluctuations in the highest prices of U.S. stocks, demonstrating the superiority of the optimized LSTM model [14]. However, the PSO method is prone to slow convergence and inefficiency in high-dimensional spaces, particularly in multimodal optimization problems or complex search spaces, leading to local optima and reduced operational efficiency [15]. In response to these challenges, several studies have explored

*Corresponding Author.

the integration of the Whale Optimization Algorithm (WOA) with deep learning models. Xin et al. combined the WOA with the LSTM model to predict the stock market, achieving significant improvements in forecasting accuracy [16]. Hasan enhanced the convergence mechanism of WOA and applied it to the optimization of time-series prediction models, yielding excellent results in temperature and humidity forecasting [17].

Inspired by the aforementioned studies, this paper proposes a novel approach that integrates an Improved Whale Optimization Algorithm (IWOA) with LSTM networks. IWOA enhances population diversity and reduces the risk of premature convergence by incorporating chaotic mapping. Additionally, it features an adaptive factor mechanism that dynamically balances exploration and exploitation during the optimization process, leading to improved efficiency and accuracy. By leveraging IWOA's robust optimization capabilities, the hyperparameters of the LSTM model are fine-tuned more effectively, enabling the model to better capture the complexity of nonlinear and chaotic patterns in financial time series.

II. METHODS

A. LSTM

In the early stages of time series forecasting, recurrent neural networks (RNNs) gained widespread use due to their capability to process sequential data. Unlike traditional feedforward neural networks (e.g., backpropagation neural networks, BPNN), which propagate signals in a single direction, RNNs introduce weighted connections between hidden layer neurons. This architecture enables the output of hidden layer neurons at each time step to depend on information from the previous time step, allowing the network to effectively capture temporal dependencies. By incorporating both feedforward and internal feedback connections, RNNs exhibit dynamic temporal behavior that influences their internal states. However, in practice, the hidden state of an RNN at each time step is determined by both the hidden layer values from the previous time step and the input values at the current time step, which restricts its ability to retain long-term memory [18].

To overcome the limitations of traditional RNNs, Graves extended the Long Short-Term Memory (LSTM) neural network, which effectively addresses these challenges [19]. LSTM replaces the hidden layer nodes of standard RNNs with specialized memory units, allowing the network to better retain and manage temporal information, particularly for modeling long-term dependencies. The core component of LSTM is the cell state, which functions as a channel for transmitting information across the network. LSTM introduces input, forget, and output gates to enhance the functionality of global memory cells. These gates regulate the retention, updating, or discarding of information at each time step, enabling the network to efficiently learn long-term dependencies. Fig. 1 illustrates the architecture of the LSTM model.

The structure of LSTM is highly efficient in managing long-term relationships within time series data, especially when events are delayed. In LSTM, three gates regulate the cell state, each employing a Sigmoid activation function and

pointwise multiplication. The Sigmoid output, ranging from 0 to 1, determines how much information passes through: a value of 0 indicates complete "blocking," while a value of 1 signifies full "pass-through." This gating mechanism enables LSTM to efficiently retain and propagate long-term dependency information in time series data. The workflow of the LSTM network is described by the following equations.

$$i_t = \sigma(W_i * [h_{t-1}, X_t] + b_i) \quad (1)$$

$$f_t = \sigma(W_f * [h_{t-1}, X_t] + b_f) \quad (2)$$

$$o_t = \sigma(W_o * [h_{t-1}, X_t] + b_o) \quad (3)$$

$$\hat{C}_t = \tanh(W_c * [h_{t-1}, X_t] + b_c) \quad (4)$$

$$C_t = f_t * C_{t-1} + i_t * \hat{C}_t \quad (5)$$

$$h_t = o_t * \tanh(C_t) \quad (6)$$

In Eq. (1) to Eq. (6), W refers to the weight vectors, while b denotes the bias terms.

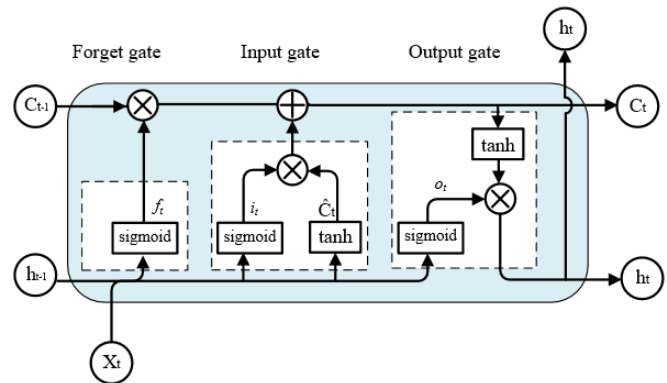

Fig. 1. Structure of LSTM.

B. WOA

The Whale Optimization Algorithm (WOA) is a novel swarm intelligence method inspired by the bubble net foraging strategy of humpback whales. This algorithm demonstrates superior performance compared to traditional optimization approaches. WOA simulates this behavior through two main search strategies: exploration and exploitation. During exploration, whales move randomly in search of prey, while in the exploitation phase, they navigate toward the prey in a spiral pattern to find the optimal solution. The algorithm uses a series of mathematical equations to simulate these behaviors, enabling it to effectively search for optimal solutions in complex and high-dimensional spaces [20]. In WOA, each candidate solution corresponds to a position within the search space, and the algorithm optimizes the objective function by mimicking the whale's hunting behavior. The algorithm operates through three main phases [21].

1) *Encircling prey*: When a whale detects the position of its prey, it adjusts its position based on the current best solution. During this process, the whale moves closer to the optimal solution by a certain proportion. The position of the whale is updated as described in Eq. (7).

$$\begin{cases} D = |C \cdot X^*(t) - X(t)| \\ X(t+1) = X^*(t) - A \cdot D \\ A = 2a \cdot r - a \\ C = 2 \cdot r \end{cases} \quad (7)$$

In Eq. (7), D represents the distance between the whale individual and its prey. t represents the iteration number; A and C are coefficient vectors; X and X^* are the current whale position and the current best whale position; a decreases linearly from 2 to 0 during the iteration; r is a random number in the range $[0, 1]$.

2) *Bubble-net attacking*: There are two mechanisms designed for Bubble-net attacking: shrinking encircling mechanism and spiral updating position.

a) *Shrinking encircling mechanism*: This mechanism is implemented using the parameters in Eq. (7). During the iterations, the behavior is achieved by linearly decreasing the value of a from 2 to 0, while A fluctuates within the range $[-a, a]$. When A is a random value between $[-1, 1]$, the whale's position is updated to lie somewhere between its original position and the current optimal position.

b) *Spiral updating position*: Initially, the distance between the whale and its prey is calculated. Then, a spiral equation is derived to simulate the whale's spiral movement, the specific equation is as follows.

$$\begin{cases} D = |X^*(t) - X(t)| \\ X(t+1) = D \cdot e^{bl} \cdot \cos(2\pi l) + X^*(t) \end{cases} \quad (8)$$

In Eq. (8), b is the spiral shape constant; l is a random value within the range $[-1, 1]$.

When the whale approaches the prey, its behaviors of shrinking encircling and spiral position updating occur simultaneously. To simulate this bubble-net attack, it is assumed that the humpback whale has a 50% chance of performing either shrinking encircling or spiral position updating. $X(t+1)$ is shown in Eq. (9).

$$X(t+1) = \begin{cases} X^*(t) - A \cdot D & p < 0.5 \\ D \cdot e^{bl} \cdot \cos(2\pi l) + X^*(t) & p \geq 0.5 \end{cases} \quad (9)$$

In Eq. (9), p is a random number in the range $[0, 1]$.

3) *Search for prey*: At this phase, the whale population performs global exploration. When $|A| > 1$, the whale population ceases to adjust its position according to the current optimal solution. Instead, the position is updated based on a randomly selected whale, with the goal of expanding the search range and seeking the optimal solution to maintain population diversity. Therefore, only a small modification to Eq. (7) is needed to obtain the mathematical model for this stage.

$$\begin{cases} D = |C \cdot X_{rand} - X(t)| \\ X(t+1) = X_{rand} - A \cdot D \end{cases} \quad (10)$$

In Eq. (10), X_{rand} represents the position of a randomly selected whale.

WOA achieves a balance between local and global exploration through its three primary operations, thereby

enhancing global search capabilities and mitigating the premature convergence problem commonly encountered in traditional optimization algorithms. As a result, WOA demonstrates superior performance in solving complex optimization problems [22].

III. PROPOSED IWOA-LSTM PREDICTION MODEL

A. IWOA-LSTM Model

The performance of an LSTM network is highly influenced by the selection of appropriate hyperparameters. However, traditional hyperparameter tuning methods often rely on manual expertise, which may not ensure optimal results across diverse scenarios [23]. To address this issue, this research proposes an improved Whale Optimization Algorithm (IWOA) integrated with the LSTM model to automate the hyperparameter optimization process.

IWOA combines Whale Optimization with Logistic Chaos Mapping to improve population diversity during initialization and prevent premature convergence to local optima, providing a more effective starting point for the optimization process. Additionally, IWOA incorporates a dynamic adjustment mechanism based on fitness variations, enabling the automatic fine-tuning of the mutation factor. This mechanism enhances the algorithm's global search capability and increases optimization efficiency.

In the IWOA-LSTM model, IWOA optimizes key LSTM hyperparameters, including the number of hidden units and the learning rate. By balancing global exploration and local exploitation, IWOA accelerates convergence and fine-tunes LSTM parameters, ultimately improving prediction accuracy. This approach minimizes manual intervention, enhancing the adaptability and performance of the LSTM network.

B. Chaotic Map Initialization

In WOA, the initialization of the population is a crucial factor that influences the optimization performance. Traditional random initialization can result in an uneven distribution of initial solutions, potentially reducing the algorithm's efficiency. To address this challenge, chaotic mapping is employed to adjust the control parameters of WOA, thereby improving the balance between exploration and exploitation. This technique enhances the algorithm's global convergence rate by generating a more dispersed and diversified initial population, thus reducing the likelihood of premature convergence to local optima.

In this study, chaotic mapping is introduced during the initialization phase of WOA, specifically utilizing the logistic chaotic mapping proposed by Prasad [24] and Yousri [25]. This mapping exhibits both random and deterministic characteristics, which facilitates the adjustment of WOA's control parameters. The initialization equation for chaotic mapping is as follows.

$$x_{i,j} = x_{i,j} * (b_j - a_j) + a_j \quad (11)$$

In Eq. (11), $x_{i,j}$ represents the position of the i -th whale in the j -th dimension. a_j and b_j denote the boundaries of the j -th dimensional space. The initialized $x_{i,j}$ is generated using the

Logistic chaotic mapping, and its iteration equation is as follows.

$$x = r * x * (1 - x) \quad (12)$$

In Eq. (12), r is the control parameter. In this study, its value is set to 4. This initialization method ensures the diversity of the population distribution, providing a strong starting point for subsequent iterations.

C. Dynamic Adjustment Mechanism

In the optimization process of WOA, applying an appropriate mutation operation after each individual's position update significantly enhances the algorithm's global search capability [26]. The mutation factor plays a pivotal role in this process. By dynamically adjusting the mutation factor based on changes in fitness and iteration step size, the algorithm effectively balances global exploration and local exploitation, thereby improving both convergence efficiency and solution accuracy.

To enable the dynamic adjustment of the mutation factor, this study proposes a fitness-based adjustment mechanism. This mechanism takes into account the current range of fitness changes, the step size, and the global optimal fitness value. By modulating the mutation factor, the algorithm achieves enhanced diversity and convergence performance. The dynamic adjustment factor is mathematically defined in Eq. (13).

$$\mu_t = \mu_{t-1} * \left(1 + \beta * \frac{|f_t - f_{t-1}|}{f_{max}} + \gamma * \sqrt{|f_t - f_{t-1}|} - \alpha * \frac{t}{T} \right) \quad (13)$$

In Eq. (13), μ_t represents the adjustment factor for the current iteration, while μ_{t-1} is the adjustment factor for the previous iteration. f_t and f_{t-1} are the fitness values for the current and previous iterations, respectively. β , γ , and α are hyperparameters that control the update of the adjustment factor. These parameters are used to measure the linear and nonlinear weights of the fitness change, as well as the effect of the time step size. In this study, they are set to 0.1, 0.2, and 0.05, respectively. t is the current iteration number, and T is the maximum number of iterations. μ_t is constrained within the range (0, 1).

After each position update, to boost the algorithm's global exploration capability, this study introduces a mutation operation based on the dynamic adjustment factor. After calculating the dynamic adjustment factor μ_t , a normal distribution random disturbance $N(0,1)$ is applied to fine-tune the individual positions. This disturbance operation not only enhances population diversity but also effectively prevents individuals from getting trapped in local optima, especially in the later stages of optimization. The specific position update equation is presented in Eq. (14).

$$x_{i,j}(t + 1) = x_{i,j}(t) + \mu_t * N(0,1) \quad (14)$$

This operation enhances the algorithm's ability to avoid local optima by introducing random disturbances, especially during the later stages of population convergence or optimization. The dynamic adjustment factor integrates fitness differences with a square root term, significantly increasing the

variation intensity during the early stages of optimization, when fitness differences are more pronounced. This approach introduces greater randomness into the search process, fostering a more thorough exploration of the global solution space.

As iterations progress, the influence of the adjustment factor is gradually reduced through a time attenuation mechanism, enabling the algorithm to transition from global exploration to local exploitation. This shift allows the algorithm to focus on refining the solution, thereby improving optimization accuracy.

Furthermore, the recursive calculation of the dynamic adjustment factor relies on the value from the previous generation. This design ensures smoother variation intensity, preventing abrupt fluctuations during the optimization process and maintaining stability. With this adaptive adjustment mechanism, the algorithm can adjust its search strategy in real-time based on changes in fitness, enabling it to maintain robust global search capabilities while avoiding premature convergence. Ultimately, this improves both optimization efficiency and solution quality.

D. The Construction Steps of IWOA-LSTM

This study employs the IWOA to optimize the LSTM neural network for predicting financial time series. Fig. 2 illustrates the overall process, with the steps detailed below:

Fig. 2. Flowchart of IWOA-LSTM.

Step 1: Data preprocessing. Normalize the original time series data adopting Min-Max scaling to bring it into the [0, 1], then partition the data into training and test sets.

Step 2: Initialize IWOA and LSTM parameters. For IWOA, set the population size, search space boundaries (for LSTM's hidden units and learning rate), maximum iterations, and dynamic adjustment parameters (β , γ , α). Use the logistic map for chaotic initialization to enhance population diversity. For the LSTM model, set the initial parameters to ensure smooth optimization.

Step 3: Train and optimize the LSTM model using IWOA by minimizing the mean squared error (MSE) through iterative updates. Evaluate the fitness of each whale in the swarm, identifying the best fitness values for both individual whales and the global solution. Use IWOA's position update formula and dynamic adjustment factor to refine whale positions, balancing global exploration and local exploitation. Continue the process until the maximum iteration threshold is reached or the global fitness threshold is achieved.

Step 4: Apply the fine-tuned LSTM model to the test data to validate its prediction capabilities.

Step 5: Evaluate the prediction performance by applying the optimized LSTM model to forecast the financial time series data. The results are then measured against five performance indicators to evaluate the model's accuracy and effectiveness.

IV. EXPERIMENTS

All programming works are implemented in the Python 3.9 environment. The computational experiments are performed on a system featuring a 12th Gen Intel(R) Core(TM) i5-1235U CPU, 16 GB of RAM, and operating on Windows 10.

A. Dataset

This study selected five globally representative stock indices as research subjects: the S&P 500 Index (Code: ^GSPC), Dow Jones Industrial Average (Code: ^DJI), FTSE 100 Index (Code: ^FTSE), Nasdaq Composite (Code: ^IXIC), and Shanghai Composite Index (Code: 000001.SS). These indices represent major economies in the Americas, Europe,

and Asia, providing comprehensive insights into the global capital market.

Specifically, the S&P 500 Index and the Dow Jones Industrial Average represent the U.S. capital market comprehensively. The S&P 500 Index includes 500 companies with the largest market capitalizations and significant industry representation, providing a broad view of the market. In contrast, the Dow Jones Industrial Average Index focuses on 30 prominent companies, often referred to as blue-chip stocks, representing major sectors of the U.S. economy. The FTSE 100 Index reflects the performance of the largest British companies by market capitalization and serves as a key benchmark for the European market. The Nasdaq Composite Index, heavily weighted by technology stocks, highlights global trends in technological innovation and growth. Lastly, the Shanghai Composite Index is a vital indicator of mainland China's capital market, encompassing all listed stocks on the Shanghai Stock Exchange.

The experimental data is obtained from <https://finance.yahoo.com/> and spans a period of 10 years, from October 23, 2014, to October 21, 2024. This timeframe encompasses significant global economic events, including the financial crisis triggered by the COVID-19 pandemic in 2020, subsequent recovery phases, and various national policy adjustments, which resulted in substantial market fluctuations. The dataset includes daily recorded basic information, providing a solid foundation for model training and testing. These data facilitate the assessment of the model's adaptability and robustness within a complex and volatile market environment. In addition, to verify the predictive ability of the model when external factors (e.g., macroeconomic indicators, social sentiment) are not introduced, the experimental design uses only historical price data for prediction. This design highlights the model's intrinsic performance in financial time series analysis, avoids interference from external variables, and objectively evaluates the performance of IWOA-LSTM in volatile market environments. The historical trends of the five stock indices are shown in Fig. 3. The detailed statistical analysis of the closing prices for each stock index is presented in Table I.

Fig. 3. Historical closing price charts for five stock indices.

TABLE I. DESCRIPTIVE STATISTICS OF STOCK CLOSING PRICES

Name	Count	Max	Min	Range	Mean	Std	Kurtosis	Skewness	Normality Test Statistic	Normality Test P-Value
^GSPC	2515	5864.67	1829.08	4035.59	3280.57	1035.14	-0.88	0.49	403.10	0.00
^DJI	2515	43275.91	15660.18	27615.73	27194.68	7082.78	-1.12	0.13	1129.42	0.00
^FTSE	2524	8445.80	4993.90	3451.90	7109.40	601.09	-0.02	-0.49	92.50	0.00
^IXIC	2515	18647.45	4266.84	14380.61	9573.88	3959.34	-1.11	0.41	1101.31	0.00
000001.SS	2427	5166.35	2290.44	2875.91	3183.23	349.92	5.52	1.45	782.03	0.00

From Fig. 3 and Table I, it is evident that the closing prices of these five stock indices (^GSPC, ^DJI, ^FTSE, ^IXIC, and 000001.SS) exhibit obvious nonlinear characteristics and high volatility, with the price trends showing irregularity and substantial noise. For example, the fluctuation range of ^DJI index is as high as 27615.73, which is significantly higher than that of the other indices, indicating extreme volatility. Although some trend changes are observed in the data, the overall price fluctuation demonstrates strong uncertainty, and the fluctuation pattern cannot be simply summarized as a linear relationship. The price fluctuations of these indices are influenced by a variety of complex factors, displaying both randomness and nonlinear characteristics. Traditional linear models struggle to effectively capture these intricate dynamics.

Conventional forecasting approaches face significant limitations in addressing the nonlinear and complex nature of stock market data, particularly in highly volatile time series. These methods, based on linear assumptions, are inadequate for capturing long-term dependencies and nonlinear trends. To overcome these challenges, this study employs the LSTM model, which excels at handling complex time series data due to its unique architecture and memory mechanism. By capturing long-term dependencies and nonlinear patterns, LSTM outperforms traditional methods, offering improved prediction accuracy and stability in the face of noise and complexity in stock market data.

B. Data Preprocessing

Data preprocessing is a critical component of data analysis, as it significantly influences model performance and prediction accuracy. In this study, the raw stock index data are cleaned to eliminate null and duplicate values, ensuring the integrity and reliability of the dataset. Subsequently, the Min-Max normalization technique is applied to scale the daily closing prices to the range [0, 1]. This normalization step mitigates the impact of varying data dimensions on model training. The equation used for normalization is in Eq. (15).

$$x_i = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (15)$$

In Eq. (15), x_i denotes the normalized data, while x_{max} and x_{min} represent the maximum and minimum value in the financial time series, respectively.

After the prediction is completed, the prediction results need to be transformed using inverse normalization. The inverse normalization equation is in Eq. (16).

$$x = (x_{max} - x_{min}) x_i + x_{min} \quad (16)$$

We prepare the data and normalize it to ensure uniform scaling and provide a stable input for the mode training.

C. Evaluation Metrics

Measuring prediction accuracy is a multifaceted task, and no single evaluation metric applies universally across different application scenarios. To comprehensively assess the model's prediction performance, this study employs five widely used evaluation metrics: Root Mean Square Error (RMSE), Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), Coefficient of Determination (R^2), and Explained Variance Score (EVS).

These evaluation metrics can be classified into error measures and fitting measures. Error measures, including RMSE, MAE, and MAPE, primarily assess the differences between predicted and actual values. Fitting measures, including R^2 and EVS, evaluate the model's fit. Specifically, the closer the R^2 value is to 1, the better the model's fit, while the closer the EVS value is to 1, the stronger the model's ability to explain the data. These five metrics together offer a comprehensive and accurate reflection of the model's prediction accuracy and fitting ability. The five evaluation metrics are expressed by the following equations:

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2} \quad (17)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |y_i - \hat{y}_i| \quad (18)$$

$$MAPE = \frac{100\%}{n} \sum_{i=1}^n \left| \frac{y_i - \hat{y}_i}{y_i} \right| \quad (19)$$

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y}_i)^2} \quad (20)$$

$$EVS = 1 - \frac{Var(y_i - \hat{y}_i)}{Var(y)} \quad (21)$$

Among them, y_i stands for the true value, \hat{y}_i represents the predicted value, \bar{y}_i denotes the mean of the financial time series, and $Var()$ refers to the variance.

To construct the input data for the LSTM model, this study employs sliding window method for time series and evaluates the impact of different time step settings on model's effectiveness. Specifically, the sliding window method uses fixed time steps to extract sequential features from stock data.

Four different time step settings are tested: 10, 20, 30, and 60. The MSE and training time of the model are calculated for each setting.

The closing price data are divided into training and test sets based on an 80:20 ratio, using various time step configurations (time_steps = 10, 20, 30, and 60). The LSTM model is trained on the training set and generates predictions for the test set. For each time step configuration, the training time (in seconds) and the MSE on the test set are recorded. Table II presents an overview of the experimental results.

TABLE II. IMPACT OF LSTM TIME STEP ON PREDICTION PERFORMANCE

Time Steps	MSE	Training Time (s)
10	0.000463	9.974107
20	0.000577	12.020250
30	0.000701	13.437092
60	0.000464	20.137358

TABLE III. MODELS COMPARED IN THIS RESEARCH

Model	Description of model parameters
IWOA-LSTM	time_steps=10, epochs=50, batch_size=32, population_size=5, units ∈ [10, 100], learning_rate ∈ [0.0001, 0.01]
WOA-LSTM	time_steps=10, epochs=50, batch_size=32, population_size=5, units ∈ [10, 100], learning_rate ∈ [0.0001, 0.01]
LSTM	time_steps=10, units=50, learning_rate=0.001, epochs=50, Dropout=0.2, batch_size=32
RNN	time_steps=10, units=50, learning_rate=0.001, epochs=50, Dropout=0.2, batch_size=32

D. S&P500 Forecasting

This study first selects the S&P 500 index (^GSPC) as the target for prediction. The dataset contains 2,515 records, spanning from October 23, 2014, to October 21, 2024, with daily closing prices. For model training, a retrospective period of 10 days is used, meaning that the closing prices from the past 10 days are employed in the prediction process. To thoroughly assess the prediction performance of each model, this study adopts five different evaluation indicators. Each model is evaluated based on these five indicators, with the best performance metrics marked in bold. The prediction comparison results for the various models on the S&P 500 index are presented in Table IV.

TABLE IV. COMPARISON RESULTS OF PREDICTIONS BETWEEN VARIOUS MODELS OF ^GSPC

Model	RMSE	MAE	MAPE	R2	EVS
IWOA-LSTM	48.1826	37.8081	0.9377%	0.9935	0.9936
WOA-LSTM	55.6435	44.2542	0.9638%	0.9913	0.9916
LSTM	70.4543	55.8142	1.2216%	0.9860	0.9863
RNN	93.7222	76.6777	1.5764%	0.9752	0.9869

As observed from the results in Table IV, the effectiveness of the IWOA-LSTM model is significantly superior to that of the other models across all evaluation metrics. Specifically, the IWOA-LSTM model outperforms WOA-LSTM in RMSE, MAE, MAPE, R², and EVS by 13.41%, 14.57%, 0.03%, 0.22%, and 0.20%, respectively. Furthermore, IWOA-LSTM shows

The experimental results reveal significant variations in both the MSE and the training duration of the model across different time step configurations. Specifically, when the time step is 10 days, the MSE of the model is 0.000463, and the training time is approximately 9.97 seconds. When the time step is increased to 60 days, the MSE slightly increases to 0.000464, while the training time rises significantly to about 20.14 seconds. Although the MSE at 60 days is similar to that at 10 days, the longer training time notably affects computational efficiency. Therefore, considering the need to balance prediction accuracy with computational efficiency, a 10-day time step is selected as the optimal configuration.

Next, the IWOA algorithm is applied to optimize the number of LSTM units and the learning rate. By leveraging IWOA, the model can dynamically fine-tune these hyperparameters, enhancing both prediction accuracy and computational efficiency. To evaluate the effectiveness of IWOA optimization, this study compares it with other popular models, including WOA-LSTM, LSTM, and RNN. Table III shows the models compared in this study and their parameters.

improvements over the LSTM model by 31.61%, 32.26%, 0.28%, 0.76%, and 0.74%, and is 48.59%, 50.69%, 0.64%, 1.88%, and 0.68% better than the RNN model in the same metrics.

In addition to evaluating prediction accuracy, this study also investigates the computational efficiency of the IWOA-LSTM model by comparing its runtime performance with that of the standard WOA during hyperparameter optimization and model training. Fig. 4 presents the comparison of their runtime performance.

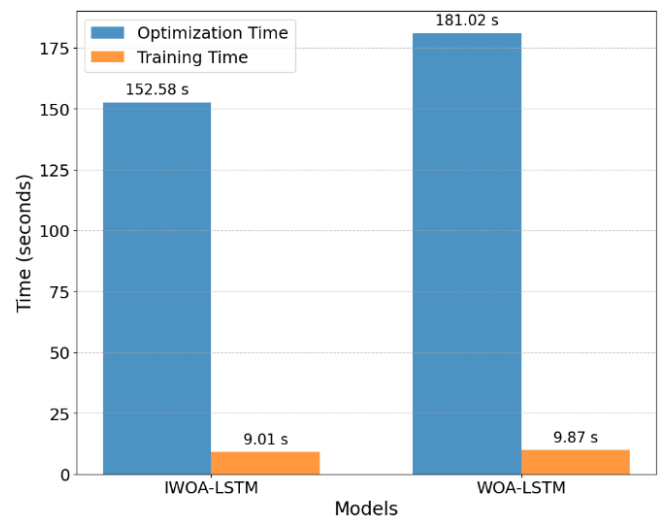

Fig. 4. Runtime comparison.

Fig. 4 compares the optimization and training times of the IWOA-LSTM and WOA-LSTM models, highlighting the performance differences. The optimization time for IWOA-LSTM is 152.58 seconds, while WOA-LSTM takes 181.02 seconds, indicating that IWOA-LSTM is more efficient in parameter optimization. This improvement is attributed to the use of logistic chaotic mapping and a dynamic adjustment factor mechanism, which enhance search precision and reduce unnecessary iterations. For training time, IWOA-LSTM takes 9.01 seconds, while WOA-LSTM takes 9.87 seconds. Although the difference is small, IWOA-LSTM shows a slight advantage, proving that improved optimization efficiency does not slow down the training process. The results show that IWOA-LSTM improves operational efficiency while maintaining predictive performance and is able to converge on complex datasets relatively quickly.

Overall, the results of these experiments on the ^GSPC stock index show that the IWOA-LSTM model performs well across all evaluation metrics. In addition to its excellent performance on these metrics, the IWOA-LSTM model also shows an advantage in hyperparameter optimization time compared to the original WOA, reflecting an improvement in the model's computational efficiency during the optimization process. This highlights the effectiveness of optimizing the LSTM hyperparameters, which not only leads to more accurate predictions but also improves computational efficiency.

Next, to provide a more intuitive view of the fitting performance of each model, the final fitting comparison results are presented in Fig. 5 and Fig. 6.

Fig. 5 demonstrates the fitting results of the ^GSPC index prediction based on different models. The curves in the figure illustrate the prediction results of the IWOA-LSTM, WOA-LSTM, LSTM, and RNN models, respectively, and are compared with the actual price curves. It can be observed that the prediction curves of the IWOA-LSTM model are closest to the actual prices, especially in most time intervals, where the prediction curves of the IWOA-LSTM almost coincide with the actual price curves, showing very high prediction accuracy. In contrast, although the WOA-LSTM model also shows relatively accurate predictions, the discrepancy between the predicted and actual values becomes more pronounced during periods of high volatility. Nonetheless, despite slight deviations in more volatile markets, the overall performance remains robust, suggesting that the model is able to effectively capture the general trend. The LSTM and RNN models show relatively lower prediction accuracies, especially in regions of high price volatility, where the predicted curves of both models deviate more from the actual prices. This suggests that the LSTM and RNN models are not as effective as the IWOA-LSTM and WOA-LSTM models in capturing complex patterns.

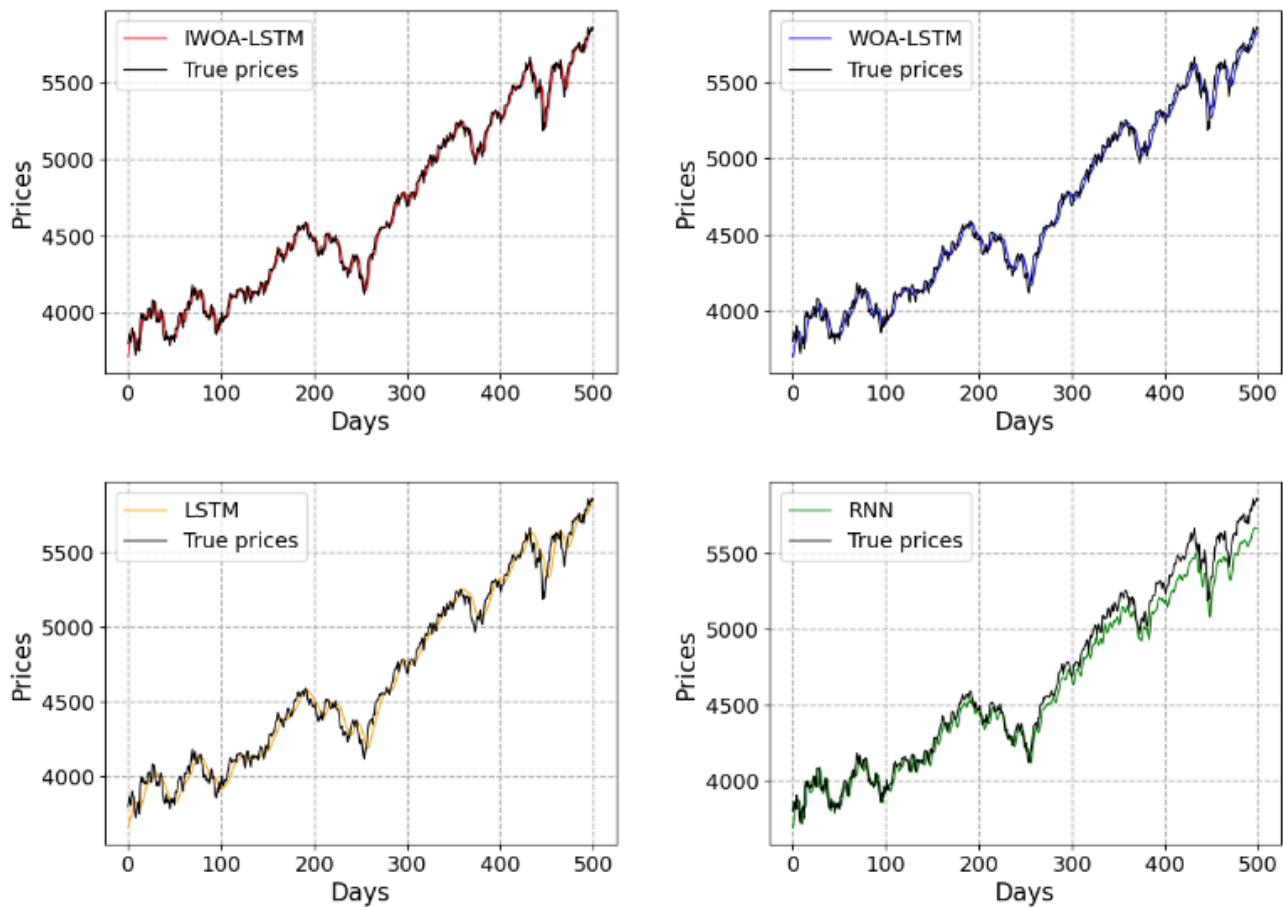

Fig. 5. Individual forecasts of four models on the ^GSPC index.

Fig. 6. Comparison of forecasts from four models on the ^GSPC index.

The illustration in Fig. 6 shows the forecast results for the last 100 days. During this period, the IWOA-LSTM prediction curve continues to outperform the other models, especially in short-term price fluctuations, where IWOA-LSTM more accurately captures the trend of stock prices. In contrast, the fitting effect of the RNN model is poor, particularly during periods of significant stock price fluctuations, where its prediction error is quite noticeable.

Overall, IWOA-LSTM performs particularly well in the ^GSPC index prediction task. It is better at capturing the complex dynamic patterns in the time series and providing high-precision prediction results, which demonstrates its advantages in financial time series forecasting.

To further validate the predictive ability of the IWOA-LSTM model, this study compares it with other improved WOA algorithms proposed by Shao [27] and Guan [28]. Apart from the improved algorithms discussed in the paper, all other parameter settings are consistent with those used in this study. Additionally, this study incorporates PSO-LSTM [29] and GA-LSTM [30], two advanced swarm intelligence optimization models. A comparative analysis is performed to evaluate the prediction performance of different optimization methods on the ^GSPC index. The comparison of prediction performance results is presented in Table V.

TABLE V. COMPARISON OF PREDICTION PERFORMANCE OF IWOA-LSTM MODEL AND OTHER IMPROVED LSTM MODEL

Model	Optimization Details	RMSE	MAE	R2
IWOA-LSTM (Proposed in this study)	Logistic chaotic mapping; dynamic adjustment factor mechanism	48.1826	37.8081	0.9935
IWOA-LSTM [27]	Tent chaotic mapping; adaptive weight	57.7395	47.2308	0.9906
WOA-BiLSTM [28]	Whale optimization algorithm optimized Bidirectional LSTM	65.0222	53.2598	0.9881
PSO-LSTM [29]	Particle swarm optimized LSTM	49.1197	38.8116	0.9931
GA-LSTM [30]	Genetic algorithm optimized LSTM	52.7665	42.0509	0.9921

From Table V, the IWOA-LSTM model achieves better prediction results compared to other models. With the integration of the logistic chaotic map and dynamic adjustment mechanism, IWOA-LSTM demonstrates improved prediction accuracy and stability. Although the other models have been enhanced, their accuracy and effectiveness in predicting financial time series do not fully match those of IWOA-LSTM. This suggests that IWOA-LSTM offers certain advantages in forecasting financial time series.

E. The Robustness and Reliability Verification

In order to conduct a deeper validation of the IWOA-LSTM model's robustness and reliability, this study performs experiments on other four famous stock indices: ^DJI, ^FTSE,

^IXIC, and 000001.SS. The corresponding experimental results are presented in Table VI to Table IX and Fig. 7 to Fig. 10.

TABLE VI. COMPARISON RESULTS OF PREDICTIONS BETWEEN VARIOUS MODELS OF ^DJI

Model	RMSE	MAE	MAPE	R2	EVS
IWOA-LSTM	344.4983	277.7575	0.7700%	0.9870	0.9888
WOA-LSTM	436.9144	357.2306	0.9766%	0.9791	0.9829
LSTM	483.1204	379.3579	1.0572%	0.9744	0.9749
RNN	632.4826	513.0577	1.3752%	0.9562	0.9732

TABLE VII. COMPARISON RESULTS OF PREDICTIONS BETWEEN VARIOUS MODELS OF ^FTSE

Model	RMSE	MAE	MAPE	R2	EVS
IWOA-LSTM	73.6150	54.8546	0.7112%	0.9502	0.9502
WOA-LSTM	73.9682	55.0725	0.7130%	0.9497	0.9500
LSTM	183.0727	157.7665	1.9980%	0.6917	0.8732
RNN	77.3710	60.2541	0.7754%	0.9449	0.9526

TABLE IX. COMPARISON RESULTS OF PREDICTIONS BETWEEN VARIOUS MODELS OF 000001.SS

Model	RMSE	MAE	MAPE	R2	EVS
IWOA-LSTM	38.1677	25.8819	0.8397%	0.9371	0.9372
WOA-LSTM	42.3903	28.5810	0.9294%	0.9224	0.9229
LSTM	56.3180	37.6384	1.2245%	0.8631	0.8631
RNN	43.9960	30.4456	0.9893%	0.9164	0.9175

TABLE VIII. COMPARISON RESULTS OF PREDICTIONS BETWEEN VARIOUS MODELS OF ^IXIC

Model	RMSE	MAE	MAPE	R2	EVS
IWOA-LSTM	208.4710	167.3047	1.1916%	0.9921	0.9923
WOA-LSTM	259.5208	211.9485	1.4697%	0.9878	0.9899
LSTM	324.4165	264.5356	1.8428%	0.9810	0.9836
RNN	327.8000	260.9647	1.7722%	0.9806	0.4920

As shown by the comparison results in Table VI to Table IX and Fig. 7 to Fig. 10, the IWOA-LSTM model demonstrates superior prediction accuracy and a better fit than other models in predicting four different stock indices (^DJI, ^FTSE, ^IXIC, and 000001.SS). The IWOA-LSTM model achieves lower errors and improved accuracy across multiple evaluation metrics (RMSE, MAE, MAPE, R², EVS). In particular, its RMSE and MAE values indicate better accuracy compared to WOA-LSTM.

Fig. 7. Comparison of forecasts from four models on the ^DJI index.

Fig. 8. Comparison of forecasts from four models on the ^FTSE index.

Fig. 9. Comparison of forecasts from four models on the ^IXIC index.

Fig. 10. Comparison of forecasts from four models on the 000001.SS index.

When compared with the LSTM and RNN models, the IWOA-LSTM model shows clear advantages, particularly in capturing the volatility of financial markets and the complexity of time series data. It demonstrates strong adaptability in the ^DJI, ^FTSE, and ^IXIC and also performs well in predicting the Shanghai Composite Index (000001.SS), with RMSE, MAE, and MAPE values lower than those of the other comparative models. Overall, the IWOA-LSTM model improves prediction accuracy and stability through optimized hyperparameter settings, demonstrating strong potential for application in financial time series forecasting, particularly in stock index prediction.

V. CONCLUSION

A novel model integrating the Improved Whale Optimization Algorithm (IWOA) with Long Short-Term Memory (LSTM) is proposed to enhance the accuracy of stock

market index forecasting. This model employs chaotic map initialization and a dynamic adjustment mechanism to optimize the LSTM network's parameters, thereby improving prediction which confirms performance. Chaotic assignment improves the global search capability of the algorithm and enables a thorough exploration of the solution space. Additionally, the dynamic adjustment factor increases WOA efficiency, optimizes LSTM hyperparameters, and improves prediction accuracy and stability.

The study focuses on five representative stock market indexes (^GSPC, ^DJI, ^FTSE, ^IXIC, and 000001.SS) and evaluates the model's performance adopting five essential evaluation metrics: RMSE, MAE, MAPE, R^2 , and EVS. These metrics comprehensively evaluate the model's prediction ability from the perspectives of error magnitude, absolute and relative error, goodness of fit, and variance explained. Experimental results show that the IWOA-LSTM model

outperforms WOA-LSTM, LSTM and RNN in all five metrics. This highlights its superior accuracy, robustness and stability.

Although this study presents an innovative approach to stock index prediction and offers valuable contributions, the IWOA-LSTM model has certain limitations. Its performance depends heavily on the range of hyperparameter values, which need to be set based on empirical experience to ensure optimal results. Additionally, although the IWOA-LSTM model reduces runtime compared to the traditional WOA algorithm, the computational cost remains relatively high. Furthermore, the validation is conducted on only five representative stock indices, limiting the sample size.

Future research will focus on expanding the dataset to include additional stock indices and broader financial market data to assess the model's generalizability and robustness. The model will also be applied to other time series tasks, such as energy forecasting and medical trend analysis, to evaluate its cross-industry adaptability and performance. Additionally, advanced optimization techniques, including the integration of metaheuristic algorithms and hybrid optimization methods, will be explored to enhance feature selection and hyperparameter tuning. Modal decomposition methods will be studied to decompose and reconstruct time series data, reducing noise and improving the model's ability to detect market fluctuations, thereby enhancing prediction accuracy and stability. Further research will also explore the correlations between the stock market and other financial markets to analyze the potential impact of external market fluctuations. Moreover, external features, such as macroeconomic indicators and social sentiment, will be incorporated to assess their influence on predictions and improve the model's adaptability in complex market environments.

Abstract—LoRaWAN networks and large places do not support Wi-Fi for multiple points. An architecture that offers dual networks to alter their supporting networks is needed for IoT device installation. The novelty in this research is that designing an architecture for multimode LoRa-MQTT with a mechanism for testing LoRa data transmission with different delays and Wireshark for testing Wi-Fi network QoS on MQTT is necessary. This hour-long LoRa network experiment shows that the End-Node can only receive one data at a time. One data set will be received if several data sets are obtained due to conflict. The second experiment showed data barely reached 70%. The signal strength or RSSI, and the node that sent the data initially decide the data received from a given node, some seconds apart, towards tested QoS with excellent packet loss, 21 ms delay, 50,616 bytes/s throughput, and 0.1426 jitter. Avoid data conflicts and loss by utilizing fewer nodes or adding end nodes in this experiment. The network service is excellent. According to this study, LoRa and MQTT can work well together. This approach could solve Internet of Things communication concerns, especially in large places that are LoRaWAN-inaccessible and Wi-Fi networks are limited.

Keywords—LoRa; MQTT; multinode; QoS; LoRaWAN

I. INTRODUCTION

Improvements in telecommunications technology are currently developing rapidly, and new telecommunications systems are starting to emerge, such as the LoRa (Long Range) protocol [1]-[3] and also MQTT [4],[5], which are used in various fields. LoRa is currently believed to be a telecommunications technology that can be used for long-distance communications because LoRa uses CSS (Chirp Spread Spectrum) modulation technology [6], which makes it possible to send low-power and long-distance data. LoRa is often used in IoT (Internet of Things) devices [7]-[9] to send data from node to node. The advantage of LoRa is that it uses non-licensed frequencies such as the AS920-923 standard, which is the LoRa frequency standard in Asia ranging from 920MHz to 923MHz so that any user can freely use this frequency.

LoRa is a technology located at the physical layer network for limited node-to-node long-distance communication [10]. It cannot be used for open networks such as Wi-Fi or GSM [11], [12], which allows data to be sent to servers. An open network is important for the Internet of Things so that users can monitor or control IoT devices. So, LoRaWAN [13] is a solution because

LoRaWAN works at the data link layer [14]. LoRaWAN allows IoT devices to send data to servers and already has been tested with a multi-client model [15]. However, the LoRaWAN network remains limited in its capabilities due to incomplete implementation across all sites, For the future, LoRaWAN must be able to be combined with cross-communication technology at different frequencies, for example at 2.4 GHz, with a large bandwidth it is possible to transfer data well such as traffic light data [16] which requires video in the data transmission process, and also Face Recognition [17] which is based on images. Some techniques such as doing split images when transmitting data are also still a challenge using LoRa's limited bandwidth. LoRaWAN Technology must also continue to be improved in terms of server security, for now, LoRaWAN Server uses AES [18] as server security, In the future, LoRaWAN technology will continue to be developed along with the development of telecommunication systems such as Lacuna Space which uses LPWAN Satellite LEO technology in its development.

Moreover, if the Internet of Things device is configured for the LoRaWAN network, this must be considered since it may provide difficulty. The site of the Internet of Things device installation lacks functionality for the LoRaWAN network. Moreover, such a broad area only facilitates the Wi-Fi network for many places. This research proposes a solution to the location issue that is incompatible with the LoRaWAN network. Moreover, a limited number of locations have Wi-Fi access. On the other hand, MQTT is usually used to communicate media of the Internet of Things. This solution is realized by integrating LoRa and MQTT to facilitate data transmission between the user and the server, or vice versa. Two communications are needed, namely LoRa and Wi-Fi [19], to send data to the MQTT broker.

The main contribution of this work is to demonstrate and analyze the LoRa-MQTT multi-node communication technology. In this research, the design of architecture LoRa-MQTT on multi-node IoT devices to send and receive data so that users can monitor data in real-time [20] and control [21] the devices installed on the IoT device. Apart from that, LoRa and Wi-Fi networks that use the MQTT protocol [22] will be analyzed using Wireshark [23] to determine the quality of service (QoS) [24]-[26] on the system. As a result, the percentage of end-node data reception sent by multi-nodes will be calculated later. Other than that, measurements will be taken of the data received by the MQTT Broker to know the system's reliability in the end.

II. METHOD AND ARCHITECTURE DESIGN

This section presents the architectural design for multimode and end-node, an IoT device consisting of an ESP32 and LoRa microcontroller [27],[28]. Two programming settings are applied to each node, namely to send data from node to end node and receive data from end nodes. Likewise, the end-node has two settings, namely receiving from each node, then the end-node will publish the data to the MQTT-broker [29]-[31]. During the publishing process, the network will be tested using Wireshark to see the quality of service on the network. Quality of service consists of packet loss, the total number of packets lost from all the data left, as in Eq. (1). Then delay is the time required for data to cover the distance from origin to destination, as in Eq. (2). Next, throughput is the actual bandwidth measured in units. A specific time is used to transfer data of a certain size, such as Eq. (3) Jitter is a variation of delay caused by the queue length in data processing and reassembly of data packets at the end of transmission due to previous failures such as Eq.(4) Delay variations will refer to all samples in Wireshark. The second setting is to subscribe to data by the end node, and the end node will send the data to the node according to the address. As shown in the block diagram in Fig. 1. In carrying out the multi-communication technique of LoRa end-nodes, a method is needed so that there is no redundancy in transmission which causes packet errors [6] such as ADR, LBT, LR-FHSS, etc, This is an essential solution.

Furthermore, Eq. (1)-Eq. (4) are the basic formulas used in making the analysis in this research and finding the right results

from the LoRaWAN analysis by comparing the theoretical and practical results so that it becomes the right solution during the process of transmitting data analysis.

$$Packet\ loss = \frac{(Packet\ transmittite - Packet\ Received)}{Packet\ transmittite} \times 100(1)$$

$$Delay = \frac{Total\ Delay}{Total\ Packets\ Received} \quad (2)$$

$$Throughput = \frac{Packet\ Received}{Time\ Transmitted} \quad (3)$$

$$Jitter = \frac{Total\ Delay\ Variation}{Total\ packets\ received - 1} \quad (4)$$

This research uses six nodes as IoT devices that will send data to the end nodes. Each node, including end nodes, has an address and channel, as shown in Fig. 1. The address of each node is different; each LoRa can be set using numbers ranging from 0 to 65535 and the same channel; this channel represents the frequency used. In this research, channel 72 is used, which represents the 922MHz frequency. Each node has the same program contents: the destination address, destination channel, and data. Data nodes consist of two types, namely analog data and digital data. Analog data represents data from sensors, and digital data represents data from actuators, which only consists of 1 and 0 or 1 for active and 0 for inactive. Address settings, channels, and examples of programming content, along with examples of data with semicolon separators sent by each node, can be seen in Table I.

Fig. 1. The design architecture of multinode LoRa-MQTT.

TABLE I. CONFIGURATION OF LoRA NODES

Node Name	Address	Channel	Target Address	Target Channel	Programming Content	Information
Node 1	31	72	10	72	0, 10, 72, 10;20;30	Key = 0 (NOT USE) Target Address=10 Target Channel=72 String Data = 10;20;30
			10	72		
Node 2	32	72	10	72		
			10	72		
Node 3	33	72	10	72		
			10	72		
Node 4	34	72	10	72		
			10	72		
Node 5	35	72	10	72		
			10	72		
Node 6	36	72	10	72		
			10	72		
End-Node	10	72	31, 32, 33, 34, 35, 36	72	From 10;20;30 to be [data1=10;data2=20;data3=30]	convert string data to JSON

The data flow process from multi-node to end-node to the user is as follows:

- 1) Data is sent from each node to the end node in the form of string data type using the LoRa network with 10 addresses and 72 channels or 922MHz frequency.
- 2) Then, the data will be converted into JSON from the end node.
- 3) Next, it is published to the MQTT Broker using a Wi-Fi network with the topic smartfarm/Address_Node/sensors with the information in Table III.
- 4) Users will subscribe to data from MQTT Broker on the same topic as number 3.

Next, the user process sends command data to move the actuator on the node as follows:

- 1) The user will send data in JSON form to the MQTT broker with the topic smartfarm/Address_Node/actuator with the information in Table III.
- 2) Then, subscribed by the end-node on the same topic as number 1.
- 3) Then, the end node converts the JSON data to String.

The end node sends data to the user's destination node according to the Address_Node on the topic.

III. RESULT AND DISCUSSION

This section presents the results and analysis of several experiments, which are divided into two. The first is an analysis of LoRa communications, which explains the results of experiments sending data from multi-node to end-node with variations in delay, and the second is an analysis of the quality of service on Wi-Fi networks with the MQTT protocol using Wireshark.

A. LoRa Communication Analysis

Define abbreviations and acronyms the first time they are used. This section presents an analysis of the experiment of sending data from six nodes to the end node. Several experiments have been carried out, namely sending data simultaneously at one time and sending data with different time delay variations at each node, as in Table II and detail conflict in Table IV.

In the first experiment, each node sends data to the end node with the same delay, namely 1 second. Only node 1 is sent during the sending process, and only data from one node can be received. This is due to data reception conflicts with other nodes. The data received from a particular node depends on the node that sent the data first with a difference of a few seconds and the signal strength or RSSI (Receive Signal Strength Indicator), as shown in Fig. 2.

TABLE II. RESULT AND ANALYZES OF VARIATION DELAY FOR SENDING DATA

No Experiment	Delay settings	Information data received by the end-node					
		Node 1	Node 2	Node 3	Node 4	Node 5	Node 5
1	Node 1,2,3,4,5,6 = 1 second	Data Received	no data	no data	no data	no data	no data
2	Node 1 = 3 minutes Node 2 = 5 minutes Node 3 = 7 minutes Node 4 = 9 minutes Node 5 = 11 minutes Node 6 = 13 minutes	Data Received with note : Data reception conflict 13 times in 1 hour with other nodes	Data Received with note : Data reception conflict 6 times in 1 hour with other nodes	Data Received with note : Data reception conflict 3 times in 1 hour with other nodes	Data Received with note : Data reception conflict 7 times in 1 hour with other nodes	Data Received with note : Data reception conflict 2 times in 1 hour with other nodes	Data Received with note : Data reception conflict 1 times in 1 hour with other nodes
3	Node 1 = 13 minutes Node 2 = 14 minutes Node 3 = 15 minutes Node 4 = 16 minutes Node 5 = 17 minutes Node 6 = 18 minutes	Data Received with note : There is no conflict within 1 hour, but after more than 1 hour there will be a conflict in receiving data with other nodes					

TABLE III. MQTT TOPIC INFORMATION

No	Topic of MQTT	Information
1	smart farm/Address_Node/sensors	Topic for data from nodes (analog or digital data). If the data is from Address 30 then Address_Node=30
2	smart farm/Address_Node/Threshold	Topic for threshold data for sensor values to move actuators. If the data is from Address 30 then Address_Node=30
3	smart farm/Address_Node/actuator	Topic command data from the user. If the user's destination is address 30 then address_Node = 30

Each node was given different data transmission delay variations in the second experiment. Within 1 hour, there were quite frequent reception conflicts. The data received by the end node will depend on the split-second difference and RSSI. From the result of the experiment, using the Greatest Common Factor (GCF), can identify which nodes are going through conflict along with which minutes as shown in Table IV, and the percentage of receiving data is 70%.

In the third experiment, delay variations were given from node 1 to node 6, starting from 13 to 18 minutes. Within 1 hour of sending data to the end node, there was no conflict in receiving data; however, after more than 1 hour, there was a conflict in receiving data, and conflicts occurred more frequently over time because the time interval delay is much longer. This multi-node system cannot communicate data at the same time. To avoid conflict in the receiver, future studies can set each node to send data separately between milliseconds and seconds.

B. Analyzes Network of MQTT Protocol

Furthermore, when the end node receives data in the string type from each node, it will convert the string data into JSON and immediately send it to the MQTT Broker. This section will present network analysis with the MQTT protocol using Wireshark to capture network data with uplinks and downlinks, as in Table V. This experiment was carried out to see the network stress level by sending data every five seconds with a data load of 118 bytes. Then, the Wireshark capture results will be processed to produce Quality of Service as in Table VI, which consists of delay, throughput, packet loss, and jitter using Eq. (1) - Eq. (4).

Fig. 2. RSSI Index from node 1 to node 6.

Moreover, from the perspective of the ITU G.1010 standard, Table VI provides an overview of the quality of service on the network that was utilized to access the MQTT Broker on the smart farm server. Because there is no packet loss, the delay value in this table falls into the category of very good. This indicates that there is no loss of data during the transmission process from the end node to the MQTT Broker. After that, the delay is considered to be very good because it is still less than 150 milliseconds; this is because the network conditions are good and the weather conditions are sunny.

The next step in the research process is to conduct experiments with a variety of weather conditions to enhance the architectural architecture of the LoRa-MQTT protocol. Therefore, the jitter is satisfactory because it is less than 75 milliseconds; it would be ideal if the jitter were zero milliseconds. In addition to this, it is essential to conduct research with two end nodes for every six nodes to get a better understanding of the design and reduce the number of data conflicts.

TABLE IV. DETAIL CONFLICT OF NODE WITHIN 1 HOUR OBSERVATION

TABLE VI. VALUE AND CATEGORY FOR PACKET LOSS, DELAY, THROUGHPUT, AND JITTER

	Packet Loss	Delay	Throughput	Jitter
Value	0%	21ms	50.616 bytes/s	0.1426ms
Category	Very Good	Very Good	No Category	Good

From the perspective of the ITU G.1010 standard, Table 6 provides an overview of the quality of service on the network that was utilized to access the MQTT Broker on the smartfarm server. Because there is no packet loss, the delay value in this table falls into the category of very good. This indicates that there is no loss of data during the transmission process from the end node to the MQTT Broker. After that, the delay is considered to be very good because it is still less than 150 milliseconds; this is because the network conditions are good and the weather conditions are sunny.

The next step in the research process is to conduct experiments with a variety of weather conditions to enhance the architectural architecture of the LoRa-MQTT protocol. Therefore, the jitter is satisfactory because it is less than 75 milliseconds; it would be ideal if the jitter were zero milliseconds. In addition to this, it is essential to conduct research with two end nodes for every six nodes to get a better understanding of the design and reduce the number of data conflicts.

IV. CONCLUSION

The issue is that the IoT device's location lacks compatibility with the LoRaWAN network, and extensive areas require Wi-Fi network connectivity for many position points. The research defines the multi-node LoRa-MQTT architecture and conducts a performance comparison of the two protocols. An experiment was conducted in the LoRa network to transmit data from six nodes to the end nodes with differing delays. The results of this experiment, conducted over one hour of observation, indicate that the End-Node can receive just one data packet at a time. If multiple data points are received, a conflict will occur, resulting in the reception of only one data point. The second trial revealed that the data obtained scarcely attained 70%. The data obtained from a certain node is contingent upon the initial node that

transmitted the data, with a few seconds of interval, in addition to the signal strength or RSSI. The subsequent part of the research involves identifying a mechanism, modulation, adjustment of delay, or procedure that facilitates data transmission. Contemplate employing a queueing method. In the investigation of the MQTT protocol network, there is 0% packet loss classified as very excellent, a delay of 21ms also categorized as very good, a throughput of 50,616 bytes/s, and a jitter of 0.1426 classified as good. This study demonstrates that the integration of LoRa with the MQTT protocol can yield a highly successful solution. This concept can address Internet of Things obstacles, including communication problems in extensive platforms that lack LoRaWAN accessibility, with Wi-Fi networks available only at certain locations.

FUTURE RESEARCH

LoRaWAN technology that is developing at this time, not only setting the Multi-Communication and transmission analysis process using MQTT but needs development from the Terrestrial Communication side to Non-Terrestrial Communication before data is received on the LoRaWAN Server. This is used in the future to reduce Packet Error and the presence of obstacles and Interferences.

ACKNOWLEDGMENT

Thanks to Riset dan Inovasi untuk Indonesia Maju (RIIM) (G2) National Research and Innovation Agency (BRIN) for providing research funding support. Thanks also to the School of Integrated Circuits and Electronics, Beijing Institute of Technology, and colleagues at the telecommunications research center and electronics research center who have contributed to the completion of this research. The author hopes that this research can be further developed and utilized as well as possible by partners.

Abstract—The rapid development and advancement of 5G technologies and smart devices are associated with faster data transmission rates, reduced latency, more network capacity, and more dependability over 4G networks. However, the networks are also more complex due to the diverse range of applications and technologies, massive device connectivity, and dynamic network conditions. The dynamic and complex nature of the 5G networks requires advanced and accurate traffic prediction methods to optimize resource allocation, enhance the quality of service, and improve network performance. Hence, there is a growing demand for training methods to generate high-quality predictions capable of generalizing to new data across various parties. Traditional methods typically involve gathering data from multiple base stations, transmitting it to a central server, and performing machine learning operations on the collected data. This work suggests a hybrid model of Long Short Term Memory (LSTM), Gated Recurrent Unit (GRU), and federated learning applied to 5G network traffic prediction. The model is assessed on one-step predictions, comparing its performance with standalone LSTM and GRU models within a federated learning environment. In evaluating the predictive performance of the proposed federated learning architecture compared to centralized learning, the federated learning approach results in lower Root Mean Square error (RMSE) and Mean Absolute Errors (MAE) and a 2.25 percent better Coefficient of Determination (R squared).

