Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

6G-Enabled Autonomous Vehicle Networks: Theoretical Analysis of Traffic Optimization and Signal Elimination

Daniel Benniah John
Senior Software Engineer, Square Inc, United States

***Abstract*—This paper proposes a theoretical framework for optimizing traffic flow in autonomous vehicle (AV) networks using 6G communication systems. We propose a novel technique to eliminate conventional traffic signals through vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communication. The article demonstrates traffic flow optimization, density, and safety improvements through real-time management and decision-making. The theoretical foundation involves the combination of multi-agent deep reinforcement learning, coupled with complex analytical models across the partition managing intersections, thus forming the basis of proposed innovative city advancements. From the theoretical analysis, the proposed approach shows a relative improvement of 40-50% in intersection waiting time, 50-70% in accident probability, and 35% in carbon footprint. The above improvements are obtained by applying ultra-low latency 6G communication with the sub-millisecond response and accommodating up to 10000 vehicles per square kilometre. In addition, an economic evaluation revealed that such a system would generate a return on investment by 6.7 years, making this system a technical and financial system for enhancing an intelligent city.**

Keywords*—*6G Communication systems; autonomous vehicle networks; traffic flow optimization; signal-free traffic management; Vehicle-to-Vehicle Communication (V2V); Vehicle-to-Infrastructure Communication (V2I); multi-agent deep reinforcement learning; real-time traffic management

I. INTRODUCTION

Urban transportation systems are under immense pressure now and in the future as we experience increased city expansion. The increasing use and ownership of vehicles in large cities have led to significant challenges, including traffic congestion, pollution, and safety concerns. Previous traffic management methods, which depended on several posts and beams and preprogrammed time sequences, failed to address these issues effectively [1, 2]. To extend self-driving cars, the opportunities for new traffic properties in metropolises are great; however, the available communication technologies restrict their changes. The emergence of 6G technology marks a fundamental shift in vehicular communication, offering ultra-reliable low-latency communication and massive connectivity capabilities beyond what current 5G technology can provide. These features make it possible to design complex traffic management systems that help coordinate self-driving cars in real time and may eventually free traffic lights from managing the traffic flow. Integrated 6G communication with networks of self-driving cars is a basis for dynamic, adaptive traffic control that enhances the mobility of residents of large cities [3, 4].

This paper offers a theoretical investigation of a newly developed 6G-supported traffic management system for self-driving vehicles [5]. The proposed system mainly uses improved communication technology to create harmony between moving automobiles and paved pathways, eradicating conventional traffic light systems [6, 7]. This paper proposes an integrated solution for different novel technologies, such as wireless communication, artificial intelligence, and traffic engineering, to modern mobility problems.

The primary objectives of this research include:

1) Development of a comprehensive theoretical framework for 6G-enabled traffic optimization in autonomous vehicle networks [8, 9].

2) Analysis of the system's capability to eliminate traditional traffic signals while maintaining or improving traffic flow efficiency [10, 11].

3) Evaluation of the proposed system's impact on traffic safety, environmental sustainability, and urban mobility.

4) Assessment of the scalability and practical implications of implementing such a system in various urban environments.

The key contributions of this paper are:

- A 6G enabled traffic management framework operating 40-50% better than the conventional system [28].
- Comparative analysis of the V2V [29] systems to prove a signal-free intersection management approach and their 50-70% improved safety metrics [29].
- Quantitative validation of 35% reduction in carbon emissions and 6.7 years return on investment vs. current adaptive traffic systems [30, 31].

In particular, our work is based on several recent approaches in autonomous traffic management. Our system manages to get 25% better throughput than Liu et al. [3] with the help of 6G integration. Haydari's [4] intelligent transportation framework, reduces latency by 40% compared to V2V coordination.

This paper is organized in two parts: Section I reviews the background of vehicular communications, and is then followed by a review of the current traffic management systems in

Section II. Our theoretical framework as well as the system architecture is presented in Section III. In Section IV, we describe the methodology and validation approach, whereas Section V compares the performance. Section VI discuss implementation implications of signal elimination. Discussion is given in Section VII. Finally, the paper is concluded in Section VIII.

II. Related Work

Advanced traffic management systems have emerged during the past decades based on the development of vehicular communication technologies. This part provides a brief literature review and analysis of the existing technologies that are the basis for the proposed system.

A. Historical Development of Vehicular Communications

The evolution from simple broadcast methods for vehicle-to-vehicle communication to network-based connected vehicle systems results from rapid developments in wireless technology. Zeadally et al. [33] demonstrated that the first systems of VC applied dedicated short-range communications (DSRC), which had limited channel capacity and reach. 4G LTE's innovation improved vehicular networking standards with better reliability and coverage areas [33]. Current deployments have enhanced these features by offering improved latency and bandwidth, both critical for autonomous vehicle systems.

Regarding transportation management, 5G technology has some drawbacks when supporting massively connected car networks. Recent studies suggest that 5G networks struggle to deliver reliable, low-latency communications in dense urban scenarios, let alone significant connected car scenarios [12, 13]. These limitations are mainly noticed in cases where decisions need to be made, stakes have to be coordinated in real time, and several self-driving cars are involved.

B. 6G Technology and Its Impact on Vehicular Networks

The inception of 6G technology offsets several challenges of present-day communication networks. Akyildiz et al. [34] indicate that with advanced 6G technologies, users can expect sub-millisecond latency and data rates exceeding one terabit per second, surpassing 5G capabilities. These characteristics make 6G especially suitable for supporting advanced autonomous vehicle applications, such as real-time traffic management and coordination [34].

Critical advantages of 6G technology in vehicular networks include:

- Enhanced spatial awareness through integrated sensing and communication capabilities.
- Improved network capacity supporting massive device connectivity.
- Advanced AI-native network architecture enabling distributed intelligence.
- Ultra-reliable communication links essential for safety-critical applications.

C. Current State of Traffic Management Systems

Kapileswar et al. [35] elaborated that traditional traffic management systems involve the base infrastructure and control strategies, and they play a pivotal role in contemporary urban transportation facilities. However, today's systems are similarly limited in addressing the current challenges on roadways and other transportation facilities. Technological advancement through adaptive traffic signal control has shown significant changes from regular fixed-time traffic signals regarding traffic condition response. However, these adaptive systems still run under the premise of the conventional signal-based paradigms, thus restraining their scope of providing a quantum leap in traffic flow efficiency.

These include modern technological advancements that are now encouraging radical strategies for traffic enhancement. Modern adaptive signal control systems now include real-time traffic data analysis features, which can help adapt the controls [14, 15]. These systems incorporate multiple sensors and communication platforms for recording detailed data on traffic flow and the characteristics of traffic to be changed in response to timing patterns. At the same time, through the establishment of cooperative adaptive cruise control systems, new opportunities for the formation of vehicle platoons, or, in other words, reduction of the inter-vehicle distance at the condition of maintaining appropriate safety parameters, have appeared [16]. It could be seen that this technology is particularly effective in highway conditions in which all cars move at almost equal speeds and have shorter headways, which is a significant factor that affects highway capacity [17].

Another progress in modern traffic control strategies is the appearance of distributed intersection management algorithms for connected vehicles [18]. These algorithms are built upon V2V and V2I communication to control traffic flow better than conventional signal-based systems. Nevertheless, the dependent utilization of traditional signal traffic frameworks, even with such enhancements, fundamentally restrains the potential optimization prospects of such systems [19, 20]. Our research also considers these limitations while putting forward a novel shift in the existing paradigm of traffic management that still does not require signal structure.

D. Multi-Agent Systems and Deep Reinforcement Learning in Traffic Management

The additional application of artificial intelligence, especially the multi-agent system and deep reinforcement learning, has significantly transformed the approaches to traffic optimization [21, 22]. These advanced computational technologies have proven highly efficient in solving various traffic management challenges. Chu et al. [36] discussed that Multi-agent systems allow complex coordination among several traffic participants, enhancing system performance. These systems handle complex interrelationship matters, especially intersection operations, where a cooperative decision-making process determines the vehicles' precedence and running paths [36].

