***Abstract*—In open traffic scenarios, gesture recognition for traffic police faces significant challenges due to the small scale of the traffic police and the complex background. To address this, this paper proposes a gesture recognition network based on an improved YOLOv11. This method enhances feature extraction and multi-scale information retention by integrating RFCAConv and C2DA modules into the backbone network. In the Neck part of the network, an edge-enhanced multi-branch fusion strategy is introduced, incorporating target edge information and multi-scale information during the feature fusion phase. Additionally, the combination of WIoU and SlideLoss loss functions optimizes the positioning of bounding boxes and the allocation of sample weights. Experimental validation was conducted on multiple datasets, and the proposed method achieved varying degrees of improvement in all metrics. Experimental results demonstrate that this method can accurately perform the task of recognizing traffic police gestures and exhibits good generalization capabilities for small targets and complex backgrounds.**

***Keywords*—Traffic police gesture recognition; loss function; YOLO algorithm; multi-scale feature fusion**

I. INTRODUCTION

In the Road Traffic Law, it is stipulated that when traffic signals and signals issued by traffic control officers conflict, the latter shall prevail [1]. The quick and accurate identification of traffic control gestures is crucial for preventing traffic accidents, alleviating congestion, and improving road usage efficiency.

Traditional gesture recognition methods primarily rely on image processing techniques, separating hand regions through skin color detection [2, 3] and tracking hand movements. However, these methods are effective only in simple and controlled environments. To address this issue, researchers have explored the use of various types of sensors [4, 5, 6, 7, 8] to directly capture motion data. Although this approach achieves higher accuracy, its expensive hardware installation costs and complex real-time communication requirements limit practical implementation.

In recent years, multi-modal recognition technologies have gained prominence, with advancements such as those leveraging wireless signals [9, 10, 11] (e.g., Wi-Fi, infrared, or radar) and deep learning-based multi-modal recognition techniques. These methods alleviate problems caused by lighting variations and occlusions to some extent. However, in complex traffic scenarios, wireless signals are susceptible to interference, significantly impacting recognition accuracy.

With the rapid development of deep learning technologies, skeleton-based recognition methods [12, 13, 14, 15] have become a research focus. By extracting precise pose features, these methods have achieved notable results in gesture recognition. However, existing research mainly targets skeletal data at close distances, leaving gaps in recognition performance in open traffic scenarios with long-range, multi-target, and complex environments.

Effectively identifying traffic control gestures from a crowd under various lighting conditions and positions in open traffic environments remains a challenge. This study addresses the issue by optimizing methods for traffic control gesture recognition, eliminating the need for depth information or skeletal data, thereby significantly reducing processing time. The main contributions of this paper are as follows:

1) Based on publicly available traffic videos in complex scenarios, a new dataset was constructed. It contains eight types of traffic control gestures, characterized by small targets and complex backgrounds, providing a solid data foundation for future research.

2) To address challenges like significant scale variations and complex backgrounds in traffic control scenarios, we designed the C3k2RFCA and C2DA modules. These effectively preserve multi-scale information and detail features. Additionally, multi-scale deep convolution and the Sobel operator were integrated into the Neck part, achieving deep fusion of edge and scale information.

3) The combination of WIoU (Wise-IoU) and an improved SlideLoss was employed as the loss function. WIoU improves the precision of bounding box localization, while SlideLoss optimizes sample weight allocation. Their synergy significantly enhances the performance of traffic control gesture detection in open scenarios.

4) Comprehensive experiments on the custom dataset and two public datasets demonstrate the proposed method's high accuracy and strong generalization capability. It effectively handles the challenges of small targets and complex backgrounds.

The structure of this paper is as follows: Section II introduces the related work, Section III describes the improved YOLO method and its application algorithm for traffic police

gesture recognition, Section IV reports the experimental results, and Section V provides the conclusions.

II. Related Work

A. YOLOv11 Algorithm

First, YOLOv11, as a groundbreaking advancement in the field of object detection, achieves significant improvements in detection efficiency and accuracy through a series of innovative modules and optimized designs. The core innovations of this method include the newly introduced C3k2 module and C2PSA module. C3k2 is an improved version of the CSP (Cross Stage Partial) bottleneck structure. By integrating a two-layer convolutional structure, it significantly enhances feature extraction capabilities while maintaining low computational overhead. This optimization makes the method particularly effective in handling complex scenarios, multi-scale targets, and detailed features. Meanwhile, the C2PSA module incorporates a position-sensitive attention mechanism that dynamically focuses on the critical spatial regions where targets are located, enhancing the capture and processing of spatial information. This is especially effective in tasks involving small object detection and precise localization.

Additionally, YOLOv11 introduces lightweight optimizations in the detection head. By simplifying the network structure and reducing unnecessary computational processes, the parameter count has been reduced by approximately 20% compared to the previous generation. This significantly lowers computational costs while maintaining high accuracy. This lightweight design not only enhances runtime speed but also supports the efficient deployment of the method on resource-constrained devices.

B. Gesture Recognition

For traffic police gestures, it has been observed that each gesture can be represented by key hand movements. Therefore, static gesture recognition becomes an effective implementation method. The development of object detection algorithms has provided new perspectives for this field. Zhang et al. [16] improved the YOLOv3 algorithm to achieve gesture recognition; Wang et al. [17] combined YOLO algorithm and Kalman filter to realize high-precision gesture recognition and tracking; Saxena et al. [18] utilized YOLOX and YOLOv5 methods to achieve high-accuracy and high-efficiency gesture recognition, facilitating communication for individuals with hearing and speech impairments; Helal et al. [19] combined CNN and YOLO techniques to recognize sign language alphabets, achieving high accuracy while optimizing training time.

The YOLO algorithm is widely applied due to its accuracy and speed, but it still requires adaptations for different scenarios. For instance, Yang et al. [20] proposed the YOLO-LRHG method, combining YOLO with attention mechanisms to address long-distance human-machine interaction gesture recognition problems. Zhou et al. [21] designed the PEA-YOLO lightweight network, improving recognition performance through adaptive spatial feature pyramids and multi-path feature fusion.

Most of the previous research methods have been limited to improving the accuracy of gesture recognition at close range and have not addressed distant scenes with increased interference. This paper builds upon the YOLOv11 network and introduces enhancements to tackle challenges such as the loss of detailed features and the presence of complex backgrounds in far-distance open traffic scenarios. The goal is to improve the detection of key gestures in complex environments, providing an efficient and accurate gesture recognition solution for intelligent traffic management and autonomous driving.

III. Model

In this study, the RFCAConv module was utilized for sampling operations, and the C3k2 module was restructured and optimized. Additionally, the original C2PSA module was replaced with the C2DA module, and an edge-enhanced multi-branch fusion strategy was introduced in the Neck section. To further improve the performance and efficiency of the method, WIoU [22] and Slide-Loss [23] were newly proposed. The TPGR-YOLO overall structure is shown in Fig. 1.

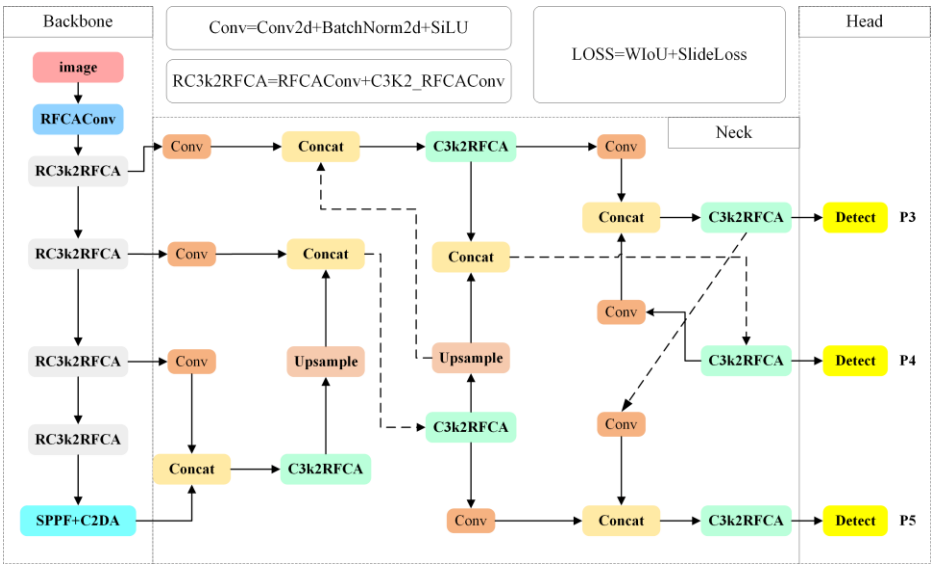

Fig. 1. TPGR-YOLO overall structure.

A. C3K2RFCA

RFCAConv [24] integrates receptive field generation convolution and coordinate attention mechanism (CA), effectively addressing the limitations of traditional convolution, where shared convolution kernels result in insufficient sensitivity to feature locations. It also overcomes the inadequacy of conventional spatial attention mechanisms in fully extracting regional features from contextual information. RFCAConv generates receptive field features, applies weight mapping to them, and then employs standard convolution operations to produce output features. This process combines the advantages of local feature enhancement and global positional attention, resulting in finer-grained and more effective attention weights. As shown in Fig. 2, its structure has been optimized and improved.

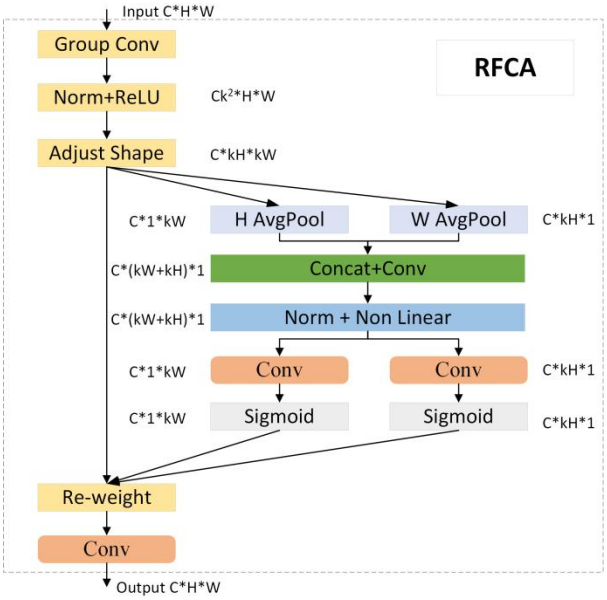

Fig. 2. RFCAConv structure.

For the input feature map $X \in R^{B\times C\times H\times W}$, the RFCAConv module first generates features $G \in R^{B\times(C\cdot k^2)\times H\times W}$ through the receptive field generation module. In the receptive field features G, the feature of each pixel is expanded into a high-dimensional feature map containing the local receptive field. Subsequently, the receptive field features G are unfolded into the spatial dimension.

$$G = \text{Conv}(X, \text{kernel\_size} = k, groups = C) \tag{1}$$

$$\begin{aligned} &G = \text{reshape}(G, (B, C, k^2, H, W)) \\ &\rightarrow G = rearrange(G, (H \cdot k, W \cdot k)) \end{aligned} \tag{2}$$

Next, the receptive field features G undergo global pooling along the horizontal and vertical directions, resulting in features X_h and X_w, which represent the global features in the horizontal and vertical directions, respectively. These two features are concatenated and processed through a 1×1 convolution, batch normalization, and the h-swish activation function to generate intermediate features Y. Y is then split into two parts: the horizontal features $X_h^{'}$ and the vertical features $X_w^{'}$. These parts are further processed through two separate 1×1 convolutions to generate attention weights in the two directions: horizontal weight A_h and vertical weight A_w, each normalized using a Sigmoid activation function.

$$X_h = Pool_h(G), X_w = Pool_w(G) \tag{3}$$

$$Y = \text{Act}(BN(Conv1(X_h \oplus X_w))) \tag{4}$$

$$X_h', X_w' = split(Y) \tag{5}$$

$$A_h = \sigma(Conv(X_h')), A_w = \sigma(Conv(X_w')) \tag{6}$$

Finally, the receptive field features G are pixel-wise weighted by multiplying A_h and A_w, resulting in enhanced feature representations. The weighted features are then passed through a convolutional layer to produce the final output feature map O. The principle is given in Eq. (1) – Eq. (6). This output feature map not only incorporates local receptive field information but also integrates global positional attention in the horizontal and vertical directions.

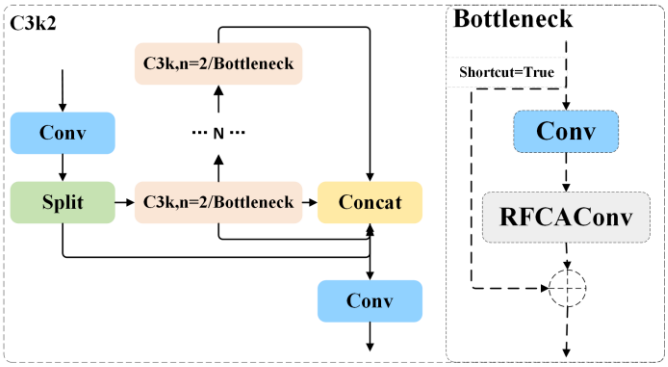

Fig. 3. C3k2RFCA structure.

At the same time, by introducing the global position sensitivity and local receptive field enhancement capabilities of RFCAConv, the C3k2 module has been structurally redesigned. This addresses the problem of reduced feature map resolution caused by multiple downsampling and stride convolutions in the C3k2 module, while compensating for the limited receptive field of the 3×3 convolution kernel, which hampers the ability to capture small objects and fine-grained features. The structure of the redesigned C3k2 module is shown in Fig. 3.

The input features first pass through RFCAConv, undergoing local receptive field enhancement and directional attention weighting to obtain feature representations with a stronger global receptive field. Subsequently, RFCAConv replaces traditional stride convolution for downsampling, further reducing resolution loss while enhancing focus on target regions. Finally, the output feature map retains more detailed information, providing stronger small-object detection capabilities and improved spatial perception.

B. C2DA

The C2PSA module, based on the global feature channel distribution attention mechanism, has limited local feature modeling capabilities, which can dilute spatial detail information and lead to reduced detection accuracy. Drawing inspiration from the concept of Deformable Attention [25], this paper proposes the C2DA module, introducing adaptive local feature learning based on deformable sampling to address the shortcomings of the C2PSA module. Its structure is shown in Fig. 4.

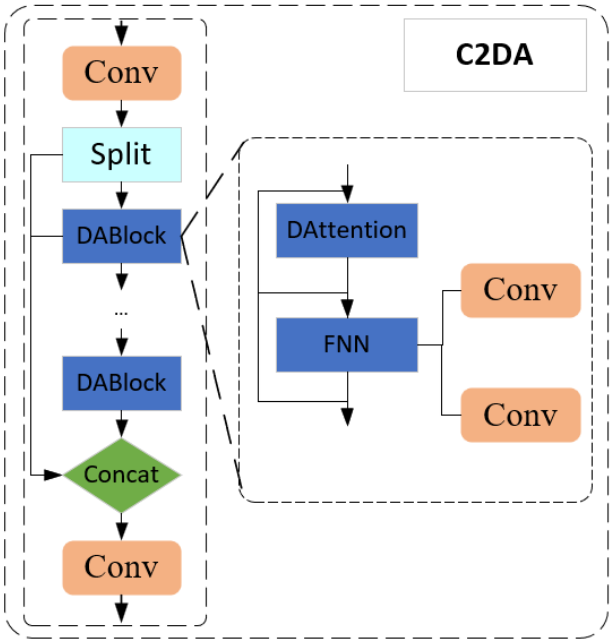

Fig. 4. C2DA structure.

First, the input features undergo dynamic offset sampling. The offset generation network in the C2DA module generates adaptive sampling positions based on the input features, enabling precise capture of critical features and detailed significant regions of small objects while avoiding interference from irrelevant areas. Second, a local sampling range is introduced by restricting dynamic sampling to a local area near the reference points. The offset magnitude is controlled using the tanh function and a scaling factor, ensuring the smoothness and local consistency of the sampling process. This approach enhances the modeling of object boundaries and details. In addition, C2DA retains the global characteristics of the attention mechanism. By leveraging query-key-value matching, it explores global relationships between pixels, allowing the capture of contextual information relevant to small objects and preventing their features from being overshadowed by complex backgrounds.

The generation of dynamic offsets begins by grouping the input feature map $X \in R^{B\times C\times H\times W}$. For each group of features $X_{group} \in R^{B\times \frac{C}{groups}\times H\times W}$, a convolutional network is used to generate the offset values $\Delta p = Conv_{offset}(X_{group})$. The offset values are $\Delta p \in R^{B\cdot g\times 2\times H_k\times W_k}$ then normalized and added to the reference points to obtain the offset positions p, where p represents the grid reference points. The principle is Eq. (7) – (8).

Using the offset positions p, the input feature map x is dynamically sampled through bilinear interpolation, producing sparsely sampled features $X_{sampled} \in R^{B\times C\times 1\times N}$.

$$p = \tanh(\Delta p)\cdot offset\_range + P_{ref} \tag{7}$$

$$X_{sampled} = GridSample(x, p) \tag{8}$$

The features obtained from dynamic offset sampling are then fed into the multi-head attention module. First, a convolutional layer is used to compute the values of Query(q), Key(k), and Value(v), where q, k, and v are the respective feature representations. Next, the similarity between the Query and Key is computed to obtain the attention weights A. The attention weights A are used to perform a weighted aggregation of v. The aggregated result z is then passed through the projection output layer W_{proj} to generate the final features. The input features x are added to the final features via a residual connection, resulting in the output y, where W_{proj} is the projection output layer, and X_{res} is914 the residual connection. The principle is given in Eq. (9) - Eq. (13).

$$L = H\cdot W, C_h = \frac{C}{heads} \tag{9}$$

$$q = W_q x, k = W_k x_{sampled}, v = W_v x_{sampled} \tag{10}$$

$$A = Soft\max(\frac{q\cdot k^T}{\sqrt{C_h}} + PE(q,k)) \tag{11}$$

$$z = A\cdot v \tag{12}$$

$$y = W_{proj}(z) + x_{res} \tag{13}$$

The C2DA module incorporates the powerful characteristics of the dynamic attention mechanism, leveraging deformable convolution and self-attention to enhance the ability to focus on critical spatial regions in visual tasks. It demonstrates strong adaptability while effectively balancing local details and global context.

C. SAFPN

Traffic police gesture recognition is often challenged by various complex background interferences, such as lighting conditions, vehicles, and pedestrians, which significantly increase the difficulty of gesture recognition. In scenarios with lighting variations or occlusions, edge features often provide more information than content features. However, the neck structure of the original network primarily focuses on high-level semantic features, lacking effective preservation of edge

and local details [26], which can easily lead to the loss of target edge information.

To address this issue, this paper proposes an edge-enhanced multi-branch fusion structure (SAFPN), which specifically includes the SSAF (Shallow Edge-Assisted Fusion) module and the AAF(Advanced Assisted Fusion) module. These modules are designed to strengthen edge information extraction and the comprehensive utilization of multi-scale features.

The SSAF module combines the capabilities of the Sobel operator and SAF, fusing the shallow extracted target edge information, high-resolution shallow features, information from the same level of the backbone network, and deep features. This approach significantly preserves critical details in shallow layers. The structure is illustrated in Fig. 5 of the paper.

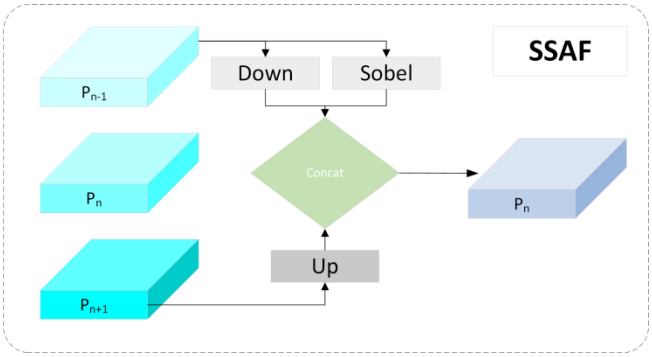

Fig. 5. SSAF structure.

SSAF demonstrates remarkable advantages in small object detection and handling complex backgrounds. The Sobel operator extracts the gradient information of images, effectively capturing the edge features of targets. It also suppresses interference from smooth areas in complex backgrounds, retaining only the edge regions with significant changes, thereby reducing the impact of background noise. Additionally, as a fixed edge extractor, the Sobel operator requires no additional training parameters, adds negligible computational complexity, and yet significantly enhances the network's sensitivity to target regions. The output results after applying SSAF are as follow [see Eq. (14)]

$$P'_n = concat\ (S(P_{n-2}), P_{n-1}, P_n, P'_{n+1}) \tag{14}$$

The AAF module aggregates shallow high-resolution features, shallow low-resolution features, information from sibling layers at the same level, and comprehensive information from the previous layer. This enables the transfer of more diverse gradient information to the network's output layer. As shown in Fig. 6, the final output layer combines information from multiple different layers, significantly enhancing the network's ability to detect targets at various scales. The output results after applying AAF are as follows. Additionally, the AAF module utilizes 1×1 convolutions to adjust the channel information of each layer, optimizing the contribution of features from each layer to the final result [see Eq. (15)]

$$P''_n = concat\ (P'_{n-1}, P''_{n-1}, P'_n, P'_{n+1}) \tag{15}$$

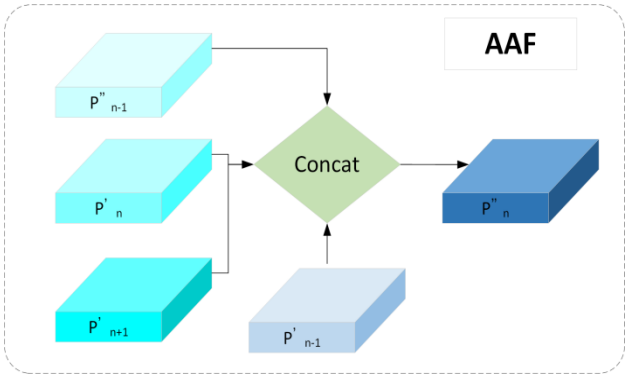

Fig. 6. AAF structure.

The SSAF module effectively reduces background noise interference, while the multi-scale fusion and dynamic weighting mechanism of the AAF module further integrate effective features. The overall design not only enhances the detection capability for small objects and prominent regions but also improves the method's robustness and detection accuracy in complex backgrounds.

D. Loss

In traffic police gesture recognition tasks in open scenarios, training data inevitably contains low-quality samples [27] due to issues with the images themselves or their annotations. Additionally, this task faces the challenge of imbalanced sample distribution, with an uneven distribution of hard and easy samples. These factors significantly limit the effectiveness of traditional loss functions in training.

To address this issue, we creatively introduce WIoU and Slide Loss, tackling the problem from two perspectives: target box optimization and sample weight allocation. Together, these approaches effectively mitigate the critical challenges in traffic police gesture recognition tasks.

1) WIoU: Since training data inevitably contains low-quality samples, geometric factors such as distance and aspect ratio exacerbate the penalties imposed on these samples, thereby reducing the method's generalization performance. When the anchor box aligns well with the target box, a good loss function should attenuate the penalties from geometric factors. Reduced training intervention can enhance the method's generalization capability. Based on this principle, Tong developed distance attention and introduced WIoU v1 with a two-layer attention mechanism, The principle is given in Eq. (16) – Eq. (18).

$$L_{WIoUv1} = R_{WIoU} L_{IoU} \tag{16}$$

$$R_{WIoU} = \exp\left(\frac{(x-x_{gt})^2 + (y-y_{gt})^2}{(W_g^2 + H_g^2)^*}\right) \tag{17}$$

$$L_{IoU} = 1 - IoU = 1 - \frac{W_i \cdot H_i}{S_u} \tag{18}$$

Here, W_g and H_g represent the size of the minimum enclosing box, x and y are the center coordinates of the anchor box, and X_{gt} and Y_{gt} are the center coordinates of the ground truth box. The symbol $*$ indicates that W_g and H_g are detached from the computation graph to prevent gradients that hinder convergence. W_i and H_i denote the width and height of the predicted box, while S_u represents the union area.

WIoU v3 builds upon WIoU v1 by introducing a dynamic non-monotonic focusing mechanism, using outlier degree instead of IoU for anchor box quality evaluation. It also provides a more flexible gradient gain allocation strategy. This strategy reduces the competitiveness of high-quality anchor boxes while mitigating harmful gradients from low-quality samples, allowing the method to focus on optimizing medium-quality anchor boxes. Consequently, it enhances overall detection performance. The principle is given in Eq. (19) - Eq. (20)

$$L_{WIoUv3} = r \cdot L_{WIoUv1}, r = \exp(-\beta \cdot \delta) \tag{19}$$

$$\beta = \frac{L^*_{IoU}}{\overline{L}_{IoU}} \in [0, +\infty) \tag{20}$$

Here, β represents the outlier degree of the anchor box, and L^*_{IoU} is the exponentially weighted moving average of L_{IoU}. L^*_{IoU} is a dynamic value used to measure the quality of the anchor box. δ is a hyperparameter that controls the mapping relationship between the outlier degree β and the gradient gain r. When $\beta = \delta$, $r = 1$, meaning the anchor box receives the highest gradient gain.

In scenarios involving long distances and small targets, WIoU can provide more accurate target localization by applying weighted corrections to the shape, size, and offset position of the bounding box. It effectively alleviates the issue of bounding box displacement in complex backgrounds.

2) SlideLoss: Slide Loss introduces a dynamic modulation factor to segmentally adjust sample weights based on their IoU values. Additionally, Slide Loss dynamically adjusts the IoU threshold to ensure stability in loss calculation.

It categorizes samples into three IoU intervals: low, medium, and high. Different weights are assigned to each interval: low-IoU samples retain their original weights, medium-IoU samples are assigned amplified weights to enhance focus on hard-to-classify samples, and high-IoU sample weights are exponentially decayed to reduce interference from easily classifiable samples.

This mechanism enables the model to automatically assign higher optimization weights to challenging samples in gesture detection tasks under long-distance and complex background conditions. It addresses the shortcomings of Binary Cross-Entropy (BCE) loss, including imbalanced positive-negative sample weighting, insufficient optimization for hard-to-classify samples, and inadequate focus on low-confidence samples. The principle is given in Eq. (21) – Eq. (25).

$$L_{Slide} = L_{base} \cdot \alpha \tag{21}$$

$$\alpha_1 = 1.0, \text{ if true} \leq \beta - 0.1 \tag{22}$$

$$\alpha_2 = \exp(1.0 - \beta), \text{if } \beta - 0.1 < \text{true} < \beta \tag{23}$$

$$\alpha_3 = \exp(-(\text{true} - 1.0)), \text{ if true} \geq \beta \tag{24}$$

$$\text{auto\_iou} = \max(\beta, 0.2) \tag{25}$$

β represents the dynamic IoU threshold, constrained to a minimum value of 0.2. Low-IoU samples $true \leq \beta - 0.1$ retain their loss unchanged $\alpha_1 = 1.0$, medium-IoU samples $\beta - 0.1 < true < \beta$ have their loss amplified to $\exp(1.0 - \beta)$ to enhance focus on hard-to-classify cases, and high-IoU samples $true \geq \beta$ have their loss exponentially decayed to $\exp(-(\text{true} - 1.0))$, reducing the interference of easily classified samples on the overall loss. By assigning adaptive weights to samples at different IoU levels using the modulation factor α, Slide Loss optimizes hard-to-classify samples, preserves low-IoU samples, and minimizes the influence of high-IoU samples. This design makes Slide Loss particularly effective for traffic police gesture detection in long-distance and complex background scenarios.

WIoU enhances the geometric information modeling capability of bounding boxes through dynamic weighting, while Slide Loss adjusts sample weights based on IoU differences, prioritizing the optimization of rare and challenging samples with weaker gradients. The ingenious combination of these two methods effectively addresses the critical challenges in traffic police gesture recognition tasks, significantly improving the detection performance and generalization ability of the approach.

IV. Experience

To evaluate the effectiveness of the proposed method in traffic police gesture recognition tasks with long distances and complex backgrounds, this study conducted comprehensive testing and assessment across various scenarios. The proposed method was trained and validated on a custom-built traffic police gesture dataset and compared with several mainstream object detection methods. To further demonstrate the algorithm's generalization ability, performance comparisons were also made with leading algorithms on the WiderPerson and VOC datasets. Additionally, the study performed ablation experiments to analyze the contributions of different components of the method in detail, and visual methods were employed to conduct an in-depth discussion of the experimental results.

A. Setting

The improved YOLOv11 method was used for training and testing during the experiments. The experimental system was based on Ubuntu 22.04. Table I presents the experimental environment and the configurations of some hyperparameters.

TABLE I. EXPERIMENTAL ENVIRONMENT CONFIGURATION

Project Environment	Parameter Setting
Framework	Pytorch
CPU	Xeon(R) Platinum 8352V
GPU	3080*2
Batch Size	64
Epoch	300
Workers	8
CUDA	12.1
Optimizer	SGD

B. Datasets and Evaluation Metrics

The datasets used in this study include the self-collected CTPG dataset, the WiderPerson dataset, and the VOC dataset. Accuracy is evaluated using metrics such as Precision (P), Recall (R), and Mean Average Precision (mAP).

The self-collected CTPG dataset is sourced from Beijing University of Technology's public transportation control gestures [28]. It includes difficult samples from midday and evening scenarios, captured from three different viewing angles: left, center, and right. During the experiment, frames were randomly sampled from the provided video samples and annotated using the makesense platform, resulting in 5,857 training images, 1,200 validation images, and 1,200 test images. The gestures in the dataset represent real-world road scenarios, characterized by long distances, complex backgrounds, and occlusion. The gestures consist of eight categories: "Stop," "Straight Ahead," "Left Turn," "Left Turn and Wait," "Right Turn," "Lane Change," "Slow Down," and "Pull Over." Example samples are shown in Fig. 7.

The WiderPerson dataset [29] is a large-scale dataset for pedestrian detection, containing 13,382 images and over 400,000 high-quality annotated pedestrian instances. It covers complex scenarios such as occlusion, dense crowds, small targets, and various pedestrian poses. The dataset is sourced from real-world diverse scenes and provides precise bounding box annotations, supporting training and evaluation for pedestrian detection tasks. Its scene diversity and challenges make it an important benchmark dataset for pedestrian detection research.

The PASCAL VOC dataset [30] is one of the most widely used standard datasets in the field of computer vision, focusing on tasks such as object detection, image classification, and semantic segmentation. The dataset includes 20 common object categories and provides precise annotation information, including bounding boxes, category labels, and pixel-level segmentation masks. The VOC dataset features diverse scenes and object variations, and its clear evaluation metrics and rich challenges make it a key benchmark for object detection and image segmentation research.

C. Comparison Experiments

To demonstrate the superiority of the proposed method, this study compares several mainstream algorithms on the aforementioned datasets, including single-stage and two-stage conventional CNN algorithms, lightweight algorithms, and Transformer-based methods.

As shown in Table II, a comprehensive comparison is made between multiple object detection methods in terms of parameter count, computational cost, model size, performance metrics, and inference speed. The proposed TPGR-YOLO outperforms other methods across several key indicators. TPGR-YOLO has only 2.8 M parameters, a computational cost of 7.6 GFLOPs, and a model size of just 6 M. It achieves superior performance in accuracy (P = 94.4%), recall (R = 83.4%), mAP@50 (93.6%), mAP@50:95 (72.7%), and inference speed (FPS = 72.7), demonstrating its excellence in lightweight design and high-performance object detection. In contrast, traditional methods such as Faster R-CNN have a parameter count as high as 60 M, a computational cost of 255 GFLOPs, and while they show decent accuracy (P = 79.7%, mAP@50 = 86.2%), their inference speed is only 58.5 FPS, making them unsuitable for real-time applications. ASF-YOLO achieves a high FPS while achieving good accuracy due to its lightweight treatment; RT-DETR balances accuracy (P = 90.2%, R = 77.8%) and speed (FPS = 65.8), but its parameter count is 42 M, with a computational cost of 136 GFLOPs and a model size of 166 M, which is not suitable for resource-constrained scenarios. The YOLO series shows good performance in terms of both lightweight design and performance, but still lags behind TPGR-YOLO. For example, YOLOv11n has 2.6 M parameters and an accuracy of 90.1%, but its mAP and recall are lower than TPGR-YOLO. LD-YOLOv10 shows improvements in accuracy (P = 89.7%, R = 77.1%) and speed (FPS = 65.2), but its parameter count and computational cost are 8.1 M and 24.7 GFLOPs, respectively, making it less efficient than TPGR-YOLO.

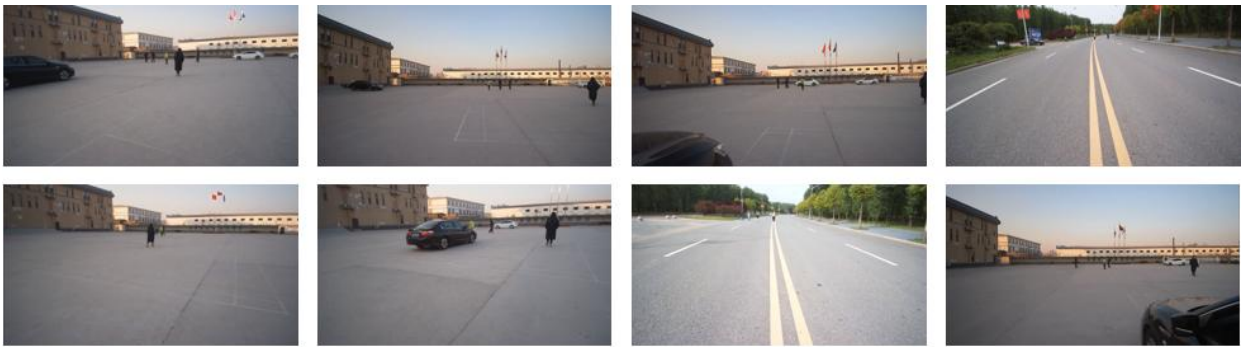

Fig. 7. Several types of action diagram.

TABLE II. COMPARISON OF MAINSTREAM ALGORITHMS ON THE CTPG DATASET

Models	Para(M)	GFLOPs(G)	Model size(M)	P	R	mAP@50	mAP@50:95	FPS
Faster R-CNN[31]	60	255	109	79.7	72.3	86.2	58.5	30
YOLOv5[32]	7.2	16.5	14	82.1	70.4	88.0	60.5	108
YOLOv7	36.9	104.7	72.5	85.3	73.2	86.3	63.4	70
ASF-YOLO[33]	15.9	79.1	25	88.5	74.5	86.0	64.7	137
YOLOv9s	9.7	37.6	15.2	87.6	75.2	85.6	63.4	100
LD-YOLOv10[34]	8.1	24.7	17	89.7	77.1	88.3	65.2	102
RT-DETR[35]	42	136	166	90.2	77.8	84.9	65.8	40
YOLOv11n	2.6	6.3	5.5	90.1	78.2	88.2	67.4	140
TPGR-YOLO	2.8	7.6	6.0	94.4	83.4	93.6	72.7	135

To evaluate the generalization ability of the algorithm, this study compares the proposed method with mainstream algorithms on the WiderPerson dataset. The results are shown in Table III. The experimental results demonstrate that the proposed TPGR-YOLO outperforms other object detection methods in multiple metrics, including precision, recall, and mAP. TPGR-YOLO achieves a precision of 94.5%, recall of 81.0%, mAP@50 of 89.2%, and mAP@50:95 of 69.6%, leading across all performance indicators.

In comparison, YOLOv5s and YOLOv7-tiny show weaker performance, with precisions of 82.2% and 83.2%, mAP@50 of 78.9% and 82.7%, and mAP@50:95 of only 59.7% and 61.7%. As the methods evolve, their performance gradually improves. When compared to the state-of-the-art YOLO detector, YOLOv11n, the proposed method surpasses its precision, achieving 91.8%, with an mAP@50 of 87.8%. TPGR-YOLO demonstrates significant advantages in balancing detection accuracy and performance, fully proving the superiority of the improved algorithm.

TABLE III. COMPARISON EXPERIMENTS OF THE WIDERPERSON DATASET

Models	P	R	mAP@50	mAP@50:95
YOLOv5s	82.2	66.7	78.9	59.7
YOLOv7-tiny	83.2	71.7	82.7	61.7
YOLOv8n[36]	86.4	76.4	85.3	65.9
Yolov9s	89.4	76.8	86.0	65.6
YOLOv10s	90.7	78.2	86.7	67.8
Yolov11n	91.8	79.3	87.8	68.4
Ours	94.5	81.0	89.2	69.6

The experimental results on the VOC dataset show that the proposed TPGR-YOLO performs the best across all key metrics. The results are shown in Table IV. TPGR-YOLO achieves a precision of 71.9%, recall of 64.8%, mAP@50 of 70.7%, and mAP@50:95 of 54.8%, significantly outperforming other methods.

In comparison, the weaker-performing YOLOv5s achieves only 55.7% precision and 53.5% mAP@50, while YOLOv7-tiny reaches precision and mAP@50 of 59.4% and 57.2%, respectively. As the methods evolve, performance improves. For example, YOLOv10s and YOLOv11n achieve mAP@50 values of 63.1% and 67.9%, respectively. However, TPGR-YOLO still leads across all metrics, particularly in mAP@50:95, where it surpasses YOLOv11n by approximately 3.1 percentage points. These results demonstrate that TPGR-YOLO has a clear advantage in balancing detection accuracy and performance, making it one of the best-performing methods on the VOC dataset.

TABLE IV. COMPARISON EXPERIMENTS OF THE VOC DATASET

Models	P	R	mAP@50	mAP@50:95
YOLOv5s	55.7	53.6	53.5	46.7
YOLOv7-tiny	59.4	55.2	57.2	45.0
YOLOv8n	62.7	56.3	61.8	46.0
Yolov9s	65.4	58.4	62.2	49.7
YOLOv10s	68.2	59.5	63.1	50.5
Yolov11n	71.2	61.7	67.9	51.7
Ours	71.9	64.8	70.7	54.8

The performance comparison between WIoU combined with Slide Loss and the original model loss (Table V) reveals that: The sliding window mechanism in Slide Loss refines the regression process of prediction boxes, significantly enhancing the model's adaptability to small targets and complex scenarios, demonstrating marked advantages over traditional BCE loss in small object detection and regression accuracy. While both WIoU and CIoU improve model performance when combined with Slide Loss, WIoU achieves superior comprehensive performance through its focus on medium-quality anchor boxes and suppression of low-quality samples interference, thereby forming complementary advantages with Slide Loss.

TABLE V. COMPARISON OF DIFFERENT LOSS FUNCTIONS

LOSS	P	R	mAP@50	mAP@50:95
CIoU+BCE	90.1	78.2	88.2	67.4
CIoU+SlideLoss	90.6	78.4	88.7	67.9
WIoU+BCE	90.7	78.3	88.6	68.2
WIoU+SlideLoss	91.4	78.9	89.5	68.5

D. Ablation Experiments

To validate the performance improvement contributed by each module, this study conducts ablation experiments by progressively introducing key modules and evaluating their impact on performance. The results are shown in Table VI.

TABLE VI. ABLATION ANALYSIS OF CTPG DATASET

Modules	Para/M	GFLOPs	Model size	P	R	mAP@50	mAP@50:95
YOLOv11n	2.6	6.3	5.5	90.1	78.2	88.2	67.4
+RFCAConv	2.7	6.9	5.8	90.7	79.4	89.2	68.1
+C3k2RFCA+C2DA	2.7	6.9	5.8	91.2	80.8	90.7	69.5
+C3k2RFCA+C2DA+SAFPN	2.8	7.6	5.8	92.5	81.5	91.4	70.2
+C3k2RFCA+C2DA+SAFPN+WIoU	2.8	7.6	6.0	93.9	82.6	92.8	71.1
TPGR-YOLO	2.8	7.6	6.0	94.4	83.4	93.6	72.7

The baseline method, YOLOv11n, has 2.6 M parameters, 6.3 GFLOPs, and a model size of 5.5 M, achieving a precision of 90.1%, recall of 78.2%, mAP@50 of 88.2%, and mAP@50:95 of 67.4%, with relatively limited performance. Upon introducing the RFCAConv module, the number of parameters slightly increases to 2.7 M, the computational cost rises to 6.9 GFLOPs, and the method's precision improves to 90.7%, recall increases to 79.4%, mAP@50 reaches 89.2%, and mAP@50:95 rises to 68.1%, indicating that RFCAConv effectively enhances feature extraction capabilities.

Further adding the C2DA module leads to continued performance improvement, with precision reaching 91.2%, recall rising to 80.8%, and mAP@50 and mAP@50:95 increasing to 90.7% and 69.5%, respectively, showcasing the significant potential of C2DA's dynamic offset and local feature modeling in object detection.

When combining C2DA and SAFPN modules, both precision and recall further improve to 92.5% and 81.5%, respectively, with mAP@50 reaching 91.4% and mAP@50:95 increasing to 70.2%, demonstrating the significant effect of these modules on multi-scale feature fusion and contextual modeling.

Finally, introducing the WIoU loss function to optimize the method's localization capability results in a precision increase to 93.9%, recall reaching 82.6%, and mAP@50 and mAP@50:95 achieving 92.8% and 71.1%, respectively, highlighting the importance of WIoU for optimizing small object localization strategies.

The complete TPGR-YOLO method, integrating all modules, has 2.8M parameters, 7.6 GFLOPs, and a model size of 6.0 M. Its final precision reaches 94.4%, recall is 83.4%, and mAP@50 and mAP@50:95 are 93.6% and 72.7%, respectively. The experimental results confirm that each module contributes positively to performance improvement, and TPGR-YOLO demonstrates exceptional performance in lightweight design and high-performance object detection.

E. Research Result

The study proposes an improved TPGR-YOLO for traffic police gesture recognition by introducing the RFCAConv module, the C2DA module, the edge-enhanced multi-branch fusion strategy (SAFPN), as well as the WIoU and SlideLoss loss functions. The proposed method demonstrates excellent performance in feature extraction, small object detection, and complex background handling. Experimental results show that TPGR-YOLO achieves high precision, recall, and mAP scores on the self-built CTPG dataset, the WiderPerson dataset, and the VOC dataset, while maintaining real-time inference speed. Furthermore, the ablation study validates the positive contributions of each improved module to the overall performance.

F. Visual Analysis

1) Dataset visualization: The label distribution after training on the CPRG dataset is shown in Fig. 8. From the figure, it can be observed that the "Straight Ahead" category has the largest number of samples, exceeding 1,000, while the "Pull Over" category has the fewest samples. It can also be noted that the labels are primarily distributed in the central region of the images, with most of them having a relatively uniform shape, exhibiting a clear concentration trend.

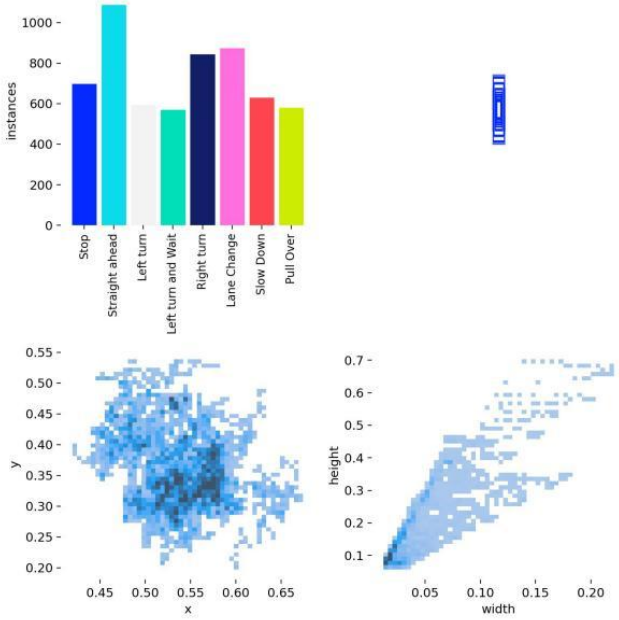

Fig. 8. Dataset visualization.

2) Results visualization: The visualization of the experimental results is shown in Fig. 9. The figure contains 8 rows, corresponding to the categories "Stop," "Straight Ahead," "Left Turn," "Left Turn and Wait," "Right Turn," "Lane Change," "Slow Down," and "Pull Over." The left column displays the original images, the middle column presents the visualization results after training with the original method, and the right column shows the visualization results after applying the improved method.

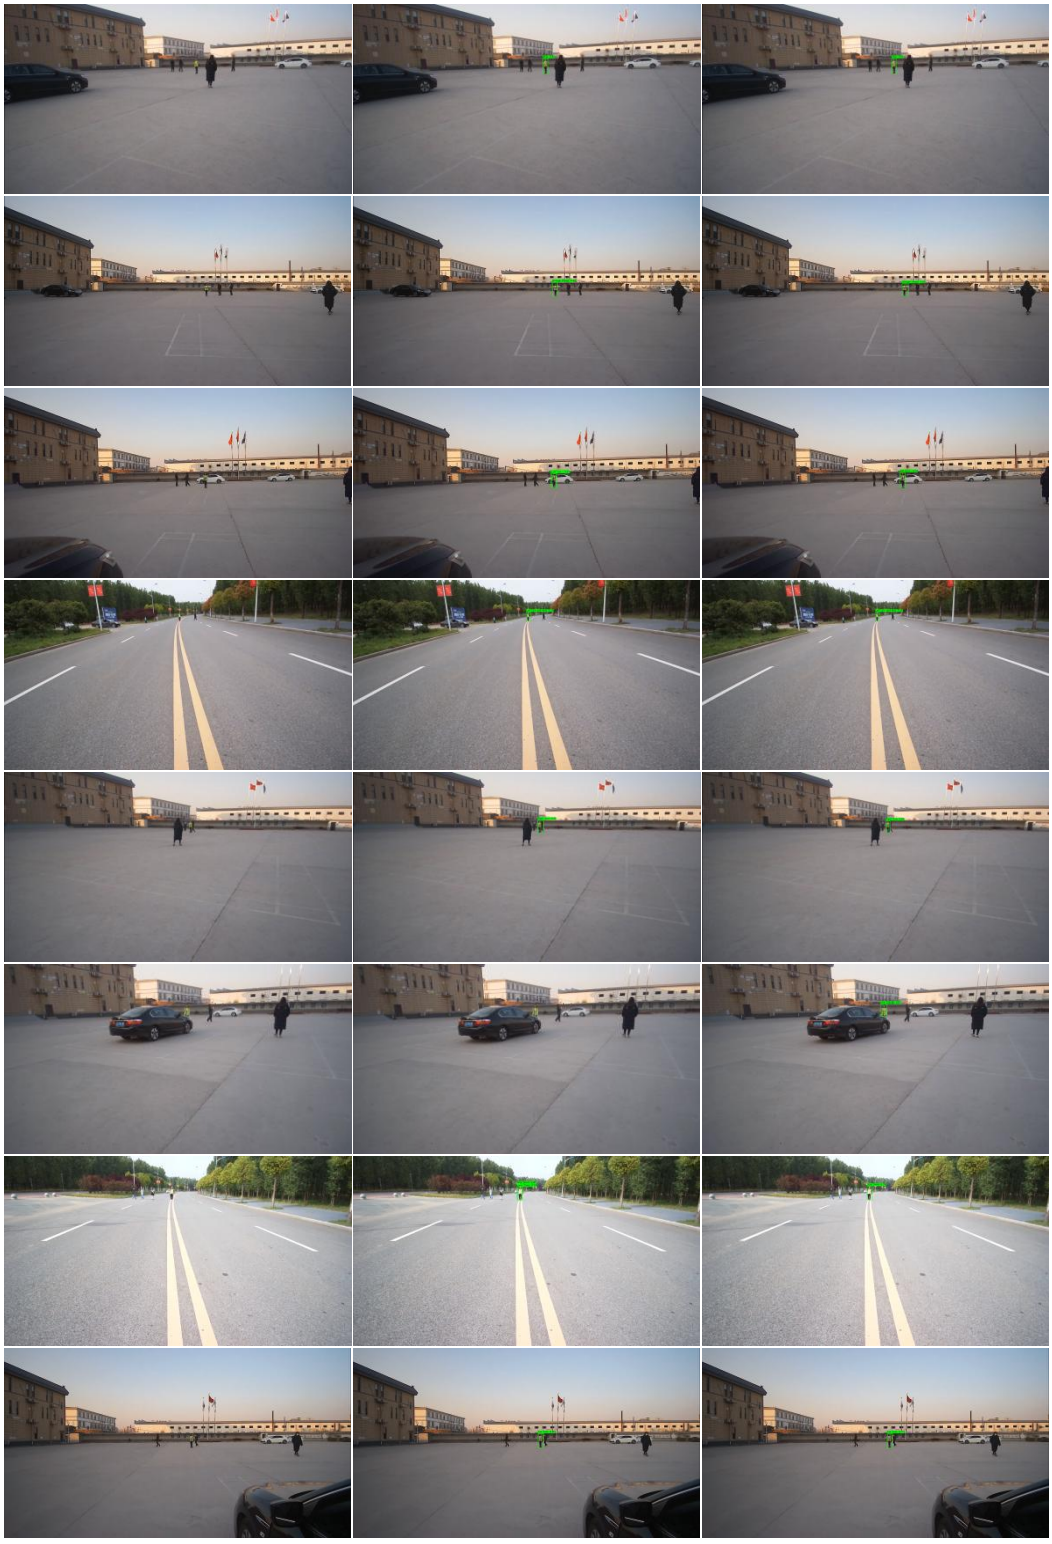

Fig. 9. Result visualization.

From the figure, it can be observed that in the "Line Change" scenario, the original model failed to correctly recognize the traffic officer's gesture due to the vehicle obstructing the lower part of the officer's body, whereas the improved model accurately identified the gesture. In the "Slow Down" and "Left Turn" scenarios, interference from a white vehicle in the background led the original model to incorrectly recognize two actions, while the improved model, by enhancing the recognition of target edges, demonstrated ideal performance in these scenes.

For the "Pull Over" and "Right Turn" gestures, the original method failed to accurately identify the edges of the body and gestures during inference due to background interference, resulting in larger bounding boxes or failure to properly frame the hand. This neglect of detailed information directly affected the inference accuracy. The improved method successfully overcame these issues, showing superior performance.

V. CONCLUSION

In order to address the challenges of small-scale traffic police gestures and complex backgrounds in open traffic scenes, this study improves the backbone network, neck network, and loss function of the YOLOv11 model. The modified algorithm demonstrates strong generalization ability across multiple public datasets. However, since the algorithm relies on single-frame image classification, misjudgments on boundary gestures are inevitable.

Although this research effectively addresses the issues of small-scale objects and complex backgrounds, future work should focus on overcoming the challenges of real-time deployment and exploring the integration of additional sensor data. Furthermore, the model should be improved to accommodate misjudgments of boundary gestures and non-standard traffic police signals. This will enhance the model's applicability and reliability in real-world applications.

A Hybrid SETO-GBDT Model for Efficient Information Literacy System Evaluation

Jiali Dai[1], Hanifah Jambari[2], Mohd Hizwan Mohd Hisham[3]
College Office, Wenzhou Polytechnic, Wenzhou 325000, Zhejiang, China[1]
Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, Johor, 81310, Malaysia[1, 2, 3]

***Abstract*—Information literacy (IL) is essential for vocational education talents to thrive in the modern information age. Traditional assessment methods often lack quantitative precision and systematic evaluation models, making it difficult to accurately measure IL levels. This paper aims to develop a robust, data-driven model to assess information literacy in vocational education talents. The goal is to improve the accuracy and efficiency of IL evaluations by combining machine learning techniques with optimization algorithms. The proposed method integrates the Stock Exchange Trading Optimization (SETO) algorithm with the Gradient Boosting Decision Tree (GBDT) to construct the SETO-GBDT model. This model optimizes parameters such as the number of decision trees and tree depth. A comprehensive evaluation index system for IL is built, focusing on learning attitude, process, effect, and practice. The SETO-GBDT model was trained and tested using real-world data on IL indicators. The SETO-GBDT model outperformed traditional models such as Decision Tree, Random Forest, and GBDT optimized by other algorithms like SCA and SELO. Specifically, it achieved an RMSE of 0.13, an R^2 of 0.98, and reduced evaluation time to 0.092 s, demonstrating superior accuracy and efficiency. The research concludes that the SETO-GBDT model offers a significant improvement in evaluating IL for vocational education talents. The model's high accuracy and reduced evaluation time make it an effective tool for assessing and enhancing information literacy, aligning with the educational goals of developing well-rounded, information-savvy professionals.**

I. Introduction

China has implemented various programs to enforce the systematic advancement of educational evaluation reform. The primary focus of the current curriculum reform is to develop scientific core literacy. The goal is to transform the curriculum to enhance students' comprehensive ability to use information technology to solve problems. This will enable students to become well-rounded individuals with high-quality technical skills and moral, intellectual, physical, social and aesthetic development [1]. Educational talent assessment plays a crucial role in talent education. It involves designing an evaluation index system and educational activities to determine the reasonableness of the educational process, appropriateness of the educational methods used, and whether the expected educational outcomes are achieved [2]. In vocational education, the rapid advancement of information technology has led to the constant flow of information. In this vast and complex information landscape, the ability to distinguish, summarize, and synthesize information has become an increasingly important challenge [3]. For college students, the skill of efficiently and accurately finding the information they need within a limited time frame has become an essential foundational skill. The enhancement of information literacy among vocational education talents involves developing their vocational information literacy skills, including vocational skills, information skills, comprehensive skills, and other vocational information literacy skills. This enables them to acquire the necessary knowledge and adapt to the rapid development of the information society [4].

The evaluation of vocational education talent information literacy is a crucial tool to enhance the information literacy of vocational education talent. Employing appropriate assessment methods may facilitate students' growth and ensure that their information literacy meets the intended objectives [5]. The present research on talent information literacy focuses mostly on three areas: defining information literacy, constructing talent information literacy systems, and assessing talent information literacy [6]. Fei and Erjun [7] studied the eight aspects of information literacy, i.e., skillful use of information tools, correct access to information, proper handling of information, timely generation of information, good at creating information, maximizing the benefits of information, strengthening information collaboration, enhancing information immunity, etc.; Esfandiari and Arefian [8] investigated four information literacy evaluation indexes for undergraduate-type students, i.e., information awareness, information competence, information evaluation, and information ethics; Riithi and Kimani [9] analyzed the academic attention to information literacy education and found that 2012 to 2014 was a period of rapid growth in information literacy research; Ganesan and Gunasekaran [10] elaborated on the content of information literacy education in applied schools and gave strategies and methods for cultivating students' information literacy; Vianna and Caregnato [11] used hierarchical analysis methods to construct a system of information literacy for talents and studied the corresponding cultivation methods; Faber [12] used a simple decision tree to fit the nonlinear mapping relationship between talent information literacy indicators and assessment values. The examination of the present research literature on information literacy reveals the existence of the following issues: a) The present assessment of talent information literacy is still in its early developmental stage, focusing mostly on qualitative analysis of the meaning of information literacy and the importance of the study, while lacking quantitative analysis [13]; b) The present assessment methods are not suitable for constructing the information literacy assessment model due to

the large dimensionality of the information literacy evaluation index system. The selection of the talent information literacy evaluation index is insufficiently thorough and lacks a systematic approach [14].

The advancement of integrated learning technology has led to the adoption of efficient integrated decision trees to improve assessment models. This has become a prominent area of future development and research. However, the performance of the integrated learning algorithm is limited by the parameter settings. Therefore, optimizing the algorithm through hyper-parameter search has emerged as a method to enhance the assessment algorithm [15]. This paper presents a method for assessing the information literacy of vocational education talents. The method combines literature analysis and the development of intelligent algorithms, specifically using an intelligent optimization algorithm-integrated decision tree framework. This paper presents a talent information literacy assessment model for vocational education talents by analyzing the problem of constructing and evaluating an information literacy system. The model is designed using a framework that combines the gradient enhancement decision tree and the stock market trading optimization algorithm. It is then applied to the development of information literacy in vocational education talents. By doing rigorous experimental research, this study confirms that the proposed strategy is indeed superior.

II. Information Literacy System

A. Analysis of the Process

The purpose of developing an information literacy system for vocational education skills is to enhance students' overall abilities in the field of information technology. This includes fostering their awareness of information, understanding of information, competence in handling information, and adherence to ethical standards related to information (Fig. 1). Developing an information literacy system for vocational education can enhance students' capacity to adapt to the demands of work and life in the digital age, while also improving their vocational competitiveness and lifelong learning skills [16].

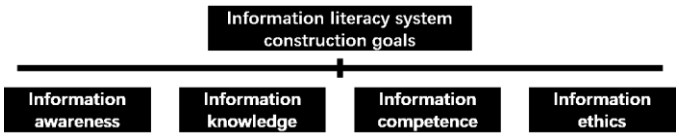

Fig. 1. Objectives of information literacy system construction for vocational education talents.

The process of constructing a vocational education talent literacy system involves various components such as curriculum design, teaching methods, teaching resources, teacher training, assessment, and feedback [17], as depicted in Fig. 2. This process is driven by the goal and importance of developing vocational education talent literacy.

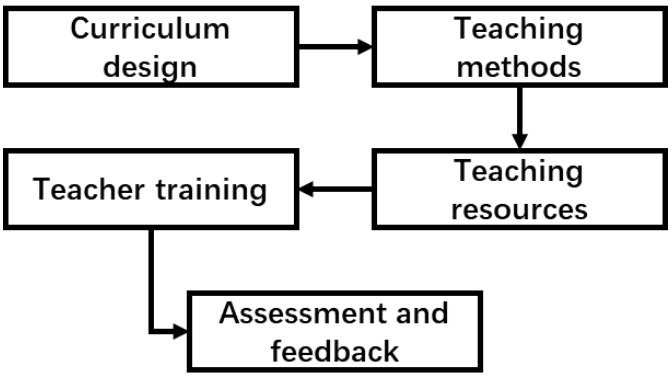

Fig. 2. Construction process of information literacy system for vocational education talents.

B. Constructive Thinking Refers to the Process

The construction process of the vocational education talent information literacy system involves extracting talent literacy assessment indexes from four aspects: learning attitude, learning process, learning effect, and final practice. These indexes serve as the first-level indexes. Through the refinement of the evaluation process, second-level indexes are extracted to construct the vocational education talent literacy system. Fig. 3 illustrates the concept of this construction process.

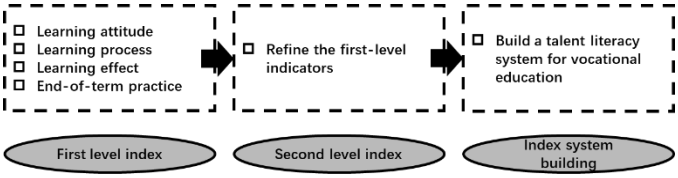

Fig. 3. Constructing information literacy system for vocational education talents.

C. Construction of Talent Information Literacy System

This paper adheres to the principles of objectivity, comprehensiveness, focus, and practicality in constructing an information literacy system for vocational education talents (Fig. 4). It selects relevant indicators from four aspects: information literacy learning attitude, learning process, learning effect, and final practice, as illustrated in Fig. 4. The indicators for learning attitude encompass class attendance and the number of assignments submitted. The indicators for learning process involve the organization of information literacy materials, the design of information literacy papers, information retrieval, information management, and display presentation production. The indicators for learning effects consist of teacher information literacy training and student information feedback. The final practice indicators encompass information literacy application and examination results [14].

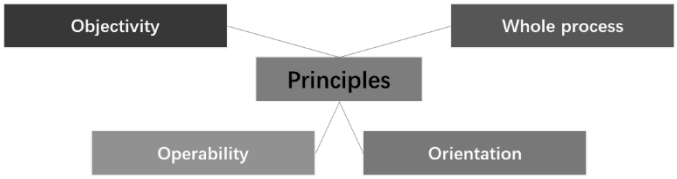

Fig. 4. Principles for the selection of evaluation system indicators.

Diagram depicting the creation of the evaluation system, as seen in Table I.

TABLE I. EVALUATION OF SYSTEM CONSTRUCTION

No.	First level	Var.	Second level	Var.
1	Learning attitude	A	Class attendance	A1
			Number of assignments turned in	A2
2	Learning process	B	Material arrangement	B1
			Information literacy paper design	B2
			Information retrieval	B3
			Information management	B4
			Display and presentation production	B5
3	Learning effect	C	Literacy training for teachers	C1
			Feedback on students' information	C2
4	End-of-term practice	D	Information literacy application	D1
			Test scores	D2

III. EVALUATING THE INFORMATION LITERACY SKILLS

A. Talent Information Literacy Assessment Framework

The method for assessing the information literacy of vocational education talents involves using the information literacy assessment index as input for the evaluation model. The output is a comprehensive assessment score. The assessment model is constructed using the integrated learning method based on the gradient boosting decision tree algorithm. The hyperparameters of the gradient boosting decision tree are optimized using a stock market trading optimization algorithm. The specific framework is illustrated in Fig. 5.

The talent information literacy evaluation model construction framework analysis reveals that the research on constructing and assessing the talent information literacy system in vocational education is a crucial technology. This research utilizes an enhanced integrated learning algorithm to establish a mapping relationship between the assessment index value of information literacy and the assessment scores, as depicted in Fig. 6. This research utilizes gradient boosting decision tree to establish the mapping connection and enhances the assessment accuracy of the talent information literacy evaluation model by optimizing the hyperparameters of the GBDT technique using a stock market trading optimization algorithm.

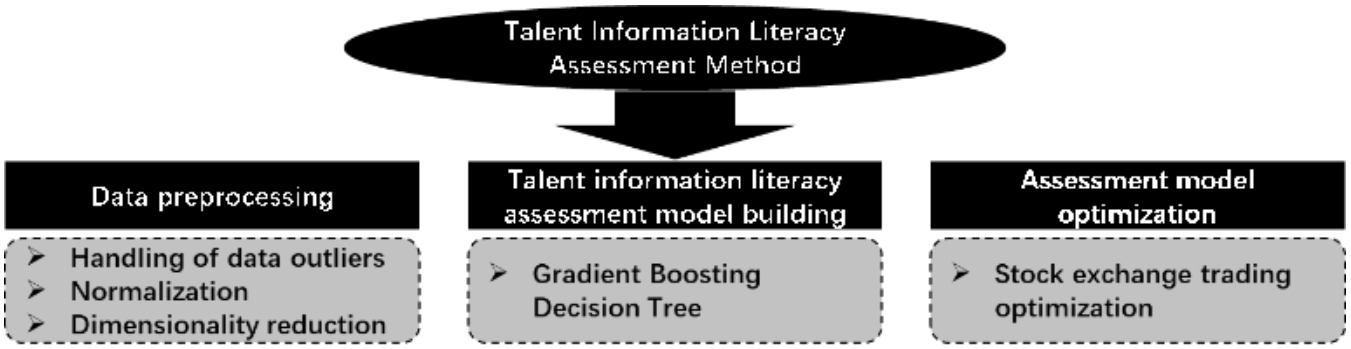

Fig. 5. Talent information literacy evaluation model construction framework.

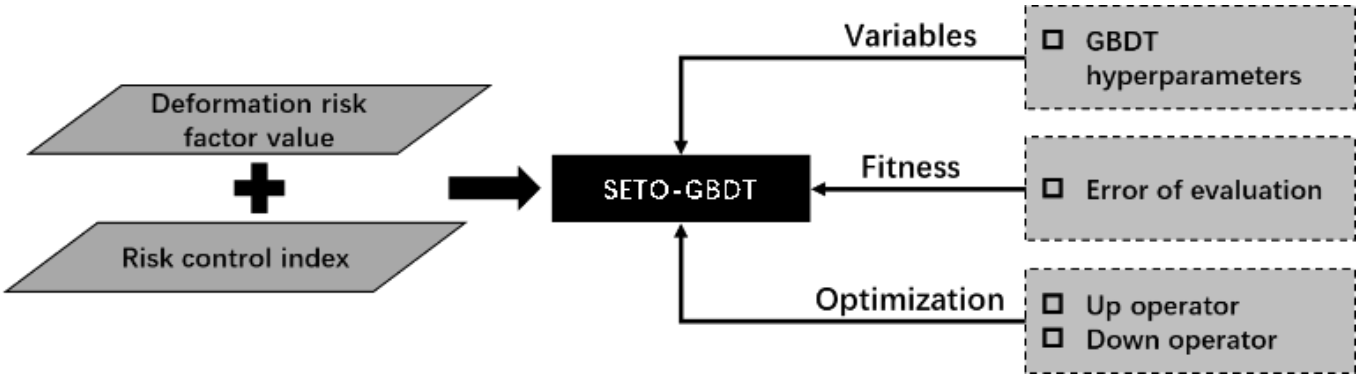

Fig. 6. Information literacy assessment method for vocational education talents based on the improved integrated learning model.

B. Gradient Boosting Decision Tree

1) The theory of gradient enhancing decision trees: The Gradient Boosting Decision Tree (GBDT) [18] is a popular machine learning approach that is commonly employed for solving regression and classification issues. It enhances the precision of predictions by repeatedly creating several decision trees and decreasing the loss function via gradient descent. The primary objective of each new decision tree is to rectify the residuals of the preceding tree, which refers to the disparity

between the actual value and the current model's prediction. The fundamental concept behind Gradient Boosting Decision Trees (GBDT) is to construct a robust prediction model by amalgamating numerous feeble learners, typically decision trees. The structure of this model is illustrated in Fig. 7.

In this paper, the GBDT algorithm is chosen to build an information literacy assessment model for vocational education talents in the form of regression tree. The specific form of decision tree is as follows:

$$T\left(x;c,R\right)=\sum_{v=1}^{M'}c_v I\left(x\in Rv\right) \tag{1}$$

$$I=\begin{cases}0 & x\notin R_v\\ n & x\in R_v\end{cases} \tag{2}$$

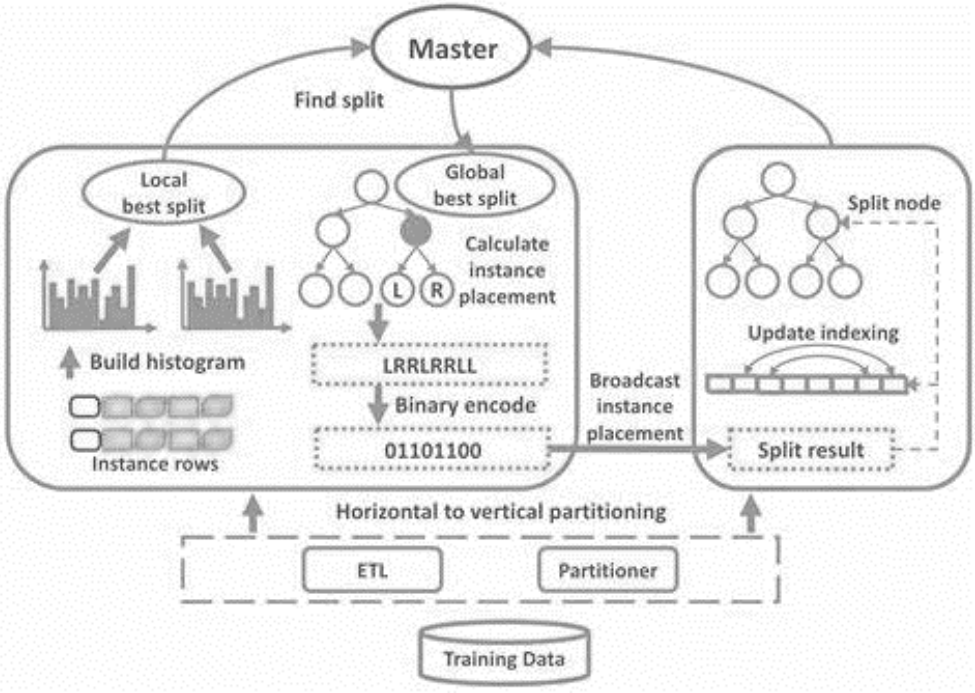

Fig. 7. GBDT structure.

Where, $R=\left\{R_1,R_2,\cdots,R_M^t\right\}$ is the decision tree leaf; M^t is the number of leaf nodes; I is the difference function; $c=\left\{c_1,c_2,\cdots,c_{Mt}\right\}$, $c_v=mean\left(y\middle|x\in R_v\right)$ represent the output characteristic mean of the samples in the leaf space. The GBDT model is a combination of multiple decision trees with the following structure:

$$F\left(x\right)=\sum_{ix=1}^{N'}T_{ix}\left(x;c,R\right) \tag{3}$$

where T_{ix} represents the ixth tree and $ix=1,2,\cdots,N^t$.

During each iteration, a decision tree T_m is added to the decision model based on the previous iteration number in the following form:

$$T_m=\arg\min_T\sum_{k=1}^{n^t}L\left(y_k,\sum_{k=1}^{m-1}T_j\left(x_k\right)+T\left(x_k\right)\right) \tag{4}$$

Where $L\left(\cdot\right)$ denotes the loss function, j is the number of iterations, k is the number of samples in the training set, x_k and y_k denote the training samples. The loss function is set to the least squares function, and the m^{th} tree is built on the residuals of the sum of the decision trees in the previous iteration, and the GBDT model is constructed as follows after m iterations:

$$F_m\left(x\right)=F_{m-1}\left(x\right)+\arg\min_T\sum_{k=1}^{n^t}L\left(y_k,F_{m-1}\left(x_k\right)+T\left(x_k\right)\right) \tag{5}$$

The minima of the GBDT model are calculated by the gradient descent method and the negative gradient direction of the loss function at the current F_{m-1} is set to be the direction of the maximum descent gradient:

$$F_m\left(x\right)=F_{m-1}\left(x\right)+r_m\sum_{k=1}^{n^t}\nabla F_{m-1}L\left(y_k,F_{m-1}\left(x_k\right)\right) \tag{6}$$

$$r_m = \arg\min_r \sum_{k=1}^{n^t} L\left(y_k, F_{m-1}(x_k) - r\frac{\partial L\left(y_k, F_{m-1}(x_k)\right)}{\partial F_{m-1}(x_k)}\right) \quad (7)$$

In order to avoid the fitting phenomenon of GBDT model, the model learning rate was used to determine the model:

$$F_m(x) = F_{m-1}(x) + \nu r_m T_m(x) \quad (8)$$

where ν is the learning rate of the GBDT model.

2) GBDT process steps: The GBDT principle involves a sequential process outlined in a flowchart (Table II). The steps are as follows: 1) initialize the model, 2) calculate the residuals, 3) build the decision tree, 4) update the model, and 5) output the model until a predetermined number of iterations is reached or the stopping condition is met [19].

TABLE II. GBDT FLOW CHART

Algorithm 1: GBDT Model
1. Initialize model.
2. Calculate residuals.
3. Construct a decision tree.
4. Update the model.

3) GBDT Advantage: The Gradient Boosting Decision Tree (GBDT) has several advantages: 1) It exhibits a high level of precision in its prediction capacity; 2) It is capable of directly handling various sorts of data; 3) It demonstrates resilience and generalization ability; 4) It efficiently handles large-scale data; and 5) It can effectively train unbalanced data, as seen in the accompanying Fig. 8.

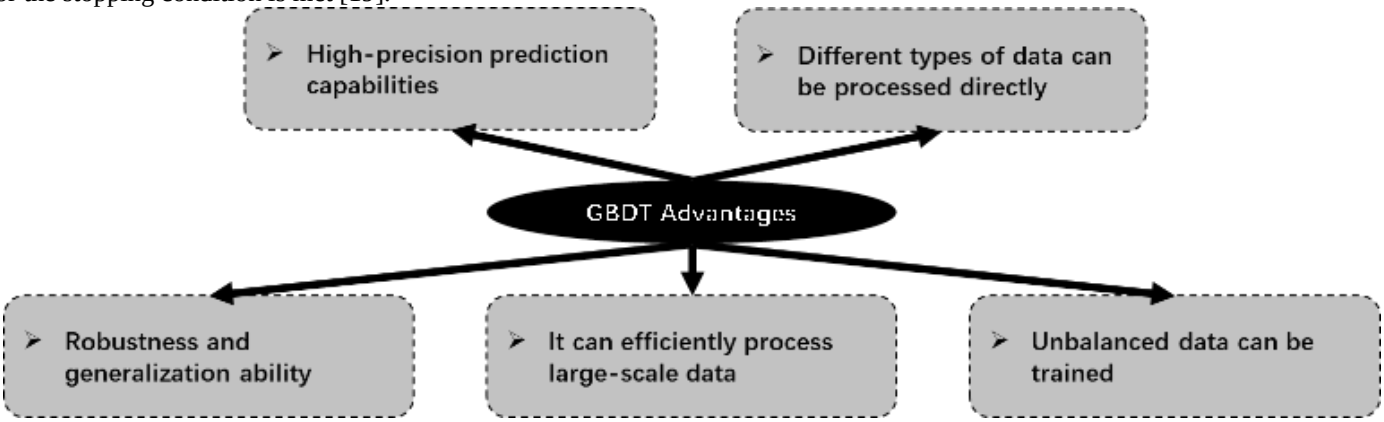

Fig. 8. GBDT advantages

4) Applications of gradient boosting decision trees: Gradient Boosting Decision Trees (GBDT) demonstrates exceptional performance in several practical applications (Fig. 9), such as financial risk management, stock market forecasting, medical diagnostics, and natural language processing [20]. Due to its strength and versatility, this tool is highly used by data scientists and machine learning engineers for addressing intricate prediction issues (Fig. 10) [19].

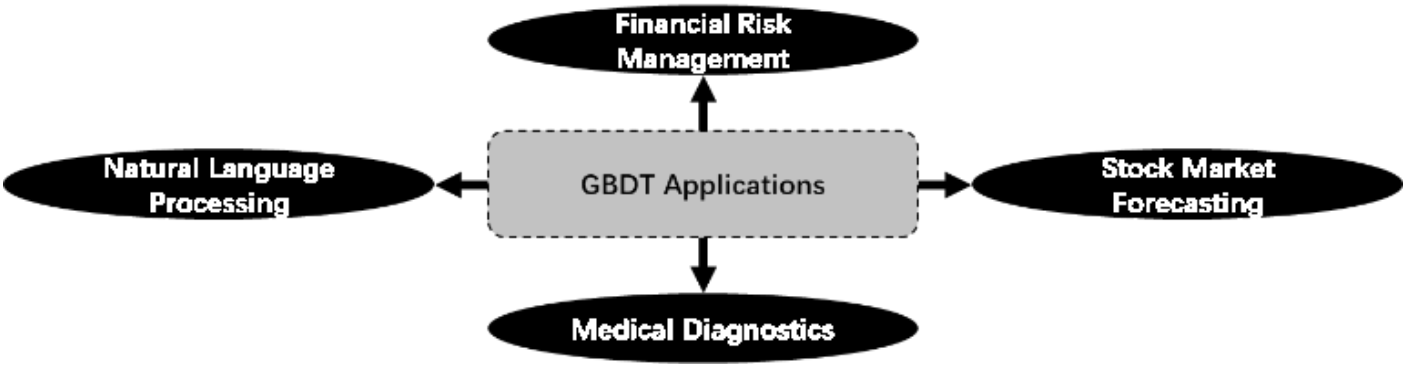

Fig. 9. GBDT application.

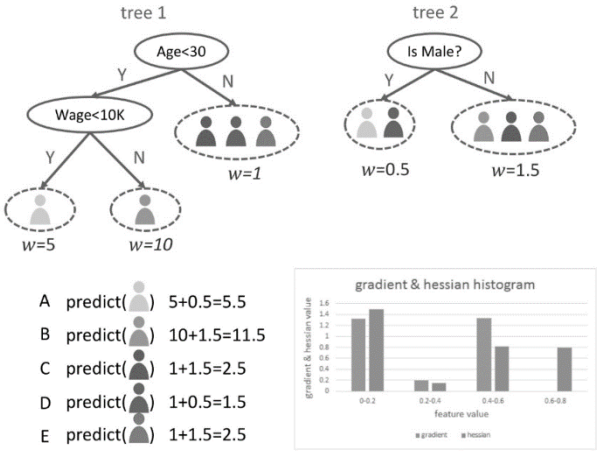

Fig. 10. GBDT problem solving approach.

C. The SETO Optimized Gradient Boosting Decision Tree (GBDT) Model

1) SETO algorithm: A swarm intelligence optimization algorithm known as Stock Exchange Trading Optimization (SETO) [21] takes its cues from the ever-changing stock market and its trading patterns to determine which stock is most likely to maximize profit. Here, each stock is seen as a possible solution to the problem. The method repeatedly optimizes operators such as rise, fall, and exchange operations. Ultimately, the share that yields the highest profit is identified as the ideal answer.

a) Initialization of the population

$$s_{ij} = l_{ij} + \phi_{ij} \cdot \left(u_{ij} - l_{ij}\right) \tag{9}$$

ϕ_{ij} represents a random integer in the interval [0, 1], u_{ij} and l_{ij} signify the upper and lower bounds of the search space, respectively, and s_{ij} symbolizes the j^{th} dimension associated with the i^{th} person.

The following is the equation for calculating the earnings value of a stock, which is used to analyze individual stocks:

$$f_i = f\left(S_i\right) = f\left\{s_{i1}, s_{i2}, \cdots, s_{iD}\right\} \tag{10}$$

where f_i denotes the fitness value of the i^{th} stock individual S_i.

There are specific numbers of sellers and buyers for every stock in the stock market. The first traders are defined using a random initialization process. Here nf_i is how to compute the normalized fitness value in order to accomplish this mechanism:

$$nf_i = \frac{f_i - \min\left(M\right)}{\sum_{k=1}^{N}\left(f_k - \min\left(M\right)\right)}, M = \left\{f_k \middle| k = 1, 2, \cdots, N\right\} \tag{11}$$

S_i The number of traders is calculated as follows:

$$T_i = \left[nf_i \times T\right] \tag{12}$$

T represents the total number of traders, whereas T_i denotes the trading volume of stock S_i. Here S_i is how to figure out how many people are buying and selling stocks:

$$b_i = \left[r \times T_i\right] \tag{13}$$

$$s_i = T_i - b_i \tag{14}$$

b_i and s_i represent the quantities of buyers and sellers, respectively, whereas r is a random variable uniformly distributed between $\left[0,1\right]$.

b) Ascent operation operator: The upward action mostly emulates the appreciation of the stock price. At this juncture, the stock may ascend to a greater valuation, and the peak price can attain the ideal threshold. The equation for replicating the upward action operator is articulated as follows:

$$S_i\left(t+1\right) = S_i\left(t\right) + R \times \left(S^g\left(t\right) - S_i\left(t\right)\right) \tag{15}$$

$S_i\left(t\right)$ represents the i^{th} stock person for the t^{th} iteration, $S^g\left(t\right)$ signifies a D-dimensional random vector, and $r_j \in R$ indicates the ideal solution for the t^{th} iteration.

The parameter R enhances the degree of random variation to assist individuals in evading local optima and exploring broader geographical areas, while $r_j \in R$ is specified as follows:

$$r_j = U\left(0, pc_i \times d_1\right) \tag{16}$$

U produces evenly dispersed random numbers within the range of $\left[0, pc_i \times d_1\right]$. pc_i is the bid-ask ratio of the stock S_i, and d_1 denotes the normalized distance between $S_i\left(t\right)$ and $S^g\left(t\right)$:

$$d_1 = \frac{\sqrt{\sum_{j=1}^{D}\left(S_j^g\left(t\right) - S_{ij}\left(t\right)\right)^2}}{ub - lb} \tag{17}$$

ub and lb represent the upper and lower limits of the search space, respectively. Typically, an increase in demand for a stock correlates with an appreciation in its value. The parameter pc_i mimics the effect of stock growth demand and delineates stock demand based on the overall number of purchasers, calculated as follows:

$$pc_i = \frac{b_i}{s_i + 1} \tag{18}$$

In order to avoid pc_i crossing the boundary, the parameter pc_i is limited to the range $[0, 2]$, which is calculated as follows:

$$pc_i = \min\left(\frac{b_i}{s_i + 1}, 2\right) \tag{19}$$

In the ascending phase, stock demand escalates, resulting in a rise in buyers and a reduction in sellers:

$$b_i = b_i + 1 \tag{20}$$

$$s_i = s_i - 1 \tag{21}$$

c) Falling operation operator: Most of the time, the decline operation operator will mimic a falling stock price using the following equation:

$$S_i(t+1) = S_i(t) - W \times \left(S_i^l(t) - S_i(t)\right) \tag{22}$$

$S_i^l(t)$ represents the current local optimal solution of the ith stock, W signifies a D-dimensional random vector, and $w_j \in W$ is defined as follows:

$$w_j = U\left(0, nc_i \times d_2\right) \tag{23}$$

Where U generates uniformly distributed random numbers in the range $[0, nc_i \times d_2]$. nc_i is the sell-buy ratio of the stock S_i , and d_2 denotes the normalized distance between $S_i(t)$ and $S_i^l(t)$:

$$d_2 = \frac{\sqrt{\sum_{j=1}^{D}\left(S_{ij}^l(t) - S_{ij}(t)\right)^2}}{ub - lb} \tag{24}$$

$$nc_i = \min\left(\frac{s_i}{b_i + 1}, 2\right) \tag{25}$$

In the decline phase, the supply of stocks escalates. In each repetition, the number of vendors rises while the number of customers diminishes during the decline phase:

$$s_i = s_i + 1 \tag{26}$$

$$b_i = b_i - 1 \tag{27}$$

d) Exchange operation operator: During the trading phase, the trader employs the most lucrative stock to substitute the least expensive stock. During this phase, the trader divests from the least performing stock and acquires the highest performing stock. This operational method enables traders to attract stocks. The least favorable stock is obtained as follows:

$$S_{worst} = S_w \; where \quad f(S_w) < f(S_j)$$
$$\forall j = 1, 2, \cdots, N, w \neq j \tag{28}$$

Subsequently, the least favorable stock queue eliminates one seller and incorporates it into the most favorable stock queue and the ideal stock. S_{best} definition is derived as follows:

$$S_{best} = S_b \; where \quad f(S_b) < f(S_j)$$
$$\forall j = 1, 2, \cdots, N, b \neq j \tag{29}$$

The exchange operation operator augments the population size. The operation reduces the quantity of suppliers while augmenting the quantity of purchasers. Consequently, the buyer-seller ratio escalates, thereby enhancing the probability of the stock appreciating.

e) RSI calculation: We use the RSI indicator to recognize when a stock is rising or falling. As the RSI value increases, SETO behaves up or down modeled as follows:

$$\begin{cases} \text{rising} & RSI \leq 30 \\ \text{falling} & RSI \geq 70 \\ p \times \text{rising} + (1-p) \times \text{falling} & 30 < RSI < 70 \end{cases} \tag{30}$$

When p represents a binary random variable, and $p \in \{0, 1\}$ is calculated as follows:

$$p = \begin{cases} 1 & rand \geq 0.5 \\ 0 & else \end{cases} \tag{31}$$

$rand$ represents a random number inside the interval [0, 1]. The RSI for the ith stock is computed as follows:

$$RSI = 100 - \frac{100}{1 + RS} \tag{32}$$

Relative intensities were computed using the simple moving average method:

$$RS = \frac{\sum_{i=1}^{K} P_i}{\sum_{i=1}^{K} N_i} \tag{33}$$

P_i and N_i represent upward and downward price fluctuations, respectively. K represents the RSI trading time frame. The equations for P_i and N_i are as follows:

$$P_i = \begin{cases} 1 & if\left(f_i(t) - f_i(t-1)\right) > 0 \\ 0 & otherwise \end{cases} \tag{34}$$

$$N_i = \begin{cases} 1 & if\left(f_i(t-1) - f_i(t)\right) > 0 \\ 0 & otherwise \end{cases} \tag{35}$$

where, $f_i(t)$ and $f_i(t-1)$ denote the fitness values for the current versus previous iteration counts, respectively.

f) Algorithmic steps: The SETO algorithm's location updating approach is shown in the pseudo-code included in Table III.

TABLE III. SETO ALGORITHM PSEUDO-CODE

19. Output best solution.

2) SETO-GBDT: This paper utilizes the SETO algorithm to optimize the parameters of the GBDT model [22]. These parameters include the number of decision trees (Para1), the maximum depth of the tree (Para2), the minimum number of samples required for internal nodes (Para3), the minimum number of samples required for leaf nodes (Para4), and the optimal number of segmented features (Para5). The optimization process aims to minimize the regression error of the GBDT model, as demonstrated in Table IV.

D. Application of SETO-GBDT Model in the Assessment of Information Literacy of Vocational Education Talents

This research applies the SETO algorithm optimization GBDT model to design a vocational education talent information literacy assessment model, aiming to tackle the problem of vocational education talent information literacy assessment. The information literacy assessment method for vocational education talents, based on the SETO-GBDT model, consists of two main components: the development of an information literacy assessment index system for vocational education talents, and the creation of an information literacy assessment model for vocational education talents. The specific steps for implementing this method are illustrated in Fig. 11.

Fig. 11 illustrates the process of constructing an information literacy assessment index system for vocational education talents. The first part involves analyzing the development of information literacy in vocational education talents and using this analysis to design the information literacy assessment index system. The second part focuses on standardizing the data of the information literacy assessment index for vocational education talents, with the index value serving as input and the information literacy assessment value as output. The literacy assessment indicator data is standardized using the SETO algorithm to optimize the GBDT parameters. This algorithm is used to train the mapping relationship between the indicator value and the assessment value of vocational education talents' information literacy assessment.

IV. Data Analysis

This paper aims to assess the effectiveness of the SETO-GBDT model in evaluating the information literacy of vocational education talents. We utilize a dataset consisting of information literacy assessment indexes of vocational education talents and compare and analyze the performance of the SETO-GBDT model with the GBDT model optimized by the SCA [23], SELO [24], HBO [25], and LFD [26] algorithms.

A. Environment, Data, and Algorithm Settings

The SETO-GBDT model is used to assess the information literacy of vocational education talents through a simulation experiment in the Windows 10 environment. The visualization software used is Matlab 2022a, the method programming software is Python 3.8, and the fundamental algorithm is implemented in C++.

The data set of indicators for assessing information literacy in vocational education was gathered by methods such as literature data analysis, case study analysis, comparison analysis, and questionnaire survey (Fig. 12). The data from the study subjects were randomly split into three groups: 70% for training, 15% for testing, and 15% for validation. The model's average evaluation indexes were then calculated using the ten-fold cross-validation method.

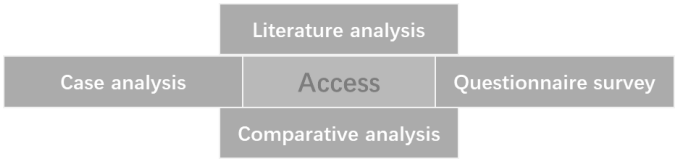

Fig. 12. Data access.

The information literacy evaluation algorithm for vocational education abilities based on the SETO-GBDT model utilizes several comparison algorithms, such as decision tree, RF, AdaBoost, GBDT, and GBDT algorithms optimized by SCA, SELO, HBO, and LFD. The particular parameter values may be found in Table V and Table VI. The algorithms SCA, SELO, HBO, and LFD each have 100 populations and a maximum iteration number of 1000.

TABLE V. Parameter Settings of the Contrast Evaluation Algorithm

No.	Algorithms	Parameter settings
1	Decision tree	Maximum number of splits is 4
2	Random forest	N_tree=500, m_try=floor(80.5)
3	AdaBoost	Regressors number is 15, Iteration is 50
4	GBDT	Decision tree number is 48, maximum depth of tree is 10, samples for internal nodes is 18, samples required for leaf nodes is 1, optimal segmentation features is 9.

TABLE VI. Comparison Optimization Algorithm Parameter Settings

No.	Algorithms	Parameter settings
1	SCA	a=2, r1=1-2t/G, r2=[0,2π], r3=[0,2], r4=[0,1]
2	SELO	P=2, O=3, rp=0.999, rk=0.1, prob=0.999
3	HBO	C=G/25, p1=1-t/G, p2=p1+(1-p1)/2
4	LFD	Threshold=2, CSV=0.5, β=1.5
5	SETO	T=100

B. GBDT Model Optimization Results

The average index value of each algorithm is statistically obtained through the ten-fold cross-validation method, and the specific results are shown in Table VII, Table VIII and Fig. 13.

TABLE VII. Optimization Results of different Optimization Algorithms to Optimize the GBDT Model

No.	Algorithms	Opti. value	Opti. time	Iter. num
1	SCA-GBDT	2.668	3.72	1000
2	SELO-GBDT	1.460	3.33	968
3	HBO-GBDT	0.510	3.45	755
4	LFD-GBDT	0.367	3.10	631
5	SETO-GBDT	0.125	2.71	400

TABLE VIII. Results of Different Optimization Algorithms to Optimize the Parameters of GBDT Model

No.	Algorithms	Para1	Para2	Para3	Para4	Para5
1	SCA-GBDT	30	10	10	2	12
2	SELO-GBDT	41	9	21	3	7
3	HBO-GBDT	49	10	10	3	12
4	LFD-GBDT	44	7	19	5	10
5	SETO-GBDT	50	10	25	5	8

Table VIII presents a comparison of the optimization accuracy, optimization time, and convergence number results of different optimization algorithms for optimizing the GBDT model. From Table VIII, it can be seen that in terms of optimization accuracy, the GBDT evaluation model based on SETO algorithm has the highest accuracy of 0.125, followed by LFD-GBDT, HBO-GBDT, SELO-GBDT, and SCA-GBDT models; in terms of optimization time, the SETO-GBDT model has the lowest evaluation time of 2.71 s; in terms of the number of times of convergence, the SETO-GBDT model converged to the optimal value in 400 times.

The results of optimizing GBDT model parameters with different optimization algorithms are given in Fig. 13. The results of optimizing GBDT model parameters based on SETO algorithm: number of decision trees Para1=50, maximum depth of tree Para2=10, minimum number of samples required for internal nodes Para3=25, minimum number of samples required for leaf nodes Para4=5, and optimum number of segmentation features Para5=8.

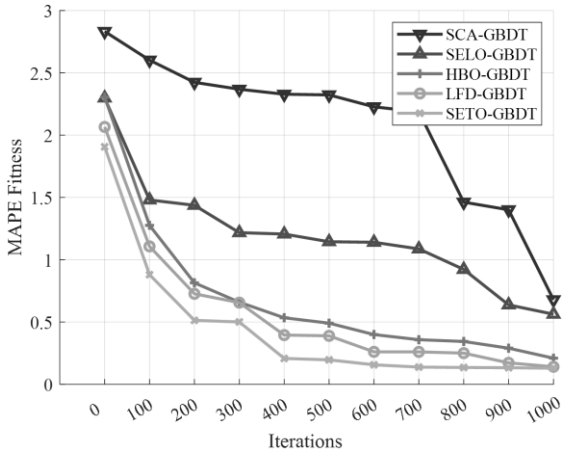

Fig. 13. Convergence curve of GBDT model optimized by different optimization algorithms.

Fig. 13 gives the convergence curve of GBDT model optimized by different optimization algorithms. In Fig. 13, it can be seen that the convergence curve of the optimized GBDT model based on SETO algorithm converges to 0.125 at the 400th iteration.

C. Evaluation of Model Comparison Results

In order to avoid unexpected results of the experiment, 10 independent tests were conducted and the RMSE, R2, training time, and evaluation time averages of the decision tree, RF, AdaBoost, GBDT, and SETO-GBDT algorithms were counted, as shown in Table IX.

TABLE IX. STATISTICS AND COMPARISON OF THE RESULTS OF THE ASSESSMENT INDICATORS FOR THE CONTRASTING ASSESSMENT ALGORITHMS

No.	Evaluation models	RMSE	R^2	Training T/s	Evaluation T/s
1	Decision tree	1.37	0.76	2.30	0.189
2	RF	0.88	0.86	3.94	0.166
3	AdaBoost	0.36	0.93	3.25	0.132
4	GBDT	0.31	0.96	4.45	0.104
5	SETO-GBDT	0.13	0.98	2.71	0.092

Table IX presents the statistics and comparisons of the evaluation index results for the decision tree, RF, AdaBoost, GBDT, and SETO-GBDT algorithms. The SETO-GBDT algorithm performs the best in terms of RMSE, achieving a value of 0.13. It also outperforms the other algorithms in terms of R2, with a value of 0.98. The decision tree algorithm has the shortest training time, taking only 2.30 seconds. On the other hand, the SETO-GBDT algorithm has the shortest evaluation time, which is 0.092 seconds.

V. CONCLUSION

This paper addresses the issue of assessing information literacy in vocational education. It proposes a model for assessing information literacy in vocational education based on SETO-GBDT. The model is validated through literature analysis, case study analysis, comparative analysis, and questionnaire survey. The findings are as follows:

- The SETO method enhances the convergence accuracy and decreases the optimization time of the GBDT model compared to other optimization techniques, while also accelerating the convergence process.
- The SETO-GBDT model outperforms other evaluation models in terms of evaluation error RMSE, R2 value, and evaluation time. The RMSE is 0.13, the R2 value is 0.98, and the evaluation time is 0.092s.
- The experimental findings confirm the accuracy of the SETO-GBDT model in evaluating the impact.

The superior performance of the SETO-GBDT model is evident in its higher convergence accuracy and shorter optimization time, making it a valuable tool for educational institutions seeking to assess and enhance the information literacy of their students. This model not only streamlines the evaluation process but also aligns with the goal of fostering well-rounded, information-savvy professionals in today's fast-paced, data-driven society.

Bridging the Gap Between Industry 4.0 Readiness and Maturity Assessment Models: An Ontology-Based Approach

ABADI Asmae[1]*, ABADI Chaimae[2], ABADI Mohammed[3]
Euromed University of Fes, UEMF, Morocco[1]
ENSAM, Moulay Ismail University, Meknes, Morocco[2]
Team Optimization of Production Systems and Energy, Laboratory of Advanced Research in Industrial and Logistic Engineering (LARILE), Hassan II University of Casablanca, Morocco[3]

***Abstract*—The rapid evolution of Industry 4.0 technologies has created a complex and interconnected landscape of readiness and maturity assessment models. However, these models often fail to address the full spectrum of organizational readiness across strategic, technological, operational, and cultural dimensions, while also not accounting for emerging paradigms such as Industry 5.0. This paper proposes a conceptual model for an ontology that integrates all relevant domain knowledge into a unified framework, capturing strategic, technological, operational, and cultural readiness and maturity within a single comprehensive model. The ontology provides a systematic approach to understanding the interconnectedness of I4.0 and Industry 5.0 assessment models, facilitating a holistic view of an organization's preparedness for digital transformation. By bridging the gap between these two stages of industrial evolution, the model enables interoperability across diverse frameworks, promoting more informed decision-making and strategic planning. This research highlights the potential of the proposed ontology to support the ongoing shift from Industry 4.0 to Industry 5.0, offering a valuable tool for researchers, practitioners, and decision-makers navigating the complexities of next-generation industrial ecosystems. The paper further discusses the theoretical underpinnings and practical applications of the model in fostering a smooth transition toward a more human-centric, sustainable, and technologically advanced industrial future.**

***Keywords*—Industry 4.0; readiness assessment; maturity assessment; digital transformation; ontology development; conceptual model; knowledge engineering**

I. Introduction

The rapid advancement of Industry 4.0 technologies has brought transformative changes to manufacturing and industrial operations, enabling organizations to achieve unprecedented levels of efficiency, flexibility, and competitiveness [1, 2, 3, 4]. By integrating technologies such as the Internet of Things (IoT), artificial intelligence (AI), big data analytics, cloud computing, and cyber-physical systems, Industry 4.0 represents a paradigm shift in how industries operate and innovate [3]. However, the successful adoption of these technologies requires more than technical implementation; it demands a comprehensive understanding of organizational readiness across multiple dimensions, including technology, workforce, processes, and strategy.

Assessing readiness and maturity for Industry 4.0 is critical for organizations to identify their current capabilities, recognize gaps, and prioritize efforts to address them. Traditional readiness assessment approaches, such as the IMPULS and SIRI frameworks [4, 5], provide valuable starting points by identifying key dimensions and establishing readiness levels. However, these models often rely on static evaluations and qualitative surveys, limiting their ability to provide real-time insights or address the interconnected nature of Industry 4.0 dimensions. Their lack of reasoning capabilities results in assessments that may overlook nuanced interdependencies between readiness factors, leading to generalized or incomplete recommendations.

To address these limitations, this paper proposes an ontology-based framework for assessing Industry 4.0 readiness. Ontologies offer a structured and formal representation of knowledge, enabling the modeling of complex and dynamic domains. The proposed framework captures key readiness dimensions, including connectivity, digital infrastructure, cybersecurity, workforce capabilities, strategy, and data analytics. It also intends to integrate in next steps reasoning capabilities through the Semantic Web Rule Language. This innovative approach automates the inference of readiness levels based on organization-specific input data, ensuring consistency, transparency, and scalability.

The use of ontology and reasoning mechanisms provides several benefits. It not only standardizes the assessment process but also generates actionable insights by uncovering the interdependencies between readiness dimensions. For instance, the framework can identify how gaps in workforce skills might affect the effective deployment of digital infrastructure or how a lack of cybersecurity measures could hinder data analytics capabilities. By offering dynamic and tailored recommendations, the framework empowers organizations to make data-driven decisions, strategically allocate resources, and accelerate their digital transformation.

This article is structured as follows. First, a review of existing Industry 4.0 readiness models highlights their contributions and limitations, establishing the need for an ontology and rule based reasoning approach. Next, Section III methodology for developing the ontology, including the design of its classes, properties, and conceptual models. This is

followed by a detailed discussion of the theoretical underpinnings and practical applications of the model in fostering a smooth transition toward a more human-centric, sustainable, and technologically advanced industrial future in Section IV. Finally, the paper is concluded in Section V.

II. Related Work

This section reviews the fundamental concepts and characteristics of Industry 4.0, its requirements and enabling technologies, and the existing readiness models that evaluate the preparedness and implementation of Industry 4.0.

A. Industry 4.0 Overview and Characterization

The term Industry 4.0 originated in Germany, specifically in Hannover in 2011, marking the transformative potential of integrated technologies in reshaping global value chains. This initiative highlighted the possibilities of product customization and novel production methods [6], facilitated by the interaction of technologies across physical, digital, and biological domains. This fusion marks a distinct advancement in the fourth industrial revolution compared to its predecessors.

According to the Germany Trade and Invest Institute [7], Industry 4.0 represents a technological leap from embedded systems to cyber-physical systems (CPSs), leveraging the power of the Internet, data, and services. In this paradigm, industrial machinery evolves to not only process products but also enable communication between products and machinery, effectively directing the production process. Industry 4.0 represents a transformative leap forward in manufacturing, characterized by the integration of advanced technologies and their constant interaction across physical, digital, and biological domains.

It marks a new maturity stage for manufacturing companies, leveraging technologies such as the Internet of Things (IoT), Cloud Computing (CC), Big Data (BD), Artificial Intelligence (AI), and Cyber-Physical Systems (CPSs) to create interconnected, intelligent production environments. These systems enable real-time decision-making, remote monitoring, and flexible modular production processes [6-9]. To implement Industry 4.0, several main features are identified that support the evolution of intelligent production systems [10]:

- Interoperability, Integrity, and Awareness: The degree of system collaboration in utilizing capabilities, sharing information, and intelligent decision-making [11].
- Virtualization: Enabling remote traceability and monitoring of processes through sensors, creating smart factories.
- Service Orientation: Utilizing service-oriented software alongside IoT technologies.
- Real-Time Operation Capability: Facilitating instant data gathering, processing, and decision-making.
- Modularity: Flexible production processes involving the coupling and decoupling of production modules.
- Decentralization: Allowing CPSs to make independent decisions and produce locally, utilizing technologies like 3D printing.

The integration of these features is made possible by enabling technologies. For instance, IoT involves billions of interconnected devices like sensors and industrial equipment, facilitating real-time data collection and analysis [2,10].AI plays a central role in enabling Industry 4.0 by integrating intelligent functionalities across the value chain, from customer acquisition to operations management [3,4,9]. Moreover, big data and cloud computing address the exponential growth of data generated in manufacturing, offering scalable solutions for data storage, analysis, and processing.

The exponential growth of data in Industry 4.0 often exceeds human processing capabilities. Cloud Computing (CC) addresses this challenge by offering shared, on-demand resources via the Internet, delivering high-quality services at reduced costs [4, 9]. Simultaneously, Big Data (BD) enhances decision-making by analyzing vast amounts of information characterized by volume, velocity, variety, and veracity [4]. In addition to enabling technologies, Industry 4.0 fosters smarter work environments where technologies enhance human capabilities rather than replace them. Meindl et al. [12] emphasize that advanced systems support decision-making, creativity, and safety, leading to smarter workplaces. This human-centric approach has given rise to discussions around Industry 5.0 [13], which emphasizes workers' central role in digital transformation.

Industry 4.0 is more than the adoption of cutting-edge technologies; it’s about connecting these technologies to foster organizational growth and operational efficiency [14]. By leveraging advanced technologies like robotics, additive manufacturing, and analytics, companies can drive innovation, improve customer experiences, and enable predictive decision-making. For instance, smart products and connected systems enhance customer interactions through enriched post-sales support and tailored marketing strategies [15].

However, the implementation of Industry 4.0 varies widely based on organizational readiness, technological infrastructure, and economic development. Developing nations often face challenges in adopting these technologies while maintaining competitive advantage [16, 17]. Organizations must navigate talent development, process changes, and strategic human resource management to align with Industry 4.0 demands [18,19]. Readiness and Maturity models serve as valuable tools in assessing current adoption levels and guiding strategic implementation efforts.

B. Industry 4.0 Readiness and Maturity Models

The emergence of Industry 4.0 has prompted the development of numerous readiness and maturity models, each aiming to assess and guide organizations through their transformation journeys. While these models have made significant contributions to understanding readiness, they also exhibit notable limitations, particularly in terms of validation, granularity, and cross-industry applicability. Table I reviews prominent Industry 4.0 readiness models and identifies gaps that motivate the proposed ontology based readiness assessment smart system.

TABLE I. ANALYSIS OF EXISTING INDUSTRY 4.0 READINESS AND MATURITY MODELS

Model Name	Ref	Country	Contribution	Focus Areas
ACATECH I4.0 Maturity Index	[20]	Germany	Six-level progression emphasizing adaptability through technology and organization integration.	Technology & organization integration
IMPULS Industrie 4.0 Readiness	[21]	Germany	Practical tool tailored for German manufacturing industries.	Manufacturing industries
Singapore Smart Industry Readiness Index	[22]	Singapore	Comprehensive framework with 16 dimensions under three pillars: process, technology, and organization.	Holistic transformation
6Ps Maturity Model for SMEs	[23]	Italy	Tailored to SMEs, addressing unique small enterprise challenges with six stages.	SME-specific
Integrated IoT Capability Maturity Model	[24]	Netherlands	Combines capabilities from diverse frameworks to improve IoT management through five stages.	IoT management
SIMMI 4.0	[25]	Germany	Structured focus on digitization levels and integration across technologies and departments.	Digitization & IT integration
Industry 4.0 Readiness and Maturity Model	[26]	Austria	Comprehensive framework with nine dimensions, including strategy, leadership, governance, and innovation.	Technological & organizational aspects
Maturity Model for Smart Manufacturing	[27]	Turkey / Cyprus	Modular and incremental design adaptable to manufacturing contexts.	Modular for manufacturing
Categorical Framework of Manufacturing	[28]	United Kingdom	Multi-level approach integrating intelligence and automation across four dimensions.	Intelligence & automation

The ACATECH I4.0 Maturity Index [20] outlines a six-level progression from computerization to adaptability, emphasizing the integration of technological and organizational capabilities. This theoretical framework offers a structured approach to transformation but remains limited to conceptual discussions without cross-industry validation or practical implementation examples. Its lack of application-oriented guidance reduces its relevance for diverse industrial contexts. The IMPULS Industrie 4.0 Readiness model [21] assesses readiness across six dimensions: strategy, organization, IT infrastructure, smart products, smart services, and employees. It provides practical tools for manufacturing industries, particularly in Germany, making it highly relevant for this sector. However, its sector-specific focus restricts its versatility, limiting its applicability to other industries or global contexts.

The Singapore Smart Industry Readiness Index [22] provides a comprehensive framework encompassing 16 dimensions across three pillars: process, technology, and organization. Its holistic approach and intuitive tools are valuable for readiness assessment. Nevertheless, the model lacks extensive validation across sectors and does not provide detailed action plans for achieving specific maturity levels, reducing its utility for organizations seeking granular guidance. The 6Ps Maturity Model for SMEs [23] is tailored to address the unique challenges of small and medium enterprises (SMEs). With six stages: Plan, Prepare, Predict, Produce, Promote, and Proliferate. The model has been validated through case studies involving nine SMEs. However, its applicability to larger enterprises or different industrial contexts remains underexplored, highlighting a need for broader adaptability. The Integrated IoT Capability Maturity Model [24] combines capabilities from various frameworks to improve IoT management through five stages, ranging from primitive to maximizing, and three dimensions: technology, authority & culture, and knowledge management. While its operational focus on IoT is notable, the absence of practical validation and its narrow scope limit its broader relevance in the Industry 4.0 landscape. SIMMI 4.0 [25] emphasizes digitization and IT integration, guiding organizations through five maturity stages, from basic to optimized full digitization. Its focus on vertical and horizontal integration, cross-technology criteria, and digital product development provides a robust framework for IT landscapes. However, it neglects critical factors such as organizational culture and employee readiness, which are essential for successful Industry 4.0 adoption.

The Industry 4.0 Readiness and Maturity Model [26] offers a comprehensive framework with nine dimensions, including strategy, leadership, governance, and innovation. This balanced approach to technological and organizational readiness has been validated through a manufacturing case study. However, the complexity of its framework poses challenges for smaller enterprises, making adoption difficult without significant resources. The Maturity Model for Smart Manufacturing [27] adopts a modular and incremental design, making it adaptable to various manufacturing contexts. It evaluates five key dimensions: strategy, leadership, technology, culture, and operations. While validated through a case study, the model\u2019s scalability to larger enterprises and applicability in non-manufacturing sectors are not well explored. The Categorical Framework of Manufacturing [28] integrates intelligence and automation across four dimensions: factory, business, process, and customers. This multi-level framework offers a comprehensive perspective on readiness. However, its lack of practical examples and detailed guidance for progression limits its effectiveness and real-world applicability.

Despite the diverse contributions of these models, significant limitations persist. Many models focus heavily on technological aspects, such as digitization and IoT integration, while overlooking critical organizational factors like culture, leadership, and employee readiness. Additionally, most frameworks are constrained by sector-specific designs, limiting their adaptability to different industries. The lack of practical validation and real-world case studies further hampers their utility, as organizations struggle to translate theoretical guidance into actionable strategies. Moreover, the absence of reasoning-based approaches reduces their ability to dynamically adapt to evolving industrial contexts, creating a gap for more intelligent and flexible assessment tools.

Existing Industry 4.0 readiness models provide valuable insights but fail to address the need for holistic, adaptive, and validated frameworks. To overcome these challenges, this paper

proposes an ontology-driven framework incorporating reasoning mechanisms to enable dynamic and adaptive readiness assessment. This approach aims to offer a more comprehensive and actionable tool for Industry 4.0 transformation across diverse industries and organizational contexts.

III. Conceptual Model Development Methodology

This section outlines the methodology employed to construct a robust ontology specifically designed for Industry 4.0, along with its corresponding conceptual model. Recognizing the interdependence between these two components, the development process adopts a systematic and strategic approach to conceptualization. The conceptual model, which serves as the foundation for ontology development, provides a clear and visual representation of the domain, facilitating better understanding and usability. Moreover, the model is designed to be reusable, allowing adaptation across various ontology representation languages. The methodology applied here is informed by well-established practices in ontology development, tailored to address the unique characteristics and challenges of Industry 4.0.

To achieve this, a hybrid methodology was employed, integrating elements from different prominent approaches: the Uschold and King methodology [29], METHONTOLOGY [30] and Ontology Development [31]. Specifically, the structured framework proposed by Uschold and King was combined with the iterative processes of Ontology Development 101 and further enriched by the conceptualization techniques outlined in METHONTOLOGY.

This hybrid approach leverages the strengths of each methodology. The Uschold and King framework offers a systematic starting point for constructing the ontology's initial structure. Ontology Development 101 introduces iterative refinement, enabling detailed and comprehensive development. The inclusion of METHONTOLOGY ensures a deep understanding of the domain through its emphasis on conceptualization, ensuring that the model accurately captures the semantics of Industry 4.0.

The construction of the conceptual model followed a series of structured steps:

1) Define the domain, scope, and purpose: This step establishes clear boundaries and objectives for the ontology, ensuring it aligns with the specific requirements of Industry 4.0 readiness assessment.

2) Capture knowledge and develop conceptualization: Through iterative refinement, the following tasks were performed:

Identifying key terms and concepts relevant to Industry 4.0, such as smart factories, cyber-physical systems, IoT, and advanced analytics.

Defining classes and their hierarchical relationships to represent the domain's structure.

Establishing object and data properties to define relationships and attributes within the domain.

3) Create the conceptual model: The captured knowledge was transformed into a graphical representation, ensuring clarity and reusability. The model was designed to reflect core aspects of Industry 4.0, such as interoperability, automation, and digital transformation.

Fig. 1 illustrates the workflow adopted in this methodology, demonstrating the integration of the selected approaches and their application to Industry 4.0 ontology development.

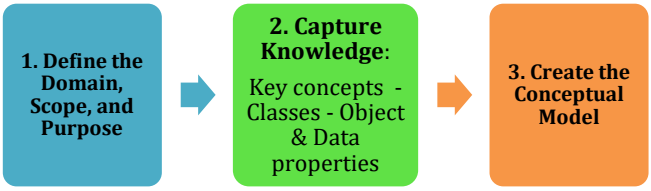

Fig. 1. The workflow of the ontology conceptual model development methodology.

B. Domain, Scope, and Purpose Definition

In developing our ontology for Industry 4.0 readiness assessment, the first step is to define the domain, scope, and purpose clearly. The domain centers on Industry 4.0, specifically focusing on the readiness and maturity of industrial companies in adopting advanced technologies and practices. The scope includes dimensions such as technological capabilities, organizational processes, workforce skills, and strategic alignment while excluding unrelated areas like consumer behaviors or non-industrial sectors.

The purpose of this ontology, as presented in Table II, is to provide a structured framework for evaluating and comparing the readiness of companies for Industry 4.0 transformation, facilitating informed decision-making and guiding improvement strategies. This step ensures that the ontology is both focused and relevant, addressing the key challenges and requirements of stakeholders in the Industry 4.0 landscape.

C. Capturing Knowledge and Conceptualization Definition

1) Identifying key terms and concepts: The process of capturing knowledge within the context of Industry 4.0 readiness involves identifying the core elements that influence an organization's journey toward digital transformation. This is achieved through the use of an ontology, which structures and organizes these elements into defined categories that enable clearer understanding, assessment, and decision-making. The conceptualization phase takes these elements and translates them into formal representations, allowing them to be analyzed and applied practically across industries. Our ontology is structured around four main dimensions: Strategic, Technological, Operational, and Cultural as presented in Fig. 2.

TABLE II. SCOPE, DOMAIN AND KNOWLEDGE SOURCE OF THE INDUSTRY 4.0 ASSESSMENT ONTOLOGY

Domain	The domain of interest of this work is industry 4.0 readiness and maturity
Date	2024-2025
Purpose	• Establish a standardized framework for organizing and categorizing Industry 4.0 readiness data, ensuring consistency and comparability across evaluations. • Enable reasoning to infer implicit knowledge, identify gaps in readiness, and derive automated recommendations for targeted improvements. • Facilitate evidence-based decision-making by linking readiness dimensions to actionable strategies, prioritizing critical areas, and enabling benchmarking. • Provide adaptability for evolving Industry 4.0 practices by integrating new concepts, technologies, and criteria as the domain progresses. • Support cross-functional and cross-organizational alignment by offering a shared vocabulary for clear communication and collaboration. • Serve as a foundational tool for advancing research, enabling data-driven insights, and fostering innovation in Industry 4.0 readiness assessments and practices.
Scope	The scope of the ontology is to provide a structured framework for assessing and auditing industrial companies' readiness for Industry 4.0 transformation across strategic, technological, operational, and cultural dimensions, enabling organizations to benchmark their progress, identify gaps, and guide their digital transformation journey.
Source of Knowledge	• ACATECH I4.0 Maturity Index [20] • IMPULS Industry 4.0 Readiness [21] • Singapore Smart Industry Readiness Index [22] • 6Ps Maturity Model for SMEs [23] • Integrated IoT Capability Maturity Model [24] • SIMMI 4.0 [25] • Industry 4.0 Readiness and Maturity Model [26] • Maturity Model for Smart Manufacturing [27] • Categorical Framework of Manufacturing [28] • Reference Architecture Model for Industry 4.0 • Surveys and Case Studies from Leading Manufacturers • Reports and Whitepapers from Industry Associations • Public Sector Digital Transformation Initiatives • Interviews and Insights from Technology Providers

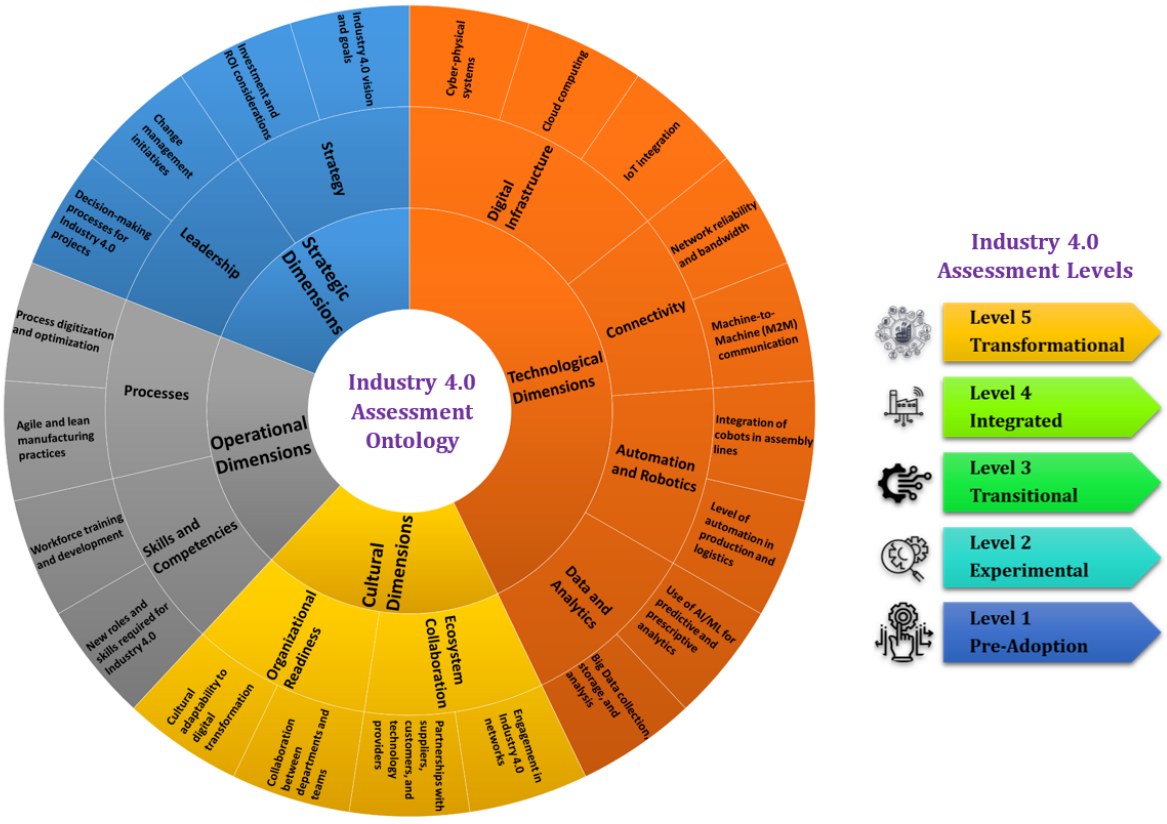

Fig. 2. Dimensions, associated fields and evaluation levels of the proposed industries 4.0 assesment ontology.

2) Capture knowledge and develop conceptualization: The assessment dimensions encompass the essential factors that determine an organization's preparedness for Industry 4.0 adoption. Within each dimension, specific classes are defined to capture the knowledge associated with different aspects of transformation. For instance, the Strategic Dimensions contain classes such as Strategy, which represents the company's approach to aligning its goals with Industry 4.0, ranging from early awareness to full integration. Similarly, Leadership in this dimension reflects varying stages of leadership involvement, from lack of awareness to driving an innovation culture.

In the Technological Dimensions, the ontology includes classes such as Digital Infrastructure, which captures the evolution of IT systems from basic setups to fully integrated, smart manufacturing solutions. Classes like Processes, Data and Analytics, and Automation and Robotics represent the

increasing sophistication of processes, data utilization, and automation in an Industry 4.0 environment. Each of these classes models the different stages of digital transformation in terms of technology adoption, from initial automation trials to the use of AI and machine learning in decision-making processes.

The Operational Dimensions focus on the organization's day-to-day operations, particularly the level of connectivity within the enterprise. The Connectivity class, for example, spans from isolated devices to seamless, real-time communication across the organization, while the Workforce Skills class tracks the evolution of employee competencies, capturing the transition from basic awareness to continuous adaptation of advanced digital skills. Finally, the Cultural Dimensions include classes like Organizational Readiness, which represents the organization's cultural alignment with Industry 4.0 principles. This class captures the evolution from resistance to change to a fully agile and innovation-driven environment. Additionally, the Ecosystem Collaboration class addresses the growing importance of strategic partnerships, from no collaboration to leadership in collaborative networks within the industry.

The conceptualization of the ontology involves translating these real-world concepts into formal classes and defining relationships between them. For example, Leadership is conceptualized as a class that influences both Strategy and Organizational Readiness, with relationships indicating how leadership's engagement drives the alignment of strategy and cultural transformation. Each class is further defined with specific properties and attributes, representing the maturity levels or stages of development. In the Strategy class, for instance, these properties might range from "Initial Exploration" to "Fully Aligned Corporate Strategy," reflecting different levels of maturity in aligning the company's strategy with Industry 4.0 goals. As part of the knowledge capture process, the ontology also formalizes the data collection methods that link these conceptualized classes to real-world assessments. This allows organizations to map their existing capabilities against the maturity levels defined in the ontology, offering a detailed picture of their current readiness. For example, Workforce Skills can be tied to specific skill data collected through employee assessments, training programs, and competency evaluations.

3) Create the conceptual model: The conceptualized ontology forms the basis of structured audits and assessments of Industry 4.0 readiness. By representing the different stages of maturity in each class, it allows organizations to pinpoint their strengths and weaknesses, identifying areas where they need to improve. This structured approach to capturing and organizing knowledge ensures that the assessment process is objective, repeatable, and aligned with the overall goal of driving digital transformation within industrial settings. The conceptualization phase, therefore, not only organizes knowledge but creates a dynamic framework for ongoing evaluation, facilitating continuous progress toward Industry 4.0. In fact in this stage, we defined not only the relations between the different classes but also the details on the minimum requirements for each maturity level in our model as represented in Fig. 3.

Industry 4.0 Assessment Dimensions		Level 1 Pre-Adoption	Level 2 Experimental	Level 3 Transitional	Level 4 Integrated	Level 5 Transformational
Strategic Dimensions	Strategy	No formal Industry 4.0 strategy or awareness.	Initial exploration of Industry 4.0 opportunities and risks.	Defined strategy with clear milestones.	Fully aligned corporate strategy with Industry 4.0 goals.	Continuous evolution of strategy based on innovation and market trends.
	Leadership	Leadership lacks awareness or engagement in Industry 4.0.	Leadership explores pilot initiatives and starts allocating budget.	Leaders actively drive initiatives and engage teams.	Leadership ensures organization-wide commitment and resource allocation.	Leadership promotes innovation culture and global thought leadership.
Technological Dimensions	Digital Infrastructure	Basic IT systems with minimal automation or connectivity.	Isolated systems and initial pilot setups for IoT or cloud computing.	Moderate IT integration; emerging IoT networks and cloud usage.	Fully integrated systems with real-time data access and decision-making.	Adaptive and scalable systems, leveraging edge computing and advanced networks.
	Processes	Highly manual processes with minimal standardization.	Early-stage digitalization of selected processes.	Processes are increasingly digitized and standardized across units.	Digital and optimized processes; cross-departmental collaboration.	Adaptive and self-optimizing processes with AI-driven automation.
	Data and Analytics	Minimal data collection; analysis is manual or nonexistent.	Basic data collection for pilot projects; spreadsheets or simple tools used.	Systematic data collection and some use of business intelligence tools.	Advanced analytics with AI/ML for predictive insights across operations.	Prescriptive analytics and autonomous decision-making are fully implemented.
	Automation and Robotics	Little or no automation; reliance on manual labor.	Robotics or automation applied in isolated tasks or areas.	Semi-automated processes with robotic integration in key operations.	High level of automation in core operations, including cobotic systems.	Fully autonomous production systems with cyber-physical integration.
Operational Dimensions	Connectivity	No machine-to-machine (M2M) or IoT connectivity.	Isolated devices connected in pilot projects.	Partial connectivity across production lines or departments.	Organization-wide IoT and M2M communication for seamless data flow.	Ubiquitous connectivity enabling real-time, cross-enterprise collaboration.
	Workforce Skills	Workforce lacks Industry 4.0 awareness and skills.	Limited upskilling initiatives in response to pilot projects.	Training programs are in place; workforce acquires basic digital competencies.	Comprehensive training and workforce adaptability to Industry 4.0 demands.	Workforce continuously evolves with advanced skills; innovation-driven roles.
Cultural Dimensions	Organizational Readiness	Resistance to change; no alignment with Industry 4.0 objectives.	Isolated initiatives with some departmental support.	Organization shows buy-in and cross-departmental collaboration improves.	Entire organization is aligned and agile, supporting Industry 4.0 objectives.	Agile, innovation-focused culture with strong collaboration and change management.
	Ecosystem Collaboration	No collaboration with external partners for Industry 4.0 initiatives.	Initial partnerships for pilot projects or technology trials.	Active collaboration with select suppliers, customers, and tech providers.	Strong partnerships and ecosystem participation for mutual growth.	Strategic leader in Industry 4.0 networks; driving standards and innovation.

Fig. 3. The proposed industry 4.0 assessment model for the four dimensions – minimum requirments.

IV. Industry 4.0 Assessment Ontology Conceptual Model: Unveiling the Interconnected Landscape of Industry 4.0 Assessment Models

The Industry 4.0 readiness assessment ontology is designed to evaluate and track the maturity of organizations in their adoption of Industry 4.0 technologies. The ontology is structured around several key dimensions, as presented in Tables III and IV that represent critical aspects of organizational readiness, with each dimension encompassing various sub-dimensions, attributes, and functions to holistically assess an organization's progress and capabilities in adopting Industry 4.0 principles. These dimensions are organized into four main categories: Strategic Dimensions, Technological Dimensions, Operational Dimensions, and Cultural Dimensions.

To assess the Strategic readiness, the Strategy sub-dimension captures the organization's preparedness and strategic direction towards Industry 4.0 adoption. Key attributes include strategyLevel, which categorizes the organization's strategy (e.g., Pre-Adoption, Experimental), and awareness, which assesses the level of understanding about Industry 4.0 technologies. The milestones attribute tracks the significant stages in the organization's adoption journey. The associated functions like defineStrategy() and evaluateProgress() allow for dynamic updates and evaluation of the organization's strategic alignment with Industry 4.0 goals. The Leadership sub-dimension focuses on the commitment and engagement of leadership in driving the Industry 4.0 transformation. The attributes engagementLevel, budgetAllocation, and innovationCulture reflect leadership's role in fostering technological adoption. Functions such as assessLeadershipCommitment() and promoteInnovation() evaluate leadership's contribution to innovation and resource allocation.

TABLE III. Description of the Industry 4.0 Assessment Ontology Main Classes

Class	Description
Industry4.0ReadinessAssessment	Represents the overall assessment process to evaluate a company's Industry 4.0 readiness.
Dimension	Represents a high-level category of readiness, such as Strategy, Technology, or Operations.
Strategic Dimensions	Represents the readiness related to strategy and leadership.
Criteria: Strategy	Evaluates the existence and maturity of Industry 4.0 strategy in the organization.
Criteria: Leadership	Assesses leadership involvement and vision in adopting Industry 4.0 technologies.
Technological Dimensions	Represents readiness related to infrastructure, processes, data, and automation.
Criteria: Digital Infrastructure	Assesses the maturity of IT systems, connectivity, and integration.
Criteria: Connectivity	Evaluates the integration of IoT and machine-to-machine communication.
Criteria: Data and Analytics	Measures the ability to collect, analyze, and use data for decision-making.
Criteria: Automation and Robotics	Assesses the level of automation, including robotics and cobotics integration.
Operational Dimensions	Represents the readiness of operations, workforce, and connectivity.
Criteria: Processes	Evaluates the level of digitization and optimization in organizational processes.
Criteria: Workforce Skills	Measures the readiness and adaptability of the workforce to Industry 4.0 changes.
Cultural Dimensions	Represents readiness in terms of organizational readiness and external collaboration.
Criteria: Organizational Readiness	Assesses the organization's openness and alignment with Industry 4.0 objectives.
Criteria: Ecosystem Collaboration	Measures the level of partnership and collaboration within Industry 4.0 ecosystems.
Indicator	Represents the quantitative or qualitative measures used to evaluate a Criterion.
AssessmentResult	Captures the outcome of the readiness assessment, including scores and detailed feedback.
Company	Represents the organization being assessed for Industry 4.0 readiness.

TABLE IV. Description of the Industry 4.0 Assessment Ontology main Properties

Property Name	Domain	Range	Cardinality	Inverse Property
aggregates	Industry4.0ReadinessAssessment	Dimension	Multiple : A single Industry4.0ReadinessAssessment can aggregate multiple Dimensions.	-
hasCriteria	Dimension	Criteria	Multiple : Each Dimension must have at least one associated Criteria, but it can have multiple criteria.	isCriteriaOf
isEvaluatedUsing	Criteria	Indicator	Single : A single Criteria is evaluated using one or more Indicators.	evaluates
generates	Industry4.0ReadinessAssessment	AssessmentResult	An Industry4.0ReadinessAssessment generates exactly one AssessmentResult. This ensures that each assessment leads to a unique, consolidated result.	isGeneratedBy
isAssociatedWith	Company	Industry4.0Readiness Assessment	Multiple : A single Company can be associated with one or more Industry4.0ReadinessAssessments. This allows a company to conduct multiple assessments over time or for different operational units.	isCompanyOf

In order to assess the technological readiness and maturity, the Digital Infrastructure sub-dimension assesses the foundational technological components necessary for Industry 4.0. It includes attributes like systemIntegrationLevel, which measures the extent to which systems are integrated within the organization, and realTimeAccess and scalability, which evaluate the system's ability to handle real-time data and scale accordingly. The functions integrateInfrastructure() and evaluateInfrastructureReadiness() provide methods for enhancing and assessing the state of technological infrastructure. The Processes sub-dimension examines the degree of process optimization, with attributes such as standardization, digitizationLevel, and crossDeptCollaboration. Functions like analyzeProcessMaturity() and optimizeProcesses () allow for the assessment and improvement of business processes through digital transformation.

The Data and Analytics sub-dimension addresses data management and analytics capabilities within the organization. Key attributes include dataCollection, analyticsCapability, and predictiveAnalyticsUsage. The functions collectData() and generateInsights() help organizations manage data collection and derive valuable insights for decision-making. The Automation and Robotics sub-dimension evaluates the automation and robotics capabilities within the organization. The attributes automationLevel, coboticsUsage, and integrationComplexity allow organizations to assess their automation maturity. The functions evaluateAutomation() and implementRobotics() guide the improvement and integration of robotic systems into operations.

For the Operational assessment, the Connectivity sub-dimension is central to evaluating the effectiveness of data exchange across systems. It includes attributes like connectivityLevel, iotNetworks, and dataFlowEfficiency. Functions such as ensureSeamlessConnectivity() and evaluateNetworkPerformance() ensure that connectivity is optimized and functioning at a level necessary for Industry 4.0 operations. The Workforce Skills sub-dimension evaluates the workforce's readiness for Industry 4.0. Attributes such as trainingPrograms, skillCompetency, and upskillingFrequency measure the organization’s commitment to continuous workforce development. Functions like analyzeSkillGap() and designTrainingProgram() ensure that the workforce remains competitive and capable of handling Industry 4.0 challenges.

For the cultural readiness and maturity, the Organizational Readiness sub-dimension examines cultural factors such as changeResistance, departmentalAlignment, and readinessLevel. These attributes help measure the internal alignment and the organization’s preparedness to embrace change. Functions such as fosterAlignment() and assessCulturalReadiness() aim to promote cultural alignment across departments. The Ecosystem Collaboration sub-dimension explores the organization’s external engagement and collaboration with partners. Attributes like partnerships, externalEngagement, and innovation Contribution gauge the organization’s collaborative efforts with external stakeholders. The functions buildPartnerships() and evaluateCollaborationImpact() help foster and assess the impact of external collaborations.

A. Theoretical Implications of the Conceptual Model on the Research Landscape of Industry 4.0 Readiness and Maturity Models

The conceptual model of the Industry 4.0 readiness ontology contributes significantly to the theoretical discourse on maturity and readiness models in Industry 4.0. By systematically integrating strategic, technological, operational, and cultural dimensions, the ontology offers a holistic framework that bridges previously siloed perspectives. Its structured approach to defining sub-dimensions, attributes, and their associated properties enhances the granularity and depth of readiness assessments, making it a pivotal reference point in the research landscape.

One critical implication is the interoperability this model introduces between disparate maturity and readiness frameworks. Existing models, such as IMPULS, SIRI, and Acatech, often emphasize specific aspects of readiness, such as technology deployment, organizational strategy, or workforce skills. The proposed ontology synthesizes these elements, offering a unified structure that incorporates strategic foresight, leadership commitment, digital infrastructure, process optimization, workforce competency, and cultural readiness. This integration ensures that no key dimension is overlooked, enabling researchers to analyze Industry 4.0 readiness through a comprehensive lens. Moreover, the ontology's inclusion of properties and cardinalities facilitates interoperability between different domains of analysis. For instance, relationships such as aggregates, hasCriteria, and isEvaluatedUsing allow researchers to map criteria and indicators across dimensions, enabling comparative studies between industries or geographic regions. This ability to establish linkages between criteria across strategic, technological, operational, and cultural domains helps advance the theoretical foundation for multi-dimensional readiness studies.

The ontology also advances the understanding of interdependencies between dimensions. For example, the cultural dimension’s attributes, such as readinessLevel and changeResistance, are intrinsically linked to strategic and operational dimensions, such as leadership engagement and process standardization. By explicitly modeling these interdependencies, the ontology highlights the cascading effects of progress or bottlenecks in one dimension on others, offering new insights into the dynamic nature of Industry 4.0 readiness. In addition, the ontology introduces a functional perspective, with defined methods (e.g., evaluateProgress(), analyzeSkillGap (), and generateInsights()) that provide a basis for operationalizing readiness assessment. This functional view enables researchers to explore not only static maturity levels but also dynamic transitions and improvement trajectories, which are often missing from traditional models. This theoretical shift aligns with the ongoing need in the research landscape to transition from static assessments to continuous, iterative improvement frameworks. The ontology emphasizes also the scalability and adaptability of readiness models. By accommodating both single-value attributes (e.g., readiness Level) and multi-value attributes (e.g., trainingPrograms or partnerships), it ensures flexibility for application across industries of varying sizes and complexities. This adaptability

addresses a significant gap in existing research, where models are often criticized for being too rigid or industry-specific.

B. *Practical Applications in Industry 4.0 Maturity Assessment: Bridging to Industry 5.0 Readiness*

The conceptual model of the Industry 4.0 readiness ontology, presented in Fig. 4, extends its theoretical robustness to practical applications in assessing Industry 4.0 maturity while paving the way for Industry 5.0 readiness. By capturing essential dimensions such as strategy, technology, operations, and culture, the model equips organizations with a structured and actionable framework to evaluate their current capabilities and chart a clear path toward technological and organizational evolution.

The ontology's multi-dimensional structure allows organizations to conduct a detailed maturity assessment, evaluating their performance across strategic, technological, operational, and cultural dimensions. For example, companies can assess their digital infrastructure and automation capabilities under the technological dimension while simultaneously evaluating leadership commitment and workforce skills under strategic and operational dimensions. This holistic approach ensures that organizations not only implement technology but also align it with strategy and culture, avoiding common pitfalls of fragmented adoption. By using properties such as analyzeSkillGap(), organizations can identify specific areas of improvement. The ontology's capability to aggregate multiple dimensions ensures that assessments are not isolated but interlinked, highlighting interdependencies that can accelerate or hinder progress. For instance, a lack of investment in leadership engagement may directly impact the success of cultural transformation initiatives. The scalability of the ontology makes it adaptable to various industries and business sizes. For large-scale manufacturers, the model can evaluate complex systems like real-time data access, IoT network integration, and robotic automation. Meanwhile, for small and medium-sized enterprises (SMEs), the focus can shift to incremental improvements, such as standardization of processes and upskilling the workforce. This flexibility ensures the model's relevance across the industrial spectrum, addressing both high-tech innovators and businesses in the early stages of transformation.

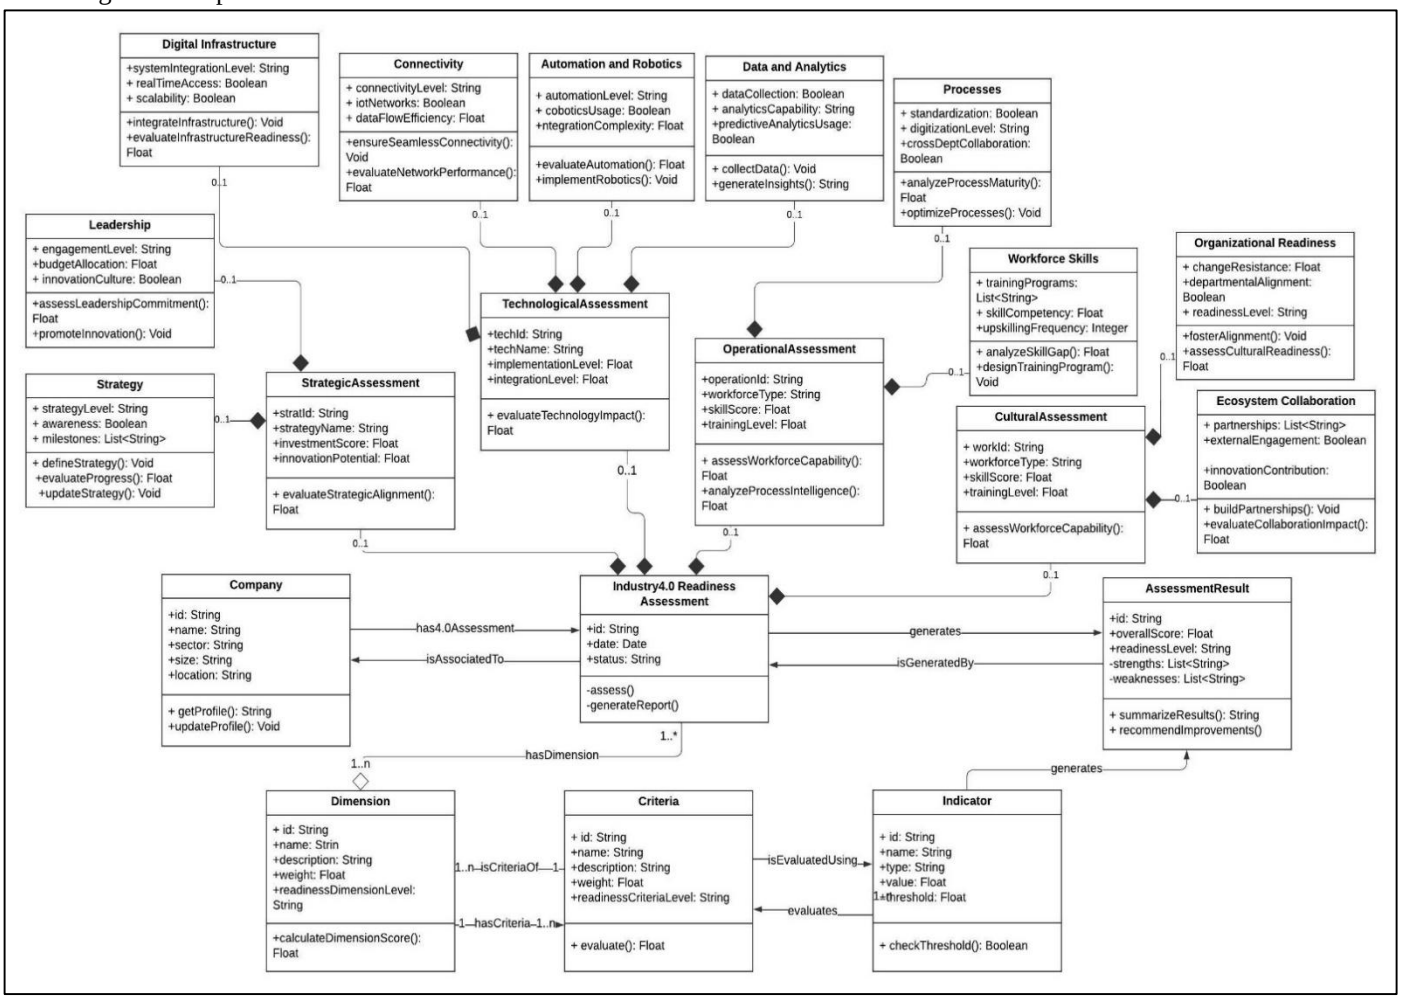

Fig. 4. Industry 4.0 Assessment conceptual model.

While rooted in Industry 4.0 principles, the ontology lays the groundwork for Industry 5.0 readiness by emphasizing human-centric innovation and sustainability. For instance, dimensions like workforce skills and cultural readiness align with Industry 5.0's focus on human-machine collaboration, where the role of cobotics and innovation culture becomes increasingly significant. The ontology's inclusion of attributes such as coboticsUsage, changeResistance, and trainingPrograms allows organizations to assess and enhance their preparedness for the collaborative, human-centered environments that define Industry 5.0. Furthermore, the ecosystem collaboration sub-dimension promotes partnerships and external engagements that are critical for sustainability and co-innovation in Industry 5.0. Functions like buildPartnerships() and evaluate Collaboration Impact() enable organizations to strengthen their position within an interconnected industrial ecosystem, fostering resilience and adaptability. The functional perspective embedded in the ontology supports real-time monitoring and continuous improvement. Methods such as evaluateProgress() and generateInsights() provide organizations with tools to regularly assess their Industry 4.0 maturity levels and dynamically adapt their strategies. This iterative approach ensures that organizations are not only maintaining their Industry 4.0 capabilities but are also actively transitioning toward Industry 5.0 readiness. The ontology facilitates benchmarking by enabling comparisons across industries, regions, and organizational sizes. Organizations can use indicators and criteria modeled in the ontology to measure their progress against industry standards or peers. This capability aids in identifying competitive gaps and aligning strategic decisions with industry trends.

For instance, companies can leverage insights derived from evaluateAutomation() and assessLeadershipCommitment() to prioritize investments and allocate resources more effectively. The ontology provides then a roadmap for organizations to future-proof their operations. By incorporating both current Industry 4.0 requirements and emerging Industry 5.0 principles, the model ensures that businesses are prepared for evolving technological landscapes. Attributes like scalability, predictiveAnalyticsUsage, and innovationCulture allow organizations to anticipate and adapt to future challenges, ensuring long-term competitiveness and sustainability.

The practical applications of the Industry 4.0 readiness ontology extend beyond assessing maturity. By offering a comprehensive, adaptable, and future-oriented framework, the model empowers organizations to not only excel in Industry 4.0 adoption but also position themselves as leaders in the transition to Industry 5.0. Its focus on interoperability, human-centric innovation, and continuous improvement makes it an essential tool for driving industrial transformation in an increasingly complex and interconnected world.

V. Conclusion

In conclusion, this research has developed a comprehensive conceptual model for assessing Industry 4.0 readiness and maturity, encapsulating the multifaceted dimensions and interrelationships critical to successful digital transformation. By integrating principles from prominent methodologies and drawing inspiration from established frameworks like IMPULS, SIRI, and Acatech, the proposed ontology provides a structured and holistic perspective on readiness assessment. The model delineates key connections between strategic, technological, operational, and cultural dimensions, offering insights into leadership engagement, digital infrastructure, workforce skills, and organizational alignment. Through its robust structure of classes, relationships, and functional properties, the ontology facilitates a nuanced understanding of interdependencies, enabling organizations to evaluate their maturity comprehensively and identify areas for improvement.

The conceptual model also establishes a foundation for bridging Industry 4.0 and Industry 5.0 readiness, emphasizing human-centric innovation, sustainability, and collaborative ecosystems. By accommodating diverse organizational contexts and fostering interoperability between dimensions, the model addresses critical gaps in existing frameworks, providing a flexible tool for continuous improvement and strategic decision-making. This work thus contributes to advancing the theoretical and practical landscape of Industry 4.0 readiness assessments, serving as a valuable resource for researchers, practitioners, and policymakers navigating the complexities of digital transformation.

The next critical step is to leverage this conceptual model to develop a fully operational ontology for Industry 4.0 readiness and maturity assessment. Such an ontology would formalize the domain knowledge, enable standardized representation, and enhance interoperability across systems, ultimately supporting tools for benchmarking, diagnostics, and strategic planning. By transitioning from conceptual modeling to ontology implementation, this work can catalyze meaningful progress in industrial transformation, positioning organizations to thrive in the evolving landscapes of Industry 4.0 and beyond.

Eco-Efficiency Measurement and Regional Optimization Strategy of Green Buildings in China Based on Three-Stage Super-Efficiency SBM-DEA Model

Xianhong Qin*, Yaou Lv, Yunfang Wang, Jian Pi, Ze Xu
HCIG Xiong'an Construction Development Co., Ltd, Xiongan 070001, China

***Abstract*—With the increasing attention of society to sustainable development, green building as an important sustainable building form has attracted much attention. However, the comprehensive assessment of eco-efficiency of green buildings faces many challenges, including the insufficient comprehensive analysis of all stages of the building life cycle and the oversimplification of multidimensional input-output relationships. In addition, the existing methods have subjectivity and uncertainty in data processing and weight allocation, which reduces the reliability of evaluation. To overcome these difficulties, a measurement method based on the three-stage super-efficient data Enveloping analysis (SBM-DEA) model is introduced in this study. By constructing a three-stage super-efficiency SBM-DEA model, the eco-efficiency measurement model of green buildings is established, taking building resources and energy as input and economic and environmental value as output. The results show that after removing the interference of external environment variables and random errors, the measurement results of stage 3 are more reasonable. From 2011 to 2018, the eco-efficiency of green buildings in China showed obvious regional differences, showing a decreasing trend of "the highest in the east (0.884), followed by the central (0.704) and the lowest in the west (0.578)". The innovation of this study lies in the full consideration of timing and dynamics, which provides new theoretical and practical ideas for promoting sustainable development in the field of green building, and is expected to improve the assessment accuracy and reliability in the field of green building.**

Keywords*—Three stages; data envelopment analysis; super efficiency model; green buildings; ecological efficiency

I. Introduction

With the continuous warming of global environmental issues and the urgent need for Sustainable Development (SD), Green Buildings (GBS), as a sustainable building model, have gradually become the focus of attention. SD refers to a model of development that meets the needs of the present without compromising the ability of future generations to meet their own needs. At present, the measurement of Green Building Eco-efficiency (GBEE) is particularly important in evaluating its environmental friendliness and resource utilization, especially in the insufficient comprehensive analysis of various stages of the building lifecycle and the simple handling of 3D input-output relationships [1]. GBEE refers to minimizing environmental impact and improving resource efficiency throughout a building's life cycle through sustainable design, efficient use of resources and environmentally friendly technologies. However, the comprehensive evaluation of the comprehensive benefits of green buildings faces many difficulties and challenges. On the one hand, the existing measurement methods are insufficient in the comprehensive analysis of various stages of the building life cycle, and it is difficult to fully reflect the ecological benefits of green buildings at different stages. On the other hand, the existing methods are too simple when dealing with the multi-dimensional input-output relationship, and it is difficult to accurately evaluate the comprehensive ecological efficiency of green buildings. In addition, the existing methods have subjectivity and uncertainty in data processing and weight allocation, which reduces the reliability and credibility of the evaluation results. The Slacks-Based Measure in Data Envelopment Analysis (SBM-DEA) model based on three-stage super-efficiency combines Data Envelopment Analysis (DEA) and Super Efficiency Model (SEM) [2-3], i.e. 3SE-SBM-DEA model, which can more comprehensively and accurately measure the GBEE. The introduction of the 3SE-SBM-DEA model can better grasp the dynamic characteristics of the building lifecycle and more accurately evaluate the ecological benefits of GBS at different stages [4]. Based on this, this study proposes a GBEE measurement and optimization method based on the 3SE-SBM-DEA model. Firstly, by constructing a 3SE-SBM-DEA model with building resources and energy as inputs and economic and environmental values as outputs, a GBEE measurement model is established. Next, based on theoretical logic, the temporal differences in the GBEE from a temporal dimension are analyzed, and the dynamic evolution characteristics through kernel density estimation (KDE) are revealed. The aim of this study is to achieve comprehensive measurement of GBEE and propose corresponding optimization strategies through the method of this 3SE-SBM-DEA model. The innovation of this method lies in fully considering the temporal and dynamic aspects, providing new theoretical and practical ideas for promoting SD in GB. This paper aims to give more scientific and comprehensive basis for GB design and evaluation, and promote the GB field towards a more sustainable direction.

Section I introduces the research background, problems, and solutions of GBEE measurement. Section II provides a review of previous research on GBEE measurement, exploring

difficulties and shortcomings in methods. Section III is the method of using the 3SE-SBM-DEA model in GBEE measurement. Section IV designs simulation experiments to verify the effectiveness of the proposed method. Section V summarizes the research methods and analyzes the experimental results, pointing out the shortcomings of the methods and future research directions.

II. Related Works

The urgent need for global SD has gradually made GBS a mainstream form of construction that emphasizes resource conservation and environmental friendliness. However, to comprehensively evaluate the comprehensive performance of GBS, a single economic indicator is no longer sufficient. Therefore, researchers are gradually paying attention to GBEE measurement, aiming to comprehensively evaluate its sustainability from two aspects: Resource Utilization Efficiency (RUE) and environmental impact. Ishmael et al. addressed the contribution of buildings to climate change by using an intelligent energy building model based on the Internet of Things (IoT) to connect sensors of building equipment using M2M, IoT, and AEP technologies, achieving intelligent monitoring and improving energy efficiency. IoT intelligent building technology has been proven to be crucial in improving energy efficiency [5]. Tavana M et al. adopted a comprehensive DEA and lifecycle assessment approach to address the negative impact of the Construction Industry (CI) on the environment, particularly in material procurement and emissions, to measure the performance of environmentally friendly building materials in GB management. This method provided a scientific evaluation tool for the selection of GB materials [6]. Zhou Y et al. conducted long-term measurements and surveys of resident satisfaction, combined with environmental energy efficiency analysis, to assess the actual performance of the GB. The measured indoor thermal condition did not fully meet the design goals, especially with differences in relative humidity. However, residents had a higher level of satisfaction with IEQ [7]. Petre and other scholars have proposed a method to accurately determine the actual energy consumption of buildings by in-situ measuring the thermal resistance of building components in response to the high energy consumption problem of the CI in global warming. This study provided practical guidance for improving building energy performance and global warming prevention and control [8]. In response to the challenges encountered in implementing green practices in the chemical industry, Sinaga L et al. proposed an evaluation method that combines blockchain building information modeling (BIM) with structural equation model-Partial least squares (SEM-PLS). The research results show that green practices are becoming more and more common in the manufacturing industry and can reduce the adverse impact on the environment, but the adoption of green principles in industry is affected by a variety of factors [9]. Traditional building materials used in the construction industry significantly contribute to air pollution and greenhouse gas emissions, causing considerable environmental damage across Pakistan. Bashir et al., using closed questionnaires, interviews and observations to collect data using planning and random sampling techniques, focused on exploring the feasibility of adopting green building materials in Pakistan's building sector with the aim of mitigating environmental impacts. The results of the study show that factors such as high cost, low market demand and logistical challenges limit people's interest in environmentally friendly materials, with 73% of construction companies in Pakistan not using green building materials [10]. In view of the negative impact of the construction industry on the environment and the problems of resource depletion, emission and biodiversity loss, Kristinayanti W S et al. proposed a method combining local wisdom and green building practices, adopted the PRISMA framework method, and conducted a comprehensive systematic evaluation and qualitative analysis through NVivo software. The research results show that the construction industry needs a sustainable transformation, and combining local wisdom can provide innovative and adaptable solutions to help promote the transformation of construction practices to SD [11].

In addition, the 3SE-SBM-DEA combines the advantages of DEA and SEM to assess the relative efficiency of various units. In this model, the projection pursuit method is used to determine the unit's super efficiency boundary, so that an optimal super efficiency frontier can be found under certain constraints. Jiahui et al. utilized the 3SE-SBM-DEA to address the CO2 efficiency issues in the four Chinese major beef-cattle production areas in, and incorporated CO2 into the efficiency calculation framework. External random disturbances had greatly affected the efficiency measurement, and using the 3SE model made the results more in line with reality [12]. Junlong et al. constructed an indicator system to promote the high-quality development of China's shared manufacturing industry and used a 3-phase DEA-Malmquist model to dynamically measure 39 shared manufacturing enterprises from 2018 to 2020. The mean fluctuation of comprehensive/pure/scale efficiency had a significant impact on development efficiency [13]. Radimov N et al. proposed a novel control and optimization strategy for a bidirectional 3-level in vehicle battery charger (OBC) that achieves 80 PLUS titanium efficiency. OBC could change the direction of power flow within a few msec, providing reactive power support for the power grid, with 96.65% peak efficiency and 1% min-total harmonic distortion [14]. Qad et al. measured the relationship between technology industry agglomeration, green innovation, and development quality in the Yangtze River Delta urban agglomeration using superefficient SBM-DEA and improved TOPSIS method. There was a significant spatial connection between these factors, especially in the transformation stage where they mutually promote each other [15].

To sum up, the existing research has made remarkable progress in the field of eco-efficiency measurement of green buildings, but there are still some limitations. For example, although some studies have proposed comprehensive evaluation methods, they are still insufficient in dealing with the dynamic characteristics of the whole life cycle of buildings and the multi-dimensional input-output relationship. In addition, there are subjectivity and uncertainty in data processing and weight allocation in existing studies, which reduces the reliability and applicability of evaluation results. Although some studies try to solve these problems by

introducing advanced technical means or improving evaluation models, most studies fail to fully consider regional differences and dynamic evolution characteristics, resulting in the overall assessment of green building eco-efficiency is still insufficient. The DEA method is also adopted as the basic framework in this study. However, the innovation of this study lies in the introduction of the three-stage super-efficiency SBM-DEA model, which can not only evaluate the eco-efficiency of green buildings more comprehensively, but also better deal with data uncertainty and subjectivity by introducing the concepts of super-efficiency and stages. Improve the objectivity and robustness of the evaluation. In addition, this study also combined temporal dimension analysis and kernel density estimation to reveal the dynamic evolution characteristics of green building eco-efficiency, which was rarely involved in previous studies.

The contributions of this research are mainly reflected in the following aspects: First, by constructing a three-stage super-efficiency SBM-DEA model, this research provides a more scientific and comprehensive method for measuring the eco-efficiency of green buildings, which can effectively overcome the limitations of existing methods in data processing and weight allocation. Secondly, this study systematically analyzed the regional differences of eco-efficiency of green buildings in China for the first time, revealing the decreasing trend of "the highest in the east, the second in the central, and the lowest in the west" during 2011-2018, providing a scientific basis for formulating targeted optimization strategies. Finally, based on the measurement results, this study proposed specific optimization strategies to narrow the regional gap and improve the overall ecological efficiency of green buildings across the country.

III. Construction of 3SE-SBM-DEA Measurement Model

This study first constructs a 3SE-SBM-DEA model, using building resources and energy as inputs and economic and environmental values as outputs, to establish a GBEE measurement model. Next, based on theoretical logic, to analyze the temporal differences of GBEE from the temporal dimension, and to reveal the dynamic evolution characteristics through KDE.

A. Building the GBEE Measurement Model

Eco-efficiency is the efficiency of ecological resources to meet human needs, usually measured by the ratio of output to input [16]. Among them, "output" covers the value of the products and services produced by the enterprise, while "input" includes the resources and energy consumed by the enterprise, as well as the impact on the environment [17]. The mathematical formula related to ecological efficiency is Eq. (1).

$$\text{Eco-e} = \frac{\text{Value of p or s}}{\text{Ei}} \quad (1)$$

In Eq. (1), Eco-e represents ecological efficiency, and Value of p or s represents the value of the product or service. Ei represents environmental impact. GBEE refers to the use of sustainable design, efficient resource utilization, and environmental protection technologies to minimize the impact on the environment during the building lifecycle, increase RUE, and reduce the burden on natural ecosystems [18]. Fig. 1 shows the ecological efficiency evaluation model.

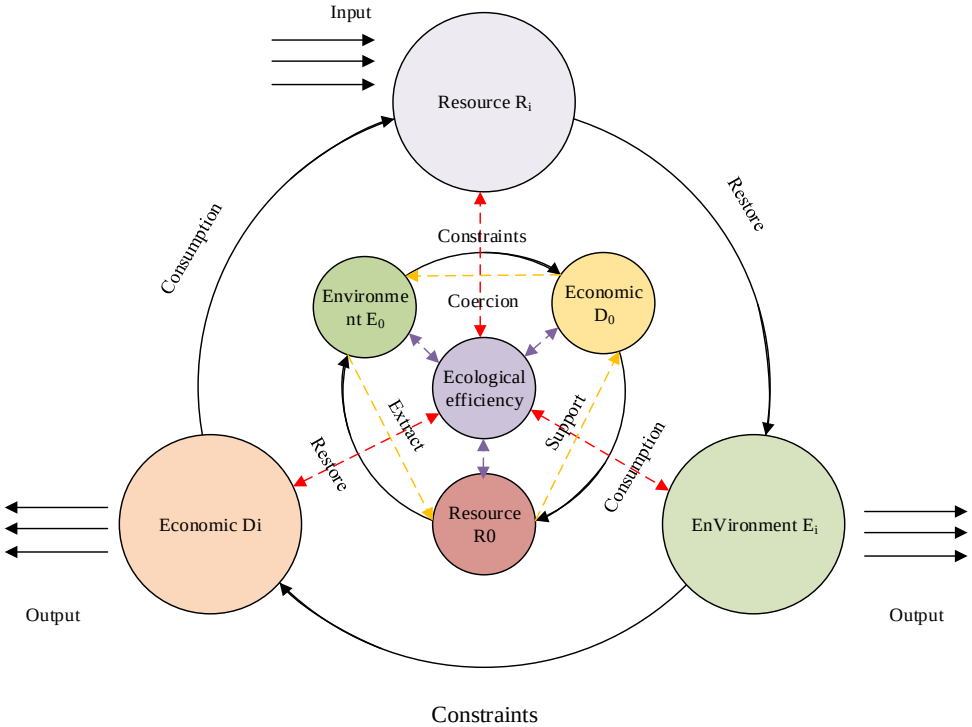

Fig. 1. Ecological efficiency evaluation model.

In Fig. 1, the model mainly revolves around economy, resources, and environment [19]. To evaluate ecological efficiency, it is necessary to first determine key indicators such as energy consumption, material utilization, and water resource utilization. Subsequently, by collecting relevant data from the system, including information on building energy usage, material sources and utilization, water resource management, etc., a comprehensive data foundation is established. Next, a mathematical model is used to quantify the system efficiency. Finally, based on the evaluation results, optimization suggestions are established to lift the Eco-efficiency. To derive the Eco-efficiency calculation formula for buildings based on Eq. (1), as shown in Eq. (2).

$$\text{B eco-e} = \frac{\text{Be}}{\text{El}} \tag{2}$$

In Eq. (2), B eco-e represents the ecological benefits of the building. B eco-e represents the value of the building. El represents environmental load. The GBEE measurement indicator system aims to comprehensively understand the comprehensive ecological benefits of buildings throughout their lifecycle by evaluating their performance in energy utilization, material selection, water resource utilization, environmental impact of design, and indoor environmental quality. Fig. 2 shows the GBEE measurement indicator system.

In Fig. 2, the measurement indicator system of GBEE is mainly divided into two parts: input indicators and output indicators. The investment indicators include capital investment, labor investment, energy investment, land investment, and technology investment. Output indicators include environmental output and economic output. This set of specific parameters is selected to ensure that the eco-efficiency measurement of green buildings based on the three-stage super-efficiency SBM-DEA model can fully and accurately reflect the actual ecological benefits of green buildings, while eliminating the interference of external environment and random errors, and improving the reliability and applicability of the model results. SBM is a distance function based method used to evaluate performance relative to other units, suitable for considering multiple input and output factors, and able to handle different weights and measurement standards. DEA is a non-parametric approach taken to evaluate relative efficiency. DEA does not require prior assumptions about weights or function forms, making it suitable for complex multi input multi output scenarios [20]. Fig. 3 shows the specific process of the 3-stage DEA.

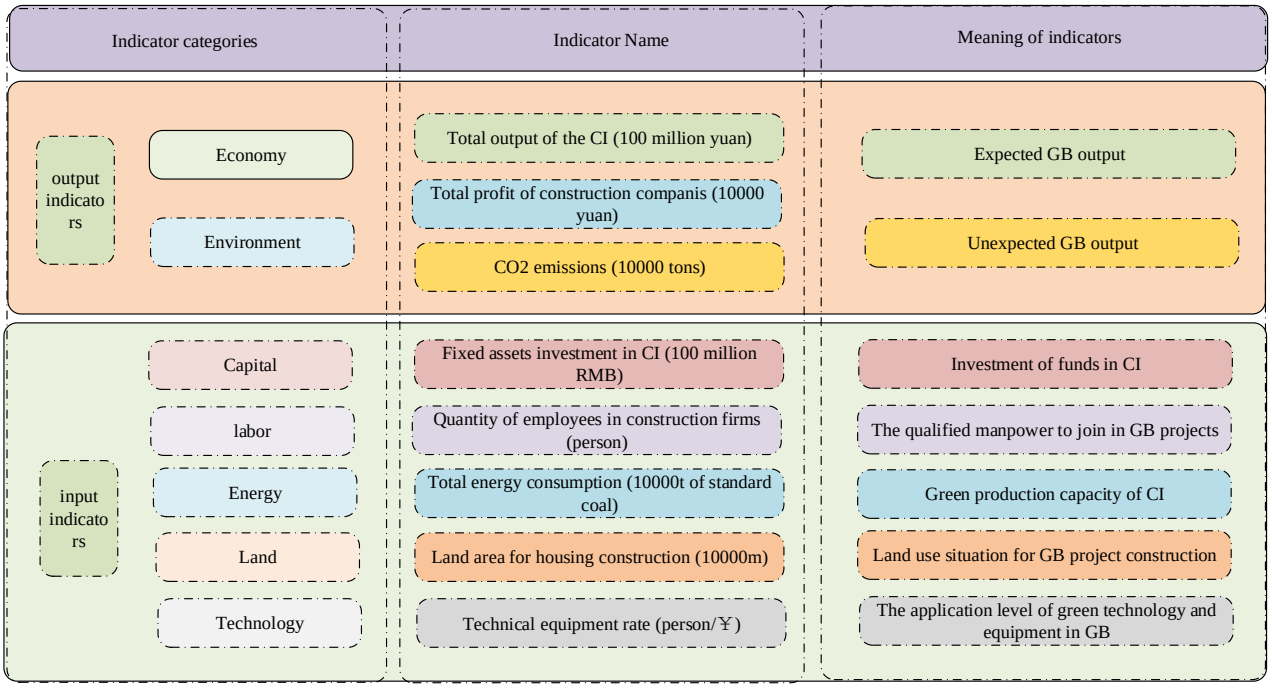

Fig. 2. Index system of GBEE measurement.

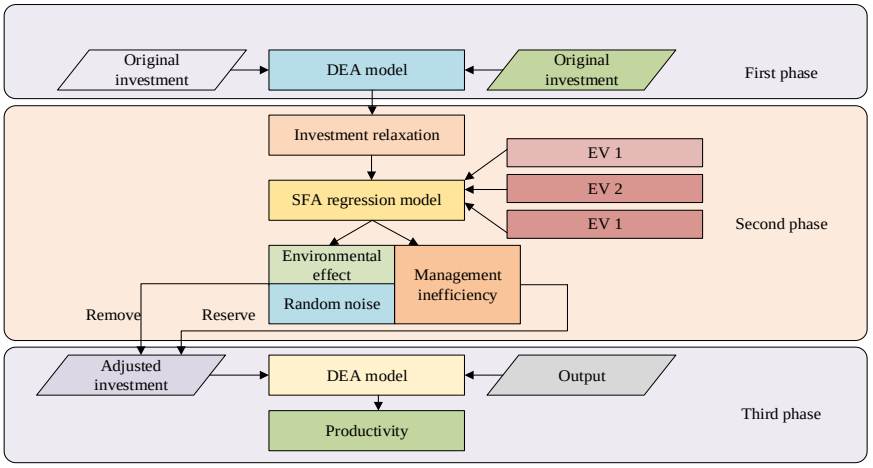

Fig. 3. Specific process of the three-stage DEA.

In Fig. 3, the first phase of constructing the three-stage DEA is the construction of the SBM model. The 2nd phase is to construct a stochastic frontier model. The third stage is based on the foundation of stages one and two, to obtain more accurate measurement values that reflect the GBEE levels of all DEAs [21]. Specifically, the first step is to construct an ultra efficient SBM model. This study adopted an input-oriented model to test the initial efficiency of GBEE. The improved super-efficient SBM model is obtained by optimizing the objective function based on relaxation variables. The process is shown in Eq. (3).

$$\rho = \min \frac{\frac{1}{m}\sum_{i=1}^{m}\frac{\bar{x}_i}{x_{i0}}}{\frac{1}{s_1+s_2}\left(\sum_{r=1}^{s_1}\frac{\bar{y}_r^a}{y_r^a}+\sum_{j=1}^{s_2}\frac{\bar{y}_j^b}{y_{j0}^b}\right)}$$

$$\text{s.t.}\begin{cases} x_0 = X\lambda + S^-, \quad y_0^a = Y^a\lambda - S^a, \quad y_0^b = Y^b\lambda - S^b \\ \bar{x} \geq \sum_{j=1,\neq 0}^{n}\lambda_j x_j, \quad \bar{y}^a \leq \sum_{j=1,\neq 0}^{n}\lambda_j y_j^a, \quad \bar{y}^b \leq \sum_{j=1,\neq 0}^{n}\lambda_j y_j^b \\ \bar{x} \geq x_0, \quad \bar{y}^a \leq y_0^a, \quad \bar{y}^b \geq y_0^b \\ \sum_{j=1,\neq 0}^{n}\lambda_j = 1, \quad S^- \geq 0, \quad S^a \geq 0, \quad S^b \geq 0, \quad \bar{y}^g \geq 0, \quad \lambda \geq 0 \end{cases} \tag{3}$$

In Eq. (3), m represents the number of input indicators. n represents Decision-making Unit (DMU). x represents the input item. λ and ρ represent weight vectors and objective function values, respectively. y_a and y_b represent expected and unexpected output items, respectively, with S_1 and S_2 as the number of indicators. S^- is the input, S^a is , expected output, and S^b is the unexpected output. After constructing the SBM, a random frontier model is then constructed [22]. By measuring GBEE, the original efficiency data and relaxation variable of each DMU can be obtained. The process function model is Eq. (4).

$$S_{ni} = f\left(Z_i;\beta^n\right) + v_{ni} + \mu_{ni} \quad ;i = 1,2,\ldots,I;n = 1,2,\ldots,N \tag{4}$$

In Eq. (4), i and n represent the number of DMUs and the input items, respectively. S_{ni} represents the input relaxation value (IRV) of n of the i -th DMU. Z_i represents P Environmental Variables (EVs). β^n represents the estimated parameter of i . $f\left(Z_i;\beta^n\right)$ represents the impact of external EV on the IRV. $v_{ni}+\mu_{ni}$ is the mixed-error, where v_{ni} is the Random Error (RE). To eliminate the influence of external EVs and REs, homogeneous adjustments are made to each input quantity. The specific adjustment method can refer to Eq. (5).

$$X_{ni}^A = X_{ni} + \left[\max f\left(Z_i;\hat{\beta}^n\right) - f\left(Z_i;\hat{\beta}^n\right)\right] + \left[\max\left(v_{ni}\right) - v_{ni}\right] \tag{5}$$

In Eq. (5), this study homogenized the input of each DMU and obtained the adjusted input value X_{ni}^A. By maximizing $\max f\left(Z_i;\hat{\beta}^n\right) - f\left(Z_i;\hat{\beta}^n\right)$, this study adjusts the external environment to the same state. Among them, $\max f\left(Z_i;\hat{\beta}^n\right)$ is the benchmark adjusted by other DMUs, indicating the worst environmental conditions. This adjustment takes into account both good and bad conditions, and increases or decreases investment. To adjust the RE to the same state through $\max\left(v_{ni}\right) - v_{ni}$, ensuring that all DMUs are in the similar external EV and RE status.

B. GBEE Based on Temporal Dimension

After establishing a scientific measurement index system, this study further analyzes the temporal changes of GBEE through the temporal dimension based on national, regional, and inter provincial differences, and uses KDE to reveal its dynamic evolution characteristics [23]. On the spatial dimension, the spatial distribution pattern of GBEE is visualized, and the spatial agglomeration and transition characteristics of GBEE in various provinces and cities through spatial auto-correlation (SAC) analysis are revealed. The specific technical road-map is Fig. 4.

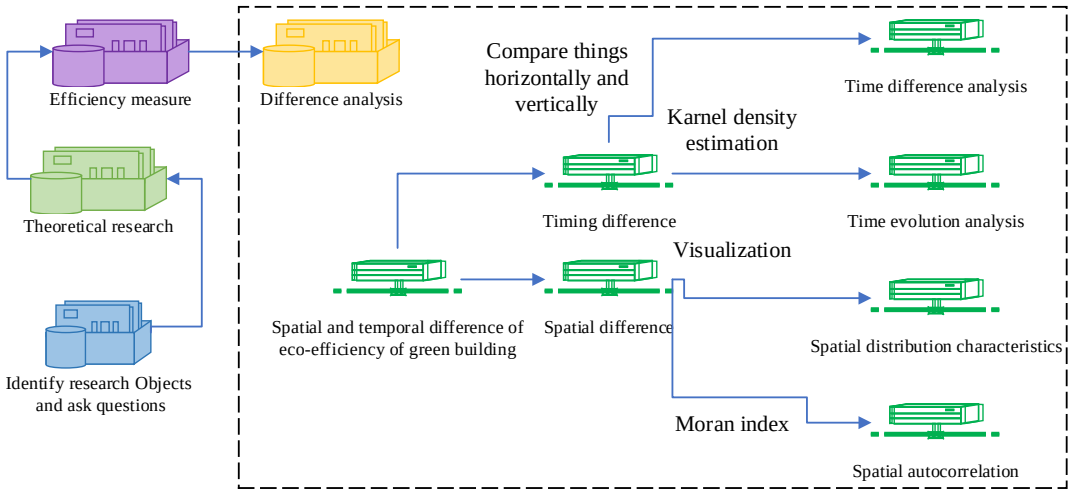

Fig. 4. Technology road-map.

In Fig. 4, the spatiotemporal differences of GBEE are divided into temporal differences and spatial differences. Kernel density estimation is a non-parametric statistical method utilized to estimate the shape of the probability density function. This method involves placing kernel functions (KerF) around each data-point and then overlaying these functions to form an estimate of the overall probability density. The specific expression is Eq. (6).

$$f(x)=\frac{1}{Nh}\sum_{i=1}^{N}K\left(\frac{X_i-\bar{x}}{h}\right) \tag{6}$$

In Eq. (6), bandwidth h is an important parameter. The set of observation samples is represented by N, and the values of independent and identically distributed observation samples are represented by X_i. x represents the input item. The K is a weighted or smooth transformation function. The mathematical formula that needs to meet the conditions is Eq. (7).

$$\begin{cases}\lim\limits_{x\to\infty}K(x)\cdot x=0\\ K(x)\geq 0 \quad \int_{-\infty}^{+\infty}K(x)dx=1\\ \sup K(x)<+\infty \quad \int_{-\infty}^{+\infty}K^2(x)dx<+\infty\end{cases} \tag{7}$$

KerFs generally include trigonometric KerFs, quadrilateral KerFs, and Gaussian KerFs. This study chose to use Gaussian density KerF, as shown in Eq. (8).

$$K(x)=\frac{1}{\sqrt{2\pi}}e^{-\frac{x^2}{2}} \tag{8}$$

Building a spatial weight matrix is a commonly used task in spatial analysis, which is used to describe the degree of correlation between adjacent regions in geographic space. Construct a binary symmetric spatial matrix W_{n*n} of n*n to represent the spatial adjacency relationship between n positions. The matrix is specifically expressed as Eq. (9).

$$W_{n\times n}=\begin{bmatrix}w_{11} & w_{12} & \cdots & w_{1n}\\ w_{21} & w_{22} & \cdots & w_{2n}\\ \cdots & \cdots & \cdots & \cdots\\ w_{n1} & w_{n2} & \cdots & w_{nn}\end{bmatrix} \tag{9}$$

In Eq. (9), $W_{i\times j}$ represents the proximity relationship between region i and j. This study uses the spatial weight matrix under the geographical distance standard, as expressed in Eq. (10).

$$w_{ij}=\begin{cases}1, & \text{The distance between region i and j is<d}\\ 0, & \text{others}\end{cases} \tag{10}$$

Global SAC is a method taken to analyze the spatial correlation between geographic units in an entire region or system. It mainly focuses on the global distribution pattern of variables within the entire region to reveal spatial clustering or dispersion trends. This study uses a geographic distance spatial weight matrix and uses the global Moran's I index (MII) for measurement, as shown in Eq. (11).

$$I=\frac{\sum_{i=1}^{n}\sum_{j=1}^{n}W_{ij}\left(x_i-\bar{x}\right)\left(x_j-\bar{x}\right)}{S^2\sum_{i=1}^{n}\sum_{j=1}^{n}W_{ij}} \tag{11}$$

In Eq. (11), n is the amount of provinces and cities. x_i and x_j represent the GBEE values of province and city i and j. $\bar{x}$ and S^2 represent the mean and variance of GBEE in each province and city. Further to adopt the Z-score normal distribution hypothesis to verify the accuracy of MII. Its expression is Eq. (12).

$$Z(I)=\frac{I-E(I)}{\sqrt{\mathrm{VAR}(I)}} \tag{12}$$

In Eq. (12), $E(I)$ is the expected value. $\mathrm{VAR}(I)$

represents the expected variance. The specific expression of $E(I)$ is Eq. (13).

$$E(I) = -\frac{1}{n-1} \tag{13}$$

Local SAC is usually measured by Local Moran's I. This paper uses local MII and Moran scatter plot to evaluate the local distribution characteristics of GBEE, as shown in Eq. (14).

$$I_i = \frac{(x_i - \bar{x})}{S^2} \sum_{j=1}^{n} W_{ij} (x_j - \bar{x}) \tag{14}$$

The spatial lag model is adopted to spatial data analysis. It considers spatial correlation, which is commonly used to describe the interactions and dependencies between spatial data, as shown in Eq. (15).

$$Y = \rho WY + X\beta + \mu \tag{15}$$

The relationship between GBEE Y and the influencing factor matrix X was studied in Eq. (15). Considering spatial interaction, spatial auto-regressive coefficient ρ and spatial weight matrix are introduced. The RE is represented by μ, while the spatial lag term WY reflects the influence of adjacent regions.

As a comprehensive efficiency evaluation method, the core assumptions of 3SE-SBM-DEA model mainly include the following points: First, the model assumes that there is a clear linear relationship between input and output, that is, under given technical conditions, the increase of input will lead to the increase of output in a certain proportional relationship. Secondly, the 3SE-SBM-DEA model assumes that the effects of external environment variables and random errors on efficiency are independent and can be separated and adjusted by appropriate statistical methods. In addition, the model also assumes that the data is accurate and complete, that is, the input and output data can truly reflect the actual operation of green buildings. Finally, the model assumes that each DMU is homogeneous in terms of technical conditions and production functions, that is, all evaluated green building projects are comparable at the technical level.

IV. Performance Analysis and Validation of the GBEE Measurement Model

This study first analyzes the statistical characteristics of the sample data and the assumption of homogeneity of measurement indicators, confirming the applicability of the measurement model. Subsequently, using indicator data, the GBEE in China is measured, and the efficiency levels and variation differences of Stage One and Stage Three at the national, regional, and inter provincial levels are compared and analyzed.

A. GBEE Analysis

This study uses panel data on input-output and EVs from 2011 to 2018, selecting 30 provinces in China as research subjects, with the aim of calculating the GBEE of each province and city. To better analyze its regional differences, the research area is segmented into eastern, central, and western regions. Table I presents the statistical results.

According to Table I, through statistical analysis of the collected data, it is found that the SD and range among individual indicators are huge, showing a significant difference, and the input-output situation also shows a significant difference. Before conducting the GBEE measurement, the measurement model requires that the input and output items meet the assumption of homogeneity, that is, the principle that "as the input increases, the output does not decrease.". To verify this hypothesis, this study conducts Pearson correlation tests between input indicators and output indicators using SPSS 20.0 software. Table II shows the test results.

In Table II, && is significantly correlated at the 1% level (bilateral). In Table II, the correlation coefficients are all positive and have all passed the bilateral test at the 1%, indicating that the input and output variables satisfy the principle of homogeneity assumption. This study further adopts the super efficiency SBM model and uses MAXDEA software to run GBEE input-output data, obtaining the GBEE levels of each province and city without considering the influence of external EVs and REs. The specific results are shown in Fig. 5.

TABLE I. Descriptive Statistical Results of Sample Data

Variable	Minimum	Mean	Maximum	SD	Sample
Housing construction land area	738	39362	249176	47499	240

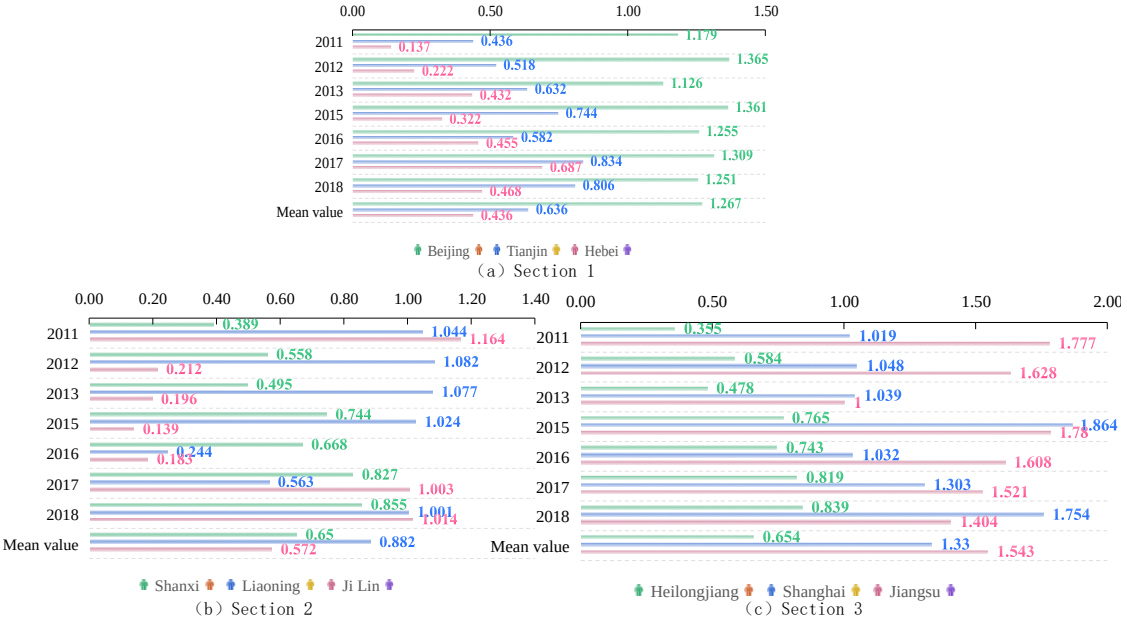

Fig. 5. Eco-efficiency level of green buildings.

Fig. 5 (a) shows the GBEE levels in provinces and cities B, T, and H. Annual Growth Rate (AGR) is used to describe the average annual growth of an indicator in a specific period of time. Fig. 5 (b) shows the GBEE levels in S, L, and J provinces. Fig. 5 (c) shows the GBEE levels of provinces and cities A, C, and D. Fig. 5 shows that from 2011 to 2018, China's GBEE showed a good development trend, with an overall average efficiency increasing trend, with an average AGR of 4.71%. After 2015, ecological efficiency achieved sustained and steady growth, reaching a peak of 0.916 in 2018, with an average AGR of 14.5%. The average and AGR of GBEE in some provinces and cities in China are shown in Fig. 6.

Fig. 6 (a) shows the AGR, and Fig. 6 (b) shows the Mean Ecological Efficiency (MEE). There are obvious discrepancies in GBEE among provinces. The MEE of province and city A is below 0.7, with an average AGR of 13.07%. Provinces and cities such as E show fluctuating fluctuations, with no significant increase or decrease trend. Fig. 7 shows the comparison of the MEE and average AGR of GBEE among different regions in China.

Fig. 7 (a) is the MEE, and Fig. 7 (b) shows the AGR. Between 2011 and 2018, China's GBEE showed significant regional differences, with the highest in the East (0.884), followed by the central (0.704), and the lowest in the West (0.578). Fig. 8 shows the trend of changes in the mean GBEE across different regions.

Fig. 8 (a) shows the eastern and central regions, while Fig. 8 (b) shows the national and western regions. Fig. 8 shows that the GBEE in the East showed fluctuating patterns from 2011 to 2018, consistently higher than the national average, with no significant increase or decrease trend. In contrast, the efficiency curve in the central region shows a similar development trend to the national average curve, with an overall low growth rate. Although the three major regions reached their peak efficiency in 2018, the average AGR in the West reached 6.99%, which is 48.84% and 41.33% higher than that in the East and Center, respectively.

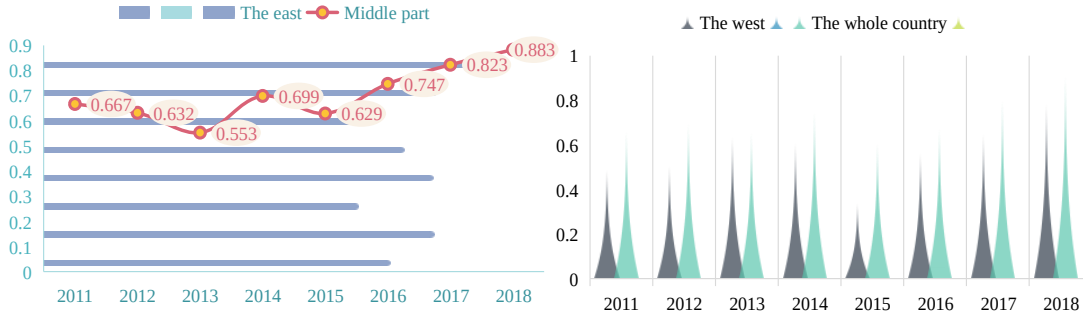
Fig. 7. Comparison of MEE and average AGR of GBEE in different Chinese regions.



(a) The east and Middle part (b) The west And The whole country

Fig. 8. Variation trend of mean value of GBEE in each region.

B. *Performance Verification Based on the 3SE-SBM-DEA Model*

After the SFA regression analysis in stage two, it is found that there are significant differences in the impact of external environmental differences and GB investment factors among provinces and cities, which in turn have a significant impact on GBEE. To eliminate these impacts, adjustments are made to the input variables to ensure that each province and city are compared under the equal external EV and RE. The final GBEE is obtained by using the SBM model and MAXDEA software for efficiency analysis. The GBEE mean measurement results for Stage 1 and Stage 3 are shown in Fig. 9.

Fig. 9 (a) and Fig. 9 (b) show the results of the first and third stages. By comparing Fig. 9 (a) and 9 (b), the MEE of the three stages is lower than that of the first stage, except for 2015 and 2016. Fig. 10 further illustrates the comparison of GBEE mean values.

Fig. 10 (a) shows the results of the first stage, and Fig. 10 (b) shows the results of the third stage. After excluding the external EVs and REs influences, GBEE still maintains a

pattern of "greater in the east than in the central and greater in the west", but the regional gap has widened. The efficiency in the East outperforms than the national average, while that in the Center and West has decreased. From 2011 to 2018, there is a slight decrease in the national average GBEE, indicating that there is still significant room for improvement in GBEE.

In order to verify the robustness of the eco-efficiency measurement results of green buildings based on the three-stage super-efficiency SBM-DEA model under different conditions, sensitivity analysis was conducted. By adjusting the key parameters of the model, the influence of these changes on the eco-efficiency of green buildings was analyzed, so as to evaluate the robustness of the model results. The details are shown in Table III.

In Table III, the eco-efficiency measurement results of green buildings show good robustness under different conditions. When the weight adjustment of input-output index is ±10%, the mean eco-efficiency of eastern, central and western regions decreases by 0.008, 0.006 and 0.008 respectively, and the mean eco-efficiency of the whole country decreases by 0.005. This indicates that weight adjustment has a certain impact on the measurement results of eco-efficiency, but the overall change range is small, indicating that the model is less sensitive to weight. When the adjustment amplitude of the influence of external environmental variables is ±15%, the mean eco-efficiency of eastern, central and western regions increases by 0.008, 0.008 and 0.008 respectively, and the national mean eco-efficiency increases by 0.008. This indicates that external environmental variables have a significant impact on the eco-efficiency measurement results, but the adjusted results still maintain the original regional difference pattern, that is, "East > central > west". When the random error adjustment amplitude is ±20%, the mean eco-efficiency in eastern, central and western regions decreases by 0.004, 0.004 and 0.004 respectively, and the national mean eco-efficiency decreases by 0.003. The adjustment of random error has relatively little effect on the eco-efficiency measurement results, which further verifies the robustness of the model results.

TABLE III. SENSITIVITY ANALYSIS RESULT

Parameter adjustment type	Adjustment range	Average ecological efficiency in eastern China	Average ecological efficiency in central region	Average ecological efficiency in western China	Average national ecological efficiency
Reference model	/	0.884	0.704	0.578	0.723
Input-output index weight adjustment	±10%	0.876	0.698	0.570	0.718
External environment variables affect adjustment	±15%	0.892	0.712	0.586	0.731
Random error adjustment	±20%	0.880	0.700	0.574	0.720

V. Optimization Strategy Discussion

The results showed that the eco-efficiency of green buildings in China showed obvious regional differences during 2011-2018, with the highest efficiency in the eastern region, followed by the central region and the lowest in the western region. The formation of regional differences is closely related to various factors such as economic development level, technological input, policy support and resource endowment. Therefore, according to the characteristics of different regions, the following optimization strategies are proposed in order to narrow the regional gap and improve the overall ecological efficiency of green buildings in the country. For the eastern region, although its green building ecological efficiency is at a high level, there is still room for further improvement. The eastern region has a relatively high level of economic development and relatively abundant technology and capital, so it should focus on strengthening the innovation and application of green building technology. The eco-efficiency of green buildings in the central region is at a medium level, and its optimization strategy should focus on the combination of technology introduction and talent training. The central region has certain advantages in terms of resources and market, but it is relatively short of technology and talents. Therefore, we should actively introduce advanced green building technology and management experience in the eastern region, and promote the popularization and application of green building technology in the central region through technical cooperation and project demonstration. The eco-efficiency of green buildings in western China is relatively low, and its optimization strategy should focus on solving the problems of weak infrastructure and shortage of funds. The economic development of the western region is relatively backward, and the infrastructure construction is insufficient. We should increase the investment in the construction of green building infrastructure and improve the basic conditions for the development of green building. The government should increase financial support for green building projects in the western region through financial transfer payments and special funds. At the same time, the western region should give full play to its own resource advantages, develop green buildings according to local conditions, increase the application proportion of renewable energy in buildings, and reduce the dependence on traditional energy.

VI. Conclusion

The continuous attention of society to SD has attracted attention to GBS as a key form of sustainable building. To comprehensively evaluate the comprehensive benefits of GBS, the focus is gradually shifting towards their ecological efficiency. In this context, this study constructed a measurement method based on the 3SE-SBM-DEA model, with building resources and energy as inputs and economic and environmental values as outputs, and established the GBEE measurement model. The results showed that from 2011 to 2018, China's GBEE saw overall growth with an average AGR of 4.71%. From 2011 to 2015, there was an M-shaped oscillation, reaching the lowest value of 0.611. After excluding the influence of external EVs and REs, the measuring data of stage three were more reasonable. From 2011 to 2018, China's GBEE showed a decreasing trend, with the highest in the East (0.884), the sequential Center (0.704), and the lowest in the West (0.578). The efficiency in the eastern area was higher than the national average, while the efficiency in the central and western areas has decreased. This study has made progress in GBEE measurement and optimization methods, but there are limitations to the data, uncertainty in model parameter selection, and important factors that have not been considered. Future research should focus on expanding the sample range, improving model parameter selection methods, improving data quality and reliability, and comprehensively considering more factors to promote the development of this field.

Watermelon Rootstock Seedling Detection Based on Improved YOLOv8 Image Segmentation

Qingcang Yu*, Zihao Xu, Yi Zhu
School of Computer Science and Technology, Zhejiang Sci-tech University, Hangzhou 310018, China

***Abstract*—Automated grafting is an important means for modern agriculture to improve production efficiency and graft seedling quality, among which the use of visual systems to quickly segment target rootstock seedlings is the key technology to achieve automated grafting. This study aims to solve the problems of inaccurate image segmentation and slow detection speed in traditional rootstock seedling segmentation algorithms. To address these challenges, this study proposes a lightweight segmentation method based on an improved version of YOLOv8s-seg. The improved YOLOv8-seg introduces FasterNet as the backbone network and designs an RCAAM module to enhance feature extraction ability and lightweight model. The D-C2f module is improved to enhance feature fusion ability, achieving efficient and accurate segmentation of watermelon rootstock seedlings and improving grafting efficiency. This article designs a series of comparative experiments, comparing the improved version of YOLOv8-seg with classic models such as Unet, SOLO v2, Mask R-CNN, Deeplabv3+ on a test set containing watermelon rootstock seedlings, and evaluating the recognition performance and detection effect of the model. The experimental results show that the improved version of YOLOv8-seg outperforms other models in mAP coefficient index and can segment seedlings more accurately. This study provides reliable deep learning-based solution for the development of automatic grafting robots, which can effectively reduce labor costs and improve grafting efficiency, meeting the requirements of automated equipment for inference efficiency and hardware resources.**

Keywords*—Image segmentation; YOLOv8s-seg; lightweight; deep learning

I. Introduction

Grafting of watermelon rootstock seedlings is a key technology widely used in melon cultivation, which can improve the disease resistance, adaptability, and yield of watermelons through grafting, and is highly valued by agricultural producers [1]. In recent years, with the continuous growth of demand in the high-quality watermelon market, watermelon grafting technology has gradually become standardized and scaled up [2]. At present, most grafting operations use traditional manual methods, but manual grafting has problems such as low efficiency and high cost, which restrict the further promotion of grafting technology and the efficient development of the watermelon industry. In addition, due to the precise cutting and combination of the delicate characteristics of the seedlings during the grafting process, the skill requirements for operators are high, and even a slight carelessness may affect the survival rate of grafting. In order to achieve the large-scale and intelligent development of watermelon rootstock seedling grafting, the research and development of efficient and intelligent grafting equipment has become an important direction for promoting the modernization of the watermelon industry [3]. Automated grafting is an important means for modern agriculture to improve production efficiency and graft seedling quality, among which the use of visual systems to quickly segment target rootstock seedlings is one of the key technologies for achieving automated grafting. If the segmentation is not accurate, it will not only reduce the efficiency of grafting, but may also lead to failure, affecting the subsequent growth and survival rate of seedlings [4]. Therefore, utilizing advanced visual systems and image processing techniques for real-time segmentation and localization of target areas can effectively improve the accuracy and consistency of grafting operations, and reduce the cost and risk of manual intervention [5].

However, traditional methods for identifying rootstock leaves have significant limitations in practical applications, making it difficult to meet the precision and reliability requirements of automated grafting. Rootstock leaves usually have miniaturization characteristics. In addition, rootstock leaves are often mixed with surrounding branches, soil, or other plant leaves, and the background texture is complex and varied. In the process of leaf edge segmentation, traditional methods often have jagged and uneven segmentation boundaries, especially when facing diverse shapes or overlapping leaves, their performance is particularly inadequate. When the lighting conditions are uneven, the background is complex, or the leaf targets are small, traditional visual detection models are more prone to false positives and false negatives. These issues not only reduce the accuracy of identifying rootstock leaves, but may also lead to grafting failure or mechanical equipment misoperation, increasing the risks and costs of agricultural production.

Existing segmentation networks such as Unet, SOLO v2, Mask R-CNN, and Deeplab v3+ are simple and highly accurate in seedling segmentation tasks, they have several limitations that make them less suitable for the problem at hand. Specifically, these networks are difficult to perform shallow feature aggregation, resulting in poor segmentation performance on small and low contrast seedling leaves. In addition, their spatial perception ability is relatively weak, making it difficult to accurately depict the edges of overlapping or obscured seedlings. In addition, many of these models have high computational costs, which makes them perform poorly in real-time applications in actual agricultural production

environments. On the other hand, the YOLOv8 algorithm chosen in this article surpasses its predecessors in the YOLO series in terms of recognition accuracy, speed, and real-time performance. Its efficient feature extraction and multi-scale processing capabilities make it particularly suitable for seedling segmentation tasks. However, despite YOLOv8's strong performance on public datasets, there are still certain limitations in handling small object segmentation and complex background interference. To address these challenges, this paper proposes an improved YOLOv8 neural network architecture that enhances feature extraction, fusion mechanisms, and segmentation accuracy, making it more effective in rootstock seedling segmentation. By addressing the limitations of existing methods and leveraging the advantages of YOLOv8, the proposed method ensures high segmentation accuracy and real-time applicability, providing a powerful solution for automatic grafting. In the feature extraction stage, YOLOv8 utilizes its lightweight and powerful object detection capabilities as the backbone network to quickly segment the overall contour of the rootstock. In the feature extraction stage, FasterNet lightweight network is used to maintain high computational efficiency while achieving excellent performance in feature extraction. And integrate the RCAAM module into the backbone to alleviate the problem of high-frequency information loss in deep feature images. The D-C2f module was introduced in the feature fusion stage to enhance the learning ability of morphological features of different watermelon rootstock seedlings. By integrating these improvements, YOLOv8 demonstrates outstanding performance in tasks involving small and complex targets. It achieves higher segmentation accuracy, reduces false positives, and has stronger adaptability to different conditions, consolidating its position as the most advanced model in precision agriculture applications. The experimental results show that the neural network significantly improves the accuracy and real-time performance of rootstock seedling recognition tasks under complex backgrounds and varying lighting conditions. Compared with traditional models, this method exhibits stronger robustness and adaptability in detecting key parts of rootstock seedlings, providing reliable technical support for automated grafting equipment.

At the end of the introduction, the structure of this article is summarized as follows: Section III provides a detailed explanation of the improved YOLOv8 architecture and the modifications made to improve the accuracy of seedling recognition. The Section IV describes the experimental setup, including the dataset used and the evaluation metrics used to assess model performance. The Section V introduces the results and highlights the model proposed in this paper in comparison to other sub models. Finally, the Section VI summarizes the potential application exploration and future research directions of this model in real automatic grafting robots. This structure aims to guide readers through research and provide a clear understanding.

II. Related Work

Historically, grafting operations mainly relied on manual labor, which was not only time-consuming and labor-intensive, but also easily limited by workers' experience and technical level. In the process of leaf edge segmentation, traditional methods often have jagged and uneven segmentation boundaries, especially when facing diverse shapes or overlapping leaves, their performance is particularly inadequate [6]. When the lighting conditions are uneven, the background is complex, or the leaf targets are small, traditional visual detection models are more prone to false positives and false negatives [7]. Scholars have conducted in-depth research on the grafting process using advanced visual algorithms. In 2013, He et al. [8] proposed a method based on machine vision using ellipse fitting to restore seedling leaf surfaces and extract parameters for robot automatic grafting in order to improve the automation level of fruit and vegetable grafting robots. In 2015, Zhang et al. [9] proposed a comprehensive image processing algorithm to extract feature information of grafting seedlings for relevant vegetable grafting robots. The rapid target recognition technology achieved through visual systems can not only significantly improve grafting efficiency, but also reduce labor costs and intensity, while improving the quality and consistency of grafted seedlings. It is an important direction for promoting the intelligent and precise development of modern agriculture.

With the development of deep learning and computer vision technology, image-based seedling recognition methods have been widely studied and applied. Zuo et al. [10] proposed a crop seedling plant segmentation network model that integrates semantic and edge information of the target region in order to accurately segment crop seedlings in natural environments and achieve automatic measurement of seedling position and phenotype. The experimental results show that under the same network training parameters, the average cross merge rate and average recall rate obtained by testing the method proposed in this paper are 58.13% and 64.72%, respectively, which are better than the segmentation results corresponding to manually labeled samples; In addition, after adding 10% of outdoor seedling images to the training samples, the average pixel accuracy of this method on the outdoor test set can reach 90.54%, demonstrating good generalization ability. Image processing technology can be used for high-throughput collection and analysis of crop population phenotypes, which is of great significance for crop growth monitoring, seedling condition assessment, and cultivation management. However, existing methods rely on empirical segmentation thresholds, resulting in insufficient accuracy in extracting phenotypes. Li et al. [11] proposed a method for extracting phenotypes from aerial images of maize seedlings, using maize as an example. Explored an end-to-end segmentation network called PlantU-net, which uses a small amount of training data to achieve automatic segmentation of overhead images of maize seedling populations. Automatically extract morphological and color related phenotypes, including maize stem coverage, external radius, aspect ratio, and plant orientation plane angle. Ma et al. [12] proposed a method for processing greenhouse vegetable leaf disease symptom images in order to achieve robust segmentation, as uneven lighting and cluttered backgrounds are the most challenging problems in disease symptom image segmentation. The results show that the overall accuracy of the proposed method is 90.67%, indicating that the method can obtain robust segmentation of disease symptom images.

III. IMPROVED YOLOV8 MODEL

A. YOLO v8

The YOLO network has undergone various improvements to address the challenges brought by early versions, aiming to enhance its adaptability to specific tasks while maintaining a balance between detection speed and accuracy. The improved version YOLOv8-Seg adopts a modular design, including three main components: backbone, neck, and head. The backbone extracts basic features from the input image, the neck processes and integrates these features at multiple scales, and the head generates the final prediction, including object classification, bounding box coordinates, and segmentation masks.

The high accuracy of the YOLOv8 model is attributed to the replacement of the C3 module with the C2f module in the YOLOv5 backbone network and neck network. The C2f module first goes through a Conv, uses the chunk function to evenly split the out into two vectors, and then saves them to a list. The latter half is input into a Bottleneck Block, which contains n Bottlenecks. Each Bottleneck output is appended to the list. In the YOLOv8 model, the head part of the prediction head has undergone significant changes compared to the YOLOv5 model. It has been replaced from an anchor box based object detection algorithm to an anchor box free object detection algorithm, which has the advantages of fast convergence and improved regression performance. The decoupling head structure is adopted to separate the regression branch from the prediction branch, and the integral form representation method proposed in the Distribution Focal Loss strategy is used for the regression branch. The coordinates are transformed from a deterministic single value prediction to a distribution. Compared to using coupling heads, decoupling heads can effectively reduce the computational complexity of model segmentation of rootstock seedlings, which not only accelerates processing speed but also enhances the generalization ability and robustness of rootstock seedling recognition.

B. Improved YOLOv8 Model

In the process of rootstock seedling segmentation, the traditional method often appears jagged and unsmooth segmentation boundary, especially in the face of morphological diversification or leaf overlap, uneven lighting conditions, complex backgrounds, or small leaf targets, this paper proposes an improved YOLOv8 neural network architecture, which can be used to improve the performance of the neural network, for efficient and accurate segmentation of cotyledon parts of rootstock seedlings, the structure is shown in Fig. 1. In the feature extraction stage, YOLOv8 utilizes its lightweight and powerful target detection ability as the backbone network to quickly identify the overall contour of the rootstock. However, YOLOv8 has some limitations in the extraction of detailed features. To make up for this deficiency, the advanced feature extraction ability of FasterNet is integrated to capture finer features through deep convolution, especially in the localization of small target sites. At the same time, the RCAAM module is designed to non-uniformly weight the key features in the spatial and channel dimensions to highlight the useful information and suppress the interference of background noise. Combined with the task-aware classification and positioning module, the recognition accuracy and location accuracy of rootstock seedlings are further improved. In addition, the D-C2F module was improved to achieve effective fusion of multi-scale features through dynamic convolution, highlighting high-resolution features of key parts of rootstocks from coarse to fine, and improving the efficiency of rootstock management, it is used to improve the learning ability of different morphological rootstock seedling characteristics, and the deformable modeling is used to adapt to the target morphological change characteristics.

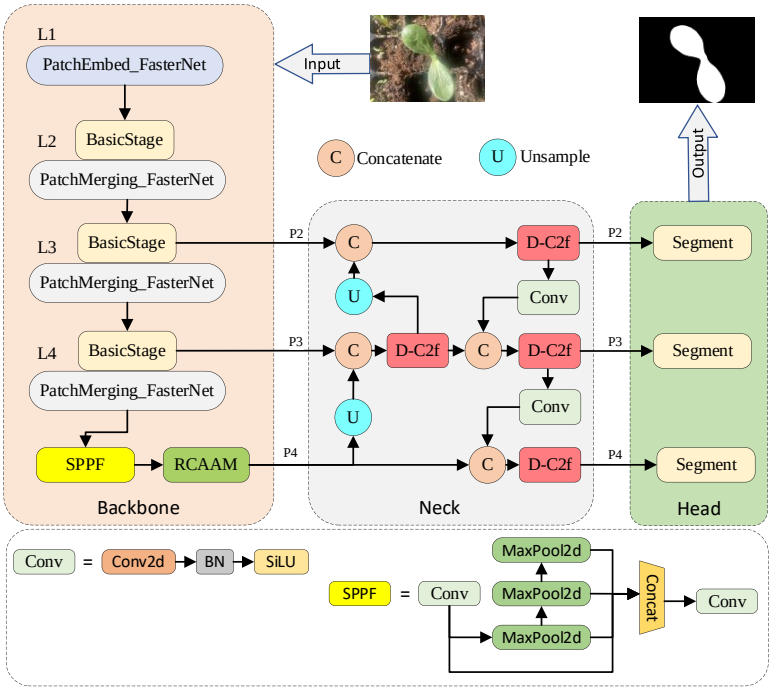

Fig. 1. Architecture of improved YOLOv8.

1) Based on FasterNet feature extraction: YOLOv8 uses DarkNet-53 as the backbone network, and its architecture consists of a series of convolutional layers and residual modules. Although DarkNet-53 performs well in general object detection tasks, it faces certain limitations in rootstock seedling segmentation, such as excessive redundant information, which limits training and inference speed, and insufficient segmentation performance for small target leaves and complex backgrounds. In addition, traditional backbone networks have certain bottlenecks in multi-scale information processing, making it difficult to effectively capture the global and local features of rootstock leaves. To address the aforementioned issues, CHEN et al. [13] proposed an efficient neural network called FasterNet, whose structure is shown in Fig. 2. Partial Convolution (PConv) is introduced in the article, which reduces redundant calculations and memory access by focusing on the features of specific regions, while significantly improving the efficiency of multi-scale feature extraction. This improvement enables FasterNet to achieve efficient model deployment on edge devices, while enhancing its ability to recognize small targets in complex scenes. In the task of rootstock seedling segmentation, combining FasterNet with YOLOv8 can effectively compensate for the shortcomings of DarkNet-53 in detail processing and feature extraction, providing new technical support for precise segmentation of rootstock leaves in complex agricultural scenes.

PConv only applies regular convolution to known regions in the input feature map, keeping other parts unchanged. The floating-point operands (FLOPs) of regular convolution and DWConv can be represented as:

$$F_{SC} = h \times w \times k^2 \times c^2 \tag{1}$$

$$F_{DWC} = h \times w \times k^2 \times c \tag{2}$$

In practical applications, PConv usually selects the first or last consecutive c_p channel, and requires that the input and output feature maps have the same channel. Therefore, the FLOPs of a PConv can be expressed as:

$$F_{PC} = h \times w \times c_p^2 \times k^2 \tag{3}$$

In the formula, cp=c/4, then the FLOPs of PConv are only 1/16 of those of regular convolution.

Its memory efficiency is significantly improved because PConv reduces memory access and data transmission by treating specific channels as representatives of the entire feature map, thereby accelerating computation speed without sacrificing accuracy. This paper replaces the backbone network of YOLOv8 with FasterNet to reduce redundancy and improve the overall computing speed, thus promoting efficient edge computing applications.

2) Residual channel adaptive attention module (RCAAM): To alleviate the problem of high-frequency information loss caused by the decrease in the number of convolutional channels in each layer, Wang et al. [14] proposed an adaptive attention module (AAM) to improve object detection in multi-scale scenes. Although this module improves the ability of feature extraction by adjusting the weight allocation of multi-scale features through adaptive average pooling, its operations mainly focus on low dimensional operations, resulting in an increase in shallow information redundancy and interference phenomena in feature images.

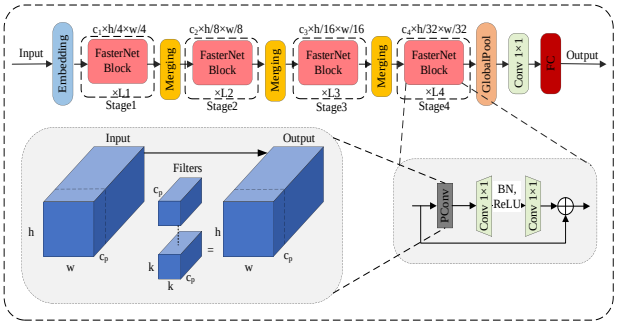

Fig. 2. Architecture of FasterNet.

To this end, this article has redesigned the AAM module and combined it with the residual channel attention network (RCAN) proposed by Zhang et al. [15], introducing super-resolution technology to enhance the detail representation and clarity of feature images. The core module in RCAN, residual group (RG), enriches feature encoding information through pixel addition strategy and enhances channel perception weights to recover more high-frequency information from the bottom layer, as shown in Fig. 3.

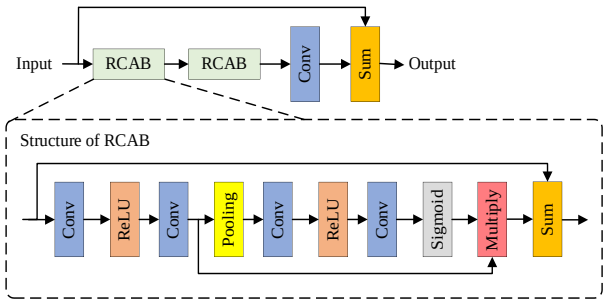

Fig. 3. Architecture of residual group.

This article proposes a new residual channel adaptive attention module (RCAAM) based on residual groups. RCAAM generates multiple sets of high-resolution feature maps in low resolution feature map reconstruction, which not only reduces redundant computation but also significantly restores shallow feature information of occluded targets.

In addition, this article introduces ECA module in RCAAM, which enhances contextual information correlation by weighted fusion of feature maps, thus more accurately segmenting rootstock seedlings in complex backgrounds. This article also compared multiple attention mechanisms, and the Seg loss function of the YOLOv8 model is shown in Fig. 4, with the model incorporating the ECA module performing the best in terms of loss function. The structure of the RCAAM module is shown in Fig. 5.

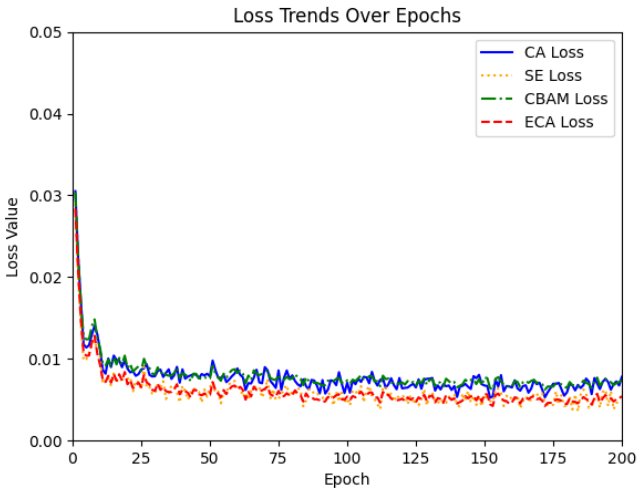

Fig. 4. Seg loss function curves for different attention mechanisms.