Keywords—5G Mobile network; machine learning; federated learning; parallel hybrid LSTM+GRU; network traffic prediction; centralized learning; dynamic network condition

I. INTRODUCTION

As witnessed the evolution of communication networks into the 5G era, the demand for high-speed, low-latency connectivity is growing exponentially. The development of 5G networks also increases data rates and complexity due to various services and multiplexed device connections; this makes network resource management of a 5G network a complicated task because of the diverse nature of network traffic conditions. The growth in the number of users and devices is increasing traffic exponentially, causing congestion in the network from many angles [1].

Due to most devices now being connected, the conventional 4G networks cannot meet the current demand. The advantages that the 5G network can provide are becoming more visible as its scope continues to expand. Compared to their 4G counterparts, 5G networks provide faster data transmission, reduced delay, expanded coverage, and greater reliability.

Managing 5G networks as they evolve and become more complicated is now one of the greatest difficulties with developing them. One critical element of this management is predicting network traffic, which has advanced greatly through machine learning techniques [1], [2].

With new elements such as millimeter waves, massive MIMO (Multiple Input, Multiple Output), and network slicing, 5G networks are much more sophisticated than their predecessors. This complexity requires sophisticated traffic control methods. Moreover, the various services of 5G, such as enhanced mobile broadband (eMBB), massive machine-type communication (mMTC), and ultra-reliable low-latency communication (URLLC) [3], imply different traffic dynamics that require prediction and control.

The huge increase in the number of devices connected leads to an increase in the volume of mobile traffic and adds stress to the system to cope with the volume of data [4]. Ericsson expects 5G subscriptions projected at approximately 610 million by the end of 2023, meaning that about one-fifth of all mobile subscriptions worldwide would be 5G [5]. The research predicted demand growth will increase to approximately 5.3 billion 5G subscriptions by 2029 [6].

5G networks allow the implementation of edge computing, which brings computation and data storage close to the network edge. By processing data at the edge, latency-sensitive applications might achieve lower network utilization levels while enjoying greater speeds, security, and privacy [7].

Network traffic forecasting was based on statistical models. Techniques such as time series analysis, regression analysis, and Markov models have been employed to forecast network behavior by leveraging historical traffic data. Time series models such as the Autoregressive Integrated Moving Average (ARIMA) are effective tools in identifying seasonal trends and irregular patterns in data over periods [8]. They make it possible to determine traffic cycles that could be predicted at intervals of a day, week, or even a month. Regression models, e.g., linear, polynomial, and multiple regression analysis, can explain such relations as the time of day, human activity, and external factors such as weather. Besides this, these models are good at understanding relationships influencing traffic volume.

Markov models such as the Hidden Markov Models (HMM) and the Markov Chain Monte Carlo (MCMC), on the other hand, apply a probabilistic technique to estimate different stages of the network, thus market appeal and ability to offer better traffic

prediction because of considering the stochasticity of the network traffic [8], [9]. Some of these traditional models have also been used for forecasting traffic.

However, with the growth of the networks, the weaknesses of these models are becoming more of a concern. In most cases, these models obtrude the linearity, which, along with the inability to manage high dimensional data, high rate of change in patterns of networks, or manage an anomaly, which is not a common phenomenon in the network [9]. This highlights the requirement for more sophisticated predictive models. Today, machine learning (ML) methods are believed to help deal with the complexities of 5G traffic, especially concerning the predictive aspect. Unlike traditional models, ML models can handle large volumes of datasets, capture nonlinear relationships, and learn and update to changes occurring in real-time.

The advantage of machine learning models is that they can discover intersectional structures or relationships that can be captured through conventional statistical means such as models by training generally on large datasets [10]. For instance, deep learning models such as Recurrent Neural Networks (RNNs) and long short-term memory (LSTM) appreciate recognizing sequential information in a given network traffic data frame rate, improving precision forecast along the time scale. Similarly, incentive-based resource allocation has been demonstrated to integrate across existing resource conditions by learning sub-network policies with dynamic structures [11].

Federated learning (FL) is projected as one of the many machine learning paradigms appropriate for 5G networks. Federated learning is a novel approach for training models without needing a central server to host raw data on devices [12]. This is highly timely in the case of fifth-generation networks (5G), as data privacy and security are critical owing to the potential proliferation of personal gadgets and the IoT. Federated Learning helps model training with privacy, bandwidth, and data constraints by leveraging edge devices in a distributed manner.

FL advancements enable privacy and more efficient model training, as the processing of network traffic data can occur at the edge of the network [13], [14]. This paper studies how predictive machine learning models based on federated learning can be employed to predict traffic in 5G networks.

The structure of the paper is as follows: Section II reviews the related work, while Section III outlines the architectures of the prediction methods. Section IV delves into the prediction methodology. The experimental results are presented in Section V, and the paper concludes in Section VI.

II. RELATED WORK

Advancements in 5G networks have made efficiently managing their dynamic and complex nature challenging. One possible solution to the above is predicting the network traffic on such a network, which is steadily receiving support in the form of machine learning advances.

The author in study [15], through network Internet traffic analysis and forecasting of input traffic flow parameters to the model, developed a 5G network traffic prediction model that

utilizes recurrent neural networks in their paper. They have employed Gated Recurrent Units (GRU) and (LSTM) to obtain a balance between optimality and viability. Such networks have acquired short-term traffic predictions since feature engineering was introduced to the model to reduce generalization errors and manage missing and corrupted data. Still, there is a need for more research on machine learning application techniques for network management and control in traditional distributed architectures.

In study [1], this paper presents a lightweight hybrid attention deep learning model for traffic prediction in 5G networks. The model integrates depthwise separable convolution with channel and spatial attention techniques to lower prediction costs. With its capacity to conserve computing resources, the model exhibits promise for use in integrated sensing, communication, and computation applications. The temporal and spatial properties of 5G network traffic data are revealed through data analysis, and the suggested model effectively addresses accuracy and complexity concerns using feature extraction and prediction capabilities.

To improve its prediction capabilities for 5G cellular network traffic flow, the authors in study [4] propose a deep learning model based on a Bidirectional Long Short-Term Memory (BiLSTM) architecture with hyperparameter optimization. The stated model demonstrates better prediction accuracy and shorter running time. Thus, it is helpful for real-time applications even though the authors did not discuss the practical limitations of deploying the model. The focus is on possible future research related to resource allocation schemes and IoT cloud architectures. Generally, the findings of the suggested Deep Learning Mobile Traffic Flow Prediction (DLMTFP) technique are encouraging for developing mobile traffic prediction in 5G networks.

In study [16], this paper proposes a Deep-Broad Learning System (DBLS) for traffic flow prediction in 5G cellular wireless networks. It explains that DBLS is suitable for 5G networks because it integrates deep representative and broad learning to provide accurate prediction while keeping the running time low. They showed that DBLS is more accurate and efficient than conventional deep neural networks. It is observed that enhancing the reasonable amounts of enhancement nodes adaptively can enhance the efficiency of the DBLS model and hence lead to high penetration prediction.

According to study [17], the study proposes to predict the traffic of the 5G network and its challenges, owing to the diversity and heterogeneous nature of the 5G traffic. To address these problems, a Smoothed Long Short-Term Memory (SLSTM) model is proposed to enhance prediction accuracy. Adjustments are made to the number of layers and hidden units based on the prediction accuracy, and seasonal time is based on the time series modeling techniques used to smooth the output sequences. This article recommends further research on other factors influencing 5G traffic to make it more applicable in practice.

In study [18], the study engages numerous cross-domain big data resources to construct a spatiotemporal cross-domain neural network model (STC-N) that enables deep learning in wireless cellular network regional traffic prediction. The method consists

of the integration of feature fusion, multi-domain data integration, timestamp-based modeling, and spatiotemporal correlations. The paper also discusses a cross-domain transfer learning approach for improved prediction performance in traffic generation.

It focuses on how cross-domain datasets interact within the prediction model and how it affects the accuracy of the prediction. Nevertheless, the analysis of different kinds and volumes of cross-domain datasets, their synthesis, and association effects on wireless cellular traffic prediction accuracy deserves further attention. Although the reporting in this paper concerns the effect of many cross-domain datasets on prediction accuracy, there is scope for investigating the best combination and weighting of this dataset.

Paper in study [19] describes a novel method of estimating the traffic flow in cellular networks utilizing counters that monitor the performance of LTE radio frequency signals. It investigates a range of machine learning models that can forecast traffic in the network depending on time. It demonstrates that while ensembles such as Gradient Boosting produce the most accurate predictions and spend longer training time, linear models operate faster but depend on preprocessing. The analysis identifies the importance of having a large volume of good quality data necessary to train machine learning models and speaks to the challenges of deployment and solutions whereby autoML may be utilized during retraining, regularization, and feature engineering.

In study [20], this paper considers the issues of mobile network forecasting as applied in a distributed manner, specifically with forecasting traffic for base stations and 5G networks overall. It evaluates different aspects of the centralized and federated learning model, pointing out the strengths of federated learning for better generalization metrics, economies of computational resources, and less carbon dioxide emission. It also highlights the role of model aggregation algorithms and data preprocessing methods in improving the predictive power of the models. The models, which include LSTM and GRU, are quite effective in federated learning scenarios.

The research presented in the paper [21] investigates the efficiency of energy usage in augmented deep-learning model architecture. It discusses federated traffic prediction mechanisms for cellular networks for optimal energy usage. It shows how the difference in the region affects the performance of a wide variety of models, such as Transformer and Length short-term memory-based models. The results demonstrate that while complicated models are more demanding in energy, the expectation is also a high increase in accuracy. This study seeks to raise the understanding of Distributed AI Technologies' environmental impacts and their pose threats to communication systems. It advocates the merits of incorporating sustainability factors into model selection.

In study [22], the paper discusses the problems of implementing FL in vehicular IoT systems, such as variable mobility, limits to communication capability, and risks of non-IID data in combination with the management of resources. Working issues in FL for autonomous driving, intelligent transport systems, and resource-sharing developments are elaborated. The authors define the areas for further explorations,

increasing FL advanced paradigms: scaling up and security on the background of the complex vehicular IoT scenarios.

III. PREDICTION METHOD ARCHITECTURES

A. Long Short-Term Memory (LSTM)

Long Short-Term Memory (LSTM) is a relatively sophisticated variant of the Recurrent Neural Network (RNN) model commonly employed in research today. One of the key aspects LSTM networks address is the long-range dependencies in sequential data, which results in higher performance in many practical applications [23]. Some use cases where LSTM networks have been highly successful include language translation, voice detection, and forecasting. This explains the popularity of LSTM networks in multiple applications and their efficiency in deep learning frameworks directed toward time series data. They encode the RNN memory with three gates alongside cell states, allowing the network to keep and erase information when necessary.

In the standard arrangement, an LSTM block consists of four extra layers and a hidden state in an RNN. Variables include Cell state (C_t), input gate (i_t), output gate (o_t), and forget gate (f_t). Each layer performs a specific operation on the others depending on how the information is created from the training data [24]. Fig. 1 shows the structure of LSTM.

Fig. 1. Architecture of Long Short-Term Memory (LSTM) [23].

The memory of LSTM network networks is represented by the cell state, which is essential to LSTMs. The cell state process resembles a production line or conveyor belt. Except for a few linear interactions like addition and multiplication, the parameter information flows directly across the chain. These interactions determine the status of the information. The information will continue to flow without modifications if no interactions exist. Through the gates, which permit optional information to pass through, the LSTM block modifies or adds information to the cell state [24].

The forget gate eliminates data no longer needed in the cell state. The gate receives two inputs, x_t (the input at that specific moment) and h_{t-1} (the output of the previous cell), which are multiplied by weight matrices before bias is added. After being run through an activation function, the output is binary. When the output for a particular cell state is 0, the information is lost, and when the output is 1, it is saved for later use [25]. The nodal output equations of the LSTM are expressed as follows.

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (1)$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (2)$$

$$C_t^{\sim} = \tan h(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (3)$$

$$C_t = f_t * C_{t-1} + i_t * C_t^{\sim} \quad (4)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (5)$$

$$h_t = o_t * \tan h(c_t) \quad (6)$$

These equations describe how an LSTM unit works, distinguishing it from simple RNN, with several gates controlling information flow. The forget gate f_t in (1) determines what portion of the previous cell state C_{t-1} should be preserved, and the input gate i_t in Eq. (2) identifies how much new information from the current input x_t and previously hidden state h_{t-1} is added to the cell state. The candidate cell state C_t^{\sim} in Eq. (3) is determined with a tanh function. The new cell state C_t combines the old cell state and the new information added, as shown in Eq. (4). The output gate o_t in Eq. (5) controls how much of the updated cell state C_t is passed on to the hidden state h_t , influencing the output at this time step. The hidden state h_t in Eq. (6) is finally computed, where the output gate o_t is applied to the tanh of the new cell state, passing it on to the next time step, thus helping the LSTM keep long-term dependencies in sequential data.

Various parameters guide the internal mechanism of the network. W_f , W_i , W_c , and W_o are the weight matrices multiplied by the forget gate, input gate, candidate cell state, and output gate, respectively, and they are used for both the previous hidden state, h_{t-1} , and current input x_t . Similarly, b_f , b_i , b_c , and b_o are the biases related to these gates and states, added to the product sum of the inputs to bias the output. The sigmoid function σ is employed in the forget gate f_t , input gate i_t , and output gate o_t to compress values between 0 and 1, indicating how much influence they should have (how much to forget, retain, and output, respectively).

B. Gated Recurrent Unit (GRU)

GRU employs a gating mechanism to regulate the information passing through the network. The gates in LSTM determine which information to keep and which to discard at every step, enabling the network to learn long-range dependencies better. The GRU has two main components: the update and the reset gates.

The update gate decides how much new information to write to the memory now, and the reset gate decides how much old information to forget. The basic idea of GRU is that the network hidden state will be updated only by selecting time steps using gating mechanisms. The gates control what information joins and leaves the network. The GRU has two gating mechanisms: reset gate and update gate. The update gate specifies the proportion of the new input to add to the hidden state, and the reset gate specifies the extent to which the previous hidden state should be erased. The GRU output is computed based on the updated hidden state [23]. The architecture is shown in Fig. 2.

The update gate calculation is the first step in a GRU. It uses the current input and the previous hidden state to decide how much to update the previous hidden state; the sigmoid is used here [24]. Here are the GRU nodal output equations.

$$z_t = \sigma(W_z \cdot [h_{t-1}, x_t] + b_z) \quad (7)$$

$$r_t = \sigma(W_r \cdot [h_{t-1}, x_t] + b_r) \quad (8)$$

Fig. 2. Architecture of Gated Recurrent Unit (GRU) [23].

$$h_t^{\sim} = \tan h(W_h \cdot [r * h_{t-1}, x_t] + b_h) \quad (9)$$

$$h_t = z_t * h_{t-1} + (1 - z_t) * h_t^{\sim} \quad (10)$$

The GRU equations have several parameters that dictate how certain elements within the input data behave over the time steps. Where update gate z_t defined in Eq. (7), uses weights W_z , biases b_z , previously hidden state h_{t-1} , and current input x_t to determine how much of the past hidden state will pass to the next step. In the same way, Eq. (8) also applies a reset gate r_t , which uses weights W_r , biases b_r , and a combined h_{t-1} and x_t to decide how much to "forget" of the past for computing the hidden state of the candidate [26].

The candidate hidden state h_t^{\sim} is calculated from weights W_h , biases b_h , reset gate r_t applied to h_{t-1} and current input x_t , processed with the tanh function as shown in Eq. (9): Finally, the new hidden state h_t in Eq. (10) is expressed as a weighted sum of the candidate hidden state h_t^{\sim} (scaled by $1 - z_t$) and the previous hidden state h_{t-1} (scaled by z_t). The weights W_z , W_r , and W_h and the biases b_z , b_r , and b_h are learned during training and determine how inputs are decoded past and current information at each time step to adjust and combine the input information [27].

IV. PROPOSED METHOD DESCRIPTION

A. LSTM+GRU Parallel Network

In the proposed parallel hybrid model, the same input is applied to both LSTM and GRU layers. This enables the model to capture two different temporal representations simultaneously. This is especially beneficial because it combines the strengths of both architectures; thus, while the LSTM capability fortifies long-term dependencies, GRU computational efficiency and faster convergence make it an essential strength for more robust feature extraction in time series prediction tasks.

The input data processed through the LSTM and GRU branches come out as outputs from these branches. The outputs are then concatenated to form a combined feature representation [27]. After passing through dense layers, the final prediction is based on this combined representation. Fig. 3 shows the structure of the parallel hybrid model LSTM+GRU.

Fig. 3. Architecture of parallel hybrid model of LSTM+GRU.

As shown in Fig. 3, the model architecture consists of an input layer that receives the 5G traffic input data. The input is fed into both the LSTM and GRU paths simultaneously. Here, the LSTM (Long Short-Term Memory) network can capture long-term dependencies in time series data, which is important for identifying trends and patterns in 5G over long periods. However, the GRU (Gated Recurrent Unit) path takes the same input with fewer, faster-to-train steps in the architecture, allowing for efficient short-term dependency capture [27], [28]. Though both networks are good at processing sequential data, both contain different complementary strengths, such as LSTM being a long-term memory network and GRU being a memory-efficient network with fewer parameters.

As illustrated in Fig. 3, after processing the input via LSTM and GRU paths, the outputs are concatenated (as shown by the circle in Fig. 3). This merging step is performed to combine the information learned by the LSTM and GRU networks. This concatenated output is fed through a dense layer, and this layer helps further process the combined feature representation extracted from the LSTM and GRU branches [28]. Finally, the dense layer is connected to the output layer, which provides the model prediction.

B. Federated Learning

Federated learning is an advanced machine learning approach that enables decentralized model training without sharing raw data between multiple devices or nodes. It is suitable for privacy-preserving scenarios, such as 5G network traffic prediction [20].

In a centralized learning setting, data brought in from different sources, such as base stations or user devices, would be aggregated in one place during model training, which can raise concerns about the privacy and security of data. With federation learning, each device or node learns a model based on its data at each device or node, and only the changes in the model (such as the weights or the gradients) are sent to the central server [21]. Afterward, this central server employs these updates to enhance the performance of the global model. Furthermore, in the context of 5G network traffic prediction, federated learning allows individual base stations or edge devices in the network to collaborate on training a predictive model without exchanging their raw traffic data. This keeps the users and network-sensitive data secure while providing realistic traffic pattern predictions [12].

In 5G networks, federated learning presents a valuable approach due to the large geographical distribution of data from numerous devices. Through the distributed learning of models locally trained on diverse data, federated learning can also improve the prediction about network congestion, traffic

demand, and resource allocation for a particular network in the future while maintaining data privacy and low communication overhead in the network [21], [22]. Fig. 4 shows a round of the federated learning process.

The federated learning process involves multiple clients or base stations (BS) and a central server, as shown in Fig. 4. In step 1, the central server sends the global model to all clients. Step 2: Clients then update their local models by locally training the model with their private data. In step 3, clients return updated model parameters to the server (aggregator) without sharing raw data. These local model updates are then sent to a central server, which uses an aggregation function (that is, namely Federated Averaging) to aggregate these local model updates to produce an updated global model in Step 4. After updating the model, it repeatedly redistributes the new model to the clients for more training iterations. In this decentralized manner, clients update the global model in a privacy-preserving way by sending model updates rather than datasets.

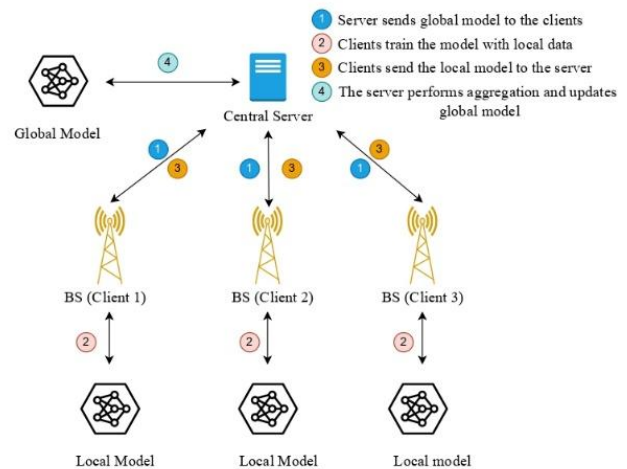

Fig. 4. Federated learning process [20].

Federated Averaging (FedAvg) is widely used due to its simplicity and effectiveness in handling non-iid (non-identically distributed) data across clients. This is common in real-world scenarios where different devices may have access to diverse datasets [12]. FedAvg also minimizes the communication overhead by reducing the frequency of interactions between the clients and the central server, making it well-suited for distributed environments.

C. Implementation of the LSTM+GRU Hybrid Model

The flowchart in Fig. 5 illustrates the steps in implementing and evaluating a hybrid LSTM+GRU model for predicting 5G network traffic, including data preparation, model training, and model testing.

1) *Data preprocessing*: This stage addresses various data quality issues, such as outliers, missing values, and data splits. Missing values were handled based on the percentage of missing data in each feature. Features with more than 50% missing values were removed, while those with less than 50% were imputed using the mean of the column.

Outliers were managed using the Interquartile Range (IQR) capping method, which can limit the impact of extreme values and improve model robustness.

The data was split into training and testing sets with three different ratios (80:20, 85:15, and 90:10). In this study, the 90:10 ratio was used as it provided the best results. The 90-10 splits mean we used 90% of the data to train the model and 10% to test it. This ensures that most of the data is used for model training and that a different portion is set aside to evaluate it.

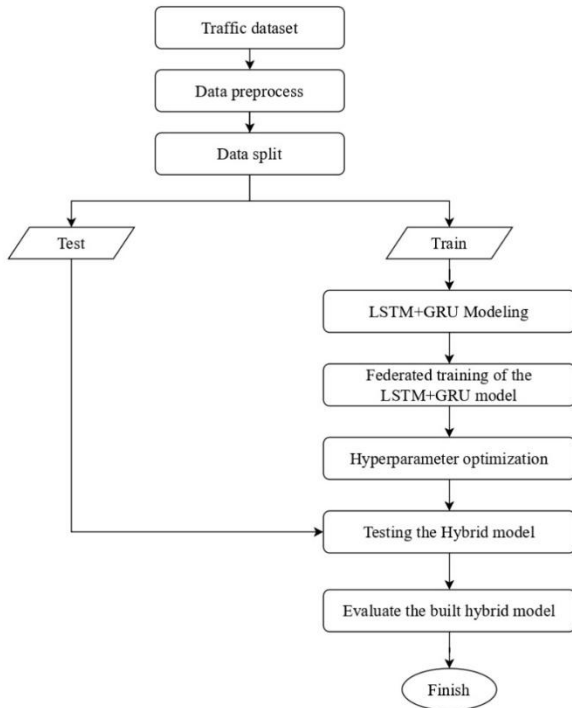

Fig. 5. Flowchart of modeling LSTM+GRU model for 5G network traffic prediction.

2) *LSTM+GRU modeling*: The hybrid LSTM-GRU model was implemented in Python and supported by TensorFlow libraries (i.e., Keras and TensorFlow Federated) using a Google Colab platform. The model had an LSTM layer of 128 units, then a GRU layer with the same number of units, and ReLU as an activation function. These layers were used in parallel (i.e., passed to an add() function). After that, the added output passes through a Dense layer with 64 units and ReLU activation. Finally, a Dense layer with 1 unit was added for the output. The Adam optimizer with a learning rate of 0.001 was used to optimize the model, and L1 and L2 regularizers (set to 0.05) were applied for overfitting prevention. The model was trained for 90 epochs with a batch size of 64.

3) *Federated training LSTM+GRU model*: The server starts the computation in federated training, and clients (base stations) join as participants. A subset of these clients are selected to receive the current global model from the server and use their local data to train [20], [21]. Once local training is done, the clients send the updated models and historical data (loss values and evaluation metrics) to the server. The server

then aggregates the locally trained models, updates the global model, and repeats the process for several federated rounds, as shown in Fig. 4. Hybrid models combining LSTM and GRU have been proposed before [27], [28]. To the best of our knowledge, this work is the first to implement a parallel LSTM+GRU network and training using federated learning for time series prediction. The study created a flexible framework to make it more realistic for network traffic prediction scenarios. After the model is trained, it is tested on the held-out testing data to see how well it predicts 5G network traffic. This step checks how well the LSTM+GRU model can predict the traffic.

4) *Hyperparameter optimization*: Hyperparameter tuning is an important part of neural network development and is usually done through trial. Table I shows the model-specific hyperparameters.

TABLE I. MODEL HYPERPARAMETERS

LSTM, GRU	LSTM+GRU
Activation: ReLU	Activation: ReLU for both branches
Output layer: linear activation	Output layer: linear activation
No. of units: 128	No. of units: 128 for both branches
Dense layer: 64 units	Dense layer: 64 units
Optimizer: Adam	Optimizer: Adam
Regularizer L1, L2: 0.06	Regularizer L1, L2: 0.05
Learning rate: 0.001	Learning rate: 0.001
Drop out: 0.4	Dropout: 0.2
Local Epochs: 3	Local Epochs: 3
Batch size: 64	Batch size: 64
Federated rounds: 10	Federated rounds:10

A validation run was done for each model to finalize the hyperparameters that gave the best performance and fit before training the final model. The training data was split 90-10 for validation during the validation process. Keras search is used for hyperparameter optimization to get the parameters shown in Table I.

5) *Evaluation metrics*: To evaluate and analyze the network model prediction results, the evaluation metrics used are the Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Coefficient of Determination (R²). The corresponding mathematical formulas are presented in Eq. (11,12,13). RMSE in Eq. (11) is particularly effective at measuring the model dispersion, where a lower RMSE indicates a higher concentration level and greater accuracy.

MAE in Eq. (12), measures the absolute differences between the predicted and actual results by taking the absolute values and then calculating the mean. A lower MAE signifies a smaller prediction error. R-squared in Eq. (13) is widely used as an optimal measure for assessing linear regression models, as it translates the prediction accuracy into a value between 0 and 1, offering an intuitive representation of the model accuracy [29]. When the model fit is ideal, the R-squared value approaches 1.

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (f_i - y_i)^2} \quad (11)$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |f_i - y_i| \quad (12)$$

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - f_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (13)$$

V. EXPERIMENTAL RESULTS

A. Dataset Description

The paper uses a 5G trace dataset from an Irish mobile telecommunication operator, as outlined in study [30]. It considers file downloading in a dynamic environment and uses the Download traffic bandwidth data produced from file downloads in a dynamic environment as the target variable. The data samples are aggregated for different days of the experimental period.

- 10,974 Samples collected from 2019/12/14/10:16:30 to 2019/12/17/08:16:23
- 4,106 Samples collected from 2020/01/16/07:26:43 to 2020/01/12:16:29
- 12,511 Samples collected from 2020/02/13/13:03:24 to 2020/02/27/20:50:06

Preprocessing steps were executed to clean and prepare the raw data for analysis. The preprocessing steps included feature normalization, missing value treatment, outlier treatment, and data samples collected on different days aggregated into one dataset. The integration finally resulted in 27,591 samples in the final dataset. Ten features were selected: GPS coordinates (longitude and latitude), timestamp, uplink bitrate, download bitrate and its download state, velocity, and several cellular signal indicators RSRQ (Reference Signal Received Quality), RSRP (Reference Signal Received Power), SNR (Signal-to-Noise Ratio), and CQI (Channel Quality Indicator). Cellular signal indicators are critical as they glimpse the network physical layer. For 5G systems, these features are pertinent since they correlate to how signal quality affects bandwidth and throughput. Velocity and geolocation information permits an exploration of how network performance may vary with mobility versus location environments; such considerations are crucial to many applications in 5G, where users typically move around a lot.

The dataset was gathered from the initial deployment phase of 5G, and it includes key performance indicators (KPIs) such as throughput, channel conditions, and context-related metrics. These metrics remain fundamental to understanding network performance, regardless of technological advancements. As 5G builds on similar foundational principles, the data provides insights that still apply today.

B. Model Comparison

This study evaluates the performance of the proposed hybrid LSTM+GRU model against standalone LSTM and GRU models in the context of 5G network traffic prediction within the federated learning framework. Both LSTM and GRU units were specifically designed to capture temporal dependencies in sequential data; however, LSTM particularly excels in modeling long-term behaviors, while GRU gives a computationally efficient alternative for short-term dependencies with a simpler structure. The hybrid model is the parallel combination of these

structures, thus permitting richer feature extraction by exploiting both strengths. Performance scores of the prediction models for 5G network traffic are shown in Table II.

TABLE II. MODELS PERFORMANCE IN 5G NETWORK TRAFFIC PREDICTION

Models/Measures	RMSE	MAE	R2
LSTM	0.2360	0.3696	0.830
GRU	0.2349	0.3656	0.833
LSTM+GRU	0.2291	0.3556	0.845

Table II highlights the superiority of the hybrid LSTM+GRU model in predicting 5G network traffic. The hybrid model achieved the lowest RMSE of 0.2291 and MAE of 0.3556, demonstrating its ability to minimize large and average prediction errors effectively. Furthermore, its R^2 value of 0.845, the highest among the models, indicates that it explains 84.5% of the variance in the data, making it the most accurate and generalized model for capturing both long-term and short-term traffic patterns. Although the stand-alone GRU model performed better than the LSTM model, the hybrid model always gave better results.

The hybrid model predictive performance is further corroborated by visualizations in Fig 6, 7, and 8, where its predictions closely align with the actual data, showing minimal deviations. This superior accuracy can be attributed to the combined architecture of LSTM and GRU. Despite the hybrid model superior performance, it is computationally more expensive due to its integrated architecture, which increases the number of parameters and requires more memory and processing power. The training time is also longer, as the model must optimize both LSTM and GRU layers.

However, in scenarios where computational resources are available, the hybrid model offers a worthwhile trade-off, as its enhanced accuracy and generalization make it ideal for applications like network optimization or capacity planning. The GRU model is a simpler yet effective alternative for environments with resource constraints or needing faster prediction. The standalone LSTM model, however, appears less suited for 5G traffic prediction due to its lower overall performance and difficulty adapting to the data's highly dynamic nature.

Fig. 6. Prediction of federated LSTM+GRU on test data.

Fig. 7. Prediction of federated GRU on test data.

Fig. 8. Prediction of federated LSTM on test data.

C. Learning Setting Comparison

The time conducted an exhaustive set of experiments on the 5G network traffic dataset to analyze the performance of deep learning models with a specific focus on the effectiveness of the federated learning framework. The study compared the LSTM+GRU hybrid model performance in centralized versus federated learning settings. A centralized learning environment involves training the model on the complete dataset on a single server, while federated learning trains local models at various participants (clients) that aggregate after each round. The model architecture consistency is maintained across both learning environments to achieve comparison equity. The LSTM+GRU hybrid model was applied in both scenarios. In the centralized learning setup, the model was trained for 90 epochs, letting the model traverse the entire dataset 90 times. Ten federated rounds and three local epochs on each client were executed for the federated learning setup. Since federated learning involves multiple clients, the total practical epochs across all clients is 90, obtained as (rounds \times clients \times local epochs). The two results obtained under different learning frameworks were compared upon completing the experiments, as shown in Table III.

TABLE III. PERFORMANCE OF FEDERATED LEARNING AND CENTRALIZED IN 5G NETWORK TRAFFIC PREDICTION

Models/Measures	RMSE	MAE	R2
Centralized	0.2438	0.3687	0.826
Federated	0.2291	0.3556	0.845

Table III highlights a comparative analysis between centralized and federated learning in predicting 5G network traffic, emphasizing the advantages of federated learning. Federated learning achieved a reduced RMSE of 0.2291 and MAE of 0.3556, outperforming centralized learning, which yielded an RMSE of 0.2438 and MAE of 0.3687. It represents a 2.25% improvement in accuracy, underscoring the benefits of federated learning decentralized architecture. Federated learning ability to aggregate knowledge from diverse client models trained on local data allows it to capture a wider range of traffic patterns. This diversity introduces variations in local models, enhancing the global model ability to learn robust and generalized representations of network traffic behavior. In contrast, centralized learning lacks this diversity, relying on a single dataset, which limits its ability to generalize across varying traffic conditions.

One key benefit of federated learning is its scalability and privacy-preserving nature. Training models locally and aggregating updates at the server level avoids transferring raw data, making it an ideal solution for scenarios requiring strict data confidentiality, such as 5G networks. However, federated learning introduces complexity in synchronizing and aggregating models across multiple clients, which can increase computational complexity. Despite this, the distributed nature of federated learning ensures that the system remains scalable and capable of handling the demands of large-scale 5G networks while offering improved predictive accuracy.

Fig. 9 and Fig. 10 provide insights into the model predictions under centralized and federated learning setups. Both setups show the LSTM+GRU hybrid model performing well across a range of bitrate values. However, the performance in regions with lower bitrates reveals a notable challenge. The predictive accuracy drops near zero bitrates, indicating that the model struggles to detect meaningful patterns in this data range. This drop in performance is likely due to sparse or noisy data in these regions, where signal characteristics are less distinct. Such underfitting in low-bitrate areas highlights a common limitation in machine learning models when dealing with sparse or low-intensity data.

Addressing this challenge would involve strategies such as augmenting the training dataset to include more low-bitrate cases, ensuring the model encounters these scenarios during training. Another approach could involve using specialized techniques that enhance the model sensitivity to sparse data regions, such as weighted loss functions or regularization techniques tailored for imbalanced datasets. These enhancements would help mitigate underfitting and improve the model robustness, enabling more accurate predictions across the

entire bitrate spectrum. By doing so, federated learning could further solidify its position as a scalable and effective solution for 5G network traffic prediction, particularly when paired with architectures like the LSTM+GRU hybrid model that captures complex patterns.

Fig. 9. LSTM+GRU model prediction in federated learning.

Fig. 10. LSTM+GRU model prediction in centralized learning.

D. Data Splitting Comparison

The preprocessed data was divided into three different ratios (80:20, 85:15, and 90:10). The three different ratios were compared in federated learning and centralized learning, and the ratio 90:10; 90% of the data for training and the remaining 10% of the data for the test yielded the best results compared to the other two ratios, as shown in Table IV, this experiment demonstrated that training on a larger proportion of data allows the model to capture more patterns and nuances in the data, ultimately leading to a better understanding of the underlying structure and relationships. The model can generalize well and perform with lower prediction errors.

TABLE IV. PERFORMANCE OF THE MODEL IN DIFFERENT SPLITS OF THE DATASET

Learning Setting	Federated Learning			Centralized Learning		
	10%	15%	20%	10%	15%	20%
Test Size/Measure						
RMSE	0.2291	0.3430	0.3553	0.2438	0.3444	0.3471

VI. CONCLUSION

Building high-quality traffic prediction models with effective generalization is an inherently complex task, given the diverse data patterns that characterize 5G network traffic. This paper studies the challenge of predicting 5G network traffic using a hybrid LSTM+GRU model along with a federated learning approach. The hybrid model outperformed the standalone LSTM and GRU models, thus proving its capability to capture both long- and short-term dependencies within the data. At the same time, the federated learning approach adds another dimension to privacy by letting the system learn from varied data on different clients without compromising data privacy. In addition, it produced lower prediction errors with better generalization than centralized learning; thus, it would be an efficient and scalable solution under resource allocation optimization towards network performance enhancement and quality-of-service improvement in complex 5G environments while preserving data confidentiality.

ACKNOWLEDGMENT

The authors extend their gratitude to the African Union Commission for their financial contribution and also to the members of the Pan African University Institute for Basic Sciences, Technology, and Innovation (PAUSTI), Nairobi, Kenya.

Abstract—Quality data is crucial for supporting the management and development of SMES carried out by the government. However, the inability of SMES actors to provide complete data often results in incomplete dataset. Missing values present a significant challenge to producing quality data. To address this, missing data imputation methods are essential for improving the accuracy of data analysis. The Generative Adversarial Imputation Network (GAIN) is a machine learning method used for imputing missing data, where data preprocessing plays an important role. This study proposes a new model for missing data imputation called the Classification and Normalization-Denormalization-based Generative Adversarial Imputation Network (CN-GAIN). The study simulates different patterns of missing values, specifically MAR (Missing at Random), MCAR (Missing Completely at Random), and MNAR (Missing Not at Random). For comparison, each missing value pattern is processed using both the CN-GAIN and the base GAIN methods. The results demonstrate that the CN-GAIN model outperforms GAIN in predicting missing values. The CN-GAIN model achieves an accuracy of 0.0801% for the MCAR category and shows a lower error rate (RMSE) of 48.78% for the MNAR category. The mean error (MSE) for the MAR category is 99.60%, while the deviation (MAE) for the MNAR category is 70%.

I. INTRODUCTION

Indonesia's SMES (Micro, Small, and Medium Enterprises) are essential in increasing economic growth and regional income. This drives the Indonesian government to continue to develop SMEs through several schemes, including providing business capital, increasing business capacity through training, and so on. As a basis for developing SMES, the government requires SMES characteristic data as a basis for decision-making. Business Intelligence is a technology to support government work in managing SMES data. Data integration is an essential foundation of business intelligence.

Extract Transform Load (ETL) is an essential process in data integration where data processing is carried out. In the data integration process, many problems will affect data quality. One of the challenges in this process is handling missing values. Missing values are problems that arise in the ETL process, more

precisely in the data extraction step. [1]. The quality of the underlying data largely determines the quality of the extracted knowledge. Therefore, data quality is a significant concern in data analysis, and data quality is a prerequisite for obtaining quality knowledge. Missing value problems occur due to missing values from an attribute caused by errors when collecting data, system errors ([2], [3]), errors in data entry, refusal or inability of respondents to provide accurate answers [4] and merging of unrelated data [5]. Missing value is a fundamental problem in data science [6].

In some applications, missing values cannot be tolerated and must be replaced with concrete values [7]. Related studies have shown that missing value imputation is beneficial and is a better option than data deletion [8]. Missing data imputation means replacing or correcting the missing data with reasonable values to achieve completeness [9]. Missing data imputation is essential because decision-making errors will occur when an incomplete data set is supported [10]. Some important impacts of handling missing data include the accuracy of statistical analysis, better interpretation, reduction of bias, and improvement of data quality ([3], [11]).

The missing value imputation approach can be broadly categorized into traditional methods and Machine Learning (ML) based algorithm methods. Traditional methods include mean [12], median, linear regression [13], and mode. Some ML-based methods include Algorithms Clustering[14], K-Nearest Neighbor (KNN) [15], Support Vector Machine (SVM) [16], Decision Trees (DT) [17], [18], Random Forest (RF)[19] dan Generative Adversarial Networks (GAN) ([20], [21], [22], [23], [24]). The ability to optimize and extract relationships between data points is an advantage of machine learning-based methods [7]. GAN is an ML method that has attracted researchers' attention in recent years. Missing values are a significant problem in data mining, big data analysis, and ML-based decision-making flows, as the final mining or analysis results can be adversely affected when incomplete data is not imputed correctly [25]. Improvement efforts have been made in several studies that underlie the GAN method, including the research presented in [26] proposes improvements in a new method, namely Generative Adversarial Imputation Nets (GAIN) [27]. In this method, the generator accurately imputes

missing data, and the discriminator aims to distinguish between observed and imputed components. Further improvements to GAIN are carried out by research [7], where the idea is to use deconvolution on the generator and discriminator (DEGAIN). This method makes improvements by adding deconvolution to eliminate correlations between data. Improvements to the imputation method are made based on the characteristics of the data structure ([28], [29]) and the characteristics of the data values. At the same time, research that focuses on the characteristics of data values is still rarely done. The characteristics of the data values are an important initial step to perform accurate imputation. High differences in data values will result in inaccurate results in data processing.

In this study, we optimized the GAIN method [27], a GAN-based algorithm, by developing an enhanced version referred to as CN-GAIN. The CN-GAIN method improves upon GAIN by incorporating data preprocessing tasks as an initial step before imputation, taking into account the characteristics of the existing data. These preprocessing steps include data classification using the k-means method and normalization/denormalization using a robust scaler. The purpose of data classification is to categorize the data based on its inherent characteristics [30]. Meanwhile, normalization and denormalization ensure that no data values disproportionately dominate the dataset. We evaluated the performance of our proposed method using a dataset of SMES from a district in South Sumatra Province. The evaluation included measuring accuracy and several error metrics such as Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Mean Squared Error (MSE). We compared the performance of CN-GAIN with the standard GAIN algorithm.

This study proposes a new method for handling missing values, with the basic method being GAIN. This paper is structured as follows. Section II discusses related works in handling missing data, especially those based on the GAIN method and the improvement efforts made. Section III explains the efforts made by researchers in handling missing values through a series of stages and the use of methods so that they can produce more accurate imputation values. Section IV carries out each planned stage, which is very important in research to determine the proposed method's results. Section V discusses the results of each stage and the results obtained. Section VI presents the conclusions of the research and future research plans.

II. LITERATURE REVIEW

Missing value is a widespread problem encountered in many data collection cases. The missing value is a value that is not stored for a variable in the desired observation [30]. Missing data is grouped into three categories, namely: (1) Missing Completely at Random (MCAR), where the data is lost entirely at random (no dependence on any variable). (2) Missing at Random (MAR), where the missing data depends on the observed variables. (3) Missing Not at Random (MNAR), where the missing data depends on the observed variables and unobserved variables [31]. Data imputation is a common way to deal with missing values where missing values are replaced by applying various methods [32]. Missing value imputation is a valuable solution in cleaning datasets, and generative machine

learning methods can produce data that is completely indistinguishable from reality. Research in missing data imputation has mainly focused on adapting existing methods to suit specific datasets and operational environments, improving model adaptability and accuracy.

Generative Adversarial Net (GAN) is an artificial intelligence algorithm designed to solve generative modeling problems. GAN algorithms can be used to fill in gaps in missing data [33]. Many attempts have been made to improve GAN-based missing data imputation ([34], [35], [36][37]). One of the GAN-based imputation methods is Generative Adversarial Imputation Nets (GAIN). In GAIN, the generator component (G) takes a real data vector, imputes missing values conditioned on the actually observed data, and gives a complete vector. Then, the discriminator component (D) gets the complete vector and tries to determine which elements are actually observed and which are synthesized [31].

Several researchers have made improvements to the GAIN method. For example, [38] focused on repairing missing data in single-cell datasets using the basic GAIN method. The proposed method is Single-Cell Generative Adversarial Imputation Nets (scGAIN). Furthermore, the research conducted [39] proposed the Generative Adversarial Multiple Imputation Network (GAMIN) method for duplicate data imputation with data loss rate more than 80%. This method is applied to image data. Optimization of the GAIN method is also carried out by [40] by performing a pre-training procedure to learn the potential information contained in the data and classifying the data using synthetic pseudo-labels which are then named Pseudo-label Conditional Generative Adversarial Imputation Networks (PC-GAIN).

In research conducted by [41] proposed the Deconvolutional Generative Adversarial Imputation Network (DEGAIN) method, which makes improvements by adding deconvolution to eliminate correlations between data. The research [42] proposed a new missing data imputation model based on data clustering with the basic GAIN method as input data. The data set used is electricity consumption with the MCAR missing value type. This imputation method is then named Clustering and Classification-based Generative Adversarial Imputation Network (CC-GAIN). CC-GAIN aims to enhance imputation accuracy by considering both time-series and pattern features in building electricity consumption data.

TABLE I. PREVIOUS RESEARCH

Ref.	Year	Method	Dataset	Type Data
[38]	2019	scGAIN	Tow dataset: Simulated and rela-word dataset	Numeric
[39]	2020	GAMIN	MNIST and CelebA	Image
[40]	2021	PC-GAIN	UCI repository and MNIST dataset	Numerical, categorical and image
[41]	2023	DEGAIN	Letter and SPAM	Image
[42]	2024	CC-GAIN	Electricity consumption data	Numeric

Table I summarizes previous research and is the basis for this research. Based on the research that has been described

previously, no previous research has implemented data preprocessing steps such as data classification, normalization, and denormalization before imputing missing data with the GAIN method. Incorporating these preprocessing steps can better prepare the data for the imputation process and potentially improve the overall performance of the method.

III. RESEARCH METHODOLOGY

Data completeness is one of several dimensions measured in determining data quality. As a data quality dimension, data completeness means the data set is free from missing values (MV or NA). Fig. 1 shows the flow carried out in this study. In this study, the steps taken are collecting data sets, creating data sets (simulation), and applying data sets to the proposed method, namely CN-GAIN and its basic method, GAIN. The last is to evaluate the data set through the prediction process.

A. Data Set

The data set used in this study is the SMES data set in South Sumatra, which was collected from 2017-2020 by the Dinas Koperasi dan UKM South Sumatra. This data is collected per period using several mechanisms, including through distributed data sheets or direct data collection by officers. There are 3301 SMES data records that were successfully collected. The fields include the type of business, manpower, investment_value, production_capacity, production_value, and bb_bp_value.

The performance of the proposed CN-GAIN imputation model is tested using SMES data as described in Table II with predetermined attributes. Table III shows the characteristics of the SMES dataset.

TABLE II. DATA SET UMKM

Investment_value	Integer	Business investment value
Production_capacity	Integer	Production capacity
Production_value	Integer	Production value
bb_bp_value	Integer	Raw material value

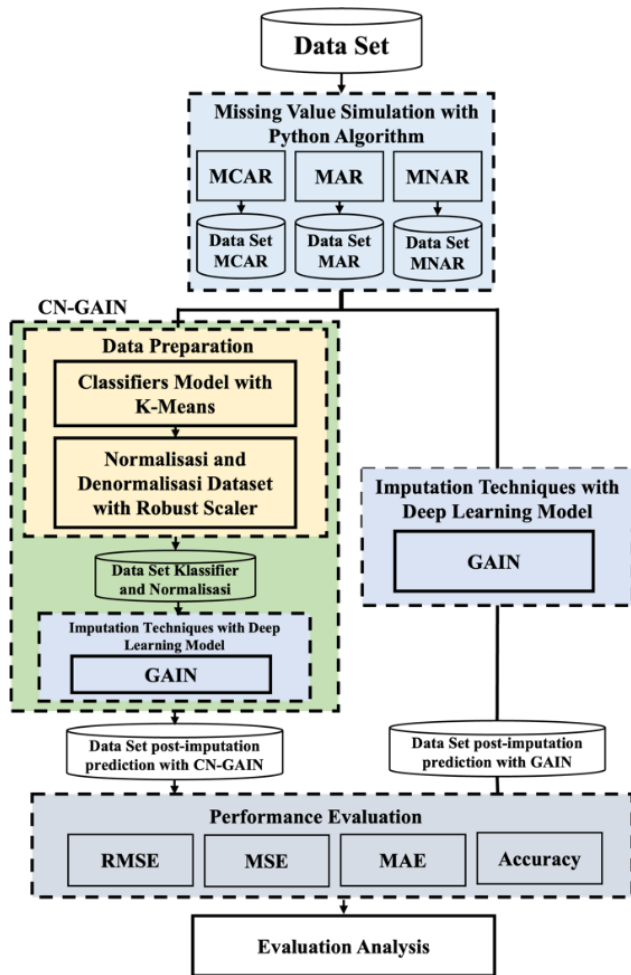

Fig. 1. Experimental flowchart.

B. Missing Value Simulation

Based on the dataset that has been obtained, the next step is to simulate the missing data. In this experiment using Python, the data set was randomly simulated into the MCAR, MNAR, and MAR categories. Algorithm 1 is a pseudo-code of the missing value simulation. By using this algorithm, complete SMES data is then removed randomly. Several Python libraries are used in this simulation, namely wget and numpy.

Algorithm 1. Pseudo-code of Missing Values simulation

```

import numpy as np
import pandas as pd
from utils import *
import torch
Function produce_NA(X, p_miss, mecha="MCAR",
opt=None, p_obs=None, q=None):
    If mecha is "MAR":
        mask = Generate MAR
    Else if mecha is "MNAR":
        mask = Generate MNAR
    Else:
        mask = Generate MCAR
    Return value
End Function
    
```

This function generates missing values in a dataset. The function relies on several libraries: numpy for numerical computations, pandas for data manipulation, and torch for deep learning tasks. The function takes the following parameters: X for the input dataset, p_miss for the proportion missing values, mecha for the mechanism for generating missing data, which can be MCAR (Missing Completely At Random), MAR (Missing At Random), or MNAR (Missing Not At Random), opt, p_obs, q are optional parameters. The function would return the dataset (X) modified with the generated missing values according to the selected mechanism.

C. Data Preparation

The data preparation stage is carried out to understand the characteristics of the data. This step consists of a collection of techniques applied to the data to improve the data quality before processing the machine learning data. Where the initial step taken is to carry out the Classifier model with K-Means, perform data normalization and data denormalization.

1) *Classifier model with k-means*: The k-means algorithm is the simplest and most commonly used clustering algorithm. This algorithm determines the number of clusters (k) that need to be grouped in a Data Set. The steps in performing clustering with the K-Means method include the following [43]:

- a) Determine the number of centroids
- b) Determine points or centroids randomly

$$D(x, y) = \sqrt{(X_1 - Y_1)^2 + (X_2 - Y_2)^2} \quad (1)$$

- c) Calculate and assign new centroids for each cluster.

$$c = \frac{\sum m}{n} \quad (2)$$

- d) Repeat step c, until there are no further changes.

2) *Normalization and denormalization dataset with robust scaler*: Normalization is done to change the value of the attribute in the dataset to have a uniform scale or range. Normalization is used to improve accuracy in classification. [44]. In this study, the normalization technique used is robust scaler. The Robust Scaler formula is stated in Eq. (3):

$$X_{scaled} = \frac{X - median(X)}{IQR(X)} \quad (3)$$

Denormalization using the Robust Scaler involves reversing the scaling process to convert the scaled data back to its original values. This is particularly useful when you want to interpret the results of your model in the context of the original data.

$$X_{Original} = (X_{scaled} \times IQR(X)) + Media(X) \quad (4)$$

D. Imputation Techniques with GAIN Model

Generative Adversarial Network (GAN) is an ML framework trained with two neural networks, namely the generator and the discriminator. The generator aims to create synthetic data that resembles real data, while the discriminator aims to distinguish between real and generated samples [46]. The GAN method is designed to generate images, GANs have been applied in various fields, including natural language processing and speech processing. The goal of GAN is to

generate images that are very similar to real images. GANs are designed for adversarial training of the generator (G) and the discriminator (D), where G is trained to create data that is most similar to the real data, and D is trained to classify the data generated by G. In the process of imputing missing data, GANs generate values that are similar to the real values by modeling the distribution of data surrounding the missing values.

1) *The generator*: The generator is trained for missing data imputation. In the generator model G, the input value is X_a and the matrix M and the noise variable Z are obtained.

$$X_m = X_a \odot M + Z \odot (1 - M) \quad (5)$$

$$X_f = X_a \odot M + G(X_m) \odot (1 - M) \quad (6)$$

2) *The discriminator*: D is used to distinguish the imputed data through G. Unlike GAN, it distinguishes between true and false data from certain constituent elements, not all generated data.

3) *Hint generator*: The hint (H) generator provides some information on the mask M to guide the training of D. This can prevent G and D from learning unintended distributions:

$$H = B \odot M + 0.5 \odot (1 - B) \quad (7)$$

E. Performance Evaluation

This phase is used to evaluate the performance of the proposed method. In this study, accuracy measurement was conducted, and three error metrics were employed to assess performance: Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), and Mean Squared Error (MSE). The rationale for using multiple error metrics is to comprehensively compare errors, as each metric offers different advantages, disadvantages, and features. The mathematical formula for calculating accuracy is presented in Eq. (8):

$$Accuracy = \frac{TN+TP}{TN+FN+FP+TP} \quad (8)$$

Root Mean Square Error (RMSE) calculates the error between the real value and the estimated value (imputed value) to measure the accuracy of imputation ([45], [46]). The difference between the predicted (hypothetical) value and the actual value. RSME is mathematically expressed as shown in Eq. (9):

$$RSME = \sqrt{\frac{\sum_{i=1}^n (X_{i}^{actual} - X_{i}^{imputed})^2}{n}} \quad (9)$$

Mean Absolute Error (MAE) is a matrix for calculating positive and negative deviations between \hat{y}_i predicted and actual values ([46], [47]). MAE is mathematically expressed as shown in Eq. (10):

$$MAE(y, \hat{y}) = \frac{1}{n} \sum_{i=1}^n |y_i - \hat{y}_i| \quad (10)$$

Mean Squared Error (MSE) calculates the average error. The average value is close to zero but not negative [46].

Mathematically, MSE is defined based on Eq. (11):

$$MSE(y, \hat{y}) = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad (11)$$

IV. EXPERIMENTAL RESULTS

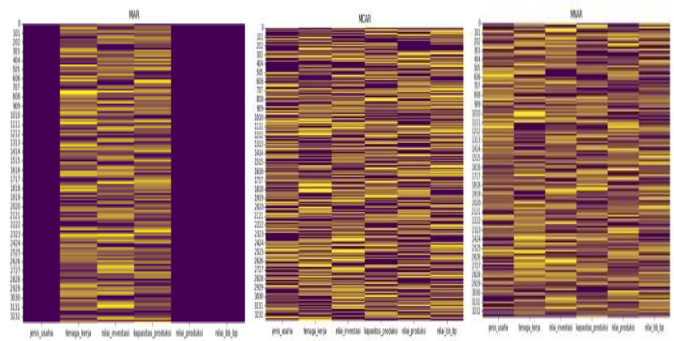

This section presents the results of each step that has been explained previously, namely the results of the missing value simulation, data pre-processing and the proposed CN-GAIN algorithm model.

A. Missing Values Simulation

Based on the python algorithm that has been created previously, where the data set is categorized into three categories of missing values, namely: MAR, MCAR and MNAR. Table IV is the result of the missing value algorithm process that has been run. While Fig. 2 is a visualization of the percentage of missing values based on the missing value category.

TABLE IV. PERCENTAGE OF MISSING VALUES IN EACH ATTRIBUTE

No	Field	MAR		MCAR		MNAR	
		MV	%	MV	%	MV	%
1	Type of business	0	0	129 3	39.1 7	130 4	39.5 0
2	Manpower	135 3	40.9 9	131 2	39.7 5	134 9	40.8 7
3	Investment_value	135 1	40.9 3	132 6	40.1 7	135 0	40.9 0
4	Production_capacity	133 4	40.4 1	132 1	40.0 2	131 7	39.9 0
5	Production_value	0	0	130 9	39.6 5	132 7	40.2 0
6	bb_bp_value	0	0	133 8	40.5 3	134 8	40.8 7

Fig. 2. Missing value visualization.

B. Classification with K-Means

Classification is carried out on datasets based on business type. jenis_usaha column appears to contain information about the type of business, but there are many unique values with variations in capitalization and wording (e.g., "Bengkel motor" and "Bengkel Motor"). Additionally, some values are particular (e.g., "Bengkel"). Hence, classification is needed. To classify these values, K-means is employed. From the existing SMES data, 10 classifications were obtained, as shown in Table V.

TABLE V. CLASSIFICATION OF UMKM DATA

Cluster	Businesses
0	Crafts
1	Vehicle Repair and Maintenance
2	Brick-making
3	Furniture, Woodworking
4	Fish Products
5	Other product manufacturing
6	Tempeh and Tofu Production
7	Agriculture and Farming
8	Snack Production
9	Beverage

C. Architecture of the Proposed CN-GAIN Model

The proposed CN-GAIN model for UMKM data imputation is based on the GAIN method. This model consists of five main modules, namely: 1) clustering, 2) normalization, 3) denormalization, 4) generator, 5) discriminator.

Algorithm 1. Pseudo-code of CN-GAIN

```

from sklearn.preprocessing import RobustScaler
import numpy as np
import pandas as pd
import tensorflow as tf
from tensorflow.keras.layers import Input, Dense
from tensorflow.keras.models import Model
Determine the classification
Draw dataset, number of clusters k
  For i = 1, ..., do
    Label (i) ← clustering(k)
  end for
Normalisasi
scaler = Initialize RobustScaler()
data_scaled = Fit the scaler to the dataframe (df) and transform the data
Denormalization
median_values = Retrieve the median of each feature from the scaler
iqr_values = Retrieve the interquartile range (IQR) of each feature from the scaler
  For each feature in data_scaled:
    original_data = (data_scaled * iqr_values) + median_values
Update Generator and Discriminator
Discriminator optimization
While training loss has not converged do
Draw samples from the dataset
For j = 1, ..., samples do
 $X_m(j) \leftarrow G(X_a(j), z(j))$ 
 $X_f(j) \leftarrow m(j) \odot (X_a(j) + (1 - m(j)) \odot X_m(j))$ 
 $h(j) \leftarrow b(j) \odot m(j) + 0.5(1 - b(j))$ 
 $y(j) \leftarrow C(X_f(j), l(j))$ 
end for
update D using adam optimizer
Generator Optimization
Draw samples from the dataset
For j = 1, ..., do
 $h(j) \leftarrow b(j) \odot m(j) + 0.5(1 - b(j))$ 
 $y(j) \leftarrow C(X_f(j), l(j))$ 
end for
update D using adam optimizer

```

Data was normalized using a Robust Scaler by subtracting the median and dividing the Inter Quartile Range (IQR). Then, data was deformedalized using Robust Scaler. The optimization

begins with discriminator D, which is tuned using a fixed generator and classification via mini-batch sD. Independent samples of Z and B, represented as z(j) and b(j), generate h(j) and Xf(j), respectively. Additionally, y(j) is derived from Xf(j) and l(j). The discriminator is optimized using Xf(j), h(j), and y(j) across all mini-batches. Then, generator G will be optimized by mini-batch s(G) while the discriminator D is updated, and the classification C remains fixed. h(j) and y(j) are computed for all mini-batches and used in optimizing G.

V. RESULT AND DISCUSSION

The dataset prepared and simulated into missing data categories (MAR, MCAR, and MNAR) is then used with the proposed steps and techniques in the data processing stage.

A. Result

The performance of the missing value imputation of the proposed CN-GAIN model is compared with the baseline model, namely the GAIN Model. Each model was tested on three missing value data categories: MAR, MCAR, and MNAR. Where each category has a different level of missing value, in this study, the percentage of missing values was created randomly using the library in python for each type of missing value category. This is different from what was done in the study [42], where the percentage of missing values ranges from 10% to 90%.

The proposed CN-GAIN model has a better accuracy rate and a low error rate. An important step is applying classification, normalization, and denormalization of data before the imputation process with the GAIN model. As a comparison, researchers also applied the GAIN model to compare accuracy and error rates. Table VI shows the results of the proposed model trial with the base model after imputation.