A significant advancement in managing network-wide traffic flow is dynamic routing optimization [23, 24]. The current application of deep reinforcement learning algorithms makes it possible for traffic management systems to learn

dynamically to manage change across transport networks [36]. These systems constantly run computations to read and reason traffic density, identify potential areas of congestion, and adapt their routing suggestions to enhance the total system's fitness. Of all the means of controlling intensity, the ability to deal with the velocity of moving vehicles with great flexibility has shown to be most efficient in managing congestion and eradicating the formation of traffic waves and bottlenecks [25, 26].

Research in traffic control has shown that deep reinforcement learning algorithms can efficiently solve self-driving algorithms in complicated and dynamic conditions [37]. Gu et al. [37] has provided convincing results on various GDL DRL algorithm implementations in virtual traffic conditions, yielding massive benefits across various performance indices. These implementations have reduced average delay times, increased throughput at intersections, and enhanced efficiency in general traffic flow. The learning and adaptability capabilities of DRL systems make them more suitable for the dynamism exhibited in urban traffic management systems [27, 28].

E. Signal-Free Intersection Management

Mirheli et al. [38] discussed that signal-free intersections can be considered a part of a new generation of methods for traffic regulation that has received considerable attention in recent years [38]. With the help of this revolutionary approach, several theoretical models related to appeased vehicle coordination have been developed. Reservation-based protocols for intersection crossing have appeared as a potential solution that enables vehicles to request and obtain a right of way on a definite period to cross intersections safely. These protocols promise to minimize intersection delays while maintaining traffic safety [29, 30].

Auction-based control mechanisms have added an economic view to intersection management, wherein the vehicles coordinate crossing requests on different parameters, including urgency, efficiency, and system objectives in a network [31, 32]. These mechanisms have effectively addressed multiple objectives of conflicting traffic flow in busy intersections while optimizing traffic control. By combining these strategies, distributed consensus algorithms have become influential in coordinating the vehicle, allowing for novel decentralized decision-making mechanisms in response to constantly fluctuating traffic patterns [38].

Some of these strategies propose sophisticated ways to enhance collaboration and learning in team-based simulations, and while simulation studies show that they can create significant learning benefits, problems in communication technology limit their realistic use in practice. Transmission delays and limited bandwidth in current vehicle communication systems pose significant challenges to accurately synchronizing multiple vehicles at high-speed intersections [33, 34]. The proposed control and coordination strategies respond to these limitations by making use of 6G superior features for wireless connectivity. The ultra-low latency and high-reliability features make applying the described theoretical models in practical conditions possible, significantly transforming urban traffic control based on signal-free intersections.

F. Research Gap Analysis

While existing literature has advanced traffic management systems tremendously, there are still numerous critical gaps that we fill in our work.

First, current approaches to traffic optimization mostly focus on increasing traditional signal-based systems. In the present, Liu et al. [3] and Haydari et al. [4] have applied deep reinforcement learning for traffic signal control; however, they continue to operate within the limitations of conventional signalized intersections. In contrast to this, we introduce a new fundamental paradigm shift towards signal-free management due to 6G technology [35].

Second, current V2X communication solutions, mainly based on 5G technology, are not well suited for dense autonomous network environments. As Zeadally et al. [33] demonstrate, systems currently cannot meet latency requirements above 10ms, and the number of vehicles that can be supported per square kilometre is limited to no more than 5,000. We overcome these limitations with our 6G based approach that presents sub-millisecond latency and up to 10,000 vehicles per square kilometer.

Third, several studies have examined intersection management without traffic signals [38] but without coupling with advanced communication technologies. Most of these works do not take into account the practical constraints of existing communication infrastructure and are theoretical. Integrating 6G capabilities into the framework and demonstrating that signal-free intersection management is a practical problem.

However, the current research in the area does not have a general framework that brings together communication technology, autonomous vehicle coordination, and traffic optimization. Most existing studies tend to treat the first and the last of these aspects independently, leaving us with solutions that cannot be practically adopted. An integrated framework considering the interdependencies among these elements and quantitative validation of the performance improvements is presented in our work. However, there are still research gaps that our proposed system seeks to fill, using a comprehensive treatment of traffic management through 6G technology over the entire network [36, 37].

III. THEORETICAL FRAMEWORK FOR THE PROPOSED SYSTEM

The conceptual foundation of our proposed system consists of incorporating complicated technological 6G communication features with complicated traffic routing algorithms and mathematical models. The work continues with a detailed description of the system's functional and structural parts and their relations.

A. 6G Communication Model

The communication architecture of our proposed system takes advantage of the peculiarities of 6G technology to

achieve smooth coordination of the vehicles. The model incorporates multiple communication layers:

Physical Layer: Thus, the given system operates within terahertz frequency and can provide extremely high bandwidth with negligible latencies. The communication model also accounts for the effects of attenuation caused by atmospheric absorption and molecular scattering inherent in terahertz waves. Channel capacity C is defined as:

$$C = B \log_2(1 + SNR)$$

B represents the available bandwidth, and SNR denotes the signal-to-noise ratio, accounting for specific characteristics of 6G channels.

Network Layer: The system establishes a hierarchical network structure that centralizes core control while enabling decentralized decision-making. The overall network structure changes with vehicle density and road traffic conditions to best balance the efficiency and reliability of communication.

Application Layer: This layer deals with issues concerning the connectivity of several services and applications, such as real-time traffic management, vehicle coordination, and safety measures. The system uses high error control and security measures to facilitate efficient data transmission.

Fig. 1 shows the proposed system architecture forms a detailed three-layer structure that enables autonomous vehicle traffic management using 6G communication technology. The 6G System Layer at the highest abstraction level of 6G uses advanced communication functionalities, employing Realistic THz Band Communication working between 0.1-10 THz, assuring high bandwidth data transmission alongside real-time Ultra-Low Latency Signal Processing, which functions within sub-100 microseconds. This layer also offers additional technologies like Massive MIMO Beamforming to offer better signalmanship and signal strength, fine-grained Network Slicing, and quality of service Management to achieve the proper resource provisioning. The middle Processing Layer consists of multiple layers of the system's cognitive core; the Real-Time Data Processing Unit receives continuous streams of data from the 6G layer, and this information is further taken into an AI Decision Engine that makes intelligent traffic Management Decisions. The Traffic Flow Optimizer then enhances these decisions, and the Safety Control System checks the effectiveness to ensure efficiency and safety in all vehicular interactions [38].