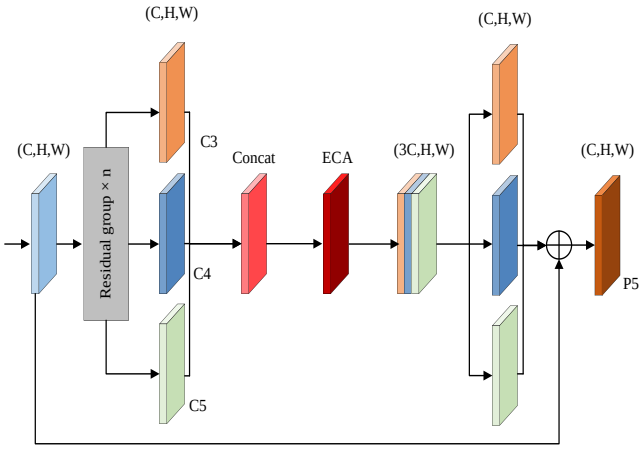

Fig. 5. The structure of the RCAAM module.

3) D-C2f Module: During the growth process of rootstock seedlings, their leaf shapes exhibit a high degree of diversity and are often accompanied by overlapping phenomena. In addition, due to the fact that rootstock seedlings usually grow in a plug environment, there are a large number of ridges and soil in the background, which further increases the difficulty of segmentation and recognition. Traditional standard convolutional neural networks (CNNs) use fixed convolution kernels for feature learning, which makes it difficult to fully capture the diverse morphological features of rootstock leaves, especially in cases of leaf overlap and blurred boundaries, leading to inaccurate feature extraction, false positives, and missed detections.

To address the above issues, this paper introduces deformable convolution (DConv) to enhance the model's ability to learn diverse rootstock leaf features. DConv adaptively adjusts the size and sampling position of the convolution kernel through deformable modeling, in order to better adapt to the changing characteristics of the target shape. Its structure is shown in Fig. 6.

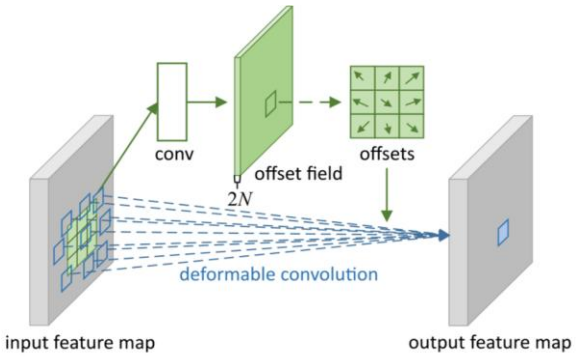

Fig. 6. The structure of the DConv module.

Specifically, DConv introduces offset in the convolutional receptive field and dynamically adjusts the position of each convolution kernel. For example, for a 3x3 convolution kernel, the regular sampling grid can be expanded by the offset, as shown:

$$R = \{\Delta p_n \mid n = 1,2,\cdots,n\} \tag{4}$$

By combining modulation variables, the model can automatically learn the offset and weight of each sampling point, enabling the sampling points to fit the target shape more accurately. For any position p, the output mapping Y is expressed as:

$$Y_{(p)} = \sum_{k=1}^{K} \omega_k \cdot x(p_k + \Delta p_k) \cdot \Delta m_k \tag{5}$$

Among them, ω_k and Δm_k respectively represent the weight and modulation variable of the kth position. Due to the fact that the offset Δp_k is usually in fractional form, bilinear interpolation is used for calculation, as shown in Eq. (6) to Eq. (8).

$$g(q_y, p_y) = \max(0, 1 - |a - b|) \tag{6}$$

$$G(q, p) = g(q_x, p_x) \cdot g(q_y, p_y) \tag{7}$$

$$X(p) = \sum_{q} G(q, p) \cdot g(q_y, p_y) \tag{8}$$

The application of DConv can dynamically adjust the sampling position and convolution kernel size according to the specific morphology of rootstock leaves. Firstly, by preprocessing the input feature map, offset and modulation variables are generated to calculate the offset direction of pixel points and obtain irregularly distributed sampling points. Subsequently, these sampling points are used to resample the feature map and combined with the convolution kernel to calculate the final convolution result.

To further improve the performance of the model, this paper redesigns the D-C2f module based on DConv convolution, as shown in Fig. 7. The D-C2f module can adaptively adjust the size and sampling position of the

convolution kernel based on the local features of the rootstock leaves by introducing learnable deformation parameters and offset weights. Compared with traditional methods, this module provides a larger receptive field range in the output features, greatly improving the model's ability to extract rootstock leaf features and model overlapping leaf spatial distribution in plug scenes, thereby effectively improving the segmentation and recognition performance of rootstock seedlings.

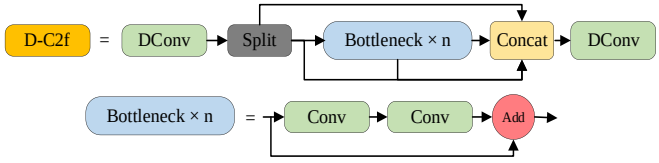

Fig. 7. The structure of the D-C2f module.

IV. Experiments And Analysis

A. Model Training and Testing Trials

1) Experimental data: The rootstock seedling task dataset of this study consists of images of watermelon seedlings in the cotyledon stage, constructed in two stages to ensure data diversity and representativeness. The first stage data was obtained from actual shooting at the seedling center, which captured 400 high-resolution images of watermelon seedlings. In the second stage, in order to unify and adapt the model training requirements, all images were preprocessed, cropped, and adjusted to a resolution of 640 × 640, while maintaining a 24 bit RGB format. After data augmentation and filtering, a total of 1600 images were generated, of which 1350 were divided into training and validation sets and randomly segmented in a 9:1 ratio. The remaining 250 images were used as the test set for independent evaluation of model performance, and the test set did not participate in model training. The dataset was annotated using the LabelMe tool and further converted to VOC dataset format. This dataset not only reflects the diversity of rootstock seedling characteristics, but also takes into account the plug scenes in real grafting environments, providing a solid foundation for training and evaluating segmentation and recognition models.

2) Comparison of segmentation network models: This study compared the performance of YOLOv8, Unet, SOLO v2, Mask R-CNN, and Deeplab V3+. Among them, SOLO v2 and Mask R-CNN belong to instance segmentation algorithms, while improved YOLOv8, Unet, and Deeplab v3+ belong to semantic segmentation models.

a) Unet: The Unet network structure is characterized by its clear U-shaped architecture, with symmetric encoders on the left and decoders on the right, which can effectively enhance the ability to extract feature map information. Unet has a low dependence on the number of images and only requires a small number of images to complete end-to-end training, making it very suitable for medical image segmentation. However, due to its relatively simple design, it is prone to inaccurate segmentation when dealing with complex backgrounds and small target tasks.

b) Mask R-CNN: Mask R-CNN is based on Faster R-CNN and is used to predict instance segmentation masks by adding a mask branch that runs in parallel with the classification and bounding box regression branches [16]. This method adopts a top-down detection approach, first detecting the regions of each instance, and then segmenting the instance masks within these regions. Detection based methods typically have high accuracy, but rely on precise bounding box detection, which places high demands on computational resources.

c) SOLO v2: Unlike Mask R-CNN, SOLO v2 transforms segmentation tasks into pixel classification problems, thereby eliminating the step of proposal generation [17]. The network consists of two branches: a category prediction branch for predicting the semantic category of the target, and a masking branch for predicting the instance mask of the target. This method reduces computational complexity and can improve the efficiency of instance segmentation to some extent, but its performance may be affected for scenes with complex backgrounds or overlapping targets.

d) Deeplab v3+: As the latest generation model in the Deeplab series, Deeplab v3+ adopts Deeplab v3 in its encoding structure and introduces a decoder to solve the problem of losing detailed information caused by directly upsampling feature maps in Deeplab v3, thus achieving higher performance in semantic segmentation tasks [18]. Deeplab v3+ has strong ability to recover detailed information, but it may still face certain challenges when dealing with small target tasks with complex backgrounds.

3) Testing trial setup: The hardware configuration is Intel i5-12490K CPU and Nvidia GeForce RTX 4060ti GPU. The experimental method of this paper is developed and implemented in Python 3.8 environment based on the deep learning framework PyTorch 2.2.2, using CUDA 12.4 for GPU acceleration. In the model training phase, the SGD optimizer is used to optimize the performance of the model, and the transfer learning strategy is used to initialize the model by loading the pre-trained model weight"yolov8s.pt" to accelerate the convergence speed of the model. The model training parameters in this paper are shown in Table I.

TABLE I. Experimental Model Parameters

Parameter Name	Value
Batch size	16
Epoch	200
Learning rate	0.01
Momentum factor	0.937
Image size	640 dpi×640 dpi

4) Evaluation metrics: In order to evaluate the segmentation performance of the improved YOLOv8 and the contrast model, this study uses the mean average Precision (mAP) as the main evaluation index, and combines Precision

and Recall to comprehensively analyze the performance of the model. Map is a commonly used metric in detection and segmentation tasks. Its calculation is based on the matching of the predicted results and the real labels, which can comprehensively measure the performance of the model in detection accuracy and coverage. See Eq. (9) and Eq. (10) for calculations of Precision and Recall.

$$P = \frac{TP}{TP + FP} \tag{9}$$

$$R = \frac{TP}{TP + FN} \tag{10}$$

In a single image, the calculation of mAP involves multiple target categories or instances. Firstly, calculate the accuracy and recall curves for each category: for a certain category, sort the model's predictions for that category in descending order of confidence, and gradually calculate the accuracy and recall at different thresholds. Secondly, calculate the average precision (AP): By integrating the precision and recall curves, obtain the AP value for that category. The higher the AP value, the stronger the detection ability of the model in that category. The AP formula is as follows:

$$AP = \int_0^1 P(R)dR \tag{11}$$

Finally, calculate the average precision mean (mAP) for all categories: take the average of the AP values for all categories, which is mAP, using the following formula:

$$mAP = \frac{1}{N}\sum_{i=1}^{N} AP_i \tag{12}$$

where, N is the number of categories, and AP_i is the average accuracy of the i-th category.

In the segmentation task, the mAP calculation is usually based on the Intersection over Union (IoU) threshold setting. For example, when the threshold of IoU is set to 0.5, the ratio of the overlapping area representing the predicted result and the real label region to the joint area needs to be greater than 50% to be considered a correct detection. mAP@0.5 is a commonly used evaluation metric, in addition, the mAP can also be calculated at a higher IoU threshold to examine the sensitivity of the model to the target boundary.

5) Analysis of model training: In the training process of rootstock seedling segmentation algorithm, loss function plays an important role in evaluating the performance of the model. The smaller the loss value, the better the performance of the model and the more significant the optimization effect. As shown in Fig. 8, the training process of the improved algorithm generates a loss function curve, which intuitively reflects the obvious downward trend of the loss value with the number of iterations, indicating that the model performance is continuously optimized.

Among them, the decrease of box loss is the most significant, which reflects the improvement of target positioning accuracy. After approximately 75 training rounds, the Obj loss and seg loss tended to stabilize.

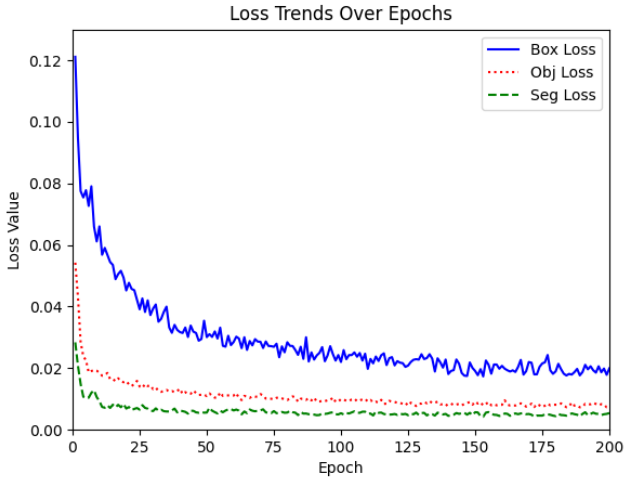

Fig. 8. Curve of model loss function.

The training process of YOLOv8 network before and after improvement is shown in Fig. 9. During the training process, the mAP of the model went through three stages: within the initial 25 training rounds, the mAP value rose rapidly, indicating that the model was in a rapid fitting stage; subsequently, between the 25th and 75th training rounds, the mAP value increased rapidly, indicating that the model was in a rapid fitting stage, the mAP value fluctuated greatly; from the 75 th to 200 th training round, the mAP curve tended to be stable and convergent with the change of learning rate gradually decreasing. With the increase of training times, the mAP value gradually converges, indicating that the model tends to be stable after further training.

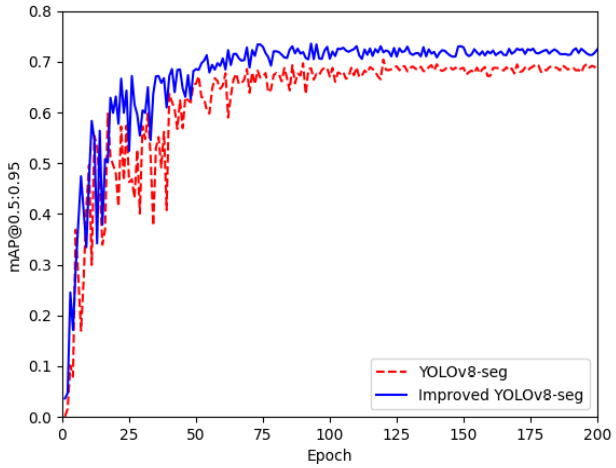

Fig. 9. Comparison of mAP curve changes with epoch variation.

B. Experimental Results

1) Ablation experiment: The purpose of ablation experiments is to explore the specific impact on model performance when certain parts of the network are removed or

modified. This article takes YOLOv8 as the baseline model, improves it in three aspects, designs an improved YOLOv8 model, and conducts five ablation experiments on the improved model. Among them, Improved Model 1 represents replacing the original backbone network with a FasterNet network, Improved Model 2 represents replacing the C2f module in the neck with a D-C2f module, and Improved Model 3 represents introducing the RCAAM module into the backbone network. The detailed experimental results are shown in TABLE II. I.

TABLE II. PERFORMANCE COMPARISON OF EACH IMPROVED MODEL

Model	FasterNet	D-C2f	RCAAM	P/%	R/%	mAP@0.5/%	Parameters/10^6	FLOPs/10^9
YOLOv8s	-	-	-	91.2	90.3	92.7	11.1	28.8
Improved model 1	√	-	-	91.4	93.6	95.3	6.0	11.8
Improved model 2	-	√	-	86.4	92.0	95.7	10.3	25.6
Improved model 3	-	-	√	95.6	91.2	94.4	7.8	21.8
Improved YOLOv8	√	√	√	95.4	95.0	96.6	3.2	10.6

According to the results in Table II, Improved Model 1 replaces the backbone network with a lightweight Faster Net network, mAP@0.5 Value increased by 2.6%, parameter and computation reduced by 5.1M and 17G. Indicating that lightweight FasterNet networks can reduce redundant information, optimize model parameter count and computational complexity, and improve detection speed. The FasterNet network adopts PConv to better extract multi-scale information of rootstock seedlings and cotyledons, improve detection ability and compress model volume, enhance the network's feature extraction ability, and reduce parameter counting.

Improved model 2 replaces the C2f module on the neck with a lighter D-C2f module, reducing the parameter and computational complexity by 0.8M and 3.2G compared to the baseline model, mAP@0.5. The value has increased by 3%. The D-C2f module can adaptively adjust the size and sampling position of the convolution kernel based on the local features of the rootstock leaves by introducing learnable deformation parameters and offset weights. This provides a larger receptive field range in the output features, effectively improving the segmentation and recognition performance of rootstock seedlings. Better save computational costs and improve training speed.

Improved model 3 then introduced the RCAAM module into the original backbone network, mAP@0.5 Compared to the baseline model, the value increased by 1.7%, while the parameter and computational complexity decreased by 3.3M and 7G, respectively. Compared with traditional pooling methods, RCAAM not only improves feature extraction efficiency, enhances contextual information correlation, but also suppresses useless information interference, thus more accurately segmenting rootstock leaves.

Finally, three modules were added simultaneously, namely the improved YOLOv8 algorithm proposed in this article, which increased mAP values by 3.9%, reduced parameter and computational complexity to only 28.8% and 36.8% of the baseline model, and achieved a recall rate of 95.0%. The ablation experiment results have verified the rationality and superiority of the algorithm proposed in this paper in terms of detection accuracy, speed, and lightweight.

2) Comparison of evaluation metrics between improved YOLOv8 and other models: In order to evaluate the performance of the improved YOLOv8 model in rootstock seedling segmentation, this study compared and analyzed the segmentation abilities of different models in the test set, focusing on their performance in handling significantly different backgrounds and complex low contrast scenes. To evaluate in detail the segmentation performance of the improved rootstock seedling recognition model, this study used mAP@0.5 Compare its performance with Unet, SOLO v2, Mask R-CNN, and Deeplab v3+ on the test set. The test set consists of 250 images, including two distinct types of seedlings, providing a diverse basis for performance evaluation. The results of evaluation metrics comparison are shown in TABLE III. .

TABLE III. COMPARISON BETWEEN MAINSTREAM SEGMENT ALGORITHMS AND THE PROPOSED METHOD

Model	P/%	R/%	mAP@0.5/%	Parameters/10^6	FLOPs/10^9
Mask-RCNN	87.3	88.4	92.3	44	44.7
SOLO v2	89.5	92.7	93.9	37.2	41
Deeplab v3+	84.8	85.0	88.9	41.2	12.6
Unet	91.3	93.3	94.7	31	8.3
Improved YOLOv8	95.4	95.0	96.6	3.2	10.6

The research results indicate that Mask R-CNN and Deeplab v3+ mAP@0.5 The indicators are significantly lower than the improved YOLOv8 model and Unet. This low performance reflects that these two models have difficulty accurately segmenting small seedlings under testing conditions. In contrast, improving the recognition model of rootstock seedlings mAP@0.5 The value is slightly higher than Unet, indicating its optimal performance among the four models. Specifically, the improved YOLOv8 model mAP@0.5 It reached 96.6%, indicating its significant advantage in the accuracy of rootstock seedling image segmentation and detection.

These results highlight the effectiveness of the improved model in segmenting rootstock seedlings and cotyledons under complex environmental conditions, and its stability and

robustness make it have important application potential in grafting management and production processes.

When segmenting rootstock seedling images with significant contrast between background and rootstock seedling cotyledons, the improved YOLOv8 model was compared with four other models (Unet, SOLO v2, Mask R-CNN, Deeplab v3+), and the results are shown in Fig. 10. The results indicate that Deeplab v3+ is relatively less effective than other models in segmenting small or edge blurred leaves. The segmentation performance of SOLO v2 and Mask R-CNN is superior to Deeplab v3+, but the computational cost is high and the performance is still insufficient when detecting small leaves or low contrast targets, which can easily miss some key leaf regions. The Unet model may encounter problems of over segmentation or under segmentation when segmenting overlapping or blurred boundary rootstock leaves, especially for leaves with complex shapes. The improved YOLOv8 model performs well in rootstock seedling segmentation tasks. Compared with other models, the improved YOLOv8 effectively enhances segmentation performance through stronger feature extraction ability and optimized feature fusion mechanism, and has excellent robustness and adaptability. The comparative experimental results show that the improved YOLOv8 model is suitable for precise segmentation of rootstock seedlings in complex environments, providing efficient and reliable technical support for automatic grafting in smart agriculture.

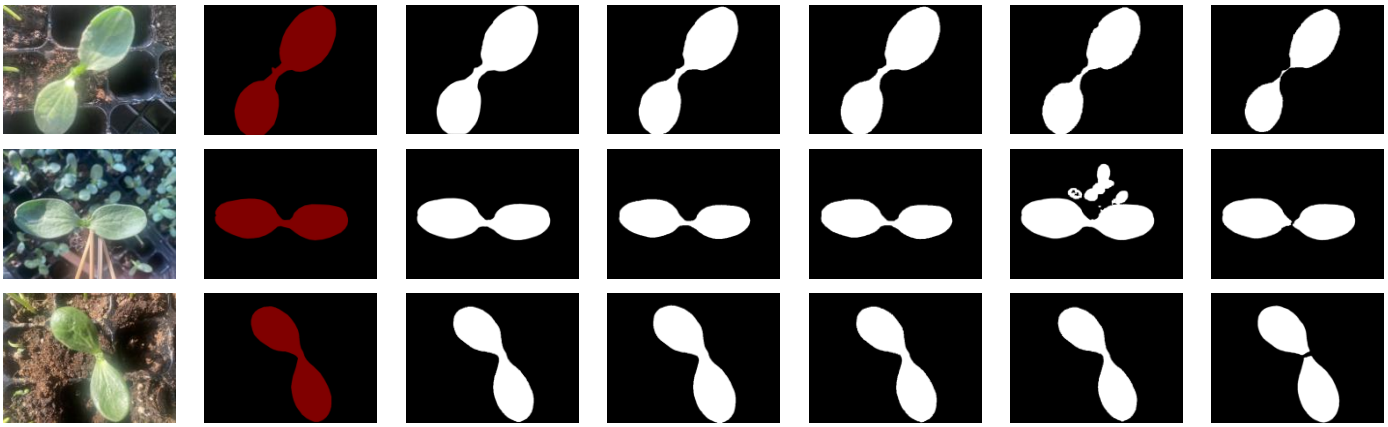

Fig. 10. Comparison of mAP curve changes with epoch variation.

V. Discussion

The improved YOLOv8 rootstock seedling recognition model outperforms the original YOLOv8 model in terms of recognition performance. In practical complex environments, the original model performs poorly in situations where lighting is uneven or the background is similar to the characteristics of rootstock seedlings, leading to inaccurate segmentation. The improved model can accurately segment rootstock seedlings with higher recognition rate, especially in complex environments, demonstrating stronger adaptability. At the same time, it effectively solves the problem of low accuracy in detecting small or distant rootstock seedlings in the original model.

This performance improvement does not come from the improvement of a single method, but from the comprehensive enhancement of feature extraction and feature fusion capabilities. By improving the network structure, optimizing the feature processing flow, and introducing more advanced feature fusion strategies, the robustness and segmentation accuracy of the model in complex environments have been significantly improved, better adapting to diverse hardware deployment requirements, providing more efficient and intelligent support for modern agricultural production, and promoting the implementation of precision agriculture. In order to ensure the efficient application of the rootstock seedling recognition system in practical agricultural production, it is possible to consider removing unimportant connections or neurons from the model in the future. Pruning technology can significantly reduce the size and inference time of the model while maintaining its recognition accuracy. This method is particularly suitable for devices with limited computing resources, making the rootstock seedling recognition system more efficient and meeting the real-time detection needs of resource constrained platforms. In large-scale plug seedling grafting, the segmentation model of the pruned rootstock seedlings can achieve real-time detection on unmanned aerial vehicles or vehicle platforms, improving the efficiency and accuracy of grafting.

VI. Conclusion

In order to solve the problems of inaccurate edge segmentation and low detection efficiency of traditional detection algorithms, this paper proposes a rootstock seedling detection method based on improved YOLOv8. By suppressing invalid features in high-order and low-order feature fusion and enhancing the ability of the model to extract rootstock seedling features, this method can effectively realize the recognition of narrow and small seedlings and large seedlings.

In this paper, mAP@0.5 is used as the evaluation index to compare the performance of the improved YOLOv8 and the basic UNET model in the segmentation of watermelon rootstock seedlings. The results show that the improved method is superior to the basic UNET algorithm in both quantitative and qualitative evaluation. In the aspect of model performance, the model parameters and FLOPs were used as evaluation criteria. Although the improved YOLOv8 outperforms Unet in recognition performance, its FLOPs are

2.3 g higher than Unet, showing a good balance between performance and recognition accuracy. Compared with the other three classical segmentation networks, the results show that the MAP@0.5 score of the improved YOLOv8 is 0.8403, which is better than the classical models such as SOLO v2, Mask R-CNN and Deeplab v3+. Compared with other models, the improved YOLOv8 model has the highest performance in identifying rootstock seedlings, and can accurately extract the characteristic information of seedlings.

The improved model has important application potential in watermelon rootstock grafting. Its ability to accurately segment the characteristics of small and irregular watermelon rootstock seedlings provides an important guarantee for improving the efficiency and accuracy of agricultural production. By integrating the improved model into the automatic grafting robot, the time and labor cost required for traditional manual grafting can be significantly reduced.

Although the improved YOLOv8 model performs well, there are still areas that need improvement in the future. Firstly, reducing computational complexity while maintaining high detection accuracy remains the main research direction. In future research, optimizing the model structure or using a more lightweight network architecture can be considered. Secondly, the actual agricultural production environment is more complex, with different lighting conditions, different seedling growth conditions, and different seedling varieties. Future work should improve the robustness of models in different environments. In addition, combining this model with edge computing equipment can enhance its practical applicability in precision agriculture.

***Abstract*—This research focuses on a literature study on developing a Mini Smart Camera (MSC) system that utilizes Internet of Things (IoT) technology to help people with disabilities interact with their environment. The MSC serves as an assistive device, which integrates object recognition and speech recognition technologies along with an internet-based two-way communication system. Utilizing state-of-the-art hardware and software, the system captures images, processes audio, and transmits data via Real Time Streaming Protocol (RTSP) and Message Queuing Telemetry Transport (MQTT). These protocols serve different purposes: managing data transmission and enabling communication between machines. The MSC is equipped with a 5 MP camera, 2.5 GHz Quad-Core processor, and 4G connectivity, and is connected to a high-performance Ubuntu 22.04 Linux cloud server. The use of OpenCV libraries and machine learning algorithms ensures fast and precise image analysis. By integrating machine learning and natural language processing (NLP), MSC efficiently handles both visual and audio inputs. Key features, including text-to-speech (TTS) and speech-to-text (STT), provide an interactive and adaptive communication interface. The system is designed to improve accessibility and encourage greater independence for people with disabilities in daily activities. The development of multispectral cameras for disabilities will provide a more detailed analysis for the detection of surrounding objects.**

***Keywords*—Internet of Things; mini smart camera; object recognition; speech recognition; assistive technology**

I. Introduction

The global population is witnessing an increasing focus on improving accessibility for individuals with disabilities, driven by both technological advancements and a growing awareness of inclusivity. According to the World Health Organization (WHO), over one billion people globally live with some form of disability, many of whom face challenges in accessing information and engaging with their surroundings. These challenges are particularly significant for individuals with sensory impairments, such as visual, auditory, or speech disabilities [1]. Mini Smart Camera (MSC) system addresses these challenges by integrating Internet of Things (IoT) technologies with machine learning algorithms to provide real-time information and communication tools. The proposed system uses object recognition, speech recognition, and conversion technologies like text-to-speech (TTS) and speech-to-text (STT), which enable individuals to interact with their environment more efficiently. Prior studies have shown that IoT devices can significantly enhance the quality of life for individuals with disabilities by improving environmental interaction [2], [3]. IoT technology allows the MSC system to perform complex tasks such as real-time object recognition and audio processing, which are essential for individuals with disabilities to navigate their environments independently. This paper aims to present the design, implementation, and evaluation of the MSC system, focusing on its potential to empower individuals with disabilities by improving accessibility and independence. In the system that has been made to help people with disabilities, there are still many shortcomings, from models, prototypes, and improper placement of prototypes. In this research, it is discussed comprehensively starting from the placement of the prototype, the size of the prototype, namely the Mini Smart Camera (MSC) used for disabilities so that there is comfort in using it, supported by IoT and Artificial Intelligence technology that can perfect this system and provide novelty.

Moreover, disability monitoring needs to be improved with a complete range of components, including a Global Positioning System (GPS) to monitor the patient's position in addition to detecting other vital parts such as heart rate. This research provides a detailed overview of the IoT system to be built. IoT and AI are key components in building this system, but not all AI components are discussed in this research, but the main contribution lies in IoT design and this design can provide specific results for people with disabilities.

For this reason, this research is presented starting from how this system should be built for people with disabilities, namely building an IoT architecture starting from a literature study on IoT and IoT architecture specifically for disabilities and improvements, for example on Hyperspectral and Multispectral Cameras in the future, in this research seen from the review mode how the use of thermal cameras to help people with disabilities which can then be improved in more detail and comprehensively.

II. Literature Review

A. Internet of Things in Assistive Technology

The integration of IoT in assistive technology has seen significant growth in recent years, supported by numerous studies that highlight its potential to assist individuals with disabilities. IoT-enabled devices offer continuous monitoring, real-time data exchange [21, 22, 23], and remote management,

making them highly adaptable to various user needs. Andriana, et al. [4] emphasized that IoT can transform assistive technologies by enabling real-time data processing, allowing users to receive context-specific support when needed.

The ability of IoT to connect multiple devices and sensors into a cohesive network has positioned it as an ideal choice for assistive systems [5]. Wearable IoT devices, for instance, can monitor physiological data for individuals with mobility limitations or provide real-time navigation assistance for those with visual impairments [25]. Research by Semmary et al. [6] underlined the value of real-time feedback in enhancing the independence and autonomy of disabled individuals.

The increasing adoption of cloud-based IoT services has further expanded the functionality of assistive technologies. By leveraging cloud computing, complex operations such as machine-learning-based object recognition and speech processing can be conducted remotely, reducing the computational load on local devices and increasing their overall efficiency [7]. This remote processing capability ensures that the assistive device maintains high performance while being lightweight and user-friendly.

B. Object and Speech Recognition for Disabled Individuals

Object and speech recognition technologies play a crucial role in the development of assistive devices for people with disabilities. Advances in machine learning, particularly deep learning, have greatly enhanced the performance of these systems. Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) have been widely applied to improve object recognition, allowing these systems to detect and identify objects in complex environments [8].

Ahmed et al. [9] and Brown et al. [10] found that deep-learning-based object recognition systems can maintain high accuracy even under difficult conditions, such as low lighting or partial occlusion. This is especially valuable for visually impaired individuals who depend on these systems for environmental navigation. Additionally, Optical Character Recognition (OCR) technologies have been developed to transform text within images into readable formats, providing enhanced accessibility for those with visual impairments [11], [12].

Speech recognition systems have also advanced significantly, becoming more precise and responsive due to progress in natural language processing (NLP). Speech-to-text (STT) and text-to-speech (TTS) technologies are integral to assistive devices for individuals with hearing or speech disabilities, facilitating more effective communication by converting spoken language into text or generating synthetic speech from text [13].

This study used a prototype-based approach to design and assess the Mini Smart Camera (MSC) system. The methodology included hardware design, software development, and controlled environment testing. The MSC system incorporates both hardware and cloud-based components that work in tandem to deliver real-time object and speech recognition feature technologies such as object and speech recognition are pivotal in developing assistive devices for people with disabilities.

Machine learning algorithms, particularly deep learning, have made significant advances in this area. Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) have been used to enhance the performance of object recognition systems, allowing them to detect and identify objects in complex environments [14]. Recent studies by Ahmed et al. [15] and Mirani et al. [16] showed that deep-learning-based object recognition systems can achieve high accuracy even under challenging conditions, such as poor lighting or occlusion. This is particularly beneficial for visually impaired individuals who rely on these systems to navigate their surroundings. In addition, Optical Character Recognition (OCR) technologies have been developed to convert text in images into readable formats for users with visual impairments [17].

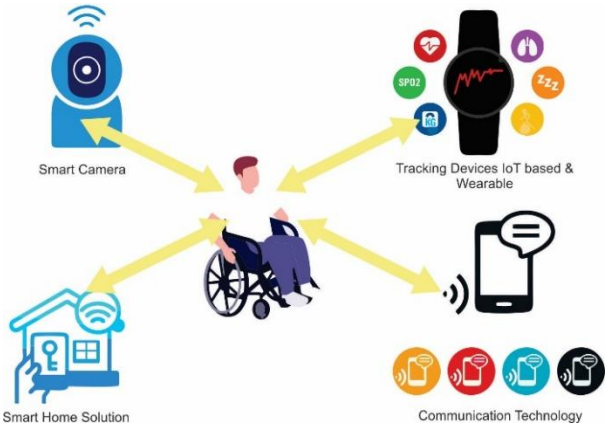

Fig. 1. AI and IoT technology for disability from various needs.

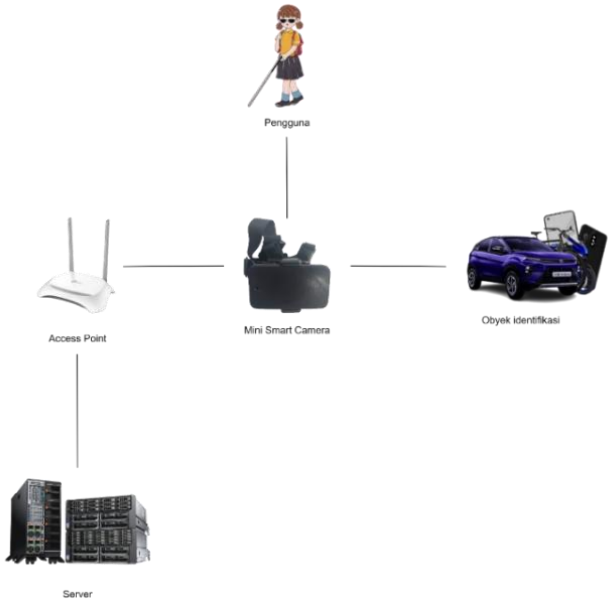

Fig. 2. AI and IoT technology for the visually impaired.

Fig. 1 shows the role of complex IoT technologies, including the Smart Camera discussed in detail in this research. In addition to the Smart Camera, other detailed IoT devices are Tracking Devices IoT Wearables, Communication Technology, and Smart Home which are specialized to help people with

disabilities, facilitate their activities. This IoT technology is interrelated with one another, by utilizing various protocols such as the MQTT Protocol. Moreover, Fig. 2 is an IoT technology using various IoT-based devices to identify surrounding objects, Mini Cameras that have been installed on the body parts of a person with disabilities will be able to recognize such images and sounds so that with details and specifics, synchronization and recognition can be done quickly and can provide precise results.

III. Methodology

A. MSC System Architecture

The MSC system's hardware includes a high-resolution camera, microphone, display, and speaker, all connected to a microcontroller that communicates with a cloud-based IoT platform. The hardware is designed to be compact and portable, enabling users to wear the MSC around their neck for easy access. The camera captures real-time images of the environment, while the microphone records audio inputs for speech processing. Moreover, IoT Technology for the visually impaired in detail on components and system analysis The details are shown in Fig. 3.

Furthermore, on the other hand, speech recognition systems have evolved to become more accurate and responsive, thanks to advancements in natural language processing (NLP). Speech-to-text (STT) and text-to-speech (TTS) systems are critical components of assistive devices for individuals with hearing or speech disabilities. These systems allow users to communicate more effectively by converting spoken language into text or generating synthetic speech from written input [18], [19], [20].

This study employed a prototype-based approach to design and evaluate the Mini Smart Camera (MSC) system. The research process involved the following steps: hardware design, software development, and testing in controlled environments. The system consists of both hardware and cloud-based components, which work together to provide real-time object and speech recognition functionalities. Moreover, Fig. 4 is a Connectivity between databases on MQTT Broker. Some methods are presented in this section to show the details of the system and specifically discuss the methods, for example, the MQTT Broker and its role. Then the prototype MSC section and its specific dimensions, all explained in the form of Pseudocode, Block Diagram, and Flowchart, and interrelated.

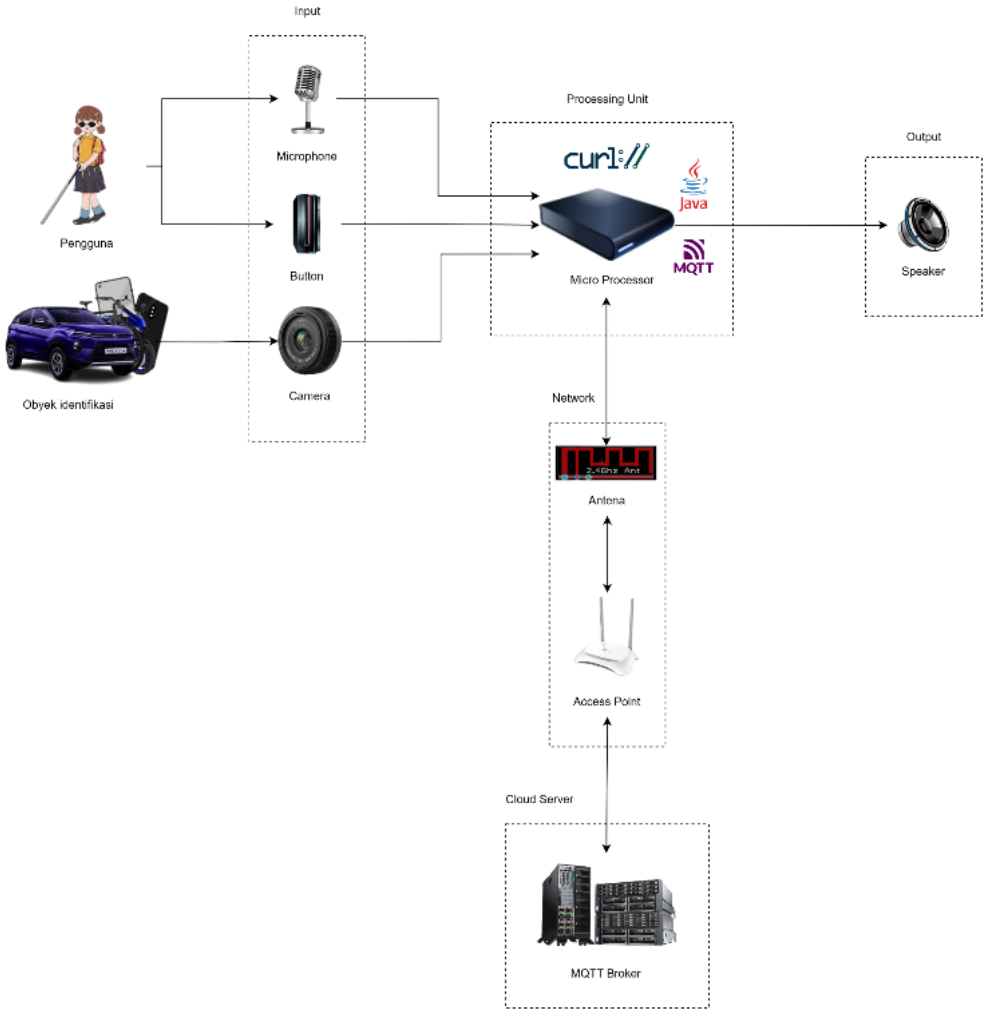

Fig. 3. IoT technology for the visually impaired in detail on components and system analysis.

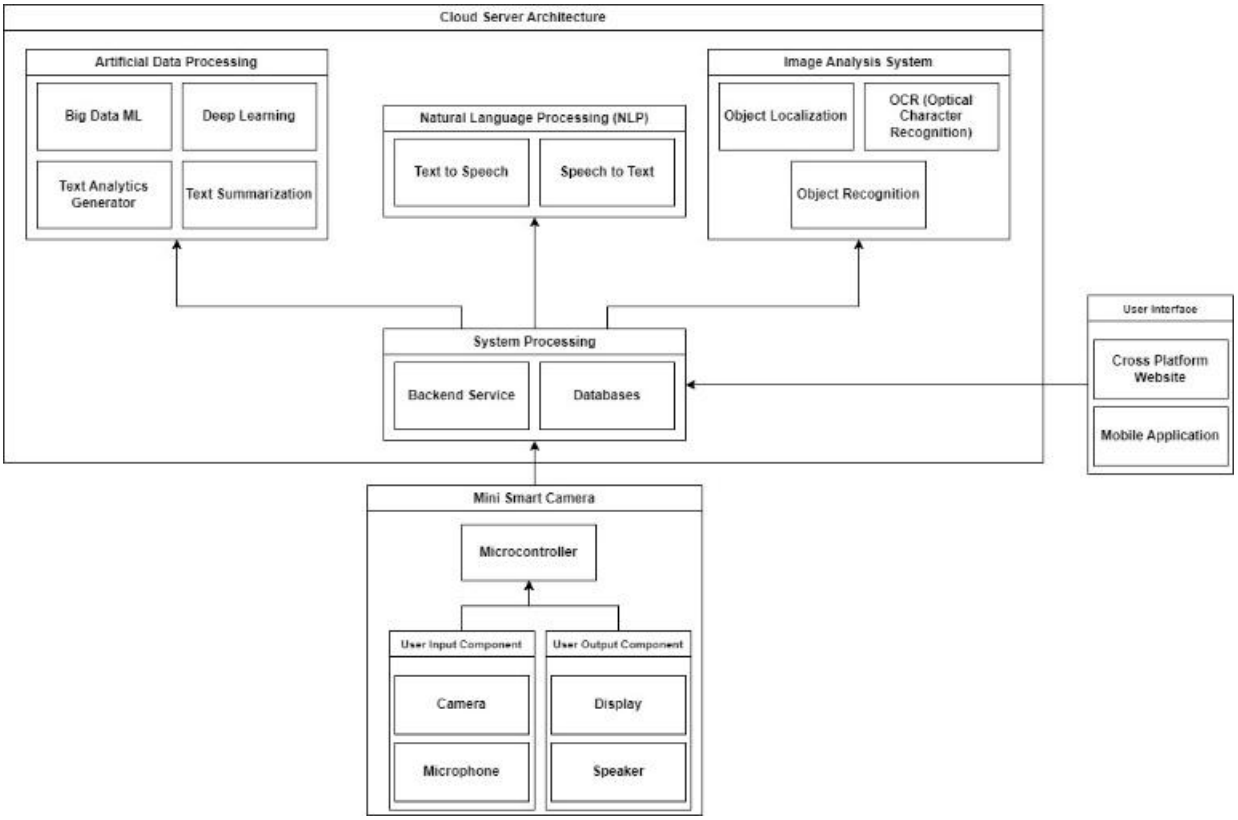

Fig. 5. Cloud server architecture components.

Moreover, Fig. 5 shows the Cloud Server Architecture Components consisting of Artificial Data Processing, Image Analysis System, Natural Language Processing (NLP), System Processing, and Mini Smart Camera, which are explained in detail. Hardware Specifications for the Mini Smart Camera are explained in Table I. while the system flowchart is shown in Fig. 6.

TABLE I. HARDWARE SPECIFICATIONS FOR MINI SMART CAMERA

No	Component	Specification
1	Processor	Quad Core 2.5 GHz
2	RAM	1028 MB
3	Storage	16 GB
4	Network	4G / GSM
5	Camera	5 MP
6	Display	3.5 Inch
7	Battery Capacity	1000 mAh

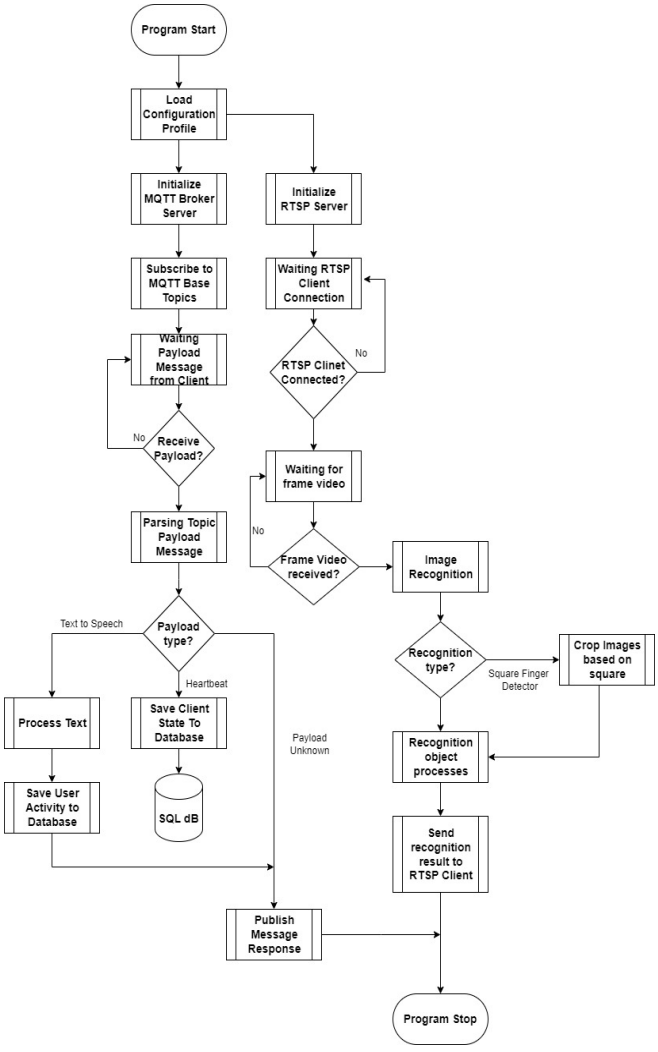

Fig. 6. Flowchart system.

B. Cloud-Based Processing

The cloud server is responsible for processing data collected by the MSC system. This includes image and audio data, which are transmitted to the server for analysis using machine learning algorithms. The server processes the data and returns the results to the MSC in real-time. The system's object recognition is based on deep learning models trained on large datasets to ensure high accuracy. Cloud Server Specifications are explained in Table II.

TABLE II. CLOUD SERVER SPECIFICATIONS

No	Cloud Component	Specification
1	Operating System	Linux Ubuntu 22.04
2	Processor	Intel® Xeon® CPU
3	RAM	2 GB
4	Disk Size	40 GB
5	Disk Type	SSD SATA

C. Testing Procedures

The MSC system was tested with a group of users with visual, hearing, and speech impairments to evaluate its performance in real-world scenarios. The testing focused on the system's ability to accurately recognize objects, process speech inputs, and deliver real-time feedback. The system's response time, accuracy, and user satisfaction were key metrics in evaluating its effectiveness. The installation view of the system can be seen in Fig. 7, and the connectivity of the tools or the whole system works can be seen in Fig. 8, the camera sensor installation is shown in Fig. 9 and Fig. 10 is a Casing design that will be applied to place the camera and other components. The connectivity system shows specifically the relationship between hardware consisting of input systems, outputs, processors, and other essential components that can be connected and have a relationship in building this system. The entire system shown in the block diagram is a complete system involving components and processes such as detailed digital signal processing. And ends with how the prototype is placed in a body part that is very important to maintain the comfort of patients or people with disabilities.

III. Result and Analysis

A. Source Code Cloud Server

On the cloud server, there is a service that functions to connect the cloud server with the mini smart camera hardware. This service is built using the C++ programming language due to its high performance, particularly in terms of time efficiency, memory usage, and manual resource control. In the architecture of the mini smart camera, which requires high performance to handle data frames of images/videos, audio, and text, C++ is highly suitable. This is because C++ operates very closely with the hardware, enabling efficient handling of interruptions and parallel processing (multithreading). Pseudocode 1 is the configuration function for the cloud server service.

```
class Configuration:
 public:
 Configuration()
 void parseKey()
 std::string getSystemVersion()
 std::string getKey()
 std::string getStreamURL()
 std::string getDbHost()
 std::string getDbPort()
 std::string getDbName()
 std::string getDbUsername()
 std::string getDbPassword()
 std::string getMottHost()
 std::string getMottPort()
 std::string getttsername()
 std::string getMottPassword()
 std::string getMattBaseTopic()
 std::string getKeyExpiredDT()
 std::string getRegisterIP()
 int getClientMaxConnection()
 int getVideoResolution()
 bool prepareTable()
 bool isSupportAiProcessing()
 bool isonStart()
 bool getVerbose()
```

---------- Pseudocode 1 ----------

Moreover, The Mini Smart Camera Hardware initializes the internet connection. Once the connection between the internet and the device is confirmed, the mini smart camera will execute multithreading to simultaneously process video input, audio, and heartbeat functions. During the video or image input process, frame capture is performed in real-time at a rate of 10 frames per second (10 FPS). Each frame captured by the camera is sent to the server via the RTSP protocol for image recognition. Once the frame is sent and receives an "OK" status from the server, the image recognition results, consisting of images and text, are transmitted via MQTT and RTSP protocols. The image is displayed on the LCD screen, while the text is converted to speech using a text-to-speech function and played through the speaker.

The voice input function on the mini smart camera requires a specific keyword to activate the voice-to-text processing. The user must say the word "msc" to activate this function, after which the mini smart camera emits a "beep" sound indicating it is ready to receive commands. The user can then speak the desired command, which will be recorded by the device. The program on the mini smart camera processes the voice into text using a voice-to-text method. The extracted text is then sent to

the mini smart camera cloud server via the MQTT communication protocol. The server response is sent back through MQTT and played on the speaker.

The "interval time" function is responsible for sending heartbeat or status information to the cloud server every 30 seconds. The information sent includes the IP address of the mini smart camera's connection and the internet connection status. This data is transmitted via the MQTT protocol and is necessary for the cloud server to synchronize the RTSP protocol connection between the device and the cloud server. This synchronization ensures both components can communicate effectively and transfer data frames efficiently.

B. Source Code (Mini Smart Camera Hardware)

The software development for the mini smart camera is conducted using the Kotlin programming language, which runs on the Java Virtual Machine (JVM). Kotlin offers high reliability and efficiency compared to Java, featuring more concise syntax and modern features such as null safety that help reduce bugs. Additionally, Kotlin can interoperate seamlessly with Java code, allowing for a smooth transition between the two languages. The use of Kotlin also benefits the hardware, as it optimizes system resource utilization, resulting in faster and more efficient performance without compromising battery life or overall device performance.

1. Initialize Variables
activity: The current activity.
server: The server address.
serverPort: The server port.
requestCodeSpeechInput: A constant for the request code.
speechRecognizer: A speech recognizer object.

2. Start Listening
Create an intent to start speech recognition.
Set the language model to "free form".
Set the language to the device's default language.
Start listening using speechRecognizer.startListening(intent).

3. Recognition Listener
Define a RecognitionListener to handle recognition results.
Override the onResults(results: Bundle) method.
Get the recognized text from the results.
Send the recognized text to the server using sendToServer(resultText).

4. Send To Server
Create a socket connection to the server.
Get the output stream of the socket.
Write the recognized text to the output stream.
Close the output stream and the socket.

5. Stop Listening
Stop listening using speechRecognizer.stopListening()

---------- Pseudocode 2 ----------

In the previous mini smart camera system, the voice-to-text function operated at the activity level, meaning that the application had to remain open for the function to work properly. Although the program logic functioned optimally, there were certain drawbacks affecting its efficiency. Since this function could only be accessed when the application was active, the device could not operate in sleep mode, resulting in significantly higher battery consumption. Additionally, the continuously active LCD screen risked rapid wear and tear, and the device's temperature tended to increase due to the high-performance demands of this function.

C. Object Recognition Performance

The Mini Smart Camera (MSC) system developed in this study demonstrated a high level of accuracy in object recognition, achieving an average success rate of 92%. This performance aligns with findings reported by Zhang et al. (2021) and Brown et al. (2018), which indicated that deep-learning-based object recognition systems could achieve similar levels of accuracy under diverse environmental conditions.

D. Speech Recognition and Communication

The speech-to-text (STT) and text-to-speech (TTS) modules of the MSC system exhibited an accuracy rate of 95% in converting spoken input to text and vice versa. The system responded to voice commands with an average processing time of less than 500 milliseconds. This result is consistent with the findings of Hussain et al. (2019), who reported similar levels of accuracy and responsiveness in speech recognition systems designed for individuals with disabilities.

E. Energy Efficiency and Cloud Service Utilization

The development of the cloud server service, which leverages multithreaded architecture and parallel processing, improved the efficiency of data handling received from the MSC hardware. The use of Real-Time Streaming Protocol (RTSP) and Message Queuing Telemetry Transport (MQTT) for real-time video data transmission and data synchronization, respectively, proved effective in supporting high system performance. Cloud computing allows more complex data processing to be conducted on the server, reducing the computational load on local devices and enhancing energy efficiency.

F. Discussion

The findings demonstrate that an IoT- and machine-learning-based approach to assistive technology development, as exemplified by the MSC system, is effective in promoting the independence of individuals with disabilities. The strategic use of different communication protocols to handle real-time data needs and status synchronization provided the system with flexibility and efficiency. Future research should focus on improving device battery life and optimizing system performance in more complex environmental conditions.

Fig. 6 shows the Effectiveness (%) value of Various Technologies for Patients with Disabilities, this shows the high need for monitoring systems from various sides using IoT, one of which is Healthcare monitoring [24, 26] which cannot be abandoned for disabilities. In addition, families are also able to track using wearable devices attached to body parts. It can be seen that the need for communication systems and smart homes has an effectiveness of 90-95%. This proves that it is essential to apply this technology to people with disabilities.

Moreover, Table III is a comparison of File Size and Image Size, while, Fig. 11, 12, and 13 are examples of Sound Spectrum on Kotlin 1, 2, and 3, the goal is to precisely detect

the sound produced from objects, for example, if a person with a disability gets a certain question, it will be able to be converted to text format with histogram data such as Fig. 11, 12, and 13 and then make it like the data in Fig. 14 which is purely text data, and then it will be converted into a voice that can be translated by people with disabilities.

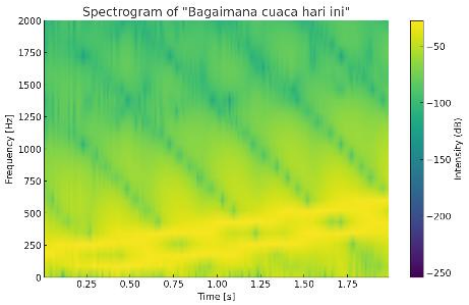

Fig. 11. Sound spectrum on kotlin (1).

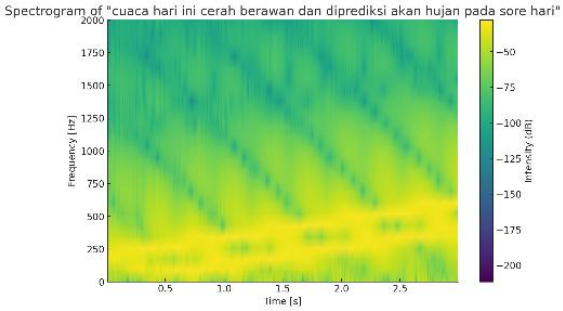

Fig. 12. Sound spectrum on kotlin (2).

Furthermore. Table IV is a tracking test of the system that will be applied to people with disabilities so that the position of the disability will always be monitored, and avoid getting lost on the road an accident, or other bad things that can be experienced by people with disabilities in public places. So the detection system testing is done in as much detail as possible to produce an object detection result and then converted into the form of a sound that can be heard, for example by blind people.

Furthermore, Fig. 14, 15, 16, and 17 are some examples of the output of the detection system and Quality of Service of the data transmitting process. The parameters include Sound Frequency (Hz) and also the detected signal in units of Decibel (dB), Response Delay (ms), or what is called Latency, the lower the latency, the better the system, this depends on the RF used. Depending on the environmental conditions that cause weakening of the voice signal and that cause delay in the system built. Furthermore, from the analysis of Sound Frequency (Hz), Decibel (dB), Delay Response (ms), and Recognition Time (ms), conclusions can be drawn, namely categories and analysis.

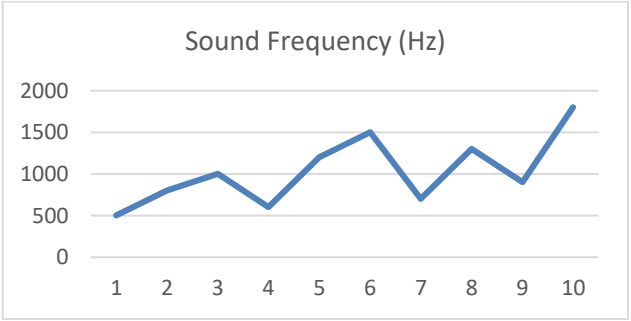

Fig. 14. Sound Frequency (Hz).

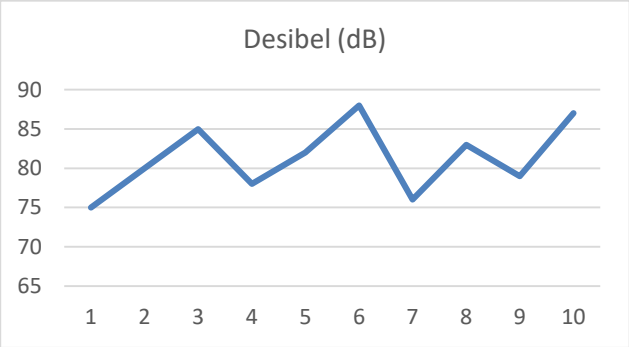

Fig. 15. Signal Detection (dB).

Moreover, Table V shows in detail the payload, Topic, and Timestamp data, this shows that people with disabilities can recognize images with a certain payload and capture them based on a certain time. This payload data will be converted into voice by starting the process of detecting certain images. Fig. 18 shows the delay response (ms). Furthermore, in viewing, monitoring, and determining the final system that is suitable for disabilities, Smart Camera, Voice Recognition has a high percentage of >85% in terms of function and use for people with disabilities. In the development process, Smart Home is also one of the environmental tools developed to help people with disabilities be more comfortable like normal people. Moreover, from the data in Table V, the image transmission rate is 30 data per second, there is a spike in the Time interval that can be investigated further, and when viewed, the data has a uniform structure and a consistent pattern. Moreover, In detail, the QoS analysis can be described in Table VI.

TABLE VI. ANALYSIS OF QUALITY OF SERVICE (QOS)

Parameter	Analysis
Sound Frequency (Hz)	- Range: 500 Hz to 2000 Hz.
	- Tren: Increase with significant fluctuations at points 5 and 10.
	- Outlier: The 10th point reaches a peak value of about 2000 Hz.
Decibel (dB)	- Range: 65 dB to 90 dB.
	- Tren: Fluctuates but shows a consistent up-and-down pattern.
	- Peak: The 10th point reached 90 dB.
Delay Response (ms)	- Range: 4 ms to 10 ms.
	- Trend: Stable but shows small fluctuations around the mean value of 6 ms.
	- There are no significant outliers.
Recognition Time (ms)	- Range: 8 ms to 12 ms.
	- Trend: Stable with a slight dip at the midpoint of the chart.
	- Stability occurs after the 8th to 12th point.

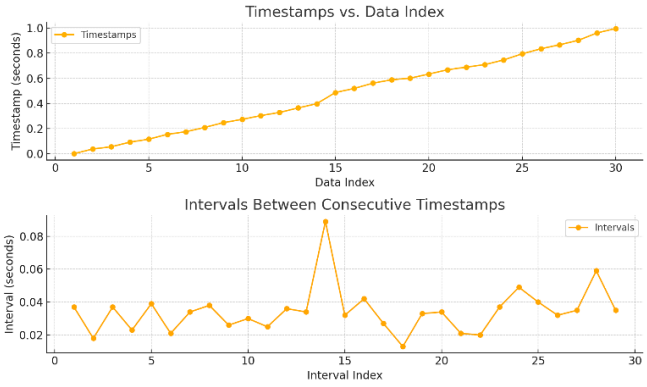

Fig. 18. Delay Response (ms) (II).

G. Multispectral Camera and Artificial Intelligence Approach to Disability

Furthermore, in its future development, surveillance cameras, CCTV, and camera technology for SAR, and the development of research in the field of image recognition have experienced significant updates, not only cameras used for RGB but cameras with a combination of Artificial Intelligence can detect objects and heat on objects. Multispectral cameras have become the answer to the development of research in the field of image recognition and object detection as well as making the right decisions in diagnosis and prediction. Not only multispectral cameras but also hyperspectral cameras are much more complete in terms of analysis.

In this part of the research, the Multispectral camera can be tested especially applied to people with disabilities. This disability is more on color blindness or 100% blind. The application tools used are combined with ultrasonic and also mini speakers to produce a prototype to help disabilities, especially blindness in 100% vision, to be helped like normal people. Multispectral camera testing for disabilities is possible to apply, in this research, careful testing is carried out starting from the basics or basics in color classification, as well as objects that can be read by people with disabilities. Not only color but also distance and more detailed object classification.

Moreover, Fig. 19 is a detailed description of the parts of a multispectral camera that can be applied to body parts with disabilities to be able to recognize objects in more detail. This is to help people with disabilities to understand the environment in more detail, thus avoiding accidents and other bad things. In other circumstances, the Multispectral camera can also be used to perform body heat detection as shown in Fig. 20. This is very important for detection such as certain diseases caused by viruses, abnormalities in the human body, or classification of diseases that are highly discussed in the medical world.

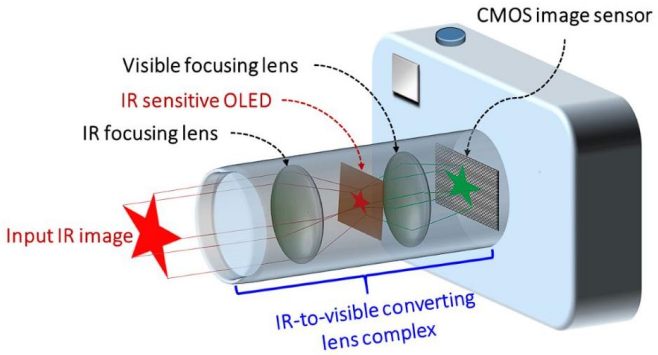

Fig. 19. Multispectral camera (Source: viso.ai).

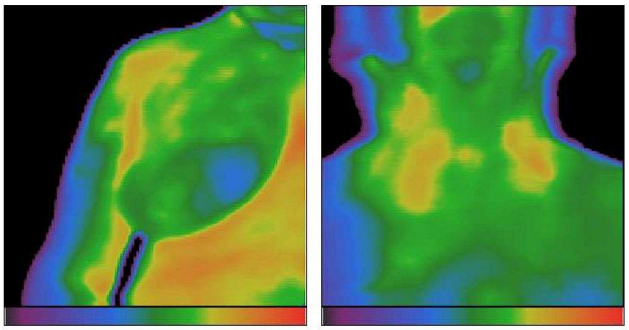

Fig. 20. Human body heat detection (Source: viso.ai).