TABLE VI. PERFORMANCE EVALUATION OF PROPOSED CN-GAIN AND GAIN

Metrics	MAR		MCAR		MNAR	
	CN-GAIN	GAIN	CN-GAIN	GAIN	CN-GAIN	GAIN
Accuracy	0.997	0.997	1.00	0.9992	1.00	0.9992
RSME	0.013	0.016	0.0077	0.0097	0.0042	0.0082
MSE	0.0007	0.0015	0.0007	0.0018	0.0006	0.0020
MAE	0.0007	0.177	0.0007	0.066	0.017	0.448

Based on the results of the trials conducted for accuracy, the MAR missing value category has the same value, which is 0.9970. for the MCAR category, the CN-GAIN method has a better accuracy level of 1.00 while the GAIN method is 0.9992. as well as for the value in the MNAR missing value category. For performance seen from the Root Mean Square Error (RMSE) has a better value, whereas the MNAR missing value category has a better value, which is 0.0042. While the performance for the Mean Absolute Error (MAE) shows a better value than this method is MAR, which is 0.0007. Finally, the performance of the Mean Squared Error (MSE) category of MNAR missing value has the best value of the proposed model, which is 0.0006. Fig. 3 compares the CN-GAIN and the GAIN methods as the basic methods for three types of missing values: MAR, MCAR, and MNAR.

Evidence of the proposed model's improvement is demonstrated by the increased performance percentage of the CN-GAIN model compared to the base model, GAIN. Fig. 4 is a visualization of the presentation of CN-GAIN performance on each type of missing value compared to the basic GAIN model. The imputation value's accuracy level occurred in the MCAR missing value category type of 0.0801% and MNAR of 0.0800, while for the MAR category type there was no increase. For the percentage of actual and imputed values (RMSE), the MNAR missing value category type has a better improvement of 48.780%.

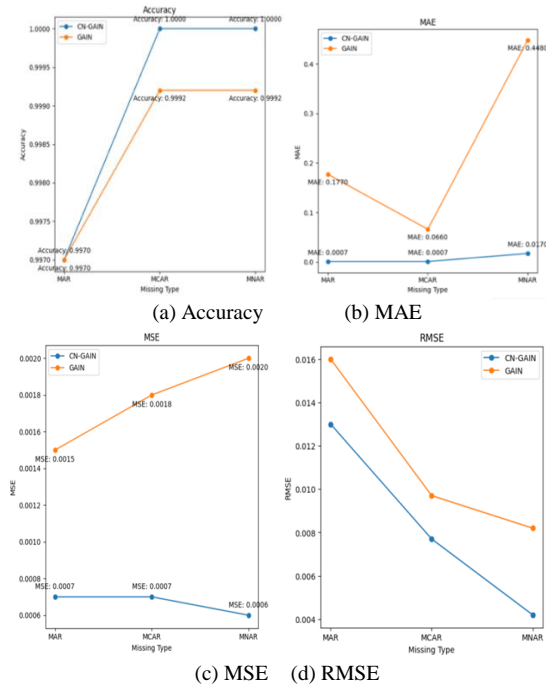

Fig. 3. Performance evaluation of different methods.

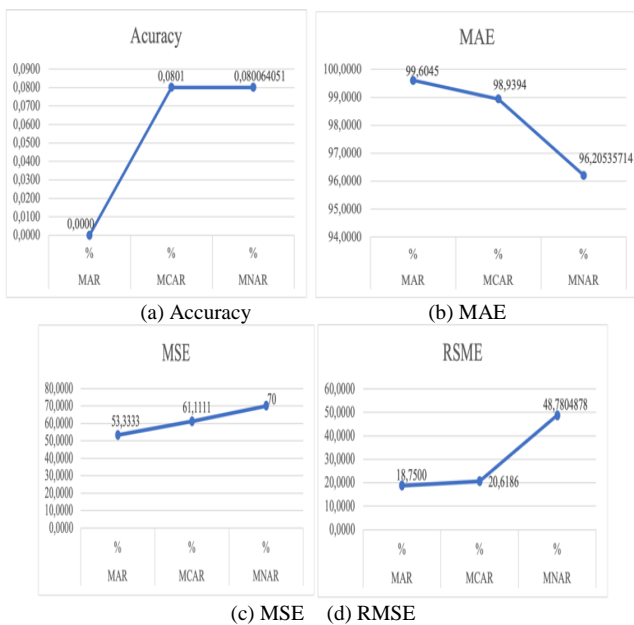

Fig. 4. Performance percentage of CN-GAIN compared to GAIN method on missing value type.

B. Discussion

Based on the results of the trials conducted, the CN-GAIN model has a better level of accuracy than its basic model, the GAIN model. While for the error rate the CN-GAIN method also has a lower error rate. The results (Table V) show that of the three types of missing values simulated, the CN-GAIN model has a relatively high increase in accuracy; only the MAR type of missing value has the same value when the accuracy level is measured. These results prove that the CN-GAIN model as a framework for handling missing values is proposed to be implemented. The classification steps carried out in data preparation make the data set classified according to its group and normalization-denormalization makes the data set in a value range that is not too far apart. This step improved the imputation process, even though there was no change or significant improvement in one type of missing value, especially in terms of accuracy in the MAR type of missing value.

From the overall results, this study has proven that the framework developed using the proposed classification and normalization-denormalization has a better level of accuracy than its standard. This study also proves that the data preprocessing carried out has a better impact on the quality of the data obtained after the value prediction is carried out.

VI. CONCLUSION AND FUTURE WORK

Incomplete SMES data is a significant challenge for SMES' proper management and development. Effective data imputation is essential to produce quality SMES data. In this study, we propose CN-GAIN, a new missing data imputation method designed to handle data with multiple data characteristics in SMES data. By making efforts to classify, normalize, and denormalize data in the data pre-processing process before imputation using the GAIN method. The CN-GAIN model performs better in predicting missing values, with an accuracy value of 0.0801% for the MCAR category and a lower error rate (RMSE), of 48.78% for the MNAR category. The average error (MSE) is 99.60% for the MAR category, and the deviation value (MAE) is 70% for the MNAR category.

For further research, researchers will test the model on other data sources with more complex data characteristics with more varied data types.

An Agile Approach for Collaborative Inquiry-Based Learning in Ubiquitous Environment

Bushra Fazal Khan, Sohaib Ahmed

Department of Software Engineering, Bahria University, Karachi, Pakistan

Abstract—The use of collaborative inquiry-based learning has been prevalent in educational contexts particularly in science education. Using such collaborative environments, learners can increase their engagement, knowledge and critical thinking skills about science. With the advancement of technologies, ubiquitous learning environments have been designed for facilitating learning in real-time contexts. Over the past few years, agile-based approaches have been implemented at higher education for inquiry-based learning activities. However, there is a lack of studies found that focuses on agile-based approach for ubiquitous collaborative inquiry learning activities at K-12 education level. Therefore, this study presents the ScrumBan Ubiquitous Inquiry Framework (SBUIF), for inquiry-based learning activities at K-12 education level. For this purpose, an application uASK has been developed on the proposed framework, SBUIF. For the evaluation purposes, computer-supported collaborative learning (CSCL) affordances along with micro and meso levels of the M3 evaluation framework has been applied. An experiment was conducted for the evaluation of uASK application in comparison with the Trello application, involving 205 to 127 seventh-grade students. Results demonstrated that uASK learners achieved higher scores as compared with Trello participants. Further, survey results indicated higher levels of engagement, satisfaction, and enjoyment among uASK users. The study concludes that uASK offers significant advantages over Trello in fostering collaborative inquiry-based learning activities in ubiquitous environment.

Keywords—K12 education; agile; ubiquitous; collaborative learning; inquiry based learning

I. INTRODUCTION

Due to the shifting context and evolving learner's needs the educational landscape faces many challenges. By introducing collaborative activities in their education, students not only develop content mastery but also enhance their communication skills, problem-solving abilities, and overall academic motivation [1]. To align students with real-world experiences they will encounter in the workspace thus preparing them for the collaborative nature of many professional environments Collaborative learning fosters many skills in students, encouraging the creation of new knowledge and understanding through dialogue and interaction [2]. An inquiry-based learning approach enables learners to actively explore questions, construct knowledge, and share findings, and has been recognized as an effective method for developing critical thinking skills [3]. Inquiry-based learning (IBL) is considered as an effective educational approach that encourages learners to engage in the learning process more deeply by taking care of their own learning, rather than passively receiving information [4].

With the advancement of technologies, the use of mobile devices in IBL environments presents unique opportunities for learning especially science education [5]. They are: (i) facilitate various levels of inquiry (ii) enhance learners' motivation and engagement (iii) provides seamless learning among various contexts and (iv) leverage between formal and informal science education. The use of mobile devices with sensor technologies can create more interactive and immersive experiences for learners that can actively engage in the learning process. This learning environment is termed as Ubiquitous learning or U-learning [6]. Recent studies highlighted that this learning environment can effectively provide benefits in learners' engagement and critical thinking skills [7][8]. Further, the use of such ubiquitous platforms can enhance student learning by capturing their attention and providing personalized learning experiences [9].

In the literature related to ubiquitous IBL, five types are identified [10]: (i) *Authentic scientific inquiry* in which learners investigate and conclude about real-world or scientific problem (ii) *Abductive science inquiry* in which learners form hypotheses based on research or observations, drawing conclusions through critical thinking (iii) *Collaborative inquiry* in which learners work in groups, understand and solve problems through a repeated process [11] (iv) *Collective whole class inquiry* in which the entire class participates in the inquiry process, collaborating towards a common goal. Learners may think critically and generate ideas for a given problem [12] and (v) *Inquiry with game component* in which learners use game component as an instructional or learning source to address inquiry problems such as combining augmented reality with inquiry environment to enhance their learning experiences [13][14]. This research follows collaborative inquiry for learning science education.

Collaborative inquiry-based learning (CIBL) has gained popularity due to its ability to enhance learners' engagement, comprehend knowledge, and foster critical thinking skills [11]. In these environments, teachers and peers provide an environment, pose problems, and offer support that promotes intellectual growth. When students work together in cooperative groups, they share the process of developing ideas. This collaboration gives them opportunities to think about and expand their own ideas as well as those of their peers.

In these collaborative settings, students can view their peers as resources, not competitors [15]. Group-based exploration allows students to collaboratively exchange ideas and experiences. Differing interpretations of concepts and processes can lead to disagreements, which may ultimately promote intellectual growth through the sharing of knowledge

and the formation of connections [12]. However, such a learning environment faces challenges in terms of processes and resources for collaboration, and requires support from fellow students, which demands energy investment in collaborative efforts.

On the other hand, the implementation of agile methodologies within the educational domain has been a topic of growing interest in both classroom and online learning environments. This approach creates an adaptive and collaborative learning experience, owing to its iterative and incremental nature [16]. Further, Agile has been successfully utilized in academic settings to teach software engineering, primarily through project-based learning approaches. In these scenarios, students work in small groups to produce software as the final learning product, simulating agile practices [17] [18]. However, the existing literature reveals a paucity of empirical research specifically addressing the adoption of any agile methodology in secondary and higher education contexts.

Scrumban, one of the agile methodologies, follows a hybrid project management framework that combines the iterative and incremental nature of Scrum with the continuous flow of Kanban [19]. This framework has been successfully applied in software development and has the potential to be adapted for instructional design and delivery in other learning environments [20]. The integration of Scrumban and inquiry-based learning in ubiquitous environment may create an approach that leverages the strengths of both methodologies. Nevertheless, such integration has not been found in the literature earlier. Therefore, this allows us to explore the use of scrumban methodology as a collaborative framework for inquiry-based learning activities at secondary school students.

This paper presents a framework that combines Scrumban principles with inquiry-based learning for ubiquitous learning environments. To assess the effectiveness of this framework, an application, 'uASK' has been developed and evaluated using the M3 evaluation framework [21] was employed. The paper later discusses the findings and their implications.

II. RELATED WORK

In the literature, there are few applications that use agile based approaches in educational settings. These studies mainly focus on IBL activities in ubiquitous environments as depicted in Table I.

ULMCI is a forum-based web application to assist learners through authentic scientific inquiry [20]. In this study, university students work on solving real-world problems to develop their programming skills, rather than just learning theory. The forum allows learners to interact, discuss, and collaborate on programming challenges. However, no agile method was used for collaboration in this [22]. In another study, two digital platforms are utilized for conducting authentic scientific inquiry for railway engineering university students [23]: 1) Edmodo, a virtual environment for disseminating educational resources and facilitating communication, and 2) Google Docs, a collaborative online writing and editing tool. These platforms were implemented using flipped classroom

approach where learners can independently study core course material outside the classroom, while in-class time is allocated to practical applications and knowledge reinforcement activities.

A research study was conducted in which university students used a digital tool called Trello for learning software engineering [24]. This tool follows Kanban, an agile methodology for managing and organizing learners' activities. Further, inquiry with game component type is applied to make learning process for engaging and interactive. In another instance, scrum methodology is used for teaching Chemistry to 11th grade students [25]. In this study, learners are involved for enhancing their engagements and learning outcomes through manual boards and face-to-face meetings rather any digital tools.

On the other hand, there are few studies that target collaborative inquiry types. In this study, scrumban methodology are followed by university students for learning about project-based web programming courses [26]. The participants in this study used Microsoft Planner, WhatsApp, and Telegram to enhance student engagement, collaboration, and project management skills. Microsoft Planner facilitated task organization and progress tracking, while WhatsApp and Telegram enabled real-time communication [26]. This approach aimed to create a collaborative inquiry earning environment mirroring real-world software development practices, potentially better preparing students for future careers.

In another research, Milićević et al. (2019) integrated Scrum methodology with OpenProject software in e-business project management courses. This approach provides university students with practical experience in agile project management through real-world e-business projects. The combination of Scrum and OpenProject facilitated collaborative inquiry, task allocation, progress tracking, and iterative development [27]. In a similar vein, Parsons et al. (2018) explored an innovative approach to teacher professional development by integrating Scrum and Kanban methodologies, commonly known as Scrumban, and implementing it through the digital platform Trello. This hybrid approach supports and tracks collaboration, allowing all team members to participate in discussions, view the workflow, share files and notes [28]. Further, learning sessions in this research facilitates participants to comprehend practical application of agile and lean concepts to enhance their professional practice.

The relevant studies indicate that the use of agile methodologies in educational context enhance learning experience for the learners [29]. Most of these studies focused on university students except for a study where high school students are involved [25]. However, that study did not use any ubiquitous inquiry type. Therefore, this indicates that there is a significant gap in literature that can implement an agile-based approach for collaborative inquiry-based learning activities in a ubiquitous environment for school students. This gap presents an opportunity in this research to explore a ubiquitous learning environment through an agile-based approach for conducting collaborative inquiry activities.

TABLE I. AGILE APPROACHES USED IN INQUIRY-BASED LEARNING UBIQUITOUS ENVIRONMENTS

Approach/Application	Agile Method	Platform	Learners	Domain Knowledge	Ubiquitous Inquiry Type
ULMCI [22]	-	Forum based application (ULMCI)	University Students	Programming	Authentic scientific inquiry
Agile CSCL [26]	Scrumban	MS Planner, Whatsapp and Telegram	University Students	Web Programming	Collaborative inquiry
IBL-CSCL in flipped classroom [23]	-	Edmodo, and Google Docs	University Students	Railway engineering	Authentic scientific inquiry
GBL Agile [24]	Kanban	Trello	University Students	Software Engineering	Inquiry with game component
Context Based Scrum [25]	Scrum	-	Grade 11	Chemistry Education	-
Scrum Agile Framework [27]	Scrum	OpenProject	University Students	E-Business Project Management	Collaborative inquiry
Agile and Lean learning [28]	Scrumban	Trello	Teachers	Agile and Lean Teaching Concepts	Collaborative inquiry

III. SCRUMBAN UBIQUITOUS INQUIRY FRAMEWORK

This study presents an innovative framework, the ScrumBan Ubiquitous Inquiry Framework (SBUIF), as shown in Fig. 1, which adapts various components from the established methods including Seamless inquiry-based learning framework (SIBLF) [30], and ScrumBan Research Framework (SBRF) [31]. The proposed SIBLF by Song et al. [30] lacks a structured approach, which in turn complicates class management. While SBRF provides structural stability, it does not incorporate inquiry elements for student scaffolding. Additionally, its design for research project management in university education renders it unsuitable for knowledge construction at the K12 level. However, by integrating these elements, SBUIF provides a comprehensive and flexible inquiry framework suitable for use in educational environments for its adaptability to real-world contexts through ubiquitous learning.

The SBUIF is categorized into eight distinct phases, each with its own unique characteristics and goals. Its objective is to create a comprehensive and dynamic learning environment that caters to the diverse needs and preferences of students. By utilizing a combination of learner-centered approaches and technology-enhanced resources, this framework strives to enhance student engagement, collaboration, and the overall quality of the educational experience. This framework also equips students with the necessary skills to engage in scientific inquiry as they develop their ability to apply critical thinking and reasoning to their observations and experiments in a ubiquitous environment. The phases of SBUIF are as under:

A. Build Awareness

The initial phase of "Build Awareness" is essential for establishing the foundation necessary for the effective implementation of the SBUIF approach. This phase focuses on building strong relationships with educators, administrators, and the learning community. This phase develops assessment

procedures that meet learning objectives and encourage stakeholder feedback. These links promote varied viewpoints and insights, improving understanding of learning objectives and context. Further, it emphasizes the need for a thorough literature review to build expertise. This review ensures that learners, teachers, and other stakeholders understand the latest research, best practices, and emerging trends in the field, laying the groundwork for the SBUIF approach.

B. Define Objective

Learners' perspectives, needs, and goals are analyzed in the second phase, "Define Objective". This stage tailors' educational programs to individual learners, making them more effective and interesting. Understanding learners' viewpoints helps instructors to create an environment that motivates and empowers them. The instructional team determines the most relevant and interesting content for the learning objectives by examining the target audience. After determining the target audience, the team can create learning objectives that match learners' needs and interests, making the content engaging and effective. This phase is critical for evaluating the learning goals alignment process to boost student engagement and involvement in their education.

C. Engage

In the third phase, learners past knowledge and experiences are activated and enhanced while meaningful connections are made between peers and instructors. Therefore, it uses collaborative and blended learning approaches to provide an engaging and participatory learning environment where learners can actively contribute knowledge, share thoughts, and have meaningful discussions. This phase can help learners to develop critical thinking and collaborative skills while giving instructors a better understanding of their progress and needs. This level uses advanced technology and a collaborative learning environment to encourage students to participate, share ideas, and learn more.

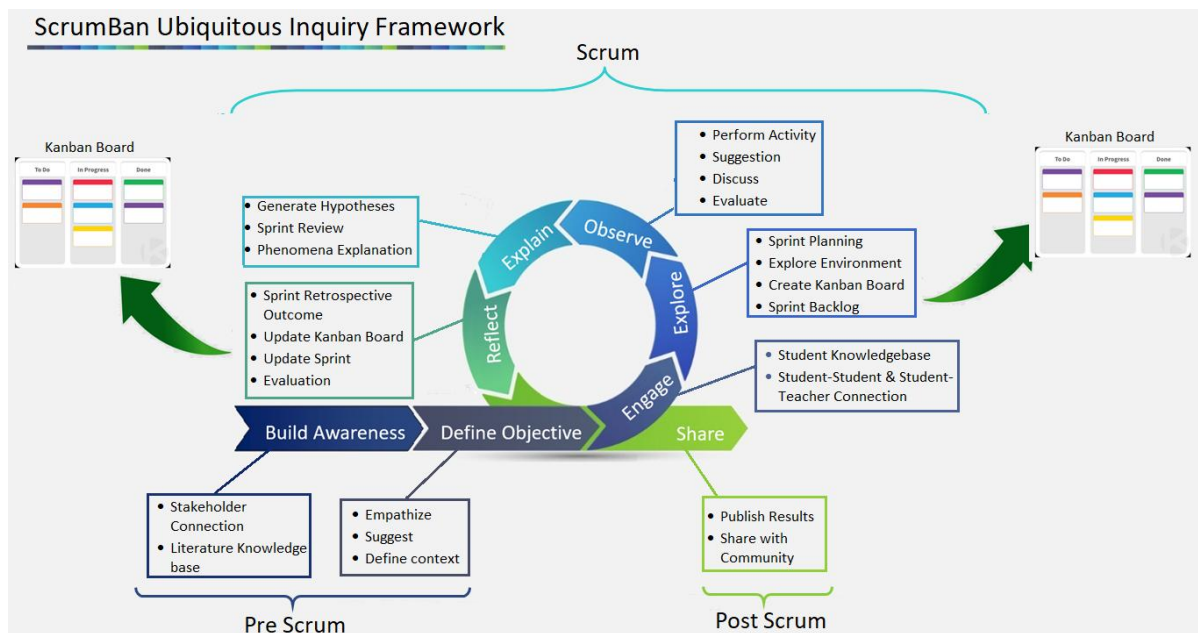

Fig. 1. Proposed ScrumBan ubiquitous inquiry framework adapted from study [30] [32].

D. Explore

Lesson design is systematic and iterative in the fourth phase, "Explore". The instructor and learners plan learning sprints during sprint planning. The sprint planning process helps instructors and learners grasp learning sprint objectives, goals, and expectations, improving learning outcomes. To ensure effective and efficient learning outcomes, educators must carefully develop and define learning sprint objectives, goals, and expectations. Instructors and students evaluate resources, technologies, and learning barriers in the Explore phase. The exploration phase includes creating a Kanban board and sprint backlog to organize and visualize learning. The Kanban board may show the status of each work, helping the team communicate progress and identify areas for improvement. Kanban boards and sprint backlogs boost teamwork and learning. This phase allows instructors to discover and correct student misconceptions and gaps in comprehension, which may be addressed with targeted interventions and additional support to improve learning.

E. Observe

In this phase, the instructor monitors student performance and provides real-time feedback and advice to improve learning and fulfill various requirements. To facilitate learning and meet various needs, the instructor analyzes learners' involvement and performance during learning activities and provides real-time feedback and advice. This phase promotes ongoing improvement through detailed discussions and activity evaluations. This allows the instructor to constantly enhance and alter the teaching method, creating a more inclusive and effective learning environment that boosts learners' engagement and educational quality.

F. Explain

During the "Explain" phase, learners are instructed to

develop hypotheses, assess the advancements achieved throughout the sprint, and obtain detailed explanations of the foundational concepts and principles. This phase is essential for facilitating learners' connections between observed phenomena and underlying theories, thereby enhancing their understanding of the subject matter. This phase offers opportunities for learners to refine hypotheses, challenge assumptions, and enhance insights through interactive discussions and constructive feedback from instructors and peers. Engaging in meaningful exchanges allows learners to explore alternative perspectives, identify new connections, and enhance their critical thinking skills. This collaborative process facilitates a nuanced and comprehensive understanding of the subject matter, thereby enhancing the ability to draw informed conclusions and address complex problems.

G. Reflect

In this phase, a comprehensive review and analysis of the entire learning process is conducted. The sprint retrospective involves a discussion between the instructor and learners regarding the outcomes, effectiveness, and implications of the sprint. The instructor and learners assess learning experiences, pinpoint areas for enhancement, and investigate methods to refine sprint instruction. The pedagogical framework undergoes continuous refinement and optimization through rigorous evaluation and debate, ensuring a highly responsive learning experience tailored to learners' diverse requirements and preferences. The Reflect phase includes the analysis of learning outcomes, the updating of the Kanban board and sprint schedules, and the execution of comprehensive mid-term evaluations. This review and assessment process enables both the instructor and learners to evaluate previous sprints, pinpoint areas for enhancement and modify the Kanban board and sprint plans accordingly.

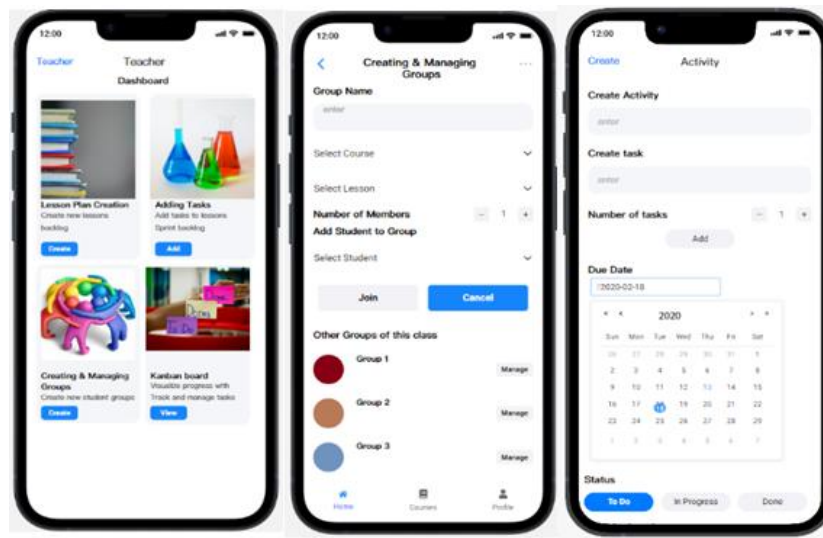

Fig. 2. uASK pre-scrum interfaces.

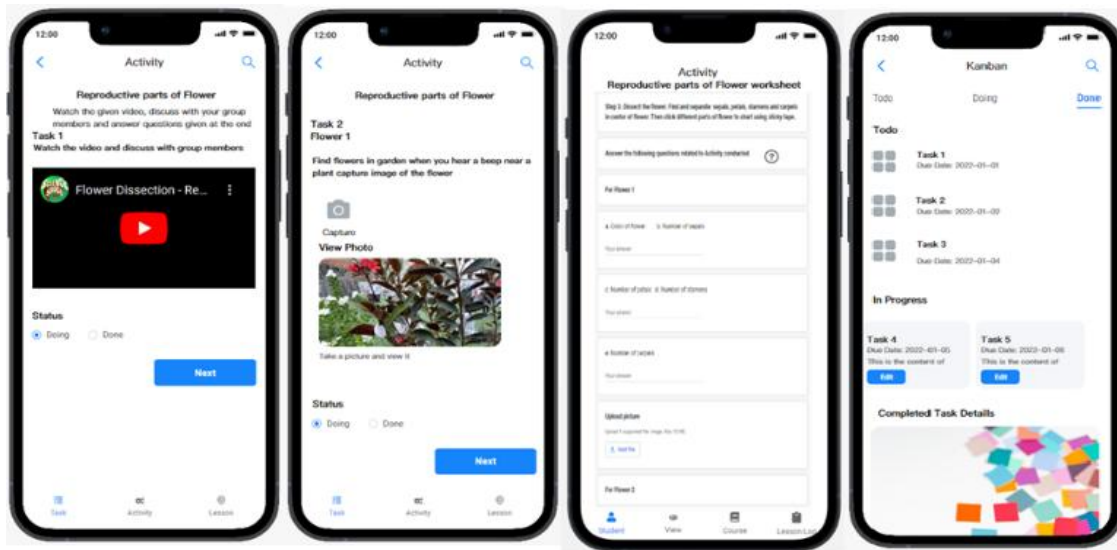

Fig. 3. Scrum activities in uASK.

H. Share

The final phase entails the publication and dissemination of research findings, best practices, and innovative pedagogical approaches developed through the implementation of the student-centered and blended learning framework. This phase of sharing promotes cross-institutional collaboration and knowledge exchange, enabling instructors from various educational institutions to convene and discuss their experiences, best practices, and innovative strategies. The feedback and perspectives obtained from the broader academic community can inform future iterations of the framework, thereby enhancing its effectiveness in addressing the diverse needs and learning styles of learners across various educational contexts. This phase of sharing is essential for the ongoing refinement and enhancement of the overall framework, facilitating the integration of diverse insights and new ideas that improve its responsiveness to the changing needs of learners.

IV. UASK APPLICATION

The proposed ScrumBan Ubiquitous Inquiry Framework (SBUIF) was implemented through the uASK application, which incorporates both Scrum and Kanban methodologies for teaching using agile as a learning pedagogy. Thus, uASK is a scrumban based collaborative learning application that provides a platform for students and teachers to facilitate their learning. The components of uASK application are mentioned as below:

A. Pre-Scrum

In pre-scrum, the teacher will be creating lesson activities and tasks along with building groups as shown in Fig. 2. The activities can be related to science education. Thus, encompassing the pre-scrum phases of build awareness and defining objectives.

B. Scrum

The next phases are categorized as scrum where the students are actively engaged in learning by interacting with each other and the environment. Along with the teacher monitoring the progress through kanban boards. In scrum, inquiry phases of engage, explore, observe, explain & reflect are included. Through these inquiry phases, students can interact with observed phenomena and explore the underlying problems. Fig. 3 shows different screens for the task of reproduction of plants through which students.

C. Post-Scrum

In the post-scrum phase, the results of the activities performed are shown and shared with group and teacher as shown in Fig. 4. The teacher will reflect upon these results and give feedback as required. These results will further be shared with the community for further exploration.

Fig. 4. uASK post-scrum activities.

V. RESEARCH METHODOLOGY

In this research, an application uASK has been developed. The uASK represents a novel application that integrates both Scrum and Kanban methodologies, offering a hybrid approach. To evaluate its effectiveness, an experiment was conducted. For this purpose, uASK was compared with one of the existing project management applications utilized in educational settings: Trello. Trello is a more established application that primarily adheres to Kanban principles. This study aimed to compare these applications in terms of their support to inquiry-based learning methods within an educational context.

A. Participants

The research involved a sample size of 127 seventh-grade students (76 boys and 51 girls) of a local school. The students

were divided into two experimental groups as a quasi-experimental research design was employed. One group was assigned to use Trello, while the other group utilized the designed application, uASK. This experimental design allowed researchers to conduct a side-by-side evaluation of how each application performed in enhancing students' learning experiences through inquiry-based approaches.

B. Experimental Design

The primary objective of this experiment was to assess whether the newly developed uASK application, which implements an innovative framework called the ScrumBan Ubiquitous Inquiry Framework (SBUIF), could demonstrate better performance in comparison to Trello, a platform which have been used in some research [28] in to support agile learning approaches. The SBUIF framework integrated into uASK represents a novel attempt to combine elements of Scrum and Kanban methodologies, tailored specifically for educational contexts.

The experiment design demonstrates a clear contrast between traditional agile-based learning methods and the enhanced SBUIF approach. By incorporating technology-driven support and guidance, the uASK application aims to provide a more structured and supportive learning environment. This comparison allows for an evaluation of the effectiveness of the SBUIF in promoting student engagement, knowledge acquisition, and collaborative learning in a K12 setting.

C. Procedure

The scrum lesson, which served as the primary activity for the experiment, was structured into seven distinct tasks, thus representing a sprint in the agile methodology.

The first task focused on imparting initial lesson knowledge. For experimental group 1, the teacher provided a traditional explanation of the topic. In contrast, experimental group 2 engaged with the subject matter through video content, allowing students to gain knowledge independently as shown in Fig. 5(a).

The second task involved a tour of a botanical garden to collect samples. Experimental group 1 adopted a random sampling approach, while experimental group 2 utilized beacon tags to guide students to specific areas and samples of interest. This technology-enhanced approach aimed to provide a more structured and targeted learning experience as shown in Fig. 5(b).

Fig. 5. Students engaged in learning activities.

For the third task, students were required to dissect samples to identify plant parts. Experimental group 1 relied on group discussions to facilitate this process. Experimental group 2, however, combined group discussions with additional support provided by the uASK application, which offered hints to aid the learning process.

The fourth task involved completing a worksheet provided through the respective applications. Experimental group 1 continued to use group discussions as their primary method for completing the worksheet. Experimental group 2, on the other hand, benefited from both group discussions and application-provided hints, offering a more scaffolded approach to worksheet completion. The fifth task was to form hypothesis on different samples provided by applications.

For the sixth task students are again building a knowledgebase through a video for Experimental group 1 and traditional lecture Experimental group 2 to learn about pollination i.e. wind and insect pollination and the last task is to form hypothesis about different flowers if they are wind or insect pollinated based on images provided by applications.

In the next section further analysis of the results from this experiment is given to draw conclusions about the relative effectiveness of the two approaches. Factors such as student performance, engagement levels, and the learning achieved would need to be assessed to determine the potential benefits of the SBUIF implemented through the uASK application compared to the more traditional Kanban-based approach using Trello.

D. Evaluation Method

Computer-Supported Collaborative Learning (CSCL) has emerged as an influential pedagogical approach that leverages digital tools to enhance group-based learning. According to Jeong and Hmelo-Silver (2016), CSCL offers seven key affordances that can significantly enrich the collaborative learning experience: (i) establishing a joint task, (ii) facilitating communication, (iii) sharing resources, (iv) engaging in productive processes, (v) co-constructing knowledge, (vi) monitoring and regulating learning, and (vii) building groups and communities. These affordances create a structured framework that promotes interaction, collaboration, and shared learning objectives, which are critical components in a group-based digital learning [32]. These affordances have been used in multiple studies as validation measures [33][34]. These have been incorporated with M3 evaluation [35][36][37] to effectively evaluate at different organizational levels.

Mapping of micro and meso evaluation to CSCL affordances is shown in Table II. For all affordances C1 to C7, at micro level, evaluation survey was used for application usability aspects while at meso levels, C4, C5 and C6 affordances are explored through pre-test and post-test scores of students. Further, at this level, C1, C2, C3 and C7 affordances are used to evaluate time logs and observations on users' activities through uASK application.

Thus, integrating CSCL affordances within the M3 Evaluation Framework enabled a multi-level analysis of the learning intervention. This structured approach provided insights into individual learner experiences and the operational environment of the learning system. By addressing these distinct levels, the evaluation framework facilitates a comprehensive understanding of the CSCL system's impact on learning outcomes, offering an evidence-based assessment of the effectiveness of collaborative learning interventions.

TABLE II. EVALUATION METHODS

CSCL affordances	M3 Evaluation Framework	
	Micro Level Method	Meso Level Methods
C1- Establishing a joint task	Application Evaluation survey	Time log & Observation through application e.g. Group formation & Task formation
C2- Facilitating communication		Time log & Observation through application i.e. chat forum
C3- Sharing resources		Time log & Observation through application e.g. videos
C4- Engaging in productive processes		Pre/post-test & Activity evaluation
C5- Co-constructing knowledge		Pre/post-test & Activity evaluation
C6- Monitoring and regulating learning		Pre/post-test & Activity evaluation
C7- Building groups and communities		Time log & Observation through application i.e. chat forum

VI. RESULTS AND ANALYSIS

The study compared the use of Trello with uASK in facilitating collaborative learning during a botany lesson. The study involved 127 grade 7 students, split into two experimental groups (63 for Trello and 64 for uASK), using a structured approach to tasks that tested different collaborative affordances.

A. Micro Level Evaluation

For micro level evaluation, application evaluation survey was used as method for evaluating CSCL affordances in both applications. Table III shows the questions of application evaluation survey with the corresponding affordance. While Fig. 6 shows the Application Evaluation survey results for both Trello and uASK. As micro level focuses on individual learner experience therefore the questions reflect users' experiences with all CSCL affordances (C1 to C7). uASK consistently scored higher across all metrics, especially in "helping with learning" and "ease of sharing information." collaboration and learning enjoyment highlight its success in Finding and Building Groups and Communities and Engaging in Productive Processes. These findings suggest that the application's structure not only enhanced individual engagement but also facilitated group cohesion, which is essential in a collaborative learning context.

Fig. 6. Analysis of application evaluation survey results.

TABLE III. QUESTIONS ASKED IN QUESTIONNAIRE

Question No	Question asked in survey	CSCL affordances
Q1	The task was well-defined and clear	C1
Q2	There were no challenges in establishing a common understanding of tasks due to application	C1
Q3	The application helped in learning	C5
Q4	The learning experience was enjoyable	C4
Q5	Navigation through the application was easy	C6
Q6	The application helped working in group	C7 & C2
Q7	It was easy to share information and files with our group	C3

B. Meso Level Evaluation

In the meso level evaluation, number of different methods are used. Learning performances of the students during pre and post-tests are evaluated through their scores. Further, students’ engagements are examined through time spent on tasks performed during different activities.

Fig. 7 and Fig. 8 depict Pre Test, Post Test and Activity performance evaluation results that evaluate CSCL affordances C4, C5 & C6. In Fig. 7, the improvement in test scores from pre-test to post-test for both experimental groups. For the Trello group, marks improved from 27.5% to 60.5%, while the uASK group improved from 24.5% to 70.5%. This demonstrates that both groups experienced significant gains in knowledge; however, the uASK group had a more substantial increase.

Fig. 7. Results of Pre and post test results for Trello and uASK.

Fig. 8. Activity performance evaluation results.

The marked improvement in the uASK group’s post-test results may be attributed to the integration of both Scrum and Kanban methodologies, which potentially enhanced students’ ability to Engage in Productive Processes and Engage in Co-construction of Learning through a structured yet flexible approach to learning tasks. The provision of guidance via beacon tags and application support might have fostered a deeper understanding, as indicated by the larger knowledge gains in the uASK group. The findings align with Jeong and Hmelo-Silver’s affordances of collaborative learning, emphasizing the effectiveness of uASK’s structured support for Engaging in Productive Processes and Hypothesis Generation (Engaging in Co-construction of Learning).

The results of evaluation of the work done on the worksheet provided through the application are given in Fig. 8. uASK results show marked improvement in the performance of students as it aids in comparison to Trello group.

Then for CSCL affordances C1, C2, C3 & C7 this study used time log observation. Fig. 9 breaks down the time spent on each task by both groups, showing variations in the average time required to complete each activity. The Trello group generally spent more time on each task compared to the uASK group, with especially high time usage in Task 1 & 6 (Knowledgebase creation), Task 2 (botanical garden sample collection), Task 4 (filling the worksheet) & hypothesis generation.

Fig. 9. Time analysis of individual activity in sprint.

The longer time spent by the Trello group suggests that the Kanban-only approach may not provide as efficient task guidance as the combined Scrum-Kanban structure in uASK, which offered hints and beacon-based support. In Task 2, where beacon tags directed students in the uASK group to specific sample areas, the decreased time suggests enhanced Monitoring and Regulation of Learning. This also suggests that uASK's guidance features facilitated quicker and more targeted completion of tasks, reflecting a higher efficiency in Establishing a Joint Task. Tasks requiring in-depth group discussion, such as Task 4, 5 and 7, saw lower completion times with uASK, possibly due to the aid of application prompts which reduced cognitive load and encouraged faster hypothesis generation.

Fig. 10 gives the total time comparison by each group to complete all tasks i.e. entire activity. The Trello group takes more time, while the uASK group completed the tasks in considerably less time. This total time difference reinforces the advantage of the uASK system in streamlining task completion through the ScrumBan inquiry framework. The 34.70%-time efficiency in uASK. The reduced time highlights enhanced Communication and Sharing Resources, as students had quicker access to task instructions and peer input, thereby fostering more effective collaborative engagement. This shorter task duration for uASK demonstrates how the affordance of Monitoring and Regulation of Learning can be operationalized to optimize task efficiency.

Overall, the combination of questionnaire feedback, time logs, and pre/post-test results illustrates how the uASK platform, leveraging the Scrum-Kanban inquiry framework, better supported the collaborative learning affordances identified by Jeong and Hmelo-Silver. The findings emphasize the impact of integrating structured yet flexible methodologies to enhance both the efficiency and depth of collaborative learning among K12 students.

Thus, it is found that uASK showed a larger improvement in post-test scores compared to Trello, indicating that it was more effective in helping students understand the content. The additional features provided by uASK, such as structured hints and guided inquiry, may have contributed to deeper learning.

Fig. 10. Time analysis of entire sprint.

Students in the uASK group completed tasks more quickly on average. The combination of Scrum and Kanban principles allowed uASK to provide more structured guidance, reducing time spent on each activity. For instance, beacon tags helped students navigate the botanical garden and locate specific samples more efficiently.

Whereas Trello lacks the structured guidance found in uASK, making it harder for students to stay on track or find specific information without teacher intervention. In the study, this was evident in the longer time taken by the Trello group to complete each task. This lack of support might make it challenging for younger or less-experienced students to engage fully with complex learning tasks.

Additionally, uASK's features, such as hints and prompts, guided students through discussions and worksheet completion. This structured support facilitated Engaging in Productive Processes and Monitoring and Regulation of Learning, as students could focus on task goals without getting stuck or needing excessive teacher intervention. But Trello's Kanban approach is good for organizing tasks but may not provide enough scaffolding for inquiry-based learning, as it does not support features like hypothesis generation, structured hints, or guided navigation. This limitation could result in superficial understanding if students struggle to access deeper content on their own.

Furthermore, Survey results showed higher levels of engagement, satisfaction, and enjoyment in learning for students using uASK. The platform's design likely created a more enjoyable learning experience, as students had access to helpful resources and did not have to rely solely on peer discussion or teacher explanations. This positive feedback suggests that uASK's approach was more user-friendly and better suited to the students' needs. Along with uASK facilitated easier sharing of information and group work, as the platform provided collaborative tools that were more responsive to real-time group needs. The structured prompts likely encouraged smoother communication and better group cohesion. However, Trello's design does not inherently support features for monitoring student progress or self-regulation in the way uASK does. Without built-in prompts or navigation aids, students may find it harder to monitor their learning path or regulate their pace effectively, leading to uneven progress within groups.

VII. CONCLUSION AND FUTURE WORK

In conclusion, this research demonstrates that the uASK application, based on the ScrumBan Ubiquitous Inquiry Framework (SBUIF), offers significant advantages over Trello in fostering collaborative learning among students. The SBUIF platform enabled more substantial improvements in test scores, with the group using SBUIF achieving an increase from 24.5% to 70.5%, compared to Trello's 27.5% to 60.5%. SBUIF's structured support, which included beacon tags, hints, and prompts, improved task efficiency, enabling students to complete activities 34.70% faster than the Trello group. This guidance helped streamline complex tasks, reduced the need for teacher intervention, and supported key collaborative learning processes, such as productive engagement and self-monitoring.

Additionally, survey results revealed higher engagement, satisfaction, and enjoyment among SBUIF users, indicating that its design better aligns with student needs for clear task instructions and collaborative tools. While Trello's simplicity may foster more independent problem-solving, it lacks the structured guidance that younger students or those new to inquiry-based learning may require, making it less effective for complex educational tasks.

However, there are certain limitations to the current study such as it does not explore the effects of SBUIF at macro level for instance how scalable the approach might be for institutions or how it could be integrated into policy. Also, there is a need to conduct longitudinal investigation for multiple sprints for deeper understanding of how the framework performs over extended learning periods.

To conclude, addressing current limitations while integrating AI-driven technologies for adaptive feedback and advanced data analytics will pave the way for a more comprehensive, personalized, and effective learning experience, ultimately enhancing student engagement, interaction, and learning outcomes in the future.

M-COVIDLex: The Construction of a Domain-Specific Mixed Code Sentiment Lexicon

Siti Noor Allia Noor Ariffin, Sabrina Tiun, Nazlia Omar

Center for Artificial Intelligence Technology-Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia
Bangi, Selangor, Malaysia

Abstract—Sentiment lexicons serve as essential components in lexicon-based sentiment analysis models. Research on sentiment analysis based on the Malay lexicon indicates that most existing sentiment lexicons for this language are developed from official text corpora, general domain social media text corpora, or domain-specific social media text corpora. Nonetheless, none of the current sentiment lexicons adequately complement the corpus utilized in this study. The rationale is that words in established sentiment lexicons may convey different sentiments compared to those in this paper’s corpus, as the strength and sentiment of words are context-dependent, influenced by varying terminology or jargon across domains, and words may not share the same sentiment across multiple domains. This paper proposes the construction of a domain-specific mixed-code sentiment lexicon, termed M-COVIDLex, through the integration of corpus-based and dictionary-based techniques, utilizing seven Malay part-of-speech tags, and enhancing Malay part-of-speech tagging for social media text by introducing a new tag: FOR-POS. The constructed M-COVIDLex is evaluated using two distinct domains of social media text corpus: the specific domain and the general domain. The performance indicates that M-COVIDLex is more appropriate as a sentiment lexicon for analyzing sentiment in a domain-specific social media text corpus, providing valuable insights to governments in assessing the sentiment level regarding the analyzed topic.

Keywords—Malay social media text; mixed-code sentiment lexicon; sentiment analysis; domain-specific; lexicon-based; informal Malay; Malay part-of-speech; public health emergencies; COVID-19 Malaysia

I. INTRODUCTION

Sentiment analysis is a critical domain within natural language processing [1-4], as sentiment constitutes a significant aspect of human communication [5,6], often articulated through ambiguous and creative language [1]. For example, text that incorporates slang is comprehensible only to particular groups [7], presenting significant challenges for analysis [1]. Analyzing sentiment is essential for understanding individuals’ beliefs regarding various issues and their decision-making processes [8-11].

Rising demand for a model that can analyze the sentiment of mixed code (also known as multilingual or cross-language language) text particularly text from social media arisen recently [12,13]. It occurred on account of (i) limited sentiment resources needed for sentiment analysis for languages other than English [14-18], such as sentiment lexicon, language tools, corpora, sentiment analysis algorithm, and sentiment classification algorithm, and (ii) the escalation of social media posts exercising

mixed code in multilingual low-resource societies [19-23]. Furthermore, mixed code sentiment analysis eases a better understanding of the sentiment enunciated in various languages [12]. Up to the present time, Malay is still considered as a low-resource language, specifically in this field [5,24] since it is less studied and resource-scarce [25,26].

Sentiment lexicons are a crucial tool in lexicon-based sentiment analysis model [27-31], for any language [32]. Lexicon-based approaches demand human involvement to build a dictionary that has positive and negative lexicons [33]. This approach is divided into dictionary-based and corpus-based [20]. The former relies on sentiment words existing in digital linguistic dictionaries such as WordNet [34] and the latter relies on sentiment words that exist in the study corpus [35]. The success of lexicon-based sentiment analysis depends entirely on a sentiment lexicon that can be constructed manually or semi-automatically [36]. Furthermore, sentiment lexicons, which are also known as lexical dictionaries, are linguistic resources that have lexicons of opinions [37,38] that are labelled as positive or negative according to their semantic orientation [37-40]. For instance, words such as *baik* (good), *bagus* (excellent), and *hebat* (great) are often labelled as words with positive sentiment, while words such as *kejam* (cruel), *jahat* (evil), dan *hodoh* (ugly) are usually labelled as word with negative sentiment. The main purpose of sentiment lexicons is to assign each word in a text a corresponding sentimental weight [41]. Sentiment lexicons are divided into two types: general domain (or all-purpose) sentiment lexicon and domain-specific sentiment lexicon. A general domain sentiment lexicon is a list of words that carry either positive or negative meanings in casual conversation [42], while a domain-specific sentiment lexicon is a list of words that carry either positive or negative meanings in a discussion about a specific domain [43,44].

Recent literature review discloses that most existing sentiment lexicons developed for the field of Malay sentiment analysis are produced using either official text corpora [45], general domain social media text corpora [46], or domain-specific social media text corpora, such as affordable housing projects [47], crisis management [48], and telecommunications [49-51]. It is possible that words in the existing sentiment lexicon do not have any sentiment or carry different sentiments than words in this paper’s corpus [52,53] considering the strength and sentiment of words depend on the context of their use and the terminology or jargon differs between domains [36]. Furthermore, it is impossible for a word to have a single score or sentiment in several domains [53-58]. For example, in Malay, the term *kacau* in the food domain carries a positive sentiment

with a score of +1, if the context of its use is to stir or mix something, such as food and the term can also carry a negative sentiment with a score of -1 in the public health emergency domain, if the context of its use is to cause chaos or anxiety. Therefore, the sentiment lexicon built from this paper's corpus is more practical since the words in the sentiment lexicon reflect the sentiment in the context of the domain being studied [55].

Moreover, sentiment lexicons can be generated using two seed words expansion methods: manual and automatic based on words in a dictionary or corpus [56]. Recent literature review reveals that these seeds words can be produced by employing part-of-speech (POS) tags extraction [59], such as adjectives [60-62], verbs [50,51], adverbs [46], and nouns [63]. POS tagging is a feature in the sentiment analysis model that groups words based on their category or role in a sentence [64]. Originally in Malay, words can be classified using four POS tags: nouns, verbs, adjectives, and task words [65]. These POS tags are known to be more suitable for tagging standard Malay text than Malay social media text [64] due to the difference in the writing structure in both texts. However, the latest enhancements on Malay POS tags by [64] have made tagging social media text much effortless, since they created new POS tags especially for mixed code word. For example, FOR-NEG tag for tagging foreign words with negative meaning and NEG tag for tagging Malay words with negative meaning. Though the newly developed Malay POS tags by [64] can tag negative meanings, they lack a tag for tagging foreign words with positive meanings. Therefore, this paper will further improve the Malay POS tags by adding a new POS tag, namely FOR-POS, for tagging foreign words with positive meanings. This enhancement is made to aid in speeding sentiment analysis process by instantly distinguishing words that carry sentiment in the corpus.

This paper presented a new polyglot sentiment lexicon that specific to the latest public health emergency issue in Malaysia which is Coronavirus 2019 (COVID-19). This sentiment lexicon is known as M-COVIDLex (Malay Coronavirus Lexicon) and consist of lexicon of two main languages in Malaysia: Malay and English. The construction of M-COVIDLex utilized a combination of corpus-based and dictionary-based techniques and seven Malay POS tags: adjectives (KA), verbs (KK), adverbs (KAD), nouns (KN), FOR-NEG, FOR-POS, and NEG. The contributions of this paper are listed as follows:

- A new domain-specific social media text corpus focusing on the topic of "the impact of the implementation of government efforts to address public health emergencies in the daily routines of Malaysians". Until the data's copyright is enforced, this corpus will be inaccessible to the public or future research.
- Enriching existing Malay Normalizer by [66] through adding four new rule elements to its existent database.
- Normalizing the generated corpus using an improved Malay Normalizer.
- Enhancing existing Malay POS tags by [64] through adding one new POS tag for tagging foreign words with positive meanings: FOR-POS.

- Tagging all words in the generated corpus with the recently enhanced Malay POS tags.
- Annotated each post in the generated corpus with its proper sentiment polarity either positive, negative, or neutral.
- M-COVIDLex: a domain-specific mixed code sentiment lexicon where each lexicon has been classified as either positive or negative sentiment word.
- The performance evaluation proves that the sentiment lexicon built from this paper's corpus is more practical in analyzing sentiment from the same domain corpus than the general domain corpus.

This paper is structured as follows. The following section (Section II) reviews the related work. In Section III, the proposed method is introduced in detail. Section IV presents experiment and obtains results. Section V discussed the experiments and obtained results and finally, Section VI concludes how this paper can be expanded to further contribute to the Malay social media text sentiment analysis fields.

II. RELATED WORKS

A. Types of Sentiment Lexicon

Sentiment lexicons are divided into two types: general domain and domain specific. General domain sentiment lexicon is a list of words that carry either positive or negative meanings in casual conversation [42], while domain-specific sentiment lexicon is a list of words that carry either positive or negative meanings in conversation about a specific domain [43,44].

A general domain sentiment lexicon is suitable for development and implementation in a model that analyzes sentiment text that is not based on any domain for the list of words in the general domain sentiment lexicon is limited to words commonly used in daily conversations and its polarity score is not sensitive to any domain [67-70]. In addition, the study by [36], [47], [71], and [72] stated that domain-specific sentiment analysis models that implement the studied domain-specific sentiment lexicon have the potential to provide better sentiment analysis results and more accurate classification results compared to the general domain sentiment lexicon. The reason for this is that the sentiment polarity scores of words in the sentiment lexicon are obtained based on their meanings in the domain studied [73,74] and sentiment analysis research is sensitive to the domain analyzed. Opinion expressions that carry sentiments, whether positive or negative, differ between domains since each domain has its own language, terminology, or jargon [53-58]. Furthermore, it is impossible for an opinion expression to have the same sentiment polarity score in all domains because words and their sentiment polarity scores are closely related depending on the domain context in which they are used [36].

In conclusion, models developed to analyze sentiment in a specific domain are encouraged to use a sentiment lexicon specific to that domain rather than a general domain sentiment lexicon. The reason for this is that the use of a correct and proper sentiment lexicon can produce good analytical accuracy.

B. Techniques for Constructing Sentiment Lexicon

Sentiment lexicons can be generated using two seed word expansion methods: manual and automatic based on words in a dictionary or corpus [56]. However, generating a comprehensive sentiment lexicon using manual expansion techniques is complicated, time-consuming, and prone to various errors [56]. Therefore, researchers prefer to use existing sentiment lexicons, such as General Inquirer [75], WordNet [34], Opinion Lexicon [76], Subjectivity Lexicon [77], SentiWordNet [78], SentiStrength [79], SenticNet [80], AFINN [81], Semantic Orientation CALculator (SO-CAL) [63], National Research Council Canada (NRC) Emotion Lexicon [82], Valence Aware Dictionary and sEntiment Reasoner (VADER) [83], LIWC [84], TextBlob [85], and Bing [86].

Dictionary-based expansion techniques require researchers to manually collect initial list of seed words and their polarities before expanding them by extracting synonyms and antonyms of each seed word from existing dictionaries [20]. Corpus-based expansion techniques also use the initial list of seed words to identify words that carry sentiment values and their polarities in the research corpus [56]. Sentiment lexicon generation using corpus-based expansion techniques is more suitable for domain-specific sentiment analysis research than dictionary-based and manual expansion techniques [9]. This is due to the technique is extremely sensitive to the domain, capable of generating sentiment lexicons specific to the domain [40], and capable of handling informal texts well, for instance social media texts [9]. However, sentiment lexicon construction using this corpus-based expansion technique is a lengthy process [87], inefficient in labelling texts with formal terms [9] and has limitations in distinguishing all opinion words compared to dictionary-based expansion techniques [9]. The reason for this is that this technique requires a large corpus to include all opinion words in the study language and large-scale corpus collection is strenuous to be prepared [9]. However, regardless of the sentiment lexicon production technique chosen by the researcher to develop or use, the overall quality of this sentiment lexicon is hard to measure [9]. A summary of sentiment lexicon construction techniques implemented by past research that analyzed Malay sentiment can be seen in Table I.

Based on Table I, the corpus-based sentiment lexicon construction technique can be implemented using the feature extraction method, where this method is done by extracting words that belong to certain POS tag such as adjectives, verbs, and adverbs. Additionally, this paper discovered that there is other POS tag that can be extracted together as they also have sentiment values, namely nouns [63]. The dictionary-based sentiment lexicon construction technique can be performed via the translation method, where the lexicon in the English dictionary is interpreted into Malay. Meanwhile, the manual sentiment lexicon production technique is executed by compounding both techniques, namely corpus-based and dictionary-based.

In conclusion, sentiment lexicons can be developed through various techniques such as corpus-based, dictionary-based, or manually. Choosing the right technique is the key to certify that the sentiment lexicon produced is of excellent quality and capable of providing good sentiment analysis.

III. METHODOLOGY

As previously mentioned, this paper aims to construct domain-specific mixed code sentiment lexicons otherwise known as M-COVIDLex through a combination of corpus-based and dictionary-based techniques along with seven Malay POS tags. The proposed M-COVIDLex construction method entails five key phases: (i) data gathering, (ii) data preprocessing, (iii) construction of M-COVIDLex, (iv) sentiment analysis, and (v) sentiment classification. Each phase is enlightened in further detail below and it is important to emphasize that the data gathering and analysis presented in this paper adhere to the terms and conditions of social media platform, X.

A. Data Gathering

This paper gathered data manually from the social media platform, X (formerly Twitter), where the data must be composed of the combination of two languages, Malay and English, concerning “the impact of the implementation of government efforts to address public health emergencies in the daily routines of Malaysians”. This sort of data is recognized as mixed code or code-switching or multilingual. To achieve this purpose, this paper employed keyword-driven data-gathering techniques [64,66,90]. The search was performed on X’s advanced search functions [64,66,89] using a predefined list of thirty-three keywords of four affected sectors during COVID-19 in Malaysia: education, safety, health, and economy (see Table II). The keywords were obtained from data issued by [91] and [92]. Nevertheless, the keywords used are restricted to the Malay

language apart from acronyms such as SOP (Standard Operational Procedure) as well as the English loanword like “moratorium” and “internet”. X’s advanced search function permits users to refine search results based on several criteria including keywords, publication date, language type, and account type, which authorizes researchers to oversee the kind of posts suitable to be extracted. For a post to be included in the search, it must have at least one keyword and was posted between March 2020 and September 2021. The sectors and keywords were selected in such a way to boost the number of posts about the selected topic and limit any extraneous posts [90]. As a result, this paper achieved in gathering 16,898 related posts which were saved in textfiles (txt). The data gathering stage is deemed complete and adequate when all posts resulting from the keyword search have been extracted.

<i>PDPR</i>			

B. Data Preprocessing

Data preprocessing plays a fundamental role in cleansing text data, specifically social media text, where typographical errors, slang terms, acronyms, and polyglot (code-mixed, code-switching, and multilingual) lexes are frequent [93]. According to [88], the existence of noise in the Malay text is not being managed at this phase [13] affirmed that various preprocessing procedures are important to alleviate noise, typographical divergences, and morphological intricacy, especially in a low-resources language, such as Malay. In this phase, the gathered data is overseen in two steps: normalization and POS tagging. Normalization is essential to diminish the presence of noise from the data that has the potential to interfere with the results of the sentiment analysis and to make the data more manageable [89]. POS tagging is needed to annotate each word in the data with a suitable POS tag.

1) *Normalization*: A recent study by [66] proposed a rule-based normalization application exclusively built to refine Malay social media text, where it achieves high accuracy in their analysis (97 percent). Therefore, in this paper, this Malay Normalizer was employed to normalize all lexicons in the gathered data as it incorporates diverse essential preprocessing procedure for Malay social media text. For instance, (i) removing noise, (ii) normalizing Malay, English, and Romanized Arabic words to their standard form, (iii) expanding abbreviations, contractions, and acronyms, and (iv) normalizing slang term, colloquialism, and dialects. Nonetheless, it is expected that the application will be inept at normalizing most of the words that exist in this paper’s gathered data seeing that it was built using a smaller corpus size. Hence, it needs to be enriched with words from this paper’s corpus. Albeit [94] exclaimed that the size of a corpus does not imply its quality and could have more noise, this enrichment is compulsory to ensure all lexicons in the corpus are normalized to their standard form. The enrichment entails adding four new rule elements to its existent database: (i) normalization of novel words, for example, slang term, dialects, and domain-specific terms, (ii) normalization of emoticons, (iii) exclusion of Malay and English question words, and (iv) elimination of English and selected Malay stop words. This supplementation effectively reduces the number of X posts from 16,898 posts to 16,600 posts, where 298 posts were removed from this paper’s corpus due to noise.

2) *POS tagging*: The normalized gathered data initially annotated using Malay POS tags by [64]. These Malay POS tags was chosen given that (i) it achieved high accuracy in their analysis (95 percent) against Malay social media text, (ii) it has been thoroughly upgraded from the previous Malay POS tags by [95], (iii) the POS tags were tailored to be able to annotate each word in the Malay social media text, for example, any foreign language exist in the corpus will be tag with FOR tag, slang term will be tag with SL tag, and dialect terms will be tag with LD tag, and (iv) standard Malay POS tags absence proper tags to label all words in this paper’s corpus since social media text are usually written using mixed code otherwise known as multilingual or code-switching [66]. Although [64] has

improved these Malay POS tags to accommodate words in Malay social media text, this paper discovered that it has yet to set up a proper tag for tagging foreign words with positive sentiments. Therefore, it needs to be improved by adding a new POS tag exclusively for tagging positive sentiment foreign words. This paper ruled out to name the newly created POS tag as FOR-POS (foreign positive). Words for the FOR-POS tag are found and extracted from the word that conveys positive meanings in the FOR-tag word list. This paper performed this improvement to aid in speeding the sentiment analysis phase by instantaneously distinguishing words that carries sentiment in the corpus.