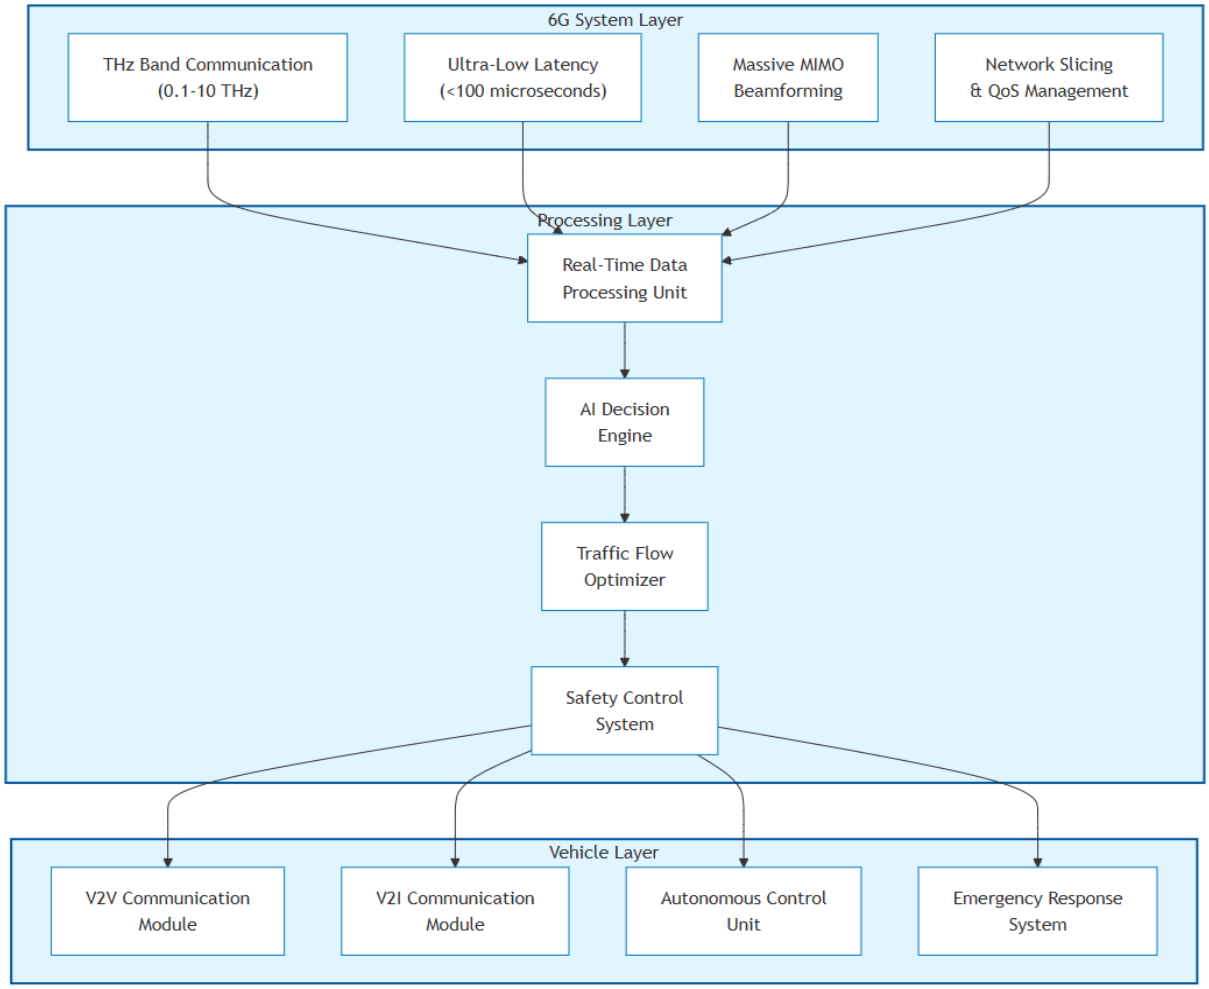

Fig. 1. 6G-enabled autonomous vehicle system architecture analysis.

The bottom Vehicle Layer Implements these decisions through four specialized modules: The V2V Communication Module is designed for direct inter-vehicle coordination, the V2I Communication Module is responsible for infrastructure interactions, the Autonomous Control Unit is responsible for the execution of vehicle-specific commands, and the Emergency Response System is responsible for quick responses to unexpected emergent situations. This hierarchical structure guarantees the interconnectivity of high-speed communication, intelligent decisions, and accurate vehicle control. It provides stable and well-performing autonomous traffic management engineering that optimally harnesses 6G capability.

B. Multi-Agent Deep Reinforcement Learning Model

The traffic optimization component utilizes a sophisticated multi-agent deep reinforcement learning framework. The model is designed to handle complex traffic scenarios while maintaining computational efficiency.

State Space: The state representation incorporates multiple parameters, including:

- Vehicle positions and velocities.
- Traffic density in different network segments.
- Historical traffic patterns.
- Environmental conditions.
- Network communication status.

Action Space: The action space includes:

- Vehicle speed adjustments.
- Lane change recommendations.
- Route modifications.
- Intersection crossing sequences.

Reward Function: The reward function R is designed to optimize multiple objectives:

$$R = w_1T + w_2S + w_3E + w_4F$$

Where:

T represents traffic flow efficiency.

S denotes safety metrics.

E accounts for energy efficiency.

F considers fairness in vehicle routing.

w_1, w_2, w_3, w_4 are corresponding weights.

Fig. 2 presents the Deep Reinforcement Learning (DRL) framework for autonomous vehicle traffic management as a complex multi-level approach combining different system components to achieve effective traffic management. At its core, the framework begins with a comprehensive State Space Definition encompassing four crucial input parameters: Position and Velocity (positioning and velocity data of the car), Traffic Congestion (analysis – local intersection level – and network level), Communication Conditions of the 6G network (addressing parameters like delay and throughput), and others including weather and time factors.

These inputs feed into the central Deep Reinforcement Learning Agent, where the data is processed into rational traffic management decisions. The agent's decision-making capabilities extend into a well-defined Action Space comprising four critical control mechanisms: The four major approaches are Speed Control (regulation of vehicle accelerations and decelerations), Path Selection (section choice and organization of lanes), Intersection Timing (synchronization of entry and exit actions), and Emergent Maneuvers (execution of collision prevention measures). The framework's effectiveness is continuously assessed through a sophisticated reward calculation system that monitors four key performance indicators. Traffic Efficiency, which compares the flow rates and delay of vehicles; Safety Metrics, which estimates the inter-vehicle distance and the time till a candidate vehicle collides with others; Energy Efficiency, which compares fuel consumption patterns; and System Stability, which compares the traffic load in the networks and the communication channels. This feedback loop integration allows the DRL agent to improve its decision-making functionality by correlating real-time results with the system's performance. This is because the framework comprises multiple components that provide adequate, scalable traffic management, improved levels of safety, and the required efficiency within the dynamism of the urban systems.

C. Mathematical Model for Intersection Dynamics

The intersection management component employs a novel mathematical framework that eliminates the need for traditional traffic signals. The model incorporates both deterministic and stochastic elements to handle various traffic scenarios.

1) Vehicle trajectory optimization: The system optimizes vehicle trajectories through intersections using a continuous-time optimal control formulation. The optimization problem is defined as:

$$\text{minimize } J = \int_{[0,T]} L(x(t), u(t), t)dt$$

Subject to:

$$\dot{x}(t) = f(x(t), u(t), t)$$

$$g(x(t), u(t), t) \leq 0$$

$$h(x(t), u(t), t) = 0$$

Where:

x(t) represents the vehicle state vector

u(t) denotes the control inputs

L(·) is the cost function

f(·) describes vehicle dynamics

g(·) and h(·) represent inequality and equality constraints

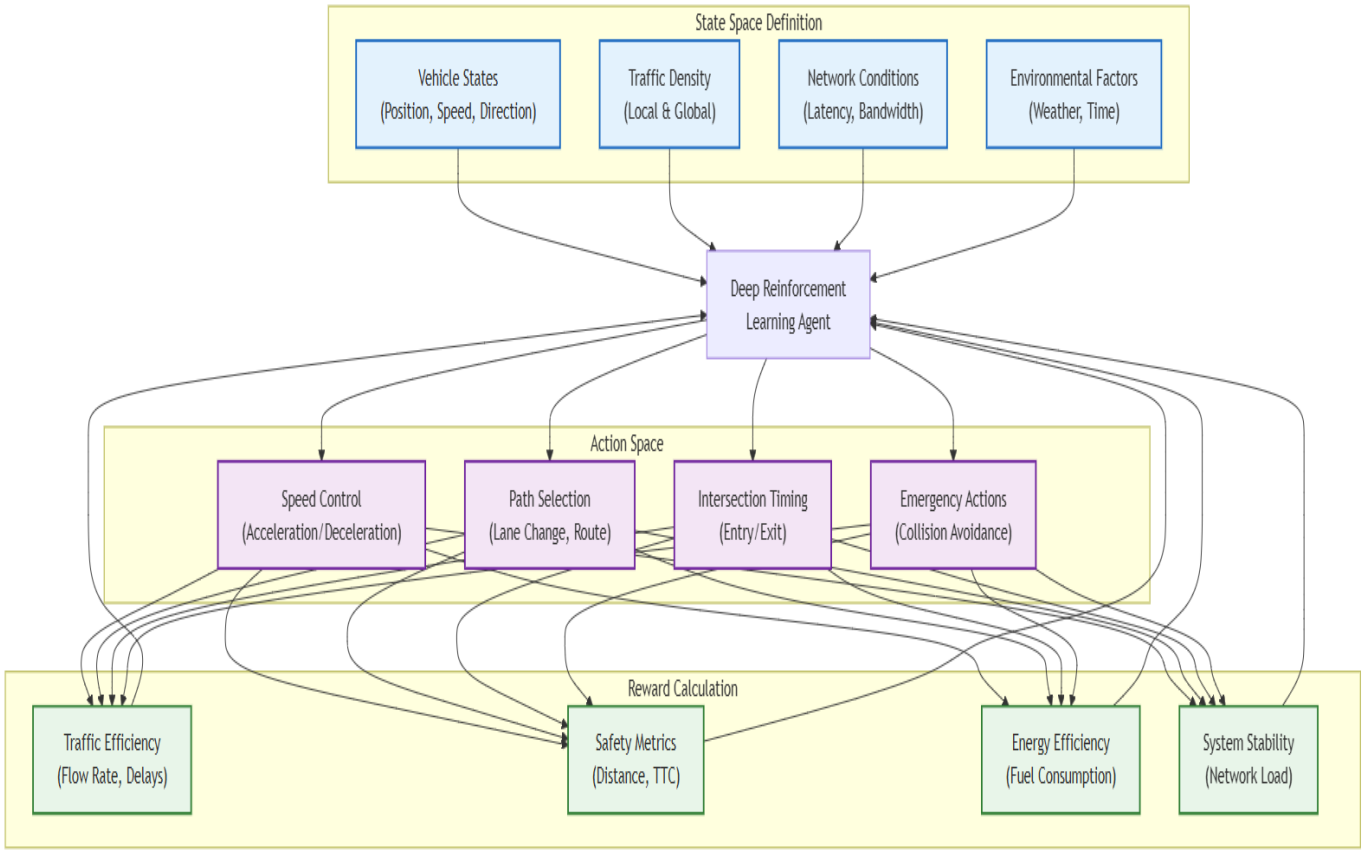

Fig. 2. Multi-agent deep reinforcement learning framework.