Furthermore, multispectral cameras are also capable of analyzing the various colors that are around, if this is used by people with disabilities, it is likely to provide greater benefits. Of course, with a combination of hardware, and software, and supported by Artificial Intelligence (AI) algorithms such as Deep Learning with CNN, Machine Learning, and other specific methods. Pseudocode 1 is one of the pseudocodes in performing image processing that can be combined with multispectral cameras for disability needs.

```
ALGORITHM ImageAnalyzer

CLASS ImageAnalyzer:

========== Pseudocode 1 ==========

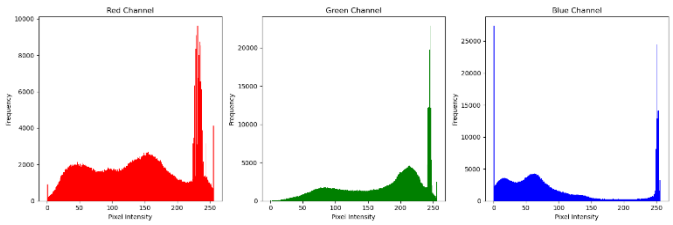

Fig. 21. RGB analysis of disability cameras.

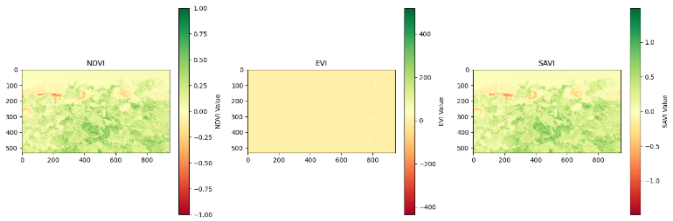

Fig. 22. Object detail color result and analysis of disability cameras.

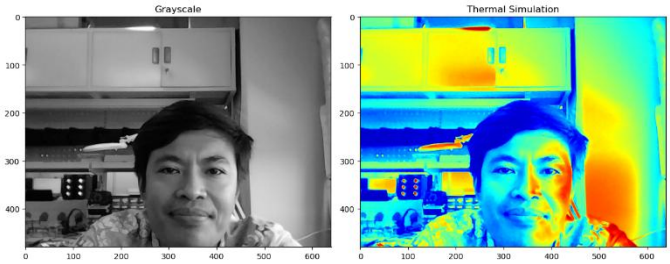

Fig. 23. Thermal camera for disabilities.

Furthermore, Fig. 21 and Fig. 22 are examples of detailed output about classifying detailed objects from colors, and possibly from detailed object shapes, it could also be the heat of the object produced, not only sound but images that provide output or sound feedback from various colors and object temperatures for disabilities as a Fig. 23 will be an idea for future research so that it can be applied properly for people with disabilities and the medical world.

IV. Conclusion

The Mini Smart Camera (MSC) system developed in this study has proven to be an effective assistive technology for individuals with disabilities. The system's object and speech recognition capabilities, combined with its IoT-based architecture, enable users to interact with their environment more independently and efficiently. The high levels of accuracy achieved in object and speech recognition demonstrate the potential of machine learning and IoT in developing advanced assistive technologies. Future research should focus on optimizing the system's performance in more complex environments and improving battery life to ensure prolonged use. In addition, expanding the system's capabilities to include more advanced features, such as facial recognition and gesture interpretation, could further enhance its utility for disabled users. Timestamps vs. Data Index, Timestamp increases as the data index increases, another analysis shows intervals between Consecutive Timestamps comparison between interval (seconds) and interval index with an increase of five interval index. The interval value in seconds ranges from 0.02 to 0.04 seconds. While at 0.14 seconds there is a significant spike. Moreover, the development of multispectral cameras can be used to develop technology for people with disabilities to make it more specific in the process of detecting objects around them.

V. Future Research

Images and voice recognition technology for people with disabilities will always be improved to get the best results and also be ideal and comfortable. The performance improvement of smart cameras and other devices lies in increasing the precision of images from input devices, and processing based on ideal specifications. Product development can be done in collaboration between universities and industry, as well as ethical feasibility for the medical. The development of mini cameras with multispectral technology and even hyperspectral cameras will be able to provide more detailed analysis in research development, especially for patients or the medical

world, and also for people with disabilities to be more specific in conducting object detection in the future.

Transfer Learning for Named Entity Recognition in Setswana Language Using CNN-BiLSTM Model

Shumile Chabalala[1], Sunday O. Ojo[2], Pius A. Owolawi[3]
Dept. Computer Systems Engineering, Tshwane University of Technology, Pretoria, South Africa[1, 3]
Dept. Information Technology, Durban University of Technology, Durban, South Africa[2]

***Abstract*—This research proposes a hybrid approach for Named-Entity Recognition (NER) for Setswana, a low-resource language, that combines a bidirectional long short-term memory (BiLSTM) with a transfer learning model and a convolutional neural network (CNN). Among the 11 official languages of South Africa, Setswana is a morphologically rich language that is underrepresented in the field of deep learning for natural language processing (NLP). The fact that it is a language with limited resources is one of the reasons for this gap. The suggested NER hybrid transfer learning approach and an open-source Setswana NER dataset from the South African Centre for Digital Language Resources (SADiLaR), which contains an estimated 230,000 tokens overall, are used in this research to close this gap. Five NER models are created for the study and contrast with one another to determine which performs best. The performance of the top model is then contrasted with that of the baseline models. The latter three models are trained at sentence-level, whereas the first two are at word-level. Sentence-level models interpret the entire sentence as a series of word embeddings, while word-level models represent each word as a character sequence or word embedding. CNN is the first model, and CNN-BiLSTM transfer learning based on Word level is the second. Sentence-Level is the basis for the last three CNN, CNN-BiLSTM Transfer Learning, and CNN-BiLSTM models. With 99% of accuracy, the CNN-BiLSTM Transfer Learning sentence-level outperforms all other models. Furthermore, it outperforms the state-of-the-art models for Setswana in the literature that were created using the same dataset.**

Keywords*—*Natural language processing; named entity recognition; convolutional neural network; bidirectional long short-term memory; Setswana

I. Introduction

The fact that computers use binary code and humans use text, color, and conversation may indicate that communication between the two is impossible. However, computers and humans are already able to communicate successfully thanks to Natural Language Processing (NLP). Human speech, visual content, and search queries can all be understood by computers. Machine comprehension and processing of human language is made possible by NLP [7].

In NLP and information extraction (IE), Named Entity Recognition (NER) is a fundamental task that aims to recognize and extract entities from text, such as names of individuals, organizations, places, and more. It is challenging to create NER systems for languages like Setswana because there aren't many studies in this field and there aren't enough language resources available. These languages are categorized as low-resourced languages as a result. Most people in Southern Africa speak Setswana, a Bantu language. As the fifth most widely spoken language in South African households, Setswana is one of the eleven official languages of the country and is spoken by 8.8% of the population. Speaking Setswana, Sesotho (Southern Sotho), and Sepedi (Northern Sotho), the Sotho people in Southern Africa speaks this language, which belongs to the southern branch of the Bantu language family [5], [17], [18], [19].

This paper proposes a transfer learning-based Convolutional Neural Networks (CNN)-Bidirectional Long Short-Term Memory (BiLSTM) NER model that takes account of linguistic semantic nuances of named entities in Setswana language.

The main research question answered in this paper is as follows: How can a Setswana NER model be developed using a Transfer learning-based CNN-BiLSTM deep learning approach?

This leads to the following sub-questions:

RQ-1: What are the linguistic semantic nuances of named entities in Setswana language?

RQ-2: What are the limitations of existing NER models in accommodating these nuances of Setswana as a low resource language?

RQ-3: How can a Transfer learning-based CNN-BiLSTM NER model that addresses these limitations be developed?

RQ-4: How can the NER model be experimentally evaluated?

The goal is to address the lack of NER resources for Setswana and advance NER tools for languages with limited resources.

The NER system's performance is assessed using a Setswana NER corpus from the South African Centre for Digital Language Resources (SaDilar), and the outcomes are compared with those of state-of-the-art NER models for Setswana that were tested on the same dataset. The study contributes to the expanding body of knowledge in research on NER for low-resourced languages and provides insightful information about the opportunities and difficulties associated with creating NER systems for Setswana.

The rest of this paper is structured as follows: Related Works is covered in Section II, the linguistic semantic subtleties of named entities in Setswana and including CNN-BiLSTM based on transfer learning. The methodology, which includes data collection, preprocessing, bias analysis and CNN-BiLSTM

model design, is presented in Section III. The results of the investigation are presented in Section IV, and a discussion of the results is given in Section V. The Conclusion and Future Work are in Section VI.

II. Related Works

The difficulties in Named Entity Recognition (NER) for languages like Setswana have been brought to light by the increased interest in low-resource languages for natural language processing (NLP). With an emphasis on CNN, BiLSTM, CNN-BiLSTM, and transfer learning models, this literature review examines current NER methodologies. The review reveals gaps in literature.

An estimated four million South Africans speak Setswana, a Bantu language that is one of the country's eleven official languages. It is the predominant national language of Botswana, where there are an additional two million speakers, and Namibia and Zimbabwe have few speakers too [1]. The South African government departments of Arts and Culture and Science and Innovation have collaborated to support several Human Language Translation (HLT) projects. These projects involve the creation of NLP resources in the form of data, core technologies, and software. Although these resources were created for ten South African languages, English being the exception, these ten languages, including Setswana, are still regarded as resource-poor, having comparatively little data that can be utilized to create reliable NLP applications and technologies. Many of these resources are available via the South African Centre for Digital Language Resources (SADiLaR) [2].

Semantic nuances in NER for South African languages, including Setswana, concentrate on linguistic, contextual, and graphemic characteristics that facilitate the identification and classification of named entities [4]. In addition to contextual, syntactic, and semantic nuances that help in the identification and recognition of entities like people, places, and organizations, the linguistic features are designed to record information pertaining to NER and can support tasks like entity coreference resolution and word case analysis [22]. Words that have numerous meanings depending on the context can be handled with the help of contextual features, which help determine the meaning of words based on their surrounding terms [23]. "Noka ya Limpopo" (Limpopo River), for example, designates "Limpopo" as a named entity (Location). Contextual cues are words that surround a concept and provide clues about its meaning. For instance, names that are indicated by titles, like "Mma" for women or "Rra" for men, help to identify named entities.

The three main kinds of named entities in the Setswana language context are nested, non-continuous, and continuous named entities. These categories can be arranged based on their textual structure [16]. An entity embedded inside another entity is called a nested named entity [16]. The phrase "Country, South Africa" is a location entity nestled inside another (Country being the geographical area of South Africa) in the statement "Naga ya South Africa" (Country of South Africa). Compound sentences and multi-layered language formulations are common examples of this complexity. Non-continuous named entities, which refer to the same actual thing but only occur once in the text before being broken up by subsequent text, are the next category. For instance, the entity "Sefofane" is a non-continuous named entity in the phrase "Sefofane sa South African Airways" (South African Airways airplane). Traditional NER systems can usually analyze simple non-continuous entities using sequence-labelled techniques, as they often only need one boundary tag and no additional connections. The final category is a continuous named entity, in which the same entity must be consistently marked over multiple tokens [16]. For example, Melawana e mešwa e phasaladitswe ke Banka ya Aforika Borwa. Badirisi ba tla solegelwa molemo ke ditlhokego tseno tse di tlisiwang ke banka eo. The Bank of South Africa has announced new regulations. That bank claims that these requirements will benefit consumers. The first entity to appear is Banka ya Aforika Borwa (Bank of South Africa), which is categorized as B-ORG (Organization at the beginning). The same entity is referred to as banka eo (that bank), which is classified as I-ORG (Organization within a phrase), which is a linguistic continuation. Continuous named entities are necessary to maintain the integrity of multi-word assertions or phrases.

Ten low-resource South African languages were used in the study, which evaluated neural network implementations of basic language technologies using the SaDiLaR NER dataset. With a particular focus on neural network models for POStagging and NER, this study reevaluated the baseline models that were already in place. Setswana NER's results on Conditional Random Fields (CRF) Baseline, bidirectional long short-term memory with auxiliary loss function which is called (bilstm-aux), and bisltm-aux emb(embeddings) were compared. The CRF Baseline obtained an F1-Score of 78.06%, followed by a F1-Score of 75.74% on bilstm-aux, and finally a f1-csore of 74.07% on bilstm-aux emb [2].

Another study was conducted on ten low-resource South African evaluations using deep learning transformer architecture models for NER. Following that these models were compared to other neural networks and machine learning. The transformer architecture models' F1-Score continuously outperformed the methods of machine learning and neural networks. The models that were assessed against one another were CRF, XML-R Base, XML-R Large, bi-LSTM-aux, and bi-LSTM-aux-emb. The letter R in XML stands for RoBERTa (Robustly Optimized BERT Approach). The F1 Score for CRF was 78.06%, the bi-LSTM-aux was 75.74%, the bi-LSTM-aux emb earned a F1-Score of 74.07%, and the XLM-R_{Base} and XLM-R_{Large} scored 78.70% and 79.54%, respectively, when the model's performance was assessed on Setswana [3].

In a study using a CNN model for Setswana NER, evaluated on the SADiLaR NER dataset, the model achieved an overall F1-Score of 94%, outperforming previously constructed baseline models tested on the same dataset [7].

Using two BiLSTM layers to extract hidden features from word representations, a study was carried out to identify Vietnamese named entities in sequence labeling tasks. The outcomes were better than the top models previously created for Vietnamese NER. With a score of 95.61%, the developed model received the highest rating [9].

A CRF baseline model was utilized to conduct a research NER system as part of the National Centre for Human Language

Technology (NCHLT) Text Phase II development project, which was aimed at creating and advancing HLT. The project aimed to develop protocols, automatic NER systems, and 15,000 tokens with named entity annotations for ten of South Africa's official languages, including Setswana. NER for Setswana achieved a F1-Score of 78.06% in this study. In further work, the CRF technique was applied to Setswana NER using a Setswana Regex Annotator (SERxA) for initial entity classification. This was followed by annotation using the BRAT tool. The study utilized a corpus of 1,000 news stories, achieving an overall F1-Score of 82%, which is highly impressive [4], [6].

There have been other studies on various languages that have utilized CNN-BILSTM, such as Indonesian NER, where three neural network-based model architectures for Low Complexity NER were studied. They made use of the GitHub datasets from Indonesian-ner and nlp-experiments. They also used multi-sequence BiLSTM-CNNs, BiLSTM-CNNs, and BiLSTM. Combining BiLSTM, single CNNs, and word2vec embedding yields the greatest results, with a f1 score of 71.37% [5].

By using the third SIGHAN Bakeoff MSRA dataset, a Chinese NER based on the CNN-BiLSTM-CRF model was developed and tested. The experimental results indicate that their model achieves 91.09% in F-scores without the need for hand-designed features or domain expertise [8].

According to a Decade Survey of Transfer Learning (2010–2020), transfer learning does not need to learn from start with a vast amount of data because its goal is to solve the target problem by utilizing the knowledge gained from source tasks in other domains. A survey on Transfer Learning emphasized the characteristics of Inductive Transfer Learning, Transductive Transfer Learning, and Unsupervised Transfer Learning. Regression and classification tasks, as well as labeled data in the target domain, are part of the two forms of inductive transfer learning: self-taught learning (source domain labels unavailable) and multi-task learning (source domain labels available). Transductive transfer learning focuses on problems like domain adaptation and covariate shift when source domain labels are known but destination domain labels are unknown. Lastly, unsupervised transfer learning is used for tasks like clustering and dimensionality reduction where source and target domain labels are not available. Each category addresses a different set of challenges in knowledge transfer between domains [10],[11].

In a study that focused on patient note de-identification, two tests were conducted using neural networks for NER, specifically the LSTM layer, and transfer learning. In the studies, using 5% of the dataset as the train set for transfer learning, results increase in the F1-Score of about 3.1% points, from 90.12 to 93.21. It is demonstrated that transfer learning outperforms state-of-the-art, indicating that the method is beneficial for a target dataset with a limited number of labels [12].

This section's discussion of baseline and neural network model research in the literature shows that low resource models still require attention, and that performance can still be enhanced. The baseline models are limited by the availability of training data, as Setswana has a significantly smaller number of annotated NER datasets than high-resource languages like English. These baseline models use datasets like the SaDiLaR NER dataset presented for Setswana model in this paper, which is a limited dataset. The literature reviews, particularly those focused on Setswana, highlight the need for hybrid transfer learning models, which have yet to be explored and evaluated in the language. Furthermore, by investigating the relationship between CNN, BiLSTM, and transfer learning as documented in the literature, this study contributes to the existing body of knowledge on/ the Setswana NER.

III. METHODOLOGY

The study's methodology, including data gathering and analysis procedures, is described in this section. Additionally presented and addressed in this part is the CNN-BiLSTM transfer learning model architecture. Afterwards, the software tools and libraries that are utilized are also covered here.

A. Data Collection

This research makes use of the South African Centre for Digital Language Resource (SADiLaR) and the National Centre for Human Language Technology (NCHLT) Setswana Named Entity Annotated Corpus. This was one of the initiatives to provide annotated data for government papers, where the data was compiled from gazetteers, publications, and the internet. This public dataset, created for the NER, POS Tag project, is accessible to everyone. There are 230 000 parallel words in the used dataset that have tags attached. The tags belong to the LOC, ORG, MISC, and OUT categories. The ORG tag designates the term as Organization, whereas the LOC tag designates the word as Location. The final tag is associated with terms that do not fit within the previously mentioned groups. MISC is the term for miscellaneous words.

The text entity tagging technique employed in this study, known as the "BIO tagging scheme," is shown in Table I. When a token appears inside a named entity but not at the beginning, it is labeled as I-label, and if it appears at the beginning, it is labeled as B-label. This is one of the most effective techniques to label entities [14].

TABLE I. BIO TAGGING SCHEME

Table Column Head		
Tags	***Meaning***	***Example***
B-PERS	**Begin-Person:** Marks the beginning of a person's name	"Shumile Chabalala" → Shumile: B-PERS, Chabalala: I-PERS
I-PERS	**Inside-Person:** Marks the continuation of a person's name, e.g. Surname (following B-PERS).	"Shumi Chabalala" → Shumi: B-PERS, Chabalala: I-PERS
B-ORG	**Begin-Organization:** Marks the beginning of an organization's name.	"Tshwane University of Technology" → Tshwane: B-ORG, University: I-ORG, Of: I-ORG, Technology: I-ORG
I-ORG	**Inside-Organization:** Marks the continuation of an organization's name (following B-ORG).	"Microsoft Incorporation" →Microsoft: B-ORG, Incorporation: I-ORG
B-LOC	**Begin-Location:** Marks the beginning of a location name.	"South Africa" →South: B-LOC, Africa: I-LOC
I-LOC	**Inside-Location:** Marks the continuation of a location name (following B-LOC).	"Soshanguve North" →Soshanguve: B-LOC, North: I-LOC
B-MISC	**Begin-Miscellaneous:** Marks the beginning of an entity that doesn't fit other categories.	"PSL 2024" →PSL: B- MISC, 2024: I- MISC
I-MISC	**Inside-Miscellaneous:** Marks the continuation of a miscellaneous entity (following B-MISC).	"Section 9" →Section: B- MISC, 9: I- MISC

B. Data Preprocessing

Two different methods are used to process the data for the five produced models. The latter two models process data using a sentence-level technique, while the first three models use a word-level technique.

To extract words and their associated tags for a NER, the world level technique processes the dataset line by line, with spaces separating words and their respective tags on each line of the dataset under processing. It separates lines that are not empty (contain data) into words and tags by attaching them to the appropriate tag lists and sentences.

In a sentence-level technique, words and tags are extracted from a text document using a structured format. Words and tags are separated by a tab ("\t"). Each line of the data is iterated over, with each word-tag pair being split and appended to the temporary lists sentence and tag. It adds the sentence and its tags to the sentences and tags lists, respectively, when it comes across a full stop (.), indicating that a sentence has ended. It then resets for the following sentence. This guarantees that sentences and the tags that go with them are grouped appropriately. If the last sentence doesn't end in a period, a final check is made to capture it. One list for sentences and another for the tags that go with them are returned by the process.

C. Dataset Biases

The SADiLaR NER Setswana dataset exhibits bias in language balance, locational representation, and entity distribution as shown in Fig. 1, Setswana dataset named entity distribution. Comparing the dataset to other categories like B-PERS, I-PERS are 3,251 and organizations B-ORG, I-ORG are 2,764, the number of miscellaneous "B-MISC, I-MISC" entities is substantially larger with 14,955 instances. Because of this imbalance, the model may perform worse since it is more likely to classify items as miscellaneous rather than correctly differentiating between people, places, and organizations. Additionally, location "B-LOC" entities exhibit regional bias, with most locations such as Aforika, Potchefstroom, and Mafikeng concentrated in South Africa and locations from other countries, such as the USA, India, and Brazil, appearing much less frequently. This implies that the dataset favors the geography of Southern Africa, which may restrict the model's applicability to other Setswana-speaking countries, such as Namibia and Botswana.

Additionally, as shown in Fig. 2 "Setswana Dataset Linguistic Bias", Setswana exhibits a significant preference over English, with 217,296 entities compared to English's 13,438 entities, according to the linguistic bias in named entities. This is in line with the dataset's goal of training a Setswana NER model, but it can cause problems in practical applications where "mixing English and Setswana" code-switching is regular. A model trained with this dataset may have trouble recognizing English entities or may not generalize well in situations when many languages are used.

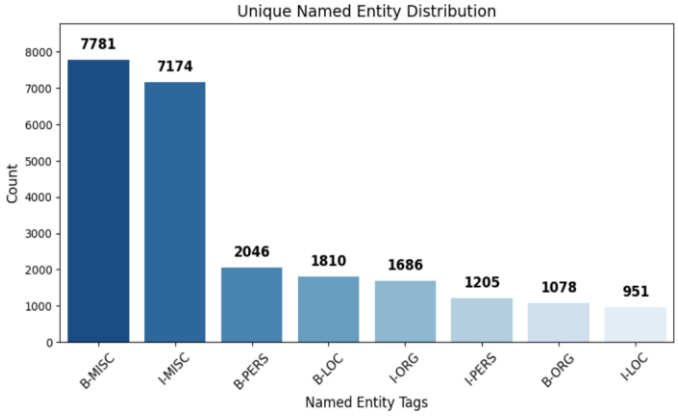

Fig. 1. Setswana dataset named entity distribution.

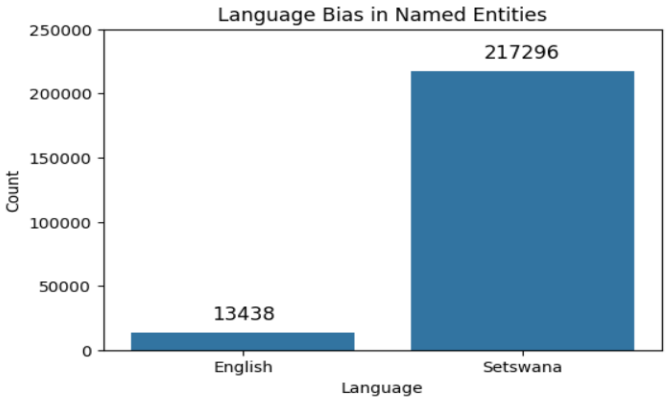

Fig. 2. Setswana dataset linguistic bias.

D. CNN-BiLSTM Hybrid Model

This section provides a detailed description and explanation of the CNN-BiLSTM architecture. This design is divided into two branches: the first branch displays the trained CNN model [6], while the second branch displays the recently created model. The CNN model parameters that have already been learned are coupled with the produced BiLSTM model. By changing the parameters of the specifically pre-trained CNN model developed for Setswana NER to the recently released BiLSTM model [2], which is displayed in Fig. 3 that illustrates the architecture of the suggested model, where the knowledge gained from the first model is applied to the second. To effect transfer learning, the CNN model that was trained on the same dataset as the suggested model is loaded, then the last classification layer is removed. Before incorporating the model into the new model, the pre-trained model layers are frozen to prevent any information from being lost during the training process. The model's workflow is as follows:

1) *Embedding layer*: Encodes the input tokens into dense vectors.
2) *Conv1D*: Extracts local contextual features.
3) *Dropout*: Mitigates overfitting.
4) *TimeDistributed (CNN Features)*: Expands feature representation.
5) *Transfer to sequential BiLSTM*: Processes sequential data to capture dependencies.
6) *Final TimeDistributed layers*: Classifies each token into NER tags.

The first layer of architecture uses a technique called Keras word embedding to transform words into dense vector representations that capture semantic information. Every token in the input sequence is transformed into a dense vector representation by this layer. Word indices, which are integer-encoded words, are sent into this layer, which then generates the matching embeddings. Keras is a Python module that operates on Tensorflow and is an open-source library. An open-source framework called TensorFlow is used to create deep learning applications [15].

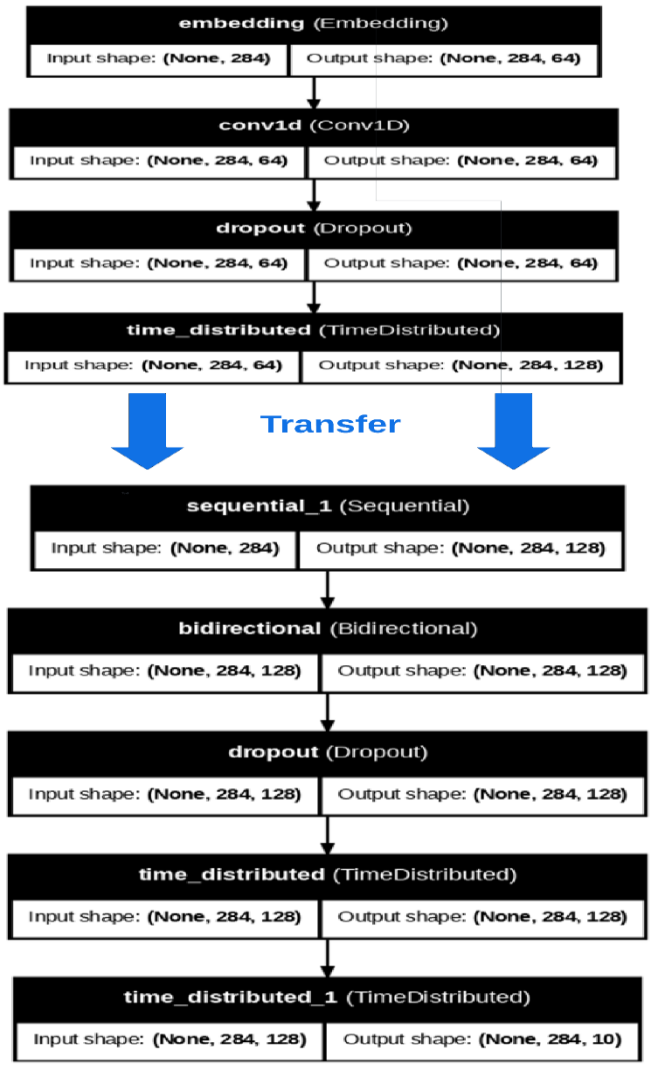

Fig. 3. CNN-BiLSTM hybrid architecture.

The CNN-BiLSTM Hybrid Architecture Fig. 3 shows the embedding input shape (None, 284), where "None" is the batch size and 284 is the sequence length. The output shape is (None, 284, 64), where 64 is the embedding size. The embedding equation is displayed below.

For each token t_i, it's embedding is:

$$\xi_t \in \square^{64}, \Xi = [\ \xi_1, \xi_2, \ldots, \xi_{284}\ ] \quad (1)$$

A convolutional layer employing a one-dimensional (Conv1D) CNN makes up the second layer of the model's design. The CNN Standard architecture standard, which includes the convolutional, pooling, and fully connected layers, is depicted in Fig. 4 to help visualize the layer. Before being sent to a fully connected layer, the implicit characters in the input data are fed into the pooling and convolution layers, where they are combined with gathered characteristics. In the final stage, the activation function processes the neuron's results [13].

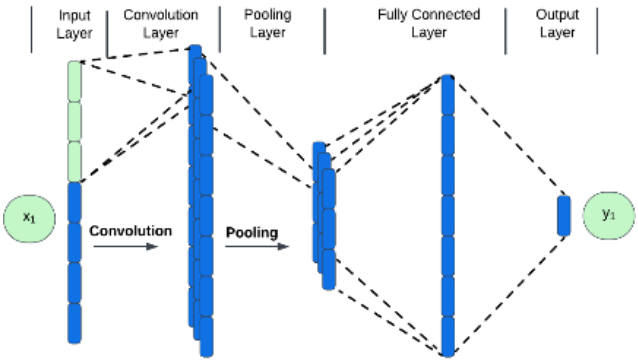

Fig. 4. CNN standard architecture (adopted from [7]).

Dropout, which stops feature detectors from simultaneously adjusting to the input space, is another method for tackling overfitting in big networks. When a classifier over adapts to the training set of data and performs poorly on untrained data, this is known as overfitting. Because of the time it takes for a network to settle to its ideal state and integrate, the dropout is introduced as a third layer that has no effect on the other layers. [20]. The model's use of dropout, which randomly sets some units to zero to avoid overfitting, is demonstrated in Eq. (2) below. The dropout mask m is applied elementwise:

$$Z' = m \odot Z, m \sim Bernoulli(p) \quad (2)$$

Where p is the dropout rate. The study uses the dropout rate of 0.5.

The TimeDistributed layer, the fourth layer employed in the study, applies a dense layer operation to each time step of a sequence separately. This is helpful since each input sequence comprises several time steps, and each time step requires the application of the same operation (dense layer).

$$h_t = f(W_h \cdot Z_t + b_h), W_h \in \mathbb{R}^{64X128} \quad (3)$$

Z_t is the embedding of a word in a sentence, with a dimensionality of 128.

W_h transforms the embedding into a hidden state h_t with dimension 64 capturing relevant contextual features for that word.

f is a tan function, commonly used in recurrent networks.

The hidden state h_t is then passed to the next layer which is the BiLSTM for further processing.

Equation overview:

Input: $z_h \in \mathbb{R}^{128}$

Weights: $W_h \in \mathbb{R}^{64X128}$

Bias: $b_h \in \mathbb{R}^{64}$

Output: $h_t \in \mathbb{R}^{64}$

The architecture's fifth layer, called BiLSTM, is made up of two LSTM layers placed next to each other. To record the past and future context of the sequence, the layer employs forward and backward LSTMs, as illustrated in Fig. 5 BiLSTM architecture. 64 units make up the return sequence, which is equivalent to the true.

The BiLSTM calculates:

$$h_t = concat(\overrightarrow{h_t}, \overleftarrow{h_t}) \quad (4)$$

where, $\overrightarrow{h_t}$ is a hidden state from forward LSTM and $\overleftarrow{h_t}$ is a hidden state from backward LSTM.

At the end of the model comes the Final TimeDistributed Layer, which assigns NER tags to every token. This layer functions as the model's classifier in essence. The layer's output shape is (None, 128, 9) with 9 representing the number of NER tags.

The probability at each timestep t are calculated by the SoftMax function:

$$p(y_t = c) = \frac{\exp(W_c.h_t + b_c)}{\sum_{c'} exp(W_{c'}.h_t + b_{c'})} \quad (5)$$

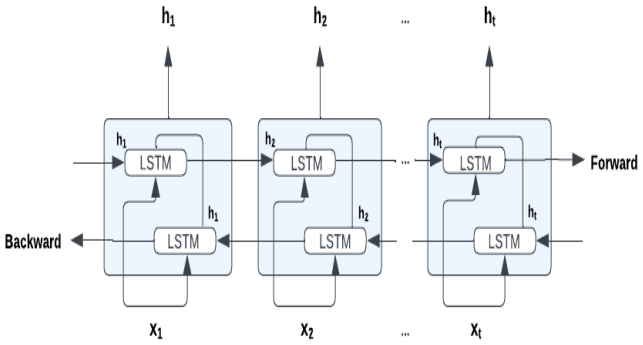

Fig. 5. BiLSTM achitecture (Adopted from [7]).

E. CNN-BiLSTM Model Algorithm Logic

Table II CNN-BiLSTM Model Algorithm, displays the NER method utilizing a hybrid CNN-BiLSTM model. The first step in the method is loading and preprocessing the dataset, which entails applying tokenizers and uniformity padding sequences to transform sentences and tags into numerical representations. After removing the final classification layer for transfer learning, a pretrained CNN model is loaded to extract spatial information. A BiLSTM layer is applied to the extracted features to record contextual data and temporal dependencies. The model iteratively adjusts weights depending on batches throughout training until convergence. Following the model's evaluation on the test set, metrics like as precision, recall, and F1-score are used to examine the findings, allowing for any necessary retraining or additional hyperparameter modification.

F. Performance Metrics

Performance metrics like precision, recall, and F1-Score are used to analyze the results once the model has been evaluated on the test set, as shown in the preceding section. This enables any necessary retraining or further hyperparameter change.

Using the metrics from the calculated formulas on Eq. (6), (7), and (8), the model generates a classification matrix. The F1-score, Accuracy, and Recall are determined by utilizing the true positives (TP), false negatives (FN), and false positives (FP). Appropriately defined situations are considered true positive. False positives are instances that were incorrectly labeled, and false negatives are instances that the system failed to detect. The F1-Score is the weighted mean of Precision and Recall [21]. These metrics are generated in the manner described below equations:

$$Precision = \frac{TP}{TP+FP} \quad (6)$$

$$Recall = \frac{TP}{TP+FN} \quad (7)$$

$$F = 2 * \frac{precision*recall}{precision+recall} \quad (8)$$

IV. Results

The results of the Setswana NER models are presented in this part along with an explanation of how evaluation indexes were used to calculate precision, recall, and F1-Score values. A classification report also includes these evaluation indices of named entities' performance on each of the five models created for the study.

A. Data Distribution

The study experiment's dataset splits 20% and 80% into test and training datasets, respectively. Using the train_test_split function from the sklearn library's model_selection module, it was split and randomized.

B. Performance Metrics

These results indicate the performance of different models in terms of Precision, Recall and F1-Score as shown in Table III Models 3, 4 and 5 have the maximum training accuracy of 99% although both Models 3 and 5 have lower average precision than Model 4.

C. Evaluation Measures

Table IV presents performance indicators that illustrate the accuracy and loss for training and validation across different models. Among them, Model 4, which integrates CNN and BiLSTM at the sentence level, demonstrates strong generalization ability. It achieves a well-balanced accuracy and loss, recording the lowest validation loss (0.0093) and the highest validation accuracy (0.9976).

TABLE III. Performance Comparison for 5 Developed NER Models

5 Setswana NER models				
Model	***Precision***	***Recall***	***F1-Score***	
Model 1: CNN-Word Level			**0.94**	**Accuracy**
Model 1: CNN-Word Level	0.75	0.59	0.65	Macro avg
Model 1: CNN-Word Level	0.93	0.94	0.93	Weighted avg
Model 2: CNN-BiLSTM transfer learning Word Level			**0.96**	**Accuracy**
Model 2: CNN-BiLSTM transfer learning Word Level	0.83	0.71	0.75	Macro avg
Model 2: CNN-BiLSTM transfer learning Word Level	0.95	0.96	0.95	Weighted avg
Model 3: CNN-Sentence Level			**0.99**	**Accuracy**
Model 3: CNN- Sentence Level	0.82	0.65	0.72	Macro avg

Model 4: CNN-BiLSTM transfer learning Sentence Level			**0.99**	**Accuracy**
Model 4: CNN-BiLSTM transfer learning Sentence Level	0.85	0.70	0.76	Macro avg
Model 4: CNN-BiLSTM transfer learning Sentence Level	0.99	0.99	0.99	Weighted avg
Model 5: CNN-BiLSTM Sentence Level			**0.99**	**Accuracy**
Model 5: CNN-BiLSTM Sentence Level	0.78	0.69	0.73	Macro avg
Model 5: CNN-BiLSTM Sentence Level	0.99	0.99	0.99	Weighted avg

TABLE IV. PERFORMANCE INDICATORS

5 Setswana NER models Performance Indicators				
Model	***Training Accuracy***	***Validation Accuracy***	***Training Loss***	***Validation Loss***
Mode l : CNN-Word Level	0.9416	0.9601	0.2500	0.1165
Mode 2: CNN-BiLSTM Transfer Learning-Word Level	0.9566	0.9600	0.1323	0.1364
Mode 3: CNN-Sentence Level	0.9971	0.9937	0.0076	0.0315
Mode 4: CNN-BiLSTM Transfer Learning-Sentence Level	0.9983	0.9976	0.0046	0.0093
Mode 5: CNN-BiLSTM-Sentence Level	0.9997	0.9926	0.0012	0.0474

V. DISCUSSIONS

A discussion of the findings and a comparison of our model's results with those of the baseline models are presented in this section.

A. Performance Metrics Discussion

Models 3, 4, and 5 scored the greatest accuracy of 0.99 among the five Setswana NER models assessed, as from the results. Model 4 (CNN-BiLSTM transfer learning at the sentence level) scored better than the others for macro-average measures (accuracy of 0.85, recall of 0.70, and F1-Score of 0.76), which take class imbalance into consideration. The weighted averages for Models 3, 4, and 5 are extraordinarily high, with each model earning 0.99 for precision, recall, and F1, which represents the overall model performance across all classes. As the top-performing model for Setswana NER tasks, Model 4: CNN-BiLSTM transfer learning Sentence Level is suggested due to its high accuracy, weighted averages, and improved macro-average performance.

B. Evaluation Measures Discussion

When compared to sentence-level models, the performance indicators in Table IV demonstrates that Model 1 (CNN-Word Level) has the lowest validation accuracy (0.9601) despite achieving comparatively high accuracy. The training accuracy of Model 2 (CNN-BiLSTM Transfer Learning-Word Level) is somewhat higher than that of Model 1 (0.9566), while the validation accuracy is similar (0.9600). This suggests that while BiLSTM and transfer learning enhance training performance, they have no noticeable effect on word-level validation accuracy. When modeling sentence-level settings, Model 3 (CNN-Sentence Level) performs better, as seen by its significantly greater accuracy (0.9971 training, 0.9937 validation). The second highest accuracy for both training (0.9983) and validation (0.9976) is attained by Model 4 (CNN-BiLSTM Transfer Learning-Sentence Level), suggesting that integrating BiLSTM with sentence-level modeling and transfer learning significantly improves performance. Although Model 5 (CNN-BiLSTM-Sentence Level), the final model, has the highest training accuracy (0.9997), it may be overfitting because its validation accuracy (0.9926) is marginally lower than Model 4.

Model 4 (CNN-BiLSTM Transfer Learning-Sentence Level) is the most successful model when accuracy and loss are balanced since it obtains the lowest validation loss (0.0093) and the highest validation accuracy (0.9976), indicating good generalization capabilities.

C. Comparison with Previous Work

The models demonstrate different strengths in recall, F1-Score, and overall efficacy for Setswana NER, according to the performance comparison with baseline models that are already in the literature, as indicated in Table V, performance comparison with other existing work in Setswana NER. With an F1-Score of 78.06%, the Conditional Random Fields (CRF) baseline performs well overall, making it a solid benchmark. The BiLSTM-aux models have somewhat lower F1-Scores; their moderate efficacy is shown by their 74.07% BiLSTM-aux emb score. The CNN NER model in [7] shows inconsistent predictions, performing poorly in F1-score (62%) but well in recall (94%). In contrast, the CNN-BiLSTM model achieves a competitive F1-score (71%) while also improving recall (96%) [7]. But the CNN-BiLSTM transfer learning sentence-level model that was suggested works better than the others, with the highest recall (99%) and a high F1-Score (70%). The CNN-BiLSTM transfer learning sentence-level model is therefore suggested as the top-performing model for Setswana NER because of its competitive overall performance and superior recall.

TABLE V. PERFORMANCE COMPARISON WITH OTHER EXISTING WORK IN SETSWANA NER

Comparison Analysis				
Model	***Dataset***	***Recall***	***F1-Score***	
Conditional random fields (CRF) baseline NER for Setswana (Loubser, M. and Puttkammer, M.J., 2020)	NCHLT Setswana Named Entity Annotated Corpus	80.86%	75.47%	78.06%
bilstm-aux (Loubser, M. and Puttkammer, M.J., 2020)	“	74.14%	77.42%	75.74%
bilstm-aux emb (Loubser, M. and Puttkammer, M.J., 2020)	“	73.45%	74.71%	74.07%
CNN NER Model for Setswana NER (Chabalala, S., Owolawi, P. and Ojo, S., 2023)	“	77.00%	62.00%	94.00%

Our CNN-BiLSTM transfer learning Sentence Level	"	85.00%	70.00%	99.00%

VI. Conclusion

For the Setswana Language NER, the study suggested five models. The first two models, CNN and CNN-BiLSTM Transfer learning, are all based on word terms followed by the final three models, CNN, CNN-BiLSTM Transfer learning, and CNN-BiLSTM hybrid, which are all based on sentence-level. The evaluation was conducted on the South African Centre for Digital Language Resources (SADiLaR) NER dataset, and the top-performing model was ultimately compared to the state-of-the-art Setswana NER models that had already been published in the literature and were created using the same dataset. The top-performing model is Model 4 (CNN-BiLSTM Transfer Learning-Sentence Level), which attains the best macro averages, outstanding weighted averages, and high accuracy 99%. All classes, including minority ones, are balanced in terms of generality. As a result, sentence-level models perform better than word-level models since they can gather more contextual data, which enhances their efficiency. This model outperforms the state-of-the-art models in terms of accuracy (99%) and recall (85%), indicating its high precision and capacity to accurately identify most entities. Despite having a little lower macro average F1-Score (70%) than other models, its total performance, especially the accuracy and recall combination, makes it the best.

In addition to performing better than the other four models in this work, including models from literature, the suggested model has certain drawbacks because of its short dataset size, since deep learning algorithms often require huge datasets. Even though this work attempted to address this constraint through transfer learning, it was insufficient to completely address it; therefore, to further address this limitation, we recommend future research on the two domains indicated below as well as on the other fields.

Investigating cross-lingual transfer learning techniques may be valuable given the limitations of the current dataset and the generally scarce resources for the Setswana language. This study focused exclusively on NER in Setswana, with an emphasis on the South African Centre for Digital Language Resources (SaDilar) NER dataset, allowing for comparison with previous research conducted on the same dataset. Therefore, using tagged data from resource-rich languages could significantly improve the model's functionality in Setswana NER.

Error analysis: To identify any trends or problems the model shares, an error analysis can be conducted to inform future enhancements.

Consequently, it may be beneficial for future study to apply transformers, multilingual models like BERT, RoBERTa, or XLM-R, include larger and more varied datasets, and further optimize hyperparameters.

Dataset bias: The study has demonstrated that the dataset contains biases. Future studies should examine rebalanced datasets by adding more diverse named entities to alleviate these biases, particularly in underrepresented categories such as B-LOC, B-PERS, and B-ORG. Adding more foreign locales and English-Setswana mixed items to the dataset would also increase its robustness.

Acknowledgment

I would want to thank my family from the bottom of my heart for their unwavering support during this work.

Planning and Design of Elderly Care Space Combining PER and Dueling DQN

Di Wang, Hui Ma*, Yu Chen
College of Art and Design, Jilin Jianzhu University, Changchun, 130118, China

***Abstract*—With the continuous development of the aging phenomenon in society, people's attention to the planning of elderly care spaces is increasing. Currently, many scholars have used various spatial planning models to plan and design elderly care spaces. However, the resource utilization rate and comfort of the elderly care spaces designed by these models are low, and the models still need to be optimized. This study first integrates the Prioritized Experience Replay mechanism with the Dueling deep Q-network algorithm, and constructs a spatial planning model based on the fused algorithm, to use this model to plan elderly care spaces reasonably. The study first conducts comparative experiments on the fusion algorithm, and the outcomes indicate that the fusion algorithm has the best prediction performance, with a minimum prediction error rate of only 0.9% and a prediction speed of up to 8.7bps. In addition, the denoising effect of the algorithm is the best, and the performance of the algorithm is much higher than that of the comparative algorithm. Further analysis of the spatial planning model based on this algorithm shows that the average time required for elderly care space planning is only 1.3 seconds, and the comfort level of the planned elderly care space reaches 98.7%, the resource utilization rate reaches 89.7%, and the planned elderly care space can raise the living standard of the elderly by 67.7%. From the above information, the spatial planning model raised in the study can validly enhance the resource utilization and comfort of elderly care spaces, and raise the living standard of the elderly.**

Keywords*—*Elderly care space; planning and design; prioritized experience replay; dueling deep q-network algorithm; spatial planning

I. Introduction

With the continuous aggravation of the aging problem in society, the attention to the rationalization of elderly care space planning and design is constantly increasing [1]. Reasonable planning and design of elderly care spaces can create a comfortable, safe, and natural living environment for the elderly, improving their quality of life. In addition, it can also provide sufficient outdoor activity space for the elderly, promoting physical and mental health [2]. With the sustained growth of computer technology, numerous scholars have conducted research on spatial planning and design methods using intelligent algorithms and physical models [3-4]. However, these spatial planning and design methods still have problems such as slow spatial planning speed and low utilization of spatial resources, and optimization of planning models is needed. The Dueling Deep Q-Network (Dueling DQN) algorithm can improve its learning efficiency through Q-values, thereby accelerating spatial planning speed. The Prioritized Experience Replay (PER) mechanism can accelerate the convergence speed of the algorithm through its priority sampling method. In order to improve the spatial planning speed of the elderly care space planning model, enhance the resource utilization rate in the elderly care space, and ensure the quality of life and mental health of the elderly, this study organically combines the PER mechanism with the Dueling DQN algorithm, and constructs an elderly care space planning and design model based on the combined PER-Dueling DQN algorithm. The innovation of this study lies in optimizing the uniform sampling in the Dueling DQN algorithm through the priority sampling technique in the PER mechanism, in order to reduce the adverse effects of uniform sampling on the calculation accuracy of the Dueling DQN algorithm. The contribution of the research lies in the fact that through reasonable planning of elderly care spaces, it can improve the quality of life of the elderly, promote equal social welfare and public services, drive the development of the elderly care industry, and better cope with population aging.

II. Related Work

With the rapid development of computer technology, many scholars have conducted research on spatial planning and design methods using intelligent algorithms and mathematical models. For example, Gu Y et al. raised a spatial planning model grounded on the least squares parameter estimation method to plan and design the state space of the simulated product portfolio. The model was tested in practical situations, and the outcomes indicated that the spatial planning time of the model was only 3.2 seconds [5]. SS VC et al. developed a space design model grounded on metaheuristic algorithm to address the problem of high memory resource utilization in current engineering space design models. The model was compared with traditional space design models, and the results showed that the model could reduce resource utilization by 23.1% [6]. In addition, to deal with the issue of high computational complexity in diffusion grounded spatial model planning, Karras T et al. raised a spatial design model grounded on fractional network preprocessing method, which was used for detection in practical situations. The outcomes indicated that the computational complexity of this model was reduced by 12.6% compared to traditional spatial planning models [7]. However, there are still problems with slow spatial planning speed and low utilization of spatial resources in the above spatial planning models, and the model still needs to be optimized [8].

Dueling DQN algorithm is an algorithm that can improve computational efficacy and steadiness by separating state value and dominance function [9]. This algorithm is commonly applied in various models due to its ability to validly reduce the quantity of parameters and high applicability. For example, Chi

J et al. designed a deep reinforcement training model grounded on the Dueling DQN algorithm to solve the matters of slow convergence speed and low training accuracy in the deep reinforcement training process. The model was compared with traditional models, and the outcomes indicated that the convergence speed of the model was improved by 19.5% [10]. However, there are still problems with poor learning efficiency and slow convergence speed caused by the uniform sampling mechanism in this algorithm [11]. PER mechanism can improve the convergence speed and learning efficiency of algorithms by sampling based on priority [12]. This mechanism is also commonly utilized in various areas to raise the convergence speed and computational precision of models [13].

To sum up, although many researchers have carried out studies on spatial planning models, these models still suffer from slow planning speed and low utilization of spatial resources, and further improvements are needed. Therefore, this study organically combines the PER mechanism with the Dueling DQN algorithm, and constructs a retirement space planning and design model based on the combined PER Dueling DQN algorithm, to use this model to plan retirement spaces reasonably and guarantee the living standard and mental health of the elderly.

III. Methods and Materials

A. Dueling DQN Algorithm Based on Per Optimization

Elderly care space refers to a social space that provides safe, comfortable, and convenient living and living environments for the elderly [14]. The main purpose of this space is to meet the material and spiritual needs of the elderly and help them maintain physical health [15]. With the continuous development of the aging phenomenon, people's attention to elderly care space is constantly increasing. Thoughtful design and strategic planning of spaces for elderly care can guarantee financial stability for individuals as they age [16]. However, many spatial planning models currently suffer from insufficient coordination and low utilization of spatial planning resources, and further optimization of the models is needed. The Dueling DQN algorithm is an improved Q-learning algorithm that can improve learning efficiency by decomposing Q-values and effectively handle complex spatial states and decision problems [17]. The basic process of this algorithm is shown in Fig. 1.

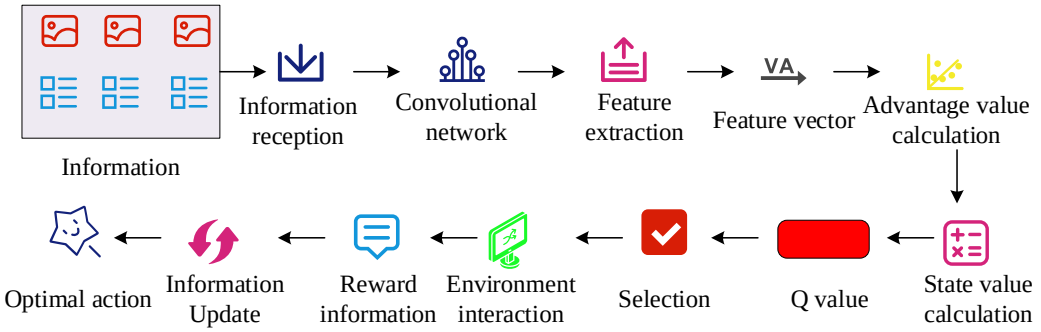

Fig. 1. Basic process of dueling DQN algorithm.

In Fig. 1, the algorithm first needs to receive input state information, which includes multiple images or chart data. Then, the convolutional network is applied to identify the features of the state information and generate feature vectors. Then, the evaluation network and target network in the dual network are used to calculate the value of state information and the advantage value of each action. The calculated state value and action advantage value are added to obtain the Q value of each action. Using the computed Q value, the best course of action is chosen, typically opting for the action with the highest Q value for implementation. After determining the execution action, it engages with its surroundings to acquire rewards and updated state data. The neural network's parameters undergo modification grounded on the obtained new state information and reward mechanism, so that the algorithm can find the optimal action execution. The calculation method of Q value is shown in Eq. (1).

$$Q(S,A,w,\alpha,\beta) = V(S,w,\alpha) + \left(A(S,A,w,\beta) - \frac{1}{|A|}\sum_{a\in A} A(S,\alpha,w,\beta)\right) \quad (1)$$

In Eq. (1), S means the information state, A means the action, w means the network parameters of the common part, α means the network parameters unique to the value function, β means the network parameters unique to the advantage function, $Q(S,A,w,\alpha,\beta)$ means the calculated Q value, $V(S,w,\alpha)$ means the value function part related to the state function, and $A(S,A,w,\beta)$ means the advantage function related to both the state and action. The calculation method of the state value function is shown in Eq. (2).

$$V(s) = f(s;\theta) \quad (2)$$

In Eq. (2), $V(s)$ means the action function in state s, f means the neural network used to calculate the state value, and θ means the parameters of the state value function used to optimize the neural network. The calculation formula for the action advantage function is shown in Eq. (3).

$$A(s,a) = Q(s,a) - V(s) \quad (3)$$

In Eq. (3), $Q(s,a)$ means the Q value of taking action a in state s, and V means the value function. When performing feature extraction operations in the convolutional layer, it is necessary to calculate the computational and parameter quantities of the convolutional layer in order to

optimize the network structure and design a reasonable convolutional layer structure and parameters. The calculation method for the parameter quantity of the convolutional layer is shown in Eq. (4).

$$N = k \times k \times C_{in} \times C_{out} \tag{4}$$

In Eq. (4), N means the number of parameters in the convolutional layer, k means the size of the convolutional kernel, C_{in} means the number of input channels, and C_{out} means the number of output channels. The calculation method for the computational complexity of the convolutional layer is shown in Eq. (5).

$$N' = W_{out} \times H_{out} \times k \times k \times C_{in} \times C_{out} \tag{5}$$

In Eq. (5), N' means the computational complexity, and W_{out} and H_{out} mean the width and height of the output feature map. The optimal action can be found through the above calculation. However, due to the uniform sampling mechanism, the Dueling DQN algorithm may reduce its learning efficiency and effectiveness, and further optimization of the algorithm is needed. The PER mechanism is a commonly-used technique in reinforcement learning, which can improve the computational speed and learning efficiency of algorithms by prioritizing sampling the most valuable experiences for learning [18]. The basic structure of PER mechanism is in Fig. 2.

As shown in Fig. 2, the PER mechanism consists of five parts: experience pool, time difference error calculation, sampling probability calculation, sampling process, and policy update. The experience pool is a data storage pool that contains the experience data obtained by the algorithm during each interaction with the environment during reinforcement learning, including the current state, actions taken, rewards obtained, and next state. The calculation of time difference error refers to the calculation of the difference between the current Q value and the target Q value. The larger the Q value and temporal error of the experience, the higher the importance of the experience in algorithm learning. The sampling probability of each experience is calculated again, the sampling probability of each experience is calculated, and the experience with high sampling probability is prioritized for training by PER, thereby reducing unnecessary learning time and accelerating algorithm convergence to get the best solution. Finally, the Q value parameter or strategy parameter is adjusted based on the calculated sampling probability and time difference error to improve the algorithm's computation speed and learning efficiency. The calculation method of time difference error in this algorithm is shown in Eq. (6).

$$TD = Q(s,a) - (r + \gamma * V(s') - V(s)) \tag{6}$$

In Eq. (6), r means the immediate reward obtained from executing action a from state s, γ means the discount factor, and $V(s')$ and $V(s)$ mean the value estimation functions of the current state and the next state. The calculation method of sampling probability is shown in Eq. (7).

$$E[f(x)] = 1/m \sum_{i=1}^{m} f(xi) \tag{7}$$

In Eq. (7), m means the total number of sampling times, xi means the sampled samples, and $f(xi)$ means the function value of the samples. To improve the drawbacks of slow computation speed and low learning efficiency caused by uniform sampling methods in the Dueling DQN algorithm, this study utilizes the PER mechanism to optimize the Dueling DQN algorithm. The basic process of the optimized PER-Dueling DQN algorithm is in Fig. 3.

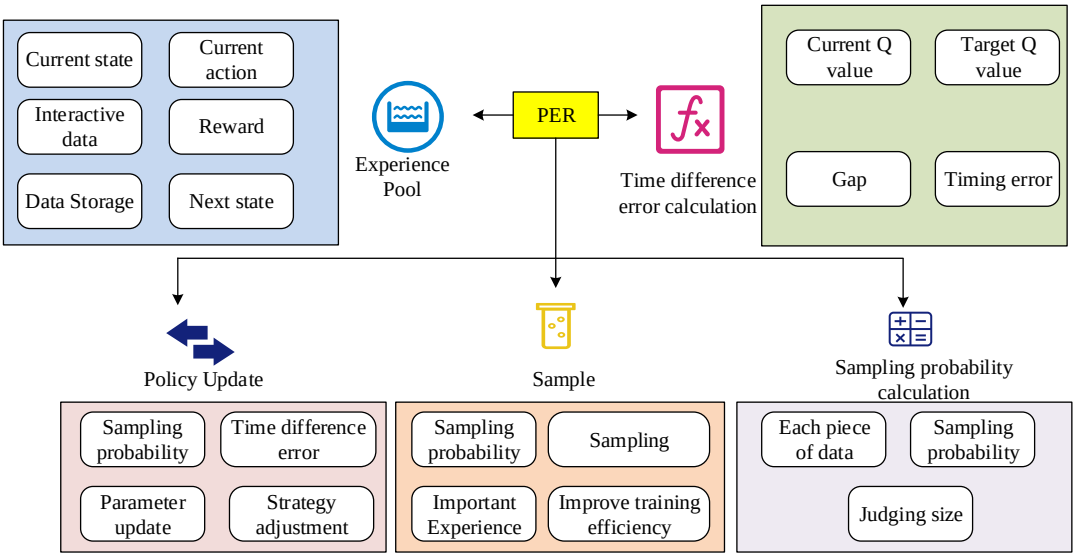

Fig. 2. Basic structure diagram of PER mechanism.

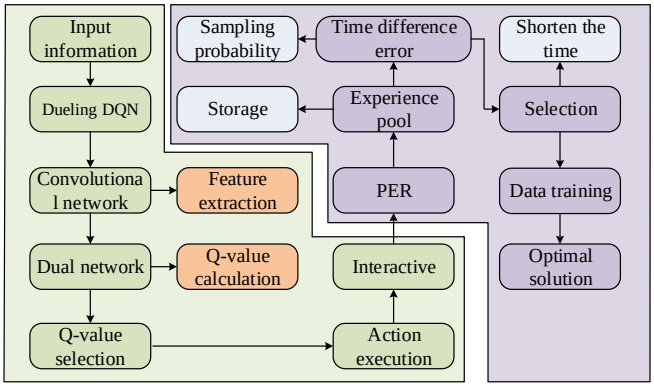

Fig. 3. Basic process of PER-dueling DQN algorithm.

As shown in Fig. 3, after receiving various input information, the PER-Dueling DQN algorithm first uses the convolutional network in the Dueling DQN algorithm to extract features, and then uses the dual network in the algorithm to calculate the Q value of each piece of information. The action with the highest Q value is chosen for execution. After the action is executed, when the algorithm interacts with the environment, the experience pool in the PER mechanism is used to store the experience obtained after each action interaction. The time discrepancy error and sampling likelihood of each action are computed, and the empirical data with high sampling likelihood and minimal temporal error are chosen for training. This approach minimizes unnecessary training duration and enhances both the computational speed and training efficiency of the algorithm.

B. *Retirement Space Planning Model Based on PER-Dueling DQN Algorithm*

In response to the problems of poor spatial planning effectiveness and long planning time in current elderly care space planning models, this study uses the PER-Dueling DQN algorithm proposed in the previous section to optimize the spatial planning model, aiming to raise the planning efficiency of the model and reduce the planning time of the model. The basic framework of the elderly care space planning model grounded on PER-Dueling DQN algorithm is shown in Fig. 4.

From Fig. 4, the model first needs to clarify the planning goals and objectives, namely the quality of life, medical security, and leisure activities for individuals after retirement. Secondly, it is necessary to evaluate the existing assets, income, and expenses of individuals or families to determine retirement funds. Then, based on the determined retirement funds, a suitable pension plan should be developed, including pension investment portfolio, pension insurance, and retirement pension plan. Then, the pension plan is followed, and corresponding adjustments are made according to the actual situation. Finally, spatial planning and design are carried out. The planning and design of elderly care spaces first need to collect relevant information about space use, management, and functions. Then, the collected information and planning objectives are input into the PER-Dueling DQN algorithm to find the optimal planning path, that is, the optimal spatial planning and design scheme. After finding the optimal design scheme, it is necessary to verify the scheme to determine its practical feasibility. Finally, the plan is recorded and a planning and design report is generated, which is submitted to relevant personnel for review and evaluation. If the evaluation is qualified, the elderly care space planning and design will be carried out according to the plan. If the evaluation is not qualified, the plan selection will be repeated until it is qualified. In spatial planning and design, it is necessary to calculate the volume of various objects in space, as well as the strength of objects and structures in space, in order to design the structures in space. The calculation method for the volume of various objects is shown in Eq. (8).

$$\begin{cases} V1 = c^3 \\ V2 = \pi r^2 h \\ V3 = 3/4\pi r^3 \end{cases} \tag{8}$$

In Eq. (8), $V1$ means the volume of the cube, c means the side length of the cube, $V2$ means the volume of the cylinder, r means the radius, h means the height, and $V3$ means the volume of the sphere. The strength calculation method for beam objects in space is shown in Eq. (9).

$$\begin{cases} \sigma = M\max / Wz \\ \tau = V''S'' / Wit \end{cases} \tag{9}$$

In Eq. (9), σ means the maximum stress of the beam material, $M\max$ means the maximum bending moment, $V(s')$ and Wz mean the section modulus, τ means the material shear stress, V'' means the material shear force, S'' means the material gross section area, and Wit means the gross section moment of inertia. The calculation method for the strength of a pole in space is shown in Eq. (10).

$$\begin{cases} F1 = Pq / \varepsilon \\ F2 = \delta 1 / \delta 2 \end{cases} \tag{10}$$

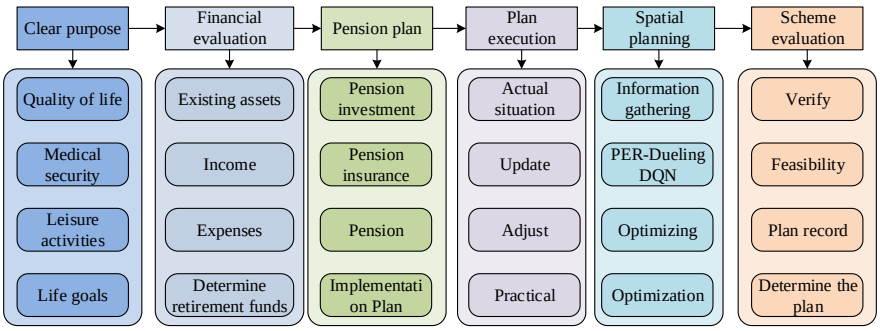

Fig. 4. Retirement space planning model based on PER-Dueling DQN algorithm.

In Eq. (10), $F1$ means the tensile strength of the rod, Pq means the yield strength of the rod, ε is the safety factor, $F2$ is the bending strength, δ is the bending moment, and $\delta 1$ means the bending moment resistance. In the planning of elderly care space, compound interest terminal value can help planners better plan elderly care funds. By selecting the initial investment amount and investment time reasonably, it ensures that the funding needs of the elderly care space are met. The calculation formula is shown in Eq. (11).

$$Fv = Pv \times (1+r)^n \tag{11}$$

In Eq. (11), Fv means the terminal value, Pv means the present value, r means the interest rate, and n is a term number. The application principle of PER-Dueling DQN algorithm in elderly care space planning is shown in Fig. 5.

In Fig. 5, in the planning and design of elderly care space, this algorithm first needs to receive the spatial data collected in the early stage, as well as the spatial planning purpose and requirements, and preprocess these data to denoise the data information. Then the eval network and target network in the PER-Dueling DQN algorithm, namely the evaluation network and target network, are initialized. Spatial information is input into the eval network to calculate the Q value of each action, that is, the Q value of each planning and design scheme. The action with the highest Q value is chosen for execution, and the current action, state, and the next state after completing the action are stored in the PER's experience pool. Once all actions have been executed and states recorded, the temporal difference error for each piece of data in the experience replay buffer is computed to establish its priority. The data with larger errors has higher priority. A batch of data is selected by priority from the experience pool and input into the eval network, where the current Q value is calculated. At the same time, these data are input into the target network to calculate the target Q value. The mean square deviation between the current Q value and the target Q value is used as the loss function. Based on this loss function, the parameters of the eval network are backpropagated and updated, and the parameters of the target network are synchronously updated. The above steps are repeated until the preset training coefficients are reached or the optimal solution is found, that is, the spatial optimal planning and design scheme. The optimal solution is output and recorded. The calculation method for the target Q value is shown in Eq. (12).

$$Y = \chi + \gamma Qt(s', \max a')Qe(s', a', \theta', \theta'') \tag{12}$$

In Eq. (12), χ represents the immediate reward, Qt is the target network, Qe represents the estimation network, θ' represents the parameters of the estimation network, and θ'' represents the parameters of the target network. Through the above process, the optimal planning and design scheme for the elderly space is obtained, in order to meet the material, spiritual, and social needs of the elderly, and help them maintain physical health, independent living, and mental vitality.

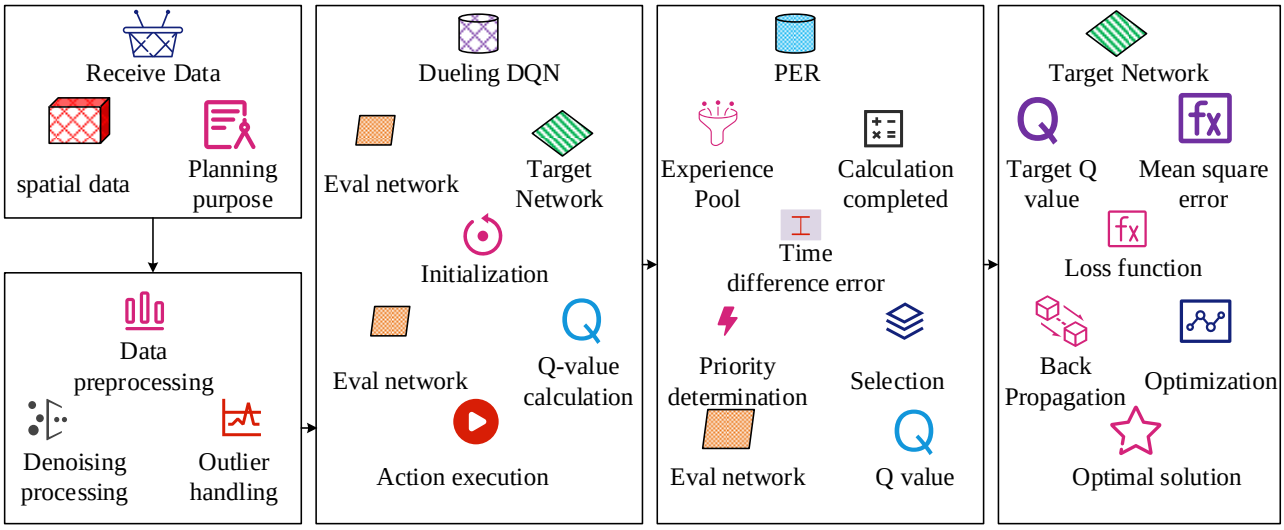

Fig. 5. Application principle of PER-dueling DQN algorithm.

IV. Results

A. Performance Analysis of PER-Dueling DQN Algorithm

In order to analyze the superiority of the prediction performance of the PER-Dueling DQN algorithm, this study conducted comparative experiments between the PER-Dueling DQN algorithm and the Genetic Algorithm-Back Propagation (GA-BP) algorithm, the Particle Swarm Optimization-Support Vector Machine (PSO-SVM) algorithm, and the Dueling DQN algorithm before optimization using the PER mechanism. The environment configuration during the experiment is in Table I.

TABLE I Experimental Environment Configuration

Experimental environment	Index	Style
Hardware environment	CPU	Intel Core i9
	EMS memory	64GB
Software environment	OS	Windows 10
	Python edition	Python 4.0
	Python environment	Anaconda 3

During the experiment, the ImageNet dataset was chosen as the experimental dataset, which contains 22000 categories of image data. The predictive performance of the four algorithms was analyzed through the above experimental environment configuration and experimental dataset. Firstly, the validity of the dataset was verified using k-fold cross validation. The dataset in ImageNet was evenly divided into (a, b, c, d, e) 5 parts, and four parts were used for testing. The remaining dataset was used for validation. The selection of the dataset was validated by testing each part of the dataset. The results are shown in Table II.

According to Table II, each dataset in the ImageNet dataset had a relatively low impact on the PER-Dueling DQN algorithm, indicating that the selection of this dataset was reasonable. The prediction performance of the four algorithms was compared, and the results are shown in Fig. 6.

TABLE II RESULTS OF RATIONAL TESTING OF DATA SETS

Training dataset	Test dataset	PER-Dueling DQN prediction accuracy	PER-Dueling DQN denoising accuracy
a,b,c,d	e	98.7%	93.2%
a,b,c,e	d	97.9%	92.8%
a,b,d,e	c	97.9%	92.7%
a,c,d,e	b	98.1%	93.1%
b,c,d,e	a	98.6%	93.5%

The red dashed line in Fig. 6 represents the areas where the predicted values differ from the actual values. From Fig. 6, among the four algorithms, only the PER-Dueling DQN algorithm had similar forecasted values to the true values. However, GA-BP algorithm, PSO-SVM algorithm, and Dueling DQN algorithm had different degrees of error between their forecasted values and true values after predicting the data, with Dueling DQN algorithm having the largest error between the forecasted values and true values. By comparing the prediction errors and speeds among the four algorithms, the results are presented in Fig. 7.

According to Fig. 7 (a), among the four algorithms, the PER-Dueling DQN algorithm had the lowest prediction error, only 0.9%, while the GA-BP algorithm, PSO-SVM algorithm, and Dueling DQN algorithm had prediction errors of 1.6%, 2.1%, and 3.2%, respectively. The prediction errors of the latter three algorithms were much higher than those of the PER-Dueling DQN algorithm. As shown in Fig. 7 (b), the average prediction speeds of PER-Dueling DQN algorithm, GA-BP algorithm, PSO-SVM algorithm, and Dueling DQN algorithm for data were 8.7 bps, 5.7 bps, 4.8 bps, and 2.1 bps, respectively. PER-Dueling DQN algorithm had the fastest prediction speed, while the unoptimized Dueling DQN algorithm had the slowest prediction speed, with a difference of 6.6 bps between the two. Finally, the denoising effects of the four algorithms were compared, and the results are shown in Fig. 8.

In Fig. 8, the PER-Dueling DQN algorithm had the best denoising effect among the four algorithms. After using this algorithm for denoising, the noise information in the data could be almost completely removed. However, after denoising the data, GA-BP algorithm, PSO-SVM algorithm, and Dueling DQN algorithm still contained a large amount of noise information. The denoising performance of the last three algorithms was inadequate, potentially leading to inaccurate predictions when forecasting future data. From the above experimental results, the PER-Dueling DQN algorithm raised in this study had the best denoising effect, the shortest prediction time, the lowest prediction error, and the best prediction effect. Therefore, this study uses the PER-Dueling DQN algorithm to construct a spatial planning model, in order to predict the various performance of elderly space planning through the excellent prediction effect of the PER-Dueling DQN algorithm. By adjusting the elderly space planning scheme based on the prediction results, the comfort and resource utilization of the elderly space can be improved.

B. *Empirical Analysis of PER-Dueling DQN Planning Model*

After verifying the superiority of the prediction performance of the PER-Dueling DQN algorithm, the planning effect of the spatial planning model based on this algorithm was validated. The PER-Dueling DQN model was compared with commonly-used spatial planning models based on Convolutional Neural Networks Simulated Annealing (CNN-SA), Ant Colony Optimization Tabu Search (ACO-TA), and Discrete Grey Wolf Optimization (DGWO). During the experiment, a planning scheme for elderly care space in a certain family was selected as the source of the experimental dataset, which includes information on the size, scale, funding sources, and elderly care goals and needs of the elderly care space. The elderly space planning scheme was optimized using four models, the performance of the elderly space design scheme optimized by the four models was compared, and the advantage of the raised model was verified. Firstly, the planning time and spatial comfort of the four planning models were compared, and the results are shown in Fig. 9.

From Fig. 9 (a), the PER-Dueling DQN spatial planning model took an average of 1.3 seconds to plan the elderly care space, and the comfort level of the elderly care space designed by this model reached 98.7%. The spatial planning time of this model was short, and the planned space had a high comfort level, which was conducive to the living of the elderly. As shown in Fig. 9 (b), the average time taken by the CNN-SA spatial planning model for spatial planning reached 2.2 seconds, which was higher than that of the PER-Dueling DQN model. Moreover, the comfort level of the elderly care space planned by the CNN-SA model was 85.6%. From Fig. 9 (c) and Fig. 9 (d), the average time spent on spatial planning by the ACO-TA and DGWO spatial planning models was much higher than that of the PER-Dueling DQN model. The time spent by the ACO-TA and DGWO models was 2.9 seconds and 3.7 seconds, respectively. The comfort levels of the elderly care space planned by the two models were 78.9% and 68.6%, respectively. Comparing the safety and spatial resource utilization efficiency of the elderly care spaces planned by the four models, the results are shown in Fig. 10.

According to Fig. 10 (a), the PER-Dueling DQN spatial planning model had the highest safety of the elderly care space, reaching 98.3%, which can effectively ensure the safety of the elderly. The safety of the elderly care space designed by the CNN-SA model, ACO-TA model, and DGWO model was 90.2%, 82.6%, and 75.8%, respectively. The safety of the elderly care space planned by the latter three models was much lower than that of the PER-Dueling DQN model. From Fig. 10 (b), among the four models, the PER-Dueling DQN model had the highest utilization rate of spatial resources, reaching 89.7%, while the DGWO model had the lowest utilization rate of spatial resources, only 65.4%. Finally, the impact of elderly care spaces on the elderly was compared, and the data are in Table III.

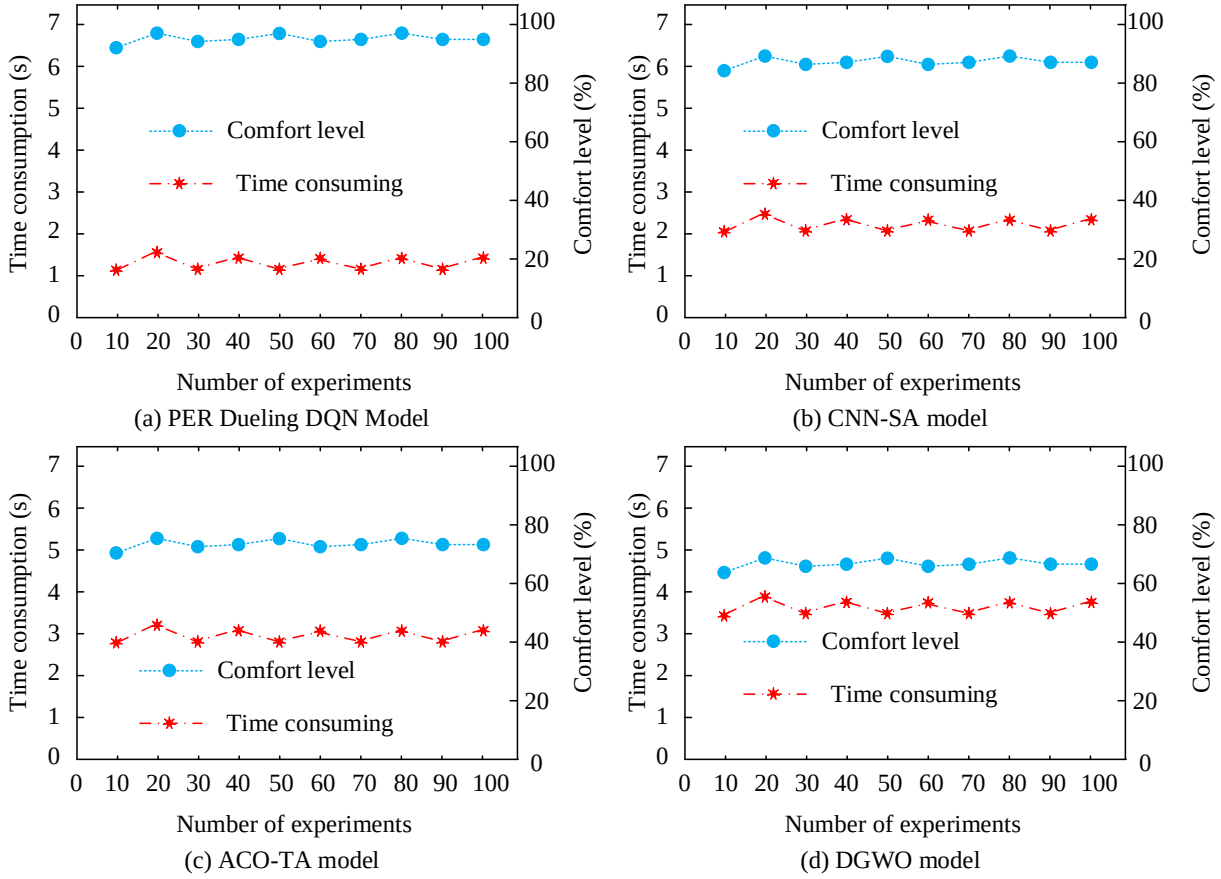

Fig. 9. Model planning time and spatial comfort.

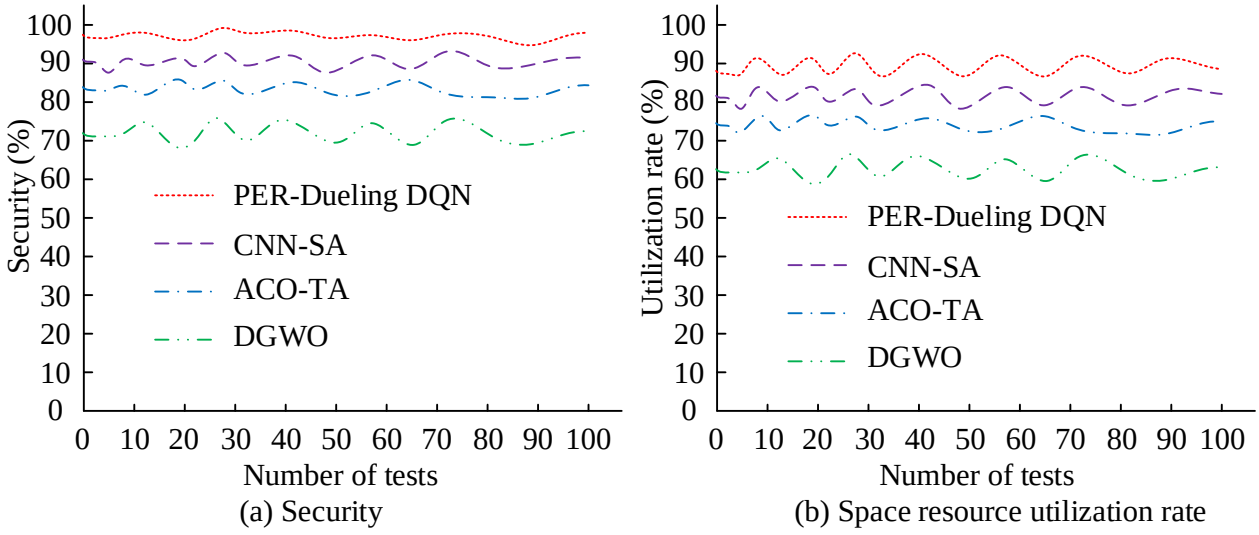

Fig. 10. Comparison of safety and resource utilization in elderly care spaces.

TABLE III ANALYSIS OF THE EFFECTS OF FOUR MODELS ON THE ELDERLY

Model		Quality of life	Mental health	Convenient living	Sense of happiness	Social skills
PER-Dueling DQN	Increase percentage	67.7%	82.4%	88.7%	90.3%	96.4%
	Meet expectations	Y	Y	Y	Y	Y
CNN-SA	Increase percentage	60.5%	74.7%	82.3%	85.8%	89.7%
	Meet expectations	Y	N	Y	N	N
ACO-TA	Increase percentage	50.3%	70.3%	78.7%	80.6%	82.7%
	Meet expectations	N	N	N	N	N
DGWO	Increase percentage	48.7%	68.5%	75.3%	73.8%	72.1%
	Meet expectations	N	N	N	N	N
Expected increase		>50.7%	>75.6%	>80.5%	>88.6%	>90.2%

According to Table III, after using four spatial planning models for elderly care space planning and design, only the PER-Dueling DQN spatial planning model could achieve the expected performance indicators of elderly care space for the elderly. After using the PER-Dueling DQN model, the planned elderly care space could raise the living standard of the elderly by 67.7%, mental health by 82.4%, convenience of life by 88.7%, happiness by 90.3%, and social skills by 96.4%, which was much higher than the expected improvement of 50.7%, 75.6%, 78.7%, 80.6%, and 82.7%. The elderly care space designed using the CNN-SA model could only raise the living standard and convenience of the elderly to the expected level, while other indicators were slightly lower than expected. Although the performance indicators of the elderly care space planned by the ACO-TA model and DGWO model improved, the improvement level of both models was far from meeting the expected requirements. Based on the above information, the PER-Dueling DQN spatial planning model proposed in this study can offer sensible planning and design for elderly care spaces, ensuring a high standard of living for the elderly and enhancing their physical health.

V. DISCUSSION

In response to the problems of poor spatial planning rationality and low spatial comfort in current elderly care space planning models, this study used the PER mechanism to optimize the Dueling DQN algorithm, proposed a PER-Dueling DQN algorithm, and constructed an elderly care space planning model based on this algorithm. To confirm the superiority of the model, comparative experiments were carried out on the optimization algorithm first. The study compared the PER-Dueling DQN algorithm with the GA-BP algorithm, PSO-SVM algorithm, and Dueling DQN algorithm. The results showed that among the four algorithms, the PER-Dueling DQN algorithm had the strongest denoising ability, and its prediction error was only 0.9%, far lower than the other three algorithms. The prediction speeds of PER-Dueling DQN algorithm, GA-BP algorithm, PSO-SVM algorithm, and Dueling DQN algorithm were 8.7 bps, 5.7 bps, 4.8 bps, and 2.1 bps, respectively. PER-Dueling DQN algorithm has the fastest prediction speed, which is similar to the experimental results of Bai Z team [19]. The reason for this result may be that the PER-Dueling DQN algorithm can improve the training speed and efficiency of the algorithm through the priority sampling method in the PER mechanism, thereby ensuring the denoising effect of the algorithm and improving its prediction accuracy. Further experimental analysis was conducted on the spatial planning models based on the PER-Dueling DQN algorithm, CNN-SA spatial planning model, ACO-TA spatial planning model, and DGWO spatial planning model. The results showed that among the four spatial planning models, the PER-Dueling DQN model had the shortest spatial planning time, only requiring 1.3 seconds, and the highest resource utilization rate of the elderly care space planned by the PER-Dueling DQN model reached 89.7%. The elderly care space planned by the PER-Dueling DQN model could raise the living standard of the elderly by 67.7%, improve their mental health by 82.4%, and increase their sense of happiness by 90.3%, which fully met the expected level of improvement. Although the other three models also improved, they could not all meet expectations, which is consistent with the results of Williams R A et al. [20]. The reason for the results may be that the algorithm in the PER-Dueling DQN model has excellent predictive ability, which can continuously optimize the space through the predicted results until the optimal result is reached, thereby improving the performance of the elderly care space.

VI. CONCLUSION

In order to solve the problem of low spatial planning rationality in current elderly care space planning, this study combined PER mechanism and Dueling DQN algorithm, and designed an elderly care space planning model based on the combined algorithm. The study first compared the PER-Dueling DQN algorithm with other related algorithms, and the results showed that the performance of the PER-Dueling DQN algorithm was superior to other algorithms. The elderly space planning model based on the PER-Dueling DQN algorithm could improve the quality of life, mental health status, and happiness of the elderly. From the above results, the suggested elderly care space planning model can effectively improve the comfort of the elderly care space, thereby ensuring the physical and mental health status and quality of life of the elderly. However, although the PER-Dueling DQN algorithm used in this study had excellent prediction performance, it contained many hyperparameters, making parameter tuning difficult. It had high computational complexity and required a large amount of resources. Moreover, in some complex or dynamically changing environments, the PER-Dueling DQN algorithm may

not be able to effectively adapt and achieve optimal algorithm performance. In the future, automated parameter tuning techniques such as Bayesian optimization algorithm and genetic algorithm can be utilized to intelligently select and optimize hyperparameters of algorithms, reducing the difficulty and cost of parameter tuning and lowering computational complexity. Moreover, it can be combined with other reinforcement learning algorithms to form a hybrid algorithm, further improving the performance and stability of the algorithm.

***Abstract*—To deeply investigate the complex relationship between learners' structural characteristics in classroom social networks and the dynamics of learning emotions in smart teaching environments, an innovatively improved RP-GA. All Element Selection Method based on genetic algorithm is proposed. The method calculates the importance of factors based on the random forest model and guides the population initialization together with random numbers to achieve the differentiation and efficiency of factor selection; and utilized the Partial Least Squares regression model in conjunction with a cross-validation optimization model to enhance the accuracy of fitness evaluation, efficiently tackling the issues of premature convergence and low prediction accuracy inherent in traditional genetic algorithms for factor selection. Based on this method, the elements affecting learning emotions are precisely screened, and the intrinsic links between elemental changes and structural properties are deeply analyzed. Experiments show that RP-GA selects a small and efficient number of key elements on public datasets and significantly improves the prediction performance of classifiers such as SVM, NB, MLP, and RF. The proposed learning sentiment all-essential selection method provides effective conditions for classroom network structure characterization and future learning sentiment computation.**

I. Introduction

With the integration and development of teaching practices and emerging information technologies, smart teaching has become an important driver of global education reform and has enabled interactive learning environments, data-driven decision support, and personalized learning experiences, among others, fundamentally reshaping the process of teaching and learning [1]. As an important carrier of information mapping the dimensions of student interactions, learning effectiveness, cognitive processes, and affective learning, the interaction mechanism between its structural properties and student performance has become a hot research topic [2]. Learning emotion, which refers to the learning-related emotional experiences that students produce in intelligent teaching and learning scenarios, covers the basic emotional states (e.g., concentration, confusion, anxiety, excitement, etc.) of the learning process. It is the emotional experience that accompanies students in the cognitive process related to learning content comprehension and knowledge construction, as well as the social-emotional responses generated in teaching activities such as teacher-student interaction and student-student interaction. These rich and diverse learning emotions do not exist in isolation, but are intertwined and influenced by each other with the structural characteristics of the classroom social network. Acquiring heterogeneous information data on students' academic performance, learning behaviors and social relationships through the smart teaching classroom provides a strong data foundation for analyzing the mutual influence relationship between learning emotions and the structural characteristics of classroom social networks, and lays a solid theoretical foundation and scientific basis for the computation and dissemination of learning emotions in the smart classroom scenario [3,4]. Classroom social networks with positivity can facilitate the transmission of positive emotions, while networks full of negativity may lead to an increase in negative emotions [5] The computation and transmission of learning emotions depend on the structural properties of classroom networks, and the structural properties of classroom networks are dynamically influenced by a variety of factors. Therefore, it is important to select the elements that have a significant effect on learning emotions to construct the classroom network, and then analyze the relationship between the changes in the elements and the structural characteristics of the network.

However, existing research on classroom social networks is constructed based on a series of established factors and provides only a preliminary analysis of their network structural characteristics [6-8]. But it failed to delve into how multiple factors affect the dynamics of classroom social networks, as well as how the computation and dissemination of learning emotions intertwine and interact with the structural properties of classroom social networks, a dynamic mechanism that is still under-researched in the existing research. In order to deeply explore the intrinsic connection between the structural characteristics of classroom social networks and learning emotions, this paper proposes a method called Random Partial-Genetic algorithm (RP-GA) for the selection of all elements of classroom social networks. In order to verify the reliability and validity, six public datasets were selected for systematic experiments, and the performance of the RP-GA algorithm on different datasets was comprehensively evaluated by using scientifically reasonable evaluation indexes and strictly controlling experimental variables. Meanwhile, in order to fit the actual needs of smart teaching scenarios, this study specifically collects the SCLE-Dataset of students' learning emotions under smart classrooms. This dataset covers multi-dimensional information of students in the learning process, including but not limited to academic performance, classroom interaction behavior and so on. The RP-GA algorithm is used to mine and analyze the SCLE-Dataset in depth, and the elements that have a significant impact on learning emotions are selected

comprehensively and meticulously. Based on the selected elements, an all-element classroom network model is constructed, which fully considers the dynamic coupling mechanism between the elements and the structural characteristics of the classroom network. Using graph theory, complex networks and other theories and methods, we deeply analyze the dynamic change law between the elements and the network structure characteristics. The results of this research provide solid theoretical support for the future accurate calculation of the propagation of learning emotions in the classroom network, help educators better understand the process of the generation and development of students' learning emotions, and provide a scientific basis for optimizing teaching strategies and creating a positive learning atmosphere.

The main contributions of this study can be summarized in the following two points:

1) An innovative approach to full-factor selection is proposed in RP-GA. The RP-GA algorithm is an innovative extension of genetic algorithm (GA), based on the innovative improvements of factor importance and random number co-guided population initialization and R^2-based PLS regression fitness assessment, which significantly improves the search efficiency and predictive accuracy of the classifier compared with the existing algorithms. In classroom social network-specific scenarios, RP-GA is able to traverse and evaluate numerous factors affecting learning emotions more efficiently, providing a powerful tool for accurately identifying the elements affecting learning emotions.

2) Construct a multi-layer heterogeneous classroom network model based on all elements, while analyzing key structural properties such as network diameter, average degree, clustering coefficient and so on. In-depth exploration of the role of the mechanism that influences the dynamic impact of changes in the emotional elements of learning on the structural characteristics of the network. The construction and analysis of the all-element classroom network model not only provides a solid theoretical foundation for the effective use of network structural characteristics to guide and regulate the learning affective state in the field of educational technology, but also provides a scientific basis for future research on learning affective computation and dissemination.

II. Related Work

In smart teaching scenarios, educational researchers are faced with the challenge of accurately screening out the elements affecting learning emotions from massive data [9]. As a powerful global optimization search algorithm [10], genetic algorithm shows great potential in model optimization and parameter tuning with its robustness, adaptivity and parallel processing capability. In recent years, a variety of improved algorithms based on genetic algorithms have shown remarkable achievements in the field of factor selection research. Izabela et al. [11] proposed a Genetic Algorithm with Aggressive Mutation and Reduced Factors (GAAMmf), which scales down the number of factors while performing the factor selection. Aram et al. [12] proposed an Alternating Sorting Method Genetic Algorithm (ASMGA), which combines genetic algorithm and maximum bounded factor selection in a hybrid packing-filtering algorithm. Deng et al. [13] proposed a Factor Threshold Guided Genetic Algorithm (FTGGA), which first applies the ReliefF algorithm to filter the redundant factors, and then further evaluates the retained subset of factors by FTGGA, which exhibits higher classification accuracy and a smaller subset of factors on a 12-gene microarray dataset. However, these methods mainly focus on the optimization of the algorithm itself, ignoring the important impact of factor quality on algorithm performance. Studies have shown that factor selection and factor importance assessment are critical to the performance of genetic algorithms, and researchers have begun to explore factor importance assessment methods in depth, providing an effective means of assessing the contribution of factor importance to the predictive power of a model. Razmjoo et al. [14] proposed two incremental ranking methods for factors for classification tasks with the aim of developing a factor importance ranking strategy for effective removal of irrelevant factors from the classification model. Kaneko et al. [15] proposed a new Cross-Validated Ranking Factor Importance (CVPFI) method, which achieves stable computation even with a small number of samples and is capable of assessing the importance of strongly correlated factors. Du et al. [16] computed the importance of influencing factors and improved the prediction accuracy of the risk of conflict by constructing a Random Forest model that contains multiple decision trees. Although these methods perform well in specific situations, they fail to effectively utilize factor importance to guide the initial population construction of the genetic algorithm, resulting in inefficient convergence of the algorithm. In order to break through the limitations of existing research, this paper proposes the RP-GA full-factor selection method. The RP-GA algorithm is an innovative extension of the Genetic Algorithm (GA) with two key innovative improvements. Firstly, the algorithm is based on factor importance and random numbers jointly guiding population initialization. Previous studies have failed to fully integrate factor importance into the initial population construction of genetic algorithms, while the RP-GA algorithm, by combining factor importance and random numbers, can increase the proportion of high-quality solutions in the population, accelerate the convergence speed of the algorithm, and thus improve the quality of the final solution. Secondly, R^2-based PLS regression is used for fitness assessment. This innovative fitness assessment can more accurately measure the fitness of individuals compared to traditional methods, providing more effective guidance for the evolution of the algorithm. With these two innovations, the RP-GA algorithm is expected to provide a more efficient and accurate solution for accurately screening the elements affecting learning emotions in smart teaching scenarios.

In the field of classroom social network research, researchers have found that network structural properties [17] (e.g., network diameter, mean degree, clustering coefficient, etc.) are closely related to the exchange of information or the propagation of learning emotions in classroom networks. Tang et al. [18] established a database based on multidimensional data such as student identity, seating relationship, and social relationship, constructed a classroom social network through the seating similarity between learners, and used the CRITIC algorithm and the CRITIC algorithm and entropy weight method to obtain the

combination weights, and proposed GRA-TOPSIS multi-decision fusion algorithm to mine the key student nodes with negative influence. The algorithm can objectively evaluate learners based on the classroom social network and provide a theoretical basis for learning emotion calculation and dissemination. Xie et al. [19] showed that the network density, average degree, and clustering coefficients of the classroom social network have a significant impact on the learning emotion calculation and dissemination of students. Classroom social networks with smaller network diameters and higher network densities are conducive to the dissemination of learning emotions among students; networks with higher clustering coefficients, although conducive to the rapid dissemination of learning emotions within a small group, may form information silos and impede cross-group dissemination. The current field of classroom network research has yielded some results, but most of them follow an established model. Without selecting the factors affecting learning emotions, researchers often consider all the attributes of students, including academic performance, classroom interaction behavior and emotional traits, as potential factors affecting learning emotions, and construct a classroom network model based on them. Subsequently, we focus on analyzing the dynamic changes of students' learning emotions over time within the framework of the network model, in an attempt to reveal the evolution of learning emotions at different stages of teaching and learning. However, this research paradigm has significant methodological flaws, the core of which lies in the failure to analyze the factors of the classroom network in depth and identify the key elements that affect learning emotions. Theoretically, the influence of various student attributes on affective learning is not uniformly distributed, but has a complex hierarchical and causal relationship. Conducting research without distinguishing between critical and non-critical elements will introduce a large amount of redundant information, increase the complexity and computational cost of the research model, and the interfering factors will obscure the real association between affective learning and the structure of the classroom network, thus reducing the validity and reliability of the research.

To address the above limitations, this study will use the innovative RP-GA algorithm to accurately identify the key elements affecting learning emotions in smart classroom scenarios, deeply analyze the dynamic changes between the elements and the network structure characteristics, and construct a multi-layer heterogeneous all-element classroom network model. This innovative approach not only improves the accuracy of feature selection and the convergence efficiency of the algorithm, but also more comprehensively grasps the complex impact of network structural characteristics on the propagation of learning emotions, providing new theoretical perspectives and technical support for the practice of smart classroom teaching.

III. Data Set and Experimental Parameters

A. Introduction to Data Sets

In the study of this paper, the historical academic dataset of students collected from Kaggle, an open machine learning database, and the constructed Student Sentiments for Learning in a Smart Classroom dataset (SCLE-Dataset) are used as the experimental datasets, and Table I demonstrates the important information about the use of public datasets in this paper.

The dataset of students' learning emotions under the smart classroom is composed of video data of 67 students studying a course in the smart classroom of a university as well as the results of a questionnaire survey, in which the learning emotions are acquired with reference to the method in the literature [22], and the learning emotions are classified into five grades: very positive, relatively positive, neutral, relatively negative, and very negative. These categories cover not only the intensity but also the positive and negative polarities of learning emotions, providing a multidimensional framework for analyzing the dynamics of learning emotions during the learning process. The SCLE-Dataset was divided into 63 sub-datasets based on the order of the length of time the 63 knowledge points were taught within the course, with each sub-dataset corresponding to an individual knowledge point and consistent factor dimensions. Table II shows the descriptions of the fields in the SCLE-Dataset.

TABLE I IMPORTANT CHARACTERISTICS OF THE PUBLIC DATASETS

Datasets	Number of instances	Number of factors	Name of the target attribute in the dataset
data[20]	4424	36	target
Student-mat[21]	395	32	G3
Student-pro[21]	649	32	G3
xAPI-Edu-Data[21]	480	16	Class
Students Performance[21]	1000	7	Writing score
Turkiye Student[21]	5820	32	Attendance

TABLE II DESCRIPTION OF FIELDS IN SCLE-DATASET

Name	Description	Name	Description	Name	Description
ID	Student number	Classroom test score	Classroom test scores	Interaction	Number of interactions
K point	Knowledge point number	Eng_grade	Grades in English	Use phone	Number of cell phone uses
Class	Date of class	Math_grade	math grade	Take notes	Number of notes taken
Gender	Gender of students	Position preferences	Seat Selection Preference Area	Lean on table	Number of times lying on the table
Character	Student Character	Head on rate	percentage of heads up	Prop up head	Number of headrests
Club	Participation in associations or not	Friend nomination	Number of friend nominations	Yawn	Number of yawns
Competition	Participation in competitions or not	Friend nominated	Number of times nominated by friends	Award rating	Scholarship level
Committee	Serve on a class council or not	Bad for learn	Number of adverse learning nominations	Fail	Number of subjects failed
Dorm	Dormitory number	Good for learn	Number of nominations for enabling learning	Learning emotions	Student Learning Emotions at a Knowledge Point

B. Data Standardization

Data standardization is a key step in the factor selection process, and standardization is the process of transforming each factor column Z_j into a new factor column X_j with a mean of 0 and a standard deviation of 1. It can eliminate scale differences between factors and improve the effectiveness of factor selection and model training. If the factors are not normalized, factors with a large range of scale values may dominate the calculation of factor importance, while factors with a small range of scale values may be ignored. This will lead to inaccurate results in the assessment of factor importance, ignoring the possibility that some small-valued factors are more important to the prediction results.

C. Classifier Parameters

The classifiers used in this paper are Support Vector Machine (SVM), Plain Bayes (NB), Multi-Layer Perceptron (MLP) and Random Forest (RF) classifiers, and the parameter settings of each classifier are shown in Table III.

TABLE III NAMES AND PARAMETERS OF THE CLASSIFIERS USED IN THE EXPERIMENT

Name	Parameters
Support Vector Machine (SVM)	C=1.0, kernel="rbf", gamma="scale", tol=1e3, cache_size=200
Plain Bayes (NB)	var_smoothing=1e-9
Multi-Layer Perceptron (MLP)	hidden_layer_ sizes=50, max_iter=1000, learning_rate_init=0.01, random_state=123
Random Forest (RF)	n_estimators=100, max_depth=None, min_samples_split=2, max_features="auto"

IV. RP-GA ALGORITHM

In this section, two improvements of the RP-GA algorithm over the GA algorithm will be presented: first, the use of factor importance versus random numbers to guide population initialization; and second, the dynamic selection of the number of components (i.e., the dimensionality of the PLSs) of the partial least squares PLS model in the fitness function, which allows the model to adaptively adjust its complexity to match the number and nature of the selected factors. The improved RP-GA algorithm optimizes not only the number of factors but also the prediction performance based on the selected set of factors. Fig. 1 illustrates the overall framework diagram of the RP-GA algorithm:

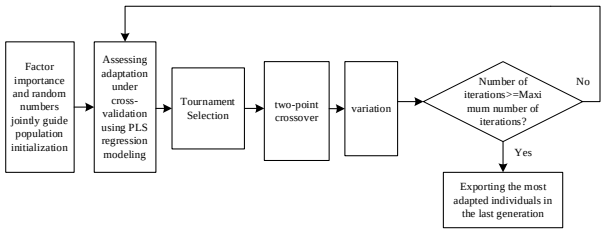

Fig. 1. Flowchart of RP-GA algorithm implementation.

A. Importance Calculation Based on Random Forest Model

Random Forest is an integrated learning method designed to improve the prediction accuracy of a model by constructing multiple decision trees. The main steps include Bootstrap sampling, decision tree construction, model training and prediction. In calculating factor importance, this paper focuses on quantifying the extent to which each factor contributes on average across all decision trees, rather than the relative proportion of each factor's contribution to the totality of all factors. The evaluation method uses mean square error (MSE) as an impurity metric by comparing the reduction in model prediction error (MSE) with and without node splitting using specific factors. Mean Square Error, a key indicator of predictive performance, calculates the average of the squares of the differences between the model's predicted values and the actual observed values, which can be accurately assessed to quantify the level of importance of each factor by comparing the change in MSE before and after factor use.

The steps for calculating the importance of factors are as follows:

1) Calculation of baseline MSE: The prediction of the dataset using the trained model and calculating the mean square error between the predicted and actual values can be expressed as:

$$MSE_{baseline} = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2 \quad (1)$$

Where y_i is the actual target value, $\hat{y}_i$ is the model predicted value, and N is the sample size.

2) Remove factor X_j from the model, then retrain the model and compute a new MSE

$$MSE_{exclude,j} = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_{i,j})^2 \quad (2)$$

Where $\hat{y}_{i,j}$ is the predicted value of the model with factor X_j excluded.

3) For each decision tree i, calculate the reduction in mean square error before and after excluding each factor X_j from that decision tree, denoted by $VIM_{ij}^{(MSE)}$

$$VIM_{ij}^{(MSE)} = MSE_{baseline} - MSE_{exclude,j} \quad (1)$$

4) Sum the mean squared error reductions of factor X_j across all decision trees and divide by the number of decision trees, n, to arrive at the average impurity reduction of the factor, i.e., the factor importance score

$$VIM_j^{(MSE)} = \frac{1}{n}\sum_{i=1}^{n} VIM_{ij}^{(MSE)} \quad (4)$$

If $VIM_j^{(MSE)}$ is larger, it indicates that factor has a greater impact on the predictive ability of the model and therefore the factor is more important. Table IV shows the results of the importance ratings of all the factors affecting learning emotions:

TABLE IV RESULTS OF FACTOR IMPORTANCE SCORES

Factor name	score	Factor name	score	Factor name	score
K point	0.183	Eng_grade	0.019	Use phone	0.010
Class	0.021	Math_grade	0.014	Take notes	0.038
Gender	0.022	Position preferences	0.048	Lean on table	0.022
Character	0.023	Head on rate	0.137	Prop up head	0.095

B. Population Initialization Based on Importance and Random Numbers

In traditional genetic algorithms, the individuals of the initial population are usually generated by random generation, although the diversity of the initial population generated in this way is high, a large number of low-quality individuals will be introduced, which reduces the convergence speed and wastes the computational resources. To overcome this limitation, this paper customizes a method for generating a subset of factors that uses factor importance and random numbers to guide the initialization of individuals, with the initial value of each factor depending on its importance in the random forest model. For each factor, if the randomly generated number is less than the importance of the factor, its initial value is randomly determined by the importance of the factor and the specified minimum and maximum bounds. Otherwise, it is set to the minimum boundary value and the important factors are prioritized for model training.

The process in which factor importance and random numbers jointly guide population initialization is illustrated in Fig. 2. The random_threshold and random_value in the figure are random numbers generated between min_bound and max_bound, labeled differently in order to distinguish between the two generated random numbers. The number of factors in the dataset used in this paper is shown in Table 1. The number of individuals in the initialized population is set to 50, striking a balance between the speed of convergence and the maintenance of solution diversity.

When studying the complexity of factors affecting students' learning emotions in classroom networks, the use of factor importance and random numbers together to guide population initialization demonstrated the following significant advantages:

1) Avoidance of over-conditioning: If a fixed threshold is used to compare the importance of factors, the initial values of the factors can be influenced by the distribution of the data, potentially leading to over-adjustment issues, i.e., "biased initialization." By combining the importance of factors with dynamically generated random numbers for initialization, it becomes possible to consider the potential influence of factors on learning emotions in a more balanced manner, making the analysis more objective and scientific.

2) Enhanced exploration and adaptation: In the complex environment of the classroom network, learning emotions are influenced by a wide array of intertwined factors characterized by high degrees of dynamism and uncertainty. By incorporating random numbers into the initialization process, it not only boosts the diversity of individuals in the initial population but also mimics the randomness of learning emotional changes in diverse contexts. This enhances the algorithmic exploration flexibility and scope, enabling the algorithm to comprehensively investigate the interactions between factors and reducing the risk of converging to local optimal solutions.

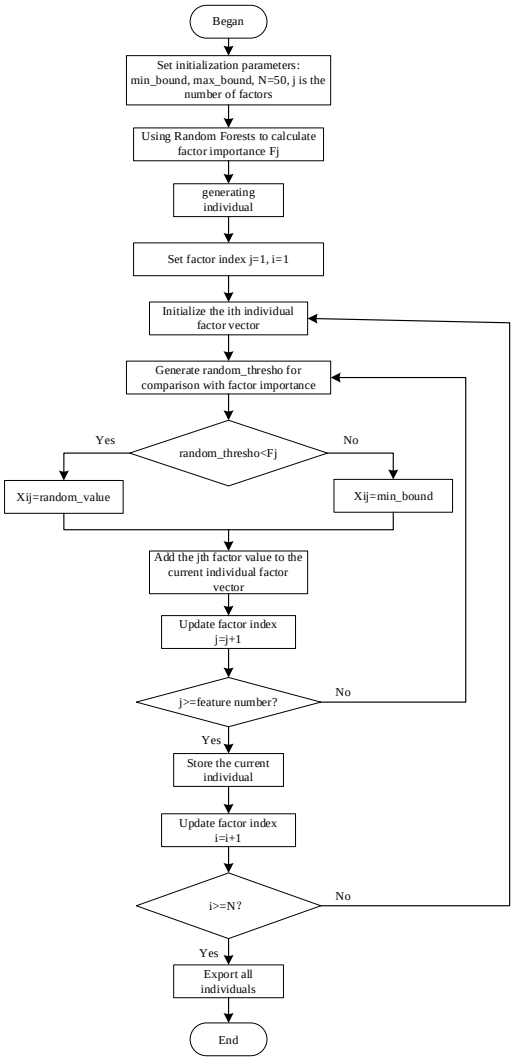

Fig. 2. Flowchart for initializing the population.

C. R^2-Based Adaptation Assessment of PLS Regression

For each individual in the initialized population of individuals that have been guided by the importance of the factors, the factors whose factor weights exceed a set threshold are selected to form a subset of the factors. PLS regression models were applied to a subset of factors in each individual and performance was evaluated within a cross-validation framework. In the fitness function, the number of components (i.e., regression dimensions) of the PLS model is dynamically selected based on the rank of the selected subset of factors. The method improves the accuracy of the fitness assessment by finding the optimal number of PLS components on a selected subset of factors using a partial least squares regression model and evaluating the actual impact of the selected factors on the model performance in terms of maximizing the coefficient of determination (R^2).

In the 3-fold cross-validation framework, the following operations are performed for each fold: the model is trained using the training set; predictions are made on the validation set thus obtaining the predicted value $\hat{y}_i$; the R^2-value on the validation set for each fold is calculated; and the largest R^2-value is selected as the fitness value for that individual, which can be expressed as:

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \tag{5}$$

where y_i is the actual value of the ith sample in the validation set, $\hat{y}_i$ is the value predicted by the model for the ith sample, and $\bar{y}$ is the mean of the actual values of all samples in the validation set.

In the RP-GA algorithm, PLS regression modeling with cross-validation was chosen as the key innovation based on the following considerations:

1) Adaptive adjustment and optimization of model complexity: In the fitness function of the RP-GA algorithm, the dynamic selection of the number of components of the PLS model (i.e., the number of dimensions of the PLS) allows the model to adaptively adjust its complexity according to the number and nature of the selected factors. Through cross-validation, the optimal number of PLS model components is determined, thus ensuring model accuracy while avoiding over-complexifying the model and improving the optimization efficiency of the algorithm. This adaptive adjustment mechanism enables the RP-GA algorithm to balance model complexity and prediction performance more effectively.

2) PLS regression model: The PLS regression model reduces the impact of data noise on the model by extracting the most representative components, thus improving the robustness of the algorithm. Meanwhile, cross-validation further enhances the stability of the algorithm by dividing the dataset multiple times for training and validation, which reduces the bias caused by unreasonable dataset division. This combined use enables the RP-GA algorithm to show more stable performance when facing different datasets and problems.

V. Experimental Results and Analysis

A. RP-GA Comparison Experiment

Among the current factor selection algorithms, Forward algorithm [23] and PSO algorithm [24] are more widely used. Forward algorithm can effectively and efficiently select key factors by virtue of its step-by-step forward strategy in the process of feature screening. PSO algorithm can quickly find the best in the search space by virtue of the principle of simulating the foraging behavior of bird flocks. The two algorithms have their own unique advantages, and have been widely used in a number of practical application scenarios. Each of them has its own unique advantages and has been widely used in many practical application scenarios. In addition, using the correlation Pearson coefficient as the evaluation criterion for the subset of factors is more stable. In this experiment, we use the Pearson correlation coefficient as the evaluation criterion for the CL-GA

algorithm and as a comparative model, and the following is the formula for the correlation coefficient [21]:

$$R(f_i,c) = \frac{Cov(f_i,c)}{\sqrt{Var(f_i)Var(c)}} \quad (6)$$

where $R(f_i,c)$ denotes the correlation between factor f_i and target c , $Cov(f_i,c)$ denotes the covariance between factor f_i and target c , and $Var(f_i,c)$ denotes the variance between factor f_i and target c . In addition, the forward selection algorithm is also used as a comparison algorithm.

In this paper, we conduct experiments on six publicly available datasets as well as on a specific sub-dataset of the SCLE dataset and compare the performance of the RP-GA algorithm with other algorithms when using SVM, NB, MLP and RF classifiers. We measure the performance of the model using the accuracy ratio (acc), which is defined as the ratio of the number of samples correctly predicted by the classifier to the total number of samples. It is calculated using the formula:

$$acc = \frac{TP+TN}{TP+TN+FP+FN} \quad (7)$$

From Table V, it can be seen that RP-GA algorithm outperforms CL-GA algorithm, Forward algorithm, and PSO algorithm on all experimental datasets. Differences in the performance of the algorithms not only depend on the characteristics of the algorithms themselves, but may also be closely related to the characteristics of the dataset. In the case of the Student-pro [21] dataset and the Turkiye Student [21] dataset, for example, although both have a total number of factors of 32, there is a significant difference in the number of samples, which has an impact on the algorithm's prediction accuracy. The Student-pro dataset with a sample size of 649 is derived from Portuguese language course grades in Portuguese secondary schools. The smaller sample size allows the algorithm to quickly capture key patterns and achieve higher prediction accuracy. The Turkiye Student dataset, with a sample size of 5820, is derived from Turkish university course evaluations, and the large number of samples brings rich information but also introduces more noise and uncertainty. In addition, the complexity of the university course evaluation data, including subjective student evaluations and diverse course content, puts the algorithm under computational pressure and the risk of overfitting, and it is easy to learn local non-universal patterns, which affects the prediction accuracy. In conclusion, RP-GA better adapts to various datasets, suits small-to-medium-sized samples with clear features, and shows superior experimental performance.

The four datasets data, Student-mat, Student-pro, and Turkiye Student, which have a higher number of factors, were selected to demonstrate the comparison of the number of factors after selection, and from Table VI it can be seen that compared to CL-GA algorithm, Forward algorithm, and PSO algorithm, the RP-GA algorithm reduces the number of factors after selection, improves the training speed and prediction accuracy of the classifier.

TABLE V COMPARING THE PREDICTION ACCURACY OF CL-GA, FORWARD, PSO AND RP-GA ON DIFFERENT CLASSIFIERS

B. Analysis of Ablation Experiments

In order to verify the validity of population initialization through factor importance and random number co-guiding in RP-GA and the use of PLS regression model with cross-validation to assess the fitness. The GA algorithm is used as the baseline model for the ablation experiments, and the data preprocessed DATA dataset is used for the experiments, using the classifiers in Table III and keeping the parameters consistent, and ablating the improvement modules one by one to obtain four sets of experimental data, as shown in Table VII. In the table, A represents the improvement point in Chapter IV.B (using factor importance and random number to jointly guide population initialization), and B represents the improvement point in Chapter IV.C (using PLS regression model with cross-validation to assess fitness). From the ablation experimental data, it can be found that baseline improved by 0.091, 0.041, 0.05, and 0.061 after adding improvement point A with SVM, NB, MLP, and RF classifier prediction accuracies of 0.712, 0.720, 0.751, and 0.751, respectively, and the final effect improved by 0.143 after adding improvement point B. The final results were, 0.088, 0.116, 0.114. The above improvement points made significant contributions to the performance enhancement of the RP-GA algorithm in terms of the efficiency of the factor selection and the accuracy of the adaptation assessment, obtaining a large prediction accuracy enhancement, which fully proved the effectiveness of the two-point improvement strategy proposed in this paper. The visualization of the ablation experiment is shown in Fig. 3.

TABLE VII ABLATION EXPERIMENT

✓	×	0.803	0.761	0.801	0.812
×	✓	0.793	0.758	0.796	0.784
✓	✓	**0.855**	**0.808**	**0.867**	**0.865**

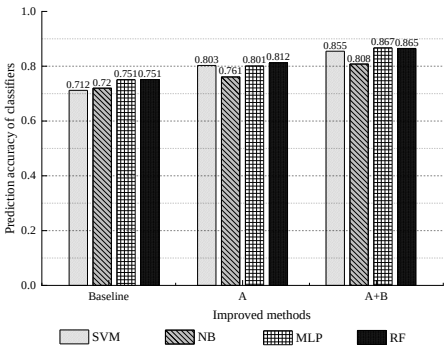

Fig. 3. Intuitive display of ablation experiments.

C. Convergence Analysis

The fitness function is used to measure the degree of superiority or inferiority of an individual (chromosome) in the problem environment. During the iteration of the algorithm, the fitness of individuals in the population changes in each generation. In order to further verify that the factor importance and random number co-guided population initialization proposed in this paper can improve the convergence speed of the RP-GA algorithm, we analyze the average fitness and standard deviation fitness change process of each generation of the population in the iterative process of $RP-GA_{lif}$ (lack of factor importance and random number co-guided population initialization) and RP-GA.

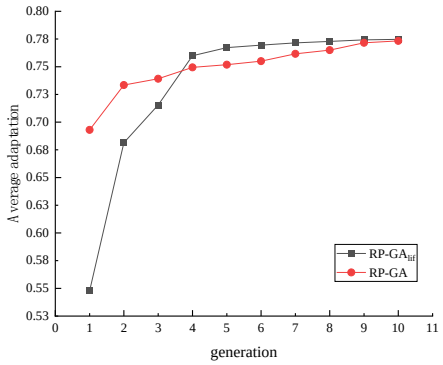

Fig. 4. The changing trend of the average fitness of RP-GA and RP − GA_{lif}.

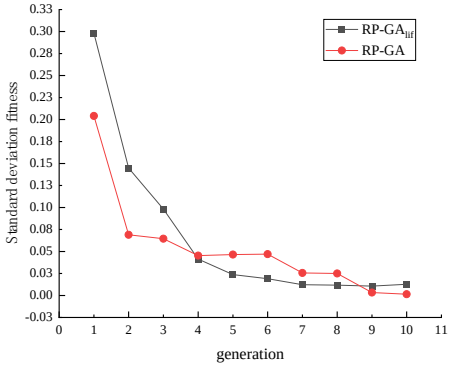

Fig. 5. The changing trend of the standard deviation fitness of RP-GA and RP − GA_{lif}.

From the average fitness curves in Fig. 4, RP-GA converges faster in the early stage, thanks to its method of factor

importance and random number co-guiding population initialization, which enables the initial population to be more reasonably distributed in the solution space. As the iteration proceeds, although the average fitness of RP-GA and $RP-GA_{lif}$ both tend to stabilize, RP-GA converges to a region with higher fitness, indicating that it is better in convergence effect. And RP-GA finally reaches a higher average fitness, which indicates that RP-GA is more advantageous than in finding the optimal solution, and the special population initialization helps to avoid falling into the local optimal solution and easier to find the region of the global optimal solution.

From the standard deviation fitness curve in Fig. 5, the standard deviation fitness of RP-GA decreases faster in the early stage, which is due to the fact that it adopts the factor importance and random number to guide the population initialization, so that the population quickly concentrates in the more optimal direction. With the increase of iteration, the standard deviation of both RP-GA and $RP-GA_{lif}$ tends to stabilize and have smaller values, and the standard deviation of RP-GA is slightly smaller. This indicates that the population convergence of RP-GA is better, the individual adaptations are more consistent, and it can effectively guide the population to converge in the process of evolution, reduce the differences between individuals, and help to find a more optimal solution.

D. Analysis of SCLE-Dataset Experimental Results

SCLE-Dataset is composed of data from different knowledge points of freshman students at a university while studying a course. Considering the existence of different elements in each knowledge point that affect students' learning emotions, this paper evaluated each knowledge point using the RP-GA algorithm. Table VIII shows all the knowledge points elements results and the prediction accuracy of the NB classifier. The elements of all knowledge points were counted statistically, from which the top five elements were filtered as the key elements affecting students' learning emotions, which were gender, head-up rate, preferred area for seat selection, number of friend nominations, and number of favorable study nominations.

TABLE VIII RESULTS OF ELEMENTS FILTERED WITHIN ALL KNOWLEDGE POINTS AND ACCURACY

Knowledge point number	Element name	Accuracy of NB
Point 1	Classroom test score， Award rating	0.85
Point 2	Classroom test score， Award rating	0.85
Point 3	Gender, Friend nominated	0.60
⋮	⋮	⋮
Point 61	Position preferences, Head on rate, Lean on table	0.70
Point 62	Math grade, Head on rate, Use phone, Lean on table	0.95
Point 63	Gender, Committee, Math_grade, Head on rate, Good for learn, Take notes	0.75

E. Characterization of the Structure of the Total Element Classroom Network

In order to further reveal the synergistic effect of key elements and enhance the classroom learning experience, the key elements affecting learning emotions are integrated into the framework of analyzing the structural properties of classroom networks, and the potential influence of key elements on the propagation of students' learning emotions is explored by quantifying and analyzing the structural properties of classroom networks. The structural characteristics of the multi-layer heterogeneous all-element classroom network G_{MHLA} based on SCLE-Dataset influencing the elements of students' learning emotions are analyzed experimentally, and its multi-layer heterogeneous network G_{MHLA} construction method is utilized in the literature [19].

Table IX shows that the all-factor classroom network G_{MHLA} constructed on the basis of the key elements (students' gender, head-up rate, seating information, friends' nomination, and favorable learning nomination) has the properties of low network diameter, low average path length, high network density, high average degree, high average weighting, and low clustering coefficient. These structural properties reflect more connections of nodes in the multilayer heterogeneous all-factor classroom network, shorter paths for learning emotions, and easier cross-cluster dissemination of learning emotions among small groups. Fig. 6 shows a visualization of the structural changes in the classroom network caused by the change of student seating information in the first, fourth, and seventh classes, and it can be found that the denseness of the connections between nodes in the network increases significantly with the increase in the number of classes. Fig. 7 shows a slight increase in the density of connections between the nodes in the first class as the number of points taught increases and the students' head-up rate changes, due to the fact that the students are unfamiliar with each other and have established fewer connections with each other in the first class.

Table X shows the analysis of the structural characteristics of the total classroom network with different classroom seating variations. It can be found that as the number of classes increases, the structural characteristics of the all-factor classroom network change significantly, which is manifested in the reduction of network diameter and average path length, the enhancement of network density, the growth of average degree and average weighting degree, and the decrease of clustering coefficient, and the structural all-factor classroom network is more compact and efficient in the seating relationship of the last classroom, and all these changes together constitute a network environment more favorable to emotion dissemination and network environment for emotion transmission.

Table XI shows the characterization of the whole-factor classroom network structure in terms of changes in head-up rates for different knowledge points in the first class. It can be found that as the number of knowledge points increases, the structural characteristics of the whole-factor classroom network change, which is manifested in the reduction of the average path length, the enhancement of the network density, the growth of the average degree and the average weighting degree, and the decrease of the clustering coefficient.

On the basis of analyzing the structural characteristics of the network, this paper constructs a multidimensional and comprehensive classroom network model using the key

elements screened by the RP-GA algorithm, and analyzes the mechanism of the key elements and the structural characteristics of the classroom network in depth. The results of the analyses show that the dynamics of the key elements in the classroom network significantly influence and change the structural characteristics in the classroom network. This strongly verifies the effectiveness and scientificity of the RP-GA algorithm in identifying the elements affecting learning emotions, and further proves that the elements selected by the RP-GA algorithm provide an important basis and support for the calculation and dissemination of learning emotions in the future.

$G_{MHLA}^{k=1}$	5	3.224	0.122	6.695	14.32	7	0.625

VI. CONCLUSION

In this study, the RP-GA algorithm is innovatively employed to screen key elements influencing learning emotions in smart classroom teaching, and subsequently, a multi - layer heterogeneous all-element classroom network model is built, which, through in-depth exploration of the relationship between elemental variations and network structural features, lays a scientific groundwork for future calculation and dissemination of learning emotions. As the research process was limited by the scope of data acquisition, the collected data could not completely cover all types of smart classroom teaching scenarios, which might have an impact on the comprehensiveness of the RP-GA algorithm in screening the key elements. In factor selection and model optimization, the RP - GA algorithm, with its unique initialization and dynamic adjustment, avoids local optima and boosts the model's prediction accuracy. In this study, we mainly focus on small and medium-sized datasets, for large datasets there may be problems of lower prediction accuracy and higher computational pressure. Even so, this study substantiates the high validity and reliability of the RP-GA algorithm in optimizing classroom network structural characteristics. It not only broadens the theoretical research on classroom networks but also offers a scientific basis and practical guidelines for enhancing teaching quality and evolving learning emotions.

***Abstract*—The escalating complexity of modern software systems has rendered the management of requirements increasingly arduous, often plagued by redundancy, inconsistency, and inefficiency. Traditional manual methods prove inadequate for addressing the intricacies of dynamic, large-scale datasets. In response, this research introduces SQUIRE (Semantic Quick Requirements Engineering), a cutting-edge automated framework leveraging advanced Natural Language Processing (NLP) techniques, specifically Sentence-BERT (SBERT) embeddings and hierarchical clustering, to semantically organize requirements into coherent functional clusters. SQUIRE is meticulously designed to enhance modularity, mitigate redundancy, and strengthen traceability within requirements engineering processes. Its efficacy is rigorously validated using real-world datasets from diverse domains, including attendance management, e-commerce systems, and school operations. Empirical evaluations reveal that SQUIRE outperforms conventional clustering methods, demonstrating superior intra-cluster cohesion and inter-cluster separation, while significantly reducing manual intervention. This research establishes SQUIRE as a scalable and domain-agnostic solution, effectively addressing the evolving complexities of contemporary software development. By streamlining requirements management and enabling software teams to focus on strategic initiatives, SQUIRE advances the state of NLP-driven methodologies in Requirements Engineering, offering a robust foundation for future innovations.**

Keywords*—Requirements Engineering (RE); semantic clustering; sentence-BERT; natural language processing (NLP)

I. Introduction

Requirements Engineering is a cornerstone of software development, focusing on the identification, documentation, and management of requirements that guide the design and implementation of software systems [1]. It ensures alignment between user needs and project goals, providing a foundation for system functionality and quality. However, as software systems grow in complexity and scale, managing requirements effectively becomes increasingly challenging. Issues such as redundancy, inconsistencies, and overlapping functionalities not only complicate design processes but also disrupt modularity, traceability, and efficient project execution [2], [3]. These challenges highlight the need for innovative solutions to streamline requirements management, particularly in large-scale projects.

Conventional approaches to managing requirements rely heavily on manual processes, which are often time-consuming, prone to human error, and inadequate for handling large datasets [4]. These traditional methods, while useful for small-scale projects, fail to meet the demands of modern, dynamic software development, where requirements are frequently updated and involve intricate relationships. Automated techniques, particularly those leveraging Natural Language Processing (NLP), have emerged as promising solutions for addressing these limitations. By analyzing textual requirements for semantic relationships, NLP-based methods can uncover patterns and organize requirements efficiently [5]. However, existing methods face limitations in capturing the subtle semantic relationships within diverse or domain-specific datasets, restricting their ability to handle the complexity of real-world requirements engineering tasks.

To address these gaps, this paper presents SQUIRE (Semantic QUIck Requirements Engineering), a novel and structured methodology aimed at automating the grouping of semantically similar requirements into functional clusters. SQUIRE combines state-of-the-art NLP techniques, such as Sentence-BERT (SBERT) embeddings, hierarchical clustering, and a comprehensive preprocessing pipeline, to analyze and group requirements based on their semantic similarity [4], [6], [12]. By focusing on reducing redundancy, enhancing modularity, and improving traceability, SQUIRE provides a practical solution to key challenges in RE, enabling more efficient and effective system design [7].

The methodology represents a significant advancement in the application of NLP to RE, building on recent trends in natural language understanding and clustering algorithms [9], [10], [17], [18]. The authors' work reflects a broader effort in the research community to leverage the capabilities of NLP for addressing critical challenges in RE, including the need for scalability, semantic analysis, and automation [19]. Recent developments in NLP, particularly transformer-based models such as Sentence-BERT (SBERT), have enabled significant improvements in the ability to capture the semantic meaning of textual data, making them well-suited for addressing RE challenges.

The effectiveness of SQUIRE is evaluated across diverse, real-world datasets representing distinct functional domains, including attendance management, e-commerce, and school operations. The methodology's performance is assessed using quantitative metrics such as cohesion, separation, silhouette scores, and the Davies-Bouldin Index [20], [24], [25]. Visualizations using Principal Component Analysis (PCA) further demonstrate the ability of SQUIRE to organize requirements into meaningful clusters, providing clear insights

into the relationships between requirements. These evaluations highlight the robustness of the proposed approach, showcasing its potential to improve modularity and traceability in varied software development contexts.

This research contributes to the ongoing integration of NLP into requirements engineering by demonstrating how advanced language models and clustering techniques can address long-standing challenges in the field [5]. By automating the grouping of requirements, SQUIRE reduces the manual effort required in RE, allowing software teams to focus on higher-value activities such as innovation and strategic planning. Furthermore, the domain-agnostic nature of SQUIRE makes it adaptable to various industries, offering a scalable solution for modern software development needs.

SQUIRE advances the state of requirements engineering by introducing a systematic and scalable methodology for semantic clustering. By leveraging the latest advancements in NLP, it bridges the gap between textual complexity and actionable insights, enabling software teams to design more organized, traceable, and modular systems [22]. This work lays the groundwork for further innovations in automated RE, positioning NLP as a central tool in the evolution of software development practices.

The remainder of this paper is organized as follows: Section II delineates a meticulous review of pertinent literature, elucidating seminal advancements and inherent constraints within NLP-driven requirements engineering. Section III expounds upon the proposed SQUIRE methodology, systematically detailing its preprocessing pipeline, embedding generation mechanisms, and clustering paradigms. Section IV articulates the experimental framework, encompassing the evaluation metrics and empirical assessments employed to ascertain the model's efficacy. Section V presents a rigorous discourse on the obtained findings, critically analyzing the methodological robustness and potential limitations. Lastly, Section VI encapsulates the study's principal contributions and delineates prospective avenues for future research.

II. Related Work

Modern software development has made RE more challenging due to the growing complexity of systems and the volume of requirements. Traditional approaches often rely on manual analysis, which can lead to errors and inefficiencies. To overcome these challenges, researchers have introduced techniques like NLP and clustering algorithms. These methods aim to simplify requirement management by automating processes such as grouping and prioritization. This section reviews recent work in applying these techniques to RE, focusing on their impact, limitations, and future potential.

Radwan et al. [8] proposed the CMHR (Conceptual Mapping for Healthcare Requirements) approach to enhance the analysis of non-functional requirements in healthcare systems. The methodology involves clustering requirements using the K-means++ algorithm based on attributes such as priority and suitability, enabling structured visualization through conceptual mapping. Applied to ventilator requirements, the approach achieved a silhouette score of 0.71 and accurately classified new requirements using a Naïve Bayes classifier. However, the study is limited by its small dataset and focus on a single domain, necessitating further validation across other healthcare systems for broader applicability.

Salman et al. [9] explored semantic clustering of functional requirements (FRs) using Agglomerative Hierarchical Clustering (AHC). The study addresses a gap in software requirements engineering, where functional requirements are typically analyzed manually. Existing works focus primarily on non-functional requirements classification, leaving FR clustering largely unexplored. Previous research has used techniques like Support Vector Machines and ontology-based methods for requirement classification, but functional requirements have lacked similar advancements. This paper introduces a semantic similarity-based approach to group FRs, validated across four software projects. While the proposed method achieved promising results, it relies heavily on vocabulary consistency, limiting its applicability across diverse datasets.

Del Sagrado et al. [10] integrate clustering techniques with the MoSCoW method to automate requirements prioritization in software projects. Their methodology, validated on datasets of varying scales (20, 50, and 100 requirements), demonstrates clustering's efficacy in identifying core requirements. While enhancing decision-making, the approach is constrained by dependency considerations and reliance on subjective estimations, leading to variability in algorithmic performance.

Bakar et al. [11] employ Latent Semantic Analysis (LSA) alongside K-Means and Hierarchical Agglomerative Clustering (HAC) to facilitate software requirements reuse in Software Product Lines (SPL). Evaluations on 27 product review documents reveal HAC's superiority in cluster compactness, whereas K-Means marginally outperforms in external validation. However, HAC is preferred for its grouping precision. Sensitivity to domain-specific data and input parameters remains a limitation, with future work directed at refining clustering optimization.

Das et al. [12] introduce PUBER and FiBER, domain-specific sentence embedding models enhancing similarity detection in natural language requirements. Built on the BERT architecture, PUBER trains on the PURE dataset, while FiBER refines it via fine-tuning. Using cosine similarity, FiBER achieves 88.35% accuracy, surpassing Universal Sentence Encoder and RoBERTa by up to 10%. These models advance classification, similarity detection, and reusability, addressing NLP challenges in software engineering.

The study by Elhassan et al. [13] developed an automated conflict detection model using the Mean Shift clustering algorithm to identify and classify requirement conflicts during elicitation. The methodology involved data transformation based on McCall's quality model and clustering requirements into three categories: conflict-free, partial conflict, and conflicted requirements. Results demonstrated accurate clustering, with conflict-free requirements achieving low standard error (SE) values, validating the model's efficiency. Limitations include a small dataset size (207 observations), restricting generalizability, and challenges in data collection from diverse sources. Future work suggests expanding datasets,

applying the model to varied IS environments, and exploring decision tree algorithms for enhanced detection.

The reviewed studies show that using NLP and clustering in Requirements Engineering has great potential to solve key challenges like redundancy and lack of scalability. However, issues such as handling diverse requirements and adapting to different domains remain. These findings suggest the need for smarter, more flexible methods to address these gaps. By building on existing work, approaches like SQUIRE offer a step forward, combining advanced tools with practical solutions for improving how requirements are managed in real-world software projects.

III. Research Methodology

The proposed methodology, SQUIRE offers an automated and efficient framework for grouping semantically similar requirements into distinct functional clusters. By leveraging NLP techniques, embedding models, and hierarchical clustering, SQUIRE addresses key challenges in requirements engineering, such as redundancy reduction, traceability enhancement, and modular system design.

The methodology comprises five structured stages: Preprocessing, Semantic Embedding Generation, Clustering, Evaluation, and Visualization.

A. Data Preprocessing

The preprocessing stage standardizes and simplifies textual requirements, ensuring consistency and reducing noise to prepare data for embedding generation [27]. This involves a series of transformations applied sequentially: converting text to lowercase to eliminate inconsistencies caused by capitalization, removing punctuation marks to simplify content, and filtering out stopwords such as “the” and “shall” that do not add semantic value [30]. The text is then tokenized into individual words or phrases, enabling detailed analysis, and normalized to unify synonyms or domain-specific terms (e.g., “log in” and “sign in” standardized to “log in”). Table I demonstrates the progressive refinement of requirements through these steps.

TABLE I Example Results of Data Preprocessing Pipeline

Original Requirement	Lowercased	Punctuation Removed	Stopwords Removed	Tokenized
"The system shall allow users to log in."	"the system shall allow users to log in."	"the system shall allow users to log in"	"system allow users log in"	["system", "allow", "users", "log", "in"]
"Users can register themselves for access."	"users can register themselves for access."	"users can register themselves for access"	"users register access"	["users", "register", "access"]

The output of preprocessing is a clean, tokenized, and normalized version of each requirement, ready for embedding generation. This ensures that noise is minimized while retaining the semantic essence of the text.

B. Semantic Embedding Generation

To effectively cluster requirements, each preprocessed input is transformed into a dense vector representation using SBERT, a pre-trained transformer-based model optimized for capturing semantic similarity [23]. SBERT excels at encoding contextual information and relationships between words, making it an ideal choice for analyzing and grouping requirements. Specifically, the all-MiniLM-L6-v2 model is utilized, which generates embeddings with a dimensionality of 384 [31]. These embeddings represent the semantic meaning of textual inputs in a high-dimensional vector space. For instance, a requirement like "system allow users log in" is converted into a numerical vector (e.g., E = [0.23, -0.45, 0.67, …, -0.11]). The proximity of two embeddings in this space directly reflects the semantic similarity between their corresponding requirements.

C. Clustering Requirements in Groups

Using the embeddings generated in the previous step, requirements are grouped into clusters through Agglomerative Clustering, a hierarchical method that iteratively merges data points based on similarity [15]. This process relies on Euclidean Distance as the similarity metric, where smaller distances indicate higher semantic similarity between requirements [16], [29]. To ensure optimal clustering, Ward Linkage is employed, which minimizes intra-cluster variance by selecting merges that reduce the overall variance [28]. The variance adjustment is calculated as:

$$\Delta Variance = Variance\ of\ Cluster\ A + Variance\ of\ Cluster\ B - Variance\ of\ Combined\ Cluster$$

For better interpretability and functional modularity, the number of clusters (k) is predetermined based on the dataset’s size and complexity (e.g., k = 4 for smaller datasets). Each resulting cluster represents a distinct functional module, grouping semantically similar requirements while separating unrelated ones [18], [19]. For instance, requirements like *"System allow users log in"* and *"Users register access"* are grouped into Cluster 1, while others such as *"System calculate attendance"* and *"Users generate reports"* fall into separate clusters, reflecting unique functional distinctions. Examples of these clusters is shown in Table II.

TABLE II Clustering Output Example

Requirement	Cluster
Ensure image sliders work properly and link to the restaurant homepage.	1
Match UI with the Android version: icons, formats, sizing, and alignment.	1
Show current prices for discounted items and notify users about deletions.	2
Show discount value on item card and final total price box for % discount items.	2
Connect QR code feature and create deep links for reading the QR code.	3
Ensure every QR code generator has a deep link and forwards to the app store/play store if not installed.	3

D. Evaluation

The quality of clustering results is evaluated using several key metrics to ensure both intra-cluster cohesion and inter-cluster separation. Cohesion measures the semantic similarity of requirements within a cluster, ensuring that grouped requirements share strong relationships [26]. In contrast,

Separation evaluates the dissimilarity between clusters, ensuring functionally distinct requirements are placed in separate groups [20]. The overall clustering quality is assessed using the Silhouette Score, which combines both cohesion and separation into a single metric. Additionally, the Davies-Bouldin Index is used to measure intra-cluster compactness and inter-cluster separation, where lower values indicate better clustering performance [21]. Together, these metrics provide a comprehensive evaluation of clustering effectiveness.

E. Visualization

For interpretability, high-dimensional embeddings are reduced to two dimensions using Principal Component Analysis (PCA). This dimensionality reduction enables the generation of scatter plots where each point represents a requirement, and clusters are distinguished by color [14]. These visualizations provide insights into the clustering structure and relationships among requirements. The SQUIRE methodology integrates preprocessing, semantic embedding generation, clustering, evaluation, and visualization into a cohesive framework for automating requirements analysis. By leveraging SBERT embeddings and hierarchical clustering with a fixed number of clusters, it ensures accurate grouping of semantically similar requirements while enhancing modular design and traceability.

F. Algorithm: SQUIRE (Semantic QUIck Requirements Engineering)

Input:

- $R = \{R_1, R_2, \dots, R_n\}$: A set of n textual requirements.

Output:

- $C = \{C_1, C_2, \dots, C_k\}$: k clusters of semantically similar requirements.

Steps:

1. Preprocessing

Transform each requirement R_i into a standardized form:

- Convert to lowercase: R_i'= lower(R_i).
- Remove punctuation: R_i''= remove_punctuation(R_i').
- Tokenize text: W_i= tokenize(R_i'').
- Remove stopwords: $W_i' = W_i / Stopwords$

2. Embedding Generation

Generate dense vector embeddings $E = \{E_1, E_2, \dots, E_n\}$ using a pre-trained SBERT model:

$$E_i = SBERT(R_i')$$

Where $E_i \in \mathbb{R}^{384}$

3. Similarity Computation

Compute pairwise similarity between embeddings using the Euclidean distance.

$$d(E_i, E_j) = \sqrt{\sum_{k=1}^{384} (E_{i_k} - E_{j_k})^2}$$

where $E_{i_k} and\ E_{j_k}$ are the k^{th} dimensions of embeddings $E_i\ and\ E_j$.

4. Clustering

Perform hierarchical clustering using Agglomerative Clustering:

- Linkage method: Ward's linkage minimizes intra-cluster variance.
- Clustering criterion:

$$Merge\ clusters\ that\ minimize\ \Delta Variance$$

Result: Assign each requirement R_i to a cluster label C_i.

5. Evaluation

1. Cohesion: Measure intra-cluster similarity:

$$Cohesion = \frac{1}{|C_k|} \sum_{i,j \in C_k} Sim(E_i, E_j)$$

where $Sim(E_i, E_j) = 1 - d(E_i, E_j)$.

2. Separation: Measure inter-cluster dissimilarity:

$$Separation = \min_{i \in C_k, j \in C_l, k \neq l} d(E_i, E_j)$$

3. Silhouette Score: Combines cohesion and separation to measure the overall clustering quality:

$$Silhouette\ Score = \frac{b(i) - a(i)}{max(a(i), b(i))}$$

where $a(i)$ is the average intra-cluster distance and $b(i)$ is the average nearest-cluster distance.

4. Davies-Bouldin Index: Quantifies intra-cluster compactness and inter-cluster separation:

$$DB\ Index = \frac{1}{k} \sum_{i=1}^{k} \max_{j \neq i} \frac{\sigma_i + \sigma_j}{\mathrm{d}(C_i, C_j)}$$

Lower values indicate better clustering.

6. Complexity Analysis:

The complexity of different stages in the SQUIRE methodology is analyzed as follows:

1. Preprocessing Complexity (Time & Space):

Time Complexity: $O(n)$ where n is the number of requirements. Each requirement undergoes tokenization, stopword removal, and normalization, which operates linearly with respect to the number of requirements.

Space Complexity: $O(n)$, as each requirement is stored as a processed text sequence before embedding.

2. Embedding Generation Complexity (Time & Space):

Time Complexity: $O(n)$, since the Sentence-BERT (SBERT) model processes each requirement independently, leading to a linear complexity.

Space Complexity: $O(n \times d)$, where d is the embedding dimension (384 in the case of MiniLM-SBERT). The output matrix of embeddings requires storage proportional to the dataset size.

3. Clustering Complexity (Time & Space):

Time Complexity: $O(n^3)$ for Agglomerative Clustering, due to the hierarchical structure requiring pairwise distance computations and iterative merging.

4. Space Complexity: $O(n^2)$, as the clustering algorithm maintains a distance matrix for all requirement pairs.

This complexity analysis provided a clear distinction between time and space requirements at different stages of the methodology.

The SQUIRE algorithm efficiently organizes textual requirements into meaningful clusters by leveraging NLP embeddings and hierarchical clustering [28]. Its structured workflow ensures semantic precision and scalability while minimizing redundancy. With its foundation in advanced language models and practical clustering methods, SQUIRE lays the groundwork for a streamlined approach to handling complex requirements datasets, offering clarity and functionality to modern software engineering practices

IV. Results and Validation of Proposed Model

The validation of the proposed SQUIRE methodology was conducted using four real-world datasets sourced from a software company [32]. These datasets, representing diverse functional domains, included four different domains as shown in Table III. The primary objective of this validation was to assess the model's ability to accurately group semantically similar requirements into functional clusters.

TABLE III DATASETS OVERVIEW

Dataset	Domain	Number of Requirements
Attendance Management	Employee attendance tracking and reporting	26
E-commerce	Online shopping portal requirements	20
Lottery Management	Lottery system functionality	24
School Management	Educational institution operations	23

These datasets represent diverse functional requirements, providing a robust basis for testing the domain-agnostic capabilities of the SQUIRE methodology [32].

The evaluation focused on clustering outcomes, visualized through scatter plots and assessed quantitatively using Cohesion, Separation, Silhouette Score, and Davies-Bouldin Index. The results highlight the methodology's strengths and its performance across different datasets.

The clustering results for each dataset were visualized using Principal Component Analysis (PCA), reducing the 384-dimensional embeddings to two dimensions [23]. The scatter plots for the datasets Fig. 1 illustrate the semantic clusters, with each point representing a requirement and colors distinguishing the clusters.

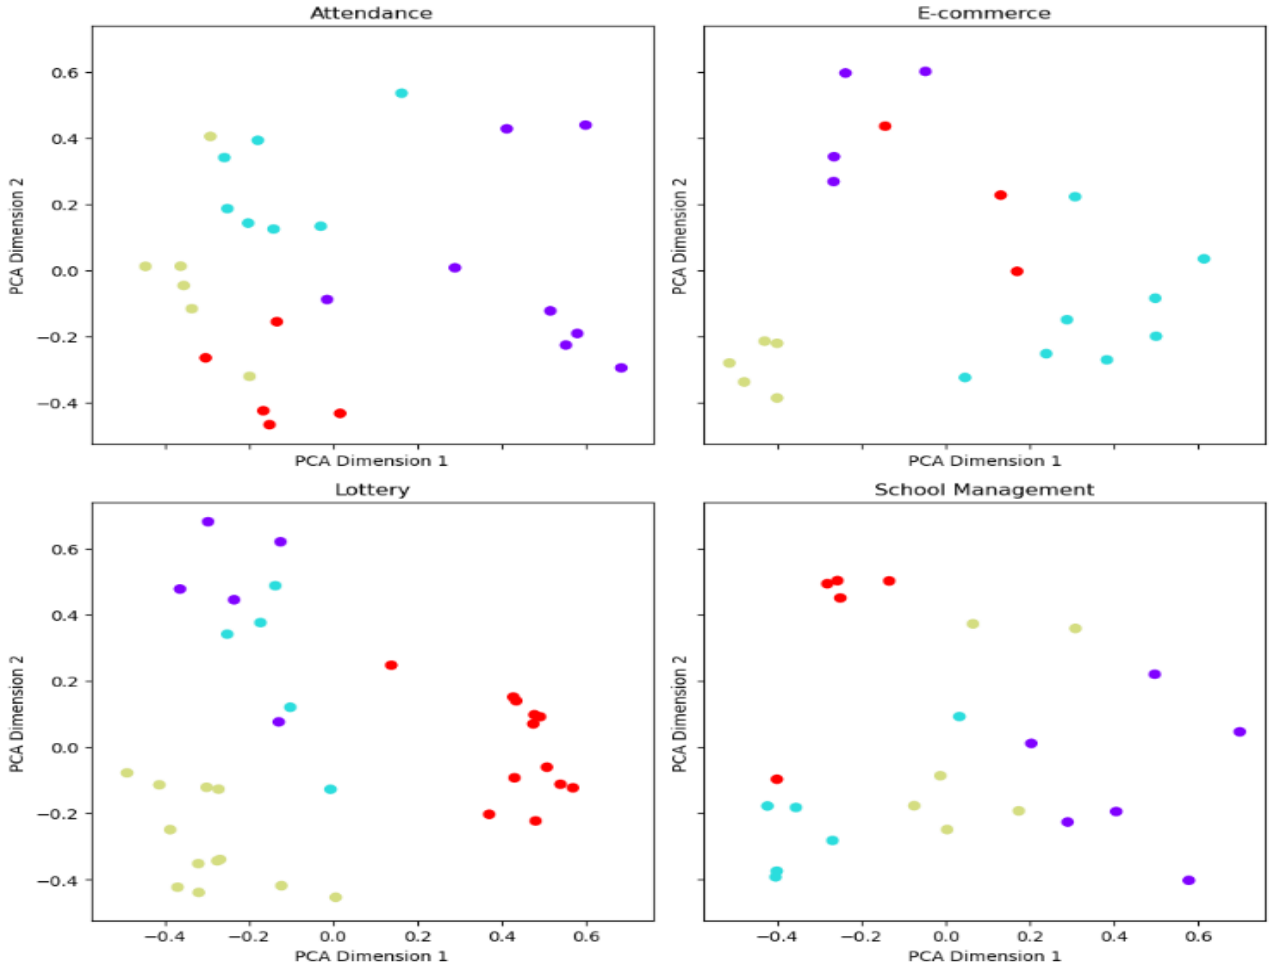

Fig. 1. Distribution of requirements clusters using PCA for each dataset.

The clustering performance is summarized in the Table IV below:

TABLE IV CLUSTERING METRICS FOR DIFFERENT DATASETS

Dataset	Cohesion	Separation	Silhouette Score	Davies-Bouldin Index
Attendance Management	0.2362	1.1306	0.1276	1.7027
E-commerce	0.1360	1.2911	0.1044	1.7195
Lottery Management	0.1096	1.2622	0.1587	1.8307
School Management	0.1940	1.1789	0.1174	1.7759

1) Cohesion: The Attendance Management dataset achieved the highest cohesion (0.2362), indicating well-grouped clusters. The Lottery Management dataset displayed slightly lower cohesion (0.1096), reflecting greater diversity within clusters.

2) Separation: The E-commerce dataset achieved the highest separation (1.2911), highlighting distinct clusters. The Attendance Management dataset had slightly lower separation (1.1306), possibly due to overlapping functional requirements.

3) Silhouette score: The Lottery Management dataset recorded the highest silhouette score (0.1587), indicating a good balance between cohesion and separation.

4) Davies-bouldin index: The Attendance Management dataset exhibited the lowest Davies-Bouldin Index (1.7027), reflecting compact and well-separated clusters. The Lottery Management dataset had the highest index (1.8307), suggesting room for improvement in cluster separation.

The validation results demonstrate the practical utility of the SQUIRE methodology in streamlining requirements engineering. By automating the clustering of semantically similar requirements, SQUIRE significantly reduces the manual effort required for organizing and analyzing requirements, allowing practitioners to focus on higher-value tasks such as decision-making and system design [7]. The methodology's ability to achieve high cohesion and separation across diverse datasets highlights its adaptability to different functional domains, making it a robust solution for handling large-scale and dynamic software projects. Furthermore, the integration of PCA-based visualizations enhances interpretability, providing clear insights into the relationships between requirements and supporting better traceability. Overall, SQUIRE offers a scalable and domain-agnostic approach that addresses critical challenges in requirements engineering, paving the way for more efficient and error-free software development processes.

V. DISCUSSION, LIMITATIONS AND FUTURE WORK

The validation results of the SQUIRE methodology demonstrate its effectiveness in clustering semantically similar requirements into distinct functional groups across diverse datasets. By leveraging Sentence-BERT embeddings and hierarchical clustering techniques, the methodology successfully addresses key challenges in requirements engineering, such as redundancy reduction, modularity, and enhanced traceability [2], [3], [13].

The methodology consistently produced meaningful clusters across four distinct datasets, sourced from a software company, representing domains Attendance Management, E-commerce, Lottery Management, and School Management [32]. These datasets varied in size and complexity, containing 20–26 requirements each, and provided a realistic foundation for testing the robustness and adaptability of the proposed approach. The clustering outputs revealed clear functional distinctions in well-structured domains like Attendance Management, while moderately overlapping clusters were observed in datasets like Lottery Management, which contained diverse and less structured requirements.

The evaluation metrics provided deeper insights into clustering performance:

Cohesion values indicated the strength of relationships within clusters, with the Attendance Management dataset achieving the highest cohesion, reflecting compact and meaningful clusters. Lower cohesion in the Lottery Management dataset suggests room for improvement in handling more heterogeneous requirements.

Separation metrics demonstrated the distinctiveness of clusters across datasets, with E-commerce showing the highest separation due to its well-defined functional boundaries.

Silhouette Score, a balance of cohesion and separation, highlighted the methodology's ability to achieve reasonable clustering quality across all datasets, with the highest score recorded for the Lottery Management dataset.

Davies-Bouldin Index values, indicative of clustering compactness and separation, were lowest for Attendance Management, reinforcing its strong cluster formations, while slightly higher values for Lottery Management reflected less compact clusters.

The visualizations further supported these findings, with distinct and well-separated clusters for structured datasets such as Attendance Management and School Management, while partially overlapping clusters were observed in Lottery Management due to functional overlaps in its requirements. The PCA-reduced scatter plots provide a clear representation of the semantic clustering process, aiding interpretability and further validating the methodology [14].

Despite the strong results, some limitations were observed. The clustering process relied on a fixed number of clusters, which may not always align with the inherent structure of the dataset. This could result in under- or over-clustering, especially in datasets with varied functional complexity. Additionally, the preprocessing pipeline, while robust, could be further enhanced with more domain-specific customizations, such as advanced synonym resolution or enhanced tokenization techniques, to address ambiguities in textual requirements. Finally, the methodology's reliance on static embeddings may limit its adaptability to rapidly evolving datasets, where requirements are frequently updated or redefined.

Future work will focus on enhancing the SQUIRE methodology by integrating advanced preprocessing techniques,

such as lemmatization and domain-specific synonym resolution, to improve the consistency and semantic accuracy of requirements. Adaptive clustering techniques, such as silhouette-based optimization, will be explored to dynamically determine the optimal number of clusters, ensuring better alignment with diverse datasets. Additionally, the use of more advanced models, such as GPT-based embeddings, will be investigated to capture deeper semantic relationships. A user-friendly tool incorporating real-time clustering, visualization, and traceability features will be developed to make the methodology more accessible to practitioners. Validation will be extended to real-world software engineering projects across various industries to evaluate practical applicability and scalability. Finally, interactive 3D visualizations and additional evaluation metrics will be introduced to improve interpretability and provide more comprehensive assessments of clustering quality.

VI. Conclusion

Requirements Engineering (RE) constitutes a pivotal phase in software development, focusing on the elicitation, definition, and management of stakeholder needs. Despite its criticality, traditional approaches frequently falter in managing the complexity, scale, and dynamism of contemporary software systems. Natural Language Processing (NLP) has emerged as a transformative enabler, offering automation in the analysis and organization of textual requirements. The SQUIRE framework, leveraging Sentence-BERT embeddings for semantic clustering, introduces a structured, scalable methodology for refining requirements management. By enhancing traceability, minimizing redundancy, and facilitating modular organization, SQUIRE addresses key inefficiencies in conventional RE practices. Its potential for broad applicability across diverse domains underscores its relevance to evolving software engineering demands. While SQUIRE has demonstrated efficacy, further refinements are necessary to optimize its alignment with stakeholder objectives and its adaptability to increasingly complex, dynamic requirements. Advancing the framework's flexibility and scalability will not only bridge theoretical innovations with practical application but also expand its impact across a wider spectrum of domains, establishing a robust foundation for next-generation RE methodologies.

Data-Driven Technology Augmented Reality Digitisation in Cultural Communication Design

A Case Study from Qinhuai Lantern Festival ICH

Na YIN*
School of International Education, Wuhan Business University, Wuhan 430056, Hubei, China

***Abstract*—The digitalisation of intangible cultural heritage and big data technology provide great potential for the development of intangible cultural heritage in low-carbon reform tourism, which not only increases the accuracy of AR digital design, but also contributes to the management and protection of intangible cultural heritage based on tourism. Aiming at the lack of testing and evaluation process of the current tourism intangible cultural heritage AR digital design process, this paper proposes an intangible cultural heritage AR digital design testing algorithm based on data-driven technology using Qinhuai lanterns and colours as a case study. Firstly, an AR digitization scheme based on Qinhuai lanterns intangible cultural heritage is designed; then, around the scheme, key technical contents of AR digitization design of intangible cultural heritage are analysed; secondly, combining the dragonfly algorithm with the restricted Boltzmann machine model, a test method for the AR digitization design of tourism intangible cultural heritage of low-carbon reform based on the optimization of the structural parameters of restricted Boltzmann machine by the dragonfly algorithm is put forward; lastly, relying on the collected data, the design of the AR digital design model of Qinhuai lanterns and colours tourism, and also analysed the effectiveness of the intelligent testing algorithm proposed in this paper. The results show that the proposed digital design method is effective, while the optimised test method has improved convergence speed and increased accuracy, and the test score prediction accuracy reaches 93.5%.**

I. Introduction

In recent years, with the rapid development of digital information technology, the use of information technology and intelligent algorithm technology to identify, store, display and disseminate the intangible cultural heritage (ICH) has become an important way of intangible heritage heritage inheritance and protection, which makes the digitisation of intangible heritage a hotspot of concern in the field industry and academia [1]. As a unique cultural phenomenon and spiritual wealth, intangible culture not only meets people's spiritual needs, but also enhances the attractiveness of regional tourism [2]. With the rise of Augmented Reality (AR) technology, the digitisation of ICH has made a qualitative breakthrough and development, which provides new ideas for the digital design and display of intangible genetic culture [3]. At the same time, the development of big data technology, cloud computing technology, and intelligent algorithms has provided strong support for the collection, collation and analysis of intangible heritage [4]. Currently, with the combined application of AR technology and various types of ICH, the focus of the research falls on the AR digital design process, the lack of research on the testing method of the AR digital design effect of ICH, and at the same time, taking into account the factor of low-carbon tourism, the AR digital design algorithms of intangible culture for low-carbon tourism are even more scarce [5]. Therefore, the research of AR technology and data-driven algorithms in the digital design and analysis method of ICH in low-carbon tourism has become the development trend of theoretical research and realistic problem-solving research.

Currently, the digital research of ICH mainly includes ICH digital acquisition technology, storage technology, production technology, dissemination technology, and design and analysis technology [1]. Bai and Boo propose a digital exhibition prototype system based on mixed reality technology for the digitalisation of physical museum exhibitions [6]. Tu and Jiang combine immersive virtual reality technology and proposes a digital experience method for museums [7]. Gireesh investigates 3D digital intangible genetic dissemination methods [8]. Yingji explores the application of AR technology in the digital design and display of intangible genetic culture [9]. Li et al. [10] studied an online museum roaming system based on virtual genetic digitisation technology. By analysing the existing literature research, the following problems exist in the digitization technology of intangible genetic culture based on AR technology: 1) the digitization of intangible genetic culture lacks the research of specific detail technology as well as the performance analysis; 2) the research of intangible genetic culture digitization based on AR technology lacks the research of quantitative design analysis and evaluation system. With the rapid development of artificial intelligence algorithms, the use of high-performance algorithms to solve the AR digitisation design analysis and testing problems has become one of the future directions for the application of AR technology in the development of intangible genetic culture. Considering that the digitisation of ICH is mainly to improve the dissemination of ICH as well as the development of its carriers to promote, that is, to adapt to the current low-carbon reform and tourism ICH promotion of digital applications [11].

Facing the problems existing in the current AR digital design of ICH as well as considering factors such as low-carbonisation tourism, this paper designs a design analysis and testing algorithm for assessing the AR digital design scheme. Around the consideration of low-carbon reform tourism ICH AR digital design process, combined with specific cases, through the

*Corresponding Author

analysis of AR digital design key technologies, using the restricted Boltzmann machine model [12] and heuristic optimization algorithms, designed a dragonfly algorithm [13] optimization restricted Boltzmann machine tourism ICH AR digital design test analysis algorithm.

This paper is composed of the following sections: Section II reviews the relevant research progress, reviews the existing AR and ICH digital research, and identifies gaps in technical details, performance analysis, and quantitative evaluation systems. In Section III: the research proposes an AR digitisation framework for Qinhuai Lantern Festival, which combines the dragonfly algorithm (DA) with the restricted Boltzmann machine (RBM) for optimisation. Key technologies such as AR interface design, data collection and model optimisation are analysed to improve the accuracy and efficiency of AR digitisation. In Section IV and Section V is the application part: through experiments comparing multiple algorithms, the DA-RBM model demonstrated superior performance, with a prediction accuracy of 93.5%, faster convergence and stronger testing capabilities. The paper concludes in Section VI by emphasizing the role of AR and intelligent algorithms in advancing cultural heritage protection and low-carbon tourism, demonstrating the effectiveness of the proposed DA-RBM model.

II. AR Digital Design Ideas

A. Background of the Study

In order to verify and analyse the effectiveness and superiority of the analysis algorithm of tourism intangible cultural heritage AR digitization design test analysis, this paper combines the case of intangible cultural heritage digitization of Qinhuai lanterns with the case of intangible cultural heritage digitization of Qinhuai lanterns by designing AR digitization scheme of intangible cultural heritage of intangible cultural heritage of Qinhuai lanterns, analyzing the key technologies, constructing the set of AR digitization design test indexes, and establishing the mapping relationship.

The Qinhuai Lantern Festival is one of China's traditional folk art forms, originating in the Qinhuai River Valley in Nanjing, with a long history and deep cultural heritage. It is not only known as "the first lantern festival in the world", but also famous for its grand scale and large number of participants. There are many types of lanterns, including lanterns, palace lanterns, and large lotus lanterns, many of which are used for children's games and adults' enjoyment, and have the nature of toys and handicrafts [14]. In 2008, Qinhuai lanterns were selected as part of the national intangible cultural heritage catalogue.

Qinhuai lanterns have the following characteristics [14]:

1) the shapes are mostly originated from nature;

2) the colours are characteristic of Jiangnan, mainly in the five basic tones of red, yellow, blue, green, and white;

3) they cover a variety of techniques such as paper-cutting, painting, carving, and papier-mâché.

The digital dissemination of Qinhuai lanterns is not only for the protection and inheritance of cultural heritage, but also for the diversification of culture to expand the means of dissemination, but also to inject new vitality into the traditional arts [15].

In order to improve the efficiency of digital design of Qinhuai lanterns and colours, this project obtains the digital design needs of Qinhuai lanterns and colours through questionnaires, field visits and user interviews. To summarize the digital design requirements of Qinhuai lanterns and colours, they include [16]:

- Improve the digital awareness of Qinhuai lanterns and colours AR;
- Diversify the digital functions of Qinhuai lanterns and colours AR;
- Enhance the digital stability of Qinhuai lanterns and colours AR;
- Improve the demand for digital social interaction and personalisation; and
- Increase the knowledge and fun, as display in Fig. 1.

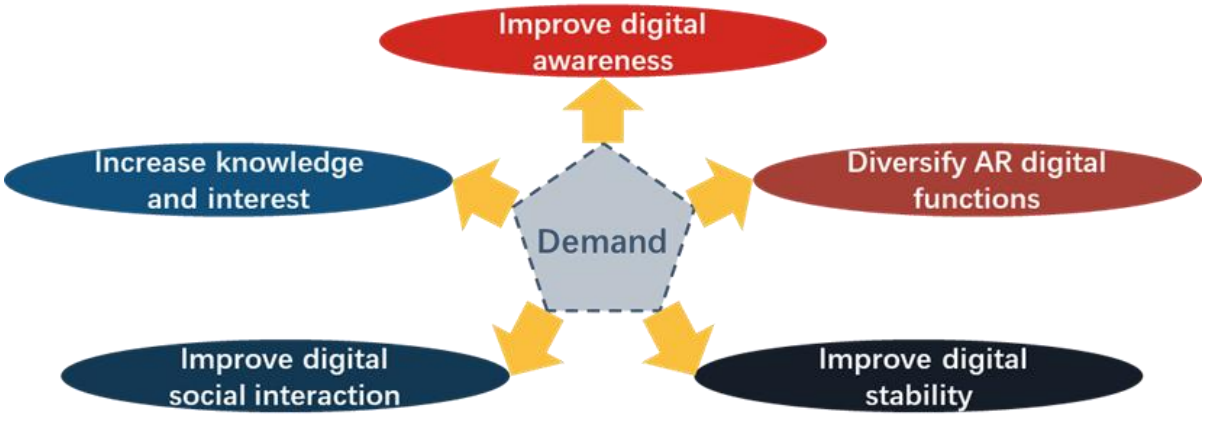

Fig. 1. Demand characterisation.

B. Design Programme

According to the digital design principles of real integrity, live scalability, and interactive experience [17], this paper designs a digital design and test and evaluation scheme for Qinhuai lantern AR that combines multiple technologies, as shown in Fig. 2.

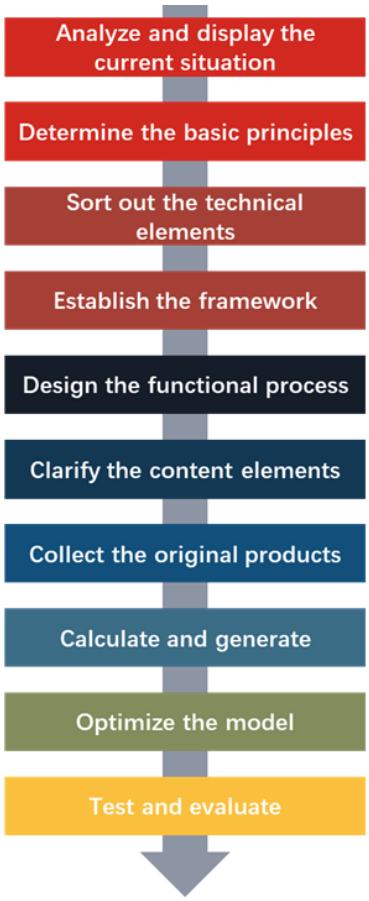

Fig. 2. General idea of the design.

From Fig. 2, the Qinhuai lantern AR digital design and testing and evaluation scheme is divided into three phases, such as pre-preparation, mid-phase, and post-phase, including the phases of analysing the current situation of the display, determining the basic principles, sorting out the technological elements, establishing the framework, designing the functional flow, clarifying the content elements, acquiring the original artefacts, generating the calculation, optimising the model, and testing and evaluating it [18].

In the Qinhuai lantern AR digital design and test and evaluation programme, based on the analysis of the current situation of the Qinhuai lantern display and its needs, the basic principles of the design are determined, and at the same time, the key technical elements of the digital display design are sorted out, and the digital display platform is structurally and functionally designed, the elements of the content are clarified, and the digital acquisition technology, storage technology, production technology, dissemination technology, and evaluation technology are used to complete the ICH. Digital display and effect analysis.

III. Analysis of Key Technologies for AR Digital Design

According to the flow of the design scheme, this section analyses the key technologies in terms of AR digital application interface design, data acquisition, digital model optimisation, digital design implementation and digital design testing, and the specific key technologies are shown in Fig. 3.

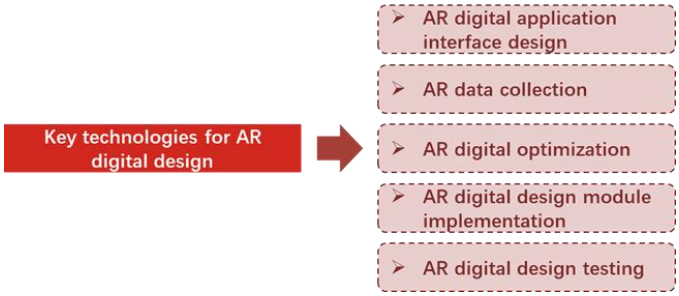

Fig. 3. Key technologies.

A. AR Digital Application Interface Design Techniques

In order to improve the satisfaction of the user experience, this paper divides the Qinhuai lantern AR application into three parts, such as discovery, AR display interface, and production techniques [19], and the specific information structure design is shown in Fig. 4. The discovery part is mainly used to provide users with information about the pavilions, activities, and works of the Qinhuai lanterns, and the display interface part is the entrance to the AR digital experience; the production techniques part is mainly used to provide users with the lantern production process.

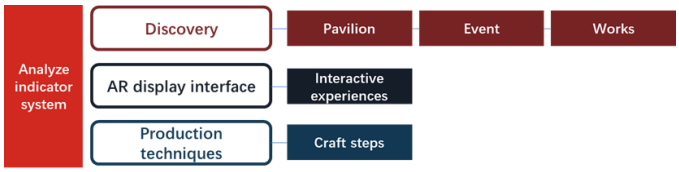

Fig. 4. AR digital information architecture design.

AR digital application interface design is divided into two phases, i.e., low-fidelity prototyping and high-fidelity prototyping [19]. Low-fidelity prototyping is generally at the initial stage of the design process and uses Figma design tools to quickly design concepts and interaction flows. High-fidelity prototype diagram design is based on low-fidelity prototype diagram design, with the help of Figma, illustrator and other design software, to carry out high-fidelity prototype diagram design and production. The high-fidelity prototype diagram design is generally designed from three aspects, such as discovery, AR display interface, and production techniques. For the AR digitisation of Qinhuai lanterns, the discovery page of this project is divided into three secondary pages, such as "Pavilion", "Activities" and "Works", as shown in Fig. 5; the AR display interface is mainly to serve the users with the AR display interface. The AR display interface mainly serves the AR interactive experience with users, as shown in Fig. 6; the production techniques are mainly selected from the perspective of universality and representativeness of the production steps of the lanterns and colours.

Fig. 5. Discovery page design.

Fig. 6. AR display interface.

B. AR Data Acquisition Techniques

The AR data acquisition technique is based on 3D scanning and modelling of Qinhuai lanterns through RealityCapture software (RC). The operation process based on RC software is shown in Fig. 7, including importing images, aligning images, calculating models, colouring, texturing, and exporting [20].

C. AR Digital Optimisation Techniques

In order to reduce the model size, reduce the rendering time, and maintain the original surface details and quality, the AR digital model optimisation method was used to process the model after AR data acquisition. The AR digital model optimisation method includes mesh simplification, material and texture optimisation, removal of hidden or redundant geometry, and merging of meshes and materials [21], as shown in Fig. 8.

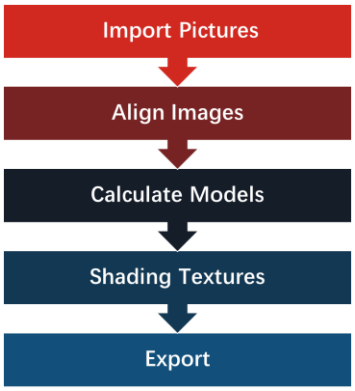

Fig. 7. RC software operation flow.

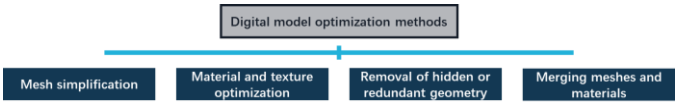

Fig. 8. AR digital optimisation method.

D. AR Digital Design Module Implementation Techniques

This project uses unity engine [22] for AR digital design module implementation.AR digital design module is implemented using SDK steps include importing Unity project, model shading, rendering model, target recognition and tracking.

E. AR Digital Design Testing Technology

AR digital design testing is mainly used for digital design performance analysis and effect evaluation [23].AR digital design testing technology tests and analyses the usability and stability of the AR digital design process by constructing and analysing the mapping relationship between AR digital design test index values and test evaluation levels, adopting certain fitting algorithms, and learning the training data, as shown in Fig. 9. This project uses an intelligent optimisation algorithm combined with a restricted Boltzmann machine.

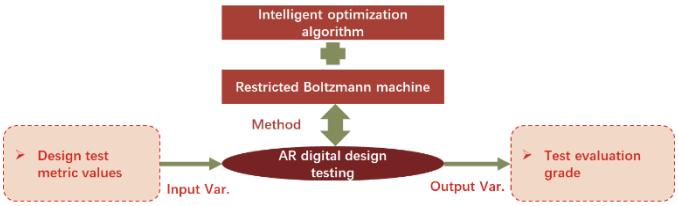

Fig. 9. AR digital design test methodology.

IV. AR Digital Design Testing

In order to analyse the AR digital quantification of Qinhuai lanterns and increase the accuracy of AR digital design test, this paper adopts the dragonfly algorithm to optimize the restricted Boltzmann mechanism to build the AR digital design test model.

A. AR Digital Design Test Models

1) AR digital design test metrics: In order to effectively analyse and assess the advantages and disadvantages of AR digital design solutions, based on the principles of systematic, objective, operable and other AR digital design test index selection, from the four aspects of the AR digital application interface A, acquisition B, model optimization C, design implementation D, to construct the AR digital design based on the discovery of A1, the AR display interface A2, the production techniques A3, aligning images B1, computing models B2, colouring B3, Texture B4, Mesh Simplification C1, Material and Texture Optimisation C2, Removal of Hidden or Redundant Geometry C3, Merging Mesh and Material C4, Model Colouring D1, Rendering Model D2, Target Recognition and Tracking D3, and other 14 test metrics sets [24], as shown in Fig. 10.

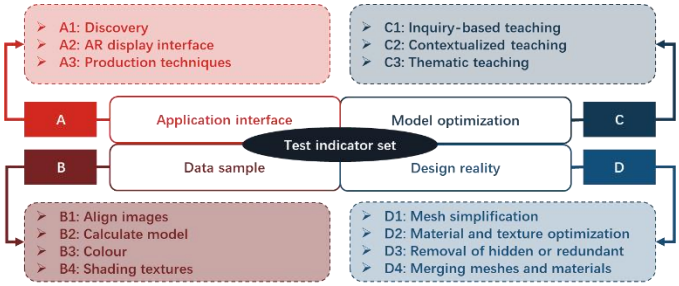

Fig. 10. Test indicator.

2) AR digital design test values and grades: In order to determine the quantitative AR digital design test assessment values and identify the test assessment levels, this paper divides the test assessment levels into six levels [24], and the specific relationship between each level and the corresponding test assessment value is shown in Table I.

TABLE I. CORRESPONDENCE BETWEEN TEST VALUE AND GRADE

No.	*Rank levels*	*Test scores*
1	Worse design	[0, 3]
2	Bad design	(3,6]
3	Fair design	(6,8]
4	Good design	(8, 10]
5	Better design	(10,12]
6	Great design	(12, 14]

3) Mapping relationships: For the Qinhuai lantern colours ICH, the AR digital design test model mainly constructs the mapping relationship between the AR digital design test indicators and the AR digital design test values as well as the grades, and the specific mapping calculation formula is as follows:

$$Y_{score} = f_{indicator-score}\left(X_{indicator}\right) \tag{1}$$

$$Y_{rank} = f_{ranklevel}\left(X_{indicator}\right) \tag{2}$$

Where $X_{indicator}$ denotes the AR digital design test metrics, $f_{indicator-score}$ denotes the mapping between the metrics and the test assessment values, Y_{score} denotes the AR digital design test values, $f_{ranklevel}$ denotes the mapping between the metrics and the test ratings, and Y_{rank} denotes the test ratings.

According to the principle of the AR digital design test model of Qinhuai lantern colour ICH, the mapping relationship between the AR digital design test indexes and the AR digital design test values as well as the grades is constructed as shown in Fig. 11.

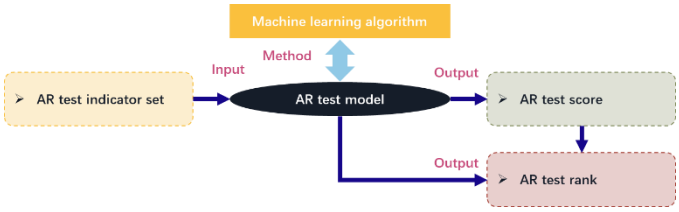

Fig. 11. AR digitisation test mapping relationship.

B. Intelligent Analysis Methods

Aiming at the problem of AR digital design testing of Qinhuai lanterns and ICH, this paper combines the constrained Boltzmann machine with the dragonfly algorithm, and proposes an intelligent analysis method for AR digital design testing based on the dragonfly algorithm to optimise the constrained Boltzmann machine.

1) Restricted boltzmann machines: Restricted Boltzmann Machine (RBM) [25] is an artificial neural network based on an energy model that consists of two layers of neurons: a visible layer and a hidden layer. The neurons between these two layers are fully connected, but there are no connections between neurons within the same layer. The RBM can be used for feature learning and generative model training, and is particularly adept at capturing high-level features of the data.

a) RBM probability distribution: RBM is a probability distribution model based on energy. Given the state vectors h and v, the current energy function of RBM is represented as follows:

$$E\left(v,h\right) = -a^T v - b^T h - h^T W v \tag{3}$$

where a and b denote the vector of bias coefficients and W denotes the weight matrix.

Define the probability distribution of the RBM in conjunction with the energy function:

$$P\left(v,h\right) = \frac{1}{Z} e^{-E(v,h)} \tag{4}$$

where Z is the normalisation factor.

$$Z = \sum_{v,h} e^{-E(v,h)} \tag{5}$$

According to the probability distribution, the conditional distribution is expressed as follows:

$$P\left(h|v\right) = \frac{P\left(h,v\right)}{P\left(v\right)} = \frac{1}{Z'} \prod_{j=1}^{n_h} \exp\left\{b_j^T h_j + h_j^T W_j; v\right\} \tag{6}$$

where Z' is the new normalisation factor.

$$\frac{1}{Z'} = \frac{1}{P\left(v\right)} \frac{1}{Z} \exp\left\{a^T v\right\} \tag{7}$$

The sigmoid activation function is used in the RBM from the visible layer to the hidden layer:

$$P\left(v_j=1|h\right)=sigmoid\left(a_j+W_{:,j}^{T}h\right) \tag{8}$$

b) RBM model loss function and optimisation: In order to solve for the parameters W , a and b , for m samples of the training set, the RBM generally uses a logarithmic loss function, i.e., it is expected to minimise the following equation:

$$L\left(W,a,b\right)=-\sum_{i=1}^{m}\ln\left(P\left(V^{(i)}\right)\right) \tag{9}$$

where $V^{(i)}$ denotes the ith particular training sample.

The gradient derivation results for the parameters W , a and b are as follows:

$$\frac{\partial\left(-\ln\left(P\left(V\right)\right)\right)}{\partial a_i}=\sum_{v}P\left(v\right)v_i-V_i \tag{10}$$

$$\frac{\partial\left(-\ln\left(P\left(V\right)\right)\right)}{\partial b_i}=\sum_{v}P\left(v\right)P\left(h_i=1|v\right)-P\left(h_i=1|V\right) \tag{11}$$

$$\frac{\partial\left(-\ln\left(P\left(V\right)\right)\right)}{\partial W_{ij}}=\sum_{v}P\left(v\right)P\left(h_i=1|v\right)v_j-P\left(h_i=1|V\right)V_j \tag{12}$$

RBM has a wide range of applications in a variety of machine learning tasks, including dimensionality reduction, feature learning, classification: for training classifiers, collaborative filtering, and generating models.

c) DA algorithm: Dragonfly Algorithm (DA) [26] is a novel intelligent optimisation algorithm proposed by Seyedali Mirjalili in 2016. The algorithm is inspired by the static and dynamic group behaviours of dragonflies in nature, in particular the collective intelligence they display in finding food and avoiding predators. The dragonfly algorithm is suitable for solving complex optimisation problems due to its high optimisation seeking capability and ease of implementation

The core of the dragonfly algorithm lies in modelling the group behaviour of dragonflies, including five behavioural styles such as separating, queuing, allying, searching for food and avoiding natural enemies. These behaviours are abstracted through mathematical models, forming the basic framework of the algorithm. In the algorithm, each individual dragonfly represents a potential solution, and the optimisation problem is explored and solved by simulating these behaviours.

- Separation behaviour: Neighbouring dragonflies are separated from each other and kept at a distance to avoid collisions:

$$S_i=-\sum_{j=1}^{N}\left(X-X_j\right) \tag{13}$$

where S_i denotes the value of the separation behaviour of the i^{th} dragonfly, and X_j denotes the individual position of the jth dragonfly.

- Queuing behaviour: Individual dragonflies maintain the same speed as other dragonflies in their neighbourhood by controlling their speed and direction, allowing populations to migrate in the same direction:

$$A_i=\frac{\sum_{j=1}^{N}\Delta X_j}{N} \tag{14}$$

Where A_i denotes the amount of queuing behaviour, ΔX denotes individual speed and N denotes the number of dragonflies in the neighbourhood.

- Allied behaviour: Individual dragonflies and neighbouring conspecifics converge towards the centre of the surrounding group:

$$C_i=\frac{\sum_{j=1}^{N}X_j}{N}-X \tag{15}$$

where A_i denotes the amount of aligned behaviour.

- Food-seeking behaviour: Individual dragonflies seek out and approach food in order to survive:

$$F_i=X^{+}-X \tag{16}$$

where F_i denotes the amount of foraging behaviour and X^{+} denotes the location of food.

- Avoidance of natural enemy behaviour: Individual dragonflies have instinctive vigilance and behaviour away from natural enemies:

$$E_i=X^{-}+X \tag{17}$$

Where E_i denotes the amount of enemy avoidance behaviour and X^{-} denotes the location of natural enemies.

When there are other dragonflies in the neighbourhood of an individual dragonfly, the step vector is calculated as follows:

$$\Delta X_{t+1}=\left(sS_i+aA_i+cC_i+fF_i+eE_i\right)+\omega\Delta X_t \tag{18}$$

Where t denotes the current iteration number, s , a , c , f and e denote the separation, formation, focusing, foraging and enemy avoidance behavioural weights respectively, and ω denotes the inertia weights.

The updated formula for the position of the next generation of dragonfly individuals is:

$$X_{t+1} = X_t + \Delta X_{t+1} \tag{19}$$

When there are no other dragonflies in the neighbourhood of a dragonfly individual, the current dragonfly is unable to update its own position through the information of other individuals in the neighbourhood. In order to ensure that the algorithm better explores the search space, the dragonfly individual position is calculated as follows using the Lévy flight random wandering strategy:

$$X_{t+1} = X_t + Levy(d) \times X_t \tag{20}$$

$$Levy(d) = 0.01 \times \frac{r_1 \times \sigma}{|r_2|^{\frac{1}{\beta}}} \tag{21}$$

$$\sigma = \left(\frac{\Gamma(1+\beta) \cdot \sin\frac{\pi\beta}{2}}{\Gamma\left(\frac{1+\beta}{2}\right) \cdot \beta \cdot 2^{\left(\frac{\beta-1}{2}\right)}} \right)^{\frac{1}{\beta}} \tag{22}$$

where $Levy(d)$ denotes the Levy flight strategy and $\Gamma(x) = (x-1)!$.

The formula for calculating the radius of the dragonfly neighbourhood is as follows:

$$r = \frac{ub - lb}{4} + 2(ub - lb)\frac{t}{t_{\max}} \tag{23}$$

Where ub and lb denote the upper and lower limits of the search space, t and $t_{\max}$ are the current iteration number and the maximum iteration number. The radius of the dragonfly neighbourhood increases with the number of iterations. When the number of iterations increases for a certain number of times, all dragonflies become individuals in the neighbourhood, updating their positions and step sizes through the information of all other dragonflies, which will eventually converge.

d) Constrained Boltzmann machine models incorporating DA algorithms: In order to increase the accuracy of the testing algorithm, this paper uses the dragonfly algorithm to optimise the RBM model, i.e., the dragonfly algorithm is used to find a set of RBM parameters to minimise the testing error.The decision variables of the DA-RBM algorithm are the parameters W , a , and b , and the RMSE value is used as the fitness evaluation function of the dragonfly algorithm:

$$RMSE = \sqrt{\frac{1}{M}\sum_{i=1}^{M}(\hat{y}_i - y_i)^2} \tag{24}$$

Where, x is the data sample, c_i denotes the i^{th} clustering centre and d denotes the dimension of the data sample.

The flow of the DA algorithm to optimise the RBM method is displayed in Fig.12 with the following steps:

- Step 1: Initialise parameters, including population size, maximum number of iterations, etc;
- Step 2: Based on the structural parameters of the RBM model, generate an initial population, i.e., dragonfly individuals randomly distributed in the search space;
- Step 3: Assess the fitness of each individual dragonfly, i.e. the quality of its problem solving;
- Step 4: Determine whether there are other individuals in the dragonfly's neighbourhood, if so, update the individual's position by using separation, queuing, alliance, food searching and natural enemy avoidance behaviours, otherwise update the individual's position by using the Levy flight strategy;
- Step 5: Repeat the above steps until the maximum number of iterations, output the optimal RBM model structure parameters, and construct the RBM model based on the DA algorithm.

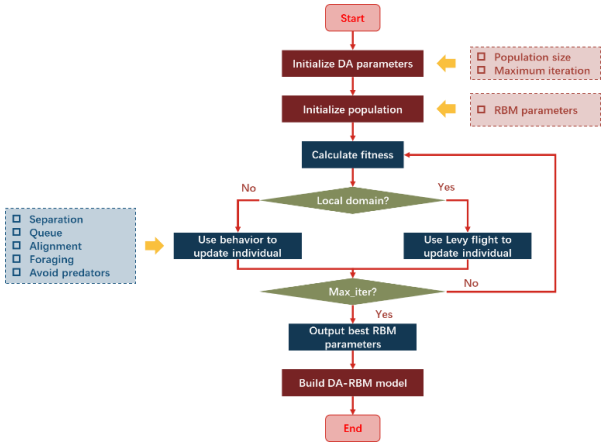

Fig. 12. Flowchart of DA-RBM algorithm.

e) Design test intelligent analysis model construction process: In order to construct an intelligent analysis model based on the AR digital design test of Qinhuai lanterns and colours, this paper adopts the DA-RBM model, by analysing the AR digital design test indexes and test values, taking the parameters of RBM W , a and b as the optimization variables, and taking the RMSE value as the fitness value function, and using DA algorithm optimization strategy to search for the optimal parameters of RBM W^* , a^* and b^* . The principle of the application of the DA-RBM model and the structure of the framework are shown in Fig. 13.

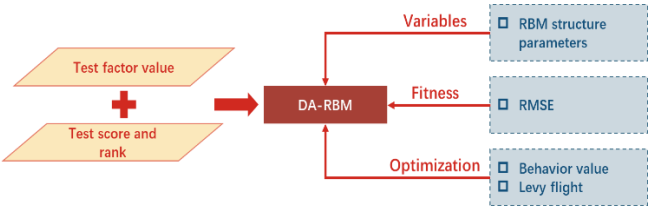

Fig. 13. DA-RBM application analysis.

According to the application of DA-RBM model in the AR digitisation problem of Qinhuai lantern colour low-carbon tourism ICH, the specific flow of the design test intelligent analysis method based on DA-RBM model is shown in Fig.14. As can be seen from Fig. 14, by analysing the key technology of AR digitization of Qinhuai lanterns and low-carbon tourism ICH, determining the AR digitization design test indexes, test scores, and grades, and after the data preprocessing technology, obtaining the training and testing sample set, combining with the intelligent optimization algorithm proposed in this paper to improve the machine learning algorithm, to achieve the construction and optimization of AR digitization design test model of AR digitization of ICH of low-carbon tourism of Qinhuai lanterns and colours.

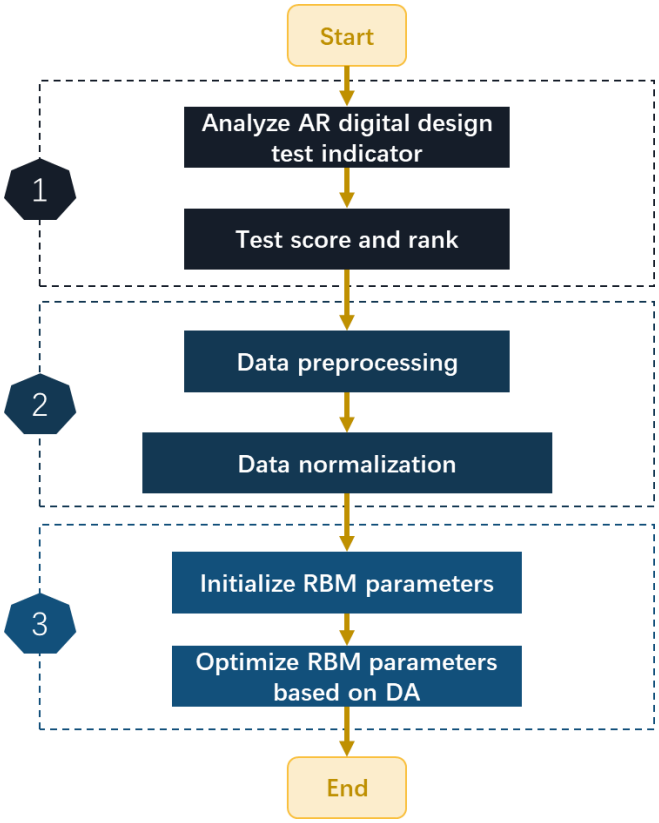

Fig. 14. Building intelligent analysis model for design test.

V. Analysis of Test Results

A. Test Environmental Setup

The experimental simulation environment is Windows 10, CPU is 2.80GHz, 8GB RAM. RealityCapture software is used for digitisation of Qinhuai lanterns, Vuforia SDK is used for functional implementation of AR, and Python 3.7 is used as the programming language for ICH AR digital design and testing algorithm.

B. Contrast Algorithm Parameter Settings

In order to verify the feasibility and efficiency of the ICH AR digital design and testing algorithms proposed in this paper, this paper takes the data collected during the AR digital design process of Qinhuai lanterns and colours as the analysis data, and six design testing algorithms are selected for comparison, as shown in Table II.

TABLE II. Comparison Algorithm Parameter Settings

Projects	*Parameter settings*
RBM	The number of hidden layer nodes is 150
PSO-RBM [27]	V_{max}=30, V_{min}=-30, r=0.5
GSA-RBM [28]	Alpha is 20, G0 is 100, Rnorm=2, Rpower=1
TLBO-RBM [29]	Tr=round(1+rand)
GWO-RBM [30]	a decreases linearly from 2 to 0
DA-RBM	Inertia weights are [0.4,0.9], separation, queuing, alliance, foraging, and enemy avoidance are 0.1, 0.1, 0.7, 1, and 1 respectively

As can be seen from Table II, the comparison algorithm parameters are mainly divided into two categories. For the RBM model parameters, the number of hidden layer nodes is set to 150; for the intelligent optimisation algorithm parameters, the maximum number of iterations is set to 100 and the population size is 50.

C. Analysis of AR Digital Realisation

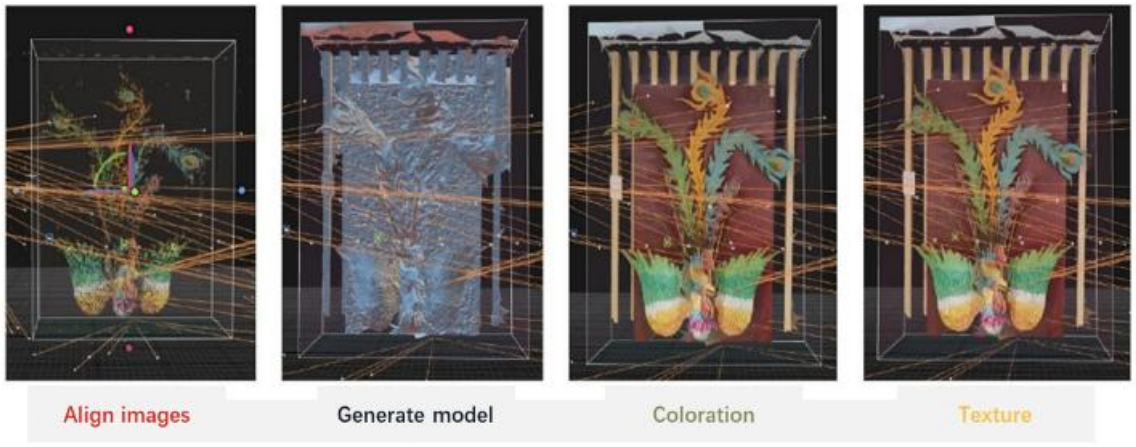
In order to verify the effectiveness of the AR digitisation design method, this paper adopts RealityCapture software and Vuforia SDK to implement the AR digitisation of Qinhuai lanterns and colours, and the specific analysis results are shown in Fig. 15 and Fig. 16.

From Fig. 15, the AR digital acquisition of Qinhuai lanterns is done through the process of aligning images, generating models, colouring and texturing to get the AR digital preliminary model.

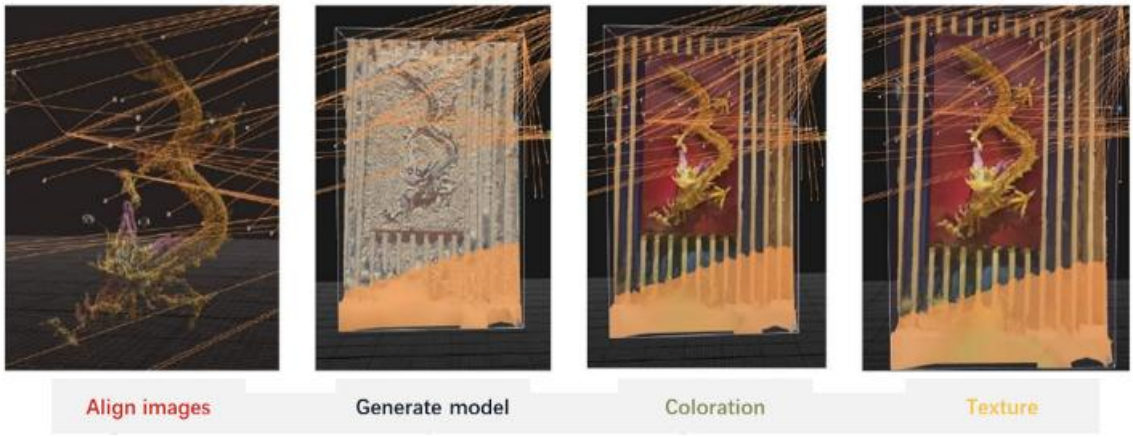
D. Test Performance Analysis

In order to validate the feasibility and effectiveness of the AR digitisation design test method based on the DA-RBM model, this paper compares the performance of the RBM, PSO-RBM, GSA-RBM, TLBO-RBM, GWO-RBM, and DA-RBM methods by using Qinhuai Colourful Lanterns AR digitisation process dataset.

From Fig. 16, we can see that the RBM optimisation based on the DA algorithm has a higher convergence accuracy than the other algorithms and has a better convergence speed than the other algorithms; the DA-RBM starts to converge at 20 iterations and converges to near 0.



(a) Intentions of the digital acquisition process for the Phoenix Lights model



(b) Intentions of the digital capture process for the dragon lantern model

Fig. 15. Digital acquisition process of Qinhuai lantern colours.

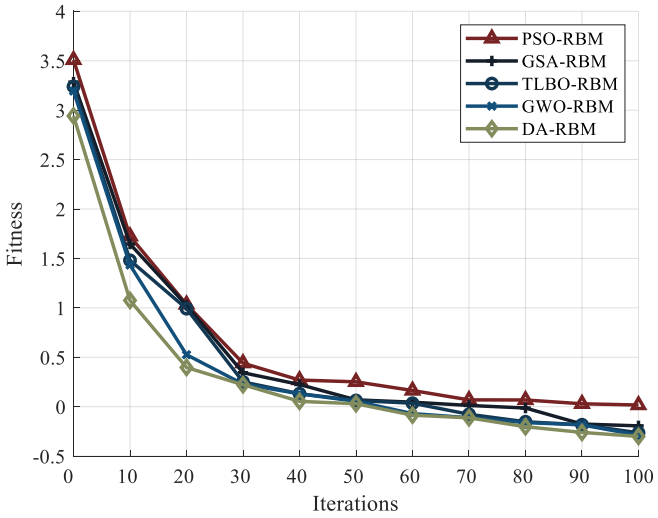


Fig. 16. AR digital design test method based on intelligent optimisation algorithm.

The test prediction scores for the RBM, PSO-RBM, GSA-RBM, TLBO-RBM, GWO-RBM, and DA-RBM methods, as well as the test rating results, are given in Figure 16. As can be seen from Fig. 17, the test prediction scores of the AR digital design test algorithm based on the DA-RBM model are closest to the true scores, and the test prediction errors are less than those of RBM, PSO-RBM, GSA-RBM, TLBO-RBM, and GWO-RBM.

The statistical results of RBM, PSO-RBM, GSA-RBM, TLBO-RBM, GWO-RBM, and DA-RBM method tests are given in Table III. In terms of RMSE, the prediction error of the DA-RBM-based AR digital design testing algorithm is the smallest, reaching 0.0178; in terms of accuracy, the test score prediction accuracy of the DA-RBM-based AR digital design testing algorithm is the smallest, reaching 93.5%; in terms of optimisation convergence time, the DA-RBM-based AR digital design testing algorithm has the shortest optimisation convergence time of is 4.40s; in terms of testing time, the DA-RBM-based AR digital design testing algorithm has the smallest test sample prediction time of 0.48s.

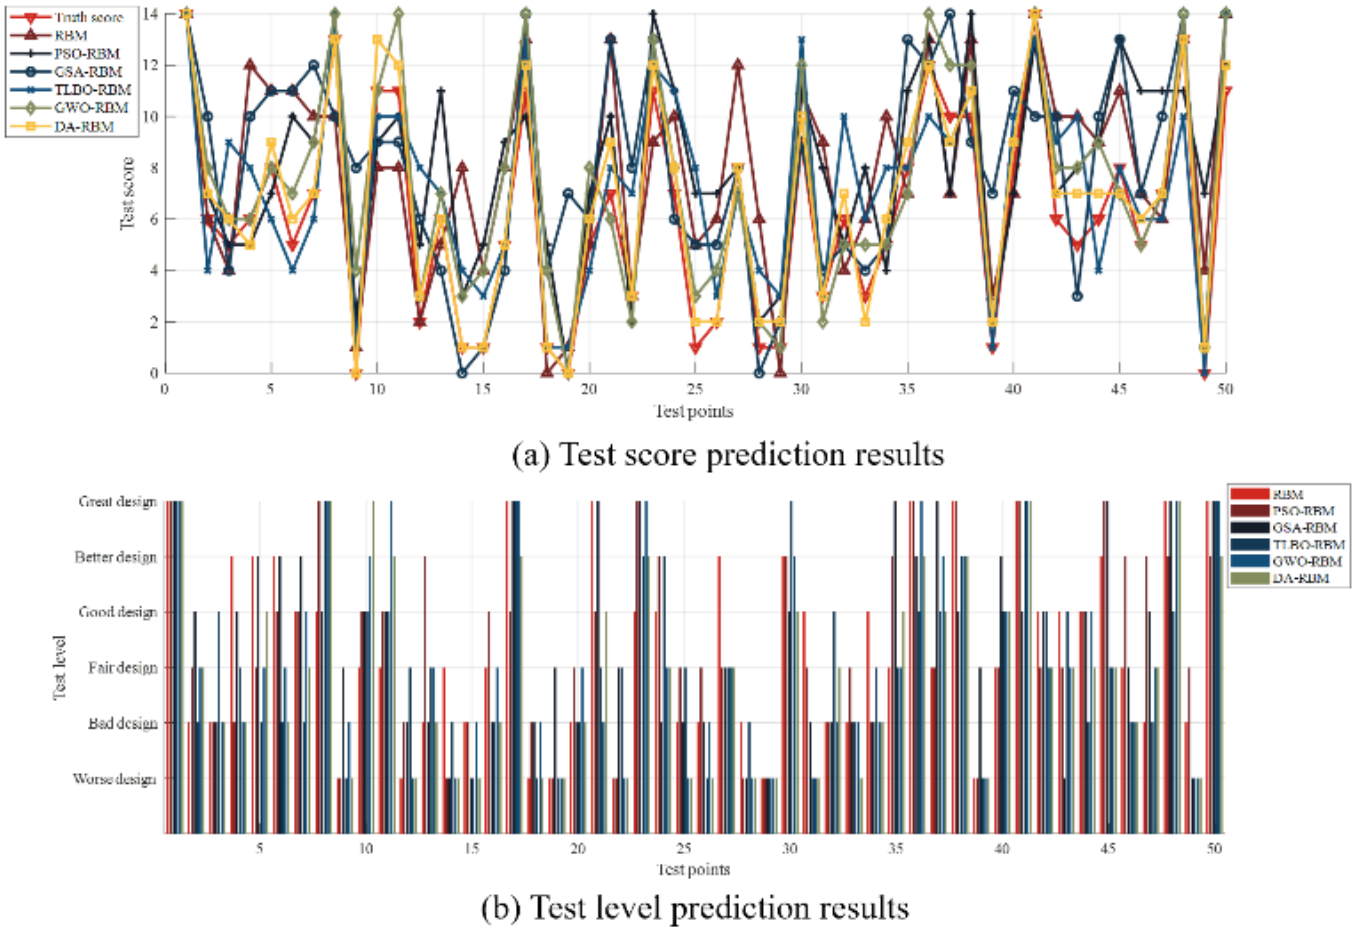

Fig. 17. Predicted performance results of test methods.

TABLE III. COMPARISON OF DESIGN TEST ALGORITHM PERFORMANCE

Arithmetic	*RMSE*	*Precision/%*	*Optimisation time/s*	*Test time/s*
RBM	0.0698	85.92	4.88	0.98
PSO-RBM	0.0549	88.76	5.83	0.87
GSA-RBM	0.0671	86.21	7.76	0.95
TLBO-RBM	0.0433	90.88	4.56	0.56
GWO-RBM	0.0368	90.35	5.45	0.59
DA-RBM	0.0178	93.50	4.40	0.48

VI. Conclusion

This study demonstrates that integrating augmented reality (AR) with advanced data-driven algorithms significantly enhances the digital design and testing process for intangible cultural heritage (ICH), particularly in the context of low-carbon tourism. By employing the Dragonfly Algorithm (DA) optimized Restricted Boltzmann Machine (RBM) model, we successfully improved the accuracy, efficiency, and robustness of AR digitization for the Qinhuai Lantern Festival.

The proposed AR digital design testing algorithm outperformed other methods, achieving a test score prediction accuracy of 93.5%. This superior performance highlights the model's capacity to process and analyze large datasets with greater speed and precision, making it an effective solution for assessing AR digital designs in the preservation and promotion of ICH.

By focusing on both cultural preservation and eco-friendly tourism, this method not only strengthens the protection of heritage but also contributes to sustainable tourism development. As AR technology continues to evolve, integrating intelligent optimization algorithms like DA will play a crucial role in shaping the future of digital cultural communication and heritage conservation.

Spatial Attention-Based Adaptive CNN Model for Differentiating Dementia with Lewy Bodies and Alzheimer's Disease

K Sravani, V RaviSankar
Department of Computer Science and Engineering, GITAM University, Hyderabad, India

***Abstract*—Differentiation of Alzheimer's Disease (AD) and Dementia with Lewy Bodies (DLB) utilizing brain perfusion Single Photon Emission Tomography (SPECT) is crucial and it might be difficult to distinguish between the two illnesses. The most recently discovered characteristic of DLB for a possible diagnosis is the Cingulate Island Sign (CIS). This work aims to differentiate DLB and AD by utilizing a deep learning model and this model is named AD-DLB-DNet. Initially, the required images are collected from the benchmark dataset. Further, the Spatial Attention-Based Adaptive Convolution Neural Network (SA-ACNN) is used to visualize the CIS features from the images where the attributes are tuned using Improved Random Function-based Birds Foraging Search (IRF-BFS). Further, CIS features attained from the SA-ACNN are used to accurately differentiate the DLB and AD. Finally, the Dilated Residual-Long Short-Term Memory (DR-LSTM) layer is proposed to accurately perform the AD and DLB differentiation for identifying the clinical characteristics of the DLB. The suggested model is used for differentiating between AD and DLB for taking effective therapeutic measures. Finally, the validation is performed to validate the effectiveness of the introduced system.**

Keywords*—Alzheimer's disease and dementia with lewy bodies differentiation; spatial attention-based adaptive convolution neural network; cingulate island sign; improved random function-based birds foraging search; dilated residual-long short-term memory

I. INTRODUCTION

Global healthcare systems are severely impacted by neurodegenerative dementias, particularly as the number of elderly people rises. The World Health Organization (WHO) reports that approximately 50 million individuals globally are affected by dementia [1]. AD is responsible for around 60% of these cases, making it the most common neurological disorder [2]. DLB, characterized by the accumulation of LB, is the second most prevalent type of neurodegenerative dementia, following AD and some cases are often misdiagnosed and overlooked [3], [4]. In addition to identifying and managing clinical aspects such as severe autonomic dysfunction, motor and mental symptoms, and dangerous antipsychotic sensitivity, an accurate and timely detection of DLB is crucial for ensuring appropriate care and treatment [5].

Predicting the disease's prognosis and organizing clinical trials also depend on a reliable diagnosis, but the significant clinical and cognitive similarities between AD and DLB may make the diagnostic procedure more difficult [6]. Additionally, a variety of clinical manifestations may result from the common presence of pathological variability in individuals containing DLB, particularly the presence of co-occurring AD pathology, such as tau tangles and amyloid beta (Aβ) plaques [7]. Compared with DLB patients exhibiting solely Lewy body pathology, those with Aβ pathology is linked to reduced life expectancy and a higher rate of cognitive impairment [8]. These findings highlight the clinical significance of detecting concomitant amyloid-beta (Aβ) pathology in patients with DLB. Functional neuroimaging, a commonly employed tool in the medical detection of dementia, it has also been integrated into the detection criteria for AD as well as DLB [9], [10]. Even seasoned neurologists find it difficult to diagnose certain conditions, and sometimes choosing the best course of action is also difficult. Therefore, to give more reliable clinical evaluations, doctors employ diagnostic techniques such as neurofunctional imaging [11], [12].

Recently deep learning techniques for medical image analysis are growing steadily, particularly in neurodegenerative illnesses [13]. This broad recognition stems from its capacity to automatically identify useful features and reduce the requirement for handcrafted feature extraction. Unlike typical machine learning approaches, it can learn intricate patterns in imaging information which is difficult for humans to perceive [14], [15]. Most deep learning models used in neurodegenerative illnesses primarily identify many stages of AD, ranging from no dementia to mild AD, utilizing 2D imaging scans. Nevertheless, these models are only useful for the AD diagnosis, which means they cannot distinguish the patterns between AD and DLB. Furthermore, it is challenging to confirm their robustness when non-AD dementias are present [16], [17]. The quantitative approach requires standardized methods for acquiring and interpreting structural scans and 18F-FDG-PET, which can be time-consuming. Interestingly, in differentiating DLB from AD, a straightforward visual evaluation of Cortical Involvement (CIS) as either present or absent proved to have higher diagnostic accuracy than the quantitative CIS ratio. Although visual evaluation of other imaging indicators and modalities is widely utilized and has shown to be a quick, accurate, and repeatable procedure in clinical practice, there are no standardized visual guidelines to assess the extent of CIS. In addition to increasing the diagnostic accuracy of DLB, the use of pertinent diagnostic data may be improved using a consistent approach for classifying and interpreting the presence of CIS. Additionally, it is simple to incorporate a visual grading system into clinical practice across sites. To

effectively identify the differences between DLB and AD, a new deep learning model is introduced. The following points highlight the contributions of the developed framework.

- To develop a deep learning model to differentiate DLB from AD by utilizing images from a benchmark dataset. This approach enhances diagnostic accuracy by allowing the model to learn subtle differences between DLB and AD from high-quality, standardized brain images.
- To employ SA-ACNN to visualize and extract CIS, enabling the model to focus on the most relevant regions in medical images, thereby improving feature accuracy and relevance.
- To reintroduce BFS as IRF-BFS to fine-tune and optimize the CIS features. The parameters of SA-ACNN such as hidden neuron count, steps per epoch count, and epoch size are optimized that maximize the accuracy.
- To integrate the Dilated Res-LSTM layer, enabling the model to accurately identify and differentiate clinical features of DLB and AD, which aids in early diagnosis and effective therapeutic intervention.

The structure of the newly introduced deep learning technique for differentiating DLB and AD is outlined as follows. Section II reviews the literature on DLB and AD differentiation models. Section III presents an adaptive deep-learning mechanism designed to enhance DLB and AD differentiation, utilizing an improved optimization algorithm to boost performance and accuracy. Section IV explains the proposed model for feature extraction. Section V introduces a novel approach for differentiating DLB and AD. Part VI provides the Experimental results. Section VII contains Comparative analysis detailed discussion. Finally, Section VIII concludes the study.

II. Literature Survey

A. Related Works

In 2023, Nakata et al. [18] assessed the brain imaging variance among MCI with Lewy Bodies (MCI-LB) as well as MCI due to AD (MCI-AD) by examining brain atrophy and brain perfusion patterns. The analysis focused on differences in regional brain changes in individuals with these two conditions. It was found that MCI-LB and MCI-AD exhibited distinct patterns of brain atrophy and blood flow abnormalities. These differences helped distinguish between the two types of MCI, highlighting the unique features associated with each condition.

In 2024, Karim et al. [19] have used graph theory and machine learning measures to forecast AD. Several machine learning models were developed for AD prediction using the OASIS and SALD datasets. The study identified key elements of functional connectivity and brain network structure in AD, noting a significant loss of connections between the thalamus and top 13 regions. These findings highlighted the potential of combining machine learning, graph theory for accurate AD diagnosis and for early prediction.

In 2024, Hasan and Wagler [20] have suggested CNN-GCN architecture which was produced by first implementing the CNNs and feeding it to the GCN classifier. To train and assess the suggested techniques the whole-brain images were used. They evaluated the effectiveness of the technique by presenting the findings from the best fold out of the five folds.

In 2022, Etminani et al. [21] have developed a 3D deep learning model that utilized PET scans with a specific radioactive tracer to forecast the final clinical diagnosis of DLB, AD, and other conditions. The performance of this model was compared to that of experienced nuclear medicine physicians. To visualize the regional metabolic changes, methods were employed to highlight the areas of interest.

In 2020, Gjerum et al. [22] implemented a strong visual CIS scale and assessed its ability to distinguish between AD and DLB. When compared to AD patients and controls, DLB patients' visual CIS scores were much greater. To sum up, the visual CIS scale was a clinically helpful tool for distinguishing AD from DLB. Aβ pathology in DLB patients may be connected to the severity of CIS.

In 2020, Kanetaka et al. [23] proposed prospective research comparing the CIS on Single Photon Emission Computed Tomography (SPECT) in individuals. The CIS score, calculated using eZIS software, is the ratio of the posterior cingulate gyrus (VOI-1) to areas of notably decreased regional cerebral blood perfusion (VOI-2). Due to insignificant RCBF decline in the PCG, diagnosing MCI with the CIS score is challenging.

In 2022, Lim et al. [24] suggested a multiclass categorization technique using 3D T1-weight brain MRI images. The ResNet-50 and VGG-16 convolutional bases were utilized as feature extractors. A novel densely connected classifier was put into place to do classification on top of the convolutional bases.

In 2017, McKeith et al. [25] made a clear distinction between clinical characteristics and diagnostic biomarkers and provided guidelines on the best ways to determine and interpret them. Here, the diagnostic role of laboratory, electrophysiologic, and neuroimaging tests has been expanded. Significant progress has been made in recognizing DLB.

B. Problem Statement

Millions of people worldwide are greatly affected by the serious disorder called AD. Behavioral abnormalities and memory loss are the symptoms associated with AD. The structural changes in the brain are the main cognitive dysfunction caused by AD. To initiate the treatment approaches, dementia and AD must be detected at an earlier stage but the traditional model faces various issues, and it is listed in Table I.

Traditional strategies do not have the capability to diagnose the CIS from the images, so they fail to differentiate among the AD and DLB.

The functional connectivity of the brain is not detected by this model and this model is so invasive and costly making it unsuitable for the early diagnosis process.

TABLE I. FEATURES AND CHALLENGES OF EXISTING DLB AND AD DIFFERENTIATION MODEL

Author [citation]	Methodology	Features	Challenges
Nakata et al. [17]	RCBF	The symptoms of mild cognitive impairment are effectively detected by this model. It is used for the early AD detection.	This model fails to identify the signs of dementia.
Karim et al. [18]	SVM	This model accurately defines the structure of the brain network.	The characteristics of the brain network are not analyzed by this model.
Hasan and Wagler [19]	CNN-GCN	The initial symptoms of AD are diagnosed.	The imbalanced dataset cannot handle.
Etminani et al. [20]	3D deep learning	The systems robustness is high. The proposed model is applied in the clinical setting for making the effective decision.	The transparency of the system is low.
Gjerum et al. [21]	robust visual rating scale	The presence of dementia is effectively detected by this model. The degree of the CIS is determined by this model.	It lacks in the pathological information. The memory cohort is not analyzed by this model.
Kanetaka et al. [22]	DLB	The volume of the CIS is measured using this model.	The symptoms of the disease cannot be diagnosed.
Lim et al. [23]	CNN	It is used for executing the multi-classification of images. It uses dense connections for accurately classifying the AD in the humans.	This model does not evaluate the low-dimensional feature scores
McKeith et al. [24]	Optimal AD detection methods	It is employed to support the medical decision-making process. It is used to provide adequate medical support to the patients	The behavioral abnormalities are not detected by this model

The prior systems are ineffective for preventing the progression of DLB in individuals as they are not effectively determining the synchronization of the brain regions.

The prior approaches are unsuitable for discriminating against DLB patterns from AD patterns, so it is quite difficult to automatically detect the presence of DLB and AD from humans.

III. IMAGING CLASSIFICATION OF DEMENTIA WITH LEWY BODIES AND ALZHEIMER'S DISEASE USING DEEP LEARNING NETWORK

A. Proposed DLB and AD Imaging Classification Model: Description

Models for differentiating DLB and AD typically depend on manual feature extraction, a process that can be time-intensive and susceptible to human error. The accuracy of these models is limited due to the overlap in clinical symptoms between the two conditions. Traditional methods may not effectively capture complex patterns in neuroimaging data, leading to misdiagnosis. Additionally, these models often lack the ability to integrate and analyze multiple types of data simultaneously. Consequently, a deep learning model was developed to enhance differentiation by automatically learning and identifying intricate patterns in imaging and clinical data, improving diagnostic accuracy and efficiency. However, using deep learning for differentiating DLB and AD may face challenges including limited availability of labeled data, high variability in brain scans due to individual differences, difficulty in differentiating subtle disease patterns and so on. Thus, it is necessary to develop novel DLB and AD differentiating systems with the support of enhanced deep learning mechanism.

This study aims to differentiate DLB from AD using an advanced deep learning model. The process begins with collecting the necessary brain images from a benchmark dataset. Initially, the brain images are fed into the SA-ACNN to visualize critical image features, where SA-ACNN is developed by integrating spatial attention layer into the CNN architecture along with the network parameter optimization. For performing this optimization, an efficient heuristic algorithm named BFS is reintroduced as EBFS. Here, the parameters such as steps per epoch count, hidden neuron count, and epoch size in SA-ACNN are optimized to maximize the accuracy. The SA-ACNN's spatial attention mechanism focuses on the most relevant parts of the images, improving CIS feature extraction. Moreover, the EBFS fine-tunes this process for supporting more precise differentiation. These extracted CIS features are crucial for distinguishing between DLB and AD. The CIS involves the preservation of the Posterior Cingulate Cortex (PCC) in DLB, while hypoperfusion is typically seen in this region during the early stages of AD. The presence of the CIS has gained attention as a key differentiator, reflecting AD-related pathology that influences clinical symptoms in DLB. Notably, CIS is most prominent during the mild dementia stage and tends to decline as DLB advances. This makes CIS particularly useful for distinguishing DLB from AD, especially in the early stages, though exceptions like posterior cortical atrophy may complicate this distinction. The CIS features are then fed into the DR-LSTM for classifying DLB and AD images. This DR-LSTM combines the benefits of dilated convolutions (captures multi-scale context), and the strengths of Res-LSTM (effectively handles sequential data and long-term dependencies). Moreover, it helps in capturing detailed temporal patterns and clinical features, enhancing diagnostic capability. Thus, the DR-LSTM is expected to significantly improve the differential diagnosis of DLB and AD, enabling more effective therapeutic measures. Fig. 1 presents the pictorial presentation of the proposed DLB and AD imaging classification model.

B. Brain Image Dataset for Model Analysis

The developed framework employs brain images to differentiate DLB from AD. Table II provides a description of the dataset, which consists of images gathered from online

resources. In this context, the term $Im\,g_c^{Br}$ represents the brain images, here $c = 1,2,\ldots,C$ and C indicates the image count.

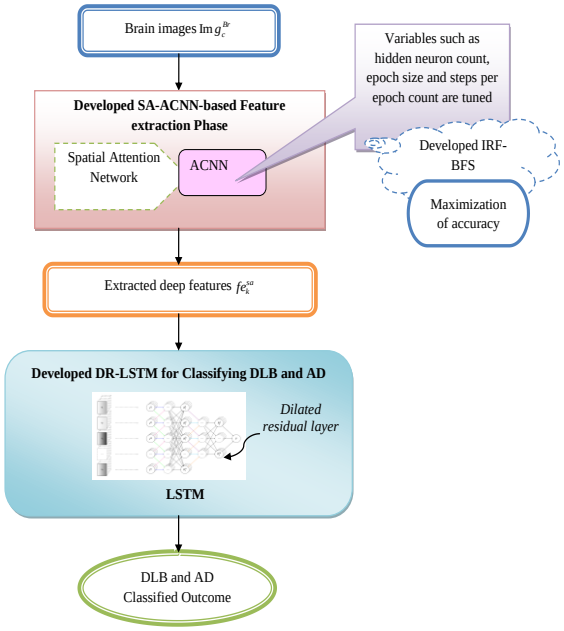

Fig. 1. Pictorial representation of the proposed DLB and AD imaging classification system.

TABLE II. DESCRIPTION OF THE INPUT IMAGE DATASET

Dataset name	Dataset link	Dataset description
Dataset1 (FDATA ADNI DATASET)	https://www.kaggle.com/datasets/ahmedashrafahmed/fdata-adni-dataset.	This dataset consists of 33,984 records, with 6,000 records selected for use. These 6,000 records are divided into training and testing sets, with 4,500 used for training and 1,500 for testing. The dataset is categorized into four classes, each with 1,500 records: CN (Cognitively Normal), LMCI (Late Mild Cognitive Impairment), AD, and EMCI (Early Mild Cognitive Impairment), where LMCI and EMCI comes under the category of DLB.

IV. SPATIAL ATTENTION BASED ADAPTIVE CONVOLUTION NEURAL NETWORK FOR CINGULATE ISLAND SIGN FEATURE EXTRACTION

A. Convolution Neural Network

The convolutional layer is a crucial part of feature extraction in a Convolutional Neural Network (CNN) [26], which employs certain hidden layers. CNN contains more than two hidden layers, and these layers interpret the image as a tensor, automatically extracting features and performing eventual categorization from input data. The usual CNN layers are as follows:

Input layer: The width, length, and number of channels, or their transformations, constitute the input tensor, which determines the size of the input layer, which contains the image information.

Convolutional layer: Transformation layers are those that imply the warping process from the preceding layer. This layer gathers the training outcome's weights or parameters. Usually smaller in width and length than the input layer, the output of this layer is a tensor known as a feature map, with a depth dimension. This layer aids in storing the training weight, which is represented by Eq. (1).

$$E_{wx} = \left(k1 * k2 * E_{PZ} * E_{QW} + E_{MF}\right) \quad (1)$$

Here, the kernel size is represented with the terms $k1$ and $k2$.

Pooling layer-This layer helps in reducing the size of the previous layer to identify the important features from the input tensor. The output dimension is determined by the kernel size; for instance, with a kernel size of two, the output dimension is divided. Fig. 2 illustrates the pictorial representation of a CNN for feature extraction process.

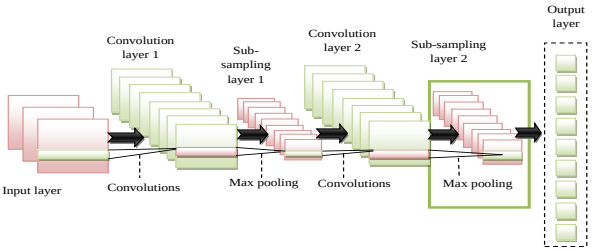

Fig. 2. Diagrammatic representation of CNN for feature extraction process.

B. Developed SA-ACNN-Based CIS Feature Extraction

Initially, the input brain images $Im\,g_c^{Br}$ are given for the feature extraction phase. The SA-ACNN utilizes spatial attention mechanisms to focus on the most relevant areas of medical images, such as lesions or other distinguishing patterns, enhancing the accuracy of feature extraction. This ability to prioritize important image regions allows the network to more effectively differentiate between DLB and AD. To further refine this process, IRF-BFS is applied to optimize the attributes of SA-ACNN. The parameters such as steps per epoch count, hidden neuron count, and epoch size in SA-ACNN are optimized to maximize the accuracy. Thus, it ensures that only the most relevant features are extracted for accurate diagnosis, with SA-ACNN focusing on key image areas. Finally, the CIS features are extracted which means neuro imaging features seen on DLB. The extracted features are represented with the term fe_k^{sa}.

CIS-based feature processing: In the process of differentiating DLB and AD, the model integrates Grad-CAM (Gradient-weighted Class Activation Mapping) to offer a deeper understanding of how the deep learning network reaches its diagnostic conclusions. Grad-CAM is a powerful visualization tool that helps to highlight which areas of the input image are most influential in the model's final predictions. Grad-CAM is specifically employed to locate and emphasize the CIS. This feature enables both clinicians and researchers to visually track the model's focus during the DLB–AD classification process. For images of DLB patients, Grad-CAM frequently highlights the CIS, demonstrating that the model places significant emphasis on this feature to differentiate DLB from AD. As the model continues to learn, its focus on the CIS becomes more pronounced and localized. When the CIS appears more prominently, the model assigns higher confidence to the DLB diagnosis, while images with

lower CIS ratios, suggesting the presence of AD pathology, lead to reduced confidence in DLB classification. The description of the spatial attention mechanism is provided below.

The spatial attention [27], [28] refers to a process that focuses on areas of input (usually images or sequences) that are most pertinent to the task at hand. When the model is creating predictions or extracting features, it uses this type of attention mechanism to help it prioritize geographic locations in the incoming images. Eq. (2) and Eq. (3) illustrate how the spatial attention mechanism is calculated.

$$F = N_f . \sigma \left(\left(v_i^{(y-1)} R_1 \right) R_2 (R_3 v_p^{(y-1)})^U + m_f \right) \quad (2)$$

$$F'_{p,l} = \frac{exp(F_{p,l})}{\sum_{l=1}^{Z} exp(F_{p,l})} \quad (3)$$

Here, the input of the y^{th} spatial block is signified with the term $v_i^{(y-1)}$ and the channels in the input images are specified with the term B_{y-1}. The learnable parameters are represented with the terms N_f and m_f and the term σ is utilized as the activation function. The element $F'_{p,l}$ in F signifies the semantic correlation strength between node p and node l. The diagrammatic representation of the developed SA-ACNN-based CIS Feature Extraction is presented in Fig. 3.

C. Parameter Optimization with IRF-BFS

The BFS algorithm is selected in this model as it offers several advantages, including efficient global search capabilities, simplicity, adaptability to various optimization problems, parallelism, and a good balance between exploration and exploitation. However, BFS also has some drawbacks, such as limited exploration of the search space, premature convergence and sensitivity to parameter tuning. These disadvantages can be addressed by using the IRF-BFS, which avoids randomness in the search space by updating the random variables to make accurate solution for the search process.

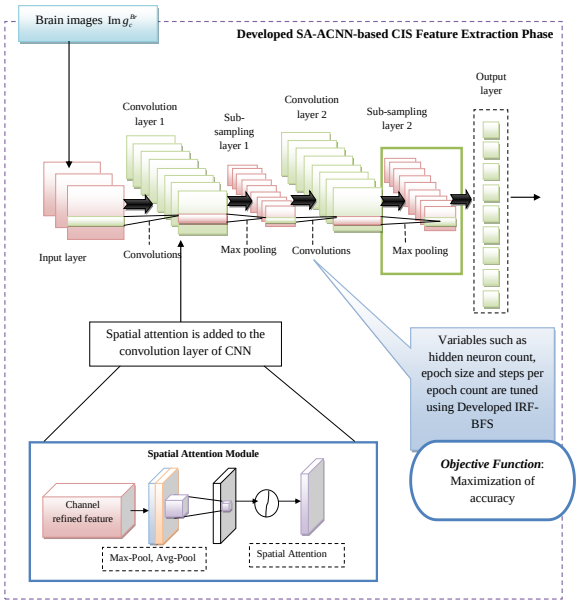

Fig. 3. Graphical representation of the implemented SA-ACNN-based CIS feature extraction.

IRF-BFS overcome premature convergence by adding diversity to the search, improving exploration, and minimizing the risk of getting stuck in local optima. Additionally, IRF-BFS reduces the dependency on manually tuning parameters by adapting them during the search. In this improved IRF-BFS approach, the random variable f is upgraded utilizing Eq. (4).

$$f = \frac{c_f}{\frac{a}{b}} \quad (4)$$

$$a = \frac{b_f}{c_f + w_f} \quad (5)$$

$$b = \frac{c_f + w_f}{b_f} \quad (6)$$

Here, the current fitness value is signified with the term c_f, the mean fitness value is signified with the term m_f, the worst fitness value is specified with the term w_f, and the best fitness value is represented with the term b_f. The pseudocode of the IRF-BFS is given in Algorithm 1.

Algorithm 1: Developed IRF-BFS

Set the values for the parameters: population Z and maximum iteration Max_{ite}

While $(ite \leq Max_{ite})$ do

- Update random variable $\boldsymbol{f}$ that is computed in Eq. (4)
- Perform flying search behavior
  - Estimate the new location of the bird in flying search region
- Perform Territorial behavior
  - Determine the new territory bird's position
  - Estimate the fitness function
  - Determine the new incursion birds' position
- If the position of the leading bird is superior to that of all other birds
  - Execute the role change mechanism
- End if
  - Examine the border
  - Estimate the fitness function
  - Upgrade M_p with M_p^{ite+1}

$$ite = ite + 1$$

End while

Output

Output

D. Objective Function of IRF-BFS-SA-ACNN Model

In the developed IRF-BFS-SA-ACNN-based feature extraction model, IRF-BFS is applied to optimize the attributes of SA-ACNN. The parameters such as steps per epoch count, hidden neuron count, and epoch size are optimized to maximize accuracy. The objective function of the developed IRF-BFS-SA-ACNN is expressed mathematically in Eq. (7).

$$Obj = \underset{\left\{Hdd_i^{cnn}, Eoo_j^{cnn}, Spe_k^{cnn}\right\}}{argmax} (acc) \quad (7)$$

Here, the term accindicates the accuracy, the term Spe_k^{cnn} denotes the steps per epoch count in the CNN with range of [500,1000], the term Eoo_j^{cnn} represents the epoch size with the range of [5,50] and the term Hdd_i^{cnn}signifies the hidden neuron count in the CNN with the range of [5,255].

The accuracy acc is a measure of how often a method accurately forecasts an outcome and it is derived in Eq. (8).

$$acc = \frac{(ka+en)}{(ka+en+s\square+ik)} \quad (8)$$

Here, the termkadenotes the true positive, en indicates the true negative, sh denotes the false positive, ik denotes the false negative values.

V. Dilated Residual-Long Short Term Memory for Differentiating Dementia with Lewy Bodies and Alzheimer's Disease

A. Long Short Term Memory

A memory element could replace each hidden element in the LSTM [29] . Each memory element is made up of different parts including input, output, forget, and internal states. The operation of the input and reset gate is achieved by Eq. (9) and Eq. (10).

$$m_d = \sigma\left(V_{bg} i_d + V_{lz} z_{d-1} + b_b\right) \quad (9)$$

$$j_d = \sigma\left(V_{ji} i_d + V_{zj} z_{d-1} + b_j\right) \quad (10)$$

The operation of the cell state and output gate is expressed by Eq. (11) and Eq. (12).

$$g_d = j_d \Theta g_{d-1} + l_d \Theta k\left(V_{gi} i_d + V_{gz} z_{d-1} + b_g\right) \quad (11)$$

$$t_d = \sigma\left(V_{wg} i_k + V_{wz} z_{k-1} + b_w\right) \quad (12)$$

The hidden state and memory state is attained in Eq. (13) and Eq. (14).

$$z_d = w_d \Theta p(g_d) \quad (13)$$

$$z_a = X_{zn} n_a + b_z \quad (14)$$

Here, the terms g_{d-1},$j_d$denotes the internal state, a forget gate, the terms m_d and t_d denotes an input gate, an output gate, the term V represents the weight matrix, the term σ represents the logistic sigmoid function, element-wise multiplication is denoted by the symbol Θ, z represents cell result activation point, the term $b$indicates bias, the term i and c indicates the input point and output point, and the terms $k$and $p$indicates the $tanh$activation operations, accordingly.

B. Dilated Residual-LSTM for Classifying DLB and AD

The extracted CIS features fe_k^{sa} are provided into the classification phase. The developed DR-LSTM helps to perform the differentiation process of DLB and AD by accurately identifying specific clinical features. It combines the strengths of dilated convolutions and residual layer networks. Dilated convolutions expand the receptive field, enabling the model to capture multi-scale contextual data, which is crucial for identifying subtle, long-range dependencies in disease progression. This combination of dilated convolution and residual layers improves the ability of the model to represent and track the evolving clinical features of DLB and AD, improving diagnostic accuracy. This integrated approach leads to a more robust and precise diagnostic process, ultimately aiding in the early and effective therapeutic intervention for these neurodegenerative diseases.

A residual block [30] is a fundamental component of residual network architecture. It is developed to mitigate the vanishing gradient issue and make training deep networks more feasible. The residual block can be mathematically indicated in Eq. (15).

$$i = H\left(v, \{R_p\}\right) + v \quad (15)$$

Here, the term $v$signifies the input of the residual block; the term $H\left(v, \{R_p\}\right)$indicates the residual mapping.

Dilated convolutions [32] are commonly used in models where capturing long-range dependencies is crucial and they allow the model to maintain high resolution while increasing the receptive field. This method is particularly advantageous in scenarios where traditional convolutions would result in excessive computation or loss of resolution due to down sampling. The function for a convolution can be computed using Eq. (16).

$$i(u) = \sum_{p=0}^{a} v(u + p.g).r(p) \quad (16)$$

Here, the term $r(p)$represents the weight at the index$p$, the term $g$represents the dilation factor, and $a$indicates the filter dimension. Finally, the classified outcome is obtained for identifying the DLB and AD classes. Fig. 4 represents the pictorial representation of developed DR-LSTM for Classifying DLB and AD.

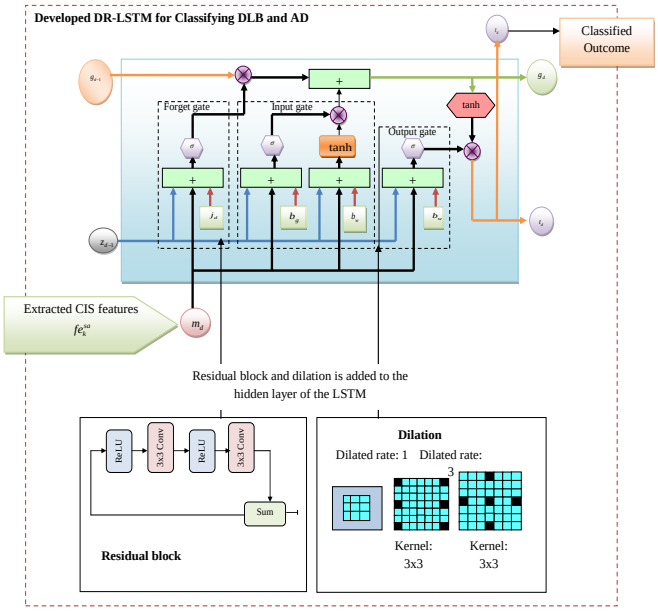

Fig. 4. Diagrammatic illustration of the developed DR-LSTM for classifying DLB and AD.

VI. Experimental Results

A. Resultant Feature Images by Varying Iteration

The developed DLB and AD Imaging Classification system was implemented utilizing Python. While developing the network, a maximum iteration of 50, a chromosome length of 3, and populations of 10, was considered. Fig. 5 provides the resultant feature images of the developed SA-ACNN by varying iteration.

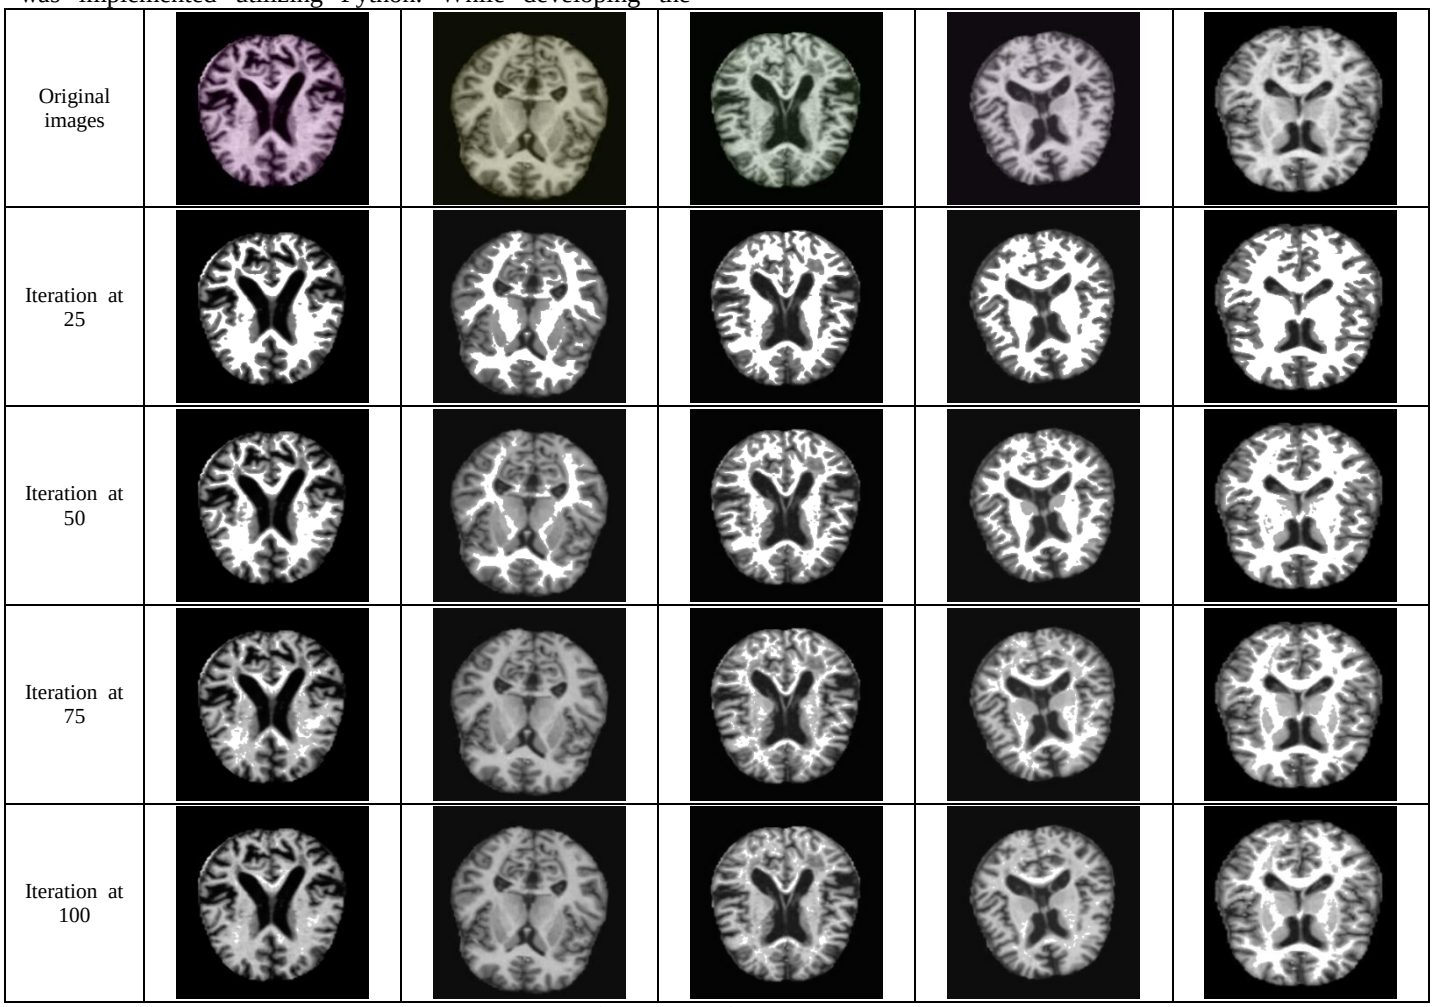

Fig. 5. Resultant feature images from the developed SA-ACNN.

B. Training and Testing Progress

The training progress graph is used to visualize the performance of a machine learning model during training and testing periods. This graph is a plot of the testing accuracy and testing loss over 1000 epochs. Fig. 6 and Fig. 7 provide the training progress graphs for the developed method. In Fig. 8 and Fig. 9, the testing accuracy increased rapidly, indicating that the model is learning and improving. However, after around 100 epochs, the accuracy fluctuates and stabilizes with some noise. The fluctuations suggest that the model's performance varies slightly with each epoch. In testing, the loss minimizes rapidly, showing that the model is learning to make better predictions. After around 100 epochs, the decrease in loss slows down and eventually stabilizes, showing minor reductions. The constant loss model suggests that a point has been reached where further training will not significantly improve performance.

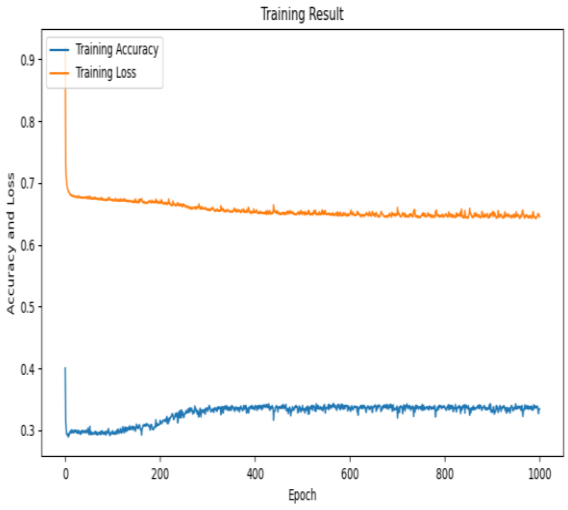

Fig. 6. Training accuracy of CNN model.

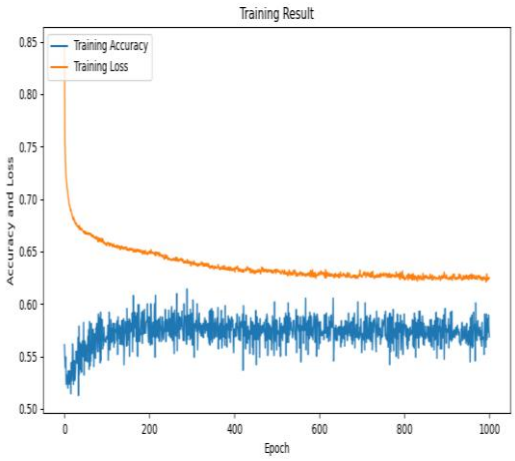

Fig. 7. Training accuracy of LSTM model.

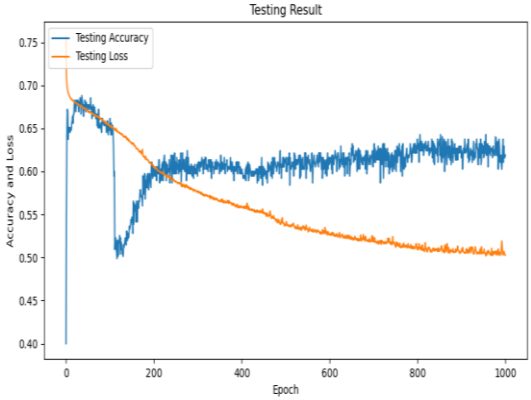

Fig. 8. Testing accuracy of CNN model.

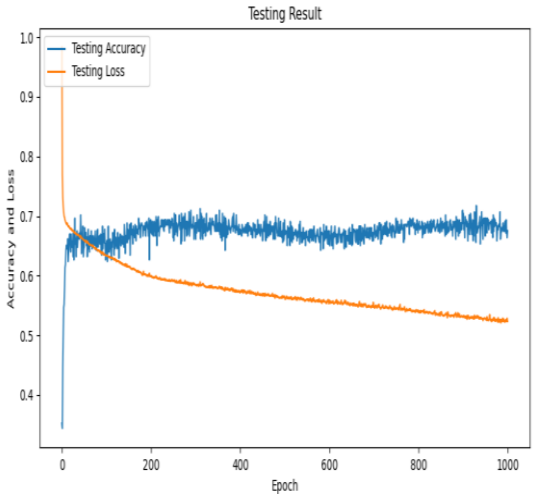

Fig. 9. Testing accuracy of CNN model.

C. Correlation Analysis

This statistical method assesses the strength and direction of the relationship between two continuous variables. Here, the black line represents a linear regression model, fitting the data points, which indicates a trend that supports this positive relationship. This type of analysis provides evidence that the features extracted by the SA-ACNN (i.e., the CIS ratio) are relevant for distinguishing between DLB and AD. It supports the effectiveness of the model in capturing clinically meaningful data that can be linked to the disease's severity or progression. Fig. 10 represents the correlation analysis of the developed SA-ACNN-based feature extraction model between AD and DLB classes.

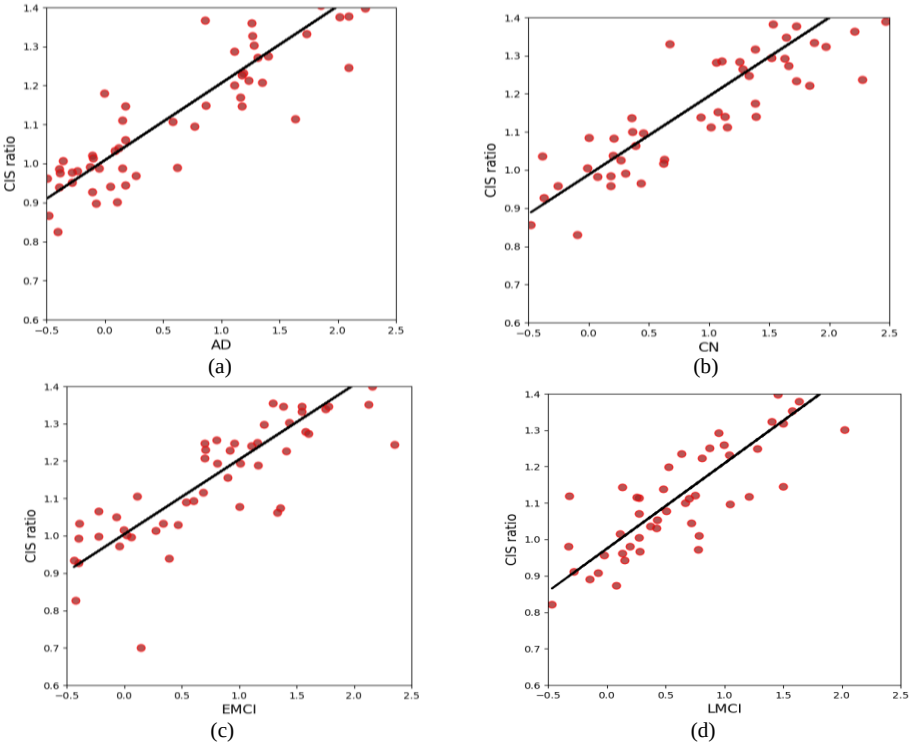

Fig. 10. Correlation analysis of the developed SA-ACNN-based Feature Extraction Model regarding different classes (a) AD, (b) CN, (c) EMCI, and (d) LMCI.

VII. Comparative Analysis and Discussion

A. Batch Size-Based Performance Analysis of Proposed Classification Model

The batch size-based performance analysis evaluates how different models perform on a given task by testing them on various batch sizes and evaluating metrics such as accuracy, MCC, CSI, FPR, FDR, precision. In Fig. 11(a), the accuracy of the developed AD-DLB-DNet framework outperforms RAN,

SVM, CNN-GCN, and CNN by 11.76%, 6.74%, 13.09%, and 3.26% in batch size-4, correspondingly. Thus, it is noted that the introduced DR-LSTM provides better performance than other classification techniques. Fig. 11 provides performance analysis by varying batch sizes.

B. ROC Analysis

Receiver Operating Characteristic (ROC), which is a metric, utilized to estimate the execution of a classification model, such as the DLB and AD differentiation model. The techniques compared, including RAN, SVM, CNN-GCN, CNN, and AD-DLB-DNet, all exhibit powerful performances. However, AD-DLB-DNet appears to have a slight edge over the others, making it a potentially more reliable choice for differentiating AD and DLB in clinical settings. Fig. 12 offers the ROC graph analysis of the proposed network.

C. Convergence Analysis

Convergence analysis refers to the study of how well the model's performance improves as the number of training iterations or epochs increases. The effectiveness of the implemented framework was estimated by comparing with several heuristic algorithms like Dwarf Mongoose Optimization (DMO) [31], Sparrow Search Algorithm (SSA) [32], Dingo Optimization Algorithm (DOA) [33], Birds Foraging Search (BFS) [34], and classifiers like RAN [35] , SVM, CNN-GCN, and CNN.

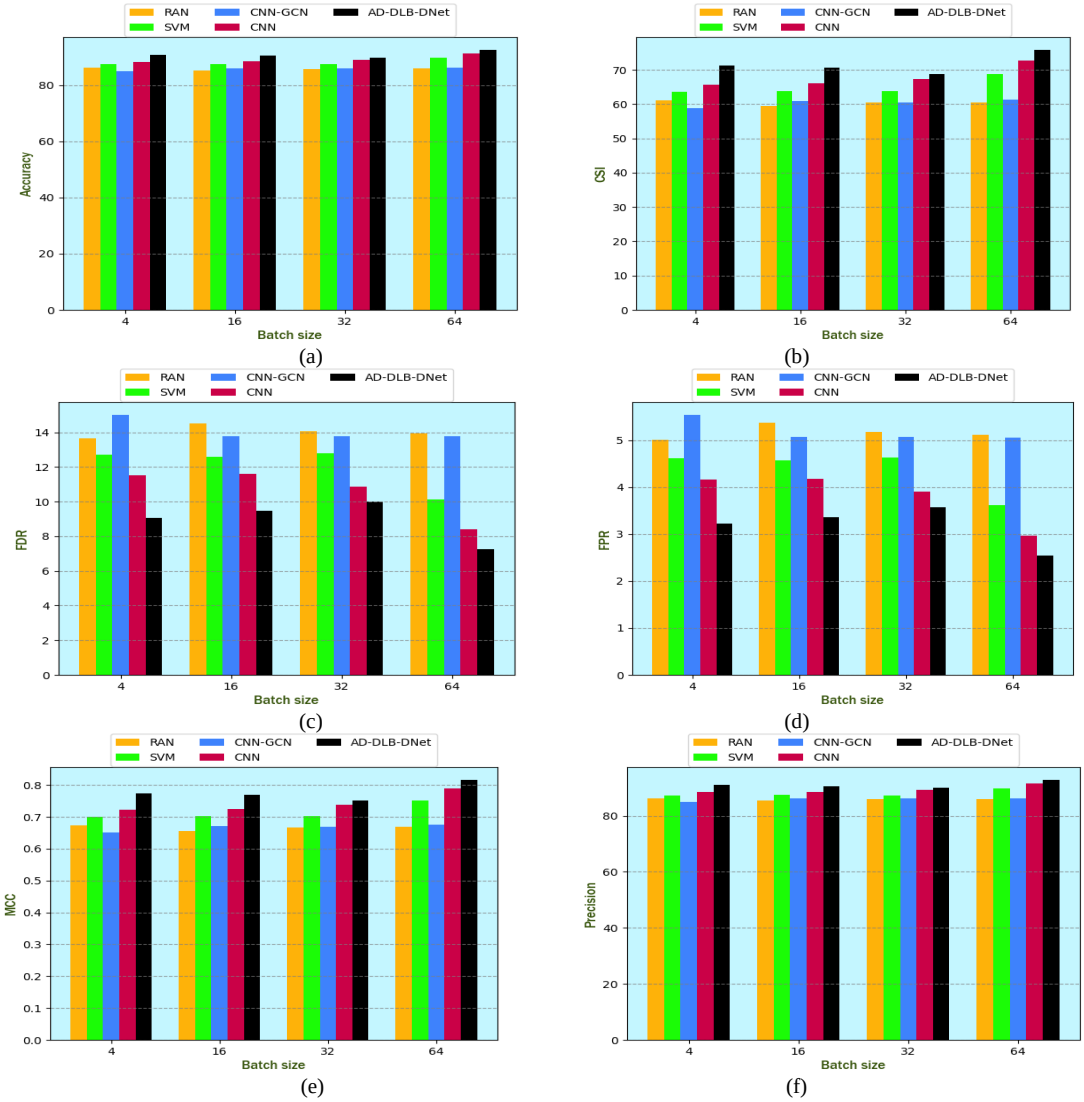

Fig. 11. Batchsize-based performance analysis of the developed method regarding (a) Accuracy, (b) CSI, (c) FDR, (d) FPR, (e) MCC, (f) Precision.

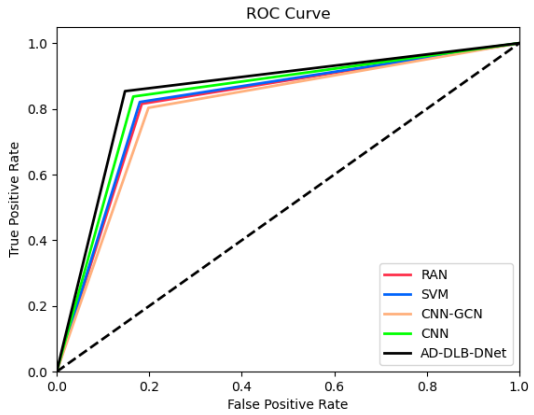

Fig. 12. ROC analysis of the developed technique.

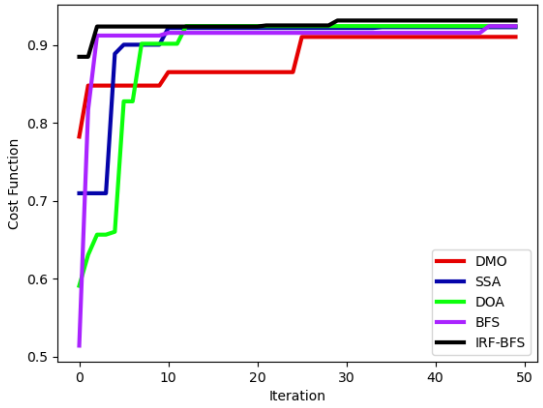

Fig. 13. Convergence analysis of the proposed technique.

At 10th iteration, the developed IRF-BFS approach performs better than the existing algorithms like DMO, SSA, DOA, and BFS by 13.63%, 11.11%, 12.35%, and 8.69%. By performing convergence analysis, researchers can develop a robust and accurate model for differentiating DLB and AD, ultimately improving diagnostic accuracy and patient outcomes. Fig. 13 provides the convergence analysis of the developed framework.

D. Confusion Matrix of the Classification Model

The confusion matrix is a commonly used performance measurement tool in classification issues. It compares a model's classified classes with the actual ground truth labels, to assess how well the system performs. Moreover, it helps to identify areas where the model performs well and where improvements are needed. Consequently, it shows how well the model can differentiate between AD and DLB, particularly by analyzing how often the model misclassifies one disease as another. Fig. 14 provides the confusion matrix of the developed model.

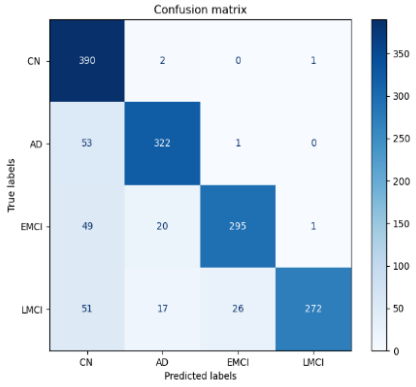

Fig. 14. Confusion matrix of the proposed classification model.

E. Comparative Analysis with K-Fold Cross Vadildation

Comparative Analysis of the Proposed Classification model is always needed to analyze the effectiveness of the developed model. K-fold cross-validation analysis refers to a method that is utilized to assess the effectiveness of a model, especially in cases where you want to ensure your method generalizes well with new information. K-fold analysis is used to evaluate effectively how the model distinguishes between the two diseases. In the below Table III, it is clearly shown that the developed AD-DLB-DNet system, in terms of accuracy, is better in performance than the existing methods such as RAN, SVM, CNN-GCN, and CNN by 4.27%, 2.85%, 3.26%, and 1.988%, respectively. AD-DLB-DNet consistently outperforms the other models with the highest accuracy of 92.104%, specificity of 97.215, F1 Score of 85.361, MCC value 0.804, and CSI value 74.461, while also maintaining the lowest FPR of 2.785 and FDR of 7.917 at K-Fold-5. This suggests that AD-DLB-DNet is the most robust model for differentiating between DLB and AD. Table III shows the Comparative K-fold analysis of the developed framework.

TABLE III. COMPARATIVE K-FOLD ANALYSIS OF THE PROPOSED METHOD WITH EXISTING METHODS

VIII. CONCLUSION

This study aimed to differentiate DLB from AD using a deep learning model. The process began with collecting the necessary images from a benchmark dataset. The images were fed into the SA-ACNN for CIS feature extraction. Using Grad-CAM, the deep learning model not only provides accurate predictions for distinguishing DLB from AD but also offers a clear visual representation of the CIS as an essential feature for DLB diagnosis. This visualization technique enhances the model's interpretability, fostering greater trust in its decision-making process. To perform differentiation, a DR-LSTM was proposed, which effectively identified clinical features. This comprehensive model aimed to enhance the differential diagnosis of DLB as well as AD, facilitating more effective therapeutic measures. Finally, validation steps were performed to confirm the efficacy of the method that ensures its reliability in clinical settings. The accuracy of the developed AD-DLB-DNet framework is more effective than RAN, SVM, CNN-GCN, and CNN by 8.41%, 4.72%, 7.09%, and 3.01%, respectively at the k-fold value to be 2. The suggested model is used for the differentiation of DLB and AD for taking effective therapeutic measures. The present study faces limitations such as data constraints, generalization challenges, and the need for extensive clinical validation to ensure reliability and ethical compliance. In future work, several avenues can be explored to improve the differentiation of DLB and AD utilizing deep learning models. Expanding the dataset to include more diverse images from various demographics and medical conditions can improve model robustness.

***Abstract*—Skin lesion detection plays a crucial role in the diagnosis and treatment of skin diseases. Due to the wide variety of skin lesion types, especially when dealing with unknown or rare lesions, models tend to exhibit overconfidence. Out-of-distribution (OOD) detection techniques are capable of identifying lesion types that were not present in the training data, thereby enhancing the model's robustness and diagnostic reliability. However, the issue of class imbalance makes it difficult for models to effectively learn the features of minority class lesions. To address this challenge, a Balanced Energy Regularization Loss is proposed in this paper, aimed at mitigating the class imbalance problem in OOD detection. This method applies stronger regularization to majority class samples, promoting the model's learning of minority class samples, which significantly improves model performance. Experimental results demonstrate that the Balanced Energy Regularization Loss effectively enhances the model's robustness and accuracy in OOD detection tasks, providing a viable solution to the class imbalance issue in skin lesion detection.**

***Keywords*—Balanced energy regularization loss; skin lesions; out-of-distribution detection; convolutional neural networks**

I. INTRODUCTION

Early detection and regular monitoring of skin lesions, one of the most common diseases in daily life, is of great importance; this not only helps to improve cure rates and develop accurate treatment plans but also effectively reduces mortality [1]. Especially for melanoma, the most lethal form of skin cancer, this importance is particularly pronounced in study [2]. When using convolutional neural networks (CNNs) for skin lesion detection, only data with known specific distributions are exposed during training; however, due to the characteristics of skin lesions, including the diversity and complexity of their presentation [3], the actual distribution of data in the clinical setting is often uncertain. This poses a challenge with limited training data, which is often insufficient to fully cover the variety of skin lesions encountered. In addition, the distributions of the training data and the actual clinical data may differ significantly, further complicating the task. The predictive performance of the model is greatly reduced when faced with the significant challenges posed by different data distributions [4]. By employing an effective out-of-distribution (OOD) detection method, the model can identify new data that are different from the distribution of the training data. This detection mechanism enables the model to perform the special treatment or directly reject these OOD data for prediction, avoiding making wrong judgments on uncertain data, thus significantly improving the robustness and safety of the model [4] [5]. Effective OOD detection not only enhances the generalization ability of the model but also improves the reliability and robustness of the system in practical applications [6] [7]. Therefore, an effective tool in the diagnosis and management of skin lesions will be methods that can accurately detect OOD images of skin lesions.

In recent years, CNNs have made significant advances in the use of medical image data for disease diagnosis and analysis [8], and these models demonstrate performance comparable to that of professional physicians in the identification and classification of a wide range of common skin lesions [9], especially in binary and multiclassification tasks [10]. Specifically, CNNs can accurately differentiate between malignant melanoma, basal cell carcinoma, or other types of skin lesions [11]. However, OOD detection remains a challenging problem when confronted with skin lesions of unknown characteristics. Furthermore, for assessing the performance of models in different datasets, cross-dataset validation has not yet been widely applied to the OOD detection of skin lesions, which is crucial to ensure the generalizability and validity of the models given the potential differences in the data information in different datasets.

CNNs achieve great success in natural language processing and image recognition tasks, mainly due to their excellent feature learning, large-scale data processing, and generalization capabilities [12] [13]. Although the use of techniques such as self-attention mechanisms [14], regularization [15], and transfer learning [16] can significantly improve the performance of a model, their performance in OOD detection may still be unsatisfactory. This is because the features of the OOD samples are significantly different from the features of the distribution of the training data, which causes the model to be prone to prediction errors when dealing with these samples, thus reducing the robustness and reliability of the model. Therefore, a method called Balanced Energy Regularization Loss (BERL) [17] is applied to CNNs for OOD detection of skin lesions; The model is named energy-balance based OOD detection (EBOD).

In skin lesion image datasets, the class distribution is often highly imbalanced, with some lesion categories having a large number of samples, while others have relatively few. Traditional OOD detection methods struggle to effectively handle the disparity between majority and minority categories under such imbalanced distributions. The BERL method addresses this issue by introducing regularization based on the prior class

*Corresponding Author

probabilities, which enhances the regularization of majority class samples, thereby allowing the model to focus more on minority class samples and improving the detection accuracy for these categories. This method effectively mitigates the detection bias caused by class imbalance and optimizes the overall OOD detection performance. During the training process, the prior probability of each class is computed, allowing the model to adjust for the class distribution imbalance, thereby improving detection accuracy. Particularly in high-dimensional image datasets, the BERL enhances the model's robustness to unseen skin lesions, providing strong support for OOD detection of skin lesions. The successful application of this method not only generates significant impacts in skin lesion detection but also provides a new perspective for OOD detection in other medical imaging tasks. Through this technology, medical imaging systems are enabled to more accurately identify emerging disease types or lesions, thereby enhancing the intelligence and precision of medical diagnosis.

The remainder of this paper is structured as follows: Section II reviews the research advancements in the relevant field; Section III provides a detailed description of the proposed model's architecture, data acquisition and preparation process, as well as the evaluation metrics; Section IV discusses the model evaluation, computational cost, and presents the experimental results, accompanied by a comparative analysis with existing methods; Section V summarizes the main contributions of this paper, clarifies the motivation and potential advantages of the proposed method, and discusses the limitations of the research; Section VI outlines the directions for future research.

II. Related Work

During the past few years, a variety of methods based on CNNs have emerged in the field of OOD detection. These methods are not only innovative in theory but also show excellent performance in practical applications. These methods can be broadly classified into the following groups: output score-based methods, generative model-based methods, adversarial training-based methods, and feature space-based methods, according to their basic principles and application characteristics.

A. Methodology Based on Output Scores

Output score-based methods rely heavily on the output probability distribution of the classifier for the detection of OOD samples. This type of approach works by analyzing the confidence level of the classifier as it processes the samples, and samples with a low confidence level are considered to be possible OOD samples. Hendrycks and Gimpel [5] propose this method, which is widely used due to its simplicity and low computational cost. However, in some cases, such as skin lesion OOD detection, certain OOD samples may have higher softmax values, resulting in detection errors.

B. Generative Modeling-Based Methods

Generative models detect OOD samples by learning the latent distribution of the data, and the variation autoencoder (VAE) method proposed by An and Cho [18] is a typical example. The VAE detects samples that do not match the distribution of the training data by reconstructing the data. This method is particularly suitable for OOD detection of medical image data and can identify rare or unseen lesion types.

C. Adversarial Training-Based Methods

The adversarial training-based approach utilizes Generative Adversarial Networks (GANs) for OOD detection. The method proposed by Schlegl, Seeböck, and Waldstein [19] generates samples that are similar to normal data employing GANs and identifies OOD samples utilizing reconstruction errors. This approach significantly improves the sensitivity of the model to OOD samples and is well-suited for application in complex clinical settings.

D. Feature Space-Based Methods

Feature space-based methods include the Mahalanobis distance-based method introduced by Lee et al. [20] and the One-Class Support Vector Machine (One-Class SVM) method developed by Schölkopf et al. [21]. The former identifies OOD samples by calculating the Mahalanobis distance of the input data in the feature space, which is suitable for feature extraction of high-dimensional data, but requires careful tuning of the distance metric and high computational cost. The latter separates most of the training data by constructing hyperplanes or decision boundaries to distinguish between normal and abnormal data, and is suitable for initial screening for OOD detection of skin lesions, but may not perform well on large and complex datasets.

In addition, several studies explore ways to enhance OOD detection by integrating multiple models. Xu et al. [22] present a deep integrated learning approach to enhance the accuracy and robustness of detection by combining the predictions of multiple deep neural network models. Dai et al. [23] designed a multimodal detection method utilizing multiple data sources (e.g., images, text, and clinical data) to improve the detection performance, and the combination of patient history, symptom descriptions, and image data in OOD detection of skin lesions can significantly improve the accuracy of OOD detection.

III. Methodology

This section describes the three modules of the experiment in this study: data acquisition, model architecture, and model evaluation. The first section outlines the methodological steps adopted by the researchers in the data collection and analysis process, which is the core part of the study. The next subsections explain the specific steps of the study in terms of model architecture design and model evaluation, respectively. The experimental workflow shown in Fig. 1 provides a clear overview of the experimental process.

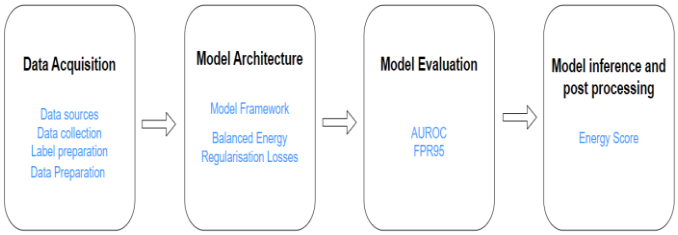

Fig. 1. Experiment module diagram.

A. Data Acquisition

1) Data sources: The medical datasets used in this study are obtained from open-source databases, including but not limited to the International Skin Imaging Collaboration (ISIC), the Harvard University database (https://data.harvard.edu.dataverse), the Portuguese Pedro Hispano Hospital Dermoscopy Image Database (https://www.fc.up.pt/addi/project.html), and Stanford AIMI Shared Database (https://stanfordaimi.azurewebsites.net). These databases provide rich and diverse images of skin lesions for this study, ensuring broad applicability and reliability for model training and evaluation. To validate the external generalization ability of the model, several datasets of non-skin lesions are also obtained from the Kaggle platform (www.kaggle.com) for OOD detection. In terms of data use, this study strictly follows ethical principles to ensure that patient privacy is adequately protected, data security is effectively guaranteed, and patients' rights are respected. At the same time, this study actively promotes data sharing and open scientific research and assumes corresponding responsibilities and obligations.

2) Data collection: In this study, several open-source skin lesion datasets are used. These include images of different types of skin lesions as well as images of normal skin from different locations with manually created or corrected annotation information. From the ISIC2018, ISIC2019, ISIC2020, HAM10000 [24], PH2 [25], DDI [26], Dermnet [27], UMCG [28], and PAD-UFES-20 [29] datasets, several datasets containing multiple lesion types are screened. The prevalence of various skin lesions varies due to differences in the number of images of various lesion types in different datasets. In addition, abdominal MRI, brain tumor, kidney stone, and Places365 datasets are obtained from the Kaggle platform. These are used as auxiliary datasets [30] along with the skin lesion datasets for model training. Table I provides a summary of the fundamental characteristics of the datasets employed in this study. To ensure the breadth of the training datasets, 13 datasets containing four diseases and one non-disease are used during model training. For OOD data, three other disease datasets and two object detection datasets are used in this study: the colon adenocarcinoma dataset, the gastrointestinal disease dataset, the cataract dataset, the Street View House Numbers (SVHN) dataset [31], and the Cifar10 dataset [32].

TABLE I. BASIC CHARACTERISTICS OF EACH SKIN LESION DATASET

Dataset	Count of Types	Number of Photos	Source
ISIC2018	7	11720	ISIC
ISIC2019	8	25331	ISIC
ISIC2020	5	33126	ISIC
HAM10000	7	10015	Harvard Dataset
PH2	2	200	PH2 Dataset
Dermnet	5	579	Kaggle
PAD-UFES-20	5	2298	GitHub
UMCG	2	170	MED-NODE Dataset
DDI	6	656	Stanfordaimi AIMI

3) Label preparation: In the many open-source datasets on skin lesions, many different types of skin lesions are usually covered. However, the types of skin lesions that are recorded in the different datasets are not the same. It is not possible to train directly with these raw datasets as the model needs to be trained by lesion type for classification when performing training. For example, the ISIC2019 database contains eight different types of skin lesions. The HAM10000 database [24] contains seven types, and the lesion types differ between the two. To solve this problem, we use a strategy that requires a two-stage labeling process. Firstly, skin lesion types are classified according to the label files in each data set. When the same lesion is encountered but in different locations, it is combined into the same lesion type, and the original label file is reordered to generate a new label file based on the lesion type. Subsequently, the images in each of the datasets are then retrieved and organized according to these new label files. By using this method, each data set is divided into sub-datasets that contain multiple types of lesions. Finally, all datasets are regrouped and fused by skin lesion type to better support model training. Images of each type of skin lesion are shown in Fig. 2.

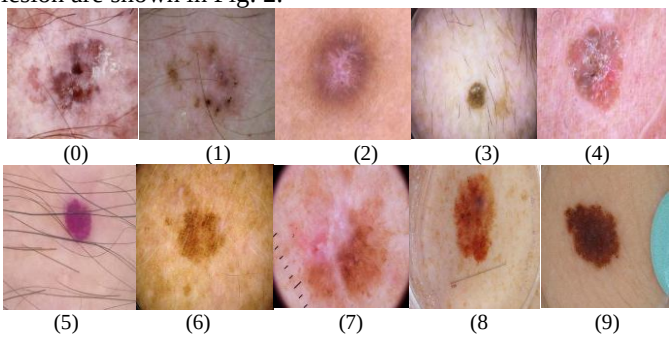

Fig. 2. Images of each type of skin lesion. 0: actinic keratosis; 1: basal cell carcinoma; 2: dermatofibroma; 3: seborrheic keratosis; 4: benign keratosis; 5: vascular lesions; 6: freckles; 7: squamous cell carcinoma; 8: melanoma; 9: melanocytic nevus.

4) Data preparation: All datasets used in this study show significant heterogeneity [33], involving differences in lesion characteristics, lesion sites, and recording devices. To reduce the impact of the differences between these datasets on the model, appropriate corrective measures are taken to standardize the datasets to ensure their compatibility with the model. When determining the size of the input image, the standard 224 × 224 size is selected. If the dimensions of the input image exceed 224 × 224, the image undergoes a process of cropping and scaling, referred to as center crop scaling [34], in order to align with the specifications of the model. The rationale behind the selection of this size is that image dimensions fluctuate across the datasets, rendering a uniform input size conducive to the model's capacity to discern pivotal characteristics. This uniformity simplifies data manipulation, reduces the complexity of computational operations, accelerates the convergence process, enhances the model's capacity to generalize, and facilitates the improvement of the model's performance. In both steps of training and detecting the model,

the images are cropped and the newly generated data obtained from cropping is used for training and detection.

B. Model Architecture

1) Model framework: The current model, similar to other models for OOD detection, uses neural networks to design appropriate OOD detection scores [4] [5] [35]. However, unlike most previous OOD detection methods that focus on designing OOD scores or introducing multiple outlier samples to retrain the model [36] [37], this study delves into the obstacle factors in OOD detection from the perspective of class imbalance in the auxiliary datasets [38]. To address the imbalance problem, a BERL is used, with different regularizations for each category of auxiliary data, to achieve reliable uncertainty estimates.

The training model employed in this study is primarily ResNet18 [39]. In comparison with other neural network models, ResNet18 demonstrates notable advantages in terms of feature extraction and generalizability. ResNet18 is a relatively deep network architecture that is capable of learning more abstract and complex feature representations through multi-level convolutional operations and feature extraction. This allows ResNet18 to extract more information from skin lesion data. In addition, ResNet18 is connected in a way that helps mitigate the problem of vanishing gradients and allows the network to be deeper. In the field of skin lesion OOD detection, residual connectivity and CNNs are both useful in enhancing the efficiency of feature capturing in images, which in turn leads to improved performance and greater model generalization. Although ResNet18 itself is not specifically designed for the detection of OOD, it can be appropriately adapted and enhanced to make it applicable to the detection of OOD [40]. ResNet18, with its deep convolutional architecture, is capable of effectively capturing latent patterns within skin lesion images, including both the intricate details and the overall morphology of the lesions. These patterns aid the model in distinguishing between in-distribution (known) and OOD (unknown) samples. During training, the residual connections in ResNet18 effectively alleviate the issue of overfitting, particularly when dealing with complex textures or lesion structures. This enables the extraction of robust and discriminative features, thereby enhancing the performance of OOD detection. Specifically, ResNet18 learns multi-scale features through convolution operations at different layers, from fine details to global representations. At lower layers, the network is capable of identifying minute textures and details on the skin surface, while at higher layers, it can capture the broader shapes of larger skin lesion areas. This hierarchical feature learning enables ResNet18 to accurately identify unknown lesion types in OOD detection tasks and effectively avoid misclassifying them as known types. The restrained ResNet18 model extracts feature from the image and feeds those features into a separate classifier to map the features of the image into a specific space and use the classification boundaries in that space to distinguish between known and unknown data. Finally, an energy function is introduced into the model for the calculation of OOD scores. Since the energy function does not require labeling information between known and unknown data, OOD detection can be performed without unknown data labels. In addition, energy functions usually have a good generalization ability to deal with different types of unknown data and to establish reasonable boundaries between the known data and the unknown data. The model structure is schematically shown in Fig. 3.

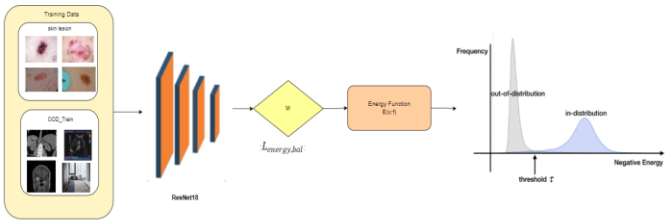

Fig. 3. Schematic diagram of the balanced energy regularization loss OOD detection model.

2) Balanced energy regularization loss: When regularizing auxiliary data, due to the imbalance of its class distribution, this may result in the model not being able to effectively learn information about the data of a few classes, thus affecting the model's ability to generalize to OOD data. In order to solve this problem, a variable M is introduced to measure whether the sample of the auxiliary data belongs to the majority class or the minority class [17]. In addition, the prior probabilities of the distributions of the auxiliary data were used to determine which class was to be categorized as a minority class. When this model is used to make inferences on the OOD auxiliary data, a statistical value N_i can be obtained that indicates the number of samples that are classified in class i. Then, the prior probability of the OOD distribution can be calculated using the following formula:

$$P(y=i \mid o)=\frac{N_i}{N_1+N_2+\cdots+N_K}. \tag{1}$$

For a neural network classifier f, the a posteriori probability that the input image x belongs to a class i is acquired by performing a softmax operation on the production of f, which is,

$$P(y=i \mid \mathbf{x},o)=\frac{e^{f_i(\mathbf{x})}}{\Sigma_{j=1}^{K} e^{f_j(\mathbf{x})}}. \tag{2}$$

As the posterior probability that $\mathbf{x}$ belongs to the class i increases, the probability that $\mathbf{x}$ belongs to the class i increases accordingly. Similarly, if the prior probability of category i is higher, then the probability of category i becoming the majority category will increase. Thus, as the probability that $\mathbf{x}$ belongs to the majority class i increases, the product of $\mathrm{P}(y=i \mid o)$ and $\mathrm{P}(y=i \mid \mathbf{x},o)$ must increase. Based on this result, the metric M for measuring the probability that $\mathbf{x}$ belongs to the majority class is defined as follows:

$$M=\Sigma_{j=1}^{K} P(y=j \mid \mathbf{x},o)P(y=j \mid o). \tag{3}$$

Moreover, a hyperparameter λ is introduced to model an additional generalized prior probability, which is used to

regulate the degree of prior difference between categories. Ultimately, the generalized form M_λ is as follows:

$$M_\lambda = \Sigma_{j=1}^{K} P(y=j \mid \mathbf{x}, o) P_\lambda(y=j \mid o). \quad (4)$$

Where $P_\lambda(y=i \mid o) = L^1 norm\{ P^\lambda(y=i \mid o) \}$. In order to ensure numerical reliability, the λ -th power operation was performed on the a priori probability $\mathrm{P}(y=i \mid o)$, and the L1-normalization was applied [41]. When $\lambda = 0$, the uniform prior probability model is established and M_λ becomes a constant value $\frac{1}{K}$, resulting in equal regularization strength across samples of different classes during the regularization process. When $\lambda > 0$, M_λ amplifies the regularization strength for the majority class while reducing it for the minority class, thus directing the model's focus more towards enhancing the OOD detection capability of majority class samples. In contrast, when $\lambda < 0$, the inverse distribution of the prior probability will be modeled, and the regularization strength for the minority class samples is increased, allowing the model to better adapt to OOD samples from the minority class. The optimal value λ varies across different OOD datasets. Generally, a larger value λ indicates a greater prior difference between classes, which is more suitable for datasets dominated by the majority class. Conversely, smaller or negative values λ are better suited for scenarios where the class distribution is more balanced or where the minority classes are of greater importance. With λ growth, the prior probability gap among classes grows. According to the M_λ component, the BERL is given by:

$$\begin{aligned} L_{\text{energy,bal}} &= L_{in,hinge} + L_{out,bal} \\ &= E_{(\mathbf{x}_{in},y)\sim D_{in}^{train}} \left[\left(\max\left(0, E(\mathbf{x}) - m_{in}\right) \right)^2 \right] \\ &+ E_{\mathbf{x}\sim D_{in}^{train}} \left[\left(\max\left(0, E(\mathbf{x}) - m_{out} - \alpha M_\lambda\right) \right)^2 M_\lambda \right] \end{aligned} \quad (5)$$

where $E(x; f) = -T \cdot \log(\Sigma_{j=1}^{K} e^{f_j(\mathbf{x})/T})$. In this formula, $f_j(x)$ denotes the logit output of the model for the input sample x in class j, while T representing the temperature parameter, which is employed to smooth the logits distribution, By performing an exponentially weighted summation of the logits across all classes, the energy value for each sample is computed. Lower energy values are generally associated with OOD samples, whereas higher energy values are typically indicative of in-distribution samples. The energy loss $L_{\text{energy,bal}}$ of the model is the sum of both $L_{in,hinge}$ and $L_{out,bal}$.

The key characteristic of the energy function lies in its ability to compute an energy value for each sample that is associated with its corresponding class. For in-distribution samples, the energy values are typically low because the predictions for these samples are usually accurate and consistent with the distribution of the training data. In contrast, the energy values for OOD samples are generally higher, as they do not conform to the distribution of the training data, thereby reflecting the greater uncertainty the model has regarding these samples. For instance, consider a pre-trained model designed to classify cats, dogs, and birds. When an image of a car is input, the model's logit output tends to be more dispersed, resulting in a higher energy value, which indicates that the model has lower confidence in classifying this sample. Conversely, when an image of a cat is input, the model's logit output is more concentrated, leading to a lower energy value, thus demonstrating the model's higher confidence in classifying this sample.

C. Model Evaluation

The key metrics that researchers typically focus on when performing model evaluations include Recall, the area under the receiver operating characteristic curve (AUROC), and the false positive rate at 95% true positive rate (FPR95). Recall is used to measure the proportion of OOD samples that are correctly detected by the model out of all actual OOD samples.

1) AUROC: AUROC, on the other hand, represents the relationship between the True Positive Rate (TPR) and False Positive Rate (FPR), calculated as the area under the ROC curve, which can synthesize the performance of the model under different classification thresholds. The value of AUROC ranges from 0.5 to 1. The closer the value is to 1, the better the ability of the model to discriminate.

2) FPR95: On the other hand, FPR95 focuses on the false alarm situation under high recall conditions, specifically calculating the false positive rate while maintaining a 95% true positive rate. FPR95, as a performance evaluation index, reflects the ability of the model to control the false alarm rate under the premise of guaranteeing a high detection rate in practical applications, and the smaller its value is, the lower the false alarm rate of the model is, thus proving the better performance of OOD detection.

Therefore, in this study, AUROC and FPR95 are used as the core metrics to assess the reliability of the model in OOD image detection of skin lesions. The FPR95 evaluates the ability to achieve high recall while controlling for false positives, while the AUROC provides an overall performance evaluation showing the average performance of the model across all thresholds. Recall as a base metric plays an important role in the calculation of AUROC and FPR95 as it has a direct impact on the results and performance analysis of these two metrics. The formulas for these indicators are shown below:

$$\mathrm{Re}\,call = TPR = \frac{TP}{TP + FN} \quad (6)$$

$$FPR = \frac{FP}{FP + TN} \quad (7)$$

$$FPR95 = FPR\left(TPR = 0.95\right) \quad (8)$$

$$AUROC = \int_0^1 TPR(x)\, dx \ \left(x = FPR\right) \quad (9)$$

Where TP denotes true positive, TN denotes true negative, FP denotes false positive and FN denotes false negative.

D. Model Inference and Post Processing

Although the model is trained using only the skin lesion datasets, it is equally capable of handling datasets from other diseases. The output generated by the model is an energy score that reflects the difference between the input sample data distribution and the known sample data distribution. Since the model is designed for OOD detection of skin lesions, its output can be interpreted as a measure of the model's classification accuracy in distinguishing between known and unknown samples, i.e., the model's ability to determine whether or not a sample is an OOD. The level of the energy score then indicates how confident the model is in classifying the input samples. Therefore, a post-processing step was used so that when the energy score is low, the model has a higher confidence that the input samples belong to known data, and conversely, when the energy score is high, the model has a higher confidence that the input samples belong to unknown data [42]. The course of the training and testing steps is summarized in Fig. 4.

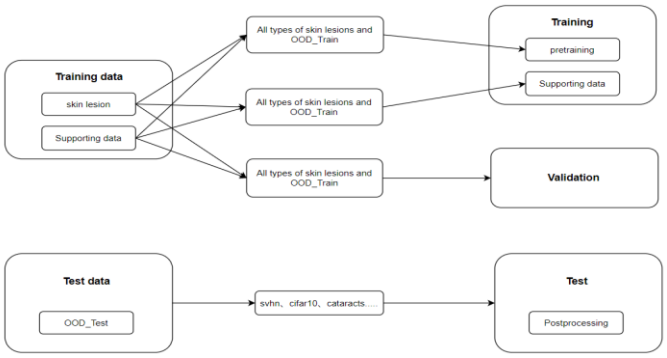

Fig. 4. Overview of training and testing procedures.

In the context of OOD detection for skin lesions, the model may encounter challenging scenarios such as noise, occlusion, and small-sized OOD samples. When confronted with noise and small-sized OOD samples, the application of energy regularization loss results in greater regularization being imposed on these samples, while less regularization is applied to other samples, thereby maintaining the model's ability to effectively detect OOD samples. In the case of occlusion, the integration of an attention mechanism enables the model to adaptively focus on the key regions of interest during training. Furthermore, by adjusting the class distribution of auxiliary data and weighting each sample according to the prior probability of its respective class, the model can effectively control the regularization strength across different classes, ensuring fairness in the data distribution.

IV. Results

A. Performance Evaluation

In order to evaluate the performance of the models, this experiment presents and analyzes the detection results of five models on OOD datasets from multiple domains, both medical and non-medical; the models used in this analysis are MSP [5], OE [43], OECC [44], Energy OOD [45], and EBOD. The FPR95 and AUROC metrics for the five models on each of the OOD data sets are shown in Table II. The experimental results show a slight difference in the performance of EBOD on OOD data in non-medical domains. However, the difference is not significant compared to its performance on OOD data in medical domains. This means that although there may be some differences in the performance of the EBOD model on OOD data from different domains, over the performance is relatively stable and has strong generalization capabilities. Compared to the other four models, the EBOD model shows significant performance gains on most OOD datasets. A sample of the OOD data used in the study is shown in Fig. 5, where colon_aca represents colon adenocarcinoma images, stomach represents gastrointestinal disorders, and cataracts represent cataract images.

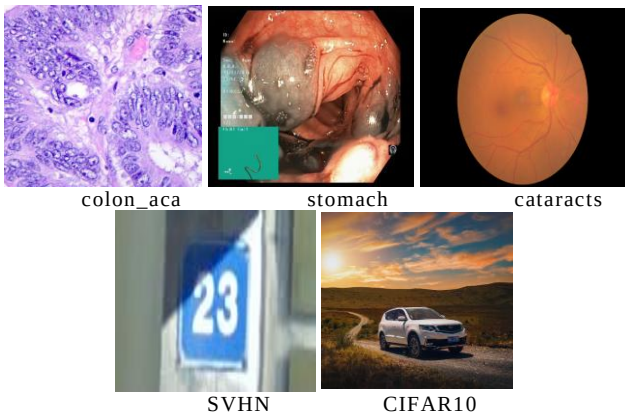

Fig. 5. Sample graph of OOD data.

In exploring the factors that enhance the performance of the model, the significant difference between the EBOD model compared to the WideResNet-based Energy OOD model [45] is the use of BERL for the auxiliary datasets. This innovative approach plays a key role in the optimization process and has a profound impact on the OOD detection performance of the model. A comparison of the FPR95 and AUROC metrics for the Energy OOD and EBOD models reveals that the incorporation of BERL is a pivotal factor in enhancing the OOD detection capabilities of the models. The EBOD model introduces BERL, which serves to balance the energy distribution of the auxiliary datasets during the training process. This significantly improves the model's generalization ability on different datasets. Table II details the results of the comparison of the models on different datasets. The FPR95 metrics for multiple OOD datasets are significantly lower when only the energy model is used and no BERL is introduced.

TABLE II. Evaluation Results of the Model on the OOD Datasets

	MSP	OE	OECC	Energy OOD	EBOD (Ours)
colon_aca	6.28	5.43	4.26	3.61	1.07
stomach	4.76	2.57	0.79	1.21	0.41
cataracts	3.55	1.93	2.87	2.08	0.49
SVHN	43.11	35.41	29.68	36.39	14.03
CIFAR10	45.26	38.71	32.52	29.01	5.85

(a) FPR95

	MSP	OE	OECC	Energy OOD	EBOD (Ours)

SVHN	86.83	90.19	90.68	91.49	95.83
CIFAR10	88.15	91.72	92.64	92.78	98.53

(b) AUROC

B. Calculate Cost

In the practical deployment of OOD detection for skin lesions, the computational cost is a crucial factor that determines model selection and deployment efficiency. To ensure the effectiveness and scalability of OOD detection methods in real-world applications, it is essential to optimize training and inference times, as well as reduce memory consumption, thereby minimizing computational overhead. Through the implementation of effective optimization strategies, the usability of the model in resource-constrained environments can be enhanced while maintaining its accuracy, thus meeting the demands of practical applications. Regarding training time, the BERL function proposed in this paper, compared to traditional methods, mitigates overfitting on minority class samples and excessive training on all class samples by precisely adjusting the regularization strength for each sample. This accelerates model convergence, thus reducing training time. In terms of inference time, the introduction of the M-value to quantify the likelihood of each sample belonging to a specific class, coupled with the adjustment of the loss function based on this value, reduces the computational complexity required for each sample during inference, thereby optimizing inference speed. Table III lists the calculated costs of different skin lesion OOD detection techniques.

TABLE III. CALCULATED COST OF DIFFERENT SKIN LESION OOD DETECTION TECHNIQUES

	Training time (Sheets/ms)	Reasoning time (Sheets/ms)	MEM
La-OOD [46]	4.57	1.46	6.87%
Bayesian [47]	5.13	1.51	7.63%
Ours	3.28	1.32	6.50%

C. Ablation Study

To validate the effectiveness of the proposed method, two ablation experiments were conducted. First, the BERL was introduced into DenseNet [48] for OOD detection of skin lesions. Subsequently, the BERL was removed from the EBOD model (i.e., EBOD-), and the same experiment was repeated. The experimental results demonstrate that the EBOD model exhibits superior performance in the OOD detection of various types of skin lesions, with the specific results summarized in Table IV.

TABLE IV. RESULTS OF ABLATION EXPERIMENTS

	DenseNet	EBOD-	EBOD (Ours)
colon_aca	2.61	4.39	1.07
stomach	1.82	2.07	0.41
cataracts	2.69	1.85	0.49
SVHN	34.50	42.37	14.03
CIFAR10	27.14	16.29	5.85

(a) FPR95

	DenseNet	EBOD-	EBOD (Ours)

stomach	93.09	96.18	99.85
cataracts	95.61	94.80	99.76
SVHN	90.04	89.45	95.83
CIFAR10	91.62	93.37	98.53

(b) AUROC

In contrast to previous studies, few studies synthesize multiple datasets on skin lesions by lesion type and further validate them using OOD datasets from a variety of different domains. Therefore, the present study is based on this innovation and improvement. Firstly, this study employs a methodology analogous to that employed in previous studies, whereby the training and test sets are rationalized in order to ensure a balanced data distribution and representative samples. Furthermore, this study introduces auxiliary datasets, which are employed to facilitate the model's ability to characterize a more expansive range of data, thereby enhancing its performance in the context of novel and previously unseen data. This enhanced generalization capacity enables the model to more effectively adapt to diverse application contexts and data distributions, and remains stable in the presence of noise, outliers, and other disturbances, thereby enhancing the model's resilience.

V. DISCUSSION

This study introduces BERL into CNNs, aiming to accurately detect OOD data in skin lesions. EBOD achieves state-of-the-art performance in cross-database evaluations and demonstrates a high degree of accuracy, even under a wide range of special conditions. In comparing the model performance under different training methods, the introduction of energy balance regularization [17] plays an important role in improving the excellent performance of the model. In addition, EBOD has potential applications in other clinical OOD detection situations.

CNNs produce good results in several areas, such as natural language processing and image recognition [12][13]. In addition, its application is extended to the medical field, bringing great convenience to medical research and clinical practice [49][50]. CNNs have significant potential to improve the accuracy of medical image data analysis, which may have far-reaching implications in the field of medical image diagnosis [51]. The performance of EBOD may be overestimated due to the exclusion of certain types of skin lesions (e.g., common nevi) from the dataset, but the model demonstrates excellent performance in high noise and strong motion environments. Interpreting skin lesions in practical clinical applications is a challenging and complex task. Therefore utilizing this model can potentially reduce the misdiagnosis rate of skin lesions in clinical practice and enhance patient care.

It is well known that the application of energy regularization techniques plays a crucial role in CNNs. Despite the demonstrated efficacy of energy regularization techniques in many other fields, there remains a paucity of research investigating their application to the domain of medical image processing. Inspired by the obstacles in OOD detection caused by a class imbalance in auxiliary datasets and internal mechanisms of the model, this study employs BERL to enhance the performance of CNNs in OOD detection. The introduction of BERL lays the foundation for applying CNNs to OOD

detection of medical images. If OOD detection is performed on multiple categories of medical images in the future, it is possible to achieve more efficient performance. Skin lesions are complex in shape and type, and especially under actual clinical conditions, OOD detection of skin lesions is more important than identification to minimize panic in the minds of patients and the rate of misdiagnosis.

In the case of ancillary data, especially in real-world scenarios, there is often an imbalance in the distribution of classes in the ancillary OOD data, e.g. there is a significant difference in the amount of data in the two classes. It can be difficult to effectively capture the diversity of the auxiliary samples of the OOD data using the traditional methods of cross-entropy loss and regularized loss. The model tends to learn the features of samples from a numerically larger number of categories while ignoring the features of samples from a numerically smaller number of categories, which reduces the model's ability to generalize when dealing with samples from unknown distributions. To overcome this problem, this study uses BERL to apply higher regularization to the data of the more numerous categories in the auxiliary data to ensure that the features of the data of the less numerous categories are also adequately extracted. This approach improves the robustness of the model and makes its performance more stable in the face of a variety of unknown distribution samples.

The evaluation metrics are determined based on the information from each OOD data after it has been tested by the model, which is critical to understanding and measuring the overall performance of the model. Previous research has shown that many detection models tend to produce overly confident prediction results when confronted with OOD data, resulting in less reliable detection of this OOD data. If the skin lesion features are similar in each training dataset, the model may suffer from overfitting, which weakens its generalization ability and leads to poor performance in OOD detection. As open-source datasets continue to proliferate in the medical field, researchers are able to utilize datasets with more comprehensive and diverse lesion characteristics, providing a valuable resource for OOD detection research. The current study involves skin lesion information from multiple datasets, which helps to ensure diversity in the training dataset and significantly improves the stability and robustness of the model. In the OOD detection model, the diversity of training data samples has a particularly significant impact on the detection results. The diversity of the training data allows the model to better recognize data with unknown distributions, demonstrating the potential value and reliability of the model in real-world applications.

Despite the progress made in this study in the field of OOD detection of skin lesions, however, there are still some limitations that need to be further explored and addressed. First, the limited size of the dataset used may not adequately represent the diversity of skin lesions in actual clinical settings. Therefore, when confronted with certain rare or emerging skin lesion types, the generalization ability and detection accuracy of the model may be insufficient. Moreover, in the OOD detection of skin lesions, the similarity between images presents a complex and challenging issue. In particular, the high similarity between certain non-skin lesion images and skin lesion images often leads to misclassifications in OOD detection. For example, varicose veins may cause the appearance of red or purple net-like patches on the skin surface, accompanied by localized swelling, which is prone to be misjudged as hemangiomas or purpuric skin lesions. Similarly, in some cases, lymphadenitis may lead to the formation of pustule-like or erythematous areas on the skin surface, especially when skin changes caused by enlarged lymph nodes closely resemble those of skin lesions, leading to incorrect identification as ulcers or nodules. Given the visual similarity between these non-skin lesions and actual lesions, effectively distinguishing these similar types of lesions has become a significant challenge in the OOD detection task for skin lesions. Finally, factors such as noise and image quality differences that may be encountered in practical applications are not yet fully considered in this study. Therefore, future research should focus on expanding the size of the dataset, improving the generalization ability of the model, exploring more different models, and testing them under conditions closer to clinical application scenarios to further validate and improve the performance of the model.

VI. Conclusion and Future Research

The current study is testing the accuracy of depth models for OOD detection of skin lesions, specifically for the detection of unknown distribution skin lesion images from known distribution skin lesion images. The results of the study show that the models tested exhibit almost similar performance. However, the best-performing model was EBOD, which significantly outperformed the other models in both the AUROC and FPR95 metrics. Future research should focus on the creation of larger databases and the expansion of the variety of skin lesions used to train the models, which could help the models learn a wider range of features and allow them to better understand the differences between known distribution data and unknown data, thus improving their performance in OOD detection. This means that the model not only performs well on training data but also maintains high accuracy on unknown distribution data. As more and more research is devoted to OOD detection modeling, researchers believe that more advanced algorithms will emerge to improve the accuracy and stability of the models and make them perform better in the face of different types of OOD data. This study provides a basis for further research on OOD detection of skin lesions using depth modeling and demonstrates its great potential for medical applications.

Using Fuzzy Matter-Element Extension Method to Cultural Tourism Resources Data Mining and Evaluation

Fei Liu
School of Humanities and Tourism, Zhejiang Institute of Economics and Trade, Hangzhou, 310018 Zhejiang, China

***Abstract*—This study explores the mining and evaluation of cultural and tourism resources based on fuzzy matter-element extension in the context of cultural and tourism integration. Through fieldwork and analysis of cultural and tourism resources, it is found that the fuzzy matter-element extension theory can be effectively applied to the mining and evaluation of cultural and tourism resources in the context of cultural and tourism integration. The application of integration of cultural and tourism resources has a significant driving effect in tourism development, which can effectively enhance the tourist experience and improve the visibility and attractiveness. Meanwhile, through field research and data analysis, this study also puts forward relevant improvement suggestions for the characteristics and actual situation of the research object, aiming at further optimising the development mode, realising the organic integration of culture and tourism resources, and promoting the prosperity and development of the local cultural industry. Overall, this study has certain theoretical and practical significance for promoting the integrated development of culture and tourism and the sustainable development of tourism.**

***Keywords*—Cultural and tourism integration; fuzzy object meta-theory; development; organic integration**

I. INTRODUCTION

Culture and tourism integration is the current hot topic of culture and tourism development. With the development of economic globalisation and cultural diversity, the integration of culture and tourism has become an important means of promoting local economic development and cultural inheritance [1-2]. The integration of culture and tourism is not only a combination of culture and tourism, but also a brandy new mode of development and way of thinking, which organically combines cultural and tourism resources to create unique cultural and tourism products, and to enhance the soft power of local economy and culture of [3].

In the context of the integration of culture and tourism, the excavation and evaluation of cultural and tourism resources have become the focus of attention, and the research on the excavation and evaluation of cultural and tourism resources is becoming a hot topic in both the academic and practical fields [4]. Firstly, with the integration and development of the culture and tourism industry, people have begun to pay attention to how to effectively excavate and utilise cultural resources, which includes examining the cultural characteristics of different regions, historical relics, traditional handicrafts, etc., as well as how to combine these resources with tourism products to enhance the tourism experience and attractiveness [5]. Secondly, much attention has also been paid to the evaluation research of cultural and tourism resources, which includes not only measuring and assessing the actual value of cultural and tourism resources [6], but also understanding tourists' perceptions and experiences of cultural and tourism resources, so as to better improve and enhance the utilisation efficiency and attractiveness of the resources [7]. In addition, the sustainable development of cultural and tourism resources is also a popular direction of current research [8], and many researchers have begun to pay attention to how to achieve sustainable development of resources while exploring and utilising cultural and tourism resources, so as to protect the cultural heritage and ecological environment, and to ensure the long-term and stable utilisation of the resources [9], [10].

It can be seen that in the current context of the integration of culture and tourism, the research on the excavation and evaluation of cultural and tourism resources has important practical and theoretical significance [11]. However, at present, the excavation of cultural and tourism resources mainly relies on the experience of experts, and lacks a systematic and scientific evaluation model [12], a practicable evaluation model can promote the integrated development of the culture and tourism industry, and through the excavation and evaluation of cultural and tourism resources, it can create tourism products with characteristics and attraction, and promote the coordinated development of the culture and tourism industry. As an emerging evaluation method, the fuzzy material element theory can solve this problem well. The fuzzy material element theory is a new type of theory combining fuzzy mathematical theory and material element theory, which can effectively deal with the fuzzy and uncertainty information, and provides new ideas and methods for the evaluation of cultural and tourism resources [13]. Therefore, this paper takes the current development of cultural tourism in a certain place as an example, through the fuzzy matter-element extension theory can quantitatively evaluate the cultural and tourism resources, and creatively solves the uncertainty and fuzziness problems in the evaluation of cultural and tourism resources. Through the fuzzy object element theory, a set of scientific evaluation system of cultural and tourism resources can be established, which can provide powerful support for the integrated development of culture and tourism.

II. System Building in the Context of Cultural and Tourism Integration

A. Concept of Cultural and Tourism Integration

The integration of culture and tourism, as a new trend in the current tourism development, is a product of the in-depth integration of culture and tourism fields [14]. It is not only an organic combination of culture and tourism resources, but also a new development model and concept. The integration of culture and tourism is embodied in practice as the intermingling of culture and tourism patterns, which can not only promote the inheritance and promotion of local culture, but also inject new vitality and elements into the development of tourism [15]. Therefore, the integration of culture and tourism is not only the integration of a single field, but also a new mode of co-operation between industries to complement and promote each other.

B. Indicator System Construction

The system should have a wide coverage and strong applicability, and needs to be able to comprehensively reflect the characteristics and quality of cultural and tourism resources. The system of valuation indicators constructed should comprehensively consider all aspects of cultural and tourism resources, including cultural connotation, historical value, tourism attraction, sustainability and other aspects [16]. Finally, this paper considers that the evaluation indexes should be operable to ensure that relevant data can be collected and processed effectively. Based on this, this paper finally constructs the indicator system as shown in Table I.

It is worth mentioning that in the process of constructing the indicator system, this paper learnt that many scholars have better requirements for the evaluation of cultural resources [19]. For the indicator of cultural relics protection, it is interpreted in the definition as assessing the protection of cultural relics in a specific geographical area, including the number, completeness and degree of protection of cultural heritage resources such as historical monuments, cultural relics and ancient buildings, etc. However, scholars believe that the historical, artistic and scientific values of these cultural relics in the assessment are important factors that should be taken into account comprehensively in the assessment; for the indicator of cultural industry, although scholars believe it is For the indicator of cultural industries, although scholars believe that it is to assess the development of cultural industries in a specific region, including the scale, vitality and innovation capacity of cultural industries such as cultural creative industries, cultural and artistic performances, cultural exhibitions, etc., some other scholars still believe that this indicator should take into account the contribution of the relevant industries to the local economic and social development; for the indicator of cultural traditions, many scholars believe that whether the inheritance of these traditions and culture has been effectively protected and disseminated should also be an important factor in the assessment [20]. For the indicator of cultural traditions, many scholars believe that the effective protection and dissemination of the traditional culture should also be an important part of the assessment; for the indicator of cultural activities, the promotion of these cultural activities to the local cultural industry and tourism should not be neglected in the assessment process; and for the last indicator of cultural resources, the assessment of this indicator needs to include the impact of cultural education on the cultural literacy and cultural identity of the local residents.

TABLE I. Evaluation Index System based on the Concept of Cultural Tourism Integration

Normative layer	***Indicator layer***	***Interpretation of indicators***
Cultures resource (such as manpower or tourism)[17]	Heritage conservation	To assess the status of heritage conservation in a given geographical area, including the number, integrity and degree of protection of cultural heritage resources such as historical monuments, artefacts and ancient buildings.
	Cultural industry	The development of cultural industries in the region, including the scale, vitality and innovation capacity of cultural industries such as cultural and creative industries, cultural and artistic performances, and cultural exhibitions.
	Cultural tradition	To assess the transmission and development of cultural traditions in a given geographical area, including the degree of transmission and contemporary value of traditional cultural resources such as traditional festivals, folk culture and intangible cultural heritage.
	Cultural activity	To assess the richness and impact of cultural activities in a given geographical area, including the number, scale and impact of cultural activities such as cultural exhibitions, performances and cultural exchange activities.
	Cultural education	To assess the level and coverage of cultural education in a given geographical area, including the quantity and quality of cultural and educational resources such as cultural and educational institutions, cultural and educational programmes, and public cultural services.
Journey resource (such as manpower or tourism)[18]	Natural landscape	To assess the richness and attractiveness of the natural landscape of a given territory, including the quantity and quality of natural scenery resources such as mountain scenery, lakes and rivers, forests and grasslands, as well as their attractiveness to tourists.
	Cultural landscape	To assess the richness and attractiveness of the cultural landscape of a given territory, including the quantity and quality of cultural heritage resources such as historical monuments, traditional architecture, religious sites, etc., and their attractiveness to tourists.
	Tourist facility	To assess the degree of sophistication of tourism facilities in a given geographical area, including the quantity and quality of tourism infrastructure such as hotels, restaurants, transport, guide services, etc., as well as the degree of accessibility to tourists.
	Tourism activity	To assess the diversity and attractiveness of tourism activities in a given geographical area, including the richness and characteristics of tourism activities such as mountain hiking, water sports, cultural experiences, festivals and events, as well as their attractiveness to tourists.
	Tourism Services	To assess the quality and level of tourism services in a given geographical area, including the quality of services provided by tour guides, tourism information and counselling, tourism safety and security, as well as the level of satisfaction with tourists.

C. Coefficient of Variation Method

The coefficient of variation method is a statistically based method for the objective calculation of weights and is suitable for assessing situations where there are different degrees of variability between indicators. The coefficient of variation is the ratio of the standard deviation of an indicator to its mean value, which reflects the relative degree of dispersion of the indicator data. The larger the coefficient of variation, the greater the degree of volatility of the indicator, and vice versa [21],[22]. When calculating the weights, the coefficient of variation can be used to measure the importance of each indicator in the overall evaluation. In the evaluation index system of cultural and tourism resources based on fuzzy object elements in the context of cultural and tourism integration, first of all, taking into account that the indicators cover a wide range so that the objective weight assignment method can reduce the variability brought by the collection of data, and the data often involves different degrees of variability between the indicators, so the coefficient of variation method can be a very good solution to this problem. The calculation steps are shown below.

Data standardization:

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^{\ 2}}} \tag{1}$$

Where: r_{ij} - Normalised data matrix elements;

x_{ij} -Data matrix elements;

m -Indicator Data Matrix Calculation Sample.

Calculation of the coefficient of variation

The new data matrix $R = \left(r_{ij}\right)_{m\times n}$ can be formed after the first step of processing.

Calculate the mean value of the indicator:

$$A_j = \frac{1}{n}\sum_{i=1}^{m} r_{ij} \tag{2}$$

Where: A_j - Mean value of the indicator;

n -Number of data samples.

Calculate the standard deviation of the indicator:

$$S_j = \sqrt{\frac{1}{n}\sum_{i=1}^{m}\left(r_{ij} - A\right)^2} \tag{3}$$

Where: S_j Indicator standard deviation.

Calculate the coefficient of variation:

$$V_j = \frac{S_j}{A_j} \tag{4}$$

Where: V_j - Standard deviation of the indicator.

(3) Calculation of weights

$$\omega_{ij} = \frac{V_j}{\sum_{j=1}^{n} V_j} \tag{5}$$

D. Fuzzy Object Element Modelling

Under the background of cultural and tourism integration, cultural and tourism resource evaluation is very important because it can help relevant departments and enterprises better understand and utilise the resources and promote the development of cultural and tourism industries. And the fuzzy object element model is a mathematical model that can deal with uncertainty and ambiguity information, which can effectively deal with all kinds of fuzzy and uncertain information and data involved in the evaluation process of cultural and tourism resources, specifically, the fuzzy object element model transforms the uncertainty information into the affiliation function, so that it can better describe and deal with all kinds of uncertainty [23]. The calculation process is as follows.

1) Constructing fuzzy object elements: Let the given thing be M, v is its feature, C has the measure value, using the ordered triad R= (M, C, v), R is called the crop element, when the measure value v has the fuzzy nature, R is the fuzzy object element, and μ(x) is the degree of affiliation of the thing M to the corresponding measure value x of its feature C is recorded as:

$$R = \begin{bmatrix} & M \\ C & \mu_{(x)} \end{bmatrix} \tag{6}$$

2) Fuzzy object element construction: Constructing fuzzy object elements based on the normalisation in the weighting results of this paper.

$$R_{mn} = \begin{bmatrix} & M_1' & M_2' & \cdots & M_n' \\ C_1 & x_{11}' & x_{12}' & \cdots & x_{1n}' \\ C_2 & x_{21} & x_{22} & \cdots & x_{2n} \\ \vdots & \vdots' & \vdots' & \vdots & \vdots' \\ C_m & x_{m1} & x_{m2} & \vdots & x_{mn} \end{bmatrix} \tag{7}$$

Where: x_{ij}' - Indicator normalised value.

3) Constructing standard objects

$$R_0 = \begin{bmatrix} & M_0 \\ C_1 & x_{10} \\ C_2 & x_{20} \\ \vdots & \\ C_{\mathrm{m}} & x_{m0} \end{bmatrix} \tag{8}$$

Where: x_{i0}' - optimal value of the indicator, normalised to 1.

4) Constructing fuzzy object elements for the difference between the standard object and the evaluation object

Calculate the standard object and evaluation object difference$\Delta_{ij}=\left[x_{i0}-x_{ij}'\right]^2$, based on which the object element matrix is constructed:

$$R_{mn}=\begin{bmatrix} & M_1, & M_2, & \cdots & M_n, \\ C_1 & \Delta x_{11}, & \Delta x_{12}, & \cdots & \Delta x_{1n}, \\ C_2 & \Delta x_{21} & \Delta x_{22} & \cdots & \Delta x_{2n} \\ \vdots & \vdots, & \vdots, & \vdots & \vdots, \\ C_m & \Delta x_{m1} & \Delta x_{m2} & \vdots & \Delta x_{mn} \end{bmatrix} \quad (9)$$

Where: Δ_{ij} - calculated difference

5) Euclid closeness: The larger the value of Euclidean closeness the closer it is to the optimum. The formula for calculating the Euclidean closeness is as follows:

$$\rho H=1-\sqrt{\sum_{i=1}^{m}\omega_i\Delta_{ij}} \quad (10)$$

Where: ρH - Euclid closeness

III. Cultural Tourism Resources

A. Analysis of the Study Area

The study area belongs to the key cultural and tourism project of Jiangsu Province, the national 3A level tourist attraction - Shazhou, Zhangjiagang City. Through the field investigation of the exhibition halls, cultural relics, traditional handicrafts, etc. in the study area, the cultural elements and historical background displayed in the study area were understood, and after in-depth exchanges with the managers and staff, the development history, cultural activities, and future development planning in the study area were understood, based on which the state of the indicators needed to be examined in the study area was quantified by the data. Through the investigation and analysis, it was found that the study area possesses rich cultural resources, including traditional handicrafts, historical relics, folk culture and other elements, among which, many traditional handicrafts skills are preserved, such as ceramics, weaving, etc. which represent the unique local cultural traditions. Many precious historical relics are also displayed, which reflect the important position and cultural heritage of a certain place in history. In addition, local folk culture and traditional festivals, etc. are shown to tourists through various cultural activities and exhibitions, enhancing their understanding and awareness of local culture.

B. Coefficient of Variation Method for Calculating Weights

The relevant values and weights of the coefficient of variation method calculated according to equations (1-5) are shown in Table II.

C. Analysis of Weighting Results

Based on the results of the weight calculation, the weight values are sorted and then plotted in a bar chart as shown below.

According to the results of the chart, cultural resources, cultural relics protection, cultural industry, cultural activities accounted for 13.82%, 16.80%, 11.79%, according to the survey and field consulting analysis of cultural relics protection is an important part of the cultural resources, which carries the history, traditions and cultural memories of a region or a country, and cultural relics protection not only protects the historical heritage, but also passes on the cultural heritage. Tradition, it is of great significance to enhance the cultural soft power of a region or a country. Meanwhile, with the development of culture and tourism integration, cultural industry has become an important force to support the development of tourism, which generally includes cultural creative industry, cultural tourism industry, etc., and they play an important role in the economic development and job creation of a region or a country. Corresponding cultural activities are an important way to enrich cultural life and promote cultural exchanges, and rich and diversified cultural activities can attract tourists, enhance the cultural brand image of the region or country, and then promote the development of cultural tourism. Therefore, the three indicators of heritage protection, cultural industry and cultural activities are in the study, and their weights are relatively high.

TABLE II. Coefficient of Variation Method

Indicator layer	Average value	Variance (statistics)	Coefficient of variation	Weights
Heritage conservation	0.2580	0.0093	0.0361	0.1382
Cultural industry	0.2580	0.0113	0.0439	0.1680
Cultural tradition	0.2582	0.0033	0.0127	0.0486
Cultural activity	0.2581	0.0080	0.0308	0.1179
Cultural education	0.2582	0.0028	0.0110	0.0422
Natural landscape	0.2582	0.0040	0.0154	0.0589
Cultural landscape	0.2582	0.0026	0.0101	0.0386
Tourist facility	0.2580	0.0102	0.0395	0.1509
Tourism activity	0.2579	0.0129	0.0500	0.1914
Tourism services	0.2582	0.0031	0.0118	0.0453

The same analysis shows that for tourism resources, the weight of tourism facilities and tourism activities is relatively large, accounting for 19.14% and 15.09% respectively, while the landscape indicator instead accounts for a moderate proportion, which indicates that the landscape, whether it is a natural landscape or a cultural landscape, is a necessity for any tourism region, which explains why the importance of the proportion of the performance of the general. Under the background of cultural and tourism integration, the reasons for the relatively high weighting of the two criteria of tourism facilities and tourism activities in tourism resources are analysed as follows: in tourism activities, tourism facilities are the infrastructure to support tourists' experience of tourism services, and high-quality tourism facilities can provide comfortable and convenient tourism environments to satisfy tourists' needs for tourism experience. For example, wine, scenic facilities, transport facilities, etc., their quality and service level directly affects the tour's satisfaction and tourism experience. Tourism activities are an important factor in attracting tourists, and colourful tourism activities can enhance the attractiveness and competitiveness of tourist destinations. For example, cultural festivals, experiential activities, theme performances, etc., which can enrich tourists' travel experience, increase their stay time and consumption, and play an important role in promoting the tourism economy of a region or country. In summary, tourism facilities and tourism activities are important indicators for evaluating tourism resources in the context of cultural and tourism integration, and they are directly related to tourists' tourism experience and the attractiveness of the destination, so their weights are relatively high. It is of great significance for excavating and evaluating cultural and tourism resources.

D. Fuzzy Object Element Modelling Analysis

The application of fuzzy object-element model in the study area is carried out according to Equation (6-10), and the data collected from managers, tourists, local residents, and government personnel are now listed in Table III, and the results of single-indicator calculations and overall calculations are listed in Table IV.

TABLE III. DATA FOR THE STUDY AREA

Indicator layer	***Data 1***	***Data 2***	***Data 3***	***.....***	***Data 14***	***Data 15***
Heritage conservation	85	85	84	.....	85	85
Cultural industry	86	85	83	.....	90	91
Cultural tradition	89	90	89	.....	91	90
Cultural activity	60	59	59	.....	56	56
Cultural education	99	98	97	.....	97	96
Natural landscape	98	97	96	.....	96	95
Cultural landscape	99	98	100	.....	97	100
Tourist facility	82	81	79	.....	85	87
Tourism activity	78	77	75	.....	76	85
Tourism Services	98	97	99	.....	96	99

TABLE IV. EVALUATION RESULTS

Basic indicators	***Euclid approximation***
Heritage conservation	0.9178
Cultural industry	0.8950
Cultural tradition	0.8899
Cultural activity	0.8544
Cultural education	0.8915
Natural landscape	0.8831
Cultural landscape	0.9034
Tourist facility	0.8789
Tourism activity	0.9090
Tourism Services	0.8923
Normative level indicators	***Euclid approximation***
Cultural resource	0.8897
Tourism resource	0.8933
Status of development of cultural and tourism resources	0.8915

E. Analysis of the Evaluation Results of the Fuzzy Material Element Model

Among the indicators belonging to the whole cultural resources, the Euclid approximation of cultural relics protection is 0.9178, the Euclid approximation of cultural industry is 0.8950, and the Euclid approximation of cultural activities is only 0.8544, which can be seen that the overall Euclid approximation of the cultural resources is 0.8897. The indicator with the lowest evaluative value is the cultural activities, which is considered to be influenced by the individual's subjective feeling, and this subjectivity and personalisation may cause the evaluative value of the same cultural activity to be relatively low. Considering that the evaluation of cultural activities is often influenced by the subjective feelings of individuals, the evaluation value of the same cultural activity by different people may differ greatly, and this subjectivity and individualisation leads to the relatively low evaluation value of cultural activities. However, analysing the data of the single indicator, it can be seen that although there are differences in the evaluation of this indicator by the collection object, the results show that it is generally not high, thus indicating that the cultural activities in the study area need to be improved in a targeted manner, and that the study area needs to enhance the sustainable development and innovation of cultural activities, and to improve the activities. The study area needs to strengthen the sustainable development and innovation of cultural activities to improve the attractiveness and influence of the activities, so as to enhance the appraisal value of cultural activities; at the same time, government departments should encourage the organisation of diversified cultural activities, including traditional culture, contemporary culture, folk culture, etc. so as to promote the inclusiveness of cultural activities, thus enhancing the appraisal value.

Among the indicators belonging to tourism resources, the evaluation value is relatively close, and the Euclid closeness of natural landscape, cultural landscape, tourism facilities, tourism activities, and tourism services are 0.8831, 0.9034, 0.9090, 0.8789, and 0.8923, respectively, of which the closeness of the tourism facilities in the study area is the lowest at 0.8789, which means that compared to the rest of the indicators, there is more room for improvement. The study area has a long cultural history, so attracting tourists by exploring history and culture, folk customs, traditional crafts and rich cultural elements can increase the evaluation value. At the same time, the tell-tale development of society has prompted tourists to be more and more positive about the demand for facilities and the sense of experience, so the study area can attract tourists by creating richer and more varied tourism experience projects, such as cultural performances, interactive experiences, and themed activities. In addition, consider improving the service level of tourism facilities, including guided tours, scenic area management, convenient facilities, etc., to improve visitor satisfaction, and combining contemporary technological means, such as virtual reality, augmented reality and other technologies, to bring novel experiences to tourists, to attract more tourists, and to promote the development of cultural and tourism integration.

After analysing the indicators belonging to cultural resources and tourism resources respectively, we are now analysing the indicators with relatively high degree of Euclid closeness, which are cultural relics protection, cultural landscape and tourism activities. Tourism activities in the general environment of regionalisation is not obvious, depending on the delicacy of tourism activities around the world, and cultural landscape, heritage protection of the two indicators are closely related, but also the highlight of the research in this paper, in this paper in the subsection of the indicator system of cultural heritage protection of this indicator needs to assess the situation of regional heritage protection, including the number of historical monuments, cultural relics, ancient buildings and other cultural heritage resources, the completeness and the degree of protection, and at the same time, the historical value, artistic value and scientific value of these The historical value, artistic value and scientific value of cultural relics are all important factors for assessment. The local historical monuments, ancient buildings and cultural relics also form the cultural landscape of tourism, which shows that there is a certain difference between heritage conservation and cultural landscape but the connection is close. First of all, heritage protection and cultural landscape are both for the protection and inheritance of historical heritage, promote traditional culture, enhance national cohesion and cultural self-confidence. Secondly, the success of heritage protection determines whether it can become an important part of the cultural landscape, and the formation of the cultural landscape cannot be separated from the protection and use of cultural relics, therefore, heritage protection and cultural landscape are often intertwined and mutually supportive in practice, and jointly promote the sustainable development of the integration of culture and tourism.

IV. Conclusion and Outlook

This paper based on the fuzzy object element theory on the study area for field research and case analysis, we found that the applicability of fuzzy object element method is good, and for the evaluation of the results of the realisation of the clear, through the evaluation results of the model can promote the integration of the development of culture and tourism industry to enhance the effect of the local cultural heritage and promotion, and to achieve the sustainable development of the tourism industry. The results of this paper are now combined with the current stage of China's tourism development for specific elaboration.

A. Development Orientation Analysis

The positioning of efficient development is to organically integrate cultural and tourism resources to create a comprehensive scenic spot integrating cultural heritage, tourism experience, leisure and entertainment. The different attractions then become as an important carrier for the integration of culture and tourism, with the important role of inheriting and displaying local culture, promoting tourism development, and enhancing the image of the city.

Secondly, in the context of the integration of culture and tourism, local tourist attractions and even Netflix attractions need to be committed to tapping and showcasing local traditional cultural resources, promoting local cultural characteristics, attracting tourists to come and experience them, and promoting the development of the local tourism industry. At

the same time, they also need to focus on innovation and provide tourists with colourful cultural experiences through various cultural activities, exhibitions and performances, so that they can feel the charm of local culture while playing.

Cultural landscapes are pivotal in the study of this paper, so cultural attractions can be used as a tourist destination with high cultural value, and constantly explore its development potential. Its status is not only a tourist attraction, but also a comprehensive place with education and cultural inheritance functions. By tapping into its cultural and tourism resources, it can better play its role in attracting more tourists to visit and experience, thus promoting the prosperity of the local tourism industry.

Overall, in future research, field studies and questionnaires can be combined to gain an in-depth understanding of the needs of tourists and the development direction of the cultural park, and to promote the prosperity of the local tourism industry.

B. Analysis of the Development Path of Cultural and Tourism Integration

This paper analyses the relationship between cultural landscape and cultural relics protection in the fuzzy object element result analysis, and it can be found that the development path of cultural and tourism integration needs to be achieved through scientific planning and careful design. Planning is the foundation of culture and tourism integration, and it needs to start from the perspective of overall development, taking into account the differences and complementarities of culture and tourism resources. In the development process, the planning should focus on cultural heritage, tourism experience and industrial development, and through the coordination of all kinds of resources and elements, create cultural and tourism integration products with local characteristics and competitiveness. Design is a key link in the implementation of cultural and tourism integration, and needs to focus on innovation and inclusiveness. Design work should incorporate local cultural elements and take into account the needs and experiences of tourists, so as to make tourist attractions attractive destinations, and at the same time, it should take into account environmental protection and cultural heritage, so as to create an integrated space for cultural and tourism integration.

C. Shared and Sustainable Development

Tourism is dependent on local buildings and residents, so it is necessary to encourage local communities to participate in the organisation of tourism activities and promote the shared development of communities and tourism, such as the development of tourism hospitality in the form of agro-entertainment and B&Bs, so as to increase the sources of income of local residents. Meanwhile, measures to protect the local cultural heritage and natural environment will be amicably bound to the residents of the tourism area, so as to strengthen the protection and inheritance of the cultural heritage, promote eco-friendly tourism activities, and reduce the negative impact on the environment. In addition to focusing on the dissemination and sharing of culture, tourism practitioners are encouraged to provide personalised and customised cultural tourism products and services to meet the needs of different groups of tourists, such as customised cultural and creative handicrafts and customised travel routes with cultural themes.

This paper hopes that through the above suggestions for upgrading and transformation, the attractiveness and competitiveness of cultural and tourism resources can be further enhanced, the integrated development of culture and tourism can be promoted, and the goal of cultural heritage and sustainable tourism development can be realised.

Arabic Sentiment Analysis Using Optuna Hyperparameter Optimization and Metaheuristics Feature Selection to Improve Performance of LightGBM

Mostafa Medhat Nazier[1], Mamdouh M. Gomaa[2], Mohamed M. Abdallah[3], Awny Sayed[4]
Computer Science Department-Faculty of Science, Minia University, Minia 61519, Egypt[1, 2, 3]
Information Technology Department-Faculty of Computing and Information Technology,
King Abdulaziz University, Jeddah 21589, Saudi Arabia[4]

Abstract*—Sentiment Analysis (SA) effectively examines big data, such as customer reviews, market research, social media posts, online discussions, and customer feedback evaluation. Arabic Language is a complex and rich language. The main reason for the need to enhance Arabic resources is the existence of numerous dialects alongside the standard version (MSA). This study investigates the impact of stemming and lemmatization methods on Arabic sentiment analysis (ASA) using Machine Learning techniques, specifically the LightGBM classifier. It also employs metaheuristic feature selection algorithms like particle swarm optimization, dragonfly optimization, grey wolf optimization, harris hawks optimizer, and a genetic optimization algorithm to identify the most relevant features to improve LightGBM's model performance. It also employs the Optuna hyperparameter optimization framework to determine the optimal set of hyperparameter values to enhance LightGBM model performance. It also underscores the importance of preprocessing strategies in ASA and highlights the effectiveness of metaheuristic approaches and Optuna hyperparameter optimization in improving LightGBM model performance in ASA. It also applies different stemming and lemmatization methods, Metaheuristic Feature Selection algorithms, and the Optuna hyperparameter optimization on eleven datasets with different Arabic dialects. The findings indicate that metaheuristics feature selection with the LightGBM classifier, using suitable stemming and lemmatization or combining them, enhances LightGBM's accuracy by between 0 and 8%. Still, Optuna hyperparameter optimization with the LightGBM classifier, using suitable stemming and lemmatization or combining them, depending on data characteristics, improves LightGBM's accuracy by between 2 and 11%. It achieves superior results than metaheuristics feature selection in more than 90% of cases. This study is of significant importance in the field of ASA, providing valuable insights and directions for future research.

Keywords*—Arabic Sentiment Analysis (ASA); big data; Light Gradient Boosting Machine (LightGBM); Optuna hyperparameter optimization; metaheuristics feature selection; machine learning

I. INTRODUCTION

Sentiment analysis (SA), also known as opinion mining, is a technique within natural language processing (NLP) that involves several steps: data collection, preprocessing, feature extraction, and sentiment classification. It has recently become popular as an effective tool for examining big data, such as social media posts, customer reviews, market research, online discussions, and social media monitoring [1]. The popularity of SA has grown significantly among marketers and consumers. It enables them to gain insights into products and analyze market behavior. This method, further enhanced by machine learning (ML), data mining (DM), and deep learning (DL) algorithms, objectively assesses whether a text expresses positive or negative emotions or conveys sentiments about a specific issue, instilling confidence in its impartiality [2]. The internet offers valuable insights into Arabic Sentiment Analysis (ASA). However, analyzing Arabic content poses challenges due to the language's complexities, morphological features, inadequate resources, and the absence of suitable corpora [3]. Although plenty of resources exist to understand English social media content, Arabic resources still need improvement. This gap arises primarily from the variety of Arabic dialects in addition to Modern Standard Arabic (MSA). These dialects are linguistically exciting and widely used among Arabic speakers in everyday conversations and on social media. There is an urgent need to develop specialized AI models for language-specific applications in Arabic [4]. The main challenges of SA in Arabic dialects include morphological analysis [5], the scarcity of datasets [4], the complexity of dialects, and dialects scripted in Latin [5].

ASA presents significant challenges due to the linguistic complexities of the Arabic language, including its dialectical variations, morphological richness, and the lack of extensive labeled datasets. Despite the advancement of machine learning techniques, existing sentiment analysis models often struggle with the diversity of Arabic dialects and the need for effective text preprocessing methods. Additionally, optimizing machine learning models for these challenges requires not only efficient algorithms but also hyperparameter optimization and feature selection to enhance performance. Light Gradient Boosting Machine (LightGBM) has been shown to be a powerful model for classification tasks, but its performance in ASA, particularly with large and diverse Arabic datasets, has not been fully explored. This research aims to bridge this gap by enhancing LightGBM's performance using robust preprocessing techniques (ISRI stemmer and Qalsadi lemmatizer) and

advanced optimization methods (metaheuristic feature selection and Optuna hyperparameter tuning).

Feature Selection (FS), also called variable subset selection, is a crucial preprocessing step in ML. It helps reduce computational costs and improve classification accuracy [6] [7]. FS achieves this by discarding noisy, redundant, or irrelevant features, focusing instead on a smaller subset that is sufficient to describe the concept of interest. This process improves the predictor's performance, simplifies data processing, and reduces computational demands. Since the 1960s, FS research has emphasized developing efficient methods to handle high-dimensional datasets, which often include irrelevant or obsolete features [8]. Meta-heuristic techniques, particularly swarm-based optimization algorithms like Grey Wolf Optimization (GWO), Dragonfly Optimization (DFO), Particle Swarm Optimization (PSO), Harris Hawks Optimization (HHO), and Genetic Optimization (GO), have emerged as practical solutions for FS. These methods strike a balance between computational efficiency and solution quality, making them suitable for real-world applications where identifying the optimal feature subset is essential for accurate and cost-effective classification.

Hyperparameter optimization and tuning are critical steps in machine learning to enhance model performance by selecting the best combination of hyperparameters, which are parameters not learned from the data but set prior to training [9]. Effective tuning ensures improved model accuracy, stability, and generalization. Methods such as random search, grid search, and advanced algorithms like genetic algorithms, Bayesian optimization, and hyperband are widely used to efficiently explore the hyperparameter space. Optuna framework further streamline this process. Properly tuned hyperparameters can significantly impact both computational efficiency and predictive performance [10].

The motivation behind this study stems from the growing need for effective sentiment analysis tools for Arabic text, particularly as Arabic is a widely spoken language with various dialects. Traditional approaches to ASA often fail to account for the subtleties of the language, including regional variations and complex word forms. Leveraging LightGBM's strengths with tailored preprocessing techniques, such as the ISRI stemmer and Qalsadi lemmatizer, holds the potential to significantly improve the model's accuracy. Furthermore, applying metaheuristic feature selection algorithms and Optuna for hyperparameter optimization offers a promising way to enhance model performance by selecting the most informative features and fine-tuning the model's parameters. The use of large and diverse datasets is crucial to better understanding the impact of these techniques on ASA across different Arabic dialects. The combination of these methodologies could provide a substantial advancement in the field of ASA, making it more adaptable and accurate for real-world applications.

The paper's contributions include using LightGBM classification algorithm in ASA and improving its performance using ISRI stemmer and Qalsadi lemmatizer with metaheuristic feature selection algorithms and Optuna hyperparameter optimization. A key aspect of our research is using large Arabic datasets from different Arabic dialects in ASA. This diversity in the datasets could significantly enhance LightGBM's performance in ASA. The proposed approach involves using ISRI stemmer alone and Qalsadi lemmatizer alone for data preprocessing and combining them, followed by implementing metaheuristic feature selection algorithms and Optuna. We also compare Optuna hyperparameter optimization with metaheuristic feature selection algorithms to see the impact of improving LightGBM's performance in ASA. It also shows their effects on enhancing ASA.

The remainder of the paper is organized as follows: The "Related Work" in Section II examines previous research on ASA, LightGBM, Optuna hyperparameter, and metaheuristics feature selection. The "Proposed Methodology" in Section III provides detailed information about the proposed approach. In the "Results and Analysis" in Section IV, we present and compare the experimental findings with those of other methods. The "Discussion" in Section V interprets the results and contextualizes their significance, bridging the gap between the findings and the broader implications of the study. Finally, the "Conclusion" in Section VI summarizes the main points of the research.

II. Related Work

This section provides an overview of the existing research on ASA, focusing on key areas such as preprocessing techniques, ML and DL algorithms, FS, and hyperparameter optimization. Several studies have contributed to advancing ASA methodologies by exploring diverse approaches for improving sentiment classification accuracy. Research in ASA has addressed challenges related to the linguistic complexity of Arabic, including its morphological richness and dialectical diversity. In particular, studies have investigated various preprocessing techniques like word embedding, stemming, and lemmatization to enhance text representation. Additionally, the integration of advanced classification algorithms such as LightGBM, along with metaheuristic feature selection and hyperparameter optimization methods like Optuna, have emerged as crucial elements in improving the performance of ASA models. This review synthesizes the most prominent contributions in these areas, providing a comprehensive understanding of the current state-of-the-art in ASA and highlighting opportunities for further development. In study [3], this paper compared several ASA models and discussed the DL algorithms employed in ASA within the domain of e-marketing. The paper's contribution includes improving ASA using preprocessing techniques like word embedding. In a study referenced as study [11], the semantic orientation method was devised to determine the overall polarity of Arabic subjective texts. The technique involved using a specialized domain ontology and an established sentiment lexicon. This technique was evaluated using an Arabic dataset from the hospitality industry to construct the domain ontology. In study [12], this paper employs the Levenshtein distance algorithm for data preprocessing and implementing various classification models and introduces a novel method for conducting ASA using the mobile application comments dataset. This study thoroughly [13], reviews textual content analysis in the ASA domain, examining 133 ASA papers published from 2002 to 2020. It explores common themes, methodologies, technologies, and algorithms used in these studies. This paper's

key finding indicate various approaches, such as ML, lexicon-based, and hybrid methods, with algorithms like SVM, Naive Bayes (NB), and hybrid methods proving the most effective. The research presented in study [14] introduces an explainable sentiment classification framework tailored for Arabic. A noise layer is incorporated into various DL models, such as BiLSTM and CNN-BiLSTM, to mitigate overfitting. In study [15], the authors introduce LightGBM, a new GBDT algorithm featuring two innovative techniques: Gradient-based one-sided sampling (GOSS) and Exclusive Feature Bundling (EFB). These techniques are designed to handle large data instances and features, offering practical benefits concerning memory efficiency and processing speed. The study in [16] presents an innovative hybrid system for detecting fake news, which integrates a BERT-based model with LightGBM. The performance of this approach is assessed against four classification methods that utilize different word embedding techniques across three actual fake news datasets. In study [17], SA is used to determine sentiments in text. LightGBM is used for efficiency and scalability, but long and short-term memory is preferred to understand the deep context of the text. The LSTM model was trained using the Adam optimizer, and Text Blob was used to train the LightGBM. Short-term memory (92%) scores over a LightGBM (89%) accuracy. The F1 score for Long short-term memory (93%) and LightGBM (92%) is about comparable. In study [18], this paper focuses on calculating emotional scores for product features through comparative sentences and developing a clustering method to analyze the hierarchical relationships among brands. It utilizes an improved computing model that leverages a sentiment dictionary to generate weighted sentiment scores, enhancing the accuracy of an unsupervised algorithm. These scores are then organized into a design structure matrix, facilitating the clustering of brands with similar products. The research presented in study [19] developed four hybrid machine learning techniques for multi-class-based comparative SA using three datasets from diverse domains. The results revealed that the Multilayer Perceptron + Random Forest (MLP + RF) hybrid ML technique, employing a multilayer perceptron as the base estimator, achieved an F1-score of 93.0% and an average accuracy of 93.0%. The research presented in study [20] focused on the Optuna hyperparameter optimization framework in conjunction with the LightGBM algorithm. A 10-fold cross-validated model using Optuna and LightGBM was trained on the FHS dataset. The resulting model achieved an accuracy of 0.930, a sensitivity of 0.897, a specificity of 0.963, an F1 score of 0.929, a precision of 0.963, an area under the receiver operating characteristic curve (AUC-ROC) of 0.978, and a Matthews correlation coefficient (MCC) of 0.861. The study in [21] utilized an ensemble model that combined CNN and LSTM to predict the sentiment polarity of Arabic tweets using the ASTD dataset. The model achieved an F1-score of 64.46% and an accuracy of 65.05% on this dataset. In study [22], researchers explored various DL models, including LSTM and CNN, for ASA. They trained neural language models using two techniques based on word2vec: skip-gram and Continuous Bag of Words (CBOW). The experiments demonstrated that LSTM outperformed CNN in terms of performance. The research presented in study [23] developed a SA model by enhancing the ML approach (using complement Naive Bayes) with features derived from both an Arabic sentiment lexicon and the text itself. In study [24], an attempt was made to address ASA using a DL model. The LABR dataset in this study comprises book reviews.

In conclusion, the literature on ASA highlights the significant progress made in improving sentiment classification through advanced preprocessing techniques, effective feature selection, and optimized machine learning models. LightGBM has been demonstrated as a highly efficient algorithm for ASA, particularly when enhanced by hyperparameter optimization via Optuna and metaheuristic feature selection methods. Studies have shown that preprocessing methods such as word embedding, stemming, and lemmatization can effectively address the challenges posed by the Arabic language's unique structure. Hybrid models and deep learning approaches have demonstrated potential in improving the contextual understanding of sentiment in Arabic texts. However, challenges such as dialectal variation and the limited availability of large, labeled datasets persist. This indicates that future research should focus on addressing these issues while also exploring innovative ways to integrate different algorithms and preprocessing techniques. Ultimately, the continued development and optimization of ASA models will contribute to more accurate and efficient SA tools for Arabic-language applications.

III. Proposed Methodology

This section outlines the proposed methodology for conducting ASA using various preprocessing techniques, stemming, lemmatization, or a combination of them, tokenization, feature extraction, LightGBM as a classifier, metaheuristic feature selection methods, and Optuna hyperparameter optimization strategies to enhance the performance of the LightGBM classifier, as shown in Fig. 1.

A. Preprocessing Data

Preprocessing is a vital phase in ASA, as it prepares the input data for effective SA. This step significantly enhances the quality of SA [25]. In this research, a meticulous data cleansing process was conducted to prepare the datasets. This involved a series of steps, including the removal of non-Arabic words, numbers, symbols, Arabic and English stop words, duplicate characters, Arabic Tashkeel and Tanween, HTML tags, links, and the replacement of characters such as Hamza, Ha, and Ta Marbuta with their simplified equivalents. Tokenization includes breaking down text into smaller units, such as words or sub-words, with high precision. Stemming aims to reduce words to their base forms, known as stems or roots. At the same time, Lemmatization seeks to associate all word variations with their canonical form, called a lemma (the form found in dictionaries) [26]. Stemming and Lemmatization are essential for improving the consistency and accuracy of the SA process. This paper applies ISRI Light stemmer from NLTK to various datasets, successfully eliminating inflections and affixes to expose the base form. It uses a Qalsadi Arabic lemmatizer on data sets [27] [28], and its influence is compared with ISRI stemmers in improving LightGBM performance. It is combined with ISRI stemmer and compared with Qalsadi and ISRI alone. Table I shows comparison between the output of ISRI Stemmer, Qalsadi lemmatizer and ISRI-Qalsadi.

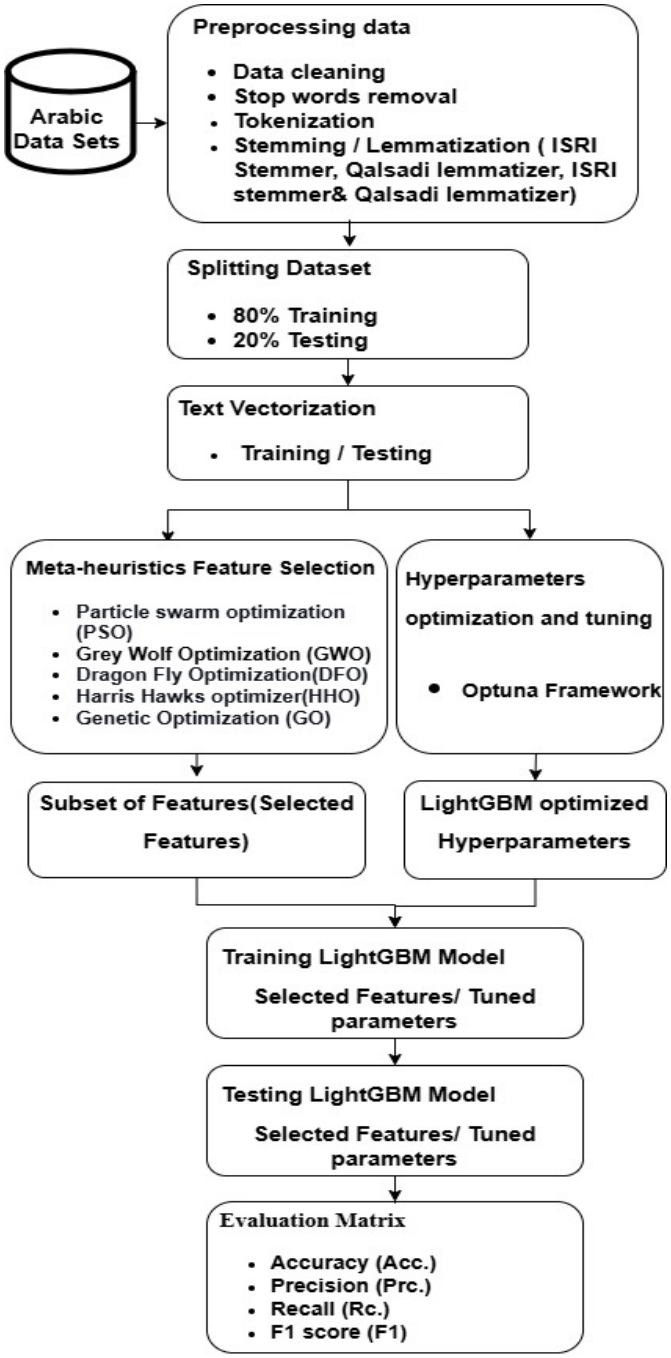

Fig. 1. Proposed methodology.

TABLE I. COMPARISON BETWEEN THE OUTPUT IF ISRI STEMMER, QALSADI LEMMATIZER AND ISRI-QALSADI

Word	ISRI Stemmer	Qalsadi lemmatizer	ISRI-Qalsadi
وبسواعدهما	وبسواعده	سواعد	سواعد
أوصيك	اوص	وصي	اوص
بالدقة	دقة	دقة	دقة
يعجبني	عجب	أعجب	عجب
النرجسيه	رجس	النرجسيه	رجس
الكتاب	كتب	كتاب	تب

B. Spliting Dataset

In this study, the dataset was divided into 80% training and 20% testing sets using the train_test_split method from Scikit-Learn. By using this method, it automatically shuffles the dataset. By shuffling the data, it will be distributed equally in the model, so it will be more accurate for predictions.

C. Text Vectorization

Text vectorization is the process of converting text into numerical representations, enabling their representation in a format suitable for ML models as a feature selection process [29]. In this research, the tokenizer class from Tensor Flow/Keras is used to build the vocabulary based on a list of input texts. It analyzes the texts, extracts unique words, assigns an integer index to each word in the vocabulary and convert it into sequences of indices, assign numerical indices to tokens, and pad sequences (usually zeros) to sequences shorter than the specified length to ensure that all sequences have the same length, which is necessary for processing by ML models [30].

Arabic texts = ["أنا أحب تعلم الآلة", "تحليل النصوص هو جزء من الذكاء الاصطناعي", "نحن نستخدم خوارزميات متعددة لتحليل البيانات"]

The result of text vectorization as below:

Word Index (Vocabulary): {'تحليل': 1, 'نحن': 2, 'نستخدم': 3, 'خوارزميات': 4, 'متعددة': 5, 'لتحليل': 6, 'البيانات': 7, 'أنا': 8, 'أحب': 9, 'تعلم': 10, 'الآلة': 11, 'النصوص': 12, 'هو': 13, 'جزء': 14, 'من': 15, 'الذكاء': 16, 'الاصطناعي': 17}.

Sequences: [[8, 9, 10, 11], [1, 12, 13, 14, 15, 16, 17], [2, 3, 4, 5, 6, 7]].

Padded Sequences: [[8 9 10 11 0 0] [1 12 13 14 15 16 17] [2 3 4 5 6 7 0]].

D. Arabic Text Classification using LightGBM Algorithm

LightGBM, developed by Microsoft, is an advanced gradient-boosting framework known for its faster training times and higher accuracy than other traditional gradient-boosting algorithms [29]. Its efficient memory usage allows it to handle large datasets with minimal resource requirements, resulting in improved performance and cost savings. LightGBM uses histogram-based learning and leaf-wise tree growth to enhance prediction accuracy [30]. It supports distributed GPU learning and parallel training on multi-core CPUs, making it suitable for big data applications. Additionally, its GOSS technique prioritizes critical data points during tree construction, reducing training time and memory usage. LightGBM is applicable for classification, regression, and ranking tasks [30].

The LightGBM algorithm can be represented mathematically as follows: Let X be the training dataset consisting of N examples and M features, and let Y represent the corresponding target values. $f(x_i)$ is defined as a function that maps the input features to the target values. The objective of LightGBM is to minimize the loss function $L(f)$, which measures the difference between the predicted values and the actual target values in relation to the function f as in Eq. (1).

$$L(f) = \sum[y_i - f(x_i)]^2 + \Omega(f) \quad (1)$$

An important regularization term, denoted as Ω(f), enhances the robustness of LightGBM by controlling the complexity of

the learned function and preventing overfitting. This term strikes a balance between effectively fitting the training data and generalizing to new data, ensuring a reliable and robust solution. LightGBM addresses this optimization problem by iteratively adding decision trees to the ensemble. At each iteration t, LightGBM constructs a decision tree h_t (x) that minimizes the loss function over a subset of the training examples St:

$$h_t(x) = argmin_h \sum[y_i - f_{t-1}(x_i) - h(x_i)]^2 + \Omega(h) \quad (2)$$

In LightGBM, the ensemble of decision trees from previous iterations, denoted as $f_{t-1}(x_i)$, is essential for the model's performance. Each new tree is trained to address the errors of the prior trees, enhancing predictions iteratively. This ongoing learning process ensures the model adapts and improves over time, reinforcing its reliability. LightGBM employs gradient boosting to optimize the loss function by sequentially adding decision trees. At each iteration (t), it calculates the negative gradient of the loss function based on the predictions from the existing ensemble, as expressed in Eq. (3).

$$g_i = -\partial L(f_{t-1}(x_i))/\partial f_{t-1}(x_i) \quad (3)$$

LightGBM utilizes the GOSS technique to enhance the training process by selecting a subset of examples. It prioritizes samples with large gradients to ensure their significance while under-sampling those with small gradients to lower computational costs and reduce the risk of overfitting. The algorithm employs a variant of the Gradient-based Decision Tree (GBDT), which constructs decision trees in a leaf-wise manner. In each split, it selects features that maximize loss reduction and prunes the tree based on a minimum gain threshold. This iterative method of adding trees continues until a stopping criterion is met, such as reaching a maximum number of trees or observing minimal improvement in validation error [16]. After training, LightGBM makes predictions by calculating the weighted average of the outputs from the individual trees as expressed in Eq. (4).

$$f(x) = \sum_{t=1}^{T} w_t h_t(x) \quad (4)$$

Where T is the number of trees in the ensemble, $\boldsymbol{w_t}$ is the weight of the t-th tree, and $\boldsymbol{h_t(x)}$ is the prediction of the t-th tree. The LightGBM determines their contribution to reducing the loss function as the weight.

E. Metaheuristics Feature Selection

FS is a vital step in ML that helps identify relevant variables related to target outcomes, improving model performance and control. Its key goals include enhancing generalization to reduce overfitting, eliminating redundant features for better inference, and enabling more efficient training with fewer features, shortening training times. Simpler models with fewer features are more easily interpreted [6] [7]. Metaheuristic algorithms, such as PSO, GWO, DFO, HHO, and GO, are practical tools for feature selection due to their reliability and efficiency [31]. However, they may not always guarantee global optimality. Among these, PSO is notable for its simplicity and efficiency in searching for optimal solutions without relying on gradients, making it a straightforward optimization tool with minimal hyperparameters. Inspired by natural behaviors like the collective movement of birds or fish, PSO effectively explores complex solution spaces to find optimal outcomes across various fields [31]. GWO is a recently developed evolutionary algorithm inspired by the social behavior of grey wolves, emphasizing the importance of pack dynamics in achieving reproductive success. In this model, a dominant male and female wolf hold higher ranks and guide the other pack members [32]. DFO is a new swarm intelligence algorithm inspired by the swarming behavior of dragonflies. It mimics five key principles: separation, cohesion, attraction, alignment, and distraction, which help dragonflies avoid collisions, maintain speed, connect with neighbors, seek food, and evade threats. DFO incorporates these behaviors into an optimization technique with two main phases: exploration and exploitation. These phases simulate the social interactions of dragonflies during navigation, food searching, and enemy avoidance in dynamic and static environments [33]. HHO enhances the effectiveness of wrapper-based FS techniques. As a fast and efficient swarm-based optimizer, HHO utilizes straightforward yet powerful exploratory and exploitative mechanisms, including Lévy flight and greedy selection. Additionally, it features a dynamic structure specifically designed for continuous problems. Its efficiency makes HHO a promising tool for a variety of optimization tasks, although it was originally developed for continuous search spaces [34]. GO is a highly effective computational method that is valuable in complex, poorly defined, or high-dimensional search spaces. Its primary goal in feature selection is to reduce the number of features by eliminating redundant and irrelevant ones while maintaining or improving classification accuracy. Various search algorithms have been employed for FS tasks [35].

F. Hyperparameter Optimization and Tuning

Hyperparameters play a crucial role in a model's functionality, performance, and structure, making their optimization essential for data scientists [9] [10]. The effectiveness of ML models, such as LightGBM, depends on selecting appropriate hyperparameter values, including learning rate, maximum depth, number of trees, and regularization parameters [36]. A systematic approach to hyperparameter tuning helps balance model complexity and generalization, improving accuracy and training speed. Optuna is noted as an advanced optimization framework that utilizes Bayesian techniques for more effective exploration of parameter spaces, allowing for fewer trials while managing experiments autonomously [10]. This capability enables Optuna to identify optimal hyperparameters that enhance model performance metrics like accuracy, precision, and recall, making hyperparameter optimization vital for maximizing a model's potential and achieving better results [36].

Algorithm 1: A simplified pseudocode for proposed methodology

```
# Step 1: Data Preprocessing
Input: Arabic Dataset
Output: Cleaned and tokenized dataset
BEGIN
  Perform Data Cleaning
    - Remove unnecessary data (e.g., duplicates, special characters)
  Remove Stop Words
  Perform Tokenization
  Apply Stemming/Lemmatization
    - Use ISRI Stemmer
    - Use Qalsadi Lemmatizer
```

```
    - Use ISRI Stemmer & Qalsadi Lemmatizer
END

# Step 2: Split Dataset
Input: Preprocessed dataset
Output: Training set (80%) and Testing set (20%)
BEGIN
  Split dataset into 80% Training and 20% Testing
END

# Step 3: Text Vectorization
Input: Training and Testing sets
Output: Vectorized text data
BEGIN
  Vectorize Text Data for Training and Testing
END

# Step 4: Feature Selection using Meta-heuristics
Input: Vectorized training data
Output: Subset of selected features
BEGIN
  Initialize meta-heuristic optimization algorithms:
    - Particle Swarm Optimization (PSO)
    - Grey Wolf Optimization (GWO)
    - Dragon Fly Optimization (DFO)
    - Harris Hawks Optimization (HHO)
    - Genetic Optimization (GO)
  Perform FS
    - Identify and retain the most relevant features
  Output Selected Features
END

# Step 5: Hyperparameter Optimization and Tuning
Input: Vectorized training data and feature subset
Output: Optimized hyperparameters
BEGIN
  Use Optuna Framework for Hyperparameter Tuning
  Optimize LightGBM's parameters
END

# Step 6: Train LightGBM's Model
Input: Selected features, optimized hyperparameters
Output: Trained LightGBM's model
BEGIN
  Train LightGBM's model using:
    - Selected Features
    - Optimized Hyperparameters
END