C. Construction of M-COVIDLex

The proposed M-COVIDLex construction method entails three steps: (i) seed word selection, (ii) seed word annotation, and (iii) synonym expansion. In this phase, the proposed method will be enlightened in detail.

1) *Seed word selection*: A seed word is a lexicon that carries either positive or negative sentiment polarity. Based on the literature review in Section II, this paper discovered that these seed words can be generated using four types of POS tags: KA, KK, KAD, and KN. Therefore, in this step, the lexicon tagged with these four POS tags will be extracted as M-COVIDLex seed words. However, since this paper's corpus is made of mixed code social media text and each lexicon is tagged using the improvised Malay POS tags, this paper decided to add three more POS tags to produce M-COVIDLex seed words. The three additional POS tags are (i) NEG, a POS tag designed specifically for negative particles in the Malay language, (ii) FOR-NEG, a POS tag for foreign language words that carry negative sentiments, and (iii) FOR-POS, a POS tag for foreign language words that carry positive sentiments. The lexicons from these seven POS tags were extracted from the corpus using the POS tagging extraction technique. The technique used specific patterns to extract all related lexicons in the corpus, and its implementation produced a list of seed words for each POS tag, where the list functions as a lexical dictionary and is needed when constructing M-COVIDLex. Algorithm 1 shows how this seed word extraction was performed for the lexicon with the KA POS tag. Fig 2 presents the result of executing Algorithm 1 and Fig 3 summarizes the total number of seed words for each POS tag in the M-COVIDLex.

Algorithm 1: M-COVIDLex Seed Word Selection

Input: tagged_corpus K_G , post S , lexicon L , part_of_speech G
Output: seed_word $M\text{-COVIDLex} = (L, G)$

```
Start
  for all  $S$  in  $K_G$  do
    for all  $L$  in  $S$  do
      find  $L == G$  (KA)
      if  $L == G$  (KA)
        add  $L$  in  $M\text{-COVIDLex}$ 
      end if
    end for
  end for
End
```

Fig. 2. Seed word selection result for lexicon with the KA POS tag.

Fig. 3. Summary of M-COVIDLex.

2) *Seed word annotation*: In this step, seed words will be annotated with either positive or negative sentiment polarity. However, only seed words with KA, KK, KAD, and KN POS tags engage in this annotation process. Seed words with NEG, FOR-NEG, and FOR-POS POS tags are exempted since their sentiment polarity is clear based on the POS tag type. The annotation process in this paper was done by the hired annotators. According to [96], an annotator is an individual appointed to annotate data according to guidelines and time limits given. The following are the guidelines criteria for selecting annotator listed by [96] and followed in this paper:

- Researchers need to figure out the type of language the annotator needs to know or be fluent in before doing the annotation task.
- The researcher needs to set up the specific knowledge that the annotator needs to know about the annotation task.
- Researchers need to make practical considerations about several things, for instance, funds, time, data size, etc.

These guidelines are crucial for researchers to be able to find and appoint annotators who meet the qualifications and criteria [47]. Table III presents the criteria and qualifications of the appointed annotator in this paper along with its references.

TABLE III. THE NEWLY REVISED CRITERIA AND QUALIFICATION OF AN ANNOTATOR USED IN THIS PAPER

Criteria & Qualification of an Annotator	References
Language: Malay native speakers and fluent in English.	[47,96]
Knowledge: Have basic knowledge of the topic and field of study.	[47,96]
Practical Consideration: <ol style="list-style-type: none"> Current academic graduate (highest): <ul style="list-style-type: none"> Malaysian Certificate of Education or Malaysian Higher Certificate of Education or Matriculation or Diploma or Degree or Master Aware of the meaning and use of current social media language. Able to give full commitment to annotating data within the specified period. 	[96]

The appointed annotator was assigned to manually annotate the lexicons based on the search results on the *Pusat Rujukan Persuratan Melayu*, or PRPM for short [89]. PRPM is an online dictionary specifically for the Malay language developed by DBP. It can be reached at the following link: <https://prpm.dbp.gov.my/>. The task of the annotator is to identify and label the sentiment polarity of words based on the definition issued by PRPM and the context of its use. Fig 4 presents some of the seed words for KA POS tag in the M-COVIDLex that have been annotated with their proper sentiment polarity.

3) *Synonym expansion*: In this step, all M-COVIDLex seed words will be expanded. This expansion aims to expand the coverage of M-COVIDLex seed word variations based on the

search results in PRPM for Malay and WordNet [34] for English.

a) *Malay lexicon synonyms*: The expansion of the Malay language lexicon synonyms was conducted based on the lexicon search results in PRPM [89] and the technique was manual [97]. This paper aims to standardize the expansion of the Malay lexicon by limiting it to level one, given the variability in the number of synonyms across different Malay lexicons. Alternative approaches to this process include expanding the lexicon by accepting all possible synonyms and antonyms.

The first step in the expansion of the Malay lexicon synonyms was to conduct a lexicon search on the PRPM homepage. Fig 5 shows the search conducted on the PRPM homepage for the lexicon *lupa* and Fig 6 shows the search results for the lexicon, where there is word information consisting of its definition and thesaurus. The second step is to extract lexical synonyms up to level one only. Lexical synonyms can be obtained in the thesaurus section. Fig 7 shows the thesaurus for *lupa*, where the lexicon has synonyms up to level three: not remembering (level one), not aware (level two), and not arising in memory (level three). The third step is to add the level one synonym to the M-COVIDLex seed words. Table IV presents examples of synonym expansion for the *lupa*, *layak*, and *usaha* lexicon.

	A	B
1	Leksikon	Polariti
2	adil	Positive
3	adillah	Positive
4	adilnya	Positive
5	agam	Positive
6	aib	Negative
7	ajaib	Negative
8	aktif	Positive
9	alang	Positive
10	alpa	Negative
11	aman	Positive
12	aneh	Negative
13	angkuh	Negative
14	asing	Negative
15	asyik	Positive
16	atasi	Positive

Fig. 4. Annotation results from several seed words in the M-COVIDLex.

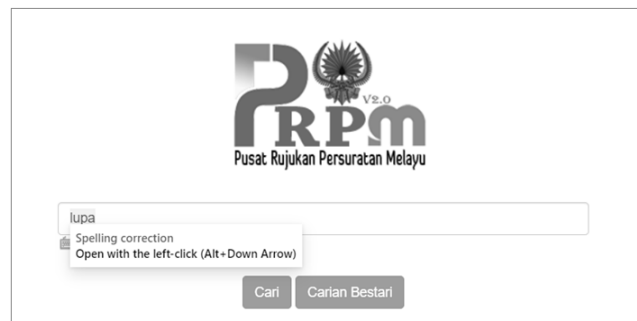

Fig. 5. Search for *lupa* on the PRPM homepage.

Fig. 6. Search results for *lupa* on the PRPM website.

TABLE IV. EXAMPLE OF SYNONYMS EXPANSION FOR MALAY LEXICON

M-COVIDLex Seed Words				
Malay Lexicon	Malay Synonym	POS Tag	Polarity	Polarity Score
<i>lupa</i>	<i>tidak ingat</i>	KK	Negative	-1
<i>layak</i>	<i>padan</i>	KA	Positive	+1
<i>usaha</i>	<i>daya upaya</i>	KN	Positive	+1

b) *English lexicon synonyms*: The expansion of the English lexicon synonyms is conducted using a lexical dictionary-based technique, namely WordNet [34]. However, this method only involves lexicons belonging to the FOR-NEG and FOR-POS POS tags. The reason for this is that only these two POS tags have the English lexicon in the M-COVIDLex seed word list. Algorithm 2 below presents how the English synonym expansion method is conducted using the WordNet application.

Algorithm 2: M-COVIDLex English Synonym Expansion

Input: seed_word *M-COVIDLex*, lexicon *L*, wordNet *W*, english_synonym *S_i*

Output: expansion *M-COVIDLex* = (*L*: *P*);

L: lexicon, *P*: lexicon_polarity

Start

```

for all L in M-COVIDLex do
    if exist L in W then
        add Si in M-COVIDLex
    end if
end for
    
```

End

D. Sentiment Analysis

Sentiment analysis is the process of deciding sentiment polarity score, where the technique that will be implemented in this paper is based on (i) grammatical rules of four Malay POS tags: KNF (negation), KP (intensifier), KB (auxiliary), and KH (conjunction), and (ii) word frequency calculations. In this paper, the order of importance of these four Malay POS tags are presumed as follows: KH > KB > KNF > KP (see Algorithm 3). This order is established by recognizing the significance of each POS tag within grammatical rules for determining sentiment polarity scores. For instance, KP POS tag is of the highest importance because of its aptitude to increase or decrease the strength of the polarity of post sentiment, hence found at the end

of the order. Fig 8 shows how the sentiment analysis phase happens, and Table V presents the criteria of sentiment polarity used in this paper.

Fig. 7. *Lupa* thesaurus on the PRPM website.

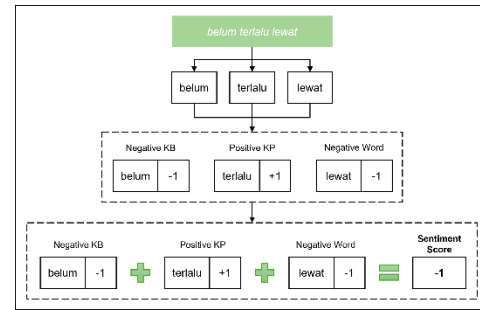

Fig. 8. Demonstration of how M-COVIDLex sentiment analysis phase analyzes the sentiment of a text.

Algorithm 3: M-COVIDLex Sentiment Analysis

Input: Post *S*, Lexicon *L*

Output: Post *S*, Lexicon *L*, Polarity *P*

Start

```

if there exists L == positive in S, then
    | score L == 1;
else exists L == negative in S, then
    | score L == -1
end if
if there exists L == conjunction in S, then
    | classify S using conjunction rules;
else if exists L == auxiliary in S, then
    | classify S using auxiliary rules;
else if exists L == negation in S, then
    | classify S using negation rules;
else if exists L == intensifier in S, then
    | classify S using intensifier rules;
else
    | classify S using word count
end if
    
```

End

TABLE V. SENTIMENT POLARITY CRITERIA USED IN THIS PAPER

Sentiment Score Criteria	Sentiment Polarity
Sentiment score value > 0	Positive
Sentiment score value = 0	Neutral
Sentiment score value < 0	Negative

E. Sentiment Classification

Sentiment classification is the process of classifying posts according to their corresponding polarity, where in this paper, the post is classified into either positive (sentiment polarity score equal to 1), negative (sentiment polarity score equal to -1), or neutral (sentiment polarity score equal to 0) based on the results

gained from sentiment analysis phase. The sentiment classification technique used in this paper is a simple classification otherwise known as lexicon-based classification [89,98]. Algorithm 4 enlightens how this sentiment classification process is executed, and Fig 9 reveals the implementation results of this phase.

Fig. 9. M-COVIDLex sentiment classification results.

Algorithm 4: M-COVIDLex Sentiment Classification

Input: Post S , Lexicon L , Positive_Word P_W , Negative_Word N_W , Conjunction_Rules R_{KH} , Auxiliary_Rules R_{KB} , Negation_Rules R_{KNF} , Intensifier_Rules R_{KP}

Output: Post S , Conjunction_Rules R_{KH} , Auxiliary_Rules R_{KB} , Negation_Rules R_{KNF} , Intensifier_Rules R_{KP} , Lexicon_Frequency K_L , DataFrame RD , Classification SC , Polarity_Score P , Sentiment $LexClass$

Start

```

count total  $P_W$  in  $S$ 
count total  $N_W$  in  $S$ 
for every  $L$  in  $S$ 
    count frequency  $L == R_{KH}$ 
    add frequency  $L$  in  $R_{KH}$  [ $RD$ ]
    print  $P$  frequency  $L$  in  $R_{KH}$  [ $RD$ ]
    count frequency  $L == R_{KB}$ 
    add frequency  $L$  in  $R_{KB}$  [ $RD$ ]
    print  $P$  frequency  $L$  in  $R_{KB}$  [ $RD$ ]
    count frequency  $L == R_{KNF}$ 
    add frequency  $L$  in  $R_{KNF}$  [ $RD$ ]
    print  $P$  frequency  $L$  in  $R_{KNF}$  [ $RD$ ]
    count frequency  $L == R_{KP}$ 
    add frequency  $L$  in  $R_{KP}$  [ $RD$ ]
    print  $P$  frequency  $L$  in  $R_{KP}$  [ $RD$ ]
end for
for every  $P$  in [ $RD$ ]
    count  $P$  in  $R_{KH}$  [ $RD$ ] +  $R_{KB}$  [ $RD$ ] +  $R_{KNF}$  [ $RD$ ] +  $R_{KP}$  [ $RD$ ]
    add  $P$  in  $SC$ 
end for
if  $P$  in  $SC == 0$ ;
    print  $P$  in  $LexClass == 0$ 
else if  $P$  in  $SC > 0$ ;
    print  $P$  in  $LexClass == 1$ 
else if  $P$  in  $SC < 0$ 
    print  $P$  in  $LexClass == -1$ 
end if

```

End

IV. EXPERIMENT AND RESULTS

The evaluation of M-COVIDLex will involve an analysis of sentiments from two distinct social media text corpora: a domain-specific corpus (the one presented in this paper) and a general domain corpus as referenced in [64].

A. M-COVIDLex

The third phase has successfully resulted in the development of M-COVIDLex, a domain-specific mixed code sentiment lexicon. The lexicon in M-COVIDLex is restricted to two sentiment polarities: positive sentiment, assigned a score of +1, and negative sentiment, assigned a score of -1. Neutral sentiment lexicons with a score of 0 are excluded from the seed words of M-COVIDLex, as they lack sentiment value. M-COVIDLex contains 6,698 lexicons associated with positive sentiment and 3,813 lexicons associated with negative sentiment.

B. Performance Evaluation

The performance of M-COVIDLex is initially assessed on a domain-specific social media text corpus, concentrating on the effects of government initiatives aimed at addressing public health emergencies on the daily routines of Malaysians. The experimental dataset corpus was derived from the execution of the second phase. This study utilized a subset of 800 posts from a total of 16,600 normalized posts. The selection of posts was conducted randomly, based on sentiment polarity, resulting in 400 posts with positive sentiment and 400 posts with negative sentiment. The chosen experimental datasets are accompanied by confusion matrix tables to derive their values. Fig 10 illustrates a portion of the data annotation results, while Table VI displays the corresponding values derived from these results.

teks	polariti	penilaian
aaron kwok years old withdraw kumpulan wang simpanan pekerja already	1	True Positive
abah bantuan sara hidup bantuan prihatin rakyat citra ilestari isinar lepas ringgit malaysia ewallet hear shit one time going lose ringgit malaysia bloody ewallets given promote cashless transactions bloody financial aid	1	False Positive
abah guru kaunseling sekolah rendah pagi abah pergi sekolah jam pagi sebentar langit masih bergelap untuk menyambut anak anak muridnya kalau sahajalah murid darjah yang menangis tak mahu sekolah abah pujuk masuk	1	True Positive
abah kau tak keluarkan duit kumpulan wang simpanan pekerja akaun bukan nak dapat okay sekali sudah okay nak harap bantuan prihatin nasional yang dapat biarlah yang perlukan duit mengeluarkan duit divaktu terdesak	1	True Positive
abah kawan yang tinggal program perumahan rakyat sudah golongan bottom forty cakap beli beras yang harganya kampung ringgit malaysia boleh makan minggu tetapi nak bayar ansuran atau sewa rumah kereta dan data internet untuk pengajaran dan pembelajaran rumah	1	False Positive

Fig. 10. M-COVIDLex data annotation results.

TABLE VI. CONFUSION MATRIX TABLE VALUES FOR M-COVIDLEX PERFORMANCE EVALUATION

Confusion Matrix	Experimental Dataset
True Positive (TP)	274 posts
False Positive (FP)	126 posts
True Negative (TN)	305 posts
False Negative (FN)	95 posts

The values presented in Table VI serve to evaluate the effectiveness and quality of M-COVIDLex in sentiment analysis

of the experimental dataset. This paper employs the following evaluation metrics to assess the performance of the proposed sentiment lexicon: (i) error rate, (ii) accuracy, (iii) sensitivity, (iv) specificity, (v) precision, and (vi) F1-score. Fig 11 illustrates the performance outcomes of M-COVIDLex, utilising the confusion matrix alongside six evaluation metrics.

Error rate. This evaluation measure was selected to assess the effectiveness of M-RuleScore in analysing the sentiment of the dataset, indicating that a lower error rate value corresponds to improved performance of the proposed M-RuleScore.

$$Error\ rate = \frac{(FP + FN)}{(TP + FP + FN + TN)} \quad (1)$$

Accuracy. This evaluation measure was selected to assess the proportion of posts accurately predicted from the entire dataset, with a higher accuracy value indicating superior performance of the proposed M-RuleScore.

$$Accuracy = \frac{(TP + TN)}{(TP + FP + FN + TN)} \quad (2)$$

Sensitivity. This evaluation measure was selected to assess the classification error of the dataset, indicating that a higher sensitivity value correlates with improved performance of the proposed M-RuleScore.

$$Sensitivity = \frac{TP}{(TP + FN)} \quad (3)$$

Specificity. This evaluation measure was selected to assess the suitability of M-RuleScore for analysing the dataset, indicating that a higher specificity value reflects improved performance of M-RuleScore in analysing negative sentiments.

$$Specificity = \frac{TN}{(TN + FP)} \quad (4)$$

Precision. This evaluation measure was selected to assess the effectiveness and robustness of the proposed M-RuleScore in analysing the sentiment of the dataset.

$$Precision = \frac{TP}{(TP + FP)} \quad (5)$$

F1-score. This evaluation measure was selected to assess the mean values of sensitivity and accuracy for the proposed M-RuleScore in analysing the dataset's sentiment.

$$F1\ -\ score = \frac{(2 \times precision \times sensitivity)}{(precision + sensitivity)} \quad (6)$$

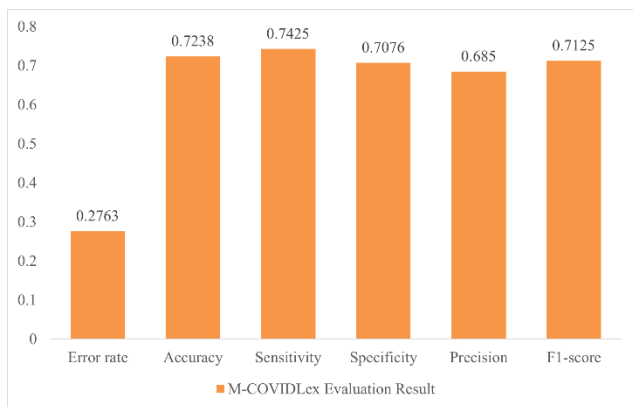

Fig. 11. M-COVIDLex performance evaluation result.

The performance evaluation results of M-COVIDLex presented in Fig 11 yield several conclusions.

- M-COVIDLex achieved an accuracy of 72.38% in the analysis of the experimental dataset. The analysis indicates that, from a total of 800 posts by Malaysians, M-COVIDLex successfully evaluated 274 posts expressing positive sentiments and 305 posts expressing negative sentiments regarding the government's response to the COVID-19 crisis.
- M-COVIDLex recorded an error rate of 27.63% in the analysis of the experimental dataset. Of the 800 posts analysed concerning the government's efforts in addressing the COVID-19 crisis and their impact on the daily lives of Malaysians, 126 posts were incorrectly classified as expressing positive sentiments, while 95 posts were misclassified as expressing negative sentiments.
- M-COVIDLex achieved a precision of 0.6850 in the analysis of the experimental dataset. The precision value indicates that, among the 400 posts predicted to express positive sentiments in the experimental dataset, only 68.50% accurately reflected positive sentiments and aligned with the government's efforts in addressing the COVID-19 crisis.
- M-COVIDLex demonstrated a sensitivity of 0.7425 in the analysis of the experimental dataset. The sensitivity value indicates that, among 369 genuinely positive posts in the experimental dataset, only 74.25% expressed positive sentiments regarding the government's efforts to address the COVID-19 crisis.
- M-COVIDLex demonstrated a specificity of 0.7076 when analysing the experimental dataset. The specificity value indicates that, among the 400 posts predicted to express negative sentiments in the experimental dataset, 70.76% accurately reflect negative sentiments opposing the government's efforts in addressing the COVID-19 crisis.

Fig. 12. Comparison of evaluation metrics between domain-specific and general domain social media text corpus.

To ensure comparability in the number of posts used for model comparison with other datasets and for evaluating the performance of M-COVIDLex, the analysis was limited to 800 posts. The performance of M-COVIDLex may be impacted by

this limitation. Evaluating performance across all 16,600 posts is likely to produce more favourable outcomes for M-COVIDLex. M-COVIDLex effectively assessed Malaysian sentiment concerning the government’s response to the COVID-19 crisis and its effects on daily life. Despite M-COVIDLex achieving an accuracy of 72.38 percent and an error rate of 27.63 percent, which are lower than many leading models in sentiment analysis for comparable domains, the performance evaluation indicates that a significant majority of Malaysians approve of and support the government’s crisis management efforts.

C. Model Comparison

This section evaluates the performance of M-COVIDLex on the general domain social media text corpus as referenced in [64]. The corpus selected by [64] was generated from Malay social media text, focussing exclusively on the contextual use of Malay social media terminology without emphasising any specific domain. The purpose of this assessment is to evaluate the suitability and effectiveness of M-COVIDLex as a sentiment lexicon for analysing sentiment within this domain. This study utilised a dataset comprising 800 posts selected from a total corpus of 1,791 posts, with 400 posts representing positive sentiment and 400 posts representing negative sentiment. The selection of these posts was conducted randomly, determined by the polarity of their sentiment. Table VII presents a comparison of the confusion matrix values for domain-specific social media text versus general domain social media text. Fig 12 presents a comparison of the evaluation metrics for the social media texts analysed.

TABLE VII. COMPARISON OF CONFUSION MATRIX VALUES BETWEEN DOMAIN-SPECIFIC AND GENERAL DOMAIN SOCIAL MEDIA TEXT CORPUS

Performance Evaluation	Domain-Specific Social Media Text Corpus	General Domain Social Media Text Corpus [64]
Corpus size	800 posts	
Positive sentiment posts	400 posts	
Negative sentiment posts	400 posts	
True Positive (TP)	274 posts	158 posts
False Positive (FP)	126 posts	242 posts
True Negative (TN)	305 posts	306 posts
False Negative (FN)	95 posts	94 posts

The comparison of M-COVIDLex performance evaluation results between the domain-specific social media text corpus dataset and the general domain social media text corpus dataset [64] in Fig 12 allows for several conclusions to be drawn.

- M-COVIDLex demonstrated superior error rates and accuracy on the domain-specific social media text corpus compared to the general domain social media text corpus. The observed result aligns with expectations, as M-COVIDLex was developed utilising lexicons that contain sentiment values within a domain-specific social media text corpus.
- The quantity of posts exhibiting positive sentiment in both datasets is identical, totalling 400 posts. Nevertheless, the sensitivity outcomes of M-COVIDLex on the domain-specific social media text corpus dataset surpass those of the general domain social media text corpus dataset. M-COVIDLex accurately predicted 274 out of 400 posts with positive sentiment in the domain-

specific social media text corpus, compared to 158 in the general domain corpus. Additionally, the classification error for M-COVIDLex in the domain-specific dataset is marginally lower than that in the general dataset. The sensitivity results indicate that M-COVIDLex effectively identified true positive posts and significantly minimised false negative posts within the domain-specific social media text corpus dataset.

- The quantity of posts exhibiting negative sentiment in both datasets is identical, totalling 400 posts. Nevertheless, the specificity outcomes of M-COVIDLex are superior in the domain-specific social media text corpus compared to the general domain social media text corpus. Although the number of negative posts indicating negative sentiment in the domain-specific social media text corpus dataset is slightly higher than in the general domain dataset, the number of negative posts misclassified as positive in the domain-specific dataset is significantly lower than in the general dataset. The findings demonstrate that M-COVIDLex effectively identifies true negative posts and minimises false positive posts within the domain-specific social media text corpus dataset.
- The precision results of M-COVIDLex are superior on the domain-specific social media text corpus dataset compared to the general domain social media text corpus dataset, exhibiting a difference of 29 percent. The findings indicate that the sentiment analysis model demonstrates improved accuracy in predicting true positive sentiment posts within the domain-specific social media text corpus dataset, thereby minimising the classification error associated with false positive posts. This result was anticipated, as the sentiment analysis is dependent on the lexicon list in M-COVIDLex.
- The F1-score results of M-COVIDLex are superior on the domain-specific social media text corpus dataset compared to the general domain social media text corpus dataset. The results demonstrate that M-COVIDLex effectively balances the analysis of sentiment within the domain-specific social media text corpus dataset.

The sentiment analysis results derived from the general domain social media text corpus dataset are more significant than those from the domain-specific social media text corpus dataset. This result demonstrates that M-COVIDLex, developed from a domain-specific social media text corpus, is exclusively appropriate for sentiment analysis within the same domain corpus. The application of this method on a general domain-specific social media text corpus is not advisable, as the resulting analysis yields significantly lower outcomes and fails to offer any valuable insights. Despite M-COVIDLex demonstrating superior performance on a domain-specific social media text corpus, its application to analyse sentiments in other specific domains, such as banking, entertainment, and food, yields a low probability of accurate sentiment analysis results for those domains. The primary purpose of constructing M-COVIDLex is to address the public health emergency related to COVID-19 in Malaysia. Given that most domains possess distinct sub-languages, the implementation of M-COVIDLex on other public

health emergency domain-specific corpora, such as Influenza, is anticipated to yield superior sentiment analysis performance compared to general domain corpora. The lexicon in M-COVIDLex includes general terms related to public health emergencies, including vaccines, protection, monitoring, and prevention. The enumeration of these general terms demonstrates that M-COVIDLex's contribution extends beyond COVID-19 to encompass other public health emergencies.

V. DISCUSSION

The experiments conducted in the previous section highlight the significance of analysing sentiment within a domain-specific social media text corpus dataset, utilizing a sentiment lexicon derived from the same corpus. The performance evaluation of M-COVIDLex on the social media text corpus dataset indicates that, despite the inclusion of 10,511 sentiment lexicons, the accuracy results remained below 80 percent. The limitations on the expansion of Malay synonyms may stem from the selection of only level one synonym words as seed words. Additionally, given that M-COVIDLex is derived from a domain-specific social media text corpus, it is logical that the accuracy results of this dataset surpass those of a general domain social media text corpus dataset. This analysis confirms the assertion from [55] that sentiment lexicons developed from domain-specific corpora are capable of providing high classification accuracy and thorough insights exclusively for that domain. The efficiency of the proposed method is significantly affected by the quality of the developed lexical dictionaries for all seven Malay POS tags [8]. The process necessitates the engagement of human resources to manually annotate the data [94], a task that is both time-consuming and costly, as indicated by multiple studies [12,29,63,99]. This proposed method may establish a baseline for future research on sentiment analysis of multilingual, code-mixed, or code-switching social media texts. Future initiatives in safety sectors during public health emergencies require the creation of an application that can analyse code-mixed sentiment on social media. A tool of this nature would facilitate prompt notifications to government entities and pertinent organisations concerning individuals who breach movement control orders, rather than relying exclusively on physical enforcement strategies such as roadblocks. The performance evaluation results of the proposed method will assist industrial researchers and relevant agencies in comprehending the Malaysian sentiment regarding government-structured relief aids during the health crisis. The performance result can be enhanced by (i) utilising a larger corpus, ideally the entire dataset of 16,600 X posts, rather than a subset, and (ii) broadening the lexical dictionaries to include a greater variety of words, including antonyms and third-level synonyms.

VI. CONCLUSION

This paper outlines a method for constructing a domain-specific mixed code sentiment lexicon, referred to as M-COVIDLex, through the integration of corpus-based and dictionary-based techniques, utilising seven Malay POS tags: KA, KK, KAD, KN, FOR-NEG, FOR-POS, and NEG. This mixed code sentiment lexicon addresses the absence of a sentiment lexicon tailored for the public health emergency context, specifically regarding COVID-19 in Malaysia. The M-COVIDLex construction method consists of five fundamental

phases: (i) Acquiring the sentiment of Malaysians from social media platform X regarding the impact of government efforts in addressing the COVID-19 crisis on their daily lives; (ii) Processing the acquired data with an enhanced Malay Normaliser and an improved set of 46 Malay POS tags; (iii) Constructing a mixed code sentiment lexicon through seed word selection, annotation, and synonym expansion; (iv) Analysing the sentiments of the acquired data using grammatical rules of four Malay POS tags: KNF, KP, KB, and KH, along with word frequency calculations; and (v) Classifying the sentiments using a lexicon-based classification technique. The evaluation of sentiment classification is conducted through a confusion matrix and six metrics: error rate, accuracy, sensitivity, specificity, precision, and F1-score. The performance evaluation of the proposed M-COVIDLex on the domain-specific social media text corpus dataset exceeds its performance on the general domain social media text corpus dataset.

ACKNOWLEDGMENT

The first author has rendered M-COVIDLex available for public use and future research endeavours. The list is available for download at the following link: <https://doi.org/10.6084/m9.figshare.26826250.v1>.

Optimized Hybrid Deep Learning for Enhanced Spam Review Detection in E-Commerce Platforms

Abdulrahman Alghaligah, Ahmed Alotaibi, Qaisar Abbas, and Sarah Alhumoud*

College of Computer and Information Sciences, Imam Mohammad Ibn Saud Islamic University (IMSIU),
Riyadh 11432, Saudi Arabia

Abstract—Spam reviews represent a real danger to e-commerce platforms, steering consumers wrong and trashing the reputations of products. Conventional Machine learning (ML) methods are not capable of handling the complexity and scale of modern data. This study proposes the novel use of hybrid deep learning (DL) models for spam review detection and experiments with both CNN-LSTM and CNN-GRU architectures on the Amazon Product Review Dataset comprising 26.7 million reviews. One important finding is that 200k words vocabulary, with very little preprocessing improves the models a lot. Compared with other models, the CNN-LSTM model achieves the best performance with an accuracy of 92%, precision of 92.22%, recall of 91.73% and F1-score of 91.98%. This outcome emphasizes the effectiveness of using convolutional layers to extract local patterns and LSTM layers to capture long-term dependencies. The results also address how high constraints and hyperparameter search, as well as general-purpose represents such as BERT. Such advancements will help in creating more reliable and reliable spam detection systems to maintain consumer trust on e-commerce platforms.

Keywords—Spam review detection; CNN-LSTM; CNN-RNN; CNN-GRU; big data; deep learning; amazon product review dataset

I. INTRODUCTION

E-commerce platforms are becoming the primary marketplaces for almost every good, replacing traditional stores in many fields. Both the seller and the customer widely accept them because they reduce costs for the seller and allow the customer to access the goods faster. Platforms like Amazon, Alibaba, and Noon dominate the global retail landscape. However, consumers face a difficult challenge when shopping online. They are unable to assess products before purchase. They tend to check online reviews and base their buying decision on them Najada and Zhu [1]. This has given rise to the issue of deceptive content, known as spam reviews. It aims to misguide consumers for specific gains. According to a report from the Department of Business & Trade from the UK government, “At least 10% of all product reviews on third-party e-commerce platforms are likely to be fake”[2]. This underlined the importance of checking the trustworthiness of online reviews. Since online reviews are important in consumers' buying decisions, spam review detection is a priority. When traditional spam detection techniques began, the focus was on areas like email. Nowadays, the focus has shifted to review-based spam detection Li et al. [3]. Spam detection can be categorized into two techniques: content-based approach and user-behavior-based approach. Content-based approach analyzes the text content only and extracts semantic relations

between words. On the other hand, the user-behavior approach focuses on the patterns of reviewer activities Li et al. [4].

Detecting spam reviews has several challenges. Spam reviews may look like genuine ones in content, making it difficult to distinguish spam from non-spam reviews. Also, spammers are always improving their techniques; they tend to use auto-generated tools to evade detection Bhuvaneshwari et al. [5]. ML started a revolution to protect consumers from scams. Traditional ML classifiers, such as Naive Bayes (NB), Support Vector Machine (SVM), and Decision Tree (DT), have good results in detecting spam reviews Rizali et al. [6]. Additionally, with the increasing complexity of the reviews, ML classifiers were not enough to handle this matter. Hence, DL comes to replace ML by showing a better performance in detecting complex patterns. However, current studies have not used DL on large datasets such as the Amazon Product Reviews dataset Hussain et al. [7] which contains 26.7 million labeled reviews. This opens a research gap to leverage hybrid deep learning models' capabilities to process large datasets, achieving superior performance. This study aims to enhance the ability to detect spam reviews by using large datasets leveraging the latest DL technologies. CNN-LSTM, CNN-RNN, and CNN-GRU were applied to the Amazon Products Reviews dataset Hussain et al. [7], which offers a rich and diverse set of labeled data. To optimize the detection process, various text preprocessing techniques are evaluated, including tokenization, lowercasing, lemmatization, stop word removal, punctuation removal, and embedding. The proposed framework provides an efficient, and accurate spam reviews detection, providing valuable insights into the impact of preprocessing techniques on detection outcomes. To verify the effectiveness of the proposed classifiers and preprocessing steps, accuracy, precision, recall, and F1Score were applied. The contributions of the paper are as follows:

1) A novel and accurate spam review detection is presented in this paper in which the accuracy is 92% through CNN-LSTM model which is quite better than results acquired from traditional ML methods leading to new detection accuracy benchmark.

2) Using the Amazon Product Review Dataset (26.7 million reviews) for demonstration, the research provides evidence for how hybrid models can be utilized to efficiently process vast-scale, diverse data, which detects an essential scalability barrier.

3) In the same work, the authors state that less preprocessing obtains better performance, since it retains

important information from the text, and that the common tendency to make more preprocessing does not favor the use of the model; these findings can provide important guidelines for the design of future models.

4) This study found that a large vocabulary size (200,000 max words) allows the model to better represent complex relationships between words, showing that careful vocabulary selection can improve spam detection effectiveness significantly.

5) This paper suggested a scalable and efficient spam detecting framework to better maintain consumer trust in the marketplace by excluding fake reviews and pretending user occurrence.

The rest of the paper is structured as follows: Section I and Section II discusses the background of spam detection and previous works in the field. Section III presents the proposed methodology. Section IV shows the result of the proposed work and discusses the findings in Section V. Finally, Section VI presents a summary of the study and future work.

II. LITERATURE REVIEW

Spam refers to deceptive content intentionally made to mislead or manipulate users for a specific gain, usually a commercial gain Jakupov et al. [8]. In online reviews, spam is a false or misleading review designed to promote or demote a particular product, store, book, or goods and services. It can influence customers purchasing decisions and damage the reputation of products on e-commerce platforms like Amazon Fei et al. [9]. Most users refer to reviews to decide whether they buy a product, as they need physical access to assess it. Studies indicate that nearly 30% of online reviews are spam Farooq [10], highlighting the issue of reviews on famous platforms such as Amazon. Spam detection in online reviews has become crucial as most e-commerce platforms rely heavily on user input to guide consumer choices. In the past decade, spam detection focused more on traditional applications like spam Short Message Service (SMS). However, in the era of online stores, especially in advanced countries like China, attention has moved towards detecting deceptive reviews Li et al. [3]. Spam detection in online reviews can be classified into content-based or user behavior-based techniques. Content-based analyzes textual features of reviews, linguistic patterns, and sentiment analysis. User behavior-based focuses on patterns like reviewing users' behavior, metadata, and social connections between reviewers Li et al. [3], Ennaouri and Zellou [11]. Usually, these techniques are combined to improve detection accuracy. Identifying spam reviews is a sophisticated task due to several challenges. One of the primary challenges is distinguishing between genuine and fake reviews. While counterfeit reviews may imitate the style and content of genuine ones, specific patterns such as overuse of promotional language or usually high volumes of reviews in short periods can provide clues Li et al. [3]. Language variability also helps in detection, as spam reviews may appear in multiple languages or use specific accents Ennaouri and Zellou [11]. Moreover, spammers continuously improve their techniques, making relying on static detection methods difficult. They may use techniques such as duplicating legitimate reviews or using an

automated system to generate spam, which can evade traditional methods Bhuvaneshwari et al. [5]. The large number of online reviews presents a scalability challenge as manual moderation becomes unfeasible for platforms like Amazon, which hosts millions of products with billions of reviews. ML and DL are powerful technologies for overcoming the challenges in spam detection. Traditional ML models, such as NB and SVM, have been used widely to classify reviews based on a content-based technique Saumya and Singh [12]. However, these models often struggle with the complexity of spam patterns in large datasets Kalaivani et al. [13], and this will be discussed in the next subsection based on related work. DL models like Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and their hybrid variants perform superiorly in detecting spam reviews Ghourabi et al. [14], Deshai and Rao [15], Shahariar et al. [16]. These models can learn complex patterns in text and capture long relations between words, making them more effective at detecting spam. Additionally, attention mechanisms, such as the one used in self-attention-based models, have successfully identified key features of spam reviews by focusing on specific text parts Bhuvaneshwari et al. [5]. The combination of DL and traditional ML technologies offers promising solutions to detect spam in online reviews. The following section will examine existing research on spam reviews using both ML and DL technologies.

A. Spam Review Detection

Many studies have discussed spam detection methods. The following subsections will discuss these studies in detail, starting with traditional ML. After that, DL studies showed promising improvement in solving this problem. "Table I" summarizes all the ten related works, from both traditional ML and DL subsections.

1) *Traditional machine learning approach for spam review detection:* Traditional ML approaches were used to solve the problem of detecting Spam reviews using classifiers such as NB, SVM, and Random Forest (RF) Ahsan et al. [17], Tripathy et al. [18]. These classifiers are usually used alongside feature selection techniques to detect fake reviews. In Kalaivani et al. [13], two traditional ML models were used to detect spam reviews. The first algorithm was SVM, while the second was NB. The dataset that was used is from Kaggle, with 20k reviews. By preprocessing the data before training the above-mentioned models, SVM achieved 76%, while NB achieved 84%. In Etaiwi and Naymat [19], the author tried a bunch of traditional ML algorithms, which are Gradient Boosted Trees (GBT), NB, RF, DT, and SVM. All these algorithms were used to train models on the Hotel Reviews dataset of 1600 reviews named Deceptive Opinion Spam Corpus (DOSC). Among all these models, SVM achieved the best accuracy with 85.5%. In Saeed et al. [20], many spam review detection approaches were evaluated. The paper proposed four detection approaches: a rule-based classifier, machine learning classifiers, a majority voting classifier, and a stacking ensemble classifier. All these approaches were trained and tested on two datasets, DOSC and Hotel Arabic Reviews Dataset (HADR). The stacking ensemble approach clearly outperformed the other approaches with

95.25% accuracy on the DOSC dataset and 99.98% on the HARD dataset by combining a rule-based classifier with a k-means classifier.

In Ibrahim et al. [21] the authors investigated the use of ensemble learning techniques to enhance spam review detection accuracy. They explored three classifiers: NB, SVM, and Logistic Regression (LR). They combined these algorithms to form an ensemble classifier. They used the Amazon dataset and got the best accuracy of 88.09%. Etaiwi and Awajan [22] explored how different feature selection methods impact the performance of spam review detection. They applied four ML algorithms: NB, SVM, DT, and RF. They used the DOSC dataset and got the best accuracy results of 87.31% with NB.

2) *Deep learning approaches for spam review detection:* Deep learning techniques have succeeded in enhancing the accuracy of spam detection. They are more effective than traditional ML approaches, which rely more on manually engineered features. DL models can automatically learn from

complex patterns, which makes them suitable for distinguishing between truthful and deceptive reviews. CNN, RNN, and hybrid approaches like CNN-RNN are widely used in the field Zhao et al. [23]. They have the potential to discover long relations between words. This section presents studies that have proposed DL techniques to detect spam reviews.

Shahariar et al. [16] presented a multi-layer perceptron (MLP) framework to detect spam reviews in the YELP and DOSC datasets. They compared the DL model with traditional ML, like NB and SVM. Their findings showed that Long Short-Term Memory (LSTM) outperformed all other algorithms with 96.75% accuracy. Deshai and Rao [15] Proposed two hybrid models integrating CNN and LSTM for fake reviews. Also, they presented LSTM-RNN for fake ratings detection. Their results showed that CNN-LSTM and LSTM-RNN methods are the most efficient, with 93.09% accuracy, using a subset of the Amazon Product Reviews dataset.

TABLE I. STATE-OF-THE-ART ALGORITHMS FOR SPAM REVIEW DETECTION

Paper	Year	Algorithm	Dataset	Best Accuracy
[13]	2023	NB, SVM	Review dataset from kaggle	84% NB
[19]	2017	GBT, NB, RF, DT, SVM	DOSC	85.5% SVM
[20]	2019	rule-based classifier, machine learning classifiers, majority voting classifier, stacking ensemble classifier	DOSC, HARD	99.98% rule-based + k-means
[16]	2019	MLP, CNN, LSTM	YELP., DOSC	96.75% LSTM
[15]	2023	CNN-LSTM, LSTM-RNN hybrid	Amazon Dataset	93.09% LSTM-RNN
[14]	2020	CNN-LSTM hybrid	UCI dataset	98.37% CNN-LSTM
[25]	2023	NB, KNN, SVM, CNN, LSTM	YELP DOSC	94.88% LSTM
[21]	2017	NB, SVM, LR	Amazon Dataset	88.09% ensemble
[26]	2020	LSTM Autoencoder	YouTube	-
[22]	2017	NB, SVM, DT, RF	DOSC	87.31% NB

Ghourabi et al. [14] proposed a hybrid CNN-LSTM model for detecting mixed text messages written in Arabic and English. They designed a model to let CNN capture n-gram features while LSTM is used to retain long-term information. They achieved an accuracy of 98.37% using a dataset from UCI repository Almeida et al. [24]. Singh et al. [25] Explored the effectiveness of DL models, especially for CNN and LSTM, the authors benchmarked ML models with DL. They emphasized the superior performance of deep learning models over traditional approaches for handling textual data. The datasets used in their study are YELP and DOSC. They got the best results using LSTM model with an accuracy of 94.88%. Saumya and Singh [26] Presented an unsupervised model for detecting spam reviews without requiring labeled data. The authors used a combination of LSTM networks and autoencoders to learn patterns of true reviews, allowing the models to distinguish reviews anomalies. They used a YouTube dataset, which includes reviews of popular videos. The authors did not use accuracy metrics in their study. The studies showed that DL approaches perform superiorly in spam review

detection, especially hybrid ones. In the next section, the gaps in existing studies will be discussed.

B. Gaps in Existing Research

Spam review detection is a hot topic that is widely covered. However, several advancements in the field, particularly in the DL field, introduce gaps and challenges that open the door to resolving this problem by applying new technologies. This section aims to discuss these challenges. These gaps need to be addressed and apply new technologies to resolve them. One primary challenge is the need for a labeled dataset Hussain et al. [27].

Hussain et al. [7] addressed this issue and solved it with Spam Review Detection using Behavioral Method (SRD-BM). However, new ML and DL technologies are needed to help in labeling the dataset and help researchers work on it in the future. Another significant challenge is the use of hybrid DL architecture on large datasets. Ghourabi et al. [14], Deshai and Rao [15], Shahariar et al. [16], Wayal and Bhandari [28] applied a hybrid method in small datasets. Applying this kind of architecture on large datasets requires vast computational

power. Fortunately, hybrid DL architecture has been applied to the Amazon Product Review Dataset, "Table II" shows the detailed distribution of the dataset. This study will discuss the proposed work in detail in the methodology section.

III. METHODOLOGY

This study demonstrated the application of three hybrid DL models for spam review detection. Each model was selected based on its ability to recognize complex patterns in large datasets and understand long-range word relations. Also, the effects of applying extensive text preprocessing will be discussed. In the following subsections, start by introducing the development environment. Then, the dataset and data preprocessing steps that convert human sentences to a readable format for the machine will be presented. After that, the feature selection process, the three models' architecture, and how each model is trained on the dataset will be described respectively.

C. Development Environment

In this study, all the preprocessing, training, and evaluation processes are conducted using Google Colab Pro. It is a solution on the cloud provided by Google to access high computational resources, utilizing the NVIDIA A100 graphics processing unit (GPU), which helped accelerate the training process across the hybrid DL models. Colab provides a high Random-Access Memory (RAM) up to 83GB and Virtual Random-Access Memory (VRAM) 40GB. It will allow the ability to load a large volume of data and preprocess it before feeding it into the neural network. Additionally, Python is the programming language used to implement the entire pipeline. Many libraries have been utilized to support this process, including Pandas and NumPy for data manipulation and preprocessing. Natural Language Toolkit (NLTK) is used to prepare text data. Scikit-learn for splitting train and test data, as well as for evaluation metrics. TensorFlow is used to train neural networks. Finally, Matplotlib and Seaborn were used to visualize the performance analysis.

D. Dataset

The dataset used for this study was acquired from Amazon Product Reviews Hussain et al. [7], which contains 26.7 million reviews written by 15.4 million reviewers on 3.1 million products. The dataset has six categories, shown in "Table II". The reviews cover many product categories, such as electronics, home and kitchen, and more, to ensure that the spam detection models are exposed to various review

patterns. The dataset's original source was unlabeled. However, Hussain et al. [7] did excellent work by labeling it using SRD-BM technique. The SRD-BM utilizes rich of behavioral features in the dataset to identify the spam and non-spam reviews, then labeling the data. In this study, the labeled dataset by the SRD-BM method was used, then preprocessing steps explained in the next section are applied.

E. Data Preprocessing

Preprocessing is an essential step to minimize the noise of the data and transform the raw text into a format that can be fed into the neural networks. However, applying the extensive preprocessing steps may upgrade or degrade the model performance HaCohen-Kerner et al. [29]. In this study, two different preprocessing steps were applied to hybrid DL models, one with extensive preprocessing steps that change the original text, another with a few steps that retain the original text. "Fig. 1." shows the preprocessing steps used in this study. For the extensive preprocessing steps, the text is converted to lowercase to standardize the input and reduce the complexity caused by case differences. This step will convert words like "Product" to "product", so they are treated as the same token. Additionally, all the punctuation marks are removed to avoid unnecessary symbols, which may add noise to the data. Another common concept in Natural Language Processing(NLP) was applied, which is Tokenization that converts text into numerical sequences to retain the frequent words in the dataset T. Limisiewicz et al. [30]. This will help reduce the noise in data and improve model efficiency. After that, Stop Words such as "is", "the", and "a" were removed. Also, it is essential to reduce every word to its root. Words like "playing" and "Played" will be reduced to "play" using a technique called Lemmatization. Also, to uniform the sequence length, Padding was used with configuration of 200 tokens in each sequence. Finally, an Embedding layer was added. It simply converts the integer sequences into dense vectors. This will allow the DL models to learn the relationship between words during the training Tegene et al. [31]. It is important to note that all these steps were applied to all the hybrid DL techniques to avoid biases in the benchmark. For the fewer preprocessing steps, only three steps were applied which are Tokenization, Padding, and Embedding. Also, for the max words parameter. Two configurations were applied, one with 10,000 and the other with 200,000 max words, this choice is due to the majority of words inside the dataset appearing very infrequently.

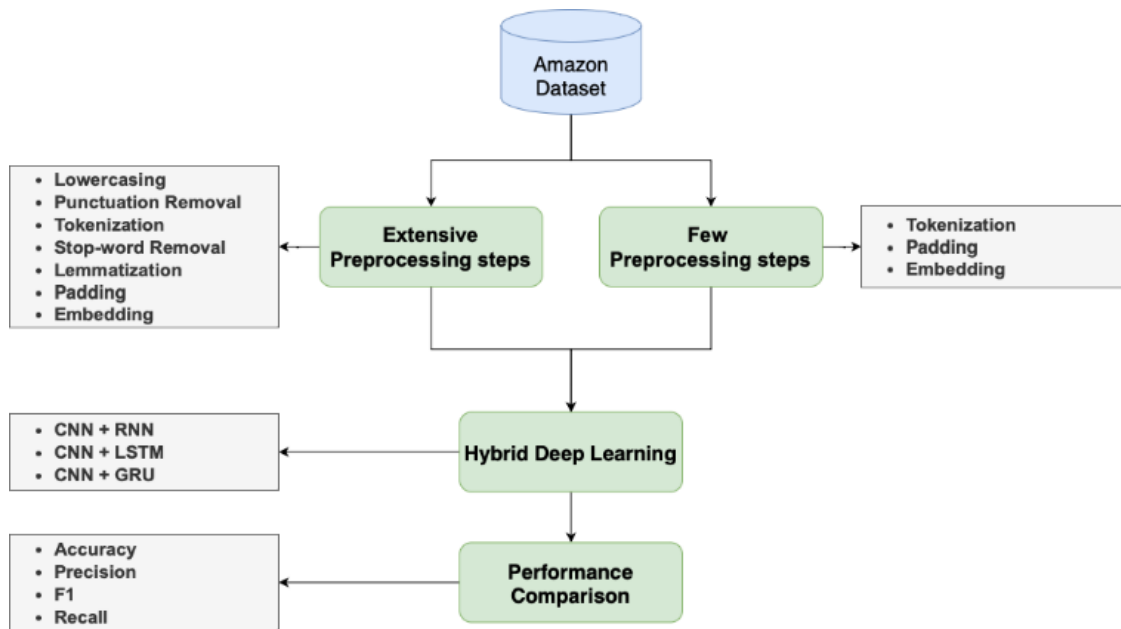

Fig. 1. Proposed system architecture.

F. Spam Review Detection

The methodology for detecting spam reviews involves designing and evaluating hybrid deep learning models. These models aim to extract both local features and long-term dependencies from textual data, leveraging the strengths of Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN), specifically Long Short-Term Memory (LSTM) and Gated Recurrent Units (GRU).

Since many people rely on reviews before purchasing products, detecting spam reviews can improve customer experience by protecting them from being scammed. Hence, this study intends to compare multiple hybrid DL approaches to reach the best classifier in this matter which are: CNN-LSTM, CNN-RNN, and CNN-GRU. Combining CNN with LSTM, RNN, and Gated Recurrent Unit (GRU) will give the ability to extract features by learning the local patterns and n-grams using the CNN layer Zhou et al. [32]. For CNN-based hybrids, the CNN component identifies key local features. Combining CNN-LSTM will make the classifier capture long-term patterns and model the temporal dependencies using the LSTM component Greff et al. [33]. Similarly, GRU can also be combined with CNN (CNN-GRU) to use its efficient gating mechanisms that will help avoid vanishing gradient problems Cho et al. [34]. Another component that can be combined with CNN is RNN (CNN-RNN), which captures context and temporal relationships in the text to help detect subtle patterns. “Table III” presents hyperparameters configuration of the implemented models.

The dataset used in this study is the Amazon Product Review Dataset, containing 26.7 million reviews across six categories. Each review x_i is labeled as spam ($y_i = 1$) or non-spam ($y_i = 0$). The raw text reviews are preprocessed to convert them into numerical representations. Two preprocessing strategies were compared: minimal and extensive preprocessing. Minimal preprocessing retained most

of the text structure, while extensive preprocessing involved steps like lowercasing, stop word removal, punctuation removal, and lemmatization.

TABLE II. AMAZON PRODUCT REVIEW DATASET

Category	Total Reviews	Total Reviewers	Total Products
Cell Phones and Accessories	3,446,396	2,260,636	319,652
Clothing, Shoes, and Jewellery	5,748,260	3,116,944	1,135,948
Electronics	7,820,765	4,200,520	475,910
Home and Kitchen	4,252,723	2,511,106	410,221
Sports and Outdoor	3,267,538	1,989,985	478,846
Toys and Games	2,251,775	1,342,419	327,653
Total	26,787,457	15,421,610	3,148,230

The input dataset can be represented as:

$$D = \{(x_i, y_i) | x_i \in R^d, y_i \in \{0,1\}, i = 1,2,\dots, n\} \quad (1)$$

Where d is the sequence length, and n is the total number of reviews. Each review x_i is tokenized and padded to ensure uniform length. The tokens are then passed through an embedding layer, which maps them into dense vector representations:

$$e_i = embedding(x_i), e_i \in R^{d \times n} \quad (2)$$

Where, the parameter m is the embedding dimension, and $d=200$ is the maximum sequence length.

The CNN layer is applied to extract local patterns and n-grams from the embedding vectors. The convolution operation is defined as:

$$c_{i,j} = ReLU(W_{conv} \times e_{i,j} + b_{conv}) \quad (3)$$

Where, the parameter W_{conv} and b_{conv} are the convolutional filter weights and biases. In addition, the operator (\times) represents the convolution operation. ReLU introduces non-linearity. The result, ci is a feature map containing extracted local patterns. To capture long-term dependencies in the text, the feature map ci is fed into an LSTM or GRU layer.

$$h_t = LSTM(C_t, h_{t-1}, C_{t-1}) \quad (4)$$

And for GRU

$$h_t = GRU(C_t, h_{t-1}) \quad (5)$$

Here, the ht parameter represents the hidden state at time t , which encodes sequential dependencies. The final hidden state h from the recurrent layer is passed through a fully connected layer to predict the probability of a review being spam:

$$p(y_i = 1 | x_i) = \sigma(W_{fc} \cdot h_i + b_{fc}) \quad (6)$$

Where, the parameter σ is the sigmoid activation function. Also, the parameter W_{fc} and b_{fc} are the weights and biases of the fully connected layer. The binary cross-entropy loss function is used to optimize the model:

$$Loss = -\frac{1}{n} \sum_{i=1}^n [y_i \log(p(y_i = 1 | x_i)) + (1 - y_i) \log p(1 - y_i = 1 | x_i)] \quad (7)$$

G. Evaluation Metrics

In our study, four evaluation metrics have been used to evaluate the models. These evaluation metrics depend on, True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN), defined as follows: TP is the number of correctly identified spam. TN is the number of reviews correctly identified as non-spam. FP is the number of non-spam reviews incorrectly identified as spam. FN is the number of spam reviews incorrectly identified as non-spam. All proposed models were evaluated using several key metrics, including Accuracy, Precision, Recall, and F1 score. Accuracy provides an overall measure of the model's performance in both positive and negative Sokolova and Lapalme [35].

$$Accuracy(ACC) = (TP + TN)/(TP + TN + FN + FP) \quad (8)$$

Precision is the evaluated proportion of correctly predicted as positive and shows model capability to avoid FP J. Davis and Goadrich [36], T. Saito and Rehmsmeier [37].

$$Precision(PR) = TP/(TP + FP) \quad (9)$$

Recall or, in other words, sensitivity, is the ratio of correctly predicted positives to all the actual positives J. Davis and Goadrich [36], T. Saito and Rehmsmeier [37].

$$Recall(RE) = TP/(TP + FN) \quad (10)$$

F1 Score is the harmonic mean of precision and Recall; it balances the two and is widely used in scenarios where precision and Recall are important.

$$F1 - score = 2 \times (PR \times RE)/(PR + RE) \quad (11)$$

These metrics are crucial to understanding the model's behavior across different situations. Therefore, they will all be

used in the next section to benchmark different Hybrid DL models.

IV. RESULTS

In this section, results of the DL models with and without the text preprocessing step are discussed. The comparison is based on the four metrics mentioned earlier, accuracy, precision, recall and F1 score. Then, the section will present a discussion of the result.

A. Results Analysis

The performance of hybrid DL models will be evaluated with and without some text preprocessing steps which are lowercasing, Stop Words removal, punctuation removal, and lemmatization. Also, two vocabulary sizes 10,000 and 200,000 max words will be used. "Table IV" shows all the results. Also, "Fig. 2." shows the models comparisons.

TABLE III. MODELS CONFIGURATIONS

Hyperparameters	CNN-LSTM	CNN-RNN	CNN-GRU
Batch size	128	128	128
Dropout	0.5 in each layer	0.5 in each layer	0.5 in each layer
Nodes	128 in LSTM layer	128 in RNN layer	128 in GRU layer
Training split	0.6	0.6	0.6
Testing split	0.2	0.2	0.2
Validation split	0.2	0.2	0.2
Epoch	10	10	10
Optimizer	Adam	Adam	Adam
Loss function	Binary cross-entropy	Binary cross-entropy	Binary cross-entropy
Vector size	128	128	128

Regarding the models trained with all the preprocessing steps, the CNN-LSTM achieved the highest performance with an accuracy of 88.88%, a precision of 88.39%, a recall of 89.52%, and an F1Score of 88.95%. The CNN-GRU model has a nearby result with an accuracy of 89%, a precision of 88.39%, a recall of 89.12%, and an F1Score of 88.75%. The CNN-RNN has the lowest performance with an accuracy of 86.64%, a precision of 87.07%, a recall of 86.05%, and an F1Score of 86.56%. All these results show that using a max word of 200,000 gives a better result than 10,000. When the models were trained by eliminating some preprocessing steps which are lowercasing, Stop Words removal, punctuation removal, and lemmatization, the CNN-LSTM also gave the best performance with an accuracy of 92%, a precision of 92.22%, a recall of 91.73%, and an F1Score of 91.98%. The CNN-GRU similarly performed well, accuracy of 92.08%, a precision of 92.22%, a recall of 91.19%, and an F1-score of 92.07%. While the CNN-RNN has the worst performance with an accuracy of 87.93%, a precision of 88.43%, a recall of 87.28%, and an F1Score of 87.85%.

The results showed that CNN-LSTM and CNN-GRU architectures give better performance without applying

extensive preprocessing steps. Among all the models, CNN-LSTM with 200,000 max words has the best overall performance compared to all the other architectures. This shows that the combination of CNN and LSTM layers with a large vocabulary is very effective in detecting spam reviews, while keeping the original text. This explains the ability of CNN-LSTM to capture both local patterns and long-term dependencies, which gives importance to understanding relationships across multiple words in a text. This result is aligned with recent studies on text classification using CNN-LSTM architecture Bhuvaneshwari et al. [5] Sagnika et al. [38].

Etaiwi and Naymat [19] showed that using many preprocessing steps affects the overall performance of spam review classification when using ML models. As in this study, the result of applying many preprocessing steps on hybrid DL models will affect the performance. When comparing the models based on the vocabulary size, 200,000 max words consistently performed better. This indicates giving the hybrid DL models a larger vocabulary helps capture more complicated relationships between words, which leads to better performance. Although the study showed a promising result, some limitations were faced. One major constraint was the use of Google Colab Pro. It is a paid service that allows you to use high computational resources, such as A100 GPUs and a high amount of RAM, with a certain number of compute units. This restricted the ability to empiric many models and try different hyperparameters. For that reason, it is recommended that future studies explore additional hyperparameter tuning to further improve model performance, as well as experimenting with pre-trained models like BERT to improve the ability to capture both local and contextual word representation. It can also help in transferring knowledge from one domain to another.