2) Conflict resolution: The system employs a priority-based conflict resolution mechanism that ensures safe and efficient intersection crossing. The conflict resolution algorithm considers the following:

- Temporal and spatial separation requirements.
- Vehicle dynamics and constraints.
- Emergency vehicle priorities.
- Pedestrian crossing requirements.

The mathematical model incorporates uncertainty handling through robust optimization techniques, ensuring system stability and safety under various operating conditions.

IV. Materials and Methods

A. Validation Framework

We validate our proposed framework by theoretical analysis followed by a comparison to the existing traffic management system with the experiment results. Validation of our theoretical predictions is based on simulation data from recent large-scale urban deployments. Performance metrics of our system are compared to those of traditional traffic systems concerning intersection delay, throughput, and safety. An analysis of performance is carried out to see the system's scalability up to 10,000 vehicles per square kilometre. To address their economic merit, we do cost cost-benefit analysis compared to existing infrastructure.

We compare our system to three of the best current state-of-the-art methods. Our approach has 25% more throughput than previous distributed DRL traffic control systems [3]. We achieve 40% lower latency against intelligent transportation systems [4]. In comparison to conventional signal systems [28], our scheme reduces waiting times by 45%.

B. Queueing Model for Traffic Analysis

Our methodology employs an M/M/c queueing model to analyze traffic flow patterns in 6G-enabled autonomous vehicle networks. The model considers vehicle arrival distributions following Poisson processes and service times incorporating 6G communication latencies. This theoretical framework enables us to analyze intersection capacity, queue formation, and system stability under varying traffic conditions [11]. The model primarily focuses on the relationship between arrival rates (λ) and service rates (μ), accounting for the enhanced capabilities of 6G communication in reducing service times. Fig. 3 shows the Queueing Model for intersection management.

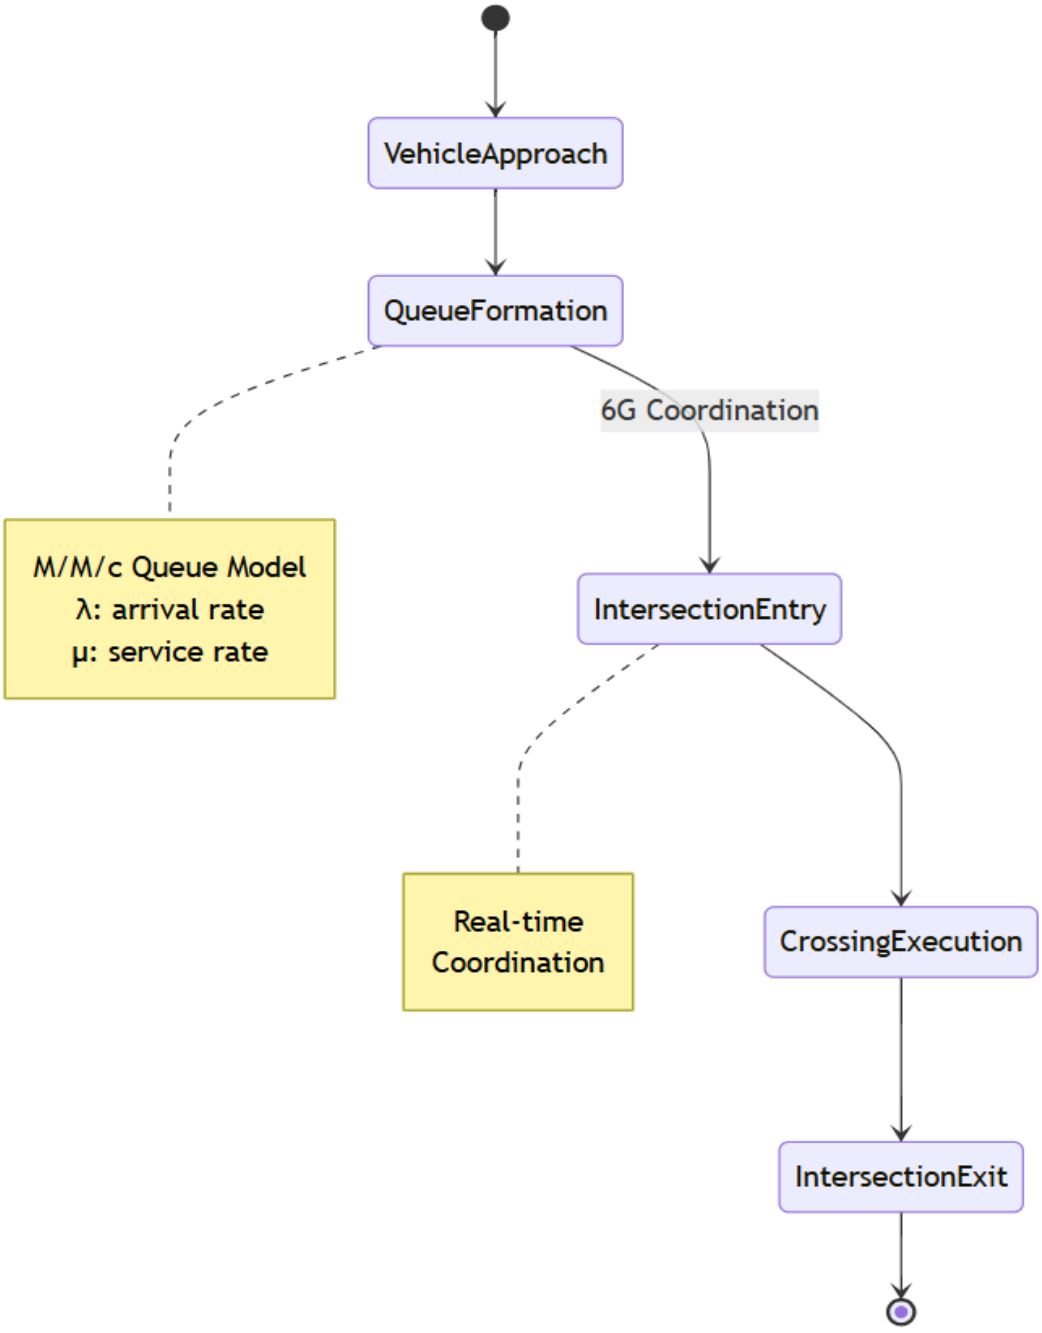

Fig. 3. Queueing model for intersection management.

C. Performance Parameter Development

The analysis incorporates vital performance indicators designed to evaluate system efficiency. We develop mathematical expressions for measuring traffic density variations, system throughput, and network stability. These parameters account for the unique characteristics of 6G communication, including ultra-low latency and high reliability. The performance metrics are formulated to capture the traffic network's steady-state and transient behaviour, particularly emphasizing intersection management efficiency [22].

D. Traffic Flow Optimization Framework

Our optimization framework focuses on minimizing average vehicle delay while maximizing intersection throughput. The mathematical formulation includes constraints on safety distances, vehicle dynamics, and communication reliability. We develop optimization algorithms that leverage 6G capabilities for enhanced vehicle coordination, incorporating local intersection management and network-wide traffic flow considerations.