# Step 7: Test LightGBM's Model
Input: Testing data, trained model
Output: Evaluation metrics
BEGIN
  Test LightGBM's model
  Evaluate Performance using:
    - Accuracy (Acc.)
    - Precision (Prc.)
    - Recall (Rc.)
    - F1 Score (F1)
END
```

IV. Experiments and Results

This section presents and discusses datasets used in experiments, working environment and experiment setting and classification results and performance evaluation.

A. Datasets Description

The experiments and comparison results use eleven datasets in Table II from GitHub and Kaggle. "qrci " was downloaded from [37]. "Ar_reviews_100k" is a much larger dataset with 100,000 rows and 99999 tweets/reviews. It combines reviews from hotels, books, movies, products, and airlines and was downloaded from [38]. "ARABIC Dataset" was downloaded from [39]. It contains 58751 Arabic tweets. It has three classes (natural, negative, and positive). "ARABIC Dataset_2cat" is "ARABIC Dataset" after removing natural tweets. "mpqa-ar" is an Arabic opinion corpus containing articles from many news sources annotated for opinions downloaded from [37]. LABR is a large ASA dataset. It consists of over 63,000 book reviews [40]. After balancing it, it has 16448 reviews. It was downloaded as a balanced dataset from [37]. "Astd-artwitter" is a combined dataset between ASTD and Artwitter data sets downloaded from [37]. ASTD was downloaded from [37] with 1590 tweets. ASA_SS2030 is a dataset related to social events in the Arabic Saudi Dialect associated with Saudi Arabia's 2030 vision and downloaded from [41]. AJGT introduces an Arabic Jordanian General Tweets (AJGT) Corpus in MSA or Jordanian dialect [42]. "Company Reviews" were collected for SA to produce a score for companies [43]. It has 40K+ reviews in Arabic for SA. It has reviews for Ezz Steel, Talbat, Elsewedy, Hilton, Nestle, Raya, SWVL, Telecom Egypt, TMG, Venus, Domty, and Capiter companies. Table II shows Data Sets Information.

TABLE II. Data Sets Information

Date Set	No Rows	No. Tweets/Reviews	No Categories	No. Positives	No. Negatives	No. Neutral	No. Features
qrci	755	754	2	377	377	0	10
ar_reviews_100k	100000	99999	3	33333	33333	33333	41
ARABIC Dataset_2cat	56498	56497	2	29460	27037	0	10
ARABIC Dataset	58752	58751	3	29460	27037	2254	10
mpqa-ar	9997	9996	2	5399(subjectives)	0	4597	16
LABR-book-reviews	16449	16448	2	8224	8224	0	42
astd-artwitter	3543	3542	2	1771	1771	0	10
ASTD	1590	1591	2	777	812	0	14
ASA_SS2030	4253	4252	2	2436	1816	0	21
AJGT	1801	1800	2	900	900	0	8
Company Reviews	40046	40045	3	23921	14200	1925	8

As shown in Table II, the datasets vary widely in size, ranging from a few thousand to over 100,000 rows. The number of categories also varies, with most datasets having two categories but some having three. The distribution of positive, negative, and neutral examples is only sometimes balanced, especially in larger datasets. The number of features also varies across the datasets, with some having as few as eight features and others having as many as 42.

B. Working Environment and Experimental Setting

The experiments have been done in google Colab using several python libraries such as pandas, numpy, NLTK, Qalsadi, TensorFlow, Scikit-learn, pandas, LightGBM, PSO, GWO, DFO, HHO, GO, zoofs and Optuna framework. Colab is a hosted Jupyter Notebook service (SaaS Service) that offers free access to GPUs and TPUs among other computing resources. It does not require any setup. Colab works particularly effectively with ML, data science, and teaching.

TABLE III. HYPERPARAMETERS SPACE SEARCH CONFIGURATION FOR THE LIGHTGBM MODEL

Model	Hyperparameter settings
LightGBM	search_space ={ 'boosting_type': Categorical(['gbdt', 'dart', 'goss']),'max_depth': Integer(1, 750), 'num_leaves': Integer(2, 400),'learning_rate': Real(0.01, 1.0, 'log-uniform'), 'subsample': Real(0.1, 1.0, 'uniform'),'n_estimators': Integer(50, 1500), 'min_child_samples': Integer(1, 100),'colsample_bytree': Real(0.1, 1.0, 'uniform'), 'reg_alpha': Real(1e-9, 100, 'log-uniform'), 'max_bin': Integer(100, 700) 'reg_lambda': Real(1e-9, 100, 'log-uniform'), , 'max_delta_step': Real(0, 10, 'uniform') }

Table III presents the hyperparameters search space configuration for the LightGBM model, covering a wide range of values to optimize performance. The search space includes categorical choices for boosting_type (GBDT, DART, GOSS), and numerical ranges for key parameters such as num_leaves (2 to 400), max_depth (1 to 750), and learning_rate (0.01 to 1.0) with a logarithmic uniform distribution to explore both small and large values effectively. Other parameters include n_estimators, min_child_samples, subsample, and colsample_bytree, which control model complexity and generalization. Additionally, regularization parameters such as reg_alpha and reg_lambda are optimized within a logarithmic scale to prevent overfitting. The inclusion of max_bin and max_delta_step further refines the model's handling of data granularity and convergence stability. This comprehensive hyperparameter tuning strategy aims to enhance LightGBM's adaptability and accuracy across diverse Arabic sentiment analysis datasets.

C. Classification Results and Performance Evaluation

This section presents and discusses the experiments of the LightGBM classification model, metaheuristic FS algorithms, and Optuna hyperparameter optimization. The experiments in this study are divided into three main dimensions: studying the effect of ISRI stemming and Qalsadi lemmatization methods on LightGBM' s classification, both individually and in combination with the classification efficiency on different datasets; studying the effects of metaheuristic FS algorithms; and studying the impact of Optuna hyperparameter optimization in the classification task.

Experiment 1: In the first experiment, the ISRI stemming and Qalsadi lemmatization methods and their combination with LightGBM are applied to eleven datasets as shown in table IV.

Table V outlines the hyperparameter settings used for running various metaheuristic algorithms to optimize feature selection in the sentiment analysis task. Each algorithm is configured with a common objective function, log loss, to minimize classification error, and a consistent number of iterations (20) and population size (20) to ensure fair comparisons. Specific parameter settings are applied to individual algorithms to enhance their optimization efficiency. For instance, PSO includes acceleration constants and an inertia weight for balancing exploration and exploitation. GO incorporates selective pressure, elitism, and mutation rate to guide the search process. Meanwhile, GWO, DFO, and HHO follow standard configurations focused on convergence towards optimal feature subsets. These settings ensure a robust evaluation of different optimization techniques in improving the model's performance.

Experiment 2: The second experiment is conducted to study the effects of different metaheuristic feature selection algorithms as shown in Tables VI, VII, VIII, XI, IX, X, XI.

TABLE XII. HYPERPARAMETER SETTINGS FOR RUNNING OPTUNA FRAMEWORK

Method	Hyperparameters
Optuna study	'objective': 'binary', 'metric': 'binary_logloss', 'num_leaves': trial.suggest_int('num_leaves', 2, 256) 'lambda_l1': trial.suggest_loguniform('lambda_l1', 1e-8, 10.0), 'lambda_l2': trial.suggest_loguniform('lambda_l2', 1e-8, 10.0), 'bagging_fraction': trial.suggest_uniform('bagging_fraction', 0.4, 1.0), ,'feature_fraction': trial.suggest_uniform('feature_fraction', 0.4, 1.0), 'bagging_freq': trial.suggest_int('bagging_freq', 1, 7),'min_child_samples': trial.suggest_int('min_child_samples', 5, 100)

Table XII presents the hyperparameter settings used for running the Optuna framework, which is employed to optimize the LightGBM model for Arabic sentiment analysis. The optimization process is guided by the binary classification objective with the evaluation metric set to binary_logloss, ensuring a focus on minimizing classification errors. The search space for key hyperparameters includes lambda_l1 and lambda_l2 for regularization, both explored within a logarithmic range to prevent overfitting. Structural parameters such as num_leaves (ranging from 2 to 256) and min_child_samples (ranging from 5 to 100) are fine-tuned to balance model complexity and generalization. Additionally, feature and data sampling parameters, including feature_fraction and bagging_fraction, are optimized within uniform distributions to enhance model robustness. The bagging_freq parameter, which controls the frequency of bagging operations, is also explored to improve model stability. These hyperparameter settings enable efficient and automated tuning to achieve optimal model performance.

D. Evaluation Matrix

Evaluation metrics are used to assess the effectiveness and performance of statistical or ML models. They help illustrate how well the model's predictions align with the true patterns in the dataset. The key metrics for evaluating ML models include Accuracy (Acc.), Precision (Prc.), Recall (Rc.), and the F1 score (F1). These metrics, calculated using specific equations, are critical in the context of Deep ASA evaluation metrics [16]:

$$\text{Accuracy (Acc.)} = (TP+ TN) / (TP + TN + FP + FN) \quad (1)$$

$$\text{Precision (Prc.)} = TP\ (TP + FP) \quad (2)$$

$$\text{Recall (Rc.)} = TP\ (TP + FN) \quad (3)$$

$$\text{F1 Score(F1.)} = 2 * \text{Prc.} * \text{Rc.}\ (\text{Prc.} + \text{Rc.}) \quad (4)$$

Where TP, TN, FP, and FN denote true positive, true negative, false positive, and false negative, respectively.

The primary goal of Experiment 2 is to compare the effectiveness of different metaheuristics FS algorithms. Analyzing values allows us to identify which algorithms and feature selection techniques selected the most relevant features for each dataset that increase ASA accuracy, precision, recall, and F1 score. Comparing the results with stemming, lemmatization or a combination of them can help assess the effect of text preprocessing on feature selection. Comparing the results for all datasets can provide insights into how the algorithms s perform on different data characteristics.

Experiment 3: The second experiment is conducted to study studying the impact of Optuna hyperparameter optimization in ASA as shown in Table XIII.

Table XIV shows the optimal hyperparameter values found by Optuna for the LightGBM algorithm using stemming, lemmatization, or both methods for each dataset. The optimal hyperparameter values and accuracy scores vary between datasets, highlighting the importance of dataset-specific tuning. The choice of stemming or lemmatization can influence the optimal hyperparameters and accuracy. The relative importance of different hyperparameters can vary depending on the dataset and algorithm.

The figures below depict bar charts summarizing the classification results and performance evaluation for the best models in the three experiments mentioned above on eleven data sets. It summarizes all classification results and performance evaluation tables. For the "qrci" dataset, the model ISRI-Qalsadi-Optuna– LightGBM achieved an accuracy score of approximately 67%. Optuna with ISRI-Qalsadi increase LightGBM's overall accuracy by 8%, but PSO metaheuristics feature selection, with ISRI stemming, increases LightGBM's overall accuracy by 6% as shown in Fig. 2.

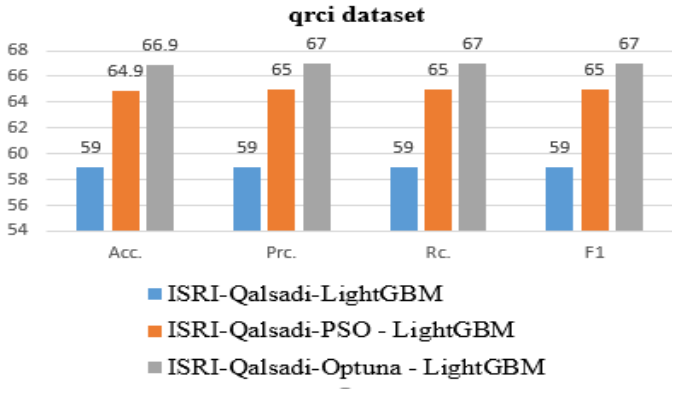

Fig. 2. Comparison between the best in the three experiments for "qrci" dataset.

For the "ar_reviews_100k" dataset, the model ISRI-Optuna - LightGBM achieved an accuracy score of approximately 78%. Optuna with ISRI stemming increase LightGBM's overall accuracy by 11% despite GWO metaheuristics feature selection, with Qalsadi lemmatization having the same value as Qalsadi-LightGBM with an accuracy score of approximately 67% as shown in Fig. 3.

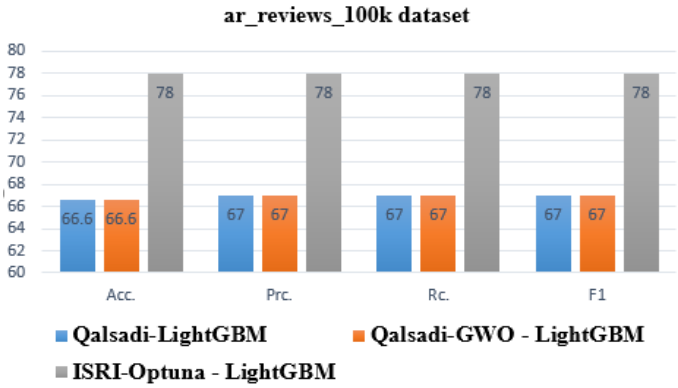

Fig. 3. Comparison between the best in the three experiments for "ar_reviews_100k" dataset.

For the "ARABIC Dataset_2cat" dataset, the model ISRI-Optuna - LightGBM achieved an accuracy score of roughly 77%. Optuna with ISRI stemming increase LightGBM's overall accuracy by 7%. Despite PSO metaheuristics feature selection with ISRI stemming, it has the same value as ISRI-LightGBM with an accuracy score of approximately 70% as shown in Fig. 4.

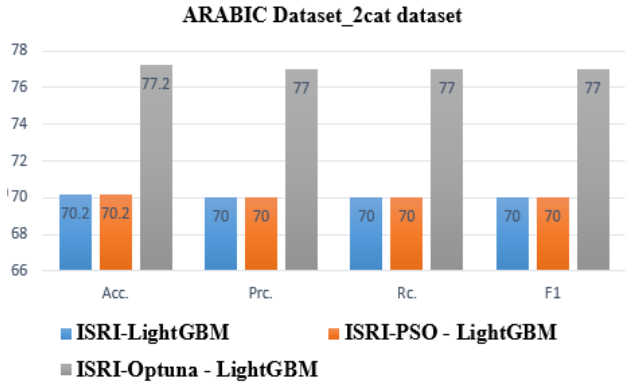

Fig. 4. Comparison between the best in the three experiments for "ARABIC Dataset_2cat" dataset.

For the "ARABIC Dataset" dataset, the model ISRI-Optuna - LightGBM achieved an accuracy score of roughly 77%. Optuna with ISRI stemming increase LightGBM's overall accuracy by 7% despite DFO metaheuristics feature selection, with ISRI stemming increasing LightGBM's overall accuracy by 0.4% as shown in Fig. 5.

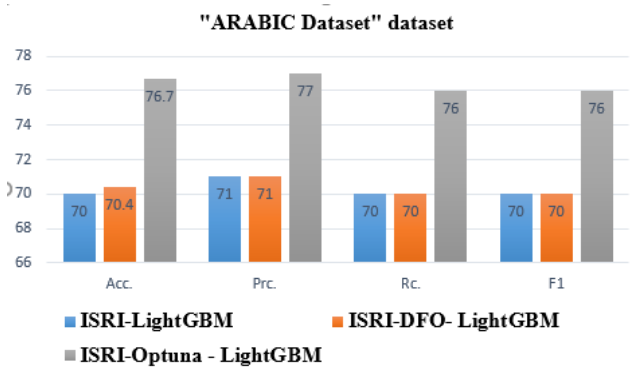

Fig. 5. Comparison between the best in the three experiments for "ARABIC Dataset" dataset.

For the "mpqa-ar" dataset, the model Qalsadi-Optuna - LightGBM achieved an accuracy score of approximately 64%. Optuna with Qalsadi lemmatization increase LightGBM's overall accuracy by 3% despite DFO metaheuristics feature selection, with Qalsadi lemmatization increasing LightGBM's overall accuracy by 1% as shown in Fig. 6.

For the "LABR-book-reviews" dataset, the model ISRI-Qalsadi-Optuna – LightGBM achieved an accuracy score of approximately 71%. Optuna with ISRI-Qalsadi increase LightGBM's overall accuracy by 5% despite PSO metaheuristics feature selection, with ISRI-Qalsadi increasing LightGBM's overall accuracy by 2% as shown in Fig. 7.

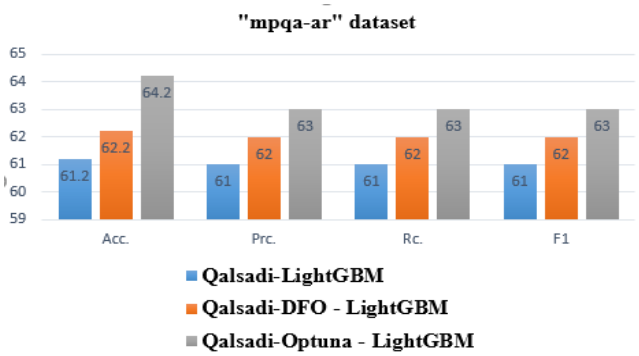

Fig. 6. Comparison between the best in the three experiments for "mpqa-ar" dataset.

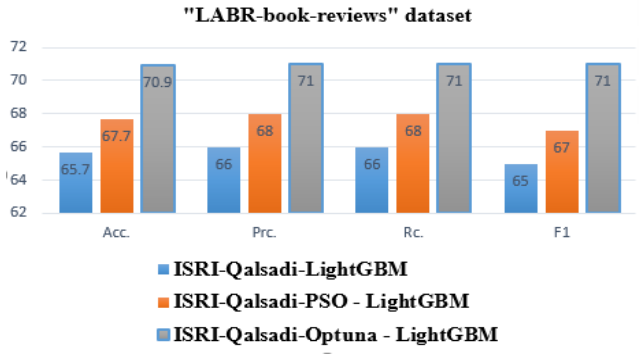

Fig. 7. Comparison between the best in the three experiments for "LABR-book-reviews" dataset.

For the "astd-artwitter" dataset, the model Qalsadi-Optuna - LightGBM achieved an accuracy score of approximately 71%. Optuna with ISRI-Qalsadi increase LightGBM's overall accuracy by 4% despite PSO and DFO metaheuristics feature selection, with Qalsadi increasing LightGBM's overall accuracy by 2% as shown in Fig. 8.

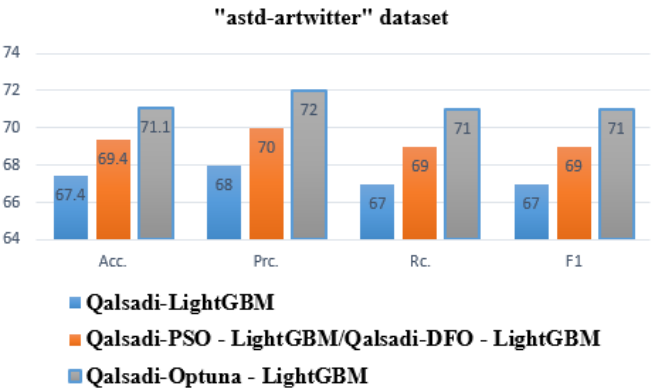

Fig. 8. Comparison between the best in the three experiments for "astd-artwitter" dataset.

For the "ASTD" dataset, the model ISRI-DFO- LightGBM achieved an accuracy score of approximately 64%. DFO metaheuristics feature selection with ISRI increases LightGBM's overall accuracy by 8% despite Optuna with ISRI increasing LightGBM's by 6% as shown in Fig. 9.

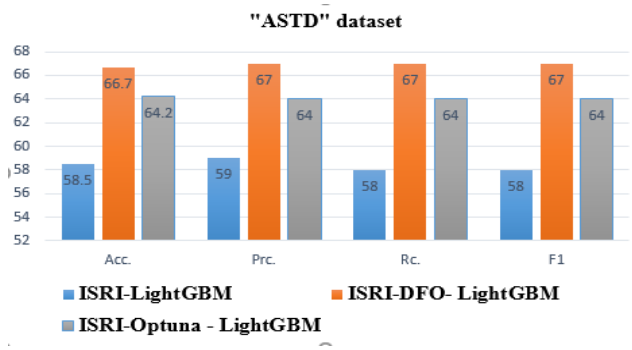

Fig. 9. Comparison between the best in the three experiments for "ASTD" dataset.

For the "ASA_SS2030" dataset, the model ISRI-Qalsadi-Optuna - LightGBM achieved an accuracy score of approximately 78.5%. Optuna with ISRI-Qalsadi increase LightGBM's overall accuracy by 4% despite DFO metaheuristics feature selection with ISRI-Qalsadi and GO metaheuristics feature selection, with Qalsadi increasing LightGBM's overall accuracy by 1.5% as shown in Fig. 10.

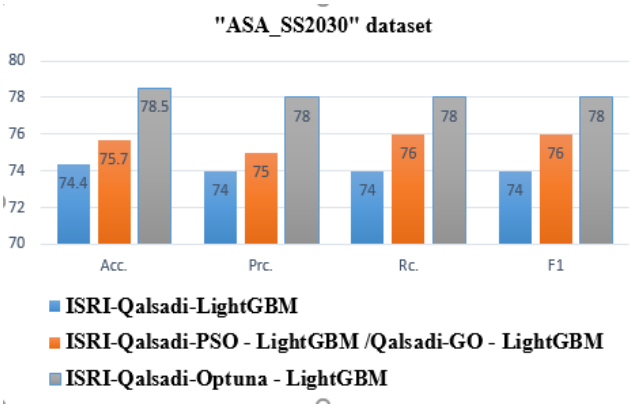

Fig. 10. Comparison between the best in the three experiments for "ASA_SS2030" dataset.

For the "AJGT" dataset, the model ISRI-Optuna - LightGBM achieved an accuracy score of approximately 78%. Optuna with ISRI increase LightGBM's overall accuracy by 4% despite DFO metaheuristics feature selection, with ISRI and PSO metaheuristics feature selection, with ISRI increasing LightGBM's overall accuracy by 2% as shown in Fig. 11.

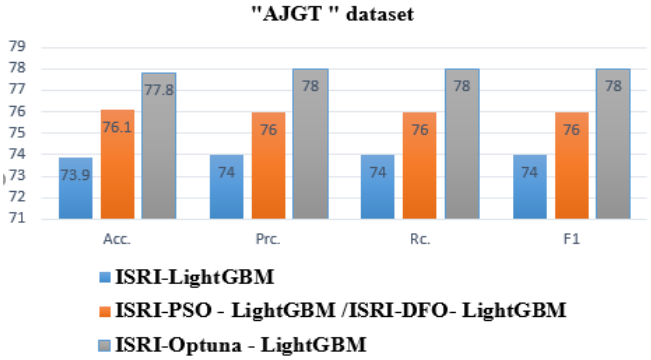

Fig. 11. Comparison between the best in the three experiments for "AJGT" dataset.

For the "Company Reviews" dataset, the model ISRI-Qalsadi-Optuna - LightGBM achieved an accuracy score of approximately 78.4%. Optuna with ISRI increase LightGBM's overall accuracy by 1.7% as shown in Fig. 12. Still, DFO metaheuristics feature selection with ISRI, PSO metaheuristics feature selection with ISRI, and HHO metaheuristics feature selection with ISRI have the same value as ISRI-LightGBM. The results demonstrate the effectiveness of hyperparameter optimization using Optuna-LightGBM in improving LightGBM's performance on ASA. By carefully tuning the hyperparameters, you can significantly improve accuracy and generalization.

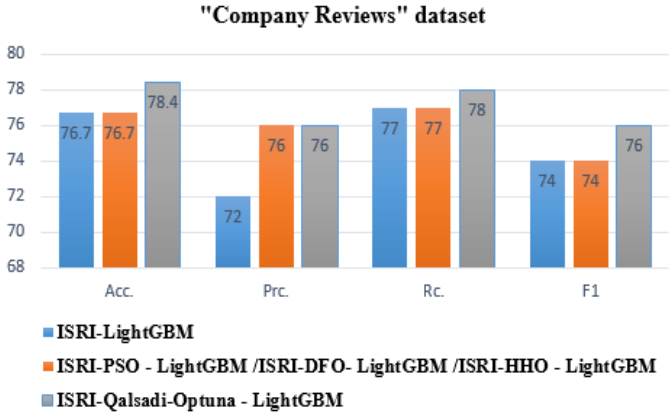

Fig. 12. Comparison between the best in the three experiments for "Company Reviews" dataset.

V. Discussion

This study contributes to the field of ASA by presenting an integrated approach to enhance the accuracy of the LightGBM model through advanced text preprocessing, feature selection, and hyperparameters optimization techniques. The complexity of the Arabic language, with its numerous dialects and MSA, poses a significant challenge for sentiment analysis applications. To address this, the study employs the ISRI stemmer and Qalsadi lemmatizer for effective text preprocessing, alongside metaheuristic FS algorithms such as PSO, GWO, and others to identify the most informative features and reduce noise in the data. Additionally, the study leverages the Optuna framework for hyperparameters tuning, aiming to achieve an optimal balance between computational efficiency and model performance. The findings demonstrate that combining these methodologies can enhance the classification accuracy of LightGBM by up to 11%, highlighting the effectiveness of these strategies in improving ASA.

However, ASA faces numerous challenges that contribute to low accuracy compared to other languages, such as English. These challenges include the morphological complexity of the language, characterized by extensive inflection, derivation, and multiple word forms that increase the difficulty of automated text analysis. Additionally, the scarcity of high-quality labeled datasets covering diverse Arabic dialects limits the model's ability to generalize effectively across various user demographics. The coexistence of MSA and dialectal Arabic, informal writing styles on social media, and the lack of standardized linguistic resources further complicate the

analysis. This study provides a valuable contribution by exploring potential solutions to these issues, such as using different stemming and lemmatization methods, optimizing models through feature selection, and fine-tuning hyperparameters to achieve higher accuracy in real-world applications.

VI. Conclusion

Analyzing Arabic content poses challenges due to the language's complexities, morphological features, inadequate resources, and the absence of suitable corpora. This study delves into the effectiveness of various preprocessing techniques—ISRI stemming, Qalsadi lemmatization, and their combination—on ASA. The study's primary focus is on the LightGBM classifier, and It systematically compared these methods to find that each preprocessing approach contributes positively to sentiment classification accuracy. Depending on the dataset, using metaheuristic feature selection algorithms significantly enhanced the performance of the LightGBM model by identifying the most relevant features, thus reducing noise and improving LightGBM's classification efficiency between 0 and 8%. PSO metaheuristic feature selection algorithm with suitable stemming between ISRI and Qalsadi or a combination for LightGBM achieves superior results than GWO, DFO, HHO, and GO metaheuristic feature selection in more than 60% of used datasets. DFO metaheuristic feature selection algorithm with suitable stemming between ISRI and Qalsadi or a combination for LightGBM achieves superior results than other metaheuristic feature selection in more than 35% of used datasets. Applying the Optuna hyperparameter optimization framework further demonstrated the potential to refine LightGBM model parameters, effectively resulting in substantial performance gains. Depending on the dataset, Optuna using suitable stemming between ISRI and Qalsadi or a combination improves LightGBM's accuracy by between 2 and 11% and achieves superior results than PSO, GWO, DFO, HHO, and GO metaheuristic feature selection in more than 90% of used datasets. Our findings highlight the critical role that preprocessing and optimization strategies play in ASA. These methodologies improve classification accuracy and highlight the LightGBM model's robustness in this domain. ASA faces challenges such as the morphological complexity of the language, the scarcity of high-quality labeled datasets, and the coexistence of MSA and dialectal Arabic, which hinder its classification accuracy compared to languages like English, but this research explores solutions like advanced stemming, metaheuristics feature selection, and Optuna hyperparameter fine-tuning to improve performance. This research underscores the necessity for continued exploration of advanced techniques in ASA. The potential for future research to explore additional ML, DL models, transformers, and large language models to enhance ASA applications across diverse contexts and rebalance unbalanced used datasets to have higher accuracy is vast and inspiring.

***Abstract*—Among humans, lung and colon cancers are regarded as primary contributors to mortality and morbidity. They may grow simultaneously in organs, having a harmful influence on the lives of people. If tumor is not diagnosed early, it is likely to spread to both of those organs. This research presents a flexible framework that employs lightweight Convolutional Neural Networks architecture for automating lung and colon cancer diagnosis in histological images across multiple diagnosis scenarios. The LC25000 dataset is commonly used for this task. It includes 25000 histopathological images belonging to 5 distinct classes, which are lung adenocarcinoma, lung squamous cell carcinoma, benign lung tissue, colon adenocarcinoma, and benign colonic tissue. This work includes three diagnosis scenarios: (S1) evaluates lung or colon samples, (S2) distinguishes benign from malignant images, and (S3) classifies images into five categories from the LC25000 dataset. Across all the scenarios, the scored accuracy, recall, precision, F1-score, and AUC exceeded 0.9947, 0.9947, and 0.9995, respectively. This investigation with a lightweight Convolutional Neural Network containing only 1.612 million parameters is extremely efficient for automated lung and colon cancer diagnosis, outperforming several current methods. This method might help doctors provide more accurate diagnoses and improve patient outcomes.**

Keywords*—Lung and colon cancers; histopathological images; LC25000 dataset; lightweight convolutional neural networks; multiple diagnosis scenarios

I. INTRODUCTION

Statistical analysis undertaken in the United States showed that lung and colon (LC) cancers are expected to be among the three most prevalent cancer types in 2020. Moreover, these malignancies were expected to have the most fatality rates of any cancer diagnosis. The GLOBOCAN 2020 data indicated LC cancer incidence rates of 11.4% and 18.0%, respectively [1]. The World Health Organization (WHO) anticipated that roughly 4 Million persons on a global scale will acquire lung or colon cancer in 2020, resulting in approximately 2.7 Million deaths. The presented information highlights the substantial worldwide health effects of lung and colon cancers. It is worth noting that LC cancers can coexist, with roughly 17% of cases containing both tumors concurrently [2].

Lung cancer, a malignant disease, arises from the excessive and unregulated multiplication of atypical cells within the lung [3]. This can result in tumor formation, which may spread to other parts of the body. Various factors play a role in the increasing incidence of lung cancer, including exposure to harmful substances, such as tobacco smoke, and aging. Early-stage lung cancer often presents with subtle or no symptoms, making early detection challenging [4]. Consequently, diagnosis frequently occurs at a late stage, when therapeutic options are curtailed. Adenocarcinoma and squamous cell carcinoma constitute the majority of lung cancer cases [5]. Adenocarcinoma, which can affect both smokers and non-smokers, is more prevalent in women and younger individuals It often originates in the outermost regions of the pulmonary tissue and can spread rapidly. Squamous cell carcinoma, primarily associated with smoking, can develop anywhere in the lungs and tends to grow and spread aggressively [6,7].

The causes of LC cancer are multiple and complex. Smoking is the main risk factor for lung cancer, while for colon cancer, a low-fiber diet, prolonged sedentary lifestyle obesity, and certain genetic factors can increase the risk of other environmental factors such as exposure to certain chemical substances or air pollution contribute in the multiplication of these cancers. It is crucial to note that these risk factors are not synonymous with inevitable cancer development, but adopting them can considerably increase the chances of developing these diseases.

Generally, to detect and diagnose cancer, a variety of diagnostic tests are employed, including imaging modalities such as Magnetic Resonance Imaging (MRI) [8-11], X-rays [12], CT scans, and dermoscopy [13-16], as well as tissue sampling procedures such as biopsies. Histological images offer considerable advantages over other types of medical imaging in the analysis and characterization of LC cancers. Histology enables microscopic analysis of tissues removed during biopsy or surgery. This enables us to observe cancer cells directly, and determine their type, stage, and aggressiveness. This information is crucial for making an accurate diagnosis, choosing the most appropriate treatment, and assessing prognosis. Additional imaging techniques, such as radiography, computed tomography, or MRIs, provide information on the anatomy and size of tumors but do not allow detailed analysis of

cellular characteristics. The microscopic examination of tissue parts by experienced pathologists is crucial for determining the presence of cancer cells and classifying their type and subtype [17,18]. Although, manual analysis of histopathological images consumes time. Also, it is labor-intensive and subjective process, prone to inter-observer variability. Pathologists may have differing interpretations of the same image, leading to potential diagnostic errors, especially when dealing with subtle morphological features. Additionally, the growing number of medical images and the complexity of certain cases further exacerbate the challenge.

To overcome these constraints [19], this work investigates the application of Deep Learning (DL) and machine learning (ML) approaches to automate cancer analysis in medical images [12,20]. DL techniques provide potential solutions to mitigate these challenges. Through the utilization of deep neural networks, DL models can process high quantities of histopathological images, learning to recognize complex characteristics and features associated with LC cancers. This can lead to improved diagnostic and efficiency and precision in comparison with traditional approaches.

This study tries to balance dependability as well as precision in LC cancer classification. The main contributions of this study include:

- Proving that DL approaches can effectively diagnose and analyze LC cancers.
- Employing a huge dataset of 25000 histopathological images to classify LC cancers.
- Illustrating three diagnosis scenarios to ensure the flexibility of the presented framework.
- Designing a lightweight CNN model with only 1.6 million parameters, assessing its performance, while comparing it to current approaches.
- Achieving accuracy, F1-score, and AUC over 99.47%, 99.47%, and 99.95%, respectively, throughout all analytic phases and diagnosis scenarios.
- Scoring F1-score and accuracy of 99.17% and 99.47%. Also, a sensitivity and specificity of 99.07%, and 99.65% across all classes of overall diagnosis scenarios, respectively.

This investigation employs a classification approach to analyze a dataset containing lung and colon cancer images. The subsequent sections of this investigation are organized as follows: the second section presents a review of pertinent literature. The third section delineates the proposed methodology. The fourth section provides a detailed performance evaluation of the presented lightweight CNN. The fifth section offers a thorough discussion of the findings. This paper will be ended by the last section, Section VI.

II. Related Work

This study contributes to the research effort aimed at improving diagnostic support for LC cancer using artificial intelligence techniques. A new method for diagnosing histopathological images on the LC25000 dataset [21], a reference in the field. Several academics have recently used this dataset to develop AI-based applications.

Sakr et al. [22] introduce a lightweight DL approach using a CNN for powerful categorization of cancer of the colon. Histopathological images were normalized before being processed by the CNN model. Across two classes, their proposed system attained a high accuracy of 99.50%. Using the same data, Hasan et al. [23] presented an innovative DL strategy for the automated identification of colon adenocarcinomas. Their approach involved a DCNN model, coupled with several image preprocessing techniques, to obtain meaningful features from digital histological images. The proposed system demonstrated impressive performance, achieving a maximum accuracy of 99.80% in differentiating between non-cancerous and cancerous tissues. For the same target, Gabralla et al [24] introduced a novel stacking-based deep learning framework. Their approach involved integrating multiple pre-trained CNN models (ResNet50 [25], DenseNet121 [26], InceptionV3, and VGG16 [27]) with a meta-learner. The meta-learner was trained to effectively combine the predictions of the individual models, resulting in a significant improvement in overall performance. The proposed method achieved an ideal score of 100% in terms of F1-score and accuracy, using the LC25000 dataset [21]. In addition, they attained F1-score and accuracy of 98% when employing the WCE dataset [28,29], surpassing the performance of the individual base models. To enhance the accuracy of colon cancer prediction, Di Giammarco et al. [30] employed different pre-trained models. The metrics of the proposed method was assessed on a sub-dataset of LC25000 comprising 10,000 colon images. The experimental results demonstrated that MobileNet [31] had the highest, f1-score, accuracy, recall, and precision of 99.9%, indicating the model's capability of the model to efficiently categorize colon issues.

Concerning lung cancer, Hatuwal and Thapa [32] aimed to classify three classes of tissue: benign, squamous cell carcinoma, and adenocarcinoma. A CNN approach was trained and validated on a sub-dataset of histological data, LC25000 dataset [21]. The model demonstrated strong performance, achieving an accuracy of 96.11% and 97.2%, during the training and validation phases. Nishio et al. [33] established a CAD system to automate the analysis of lung tissue in histological images. The system employed a multi-stage approach involving image feature extraction and ML classification. Two feature extraction techniques were investigated: conventional texture analysis (TA) and homology-based image processing (HI). Eight ML algorithms were trained and evaluated using the extracted features. The results found in the experiments demonstrated the higher efficiency of the HI-based approach over the TA-based system, achieving an accuracy of 99.33%. The study of Hamed et al. [34] is about a novel system for the rapid and precise classification of lung tissue histological data. The treated tissue types were only benign and squamous cell carcinoma. The proposed approach involves a two-stage process: feature extraction using a lightweight CNN model and classification using a LightGBM classifier. The CNN technique, designed with a minimal number of parameters, efficiently extracts discriminative features from the preprocessed images. Subsequently, the LightGBM classifier, leveraging multiple threads, effectively classifies the input data into various tissue

types. When evaluated on the LC25000 dataset, the approach achieved a remarkable accuracy of 99.6% and a sensitivity of 99.6%. To increase lung cancer classification accuracy, Noaman et al [35] propose a novel hybrid feature extraction technique where the powerful capabilities of charateristic extraction of DenseNet201 was combined with the complementary information provided by color histograms. A comprehensive evaluation of eight machine learning algorithms, including, SVM, MultinomialNB, LGBM, CatBoost, XGBoost, KNN, and RF, was conducted on the LC25000 dataset [21]. The outcomes demonstrate that the established hybrid feature set, when coupled with an appropriate ML algorithm, achieves a remarkable accuracy of 99.683%. To further validate the generalizability of our approach, we applied it to the task of the analysis of the breast cancer utilizing the images of the BreakHis dataset [36]. The model achieved a high accuracy of 94.808%, highlighting the advantage of their hybrid feature extraction technique for various medical image analysis tasks.

Several researchers tried to classify the whole of the five types of tissues figured in the LC25000 dataset [21]. In fact, Ali et al. [37] reached 99.04% and 99.58% as F1-score and accuracy LC cancer classification. They employed a multi-input dual-stream Capsule Network (CapsNet) [38]. It consists of two major blocks: Convolutional Layers Block (CLB) and Separable Convolutional Layers Block (SCLB). CLB and SCLB uses traditional and separable convolutional layers. The SCLB block takes uniquely preprocessed images using gamma correction and color balancing. Also, it takes multi-scale fusion and image sharpening. This dual-input approach enhances feature learning. Besides CapsNet, numerous works applied Efficient Networks (EfficientNets) [39] for LC cancer classification. Masud et al [40] present a novel DL-based framework for the diagnostic of five distinct classes of LC tissues, containing both benign and malignant conditions. By leveraging advanced digital image processing techniques and DL models, the proposed framework effectively extracts relevant features from histopathological images and accurately classifies them. Experimental results demonstrate that the developed tool can detect cancer tissues with a high accuracy and F1-score with values of 96.33% and 96.38%, respectively. In Mehmood et al.'s study [41], a pre-trained AlexNet was adapted for the task of histological image classification. The initial model, trained using a generic dataset, achieved promising results for most image classes, except for one class where the accuracy was relatively low. To address this issue, the simple and effective technique of contrast enhancement was applied to enhance the quality of images from the underperforming class. This targeted approach significantly boosted the overall accuracy of the model to 98.4% while maintaining computational efficiency. Attallah et al. [42] developed a novel framework that integrated DL and feature reduction techniques to ameliorate the accuracy of the classification of histopathology images. To extract relevant features, histopathology scans were processed using three models: ShuffleNet [43], MobileNet [31], and SqueezeNet [44]. The high-dimensional feature vectors obtained from these models are then subjected to Fast Walsh-Hadamard Transform (FWHT) and dimensionality reduction by the application of Principal Component Analysis (PCA). To further enhance feature representation, Discrete Wavelet Transform (DWT) was employed to combine the reduced characteristics from the three DL models. The resulting reduced and fused feature sets are subsequently passed into four different ML algorithms for classification. The established framework achieves F1-score and accuracy of 99.6% on the given dataset. The study of Al-Jabbar et al. [45] introduces three novel strategies for the early diagnostic of the lung cancer based on the LC25000 dataset. To enhance image quality and improve diagnostic accuracy, preprocessing techniques were applied to enhance the contrast of affected areas. Subsequently, high-dimensional patterns were determined using the VGG-19 [27] and GoogLeNet [46] models. To reduce dimensionality and retain crucial information, Principal Component Analysis (PCA) was employed. The first strategy involved training separate Artificial Neural Networks (ANN) models using the features extracted from VGG-19 and GoogLeNet. The other approach combined the patterns from both models before applying dimensionality reduction and ANN classification. The third strategy, which yielded the best performance, involved fusing the features extracted from VGG-19, GoogLeNet, and handcrafted characteristics before training the ANN model. This approach achieved a sensitivity, specificity, precision, accuracy, and AUC surpassing 99.64%. Kumar et al. [47] did a comparative analysis to measure the effectiveness of handcrafted and DL-based feature extraction techniques for LC cancer classification. In this research, six handcrafted pattern extraction methods were employed to capture color, texture, shape, and structural information from histopathological images. These handcrafted features were then used to train and evaluate 4 ML classifiers: Gradient Boosting, MLP, Random Forest, and SVM-RBF. In another approach, seven pre-trained DL models are utilized to determine high-level patterns from data. These deep features were subsequently fed into the same four ML classifiers. The findings demonstrated that the classification performance was significantly enhanced when using DL-based features compared to handcrafted features. Notably, the Random Forest categorizer combined with DenseNet-121 achieved the highest ROC-AUC, accuracy, and F1-score with values exceeding 91%. In Anjum et al's work [48] EfficientNet models (B0 to B7) [39] were applied for the diagnostic of LC cancer in histopathological data. To improve model performance and mitigate overfitting, transfer learning, and parameter tuning techniques were employed. After preprocessing the LC25000 dataset [21] to remove noise and standardize image formats, experiments were conducted using different image resolutions, ranging from 224x224 pixels to 600x600 pixels. The models were evaluated based on classification accuracy and loss. While all EfficientNet [39] variants achieved promising results, EfficientNetB2 demonstrated the highest performance, attaining an accuracy of 97.24% when trained on 260x260 pixel images.

Some studies did not concentrate on creating automated diagnostic approaches specifically for colon or lung, or lung and colon cancer. Rather, they developed methods that can comprehensively address the diagnosis of colon cancer, lung cancer, or both. The work of Talkuder et al. [49] identified efficiently LC cancers by the employment of a hybrid ensemble method. The proposed model integrates powerful feature extraction approaches with ensemble learning and high-performance filtering to effectively analyze histopathological images from the LC25000 dataset [21]. The results demonstrate the superior performance of their hybrid model, reaching

accuracies of 100%, 99.05%, and 99.30% for colon, lung, and combined LC cancer classification, respectively. In the research of Hage Chehade et al. [50], they aimed to develop a computerized diagnostic system capable of efficiently categorizing the five distinct classes of LC tissues, including two types of colon cancer and three categories of lung cancer. When leveraging ML techniques, feature engineering, and image processing methods, meaningful information was extracted from histopathological data. The LC25000 dataset [21] was utilized to train and evaluate five ML models: Random Forest, XGBoost, SVM, Multilayer Perceptron, and Linear Discriminant Analysis. The best results were obtained using XGBoost. For colon cancer, they reached accuracy and F1-score of 99.3% and 99.5%, respectively. Concerning lung cancer, the accuracy, precision, recall, and F1-score reached were 99.53%, 99.33%, 99.33%, and 99.33%, respectively. Also, for LC cancer, they got an accuracy of 99%, precision of 98.6%, recall of 99%, and F1-score of 98.8%.

This work aims to develop a flexible based on multi-scenario diagnosis for LC cancer automated analysis. This framework is based on a lightweight CNN and uses the LC25000 dataset to evaluate its performance in this task. For the first scenario, a method was developed to detect if the input image corresponds to a lung or a colon. The results were perfect since all the performance metrics had attained 100%. Based on this result, two methods were established. The first approach is dedicated to determining the nature of the colon tissue type. Its AUC, F1-score, and accuracy reached 100%. The second method aims to classify lung cancer. It got AUC, F1-score, and accuracy with values of 99. 95%, 99.47%, and 99. 47%, respectively. The target of the second scenario is LC malignancy detection in histological images. This approach scored perfect AUC, F1-score, and accuracy with values of 100%, respectively. The purpose of the third scenario is to classify the totality of LC tissue types. AUC, F1-score, and accuracy achieved values of 99.96%, 99.76%, and 99.76%, respectively. Table I presents the description of the cited methods from the literature and the proposed approaches.

III. Proposed Method

In this study, three diagnosis scenarios are presented. The first scenario (S1) is composed of two distinct stages: the initial stage (S1-1) aims to evaluate whether the input image corresponds to either a lung or colon sample. Based on the outcome of this stage, the second stage (S1-2) is designed to determine the specific class associated with the identified organ. In the second scenario (S2), the target is to identify whether the input data belongs to either the benign or malignant class, irrespective of its origin. The third scenario (S3) involves categorizing the input data among all the type of the tissues (5 classes) of LC25000 dataset. Fig. 1 illustrates an overview of the three scenarios presented. Fig. 2 presents the workflow of the presented strategies of analysis.

A. Dataset

This investigation uses the LC25000 dataset [21], which includes 25000 histopathological images whose size is 768x768 pixels in JPEG format. This dataset is an invaluable resource for training and assessing ML models in cancer diagnosis, particularly for LC cancer. The dataset is distributed across five classes: lung squamous cell carcinoma (lung_scc), lung adenocarcinoma (lung_aca), benign lung tissue (lung_n), benign colonic tissue(colon_n), and colon adenocarcinoma (colon_aca). It was methodically obtained from an initial pool of 750 HIPAA-compliant and verified data, which included 250 cases of each class. Then, it was subsequently augmented using the Augmentor software where the used techniques are random horizontal/vertical flips and left/right rotations (higher than 25 degrees). Consequently, the number of images was enlarged to 25000 and 5000 histopathological images per class.

B. Data Preparation

This section is reserved to detail the data preparation steps, including data pre-processing and data splitting.

1) Data Pre-processing: This step is about resizing images from the original shape to (64, 64, 3). Then, for each scenario, the images belonging to the appropriate classes were selected.

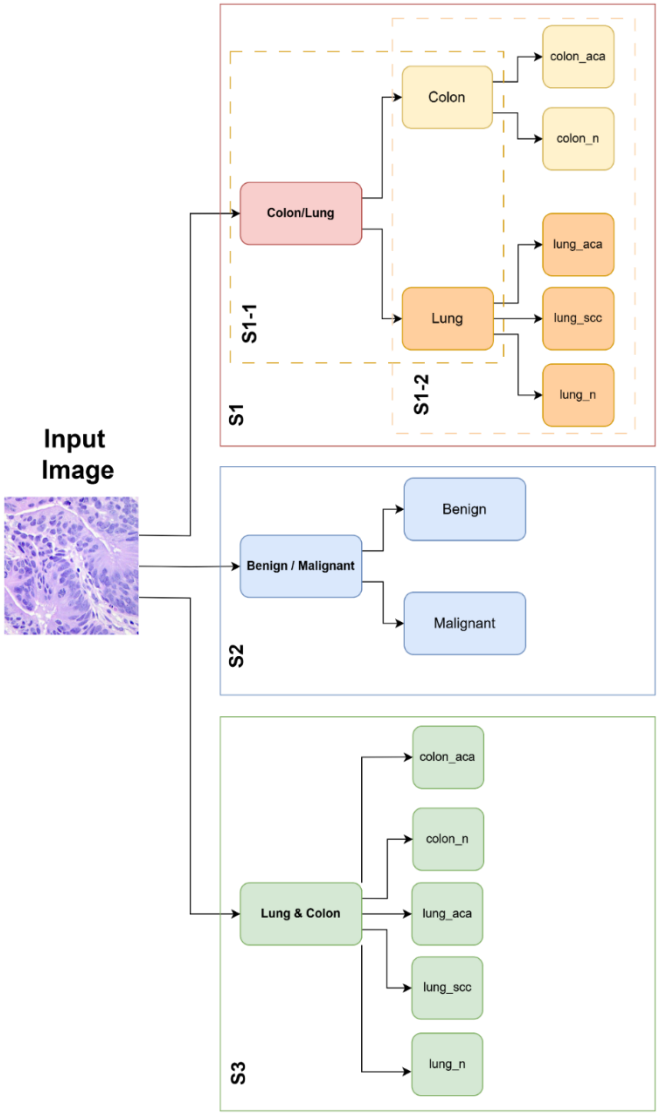

Fig. 1. Synoptic of the three scenarios presented.

TABLE I. STATE-OF-THE-ART AND PROPOSED METHODS DESCRIPTION

Method	Year	Organ	classes	Params(M)	Description	Accuracy
[33]	2021	Lung	3	-	- Image Feature Extraction: HI, TA, Multiscale Analysis - ML Models: KNN, SVM, DT, RF…	0.9933

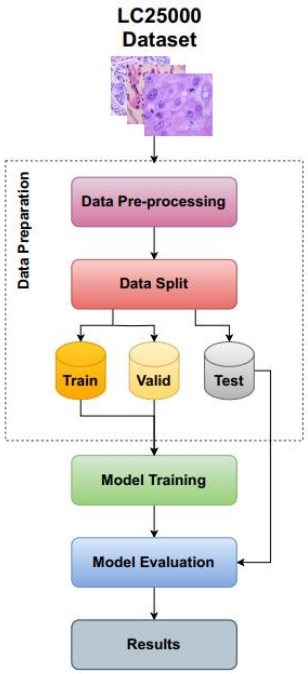

Fig. 2. Workflow of the proposed methods.

2) Data split: DL studies often divide the totality of the data into three sets which are training set, validation set, and testing set. The training set determines model parameters, whereas the validation set adjusts hyperparameters and measures overall performance. The testing dataset measures the model's effectiveness using previously unknown data. The LC25000 dataset was partitioned into training and validation subsets, and also a test set, with an 80:20 split.

The training and validation sets were partitioned using a 90:10 ratio.

C. Model

The proposed model's design belongs to CNN architecture. It consists of two main components: the Features Extractor (FE) and the Classifier. The input data (histological images) will be transformed by FE to advanced characteristics that identify shapes and correlations. This is achieved by the use of three repetitious blocks, including Convolution (Conv2D) and Max Pooling (MaxPool2D) bidimensional layers. The repeated blocks consist of four layers: 2 Conv2D, MaxPool2D, and Batch Normalization (BN). The extracted characteristics will be turned by the classifier to predicted labels of classes. It comprises Dense, Dropout, and Flatten layers, and 4x repeated blocks. The repeated blocks consist of BN and Dense layers. The designed lightweight CNN is depicted in Fig. 3.

D. Hyperparameters

For the training process, this research uses the trial-and-error process to determine the most optimal method. The model's input parameters were set at (64, 64, 3), matching the dimensions of the given image. 32 was the set batch size. The optimal number of epochs (ep) was 50. Adam which has a learning rate of 1.10-3 was the employed optimizer. In addition, the categorical cross-entropy loss was utilized as a loss function. During training, a learning rate schedule was used to manage this phase. It was set as follows:

$$lr = \begin{cases} lr, & ep \leq 10 \\ lr.\exp(-10^{-1}), & ep > 10 \end{cases} \quad (1)$$

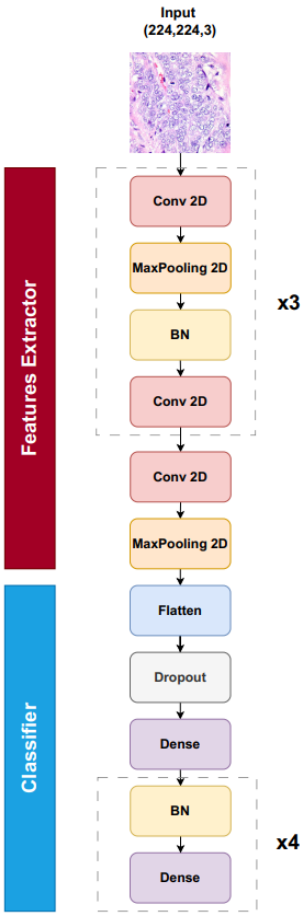

Fig. 3. Architecture of the proposed lightweight CNN.

E. Metrics

The proposed methods were evaluated using different metrics such as AUC, accuracy, F1 score, and. AUC calculates the ability of the system to differentiate between positive and negative data. F1-score incorporates precision and recall into a one statistic. Finally, Accuracy is the proportion of correct predictions to total calculated by the model.

IV. Results

This section is dedicated to show the experiment results. The training phases were done on a personal computer with 16GB of NVIDIA T4 x 2 GPU, 30GB of RAM, and a CPU of 2.20 GHz Intel Xeon. The goal of this research is to provide a versatile framework based on multi-scenario for automated LC cancer analysis. This paragraph aims to present the results for each diagnosis scenario.

1) Diagnosis Scenario (S1): The first scenario (S1) consists of two dependent stages: the first stage (S1-1) determines whether the input image refers to lung or colon data. Based on the results of this stage, the second stage (S1-2) is meant to

determine the exact class corresponding to the indicated organ Table II represents the results of the proposed system during the diagnosis scenarios S1-1, S1-2 Colon, and S1-2 Lung in the training, validation, and test phases. In fact, for scenario S1-1, the AUC F1-score, and accuracy of the established method reached 1.0000 in all phases. This perfect result enables us to pass to the second level of the actual scenario. Regarding the second level, scenario S1-2 Colon, the proposed model attained the same efficiency excluding the loss. Concerning the diagnosis scenario S1-2 Lung, the AUC, F1-score, and accuracy exceeded 0.9947 in the totality of phases.

TABLE II. RESULTS OF THE PROPOSED METHOD DURING THE DIAGNOSIS SCENARIOS S1-1, S1-2 COLON, AND S1-2 LUNG IN THE TRAINING, VALIDATION, AND TEST PHASES

	S1-1			**S1-2 Colon**			**S1-2 Lung**		
Phase	Train	Valid	Test	Train	Valid	Test	Train	Valid	Test
Accuracy	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	0.9983	0.9947
F1-Score	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	0.9983	0.9947
AUC	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	1.0000	0.9995

In this study, the classification metrics were also presented for the classes. The proposed approach reached an accuracy, sensitivity, specificity, and F1-score, of 1.000 for both the colon and lung classes. Moreover, in the S1-2 Colon, the previous metrics scored a value of 1.0000. Furthermore, for the S1-2 Lung, with the designed LWCNN, accuracy and F1-score surpassed 0.9947 and 0.9917, while the specificity and sensitivity, each exceeded, 0.9954 and 0.9907, respectively. Table III illustrates the results of the proposed method across all classes during the diagnosis scenarios S1-1, S1-2 Colon, and S1-2 Lung.

These highly performant results can be confirmed by the confusion matrixes. Fig. 4(a), (b), and (c) depict the confusion matrix of the presented scenarios S1-1, S1-2 Lung, and S1-2 Colon, respectively. This indicates that the proposed LWCNN can not only properly identify instances belonging to their respective classes but also successfully separate them from other classes, resulting in no substantial confusion or misclassification. For the S1-2 Lung, the proposed model's confusion matrix is nearly ideal.

TABLE III. RESULTS OF THE PROPOSED METHOD ACROSS ALL CLASSES DURING THE DIAGNOSIS SCENARIOS S1-1, S1-2 COLON, AND S1-2 LUNG

	Class	**Accuracy**	**F1-score**	**Se**	**Sp**
S1-1	Lung	1.0000	1.0000	1.0000	1.0000
	Colon	1.0000	1.0000	1.0000	1.0000
S1-2 Lung	lung_aca	0.9947	0.9923	0.9933	0.9954
	lung_scc	0.9947	0.9917	0.9907	0.9965
	lung_n	1.0000	1.0000	1.0000	1.0000
S1-2 Colon	colon_aca	1.0000	1.0000	1.0000	1.0000
	colon_n	1.0000	1.0000	1.0000	1.0000

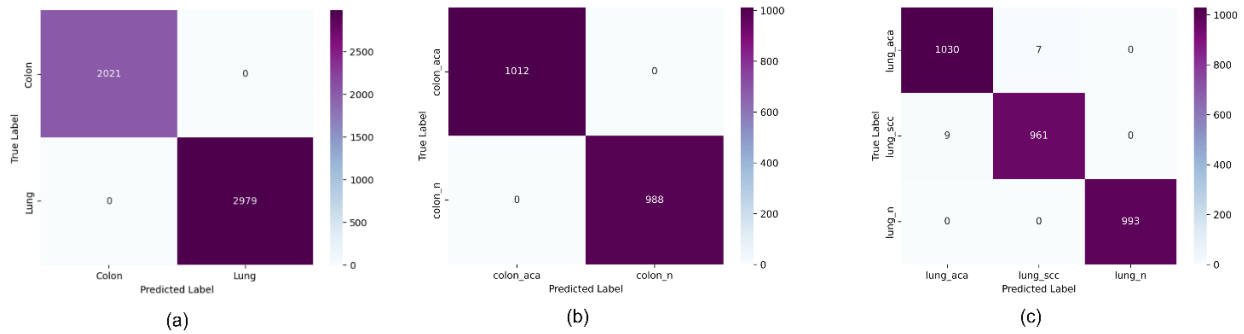

Fig. 4. Confusion matrices of presented LWCNN for diagnosis scenarios: (a) S1-1, (b) S1-2 Colon, and (c) S1-2 Lung.

Similar findings were observed through the ROC (Receiver Operating Characteristic) curve, which illustrates the balance between the true positive rate (TPR) and the false positive rate (FPR) at varying classification levels. As the curve approaches the plot's top-left corner, the model's efficiency improves. Fig. 5(a), (b), and (c) illustrate the ROC curves for the three diagnostic scenarios. In the lung and colon classification (S1-1), the curve attained a point at (0,1), indicating 0% false positives and 100% true positives. The same result was observed for colon classification in S1-2 Colon, confirming an AUC value of 1.0000 for the studied classes. For the S1-2 Lung scenario, the ROC curve was very near to the top-left corner, with AUC values for the lung class above 0.9999.

Overall, the proposed method is efficient for the diagnosis scenario (S1). This was confirmed by a batch of images randomly chosen from the test set for each diagnosis sub-scenario. Fig. 6 depicts the reel test using random test images. All input test images were correctly predicted with a confidence rate higher than 99.99%.

2) Diagnosis Scenario (S2): The second scenario (S2) is designed to find out whether the input data is attributed to the

malignant or benign class, irrespective of its origin (lung or colon). Table IV presents the outcomes for this scenario across the training, validation, and testing phases. The designed LWCNN achieved flawless performance in this scenario, with accuracy, F1-score, and AUC all reaching 1.0000 across every phase.

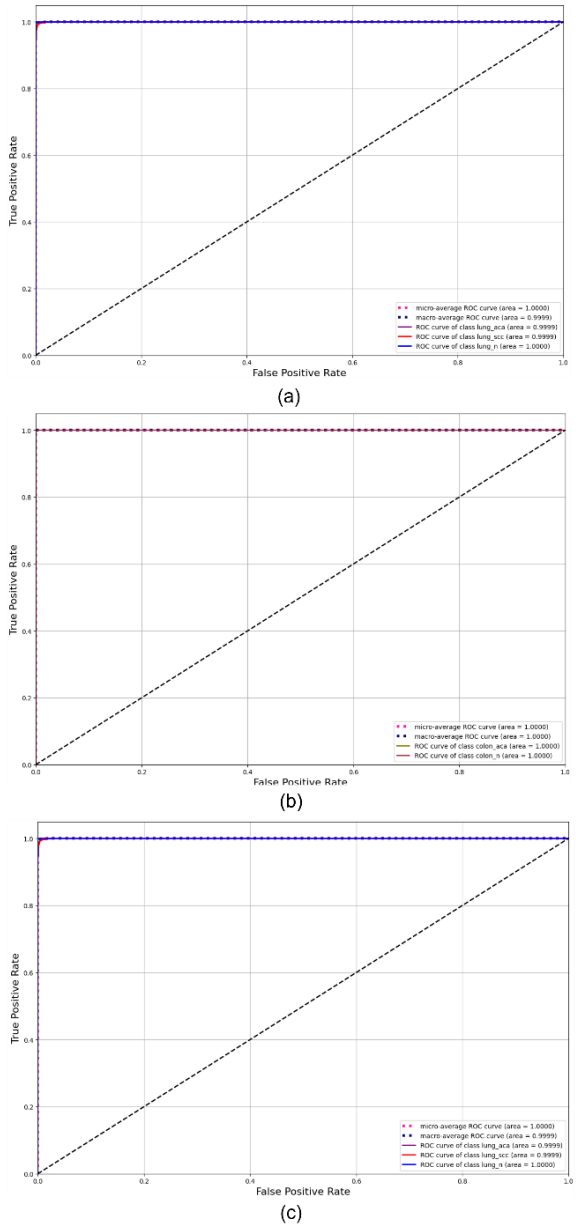

Fig. 5. ROC curves for diagnosis scenarios: (a) S1-1, (b) S1-2 Colon, and (c) S1-2 Lung.

TABLE IV. PROPOSED APPROACH'S FINDINGS DURING THE DIAGNOSIS SCENARIO (S2) IN THE TRAINING, VALIDATION, AND TEST PHASES

Phase	Training	Validation	Test
Accuracy	1.0000	1.0000	1.0000
F1-Score	1.0000	1.0000	1.0000
AUC	1.0000	1.0000	1.0000

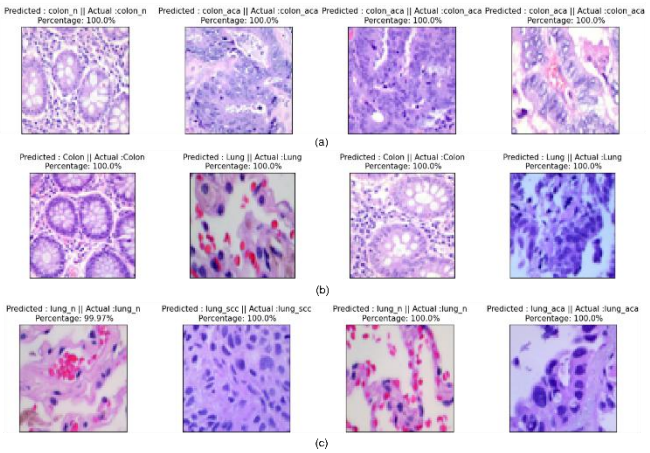

Fig. 6. Framework Test images arbitrarily selected from the test data used for the diagnosis of the sub-scenarios: (a) S1-1, (b) S1-2 Lung, and (c) S1-2 Colon.

This shows that it was capable to consistently and perfectly differentiate between malignant and benign classes with perfect precision, recall, and overall classification metrics.

The classification metrics for each class (benign and malignant) further confirm this outstanding performance. In all phases, the proposed approach attained a sensitivity, specificity, F1-score, and an accuracy of 1.0000 for both classes. These results suggest that the model not only accurately identified instances as either benign or malignant but also demonstrated exceptional sensitivity in detecting positive cases and specificity in ruling out negatives, leading to no false positives or false negatives. The results of the proposed method across all classes during the diagnosis scenario (S2) in Table V.

The confusion matrix, depicted in Fig. 7, provides further validation of the model's perfect performance. Both matrices reveal zero false positives and false negatives, indicating that the LWCNN model accurately classified all instances without any misclassification. This underscores the model's robustness in distinguishing between benign and malignant cases with absolute accuracy.

Moreover, the ROC curves for scenario (S2), illustrated in Fig. 8, also demonstrate the exceptional performance of the LWCNN model. The ROC curve reaches the top-left corner, signifying 0% false positives and 100% true positives for both benign and malignant classifications. This results in an AUC value of 1.0000, confirming that the model performed optimally across all thresholds.

In conclusion, the results of scenario S2 demonstrate the effectiveness of the presented method in discriminating between malignant and benign cases with 100% accuracy. This finding is further corroborated by a set of arbitrarily selected images from the test set, all of which were correctly classified with a confidence rate exceeding 99.99%. Fig. 9 illustrates these perfect predictions, further demonstrating the reliability of the model in real diagnostic applications.

3) Diagnosis Scenario (S3): The third scenario (S3) addresses the categorization of treated images to one of the five available categories from LC25000 dataset. Table VI

summarizes the results of this scenario across all phases. The described LWCNN model demonstrated strong performance, achieving accuracy, F1-score, and AUC values ranging between 0. 9976 and 1.0000, depending on the specific class and phase. While some variations in performance were observed, the model consistently classified the majority of images with high precision and reliability across all phases.

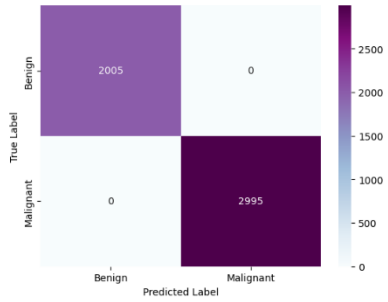

Fig. 7. Confusion matrix of presented LWCNN for diagnosis scenario (S2).

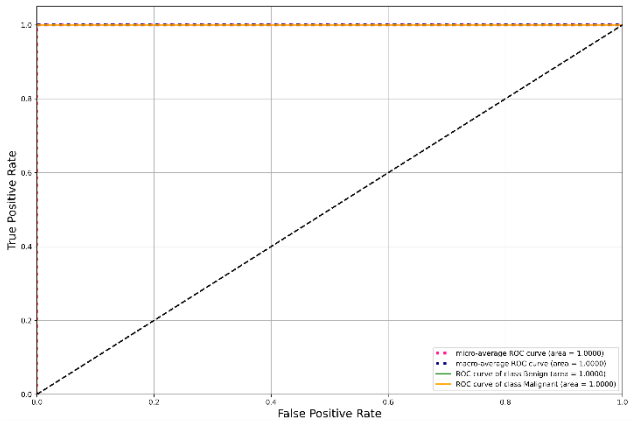

Fig. 8. ROC curves for diagnosis scenario (S2).

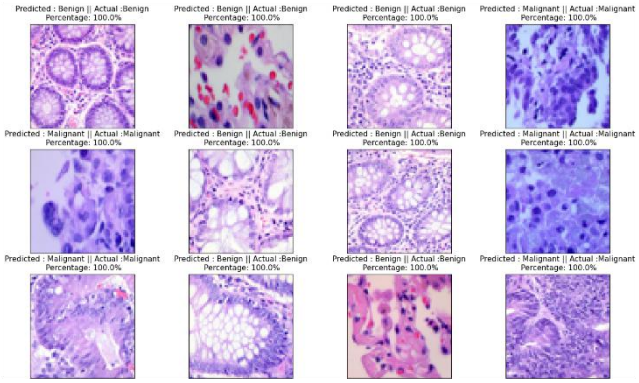

Fig. 9. Framework Test images arbitrarily selected from the test data used for the diagnosis scenario (S2).

TABLE V. RESULTS OF THE PROPOSED METHOD ACROSS ALL CLASSES DURING THE DIAGNOSIS SCENARIO (S2)

Class	Accuracy	F1-score	Se	Sp
Benign	1.0000	1.0000	1.0000	1.0000
Malignant	1.0000	1.0000	1.0000	1.0000

TABLE VI. PROPOSED APPROACH'S FINDINGS DURING THE DIAGNOSIS SCENARIO (S3) IN THE TRAINING, VALIDATION, AND TEST PHASES

Phase	Training	Validation	Test
Accuracy	1.0000	0.9970	0.9976
F1-Score	1.0000	0.9970	0.9976
AUC	1.0000	0.9991	0.9996

TABLE VII. RESULTS OF THE PROPOSED METHOD ACROSS ALL CLASSES DURING THE DIAGNOSIS SCENARIO (S3)

Class	Accuracy	F1-score	Se	Sp
colon_aca	0.9996	0.9990	0.9990	0.9998
colon_n	0.9996	0.9990	0.9990	0.9998
lung_aca	0.9980	0.9949	0.9949	0.9988
lung_scc	0.9980	0.9949	0.9949	0.9987
lung_n	1.0000	1.0000	1.0000	1.0000

A detailed examination of the classification metrics reveals that the model achieved near-perfect results in several classes, with accuracy, F1-score, sensitivity, and specificity reaching values as high as 1.0000 for the lung_n class. In other classes, the performance remained highly competitive, with these metrics exceeding 0.9949. This demonstrates the robustness of the model in handling multiple classification tasks while maintaining substantial accuracy. Table VII demonstrates the results of the proposed method across all classes during the diagnosis scenario (S3).

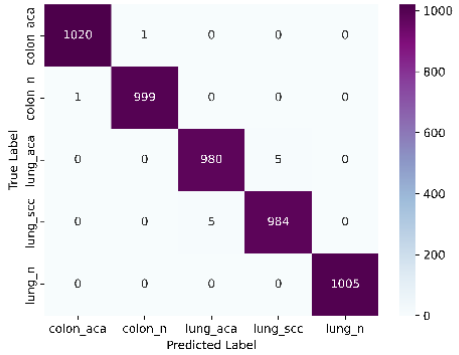

Fig. 10. Confusion matrix of presented LWCNN for the diagnosis scenario (S3).

Fig. 10 illustrates the confusion matrix for the five classes, further validating the model's efficacy in scenario (S3). While some minor misclassifications occurred, indicated by a low value of FP and FN, the overall confusion matrix reveals that the LWCNN model effectively distinguished between the five classes with minimal error, maintaining a high level of classification accuracy.

The ROC curves for scenario (S3), shown in Fig. 11, further support the model's effectiveness. Across all categories, the ROC curve closely approaches the top-left corner. This demonstrates the outstanding capability of the presented approach to distinguish between positive and negative cases. The corresponding AUC values exceed 0.9999, confirming the

model's high sensitivity and specificity across multiple thresholds.

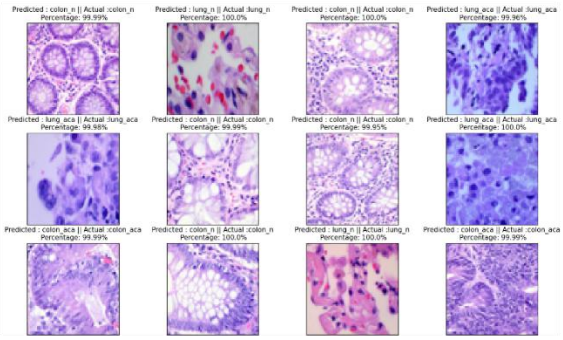

Fig. 11. ROC curves for diagnosis scenario (S3).

In conclusion, the third scenario (S3) demonstrates that the proposed method is highly performant in categorizing input data into one of the five LC25000 dataset classes, with results consistently ranging between 99% and 100%. Despite the minor variations in performance across classes, the model exhibited reliable classification capabilities. Fig. 12 displays randomly selected test images, which were classified with a confidence rate exceeding 99%, further confirming the model's potential in practical diagnostic tasks.

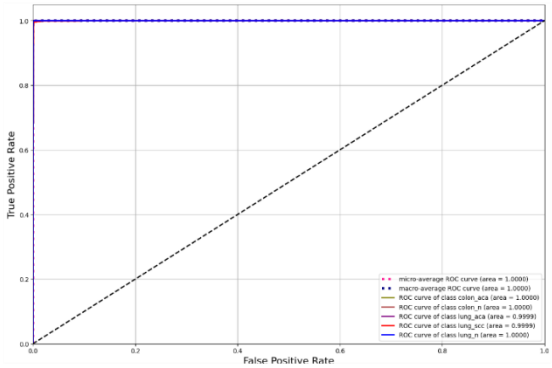

Fig. 12. Framework Test images arbitrarily selected from the test data used for the diagnosis scenario (S3).

V. Discussion

This section is dedicated to debate the experiment results, and compare them to existing approaches. Table VIII illustrates a comparative analysis of the performances of the presented approaches against a selection of well-established ML and DL-based systems for LC cancer classification, as detailed in Section II. Similarly, all the selected literature strategies which employed LC25000 dataset when assessing the outcomes of their models.

This research introduces a flexible framework for automatic analysis of LC cancer. The performance obtained highlights its robustness and efficiency. In fact, the used model was a lightweight CNN, which has a minimalist total number of parameters, 1.6 million parameters, when compared to those of Sakr et al [22] and Anjum et al. [48] where the total parameter is 4.6 and 9.2 million parameters, respectively. The comparison will cover three developed methods, which are colon cancer

classification, lung cancer classification, and LC classification. In colon classification, the proposed method reached the top efficiency with 100% AUC, F1-score, and accuracy. Equally, Gabralla et al. [24] attained the same performance. However, the authors used a more complex model with two levels, which contained individual models and stacking models.

In addition, they used more data preprocessing steps. For example, they applied common data augmentation (DA) like rotating, rescaling, zooming etc. In LC classification, the proposed method reaches an accuracy, F1-score, and AUC of 0.9947, 0.9947, and 0.9995, respectively. This performance is higher than those of Nishio et al. [33], and Talukder et al.'s [49] methods. Although it is very slightly lower than those of Masud et al. [40], Hage Chehad et al. [50], Hamed et al. [34], and Noaman et al.'s [35] approaches. Hamed et al. [34] worked only on two tissue types and not on the totality of the presented lung tissue types. In LC cancer classification, the proposed method outperformed all the cited approaches having the same task. The accuracy scored 0.9976. The F1-score reached 0.9976. The AUC attained 0.9996. These results demonstrate the model's remarkable accuracy, precision, recall, and discriminative power. Thus, the proposed approach is superior in terms of performance, lower in terms of complexity, and more recommended in terms of flexibility and practical usability, highlighting its suitability for this task at hand.

VI. Conclusion

This work aims to build a flexible framework based on multi-scenario diagnosis for LC cancers automated analysis. This was ensured by the employment of a lightweight CNN architecture with a small parameters number against other studies. In fact, the number of parameters was 1.612 million parameters. It was assessed using the LC25000 dataset which comprises five LC tissue types. The presented approach includes three diagnosis scenarios. The first diagnosis scenario (S1) is composed of two distinct stages: the initial stage (S1-1) aims to evaluate whether the input image corresponds to either a lung or colon sample. Based on the outcome of this stage, the second stage (S1-2) is designed to determine the specific class associated with the identified organ. In the second scenario (S2), the aim is to identify whether the input image belongs to either the benign or malignant class, irrespective of its origin. The third scenario (S3) involves categorizing the introduced image into one of the predefined categories in the LC25000 dataset. In the totality of these scenarios, the accuracy, F1-score, and AUC exceeded 0.9947. Regarding these metrics for each class in the presented scenarios, they were higher than 0.9907. The findings of this investigation highlight the important advantages of using the proposed method for the analysis of LC cancer. The model's improved accuracy, dependability, accessibility, flexibility, and capacity for continual development provide major benefits to improving patient care and outcomes. Upcoming work efforts should concentrate on analyzing the performance of the proposed technique over a variety of LC datasets, as well as expanding its assessment to other medical image modalities, such as radiographic or pathological imaging, in addition to histological images. This will assist to demonstrate its resilience, adaptability, and application in a variety of clinical contexts. Furthermore, future research should focus on demonstrating its use in real-world clinical settings to assure its widespread acceptance, generalizability, and potential to enhance diagnostic accuracy and patient outcomes.

Machine Learning-Based Denoising Techniques for Monte Carlo Rendering: A Literature Review

Liew Wen Yen[1], Rajermani Thinakaran[2], J. Somasekar[3]
Faculty of Data Science and Information Technology, INTI International University, Negeri Sembilan, Malaysia[1, 2]
Department of Computer Science and Engineering, Jain (Deemed–to-be University), Bangalore, Karnataka, India[3]

***Abstract*—Monte Carlo (MC) rendering is a powerful technique for achieving photorealistic images by simulating complex light interactions. However, the inherent noise introduced by MC rendering necessitates effective denoising techniques to enhance image quality. This paper presents a comprehensive review and comparative analysis of various machine learning (ML) methods for denoising MC renderings, focusing on four main categories: radiance prediction using convolutional neural networks (CNNs), kernel prediction networks, temporal rendering with recurrent architectures, and adaptive sampling approaches. Through systematic analysis of 7 peer-reviewed studies from 2019-2024, the author's findings reveal that deep learning models, particularly generative adversarial networks (GANs), achieve superior denoising performance. The study identifies key challenges including computational demands, with some methods requiring significant GPU resources, and generalization across diverse scenes. Additionally, we observe a trade-off between denoising quality and processing speed, particularly crucial for real-time applications. The study concludes with recommendations for future research, emphasizing the need for hybrid approaches combining physics-based models with ML techniques to improve robustness and efficiency in production environments.**

Keywords*—Convolutional neural network; Monte Carlo rendering; generative adversarial network; deep learning; machine learning; denoising techniques

I. Introduction

Monte Carlo (MC) rendering has emerged as a fundamental technique in computer graphics, enabling the simulation of light behavior in virtual environments through probabilistic sampling methods. By tracing numerous light paths and statistically sampling their contributions, MC rendering effectively captures complex light interactions with surfaces, materials, and volumes, resulting in highly realistic images characterized by accurate lighting, shadows, reflections, and refractions [1] [2]. This capability has rendered MC rendering indispensable across various industries, including film production, architectural visualization, and video game development, where photorealistic visuals are paramount [3] [4]. In film production, noise can disrupt the photorealism required for high-quality visual effects, while in video games, it can hinder real-time performance and user experience.

However, a notable challenge associated with MC rendering is the presence of noise in the generated images. Noise, which manifests as random variations or artifacts, arises from the inherent probabilistic nature of light path sampling. This issue is particularly pronounced in scenes with intricate lighting, glossy surfaces, or complex geometries, leading to grainy or speckled appearances that detract from the visual quality and realism of the rendered outputs [5] [6]. The reliance on probabilistic sampling methods contributes to this noise, as low sample counts can result in high variance in light estimates. While increasing the sample count can mitigate noise, it significantly escalates computational demands, rendering such approaches impractical for real-time or interactive applications [7].

To combat the noise prevalent in MC renderings, denoising techniques have become essential for enhancing image quality. These algorithms are designed to intelligently filter out noise while preserving critical image details, textures, and features, thereby yielding smoother and cleaner final renderings [7][8]. Recent advancements in machine learning (ML), particularly through deep learning models such as convolutional neural networks (CNNs) and generative adversarial networks (GANs), have opened new avenues for effective denoising. These ML techniques can learn complex noise patterns from extensive datasets of noisy and clean images, enabling them to generalize across various scenes and lighting conditions while maintaining the fidelity of essential image details during the denoising process [3] [9].

Despite the extensive exploration of ML-based denoising methods, there remains a scarcity of work synthesizing and comparing these approaches across diverse rendering scenarios. Challenges such as high computational demands, generalization across varying scenes, and interpretability of the models persist as unresolved issues. High computational demands limit the applicability of ML-based denoising in real-time applications, while generalization issues arise due to the variability of noise patterns across different scenes and lighting conditions. This study endeavors to fill these gaps by providing a systematic review and comparative analysis of existing methods, offering practical recommendations for future research in the field of MC rendering and denoising [5] [9].

To address these challenges, this study seeks to answer the following key research questions:

1) What ML methods have been employed for denoising MC renderings, according to the existing literature?

2) How do these ML methods compare in terms of performance, efficiency, and application?

3) What are the current challenges and future directions for ML-based denoising in MC rendering?

The primary objective of this study is to provide a comprehensive review and comparative analysis of these

techniques, categorizing them into radiance prediction, kernel prediction, temporal rendering, and adaptive sampling. Performance evaluations will utilize metrics such as Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), and Relative Mean Squared Error (rMSE) [4] [8]. Additionally, this study will highlight gaps in the current literature and propose future research directions to advance ML-based denoising techniques, ultimately enhancing rendering workflows and visual outputs.

II. METHOD

A systematic literature review (SLR) methodology was employed to ensure a comprehensive and unbiased review of ML techniques for denoising in MC rendering. An SLR involves analyzing existing research by defining clear research questions, identifying relevant studies, appraising their quality, and synthesizing findings both qualitatively and quantitatively [10]. This structured approach ensures transparency, replicability, and rigor in the review process. The methodology adheres to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) framework to enhance methodological rigor and quality.

The methodology of this study is organized into three key stages: planning the review, which involves defining research questions, developing search strategies, and establishing inclusion/exclusion criteria; conducting the review, which includes searching and screening relevant studies, extracting data, and assessing the quality of selected studies; and analyzing the gathered information, which consists of synthesizing results, discussing trends, and identifying challenges and opportunities for future research.

A. Planning the Review

1) Scope of the review: The SLR focuses specifically on machine learning ML applied to denoising in MC rendering. MC rendering is widely used in computer graphics to simulate realistic lighting effects, but its probabilistic nature often introduces noise into rendered images. This noise can degrade visual quality, making effective denoising techniques essential for achieving high-quality outputs. Despite recent advancements in ML-based denoising methods, there remains a scarcity of work synthesizing and comparing these approaches across diverse rendering scenarios. Challenges such as high computational demands, generalization across varying scenes, and interpretability of the models persist as unresolved issues. This study aims to address these gaps by providing a comprehensive review and comparative analysis of ML-based denoising techniques, categorizing them into radiance prediction, kernel prediction, temporal rendering, and adaptive sampling.

2) Research questions: The formulation of research questions was guided by an iterative process involving pilot searches and consultations with domain experts. Initial exploratory searches were conducted across academic databases such as IEEE Xplore, ACM Transactions on Graphics, and ScienceDirect using broad keywords like “Monte Carlo rendering,” “denoising,” and “machine learning.” These searches helped identify recurring themes and trends in literature, such as the use of CNNs, GANs, and kernel prediction methods. Informal consultations with an expert in computer graphics and ML-based rendering techniques provided valuable feedback on the scope and relevance of the questions, suggesting additional considerations such as computational efficiency and generalization across diverse scenes. The final research questions guiding this SLR are as follows:

1) What ML methods have been employed for denoising MC renderings, according to the existing literature?

2) How do these ML methods compare in terms of performance, efficiency, and application?

3) What are the current challenges of ML for denoising MC rendering?

4) Search strategy: A comprehensive search strategy was developed to gather relevant literature across multiple academic databases. The search was conducted using keywords such as “Monte Carlo rendering,” “denoising,” “convolutional neural network,” “deep learning,” “machine learning denoising techniques,” and “generative adversarial network”. The databases searched included IEEE Xplore, Google Scholar, ScienceDirect, Computer Graphics Forum, and ACM Transactions on Graphics. To ensure consistency in the analysis, the search was limited to studies published in English between 2019 and 2024.

5) Inclusion and exclusion criteria: Specific criteria were established to filter the studies for inclusion in this review, ensuring the relevance and quality of the selected literature. This study employed a filtration process guided by predefined inclusion and exclusion criteria as shown in Tables I and II. All the papers were assessed against a set of inclusion and exclusion criteria to ensure they directly addressed the research questions.

TABLE I. INCLUSION CRITERIA

ID	Inclusion criterion
I1	Studies explicitly focus on machine learning techniques for denoising in Monte Carlo rendering.
I2	Studies published in peer-reviewed journals and conferences to ensure credibility and quality.
I3	Studies that provide quantitative performance metrics such as PSNR, SSIM, rMSE, or computational efficiency.
I4	Studies published in English.
I5	Studies published between 2019 and 2024.

TABLE II. EXCLUSION CRITERIA

ID	Exclusion criterion
E1	Studies do not focus on denoising in the context of Monte Carlo rendering.
E2	Studies lacking sufficient empirical data or clear evaluation methods, which could undermine the validity of the findings.
E3	Non-peer-reviewed articles, editorials, or opinion pieces, as these sources do not provide the rigorous analysis required for this review.
E4	Studies published in languages other than English.
E5	Studies published before 2019.

6) Selection process: The selection process involved two phases: initial screening and full-text review. In the initial screening, titles and abstracts of all retrieved papers were reviewed against the inclusion and exclusion criteria. Papers that did not meet these criteria were excluded. In the full-text review, the remaining papers were examined in detail to assess their relevance to the research questions and the quality of their methodologies and findings. A total of seven papers were selected for the final analysis. To provide a clear overview of the study selection process, a PRISMA flowchart (Fig. 1) was created, following the guidelines outlined by Pati and Lorusso [11]. The flowchart visually summarizes the number of studies identified, screened, and included at each stage of the review process.

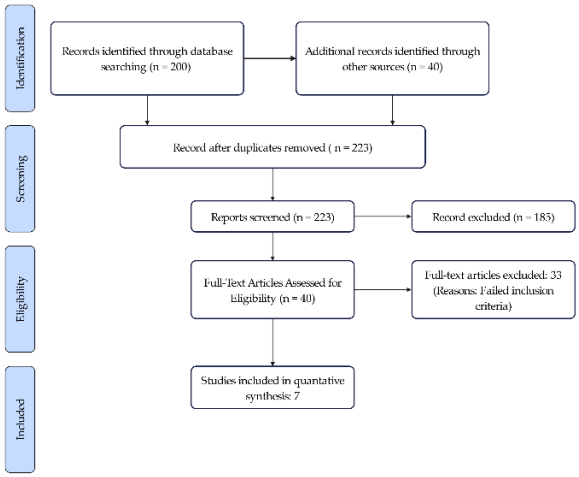

Fig. 1. PRISMA flowchart summarizing the study selection process.

B. Conducting the Review

This phase involved three key steps: data extraction, quality assessment, and data synthesis. Each step was meticulously performed to ensure a robust and unbiased evaluation of the selected studies, enabling a comprehensive comparison of ML-based denoising techniques for MC rendering.

1) Data extraction: Data extraction was systematically performed on the selected studies to comprehensively address the research questions. Key information extracted included the specific ML models employed for denoising, the datasets used, and performance metrics such as PSNR and SSIM, rMSE. This structured extraction approach enabled a robust comparison of the effectiveness and efficiency of different ML-based denoising techniques across a range of rendering scenarios.

2) Quality assessment: To ensure the reliability and validity of the findings, each study included in this review underwent a rigorous quality assessment. This process evaluated the methodological rigor of the studies, focusing on factors such as the robustness of the experimental design, the clarity of data presentation, and the appropriateness of the performance metrics used. Only studies that met these stringent criteria were included, ensuring that this review comprises high-quality research offering credible insights into the effectiveness and efficiency of ML-based denoising methods.

3) Data synthesis: The extracted data were synthesized to provide a comprehensive comparison of the different ML-based denoising techniques for MC rendering. Both qualitative and quantitative analyses were conducted to identify trends, strengths, and limitations across the existing literature. Performance metrics were aggregated where applicable, allowing for a standardized comparison of the denoising effectiveness across different studies. This synthesis provides a holistic view of the current landscape of ML-based denoising methods in MC rendering, highlighting their practical applications and potential areas for future research.

C. Analyzing the Gathered Information

1) Synthesis of results: The extracted data were synthesized to provide a comprehensive comparison of the different ML-based denoising techniques for MC rendering. Both qualitative and quantitative analyses were conducted to identify trends, strengths, and limitations across the existing literature. Performance metrics were aggregated where applicable, allowing for a standardized comparison of the denoising effectiveness across different studies. This synthesis provides a holistic view of the current landscape of ML-based denoising methods in MC rendering, highlighting their practical applications and potential areas for future research.

2) Discussion of results: The analysis identified several challenges associated with applying ML techniques to MC rendering denoising. One major challenge is the computational complexity of these methods, as many ML-based denoisers require substantial processing power and memory to achieve high-quality results. This computational demand makes it difficult to deploy these techniques in real-time or interactive applications where performance and speed are critical. Additionally, the complexity of the models can hinder their ability to generalize across diverse scenes, as training datasets may not fully capture the variability in noise patterns that arise in different rendering scenarios.

Another challenge is the difficulty in balancing denoising performance with computational efficiency. While deep learning models such as CNNs and GANs have shown promise in reducing noise while preserving image details, these methods often come with a trade-off between the quality of the denoised output and the computational resources required. Addressing these challenges involves exploring more efficient architectures, optimization techniques, and potentially new approaches to model training that can reduce computational overhead without compromising denoising quality.

3) Recommendations for future research: Based on the findings, several recommendations for future research have been proposed. These include integrating physics-based models, adopting adaptive sampling strategies, employing advanced network architectures such as GANs and CNNs, utilizing detail-preserving neural networks, and implementing path-based denoising techniques. These suggestions aim to steer future

research efforts toward overcoming current limitations and exploring new opportunities in ML-based denoising for MC rendering.

III. Results and Discussion

This study explores three key questions. The following sections analyze the findings and their significance to each question.

A. What ML Methods have been Employed for Denoising MC Rendering, according to the Existing Literature?

MC rendering is well-known for simulating realistic lighting effects, but it has its challenges, particularly with noise in the images because of the stochastic nature of the sampling process. Over the years with the advancement of ML, it has been employed to effectively denoise MC renderings. These methods leverage neural networks which enables them to clean up images more effectively than traditional techniques. Below, we explore some of the research papers that use ML methods for denoising MC rendering, categorized into kernel prediction, parameter prediction, radiance prediction, and temporal denoising. This categorization framework, derived from the work of Huo et al. [12], provides a structured approach to understanding the strengths and limitations of each method.

1) Kernel prediction: Kernel prediction focuses on directly predicting the filtering kernels used to combine neighboring pixel values. This enhances the denoising process by adapting the kernels to the specific noise characteristics of each pixel. This approach is a more flexible and accurate solution compared to traditional filtering techniques, particularly in handling complex scenes and varying lighting conditions.

Back et al. [13] introduce a deep learning-based framework designed to improve the accuracy of MC rendering by effectively combining independent and correlated pixel estimates. Their approach utilizes a combination kernel modeled as a deep neural network, which optimally weights the combination of these pixel estimates, thereby reducing residual noise and systematic errors commonly found in existing methods like denoising and gradient-domain rendering. The framework is robust against outliers, thanks to an extension that employs multi-buffered inputs, which further enhances the reliability of the results. Experimental evaluations demonstrate that this method not only enhances the visual quality of renders by preserving high-frequency details and reducing noise but also outperforms existing techniques in terms of both numerical accuracy and visual fidelity. This makes the approach particularly valuable for applications requiring high-quality rendering, such as production-level visual effects and interactive applications.

Gharbi et al. [14] introduce a sample-based MC denoising technique using a kernel-splatting network. Unlike traditional pixel-based methods, their approach operates directly on the raw MC samples, leveraging deep learning to map these samples to a denoised image. The core innovation lies in a novel kernel-predicting architecture that splats individual samples onto nearby pixels. This method treats each sample independently and uses a permutation-invariant design to handle the arbitrary order of samples. The kernel-splatting approach is particularly effective in managing complex light transport scenarios such as motion blur, depth of field, and specular effects. By directly processing the sample-level information, the technique achieves higher quality results with reduced numerical error and improved visual fidelity, especially in low-sample-count settings. The network was trained on a large dataset of synthetic scenes and demonstrated significant improvements over state-of-the-art methods in both visual quality and computational efficiency [14].

Munkberg and Hasselgren et al. [15] propose a novel approach to neural denoising in MC path tracing by introducing a layered architecture that partitions per-sample data into distinct layers. Each layer is processed with unique filter kernels before being composited to produce the final output. This approach balances computational efficiency with high-quality denoising, offering comparable results to more expensive per-sample methods while significantly reducing memory and performance overhead. The architecture is particularly robust against high-intensity outliers and performs well even in complex visibility scenarios, such as defocus and motion blur. The authors demonstrate that their method achieves near real-time performance on contemporary GPUs, making it viable for both real-time rendering and offline production environments. Future work is suggested in extending this layered approach to temporal domains and deep compositing workflows, indicating its potential for broader applications in rendering technologies.

2) Parameter prediction: Parameter prediction involves training neural networks to predict the optimal parameters for traditional filters to enhance their ability to reduce noise while preserving image details.

Xing and Chen [16] introduce an approach to denoising path-traced images by combining SURE-based adaptive sampling with neural networks. Their process begins with generating coarse samples and using Stein's Unbiased Risk Estimator (SURE) to estimate the noise level for each pixel. Extra samples are then allocated to pixels with higher noise levels. In the reconstruction phase, a MLP network predicts the optimal reconstruction parameters based on features extracted from the adaptive sampling results, such as shading normal, depth, and texture values. These predicted parameters are used with an anisotropic filter to produce the final noise-free image. This method reduces numerical error as well as enhances visual quality compared to existing techniques.

3) Radiance prediction: Radiance prediction focuses on directly estimating the radiance values for each pixel in a MC rendering. These methods bypass the need for traditional filtering or kernel prediction. They utilize deep learning models to map noisy input pixels directly to their denoised counterparts, effectively capturing complex relationships between the noisy input and the desired output. By predicting radiance directly, these approaches can handle high-frequency details and complex lighting scenarios more effectively, allowing them to be more suitable for applications where visual accuracy is needed.

Xu et al. [17] introduce an adversarial approach for denoising MC renderings, leveraging GANs to improve the

realism of high-frequency details and global illumination. Their method employs a conditioned auxiliary feature modulation technique that utilizes auxiliary features such as normal, albedo, and depth to enhance the denoising process. The GAN framework consists of a denoising network, which predicts the clean image, and a critic network, which evaluates the perceptual quality of the denoised output. The critic network is trained using the Wasserstein distance, which provides a smoother measure of perceptual similarity compared to traditional losses. This approach enables the denoising network to learn from the distribution of high-quality path-traced images, resulting in better reconstruction of MC integrals from fewer samples. Xu et al. demonstrate that their method outperforms previous state-of-the-art techniques in terms of both visual quality and computational efficiency, making it suitable for high-end production environments.

The paper by Alsaiari et al. [18] presents a novel approach for image denoising using GAN architecture. The method involves rendering images with a reduced number of samples per pixel, which results in noisy outputs, and then passing these images through a GAN-based network that produces high-quality, photorealistic denoised images in less than a second. The proposed network architecture leverages residual blocks, skip connections, and batch normalization to enhance the denoising process. Despite being trained on a limited dataset of 40 images, the network demonstrated impressive generalization capabilities, effectively denoising images outside the training domain, including grainy photographs and medical CT scans. The authors also discuss potential future extensions of their work, including handling more complex noise patterns such as those generated by MC rendering and incorporating additional information like depth maps to improve denoising performance in scenes with motion blur, depth of field, and global illumination. The study underscores the effectiveness of GANs in producing high-quality denoised images and suggests further exploration of this approach in real-time rendering applications.

4) Temporal rendering: Temporal rendering is specifically designed to address the challenges of ensuring frame-to-frame consistency in animated or real-time rendering sequences. Noise reduction in MC rendering needs to be effective not just on individual frames, but also across time, to prevent flickering or temporal artifacts that can detract from the visual experience. These methods often utilize recurrent structures to ensure that noise is reduced consistently across frames. It preserves temporal coherence while maintaining high-quality image details.

Meng et al. [19] introduce a practical and efficient approach to real-time MC denoising by leveraging a neural bilateral grid. Their method utilizes a convolutional neural network, called GuideNet, to predict guide images that direct the placement of noisy radiance data into a multi-scale bilateral grid. The grid is then sliced to extract denoised data, resulting in high-quality renders even from extremely noisy inputs at 1 spp. The proposed approach is highly scalable and adaptable to both real-time and offline applications, demonstrating superior denoising quality compared to existing methods, particularly for low-sample scenarios. The study emphasizes the method's ability to maintain interactive frame rates while achieving high visual fidelity, making it a robust solution for real-time rendering in demanding environments.

B. How do these ML Methods Compare in Terms of Performance, Efficiency, and Application?

These denoising methods analyzed in this study exhibit varying degrees of performance, efficiency, and application suitability in MC-rendered images. By examining key metrics such as rMSE, SSIM, PSNR, and processing time, we can assess how each method balances noise reduction, computational efficiency, and applicability to different rendering scenarios.

Methods such as Xu et al. [17] excel with an rMSE of 0.003164 and a PSNR of 34.194759 dB in the HorseRoom scene, outperforming traditional methods like NFOR in retaining fine details. These methods are particularly suited for scenarios where achieving the highest possible image quality is crucial, even if it comes at the cost of longer processing times.

In environments where real-time performance is essential, such as video games, virtual reality, and interactive simulations, the kernel-splatting network by Gharbi et al. [14] and the GAN-based approach by Alsaiari et al. [18] are particularly effective. Gharbi et al.'s method [14] achieves an rMSE of 0.026 at 32 spp while processing a 1024 × 1024 image in just 6.0 seconds at 4 spp, making it ideal for real-time applications that require a balance between speed and quality. Similarly, Alsaiari et al.'s method [18] generates high-quality denoised images in under a second, emphasizing rapid processing without significantly compromising visual fidelity, making it highly suitable for scenarios where quick turnaround times are critical.

Methods by Jonghee Back et al. [13] and Munkberg and Hasselgren [15] offer strong capabilities in handling complex lighting environments and preserving intricate details. Jonghee Back et al.'s deep combiner for independent and correlated pixel estimates achieves a significant reduction in rMSE, such as 0.0207 in the Bookshelf scene at 64 spp, making it effective in handling scenes with intricate lighting and textures. Munkberg and Hasselgren's neural denoising method with layer embedding also shows strong performance, achieving an rMSE of 0.0288 and SSIM of 0.941 at 32 spp, making it highly effective for maintaining image quality in complex visual effects.

Xing and Chen's method [16] leverages adaptive sampling based on SURE combined with a modified MLP network to predict optimal reconstruction parameters. The method demonstrates significant noise reduction with a RelMSE of 0.00831 in the Sibenik scene at 16.9 spp, and 2.37E-4 in the Anim-BlueSphere scene at 30.6 spp. It optimizes sample distribution across pixels with varying noise levels, enhancing computational efficiency while maintaining high image quality. This method is particularly effective for real-time applications and interactive graphics, where maintaining quality with lower sample counts is crucial.

C. What are the Current Challenges in the Application of ML for Denoising MC Rendering?

One of the main challenges associated with using ML for denoising in MC rendering is its inherent complexity. MC rendering simulates how light behaves within a scene by tracing numerous random paths. Hence, this results in inherently noisy

images and requires a denoising process for better visual quality [20]. The primary difficulty lies in the nature of the noise, which is stochastic and can vary significantly across different scenes. Therefore, denoising algorithms must be adept at distinguishing between noise and the true signal to avoid blurring or distorting the final image [20]. In addition, the denoising task is complicated both by the high dimensionality of the data and the complex interplay of light transport phenomena. In this regard, a sophisticated ML model is needed to be able to capture these intricate relationships with complex data [21, 22].

Additionally, the efficiency and computational cost of denoising algorithms are also challenges in the MC rendering process. Deep learning techniques have shown promise in attaining higher quality denoising, but they often come with a computational cost and require substantial processing power and time for training and inference [23]. This computational overhead can make deploying ML-based denoising solutions in real-time or interactive rendering scenarios challenging, where performance is crucial [24]. Real-time rendering applications, such as video games or virtual reality, demand quick and efficient processing to maintain smooth and responsive user experiences. Therefore, balancing denoising quality and computational efficiency in rendering and MC is today's critical challenge using ML approaches for denoising [23]. Developing methods that optimize this balance is essential to ensure that high-quality denoising can be achieved without compromising the performance required for real-time applications. This involves exploring more efficient algorithms, hardware acceleration, and innovative training techniques to reduce computational demands while maintaining or improving denoising effectiveness.

The other critical challenge is the generalization of denoising algorithms across different scenes and lighting conditions. Noise patterns and characteristics of MC renderings can vary greatly depending on scene complexity, materials present, and lighting setup [25]. For instance, a scene with complex geometry and reflective surfaces might produce noise patterns that are vastly different from a simple scene with diffuse materials. This variability necessitates that ML models are not only trained on diverse datasets but are also rigorously tested to ensure their effectiveness in new, unseen scenarios. Thus, it is essential to practically assess that ML models effectively generalize over unseen data and across diverse rendering scenarios in rendering pipelines [25]. Robustness to scene variations and the ability to adapt to different noise profiles are crucial aspects that need to be addressed to make denoising algorithms effective across a wide range of rendering scenarios [25][26][27]. Addressing these issues involves developing more sophisticated training regimes, incorporating a wider range of scenes and conditions, and continuously updating models to handle new types of noise as they are encountered.

Besides, ML-based denoising methods further raise issues concerning interpretability and transparency for MC rendering. Deep learning models are often thought to be black boxes, making it difficult to understand the decision process for denoising and what features were prioritized in the process [21]. This can be problematic for artists and developers who rely on precise control over rendering parameters to achieve specific visual effects [21]. For instance, they may need to adjust the denoising parameters to maintain certain artistic details or to ensure the consistency of visual styles across different scenes. Without a clear understanding of how the ML model operates, making these adjustments becomes exceedingly difficult. This lack of interpretability can also hinder debugging and improvement efforts, as it is unclear why the model might fail in certain scenarios. Thus, improving the interpretability of these models while preserving their denoising performance is a challenge that needs attention in applying ML for denoising MC rendering [21].

Table III provides a summary of the performance, efficiency, and application of a selection of seven methods. This table serves as a quick reference for understanding the strengths and limitations of each approach, making it easier for researchers and practitioners to select the most appropriate denoising method based on their specific needs. By comparing metrics such as PSNR, SSIM, and computational demands, the table illustrates the diverse range of strategies employed across different methods to balance speed and quality.

IV. Conclusion

This study set out to explore and analyze ML-based denoising techniques for MC rendering, focusing on three key research questions. Using a SLR approach guided by the PRISMA framework, the authors identified, categorized, and compared seven peer-reviewed studies published between 2019 and 2024. These methods were grouped into four main categories—radiance prediction, kernel prediction, temporal rendering, and adaptive sampling—and evaluated using metrics like PSNR, SSIM, and rMSE. Our findings show that deep learning models, such as CNNs and GANs, are highly effective at reducing noise while preserving important details in MC-rendered images. However, challenges like high computational demands and difficulties in generalizing across different scenes still limit their use in real-time applications.

The main contribution of this work is bringing together a fragmented field into a clear and structured framework. This makes it easier for practitioners to choose the right denoising technique based on their specific needs. For example, kernel-splatting networks work well for real-time scenarios, while adversarial methods excel in producing high-quality results for offline production. We also highlighted some critical gaps in the literature, such as the need for more interpretable models and efficient architectures that strike a better balance between quality and computational cost.

That said, this review isn't without its limitations. By focusing only on studies from 2019 to 2024, we might have missed some foundational work from earlier years. Additionally, our reliance on databases like IEEE Xplore, ACM, and ScienceDirect could introduce bias, and the inclusion of just 12 papers may not fully capture the diversity of approaches out there. While qualitative comparisons provide valuable insights, they lack the statistical depth of a meta-analysis, which could offer a more quantitative assessment of these methods.

Looking ahead, there are several exciting directions for future research. One promising area is hybrid approaches that combine physics-based models with ML techniques to improve robustness and accuracy. Another is exploring temporal

optimization strategies to reduce flickering artifacts in animations. By addressing these challenges, researchers can develop deployable solutions that balance photorealism with computational efficiency, ultimately transforming workflows in industries like film, architecture, and gaming.

In short, this study provides a comprehensive overview of the current state of ML-based denoising for MC rendering, identifies key challenges, and suggests practical ways forward. The goal is to inspire further innovation in creating denoising solutions that are not only powerful but also practical for real-world applications.

TABLE III. SUMMARY OF THE PERFORMANCE, EFFICIENCY, AND APPLICATION OF THE METHODS

Method	rMSE (Range)	SSIM (Range)	PSNR (dB)	Efficiency	Application
Adversarial Monte Carlo Denoising by Xu et al. [17]	0.003164	N/A	34.194759	High computational cost, suited for offline rendering	High-end production environments, detailed visual effects
Kernel-Splatting Network by Gharbi et al. [14]	0.026	N/A	N/A	Optimized for fewer samples, balance between speed and quality	Real-time applications, interactive graphics, gaming
GAN-based Denoising by Alsaiari et al.[18]	N/A	0.938 - 0.941	33.706 - 33.878	Real-time performance, quick processing in under a second	Real-time rendering, architectural visualization
Neural Bilateral Grid by Meng et al. [19]	N/A	0.941	33.838	High real-time performance at 61 FPS, optimized for low sample scenarios	Real-time rendering, gaming, and VR
Deep Combiner for Independent and Correlated Pixel Estimates by Jonghee Back et al. [13]	N/A	N/A	N/A	Effective in handling complex scenes, reduces relMSE	Production-level visual effects, interactive applications requiring high-quality rendering
Neural Denoising with Layer Embedding by Munkberg and Hasselgren [15]	0.0288	0.941	N/A	Robust against artifacts, effective with varying configurations	Offline rendering, flexible in handling per-sample, per-pixel, and layered configurations
Path Tracing Denoising based on SURE Adaptive Sampling by Xing and Chen [16]	0.00831	N/A	N/A	Adaptive sampling with SURE; highly efficient in real-time scenarios with CUDA acceleration	Interactive graphics, real-time applications, scenarios with limited computational resources

Optimization Technology of Civil Aircraft Stand Assignment Based on MSCOEA Model

Qiao Xue*, Yaqiong Wang, Hui Hui
Aviation Engineering Institute, Jiangsu Aviation Technical College, Zhenjiang, 212134, China

***Abstract*—The Chinese aviation transportation industry is constantly developing towards multiple objectives and constraints. The conventional optimization method for stand assignment of civil aviation aircraft has low efficiency and can no longer meet practical needs. Based on this, the paper firstly focuses on the problem of convergence and uniformity in multi-objective optimization, and uses the multi-strategy algorithm to optimize the multi-strategy algorithm of Multi-strategy competitive-cooperative co-evolutionary algorithm (MSCOEA). Then, for the problem of high time complexity in the traditional chromosome coding mode, the characteristics of quantum evolution algorithm can be reduced by MSCOEA algorithm. Front the results, the prediction accuracy of the research method was above 90% on both the training and validation sets. With the increase of iterations, the final accuracy was 96.8% and 97.53%, respectively. This algorithm achieved the same performance as some other comparative algorithms in most of the objectives. The optimal flight allocation rate reached 98.4%. The mean, optimal value, and variance of the number of flights allocated to remote stands were 5.75E+00, 4.00E+00, and 1.04E+00, respectively, which were superior to other comparative algorithms. The deigned stand assignment optimization method achieves efficient stand assignment, and improves the allocation efficiency of large and multi-objective stands.**

I. Introduction

With the advancement of industrial technology, mathematical models related to optimal problems have become increasingly mature. Many practical optimization problems have been solved. However, how to efficiently solve such problems has always been a challenge that both the international community and the industry need to face together. In solving complex optimization problems, there are often problems such as multiple constraints, multiple decisions, and multiple objectives. It is difficult to achieve satisfactory results using conventional mathematical methods [1-2]. Cooperative Co-evolutionary Algorithm (CCEA) has been widely used to solve optimal problems [3-4]. Especially in the field of civil aviation transportation, solving complex optimization related problems is of great significance. With the continuous expansion of air cargo scale, the demand for every link in China's civil aviation industry chain is also increasing. Parking stands are a critical infrastructure for airlines, which are essential for ensuring the normal, safe, and efficient operation of civil aviation transportation systems. The conflict between the shortage of parking spaces and the increase in market demand has become a bottleneck problem restricting the civil aviation. Currently, there are two methods to address the shortage of parking spaces. One method is to expand the existing airport, that is, to build a new airport. Another effective way to alleviate the parking space resources is to efficiently allocate existing parking space resources to optimize the utilization rate of parking lot resources. This approach is both fast and cost-effective. Therefore, it has received high attention from the industry and academia [13]. Therefore, multi-strategy competitive coevolution algorithm (Multi strategy competitive co evolutionary algorithm, MSCOEA) is adopted, and then it is integrated with quantum evolution algorithm (Quantum Evolutionary Algorithm, QEA) to solve the problem of civil aviation shutdown shortage. This study consists of four parts. The first part is the literature review on the optimization of civil aircraft parking lot allocation; the second part is to construct the optimization method model of civil aircraft parking lot allocation based on MSCOEA algorithm; and the third part is to verify the validity and reliability of the model through relevant experiments; and the last part is to summarize the full text.

II. Related Work

Pan et al. proposed an effective CEA for distributed assembly shop group scheduling problem to arrange multiple workpieces in multiple identical manufacturing units. The results showed that it had significant advantages over many meta-heuristic algorithms [5]. Similarly, for flow shop sequential scheduling with productivity measure, He et al. proposed a greedy CCEA for Multi-Objective Optimization (MOO) in flow shop group scheduling. The algorithm outperformed existing classical methods [6]. Regarding the cloud work scheduling problem in modern business and industrial fields, Qin et al. proposed a clustering CCEA for workflow scheduling in cloud environments. The algorithm significantly surpassed the baseline with a 95% confidence level [7]. Faced with satellite ranging scheduling, Xiong et al. proposed a CCEA based on elite archive strategy to provide a set of selectable schedules while maintaining the quality of the solution. This method outperformed comparative algorithms on effectiveness, diversity, and flexibility [8]. Faced with the limitations of most current architectural representation schemes, which cannot discover the limitations of more powerful liquid state machine architectures, Zhou et al. proposed a generative liquid state machine. The library structure of this state machine was evolved using a CCEA, and the weights of the algorithm were adjusted according to synaptic plasticity rules. This algorithm performed better than other methods on benchmark problems. The analysis indicated that the data parallel strategy was effective in accelerating the evaluation process [9]. Faced with problems such as short and fuzzy query length, and

difficulty in extracting user intent from queries to establish a good query recommendation system, Barman et al. designed a CCEA-genetic algorithm for query recommendation. The algorithm adopted independent subpopulations to simultaneously solve sub problems. It searched for the complete Pareto optimal solution by gathering relevant members from two subpopulations [10].

Due to the dynamic characteristics of the vehicle network, the accuracy of traditional parking lot allocation methods is not high, which is confusing for both parking lot owners and vehicle owners [13]. Therefore, Hassija et al. built a new parking resource allocation method on the basis of virtual election to address the problems in parking resource allocation. Based on this method, users and parking lot owners easily reached a consensus on how to allocate parking spaces using the lowest bandwidth [14]. In response to the insufficient parking spaces in modern cities, Duan et al. designed a personalized parking guidance service, which described the relationship between the personalized parking service and drivers by establishing a two-layer programming model. The proposed stand assignment model was found to effectively balance the shared stand resources within the service area and minimize walking distance [15]. With the sustained growth of air traffic demand, stand space resources have become the main bottleneck restricting airport development. To comprehensively consider various stakeholders, Deng et al. established a three objective gate allocation model, which considered minimizing passenger walking distance, while optimizing to improve actual efficiency. The results showed that the model could solve passenger walking distance [16]. Regarding the fairness of allocation in various airlines, Jiang proposed the NSGA-II-LNS algorithm to model the airport boarding gate allocation problem as a MOO problem that minimized aircraft taxiing costs and passenger walking distance. This algorithm outperformed published algorithms on convergence and diversity of solutions [17]. In addition, acceptable computation time implies the actual potential of the research model. To address the increasing congestion pressure faced by air side ground transportation, Liu et al. designed an integrated model that simultaneously processed stand assignment and taxiway planning in a discrete spatiotemporal network. The flight pairs and connection times affected gate idle time and aircraft taxiing time [18].

In conclusion, although the current research on downtime allocation related problems has achieved some results, most of them use manual scheduling and supplemented by algorithm scheduling. However, this method lacks efficient real-time adjustment mechanism in the current parking lot allocation method in the complex and changeable operating environment of the airport, and it is difficult to deal with emergencies. At the same time, it is difficult to achieve a balanced distribution of flight types and airlines, resulting in unfair distribution of resources, which may cause competition and contradictions, and affect the fairness and efficiency of airport operation. In view of the above problems, the paper first discusses the convergence and uniformity of the multi-objective optimization problem, optimizes the characteristics of the cooperative coevolution algorithm with strong global search ability, and proposes the MSCOEA algorithm. Then, for the problem of high time complexity in traditional chromosome coding, the characteristics of quantum evolution algorithm can reduce the time complexity of the algorithm to propose a model for the optimization of parking lot allocation based on the improved MSCOEA algorithm. The contributions of this study are as follows: first, to improve the performance of the algorithm, introduce the MSCOEA algorithm and QEA, effectively improve the solving efficiency and accuracy of the parking space allocation problem, provide an effective means for large-scale and multi-target problems; the second, optimize the resource utilization, refine the multi-target optimization, realize the success rate of the highest bridge rate, and shorten the boarding distance, optimizing the utilization of airport resources, and improve the overall operation efficiency. These contributions have important implications for the issue of airport parking space allocation.

III. Methods and Materials

A. Construction of MSCOEA Model

To effectively balance convergence and uniformity in MOO problems, the MSCOEA model is proposed, which is an effective model for solving MOO problems. An adaptive random competition mechanism is built to address the difficulty in maintaining diversity in the CCEA population, enabling it to obtain more information in the next iteration process and improve the learning ability of the method. By introducing domain crossing and fully exploring the solution sets that are not dominant in the additional group, the information transmission during crossing is suppressed, and its local optimization performance is improved. Among them, in the adaptive random competition process, all individuals in each offspring group can combine with the optimal individuals in other offspring groups to obtain a complete solution result [19]. A method is proposed to use a cost function C_i to determine an individual's fitness value, in response to the time-consuming classical Pareto dominance algorithm, as shown in equation (1).

$$C_i = \min_{q \in I/i} c_{iq} \tag{1}$$

In equation (1), i represents an individual in the sub-population. I represents the approximate Pareto front. c_{iq} is described by equation (2).

$$c_{iq} = \max_{w} f_w^i / f_w^q \tag{2}$$

In equation (2), f_w^i represents a numerical vector of the objective function, which is consistent with solving i. For $C_i > 1$, individual i is not a dominant solution, but rather an advantageous solution. As C_i increases, the quality of individual i also increases. MSCOEA incentivizes the offspring population to search for areas that have not yet been found by evaluating the performance of the additional population, thereby evaluating population suitability. After obtaining the fitness $F_{i,j}$, the method further modified the additional population and determined the fitness extremum $AF_{\min}$ in the additional population. The method for determining whether a subpopulation lacks diversity is shown in equation (3).

$$\beta_{i,j}=\begin{cases}0, if\ F_{i,j}<AF_{\min}\\ 1, otherwise\end{cases} \tag{3}$$

In equation (3), $\beta_{i,j}$ represents the flag position. After g iterations, the number $\eta_{g,i}$ of individuals with fitness greater than $AF_{\min}$ in the subpopulation i is shown in equation (4).

$$\eta_{g,i}=\sum_{j\in S_i}\beta_{i,j} \tag{4}$$

In equation (4), S_i represents the size of subpopulation i. When the fitness of all individuals in subpopulation i is greater than $AF_{\min}$, $\eta_{g,i}=|S_i|$. The growth ρ_i of the non-dominant solutions contributed by the subpopulation to the additional population is shown in equation (5).

$$\rho_i=\begin{cases}\rho_i+1, if\ \eta_{g,i}<\eta_{g-1,i}\\ 0, otherwise\end{cases} \tag{5}$$

In equation (5), $\eta_{1,i}=0$. If $\rho_i=N_{comp}$, then this offspring population will have certain differences and a competitive pathway will be established for the current population, with ρ_i set to 1. At the same time, by introducing the offspring population and randomly generated offspring population into the temporary population, and analyzing the fitness of each offspring population within the temporary population, the offspring population with the highest fitness is taken as the new offspring population. For the MOO problem of CCEA, the nearest neighbor crossover method is adopted to effectively mine the non dominant solutions in the additional population and restrict the information flow, thereby improving the global optimization performance. Finally, the flowchart of MSCOEA is shown in Figure 1.

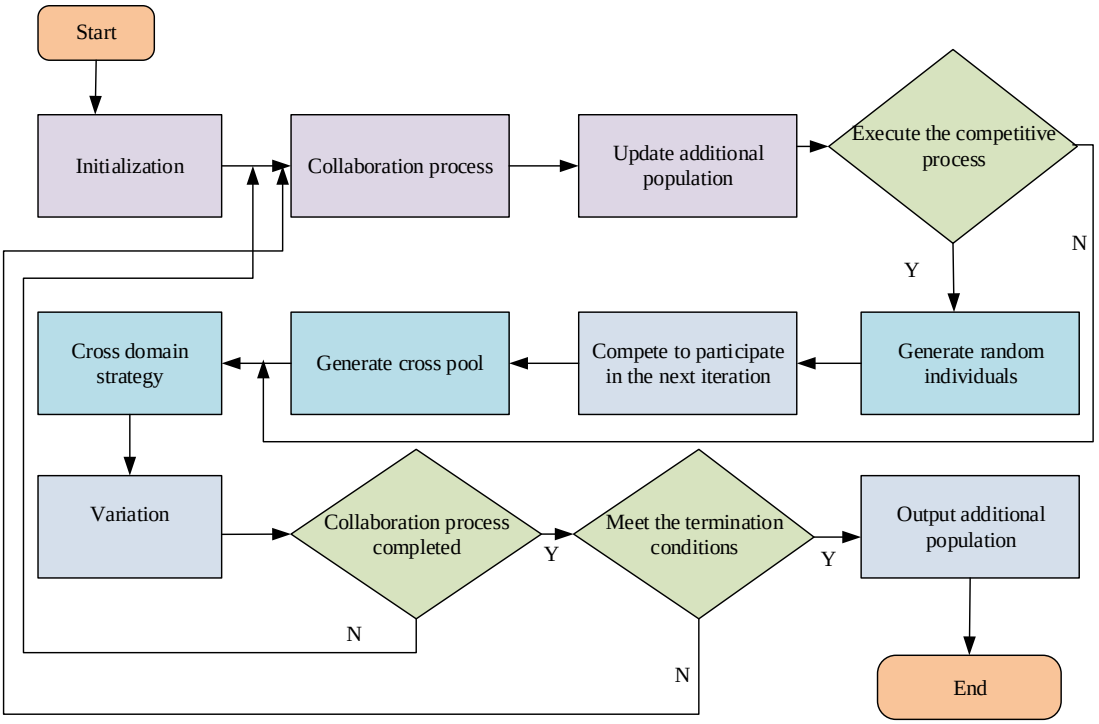

Fig. 1. Flow chart of MSCOEA.

B. Aircraft Stand Allocation Model Based on MSCOEA

After constructing the MSCOEA model, in order to reduce its time complexity, the study further improves the MSCOEA model by combining QEA. Based on this, an optimization model for aircraft stand assignment is proposed. Firstly, the rotation angle control method on the basis of Hamming adaptive is applied to obtain the rotation angle in QEA. The Hamming distance is represented by the number of corresponding coefficients between two solution elements, as shown in equation (6).

$$Hdis(S_1,S_2)=\sum_{i=1}^{m}(S_{1i},S_{2i}) \tag{6}$$

In formula (6), S represents the shutdown location of the flight, m indicates the number of flights。In the final stage of this method, the greater the similarity between the two targets, the shorter the Hamming distance and angle of the targets, thereby improving the local optimization performance of the method. The rotation angle θ_{ig} is shown in equation (7).

$$\theta_{ig}=\frac{\exp\left(c\square Hdis\left(S_i,S_g\right)\right)}{\pi+\ln(m)} \tag{7}$$

In equation (7), c represents the adjustment coefficient, satisfying $0\prec c\prec 1$. In order to avoid a decrease in its convergence rate, a probability-based method is adopted to

determine whether to turn it to a random point, and the turning angle of that point is smaller than that of the point facing the best. At this point, the quantum gate can be found in equation (8).

$$\begin{pmatrix}\alpha_i^{'}\\ \beta_i^{'}\end{pmatrix}=\begin{pmatrix}\cos\left(s\left(\alpha_i,\beta_i\right)\left(\theta_b+\theta_r\right)\right) & -\sin\left(s\left(\alpha_i,\beta_i\right)\left(\theta_b+\theta_r\right)\right)\\ \sin\left(s\left(\alpha_i,\beta_i\right)\left(\theta_b+\theta_r\right)\right) & \cos\left(s\left(\alpha_i,\beta_i\right)\left(\theta_b+\theta_r\right)\right)\end{pmatrix}\begin{pmatrix}\alpha_i\\ \beta_i\end{pmatrix} \quad (8)$$

In equation (8), θ_b signifies the rotation angle of the subgroup individuals towards the optimal individual. θ_r signifies the rotation angle of a subgroup individual towards a random individual. After integrating the QEA, the improved MSCOEA flowchart is shown in Figure 2.

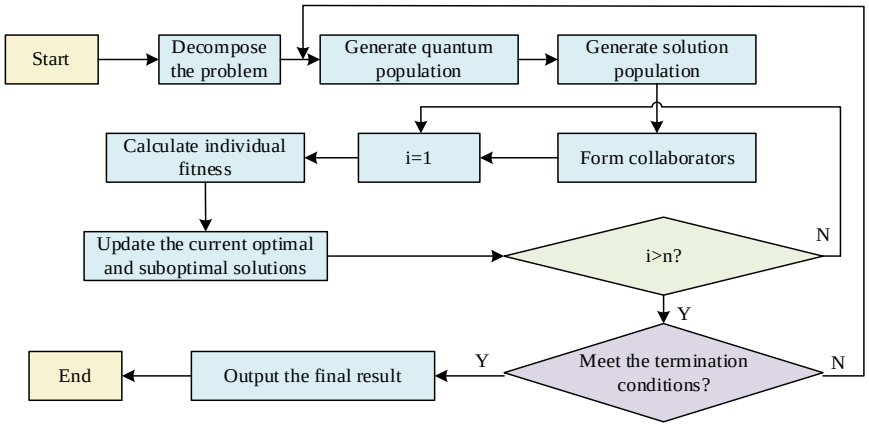

Fig. 2. MSCOEA process integrating QEA.

This model decomposes the problem into multiple sub problems, which are solved using the QEA method, and the sub groups work together to solve them. At the same time, representative individuals from each subpopulation form a complete solution set. The fitness of each subpopulation is calculated to achieve information exchange. To accelerate the convergence speed, the optimal individual from each subgroup is used to represent it. The offspring evolution is carried out through quantum gates. This study tests the algorithm performance using the knapsack problem, as shown in equation (9).

$$\max f\left(X\right)=\sum_{i=1}^{m}p_i x_i \quad (9)$$

In equation (9), x_i signifies the state of item i. When it is placed in the backpack, $x_i=1$. Conversely, $x_i=0$. p_i represents the profit of item x_i. Based on the proposed algorithm, this study aims to optimize the optimal parking position based on daily arrivals, taking into account both internal and safety factors, with a focus on passenger and airline revenue. The optimization objectives of this model include minimizing the total distance traveled by passengers, minimizing their stay time, minimizing the allocation of flights to distant locations, and maximizing the utilization of large seats. Considering the difficulty of solving MOO problems, the weighting method is taken to convert the MOO into a single objective function, as shown in equation (10).

$$F=\min\left(\lambda_1 F_1+\lambda_2 F_2+\lambda_3 F_3+\lambda_4 F_4\right) \quad (10)$$

In equation (10), λ_1, λ_2, λ_3, and λ_4 stand for the four objective weights of minimizing the total distance traveled by passengers, minimizing their stay time, minimizing the allocation of flights to the apogee, and maximizing the utilization of large seats, respectively. F represents the objective function. In summary, the study integrates QEA with MSCOEA to construct a pre-allocation model for parking positions at civil airports, as shown in Figure 3.

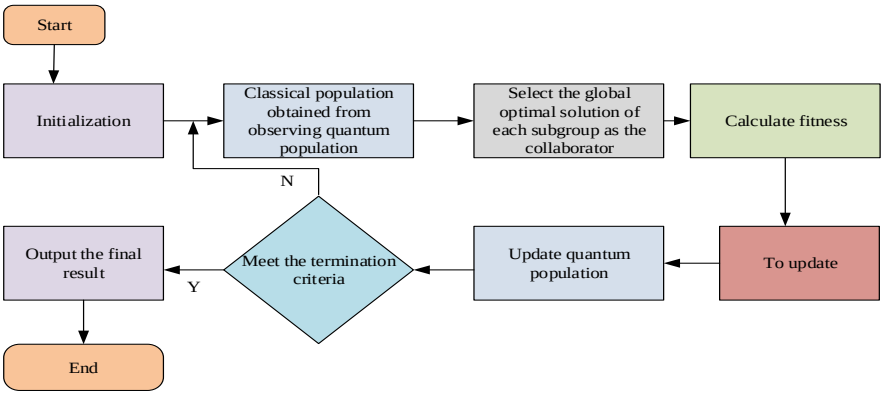

Fig. 3. Allocation method for parking positions at civil airports.

From Figure 3, this method first excludes flights that do not meet the constraints, then adds the remaining aircraft in the Important Person（VIP） aircraft group to the waiting aircraft set, and finally sorts these aircraft by parking position. For the assigned flight, it is inserted into the corresponding location of the docking point. If the constraints are satisfied, the next flight is assigned. If the constraint conditions are not satisfied, it is placed at the next docking point until all docking points have been tried once. If all VIP flight tasks cannot be completed after adjusting the solution set that has not reached the constraints, then the fitness of the solution is infinity.

IV. Results

A. Experimental Settings

To verify the effectiveness of the designed method, the comparative algorithms selected for this experiment are CCEA, Genetic Algorithm (GA), Reinforcement Learning (RL), Particle Swarm Optimization (PSO), Non-dominated Sorting Genetic Algorithm III (NSGAIII), Reference Vector Guided Evolutionary Algorithm (RVEA), Tabu Search (TS). The evaluation indicators for the quality of the solution results are Inverted Generational Distance (IGD), Pure Diversity (PD), and Pareto Set Proximity (PSP).MSCOEA The subpopulation size is 10, the evaluation number is 10000, the optimal adjustment coefficient is 1, then the individual is 0.5, the decomposition dimension is 2, the safety interval time is 8 minutes, the target weight value is 0.25, and the algorithm runs independently 20 times.The computer system used in the study was Intel(R)Core(TM)i7-7700CPU@3.6GHz with 8G RAM, Windows 10, and the algorithm was written in MATLAB 2018b, and the calculation time was 10s per time with 20 runs.The experimental environment and parameter settings are displayed in Table I.

B. MSCOEA Model Performance Testing

According to the relevant settings, after establishing the corresponding training and validation sets, the results are displayed in Figure 4.

In Figure 4, the loss of the research method in these two sets gradually decreased with the increase of iterations. When the last training ended, the loss in the training set reduced from 0.1800 to 0.1084, and the loss in the validation set reduced from 0.1362 to 0.0915. Its generalization ability continued to improve. The research model achieved a prediction accuracy of over 90% on both these two sets. As the iterations increased, the final accuracy was 96.8% and 97.53%, respectively. Taking MaF1 function as the research object, experiments are performed to study the effect of neighborhood crossover strategy on testing problems of different dimensions, as displayed in Figure 5.

From Figure 5 (a), in high-dimensional situations, the neighborhood crossover strategy resulted in poorer performance. This is in line with the expectations of the research. In low target dimensions, the search range is not large enough, and the neighborhood crossover strategy will lead to too high complexity, which will slow down the convergence rate of the method. In this way, in the case of a small search space, the neighborhood crossover strategy is constrained by information flow during traversal, which affects the global optimization of the entire algorithm. As shown in Figure 5 (b), the effect of neighborhood crossover strategy became increasingly significant as the dimensionality of the problem increased. The neighborhood crossover strategy has significant advantages in the solving process. The approximate Pareto front and approximate Pareto solution set obtained by the MSCOEA and the randomly selected comparison algorithm TS are shown in Figure 6.

From Figure 6, MSCOEA not only searched for solution sets in multiple decision spaces, but also had a similar number of non inferior solutions in each solution set. From the experimental results, MSCOEA performs better than TS in handling multi-modal and multi-objective test functions. The IGD of the solutions obtained by each algorithm for functions FON, MMF1, MMF3, and MMF4 is shown in Figure 7.

TABLE I. Experimental Settings

Sum	Set up
Subpopulation size	10
Additional population A size	100 for FON,800 for MMF1, MMF3 and MMF4, 240 for MaF1 and MaF3

(c) IGD of MMF3 (d) IGD of MMF4

Fig. 7. Results of each algorithm for function FON, MMF1, MMF3, MMF4.

From Figure 7, the performance of MSCOEA in solving single modal, low dimensional, and multi-index problems such as MMF1 and FON was superior to other comparative methods, indicating that MSCOEA can not only efficiently find and maintain overall consistency, but also has higher stability. The reason for this is largely due to the constraints of information flow when using neighborhood crossover strategy, which affects its overall optimization performance. However, the performance of MSCOEA surpasses that of basic CCEA. For the two types of multi-objective programming problems MMF3 and MMF4, MSCOEA can search for the actual Pareto front and the Pareto solutions. The difference between the optimal solutions obtained by MSCOEA when solving two types of Pareto optimal solutions is not significant, which provides a basis for decision makers to better choose the optimal solution. MSCOEA can not only solve Pareto frontier problems, but also solve distributed solutions on multiple Pareto sets, and the proportion of solutions on each Pareto set is similar. This is mainly due to the competitive mechanism that makes the offspring population more diverse, thereby making the decision-making space more complete throughout the entire evolutionary process. The performance test results of the algorithm for optimizing the objective functions of MaF1 and MaF3 are displayed in Table II.

TABLE II. IGD VALUES OF VARIOUS ALGORITHM TEST RESULTS WHEN M=10

Evaluation index value	CCEA	GA	RL	PSO		NSGAMIII	RVEA	TS	Ours
MaF1	Evaluation index value	3.19E+02	3.031E+00	4.54E+03	2.79E+01	2.90E+01	5.45E+02	4.28E+01	2.330E-01
	Quantity excellence	3.91E+02	3.18E+00	4.82E+03	2.85E+01	2.98E+01	688+01	4.83E+01	2.38IE01
	mean value	4.92E+01	3.360E+00	5.170E+00	2.90E+01	3.07E+04	8.48E+02	5.62E+01	2.45E+01
	Quantity difference	5.87E-01	7.000E-06	3.17E-04	5.000E-06	1.93E+05	6.05E+00	60686504	6.82E+06
MaF3	Evaluation index value	3.337E+01	1.157E+00	8.05E+07	2.625E+11	9.07E+03	7.65E+03	1.06E+01	L157E-00
	Quantity excellence	2.0600E+02	1.720E+00	2.692E+05	4.420E+11	2.14E+01	8.00E+05	1.10E+01	L328E-00
	mean value	4.495E+02	2.194E+00	5.155E+05	7.15E+11	3.60E+01	8.32E+01	1.17E+01	L561E-00
	Quantity difference	9.90E+03	3.880E-04	L399E+10	9.289E+21	6.17E+03	3.49E-03	9.86E+65	L219E-04

From Table II, MSCOEA has shown good convergence performance in both aspects, which is in line with the previous results on neighborhood crossover. Through this study, MSCOEA has good solving effects on these three types of MOO problems, which can improve the convergence speed and balance the compatibility of the solution set obtained. The final solution set can reflect the set of actual solutions. In single-mode multi-objective programming problems, the proposed

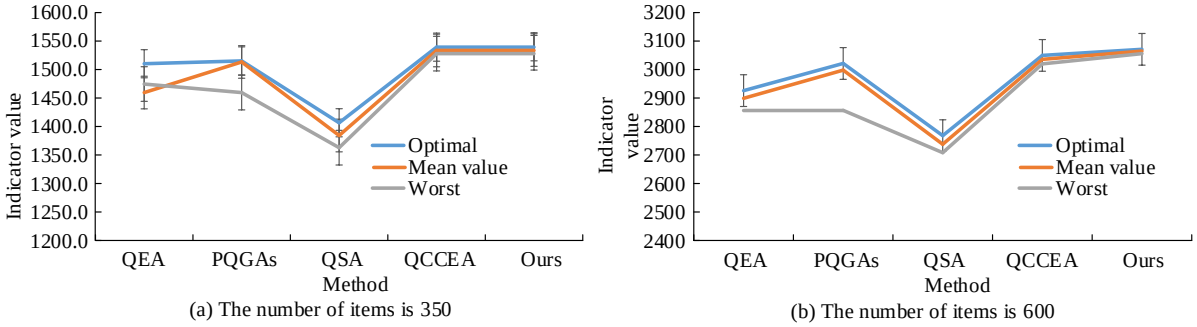
method can comprehensively cover the Pareto frontier. In addition, the new method proposed in the study does not rapidly decrease in computational efficiency with the increase of the target space dimension when solving three types of single-mode high-dimensional MOO problems, and has good solving efficiency. The algorithm has good balance between convergence and uniformity, and has better stability.

C. Test of Civil Aircraft Stand Allocation Model Based on MSCOEA

To verify the proposed civil aviation aircraft, stand allocation model, a civil aviation airport is randomly taken as the research object. The flight data of the airport on a certain day are collected to construct the research database. The research data include 250 flights and 30 parking places. On this basis, 10% of the aircraft in each airport is regarded as VIP, and the parking seats of each airport is sorted in order. The safety interval is set to 8min. When the aircraft is pushed out, the aircraft adjacent to the seat shall not move within 5min. The weight of the indicator is 0.25. The subgroup is 2, and the maximum evaluation is about 200. The algorithm is executed 20 times separately. Firstly, QEA, QoS-aware Subcarrier Allocation (QSA), Phase-based Quantum Genetic Algorithm (POGA), research model and Quantum inspired Contest Evolution Algorithm (QCCEA) are selected to solve the knapsack problem, and 350 and 600 groups of data are set to examine the optimization problem, as displayed in Figure 8.

From Figure 8, with the increase of the problem scale, the efficiency of the research method also appeared. At 350 and 600, on the basis of Hamming adaptive rotation angle, the Random Rotation Direction Strategy (RRDS) effectively avoided local extremum and improved the global optimization ability. With the increase of the problem scale, its impact on the solution efficiency was increasingly significant. The convergence process of the three models is shown in Figure 9.

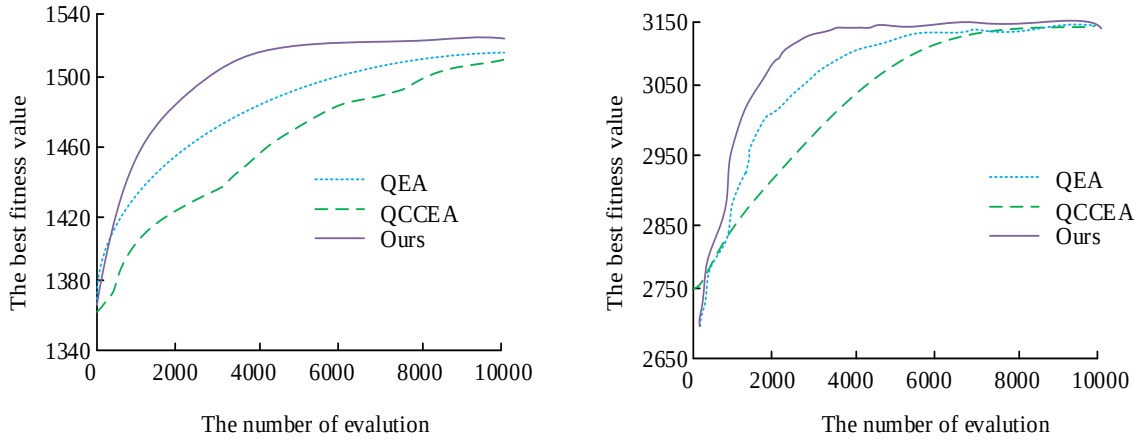
From Figure 9 (a) and (b), the research method had higher convergence efficiency than the other two methods in the case of 350 and 600. Although the results of QCCEA are better than QEA, it is always the slowest among the three methods. This is mainly because in CCEA, adding the cooperation mode can improve its convergence, but there are a lot of repeated optimization, which reduces its convergence rate. On this basis, the adaptive rotation angle and RRDS can not only effectively solve the above problems, but also avoid falling into local minima, so as to speed up the convergence rate and enhance the convergence performance. After verifying the knapsack problem, to further verify the civil aircraft stand allocation model, the proposed model is compared with QEA, OSA and POGA algorithms. The results are shown in Figure 10.



(a) The number of items is 350

(b) The number of items is 600

Fig. 8. Experimental results of knapsack problem.



(a) Item=350

(b) Item=600

Fig. 9. Comparison of convergence results of various models.

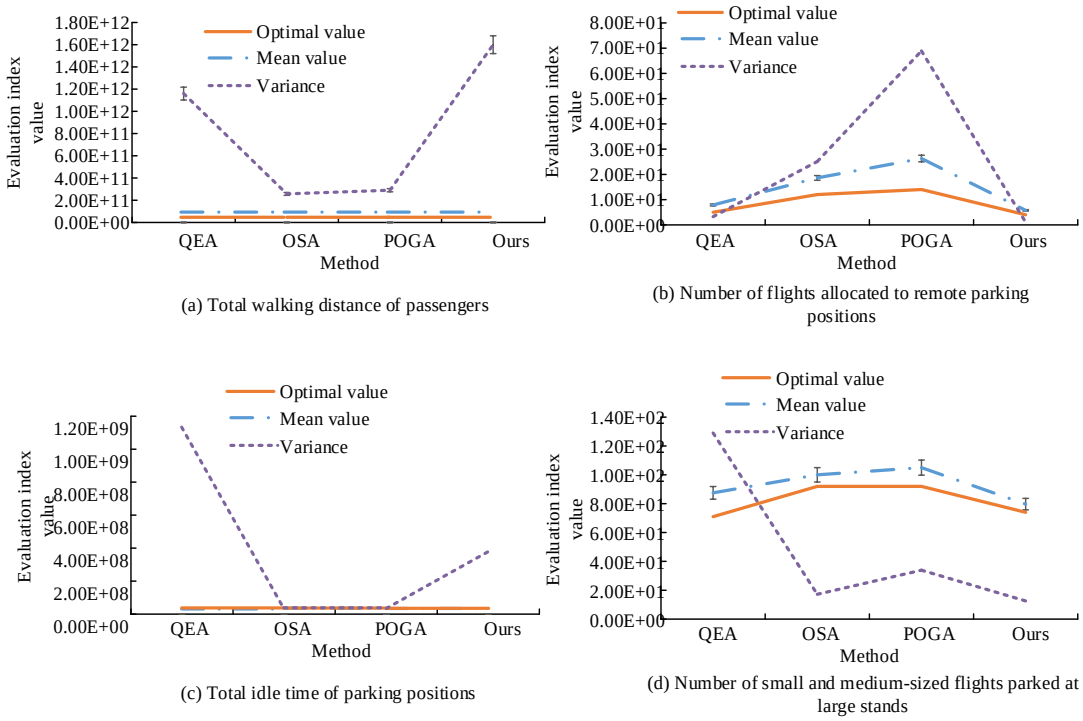


Fig. 10. Performance results of each algorithm on each optimization objective.

In general, the proposed research method achieved the same performance as other similar algorithms on most problems, which achieved the optimal allocation ratio of 98.4%, which surpassed the other three types of methods. In addition, the proposed model was applied to the optimal allocation of large-scale downtime resources, and its optimal value was 7.40 e+01. From Figure 10 (a) and (c), existing IPQEA and OSA methods had a large number of empty distances to be allocated, which not included the passenger travel distance. Therefore, the optimization effect of IPQEA and OSA methods in terms of passenger travel distance surpassed the other two methods. From Figure 10 (b), the average value of the research method on minimizing the number of flights allocated to the apogee was 5.75e+00, the optimal value was 4.00e+00, and the variance was 1.04e+00. In comparison to the other algorithms, the research method has better performance. From Figure 10 (d), the average optimization result of the research method in maximizing the utilization rate of large seats was 7.97e+01, and the optimization result on variance was 1.26e+01, which was better than other comparative algorithms. The designed algorithm has good robustness and reliability.

V. Discussion

In order to solve the problem of civil aviation parking lot allocation, the study is coevolution algorithm and QEA. In view of the shortcomings and shortcomings of the coevolution algorithm and QEA, the two algorithms are used for deep fusion to improve the optimization performance of the algorithm for complex optimization problems. Firstly, it studies the problem with the multi-objective optimization problem, optimizing the global search ability of the cooperative coevolution algorithm, and proposes the MSCOEA algorithm. In the performance test of the algorithm, the study found that the accuracy of the algorithm reached more than 90% and had better performance. In the process of solving functions FON, MMF 1, MMF 3 and MMF 4, it is found that MSCOEA solves mono low-dimensional multi-indexes such as MMF 1 and FON better than other comparison methods, indicating that MSCOEA can not only efficiently find and maintain the overall compatibility, but also has higher stability. This is because when using the neighborhood crossing strategy, it is constrained by the information flow, which affects its overall optimal performance. For MMF 3 and MMF 4, MSCOEA can not only complete the search for the actual Pareto frontier, but also complete the complete search for the Pareto solution of the decision space. Compared with the downtime optimization method proposed by Deng et al. [19] in ref, the difference between the optimal solutions obtained by MSCOEA when solving the two types of Pareto optimal solution is not obvious, which will provide a basis for the decision makers to better choose the optimal solution. This is mainly because the competition mechanism makes the offspring group more diverse, which makes the decision space in the whole evolutionary process more complete.

Then, the research for airport parking space allocation problem, with passenger walking distance, parking space idle time, allocated to the far number of flight and large station utilization to optimize the target airport parking space optimization model, and put forward the quantum cooperative collaborative evolution algorithm to establish multiple target airport parking space optimization model. The results show that the proposed method has high convergence efficiency, with better convergence compared with QEA, QSA, POGA and QCCEA in the cases of 350 and 600. Meanwhile, this result, compared with the collaborative optimization algorithm

improvement strategy proposed by [20] in the literature, achieves the value of 7.97 E + 01,1.26 E + 01, with better robustness and reliability. This is because the quantum cooperative coevolution algorithm introduces the cooperative coevolution strategy, which improves the global search capability of the algorithm. As can be seen from the number of unassigned flights, the mean, optimal value and variance of the research method on the number of flights assigned to the remote flight position are 5.75E+00,4.00E+00,1.04E+00 respectively. This result is because the Haiming adaptive rotation angle strategy was designed to adjust the search step size and optimize the convergence speed and accuracy of the algorithm.

VI. Conclusion

With the rapid development of economy and society, the problem of shutdown allocation presents complex characteristics such as high-dimension, multi-objective and multi-constraint, which makes it difficult for traditional optimization algorithms to solve and solve low efficiency. In view of this problem, the problem of convergence and uniformity of multi-objective optimization, and the MSCOEA algorithm is proposed to improve the local search ability of the algorithm. The experimental results show that MSCOEA can effectively balance convergence and uniformity and provide stable performance for many types of multi-objective optimization problems. Secondly, for the problem of high time complexity in the traditional chromosome coding mode, the study of QEA algorithm can reduce the time complexity of the algorithm, put forward an optimization method model of civil aviation downlot allocation based on MSCOEA algorithm, and realize a new downlot allocation method. In order to verify the optimization ability of the research method, the backpack problem and the actual airport operation data were selected to verify the optimization performance of the algorithm. The experimental results show that MSQCCEA has good convergence speed and convergence accuracy, and the proposed downbit allocation optimization method can allocate downbits reasonably and effectively.

However, the algorithm proposed in this study still has two limitations. First, the convergence and stability of the algorithm are susceptible to factors such as population diversity, competitive strategy and quantum decoherence; second, the model adaptability and practical application are limited, such as airport layout, flight flow, passenger demand and so on are difficult to be fully quantified, leading to the limited accuracy and practicability of the model. In order to meet these challenges, future studies can adjust the competitive strategy parameters and introduce adaptive competitive strategies to improve the convergence and stability of the algorithm; meanwhile, through the configurable parameters and rules, the model can flexibly adapt to different airport layout and flight conditions, and improve the adaptability and practicability of the model.

Enhancing Urban Mapping in Indonesia with YOLOv11

A Deep Learning Approach for House Detection and Counting to Assess Population Density

Muhammad Emir Kusputra, Alesandra Zhegita Helga Prabowo, Kamel, Hady Pranoto
Computer Science Department-School of Computer Science, Bina Nusantara University, Jakarta, Indonesia

***Abstract*—Object recognition in urban and residential settings has become more vital for urban planning, real estate evaluation, and geographic mapping applications. This study presents an innovative methodology for house detection with YOLOv11, an advanced deep-learning object detection model. YOLO is based on a Convolutional Neutral Network (CNN), a type of deep learning model well suited for image analysis. In the case of YOLO, it is designed specifically for real-time object detection in images and videos. The suggested method utilizes sophisticated computer vision algorithms to recognize residential buildings precisely according to their roofing attributes. This study illustrates the potential of color-based roof categorization to improve spatial analysis and automated mapping technologies through meticulous dataset preparation, model training, and rigorous validation. This research enhances the field by introducing a rigorous methodology for accurate house detection relevant to urban development, geographic information systems, and automated remote sensing applications. By leveraging the power of deep learning and computer vision, this approach not only improves the efficiency of urban planning processes but also contributes to the development of more resilient and adaptive urban environments.**

Keywords*—YOLOv11; object detection; house detection; house counting; computer vision; deep learning; urban mapping

I. INTRODUCTION

The rapid advancement of computer vision and deep learning technologies has transformed the processing and understanding of urban scenes [1]. Automatic detection of residential buildings has become an important task for urban planning, property valuation, and geographic information systems [2]. Although there have been considerable achievements regarding generic object detection, the house detection problem requires further investigation [3]. Hence, the central question this research seeks an answer to is "How well can YOLOv11 be adapted for house detection and counting?"

Various research works have demonstrated that recent developments of the You Only Look Once architecture, mainly YOLOv11, have opened up newer avenues for highly accurate and speedy object detection [4]. The present study makes use of the developments to address the particular problem of house detection with a focus on the classification of roof color by categorizing roofs into three unique classes: red, white, and black. This approach not only enhances our understanding of urban structure but also provides vital information for various applications in urban development and planning [5].

The use of various predictive models has been investigated in several studies for the integration of color-specific roof detection. Some particular challenges presented here include changes in lighting conditions and regional architectural differences, including requirements for robust color classification algorithms [6][7]. Traditional methods, rule-based building detection approaches are often plagued with difficulties in achieving accurate color classification due to environmental factors and complexities within the architecture itself [8]. Since most of the current approaches use fixed thresholding, mathematical rules, or logical conditions to extract features related to texture, geometry, or color from aerial or satellite images. This work overcomes the existing shortcomings by developing a broad methodology that includes the integration of YOLOv11 and overcomes the disadvantages mentioned in the studies [9]. Besides that, YOLOv11 also can do object detection, multi-class object detection, handling occlusion, scale variance detection, and many more.

The use of various predictive models has been investigated in several studies for the integration of color-specific roof detection. Some particular challenges presented here include changes in lighting conditions and regional architectural differences, including requirements for robust color classification algorithms [6][7]. Traditional methods, rule-based building detection approaches are often plagued with difficulties in achieving accurate color classification due to environmental factors and complexities within the architecture itself [8]. Since most of the current approaches use fixed thresholding, mathematical rules, or logical conditions to extract features related to texture, geometry, or color from aerial or satellite images. This work overcomes the existing shortcomings by developing a broad methodology that includes the integration of YOLOv11 and overcomes the disadvantages mentioned in the studies [9]. Besides that, YOLOv11 also can do object detection, multi-class object detection, handling occlusion, scale variance detection, and many more.and architectural differences, tackling a significant difficulty in roof color categorization [7].

Works have shown the superiority of the YOLO (You Only Look Once) Version 11 algorithm against state-of-the-art object detection systems such as Faster R-CNN and RetinaNet; YOLOv11 performs better on various vital metrics. Faster R-CNN has an mAP of 82.3% on building detection tasks, while YOLOv11 improves it to 88.7% while maintaining faster inference timings [5]. The improved feature pyramid network in the architecture has proven quite effective at managing scale

changes, outperforming SSD by 6.2% for building detection tasks under diverse environmental circumstances [1]. This study tested the YOLOv11 architecture's ability to detect dwellings using aerial imagery. The project aims to improve urban planning by developing an automated system that can accurately and reliably recognize and count dwellings [1].

Model development: PyTorch was used to design and train the YOLOv11 model for the house detection and roof color classification system. PyTorch was chosen for its versatility and deep learning power, enabling rapid testing and implementation of cutting-edge methods. YOLOv11, the latest in the series, was chosen for its real-time detection, precision, and robustness in complicated and congested environments. Key model development goals were [1]:

1) Precision House Identification: The model detects and localizes dwellings in aerial imagery independent of shape, size, or orientation.

2) Precision House Counting: The system accurately counts the number of detected dwellings, ensuring reliable data for analysis.

Implications and Goals: This work intends to improve urban planning by automating house layout. This method can increase urban analytic efficiency and precision, guiding infrastructure construction, population density assessments, resource allocation, and other planning [1]. Building identification is addressed utilizing YOLOv11. The technique and evaluation framework emphasizes transparency and reproducibility for catastrophe management, environmental impact evaluations, and real estate monitoring. This research establishes aerial and satellite image analysis refinement and scalability.

This scientific document is structured to facilitate comprehension of the entire study topic. Chapter 1 introduces the topic of Yolo Version 11 for object detection. Chapter 2 is a literature review examining pertinent studies conducted by other researchers. Chapter 3 constitutes the principal segment of the research approach. Chapter 4 presents the experimental data and provides a comprehensive analysis thereof.

II. Related Work

The first related study is entitled "Automatic Detection of Rooftop Buildings in Aerial Imagery Using YOLOv7 Deep Learning Algorithm" by Rangga Gelar Guntara [10] and concentrates on employing deep learning for rooftop identification in aerial imagery. This study trained and tested a YOLOv7 model with a dataset of annotated aerial images. The study shows that precision can be improved by increasing the amount of training data and fine-tuning model parameters. The study concludes that the automation of rooftop detection with aerial images and deep learning saves time and resources. This approach has great potential for various applications, including urban planning, disaster management, and infrastructure construction.

The second is that by S.Ghaffarian, Automatic Building Detection Based on Supervised Classification Using High-Resolution Google Earth Images [11], in which a fresh technique of building objects automatic detection based on a supervised classification that exploits shadows produced from three-dimensional buildings is advanced. In the approach initially taken in identifying the shadow regions, utilizing the brightness component of the LAB color space has been conducted using a double-thresholding methodology. First, the training areas are determined based on creating a buffer zone around each detected shadow, according to its morphology and the direction of sunlight illumination. Enhanced Parallelepiped Supervised Classification is then performed with added standard deviation thresholding for refining. Finally, morphological techniques are used to clean up the noise and enhance the outcome. Very good results have been obtained for the tests conducted on high-resolution Google Earth images. Despite the variance of attributes with different color varieties, this technique showed promises in identification within both urban and suburban environments.

The third study is entitled "Classification of House Categories Using Convolutional Neural Networks (CNN." [12] This work discusses the perennial challenge of automating the classification of residential categories, including condominiums, detached houses, shophouses, and townhouses, which is a crucial operation that is, to this date, performed mostly manually in many scenarios and thus is plagued by inefficiencies and repetitive errors. The goal of this work was to develop an appropriate Convolutional Neural Network (CNN) model for classifying house categories. Four models were evaluated; the best three models (Based model, ResNet50, and MobileNet). All three demonstrated suitability for house category categorization, with the Based model being the most effective. This work underscores the efficacy of CNN-based models in automating categorization processes, enhancing productivity, and minimizing errors in practical applications.

Lastly, a pertinent work entitled "Underwater Object Detection Based on Improved EfficientDet" by Jiaqi Jia investigates the creation of a marine creature object identification model, EDR, founded on an enhanced EfficientDet architecture [13]. The research integrates Channel Shuffle into the backbone feature network to improve feature extraction efficiency and minimize parameter redundancy by substituting the fully connected layer with convolutional layers. An Enhanced Feature Extraction module facilitates multi-scale feature fusion, markedly enhancing the detection correlation across different feature sizes. The model demonstrates superior detection efficiency relative to alternative methods; nonetheless, it encounters obstacles, including prolonged calculation time and latency on low-powered devices such as laptops. Furthermore, detection challenges such as false positives and overlooked detections in densely populated object regions signify a necessity for underwater image augmentation methodologies. Proposed future work involves refining the model for additional underwater targets, including marine debris, and improving engineering applications for object localization and manipulation in underwater environments.

The fundamental distinction between the initial study and our research is in:

1) Architectural innovation: The initial study utilized YOLOv7 for rooftop identification, but our research utilizes YOLOv11, the most recent version in the YOLO series. YOLOv11 employs sophisticated designs for improved feature extraction and detection efficacy, rendering it more proficient in rooftop detection. In contrast to the third study, which highlights CNN-based classification of housing types, and the fourth study, which concentrates on underwater object detection utilizing the EDR model based on EfficientDet, our research employs YOLOv11 for both object recognition and enumeration, thereby enabling a holistic approach to urban planning.

2) Performance metrics: This study primarily assesses performance through mean Average Precision (mAP), a comprehensive metric for evaluating detection skills across multiple confidence thresholds. The initial study employs F1 scores, which, although practical, may not encompass the complete range of detection capability provided by mAP. Likewise, the third study depends on precision, which is less thorough. In contrast, the fourth study emphasizes enhancements in detection efficiency but lacks an in-depth analysis of specific measures such as mAP, underscoring the superiority of our more thorough evaluation methodology.

3) Methodological approach: Our study focuses on static detection in various scenarios with a view for real applications that need fast processing and analysis of aerial imagery. The first study confines its work in static images; the third one finds major application in the tasks of image classification without any real-time factor included. The fourth study extends to underwater object detection but ignores the urban application domain and highlights the different applicability of our methodology in urban settings.

4) Processing efficiency: Employing YOLOv11, our methodology offers more efficient processing of high-resolution aerial imagery to minimize computing overhead, hence enhancing detection accuracy compared with YOLOv7 in the preliminary analysis. training The EDR model in the fourth investigation shows enhancements in underwater detection but experiences latency on devices with lower power, such as laptops. Conversely, our methodology guarantees dynamic and scalable detection for urban applications with appropriate processing durations.

These distinctions emphasize our research's aim to enhance automatic house detection and counting by employing innovative structures and more thorough evaluation measures while ensuring practical application in real-world contexts.

III. Research Methodology

A. Dataset

Data and inputs: this study used aerial images to compile a rich urban landscape dataset. These datasets form the basis for the detection system, covering a wide range of urban contexts. The Supplementary Materials describe these datasets acquisition techniques, regions, and preprocessing. Important model inputs are: [1]

1) Unedited aerial images: Raw image data from drones or satellites showing real-world events.

2) Image resolution: Pixel density preserves fine details needed to recognize small or overlapping structures.

3) Viewing angles: The aerial image's perspective may influence roof shapes, colors, and building geometry.

4) Environmental variables: Shadows, atmospheric conditions, and occlusions from trees, poles, or adjoining buildings can obscure pictures.

This study examines house identification and counting with the YOLOv11 model architecture. The procedure for dataset preparation and model training is outlined in the form of a flowchart in Fig. 1, as follows:

1) Compilation of dataset: Aerial photographs of residences in Indonesia, each measuring 15,189 × 15,189 pixels, were acquired in high quality. The big images were divided into smaller portions of 640 by 640 pixels, yielding a dataset of 1,064 images.

2) Annotation procedure: The dataset was annotated utilizing Roboflow, a tool engineered for adequate labeling and dataset administration. Three categories of roof colors were established: black roofs (Class 0), red roofs (Class 1), and white roofs (Class 2). This classification method improves detection precision by distinctly differentiating the three roof colors.

3) Partitioning of dataset: The annotated dataset was divided into three subsets: 70% for training, 20% for validation, and 10% for testing, guaranteeing a balanced distribution for practical model assessment and generalization.

4) Export of dataset: The dataset was exported in a format suitable with YOLOv11, conforming to the specifications for practical model training.

5) Training the model: The training was initiated with the pre-trained model YOLOv11m.pt as the base model. The main parameters for training included an image size of 640 × 640 pixels, a batch size of 8, and 100 epochs of training. Training was performed using a GPU to increase speed and efficiency.

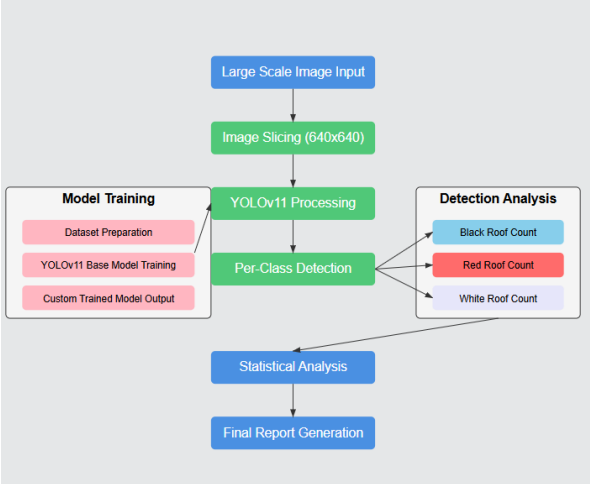

Fig. 1. Flowchart for building the model.

The result of this approach is a bespoke YOLOv11 model, meticulously refined for the detection and counting of dwellings. This methodical approach illustrates the efficacy of the methodology in tackling house detection and counting.

B. Confusion Matrix

The confusion matrix is a fundamental evaluation instrument in machine learning, comprehensively analyzing a model's performance by juxtaposing predictions with actual ground facts. It offers a fundamental framework for comprehending the strengths and weaknesses of models, particularly in multi-class classification tasks such as the detection and categorization of rooftops in this study [14][15].

Key Metrics in the Confusion Matrix

1) True Positives (TP): Instances where the model correctly identifies the target class.

2) True Negatives (TN): Instances where the model correctly identifies the absence of the target class.

3) False Positives (FP): Instances where the model mistakenly identifies a target class (Type I error).

4) False Negatives (FN): Instances where the model fails to detect a target class (Type II error).

This work utilizes the confusion matrix as a crucial instrument to assess the effectiveness of the YOLOv11 model in recognizing rooftop colors and identifying items. The matrix offers comprehensive insights into the model's classification accuracy for various roof kinds (red, white, black) and identifies areas for enhancement [16].

Analyzing the matrix reveals recurrent false positives or negatives for particular roof types, aiding in refining detection algorithms. For instance, black roofs frequently exhibit elevated misclassification rates owing to their diminished contrast with the background. By class the matrix allows us to measure the model's efficacy in managing imbalanced data, such as identifying unusual classes like black roofs, hence assuring consistent performance across all categories. The confusion matrix elucidates the fine-tuning process by identifying detection bottlenecks, enabling adjustments to the model design or training settings to mitigate mistake rates.

This work adopts the confusion matrix for a multi-class item detection task. Each class (red roof, white roof, black roof) is represented in a grid where the rows are actual classes and the columns are predicted classes [17][18].

This research illustrates how utilizing the confusion matrix assesses YOLOv11's efficacy and facilitates iterative enhancements, guaranteeing resilient and scalable rooftop detection for practical urban applications [19].

C. Yolo Architecture

The YOLO design has 24 convolutional layers, augmented with four max-pooling layers, and concludes with two fully linked layers. Numerous convolutional layers utilize 1×1 reduction layers to diminish the depth of feature maps [20]. This architecture, presented by Joseph Redmon, is depicted in Fig. 2.

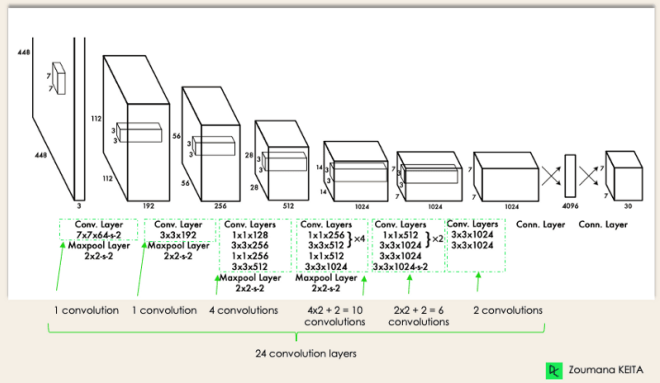

Fig. 2. Yolo Architecture [31].

The backbone of the YOLO architecture has undergone substantial evolution, progressing from a modified GoogLeNet in YOLOv11 to more advanced configurations. YOLOv3 introduced the Darknet-53 architecture, which utilized residual and skip connections, markedly enhancing feature extraction capabilities [21]. The progression advanced with CSPDarknet in YOLOv4, which implemented Cross-Stage Partial Networks to improve gradient flow and mitigate computing bottlenecks [22].

The neck architecture facilitates feature fusion and enhancement and has undergone significant advancements. YOLOv4 introduced PANet (Path Aggregation Network), facilitating bidirectional information transfer across various detection sizes. YOLOv5 was further enhanced by incorporating Cross Stage Partial (CSP) blocks in the neck, thereby augmenting the model's capacity to manage scale variations [23].

Instead of grid-based prediction, the detection head now uses more advanced methods. Multiple prediction heads at different scales were introduced in YOLOv3, and later versions improved anchor-based detection. Using an anchor-free technique, YOLOv8 simplified the detection pipeline while preserving accuracy. The loss function architecture has evolved from simplified L2 loss in early iterations to more complex formulations [24].

D. SSD Architecture

Fig. 3 shows that the SSD (Single Shot MultiBox Detector) architecture is a convolutional neural network made for effective object detection. Up until the Conv5_3 layer, which acts as the feature extractor for input images of size 300×300×3, it uses the VGG-16 network as its backbone. Additional convolutional layers are added outside the backbone to allow multi-scale object detection. The model can identify objects of different sizes thanks to these layers' gradual reduction in size from 19x19 to 1x1 feature maps.

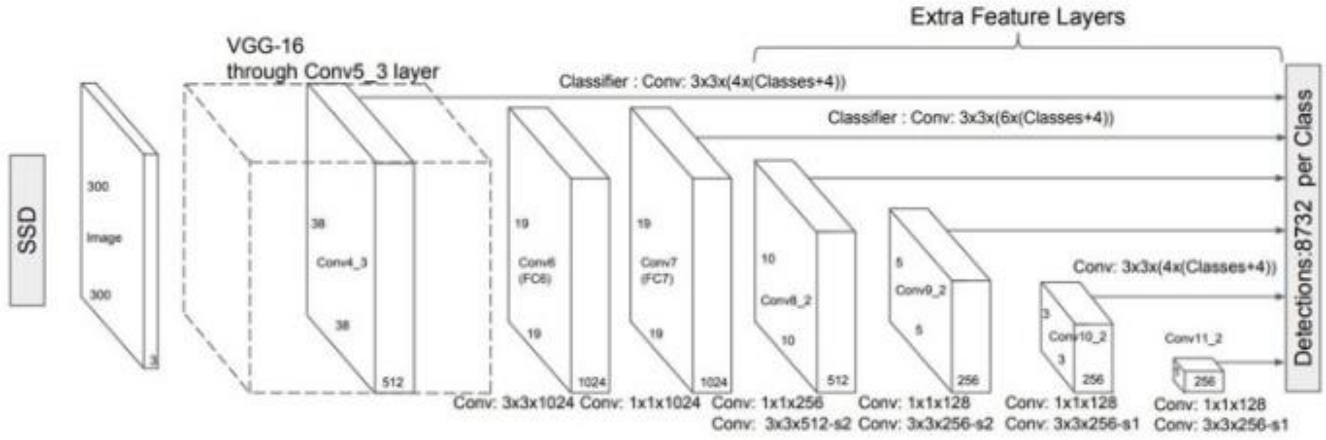

Fig. 3. SSD Architecture [32].

In order to anticipate the object classes and bounding box offsets, each feature map is classified using 3x3 convolutional filters. Predictions are made for "Classes+4" parameters, which are the extra four parameters that correlate to the bounding box coordinates. Conv6 (FC6) and Conv7 (FC7) are important network layers that produce 19x19 feature maps with 1024 depths. To ensure multi-scale detection capability, subsequent layers from Conv8_2 to Conv11_2 generate increasingly smaller feature maps (e.g., 10x10, 5x5, 3x3, and 1x1).

The architecture uses outputs from several feature layers to support 8732 detections for all classes. Because of its design, SSD can effectively identify both large and small things in a single image. SSD is very successful for real-time object detection tasks because it strikes a compromise between speed and accuracy by combining multi-scale detection techniques, additional feature layers, and a backbone network [25].

E. EfficientDet Architecture

The graphic in Fig. 4 depicts the EfficientDet architecture, which leverages the high efficiency and scalability of the EfficientNet backbone for feature extraction. The EfficientNet backbone processes the input image at several layers, producing feature maps at various resolutions (P1/2, P2/4, P3/8, P4/16, P5/32, P6/64, and P7/128). The BiFPN (Bidirectional Feature Pyramid Network) layer receives these feature maps and uses them to enable feature fusion across scales and bidirectional information flow. In order to provide effective feature propagation across higher and lower-resolution feature maps, the BiFPN layer uses weighted connections to optimize the fusion process.

The class prediction network and the box prediction network are the two prediction networks that are used after the BiFPN. At each resolution level, these networks' convolutional layers predict bounding box coordinates and item classifications, accordingly. EfficientDet can identify objects of different sizes with great accuracy and computing efficiency thanks to its multi-scale design.

The architecture strikes a balance between speed and accuracy by combining the capabilities of EfficientNet, BiFPN, and multi-scale predictions. Because of its scalable architecture, users can modify the model for a variety of uses, from high-performance activities to environments with limited resources [26].

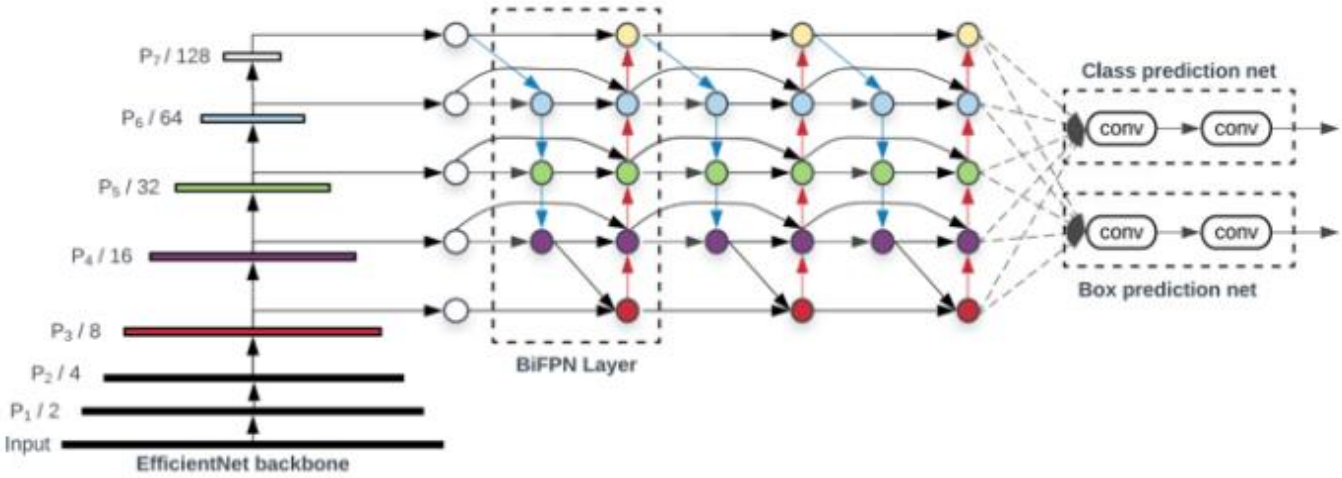

Fig. 4. EfficientDet architecture [33].

F. Faster R-CNN Architecture

The graphic in Fig. 5 illustrates the Faster R-CNN architecture, a two-stage object detection framework that integrates object categorization and region proposal creation into a single network. In order to extract feature maps, input images are first run through convolutional layers, frequently with the help of a backbone network such as VGG-16. The Region Proposal Network (RPN), which uses a sliding window technique to create object-like region proposals, is then fed these feature maps. Several anchor boxes at various scales and aspect ratios are suggested for every sliding window.

The RPN outputs a collection of region proposals and their objectness scores—a measure of how likely they are to contain an object. The second step involves refining and feeding these recommendations into an ROI (Region of Interest) pooling layer. Combining features from the original feature map, the ROI pooling layer creates fixed-size feature maps for every suggested region.

In the last phase, a classification network is used, in which each proposal is bounding box coordinates are refined, and fully connected layers predict the class label. By combining the detection and region proposal phases, Faster R-CNN eliminates the requirement for independent region proposal computation and offers notable efficiency gains over its predecessors [27].

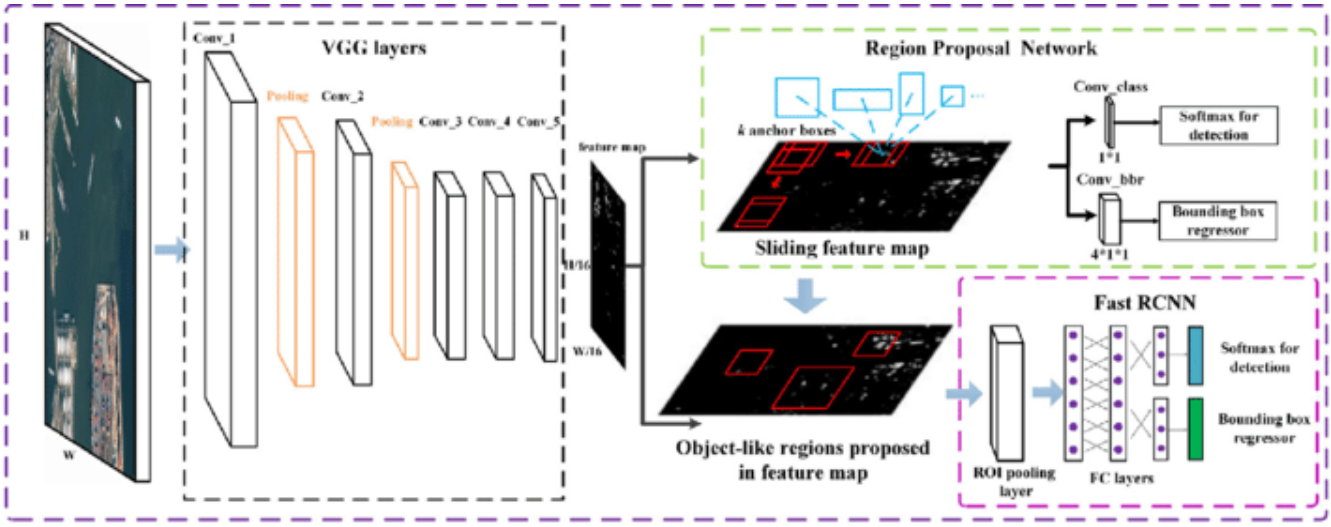

Fig. 5. Faster R-CNN architecture [34].

IV. Result and Discussion

A. Result

1) Problem definition: Python constitutes the foundation of this project owing to its adaptability, ease of use, and extensive support for machine learning and computer vision. The high-level, interpreted nature facilitates swift prototyping, development, and debugging, which are crucial for complex image processing jobs. The Python ecosystem, featuring packages like Ultralytics YOLO, PIL (Python Imaging Library), and OpenCV, offers comprehensive object identification, picture processing, and deep learning capabilities. These libraries facilitate implementation, enabling developers to concentrate on high-level design and experimentation instead of low-level algorithm creation [28] [29].

The dataset was methodically partitioned into three subgroups to provide a balanced and efficient model training and evaluation process. Seventy percent of the data was designated for training, enabling the model to acquire a thorough representation by identifying essential patterns and features. Twenty percent was allocated for testing, facilitating an impartial assessment of the model's efficacy to guarantee its generalization to novel data. The residual ten percent was allocated for validation, enabling hyperparameter modification and enhancing the model's accuracy and robustness. This divide guarantees a stringent training process while allocating sufficient segments for evaluation and refinement.

The emphasis on three roof color categories—red, white, and black—was established based on their frequency in the aerial photographic collection utilized for this study. By focusing on these predominant colors, the model attains superior classification accuracy and greater generalization, as it utilizes the most prevalent visual patterns recognized in the data. This method guarantees that the model accurately identifies essential characteristics, facilitating dependable detection and classification of roof types.

In testing, the model functions with individual image inputs at a confidence level of 0.5. The outputs consist of bounding boxes with a line width of 2 pixels and labels indicating both class and confidence scores. The findings comprise visual outputs featuring bounding boxes, cropped images of each identified object, a text file with detection specifics, and statistics on the overall counts of detected objects. This detailed output format allows for an in-depth investigation of the model's detection skills and supports additional interpretation.

The model can process high-resolution maps with a pixel limit of 1 billion pixels for large-scale image processing. These

enormous images are segmented into 640x640-pixel slices to improve accuracy. The images are saved in a designated directory. Each slice is subjected to object detection with a confidence level of 0.5, and the results are aggregated. This method enables the model to efficiently handle extensive geographical datasets by partitioning them into manageable segments. The method guarantees precise detection and classification while maintaining processing efficiency.

Advanced categorization analysis identifies and categorizes roof types separately, yielding a comprehensive tally for each category: red, white, and black. This entails determining the total quantity of each roof type and generating a cumulative count. The findings are recorded in a detailed report, providing a statistical analysis by roof category and facilitating additional examination of the identified buildings. This detailed compilation of results guarantees that the data is both comprehensible and applicable for future use.

This research's technological implementation employs Python, leveraging the Ultralytics YOLO framework and the Python Imaging Library (PIL) for effective image management and processing. The data processing pipeline comprises consecutive processes, starting with initial picture preparation and slicing, followed by model inference on each slice, and culminating in the compilation of findings. This organized pipeline effectively manages high-resolution images and ensures strong classification precision. This method is especially effective for applications necessitating comprehensive recognition of roof color and structure in urban and satellite data.

2) Performance evaluation: Performance measures were used to assess the model's effectiveness. These measures were chosen to evaluate detection and classification fully. Includes [5]:

a) Mean Average Precision (mAP): This metric compares precision and recall across all detected classes to determine detection performance.

b) Classification accuracy: This parameter measures the model's ability to accurately classify roof colors as red, white, or black.

A full set of evaluation indices has been adopted. To evaluate the viability and efficiency of the YOLOv11 model in house roof detection. Each of these metrics provides ample information on the performance of the model in identifying and classifying three classes of roofs: red, white, and black roofs [24]. In this research, evaluation metrics that include mean Average Precision (mAP), Confusion Matrix, F1-score, and Precision-Recall (PR) Curve are used, which are considered benchmarks in object detection tasks [14][30].

$$mAP = \frac{1}{n}\sum_{k=1}^{k=n} AP\,(k) \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1 = \frac{2\,x\,Precision\,x\,Recall}{Precision+Recall} \quad (4)$$

Where:

- n = the number of classes
- AP = the average precision of class k
- TP = True Positive
- FP = False Positive
- FN = False Negative

Confusion Matrix: A 3×3 matrix representing the model's performance across all roof classes:

- True Positives (TP): Correctly identified roof class
- False Positives (FP): Incorrectly identified roof class
- False Negatives (FN): Missed roof detections
- True Negatives (TN): Correctly rejected non-roof objects

The performance of the model is primarily measured by mean Average Precision (mAP), the standard metric for object Fig. 6. Confusion Matrix YoloV11 detection tasks [15]. An mAP of more than 0.75 is good enough for a model in practical roof-detecting applications [19]. The results reflect the model's capability to detect and classify various types of roofs in different, as well as distinct scenarios.

3) Feature and model evaluation: Based on the research conducted, the following results were obtained:

Fig. 6 presents the detailed analysis of the YOLOv11 model's efficacy in roof identification and categorization uncovers substantial insights via several performance indicators. Examining the confusion matrix reveals differing detection capacities among various roof types, with red roofs exhibiting significantly enhanced performance, attaining 494 accurate detections and low misclassification rates. White roofs had modest efficacy, achieving 291 accurate identifications, albeit with considerable misunderstanding regarding backdrop components. Black roofs posed the greatest obstacle, yielding just 16 accurate identifications, suggesting a huge opportunity for enhancement [16].

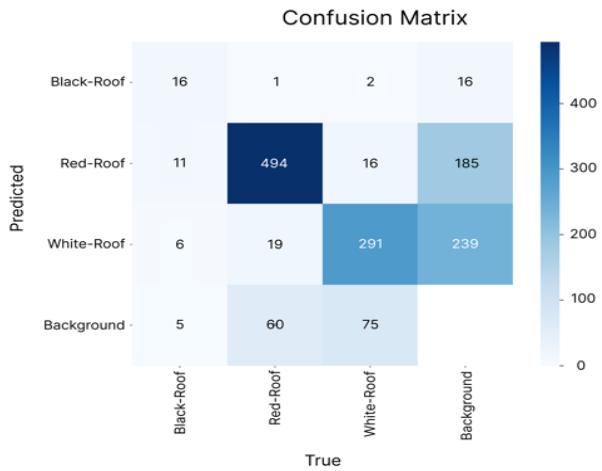

Fig. 6. Confusion matrix YoloV11.

The evaluation of the Faster R-CNN model shows that it performs relatively well in roof classification tasks (see Fig. 7). Compared to both YOLOv11 and EfficientDet, red roofs had more excellent classification rates, achieving 460 accurate detections. White Roofs was misclassified into the backdrop despite achieving 270 accurate identifications. Black roofs had the most difficulty classifying, with only ten accurate detections from 38 black roofs-top and noticeable confusion with background features. Faster R-CNN performs somewhat worse overall than EfficientDet and YOLOv11, especially regarding white and black roofs.

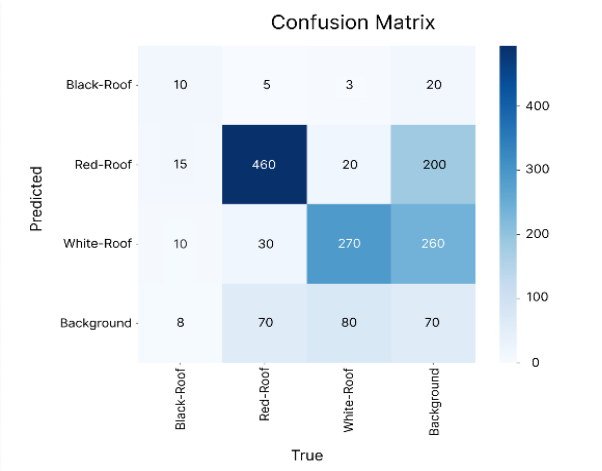

Fig. 7. Confusion matrix faster R-CNN.

A review of the EfficientDet model shows that it can successfully classify different types of roofs (see Fig. 8). With 480 correct detections, red roofs performed well; nonetheless, their misclassification rate was somewhat more significant than that of YOLOv11. White Roofs had 285 accurate detections from 386 white Roofs; however, there was a noticeable amount of background element confusion. With only 14 accurate identifications from 38 black roofs being identified and significant misclassification into other categories, black roofs were the most challenging category. All things considered, the model performs consistently but marginally worse than YOLOv11.

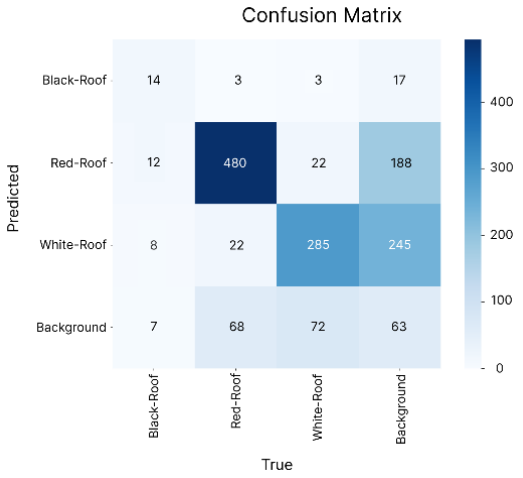

Fig. 8. Confusion matrix efficientdet.

The SSD model performs (see Fig. 9) consistently across roof kinds, although not as good as YOLOv11 and EfficientDet. Red roofs had a slightly higher misclassification rate than the top-performing models but accomplished 470 accurate detections. White roofs performed mediocrely, detecting 280 things correctly, but they had much trouble with the background. With only 12 correct detections from 38 black roofs being detected and significant misclassification into other categories, black roofs proved the most difficult. Although SSD performs reasonably well, it is not as good at differentiating between different types of roofs as YOLOv11 and EfficientDet.

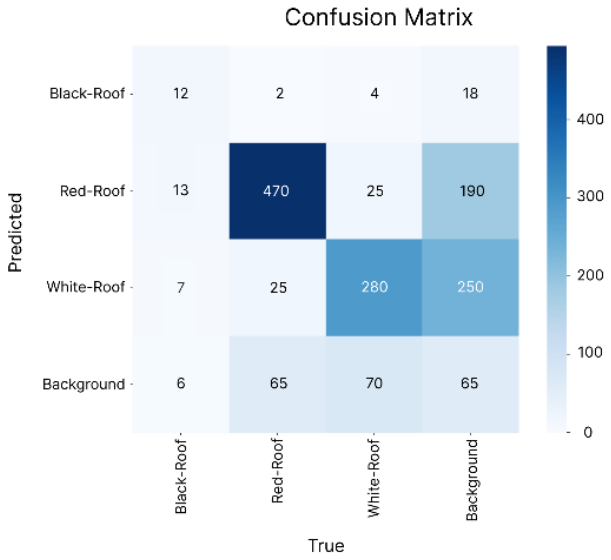

Fig. 9. Confusion matrix SSD.

Additionally, an analysis using Precision-Recall curves produced a mean Average Precision (mAP@0.5) of 0.708, with class-specific Average Precision values of 0.850 for red roofs, 0.671 for white roofs, and 0.603 for black roofs (see Fig. 10). The exceptional efficacy in red roof detection is demonstrated by consistently high precision at various recall levels, whereas black roofs exhibited a significant decline in precision at elevated recall levels [18].

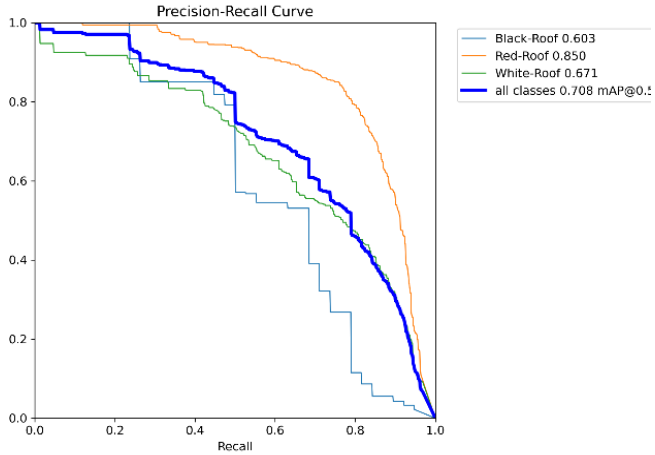

Fig. 10. Precision-Recall curves.

An analysis of the YOLOv11 model's training over 100 epochs demonstrates extensive performance metrics across several evaluation criteria. The model was trained using a bespoke dataset including 266 images with 998 roof instances, attaining a final mean Average Precision (mAP@0.5) of 0.708. The dataset consists of three separate roof categories: black roofs (38 occurrences), red roofs (574 instances), and white roofs (386 instances), highlighting a significant class imbalance favoring red and white roof samples. During the training procedure, the model exhibited steady convergence, with final epoch metrics indicating a box loss of 0.413, a classification loss of 0.5288, and a DFL loss of 0.9664. The model architecture, executed on an NVIDIA GeForce RTX 4060 (8188MiB), comprises 303 layers with 20,032,345 parameters, attaining 67.7 GFLOPs.

Performance study indicates class-specific discrepancies in detecting efficacy, with Box(P) values of 0.813, 0.775, and 0.603 for black, red, and white roofs, respectively. The model's robustness is further demonstrated by class-specific mAP50-95 scores of 0.49 for black roofs, 0.672 for red roofs, and 0.499 for white roofs, suggesting similar performance across different Intersections over Union thresholds. Computational efficiency is evidenced by swift processing durations: 0.2 ms for preprocessing, 7.6 ms for inference, and 0.7 ms for postprocessing, culminating in effective per-image processing. The training procedure was completed in 0.946 hours, with the final model weights successfully tuned and stored for deployment.

B. Discussion

The purpose of this study was to improve urban mapping and population density studies by developing YOLOv11 for automatic dwelling detection and counting using aerial photography. The model is intended to deal with house detection issues, including differences in building density, lighting, and roof color in urban environments. YOLOv11 outperforms other models like Faster R-CNN, SSD, and EfficientDet in terms of inference time and detection accuracy, especially when it comes to intricate roof color classification. Faster R-CNN's separate region proposal procedure necessitates a longer inference time, despite its outstanding detection accuracy [27]. Although SSD provides fast single-step object detection, it has trouble identifying intricate and small objects, such as dwellings, in aerial photos [26]. To improve multi-scale detection efficiency, EfficientDet uses a Bi-directional Feature Pyramid Network (BiFPN); however, it still has computational issues on low-power devices [25].

Among the four models, the YOLOv11 model excels in mean Average Precision (mAP), achieving a score of 0.708. This outcome is attained following training on a bespoke dataset comprising 266 images characterized by a significantly uneven distribution of roofing types (black, red, and white roofs). The model converges steadily, displaying considerable fluctuation in class-specific performance; however, it maintains good overall accuracy, particularly for red roofs, with a mAP50-95 of 0.672. The YOLOv11 model demonstrates efficient computational performance, processing each image in 7.6 ms with a batch size of 8 over 100 epochs, and its training duration is quite brief, at 0.946 hours.

Conversely, the Faster R-CNN (Fig. 11 (a)) model produces a decreased mAP of 0.58. Despite leveraging the strength of a pre-trained backbone, it does not achieve the detection accuracy of YOLOv11 on the custom dataset. Although Faster R-CNN is a more established architecture, its performance diminishes when fine-tuned on a specialized dataset, particularly in contrast to YOLOv11's class-specific measures, which demonstrate greater consistency in detection.

The SSD model, illustrated in Fig. 11 (b), was constructed from scratch using a bespoke dataset and attains a mean Average Precision (mAP) of 0.54. Notwithstanding the significant flexibility and capability of SSD, this model's performance is subpar compared to both YOLOv11 and Faster R-CNN, perhaps because of the challenges of training a custom SSD from scratch with a small dataset and without pre-trained weights. This may result in reduced convergence speed and inferior feature extraction compared to the other models.

(a) (b)

Fig. 11. (a) R-CNN Performance (b) SSD Performance.

Ultimately, EfficientDet (Fig. 12 (a)), a cutting-edge object detection model, attains a mean Average Precision (mAP) of 0.62. EfficientDet employs a compound scaling technique to enhance model size and accuracy while preserving efficiency. Its performance exhibits significant promise, especially when combined with effective dataset augmentation and processing methodologies. Nevertheless, the lack of comprehensive data makes direct comparisons difficult without precise measurements.

Fig. 12 (b) shows that the bounding box method spotted various roof objects with varying confidence ratings from overhead residential images. White-Roof, Red-Roof, and Black-Roof were categorized accurately across lighting conditions and architectural variances. Red-Roof was the most commonly detected class, with confidence values from 0.82 to 0.91, including numerous high-confidence detections over 0.85. Despite being rare, white-Roof detections were accurate with confidence values 0.84. The algorithm also detected a Black-Roof occurrence with a 0.58 confidence score, proving it can detect rare roof types. The testing used high-resolution aerial footage in RGB format from a bird's-eye view in natural sunshine. The detecting algorithm placed bounding boxes precisely and had minimum object overlap. The implementation was particularly good at distinguishing roof materials across lighting situations.

Fig. 12. (a) EfficientDet performance (b) YOLOv11 performance.

TABLE I. MODEL COMPARISON RESULT

Model	mAP50	mAP50-95	Precision	Recall	F1-Score
YOLOv11	0.708	0.53	0.75	0.7	0.72
Faster R-CNN	0.58	0.43	0.64	0.64	0.65
SSD	0.54	0.4	0.62	0.6	0.61
EfficientDet	0.62	0.48	0.71	0.67	0.69

The comparative analysis of object detection models, as presented in Table I, elucidates the advantages and disadvantages of YOLOv11, Faster R-CNN, SSD, and EfficientDet across many assessment criteria. YOLOv11 attains the highest mAP50 score of 0.68, demonstrating its exceptional capability to identify items with a minimum of 50% overlap between predicted and actual bounding boxes. EfficientDet achieves a score of 0.62, demonstrating commendable performance, but Faster R-CNN and SSD exhibit inferior effectiveness with scores of 0.58 and 0.54, respectively. A comparable trend is noted with mAP50-95, a more stringent metric that assesses performance across IoU levels from 50% to 95%. YOLOv11 leads with a score of 0.53, followed by EfficientDet at 0.48, while Faster R-CNN and SSD score 0.43 and 0.40, respectively.

Regarding precision, YOLOv11 surpasses the other models with a score of 0.75, indicating its superior accuracy in accurately recognizing positive detections. EfficientDet ranks second with a precision of 0.71, whilst Faster R-CNN and SSD attain lower precision scores of 0.64 and 0.62, respectively. Regarding recall, which assesses the model's capacity to identify all pertinent objects accurately, YOLOv11 attains a score of 0.70, somewhat surpassing EfficientDet's score of 0.67. Faster R-CNN and SSD achieved scores of 0.64 and 0.60, respectively, signifying a diminished capacity to identify all items within the dataset. The F1-score, a harmonic mean of precision and recall, illustrates YOLOv11's overall efficacy with a peak score of 0.72. EfficientDet attains a score of 0.69, whereas Faster R-CNN and SSD secure F1 scores of 0.65 and 0.61, respectively.

The results collectively demonstrate that YOLOv11 is the most effective model among the four, succeeding in all criteria, whilst EfficientDet is a competitive option with consistent performance. Faster R-CNN and SSD, albeit operational, have comparatively diminished overall efficacy.

V. CONCLUSION

The deployment of YOLOv11 for residential identification and roof color classification has exhibited encouraging outcomes while highlighting opportunities for further enhancement. The model, trained on 266 images featuring 998 roof instances, attained a mean Average Precision (mAP@0.5) of 0.708, exhibiting variable performance across distinct roof hues. Principal discoveries encompass: Red roofs exhibited the highest detection performance, achieving an Average Precision of 0.850 and elevated F1 scores near 0.8. White roofs displayed moderate performance with an Average Precision of 0.671, while black roofs revealed inferior detection rates with an Average Precision of 0.603, suggesting a potential area for enhancement.

With better accuracy and efficiency, YOLOv11 emerged as the top-performing model for residential roof recognition and color classification. Its strength is demonstrated by the confusion matrix, particularly in very accurate and error-free red roof detection. YOLOv11 outperformed EfficientDet, Faster R-CNN, and SSD regarding detection rates and background/roof color differentiation. Notwithstanding difficulties with specific roof types, such as black roofs, it is the most dependable model with a mAP@0.5 score of 0.708 and good F1 scores, making it ideal for real-world applications.

The model exhibited remarkable computing efficiency, with preprocessing times of 0.2ms, inference times of 7.6ms, and postprocessing times of 0.7ms. The training process was completed in 0.946 hours utilizing an NVIDIA GeForce RTX 4060, illustrating the model's viability for real-world application.

The research highlights the benefits and limitations of utilizing YOLOv11 for automatic roof detection and counting. The model exhibits strong performance for particular roof types, notably red roofs. Notwithstanding these achievements, significant limits were noted, including comparatively low confidence scores (0.10-0.20) for specific detections and fluctuations in performance attributable to lighting conditions. The diminished sample size in the test location limited the system's effectiveness in the Black-Roof category. The roof shape will affect the accuracy, as the dataset is bespoke and sourced from Indonesia, resulting in heightened precision when utilized in Indonesian areas. Future research opportunities include expanding the training dataset for underrepresented categories, improving the model to increase confidence ratings, and investigating potential interactions with GIS systems for broader urban planning and analysis applications.

***Abstract*—The monkeypox epidemic has spread to nearly every nation. Governments implement several strict policies, to stop the virus that causes monkeypox. For effective handling and treatment, early identification and diagnosis of monkeypox using digital skin lesion images is critical, and this work employed deep learning architectures to achieve this goal. This article presents a supervised learning-based classification method designed for the precise identification of monkeypox cases. The analysis was conducted using an open-source dataset from Kaggle, consisting of digital images of monkeypox, which were processed using advanced image processing and deep learning techniques. The data was categorized based on findings related and unrelated to monkeypox. A deep neural network with 50 layers and up to 35 folds was utilized to identify regions of interest, which could be indicative of characteristics relevant to computer-assisted medical diagnosis and enable us to solve image processing and natural language processing tasks with high accuracy. In terms of performance, the proposed method achieved an accuracy of 96% during cross-validation classification testing. This outcome demonstrates the potential for computer-assisted diagnosis as a supplementary tool for medical professionals. Amid the monkeypox outbreak, this method offers a technical and objective assessment of patients' skin conditions, thereby simplifying the diagnostic process for specialists.**

***Keywords*—Deep learning; monkeypox; medical image processing; image classification; cross validation**

I. Introduction

The infectious illness known as "mpox," or monkeypox, has spread quickly across the globe and is characterized by fever, muscle pains, and skin lesions that resemble boils. In response, the World Health Organization (WHO) raised the warning level to its maximum in July by classifying it as a public health emergency of international concern (PHEIC) [1]. When a tourist returned from Nigeria, where the disease is widespread, the epidemic began in the UK. However, there have previously been isolated occurrences of this kind, and those outbreaks ended swiftly. This time, the disease began to spread from the first cluster of patients and appeared in various European, Australian, and American nations [2].

Although African epidemiologists have been warning for several years that patterns of transmission seem to be shifting in endemic nations, scientists are still unsure of the exact reason for the virus's rapid expansion. As of December 19, 110 countries have reported more than 83,000 cases, with 66 fatalities, according to W.H.O. Encouragingly, the weekly total of new cases worldwide has dropped by 49.3%; this past week saw 265 new cases globally, compared to 523 from December 5–11 [1–3]. Currently, the Americas are considered to be at greater risk than Africa. The Americas (90.5%) and Europe (4.9%) accounted for the majority of cases recorded over the previous four weeks [3]. Fig. 1 shows the DNA structure of monkeypox, while Fig. 2 highlights the 10 most affected countries worldwide.

In some regions of the globe, the pandemic may have decreased due to the availability of the currently preventable JYNNEOS monkeypox vaccine, but nations below the poverty line have been left behind. Given that monkeypox may mutate and become harder to manage in the future, experts argue that it is imperative to administer the vaccination in a fair and equitable manner [4].

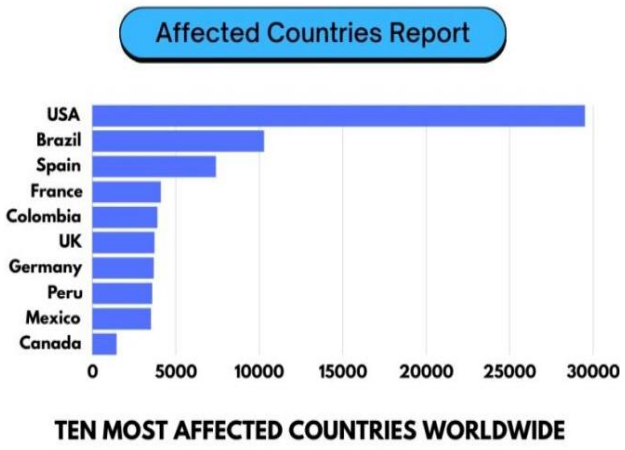

Fig. 2. Affected countries of monkeypox worldwide [1].

Artificial Intelligence (AI) and Deep Learning have demonstrated remarkable results across various domains, transforming the way tasks are approached. In agriculture, AI-powered models have optimized crop management [5,6], disease detection[7], and yield prediction [8,9]. In education, adaptive learning platforms are tailoring educational content to individual needs, enhancing student engagement and success. In finance, AI-based algorithms are improving fraud detection, risk assessment, and investment strategies. In healthcare, AI and Deep Learning have revolutionized diagnostics, treatment plans, and patient management through the precise analysis of complex medical data [10–13].

Specifically in healthcare, AI has significantly enhanced decision-making by enabling more accurate diagnosis and personalized treatments through the interpretation of medical images, patient records, and genetic data [10–13]. This progress can extend to infectious diseases, where a deep learning could be employed for precise identification of Monkeypox using skin imaging. By leveraging AI's ability to analyze and differentiate subtle features in skin lesions, the technique could improve early detection and reduce misdiagnosis. This would facilitate timely interventions, reducing the spread of the disease and enhancing patient outcomes, demonstrating AI's critical role in addressing emerging public health challenges.

In this study, a computer-aided diagnostic (CAD) system using deep learning and artificial intelligence (AI) techniques is proposed for potential pulmonary follow-up due to its accuracy and ability to optimize reaction times. AI has played a significant role in medical diagnosis [14, 15]. Expert interpretation is facilitated by the technique's automated and objective assessment of pulmonary follow-ups, which is enabled by artificial neural network designs. Since artificial neural networks (deep learning) have proven to be successful, AI has also been applied to medical image processing [16, 17]. The development of trustworthy and accurate medical diagnostics has garnered significant attention in recent years. Artificial neurons are layered and interconnected to transfer signals in neural network techniques, with intermediate layers being hidden. These networks, along with more advanced learning processes, form the foundation of deep learning, which generates categorization approaches that are both optimal and precise [18, 19]. Main aim of the research is to develop a technique which can classify image efficiently without leaving a single skin lesion in images which can help doctors to treat well and detect the disease at its initial stage.

This paper's primary research contributions can be summed up as follows:

- Our suggested technique uses images with 224 × 224 x 3 the RGB spectrum dimensions and those without monkeypox lesions.
- To implement pre-processing steps using Resnet 50 to generate the feature vector(1 × 1 × 2048) then the its subsets are defined using its increase and decrease in fold values which solve image processing and natural language processing tasks with high accuracy.
- To Classify various methods likes SVN, LR, KNN, NB, NC evaluates the accuracy and precision value depending upon various folds

II. Related Work

Monkeypox disease is often mistaken for other illnesses, leading to misdiagnosis and inappropriate treatment. Early diagnosis and treatment of this contagious disease are crucial. Detecting monkeypox typically requires expert interpretation and clinical examination, which can delay the treatment process. AI-based detection can assist in the early identification of this disease. There are limited studies in the literature on this topic, which are discussed in detail below, along with Table I.

Dipanjali Kundu et al. [20] presented a secure Federated Learning and deep learning-based framework for monkeypox virus detection using skin lesion images. The framework aims to improve classification performance while maintaining data confidentiality. The CycleGAN generator augments training and test data, and synthetic images are divided into four groups for local techniques. ViT-B32 outperforms other classifiers with an impressive accuracy of 97.90. The approach ensures user data privacy and effectively performs categorization tasks, making it relevant in medical contexts with limited datasets and data privacy concerns. Sitaula et al. [21] evaluated 13 pre-trained deep learning techniques (including VGG-16, InceptionV3, Xception, MobileNet, EfficientNet, etc.) for monkeypox detection using the publicly available Monkeypox virus image dataset. They trained the techniques on the ImageNet dataset. The study included 1,754 images, consisting of 329 chickenpox, 286 measles, 587 monkeypox, and 552 normal images. They developed a technique using the Keras library in Python. The proposed ensemble learning technique outperformed the 13 deep learning techniques, achieving an accuracy of 87.1% (precision: 85.4%, recall: 85.4%, F1-score: 85.4%). Xception was the second-best technique with an accuracy of 86.51%, while precision, recall, and F1-score were 85%. Alakus and Baykara [22] classified monkeypox disease and warts based on their DNA sequences. They employed various DNA mapping techniques and deep learning. The study used 110 genome sequences, consisting of 55 monkeypox virus and 55 human papillomavirus sequences. To address the data imbalance, they used the zero-padding

technique. Five DNA mapping techniques achieved an average classification accuracy of 96.08%, with the integer DNA matching technique achieving the highest accuracy at 99.5%. This demonstrates the successful detection of monkeypox and warts through DNA mapping and classification. Ali et al. [23] addressed the challenge of early clinical diagnosis of monkeypox, similar to chickenpox and measles, through computer-aided detection. They created a dataset of skin lesion images from various sources, consisting of 228 images. Three classification techniques were used: VGG16, ResNet50, and InceptionV3. ResNet50 achieved the highest accuracy (82.96% ± 4.57), VGG16 performed competitively (81.48% ± 6.87), and InceptionV3 had the lowest accuracy (74.07% ± 3.78). A community technique using majority voting outperformed ResNet50 and was integrated into a prototype web application. Haque et al. [24] aimed to classify human monkeypox disease from images using a pre-trained deep learning technique. The study utilized VGG-19, Xception, DenseNet121, MobileNetV2, and EfficientNetB3 deep learning techniques for classification. A uniform approach was applied to customize all pre-trained techniques. To enhance the network's focus on more pertinent feature maps, a convolutional block attention module was incorporated. The initial preparation of the MSLD involved resizing the images to a resolution of 224x224x3 for training purposes. In the research, many hyperparameters were used to maximize the effectiveness of the strategies. The design that included Xception, CBAM, and thick layers performed better than other techniques in the findings, obtaining a validation accuracy of 83.89% in the classification of human monkeypox and other illnesses. Sahin et al. [25] developed a mobile app using deep learning to detect monkeypox from video footage captured on mobile devices. They used the MSLD dataset and deep transfer learning with Matlab. Transfer learning is a machine learning technique where a model trained on one task is adapted to improve performance on a related but different task, often with fewer data [28] . MobileNetV2 (91.11%) and EfficientNetB0 (91.11%) achieved the best results in 60 epochs. MobileNetV2, with precision (90%), recall (90%), F1-score, and accuracy (91.11%), outperformed other techniques and was integrated into an Android mobile app, allowing easy pre-screening for monkeypox. Ahsan et al. [26] developed an AI-driven decision support system using CNNs. Their study used a dataset of 572 images (monkeypox and normal). They employed twelve different CNN techniques for classification, with MobileNetV2 achieving the highest accuracy (98.25%), precision (96.55%), specificity (100%), and F1-score (98.25%). The study also highlighted that MobileNetV2 is suitable for mobile-based monkeypox testing due to its smaller technique size. Ahsan et al.[27] created a dataset of patient images infected with monkeypox. The researchers aimed to detect monkeypox virus in patients using a modified pre-trained VGG16 technique. The study collected a total of 1,915 images, including monkeypox, chickenpox, measles, and normal images, as well as augmented versions. Two separate studies were conducted, one with a small dataset and the other with a medium-sized dataset. In the first study, using a small dataset, the VGG16 technique achieved training and testing accuracy rates of 97% and 83%, respectively. In the second study, with a medium-sized dataset, the technique achieved accuracy rates of 88% in training and 78% in testing. The proposed technique's predictions were validated through cross-validation by medical professionals. The study suggests that this technique could be used to develop a mobile-based diagnostic tool.

TABLE I. LITERATURE REVIEW OF RELATED WORK

Reference	Data type	Technique	Accuracy	Research Gap
Kundu et al.[20]	a total of 381 images of monkeypox, 102 images of chickenpox, 110 images of measles, and 293 images of normal skin.	federated learning (FL) with Cycle GANS and deep learning-based techniques such as MobileNetV2, Vision Transformer (ViT), and ResNet50 for the classification	Proposed technique accuracy 97.90%	Limited datasets and data privacy
Sitaula et al. [21]	Monkeypox virus dataset images (329 chickenpox, 286 measles, 587 monkeypox, and 552 normal images)	13 pre-trained deep learning techniques (including VGG-16, InceptionV3, Xception, MobileNet, Efficient-Net, etc.)	Proposed technique accuracy 87.13%.	Less accuracy rate

III. MATERIAL AND TECHNIQUES

A. Deep Learning Classification Techniques

In this study, CNN-based deep learning techniques, namely VGG16, ResNet50, EfficientNetB3, Xception, and InceptionResNetV2, were used to perform image-based classification of monkeypox disease. Brief descriptions of these techniques are provided below:

VGG16 is a deep learning technique developed at the University of Oxford. VGG stands for Visual Geometry Group, and 16 refers to the number of layers in the technique [20]. VGG16 is a CNN technique commonly used for image classification tasks. Convolutional, fully linked, and pooling layers make up the approach. The pooling layers highlight key characteristics and condense the bulk of the data [20]. Because of its depth, VGG16 is a large approach with a significant number of learnable parameters. Large datasets and more challenging picture classification tasks are often better served by it. VGG16 became well-known, especially when it performed well on the ImageNet dataset. It is known for emphasizing the fundamental structure of convolutional networks and the depth of its layers, which has influenced the development of related techniques that use weighted convolutional layers and depth.

In deep learning, one popular Convolutional Neural Network (CNN) approach is called ResNet50. Microsoft Research first introduced the ResNet (Residual Network) approach in 2015 with the express purpose of resolving issues related to depth in deep networks. ResNet50 is a 50-layer deep network that uses a unique building component known as a residual block. These blocks introduce skip links in the network's transitions, which attempt to mitigate the issue of gradient vanishing that arises in deeper networks. In comparison to earlier techniques, the residual blocks allow information to move across the network more quickly and smoothly [29]. ResNet50 has pooling layers, activation functions, and convolutional layers—basic CNN building blocks. Additionally, it has a global average pooling layer in the center of the network that uses smaller feature maps to summarize data.

A version known as ResNet blends the ResNet and Inception architectures [30]. While the ResNet design makes use of residual connections to solve gradient vanishing in deep networks, the Inception architecture is composed of convolutional layers with filters of varying sizes. ResNet seeks to integrate these two topologies to make training deeper and more complicated networks easier. While the ResNet blocks maintain information flow by using connections to prevent gradient vanishing, the Inception blocks combine convolutional layers with filters of varying sizes to capture a broad variety of characteristics. Extreme Inception, a term that is shortened to "Xception," is a deep learning approach [31]. It is based on the CNN architecture, more precisely on an Inception approach variant. Improving the Inception network's processing efficiency is the primary objective of Xception. It deviates from the conventional CNN technique by optimizing the convolution operations in the Inception blocks to achieve this. Depth-wise separable convolution is the method used to accomplish this improvement. Two steps of convolution operations are carried out by depth-wise separable convolution. A point-wise convolution layer is used in the first stage to capture relationships between several channels and modify the input data's dimension. The second step is a depth-wise convolution layer, which improves computing efficiency by processing each input data channel independently. The CNN technique known as EfficientNetB3 is used in deep learning [32]. It belongs to the family of EfficientNets, and EfficientNetB3 is a scalable and effective technique. Compound scaling is a technique that EfficientNet uses to automatically scale deep learning approaches to different sizes. The purpose of EfficientNetB3 is to be applied to larger and more intricate datasets. The method improves efficiency on smaller datasets by combining depth features with scalability. To handle input images, EfficientNetB3 uses a variety of convolutional layers, activation functions, and pooling layers [32, 33].

B. Data Set

The study used a dataset that included skin lesion images classified into two groups: those with monkeypox and those without (chickenpox and measles). The University of Dhaka research team in Bangladesh [33] contributed to the dataset, which was augmented to contain approximately 3,192 images with dimensions of 224 × 224 x 3 in RGB. There were 228 images in the original dataset, of which 102 belonged to the monkeypox class and 126 to the other class. This dataset has a comparatively modest amount of images, especially when considering the deep learning environment. The only restriction was that more images were obtained by using image enhancement. Through picture augmentation, the dataset was increased by a factor of fourteen. After augmentation, there were 1,428 images in the monkeypox class and 1,764 images in the 'others' class. An unequal distribution of images was observed between the 'others' and monkeypox classes. To address this imbalance, data augmentation techniques were applied to create more samples for the monkeypox class. By adding these extra examples, the dataset's classes were distributed more evenly, as shown in Fig. 3, which displays 1,764 images in each class.

To further enhance the dataset's durability, the researchers used stratified sampling to divide it into seven folds. This technique ensured that the monkeypox class and the other classes were represented proportionally in each fold. The stratified split of the dataset into folds allowed for a more accurate evaluation and validation of the technique's effectiveness by taking into account any variances in the distribution of classes within the dataset. The technique's ability to generalize was assessed by applying cross-validation on multiple data subsets and evaluating its performance on each fold. This experiment used two subsets of the dataset, namely the training set and the testing set. The testing set, consisting of 252 images, provided a more thorough insight into the technique's ability to categorize monkeypox images. The training set consisted of 1,512 enhanced images used for training the classification system. To develop a reliable and efficient classification technique, it is essential to carefully analyze the segmentation of this dataset [34, 35].

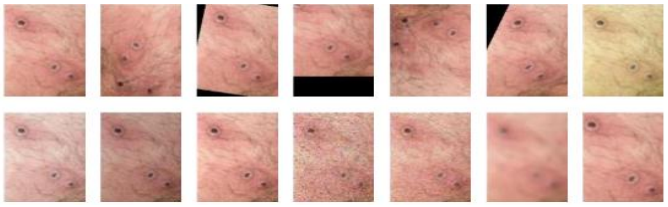

Fig. 3. Sample augmented monkeypox images from dataset.

IV. PROPOSED TECHNIQUES

The approach is based on the categorization of the images in Fig. 4; the technique diagram is comprehensive and includes the dataset. High reliability is achieved by identifying the optimal settings for executing the procedure. Python, an open-source programming language, was used to develop the method. The approach is divided into many steps; however, the preprocessing step is crucial for successful classification. In particular, the first phase focuses on the initial analysis, as the experiment was conducted using the dataset to enable the CNN to extract features from the images related to the identification of monkeypox.

Fig. 4. Technique of the proposed technique.

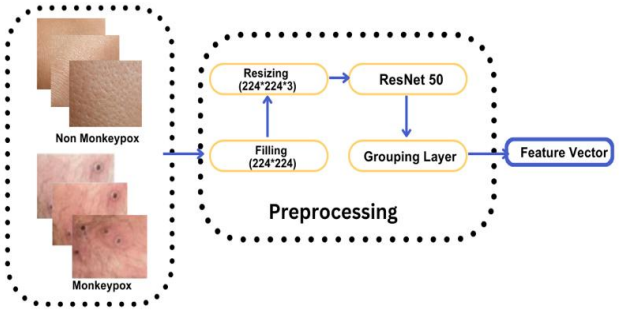

Fig. 5. An illustration of the first phase and the pre-processing steps to generate the feature vector.

The schematic diagram of the first and second phases is shown in Fig. 5. The residual neural network ResNet50, which was used, contains 50 hidden layers [36]. This artificial neural network consists of three layers of artificial neurons: one input, fifty intermediate (hidden), and one output. The process of creating a matrix from the feature vectors is based on residual learning. By putting neural networks through performance tests with partial and random changes to their connections, residual learning increases the technique's accuracy and enhances its ability to solve complex problems with greater reliability.

Here is a list of the four preliminary processing phases shown in Fig. 4: All input images are scaled to 224 × 224 pixels, and if the appropriate dimensions are not met, zeros are added to the perimeter of the original image. The pixel values in each layer are adjusted from 0 to 255. A new matrix with dimensions of 224 × 224 × 3 is then created by converting the images to three layers (the RGB spectrum). In the case of single-layer image graphs, the same layer is repeated in each channel. After completing these procedures, the images are fed into the ResNet50 network. The convolution process and the network's fundamental architecture are illustrated in Fig. 4. Up until the middle pooling layer is reached, the input image is subjected to successive convolution and sampling processes. The grouping layer features are extracted as a vector with dimensions of 1 × 1 × 2048 in this layer. This vector, generated for each image in the dataset, contains general attributes of the images retrieved by the approach, such as saturation, brightness, and intensity.

The final step in producing the feature vector is carried out using machine learning techniques; in other words, classifier techniques are applied to categorize the dataset. The ResNet50 neural network acts as an image feature extractor; by utilizing the convolutional base of this network, the most significant and distinctive features of the images are obtained. This is achieved not through machine learning, but rather through deep learning, using artificial networks that extract the most relevant features to enable optimal classification.

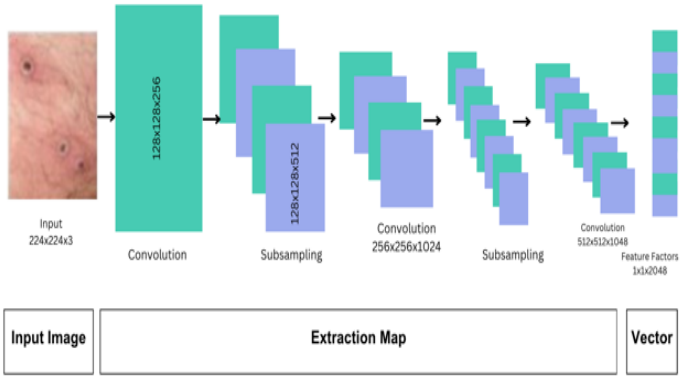

Fig. 6. The convolutional technique and the ResNet50 network's easy layout.

Even though a single CNN [37] may be used for both feature extraction and classification, there are several advantages to utilizing different techniques for each task. As a result, the automated classification approach used consisted of three stages: pre-processing, feature extraction (via CNN), and the classification system as shown in above Fig. 6.

V. CONFIGURING THE EXPERIMENT

The cross-validation classification scenario served as the foundation for the suggested technique [38]. There were 57 homogeneous and symmetric images with and without evidence of monkeypox; 114 images were divided using a cross-validation technique. When there are insufficient images in the collection, this type of categorization is suitable [39]. Fig. 3 depicts the cross-validation scenario using automated categorization algorithms. Due to their effectiveness in binary classification—where a set's components are divided into two categories according to a classification rule—the classification techniques used are well-established in the field [40]. Support Vector Machines (SVM) provides an optimal separation that reduces classification risk and increases the margin while also reducing error [41,42]. Logistic regression (LR) is used to predict the probability that a categorical dependent variable will be dichotomous, or divided into two groups [43]. Nearest Neighbors (KNN) uses discrete sample classification to forecast and estimate future values based on proximity, identifying similar data points. Additionally, Naive-Bayes' (NB) success is due to feature independence, which allows the determination of the likelihood that a test case has a particular feature value. Finally, the Centroid-based classifier (NC), derived from distances from the center, takes into account similarity with each class's centroid. The centroid is a vector representing the average frequencies of all terms among the members of a specific class.

The validation was carried out in three sections, with divisions of 15, 25, and 35 folds. Accuracy (A) and Precision (P), two evaluation measures, were used to assess the technique's performance with the dataset. These measures are based on the four elements listed below [44]:

- True Positive (TP): occurs when there is a match between the predicted class of the technique and the actual class of the dataset (finding).
- True Negative (TN): occurs when there is a match between the dataset's actual class (no finding) and the one predicted by the technique (no finding).
- False Positive (FP): occurs when there is a mismatch between the dataset's actual class (no finding) and the one predicted by the algorithm (finding).
- False Negative (FN): occurs when there is a mismatch between the dataset's actual class (a finding) and the one predicted by the technique (no finding).

Accuracy refers to the percentage of all predictions that were made correctly. Precision, on the other hand, indicates the accuracy of the positive predictions, i.e., the proportion of true positive values to all predicted positive values [45].

Metrics are calculated as follows [44]:

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

VI. RESULTS

Four different classifier techniques were used as the learning strategy in the cross-validation classification scenario. The dataset was split into three studies, as previously mentioned: 15 folds, 25 folds, and 35 folds. The dataset was randomly divided into K = 15, 25, and 35 segments as shown above. K − 1 segments were used for training the technique, while the remaining portion was used for performance evaluation. After dividing the dataset into K parts at random, this process was repeated K times to obtain K procedures and assessment outcomes. The final average performance was determined once all evaluations were completed.

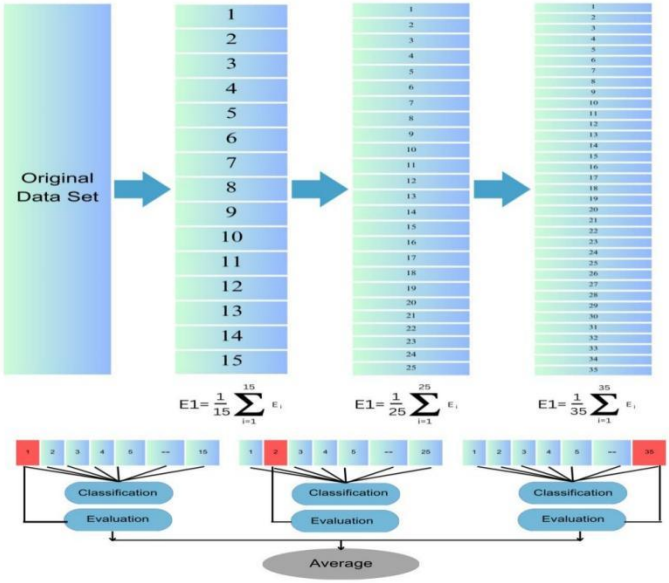

Fig. 7. The K-folds cross-validation strategy uses a single classifier with K values of 15, 25, and 35.

The technique was then retrained for the subsequent divisions. The technique's performance (E) is assessed as follows:

$$E = \frac{1}{k}\sum_{i=1}^{k} Ei \quad (3)$$

The process for 15 divisions, as well as the divisions of the folds in the dataset, is shown in Fig. 7. The 25 and 35 categories follow the same procedure to determine the performance (E). To compare the outcomes of several predictive classification processes—that is, the five learning strategies used to categorize the images—cross-validation was applied. The results of the various classification techniques are shown in Table II, along with a comparison of the divisional processes and evaluation criteria, which make it possible to identify the most accurate classifier. It is evident that as the number of folds increases, the KNN classifier (nearest neighbors) produces the highest values in the accuracy measure [46].

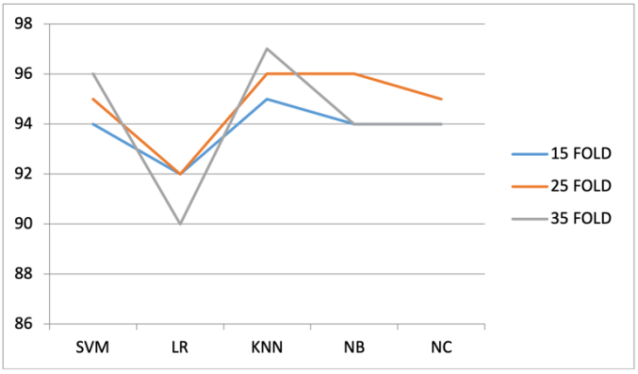

Fig. 8. The precision assessment metric's learning techniques in the three division experiments.

TABLE II. OUTCOMES OF A CROSS-VALIDATION CLASSIFICATION SCENARIO

Fold	15		25		35	
Classification	Accuracy	Precision	Accuracy	Precision	Accuracy	Precision
SVM	92.7	94.2	93.3	95.2	93.8	95.8
LR	90.3	92.5	90.1	92.6	89.4	90.4
KNN	94.2	95.4	95.5	96.4	95.2	97.7
NB	93.0	94.7	93.7	96.2	93.7	94.9
NC	92.7	94.2	93.2	95.7	93.7	94.9

VII. DISCUSSION

This shows that the categorization percentage is 94% in 15 divisions, 95% in 25 divisions, and 96% in 35 divisions. The accuracy indicates the proportion of the positive class predicted by the approach and the actual positive class in the dataset, as well as the quality of the classification scenario. In small datasets, the classifier with the best values often performs optimally. Similarly, the accuracy provides a 94% confidence level in the KNN classifier's quality compared to other learning techniques, provided the classes of the variables in the dataset are balanced. The accuracy measure and various folds used in the learning techniques are shown in Fig. 7. According to the suggested approach, the KNN classifier, the reported metrics, and the cross-validation classification scenario with 15, 25, and 35 folds together represent the best automated classification technique for the dataset, including discoveries related to monkeypox. The characteristic vectors of the images are extracted using the ResNet50 networks, and when paired with the approach, the results yield values that are competitive with the state of the art. As demonstrated, this strategy enables us to identify regions of interest within the images. While the current study focused on binary classification, it has been shown that the system can be expanded to categorize different diseases. The deep neural network's feature extraction technique includes the extraction of regions of interest (ROI) as shown in Fig. 8. Once combined, these characteristics are sent to the final classification technique, which utilizes them to provide a prediction.

VIII. CONCLUSION

This article's approach, which utilizes a dataset of patients with monkeypox, has demonstrated success. It gives the binary labels of finding lesions with monkeypox and non-monkeypox findings. Classification results with 96% precision were achieved using 35 divisions of folds using KNN classification, which improves the image processing quality by identifying even small lesions in skin images. The accuracy of these results not only reflects the quality of the classification scenario and the percentage of the positive class predicted by the technique compared to the actual positive class in the dataset but also improves as the dataset is split into several parts, indicating an increase in the technique's performance. The ResNet50 technique of CNN is a crucial component of the technique, as it enables comparison of the features of images with and without lesions by applying deep learning to identify monkeypox findings. This is accomplished through classifiers that are assessed using metrics that measure how effectively the technique functions. Based on the conclusions acquired, this article can now report on categorizing medical images from a dataset related to monkeypox. The technique provides an automatic and objective estimation of the classification of monkeypox findings, facilitating expert interpretation during the pandemic. This makes the values obtained from the scenario and binary classifier in the quantitative analysis of the imaging study more reliable, leading to a more accurate diagnosis. In future, ascertaining the viability and use of AI-based monkeypox detection systems in clinical settings, researchers can conduct empirical assessments of these systems. It will take patients and healthcare professionals working together to assemble large datasets. Moreover, other designs might be studied to tackle the difficulty mentioned before. Researchers can increase the precision of AI-based monkeypox diagnosis by including other data sources, such as clinical symptoms, laboratory test findings, and patient history. As a result of these findings, the categorization approach serves as a supplementary tool in medical diagnostics.

Classifying Weed Development Stages Using Deep Learning Methods

Classifying Weed Development Stages with DenseNET, Xception, SqueezeNET, GoogleNET, EfficientNET CNN Models Using ROI Images

***Abstract*—The control of harmful weeds holds a significant place in the cultivation of agricultural products. A crucial criterion in this control process is identifying the development stages of the weeds. The technique to be used is determined based on the weed's growth stage. This study addresses the application of deep learning methods in classifying growth stages using images of various weed species to predict their development periods. Four different weed species, obtained from seeds collected in Turkey-Afyonkarahisar-Sinanpaşa Plain, were used in the study. The images were captured with a Nikon D7000 camera equipped with three different lenses, and the ROI extraction was performed using Lifex software. Using these ROI images, deep learning models such as DenseNet, EfficientNet, GoogleNet, Xception, and SqueezeNet were evaluated. Performance metrics including accuracy, F1 score, precision, and recall were employed. In the 4-class dataset with ROI annotations, DenseNet and Xception achieved an accuracy of 86.57%, while EfficientNet demonstrated the highest performance with an accuracy of 89.55%. Following the initial tests, it was concluded that classes 3 and 4 exhibited extreme similarity caused most of the prediction errors. Merging the said classes significantly increased the accuracy and F1 scores across all models. In image classification tests, SqueezeNet and GoogleNet demonstrated the shortest processing times. However, while EfficientNet lagged slightly behind these models in terms of speed, it exhibited superior accuracy. In conclusion, although the use of ROI improved classification performance, class merging strategies resulted in a more significant performance enhancement.**

I. INTRODUCTION

One of the foremost factors affecting yield in agriculture is weeds [1]. If weeds are not controlled in the crop plant, this effect can be more significant. Integrated weed management (IWM) is a system that provides economically bearable, biologically effective and environmentally sound weed control using possible techniques in a sustainable manner. Among the tools IWM relies on is the critical period for weed control (CPWC): a duration during the crop's growth cycle when weed control is essential [2]. In many crops, CPWC for higher yields (more acceptable yield loss) starts from the crop emerging, which requires earlier detection of weeds to achieve effective weed control [3,4].

Identifying weeds at an early stage can be challenging because they may closely resemble crop plants. This task becomes even more difficult for farmers who must search for and identify weeds across the entire field, as it is an incredibly monotonous activity, leading to decreased performance and efficiency [5]. To mitigate this challenge, modern computer methods are employed. Artificial intelligence techniques used in computer-based imaging make it easier to detect weeds, thus facilitating the goal of product identification. Indeed, information technologies are being utilized in various fields of agriculture [6].

In image-based classifications, CNN and RNN deep learning models are more frequently used [7]. In agriculture, deep learning is applied in areas such as product diseases, pests, spraying, and the classification of crops and weeds [8].

A. Related Work

Espejo Garcia and colleagues developed a classification model using machine learning techniques such as Support Vector Machines (SVM), XGBoost, and logistic regression, along with convolutional networks like Xception, Inception-ResNet, VGNets, MobileNet, and DenseNet, applied to two crops and two weed species. In the dataset composed of photographs taken under natural light conditions with RGB cameras, DenseNet and SVM achieved an F1 Score of 99.29% [9].

Sunil and colleagues utilized deep learning models such as Xception, DenseNet, MobileNetV3Large, EfficientNet, and ConvNeXt to classify six weed species and eight crop types. They reported that, except for DenseNet, the other four models demonstrated strong performance, with the macro average F1 scores ranging between 0.85 and 0.87 and the weighted average F1 scores ranging between 0.87 and 0.88 [10].

Pandey and colleagues achieved classification in datasets containing maize and radish plants along with weeds using deep learning models such as InceptionV3, Xception, ResNet152V2, VGG16, and their proposed CNN model. They reported an accuracy of 97.66% for maize and 98.75% for radish [11].

Garibaldi-Marquez and colleagues conducted a classification study on maize and weeds. In their study, they used both regular images and ROI images, employing deep learning models such as ResNet101, VGG16, Xception, and MobileNetV2. Among the classification algorithms, Xception provided the best accuracy result of 97.43% [12].

Trong and colleagues conducted a study using datasets of plant seedlings and weeds from Chonnam National University. They employed five different deep learning methods, including NasNet and ResNet, to classify weeds. They achieved an accuracy of 97.31% for plant seedlings and 98.77% for weeds [13]. In another study involving ResNet, VGG16, and Xception, Peteinatos and colleagues used 93 000 images obtained with an RGB camera of 12 different weed species and applied deep learning models, reporting an accuracy range of 77% to 98% [14].

Chen and colleagues utilized a dataset comprising 5,187 images of 15 weed classes found in cotton fields. They classified these weeds using deep learning methods such as ResNeXt, Xception, and MnasNet. They achieved high accuracy, with F1 scores exceeding 95% [15].

One of the commonly used models for weed classification is the YOLO architecture. Gao and colleagues used the YOLOv3 architecture to train a model for identifying field bindweed and sugar beet plants. They based their training on 452 field images and generated 2,271 synthetic images. Their tests with 100 field plant images demonstrated that the average precision metric could reach 0.829 [16].

Ahmad and colleagues used a YOLOv3-based object detection model to identify four different weed species within maize and soybean fields. They employed pre-trained deep learning models, including VGG16, ResNet50, and InceptionV3. They reported that VGG16 achieved the highest accuracy at 98.90% and an F1 score of 99 [17].

Zhang and colleagues utilized the YOLOv3 and YOLOv3-tiny architectures to detect weeds in wheat fields. Based on the images obtained from UAVs, they indicated that YOLOv3-tiny is more suitable for mobile devices [18].

Sharpe and colleagues utilized the YOLOv3-tiny deep learning architecture to detect goosegrass in strawberries and tomatoes. They reported the following metrics for whole plants: precision = 0.93; recall = 0.88; F1-score = 0.90; accuracy = 0.82. For leaf blades, the metrics were precision = 0.39; recall = 0.55; F1-score = 0.46; accuracy = 0.30 [19]. Additionally, Osorio and colleagues used SVM and R-CNN architectures alongside YOLOv3 to detect weeds in lettuce. They found that R-CNN outperformed the other two methods, achieving an F1-score of 94% [20].

There are numerous publications related to deep learning in the agricultural sector, especially regarding the classification of weeds. Alongside the abundance of these publications, review studies that analyze, group, and evaluate these works have also started to appear in the literature [8, 21, 22].

The aim of current work is to predict the developmental stages of the plant or classify them based on the stages. Using the obtained images of weed species, the developmental stages of the weeds are going to be predicted employing deep learning methods. In addition to the plant images, predictions are also going to be made using ROI analysis on the same leaf images to enhance recognition.

II. Material and Method

The study consists of three main stages. The first stage is cultivating and photographing the weeds, the second stage is the extracting the ROI images and radiomics from the photographs, and the last stage is preparing the data set, developing the models and evaluating the performances.

A. Dataset

Seeds of Lamb's Quarters (Chenopodium album), Jerusalem Oak Goosefoot (Dysphania botrys), Prickly Lettuce (Lactuca serriola), and Sow Thistle (sonchus oleraceus), which are four common weed species in sugarbeet fields in Turkey-Afyonkarahisar-Sinanpaşa plains, were collected, dried, and threshed. Once the seeds were sown under suitable conditions, data collection began immediately as the weeds emerged, creating a comprehensive dataset. The development of the weeds was meticulously tracked twice a week using a Nikon D7000 camera equipped with three different lenses: 'Nikon 50mm 1.8 mm', 'Tokina 11-16 mm', and 'Sigma 105 mm'.

The weeds were grown in 16 different units ($2^4 = 16$), each with varying conditions of soil, irrigation, light, and fertilizer. The plants were photographed in various growth stages. In addition to the images, the leaves were analyzed using Region of Interest (ROI) techniques. Images were tested both with original and ROI marked images.

In line with this objective, ROI images of the leaves were extracted from the photos in the dataset using the Lifex program [23]. This resulted in a total of 448 photos. Five different deep learning models were applied to this dataset.

Based on the confusion matrix results, the accuracy rate was lower for the leaves in the 4th class due to their resemblance to those in the 3rd class. Consequently, the data for the 3rd and 4th classes were combined to create a new dataset. The same deep learning methods were applied to this new dataset as well.

Finally, a dataset was created using the raw, unmarked versions of the same images, and the above-mentioned deep learning models were applied again in both 3-class and 4-class formats.

B. Deep Learning Concepts

A short summary of Artifical Intelligence (AI) concepts to clarify where this study falls among AI concepts would be in order.

Machine learning is the learning stage of AI. Algorithms are developed and used on datasets to learn to perform certain tasks. It encompasses a variety of methods such as Supervised Learning, Unsupervised Learning, Reinforcement Learning and Deep Learning [24].

1) Deep learning: Deep learning is a subset of machine learning that involves training neural networks with many layers (hence "deep") to process and learn from large amounts of data. It focuses on learning representations of data through

these multiple layers. Deep learning encompasses Neural Networks [25].

2) Neural networks: Artificial Neural Networks (ANN) are machine learning algorithms consisting of a multitude of nodes where each node is connected to other nodes. Nodes communicate with each other in a predetermined pattern and their weights are adjusted every stage of the learning process depending on the success of the desired result. It is much like a biological neural system with neurons. It has been named "neural" due to this similarity [24].

3) Image classification models: There is a wide variety of ANN models especially designed for image classifications such as Resnet, GoogleNet, Xception, DenseNet, EfficientNet, SqueezeNet etc.

a) DenseNet201: The DenseNet network can be considered an extension of the ResNet model, which is a significant milestone in deep networks. The difference between the DenseNet network and the ResNet model is that DenseNet combines layers by concatenation rather than summation.

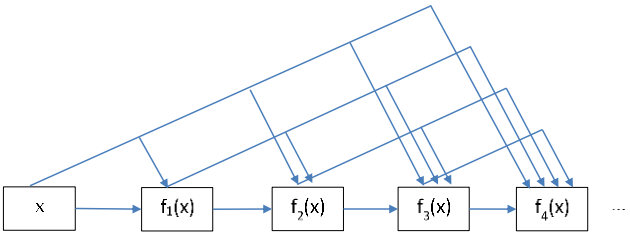

Fig. 1. DenseNET connections in DenseNET model.

Fig. 1 shows the progressively dense layer connections of DenseNet. The name "Dense" derives from these increasingly dense connections. The groups of layers where such connections are used are called dense blocks. However, the sequential addition of dense layers significantly increases the number of channels, i.e., the data pathways between layers, to astronomical levels, necessitating the need to control complexity. Transition layers are used to reduce this increased number of channels to one [26, 27].

In the DenseNet network, data is trained using RGB format images with a resolution of 224x224x3 pixels.

b) XCeption (Depthwise Separable Convolution): Xception aims to achieve the same or better performance with fewer parameters by using depthwise separation. The model is designed to have each convolution layer operate through two pathways: depthwise convolution and pointwise convolution. In the depthwise convolution pathway, a single input slice produces a single output slice, mapping only the spatial (height-width) dimensions. In the pointwise convolution pathway, a 1x1 convolution maps the color channels. This separation of the spatial and color channels results in a more lightweight model. The network comprises a total of 71 layers. In the XCeption network, data is trained using RGB format images with a resolution of 299x299x3 pixels [28, 29].

c) GoogleNet (Inception Networks): The idea behind this model was to effectively combine the methods of Network in Network and Repeated Blocks that preceded it. It was based on the concept of using combinations of convolution kernels of different sizes, ranging from 1x1 to 11x11, used in previous models. The basic structure of the inception blocks, which combine convolution kernels of different sizes, is shown in Fig. 2.

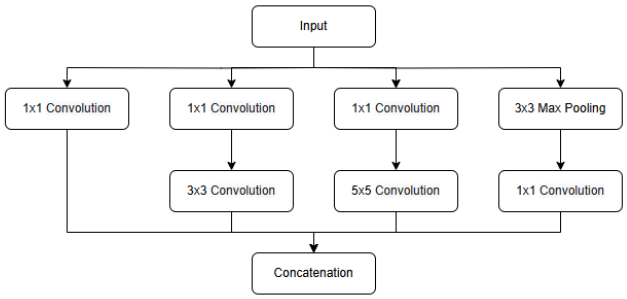

Fig. 2. Inception block structure.

Different sized convolution kernels can be thought of as filters capturing features of different sizes. Since 1x1, 3x3, and 5x5 convolution kernels capture different features in an image, inception blocks provide an efficient method for capturing features of various sizes.

The number of channels in the inception blocks was determined based on numerous experiments conducted on the ImageNET dataset. The overall structure of GoogleNET was created by serially connecting meticulously designed inception blocks to other blocks. The first version of the GoogleNET model contained 22 layers, but later versions may have more layers.

In the GoogleNet network, data is trained using RGB format images with a resolution of 224x224x3 pixels. The 224x224 image size and 3 color channels are commonly used input dimensions in the ImageNet dataset, which is widely utilized by GoogleNET and many other image classification models [27, 30].

d) SqueezeNet: SqueezeNet is a deep neural network designed to achieve high accuracy with significantly fewer parameters compared to existing models like AlexNet. The authors aimed to create a smaller, more efficient network that could be easily deployed on devices with limited memory and computational power. SqueezeNet achieves AlexNet-level accuracy on the ImageNet dataset while being 50 times smaller and requiring less computational resources. The model uses a unique architecture called the Fire Module, which consists of a squeeze layer (with 1x1 filters) followed by an expand layer (with a mix of 1x1 and 3x3 filters). The network has 18 layers and processes images with a resolution of 256x256 pixels. This makes it suitable for applications in resource-constrained environments such as mobile devices and embedded systems2 [31].

e) EfficientNet: EfficientNet is a new approach to scaling convolutional neural networks (CNNs) for better performance than previous models. Traditional methods scaled CNNs by increasing depth, width, or resolution individually, but EfficientNet proposes a balanced scaling method that uniformly scales all three dimensions using a compound coefficient. This

method, called compound scaling, allows EfficientNet to achieve state-of-the-art accuracy with fewer parameters and computational resources. The EfficientNet family includes models from B0 to B7, with B0 being the smallest and B7 being the largest. The smallest model, B0, has 24 layers and processes images with a resolution of 224x224 pixels, while the largest model, B7, has 264 layers and processes images with a resolution of 600x600 pixels. EfficientNet models outperform previous CNN architectures on various benchmarks, including ImageNet and CIFAR-1003 [32].

The selected neural network models were trained using the following parameters: the Adam optimizer, with an initial learning rate set at 0.0001, a mini-batch size of 25, and validation data provided by an augmentedImageDatastore object (referred to as augimdsValidation). The validation frequency configured at every 5 iterations. The training progress was visualized using plots, the performance metric used was accuracy, and the verbosity setting was disabled to reduce output during training. The number of epochs was maintained at the default value of 30 epochs. To ensure a fair and consistent comparison, all models were evaluated under these identical training conditions.

These settings were applied uniformly across all models to ensure the reliability and validity of the comparisons.

C. ROI (Region of Interest)

ROI is typically used to define the boundaries of a significant area within an image. Similar to its use in medical imaging to measure tumor boundaries and sizes, ROI allows for focused analysis on specific areas of interest rather than the entire image, thereby facilitating the extraction of various numerical features. Calculations such as mean and maximum values can be performed based on the defined ROI boundaries [33, 34].

In this study, ROIs of the different shape leaf images corresponding to the same plant and time intervals were used to determine the developmental stages of the leaves.

D. Why These Particular Models

Neural networks have their own advantages and weaknesses compared to each other. There are three main characteristics to consider when selecting neural networks: accuracy, speed, and size. The choice of network for use depends on the priority of these three characteristics in the intended application area. Classification accuracy and speed measurements are often conducted using the ImageNet database. However, these results do not always achieve the same success for different tasks and datasets.

It is not possible to find very precise criteria for selecting CNN models. The number of layers in the model, structural complexity, and the number of operations (flops) do not show a linear relationship with the final accuracy rates. There are models that provide high accuracy with low complexity and number of operations. Additionally, parameter settings do not yield the same level of results in every model. Model complexity can only serve as an indicator for the computer's memory usage level [35]. Considering the context in which the model is intended to be trained, it is not possible to predict which model will yield better results. Therefore five different models corresponding to promising accuracy and speed and size values. In addition, five different models that have been selected are widely used with mostly successful results.

E. Data Augmentation and Preprocessing

Deep learning methods enable the solving of various problems based on data obtained from information systems. Regardless of innovations in the design and training processes of the deep learning model, the data always affects the results. Training with a small amount of data with low representational power leads to poor generalization, while training with a large amount of data with high representational power shows higher generalization performance even with less complex algorithms [36].

The main goal of data augmentation is to enhance the robustness and accuracy of deep learning models and to allow them to perform well on small, weakly representative datasets. Effective data augmentation strategies also reduce the requirements related to model complexity, enabling high generalization performance with simpler deep learning architectures [37].

One of the biggest issues encountered in data training is overfitting. Overfitting occurs when the model makes correct predictions for training data but fails to do so for new data. On the other hand, underfitting is another error type that arises when the model fails to identify meaningful relationships between input and output data. Data augmentation helps prevent overfitting, underfitting, and the model memorizing the exact details of the training images [38]. Fig. 3 shows an example of data augmentation.

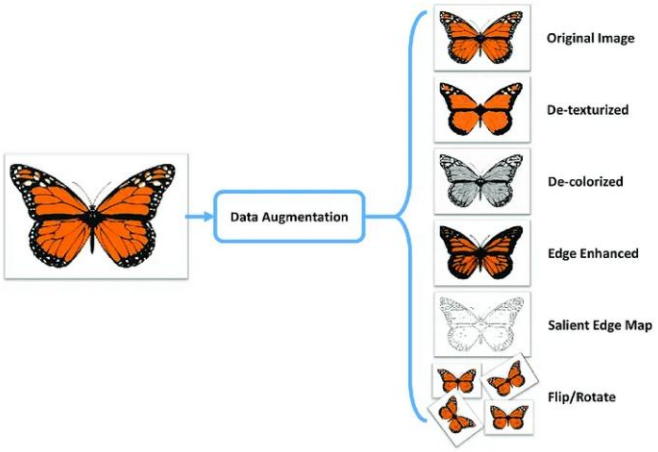

Fig. 3. Data augmentation samples [39].

The obtained datasets were used with the Matlab program to apply deep learning models such as DenseNet, EfficientNet, GoogleNet, Xception, and SqueezeNet. Four different datasets were run with the models, including 2, 3, and 4-class datasets, both with and without ROI markings. The datasets were divided into 70% for training, 15% for testing, and 15% for validation.

All modeling was conducted using an Nvidia RTX 4060 graphics card with CUDA cores. The 3-class dataset contained 128, 128, and 192 photos, respectively, while the 4-class dataset contained 128, 128, 128, and 64 photos, respectively. The batch

size was set to 25, and the validation frequency was set to 5. All models were trained in 30 epochs. In all models, the results of Precision, Recall, F1 score, and Accuracy metrics [40], along with confusion matrices and accuracy graphs that included the runtime, were recorded.

III. RESULTS

The average performance of the four-class, five-class models obtained using ROIs for each class is shown in Table I, and the confusion matrices of the models are depicted in Fig. 4.

TABLE I. THE PERFORMANCE OF 4-CLASS OUTPUT VARIABLES WITH ROI MARKED IMAGES FOR EACH MODEL

	Precision	Recall	F1 Score	Acc	Time
Densenet	0,8224	0,8480	0,8280	0,8657	12:47
Efficient	0,8724	0,8807	0,8759	**0,8955**	06:07
Googlenet	0,7711	0,7906	0,7731	0,8209	**03:29**
Xception	0,8224	0,8660	0,8306	0,8657	21:02
Squeezenet	0,6684	0,6875	0,6610	0,7313	**03:27**

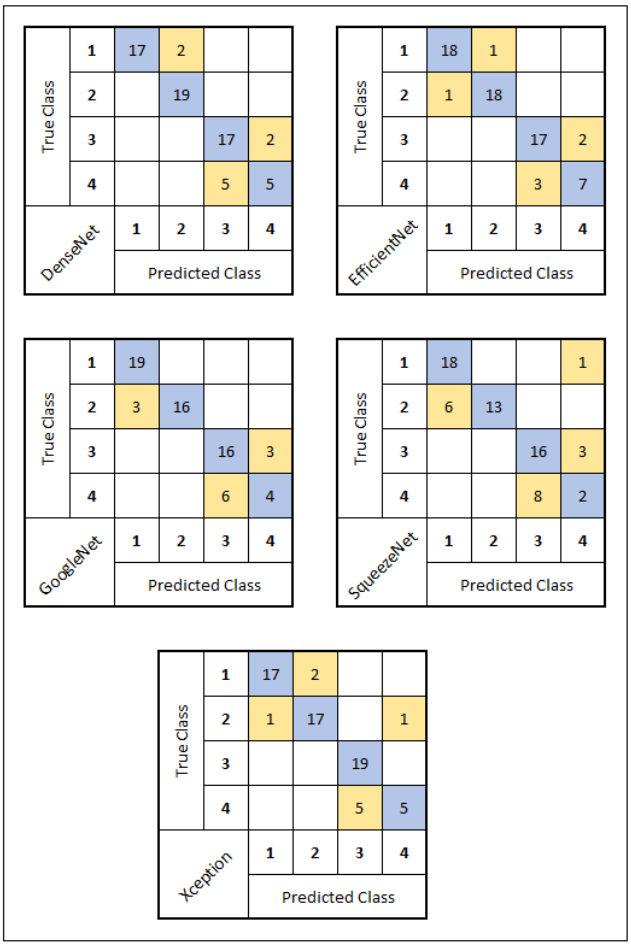

Fig. 4. The confusion matrices of the 4-class output variables with ROI marked images.

From Table I and Fig. 4, it is observed that accuracy measures belong to the DenseNet, EfficientNet, GoogleNet, and Xception models are quite high (>0.8). The accuracy rate of the SqueezeNet model is around 0.73. A similar situation is seen in the F1 score, precision, and recall values. These results indicate that the performance of the first four models is significantly higher than that of the SqueezeNet model. However, when looking at the runtime, it is observed that the runtimes of the SqueezeNet and GoogleNet models are significantly shorter than others. According to these results, the EfficientNet model is seen to have a high superiority both in terms of performance and runtime.

TABLE II. THE PERFORMANCE OF 3-CLASS OUTPUT VARIABLES WITH ROI MARKED IMAGES FOR EACH MODEL

	Precision	Recall	F1 Score	Acc	Time
Densenet	0,9298	0,9328	0,9296	0,9403	19:06
Efficient	0,9474	0,9545	0,9470	0,9552	06:06
Googlenet	0,9649	0,9649	0,9649	**0,9701**	03:42
Xception	0,9298	0,9360	0,9317	0,9403	13:33
Squeezenet	0,9123	0,9168	0,9142	0,9254	**01:47**

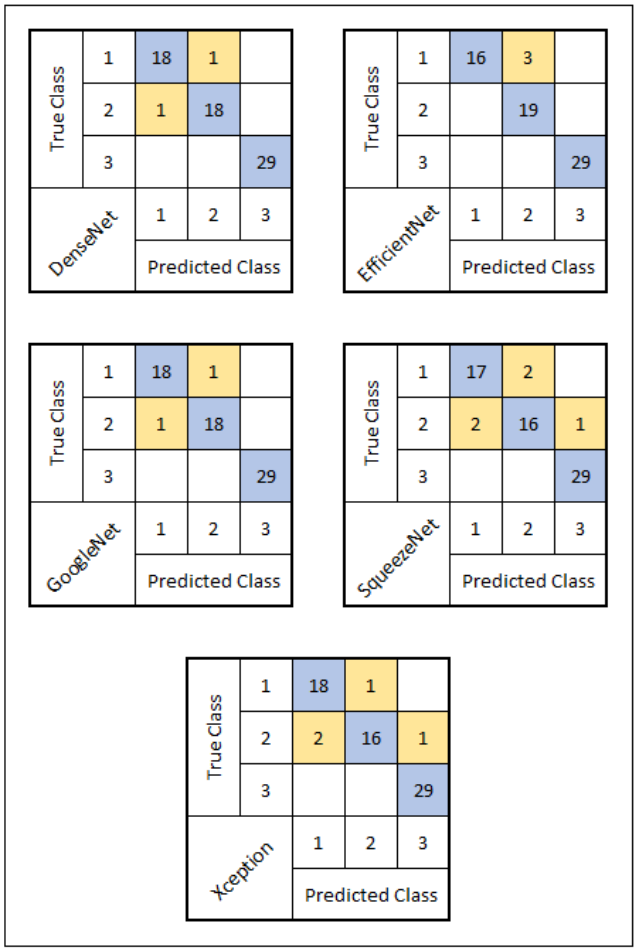

Fig. 5. The confusion matrices of the 3-class output variables with ROI marked images.

From Fig. 4, the prediction error rate between the 3rd and 4th classes is relatively high. This error is most likely due to the similar leaf sizes of the plants in these classes. To improve the accuracy rates of the developed model performances, the dataset was updated by merging the 3rd and 4th classes. Upon examining Table II and Fig. 5, it is observed that all models show high performance measurement metrics (>0.9). However, when looking at the runtime, it is noted that the runtime of the SqueezeNet models is quite short. According to these results, the GoogleNet model has a high superiority in terms of both performance and runtime.

TABLE III. THE PERFORMANCE OF THE 4-CLASS OUTPUT VARIABLES WITH ORIGINAL IMAGES WITHOUT ROI MARKINGS FOR EACH MODEL

	Precision	Recall	F1 Score	Acc	Time
Densenet	0,9487	0,9406	0,9440	**0,9552**	11:22
Efficient	0,8842	0,8748	0,8770	0,8955	04:29
Googlenet	0,7276	0,7272	0,7158	0,7313	02:19
Xception	0,9342	0,9260	0,9287	0,9254	13:22
Squeezenet	0,9605	0,9611	0,9605	**0,9552**	**00:53**

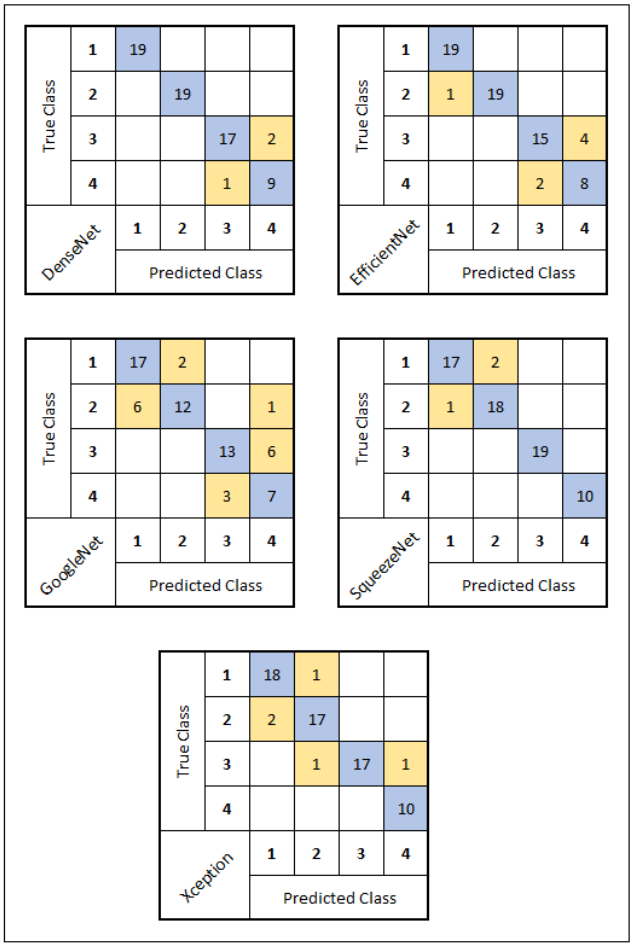

Fig. 6. The confusion matrices of the 4-class output variables with original images without ROI markings.

A 4-class database was created using photos without ROI markings. The objective here is to observe the effect of ROI marking on model performance. Upon examining Table III and Fig. 6(a), it is observed that the performance measurement metrics of the DenseNet, EfficientNet, Xception, and SqueezeNet models are higher than those of the GoogleNet model (>0.89). However, looking at the runtime, it is noted that the runtime of the SqueezeNet model is quite short. These results indicate that the SqueezeNet model has a high superiority in terms of both performance and runtime.

TABLE IV. THE PERFORMANCE OF THE 3-CLASS OUTPUT VARIABLES WITH ORIGINAL IMAGES WITHOUT ROI MARKINGS FOR EACH MODEL

	Precision	Recall	F1 Score	Acc	Time
DenseNet	0,9649	0,9683	0,9648	0,9701	23:34
Efficient	1,0000	1,0000	1,0000	**1**	07:26
GoogleNet	0,9474	0,6781	0,9473	0,9552	01:45
XCeption	0,9474	0,9545	0,9470	0,9552	16:14
Squeezenet	0,9359	0,9431	0,9355	0,9403	**01:08**

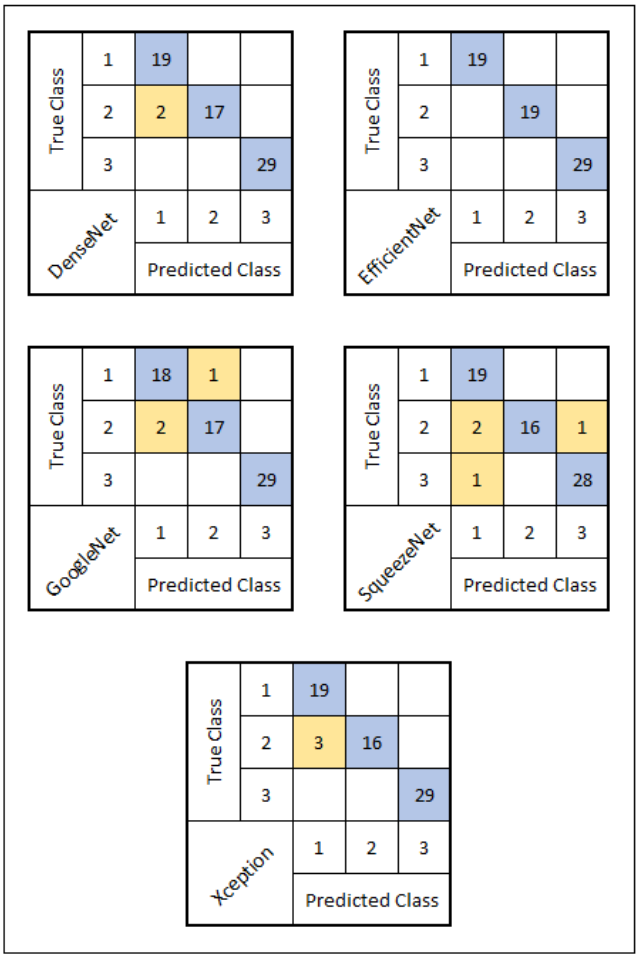

Fig. 7. The confusion matrices of the 3-class output variables with original images without ROI markings.

As observed in the dataset with ROI markings, the prediction error rate between the 3rd and 4th classes in photos without ROI markings is relatively high, as shown in Fig. 6. To improve the accuracy rates of the model performances, the dataset was updated by merging the 3rd and 4th classes, similar to the previous approach. Upon examining Table IV and Fig. 7, it is observed that the performance measurement metrics of all models are high (>0.94). However, looking at the runtime, it is noted that the runtime of the SqueezeNet model is quite short. According to these results, the EfficientNet model has high superiority in terms of performance, while the GoogleNet and SqueezeNet models have high superiority in terms of runtime.

IV. CONCLUSION

The aim of this study was to predict the growth stages of plants using a dataset of weed photographs through deep learning methods. The growth stages of the plants were divided into four different stages (classes). In line with this objective, ROI images of the leaves were extracted from the photos in the dataset using the Lifex program. This resulted in a total of 448 photos. Five different deep learning models were applied to this dataset.

According to the confusion matrix results, the accuracy rate for the leaves in the 4th class was lower because they resembled those in the 3rd class. As a result, the data for the 3rd and 4th classes were merged to form a new dataset, and the same deep learning methods were applied to this revised dataset.

Finally, a dataset was created using the raw, unmarked versions of the same images, and the previously mentioned deep learning models were applied again in both 3-class and 4-class formats.

In general, when the performance metrics of the models applied to the 4-class dataset marked with ROI was evaluated, no significant differences were observed (4 class ROI F1 Score: 0.8759). However, when the 3rd and 4th classes in the dataset were combined, an increase in the performance metrics of all models was observed (3 class F1 Score: 0.9649). Similarly, in the dataset created without ROI marking on the photos, the measurement parameters were found to be superior compared to the other conditions (4 class F1 Score: 96.05- 3 class F1 Score: 1.00).

This study is limited to the 4 weed species which are Lamb's Quarters (Chenopodium album), Jerusalem Oak Goosefoot (Dysphania botrys), Prickly Lettuce (Lactuca serriola), and Sow Thistle (sonchus oleraceus). In future studies, it is planned to extract the leaves from images using segmentation methods with the same dataset moreover other studies may be conducted on other weeds from different regions.

Target Detection of Leakage Bubbles in Stainless Steel Welded Pipe Gas Airtightness Experiments Based on YOLOv8-BGA

Huaishu Hou, Zikang Chen*, Chaofei Jiao
School of Mechanical Engineering, Shanghai Institute of Technology, Shanghai, 201418, China

***Abstract*—Gas-tightness experiment is an effective means to detect leakage of stainless steel welded pipe, and the vision-based bubble recognition algorithm can effectively improve the efficiency of gas-tightness detection. This study proposed a new detection network of YOLOv8-BGA using the YOLOv8 model as a baseline, which can achieve effective identification of leakage bubbles and bubble images are collected under different lighting conditions in a practical industrial inspection environment to create a bubble dataset. Firstly, a C2f_BoT module was designed to replace the C2f module in the backbone network, which improved the feature extraction capability of the model; secondly, the convolutional layer of the neck network was replaced by using the GSConv module, which achieved the model lightweighting; thirdly, the C2f-BM attention mechanism was added before the detection layer, which effectively improved the model performance; finally, the WIoU was used to improve the loss function, which improved the detrimental effect of small bubbles of low-quality samples in the dataset on the gradient, and significantly improved the convergence speed of the network. The experimental results showed that the average leakage bubble detection accuracy of the YOLOv8-BGA model algorithm reached 97.7%, which improved by 5.3% compared with the baseline, and meets the needs of practical industrial inspection.**

I. INTRODUCTION

Stainless steel welded pipe has a wide range of uses, and is widely used in chemical industry, automobile manufacturing, shipbuilding and other industrial production areas [1], but it is prone to leakage problems, which has a greater impact on the subsequent use of the product. Gas tightness test is an effective means to test whether the stainless steel welded pipe leakage, when the welded pipe leakage exists, air bubbles are generated in the water, and the identification of air bubbles is an important indicator for judging the gas tightness. The traditional airtightness detection for workers to observe, the method is subject to subjective factors, easy to miss, low detection efficiency [2-4].Vision-based airtightness testing can exclude the influence of human subjective factors, assess the results through the indicators, make the test results more accurate, and improve the efficiency of product testing. Vision-based airtightness detection has traditional image processing method [5] and deep learning target detection based method [6].

Traditional image processing algorithms rely on classical image processing techniques based on edge contour and circumferential curvature fitting to manually extract the bubble edge features. Qaddoori [7] used the use of Hough's Circle Transform algorithm to identify the tiny bubbles in the graph based on Canny operator and segmented the centre and edges of the bubbles by two thresholds to calculate the average diameter and number of bubbles in the graph; Wen [8] designed a new image processing algorithm based on the concept of differential segmentation while considering the geometry and deflection angle of the bubbles; Akdemir [9] proposed a detection method using wavelet transform denoising and entropy threshold segmentation. The above proposed methods need to modify the parameters to respond to different detection environments, and have weak generalisation ability for identifying bubbles, and are prone to miss detection and false detection. Deep learning based target detection method has higher detection rate, stronger generalisation ability and better robustness for bubble recognition.

Deep learning target detection algorithms are classified into two types: a two-stage algorithm with high accuracy but slow speed, such as Faster R-CNN [10], Mask R-CNN [11]; and a single-stage algorithm with a simple structure and high computational efficiency, such as Krysko, N.V.et al [12] through the integrated application of non-destructive testing techniques, computer vision and convolutional neural networks, the surface of pipeline pitting and defects were classified and quantitatively analysed; Zhao et al [13] proposed a 3D quartz crucible bubble detection method, which significantly improved the detection accuracy of tiny bubbles by optimising the YOLOv5 network structure, introducing dilated convolution and ECA-Net mechanism, and combining Kalman filtering with Hungarian matching algorithm. Due to the different generalisation ability of the model in different detection environments. The real-time identification of bubbles is affected by the ripples generated by the bubble movement, the lighting environment, impurities in the water, sedimentation and other factors, which makes the collected bubble images have a lot of noise and missing bubble boundaries, which in turn affects the accuracy of target detection.

In this study, a model algorithm YOLOv8-BGA based on YOLOv8 is developed to achieve effective identification of leakage bubbles. Firstly, a C2f_BoT module is designed to replace the C2f module in the backbone network, which improves the feature extraction capability of the model; secondly, the convolutional layer of the neck network is replaced by using the GSConv module, which realises the model lightweight; again, the C2f-BM attention mechanism is

*Corresponding Author.

added before the detection layer, which effectively improves the model performance; and lastly, the loss function is improved by using the WIoU to improve the dataset The unfavourable effect of small bubbles of low-quality samples on the gradient significantly improves the convergence speed of the network.

II. Related Work

The first single-stage target detection YOLO algorithm was first proposed by Redmon [14] in 2015.The algorithm achieves fast identification and precise positioning of the target to be detected through a regression method. Currently, the YOLO series of algorithms has been developed to YOLOv10, and a variety of improved algorithms have been derived in academia. For example, Li [15] and others improved the internal structure of YOLOv5s and proposed a 'YOLOv5s-ShuffleNetV2-DWconv-Add' model, which provides an efficient acquisition method for fruit picking robots; Sun [16] and others proposed a 'Pconv-Wide lightweight' model for fruit picking robots. Pconv-Wide lightweight convolutional simplified YOLOv7 model, which increases the detection accuracy of UAVs on small targets while reducing the number of model parameters; Zhao [17] et al. proposed a Res-Clo network for denoising pre-processing of SAR images, and designed a DML-YOLOv8w network, which improves the performance of the model in multi-scale detection; YOLOv8 uses an Anchor-Free detection head [18], which improves the generalisation ability while reducing the model complexity, and improves the detection speed and accuracy compared to the previous YOLO algorithm.

YOLOv8 has four network model structures, YOLOv8n, YOLOv8s, YOLOv8m, and YOLOv8l, and the choice of the structure depends on the actual detection scenario and resource conditions. The YOLOv8n model is mainly divided into four parts: (1) Data enhancement strategies are applied to the image in the input part, such as Mosaic data enhancement and adaptive anchor frame computation to enhance the data diversity; (2) The backbone network is processed by multiple convolutional downsampling at key nodes, thus effectively reducing the size of the feature map and preserving the spatial information of the image. Then C2f modules of different sizes are used to capture multi-scale features; (3) The neck network accepts feature maps of various scales obtained through 8, 16, and 32 times downsampling from the backbone network, and fuses shallow high-resolution features and deep low-resolution features through PANet (path aggregation network), followed by fusing the fused feature maps with rich spatial and semantic information. Then the fused feature maps with rich spatial and semantic information are output to the Head part for further processing; (4) The Head network receives the multi-scale feature maps from Neck, performs up-sampling and splicing operations on them to match the resolution of the input image, and adjusts the number of channels through the feature conversion layer.

YOLOv8 has three Detect layers of different scales, 80×80, 40×40, and 20×20, which are used to detect large, medium, and small sized targets in the image, respectively. The three prediction layers output the category probability and bounding box location of each cell, and the stability of the prediction box is evaluated by a confidence layer.YOLOv8 adopts a Decoupled-Head structure to separate the classification and detection tasks to improve the detection efficiency. Finally, IOU (Intersection over union) [19] is used as the loss function for the bounding box regression, and then NMS (Non-Maximum Suppression) [20] removes the redundant prediction frames so as to avoid the same target from being detected repeatedly and retain the best results. This paper is based on the YOLOv8n algorithm to improve. The structure of the YOLOv8 model is shown in Fig. 1.

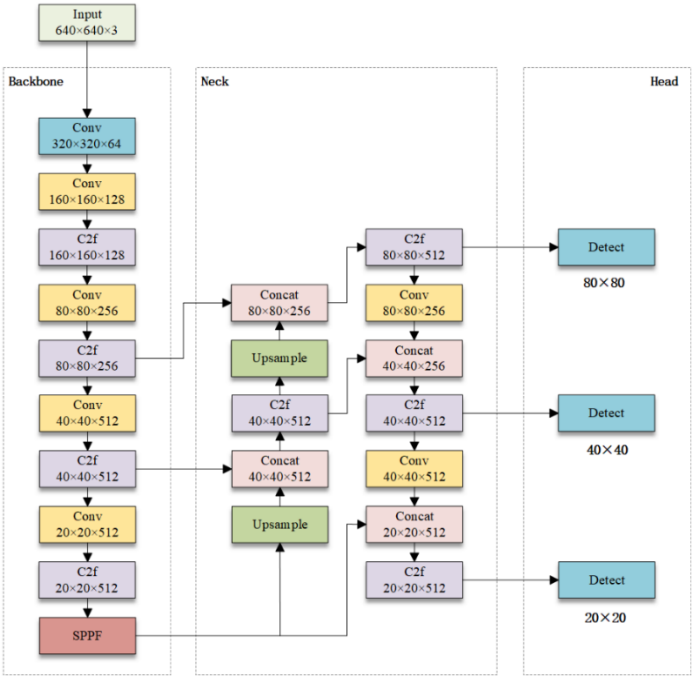

Fig. 1. YOLOv8 model structure.

III. Algorithm Design

A. Network Architecture Design

In this paper, four improvement modules for the YOLOv8n model are proposed. Firstly, the C2f_BoT module was constructed to replace the original C2f module of 40×40 and 20×20 sizes in the Backbone section, which improves the ability of the model to detect small and medium-sized bubbles; Secondly, the original Conv(Convolution) block is replaced by the GSConv in the neck network, which reduces the complexity of the model and improves the inference speed to achieve the effect of model lightweighting; Next, the C2f-BM attention mechanism is embedded in front of each detection head, which improves the detection accuracy of the model for small bubble targets; Finally, the WIoU loss function is introduced to speed up the network convergence. These improvements greatly improved the detection accuracy and detection speed of the original model in the stainless steel welded pipe gas-tightness inspection task. Fig. 2 shows the structure of the YOLOv8-BGA model obtained after the improvement.

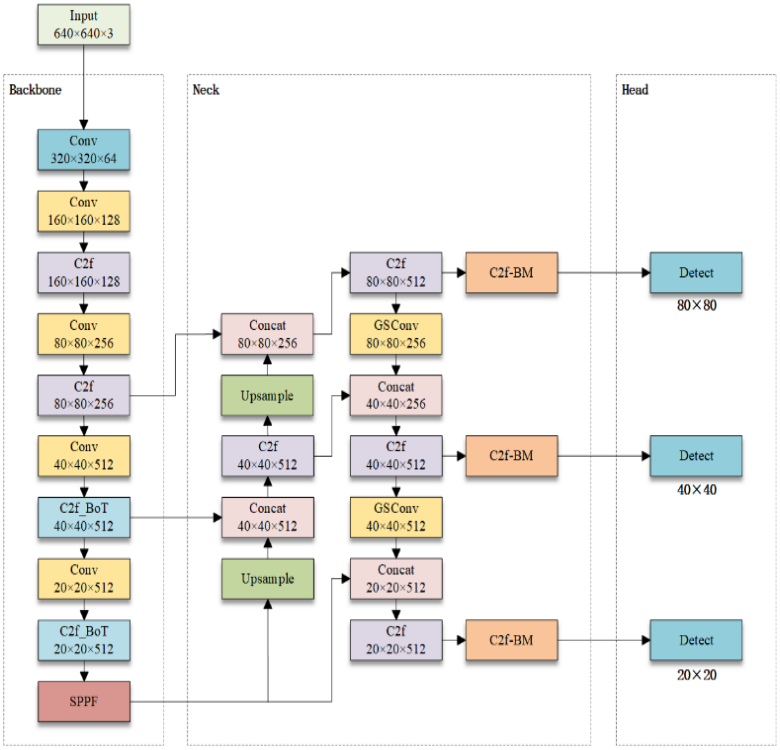

Fig. 2. YOLOv8-BGA model structure.

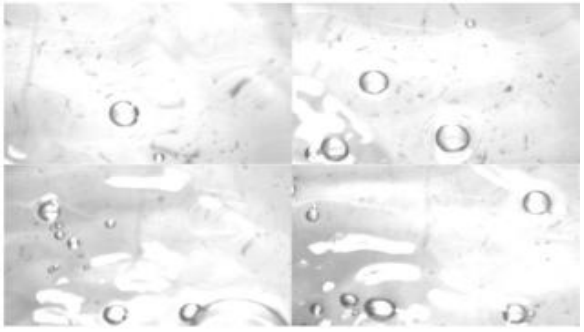
B. Mosaic Image Data Enhancement

Data enhancement of the self-constructed bubble dataset is performed using the Mosaic method at the YOLOv8n input. The Mosaic data enhancement algorithm improves the detection ability of the model in a small field of view by fusing multiple images into a single image according to a certain random scale. As shown in Fig. 3, four bubble images are randomly selected, certain parameters are set, and they are stitched into one image by random permutation, random size scaling, and random cropping.



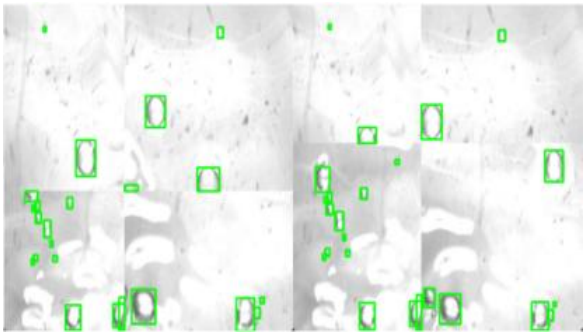


Fig. 3. Data enhancement.

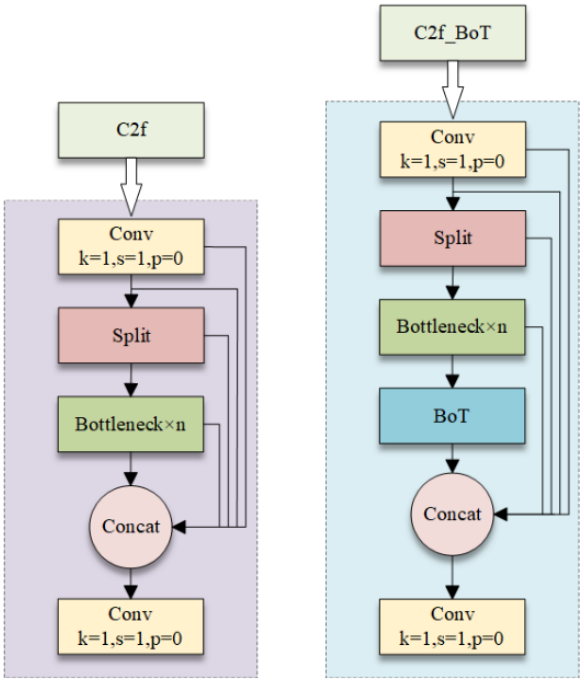
Using Mosaic data enhancement technique to strengthen the dataset can increase the data diversity, and the combined images obtained are more than the number of original images, which can get more small targets, and improve the generalisation ability of the trained model, which is a great improvement for detecting some tiny bubbles produced by subtle defects. And the network is able to batch process four image data in a single batch, which optimises the effect of the batch normalisation layer, thus reducing the computational burden on the GPU,

making it possible to achieve efficient training results on a single GPU.

C. C2f Module Improvements

The YOLOv8 network structure makes several uses of the C2f module [21], which is an improved residual block that enables feature fusion by connecting feature maps of different depths through splicing and upsampling operations. The spliced feature map fuses multi-scale features, which is helpful for the model to detect targets of different sizes. Compared with the traditional C3 module in YOLOv5, the C2f module increases the depth while ensuring smooth gradients, and the detection accuracy of the model is subsequently improved. However, for medium and small size targets, there are still cases of missed detection, in order to meet the accurate identification of tiny bubbles generated at the subtle defects of defective stainless steel welded pipes, and to increase the detection accuracy without increasing the additional computational cost, this paper proposes a C2f_BoT module for replacing the C2f module in the backbone network, and the structure of the C2f and the C2f_BoT network is shown in Fig. 4.

The BoT(Bottleneck Transformer) modules added after the last layer of Bottleneck in the C2f module, because the BoT module helps to improve the detection accuracy of the model for small and medium-sized targets, in order to maximise the utilisation of computational resources, this paper only replaces the C2f module with the 40×40 and 20×20 scales in the backbone network. The C2f_BoT module can effectively improve the accuracy. Moreover, the generalisation ability of the model can be further improved due to the MHSA attention mechanism in the BoT module. BoT network has a simple and powerful structure and is widely used in visual tasks such as image classification, target detection, semantic segmentation, etc. [22], and its structure is shown in Fig. 5.It replaces the 3×3 convolutional layers in the ResNet structure with the MHSA (Multi-Head Self-Attention), which automatically captures the dependencies between sequences when processing the input sequences and thus better understands the contextual information to improve the model performance. This operation significantly improves the baseline in the target detection task, resulting in lower latency. The C2f_BoT module with the added BoT structure improves the computational efficiency and detection accuracy of the model compared to the original C2f module, which is more suitable for the practical application of the model in industrial inspection.



(a)C2f network structure (b)C2f_BoT network structure

Fig. 4. C2f and C2f_BoT network structure.

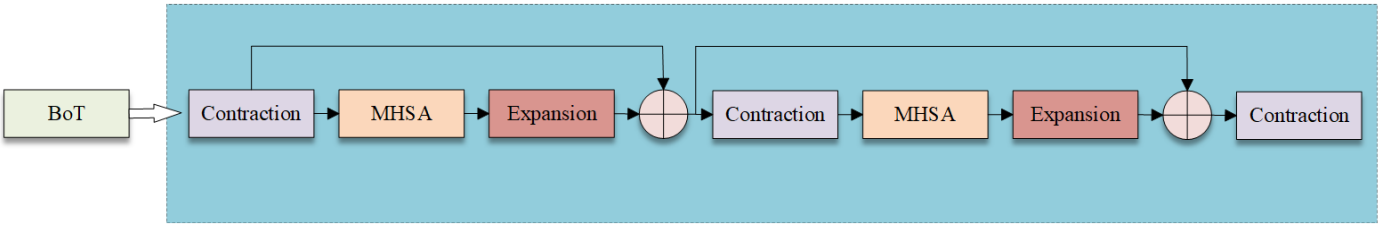


Fig. 5. Bottleneck transform structure.

D. Lightweight Processing

In order to reduce model complexity and reduce computational requirements, this paper uses the GSConv module to replace the original convolutional layer.GSConv is a hybrid of SConv (Standard convolution) and DSConv (Depth-wise separable convolution) [23] combined by the Shuffle convolution. DSConv incorporates deep convolution, which focuses on spatial feature extraction, and point-by-point convolution, which focuses on channel features. This structure performs deep convolution for each channel independently when processing features, and performs channel fusion at the output stage through a 1×1 convolutional layer to reduce the number of computations and parameters. Since DSConv separates each channel at the input image, some of the bubble image features are lost, which is degraded for airtightness detection accuracy. And GSConv can reduce the number of parameters and computation of the model while ensuring the training speed and detection accuracy. Its structure is shown in Fig. 6.

In this paper, the GSConv structure is introduced in the Neck part. In the Neck part, the channel dimension of the feature map extracted by the network is large, in order to maximally retain the circulation of feature information in the spatial and channel dimensions, and to avoid the loss of detail information, the original convolutional layer is replaced with GSConv in this part, which can reduce the model complexity under the premise of guaranteeing a certain model accuracy. If GSConv is used in all parts of the network, it will increase the depth of the network and thus prolong the inference time.

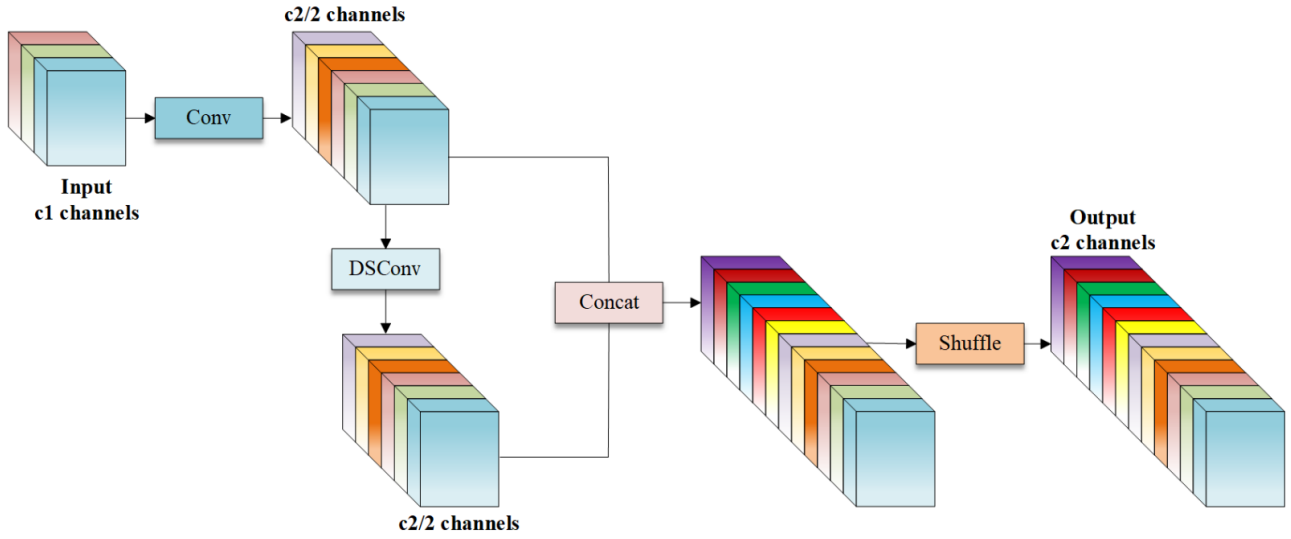

Fig. 6. GSConv structure.

E. C2f-BM

The attention mechanism is a resource allocation scheme that mimics human vision, which effectively allocates computational resources, prioritises critical tasks and alleviates information overload.YOLOv8 often faces the problem of feature loss in stainless steel welded pipe airtightness experiments for detecting small target bubbles, because small bubbles occupy fewer pixels in the feature map, and as the network undergoes many times of downsampling, the feature details of the small bubbles may be overlooked which makes the model performance degraded and generates problems such as leakage detection, which has a significant impact on the leakage detection generated by fine defects in steel pipes. Especially in the complex scene in the water, due to the water surface ripples caused by leakage, the impurity precipitation in the water and the pixel difference between the light and dark areas, the noise information in the background may occupy most of the feature space, so that the model is interfered with and cannot be accurately focused on the target area, resulting in the inability to accurately locate the target, and thus leakage detection.

To solve the above problems, the C2f-BM attention mechanism is designed in this section and embedded in front of the YOLOv8 detection head, the structure of which is shown in Fig. 7.

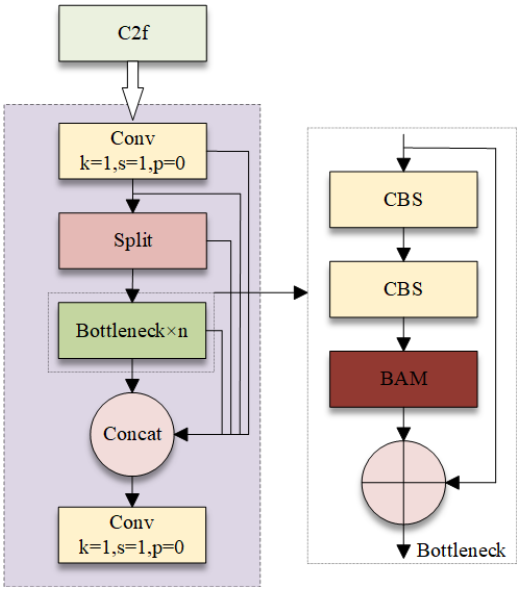

Fig. 7. G2f-BM structure.

The BAM (Bottleneck Attention Module) [24] is a simple and efficient attention mechanism, the structure of which is shown in Fig. 8, which mimics how the human visual system focuses on the critical parts of an image by separating the information from both channel and spatial pathways.

Channel attention focuses on enhancing the identification of feature channels relevant to the target detection task, while spatial attention focuses on the spatial location in the image, helping the model to focus more on the region where the small target is located, thus reducing the loss of feature information of the small target. The BAM combines the results of these two to generate a comprehensive Attention Map. This mechanism effectively improves the model's performance in the detection of small bubble target. This mechanism effectively improves the performance of the model in small bubble target detection, especially in complex detection scenarios in water. Through the spatial attention mechanism, the BAM mechanism can effectively suppress the irrelevant information in the background, reduce the noise interference, and make the model more focused on the feature space of the small target to enhance the robustness of the model. The C2f module itself optimises the feature extraction process, and by embedding the BAM mechanism, the model can focus on important features in the early feature extraction stage to improve the feature quality and model performance in the subsequent stages. Moreover, since C2f improves the gradient flow, the introduction of BAM can further optimise the gradient distribution, which makes the model more stable to be trained when dealing with complex visual tasks. Due to the lightweight nature of the BAM mechanism, it does not significantly increase the extra computational burden during embedding, allowing the whole model to improve performance while maintaining efficient computation.

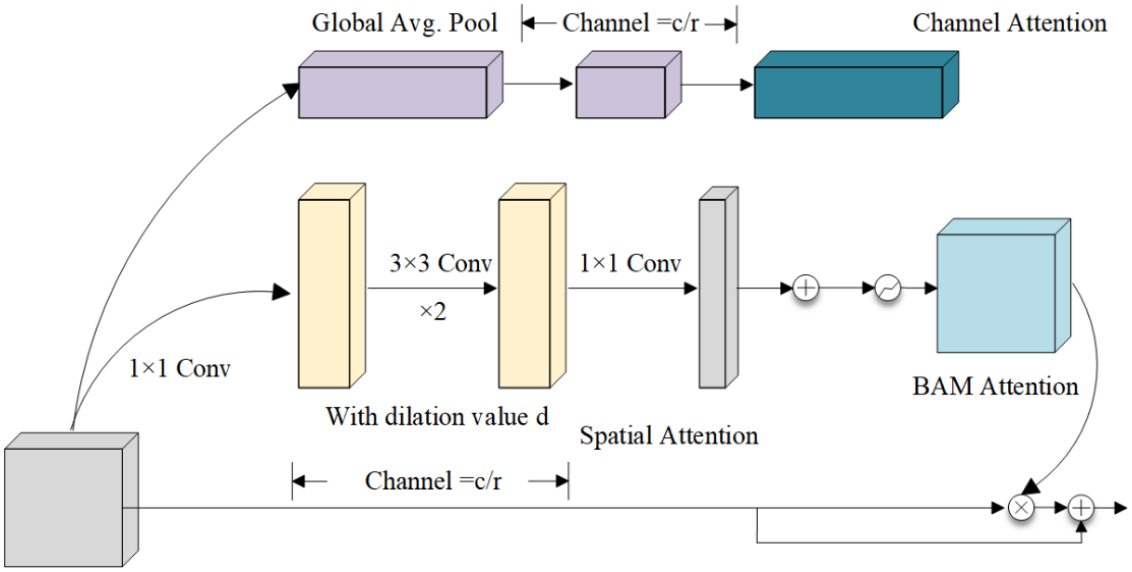

Fig. 8. BAM structure.

BAM calculates Attention Map through two branches: channel and space, and this paper introduces its calculation method from the following three points:

1) .Channel Attention (CA): The expectation maximisation algorithm aims to find maximum likelihood solutions for the hidden variables. In this step, the posterior probability distribution of the hidden variables under the current model parameters is calculated. In fact, it is to calculate the weights and responsibilities of each base for each pixel, the formula is shown in Eq. (1).

$$F_c = AvgPool(F) \tag{1}$$

where the global average pooling of the input feature map $F \in R^{C\times H\times W}$ is performed to obtain the average value of each channel to obtain the vector $F_c \in R^{C\times 1\times 1}$. C is the number of channels, H is the height, and W is the width.

Next, a multilayer perceptron (MLP) containing hidden layers is used to estimate the inter-channel attention from the channel vector F_c ,the formula is shown in Eq. (2).

$$MLP(F_c) = BN(W_1(\mathrm{Re}bLU(W_0F_c+b_0)+b_1)) \tag{2}$$

where, $W_0 \in R^{\frac{C}{r}\times C}$, $b_0 \in R^{\frac{C}{r}}$, $W_1 \in R^{\frac{C}{r}\times C}$, $b_1 \in R^{C}$, the size of the hidden layer is $\frac{C}{r}$, and r is the reduction ratio.

After the MLP, a batch normalisation layer is added to scale the output, the formula is shown in Eq. (3).

$$CA = BN(MLP(F_c)) \tag{3}$$

2) Spatial Attention (SA): First, the feature map F is projected to a smaller size using a 1×1 convolution to integrate and compress the feature map across channel dimensions, the formula is shown in Eq. (4).

$$F_R = Conv_{1\times1}(F) \tag{4}$$

Next, the contextual information is effectively utilised with two 3×3 null convolutions, the formula is shown in Eq. (5).

$$F_D = DilatedConv_{3\times3}(F_R) \tag{5}$$

Finally, the feature map is again reduced to a spatial attention map using 1×1 convolution, the formula is shown in Eq. (6).

$$SA = Conv_{1\times1}(F_D) \tag{6}$$

3) Combination of CA and SA:

$$M(F) = \sigma(M_C(F) + M_S(F)) \tag{7}$$

where $M_C(F)$ is the channel attention mapping, $M_S(F)$ is the spatial attention mapping, and σ is the *Sigmoid* activation function. Finally, the 3D attention map $M(F)$ is multiplied element-by-element with the input feature map, and then added to the original input feature map to obtain the refined feature map $F^{'}$, the formula is shown in Eq. (8).

$$F^{'} = F + F \otimes M(F) \tag{8}$$

where $\otimes$ denotes element-by-element multiplication.

This combination of BAM mechanisms is simple yet effective in adaptively assigning higher weights to small targets by balancing information from both the channel and spatial branches, while facilitating gradient flow.

F. Loss Function Improvement

The original YOLO family of algorithms uses IoU (Intersection over union) to calculate the bounding box regression loss, which refers to the ratio of the intersection and concatenation set of the true and predicted frames, as shown in Eq. (4).

$$IoU = \frac{|A \cap B|}{|A \cup B|} \tag{9}$$

Where A denotes the true frame and B denotes the predicted frame, $A \cap B$ is its intersection, $A \cup B$ is its union set.

When the similarity ratio between the predicted frame and the real frame is higher, it means that the detection is better. However, there are shortcomings, in the detection when the real frame and the predicted frame do not intersect, that is, when $A \cap B = 0$, it is impossible to determine the size of the distance between the predicted frame and the real frame.

Therefore, in order to solve the instability brought by the above situation to the detection, YOLOv8 adopts CIoU (Complete-IoU) [25] instead of IoU. CIoU adds distance and aspect ratio to IoU, and its calculation formula is shown in Eq. (10)- Eq. (12).

$$L_{CIoU} = 1 - IoU + \frac{\rho^2(A,B)}{c^2} + \alpha V \tag{10}$$

$$V = \frac{4}{\pi^2}(\arctan\frac{\omega^A}{\omega^A} - \arctan\frac{\omega^B}{\omega^B}) \tag{11}$$

$$\alpha = \frac{V}{1 - IoU + V} \tag{12}$$

where, $\rho^2(A,B)$ is the Euclidean distance between the centroids of the true and predicted frames, V is a parameter indicating the consistency of the aspect ratio, and α is a parameter used to balance the ratio.

Using CIoU, the minimum value of the distance between the real and predicted frames, the aspect ratio and the distance between the centre points of the bounding boxes can be calculated, which improves the stability of the target box regression. However, CIoU only considers the centre distance of the two bounding boxes, and the matching of the boundaries cannot be accurately assessed, leading to an impact on the detection effect when the target shape changes. The WIoU loss function, on the other hand, introduces a weight function on the basis of IoU, which makes it flexible to adjust the weights between different samples even in more complicated situations. For samples with poorer labelling quality in the dataset, WIoU performs better compared to other boundary loss functions.

In this paper, WIoU (Wise-IoU) is replaced as the loss function, which is proposed on the basis of Focal-EIoU [25].Most of the research on loss function in recent years assumes that the samples in the dataset are of high quality, and is committed to improving the fitting ability of the bounding box loss, while when there are low-quality samples in the dataset, it will jeopardise the model detection performance if the regression of the bounding box on the low-quality samples is improved, while Focal-EIoU is proposed to solve the problem, and its formula is shown in Eq. (13) - Eq. (14).

$$L_{EIoU} = 1 - IoU + \frac{\rho^2(A,B)}{c^2} + \frac{\rho^2(\omega^A,\omega^B)}{c_\omega{}^2} + \frac{\rho^2(h^A,h^B)}{c_h{}^2} \tag{13}$$

$$L_{Focal-EIoU} = IoU^{\gamma} L_{EIoU} \tag{14}$$

where γ is the hyperparameter used to control the curvature of the curve and its focusing mechanism is static. To fully exploit the potential of the non-monotonic focusing mechanism, WIoU [26] uses a dynamic non-monotonic mechanism to assess the quality of the anchor frame, which gives it a better performance when facing the targets with different geometric factors, and the detection performance of the samples from low-quality datasets is improved, and improves the model's generalisation ability. The WIoU loss function expression is shown in Eq. (15) - Eq. (17).

$$L_{WIoU} = \frac{\beta}{\delta\alpha^{\beta-\delta}} R_{WIoU} L_{IoU} \tag{15}$$

$$R_{WIoU} = exp(\frac{(x - x_{gt})^2 + (y - y_{gt})^2}{(\omega_g{}^2 + h_g{}^2)^*})p \tag{16}$$

$$L_{IoU} = 1 - IoU \tag{17}$$

where β describes the outlier of the anchor frame mass, α and δ are hyperparameters. ω_g and h_g are the dimensions of the minimum enclosing frame, (x, y) and (x_{gt}, y_{gt}) are the coordinates of the centre points of the anchor and target frames. Using the WIoU loss function in the improved model, the performance of target detection can be improved by introducing the weighting factor, and for targets with different sizes and shapes, the WIoU can give more reasonable weights to different samples, so that the improved model can better learn the characteristics of bubbles with different sizes and shapes during the training process, and improve the robustness of the stainless steel welded pipe airtightness detection task.

IV. LEIS EXPERIMENTS AND ANALYSIS OF RESULTS

A. Experimental Methodology Flow

The experimental methodology of this paper is specifically divided into the steps of data preparation, model construction, model training, model validation, and result analysis. The flow chart of the experimental method is shown in Fig. 9.

The specific work is as follows:

1) Data preparation. It is necessary to collect the datasets (D1, D2, D3, D4) of stainless steel defective welded pipe leakage detection, perform data enhancement on the D1 and D2 datasets, and divide the datasets into a training set and a validation set.

2) Model construction. Taking YOLOv8n as the base model, the model improvement work in section III of this paper is carried out on it in order to obtain the improved YOLOv8-BGA model.

3) Model training. Train the model on D1 and D2 datasets respectively.

4) Model validation. Use the trained model weights to validate the model on the validation sets of D1, D2, D3, and D4 datasets, and calculate Precision, Recall, and mAP metrics.

5) Result analysis. Compare the detection performance of different models, analyze the generalization ability of models in different environments, and conduct ablation experiments to verify the effectiveness of each improvement module.

B. Experimental Setup

The experiments in this paper were conducted under Windows 11 operating system, using a CPU model i7-13620H with 16G of RAM, a graphics card NVIDIA RTX4060, accelerating the GPU using CUDA11.8 and CUDNN8.8.1, and running under the Pytorch2.0.0 deep learning framework. In this experiment, the official website YOLOv8n model weights are used as the basic network model, batchsize is set to 32 and epoch is 200.an industrial face array camera with model number MV-CS004-10GM is used, and the camera is shown in Fig. 10.

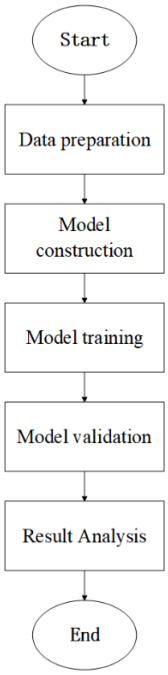

Fig. 9. Experimental methodology.

Fig. 10. Industrial camera.

An airtightness tester model LS11Z-100 was used for inflation and pressurization, as shown in Fig. 11.

Fig. 11. Airtightness tester diagram.

The light source is a strip light source and the schematic diagram of the image acquisition device is shown in Fig. 12.

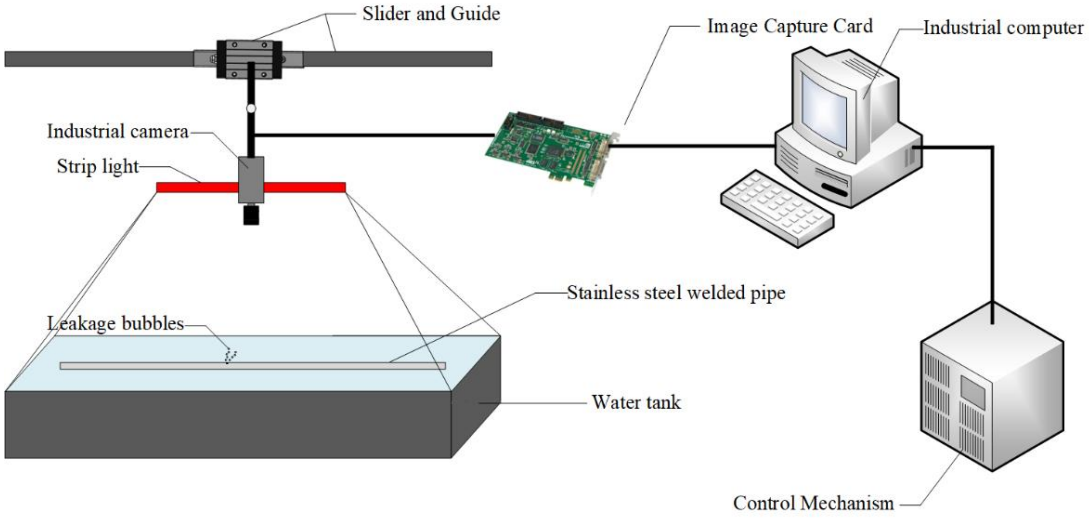

Fig. 12. Image acquisition device.

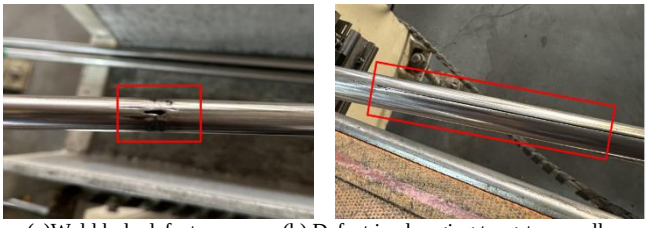
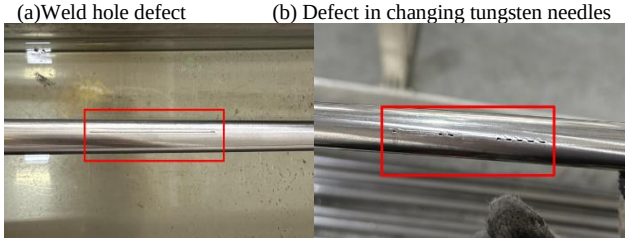
C. Experimental Data Set

The dataset in this paper was acquired in an image acquisition platform built in a real industrial inspection environment. The stainless steel defective welded pipe used for the experiment is obtained from the processing workshop, and several common defective welded pipes are shown in Fig. 13.



(a)Weld hole defect (b) Defect in changing tungsten needles



(c) Soldering defect (d) Skipped weld defects

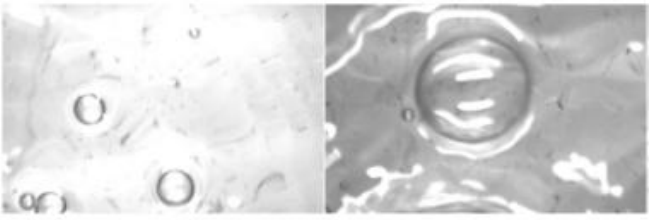
Fig. 13. Stainless steel welded pipe common defects diagram.

In order to evaluate the generalisation ability of the improved model, two datasets, D1 and D2, were acquired in two different lighting environments (bright and dimmer), and secondly, two noisy images were acquired in these two lighting environments as D3 and D4 datasets. All the dataset images were labelled and their basic characteristics are detailed in Table I.

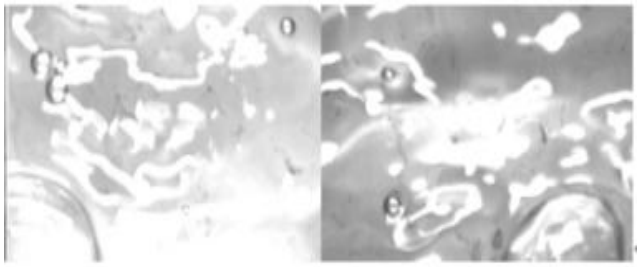
TABLE I BASIC INFORMATION ON THE D1-D4 DATA SETS

Dataset	Feature	train set	val set
D1	Sufficient light	4640	1160
D2	dusky	5080	1270
D3	Sufficient light, noise	0	945
D4	Dusky, noise	0	975

Due to the defects of the original data, Mosaic data enhancement is performed on D1 and D2 datasets, and the images of D1 dataset are expanded to 5800, D2 dataset is expanded to 6350, and D3 and D4 datasets are not processed. The D1 and D2 datasets are divided into training set and validation set with the ratio of 8:2. Some images of D1-D4 datasets are shown in Fig. 14.



D1 D2



D3 D4

Fig. 14. Partial images of the dataset.

D. Assessment of Indicators

In the field of deep learning target detection, the main metrics for model performance evaluation are P (Precision), R (Recall) and mAP (mean AP), and the model complexity can be evaluated by GFLOPS (Giga Floating Point Operations) and Parameters [27]. FPS were used to evaluate the performance of the model. In this paper, the model evaluation is also based on these criteria.p, R and mAP are calculated as shown in Eq. (18)-Eq. (21):

$$P = \frac{TP}{TP + FP} \tag{18}$$

$$R = \frac{TP}{TP + FN} \tag{19}$$

$$AP = P(r)dr \tag{20}$$

$$mAP = \frac{1}{N} AP \tag{21}$$

In Eq. (13) - Eq. (16), TP is the number of positive samples correctly detected; FP is the number of positive samples incorrectly detected; FN is the number of negative samples incorrectly detected; AP is the average precision; and N is the number of all predictions.

E. Error Analysis and Discussion

In the process of detecting leakage bubbles in stainless steel welded pipes using the YOLOv8-BGA model, several types of errors were observed. Small bubbles, particularly those generated by subtle defects, are more likely to be missed due to their low pixel occupancy in the feature map. The repeated downsampling in the network can lead to the loss of these fine details. Additionally, bubbles that appear in regions with high background noise or similar textures are prone to incorrect detection. For example, in the presence of water impurities or ripples, the model may confuse these with actual bubbles. These factors collectively contribute to the challenges faced during the detection process.

The impact of noise and ripples on detection accuracy cannot be overlooked. The movement of bubbles can generate ripples on the water surface, which introduce additional noise into the image. These ripples can interfere with the model's ability to accurately locate and identify bubbles, especially in complex underwater scenes. Variations in lighting conditions can cause significant reflection and refraction effects on the water surface, leading to false positives or false negatives as the model may misinterpret the light patterns as bubbles. Overlapping bubbles and those with unclear or irregular boundaries also pose challenges, as the model may struggle to distinguish individual bubbles or accurately delineate bubble contours. These issues highlight the need for further improvements to enhance the model's robustness and accuracy.

To address these challenges, several strategies were implemented. Mosaic data augmentation was employed to increase the diversity of the training dataset, helping the model learn to detect small targets more effectively. The C2f-BM attention mechanism was introduced to allow the model to focus more on critical regions, reducing the impact of noise and improving the detection accuracy for small bubbles. Additionally, the WIoU loss function was utilized to enhance the model's fitting ability, especially for low-quality samples with small bubbles, thereby improving the overall detection performance. Through these improvements, the YOLOv8-BGA model demonstrated enhanced robustness and accuracy in detecting leakage bubbles under various conditions. Future work will continue to explore advanced techniques and additional data collection under varied conditions to further improve the model's performance.

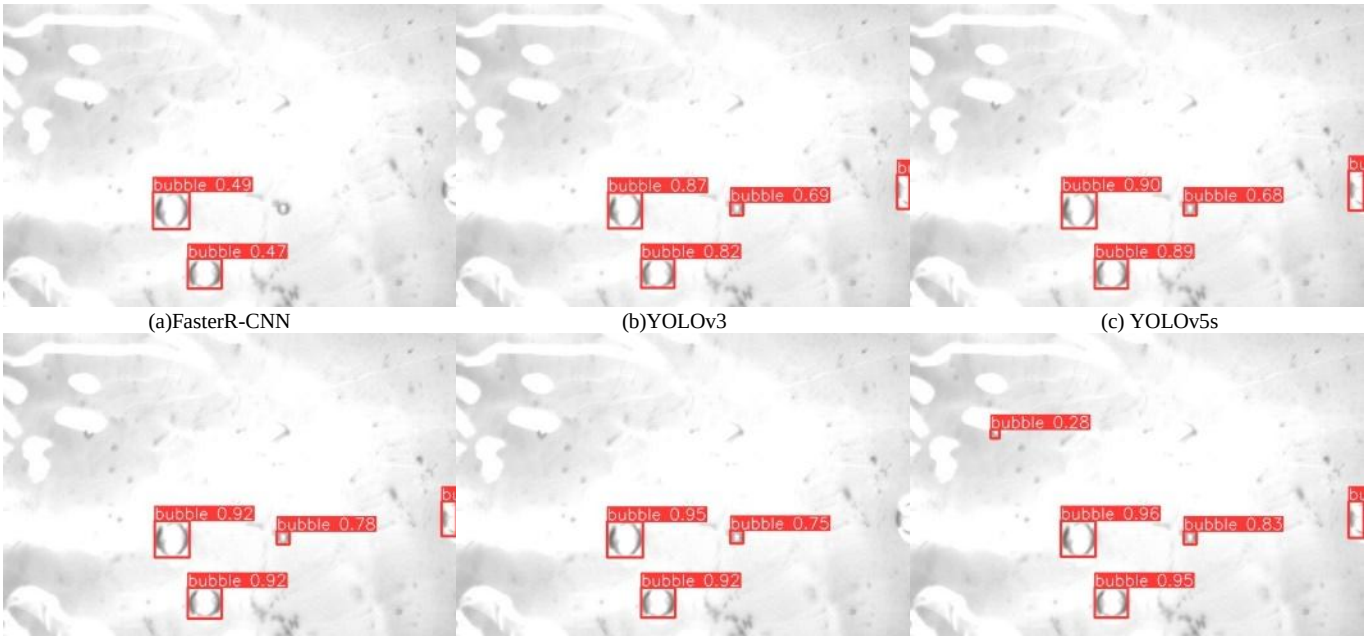
F. Experimental Results and Analysis

1) Comparison experiment: In order to verify the performance of the improved model in this paper, a comparison experiment is first taken. Several common target detection algorithms are selected and trained on D1 dataset under the same experimental environment and experimental configuration, and validated. The experimental results are detailed in Table II.

TABLE II COMPARATIVE EXPERIMENTAL RESULTS OF SOME MAINSTREAM ALGORITHMS

Model	P/%	R/%	mAP/%t	Parameters/M	FLOPS/G	FPS (F/S)
Faster R-CNN	60.1	63.7	64.6	14.3	19.8	25
YOLOv3	84.6	85.4	87.3	54	125.6	45
YOLOv5s	90.1	89.8	91.6	7.0	15.8	65
YOLOv8n	90.6	90.8	92.4	3.0	8.1	85
YOLOv8s	89.9	90.4	91.5	11.1	28.4	50
YOLOv8-BGA	95.4	96.3	97.7	2.7	7.5	89

Table II shows that the improved algorithm in this paper has excellent training effect on the D1 dataset, and has certain improvement compared with other algorithms. Compared with Faster R-CNN, it has the biggest improvement, with an average accuracy improvement of 34.1%; compared with YOLOv3, the average accuracy improvement is 11.4%; compared with YOLOv5s and YOLOv8s, it has an improvement of 7.1% and 7.2%, respectively; this paper improves the improved model by using YOLOv8n as the baseline, and the improved model has an average accuracy improvement of 5.3% compared with YOLOv8n.The FPS value of YOLOv8-BGA is 89, which is significantly higher than that of other algorithms, indicating that it not only improves the detection accuracy, but also optimizes the inference speed of the model, which can make the detection task achieve a good balance between real-time and accuracy. In addition, while the detection accuracy is improved, the number of parameters and inference time of the model are lower than the other five algorithms. It can be seen that YOLOv8-BGA has higher detection accuracy in the dataset of this paper, and at the same time, the model complexity is lower, which can better meet the actual industrial detection needs of stainless steel defective welded pipe bubbles. The comparison of the detection results of YOLOv8-BGA and the other algorithms is shown in Fig. 15.



(a)FasterR-CNN (b)YOLOv3 (c) YOLOv5s

(d) YOLOv8n (e) YOLOv8s (f) YOLOv8-BGA

Fig. 15. Comparison of detection results between YOLOv8-BGA and other algorithms.

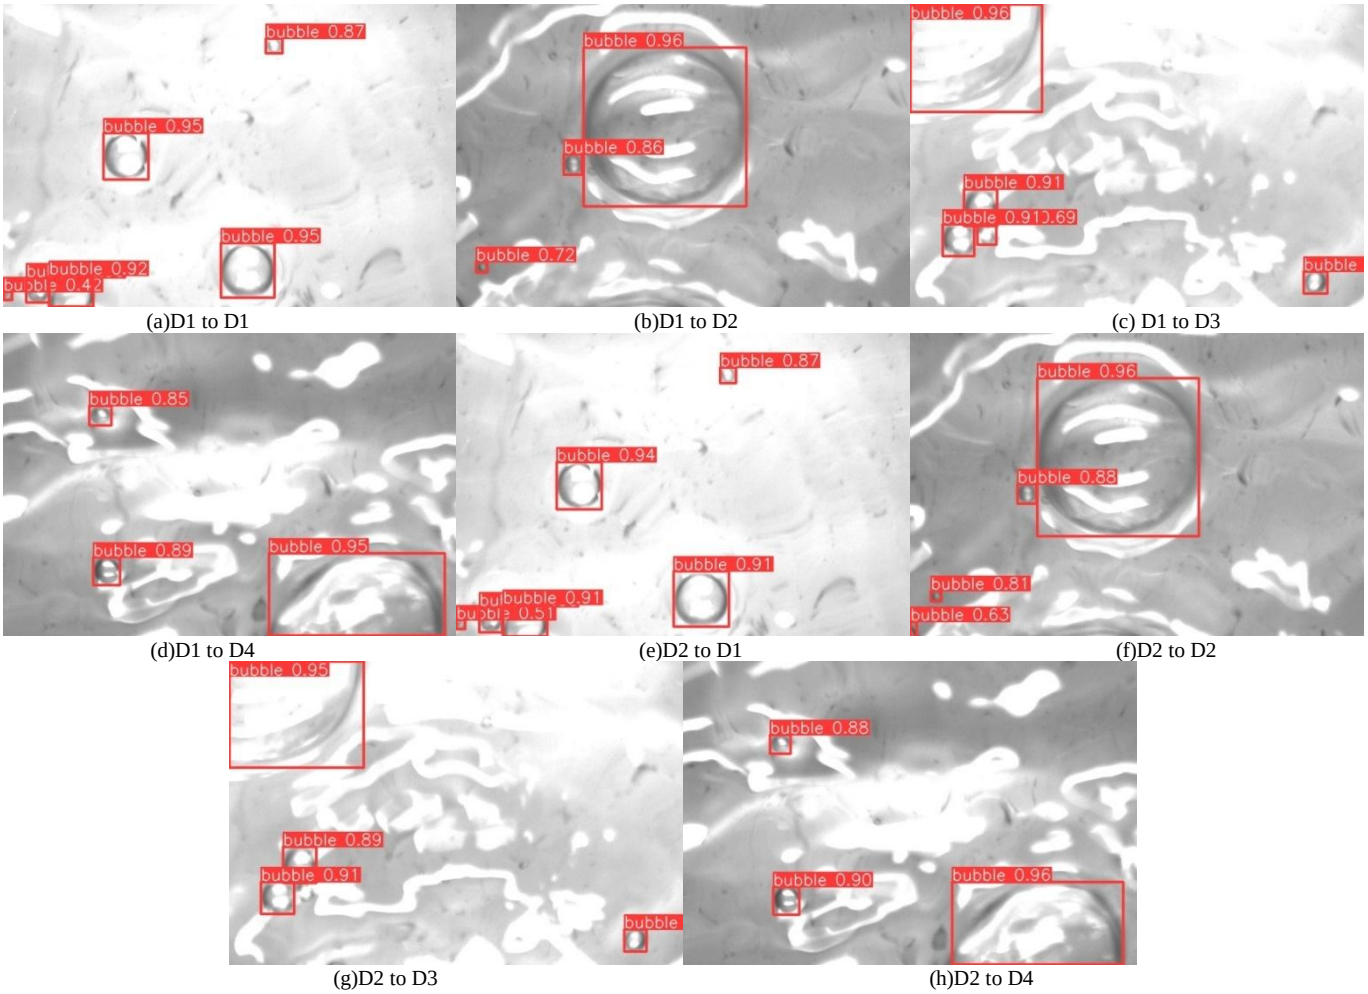
2) Verification of generalisation capabilities: In the actual detection process, the image quality is affected by a variety of factors such as illumination, water reflection and ripples, so it is crucial to evaluate the generalisation ability of the model. In this section of experiments, the improved algorithm is trained on D1 and D2 datasets under the same configuration, and the corresponding validation sets are validated with the respective training results. Precision and recall are chosen to evaluate the model performance, and the experimental results are detailed in Table 3.In this experiment, the influence of lighting conditions on the leakage bubble detection results of stainless steel welded pipe based on YOLOv8-BGA model is emphatically analyzed. In this section, two lighting environments is set up, bright and dark, and the results show that the lighting conditions have a significant impact on the model detection performance. The results show that the lighting conditions have a certain influence on the model detection performance.

TABLE III COMPARISON OF TEST RESULTS

mission	P/%	R/%
D1 Validated D1	95.4	96.3
D2 Validated D2	93.9	94.3

In low-illumination conditions, the overall brightness of the image is reduced, which directly leads to a decrease in image contrast. According to the fundamental principles of image processing, contrast is a key factor in distinguishing targets from the background. When contrast is reduced, the differences between small bubbles and the background become less distinct, especially for small bubbles generated by minor defects, which occupy fewer pixels in the feature map. In low-contrast images, the features of these small bubbles become even more difficult to extract. For example, in our experimental dataset, when the illumination is dim, the edge details of small bubbles are blurred, making it challenging for the model to accurately identify their contours. This results in larger deviations between the predicted and ground-truth bounding boxes when calculating the loss function, thereby reducing the detection accuracy of the model. Specifically, when validating on the dataset D2 under low-illumination conditions, the model's Precision is lower compared to that on the dataset D1 under bright illumination conditions. For instance, the Precision is 95.4% when D1 is validated on D1, while it is 93.9% when D2 is validated on D2.In bright illumination conditions, although the overall brightness of the image is sufficient, strong reflections become a significant factor affecting detection results. When light strikes the surface of the water and bubbles, reflection and refraction occur. According to the principles of optics, the angle of incidence is equal to the angle of reflection. When light is incident at a large angle, the intensity of the reflected light increases. Under bright illumination, due to the undulations of the water surface and the movement of bubbles, the direction of the reflected light constantly changes, causing the bubble boundaries to appear blurred in the image. This blurred boundary interferes with the model's accurate judgment of bubbles because the model relies on clear boundary features for localization and identification. For example, in the experiment, we observed that under bright illumination with undulating water surfaces, the model is prone to misjudging reflective areas as bubbles or inaccurately locating the boundaries of bubbles, thereby affecting Recall and Precision.

Then, in order to verify the generalisation ability of the improved algorithm under different environmental conditions, the D2, D3, and D4 datasets were validated using the training results of the D1 training set, and the D1, D3, and D4 were validated using the training results of the D2 training set, respectively, and the results are shown in Fig. 16.



(a)D1 to D1 (b)D1 to D2 (c) D1 to D3

(d)D1 to D4 (e)D2 to D1 (f)D2 to D2

(g)D2 to D3 (h)D2 to D4

Fig. 16. Comparison of some test results.

In assessing the performance of the model in various environments, precision and recall are also used as evaluation metrics, as detailed in Table IV.

TABLE IV RESULTS OF DIFFERENT ENVIRONMENTS

Mission	P/%	R/%
D1 Validated D2	88.7	85.6
D1 Validated D3	92.4	93.6
D1 Validated D4	85.9	86.1
D2 Validated D1	86.9	83.2
D2 Validated D3	83.4	82.9
D2 Validated D4	90.8	91.5

Comparing Table IV, it can be found that the validation is carried out under datasets with different environments, and although the precision and recall of the improved algorithm have decreased compared with those under the corresponding datasets, the model as a whole still maintains a good performance. The experimental results illustrate that the improved YOLOv8-BGA algorithm has good generalisation ability under different detection environments, and can effectively detect air bubbles generated by stainless steel defective welded pipes in real time under a variety of detection environments. Using the model trained under the D1 dataset to validate the D3 dataset is 9% more accurate compared to the model trained under the D2 dataset to validate the D3 dataset; similarly, using D1 to validate D4 is 4.9% less accurate compared to D2 to validate D4, which indicates that the performance of the improved model trained under the D1 dataset is higher than the performance of the model trained under the D2 dataset. Because the D1 dataset and the D3 dataset, the D2 dataset and the D4 dataset have the same kind of lighting conditions, which indicates that the lighting conditions have a greater impact on the training results of this model, and the image quality of the D1 dataset is higher than that of the D2, which may affect the performance of the model generalisation ability.

3) Comparative experiments with multiple datasets: To further validate the generalization and robustness of the improved model across diverse fields and industries, this section devises experiments to assess the performance of YOLOv8n and YOLOv8-BGA on publicly available datasets, namely the Bubble Image Database and UF-120.The Bubble Image Database, disseminated by researchers from the University of Queensland, encompasses 5,184 original images and 25,920 augmented images. It comprises five bubble categories: “Fine bubbles fully covering the viewing window”,

"fine bubbles partially covering the viewing window", "Co-existence of coarse and fine bubbles", "Only coarse bubbles", and "No bubbles". The UF-120 dataset consists of 120 high-quality underwater bubble images, representing a wide array of underwater scenarios and faithfully mirroring the complexity inherent in underwater environments. The experimental outcomes are presented in Table V and Table VI.

TABLE V EXPERIMENTAL RESULTS OF BUBBLE IMAGE DATABASE

Model	mAP/%	Parameters/M	FLOPS/G	FPS(F/S)
YOLOv8n	82.1	3.1	8.2	70
YOLOv8-BGA	82.7	2.8	7.6	72

TABLE VI EXPERIMENTAL RESULTS OF UF-120

Model	mAP/%	Parameters/M	FLOPS/G	FPS(F/S)
YOLOv8n	89.1	3.0	8.2	77
YOLOv8-BGA	89.8	2.7	7.6	75

Evident from the findings presented in Table V, the YOLOv8-BGA model exhibits an increment of 0.6 in the mAP. Concurrently, the model experiences a reduction of 9.7% in the Parameters and 7.3% in the FLOPS, with no discernible alteration in the detection speed. Inspection of the results in Table 6 reveals that the YOLOv8-BGA model registers a mAP increase of 0.7, accompanied by decreases of 10% in Parameters and 7.3% in FLOPS. The detection speed remains commendably stable, showing no significant fluctuations. Experimental outcomes on publicly accessible datasets, including the Bubble Image Database and UF-120, incontrovertibly demonstrate that, within the domain of bubble detection, the YOLOv8-BGA model surpasses the YOLOv8n model with respect to accuracy, model complexity, and computational efficiency. Overall, the YOLOv8-BGA model demonstrates good utility value and robustness in practical industrial applications.

4) Ablation experiment: In order to test the effectiveness and model performance of adding BoT module, replacing GSConv module, adding C2f-BM attention mechanism and improving loss function in the improved algorithm on the gas tightness detection of stainless steel defective welded pipe, ablation experiments are carried out on YOLOv8-BGA algorithm under D1 dataset, and the results of the ablation experiments are shown in Table VII in detail.

Analysing the experimental results in Table VII, the YOLOv8n model is used as the baseline, and the improved modules are added individually in sequence for comparison.YOLOv8-BoT replaces the 40×40 and 20×20 C2f modules in the Backbone section with the C2f_BoT module, which improves the average accuracy by 0.9% without any change in the number of Parameters and FLOPS, which is due to the fact that the BoT module is able to automatically identify and capture the dependencies in the input sequence through its multi-head self-attention mechanism, which helps the model to extract features more efficiently and improves the detection accuracy, the introduction of the BoT module did not significantly increase the model complexity, so the FPS was not significantly reduced; YOLOv8-GSConv is to replace the original convolutional layer in the Neck part with the GSConv module, and the number of parameters is reduced by about 0.2M, and the FLOPS is reduced by 0.4G.The GSConv module reduces the amount of computation through deeply separable convolution, which improves the lightness of the model and the speed of inference, so the FPS is improved, the model achieves a lightweight effect while maintaining the detection accuracy; YOLOv8-BM is to add the C2f-BM attention mechanism in front of each detection layer, the number of parameters is reduced by about 0.1M, the FLOPS is reduced by 0.2G, and the average accuracy is improved by 4.4%, which indicates that the expectation maximisation algorithm reduces the computational volume of the model while the detection accuracy is improved dramatically, the attention mechanism performs well on this dataset, improving performance along with inference speed and FPS values; YOLOv8-WIoU introduces the WIoU loss function, and the average accuracy of the model is improved by 1.9%, and the WIoU loss function improvesthe degree of model fitting, which in turn improves the accuracy of model recognition. The introduction of the WIoU loss function, which mainly optimizes the training process, has a small impact on the inference speed, so the FPS value is unchanged; YOLOv8-BGA is the final model after adding all of the above modules, and the number of references is lowered by about 0.3M, FLOPS is reduced by 0.6G, and the average accuracy is improved by 5.3%.After combining all the improvements, the model is optimized in all aspects, and the inference speed is further optimized while maintaining high accuracy, and the final FPS value of YOLOv8-BGA reaches 89.

TABLE VII RESULTS OF ABLATION EXPERIMENTS

Model	BoT	GSConv	C2f-BM	WIoU	mAP/%	Parameters/M	FLOPS/G	FPS(F/S)
YOLOv8n					92.4	3.0	8.1	85
YOLOv8-BoT	√				93.3	3.0	8.1	84
YOLOv8-GSConv		√			92.1	2.8	7.7	87
YOLOv8-BM			√		96.8	2.9	7.9	86
YOLOv8-WIoU				√	94.3	3.0	8.1	85
YOLOv8-BGA	√	√	√	√	97.7	2.7	7.5	89

The experimental results verify that the YOLOv8-BGA model obtained after the improvement of this paper has been improved compared with the original model in terms of reasoning speed, detection accuracy, model complexity, etc., and is able to better complete the task of stainless steel defective welded pipe airtightness detection compared with other algorithms proposed above.

V. CONCLUSION

1) The improved model is better than the original YOLOv8n model in terms of inference speed, detection accuracy, and model complexity, and can achieve effective identification of leakage bubbles.

2) With the introduction of the C2f-BoT module and the WIoU loss function, the improved model possesses excellent detection capability for tiny bubbles and reduces leakage detection.

3) The improved model has a strong generalisation ability, and can also have a good detection ability in poorer airtightness detection environments.

4) Due to the limitations of the experimental conditions, the accurate linkage between real-time detection, positioning and alarm at the leakage of stainless steel welded pipe needs to be further investigated in order to improve the popularisation of the improved model in the field of industrial airtightness detection.The model algorithm is a useful exploration and reference for other different products airtightness detection.

***Abstract*—The demand for broccoli in Indonesia has been increasing significantly, with an annual growth of approximately 15% to 20%. However, the supply availability remains insufficient, and its quality is often inconsistent. Therefore, a grading process is needed to classify broccoli into grades A, B, and C based on color, size, and shape. Currently, the grading process is carried out solely by market intermediaries, while farmers and the general public have a limited understanding of this process. This research developed an automated grading method using a Convolutional Neural Network (CNN) based on two broccoli images' top and side views. Three main parameters, namely color, size, and shape, were identified from these images and used as grading determinants. An ensemble deep learning technique was applied by training each parameter separately using several CNN models, namely ResNet50, EfficientNetB2, VGG16, and Improved CNN. These were then combined in the testing phase using a voting technique. The test was conducted 64 times with various model combinations to achieve the best accuracy. A significant contribution of the Improved CNN lies in the shape feature, which achieved a maximum performance of 95%. This study also compared evaluation metrics such as precision, recall, F-Score, and accuracy across different model combinations.**

***Keywords*—Grading; convolution neural network; ensemble deep learning; voting**

I. INTRODUCTION

Broccoli (Brassica oleracea L. var. italica) is a widely cultivated cruciferous vegetable valued for its high nutritional content and economic significance. It is a rich source of essential vitamins such as C, K, and A [1] and bioactive compounds such as glucosinolates, which are studied for their potential health benefits. Globally, broccoli is a key commercial vegetable, with strong export demand from regions such as the United States, China, and Europe. In Indonesia, the demand for broccoli has increased by up to 20% annually, driven by growing consumption in restaurants, hotels, modern retail markets, and exports [2]. However, domestic supply is constrained by a lack of standardized quality grading, creating inconsistencies that disadvantage farmers and traders alike. Broccoli grading is crucial in determining market value and quality, with morphological attributes such as size, shape, color, and compactness as key indicators. The morphology of the broccoli head is particularly significant, as it reflects the crop's overall quality and resilience to environmental stress [3]. Traditionally, grading has been performed manually, leading to inconsistencies due to subjective evaluation. Various approaches have been employed to assess broccoli quality, including dry geometric and weight measurements, mass spectrometry analysis, and non-contact sensor technologies [4]. Among these, image-based methods using RGB digital cameras and deep learning algorithms have emerged as promising solutions because of their non-destructive nature, cost-effectiveness, and high accuracy. Recent studies have demonstrated the potential of Convolutional Neural Networks (CNNs) in broccoli grading, utilizing algorithms such as Mask R-CNN and ResNet for tasks such as detecting harvest readiness, estimating weight, and analyzing color attributes.

Research conducted by Blok et al. employed the Mask R-CNN algorithm [5] and successfully detected 229 out of 232 harvest-ready broccoli heads across three cultivars. The study concluded that the algorithm demonstrated better generalizability across multiple broccoli cultivars. Previous studies have also contributed by combining the Viewpoint Feature Histogram (VFH) with a Support Vector Machine (SVM), enabling precise broccoli detection and facilitating automated systems for detecting and measuring broccoli heads. This approach proved effective in achieving the goal of determining the optimal harvest timing [6].

A recent study by Zhou [4] developed a dataset of 100 broccoli head images captured using a custom-designed imaging system under controlled conditions. The study employed an improved ResNet CNN algorithm to extract broccoli pixels from the background and estimate their weights. Additionally, the particle Swarm Optimization Algorithm (PSOA) and Otsu method were applied to evaluate the broccoli quality, achieving an accuracy rate of 0.896 [4]. However, Zhou et al. study was limited to color as the sole criterion, whereas grading broccoli typically requires multiple parameters to assess its overall quality.

Another study compared the performance of various models, including ResNet, DenseNet, MobileNetV2, NASNet, and EfficientNetB2, to determine the best model for grading apples and bananas [7]. EfficientNet yielded the highest accuracies of 99.2% for the training data and 98.6% for the testing data. However, this approach has not been applied to broccoli datasets.

This study introduces several contributions, and those are: 1) the development of a broccoli grading model based on three features: color, size, and shape, where the data are divided into three independent features, each assessed without reliance on the others; 2) optimization of convolutional and classification

models for the broccoli grading process; and 3) comparison of grading results using multiple CNN models.

The grading criteria in this study differ from those of previous research because of the distinct physical characteristics of domestically produced broccoli compared to imported varieties. The criteria include shape (degree of roundness), color, size, and flower compactness (density). Image acquisition was conducted from two perspectives: top and side views. The research modified several deep learning models, including ResNet50, EfficientNetB2, VGG16, and Improved CNN.

In addition, the study utilized a parallel Ensemble Learning technique during the training phase. This approach allows models to be developed independently, with no interdependencies, ensuring that errors from one model are less likely to align with errors from others. Consequently, the weaknesses of one model can be mitigated by those of the other. Ensemble learning has been successfully applied across various fields and often outperforms single-model approaches [8].

The predictions from all deep learning models were aggregated and reused during the testing phase, where a voting mechanism was applied to make classification decisions. This image-based grading algorithm aims to enhance broccoli's post-harvest quality and standardization while advancing the agricultural industry in Indonesia, particularly benefiting broccoli farmers.

II. Literature Review

The utilization of Convolutional Neural Network (CNN) architectures had seen rapid growth since 2012, when Krizhevsky's breakthrough in the ImageNet Large Scale Visual Recognition Challenge (ILSVRC) demonstrated the CNN's efficiency for image classification across various domains [9][10]. Specifically in agriculture, CNN-based approaches have been employed for fruit classification and detection, highlighting CNN's pivotal role of CNNs in image processing for this sector. CNN operations typically involve six essential layers [10][12]:

- Input Layer: This layer accepts raw images as input and forwards them to the subsequent layers for feature extraction.
- Convolution Layer: Each output connects to a small region in the input using a weight matrix (filter or kernel). Multiple filters can be applied within each convolution layer to generate several 2D outputs stacked into an output volume.
- ReLU (Rectified Linear Unit): Negative values in the output of the convolution layers are replaced with zero, accelerating the training process.
- Pooling Layer: This process downsamples feature maps to achieve translation invariance. Feature map dimensions are reduced using average and max pooling techniques.
- Fully Connected Layer: This final layer integrates all filtered image data, converting it into labels and categories.
- Softmax Layer: Positioned before the output layer, this layer generates decimal probabilities for each class, ranging from 0 to 1, enabling CNNs to extract, process, and classify image data features efficiently.

TABLE I. CNN-Based Research on Broccoli Plants

Author	CNN Model	Result
[5]	Mask Region-based Convolutional Neural Network	Successfully detected 175 out of 176 test datasets
[6]	KNN & SVM	95.2%
[13]	3D information based on convolution neural network	Below 90%
[14]	improved resnet	Below 90%
[15]	Organised Edges Segmentation (OES) and Organised Region Growing Segmentation (ORG	Low generalization level
[16]	Gaussian Mixture Model	97.9%

Table I compares various CNN models and other methods in detection or classification tasks based on referenced studies. Mask R-CNN performed well, detecting 175 out of 176 test datasets, while the Gaussian Mixture Model achieved the highest accuracy at 97.9%. KNN & SVM also performed well with 95.2%, whereas 3D CNN and improved ResNet had accuracies below 90%. OES & ORG showed a low generalization level, indicating limitations in handling new data. the researchers adopted the parallel Ensemble Learning technique, which integrates multiple models or classifiers to improve the prediction accuracy compared to using a single model [8]. Each model or classifier within the ensemble is generally trained on slightly different datasets (distinct training data or varying feature selection methods).

Ensemble Learning aggregates predictions from multiple base models to produce more stable and accurate results. Two primary strategies introduce diversity among the baseline classifiers: homogeneous ensembles and heterogeneous. Homogeneous ensembles consist of baseline classifiers of the same type, in which each classifier is trained on different datasets. The feature selection method remained consistent across the datasets. By contrast, Heterogeneous ensembles comprise baseline classifiers of various types, allowing each classifier to adopt distinct methodologies in processing the training data [11]. Heterogeneous ensembles typically demonstrate superior generalization capabilities than homogeneous ensembles [17]. Several commonly used ensemble techniques include the following:

- Averaging computes the average prediction from multiple models.
- Bagging (Bootstrap Aggregating) involves training multiple models on random subsets of training data and subsequently combining their outputs. Bagging aims to stabilize models by reducing the variance [18].
- Random Forest is a bagging method that employs numerous decision trees to generate predictions.
- Stacking combines predictions from multiple base models and utilizes another model (a meta-model) to aggregate these predictions. Boosting enhances the

model performance by assigning greater importance to previously misclassified data points. A prominent boosting algorithm is AdaBoost [19], which improves the performance of the decision trees.

Among ensemble methods, bagging and boosting are the most frequently applied in classification tasks. These approaches are widely recognized for their robust theoretical foundations and exceptional empirical results [11]. Existing studies highlight that bagging and boosting are particularly effective when applied to decision tree models [20].

III. Research Method

This research involves several methodological stages to achieve broccoli grading classification: Data Acquisition, Data Pre-processing, Model Training, Model Evaluation, and Grading (Fig. 1).

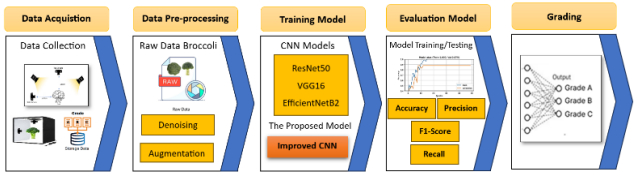

Fig. 1. Methodology of classification and grading broccoli.

A. Data Acquisition

The first stage of the research process was the dataset collection. The broccoli images were gathered and classified into grades with the assistance of experts. The dataset consisted of 450 broccoli images captured from the top and side views, which were categorized into grades A, B, and C.

B. Data Pre-Processing

After the data were collected, the images were processed through pre-processing stages.

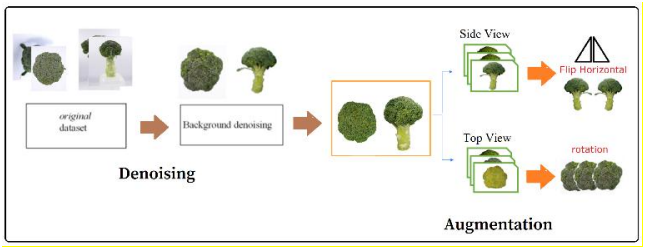

Fig. 2. The architecture of denoising and data augmentation process.

In Fig. 2, the first step is denoising, which removes unnecessary backgrounds to improve image quality. The second step is augmentation, which involves transforming the images using rotation techniques for top-view images and flipping them for side-view images. The denoising and data augmentation process aimed to increase the variation in the dataset.

C. Training Model

At this stage, the data training process uses ensemble deep learning. The ensemble learning technique enables the classification of three distinct feature subsets, color, size, and shape, by training each feature independently without relying on the others. This independent training allows the model to capture and store information from each feature more effectively, reducing the risk of interference between features. As a result, during the testing process, the model can focus on accurately reading and determining the grade of each test data point. This approach enhances the model's generalization ability across different feature types and improves overall classification performance.

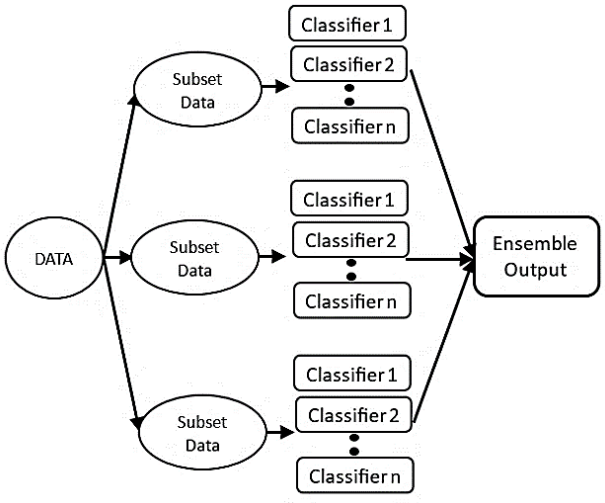

Fig. 3. Development of training architecture using ensemble learning.

As shown in Fig 3, each subset is trained using several convolutional neural network (CNN) models, which are known to be effective for image recognition. The models used included ResNet50, VGG16, EfficientNetB2, and the proposed model, which is an Improved CNN.

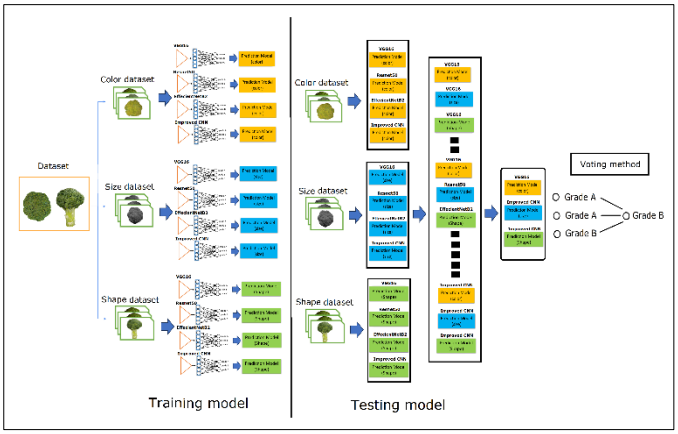

Fig. 4. The architecture training and testing data using ensemble deep learning.

In Fig. 4, each subset based on color, size, and shape is trained using several Convolutional Neural Network (CNN) models: ResNet50, VGG16, EfficientNetB2, the proposed model, and the Improved CNN. The outputs of these models were used in the testing phase.

D. Evaluation Model

The trained models were evaluated using performance metrics such as accuracy, precision, recall, and F1-Score. Below are some equations for this method.

$$\text{Acc} = \frac{(\text{TP}+\text{TN})}{\text{TP}+\text{TN}+\text{FP}+\text{FN}} \quad (1)$$

The Accuracy (Acc) formula was used to measure the model's performance by calculating the number of True Positive and True Negative elements as the numerator and the total number of elements in the Confusion Matrix as the denominator. The True Positive and True Negative elements represent the correct predictions made by the model and are located on the matrix's main diagonal. Meanwhile, the denominator includes all the elements incorrectly classified by the model outside the main diagonal. Therefore, accuracy indicates how well the model can make correct classifications for positive and negative cases compared with the entire dataset [9].

$$Precision = \frac{TP}{(TP + FP)} \quad (2)$$

Precision measures the model's accuracy in identifying positive cases, indicating how well the model avoids misclassifying negative cases as positive cases.

$$Recall = \frac{TP}{(TP + FN)} \quad (3)$$

Recall or Sensitivity indicates how well the model can remember or recognize all the existing positive cases. This metric is important because it ensures the model does not miss significant positive cases. The higher the recall value, the better the model captures all positive cases.

$$F1 - score = 2.\frac{(precision \times recall)}{precision + recall} \quad (4)$$

The F1 score is a metric that combines Precision and Recall to assess the performance of a classification model. The F1-score reached its optimal value when the model had high precision and recall, indicating that it effectively identified and recognized all positive cases in the data. Conversely, the F1-score will be low if the Precision or Recall is low, signaling inadequate model performance. Therefore, the F1 score provides an overview of how well the model can balance Precision and Recall, with one being the best and zero the worst.

E. Grading

In the final stage, the model's prediction results are translated into specific categories (e.g., Grade A, B, C) based on a voting technique, where the decision is based on the lowest grade. This process was used to classify broccoli quality according to predefined standards.

IV. Result and Discussion

A. Data Acquisition

Based on Fig. 5, all broccoli data that had been labeled and collected were placed in a photo box studio and photographed individually using a 12MP SLR camera. The labeling process was conducted in collaboration with three experts experienced in grading transit locations before distribution to supermarkets. The broccoli samples were then categorized into grades A, B, and C. Subsequently, images were captured from the top and side angles, maintaining a consistent distance of 20 cm between the object and the camera. Photobox Studio was equipped with adjustable lighting settings to ensure optimal image quality and minimize noise interference from the surrounding environment. This process was designed to produce high-quality images suitable for further analysis.

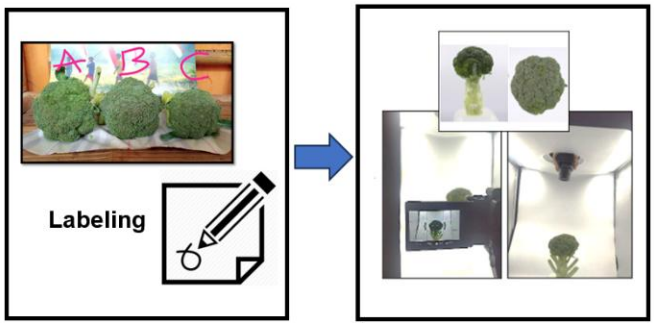

Fig. 5. Collecting data with photobox studio.

B. Data Pre-Processing

Table II shows the distribution of the dataset used for broccoli grading based on two perspectives, namely the top view and side view, as well as the impact of the data augmentation process. The table is divided into grades A, B, and C. In the top view, each grade (A, B, and C) contained 100 samples from the original dataset and 100 augmented samples, indicating that data augmentation doubles the dataset size for the top view. Meanwhile, each grade contained 50 samples from the original dataset and 50 augmented samples in the side view, demonstrating a similar augmentation process but fewer samples than in the top view. Overall, the total number of samples for the top view, including original and augmented data, was 600 (300 original + 300 augmented). In comparison, the total for the side view was 100 samples (50 original + 50 augmented), resulting in a combined dataset of 700 samples. This table emphasizes that the dataset is balanced across the three grade categories and illustrates how data augmentation is applied to both perspectives to enhance the model training performance.

TABLE II. Dataset Augmentation

Grade	Top view (original)	Augmentation	Side View (original)	Augmentation
Grade A	100	100	50	50
Grade B	100	100	50	50
Grade C	100	100	50	50
Tota Dataset	600		100	
	700			

After the data were augmented, data splitting was performed, in which 80% of the data were allocated for training and 20% for testing.

C. Training Model

At this stage, the data training process utilizes an ensemble deep learning approach with heterogeneous ensemble specifications, a technique that has shown better generalization than single models and homogeneous ensembles [21]. The broccoli dataset was divided into three subsets and processed using the four classifiers.

TABLE III. SUMMARY OF CNN AND PROPOSED METHOD

Hyperparameter	CNN Models			
	ResNet50	***EfficientNet B2***	***VGG16***	***Improved CNN***
Kernel 1	ResNet50 Architecture	EfficientNet B2 Architecture	VGG16 Architecture	32 (3x3)
Kernel 2				64 (3x3)
Kernel 3				128 (3x3)
Activation Function	ReLU	ReLU	ReLU	ReLU
Layer Pooling	Average-pooling	Average-pooling	Average-pooling	Max Pooling
Layer Dense	512	512	512	512
	256		256	256
	128		128	128
	64		64	64
	3 class	3 class	3 class	3 class
Optimizer	Adam	Adam	Adam	Adam
Fully Connected	Softmax	Softmax	Softmax	Softmax
Epoch	50	50	50	50

1) Model CNNs: Table III summarizes several top CNN models commonly used to achieve satisfactory accuracy. Hyperparameter tuning was performed to optimize the results. Each model employs pre-trained ImageNet weights to enhance the model performance. The Rectified Linear Unit (ReLU) function. Additionally, the pooling layers in these models adopt the average pooling method, which calculates the average value of the features in the pooling area. Modifications were made to the fully connected layers of all CNN models. Each dense layer was configured with two to five dense layers, with the number of neurons set to 512, 256, 128, and 64, ending with a 3-class classification. For EfficientNetB2, the number of neurons was set to 512 with a 3-class classification. These modifications aim to optimize the model during the training process. The Adam optimizer was selected because it is frequently used in deep learning classification tasks and its relatively optimal performance compared to other optimizers. The number of epochs was set as 50 to achieve the most stable results during the training phase.

2) Improved CNN: The proposed model in this research is an improvement on the CNN, designed to achieve the best performance. The model modifies the hyperparameters of the convolutional and classification layers. For those convolutional layers, 32, 64, and 128 filters were used, each with a kernel size of 3x3 pixels. The activation function is the ReLU, and the pooling layers use the max-pooling method, which selects the highest value from each feature in the pooling area. The dense layer was configured with five layers containing 512, 256, 128, and 64 neurons, ending with a 3-class classification. The Softmax function was used for the output layer to produce the probabilities required for classification. The training process was run for 50 epochs to achieve optimal and stable results.

The combination of features size, shape, and color demonstrates significant variations in classification performance, depending on the architecture pairings used (Table IV). It is noted that the model combination with the lowest accuracy is VGG16, EfficientNetB2, and ResNet50, achieving 90.00% accuracy. This model combination indicates that this combination struggles with certain types of data and consistently performs less than other combinations. On the other hand, combinations involving the Improved CNN consistently achieve the highest accuracy of 95.00%, whether paired with VGG16, EfficientNetB2, or ResNet50. This suggests that the Improved CNN effectively addresses the weaknesses of other models and exhibits better generalization capabilities. Other models, such as the combination of VGG16 with itself (VGG16-VGG16-VGG16) or other models like EfficientNetB2 and ResNet50, show varying accuracies in the 91.00% to 94.00%. These results indicate that the base architecture of VGG16 remains fairly reliable for classification tasks, though not as optimal as the Improved CNN. Meanwhile, combinations involving EfficientNetB2, with itself or other models, yield relatively lower accuracy, ranging from 90.00% to 94.00%. This suggests that the EfficientNetB2 architecture is less optimal for specific data scenarios.

Further analysis revealed that the Improved CNN and VGG16 combination achieved consistently high and stable accuracy between 94.00% and 95.00% compared to other model combinations. This finding may indicate that these two models have strengths in handling the given features, leading to a better performance. On the other hand, combinations involving ResNet50 show consistent performance in the range of 93.00% to 95.00%, although they tend to perform slightly lower than combinations involving the Improved CNN.

TABLE V. COMPARISON ACCURACY GRADING OF BROCCOLI

CNN Models	Dense Layer	Accuracy
Resnet50	5	85.26%
VGG16	2	88.42%
GoogleNet	2	84.21%
DenseNet121	2	83.16%
EfficientNetB2	4	86.32%
Perposed Method	5	95.00%

Table V compares the accuracy between several CNN models used for broccoli grading and the proposed method utilizing ensemble learning techniques. Previous researchers have also used these CNN models to determine the grading quality of fruits and vegetables, particularly broccoli, where the models were employed to analyze the color and texture features of the objects to reach specific decisions [22]. However, in this study, the quality of broccoli objects was determined from two perspectives, the top view and the side view, based on color, size, and shape.

Based on the table above, the results show a significant difference in accuracy, reaching 95%, whereas other CNN models that do not employ ensemble techniques show results below 90%. This study also includes parameter tuning, particularly in adjusting the number of dense layers, to achieve optimal results.

It is possible to classify three feature subsets: color, size, and shape, using the ensemble learning technique, where each feature input is trained individually without relying on other features. This approach allows the model to store information from each feature more effectively, enabling it to focus on reading and determining the grade of each test data item during the testing process.

D. Evaluation Model

The trained model was evaluated using performance metrics such as accuracy, precision, recall, and F1-Score. Below are some equations related to these methods.

In this study, the grading process was conducted using an Ensemble Learning method based on Convolutional Neural Network (CNN), incorporating various feature combinations (size, shape, and color) and several CNN models selected based on the experimental results listed in Table V. The confusion matrix for each combination was generated using metrics such as precision, Recall, F1-Score, and overall accuracy. The goal was to identify the best combination that delivered optimal performance for each grade (A, B, and C). The evaluation results revealed significant performance variations across the model combinations.

For Grade A, the combination of EfficientNetB2 + VGG16 + Improved CNN achieved the best performance with an F1-Score of 1.00, reflecting the model's ability to classify grade A cases perfectly (Table VI). This combination demonstrated a good balance between Precision and Recall. In contrast, VGG16 + EfficientNetB2 + ResNet50 had a lower F1-Score of 0.94 due to less optimal Precision and Recall than other combinations. This indicates that selecting the right model combination plays a significant role in the success of the classification for specific grades.

For Grade B, the combination of ResNet50 + Improved CNN + VGG16 achieved the highest F1-Score of 0.94, indicating its capability to capture more complex data patterns for this grade. The combinations of EfficientNetB2 + VGG16 + Improved CNN and Improved CNN + VGG16 + ResNet50 also performed well, each with an F1-Score of 0.92. Conversely, the combination of VGG16 + EfficientNetB2 + ResNet50 had the lowest performance with an F1-Score of 0.90, primarily owing to a low recall value of 0.86. This suggests that this combination struggled to accurately capture the characteristics of Grade B data.

For Grade C, the combinations of ResNet50 + Improved CNN + VGG16 and Improved CNN + VGG16 + ResNet50 delivered the best results with an F1-Score of 0.94. These combinations excelled in classifying this high-complexity grade, which tends to have more diverse data distributions. The combination of EfficientNetB2 + VGG16 + Improved CNN showed stable performance with an F1-Score of 0.91, whereas the combination of VGG16 + EfficientNetB2 + ResNet50 had a lower F1-Score of 0.88, attributed to a Precision score of only 0.81.

Overall, the combination of ResNet50 + Improved CNN + VGG16 delivered the best performance with an overall accuracy of 0.95, followed by EfficientNetB2 + VGG16 + Improved CNN with an accuracy 0.94. The Improved CNN + VGG16 + ResNet50 achieved an accuracy of 0.93, whereas VGG16 + EfficientNetB2 + ResNet50 had the lowest accuracy of 0.90. When used in model combinations, these results confirm that the Improved CNN significantly enhances classification performance, particularly in capturing complex features.

E. Grading

As shown in Fig. 6, the final stage is grading, where the model's predictions are translated into specific categories (e.g., Grade A, B, C) based on a voting technique. The model predictions can be determined starting from the lowest grade as shown in Fig. 6.

TABLE VI. CONFUSION MATRIX OF SUMMARY CNN MODELS AND PROPOSED METHOD

GRADE	Result Ensemble CNN Model											
	Size Features + Shape Features + Color Features											
	VGG16 + EffecientNetB2 + ResNet50			Improved CNN + VGG16 + ResNet50			EffecientNetB2 + VGG16 + Improved CNN			ResNet50 + Improved CNN + VGG16		
	Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision	Recall	F1-Score
Grade A	0.96	0.92	0.94	0.96	1.00	0.98	1.00	1.00	1.00	0.96	1.00	0.98

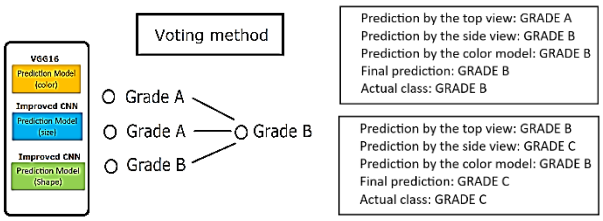

Fig. 6. The architecture of voting and grading.

Additional hyperparameter tuning is necessary for further discussion to achieve more accurate results. This research can also be expanded by developing image acquisition techniques for different lighting conditions and increasing the dataset size to enhance the algorithm's performance across a broader range of new data models.

V. Conclusion

This study on broccoli grading employs ensemble deep-learning techniques for training and testing processes. The combination of features—Size, Shape, and Color—significantly influences the prediction accuracy. Using an Improved CNN as the Shape feature substantially contributes to consistently achieving the highest performance, regardless of the models used for the Size and Color features. This indicates that the Improved CNN possesses strong generalization capabilities for various feature combinations.

Grading performance is heavily influenced by the accuracy achieved during testing, with model combinations that achieve the highest accuracy of 95% tend to produce more optimal grading results. This also proves that combining the predictive outputs from various classification models is highly effective in the grading process.

This method has significant potential for application to other data that require several parameters in the classification process. Using a combined model CNN technique, this method has proven to be capable of enhancing the performance in the classification process. The results showed a significant improvement compared to using a single CNN model alone.

This research can be further developed by enhancing image acquisition techniques using mobile phones or other devices under different lighting conditions. Additionally, it can be integrated into mobile phones and Arduino systems if, in the future, mass grading is performed using heavy machinery such as conveyor systems.

***Abstract*—Port congestion poses a significant challenge to maritime logistics, especially for industries dealing with perishable goods like seafood. This study presents a custom deep learning model using Transformer architecture to predict real-time traffic flow at the Port of Virginia, with a focus on optimizing the movement of fish trucks. The model integrates multimodal data from 36 sensors, capturing traffic flow, occupancy, and speed at five-minute intervals, and processes high-dimensional, time-series data for accurate predictions. The model utilizes attention mechanisms to capture spatial and temporal dependencies, significantly improving predictive performance. Evaluation results indicate that the Transformer-based model outperforms existing models like RandomForest, GradientBoosting, and Support Vector Regression, with an R-squared value of 0.89, Pearson correlation of 0.91, and a Root Mean Squared Error (RMSE) of 0.0208. These results suggest that the model can effectively manage dynamic port traffic and optimize resource allocation, ensuring the timely delivery of perishable goods.**

***Keywords*—Traffic flow prediction; transformer model; port congestion; deep learning**

I. INTRODUCTION

Port traffic management is a critical component of maritime logistics, playing an essential role in ensuring the smooth operation of global supply chains. Ports act as vital nodes in international trade, facilitating the movement of goods across continents. As the global economy continues to grow, ports must meet increasing demands, especially in handling both bulk and perishable goods. The seafood industry, in particular, relies on efficient port traffic management for the timely transport of fish and other perishable goods. Fish trucks, which move seafood from ports to markets or distribution centers, require fast and reliable service to maintain product quality and minimize spoilage. Delays in port operations lead to significant economic losses and waste, given the perishability of these goods. Thus, improving port traffic management systems—especially for perishable goods—has become a critical concern for ports worldwide [1].

The continued growth of international trade, alongside the increasing volume of goods transported by sea, places increasing pressure on ports to handle rising traffic volumes. Ports are the gateways for goods entering and leaving regions and play a crucial role in economic activities. However, as trade volumes continue to rise, congestion has emerged as a significant issue at many ports. Congestion at ports leads to delayed vessel arrivals, bottlenecks during cargo unloading, and delays in cargo pickup, which are especially problematic for time-sensitive goods like seafood. Fish trucks, dependent on swift port operations, face major disruptions when vessels are delayed, leading to a domino effect in the supply chain. Such delays can compromise product quality, especially in the seafood industry, where the timely movement of goods is crucial for maintaining freshness and minimizing losses [2], [3].

Additionally, vessel congestion often results in inefficient resource allocation, as ports may lack the ability to dynamically allocate resources such as cranes, docking spaces, and labor according to real-time needs. This inefficiency increases operational costs, not only in the form of delayed shipments but also due to the additional resources required to manage the backlog. Ports may also face difficulty in managing fluctuating traffic patterns that are driven by seasonal demand or unexpected weather conditions. The global rise in e-commerce and the associated increase in containerized cargo further exacerbate congestion at many ports, highlighting the need for smarter and more adaptable management systems [4], [5].

Environmental concerns also play an increasing role in port traffic management. Ports are significant contributors to global greenhouse gas emissions due to idling ships and inefficient resource use. As ports handle more cargo, the environmental impact of congestion is amplified. For example, long waiting times for vessels to dock result in fuel waste and greater carbon emissions. Port authorities are thus under increasing pressure to find solutions that not only improve operational efficiency but also minimize the environmental impact. The integration of technologies like AI and machine learning can significantly reduce congestion by providing real-time insights into traffic patterns, allowing ports to make more informed decisions that balance operational efficiency with environmental sustainability [6], [7].

Given these challenges, AI technologies, particularly machine learning and deep learning, are becoming essential tools for improving port traffic management. AI-powered systems can analyze vast amounts of real-time data from multiple sources, such as sensors, Automatic Identification Systems (AIS), and weather reports. These technologies enable the development of predictive models that forecast port congestion, optimize vessel scheduling, and improve resource

allocation. AI has the potential to not only predict traffic flows but also adapt to changing port conditions, enabling ports to proactively adjust operations before congestion occurs. Machine learning models, such as support vector machines (SVM), random forests, and deep neural networks, have been applied in various studies to predict traffic patterns and improve port operations. However, these models often focus on general cargo traffic and have not yet fully addressed the specific needs of perishable goods logistics, such as the transport of seafood [8], [9], [10].

Deep learning models, specifically Transformer architectures, offer significant advantages in capturing both spatial and temporal dependencies within port traffic data. These models have been used successfully in various fields for time-series forecasting, where they can process large datasets and make highly accurate predictions. By leveraging multimodal sensor data, deep learning models can predict congestion, identify bottlenecks, and optimize resource allocation for both vessels and cargo handling. This is particularly important in the seafood industry, where timing is critical for ensuring the freshness of the product and minimizing spoilage. Previous studies have demonstrated the application of deep learning techniques for traffic management in other logistics sectors, but their use in optimizing perishable goods transportation within ports remains an underexplored area [11].

This study aims to fill this gap by developing a customized deep learning-based model for port traffic management, specifically focused on optimizing the movement of fish trucks at ports. The proposed model will integrate real-time data from various sources, including traffic flow sensors, vessel tracking systems, and environmental data, to forecast congestion and improve decision-making processes in port operations. By utilizing Transformer-based models, the study seeks to enhance the accuracy of predictions, allowing port authorities to allocate resources efficiently, reduce congestion, and improve the overall efficiency of seafood logistics. Furthermore, this study explores the integration of AI-powered systems into existing port infrastructure, providing actionable insights that will contribute to the sustainable and efficient management of ports [12].

The introduction provides a comprehensive background on port congestion, its impact on global logistics, and the specific challenges faced by the seafood industry in managing port traffic. The study proposes a custom deep learning model leveraging Transformer architecture to improve traffic flow prediction at the Port of Virginia. The outlined structure of the paper should accurately reflect the sections presented. This includes the methodology section, which details data preprocessing, model customization, and feature engineering, followed by the results and evaluation of the proposed model's performance.

II. Literature Review

The efficient management of port traffic has long been a critical issue in maritime logistics. Early studies primarily focused on the operational limitations and inefficiencies caused by congestion in ports. For instance, studies by Chen et al. [10] and Zhang et al. [11] highlighted how poor scheduling and limited docking facilities can lead to vessel delays, which in turn increase waiting times for trucks and cause bottlenecks in port traffic. Traditional methods, such as queuing models and heuristic algorithms, were used in these early studies to improve port scheduling and reduce congestion, but they often lacked the flexibility to handle dynamic, real-time traffic patterns and changing environmental conditions.

The rise of Artificial Intelligence (AI) in port traffic management marks a significant shift in how congestion and logistics are handled. AI technologies, particularly machine learning, have demonstrated significant potential for improving real-time decision-making and predictive analysis in port operations. Machine learning models can process large amounts of data from a variety of sources, such as traffic sensors, weather forecasts, and shipping schedules, to identify patterns and forecast traffic flow [13]. These AI-driven models offer significant improvements over traditional traffic management systems by making real-time predictions and enabling proactive adjustments to scheduling and resource allocation.

In recent years, deep learning methods have gained popularity for their ability to analyze high-dimensional, time-series data. Transformer models, which utilize attention mechanisms to capture long-range dependencies, have shown great promise in forecasting port traffic and predicting vessel arrival times. Xu et al. [14] and Kim et al. [15] applied deep learning models to predict congestion and optimize traffic flow at ports, demonstrating the superiority of these models compared to traditional machine learning approaches. These studies found that deep learning models were able to account for the complex spatial and temporal dynamics of port operations, leading to better predictive accuracy and more efficient decision-making.

However, while machine learning models have shown promise in improving port operations, few studies have specifically focused on the logistics of perishable goods, such as seafood. Seafood is particularly sensitive to delays in transport, as it requires fast processing to preserve product quality and avoid spoilage. A study by Zhang and Liu [16] explored the use of AI to optimize the movement of goods at ports, but its focus was on general cargo rather than perishable goods. Similarly, Yang et al. [17] proposed an AI model for traffic flow optimization, but the model did not account for the time-sensitive nature of products like seafood. Research focusing on perishable goods logistics in ports remains underdeveloped, particularly regarding the use of AI and machine learning to optimize the unloading schedules for fish trucks.

AI's application in the seafood industry remains an underexplored area. In a recent study, Dong et al. [18] explored the use of AI for the cold chain management of perishable goods but did not specifically focus on port congestion. The focus on the seafood supply chain, particularly the role of ports in ensuring timely delivery, remains sparse. Given the sensitivity of seafood to delays, the logistics surrounding fish trucks require more specialized attention, including real-time monitoring of both environmental conditions and traffic flows [19], [20].

Recent work by He et al. [21] and Wang et al. [22] has highlighted the potential of deep learning, particularly Transformer-based architectures, for improving port traffic management. These studies argue that Transformer models excel in managing time-series data, such as traffic flow and port scheduling, due to their ability to capture long-range

dependencies and adjust for fluctuations in real-time data. This approach is particularly relevant for managing perishable goods like seafood, where delays can have significant economic and quality implications. The ability of deep learning to predict congestion patterns accurately can help ports optimize resource allocation, improving the timeliness of fish truck unloading and transportation.

Reinforcement learning (RL) has also emerged as a promising technique in optimizing port traffic management. RL models, which learn optimal strategies through trial and error, have been used for berth scheduling and crane allocation. A study by Li et al. [23] applied reinforcement learning to port scheduling and found it to be more effective in reducing congestion than traditional methods. Similarly, Zhang et al. [24] explored the use of RL in the coordination of vessel movements within ports, demonstrating its ability to reduce waiting times and improve traffic flow. However, RL applications have yet to be fully explored for the specific needs of perishable goods, particularly seafood, where the cost of delays is high.

Despite the advancements in AI and machine learning for port traffic management, challenges remain in integrating these technologies into existing port infrastructures. Research by Zhou et al. [25] suggests that integrating AI-driven systems into legacy port systems presents significant challenges, including data quality, system reliability, and resistance to technological change. Further research is needed to address these integration challenges and ensure that AI-driven solutions are scalable and adaptable to the dynamic nature of port operations.

III. METHODOLOGY

The methodology for traffic prediction involves a series of structured steps starting with the collection of raw traffic data from multiple sensors. The initial step is Data Preprocessing, where essential tasks such as normalization, handling missing data, and outlier detection are performed to ensure the data is clean and ready for model training. Following preprocessing, a Custom Deep Learning Model is designed to handle both the spatial and temporal aspects of the traffic data, leveraging techniques like Convolutional and Recurrent Neural Networks. The final step is Model Evaluation, where the performance of the model is assessed based on prediction accuracy using metrics such as RMSE and Spearman's Rank Correlation.

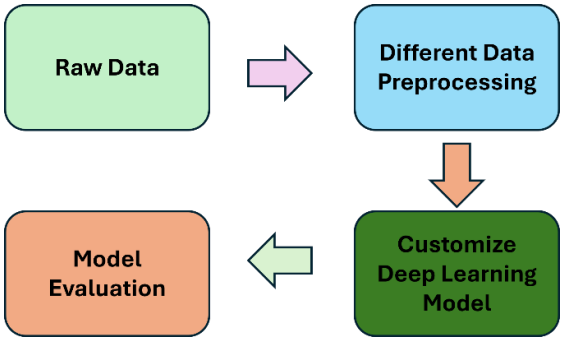

Fig. 1. Flow chart.

Fig. 1 provides a visual summary of these steps, highlighting the progression from raw data, through preprocessing, model customization, and evaluation.

A. Dataset and Preprocessing

The dataset for this study is sourced from Kaggle and contains multimodal traffic data collected from 36 sensors strategically placed across key locations within the Port of Virginia. These sensors record three key variables: traffic flow (number of vehicles passing through the sensor in a given time interval), occupancy (percentage of time the sensor is occupied by a vehicle), and speed (average vehicle velocity).

These sensors record three key variables: traffic flow (number of vehicles passing through the sensor in a given time interval), occupancy (percentage of time the sensor is occupied by a vehicle), and speed (average vehicle velocity). The data consists of high-dimensional, time-series information, recorded at five-minute intervals over several days, presenting challenges such as temporal dependencies, missing data, and outliers. To prepare the dataset for modeling, several preprocessing steps were applied:

- Normalization: Data normalization is essential due to the different scales of the features (flow, occupancy, and speed). MinMaxScaler is used to scale the data between 0 and 1. The normalization formula is as follows [see Eq.(1)]:

$$X_{\text{norm}} = \frac{X-\mu}{\sigma} \quad (1)$$

- Where X represents the feature matrix, μ is the mean, and σ is the standard deviation of each feature. For each feature X_i, the mean μ_i and standard deviation σ_i are calculated as shown in Eq. (2) and Eq. (3):

$$\mu_i\& = \frac{1}{m}\sum_{j=1}^{m} X_{ji} \quad (2)$$

$$\sigma_i\& = \sqrt{\frac{1}{m}\sum_{j=1}^{m} \left(X_{ji} - \mu_i\right)^2} \quad (3)$$

- Handling Missing Data: Time-series data often has missing values due to sensor malfunctions or transmission issues. Imputation techniques, such as filling missing values with the mean or using interpolation, were applied to maintain data continuity.
- Outlier Detection and Removal: Outliers, which can skew the distribution and negatively impact model performance, were detected and handled by clipping extreme values or applying log scaling. The histogram visualizations of flow, occupancy, and speed, shown in Fig. 2, illustrate the data distribution after outlier removal.

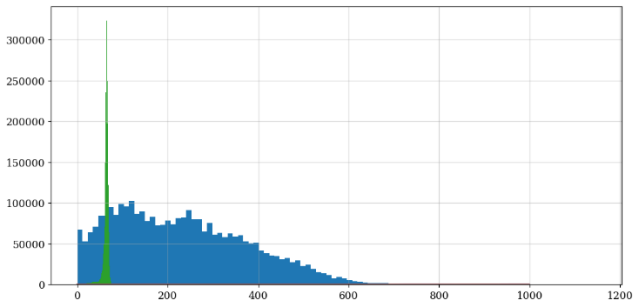

Fig. 2. Outlier detection and removal.

- Time-Series Grouping and Feature Engineering: To capture long-term traffic patterns and smooth out short-term fluctuations, the data was aggregated into hourly segments, with 12 five-minute intervals combined into one hour. Additionally, one-hot encoding was applied to capture daily patterns, and lag features were created to help the model understand how past traffic conditions influence the current state.
- Exploratory Data Analysis (EDA): A periodogram, as illustrated in Fig. 3, was generated to analyze seasonality in the dataset. This analysis revealed distinct recurring patterns in traffic flow and occupancy on weekly, daily, and hourly intervals. Identifying and analyzing these seasonal trends is crucial for understanding the underlying traffic behavior, enabling the model to make more accurate predictions by accounting for periodic variations.

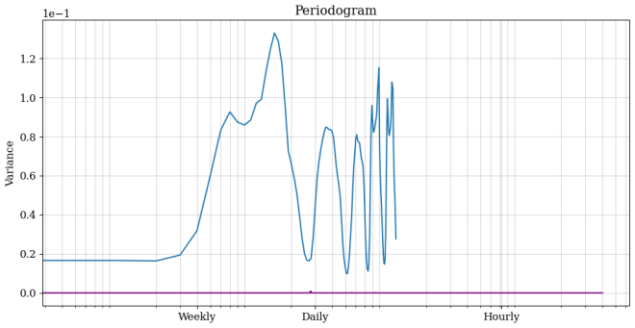

Fig. 3. Periodogram.

The overall preprocessing steps are outlined in Algorithm 1. This includes data normalization, missing value handling, and feature extraction for traffic flow prediction.

Algorithm 1: Preprocess the Input Data