Fig. 2. Models comparisons.

TABLE IV. MODELS RESULTS

Model	Preprocessing	Max Words	Accuracy	Precision	F1	Recall
CNN+LSTM	Few	10,000	92.13%	92.77%	92.07%	91.38%
CNN+RNN	Few	10,000	88.44%	87.45%	88.59%	89.76%
CNN+GRU	Few	10,000	91.75%	92.56%	91.67%	90.80%
CNN+GRU	Few	200,000	92.08%	92.22%	92.07%	91.19%
CNN+LSTM	Few	200,000	92%	92.22%	91.98%	91.73%
CNN+RNN	Few	200,000	87.93%	88.43%	87.85%	87.28%
CNN+GRU	Extensive	10,000	88.67%	89.63%	88.53%	87.46%
CNN+LSTM	Extensive	10,000	88.72%	88.84%	88.76%	89.07%
CNN+RNN	Extensive	10,000	86.36%	86.73%	86.29%	85.85%
CNN+GRU	Extensive	200,000	89%	88.39%	88.75%	89.12%
CNN+LSTM	Extensive	200,000	88.88%	88.39%	88.95%	89.52%
CNN+RNN	Extensive	200,000	86.64%	87.07%	86.56%	86.05%

V. DISCUSSIONS

The experimental results revealed that hybrid deep learning models are effective in spam review detection, specifically for CNN-LSTM and CNN-GRU architectures. A simple CNN-LSTM model with very little preprocessing, and vocabulary of 200,000 outperformed others on a consistent basis. This shows that the model is capable of capturing rival patterns locally and the long-term dependence as observed by Bhuvaneshwari et al. Sequential models like LSTM: LSTMs have proven to be the backbone of text classification in various tasks Bhuvaneshwari et al. [5]. CNN-GRU model also provided competitive

performance, which further confirms that the combined structures are proven efficient in these applications.

Our hybrid deep learning models have performed significantly higher than the traditional machine learning approaches (Support Vector Machines (SVM) and Naive Bayes (NB)). Studies, for example Etaiwi and Naymat [19], highlighted SVM performance with smaller datasets like DOSC, achieving high accuracies (even up to 85.5%). On the much larger dataset of the Amazon Product Review, our CNN-LSTM model reached 92% accuracy, while ML models underperformed dramatically. This large increase demonstrates that the merits of deep learning to effectively learn complex patterns in large-scale data.

Fig. 3. Models Comparisons in terms of heatmap by different parameter sizes.

Fig. 3 represented the heatmaps for the performance of different models (CNN+LSTM, CNN+GRU, CNN+RNN) across key metrics: Accuracy, Precision, F1, and Recall. The heatmaps provide a clear comparison for the proposed hybrid system based on preprocessing type and vocabulary size, highlighting the effectiveness of minimal preprocessing and large vocabulary sizes.

Also, it is in accordance with the results of Ghourabi et al. [14] CNN text classification which has shown that CNN-LSTM hybrid could successfully learn n-gram features as well as long-term dependencies. However, they performed their study from a smaller dataset with a restricted size of vocabulary. This study used larger vocabularies than used in the previous study to train the models, and our results appear to expand on these findings, suggesting that larger vocabularies produce even better models, at least on some data sets, this further boost in size compares to a level of detail in relationships examinable within the text.

Fig. 4 bar chart highlights that CNN+LSTM with minimal preprocessing and a large vocabulary size (200k) achieves the highest accuracy, followed closely by CNN+GRU under similar conditions. Models with extensive preprocessing generally show lower accuracy. An interesting takeaway is the effect of preprocessing on model performance. As also mentioned by HaCohen-Kerner et al. [29] among others, aggressive preprocessing like lemmatization and stop word removal limited the models' ability to pick up any useful signals. On the other hand, less preprocessing helps the models keep the richness of the original text, which performed better. This is an important finding because it counters the widespread assumption that more preprocessing is always a good thing for model performance.

Fig. 4. A bar chart comparing the accuracy of different models and preprocessing configurations.

CNN-LSTM model has shown the best performance with less preprocessing steps and using large vocabulary size thus providing a very practical way for spam review detection. The benefit of preserving its original text is that this model can utilize its full potential to find hard to detect spam. This method is especially beneficial when the datasets are large, and context retention is essential for efficient classification. Moreover, this study shows that the proposed model is deployable efficiently under limited resources on cloud platforms such as Google Colab Pro.

Despite these optimistic results, there were several limitations to the study. However, the need for labeled datasets presents a critical issue because manual labeling is often a laborious, inconsistent process. Semi-supervised or Active Learning based techniques may also be a direction for future research to automate the labeling process as well as further explore the state-of-the-art discussed in the previous section for a better initial core for semi-supervised learning. For even better performance, pretrained models like BERT can be utilized, as they are able to learn much more complex relationships, as shown recently in the field of NLP.

Therefore, this study offers a solid foundation for hybrid deep learning models to detect spam reviews. The solution proposed not just increases detection accuracy but also provides a scalable approach with the use of dataset used in e-commerce enabling a better legitimate and deterring e-commerce platforms.

VI. CONCLUSION AND FUTURE WORK

This research has underlined the importance of combining many deep learning architectures to achieve optimal results in detecting spam reviews. It showed the capabilities of CNN and the sequential learning strength of LSTM and GRU. This contribution will help e-commerce platforms to build consumer trust by detecting spam reviews effectively. Another superior contribution of this paper is the impact of preprocessing steps on hybrid DL models' performance. Interestingly, when eliminating some of preprocessing steps the models performed better than those trained with all preprocessing steps. The combination of large datasets with hybrid DL models showed promising results in spam detection. However, the study identified a key limitation, the need for new labeled datasets for online spam reviews. As spamming techniques evolve, addressing this limitation in future work will encourage researchers to keep datasets updated for recent spam behaviors. Also, exploring recent ML techniques to automate the task of labeling the datasets is important. Methods such as semi-supervised learning or active learning could be implemented to get accurate datasets, reducing the dependence on manually labeled datasets. Furthermore, empiric hyperparameters and optimizers may further improve the performance of the models. Finally, the findings of this study indicate that the CNN-LSTM model using 200,000 max words outperformed other Hybrid DL models with an accuracy of 92%, a precision of 92.22%, a recall of 91.73%, and an F1Score of 91.98%.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Imam Mohammad Ibn Saud Islamic University for funding and supporting this work through Graduate Students Research Support Program.

Abstract—In the context of the rapid development of e-commerce and the increasing demands for logistics services, particularly in the face of challenges posed by public health emergencies, this paper explores how to integrate supply chain resources and optimize delivery processes. It provides an in-depth analysis of the characteristics of the Fourth Party Logistics Routing Optimization Problem (4PLROP) in complex environments, specifically focusing on the impacts of infection risk and delay risk, and proposes a new risk measurement tool. By constructing a mathematical model aimed at minimizing Conditional Value-at-Risk (CVaR) and improved Q-learning algorithm, the study addresses the 4PLROP while considering cost and risk constraints. This approach enhances the efficiency and service quality of the logistics industry, offers effective strategies for 4PL companies in the face of uncertainty, and provides customers with safer and more reliable logistics solutions, contributing to sustainable development.

Keywords—Logistics services; public health emergencies; logistics routing optimization; improved Q-learning algorithm; CVaR; infection risk

I. INTRODUCTION

As the limitations of Third Party Logistics (3PL) capabilities become increasingly apparent, the traditional route planning problem is transitioning into the more complex Fourth Party Logistics Routing Optimization Problem (4PLROP). 4PL, known as the integrator of supply chains, consolidates its own resources, capabilities, and technologies, as well as those of other 3PL providers, to offer comprehensive supply chain solutions to clients. The concept of 4PL has garnered widespread attention from both the industry and academia since its inception. Presently, 4PL enterprises or platforms such as UPS, Cainiao, and Ningbo Fourth Party Logistics Market have established long-term cooperative relationships with manufacturing enterprises like Haier, providing them with specialized logistics and transportation services. In the academic sphere, numerous scholars have conducted research on various aspects of 4PL, including route optimization [1], network design [2], risk management [3], combinatorial auctions [4]-[5], supply chain integration [6], and information technology application [7]. Route optimization in 4PL, as one of the core issues at the tactical layer of 4PL operation and management, has been receiving considerable scholarly attention in recent years. It integrates 3PL and route selection decisions to enhance the efficiency of logistics transportation [8].

In the advent of public health emergencies, the logistics industry has played a pivotal role in ensuring resource supply, yet such occurrences also introduce new challenges and risks to

route planning. During the 2020 pandemic, international and Hong Kong, Macau, and Taiwan air passenger volumes plummeted by over 15%, particularly in key logistics hubs like Wuhan, where containment measures significantly impacted logistics routes. To circumvent high-risk pandemic areas, logistics enterprises were compelled to rechart transportation routes, which not only heightened the complexity of route planning but also augmented the time required. These shifts demand that logistics enterprises factor in the risks posed by pandemics during the planning process. 4PL must consider the risks brought about by pandemics and other public health emergencies, employing agile supply chain management and efficient resource allocation to mitigate the impact of these risks on the logistics network. In 4PL, such risk management is especially crucial. As the coordinator and integrator within the supply chain, 4PL is tasked with managing the demands and risks of multiple clients while ensuring service quality.

This article delves into the 4PLROP, which takes into account the risks of infection and delays, against the backdrop of the pandemic. Cities are categorized based on risk levels, and the infection risks of various cities are assessed using quantitative methods. Leveraging the extensive application of Conditional Value-at-Risk (CVaR) in the optimization domain, a mathematical model is established with the objective of minimizing CVaR, and constraints are set for delivery costs and infection risks. An improved Q-learning algorithm is employed to solve this model, aiming to identify the route that satisfies the conditions of the lowest CVaR for both infection risks and delivery costs. In this manner, 4PL can better adapt to the ever-changing market environment, ensuring the stability and efficiency of the supply chain.

The principal contributions of this article are as follows:

- In the context of public health emergencies, a novel 4PL route optimization problem that concurrently considers the risks of infection and delays has been investigated;
- The CVaR metric is employed to characterize risks, and a nonlinear programming model is established with constraints on delivery costs and infection risks, aiming to minimize the risk as the objective;
- An improved Q-learning algorithm is proposed to solve the model presented. Through this approach, 4PL can better adapt to the ever-changing market environment, ensuring the stability and efficiency of the supply chain.

The remainder of this article is structured as follows:

The remainder of this article is structured as follows: Section II provides a review of literature pertaining to 4PL route-related studies. Section III delineates the problem and elucidates the model and notation employed. Section IV applies the Q-learning algorithm to the 4PL route optimization problem, where the optimal path planning is achieved through the establishment of action-state pairs, construction of a reward function, enhancement of exploration strategies, and model training. Section V validates the efficacy of the improved Q-learning algorithm in the context of 4PL route optimization through experimental analysis, demonstrating the algorithm's high solution speed and stability across various scales of test cases, and its ability to provide customers with delivery routes that minimize risk at a specific confidence level. Section VI presents our conclusions and prospective directions for future research.

II. LITERATURE REVIEW

In the context of public health emergencies, a plethora of theoretical foundations and practical case studies has been provided by existing research to address the 4PLROP. Within this section, an exhaustive review of the pertinent literature on 4PLROP has been conducted. The existing research delineates the complexities and challenges posed by the emergence of public health crises on 4PLROP, highlighting the need for innovative approaches to mitigate the associated risks and delays.

In the field of 4PLROP, a relatively early study dates back to 1998. The concept of 4PL was initially introduced by Andersen Consulting [9]. Since then, based on this concept, a plethora of research on 4PLROP has been conducted: Huang et al. [10] conducted research on the 4PLROP with uncertain delivery time in emergencies. Huang et al. [11] proposed an improved genetic algorithm based on simple graphs and the Dijkstra algorithm to preclude the emergence of infeasible solutions in 4PLROP. Ren et al. [12] designed a genetic algorithm embedded with the Dijkstra algorithm to solve the 4PLROP problem, thereby laying the foundation for the research on 4PLROP. The existing studies can generally be categorized into two types. The first type is the 4PL route planning problem in a deterministic environment, and the second type is the 4PLROP in an uncertain environment.

In the realm of deterministic environment, an early scholar established a directed graph model to optimize the selection of routes, transportation modes, and third-party logistics providers [13]. Subsequently, a 4PL optimization model was constructed by another scholar to streamline the corresponding 4PLROP [14]. Thereafter, a 4PLROP approach based on the immune algorithm was proposed by some scholars, enhancing the algorithm's capability to address 4PLROP [15]. Building on this foundation, a mathematical model for point-to-point multi-task 4PLROP without edge repetition was established by other scholars, considering the cost and time attributes of each node and edge, and an ant colony optimization algorithm was designed to solve the path optimization problem [16]. Recently, Zhou et al. [17] addressed the 4PLROP problem considering cost discounts by minimizing operational costs, taking into account customer delivery deadlines and transportation capacity constraints. Cai et al. [15] minimized the linear

combination of transportation and time costs by considering certain customer preference factors.

In the realm of uncertainty, Huang et al. [18] proposed an uncertain programming model for the 4PLROP in emergency situations. The effectiveness of this model was verified through comparison with the stochastic programming model and numerical experiments. Huang et al. [19] transformed the uncertainty theory into a deterministic model and designed an improved genetic algorithm for solving to address the 4PLROP in an uncertain environment. Lu et al. [20] solved the uncertain delivery time control model of 4PLROP through the genetic algorithm. Lu et al. [21] dealt with the 4PLROP problem under the conditions of uncertainty in 3PL transportation time, transportation cost, node transfer time and transfer cost, and designed a solution model using the grey wolf optimization algorithm improved by the ant colony system. Lu et al. [22] considered the uncertainties in transportation time and cost caused by seasonal and human factors, constructed a multi-objective chance-constrained programming model aiming to minimize transportation time and cost, and proposed a hybrid beetle swarm optimization algorithm combined with the Dijkstra algorithm to solve the problem. Ren et al. [23] established a 4PLROP chance model with time windows and random transportation time under the constraint of total transportation cost, aiming to maximize the chance that the total transportation time meets the time windows. And the ant colony algorithm was used to solve the deterministic model. Gao et al. [24] applied the uncertain stochastic programming model to solve the 4PLROP with random demand and uncertain transportation and transshipment times, aiming to minimize the total transportation cost under various constraints. Recently, Ren et al. [25] aimed to examine the impact of decision-makers' risk preferences on the 4PLROP, contributing to the analysis of logistics behavior and route integration optimization in uncertain environments.

In addition to the aforementioned studies, recent years have witnessed a growing focus on the risk factors in 4PLROP. Deng et al. [26] utilized the ant-colony algorithm to address the mathematical model of 4PLROP, where the Value at Risk (VaR) was employed to represent the delay risk in an uncertain environment. Bo et al. [27] carried out research on the 4PLROP with tardiness risk by introducing VaR to measure the time-related risk. Wang et al. [28] established a mathematical model considering customers' risk-averse behavior and studied the 4PLROP in the context of customers' risk-avoidance behavior. Recently, Liu et al. [29] introduced the risk value VaR to measure the risk of delays, which has been a significant advancement in the risk assessment of 4PLROP.

The probability that the delay quantity is less than a certain value, as denoted by VaR, is required to be greater than or equal to the confidence level prescribed by the client. However, it merely takes into account the likelihood of the occurrence of delay risks, without considering the mean of such risks when they materialize under extreme conditions. The conditional mean of delay risks exceeding VaR can be determined by the CVaR model. By integrating the risk level of the distribution plan and the anticipated delay risks, rational decisions concerning distribution services can be formulated.

In summary, while the existing literature encompasses a multitude of aspects of 4PLROP, there is still a deficiency in addressing the infection risks and delays associated with public health emergencies. This article provides a novel perspective and practical methodologies for this field of research by constructing corresponding mathematical models based on CVaR and employing an improved Q-learning algorithm. The aim is to assist 4PL systems in better adapting to the ever-changing market environment, ensuring the stability and efficiency of the supply chain.

III. PROBLEM DESCRIPTION AND MODEL ASSUMPTIONS

A. The Path Optimization Problem in the Context of the Pandemic

In environments where logistics warehouses and transfer node cities are densely populated with personnel and abundant goods, the potential risk of virus transmission during the pandemic cannot be overlooked. Especially in the context of ongoing pandemic prevention and control, 4PL service providers must ensure that only goods, and not viruses, are transported by vehicles while maintaining smooth logistics operations. Consequently, stringent monitoring of infection risks in logistics transportation has become a crucial component of epidemic prevention efforts.

During the special period of the pandemic, to avoid potential infections in high-risk areas, this paper has developed a specific planning strategy for delivery routes, incorporating infection risk constraints. This issue can be specifically described as follows: as graphical illustration of the process in Fig. 1, a multi-layer graph "G=(V,E)" is used to represent the 4PLROP, where " $|V|=n$ " is the set of node cities and E is the set of edges. The node city s represents the supply city, node city t represents the destination city, and other node cities representing transfer node cities. The number of node cities " $|V|=n$ " indicates the total number of node cities, each of which has attributes such as time, cost, carrying capacity, and reputation. Since there may be multiple 3PL suppliers offering services between any two node cities, there are multiple edges between any two node cities in the graph (each edge represents a different 3PL, identified by a unique number). Consequently, each edge has different attributes related to time, cost, capacity, and reputation, meaning that each 3PL has its corresponding properties. Therefore, when selecting transfer node cities and 3PL suppliers, it is necessary to comprehensively weigh various factors to ensure that the chosen path is not only cost-effective and time-efficient but also minimizes infection risks to the greatest extent possible.

The goal is to provide customers with a delivery plan that meets cost budget and infection risk control requirements while minimizing CVaR, ensuring that goods are delivered safely and on time. Therefore, the following assumptions are proposed to address the aforementioned research issues:

- (1): It is assumed that infection risks only exist at node cities where 3PL suppliers are changed and where handling and unloading occur, while the transportation between node cities is considered risk-free.

- (2): It is assumed that the level of infection risk is directly related to the cumulative number of locally confirmed cases in the city over the past 14 days, and that high-risk node cities are strictly avoided. The specific risk assessment method will be detailed in Section III (C).

Fig. 1. 7-node problem description.

B. Parameters and Variables

By defining the following parameters and variables to establish a mathematical model, as shown in Table I.

TABLE I. DEFINITIONS OF PARAMETERS AND VARIABLES

Symbol	Definition description
r_{ij}	The number of 3PL providers that can offer delivery services between the node city i and node city j (namely, the number of edges between the two node cities).
C_{ijk}	The transportation cost required by the k -th 3PL provider for delivery services between the node city i and node city j .
T_{ijk}	The random transportation time required by the k -th 3PL provider for services between the node city i and node city j .
C'_j	The transshipment cost required when passing through node city j .
T'_j	The random transshipment time required when passing through node city j .
R	The set of node cities and edges contained in the path is, namely, $R=\{v_s, \dots, v_i, k, v_j, \dots, v_t\}$. As shown in Fig. 1, the red path can be represented by $R=\{v_s, 2, v_2, 1, v_3, 2, v_t\}$.
$x_{ijk}(R)$	Decision variable. When the 3PL provider represented by the k -th edge between city i and node city j provides the distribution task, it takes 1; otherwise, it takes 0. As shown in (1).
$y_j(R)$	Decision variable. If the city represented by node city j provides the transshipment task, it takes the value of 1; otherwise, it takes 0. As shown in (2).
X_j	The cumulative number of local confirmed cases within 14 days in node city j .
f	The unit person-time infection risk of the cumulative number of local confirmed cases within 14 days.
F_0	The maximum acceptable infection risk for customers.

$$x_{ijk} = \begin{cases} 1, & \text{The } k\text{-th edge between } i \text{ and } j \\ & \text{belong to path } R \\ 0, & \text{else} \end{cases} \quad (1)$$

$$y_j(R) = \begin{cases} 1, & \text{node city } j \text{ belong to path } R \\ 0, & \text{else} \end{cases} \quad (2)$$

C. Quantification of the Infection Risk

This paper studies the 4PLROP during the early stages of the pandemic. Therefore, it draws on the classification of cities into low, medium, and high-risk areas established in the early phase of the pandemic to assign infection risk values to the node cities, as shown in Table II.

TABLE II. RISK CLASSIFICATION CRITERIA

Risk rating	Classification criterion	Response policies
Low-risk area	Within 14 days, without any new or existing confirmed cases.	Strengthen external prevention and control, fully restart production and daily life, and lift road traffic restrictions
Medium-risk area	Within 14 days, if the number of new confirmed cases is ≤ 50 or there are no cluster outbreaks, even if the cumulative confirmed cases exceed 50.	Implement a dual prevention and control strategy, steadily and orderly restore the normal state of production and daily life
High-risk area	Cumulative cases exceed 50, and there have been cluster outbreaks in the past 14 days.	Implement strict management with dual-direction prevention and control, ensuring that the pandemic does not spread or overflow

According to the defined standards, when assessing the COVID-19 infection risk in a certain area, the number of locally confirmed cases over a continuous fourteen-day period is considered. If an area has no locally confirmed cases or has no new cases for fourteen consecutive days, it is regarded as low-risk. If there are new cases within fourteen days but the cumulative confirmed cases do not exceed 50, it is classified as a medium-risk area. When the cumulative confirmed cases exceed 50, the area is considered high-risk. Given that the incubation period of the COVID-19 virus is fourteen days and that travel codes also reference the travel history within the last fourteen days, this paper uses the number of locally confirmed cases in a node city over the past fourteen days as the basis. The infection risk f is quantified in terms of the number of confirmed cases per person. For example, if the cumulative confirmed cases in a node city within fourteen days amount to 25, then the infection risk is $25f$. Moreover, infection risk occurs only during the transfer at the node city.

D. Mathematical Model

Under the confidence level β , when minimizing CVaR, calculate the distribution path with the minimum average overdue risk. Add the infection risk constraint and establish the following mathematical model:

$$\begin{aligned} & \min(\sum_{i=1}^n \sum_{j=1}^n \sum_k^{r_{ij}} \mu_{ijk} x_{ijk}(R) + \sum_{j=1}^n \mu_j y_j - T_0) + c_1(\beta) \\ & \times \sqrt{\sum_{i=1}^n \sum_{j=1}^n \sum_k^{r_{ij}} \delta_{ijk}^2 x_{ijk}^2(R) + \sum_{j=1}^n \delta_j^2 y_j^2(R)} \quad (3) \\ \text{s.t.} \quad & \sum_{j=1}^n X_j f y_j \leq F_0 \quad (4) \end{aligned}$$

$$\sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^{r_{ij}} C_{ijk} x_{ijk}(R) + \sum_{j=1}^n C'_j y_j(R) \leq C_0 \quad (5)$$

$$\Delta T = \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^{r_{ij}} T_{ijk} x_{ijk}(R) + \sum_{j=1}^n T'_j y_j(R) - T_0 \quad (6)$$

$$R = \{v_s, \dots, v_i, k, v_j, \dots, v_k\} \in G \quad (7)$$

$$x_{ijk}(R), y_j(R) \in \{0, 1\} \quad (8)$$

$$X_j < 50 \quad (9)$$

Among them, Constraints (4) the capacity limit for the infection risk, F_0 denotes the maximum acceptable infection risk given by the customer. Constraints (5) the capacity limit for the delivery cost, where C_0 is the maximum cost acceptable to the customer. Constraints (6) is the expression of the overdue quantity ΔT , which is a random variable. Constraints (7) reflects the path to ensure that the path is a legal connected path from the initial node city to the destination city. Constraints (8) manifests $x_{ijk}(R)$ and $y_j(R)$ are decision variables. Constraints (9) conveys that the transportation path cannot pass through high-risk areas.

IV. ALGORITHM DESIGN

When the improved Q-learning algorithm is employed to address the 4PLROP, the primary procedures encompass the initialization of parameters, the establishment of action-state settings, the construction of the reward function, the formulation of exploration strategies and the training of the model.

A. Action-state Setting

This paper combines improved Q-learning with the 4PLROP, viewing the choice of actions as related to the selection of 3PL suppliers and treating node cities as different states. Let s represent the current state (the current node city). The corresponding 3PL suppliers for this node city can be represented by the action space $A = \{a_1, a_2, \dots, a_k, \dots, a_K\}, k=1, 2, \dots, K$. Each action-state pair corresponds to a Q-value.

Taking the 7-node for example, refer to Fig. 1 for the illustration, the initial node city can be regarded as the initial node city s . The node cities connected to the initial node city are node city 1 and node city 2. There are three selectable 3PL suppliers corresponding to the route from the initial node city to node city 1, labeled as 1, 2, and 3, which can be designated as actions α_1, α_2 and α_3 . Similarly, there are four selectable 3PL suppliers for the route from the initial node city to node city 2, labeled as 1, 2, 3, and 4, which can be designated as actions $\alpha_4, \alpha_5, \alpha_6, \alpha_7$. Thus, there are 7 actions available at the initial node city. When choosing actions α_1, α_2 and α_3 at the initial node city, the next state transitions to node city 1. Likewise, when choosing actions $\alpha_4, \alpha_5, \alpha_6, \alpha_7$ at the initial node city, the next state transitions to node city 2. The action sets for the other node cities can be defined in a similar manner. Using the 7-node as an example, the selected actions and their corresponding next states are shown in Table III.

TABLE III. 7-NODE PROBLEM ACTIONS AND CORRESPONDING NEXT STATES SETTINGS

The selected actions	Corresponding to the next state
A={a ₁ ,a ₂ ,a ₃ }	Transfer node city 1
A={a ₄ ,a ₅ ,a ₉ }	Transfer node city 2
A={a ₁₀ ,a ₁₁ ,a ₁₄ ,a ₁₅ ,a ₁₆ }	Transfer node city 3
A={a ₁₂ ,a ₁₃ ,a ₂₁ ,a ₂₂ ,a ₂₃ }	Transfer node city 4
A={a ₁₇ ,a ₁₈ ,a ₁₉ ,a ₂₀ ,a ₂₄ ,a ₂₅ }	Transfer node city 5
A={a ₂₆ ,a ₂₇ ,a ₃₃ }	Demand node city t

B. The Construction of the Reward Function

Since the Q-learning algorithm is based on the Markov Decision Process (MDP) model, a discrete reward and punishment function is adopted for computational convenience [30]. Given that transportation tasks cannot pass through high-risk areas, the number of infections at the transfer node cities along the path must not exceed 50. Therefore, when the number of infections in a certain city j is less than or equal to 50, the reward is 1. Conversely, when the number of infections in city j exceeds 50, the reward is -100, as depicted in Eq. (10).

$$r_0(s,a) = \begin{cases} 1 & \text{if } X_j \leq 50 \\ -100 & \text{if } X_j > 50 \end{cases} \quad (10)$$

When there is a connection between node city i and node city j and j is not the destination, the reward is 1. When there is no connection between node city i and node city j , the reward is -1. When there is a connection between node city i and node city j and j is the destination, the reward is 100, in (11) illustrates this concept.

$$f(x) = \begin{cases} 1, & i, j \text{ are connected}; j \text{ is not the end node city;} \\ -1, & i, j \text{ are not connected;} \\ 100, & i, j \text{ are connected}; j \text{ is the end node city} \end{cases} \quad (11)$$

Considering the magnitude of rewards is related to the mean and variance within the objective function, and also needs to meet certain constraints, the reward function for this issue can therefore be rewritten as shown in study (12). The parameter ω_1 is inversely proportional to the distribution cost corresponding to the selected 3PL supplier and transfer node city, that is, the smaller the distribution cost, the greater the reward value obtained, as illustrated in study (13). In a parallel manner, ω_2 is inversely proportional to the mean value of the distribution time corresponding to the selected 3PL supplier and transfer node city. When the mean value of the random time is smaller, the greater the reward value obtained, as evidenced in study (14). The parameter ω_3 is inversely related to the average distribution time associated with the selected 3PL supplier and transfer node city, When the variance is smaller, the corresponding reward value is greater, where k_1 and k_2 are the weighting coefficients of the reward function, as detailed in study (15). Additionally, ω_4 is correlated with the infection count at the node city, as elucidated in study (16).

$$r = \omega_1 r(s,a) + \omega_2 r(s,a) + \omega_3 r(s,a) + \omega_4 r_0(s,a) \quad (12)$$

$$\omega_1 = \frac{k_1}{C_{ijk} + C_j} \quad (13)$$

$$\omega_2 = \frac{k_2}{\mu_{ijk} + \mu_j} \quad (14)$$

$$\omega_3 = \frac{1 - k_1 - k_2}{\delta_{ijk}^2 + \delta_j^2} \quad (15)$$

$$\omega_4 = \frac{1}{X_j} \quad (16)$$

C. The Exploration Strategy of Improved Q-learning Algorithm

When the agent interacts with the environment to learn, it must choose known actions that maximize the reward while also ensuring that it can learn more experiences in an unknown environment, thereby laying the foundation for obtaining more cumulative rewards. Therefore, it is essential to establish an appropriate exploration strategy to achieve optimal training results. The traditional Q-learning algorithm typically employs the ϵ -greedy strategy as its exploration method.

The mathematical description of the ϵ -greedy strategy is as follows:

$$\pi(a,s) = \begin{cases} \arg \max Q(s,a) & 1 - \epsilon \\ q_{random} & \epsilon \end{cases} \quad (17)$$

Eq. (17), it can be understood as randomly selecting the selectable actions in the current state with a certain probability ϵ , and choosing the action corresponding to the maximum Q value among the current actions with a probability of $1 - \epsilon$.

When using the Q-learning algorithm to address the 4PLROP, the environment is relatively simple, and both states and actions are limited. Therefore, it is necessary to establish a corresponding reinforcement learning environment based on the characteristics of the problem. To better explore the environment, this paper adopts a random strategy more suitable for the problem to select actions. According to the reward matrix established by the reward function, it is observed that in the current state, when the reward value is -1, the two node cities are disconnected. Therefore, the exploration strategy is set to randomly select actions with reward values greater than -1 in the current state to reduce exploration time.

D. Model Training

By designing a Q-table to train the agent, each row in the Q-table represents all the states available to the agent, while each column represents the actions the agent can perform in the corresponding state. Each state in the multi-layer graph represents different node cities, and each action represents different 3PL suppliers in the multi-layer graph. Initially, all states in the Q-table are set to 0. The reward values obtained from executing different actions (selecting different suppliers) are then calculated based on the reward matrix established by the reward function, and the values of the elements in the Q-table are updated using Eq. (18). Each iteration is considered a training session for the agent. During each training session, the agent attempts to move from the initial node city to the destination node city, updating the elements in the Q-table after executing each action.

$$Q^*(s,a) \leftarrow Q(s,a) + \alpha [R(s,a,s) + \gamma \max_{a'} Q(s,a') - Q(s,a)] \quad (18)$$

E. The Flow Chart of Q-learning Algorithm

When using the improved Q-learning algorithm to solve the 4PLROP, firstly, based on the existing data, the elements in the matrix are initialized by using the reward function. Since there are multiple different 3PL suppliers between two node cities, that is, one state corresponds to multiple ones. Therefore, it is necessary to set the actions corresponding to each state, and then train and update the matrix Q through the setting of the matrix R and related parameters. Finally, the optimal path planning can be obtained based on the Q-table. The flowchart of the 4PLROP using the improved Q-learning algorithm is shown in Fig. 2. The specific steps are as follows:

Step 1: Load the known data information in MATLAB.

Step 2: Initialize the parameters γ , α and the Q-table, set the initial state and the final state, and at the same time, use the given data Eq. (12) to construct the reward matrix R.

Step 3: Set the initial state as the initial node city.

Step 4: Determine the action through the random selection strategy, that is, select a feasible 3PL supplier.

Step 5: Perform the action α (namely, select a 3PL supplier of the current node city), and then transfer to the new state s' (node city). Update the Q-table based on the reward matrix R and preset parameters.

Step 6: Determine whether s' is the final node city. If not, return to Step 4; if yes, proceed to Step 7.

Step 7: Determine whether the set number of training times has been completed. If not, return to Step 3 to continue training; if yes, proceed to Step 8.

Step 8: The training process is over and the final Q-table is output.

Step 9: Combine the Q-table to determine and output the best logistics distribution plan.

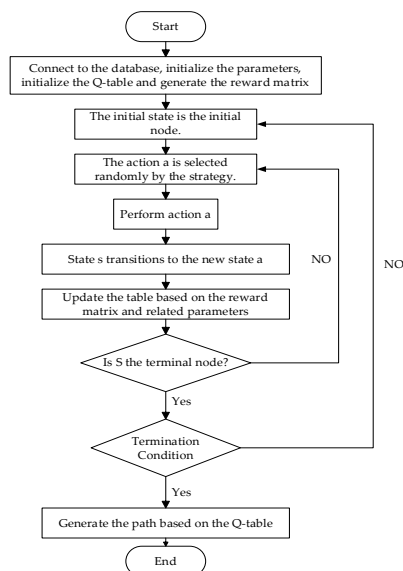

Fig. 2. Flow chart of improved Q-learning algorithm.

V. EXPERIMENTAL RESULTS AND ANALYSIS

Referring to Fig. 3, it is the epidemic data chart for some periods in 2022. Fig. 4 illustrates the cumulative number of confirmed cases in some cities across the country within 14 days. These are used as the data references for this section. The relevant data comes from the National Health Commission of China and the health commissions of various provinces and cities.

This section first takes the 7-node as an example to analyze the influence of the training times episode, discount factor γ , and learning rate α in the Q-learning algorithm on the calculation results, and obtains a set of optimal parameter combinations. Then, it solves the mathematical model with the constraint conditions of the delivery cost and the infection risk and the objective function of minimizing CVaR. Finally, the best distribution path obtained from the corresponding example is visualized. The software used by the algorithm is MATLAB 2023a, and the operating environment is Intel(R) Core(TM) i7-2600 @3.40GHz.

Fig. 3. Epidemic data chart for partial periods in 2022.

Fig. 4. Cumulative number of confirmed cases within 14 days in some cities.

A. Parameter Test

The parameters within the improved Q-learning algorithm are rigorously tested through extensive experimental simulations. This is achieved by keeping all other parameters constant and observing the impact of variations in a single parameter on the solution outcomes. The efficacy is denoted by the optimality rate, which represents the probability of obtaining the best solution during the execution of the algorithm.

Through repeated experiments on $k1$ and $k2$ in the reward function in different sized examples, when the values of $k1$ and $k2$ are the data in Table IV, the algorithm has the best solution effect.

TABLE IV. PARAMETER SETTINGS FOR DIFFERENT INSTANCES

Number of node	k1	k2	episode	CVaR	Best path	Time
7	0.1	0.8	100	27.789 2	$R=\{v_s, 2, v_2, 2, v_3, 1, v_t\}$	0.9s
15	0.1	0.2	200	12.158 9	$R=\{v_s, 3, v_3, 2, v_6, 3, v_{13}, 2, v_t\}$	1s

Fig. 5-7 offer a graphical representation of the data, the parameter test process of the improved Q-learning algorithm for solving the 7-node example is presented when the confidence level is 0.9, the infection risk constraint is 8.5×10^{-5} , and the cost constraint is 80. Wherein the "best rate" refers to the probability that the best solution is achieved during the algorithm's execution, with the total number of runs set to 100. The test results show that the best parameters of the improved Q-learning algorithm are $\gamma=0.8$, $\alpha=0.9$ and episode = 100, respectively.

B. Case Analysis

To validate the effectiveness of the proposed model, we solved two instances of different scales, with 7-node and 15-node, and obtained the corresponding minimum CVaR values and the best routes. The information related to the 7-node and edges is shown in Table V and Table VI. Due to the large amount of information from the 3PL suppliers, only partial information is provided in Table VI.

TABLE V. 7-NODE CALCULATION EXAMPLE RELATED INFORMATION

Node	Cost	The mean of random time	The variance of random time	The number of infections

s	2	2	17	17	196
s	2	3	19	14	169
s	2	4	15	20	329

As depicted in Fig. 8, it is the path diagram corresponding to the solution result of 7-node. Among them, the black pentagram s represents the initial node city, the black pentagram t is the destination node city, and the node city 4 marked by the red pentagram indicates the transfer node city that does not meet the constraint of the number of infections. That is, transfer node city 4 is in a high-risk area, so the path cannot pass through node city 4. The other transfer node cities that meet the constraint of the number of infections. The path marked by the blue thick line is the distribution path corresponding to the minimum CVaR that satisfies the constraints of cost and the infection risk, and the detailed data is shown in Table VI.

Fig. 8. 7-node solution path diagram.

The information is summarized in Table VII, the solution of the CVaR model of the 7-node problem are given under different confidence levels when the cost constraint $C_0=80$ and the maximum acceptable the infection risk given by the customer is 8.5×10^{-5} . Among them, " β " represents the confidence level, that is, the degree of risk aversion of the customer, " $CVaR$ " is the best solution obtained by the CVaR model (the evaluation criterion is the objective function), " $Best\ path$ " is the distribution path corresponding to the best solution obtained, " F " is the infection risk corresponding to the distribution path of the best solution obtained, " $Best\ rate$ " indicates the probability that the best solution obtained by the algorithm accounts for the total number of runs of the algorithm. At this time, the total number of runs is 100, and " $Time$ " is the running time of the algorithm for one run, in seconds.

TABLE VII. SOLUTION OF 7-NODE PROBLEMS AT $T_0=70$, $C_0=80$ AND $F_0=8.5 \times 10^{-5}$

β	episode	CVaR	Best path	F	Best rate	Time
0.9	100	27.7892	$R=\{v_s, 2, v_1, 1, v_3, 1, v_t\}$	7.352×10^{-5}	0.98	0.9s
0.95	100	35.1168	$R=\{v_s, 2, v_1, 1, v_3, 1, v_t\}$	7.352×10^{-5}	0.98	0.9s
0.99	100	49.4634	$R=\{v_s, 2, v_1, 1, v_3, 1, v_t\}$	7.352×10^{-5}	0.98	0.9s

According to the data in Table VII, when the confidence level is 0.9, the Delivery Cost is $C_0=80$, and the infection risk constraint is $F_0=8.5 \times 10^{-5}$, the obtained optimal CVaR value is 27.7892, indicating that the corresponding average delay risk of the distribution task is 27.7892, the corresponding distribution cost is 80, the infection risk is 7.352×10^{-5} , and the corresponding best distribution path is $R=\{v_s, 2, v_1, 1, v_3, 1, v_t\}$, indicating that when transporting from the source node city s to the destination node city t ,

the destination node city t , the selected transfer node cities are 1 and 3 respectively, and the 3PL supplier number selected between each two transfer node cities is 2, 1, 1; when the confidence level is 0.95, the cost constraint is $C_0=80$, and the infection risk constraint is $F_0=8.5 \times 10^{-5}$, the obtained minimum CVaR value is 35.1168, indicating that the corresponding average delay risk of the distribution task is 35.1168, the corresponding distribution cost is 80, the infection risk is 7.352×10^{-5} , and the corresponding best distribution path is $R=\{v_s, 2, v_1, 1, v_3, 1, v_t\}$, indicating that when transporting from the source node city s to the destination node city t , the selected transfer node cities are 1 and 3 respectively, and the 3PL supplier number selected between each two node cities is 2, 1, 1.

The relevant information of 15-node is shown in Table VIII. Since there are 91 rows of information corresponding to the 3PL supplier of 15-node, only a partial information is displayed in Table IX.

Fig. 9 depicts the detail, it is the path diagram corresponding to the solution result of 15-node. Among them, the black pentagram *s* represents the initial node city, and the black pentagram *t* is the destination node city. The node cities marked with red pentagrams 2, 4, and 7 are transfer node cities that do not meet the constraint of the number of infected people, that is, transfer node city 2, node city 4, and node city 7 are in high-risk areas, so the path cannot pass through node city 2, node city 4, and node city 7. The remaining transfer node cities that meet the constraint of the number of infected people. The path marked with the blue thick line is the distribution path corresponding to the minimum CVaR that satisfies the cost and the infection risk constraints obtained, and the detailed data is depicted in Table X.

Fig. 9. 15-node solution path diagram.

The solution of the CVaR model of the 15-node problem are given by Table X under different confidence levels, when

the cost constraint is $C_0=115$ and the maximum acceptable the infection risk given by the customer is 1.6×10^{-4} .

TABLE X. SOLUTION OF 15-NODE PROBLEM WHEN $T_0=70$, $C_0=115$, $F_0=1.6 \times 10^{-4}$

β	episode	CVaR	Best path	F	Best rate	Time
0.9	200	12.1589	$R=\{v_s, 3, v_3, 2, v_6, 3, v_{13}, 2, v_t\}$	1.28×10^{-4}	0.98	0.9s
0.95	200	14.2909	$R=\{v_s, 3, v_3, 2, v_6, 3, v_{13}, 2, v_t\}$	1.28×10^{-4}	0.98	0.9s
0.99	200	18.4651	$R=\{v_s, 3, v_3, 2, v_6, 3, v_{13}, 2, v_t\}$	1.28×10^{-4}	0.98	0.9s

It can be known from the data in Table X that when the confidence level is 0.9, the cost constraint $C_0=115$, and the infection risk constraint $F_0=1.6 \times 10^{-4}$, the obtained optimal CVaR value is 12.1589, indicating that the corresponding average delay risk of the distribution task is 12.1589. The corresponding distribution cost is 115, and the infection risk is 1.28×10^{-4} . The corresponding best distribution path is $R=\{v_s, 3, v_3, 2, v_6, 3, v_{13}, 2, v_t\}$, indicating that when transporting from the source node city *s* to the destination node city *t*, the selected transfer node cities are 3, 6, and 13 respectively, and the number of the 3PL supplier selected between each two node cities is 3, 2, 3, 2. When the confidence level is 0.95, the cost constraint $C_0=115$, and the infection risk constraint $F_0=1.6 \times 10^{-4}$, the obtained optimal CVaR value is 14.2909, indicating that the corresponding average delay risk of the distribution task is 14.2909. The corresponding distribution cost is 115, and the infection risk is 1.28×10^{-4} . The corresponding best distribution path is $R=\{v_s, 3, v_3, 2, v_6, 3, v_{13}, 2, v_t\}$, indicating that when transporting from the source node city *s* to the destination node city *t*, the selected transfer node cities are 3, 6, and 13 respectively, and the number of the 3PL supplier selected between each two node cities is 3, 2. When the confidence level is 0.99, the cost constraint $C_0=115$, and the infection risk constraint $F_0=1.6 \times 10^{-4}$, the obtained optimal CVaR value is 18.4651, indicating that the corresponding average delay risk of the distribution task is 18.4651. The corresponding distribution cost is 115, and the infection risk is 1.28×10^{-4} . The corresponding best distribution path is $R=\{v_s, 3, v_3, 2, v_6, 3, v_{13}, 2, v_t\}$, indicating that when transporting from the source node city *s* to the destination node city *t*, the selected transfer node cities are 3, 6, and 13 respectively, and the number of the 3PL supplier selected between each two node cities is 3, 2.

The above data indicates that when the cost constraint and the infection risk constraint remain unchanged, as the confidence level increases, the corresponding optimal distribution path will not change, so the infection risk faced will not change either. However, the average delay risk faced by customers will be higher. Therefore, by using this model, 4PL suppliers can combine the customers' aversion to risk and

consider the impact of the infection risk on the distribution plan, so that the distribution path does not pass through high-risk areas, and at the same time, provide customers with the distribution path with the smallest average delay risk that meets the customer's infection risk and cost requirements under the given confidence level. It not only reduces the risk of virus transmission, but also provides customers with a green and efficient delivery solution with the lowest delay risk under a specific confidence level, helping the logistics industry move towards a safer and more sustainable future.

The confidence level selected by clients is significantly influenced by their risk preferences. A higher confidence level may be chosen by clients who are averse to delay risks in order to enhance security, whereas clients with a propensity for taking risks may opt for a lower confidence level to increase the diversity of viable routes. Consequently, our plan is meticulously aligned with the clients' risk preferences, enabling the formulation of bespoke control schemes. Utilizing this plan, 4PL providers can fully take into account the clients' aversion to delay risks, devising distribution routes that circumvent high-risk zones and achieve minimization of the mean delay risk under the specified confidence level. This approach not only mitigates the infection risk but also delivers a green and efficient distribution solution with the minimal delay risk at a particular confidence level, thereby aiding the logistics industry in forging a safer, more efficient, and sustainable distribution system.

C. Algorithm Comparison

In this paper, two distinct algorithms were utilized to tackle the 4PLROP: the Genetic algorithm embedded with the Dijkstra algorithm and the improved Q-learning algorithm. With the aim of assessing the efficacy of these algorithms across varying problem scales, three case studies of differing magnitudes were selected for analysis, encompassing 7 nodes, 15 nodes, and 30 nodes respectively. A comparative examination of the solution outcomes derived from these algorithms on the aforementioned case studies facilitates a profound comprehension of their divergent performances in terms of solution efficiency, solution quality, and stability. This, in turn, furnishes a more efficacious basis for algorithm selection in addressing real-world logistics routing optimization issues. Subsequently, in an endeavor to further scrutinize whether the improved Q-learning algorithm exhibits significant performance enhancements over the traditional Q-learning algorithm, a comparative study was undertaken between the improved Q-learning algorithm and the traditional Q-learning algorithm.

The Genetic algorithm embedded with the Dijkstra algorithm and the improved Q-learning algorithm are used to solve three examples of different scales. The comparison data are demonstrated in Table XI. It can be known from the data in Table XI that when solving the small scale problem of 7-node, both the improved Q-learning algorithm and the Genetic algorithm embedded with the Dijkstra algorithm can find the optimal solution, but the latter shows an inferior solving speed. With the increase of the solving scale, the improved Q-learning algorithm presents a higher solving speed and solving quality. Although the Genetic algorithm embedded with the Dijkstra algorithm can find the optimal solution, the number of

iterations and time increase significantly. The main reason is that in this algorithm, a simple graph is first generated, and the Dijkstra algorithm is used to find the optimal path on the simple graph, and then the Genetic algorithm is used for optimization. This leads to the possibility that different simple graphs may find the same path, thereby delaying the optimization convergence process and rapidly increasing the solving time.

TABLE XI. COMPARISON OF RESULTS OF DIFFERENT ALGORITHMS

Node	Algorithm	CVaR	Best path	Best rate	Time
7	Improved Q-learning	22.0456	$R=\{v_s, 2, v_2, 2, v_3, 1, v_t\}$	1	0.9s
	Embedded Dijkstra's Genetic Algorithm	22.0456	$R=\{v_s, 2, v_2, 2, v_3, 1, v_t\}$	0.95	19.4s
15	Improved Q-learning	3.7728	$R=\{v_s, 1, v_2, 2, v_6, 3, v_{13}, 2, v_t\}$	0.98	1s
	Embedded Dijkstra's Genetic Algorithm	3.7728	$R=\{v_s, 1, v_2, 2, v_6, 3, v_{13}, 2, v_t\}$	0.94	24.5s
30	Improved Q-learning	13.641	$R=\{v_s, 1, v_4, 2, v_8, 1, v_{12}, 1, v_{15}, 2, v_{18}, 4, v_{21}, 1, v_{25}, 1, v_t\}$	0.95	1.5s
	Embedded Dijkstra's Genetic Algorithm	13.641	$R=\{v_s, 1, v_4, 2, v_8, 1, v_{12}, 1, v_{15}, 2, v_{18}, 4, v_{21}, 1, v_{25}, 1, v_t\}$	0.9	28.5s

Fig. 10-12 provide a visual representation, they respectively represent the comparison curves of the traditional Q-learning algorithm and the improved Q-learning algorithm when solving 7-node, 15-node and 30-node. In the table, iQlearning refers to improved Q-learning algorithm.

Fig. 10-12 offer a graphical summary of the results, the red curve represents the solution curve of the traditional Q-learning algorithm, and the exploration strategy adopted is the ϵ -greedy strategy, where the value of ϵ is 0.5; the green curve represents the solution curve of the improved Q-learning algorithm described in this paper, and the strategy adopted is to randomly select actions with a reward value greater than -1 in the current state.

Fig. 10. Comparison of two algorithms at 7-node.

Fig. 11. Comparison of two algorithms at 15-node.

Fig. 12. Comparison of two algorithms at 30-node.

When solving the 7-node problem, both the improved Q-learning algorithm and the traditional Q-learning algorithm can converge relatively quickly, but the former has higher stability and a relatively faster convergence speed. As the problem scale increases, the improved Q-learning algorithm shows higher stability and solution speed. Through the performance of the traditional Q-learning algorithm and the improved Q-learning algorithm in different examples in the above text, it can be seen that the improved algorithm has a faster exploration speed, stronger stability, and a faster convergence speed, which has strong practical significance in solving the 4PLROP.

In summary, this paper has drawn the following conclusions through a comparative analysis of the solution performance of the Genetic algorithm embedded with the Dijkstra algorithm and the improved Q-learning algorithm on case studies of varying scales, as well as the performance disparities between the improved Q-learning algorithm and the traditional Q-learning algorithm: The improved Q-learning algorithm has demonstrated significant performance advantages in addressing the 4PLROP, whether it be in small-scale or large-scale issues, including a faster solution speed, a higher solution quality, and a stronger stability. This indicates that the improved Q-learning algorithm is an effective and practical solution method, capable of providing robust support for path optimization in actual logistics distribution. In the future, we will continue to conduct in-depth research and optimization of this algorithm to further enhance its adaptability and solution efficiency in complex logistics

environments, thereby offering a more comprehensive solution for the resolution of 4PLROP.

VI. CONCLUSIONS

In the context of a severe pandemic environment, the stability and efficiency of logistics services are crucial for ensuring the continuity of societal operations and the well-being of the populace. Particularly against the backdrop of the dual carbon goals (Carbon Peak and Carbon Neutrality), it is imperative not only to meet the demands of minimizing the risk of delivery delays for clients but also to give due consideration to the prevention and control of infection risks, as well as the imperatives of energy conservation and emission reduction. Together, these efforts weave a logistics network that is green, secure, and efficient, contributing to the sustainable development of the planet.

The present article introduces the CVaR measure and constructs a novel mathematical model. This model not only incorporates distribution costs and infection risks as significant constraints but also aims to minimize the CVaR as the optimization target. Through this model, it ensures that distribution plans can meet the requirements of cost effectiveness and risk control under the complex and variable epidemic environment. To satisfy the demands of this model, the reward and punishment mechanisms in the Q-learning algorithm have been redesigned to more accurately reflect the various risks and cost factors in the actual distribution process. By solving different cases, the lowest CVaR distribution routes that meet the requirements of cost and customer infection risks are obtained. Customers can obtain multiple schemes according to their risk preferences and take corresponding measures. This article provides scientific decision making basis and efficient and safe distribution plans for the 4PL, promoting the logistics industry to move towards a low-carbon, environmentally friendly, and sustainable direction.

Meanwhile, the probability distribution of the stochastic distribution time and transit time is known in this study. When these parameters are unknown, our research is intended to be extended to a robust 4PLROP considering infection risk and delay risk. We anticipate that the improved Q-learning algorithm and the Genetic algorithm embedded with the Dijkstra algorithm will continue to shine brightly. Their potential in 4PLROP is boundless. Moreover, we envision a future where they are seamlessly integrated into various other crucial aspects of the logistics and transportation ecosystem.

Abstract—Correct precision techniques have far not been introduced for modeling the modality risk in Intensive Care Unit (ICU) patients. Traditional mortality risk prediction techniques effectively extract the data in longitudinal Electronic Health Records (EHRs), that ignore the difficult relationship and interactions among variables and time dependency in longitudinal records. The proposed work, developed the Convolutional Neural Network – Bidirectional-Long Short-Term Memory (CNN-Bi-LSTM) method for personalized treatment analysis using EHR data. The CNN extracts the significant features from relevant features, focused on spatial-based relationships. Then, the Bi-LSTM layer captured the sequential dependencies and temporal relationships in patient histories that are essential to understand the treatment results. The Circle Levy flight – Ladybug Beetle Optimization (CL-LBO) integrates the circle chaotic map and Levy flight process in traditional LBO to select relevant features for classification. The proposed method reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% Area Under Curve (AUC) when compared to LSTM.

Keywords—*Bidirectional-long short-term memory; circle chaotic map; convolutional neural network; electronic medical records; Intensive Care Unit (ICU); ladybug beetle optimization*

I. INTRODUCTION

The healthcare centers are responsible for maintaining patient documents tracked to analyze the disease [1]. Manually handling the document is a difficult task, as the documents get lost, damaged, or destroyed [2]. Collecting confidential information during the readmission of patients became difficult and delayed the patient's treatment [3]. Securing the information of the medical data helps for the analysis of existing disease types, and maintains the confidential patient data [4-6]. Electronic Health Records (EHR) is a digital platform for the data storage and maintenance of medical patient history for future analysis [7]. The EHR allows the providers to access the details of the patients easily and quickly which provides more information of the patients to get better treatment [8-10]. The EHR platform also improves communication among healthcare that enhances coordination to reduce medical errors [11]. In the unavoidable and increasing digital transformation process of national healthcare system management, a significant size of structural EHR data is available [12].

The advancement in recent technologies has introduced many applications for the automatic recording and maintenance of medical patient history [13, 14]. Deep Learning (DL) and Machine Learning (ML) methods are introduced for automatic analysis of medical data. These methods undergo training to predict the result of data [15]. The Intensive Care Unit (ICU) technologies and automatic system development have effectively improved the efficiency of healthcare professionals including caregivers, nurses, and doctors [16]. The EHR is used for model training to learn details present in data [17]. The Medical Information Mart for Intensive Care III (MIMIC-III) dataset is considered as input for DL and ML methods. The study focused on solving the feature selection and dimensionality problems to maximize the performance of the model. The oversampling method is used in the pre-processing step to balance the data, fitness function-based optimization technique is used in the feature selection process to improve classification accuracy and prediction.

The essential contributions of the proposed framework are, the Synthetic Minority Over-Sampling Technique (SMOTE) is introduced in the pre-processing phase to balance the classes in data, which enhances the performance and generalization capability of the method, the Circle Levy flight – Ladybug Beetle Optimization (CL-LBO) based feature selection algorithm is developed to choose relevant and appropriate features whole feature subset, which helps to enhance the classification performance, the CL-LBO integrated the circle chaotic map and Levy flight in traditional LBO, which enhances the searchability and convergence rate of LBO to select relevant features, the Convolutional Neural Network – Bidirectional-Long Short-Term Memory (CNN-Bi-LSTM) is developed for classification to focus much on spatial-based relationships and to capture the sequential dependencies and temporal relationships in patient histories.

The previous research is analyzed in a literature survey is given in Section II. The proposed method explains the process of personalized treatment analysis using the proposed methodology presented in Section III. The results of the proposed model have been examined and compared with existing machine learning models in Section IV. Finally, the paper is concluded in Section V.

II. LITERATURE REVIEW

Fang Yang et al. [18] presented a deep morality risk prediction based on longitudinal EHR data. The LSTM model was used as a classifier to predict mortality rate. Visit-level and variable-level attention mechanisms were used to solve the gradient vanishing issue that occurred during the model training to predict appropriate outcomes that enhanced the efficiency of the model. However, the missing values presented in the data caused an overfitting problem during the process of training that affected the accuracy of prediction and reduced the performance of the model.

Shuai Niu et al. [19] presented a model to predict congestive heart failure mortality based on the feature selection method. Various ML techniques like Decision Tree (DT), Logistic Regression (LR), Random Forest (RF), and Gradient Boosting (GB) were used as a classifier to predict the mortality rate. The Partial Swarm optimization (PSO)-based feature selection algorithms were utilized to select significant details of features that enhanced the accuracy of prediction and classification. However, the model struggled to interpret the pattern of features due to huge variables present in the data affected the training of the model to predict accurate outcomes and reduced the accuracy of classification. Maria Bampa et al. [20] presented a multimodal clustering technique for understanding the patient phenotype. A Multimodal Autoencoder (MMAE) model was used as a classifier to group the disease based on similar features. The model strength was enhanced by combining multiple modalities to improve the clustering of data and enhance the accuracy of classification. However, the model suffered from getting the approximate hyperplane required for the classification due to a huge number of variables that reduced the accuracy of classification.

Belel Alsinglawi et al. [21] presented a ML framework for the prediction of lung disease in hospitals. The RF algorithm was used as a classifier to predict the type of lung disease. The SMOTE was utilized to solve imbalance issues of the data that enhanced the training of the model to predict accurate outcomes. However, the model failed to identify the significant details of the data due to a dimensionality issue that reduced the accuracy of classification. Hua Shen [22] presented the Recurrent Neural Network (RNN) model to improve the prediction of diseases in healthcare. An attention mechanism was used to reduce the gradient vanishing problem that occurred during the training process where the maximum gradients were retained which increased the accuracy of prediction to get the approximate outcome. However, the model suffered from gradient vanishing issues where the gradients vanished during the training process which affected the accuracy of classification.

Sapiah Sakri et al. [23] presented a hybrid model to predict sepsis disease based on extracted features. Convolutional Neural Network (CNN) and Bi-directional LSTM models were combined to classify sepsis disease. The spatial and temporal features of the data were used to select the significant details of the data where the model identified the pattern of selected features that enhanced the performance of the models. However,

the extra layers present in the neural network affected the interpretability of the model that reduced the accuracy of classification. Sarika R. Khope et al. [24] presented a featured engineering-based disease prediction Artificial Neural Network (ANN). The encoding method was utilized to eliminate the outer lines of the features and improve the accuracy of prediction and classification. The feature engineering technique was used to get significant details of the data that enhanced the accuracy of prediction. However, the overfitting issue occurred during the process because the irrelevant features present in the data fit the model and learned the noises that affected the accuracy of classification.

Chang Liu et al. [25] presented a different ML models like K Nearest Neighbor (KNN), DT, NB, LR, and RF for the early prediction of Multiple Organ Deficiency Syndrome (MODS). Kernel Shapley Additive exPlanations (SHAP) was utilized to enhance the quality of data. The ML methods used here enhanced the potential of the prediction by clustering the data which enhanced the accuracy of classification. However, the model struggled to identify the appropriate hyperplane required to classify the data approximately which reduced the accuracy of prediction and classification. Vinod Kumar Chauhan et al. [26] presented a DL-based attention model to enhance the classification of HER data. The LSTM model was used as a classifier along with a cross-attention-based transformer model for the prediction of the accurate disease. The LSTM model focused on identifying the significant features of data that enhanced classification accuracy. However, the model performance was reduced due to poor hyperparameter tuning due to a lack of efficient optimal value that reduced the accuracy of classification.