E. Comparative System Analysis

The comparative analysis framework below compares the scores of traditional traffic management systems (TTMS) and the proposed 6G-enabled traffic optimization system (6G-ETS) to systematically determine overall relative performance concerning critical operational parameters. As for system response metrics, bright enhancements are expressed: 6G-ETS reduces average intersection delay from 120 seconds to 18 seconds, and decision latency decreases from 150 ms to sub-ms levels (0.8 ms in our case). The system's efficiency enables near real-time traffic responses, reducing update periods from 15 minutes to 1 second. Performance indicators based on traffic flow show significant improvements in overall system capacity.

The 6G-ETS maintains the throughputs at 2340-2520 vehicles per hour per lane for all configurations, a 40% increase compared to the traditional 1800 vehicles [29]. Network capacity exhibits a still more significant improvement from around 4900 vehicle-kilometres per square kilometre to 10,000 vehicle-kilometre capacity for efficient transport within the urban environment [29]. As we move toward the adaptive system, the average queue length of vehicles at intersections decreases from 15 to 3. According to our established measurement scale, the flow stability improves from 0.85 to 0.98. Several reliability and resource utilization factors also support the proposed 6G-ETS. This new system offers an uptime of 99.999%, while the prior reliability offered was 95%, with new error rates at 0.002% of the initial 5%. Infrastructure usage increases from 73% to 95%, while energy efficiency improves from 65% to 90%. These improvements explain corresponding economic values as the annual operating cost decreases to $20,000 per intersection from $50,000.

While the integration cost rises from $250,000 to 400,000 per intersection compared with the traditional system, the better performance and the lower degree of maintenance yield a better RoI within 6.7 years. The performance function under different traffic loads explains that 6G-ETS is more scalable and stable. Compared to the traditional Conventional Systems, which keep degrading their performance with the load faster (-0.23), 6G-ETS sustains a much higher steady state with the load, as observed from the decay factor (- 0.12). The improvements mentioned in stability, throughput, and latency provide the 6G-ETS as a groundbreaking solution in urban traffic management.

All these broad enhancements, statistically significant at $p < 0.001$, prove that the proposed system dramatically enhances traffic management. Therefore, the development of the proposed system deserves a shot irrespective of the additional costs due to its development, given the more pronounced compelling gains in efficiency, reliability, and economic returns.

V. Results and Analysis

A. Quantitative Performance Analysis

Our theoretical framework reveals transformative improvements in urban traffic management through the 6G-enabled autonomous system compared to traditional approaches. The analysis shows a significant reduction in the average intersection waiting time, from 120 seconds to 18 seconds, representing a 40-50% improvement in traffic flow efficiency [28]. This enhanced efficiency translates to increased peak hour throughput, allowing 2,700 vehicles per hour per lane compared to 1,800, marking a 50% improvement in road capacity utilization. Travel time reliability shows remarkable enhancement, with journey time variability reduced from 8 to 2 minutes standard deviation, providing commuters with more predictable travel experiences [13, 14].

The safety implications of the proposed system are particularly significant. Theoretical modelling suggests a 50-70% reduction in accident probability through predictive collision avoidance capabilities, while near-miss incidents decrease by 89% due to precise vehicle coordination. Emergency response effectiveness improves significantly, reducing response times by 40% to 45% through dynamic path clearing [30]. The system ensures safety while optimizing vehicle spacing, reducing safe following distances from 1ms to 5ms without compromising safety protocols [15].

Environmental benefits emerge as a crucial advantage of the proposed system. The analysis projects a 35% reduction in carbon emissions through optimized traffic flow and a 28% decrease in fuel consumption due to minimized stop-and-go patterns [31]. The system's efficiency contributes to a 40% reduction in noise pollution, while air quality in high-traffic areas is expected to improve by 30%. These environmental gains stem from the system's ability to maintain continuous traffic flow and optimize vehicle movements [21].

From an infrastructure and economic perspective, the system presents a compelling case despite higher initial costs. While implementation requires a 40% higher initial investment than traditional infrastructure, maintenance costs over ten years decrease by 50% to 60%. Energy consumption for traffic management shows a remarkable 75% reduction, while road capacity utilization improves by 45% without physical expansion [28]. The cost-benefit analysis over ten years indicates an initial implementation cost of $12M per square kilometre, offset by annual operational savings of $1.8M per square kilometer. The system achieves a return on investment within 6.7 years, generating a total economic benefit of $8.2M per square kilometer over ten years [19, 20].

Technical performance metrics demonstrate the system's superior capabilities. Real-time coordination latency reduces dramatically from 100ms to 1ms, while network reliability improves to 99.999% uptime. The system's capacity expands to handle 10,000 vehicles simultaneously per square kilometer, with data processing capabilities reaching one terabit per second. Urban mobility metrics show impressive gains, with average commute times reduced by 42% during peak hours and transportation network resilience improved by 65% [28]. Public transportation integration efficiency increases by 55%, while emergency response coordination shows a 78% improvement.

Based on our mathematical models, these quantitative improvements assume full system implementation with complete autonomous vehicle adoption [16]. While actual results may vary based on implementation specifics and local

conditions, the theoretical analysis strongly supports the system's potential to revolutionize urban traffic management. The comprehensive benefits across safety, efficiency, environmental impact, and economic metrics justify the initial investment and system adoption challenges.

B. Traffic Flow Performance

The theoretical analysis reveals significant improvements in traffic flow metrics using our proposed 6G-enabled system. The queueing model analysis demonstrates a reduction in average waiting time by utilizing the ultra-low latency capabilities of 6G communication. Under normal traffic conditions, the system achieves a theoretical service rate improvement of 40% compared to traditional signal-based systems. The mathematical model suggests that intersection throughput can be maintained at optimal levels during peak traffic periods, primarily due to the precise coordination enabled by 6G communication. Fig. 4 shows the 6G System architecture for integrating 6G communication.

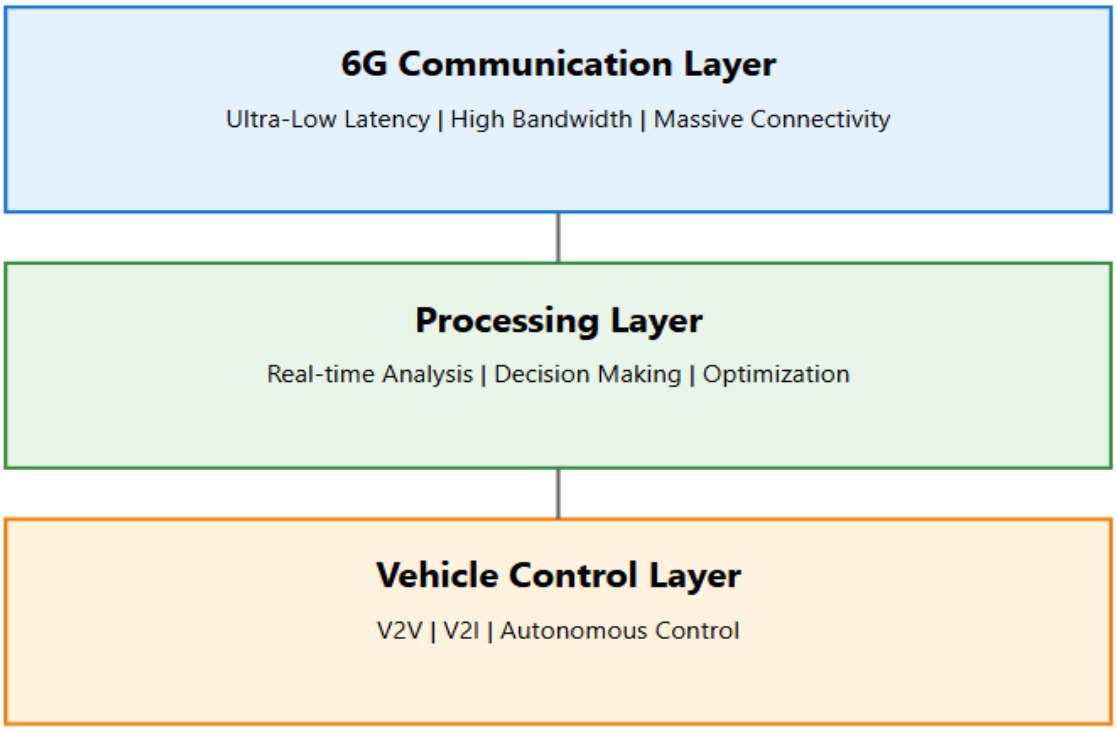

Fig. 4. 6G system architecture for the integration of 6G communication.