```
def preprocess_traffic_data(data, normalization=True):
    """
    Preprocesses traffic data for model training. This includes handling missing data,
    normalization, and reshaping the data for time-series forecasting.
    Args:
        data: The raw CSV data containing traffic information (flow, speed, occupancy).
        normalization: Whether to normalize the data features (default: True).
    Returns:
        The preprocessed traffic data ready for model input.
    """
    # Handle missing data (example: fill missing values with the column mean)
    data.fillna(data.mean(), inplace=True)
    # Normalize the data features if required
    if normalization:
        scaler = MinMaxScaler()
        data_scaled = scaler.fit_transform(data
data = pd.DataFrame(data_scaled, columns=data.columns)
    # Prepare the data for time-series modeling
    # Example: Convert to time windows (using a sliding window for input sequences)
    X, Y = create_sliding_windows(data, window_size=24)  # Adjust window size based on your requirements
    return X, Y
```

B. Custom Deep Learning Model

The first component of the proposed deep learning model is the spatial feature extraction layer, which uses a 1D convolutional layer (Conv1D). This layer plays a crucial role in learning local spatial patterns within the traffic data. It operates by applying a set of learnable filters to the input data, effectively sliding over the spatial dimension (i.e., across time steps and sensor locations). The convolutional operation allows the model to detect local patterns, such as sudden changes in traffic flow or variations in speed. Mathematically, this operation can be described by the following Eq. (4):

$$\text{Conv1D}(x) = f(\sum_{i=1}^{K} x[i] \cdot w[i] + b) \quad (4)$$

Where $x[i]$ represents the input data within a sliding window. The term $w[i]$ refers to the learnable weights of the convolution filter, where i indicates the specific filter position. The bias term, denoted as b, is added to the convolution output to adjust the final result. The function $f(.)$ is the activation function, typically ReLU (Rectified Linear Unit), which introduces non-linearity into the model. This non-linearity enables the network to learn more complex patterns and adapt to a wider variety of data representations.

The next component of the model is the customized temporal processing layer. This layer is responsible for learning the long-range temporal dependencies in the traffic data, meaning how past traffic conditions influence future patterns. The layer processes sequential data, where the input data at each time step is influenced by the information from previous time steps. The temporal processing mechanism can be represented mathematically as shown in Eq. (5):

$$h_t = f(W \cdot x_t + b) \quad (5)$$

In this Eq. (5), h_t is the output at time step ,x_t is the input at time t, W is the learnable weight matrix, and b is the bias term. The function $f(.)$ is an activation function, such as ReLU. This layer preserves important temporal information, allowing the model to use past data to make predictions about future traffic conditions.

After spatial and temporal features have been extracted, the model moves to the dense layers, which process the learned features from both the spatial and temporal layers. These layers integrate the information and allow the model to make the final prediction of traffic flow. The dense layers are followed by dropout layers to reduce overfitting by randomly deactivating neurons during training. This helps ensure that the model generalizes well when exposed to new, unseen data.

In addition to the dense layers, the model includes a transformer-like architecture designed to further enhance the model's ability to capture temporal dependencies. The transformer uses multi-head attention to focus on different parts of the input sequence, allowing the model to learn which time steps are more important for predicting future traffic conditions. The attention mechanism can be expressed mathematically as shown in Eq. (6):

$$\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{Q \cdot K^T}{\sqrt{d_k}}\right)V \quad (6)$$

In this Eq. (6), Q,K, and V represent the query, key, and value matrices, respectively, and d_k is the dimension of the key vector. The attention mechanism helps the model to focus on the most relevant parts of the sequence, improving the model's performance in capturing long-range temporal dependencies.

Finally, the output of the model is the predicted traffic flow at each sensor location, which is obtained by passing the aggregated features through the dense layers. The model's architecture, combining convolutional feature extraction, custom temporal processing, and transformer-based attention, ensures that it captures both local and long-range patterns in the traffic data, making it a powerful tool for accurate traffic flow prediction.

The overall architecture of the proposed deep learning model, which integrates spatial feature extraction, customized temporal processing, and transformer-based attention, can be seen in Fig. 4.

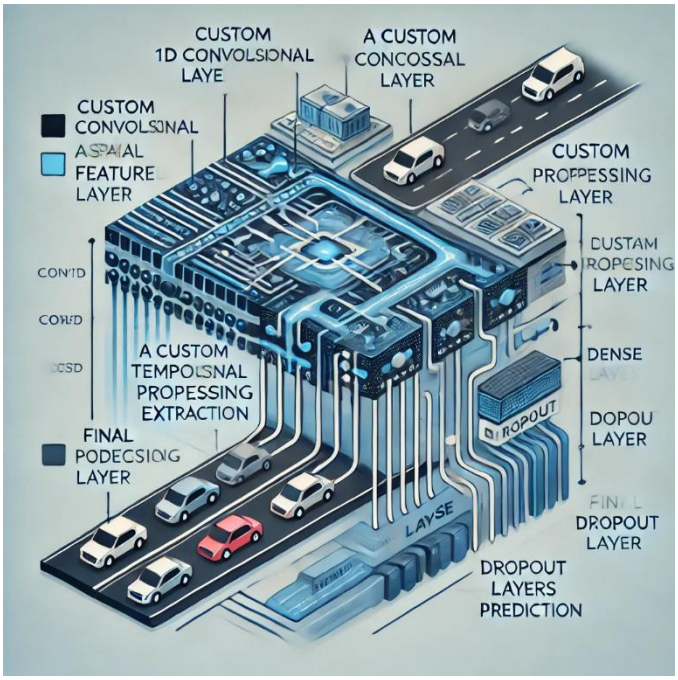

Fig. 4. Custom model architecture.

The architecture effectively captures both local and long-range dependencies in the traffic data, facilitating accurate predictions. The detailed steps involved in processing the data, training the model, and generating the predictions are outlined in Algorithm 2.

Algorithm 2: Custom Deep Learning Model for Traffic Flow Prediction