Ho-Joon Lee et al. [27] presented an ensemble consensus model based on HER for the classification of strokes. A stroke classifier technique was used to predict the outcome of the model. The Principal Component Analysis (PCA) technique was employed to minimize the dimensionalities of data and enhance the accuracy of classification. However, the model interpretability was challenging due to missing values presented in data that reduced the accuracy of classification.

From the overall analysis, the existing researches have limitations such as overfitting issues occurring during the process because the irrelevant features present in the data fit, dimensionality issues, struggle to interpret the pattern of features, and the missing values presented in the data caused an overfitting problem.

To mitigate these limitations, the CNN-Bi-LSTM method for personalized treatment analysis using EHR data is developed. The CNN extracts the significant features from relevant features, focused on spatial-based relationships. Then, the Bi-LSTM layer captured the sequential dependencies and temporal relationships in patient histories that are essential to understand the treatment results. The SMOTE technique is employed in the pre-processing phase to balance the classes in data.

Fig. 1. Proposed architecture of personalized treatment analysis using EHR data.

The CL-LBO integrates the circle chaotic map and Levy flight process in traditional LBO to select relevant features for classification. This process improves the process of personalized treatment with high classification accuracy.

III. PROPOSED METHOD

The DL-based technique is developed in this work for personalized treatment analysis using EHR data. The MIMIC III dataset is used for personalized treatment and the data is pre-processed by using one-hot encoding and SMOTE techniques. Then, the relevant features are chosen by using CL-LBO that integrated the circle chaotic map and levy flight process. At last, the CNN-Bi-LSTM method is developed to classify features in data with classification accuracy. Fig. 1 describes the process of personalized treatment analysis using EHR data.

A. Dataset

The dataset used for this research is MIMIC III dataset [28] which includes 1177 cases for in-hospital mortality prediction and has a total of 51 features. The value of 0 represents life and 1 represents death. The BMI, gender, and Age are demographic factors studied. The essential signs are blood pressure, heart rate, respiratory rate, blood temperature, urine result, and saturation pulse oxygen. The characteristics of comorbidity include atrial fibrillation, depression, hyperlipidemia, hypertension, and diabetes. The white blood cells, basophils, lymphocytes, red blood cells, neutrophils, potassium, anion gap, sodium, bicarbonate, lactate, chloride, creatinine, calcium, magnesium, prothrombin time and creatine kinase are the laboratory variables.

B. Pre-processing

The pre-processing of data is employed to issue of imbalance samples is dissimilar from copy sample mechanism in random oversampling. The SMOTE technique synthesized the new samples among two minority samples by linear interpolation,

which efficiently mitigates overfitting issue caused through random oversampling that makes balanced class distribution and enhances generalization capability of classifier [29].

The basic principle of SMOTE technique initially, choose every sample x_i from minority samples as the origin sample of a new synthetic sample, next, in accordance with up-sampling magnification n , randomly choose any neighboring samples k of similar classes in the sample x_i is an auxiliary sample in producing new samples, repeated n times, next linear interpolation is done among each sample and every auxiliary sample by using Eq. (1), and at last n synthesized samples are produced.

$$x_{new,attr} = x_{i,attr} + rand(0,1) \times (x_{j,attr} - x_{i,attr}) \quad (1)$$

In Eq. (1), the $x_{new,attr}$ for $attr = 1, 2, \dots, d$ represents $attr - th$ attribute value in i th sample of the majority sample, the $rand(0,1)$ represents a random number between 0 and 1, the x_{ij} for $j = 1, 2, \dots, k$ represents j th nearest neighbor sample of x_i , the x_{new} is the new sample synthesized among j and x_{ij} .

1) *One-hot encoding*: One-hot encoding is called as the one-bit effective encoding. This technique utilizes N-bit status registers for encoding N states. Every state has an independent register bit and one bit is valid. This technique is a representation of categorical variables in binary vectors with the benefit which transforming sample dataset to develop which is easy for utilizing the ML, particularly in classification algorithm. This process effectively enhances the measuring speed and method's performance.

C. Feature Selection

The general procedure of numerous metaheuristic algorithms is same to each other. In the proposed procedure, initial population of algorithms is sorted and evaluated depended on its evaluation. Next, population is updated and reevaluated.

After repeating the necessary updating and evaluation process for population, the optimal solution is described.

The LBO is motivated by coordination movements of ladybugs to identify the position with much heat. For this process, initial population that has $N(0)$ ladybugs are taken and the last population contains $N(k_{max})$ ladybugs and optimum fitness function is determined. Then, the LBO modeling is processed in three phases.

1) *Population updation*: The initial population includes $N(0)$ ladybugs that are positioned randomly in search area depended in uniform distribution. The ladybugs population is estimated with determined fitness function and sorted. Next, population moved to position with much heat in accordance with coordination movement. Because of the ladybug's nature which always moved in coordination with a swarm of ladybugs when searching for an appropriate position, the ladybugs follow each other by signals emitted through group members. Hence, much inclined to move towards it from ladybugs. In the proposed model, front ladybugs who have cable identify the position with more heat than others. For exploration and exploitation of the algorithm, the mutation phase is taken for certain individuals of the population that are randomly assigned to certain individuals in every iteration. However, at every phase of position update in population, its location in the search area is updated in accordance with other positions or mutation phases that are represented below.

2) *Updating the position of other ladybugs*: In every phase, entire positions of ladybugs are evaluated and updated. The old and new position of ladybugs are combined and optimal groups are selected in accordance with its fitness function values. The new population is assigned for updating and evaluating in following iteration. For updating every member of population in every iteration, another population member is chosen by utilizing the technique which is described. For instance, consider that goal is to update i th population of ladybug and j th population of ladybugs have selected for updating the member. Taken the location of i th ladybug in k th iteration is represented as $x(k)$. This ladybug moves in the outcome of three vectors for updating in $(k + 1)$ iteration moves a little towards j th ladybug and move in the direction of j th ladybug towards $(j - 1)$ th ladybug. To avoid local optima for movements of i th ladybugs and to maintain the balance between exploration and exploitation, the third direction is also taken, that is coefficient of their present position. All the determined movements are required to be multiplied through random values to sustain the random search. Moreover, the third movement that is assigned for avoiding the local optima is multiplied through the ratio of individual heat value to all heat values of the population. As an outcome, population members that are trapped in local optima have a chance to outflow local optima due to its high coefficient of third movement. The mathematical formula for the new position of i th ladybug is given as Eq. (2),

$$x_i(k + 1) = x_i(k) + rand \times (x_j(k) - x_i(k)) + rand \times (x_j(k) - x_{j-1}(k)) + rand \times |C_i|^{\frac{k}{N(k)}} \times x_i(k) \quad (2)$$

In equation (2), the C_i represents the same proportion of i th ladybird cost to total cost of entire ladybirds in k th iteration of developed algorithms. The mathematical formula for parameter value is measured by using Eq. (3),

$$C_i = \frac{f(x_i(k))}{\sum_{t=1}^{N(k)} f(x_t(k))} \quad (3)$$

The Roulette-wheel selection is assigned for selecting the j th ladybug is utilized for updating the i th ladybug location using Eq. (3). In the general equation, for choosing j th ladybug from $N(k)$ ladybugs, the distance between 0 and 1 is separated to $N(k)$ unequal phases. Every phase corresponds to one of ladybugs and length of every phase is inversely relevance to fitness function of respective ladybug. For ladybug with much optimum fitness function, length of respective phase is higher. Next, the random number among 0 and 1 is selected. In present phase, random number determined in that phase of separation is positioned. The respective ladybug of the chosen phase is selected as j th ladybug. This is clear that ladybugs with warmer positions have a high chance of being selected. The P vector respective to the population with $N(k)$ ladybugs are determined. The Roulette-wheel selection expected a represents input vectors like P and its mathematical formula is given as Eq. (4),

$$P = [P_1, P_2, \dots, P_{N(k)}], P_i = e^{-\beta \frac{f(x_i(k))}{f_{worst}}} \quad (4)$$

In Eq. (4), the β represents pressure coefficient in Roulette-wheel selection technique and f_{worst} represents worst value of fitness function for present iteration in the process of algorithm. The higher β , the optimal ladybugs of population have a good chance of being chosen in Roulette-wheel selection. This is clear that new location of i th ladybug is defined through outcome of three vectors r_1, r_2 and r_3 .

3) *Updation in accordance with mutation process*: Considering the mutation is updation process of the population is critical for exploration of unidentified phases of search area and escapes from local optima. The mutation phase in search area causes the maximum speed of algorithm. Therefore, updation technique of every position of the ladybug includes in accordance with other ladybugs and mutation is randomly defined. Considers the i th ladybug is mutated. The amount of decision variables of i th ladybug is mutated and its mathematical formula is given as Eq. (5),

$$n_m = round(n \times \mu_m) \quad (5)$$

In Eq. (5), the μ_m represents mutation rate and the n represents length of decision variable. Hence, n_m represents variables presented in n variables of i th ladybug is chosen randomly. Next, random variables in the feasible phase are replaced for choosing location of i th ladybug.

4) *Updating the number of population size*: In searching for warm place that is common for ladybugs to disappear and lost.

The ladybug moves away from annihilate and others because of cold. The mathematical methods for the annihilation of ladybugs in search are taken in LBO. The mathematical formula for the number of ladybugs in different phases is measured by using Eq. (6),

$$N(k + 1) = \text{round} \left(N(k) - \text{rand} \times N(k) \left(\frac{NFE}{NFE_{max}} \right) \right) \quad (6)$$

In Eq. (6), the NFE represents the number of function estimations and the NFE_{max} represents a maximum of NFE. Whether the amount of function evaluation is stopping criteria of LBO. Whether several iterations are a condition to terminate the algorithm. The mathematical formula for the ladybug in every iteration is given by using Eq. (7),

$$N(k + 1) = \text{round} \left(N(k) - \text{rand} \times N(k) \left(\frac{k}{k_{max}} \right) \right) \quad (7)$$

Fig. 2. Architecture of CNN-Bi-LSTM network.

In Eq. (7), the k represents iteration and the k_{max} represents maximum iteration.

5) *CL-LBO*: Enhanced non-linear LBO algorithm depended on Circle chaotic map and Levy flight process is introduced in the proposed work. Firstly, initialize the population by utilizing a circle chaotic map to maximize bee diversity. The integration of LBO and levy flight provides an algorithm with high capability in global exploration. Additionally, the non-linear adaptive weight operator is implemented for modifying the weight coefficient of bee following behavior in CL-LBO. The relationship between global exploration and local exploitation in the iteration process is effectively balanced. The chaotic values of actual circle operation are grouped in the range of [0.2, 0.5]. For making uniform chaotic value distribution, the mathematical method of the Circle chaotic mapping strategy is enhanced. The numerical expression for the circle chaotic map is given as Eq. (8),

$$x_{i+1} = \text{mod}(x_i + 0.2 - (0.5/2\pi) \sin(2\pi x_i), 1) \quad (8)$$

In Eq. (8), the x_i represents i th chaotic particle and the x_{i+1} represents $(i + 1)$ th chaotic particle. The frequency histogram and plot of the initial candidate solution of the circle chaotic mapping process.

a) *Levy flight*: The trajectory and movement of several little insects and animals in life have Levy flight characteristics. The insects and animals include flies and ants. Numerous animals in natural usage of Levy flight strategy are the essential path of foraging. The Levy flight is the process compatible with Levy distribution. The step size of the Levy flight is mixed and random with short and long distances that make it easy to search the huge scale and with unknown scope compared with Brownian motion. In the searching procedure, the Levy process utilized little steps for walking and long steps for jumping,

which allowed it for effective of local attraction points. Hence, in the random searching issue, numerous heuristic algorithms adopted this strategy for changing the iteration process that effectively supports the algorithm to get the influence of local attraction points. The mathematical formula for the strategy is given as Eq. (9),

$$L(s) \sim |s|^{-1-\beta} \quad (9)$$

In Eq. (9), the β in is range [0, 2], the s represents step size and the $L(s)$ represents the probability density of step size in accordance with Levy modeling.

6) *Fitness function*: For calculating the fitness value of generated CL-LBO agents, the Mean Square Error (MSE) fitness function is dependent on measuring the difference between original and predicted values through produced agents for training samples. The mathematical formula for MSE is in Eq. (10),

$$MSE = \frac{1}{n} \sum_{i=1}^n (y - \hat{y})^2 \quad (10)$$

In Eq. (10), the y describes the actual value, the \hat{y} describes the predicted value and the n describes a number of instances in the training set. From the CL-LBO algorithm, the 21 selected relevant features are given to the classification phase for further process.

D. Classification

The classification is performed by using the CNN-BiLSTM network. Initially, the architecture is developed for leveraging the advantages of CNN to filter and remove the noisy data and obtain substantial data from time series. The noisy data is eliminated by using dimensionality reduction. Hence, inappropriate data (noise) is not involved in minimized matrix. The significant data in the hidden interval is attained through employing the process of convolutional such as kernel matrix or filter passed by input matrix, various characteristics based on

kernel and that obtained the hidden data. Next, the design is developed to pull the ability of the Bi-LSTM setup for modeling and forecasting both short and long-term dependencies in temporal data. In this design, the input data is processed twice, concurrently from left to right and from right to left. Both context readings are combined into results and provide much more comprehensive data of information context than unidirectional LSTM. Here, The CNN functions as the encoder that identifies and extracts features from the input data, whereas the BiLSTM assists as the decoder, analyzing historical dependencies in the data stream. The CNN block contains the CNN layer, pooling layer, and flattening process. The output from the CNN block is conceded as input to the BiLSTM block. This block contains a BiLSTM layer, a dropout layer, and a dense layer. The convolutional and pooling layers are included to mine features from the data, operating it in a matrix format. Fig. 2. demonstrates the design of CNN-BiLSTM network architecture.

1) *CNN block*: The convolution and pooling layer are used to filter the incoming information for extracting significant data from the matrix. The convolution process is done through a convolution layer among input and small matrices known as filters and kernels. Generally, numerous filters are included as sliding windows with a certain height and width. These filters slide across the input matrix with a specified stride, assigning a convolution operation to each overlapping sub-region of the matrix. This procedure produces a convoluted matrix that bags a specific feature of the original input matrix. By using multiple convoluted features, the technique delivers a more specific representation of the input matrix. Consider H as an input matrix, the I represents kernel matrix and the indices m and n signifies the rows and columns of the subsequent matrix, respectively and its mathematical formula is given as Eq. (11) and Eq. (12),

$$R[m, n] = (H \cdot I)[m, n] \quad (11)$$

$$= \sum_j \sum_k I[j, k] \cdot H[m - j, n - k] \quad (12)$$

The convolution layer utilizes the ReLU activation function, which is a majorly used activation function. Its primary benefit is that it does not activate all neurons at the same time and transforms entire negative values to 0. Because of this, ReLU has high computation efficiency. The ReLU is six times quicker than other activation functions like tanh. The mathematical formula for the ReLU activation function is given as Eq. (13),

$$f(X) = x^+ = \max(0, x) \quad (13)$$

The max pooling layer will follow the convolution layer and turns as a sub-sampling technique to decrease the dimensions of the convolution matrix. It attains this by removing definite values while retaining key features recognized by each filter. For every patch of the matrix, it chooses the heights value, creating new matrices that helps as condensed notations of the convolution matrices. This pooling procedure improves the robustness of the technique. Finally, the pooling layer is tracked by a flattening procedure, which opens the values into a one-dimensional format to make the input for next layers.

2) *Bi-LSTM block*: The next segment of the method contains the BiLSTM module, which encompasses the BiLSTM network, a dropout layer, and a dense layer. To know the model and the performance of the BiLSTM network initially describes the one-directional LSTM network. The LSTM network is one of its kind of RNN, At this juncture they utilizes cyclic links in its inner layers which give short-term memory for the method and the capability to process thesequential data. Therefore, classical RNN have a problem known as the long-term dependencies issue, the poor memory of previous data as the neurons number increases. The LSTM network resolves this issue by storing relevant data by entire LSTM units in a type of conveyor belt called memory cell. Every LSTM unit includes a memory cell and 3 gates that regulate data flow by determining which data is forgotten and which one remains in the method. This is primary for learning the long-term dependencies through LSTM and resolving issues. In LSTM, three gates are there such as forget, input, and output gates. The parameters of the network used are Adam optimizer, softmax activation function, 50 epochs, and 64 batch sizes.

In forget gate, the sigmoid function is employed for data included in the present input X_t and past hidden state $(h - 1)$. This process is represented as f_t returned the value among 0 and 1 which represents the percentage of data. The input gate considers data from present data and past hidden states and is passed by the second sigmoid function, transforming the data to values between 0 and 1. The similar data passed by the tanh function that supports to regulation of the network returns the value among -1 and 1. Next, the sigmoid result i_t is multiplied through \tanh result for determining which data is significant to keep. Now, there is enough data for executing the cell state. Initially, past cell state is multiplied through forget result. Next, result of input gate is included, updates cell state with new values considered relevance through network. The outcome of these two processes is provided as new cell state. At last, the output gate is provided, which determines value of following hidden state. Initially, data from present input and from past hidden state passed by third sigmoid function. Next, new cell state passes by tanh function. The mathematical formula for LSTM cell is given from Eq. (14) to Eq. (19),

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (14)$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (15)$$

$$\hat{C}_t = \tanh(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (16)$$

$$C_t = f_t \cdot C_{t-1} + i_t \cdot \hat{C}_t \quad (17)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (18)$$

$$h_t = o_t \cdot \tanh(C_t) \quad (19)$$

In Eq. (14) to Eq. (19), the σ describes the sigmoid function, the \tanh describes the hyperbolic tangent function, x_t is input data, the h_t is a hidden state in time, the W_x and b_x are the weight matrix and bias vector. The Bi-LSTM network includes forward and backward LSTM networks. The forward LSTM utilizes the input sequence of values ranging from $t - k$ to t

when backward LSTM utilizes input sequence range from t to $t - k$. The result of the BiLSTM layer is attained by using Eq. (20),

$$Y_t = \sigma(\vec{h}_t, \vec{h}_t) \tag{20}$$

Here, the sigmoid function unified the results of unidirectional LSTM networks. The BiLSTM utilizes the dropout method for regulating the over-fitting.

IV. EXPERIMENTAL RESULTS

The performance of developed technique is simulated by using python environment and used system configurations are i5 processor, 8 GB RAM and windows 10 (64 bit) The evaluation metrics utilized to assess performance are accuracy, recall, f1-score, precision and AUC/ROC. The True Negative (TN) and True Positive (TP) values represents the ability of classifier method for predicting the presence or absence of sepsis in patient. The False Negative (FN) and False Positive (FP) values represents incorrect predictions identified by methods. The accuracy represents ratio of actual positive observations to total number of positive instances. The recall executes whole fraction of positive instances. The f1-score calculates mean of precision and recall. The mathematical formula for evaluation metrics is given from Eq. (21) to (24),

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \times 100 \tag{21}$$

$$Precision = \frac{TP}{TP+FP} \times 100 \tag{22}$$

$$Recall = \frac{TP}{TP+FN} \times 100 \tag{23}$$

$$F1 - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \times 100 \tag{24}$$

In Table I, the feature selection algorithm CL-LBO is evaluated with different metrics on the MIMIC III dataset. The Honey Badger Optimization (HBO), Ant Colony Optimization (ACO), and Squirrel Search Algorithm (SSA) are the other feature selection algorithms considered to evaluate performance of CL-LBO algorithm. The developed feature selection algorithm reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% AUC when compared with other algorithms.

TABLE I. PERFORMANCE OF FEATURE SELECTION ALGORITHM

Feature selection algorithms	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	AUC (%)
HBO	94.75	94.60	94.50	94.55	94.85
ACO	95.65	95.50	95.40	95.45	95.70
DSSA	96.85	96.70	96.60	96.65	96.90
CL-LBO	99.85	99.60	99.50	99.55	99.95

In Table II, the performance of classifier is evaluated using whole feature set with different metrics on the MIMIC III dataset. The RNN, Gated Recurrent Unit (GRU), and LSTM are the other classifiers considered to evaluate the performance of the CNN-LSTM network. The classifier with whole feature set reached 96.45% accuracy, 96.58% precision, 96.98% recall, 96.51% f1-score, and 96.45% AUC.

TABLE II. PERFORMANCE OF CLASSIFIER USING WHOLE FEATURE SET

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	AUC (%)
RNN	93.50	93.60	93.70	93.65	93.40
GRU	94.80	94.85	94.90	94.87	94.75
LSTM	95.60	95.65	95.75	95.70	95.50
Proposed CNN-LSTM	96.45	96.58	96.98	96.51	96.45

In Table III, the performance of the classifier is evaluated using selected relevant features with different metrics on the MIMIC III dataset. The RNN, GRU, and LSTM are the other classifiers considered to evaluate the performance of the CNN-LSTM network. The classifier with selected relevant features reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% AUC when compared to other classifiers.

TABLE III. PERFORMANCE OF CLASSIFIER USING SELECTED RELEVANT FEATURES

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	AUC (%)
RNN	95.45	95.20	95.10	95.15	96.10
GRU	96.85	96.50	96.40	96.45	97.20
LSTM	97.75	97.60	97.50	97.55	98.10
Proposed CNN-LSTM	99.85	99.60	99.50	99.55	99.95

In Table IV, the performance of the activation function is evaluated with various metrics on the MIMIC III dataset. The Tanh, Rectified Linear Unit (ReLU) and sigmoid are other activation functions considered to evaluate the performance of the softmax function. The classifier with the softmax function reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% AUC when compared to other activation functions.

TABLE IV. PERFORMANCE OF ACTIVATION FUNCTION

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	AUC (%)
Tanh	94.58	94.40	94.30	94.35	94.68
ReLU	95.75	95.60	95.50	95.55	95.89
Sigmoid	96.85	96.70	96.60	96.65	96.99
Softmax	99.85	99.60	99.50	99.55	99.95

In Table V, the performance of the optimizer is evaluated with various metrics on the MIMIC III dataset. The AdaGrad, Adamax, and Stochastic Gradient Descent (SGD) are other optimizers considered to evaluate the performance of the Adam optimizer. The classifier with Adam optimizer reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% AUC when compared to other optimizers.

TABLE V. PERFORMANCE OF OPTIMIZER

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	AUC (%)
AdaGrad	94.53	94.47	94.32	94.39	94.61
Adamax	95.76	95.63	95.54	95.58	95.82
SGD	96.87	96.73	96.65	96.69	96.91
Adam	99.85	99.60	99.50	99.55	99.95

In Fig. 3, the accuracy vs. epoch graph is represented for the developed classifier. The training accuracy, after some epochs, is close to 100% represents that the classifier has learned to classify the data accurately. The validation accuracy enhances the training process, represents that it stabilizes the model during training. There is only a small gap between training and validation accuracy representing that the model has better generalization capability and there is no overfitting. The validation accuracy stabilizes the model without any drop. In Fig. 4, the loss vs. epochs is represented for the developed classifier. The training loss continues to decline plateaus at less value, representing that the model has minimized errors in training data. The validation loss minimized in the initial phase represents that the method maximizes its performance on unseen data. After certain epochs, validation loss stabilizes the model. There is less gap between training and validation loss, which represents that the model is not overfitting.

Fig. 3. Accuracy vs. Epochs.

Fig. 4. Loss vs. Epochs.

A. AUC/ROC Curve

By using the AUC/ROC curve, Fig. 5 represents the connection between True Positive Rate (TPR) and False Positive Rate (FPR) by utilizing the AUC/ROC function. The ROC determines the ability of classifier for differentiating their

classes. While AUC is substantial, the prediction of the method is correct.

B. Comparative Analysis

In Table VI, performance of the implemented technique is compared to existing techniques like LSTM [18], Ensemble ML [19], and CNN-Bi-LSTM [23] with different metrics on MIMIC III dataset. The CNN extracts the significant features from relevant features, focused on spatial-based relationships. Then, the Bi-LSTM layer captured the sequential dependencies and temporal relationships in patient histories that are essential to understand the treatment results. CL-LBO integrates the circle chaotic map and Levy flight process in traditional LBO to select relevant features for classification. The proposed technique reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% AUC when compared to existing techniques.

Fig. 5. ROC curve.

TABLE VI. COMPARATIVE ANALYSIS

Methods	Dataset	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	AUC (%)
LSTM [18]	MIMIC III	-	77.00	79.87	78.24	85.01
Ensemble ML [19]		92.80	-	-	-	83.00
CNN-Bi-LSTM [23]		99.15	99.16	99.15	98.85	-
Proposed technique		99.85	99.60	99.50	99.55	99.95

C. Discussion

The outcomes of the proposed technique are evaluated with the MIMIC III dataset using various evaluation metrics. The developed CL-LBO feature selection algorithm is evaluated with different optimization algorithms of HBO, ACO, and DSSA. The developed classifier is evaluated with default features and with selected relevant features. Additionally, the performance of the classifier is evaluated with an activation function and different optimizers. Moreover, the performance of the developed technique is compared with LSTM [18],

Ensemble ML [19], and CNN-Bi-LSTM [23] with different metrics on the MIMIC III dataset. These existing algorithms have drawbacks such as overfitting issues occurring during the process because of the irrelevant features present in the data fit, dimensionality issues, struggled to interpret the pattern of features and the missing values presented in the data caused an overfitting problem. To mitigate these drawbacks, the CNN-Bi-LSTM method for personalized treatment analysis uses EHR data. The CNN extracts the significant features from relevant features, focused on spatial-based relationships. Then, the Bi-LSTM layer captured the sequential dependencies and temporal relationships in patient histories that are essential to understand the treatment results. The SMOTE technique is employed in the pre-processing phase to balance the classes in data. The CL-LBO integrates the circle chaotic map and Levy flight process in traditional LBO to select relevant features for classification. This process improves the process of personalized treatment with high classification accuracy. By using this technique, in this article, the developed technique reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% AUC when compared to existing techniques.

V. CONCLUSION

The traditional mortality risk prediction techniques effectively extract the data in longitudinal EHRs that ignore the difficult relationship and interactions among variables and time dependency in longitudinal records. In the proposed work, the CNN-Bi-LSTM method is developed for personalized treatment analysis using EHR data. The MIMIC III dataset is used in this article and the data is balanced by using SMOTE and the balanced data is encoded by using the one-hot encoding technique. Then, the relevant features from pre-processed data are selected by using the developed CL-LBO algorithm. Here, the circle chaotic map and levy flight process are integrated with the traditional LBO algorithm to enhance the search capability and convergence rate of the algorithm. Then, the CNN extracts significant features from relevant features, focused on spatial-based relationships. Then, the Bi-LSTM layer captured the sequential dependencies and temporal relationships in patient histories that are essential to understand the treatment results. The proposed method reached 99.85% accuracy, 99.60% precision, 99.50% recall, 99.55% f1-score, and 99.95% AUC when compared to LSTM. In the future, different DL-based will be used to further enhance the process of personalized treatment analysis.

Abstract— In the digital age, online shoppers heavily depend on product feedback and reviews available on the corresponding product pages to guide their purchasing decisions. Feedback is used in sentiment analysis, which is helpful for both customers and company management. Spam feedback can have a negative impact on high-quality products or a positive impact on low-quality products. In both cases, the matter is bothersome. Spam detection can be done with supervised or unsupervised learning methods. We suggested two direct methods to detect feedback orientation as 'spam' or "not spam", also called "ham," using the deep learning model and the LSI (Latent Semantic Indexing) technique. The first proposed model uses only dense layers to detect the orientation of the text. The second proposed model uses the concept of LSI, an effective information retrieval algorithm that finds the closest text to a provided query, i.e., a list containing spam words. Experimental results of both models using publicly available datasets show the best results (89% accuracy and 89% precision) when compared to their corresponding benchmarks.

Keywords—Spam; supervised learning methods; unsupervised learning methods; LSI; dense; deep learning

I. INTRODUCTION

The company is shocked when there is a complaint about their high-quality product. How did they find the complaint? Obviously, from the webpage concerned with the feedback of the customer, if a complaint is factual, it can be found in a product; if not, these types of comments degrade the product's star rating or sentiment score. Before sentiment analysis, these comments or reviews should be filtered. These reviews can be considered spam. Researchers have done much work to separate spam from the given reviews [1]. Most spam is delivered as emails, so there should be a strong filter to detect the spam.

Classifiers trained using a combination of features are more effective than those learned using only one type of feature [2]. A machine learning algorithm has also been investigated for filtering spam emails [3]. Most supervised machine learning algorithms are not suitable for spam detection due to the lack of features or words that indicate the hint that the review is actual or not [4]. Although Support Vector Machines (SVM) is an important and powerful technique for detecting reviews as spam. However, for big data, the efficiency of SVM is reduced because of the many data processing complexities [5].

Unsupervised learning algorithms has also been investigated for spam detection such as clustering algorithm [6] has proved that these algorithms are well suited for spam clustering. A novel unsupervised text mining model was developed and integrated into a semantic language model for detecting untruthful reviews [7]. Unsupervised methods are currently unable to match the performance of supervised learning methods, research is limited, and results are inconclusive, warranting further investigation [8].

Deep learning is a new trend, through which classification can be done in a very descent way. This learning can be learned automatically, without predefined knowledge explicitly coded by the programmers. Although previous work which has been done on spam detection is based on bidirectional LSTM (Long Short Term Memory) [9] a resource hunger technique. The proposed work develops a simple sequential dense layer's model using scaling of data to detect spam text and found best performance, which require less computational processing.

The supervised learning approach employs training data based on labels ("ham" and "spam") sent to a classifier, which detects "spam" using this learned corpus. Unsupervised learning, on the other hand, necessitates the discovery of rules and patterns from supplied data. Both techniques need a significant amount of work, but, in this case, the suggested methodology does not necessitate the use of training data or rules. Latent Semantic Indexing was used to filter the "spam" and "ham" (not-spam), reviews. LSI is simple to comprehend, execute, and employ. When compared to other approaches, the results of LSI are far more precise and speedier. It seeks the most representational, rather than the most discriminative, qualities for document representation [10] The manually compiled Spam Words (SW) list includes 956 entries, which might be used in spam reviews [11]. This study makes the following key contributions:

- A method has been suggested to make a sequential deep learning model with scaling that can tell when text is spam.
- A method is proposed to detect reviews as either "spam" or "ham" using Latent Semantic Indexing (LSI) with an Automatic Generated Query (AGQ) that serves as a major input to LSI. Hence, there is no need to provide a separate query.

A. Significance of the Study

This study emphasizes the critical importance of maintaining the integrity of customer feedback systems by filtering spam reviews. Genuine feedback is essential for ensuring accurate product sentiment scores and star ratings. By addressing the issue of spam detection, the research highlights how filtering out non-factual reviews can prevent negative impacts on product perception. Additionally, the study advances the field by exploring modern machine learning and deep learning techniques, demonstrating their potential to improve spam detection accuracy while overcoming computational challenges in handling large datasets. These innovations contribute to more reliable systems for analyzing customer reviews.

B. Key Contributions

The study makes several notable contributions to the field of spam detection. First, it proposes a sequential deep learning model with data scaling, which not only achieves high performance but also requires significantly lower computational resources compared to traditional methods. Second, it introduces the integration of Latent Semantic Indexing (LSI) with an Automatic Generated Query (AGQ), enabling the filtering of "spam" and "ham" reviews without the need for a predefined query. This innovation simplifies the detection process and improves efficiency. Lastly, the research demonstrates that LSI outperforms existing approaches by providing more precise and faster results, focusing on representational features for document representation rather than solely discriminative ones.

C. Research Gap

Despite substantial progress in spam detection, significant gaps remain in existing methodologies. Supervised machine learning methods often fail to achieve optimal results due to insufficient features or words that indicate the authenticity of reviews. Additionally, Support Vector Machines (SVM), though recognized as a powerful technique, face reduced efficiency when dealing with large datasets because of data processing complexities. While unsupervised learning methods, such as clustering algorithms, have shown potential, their performance is still inferior to supervised techniques, and research in this area is limited and inconclusive. Furthermore, current deep learning approaches, such as bidirectional LSTMs, are resource-intensive, highlighting the need for simpler yet effective models that can be practically implemented for large-scale spam detection tasks.

II. RELATED STUDY

Deep learning has gained significant prominence across various research domains, including applications in natural image processing [12], electricity theft detection [13], diagnosis of human and animal diseases [14][15], and sentiment analysis [16].

For Sentiment analysis, filtration of objective reviews not necessary but also filtration of spam reviews will also increase the accuracy of sentiment analysis. With respect to sentence polarity, there is lot of studies which is about determining the sentiment orientation of a review or comment [17]. Sentiment orientation means that a positive opinion will be an exact

positive, and a negative opinion will be an exact negative [18]. The view, assessment or feeling of a person towards a product, aspect [19], or service is known as a sentiment. Most of the work on reviews or blogs is based on sentiment analysis based on binary classification i.e. positive or negative classes [20]. As text classification is done using machine learning based [21], deep learning based [22] and score based approaches [23]. Training data is used in machine learning and deep learning approaches while different rules based on attributes and entities are used in other methods. To find polarity of opinion based on aspects, lot of researches has been done to extract aspect and aspect based sentiment analysis [24]. Besides machine learning, lot of sentiment analysis work has also been done by deep learning from different dimensions [25]. Work of [26] used word2vec to reduce number of parameters by considering of bag of words in deep learning. Authors [27] investigated the impact on performance over multiple runs by changing hyper parameters for convolutional neural network. OpCNN model based on k-max pooling was presented in [28] by considering word order problem of Chinese. Sentiment classification on tweets to detect tweet as either positive or negative was implemented by LSTM neural network [29].

Different research techniques are available for spam filtration such as filtering Technique based on content [30], spam filtering technique based on heuristic rules [31], spam filtering technique based on previous likeness [32], adaptive spam detection [33] etc. There are many proposed email classification techniques, which detect the spam emails such as case-based technique [9], ANN (Artificial Neural Networks) [34] and SVM (Support-Vector-Machine) [35]. For this purpose LSI (Latent Semantic Indexing) is better [36]. For clustering purpose LSI has also been considered to filter unwanted emails in Chinese and English [37][38].

III. PROPOSED METHODOLOGY

Generally, tasks of proposed work consist of different steps shown in Fig. 1. Manual Feature extraction work excluded in deep learning because it is responsibility of deep learning model-training to handle it automatically.

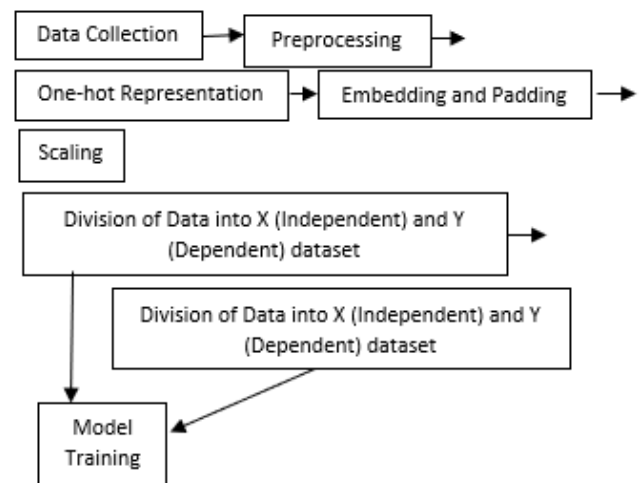

Fig. 1. Steps of proposed work.

The used dataset consists of two columns; one contains text, and the other has a decision as spam or ham [2]. The data set contains 20718 texts, of which 10369 are spam and 10349 are ham. The preprocessing process removes irrelevant opinions, duplicate words, extra spaces, and stop words. It also involves tokenization, converting all words into lower cases, contractions, stemming, and lemmatization. The one-hot encoding process is used to convert categorical variables into a form that the machine can easily read. The one-hot encoding performs better in prediction. The proposed work package from TensorFlow. The next step is embedding and padding, where a large sparse vector represents each word with a score (representing an entire vocabulary), and padding adds zeros at the end or start of the sequence to make the sample the same size as the sequence. The proposed work uses embedding and pad sequences packages from TensorFlow.

To train proposed model, we require training data which is a complete set of dependent (Y) and independent (X) variables, across a model can learn. Proposed model has used train_test_split package for this purpose.

A. Model Training on Dataset

This model consists of only dense layers. The name indicates that layers are fully connected through the neurons in a network layer. Each neuron in a layer collects input from all the neurons that appeared in the previous layer, thus, they are densely attached. Fitting of model is shown in Fig. 2.

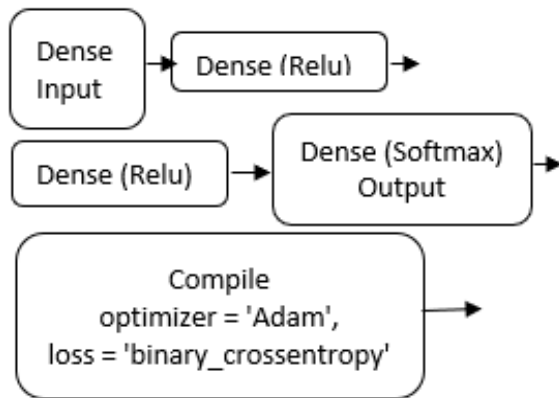

Fig. 2. Model structure of dense layers.

B. Training of Model without Scaling

A simple sequential model has been created with four dense layers. First and last layers are input and output layers and remaining two are hidden layers. Description of model is given below in Table I.

TABLE I. SUMMARY OF MODEL

Layer (type)	Output Shape	Param #
dense (Dense)	(None, 400)	160400
dense_1 (Dense)	(None, 20)	8020
dense_2 (Dense)	(None, 15)	315
dense_3 (Dense)	(None, 1)	16
Total params: 168751		
Trainable params: 168751		
Non-trainable params: 0		

First three layers are using activation function 'relu' and output layer is using activation function 'softmax'. A 'binary_crossentropy' loss function is used, because 'spam' or 'ham' is a binary problem. Proposed model has been compiled using 'adam' optimizer, because we are using batch option and there also there is neither 'vanishing gradient problem' will occur nor 'dead neurons' will occur. Different attempts have been made to achieve high accuracy based on epoch and batch size. But achieved 69% at 100 epochs with 40 batch-size shown in Table II.

TABLE II. ACCURACIES OF MODEL (WITHOUT SCALING) WITH DIFFERENT ATTEMPTS

Epochs	Batch Size	Accuracy
10	40	0.63
50	40	0.68
100	40	0.87
100	100	0.86

C. Training of Model with Scaling

Here scaling concept is used to enhance the accuracy.

To normalize the range of independent variables, scaling feature is used. Its basic purpose is to convert the whole independent variables into range 0 to 1, because this range is very suitable for deep learning models [39].

TABLE III. ACCURACIES OF MODEL (WITH SCALING) WITH DIFFERENT ATTEMPTS

Epochs	Batch Size	Accuracy
10	40	0.80
50	40	0.88
50	100	0.84
Previous Work[28]	0.82	0.82

Different attempts have been made to achieve high accuracy based on epoch and batch size, shown in Table III. And achieved 88% at 100 epochs with 40 batch-size. Remaining measures of confusion matrix are given below in Table IV. Performance of model with respect to loss and with respect to accuracy is shown in Fig. 3.

Fig. 3. Performance of model with respect to Loss and Accuracy.

TABLE IV. DIFFERENT MEASURES OF CONFUSION MATRIX

Proposed Work	Precision	Recall	F1-score
0	0.93	0.83	0.87
1	0.80	0.92	0.86
weighted avg	0.87	0.88	0.87
Previous Work[28]	0.82	0.78	0.80

opCNN [28] achieved 84% accuracy while proposed deep learning model achieved 88% accuracy. Furthermore, since deep learning models require a lot of resources such as Keras, TensorFlow, Activation Functions, etc., further supervised and unsupervised machine learning models also earn unsatisfactory accuracy for spam detection. In contrast, the proposed LSI technique is comparatively effective.

IV. SPAM DETECTION USING LSI

Major inputs to the proposed model are "reviews" and "automatically generated queries" (AGQ). After processing through LSI, the output is measured in terms of scores. A decision based on these scores will be made, i.e., whether the review is spam or not. Here, the classification category is "spam" and "ham" (not spam). The decision depends upon the pivot value; in the result section, we made different attempts to find the pivot value. If the score of each review is greater than the pivot value, it will be considered "spam," otherwise "ham." The whole process is depicted in Fig. 4.

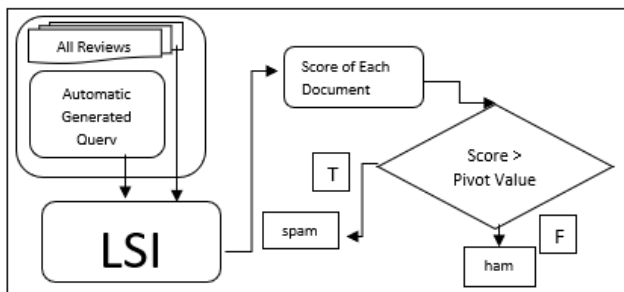

Fig. 4. Proposed framework.

A. Latent Semantic Indexing

The LSI proposed by [40] is an efficient information retrieval algorithm. In LSI, there is a cosine similarity measurement between the coordinates of a document vector and the coordinates of a query vector. The result of cosine similarity measurement "1" means the document is 100% and the result of cosine similarity measurement "0" means the

document is very far from a query. A feature matrix from the frequencies of all words in the documents and query will be formed, and singular value decomposition (SVD) will be calculated from this matrix. Singular value decomposition (SVD) can be used to determine the coordinates of the documents and the query. Three matrices, S, V, and U can be easily extracted from SVD. The document coordinates will be determined from S and V as depicted in the algorithm shown in Fig. 5. Finally, a cosine similarity function is applied to these coordinates to find the texts that best match the spam query [41]. Based on LSI techniques algorithm for proposed work is shown in Table V.

TABLE V. ALGORITHM FOR SPAM DETECTION USING LSI

Function LSI (AllReviews, AGQ)
1. Matrixf: Frequency Matrix from AllReviews
2. Matrixq: Query Matrix from AGQ from List of Spam words and Reviews
3. V, S, U = numpy.linalg.svd(Matrixf)
4. UK = Rank 2 Approximation of U
5. VK = Rank 2 Approximation of V
6. SK = Rank 2 Approximation by taking two columns and two rows of S
7. CoorR: Each row of V relates to Coordinates of a Review
8. Query Coordinates: Coorq = (Matrixq)TUKSk-1
9. Find dot product of Coorq with each document coordinates CoorR
10. $U_{x=1}^m(CoorR, Coorq) = \frac{\sum_{i=1}^n CoorR(i) * Coorq(i)}{\sqrt{\sum_{i=1}^n (CoorR(i))^2} \sqrt{\sum_{i=1}^n (Coorq(i))^2}}$
11. Return (Score of all Documents)
End Function

B. Preprocessing

First of all, it is very necessary to remove noise from the reviews, Eq. (1), Eq. (2), Eq. (3) and Eq. (4) are used to filter the reviews based on stop words and negations.

$$R = U_{x=1}^n R_x \quad (1)$$

$$C(x) = U_{i=1}^n R_i \quad (2)$$

$$FC(x) = U_{i=1}^n \{Antonyme(C_i), \text{ if } C_{i-1} \notin Negations\} \quad (3)$$

$$FC(x) = U_{i=1}^n \{T_i, \text{ if } T_i \notin StopW\} \quad (4)$$

where $x = 1, 2, 3...n$, StopW means stop words, R represents the total number of reviews, C(x) represents the chunks of the xth reviews, and FC(x) represents the filtered chunks of the xth reviews.

C. AGQ (Automatic Generated Query)

All reviews I and a list of spam words (SW already identified in the introduction) are major inputs for AGQ. The intersection of chunks of each review and spam words (SW) will be determined. Then this list will be updated with AGQ as a union. If a chunk does not belong to SW, then it will be checked in the dictionary (WordNet). If this chunk is not present in the dictionary, then it will also be added in AGQ as a union. Because sometimes spam reviews also contain meaningless words. Since the motive of the proposed model is to find those reviews close to spam words, i.e., AGQ, the whole process is shown in Fig. 6, and the creation of AGQ has been portrayed in Eq. (5) and Eq. (6).

Fig. 5. Process for generating automatic query.

$$AGQ = \bigcup_{x=1}^n \{FC(x)_i, \bigcup_{i=1}^n. \text{if } FC(x)_i \in SW \quad (5)$$

$$AGQ = AGQ \text{ UNION } \bigcup_{x=1}^n \{FC(x)_i, \bigcup_{i=1}^n. \text{if } FC(x)_i \neq SW \text{ AND } FC(x)_i \neq \text{WordNet} \quad (6)$$

where $x = 1, 2, 3 \dots n$ and $FC(x)_i$ means i th words of x th review. AGQ contains those words from all reviews which belongs to SW (spam words) and those which does not belong to wordnet dictionary.

D. Scoring

Already we have determined $FC(x)$ and AGQ. Now Eq. (7) will find the score of each review $FC(x)$ with spam-query AGQ.

$$LSI(\text{Score})_x = \bigcup_{x=1}^n (LSI_x(FC(x), AGQ)) \quad (7)$$

Decision

If LSI score is greater than pivot value, it means review is ‘spam’ because it is closest with spam query otherwise considered as ‘ham’. Following equation Eq. (8) is used for filtering purpose.

$$R_{\text{decision}}(x) = \bigcup_{x=1}^n \begin{cases} \text{spam}_x, & \text{if } (LSI(\text{Score})_x) > \text{Pivot Value} \\ \text{ham}_x, & \text{else} \end{cases} \quad (8)$$

V. EXPERIMENTAL RESULTS AND DISCUSSIONS

The SMS Spam Collection is a set of SMSs tagged messages that have been collected for SMS Spam research [42]. It consists of column v1 and v2. Column v1 contains 5,574 English messages with label ‘ham’ and ‘spam’ and column v2 contains the text of message. The sample listing of the said datasets is presented in Table VI.

TABLE VI. SAMPLE SMS FROM DATASET

v1	v2
ham	Absolutely wonderful – silky and sexy and comfortable
ham	This dress is perfection! So pretty and flattering.
Ham	Super cute and comfy pull over. Sizing is accurate. Material has a little bit of stretch.
Ham	Loved this top and was really happy to find it on sale!
Spam	100 dating service call 09064012103 box334sk38ch
spam	FREE entry into our 250 weekly competition just text the word WIN to 80086 NOW 18 T&C www.txttowincouk
spam	XXXXMobileMovieClub To use your credit click the WAP link in the next txt message or click here httpwap xxxmobilemovieclubcom?n=QJKGIGHJJGCBL
spam	500 New Mobiles from 2004 MUST GO Txt NOKIA to No 89545 & collect yours today From ONLY 1 www.4tbiz 2optout 08718726270150gbpmtmsg18

A confusion matrix [43] is formed from the four outcomes produced as a result of binary classification. A binary classifier predicts all data instances of a test dataset as either ‘spam’ or ‘ham’. This classification (or prediction) produces four outcomes -true spam (TS), -false spam (FS), -true ham (TH) and -false ham (FH).

Here, in start 0.7 was considered as pivot value, then achieved accuracy was 84%, at pivot values 0.8 & 0.9 accuracy was 88% while at 0.99 accuracy was 54%. So, 0.8 or 0.9 can be considered as pivot value as shown in Fig. 7. Graphs of Confusion matrices at different scores in Fig. 6, also predict that values greater or equal to 0.8 and less or equal to 0.9 can be considered as pivot value.

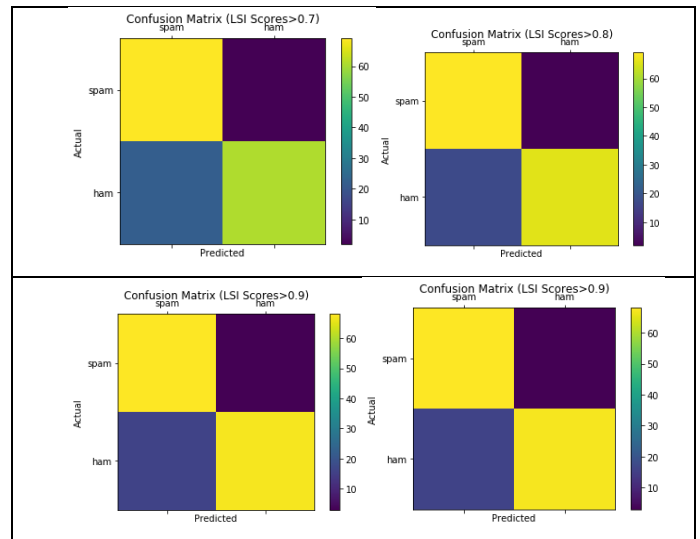

Fig. 6. Confusion matrices at all selected scores.

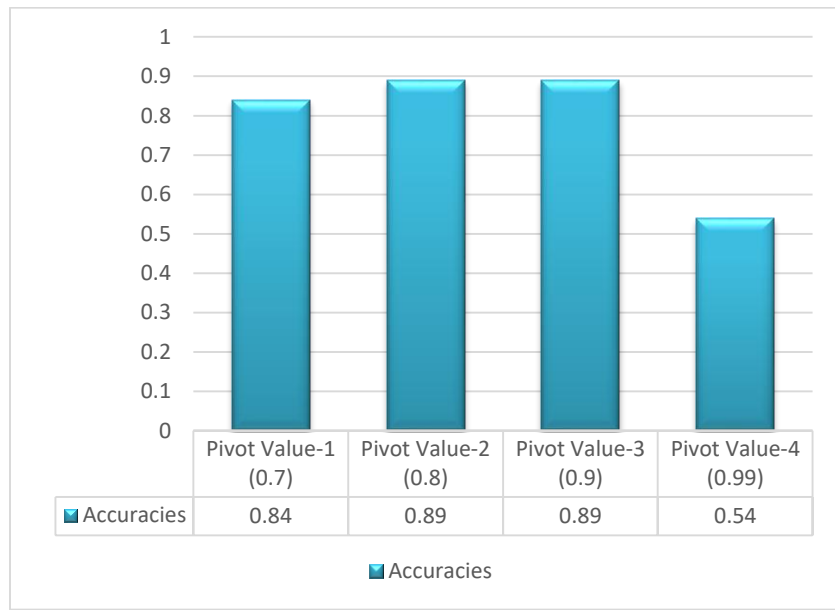

Fig. 7. Accuracies at different scores.

Table VII shows some of sampled documents based on proposed method to detect text as ‘ham’ or ‘spam’ using LSI-score greater than pivot values 0.8 and 0.9.

TABLE VII. SAMPLE OF DOCUMENTS WITH LSI SCORES GREATER THAN 0.8 AND 0.9

S. No	Reviews	LSI Score	Actual	Detected Based on Score > 0.8	Detected Based on Score > 0.9
1	d[0]	0.99982	Ham	Spam	spam
2	d[1]	0.337082	Ham	Ham	ham
3	d[2]	0.492025	Ham	Ham	ham
4	d[3]	0.491148	Ham	Ham	ham
5	d[4]	0.989738	Ham	Spam	spam
6	d[5]	0.551706	Ham	Ham	ham
7	d[6]	-0.18123	Ham	Ham	ham
8	d[7]	-0.21559	Ham	Ham	ham
9	d[8]	0.271523	Ham	Ham	ham
10	d[9]	0.431423	Ham	Ham	ham
20	d[82]	0.975451	Spam	Spam	spam
21	d[83]	0.976627	Spam	Spam	spam
22	d[84]	0.976538	Spam	Spam	spam

Now at detected pivot values, proposed model achieved 0.89 precision and 0.88 recall as shown in Table VIII.

TABLE VIII. STATISTICAL RESULTS AT DIFFERENT PIVOT VALUES

Pivot Values	Class	Precision		Recall		F1-Score
0.8	Ham	0.97	0.80	0.80	0.80	0.87
	Spam	0.80	0.80	0.97	0.80	0.88
	Avg	0.89	0.80	0.88		0.88
0.9	Ham	0.96		0.81		0.88
	spam	0.81		0.96		0.88
	avg	0.89		0.88		0.88

Recently accuracies of supervised learning approaches have been increased, while unsupervised approaches are still working on increasing the efficiency. Because major used source are spam words, which are not only present in spam-text while also in ham-text. Table IX is showing that proposed model gained high performance with respect Supervised, Unsupervised, Combined and Active Learning.

TABLE IX. COMPARISON WITH DIFFERENT APPROACHES

Methods	Precision	Accuracy
Supervised Learning Methods	49%	78%
Unsupervised Learning Methods	42%	80%
Combined Approach	64%	83%
Adaptive Resonance Theory (ART)	75%	89%
Active Learning	87%	88%
Proposed Work	89%	89%

VI. CONCLUSION

Spam is a serious issue that is not just annoying to the end-user but also financially damaging and security risks. In this paper, state-of-the-art models and LSI model were experimented against the task of detecting spam emails. To validate the generalization capabilities of the proposed method, its experimental results have been compared with CNN and OPCNN models. CNN achieved 82% and opCNN achieved 84% accuracy while proposed deep learning model achieved 88% accuracy. Although accuracy of proposed model is less than the accuracy of another base line whose accuracy is 96% (Spam with Deep Model). But this work uses bidirectional LSTM, which is computationally expensive and also uses reviews with sequence length less than 300 with dataset length 5000. Proposed work has been implemented on

20718 lengths of dataset also containing reviews with length more than 300.

Another less computationally expensive proposed model has been implemented using LSI concept to detect ‘spams’ from given data. The major theme of this work is to avoid laborious work for detecting patterns and making rules and implementation from machine learning methods. Based on the experimental results through confusion matrix, it found that results generated from the proposed method show a significant improvement from existing techniques related not only to precision and accuracy, but also to recall and f1-score which are 88% shown in Table IX. Fig. 8 shows that the proposed work provides better results than previous approaches.

Fig. 8. Comparison of proposed LSI work with alternative approaches.

VII. LIMITATIONS AND FUTURE WORK

This study demonstrates significant progress in spam detection; however, certain limitations remain that open avenues for future research. The dataset used in this study comprises 5,574 English-language messages, which, while effective for the current analysis, limits the generalizability of the findings. Future work could focus on increasing the dataset size and incorporating data from other languages to improve model robustness and applicability across diverse linguistic contexts. Additionally, the automatic query process in this work relies on the WordNet dictionary. While effective, the exploration of other dictionaries or lexical resources could enhance the flexibility and accuracy of the query generation process. The pivot value of 0.7, achieved with the current dataset size, may vary with larger or smaller datasets, suggesting the need for further investigation into optimal pivot values for datasets of different sizes.

ACKNOWLEDGMENT

This project was funded by the Deanship of Scientific Research (DSR) at King Abdulaziz University, Jeddah, under

Grant No. 94-830-1442. The authors, therefore, acknowledge with thanks DSR for technical and financial support.

A Deep Learning for Arabic SMS Phishing Based on URLs Detection

Sadeem Alsufyani, Samah Alajmani

Department of Information Technology, College of Computers and Information Technology, Taif University, Taif, Saudi Arabia.

Abstract—The increasing use of SMS phishing messages in Arab communities has created a major security threat, as attackers exploit these SMS services to steal users' sensitive and financial data. This threat highlights the necessity of designing models to detect SMS messages and distinguish between phishing and non-phishing messages. Given the lack of sufficient previous studies addressing Arabic SMS phishing detection, this paper proposes a model that leverages deep learning models to detect Arabic SMS messages based on the URLs they contain. The focus is on the URL aspect because it is one of the common indicators in phishing attempts. The proposed model was applied to two datasets that were in English, and one dataset was in Arabic. Two datasets were translated from English to Arabic. Three datasets included a number of Arabic SMS messages, mostly containing URLs. Three deep learning models—CNN, BiGRU, and GRU—were implemented and compared. Each model was evaluated using metrics such as precision, recall, accuracy, and F1 score. The results showed that the GRU model achieved the highest accuracy of 95.3% compared to other models, indicating its ability to capture sequential patterns in URLs extracted from Arabic SMS messages effectively. This paper contributes to designing a phishing detection model designed for Arab communities to enhance information security within Arab communities.

Keywords—Phishing; URL phishing; SMS phishing; GRU; BiGRU; CNN

I. INTRODUCTION

Cybersecurity refers to one or more of the following three things as a set of security measures and other activities aimed at first protecting computer hardware and networks, related hardware and software, as well as the information they contain and transmit, including software and data. This protection includes protection against attacks, disruptions, or threats. Second, the status or quality of protection from threats. Third, expand the scope for public discussions aimed at the process of implementing and improving those activities and quality [1]. Therefore, a cyberattacks is an attempt by attackers to infiltrate information systems at the level of an individual or organization in a deliberate way. A cyberattack aims to disrupt the resources of the target victim's system by stealing his confidential information and disrupting the main functions of his system. After that, network assaults come in several types. The attackers search for the type of ransom after carrying out network attacks on organizations. This threat is not limited only to large companies but also includes medium and small organizations. The reason lies in the fact that medium and small organizations do not have high-level security measures, and this makes attackers also focus on medium and small companies and find out their vulnerabilities [2]. Cyberattacks have become widespread in our daily lives, affecting government institutions,

from the economic side to trade, as well as banks and hospitals. Malware, phishing, social engineering attacks, botnets, password attacks, man-in-the-middle attacks, and other types of cyberattacks are among the most prevalent types [3]. Therefore, preserving private data against social engineering threats such as phishing attempts is the primary objective of information security. To protect private data from these types of social engineering assaults, consumers, website developers, and experts have been particularly concerned about security vulnerabilities in every company [4]. Social engineering refers to the tactic of manipulating individuals to obtain unauthorized access to data. This method falls under the broader category of information security. People are the weakest point, the focal point of most organizations because they pose a threat to their organizations. If sensitive information about the organization is compromised, it falls into the wrong hands. Organizations usually use advanced security measures to minimize the chances of unauthorized individuals accessing that information. An organization needs to prevent its employees from succumbing to social engineering attacks. Most humans react emotionally, so they are more vulnerable than machines most often. The greatest threat that an organization poses to having sensitive information is human, not technical protection because they constitute the essence of an organization. As a result, attackers have concluded that using a human to get unauthorized access to an organization's data and communication technology infrastructure is more straightforward than attempting to breach security mechanisms [5]. Phishing attacks are prevalent in social engineering attacks. The attacker entices users to send fake messages such as winning a prize, sending a message from a fake social media account, or hacking passwords. These messages seem to be an order from a trusted entity, such as a bank disclosing information to achieve financial gain. Social engineering techniques with some fraudulent tactics are ingeniously used to entice users to acquire information. Fraudulent methods can connect to a message, phone, or fake email. Scammers send fake messages to many internet users. These attacks target people who lack sufficient knowledge about cyberattacks and their security. They are led to assume that the messages are from a legitimate organization. The core goal of phishing attacks is to search for the vulnerabilities of the intended user. The attacker always finds ways to make the targeted victims visit a phishing site. By designing fake messages in a way that makes them appear reliable, including a link that transports them to this fraudulent site, it is easy to target and deceive victims [4]. Phishing includes several types of attacks targeting users, such as voice phishing, email phishing, SMS phishing, website phishing, and social media phishing [6]. SMS phishing, also referred to as smishing, is a kind of phishing

that utilizes short message service (SMS) technology. This type of phishing exploits SMS messages on smartphones. The smishing happens in two major methods. The first is when an SMS message is sent from a reliable source, such as a bank or system administrator. The second way occurs when the victim receives an SMS message containing private content, such as an account block or stolen identity. Subsequently, the victim will be sent to a deceptive website or contacted via phone number to confirm their data [7].