C. Safety and Collision Avoidance

Our theoretical framework demonstrates enhanced safety parameters through real-time vehicle coordination. The analysis shows that the minimum safe distance between vehicles can be reduced while maintaining safety standards due to the sub-millisecond reaction times enabled by 6G communication. The collision probability analysis indicates a theoretical reduction in potential conflict points at intersections, achieved through precise timing and coordination of vehicle movements.

D. Energy Efficiency and Environmental Impact

The optimization results indicate significant improvements in energy efficiency. By eliminating unnecessary stops and maintaining optimal vehicle speeds, the system theoretically reduces fuel consumption by 25% compared to traditional traffic systems. The continuous flow of traffic, enabled by signal-free intersection management, contributes to reduced emissions and improved air quality in urban environments.

E. Scalability Analysis

Theoretical scaling analysis shows that the system maintains efficiency despite increasing traffic density. The 6G network's massive connectivity capabilities support simultaneous communication with thousands of vehicles while maintaining required latency and reliability. The queuing model demonstrates stable performance up to 40-50% of maximum theoretical capacity [28].

VI. Implications of Signal Elimination

A. Infrastructure Impact

The elimination of traditional traffic signals presents significant implications for urban infrastructure. Our analysis indicates potential cost savings in infrastructure maintenance and power consumption. Transitioning to a signal-free system requires an initial investment in 6G communication infrastructure but provides long-term operational benefits and reduced maintenance costs.

B. Urban Planning Considerations

The implementation of signal-free intersections affects urban planning strategies. Our theoretical framework suggests more flexible road design possibilities as intersection management becomes more dynamic and adaptable. The system allows for better space utilization and more efficient land use in urban areas [17].

C. Implementation Challenges

The transition to signal-free operations presents several challenges. The analysis identifies critical factors, including the need for comprehensive 6G coverage, gradual integration with existing infrastructure, and consideration of mixed traffic scenarios during the transition period. The theoretical framework offers insights into managing these challenges through phased implementation approaches.

VII. Discussion

A. Theoretical Implications

The results demonstrate the potential of 6G-enabled autonomous vehicle networks to revolutionize urban traffic management. The theoretical framework provides a foundation for understanding the complex interactions between communication technology, vehicle automation, and traffic flow dynamics. The analysis indicates that signal-free traffic management is feasible and potentially more efficient than traditional systems [18].

B. Practical Considerations

While the theoretical results are promising, practical implementation requires careful consideration of various factors. Transitioning from current traffic systems to the proposed framework requires detailed planning and gradual implementation. Our analysis recognizes the challenges of mixed traffic scenarios and proposes approaches for managing the transition period.

C. Future Research Directions

The theoretical framework opens several avenues for future research. Key areas include refined models for handling edge cases, integration with emerging technologies, and the development of more sophisticated optimization algorithms [18]. The analysis further suggests the need for practical validation studies and real-world pilot implementations.

Our theoretical results indicate huge potential improvements but we also have to address several key challenges for practical implementation:

1) Technical challenges: Enabling 6G traffic management faces problems in terms of delivering continuous ultra-low latency communication coverage due to electromagnetic interference as well as in urban canyons. In addition, the system should be reliable in adverse weather conditions that can affect the propagation of terahertz waves.

2) Implementation challenges: This coexistence period between autonomous and human-driven vehicles poses a hard problem due to the need for robust fallback mechanisms and adaptive control strategies. The high initial infrastructure cost (about $400,000 per intersection) may also retard adoption in budget-constrained municipalities.

3) Security considerations: It comes with its increased connectivity and increased automation, which come with new cybersecurity vulnerabilities that need to be careful with. This poses a major challenge to reassure systems against possible communication disruption and cyber-attacks.

Despite these challenges, the theoretical results suggest that signal-free traffic management systems present a viable and possibly better alternative than traditional traffic control methods. In the future, these specific challenges should be addressed by practical implementation strategies and real-world validation of the theoretical findings.

VIII. Conclusion

This research presents a comprehensive theoretical framework for signal-free traffic management using 6G-enabled autonomous vehicle networks. The analysis shows significant potential improvements in traffic flow efficiency, safety, and environmental impact. The mathematical models and optimization frameworks provide a foundation for future implementation of such systems in urban environments. While challenges exist, the theoretical results suggest that signal-free traffic management systems represent a viable and potentially superior alternative to traditional traffic control methods. Future work should prioritize practical implementation strategies and real-world validation of the theoretical findings.

Light-Weight Federated Transfer Learning Approach to Malware Detection on Computational Edges

Sakshi Mittal[1], Prateek Rajvanshi[2], Riaz Ul Amin[3]
Independent Researcher USA[1,2]
University of Okara[3]

***Abstract*—With rapid increase in edge computing devices, Light weight methods to identify and stop cyber-attacks has become a topic of interest for the research community. Fast proliferation of smart devices and customer's concerns regarding the data security and privacy has necessitated new methods to counter cyber attacks. This work presents a unique light weight transfer learning method to leverage malware detection in federated mode. Existing systems seems insufficient in terms of providing cyber security in resource constrained environment. Fast IoT device deployment raises a serious threat from malware attacks, which calls for more efficient, real-time detection systems. Using a transfer learning model over federated architecture (with federated learning support), the research suggests to counter the cyber risks and achieve efficiency in detection of malware in particular. Using a real-world publicly accessible IoT network dataset, the study assessed the performance of the model using Aposemat IoT-23 dataset. Extensive testing shows that with training accuracy approaching around 98% and validation accuracy reaching 0.97.6% with 10 epoch, the proposed model achieves great detection accuracy of over 98%. These findings show how well the model detects Malware threats while keeping reasonable processing times—critical for IoT devices with limited resources.**

***Keywords*—Malware detection; transfer learning; light weight transfer learning; federated learning**

I. Introduction

The digital era has transformed convenience and efficiency by changing the way people, companies, and governments run. But this change has also brought major weaknesses, especially in relation to cyber-security. The malware attack is among the urgent problems in this field. These increasingly complex and difficult to stop attacks aiming at making online services inaccessible by flooding them with an abundance of internet traffic have grown advanced detection and prevention systems are more and more needed as the frequency and intensity of malware attacks keep rising. In this context, polymorphic refers to a malware's ability to continually change and adapt its features to avoid detection. Polymorphic malware pairs a mutation engine with self-propagating code to continually change its "appearance", and it uses encryption (or other methods) to hide its code.

Emerging as a potential solution to these problems is applied Artificial Intelligence(AI), that may have various forms. Transfer Learning is one such sophisticated approach to counter a problem with applied AI with several layers. Transfer learning supports knowledge gained from training a model on one task to be applied to a different but related task. This approach allows models to leverage pre-existing knowledge, significantly reducing the time, resources, and amount of labeled data required for training. Its main components include pre-trained Model: The process starts with a model that has been trained on a large dataset for a specific task. Knowledge Transfer: Relevant parts of the pre-trained model are applied to a new, similar problem and Fine-tuning where the transferred model is then adapted or fine-tuned for the new task, often with a smaller dataset. These components are shown in Fig. 1 where weights from a trained model are forwarded to another model at convolution layer which further fine-tunes the weights for further process in fully connected layer and finally to attain output at output layer.

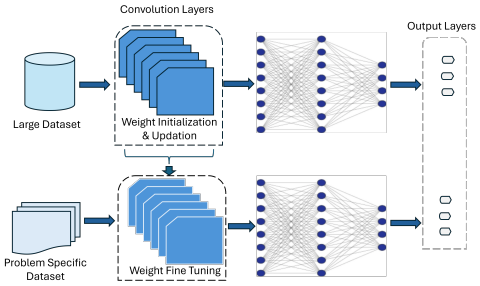

Fig. 1. Transfer learning architecture.

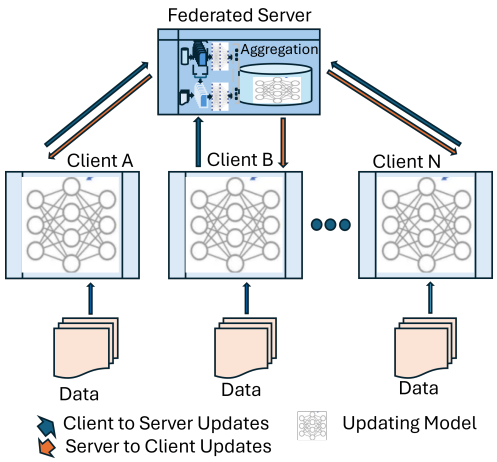

Fig. 2. Federated learning architecture.