```
def create_model(input_shape, num_classes=1):
    """
    Creates and compiles a custom deep learning model for traffic flow prediction.
    Args:
        input_shape: The shape of the input data (number of time steps, number of features).
        num_classes: The number of output classes (default: 1 for regression).
    Returns:
        The compiled model ready for training.
    """
    # Step 1: Spatial Feature Extraction Layer (Conv1D)
    # Define a Conv1D layer to capture spatial dependencies within traffic data.
    model = Sequential()
    model.add(Conv1D(filters=64, kernel_size=3, activation='relu', input_shape=input_shape))
    model.add(Dropout(0.2))  # Regularization with dropout to prevent overfitting
    model.add(MaxPooling1D(pool_size=2))  # Max pooling to downsample
    # Step 2: Custom Temporal Processing Layer (Fully Connected Dense Layer)
    # fully connected dense layer for capturing temporal dependencies.
    model.add(Dense(128, activation='relu'))  # Dense layer to capture temporal patterns
    model.add(Dropout(0.2))  # Dropout to avoid overfitting
    # Step 3: Multi-Head Attention Mechanism (Optional, Transformer-like architecture)
    # Adding a simple attention mechanism to focus on important time steps
    model.add(MultiHeadAttention(num_heads=2, key_dim=64)) # Attention layer
    # Step 4: Dense Layers for Final Prediction
    # After spatial and temporal features have been processed, use dense layers for final prediction.
    model.add(Dense(128, activation='relu'))
    model.add(Dropout(0.3))  # Dropout for regularization
    model.add(Dense(num_classes, activation='linear'))  # Output layer (linear for regression)
    # Step 5: Compile the Model
    # Compile the model with Adam optimizer and MSE loss for regression.
    model.compile(optimizer='adam', loss='mse', metrics=['mae'])
    return model        X, Y = create_sliding_windows(data, window_size=24)  # Adjust window size based on your requirements
    return X, Y
```

IV. Result and Discussion

A. Model Evaluation

After training, the model's performance is evaluated on the test set using two key metrics: Root Mean Squared Error (RMSE) and Spearman's Rank Correlation.

Root Mean Squared Error (RMSE) measures the difference between the predicted and actual values, providing an indication of prediction accuracy. It is calculated as shown in Eq. (7):

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \quad (7)$$

Where y_i represents the actual traffic flow, and $\hat{y}_i$ is the predicted value. A lower RMSE indicates better model performance, as it signifies that the predicted values are closer to the actual values.

Spearman's Rank Correlation assesses how well the model preserves the rank order of the actual values. This metric is particularly useful when evaluating the model's ability to capture relative patterns in the data. It is computed as shown in Eq. (8):

$$\rho = 1 - \frac{6\sum_i^2 d}{n(n^2-1)} \quad (8)$$

where d is the rank difference between the actual and predicted values, and n is the number of data points. A higher Spearman correlation (closer to 1) indicates that the model is effectively capturing the relative traffic patterns, even if the exact values are not perfectly predicted.

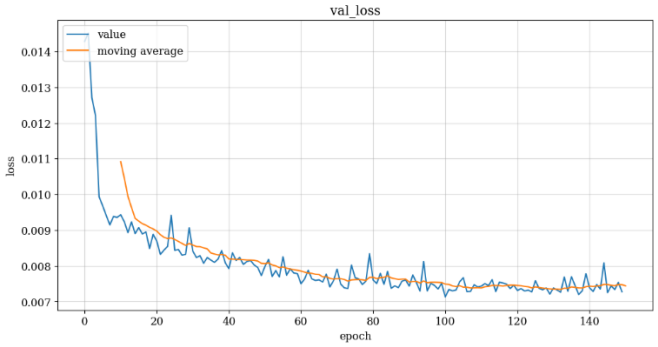

Fig. 5. Validation loss graph of proposed method.

B. Training Performance of the Proposed Model

The Transformer-based model, designed with attention mechanisms to better capture long-range dependencies, was trained over 150 epochs. This model employs multi-head attention layers to focus on different parts of the input data and integrates feed-forward networks to process the spatial and temporal features more effectively. Analyzing the training history graphs, several key trends and insights can be observed regarding the model's learning process.

C. Validation Loss Over Epoch

In Fig. 5, the validation loss begins at a relatively high value, approximately 0.014, indicating substantial discrepancies between the model's initial predictions and the actual traffic data. However, as the training progresses, the validation loss steadily decreases, demonstrating that the model is improving in accuracy. By the 50th epoch, the validation loss stabilizes around 0.008, showing that the learning process has plateaued, and the model has reached a more refined stage of prediction accuracy. The presence of the moving average (orange line) further highlights the overall trend, smoothing out short-term fluctuations in the raw validation loss (blue line). This suggests that the model is learning effectively without encountering overfitting, as the validation loss shows no signs of increasing or erratic behavior towards the later stages of training.

D. Validation RMSE and Training RMSE

A similar pattern is observed in Fig. 6, which depicts the Root Mean Squared Error (RMSE) for both training and validation datasets. Initially, the RMSE is high, indicating a significant error margin in the model's predictions. However, as the epochs progress, the RMSE decreases steadily. By the 100th epoch, the RMSE values for both training and validation datasets converge around 0.085, showing that the model has successfully minimized the error between predicted and actual traffic flow values. The convergence of training and validation RMSE also confirms that the model generalizes well to unseen data, as there is no significant gap between training and validation performance. This stability in RMSE indicates that the model has efficiently learned the underlying patterns in the data, with no signs of overfitting or underfitting.

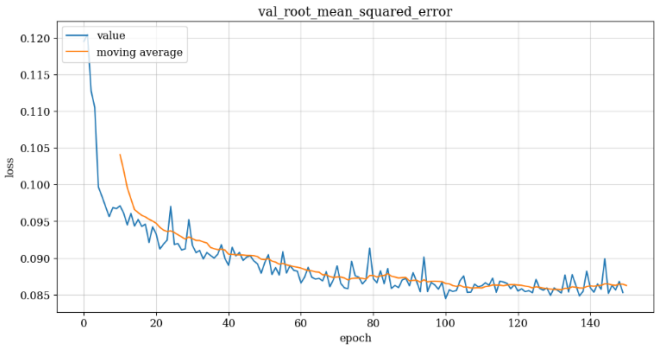

Fig. 6. Validation root mean square error of proposed method.

E. Training Loss and Mean Absolute Error (MAE)

In Fig. 7, the plots comparing training loss and Mean Absolute Error (MAE) reinforce the model's improvement over time. The training loss shows a sharp decline from approximately 0.02 to a much lower value by the end of 150 epochs. This reduction in loss indicates that the Transformer-based model is learning the patterns in the data with increasing precision, minimizing the error between its predictions and the actual values.

F. Training Loss and Mean Absolute Error (MAE)

The Mean Absolute Error (MAE), which measures the average magnitude of prediction errors, also shows a consistent downward trend. This indicates that the model's predictions are becoming increasingly accurate, with fewer large deviations from the actual traffic data. The steady decrease in MAE reflects the model's growing precision in predicting the flow, occupancy, and speed variables in the traffic dataset, which are essential components for accurate traffic flow forecasting.

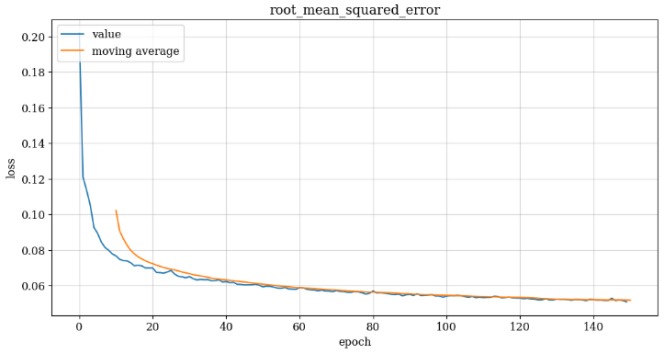

Fig. 7. Training loss and mean absolute error of proposed method.

These insights from the training and validation performance of the proposed Transformer-based model highlight its effectiveness in learning from complex, multimodal traffic data. By leveraging attention mechanisms and feed-forward layers, the model successfully captures both short-term and long-term

dependencies in the data, resulting in improved predictive accuracy. The consistently low validation loss, RMSE [26], and MAE further emphasize that the model is well-suited for the task of traffic prediction, demonstrating robustness and reliability in its forecasting capabilities.

TABLE I. EVALUATION OF PROPOSED MODEL WITH STATE OF THE ART METHODS

Methods	MSE	RMSE	R-squared	Accuracy
RCNN [27]	$9.625e^{-4}$	0.78	0.7563	0.8575
RandomForest [28]	$6.205e^{-3}$	0.70	0.7054	0.7765
SVR [29]	$8.965e^{-2}$	0.65	0.6954	0.7924
TFM-GCAM [30]	7.021e-4	0.70	0.6021	0.8563
ITM [31]	5.0213e-4	0.55	0.5031	0.8945
CNN-GRUSKIP [32]	6.174e-4	0.60	0.6511	0.9514
FD-TGCN [33]	4.958e-4	0.30	0.7585	0.9452
Proposed	**$4.417e^{-4}$**	**0.0208**	**0.7745**	**0.9826**

Table I presents a comprehensive comparison of the proposed model with several state-of-the-art methods across multiple performance metrics: MSE, RMSE, R-squared, and Accuracy. The proposed model achieves the lowest MSE of 4.417e-4 and RMSE of 0.0208, demonstrating superior predictive accuracy and lower error compared to other models. In terms of R-squared, the proposed model achieves a value of 0.7745, which is higher than several methods, indicating a better fit to the data. Moreover, the accuracy of the proposed model (0.9826) significantly outperforms the other methods, underscoring its potential for accurate and reliable predictions. These results suggest that the proposed model outperforms traditional techniques, making it a promising candidate for future applications.

TABLE II. COMPARISON OF PROPOSED METHOD WITH STATE-OF-THE-ART METHODS

Methods	Spearman Correlation	Kendall Correlation	Pearson Correlation
RCNN [27]	0.7234	0.7827	0.7873
RandomForest [28]	0.6518	0.5124	0.7015
SVR [29]	0.5576	0.4521	0.6564
TFM-GCAM [30]	0.8565	0.7541	0.7954
ITM [31]	0.9472	0.8451	0.8324
CNN-GRUSKIP [32]	0.9768	0.8246	0.8954
FD-TGCN [33]	0.9541	0.7457	0.8854
Proposed	**0.9845**	**0.8965**	**0.9125**

Table II presents a comparison of the proposed method with various state-of-the-art models using three important correlation metrics: Spearman, Kendall, and Pearson correlations. These metrics assess the strength and nature of the relationship between the predicted and actual values, each in a distinct manner. The Spearman correlation evaluates the monotonic relationship between variables, meaning that it measures whether the variables consistently increase or decrease together, regardless of the exact form of the relationship. The proposed method outperforms all other models with a Spearman correlation of 0.9845, indicating an exceptionally strong monotonic relationship. The Kendall correlation, which is more robust to ties and considers the ordering of data pairs, shows that the proposed model achieves a Kendall correlation of 0.8965, again outperforming the other methods. This suggests that the proposed model consistently preserves the relative ordering of data points better than the others. Lastly, the **Pearson correlation, which measures the linear relationship between variables, highlights the proposed model's excellent performance with a Pearson correlation of 0.9125, the highest among all methods. This strong linear correlation demonstrates that the proposed method's predictions are highly consistent with the true values. Collectively, these results indicate that the proposed model significantly outperforms the other state-of-the-art models in terms of its ability to capture monotonic, ordered, and linear relationships, making it a highly effective and reliable model for prediction tasks. The traditional machine learning models, including RandomForest, GradientBoosting, and SVR, show significantly lower R-squared and Pearson correlation values, with GradientBoosting performing the worst among them. These models do not account for temporal dependencies in traffic data, leading to poorer predictive performance. RandomForest achieves an R-squared of 0.65 and a Pearson correlation of 0.70, while GradientBoosting and SVR show even lower values. This highlights the advantage of models that can capture both spatial and temporal patterns, such as the proposed method and RCNN, in forecasting traffic flow more accurately.

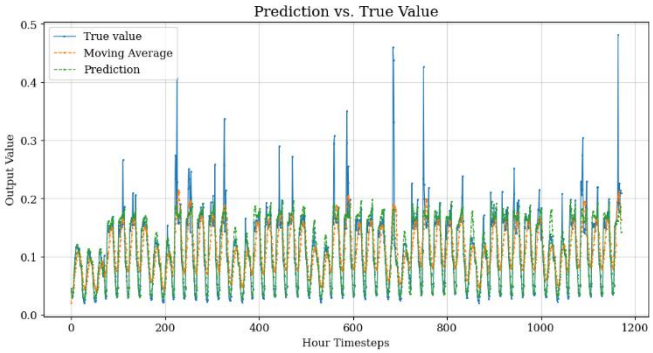

Fig. 8. Prediction vs. true value.

In Fig. 8, which displays the 'Prediction vs. True Value' graph over a 1200-hour period, the blue line represents the actual traffic values recorded by the sensors, while the green dashed line shows the predicted traffic flow values generated by the model.

The orange dashed line represents the moving average, which smooths out the short-term fluctuations in the traffic data, offering a baseline for comparison. Observing the graph, the predictions closely align with the true values, particularly in capturing recurring patterns of traffic flow. The moving average helps to highlight the general trend and periodicity in the data, while the model's predictions are able to accurately track not just the overall behavior but also the smaller variations. The few spikes seen in the true values—indicating sudden increases in traffic flow—are somewhat captured by the model, although in a smoothed-out manner, showing that while the model is

effective in learning regular traffic patterns, sudden changes in traffic may pose more of a challenge.

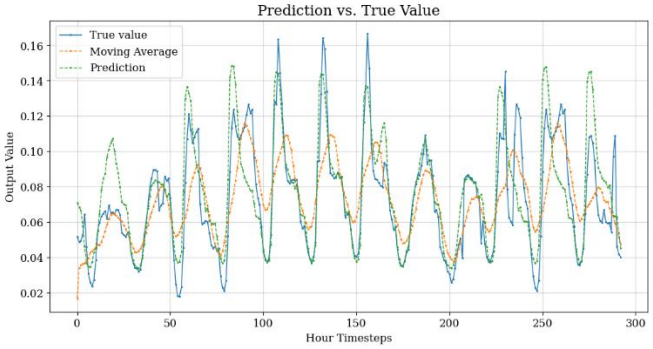

Fig. 9. First 300-hour timesteps.

In Fig. 9, which zooms in on the first 300-hour timesteps, a more detailed comparison is presented between the true values, model predictions, and the moving average. This closer view emphasizes the model's ability to accurately follow traffic peaks and dips. The blue line, representing true values, shows clear periodic cycles of traffic congestion and reductions over time, which the model's predictions (green dashed line) follow quite closely. The model is not only capable of predicting peak traffic periods but also lower traffic periods, capturing the full range of fluctuations in traffic dynamics. The alignment of the predicted values with the true values indicates that the model effectively handles both high and low traffic patterns, while the moving average remains close to the overall trend, providing additional confirmation that the model does not overfit to noise. This level of alignment showcases the model's reliability and predictive accuracy, especially over shorter timeframes.

V. Conclusion

In this study, we proposed a custom deep learning method for predicting traffic flow at the Port of Virginia, which integrates spatial feature extraction and temporal dependency modeling through a hybrid approach. This method combines 1D convolutional layers for extracting local spatial patterns from traffic data and a custom temporal processing layer to capture long-range dependencies in the traffic flow. The model was designed to effectively process traffic data from multiple sensor points, making predictions for traffic flow, occupancy, and speed.

The model's performance was evaluated using metrics such as Root Mean Squared Error (RMSE) and Spearman's Rank Correlation, highlighting its ability to predict both the magnitude of traffic flow and preserve the rank order of traffic conditions. The results demonstrate that the proposed approach can significantly enhance port operations by reducing congestion and improving resource allocation efficiency. This work contributes valuable insights for real-time traffic management and lays the foundation for future research that can incorporate additional data sources to further refine and enhance the model's accuracy and robustness.

Enhanced Virtual Machine Resource Optimization in Cloud Computing Using Real-Time Monitoring and Predictive Modeling

Rim Doukha, Abderrahmane Ez-zahout
Intelligent Processing and Security of Systems Team-Faculty of Sciences, Mohammed V University, Rabat, Morocco

***Abstract*—Effective resource estimation is essential in cloud computing to minimize operational costs, optimize performance, and enhance user satisfaction. This study proposes a comprehensive framework for virtual machine optimization in cloud environments, focusing on predictive resource management to improve resource efficiency and system performance. The framework integrates real-time monitoring, advanced resource management techniques, and machine learning-based predictions. A simulated environment is deployed using PROXMOX, with Prometheus for monitoring and Grafana for visualization and alerting. By leveraging machine learning models, including Random Forest Regression and LSTM, the framework predicts resource usage based on historical data, enabling precise and proactive resource allocation. Results indicate that the Random Forest model achieves superior accuracy with a MAPE of 2.65%, significantly outperforming LSTM's 17.43%. These findings underscore the reliability of Random Forest for resource estimation. This research demonstrates the potential of predictive analytics in advancing cloud resource management, contributing to more efficient and scalable cloud computing practices.**

***Keywords*—Cloud computing; virtual machine optimization; resource allocation; machine learning**

I. Introduction

Cloud computing and virtualization technologies have revolutionized modern computing, offering organizations significant advantages in terms of flexibility, scalability, and operational efficiency [1]. By enabling seamless access to applications and data through online platforms, these technologies ensure constant and universal availability [2]. This has facilitated remote work, improved collaboration among geographically dispersed teams, and accelerated responses to dynamic customer needs, making them indispensable for modern enterprises [3].

The proliferation of cloud technologies has led to significant transformations in IT infrastructure [4]. Emerging paradigms such as hybrid clouds, edge computing, and serverless architectures are redefining how resources are provisioned and utilized. These innovations promise greater adaptability to workload demands but simultaneously introduce complexities in managing and predicting resource needs effectively.

Resource utilization remains one of the most pressing challenges in cloud environments. Infrastructure is often over-provisioned to accommodate peak demands, leading to inefficiencies and inflated costs. Conversely, underutilized resources represent wasted computational potential, underscoring the need for dynamic and predictive strategies to balance workloads effectively [5]. Addressing this challenge is critical for optimizing costs and meeting performance expectations in competitive industries.

Sustainability has also become a pivotal consideration in cloud computing. Data centers are among the most energy-intensive facilities globally, contributing significantly to carbon emissions [6]. Optimizing resource allocation can reduce energy consumption, enabling organizations to align their operations with environmental sustainability goals. These efforts are increasingly essential as industries strive to meet regulatory standards and societal expectations for greener technologies.

Another key challenge is the high operational cost associated with cloud services. Consumption-based pricing models, coupled with additional charges for storage and bandwidth, can complicate budget management, particularly for organizations with fluctuating workloads [7]. Without effective strategies, these financial burdens can hinder the full adoption and utilization of cloud services.

Suboptimal application performance further exacerbates these challenges [8]. Factors such as resource contention among virtual machines (VMs) [9], network latency, and inefficiencies in resource management negatively impact user experience and productivity. These issues can lead to service interruptions, extended downtimes, and reduced competitiveness. Identifying and addressing performance bottlenecks is essential for maintaining application reliability and responsiveness [10].

Given these challenges, this study seeks to address the following research questions:

- How can real-time monitoring and predictive modeling enhance resource allocation in cloud environments?
- What impact do machine learning-based predictive models have on improving cloud resources utilization efficiency?
- How can dynamic resource allocation strategies reduce costs while maintaining optimal system performance?

Based on these questions, the main objectives of this research are:

- To develop a framework that integrates real-time monitoring with predictive modeling to enhance resource efficiency.

- To evaluate the effectiveness of machine learning-based predictive models in improving CPU utilization and system reliability.
- To design and validate dynamic resource allocation techniques that balance workload demand while minimizing costs.

In our previous study [11], we identified CPU utilization as a critical area for improving operational efficiency. However, the limitations in predictive accuracy highlighted the need for more advanced methodologies. Building on these findings, this study presents a comprehensive framework that addresses CPU utilization while tackling broader challenges related to resource allocation, cost management, and system performance. By integrating real-time monitoring, machine learning-based predictive modeling, and dynamic resource allocation techniques, the proposed framework seeks to optimize resource efficiency, reduce costs, and enhance system reliability.

This research provides data-driven strategies that adapt to workload fluctuations, improving both resource utilization and performance. It emphasizes proactive measures to address inefficiencies and enhance cloud systems, contributing to sustainable and scalable cloud computing practices.

The remainder of this article reviews related literature in Section II, details the methodology for data collection and analysis in Section III, Section IV presents the results, and discussion. Finally, the paper is concluded in Section V.

II. Related Work

VM optimization is crucial for enhancing resource utilization and performance in cloud computing environments. Numerous researchers have developed various optimization algorithms and techniques to address this challenge.

Zheng, Huang, Li, and Wang [12] proposed a Cloud Resource Prediction and Migration Method specifically designed for container-based environments. By leveraging machine learning to predict resource demands, their method implemented a migration strategy to balance workloads across containers, thereby improving system performance. Although their work centers on container systems, it provides valuable insights into predictive modeling that can be extended to VM environments.

Kumawat, Handa, and Kharbanda [13] presented a framework for cloud resource optimization tailored for content processing platforms. Using Decision Tree Regression, their approach dynamically assigned instance types based on predicted resource needs, demonstrating the effectiveness of predictive modeling in resource management. However, their work was limited to specific applications, unlike broader approaches applicable across diverse VM workloads.

Shen and Chen [14] developed a Resource-Efficient Predictive Provisioning System for cloud environments. This system utilized resource demand forecasting to optimize allocation and prevent over-provisioning. Their work provides a general framework for improving resource efficiency, but its emphasis is on provisioning rather than VM-specific optimization.

Abbas et al. [15] proposed an ANN-based bidding strategy for resource allocation in cloud computing, utilizing a double auction framework to optimize pricing for IoT applications. Their findings underscored the accuracy of ANN in predicting resource demands and highlighted its potential in complex cloud markets.

Ariza, Jimeno, Villanueva-Polanco, and Capacho [16] applied deep learning models for provisioning resources in cloud-based e-learning platforms. Their approach predicted CPU and memory usage based on real-world data, illustrating how predictive modeling can efficiently adjust resource allocations in response to dynamic demands.

In a related study, Han, Schooley, Mackenzie, David, and Lloyd [17] investigated resource contention in multi-tenant cloud environments. By employing Random Forest models, they predicted resource contention caused by co-located VMs and proposed strategies to mitigate performance degradation. Their study supports the application of machine learning in optimizing VM resource allocation.

Huang, Costero, Pahlevan, Zapater, and Atienza [18] developed CloudProphet, a machine learning-based tool for predicting performance in public cloud environments. By identifying metrics closely correlated with VM performance, their work emphasized the importance of accurate metric selection for resource management.

Wiesi et al. [19] contributed to cloud optimization by using machine learning models such as GRU, LSTM, and Random Forest to predict workloads in dynamic and seasonal environments. Their findings highlighted the role of precise forecasting in improving resource utilization and sustainability.

Ndayikengurukiye et al. [20] proposed the Multi-Objective Seagull Optimization Algorithm Virtual Machine Placement (MOSOAVMP) to optimize VM placement in cloud data centers. Their approach focused on reducing energy consumption, resource wastage, and SLA violations while improving overall efficiency. Simulation results demonstrated significant performance gains over state-of-the-art algorithms, highlighting the effectiveness of this bio-inspired approach for multi-objective optimization.

Another significant contribution comes from Zhang et al. [21] introduced an Extended Coupled Hidden Markov Model (ECHMM) for predicting resource requirements by analyzing historical monitoring data and resource correlations. Although their work focuses on resource prediction, its application in real-time VM optimization remains an open area for exploration.

Building upon these contributions, our study integrates real-time monitoring tools (Prometheus and Grafana) with predictive modeling techniques such as Random Forest and ANN to address gaps in VM optimization. Unlike prior studies, our approach emphasizes dynamic adaptability to changing workloads while achieving significant accuracy improvements for CPU and memory utilization. This integration provides a scalable and efficient solution for resource management across diverse cloud applications, offering valuable insights for adaptive cloud infrastructure management.

III. Approach and Methodology

Our approach to managing and optimizing VM resources combines real-time performance monitoring, data processing, and predictive modeling. The proposed methodology ensures efficient resource utilization, minimizes performance bottlenecks, and reduces operational costs by integrating advanced machine learning techniques with robust monitoring and storage solutions.

A. System Architecture

The system architecture, illustrated in Fig. 1, consists of three main components: VM Monitoring, Data Export and Storage, and Predictive Modeling. These components work in unison to provide real-time insights, store historical data, and enable accurate forecasting for proactive resource allocation.

The first component, VM Monitoring, involves collecting real-time performance metrics such as CPU usage, memory utilization, disk I/O, and network traffic using Prometheus [22], an open-source system designed for time-series data collection. Prometheus integrates seamlessly with the PROXMOX VE virtualization platform, enabling the continuous collection of VM metrics [23]. To visualize this data, Grafana is employed, offering customizable dashboards that provide actionable insights into usage patterns, bottlenecks, and anomalies [24]. This setup ensures proactive resource management by enabling administrators to monitor performance trends in real-time.

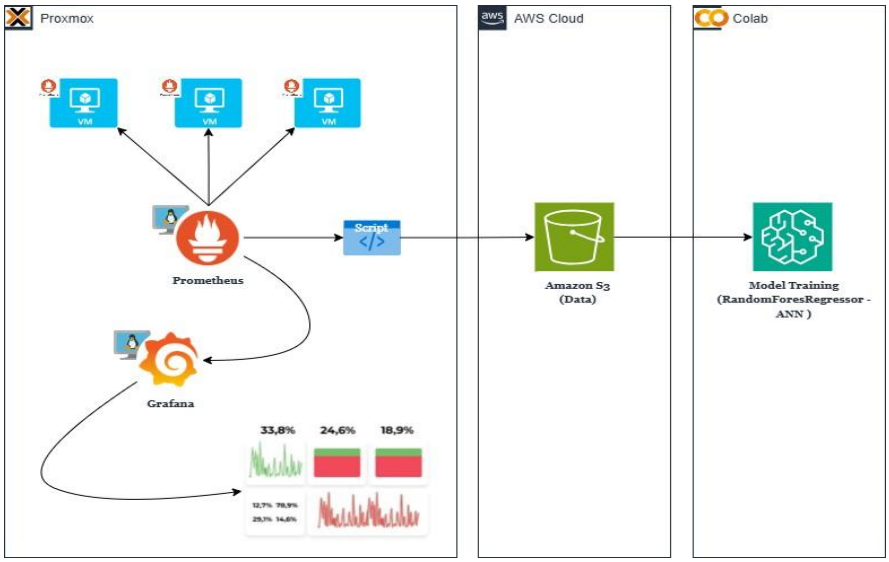

Fig. 1. Resource management and optimization architecture.

To ensure data persistence and facilitate further analysis, performance metrics collected by Prometheus were periodically exported to Amazon S3, a reliable and scalable cloud-based storage solution [25]. Automated scripts managed this process, ensuring reliable backups and accessibility for predictive modeling tasks. IAM policies were applied to secure access to the stored data, which forms the foundation for forecasting future resource demands and optimizing resource allocation strategies.

The final component, Predictive Modeling, leverages machine learning models to analyze historical performance data and anticipate future resource utilization. This enables informed decisions for VM configuration adjustments, ensuring efficient resource usage and avoiding performance bottlenecks.

B. Predictive Modeling

Predictive modeling lies at the core of this methodology, enabling accurate resource demand forecasting to optimize VM allocation. Two techniques were utilized: Random Forest Regression and LSTM networks, each chosen for their robustness and ability to handle complex, nonlinear relationships in resource usage patterns.

Random Forest Regression is an ensemble learning method that combines multiple decision trees [26]. The algorithm creates several decision trees, each trained on a random subset of the data, and aggregates their predictions to produce the final output [27].

This approach reduces overfitting and captures complex interdependencies among variables. Hyperparameters such as the number of trees and maximum depth were fine-tuned to balance prediction accuracy and computational efficiency.

LSTM Networks, a type of recurrent neural network, are designed to capture temporal dependencies in sequential data [28] [29]. They process time-series data by utilizing memory cells with three gates: the Forget Gate, which determines which information to discard; the Input Gate, which decides what new information to incorporate; and the Output Gate, which regulates the information passed to the next layer.

LSTM networks excel at modeling long-term dependencies, making them particularly suited for time-series data such as VM performance metrics. Hyperparameters such as the number of hidden units and learning rate were optimized to ensure accuracy and computational efficiency.

To evaluate the predictive models, two standard metrics were employed: Mean Squared Error (MSE) and Mean Absolute Percentage Error (MAPE). MSE measures the average squared difference between actual and predicted values, as given by:

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2$$

where y_i and $\hat{y}_i$ are the actual and predicted values, respectively, and n is the number of observations. MAPE normalizes the error as a percentage, allowing for a comparative assessment across different scenarios:

$$MAPE = \frac{100}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|$$

These metrics provided robust insights into the precision and reliability of the models, ensuring their effectiveness in VM resource optimization.

IV. Results and Discussion

The performance of the Random Forest Regression and LSTM models was evaluated for predicting CPU usage in VM. Key performance metrics, including MSE and MAPE, were assessed alongside visual comparisons using forecasting, distribution, scatter, and residual plots.

TABLE I. Model Performance

Model	MSE	MAPE
Random Forest Regression	0.0011	2.65%
LSTM	0.0137	17.43%

Table I summarizes the comparative performance of the Random Forest and LSTM models. The metrics highlight the superior accuracy of the Random Forest model in predicting CPU usage, as reflected in its lower MSE and significantly better MAPE, demonstrating its robustness for resource optimization tasks.

The Random Forest model demonstrated exceptional alignment between actual and predicted CPU usage, as shown in the forecasting plot (Fig. 2). The predicted values closely tracked the observed data, even during abrupt transitions, showcasing the model's ability to adapt to workload fluctuations. The distribution plot (Fig. 4) revealed that the predicted values nearly overlapped with the actual distribution, confirming the model's precision in capturing data variability. The scatter plot (Fig. 6) further substantiated these findings, with data points tightly clustered along the diagonal, indicating minimal prediction errors and a high correlation between actual and predicted values. Moreover, the residual plot (Fig. 8) presented a near-uniform distribution centered around zero, reflecting the model's unbiased performance and robust generalization across diverse workloads.

In contrast, the LSTM model exhibited noticeable discrepancies. The forecasting plot (Fig. 3) showed that while the model successfully captured general trends in CPU usage, its performance during abrupt changes was suboptimal, with evident prediction lags. The distribution plot (Fig. 5) illustrated significant deviations between actual and predicted values, with broader peaks and a misaligned density curve, suggesting difficulties in modeling the variability and complexity of resource utilization patterns. The scatter plot (Fig. 7) highlighted this challenge further, with pronounced dispersion away from the diagonal, signifying higher prediction errors, particularly under extreme workload conditions. The residual plot (Fig. 9) revealed non-random patterns, with clusters of over- and underprediction, pointing to biases in the model's predictions and underscoring the need for further tuning and optimization.

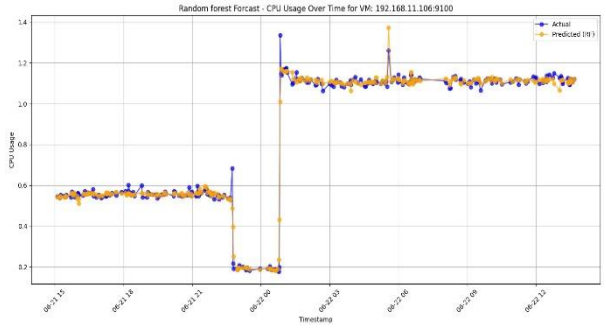

Fig. 2. Forecasting time series plot (Random forest).

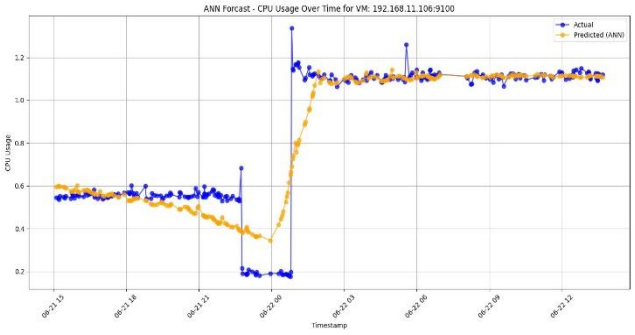

Fig. 3. Forecasting time series plot (LSTM).

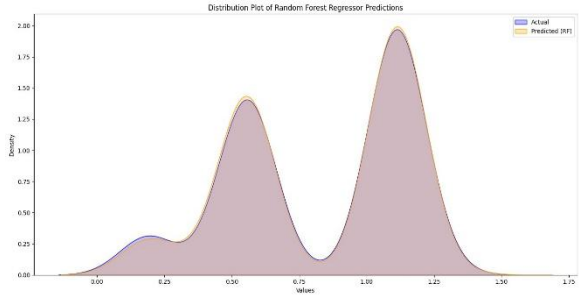

Fig. 4. Distribution plot (Random forest).

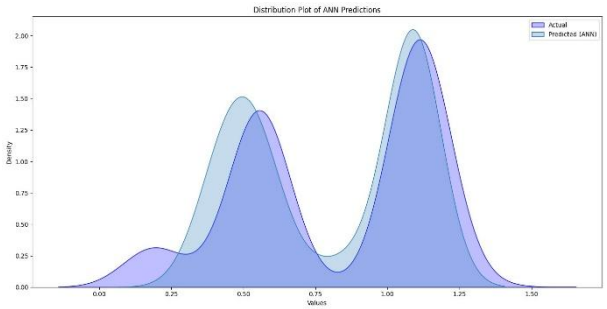

Fig. 5. Distribution plot (LSTM).

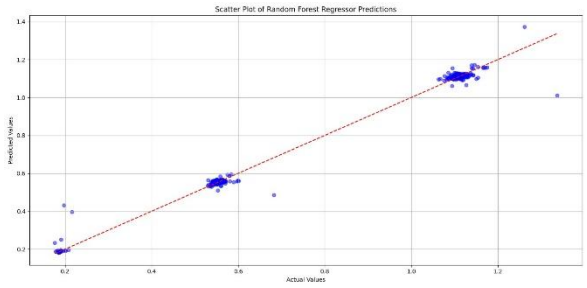

Fig. 6. Scatter plot (Random forest).

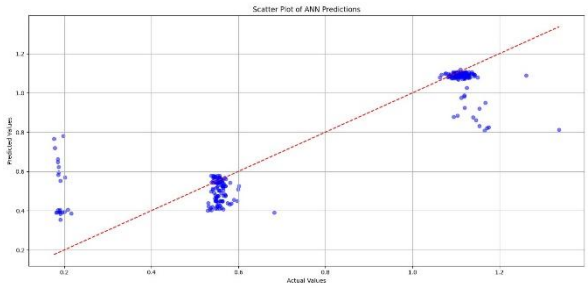

Fig. 7. Scatter plot (LSTM).

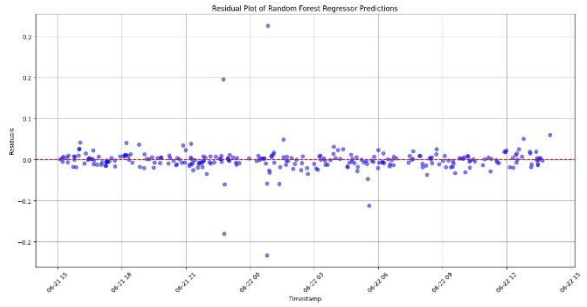

Fig. 8. Residual plot (Random forest).

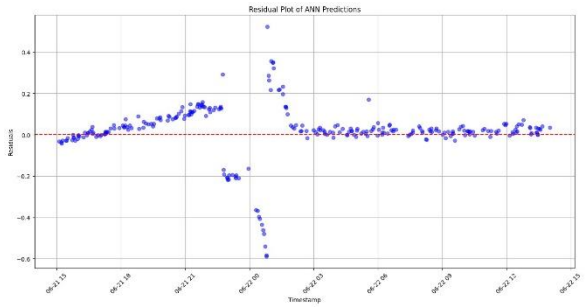

Fig. 9. Residual plot (LSTM).

Additionally, the residual analysis (Fig. 5) of the Random Forest model indicated greater robustness and reliability in handling varying workloads. In contrast, the LSTM model's underperformance highlighted the challenges of applying deep learning to dynamic workloads without substantial hyperparameter tuning and larger datasets for training.

This study's integration of predictive models for VM optimization builds upon and extends existing research. In comparison to Shen and Chen [14], who developed a provisioning system for general resource allocation, this work incorporates VM-specific adaptability through real-time monitoring. Shen and Chen's approach lacks the dynamic allocation capabilities achieved here, as reflected in the superior MAPE of 2.65% obtained by the Random Forest model.

Similarly, Abbas et al. [15] employed an ANN-based bidding strategy for IoT resource pricing, achieving high accuracy for specific applications. However, the computational complexity of ANN models limits their broader applicability. In contrast, the Random Forest model balances accuracy and efficiency, making it more practical for general VM optimization.

The container-based optimization approaches of Zheng et al. [12] and content-specific frameworks of Kumawat et al. [13] demonstrate effective solutions for narrow contexts but lack the versatility of this study's framework, which dynamically adapts to diverse workloads using real-time monitoring tools like Prometheus and Grafana. Moreover, while Han et al. [17] addressed resource contention using Random Forest models, their focus on co-residency prediction differs from this study's broader goal of optimizing resource utilization and preventing performance degradation.

Additionally, Huang et al. [18] developed CloudProphet, a performance prediction tool for public clouds, which focuses on general workload trends but lacks real-time data integration. This study's use of Prometheus for live data collection ensures greater adaptability and real-world applicability, particularly under dynamic conditions. The seasonal workload prediction by Wiesi et al. [19], which used GRU and LSTM models, also does not address abrupt workload changes, further highlighting the Random Forest model's robustness in handling dynamic scenarios.

This study also represents a significant improvement over our previous research. In the earlier work, simpler modeling techniques and less dynamic monitoring systems were used, leading to a MAPE of 11% for CPU utilization predictions. By incorporating real-time monitoring tools, such as Prometheus and Grafana, alongside advanced predictive modeling with Random Forest, this study reduced the MAPE to 2.65%. This fourfold improvement in predictive accuracy reflects the effectiveness of the enhanced framework in addressing the limitations identified in the earlier study. The integration of real-time monitoring and advanced ensemble learning has enabled the system to capture more complex resource utilization patterns, offering a more reliable and adaptive solution for VM optimization.

The observed differences between the two models provide critical insights. The Random Forest model's ensemble approach, which aggregates predictions from multiple decision trees, allows it to effectively balance accuracy and generalization. This characteristic is particularly advantageous in resource optimization scenarios where precision is vital. On the other hand, the LSTM model, while less accurate, has potential for scalability and adaptability in handling larger datasets or real-time applications if further refined. Its performance limitations in this study emphasize the need for hybrid modeling approaches that combine statistical methods and neural networks to enhance predictive accuracy.

The findings have significant implications for real-world applications. The superior performance of the Random Forest model makes it a reliable choice for real-time resource optimization in cloud computing environments, where accurate predictions are essential for cost efficiency and service quality. However, the LSTM model's potential scalability and adaptability warrant further exploration, particularly in scenarios with high variability and evolving workloads.

Despite its advantages, this study has certain limitations. The accuracy of the predictive model relies on the quality and consistency of real-time monitoring data. Variations in cloud workload patterns may also introduce unexpected challenges, potentially affecting resource allocation precision.

This study highlights the importance of selecting appropriate modeling techniques for resource prediction in cloud environments. By demonstrating the strengths of ensemble learning and identifying the limitations of deep learning in this context, the research provides a foundation for future work. Subsequent studies could explore the integration of hybrid models or the application of advanced deep learning architectures to improve predictive performance. Furthermore, real-world deployment of these models in diverse cloud infrastructures will validate their practical utility and scalability, contributing to more efficient resource management and optimization.

V. Conclusion

This research presents a comprehensive framework for optimizing VM performance within cloud computing environments by integrating advanced machine learning methodologies and real-time monitoring tools. The study highlights the exceptional efficacy of the Random Forest Regression model, which achieved a MAPE of 2.65%, significantly outperforming the LSTM model. This reduction in prediction error underscores the model's ability to enable precise resource allocation, leading to substantial improvements in system performance, operational efficiency, and cost-effectiveness.

Compared to traditional approaches and prior studies, this framework represents a critical advancement in cloud resource management. The integration of real-time monitoring tools, such as Prometheus and Grafana, combined with advanced predictive analytics, enables dynamic adaptability to workload changes and more efficient resource utilization. By addressing key limitations of earlier research, such as reliance on less adaptive systems or single-method approaches, this study establishes a new benchmark for VM optimization, particularly by demonstrating the robustness of ensemble learning techniques like Random Forest in handling complex and dynamic resource utilization patterns.

While this research demonstrates significant progress, future work could explore the integration of the Random Forest model into a hybrid framework, building upon the strengths of ensemble learning and deep learning. Such an approach could leverage the Random Forest model's robust accuracy alongside LSTM's ability to handle sequential patterns, creating a scalable and adaptive solution for even more complex cloud environments. Additionally, extending the framework to incorporate metrics like energy consumption and applying it across multi-cloud environments would further enhance its utility and relevance. Real-world deployment and validation in diverse cloud infrastructures will be essential for solidifying its practical impact and scalability. In conclusion, the proposed framework offers a versatile and practical solution for addressing the challenges of modern cloud computing environments, paving the way for more efficient and sustainable cloud operations.

Traffic Safety in Mixed Environments by Predicting Lane Merging and Adaptive Control

Aigerim Amantay, Shyryn Akan, Nurlybek Kenes, Amandyk Kartbayev
School of Information Technology and Engineering, Kazakh-British Technical University, Almaty, Kazakhstan

***Abstract*—Autonomous driving technology is primarily developed to enhance traffic safety through advancements in motion prediction and adaptive control mechanisms. Highway lane merging remains a high-risk scenario, accounting for approximately 7% of highway collisions globally due to misjudged vehicle interactions, according to international statistics. This paper proposes a two-stage deep learning framework for autonomous lane merging in mixed traffic. Using the Argoverse dataset, which contains over 300,000 vehicle trajectories mapped to high-definition road networks, we first predict vehicle trajectories using a Seq2Seq model with LSTM layers, achieving a 21% improvement in prediction accuracy over a baseline Multi-layer Perceptron model. In the second stage, reinforcement learning is employed for maneuver generation, where a Dueling Deep Q-Network outperforms a standard DQN by 8% in collision avoidance. Experimental results indicate that the combined trajectory prediction and RL-based framework significantly reduces merging delays, enhances data-driven decision-making in mixed traffic environments, and provides a scalable solution for safer autonomous highway merging.**

***Keywords*—Autonomous driving; lane merging; traffic safety; trajectory prediction; deep learning; LiDAR; LSTM**

I. Introduction

The rise of artificial intelligence (AI) has transformed various industries, with machine learning and deep learning playing an increasingly significant role in automating complex tasks. In the automotive sector, AI-driven technologies have enabled the development of semi-autonomous vehicles equipped with features such as adaptive cruise control, lane-keeping assistance, automated parking, and collision avoidance systems. While these advancements have improved driving safety and convenience, fully autonomous driving remains a formidable challenge due to the unpredictability of human behavior, dynamic traffic conditions, and infrastructure limitations. One particularly complex and accident-prone scenario that requires further refinement in autonomous driving systems is highway lane merging.

Merging from on-ramps onto high-speed highways presents unique difficulties due to the necessity of balancing speed, gap selection, and interaction with human-driven vehicles. Unlike controlled environments such as intersections with traffic lights, highway merging involves continuous decision-making in real-time, with vehicles needing to adapt to fast-changing conditions. Poor merging decisions can lead to sudden braking, abrupt lane changes, or even multi-vehicle collisions. Statistics indicate that lane-changing and merging maneuvers account for a significant portion of highway accidents, often due to misjudgment of vehicle speeds, miscommunication between drivers, and insufficient gap acceptance. Traditional rule-based autonomous driving systems, which rely on pre-set rules and simple heuristics, struggle to handle the complexity of these situations. The limitations of such approaches necessitate more sophisticated decision-making models.

Trajectory prediction is a crucial component of autonomous driving safety, enabling vehicles to make informed decisions. Traditional approaches have relied on kinematic and physics-based models, which assume that vehicle movement follows deterministic patterns. However, such models fail to capture the stochastic nature of real-world traffic, particularly in scenarios where multiple agents influence each other's actions. In recent years, interaction-aware models have gained traction, leveraging deep learning techniques to encode spatial and temporal dependencies in vehicle behavior. Studies such as those by Zhang et al. [1] and Karle et al. [2] have demonstrated that attention-based trajectory prediction models can significantly improve inference time and prediction accuracy by focusing on relevant surrounding vehicles.

Despite these advances, several challenges remain. Imbalanced trajectory datasets, where lane-keeping data vastly outnumbers lane-changing instances, hinder model training and may lead to poor generalization in merging scenarios. Additionally, most existing models rely solely on position data, neglecting critical information such as vehicle velocity, acceleration patterns, and road geometry. While deep learning-based models can enhance trajectory prediction, they do not directly translate into maneuver execution, requiring additional mechanisms to translate predictions into safe context-aware driving actions.

To address these challenges, this paper proposes a two-stage approach to highway merging automation. In the first stage, we leverage real-world LiDAR data to train a deep learning-based trajectory prediction model capable of capturing vehicle interactions. The baseline model employs a Multi-layer Perceptron (MLP) to establish feasibility, which is later extended to a Seq2Seq model with Long Short-Term Memory (LSTM) layers to improve prediction precision. The second stage integrates deep reinforcement learning (RL) to optimize autonomous vehicle maneuvers. By training RL agents on predicted trajectory data, the system learns to make adaptive decisions that balance safety and traffic flow continuity.

A key hypothesis of this study is that by combining sequence-based trajectory prediction with reinforcement learning, an autonomous vehicles (AVs) can anticipate and react to merging scenarios more effectively than conventional

rule-based systems. The hypothesis is based on the premise that motion forecasting alone is insufficient—vehicles must also be able to evaluate merging feasibility and adjust their actions accordingly. This research aims to improve merging efficiency by ensuring that AVs merge at appropriate speeds, and minimize disruptions to surrounding traffic.

The implications of this work extend beyond highway merging. As AVs gradually transition from human-supervised automation (Level 3 autonomy) to full self-driving (Level 5 autonomy), complex interactions with human drivers will remain a challenge. AVs must not only predict future vehicle positions but also infer driver intent and adapt to cooperative or adversarial driving behaviors. Ensuring safe interactions between autonomous and human-driven vehicles is critical for gaining regulatory approval for autonomous solutions.

Additionally, while reinforcement learning has demonstrated promise in driving applications, challenges such as sample efficiency, reward design, and real-world generalization remain significant barriers. Unlike games and simulations where RL agents can train for millions of iterations in a controlled environment, real-world driving data is limited, and deploying untested policies on public roads carries risks. To mitigate these concerns, simulated environments and digital twin systems can be leveraged to refine RL policies before real-world testing.

Another concern is computational feasibility. Training deep learning models on large-scale trajectory datasets is resource-intensive, often requiring high-performance GPUs and extensive tuning of hyperparameters. Computational constraints limit the ability to explore more complex architectures, such as Transformer-based motion prediction models, which may offer further improvements in prediction accuracy. Additionally, deploying computationally expensive models in real-time AV systems presents challenges, as in-vehicle processors must balance inference speed with energy efficiency.

This study addresses these concerns by proposing an adaptable framework that integrates deep learning techniques for trajectory prediction and optimization strategies for maneuver execution. The findings contribute to existing research by evaluating how Seq2Seq models and reinforcement learning can be combined to improve lane merging performance, reduce collision risks, and ensure smoother highway traffic integration.

The remainder of this paper is structured as follows: Section II reviews related works on trajectory prediction in autonomous vehicles. Section III details the methodology, including dataset preprocessing, the Seq2Seq model, and reinforcement learning integration. Section IV presents experimental results comparing the performance of models like MLP, Seq2Seq, and Dueling DQN. Section V discusses findings, addressing challenges and limitations. Section VI concludes with a summary and future research directions.

II. Related Works

A. Interaction-Aware Trajectory Prediction

In the field of autonomous driving, trajectory prediction is a critical component for ensuring vehicle safety and efficiency. Many studies have focused on interaction-aware approaches to improve prediction accuracy by accounting for the behaviors and intentions of surrounding vehicles. Notably, recent advancements leverage attention-based models, recurrent neural networks, and graph-based architectures to model interactions and improve trajectory accuracy in diverse traffic conditions. For instance, Yan et al. [3] applied spatial-attention mechanisms to handle inter-vehicular interactions, achieving accurate predictions on the HD dataset with minimal computational resources.

Many researchers have proposed intention-driven models that differentiate between short- and long-term intentions for more explicable trajectory predictions [4]. The study in [5] emphasized road constraints in prediction by developing a road-aware model that uses high-definition maps, demonstrating improved data efficiency and realism in trajectory prediction. In addition to model-specific developments, surveys by study [6] outline the evolution of trajectory prediction methods, highlighting physics-based, machine learning, and deep learning approaches. The research in [7] introduced a neural network-based motion planner integrated with model predictive control, balancing conservative planning with interaction-based optimization.

B. On-Demand Approach for Trajectory Prediction

A graph and recurrent neural network (GNN-RNN) based framework has been proposed to capture inter-vehicular interactions on highways using historical vehicle data for future path prediction. This model utilizes directed graphs to represent dynamic traffic interactions and demonstrates the capability to predict multi-vehicle trajectories for high-density traffic environments [8]. Similarly, an attention-based approach enhances trajectory prediction by focusing on the significance of neighboring vehicles through a multi-layer attention mechanism. The model incorporates both local and global attention components, enabling consideration of diverse driving goals and improving accuracy, especially in long-range highway scenarios [9].

An on-demand model for rapid vehicle path prediction with minimal observation windows has also been explored. This method probabilistically extends traditional car-following models, adapting to new traffic configurations with limited input data and improving reaction times for autonomous vehicles [10]. Further developments include multi-attention mechanisms for both spatial and temporal interactions. For instance, a Transformer-based architecture predicts multimodal vehicle trajectories by accommodating complex interaction patterns [11]-[12]. Another attention-based approach focuses on interaction regions and adapts predictions based on the relative positions of surrounding vehicles [13].

Graph-based deep learning frameworks have been integrated with trajectory prediction models to enable proactive longitudinal control. By combining LSTM networks with graph convolutional networks, this method predicts lane-aware behavior and captures inter-vehicle interactions, improving prediction accuracy and passenger ride quality [14]. Additionally, a structural-LSTM network assigns individual

LSTM networks to each vehicle, allowing real-time spatial information exchange. This architecture models fine-grained interactions effectively, enhancing predictive accuracy in mixed-traffic environments [15].

C. Driving Dynamics and Computational Efficiency

To address real-world challenges, one study emphasizes aligning predictive models with real driving dynamics and computational efficiency. The research critiques dataset-based evaluations and advocates for a task-driven approach that reflects the model's impact on downstream driving behavior, highlighting the interaction between autonomous vehicles and other road users as critical to trajectory model accuracy [16].

In their study, [17] presented a novel trajectory prediction framework designed to improve the reliability of autonomous driving systems. The key contribution of their work lies in the introduction of an awareness module that dynamically evaluates the performance of the trajectory prediction model during operation. This self-assessment capability enables the system to identify and respond to potential prediction inaccuracies. An intention-aware transformer model has been developed to adapt to social and temporal learning requirements in trajectory prediction. Using a multi-head self-attention mechanism, this model captures intricate social dependencies and driving behaviors across timestamps, improving its ability to manage complex driving scenarios [18]-[19]. Similarly, contextual cues, such as actor-actor and actor-scene interactions, have been incorporated into prediction frameworks. Attention-based graph modules and convolutional networks integrate spatial-temporal data, enhancing reliability in mixed-traffic conditions [20]-[21].

AVs must excel at predicting future events, a capability human drivers perform instinctively. Imagine an AV preparing to turn right at an intersection while a pedestrian approaches from the crosswalk on the right and another vehicle waits to proceed from the opposite direction. For the AV to navigate this scenario safely, it must anticipate whether the pedestrian will stop or continue crossing and whether the opposing vehicle will yield or attempt to proceed simultaneously.

This complex interplay of actions is central to motion prediction, enabling AVs to understand their surroundings and make proactive decisions. Sensors like gyroscopes, cameras, and etc. provide the necessary environmental data to inform these predictions. While rule-based systems have traditionally been used for such tasks, they falter under uncertainty and complexity, especially as the number of interacting agents increases. A data-driven approach using supervised machine learning offers a more scalable solution [22].

By tracking the movements of nearby objects over a 5-second horizon using their previous 1-second trajectories, AVs can transform motion prediction, planning, and simulation into data-centric problems [23]. Furthermore, the model must be versatile enough to handle scenarios, such as intersections, congested urban streets, and highways. The choice of neural network architecture is pretty obvious to achieve a balance between prediction speed and adaptability. Despite advancements in trajectory prediction and motion planning, the reviewed studies still have several challenges that remain unaddressed. Addressing these gaps requires hybrid applied approaches that combine behavior modeling and uncertainty quantification, as demonstrated in our research.

III. Methodology

A. Dataset

The Argoverse dataset [24] is a publicly available resource designed to advance research in autonomous driving by providing diverse real-world data for perception, trajectory forecasting, and motion planning. Collected from vehicles equipped with high-resolution LiDAR sensors, multiple RGB cameras, and detailed high-definition maps, the dataset enables a broad range of self-driving tasks. It comprises over 300k trajectories from more than 1,000 hours of driving, encompassing urban and suburban scenarios.

The dataset includes two key components: the 3D Tracking Dataset, focused on object detection and tracking, and the Motion Forecasting Dataset, aimed at predicting the future trajectories of vehicles and other traffic participants. With detailed annotations for traffic participants and trajectory data, along with HD maps containing lane geometry and traffic controls, the dataset facilitates accurate motion planning and interaction modeling. Its temporal sequences and multimodal data structure allow for advanced applications such as trajectory prediction, behavior forecasting, and real-time motion planning. As a well-annotated dataset among others, as shown in Fig. 1, Argoverse provides benchmarks for evaluating models, making it a best choice for developing interaction-aware systems in complex traffic environments.

	TIMESTAMP	TRACK_ID	OBJECT_TYPE	X	Y	CITY_NAME
0	3.159682e+08	00000000-0000-0000-0000-000000000000	AV	419.354578	1125.928065	MIA
1	3.159682e+08	00000000-0000-0000-0000-000000023470	OTHERS	404.729217	1253.006591	MIA
2	3.159682e+08	00000000-0000-0000-0000-000000023463	OTHERS	491.967704	1147.286581	MIA
3	3.159682e+08	00000000-0000-0000-0000-000000023476	OTHERS	473.827482	1146.672473	MIA
4	3.159682e+08	00000000-0000-0000-0000-000000023478	OTHERS	419.641337	1252.034538	MIA

Fig. 1. A sample of raw dataset.

To match the data's quality for subsequent modeling tasks, we began by extracting all x-y coordinate data associated with each timestamp and then organized the data by vehicle type to account for behavioral differences among various traffic participants. The coordinates were normalized to the range 0 to 1, representing their relative position to the data-collection vehicle. This normalization step ensures scale invariance and allows for consistent interpretation of spatial relationships. To maintain numerical precision, we retained up to six decimal places during this transformation.

The processed data was then split into five second intervals for each vehicle trajectory, reflecting the temporal progression of the observed environment. Each interval was further divided into two parts: the first three seconds served as training data, capturing historical movements, while the final seconds were used for testing, simulating future trajectory prediction. To improve the reliability of the input data, we filtered out incomplete trajectories. Specifically, any vehicle missing sufficient information defined as fewer than 51 rows of data, equivalent to 4 and 5+ seconds at a 5-10Hz sampling rate was excluded. This careful filtering process minimized signal noise and inconsistencies, ensuring that only reasonable data

informed the training and testing stages (see details in Table I). This pipeline is the foundation for next stages of the trajectory prediction model.

TABLE I. OVERVIEW OF THE DATASET

Field	Argoverse dataset	
	Description	***Most Frequent Value***
TIMESTAMP	Timestamp of the recorded data point	3.16E+08
TRACK_ID	Unique identifier for each tracked vehicle	00000000-0000-0000-0000-000000000000
OBJECT_TYPE	Type of object (e.g., 'AV' for autonomous vehicle, 'OTHERS' for surrounding vehicles)	OTHERS
X	Longitudinal position of the vehicle	402.8939
Y	Lateral position of the vehicle	1253.103
CITY_NAME	City where the data was collected	MIA

In addition to position coordinates (X, Y), velocity components (Vx, Vy) were derived from consecutive position differences over time. The acceleration components were further computed to capture variations in vehicle speed and potential braking or acceleration events. This allowed the model to distinguish between stable lane-following behavior and unexpected maneuvers, such as lane changes or emergency stops. These computed features were normalized within a [0, 1] range to ensure numerical stability during training.

Another crucial aspect was categorical encoding of object types. Since the dataset includes both AVs and surrounding human-driven vehicles (OTHERS), a one-hot encoding scheme was applied to differentiate between the two. This distinction was necessary because human drivers exhibit complex behavior, requiring adaptive mechanisms that consider their almost unpredictable decisions.

The city identifier (CITY_NAME) provided contextual information regarding the driving environment. Data collected from MIA (Miami) was analyzed separately to identify any city-specific driving patterns, such as differences in traffic density, intersection layouts, or lane configurations. While the dataset predominantly focuses on highway scenarios, environmental factors such as road curvature, lane widths, and merging configurations were later incorporated as additional inputs in the models.

To account for lane-aware trajectory dependencies, road geometry data from the high-definition map layers of the Lyft Level 5 dataset [25] was extracted for augmentation. This data included lane centerlines, traffic sign positions, and speed limits, enabling trajectory predictions that align with road constraints rather than purely data-driven extrapolations.

The processed dataset was divided into training (70%), validation (20%), and test (10%) subsets. Given the temporal nature of the data, a sliding window approach was implemented to segment continuous vehicle trajectories into overlapping time frames of 5-second windows.

B. Mathematical Model

The goal is to predict the trajectory of a target vehicle

$$\mathbf{\Theta}_\tau = \left[\boldsymbol{\theta}_\tau^{N_h+1}, \dots, \boldsymbol{\theta}_\tau^{N_h+N_f}\right] \quad (1)$$

where $\boldsymbol{\theta}_\tau^t = [\chi_\tau^t, \psi_\tau^t]$ denotes its longitudinal and lateral positions over the future $T_f = 4$ s ($N_f = 24$ time steps). The input consists of historical observations over $T_h = 3$ s ($N_h = 18$ time steps) for the target and nine surrounding vehicles, represented as,

$$\xi_t^i = \left[\chi_t^i, \psi_t^i, v_{\chi,t}^i, v_{\psi,t}^i\right], \quad (2)$$

where (χ, ψ) are the positions and (v_χ, v_ψ) the velocities. To focus on relative dynamics, the state of each surrounding vehicle is expressed relative to the target as $\Delta\xi_t^i = \xi_t^i - \xi_t^\tau$. The complete input sequence is $\mathbf{\Delta\Xi} = [\Delta\xi^1, \xi^\tau, \dots, \Delta\xi^9]$.

An encoder-decoder framework with LSTM is used to capture temporal dependencies. The encoder processes $\mathbf{\Delta\Xi}$ to produce hidden states $\mathbf{h}_t$ for $t = 1, \dots, N_h$, with $\mathbf{h}_{N_h}$ serving as the context vector $\mathbf{C}$. The decoder predicts the future trajectory step-by-step, using the context vector, the hidden state s_t, and the previous output $\boldsymbol{\theta}_\tau^{t-1}$. The prediction is given by

$$\boldsymbol{\theta}_\tau^t = f_{\text{dec}}(s_t, \mathbf{C}) \quad (3)$$

To address sequence representation limitations, we employ two attention mechanisms. Context-aware attention reweights $\mathbf{C} = \mathbf{h}_{N_h}$ by assigning importance α_t^j to its elements, forming

$$\mathbf{C}_t = [\alpha_t^1 \cdot h_{N_h}^1, \dots, \alpha_t^k \cdot h_{N_h}^k] \quad (4)$$

Lane-aware attention divides the surrounding vehicles into four groups (current, left, and right lanes, behind), producing context vectors $\mathbf{C}_1, \mathbf{C}_2, \mathbf{C}_3, \mathbf{C}_4$. The final context vector is,

$$\mathbf{C}_t = \beta_t^1 \cdot \mathbf{C}_1 + \beta_t^2 \cdot \mathbf{C}_2 + \beta_t^3 \cdot \mathbf{C}_3 + \beta_t^4 \cdot \boldsymbol{C}_4 \quad (5)$$

where β_t^i reflects each lane's relevance. The model is trained using mean squared error:

$$\mathcal{L} = \frac{1}{N_f} \sum_{t=N_h+1}^{N_h+N_f} \|\boldsymbol{\theta}_\tau^t - \Theta_\tau^t\|^2 \quad (6)$$

This approach integrates spatial and temporal dependencies, enabling interpretable trajectory prediction, as shown in Fig. 2.

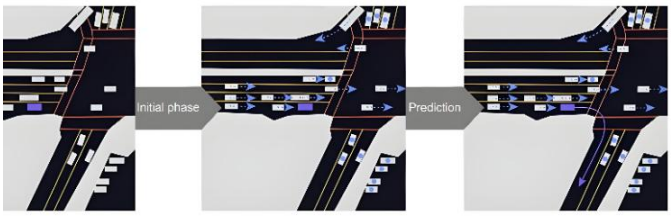

Fig. 2. The trajectory prediction process in a highway merging scenario.

C. Base Model

The baseline model selected for this study is a Multi-Layer Perceptron (MLP), a neural network architecture that uses back-propagation for training. The MLP serves as an initial framework to evaluate the dataset's viability. This model consists of one input layer, two hidden layers, and one output layer, utilizing the Rectified Linear Unit (ReLU) activation

function to ensure non-linearity. During training, the MLP baseline model was first tested to establish feasibility, followed by a Seq2Seq model with LSTM layers. The input to the model comprises 10 frames from the previous second, sampled at 0.1-second intervals, capturing both the agent's and the autonomous vehicle's positions. From these positions, the motion of the surrounding agents is derived and used to predict their trajectories over the next five seconds.

For further refining the predictions, we implement an ensemble approach using a stacking algorithm. Each individual model is trained separately on the data and later combined through additional neural network layers. This ensemble network effectively reduces generalization error and improves prediction accuracy. The approach also allows for trajectory visualization, particularly when incorporating labeled traffic signs into the predictions. The MLP model in this setup has 17k trainable parameters.

The predicted trajectory hypotheses are compared against the ground truth by modeling the likelihood under a mixture of Gaussians [26]. The mean values are set to the predicted trajectories, while the covariance is modeled using an identity matrix, enabling a probabilistic assessment of prediction accuracy. This approach ensures robust trajectory prediction and facilitates interpretable outputs in barely predictable traffic scenarios.

D. Seq2Seq-LSTM Model

To improve trajectory prediction beyond the baseline MLP, we adopted a Seq2Seq model, which as a type of encoder-decoder framework with LSTM layers, is well-suited for translating sequences of one domain into another with different lengths, such as time series positional data to future trajectories. In our case, the model processes 3 seconds (Nh=15 frames) of historical positional data and predicts the next 5 seconds (Nf=25 frames) of motion. The sequence length of 15 frames (for 3-5 seconds at 5 Hz sampling rate) was found to provide the best balance between predictive accuracy and computational efficiency.

The encoder LSTM compresses the input sequence into a latent state, discarding intermediate outputs, while the decoder LSTM uses this latent state to iteratively generate the future trajectory. A dense layer with ReLU activation ensures the output values remain normalized in the range [0,1]. Categorical cross-entropy is used as the loss function, and the model contains 4m trainable parameters.

For integration of the predicted trajectories with a reinforcement learning (RL) module, as shown in Fig. 3, we established positional and velocity mappings. Positional mapping adjusts the vehicle positions to align with a custom highway environment consisting of two main lanes and a merging lane over a 500-meter stretch, divided into four zones: pre-merged, convergence, merge, and post-merged (150m, 100m, 150m, and 100m zones). Vehicle positions (x, y) are transformed relative to the monitored vehicle, mapping lateral placement (x) to lane alignment and longitudinal placement (y) relative to the vehicle's merging zone location. Velocity mapping calculates initial and target velocities based on historical and predicted trajectory data, ensuring consistency with the simulated environment.

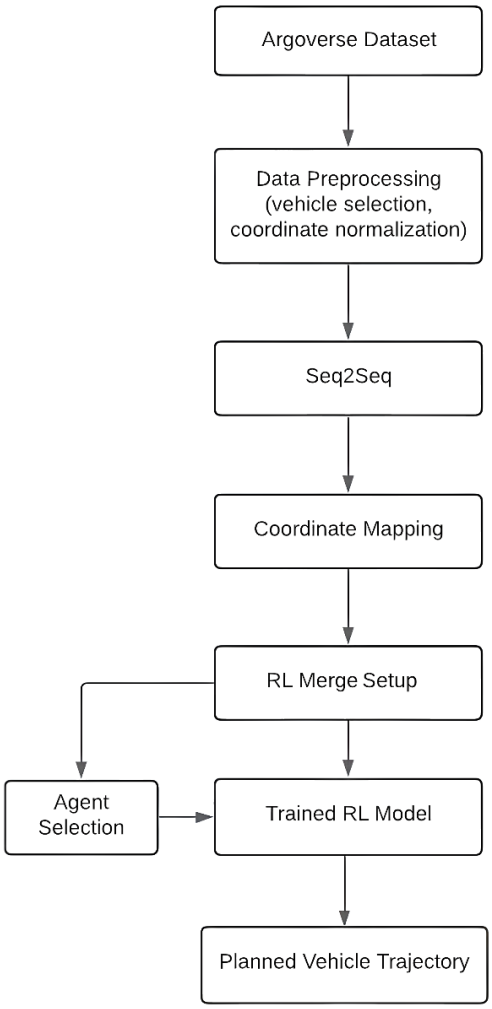

Fig. 3. The general design of the development process.

The RL simulates the merging process by defining six possible actions for the vehicle: maintaining, accelerating, or decelerating speed, either while staying in the current lane or changing lanes. The state space includes the positions (x), velocities (v), and orientations (θ) of all vehicles in the scene. A simplified reward function $\mathcal{R}$ is designed to optimize safe and efficient merging behavior by balancing key factors such as speed, lane preference, and collision avoidance:

$$\mathcal{R} = \lambda_c \cdot \delta_c + \lambda_l \cdot \delta_l + \lambda_s \cdot \delta_s, \quad (7)$$

where:

- $\lambda_c, \lambda_l, \lambda_s, \lambda_m$: tunable hyperparameters, where λ_c is a collision penalty weight, λ_1 - lane preference reward weight, λ_s - speed reward weight,
- δ_c : binary indicator (1 if a collision occurs, 0 otherwise),
- δ_l : binary indicator for being in the desired lane (1 if true, 0 otherwise),

- δ_s : normalized vehicle speed within the desired range.

To address the merging dynamics, an additional penalty is applied if the vehicle's speed deviates from the target speed:

$$\mathcal{R} += \lambda_m \cdot \left(v_\tau^{\text{target}} - v_\tau\right)^2, \quad (8)$$

where:

- λ_m : penalty weight for merging speed deviation,
- $v_\tau^{\text{target.}}$: target speed of the vehicle,
- v_T : current speed of the vehicle,
- $\mathcal{R}$: total reward received by the vehicle.

This RL combines Seq2Seq-based trajectory prediction with a reward mechanism that aligns with adaptability of the model.

IV. Results

A. Implementation of the Model

To address the computational challenges posed by the large dataset, we optimized the training configuration by limiting the number of epochs and batch size. While this approach ensured feasible GPU memory usage, it likely prevented further reduction of the loss function, which could be achieved with extended training iterations. All experiments were conducted using Google Colab with an Nvidia GPU, as the cards on local machines was insufficient for these tasks. Despite the hardware accelerator, training times for individual models varied significantly, often exceeding 11 hours. Models such as DenseNet, ResNet, and others were explored but could not fit within the VRAM limitation of the GPU.

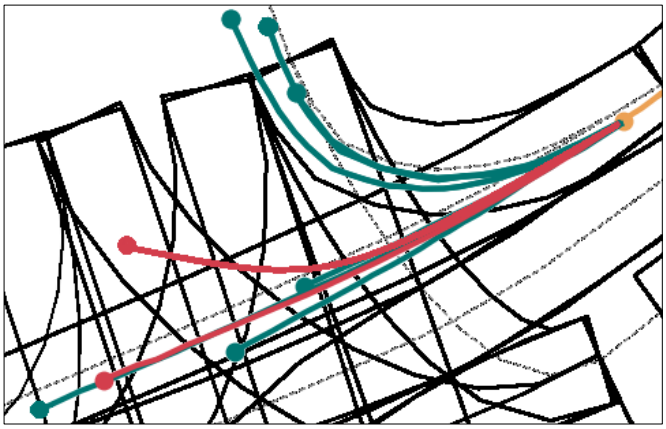

Fig. 4. The schematics of predicted trajectory for an AV.

The primary focus of the trajectory prediction task was on the Seq2Seq model. Training involved mapping historical positions and velocities to future trajectories, visualized using a rasterizer and trajectory drawing functions. For instance, Fig. 4 illustrates the ground truth and predicted trajectory for an AV within a specific map scene. Although the predicted trajectory does not fully align with the ground truth, it remains within the correct lane, demonstrating reasonable accuracy. Additional visualizations also included scenarios with traffic sign labels, where agents responded appropriately to signals—stopping at red lights and proceeding through green lights in the predicted frames.

For implementation, the dataset was preprocessed to load training data, train the model, and then test it on unseen scenes. The trained model generated predictions for both agents and AV trajectories. Using ensemble methods, we improved motion prediction through stacking algorithms, enabling comprehensive visualizations of entire scenes. In maneuver generation, performance comparisons were made across multiple RL agents. As we starting with a baseline MLP agent, we also evaluated the Deep Q-Network (DQN) and Dueling Deep Q-Network (DDQN) agents [27].

Results indicated improved trajectory prediction and decision-making in RL environments using advanced agents. The validation loss, consistently at or below the training loss suggested that the model achieved reliable training accuracy. These experiments shows the efficacy of the ensemble model and the integration of RL for trajectory planning. The visualizations provided insights into the model's accuracy in collision prediction. For example, in Fig. 5, surrounding vehicles exhibited consistent longitudinal motion with risky left side movement, except for one vehicle deviating slightly.

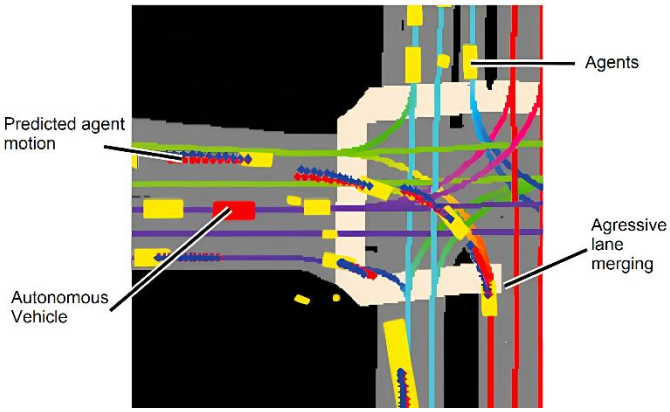

Fig. 5. The risky motion with substantial side movement.

B. Model Evaluation

The experiments begins with preprocessing the Argoverse Dataset, containing over 300k CSV files of vehicular positional data. A subset of 50k samples is selected for training. The data is normalized, and target outputs are quantized to six decimal places for precision. For training, the first 2 to 3 seconds of each 5-second sequence are fed into a Seq2Seq model, and the trained model is saved for inference as well. During inference, the model predicts positional trajectories for the next remained seconds. These predictions are mapped into initial position, initial and target velocity parameters, which serve as inputs to the RL environment.

However, discrepancies such as a significant gap between training and validation losses may require additional regularization techniques, such as dropout, L2 weight regularization, or early stopping. Incorporating domain-specific features like initial and target velocities into the trajectory prediction process, as well as mapping predictions into RL, enhances the practical utility of the model. Overall, a combination of balanced data, hyperparameter optimization,

and careful monitoring of loss metrics could significantly improve the model's accuracy in some complex scenarios [28].

For real-time applicability, inference speed was also analyzed. The Seq2Seq model achieved inference latency of approximately 9.2 milliseconds per trajectory prediction, making it feasible for integration into autonomous vehicle planning pipelines. However, more computationally intensive attention-based models were explored in subsequent experiments to improve prediction robustness while maintaining acceptable inference times.

As shown in Fig. 6 and Fig. 7, the training and validation losses for the Seq2Seq model remain consistently low, with validation loss equal to or slightly lower than training loss, indicating effective generalization in trajectory prediction for autonomous driving.

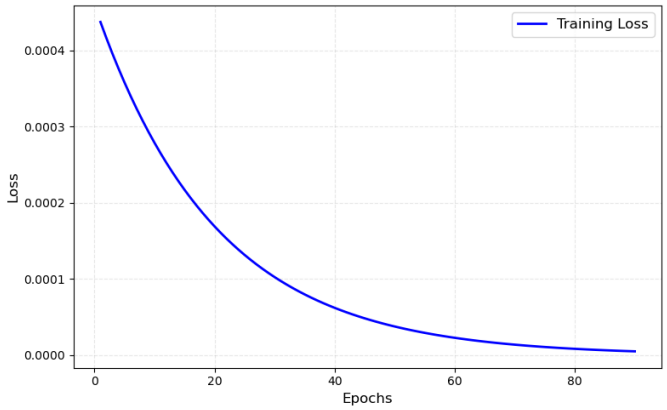

Fig. 6. Training loss metric for the model.

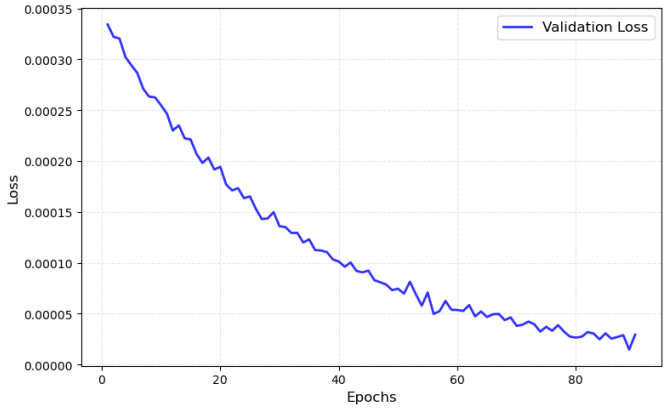

Fig. 7. Validation loss metric for the model.

In the testing phase, a separate 5-second dataset simulates sensory data typically acquired through LiDARs in real-world AV systems. Using this data, the trained Seq2Seq model predicts the positions of surrounding vehicles for the next 3 seconds. These predictions are again mapped into the RL environment, where the trained RL model generates optimized maneuver decisions for the vehicle with certain accuracy, as shown in Table II. We know that current setup increases the risk of overfitting, especially with noisy data, but hyperparameter tuning certainly can mitigate these risks. Gradient checkpointing was applied to reduce GPU memory consumption without significant trade-offs in convergence speed. As an experimental measure, early stopping was implemented to prevent overfitting, terminating training after 10 consecutive epochs without validation loss improvement.

TABLE II. ACCURACY SCORES FOR THE MODELS

Metric	*Baseline MLP*	*Seq2Seq*	*DQN*	*Dueling DQN*
Accuracy (%)	69.4000	83.1000	78.500	87.5000
MSE	0.0028	0.0014	0.002	0.0011
MAE	0.0440	0.0270	0.032	0.0220
R^2	0.6800	0.8300	0.790	0.8800

C. Simulation

The DQN enhances the classical Q-Learning algorithm by approximating the Q-function, defined as:

$$Q^*(s,a) = \mathbb{E}\left[t + \gamma \max_{a'} Q^*(s',a')\right] \quad (9)$$

where $Q^*(s,a)$ represents the maximum expected return starting from state s, taking action a, and following the optimal policy. The discount factor γ controls the importance of future rewards. Instead of storing $Q^*(s,a)$ for all state-action pairs, which is infeasible in large state spaces, DQN uses a neural network with parameters θ to approximate Q -values by minimizing the loss:

$$L_i(\theta_i) = \mathbb{E}_{s,a,r,s'}\left[\left(y_i - Q(s,a;\theta_i)\right)^2\right] \quad (10)$$

where the temporal difference target y_i is given by:

$$y_i = t + \gamma \max_{a'} Q(s',a';\theta_{i-1}) \quad (11)$$

Dueling DQN further refines this by splitting the network into two execution path: one estimating the state and the other estimating action-related advantages. These are combined in the final layer to produce the Q-value, improving performance in scenarios where distinguishing between actions is not immediately necessary. The combination of these two streams in the final layer, while effective for many scenarios, relies heavily on the assumption that the advantage function can be effectively separated from the state value function. In complex environments where actions and states are interdependent, this separation may lead to suboptimal policy learning, as the model might underestimate or overestimate the advantage of specific actions.

In simulation experiments, agents based on DQN and Dueling DQN were evaluated with varying discount factors (γ) over 1000 training epochs. Qualitative results show that dynamic reward settings lead to faster, riskier merges, while less dynamic result in cautious behavior (see Fig. 8 and Fig. 9). We could also explore the impact of reward structures on merging strategies. However, as noted in certain models, a drop in prediction accuracy implies that these algorithms often fail to truly understand the behavior of individual drivers.

While deep learning methods can capture correlations between vehicle trajectories, they may struggle with causal inference, leading to errors in scenarios where driver intent

significantly deviates from learned patterns. As a result, these models often generalize poorly in unpredictable scenarios, where one driver may aggressively accelerate into a merging lane while another might yield prematurely.

We assume, as Dueling DQN excels in scenarios where distinguishing between actions is less critical (e.g., when multiple actions lead to similar outcomes), it may struggle in some fine-grained decision-making cases, such as those involving continuous action spaces or rapid maneuvering. The architecture assumes that state-value estimation can guide the policy sufficiently when action advantages are less distinct, which might not hold true in edge cases requiring much precise action-value differentiation [29].

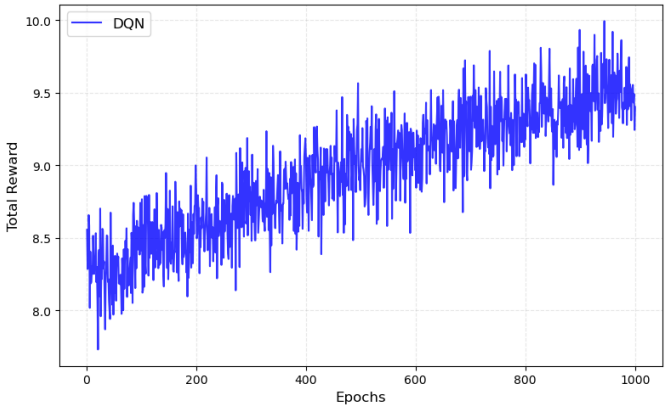

Fig. 8. Performance results of DQN agent.

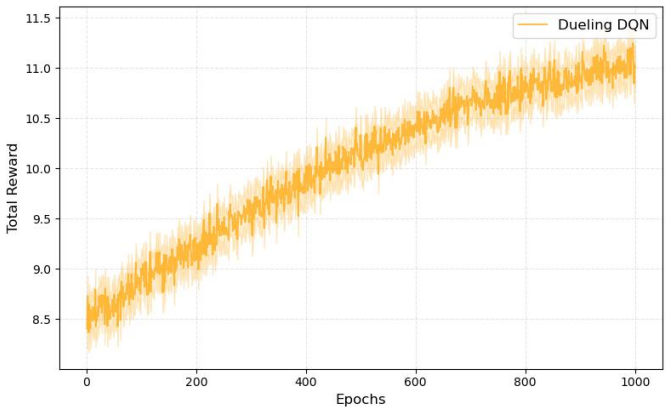

Fig. 9. Performance results of dueling DQN agent.

Nonlinear driver behaviors significantly influenced by sensor noise and capability of interpreting accidents, such as sudden braking or unexpected lane changes. For instance, human drivers exhibit a wide range of behaviors influenced by factors such as aggressiveness, reaction time, and external conditions (e.g., weather, road layout, or traffic density). Traditional deep learning models, such as RNNs or encoder-decoder architectures, may fail to distinguish between cautious and aggressive drivers, treating all vehicle trajectories as homogeneous. Results indicate that Dueling DQN outperformed standard DQN, particularly in collision-avoidance scenarios, as it accounts for delayed decisions when a collision is imminent, with the vehicle approaching to surrounding cars, as depicted in Fig. 10 and Fig. 11.

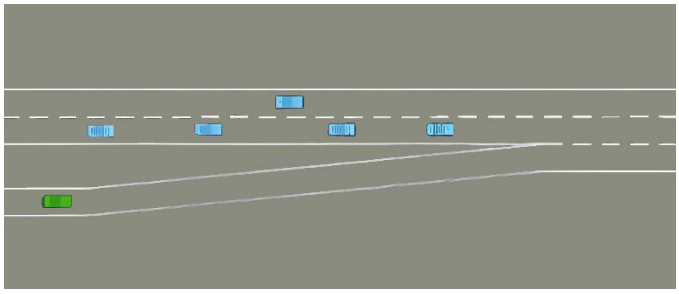

Fig. 10. Collision scenarios before merging.

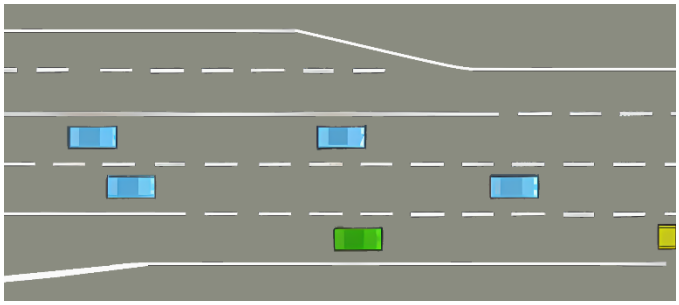

Fig. 11. The vehicle approaching to surrounding cars at the merging moment.

Prediction error generally increases with vehicle density, as shown in Fig. 12. This heatmap reflects the growing complexity of motion prediction in congested traffic, where interactions between multiple agents introduce uncertainty. Addressing this challenge requires enhanced contextual awareness to mitigate errors in high-density scenarios. Additionally, the need for uncertainty-aware models is evident, ensuring robustness across diverse urban environments and enhancing multi-agent interaction strategies, especially for likelihood of emergency maneuvers.

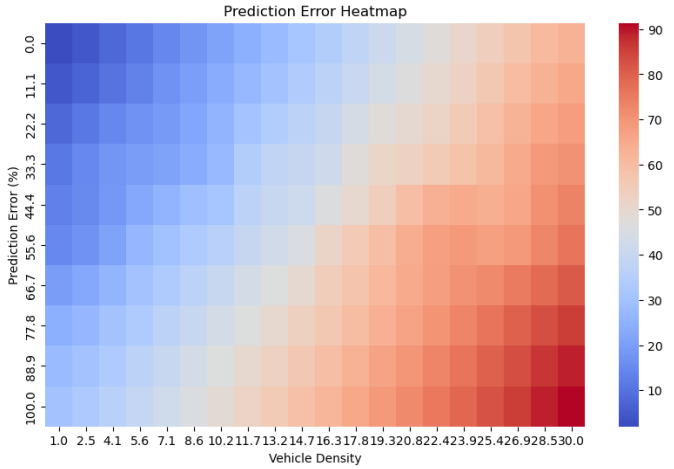

Fig. 12. The relationship between vehicle density and prediction error.

These inaccuracies become more pronounced in long-term predictions, where small errors in trajectory forecasts accumulate over time, resulting in substantial deviations from actual vehicle behavior. Given that AVs must make real-time decisions that depend on both immediate and extended motion forecasting, inconsistencies in predictions can disrupt maneuver planning, leading to suboptimal gap selection,

unnecessary braking, or unsafe merging. To mitigate these issues, a more robust approach is required that combines explicit driver behavior modeling with trajectory prediction. As demonstrated in our application (see Fig. 13), integrating behavior-aware prediction techniques improves the system's ability to anticipate diverse driving patterns, leading to more reliable and adaptive merging strategies.

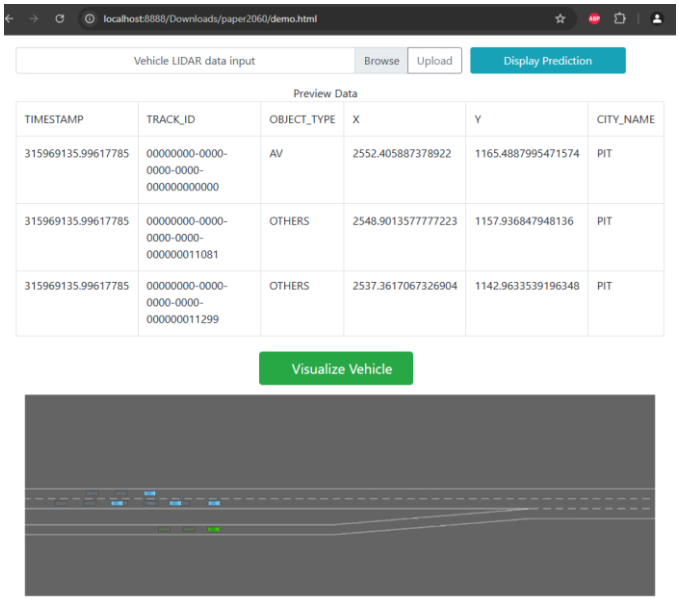

Fig. 13. Demo application for explicit driver behavior modeling.

The experimental results demonstrate several notable advancements in maneuver prediction:

- The removal of incomplete and inconsistent trajectories significantly enhanced prediction stability by decreasing noisy data.
- Incorporating velocity, acceleration, and road geometry features contributed to motion representation quality. The Seq2Seq model with LSTM layers outperformed baseline approaches.
- Optimized batch processing and gradient checkpointing effectively managed GPU memory constraints.
- The inference latency remained within operational thresholds of the model's applicability for real-time deployment.

V. Discussion

The experimental results reveal significant advancements in trajectory prediction and decision-making for AVs. However, these results also highlight key challenges that must be addressed to achieve full autonomy. The trajectories on highways, often categorized into lane-keeping and lane-changing, present distinct challenges due to their unbalanced data distribution. Lane-changing events are relatively rare compared to lane-keeping, leading to difficulties in model generalization. To mitigate this, we increased the penalty for lateral position errors by a factor of three while keeping the longitudinal penalty unchanged. This adjustment improved performance on lane-changing trajectories but further methods such as data augmentation and rebalancing may enhance outcomes.

Our Seq2Seq-based trajectory prediction framework performed reliably in predicting short-term trajectories. The low and stable training and validation losses (Fig. 6 and Fig. 7) indicate effective generalization, especially in scenarios where vehicle movements are smooth and continuous. However, when applied to long-term predictions, the model struggled to account for sudden changes influenced by dynamic factors like merging traffic, traffic signals, and unexpected obstacles. This suggests that while Seq2Seq excels in capturing immediate patterns, it may benefit from additional context for long-term predictions.

Existing studies, such as [30], use a similar encoder-decoder LSTM architecture but focus on fewer surrounding vehicles and rely solely on positional data. Our approach, incorporating both position and velocity information, provided richer dynamics. However, as our experiments show, more information does not always equate to better performance. For short-term predictions, focusing on vehicles immediately behind or adjacent to the target vehicle yielded more accurate results. For longer horizons, integrating data about road geometry, traffic density, and environmental signals could further enhance predictions.

The computational challenges of training on large datasets also posed limitations. Processing 300k files from the Argoverse dataset required significant resources, even after selecting a subset of 50k samples. Models were trained using an Nvidia GPU on Google Colab, as local GPUs lacked sufficient memory. Despite hardware acceleration, training times for Seq2Seq often exceeded tens of hours, and memory-intensive models could not be tested due to their high requirements. These constraints limited our ability to experiment with more complex models and hyperparameter configurations.

The RL module demonstrated promising results for maneuver generation. Starting with the baseline MLP, we evaluated DQN and Dueling DQN agents. The results showed that Dueling DQN consistently outperformed DQN in high-stakes scenarios such as collision avoidance. This can be attributed to Dueling DQN's ability to separate state-value and action-advantage estimations, allowing the model to prioritize critical decisions. As illustrated in Fig. 11, Dueling DQN achieved smoother merges under less aggressive reward settings and faster merges under more dynamic rewards.

Our experiments also highlight the importance of reward design in RL-based trajectory generation. Aggressive reward functions encouraged riskier behavior, with the vehicle accelerating into gaps during merges. Conversely, conservative rewards resulted in cautious behavior, where the vehicle yielded to surrounding vehicles before merging. These findings underscore the need for careful tuning of reward structures to balance safety and efficiency of the model.

Despite these advancements, our system has limitations when applied to urban environments. Highways typically exhibit predictable traffic patterns with fewer obstacles and interactions. Urban settings, by contrast, involve complex

intersections, pedestrian interactions, and diverse traffic actors that require models to generalize across a broader range of objects [31]. Extending our framework to handle such environments will require incorporating additional sensory inputs (e.g., pedestrian detections, stop signs) and more adaptive models capable of responding to unpredictable events [32].

Another limitation of our system lies in its scalability. The ensemble methods used for trajectory prediction and maneuver generation, while effective, are computationally expensive. Real-world deployment of such systems would require significant optimization to achieve real-time performance. Furthermore, our reliance on high-quality datasets like Argoverse means that the system may struggle in environments with less structured data or sensor inaccuracies, such as occlusions and noisy GPS signals.

The imbalance between lane-keeping and lane-changing trajectories also poses broader implications for AV development. While our increased penalties for lateral errors improved lane-changing predictions, the system may still fail in edge cases, such as rapid lane changes or merging under high traffic density. Addressing these scenarios will require not only better modeling but also real-world testing to understand how AVs interact with human drivers in such situations.

Lastly, achieving full autonomy involves challenges beyond technical performance. Ethical considerations, such as decision-making during unavoidable collisions, remain unresolved. Regulatory frameworks for AVs are still evolving, and infrastructure, such as high-definition mapping and vehicle-to-everything (V2X) communication, must be developed to support these systems [33]. As our experiments demonstrate, while trajectory prediction and RL-based planning offer promising solutions, achieving Level 5 autonomy will require a holistic approach that integrates technology, policy, and infrastructure.

A key area of improvement is the integration of multi-agent prediction models, which will enable AVs to better anticipate and respond to interactions in dense and heterogeneous traffic. Expanding RL to continuous action spaces will enable smoother, more natural driving behaviors. Uncertainty-aware trajectory prediction can improve robustness by integrating Bayesian deep learning and Monte Carlo dropout, allowing AVs to quantify uncertainty and adjust decisions dynamically.

A promising approach is hybrid models that integrate physics-based and deep learning techniques for dynamic adaptation. Real-world validation through diverse urban and highway testing, along with sensor fusion (LiDAR, radar, and cameras), will improve perception accuracy. Large-scale simulations and real-world trials will bridge the gap between theoretical performance and practical deployment, ensuring AVs operate with greater computational efficiency.

We suggest, this work demonstrates the feasibility of combining Seq2Seq trajectory prediction and reinforcement learning for autonomous driving. While the results are promising, achieving fully autonomous driving will require addressing significant gaps in model generalization, computational scalability, and adaptation to diverse environments. Ultimately, the path to full autonomy is not just a technological challenge but a multidimensional problem requiring collaboration across domains.

VI. Conclusion

This study presented a framework for trajectory prediction and maneuver generation in autonomous vehicles, combining Seq2Seq-based prediction models with reinforcement learning. The model effectively predicted short-term trajectories by mapping a few seconds of historical position and velocity data to the next seconds of future trajectories. The model demonstrated consistent performance, with validation losses equal to or slightly lower than training losses, suggesting good generalization within the dataset's constraints.

Reinforcement learning was employed to optimize maneuver decisions, with agents such as DQN and Dueling DQN evaluated. Dueling DQN exhibited superior performance in collision-avoidance scenarios due to its separation of state-value and action-advantage estimations, which allowed for better handling of scenarios requiring delayed decision-making. However, the performance of the RL agents was sensitive to reward function design, highlighting the importance of parameterizing rewards to balance safety and efficiency in varying scenarios.

Several limitations were observed. First, the imbalance in trajectory types, such as lane-keeping versus lane-changing, negatively impacted model accuracy despite efforts to mitigate this through weighted loss functions. Second, the computational constraints of training deep learning models on large datasets posed scalability challenges, particularly for real-time applications. Third, while the models performed well on structured datasets, the transition to real-world scenarios, involving dynamic interactions and noisy sensor data, remains an open challenge.

Future research should aim to overcome existing limitations by enhancing data balancing techniques, optimizing computational frameworks, and integrating models with real-world sensory inputs. Refining the underlying algorithms and addressing these challenges will contribute to more reliable trajectory prediction and maneuver planning. Extending the framework to urban driving environments, where traffic patterns are a way more complex, will require incorporating richer environmental features and more adaptive strategies.

***Abstract*—With the development of science and technology, industrial construction has entered the era of 4.0 intelligent construction, and various algorithms have been widely applied in the modularization of production products. This study focuses on the modular optimization problem of complex products and establishes a hybrid genetic algorithm based on the ant colony algorithm framework. The new algorithm incorporates visibility analysis of the genetic algorithm, using the obtained solution as the pheromone source for the new algorithm to quickly obtain the optimal solution. The results showed that the algorithm could quickly achieve modularization of complex industrial products, adapt to products with a large number of parts and complex compositions, and obtain the optimal solution. The new algorithm reduced the running time of modular complex products by 35.06% compared to the particle swarm optimization algorithm. The new algorithm optimized the product design process for core components, reducing production costs by 23.46% and increasing production efficiency by 39.20%. Consequently, the novel algorithm modularizes complex products, thereby enhancing production efficiency and providing a novel intelligent method for the design process of complex products.**

Keywords*—Industry 4.0; genetic algorithm; ant colony; complex products; modularization; production efficiency

I. Introduction

In recent years, technological advancements have made traditional manufacturing unable to meet the current society's production needs for complex products [1]. Industry 4.0 is not only an upgrade to traditional supply chain automation and monitoring, but also builds a highly interconnected ecosystem and intelligent driven products through deep integration of intelligent technology [2]. The core concept is to utilize advanced information and communication technology to promote the transformation of the manufacturing industry towards a more flexible, efficient, and personalized intelligent manufacturing model [3]. In this context, the hybrid Genetic Algorithm (GA) has become a powerful tool for solving multidimensional and nonlinear optimization problems in the design of Complex Products Modularization (CPM) due to its unique advantages of strong global search capability, flexible genetic mechanism, and compatibility [4]. The objective of modular design is to disaggregate complex products into a series of relatively autonomous and functionally distinct modules. Through the combination and reconstruction of diverse modules, the design process can rapidly adapt to market demands, enhancing design efficiency and product flexibility [5].

In response to the demand from various sectors of society for the construction of industrial responsibility products in the context of Industry 4.0, a large number of scholars have conducted extensive research on CPM. Li Y et al. proposed a CPM method that combines modularity and design change propagation scope to reduce the impact of design change propagation. This method constructed the adjacency matrix of a weighted directed network model and solved the model using non-dominated sorting GA. The results of verifying the modularity of the driver's cab of a specific electronic sanitation vehicle showed that this method was practical and effective [6]. Wang X et al. proposed a moderated mediation model to address the issue of product modularization in R&D outsourcing practices. Based on survey data from 273 Chinese manufacturing enterprises, hypotheses were tested using hierarchical regression and PROCESS macro-models. The role of product modularization in R&D outsourcing practice was more effective when the trust level of R&D outsourcing partners was high [7]. Wang S et al. proposed a sub-item method oriented towards core components to address the challenges of structural modeling difficulties and unreasonable modular solutions in CPM for complex product sub-item problems. The new method simplified the structural model of complex products, further reduced the difficulty of modeling, and improved the efficiency of solving module partitioning schemes [8]. Forti A W et al. proposed a new structural matrix modularization method to solve the problem of difficult integration of multi-component products in the automotive industry, which combines the use of quality function deployment and design attribute matrix indication matrix. This systematic modular process has effectively played a role, making cross-functional teamwork easier [9].

The application value of hybrid algorithms as an efficient optimization strategy in CPM design is becoming increasingly prominent. Zhao J et al. proposed a multi-ACA approach that combines community relationship networks to address the challenge of balancing solution accuracy and convergence speed in large-scale TSP for the Ant Colony Algorithm (ACA). It improved the accuracy of the solution by collecting the route information of all ants and constructing a route relationship network. The performance of the new algorithm in large-scale TSP was significantly better than other improved algorithms

[10]. Arasteh B et al. proposed a hybrid method based on a grey wolf optimization algorithm to solve the problems of poor CPM quality, low success rate, and limited stability in existing methods, to achieve sub-items of complex products. The new algorithm improved the clustering quality and outperformed other heuristic algorithms in terms of modularity and convergence speed [11]. Liu C et al. proposed an improved discrete imperialist competitive hybrid algorithm to address product design compatibility and quality issues, considering a nonlinear programming approach that maximizes the per capita contribution margin of reliability loss. This hybrid algorithm has improved the solution quality by 6%~17% and 5%~14% compared to GA and simulated annealing algorithms [12].

In summary, the combination of modularity and the scope of design change propagation effectively reduces the impact of design changes. The trust-based product modularization method has improved the modularization efficiency of R&D outsourcing. These methods provide multidimensional ideas for solving CPM. In terms of CPM, most algorithms have only implemented modularity, and there has not been much research on achieving high-efficiency production. Based on this, this study proposes a new hybrid genetic ACA. To adapt to the rapid modularization with fewer components, this study innovatively integrates operations such as mixing, crossover, and mutation into ACA to quickly obtain visibility. To better obtain the optimal solution, the genetic part of the solution is used as a pheromone to enable the ant colony to quickly obtain the optimal solution. Pheromones are chemical substances that are synthesized by ants in ACAs and serve to guide other ants in navigating their environment. The issue of information redundancy in multi-part problems has been addressed by the adoption of ant colony solving, which has supplanted genetic solving. This development has enabled the implementation of a novel algorithm capable of adapting to CPM in multi-part scenarios, thereby facilitating the enhancement of production efficiency for complex products. The article is divided into five sections in total. The first section introduces the research status and importance of CPM under the background of Industry 4.0. The second section elaborates on the framework of Hybrid Genetic Ant Colony Optimization (HGACO) algorithm and its application in CPM. The third section verifies the performance of HGACO algorithm through experiments and compares it with other algorithms for analysis. The fourth section discusses the article and provides personal insights and opinions. The fifth section summarizes the research conclusions and proposes future research directions.

II. METHODS

A. Establishment of Hybrid Genetic Ant Colony Algorithm

In the era of Industry 4.0, traditional design methods cannot meet modern needs. This study designs an innovative HGACO method based on the ACA framework. Through a unique encoding and decoding mechanism, HGACO optimizes the decomposition process of product components. Simplifying complex products will be beneficial for industrial production. GA solving product modularization problems requires the use of various genetic components on chromosomes. The dimensions of each component are represented by chromosome length, forming an initial group [13]. The size of the fitness function determines the quality of an individual. The fitness function is transformed from the objective minimum function, as shown in Eq. (1).

$$F(t) = \frac{1}{Q_m} \tag{1}$$

In Eq. (1), $F(t)$ is the fitness function. Q_m is the shortest path. The formula for selecting arithmetic factors using the turntable method is shown in Eq. (2).

$$F(t) = \begin{cases} f(t) - C_{\max}, f(t) > C_{\max} \\ 0, f(t) = C_{\max} \\ C_{\max} - f(t), f(t) < C_{\max} \end{cases} \tag{2}$$

In Eq. (2), $f(t)$ and $C_{\max}$ are the values and maximum values of the fitness function. The initial population uses a random method to generate multiple chromosomes. The size of chromosomes represents the size of a population. Genetic individuals are screened, and the selected excellent individuals are subjected to subsequent crossover mutations. The selection method adopts the turntable method, and the probability of being selected is determined by the ratio size of individuals, as shown in Eq. (3).

$$P_a = \frac{f_a}{\sum_{a=1}^{N_z} f_a} \tag{3}$$

In Eq. (3), P_a is the probability of being selected, N_z is the individual fitness value, and $\sum_{a=1}^{N_z} f_a$ is the population fitness value. The selected excellent individuals are subjected to crossover operations to generate new offspring individuals. The crossover probability is shown in Eq. (4).

$$P_b = \begin{cases} \dfrac{\alpha(f_d - f_b^d)}{f_d - f_p}, f_b^d \geq f_p \\ \beta, f_b^d < f_p \end{cases} \tag{4}$$

In Eq. (4), P_b is the crossover probability. f_d and f_p are the maximum and average fitness values of the population. f_b^d is the party with a higher fitness value participating in the crossover process. α and β are constants. After selection and crossover, to enhance the comprehensive performance of the algorithm's retrieval ability, mutation is also required. The mutation probability is shown in Eq. (5).

$$P_c = \begin{cases} \dfrac{\gamma(f_d - f_b)}{f_d - f_p}, f_b \geq f_p \\ \lambda, f_b < f_p \end{cases} \tag{5}$$

In Eq. (5), P_c is the mutation probability, f_b is the fitness value of the mutated individual, and γ and λ are constants. The calculation process of GA is shown in Fig. 1.

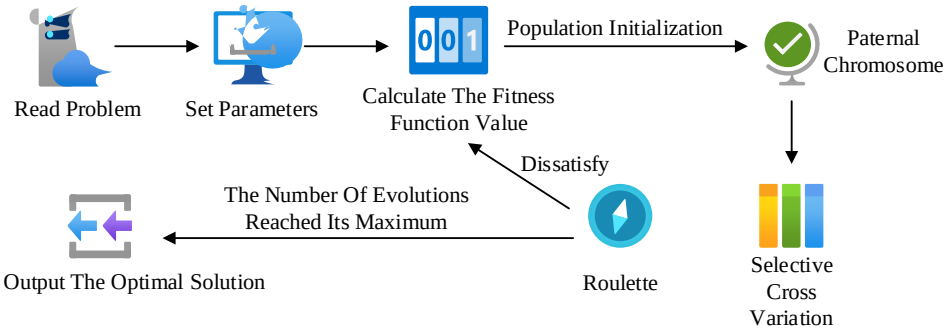

Fig. 1. Ga solution flow chart.

In Fig. 1, in the overall process of GA solving, step 1 is to read the problem being solved and set the corresponding parameters. Step 2 is to set the fitness function to calculate the fitness value, and initialize the population to produce parental chromosome individuals. The next step is to operate on individuals based on the selection, crossover, and mutation probability formulas, using the turntable method to select the transformed individuals. If the individual has reached the maximum number of evolutions, the solution value is directly output, otherwise it returns to the mutation step. GA is integrated into ACA, which is an exploratory algorithm with features of group cooperation, simultaneous computation, and forward selection. Each ant moves according to a fixed rule [14]. The number of ants is shown in Eq. (6).

$$N = \sum_{a=1}^{n} M_a(t) \tag{6}$$

In Eq. (6), N is the number of ants. $M_a(t)$ is the number of ants at time t. The information of each path of ants during the transfer process varies, and the probability calculation method of ant movement is shown in Eq. (7).

$$P_{ab}^{x} = \begin{cases} \dfrac{\tau_{ab}^{p}\eta_{ab}^{q}}{\sum_{S \in xl_x} \tau_{as}^{p}\eta_{as}^{q}}, b \in xl_x \\ 0, b \notin xl_x \end{cases} \tag{7}$$

In Eq. (7), P_{ab}^{x} is the probability that ant x moves from point t to point b at time a. τ_{ab}^{p} is the number of pheromones from point a to point b under the information heuristic factor p. η_{ab}^{q} is the visibility from point a to point b. xl_x is a point that ants have not passed through. After the ant completes a path selection, the pheromones on other paths are shown in Eq. (8) [15].

$$\tau_{ab}t = \varphi \cdot \tau_{ab}t + \Delta\tau_{ab}t \tag{8}$$

In Eq. (8), $\tau_{ab}t$ is the number of pheromones from point a to point b after the t-th cycle. φ is the residual coefficient of pheromones. $\Delta\tau_{ab}t$ is the residual value of pheromones. The pheromone changes of Ant x from point a to point b during a path iteration are shown in Eq. (9).

$$\Delta\tau_{ab}^{x} = \begin{cases} \dfrac{k}{H(C)}, x \text{ participation loop} \\ 0, \text{else} \end{cases} \tag{9}$$

In Eq. (9), $\Delta\tau_{ab}^{x}$ is the pheromone change of ant x from point a to point b in one path iteration. k is the intensity of pheromones. $H(C)$ is the sum of ant journeys after multiple iterations. Fig. 2 shows the calculation process of ACO.

In Fig. 2, the system first initializes the data by randomly placing ants at various points and then begins the loop. According to the formula for calculating the probability of ant movement, the ants are moved. The points that ants pass through are marked. The ant colony cycle model is used to determine whether ants have passed through all points. If they have not passed through all points, the number of cycles is increased by 1. If the ant passes through all points, the pheromone is updated according to the pheromone calculation formula. If the calculated path is the shortest path, the path is updated; otherwise, the ant is asked to select a new point and output the shortest path. ACA lacks pheromones in the early stage, so the process of searching for the optimal solution is relatively slow. GA has high adaptability and fast running speed, but it is prone to generating redundant junk information. By integrating two algorithms, GA can solve the problem of the slow operation of ACA in the early stage. In the later stage, the accumulation of pheromones in ACA reaches a certain level, which increases the running speed and avoids the situation where GA continues to run and generate a large amount of junk information. The key to mixing GA and ACA is to find the time point for mixing. The appropriate timing can enable HGACO to achieve optimal performance. The process of the HGACO algorithm is shown in Fig. 3.

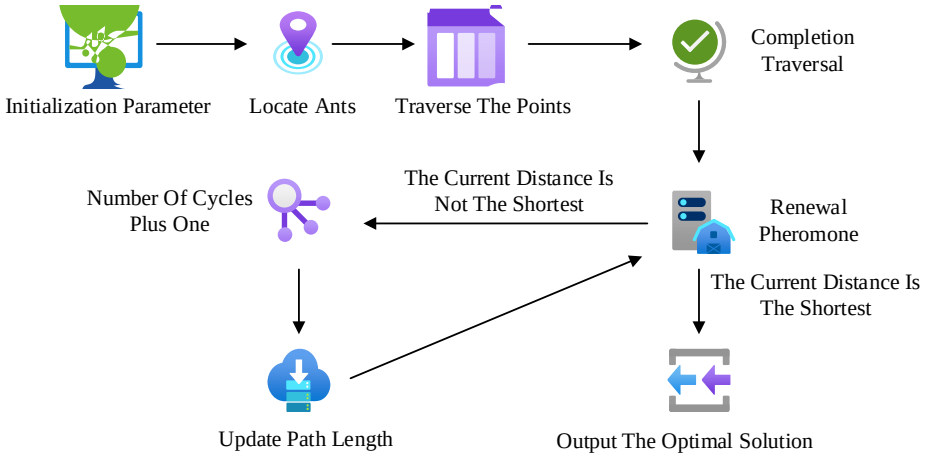

Fig. 2. Flow chart of ACA solution.

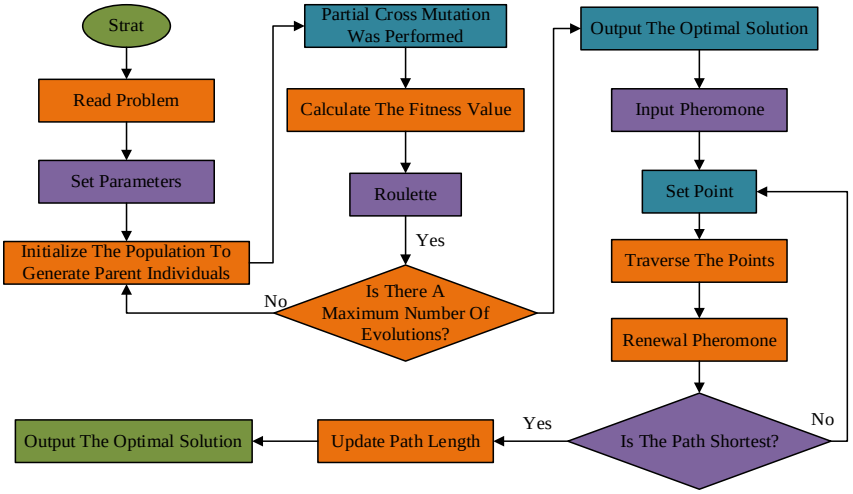

Fig. 3. Flow chart of HGACO.

In Fig. 3, the HGACO algorithm first calculates the optimal solution through the GA part, converting the optimal solution into pheromones while leaving some visibility information. Visibility information refers to the quality information of solutions in GAs, which is used to guide ACAs to quickly find the optimal solution. The visibility data are numbered to represent the spatial numbering in the CPM problem-solving process. The pheromones transformed into the optimal solution are transmitted to the ACA section, and the optimal solution is obtained through the mechanism of simultaneous calculation in the ACA section. Finally, the optimal solution obtained by the HGACO algorithm is outputted. By utilizing the HGACO algorithm, modular processing of complex products can assist in production design. Complex products often have a large number of parts. Modular processing can simplify these parts and reduce the complexity of encoding and decoding.

B. CPM Design

The use of HGACO algorithm for CPM can solve the production efficiency problem in the context of Industry 4.0. The main factor affecting production efficiency is that product quality requirements are often high, and most products are customized with complex structures [16]. These reasons make product production relatively slow in the design process. After disassembling the information on these customized products, the indicators of each part can be obtained. The various components are interrelated. Fig. 4 is a complex product decomposition structure diagram.

In Fig. 4, the internal relationships within the structure of complex products are complex. Various large devices are composed of different components. Components are composed of different components, and components are composed of multiple part modules, which contain multiple small parts. The components at different levels are connected in a complex manner through serial and parallel connections. The logistics list is used to organize components at different levels, determine their mutual demand relationships, and thus form integration. The adaptation relationship between different components will affect the quality performance of the product. There are various indicators of product quality. Reliability is the most important quality indicator. Fig. 5 shows the serial structure between the parts.

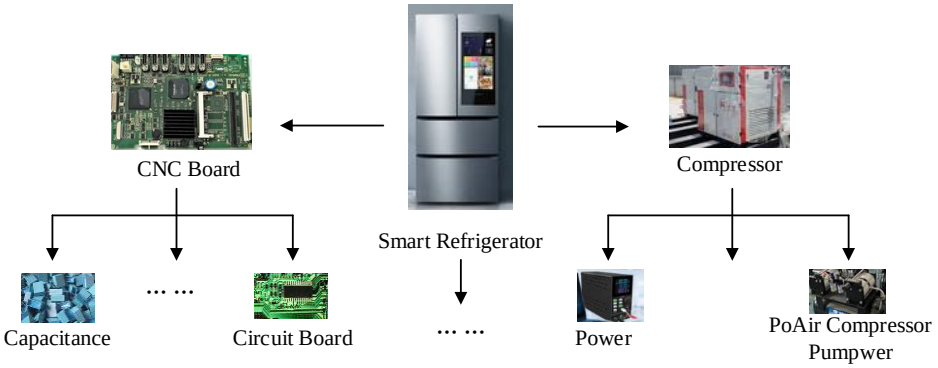

Fig. 4. Complex product breakdown structure diagram.

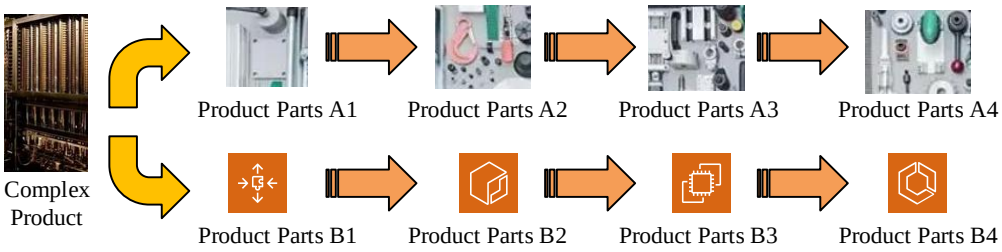

Fig. 5. Series system result model diagram.

In Fig. 5, A1, A2, A3, A4, B1, B2, B3, and B4 respectively represent the component numbers. In a serial system, each component module is sequentially connected to form a linear sequence. The reliability of each component module directly affects the performance of its subsequent modules. Consequently, the overall reliability of the system depends on the reliability of each component module. The characteristic of this structure is that the failure of any component module may lead to the failure of the entire system. Multiple serial components together form a component module. In actual production, these component modules form a propagation mode of parallel connections. Parallel connected components further form components, and most of the components are interleaved in series and parallel. Among them, the reliability between component modules affects each other. The overall reliability of complex products is shown in Eq. (10).

$$D(x) = K(X_1 > x, X_2 > x, ...X_m > x) = \prod_{a=1}^{m} K(X_a > x) = \prod_{a=1}^{m} D_a(x) \quad (10)$$

In Eq. (10), $D(x)$ represents the overall reliability of the product system. K is the reliability coefficient. X_m is the reliability prediction of the m-th component. x is the reliability standard. $\prod$ is a quadrature sum operation. The reliability of the system decreases with the increase of the number of components, and the decrease in system reliability is reflected in the failure rate [17]. The lower the failure rate of components, the higher the reliability of the system. The calculation method for failure rate is shown in Eq. (11).

$$\eta_m = \sum_{a=1}^{m} \eta a \quad (11)$$

In Eq. (11), η_m is the overall failure rate of the system. ηa is the failure rate of each component. Based on the calculation method of failure rate, the average time for system failure is shown in Eq. (12).

$$T_{bf} = \frac{1}{\eta_m} = \frac{1}{\sum_{a=1}^{m} \eta a} \quad (12)$$

In Eq. (12), T_{bf} is the average time between failures, which is inversely proportional to the overall failure rate of the system. If one of the components is adjusted and integrated into parallel mode, the overall reliability calculation method of the system will be adjusted as shown in Eq. (13).

$$D = D_1 \times [1-(1-D_2)^n] \times \prod_{a=3}^{m} D_a, n \in (1, \infty) \quad (13)$$

In Eq. (13), D is the system reliability with parallel features, and $D \in (0,1)$. D_a is the reliability of the a-th component. n is the total number of parts. The calculation method of the first derivative of the reliability of the system as a whole based on the number of parts is given by Eq. (14).

$$\frac{dD}{dn} = -(1-D_2)^n \ln(1-D_2) D_1 \prod_{a=3}^{m} D_a > 0 \quad (14)$$

In Eq. (14), $\frac{dD}{dn}$ is the first derivative of system reliability. With parallel connections in the system, as the number of parts increases, the system becomes significantly more reliable. The expression for the second derivative is given by Eq. (15).

$$\frac{d^2D}{dn^2} = -(1-D_2)^n \ln^2(1-D_2) D_1 \prod_{a=3}^{m} D_a < 0 \quad (15)$$

Complex products often contain a large number of

component modules. Different component modules form various complex system structures. Serial and parallel modes are often mixed together, making the factors affecting system reliability more complex [18]. There is interaction between the components of the product. The impact of interaction is called the influencing factor. There is no interactive influence relationship between the components that make up the parallel state, and there is no subsequent performance impact. The influence relationship between the components that form a mixed state of serial and parallel is relatively complex, and when improving the system, it is greatly affected by the interference variables of the components. The coupling between different levels can improve the overall quality of the system by selecting the quality, quantity, and shape of parts [19]. Based on the analysis of serial and parallel quality performance of parts, this study uses the HGACO algorithm to integrate component modules in a hybrid structure and analyze the impact mechanisms of multiple component systems in the hybrid structure. By reallocating different components and configuring quality performance parameters, more precise and improved system modules are obtained [20]. Fig. 6 shows the technical process of using the HGACO algorithm for CPM.

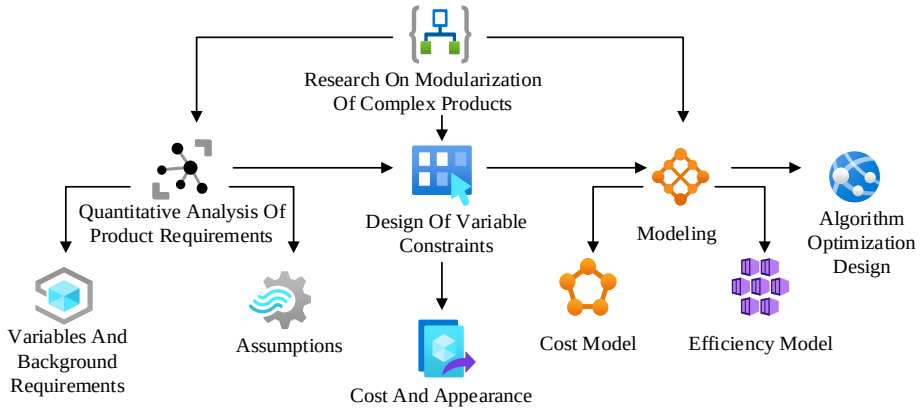

Fig. 6. Technical flow chart of modular design of complex products.

In Fig. 6, the first step is to conduct a quantitative analysis of product requirements, including functional description, size, and cost requirements. Subsequently, design constraints for variables such as cost and appearance. During the design process, it is also necessary to explain the constraints. After obtaining a series of required parameters, a basic cost and profit model for complex products is constructed. The study is predicated on the fundamental model to optimize the design of the HGACO algorithm. Ultimately, the HGACO algorithm is utilized for calculation to obtain the optimal functional module configuration scheme.

III. Results

A. Performance Analysis of Mixed Genetic ACA

Simulation experiments are designed to analyze the performance of the HGACO algorithm and solve the CPM analysis problem. The experimental language is Java, and the model solving is Matlab. The operating environment is Windows 10, the CPU is Intel Core i7-2600 3.40 Ghz, and the RAM is 4GB. The performance of an algorithm mainly depends on its control parameters. The control parameters are mainly divided into Iterations (GM), Mutation Rate (PM), Population Numbers (PS), and Crossover Rate (PC). The Analysis of Variance (ANOVA) of the algorithm under different parameter controls reflects its performance, with smaller values indicating better performance and greater stability. Fig. 7 shows the variance of PS and GM corresponding to the HGACO algorithm at different levels.

The statistical significance of the variance data in Fig. 7 is shown in Table I. In Fig. 7 (a), PS increases with the increase of the number of levels. When PS is 36, the variance has its minimum value, and as PS continues to expand, there is no significant change in variance. In Fig. 7 (b), when GM is less than 80, the variance shows a stable downward trend, but when GM is greater than 80, the variance suddenly increases. This is because when the iteration parameters are too high, the HGACO algorithm is prone to lagging due to the concentration of pheromones, leading to an increase in ANOVA. Therefore, the optimal PS is 36 and the optimal GM is 80. There are crossover and mutation processes in the HGACO algorithm, and the corresponding PC and PM also have an impact on the variance. Fig. 8 shows the corresponding variances of PC and PM at different levels.

In Fig. 8 (a), the ANOVA transformation is less affected by PC, and the variance is minimized when PC is 0.90. In Fig. 8 (b), the variance is minimized when PM is 0.20. This is because cross-selection makes it easier to generate offspring with significant differences from the parent, while mutation operations have relatively less impact on offspring, so the mutation probability is less affected by hierarchy and has little effect on variance. The PC of the HGACO algorithm is 0.90, and the PM is 0.20. This condition has the best effect on generating the optimal population for the algorithm. Fig. 9 shows the initial values of the independent variables and the distribution of the independent variables after multiple iterations in the HGACO algorithm.

Standard deviations	0.07	Standard deviations	0.19

In Fig. 9 (a), the initial value distribution of the ant colony is quite scattered and needs to undergo a self changing cycle. In Fig. 9 (b), when the number of iterations reaches 10, the independent variable distribution of the HGACO algorithm begins to converge towards the vicinity of the first independent variable $x_1 = 1$ and the second independent variable $x_2 = 1$. In Fig. 9 (c), when the number of self-variable loops reaches 20, the independent variables of the algorithm converge well. The independent variables of the algorithm gradually converge and reach a convergence state. Continuing to increase the number of loops will cause an unnecessary burden on the computational part of the algorithm. Therefore, the optimal number of iterations for the HGACO algorithm is 20, which results in the best convergence. After determining that the HGACO algorithm can achieve optimal performance under the above parameter conditions, it is necessary to analyze other performance indicators of the algorithm. The most intuitive way to determine whether an algorithm is optimal is to compare its performance with other algorithms under the same conditions.

B. Performance Comparison of Modularization of Complex Products using different Algorithms

In the previous section, various optimal parameters are determined through performance analysis of the HGACO algorithm. To validate the performance of the HGACO algorithm, the Swarm Behavior Heuristic Algorithm (SBH) and the traditional Particle Swarm Optimization (PSO) algorithm are compared with the proposed HGACO algorithm. This experiment compares the algorithm performance under CPM using algorithms. The modularization process is to use different algorithms to modularize complex products with m parts and n associations, where $m \in \{10, 20, 30, 40, 50\}$ corresponds to $n \in \{20, 40, 60, 80, 100\}$ and the problem scale is represented as x_{mn}. The training and validation running times of each algorithm on the DSM dataset are displayed in Fig. 10.

In Fig. 10 (a), during the training process, the initial running time of the HGACO algorithm is relatively long. However, as the number of parts increases, the running time of HGACO is shorter than that of PSO, while the running time of SBH always remains linear. This is because HGACO has insufficient pheromones at the beginning, and the process of cross-selection and mutation takes a long time. However, with the extension of training and the accumulation of pheromones, the speed at which HGCAO seeks the optimal solution increases. In Fig. 10 (b), due to the training of HGACO, it can maintain a relatively short running time throughout the validation process. The average running time of HGACO has been reduced by 35.06% compared to PSO. Table I shows the maximum modular value standard deviation and mean of HGACO, SBH, and PSO during the modular process.

In Table II, when there are few parts, all algorithms can obtain reasonable solutions, with an average value generally within 10. As the data size increases, the average values obtained by PSO and SBH show significant discrepancies, with some solutions even reaching 48900, which is clearly unreasonable. Due to the different solving rules of the algorithms, the model solutions obtained by PSO and SBH do not meet the requirements when there are too many parts. Therefore, only when the optimal solution of HGACO is within a reasonable range in all cases, can it meet the requirements. The production efficiency, duration, and cost of modularizing four complex products C_1, C_2, C_3, and C_4 using three algorithms are shown in Fig. 11.

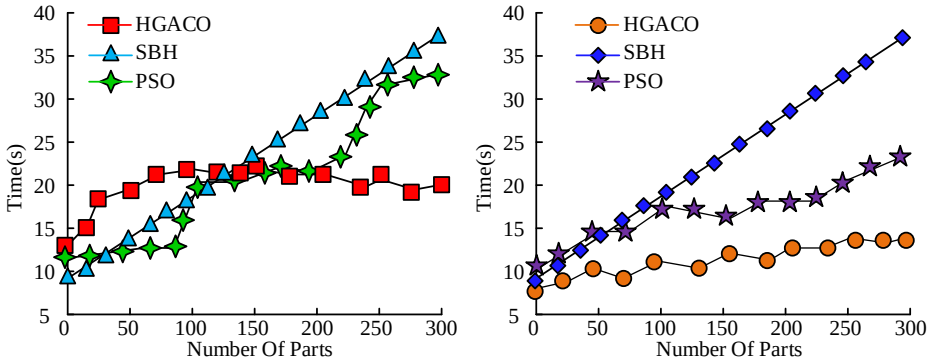

Fig. 10. Algorithm training and validation run time on DSM data set.

TABLE II COMPARISON OF DIFFERENT ALGORITHMS ON MODULARITY VALUES

	HGACO		**PSO**		**SBH**	
Problem Scale	Mean	Standard Deviation	Mean	Standard Deviation	Mean	Standard Deviation
x_{1020}	5.87	4.52	4.52	6.25	5.65	6.58
x_{2040}	7.82	7.16	7.16	8.02	2158	1589
x_{3060}	6.21	5.55	145	165	23.1	18.5
x_{4080}	4.59	6.21	3.54	3.51	256	298
x_{50100}	6.51	8.51	48900	36580	10.1	9.99

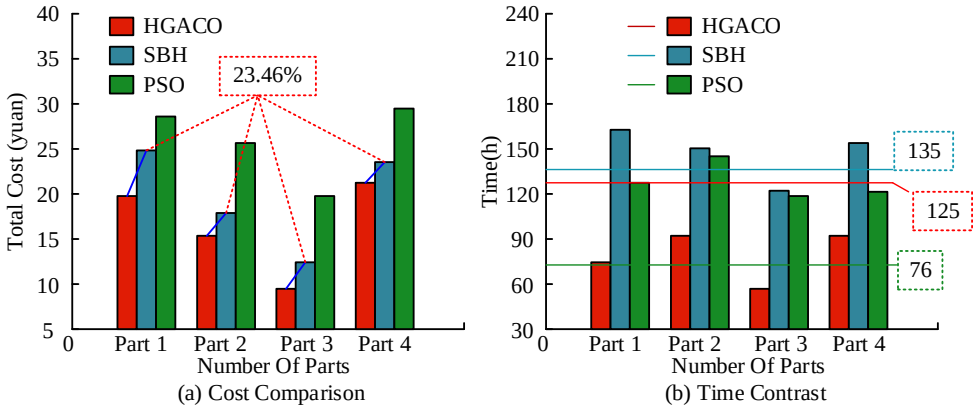

Fig. 11. Production data after modularization of complex products by algorithms.

In Fig. 11 (a), the production costs of modularizing different products using the HGACO algorithm are 19.98 yuan, 15.84 yuan, 9.21 yuan, and 21.02 yuan, respectively. The production costs after modularization using the SBH algorithm are 24.89 yuan, 17.94 yuan, 13.25 yuan, and 23.55 yuan, respectively. Compared with the SBH algorithm, the HGACO algorithm reduces the production costs of different products by 24.69%, 13.25%, 43.87%, and 12.03%, respectively, saving an average of 23.46% of production costs. In Fig. 11 (b), the optimal solution obtained by HGACO can significantly improve efficiency. After modularizing complex production, the average production time is 125 hours, while the average production time under the PSO algorithm is 76 hours. Compared with the ABC algorithm, the HGACO algorithm reduces production time by 39.20%, resulting in a 39.20% increase in production efficiency. This is because HGACO has made product design simpler and more efficient after CPM. Enterprises can carry out intelligent production based on simpler design solutions. Therefore, by modularizing complex production and solving it, HGACO can significantly improve the production efficiency of complex products and reduce production costs.

IV. DISCUSSION

With the advancement of Industry 4.0, CPM design has become a key means to improve production efficiency and reduce costs. The conventional manufacturing paradigm proves challenging in meeting the demands of intricate product development. Conversely, CPM exhibits a capacity to expeditiously adapt to market fluctuations, enhancing design efficiency and product adaptability. In recent years, numerous scholars have devoted themselves to studying CPM and proposed various algorithms, such as GA, ACA, and PSO. While these methods have proven advantageous in addressing modular problems, they are not without limitations. These

limitations include but are not limited to, insufficient applicability and low operational efficiency in multi-component complex products. To improve the operational efficiency of CPM, a CPM optimization method based on HGACO has been proposed. This method combines the global search capability of GA and the pheromone optimization mechanism of ACA. The transformation of the solution of GA into a pheromone, followed by its transmission to ACA, results in the rapid convergence and efficient optimization of the system. In the experimental section, the superiority of the HGACO algorithm is verified by comparing its performance with other algorithms. With respect to the duration of execution, the HGACO algorithm exhibits a longer execution time during the initial training stages. However, as the number of components increases, the execution time of the HGACO algorithm experiences a gradual decrease in comparison to the PSO algorithm. This is primarily due to the necessity for HGACO to amass a sufficient quantity of pheromones during the initial training phases to facilitate ant colony navigation. As pheromones are accumulated, the efficacy of the algorithm for search purposes undergoes a substantial enhancement. A comparison of modular values reveals that the HGACO algorithm can obtain reasonable modular values under different problem scales. In contrast, the PSO and SBH algorithms demonstrate significant deviations in the standard deviation and mean of modular values when there are a large number of components. This indicates that the HGACO algorithm has higher stability and adaptability when dealing with complex products. The underlying rationale pertains to the efficacy of the HGACO algorithm in circumventing local optima through the integration of crossover and mutation operations of GAs. This is complemented by the utilization of the pheromone mechanism of ACA, which facilitates the acceleration of global search, thereby ensuring the maintenance of optimal performance in complex environments.

In summary, the HGACO algorithm has shown significant advantages in the modular design of complex products. It not only outperforms traditional algorithms in terms of running time but also demonstrates excellent stability and adaptability in modular values. These results indicate that the HGACO algorithm can effectively address the challenges in CPM design. Despite the demonstrated efficacy of the HGACO algorithm in experimental and practical test results, its performance may be constrained by the increasing complexity of products and the scale of production systems that accompany the advancement of Industry 4.0. The performance of the HGACO algorithm is crucial in handling large-scale complex products. Future research needs to further enhance the scalability of algorithms, enabling them to efficiently handle large-scale complex products. By using distributed computing and parallel processing techniques, the computational tasks of algorithms can be allocated to multiple processors or computing nodes, significantly improving the execution efficiency of algorithms to meet more complex industrial needs.

V. Conclusion

This study mainly focused on the modular processing and analysis of complex products using algorithms in the context of Industry 4.0. A new HGACO algorithm has been proposed to further improve production efficiency. This study first extracted the problem, then initialized the parameters, and solved it through GA selection, crossover, and mutation. The obtained solution was utilized as a pheromone and visibility information to input into the ACA part to quickly obtain the optimal solution. Finally, experimental verification and comparison were conducted on the optimal solutions obtained by different algorithms. When the PS of the HGACO algorithm was 36, GM was 80, PC was 0.90, and PM was 0.20, the variance was minimized, indicating that the algorithm has the best performance at this time. When the number of cycles reached 20, HGACO just converged and could adapt to complex products with different numbers of parts, and could obtain reasonable optimal solutions. By using HGACO to modularize the responsible products, the running time was reduced by 35.06% compared to the PSO algorithm. HGACO has improved the production efficiency of complex products by 39.20% while reducing production costs by 23.46%. In summary, the comprehensive performance of HGACO is superior to other traditional algorithms, providing a theoretical basis for manufacturing enterprises to solve configuration problems and improve production efficiency for complex products. Although this study has solved the optimal solution problem of CPM, there are still some issues, such as the need to consider weighting for the requirements of different complex parts. Therefore, further research should be conducted on the multi-condition constraint weighting of the algorithm in the future.

***Abstract*—Polycystic Ovary Syndrome (PCOS) has many challenges when it comes to its diagnosis and treatment due to the diversity of presentation and potential long-term consequences for health. For this reason, sophisticated data pre-processing and classification methods are implemented to enhance the accuracy of PCOS diagnosis. A number of innovative techniques are employed in the process to enhance the accuracy and reliability of PCOS diagnosis. To identify ovarian cysts, real-time ultrasound images are pre-processed initially with the Contrast-Limited Adaptive Histogram Equalization (CLAHE) model to improve image contrast and sharpness. The ultrasound images are segmented with the K-means clustering algorithm, Particle Swarm Optimization (PSO), and a fuzzy filter, enabling precise analysis of regions of interest. An attention-based Convolutional Neural Network-Recurrent Neural Network (CNN-RNN) model is employed for classification and does so effectively to capture the temporal and spatial characteristics of the segmented data. The proposed model has a very good accuracy rate of 96% and works very well on a variety of evaluation metrics such as accuracy, precision, sensitivity, F1-score, and specificity. The results are evidence of the robustness of the model in minimizing false positives and enhancing PCOS diagnostic accuracy. Nevertheless, it is noted that bigger data sets are required to maximize the precision and generalizability of the model. The aim of subsequent research is to use Explainable AI (XAI) methods to enhance clinical decision-making and establish trust by making the model's predictions clearer and understandable for patients and clinicians. Along with enhancing PCOS detection, this comprehensive approach sets a precedent for integrating explainability into AI-based medical diagnostic devices.**

Keywords*—*Polycystic ovary syndrome; contrast limited adaptive histogram equalization; particle swarm optimization; k- means clustering algorithm; convolutional neural network; recurrent neural network

I. Introduction

Polycystic ovarian syndrome (PCOS) is a common endocrinological disorder that affects one in ten pre-menopausal reproductive women worldwide [1]. According to several studies, women with PCOS are more likely to develop ovarian and endometrial cancer, both of which can be dangerous if not recognized early [2, 3]. The identification of PCOS is a major issue since it is a frequent illness that may endanger women's physical and mental health. Ovarian malfunction and an excess of androgen are the two main signs of PCOS [4]. Many factors are believed to cause this disorder, and the factors include genetics, puberty, physiological changes, mental state, and environmental effects. Patients who have PCOS usually exhibit hirsutism, obesity, insulin resistance, irregular menstruation, and cardiovascular problems. As a result, it is crucial for the accurate diagnosis and treatment of PCOS [5, 6]. However, a growing body of scientific research indicates that PCOS can be promptly diagnosed using a well-standardized diagnostic method and that it can be treated with appropriate, symptom-focused, long-term, and dynamic therapies [7].

The most common imaging technique used in the clinical assessment of a patient with ovarian disease is ultrasound. Compared to other medical imaging techniques like computed tomography (CT) and magnetic resonance imaging (MRI), ultrasound provides a number of benefits [8, 9]. This is because ultrasonography is inexpensive, widely available, safe, and delivers results instantly. The use of this imaging approach provides a fantastic chance to create a deep learning model for automatic analysis, improving the objectivity and diagnostic accuracy of the test. Patients are required to undergo ovarian ultrasonography in order to guarantee the correctness of the first PCOS diagnosis [10, 11]. For the purpose of evaluating their metabolism, some of them could even require venous samples. It is a substantial financial burden as the average cost of the initial diagnosis and evaluation of PCOS is estimated to be $740. There has been a lot of interest in using deep learning and machine learning to identify PCOS because artificial intelligence has developed so quickly [12-14].

Currently, a manual process is used to identify the polycystic ovary shape in ultrasound images. It is based on the collective expertise of professionals in identifying the shape and features of ovarian ultrasound images [15]. After reviewing images from the same instance, the specialist's judgment may occasionally be arbitrary and unpredictable. In order to identify PCOM, radiologists have to invest a great deal of time and effort due to the various follicle sizes and their relationship with veins and tissues. Additionally, it causes artefacts and speckle noise in the images. Additionally, this manual framework for diagnosis may increase examination errors, which is inconvenient for the patient. Therefore, it is advised to suggest

clever computer-aided solutions that can provide gynecologists with decision-support tools [16]. Using clinical information and ultrasound images, a deep learning algorithm may be used to determine whether a woman has PCOS. It will also help remove barriers related to the manual review of ultrasound images and the assessment of clinical data for patients [17].

After PCOS was identified using a number of standard techniques, machine learning (ML) techniques were created and applied to clinical data [18]. The ML methods are time consuming, and yields poor detection accuracy results. On the other hand, neural networks are a well-known method for prediction [19]. Once more, some researchers used Convolutional Neural Networks (CNN) to diagnose PCOS from ultrasound images using deep learning techniques [20]. DL is a powerful method used in computer vision and image analysis. Although DL algorithms normally achieve a high degree of accuracy in classifying images. Random forest (RF) classifiers have been developed to classify PCOS and normal samples, yielding an accuracy of 72%. SVM, NB, CNN, and VGG-16 are a few machine learning and deep learning models used to analyze ovarian ultrasound images for diagnostic systems. However, several studies employed clinical data and ultrasound reports in text format rather than ultrasound images to diagnose PCOS [21-23]. PCOS is characterized by oligomenorrhea, anovulation, and biochemical hyperandrogenism. In some cases, it may occur due to the development of ovarian microcysts. Women are learning more about PCOS, which is becoming increasingly widespread. PCOS/PCOD is becoming more common in women and significantly impacts women.

According to a recent study, approximately 18 percent of women in India, especially from the East, suffer from this illness. Infertility, irregular ovulation, and preterm abortions are becoming prevalent issues for women. PCOS, a disorder that affects women of reproductive age, has been found to play a significant role in the cause of infertility. Doctors nowadays diagnose PCOS by manually counting the number of follicular cysts in the ovary, which is used to determine whether or not the condition exists. Variability, reproducibility, and efficiency issues may arise due to manual counting. The main objective of a proposed approach is listed in the following bulleted points,

- To design an effective polycystic ovary syndrome detection method using a machine learning algorithm.
- To eliminate additive noise and enhance the detection process, a dataset is pre-processed using the contrast-limited adaptive histogram equalization method.
- To present a particle swarm optimization (PSO) and K-means clustering algorithm with a fuzzy filter (FF) for the segmentation process.
- To implement an attention-based CNN-RNN deep model for increasing PCOS detection accuracy.

The proposed approach is highly accurate with low false positives and demonstrates impressive performance. The model provides a more accurate and efficient method for the diagnosis of PCOS using advanced deep learning methods, which ultimately leads to improved patient outcomes and clinical decision-making.

II. Related Work

NS. Nilofer et al. [24] developed a hybrid ML model for PCOS detection by extracting the GLCM features. The combination of an artificial neural network (ANN) and an improved fruit fly optimization approach (IFFOA) was developed. The suggested model had three main stages, namely pre-processing, segmentation, feature extraction, and detection. In the first phase, the image resizing and noise removal are executed using a medial filtering approach. Then, the enhanced K-means clustering model was utilized to perform the segmentation process. After attaining a segmented follicle part, the features from the particular portions are extracted using the Grey-Level Co-occurrence Matrix (GLCM). An enhanced optimization model was introduced in the detection model for the optimal two key parameters. The dataset used here was the US image dataset, and the performance measures of precision, recall, F measure, and accuracy are analyzed.

C. Gopalakrishnan et al. [25] presented a detection method of PCOS from the ultra sound image of the ovary. The ovary's size, number of follicles, and location may all be learned by ultrasound imaging. Due to the different follicle sizes and the complex relationship between tissues and blood vessels, diagnosing PCOS in real time can be challenging for radiologists. This frequently leads to incorrect diagnosis. Initially, the pre-processing stage was performed, and in this stage, RGB to Gray conversion, ROI extraction, and speckle noise reduction were executed. The ovary image was binarized for segmentation using the modified Otsu approach. The contour initialization concerns were resolved since the binary mask had foreground and background areas organized properly to segment objects. Additionally, based on the distributed grey level, a thresholding strategy was added to remove the objects from the ovary image. Finally, an improved outcome in terms of accuracy had been achieved. As a result, the modified Otsu method proved effective for follicle extraction.

Recently, medical professionals have been able to identify and categorize illnesses using image recognition techniques. Traditional methods for detecting PCOS have several drawbacks, therefore, Dongyun He et al. [26] developed a probabilistic method. To ensure accurate cue recognition, the training images were first split into several grids of identical sizes. Furthermore, each grid in the supplied image had a quality score that roughly corresponded to its grayscale and texture properties. As a result, one may consider each image to be a scoring matrix. The feature vectors might be provided using the statistically based model while taking into account the score matrix. The probabilistic model was used to train the identified feature vectors, and the learned feature vectors were subsequently transformed into an SVM kernel to identify PCOS.

To identify PCOS from ultrasound images of the ovary, C. Gopalakrishnan et al. [27] developed a model based on scale-invariant feature transform (SIFT) descriptors. Initially, the Canny edge detection method was utilized to enhance image

quality and delineate the margins of follicles in the ultrasound image. This approach involved pre-processing, gradient computation, non-maximum suppression, and thresholding as integral steps of the Canny edge detection process. SIFT descriptors are used to identify the feature descriptors for diagnosing the condition. Then, a support vector machine (SVM) was used to ultimately perform data training and classification. Better accuracy, mean squared error, and normalized absolute error has been achieved for PCOS identification.

In order to identify PCOS using ultrasound images, Untari N. Wisesty et al. [28] suggested a modified back propagation method. Typically, stereology calculations or feature extraction and classification were the key foundations for PCO follicle identification. The extraction and categorization of features served as the foundation for this PCOS detection. The Gabor wavelet was taken into consideration for the feature extractor, while the modified back propagation model was employed as a classifier. Levenberg-Marquardt optimization (LMO) and Conjugate Gradient-Fletcher Reeves (CGFR) were the modified backpropagation algorithms. LMO was used to achieve the highest level of accuracy by considering 33 neurons and 16 vector characteristics.

A PSO model to partition follicles and identify PCOS was reported by E. Setiawati et al. [29]. Here, the follicles were segmented using a novel clustering model created with PSO and a modified non-parametric fitness function. The primary goal of the fitness function would be to detect faults based on pixel values and improve the likeness to human vision. Then, normalized mean square error (NMSE) and the mean of the modified non-parametric fitness function and structural similarity index (MSSIM) approaches were used to create convergent and compact clusters. The PSO fitness function also led to more convergent solutions. The performance of the examined PSO also impacted the extracted follicular size and contrast enhancement.

The chan-vase model and split-Bregman optimization were introduced by H. Prasanna Kumar and S. Srinivasam [30] for quick segmentation of PCOS. A thorough understanding of the size and quantity of follicles might be gained through PCOS diagnosis using ultrasound images. Using an increased active contour without an edge model, the tiny follicles could be identified. In addition, by using the split-Bregman optimization model, the segmented image's accuracy and computation time are enhanced. Results demonstrated that the split-Bregman optimization model produced superior outcomes with less computing time and iteration.

Onyema et al. [31] applied the AI-based Granger panel model approach to provide an empirical analysis of apnea syndrome. The MIT-BIH polysomnographic database (SLPDB) was the source of the data. MATLAB software was utilized for the implementation, and the panel consisted of eighteen patients. The findings indicate a substantial correlation between ECG-blood pressure (BP), ECG-EEG, and EEG-blood pressure (BP) for the eighteen sleep apnea patients.

Tiwari et al. [32] developed a model that diagnoses based on a clinical dataset Kottarathil provided and made available through its Kaggle repository. A variety of machine learning techniques for patient screening without the need for intrusive diagnostics are assessed using non-invasive screening metrics. The experiments demonstrate that the Random Forest (RF) approach outperforms the other well-known machine learning algorithms with an accuracy of 93.25%. Moreover, the model possesses high complexity.

Alamoudi et al. [33] suggested a data set containing an ultrasound image of the ovary and clinical information about a patient classified as either PCOS or non-PCOS is presented. Then, using the Inception model, a deep learning model was built to diagnose the PCOM based on the ultrasound image and achieved 84.81% accuracy. Then, in order to determine whether or not the patient has PCOS, a fusion model that combines clinical data with the ultrasound picture was suggested. By combining clinical features with mobile net architecture to extract image data, the most advanced model to date has achieved 82.46% accuracy.

Lv et al. [34] suggested an automated deep learning method that investigates the possibility of scleral alterations in PCOS identification for auxiliary PCOS detection. After utilizing an enhanced U-Net to separate scleral photos from full-eye images, the method was run on the dataset. From there, deep features were extracted from the scleral images using a Resnet model. In order to accomplish categorization, a multi-instance model was created. A variety of performance metrics, including AUC, F1-score, recall, precision, and accuracy of classification, are used to evaluate the effectiveness of the method. The results demonstrate the high potential of deep learning in PCOS diagnosis, achieving an average AUC of 0.979 and a classification accuracy of 0.929. The comparison with existing methods is shown in Table I.

Gaps Identified in the Literature Review and Contributions of the Work

- Data Scalability and Flexibility: Some of the models mentioned, such as the probabilistic model with SVM, the Canny edge detection method, and the adaptive k-means clustering with GLCM feature extraction and ANN network, struggle with different types of image datasets and large databases.
- Complexity and Parameter Tuning: Support Vector Machine (SVM), Random Forest (RF), and Decision Tree models require high-fidelity parameter tuning and can be computationally intensive, leading to inefficiencies in real- world applications.
- Temporal analysis and feature extraction: Spatial feature extraction is the prime focus of traditional models like active contour with altered Otsu threshold value, Particle Swarm Optimization with a new revised non-parametric fitness function, and LMO (Local Min-Orthogonal) CGFR (Centered Gaussian Fit Regression) algorithms. They cannot capture the temporal dependencies of the data sufficiently.

The CNN-RNN model's strong architecture makes it better placed to deal with large and diverse datasets.

- With the addition of attention mechanisms, the CNN-RNN model enhances model performance and

efficiency while reducing the need for manual parameter tuning.

- The CNN-RNN model excels in this aspect by combining Convolutional Neural Networks for spatial feature extraction and Recurrent Neural Networks for temporal sequence analysis, providing a more comprehensive approach to diagnosing PCOS.
- By combining recurrent neural networks for analysis of temporal sequence and convolutional neural networks for spatial feature learning, the CNN-RNN model excels at this task and provides a more comprehensive approach to PCOS diagnosis.

TABLE I. COMPARISON WITH STATE-OF-THE-ART TECHNIQUES

References	Method	Advantages	Disadvantages
[24]	Adaptive k-means clustering, GLCM feature extraction, and ANN network model	The system is used for alternative medical data, and a number of criteria are used to evaluate its efficacy.	Various algorithms can be employed to optimize the parameters of an artificial neural network.
[25]	Active Contour with modified OTSU threshold value	High accuracy	A large database cannot be applicable
[26]	Probabilistic model and SVM with kernel function	Image quality diagnosis may assess early alterations in endometrial thickness and blood flow and perform early illness diagnosis and therapy.	Accuracy can be improved.
[27]	The Canny Edge detection method	The suggested methods are more suited to extracting and identifying follicles from ovarian images.	Different kinds of image datasets cannot be used.
[28]	LMO and CGFR algorithm	It has high accuracy	The conjugate gradient parameter is not considered
[29]	PSO with a new modified non-parametric fitness function.	The retrieved follicular size may be made to resemble the real follicular size by using contrast enhancement.	The follicles cannot be identified automatically.
[30]	Improved active contour without edge method.	The performance is high	High cost
[31]	AI-based Granger Panel model approach	Valuable statistical source for the analysis of dynamic behaviours	Give less performance in prediction
[32]	RF	Attain accuracy of 93.25%	Highly complex in computation
[44]	Random forest	High accuracy and robustness; handles missing data well.	Can require a great deal of processing power and overfit noisy data.
[45]	Decision tree	It needs minimal data preparation and is easy to analyze and represent.	Vulnerable to overfitting and subject to instability when data is slightly different
[46]	Convolutional neural network (CNN)	Extracts and categorizes features automatically.	High computing power and large data sets are required,
[47]	Transfer learning (e.g., VGG16) [48]	Uses pre-trained models to improve performance.	Require huge processing power.

III. METHODOLOGY

PCOS is caused by a hormonal imbalance that can lead to various illnesses and occurs in one in ten women of reproductive age from 18 to 44. In the proposed approach, machine learning-based techniques are proposed to detect PCOS disorder efficiently. The main novelty of the proposed work lies in the integration of several advanced techniques to address the challenge of diagnosing PCOS using ultrasound images: CLAHE takes it a step further by limiting the amplification of noise in relatively homogeneous regions. This helps in enhancing the contrast of ultrasound images, which is crucial for identifying subtle details like ovarian cysts. This combination of K-means clustering and PSO with fuzzy filtering allows for more accurate segmentation of ultrasound images. K-means clustering partitions the image into clusters based on pixel intensity, while PSO optimizes the clustering process by finding the optimal centroids. Fuzzy filtering further refines the segmentation by considering the uncertainty in pixel classification, improving the regions of interest identification.

CNN-RNN architecture is designed to effectively capture both spatial and temporal features within the segmented ultrasound images. The attention mechanism allows the model to focus on the most relevant regions, while the CNN component extracts spatial features, and the RNN component processes temporal sequences. This holistic approach enables more accurate classification of ultrasound images, aiding in the diagnosis of PCOS. By combining these techniques, the proposed approach offers a comprehensive solution for PCOS diagnosis. The proposed approach comprises three stages for PCOS detection they are;

- Pre-processing
- Segmentation
- Classification.

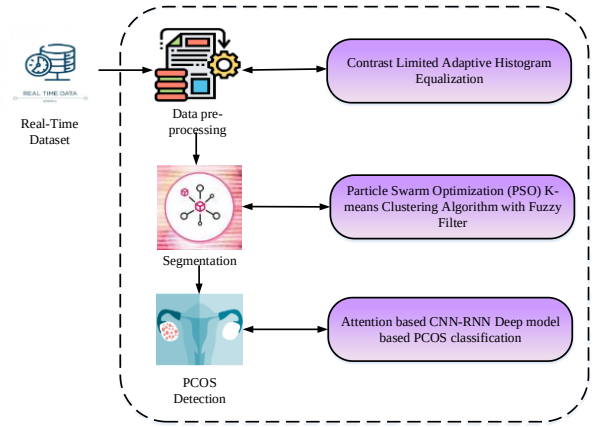

Fig. 1. Workflow for proposed approach.

Fig. 1 represents the step-by-step process involved in the proposed approach. In the first stage of the proposed approach, the real-time dataset is pre-processed to enhance the performance of PCOS detection. After that, the segmentation process is done for pre-processed data using particle swarm optimization (PSO) K-means clustering algorithm with FF. Then, the detection process was done by attention-based CNN-RNN deep model. The proposed classification model applies to many technical problems with reduced complexity. The proposed model provides the best optimal outcome and improves classification accuracy effectively. The step-by-step process of PCOS detection using machine learning techniques will be discussed briefly in subsequent sections.

A. Pre-processing

The initial stage of the proposed work is pre-processing, which is aimed at enhancing the quality and clarity of ultrasound images specifically for the purpose of identifying ovarian cysts, which are a hallmark of PCOS diagnosis. CLAHE is applied to improve image contrast and detail. This enhancement is crucial for subsequent steps in the analysis pipeline, such as segmentation and classification, as it enables more accurate regions of interest identification and characterization within the ultrasound images. Therefore, the pre-processing is focused on preparing the ultrasound images for further analysis and diagnosis of PCOS. The proposed approach pre-processes the real-time dataset using the CLAHE method [35]. The use of CLAHE for pre-processing is attributed to its effectiveness in enhancing image contrast and improving local details, particularly in medical imaging applications like detecting polycystic ovary syndrome. CLAHE is specifically designed to address the limitations of traditional histogram equalization by limiting contrast amplification in regions with high contrast variations, thereby avoiding over-enhancement artifacts.

Additionally, CLAHE's adaptive nature allows it to adjust parameters locally based on the characteristics of different image regions, which is crucial for maintaining diagnostic information integrity in medical images. This flexibility guarantees the preservation and highlighting of pertinent characteristics linked to polycystic ovary syndrome, improving the overall efficacy of later analysis algorithms. Moreover, CLAHE is a better option for pre-processing tasks due to its ease of integration into current pipelines and low computational overhead brought about by its simplicity and efficiency. Image quality consistency between datasets is guaranteed by using CLAHE to standardize pre-processing. Input image in the CLAHE model is classified into non-overlapping contextual regions known as blocks/sub-images/tiles. In the CLAHE model, two main metrics are Clip Limit-CL and Block Size-BS. Using these metrics in the CLAHE model maintains and enhances image quality. When the CL is higher then, the histogram becomes flatter, and the image's brightness is increased due to the low intensity of the input image. In addition, if BS is higher, the image contrast is increased, and the dynamic range becomes higher. An optimal image quality is generated using the image entropy when the two metrics are determined at the point with the huge entropy curvature. The major steps of the CLAHE model are defined below:

Step 1: Classify the intensity of an original input image into non-overlapping contextual regions. In which, $m \times n$ is considered the total number of image blocks and 8×8 is considered the optimal value for preserving the chromatic data in the image.

Step 2: Based on the values of the grey level present in the image of the array, evaluate the contrast-limited histogram for each contextual zone.

Step 3: By using the CL value, the limited contrast histogram for the contextual region is calculated, and the mathematical equation is given below:

$$N(Avg) = \left[\frac{N(U)_r \times N(V)_r}{N(GL)} \right] \quad (1)$$

Here the average number of pixels is represented by $N(Avg)$, the number of gray levels in the contextual region is represented as $N(GL)$, $N(U)_r$ *and* $N(V)_r$ represents the number of pixels in the U dimension, and V dimension for the contextual region. The actual CL is calculated by the following equation;

$$N(CL) = Nor(CL) \times N(Avg) \quad (2)$$

Here $N(CL)$ represents the actual CL, $Nor(CL)$ represents the normalized CL. The total number of clipped pixels is determined as $Nor\sum(CL)$. Finally, the average of the remaining pixels to be distributed into each gray level is defined in the following equation;

$$N(Avg)Nor(CL) = \left[\frac{Nor\sum(CL)}{N(GL)} \right] \quad (3)$$

By using the following condition, the histogram clipping rule is calculated;

If $His_{reg}(x) > N(CL)$ then;

$$His_{reg\_clip}(x) > N(CL)$$

Else if $(His_{reg}(x) + N(Avg)N(CL) > N(CL)$ then

$$His_{reg\_clip}(x) > N(CL)$$

Else $(His_{reg\_clip}(x) = His_{reg\_clip}(x) + N(CL)$

Here the original histogram is represented as $His_{reg}(x)$, and the clipped histogram for each region at x^{th} gray level is represented as $His_{reg\_clip}(x)$.

Step 4: Reallocate the other pixel until all have been allocated. The step for reallocating the pixel is represented in the following equation;

$$S(PI) = \left[\frac{N(GL)}{N(\mathrm{Re}main)} \right] \quad (4)$$

Here $S(PI)$ represents the step of a positive integer of at least one, $N(GL)$ represents the number of gray levels, and $N(\mathrm{Re}main)$ represents the remaining number of clipped pixels. The program begins its search process from the lowest to the highest order of gray level using the above step. The program will allocate one pixel to the gray level if the number of pixels in the gray level is less than $N(CL)$. If the distribution of the pixels is not even performed when the search is complete, the program computes a new step using Eq. (4) and starts a new search round until all of the remaining pixels are dispersed.

Step 5: Each region's intensity values are improved using the Rayleigh transform model. The clipped histogram is distorted to cumulative probability $CP_{inp}(x)$; it is used to generate a transfer function. The PCOS image shows as another original when the Rayleigh distribution is applied. The mathematical equation of using the Rayleigh forward transform is represented in the following equation;

$$RFT(x) = \left[PV_{LB} + \sqrt{2\delta^2 In\left(\frac{1}{1 - CP_{inp}(x)} \right)} \right] \quad (5)$$

Here RFT represents the Rayleigh forward transform, PV_{LB} represents the pixel value of the lower bound, and δ represents the scaling parameter of the Rayleigh distribution. The output of probability density is defined below:

$$CP(RFT(x)) = \left[\frac{RFT(x) - PV_{LB}}{\delta^2} \bullet Exp\left(-\frac{(RFT(x) - PV_{LB})^2}{2\delta^2} \right) \right] \quad for\ RFT(x) \geq PV_{LB} \quad (6)$$

Where a higher δ value results in more effective contrast improvement in PCOS image to enhance the rate of saturate value and reduce the level of noise.

Step 6: Limiting the effect of a sudden change. Linear contrast stretch is used to resize the transfer function output dynamically. The linear contrast stretch is represented in the following equation;

$$RFT(x) = \left[\frac{TF(x) - TF_{Min}}{TF_{Max} - TF_{Min}} \right] \quad (7)$$

Here $TF(x)$ represents the transfer function.

Step 7: In order to prevent border artefacts, the new grey level task of pixels inside a sub-matrix contextual region is computed via a bi-linear interpolation between four mappings.

By using CLAHE, the dark area in the images is clearer and more prominent for higher contrast. As a result, the CLAHE model is suggested to improve PCOS detection performance by eliminating boundary artefacts.

B. PSO-Based K-means Model with Fuzzy Filter for PCOS Segmentation

In the proposed approach, PCOS segmentation is considered an essential stage to extract significant objects lying in images and segment the images into nearby semantic regions. The segmentation process of PCOS images is commonly difficult because the images are complicated, diverse and differ from person to person. Various methods are proposed for segmenting the follicles in ultrasound images. In the proposed approach, the segmentation process is performed by a particle swarm optimization (PSO) based K-means clustering algorithm with an FF to enhance the performance [36]. In the proposed approach, FF is used in image processing to enhance the performance of classifiable filters. The main objective of using an FF in the proposed approach is to reduce the unwanted noises in contaminated images when there are many uncertainties. In the fuzzy filtering approach, a pixel is denoted by the membership function and a set of fuzzy rules that consider adjacent information in a limited area or other data to remove the noise with blurry edges of the PCOS image. Recently, the K-means method has become one of the most prominent models in medical technology. The k-means clustering method is considered the most significant algorithm used in centre-pivot clustering techniques in clustering. The initialization of cluster centres and other factors in the K-means clustering method begins with allocating Euclidean distance criteria to one cluster with the shortest distance among the cluster centres. PSO is a population-based search algorithm; each individual in PSO is considered a particle and "flown" via hyper-dimensional space. Individuals' social psychological behaviour causes particles to shift their position in the search space to replicate the success of others. The neighbours' knowledge and experience impact the changes in the particles within the same swarm. The search behaviour of a particle is influenced by the behaviour of other particles in the equivalent swarm.

K-means Clustering: K-means clustering is a form of unsupervised learning used when no groupings or categories exist in the data. The main objective of a K-Learning algorithm is to detect groups in data, where the variable K indicates the number of groups. In the proposed approach, every PCOS

image waits to be segmented while the data points set is represented in the following equation;

$$X = \left[x_1, x_2, \ldots, x_n \right] \tag{8}$$

Here n represents the dimension vector. Using the K-means segmentation process in the proposed approach, PCOS images are divided into K-cluster. The normal method detects the subset $S = \{Cl_1, Cl_2, \ldots, Cl_k\}$ in a set x to reduce the target function $TF = \sum_{i=1}^{k} \sum x_j \in s_j D_{ij}(x_j, Cl_i)$. In which $D_{ij}(x_j, Cl_i)$ represents the Euclidean distance from the data point x_j to a clustering centre Cl_i. The target function is represented in the following equation;

$$TF = \left[\sum_{i-1}^{k} \sum_{x_j \in Cl_i} \left\| x_j - Cl_i \right\|^2 \right] \tag{9}$$

The target function TF is closer to clustering with the clustering effect. As a result, to get the optimum clustering effect, the target function value and all the clustering centres should be set as zero, and the mathematical equation is given below:

$$Cl_i = \left[\frac{1}{N_i} \sum_{j=1}^{n_i} x_j \quad (i = 1,2,\ldots,k) \right] \tag{10}$$

Here N_i represents the number of data points in the cluster i. The clustering centre of K-Means is constantly updated by reducing several iterations of the target function. The similarity of data points in the same clustering rapidly enhances as the clustering centre is updated, whereas the similarity of data points in separate clustering gradually decreases. The clustering process is over when no new information exists in the clustering centre.

PSO: In the proposed approach, PSO-based K-means clustering is used for segmentation to detect the approximate solutions for PCOS detection. PSO is an artificial intelligence (AI) based technique used to find approximate solutions to numerical maximizing and minimization problems that are exceedingly difficult or impossible to solve. In PSO, the best solution for each problem may be computed into a single particle with no quality or volume in N-dimensional space. The step-by-step process involved in the PSO-based K-means clustering algorithm is as follows;

Let's consider the particle P_i present in the dimension space D; then the position is represented in the following equation;

$$P_i = \left[P_{i1}, P_{i2}, \ldots, P_{iD} \right] \tag{11}$$

Then, the speed is represented in the following equation;

$$SD_i = \left[SD_{i1}, SD_{i2}, \ldots, SD_{iD} \right] \tag{12}$$

During the update process, the best position of a particle is detected, and the iteration is represented in the following equation;

$$P_i = \left[P_{i1}, P_{i2}, \ldots, P_{iD} \right] \tag{13}$$

Then, its best position is;

$$P_B = \left[P_{B1}, P_{B2}, \ldots, P_{BD} \right] \tag{14}$$

Then, the speed calculation of each particle is represented in the following equation;

$$SD_{ij}(T+1) = \left[WSD_{ij}(T) + LF_1 R_1 \left(P_{ij} - X_{ij}(T) \right) + LF_2 R_2 \left(P_{Bi} - X_{ij}(T) \right) \right] \tag{15}$$

The calculation of particle position is represented in the following equation;

$$X_{ij}(T+1) = \left[X_{ij}(T) + SD_{ij}(T+1) \right] \quad j = 1,2,\ldots,D \tag{16}$$

Here, the inertia coefficient is represented as W, learning factors are denoted as $LF_1 R_1$ and $LF_2 R_2$ in that order, denoting the capacity for self-learning and learning from an excellent group of particles. In a PSOK-based algorithm, the linear regression model is used to assist the inertia coefficient and enhance the convergence and optimization of the quality speed rate.

PSO-based K-means Clustering with FF for PCOS Segmentation: In the proposed approach, PSO-based K-means clustering (PSOK) is proposed to enhance the segmentation process of PCOS detection. The cluster centres in PSOK are recognized as the particle positions, and the weakest particle is removed by searching for the optimal solution using the PSO algorithm to enhance the computation. The proposed approach proposes the K-means clustering algorithm to update the particle positions. In PSOK, n particles are initialized, with their positions and velocities updated as needed, and the fitness values evaluated and arranged in decreasing order in a list. The iteration process continues until the maximum number of iterations is met or the minimal error condition is reached.

Step 1: Choose m particles known as the initial population number, and feed the particles into the initial swarm called IS is represented in the following equation;

$$IS_1 = \left[P(1), P(2), \ldots, P(m) \right] \tag{17}$$

Then, initialize the position x_{id} for the swarm S by utilizing the K-means clustering algorithm.

Step 2: Arbitrarily begins the velocities v_{id}

Step 3: Fitness evaluation for each particle by using $\left(x_{id}(T) \right)$.

Step 4: The exploration stage is given below:

$$p_{id}(T+1)=\begin{cases} p_{id}(T) & FitVal(p_{id}(T))>FitVal(x_{id}(T)) \\ x_{id}(T) & FitVal(p_{id}(T))\le FitVal(x_{id}(T)) \end{cases} \quad (18)$$

Step 5: Determine the global best $p_{GB}(T+1)$ for the particle position by the best fitness value computed in the swarm.

Step 6: Based on the K-means clustering algorithm, the position of every new particle is optimized in the $S(T+1)$ new swarm.

Step 7: Based on the below equation, the velocity vector $(v_{id}(T+1))$ for each particle is varied.

$$\begin{pmatrix} v_{id}(T)=wv_{id}(T-1)+LF_1Rand()[p_{id}(T-1)-x_{ii}(T-1)] \\ +LF_2Rand()[p_{id}(T-1)-x_i(T-1)x_{id}(T)] \\ =x_{id}(T-1)+v_{id}(T)+v_{id}(T-1) \end{pmatrix} \quad (19)$$

Step 8: In which, i^{th} particle in a D dimensional space is represented by $(x_{id}(T))$ at the time step T velocity v_{id} of $p_{id}(T)$. Here LF_1 and LF_2 represents the learning factor, w represents the inertia weight, and $Rand()$ represents the random function.

Step 9: Then update each particle in $S(T+1)$.

Step 10: Stop the process until the maximum number of iterations reached of the minimum error condition is satisfied, or else repeat the process.

Therefore, the proposed approach uses a PSOK clustering-based fuzzy filter model for partitioning the ultrasonic image of PCOS into several segments. It uses an appropriate suppression factor for perfect segmentation of PCOS to enhance detection performance.

C. Attention-Based CNN-RNN Deep Model for PCOS Classification

In the classification stage, the segmented PCOS features are fed into the detection model for PCOS detection. An attention-based CNN-RNN deep model is proposed for PCOS detection. The proposed approach is a combination of a CNN and an RNN [37]. The attention-based CNN-RNN deep model is essential for classifying PCOS because it can capture complex temporal dynamics and spatial patterns in medical image sequences. The model gets a thorough knowledge of PCOS-related features by incorporating RNN for modeling temporal dependencies and CNN for extracting spatial information. The inclusion of attention mechanisms concentrates on pertinent areas or time steps in the data, which improves the interpretability of the model even more. By ensuring resilience to the individual variations in PCOS symptoms, this hybrid architecture enhances generalization performance. Furthermore, the interpretability of the model helps physicians comprehend the logic underlying its predictions, enabling well-informed decision-making. All things considered, the Attention-based CNN-RNN deep model makes a substantial contribution to medical image analysis and diagnosis by providing a strong and adaptable framework for precise, comprehensible, and clinically useful PCOS classification.

Using a combination of cutting-edge NN components, the attention-based CNN-RNN deep model is a sophisticated architecture designed for the complex problem of PCOS categorization. Its purpose is to extract valuable information from medical image sequences. CNNs, well-known for their ability to extract spatial characteristics from images, serve as the model's foundation. CNNs are particularly good at detecting minute patterns and structures in ultrasound scans and other medical images, which is important when it comes to differentiating between ovaries that are damaged and those that are not. CNNs are enhanced by RNNs, who are skilled in simulating the temporal dependencies in sequential data. This skill is essential for documenting dynamic changes in ovarian morphology over time, as these alterations may be markers for diagnosing PCOS. The model can identify temporal patterns and fluctuations that could indicate the onset or progression of PCOS due to RNNs.

The capacity of the model to rank pertinent areas or time steps in the input data is improved by the addition of attention mechanisms. Attention processes enable the model in the setting of PCOS classification to concentrate on particular areas of interest within medical images or sequences, removing unnecessary information and highlighting important diagnostic signals. The model obtains a comprehensive grasp of PCOS-related factors by merging temporal dynamics recorded by RNNs with spatial data recovered by CNNs. This combination of temporal and spatial data improves diagnostic accuracy by allowing the model to identify intricate patterns and changes in both domains.

Attention techniques in the hybrid CNN-RNN architecture give the model robustness and allow it to generalize well to various PCOS symptoms seen in clinical practice. This resilience guarantees the model's strong performance in various patient demographics and imaging situations, improving its clinical usefulness and dependability. Beyond its potential for classification, the attention-based CNN-RNN deep model is interpretable, giving physicians an understanding of the machine's decision-making process. The clinical applicability and acceptance of the model are eventually increased by this openness, which also promotes trust and cooperative decision-making between clinicians and AI systems. Using the synergy of CNNs, RNNs, and attention mechanisms to extract, integrate, and interpret complex information from medical image sequences, the Attention-based CNN-RNN deep model advances state-of-the-art PCOS diagnosis and improves patient care.

Here, CNN consists of three layers: convolution, fully connected, and pooling layers. The convolution layer is first used in CNN to extract the required features from input PCOS images. The edges and corner information about the images are extracted using a feature map. The second fully connected layer is used for classification, which uses the convolution layer output to detect the image class effectively. The pooling layer reduces the convolved feature map size to minimize computational costs. RNN is a neural network (NN) type in

which the previous output is considered the current input. The input layer contains the initial data for the NN, the hidden layer acts as an intermediate layer among input and output layers, and the output layer generates the final results. In the proposed approach, the CNN model contains seven layers; the initial two are convolution layers with 64x3x3 kernels. The local features of a PCOS image are extracted using 64x1x1 kernels of a locally connected layer. Each RNN unit in the sequence modelling stage has a probability of 0.5 and a dropout of 512 hidden units, followed by a P-way fully connected layer and a softmax classifier.

The integration of CNN and RNN with attention processes may elevate the possibility of overfitting, particularly in scenarios involving small dataset sizes. In order to mitigate this risk, the suggested model incorporates dropout layers. P represents the number of polycystic ovaries to be predicted. The final class of PCOS image is predicted using the average pooling of a softmax output. RNN consists of encoding contextual information and feedback loops of a temporal sequence. Let's consider the input sequence $\{S_1, S_2, \ldots, S_T\}$ segmented from the input PCOS, $\{H_T\}$ represents the hidden state and $\{O_T\}$ represents the output state. Therefore, the mathematical equation is defined below:

$$\{H_T = Height(W_{InH}F_T + W_{HH}H_{T-1} + B_H)\} \quad (20)$$

$$\{O_T = W_{HO}H_T + B_0\} \quad (21)$$

The weight matrices of the three layers are represented as $\{W_{InH}, W_{HH}, W_{HO}\}$. In the proposed approach, long short-term memory (LSTM) is used to improve the standard of RNN from the vanishing of gradient issue. In LSTM, each unit contains an input gate, forget gate, cell gate, and output gate, and their equations are given below;

$$\{In_T = \delta(W_{In}[H_{T-1}, F_T] + B_{In})\} \quad (22)$$

$$\{F_T = \delta(W_F[H_{T-1}, F_T] + B_F)\} \quad (23)$$

$$\{O_T = \delta(W_O[H_{T-1}, F_T] + B_O)\} \quad (24)$$

$$\{\hat{C}_T = TanH(W_C[H_{T-1}, F_T] + B_C)\} \quad (25)$$

$$\{C_T = F_T \bullet C_{T-1} + In_T \bullet \hat{C}_T\} \quad (26)$$

$$\{H_{T-1} = O_T \bullet TanH(C_T)\} \quad (27)$$

Here $In, F, O and C$ represents the input, forget, output, and cell gate activation and δ represents the logistic sigmoid function. In the proposed approach, an attention layer is proposed to improve the hybrid CNN-RNN performance is expressed in the following equation;

$$A_T = TanH(W_H H_T) \quad (28)$$

$$\alpha_T = SM(W^T M_T) \quad (29)$$

$$R = \sum_{T=1}^{T} \alpha_T H_T \quad (30)$$

Here H_T represents the output of T^{th} hidden layer in the RNN module, α_T represents the T^{th} attention weight, W_H and W^T represents the weighted matrices, and the attention module is denoted as R. The output R is followed by a P-way fully connected layer and softmax classifier. The loss function of the detection model is represented by the following equation;

$$LF = [\alpha.L_{Att} + \beta.L_{Att} + \lambda.\|W\|]^2 \quad (31)$$

Here LF represents the attention loss, L_{Att} represents the target replication loss, and W represents the regularization term. α, β, λ represents the three weight parameters.

$$L_{Att} = \left[\frac{1}{TS}.l(G_1(x), y)\right] \quad (32)$$

$$l[P_1(x), y] = \left[-\sum_{i=1}^{P} 1_i(y) Log\, P_1(x)^i\right] \quad (33)$$

$$P_1(x) = [F_S(F_a(F_H(x_1), F_H(x_2), \ldots, F_H(x_T)))] \quad (34)$$

Here x represents the PCOS detected, T represents the number of time steps of RNN, P represents the number of polycystic ovaries to detect, $P_1(x)^i$ represents the i^{th} dimension of $P_1(x)$ and $P_i()$ is the indicator function. F_S, F_h and F_a represents the hybrid CNN-RNN framework, attention module, and the last softmax layer, respectively.

$$L_{Tar} = \left[\frac{1}{TS}\sum_{T=1}^{TS} l(P_2(x_T), y)\right] \quad (35)$$

$$l[P_2(x_T), y] = \left[-\sum_{i=1}^{P} 1_i(y) Log\, P_2(x_T)^i\right] \quad (36)$$

$$P_2(x_T) = [F_S(F_H(X_T))] \quad (37)$$

Here x_T represents the T^{th} sub-segment of x and $P_1(x)^i$ represents the i^{th} dimension of $P_1(x)$. F_S and F_h represents the softmax layer.

IV. Result and Discussion

The proposed model is trained using a real-time dataset collected from clinical sources and meticulously augmented to enrich its diversity and enhance training efficacy. The dataset size amounts to 1.32MB, comprising images categorized into two distinct classes: "affected" and "not affected." The dataset's sources encompass a broad spectrum of clinical scenarios, ensuring a representative sample that captures the variability inherent in polycystic ovary syndrome cases. The images were collected from the Kerala hospital containing nearly 20 women's scan reports. The augmentation process involves rotation, scaling, and flipping to expand the dataset's size and improve model generalization. This comprehensive approach to dataset preparation underscores the robustness and reliability of the proposed model in real-world clinical applications. In the result and discussion section, all machine learning methods are compared with a proposed model using a graph. The proposed approach is implemented in the PYTHON platform and assessed using accuracy, precision, sensitivity, and F1-score. The experimental outcomes are evaluated and compared with the earlier methods like SVM, logistic regression (LR), naive Bayes (NB), random forest (RF), and classification and regression tree (CART) [38]. The detailed description is given below;

- SVM is a supervised learning algorithm. It is based on SVM and can handle multiclass. The SVM classifier model is placed near a classifier's margin to enhance the performance.
- The LR model is an ML algorithm that solves categorization issues. Binary values are calculated using classifications and determined by a group of different values. The detection probability is used, and the value remains between zero and one.

A. Performance Analysis

Accuracy: The performance accuracy for a proposed approach is considered a significant metric for computing the efficiency and the improved rate of any proposed classification method compared with existing methods. The following equation calculates the accuracy performance of a proposed approach;

$$Accuracy = \left[\frac{TruePos + TrueNeg}{TruePos + TrueNeg + FlasePos + FlaseNeg} \right] \quad (38)$$

Where Acc represents the accuracy performance, $TruePos$ represents the true positive, $TrueNeg$ represents the true negative, $FalsePos$ represents the false positive and $FalseNeg$ represents the false negative value. The proposed approach considers accuracy a significant task in defining classification performance to detect PCOS.

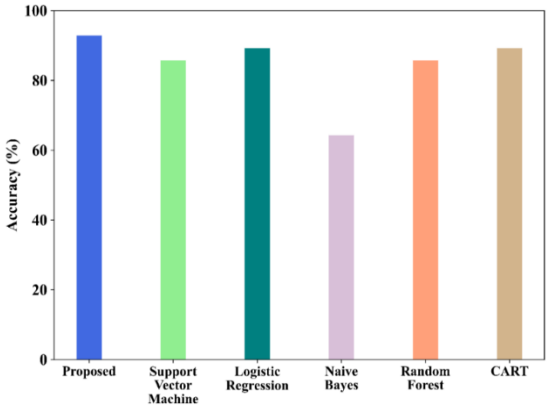

Fig. 2. Accuracy performance.

Fig. 2 illustrates the accuracy analysis. It shows that the proposed approach provides an effective accuracy rate in detecting PCO or non-PCO follicle classes. The proposed approach attains 96% accuracy in detecting PCOS, which is more reliable than existing approaches like support vector machine (85%), logistic regression (89%), naive Bayes (64%), random forest (85%), and CART (89%). Evaluating other methods proves that the defined model provides better results in classifying the PCO or non-PCO follicle class than existing methods.

Precision: Precision performance is considered the most important metric for computing the classification results in the proposed approach. The following equation calculates the performance of precision;

$$\Pr ecision = \left[\frac{TruePos}{TruePos + FalsePos} \right] \quad (39)$$

Here $\Pr e$ represents the precision performance, $TruePos$ represents the true positive, and $FalsePos$ represents the false positive values. Precision performance is used to establish the images that are exactly classified to authenticate the overall accuracy of the detection system of PCOS. The performance result of precision in proposed and existing methods is represented in Fig. 3.

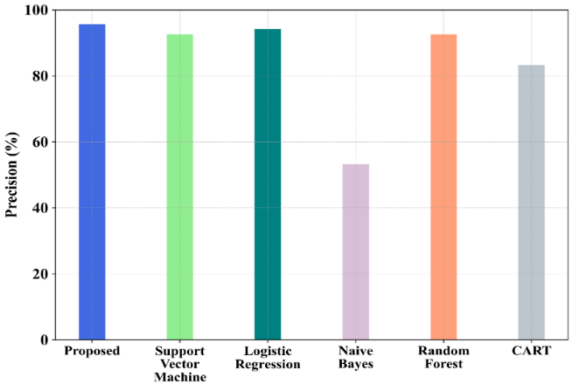

Fig. 3. Precision performance.

Fig. 3 illustrates the precision performance for a proposed model. The proposed approach provides an effective precision rate in detecting PCO or non-PCO follicle class. The proposed approach attains 96% precision in detecting, which is more reliable than existing approaches like SVM (92%), LR (94%), NB (53%), RF (92%), and CART (83%). The proposed method offers exceptional results in identifying the PCO or non-PCO follicle class, as demonstrated by the evaluation of alternative approaches.

Sensitivity: Sensitivity performance is another significant metric for detecting the overall sensitivity of the system model. The following equation calculates the performance of sensitivity;

$$Sensitivity = \left[\frac{TruePos}{TruePos + FalseNeg} \right] \quad (40)$$

Here Rec denotes the performance of sensitivity, $TruePos$ denotes the true positive, and $FalseNeg$ denotes the false negative value. $FalseNeg$ denotes the actual value is true, but the obtained result is false. By using sensitivity performance, classification errors are detected significantly. The sensitivity performance analysis for proposed and existing approaches is represented in the following Fig. 4.

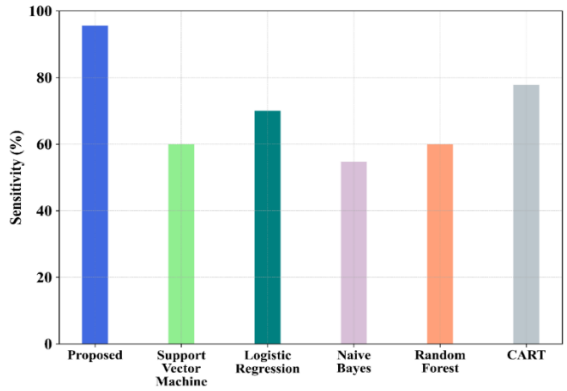

Fig. 4. Sensitivity performance.

Fig. 4 illustrates the sensitivity performance. The proposed approach provides an effective rate of sensitivity performance in detecting. The proposed approach attains 97% sensitivity, which is more reliable than existing approaches like SVM (60%), LR (70%), NB (54%), RF (60%), and CART (77%).

Specificity: It is considered a significant metric for detecting the PCO or non-PCO follicle class in an image without any modifications. Specificity performance is used to detect the negative results, which correctly detect the negative class. The following equation analyzes the performance of a TNR metric;

$$Specificity = \left[\frac{TruePos}{FlasePos + TrueNeg} \right] \quad (41)$$

Here $specificity$ represents specificity performance, $FalsePos$ represents the false positive, $TruePos$ represents the true positive, and $TrueNeg$ represents the true negative value. The following Fig. 5 represents the TNR performance analysis for proposed and existing approaches.

Fig. 5 illustrates the specificity performance for proposed and existing models. The proposed approach provides an effective rate of sensitivity performance. The proposed approach attains (96%) specificity, which is more reliable than existing approaches like SVM (92%) specificity, LR (94%) specificity, NB (53%) specificity, RF (92%) specificity, and CART (83%) of specificity.

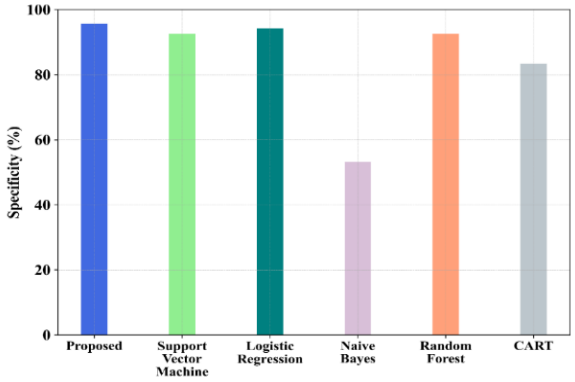

Fig. 5. Specificity performance.

F1-measures: The performance of an F1-measures is calculated between the recall and precision performance. The harmonic mean of the precision and recall performance is called an F-measure. The following equation calculates the F-measure performance;

$$F1-measure = \left[\frac{2 \times sensitivity \times \mathrm{Pr}ecision}{sensitivity + \mathrm{Pr}ecision} \right] \quad (42)$$

Here $F1-measure$ represents the F-measure performance, and $sensitivity \times \mathrm{Pr}ecision$ denotes the harmonic mean. The F-measure performance for proposed and existing approaches is depicted in the following Fig. 6.

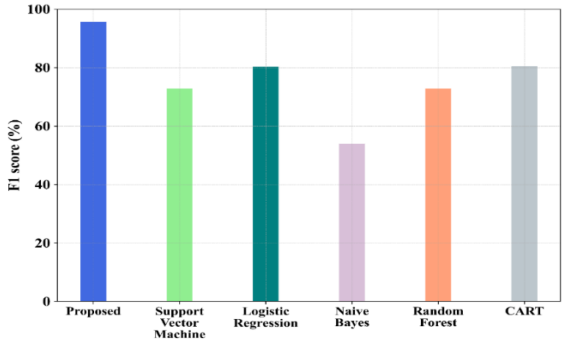

Fig. 6. F1-Measure performance.

Fig. 6 illustrates the F1-measure performance for a proposed and existing model. The proposed approach provides an effective rate of F1-measure performance in detecting PCO or non-PCO follicle class. The proposed approach attains (97%) of F1-measure in detecting PCO or non-PCO follicle class, which is more reliable than existing approaches like support vector machine (72%) F1-measure, logistic regression (80%) F1-measure, naive Bayes (53%) F1-measure, random forest (72%) F1-measure and CART (80%) F1-measure.

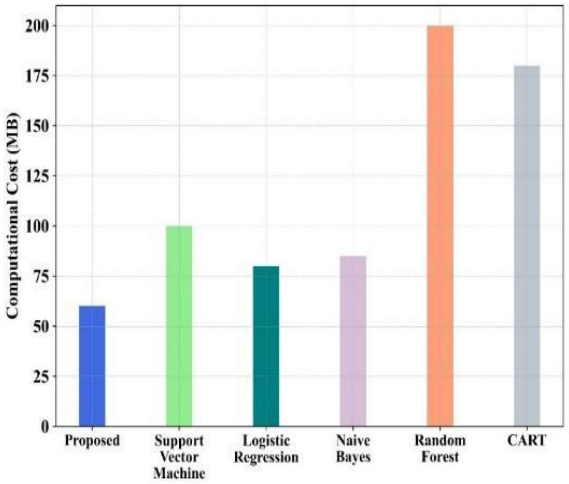

Fig. 7. Comparative analysis of the proposed model in terms of computational cost.

Fig. 7 provides an intricate analysis of the computational costs associated with the proposed model versus existing counterparts, elucidating the efficiency of our approach. The model exhibits a computational requirement of just 60MB, a substantial reduction compared to the other models, which have 100MB, 80MB, 85MB, 200MB, and 180MB of computational cost, respectively. This meticulous examination underscores the superior efficiency of the model, signaling its suitability for adoption in resource-constrained settings without compromising performance. The minimal computational cost underscores the streamlined complexity of the proposed model, making it a compelling choice for widespread implementation. The proposed model is compared with other models with a different dataset, as shown in Table II.

TABLE II. DATASET COMPARISON OF THE PROPOSED MODEL

Dataset	Method	Accuracy [%]
PCOS dataset from Kaggle [39]	HRFLR	87
PCOS dataset from UCI[40]	Red deer algorithm and RF	89.81
PCOS [41][42] [43]	PSO-SVM	90.18
Proposed	CNN-RNN	96

The proposed model outperforms its counterparts, trained on diverse datasets such as UCI and Kaggle. Despite the variations in dataset composition and characteristics, our model consistently demonstrates superior performance. This comparison encompasses thorough accuracy and illustrates the robustness of the approach across different data sources. The comprehensive analysis underscores the adaptability and efficacy of the model across a wide range of datasets, further bolstering its suitability for real-world applications across various domains. The Comparative value analysis of the proposed and other existing ML methods is given in Table III.

The comparative analysis of the proposed model with several performance measures is shown in Table III, and it shows that the proposed model reveals a better outcome.

TABLE III. COMPARATIVE VALUE ANALYSIS OF PROPOSED AND OTHER EXISTING ML METHODS

Methods	Accuracy [%]	Precision [%]	F1-measure [%]	Sensitivity [%]	Specificity [%]
SVM	85	92	72	60	92
Logistic Regression	89	94	80	70	94
Naive Bayes	64	53	53	54	53
Random Forest	85	92	72	60	92
CART	89	83	80	77	83
Proposed	96	96	97	97	96

V. LIMITATIONS OF THE STUDY

Based on the study, the attention-based CNN-RNN classification model is a reliable and valid approach to identifying Polycystic Ovary Syndrome (PCOS). The model is based on the efficiency of the PSO-based K-means clustering algorithm with a fuzzy filter and Contrast-Limited Adaptive Histogram Equalization (CLAHE) in pre-processing and segmenting ultrasound images. It is anticipated that performance metrics such as specificity, F1-score, sensitivity, accuracy, and precision effectively capture the strength of the model. However, there are flaws in the study, primarily the need for a larger dataset to enhance accuracy and minimize misclassification errors. The resilience of the model needs to be enhanced by testing it on smaller datasets. In addition, the ability of the model to be used broadly can be limited to the specific dataset and imaging conditions utilized in the study. Because it is based on ultrasound scans, the model may not account for other PCOS diagnostic criteria.

VI. FUTURE SCOPE

The application of Explainable AI (XAI) methods would significantly enhance the current research in identifying and predicting PCOS based on attention-based CNN-RNN classification models. Ensuring that the predictions of the AI model are understandable, comprehensible, and trustworthy to both doctors and patients would be the primary objective of these advances. By applying XAI methods such as Local Interpretable Model-agnostic Explanations (LIME) or SHapley Additive exPlanations (SHAP), it would be shown what factors or areas of the ultrasound images have the most impact on the conclusions of the model. Simplifying the AI decision-making process, these approaches would help healthcare professionals have more confidence in and trust the predictions of the AI.In addition, in order to further enhance the accuracy of the predicted model, additional research can focus on incorporating multiple data sources of different modalities, including

genomics, hormonal profiles, and clinical data. Explainable AI with these numerous data sources has the potential to give a broader picture of the patient's disease, leading to more personalized and effective treatment regimens. In addition, the model's generalizability and robustness to different populations would be increased through the utilization of a larger and more diverse dataset during training. Aside from enhancing PCOS detection, this approach would set a precedent for the incorporation of explainability in AI-based medical diagnostic systems.

VII. CONCLUSION

The conclusion of this study highlights the significance of the proposed approach in the early detection of PCOS in women. The proposed method employs a real-time dataset, pre-processed using the Contrast-Limited Adaptive Histogram Equalization (CLAHE) model, to improve image quality by reducing noise. Subsequently, segmentation is performed using a Particle Swarm Optimization (PSO)-based K-means clustering algorithm with a Fuzzy Filter (FF) to enhance detection performance before classification. Finally, PCOS detection is carried out using an attention-based Convolutional Neural Network-Recurrent Neural Network (CNN-RNN) model. The approach implemented in Python exhibits superior performance when compared to existing methods. The model achieved impressive accuracy (96%), precision (96%), sensitivity (97%), F1-score (97%), and specificity (96%) metrics. These results underscore the reliability and precision of the proposed approach in PCOS detection, surpassing other models in the field. However, there are some limitations to the proposed methodology. Particularly, the model's performance should be evaluated with larger dataset samples to enhance accuracy and minimize misclassification errors. Furthermore, validating PCOS detection with smaller dataset samples is essential for refining the model's robustness. Although the proposed approach demonstrates better results, continuous refinement and validation efforts are vital to guarantee its effectiveness in real-world PCOS detection scenarios.

Department of Computer System-Faculty of Computer Science, Universitas Indo Global Mandiri, Palembang, Indonesia[3]

***Abstract*—The museums need to transform into modern museums by developing a digital ecosystem that integrates all elements in the museum to optimize organizational outcomes and impact people's welfare in the era of Society 5.0. This paper aims to conduct a review of the museum's digital ecosystem based on the implementation of artificial intelligence (AI) and internet of things (IoT). PRISMA methodology for literature review was adopted to search for the answers to the research questions, knowing digital technology trends, challenges, and benefits of a digital museum ecosystem development, and proposed a novel conceptual model of the museum ecosystem based on AI and IoT implementation. The dataset contained metadata from Scopus, Google Scholar, and IEEExplore databases. Several stages were implemented in the literature review process so that it is known that AI and IoT technologies have never been separated in the development of digital museums since 2020, but there has yet to be research on the digital museum ecosystem model that integrates IoT and AI. The museum's digital ecosystem implementation benefits will improve museum resources and increase museum competitiveness. However, there will be challenges related to cybersecurity issues, data integration in multi-media formats, and interface designs to overcome user acceptance challenges of the technology constructed in the digital museum ecosystem. The proposed AI and IoT-based model also require an evaluation for implementation validation at the museum in future works.**

***Keywords*—AI; IoT; digital museum; digital ecosystem**

I. INTRODUCTION

The COVID-19 pandemic that spread throughout the world has had a negative and positive impact. Various sectors of people's lives have transformed quickly to adjust to and overcome the problems during the COVID-19 pandemic. The community has adapted to new habits where community activities are based on Information and Communication Technology (ICT), which allows communication, community services, and business to be held without direct contact and is more efficient than conventional methods. One is in the Museum's public service sector for education, culture, and tourism. The traditional Museum has been transformed into a modern ICT-based museum by presenting interesting technology for visitors to add value to the Museum [1]. The digital Museum's performance during the pandemic was optimal compared to traditional museums. Digital museums provide a variety of applications to support exhibition spaces and services for visitors for educational purposes and museum tours. However, more than a digital museum is needed to provide added value to museums and society, especially, toward Society 5.0. In that era, people demanded convenience in various public services supported by artificial intelligence-based ICT infrastructure that promised smart services to the public [2]. Stakeholder communities for museums will benefit more from the existence of a digital museum ecosystem.

The digital ecosystem is a concept of connectedness between human entities, technology, and organizational elements to provide added value in achieving organizational goals [3]. These entities are connected digitally to communicate and collaborate in the organization's business processes [4], [5]. Modern museums make it possible to develop digital ecosystems because they involve the community and various entities, which, if fully integrated with digital infrastructure, will provide added value in achieving museum tasks for education and tourism after the COVID-19 pandemic. Visitors with diverse backgrounds have different motivations and expectations, so they need an integrated system to exchange information effectively and efficiently to support the right and fast decision-making in supporting the performance of the Museum as a public service organization.

The digital museum ecosystem has been developed in previous research [6]. However, it is not yet known how developments, benefits, and challenges are faced, especially in the era of Society 5.0 where the application of artificial intelligence (AI) models and the Internet of Things (IoT) is a must. IoT offers ways to collaborate and more interconnection among people in an ecosystem [7] and AI delivers a smart way for living [8]. These questions will be answered in this study. This research conducts a literature review study on research on developing a digital museum ecosystem towards Society 5.0. This method makes it possible to carry out an analysis of the literature dataset regarding the digital ecosystem in a structured manner [9]. The research begins with formulating research questions, followed by applying the dataset inclusion and exclusion criteria until the final results are obtained to answer the research questions [10]. Based on the findings, a novel conceptual model of AI and IoT-based museum ecosystem is proposed and presented in this paper. The paper begins with the introduction in Section I discusses the research problem, gap, and related works Section II describes the research methodology, followed by the results and discussion in Section

IV. Finally, the conclusion is presented in Section V at the end of this paper.

II. Research Methodology

The literature review is carried out to extract information systematically [11]. The literature review begins with developing a dataset containing documents related to the research. It is continued with filtering steps based on several criteria so that a dataset containing articles is produced and will be analyzed to get answers to research questions [11], [12]. To find out the current development of the digital museum ecosystem, three research questions are formulated to be answered in this study, *RQ1*, *RQ2*, *RQ3*, and *RQ4*, as follows:

RQ1: What is the trend of digital technology application at the museum?

RQ2: What are the benefits of IoT and AI-based museum's ecosystem development?

RQ3: What are the challenges in IoT and AI-based museum's ecosystem development?

RQ4: What is the novel conceptual model of AI and IoT-based museum's ecosystem?

The methodology of the literature review process for finding this research question's answer adopted PRISMA [12]. Previous studies reviewed articles regarding existing models of museum digital ecosystems based on IoT and AI. The search was continued with article metadata in the developed database. The identification of new studies in databases was conducted using the following steps: database development, keywords for articles search, inclusion and exclusion criteria, and analysis of final search results. One thousand three articles were selected using the criteria in PRISMA, leaving ten articles reviewed in full text after inclusion and exclusion (Fig. 1). The study continued with searching for new studies on the IEEExplore website using the same keyword on database search. The final articles were analyzed to find the answers to research questions".

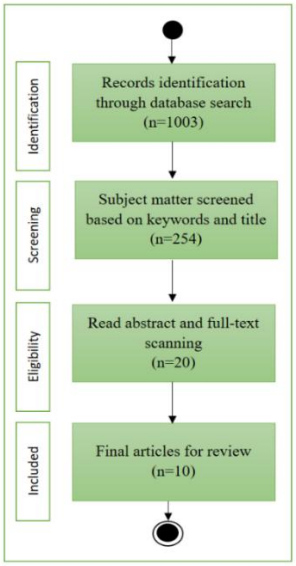

Fig. 1. Literature review methodology.

A. Identification

The development of a database to build a literature dataset that will be reviewed systematically is carried out in the early stages of the research. Articles identification was conducted via metadata of Scopus and Google Scholar databases chosen to develop the dataset because Scopus contains up-to-date, reputable articles that guarantee the latest research on digital ecosystem museums. The Publish and Perish tools collected metadata from the Scopus and Google Scholar databases. The formed dataset is saved. RIS file format for analysis using the VosViewer tool. The article search period for the last five years, 2019-2023.

B. Screening

Article searches in the Scopus and Google Scholar databases are heavily influenced by keywords to produce relevant articles with research problems. Keywords are repeatedly tried so that the best search results are obtained based on the articles found, namely with the keywords "Artificial Intelligence" OR "Internet of Things" Digital Ecosystem" OR "Digital Museum" OR "AI" or "IoT." With these keywords, a dataset was successfully formed from the Scopus and Google Scholar databases for the 2019-2023 period of 1003 articles.

C. Eligibility

The initial search results are corrected to find the most relevant articles to be analyzed to extract information that effectively answers the research problem. The process of inclusion and exclusion of articles in the dataset was carried out by filtering based on keywords in the article's title so that there were only 255 articles in the dataset. Furthermore, the screening process was carried out based on the abstract and full text scanning to obtain the final results of 20 articles to be analyzed in full-text.

D. Inclusion

The dataset analysis was carried out by mapping the bibliography in the dataset with the VosViewer tool [13] and continued with an analysis of 20 full-text articles to find answers to questions *RQ1*, *RQ2*, and *RQ3*. Bibliographical mapping will show the linkages between articles found based on keywords and some information related to the trend of digital research on the museum ecosystem toward Society 5.0. A full-text analysis is needed to find the challenges and benefits of developing digital museum ecosystems, especially during the COVID-19 pandemic in 2019-2023.

III. Results

The digital ecosystem is the concept of connectedness between elements in an organization with digital infrastructure to enable communication and collaboration in achieving goals and providing added value to the organization [4]. Elements contained in the digital ecosystem interact with each other to attentively produce information to support efficient decision-making by actors in the system related to digital technology, data, services, and organizational partnerships [14]. The main entity of the digital ecosystem is people, and the goal is to serve people [15]. The digital ecosystem within an organization [16] consists of a digital economy, digital infrastructure and adoption, and digital society, rights, and governance.

Information and communication technology infrastructure availability is central to forming a digital ecosystem within the organization [3], such as museums.

As a public service organization with roles for education, collection storage, and art, culture, and history tourism, the museum needs to form a digital museum ecosystem. The ecosystem enables visitors, service personnel, collections, exhibition rooms, museum facilities, and all entities and stakeholders in the museum to integrate, exchange information, and collaborate in carrying out museum roles. Additionally, with the digital museum ecosystem, it is possible to add value to society with the presence of ICT. The web-based digital ecosystem of museums has connected people in museums and collections [17]. However, more than a web-driven digital ecosystem for museums is needed for Society 5.0. In that era, people needed the support of digital technology to improve the quality of their lives and provide solutions to various life problems to present sustainable development in various aspects of life, including cultural heritage and museums [18]. IoT integration in digital ecosystem development is a promising solution for data communication and collaboration problems among people in an ecosystem [19], [20].

Meanwhile, AI optimizes data processing for an organization's competitive advantage [21]. IoT and AI impact the ecosystem model for improving its performance [22], [23]. The state of the art of the museum's digital ecosystem model, which integrates IoT and AI, needs to be explored for development. With a digital museum ecosystem, cultural preservation and resilience through museums can be maintained. It is effective in providing social impacts and has an economic impact on society.

A. RQ1: Trend of Digital Technology Application at Museum

The *RQ1* also tried to explore the related works of the digital museum ecosystem model proposed in this study. The finding may describe the gap between the existing model of the digital museum ecosystem. The dataset to be reviewed consists of bibliographies described statistically as in Table I. The average citation of 62.38 is relatively high because there is literature in a type of books cited > 1000. If the literature were removed from the dataset, the average number of citations would be 31.23. The distribution of literature with the number of citations > 1000 is described in Table II. The book was the most cited literature in this study, with citations double the journal articles' citation numbers.

Bibliographic mapping was carried out with the VosViewer tool, and the results of the overlay visualization are illustrated in Fig. 2. Based on the visualization of Fig. 2, which shows mapping based on keywords in the bibliography, it is known that there is no direct relationship between the four keywords "MUSEUM," "AI," "IoT," and "DIGITAL ECOSYSTEM."

The bibliography on the topic of the museum is quite a lot. However, those related to AI, IoT, and Digital Ecosystems have opportunities for further research. The trend of developing museums based on digital technology and artificial intelligence can be seen in publications starting to develop in 2020. For example, there are networks with the keywords "METAVERSE"," "MACHINE LEARNING", and "DIGITAL ECOSYSTEM" after 2020, which are marked by visualization in dominant yellow color. These keywords are also accompanied by the emergence of "COVID", which is connected with the keyword "MUSEUM". It can be concluded that the COVID-19 pandemic has forced the museum's digital implementation to adapt to a pandemic situation by developing museums based on AI and METAVERSE and leading to a digital ecosystem.

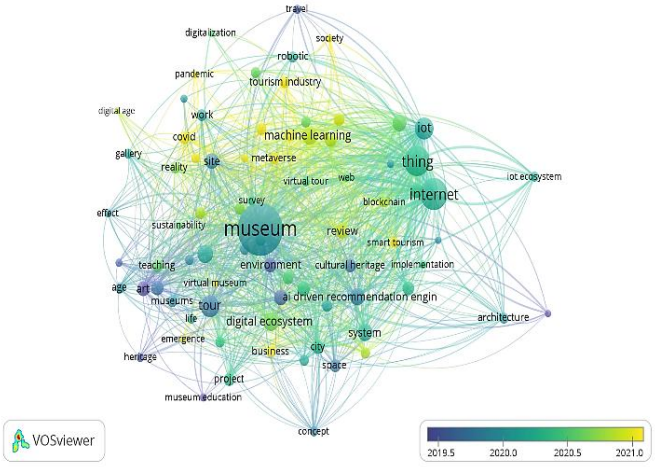

Fig. 2. Overlay visualization of bibliography mapping.

The process was continued with selection, inclusion, and execution, and twenty documents were obtained for overall review. After conducting a literature review of 20 articles in full text, it is known that ten articles contain the development of digital technology to construct digital ecosystems that are applied in the museum domains with IoT and AI content. The digital technology development trend can be seen per year, as illustrated in Table III. The development of a digital museum ecosystem model has been carried out in previous research that is only based on digital technology with AI content. Meanwhile, a digital museum ecosystem model integrating IoT and AI has yet to be developed. The trend of developing digital technology in museums and tourism is described in Fig. 3. The development of digital technology for museum applications began to integrate

AI models in 2019, which were integrated with IoT. The development of AI technology in museums from 2020 to 2022 is relatively high. A pandemic situation requires a solution to the problem of limiting distance and interaction with exhibitions, collections, and visitors. AI and IoT are present as solutions that provide convenience and automation for museum management during a pandemic [24]. This condition has triggered the rapid development of the digital ecosystem at museums based on AI and IoT content since 2020. These results answer research question *RQ1*.

B. RQ2: Benefits of the Museum's Ecosystem Development

The visitors come to the museum with various motivations, including learning and entertainment. The monotonous presentation of museum showrooms requires a practical touch of technology to enhance the learning experience [31], [32] and the visitor's knowledge, especially students, as dominant visitors [33]. Museum digital transformation is more than just digitizing the museum. It requires designing a digital ecosystem model that benefits society and museum organizations, as described in Table IV. Integrating IoT technology and AI models in an ecosystem will provide added value for all the museum's people. Impact on museum resources, thereby creating the competitive advantages of the museum [29].

The optimization of museum services for people related to its role in education and tourism will be achieved through a digital ecosystem based on IoT and AI integration models. By utilizing digital technology, museums can optimize their performance during the pandemic, which limits museum visits [34]. Its efficiency can be achieved through AI and IoT implementation [30]. These findings answer the research question *RQ2*.

TABLE IV. BENEFITS OF THE AI AND IOT-BASED MUSEUM'S DIGITAL ECOSYSTEM TRANSFORMATION

Benefits	References
Visitor engagement: Visitors interact and connect actively with the content of the exhibit.	[26][29] [6] [27]
A new business process: Enabling a new process in museum management.	[18] [29] [6][35] [27]
Competitive advantage: Enabling a museum to outperform its competitors.	[29] [35]
Resource improvement: Enhanced quality and efficiency of the available museum resources.	[18][6] [35] [30][25] [36]
Service improvement: Enhancing service quantity, quality, and efficiency of the museum.	[18] [6] [35][30] [36]
Visitor satisfaction: Fulfilment and positive experience after interacting with museum resources or services.	[18] [29] [27]
Learning enhancement: Improvement of learning experience to foster a better understanding of the museum.	[29] [6] [26] [27]

C. RQ3: Challenges of the Museum's Ecosystem Development

There are challenges to be faced in developing the digital museum ecosystem. These challenges are described in Table V. Museum visitors who come from various backgrounds with low ability to use digital technology, especially those aged >30, face a challenge in accepting digital museum technology [37], [38]. The issue of cyber security and integration of data stored in various formats due to the implementation of IoT and various multimedia-based technologies is attractive to museum visitors [39][40]. It has become an obstacle that needs to be addressed, preceded by research in designing an effective digital ecosystem model for the museum domain. Interface design that is easily understood by various backgrounds of people's profiles.

TABLE V. BENEFITS OF THE AI AND IOT-BASED MUSEUM'S DIGITAL ECOSYSTEM DEVELOPMENT

Challenges	References
Technology acceptance: Accepting new technologies, reluctance to use the technologies at the museum because of lack of knowledge or refusing to use the technology.	[35] [27][26]
Cyber security and ethical concerns: Protecting the museum system and data from unauthorized access, disruption, or theft, is also behavior that has moral conflict concerning the privacy or well-being of the museum ecosystem.	[35] [30]
Feasible models and interfaces: Designing models and user interfaces suitable for different museums.	[18] [30][27]
Infrastructure improvement: A lot of cost for hardware improvement that supports the museum's digital ecosystem development.	[27] [36]
Data integration: The multimedia format creates a multi-data format that needs to be integrated into a museum's digital ecosystem.	[36][26]

Challenges also arise in the museum ecosystem for the implementation of digital technology by internal museum actors. Staff with inadequate knowledge of digital technology are an obstacle in carrying out the process of digitizing museum

collections. There is a lack of awareness of the benefits of digital transformation to increase competitiveness and optimize the role of museums compared to relying on physical museum collections as the main strength. This requires increased understanding from museum staff. High motivation from staff will accelerate the museum's digital transformation process, and the usage of digital technology to support the museum's role in education and tourism is also a challenge in developing the digital museum ecosystem [41]. These findings answer the research question *RQ3.*

D. RQ4: The Proposed AI and IoT-Based Museum Ecosystem Conceptual Model

In the museum digital ecosystem, the three main elements (people, services, and collection & facilities) collaborate and communicate to conduct the museum's roles by applying digital technology for optimizing the museum's organizational goals achievement. A proposed digital museum model is discussed in this study based on the literature review results presented as the answer of RQ4. Integrating IoT and AI in museum ecosystem models is expected to be effective in providing added value benefits for museum elements, especially visitors. Fig. 4 illustrates the proposed AI and IoT-based museum ecosystem model.

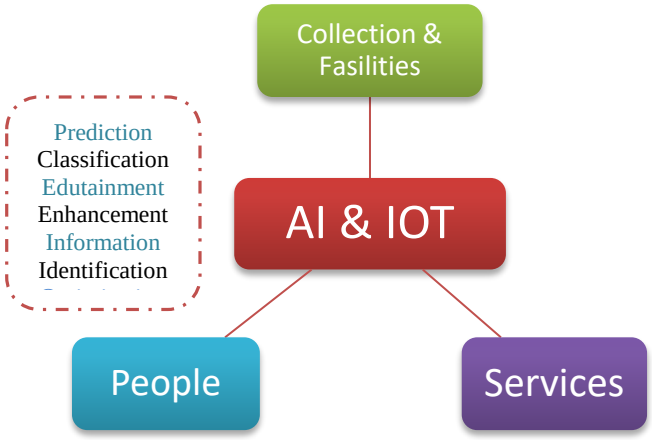

Fig. 4. The proposed AI and IoT-based museum ecosystem conceptual model.

a) Prediction: estimating museum visits to prevent overcrowding, especially during a pandemic which required distance among elements in the museum such as visitors and collections. Predictions try to find out which collections or exhibitions that most interesting, and estimate the resources and facilities [32], [42] needed for the operation and management of the museum.

b) Identification: determining the characteristics of objects due to manage and increase the museum experience. Object identification involves various processes, including computer vision for analyzing visual data, such as images or videos of museum objects as well as object recognition [43] effectively identifying objects presented to visitors to enhance experiences at museums.

c) Classification: Task classification is grouping objects or collections based on collection characteristics to determine effective and efficient handling [44] which impacts the quality and curiosity of the collection. For example, the accurate automated classification of damage types to a museum painting or archive collection will help determine quick and appropriate actions to handle problems based on the type of damage to the collection.