Therefore, with the increasing prevalence of phishing attacks received through SMS, research targeting Arabic-speaking communities to detect Arabic SMS messages containing URLs remains insufficient. This gap poses a significant security threat to Arabic-speaking users and can lead to the loss of sensitive personal and financial data. While existing phishing detection solutions have targeted SMS messages in English, Arabic SMS messages based on URLs are relatively unexplored. The significance of this paper lies in its contribution to addressing the gap in phishing detection models specifically designed for Arabic SMS messages containing URLs. By leveraging deep learning models, this paper aims to mitigate the risk of phishing threats faced by Arabic-speaking users. Thus, the key challenges addressed in this work are: (1) how can URLs extracted from Arabic SMS messages be analyzed to determine whether the message is phishing or non-phishing? (2) what is the appropriate deep learning model for effective classification and detection of Arabic SMS phishing based on URLs? Accordingly, the paper proposes a proposed model to bridge this gap through several contributions. First, provide a model for detecting Arabic SMS messages based on URLs and determine the type of message, whether phishing or non-phishing, depending on the analysis of the URL contained in the Arabic SMS message. Second, we created a dataset of 16,521 Arabic SMS messages, which helps provide a dataset for future research in the field of Arabic SMS detection, then extracted and analyzed URLs from Arabic SMS using deep learning models: CNN, BiGRU, and GRU. Finally, evaluate and compare the performance of models for deep learning in the classification of Arabic SMS messages based on URLs, whether phishing or non-phishing. The results of this paper can benefit financial institutions and telecommunications service providers by providing an effective tool to protect sensitive data and reduce financial losses caused by SMS-based phishing threats.

The rest of this paper is organized as follows: Section II provides a review of related works. Section III presents the methodology. Section IV presents the results and discussions. Finally, Section V presents the conclusion and future work of the paper.

II. RELATED WORKS

In this section, we review several related works on SMS phishing detection with deep learning and machine learning methods.

Mishra & Soni, 2023 [8] presented a two-stage SMS phishing detection model. The first stage was URL validation domain checking. The second stage was SMS classification. The URL domain was checked, and SMS classification categorized the messages' text content and extracted some useful features. Finally, the system used a backpropagation algorithm to classify

the messages and was evaluated using the SMS dataset. The results showed an accuracy rate of 97.93%.

Mishra & Soni, 2020 [9] suggested the Smishing Detector model, which detected SMS phishing messages with minimal false positives. The model analyzed content through a Naïve Bayes classification. Four modules provided this model: APK Download Detector, SMS Content Analyzer, URL Filter, and Source Code Analyzer. The results demonstrated an overall accuracy rate of 96.29%.

Agrawal et al., 2023 [10] developed a model to detect fraudulent SMS. The model's design involved two phases: the first phase used a hybrid model for SMS message classification, whereas the examination of URLs was the second phase. Random Forest, Naïve Bayes, and Extra Tree classifiers were used in their hybrid model. The results showed that the Random Forest, Multinomial Bayes classifier, and Extra Tree classifier achieved 96.25% accuracy and 99.38% precision.

Prasanna Bharathi et al., 2021 [11] applied two well-known algorithms to categorize spam SMS: a Support Vector Machine and Naïve Bayes. 96.19% accuracy percent was achieved by the Naïve Bayes algorithm. 98.77% accuracy was achieved with the Support Vector Machine algorithm approach.

Wu et al., 2018 [12] introduced a novel approach to detecting SMS phishing utilizing oversampling technology to enhance feature selection and improve accuracy. They utilized three types of features, namely symbol features, subject features, language query features, and word calculation (LIWC). They applied one of the oversampling methods called the Adasyn adaptive synthetic sampling approach. The BPSO binary particle swarm was used to analyze the three feature types and then select the optimal combination of all the features. The experiment was performed on the Almeida et al. dataset, which contained 5574 messages in English. They used the Random Forest classification algorithm to obtain detection findings. The findings showed that the two methods offered by ADASYN and BPSO achieved the highest accuracy rate of 99.01%.

Oswald et al., 2022 [13] proposed an intent-based approach that efficiently handled the filtering of SMS spam, textual and semantic features of SMS messages were created using 13 pre-defined intent labels. Multiple pre-trained NLP models were applied to generate textual contextual embeddings. For the pre-defined labels, intent scores were computed. Several supervised learning classifiers were used to filter spam or ham. The results showed that the DistilBERT+SVM (Poly) model performed well with an accuracy (98.07%), precision, and recall (~0.97).

Tuan et al., 2023 [14] evaluated five algorithms on three various Vietnamese datasets: Support Vector Machine, Random Forests, Naïve Bayes, Convolutional Neural, and Long Short-Term Memory to evaluate the efficiency of spam detection in Vietnamese SMS. The results showed that the CNN and LSTM, supported by the transformer PhoBERT model, were more effective than the conventional models for machine learning. The LSTM model obtained the greatest accuracy of 97.77%, on the Vietnamese full-dialect dataset, while the CNN and PhoBERT models showed a high accuracy of 95.56% on the non-diacritic Vietnamese dataset.

The University of Baghdad et al., 2021 [15] suggested a new approach for detecting SMS spam that focused on improving the binary particle swarm based on fuzzy rule selection. Initially, the significant features of the SMS spam dataset were extracted. Then, a fuzzy collection of rules was produced using the features that were extracted. The most reliable fuzzy rules, which lowered complexity and enhanced model performance, were finally chosen using a binary particle swarm. The findings demonstrated that the suggested model achieved an F-measure of 94.6%, recall of 98.8%, accuracy of 98.5%, and precision of 90.8%.

Amir Sjarif et al., 2020 [16] proposed a method for classifying spam SMS messages through a variety of techniques for data mining. Algorithms such as Multinomial Naïve Bayes, Support Vector Machine, Naïve Bayes, and K Nearest Neighbor with different values of K = 1, 3, and 5 were trained and assessed using the dataset from the UCI machine learning repository. Each algorithm's performance was compared to determine which best-fitting classifier performed better in terms of accuracy, error, processing time, kappa statistics, and the lowest number of false positives. The SVM algorithm outperformed the other classifiers in terms of accuracy, with an average accuracy of 98.9% for detecting and labeling spam text messages. In terms of the error coefficient, the KNN algorithm had the highest error with K = 3 and K = 5, while SVM had the lowest error, followed by the Multinomial Naïve Bayes algorithm.

Uddin et al., 2024 [17] addressed spam detection using a transformer-based Large Language Models (LLMs) approach that was refined and optimized. The benchmark SMS spam dataset was used to detect spam messages. The imbalance problem in the data was mitigated by implementing methods for data augmentation, such as back translation. In addition, calculated the scores of positive and negative coefficients that detected and explained the transparency of the fine-tuned model in detecting spam messages using explainable artificial intelligence (XAI) techniques. Traditional models for machine learning and transformer-based models' performances were compared. The experiments showed that the refined and optimized BERT model with the variant model RoBERTa obtained the highest accuracy of 99.84%.

Ali et al., 2023 [18] proposed a new model for detecting SMS spam using (MLP) Multiple Linear Regression to extract seven features from each message. The message detection process was entrusted to the feature weight and Extreme Learning Machine (ELM). MLR was used to weigh the seven extracted features. The SMS was classified as spam or ham by ELM. The suggested model was evaluated for recall, F-measure, precision, and accuracy, and showed scores of 98.7%, 95.9%, 93.3%, and 98.2%, respectively.

Sonowal, 2020 [19] identified the greatest collection of features for the detection of SMS phishing by employing four ranking algorithms: Spearman's rank correlation, Pearson rank correlation, Kendall rank correlation, and Point biserial rank correlation, along with machine learning algorithms. According to the findings, the AdaBoost classifier provided the highest accuracy. When compared to other correlation algorithms, the Kendall rank correlation algorithm provided the best accuracy. Therefore, this finding proved that the ranking algorithm could

provide 98.40% accuracy and 61.53% reduction in feature dimensions.

Giri et al., 2023 [20] suggested various deep neural networks for spam SMS classification. The Tiago dataset was used, and some steps were taken to start with preprocessing and then feeding these preprocessed messages into two different models of deep learning (Long Short-Term Memory Network with Convolution Neural Network) with simple architectures. Word embedding techniques (BUNOW and GloVe) were combined to enhance the two basic architectures' accuracy with the deep learning models. The results after using the two-word embedding techniques in text categorization, demonstrated an accuracy of 98.44% with the CNN LSTM BUNOW model.

Table I summarizes the previous studies that contributed to SMS phishing message detection solutions.

TABLE I. COMPARISON OF PREVIOUS STUDIES ON SMS PHISHING USING MACHINE LEARNING AND DEEP LEARNING DETECTION

III. METHODOLOGY

The proposed methodology is based on the process of detecting Arabic SMS phishing messages based on URLs, which uses models for deep learning such as GRU, CNN, and BiGRU to examine and categorize these Arabic SMS messages. The process begins with the step of identifying SMS messages that contain URLs, which are often indicative of phishing tries.

Once identified, the Arabic SMS messages are classified based on the presence of URLs for further analysis. This analysis step is fundamental for understanding the type of content of Arabic SMS messages, with a focus on the URLs embedded within the Arabic SMS messages. The methodology evaluates patterns and characteristics that are usually related to phishing, such as suspicious domains or malicious URLs. The cleaned dataset experiences an inspecting process, where each Arabic SMS message is evaluated for the presence of a URL. After that, the URLs are extracted from the Arabic SMS messages and passed to the URL-based classification. The classification step utilizes models for deep learning, such as GRU, CNN, and BiGRU, to process and analyze the extracted URL dataset. These models were selected for their capability to capture sequential patterns, spatial features, and contextual dependencies, which are important in the process of detecting phishing tries.

Fig. 1 illustrates the overall methodology proposed in this paper, illustrating the steps in classifying Arabic SMS messages based on URLs based on the proposed models for deep learning.

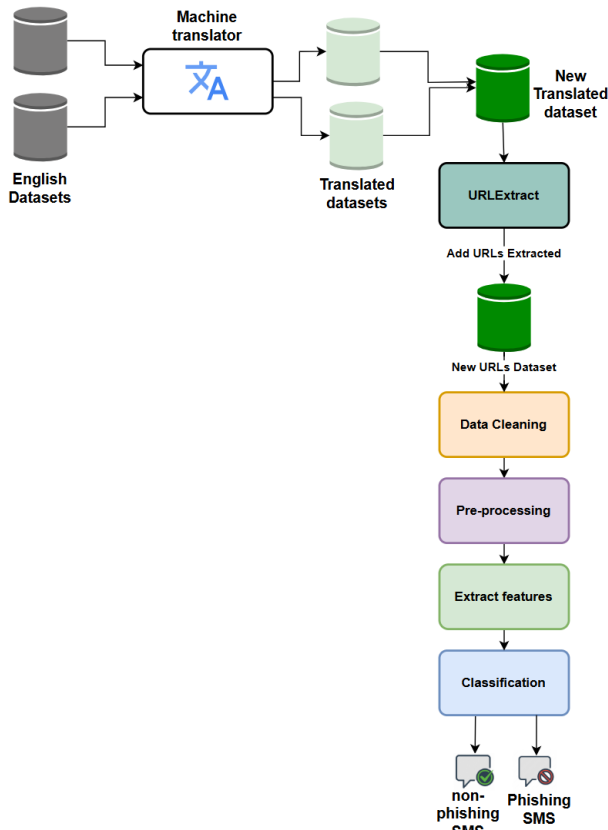

Fig. 1. The process of proposed Arabic SMS messages based on URLs detection.

The steps are explained as follows:

A. Step 1: SMS Messages Dataset and Translation

The datasets used in this process were obtained from three different sources: the first dataset from [21], the second dataset from the UCI Repository [22] and the third dataset from Kaggle [23]. The two sources contain [22] and [23] English datasets, which necessitate the use of machine translation, such as Google Translate, to convert SMS messages from English to Arabic.

This translation is necessary for the process of checking whether the SMS messages contain URLs or not, to classify Arabic SMS messages based on the type of the URL, whether it is phishing or non-phishing. SMS messages can be automatically translated using machine translation, a technology built on artificial intelligence systems.

Google Translate was utilized in our proposed model to translate two English datasets into Arabic. The file upload feature in Google Translate allowed us to translate the content of both datasets completely and comprehensively and convert them into Arabic to support the proposed model. After the translation process was successful, we downloaded the translated dataset file. This step is essential to support our proposed model to ensure the availability of an Arabic SMS dataset. We translated the two datasets [22] and [23] that were originally in English and then translated into Arabic using Google Translate.

B. Step 2: Merge the Dataset

This step creates a dataset containing a large number of SMS messages translated into Arabic, some of which include URLs in their content. The merging process was according to some steps:

1) *First step:* Column data type is identical. This rule indicates that the first column represents the label of each Arabic SMS message, whether it is non-phishing or phishing. The second column contains the text of the Arabic SMS message, which is of type text.

2) *Second step:* The number of columns is identical. This rule indicates that all the datasets have the same number of columns. Our dataset contains only two columns: The first column represents the label of the Arabic SMS message, categorizing it as either non-phishing or phishing. The second column represents the text of the Arabic SMS message.

After the merging process, we reached three datasets comprising a total of 16,521 Arabic SMS messages. Most of these messages include URLs, which will achieve our goal of detecting Arabic SMS phishing messages based on the URL they contain.

C. Step 3: URLs Dataset

We collected a dataset of URLs to support expanding the URL dataset to train and accurately classify deep learning models. The auxiliary dataset was collected from [24], which includes 20,000 URLs, categorized as either non-phishing or phishing. The dataset consists of two columns: the first column represents lists of the URLs, and the second column represents the type of URLs, whether non-phishing or phishing.

D. Step 4: URL Extraction and Merging Dataset

The dataset is processed by the URL classification component, starting with the extraction of URLs from the SMS messages using the URLExtract library, a Python library that extracts URLs from Arabic SMS messages. All URLs extracted from Arabic SMS messages are saved and merged with a new dataset [24] containing a large number of URLs. Merging these URLs with the new URL dataset enhances the expansion of the

URL dataset, which improves the accuracy of the training and classification using deep learning models.

E. Step 5: Data Cleaning

After completing the previous step of preparing the URL dataset, the next step is cleaning the dataset. Any unnecessary elements are removed. The cleaning process includes the following:

1) *Removing duplicate URLs*: This refers to eliminating duplicate entries where the same URL or the same rows are repeated.

2) *Removing null values*: This refers to removing cells that contain null or missing values, i.e., the URL is not provided or the label is missing.

F. Step 6: Pre-Processing Process

Preprocessing is an important step in improving data quality. This directly contributes to enhancing the accuracy and capability of the model. By thoroughly preparing the dataset, we ensure that it enhances feature extraction, helping the model provide more reliable and precise classification results.

One of the fundamental preprocessing tasks includes dealing with the URLs within the dataset. This includes various tasks that contribute to normalizing and standardizing URLs to remove inconsistencies and duplication. Key steps include:

1) *Converting characters to lowercase*: All characters in URLs are changed to lowercase. This helps to avoid handling the same URL with different letter cases as individual entities.

For example: ForExample.com

After the conversion process, it forexample.com

2) *Removal of numbers*: Any numeric values within URLs that are not appropriate to the classification task are removed to streamline the dataset and reduce noise.

3) *Removal of extra spaces*: Unnecessary spaces within URLs are removed to ensure consistency in data formatting and prevent errors during processing and classification.

4) *Removal of symbols*: Many of the elements that do not significantly contribute to the classification process are removed to avoid unnecessary complexity.

By performing these preprocessing steps, the dataset becomes more accurate, allowing the model to focus on the important aspects of the data. This approach lays the foundation for a more effective feature extraction process, leading to enhanced performance in data classification.

G. Step 7: Extraction Features

Features are extracted using lexical features. Lexical features are derived from the textual and structural components of URLs. The motivation for using lexical features is to rely on the appearance of a URL to determine the type of phishing or non-phishing. These features are commonly used in phishing detection systems and machine models to classify URLs as phishing or non-phishing [25].

1) *Features based on length*: These features depend on the length of many URL components:

a) *URL length*: Refers to the overall number of characters in the URL, including the protocols, hostname, path, queries, and any additional parameters.

b) *Path length*: Refers to the length of the URL path, which indicates a specific page or resource on the site.

c) *Hostname length*: Refers to the length of the part of the URL that identifies the server or site.

d) *Top-level domain length*: Refers to the top-level domain's length, indicating the type or geographic region of the site.

e) *First directory length*: Refers to the length of the first directory, which is the first part after '/' in the path.

2) *Features based on count*: Refers to the dependence of features on the number of times certain patterns appear within URLs. They are useful for analyzing URLs and discovering patterns that indicate phishing or non-phishing.

a) *Number of dashes*: Refers to the number of '-' symbols repeated within the URL. Its significance lies in identifying suspicious URLs that use many dashes in the process of dividing long parts of the URL.

b) *Number of @ in the URLs*: Refers to the total number of '@' symbols that appear. Its importance lies in the fact that some URLs contain the '@' symbol, which indicates attempts to redirect users within the URL.

c) *Number of question marks*: Refers to the count of '?' symbols in the URL. These are often used for creating queries, which attackers may use to collect user data.

d) *Number of percentage signs*: Refers to counting the number of '%' symbols in the URL, often used in encoding. Attackers may exploit this to hide parts of the URL or include special characters.

e) *Number of HTTP instances*: Count how many times HTTP appears in the URL. Some phishing URLs misuse HTTP to redirect the user.

f) *Number of HTTPS instances*: Count how many times HTTPS appears in the URL.

g) *Number of WWW instances*: Count the repetitions of WWW in the URL.

h) *Number of dots in the URLs*: Refers to the count of '.' dots. Phishing URLs may use excessive dots in domain names to appear similar to legitimate sites.

i) *Number of equal signs in the URLs*: Refers to the number of '=' symbols repeated in the URL, often used in query transactions. A high frequency may indicate data-collection attempts.

3) *Features based on binary*: Malicious URLs often use techniques to obscure their true identity, complicating detection by users and security systems. One popular tactic is replacing domain names with IP addresses (IPv4 or IPv6).

For example, instead of using a domain like: <http://forexample.com/phishing>

An attacker may use an IPv4 address and convert it to:
<http://196.168.1.1/phishing>

This is for the case where the domain name changed from the identifiable to IPv4.

As for if the attacker uses an IPv6 instead of using the domain name.

For example: <http://forexample.com/phishing>

and converted it to: <http://2001:db8:ff00:42:8329/phishing>

Attackers exploit users' limited familiarity with IP addresses compared to domain names, making them more likely to click on these URLs without suspicion. However, using IP addresses instead of domain names can bypass detection systems that rely on domain-based pattern analysis, enhancing phishing or malware distribution capabilities.

H. Step 8: Classification Process

After completing the previous steps, which include dataset splitting, model building, and classification, the process is as follows:

1) *Data splitting*: The dataset is split into two groups:

a) *Training Group*: Refers to the data used to train the models.

b) *Testing Group*: Refers to the data used to evaluate the performance of the model.

c) The dataset is split with 70% for training and 30% for testing.

2) *Model building*: In our proposed model, the datasets are passed to different deep learning models, namely GRU, CNN, and BiGRU.

a) *CNN model*: This model is known as Convolutional Neural Network. In terms of data, it was developed as a method to handle it in various types. The structure and operation of the brain's visual cortex served as the model's inspiration [26].

b) *BiGRU model*: This model stands for Bidirectional GRU and contains a two-layer reinforcement neural network. This design allows the two layers of the output layer to fully integrate the contextual data of the input data sequence at every moment. The basic concept behind this model is that the input sequence is processed by both the forward and backward neural networks [27].

c) *GRU model*: It is a type of RNN, GRU short for Gated Recurrent Units. It contains GRU units, which are used for deep learning, particularly effective in processing sequential data for applications [28].

3) *Classification*: URLs are classified using deep learning models such as GRU, CNN, and BiGRU.

The results then indicate that this URL-based SMS is either phishing or a non-phishing message.

I. Step 9: Model Evaluation

The model evaluation process plays a crucial role in the evaluation performance of three models for deep learning in our proposed model. The evaluation process is based on four major criteria: precision, accuracy, recall, and F1 score. These criteria

are essential to providing a comprehensive understanding of the model's ability to classify Arabic SMS messages containing URLs as non-phishing or phishing. By analyzing these criteria, we can determine the model that performs best in the particular task of detecting phishing in Arabic SMS. Following is an explanation of each of the four evaluation criteria:

First, the parameters used to evaluate the performance of models for deep learning are explained:

- **True Positive (TP)**: Represents the number of URLs that were correctly classified as positive, indicating that phishing URLs were correctly classified as phishing.
- **True Negative (TN)**: Represents the number of URLs that were correctly classified as negative, indicating that non-phishing URLs were correctly classified as non-phishing.
- **False Positive (FP)**: Represents the number of URLs that were incorrectly classified as positive category, i.e., non-phishing URLs that were incorrectly classified as phishing.
- **False Negative (FN)**: Represents the number of URLs incorrectly classified as belonging to the negative category, i.e., phishing URLs that were incorrectly classified as non-phishing.

Next, we will explain the four evaluation criteria:

- **Accuracy**: This metric is used to evaluate the quality of classification. It considers the rate of correct classification across all categories, rather than the distribution of the dataset. It reflects the number of correct predictions made by the model, whether the classifications are positive, i.e., identifying URLs as phishing, or negative, i.e., identifying URLs as non-phishing. A higher accuracy value indicates that the model is effectively classifying Arabic SMS messages based on URLs. It is represented by the following Eq. (1):

$$\text{Accuracy} = \frac{\text{TN} + \text{TP}}{\text{TN} + \text{FP} + \text{FN} + \text{TP}} \quad (1)$$

- **Recall**: It represents the percentage of actual phishing URLs correctly identified by the model. It indicates the model's ability to detect all phishing instances. A higher recall rate means that the model is less likely to ignore phishing URLs. It is represented by the following Eq. (2):

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \quad (2)$$

- **F1 Score**: It refers to the average between precision and recall, providing an integrated view of model performance, commonly used to assess the performance of the model in unbalanced classification problems. It is represented by the following Eq. (3):

$$\text{F1 Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (3)$$

- **Precision**: It refers to correct positive predictions, i.e., URLs that were correctly identified as phishing. An

increase in precision indicates the model is less likely to mistakenly classify non-phishing URLs as phishing. It is represented by the following Eq. (4):

$$\text{Precision} = \frac{TP}{TP+FP} \quad (4)$$

IV. RESULTS AND DISCUSSIONS

A. Results

In this section, we present the performance of the proposed models for detecting Arabic SMS messages based on URLs. Three deep learning models were utilized: CNN, BiGRU, and GRU. Fig. 2 illustrates a comparison of the deep learning models' accuracy.

Fig. 2. Accuracy performance of three models for deep learning: CNN, GRU, and BiGRU.

Fig. 2 provides a detailed comparison of the performance of the three models proposed for deep learning in our proposed model for detecting Arabic SMS messages based on URLs. The classification focuses on determining whether an Arabic SMS message is phishing or non-phishing based on the type of URL extracted. The comparison was based on the accuracy achieved by each model. The GRU model demonstrates the best performance among the three models, achieving a superior accuracy rate of 95.33%. This high accuracy focuses on the GRU model's ability to effectively learn temporal dependencies in sequential data, making it particularly suitable for analyzing datasets. While the BiGRU model ranked second with an accuracy rate of 94.42%, slightly lower than the GRU model, the BiGRU's bidirectional architecture enables it to capture context in both the forward and backward directions. The CNN model achieved an accuracy rate of 93.59%, which, although lower than the GRU and BiGRU models.

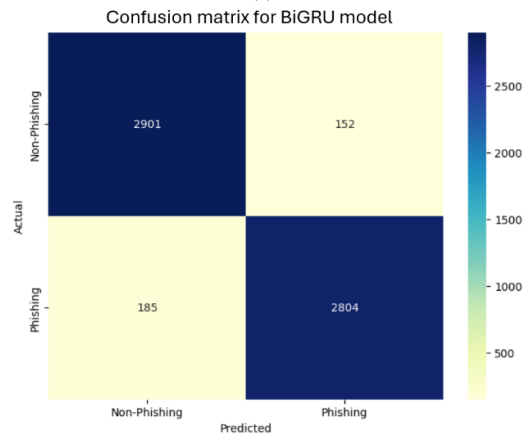

From the graph in Fig. 2, it is clear that the GRU model outperforms the others in terms of accuracy. This superior performance demonstrates that the GRU is the most effective for the task of classifying Arabic SMS messages based on URLs in this paper.

Fig. 3, presents a confusion matrix for the three deep learning models, CNN, BiGRU, and GRU, used to classify Arabic SMS messages based on URL type as phishing or non-phishing. Confusion matrix (a) shows the performance of the CNN model. It correctly classified 2709 phishing URLs as phishing and correctly classified 2946 non-phishing URLs as non-phishing. However, it incorrectly classified 107 non-phishing URLs as phishing and incorrectly classified 280 phishing URLs as non-phishing.

Confusion matrix (b) displays the performance of the BiGRU model, which correctly classified 2901 non-phishing URLs as non-phishing and correctly classified 2804 phishing URLs as phishing. Nevertheless, it incorrectly classified 152 non-phishing URLs as phishing and incorrectly classified 185 phishing URLs as non-phishing. Confusion matrix (c) illustrates the results of the GRU model, which correctly classified 2892 non-phishing URLs as non-phishing and correctly classified 2868 phishing URLs as phishing. However, incorrectly classifying 161 non-phishing URLs as phishing and incorrectly classifying 121 phishing URLs as non-phishing.

TABLE II. A COMPREHENSIVE COMPARISON OF THE THREE PROPOSED MODELS, NAMELY CNN, BiGRU, AND GRU

Models	Evaluation Metrics %				Time (seconds)	
	Accuracy	Precision	Recall	F1 score	Train	Test
CNN	93.59	96.20	90.63	93.33	8.19	0.70
GRU	95.33	94.68	95.95	95.31	32.16	1.33
BiGRU	94.42	94.86	93.81	94.33	190.69	3.27

Based on Table II, a comprehensive comparison of the three proposed models, namely CNN, BiGRU, and GRU, is presented. This comparison is based on several performance metrics, namely precision, F1, recall, and accuracy, as well as two additional elements: the time required for training and testing. This analysis helps to understand the strengths and weaknesses of each model. The GRU model achieved the highest accuracy rate compared to the other two models at 95.33%, which indicates its strength in classification. While the precision was 94.68%, slightly lower than that of the CNN model, the recall was 95.95%, the highest among the models, indicating the model's ability to detect Arabic SMS phishing messages more effectively based on the URLs. The F1 score also had the highest result at 95.31%, reflecting a strong and balanced performance. As for the training and testing time performance, the training time was 32.16 seconds, and the testing time was 1.33 seconds, which is slower than CNN but faster than BiGRU. The BiGRU model followed, achieving a lower accuracy than GRU, at 94.42%, which is the average between the two models, CNN and GRU. It achieved a recall percentage that was lower than GRU but higher than CNN, which was 93.81%. As for the precision, it was also average among the other models, at 94.86%, slightly lower than GRU. The F1 score was 94.33%. In terms of training and testing time, it achieved a training time of 190.69 seconds and a testing time of 3.27 seconds, making it the slowest model in both training and testing, due to the processing of texts in both directions, i.e., reading from beginning to end and from end to beginning. The last model was the CNN model, which achieved an accuracy rate of 93.59%, which is a reasonable performance, but it is lower compared to the other models. In terms of recall, it was the lowest, indicating that it may miss some phishing messages, which was 90.63%. However, in terms of precision, it was the best among the other models, indicating that the model avoids false positives to a large extent, with a precision of 96.20%. The F1 score was 93.33%, reflecting a balanced result between precision and recall. In terms of training and testing time, the training time was 8.19 seconds, and the testing time was 0.70 seconds. This indicates that it is the fastest model in both training and testing among all the models, making it an excellent choice for practical applications in time-critical situations.

B. Discussions

The results indicate that GRU is the most effective model for classifying Arabic SMS messages based on URLs, due to its high accuracy, recall, and balanced F1 score. This makes it able to learn temporal dependencies perfectly in analyzing sequential data, such as Arabic SMS messages containing URLs. Although

the BiGRU model was able to capture context from both directions, forward and backward, it took longer training and testing time, which can limit its practical application in real-time scenarios. While the CNN model was the fastest, it performed poorly in accuracy and recall, making it an excellent choice when speed is considered. Therefore, the results emphasized that the GRU model outperforms both BiGRU and CNN in terms of accuracy and recall, which indicates its strength in processing sequential data and provides the best balance between speed and classification, making it the superior choice for detecting Arabic SMS phishing messages based on URLs. However, the CNN model provided the fastest training and testing time, but it provided the lowest recall, indicating a higher probability of missing Arabic SMS phishing messages based on URLs, which reduces its reliability compared to GRU and BiGRU. The BiGRU model is an alternative solution when the demand for contextual understanding is high. Therefore, based on the paper's goal of choosing a deep learning model that provides better accuracy in detecting Arabic SMS phishing messages based on URLs, the GRU model is the most suitable choice that achieves this goal based on the previous results.

V. CONCLUSION AND FUTURE WORK

The rapid development and widespread use of smartphones have led to an increase in cyber-attacks targeting smartphones, including SMS phishing attacks. This paper proposed a model for detecting Arabic SMS phishing messages based on URLs using models for deep learning, namely GRU, CNN, and BiGRU. We assessed the performance of these deep learning models and compared their accuracy and effectiveness in the detection process. The GRU model illustrates superior performance with an accuracy of 95.3%, demonstrating its capability to effectively process data sequences and capture contextual relations within the dataset. This high level of accuracy makes the GRU model an excellent candidate for applications where accuracy is critical. Although the CNN model achieved a slightly lower accuracy of 93.6%, it was capable of better in faster training time compared to the GRU model. This makes CNN a strong option for real-time scenarios requiring faster processing as a priority. The BiGRU model achieved an accuracy of 94.4%, which is lower than GRU but higher than CNN, although it did not outperform GRU in terms of performance. Its bidirectional structure allowed it to capture contextual data in both forward and backward directions, making it the suitable option in certain applications. These results emphasized the significance of selecting the appropriate model based on certain requirements, such as accuracy or speed.

This paper has achieved valuable objectives, but it has some limitations. First, the dataset used was relatively small and translated from English to Arabic due to the lack of a supporting Arabic dataset in this field, which may affect the results. Second, the models were assessed based on URLs as a phishing indicator, excluding other indicators that may be used as phishing processes, such as email and phone numbers. In future work, we aim to expand the Arabic dataset, compare the proposed models with other deep learning techniques to mitigate phishing detection in Arabic SMS messages and extend the proposed model to include other indicators such as email and phone numbers. These proposals aim to create a more

comprehensive solution to mitigate SMS phishing messages in Arabic-speaking communities.

Jordanian Currency Recognition Using Deep Learning

Salah Alghyaline

Department of Computer Science, the World Islamic Sciences and Education University, Amman, Jordan

Abstract—Automatic Currency Recognition (ACR) has a significant role in various domains, such as assessment of visually impaired people, banking transactions, counterfeit detection, digital transformation, currency exchange, vendor machines, etc. Therefore, developing an accurate ACR system enhances efficiency across several domains. The contribution of this paper is three-fold; it proposed a large dataset of 2799 images and seven denominations for Jordanian currency recognition. The second contribution proposed an efficient multiscale VGG net to recognize Jordanian currency. Third, popular CNN architectures on the proposed dataset will be evaluated, and the result will be compared with the proposed architectures. Four metrics were used in the evaluation. The experimental result showed the accuracy of the proposed Multiscale VGG outperformed VGG16, DenseNet121, ResNet50, and ResNet101 and achieved 99.88%, 99.88%, 99.89%, and 99.98% accuracy, precision, sensitivity, and specificity.

Keywords—Automatic currency recognition; deep learning; VGG

I. INTRODUCTION

Currency recognition uses image processing techniques to identify currency. People use currency in their daily lives, and it is important to develop an automatic way to recognize it [1]. Currency recognition systems have many applications, such as ATM machines, vendor machines, money exchange shops, bank systems, blind people's assistants, and the detection of fake currency [2]. According to a study in 2020, 43.3 million people were blind, and 258 million had low vision ability, most of them from developing and poor countries [3].

Deep learning approaches showed super results in the image processing field [4]. Many approaches in the literature were proposed to develop currency recognition systems for different currencies worldwide. There are more than 180 currencies worldwide, and each country has its specifications for currency in terms of size, paper, pattern, and color [5]. Here is a shortage of publicly available datasets for Jordanian currency¹.

This study reviews the literature on Jordanian currency recognition and proposes a new dataset that includes 2799 images representing seven denominations of Jordanian currency. The proposed dataset includes paper banknotes and metals. Moreover, the proposed dataset is evaluated on different Deep learning architectures, and some of these architectures were modified to improve recognition accuracy.

The paper is organized as follows: Section II reviews the related work in automatic currency recognition. Section III presents the materials and methodology. This includes the

proposed dataset, the CNN architectures used, and the proposed Multiscale VGG. Implementation Details are described in Section IV. It consists of an experimental environment, model parameter settings, performance metrics, and experimental results. Finally, Section V concludes the paper.

II. RELATED WORKS

A. Recognition of Currency

Due to rapid technological advancement, many applications require automatic currency recognition, such as detecting fake currency in vending machines and ATMs and assisting visually impaired persons [6].

Many approaches were proposed in the literature to address automatic currency recognition; some of them used traditional methods such as histogram analysis, edge detection, descriptors-based features like Histogram of Oriented Gradients (HOG) [7], Speeded-Up Robust Features (SURF) [8] and Scale-Invariant Feature Transform (SIFT) [9]. After extracting the image features, the simple way to predict the class label is to use Template matching between the extracted features and the predefined feature. Support Vector Machines (SVM), k-nearest Neighbors (k-NN), and Random Forests are also used by many approaches to classify the extracted features. These traditional approaches are usually computationally efficient but could struggle with challenged images with noise such as lighting, clutter, occlusion, orientation and background; moreover, they extracted a limited number of features [10] [11].

Deep learning has shown superior results in image recognition during the last few years. Many CNN architectures have been proposed and used broadly in image processing and computer vision applications, such as VGG [12], DenseNet121 [13], Resnet [14], and Inception V3 [15]. It is reported that deep learning achieved high accuracy in automatic currency recognition [16] [17] [18][19].

B. Literature Review

Automatic currency recognition is significant in people's daily lives, helping blind people or those with vision problems, automatic selling machines, detecting fake bank notes, and banking applications. Therefore, many approaches were proposed to address this problem.

The study in [2] proposed a system to recognize Indian real currency from fake; the system starts with noise removal by converting the image into a grayscale image and resizing it into a fixed dimension. Then, the image histogram is extracted, and template matching is used to determine whether the currency is real or not.

¹<https://drive.google.com/drive/folders/1faAhWB7B8CohvTBTAxhNp5C2m4HuPa8A>

The study in [20], developed a mobile application to recognize Yemeni paper currency. 1600 images and four currency denominations were used. The images trained on the MobileMe architecture, a group of images ranging from 18 to 29, were used to evaluate the model accuracy; the model achieved 100% accuracy.

The study in [21], proposed an approach to recognize three Nigerian paper currencies. The approach is based on a color histogram for feature extraction and a rule-based technique for image classification. The dataset includes 300 images, and the approach achieved 98.66% accuracy.

The study in [16] is employed to recognize Indian banknotes. Four CNN architectures were implemented using a basic sequential model, VGG 16, AlexNet, and MobileNet architectures were trained and tested on a dataset of 1270 images. The approach achieved 97.98%, 92.81%, 89%, and 71.66% on the four architectures, respectively.

The research [22] developed an approach to recognizing US banknotes. The approach is based on the Speeded-UP Robust Features (SURF) descriptor and uses template matching to recognize currency.

The research [23] developed a banknote recognition system for three countries: the US, Egypt, and Saudi Arabia. SURF was used for key-point detection, a histogram of oriented gradients (HOG), and the scale-invariant feature transform (SIFT) were used to describe the features. A support Vector Machine (SVM) was used to classify the features into 12 classes of currency denominations. The system achieved a 99.2% accuracy rate.

The study in [24] developed a system using Python and Raspberry Pi to distinguish original and counterfeit 100 NTD; Mean Gray Values (MGVs) were analyzed in specific regions; these regions represent note security regions.

The research in [25] proposed an open dataset for the Indian currency. The dataset includes 5125 images resized into 1280 × 768 pixels, captured by a Galaxy A33 5G and Apple iPhone 6. The dataset includes four denominations (10, 20, 50 and 100

Rupees), including the new and old shapes of these denominations.

Faster R-CNN and YOLOv5 [17] were trained to recognize rupiah banknotes. A dataset of 1120 images that represent eight classes is used to make the comparison. R-CNN and YOLOv5 achieved accuracies of 98.65% and 82.1%, respectively.

The study in [18] proposed CNN architecture to predict four currencies: the US dollar, Euro, Jordan dinner, and Korean won. The architecture is an improved version of YOLO-v3 architecture. It consists of 69 conventional layers. The model was evaluated on a dataset of 21,020 images and achieved an accuracy of 83.96%. The Jordanian currency includes nine denominations, and the images are 1024×1024 pixels.

III. MATERIALS AND METHODOLOGY

A. Proposed Dataset

The dataset was collected from college students whose ages ranged from 18-22. The students used their phones, which have various characteristics. Each person was asked to capture the currency on both sides, and each side was captured from two angles.

Fig. 1 shows sample pictures from each denomination. The captured images were taken in different conditions of lighting, orientation, background, sizes, and quality. The images include many challenges, such as background objects, some parts of the currency not being captured, being taken from different distances, some parts of the currency being damaged, being captured in different lighting conditions, and being captured from different phones. The captured images were resized into 448×448 pixels. The dataset includes 2799 images with JPEG formats represent seven denominations of the Jordanian currency as follows: 50JD: 409 images, 20JD: 397 images, 10JD: 419 images, 5JD:419 images, 1JD: 425 images, 50 piasters: 363 images, 25 piasters: 367, as shown in Fig 2. The Jordanian banknotes and coins have old and new shapes, and both are used now. There are differences in the color, security features, and regions, as shown in Table I which makes it difficult to recognize them.

Fig. 1. Sample pictures from the proposed Jordanian currency dataset including images taken under different conditions: (a) 25 piasters (b) 50 piasters (c) 1JD (d) 5 JD (e) 10JD (f) 20 JD (g) 50 JD.

B. CNN Architectures

A set of popular CNN architectures was adopted in this paper. VGG has a simple structure and is considered a baseline for image classification tasks. ResNet shows a significant result when training deep networks with residual connections. DenseNet121 improved feature reuse by concatenating features from different layers.

The research in study [12] VGG developed at the University of Oxford by the Visual Geometry Group (VGG) in 2015. They studied the effect of increasing the number of convolutional layers from 16 to 19. The architecture achieved state-of-the-art on the ImageNet Challenge 2014. VGG16 has a simple and effective structure; it includes a sequence of five blocks. Each block consists of two to four convolutional layers followed by a max pooling. Finally, the features are flattened using four fully connected layers. The last layer represents the number of classes. The convolutional layers are 3x3 windows, and filter sizes range from 64 to 512. The max pooling is a window of 2x2 to reduce the feature size to half. Relu is used for activations, Table II explains the architecture of VGG16 model.

TABLE II. THE ARCHITECTURE OF VGG16

Layer Type	Filter Size	Number of Filters	Output Size	Details
Input	-	-	224x224x3	RGB image input
Convolution (x2)	3x3	64	224x224x64	Two 3x3 conv layers with ReLU
Max Pooling	2x2	-	112x112x64	Stride 2

Output (SoftMax)	-	Number of classes	1x1xNumber of classes	Classification layer

DenseNet introduced [13] the dense connection between CNN layers. Each CNN layer is connected with other layers in a forward manner. The architectures achieved state-of-the-art results on ImageNet, SVHN, CIFAR-10, and CIFAR-100 datasets. The architecture includes four Dense Blocks and three Transition Layers. The Dense Block consists of a group of convolutional layers that are densely connected. Each dense

layer includes Batch Normalization, ReLU, 1x1 Convolution and 3x3 Convolution. At the same time, the Transition layers include 1x1 Convolution and 2x2 Average Pooling layers to reduce the size of the feature map, Table III presents the architecture of DenseNet121 model.

ResNet baseline architecture [14] was derived from the VGG architecture. It uses the same filler size of 3x3 and a pooling layer to down sample the feature map. However, it reduced the number of filters compared with VGG, which reduced the model size and introduced the residual networks instead of learning unreferenced data from the network layer. The network is 8x deeper than VGG; however, it is reported that the mAP of VGG16 and ResNet101 on PASCAL VOC 2007/2012, was 70.4% and 73.8%, with 3.2% improvement. In comparison, the VGG16 gained a 6% improvement (21.2% TO 27.2%) on the COCO dataset compared to VGG16. Stated the first place in the ILSVRC 2015 classification competition. The residual is calculated according to Eq. (1) if the input and output feature map have the same dimensions; if not, Eq. (2) is used.

$$y = \mathcal{F}(x, W_i) + x \quad (1)$$

TABLE III. ARCHITECTURE OF DENSENET121

Layer Type	Output Size	Filter Size / Details
Input	224x224x3	RGB image
Convolution	112x112x64	7x7 conv, stride 2
Max Pooling	56x56x64	3x3, stride 2
Dense Block 1	56x56x256	6 bottleneck layers (growth=32)
Transition Layer 1	28x28x128	1x1 conv, 2x2 avg pool
Dense Block 2	28x28x512	12 bottleneck layers
Transition Layer 2	14x14x256	1x1 conv, 2x2 avg pool
Dense Block 3	14x14x1024	24 bottleneck layers
Transition Layer 3	7x7x512	1x1 conv, 2x2 avg pool
Dense Block 4	7x7x1024	16 bottleneck layers
Global Avg Pooling	1x1x1024	
Fully Connected Layer	Number-of-classes	

where \mathcal{F} is the residual mapping, x and y are the input and the output. W_i is the weights of the convolutional layers in the residual block.

$$y = \mathcal{F}(x, W_i) + W_s x \quad (2)$$

W_s is the weight of the 1x1 convolution used for projection.

InceptionV3 [26] reported that it is computationally more efficient compared with VGG architecture. Therefore, it can be trained and tested using bigger data. The architecture includes a sequence of inception modules. Each inception module represents several convolutional and pooling layers that operate in a parallel fashion and are then concatenated together. As shown in Fig. 3 [27], there are 1x1 convolutional layers used to reduce the feature size and feature extraction: 3x3 and 5x5 convolutional layers to capture spatial features. Max pooling and average pooling are used for feature-down sampling.

Fig. 3. The inception module.

C. Multiscale VGG

VGG net has a simple structure of a sequence of CNN blocks. Each block includes several convolution layers with different filters with a fixed size, followed by a max pooling layer to reduce the feature size by 50% compared with the previous block. Fig. 4 and Fig. 5 show the proposed multiscale VGG architecture to recognize currency. The proposed model improved the VGG model architecture by implementing a

multiscale VGG net to recognize Jordanian currency. The multiscale VGG net captures features with different respective fields compared with VGG architecture. Using multiple scales images, the last max-pooling layers of VGG extract four scales of feature map 7×7 , 5×5 , 3×3 , and 1×1 . The proposed multiscale VGG improves recognition rates by handling the variation of captured image sizes. The model can be applied to other currencies. The model learns text, color, security patterns and symbol features that exist in all other currencies. The trained model can also be fine-tuned and trained one other currencies, which can reduce the training time. The proposed dataset includes images with 448×448 size; the images are cropped from the center into 224×224 . The input image with 224×224 size is resized into four scales: scale 1: 100%, scale 2: 75%, scale 3: 50%, and scale 4: 25% and passed into parallel four VGG nets. The outputs of the four scales are flattened and concatenated, then passed into a fully connected layer of 256 size, followed by a 50% dropout layer, and finally, a fully connected layer with size 7 (number of classes). The four scales capture more fine-grained local features (e.g., edges or textures) compared with one scale feature. The final extracted feature before the first flattened layer encodes the spatial and semantic and includes the most informative features for classification. The sizes of extracted features from the last block of convolutions are 7×7 for scale 1, 5×5 for scale 2, 3×3 for scale three and 1×1 for scale 4.

Fig. 4. The architecture of the proposed automatic multiscale currency recognition system.

Fig. 5. Four scales of VGG16 architecture and the input images are (a) 224×224 (b) 168×168 (c) 112×112 (d) 56×56.

IV. IMPLEMENTATION DETAILS

A. Experimental Environment

The experiments were done in a Windows 10 and Jupyter Notebook environment. The processor is an Intel(R) Core (TM) i5-8600K CPU @ 3.60GHz. The installed RAM is 40.0 GB, and the GPU is a GTX1080 with 8 GB memory.

B. Model Parameter Settings

Table IV shows the parameters that were used to perform data augmentation while training the model.

TABLE IV. DATA AUGMENTATION USED DURING TRAINING

Augmentation Parameter	Value	Description
Rotation Range	20	up to 20 degrees
Width Shift Range	0.2	Horizontal shift by up to 20% of the image width
Height Shift Range	0.2	Vertical shift by up to 20% of the image height
Shear Range	0.2	up to 20%
Zoom Range	0.2	Zoom in or out by up to 20%
Horizontal Flip	TRUE	Randomly flips the image horizontally

C. Performance Metrics

Four metrics were used to evaluate the performance of the different CNN models in the dataset.

Accuracy: It measures the total of correctly predicted images compared to the total number of tested images.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \times 100 \quad (3)$$

Precision: The percentage of true positive compared with all positive prediction; high precision indicates fewer false positive

$$\text{Precision} = \frac{TP}{TP+FP} \times 100 \quad (4)$$

Sensitivity (Recall): It measures the model's capacity to detect every real positive case. Therefore, the ratio of the true positives to the total of the true positives and false negatives is used to compute it.

$$\text{Sensitivity} = \frac{TP}{TP+FN} \times 100 \quad (5)$$

Specificity: It calculates the proportion of accurately categorized negative events to all negative instances that really occurred:

$$\text{Specificity} = \frac{TN}{TN+FP} \times 100 \quad (6)$$

where *TP* denotes True Positive, *TN* is True negative, *FP* is False Positive and *FN* represent False negative.

D. Experimental Results

This section shows the performance of the proposed Multiscale VGG net and compares it with the VGG16, DenseNet12, ResNet50, ResNet101, and InceptionV3. Four metrics are used in the evaluation: accuracy, precision, sensitivity, and specificity. 70% of the dataset samples were used in training the model, whereas 30% were used to test the model. As shown in Table V, using multiple scales of the VGG16 improved the recognition rates compared with the base model VGG16. VGG16 achieved 98.92% accuracy, whereas adding features from multiple scales improved accuracy in all combinations. The highest accuracy occurred when combining features from scale 1 and scale 0.75, where the accuracy reached 99.88%, with a 0.96% improvement compared with VGG16. The precision, sensitivity, and specificity reached 99.89%, 99.89%, and 99.98%, respectively.

TABLE V. PERFORMANCE EVALUATION OF PROPOSED MULTISCALE VGG AT DIFFERENT SCALE VALUES 100%, 75%, 50% AND 25%

Models	Accuracy	Precision	Sensitivity	Specificity
VGG16	98.92%	98.96%	98.90%	99.82%
VGG16 SCALES 1,0.75,0.5,0.25	99.64%	99.66%	99.64%	99.94%
VGG16 SCALES 1,0.75	99.88%	99.89%	99.88%	99.98%
VGG16 SCALES 1,0.75,0.5	99.88%	99.88%	99.89%	99.98%
VGG16 SCALES 1,0.5,0.25	99.76%	99.78%	99.76%	99.96%
VGG16 SCALES 1,0.5	99.76%	99.78%	99.75%	99.96%

Table VI shows that the proposed method and InceptionV3 achieved 99.88% accuracy, after DenseNet121 with 99.52% accuracy, followed by ResNet101 with 99.28% accuracy. The precision, sensitivity, and specificity metrics showed that the

proposed multiscale and InceptionV3 achieved the best result, followed by DenseNet121 and ResNet101, respectively. Table VII shows the inference time and the model parameters. The VGG16 SCALES 1,0.75 runs in real-time and requires 200 ms to predict the class label for a patch of 32 images. At the same time, the model used 39,130,759 parameters.

TABLE VI. PERFORMANCE EVALUATION OF PROPOSED MULTISCALE VGG WITH OTHER CNN KNOWN CNN ARCHITECTURES

Models	Accuracy	Precision	Sensitivity	Specificity
VGG16	98.92%	98.96%	98.90%	99.82%
VGG16 SCALES 1,0.75	99.88%	99.88%	99.89%	99.98%
DenseNet121	99.52%	99.52%	99.52%	99.92%
ResNet50	99.16%	99.18%	99.17%	99.86%
ResNet101	99.28%	99.31%	99.30%	99.88%
InceptionV3	99.88%	99.89%	99.88%	99.98%

TABLE VII. INFERENCE TIME IN TERMS OF MS PER PATCH (PATCH=32 IMAGES) AND NUMBER OF PARAMETERS USED BY THE MODEL

Models	MS/Patch	#Parameters
VGG16	81	21,139,271
VGG16 SCALES 1,0.75	200	39,130,759
DenseNet121	78	19,884,615
ResNet101	146	68,350,343
InceptionV3	97	22,329,127

836 images were used to test the proposed architecture. The confusion matrix in Fig. 6 shows that the Multiscale VGG architecture accurately predicted 835 pictures, and only one image for 10 JD was predicted to be 50 JD.

Fig. 6. Confusion matrix for the proposed multiscale VGG.

V. CONCLUSION

This paper proposed a dataset for Jordanian currencies and proposed Multiscale VGG architectures to recognize Jordanian currencies automatically. The dataset includes 2799 images for seven denominations (25piasters, 50piasters, 1JD, 5JD, 10JD, 20JD, 50JD). The images were captured in different conditions of lighting, backgrounds, clutter, occlusion, and orientation. Moreover, the experimental results showed that the proposed

Multiscale VGG architectures achieved the best accuracy, precision, sensitivity, and specificity compared with VGG16, DenseNet121, ResNet50, and ResNet101.

Abstract—In the field of visual camouflage, generating a high-quality background image that seamlessly blends with complex foreground objects and diverse background environments is a critical task. When dealing with such complex scenes, the existing techniques have insufficient foreground feature extraction, resulting in insufficient fusion of the generated background image with the foreground objects, making it difficult to achieve the desired camouflage effect. In order to solve this problem and achieve the goal of higher quality visual camouflage effect, this paper proposes a new foreground feature-guided camouflage image generation method (Object Enhancement Module - Diffusion Refinement, OEM-DR), which generates camouflage images by enhancing the foreground features to guide the background. The method firstly designs a new object enhancement module to optimize the attention mechanism of the model, and eliminates the attention weights that have less influence on the output through pruning strategy, so that the model focuses more on the key features of the foreground objects, and thus guides the generation of the background more effectively. Second, a novel detail optimization framework based on diffusion strategy is constructed, which maintains the integrity of the global structure of the image while performing fine optimization processing on the local details of the image. In experiments on standard camouflaged image datasets, the proposed method in this study achieves significant improvement in both FID (Fréchet Inception Distance) and KID (Kullback-Leibler Divergence) evaluation metrics, which verifies the feasibility of the method. This suggests that by strengthening foreground features and detail optimization, the fusion between background images and foreground objects can be effectively improved to achieve higher quality visual camouflage effects.

Keywords—Camouflage image; foreground features; object enhancement; detail optimization

I. INTRODUCTION

In the field of visual perception, camouflage image generation is a challenging task that aims at generating background images that can skillfully mask foreground objects for visual concealment. This technique plays an important role in several practical application areas such as pest detection, healthcare [2], and autonomous driving [8]. With the advancement of computer vision techniques, especially in the fields of style migration [9], image editing [10] and image generation [11], new ideas have been provided to address the challenges of camouflage image generation. The Poisson image editing method proposed by Di Martino et al. [10] brought innovations in the field of image editing by allowing researchers to work with the image in a natural and intuitive manner content. The pioneering work of Chu et al. [12] on camouflage image

generation demonstrated how to generate hard-to-detect images by mimicking the camouflage mechanisms of natural organisms. The work of Huang and Belongie [9] further advanced the development of style-migration techniques, which allow us to change the style of an image to fit different contexts while keeping its content intact. Zhang et al. [13] proposed generating camouflaged images that can blend in with complex backgrounds by learning a large amount of natural image data. Li et al. [14] further proposed a camouflaged image generation network that does not require specific positional information. The work of Zheng et al. [15] provides a new solution for high fidelity image complementation by bridging global contextual interactions. Lugmayr et al. [16] provided a new idea for background complementation of camouflaged images by using denoising diffusion probabilistic model for image restoration.

However, despite the many advancements in existing technologies, several key issues remain. Firstly, most methods rely on manually selected backgrounds, which not only limits the diversity of generated samples but also significantly increases the cost of data collection. Secondly, these methods may perform poorly in complex and variable environments, as they often depend heavily on the precise extraction of background and foreground features. The LAKE-RED model [17], although innovative in generating camouflage images by fusing training backgrounds with extracted foreground features, may face challenges in complex or changing environments due to its reliance on precise feature extraction.

To address these issues, this study proposes a new object enhancement strategy. Inspired by the work of Dhariwal P et al. [19], this study utilizes weight sparsification and pruning to enhance the model's understanding and learning of deep features of target objects. This strategy aims to reduce dependence on precise feature extraction and improve the model's adaptability in complex environments.

Furthermore, camouflage images often lack detail optimization during generation, which can weaken their camouflage effect. Unnatural transitions in texture, color, or edge areas may reduce their concealment. To solve this, inspired by the work of Yang L et al. [18], this study designs a method to enhance the model's feature expression ability using non-zero weights after diffusion pruning, optimizing the connection between foreground and background to improve the quality of camouflage images.

In the following sections of this paper, the study will be explored in depth. The related work in Section II will review and analyze the technologies and methods involved in this study,

clarifying its position and value in the field of camouflage image generation. The OEM-DR in Section III will detail the proposed new method, including the design and implementation of the object enhancement strategy, and how non-zero weights after diffusion pruning enhance the model's feature expression. The experiments in Section IV will design and conduct a series of experiments to verify the effectiveness and performance of the proposed method, including comparative and ablation experiments with existing methods. Finally, the conclusion in Section V will summarize the main achievements and contributions of this study, discuss existing limitations, and suggest directions for future work.

II. RELATED WORK

A. Camouflage Image Generation

The goal of camouflage image generation is to create images of target objects that blend highly with the background and are difficult to detect. Early methods mainly relied on image processing techniques. For example, Chu et al. [12] hid the target by inserting similar textures and colors through image editing. Although these methods could achieve basic camouflage, the quality and diversity of the generated images were limited. With the development of deep learning, methods based on deep generative models have become mainstream. Zhang et al. [13] proposed a deep camouflage image generation model that learns complex camouflage patterns and generates more realistic images. Li et al. [14] developed a camouflage generation network without location information, which automatically learns the relationship between the target and the background, thereby improving the quality of the generated images. In the latest research, Zhao et al. [17] introduced the LAKE-RED method, which combines latent background knowledge retrieval with diffusion models to generate high-fidelity and diverse camouflage images. Yang et al. [18] provided a comprehensive review of diffusion models, covering their applications in camouflage image generation and other fields, offering valuable references for research. These advancements indicate that deep learning, especially diffusion models, holds great potential in camouflage image generation. Future research can further explore their combination with camouflage tasks to generate higher quality and more diverse camouflage images.

B. Data Augmentation

Data augmentation is crucial for enhancing the performance of deep learning models, especially when the number of samples is limited. It improves the model's generalization ability by generating more training samples. In the tasks of camouflage image detection and segmentation, data augmentation is particularly important because it is difficult to obtain camouflage images and their patterns are diverse. Fan et al. [1] enhanced the data by randomly inserting camouflage targets, which is a simple but effective way to improve detection performance. Le et al. [4] explored data augmentation in their Anabran network, such as random cropping and rotation, but mainly focused on geometric transformations and simple editing, which had limited enhancement of the diversity of

camouflage patterns. The development of diffusion models has brought new ideas to data augmentation. Dhariwal and Nichol [19] proposed an image synthesis method based on diffusion models, which generates high-quality images and performs excellently in multiple tasks, providing a new direction for camouflage image generation and data augmentation. Binkowski et al. [20] improved the MMD GAN training method, enhancing the quality and diversity of the generated images. Heusel et al. [21] introduced a two-time-scale update rule for GAN training, proving that it converges to a local Nash equilibrium, providing theoretical support for the training of generative models. These studies show that combining advanced generative models such as diffusion models with the task of camouflage image generation can generate richer and more diverse training data. Future research can further explore this combination to improve the performance of camouflage image detection and segmentation models.

III. OEM-DR MODEL

A. An Overview of the Proposed Framework

As shown in Fig. 1, the OEM-DR model starts from low-level image feature extraction and highlights important details in the image through the object enhancement module, which introduces sparsity to optimize the weight distribution, and then employs a pruning strategy to reduce the computational burden. The detail optimization module further enhances the image quality, which facilitates the fusion and generalization of the model to new data while retaining key information through the diffusion process. Finally, the model performance is tuned and optimized through the computation of the loss function. The specific details of these steps are elaborated in this section.

B. Object Enhancement Based on Sparse Pruning

In order to address the model's deficiency in object information learning, an object enhancement module is designed in this study. The purpose of this module is to deepen the model's understanding and learning of deep features of the target object through refined feature selection and enhancement. This study aims to further encode the object features through this enhancement module to achieve deeper understanding of foreground feature information in images. The working mechanism of this module is explained in detail in the following section, and its structure is detailed in Fig. 2.