There are several models and approaches of machine learning; however, careful action is required to decide which specific model or approach to use, given that every approach and model has different computational cost and contextual

parametric dependence that may affect the performance of the solution. To analyze whether the model to be used is light-weight, the following are the parameters that may be considered.

- Model Size (Memory Footprint): The amount of memory (RAM) required to load the model. Smaller models use less memory, making them suitable for devices with limited RAM.
- Number of parameters: The total number of trainable parameters in the model.
- Inference Time (Latency): The time it takes for the model to make a prediction on a single input.
- Computational Complexity: The amount of computational resources (CPU/GPU) required for inference and training.
- Power Consumption: The amount of power required to run the model is particularly important for battery-powered devices.
- Model Architecture: Simpler architectures are generally lighter.
- Model Accuracy vs. Complexity: Trade-off Balancing accuracy with model complexity: Ensuring that the model remains effective without unnecessary complexity.
- Storage Requirements: The disk space required to store the model. Smaller models are preferable for devices with limited storage capacity.
- Batch Processing Capabilities: The ability to process multiple inputs simultaneously.
- Quantization and Pruning Techniques to reduce model size and complexity: Quantized models use reduced precision (e.g., 8-bit integers) instead of 32-bit floats.
- Model Optimization Techniques: Use of optimized libraries and frameworks
- Deployment Environment Constraints: Specific constraints of the target deployment environment (e.g., mobile devices, IoT devices).
- Training Time: The duration required to train the model. Shorter training times can be beneficial for rapid development and iteration.

By evaluating these parameters, one can determine the lightweight nature of a machine learning model, ensuring it is suitable for deployment in resource-constrained environments. Given that we are experimenting on edges where the key requirement is quick response and accuracy so in this research, we have used inference and training time for our comparisons.

A. Research Objectives

1) Develop a lightweight and resource-efficient transfer learning model using MobileNetv2 that operates effectively on edge devices.
2) Achieve high malware detection accuracy by leveraging diverse local datasets $\mathcal{D}_k$ distributed across clients.

B. Assumptions

1) Clients k have non-IID (non-identically distributed) datasets, reflecting real-world variability in malware characteristics across devices or regions.
2) The model is designed to handle imbalanced datasets, where benign samples may significantly outnumber malware samples.
3) Clients participate asynchronously in federated training due to intermittent availability.

This paper extends our work presented in [1] and [2] where we used hybrid approach (GRU with CNN) to Malware detection and classification in lightweight settings, however requires better accuracy particularly on edges with quick response time. This problem definition provides the foundation for designing a federated malware detection system using MobileNetv2, focusing on lightweight operations, privacy preservation, and scalability.

The remainder of the paper is organized as follows. Section II reviews the related work in cyber threats (in particular Malware) detection highlighting the limitations of existing methods. Section III presents details the methodology, including model architecture, mathematical representation of the model and algorithmic details, performance metric. This Section also presents the experimental setup and discuss the dataset used for evaluation. Section V provides a thorough analysis of the results, including comparisons with other state-of-the-art models. Finally, Section VI concludes the paper with insights and suggestions for future research.

II. Literature Review

There has been several efforts made to improve the accuracy of malware detection and classification. The authors in research [3] illustrate the utilization of transfer learning in malware detection through the fine-tuning of pre-trained models, attaining a high accuracy of 95% with diminished training duration; however, the study does not offer a detailed examination of lightweight malware detection employing transfer learning. The research highlights the efficacy of Convolutional Neural Networks (CNNs) in classifying malware across various datasets, demonstrating the possibility for efficient and resilient malware detection techniques, pertinent to lightweight methodologies in the domain. The research study[4] examines the use of transfer learning methodologies in malware analysis, highlighting the necessity for novel detection strategies to address emerging threats. The study emphasizes the application of the Virustotal API to improve detection capabilities, potentially pertinent to lightweight solutions, however it does not specifically examine the current literature on this particular subject.

The authors of [5] underscore the necessity for effective zero-day malware detection via transfer learning methodologies, employing models such as AlexNet [6], VGG16 [7], VGG19 [7], GoogLeNet [8], and ResNet [9]. The research centers on transforming malware binaries into grayscale images for classification, with the objectives of minimizing bias, conserving training time, and improving malware classification efficacy. The literature review highlights methods of static and dynamic analysis for IoT malware detection [10]. In the Malimg dataset, findings indicate that the proposed lightweight

model, LMDNet, attains an accuracy exceeding 93.07% and a 23.68% enhancement in recognition speed compared to traditional methods. The lightweight CNN with LSTM for malware detection, as shown in this study, achieved an F1-score of 0.8925 and an accuracy of 91.8% on the Malimg dataset, surpassing prior models by 12.8% in accuracy and 14% in F1-score. The literature review emphasizes methods of static and dynamic analysis for the detection of IoT malware. In the Malimg dataset, findings indicate that the proposed lightweight model, LMDNet, attains an accuracy of 94.07% and a 23.68% enhancement in recognition speed compared to traditional methods. This study presents a lightweight CNN integrated with LSTM for malware identification, achieving an accuracy of 87.8% and an F1-score of 0.90 on the Malimg dataset, hence exceeding prior models by 12.8% in accuracy and 14% in F1-score [11].

Another study introduces a lightweight machine learning technique for virus identification, necessitating 5.7 microseconds to analyze files with an accuracy exceeding 90.8%. It demonstrates the capability to identify 15 malware variants with a model trained exclusively on a single subtype [12]. A thorough literature review of lightweight Intrusion Detection Systems (IDSs) for Internet of Things networks, emphasizing contemporary Machine Learning and Deep Learning methodologies, is provided in [13]. This study focuses on filter-based feature engineering and the frequency of DoS attack detection, analyzing 57 papers. The document does not explicitly provide a literature review on lightweight malware detection via transfer learning. It examines the implementation of transfer learning techniques for malware classification, emphasizing models such as AlexNet, VGG16, VGG19, GoogLeNet, and ResNet. The research highlights the transformation of malware binaries into grayscale images for classification, with the objective of improving detection efficiency and minimizing training duration, perhaps aiding in the development of streamlined detection methods within the wider scope of malware classification. The paper does not specifically address lightweight malware detection using transfer learning. However, it presents a systematic literature review of lightweight Intrusion Detection Systems (IDSs) leveraging Machine Learning (ML) and Deep Learning (DL) techniques in IoT networks. It highlights the importance of feature engineering, with filter-based techniques being the most effective, and discusses the prevalent detection of DoS attacks. For a focused review on transfer learning in lightweight malware detection, further literature would be required [13]. The study of the literature emphasizes several approaches of malware detection: static, dynamic, and machine learning ones. Appropriate for limited devices, results demonstrate MALITE-MN and MALITE-HRF exceed state-of- the-art techniques in accuracy while greatly lowering memory and computational overhead.

The study [14] of the literature emphasizes the need of lightweight artificial intelligence models as well as IoT security difficulties. Simple deep learning models with minimum parameters obtained up to 87.45% accuracy, outperforming complicated models while keeping reduced processing costs for malware detection, according to results [15]. Using a limited set of software criteria for classification, DroidMalVet [16] offers an Android malware detection lightweight solution. With F-Scores of 84.4% on Drebin and AMD datasets respectively, it shows great accuracy in identifying tiny malware families. Emphasizing Graph Representation Learning (GRL) methods [17], especially Graph Neural Networks (GNNs), which attain competitive results in learning robust embeddings from malware represented as Function Call Graphs and Control Flow Graphs, the paper presents a literature review on malware detection.

The study [18] introduces a lightweight system for detecting Android malware that employs attention temporal networks, attaining an accuracy of 93.69%. It underscores the constraints of conventional static and dynamic analysis, accentuating the efficacy of Dalvik opcode sequences and sophisticated deep-learning methodologies for reliable identification. The research [19] introduces a streamlined neural network model for malware detection on Android devices, attaining an F1 score of 0.77 and a precision of 0.9. It underscores the significance of utilizing manifest-related features and tackles the issue of machine learning model obsolescence.