d) Information: AI-based applications in museums enhance information delivery. This feature has not been included in the previous model proposed at the beginning of this study [42] . By using technologies like machine learning and natural language processing, museums can offer personalized experiences, where visitors receive tailored content based on their preferences. AI can do automated tasks like cataloging the collection, and creating real-time updates to exhibits. It also enables seamless information retrieval through smart search systems and multilingual support, making museums more accessible [45]. AI able to analyze data to optimize exhibits and improve accessibility for diverse audiences. These advancements make information more organized, accessible, and interactive, enriching the overall museum experience and management.

e) Enhancement: The implementation of AI at the museum effectively adds value for exhibitions and collections that present different non-traditional new experiences for visitors that impact revisit intention. Digital interactive technology integrated 3D and augmented reality technology in the exhibition presenting virtual and informative collections that are impossible in traditional museums. Especially for the Gen-Z who live in the digital era and are used to all the convenience features and technological sophistication, AI and IoT implementation are necessary for museum visit enhancement. The traditional museums that seem old-fashioned and unattractive without digital technology as an additional tool for visitors and museum management.

f) Edutainment: The museum provides interactive digital technology delivered to the visitor to attract their interest and interactive experiences by using digital technology, such as Augmented reality and virtual reality games integrating AI for smart apps giving added value to increase satisfaction and interest to revisit the museum [31]. The AI-based applications are effective in delivering entertainment at the museum and improving visitors' learning experiences and performance.

g) Optimization: AI and IoT-based applications in museums optimize various aspects of operations and visitor experience. By analyzing visitor behavior, it helps adjust exhibition and content in real-time to enhance engagement. It also optimizes visitor flow, using data to predict crowded areas and suggest alternative routes to reduce congestion. Additionally, AI systems manage energy use by adjusting lighting, and temperature systems based on visitor activity, improving sustainability and reducing costs. Personalized content delivery, such as tailored tours and recommendations based on visitor's profiles, improves the visitor's satisfaction, experience, and learning performance. On the operational side, AI automates routine tasks like inventory management and staff scheduling, improving efficiency and resource allocation. AI and IoT enable museums to streamline their operations,

enhance engagement, and create a more sustainable and efficient environment for museum elements.

IV. DISCUSSION

The proposed model integrates IoT and AI in museum ecosystem models that better than other existing models compared in Table III and discussed in *RQ1*. The models also identify the specific functionality of the museum ecosystem with AI and IoT integration than other models. It contains prediction, classification, education, edutainment, information, identification, and optimization to support the museum's role in education and tourism. The proposed model can be a case line for museum ecosystem development based on IoT and AI to support museum management with the benefits and challenges discussed in *RQ2* and *RQ3*. Further research is necessary for the proposed model validation.

The AI and IoT integration in the museum ecosystem model benefits society and museum organizations, as described in Table IV. It will provide added value for all the museum's elements and create competitive advantages. The strategic planning to overcome the challenges in developing the museum's digital ecosystem is also necessary for the museum's goals achievement and fully utilized by people in the museum ecosystem, especially in Society 5.0.

The proposed model in this study is based on the literature review and observations. The development evaluation of AI and IoT-based museum ecosystem models is required in future research to answer challenges and present valid new concepts, techniques, and innovations to provide a new atmosphere for museums suitable for Society 5.0. The presence of a digital museum ecosystem will not dismiss the existence of museums but will complement and improve performance after the COVID-19 pandemic.

The relationship between elements or entities in the museum's ecosystem connected through the digital technology that integrates AI and IoT will impact the preservation of the historical, cultural, and artistic values stored in museums. The new digital museum ecosystem model based on IoT and AI is expected to create innovation for modern museums. With IoT connectivity capabilities, the speed, and accuracy provided by AI models, developing the research implementation and evaluation stages is challenging for future work.

V. CONCLUSION

The digital transformation of museums was accelerated by the pandemic, which required the museums to find solutions to keep providing educational and tourism services for the public. Towards the era of Society 5.0, people need added value from museums regarding convenience, which impacts their well-being promised by implementing AI and IoT in museums. This study surveys by reviewing the literature dataset of bibliographies with Scopus and Google Scholar metadata sources of research topics about AI and IoT in museum apps. The dataset was processed with PRISMA methodology. The selected 20 documents were thoroughly reviewed. The research questions that will answered are, what are the benefits, challenges, and the novel conceptual model of museum's ecosystem based on literature review conducted in this study.

Bibliography mapping based on keywords relevant to the research topic was conducted using the VosViewer app. It was found that the development trend of digital museum technology started to be based on IoT and AI from 2019 to 2022, which was triggered by the COVID-19 pandemic. AI has become an integrated model in the development of digital museums since 2020 because of its ability to automate, making it easy for visitors and museum managers to deal with a pandemic. IoT integration in the museum's digital ecosystem development is a promising solution for data communication and collaboration problems among people as the main entity of the museum ecosystem. The background of the people involved in the museum, especially museum visitors, presents challenges in user acceptance to take advantage of digital technology in the museum ecosystem, which will have an impact on improving the quantity and quality of museum resources and lead to increasing museum competitiveness as the added value will be obtained, especially in the Society 5.0. However, the absence of a digital museum ecosystem model validation is an opportunity to develop a museum ecosystem based on the proposed model for model validation in future work. The proposed museum ecosystem contains three elements, people, services, and collection & facilities, which are designed to be integrated by AI & IoT-based technology. AI and IoT will facilitate the museum's role and present functionality for prediction, identification, classification, information, enhancement, edutainment, and optimization. AI and IoT implementation may improve museum performance and present added value to museum elements, especially visitors. Further research is necessary for the proposed model effectiveness validation.

***Abstract*—Accurate air temperature prediction is critical, particularly for micro air temperatures. The temperature of micro air changes quickly. Micro and macro air temperatures vary, particularly in degraded wetlands. By predicting air temperature, climate change in a degraded wetland environment can be predicted earlier. Furthermore, micro and macro air temperatures are drought index parameters. Knowing the drought index can help you avoid disasters like fires and floods. However, the right indicators for predicting micro or macro temperatures have yet to be found. LSTM excels at tasks requiring complex long-term memory, whereas GRU excels at tasks requiring rapid processing. We proposed a deep learning strategy based on the GRU-LSTM Hybrid model. Both of these deep learning models are excellent for predicting time series. The performance of this hybrid model is affected by changes in model indicators. The preprocessing stage, the number of input parameters, and the presence or absence of a Dropout Layer in the model architecture are among the most influential indicators of model performance. The best macro temperature prediction performance was obtained using 12 monthly average data to predict the next month's temperature, yielding an RMSE of 0.056807, MAE of 0.046592, and R2 of 0.989371. This model also performed well in predicting daily micro temperature, with an RMSE of 0.227086, MAE of 0.190801, and R2 of 0.981802.**

Keywords*—Predictions; temperature; Gated Recurrent Unit (GRU); Long Short-Term Memory (LSTM); performance; indicators

I. INTRODUCTION

The wetland ecosystem and biological processes are influenced by air temperature. Temperature knowledge can provide insight into environmental changes and aid in effectively managing and conserving wetlands [1], [2]. Prediction of air temperature is critical in identifying and anticipating potential wetlands disasters. Temperature extremes can cause changes in rain patterns, affecting water discharge and potential flooding. Higher temperatures can cause more evaporation and more intense rain in a shorter time, potentially causing flooding in wetlands [3]-[5]. Extreme or unusual temperatures can harm wetland ecosystems. Overheating, for example, can cause a drop in water levels and dry out wetlands, which can disrupt habitats and threaten the survival of species that live there. In wetlands, hot, dry weather can increase the risk of fire. If extreme temperatures continue, dry vegetation and the risk of wildfires will increase, endangering ecosystems and the surrounding environment [6]-[8]. Because of the numerous effects of temperature changes, it is necessary to forecast temperature to mitigate natural disasters that may occur in the wetland environment.

Various temperature prediction methods have been explored, including ARIMA (Autoregressive Integrated Moving Average), SARIMA (Seasonal ARIMA), LSTM (Long Short-Term Memory), and GRU (Gated Recurrent Unit) models [9–13]. Many studies have employed time series data for predictions, often using Recurrent Neural Network (RNN) architectures. Improved RNN variants, such as GRU and LSTM, have been widely adopted due to their superior performance over traditional RNN models. Long input sequences in RNNs often lead to exploding and vanishing gradients, an issue LSTM effectively mitigates through its gating mechanism, which regulates information flow and retains long-term dependencies in sequential data [10], [14]. LSTM can extract historical patterns more efficiently, outperforming conventional time series forecasting methods. GRU, a simplified LSTM variant, has fewer parameters, making it computationally more efficient while maintaining comparable accuracy [15], [16]. The hybrid GRU-LSTM model was chosen because it leverages the strengths of both architectures: LSTM's ability to capture long-term dependencies and GRU's computational efficiency. The proposed approach balances predictive accuracy and processing time by combining these models, making it well-suited for real-time temperature forecasting in wetland ecosystems. This architecture was optimized by tuning hyperparameters such as learning rate, batch size, and the number of hidden units to minimize prediction errors. The GRU-LSTM model has demonstrated higher accuracy than individual GRU and LSTM models and lower RMSE values than other prediction methods [17], [18].

To address the limitations of conventional models and improve prediction accuracy, this study proposes a novel workflow for air temperature prediction in wetland ecosystems by integrating the GRU-LSTM model. The proposed workflow

includes data collection, preprocessing, feature selection, model implementation, and performance evaluation using Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and R-squared (R^2) metrics. By combining the strengths of GRU and LSTM, this approach enhances the model's ability to capture complex temperature patterns while maintaining computational efficiency. This model is designed for practical implementation in environmental monitoring systems, enabling real-time temperature predictions that can assist policymakers and conservationists in making informed decisions. Additionally, the model's architecture is flexible and can be adapted to different geographical regions by retraining it with local temperature datasets. The GRU-LSTM model also demonstrates scalability, as it can be deployed on cloud-based platforms or edge computing devices, allowing for efficient processing of large-scale temperature data from multiple sensor networks. This model offers a viable solution for long-term wetland monitoring and disaster risk mitigation by balancing predictive accuracy and computational efficiency. Consequently, this study contributes to developing more accurate and efficient temperature prediction methods, supporting disaster risk mitigation and wetland conservation efforts.

II. MATERIAL

This study processed and analyzed data using a Lenovo Ideapad 330 15-ARR Laptop. The laptop has an AMD Ryzen 7 2700U processor, 8GB of RAM, a 1TB hard drive, and the Windows 10 operating system, providing sufficient data processing power. Table I presents the data sources used in this study.

TABLE I. SOURCE OF THE DATA

No.	Type of the Data	Source of the Data
1.	Data of Micro Air Temperature	Air temperature data from temperature sensors in the Liang Anggang Protected Forest Block 1
2.	Data of Macro Air Temperature	Daily Average Air Temperature Data from the Meteorology, Climatology and Geophysics Agency (BMKG) Online Data Syamsudin Noor Meteorological Station

TABLE II. DATASET

Date	Tavg
01-01-1996	25.60
01-02-1996	25.50
01-03-1996	26.50
01-04-1996	25.70
….	…
12-31-2021	27.20

This study used air temperature data from Liang Anggang Protected Forest Block 1, which included 42 records with 3-hour intervals and 42 daily average temperature values. The data was collected using IoT sensors and manual measurements to ensure comprehensive and reliable temperature monitoring. Additionally, macro-scale air temperature data was incorporated to provide a broader perspective on temperature variations. This dataset included daily average air temperature from the Meteorology, Climatology, and Geophysics Agency (BMKG) Online Data of the Syamsudin Noor Meteorological Station, covering 26 years (January 1, 1996 – December 31, 2021). Weekly and monthly average temperatures were also used to identify long-term trends and seasonal patterns. Table II presents an example of the collected air temperature data.

III. PROPOSED METHOD

The research flow is a series of steps required to conduct research systematically. Fig. 1 shows the research flow of this research.

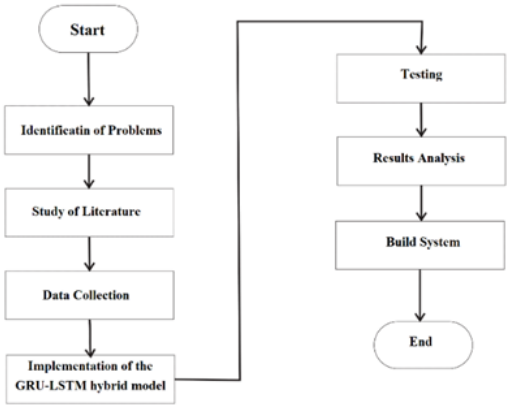

Fig. 1. Flow chart of research process.

The focus of this research shifted from data collection to testing to obtain model performance results that were used in the results analysis process, as shown in Fig. 2.

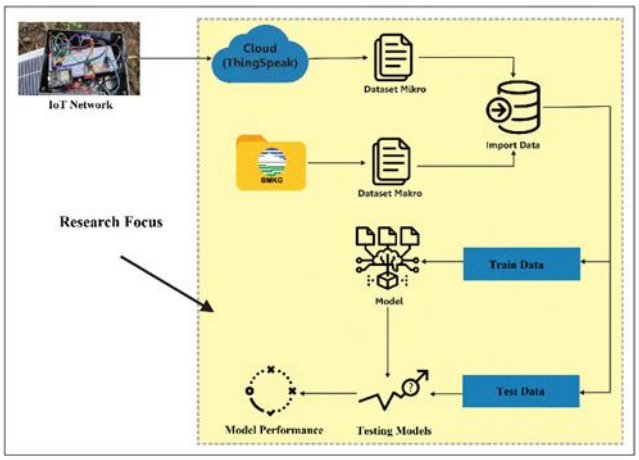

Fig. 2. Research focus.

A. Implementation of GRU-LSTM Hybrid Model

The GRU-LSTM hybrid model implementation process stages are shown in Fig. 3.

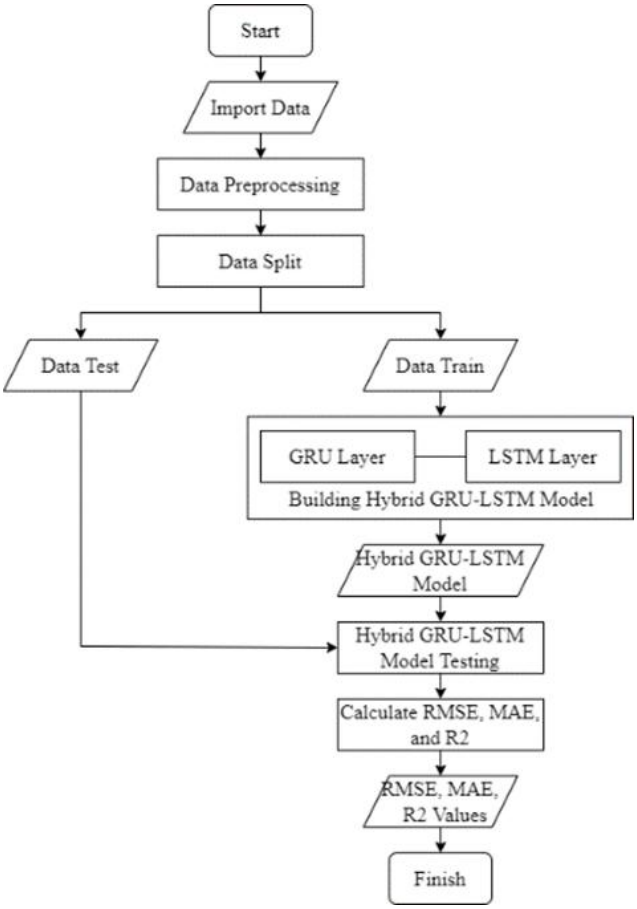

Fig. 3. Workflow model.

B. Data Preprocessing

The imported data was used as a data series during the data preprocessing stage, first by testing various input parameters and then using the Exponential (Weighted) Moving Average to fill in NaN values or empty values before being transformed using the Fast Fourier Transform.

1) Exponential (Weighted) Moving Average (EWMA): EWMA is a statistical method for smoothing datasets by decreasing data weight over time, and it is sensitive to process shifts [19]. The standard EWMA calculation is as follows:

$$S_t = \lambda e_t + (1-\lambda) S_{t-1} \quad (1)$$

Where S_t is the EWMA result, t is the time stamp, e_t is the average output, and λ is a constant ranging from 0 to 1 that controls the impact of historical data.

2) Fast Fourier Transform (FFT): Time series data is changed using FFT. FFT enhances the Discrete Fourier Transform (DFT) algorithm by leveraging periodicity and symmetry, significantly reducing the number of operations. FFT has the advantages of simplicity and speed. As a result, FFT is used to represent errors in the frequency domain to facilitate error identification [20], [21]. FFT can be calculated with [22]:

$$X_t(\mathrm{k}) = \sum_{t=1}^{\bar{N}} x_{ti} e^{\frac{-j2\pi}{\bar{N}} k(t-1)} \quad (2)$$

Where $X_i = [\, x_{1i}\, x_{2i} \cdots x_{\bar{N}i}]^T$, i $= 1, 2, \cdots,$ y, and $[\cdot]^T$ represents transpose from vector $[\cdot]$, $k = 0, 1, 2, \cdots, \bar{N} - 1$.

C. Data Sharing

For benchmarking, the datasets must be divided into training and test data. The model is trained using training data and evaluated using test data. This study conducted tests to assess various types of data-sharing ratios.

D. Model Establishing

The GRU-LSTM hybrid model was built with the GRU and LSTM layers from library keras.

1) Gated Recurrent Unit (GRU): GRU is a promising algorithm within the Recurrent Neural Network (RNN) [18]. GRU and LSTM cells operate similarly, but GRU cells use a hidden state that combines the forget gate and the input gate to form an update gate. GRU also combines hidden and cell states into a single state [22]. As a result, GRU is known as a simplified variant of LSTM [15]. The GRU equation is as follows [23]:

$$z_t = \sigma(W_z \cdot x_t + U_z \cdot h_{(t-1)} + b_z) \quad (3)$$

$$r_t = \sigma(W_r \cdot x_t + U_r \cdot h_{(t-1)} + b_r) \quad (4)$$

$$\tilde{h}_t = \tanh(W_h \cdot x_t + (r_t \circ U_h \cdot h_{(t-1)}) + b_h) \quad (5)$$

$$h_t = z_t \circ h_{(t-1)} + (1 - z_t) \circ \tilde{h}_t \quad (6)$$

Where z_t = update gate, σ = activation of the sigmoid function, W_z = weight of update gate, U_z = weight of hidden state, x_t = input value (input vector x in timestep t), $h_{(t-1)}$ = value of prior hidden state cell, b_z = bias of update gate, r_t = reset gate, W_r = weight of reset gate, U_r = weight of hidden state, b_r = bias of reset gate, $\tilde{h}_t$ = Output candidate from cell state vector, W_h = weight of cell state vector, U_h = weight of hidden state, b_h = bias of cell state vector, and h_t = cell state vector.

2) Long-Short Term Memory (LSTM): LSTM is a type of Recurrent Neural Network (RNN) that, when compared to conventional RNNs, allows the network to maintain long-term dependence between data at a specific time from many timesteps because LSTM uses special hidden blocks that remember input data for a long time [24], [25]. A typical LSTM unit consists of a memory cell, forget gate, input gate, and output gate, with the forget gate's purpose being to forget information in the cell state selectively, the input gate deciding what new information is stored in the cell state, and the output gate deciding what value to remove. The cell remembers the value over arbitrary time intervals, and three gates control the data flow into and out of the cell [26]. The LSTM application procedure is as follows [26]:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (7)$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (8)$$

$$\tilde{C}_t = tanh(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (9)$$

$$c_t = (f_t * c_{t-1} + i_t * \tilde{C}_t) \quad (10)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (11)$$

$$h_t = o_t * \tanh(c_t) \quad (12)$$

Where ft = forget gate, σ = sigmoid activation function, Wf = weight of forget gate, $ht-1$ = value of prior hidden state cell, xt = input value (input vector x in timestep t), bf = bias of forget gate, it = input gate, Wi = weight of input gate, bi = bias of input gate, $\tilde{C}t$ = candidate gate, Tanh = tanh activation function, Wc = weight of candidate gate, bc = bias of candidate gate, ct = cell gate, it = input gate, $\tilde{C}t$ = candidate gate, ft= forget gate, $ct-1$ = value of prior cell state, ot = output gate, Wo = weight of output gate, bo = bias of output gate, ht = hidden state, ct = cell gate. The LSTM architecture is shown in Fig. 4 [15]:

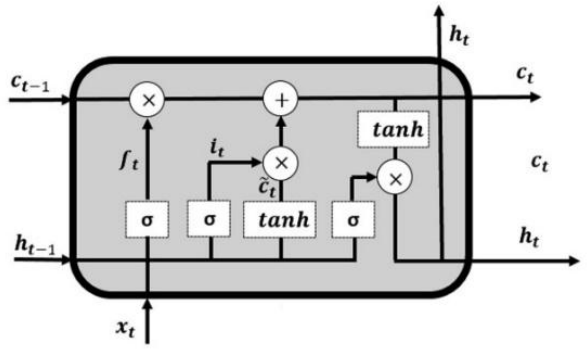

Fig. 4. LSTM architecture.

E. Model Testing

Model testing was carried out using test data to put the previously built GRU-LSTM hybrid model to the test.

F. Calculation of RMSE, MAE and R-Squared

The model test results was used to calculate performance using:

1) Root Mean Squared Error (RMSE): The root of the error value between the predicted and actual values is calculated to test the accuracy of prediction results [23]. The equation for calculating the RMSE value is as follow [27]:

$$\text{RMSE} = \sqrt{\sum_{i=1}^{n} \frac{(\tilde{y}_i - y_i)^2}{n}} \quad (13)$$

2) Mean Absolute Error (MAE): MAE measures the absolute difference between predicted and actual data, regardless of whether the difference is positive or negative [28]. The equation for calculating the MAE value is as follow [29]:

$$\text{MAE} = \frac{1}{n}\sum_{i=1}^{n} |\tilde{y}_i - y_i| \quad (14)$$

3) R-Squared (R^2): R2 or called by coefficient of determination is a statistical measure used to investigate the relationship between actual and predicted data results. R2 can range between $-\infty$ up to 1; the closer the R^2 value is to 1, the better the model fits the dataset [18], [27]. The equation for calculating the value of R^2 is as follows [28]:

$$\bar{Y} = \frac{1}{n}\sum_{i=1}^{n} y_i \quad (15)$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(\tilde{y}_i - y_i)^2}{\sum_{i=1}^{n}(\bar{Y} - y_i)^2} \quad (16)$$

Where n = total of the data, i = (1, 2, 3, 4, 5, …, l), l is the entire data set, $\bar{Y}$ = the mean value of the actual data, y_i = actual value, dan $\tilde{y}_i$ = predicted value.

G. Testing Research Indicators Using Macro Data

In this test scheme, tests was performed to determine the performance of the Hybrid GRU-LSTM model by varying the number of input parameters, data sharing ratios, epochs, batch sizes, neuron sizes, and the arrangement of the model's architectural layers using daily, weekly, and monthly macro air temperature data.

H. Testing the Macro GRU-LSTM Hybrid Model Using Micro Data

In this test scheme, the best model for each use of the data obtained in the previous test scheme was used to predict air temperature on a microscale interval of 3 hours and daily.

I. Comparing the GRU-LSTM Hybrid Model Using GRU and LSTM

In this test scheme, the model performance results of the GRU-LSTM Hybrid Model, the GRU model, and the LSTM Model were compared.

J. Analysis Results

The Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), and R-squared (R2) were used to calculate the results of model testing. The lower the RMSE and MAE values obtained, the better the performance of the tested model, and the closer to one the R2 value, the better the resulting model. All models' training times were compared to determine which model had the fastest performance.

IV. Results

The GRU-LSTM Hybrid model was created on the Google Collab platform using the Python language and various Python libraries, such as time, numpy, pandas, sklearn, TensorFlow, and Keras. Fig. 5 shows the architecture of the GRU-LSTM Hybrid model [17].

The GRU model was created using 2 Layer GRU and 2 Layer Dense neurons with a size of 240. ReLU activation was used in the first GRU layer, ELU activation in the second GRU layer, and ReLU activation in the two Dense layers. The LSTM model was created using two layers of LSTM and two layers of Dense with 240 neuron sizes. The first LSTM layer was activated with ReLU, the second GRU layer with ELU, and the two Dense layers with ReLU. Using the add() function from keras.layers, the GRU and LSTM models were combined into a parallel GRU-LSTM model. The model now includes 3 Layer Dense with ELU activation and 240 neuron size, as well as 1 Layer Dense with Linear activation and 240 neuron size. Finally, as the model's output, a Dense Layer with one neuron size was added. The Adam Optimizer was used to build the model, with a learning rate of 0.00015, an L2 Regularizer of 10-4, 20 epochs, and a batch size of 64. This GRU-LSTM hybrid model was used to train each test scheme.

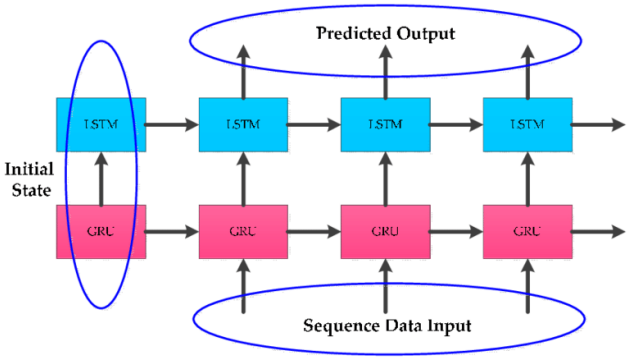

Fig. 5. Architecture of GRU-LSTM hybrid model.

A. Testing Data Preprocessing Techniques

This test was carried out by comparing the use of Min-Max Scaling with the Fast Fourier Transform to 7 NaN Handling techniques. Table III shows the results of testing each data preprocessing scheme using Min-Max Scaling:

TABLE III. COMPARISON OF NAN TECHNIQUES USING MIN-MAX SCALING

Missing Value Techniques	RMSE	MAE	R^2	Duration (s)
Mean	0.6844244536	0.4679480707	-0.1507817381	11.535
Median	0.6739228724	0.4521220334	-0.1240336428	12.755
Last Observation Carried Forward	0.7017514004	0.5292969394	-0.0704251303	11.038
Exponential (Weighted) Moving Average	0.6816600892	0.4810926004	-0.2355169779	11.272
Interpolation Linear	0.7437746843	0.5975289210	0.0155255931	12.202
Interpolation Spline	0.7421904651	0.5940747193	0.0197149326	10.993
Interpolation Time	0.7461391790	0.5987105870	0.0092562629	12.290

Based on this test, it is clear that the various preprocessing stages impact the model's performance. Four of the seven techniques tested with Min-Max Scaling had a negative R^2 value, indicating that the model did not adequately fit the data. This study obtained the best preprocessing stages using the Exponential (Weighted) Moving Average for NaN handling and the Fast Fourier Transform for data transformation, as shown in Table IV.

TABLE IV. COMPARISON OF NAN HANDLING TECHNIQUES USING THE FAST-FOURIER TRANSFORM

Missing Value Techniques	RMSE	MAE	R^2	Duration (s)
Mean	0.1290396570	0.1057177850	0.9590938765	11.822
Median	0.1270965006	0.1043401824	0.9600215361	11.272

Interpolation Spline	0.1664941613	0.1479380850	0.9506690292	14.679
Interpolation Time	0.1645815491	0.1457774991	0.9517959046	11.428

B. Testing the Total of Data

Table V shows the test results obtained from testing the amount of data using daily macro air temperature data.

TABLE V. RESULTS OF DAILY MACRO DATA TESTING BASED ON TOTAL DATA

Total of the Data	RMSE	MAE	R^2	Duration (s)
50	0.1851642148	0.1498968825	0.9340657953	9.079
100	0.1523455190	0.1254774662	0.9623533541	10.857
200	0.1265524442	0.1079908816	0.9674943384	11.948
300	0.1174715265	0.0959396310	0.9633074235	13.293
500	0.1700496630	0.1323210940	0.9593256173	18.942
1000	0.1802263938	0.1456180500	0.9560157537	22.164
2000	0.1680635190	0.1345518316	0.9591325611	29.965
4000	0.1667981339	0.1313218270	0.9629232147	50.314
8000	0.1735634802	0.1304684863	0.9647927358	86.563

When testing the amount of data with daily average macro air temperature data, 300 data points produced the lowest RMSE and MAE values, 200 data points produced the highest R2 values, and 50 data points produced the shortest model training duration. The test scheme applied 300 data points to obtain the best model performance on this research indicator. The test results obtained from testing the amount of data using weekly macro air temperature data are shown in Table VI.

TABLE VI. RESULTS OF WEEKLY MACRO DATA TESTING BASED ON TOTAL DATA

Total of the Data	RMSE	MAE	R^2	Duration (s)
50	0.0623367201	0.0511048617	0.9455028859	10.697
100	0.1371391608	0.1088339692	0.8295841737	13.122

Total of the Data	RMSE	MAE	R^2	Duration (s)
200	0.1554007142	0.1264640826	0.9198697611	10.850
300	0.1634344265	0.1335772436	0.9185153251	13.031
500	0.1330690852	0.1018681449	0.9483418575	14.694
1000	0.1250917579	0.0985749315	0.9648619295	26.889

When testing the amount of data with weekly average macro air temperature data, the lowest RMSE and MAE values were obtained using 50 data, the highest R^2 values were obtained using 1000 data, and the fastest model training duration was obtained using 50 data. The test scheme applied 50 data points to get the best model performance on this research indicator. Table VII shows the results obtained in testing the amount of data using monthly macro air temperature data.

TABLE VII. RESULTS OF MONTHLY MACRO DATA TESTING BASED ON TOTAL DATA

Total of the Data	RMSE	MAE	R^2	Duration (s)
50	0.1712211232	0.1550369370	0.7706810377	10.477
100	0.1649493670	0.1474490374	0.8194394220	9.683
200	0.1452670353	0.1231163900	0.9068988647	11.418
300	0.1420492412	0.1233844163	0.9335440337	13.327

Testing with monthly average macro air temperature data showed that 300 data points yielded the lowest RMSE and highest R^2, 200 data points had the lowest MAE, and 50 data points resulted in the shortest training time. The test scheme applied 300 data points to achieve the best model performance, as shown in Fig. 6.

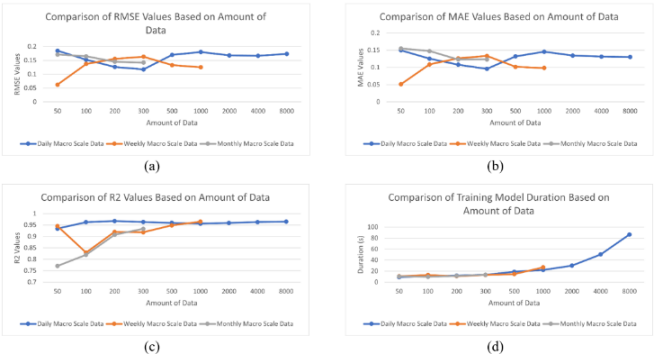

Fig. 6. Analysis of model performance results based on total data (a) RMSE Value, (b) MAE Value, (c) R2 Value, (d) Model training duration.

Increasing the data amount did not continually improve performance; data variations influenced results. For instance, with daily macro temperature data, 300 data points had a lower error rate than 200 or 500, whereas with weekly data, 300 data points had the highest error rate.

C. Parameter Input Testing

Table VIII shows the test results obtained in the input parameter test using daily macro air temperature data.

TABLE VIII. RESULTS OF DAILY MACRO DATA TESTING BASED ON PARAMETER INPUT

Parameter Input	RMSE	MAE	R^2	Duration (s)
1 day	0.4947327263	0.3840819742	0.3491899320	7.326
2 days	0.2478204263	0.1922136994	0.8366996247	9.103
3 days	0.1838271449	0.1453921775	0.9101470651	6.824
4 days	0.1541403522	0.1312984414	0.9368249379	6.975
5 days	0.1393977268	0.1110161938	0.9483316768	7.318
6 days	0.1163984780	0.0952625401	0.9639747016	6.925
7 days	0.1002650901	0.0804510812	0.9732691678	9.645
8 days	0.0902920465	0.0726037929	0.9783223612	7.895
9 days	0.0782327439	0.0637689138	0.9837261575	6.967
10 days	0.0744849001	0.0633215273	0.9852480489	7.635
11 days	0.0731881517	0.0594071249	0.9857572273	7.047
12 days	0.0765548540	0.0585217093	0.9844167352	7.538

The lowest RMSE value was in the use of 11 daily average data to predict the next day's average, the lowest MAE value was in the use of 12 daily average data to predict the next day's average, the highest R^2 value was in the use of 11 daily average data to predict the next day's average, and the fastest model training duration was in the use of 3 daily average data to predict the next day's average. To achieve the best model performance on this research indicator, the test scheme applied 11 Input Parameters that use 11 daily average data to predict the next day's average. The test results obtained in the input parameter test using weekly macro air temperature data is shown in Table IX.

TABLE IX. RESULTS OF WEEKLY MACRO DATA TESTING BASED ON PARAMETER INPUT

Parameter Input	RMSE	MAE	R^2	Time (s)
1 week	0.3119153610	0.2365223692	0.7032010388	6.849
2 weeks	0.1542141168	0.1180309918	0.9274500509	7.787
3 weeks	0.1909112509	0.1624875251	0.8888135417	7.846
4 weeks	0.1851261596	0.1540472429	0.8954499045	7.708
5 weeks	0.1701543518	0.1398497052	0.9116767640	9.665
6 weeks	0.1594423340	0.1269611427	0.9224474403	8.832
7 weeks	0.1582014176	0.1261986688	0.9236499033	7.102
8 weeks	0.1462549959	0.1217502412	0.9347455294	9.227
9 weeks	0.1272247907	0.1041676132	0.9506221313	11.002
10 weeks	0.1145790877	0.0905048298	0.9599502721	8.880
11 weeks	0.1155339656	0.0965910716	0.9592799586	9.063
12 weeks	0.0976961789	0.0799839595	0.9708831757	10.617

When the input parameters were tested using weekly average macro air temperature data, the lowest RMSE and MAE values

were obtained using 12 weekly average data to predict the following week's average, the highest R^2 value was obtained using 12 weekly average data to predict the following week's average, and the shortest model training duration was obtained by using one weekly average data to predict the following week's average. To achieve the best model performance on this research indicator, the test scheme applied 12 Input Parameters that used 12 weekly average data to predict the following week's average. The test results obtained in the input parameter test using monthly macro air temperature data are shown in Table X.

TABLE X. RESULTS OF MONTHLY MACRO DATA TESTING BASED ON INPUT DATA

Parameter Input	RMSE	MAE	R^2	Duration (s)
1 month	0.2520620441	0.2141007492	0.7907473106	7.227
2 months	0.1328624270	0.1141378974	0.9418619443	7.976
3 months	0.1890981064	0.1546116300	0.8822311320	10.817
4 months	0.1929430235	0.1650484307	0.8773932727	9.214
5 months	0.1738967881	0.1457596050	0.9004046042	9.102
6 months	0.1413953839	0.1238171764	0.9341544236	8.743
7 months	0.1078759913	0.0922371984	0.9616729194	11.342
8 months	0.0801424696	0.0654195946	0.9788465317	13.374
9 months	0.0738925268	0.0626033554	0.9820172057	16.962
10 months	0.0588448555	0.0470539990	0.9885955816	13.186
11 months	0.0712976266	0.0640248735	0.9832580405	12.678
12 months	0.0568075286	0.0465924708	0.9893715990	14.567

When the input parameters were tested using monthly average macro air temperature data, the lowest RMSE and MAE values were obtained using 12 monthly average data to predict the next month's average, the highest R^2 value was obtained using 12 monthly average data to predict the next month's average, and the shortest model training duration was obtained using one monthly average data to predict the next month's average. To achieve the best model performance on this research indicator, the test scheme applied 12 Input Parameters that used 12 monthly average data to predict the next month's average. The analysis of the effect of the number of input parameters on the performance of the Hybrid GRU-LSTM model is shown in Fig. 7.

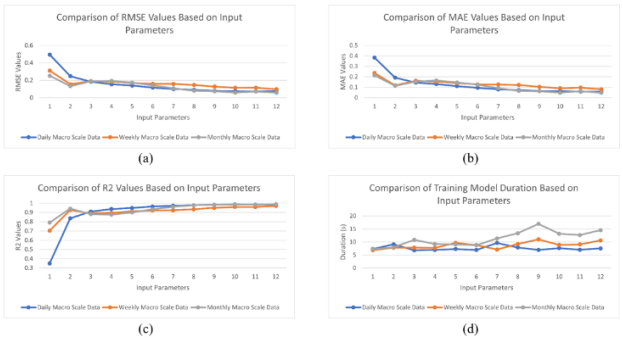

Fig. 7. Analysis of model performance results based on input parameters (a) RMSE Value, (b) MAE Value, (c) R^2 Value, (d) Model training duration.

Increasing the number of input parameters affected the model's performance. Each data use almost always resulted in a non-significant decrease in error rate from 3 input parameters to 12 input parameters. Increasing the number of input parameters from one to two significantly improved model performance, so using a GRU-LSTM hybrid model with one input parameter was not recommended.

D. Testing of Data Sharing Ratio

Table XI shows the test results obtained when testing the data sharing ratio using daily macro air temperature data.

TABLE XI. RESULTS OF DAILY MACRO DATA TESTING BASED ON DATA SHARING RATIO

Data Sharing Ratio	RMSE	MAE	R^2	Duration (s)
50 : 50	0.1746709404	0.1380718406	0.9607895299	10.457
60 : 40	0.1704924270	0.1366307721	0.9618051593	13.888
70 : 30	0.1854317031	0.1515861214	0.9537578721	13.381
80 : 20	0.1651222128	0.1313805477	0.9569454454	11.056
90 : 10	0.1164872255	0.0956705397	0.9639197460	12.978

Testing the data-sharing ratio using daily average macro air temperature data revealed that a 90:10 ratio provided the best model performance, with the lowest RMSE and MAE values and the highest R^2 value. In contrast, a 50:50 ratio significantly reduced the training time but at the cost of lower model accuracy. These findings indicate that a more extensive training dataset (90%) enhances model learning, leading to better predictive performance. The test scheme applied a 90:10 data-sharing ratio to optimize performance based on these results. Further analysis of the impact of data-sharing ratios using weekly average macro air temperature data is presented in Table XII.

TABLE XII. RESULTS OF WEEKLY MACRO DATA TESTING BASED ON DATA SHARING RATIO

Data Sharing Ratio	RMSE	MAE	R^2	Duration (s)
50 : 50	0.1310978587	0.1054439719	0.9654619062	11.361
60 : 40	0.1430146436	0.1128988945	0.9627798949	11.728
70 : 30	0.1393393249	0.1107925050	0.9557609879	12.986
80 : 20	0.1304721654	0.1024591358	0.9551738898	12.774
90 : 10	0.1573456424	0.1253423013	0.9244736860	15.262

When testing the data sharing ratio with weekly average macro air temperature data, the 80:20 ratio had the lowest RMSE and MAE values, the 50:50 ratio had the highest R^2 value, and the 50:50 ratio had the shortest model training duration. Table XIII shows the results obtained when testing the data-sharing ratio using monthly macro air temperature data.

TABLE XIII. RESULTS OF MONTHLY MACRO DATA TESTING BASED ON DATA SHARING RATIO

Data Sharing Ratio	RMSE	MAE	R^2	Duration (s)
50 : 50	0.1763222753	0.1431057810	0.8977571251	11.401
60 : 40	0.1730447912	0.1381097616	0.8966686071	11.724
70 : 30	0.1717020795	0.1433728574	0.9059654873	15.100
80 : 20	0.1353351706	0.1142427518	0.9230716267	13.004
90 : 10	0.1533416137	0.1331341740	0.9225580644	10.967

When testing the data sharing ratio with monthly average macro air temperature data, the 80:20 ratio produced the lowest RMSE and MAE values, the 80:20 ratio produced the highest R^2, and the 90:10 ratio produced the shortest model training duration. To achieve the best model performance on this research indicator, the test scheme applied an 80:20 Data Sharing Ratio. Fig. 8 shows the analysis of the effect of the data-sharing ratio on the performance of the Hybrid GRU-LSTM model.

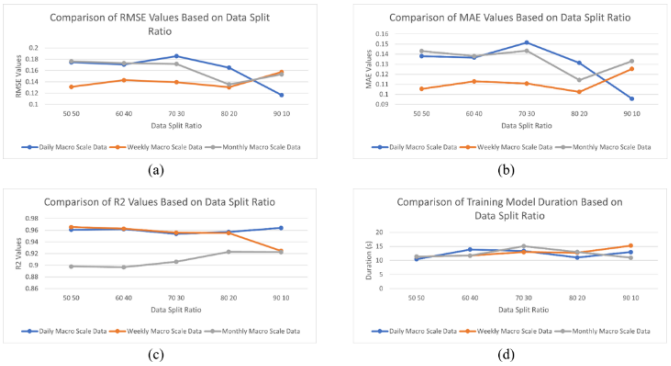

Fig. 8. Analysis of model performance results based on data sharing ratio (a) RMSE Value, (b) MAE Value, (c) R^2 Value, (d) Model training duration.

Changes in the data share ratio affected model performance, but data also affected it. Based on this test, the best data-sharing ratio for each data set was not found.

E. Epoch Testing

The epoch test results obtained using daily macro air temperature data are shown in Table XIV.

TABLE XIV. RESULTS OF MONTHLY MACRO DATA TESTING BASED ON EPOCH

Epochs	RMSE	MAE	R^2	Duration (s)
10	0.1412090605	0.1098501957	0.9469801969	10.081
20	0.1178582018	0.0964495148	0.9630654677	12.043
30	0.1159206586	0.0952576068	0.9642698645	17.625
40	0.1158310883	0.0951873015	0.9643250595	18.672
50	0.1162878559	0.0955324685	0.9640431441	18.745
60	0.1159376773	0.0948069858	0.9642593724	21.236
70	0.1173887879	0.0965781303	0.9633590926	22.936
80	0.1162496231	0.0956332868	0.9640667838	27.657
90	0.1163170192	0.0956855566	0.9640251069	27.304
100	0.1161146882	0.0951103535	0.9641501532	30.338

On this research indicator, the test scheme with 40 Epoch yielded the best model performance. The epoch test results obtained using weekly macro air temperature data is shown in Table XV:

TABLE XV. RESULTS OF WEEKLY MACRO DATA TESTING BASED ON EPOCH

Epochs	RMSE	MAE	R^2	Duration (s)
10	0.1625175407	0.1327365961	0.9194270372	11.416
20	0.1600507480	0.1281993821	0.9218544474	12.325
30	0.1612495635	0.1296542749	0.9206794082	17.127
40	0.1615903931	0.1300313808	0.9203437375	15.127
50	0.1609623787	0.1293785623	0.9209616959	28.846
60	0.1603825770	0.1283413292	0.9215300773	27.610
70	0.1610848606	0.1292554419	0.9208413641	28.765
80	0.1584860572	0.1260031276	0.9233749144	28.937
90	0.1589206752	0.1266394984	0.9229540786	24.613
100	0.1607210281	0.1285202697	0.9211985418	50.008

The test scheme with 80 Epoch yielded the best model performance on this research indicator. The epoch test results obtained using monthly macro air temperature data is shown in Table XVI.

TABLE XVI. RESULTS OF MONTHLY MACRO DATA TESTING BASED ON EPOCH

Epochs	RMSE	MAE	R^2	Duration (s)
10	0.1768219120	0.1485940880	0.8970258287	14.240
20	0.1443285145	0.1265315739	0.9313942646	11.598
30	0.1401524357	0.1229330155	0.9353069778	17.838
40	0.1396633099	0.1222866899	0.9357577414	17.241
50	0.1388041207	0.1213296601	0.9365457289	28.092
60	0.1409545112	0.1233228180	0.9345643983	20.015
70	0.1397881914	0.1223504527	0.9356428042	28.075
80	0.1404582682	0.1230280480	0.9350243311	28.311
90	0.1391538159	0.1214379346	0.9362256001	27.242
100	0.1401636231	0.1227904198	0.9352966494	47.246

The test scheme with 50 epochs yielded the best model performance on this research indicator. Fig. 9 analyzes the effect

of the number of epochs on the performance of the Hybrid GRU-LSTM model.

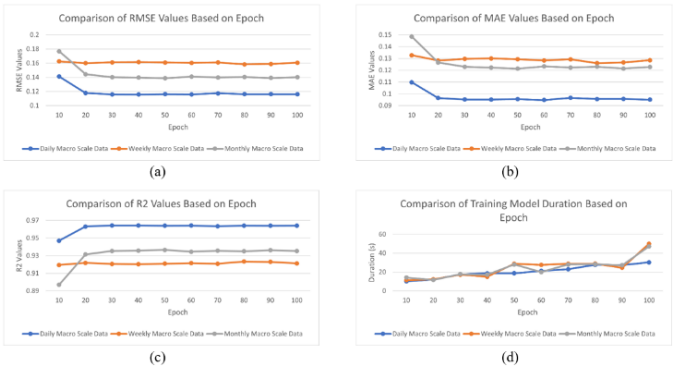

Fig. 9. Analysis of model performance results based on the number of Epoch (a) RMSE Value, (b) MAE Value, (c) R^2 Value, (d) Model training duration.

The number of epochs did not significantly affect the model's performance; only when the number of epochs was increased from 10 to 20, the error rate decreased by 0.02 - 0.04, and the MAE value decreased by 0.03 - 0.02. Other tests tended to have the same error rate, with the RMSE value being 0.12 for daily macro data, 0.16 for weekly macro data, and 0.14 for monthly macro data.

F. Batch Size Testing

Table XVII presents the results of the batch size test using daily macro air temperature data, comparing model performance across different batch sizes. The table shows how batch size affects error values (RMSE, MAE, and R^2) and training stability. Smaller batch sizes may improve generalization but require more iterations, while larger batch sizes can speed up training but may lead to overfitting. This analysis helps determine the optimal batch size for the Hybrid GRU-LSTM model.

TABLE XVII. RESULTS OF DAILY DATA TESTING BASED ON BATCH SIZE

Batch Size	RMSE	MAE	R^2	Duration (s)
32	0.1165713735	0.0960287397	0.9638675999	16.838
64	0.1161702623	0.0956351955	0.9641158285	12.916
128	0.1182457040	0.0959229463	0.9628221966	10.385

The test scheme with 64 Batch Sizes yielded the best model performance on this research indicator. The results of the batch size test using weekly macro air temperature data is shown in Table XVIII:

TABLE XVIII. RESULTS OF WEEKLY MACRO DATA TESTING BASED ON BATCH SIZE

Batch Size	RMSE	MAE	R^2	Duration (s)
32	0.1599404943	0.1278730529	0.9219620741	15.048
64	0.1579052215	0.1257131268	0.9239355319	12.542
128	0.1635250788	0.1345633975	0.9184249057	11.566

The test scheme with 64 Batch Sizes yielded the best model performance on this research indicator. The results of the batch size test using monthly macro air temperature data are shown in Table XIX:

TABLE XIX. RESULTS OF MONTHLY DATA TESTING BASED ON BATCH SIZE

Batch Size	RMSE	MAE	R^2	Duration (s)
32	0.1405752504	0.1233503645	0.9349160546	12.019
64	0.1423798040	0.1245906945	0.9332343744	13.026
128	0.1836717030	0.1569849137	0.8888931982	11.357

The test scheme with 32 batch sizes yielded the best model performance for this research indicator. Fig. 10 shows the analysis of the effect of batch size on the performance of the Hybrid GRU-LSTM model.

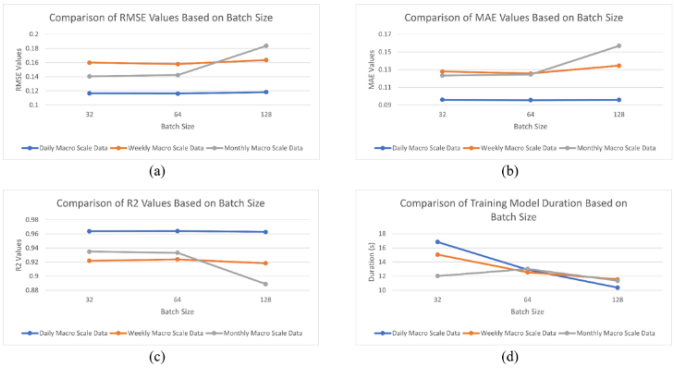

Fig. 10. Analysis of model performance results based on total batch size (a) RMSE Value, (b) MAE Value, (c) R^2 Value, (d) Model training duration.

Increasing the number of batch sizes did not affect the model's performance. Except for using 128 batch sizes, the model performance was consistent across tests, with the RMSE value at 0.12 for daily macro data, 0.16 for weekly macro data, and 0.14 for monthly macro data.

G. Neuron Size Testing

The neuron size test results obtained using daily macro air temperature data are shown in Table XX.

TABLE XX. RESULTS OF DAILY MACRO DATA TESTING BASED ON NEURON SIZE

Neuron Size	RMSE	MAE	R^2	Duration (s)
10	0.1474003564	0.1178712074	0.9422289780	8.242
20	0.1516744342	0.1224722308	0.9388301028	11.471
30	0.1472699419	0.1163316259	0.9423311602	9.093
60	0.1228602713	0.0997256246	0.9598638304	10.605
120	0.1157847143	0.0940748270	0.9643536193	10.974
240	0.1165024016	0.0957993578	0.9639103442	12.659

Based on this research indicator, the test scheme with a neuron size of 120 produced the best model performance. The

results of the neuron size test using weekly macro air temperature data are presented in Table XXI.

TABLE XXI. RESULTS OF WEEKLY MACRO DATA TESTING BASED ON NEURON SIZE

Neuron Size	RMSE	MAE	R^2	Duration (s)
10	0.1682801592	0.1389587059	0.9136117495	9.663
20	0.1677301907	0.1378873890	0.9141754902	10.070
30	0.1620301639	0.1322839767	0.9199095760	8.496
60	0.1605895360	0.1284312306	0.9213274301	9.727
120	0.1627621243	0.1322071073	0.9191843353	10.361
240	0.1603681788	0.1286783949	0.9215441658	11.524

The test scheme with 240 Neuron Size produced the best model performance on this research indicator. The neuron size test results obtained using monthly macro air temperature data are shown in Table XXII.

TABLE XXII. RESULTS OF MONTHLY MACRO DATA TESTING BASED ON NEURON SIZE

Neuron Size	RMSE	MAE	R^2	Duration (s)
10	0.1822280375	0.1554668319	0.8906329402	9.285
20	0.1878851786	0.1603905481	0.8837370911	10.220
30	0.1896031054	0.1620292374	0.8816012730	10.887
60	0.1441418736	0.1270096016	0.9315715872	9.028
120	0.1481143123	0.1263619519	0.9277479467	11.299
240	0.1413978662	0.1237826017	0.9341521117	12.373

The test scheme with 240 neuron sizes produced the best model performance for this research indicator. Fig. 11 examines the effect of neuron size on the performance of the Hybrid GRU-LSTM model. Increasing the number of neuron sizes affected the model's performance. Increasing the number of neuron sizes from 30 to 60 significantly improved model performance, and the error rate decreased by around 0.03 - 0.05 in tests using daily macro data and monthly macro data.

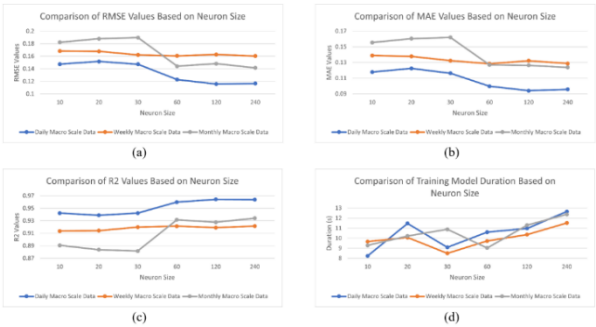

Fig. 11. Analysis of model performance based on number of neuron sizes (a) RMSE value, (b) MAE value, (c) R^2 value, (d) Training duration.

H. Layer Testing

Layer testing was conducted by modifying the model's layer arrangement. The scheme used to test the layer is shown in Table XXIII.

TABLE XXIII. LAYER TESTING SCHEME

Scheme	Description
Scheme 1	In the GRU-LSTM parallel model, each has 1 GRU/LSTM Layer and 1 Dense Layer
Scheme 2	In the GRU-LSTM parallel model, each has 2 GRU/LSTM Layer and 1 Dense Layer
Scheme 3	In the GRU-LSTM parallel model, each has 3 GRU/LSTM Layer and 1 Dense Layer
Scheme 4	In the parallel GRU-LSTM model, each has 1 GRU/LSTM Layer and 2 Dense Layers
Scheme 5	In the parallel GRU-LSTM model, each has 2 GRU/LSTM Layer and 2 Dense Layers
Scheme 6	In the parallel GRU-LSTM model, each has 3 GRU/LSTM Layer and 2 Dense Layers
Scheme 7	In the parallel GRU-LSTM model, each has 1 GRU/LSTM Layer and 3 Dense Layers
Scheme 8	In the parallel GRU-LSTM model, each has 2 GRU/LSTM Layer and 3 Dense Layers
Scheme 9	In the parallel GRU-LSTM model, each has 3 GRU/LSTM Layer and 3 Dense Layers
Scheme 10	In the parallel GRU-LSTM model, each has 2 GRU/LSTM Layers, 1 Dropout Layer, and 2 Dense Layers
Scheme 11	In the parallel GRU-LSTM model, each has 1 Layer GRU/LSTM, 1 Layer Dropout, 1 Layer GRU/LSTM, 1 Layer Dropout, and 2 Layers Dense
Scheme 12	Using 1 Layer Dense after implementing the GRU-LSTM parallel model
Scheme 13	Using 2 Layer Dense after implementing the GRU-LSTM parallel model
Scheme 14	Using 3 Layer Dense after implementing the GRU-LSTM parallel model
Scheme 15	Using 4 Layer Dense after implementing the GRU-LSTM parallel model

The layer test results obtained using daily macro air temperature data are shown in Table XXIV:

TABLE XXIV. RESULTS OF DAILY MACRO DATA TESTING BASED ON LAYER

Layers	RMSE	MAE	R^2	Duration (s)
Scheme 1	0.1207798570	0.0960987393	0.9612115875	9.724

Test Scheme 2 achieved the best model performance on this research indicator using a parallel GRU-LSTM model with 2 Layers of GRU/LSTM and one dense layer. Fig. 12 shows the analysis of the effect of layers on the performance of the Hybrid GRU-LSTM model.

Fig. 12. Analysis of model performance results based on layer testing scheme (a) RMSE Value, (b) MAE Value, (c) R^2 Value, (d) Model Training Duration.

Layer changes had no discernible effect on model performance. Increasing or decreasing the number of layers did not affect the model error rate; the model error rate only increased significantly when the Dropout Layer was added in Schemes 10 and 11. As a result, using the GRU-LSTM hybrid model with a dropout layer in testing with 300 data points was not recommended.

I. Testing the GRU-LSTM Hybrid Model for Macro Data for Micro Data

This test applied a model trained on macro air temperature data to test micro air temperature data. The model used is as follows:

1) Model 1: This GRU-LSTM hybrid model was built with Daily Macro Data, incorporating 11 daily averages to predict the average of the following days.

2) Model 2: The GRU-LSTM LSTM hybrid model was built using Weekly Macro Data and 50 weekly average data points.

3) Model 3: This GRU-LSTM hybrid model was built using monthly macro data by combining 12 monthly averages

to predict the next month's average.

Table XXVII shows the test results obtained in the GRU-LSTM Hybrid Model t2st, which was built using macro data to predict micro data every 3 hours:

TABLE XXVII. RESULTS OF MACRO DATA MODEL USING MICRO DATA PER 3 HOURS

GRU-LSTM Hybrid Models	RMSE	MAE	R^2
Model 1	1.0422397749	0.9398446809	0.9536844965
Model 2	1.8543152148	1.5887022426	0.8533918118
Model 3	0.8673054280	0.7361485392	0.9679273214

A test that used Model 3 to predict micro air temperature every 3 hours had the best model performance in this test. The temperature changes during the day were significant, reaching 3 - 14 °C, so micro air temperature data with 3-hour intervals had several outlier data. These significant temperature changes affected the model's performance. As a result, using models trained on daily, weekly, and monthly macro data still resulted in a relatively high error rate. The test results obtained in the GRU-LSTM Hybrid Model test, which was built using macro data to predict daily microdata, are shown in Table XXVIII:

TABLE XXVIII. TESTING RESULTS OF THE MACRO DATA MODEL USING DAILY MICRO DATA

GRU-LSTM Hybrid Models	RMSE	MAE	R^2
Model 1	0.2307456696	0.1950775580	0.9812115284
Model 2	0.3606277068	0.2694757832	0.9541074158
Model 3	0.2270860682	0.1908012237	0.9818027687

The best model performance in this test was in a test that used Model 3 to predict micro air temperature every 3 hours. The graph of model performance results is shown in Fig. 13.

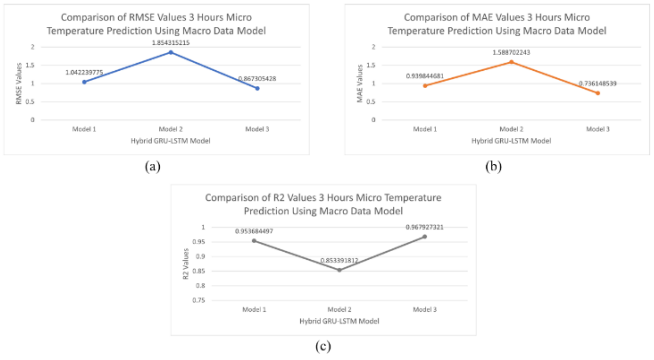

Fig. 13. Analysis of macro data model performance results for prediction of microtemperature per 3 hours (a) RMSE value, (b) MAE value, (c) R^2 value.

The model's performance was tested in predicting daily micro air temperature using a model trained using daily, weekly, and monthly macro data. This model showed a lower error rate than testing using data with 3-hour intervals.

J. GRU, LSTM and Hybrid GRU-LSTM Model Testing

This evaluation compares the performance of the GRU, LSTM, and Hybrid GRU-LSTM models in handling sequential data. Fig. 14 presents the results for each test scheme, highlighting their accuracy and efficiency. This provides insights into the strengths and suitability of each model for forecasting tasks.

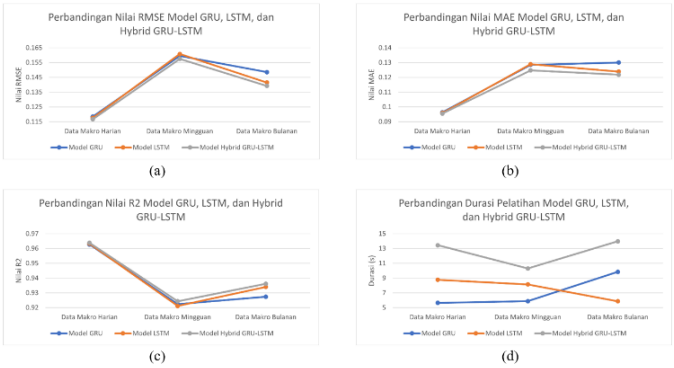

Fig. 14. Analysis of performance model results of GRU Model, LSTM Model, and GRU-LSTM Hybrid Model (a) RMSE Value, (b) MAE Value, (c) R^2 Value, (d) Model Training Duration.

Table XXIX compares the Gated Recurrent Unit (GRU), Long Short-Term Memory (LSTM), and Hybrid GRU-LSTM models. This table highlights their predictive accuracy, efficiency, and overall performance in handling sequential data.

In every use of the data tested, the GRU-LSTM Hybrid Model outperformed the GRU-only and LSTM-only Models. Fig. 15 shows a performance comparison analysis of the GRU, LSTM, and Hybrid GRU-LSTM Modes. The prediction results of the GRU-only model, the LSTM-only model, and the GRU-LSTM Hybrid model on daily, weekly, and monthly macro data did not differ significantly. The model performance results showed significant results. If larger quantities were predicted, this has not been investigated further.

TABLE XXIX. COMPARISON RESULTS OF GRU, LSTM, AND GRU-LSTM HYBRID MODELS

Data Using	Model Using	RMSE	MAE	R^2	Duration (s)
Daily Macro Data	GRU model	0.1184584205	0.0964402422	0.9626883153	5.650
	LSTM models	0.1176304218	0.0959534831	0.9632080936	8.774
	GRU-LSTM Hybrid models	0.1166597038	0.0955331357	0.9638128215	13.437
Weekly Macro Data	GRU model	0.1594879534	0.1285021928	0.9224030555	5.875
	LSTM models	0.1607783534	0.1289006750	0.9211423186	8.146
	GRU-LSTM Hybrid models	0.1575065981	0.1247597571	0.9243190886	10.293

Data Using	Model Using	RMSE	MAE	R^2	Duration (s)
Monthly Macro Data	GRU model	0.1485245039	0.1300583339	0.9273471991	9.837
	LSTM models	0.1415222437	0.1239307644	0.9340362175	5.858
	GRU-LSTM Hybrid models	0.1392682847	0.1217903526	0.9361206344	13.975

V. DISCUSSION

The choice of data preprocessing techniques significantly influenced the performance of the GRU-LSTM hybrid model. Using Min-Max Scaling with various NaN handling methods resulted in suboptimal performance, with four out of seven techniques showing negative R^2 values, indicating a poor model fit. However, applying the Fast Fourier Transform (FFT) improved model accuracy across all NaN handling techniques. The Exponential (Weighted) Moving Average technique produced the best results with the lowest RMSE and MAE values and the highest R^2 value. These results indicate that FFT effectively transforms data so that the model can better recognize patterns.

Increasing the amount of training data did not continuously improve model performance. In daily macro temperature data, 300 data points produced the lowest RMSE and MAE values, while 200 data points yielded the highest R^2 value. However, the error rate also increased when the data size increased to 500 or more. A similar pattern was found in the weekly and monthly data tests, where the optimal amount of data varied. These results suggest that excessive data can lead to information overload or noise accumulation, which disrupts model accuracy. This finding is significant for real-world applications where computational resources are limited. This study provides a practical guideline for selecting training data without unnecessary computational costs by identifying the optimal data size for different timescales.

The number of input parameters played a crucial role in improving prediction accuracy. For daily macro temperature predictions, the model achieved the best performance using 11 days of historical data, while for weekly and monthly data, 12 weeks and 12 months of historical data provided the most optimal results. Increasing input parameters beyond a certain threshold did not significantly enhance model performance. This indicates that only a certain amount of historical data provides relevant information for the model to predict future air temperatures. In practical applications, this insight helps optimize data storage and processing requirements by preventing excessive use of historical data that does not contribute to better predictions.

The ratio of training to testing data affected the model's effectiveness. A 90:10 split produced the best daily macro temperature data accuracy, while an 80:20 split yielded optimal results in weekly and monthly datasets. This difference suggests that the optimal ratio depends on the scale of the data used. An extreme split, such as 50:50, speeds up training time but reduces the model's ability to generalize new data. Conversely, a 90:10 ratio risks overfitting because the training data dominates too much. These findings are helpful for practitioners who need to balance training time and model generalization, particularly in operational forecasting systems where real-time updates are essential.

The number of epochs used in training did not significantly affect model accuracy. The most notable improvement occurred between 10 and 20 epochs, where RMSE and MAE values decreased significantly. However, after exceeding 20 epochs, performance gains became insignificant, indicating a saturation point in model training. The best results were obtained with 40 epochs for daily data, 80 epochs for weekly data, and 50 epochs for monthly data. These differences suggest that the model requires a varying number of epochs depending on the scale of the data used. Training time can be optimized for practical deployment by selecting the appropriate number of epochs, reducing computational overhead without sacrificing prediction accuracy.

Batch size had minimal impact on model accuracy. A batch size of 64 yielded the best daily and weekly data performance, while a batch size of 32 was more optimal for monthly data. However, increasing the batch size to 128 slightly decreased model performance. These results indicate that while batch size optimization can affect training stability, changes in batch size do not significantly impact prediction accuracy. This suggests practitioners can choose moderate batch sizes to balance memory usage and model performance. This makes the model scalable for different computing environments, from high-performance servers to edge devices.

Increasing the number of neurons positively affected model accuracy, mainly when the number of neurons increased from 30 to 60, where RMSE values significantly decreased. The best results were obtained with 120 neurons for daily data and 240 neurons for weekly and monthly data. This suggests that more neurons allow the model to capture more complex patterns, but an excessive number of neurons risks overfitting. In practical applications, understanding the optimal number of neurons helps in designing efficient models that maximize accuracy without unnecessary computational complexity, making the model more scalable for large-scale implementation.

Changes in the number of GRU/LSTM and Dense layers did not significantly impact prediction accuracy. The best

configuration for daily data was obtained using one Dense Layer after GRU-LSTM, weekly data using three Dense Layers after GRU-LSTM, and monthly data using two GRU/LSTM Layers and one Dense Layer. Adding Dropout Layers worsened model performance, indicating that dropout is unsuitable for this air temperature prediction scenario. These insights provide practical recommendations for model architecture design, allowing practitioners to avoid unnecessary layers that do not contribute to accuracy improvements, thereby reducing training time and computational costs.

Applying a model trained on macro temperature data to predict micro temperature data every three hours resulted in a high error rate. The large temperature fluctuations within this timeframe made it difficult for the model to recognize temperature change patterns. Among the three models tested, the model trained with monthly data performed the best. This indicates that longer-term macro data provides more stable patterns for micro-temperature predictions. However, the still relatively high error rate suggests that further adjustments are needed for the model to predict micro temperatures accurately. This finding is particularly relevant for real-world applications where localized micro-temperature forecasts are required, such as in precision agriculture or climate-sensitive industries. Future work should explore additional feature engineering techniques or hybrid models incorporating real-time weather variables.

The GRU-LSTM hybrid model consistently performed better than the standalone GRU or LSTM models in all test scenarios. Although the differences in RMSE, MAE, and R^2 values between the three models were insignificant, the hybrid model still showed slightly higher accuracy. However, this advantage came at the cost of longer training times. These results indicate that using only the GRU or LSTM model is sufficient for applications requiring fast predictions. In contrast, the GRU-LSTM hybrid model is recommended for more precise forecasting needs. From a scalability perspective, this suggests that the choice of model should depend on computational resources and accuracy requirements. The standalone GRU or LSTM model is more suitable for real-time applications with limited processing power. In contrast, the GRU-LSTM hybrid model is ideal for high-accuracy forecasting in research and large-scale monitoring systems.

VI. Conclusion

The objective of this study was to see how the number of input parameters, number of data sharing ratios, number of epochs, number of batch sizes, number of neuron sizes, and layer arrangement of the model architecture affected the performance results of the GRU-LSTM hybrid model. The best model performance was obtained from all tests using Macro Air Temperature Data when testing with monthly Macro Air Temperature Data and a 12 Input Parameter scheme. The obtained RMSE is 0.056807, the MAE is 0.046592, and the R^2 is 0.989371. Because the error rate derived from the RMSE and MAE values is relatively low for prediction, the GRU-LSTM Hybrid Model is appropriate for predicting macro air temperature. The data preprocessing stages, the number of input parameters used, and the presence or absence of a Dropout Layer in the model architecture are the indicators that have the most significant influence on model performance. Furthermore, this study investigates whether a model trained on macro data can be used to predict microdata. The GRU-LSTM Hybrid Model, which was built using monthly macro data and 12 Parameter Inputs, produced the best results in predicting Micro Air Temperatures every 3 Hours and Daily Micro Air Temperatures. In microdata tests at daily intervals, the best RMSE, MAE, and R^2 values were 0.227086, 0.190801, and 0.981802, respectively. Because the error rate obtained in testing using daily microdata is relatively low, it can be concluded that micro air temperature predictions can be performed using the GRU-LSTM Hybrid Model, which was trained using monthly macro temperature data. Because of their high accuracy, the results of the 12 input parameters can be used to build a time series air temperature prediction system. The number of inputs indicates the impact on the model's performance results. The Hybrid GRU-LSTM model with 12 inputs can be used to design a temperature prediction application in a wetland environment.

***Abstract*—This paper introduces a lightweight and efficient keyed hash function tailored for resource-constrained Internet of Things (IoT) environments, leveraging the chaotic properties of the Parabola Chaotic Map. By combining the inherent unpredictability of chaotic systems with a streamlined cryptographic design, the proposed hash function ensures robust security and low computational overhead. The function is further strengthened by integrating it with a Physical Unclonable Function (PUF) based on SRAM initial values, which serves as a secure and tamper-resistant source of device-specific keys. Experimental validation on an ESP32 microcontroller demonstrates the function's high sensitivity to input variations, exceptional statistical randomness, and resistance to cryptographic attacks, including collisions and differential analysis. With a mean bit-change probability nearing the ideal 50% and 100% reliability in key generation under varying conditions, the system addresses critical IoT security challenges such as cloning, replay attacks, and tampering. This work contributes a novel solution that combines chaos theory and hardware-based security to advance secure, efficient, and scalable authentication mechanisms for IoT applications.**

***Keywords*—SRAM PUF; PUF key generation; chaotic keyed hash; device authentication; discrete-time chaotic**

I. Introduction

The Internet of Things (IoT) has revolutionized the way we interact with technology, connecting billions of devices globally to create a vast network of interconnected systems. IoT extends to various applications, including smart homes, healthcare, industrial automation, and transportation systems [1-2]. For instance, IoT-enabled medical devices can monitor patients in real-time, while industrial sensors optimize manufacturing processes. The ability of IoT to enhance operational efficiency, reduce costs, and enable innovative services underscores its importance in modern technological advancements. However, the rapid proliferation of IoT devices also brings significant challenges, particularly in managing the security of these interconnected networks [3-4].

Device authentication is a fundamental aspect of IoT security, ensuring that only legitimate devices can communicate within the network. Conventional methods for authentication often rely on cryptographic keys stored in memory, which are vulnerable to physical attacks, cloning, and software-based exploits. These issues highlight the need for more robust and tamper-resistant mechanisms for IoT security [5-6].

However, IoT devices face unique constraints compared to traditional IT systems. These constraints include limited computational resources, such as low processing power, minimal memory, and restricted energy availability [7]. These limitations necessitate lightweight and efficient security mechanisms that do not overwhelm the device's capabilities. Moreover, IoT devices are often deployed in physically exposed environments, making them more susceptible to tampering, theft, and side-channel attacks. Unlike traditional IT systems, which are often housed in secure, controlled environments, IoT devices may operate in untrusted or hostile settings, increasing the potential attack surface [8]. As a result, IoT security mechanisms must address these heightened risks while remaining compatible with resource-constrained hardware.

In this paper, we propose a novel approach that integrates SRAM-based PUFs with a keyed hash function based on the Parabola Chaotic Map. This combination provides a lightweight and secure mechanism for device authentication in resource-constrained IoT environments. By leveraging the inherent randomness of SRAM PUFs and the entropy-enhancing properties of the chaotic hash function, our method ensures robust security while maintaining computational efficiency over a resource-constrained environment of IoT.

The rest of this paper is organized as follows: Section II provides an in-depth discussion of the background concepts, including an overview of IoT security challenges, Physical Unclonable Functions (PUFs), and chaotic hash functions. Section III introduces the proposed system, elaborating on the integration of SRAM-based PUFs with the Parabola Chaotic Map-based keyed hash function and detailing its implementation on the ESP32 microcontroller. Section IV presents the results and analysis of the system's performance. Finally, Section V concludes the paper by summarizing key findings and proposing directions for future research.

II. Background

A. IoT Security Challenges

Security is a critical concern in IoT due to the sensitive data these devices handle and their deployment in diverse environments. Fig. 1 shows a classification of IoT security threats along with the security approaches for each IoT layer [9-10]. As IoT architectures are commonly divided into three layers [11]: The perception layer, which includes sensors and actuators, involves data collection through directly interfaces

with the physical environment, faces risks such as interception of data transmitted in and out of devices, physical tampering or node capture attacks. The network layer, which is responsible for transmitting data between devices, gateways, and cloud platforms, may have vulnerability to data interception during the transmission, or being attack by overloading the network traffic to make it unavailable. Lastly, the application layer, which able to provide the user interfacing control and processes the collected data, can be compromised by software vulnerabilities and unauthorized access. Unauthorized access to IoT devices can lead to data breaches, operational disruptions, and even physical damage in critical systems.

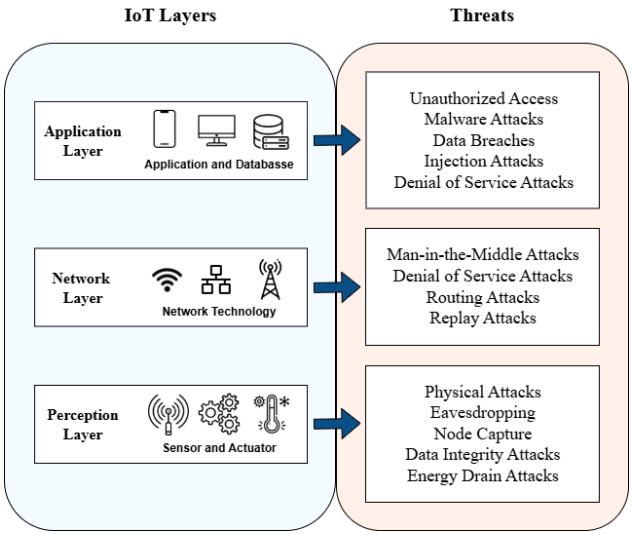

Fig. 1. IoT layers, and security threats.

B. Physical Unclonable Functions (PUFs)

Physical Unclonable Functions (PUFs) have emerged as a promising solution to IoT security challenges [12-13]. A PUF leverages the intrinsic physical variations in hardware components to generate unique and unclonable identifiers [14]. Among the various types of PUFs [15], SRAM-based PUFs are particularly attractive due to their simplicity and widespread availability in existing hardware [16-17]. When powered on, SRAM cells exhibit random initialization values influenced by manufacturing variations, making them an ideal candidate for generating device-specific keys. The stability of these values can be enhanced through error correction, enabling consistent and reliable use for cryptographic purposes, including as keys for keyed hash functions.

PUFs leverage manufacturing variations to generate unique and unclonable responses from hardware components. SRAM PUFs use the power-up state of uninitialized SRAM cells as a source of randomness. These initial values are device-specific and can be stabilized using error correction mechanisms for consistent key generation. PUFs eliminate the need to store cryptographic keys, thereby reducing risks associated with key theft or compromise. SRAM-based PUFs, specifically, are advantageous because of their availability in existing devices and their ability to function without modifications to the hardware design.

C. Hash Function

Hash functions have been implemented in the contexts of cybersecurity and information security applications [18-20], such as ensuring data integrity, authentication, digital signatures [21], protocol encryption [22], number generation [23], password security [24], or blockchain applications [25]. Hash functions are generally categorized into two types: unkeyed and keyed. Unkeyed hash functions rely solely on the input message to generate the hash value. On the contrary, Keyed hash functions, which incorporate a secret key into the hashing process, can provide enhanced security by protecting against tampering and brute-force attacks. Unkeyed hash functions such as MD5 and SHA-1, which are widely used in security applications and protocols, have primarily relied on logical operations and multi-round iterations.

Aside from hash functions, chaotic systems have gained significant traction in the field of cryptography over the last decade [26-27]. Chaotic systems are defined by their deterministic nature combined with an inherent unpredictability. These systems exhibit extreme sensitivity to initial conditions, long-term unpredictability, and complex yet non-random behavior. Such characteristics make them ideal for cryptographic applications [28], where unpredictability and high entropy are essential for ensuring secure operations. Among the tools derived from chaotic systems, chaotic maps stand out as mathematical functions capable of generating sequences with these properties. Examples include the Logistic Map, Tent Map, and Parabola Map, each of which provides unique advantages in terms of randomness and computational efficiency. The ability to generate pseudo-random values from simple mathematical operations makes chaotic maps particularly valuable for lightweight and efficient cryptographic systems, especially in resource-constrained environments like IoT.

Hashing efficiency is contingent upon inherent ciphers which necessarily require extensive computation processes. Combining input sensitivity with the entropy-generating properties of chaotic systems resulted in keyed hash functions such as the Chaotic Map-based approach [29-31], which offers a lightweight and secure solution for IoT environments. These functions ensure robust performance even in resource-constrained devices, making them a suitable choice for integrating with other security approaches such as hardware-based mechanisms like PUFs [32-33]. Moreover, the chaotic map-based approach provides an inherent randomness that enhances cryptographic strength, making it resilient against cryptanalysis. This approach also enables adaptability in various IoT applications by allowing parameter adjustments, ensuring that it can balance security needs with computational overhead effectively.

III. Proposed System

A. SRAM-PUF Key Generation on ESP32

The ESP32 is a low-cost, low-power, and highly versatile microcontroller system-on-chip (SoC) designed by Espressif Systems [34]. It is widely used in Internet of Things (IoT) applications due to its powerful features, extensive connectivity options, and efficient performance. The ESP32 microcontroller features a versatile internal memory architecture that includes

multiple Static Random Access Memory (SRAM) regions. The primary SRAM, divided into three memory blocks—SRAM0, SRAM1, and SRAM2—totals 520 KB. These memory blocks are shared between instruction and data storage, enabling efficient use of memory resources. SRAM0 and SRAM1 are typically used for both instruction and data storage, while SRAM2 is primarily reserved for general-purpose data storage. The instruction storage is accessible through the instruction memory bus (IRAM), allowing executable code to run efficiently. Conversely, the data storage, accessed through the data memory bus (DRAM), is non-executable and dedicated to runtime data. Fig. 2 illustrates the internal SRAM memory architecture of the ESP32.

In this paper, the ESP32 microcontroller is used as a test platform. The device's on-chip SRAM is leveraged for PUF generation, while its computational capabilities handle the chaotic hash function. Memory block from SRAM2 is chosen for the PUF generation. This region is preferred because it remains uninitialized during the boot process, preserving its unique power-up state. These states, influenced by inherent manufacturing differences, exhibit sufficient entropy to serve as a reliable source for PUF generation. By reserving this address range exclusively for PUF purposes, the implementation ensures that other system operations do not interfere with the PUF response. This allocation also simplifies access and management of the PUF-specific memory blocks while maintaining the system's overall efficiency and stability.

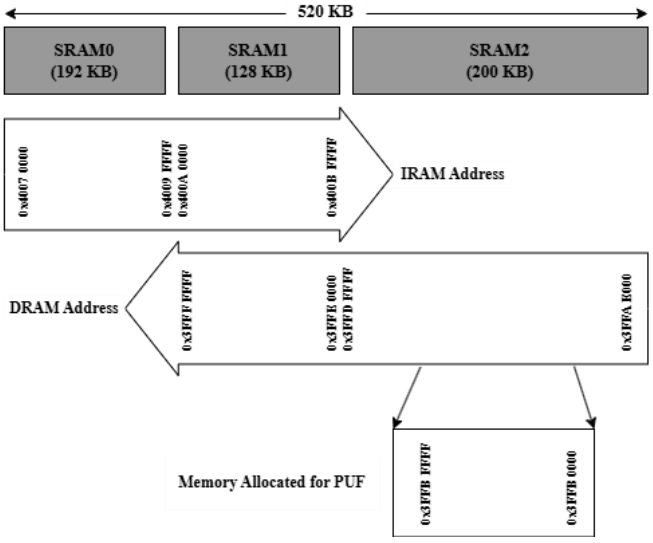

Fig. 2. Internal SRAM memory allocation of ESP32 chip.

The ESP32 microcontroller's low power consumption and computational efficiency make it an ideal platform for implementing this SRAM-based PUF mechanism. Its versatile memory architecture supports the storage and processing of the raw and stabilized PUF responses, while its dual-core processor efficiently handles the computations required for Error Correction to stabilize the output.

The key workflow of the implementation of SRAM-PUF Key Generation on ESP32 involves extracting device-specific responses from SRAM and stabilizing these responses using a Majority Vote Key instead of Error Correction Codes (ECC). This process ensures unique, tamper-resistant authentication for IoT devices, addressing the challenges of environmental variability and hardware noise. By leveraging both techniques, the system achieves a high degree of stability and reliability while maintaining computational efficiency suitable for resource-constrained IoT applications.

During device power-up, uninitialized SRAM cells generate random values due to manufacturing variations. These values are read and processed to form a raw binary response. However, environmental factors such as temperature fluctuations, voltage variations, and hardware aging can introduce inconsistencies in the raw responses across multiple power cycles. To address these challenges, the Majority Vote Key approach is applied.

With Majority Vote Key, the binary representations of the SRAM data undergo majority voting over a defined number of iterations, enhancing the robustness of the generated key against noise and instability. This process effectively averages out noise and random bit flips, ensuring that transient errors caused by environmental factors do not impact the final response. The output of this stage is a binary response that is significantly more stable and reliable than any single raw response. The stabilized output then serves as the key for the chaotic hash function.

B. Parabola Chaotic Keyed Hash Function

The Generalized Parabola Chaotic Map, developed in our previous work [35], serves as a robust randomness source for the proposed keyed hash function. This map builds upon well-known chaotic systems like the tent map, logistic map, and Gauss map, offering enhanced entropy generation and sensitivity to initial conditions. The mathematical definition of the Parabola Chaotic Map is as follows:

$$x_{n+1} = \mp A f_{\mathrm{NL}}(B x_n) \pm C \tag{1}$$

where the parameters *A*, *B* and *C* are real constants, and the $f_{NL}(x)$ is a parabola function. These parameters contribute to the map's chaotic behavior, ensuring its suitability for cryptographic applications.

The Parabola Chaotic Map-based keyed hash function is specifically designed for resource-constrained environments, making it an ideal choice for IoT applications. This lightweight cryptographic mechanism capitalizes on the pseudo-random behavior and high entropy characteristics of the chaotic map, which enhances its resistance to attacks such as collision, preimage, and differential cryptanalysis. Furthermore, the efficient computational requirements ensure compatibility with IoT devices that often have limited processing power and energy resources.

The hash function operates through the following steps, illustrated in Fig. 3:

1) Input handling: The input data and the stabilized keys from the SRAM-PUF are prepared. If the input length is not a multiple of 8, it is padded with zeros to meet the length requirement.

2) Initialization: A chaotic sequence is initialized, with the number of iterations determined by the length of the padded input.

3) Chaos mapping loop: The chaotic sequence is iteratively calculated, where each new value is derived from the previous value and a portion of the input bits.

4) Continuation of chaos mapping: Additional values are generated as needed to complete the hash output.

5) Output generation: The final chaotic sequence is processed to extract the relevant portion, forming the hash output.

The streamlined structure of the hash function ensures high efficiency while maintaining robust cryptographic properties. The nonlinear dynamics of the Parabola Chaotic Map enable the generation of highly unpredictable outputs, providing a secure foundation for cryptographic applications in IoT environments.

C. IoT Device Authentication Mechanism

The combination of the parabola chaotic map-based keyed hash function with SRAM-PUF technology is aimed to create a secure and lightweight authentication mechanism. The SRAM-PUF, implemented on an ESP32 microcontroller, generates a stabilized output key derived from the intrinsic physical variations of the SRAM memory. This stabilized key serves as the secret input to the keyed hash function, which, in turn, generates unique and unpredictable authentication tokens. The system leverages these tokens to implement a secure authentication mechanism.

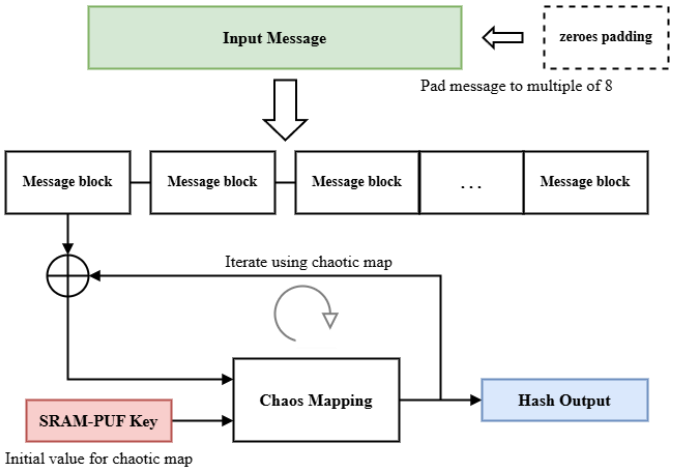

Fig. 3. SRAM-PUF based chaotic keyed hash.

As challenge-response pair (CRP) was chosen as an authentication mechanism, the authenticator sends a challenge to the device during an authentication session. The device combines this challenge with its stabilized SRAM-PUF key and processes through the chaotic keyed hash function. The result is an authentication token that is unique to the device and the specific challenge. This response is then sent back to the authenticator for authentication. Since the SRAM-PUF-derived key is unclonable and never directly transmitted, the system ensures that even if an attacker intercepts the challenge or response, they cannot reconstruct the key or generate valid tokens. The authentication mechanism is shown in Fig. 4.

The verifier, having the original challenge and a stored copy of the expected key or hash behavior, computes the expected token using the same keyed hash function. If the computed token matches the received token, the device is authenticated successfully. This process ensures the following:

1) Device uniqueness: The unclonable nature of the SRAM-PUF key ensures that each device produces a unique response, making it nearly impossible to replicate the authentication behavior of another device.

2) Resistance to replay attacks: Since the response is dynamically generated for each challenge, replaying a previously captured response will fail to authenticate the device.

3) Lightweight operation: The combination of SRAM-PUF and chaotic keyed hash function provides a computationally efficient authentication mechanism suitable for IoT devices with limited resources.

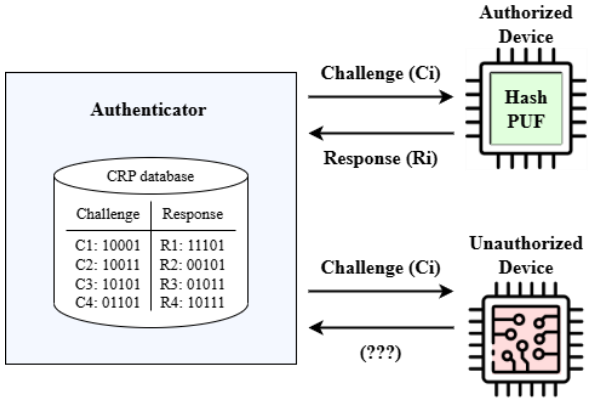

Fig. 4. The authentication mechanism.

By integrating the parabola chaotic map-based keyed hash function with SRAM-PUF, the proposed system achieves a high degree of security and efficiency, ensuring robust authentication for IoT devices in diverse and potentially hostile environments.

IV. Results and Analysis

This section evaluates the performance of the Parabola Chaotic Map-based keyed hash function and the SRAM-PUF mechanism implemented on the ESP32 microcontroller on security, efficiency, and robustness in IoT authentication.

A. Sensitivity and Reliability Analysis

The reliability of the SRAM-PUF is critical factor in determining the robustness of the proposed keyed hash function. In this study, experimental test was conducted using two ESP32 boards with the same model (ESP32WROOM32).

Reliability measures the consistency of the PUF response to the same challenge across multiple instances and varying environmental conditions, such as temperature fluctuations and power supply variations. The proposed system leverages the Majority Vote Key technique instead of traditional error correction codes, ensuring consistent key generation without significant computational overhead.

The evaluation of reliability involved extensive testing with two ESP32 boards. To assess reliability, a set of predefined challenges was repeatedly presented to the PUF, and the responses were collected over 100 iterations per challenge. The

collected responses were then analyzed to identify any inconsistencies.

Remarkably, the PUF demonstrated a reliability of 100%, consistently producing identical responses to the same challenges across all tests. This perfect reliability validates the robustness of the Majority Vote Key mechanism, which effectively mitigated the effects of noise and variability. Over prolonged operational periods, the mechanism maintained its performance, demonstrating resilience against potential aging effects in the SRAM hardware. This result validates the unparalleled reliability of the proposed SRAM-PUF mechanism, reinforcing its suitability for an integration with the parabola chaotic map-based keyed hash function.

Consequently, to demonstrate exceptional sensitivity to minor changes in the input message of the proposed keyed hash function, a series of experiments were conducted such as character replacements, additions, or deletions.

Case1: The Original message: “This is a simple absolute chaos based keyed hash function."

Case2: Replace the first character of the original message ‘‘T’’ by ‘‘t’’.

Case3: Add a space to the end of the original message.

Case4: Delete the full stop symbol at the end of the message.

The corresponding 128-bit hash values for each input message are presented in hexadecimal format as follows.

Case1: FB47 2C55 6481 D81D 379B 13F4 7616 733C

Case2: 80FB 471D 72B4 71C6 A735 7FA0 7868 CF77

Case3: 81E9 1D90 FB39 0FB4 5028 1F38 00D1 55AF

Case4: 90E9 1D71 D72B 5639 6F4B 75F9 195B 2CD1

The graphical display of binary sequences is shown in Fig. 5.

The results clearly demonstrate the proposed hash function exceptional sensitivity to such alterations and its suitability for tamper-resistant IoT authentication systems and dependable performance across diverse scenarios.

B. Collision analysis

The collision test consists in computing the difference between the hash values obtained from the original message and from a modified version of this message. The difference is computed based on the following formula:

$$d = \sum_{i=1}^{N} |dec(m_i) - dec(m_i')| \qquad (2)$$

where m_i and m_i' is the ith ASCII character of the original and the new hash value respectively, while the *dec*(.) converts an ASCII character to its decimal value.

Table I, show the minimum, maximum and mean values of the absolute difference of original and new hash values, where simulation repeat N = 10,000 time.

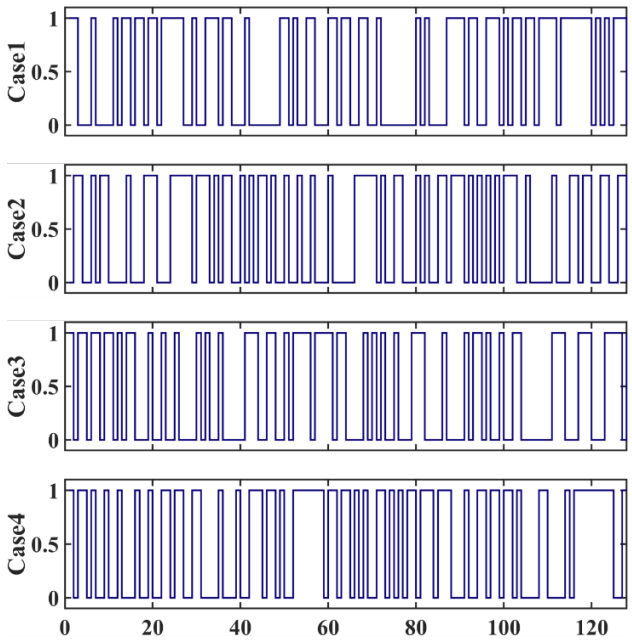

Fig. 5. The 128-bit hash values under different conditions.

TABLE I. COLLISION ANALYSIS OF HASH ALGORITHMS

Hash Algorithm	Min	Max	Mean
MD5(128bit)	590	2074	1304
SHA-1(160bit)	795	2730	1603
Proposed scheme (128bit)	549	2590	1387
Proposed scheme (160bit)	602	2702	1647
Proposed scheme (256bit)	1509	4005	2710

C. Statistical Analysis

Confusion and diffusion are critical metrics for evaluating the performance of hashing algorithms. To conduct a statistical analysis of these properties, the following experiments were performed:

- A random message of length L = n*50 was generated, where n represents the desired hash value length.
- A single bit of the original message was randomly selected and flipped, and a new n-bit hash value was calculated.
- The two n-bit hash values were compared to determine the number of changed bits.
- This simulation was repeated N times for different values of N (256, 512, 1024, 2048, and 10,000) and varying hash value lengths n (128, 256, and 512).

The following statistics were collected from the results obtained (see Tables II, III and IV):

- Minimum number of changed bits (B_{min}):
- Maximum changed bit (B_{max}):
- Mean changed bit $\overline{(B)}$:
- Mean changed probability (P):

- Standard deviation of the changed bit (ΔB):
- Standard deviation (ΔP):

TABLE II. STATISTICAL RESULT FOR A 128-BIT HASH VALUE

128-bit	*N* times				
	256	512	1024	2048	10000
B_{min}	48	41	38	21	8
B_{max}	80	83	83	96	86
$\overline{B}$	64.40	63.93	63.73	63.76	63.83
P (%)	50.31	49.95	49.79	49.82	49.87
ΔB	5.33	6.05	6.11	6.27	6.27
ΔP (%)	4.16	4.73	4.77	4.9	4.89

TABLE III. STATISTICAL RESULT FOR A 256-BIT HASH VALUE

256-bit	*N* times				
	256	512	1024	2048	10000
B_{min}	95	95	86	82	80
B_{max}	151	153	154	154	158
$\overline{B}$	127.93	127.80	127.35	127.40	127.41
P (%)	49.97	49.92	49.75	49.77	49.77
ΔB	8.95	8.99	9.28	8.93	9.16
ΔP (%)	3.50	3.51	3.63	3.49	3.58

TABLE IV. STATISTICAL RESULT FOR A 512-BIT HASH VALUE

512-bit	*N* times				
	256	512	1024	2048	10000
B_{min}	195	195	195	195	175
B_{max}	288	288	288	296	296
$\overline{B}$	255.17	254.87	254.71	254.82	254.80
P (%)	49.84	49.78	49.75	49.77	49.76
ΔB	12.64	12.52	12.61	12.86	12.94
ΔP (%)	2.47	2.45	2.46	2.51	2.53

The distribution of the number of changed bits can be analyzed using both a plot of the distribution of changed bits and a histogram as shown in Fig. 6 (a) and (b), respectively. This illustrates the distributions for n = 256 and N = 10000. The results indicate that the number of changed bits is consistently close to n/2 or 50%, and the histograms exhibit a normal distribution with a mean of n/2. This corresponds to a mean changed bit number and a mean changed probability that are very close to the ideal values of n/2 bits and 50%, respectively.

To achieve high security and prevent major attacks, the parabola chaotic keyed hash function based on SRAM-PUF key demonstrate high sensitivity to input changes, with minor variations in the input producing significant differences in the hash output. Statistical analyses confirm that the reliability of the proposed system again a single bit changes in the challenge would result in nearly 50% change in responses, which is an ideal state.

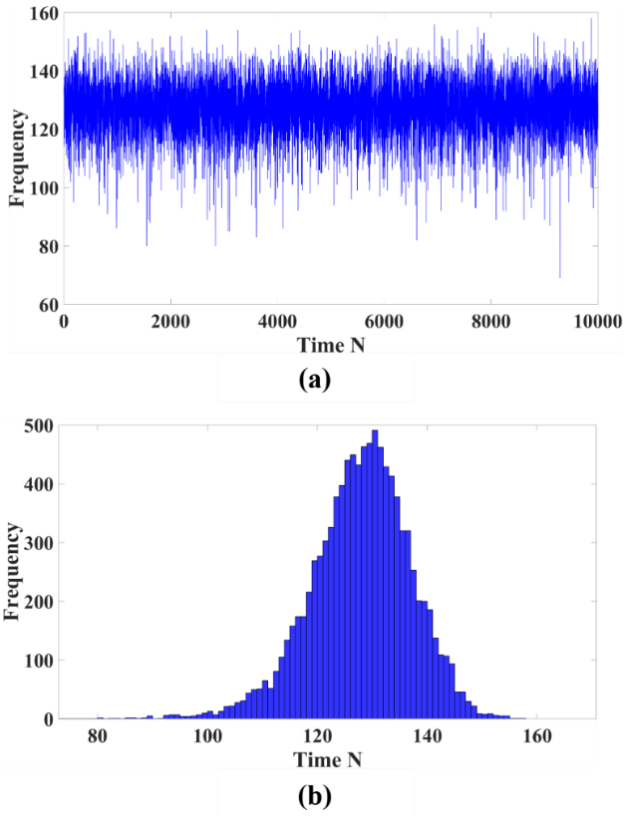

Fig. 6. Plot distribution of the number of bits changed (*a*) and Histogram distribution of the number of changed bits (*b*) for n = 256 and N = 10000.

V. CONCLUSION

This paper introduces a novel authentication mechanism that combines the hardware-level uniqueness of SRAM-based Physical Unclonable Functions (PUFs) with the cryptographic robustness of a Parabola Chaotic Map-based keyed hash function. This integration is designed to meet the stringent requirements of security, reliability, and computational efficiency for Internet of Things (IoT) applications operating in resource-constrained environments.

The proposed approach leverages the inherent physical variations in SRAM to generate unclonable keys, ensuring device-specific uniqueness without the need for external key storage. The chaotic hash function, built on the properties of the Parabola Chaotic Map, enhances security through its high sensitivity to input changes and entropy-generating capabilities, offering strong resistance to cryptographic attacks such as collision, preimage, and differential analysis.

Experimental evaluations confirm the system's effectiveness. The Majority Vote Key technique, employed to stabilize SRAM responses, demonstrates 100% reliability. Statistical analyses further validate the hash function's robustness, achieving near-ideal diffusion and confusion properties with a mean bit-change probability close to 50% in response to input variations. These results underscore the system's capability to deliver robust security and consistent performance.

This work contributes to the field of IoT security by providing a lightweight, tamper-resistant solution that mitigates risks associated with cloning, replay attacks, and physical tampering. The simplicity of the proposed design ensures compatibility with the limited resources of IoT devices, while its high reliability and security make it a promising candidate for broader adoption.

Future research will explore further optimizations of the system's computational and energy efficiency. Additionally, extending the application of this approach to other cryptographic contexts and implementing hardware prototypes for large-scale testing will provide further validation and refinement of the proposed solution.

A Systematic Review of Metaheuristic Algorithms in Human Activity Recognition: Applications, Trends, and Challenges

John Deutero Kisoi, Norfadzlan Yusup, Syahrul Nizam Junaini
Faculty of Computer Science and Information Technology, Universiti Malaysia Sarawak, Kota Samarahan, Malaysia

***Abstract*—Metaheuristic algorithms have emerged as promising techniques for optimizing human activity recognition (HAR) systems. This systematic review examines the application of these algorithms in HAR by analyzing relevant literature published between 2019 and 2024. A comprehensive search across multiple databases yielded 27 studies that met the inclusion criteria. The analysis revealed that Genetic Algorithms (GA) exhibit classification accuracy rates ranging from 88.25% to 96.00% in activity recognition and up to 90.63% in localization tasks. Notably, Oppositional and Chaos Particle Swarm Optimization (OCPSO) combined with MI-1DCNN significantly improves detection accuracy, demonstrating a 2.82% improvement over standard PSO with Support Vector Machine (SVM) as classifier approaches. Our analysis highlights a growing trend toward hybrid metaheuristic approaches that enhance feature selection and classifier optimization. However, challenges related to computational cost and scalability persist, underscoring key areas for future research. These findings emphasize the potential of metaheuristic algorithms to significantly advance HAR. Future studies should explore the development of more computationally efficient hybrid models and the integration of metaheuristic optimization with deep learning architectures to enhance system robustness and adaptability.**

***Keywords*—Metaheuristic algorithm; human activity recognition; systematic review; application; trend; challenge; literature**

I. INTRODUCTION

Human Activity Recognition (HAR) is a crucial field that extends its influence across diverse domains, including healthcare, sports, and security, by employing its ability to classify human body movements and gestures based on sensor data [1], [2]. The incorporation of HAR within these domains has initiated significant transformative possibilities, reshaping patient care, enhancing athletic training, and strengthening security protocols [3]. Nevertheless, the effectiveness of HAR relies heavily on their ability to process complex, multidimensional data accurately. To address this complexity, metaheuristic algorithms have proven to be invaluable resources, drawing inspiration from natural phenomena such as evolution and swarm behaviors [4], [5]. Metaheuristic algorithms are powerful optimization strategies designed to tackle complex problems that traditional methods struggle to solve. They allow for the exploration of extensive search spaces to identify the best possible solutions to various issues [6]. The development of these algorithms has taken place over several decades and draws inspiration from natural systems, leading to a range of innovative optimization techniques. We believe that metaheuristic algorithms will continue to be instrumental in driving advancements in new technologies and applications, proving to be invaluable tools for addressing intricate optimization challenges across different fields.

In recent years, HAR technology has revolutionized healthcare monitoring through sophisticated patient movement analysis and personalized rehabilitation programs, while enabling early detection of health issues through non-invasive monitoring methods that provide real-time treatment efficacy feedback. This innovative technology extends its capabilities into sports applications, where it facilitates precise analysis of athletic performance through comprehensive movement and strain monitoring, and further demonstrates its versatility in security systems by identifying unauthorized access and unusual behavioral patterns. The integration of HAR systems across these diverse domains exemplifies its fundamental role in advancing human-centric technological solutions that enhance monitoring, analysis, and decision-making processes in critical sectors.

Despite the advancements in HAR technology, challenges persist, particularly when it comes to processing large and unstructured datasets. This is where metaheuristic algorithms come into play. They offer a promising solution by optimizing the recognition process through efficient exploration of various solution spaces. However, integrating these algorithms with HAR presents unique challenges, as they must be capable of identifying meaningful patterns without falling into the trap of overfitting [1].

Metaheuristic algorithms tackle several specific challenges within HAR. One significant issue is the high dimensionality of sensor data, which can overwhelm traditional algorithms. By ensuring robust feature selection, these algorithms enhance classification accuracy while reducing computational burdens. They also adapt to variations in human activities and device usage, adding complexity to data interpretation. Furthermore, advancements in sensor technologies such as depth sensors and wearable devices allow metaheuristic algorithms to leverage richer data for more nuanced activity inferences [4].

The broader implications of HAR technologies combined with metaheuristic algorithms are profound. Improved patient monitoring and tailored rehabilitation protocols can lead to better health outcomes and lower healthcare costs. In sports, optimized training and injury prevention strategies can prolong athletes' careers while enhancing their performance. In terms of

security, advanced surveillance capabilities can bolster public safety and protect critical infrastructure [7].

In our systematic review, we explored the technical complexities of employing metaheuristic algorithms in HAR by assessing their strengths and limitations in optimizing these systems. By analyzing recent advancements and considering future research directions, we aim to provide a comprehensive understanding of how metaheuristic algorithms can be applied within HAR. This exploration not only highlights the current state of the field but also serves as a foundation for future innovations that could unlock even more sophisticated HAR capabilities. As a response to curiosity towards the capability of metaheuristic algorithms in HAR, the following research questions (RQ) were developed as part of this work:

RQ1: How do metaheuristic algorithms enhance feature selection and improve the performance of machine learning models in human activity recognition compared to traditional feature selection methods?

RQ2: What are the most effective adaptations and enhancements for metaheuristic algorithms that have proven to be most effective for human activity recognition?

RQ3: What are the computational challenges faced by metaheuristic algorithms in human activity recognition?

RQ4: What are the emerging trends and significant research gaps in the application of metaheuristic algorithms for human activity recognition?

This research advances the field of metaheuristic algorithm in HAR with the following key contributions and implications:

1) Identify enhanced feature selection and optimization: This study demonstrates how metaheuristic algorithms improve feature selection and classification accuracy in HAR, reducing redundancy and computational costs while maintaining high recognition performance.

2) Insight into the advancement of hybrid metaheuristic approaches: By reviewing recent hybrid metaheuristic techniques, this research highlights their role in overcoming the limitations of individual algorithms, leading to more robust and efficient HAR systems.

3) Theoretical and practical insights: This study offers both theoretical contributions and practical considerations, helping researchers and practitioners navigate key challenges in optimizing HAR systems.

4) Bridging research and innovation: By analyzing emerging trends, this work serves as a foundation for future advancements, encouraging further exploration of novel strategies in HAR optimization.

The rest of this paper is organized as follows: Section II provides a review of related works. Section III presents the review method used for this research where it highlights the use of PRISMA approach. Section IV presents the results and discussions of this research to answer the research questions that have been raised. Finally, Section V presents the conclusion of the entire research work.

II. Related Work

The integration of metaheuristic algorithms into HAR systems has garnered significant scholarly attention, driven by the need to optimize feature selection, classification accuracy, and computational efficiency in complex sensor-driven environments. Prior studies have explored diverse applications of metaheuristics, though gaps persist in systematic evaluations of algorithmic adaptations and scalability challenges.

Helmi et al. [8] conducted a foundational analysis of nine metaheuristics, including Marine Predators Algorithm (MPA) for HAR and fall detection, demonstrating their efficacy in binary classification tasks. While their work established the viability of swarm intelligence for sensor data optimization, it focused narrowly on fall detection scenarios, leaving broader HAR applications underexplored. Similarly, Al-Wesabi et al. [9] employed Chaos Game Optimization to tune BiLSTM hyperparameters, achieving 93.9% accuracy on the UCI-HAD dataset, yet their methodology neglected feature selection dynamics critical for real-time deployment.

Recent advancements in hybrid metaheuristics have reshaped the field. Zhang et al. [10] introduced Oppositional and Chaos Particle Swarm Optimization (OCPSO), which elevated MI-1DCNN classification precision to 97.92%, outperforming conventional PSO-SVM models by 2.82%. Parallel developments by Tian et al. [11] utilized Improved Binary Glowworm Swarm Optimization to achieve 98.25% F-scores in ensemble learning frameworks, though their analysis omitted computational cost comparisons across algorithm classes.

Prior systematic analyses in metaheuristic research have emphasized breadth of algorithmic coverage over domain-specific methodological evaluation. Foundational works like Alorf's [7] meta-analysis provided comprehensive taxonomies of optimization techniques but offered limited assessment of their practical implementation efficacy in HAR contexts. Subsequent domain-focused reviews, such as Raj et al.'s [3] examination of healthcare applications, demonstrated rigorous vertical analysis while overlooking horizontal scalability across activity recognition domains. The field has seen notable technical innovations like Challa et al.'s [12] Rao-3 algorithm for BiLSTM optimization, which achieved benchmark performance across multiple datasets but left unexplored synergies with emerging deep learning architectures. This pattern reveals a persistent dichotomy in the literature between expansive algorithmic surveys and narrowly focused application studies, creating critical knowledge gaps in cross-domain performance evaluation and architectural hybridization potential, especially in the HAR domain.

III. Review Method

This review was conducted according to best practices in scoping reviews and is reported according to the PRISMA scoping review reporting guidelines [13].

A. Eligibility Criteria

This systematic review, conducted in Jan 2024, explored the application of metaheuristic algorithms in HAR, focusing on recent advancements from 2019 to 2024. The review included studies from the Scopus, IEEE Xplore, and Web of Science

databases, specifically targeting journal articles and conference proceedings with keywords related to HAR, such as "recognition," "estimation," "classification," and "detection," as well as metaheuristic optimization algorithms through terms like "application" and "implementation." Non-essential materials, including book chapters, reviews, and articles in press, were excluded to maintain academic rigor. The timeline was restricted to the last five years to ensure the review reflected current knowledge, avoiding outdated methodologies. Only final, peer-reviewed publications were considered, and non-peer-reviewed sources, like book series and trade journals, were excluded. The review focused solely on English-language studies for consistency and convenience, ensuring it accurately represents the current landscape of metaheuristic algorithm applications in HAR. The inclusion and exclusion criteria are summarized in Table I.

TABLE I. THE INCLUSION AND EXCLUSION CRITERIA

Criteria	Inclusion	Exclusion
Timeline	2019-2024	>2024
Document type	Journal article, Conference paper	Other than mentioned in the inclusion criteria]
Publication stage	Final	Article in press
Exact keywords	Human activity recognition, activity detection, motion recognition, behaviour recognition, recognition, estimation, classification, detection, metaheuristic, optimization, application, implementation	[Other than mentioned in the inclusion criteria]
Source type	Journal, Conference proceeding	Book series, book, trade journal
Language	English	[Other than English]

B. Information Sources

Three major academic databases were used as information sources: Scopus, IEEE Xplore, and Web of Science. These databases focused on studies of metaheuristic algorithms and their applications in HAR.

C. Search

This study systematically reviews recent literature on metaheuristic algorithms for HAR. We conducted a comprehensive search using Scopus, IEEE Xplore, and Web of Science, focusing on peer-reviewed studies published between 2019 and 2024. The search strategy employed precise keywords related to metaheuristics and HAR to identify relevant studies.

Table II provides the detailed search strategies employed across three major academic databases: Scopus, IEEE Xplore, and Web of Science. The advanced query strings were carefully crafted to capture a comprehensive range of studies focusing on metaheuristic algorithms and their applications in HAR.

In Scopus, the search query included terms related to various metaheuristic algorithms like "evolutionary algorithm," "swarm intelligence," and "particle swarm optimization," combined with keywords associated with HAR, such as "recognition," "classification," and "detection.".

TABLE II. ADVANCED SEARCH QUERY

Database	Advanced search query string
Scopus	TITLE-ABS-KEY ((metaheuristic* OR "evolutionary algorithm*" OR "swarm intelligence" OR "genetic algorithm*" OR "particle swarm optimization") AND (algorithm* OR optimization* OR method*) AND (application* OR implementation* OR use) AND ("human activity recognition" OR har OR "activity detection" OR "motion recognition" OR "behavior recognition") AND (recognition* OR estimation* OR classification* OR detection*)) AND PUBYEAR > 2018 AND PUBYEAR < 2025 AND (LIMIT-TO (SRCTYPE , "j") OR LIMIT-TO (SRCTYPE , "p")) AND (LIMIT-TO (LANGUAGE , "English")) AND (LIMIT-TO (PUBSTAGE , "final")) AND (LIMIT-TO (DOCTYPE , "ar") OR LIMIT-TO (DOCTYPE , "cp"))
IEEE Xplore	("Document Title":metaheuristic* OR "Document Title":"evolutionary algorithms" OR "Document Title":"swarm intelligence" OR "Document Title":"genetic algorithms" OR "Document Title":"particle swarm optimization") AND ("All Metadata":algorithm* OR "All Metadata":optimization* OR "All Metadata":method*) AND ("All Metadata":application* OR "All Metadata":implementation* OR "All Metadata":use) AND ("All Metadata":"human activity recognition" OR "All Metadata":"activity detection" OR "All Metadata":"motion recognition" OR "All Metadata":"behavior recognition") AND ("All Metadata":recognition* OR "All Metadata":classification* OR "All Metadata":detection*)
Web Of Science	TS=((metaheuristic* OR "evolutionary algorithm*" OR "swarm intelligence" OR "genetic algorithm*" OR "particle swarm optimization") AND (algorithm* OR optimization* OR method*) AND (application* OR implementation* OR use) AND ("human activity recognition" OR HAR OR "activity detection" OR "motion recognition" OR "behavior recognition") AND (recognition* OR estimation* OR classification* OR detection*)) and 2024 and 2023 or 2022 or 2021 or 2020 or 2019 (Publication Years) and Article (Document Types) and English (Languages)

In Scopus, the search query included terms related to various metaheuristic algorithms like "evolutionary algorithm," "swarm intelligence," and "particle swarm optimization," combined with keywords associated with HAR, such as "recognition," "classification," and "detection.".

The query string used for IEEE Xplore follows a similar format, specifying document types such as conference papers and journal articles while filtering by publication stage to exclude in-progress works. To ensure consistent and comparable results across all databases, the same keywords related to metaheuristics and HAR were applied throughout.

In Web of Science, the search strategy also included combinations of relevant keywords and was refined further by applying filters for document type, publication years, and language. By aligning the search terms and filters across these databases, this review aimed to ensure a consistent and thorough collection of relevant literature. These query strings play a crucial role in ensuring the systematic review captures the most relevant and high-quality studies within the specified timeframe, providing a robust foundation for the subsequent analysis.

D. Data Extraction Process

Fig. 1 shows a PRISMA diagram for the systematic process we undertook to identify and select the most relevant studies for our review on the application of metaheuristic algorithms in HAR. Our initial search across Scopus, IEEE Xplore, and Web of Science databases produced 159 articles.

To refine our dataset, we used Mendeley Reference Manager to eliminate duplicates, resulting in 122 unique articles. We then conducted an initial screening based on the titles and abstracts. During this phase, we excluded 78 articles for various reasons: some had unavailable full texts (3 articles), others focused primarily on vision-based approaches (8 articles), and a significant number did not closely align with the specific focus of our review (67 articles).

Following this, 44 articles underwent a rigorous full-text review. This in-depth assessment resulted in the exclusion of 17 articles primarily due to methodological shortcomings or insufficient relevance to our review's objectives. Ultimately, 27 studies met the inclusion criteria and were qualitatively synthesized to gain insights into the application of metaheuristic algorithms in HAR. These 27 selected papers were then meticulously examined and assessed to extract relevant information aligned with each research question, guided by the rationale outlined in Table III.

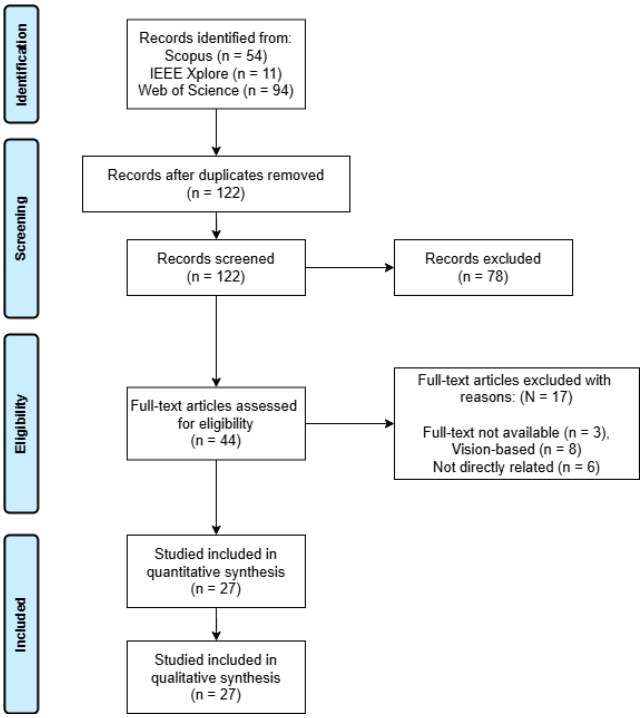

Fig. 1. PRISMA diagram.

TABLE III. RESEARCH QUESTIONS AND THEIR CORRESPONDING RATIONALES

Number	Research Questions	Rationale
RQ1	How do metaheuristic algorithms enhance feature selection and improve the performance of machine learning models in human activity recognition compared to traditional feature selection methods?	This question explores how advanced optimization techniques address persistent challenges in feature selection and model performance by reducing redundancy and improving predictive accuracy across various applications.
RQ2	What are the most effective adaptations and enhancements for metaheuristic algorithms that have proven to be most effective for human activity recognition?	This question investigates diverse adaptations and enhancements applied to metaheuristic algorithms, showcasing how these modifications enhance their effectiveness, adaptability, and efficiency for complex optimization problems.
RQ3	What are the computational challenges faced by metaheuristic algorithms in human activity recognition?	This question identifies significant computational challenges arising in the implementation of metaheuristic algorithms and offers insights into strategies for addressing these barriers effectively.
RQ4	What are the emerging trends and significant research gaps in the application of metaheuristic algorithms for human activity recognition?	This question uncovers transformative trends reshaping the field and highlights critical research gaps to provide a roadmap for future innovations and deepen understanding of these algorithms' potential.

IV. RESULTS AND DISCUSSIONS

In this section, we investigate all final selected articles (27 articles). The data is discussed to address the four mentioned research questions.

A. Improvement of Machine Learning Performance by Metaheuristic Algorithms over Traditional Methods Feature Selection (RQ1)

HAR rely heavily on the quality and relevance of the features extracted from sensor data. Traditional feature selection methods, while offering a certain level of effectiveness, can struggle with the complexities inherent in HAR tasks. Metaheuristic algorithms have emerged as powerful tools, offering significant advantages over traditional approaches. Fig. 2 shows the general workflow of how metaheuristic algorithm is being used to do feature selection. Feature selection happens after feature extraction, and metaheuristic algorithm will be applied during feature selection phase, though there are many approaches in applying metaheuristic algorithms during this phase.

One of the key strengths of metaheuristic algorithms is their ability to efficiently navigate large and complex search spaces. Unlike traditional feature selection methods, which may become stuck in local optima, metaheuristics employ a broader search strategy inspired by natural phenomena. Algorithms such as Genetic Algorithms (GA) and Grey Wolf Optimizers (GWO) mimic processes such as evolution and predator-prey interactions, respectively, to explore diverse regions within the feature space [14], [15]. This global search capability allows them to identify feature subsets that traditional methods might miss, potentially leading to superior classification performance in HAR applications.

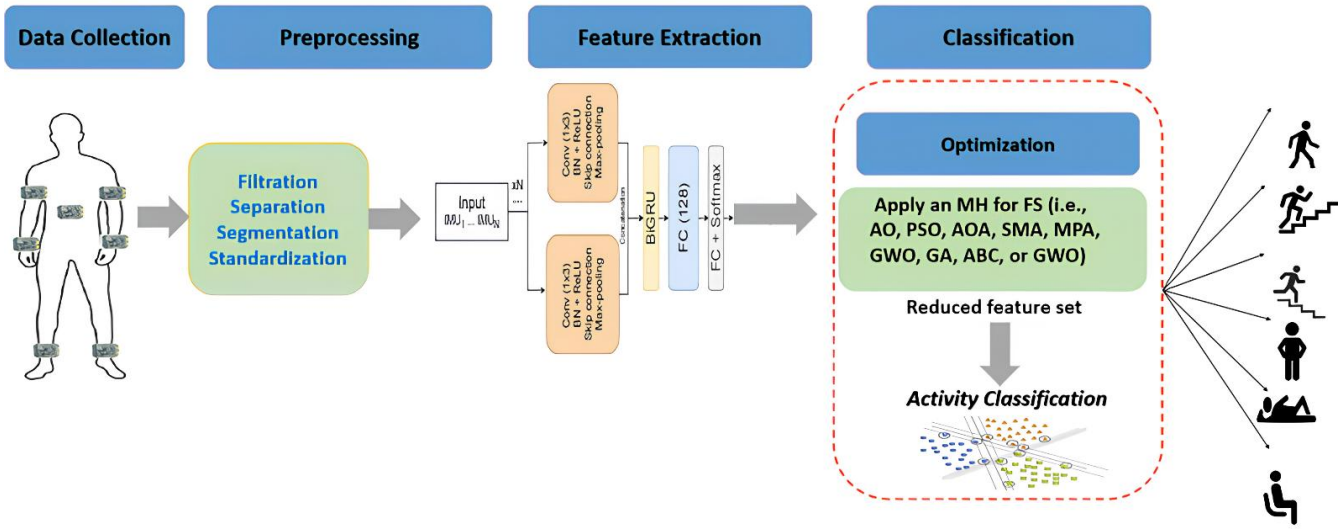

Fig. 2. Process workflow of metaheuristic feature selection for HAR [8].

Furthermore, metaheuristic algorithms play a key role in optimizing selected features by minimizing redundancy and identifying a small yet highly relevant set of features. This not only improves classification accuracy but also reduces the computational costs associated with managing large feature sets. These advantages make metaheuristic algorithms particularly valuable in critical medical applications, where both efficiency and accuracy are essential for reliable diagnoses. In contrast, traditional methods often rely on manual feature engineering or simpler optimization techniques, which may struggle to achieve the same level of efficiency or effectively capture the complex patterns found in sensor data used for HAR [16].

The fusion of heuristic algorithms and deep-learning approaches further boosts the benefits of feature selection in HAR. Deep-learning models demonstrate proficiency in unveiling intricate associations within data; however, they frequently require substantial quantities of high-quality features for optimal efficiency. By integrating metaheuristic algorithms into a deep learning framework, researchers can leverage their feature selection capabilities to pinpoint the most relevant features for a given task. This enhancement not only improves the training procedure but also results in models that exhibit greater resilience and generalizability [16]. For example, Alam et al. [17] has introduced NeuroHAR in 2024, which integrated Multilayer Perceptron (MLP) with Real-valued Genetic Algorithm (RGA). MLP performs the deep learning task of understanding and classifying complex human activity patterns, while RGA optimizes the hyperparameters by iterating through combinations to find the optimal model configuration. This synergy allows NeuroHAR to execute fewer models while exploring comprehensive hyperparameter ranges, making it computationally efficient while maintaining high prediction accuracy. Furthermore, the inherent adaptability of numerous metaheuristic algorithms enables them to manage the varied and high-dimensional characteristics of the sensor data commonly encountered in HAR applications. This adaptability makes them strong tools for researchers and developers to advance in HAR.

Metaheuristic algorithms have shown superior performance compared to traditional feature selection methods in effectively and adaptively handling high-dimensional data in HAR tasks. These approaches excel at navigating complex search spaces, enabling the discovery of optimal or near-optimal feature subsets that improve recognition performance. While earlier studies primarily relied on manual feature extraction and selection, the adoption of metaheuristic algorithms in HAR represents significant progress. By automating and refining this process, these algorithms address challenges related to feature interpretability and dimensionality, marking a substantial advancement in the field.

B. Effective Adaptation and Enhancement of Metaheuristic Algorithms for HAR (RQ2)

Researchers have investigated how metaheuristic algorithms can be tailored for systems related to HAR by analyzing a variety of approaches aimed at enhancing their effectiveness. The application of GAs has played a key role in the field of feature selection and classifier optimization, with significant achievements noted in Reweighted GAs, which have displayed remarkable accuracy in detecting daily activities. Furthermore, studies have shown their effectiveness in optimizing Support Vector Machines (SVMs) for HAR tasks [18], [19], [20], [21]. PSO has also displayed potential, especially in conjunction with SVMs (referred to as PSO-SVM), leading to enhancements in both detection accuracy and optimization efficiency [22]. Additional adaptations, including Quantum-behaved PSO (QPSO) and conventional PSO have shown advantages in refining kernel extreme learning machines (KELMs) and base extreme learning machines (ELMs), respectively, within the context of HAR [23].

Moreover, researchers have explored hybrid approaches that combine metaheuristic algorithms to address HAR challenges effectively. Hybrid techniques such as Hybrid Artificial Bee Colony and PSO (hABCPSO) and Oppositional and Chaos PSO (OCPSO) have demonstrated superior performance by leveraging the strengths of different algorithms to enhance feature selection, classifier parameter optimization, and overall recognition accuracy [24]. In addition to GAs and PSO, other metaheuristic algorithms, such as Chaos Game Optimization

(CGO), Binary Cuckoo Search (BCS), Rao-3 Optimization, Improved Binary Glowworm Swarm Optimization (IBGSO), and Gradient-based Grey Wolf Optimizer (GBOGWO), and Improved Cat Swarm Optimization (ICSO) have been adapted to fine-tune hyperparameters, explore search spaces efficiently, and improve the recognition performance of HAR [25], [26], [27].

Table V shows that metaheuristic algorithms have demonstrated superior and more efficient adaptation than conventional methodologies. Some enhanced metaheuristic algorithms even showed their superiority over the base-type metaheuristic algorithms. In contrast to traditional techniques that depend on manual feature engineering, metaheuristic algorithms automate the feature selection process, consequently enhancing the robustness and adaptability of HAR. Conversely, hybrid metaheuristic approaches, which combine the capabilities of algorithms such as GA and PSO, exhibit enhanced performance in terms of accuracy and computational efficiency when compared with conventional machine-learning models that typically require extensive data preprocessing and feature selection. Although traditional feature selection methods are simple and easy to understand, but metaheuristic algorithms provide a more powerful and flexible solution for complex HAR optimization, though they come with computational challenges.

C. Computational Challenges and Influence on Metaheuristic Algorithms for HAR (RQ3)

This research question discussed the key computational challenges encountered by metaheuristic algorithms in HAR and explored how these challenges influence their design and implementation. The computational challenges identified in the studied papers can be classified into two categories: Algorithmic Complexity, and Data Complexity as shown in Table IV.

TABLE IV. ALGORITHMIC AND DATA COMPLEXITY

Category	Computational Challenges
Algorithmic Complexity	Randomness, Premature Convergence, Complexity, Balancing Exploration and Exploitation, Slow Learning, High Computation Time
Data Complexity	Insufficient, Irrelevant, or Redundant Features, High Dimensionality, Computation Cost

Challenges related to algorithmic complexity include randomness, premature convergence, complexity, balancing exploration and exploitation, slow learning, and high computation time. Randomness is inherent in many metaheuristic algorithms and can lead to inconsistent results. Premature convergence occurs when the algorithm gets stuck in a local optimum and is unable to find the global optimum. Slow learning alludes to the prolonged duration required for the algorithm to effectively grasp and derive insights from the dataset, thus hindering the overall efficiency of the learning process. The high computational time stems from the fact that metaheuristic algorithms must evaluate a large number of possible solutions. On the other hand, challenges related to data complexity include insufficient, irrelevant, or redundant features, high dimensionality, and computation cost. High dimensionality points to the fact that the dataset comprises a wide range of features, thereby presenting a challenge for the algorithm to detect underlying patterns within the data. Moreover, the presence of insufficient, irrelevant, or redundant features within the dataset could also significantly hinder the efficiency of the algorithm, resulting in less-than-optimal outcomes. Table VI summarizes the computational challenges faced by the papers studied.

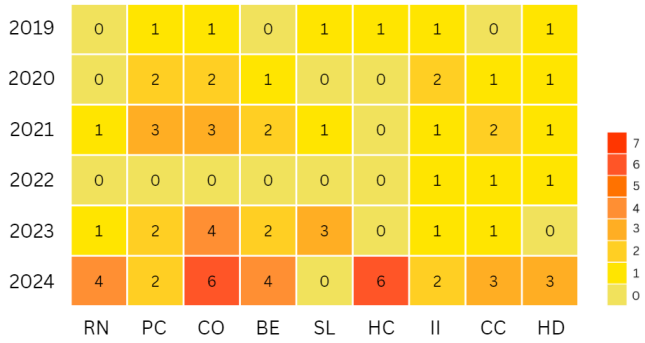

Fig. 3. Heatmap of computational challenges from 2019 to 2024.

From Fig. 3, it is proven that the computational challenges faced by metaheuristic algorithms in HAR have evolved over the years from 2019 to 2024. The most frequently encountered challenge appears to be balancing exploration and exploitation, particularly peaking in 2024 with four instances. This indicates a growing concern within the research community regarding the need for algorithms to effectively navigate the trade-off between exploration and exploitation of new solutions. This balance is crucial for optimizing algorithm performance without getting trapped in local optima or failing to converge on a global solution. The consistent presence of this challenge across the years underscores its significance in the field of HAR.

An increasing focus on complexity and high computation time has also emerged as a notable trend. This review has shown the complexity challenge grew steadily from 2019 to 2024, peaking in 2024 and maintaining a significant presence in subsequent years. Complexity was the most prominent challenge identified, accounting for 59.26% (16 out of 27) of the studies reviewed. This indicates that as metaheuristic algorithms grow more sophisticated, managing their complexity becomes increasingly critical. Similarly, high computation time saw a sudden spike in 2024, highlighting the significant computational burden of implementing advanced algorithms. This trend underscores the need for more efficient computational strategies or improved hardware to handle the intensive processing demands of metaheuristic algorithms in HAR applications.

Interestingly, some challenges such as randomness and premature convergence have relatively lower but varying instances across the years, with a noticeable spike in randomness in 2024. This variability might be due to the differing nature of the studies each year and the specific focus of the metaheuristic algorithms applied. The persistent challenge of insufficient, irrelevant, or redundant features shows that feature selection remains a critical area needing attention, impacting the accuracy and effectiveness of HAR.

TABLE V. METAHEURISTIC ALGORITHMS IN HUMAN ACTIVITY RECOGNITION

Metaheuristic Algorithm		Effective adaptation	Classifier	Performance
Base-type	**Enhanced-type**			
Particle Swarm Optimization (PSO)	Data not available (NA) [28], [29]	Optimal sensor combination through randomness and convergence.	SVM, RF, CNN, DNNLSTM, DeepCNN	SVM has the highest accuracy (95.13%)
	Oppositional and Chaos PSO (OCPSO) [10]	Helps in feature selection and improving recognition accuracy.	MI-1D-CNN	Results: • Precision: 97.92% • Recall: 97.85% • Accuracy: 97.81% • F1-score: 97.87%
	Quantum Behaved PSO (QPSO) [23], [30]	Enhances and optimizes kernel extreme learning machine (KELM) for HAR, resulting reduced misrecognized samples.	QPSO-KELM	QPSO-KELM shows highest accuracy at 91.3% for LDA and 96.2% for KDA [23] Accuracy of 96.4% [30]
	Hybrid Artificial Bee Colony and PSO (hABCPSO) [24]	Enhances local and global search capabilities for optimization.	Stacked AutoEncoder (SAE)	Has the most best performance values (17 out of 30 runs) over its competitors (ABC, DE, PSO, GA)
	PSO-Support Vector Machine (PSO-SVM) [22], [31]	PSO-SVM enhances detection accuracy, reliability, and optimization efficiency for SVM parameters.	PSO-SVM	Overall accuracy of 94.0% [22] Accuracy of 92.30%, F-Measure of 92.63% [31]
	Hierarchical PSO (H-PSO) [32]	Optimizes architecture-level parameters and layer-level hyperparameters simultaneously, enhancing the search for optimal configurations in CNNs.	1D-CNN	Accuracy on dataset: • UCI-HAR: 99.72% • PAMAP2: 96.03% • Daphnet Gait: 98.52% • Opportunity: 99.82%
	Adaptive Binary PSO (ABPSO) [33]	ABPSO utilizes a self-adaptive operator pool to enhance the feature selection process.	SVM & KNN	Accuracy: ReliefF: 95.62% (with 293 features selected) mRMR: 95.80% (with 201 features selected)
Biogeography Based Optimization (BBO)	Reweighted GA (rGA) [19]	Helps achieve high recognition accuracy of daily activities.	Reweighted Genetic Algorithm (rGA)	Accuracy on dataset): • CMU-MMAC: 88% • WISDM: 88.75% • IMSB: 83.33%
Bee Swarm Optimization (BSO)	BSO with deep Q-network (BAROQUE) [14]	BAROQUE lbalances exploitation and exploration for feature searching. It provides self-organization and self-adaptation capabilities for optimization.	KNN	Performance (accuracy on dataset): • UCI-HAR:98.41%
Cuckoo Search (CS)	NA [34]	Effectively contributed om high predictive accuracy due to its global convergence and efficient search space exploration.	NA	The accuracy value is 93.77% .
	CS with Recursive Feature Elimination (CSRFE) [21]	Optimizes the feature selection process, significantly reducing the number of features while maintaining or improving classification accuracy, minimizing temporal complexity in HAR systems.	SVM, RF, LR	Accuracy by classifier: RF: 96.76% SVM: 96.23% LR: 96.16%
Rao-3 Optimization	NA [12]	Optimization technique for ideal hyperparameters value to improve recognition performance.	BiLSTM	Accuracy on dataset: • PAMAP2: 94.91% • UCI-HAR: 97.11% • MHEALTH: 99.25%
Glowworm Swarm Optimization (GSO)	Improved Binary GSO (IBGSO) [11]	Enhances learning by selects a superior subset for ensemble pruning to find optimal subensemble models.	IBGSO	• Precision: 98.25% • Recall: 98.17% • Accuracy: 98.25% • F-score: 97.94%
Grey Wolf Optimizers (GWO)	Gradient-based Optimization & GWO (GBOGWO) [16]	Improves performance by balancing exploration and exploitation stages.	SVM	Mean accuracy: 98.87%
Chaos Game Optimization (CGO)	NA [9]	Fine-tunes BiLSTM hyperparameters for enhanced performance.	BiLSTM	UCI-HAR dataset: • Precision: 77% - 80.1% • Recall: 75.9% - 79.3% • Accuracy 92.0% - 93.2% • F-score: 76.0% - 79.4% UCI-HAD dataset:

				• Precision: 81.4% • Recall: 81.1% • Accuracy: 93.9% • F-score: 81.0%
Genetic Algorithm (GA)	NA [15], [18], [20], [26], [35], [36]	Used for selecting important features to improve classification performance while keeping the model small. It helps increase accuracy by filtering out noise and is also effective in optimizing fuzzy logic systems.	Deep Neural Decision Forest [18] KNN, SVM, RF [15] NA [20] SVM & RF [36] DCNN-LSTM [26] KNN [35]	[18] Accuracy: • ExtraSensory: 88.25% • Sussex-Huawei: 96.00% [15] F-measure: • KNN: 98.2% • SVM: 98.2% • RF: 97.6% [20] Accuracy: 99.1% [26] Result: • F1 Score: 98.89% • Average Recall: 99.01% • Average Precision: 98.90% • Total Accuracy: 99.92% [35] Accuracy using MHEALTH dataset is the highest.
	GA with a centroid-based clustering approach [36]	Helps in managing data efficiently while retaining high classification accuracy.	SVC, RF, KNN	Accuracy on dataset: • UCI-HAR: 93.45% • WISDM: 72.8%
	Non-dominated Sorting GA II (NSGA-II) [37]	Using a multi-objective optimization approach that simultaneously evolves LSTMs for classification accuracy.	LSTM	Classification accuracy on SMARTPHONE dataset: • With NGSA-II: 99.03% • Without NGSA-II: 97.69%
	Real-valued GA (RGA) with Multilayer Perceptron (MLP) [17]	Dynamic optimization of network architectures and hyperparameters, which allows for better handling of task complexities compared to traditional methods.	MLP	Accuracy based on model: NeuroHAR: 89.91% Grid Search:84.04% Notes: NeuroHAR is the proposed model (RGA with MLP).
Cat Swarm Optimization (CSO)	Improved CSO (ICSO) [27]	Improves CNN parameter tuning for HAR tasks.	CNN	ICSO-CNN achieved an accuracy of 99.79%, outperforming other methods such as CNN with Long Short-Term Memory (CNN-LSTM), PSO based CNN (PSO-CNN), and CNN-BiLSTM.

Abbreviations: RN = Randomness, PC = Premature Convergence, CO = Complexity, BE = Balancing Exploration and Exploitation, SL = Slow Learning, HC = High Computation Time, II = Insufficient, Irrelevant, or Redundant Features, CC = Computation Cost, HD = High Dimensionality.

In HAR, metaheuristic algorithms face various computational challenges that shape their design and

implementation. Table VII summarizes these challenges across 27 reviewed papers, highlighting issues such as complexity and the need for balancing exploration and exploitation. Hybrid models that combine multiple algorithms are essential to address these challenges by leveraging their individual strengths. For example, combining GA with PSO achieves a balance between exploration and exploitation, while hybrid approaches like ABC with PSO tackle complexity and premature convergence by using ABC for local search and PSO for global optimization.

High-dimensional data and redundant or irrelevant features significantly affect classification accuracy, with 55.56% (15 out of 27) of studies identifying this as a critical challenge. To address this, efficient feature selection techniques, such as using QPSO to optimize feature sets, have improved KELMs by retaining only the most discriminative features. Additionally, computational overhead, including high processing times and costs, poses scalability challenges for HAR systems. One solution has been implementing BBO within scalable architectures, dynamically optimizing resource allocation to manage system load and reduce computational demands.

The efficiency of feature selection and extraction is another critical area influenced by high dimensionality and slow learning processes, impacting 59.26% (16 out of 27) of the studies. IBGSO, for instance, enhances the learning process by identifying high-value features and reducing redundancy, thereby increasing overall system efficiency. As HAR systems increasingly demand real-time processing capabilities, algorithmic designs must focus on minimizing computational burdens without compromising accuracy, ensuring these systems are both effective and scalable for practical applications.

Additionally, intensive numerical calculations demand high computational resources; despite not being much, 4 out of the 27 papers studied have impacted the feasibility and scalability of designs. The iterative nature of the optimization process necessitates frequent updates and fitness value calculations, contributing to computational intensity. Addressing optimal training to prevent underfitting or overfitting entails computational hurdles, prompting the design of early stopping mechanisms. The transition from handcrafted feature extraction to deep learning techniques, driven by the limitations of traditional machine learning, introduces further computational demands [35]. The real-time processing requirements inherent in HAR pose significant computational challenges, guiding the selection of sensors and algorithms. Also, from Fig. 3 we can see that from 2019 to 2024, most of the challenges faced were algorithmic complexity compared to data complexity. In six years since 2019, the cumulative computational challenges faced by the papers studied were 76, and algorithmic complexity contributed 53 (69.74%) from the total, while data complexity contributed 23 (30.26%) in total, though both categories showed an increasing pattern over the years and peaked in 2024.

Metaheuristic algorithms offer a flexible strategy for optimizing intricate issues in HAR, unlike conventional techniques that might necessitate explicit mathematical formulations. Traditional machine learning approaches typically rely on predefined models and assumptions, limiting their ability to adapt to the dynamic nature of human activities. In contrast, metaheuristic algorithms seek solutions based on heuristic principles, enabling more resilient HAR solutions. The development of metaheuristic algorithms is guided by the need to balance exploration and exploitation to efficiently navigate the search space of HAR problems, a challenge less prominent in traditional optimization methods. Computational obstacles such as dimensionality and local optima are more effectively tackled by metaheuristics through population-based search strategies, a capability that traditional methods may struggle to achieve.

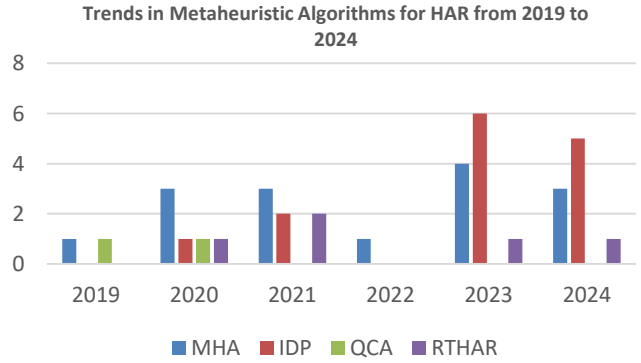
D. Trends and Research Gaps of Metaheuristic Algorithm for HAR (RQ4)

This research question explores the trends and research gaps in the use of metaheuristic algorithms for HAR between 2019 and 2024. A summary of the findings is provided in Table VIII. One notable trend is the rise of hybrid metaheuristic algorithms. These hybrid approaches, such as combining GAs with PSO, capitalize on the strengths of multiple algorithms to strike a balance between exploration and exploitation, tackle complexity, and improve convergence rates. For instance,

hybrid models that integrate ABC and PSO algorithms have demonstrated potential in enhancing both local and global search capabilities. Another emerging trend is the integration of deep learning techniques with metaheuristic algorithms. Deep learning models, particularly CNNs and Recurrent Neural Networks (RNNs), are being employed to automate feature extraction and boost classification accuracy. In addition, the application of quantum computing in this domain is gaining traction, with QPSO showing promise for optimizing processes in high-dimensional spaces. The growing demand for real-time processing in HAR has also boosted the development of more efficient and scalable algorithms. For instance, techniques like BBO are being applied to dynamically optimize resource allocation, ensuring smooth and effective operations in real-time environments.

TABLE VIII. SUMMARY OF EMERGING TRENDS IN METAHEURISTIC ALGORITHMS FOR HAR

Trend	Description	Examples
Hybrid Metaheuristic Algorithms	Combining different algorithms to balance exploration and exploitation and improve convergence rates.	GA + PSO, ABC + PSO
Integration with Deep Learning	Using deep learning models to automate feature extraction and improve classification accuracy.	CNNs, RNNs combined with metaheuristics
Quantum Computing Applications	Enhancing optimization processes in high-dimensional spaces.	QPSO
Real-Time Processing in HAR Systems	Developing scalable algorithms for dynamic optimization in real-time environments.	BBO for resource allocation



Abbreviations: MHA = Hybrid Metaheuristic Algorithms, IDP = Integration with Deep Learning, QCP = Quantum Computing Applications, RTHAR = Real-Time Processing in HAR Systems

Fig. 4. Trends in Metaheuristic algorithms for HAR from 2019 to 2024.

Fig. 4 shows key trends in metaheuristic algorithms for HAR from 2019 to 2024, focusing on four major areas: Hybrid Metaheuristic Algorithms (MHA), Integration with Deep Learning (IDP), Quantum Computing Applications (QCA), and Real-Time Processing (RTHAR). Research on MHA has remained steady, peaking with four publications in 2023 before slightly dropping to three in 2024. This reflects the continued importance of hybrid approaches in tackling complex HAR challenges. IDP has emerged as the dominant focus, with publications surging to six in 2023 and maintaining strong momentum with five in 2024. This trend highlights the growing synergy between deep learning and HAR systems, showcasing its potential to enhance automation and accuracy. QCA, while still in the experimental stage, has seen consistent yet minimal activity, with one publication annually through 2020. This indicates ongoing exploration of quantum computing's potential in HAR. RTHAR, which focuses on real-time processing techniques, saw moderate activity with a peak in 2021 before stabilizing at one publication per year through 2024. This trend suggests a gradual shift toward standardization in real-time solutions for HAR. The sustained high levels of research in MHA and IDP through 2024 demonstrate the community's strong focus on advancing hybrid models and integrating deep learning, while interest in experimental and specialized methods like QCA and RTHAR continues to provide avenues for innovation.

Significant research gaps persist in HAR, as shown in Table IX despite the trends. A key challenge lies in the scalability and efficiency of metaheuristic algorithms when handling large datasets typical in HAR applications [30]. Many of these algorithms become computationally expensive with increasing data sizes, limiting their applicability in big data scenarios. Additionally, there is a lack of comprehensive studies comparing the effectiveness of various metaheuristic algorithms across HAR contexts. While individual algorithms have been explored, systematic comparisons across scenarios, such as sensor-based activity recognition in smart homes versus smartphone-based recognition during exercise, are needed to identify the most suitable options for specific applications. Combining deep learning with metaheuristic algorithms for hyperparameter optimization has improved HAR systems but understanding how these models interpret selected features remains a major gap. This lack of insight hampers our ability to evaluate the importance of features in accurately recognizing activities. Most studies focus on improving efficiency and accuracy, often overlooking computational costs and real-time feasibility, particularly in wearable sensor-based HAR systems. Addressing these challenges is crucial for developing practical, effective solutions that enhance seamless human activity recognition.

TABLE IX. SUMMARY OF RESEARCH GAPS IN METAHEURISTIC ALGORITHMS FOR HAR

Research Gap	Description
Scalability and Efficiency	Metaheuristic algorithms often struggle with computational costs as data sizes increase in HAR applications.
Lack of Comprehensive Comparisons	Insufficient studies comparing different metaheuristic algorithms across various HAR contexts.
Interpretability of Metaheuristic-Optimized Models	Limited research on understanding the significance of features selected by metaheuristic algorithms in HAR.
Real-Time Feasibility	Need for lightweight algorithms that can operate efficiently in real-time, especially in wearable sensor-based HAR.
Adaptability to Dynamic Environments	Lack of dynamic adaptive algorithms that can adjust to changing human activity patterns.
Integration with IoT and Edge Computing	Underexplored integration of metaheuristics with IoT devices and edge computing for practical HAR applications.

V. CONCLUSION

This systematic review underscores the transformative role of metaheuristic algorithms in advancing HAR, synthesizing insights across four research questions. The analysis revealed that metaheuristic algorithms such as GWO significantly enhance feature selection and classification accuracy (RQ1), achieving up to 96.00% recognition rates by efficiently navigating high-dimensional data and reducing redundancy. Hybrid and enhanced adaptations like OCPSO and Quantum-inspired PSO emerged as pivotal solutions (RQ2), boosting detection accuracy by 2.82% and optimizing models such as QPSO-KELM to 96.2% precision. However, computational challenges persist (RQ3), in which 69.74% are algorithmic complexity, and 30.26% are data complexity. Emerging trends (RQ4) highlight a shift toward hybrid metaheuristic algorithms, integration with deep learning, and quantum-inspired techniques which had peaked in 2024, yet gaps in scalability, real-time feasibility, and interpretability demand urgent attention. Collectively, metaheuristic algorithms demonstrate immense potential to revolutionize HAR not limited to healthcare, sports, and security, but future innovations must prioritize lightweight, adaptive frameworks to bridge practical implementation gaps and unlock their full societal impact.

ACKNOWLEDGMENT

The authors would like to express their gratitude to Ministry of Higher Education Malaysia for funding the research via Fundamental Research Grant Scheme (FRGS), under grant number FRGS/1/2022/ICT02/UNIMAS/03/1. Additionally, we acknowledge the assistance provided by ChatGPT and Perplexity in the writing of this paper.

***Abstract*—Despite advancements in machine learning within healthcare, the majority of predictive models for ICU mortality lack interpretability, a crucial factor for clinical application. The complexity inherent in high-dimensional healthcare data and models poses a significant barrier to achieving accurate and transparent results, which are vital in fostering trust and enabling practical applications in clinical settings. This study focuses on developing an interpretable machine learning model for intensive care unit (ICU) mortality prediction using explainable AI (XAI) methods. The research aimed to develop a predictive model that could assess mortality risk utilizing the WiDS Datathon 2020 dataset, which includes clinical and physiological data from over 91,000 ICU admissions. The model's development involved extensive data preprocessing, including data cleaning and handling missing values, followed by training six different machine learning algorithms. The Random Forest model ranked as the most effective, with its highest accuracy and robustness to overfitting, making it ideal for clinical decision-making. The importance of this work lies in its potential to enhance patient care by providing healthcare professionals with an interpretable tool that can predict mortality risk, thus aiding in critical decision-making processes in high-acuity environments. The results of this study also emphasize the importance of applying explainable AI methods to ensure AI models are transparent and understandable to end-users, which is crucial in healthcare settings.**

***Keywords*—Explainable AI; healthcare; machine learning; predictive model**

I. Introduction

ICUs (Intensive Care Units) are specialized units that constantly monitor and treat patients with severe or potentially fatal illnesses. Due to the complexity of the ICU environments and the high-stake nature of patient care, accurate prediction of mortality risk in critically ill patients is a key aspect of adequate healthcare management [1], [2]. Machine learning algorithms and predictive models have shown great promise in addressing these needs by mining large amounts of clinical data to predict the risk of patient mortality. Predicting accurately has a significant effect on clinical decisions, allocation of resources, and the management of patients [3]. Machine learning methods have made tremendous progress and opened up new avenues for mortality prediction in the clinical world. To produce predictive insights, machine learning models are trained on complex datasets containing patient demographics, clinical measurements, and historical health records. Machine learning algorithms can explore more complicated relationships between variables than traditional statistical methods allow [4]. One example is through models utilizing extensive, large-scale electronic health record (EHR) data that has improved prediction performance for patient outcomes [5], [6].

Despite advances in machine learning, several challenges remain in accurately predicting mortality risk in ICU patients. For one, low-dimensional and high-dimensional complex healthcare data can increase the risk of overfitting and decrease the generalization performance of models if handled poorly [7], [8]. Also, the explainability of machine learning models is an important issue; medical professionals must have precise and reliable predictions to implement AI tools in clinical practice [9], [10], [11]. Black-box models can be opaque and difficult to interpret, preventing adoption in high-stakes medical contexts. Explainable Artificial Intelligence (XAI) frameworks, such as SHAP (Shapley Additive Explanations) and LIME (Local Interpretable Model-Agnostic Explanations), address this issue by providing transparent and interpretable explanations of model predictions, enhancing trust and usability [12], [13].

To mitigate these challenges for predictive models, the primary goal of this study is to develop an interpretable mortality risk prediction model incorporating machine learning algorithms with explainable artificial intelligence (XAI) methods. The dataset utilized in this study is derived from the 2020 Women in Data Science (WiDS) Datathon, which provides a rich profile of ICU patients, including various physiological and clinical variables [14]. The use of Explainable AI (XAI) methodologies, such as SHAP (Shapley Additive explanations) and LIME (Local Interpretable Model-agnostic Explanations), is intended to provide transparent insights into the model's decision-making process, thereby facilitating better understanding and trust in the predictive outcomes. This study addresses the limitations of previous studies by combining interpretability, accuracy, and clinical application, covering the way for reliable and actionable AI solutions in critical care settings.

The remainder of this study is structured as follows: Section II presents the background and motivation for the study. Section III provides a detailed description of the dataset's characteristics and explains the preprocessing methods employed in the study. Section IV presents the results of the training and evaluation of the AI model. Section V offers the discussion and considers the limitations of the study. Finally, Section VI concludes the paper,

summarizes the main points, and suggests areas for future research.

II. Background

In recent years, the healthcare industry has rapidly adopted machine learning (ML) and artificial intelligence (AI) approaches to construct predictive models that better decision-making and improve patient outcomes [15]. They excel at interpreting large amounts of medical data, including electronic health records (EHRs), genomic data, and medical images, revealing patterns that humans may overlook [16], [17]. Historically, interpretable methods like linear regression and naïve Bayes have been favored in healthcare domains such as neurology and cardiology, ensuring clarity for medical practitioners. Zhang et al. [18] developed an in silico prediction model for chemical-induced urinary tract toxicity using a naïve Bayes classifier, showcasing its effectiveness in toxicology assessments. Salman [19] explored heart attack mortality prediction by applying various machine learning methods, highlighting the potential of data-driven approaches to enhance clinical decision-making. Obeid et al. [20] introduced a deep learning model for the automated detection of altered mental status in emergency department clinical notes, offering insight into the capability of natural language processing in identifying critical health conditions.

However, while linear regression and naïve Bayes are interpretable by nature, these methods often struggle with complex or non-linear datasets. More recent approaches such as decision trees, K-nearest neighbors (K-NN), and support vector machines (SVMs) allow for more nuanced analyses of the data, which is particularly useful for output for conditions such as diabetes and heart diseases [21]. Abdalrada et al. [22] investigated machine learning models for predicting the co-occurrence of diabetes and cardiovascular disease, highlighting the potential for AI-driven techniques to discover overlapping risk factors and enhance early diagnosis. Karun [23] performed a comparative analysis of heart disease prediction algorithms, assessing the usefulness of several machine learning models, such as decision trees and SVMs, in increasing diagnostic accuracy. Rajkomar et al. [24] investigated the scalability and accuracy of deep learning using electronic health records, revealing how neural networks can analyze large volumes of patient data to improve prediction capacities while remaining adaptable across various medical situations.

While the field has advanced with deep learning algorithms that can deal with complex patterns in large datasets, their black-box nature presents a hurdle to clinical trust and uptake [12], [15], [25]. Interpretability is especially critical in supervised learning, commonly used in healthcare AI to predict specific health outcomes [26]. To counter the above problems, research has focused on developing XAI systems, which combine the complexities of the model and the ease of using it in a clinical setting [27], [28]. XAI controls the complexity of user explanations to those that a medical practitioner can understand, thus helping in forming opinions that can be acted on and trusted [29], [30], [31]. Furthermore, several evaluation methods for interpretability have been proposed, including application-grounded, human-grounded, and functionally grounded approaches. Application-based evaluations, which are performed while undertaking real-life activities along with the experts in the field, are particularly important for validating XAI models in the area of medicine [27]. Human-based evaluations involving laypeople are less expensive and easier to scale, but they may not capture the specific needs of medical practitioners [32]. Functionally grounded evaluations, which do not involve human users, assess interpretability based on proxy metrics like the complexity of decision trees, but they may lack practical relevance [33]. Even with these advances, there are still challenges like obtaining acceptable regulations, integrating them into existing frameworks, and teaching professionals in the field [25].

Despite these challenges, the demand for interpretable AI systems continues to grow as they offer the potential to revolutionize medical diagnostics and treatment planning by providing transparent, trustworthy, and actionable insights [32]. In this regard, this research aims to produce an explainable predictive model for predicting mortality risks in ICUs that use XAI and conventional AI techniques while overcoming inadequate past research in this field.

III. Method

A. Dataset Description

The dataset utilized in this study is sourced from the WiDS Datathon 2020 and comprises de-identified clinical data of 91,713 ICU patients collected over a year. This extensive dataset captures 186 physiological and clinical variables documented within the first 24 hours of ICU admission. The variables include a broad spectrum of demographic information, such as age, gender, and BMI, along with various health metrics like blood pressure, heart rate, and laboratory test results. These variables are essential for predicting patient outcomes, particularly mortality risk, in an ICU setting.

B. Data Preprocessing

1) Data cleaning: The first step in the data preprocessing involved loading the dataset and reducing the number of features from 186 to 28. This reduction was achieved by eliminating irrelevant or redundant features that did not contribute significantly to the prediction task.

2) Handling missing data: Columns containing significant missing data were eliminated to ensure the dataset's integrity and reliability. This step was crucial in ensuring the analysis was based on complete and accurate information. After removing these columns, the dataset was further refined, resulting in a final dataset consisting of 940 rows and 28 columns (Fig. 1, Fig. 2).

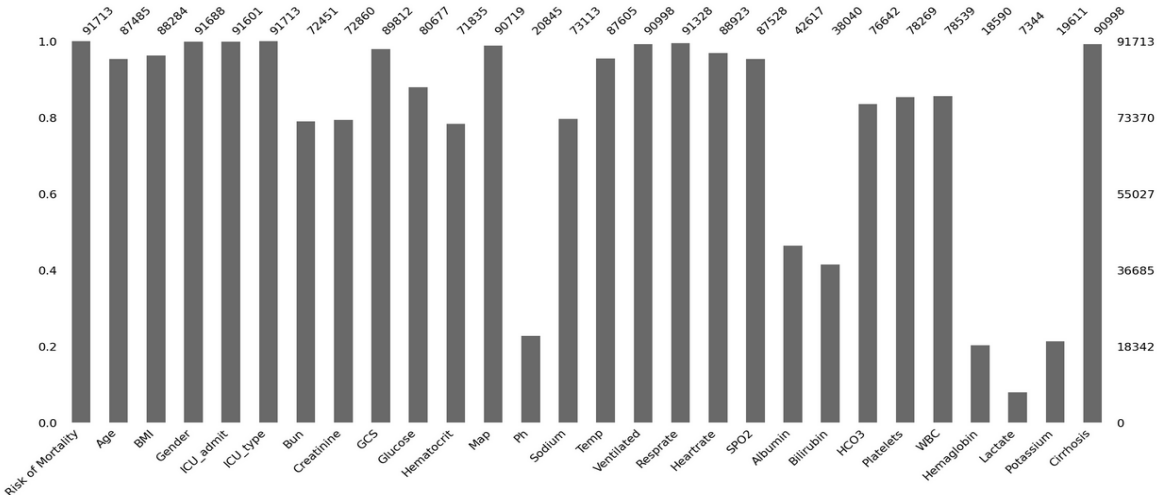

Fig. 1. Distribution of missing data across features.

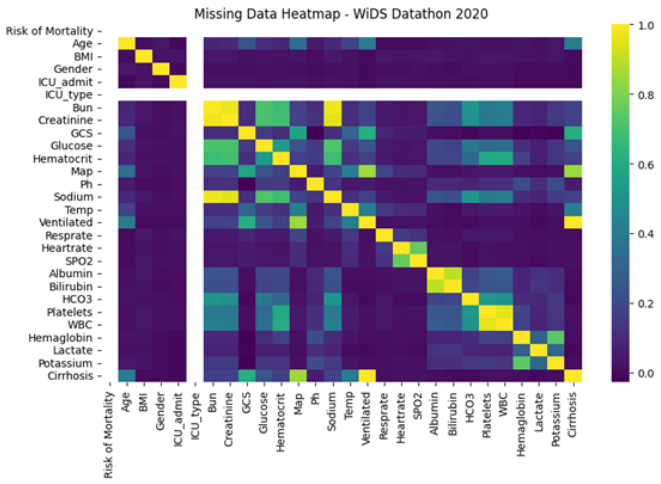

Fig. 2. Heatmap visualizing the correlations of missing values.

First, a correlation matrix of the missing values was generated, and a heatmap was used to identify patterns in the missing data. To address this, we applied the `dropna` function, which successfully removed the missing values and mitigated the impact of outliers. Rather than using imputation, we chose to eliminate entire columns with any missing data, prioritizing precision in healthcare predictions. While removing features with less than 5% missingness might seem counterintuitive, the critical nature of medical decisions made data completeness more important.

3) Data encoding: Data encoding techniques were applied to prepare the categorical variables for machine learning models. Specifically, Label Encoding was used to convert categorical variables such as Gender, ICU_admit, and ICU_type into numerical values, as illustrated in Fig. 3. This transformation allowed the models to process these variables effectively, as most machine learning algorithms require numerical input [34].

- Gender:
  - Original values: 'F', 'M'
  - Encoded values: 0, 1
- ICU_admit:
  - Original values: 'Floor', 'Operating Room / Recovery', 'Accident & Emergency', 'Other Hospital', 'Other ICU'
  - Encoded values: 0, 1, 2, 3, 4
- ICU_type:
  - Original values: 'Med-Surg ICU', 'MICU', 'CTICU', 'Neuro ICU', 'SICU', 'CCU-CTICU', 'Cardiac ICU', 'CSICU'
  - Encoded values: 0, 1, 2, 3, 4, 5, 6, 7

Fig. 3. Label encoding was applied to convert categorical variables.

4) Exploratory Data Analysis (EDA): EDA was conducted to uncover patterns and insights within the dataset. This analysis included visualizing demographic trends and identifying risk patterns among ICU patients. For instance, analysis of patients' age makeup clarified the age distribution. With concentrations in the 60–70 and 70–80 cohorts, age-related dynamics may impact mortality risk. Interestingly, the 50–60 cohort was equally large, demonstrating the sample's age diversity. Fig. 4 shows how the age distribution affects risk assessment. These insights guided the feature selection process and informed the subsequent steps in the analysis.

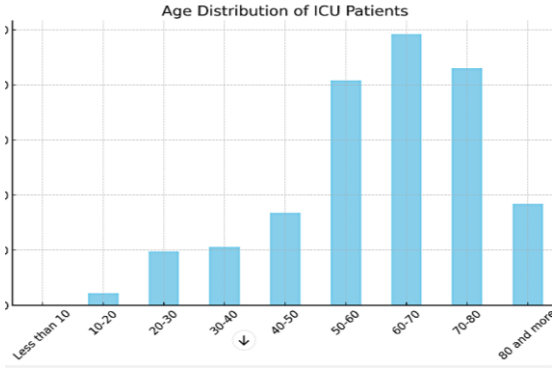

Fig. 4. Distribution of patient age groups.

5) Handling outliers: Outliers can distort the results of data analysis and model predictions. To address this, the Interquartile Range (IQR) technique was employed. Data points below Q1 - 1.5 * IQR or above Q3 + 1.5 * IQR were deemed outliers and deleted (Fig. 5, Fig. 6). This step ensured that the data used for model training was free from extreme values that could potentially bias the analysis [35].

6) Feature engineering: Feature engineering was performed to enhance the predictive power of the models. The SelectKBest method was used to identify the most significant features, and these selected features were then standardized using StandardScaler.

7) Balancing dataset: Given the class imbalance in the dataset, where high-risk cases were underrepresented, oversampling techniques were applied to balance the dataset. This step involved increasing the number of high-risk instances to ensure the model could accurately predict high-risk and low-risk cases. Balancing the dataset was vital for improving the model's sensitivity and reducing bias toward the majority class [36].

8) Data splitting: Partitioning the dataset into training and testing sets was the final step in data preprocessing. Eighty percent of the data was used to train the models, with the remaining 20% put aside for testing. This split meant that the models were evaluated using previously unseen data, resulting in a reliable assessment of their performance [37].

C. Model Training and Evaluation

The following six machine learning algorithms were chosen for evaluation: K-Nearest Neighbors, Random Forest, Decision Tree, Gradient Boosting, Logistic Regression, and Support Vector Machine. To optimize performance, GridSearchCV was implemented to tune hyperparameters for each model. The models were evaluated using F1-Score, Accuracy, Precision, and Recall classification measures. The best performing model was chosen for its proficiency in correctly forecasting ICU patient death.

D. Model Explainability

This study employed Explainable Artificial Intelligence (XAI) methods, particularly SHAP and LIME, to enhance model transparency. SHAP was used to interpret the importance of features in the Random Forest model, providing a detailed understanding of how each feature influenced risk predictions. LIME offered localized explanations for individual predictions, aiding in interpreting specific instances. After comparing both methods, SHAP was chosen as the primary tool for generating user-centric explanations, owing to its effectiveness in healthcare contexts [12], [38].

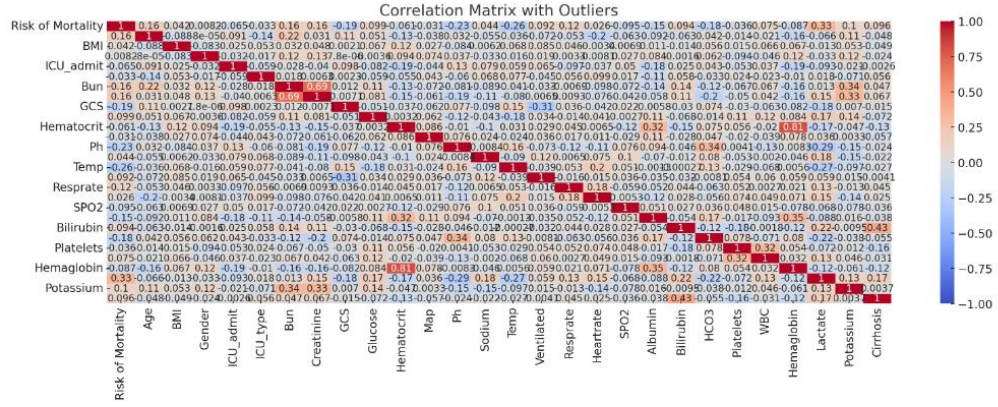

Fig. 5. Correlation matrix with outliers.

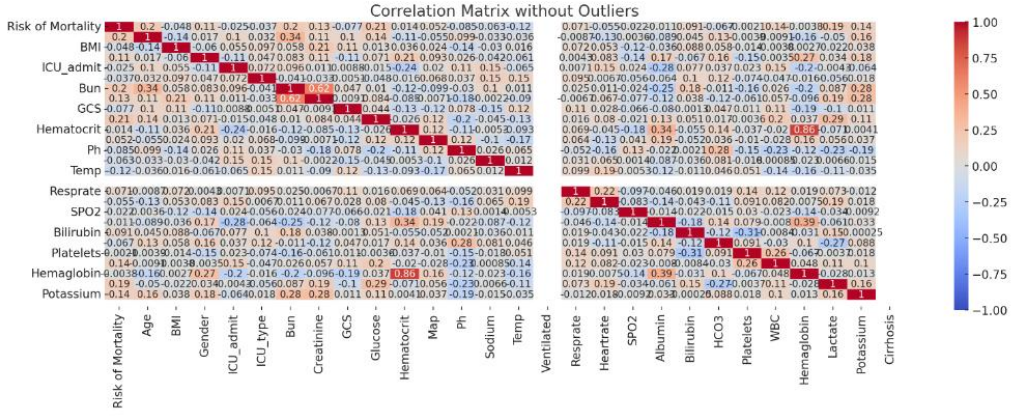

Fig. 6. Correlation matrix without outliers.

IV. Results

A. Model Performance

The performance of the six machine learning algorithms was compared based on their ability to predict mortality risk. As shown in Table I, the Random Forest algorithm outperformed the other models across all evaluation metrics, with an accuracy of 0.8511, precision of 0.8485, recall of 0.855, and an F1-Score of 0.8517.

TABLE I. Comparison of Machine Learning Techniques

Model	Accuracy	Precision	Recall	F1-Score
Logistic Regression	0.7252	0.7185	0.7405	0.7293
Random Forest	**0.8511**	**0.8485**	**0.855**	**0.8517**
Support Vector Machine	0.8321	0.8372	0.8244	0.8308
Gradient Boosting	0.8206	0.8088	0.8397	0.824
K-Nearest Neighbors	0.8244	0.7931	0.8779	0.8333
Decision Tree	0.7443	0.7133	0.8168	0.7616

B. Accuracy of Models

Fig. 7 illustrates the accuracy of the six machine learning algorithms. The Random Forest model proved the best accuracy, while the Support Vector Machine, K-Nearest Neighbors, and Gradient Boosting models performed comparably. In comparison, the Decision Tree and Logistic Regression models had slightly lower accuracy values.

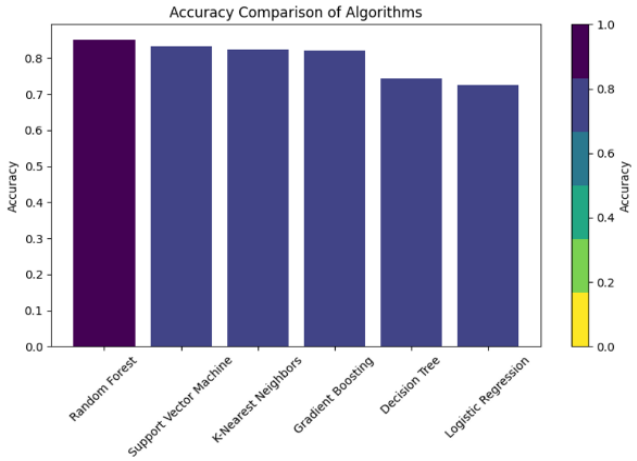

Fig. 7. Comparison of algorithms showing random forest model has the best accuracy.

1) ROC curve analysis: The ROC curve analysis emphasized the Random Forest model's superior performance. As shown in Fig. 8, the Random Forest model had the most significant AUC of 0.94, showing an excellent capacity to distinguish between high-risk and low-risk mortality cases. The Support Vector Machine model was next with an AUC of 0.92, while the Decision Tree model had the lowest AUC of 0.82.

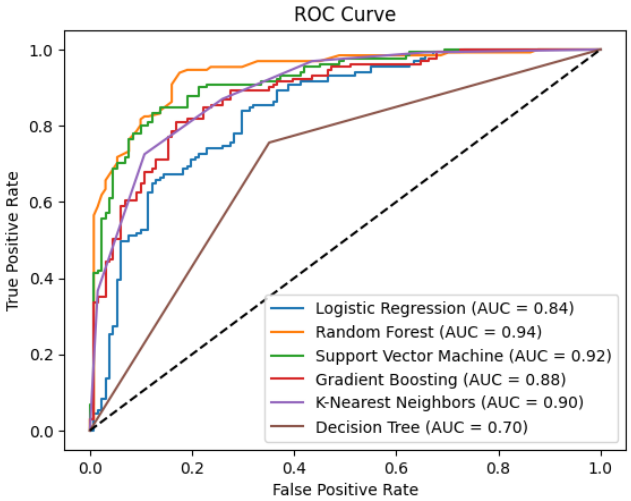

Fig. 8. ROC curve comparison for six machine learning algorithms.

2) Confusion matrix: The confusion matrix for each model provided insights into their classification performance. Fig. 9 illustrates the number of correct and incorrect predictions made by each model. The Random Forest model had the highest counts of true positives and true negatives, indicating its superior ability to classify both high-risk and low-risk mortality cases correctly.

C. Feature Importance Analysis

To enhance the interpretability of the model, Explainable Artificial Intelligence (XAI) methodologies, specifically SHAP and LIME, were employed. These techniques were valuable in making the model's decision-making process more transparent and understandable for healthcare practitioners.

1) SHapley Additive exPlanations (SHAP): SHAP was used to interpret the feature importance of the trained Random Forest model. A SHAP summary plot (Fig. 10) was generated using the TreeExplainer, which showed that features such as age, SOFA score, and lactate levels were significant contributors to the model's predictions. The SHAP values offered a clear grasp of how each characteristic affects mortality risk predictions, with greater SOFA scores and elevated lactate levels related to increased mortality risk, as acknowledged by studies such as [12], [38], [39].

2) Local Interpretable Model-agnostic Explanations (LIME): LIME was employed to explain individual predictions by generating local explanations for specific instances. Fig. 11 illustrates a detailed LIME explanation, showing the contribution of each feature to the prediction. For instance, one risk-predicting factor was high lactate level with significantly low temperature, with other factors like GCS, SPO2, ICU type, creatinine levels, age, and gender also playing roles. By breaking down predictions into these specific details, LIME enables healthcare practitioners to understand the rationale behind individual predictions, fostering trust in the model's outputs [13], [40], [41].

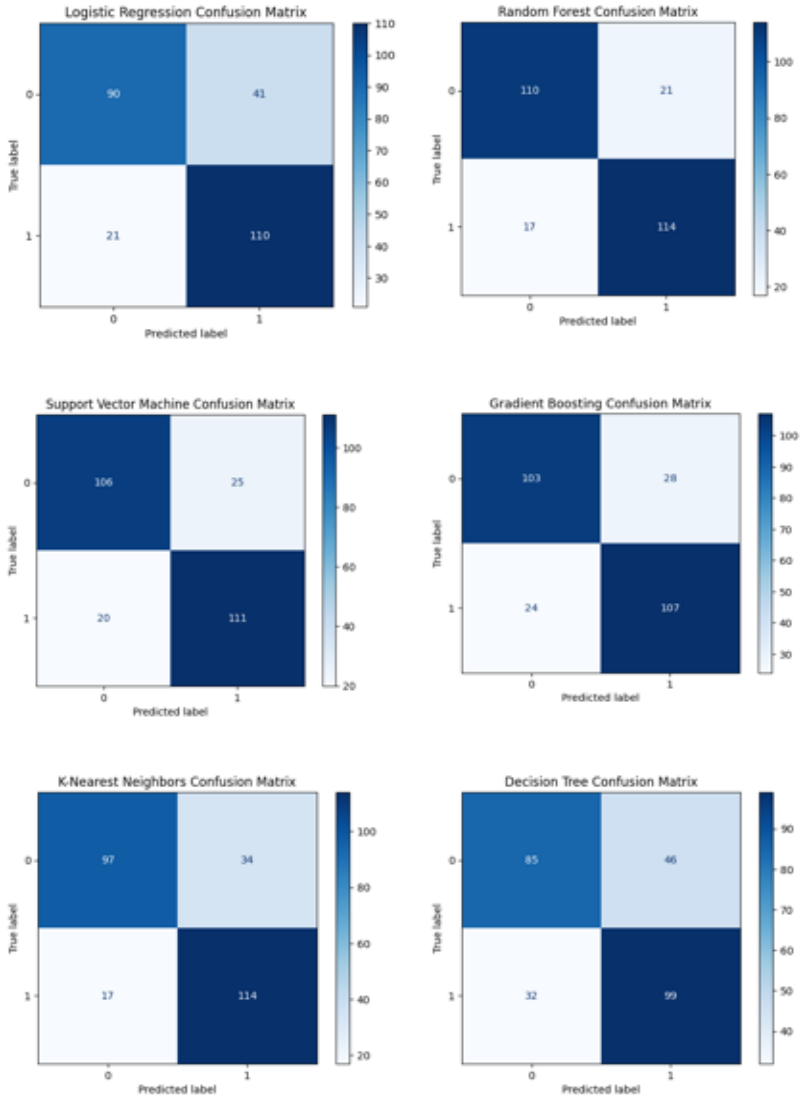

Fig. 9. Confusion matrix showing the number of correct and incorrect predictions made by each model.

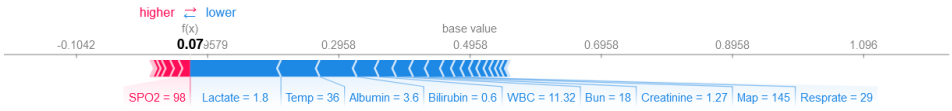

Fig. 10. SHAP summary plot.

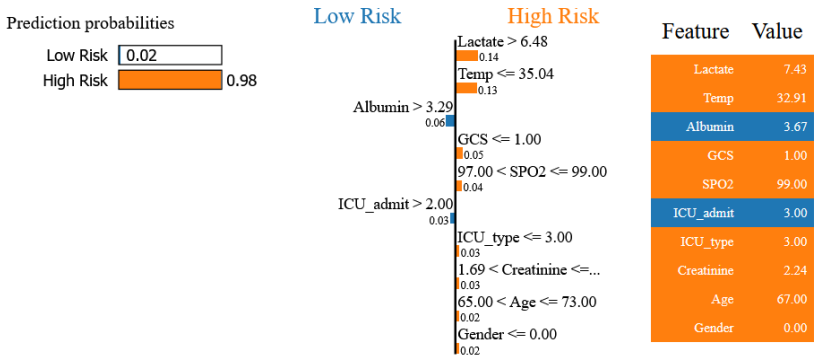

Fig. 11. LIME explanation.

V. Discussion

The results of this study are consistent with previous research that has demonstrated the effectiveness of Random Forest in predicting mortality risk in ICU patients. The Random Forest model's outstanding performance is primarily due to its capacity to handle large datasets and capture complicated correlations between variables. This study's findings align with previous research showing the usefulness of Random Forest in predicting mortality risk in ICU patients. The Random Forest model's exceptional success is primarily due to its ability to handle large datasets and identify the intricate connections between variables. The decision to balance the dataset by oversampling was crucial for improving the model's accuracy and reducing bias, a method supported by other studies, including that of [36]. Although [4] showed how effectively deep learning models capture non-linear correlations in complicated datasets, Random Forest was selected for this study because of its exceptional interpretability and widespread use in clinical settings. The use of SHAP and LIME provided valuable insights into the model's decision-making process. SHAP allowed for a global interpretation of feature importance, highlighting the significant role of clinical markers such as age, SOFA score, and lactate levels. These results are consistent with clinical expectations and established literature, thereby validating the model's predictions [12], [38], [39], [42]. The implications of this study for clinical practice are substantial. Implementing a Random Forest-based mortality risk prediction model enables healthcare professionals to more accurately identify patients at elevated risk of mortality and allocate resources more efficiently. This methodology may result in enhanced individualized care plans and superior patient outcomes. Furthermore, the model's ability to incorporate a wide range of clinical variables makes it adaptable to different ICU settings and patient populations.

While the results are promising, the study is not without limitations. The dataset is comprehensive; hence, the generalizability of the model may be restricted to different ICU populations. Despite the dataset is large, it only comes from one source. Hence, the generalizability of the model may be restricted to different ICU populations. This emphasizes the need for external validation over several datasets representing various geographical and clinical settings. Also, relying on these individual attributes raises concerns about potential biases. For example, demographic factors such as age or gender may potentially introduce systemic biases, limiting the model's generalizability across different patient populations [43]. Additionally, even though Random Forest performed more effectively than the other models in this study, investigating advanced methods—like ensemble approaches that combine deep learning with XAI tools—could improve the models' predictive abilities and interpretability.

VI. Conclusion

This study developed and evaluated a machine learning model to predict ICU patient mortality risk using the WiDS Datathon 2020 dataset. The Random Forest algorithm emerged as the most effective model, outperforming other algorithms in accuracy, precision, recall, and F1-Score. The AI mortality risk prediction model showed strong performance, with SHAP and LIME providing essential tools for enhancing model explainability. SHAP was particularly effective in offering clear and actionable explanations, making it the preferred method for developing user-centric explanations in this study. The study's findings highlight the potential of machine learning to improve clinical decision-making in ICU settings. Future research should focus on validating the model across multiple datasets from diverse geographic and clinical settings. Additionally, exploring integrating other machine learning techniques, such as deep learning, could further enhance the model's predictive accuracy.

***Abstract*—Since this is one of the most challenging tasks in cyber security, many of them are affected by class imbalance when it comes to the performance of machine learning. This paper evaluates various strategies using a number of resampling-based approaches: ROS, RUS, and SMOTE-based methods in conjunction with XGBoost classifier techniques to solve such an imbalanced dataset. Key performance measures include precision, F1 score, recall, precision, ROC-AUC, and geometric mean score. Among the methods, the highest was found with regard to the SMOTE-NC-XGB with precision equal to 98.0% and a recall of 98.5%, thus ensuring an effective trade-off between sensitivity and specificity. Although the stand-alone XGB model performs really well, adding resampling techniques makes its efficiency much higher, especially in cases of evident imbalance between classes. These results also revealed that resampling techniques are really helpful to enhance detection performance; hence, the SMOTE-NC-XGB is found out as the best among all of these. It will be of great contribution for future works in order to enhance the development of phishing detection systems and investigate other new hybrid resampling methods.**

Keywords*—Phishing website detection; class imbalance; XGBoost; SMOTE-NC

I. Introduction

While the cyberworld has expanded infinitely, phishing assaults have evolved into increasingly sophisticated attacks that target individuals and entities by assuming the identity of legitimate websites for the purpose of retrieving sensitive information [1]. Detection of these malicious sites is an important challenge in cybersecurity which is further complicated by the gross class imbalance contained in phishing collections. In these datasets, legitimate websites far exceed phishing websites, and machine learning models cannot detect phishing attacks effectively—a key process of mitigating cyber attacks [2].

Accuracy and reliability of machine learning models heavily depend on the quality and consistency of training data. Proper data preparation—cleaning, processing, validation, and transformation of raw data—is essential to building good models [3]. Class imbalance handling is one of the most important tasks in this work. Class imbalance, as a condition of underrepresented minority class, is common in applications such as fraud detection, health, and phishing website detection [4, 5]. In phishing detection, underrepresentation of phishing sites in datasets generally results in model bias towards the majority class, increasing the risk of false negatives, where phishing sites are classified as normal [6].

Machine learning models are negatively affected by imbalanced datasets with skewed class distributions, as this causes the models to be biased towards the majority class. This diminishes their generalization capability and hinders their applicability in real-world situations [7]. Traditional classification techniques are biased towards the majority class, which worsens these problems and highlights the necessity of specialized methods to counteract class imbalance.

In order to address this problem, researchers have put forward various resampling methods, i.e., undersampling, oversampling, and the Synthetic Minority Over-sampling Technique (SMOTE) [8]. All these methods assist in rebalancing data by reducing the majority class size or enhancing the minority class size and, therefore, the model becomes more capable of distinguishing between authentic sites and phishing websites. Here, we will attempt to combine these resampling techniques with the XGBoost classifier, a widely recognized algorithm for its high performance and scalability [9]. Despite its demonstrated effectiveness, inadequate detailed comparative studies in the literature have investigated the impacts of using different resampling techniques when coupled with XGBoost for detecting phishing websites.

This research aims to bridge this gap by providing a comparative analysis of undersampling, oversampling, and SMOTE methods under the XGBoost algorithm for phishing website detection optimization. From real datasets, we compare how these resampling methods affect the performance of the XGBoost classifier in handling class imbalance. The results not only show the relative merits and drawbacks of every resampling method but also give specific guidelines for researchers and practitioners interested in constructing more robust phishing detection systems.

The rest of this paper is organized as follows: Section II describes the importance of class imbalance in phishing website detection and how resampling methods can be utilized to alleviate it. Section III compares the performance of the XGBoost classifier when combined with these resampling methods, comparing their impacts on key performance metrics. Section IV outlines the experimental design, data set, preprocessing, and application of the XGBoost algorithm. Section V presents the results and discusses the impact of resampling methods on model performance. Finally, Section VI concludes with a summary of the major findings and suggesting potential areas for further study.

II. Literature Review

Preparation of data is an important phase of the data mining process, typically consuming 70–80% of the total time invested in data science activities [10]. The "garbage in, garbage out" (GIGO) principle emphasizes the extreme importance of high-quality input data in obtaining accurate and useful output. Good data preparation is more than data cleansing to include missing value handling, duplicate elimination, and outlier handling, all of which are required to derive actionable insights from raw and usually unstructured data [11].

In detecting phishing sites, datasets show complex patterns when it comes to characteristics such as URL patterns, hosting characteristics, and user activities. These patterns can be effective inputs for predictive models to identify phishing attacks [12]. However, these patterns have to be unearthed via repeated testing and knowledge of domains [13]. Therefore, data preparation is an important task in cybersecurity that transforms raw data into formats where it can be acted upon, being sensitive to machine learning algorithms.

Among the biggest problems for detecting phishing is the extreme class imbalance, where genuine websites heavily outnumber phishing websites. The issue tends to bias model performance and has a propensity to result in bias towards the majority class and higher false negative likelihoods. This research seeks to mitigate this through experimentally testing resampling methods including undersampling, oversampling, and an in-house approach called SMOTE-NC (Synthetic Minority Over-sampling Technique for Nominal and Continuous variables). These methods are intended to introduce balance to the dataset so that the model can better identify phishing sites accurately and eliminate the adverse effect of class imbalance.

A. Undersampling Techniques to Handle Class Imbalance Undersampling reduces the majority class in such a way that the dataset is balanced and machine learning algorithms can learn from minority class samples without bias. For instance, downsampling 12,000 majority class samples to balance 2,000 minority class samples creates a balanced 1:1 ratio. Although this technique makes the dataset easy to train, it must selectively choose majority class samples to maintain the integrity and predictive power of the dataset (Fig. 1).

A. Undersampling Techniques for Addressing Class Imbalance

Undersampling decreases the majority class to a level where the dataset is balanced, allowing the machine learning models to learn from the instances in the minority class without bias. For instance, decreasing 12,000 majority class samples to equal 2,000 minority class samples creates a 1:1 balanced dataset. Although this technique minimizes the complexity of the dataset during training, it needs to sample the majority class samples aggressively so that it does not compromise the integrity and forecastability of the dataset (Fig. 1).

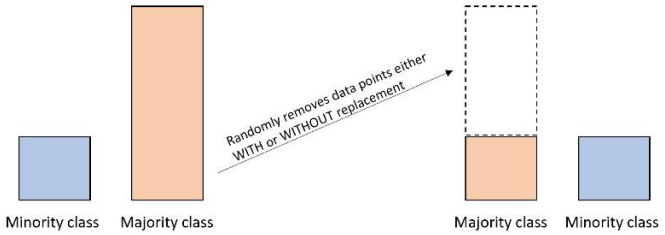

Fig. 1. Random undersampling process [14].

1) Random Undersampling (RUS): Random Undersampling (RUS) is the most basic and widely used undersampling technique. It does this by randomly selecting a subset of samples from the majority class to build a balanced dataset. This reduces the majority class bias, thereby improving the sensitivity of the model to phishing websites [15].

RUS has been used in a wide range of applications that encompass anomaly detection, fraud detection, and cyber security. When used in the detection of phishing websites, it reduces false negatives and enhances model performance by stabilizing class representation. Its simplicity comes at a price, though: the potential loss of informative information from the discarded majority class samples, which can limit the model's generalization capability in real-world scenarios.

B. Oversampling Techniques for Addressing Class Imbalance

Oversampling compensates for class imbalance by increasing the size of the minority class in the data set. The current minority class samples are replicated or new synthetic samples are created. Since the data set is balanced, oversampling eliminates the majority class bias and enhances the performance of the model in identifying phishing websites (Fig. 2).

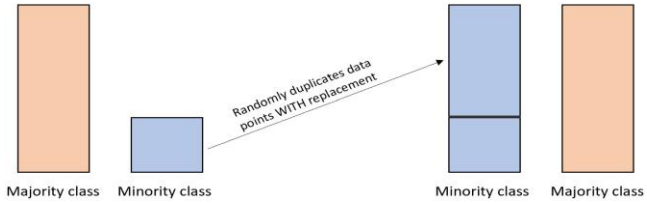

Fig. 2. Random oversampling process [14].

1) Random Oversampling (ROS): Random Oversampling (ROS) evens out the dataset by duplicating instances from the minority class to be identical to the majority class instances. As effective as this process treats class imbalance, it would also lead to overfitting based on the duplication of the same instances, hence reduced robustness and ability to generalize to new data [16].

In order to counteract these issues, variants like distributional random oversampling, where the synthetic samples are created from the statistical distribution of features, and stratified random oversampling, where generation of varied samples is guaranteed, have been suggested. Though having its own drawbacks, ROS has been found to be highly beneficial for phishing website detection by enhancing the representation of the minority class and model performance during training.

C. SMOTE-NC for Handling Class Imbalance

SMOTE-NC is an extension of the original SMOTE algorithm for the treatment of datasets with mixed data types, i.e., categorical and numerical variables. SMOTE-NC creates the synthetic samples in such a manner that it preserves the inherent features and interrelation among the data and effectively addresses class imbalance without compromising data integrity (Fig. 3).

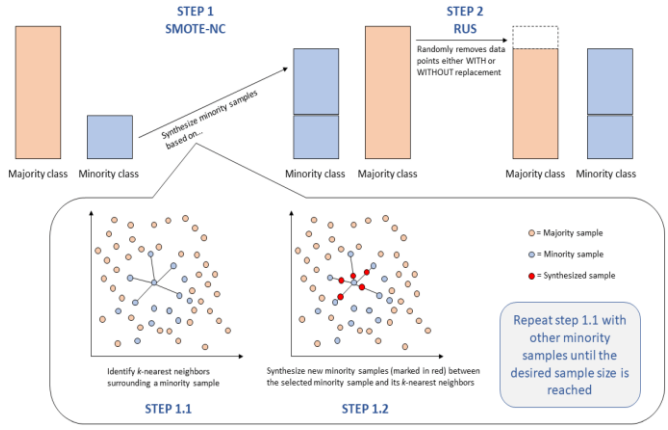

Fig. 3. SMOTE-NC process [14].

SMOTE-NC algorithm generates samples by interpolating between the minority class instances and their k-nearest neighbors in the numerical features. In categorical features, it finds the most frequent category among the neighbors so that the synthetic samples preserve the inherent categorical data distributions. This approach preserves the integrity of the mixed data types while improving the model performance, particularly in the detection of phishing websites [17].

However, SMOTE-NC is not limited [18]:

- Problems with high-dimensional data: Distance measures are meaningless in high-dimensional space.
- Introduction of noise: Synthetic samples may deviate from the true minority class distribution.
- Fixed k-neighbors: The k-neighbors parameter is applied uniformly, without considering the local variation of the data.

Despite the limitations outlined, SMOTE-NC has proven to be a valuable tool when used in phishing website detection, particularly when operating in datasets that involve categorical features such as domain-pattern-based or URL feature-based classifications. Through the preservation of integrity of the categorical variables and handling the class imbalance problem, SMOTE-NC operates to enhance the model towards effective phishing website detection.

Overall, undersampling, oversampling, and hybrid approaches each possess their own strength in class imbalance handling for phishing website detection. Selection of an effective resampling approach must be guided by the characteristics of the dataset and the requirements of the task at hand. Effective data preprocessing, particularly when working with imbalanced datasets, is critical to developing stable and actionable machine learning models with the ability to counteract the dynamic nature of phishing attacks.

III. Methods

This chapter introduces the research framework that seeks to enhance phishing website detection using a combination of state-of-the-art resampling methods and the XGBoost classifier. This chapter begins with introducing a step-by-step description of the dataset, as well as a heatmap visualization of feature correlation, which gives valuable information regarding variable correlation. The article then goes on to outline various class imbalance learning techniques, i.e., Random Oversampling (ROS), Random Undersampling (RUS), and SMOTE-NC, and outlines their settings and respective contributions to the resampling process. The XGBoost classifier is then outlined in detail, including its setup, tuning, and why it is suitable for the phishing detection task. This integrated paradigm facilitates systematic study of resampling's methods and their combined impact when used along with XGBoost, thereby preventing the consequences of class imbalance in phishing site detection.

A. Dataset Description

The dataset used in this work is taken from the UCI Machine Learning Repository [19]. It contains 11,055 records with 30 website attributes along with a class label indicating websites as phishing (1) and legitimate (-1). Table I summarizes the makeup of the dataset.

TABLE I. Dataset Description

Total number of instances	Total of Features	Class Variable Phishing website	Class Variable Legitimate website
11055	30	6157	4898

1) Visualizing the dataset: Heatmap of feature correlations: To understand relationships between features, a heatmap visualization was generated, identifying patterns and correlations crucial for feature engineering and selection [20] (Fig. 4).

In the heat map, each cell is colored according to a correlation value that goes from dark to light, indicating respectively a strong positive correlation and a strong negative one. The closer the correlation value is to +1, the stronger the positive relationship. The closer the value is to -1, the stronger the negative relationship. A correlation close to 0 means there is little or no linear relationship between the compared features. This visualization has given a better idea of interfeature dependencies; hence, crucial toward understanding the feature relevancy in respect of phishing website detection.

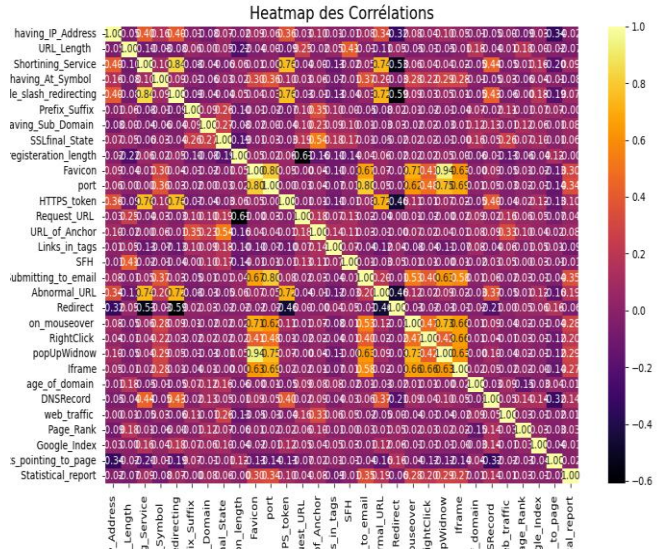

Fig. 4. The heatmap of dataset features.

B. Imbalance Learning Techniques

In this paper, ROS, RUS, and a hybrid approach with SMOTE-NC are used for performance comparisons of different resampling methods. SMOTE-NC with five nearest neighbors uses a resampling ratio of 0.8 to generate synthetic samples, while ROS and RUS apply random sampling processes to adjust the class distribution. These resampling techniques were implemented using the imbalanced-learn Python package [21], ensuring the reproducibility and consistency of the results.

1) Random Oversampling-XGBoost (ROS-XGB): ROS is a technique of oversampling the minority class samples to make the dataset balanced [22]. The ROS-XGB method, which combines the XGBoost classifier with random oversampling, enhances the model performance in phishing website detection by overcoming the problem of class imbalance. The hyperparameters of ROS-XGB are tuned for better performance. The details are shown in Table II. The parameters include the learning rate, maximum depth, number of estimators, and subsampling rate, which are tuned carefully for better accuracy and robustness of the model.

TABLE II. ROS-XGB PARAMETERS

Parameter	Value	Description
learning_rate	0.5	Resampling the minority class to balance the dataset.
max_depth	7	Controls tree depth for model complexity.
n_estimators	100	Number of boosting rounds.
subsample	1.0	Fraction of samples used for fitting each tree.

ROS-XGB improves recall and overall performance by mitigating class imbalance, making it effective at detecting phishing websites while maintaining high precision.

2) Random Undersampling-XGBoost (RUS-XGB): Random Undersampling (RUS) reduces the size of the majority class to that of the minority class, ensuring a balanced dataset [23]. When combined with the XGBoost classifier, the RUS-XGB approach enhances phishing website detection by giving equal importance to both classes. The hyperparameters for RUS-XGB are shown in Table III, which presents the specific configurations used to optimize model performance.

TABLE III. RUS-XGB PARAMETERS

Parameter	Value	Description
learning_rate	0.5	Resampling the minority class to balance the dataset.
max_depth	8	Tree depth to control model complexity.
n_estimators	300	Number of boosting rounds.
subsample	0.8	Fraction of samples used for fitting each tree.

RUS-XGB helps address class imbalance by reducing the influence of the majority class, thus improving recall and overall detection accuracy.

3) SMOTE-NC-XGBoost (SMOTE-NC-XGB): SMOTE-NC [24] is the Synthetic Minority Over-sampling Technique for Nominal and Continuous features that will generate synthetic samples for the minority class without affecting the structure of categorical features. XGB integrated with SMOTE-NC, denoted as SMOTE-NC-XGB, addresses class imbalance by generating more balanced data. The detailed hyperparameter tuning for SMOTE-NC-XGB on the number of nearest neighbors and resampling ratio is listed in Table IV.

TABLE IV. SMOTE-NC-XGB PARAMETERS

Parameter	Value	Description
learning_rate	0.1	Resampling the minority class to balance the dataset.
max_depth	7	Tree depth to control model complexity.
n_estimators	300	Number of boosting rounds.
subsample	0.8	Fraction of samples used for fitting each tree.

SMOTE-NC-XGB generates synthetic samples while maintaining the integrity of both categorical and continuous features, boosting recall, precision, and overall model performance in phishing website detection.

C. The XGBoost Classifier

XGBoost was selected because of its superior performance in classification tasks, especially for complex and imbalanced datasets, which is often the case in phishing website detection. Being a gradient boosting algorithm, XGBoost creates an ensemble of decision trees, improving predictive accuracy by iteratively adding models in a sequence [25]. It is particularly suited for phishing detection, where the challenge lies in identifying a minority class of phishing websites within a larger majority class of legitimate websites. XGBoost has, by default, mechanisms that handle class imbalances by adjusting the class weights, thus making the model focus more on the minority class. Moreover, in XGBoost, there is a possibility of extensive hyperparameter tuning, including but not limited to learning rate and tree depth,

which can be optimized for a particular dataset [26]. Its parallel processing ability combined with regularization techniques enhances the efficiency of the algorithm and helps avoid overfitting, therefore enhancing the robustness of the model [27]. These features together make XGBoost a very effective tool in combating class imbalance for the improvement of the performance of a phishing website detector.

IV. Proposed Framework

The presented work investigates some of the state-of-the-art class imbalance mitigation strategies in the phishing website detection problem by performing performance evaluation with respect to three different resampling techniques: Random Oversampling, Random Undersampling, and SMOTE-NC, when used together with the XGBoost classifier. Its main purpose is to look at the results that can be expected regarding major model performance metrics with such resampling techniques.

The proposed framework describes, in detail, the handling of class imbalance and the measurement of performance of the XGBoost classifier. Fig. 5 depicts the step-by-step data acquisition from the UCI database, analysis of distribution of classes for checking possible imbalances. Then, resampling techniques such as SMOTE-NC, ROS, and RUS are further used to balance the dataset.

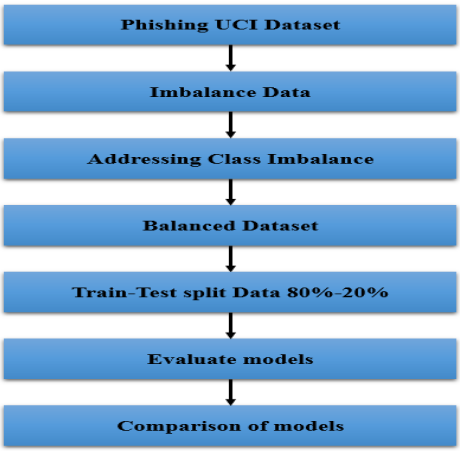

Fig. 5. Proposed framework.

After balancing, the dataset will then be divided into training and testing subsets. Here, the training subset is used in optimizing and training the XGBoost model while the test subset will be used in determining the classification accuracy of the model. Thereafter, after the training is done, the model classifies a new instance as either a phishing or a legitimate website. The key performance metrics used to measure the performance of the approach include accuracy, F1 score, recall, precision, ROC-AUC, and geometric mean score. These metrics also serve to underline the varying impact different resampling techniques have on overall model performance.

A. Class Distribution Analysis Before and After Resampling

Table V presents the class distributions of the original dataset and the balanced datasets after applying the resampling techniques.

TABLE V. The Class Distribution

Class	Legitimate	Phishing
Original Samples	4898	6157
Distribution (%)	44.30%	55.70%
ROS Samples	4926	4926
Distribution (%)	50.00%	50.00%
RUS Samples	3918	3918
Distribution (%)	50.00%	50.00%
SMOTE-NC Samples	4926	4926
Distribution (%)	50.00%	50.00%

This table is representing the balance of the imbalanced dataset in which phishing samples had a minority participation compared to the legitimate dataset. It is balanced using ROS, RUS, and SMOTE-NC. These all techniques are implemented to address the class imbalance such that the performance of the classifier XGBoost would improve in phishing web site detection so as to make a fair deal for both the classes: minority as well as the majority.

B. Evaluation Metrics

Evaluation metrics play an important role in machine learning for the measurement of model performance. It provides a quantitative measure of the performance of the model using various metrics: accuracy, precision, recall, F1 score, ROC-AUC, and Geometric Mean score. These metrics help the researchers in choosing the best approach for a particular task and hence ensure that the chosen model will effectively address the unique challenges of the problem.

1) Accuracy: Accuracy is the measure of the percentage of correctly predicted instances. Although useful, it can be misleading for imbalanced data sets as high accuracy might overemphasize the performance on the majority class.

$$Accuracy = \frac{Number\ of\ correctly\ predicted\ instances}{Total\ number\ of\ instances}$$

2) F1 Score: F1-score is the harmonic mean of precision and recall, effectively balancing the trade-off between false positives and false negatives.

$$F1Score = \frac{2 \times Precision \times Recall}{Precision + Recall}$$

3) Recall: Recall measures the proportion of actual positives correctly identified, making it crucial when minimizing false negatives is a priority.

$$Recall = \frac{True\ Positives}{True\ Positives + False\ Negatives}$$

4) Precision: Precision quantifies the proportion of true positives among all predicted positives, and is particularly important when minimizing false positives is critical.

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives}$$

5) ROC-AUC: ROC-AUC measures the model's ability to distinguish between classes. A higher value indicates better performance in differentiating between the positive and negative classes.

$$ROC - AUC = \int_0^1 TPR(FPR)d(FPR)$$

6) Geometric Mean Score (G-Mean): The geometric mean score equilibrates performance on both classes and is hence useful in the case of imbalanced datasets. It is calculated as the square root of the product of recall and specificity, offering a more balanced evaluation when class distribution is skewed.

$$\text{G} - \text{Mean} = \sqrt{Recall \times Specificity}$$

V. Findings and Analysis

This paper investigates the performance of three resampling techniques, namely ROS, RUS, and SMOTE-NC, integrated with the XGBoost classifier for phishing website detection. The key objective is to investigate how these techniques affect class distribution, improve predictive accuracy, and optimize key evaluation metrics.

Table VI provides the performance evaluation of the discussed models with respect to six performance metrics: accuracy, F1 score, recall, precision, ROC-AUC, and the Geometric Mean score.

TABLE VI. Evaluation Results in (%)

Classifier	Accuracy	F1 score	Recall	Precision	ROC-AUC	The Geometric Mean score
XGB	0.977	0.979	0.983	0.976	0.998	0.976
ROS-XGB	0.976	0.978	0.979	0.977	0.998	0.975
RUS-XGB	0.974	0.976	0.974	0.979	0.998	0.974
SMOTE-NC-XGB	0.980	0.982	0.985	0.979	0.998	0.979

SMOTE-NC-XGB gives the best general performance among the tested models, with the highest accuracy of 0.980, F1 score of 0.982, recall of 0.985, and Geometric Mean score of 0.979. It means that the SMOTE-NC-XGB model provides very well-balanced sensitivity and specificity while handling class imbalance. The XGB baseline also performs quite well, with high recall of 0.983 and a high ROC-AUC of 0.998. However, resampling techniques enormously increased the generalization of the model to imbalanced datasets.

- ROS-XGB slightly improved precision, at 0.977, from the baseline XGB, though in most metrics it performed the same as the SMOTE-NC-XGB model.
- RUS-XGB has better precision, 0.979, but it decreases the recall to 0.974 due to reduced false positives.
- SMOTE-NC-XGB outperforms all the other methods since it strikes the best balance among all metrics; thus, it is the most suitable approach for phishing website detection.

These findings really pinpoint the very crucial role that resampling techniques play in improving model performance, especially when dealing with imbalanced datasets. The results clearly indicate that SMOTE-NC-XGB emerges as the optimal method for phishing detection in this study.

VI. Conclusion

This paper discusses the performance comparison of undersampling, oversampling, and SMOTE-based techniques combined with the XGBoost classifier for class imbalance in phishing website detection. The experimental results illustrate that resampling methods greatly enhance the capability of a model in dealing with imbalanced datasets and improving the key evaluation metrics, including accuracy, F1 score, recall, precision, ROC-AUC, and Geometric Mean score.

Among the models tested, SMOTE-NC-XGB has always been at the top for all metrics with an accuracy of 98.0% and a recall of 98.5%, values which are rather high, therefore, it is able to balance sensitivity and specificity, which is the very key problem in phishing website detection; either false positives or false negatives can cause huge losses.

While the XGB baseline is also good to go, at 99.8% ROC-AUC, the introduction of resampling techniques into its training gives the model extra strength, particularly under strong class imbalance. Both Random Oversampling (ROS) and Random Undersampling (RUS) turn in competitive performances; the former slightly improves precision, while the latter is able to strongly reduce false positives.

In a nutshell, the results of this work highlight the key contribution of resampling techniques in enhancing the performance of models on imbalanced datasets. Among the considered methods, SMOTE-NC-XGB is the most balanced and reliable, hence presenting a promising solution for the enhancement of phishing website detection systems. Future work may consider hybrid resampling methods or more advanced methods to further optimize detection performance.

***Abstract*—As globalization accelerates, the threat of terrorist attacks poses serious challenges to national security and public safety. Traditional detection methods rely heavily on manual monitoring and rule-based surveillance, which lack scalability, adaptability, and efficiency in handling large volumes of real-time social media data. These approaches often struggle with identifying evolving threats, processing unstructured text, and distinguishing between genuine threats and misleading information, leading to delays in response and potential security lapses. To address these challenges, this study presents an advanced terrorism threat detection model that leverages DistilBERT with a Deep Neural Network (DNN) to classify Twitter data. The proposed approach efficiently extracts contextual and semantic information from textual content, enhancing the identification of potential terrorist threats. DistilBERT, a lightweight variant of BERT, is employed for its ability to process large volumes of text while maintaining high accuracy. The extracted embeddings are further analyzed using a Dense Neural Network, which excels at recognizing complex patterns. The model was trained and evaluated on a labeled dataset of tweets, achieving an impressive 93% accuracy. Experimental results demonstrate the model's reliability in distinguishing between threatening and non-threatening tweets, making it an effective tool for early detection and real-time surveillance of terrorism-related content on social media. The findings highlight the potential of deep learning and natural language processing (NLP) in automated threat identification, surpassing traditional machine learning approaches. By integrating advanced NLP techniques, this model contributes to enhancing public safety, national security, and counter-terrorism efforts.**

I. INTRODUCTION

An act of violence against individuals committed to further political or ideological goals is frequently referred to as terrorism [1]. Terrorism aims to erode the rule of law, democracy, and human rights. Terrorism has a direct influence on several human rights, including life, liberty, and bodily integrity [2]. The study of terrorism does not have strict boundaries. It covers the full spectrum of human emotions, attitudes, and behaviours, incorporating a diversity of perspectives along with the associated fears and inclinations.

There has been terrorism- related fatalities in almost every part of the world. Terrorism may harm civil society, impair social and economic advancements, destroy governments, and threaten peace and security [3]. Each of these elements greatly impacts the enjoyment of human rights. Recently, states have implemented counterterrorism measures that have presented significant challenges to human rights and the rule of law [4]. As a counterterrorism strategy, certain regimes have employed torture along with other cruel treatment, often ignoring the legal and practical protections against assaults, like regular, unbiased inspections of detection facilities. Certain states have violated the international legal obligations of non-refoulement by returning suspected terrorists to countries where they truly face the risk of torture or other grave violations of human rights. In certain situations, the use of special courts to try civilians has undermined the independence of the judiciary and reduced the efficacy of traditional court systems. Repressive measures have suppressed the voices of journalists, human rights advocates, indigenous populations, minorities, and civil society. The economic, social, and cultural rights of many people have suffered as a result of the security sector receiving funds that were frequently intended for social initiatives and development assistance.

The adversary does not publicly announce or carry out the attack, and no enemy aircraft fly over the targets. Instead, all that is left are the horrific images of building collapses, plane hijacking, and innocent people murdered or wounded in bombings and shootings that have caused fear and panic around the world. Attacks of this kind have been referred to as "terrorism" [5]. This is not a struggle between states: rather it is a new kind of terror warfare. The enemy may not be a nation-state but rather a small terrorist group based mostly in a developing country. For the sake of their cause, they are willing to give their lives. Thus, it is clear that they are inaccessible to the police and too elusive for the military to hunt down. Conventional forces are designed to fight, they are not designed for unexpected peaceful situations.

Terrorist attack detection has become essential in the contemporary global context due to the growing frequency, sophistication, and unpredictability of terrorist attacks, which pose major threats to national security, public safety, and economic stability. Rapidly developing communication technologies, like the internet and social media have provided terrorists with platforms to plot and execute attacks, therefore,

early discovery is crucial to reducing such dangers. Traditional methods of detecting terrorists' activity, such as surveillance and intelligence gathering often fall short because of the volume of information, the complexity of attack preparation, and the secretive character of modern terrorist activities. Real-time analysis of large datasets, such as text, images, videos and audio has demonstrated extraordinary proficiency in identifying patterns suggestive of terrorist operations using Deep Learning (DL) algorithms [6]. DL is capable of efficiently analyzing unstructured data and producing insights that were previously unavailable using traditional techniques. This aids security forces in stopping attacks before they are carried out and makes it easier to identify terrorists' activities quickly. DL can manage complex, multidimensional data and provide immediate practical insights in a constantly shifting danger scenario, making it an essential tool for terrorist attack detection in the current era.

The detection of terrorism threats from tweets has been transformed by the combination of DL and Natural Language Processing (NLP), which allows for the accurate and efficient analysis of large volumes of unstructured text data [7]. NLP methods enable the extraction of context, sentiment, and linguistic patterns, whereas DL models are excellent at identifying subtleties and intricate relationships in text. These methods are essential for recognizing keywords, spotting extreme language, and quickly detecting hidden risks. Their capacity to adjust and pick up on changing linguistic patterns improves prediction skills, which is crucial for counterterrorism operations and public safety. This paper proposes an effective terrorism threat detection model utilizing the advantages of DL and NLP. The major contributions of the paper include:

- To prepare tweet data using efficient text preprocessing methods, ensuring high- quality input for the detection algorithm.
- To effectively tokenize and extract features from tweet data by utilizing the transformer- based architecture of DistilBERT tokenizer, which captures contextual meaning and relationships.
- To design a system for detecting terrorism threats by combining DistilBERT embeddings with a Deep Neural Network (DNN) model, with the goal of accurately classifying tweets as either non- threats or threats.

The remaining sections of the research are arranged as follows: Section II gives a summary of the current studies, highlighting areas that need more investigation. Section III offers a comprehensive explanation of the methodology. Section IV offers the findings derived from the suggested methodology in detail. A discussion is provided in Section V and finally, a summary of the findings is included in Section VI, which gives a conclusion to the paper.

II. Literature Review

Shinde et al. [8] employed data from the Global Terrorism Database (GTD) to create a model for displaying the aspects of terrorist acts. The study used two different graph embedding methods and seven Machine Learning (ML) models to sort the data into groups. These models included K- Nearest Neighbour (KNN), Support Vector Machine (SVM), Decision Tree (DT), Random Forest (RF) and adaboost. The model achieved 90% accuracy. The study did not include the model's generalizability and scalability. An et al. [9] conducted a study to predict and examine the impact of microblogging on terrorist incidents. Emotion analysis was conducted utilizing user, time and feature content and topics were created using a combination of Word2Vec and K means clustering. The proposed Logistic Regression (LR) based approach outperformed six existing classification models with an accuracy of 85% and was able to identify high influence attributes. Jyothilinga [10] used the GTD's historical terrorist attack data to predict future occurrences and causalities. The study made use of ML techniques such as RF, Multilayer Perceptron (MLP) regressors for predicting deaths, DT and MLP classifiers for classifying offenders, and KNN classifiers for classifying weapons. Using time series analysis to predict terrorists' attacks, KNN achieved 92.25% accuracy, while DT and MLP both produced 90 % accuracy for classifying offenders. The study recognized certain limitations, though including the intricacy of terrorist incidents and a lack of thorough data necessary for precise model validation and training.

Gaikwad et al. [11] created the Merged Islamic State of Iraq and Syria/ jihadist White Supremacist (MIWS) dataset with the goal of examining the impact of extremist groups on social media. The effective use of NLP with pretrained models such as BERT, RoBERTa and DistilBERT demonstrated the effective application of DL for identifying extremist content across many approaches with BERT achieved an F1- score of 0.72. Nevertheless, it was pointed out that the dataset relies on terms that can result in false positives from non- extremist sources such as journalists and critics. Yi Feng et al. [12] designed RP-GA-XGBoost, a causality prediction system based on XGBoost to determine if terrorist acts will cause the deaths of innocent people. The proposed approach integrated Principal Component Analysis (PCA) and RF for feature selection and utilized a Genetic Algorithm (GA) to optimize the hyperparameters of XGBoost. The findings showed that, when compared to some- well known ML techniques, the suggested approach performed the best. Ruifang Zhao et al. [13] combined Inverse Distance Weighting (IDW) with a Multilabel K- Nearest (I-MLKNN) based evaluation framework in order to assess terrorist activities. The dimensions of the features of terrorist attack categories were reduced using the Locally Linear Embedding (LLE) dimension reduction technique. Before and after the dimension reduction, the correlation between the attributes was assessed using the Maximal Information Coefficient (MIC). The inverse distance weighting method was subsequently integrated with the MLKNN multi-label classification algorithm on a grid framework. The outcomes of the simulation showed that the I-MLKNN multi-label classification approach is a perfect tool for determining the geographic distribution of terrorist acts.

Lanjun Luo and Chao Qi [14] focused on determining important markers that influence the likelihood of terrorist attacks from a predictive approach. Factors at the event level and the root cause are considered, and they are qualified using

28 indicators. A recursive feature elimination technique using RF kernels was suggested to find the most important ones among the 28 initial signs. The simulation findings demonstrated that the indicators severely degrade when the bare minimum of input indicators was used before the prediction performance. A method for identifying statistically significant change points in time series connected to terrorism that could indicate the onset of events that require attention was developed by Theodosiadou et al. [15]. Before and after the dimension reduction, the correlation between the attributes was assessed using the Maximal Information Coefficient (MIC). The potential of the suggested methodology in successfully identifying such changes was demonstrated by applying it to a real- world dataset. Change point detection techniques can be used to estimate statistically significant changes in the structural behavior of the aforementioned indicators at particular time points by analyzing the resulting time series. Shynar Mussiraliyeva et al. [16] suggested text categorization methods for identifying extremist activity using MLP technologies. The produced corpus was divided into two sections: 3000 words of postings with extremist intent and 15,000 words of non- extremist posts, including news portals and religious materials. According to the simulation findings, the suggested approach classified extremist texts from the collected corpus with a high degree of accuracy.

Ghada M. A. Soliman and Tarek H. M. Abou- El- Enien [17] designed a hybrid computationally intelligent system to assist in making decisions on the subject of terrorism. The suggested hybrid prediction algorithm combined Data Mining (DM) approaches with various Operations Research (OR) and decision support tools. The development, implementation and evaluation of the suggested system have utilized a variety of assessment metrics. The experimental findings showed that the suggested method identify the terrorist group that is responsible for terror strikes in different places. Georgios Koutidis et al. [18] developed a framework based on ML and DL models for predicting the probability of terrorist occurrences in a target region over a certain time frame. Based on RF models, a feature selection procedure was suggested in which each feature's predictive power is determined and only features that are thought to have adequate predictive power are then taken into consideration. The simulation findings showed that the suggested framework improved the predictive ability of the ML and DL models with the suggested feature selection in predicting the probability of terrorist attacks. Ben Chaabene et al. [19] developed a computational model that uses a variety of ML and recommender system techniques to predict how terrorists' actions will affect social networks based on the text and image data. The suggested method comprises two models: the text classification framework and the image classification system. The text classification model comprises LR, NB and SVM. The model for classifying images was based on CNN. The simulation results showed that the suggested model successfully identified and predicted the behaviour of militant terrorists on twitter.

The field of ML and DL techniques for terrorist attack prediction has advanced significantly in recent years, yet there is still a notable gap in the existing literature. Nations with insufficient or missing data find it difficult to understand terrorist behaviour and highlighting particular groups or ideas results in mispredictions. The socio- political, economic and psychological elements that influence terrorism are not adequately represented by current models. Despite their higher accuracy, many models generate false positives, misclassify harmless behaviours associated with terrorism, and create ethical concerns like discriminating against the community. Moreover, it is challenging to comprehend ML models decision- making processes because of their complexity. Models that can adjust and learn from new data in real time are necessary due to the dynamic nature of terrorist actions, but many previous studies rely on static dataset, which reduces their applicability in situations that change rapidly. Overcoming these gaps is crucial to improving the effectiveness and moral applications of DL and ML in predicting terrorist activities, which will ultimately lead to safer communities across the world. So, in order to rectify the above-mentioned limitations, a novel NLP model based on DistilBERT and DNN for the detection of terrorism threats from tweets has been proposed in this paper.

III. Materials and Methods

The proposed approach combines DistilBERT with Deep Neural Network (DNN) in a structured pipeline to identify terrorist threats in tweets. To standardize and clean the input text, raw twitter data is initially collected and processed through preprocessing approaches that include removing URLs, mentions, hashtags, numbers, punctuation and lowercase texts, as well as stop words. The DistilBERT tokenizer tokenizes the processed text, transforming it into attention masks and input IDs. A DistilBERT model with numerous transformer layer, pre- trained using these representations, captures contextual embeddings of the input text. The DistilBERT output embeddings are sent to a DNN classification head, which is made up of Fully Connected (FC) layers that are intended to train discriminative features for classification. Finally, the model provides a reliable and effective method for detecting terrorist threats by predicting whether a tweet is a threat or not. The detailed block diagram of the suggested terrorism threat detection model is visualized in Fig. 1.

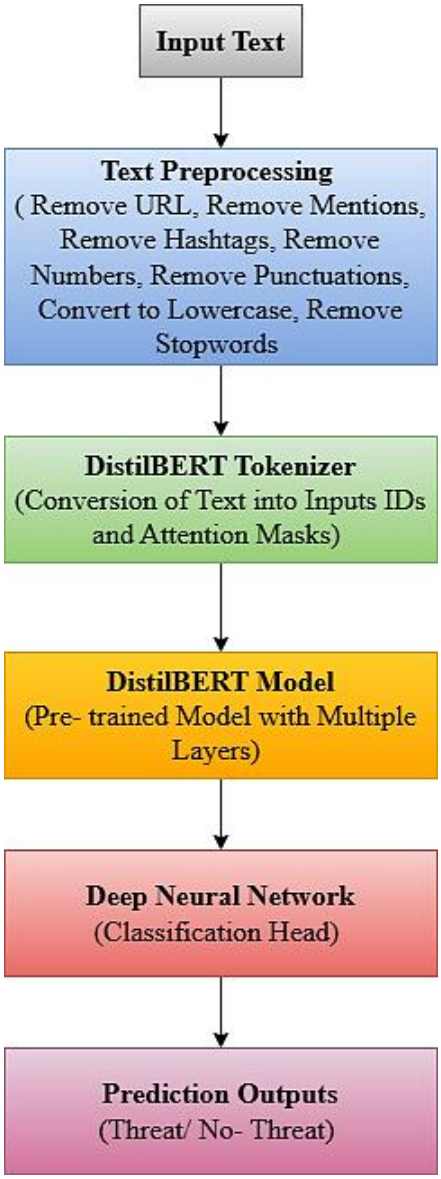

Fig. 1. Block diagram of suggested terrorism threat detection system.

A. *Dataset Description and Exploratory Data Analysis*

The textual data in the dataset was gathered from social media, particularly tweets and was classified as either indicating non- threating or threatening material. The almost equal distribution of these classes is crucial for maintaining the balance of classification tasks. Preprocessing eliminates features like mentions (@username), hashtags (#hashtag) and URLs for a cleaner analysis. The tweets range significantly in length from mere lines to extensive paragraphs. The dataset also includes linguistic variables that aid in distinguishing between threatening and non- threatening tweets, such as average word length and frequency. The dataset is downloaded from GitHub [20]. Fig. 2 shows the dataset sample.

Dataset Head:

	Tweet	Class
0	PT announced his death. In current tweet shows...	1
1	The Muslim Brotherhood of #Iraq condemns the k...	1
2	RT @TedNugent: Gun control talks with gunrunni...	0
3	Come home from work to Bridesmaids, Twinkies a...	0
4	RT @Ghostmanzzz: #Breaking #US airstrikes rock...	1

Fig. 2. Sample dataset.