In the forward propagation process of the model, the deep representation of foreground features f_g is extracted by a multilayer perceptron (MLP). the pre-trained background embedding matrix is subsequently transposed and the batch dimension is increased in order to obtain the background embedding vector C . The query vector q is obtained by applying a linear transformation layer to $f_g.C$ is used as the key k and the value v . The similarity matrix S_m is computed by using the einsum function for querying q and key k . matrix S_m , which is computed as follows:

$$S_m = \text{einsum}(q, k) \quad (1)$$

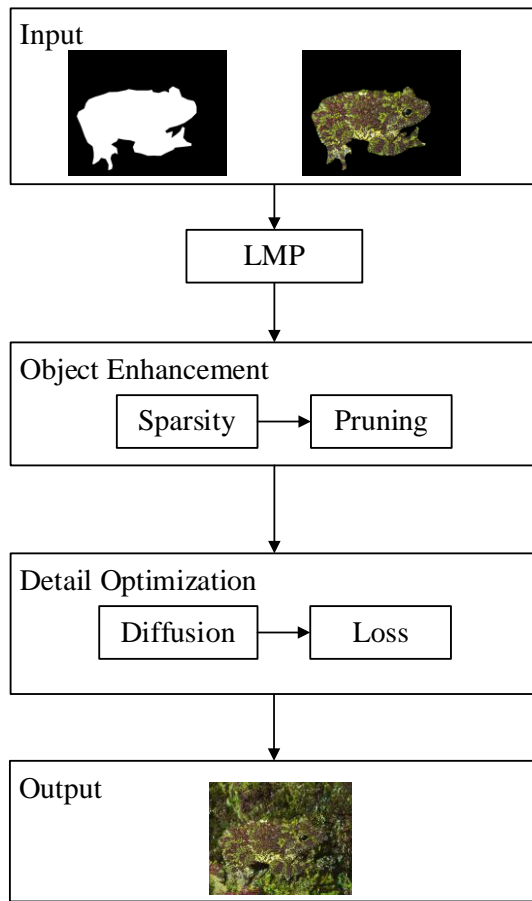

Fig. 1. OEM-DR model framework.

In this paper, we quantify sparsity by calculating the attentional weight of S_m and subsequently determining the pruning threshold. The L_1 norm l_{n1} and L_2 norm l_{n2} of the attention weight matrix A are computed with the following equations:

$$l_{n1} = \sum_{i=1}^n |a_i| \quad (2)$$

$$l_{n2} = \sqrt{\sum_{i=1}^n a_i^2} \quad (3)$$

Where a_i is the i -th element in the attention weight matrix A and n is the total number of elements.

The sparsity ratio R is defined as follows:

$$R = \frac{l_{n1}}{l_{n2} + \varepsilon} \quad (4)$$

Where ε is a negligible positive number added to prevent division by zero.

A Boolean mask P is generated using the sparse ratio R . Each element of this mask is determined by the condition:

$$P = \begin{cases} T, A > R \\ F, A \leq R \end{cases} \quad (5)$$

The initial pruning is accomplished by setting the elements of A for which P is F to zero through the product operation, as follows:

$$A_p = A \square P \quad (6)$$

Fig. 2. Object enhancement module structure diagram.

Further, the L_1 norm A_{p1} of the pruned attention weight A_p is calculated using Eq. (2) and the pruning threshold T_p for each attention head is determined by the pruning ratio P_r as follows:

$$M_{AP} = \max(A_{p1}) \quad (7)$$

$$T_p = M_{AP} \times P_r \quad (8)$$

M_{AP} in Eq. (7) represents the maximum value of the computed L_1 norm on the last dimension of the weight matrix A_p .

The pruned weight matrix S_a is then obtained by generating a Boolean mask using the pruning threshold T_p through the operations of Eq. (5) and Eq. (6), and then the elements of A_p Ap below T_p are set to zero through the product operation in order to complete the pruning process.

C. Diffusion-based Detail Optimizer

In order to cope with the performance degradation caused by performing pruning, this study adds the DR module after pruning. the purpose of the DR module is to maintain or even improve the predictive performance of the model after pruning, and to enhance the generalization ability of the model to ensure the model's adaptability and accuracy to new data.

Referring to Fig. 3, the input to the DR module is the pruned weight matrix S_a . The influence of the non-zero weights retained after pruning is spread to the adjacent zero-weight regions through an iterative process, with a view to maintaining or even enhancing the generalization capability of the model while reducing the complexity of the model. The details of the operation are described below.

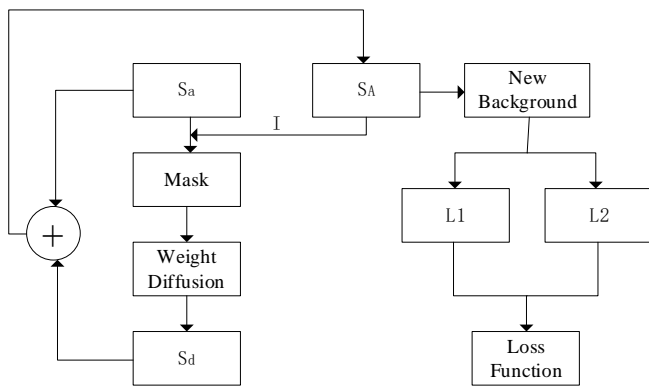

Fig. 3. Diffusion optimizer structure diagram.

First, a Boolean mask M is initialized to identify the location of the non-zero weights in S_a . This mask is obtained by comparing S_a with zero, where the non-zero element corresponds to a mask value of True.

Next, I iterations are executed, and in each iteration the following steps are performed:

First M is shifted one position to the right along the last dimension (feature dimension) to obtain the new mask M_n . This step simulates the process of diffusion of non-zero weights to the right along the feature dimension.

Next, the update of the weights is computed as follows:

$$S_d = S_a \times (1 - D \times (1 - M_n)) \quad (9)$$

D is a factor between 0 and 1 used to adjust the magnitude of the weight update.

The calculated update is then applied to S_a and the updated weights are:

$$S_A = S_d + S_a \quad (10)$$

Finally, a non-negative constraint is imposed to ensure that all weight values are non-negative. After I iterations, the post-diffusion weight matrix S_A is obtained.

In the second step, L_1 and L_2 regularization losses are introduced to process the new background P_n obtained after training with the features T_a of the target image as a way to achieve fine tuning of the model complexity. The new foreground image P_n is generated in the following way: in the background region identified by the mask, this paper replaces the original foreground f with the background feature S_A ; while in the foreground region, f is kept unchanged. Thus, the updated foreground image P_n is obtained. The L_1 and L_2 regularization losses operate as follows:

The L_1 loss measures the error by calculating the absolute value of the difference between the predicted value and the target value, and its mathematical expression is shown below:

$$L_1 = \lambda_1 \sum_{i=1}^n |w_i - w_i^{T_a}| \quad (11)$$

The L_2 loss measures the error by calculating the square of the difference between the predicted value and the target value, the mathematical expression of which is shown below:

$$L_2 = \lambda_2 \sum_{i=1}^n (w_i - w_i^{T_a})^2 \quad (12)$$

The w_i denotes the actual value of the i -th image, $w_i^{T_a}$ denotes the target value of the i -th image, and λ_1 and λ_2 denote the weights occupied by the two losses, respectively.

The L_1 and L_2 losses are combined into the total loss according to certain weights to realize the joint control of model complexity. The combined total loss function is defined as:

$$L = L_1 + L_2 \quad (13)$$

The main role of L_1 and L_2 losses is to prevent model overfitting and improve model generalization. Specifically, the L_1 loss helps with feature selection, while the L_2 loss helps with parameter stability.

IV. EXPERIMENT

A. Datasets

Following the research on covert object detection (COD) [3], this paper uses 4040 real images (3040 from the COD10K [1] dataset and 1000 from the CAMO [26] dataset) to train the model. To validate the generation performance, this study collects image-mask pairs from different domains and constructs a test dataset consisting of three subsets: covert objects (CO), salient objects (SO) and general objects (GO) [17]. In CO, there are 6473 image pairs from CAMO [4], COD10K [1] and NC4K [5]. We then randomly selected 6473 images from well-known salient target detection datasets (e.g., DUTS [6], DUT-OMRON [7], etc.) and segmentation datasets to evaluate the performance of the model on open domain data.

B. Evaluation Metrics and Parameter Setting

Following the good practices of AIGC and COD, the InceptionNet-based metrics FID [20] and KID [17] are chosen in this paper to measure the quality of the generated covert images. Once the image features have been extracted via InceptionNet, the distance between them is calculated to indicate the level of similarity between the model output and the target dataset. Unlike normal images, well-synthesized covert images should not contain easily recognizable objects, and extracting discriminative features is more challenging. A lower value of FID [2] indicates that the generated image is more similar to the real image in terms of visual features, which usually implies a better generation. KID [21] by kernel method is able to capture more sensitively the differences between the generated image and the real image, especially in terms of image detailed features. A lower value of KID [21] indicates that the quality of the generated image is closer to the real image.

In this paper, we use a latent diffusion model, pre-trained on a restoration task as an initialization. The model was designed to handle images and masks of size 512×512 and compressed to a potential space of $128 \times 128 \times 3$ using the pre-trained VQ-VAE. During the training process, the focus is on improving the model's understanding and learning of the deep features of the target object through object augmentation and regularized diffusion strategies, and does not fine-tune the autoencoder and

decoder components. The existing conditions are optimized and enhanced by the modules proposed in this paper. Parameter optimizations, such as initialization, data enhancement, and batch size, are set similar to the original paper. Finally, the model generates the artifact images and resizes them to align with the original input. This paper uses PyTorch for all experiments and a GeForce RTX 4060ti GPU for all experiments.

C. Comparison and Analysis of Model Results

To verify the effectiveness of the OEM-DR model, this paper selects the following nine models for comparison: The AB model [9] achieves seamless image region blending based on the Poisson equation, enabling the source image to naturally blend into the target background. The AdaIN model [12] rapidly accomplishes real-time arbitrary style transfer through adaptive instance normalization technology, converting the style while maintaining the image content unchanged. In the field of camouflage image generation, the CI model [11] imitates the camouflage mechanism of natural organisms to generate images that are difficult to detect; the DCI model [13] and LCGNet model [14] utilize deep learning to generate camouflage images that blend with complex backgrounds, with LCGNet being more flexible as it does not require specific location information; the LAKE-RED model [17] combines potential background knowledge retrieval with diffusion models to enhance the quality of camouflage images. In addition, the TFill model [15] achieves high-fidelity image completion by bridging global context interaction, while the RePaint-L model [16] performs image restoration based on denoising diffusion probabilistic models, generating content for missing areas. The LDM model [10] proposes a high-resolution image synthesis method based on latent diffusion models, promoting the development of high-quality image generation technology.

Table I shows the comparison of experimental results of various models on the dataset. Compared with the AB, CI, AdaIN, DCI, LCCNet models, which realize the camouflage effect by fusing the background with the foreground, EM-DR guides the background generation according to the features of the foreground, so that the generated image background is closer to the foreground and the foreground is more hidden.

TABLE I. COMPARISON OF EXPERIMENTAL RESULTS IN VARIOUS MODELS

Methods	Input	Camouflaged Objects		Salient Objects		General Objects		Overall		
		FID↓	KID↓	FID↓	KID↓	FID↓	KID↓	FID↓	KID↓	
Image Blending	AB ^[9]	F+B	117.11	0.0645	126.78	0.0614	133.89	0.0645	120.2	0.0623
	CI ^[11]	F+B	124.49	0.0662	136.3	0.738	137.19	0.0713	128.5	0.0693
	AdaIN ^[12]	F+B	125.16	0.0721	133.2	0.0702	136.93	0.0714	126.9	0.0703
	DCI ^[13]	F+B	130.21	0.0689	134.92	0.0665	137.99	0.069	130.5	0.0673
	LCGNet ^[14]	F+B	129.8	0.0504	136.24	0.0597	132.64	0.0548	129.9	0.055
Image Inpainting	TFill ^[15]	F	63.74	0.0336	96.91	0.0453	122.44	0.0747	80.39	0.0438
	LDM ^[10]	F	58.65	0.038	107.38	0.0524	129.04	0.0748	84.48	0.0488
	RePaint-L ^[16]	F	76.8	0.0459	114.96	0.0497	136.18	0.0686	96.14	0.0498
	LAKE-RED ^[17]	F	39.55	0.0212	88.7	0.0428	102.67	0.0625	64.27	0.0355
	Ours	F	37.44	0.0181	86.9	0.0387	100.48	0.0581	61.52	0.0311

Compared with TFill and LDM models, EM-DR strengthens the feature screening of foreground features, mainly in its ability to refine and optimize, which gives it an advantage in preserving the details of important foreground objects in the image. TFill and LDM, on the other hand, while having their advantages in texture synthesis and learning-based approaches, may require additional tuning or optimization to better handle foreground features in specific cases. Compared to the benchmark model LAKE-RED, EM-DR achieves significant improvements in all metrics, further demonstrating its ability to adequately enhance foreground features when generating camouflaged images, thus providing foreground camouflage effects.

Compared with the baseline model on the CO dataset, the FID metrics improved by 5.3% and the KID metrics improved by 14.6%, on the SO model, the FID metrics improved by 2% and the KID metrics improved by 9.5%, on the GO model, the FID metrics improved by 2.1% and the KID metrics improved by 7%, and on the whole the FID metrics improved by 4.3% and the KID metrics improved by 12.3%. by 4.3% for FID and 12.3% for KID. These improvements indicate that the EM-DR model shows better performance in the task of generating camouflage images, and the improvements in FID and KID metrics indicate that the images generated by the new model are closer to the real images in terms of visual and statistical properties.

D. Ablation Study

In order to verify the impact of the object enhancement module and diffusion optimizer mentioned in this paper on the model performance, ablation experiments are conducted on datasets containing CO, SO and GO, and the results are summarized in Table II.

TABLE II. ABLATION STUDY RESULTS

Methods		OEM	DR
CO	FID↓	37.67	37.77
	KID↓	0.0183	0.0187
SO	FID↓	85.85	87.92
	KID↓	0.0381	0.0391
GO	FID↓	102.07	102.57
	KID↓	0.0599	0.0599
Overall	FID↓	61.73	62.51
	KID↓	0.0313	0.0317

First, the OEM module is individually validated in this paper. Compared with the LAKE-RED model, OEM achieves significant improvement in both FID and KID, especially on the SO dataset. This indicates that OEM not only makes the camouflage images generated on hidden objects as well as ordinary objects close to the real image in terms of enhanced foreground features, but also generates camouflage images on salient objects even closer to the real image.

Secondly, the DR module is individually validated in this paper. Compared to the LAKE-RED model, DR also achieves significant improvement in both FID and KID but lacks in SO dataset compared to the OEM module.

In summary, the OEM and DR modules show excellent advantages in the camouflage image generation task, effectively improving the model performance.

E. Example of Analysis

In order to visualize the improvement of the OEM-DR model mentioned in this paper compared to the benchmark model LAKE-RED, several examples are selected for visualization.

Fig. 4. OEM-DR Model visualization examples.

Fig. 4 visualizes the performance of the OEM-DR model proposed in this study compared with other benchmark models in generating camouflaged images. The figure groups the images according to different model sources: Fig. 4 (a) and 4 (b) are generated by the CO model, Fig. 4 (c) and 4 (d) by the SO model, while Fig. 4 (e) and 4 (f) are from the GO model. Taking the toad in Fig. 4 (a) as an example, the image generated by the OEM-DR model shows a more natural fusion between the background and the foreground, and the details of the background are optimized so that the foreground objects do not appear to be abrupt, which achieves a better camouflage effect visually. Similarly, in Fig. 4 (f), although the camouflaged objects are not completely hidden, the OEM-DR model still demonstrates its advantages in improving the overall image quality. The comprehensive comparison results show that the OEM-DR model has a significant advantage in generating images that contribute to effective camouflage, and is able to generate high-quality camouflage images that are more natural and rich in details.

Since both image generation quality and camouflage effectiveness need to be perceived by humans, this paper conducts a user study to obtain subjective judgments on the generation results. In this paper, 10 researchers in AI related

fields are invited to judge which of the images in Fig. 4 are not easily detectable. According to the judgment results except Fig. 4 (b) all others are considered to be less detectable in the foreground in the images generated by OEM-DR, which fully demonstrates the quality of OEM-DR in image generation and the effectiveness of the camouflage effect.

F. Discussion

In this study, the OEM-DR model significantly enhanced the performance of camouflage image generation through the object enhancement module and the diffusion optimizer. Compared with various existing models, OEM-DR excelled in terms of FID and KID metrics, particularly when dealing with salient objects. Although the model has the limitation of high computational resource demands, this is expected to be overcome in the future through algorithm optimization and hardware acceleration. The OEM-DR model provides a new perspective and methodology for the field of camouflage image generation, holding broad prospects for application.

V. CONCLUSION

In this paper, an innovative camouflage image generation method based on sparse pruning and weight diffusion is proposed. First, a new object enhancement module is designed, which effectively improves the extraction of key features in the foreground by the model, and thus significantly improves the authenticity of the camouflage image generation. Second, a detail optimization module based on the weight diffusion strategy is constructed, which improves the quality of the generated images by optimizing the background image generation process. In the experiments on CO, SO and GO datasets, this paper demonstrates excellent performance. Future research in camouflage visual perception will be continued to further propose feasible solutions.

However, it is worth noting that although this study has achieved certain results in the field of camouflage image generation, it faces the challenge of balancing computational complexity and efficiency during the implementation of the weight diffusion strategy. In future research work, this study will be committed to optimizing the adaptive weight diffusion strategy, dynamically adjusting the diffusion parameters according to the training progress of the model and the unique characteristics of the dataset. The exploration and optimization in this direction are aimed at promoting the continuous progress and development of camouflage image generation technology.

Abstract—Adopting digital finance solutions is crucial for enhancing efficiency and competitiveness within the financial services industry, particularly for Micro, Small, and Medium Enterprises (MSMEs). This study examines the factors influencing the use and acceptance of a sharing-based digital system enhanced with a Generative AI website (E-Mudharabah), employing the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT). In this article, the Generative AI-enhanced profit-sharing digital systems called E-Mudharabah. It is a web-based management system facilitating capital management for financiers, consultants, and MSME actors. The research integrates key variables from both models, including Perceived Ease of Use, Perceived Usefulness, Performance Expectancy, Social Influence, Facilitating Conditions, Habit, and Technology Self-Efficacy, to assess their impact on Behavioral Intention and Actual Usage. The study utilizes a quantitative approach, gathering data through surveys and analyzing it using the Partial Least Squares Structural Equation Modeling (PLS-SEM) method. Results indicate significant positive effects of perceived usefulness, performance expectancy, and social influence on the behavioral intention to use E-Mudharabah. The findings underscore the role of user-friendly interfaces and societal acceptance in driving adoption. Perceived Usefulness was the most significant variable influencing Behavioral Intention and Actual Usage (p -value < 0.001). Additionally, Social Influence and Facilitating Conditions were shown to have substantial effects, highlighting the importance of user support and societal acceptance in technology adoption. The research also underscores the role of Technology Self-Efficacy in enhancing user confidence and engagement with the platform. These findings suggest that improving digital finance solutions' perceived benefits and ease of use while fostering a supportive environment can significantly boost their adoption rates.

Keywords—Digital finance; Generative AI; TAM; UTAUT; MSMEs

I. INTRODUCTION

As the spread of information technology is becoming more widespread, especially in the financial services industry, some parties need to adopt new information technologies that can improve their cost structure, and efficiency and improve their competitive position [1]. Increasing income and maintaining

productivity for every MSME business actor is important in distributing funds or capital [2], [3].

Digitalization is the application of steps that arise from innovation in an organization [4]. Digital adaptation is defined as the ability to utilize digital technology through the use of digital tools and online platforms that increase competitiveness [5]. An organization or company should transform and be able to adapt to innovate and compete in an almost digitized world [6].

Digital finance has shown tremendous potential in reaching previously underserved and underserved populations by offering tailored financial services and products [7]. Online banking is becoming one of the more efficient ways and adopting online banking will have a positive impact on bank performance in the future [8]. Flexibility, informality, and control styles support the development of strategies that enable MSMEs to face environmental demands based on innovative and sustainable solutions [9].

E-Mudharabah is a digitalization solution designed as a website-based management information system to make it easier for several parties, including financiers, consultants, and MSME actors to manage and regulate capital schemes [3]. Implementing such digital solutions is expected to enhance the efficiency and effectiveness of financial management within MSMEs.

According to Venkatesh et al. [10], adding UTAUT to the TAM model means adding variables and validation, which of course will also increase the findings to be tested from models that are stated in other contexts [11]. This allows for more complex predictions about technology adoption [12], especially adopting new or innovative technologies [13]. The findings of Venkatesh and Bala [14] by adding elements of UTAUT to the TAM make social and organizational factors increasingly important because there are elements related to the social, psychological, and organizational environment. In addition, according to Venkatesh et al. [10], Zhou et al. [13], the combination of TAM and UTAUT is used for models with adaptive conditions to technological changes and user behavior that changes at any time.

Despite extensive studies on TAM and UTAUT, few have explored their integration in the context of MSMEs adopting AI-enhanced financial tools like E-Mudharabah. This study seeks to bridge this gap by combining these models to offer deeper insights into user adoption behaviors, addressing limitations in previous frameworks that overlooked context-specific variables such as technology self-efficacy and facilitating conditions. These models function as techniques to estimate the likelihood of a population adopting remote technology by incorporating relevant additional variables [15]. This research was conducted to measure the factors that affect the acceptance and utilization of Mudharabah, which has been digitized into a website using a combined Technology Acceptance Model and Unified Theory of Acceptance and Use Technology.

The remainder of this paper is organized as follows: Section II presents the literature review on TAM and UTAUT models and their applications. Section III describes the research methodology, including data collection and analysis methods. Section IV discusses the results, highlighting the key findings. Finally, Section V concludes with implications, limitations, and avenues for future research.

II. LITERATURE REVIEW

Previous studies predominantly examined TAM or UTAUT in isolation, failing to capture their synergistic potential in addressing multifaceted adoption challenges. This study contributes by integrating these models, adding constructs such as Technology Self-Efficacy, and contextualizing the analysis within MSMEs, which are pivotal to economic growth yet underrepresented in such research.

A. Technology Acceptance Model (TAM)

The TAM model is a model used to identify the acceptance and use of a new technology and information system [16]. TAM was developed to improve understanding related to the user onboarding process such as providing new theoretical insights into the design and implementation of information systems successfully designed to evaluate new systems before their implementation [17].

Perceived Ease of Use (PEoU) is interpreted as a value that measures the extent to which a person's confidence in using the system will be free from physical and mental effort [17], in other words, a person does not accept difficulties, but the ease received by using a system [18].

Davis defines perceived usefulness (PU) as the level of trust a person has in using a system that improves an individual's job performance [17] and gets other benefits such as improving his or her job performance [18].

The research of Pitafi & Ali [19] provides an overview that actual use (AU) can be assessed according to the quality of a better system.

B. Unified Theory of Acceptance and Use of Technology (UTAUT)

UTAUT is a tool that can be used to assess the success rate of the introduction of new technology and help understand the

beneficial factors of a user population from internal or external that are the drivers of acceptance so that users can accept adopting new technology and using the system [20]. Ding et al. [21] interpret the use of the UTAUT model as an integrative model whose use is aimed at predicting the availability of an individual to adopt new technologies.

Performance Expectancy is defined as the individual level at which a person is confident that using a system or technology can help improve job performance [20] and can increase a person's efficiency or output [22].

Facilitating Condition is an individual factor that believes that an organization supports the use of the system through adequate infrastructure and technology [20].

Social influence is defined as a direct influence on behavior or can be referred to as the level to which a person feels that another important person can make him believe that he must use a new system [20]. According to Singh et al [22], Social effects or factors are user influences obtained through other people related to the use of the system.

In a study conducted by Venkatesh et al., [10], Habit is an additional construct variable in UTAUT which is described as various user habits that have an impact and influence on the use of a technology.

Behavior Intention is the intention and desire of an individual [23] that influences to use of a technology [24] Hidalgo-Crespo & Amaya-Rivas [25] explain Behavior intention as an effort to encourage a person based on certain habits.

C. Technology Self-Efficacy

Self-efficacy is an assessment of oneself regarding beliefs about individual abilities [26]. Self-Efficacy is an important construct that measures a person's confidence in the ability to display a particular behavior [27], through endurance and perseverance to overcome difficulties, the anxiety faced, and the level of success achieved afterward [28]. Technology Self-Efficacy in Saville & Foster research [29] is defined as a measurement of a person related to the level of confidence in the successful use of a technology.

D. Comparison of Acceptance Models

This sub-section discusses the comparison of case studies with various acceptance models over the last five years.

III. RESEARCH METHODOLOGY

A. Research Model and Hypothesis

The research model shown in Fig. 1 is a path research model, which is used to determine the relationship between variables [36]. In this study, a combination of TAM and UTAUT models was used to determine the factors that affect the use and acceptance of E-Mudharabah. The selection of TAM and UTAUT is based on a literature study from previous studies that recommend a model merger experiment as shown in Table I. Some of the variables that were not used in this study were based on a literature study on the results of previous studies where these variables were considered insignificant.

TABLE I. COMPARISON OF ACCEPTANCE MODELS IN THE LAST FIVE YEARS

Author and Research Model	Variable Construct	R ²	Insignificant Variable
[30] Liu et al., 2022, TAM	Behavior Intention	77.2%	Perceived Ease Of Use
[31] Förster, 2024, TAM	Use Behavior	0.6%	Behavior Intention
[32] Uzir et al., 2023, Modified TAM	Behavior Intention	68.3%	Perceived Financial Cost
[33] Altes et al., 2024, Modified TAM	Behavior Intention	-	Perceived Ease Of Use, Perceived Cost, Voluntariness, Experience
[34] Mukred et al., 2024, Modified TAM	Behavior Intention	37.1%	Perceived Ease Of Use
[35] Chen et al., 2024, UTAUT	Behavior Intention	82.5%	Effort Expectancy
[36] Yee et al., 2024, UTAUT	Behavior Intention	-	Social Influence
[37] Sultana et al., 2023, Modified UTAUT	Behavior Intention	-	Social Factor, Personal Innovativeness
[38] Bellet & Banet, 2023, Modified UTAUT	Intention To Use	89.4%	Anxiety, Price Value, Satisfaction
[39] Han et al., 2024, Modified UTAUT	Behavior Intention	17.4%	Facilitating Condition, Social Influence, Perceived Negative Outcomes, Trust
[40] Rejali et al., 2024, TAM-UTAUT	Behavior Intention	76.1%	Green Perceived Usefulness
[41] Edo et al., 2023, TAM-UTAUT	Behavior Intention	28.3%	Perceived Ease Of Use, Social Influence,
[42] Bajunaied et al., 2023, Modified TAM - UTAUT	Behavior Intention	49.3%	Social Influence, Privacy Inhibitors

The TAM variables used in this study were Perceived Ease of Use, Perceived Usefulness, and Actual Use. The UTAUT variables used were Performance Expectancy, Social Influence, Facilitating Conditions, Habit, and Behavioral Intention. The researcher also added that the Technology Self-Efficacy variable is an important construct that measures a person's confidence in the ability to display certain behaviors [27], through endurance and perseverance to overcome difficulties, anxiety faced, and the level of success achieved afterward [28].

In Fig. 1, the hypothesis that arises as a result of the model built is also explained. The following is a description of the hypothesis based on Fig. 1.

H1: Perceived Ease of Use (PEOU) factor has a positive effect on Behavior Intention (BI) of E-Mudharabah applications.

H2: Perceived Usefulness (PU) factor has a positive effect on Behavior Intention (BI) of E-Mudharabah applications.

H3: Performance Expectancy (PE) factor has a positive effect on Behavior Intention (BI) of E-Mudharabah applications.

H4: Social Influence (SI) factor has a positive effect on Behavior Intention (BI) of E-Mudharabah applications.

H5: Facilitating Conditions (FC) factor has a positive effect on Behavior Intention (BI) of E-Mudharabah applications.

H6: Habit (HB) factor has a positive effect on Behavior Intention (BI) of E-Mudharabah applications.

H7: Technology Self-Efficacy (TSE) factor has a positive effect on Behavior Intention (BI) of E-Mudharabah applications.

H8: Behavior Intention (BI) factor has a positive effect on the Behavior Intention (BI) of E-Mudharabah applications.

Fig. 1. Research model.

H9: Perceived Ease of Use (PEOU) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications.

H10: Perceived Usefulness (PU) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications.

H11: Performance Expectancy (PE) factor has a positive effect on the Actual Use (AU) of E-Mudharabah applications.

H12: Social Influence (SI) factor has a positive effect on the Actual Use (AU) of E-Mudharabah applications.

H13: Facilitating Conditions (FC) factor has a positive effect on the Actual Use (AU) of E-Mudharabah applications.

H14: Habit (HB) factor has a positive effect on the Actual Use (AU) of E-Mudharabah applications.

H15: Technology Self Efficacy (TSE) factor has a positive effect on the Actual Use (AU) of E-Mudharabah applications.

H16: Perceived Ease of Use (PEOU) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications through Behavior Intention (BI)

H17: Perceived Usefulness (PU) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications through Behavior Intention (BI).

H18: Performance Expectancy (PE) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications through Behavior Intention (BI).

H19: Social Influence (SI) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications through Behavior Intention (BI).

H20: Facilitating Conditions (FC) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications through Behavior Intention (BI).

H21: Habit (HB) factor has a positive effect on Actual Use (AU) of E-Mudharabah applications through Behavior Intention (BI).

H22: Technology Self Efficacy (TSE) factor has a positive effect on the Actual Use (AU) of E-Mudharabah applications through Behavior Intention (BI).

B. Data Measurement

This study uses the Likert scale, which is a data measurement technique obtained through a survey to measure individual attitudes and opinions with five options of analytical responses, namely strongly disagree, disagree, undecided, agree, and strongly agree [43]. In this study, the variables are measured based on indicators as shown in Table II. The list of indicators was obtained and processed from literature studies as shown in Table I.

C. Data Collection

The target population is one of the MSMEs in the district in East Java which totals 93. They are a group of food and beverage entrepreneurs. The sample calculation technique uses the Slovin formula with a total sample obtained using the Slovin formula which is 75.

$$v = N / (1 + N\epsilon^2) \tag{1}$$

$$v = 93 / (1 + 93(0.05)^2)$$

$$v = 93 / 1.2325$$

$$v = 75$$

The sample of MSMEs that meet the criteria by filling out the entire questionnaire is 72 MSMEs, then the sample that does not provide a complete response will be eliminated [41].

D. Data Analysis

In this step, to test the variables and the relationships between the variables, the researcher uses Structural Equation Model (SEM) analysis. Briefly about SEM analysis is a validation test, reliability test, regression test, and hypothesis test. In this study, the statistical process uses the SMART PLS 4 application.

TABLE II. VARIABLES AND INDICATORS

No	Variable	Indicator	Code
1	Perceived Ease of Use (PEOU)	Easy to use	PEOU1
		Fast learning	PEOU2
		Clear interaction	PEOU3
		Interaction understood	PEOU4
		It doesn't require much effort.	PEOU5
2	Perceived Usefulness (PU)	Increase productivity	PU1
		Making work more efficient	PU2
		Useful for work	PU3
		Improve performance	PU4
3	Performance Expectancy (PE)	Increasing performance expectations	PE1
		Reach your goals faster.	PE2
		Increase job effectiveness	PE3
		Increase productivity	PE4
4	Social Influence (SI)	MSME managers encourage the use of	SI1
		Organizational influence	SI2
		Business owner support	SI3
5	Facilitating Condition (FC)	Resources available	FC1
		Enough knowledge	FC2
		Compatible with other technologies	FC3
		Help is always available.	FC4
6	Habit (HB)	Become a habit	HB1
		Used daily	HB2
		Automatic usage	HB3
		Routine habits	HB4
7	Technology Self-Efficacy (TSE)	Confident in ability	TSE1
		Can get work done without assistance	TSE2
		Can used with little information	TSE3
		Get the job done with confidence	TSE4
8	Behavioral Intention to Use (BI)	Intended use in employment	BI1
		Recommend to others	BI2
		Plan to continue using	BI3
		Interested in exploring features	BI4
9	Actual Use (AU)	Always use the system	AU1
		Uses most of the features	AU2
		Using in the job	AU3
		Relying on the system for tasks	AU4

IV. RESULT AND DISCUSSION

A. Data Demographics

Based on sub-section III.C, the total number is 75 respondents, but after a review of filling out the questionnaire, there are only 72 respondents who are complete and can be further analyzed.

Table III explains the age of the respondents where the average number of respondents is those aged 21 to 35 years. The last education is the most at the higher education level. This shows the form of mentoring and graduates from higher education in the Regency X area of East Java choose to do entrepreneurship in the food and beverage sector.

TABLE III. DEMOGRAPHICS CONDITION

	Samples (N=72)	%
Gender		
Male	27	37.5
Female	45	62.5
Age		
<20	12	16.7
21 – 35	34	47.2
>35	26	36.1
Level of Education		
Junior/Senior High School	11	15.3
Diploma	23	31.9
Bachelor	31	43.1
Other	7	9.7

B. Measurement Model Analysis (Outer Model)

Measurement analysis is carried out by paying attention to the validity and reliability values obtained through convergent validity and discriminant validity, and the reality values obtained through the reliability of constructs and indicators [23].

Convergent validity is considered to meet satisfactory criteria if the measurement items have high values in their respective constructs [40]. The Valid Criterion if the loading factor is greater than equal to 0.7 (≥ 0.7), and the measurement value of AVE (Average Variance Extracted) is greater than equal to 0.50 (≥ 0.5) [29]. Table IV shows the validity of all variables and their indicators, while Fig. 2 shows the outer loading of each variable.

The constructive/latent variable is stated to meet the convergent validity assumption if the AVE value is greater and higher than 0.5 [23]. So all latten or construct variables in this study shown in Table IV meet the Convergent Validity criteria.

The validity of Discrimination is attributed to the ability of measurement variables to distinguish between the objects being measured [18]. Validity discriminants are defined as diagonal relationships between variables [44]. The validity of discrimination is associated with the ability of measurement items to distinguish between the objects being measured [18].

This study uses the Fornell – Lacker Criterion and Cross Loading methods to determine the discriminatory validity value of all research variables with the results of the calculation of the Fornell – Lacker Criterion in Table IX and the results of Cross Loading in Table X. Both the table is located at the end of the article.

Convergent validity is considered to meet satisfactory criteria if the measurement items have high values in their respective constructs [40]. The Valid Criterion if the loading factor is greater than equal to 0.7 (≥ 0.7), and the measurement value of AVE (Average Variance Extracted) is greater than equal to 0.50 (≥ 0.5) [29]. Table IV shows the validity of all variables and their indicators, while Fig. 2 shows the outer loading of each variable.

The reliability of the research variables can be determined using composite variables [5], with reliable data criteria if the composite reliability value is greater than 0.70 (>0.70) and the Cronbach's alpha value is greater than 0.70 (>0.70) [29].

Cronbach's Alpha is used to evaluate the consistency of internal constraints [31], and satisfactory internal consistency if the value of Cronbach's Alpha and the Composite Reliability value of each variable exceed the value of 0.7 [39].

Thus, based on Table V with the measurement of data for each research variable, it shows that nine research variables meet the criteria of reliability with a Cronbach's Alpha value and a Composite Reliability value greater than the value of 0.7.

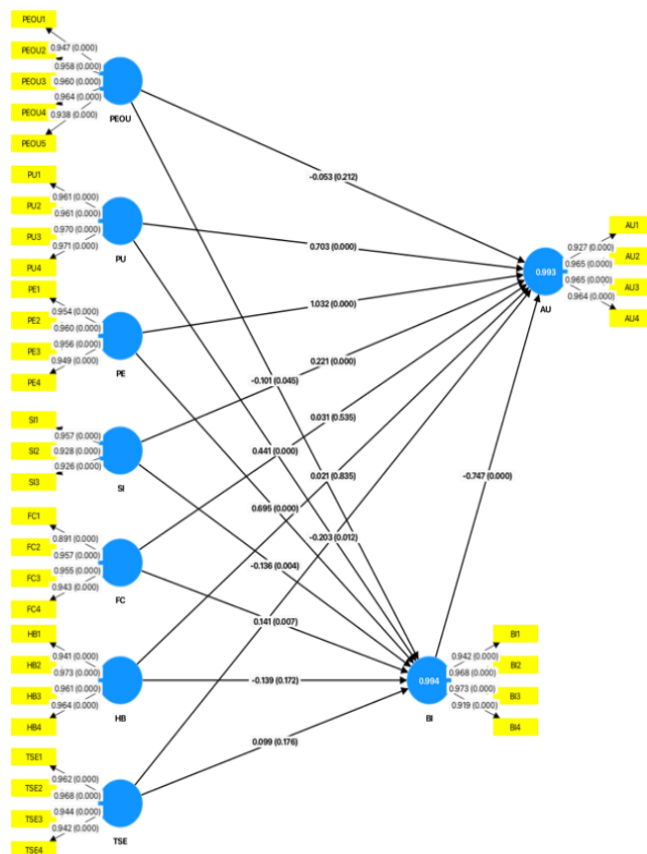

Fig. 2. Output line diagram.

TABLE IV. CONVERGENT VALIDITY

Variable	Indicator	Loading Factor	Valid/No	AVE

TSE	0.967	0.968	0.976

PeoU: Perceived Ease of Use; PU: Perceived Usefulness; PE: Performance Expectancy; SI: Social Influence; FC: Facilitating Conditions; HB: Habit; TSE: Technology Self Efficacy; BI: Behavior Intention; AU: Actual Use of E-Mudharabah

C. Structural Model Analysis (Inner Model)

According to Hidalgo-Crespo & Amaya-Rivas in the study [25], Structural is used to describe the path coefficient, show the relationship of each research variable to the constructed variable, and determine the significant statistical value.

TABLE VI. R-SQUARE VALUE

Variable	R-Square Adjustment	Result
AU	0.993	Strong
BI	0.994	Strong

AU: Actual Use of E-Mudharabah; BI: Behavior Intention

The value of the R-Square Determinant is used to indicate the magnitude of the strength [23] and the magnitude of the influence of independent variables on the dependent variables which are divided into three namely [45]:

- 1) A value of determinant more than 0.67 (>0.67) is a Strong category.
- 2) Moderate category if the R-Square determinant value is between 0.33 – 0.67.
- 3) The category is weak if the R-Square determinant value is between 0.19 – 0.33.

Based on the results of the R-Square calculation in Table VI, the AU and BI construct variables are included in the strong category with values of 0.993 (99.3 %) and 0.994 (99.4 %).

This means that the AU dependent variable is influenced by the independent variable as a whole as much as 99.3% and the remaining 0.7% is influenced by other variables that were not tested in the study. Likewise, the BI dependent variable was influenced by the independent variable as a whole as much as 99.4% and the remaining 0.6% was influenced by other variables that were not tested in the study.

F-square or effect size is a measurement that assesses the relative impact between independent variables on dependent variables which are divided into several category classifications, namely strong categories with an f-square value of more than 0.35, medium categories with an f-square value of more than 0.15, and weak categories with an f-square value of less than 0.02 [45].

Based on the results from Table VII, several factors significantly influence both Behavior Intention and Actual Use of the E-Mudharabah system. Performance Expectancy (PE) emerged as the most influential factor on behavioral intention,

with an F-Square value of 2.689, indicating that users have high expectations that the E-Mudharabah platform will enhance their performance. Users believe that this system will help them achieve their goals more efficiently and improve their overall work effectiveness.

Perceived Usefulness (PU) also plays a crucial role in shaping users' behavioral intentions, with an F-Square value of 0.819. This suggests that users view the E-Mudharabah system as a valuable tool in their daily operations, which in turn, increases their likelihood of continued use. The perception that the system significantly benefits their work encourages users to integrate it into their routines.

TABLE VII. F-SQUARE VALUE

Path	F-Square	Result
PEOU → BI	0.120	Medium
PU → BI	0.819	Strong
PE → BI	2.689	Strong
SI → BI	0.173	Strong
FC → BI	0.163	Strong
HB → BI	0.050	Medium
TSE → BI	0.053	Medium
BI → AU	0.515	Strong
PEOU → AU	0.027	Medium
PU → AU	1.054	Strong
PE → AU	1.485	Strong
SI → AU	0.360	Strong
FC → AU	0.006	Weak
HB → AU	0.001	Weak
TSE → AU	0.195	Strong

PeoU: Perceived Ease of Use; PU: Perceived Usefulness; PE: Performance Expectancy; SI: Social Influence; FC: Facilitating Conditions; HB: Habit; TSE: Technology Self Efficacy; BI: Behavior Intention; AU: Actual Use of E-Mudharabah

Additionally, Perceived Ease of Use (PEOU) affects both Behavior Intention and Actual Use, with F-Square values of 0.120 and 0.027, respectively. This indicates that the easier users find the system to use, the more likely they are to adopt and sustain its use. Simplifying the user interface and ensuring that the system is accessible and user-friendly can significantly enhance user adoption.

Other factors such as Facilitating Conditions and Social Influence also significantly impact behavioral intention and actual usage. Social Influence, with an F-Square value of 0.173, underscores the importance of support from colleagues or superiors in encouraging the use of the system. Facilitating Conditions, which scored an F-Square value of 0.163 for Behavior Intention, suggests that the availability of resources and adequate technical support also contribute to users' willingness to use the system consistently.

From the results of this f-square test, it can be concluded that the pathway with the strongest influence on Behavior Intention (BI) is Performance Expectancy (PE) with the largest f-square value. Meanwhile, the pathways with the strongest influence on Actual Use (AU) are Performance Expectancy (PE) and Perceived Usefulness (PU). The pathways with the weakest influence on Actual Use (AU) are Facilitating Condition (FC) and Habit (HB). This shows that factors such as perceived usability and performance expectations are highly

influential in determining actual intention and use while supporting conditions and habits have a lower influence.

The hypothesis testing in this study uses the bootstrap technique with a significance value of 5% (0.05). Hypothesis acceptance is determined in P-Values [4], with the P-Value criterion being less than 0.05, so it is identified as a significant variable relationship to the latent/construct variable [33].

D. Discussion

After calculating the hypothesis in Table VIII, there are 22 research hypotheses with a total of 15 hypotheses that are accepted by influencing latent variables and seven research hypotheses that are rejected.

Based on the hypothesis testing results, several key insights emerge about the factors influencing MSMEs' usage of the Modified E-Mudharabah website (Micro, Small, and Medium Enterprises). Perceived Ease of Use (PEOU) plays a significant role in shaping Behavioral Intention (BI), suggesting that when MSME users find the E-Mudharabah system easy to use, they are more likely to intend to use it. However, PEOU does not directly affect Actual Use (AU); its influence on AU is mediated through BI. This highlights the importance of designing user-friendly interfaces to enhance user intentions, which translates into actual usage. For MSMEs, simplifying the user experience is crucial as it can reduce the time and effort required for them to adapt to new technology, allowing them to focus more on their core business activities.

TABLE VIII. HYPOTHESIS TESTING RESULT

	Hypothesis Path	T-Val	P-Val	Result
H1	PEOU → BI	1.949	0.026	Accept
H2	PU → BI	6.279	0.000	Accept
H3	PE → BI	9.691	0.000	Accept
H4	SI → BI	3.035	0.001	Accept
H5	FC → BI	2.596	0.005	Accept
H6	HB → BI	1.349	0.089	Reject
H7	TSE → BI	1.391	0.082	Reject
H8	BI → AU	4.645	0.000	Accept
H9	PEOU → AU	1.292	0.098	Reject
H10	PU → AU	7.735	0.000	Accept
H11	PE → AU	7.519	0.000	Accept
H12	SI → AU	3.650	0.000	Accept
H13	FC → AU	0.654	0.257	Reject
H14	HB → AU	0.219	0.413	Reject
H15	TSE → AU	2.522	0.006	Accept
H16	PEOU → BI → AU	1.757	0.040	Accept
H17	PU → BI → AU	4.424	0.000	Accept
H18	PE → BI → AU	4.453	0.000	Accept
H19	SI → BI → AU	2.537	0.006	Accept
H20	FC → BI → AU	1.994	0.023	Accept
H21	HB → BI → AU	1.438	0.075	Reject
H22	TSE → BI → AU	1.388	0.083	Reject

PeoU: Perceived Ease of Use; PU: Perceived Usefulness; PE: Performance Expectancy; SI: Social Influence; FC: Facilitating Conditions; HB: Habit; TSE: Technology Self Efficacy; BI: Behavior Intention; AU: Actual Use of E-Mudharabah

Perceived Usefulness (PU) is a crucial determinant, directly impacting both BI and AU. MSME users are more inclined to use the E-Mudharabah system if they perceive it as useful, confirming that practical benefits and functional advantages are strong motivators for adoption. Additionally, PU's indirect influence through BI underscores its comprehensive effect on user behavior. This finding emphasizes the need for continuous

improvements and updates that enhance the system's utility, ensuring it meets the specific needs and expectations of MSMEs effectively. By demonstrating tangible benefits such as increased efficiency, better financial management, and access to broader markets, the E-Mudharabah system can become indispensable for MSMEs.

PEOU: Perceived Ease of Use; PU: Perceived Usefulness; PE: Performance Expectancy; SI: Social Influence; FC: Facilitating Conditions; HB: Habit; TSE: Technology Self Efficacy; BI: Behavior Intention; AU: Actual Use of E-Mudharabah

Performance Expectancy (PE) and Social Influence (SI) also emerge as significant factors in the context of MSMEs using the E-Mudharabah system. PE, which reflects users' belief that using the system will help them achieve desired business outcomes, significantly affects both BI and AU. Similarly, SI, the influence of peers and social networks, plays a vital role in shaping MSME user attitudes and behaviors towards the system. These findings suggest that promoting the system's effectiveness through success stories and leveraging social networks for endorsement can significantly boost user engagement and acceptance among MSMEs. Encouraging word-of-mouth and positive reviews from other MSMEs can create a supportive community that facilitates wider adoption.

Facilitating Conditions (FC), which refer to the availability of resources and support for using the system, significantly influence BI and indirectly affect AU through BI for MSMEs. This implies that providing adequate support, such as training programs, technical assistance, and user manuals, is essential for fostering user intentions, which in turn drives actual usage. However, FC does not directly impact AU, indicating that while supportive conditions are necessary, they alone are not sufficient to ensure usage without the mediation of BI. For MSMEs, ensuring that they have the necessary infrastructure and support to integrate the E-Mudharabah system into their operations is crucial for its successful adoption.

Interestingly, Habit (HB) and Technology Self-Efficacy (TSE) show distinct patterns of influence among MSME users. HB, or the extent to which users perform behaviors automatically due to learning, does not significantly impact BI or AU. This suggests that habitual behavior may not be a strong predictor in this context, and efforts should focus more on enhancing users' perceptions of ease and usefulness. On the other hand, TSE, which reflects users' confidence in their ability to use the system, directly influences AU but not BI. This indicates that MSME users' self-efficacy in using the technology is crucial for actual usage, even if it doesn't directly shape their intentions. Providing training and resources to boost the confidence of MSME users in their ability to effectively use the E-Mudharabah system can lead to higher actual usage.

Finally, Behavioral Intention (BI) itself is a significant predictor of AU. This confirms the pivotal role of BI in the adoption process, indicating that strategies aimed at enhancing BI—through improving PEOU, PU, PE, SI, and providing adequate FC—are likely to increase actual usage of the E-Mudharabah system among MSMEs. By understanding and addressing these factors, developers, and policymakers can optimize the system to better meet the needs of MSMEs, promoting widespread adoption and helping these enterprises to thrive in the digital economy.

Behavioral Intention (BI) serves as a critical mediator between several factors (Perceived Ease of Use, Perceived Usefulness, Performance Expectancy, Social Influence, Facilitating Conditions) and Actual Use (AU). This mediation highlights that while these factors are essential in influencing users' intentions, the actual usage of the e-Mudharabah system is predominantly driven by the intention to use it. This finding underscores the importance of enhancing users' intentions to

use the system as a pathway to achieving higher actual usage rates. By focusing on improving factors that drive behavioral intention, developers can indirectly increase the actual adoption and use of the system.

Perceived Usefulness (PU) has a strong direct impact on both Behavioral Intention (BI) and Actual Use (AU). Additionally, its indirect impact through BI further enhances its overall influence on AU. Users' perception of the system's usefulness is a pivotal factor in both their intention to use and their actual usage of the system. When users believe that the e-Mudharabah system will significantly benefit their work and improve their performance, they are more likely to adopt and utilize it.

Social Influence (SI) significantly affects both Behavioral Intention (BI) and Actual Use (AU), indicating that the opinions and behaviors of peers and social networks play a crucial role in technology adoption. This result highlights the power of social validation in driving the adoption of new technologies. Users are more likely to use the e-Mudharabah system if they see their peers and social networks endorsing and using it.

Habit (HB) and Technology Self-Efficacy (TSE) do not significantly impact Behavioral Intention (BI), although TSE does have a direct effect on Actual Use (AU). This suggests that habitual behavior and confidence in using the technology are not primary drivers of intention or actual use in this context. These findings indicate that simply relying on users' habitual behavior or their confidence in using technology may not be sufficient to drive the adoption and usage of the e-Mudharabah system. Other factors, such as perceived ease of use, usefulness, and social influence, play more critical roles.

In this study, the intention and desire of MSMEs to use the E-Mudharabah information system is not influenced by the habit and level of trust in a technology, but is positively influenced by the convenience of the E-Mudharabah information system, the benefits received by using the E-Mudharabah information system, the usefulness of the E-Mudharabah information system, the adequate conditions to use an information system and the influence of someone who has used an information system E-Mudharabah.

In contrast to the research by Putri et al [23] which discusses the acceptance of financial technology, it shows that the ease of adoption of technology does not affect a person's desire to use the information technology. Table IV explains that the convenience, usefulness and benefits, social influence, and condition of facilities in MSME places can arouse a person's intention to use and operate the E-Mudharabah information system, while individual habits and abilities cannot be an influence to make the intention to use the E-Mudharabah information system.

V. CONCLUSION

The study underscores the substantial impact of various factors on the intention of MSME (Micro, Small, and Medium Enterprises) actors to utilize the E-Mudharabah information system. It reveals that the intention to adopt this technology is significantly influenced by ease of use, perceived usefulness, and the tangible benefits offered by the system. Social

influence—peer pressure or encouragement from the social environment—and the state of MSME facilities also play a pivotal role. These factors collectively account for an impressive 99.4% of the variance in the intention to adopt the E-Mudharabah information system, indicating their overwhelming importance. However, the study also notes that habitual familiarity with the system and the technical ability of individuals to use it do not significantly drive their intention to adopt the technology.

Moreover, when moving from intention to actual adoption and utilization, the system demonstrates a similarly strong positive impact. The transition from intention to real-life usage is influenced by the benefits perceived by MSME actors, social support, and their readiness, with a high explanatory value of 99.3%. This finding emphasizes that while intention is critical, the practicality and value of the system in addressing specific business needs also significantly drive adoption.

However, the research acknowledges a limitation in its current methodology, specifically the lack of discriminant validity. This issue implies that while the findings are robust, they may not fully capture the nuanced distinctions among variables or populations. To enhance the reliability and applicability of future studies, researchers should expand the target sample size and diversify the population of MSMEs under investigation. This approach will help refine the measurement tools and ensure the data better represents the broader MSME landscape.

While the study demonstrates the significant impact of perceived usefulness and performance expectancy, it does not account for longitudinal adoption trends. Future studies should adopt longitudinal designs to evaluate sustained usage and investigate additional factors such as cultural influences and economic conditions.

ACKNOWLEDGMENT

This research was supported by the Ministry of Education, Culture, Research and Technology of Indonesia. We thank our colleagues from Universitas Merdeka Malang, Indonesia who provided insight and expertise that greatly assisted the research.

DeepLabV3+ Based Mask R-CNN for Crack Detection and Segmentation in Concrete Structures

Yuewei Liu 

School of Civil Engineering and Architecture, Wenzhou Polytechnic, Zhejiang, 325000, China

Abstract—In order to solve the problem of concrete structure crack detection and segmentation and improve the efficiency of detection and segmentation, this paper proposes a crack detection and segmentation method for concrete structure based on DeepLabV3+ and Mask R-CNN algorithm. Firstly, a crack detection and segmentation scheme is designed by analysing the crack detection and segmentation problem of concrete structure. Secondly, a crack detection method based on Mask R-CNN algorithm is proposed for the crack detection problem of concrete structure. Then, a crack segmentation method based on DeepLabV3+ algorithm is proposed for the crack segmentation problem of concrete structure. Finally, bridge crack image data is used for the crack detection and segmentation of concrete structure. Finally, the concrete structure crack detection and segmentation method is validated and analysed using bridge crack image data. The results show that the Mask R-CNN model has better performance in the localisation and identification of cracks, and the DeepLabV3+ model has higher accuracy and contour extraction integrity in solving the crack segmentation problem.

Keywords—DeepLabV3+; Mask R-CNN; concrete structure; crack detection and segmentation; deep learning algorithm

I. INTRODUCTION

With the rapid development of the society, the state's investment in infrastructure such as roads, bridges and buildings is increasing [1]. Most of the above infrastructures are composed of concrete. And the concrete structure may produce cracks for various reasons, which has a great impact on its subsequent use as well as safety [2]. The causes of cracks in concrete facilities include the following: 1) thermal expansion and contraction of concrete produces a large number of cracks; 2) frequent vehicle trips put a great deal of pressure on the highway nucleus bridges, resulting in cracks; 3) too high or too low a standard of concrete ratios cause cracks in the structure; and 4) improper construction causes the concrete shrinkage nucleus to crack prematurely. If the concrete cracks are not repaired in time may lead to highway fracture, bridge nuclear construction facilities collapse, endangering traffic travel [3]. Traditional concrete crack detection and maintenance using manual methods, not only consume manpower and material resources, but also inaccurate detection results, high risk, easy to accident [3]. In order to facilitate the detection of concrete crack nuclei to reduce the risk of detection, artificial intelligence technology is used, not only to improve the traditional image processing technology problems, but also to detect the good results [4]. Concrete structure crack detection and segmentation research is mainly divided into concrete crack detection, crack segmentation and other issues research. The current concrete crack detection methods are divided into contact detection method, non-contact

detection method, and image crack detection method [5-7]. Contact detection method is generally manual detection method, is through visual inspection or measurement attack to detect and record the crack size and location, this method is simple, but has great limitations [5]. Non-contact detection methods are generally used to detect cracks with the help of existing infrared, radar and other equipment, the use of which not only does not have a bad effect on the concrete being detected, but also solves the problem of losses due to human error in judgment [6]. Image crack detection method mainly uses image segmentation technology to detect concrete cracks, which includes segmentation algorithms such as thresholding, region growing, edge detection, etc. This method has the advantages of high detection efficiency and low cost [7]. Xiao et al. [8] proposed the histogram bimodal method to segment the image. Xi et al. [9] proposed the OTUS algorithm to detect cracks, which not only can effectively detect small and irregular cracks, but also the detection accuracy reaches 85%. Li and Yang [10] used osmotic hair to detect the concrete cracks, and got a better result. Moezi et al. [11] combined the seepage theory with the adaptive Canny operator to improve the effect of the detection algorithm. Although the traditional data image detection method is low cost and simple to operate, it is only adapted to simple environments, and the detection segmentation results are not ideal. With the development of artificial intelligence technology, deep learning algorithms are introduced into the image crack detection segmentation problem. Cha et al. [12] used deep learning technology CNN to identify cracks on building surfaces, and achieved 98% accuracy. Zhang et al. [13] used Mask-RCNN combined with FPN feature pyramid network module kernel Resnet model to improve the extraction accuracy of crack disease features, and showed a better recognition accuracy. Li et al [14] for the problem of extracting cracks on concrete surfaces, and proposed an improved lightweight global convolutional network image segmentation model for pavement cracks. Kim and Cho [15] uses the PSPNet semantic segmentation platform for model detection of highway bridge cracks, which shows good detection results.

Although these methods have made significant progress in improving the accuracy and efficiency of crack detection, there are still some shortcomings [16]: (1) the segmentation models suffer from the presence of pooling layers, which leads to the loss of some positional information, restricting their ability to accurately identify fine cracks; (2) some of the structures sacrifice the feature resolution in successive pooling operations or convolutional steps, which makes the prediction task limited and affecting the performance of image segmentation; (3) various types of detection models still need to be further verified for their performance and stability in practical applications.

Concrete crack detection and segmentation is crucial to ensure the safety of concrete structures. For the current concrete crack detection and segmentation problems, this paper proposes Mask R-CNN [18] based on DeepLabV3+ [17] for concrete structure crack detection and segmentation, and the specific contributions of the paper are as follows: (1) analyse the concrete structure crack detection and segmentation problems, and put forward the research scheme; (2) around the concrete structure crack detection problems, put forward the concrete structure crack detection model based on the Mask R-CNN algorithm; (3) A crack segmentation model based on DeepLabV3+ algorithm is proposed for the concrete structure crack segmentation problem; (4) The proposed method is analysed and validated using concrete crack data, and the results show that the model method improves the detection efficiency and accuracy of concrete.

II. CRACK DETECTION AND SEGMENTATION IN CONCRETE STRUCTURES

A. Analysis of the Problem

As one of the common defects in concrete structures, cracks have a direct impact on the safety and durability of bridges. The detailed analysis of cracks in concrete bridges (Fig. 1) can provide a comprehensive understanding of the health status of bridge structures and provide a scientific basis for timely maintenance and repair of bridges [19].

Fig. 1. Schematic diagram of concrete bridge cracks

Concrete crack characteristics mainly include: 1) crack morphology and distribution, which mainly reflects the bridge structure force and deformation process; 2) crack size and shape, the size of which is directly related to the degree of damage to the structure, and its distribution pattern can reflect the structural uneven force, deformation inconsistency and so on, as shown in Fig. 2.

For the task of crack detection in concrete bridges, the concern is the morphology of the cracks. Currently, according to the morphology, concrete cracks are classified into linear cracks and web-like cracks (Fig. 3). Deep learning algorithm-based crack detection method for concrete bridges needs to be targeted at different scales, can effectively detect cracks of various sizes and shapes, and can cope with different lighting conditions and environmental changes, the specific analysis is shown in Fig. 4.

(b) Reticulated cracks.

Fig. 3. Concrete bridge crack patterns.

Fig. 4. Concrete bridge crack detection problem analysis.

In the task of concrete bridge crack detection, only crack target detection is not enough, and the introduction of image segmentation model based on deep learning is crucial. The concrete bridge crack segmentation study is not only able to accurately locate each crack, but also able to accurately segment the outline of the crack, which is analysed as shown in Fig. 5.

Fig. 5. Analysing crack segmentation problems in concrete bridges.

B. Design of Crack Detection and Segmentation Programmes for Concrete Structures

According to the analysis of concrete structure crack detection and segmentation problem, this paper adopts deep learning algorithm to construct concrete structure crack detection and segmentation model, the specific design scheme is shown in Fig. 6. Concrete structure crack detection and segmentation scheme design from two modules to study the concrete structure crack analysis problem, the first module is the concrete structure crack detection model construction, using deep learning algorithms (Mask R-CNN) to locate the overall location of the crack; the second module is the concrete structure crack segmentation model construction, using deep learning algorithms (DeepLabV3+) to segment the crack contour of the cracks.