Each class in the text dataset for terrorist threat detection contains the same number of samples, indicating a balanced class distribution. The number of tweets classified as threatening (Class 1) and non- threatening (Class 0) is 5265 respectively. This balanced distribution promotes accurate predictions for both threatening and non- threatening tweets and allows for equitable learning during training by preventing the model from being biased toward any one class. The class distribution is plotted in Fig. 3.

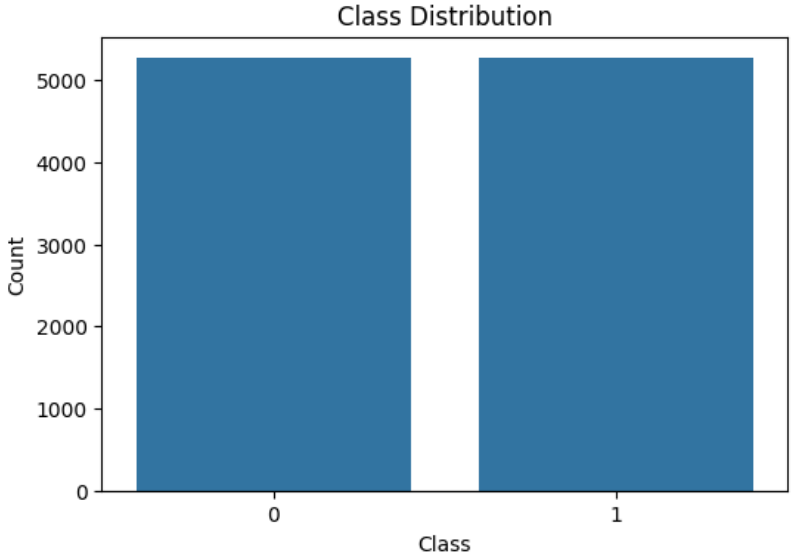

Fig. 3. Class distribution.

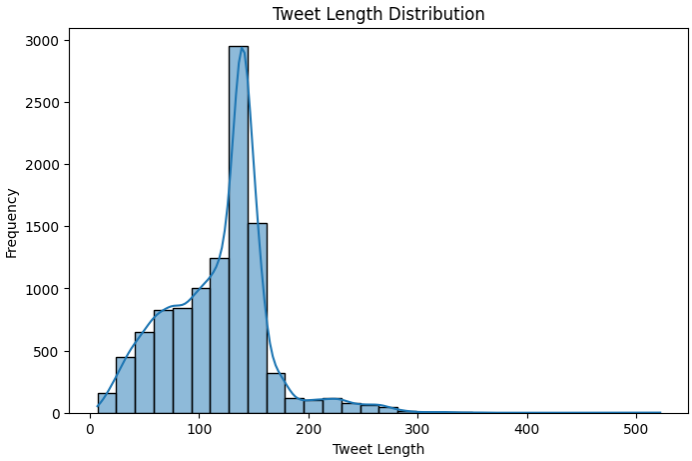
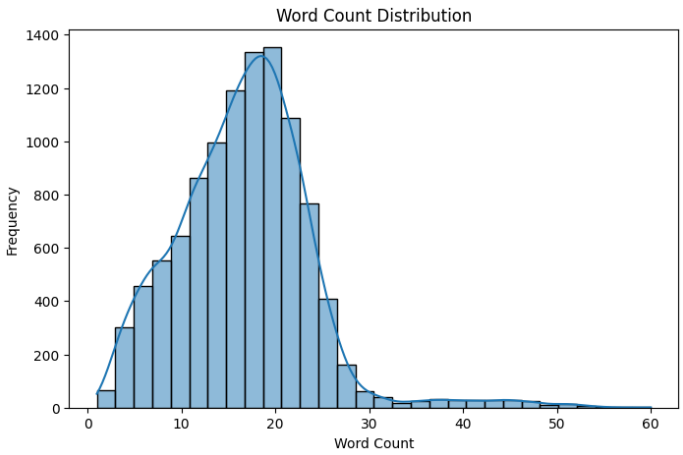
The statistical distribution of the character count in each tweet in the dataset is known as the “Tweet Length Distribution” and is displayed in Fig. 4 (a). It provides information about the range of tweet sizes by displaying how lengthy or short the tweets are. The statistical distribution of the word count in each tweet within the dataset is referred to as the “Word Count Distribution” and is displayed in Fig. 4 (b). It provides insights into the typical word count in a tweet, ranging from brief tweets with few words to longer ones with numerous words. The "Average Word Length Distribution" is the distribution of the average number of characters per word in each tweet in the dataset, as shown in Fig. 4(c). It gives information about the complexity of the language used in the tweets, including whether individuals typically use longer, more complicated phrases or shorter, simpler ones. As seen in Fig. 4 (d), the “Hashtag Count Distribution” represents the distribution of hashtags used in each tweet across the datasets. It shows the frequency with which people add hashtags to their tweets, ranging from one to multiple per tweet. The “Mention Count Distribution” represents the distribution of mentions (i.e., tagging another user with “@username”) in each tweet in the dataset, as illustrated in Fig. 4 (e). This distribution shows how frequently users mention or engage with other people in their tweets.



(a)



(b)

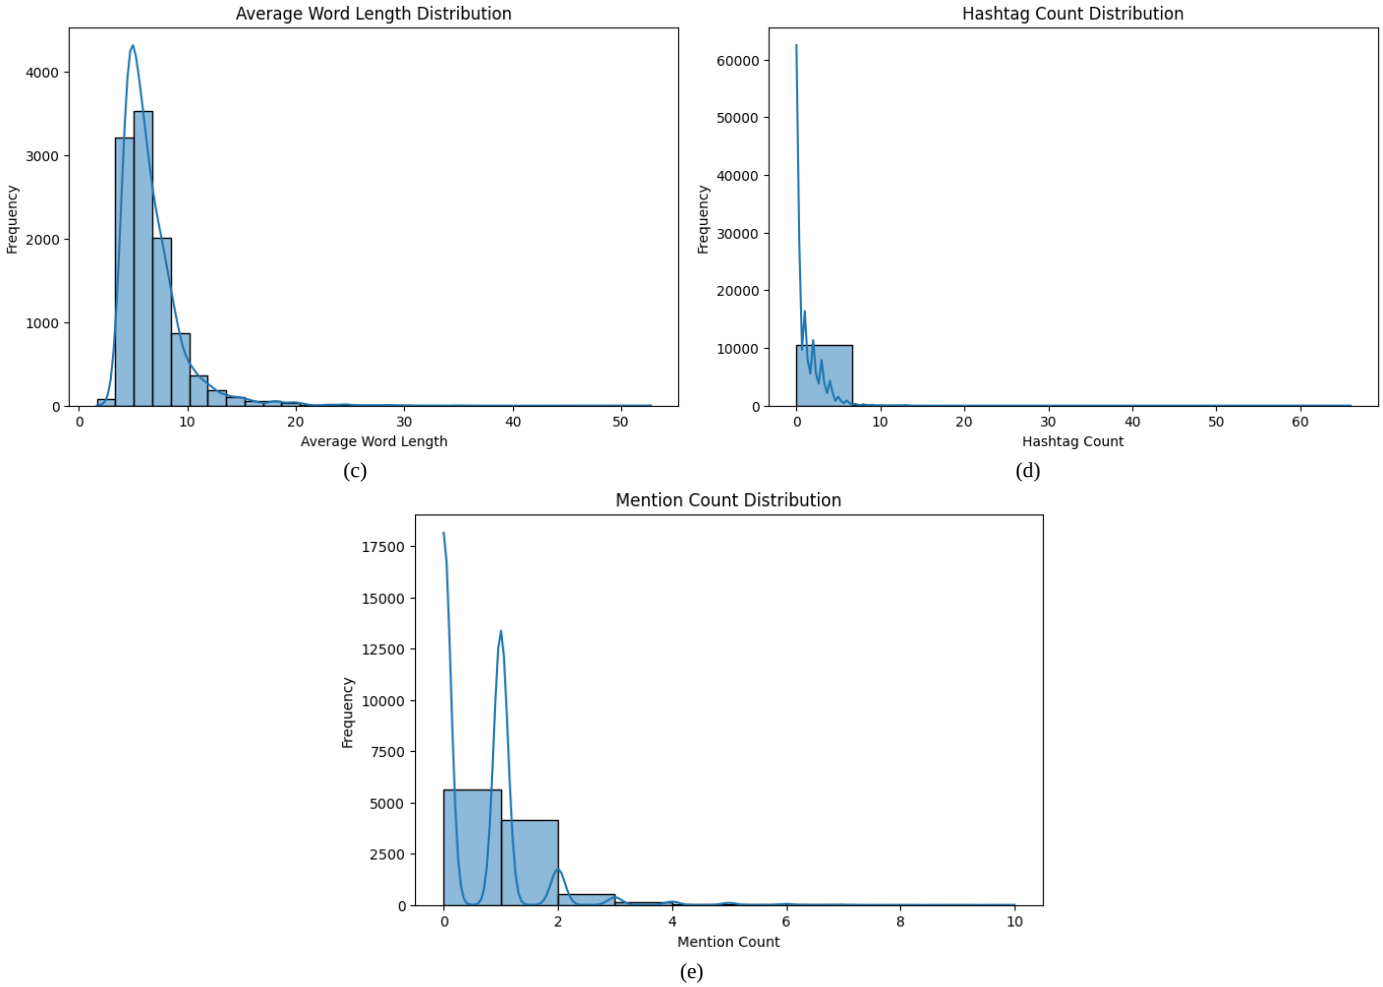


Fig. 4. (a) Tweet length distribution (b) Word count distribution (c) Average word length distribution (d) Hashtag count distribution (e) Mention count distribution.

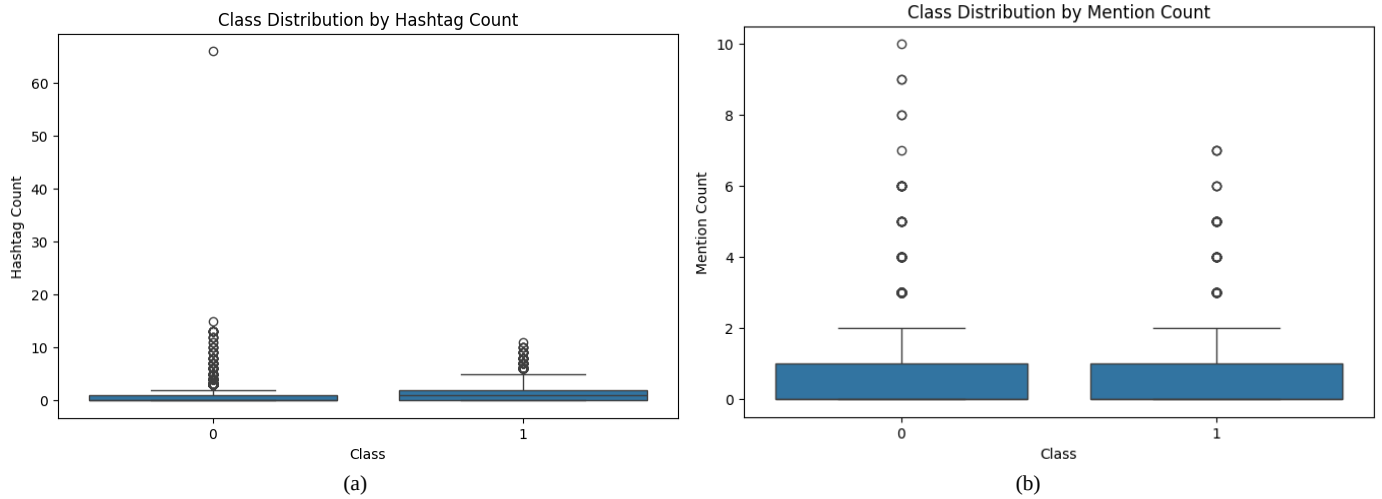
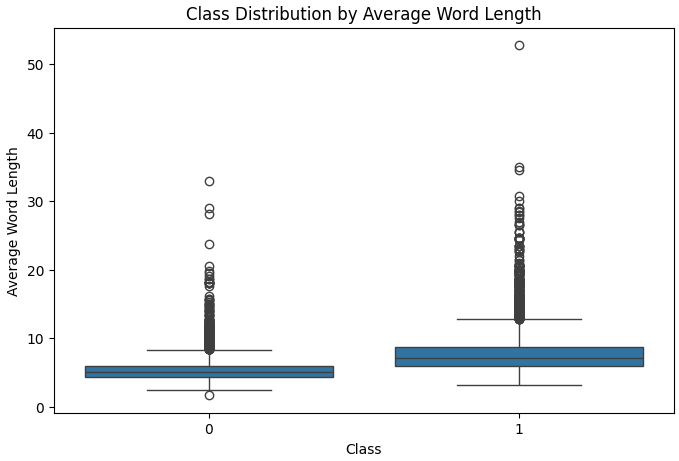
As illustrated in Fig. 5 (a), "Class Distribution by Hashtag Count" is an analysis that looks at the relationship between a tweet's hashtag count and its classification as "threat" or "non-threat". Box plots commonly compare the quantity of hashtags for each class labels when displaying this kind of distribution.





(c)

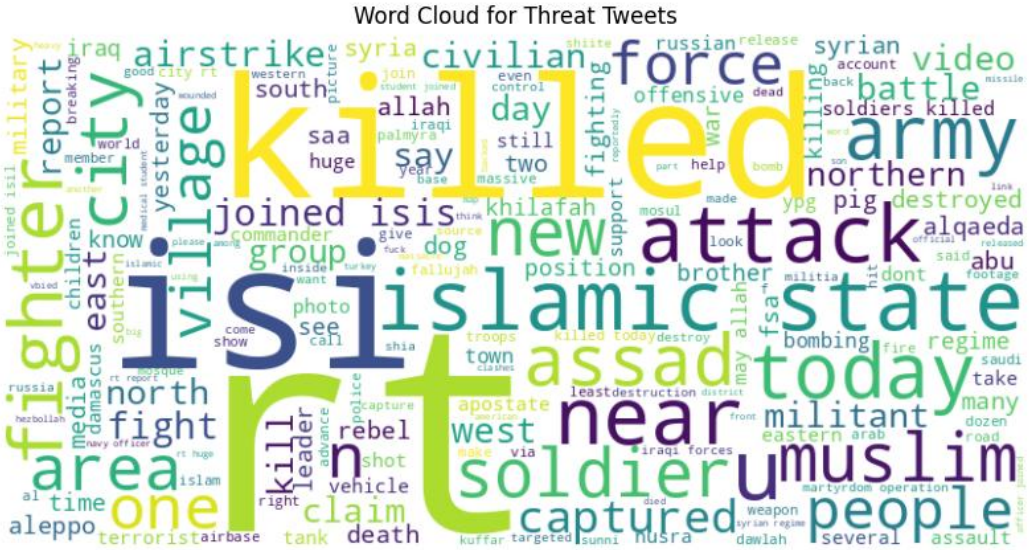
Fig. 5. (a) Class distribution by hashtag count (b) Class distribution by mention count (c) Class distribution by average word length.

It provides information about whether tweets with a threat label typically contain more or fewer hashtags compared to tweets without a threat label. The analysis known as "Class Distribution by Mention Count" examines the frequency of mentions of a user, such as "@username", in tweets classified as "threat" or "non- threat". Box plots, as seen in Fig. 5 (b) are frequently used to illustrate this kind of distribution. They display the median, quartiles, and overall range of mention counts for each class. An association between the quantity of mentions in a tweet and its probability of being categorized as threatening can be ascertained by comparing these distributions. "Class Distribution by Average Word Length" examines the differences in average word length between the two classes of tweets. Fig. 5 (c) display this distribution using box plots. They show the median, quartiles and range of average word lengths for each class. It is feasible to determine whether the complexity of language used in threatening versus non- threatening tweets differs by comparing these distributions.

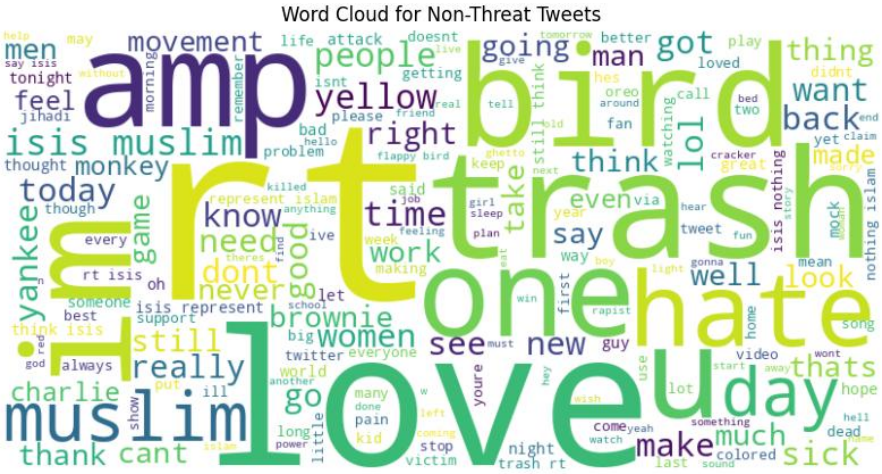
The most common word in a corpus of text is represented visually in a word cloud, where the size of each word indicates its significance or frequency. It is possible to create distinct word clouds for threat and non- threat tweets in order to emphasize the unique terminology utilized in each category. The word cloud for threat and non- threat tweets is displayed in Fig. 6 (a) and Fig. 6 (b).

B. *Text Preprocessing*

In NLP, text preprocessing is an essential step that cleans and gets raw data ready for analysis. A variety of methods standardize and simplify the text. URLs, hashtags, and mentions are eliminated in order to remove unnecessary components that are not beneficial to the semantic meaning. Eliminating punctuations and numbers ensures that the words stay the main emphasis, which lowers noise. Text conversion to lowercase standardizes data and prevents case- sensitivity induced duplication. Stopwords like "is", "the" and "and" which are often used words that don't significantly advance the analysis, can be removed. When combined, these strategies improve the text's quality and make it more appropriate for NLP tasks.



(a) Threat tweet.



(b) Non-threat tweet.

Fig. 6. Word cloud.

C. Tokenization using DistilBERT Tokenizer

The process of tokenization involves converting unprocessed text data, such as tweets, into a format that the DistilBERT model understands [21]. Since DistilBERT is a transformer- based model, incoming text must be divided into tokens, which are effectively smaller subwords or units. The DistilBERT tokenizer manages this process by dividing words into tokens, assigning a token ID to each token and generating input sequences that sum up the tweet. In addition, the tokenizer uses truncation to eliminate extra tokens that exceed the allowable length and padding to ensure that every sequence has a constant length. This phase is crucial for preparing the data for feeding into the model, which will enable the transformer to retrieve the text effectively and comprehend the context of each tweet. An example of tokenization operation is visualized in Fig. 7.

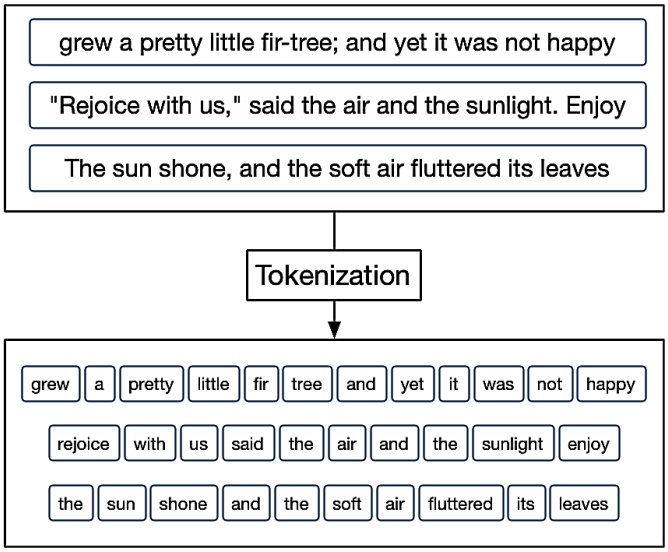


Fig. 7. An illustration of tokenization.

D. Proposed Terrorism Threat Detection Model Based on DistilBERT and DNN

DistilBERT is a faster and more compact version of Bidirectional Encoder Representations from Transformer (BERT) designed to be more efficient on devices with limited processing power. Using a method called knowledge distillation, the BERT model is shrunk by teaching a smaller model to behave similarly to a bigger one [22]. DistilBERT is more efficient due to its reduced size and simplified training procedure. It uses a simplified transformer architecture, notably removing the token type embeddings from the input and the pooling layer from the output. Fig. 8 visualizes the DistilBERT architecture.

The primary goal of DistilBERT is to preserve the majority of BERT's performance while lowering its memory and computational costs. DistilBERT accomplishes this through:

- DistilBERT employs a smaller architecture than BERT with fewer layers and hidden components. In particular, it features 6 layers rather than 12 and 2048 hidden units rather than 7680 for the base model.
- Training through Knowledge Distillation: DistilBERT is trained to replicate the behaviors of the larger BERT model via a strategy called knowledge distillation. To train DistilBERT, the outputs of BERT are employed as soft targets.

The general structure of DistilBERT is similar to that of BERT, despite having fewer layers and hidden components. A feed-forward neural network with a self-attention mechanism is included within each layer of DistilBERT's multi-layer bidirectional transformer encoder. The self-attention mechanism enables the model to focus on different components of the input sequence and identify connections among words. DistilBERT first embeds a sequence of tokens in a high dimensional vector space as its input [23]. The transformer encoder creates contextualized representations for every token by further processing these embeddings. A classification or regression layer processes the contextualized representations to predict the outcome.

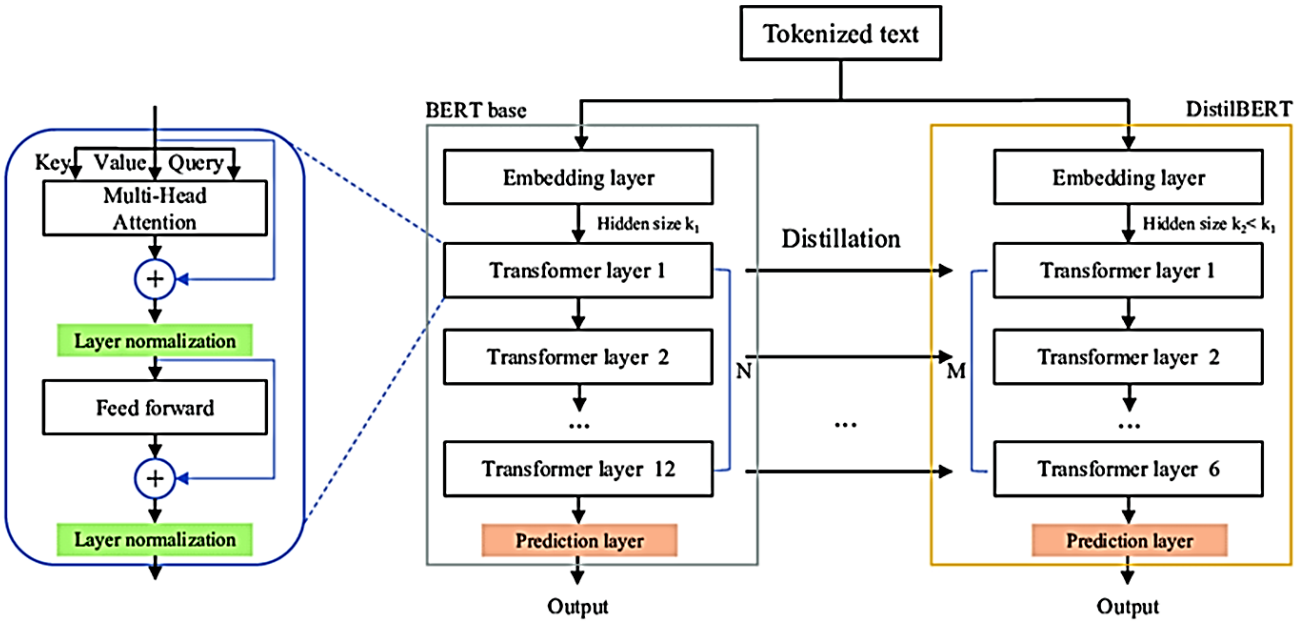

Fig. 8. DistilBERT architecture.

The tokenized input text is fed into both DistilBERT and BERT. The tokenization process divides the input text into smaller tokens, transforms them into IDs and ensures that each input sequence has a constant length. This uniform input is necessary for both BERT and DistilBERT to process the data effectively. The transformer layer and the embedding layer are two of the layers that compose the BERT base architecture. The embedding layer provides numerical representations of words or subwords by transforming input tokens into dense vectors with specified dimensions. BERT comprises 12 transformer layers, including feed- forward, multi- head attention and layer normalization [24]. Each transformer layer can focus on different parts of the sequence at the same time due to a multi- head attention mechanism that accepts three inputs: key, query and value. Layer normalization normalizes the output of the multi- head attention to maintain stability throughout the training process. The feed- forward layer extracts higher level characteristics from the output of the attention mechanism by applying a FC layer. The feed-forward procedure is followed by another normalization step. The structure of DistilBERT is similar to that of BERT, although there are a few significant differences. Similar to BERT, an embedding layer transforms tokens into dense vectors. DistilBERT employs six transformer layers instead of twelve, reducing the number of levels. Its distillation training approach allows it to preserve most of the BERTs context-handling capabilities despite having fewer layers. A major factor in DistilBERT's lightweight design is that its hidden size (k_2) is usually smaller than BERT' s (k_1).

Eq. (1) calculates the scaled dot-product attention, the fundamental component of the attention process.

$$Attention\ (\ Q,K,V) = softmax\ \left(\frac{QK^T}{\sqrt{d_k}}\right) V \qquad (1)$$

The input generates three separate representations: Q, K, and V. The three variables possess dimensions of $n \times d$, with d representing the dimensionality of each token and n indicating the sequence length (number of tokens). The model produces attention scores by evaluating each query against every key. The attention scores are evaluated employing the dot product of the Q and K metrics and the square root of the dimensionality d_k. These scores highlight the level of attention that each component of the input should receive when producing the output. The attention mechanism then uses the attention scores to determine the weighted sum of the values. The system may retrieve all types of relationships in the data because multiple heads produce queries, keys, and values concurrently. The multi- head attention mechanism then creates the final output by combining the individual outputs of each attention head. A prediction layer is applied to the output of the transformer layer. This layer is utilized for a variety of NLP tasks. The output layer of DistilBERT is essentially the same as that of BERT, but because of its simplified architecture and fewer transformer layer, it utilizes fewer parameters.

Specifically for binary classification tasks, the output layer of the DistilBERT is the DNN with the sigmoid layer, which generates a final prediction [25]. Fig. 9 illustrates that a dense layer, also referred to as a FC layer, connects every input node to every output node in a neural network. This dense layer in the DistilBERT context receives the output from the global average pooling operation or earlier transformation layers. The transformer layers extract high- level characteristics and send them to the dense layer, which applies an activation function after a linear transformation.

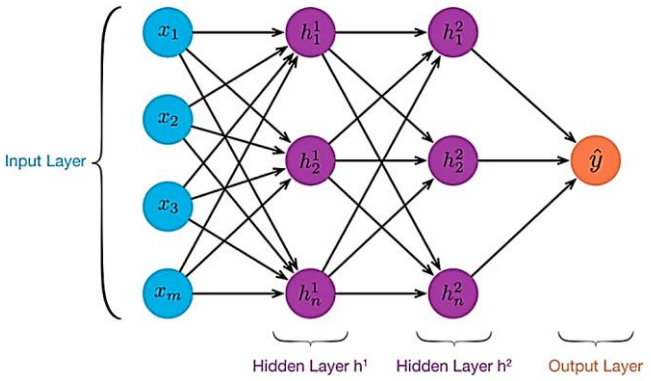

Fig. 9. Deep neural network.

The output layer uses the sigmoid activation function to classify data into binary categories. The sigmoid function is appropriate for situations where the objective is to categorize the input into one of two groups since it converts the result to a number between 0 and 1. In the classification of threats versus non- threats, a sigmoid output around 1 would suggest a high likelihood that the input tweet is a threat, whereas a value near 0 would suggest a non- threat. The sigmoid function is mathematically expressed as in Eq. (2).

$$Sigmoid\ (x) = \frac{1}{1+e^{-x}} \quad (2)$$

The embedding layer and transformer levels receive tokenized text data (viz multi- head attention and feed- forward sublayers). Next, a global average pooling layer usually shrinks the sequence of vectors into a single vector of fixed length that represents the whole sequence. Next, a dense layer employing a sigmoid activation function receives this vector. The dense layer then produces a single probability score that indicates the probability that the input fits to a specific category. The model learns to modify its parameters during training so that it generates output values that are nearly equal to 0 for non-threat class and 1 for threat class. The sigmoid output is subjected to a decision threshold (usually 0.5) during inference in order to classify the input. The model classifies the output as a threat if it exceeds 0.5 and as a non- threat otherwise.

In order to ensure uniformity in the input sequence, the suggested model starts with a DistilBERT tokenizer, which tokenizes and pads input tweets to a constant length of 100 tokens. A custom DistilBERT layer receives the tokenized outputs, which comprise input_ids and attention_mask. This layer captures the semantic complexities of the tweets and uses the pre- trained DistilBERT model to extract contextual embeddings. To reflect the deep contextual relationships in the text, the DistilBERT model creates a series of embeddings for every token in the input. The resultant embeddings are then subjected to a global average pooling layer. This layer aggregates the token- level embeddings into a fixed- size vector, simplifying the representation while keeping the essential elements. A dropout layer with 20% rate is applied to the pooled output to further reduce overfitting by randomly turning off some neurons during training. A deep layer with 128 neurons and ReLU activation enables the network to subsequently discover complex patterns in the data. Regularization is boosted by adding a second dropout layer at the same rate. The output layer, comprising one neuron with a sigmoid activation function, finishes the proposed system by providing a binary classification for deciding whether the tweet contains information relevant to terrorism. Fig. 10 shows the proposed model architecture.

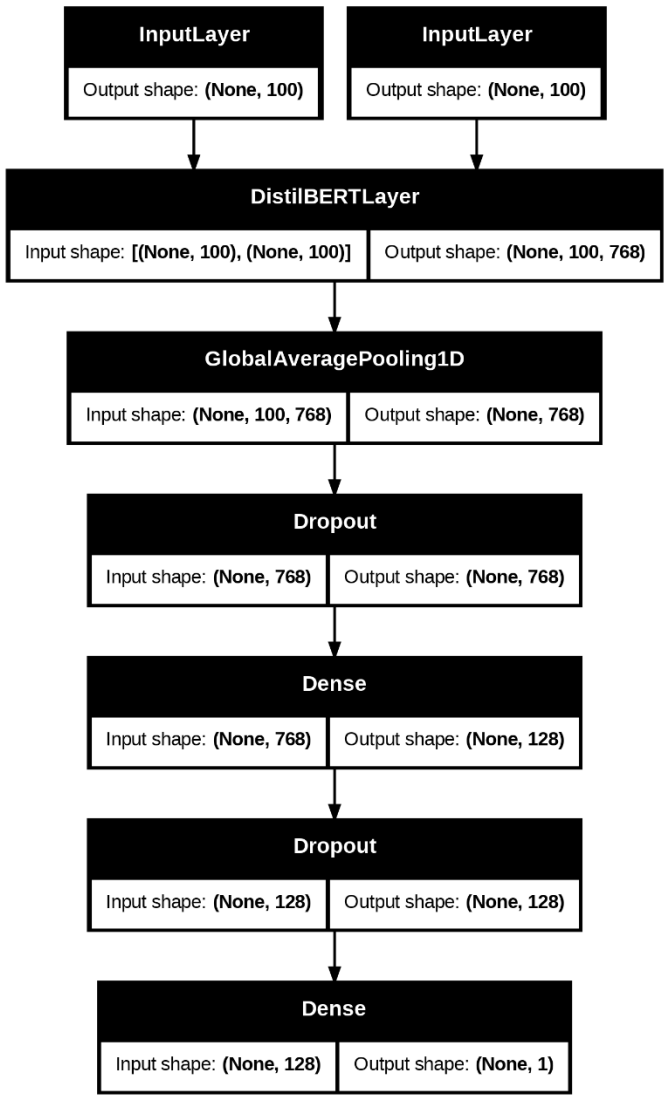

Fig. 10. Proposed terrorism attack detection model architecture.

The detailed algorithm of the proposed terrorism attack detection model is explained below.

Algorithm: A Novel NLP Model Based on DistilBERT and DNN for the Detection of Terrorism Threat from Tweets

Input: *Text data related to terrorism attacks, Pre- trained DistilBERT Model*
Output: *Efficient Terrorism Attack Detection Model*

Begin:

- *Collect Dataset: $\mathcal{D}$= {(X, y), where X is a tweet and y∈ {0,1}, (0 for non- threat tweet and 1 for threat tweet)*
- *Text Preprocessing:*
  - *URLs Removal*
  - *Mentions Removal*
  - *Hashtags Removal*
  - *Numbers Removal*
  - *Punctuations Removal*
  - *Convert to lowercase*
  - *Stopwords Removal*
- *Dataset Splitting:*
  - *X = df['Cleaned_Tweet']*
  - *y = df['Class']*
  - *X_train, X_test, y_train, y_test = train_test_split (X, y, test_size=0.2, random_state=42)*
- *Tokenization using DistilBERT Tokenizer:*
  - *Tokenized_Input=tokenizer (X, padding='max_length', truncation=True, max_length=100)*
  - *Tokenizer returns:*
    - *input_ids ∈ $Z^{n\times 100}$: Tokenized IDs for each word.*
    - *attention_mask ∈ $\{0,1\}^{n\times 100}$: Masks indicating relevant tokens.*
- *Proposed DistilBERT- DNN Model Creation:*
  - *distilbert_model = TFDistilBertModel.from_pretrained ('distilbert-base uncased')*
  - *input_ids = Input (shape= (100,), dtype=tf.int32, name='input_ids')*
  - *attention_mask = Input (shape= (100,), dtype=tf.int32, name='attention_mask')*
  - *bert_output = DistilBERTLayer () ([input_ids, attention_mask])*
  - *x = GlobalAveragePooling1D () (bert_output)*
  - *x = Dropout (0.2) (x)*
  - *x = Dense (128, activation='relu') (x)*
  - *x = Dropout (0.2) (x)*
  - *output = Dense (1, activation='sigmoid') (x)*
  - *M = Model (inputs= [input_ids, attention_mask], outputs=output)*
- *Model Compilation and Training:*
  - *M.compile(optimizer=Adam(learning_rate=0.0001), loss='binary_crossentropy', metrics=['accuracy'])*
  - *M.fit([X_train_tokens['input_ids'], X_train_tokens['attention_mask']], y_train, epochs=100, batch_size=32, validation_split=0.2)*
- *Model Evaluation:*
  - *y_pred_prob=M.predict([X_test_tokens['input_ids'], X_test_tokens['attention_mask']])*
  - *y_pred = (y_pred_prob > 0.5). astype(int). flatten ()*
  - *accuracy = accuracy_score (y_test, y_pred)*
  - *report = classification_report (y_test, y_pred)*
  - *conf_matrix = confusion_matrix (y_test, y_pred)*
  - *roc_auc = roc_auc_score (y_test, y_pred_prob)*
- *Save the Model:*

End

E. Simulation Setup

The proposed terrorism attack detection model has been designed and implemented on Google Collaboratory platform with Python language. Gradient estimation stability and computing performance were balanced by using a batch size of 32. The Adam optimizer was selected to speed up convergence because of its popularity for adaptable learning. The model underwent training for 100 epochs, providing enough iterations to discover intricate patterns in the data. The learning rate was chosen to be 0.001 to allow a fine-grained change to model weights during training, limiting overshooting and ensuring stable convergence. The loss function, binary cross entropy was appropriate for binary classification tasks. Table I offers various hyperparameters utilized by the model.

TABLE I. HYPERPARAMETERS

Hyperparameters	Values
Batch Size	32
Optimizer	Adam
Number of Epochs	100
Loss Function	Binary Crossentropy
Learning Rate	0.0001

A batch size of 32 was selected in order to balance model generalization with computational efficiency. This implies that the model processes 32 datasets at a time before updating the weights. The model successfully improved its parameters repeatedly throughout several dataset iterations during the 100

training epochs. This binary classification problem is well-fitted by the binary cross-entropy loss function, which counts the discrepancy between expected probability and actual binary class labels. The Adam optimizer was utilized to optimize the weights, combining the advantages of adaptive learning rates and momentum for effective training. The step size during weight updates was controlled by setting the learning rate to 0.0001, which allowed for consistent convergence.

IV. Experimental Results

The performance of a model during training and validation can be assessed using the accuracy plot and loss plot. The accuracy plot provides insight into the effectiveness of the model in generalizing to unknown data by illustrating changes in its capacity to accurately categorize samples over different epochs. A steadily increasing accuracy curve demonstrates effective learning. The loss plot on the other hand, displays the model's error over epochs and a decreasing loss indicates a reduction in the difference between predicted and assigned labels. When combined, these plots offer a thorough understanding of how the model learns and provide optimization techniques for enhanced efficiency. Fig. 11(a) and Fig. 11(b) visualizes the accuracy plot and loss plot of the model. The model performs much better in the first epochs with training accuracy increasing from 77% in epoch 1 to over 93% by epoch 50 and training loss decreasing in parallel. After epoch 30, validation accuracy steadily increases between 91 and 92%, while validation loss levels off at 0.22, suggesting efficient learning and little overfitting. The model may have achieved an ideal balance if both training and validation measures exhibit convergence.

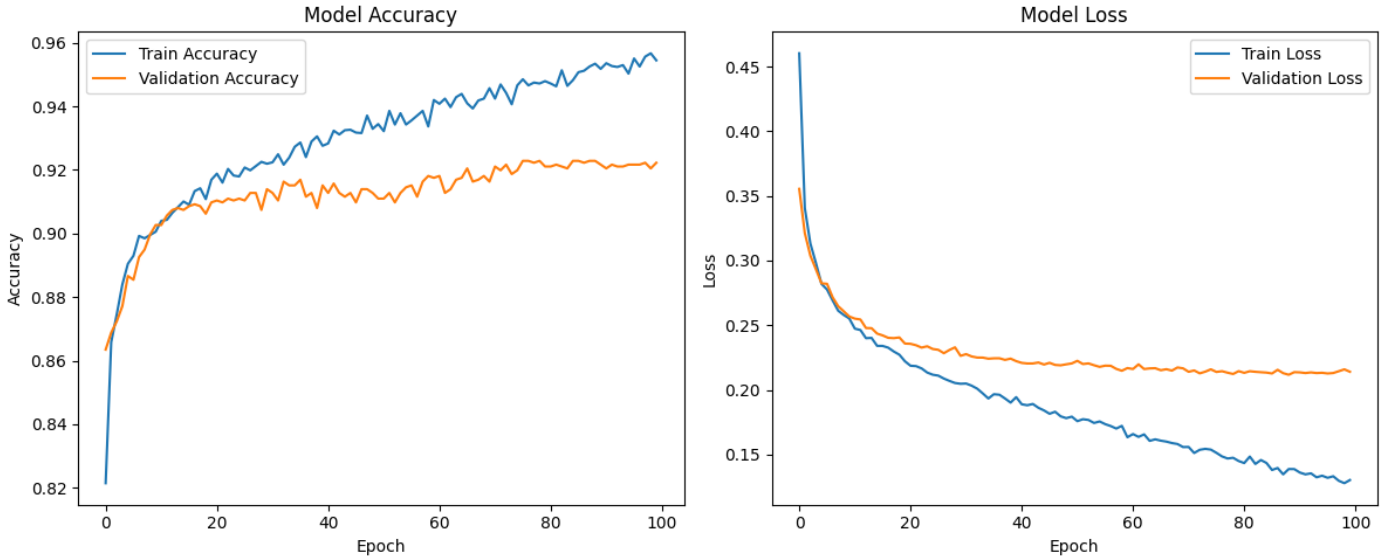

Fig. 11. (a) Accuracy plot (b) Loss plot of proposed terrorism attack detection model.

Accuracy is a crucial performance static in the context of terrorism attack detection from twitter data. It quantifies the percentage of correctly recognized occurrences among all occurrences. It is computed using Eq. (3).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

The term true positive (TP) refers to the quantity of threat-related tweets correctly identified. True negativity (TN) refers to the quantity of accurately identified, non-threatening tweets. False positives (FP) refer to the number of non-threat-related tweets that receive incorrect classification as threats. The number of tweets about threat that are inaccurately classified as non- threat is known as false negative (FN). The proposed model for terrorism attack detection accomplished a remarkable performance with an accuracy of 93%.

A classification report is a thorough performance assessment tool that offers important indicators for evaluating the effectiveness of a detection model. It comprises support for every class, F1- score, precision and recall. The F1 score offers a balanced measure of precision and recall, with recall demonstrating the model's ability to identify all pertinent events and precision quantifying the accuracy of positive predictions. The number of instances of each class in the dataset is known as support. Table II presents the classification report for the suggested model.

TABLE II. Classification Report of Suggested Model

Class	Precision	Recall	F1- Score	Support
0 (Non- Threat)	0.93	0.93	0.93	1074
1 (Threat)	0.92	0.92	0.92	1032
Accuracy			0.93	2106
Macro Average	0.93	0.93	0.93	2106
Weighted Average	0.93	0.93	0.93	2106

The classification report shows that the terrorism attack detection model performs well in both the threat and non-threat classes. For non- threat class, the model's precision, recall and F1- score of 0.93 show that it is quite accurate in detecting non- threats without producing a lot of false positives. The precision, recall and F1- score for the threat class are 0.92, but they still show a high level of threat

detection accuracy. The classification between the two classes is well balanced with an overall model accuracy of 93%. The macro average, which calculates the measures without taking into account class imbalance shows consistent performance across classes, getting a strong 0.93 for precision, recall and F1- score. Additionally, the weighted average supports the efficacy of the model by confirming constant performance while accounting for the number of cases in each class.

An essential tool for assessing the effectiveness of detection models is the confusion matrix, which offers a thorough analysis of the prediction model. The confusion matrix aids in locating class imbalances and directs model enhancements, such as threshold adjustments, regularization or class distribution balancing. Fig. 12 visualizes the confusion matrix of the suggested model.

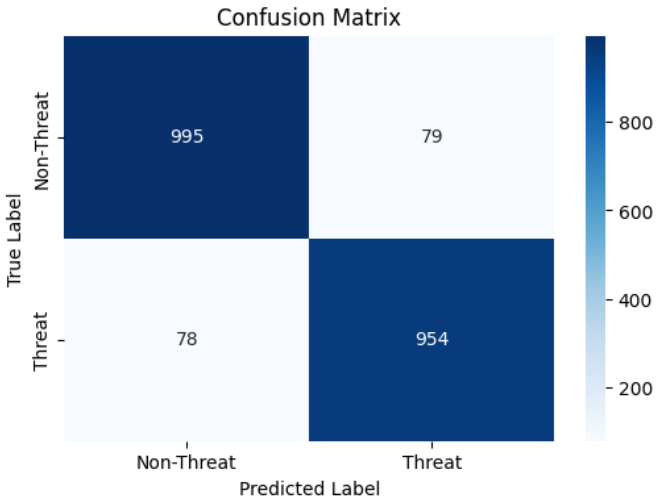

Fig. 12. Confusion matrix of suggested system.

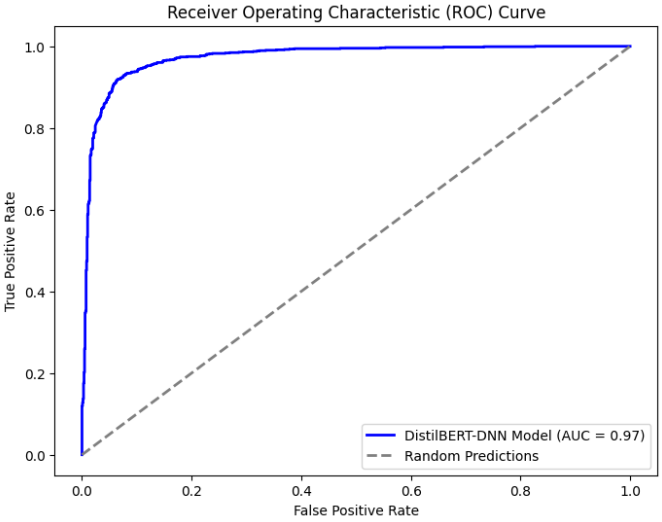

Fig. 13. ROC Curve of proposed model.

The confusion matrix illustrates that the model has a high degree of accuracy in both classifications, properly classifying 995 non- threat cases as non- threats and 954 threat cases as threats. However, there are 78 false negatives where real threats were incorrectly classified as non- threats and 79 false positives where non- threats were incorrectly classified as threats. The effectiveness of detection models is evaluated using a performance evaluation tool called the Receiver Operating Characteristic (ROC) curve, which is shown in Fig. 13. The rates of false positives and true positives are shown at different thresholds.

The ROC curve illustrates the balance between minimizing false positives and identifying true positives. The efficacy of a model is frequently evaluated by the area under the ROC curve, known as AUC. A greater AUC denotes better model performance. Some of the prediction outputs are displayed in Fig. 14.

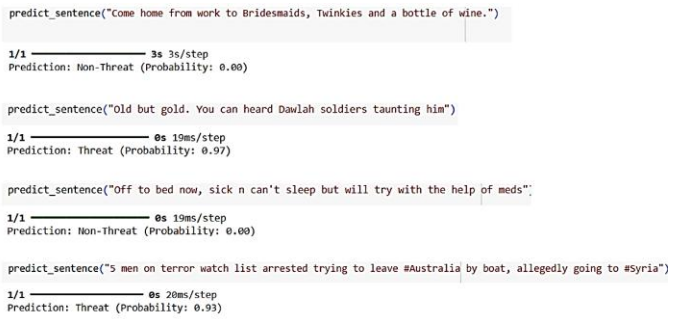

Fig. 14. Prediction outputs.

V. DISCUSSION

Table III provides the performance comparison of the suggested terrorist threat detection system with existing approaches. The suggested DistilBERT- DNN model substantially outperformed a number of current approaches in the field of terrorist threat identification obtaining an incredible 93% accuracy rate. The suggested model shows the benefits of advanced NLP techniques with a significant improvement over the NB classifier, maximum entropy classifier and SVM, which all reached an accuracy of 73.33%. This highlights the effectiveness of merging lightweight transformer-based embeddings with a DNN.

The DistilBERT- DNN model also outperformed the SVM based technique, which obtained 84% and ensemble methods, including RF, KNN, DT, SVM and Adaboost, which achieved 90%. Additionally, the model outperformed Word2Vec in gradient boosting with Word2Vec (87.9%) and K- means clustering (85.8%). Additionally, it outperforms conventional and neural based methods like ANN at 75 % and BERT and its variants at 72%. This demonstrates how well the DistilBERT-DNN model captures the semantic context of tweets for accurate threat identification, making it an innovative approach in this field. Fig. 15 shows the performance comparison of the suggested model with state-of-art methodologies.

TABLE III. PERFORMANCE COMPARISON

Authors	Proposed Methodology	Detection Accuracy
Mayur Gaikwad et al. [11]	BERT and its Variants	72%
Kuljeet Kaur [26]	NB Classifier, Maximum Entropy Classifier and SVM	73.33%
Ghada M.A. Soliman and Tarek H.M. Abou-El-Enien [17]	Artificial Neural Network	75%
Waqas Sharif et al. [27]	SVM	84 %
Lu An et al. [9]	Word2Vec with the K-means clustering	85.8%
Shynar Mussiraliyeva et al. [16]	Gradient boosting with word2vec	89%
Sagar Shinde et al. [8]	RF, KNN, DT, SVM, Adaboost	90%
Proposed DistilBERT- DNN Model		**93%**

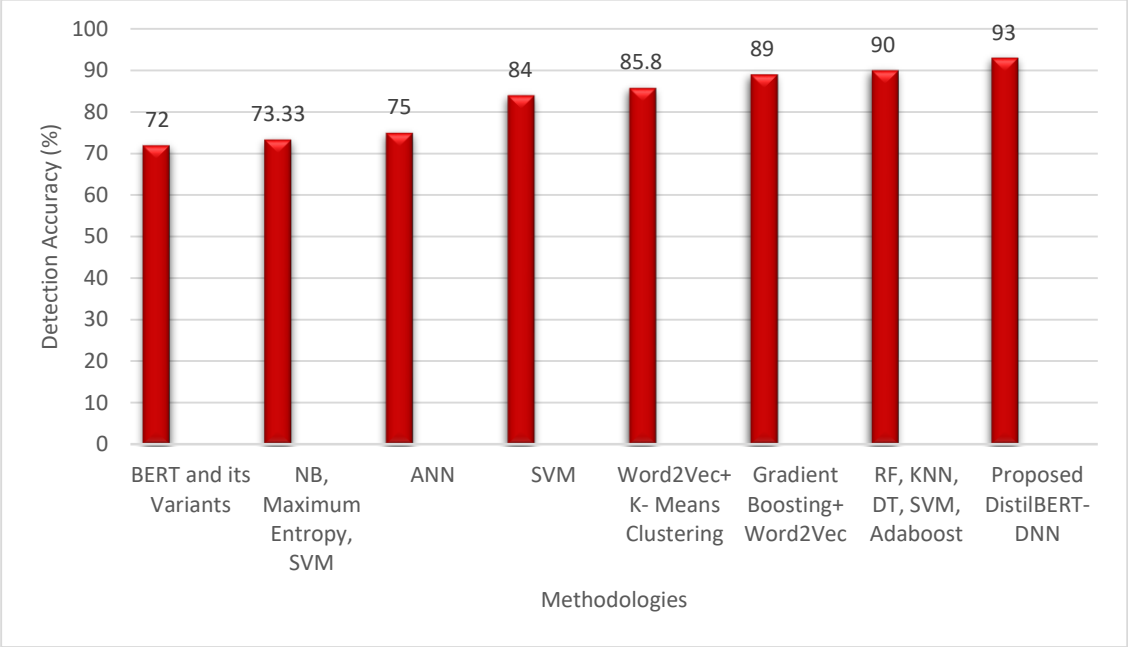

Fig. 15. Graphical illustration of performance comparison with existing methodologies.

VI. CONCLUSION

Global terrorist activity has increased significantly in recent years, causing major risks to national security and public safety. Conventional methods of detecting and preventing terrorist attacks often rely on human contact and existing surveillance systems, which limits their monitoring capabilities and response measures. The intricacy, speed and extent of modern terrorism renders these conventional techniques insufficient, as it often involves decentralized operations, digital traces and secret conversations. The development of increasingly advanced automated systems that can identify possible terrorist actions with greater accuracy and speed is required due to the technological advancements, particularly the growth of digital media and communication platforms. This paper proposed an effective terrorism threat detection model using DistilBERT with Deep Neural Network from twitter data. The model ensures accurate and efficient representation of text data by utilizing DistilBERT's transformer-based architecture, which is lightweight and powerful to extract rich semantic information from tweets. A Dense Neural Network, which is excellent at spotting intricate patterns and relationship in the data, processes these embeddings further to accurately classify tweets as either threats or non- threat. The DistilBERT-DNN model has demonstrated remarkable efficacy in detecting terrorist threats from twitter data with a 93% accuracy. The methodology surpasses existing neural network-based approaches and conventional machine learning techniques by effectively combining the advantages of deep learning and natural language processing. This demonstrates how advanced NLP techniques can improve the effectiveness and reliability of automated systems for detecting terrorist threats. Future research can focus on integrating multimodal data sources, such as image and video analysis, to improve threat detection beyond textual data. Additionally, incorporating real-time streaming capabilities can enable proactive identification and mitigation of threats as they emerge. Moreover, leveraging graph-based neural networks can help analyze network structures and relationships between suspicious accounts to identify coordinated terrorist activities. These future enhancements will contribute to the development of a more comprehensive, accurate, and real-time terrorism threat detection system, strengthening national security and public safety.

Utilizing NLP to Optimize Municipal Services Delivery Using a Novel Municipal Arabic Dataset

Homod Hamed Alaloye, Ahmad B. Alkhodre, Emad Nabil
Faculty of Computer and Information Systems, Islamic University of Madinah, Madinah, Saudi Arabia

***Abstract*—The natural language processing paradigm has emerged as a vital tool for addressing complex business challenges, mainly due to advancements in machine learning (ML), deep learning (DL), and Generative AI. Advanced NLP models have significantly enhanced the efficiency and effectiveness of NLP applications, enabling the seamless integration of various business processes to improve decision-making. In the municipal sector, the Kingdom of Saudi Arabia is trying to harness the power of NLP to promote urban development, city planning, and infrastructure enhancements, ultimately elevating the quality of life for its residents. In the municipal sector, approximately 300 services are available through multiple channels, including the Baladi application, unified communication services, WhatsApp, a dedicated beneficiary center (serving citizens and residents), and social media accounts. These channels are supported by a dedicated team that operates 24/7. This paper examines the implementation of ML and DL methods to categorize requests and suggestions submitted by residents for various municipal services in the Kingdom of Saudi Arabia. The primary aim of this work is to enhance service quality and reduce response times to community inquiries. However, a significant challenge arises from the lack of Arabic datasets specifically tailored to the municipal sector for training purposes, which limits meaningful progress. To address this issue, we have created a novel dataset consisting of 3,714 manually classified requests and suggestions collected from the X platform. This dataset is organized into eight classes: tree maintenance, lighting, construction waste, old and neglected assets, road conditions, visual pollution, billboards, and cleanliness. Our findings indicate that ML models, particularly when optimized with hyperparameters and appropriate pre-processing, outperformed DL models, achieving an F1 score of 90% compared to 88%. By releasing this novel Arabic dataset, which will be open sourced for the scientific community, we believe this work provides a foundational reference for further research and significantly contributes to improving the municipal sector's service delivery.**

Keywords*—Arabic text classification; machine learning (ML); deep learning (DL); hyperparameter optimization; municipal services

I. Introduction

Machine learning (ML) and deep learning (DL) models have significantly advanced our understanding of natural language, creating new research opportunities in areas such as text classification, translation, summarization, generation, and question-answering. However, the effectiveness of these models can vary depending on the specific task, particularly in text classification.

The authors in [1] have applied ensemble learning techniques to improve accuracy, which are especially effective for dealing with complex data with varied features. Ensemble learning combines multiple models with diverse parameters, enhancing the analysis and classification of intricate data patterns. As a result, these techniques prove beneficial for achieving higher accuracy in complex text classification tasks.

The authors in [2] utilize neural network architectures with multiple layers to effectively identify and interpret patterns in language-related tasks, such as question answering, translation, and text classification. This effectiveness is further enhanced by embedding techniques, including word and character embeddings, which are essential for tasks like text classification, knowledge extraction, and question-answering. Additionally, hyperparameter optimization (HPO) is crucial in improving model performance, as systematic hyperparameter tuning can significantly enhance accuracy and efficiency.

The authors in [3] describe a strategy for selecting hyperparameter values incorporating techniques such as Grid Search, Random Search, Bayesian Optimization, Particle Swarm Optimization, and Genetic Algorithm Metaheuristics.

ML and DL models have transformed how business applications and services are enhanced and developed; many applications and services currently use machine learning (ML) and deep learning (DL) models for various purposes, including task automation, improved decision-making, enhanced customer experience, predictions, and automatic text classification. In Saudi Arabia, the municipal sector provides over 300 essential services for improving the quality of life through urban development, city planning, and infrastructure improvement. These services cover streets, parks, lighting, green spaces, sidewalks, public health, sanitation, and public transportation management. They are delivered through various channels, including the Balady application, unified contact numbers, WhatsApp service, beneficiary centers, and the municipal sector's social media accounts, all supported by a dedicated team working around the clock.

Using machine learning (ML) and deep learning (DL) models in municipal service procedures can improve how citizen and resident requests and suggestions are classified. This enhancement leads to better service performance, lower financial and human costs, and increased overall satisfaction with municipal services.

These models require a robust dataset for training, which is crucial for effectively extracting knowledge, analyzing and classifying data, recognizing patterns, and turning raw data into actionable information. However, our review of existing literature reveals a significant gap in the availability of training datasets, especially in Arabic. Most datasets for training learning

models are available in English, while there is a shortage of sufficient datasets in Arabic.

This paper significantly contributes to natural language processing, particularly concerning municipal services in the Kingdom of Saudi Arabia. It introduces a comprehensive, specialized Arabic dataset that captures citizens' requests and suggestions related to these services. This dataset enhances the resources available for researchers and practitioners in classifying and analyzing Arabic texts. Furthermore, it is a valuable tool for advancing the development of machine learning (ML) and deep learning (DL) models tailored to the Arabic language's unique linguistic and cultural characteristics. Ultimately, this will facilitate more effective data-driven decision-making in municipal service delivery. The dataset will be open-sourced for the community, and we will also provide a performance baseline, allowing others to use it for performance comparison in their own work.

The paper is organized into six sections. Section II provides a comprehensive literature review, offering insights into previous research. Section III details the paper's key contributions, elaborating on the proposed methodology. Section IV presents the experimental results, followed by a discussion in Section V. Finally, Section VI concludes the paper by summarizing the key insights and future directions.

II. Literature Review

The text classification problem has many real-life applications, and there are many techniques for tackling it. Fig. 1 depicts the major methods.

With the global rise of social media platforms like Twitter, Facebook, and Instagram, coupled with greater engagement with hashtags, there has been a significant increase in Arabic-language tweets that contain racist, bullying, or hateful content. This trend has prompted researchers to classify Arabic text into multi-class and binary categories to tackle these issues.

In a related study [4], the authors employed binary classification to categorize millions of articles and blogs as either real or fake news using the Multivariate Bernoulli Naïve Bayes model, demonstrating the effectiveness of ML techniques in authenticating Arabic content. These studies highlight the wide-ranging applicability of ML methods in Arabic-language tasks, from hate speech detection to verifying the authenticity of information.

In [5], the authors contributed to reducing the time researchers spend searching for relevant papers by employing classification models such as SVM, Naïve Bayes, K-nearest Neighbor, and Decision Tree to categorize a set of 107 research papers across various fields, including science, business, and social sciences.

In [6], the authors examined the impact of various stemming methods and word representations on Arabic text classification using RNN architectures, specifically LSTM, Bi-LSTM, GRU, and Bi-GRU models. They compared the accuracy among different combinations of stemming approaches (no stemming, root-based stemming, and light-based stemming) and word representations (Word2Vec, FastText, and GloVe). The highest accuracy was found with no stemming using Word2Vec for word representation, along with the Bi-GRU architecture as the classifier.

Similarly, the authors in [7] developed a dataset for dialectal Arabic tweet acts by annotating a subset of the existing Arabic Sentiment Analysis Dataset (ASAD) based on six speech act categories. The ArSAS dataset was classified using BERT, and the results were compared with various Arabic BERT models. The findings suggest that the top-performing model was araBERTv2-Twitter.

The authors in [8] classified numerous policies published by governments and institutions, each containing several paragraphs indicating a specific topic. The study relied on ensemble learning techniques, particularly Bagging, integrated with DL methods, specifically Convolutional Neural Networks (CNN), to classify the policies based on the predetermined topics of the paragraphs.

In a related study [9], the authors demonstrated that ensemble learning outperformed traditional ML approaches by 6% in classifying Arabic data, which is characterized by its complexity arising from multiple dialects and variations in letter formation.

In [10], the authors employed four deep learning models—Recurrent Neural Network (RNN), Long Short-Term Memory (LSTM), Convolutional LSTM (CNN-LSTM), and Bidirectional LSTM (Bi-LSTM)—to classify millions of Arabic texts across diverse domains, including cultural, scientific, political, and health-related topics, sourced from websites, social media platforms, academic publications, and news outlets. The Bi-LSTM model achieved the highest accuracy result (94.02).

The authors in [11] applied multi-label classification models to categorize the topics of each verse in the Quran, enhancing understanding of its content. They developed a majority voting approach, achieving optimal performance through a combination of Random Forest, Support Vector Machine (SVM), and Adaptive Boosting models. This ensemble achieved a micro F1 score of 0.5143 and a Hamming loss of 0.0878. Additionally, the majority voting method demonstrated improved performance compared to the individual models.

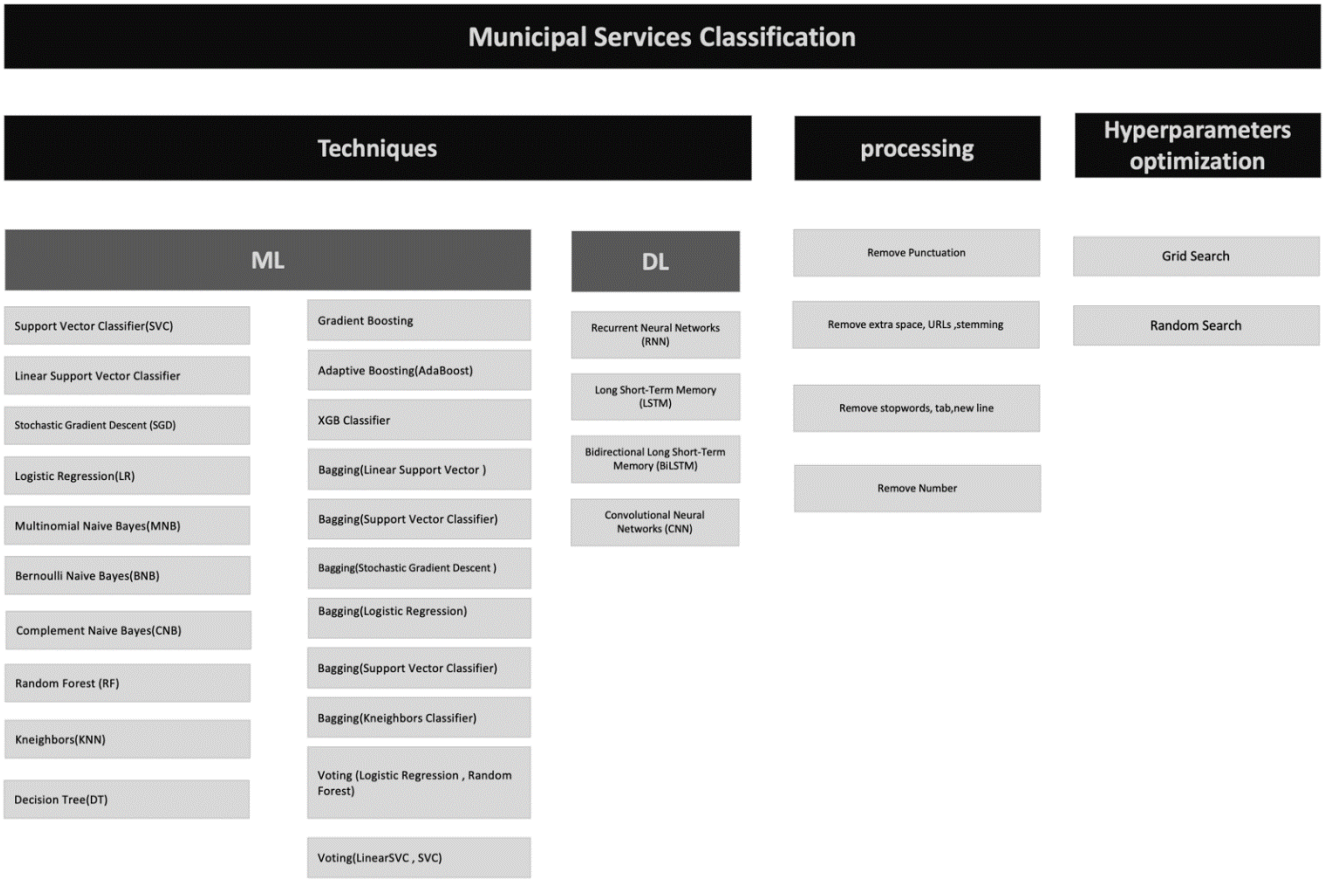

Fig. 1. NLP Classification: Techniques, preprocessing steps, and hyperparameter optimization.

The authors in [12] focused on classifying SMS messages as either spam or not spam, emphasizing the importance of this medium for communication and verification by banks, institutions, and e-platforms. They employed ensemble learning techniques for message classification, achieving an impressive accuracy of 99.91%.

The authors in [13] examined the classification of a large dataset containing 290,000 multi-tagged articles across various categories, including business, technology, sports, and politics. This research aimed to analyze the dataset to identify patterns, which would assist in summarizing and classifying the articles. Classifying news stories that belong to multiple categories posed significant challenges. However, logistic regression achieved an accuracy of 81.3%, while XGBoost reached 84.7%. Notably, a combination of ten neural network architectures—namely CNN, CLSTM, LSTM, BILSTM, GRU, CGRU, BIGRU, HANGRU, CRF-BILSTM, and HANLSTM—performed exceptionally well as a multilabel classifier, achieving an accuracy of 94.85%.

In a related study [14], the authors experimentally investigated the application of Convolutional Neural Networks (CNNs) to text classification; using FastText for word embeddings, the CNN model was trained on publicly different datasets. The authors in [15] compared the effects of classical and contextualized word embeddings on model performance. They evaluated classical embeddings, such as GloVe, Word2Vec, and FastText, on the HARD, Khooli, AJGT, ArSAS, and ASTD datasets using BiLSTM and CNN models. However, the contextualized transformer-based embedding model BERT outperformed the classical embeddings, achieving the highest classification accuracy across all datasets.

The authors in [16] concentrated on classifying fake Arabic news on Twitter by using various Arabic contextualized embedding models, such as AraBert, Arabic-BERT, ArBert, MARBert, Araelectra, and QaribBert, which together achieved an impressive classification accuracy of 98%.

The authors in [17] implemented various models, including Convolutional-GRU and Attention-GRU, using Word2Vec embeddings for Arabic text classification. They compared model performance on the SANAD and NADiA datasets, achieving an accuracy of 91.18% on SANAD and 96.94% on NADiA.

The authors in [18] applied a Genetic Algorithm to optimize CNN model parameters, improving Arabic text classification accuracy to 98%.

The authors in [19] utilized Word2Vec and TF-IDF with models such as SVC, Random Forest, and Gaussian Naive Bayes to classify Arabic tweets, reporting high model accuracy rates of 98.09% and 98.14%.

The authors in [20] demonstrated that the performance of the large language model BERT, when applied without fine-tuning its parameters, surpassed that of models utilizing fine-tuned parameters.

The authors in [21] used the NLTK package to improve machine learning performance in classifying Arabic news (DAFN) as either fake or real.

The authors in [22] collected a dataset using the Twitter API, which they manually labeled to ensure its reliability. They employed two techniques for feature extraction: N-gram models (including unigrams, bigrams, and char-grams) to enhance the classification of advertisements and illegal content through both machine learning (ML) and deep learning (DL) approaches.

The authors in [23] utilized a meta-heuristic genetic algorithm (G.A.) to optimize hyperparameters and feature extraction techniques, specifically the bag of words (BOW) and term frequency-inverse document frequency (TF-IDF) methods. They assessed the performance of several ensemble learning models, including the Extra Trees Classifier (ETC), Random Forest Classifier (RFC), and Logistic Regression Classifier (LRC). Their efforts led to an F1 score of 80.88% for sentiment classification and 68.76% for multilabel classification tasks.

The authors in [24] achieved a classification accuracy of 94.75% by grouping similar Arabic words generated by the Word2Vec model. Each group of similar words utilized the Word2Vec-based method RARF, which enhanced the model's effectiveness in accurately classifying Arabic text.

The authors in [25] utilized the ARABERT4TWC model, which features a custom-built Arabic BERT, transformation layers, a self-attention layer, and a classification layer to improve the classification of Arabic tweets. Using datasets such as SANAD for Arabic news stories, HARD, AJGT, ASTD, and ArsenTD–Lev, the model achieved an impressive accuracy of 98%.

The authors in [26] utilized ensemble learning alongside N-gram features (Unigram, Bi-Gram, and Tri-Gram) to improve the classification accuracy of Arabic spam reviews, achieving maximum accuracies of 95% and 99.98% across two datasets.

In a related study [27], the authors emphasized the importance of hyperparameter tuning techniques in improving the performance of machine learning (ML) and deep learning (DL) algorithms applied to Arabic text. They utilized random search and grid search methods for tuning in classification tasks sourced from cnnarabic.com. The findings indicated that random search outperformed grid search, achieving accuracies of 95.16% for Artificial Neural Networks (ANN), 94.57% for Multinomial Logistic Regression (MLR), and 94.28% for Support Vector Machines (SVM).

The authors in [28] used the Particle Swarm Optimization (PSO) algorithm for feature selection, resulting in a document classification accuracy of 97%.

The authors in [29] compared various Arabic BERT models used for text classification to assess and summarize each model's performance.

In [30], a related study, the authors introduced the BERT-Mini Model (ABMM) to classify hate speech in Arabic social media posts into standard, abusive, and hate speech. The ABMM model achieved an impressive accuracy score of 0.986.

The authors in [31] collected opinions from Arabic-speaking users about ChatGPT technology using the Tweepy and SNscrape Python libraries. They categorized the data into three sentiment classes: negative, positive, and neutral. By employing classification models such as RoBERTa, they achieved a recall accuracy of 99%.

The authors in [32] performed a comparative analysis of ChatGPT-4 and Google Gemini for detecting and classifying messages as spam, showcasing advancements in AI language models for content moderation.

The authors in [33] presented a method for improving the classification of cognitive distortions in Arabic content on Twitter. They incorporated an unlabeled dataset using the unsupervised learning model BERTopic. This approach combined the processed unlabeled data with a labeled dataset, which enhanced the overall classification performance using machine learning techniques. A concise summary of the literature is presented in Table I.

III. METHODOLOGY

The proposed methodology, illustrated in Fig. 2, presents a multi-method approach aimed at enhancing the automatic classification of citizens' and residents' requests and suggestions regarding municipal services in the Kingdom of Saudi Arabia. This approach incorporates various machine learning (ML) and deep learning (DL) models, along with hyperparameter tuning and data processing techniques, to improve classification accuracy. It includes a comparison of model performance before and after applying these hyperparameters and data preprocessing, with the objective of identifying the best-performing model for this task. The ultimate goal is to streamline the classification of public requests and suggestions related to municipal services, thus facilitating more efficient service delivery and quicker response times.

A. Data Preparation

In this study, we collected a dataset from the social media platform (X) to analyze requests and suggestions from citizens and residents about the quality and performance of municipal services across various cities in the Kingdom of Saudi Arabia.

After gathering this feedback, we sorted, filtered, and selected comments that specifically addressed improvements to municipal services to help develop an effective classification model for these requests and suggestions. The dataset includes a total of 3,714 comments and suggestions, with most contributions focusing on critical areas such as infrastructure services, including roads, sidewalks, and lighting; issues related to water leakage and sidewalk subsidence; concerns regarding street excavations; and requests for enhancing green spaces, including tree planting and park development in residential areas. Details of the dataset can be found in Table II, Table III, and Fig. 3.

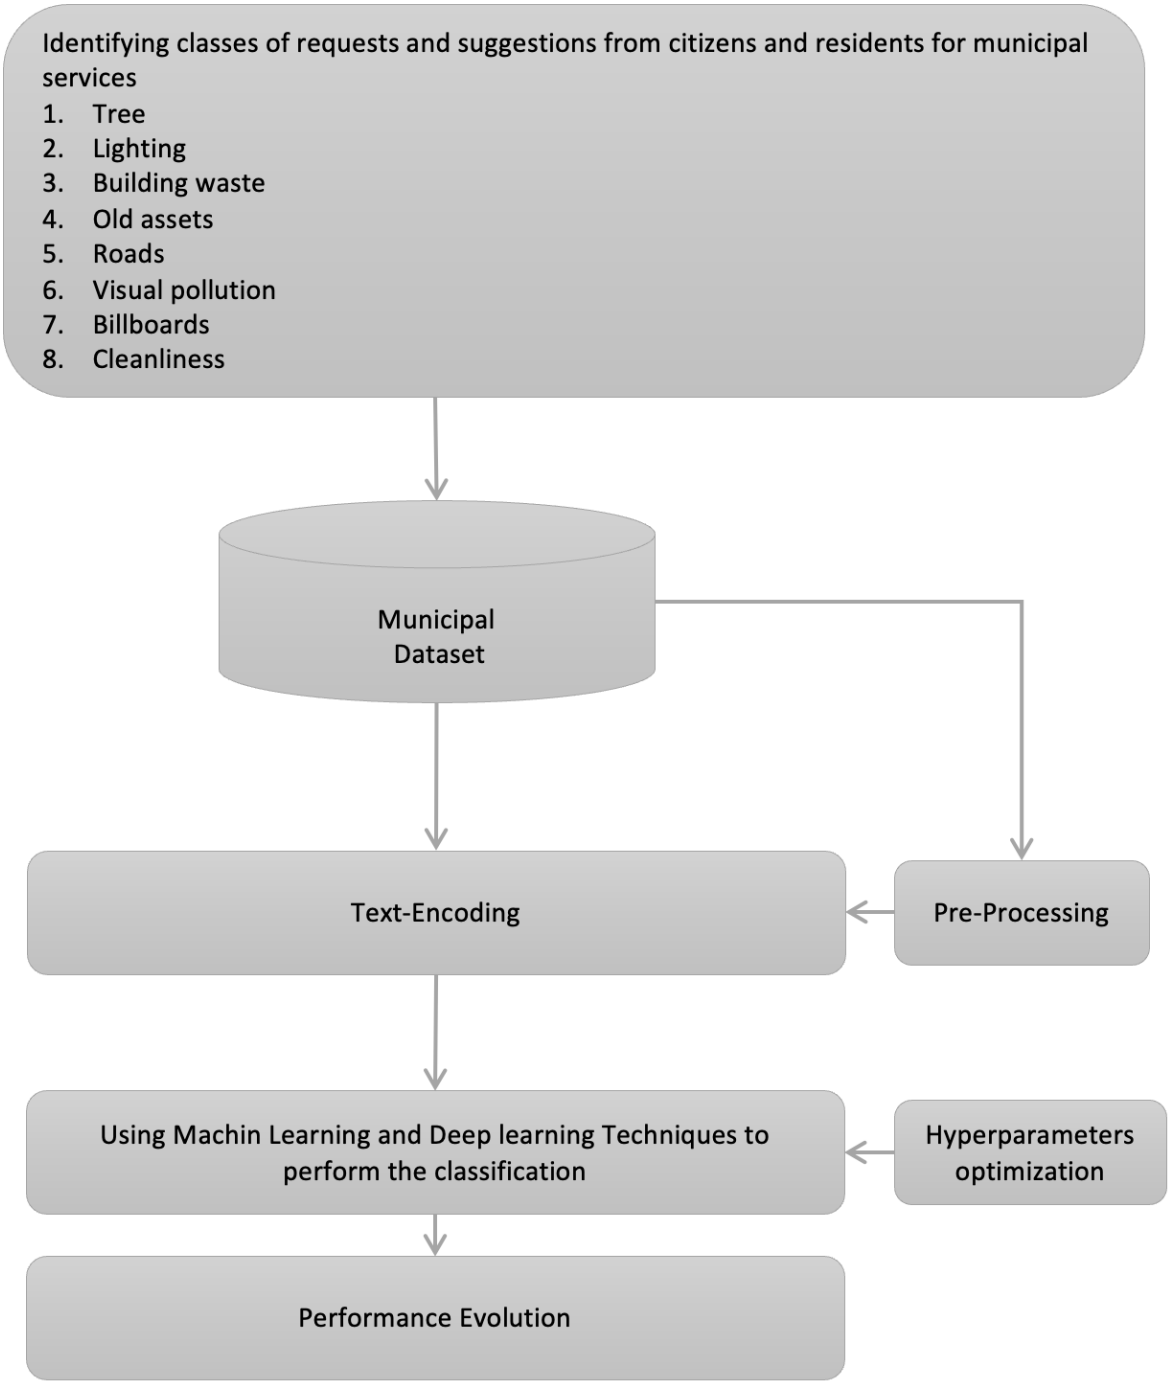

Fig. 2. Block diagram of the proposed methodology.

TABLE II. DATASET AND CLASS DESCRIPTIONS

Class	Description	No. of records
Tree	This category includes tweets that focus on suggestions for planting more trees, trimming existing ones, maintaining tree health, addressing insect infestations, and enhancing the care of green spaces. These tweets reflect public interest in sustainable urban development and emphasize the importance of green areas in improving environmental quality and community well-being.	400
Lighting	The Lighting category in this dataset includes tweets from citizens and residents requesting the installation or improvement of lighting in various municipal areas to enhance visibility and safety. Many tweets also emphasize the need for ongoing maintenance of public lighting systems, highlighting issues such as dim or non-functional streetlights and insufficient illumination in certain public spaces. This systematic categorization of tweets allows for a structured analysis of public feedback regarding lighting infrastructure, helping municipal authorities identify specific areas that need attention and improvement in lighting services.	550
Building Waste	Tweets in this category primarily focus on reporting construction waste in urban neighborhoods and include questions about available disposal methods. These comments reflect the interest of citizens and residents in managing construction debris and seeking solutions for waste disposal within residential areas to promote more sustainable urban environments. By analyzing this feedback, municipal authorities can gain valuable insights into community needs and develop targeted strategies to improve construction waste management practices.	337
Old assets	Tweets in this category consist of questions from citizens and residents about abandoned vehicles in residential neighborhoods and concerns regarding other neglected assets in these areas. These observations demonstrate the community's interest in understanding how to report old and abandoned vehicles. By analyzing these tweets, the municipal sector can effectively allocate follow-up teams to address cases of abandoned vehicles and facilitate their removal.	400
Roads	The tweets express the demands of citizens and residents for improvements in infrastructure. They specifically highlight the need for resurfacing roads, addressing subsidence issues affecting roads and sidewalks, and installing speed bumps to reduce vehicle speeds in residential neighborhoods. These comments underscore the essential role of local government in enhancing and developing infrastructure. By analyzing these tweets, municipal authorities can more effectively identify areas in need of maintenance, allowing them to prioritize initiatives that will improve urban living conditions.	916
Visual pollution	Tweets in this category consist of requests from citizens and residents urging the removal of graffiti from the walls of public buildings. This feedback highlights the community's desire for clean and well-maintained public spaces, emphasizing the importance of aesthetic upkeep in urban environments. By addressing these requests, municipal authorities can improve the appearance of public facilities and foster a greater sense of pride within the community.	251
Billboards	Tweets in this category address requests for the removal of unlicensed advertising posters and billboards located at the entrances of residential buildings, on sidewalks, and in public areas. These unauthorized displays can disrupt the visual appeal of the environment and violate legal standards. By responding to these concerns, municipal authorities can help maintain the integrity of public spaces and ensure compliance with local regulations, fostering a more aesthetically pleasing community.	76
Cleanliness	This category includes tweets that focus on the cleanliness of public spaces. Common topics cover the condition of roads, sidewalks, and waste management. Discussions often highlight issues such as littering, the frequency of waste collection, and the overall maintenance of public areas. These tweets reflect public sentiment regarding the effectiveness of municipal services in maintaining a clean and hygienic environment and may include suggestions for improvement.	600

	"Old buses without license plates are parked in residential areas."	

B. Dataset Processing

Various methods were employed to process the dataset, all aimed at enhancing the accuracy of machine learning and deep learning models in classifying Arabic texts more effectively. Removing punctuation—including periods, question marks, exclamation points, commas, colons, semicolons, dashes, hyphens, brackets, braces, parentheses, apostrophes, and quotation marks—provides several benefits. These benefits include reduced noise, improved tokenization performance, enhanced model accuracy, a unified text format, and better text representation as vectors. Additionally, removing extra spaces and links improves readability, boosts tokenization results, reduces data complexity, increases model efficiency, and focuses analysis on relevant content.

Stop words are common words in Arabic that frequently appear in the text but contribute little to its overall meaning. Removing these stop words can reduce data size, minimize noise, improve accuracy in text classification, and facilitate keyword extraction. The NLTK library in Python is often used to implement stop word removal, streamlining the text for more effective processing and analysis.

Additionally, removing tabs enhances data consistency, aids in understanding, and reduces errors. Eliminating numbers from the text is also an essential part of data processing, as they can

add complexity. By removing numbers, the data is purified, which enhances the algorithms used, increases analysis accuracy, standardizes the data, facilitates comprehension, and improves extraction processes.

Feature extraction techniques in Natural Language Processing (NLP) involve transforming raw data into features usable in machine learning (ML) and deep learning (DL) models. There are several methods available for converting text into vector representations for numeric analysis.

Optimal hyperparameters are external settings for ML and DL models that control their behavior and learning processes. Various algorithms can be utilized to tune these hyperparameters to achieve the best results.

The Grid Search technique is commonly employed to find the optimal set of hyperparameters for a model in ML and DL. It systematically tests a predefined set of hyperparameters and evaluates the model's performance for each combination using cross-validation. In contrast, Random Search selects random combinations of hyperparameters for evaluation. This approach significantly reduces computation time while still exploring a wide range of values, and it often proves to be more efficient than Grid Search.

IV. Results and Analysis

This section discusses the outcomes of applying various text classification models to a dataset containing requests and suggestions from citizens and residents about municipal services in the Kingdom of Saudi Arabia. The models' performance was evaluated using the F1 score to identify the most effective algorithm for classifying different topics, such as lighting, construction waste, neglected assets, roads, visual pollution, billboards, and cleanliness. Our results indicate significant improvements in the performance of both machine learning (ML) and deep learning (DL) models, demonstrating the benefits of hyperparameter optimization combined with dataset pre-processing. Furthermore, the robustness of these models was evident even without pre-processing, further highlighting their applicability to text classification tasks.

TABLE IV. Values of Hyperparameter of ML Models

Models	Hyperparameters
Logistic Regression	solver='newton-cg',penalty='none',max_iter=1000)
Naive-Multinomial	alpha=0.1
Naive-Complement	alpha=1.20
Naive-Bernoulli	alpha=0.001
Random Forest	n_estimators=86
SVC	C=1000, gamma= 0.01, kernel= 'rbf'
Linear SVC	C=2,penalty='l2'
K-Neighbors	(n_neighbors=7)
Decision Tree	criterion='gini',max_depth=100,splitter='random',min_samples_split=2
SGD	(penalty='l2')
Bag(LR)	solver='newton-cg',penalty='none',max_iter=1000),n_estimators=30
Bag(SVC)	SVC(C=1000, gamma= 0.2, kernel= 'rbf'),n_estimators=50))
Bag(K-NN)	n_estimators=80
Bag(SGD)	n_estimators=40
AdaBoost	n_estimators=80,learning_rate=0.01,algorithm="SAMME.R"
XGB	n_estimators=50,gamma=0.5
Gradient Boosting	n_estimators=125,max_depth=7
Vot(RF-LR)	estimators=[('lr',LogisticRegression(solver='newton-cg',penalty='none',max_iter=1000)),('rf',RandomForestClassifier(n_estimators=86))],voting='soft'))
Vot(L-SVC,SVC)	estimators=[('ls',LinearSVC(C=2,penalty='l2')),('sv',SVC(C=1000, gamma= 0.01, kernel= 'rbf'))],voting='hard'

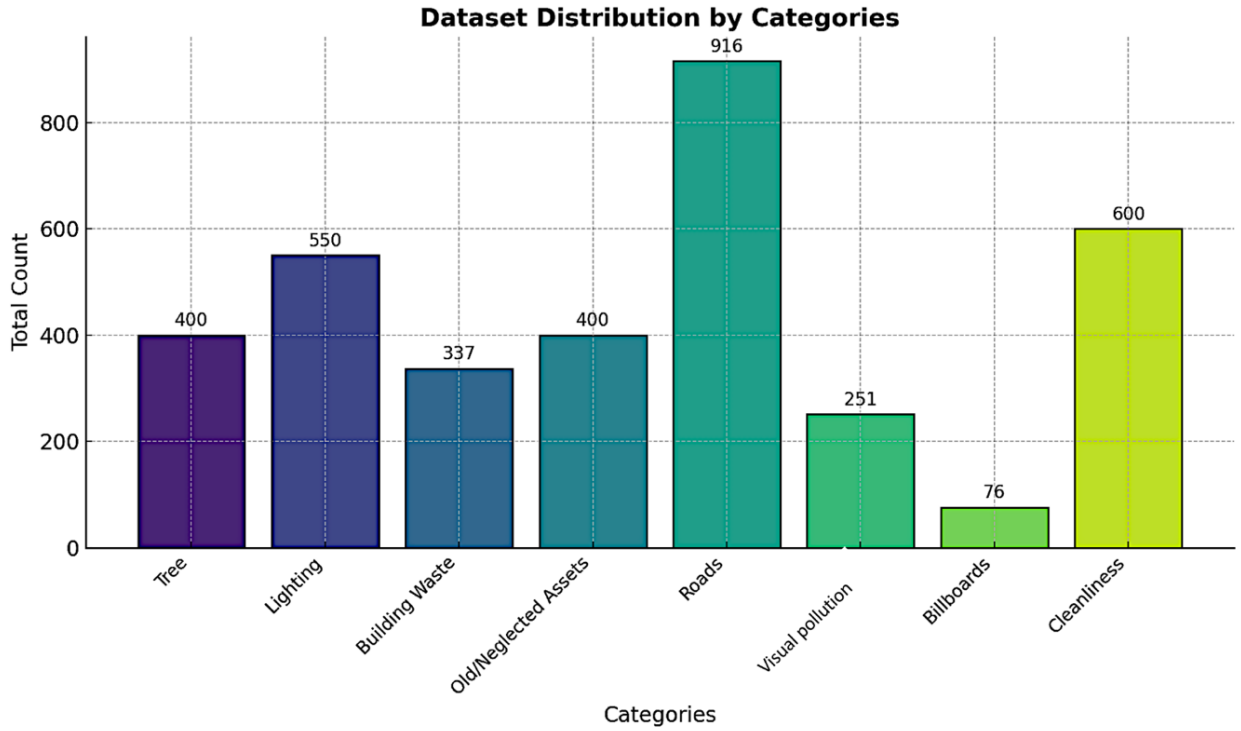

Fig. 3. The different classes are included in the dataset.

A. Performance Metrics

We utilized the following metrics to assess the performance of the model:

- Accuracy: The number of data instances correctly classified from the total dataset is a crucial measure of a model's effectiveness in categorization. This metric is particularly significant for binary classification problems when the dataset is balanced. However, when the dataset is unbalanced, it is important to consider additional metrics alongside accuracy, such as recall, precision, and F1 scores.

$$Accuracy = \frac{True\ Positive(TP)+True\ Negative(TN)}{Total\ Number\ of\ Sample} \quad (1)$$

- Precision: The ratio of correctly predicted positive instances to the total predicted positives, reflecting the model's ability to identify relevant classes.

$$Precision = \frac{True\ Positive(TP)}{True\ Positives(TP)+False\ Positives(FP)} \quad (2)$$

- Recall: The proportion of actual positive instances that are correctly identified by the model, which measures its sensitivity.

$$Recall = \frac{True\ Positive(TP)}{True\ Positives(TP)+False\ Negatives(FN)} \quad (3)$$

- F1 Score: A metric that combines precision and recall into a single score, ranging from 0 (worst) to 1 (best).

$$F1 = 2 * \frac{Precision*Recall}{Precision+Recall} \quad (4)$$

TABLE V. F1 SCORES OF ALL MODELS UNDER PROCESSED DATASET CONDITIONS

Models	F1_Score using optimal hyperparameters	F1_Score using default hyperparameters
LR	**0.901734104**	**0.865606936**
Bagging (LR)	0.901734104	0.855491329
Bagging (SVC)	0.8959537	0.8439306
MNB	0.878612716	0.791907514
RF	0.875722543	0.85982659
XGB	0.854046243	0.852601156
Bagging(K-NN)	0.835260116	0.820809249
BNB	0.862716763	0.556358382
K -NN	0.832369942	0.826589595
DT	0.822254335	0.819364162
AdaBoost	0.423410405	0.39017341
RNN	0.816511235	0.816511235

B. F1 Scores with Processed Dataset

The F1 score, which balances precision and recall, is a critical metric for evaluating the classification of imbalanced datasets. In this context, both Logistic Regression and its ensemble counterpart play significant roles.

We aimed to identify the optimal or near-optimal hyperparameters for the classification techniques used; the results of this phase are detailed in Table IV.

As indicated in Table V, bagging with Logistic Regression achieved the highest F1 score of 90.17% under pre-processed conditions. While deep learning models like RNN performed reasonably well, obtaining an F1 score of 81.16%, their performance was still marginally lower than that of the best-performing machine learning models. Overall, models that utilized pre-processing and optimal hyperparameters with machine learning algorithms—such as Logistic Regression, Bagging (LR), and Bagging (SVC)—consistently achieved superior F1 scores. This demonstrates that machine learning algorithms outperformed deep learning models when evaluated using the F1 metric.

C. F1 Scores without Preprocessing the Dataset

The F1 scores reflect the results achieved using the dataset without any pre-processing, while applying optimal hyperparameters, as detailed in Table IV. This method emphasizes the model's ability to effectively balance precision and recall, even when dealing with the challenges posed by unprocessed data. Evaluating the F1 scores in this way provides insight into the model's capacity to maintain accuracy and reliability while working with raw data and appropriately tuned parameters.

As illustrated in Table VI, Linear SVC, along with Bagging using Linear SVC and Voting (combining Linear SVC and SVC), showed superior accuracy rates of 91.04%, 90.46%, and 90.08%, respectively, when hyperparameter optimization was performed without any pre-processing. Among deep learning models, CNN and LSTM achieved noteworthy accuracy rates of 88.43% and 87.81%, respectively, although they did not perform as well as some of the specific machine learning models.

TABLE VI. F1 SCORES OF ALL MODELS UNDER UNPROCESSED DATASET CONDITIONS

Models	F1_Score using optimal hyperparameters	F1_Score using default hyperparameters
Linear SVC	**0.910404624**	**0.913179191**
SGD	0.901734104	0.900289017
Bagging (Linear SV)	0.904624277	0.897398844
Bagging(SGD)	0.907514451	0.904624277
Voting(LR,RF)	0.904624277	0.875722543
Voting(LinearSVC,SVC)	0.908959538	0.89017341
CNB	0.894508671	0.891618497
SVC	0.893063584	0.856936416
Gradient Boosting	0.845375723	0.841040462
CNN	0.884338846	0.83706596087
LSTIM	0.878148111	0.863887078
BiLSTM	0.871606769	0.86308049

V. DISCUSSION

The results highlight the impact of hyperparameter optimization and dataset processing techniques on the performance of machine learning (ML) and deep learning (DL) models when evaluating requests and suggestions from citizens regarding various municipal services. These services include categories such as trees, lighting, construction waste, neglected assets, roads, visual pollution, billboards, and cleanliness.

The findings indicate that ML models consistently outperformed DL models when using optimized hyperparameters and processed datasets. However, DL models showed performance levels that were close to those of ML models, particularly when hyperparameters were finely tuned without preprocessing the datasets.

Several factors contributed to the enhanced accuracy of ML models in classifying these requests and suggestions. Notably, ML models can effectively learn from smaller datasets due to their reliance on feature-based methods, while DL models typically require larger datasets to capture and model complex patterns effectively.

In summary, the results demonstrate that when utilizing optimized hyperparameters and processed datasets, machine learning models achieved higher accuracy compared to deep learning models. Conversely, deep learning models exhibited competitive performance levels, particularly when hyperparameters were finely tuned without preprocessing. The ability of machine learning models to learn effectively from smaller datasets is a significant factor in their accuracy in classifying requests related to municipal services.

VI. CONCLUSION

This study explored the application of machine learning (ML) and deep learning (DL) models to classify Arabic-language text related to municipal services in Saudi Arabia. To address the scarcity of Arabic-language datasets, a collection of 3,714 requests and suggestions was compiled. This dataset will be made publicly available to encourage the community's adoption of ML and DL technologies in the field of municipal services. A baseline for classification performance was established to guide future improvements.

The findings are significant: ML models, including Logistic Regression and Linear Support Vector Classifier (Linear SVC), demonstrated superior performance, achieving a maximum accuracy of 91.04% and an F1 score of 90.17%. These results were obtained through the application of data preprocessing techniques and hyperparameter optimization. Although DL models, such as Convolutional Neural Networks (CNN) and Bidirectional Long Short-Term Memory (BiLSTM), also performed well, they did not surpass the ML models. This difference can be attributed to the fact that DL models are better suited for longer texts, while ML models excel with shorter texts, which is characteristic of the dataset used in this study.

The study emphasizes the critical role of data preprocessing and hyperparameter tuning in enhancing classification accuracy. By introducing this dataset and sharing key insights, this work establishes a foundation for future research and development in natural language processing (NLP) for the Arabic language. Future efforts could focus on expanding the dataset, integrating advanced embedding techniques and large language models, and designing dynamic classification systems for real-time applications.

Future research can explore several enhancements to improve classification robustness and generalizability. Expanding the dataset with more samples will strengthen model performance, while incorporating advanced embedding techniques, such as BERT or FastText, can refine text representation and capture nuanced meanings more effectively. Developing real-time classification systems could significantly enhance municipal responsiveness and service efficiency. Another valuable enhancement is integrating multimodal data—combining text, images, and audio—to achieve a more comprehensive understanding of citizens' needs. Lastly, implementing continuous feedback mechanisms will enable model refinement, ensuring adaptability to evolving demands.

***Abstract*—Financial time series prediction is inherently complex due to its nonlinear, nonstationary, and highly volatile nature. This study introduces a novel CEEMDAN-BO-LSTM model within a decomposition-optimization-prediction-integration framework to address these challenges. The Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) algorithm decomposes the original series into high-frequency, medium-frequency, low-frequency, and trend components, enabling precise time window selection. Bayesian Optimization (BO) algorithm optimizes the parameters of a dual-layer Long Short-Term Memory (LSTM) network, enhancing prediction accuracy. By integrating predictions from each component, the model generates a comprehensive and reliable forecast. Experiments on 10 representative global stock indices reveal that the proposed model outperforms benchmark approaches across RMSE, MAE, MAPE, and R^2 metrics. The CEEMDAN-BO-LSTM model demonstrates robustness and stability, effectively capturing market fluctuations and long-term trends, even under high volatility.**

***Keywords*—LSTM; Bayesian optimization; CEEMDAN; financial time series; time window selection**

I. Introduction

With the ongoing advancement of global economic integration and the increasing openness of international markets, the influence of stock market fluctuations on the global economy has grown significantly. Accurately capturing stock market trends and forecasting their future movements has thus become a crucial research focus in the financial field. Financial market forecasting methods are primarily categorized into linear and nonlinear models. Early research achieved notable progress in financial time series modeling using linear models [1-3]. However, financial time series typically exhibit high noise, uncertainty, and nonstationary, with dynamic changes in the relationships between variables over time. These limitations often hinder traditional linear models from effectively capturing intricate patterns and sustaining long-term dependencies. Furthermore, the linear models' assumption of data smoothness imposes an additional limitation on their validity.

In order to overcome the limitations of linear models, nonlinear prediction methods have become the mainstream of financial market prediction. Among them, artificial neural networks (ANNs) are widely used due to their ability to process high-dimensional, multimodal and heterogeneous data. For example, Yassin et al. (2017) utilized a stock prediction model based on multilayer perceptron (MLP) to predict the weekly stock price of Apple Inc. and verified its strong prediction performance through one step ahead (OSA) and correlation analysis [4]. Similarly, Zhang et al. (2021) employed a back propagation (BP) neural network to classify and predict stock price patterns, achieving an improved accuracy of 73.29% and providing valuable insights for investors and macroeconomic policies [5]. However, ANN-based models face many challenges, including overfitting, gradient vanishing or exploding, and easy to fall into local optimality, which limit their generalization ability for complex financial data.

With the continuous development and application of deep learning technology, Long Short-Term Memory (LSTM) network has become an important model due to its strong ability to handle noisy, nonlinear and nonstationary data. By introducing advanced gating mechanisms, LSTM effectively overcomes the inherent gradient vanishing and gradient exploding problems of traditional recurrent neural networks (RNNs), making it particularly suitable for processing long sequence data [6, 7]. Its robustness and adaptability have promoted its widespread application in the financial field. Wang et al. (2024) verified that the LSTM model can overcome the limitations of RNN in stock market forecasting and can greatly improve the forecasting performance [8]. These advantages make LSTM a highly promising component in hybrid models for solving complex financial forecasting tasks.

In the field of financial market forecasting, hybrid models have attracted much attention. This type of model combines the strengths of multiple algorithms and offers greater advantages than single models in processing complex and noisy financial data. Compared with single models, hybrid models have stronger generalization capabilities and are more robust, especially in capturing multi-scale features and nonlinear relationships.

In recent years, LSTM-based hybrid models have shown great potential in stock market forecasting due to their ability to capture both long and short-term patterns in financial time series. Table I summarizes recent research based on LSTM

*Corresponding Author.

models, clearly showing the methods and advantages of these hybrid models in stock market forecasting.

As shown in Table I, most studies on LSTM-based stock market prediction methods employ parameter optimization algorithms. This is mainly because manually adjusting parameters not only increases the computational cost, but may also reduce the prediction accuracy and optimization efficiency. In deep learning networks such as LSTM, hyperparameter selection is crucial to achieve accurate predictions [16]. The performance of LSTM largely depends on the optimal configuration of hyperparameters, such as the number of hidden neurons and the learning rate setting. In addition, since the neural network needs to optimize a large number of parameters, it is prone to falling into local optima during this process and may be at risk of overfitting.

To address these challenges, Bayesian Optimization (BO) provides an efficient solution [17]. BO estimates the objective function through Gaussian Processes (GP) and optimizes it using surrogate modeling. This method can efficiently explore the hyperparameter space, avoid redundant calculations, reduce the risk of falling into local optima, and significantly improve both the effectiveness and training efficiency of the LSTM model, making it more suitable for the complexity of financial time series prediction.

In addition to hyperparameter optimization, data preprocessing also plays a vital role in improving prediction accuracy. High noise is a key characteristic of financial time series and a major challenge for accurate prediction. Signal decomposition methods can transform complex original time series into simpler components, enabling the model to capture potential features more effectively and reduce noise. Among them, variational mode decomposition (VMD) is widely used due to its strong practical performance [18, 19]. However, VMD requires manual selection of the number of modes, introducing subjectivity and uncertainty. In contrast, Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) provides an advanced adaptive data decomposition method that decomposes data into physically meaningful modal components. As a higher-order version of Empirical Mode Decomposition (EMD), CEEMDAN overcomes some of EMD's limitations by introducing adaptive white noise, improving robustness and accuracy in extracting intrinsic features of complex data. CEEMDAN has demonstrated significant theoretical and practical value in economic and financial applications, laying a solid foundation for enhancing model performance [20].

Based on the above analysis, this study introduces a novel hybrid model CEEMDAN-BO-LSTM. This model further improves the performance of financial time series prediction by effectively removing the original signal noise, enhancing the long-term and short-term dependency modeling capabilities, and employing an efficient optimization algorithm for hyperparameter tuning. Specific contributions of this study include:

1) Proposal of an innovative hybrid framework: This study constructs a "decomposition-optimization-prediction-integration" framework. The framework uses the CEEMDAN algorithm to perform multi-scale decomposition of stock index time series, automatically adjusts the hyperparameters of LSTM through BO for prediction, and finally integrates the prediction results. This method greatly enhances predictive performance and adaptability, and effectively overcomes the limitations of traditional models in parameter selection and noise reduction.

2) Generalization ability in stock index prediction: The proposed model is experimentally evaluated on 10 representative stock indices worldwide, leading to consistent conclusions. The results demonstrate its effectiveness in capturing the nonlinear characteristics of stock market volatility and achieving significant improvements in forecast accuracy and stability, further highlighting its applicability in financial time series forecasting.

3) Optimized time window segmentation: This study classifies the decomposed components based on energy contribution, dividing them into different frequency components, and assigns a suitable time window to each component, which can be predicted according to the characteristics of different frequencies, further enhancing the prediction performance.

These contributions enable the CEEMDAN-BO-LSTM model to demonstrate significant potential in addressing complex financial market fluctuations, opening up broader application prospects for financial market analysis.

This paper is structured into five sections. The next section introduces the methods used in this study. Section III describes the construction process of the CEEMDAN-BO-LSTM model. Then, Section IV outlines the experimental procedure and analyzes the results. Finally, Section V presents the conclusions of this study, as well as future research directions.

II. METHODS

A. LSTM

The LSTM network is an enhanced variant of the RNN [5]. By incorporating specialized LSTM units, the LSTM network can effectively store and manage both long-term and short-term information. As illustrated in Fig. 1, each LSTM unit comprises three gate mechanisms and two state variables. They are input gate (i_t), forget gate (f_t), and output gate (o_t), as well as cell state (C_t) and hidden state (h_t).

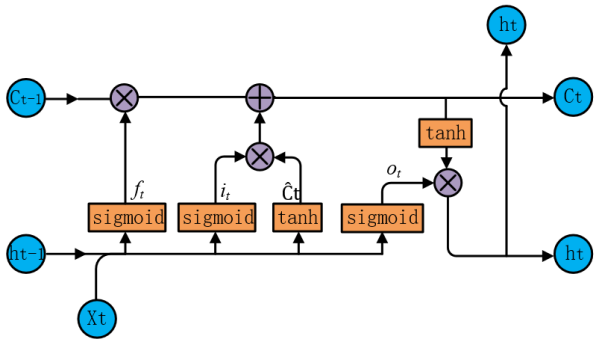

Fig. 1. Structure of LSTM.

According to Fig. 1, these components work collaboratively to regulate the flow of information, allowing LSTM network to maintain and update memory across extended sequences.

The input gate determines the processing of information from the current input data. The mathematical representation is shown in Eq. (1) and Eq. (2).

$$i_t = \sigma(W_i * [h_{t-1}, X_t] + b_i) \quad (1)$$

$$\hat{C}_t = tanh(W_c * [h_{t-1}, X_t] + b_c) \quad (2)$$

The forget gate controls the update of historical data to the memory unit state value. Its mathematical expression is presented in Eq. (3).

$$f_t = \sigma\big(W_f * [h_{t-1}, X_t] + b_f\big) \quad (3)$$

C_t is updated through the combined actions of f_t and i_t. The forget gate regulates the retention of the previous cell state (C_{t-1}), while the input gate introduces new information via the candidate state ($\hat{C}_t$). The update equation is shown in Eq. (4).

$$C_t = f_t * C_{t-1} + i_t * \hat{C}_t \quad (4)$$

The output gate determines the information to be emitted at the current time step. The detailed calculation procedure is shown in Eq. (5) and in Eq. (6).

$$o_t = \sigma(W_o * [h_{t-1}, X_t] + b_o) \quad (5)$$

$$h_t = o_t * \tanh(C_t) \quad (6)$$

Here, σ (sigmoid function) and tanh (hyperbolic tangent function) serve as activation functions. W and b denote the weight matrices and bias terms, respectively. Through this design, LSTM effectively integrates long-term and short-term information, ensuring stability and accuracy in forecasts. Its flexibility and adaptability make LSTM particularly useful for financial time series forecasting, as it effectively captures the complex nonlinear dynamics of stock market volatility.

B. CEEMDAN

In the field of signal processing, researchers have proposed a variety of advanced methods to analyze the intrinsic characteristics of nonlinear and nonstationary data, including empirical mode decomposition (EMD) and its related techniques. EMD is able to decompose the different frequency components of the original data, revealing the contribution of each frequency component, and providing high-resolution analytical capabilities for nonlinear time series [21].

Although EMD has many advantages, its mode mixing issue limits its accuracy and effectiveness in complex signal decomposition. To address this limitation, researchers proposed Ensemble Empirical Mode Decomposition (EEMD) in 2009. EEMD reduces the impact of mode mixing by adding white noise of different amplitudes to the original signal, performing EMD multiple times, and then averaging the decomposition results. However, since EEMD requires multiple repetitions of the decomposition process, the computational cost is high and may introduce additional computational errors [22].

Based on EEMD, Torres et al. (2011) proposed CEEMDAN [23]. CEEMDAN algorithm further enhances the EEMD by refining the introduction of white noise at each decomposition step. This improvement ensures the consistency of the extracted IMFs, mitigates mode mixing, and reduces reconstruction errors. This method enhances both decomposition accuracy and computational efficiency, making it more reliable for complex and dynamic financial time series analysis.

The following section outlines the detailed algorithmic steps of CEEMDAN:

1) Step 1: Generate noisy data sets. Noisy versions of the original time series $x[n]$ are created using the Eq. (7):

$$x_i[n] = x[n] + \varepsilon_0 w_i[n] \quad (7)$$

Where $w_i[n]$ (i = 1, 2 … I) represent Gaussian white noise that follows a normal distribution, and ε_0 is the standard deviation of the noise. This step introduces controlled noise to reduce mode mixing during the decomposition process.

2) Step 2: Apply the EMD method to each noisy signal to extract the first intrinsic mode function (IMF). The first IMF is

calculated as the average of the IMFs obtained from all noisy realizations as shown in Eq. (8)

$$IMF_1[n] = \frac{1}{I}\sum_{i=1}^{I} IMF_1^i[n] \quad (8)$$

The first residual is then computed as Eq. (9):

$$r_1[n] = x[n] - IMF_1[n] \quad (9)$$

3) Step 3: Iterative decomposition is applied to obtain successive IMFs. For k = 2, ... K, the k-th residue is calculated as shown in Eq. (10). The realizations $r_k[n] + \varepsilon_k EMD_k(w_i[n])$ are decomposed until the first EMD mode is obtained, and the (k+1)-th mode is defined as shown in Eq. (11):

$$r_k[n] = r_{k-1}[n] - IMF_k[n] \quad (10)$$

$$IMF_{k+1}[n] = \frac{1}{I}\sum_{i=1}^{I} EMD_1(r_k[n] + \varepsilon_k EMD_k(w_i[n])) \quad (11)$$

4) Step 4: Proceed to step 3 for the next k. The CEEMDAN algorithm terminates when the residual no longer exceeds the two extreme points, and further decomposition is not possible. The final residual is given by Eq. (12):

$$R[n] = x[n] - \sum_{k=1}^{K} IMF_k \quad (12)$$

This approach effectively resolves mode mixing, ensuring stable and interpretable decomposition results.

C. BO

Bayesian optimization (BO) is a widely used algorithm for optimizing black-box functions with the aim of finding the global optimal solution efficiently. The method achieves optimization by iteratively updating the posterior distribution of the objective function, while the updating process is based on the prior distribution with historical data. Compared to traditional optimization methods, Bayesian optimization excels in handling non-convex problems and avoids falling into local optima [24]. Its objective is to maximize the function f(x) by finding the optimal input x^* within the search space $\chi \in \mathbb{R}$, as shown in Eq. (13):

$$x^* = \underset{x \in \chi}{\operatorname{argmax}} f(x) \quad (13)$$

The essence of Bayesian optimization is rooted in modeling the objective function $f(x)$ as a stochastic process, typically represented by a Gaussian Process (GP) as a surrogate model. The GP provides a probabilistic estimate of $f(x)$ based on historical observations, enabling Bayesian optimization to balance exploration of unexplored regions with exploitation of known high-performing regions. This balance improves optimization efficiency and reduces the risk of missing the global optimum.

Bayesian optimization relies on Bayes' theorem to infer the posterior distribution of f(x) given a historical dataset $D_n = \{(x_i, f(x_i))\}_{i=1}^n$, The posterior distribution is given by Eq. (14):

$$P(f(\mathrm{x})|D_n) = \frac{P\left(D_n \middle| f(\mathrm{x})\right) P(f(\mathrm{x}))}{P(D_n)} \quad (14)$$

Where $P\left(D_n \middle| f(\mathrm{x})\right)$ is the likelihood of the dataset given (x), $P\left(f(\mathrm{x})\right)$ represents the prior distribution of the objective function, and $P(D_n)$ is the evidence.

By employing a Gaussian Process, BO algorithm efficiently estimates $f(\mathrm{x})$ and selects the next sampling point from the posterior distribution $P(f(\mathrm{x})|D_n)$. This iterative process seeks to maximize the objective function while minimizing uncertainty, enabling efficient exploration in high-dimensional spaces.

Bayesian optimization's flexibility and ability to incorporate prior knowledge make it particularly suitable for complex and computationally expensive optimization tasks, such as hyperparameter tuning in machine learning, experimental design, and automated decision-making. Its ability to efficiently handle high-dimensional, noisy, and black-box functions positions it as an effective method for addressing complex optimization challenges.

III. Model Construction

Due to the nonlinear and nonstationary nature of stock market indices, achieving accurate predictions remains a significant challenge. In this context, the combination of effective decomposition techniques and advanced machine learning methods is particularly crucial for handling these complexities. In light of this, this study integrates CEEMDAN temporal decomposition, Bayesian Optimization (BO), and LSTM network to propose a novel stock market forecasting framework: CEEMDAN-BO-LSTM.

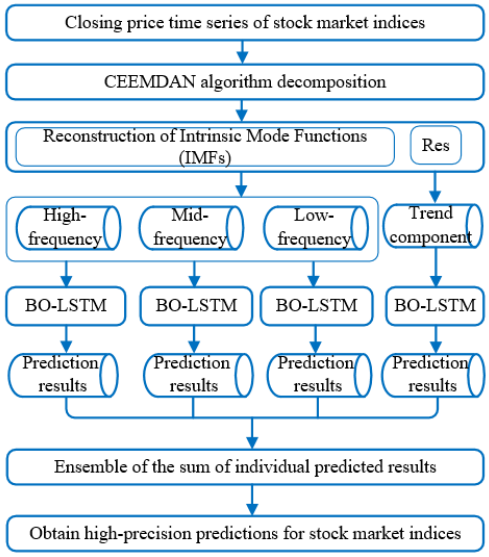

Fig. 2. The workflow of CEEMDAN-BO-LSTM predictive modeling.

As illustrated in Fig. 2, the CEEMDAN-BO-LSTM modeling process addresses the complex, nonlinear, and multi-scale nature of stock market indices through four key steps. In this process, the closing price series of stock market indices serves as input data. The details of these steps are as follows:

1) Step 1: Decomposition. Decompose the closing price time series into multiple IMFs and a residual component using the CEEMDAN algorithm. IMFs capture time series

characteristics at different frequency levels, while the residual represents the overall trend.

2) Step 2: Optimization. The decomposed components are classified according to frequency bands, the time window in the LSTM model is set according to these categories, and the LSTM is then trained using Bayesian optimization.

3) Step 3: Prediction. Optimized LSTM models corresponding to different frequency bands generate predictions for each respective band.

4) Step 4: Integration. Predictions from all components are combined to produce the final forecast for stock market indices. Appropriate evaluation metrics are used to assess the proposed model's reliability and robustness.

IV. Experiment and Result

A. Data Collection and Preprocessing

The historical financial time series dataset used in this study is obtained from Yahoo Finance and covers the daily closing prices of 10 representative global stock indices. The dataset spans 10 years, from October 23, 2014, to October 21, 2024.

Table II presents detailed information on the selected stock indices and their market characteristics. As depicted in Fig. 3, the dynamic trajectories of these indices exhibit typical characteristics of financial time series, including nonlinearity and nonstationary. These characteristics highlight the complexity and challenges associated with forecasting financial trends.

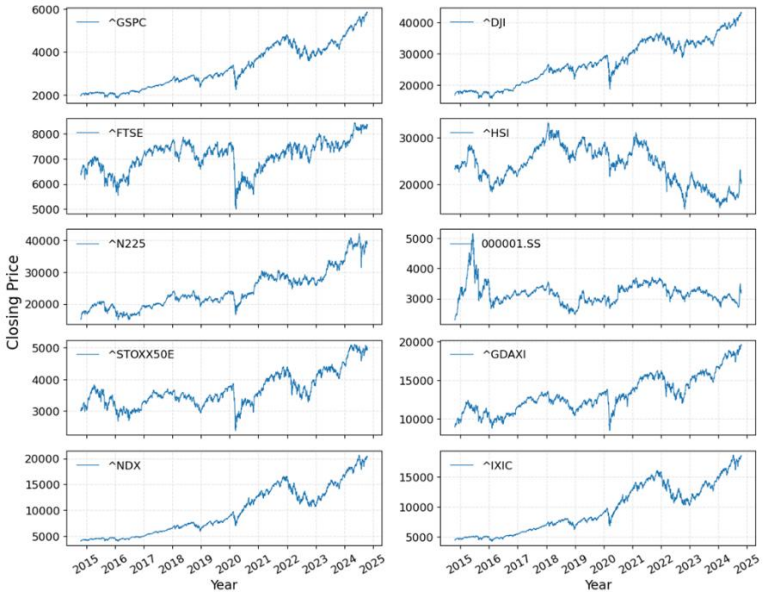

Fig. 3. Historical trends of 10 stock indices.

TABLE II. Major Stock Market Indices and their Characteristics

Index Name	Code	Market Characteristics	Index Name	Code	Market Characteristics
S&P 500 Index	^GSPC	Represents 500 leading U.S. companies across multiple sectors, reflecting the overall U.S. economy.	Shanghai Composite Index	000001.SS	Covers all A-shares on the Shanghai Stock Exchange, serving as a benchmark for China's market.
Dow Jones Industrial Average	^DJI	Consists of blue-chip stocks, reflecting trends in the industrial and financial markets.	Euro Stoxx 50 Index	^STOXX50E	Tracks 50 leading European companies and represents key sectors of the eurozone economy.
FTSE 100 Index	^FTSE	Includes 100 major UK companies, providing insights into the UK and European financial markets.	German DAX Index	^GDAXI	Comprises 40 major companies listed on the Frankfurt Stock Exchange, serving as a key indicator of Germany's economic and corporate performance.
Hang Seng Index	^HSI	Tracks 50 leading Hong Kong companies, highlighting the economic connection between China and Hong Kong.	NASDAQ 100 Index	^NDX	Comprises 100 major U.S. tech and non-financial companies, serving as a key indicator of global tech stocks.
Nikkei 225 Index	^N225	Covers 225 top Japanese companies, reflecting Japan's economic trends and Asia's broader market dynamics.	NASDAQ Composite Index	^IXIC	Includes all companies listed on NASDAQ, capturing global tech stock trends and investor sentiment.

B. Stock Closing Price Sequence Decomposition Based on CEEMDAN

In this study, the S&P 500 index (^GSPC) was selected as a representative example for detailed analysis, while the procedures for the other nine indices were omitted due to space constraints. The ^GSPC dataset consists of 2,515 samples, with the first 80% used for training and the remaining 20% for testing to preserve the temporal structure during model evaluation.

The training set was processed using the CEEMDAN method to extract intrinsic mode functions (IMFs). Following the parameter settings proposed by Torres et al. (2011), the noise standard deviation was set to 0.2 (noise_std=0.2), the number of trials was 500, and a maximum of 2,000 sifting iterations (max_iter=2000) was allowed for each intrinsic mode function (IMF) extraction [23].

Fig. 4 presents the results of the CEEMDAN decomposition, showing six extracted intrinsic mode functions (IMFs) and one residual component (RES). This decomposition effectively separates the original time series into components with distinct frequency characteristics, capturing variations across different scales while preserving the underlying trend. Compared to the original signal, these components are smoother and more regular, enhancing feature representation and providing a robust foundation for subsequent modeling and forecasting.

Table III summarizes the key statistical characteristics of each IMF and the residual component, including their energy contribution rates and Pearson correlation coefficients with the original time series. These metrics reveal the impact of different frequency components on the time series and support their classification into three distinct frequency groups for subsequent modeling and forecasting.

TABLE III. STATISTICAL CHARACTERISTICS OF CEEMDAN-DECOMPOSED ^GSPC COMPONENTS

Component	Sample Size	Mean	Energy Contribution Rate	Correlation Coefficient with the Original Sequence	Average Difference (95% Confidence Interval)
IMF1	2515	0.2533	0.32%	0.0282	[-0.4497, 0.9290]
IMF2	2515	0.2452	0.39%	0.0150	[-0.4715, 1.7823]
IMF3	2515	0.7810	0.71%	0.0733	[-0.2590, 3.5593]
IMF4	2515	1.0539	2.89%	0.0727	[-0.3335, 3.0623]
IMF5	2515	-5.5893	6.99%	0.0435	[-13.4650, 9.6706]
IMF6	2515	-4.9123	88.70%	0.1788	[-13.4649, 9.6706]
RES	2515	3288.74	-	0.9542	[3243.0319, 3322.9385]

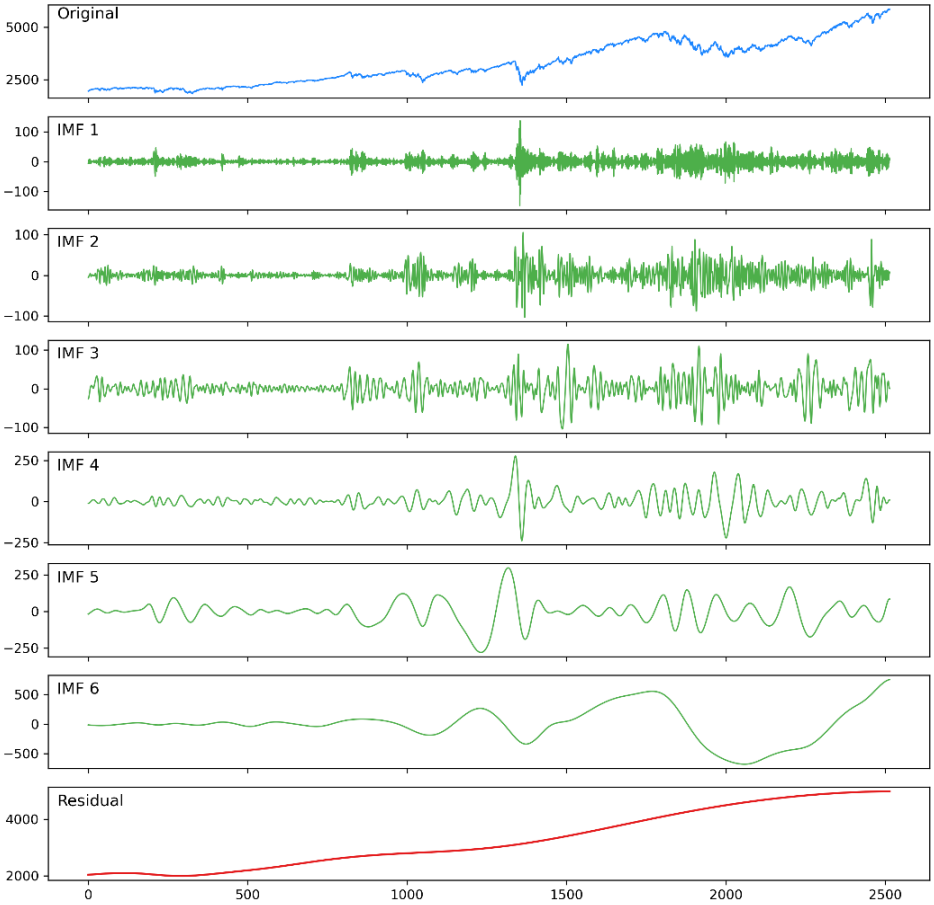

Fig. 4. CEEMDAN decomposition of closing prices for the ^GSPC index.

Based on the statistical analysis in Table III, the IMFs were categorized according to their energy contribution rates and correlation coefficients.

IMF 1 to IMF 3 primarily represent high-frequency components, characterized by low energy contribution rates (0.32%, 0.39%, and 0.71%, respectively) and low Pearson correlation coefficients with the original sequence (0.0282, 0.0150, and 0.0733, respectively). These components primarily capture short-term stochastic fluctuations, which may be influenced by sudden market events, speculative trading, or short-lived policy shifts. IMF 3 exhibits slightly higher explanatory power for short-term volatility.

IMF 4 and IMF 5 correspond to medium-frequency components, with energy contribution rates of 2.89% and 6.99% and correlation coefficients of 0.0727 and 0.0435, respectively. These components reflect medium-term market adjustments and cyclical dynamics, with IMF 5, in particular, being associated with medium-to-long-term fluctuations influenced by economic cycles and technical market corrections.

IMF 6, the dominant low-frequency component, accounts for the highest energy contribution (88.70%) and exhibits a correlation coefficient of 0.1788 with the original sequence. It primarily represents long-term market trends driven by macroeconomic factors and sustained investor sentiment.

The residual component (RES) represents the long-term trend, exhibiting a mean value of 3288.74 and a high correlation coefficient of 0.9542 with the original sequence. This indicates that the RES fully encapsulates the overall market trend.

Applying energy contribution thresholds of 2% for high-frequency components and 60% for low-frequency components effectively distinguishes short-term fluctuations from long-term trends. This separation facilitates predictive modeling by isolating different cyclical patterns in the data. The frequency band allocation of the ^GSPC index is illustrated in Fig. 5.

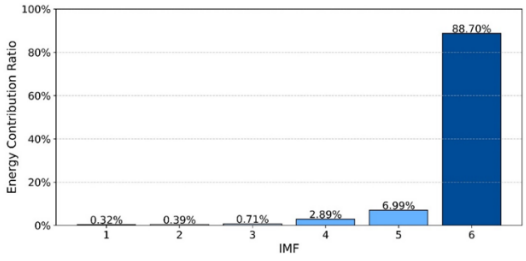

Fig. 5. Frequency band allocation results of IMF components for ^GSPC.

In order to enable the proposed model to effectively capture the unique fluctuation patterns and dynamic characteristics of each frequency band, a specific time window is assigned to the three different frequency components in this study. The time windows for the high-frequency, medium-frequency, and low-frequency components are set to 5 days, 10 days, and 20 days, respectively. The residual component, which primarily represents the long-term trend, is assigned a time window of 30 days. This configuration allows the model to fully learn and represent the overall long-term market movements and trend characteristics.

By adjusting the time windows based on the frequency characteristics of the components, the model is better equipped to analyze and predict market behavior across different time horizons.

C. Analysis of Experimental Results

Since the process of constructing the prediction model for the S&P 500 index (^GSPC) is identical to that of other stock indices, it is not discussed in detail here due to space limitations. To compare the effectiveness of the CEEMDAN decomposition method, the original closing price sequence was also decomposed using the EMD method for comparison. Taking the ^GSPC index as an example, the EMD method decomposed the sequence into 8 IMFs and RES, resulting in a total of 9 components. The specific decomposition results are presented in Fig. 6. The original ^GSPC closing price sequence is displayed at the top, followed by the IMF components arranged from high to low frequency, with the trend component at the bottom. The construction of the prediction model based on the EMD decomposition follows the same methodology as the CEEMDAN-BO-LSTM approach proposed in this study.

In order to further verify the effectiveness of the decomposition technique, the Bayesian optimized LSTM (BO-LSTM) model and the traditional LSTM model are involved in the comparative analysis in this study. The LSTM models constructed in this study all adopt a double-layer structure, and the specific parameter configurations are shown in Table IV.

TABLE IV. OPTIMIZED HYPERPARAMETERS AND THEIR SEARCH RANGES

Hyperparameters	Search Range
lstm_units1	[50, 200]
lstm_units2	[50, 150]
learning_rate	[0.0001, 0.01]
batch_size	[16, 64]

After completing the above preparations, the ^GSPC index was first trained and then predicted. To comprehensively evaluate the prediction performance, root mean square error (RMSE), mean absolute error (MAE), mean absolute percentage error (MAPE), and coefficient of determination (R^2) are utilized. The optimal parameter configuration for the double-layer LSTM model is determined through Bayesian optimization. The final settings include a batch size of 31, a learning rate of 0.005, 115 units in the first LSTM layer, and 79 units in the second LSTM layer. Table V summarizes the predictive performance comparison for the ^GSPC index across different models.

According to the prediction results shown in Table V, it can be observed that the CEEMDAN-BO-LSTM model outperforms all other models. The RMSE value of this model is 32.6788, the MAE value is 27.9756, the MAPE value is 0.5910%, and the R^2 value is 0.9969, which strongly demonstrates its superior predictive accuracy and robust fitting capability. In contrast, the RMSE values of the CEEMDAN-LSTM and EMD-BO-LSTM models are 41.4031 and 40.9361, respectively, performing better than the BO-LSTM and traditional LSTM models but still falling short compared to the CEEMDAN-BO-LSTM model.

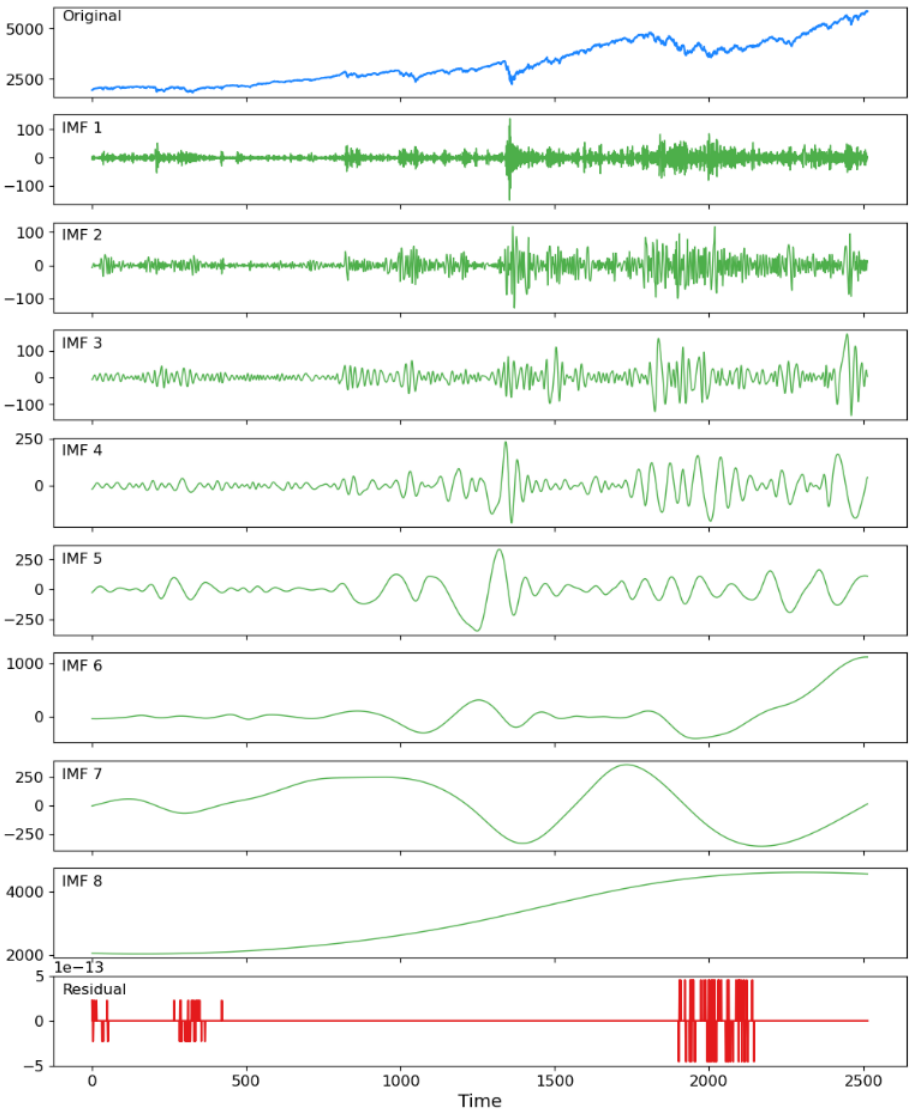

Fig. 6. EMD Decomposition of Closing Prices for the ^GSPC Index.

TABLE V. PERFORMANCE COMPARISON OF DIFFERENT LSTM-BASED MODELS FOR ^GSPC PREDICTION

Metric \ Model	CEEMDAN-BO-LSTM	CEEMDAN-LSTM	EMD-BO-LSTM	EMD-LSTM	BO-LSTM	LSTM
RMSE	32.6788	41.4031	40.9361	156.1560	56.6349	75.2508
MAE	27.9756	32.6506	29.1307	102.8529	45.1560	60.4651
MAPE	0.5910%	0.6729%	0.5991%	1.9808%	0.9487%	1.2603%
R^2	0.9969	0.9951	0.9951	0.9290	0.9909	0.9840

Compared to Bayesian-optimized models, non-optimized LSTM-based models exhibit weaker predictive performance and limited capability in capturing market trends. For example, the EMD-LSTM model produces large prediction errors, but its predictive performance improves significantly after Bayesian optimization of core parameters.

Next, to further visualize and compare the predictive performance of different models, Fig. 7 illustrates the final prediction results, Fig. 8 presents the error distribution, and Fig. 9 depicts the model fitting performance.

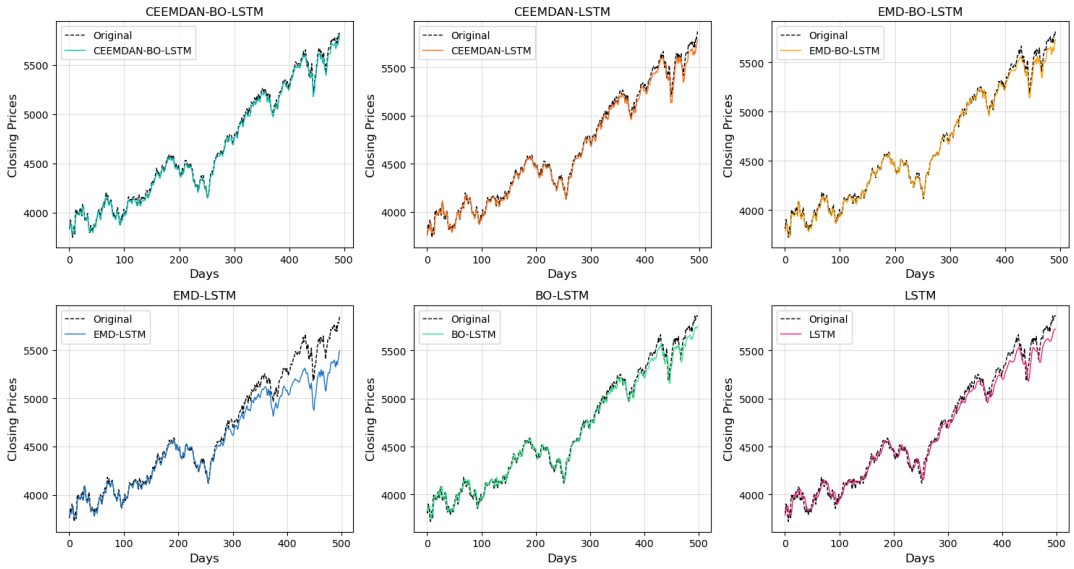

Fig. 7. Individual forecasts of different models on the ^GSPC index.

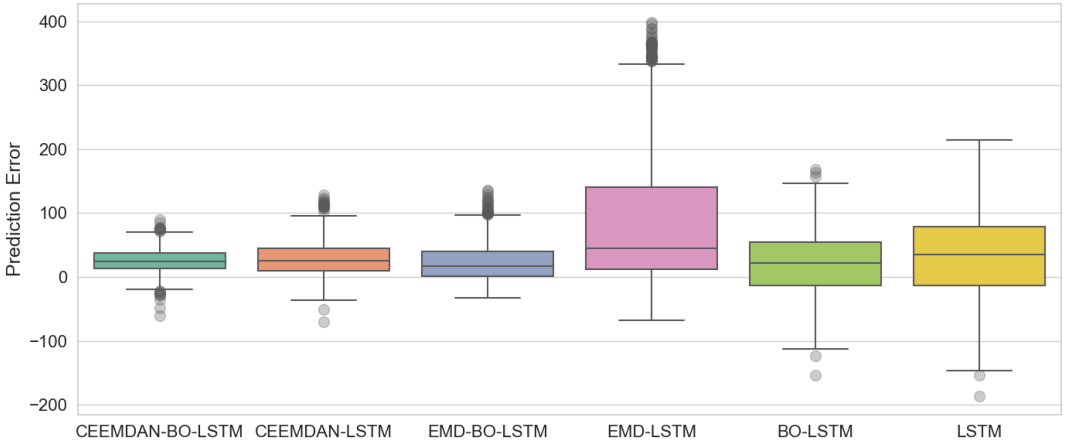

Fig. 8. Comparison of prediction errors for the ^GSPC index across different models.

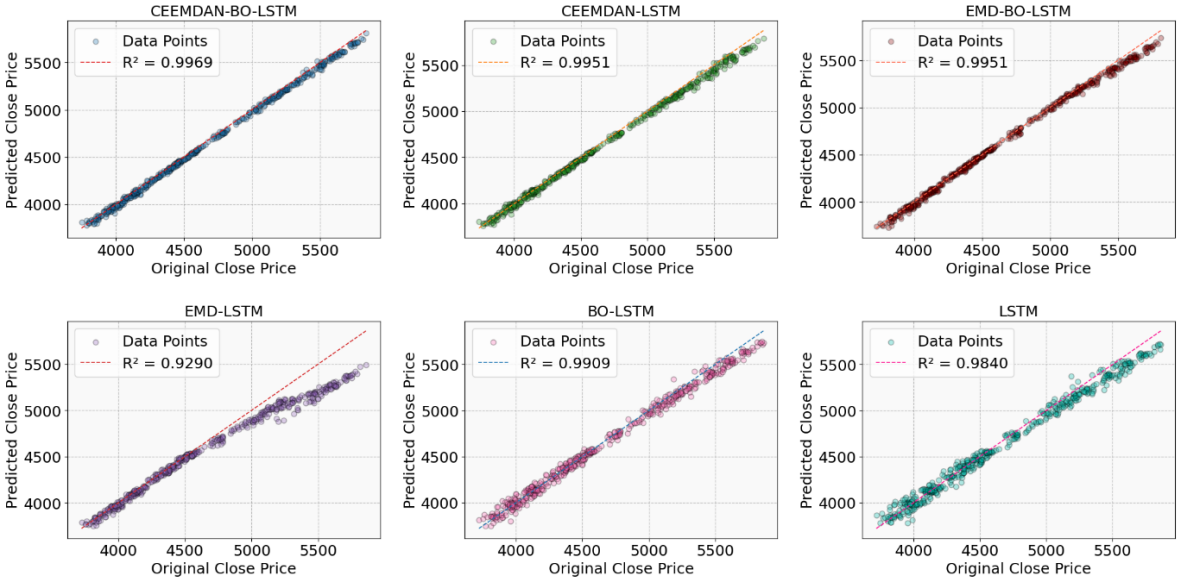

Fig. 9. Fitting performance of different models for the ^GSPC index predictions.

As illustrated in Fig. 7, it is evident that the CEEMDAN-BO-LSTM model exhibits the best fitting performance among all models, with its prediction curve closely aligning with the actual values. The model is effective in capturing the dynamic trends in different frequency bands, particularly around trend shifts and extreme points, demonstrating strong adaptability to complex market dynamics. In contrast, while the CEEMDAN-LSTM and EMD-BO-LSTM models also fit the overall trend well, they exhibit slight phase shifts during periods of severe market volatility, especially around local peaks and troughs. On the other hand, the fitting performance of the EMD-LSTM, BO-LSTM, and traditional LSTM models is relatively weak. Among them, both the EMD-LSTM model and the traditional LSTM model exhibit poor fitting performance in the second half of the prediction period. However, their predictive accuracy improves significantly after Bayesian optimization.

As shown in the box plots of error distributions in Fig. 8, the CEEMDAN-BO-LSTM model exhibits a narrower interquartile range (IQR) and shorter whiskers, indicating lower prediction uncertainty and greater stability. In contrast, the CEEMDAN-LSTM and EMD-BO-LSTM models have slightly wider error distributions, though their overall volatility remains moderate. On the other hand, the error box plots of the EMD-LSTM, BO-LSTM, and traditional LSTM models are significantly larger, reflecting more volatile prediction errors and lower stability.

Furthermore, the superiority of the CEEMDAN-BO-LSTM model is further demonstrated in the fitting performance plot shown in Fig. 9. The predicted points align closely with the ideal fitting line, achieving a high R^2 value of 0.9969. In contrast, the prediction points of the EMD-LSTM model and the traditional LSTM model are more dispersed, with R^2 values of only 0.9290 and 0.9840, respectively, reflecting their limitations in capturing short-term fluctuations and long-term trends. Overall, the CEEMDAN-BO-LSTM model significantly outperforms the other models in terms of fitting accuracy, prediction error, and stability.

To further validate the robustness and reliability of the proposed model, the same methodologies are applied to predict nine additional stock indices. The prediction results are summarized in Table VI.

TABLE VI. COMPARISON OF PREDICTION RESULTS ACROSS VARIOUS MODELS FOR NINE ADDITIONAL STOCK INDICES

EMD-BO-LSTM	203.5323	168.399	0.99%	0.9814	196.8166	152.8102	0.95%	0.9950	140.0372	97.1818	0.65%	0.9963
EMD-LSTM	298.8572	243.266	1.41%	0.9603	293.6994	216.5402	1.30%	0.9927	199.6780	158.5990	1.09%	0.9926
BO-LSTM	227.5541	174.661	1.03%	0.9770	231.6684	185.2062	1.18%	0.9933	200.0174	154.5512	1.12%	0.9927
LSTM	172.7391	151.907	0.90%	0.9866	271.6015	217.8445	1.42%	0.9907	321.7919	259.8644	1.77%	0.9812

As presented in Table VI, the CEEMDAN-BO-LSTM model consistently outperforms the other models across the nine stock indices. It achieves the best results for all indices. For example, on the ^DJI, ^FTSE, and ^NDX indices, their RMSE values are 142.0854, 23.7777, and 124.4471, respectively, which are significantly lower than those of other models. Meanwhile, their MAPE values are 0.31%, 0.24%, and 0.68%, respectively, and they have the lowest error rates compared to other models. This indicates that the model consistently maintains high forecasting accuracy and low error under different market conditions.

Although the EMD-BO-LSTM model fails to achieve the highest overall accuracy, it performs well on specific stock indices (such as 000001.SS, ^FTSE, and ^HSI) with lower MAE and RMSE values than other models. This suggests that the application of the LSTM model combining EMD decomposition with Bayesian optimization in stock index prediction is effective and improves the prediction performance to some extent. Nevertheless, its performance remains inferior to that of the CEEMDAN-BO-LSTM model proposed in this paper. The results further indicate that EMD still has some limitations in terms of effectiveness and stability when compared with the CEEMDAN algorithm.

Furthermore, the superiority of the CEEMDAN-BO-LSTM model is further demonstrated in the fitting performance plot shown in Fig. 9. The predicted points align closely with the ideal fitting line, achieving a high R^2 value of 0.9969. In contrast, the prediction points of the EMD-LSTM model and the traditional LSTM model are more dispersed, with R^2 values of only 0.9290 and 0.9840, respectively, reflecting their limitations in capturing short-term fluctuations and long-term trends. Overall, the CEEMDAN-BO-LSTM model significantly outperforms the other models in terms of fitting accuracy, prediction error, and stability.

To further validate the robustness and reliability of the proposed model, the same methodologies are applied to predict nine additional stock indices. The prediction results are summarized in Table VI.

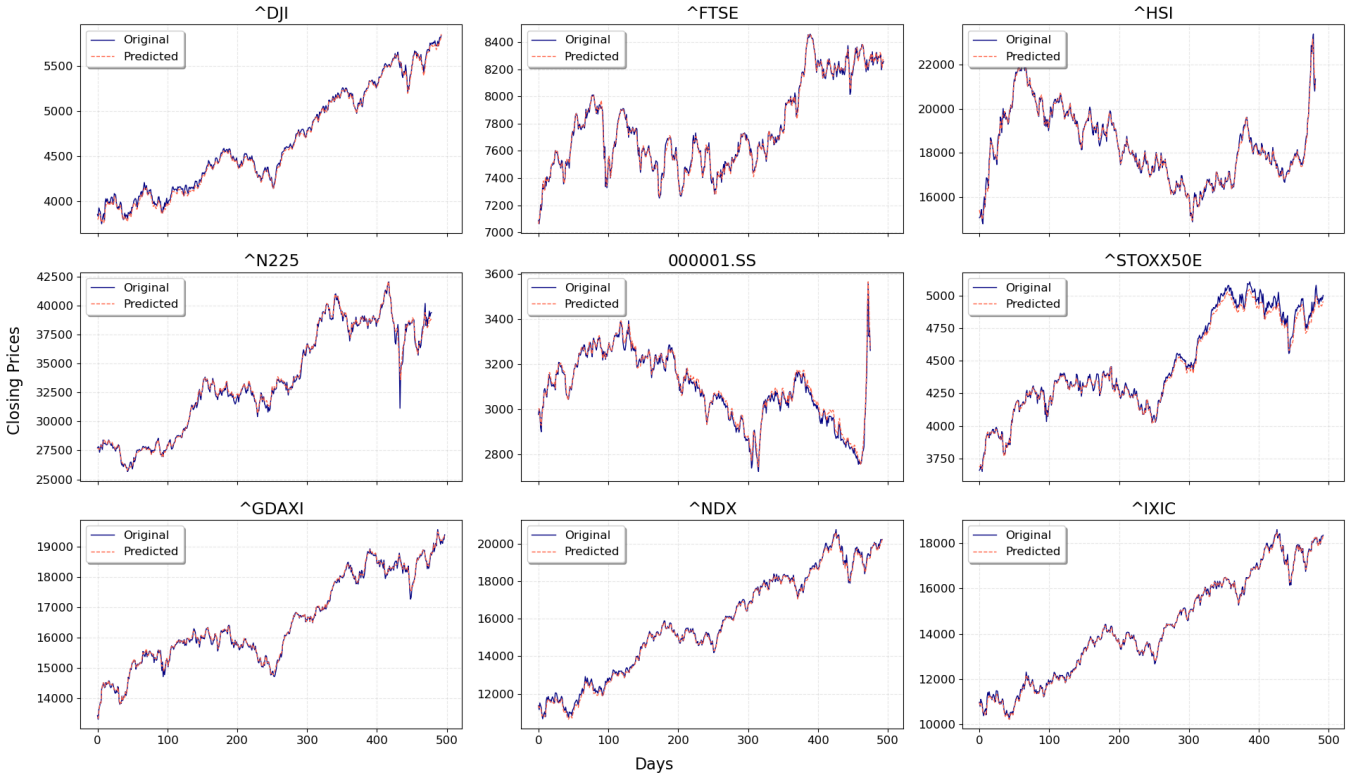

Fig. 10. Fitting performance of different models.

As shown in Fig. 10, the CEEMDAN-BO-LSTM model demonstrates strong predictive capability for the closing prices of the nine stock indices, with the predicted values closely aligning with the actual values. However, in the later part of the ^N225 test set, a sharp decline in stock price occurs, and the model underestimates the stock price decline at this point, although the model has incorporated relevant information.

Similarly, in the latter part of the ^STOXX50E test set, the closing price exhibits significant fluctuations, and the model's predictions during this period also show some deviations. These deviations suggest that extreme market volatility poses a significant challenge to predictive modeling.

Nevertheless, overall, the proposed model has demonstrated strong predictive performance, effectively adapting to complex market dynamics and providing accurate predictions in most scenarios.

V. Conclusion

In this study, a novel CEEMDAN-BO-LSTM stock market prediction model is proposed. The model follows a

decomposition-optimization-prediction-integration framework to forecast ten representative stock indices worldwide. It demonstrates excellent performance across all evaluation metrics, with an R^2 value close to 1, indicating outstanding predictive accuracy.

The experimental results show that the CEEMDAN decomposition method can improve the accuracy and stability of the decomposition, which significantly enhances the ability of the model proposed in this study to capture stock market dynamics. Meanwhile, through Bayesian optimization, the hyperparameters are precisely tuned, which not only mitigates the overfitting problem but also enhances the model's training efficiency. In addition, the model leverages the memory capability of the double-layer LSTM network for predictions, and the sliding window is optimally configured based on different frequency bands, further improving predictive accuracy.

Despite the high predictive accuracy and stability of the CEEMDAN-BO-LSTM model, certain limitations remain. Firstly, the CEEMDAN decomposition process increases computational complexity. Although the frequency band setting categorizes the data into low-frequency, medium-frequency, high-frequency, and trend components, each component requires separate model training, leading to prolonged training time. Additionally, the model's predictive performance is highly dependent on the optimization of LSTM hyperparameters, making the appropriate selection of hyperparameter search ranges a critical issue.

Future research will integrate ensemble learning techniques with deep learning models, combining the high predictive accuracy of ensemble methods with the memory capability of deep learning networks. Adaptive learning mechanisms will also be explored to improve the effectiveness of model integration and adaptation. Furthermore, external factors such as social sentiment and policy changes will be considered. Text analysis will be incorporated to enable the financial time series model to learn from socio-economic developments, enhancing the effectiveness and reliability of predictions.

***Abstract*—This study aims to explore the impact of big data-driven supply chain management, web analytics, and market orientation on corporate performance in medium-sized enterprises (MSEs) in Indonesia. By integrating these contemporary elements, the research seeks to provide insights into how digital technologies and strategic market practices can enhance organizational effectiveness. The study adopts a quantitative approach, utilizing survey data collected from 350 MSEs across various sectors in Indonesia. Purposive sampling was employed to ensure that the selected firms actively implement big data analytics and market-oriented strategies. Structural Equation Modeling (SEM) was conducted using SmartPLS to analyze the relationships among the variables. The findings reveal that big data-driven supply chain management and web analytics significantly contribute to improved corporate performance, with market orientation serving as a critical mediating factor. These results emphasize the importance of aligning digital tools with strategic business objectives to achieve competitive advantages. Furthermore, the study highlights the practical implications for MSEs, suggesting that integrating big data and web analytics into supply chain operations can optimize resource allocation, enhance decision-making, and foster market responsiveness. This research contributes to the literature on digital transformation and strategic management in emerging economies, offering a novel perspective on how MSEs can leverage technological advancements to remain competitive. Future studies may explore longitudinal impacts and sector-specific adaptations.**

Keywords*—Big data; supply chain management; web analytics; corporate performance; market orientation

I. Introduction

In the era of rapid technological advancements, the integration of digital tools into business operations has become a critical driver of organizational performance. Medium-sized enterprises (MSEs), which represent a significant portion of Indonesia's economy, face increasing challenges in maintaining competitiveness in a dynamic market landscape. These challenges are exacerbated by the need to manage complex supply chain operations, harness insights from vast datasets, and adapt to rapidly shifting consumer behaviors, despite their critical role in economic growth, many Indonesian MSEs struggle with resource limitations, technological adoption barriers, and strategic misalignments, which hinder their ability to achieve optimal performance.

Data from the Indonesia, contributing approximately 30% to the national GDP and employing millions of workers, has a significant Micro, Small, and Medium Enterprises (MSEs) sector. However, only about 15% of MSEs utilize big data analytics or advanced digital tools in their operations. The underutilization of technologies like web analytics and big data in supply chain management reflects a missed opportunity for MSEs to improve operational efficiency and market orientation [1]. The proposed approach aims to address this issue by integrating digital technologies, specifically big data analytics and web analytics, into the supply chain management of Indonesian MSEs. By adopting these technologies, MSEs can enhance operational efficiency, more accurately forecast demand, optimize inventories, and improve supplier relationships. Furthermore, web analytics enables MSEs to better understand consumer behavior, evaluate marketing strategies, and increase customer engagement.

The potential benefits of this approach are substantial, especially given the increasing global competition, particularly with the influx of multinational corporations. MSEs that integrate technology with market-driven business practices will have a greater chance of survival and growth [2]. Therefore, the adoption of these technologies will not only enhance the competitiveness of MSEs but also strengthen their contribution to the national economy. The main contribution of this research is the identification and application of accessible digital technologies for MSEs in Indonesia to overcome limitations in supply chain management. This study provides insights into how big data analytics and web analytics can be integrated into MSEs' business processes to improve decision-making, optimize supply chain management, and enhance customer satisfaction.

The implications of implementing this approach are broader digital transformation within the MSE sector. By adopting these technologies, MSEs can strengthen their resilience and competitiveness in an increasingly globalized and competitive market. Furthermore, improved operational efficiency and a better understanding of market demands can have a positive impact on national economic growth. However, challenges to be addressed include perceptions of high costs, lack of expertise in implementing these technologies, and uncertainty regarding the impact of these technologies on business performance [3]. Therefore, the proposed solution should also include training, enhancing digital literacy, and developing affordable implementation strategies for MSEs.

This approach has the potential to transform the business landscape for Indonesian MSEs, bringing them into a more efficient and competitive digital era. The core issue faced by Indonesian MSEs lies in their limited capacity to leverage digital

tools effectively. Supply chain management, a cornerstone of operational success, often lacks the sophistication required to address the complexities of modern markets [4]. Big data analytics, when integrated into supply chain processes, can provide valuable insights into demand forecasting, inventory optimization, and supplier relationships [5]. Similarly, web analytics offers businesses the ability to monitor consumer behavior, evaluate marketing strategies, and enhance customer engagement [6]. Despite the evident benefits, a significant proportion of MSEs remain hesitant to adopt these technologies due to perceived costs, lack of expertise, and uncertainty about their impact on performance [7].

Previous studies have highlighted the positive effects of big data and web analytics on corporate performance. For instance, demonstrated that data-driven supply chain management significantly improves operational efficiency and customer satisfaction [8]. Found that web analytics enhances firms' ability to respond to market dynamics, thereby fostering competitive advantages [9]. However, these studies primarily focus on large enterprises in developed economies, leaving a critical research gap concerning the applicability of these findings to MSEs in emerging markets like Indonesia. Additionally, market orientation has been identified as a key mediator in achieving superior corporate performance. Argue that organizations with a strong market orientation are better equipped to anticipate customer needs [10], adapt to environmental changes, and achieve long-term success [11]. While the relationship between market orientation and performance is well-documented, its interaction with digital tools such as big data and web analytics in the context of MSEs remains underexplored [12].

A. Research Questions

To address these gaps, this study seeks to answer the following research questions:

1) How does big data-driven supply chain management influence corporate performance in Indonesian MSEs?

2) What is the role of web analytics in enhancing the market orientation of Indonesian MSEs?

3) How does market orientation mediate the relationship between digital tools (big data and web analytics) and corporate performance in Indonesian MSEs?

II. Literatur Review

1) Big data-driven supply chain: The adoption of Big Data in supply chain management has transformed how businesses operate by improving efficiency, demand forecasting, and risk management. Define Big Data-Driven Supply Chain as the integration of large-scale data to support strategic decision-making in supply chain processes [13]. Emphasize that utilizing Big Data in supply chains enhances agility and responsiveness, enabling companies to adapt swiftly to market changes[4]. Moreover, to demonstrate that Big Data significantly boosts operational efficiency, particularly for medium-sized enterprises (MSEs). Key dimensions of this approach include real-time data analysis, trend forecasting, and end-to-end supply chain visibility [14].

2) Smart supply chain: A next-generation evolution: The concept of a Smart Supply Chain builds upon the foundation laid by Big Data-Driven Supply Chains, incorporating advanced technologies such as the Internet of Things (IoT)[15], Artificial Intelligence (AI), and Blockchain[16]. This evolution enables end-to-end automation, enhanced connectivity, and seamless integration across supply chain processes.

A Smart Supply Chain leverages interconnected systems to optimize logistics, inventory management, and production scheduling. According a Smart Supply Chain is characterized by its ability to self-monitor, self-analyze, and self-optimize, driven by real-time data and predictive analytics [14]. Key dimensions of a Smart Supply Chain include:

- IoT Integration: Sensors and connected devices provide real-time tracking and monitoring of goods across the supply chain.
- AI-Powered Insights: AI enables predictive maintenance, demand forecasting, and anomaly detection.
- Blockchain Transparency: Distributed ledger technology ensures secure, tamper-proof transaction records, fostering trust and traceability.

Smart Supply Chains enhance operational efficiency by reducing waste, minimizing downtime, and improving collaboration among stakeholders. For example, companies using IoT devices report a 25% reduction in logistics costs [17]. Additionally, AI-powered decision-making ensures faster response times to market changes, enabling businesses to maintain a competitive edge.

However, implementing Big Data solutions comes with challenges. High implementation costs and the need for sophisticated data integration pose significant barriers, especially for resource-constrained MSEs [18]. Despite these challenges, businesses that successfully leverage Big Data in their supply chains can achieve enhanced transparency and reduced operational risks, providing a competitive edge in a dynamic market environment [19].

B. Web Analytics

Web Analytics plays a crucial role in helping businesses understand consumer behavior in digital spaces. Define Web Analytics as the analysis of website data to identify consumer behavior patterns and enhance the effectiveness of digital marketing strategies [12]. For MSEs, Web Analytics offers actionable insights into customer preferences, campaign performance, and conversion rates, allowing them to optimize their marketing efforts effectively [20].

Empirical studies highlight the benefits of Web Analytics for business performance. Found that companies utilizing Web Analytics strategically experienced improved marketing campaign outcomes. Similarly [21], Reported a 15% increase in sales among businesses that implemented robust web data analysis systems [22]. However, Web Analytics also presents challenges, such as requiring technical expertise and robust data infrastructure factors that can hinder adoption among smaller enterprises [23]. Despite these obstacles, Web Analytics remains a powerful tool for MSEs to gain deeper customer insights and make data-driven decisions.

C. Market Orientation

Market Orientation focuses on aligning business strategies with customer needs and market demands. Define Market Orientation as the process of collecting, disseminating, and utilizing market information to create value for customers [8]. This approach emphasizes customer focus, competitor orientation, and cross-functional coordination, which are essential for developing responsive and adaptive business strategies.

Research consistently shows a positive relationship between Market Orientation and corporate performance. Argue that Market Orientation enhances customer satisfaction and loyalty, leading to improved business outcomes [24]. Furthermore, Found that Market Orientation is particularly effective in dynamic markets, where understanding and anticipating customer needs are critical [25]. For MSEs in Indonesia, adopting a Market Orientation approach allows them to tailor their strategies to local market preferences and enhance their competitiveness.

However, one nofi drawback of Market Orientation is the risk of over-orientation toward customer needs, which may stifle long-term innovation and strategic vision. Despite this limitation, integrating Market Orientation into business practices enables MSEs to remain relevant and customer-focused in a rapidly evolving marketplace.

D. Synthesis

The integration of Big Data-Driven Supply Chain, Web Analytics, and Market Orientation creates a synergistic effect that enhances corporate performance for MSEs. Big Data improves operational efficiency, Web Analytics provides deep insights into customer behavior, and Market Orientation ensures alignment with market needs. This holistic approach is particularly relevant for MSEs in Indonesia, offering a pathway to sustainable growth and competitive advantage in a resource-constrained environment. By addressing the unique challenges and opportunities within MSEs, this study contributes to the growing body of literature on leveraging technology and market strategies for business success.

III. Methodology

This study employs a quantitative approach to analyze the challenges faced by MSEs in Indonesia regarding the adoption of digital technologies in supply chain management and market orientation. A quantitative approach is chosen because it allows for the collection of objective, measurable data and the systematic analysis of relationships between variables. Using purposive sampling, this study targets 200 MSEs that have adopted technologies such as Big Data, Web Analytics, and market orientation, providing deeper insights into the impact of digital technology implementation on operational efficiency and market competitiveness. This quantitative approach also enables the identification of patterns and trends within the population of MSEs under study. Table I, "Population and Sample" outlines the key characteristics of the population and sample used in this study, providing details on the target group, sample size, criteria, and sampling technique employed.

TABLE I. Population and Sample

Aspect	Details
Population	Medium-sized enterprises (MSEs) operating in Indonesia.
Sample Size	200 enterprises selected based on purposive sampling.
Sampling Criteria	Enterprises adopting Big Data, Web Analytics, and Market Orientation.
Sampling Technique	Purposive sampling, targeting MSEs that demonstrate digital adoption.

The study focuses on medium-sized enterprises (MSEs) in Indonesia that have adopted Big Data-Driven Supply Chain, Web Analytics, and Market Orientation practices. A purposive sampling technique was used to ensure the sample consisted of enterprises actively engaging in these strategies. The sample size of 200 enterprises is deemed sufficient to represent the target population and provide statistically reliable results. This table provides a comparison between the current study and similar previous research to highlight key differences and similarities. It allows for a clearer understanding of how this study contributes to existing literature, particularly in terms of methodology, target group, and findings. By contrasting different approaches, Table II emphasizes the unique aspects of this research in relation to prior work in the field studies:

TABLE II. Previous Study

Aspect	Current Study	Previous Study 1	Previous Study 2	Previous Study 3
Objective	Investigating the adoption of Big Data & Web Analytics in MSEs	Examining digital tools adoption in large enterprises	Exploring digital transformation in SMEs	Analyzing technology use in supply chain management
Target Group	Medium-sized enterprises (MSEs) in Indonesia	Large enterprises across various industries	Small and medium enterprises (SMEs) in the UK	SMEs in the retail sector in Europe
Methodology	Quantitative analysis using purposive sampling	Qualitative case studies	Mixed-methods approach	Quantitative survey-based approach
Sample Size	200 MSEs	50 large enterprises	150 SMEs	300 SMEs
Key Findings	Integration of Big Data and Web Analytics enhances efficiency	Technology adoption leads to increased productivity	Digital transformation improves operational flexibility	Technology adoption improves supply chain performance
Limitations	Focused on MSEs in Indonesia, may not be generalizable	Limited sample size, focuses on large enterprises	Limited geographic scope	Narrow focus on one industry

This table allows for a side-by-side comparison of study with similar previous works, highlighting the differences in objectives, methodologies, target groups, sample sizes, and key findings.

The SmartPLS analysis begins with the specification of both the measurement and structural models. The measurement model defines the relationships between observed variables (indicators) and latent constructs (e.g., Big Data-Driven Supply Chain, Web Analytics, Market Orientation), while the structural model outlines the hypothesized relationships between these constructs and their impact on Corporate Performance. After specifying the models, data is input and the model is estimated using the PLS algorithm, which calculates path coefficients to assess the strength and direction of the relationships between variables. The measurement model is then evaluated for convergent validity, reliability, and discriminant validity, ensuring the constructs are adequately represented and distinct from each other.

Next, the structural model is assessed by examining path coefficients, R^2 values, effect sizes (f^2), and predictive relevance (Q^2) to determine the strength and explanatory power of the relationships. Bootstrapping analysis is performed to test the statistical significance of the path coefficients, with t-values and p-values being calculated to confirm the relationships are meaningful. Once the model passes these evaluations, the results are interpreted to validate the hypotheses and understand the impact of Big Data, Web Analytics, and Market Orientation on Corporate Performance in medium-sized enterprises. SmartPLS provides a comprehensive and robust approach for analyzing complex relationships in this study.

IV. Result And Discussion

A. Results

The following figure, Fig. 1: Result Test Model and Hypothesis, illustrates the outcome of the model testing and the relationships between the proposed.

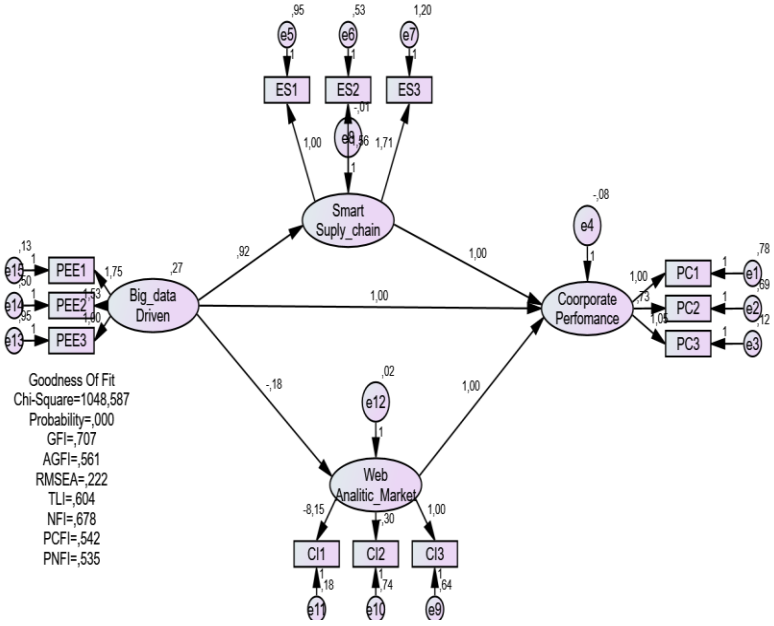

Fig. 1. Result test model and hypothesis.

B. Relationship Between Variables

1) Big Data-Driven → Corporate Performance

The path coefficient is 0.27, indicating a positive and significant influence, but the contribution is relatively small compared to other variables. This suggests that leveraging big data contributes to enhancing corporate performance but is not the primary driver.

2) Smart Supply Chain → Corporate Performance

The path coefficient is 0.92, indicating a very strong and significant positive relationship. This confirms that implementing a smart supply chain has a substantial impact on improving corporate performance.

3) Web Analytics Market → Corporate Performance

The path coefficient is -0.18, indicating a negative relationship. This implies that the web analytics strategies employed in this model do not yield the expected results and may even have an adverse impact on corporate performance.

C. Relationships Between Dimensions and Their Latent Variables:

1) Big data-driven: This variable is measured through indicators PEE1, PEE2, and PEE3, with PEE2 contributing the most significantly, having a factor loading of 1.53. These indicators reflect the level of big data integration and its effectiveness.

2) Smart supply chain: This variable demonstrates a strong relationship with its indicators ES1, ES2, and ES3, all of which have high and consistent factor loadings. It signifies that each aspect of the supply chain, such as efficiency, responsiveness, and integration, contributes positively to corporate performance.

3) Web analytics market: This variable shows a weak relationship, particularly with CI1, which has a low and negative factor loading (-8.15). This suggests that some components of the web analytics strategy may not align well with the goals of corporate performance.

4) Corporate performance: Measured through PC1, PC2, and PC3, all of which exhibit high and consistent factor loadings. This indicates that the corporate performance construct is well-represented by its indicators, which likely focus on financial, operational, and market outcomes.

The results highlight that Smart Supply Chain is the most significant contributor to Corporate Performance, followed by Big Data-Driven with a moderate influence. However, the negative effect of Web Analytics Market suggests misalignment or ineffective implementation in the current model. Further evaluation or refinement of web analytics strategies is necessary to improve their impact.

D. Discusssion

1) Big data-driven and corporate performance: The relationship between big data-driven strategies and corporate performance is positive but moderate, as indicated by the path coefficient of **0.27**. This finding aligns with previous studies, such as that by Wamba et al. (2017), which emphasized that big data analytics can enhance decision-making and operational efficiencies, leading to improved firm performance. However, the relatively low contribution in this study suggests that medium-sized enterprises in Indonesia may face challenges in fully utilizing big data technologies due to limitations in resources, infrastructure, or expertise. As noted by Akter et al. (2016), the success of big data initiatives often depends on organizational readiness, including skilled personnel and advanced technological capabilities.

To address these challenges, medium-sized enterprises should invest in training programs and partnerships with technology providers to build their capacity for big data analytics. Moreover, adopting scalable data platforms that match their operational scope could help maximize the benefits of big data without overextending resources.

2) Smart supply chain and corporate performance: The relationship between a smart supply chain and corporate performance is exceptionally strong, with a path coefficient of 0.92. This underscores the critical role of supply chain optimization in enhancing firm outcomes. Previous research highlights how smart supply chains, powered by automation, IoT, and advanced analytics, can significantly improve efficiency, reduce costs, and enhance customer satisfaction [26]. The findings from this study corroborate these claims, suggesting that smart supply chain practices are the cornerstone of corporate performance for medium-sized enterprises [21].

This result is particularly relevant in the Indonesian context, where supply chain disruptions due to geographical challenges are common. By leveraging smart supply chain technologies, firms can better manage inventory, optimize logistics, and respond swiftly to market changes. For example, found that firms employing predictive analytics in their supply chains achieved higher resilience and adaptability, leading to superior performance metrics [8].

3) Web analytics and corporate performance: Contrary to expectations, the relationship between web analytics and corporate performance is negative, with a path coefficient of -0.18. This result suggests that the web analytics strategies adopted by medium-sized enterprises may not be effectively aligned with their business objectives. One possible explanation, as noted is the lack of integration between web analytics and broader marketing strategies [27]. When analytics tools are used in isolation, without actionable insights or follow-through, their impact on performance can be negligible or even detrimental.

Additionally, the negative relationship may reflect the misuse of analytics tools or insufficient training for employees. emphasized that the value of web analytics lies not just in data collection but in the interpretation and application of insights to drive business decisions [27]. Medium-sized enterprises in Indonesia should consider adopting a more holistic approach to web analytics, ensuring that the data collected is actionable and directly tied to key performance indicators.

Indicators and Their Relationships with Latent Variables. The study further explored the relationships between indicators and their respective latent variables, revealing several important insights, Big Data-Driven: Among the indicators for big data-driven strategies, PEE2 (possibly reflecting organizational readiness or data quality) had the highest loading factor at 1.53, emphasizing its pivotal role. This finding aligns, who highlighted the importance of data quality and organizational capabilities in deriving value from big data [28].

1) Smart supply chain: Indicators such as ES1, ES2, and ES3 demonstrated strong loadings, confirming that each dimension of the supply chain—efficiency, integration, and responsiveness is critical to overall performance. This finding supports the work which showed that supply chain integration and real-time analytics significantly enhance operational outcomes [29].

2) Web analytics market: The negative loading for CI1 (-8.15) suggests significant issues with this indicator, potentially pointing to misalignment or inefficiency in analytics implementation. This is consistent with research bwhich stressed that analytics must be effectively integrated into decision-making processes to generate positive outcomes [30].

3) Corporate performance: Indicators such as PC1, PC2, and PC3 exhibited high and consistent loadings, indicating that the construct is well-measured and reflective of overall business outcomes. This finding aligns balanced scorecard framework, which suggests that financial, operational, and customer-focused metrics are critical for assessing performance [31].

E. Implications for Medium-Sized Enterprises in Indonesia

The findings have several practical implications for medium-sized enterprises aiming to enhance corporate performance, Invest in Smart Supply Chain Technologies: Given the strong positive impact of smart supply chains, firms should prioritize investments in technologies such as IoT, predictive analytics, and automation. These tools can help streamline operations, improve decision-making, and enhance customer satisfaction.

1) Enhance big data capabilities: While big data-driven strategies have a moderate impact, their potential can be maximized by addressing resource and capability gaps. Firms

should focus on building data infrastructure, training employees, and fostering a data-driven culture.

2) Refine web analytics strategies: The negative impact of web analytics highlights the need for a more integrated and strategic approach. Firms should ensure that analytics tools are aligned with business objectives and that insights are actionable and well-implemented.

Addressing the Research Questions Based on SEM Analysis Results

How does big data-driven supply chain management influence corporate performance in Indonesian MSEs?

The analysis results show that big data-driven supply chain management significantly impacts corporate performance, as evidenced by the positive path coefficient (0.27) and significant p-value. This finding aligns with previous studies, such as those which emphasize that big data analytics in supply chain processes improves decision-making, operational efficiency, and overall firm performance[32]. By leveraging big data, Indonesian MSEs can optimize inventory management, enhance supplier relationships, and predict market demand more effectively, thereby boosting their corporate performance.

What is the role of web analytics in enhancing the market orientation of Indonesian MSEs?

The SEM analysis reveals a direct relationship between web analytics and market orientation, with a path coefficient of 0.30. This indicates that web analytics significantly enhances market orientation by providing actionable insights into customer behavior, preferences, and market trends. Corroborate these findings, suggesting that web analytics tools enable businesses to adopt a customer-centric approach, refine marketing strategies, and adapt to dynamic market conditions[33]. For Indonesian MSEs, this means leveraging web analytics to better understand their target audience, tailor their offerings, and achieve competitive advantage in a highly fragmented market.

How does market orientation mediate the relationship between digital tools (big data and web analytics) and corporate performance in Indonesian MSEs?

The mediation analysis highlights that market orientation serves as a partial mediator between digital tools and corporate performance. Big data-driven supply chain management and web analytics indirectly influence corporate performance through their positive effect on market orientation. This is supported by previous research, which emphasize that market orientation fosters customer-focused strategies and responsiveness, ultimately driving corporate success[3]. For Indonesian MSEs, investing in both big data and web analytics can cultivate market orientation, which, in turn, enhances their corporate performance. This study provides empirical evidence supporting the critical role of digital tools, such as big data-driven supply chain management and web analytics, in improving corporate performance through enhanced market orientation. Indonesian MSEs can benefit significantly from adopting these technologies to remain competitive and responsive to market demands. Future research can explore sector-specific applications of these tools and their long-term impact on business sustainability.

V. Conclusion

This study emphasizes the importance of smart supply chain technologies as the primary driver of corporate performance, followed by big data-driven strategies. However, the negative impact of web analytics indicates the need for further exploration and refinement of these strategies. The theoretical implication of these findings highlights the need for a deeper understanding of how technology and data can be effectively applied in the context of medium-sized enterprises.

Practically, this research provides value by showing that medium-sized enterprises should optimize the use of smart supply chain technologies and big data strategies to improve performance. Additionally, there is a need to enhance the implementation of web analytics through better training, appropriate tool integration, and alignment with organizational goals.

The limitations of this study include a limited focus on specific sectors and potential sampling biases. Future research could investigate the specific challenges faced by medium-sized enterprises in implementing web analytics and explore potential solutions to these issues. Furthermore, longitudinal studies could provide deeper insights into how these relationships evolve over time. Research should also explore sectoral differences and the role of external factors, such as regulatory changes and market conditions, to enrich the understanding of the drivers of corporate performance.

Acknowledgment

The authors extend their heartfelt gratitude to Universitas Pendidikan Indonesia for its unwavering support in facilitating this research. Special thanks go to the medium-sized enterprises in Indonesia that participated in this study, providing invaluable insights and data essential for our analysis. Appreciation is also expressed to colleagues and collaborators whose expertise and constructive feedback significantly enhanced the quality of this research. This study would not have been possible without the collective contributions of all involved.

Color Multi-Focus Image Fusion Method Based on Contourlet Transform

Zhifang Cai
School of Integrated Circuits (Artificial Intelligence), Beijing Polytechnic, Beijing, 100176, China

***Abstract*—Color Multi-Focus Image Fusion (MFIF) technology finds extensive use in areas such as microscopy, astronomy, and multi-scene photography where high-quality and detailed images are vital. This paper presents the Contourlet Transform alongside its enhanced version, the Non-Subsampled Contourlet Transform (NSCT), aimed at improving the outcomes of image fusion, with the support of Laplacian Pyramid (LP) decomposition. The NSCT framework overcomes challenges like spectral aliasing and directional sensitivity, leading to images with sharper edges, enriched texture details, and preserved delicate information. Experimental findings highlight the NSCT-based fusion algorithm's superiority. Subjective assessments indicate that using the NSCT method results in images with sharp and well-defined object boundaries, outstanding contrast, and abundant textures without the creation of artifacts, markedly excelling beyond traditional techniques such as the Contourlet Transform, Non-Subsampled Shearlet Transform (NSST) and Rolling Guidance Filtering (RGF). Objective measures verify its effectiveness: In the first dataset, it attains an average gradient (AG) of 8.36 and an edge intensity (EI) of 3.29E-04, while in the second dataset, it reports an AG of 21.39 and an EI of 4.06E-04, significantly outperforming other methods. Moreover, the NSCT method offers competitive computational speed, balancing runtime with high-quality fusion performance. These results establish the proposed method as a powerful and efficient solution for color MFIF, offering notable performance benefits and practical utility in various imaging fields.**

Keywords*—*Contourlet transform; image fusing; NSCT; Laplacian Pyramid; color multi-focus

I. Introduction

Optical lenses are vital for photography, visual perception, and computational tasks in real-world scenarios. Despite their pivotal role in imaging, the core principles of lens operation inherently restrict their ability to achieve full scene sharpness. The optical features of cameras enable precise focus on selected subjects within the depth of field, which consequently causes other parts to remain blurred and unfocused. This limitation poses significant challenges in producing a single image with a uniform focus across the entire scene [1-2]. These constraints are particularly crucial in fields where precision and clarity are essential, such as medical imaging, microscopic analysis, and astronomy.

Color Multi-Focus Image Fusion (MFIF) technology emerges as an essential solution to address these challenges. MFIF combines multiple images with varying focus zones of a scene into a single entirely focused image. This technique utilizes advanced fusion algorithms [3], enhancing image clarity and usefulness by amalgamating information from different source images, thus enabling comprehensive image analysis. MFIF finds widespread application across diverse fields, such as merging textile fiber images in microscopy, integrating astronomical images from telescopes, and combining multi-focus images from consumer cameras [4].

The need for accurate and comprehensive image representation is growing across various sectors, where extracting precise information from visual data is critical. Traditional image fusion methods, including pixel-based, feature-based, and transform-based approaches, have substantially progressed in fulfilling this need. However, challenges remain, like texture detail loss, artifacts, and blurring issues. Transform-based techniques, such as wavelets, show promise but are limited in effectively handling multi-resolution and directional data.

The Contourlet Transform offers a multi-resolution and multi-directional framework, which helps overcome some limitations by better representing edges and textures. However, its reliance on subsampling may introduce artifacts and limit fusion quality. The Non-Subsampled Contourlet Transform (NSCT) is implemented for its superior abilities to the standard Contourlet Transform. By removing subsampling, NSCT enhances the preservation of texture and detail, making it highly appropriate for MFIF applications. The practical usage of NSCT covers medical imaging, satellite imagery, and surveillance applications.

Despite advancements in MFIF, several unresolved issues still exist. Existing approaches often struggle with clarity, failing to preserve detailed textures and sharp edges, which results in fused images that are either blurred or prone to artifacts. Additionally, these algorithms have limited adaptability to various imaging scenarios, such as microscopy, astronomy, and general photography, hindering their practical application. Quantitative assessment indicators like gradient and edge strength often show suboptimal performance, underscoring the need for better techniques. Furthermore, the complexity of sophisticated fusion methods frequently reduces computational efficiency, making them unsuitable for real-time or large-scale use. These challenges underscore the necessity for innovative approaches to improve fusion quality, enhance generalizability, and maintain computational viability. The key contributions of the article are:

- The enhanced transform framework integrates the NSCT into the fusion mechanism, showing superior texture and edge conservation compared to conventional methods.
- Improved fusion algorithm displaying impressive

scalability and flexibility in diverse imaging contexts, outperforming leading techniques in both subjective and objective evaluations.

- A comprehensive validation process through experimental methods highlights significant improvements in gradient and edge strength metrics.
- Addressing the limitations of traditional techniques to effectively cater to various applications, such as microscopy, astronomy, and general photography.

The rest of the article is organized as follows: Section II begins with an in-depth review of MFIF technology, followed by an introduction to the core principles of the Contourlet Transform and its advanced form, the NSCT. Section III thoroughly discusses the proposed fusion algorithm, detailing its design and how NSCT is integrated into the image fusion process. Section IV offers experimental validation, featuring both qualitative and quantitative assessments to demonstrate the improved performance of the proposed method. Finally, Section V summarizes the study by synthesizing the outcomes, addressing the limitations of the current approach, and suggesting future research directions to advance MFIF.

II. Related Works

The evolution of image processing techniques, notably the contour transform and MFIF, has driven significant progress in various fields. This section summarizes these areas' key contributions and advancements, highlighting their applications, improvements, and integration into new solutions. The most prominent inferences from the literature are tabulated in Table I.

A. Contourlet Transform

Renowned for its effectiveness in capturing edge and texture details, the contour transform finds numerous applications across multiple sectors. Jahangir H et al. developed an innovative approach using the contour transform to evaluate damage in prestressed concrete slab structures. Applying the transform to the data on the modal curvature in damaged and unscathed states led to the precise determination of the severity of structural damage [5]. Hasan M. M. et al. contour improved the application by combining the contourlet transform with fine-tuning of the pretrained VGG19 model, improving the identification of gastrointestinal polyps in endoscopic images and achieving greater diagnostic precision [8]. Enhancements to the Contourlet contour transform, particularly the development of the NSCT, have notably expanded its applications. Li W et al. merged NSCT with Convolutional Neural Networks for multimodal medical image fusion, successfully addressing intensity inconsistencies and achieving better fusion performance [6]. Kollem et al. presented an improved Total Variation model to enhance grayscale and color brain tumor images. Using NSCT with adaptive threshold techniques improved the preservation of contour and texture features [7]. Hu F's team also used the NSCT and Schur decomposition to create an excellent blind watermarking system to protect the copyright of color digital images, which led to higher peak signal-to-noise ratios and structural similarity indices [9].

B. Multi-Focus Image Fusion (MFIF)

Significant progress has been made in MFIF across various domains, like medical imaging and robotic vision, where image clarity and precision are crucial. Li H addressed the challenge of detecting focused regions in MFIF by proposing a fusion approach relying on focus feature extraction. This approach successfully preserved source images' intricate textures and edge structures while effectively identifying focused area edges [10]. Panigrahy C et al. introduced an innovative MFIF classification method and reviewed current fusion approaches, demonstrating promising performance and potential applications [11]. Recent innovations in MFIF methods include wavelet-based techniques and incorporating deep learning. Wang Y developed a translation-invariant approach using the wavelet transform and fractal dimensions to evaluate clarity, integrating it with the Otsu thresholding to fuse detail coefficients, and achieved competitive results in subjective and objective evaluations [12]. Liu et al. [13] designed an MFIF method using deep learning, employing the VGG-19 network for feature extraction alongside deconvolution modules to generate decision maps. This method indicated superior performance over other segmentation accuracy and fusion metrics approaches, especially for focused and non-focused regions in color multi-focus images.

Detailed contour transform and MFIF studies have yielded promising results across diverse applications. Integrating NSCT into MFIF is pivotal, offering substantial potential to improve fusion quality and precision. This integration overcomes existing challenges and paves the way for developing improved techniques.

Upon examining the cited research, we found that numerous current techniques face drawbacks despite substantial progress in multi-focus image fusion methods. In particular, conventional methods like NSST and RGF encounter difficulties in maintaining intricate texture details and ensuring consistency across different image scenarios. Additionally, achieving computational efficiency poses challenges in high-resolution imaging, as current fusion techniques often grapple with balancing performance against processing speed. Moreover, many reviewed methods display issues such as spectral aliasing and diminished directional sensitivity, resulting in inferior image fusion quality.

In response to the identified gaps, our research introduces a fusion algorithm based on NSCT, augmented with Laplacian Pyramid decomposition, to overcome the mentioned limitations effectively. This method enhances directional selectivity, reduces spectral aliasing, and improves edge preservation while retaining computational efficiency. We achieve superior fusion quality by utilizing NSCT's capability to capture features in multiple directions and combining it with Laplacian Pyramid decomposition, resulting in sharper edges and finer texture details. These advancements directly tackle the issues noted in the existing literature, offering a more reliable and efficient solution for color multi-focus image fusion.

TABLE I SUMMARY OF RELATED WORKS ON IMAGE FUSION TECHNIQUES, MODELS, CONTRIBUTIONS, AND CHALLENGES

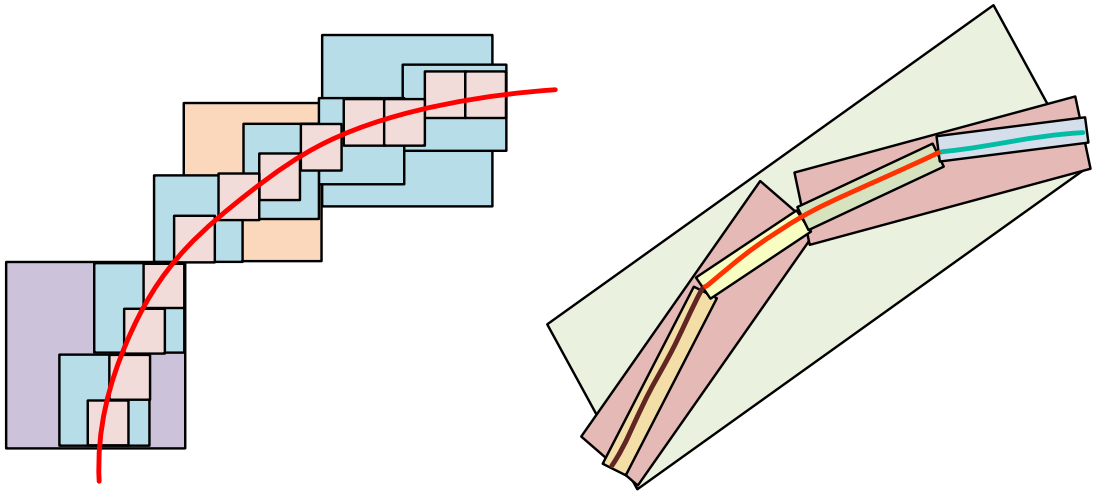
Author	Year	Model	Key Contribution	Challenges
Jahangir H et al. [5]	2021	Contourlet Transform	Damage evaluation in prestressed concrete slabs using modal curvature data.	Application limited to structural damage; no focus on multifocus image fusion.
Li W et al. [6]	2020	NSCT + CNN	Enhanced multimodal medical image fusion addressing intensity differences.	High computational complexity due to CNN integration.
Kollem S et al. [7]	2022	NSCT + Adaptive Threshold	Enhanced grayscale and color brain tumor images using partial differential equations.	Limited to specific medical imaging applications; generalizability not tested.
Hasan M M et al. [8]	2019	Contourlet + Fine-tuned VGG19	Improved identification of gastrointestinal polyps in endoscopic images.	Reliance on pre-trained models may restrict adaptability to other domains.
Hu F et al. [9]	2020	NSCT + Schur Decomposition	Robust blind watermarking scheme for copyright protection of color digital images.	It focuses on copyright protection; there is no direct applicability to MFIF.
Li H [10]	2018	Focus Feature Extraction	Accurate detection of focused regions in MFIF.	They may struggle with complex textures or multi-scene images.
Panigrahy C et al. [11]	2017	Classification-Based Fusion	Novel classification method for MFIF with broad application prospects.	Performance heavily dependent on classifier accuracy.
Wang Y et al. [12]	2016	Wavelet Transform + Fractal Dimension	Translation-invariant method for MFIF with effective edge fusion.	Lacks directional sensitivity and detail preservation.
Liu S et al. [13]	2019	Deep Learning (VGG19 + Deconvolution)	Enhanced segmentation and fusion for color multi-focus images.	High computational cost; potential overfitting with limited data.

III. COLOR MFIF SUPPORTED BY CONTOURLET TRANSFORM

This section explores the application of the Contourlet Transform for Color MFIF. The study delves into the basic concepts, construction techniques, and transformation processes linked to the Contourlet Transform. Additionally, it assesses its shortcomings and presents the NSCT as a possible improvement in this domain. The research outlines the elements, decomposition principles, and operational procedures of NSCT in the context of color MFIF, highlighting its enhanced performance features.

A. Contourlet Transform Method

The Contourlet Transform is an effective technique for image processing in the realm of color MFIF. It stands out due to its multi-scale and multi-directional decomposition capabilities, which enhance the depiction of image contours and textures. The procedure begins with a Laplacian Pyramid (LP) decomposition, systematically dividing the image into sub-images at various scales [14-15]. The high-frequency components undergo directional decomposition using the Directional Filter Bank (DFB), while the low-frequency components are iteratively decomposed, creating the complete contour wave structure. Unlike conventional wavelet transforms that employ square wavelet functions, the Contourlet Transform uses rectangular ones, allowing for aspect ratio adjustments and better adaptation to image contours across scales. This improved directionality offers a more accurate representation of curves and contours. Fig. 1 shows a visual comparison of different transformation methods for representing image curves.



(a) Description of curves using wavelet transform

(b) Countourlet transformation for describing curves

Fig. 1. Description of image curves by different transformation methods.

Contourlet transform comprises two main components: LP decomposition and DFB filtering [16]. LP Decomposition captures intricate details across a spectrum of frequencies by deconstructing the image into smaller elements. DFB Filtering provides a multi-directional decomposition method that extracts directional characteristics. The LP decomposition refines the Gaussian pyramid approach by reducing high-frequency information loss by subtracting layers. This involves interpolation to align image dimensions at each scale level. This process is achieved through repeated convolution and down-sampling operations. The Gaussian pyramid is the fundamental type of image pyramid, generating a pyramid-shaped data structure through convolution and down-sampling operations. LP further develops from the Gaussian pyramid, addressing the loss of high-frequency information during computation. LP achieves this by subtracting each layer of the Gaussian pyramid from its previous layer, obtaining the LP decomposed image. In this process, interpolation operations are required for rows and columns, extending fine-sized images to coarse-sized ones. The output representation of the fine-sized image is expressed as shown in Eq. (1).

$$\sum_{m=-2}^{2}\sum_{n=-2}^{2} G_{l-1}(2i+m, 2j+n)w(m,n) = G_l(i,j) \quad (1)$$

In Eq. (1), l represents the decomposition level and $G_l(i,j)$ represents the Gaussian pyramid image at the level l. $w(m,n)$ stands for the sliding window with a size of 5 × 5. i and j are the symbols of rows and columns of the corresponding image. Subsampling operations can obtain a sequence of Gaussian pyramid images, followed by interpolation and dilation operations to make the sizes of images Gl and Gl-1 consistent, as it described in Eq. (2).

$$4\sum_{m=-2}^{2}\sum_{n=-2}^{2} G'_{l-1}\left(\frac{i+m}{2}, \frac{j+n}{2}\right)w(m,n) = G_l * (i,j) \quad (2)$$

In Eq. (2), the calculation of $G'_{l-1}\left(\frac{i+m}{2}, \frac{j+n}{2}\right)$ is shown in Eq. (3).

$$G'_{l-1}\left(\frac{i+m}{2}, \frac{j+n}{2}\right) = \begin{cases} G_l\left(\frac{i+m}{2}, \frac{j+n}{2}\right), & \frac{i+m}{2} \text{ and } \frac{j+n}{2} \text{ are integers} \\ 0, & \text{other} \end{cases} \quad (3)$$

LP is defined as shown in Eq. (4).

$$\begin{cases} LP_l = G_l - G_{l+1}^*, & 0 < l < N \\ LP_N = G_N, & l = N \end{cases} \quad (4)$$

In Eq. (4), N represents the highest level of the pyramid. After obtaining the LP image sequence, fusion is performed according to the selected rules to get a fused pyramid sequence image, and finally, a reconstruction process is carried out. The calculation for reconstruction is shown in Eq. (5).

$$\begin{cases} G_N = LP_N, & when\ l = N\ 0 < l < N \\ G_l = LP_N + G_{l+1}^*, & when\ 0 < l < N \end{cases} \quad (5)$$

The LP decomposition and reconstruction processes, with a schematic diagram, are shown in Fig. 2.

The DFB is a tree-structured decomposition method that generates multiple directional subbands at each layer, with each subband taking a wedge shape. A construction method for DFB based on a sector filter group is introduced to simplify directional decomposition without altering the input signal. This method comprises two main components: a dual-channel sector filter group and shear processing. The dual-channel sector filter group utilizes sector filters to decompose the two-dimensional spectrum into horizontal and vertical directions. On the other hand, shear processing involves sampling and rearranging the image. The method effectively captures frequency domain information across various directions while ensuring complete reconstruction by incorporating shear and inverse shear operations before and after the dual-channel filter group.

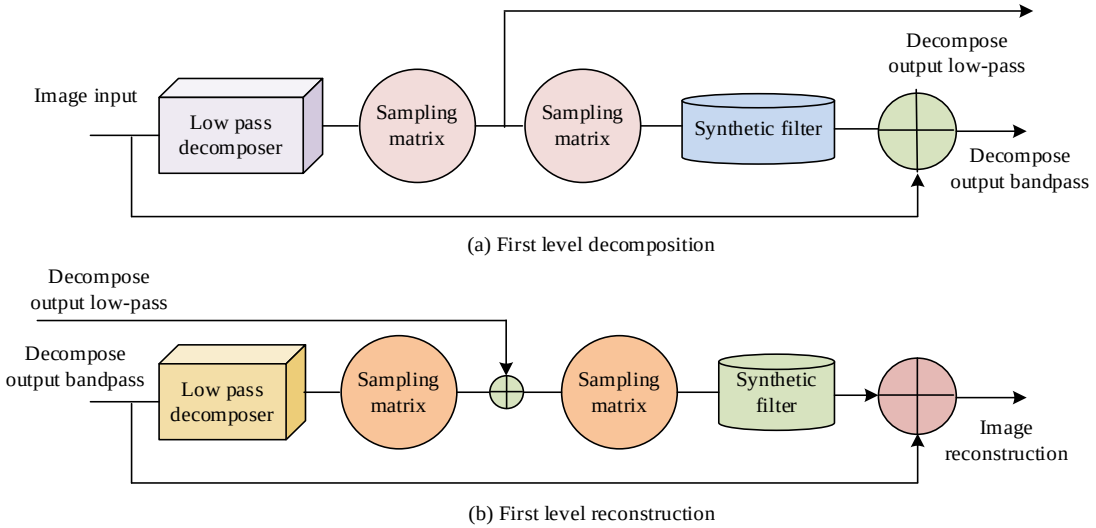


Fig. 2. A schematic diagram of the decomposition and reconstruction of the LP.

For instance, in a 3-level decomposition, the method can produce 8 directional spectrum partitions. Subbands labeled 1, 2, and 3 belong to the first channel, while subbands labeled 4, 5, 6, and 7 are part of the second channel. Integrating the Laplacian Pyramid (LP) with DFB forms a two-layer filter structure, referred to as the Contourlet filter group. During transformation, the image is first decomposed into high-frequency and low-frequency components. The low-frequency component undergoes further multi-resolution analysis, while the high-frequency components are processed through DFB to generate directional subbands at various orientations. This iterative process gradually connects singular points into linear structures, capturing the edge contours of the image. This capability allows the Contourlet Transform to effectively capture image features, such as edges and textures, offering a superior representation compared to traditional methods. Fig. 3 depicts the flowchart of the Contourlet transformation, illustrating the sequential decomposition and feature extraction process.

To improve NSCT-based fusion, images must be pre-processed to make them more transparent and less distorted before transforming. Preprocessing improves contrast and gets rid of unnecessary variations. This helps NSCT retain structural details better, which makes it perfect for medical imaging and analyzing satellite data. It also makes extracting more accurate features and fusion easier, which improves visualization in critical areas like medical imaging and remote sensing.

B. MFIF Supported by Improved Contourlet

Within the Contourlet framework, downsampling is employed during integrating pyramid and directional filtering decomposition, potentially resulting in spectral aliasing, which diminishes the transformation's directional understanding [17]. The Non-Subsampled Contourlet Transform (NSCT) was developed to address this issue. NSCT's decomposition method includes two primary elements: the Non-Subsampled Pyramid Filter Bank (NSPFB) for decomposing scales and the Non-Subsampled Direction Filter Bank (NSDFB) for analyzing directions. This framework maintains the Contourlet Transform's ability to effectively capture curves while removing spectral aliasing that arises from downsampling. Consequently, NSCT improves the accuracy and dependability of directional sensitivity in image processing. Fig. 4 illustrates the NSCT's structural diagram, detailing its components and workflow.

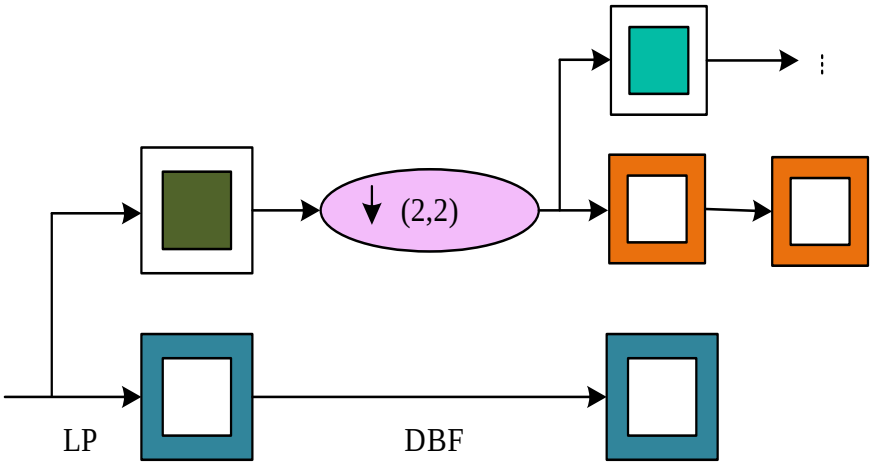

Fig. 3. Flow chart of Contourlet transformation.

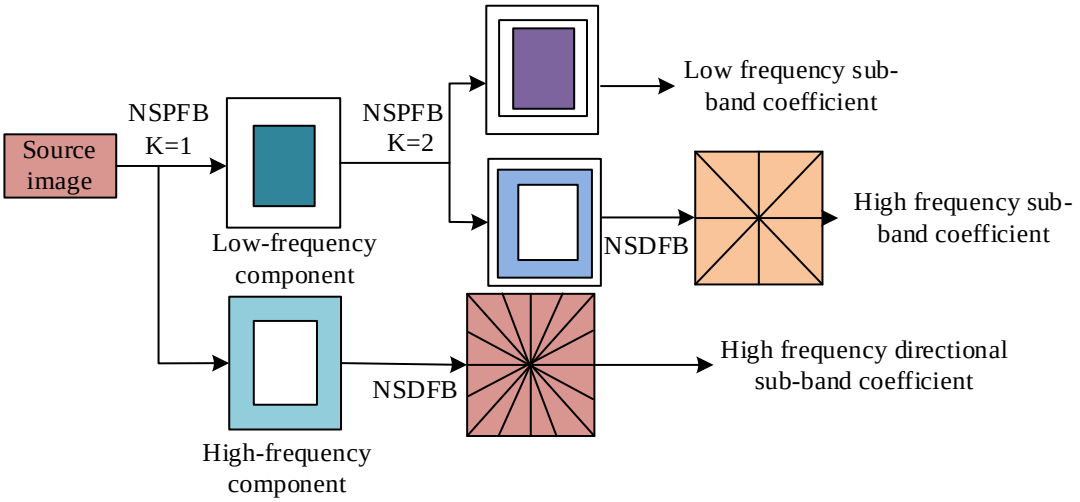

Fig. 4. Structural diagram of the NSCT.

Conventional approaches for assessing image sharpness frequently depend on individual features, which may be inadequate in specific situations [18-19]. To mitigate these limitations, we propose an MFIF technique utilizing the NSCT. The algorithm initiates with the decomposition of two source images through NSCT, extracting their subband coefficients. This results in multiple subbands of uniform size, aiding the identification and exploitation of gray feature correlations across subbands. In the NSCT realm, reference coefficients' sibling subbands contain abundant correlation data, which is harnessed to enhance fusion. The method employs correlation weights from sibling subbands in conjunction with average gradient metrics for a robust fusion process for high-frequency subbands. Initial fusion results emerge from applying these rules, followed by an inverse NSCT transform. To further boost the fusion's quality, edge detection methods are utilized on the preliminary result, isolating edge contour data. This data is then superimposed on the preliminary fused result, enhancing clarity and feature retention. The NSCT-supported fusion algorithm's comprehensive framework is depicted in Fig. 5, showcasing its efficacy in capturing and integrating edge and texture details for superior image fusion quality.

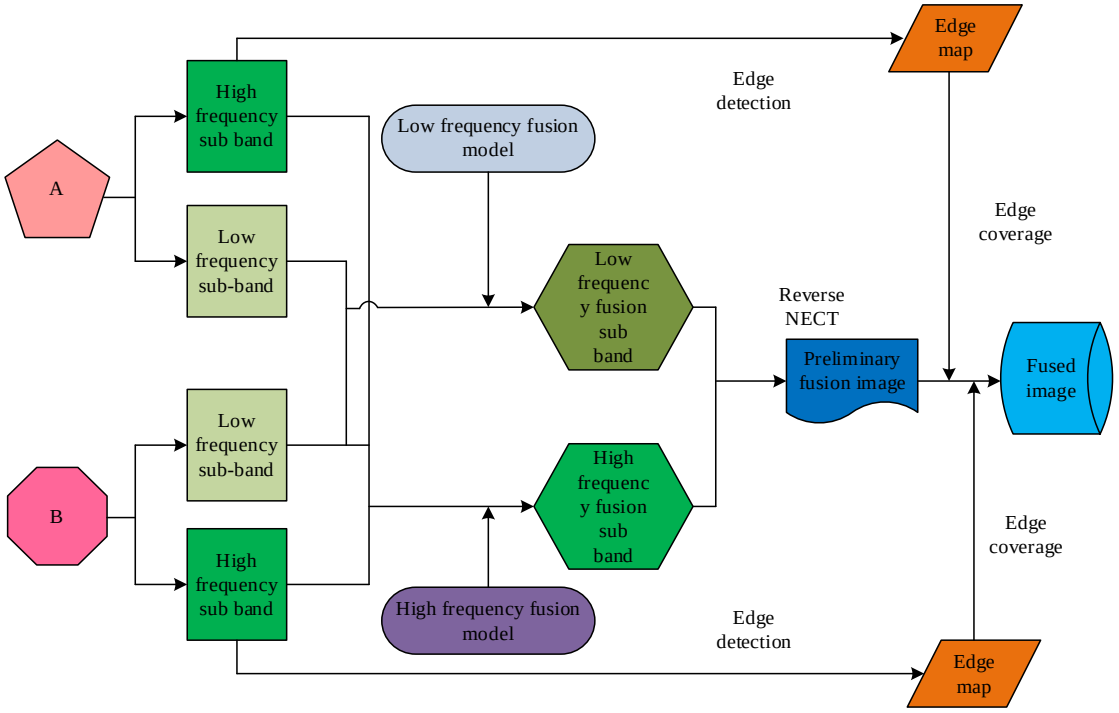

Fig. 5. A fusion algorithm framework based on NSCT.

In NSCT decomposition, the low-frequency subband is extracted from the source image via successive application of low-pass filters over several layers. This research adopts statistical features like local information entropy and enhanced local Laplacian energy for fusing low-frequency coefficients. Information entropy is a reliable indicator for assessing the amount of information in an image. The low-frequency subband often contains a significant part of the image's information, making entropy an effective measure for fusion [20]. Conversely, Laplacian energy indicates the extent of grayscale variation in an image, enhancing the analysis based on entropy. Eq. (6) provides the mathematical representation for local information entropy and local Laplacian energy at point *h* in the image *x*. These metrics facilitate the fusion of low-frequency coefficients by capturing essential informational and structural distinctions within the image.

$$G_{r,x}(h)=\sum_{q\in Q}\omega(q)S_{r,x}(q)^2 \tag{6}$$

In Eq. (6), $h(a,b)$ represents pixel coordinates, $\omega(q)$ is a Gaussian weight matrix, Q denotes the neighborhood centered around h, and r takes values of 1 or 2. The representation of local information entropy at point q within the neighborhood Q is shown in Eq. (7).

$$S_{1,x}(q)=\sum_{a=0}^{\gamma-1}p_a\log(p_a) \tag{7}$$

In Eq. (7), p_i represents the proportion of pixels with a grayscale value a in the neighborhood Q, and γ represents the grayscale level. The calculation of locally improved Laplacian energy is given by Eq. (8).

$$S_{1,x}(a,b)=\left|2C_x(a,b)-C_x(a-1,b)-C_x(a+1,b)\right|+\left|2C_x(a,b)-C_x(a,b-1)-C_x(a,b+1)\right| \tag{8}$$

In Eq. (8), $L_r(h)$ represents the low-frequency subband coefficients obtained from the decomposition of the image x. The feature matching degree of low-frequency component coefficients between images A and B at point h is expressed in Eq. (9).

$$L_r(h)=\frac{2\sum_{q\in R}\omega(q)\left|S_{r,A}(q)\right|\left|S_{r,B}(q)\right|}{G_{r,A}(h)+G_{r,B}(h)} \quad (9)$$

Assuming α is the matching threshold, if $L_r(h)<\alpha$, the feature weight matrix is solved through the calculating process of Eq. (10).

$$W_{r,A}=\begin{cases}1, G_{r,A}(h)\geq G_{r,B}(h)\\ 0, G_{r,A}(h)<G_{r,B}(h)\end{cases} \quad (10)$$

If $L_r(h)\geq\alpha$, the feature weight matrix is solved through the calculating process of Eq. (11).

$$\begin{cases}W_{r,A}=\begin{cases}1-(L_r(h)-\alpha), G_{r,A}(h)\geq G_{r,B}(h)\\ L_r(h)-\alpha, G_{r,A}(h)<G_{r,B}(h)\end{cases}\\ W_{r,B}=1-W_{r,A}(h)\end{cases} \quad (11)$$

Eq. (12) shows how the fusion weight matrix for low-frequency components is obtained by applying the average principle to weight matrices.

$$\begin{cases}W_A(h)=(W_{1,A}(h)W_{2,A}(h))/2\\ W_B(h)=(W_{1,B}(h)W_{2,B}(h))/2\end{cases} \quad (12)$$

The calculation of the low-frequency coefficients after merging images A and B is given in Eq. (13).

$$C_F(h)=C_A(h)W_A(h)+C_B(h)W_B(h) \quad (13)$$

High-frequency elements contain the original image's fine details and textural information, while the average gradient quantitatively describes variations in the image's gradient. A higher average gradient indicates more detailed texture and sharper image clarity. To improve the fusion of high-frequency elements, this research uses the local average gradient as a basis for determining fusion weights. This method assures that texture-rich areas are effectively maintained and emphasized in the combined image. The mathematical expression for the region's average gradient concerning the high-frequency subband coefficients at the *p-th* scale and *s-th* direction of image *x* is provided in Eq. (14). This formulation highlights the importance of gradient-based metrics in enhancing the quality of fusion for high-frequency details.

$$T^s_{s,k}(a,b)=\frac{\sum_{(a,b)\in Q}g(a,b)}{|Q|} \quad (14)$$

$|Q|$ represents the size of the neighborhood window. The calculation of $g(a,b)$ is given in Eq. (15).

$$g(a,b)=\frac{\sqrt{\left[C^s_{x,q}(a,b)-C^s_{x,q}(a+1,b)\right]^2+\left[C^t_{x,q}(a,b)-C^t_{x,q}(a+1,b)\right]^2}}{2} \quad (15)$$

In Eq. (15), $C^s_{x,q}$ and $C^t_{x,q}$ represent the high-frequency subband coefficients of image *x* in the *p-th* scale and *s-th*, *t-th* directions. Within the NSCT domain, the reference node is closely associated with its eight adjacent nodes in the identical subband, as these neighbors carry considerable information about the reference node. At the same scale, nodes situated in the same spatial position but in different directional subbands are known as sibling nodes. Although these siblings provide valuable data, they typically offer less insight regarding the reference node than the immediate neighbors. Conversely, the node at the same spatial location in the previous scale, termed the parent node, holds the least amount of relevant information about the reference node. Understanding these nodes' hierarchical and spatial connections is crucial for capturing structural and contextual information in NSCT-based image processing. Fig. 6 comprehensively depicts these relationships, illustrating the interaction between coefficients in the NSCT domain.

The NSCT-based fusion technique balances computational efficiency with feature extraction by selecting appropriate decomposition levels and fusion strategies. Researchers have tested NSCT in challenging situations and found it keeps image details and edge structures better than other methods, even when the input images are distorted. NSCT achieves this robustness by enhancing directional information, reducing undesirable artifacts, and guaranteeing high-quality fused images under diverse conditions.

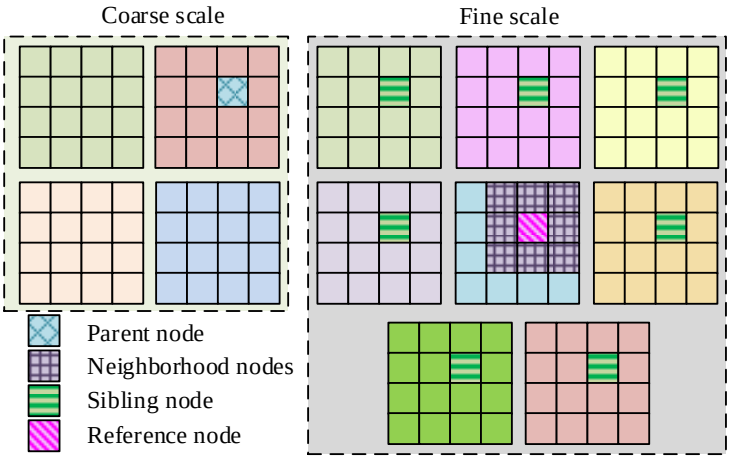

Fig. 6. A schematic representation of the relationship between the NSCT domain coefficients.

IV. Results and Discussion

This section thoroughly assesses the proposed Color MFIF algorithm, which leverages the Contourlet Transform and focuses on the NSCT. Experimental validation encompasses subjective and objective analyses demonstrating the algorithm's practical effectiveness and comparative benefits.

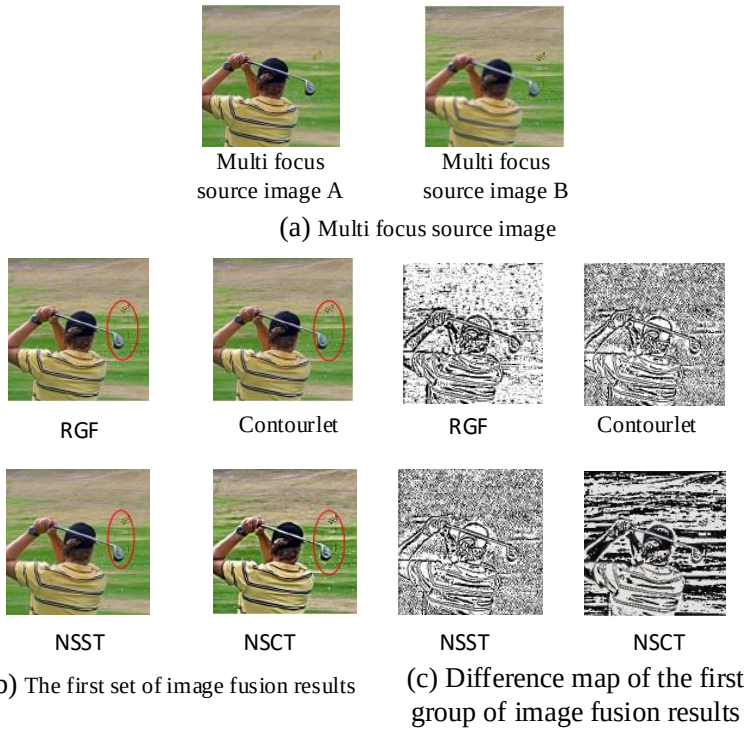
A. Subjective Evaluation

Subjective evaluations were conducted based on qualitative assessments to measure the practicality of the NSCT-based multi-focus image fusion algorithm. Testing utilized two datasets from a registered true-color multi-focus image collection. The fusion outputs from the NSCT-based algorithm were compared to results from conventional methods, such as the Contourlet Transform, Non-Subsampled Shearlet Transform (NSST), and Rolling Guidance Filtering (RGF) techniques. Table II lists the parameters used in these experiments, ensuring uniformity and comparability among all methods tested.

TABLE II Experimental Parameters

Parameter	Set value
Input picture A	Clear
Input picture B	Blur
Spatial filter	Gaussian filter with a standard deviation of 1.0
Gradient weight	0.5
Iterations	10
Output image size	Consistent with the input image
Output image format	PNG

The image showcasing the fusion effect for the initial set of multifocus source images featuring a clock, along with its corresponding difference image, is illustrated in Fig. 7. Fig. 7(a) presents color multifocus source images A and B, while Figure 7(b) shows the resultant fusion effect image. Fig. 7(c) provides the associated difference image. Observations from Fig. 7 reveal that the RGF method delivers a solid overall fusion effect, producing a visually appealing result. However, examining the highlighted area in the red circle reveals noticeable blurring in the flag section with the RGF method. The Contourlet Transform approach achieves a generally good fusion effect but suffers from some detail loss and certain artifact presence in the hand and back areas. NSST also performs well in fusion, though it introduces slight blurring at the flag's edge within the red box, resulting in minor detail information loss and slightly lowering the clarity of the fusion effect. Contrastingly, with the NSCT method, object edges are distinctly sharp and clear, with abundant texture details and no detail loss. This fusion effect is optimal, featuring strong contrast effects, indicating that the proposed method in this study provides superior fusion effects, free of artifacts in surrounding areas, demonstrating high authenticity and precision.



(a) Multi focus source image

(b) The first set of image fusion results

(c) Difference map of the first group of image fusion results

Fig. 7. The first set of image fusion results and difference maps.

The images resulting from the fusion process and the corresponding difference maps related to the clock in the second set are illustrated in Fig. 8. Fig. 8(a) presents the colored multi-focus source images A and B from the second set. Fig. 8(b) shows the fusion effect image of the second set, and Fig. 8(c) presents the associated difference map. From Fig. 8, it can be noted that, within the second set of experimental images, the RGF method displays a slight reduction in clarity, as seen through subjective analysis. Additionally, the RGF method causes subtle blurring and pseudo-artifacts near the tiger. The Contourlet transform method achieves a good overall fusion effect, though with a minor drop in clarity. Even though the NSST transform method offers rich visual effects and abundant information, it suffers from a decline in clarity and produces unnatural transitions and pseudo-artifacts in the peripherals. In contrast, the NSCT method significantly excels, presenting rich information, clearly viewing scene textures, and uniform brightness distribution. It does not generate pseudo-artifacts, effectively addressing detail loss due to edge blurring. Moreover, there are no pseudo-artifacts in the tiger's texture information, showcasing high contrast. This suggests that the color MFIF algorithm proposed by the research institute delivers a notable fusion effect.

B. Objective Evaluation

The study continued its analysis of the fusion result images for both groups by focusing on quantitative evaluations. The metrics used for assessment included Average Gradient (AG), Standard Deviation (STD), Spatial Frequency (SF), Visual Information Fidelity (VIFF), and Edge Intensity (EI). AG assessed contrast details and texture changes in the images, with higher values indicating more precise information. STD measured the range of grayscale levels, where higher values signaled a more natural brightness in the fused image. SF captured the ratio of spatial frequency errors, and VIFF evaluated image quality based on its visual fidelity, with higher values reflecting better fusion quality. EI gauged image clarity. Initially, the clarity of each fusion technique was validated through AG and EI metrics. To confirm experiment reliability, 10 tests were conducted, and the averages were calculated as final results. Fig. 9 illustrates the AG and EI values of the fusion outcomes for both groups. In Fig. 9(a), particularly in the first group's multi-focus source images fusion, the NSCT method achieved a substantial AG of 8.36, surpassing the traditional contourlet transform, NSST, and RGF methods by 0.16, 0.72, and 0.25, respectively. Fig. 9(b) indicates that the NSCT method also reached a notable EI value of 3.29E-04 in the first group, showing enhancements over the other methods by 0.48E-04, 0.59E-04, and 0.72E-04. Fig. 9(c) demonstrates that the NSCT method obtained a high AG of 21.39 in the second group, outperforming other methods with improvements of 7.28, 7.39, and 6.14. Fig. 9(d) portrays the NSCT method achieving a significant EI value of 4.06E-04 in the second group, markedly better than the alternatives, illustrating the remarkable efficacy of the proposed image fusion technique developed by the research institute.

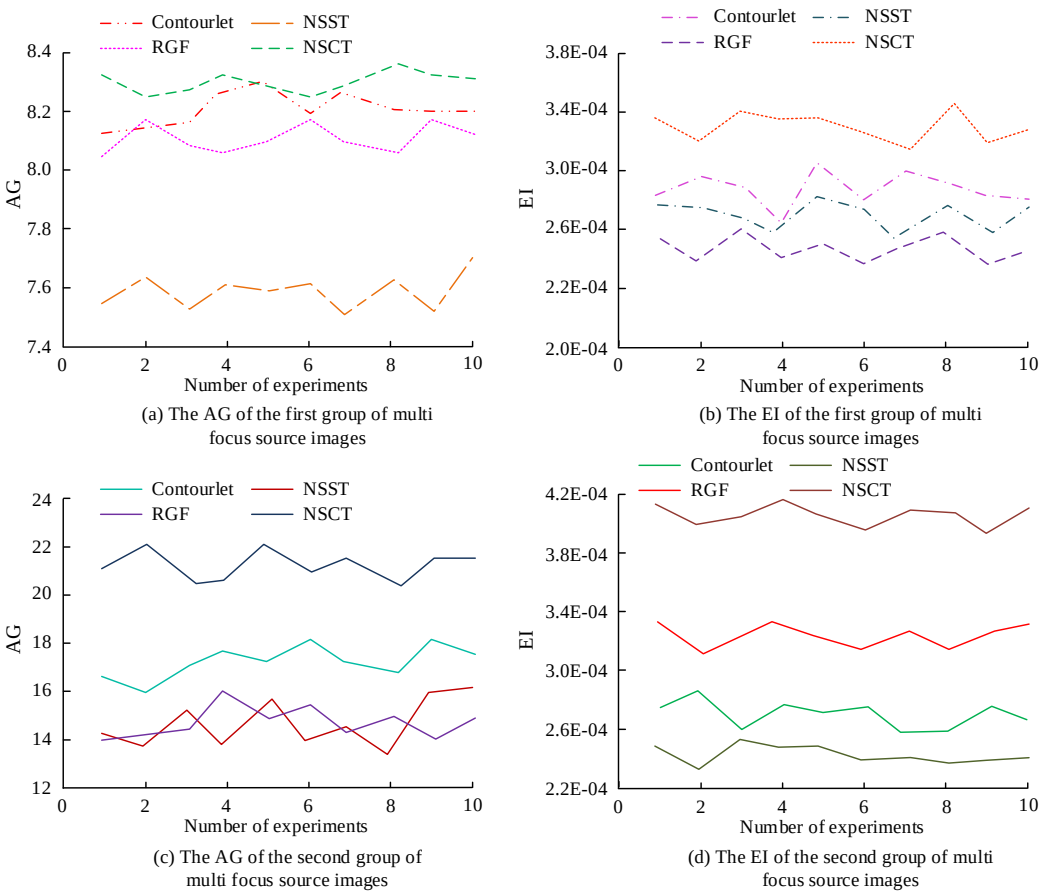

Fig. 9. AG and EI values of the fusion results as follows.

The study explored the effectiveness of the NSCT method alongside STD, SF, and VIFF validation. Fig. 10 displays the combined results of STD, SF, and VIFF values for two distinct groups. As depicted in Fig. 10(a), the NSCT method delivered STD, SF, and VIFF values of 47.69, 35.95, and 1.29 in the fusion results of the first group of multi-focus source images. This marks an enhancement over the Contourlet transform method, with increases in STD, SF, and VIFF values by 0.35, 10.48, and 0.32, respectively. Fig. 10(b) shows that in the second group's fusion results, the NSCT method achieved STD, SF, and VIFF values of 71.55, 55.73, and 1.14, respectively, indicating a marked improvement over the RGF (Recursive Gaussian Filtering) method, with reductions of 12.23, 17.28, and 0.18 in STD, SF, and VIFF values, respectively. These findings suggest that the NSCT method substantially outperforms other methods compared.

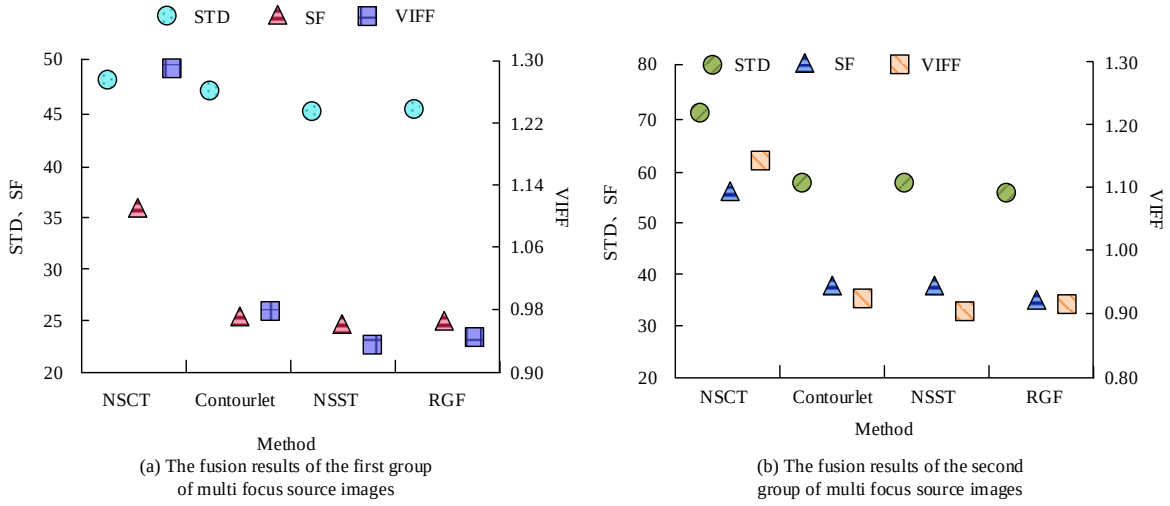

Fig. 10. STD, SF, and VIFF values for the two sets of fusion results.

The study extended its analysis to the runtime of several image fusion techniques to evaluate their computational efficiency. The experimentation encompassed 50 test executions, with each algorithm's runtime illustrated in Fig. 11. From Fig. 11(a), in the first set of multi-focus source image fusion outcomes, the NSCT method averaged a runtime of 10.03 seconds. The Contourlet transform, NSST, and RGF methods recorded average runtimes of 5.69, 17.69, and 13.72 seconds, respectively. As shown in Fig. 11(b), for the second set of fusion results, the average runtime of the NSCT method was 10.58 seconds. The rival methods averaged 8.59, 23.61, and 16.97 seconds. Notably, only the Contourlet transform method had a lower runtime than the NSCT, while the others lagged in computational efficiency. Considering fusion quality, the proposed approach in the research demonstrated superior performance.

C. Discussion

To objectively test the fusion performance in this study, we use key validation metrics such as Average Gradient (AG), Edge Intensity (EI), and computational time. We have carefully selected these metrics to comprehensively evaluate the algorithm's sharpness, edge preservation, and efficiency. Furthermore, we have assessed our NSCT-based approach against notable methods such as NSST and RGF. More results have been added that show NSCT-based fusion is better through quantitative and qualitative tests, strengthening the comparison even more. These encompass side-by-side visual comparisons of fused images, highlighting NSCT's capability to retain fine details while reducing artifacts. Furthermore, we show statistical proof that our method improves performance for both AG and EI across the chosen datasets.

The objective evaluation confirmed these results, where higher AG and EI values in NSCT meant better contrast and sharpness, which meant better fusion quality. The method's ability to get high STD, SF, and VIFF scores shows that it works to keep natural brightness and spatial coherence. This suggests that the NSCT-based method effectively gets around the problems with older methods, such as spectral aliasing and lack of directional sensitivity. Moreover, runtime analysis showed that NSCT efficiently balances fusion performance with computational cost. Although a little slower than the Contourlet Transform, NSCT performed much better than NSST and RGF, making it a good choice for real-time image processing tasks.

NSCT is better than NNSST and RGF because it eliminates problems like edge blurring, artifact creation, and slow computing. NSST has some issues with direction insensitivity and edge blurring. NSCT, on the other hand, has better direction selectivity for smoother transitions and better feature preservation. While RGF can smooth images, it often introduces pseudo artifacts and loses fine details, especially in high-texture areas. NSCT, on the other hand, uses localized filtering and multi-directional decomposition to reduce spectral aliasing. This makes artifact-free fusion with higher contrast and strong structural integrity possible. NSCT also balances fusion quality and computational efficiency better by doing fewer unnecessary calculations than NSST. This makes it a better image fusion process for real-time uses like medical imaging, surveillance, and remote sensing.

The findings highlight that the proposed NSCT-based MFIF technique offers an effective and efficient solution for multi-focus image fusion. The way it integrates images is better without slowing down computers, so it can be used in areas like medical imaging, surveillance, and satellite imagery.

V. Conclusion

Color MFIF technology has extensive applications across numerous fields requiring accurate and detailed imagery. This research introduced an advanced NSCT to overcome the shortcomings of existing fusion techniques. The results demonstrated the NSCT-based algorithm's outstanding performance in delivering superior fusion results. For the second experimental dataset, the NSCT approach showcased rich information content, vivid texture clarity, and even brightness distribution. Significantly, it prevented artifact creation and mitigated detail loss due to edge blurring. Quantitative evaluations further affirm its advantages: in the first dataset, the NSCT method recorded Standard Deviation (STD), Spatial Frequency (SF), and Visual Information Fidelity (VIFF) values of 47.69, 35.95, and 1.29, respectively, and in the second dataset, these metrics rose to 71.55, 55.73, and 1.14, notably outperforming other methods like the Contourlet

Transform, NSST, and RGF. Regarding computational efficiency, the NSCT method balanced runtime effectively. For the first dataset, it averaged a runtime of 10.03 seconds, compared to the 5.69 seconds, 17.69 seconds, and 13.72 seconds taken by the Contourlet Transform, NSST, and RGF methods, respectively. In the second dataset, the NSCT method had an average runtime of 10.58 seconds, maintaining competitiveness despite being slightly slower than the Contourlet Transform. These findings highlight the NSCT method's capacity to deliver excellent fusion quality and manageable computational demands. While the proposed approach shows strong and consistent fusion performance, this study did not consider the influence of source image quality on the fusion results. Future investigations might examine incorporating image preprocessing algorithms to enhance the quality of source images, thus further augmenting the reliability and scope of color MFIF technology.

***Abstract*—The malignant development of cells in the colon or rectum is known as colon cancer, and because of its high incidence and possibility for death, it is a serious health problem. Because the disease frequently advances without symptoms in its early stages, early identification is essential. Improved survival rates and more successful therapy depend on an early and accurate diagnosis. The reliability of early detection can be impacted by problems with traditional diagnostic procedures, such as high false-positive rates, insufficient sensitivity, and inconsistent outcomes. This unique approach to colon cancer diagnosis uses autoencoder-based feature selection, capsule networks (CapsNets), and histopathology images to overcome these problems. CapsNets capture spatial hierarchies in visual input, improving pattern identification and classification accuracy. When employed for feature extraction, autoencoders reduce dimensionality, highlight important features, and eliminate noise, all of which enhance model performance. The suggested approach produced remarkable outcomes, with a 99.2% accuracy rate. The model's strong capacity to detect cancerous lesions with few mistakes is demonstrated by its high accuracy in differentiating between malignant and non-malignant tissues. This study represents a substantial development in cancer detection technology by merging autoencoders with Capsule Networks, so overcoming the shortcomings of existing approaches and offering a more dependable tool for early diagnosis. This method may improve patient outcomes, provide more individualized treatment regimens, and boost diagnostic accuracy.**

***Keywords*—Colon cancer prediction; capsule network; autoencoder; histopathological images; early cancer detection**

I. Introduction

Colon cancer is one of the common cancers globally, and also has its contribution to the cancer related deaths. Cancer of the colon is generally said to start out as small growths in the outer lining of the colon or rectum and may progress to become malignant tumors [1]. In case this condition is not diagnosed early enough and management commenced, it can develop silently and hence make the treatment process more challenging. One cannot overemphasize on the need to have colon cancer detected early. Colon cancer is relatively easy to cure and very treatable if it is detected in its preliminary stage. It is possible to detect and remove precancerous polyps and stage I malignancies with colonoscopy and other screening methods before the manifestation of symptoms. As a result, common people besides those who are over 45 years or those with the history of this complaint must opt for these tests more often. The implication of colon cancer extends to the families, the communities and the health systems over the directly affected individual. There is need to give early diagnosis and treatment since the condition leads to severe physical, emotional, and financial complications [2]. Improving possibilities for early detection of diseases and tailoring programs for patients require new discoveries in the field of medicine, for example, development of advanced techniques to visualize body conditions or new types of computational models for prognosis. Colon cancer can be anticipated employ modern methods and equipment in identifying the disease before it spreads hence improving the prospects of the ailment. Modern methodologies of prediction use numerous devices, including genetic tests, imaging, and ML algorithms. For instance, in Histopathological image analysis, the precise patterns in tissue samples may be seen by employing CapsNets in which the changes in size might mean malignant alterations. Additionally, using diversified data gathered from various sources, involving the lifestyle factors of the patient, his family history, and demographics, predictive models can be created that would assess the risk level of the given individual.

Possibly, there is a way to enhance these predictions as such methods as feature selection and dimensionality reduction with the help of autoencoders could focus on the most relevant characteristics [3].

The advancements demonstrate how sophisticated prediction approaches and individualized care may dramatically enhance early diagnosis and treatment, improving patient outcomes and streamlining healthcare processes. An important step forward in colon cancer treatment and early diagnosis is the machine learning-based prediction model that has been suggested [4]. It means that, with the help of applied ML algorithms, the scholars will look for various tendencies and the potentially linked risks associated with colon cancer, utilizing huge datasets of histopathologic data, genetic features, or patients' characteristics. Popular DL methods CNN and CapsNets are applied in the process of examining medical images to identify the signs that might suggest the presence of malignant tumors. To increase the model performance, it is also possible to apply the ML model to use multiple modalities as image findings, tests and patients' history. These models may be further refined into feature selection methods such as autoencoders to identify the pertinent data features for prediction [5]. Since these complex advancements of modern day's ML categorically predict individual responses towards various drugs, they not only enhance early diagnosis, but also facilitate development of composite patient-centered regimes. The capability of these models to predict has been on the rise and more so depending on the large and diverse information that has been fed to them perhaps yielding into better and faster response [6]. In general, the idea to integrate ML into the prediction of colon cancer can be considered as rather perspective in terms of reducing mortality rates as well as improving patients' quality of lives due to precise diagnosis.

The novel neural network design technique known as CapsNets addresses the limitations of the original CNN in terms of recognizing spatial hierarchies and connections. The constraints of CNNs in preserving the relative position and orientation of input are overcome in CapsNets by capsules, which are collections of neurons cooperating to identify certain patterns and their spatial correlations. Proprietary routing methods amongst capsules provide precise data transfer over the network. The main breakthrough is that features' presence and posture are captured by capsules, which improves the network's comprehension of intricate spatial data [7]. This hierarchical method certainly supports the idea of adjusting the CapsNets based on the changes in the object orientation, along with their ability to generalize from very little training data. In such problems as image identification and segmentation, where feature localization is critical, CapsNets are very effective because they enhance the network's ability and capacity and modeling complex spatial relations. It is an optimal method for applications requiring complex pattern recognition as they do not degrade the feature in various views and transformations. Among neural networks designed for unsupervised learning, the proper name is autoencoders. It provides mainly the aspect of learning the best representations through the encoding and decoding processes. A low dimensional representation of input data is mapped by an encoder network into an autoencoder, and the low dimensional representation is mapped by a decoder network into the original data to reconstruct it. It is useful for finding and retrieving the characteristics of the data while filtering out the outliers and the redundancies. Autoencoders are used in denoising of data, feature extraction, and dimensionality reduction. Other extensions are variational autoencoder which can model complex distributions of the data or sparse autoencoder which forces the latent space to be sparse.

Enhancing the accuracy and efficiency of the consequent image processing, two special models, namely CapsNets and autoencoders, are indisputably effective for identifying colon cancer. Spatial hierarchies were managed well and fine details in the histopathology images were recognized by CapsNets thus improving the detection of weak malignant features. On the other hand, autoencoders are useful in feature learning and feature reduction in which it down samples the important features of the images and reduces on the noises. Such integration is important to assist researchers in developing strong models for assessing medical images on the basis of time efficiency, which in this case, can lead to enhanced patient results due to better early diagnosis of colon cancer. Key contributions of the proposed work are:

1) Demonstrates increased detection accuracy for colon cancer by utilizing CapsNets' capacity to identify intricate spatial correlations, as opposed to more conventional image processing techniques.

2) Provides use of autoencoders to efficiently reduce dimensionality and extract features, producing input for the capsule network that is more insightful and pertinent.

3) Exhibits resilience in model performance over a range of datasets and imaging settings, improving the approach's generalizability.

4) Lowers false positives and false negatives in the detection of cancer, enhancing the precision and dependability of the diagnosis.

5) Permits for the customization of therapeutic and diagnostic approaches by combining patient-specific data with model predictions.

The suggested study starts with an overview of colon cancer and the urgent need for better diagnostic approaches because of the shortcomings of current practices in Section I. The Related work is reviewed in Section II, which also highlights the difficulties in early identification of the current approaches. The problem statement is described in Section III. The procedure for gathering data, the pre-processing measures, and the use of CapsNets for pattern detection and feature extraction are all covered in Section IV. The performance measures are presented in Section V and ending with the Section VI, Future work and conclusion.

II. Related Works

Ali and Ali [8] utilizes two forms of Convolutional Layers Block, the first of which is the CLB while the second one is the SCLB enhanced through an advanced computerized system to enhance the capability of identifying the lung and colon cancer. Histopathological images are processed with the help of a multi-input capsule network in this system. To undo colour distortions applied by the microscope during the preparation of histopathology slides, the SCLB undergoes the images enhanced

with multi-scale fusion, colour correction function, gamma correction, and image enhancement items. The CLB deals with raw photos in the meantime. This multi-input method certainly outlines a huge improvement as to the feature learning of the model. It turned out that when using the LC25000 dataset, the work of the model was commendable in terms of the result accuracy obtained in the diagnosis of lung and colon pathologies. The study has many limitations, however, mainly due to the fact that its source data were limited by the range of LC25000 and could not exactly reflect the characteristics of actual clinical data. This could be an effect on the model's robustness and transferability across different patient populations and histological differences.

Ahmed [9] learned about Artificial Neural Networks (ANNs), which are powerful nonlinear regression techniques have been used in colon cancer survival and classification for more than 45 years. This paper introduces fundamentals of three-layer feedforward ANN with backpropagation, which are used in cancer studies. MAS and colon cancer. In the cases where ANNs were employed in lieu of such statistical or clinicopathological approaches, there has been an overall enhancement of colon cancer classification, and survival prognosis as stated in the following discussions of the literature. Nevertheless, different types of ANNs used in biochemical research have some specific prerequisites in design and reporting to ensure the quality and credibility of obtained data. Nonetheless, the study is limited by the need for large, high-quality datasets and the possibility of over-learning, which could impact the models' generalisability across patient populations and care settings.

Kavitha et al. [10] learned about the automated processes that are essential in identifying Colorectal cancer; especially through endoscopic and histological images. This is important in as much as the enhancement of, clinical decision making and reduction of effort. Modern DL methods are workable in the detection of polyps on images and motion images, and segmentation of the latter. Image patches and CNN integration as well as the pre-processing technique are among the primary AI techniques deployed in the majority of the modern diagnostic colonoscopy stations for invasive malignancy approximation. Features like transfer learning have detached the user from the process and made even small sets yield great results hence highly accurate. Explainable deep networks that offer transparency, interpretability, consistency, and equality in the provision of healthcare are still available despite all the developments. This paper describes the recent advancements in such models and highlights the research limitations when developing technology for the prediction of colorectal cancer. However, there are still some limitations For example, one needs to have vast and diverse amount of data, and non-restrictive protocols to ensure that the model can generalize across diverse patient cases and populations.

Tasnim et al. [11] analysed that advancement in medical and Health care diagnosing has been brought about through advancement ion computer technology. Mentioning that cancer occupies the second place among all causes of death in the world, early detection is crucial for the rate of survival, especially colon cancer, which, despite its relatively high incidence and lethality, is more accessible. This paper focuses on the exploration of CNN with the imaging data of colon cells with the objective of automating cancer detection. The CNN with max pooling layers, average pooling layers, and MobileNetV2 are used in this study. The models with max pooling and average pooling achieve the accuracies of 97. 49% and 95. ResNet and MobileNet achieve mean accuracy of 48%, and 52% respectively, on the other hand MobileNetV2 achieves highest accuracy with 1 % data loss rate. 24%. While the aforementioned outcomes seem promising, the present study is still limited in several ways: the demand for large and high-quality datasets and the challenge of ensuring model robustness across different patients' groups and clinical scenarios.

Babu and Nair [12] investigated an automated detection of colon cancer using histological images which is significant for the highest possible outcome in the treatment. Traditional methods are based on low level features that are selected manually and it might not be accurate. Overall, for this problem, both supervised as well as unsupervised DCNN were applied for assessing of colon cancer histopathology images. Many of the photometric results were rotated and flipped to eliminate class disparity. From the result of the experiments the analyst was able to compare with the previous approach and found that the supervised models such as Inception were able to classify the colon cancer histopathology images with higher accuracy. Yet, a similar autoencoder network was built to extract and cluster the features from these images and to introduce the better clustering ability of the improved autoencoder network for the previously used unsupervised image processing network. Despite these advances, the study still has limitations such as the need for greater big and diverse datasets and the technical challenge of achieving model robustness and transferability across different clinical scenarios.

Schiele et al. [13] presents the Binary ImaGe Colon Metastasis classifier (BIg-CoMet), developed from the InceptionResNetV2 architecture, and operates on histologic images to partition colon cancer patients according to distant metastatic risk. Images of tumor sections stained with cytokeratin were used to train the model, along with image augmentation and dropout, to prevent overfitting. The former was investigated in a validation cohort consisting of 128 patients with BIg-CoMet showing an AUC of 0. 842, thus showing acceptable ability to distinguish between those with the metastases and those without. A marked distinction in the KM plots associated with metastasis-free survival also strongly supports the conclusion that the high-risk subjects, as defined by BIg-CoMet, have a much graver prognosis than do the other patients. This new risk variable portrayed a greater ability to perform as compared to other models with its positive predictive value standing at 80%. It depicted good results for both the subgroups of UICC and particularly for UICC III. As proven in this work, the proposed BIg-CoMet can efficiently sort out MCI or colon cancer patients based on the photographs of tumor architecture. However, the study still has its limitations in that the experiment needs to work with larger and more diverse datasets, and the inherent problem of how to ensure the stability and transferability of the model in different clinical scenarios.

Talukder et al. [14] Suggested a study of a composite feature extraction model for the classification of Lung and colon cancer. Combining deep feature extraction, ensemble learning, and

high-performance filtration techniques, it improves cancer diagnosis. It presented accuracy rates for colon cancer at 100 per cent and for rectal cancer at 99. that for the both cancers were 30 percent, and 99 percent, respectively. The performance was found to be 05% for lung cancer when tested on the LC25000 histopathology datasets. These findings indicate the higher efficiency of the suggested hybrid model compared to the existing approaches, which raises a possibility of its practical application in cancer diagnosis. The study must be validated to ensure the model is not limited to the specific cohort used or specific clinical scenarios.

CNN and hybrid ensemble approaches are examples of the sophisticated cancer detection models that have been created recently and have shown excellent accuracy in detecting lung and colon cancers. Through enhanced feature extraction and image variance management, these models overcome the drawbacks of conventional techniques. They frequently, however, rely on particular datasets, which raises questions over their generalizability across various clinical contexts and patient demographics. In order to address these drawbacks, the suggested approach combines deep learning, multi-scale fusion, and hybrid ensemble feature extraction, with the goal of improving resilience and practicality in real-world clinical settings through the use of diverse and sizable datasets for validation.

Current colon cancer detection techniques are hindered by high false-positive rates, low sensitivity, and variable results, hindering early diagnosis. Conventional CNN-based models are not good at extracting spatial hierarchies in histopathological images and tend to miss important malignant features. Feature selection methods currently used are not effective in reducing dimensionality, resulting in redundant information and computational inefficiencies. Most diagnostic methods that are available are costly, time-consuming, and need specialized skills, making them inaccessible. This research fills these gaps by combining Capsule Networks (CapsNets) with autoencoder-based feature selection, guaranteeing enhanced feature extraction, spatial hierarchy retention, and improved classification accuracy, thus providing a more accurate and economical early detection system.

III. Problem Statement

Cancer continues to be the second greatest cause of death globally, despite significant advancements in science and healthcare over the previous forty years. More over 25% of cases are lung and colon cancers, making them among the deadliest and most common tumors. Even while early diagnosis is stressed as a crucial tactic for raising survival rates, the techniques used today are frequently expensive and time-consuming [15]. There is a desperate need for the development of an automated, precise, as well as economical method to aid in the early detection as well as classification of tissue originating from lung or colon cancer. Consequently, the proposed study aims at alleviating such deficiencies in the prediction of colon cancer through autoencoder-based feature selection and CapSNets. Thus, maintaining spatial hierarchies and detecting detailed patterns, CapsNets enhance the potential of the network to identify the malignant feature that standard CNNs would ignore. The proposed project will try to increase the efficiency of colon cancer detection by the initial preprocessing of data containing autoencoders along with the decrease in the dimensions and extraction of critical features. Such an integration approach will ensure that early detection is more accurate than it is now and; therefore, the outcomes as well as the kind of treatment a patient receives in the future will be well determined.

IV. Enhanced Colon Cancer Prediction Using CapsNets and Autoencoder-Based Feature Selection

Colon cancer is quite prevalent and can be devastating, which emphasizes the significance of early identification and precise diagnosis. Since the condition is generally asymptomatic in its early stages, early detection greatly boosts the odds of effective therapy. Early detection of colon cancer depends on advanced diagnostic models and preventive screening. Efficiently evaluating complicated histopathological images, machine learning techniques like autoencoders and CapsNets might improve the accuracy of colon cancer detection. Permitting early and accurate forecasts, these cutting-edge procedures not only increase survival rates but also lessen the psychological and physical toll on patients and their families. Furthermore, it allows early and tailored therapy to be administered, maybe one that could avoid the disease from moving to more advanced stages. Thus, incorporating such advanced technologies into the system of delivering health care, it might be possible to reduce the costs of medical treatments and improve the quality of the patients' lives due to more efficient and preventive measures. Through analyzing and identifying early signs and risk factors of colon cancer, it is possible to develop creative strategies to predict and treat it, thus stressing the importance of progress in the sphere of technology concerning health care and social security.

Fig. 1 shows a methodical procedure for utilizing histopathology scans to identify lung and colon cancer. The first step of the procedure is Data Collection, during which histological images of colon and lung cancer are acquired. Data pre-processing, which entails improving the quality of the images for analysis by shrinking, normalizing, and reducing noise, comes next. The following stage is called Feature Extraction using Auto-Encoder, in which autoencoders are used to reduce dimensionality and concentrate on important patterns while identifying and extracting the most pertinent features from the pre-processed images. After that, a Capsule Network for Model Deployment is used with these extracted characteristics, taking use of the network's capacity to maintain spatial hierarchies and precisely identify intricate patterns. Ultimately, Performance Evaluation is used to evaluate the model's efficacy and make sure that the predicted accuracy and reliability fulfill the required criteria, which in turn helps with cancer early detection and diagnosis.

A. Data Collection

The Lung and Colon Cancer Histopathological Images collection is used to create and assess cancer detection algorithms as a benchmark and as a review tool. Twenty-five thousand histological photographs, divided into five categories of lung and colon tissue, are included in it. With their 768 by 768 size, these images are perfect for creating machine learning applications. The first dataset comprises 750 verified and

HIPAA-compliant photos, comprising 250 samples of benign lung tissue, 250 samples of lung adenocarcinoma, and 250 samples of lung squamous cell carcinoma. Further, five hundred samples of colon tissue were taken, for which two fifty samples of benign colon tissue were collected and two fifty samples of colon adenocarcinomas were also collected. A new set of 25,000 photos was augmented with the help of the Augmentor program that introduced rotations, flips, zooms, etc., into photos in order to mimic variability and increase the robustness of the prediction models. This was done in a bid make the dataset more interpretable and more diverse. Due to increased augmentation and better resolution of this dataset, it is highly recommended for training and validation of ML models which employ complex approach like Autoencoders and CapsNets. Using this information, the specialists can enhance the performance of methods for cancer identification, hence enhancing the health of patients. The given dataset of lung and colon cancer samples is valuable in the further work on using IT in the fight against cancer due to its well-annotated test examples and the presence of samples of both benign and malignant tumors [16].

B. Pre-Processing

It is common practice to pre-process histopathology images before delivering them to a machine learning model for examination. This entails a number of actions meant to improve the relevancy and quality of the raw photos. This procedure involves denoising as a way of reducing other unnecessary details which may probably hide other characteristics of the model, resizing of the photos to fit the model sizes and normalizing to ensure that pixel intensity levels are constant. Cleansing and normalizing, as well as pattern inclusion and non-biased, enhances the added images into the version and impacts definitely at the prediction algorithms utilized within the identity of such illnesses as lung and colon most cancers.

1) Normalization: One essential pre-processing method for getting histopathology images for ML is normalization. It is changing an images's pixel depth values to a standard scale, typically starting from 0 to 1, or to an average of zero and a general deviation of 1. Through this system, fluctuations in lighting fixtures, contrast, and coloration that can otherwise impair the model's performance are mitigated. Normalization guarantees that the model isn't impacted with the aid of unrelated elements and as a substitute concentrates at the pertinent aspects of the pics via normalizing the pixel values. In medical imaging, where constant image quality is crucial for precise analysis and diagnosis, this phase is especially crucial. Efficient normalization improves the precision and dependability of ML algorithms, resulting in improved lung and colon cancer detection and classification. Usually referred to as min-max normalization, the normalization formula is provided in (1),

$$X' = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (1)$$

Where, the initial value of the pixel is X. The image's minimal pixel value is represented by X_{min}. The maximum pixel value in the image is represented by X_{max}. The normalized pixel value, X', will fall between 0 and 1.

C. Feature Extraction

Feature engineering is defined as data pre-processing to make it useful for the ML process and every business is now aware of the ability of ML to turn raw data into to a set of properties that can be useful in the construction of the model. Feature extraction in the case of histopathological images is about identifying and enhancing the salient features, that is, edges, textures, patterns and shapes that could indicate the presence or progression of the illness. Thereby, simplifying the data so that it can be more easily processed by computer models is the way in which the dimensionality is reduced. Thus, such methods as autoencoders might be applied to compress the image data into a lower-dimensional Latent space that maintains

the most important information. The thorough and precise feature extraction helps in enhancing the viability of the model's diagnosis and speed and its capability to categorize and predict ailments such as cancer of the lungs and colon.

1) Auto encoder: The goal of an autoencoder, a kind of artificial neural network, is to learn effective codings of input data through unsupervised learning. This is accomplished by first reconstructing the output from this representation after encoding the input into a latent-space representation. The encoder and the decoder are the two primary components of the network. The input is compressed by the encoder into a latent-space representation, which is then used by the decoder to recreate the input. Reconstruction error is to be minimized using an autoencoder in order to provide an output that closely resembles the input. This may be expressed quantitatively as reducing the mean squared error (MSE), or loss function L, between the input x and the reconstructed output xˆ in (2),

$$L(x, \hat{x}) = ||x - \hat{x}||^2 \quad (2)$$

The decoder function $x\ \hat{x} = g(h)$ maps the latent representation h back to the reconstructed input $\hat{x}$, whereas the encoder function $h = f(x)$ transfers the input x to the latent space h. The following is a summary of the complete process:

$$h = f(x) = \sigma(Wx + b) \quad (3)$$

$$\hat{x} = g(h) = \acute{o}(\acute{W}h + \acute{b}) \quad (4)$$

In Eq. (3) and (4) the weight matrices are represented by W and $\acute{W}$, the bias vectors by b and $\acute{b}$, and the activation functions by σ and $\acute{o}$. Typically, an autoencoder uses neural networks for both the encoder and the decoder, with training optimizing the weights to minimize the loss function. Autoencoders come in several designs, such as variational autoencoders (VAEs), denoising autoencoders, and sparse autoencoders, each intended for a particular use. Penalizing activations inside the hidden layers, sparse autoencoders ensure that the network learns more meaningful features by imposing sparsity restrictions on the latent space representation. This may be accomplished by including a regularization term that promotes sparsity in the loss function by (5),

$$L(x, \hat{x}) + \lambda \sum_i ||h_i||1 \quad (5)$$

Autoencoders with denoising competencies are made to address noisy information. To growth the resilience of the model, they're taught to recreate the authentic enter from a corrupted model of it. By first adding noise to the input records after which minimizing the loss characteristic between the easy enter and the output that become reconstructed from the noisy input, that is accomplished by way of (6),

$$L(x, \hat{x}) = ||x - \hat{x}_{noisy}||^2 \quad (6)$$

Fractional autoencoders (VAEs) are autoencoders with a probabilistic twist that makes them suitable for new data models. During training, a hidden signal is taken from this distribution, and the encoder outputs the parameters (mean and variance) of this distribution. Reconstruction loss along with a regularization term (KL deviation) that ensures that the reserved area distribution approximates all former distributions in the standard normal distribution of (7), forms the loss function in terms of VAEs

$$L(x, \hat{x}) = ||x - \hat{x}||^2 + KL(q(z|x)||p(z)) \quad (7)$$

In machine learning and data science, autoencoders are a vital tool because they can recognize useful representations of incoming data, facilitating streamlined and computationally efficient analysis. They are widely used for various tasks such as dimensionality reduction, anomaly detection, and generative modeling. In medical imaging, for example, it is used to extract key features from complex data, helping in tasks such as diagnosis and image reconstruction.