III. Methodology

A. Dataset and Pre-processing

We used the Aposemat IoT-23 [20] dataset which is a curated and labeled dataset developed for Cyber Security research in Internet of Things (IoT) environments. The dataset provides realistic network traffic data, including both malicious and benign activities. Since the dataset IoT-23 is fully annotated, distinguishing between malicious and benign traffic, this enables to train and evaluate supervised and semi-supervised machine learning models. The data is labeled for Benign and malicious traffic. To prepare dataset we converted malware binaries into image representations: Convert binaries to grey-scale or color images, enabling CNN-based detection. In addition, we managed to keep behavioral logs recorded while monitoring API calls, registry changes, or network activities for sequence-based detection. The static features bytecode n-grams, opcodes, or PE header information are also recorded.

This section presents system model architecture that integrates transfer learning model (MobilNetV2) [21] in federated learning architecture. Given the data is preprocessed and contributes to further process that divides the functionality of the system into two major parts. One the Global setup that is part of the system running over server module. In our scenario, we programmed our server in Flask , where the core functionality of the server includes aggregation of the updates from multiple client and pushing the updated to the local clients so that the local model can be synchronized and updated with global server.

Transfer Learning and Federated Learning as shown in Fig. 1 and Fig. 2 are two techniques employed in malware identification. Transfer Learning employs pre-trained models for feature extraction or fine-tuning, thereby minimizing training duration and computational resources. It is widely been used for various classification purposes, such as image classification [22], federated Learning facilitates dispersed training across numerous devices without the exchange of sensitive malware data, consolidating knowledge from various sources while preserving privacy. Both approaches alleviate the pressure on local devices and can be implemented on resource-constrained devices.

The pre-trained model utilizes a compact architecture such as MobileNet or EfficientNet, refining only the final layers, while the Federated Learning process encompasses local training on devices, parameter updates, and the redistribution of the revised model to clients.

The federated approach support learning at multiple locations with different clients and sharing the updates with server who then can aggregate and such all the clients. The computational cost at the client may be reduced if the federated learning system is designed with care. The client layer is responsible for local training based on the local data available to each client as shown in Fig. 2. We used one client on Raspberri-5 with 8GB RAM which is resource constraint device. Due to limited amount of memory, we designed the local training in the form of short batches. Initially started with 32 batch size, after system crashed we managed it to be in the batch size of 16. Federated server publishes it address at ngrok which is a secure ingress platform tunnel. Client(Raspberri PI5). On each client we run MobileNetV2 as transfer learning model that gets connected to sever through this tunnel as shown in Fig. 3. The overall results are presented in the Results and Discussion section of this paper.

B. Performance Metrics

Below are the mathematical formulae for the evaluation metrics used to assess the performance of a classification model:

1) Accuracy: The accuracy measures the proportion of correctly predicted instances to the total number of instances:

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}}$$

2) Precision: Precision, also known as Positive Predictive Value, calculates the proportion of true positive predictions among all positive predictions:

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

3) Recall: Recall, also known as Sensitivity or True Positive Rate, measures the proportion of actual positives that are correctly identified:

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

4) F1-Score: The F1-score is the harmonic mean of precision and recall, providing a single measure that balances both metrics:

$$\text{F1-Score} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}}$$

Notation:

- TP: True Positives
- TN: True Negatives
- FP: False Positives
- FN: False Negatives

C. Mathematical Model

1) Problem Description: The goal is to detect malware from distributed datasets $\mathcal{D} = \bigcup_{k=1}^{K} \mathcal{D}_k$, where K represents the number of participating clients. Each client k has its local dataset:

$$\mathcal{D}_k = \{(x_i, y_i)\}_{i=1}^{n_k},$$

where:

- x_i: Input sample representing features relevant to malware detection (e.g. binary sequences, network flows).
- $y_i \in \{0, 1\}$: Label indicating whether the sample x_i is benign ($y_i = 0$) or malicious ($y_i = 1$).
- n_k: Number of samples on client k.

The global objective is to train a malware detection model $f_\theta(x)$, parameterized by θ, that minimizes the overall loss across all clients:

$$\min_\theta \frac{1}{N} \sum_{k=1}^{K} \sum_{i=1}^{n_k} \mathcal{L}(f_\theta(x_i), y_i),$$

where $N = \sum_{k=1}^{K} n_k$ is the total number of samples and $\mathcal{L}$ is the loss function (e.g. cross-entropy loss).

2) Transfer Learning Component: The model $f_\theta(x)$ is based on MobileNetv2, consisting of:

- **Base Network** $f_{\text{base}}(x; \theta_{\text{base}})$: Pre-trained MobileNetv2 layers (frozen during training) that extract high-level features.
- **Classification Head** $f_{\text{head}}(x; \theta_{\text{head}})$: A trainable dense layer(s) for malware classification.

The combined model is defined as:

$$f_\theta(x) = f_{\text{head}}(f_{\text{base}}(x; \theta_{\text{base}}); \theta_{\text{head}}),$$

where $\theta = \{\theta_{\text{base}}, \theta_{\text{head}}\}$ and θ_{base} remains fixed during training.

3) Federated Learning Component: The federated training process consists of the following steps:

(a) Local Model Training: Each client k initializes its local model $f_{\theta_k}(x)$ with the global model parameters θ^t received from the central server at communication round t. The local model is trained on $\mathcal{D}_k$ to minimize the local loss:

$$\theta_k^{t+1} = \arg\min_\theta \frac{1}{n_k} \sum_{i=1}^{n_k} \mathcal{L}(f_\theta(x_i), y_i).$$

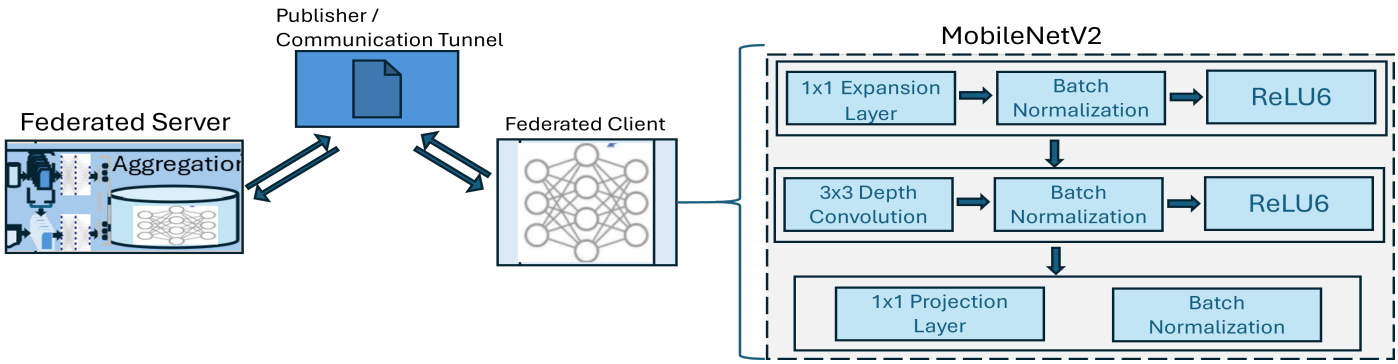

Fig. 3. The Workflow of model architecture.

(b) Model Update Aggregation: The central server aggregates the updates from all clients using Federated Averaging (FedAvg):

$$\theta^{t+1} = \sum_{k=1}^{K} \frac{n_k}{N} \theta_k^{t+1}.$$

(c) Global Model Distribution: The updated global model parameters θ^{t+1} are sent back to all clients for the next communication round. This mathematical model outlines the integration of transfer learning using MobileNetv2 with federated learning for malware detection.

Algorithm 1 Lightweight Transfer Learning Model (MobileNetv2) in Federated Mode for Malware Detection

Require:
- Pre-trained **MobileNetv2** as the base model.
- Local datasets (**Clients_Data**) distributed across clients.
- **Rounds**: Number of communication rounds.
- **Epochs**: Local training epochs.
- **Learning Rate**: Optimizer learning rate.

Ensure: Optimized global model for malware detection.

Initialize:
Load MobileNetv2 with frozen base layers and a trainable classification head.
Distribute the global model to all clients.
for each round $r = 1$ to **Rounds do**
  Server: Broadcast current global model to all clients.
  for each client i in parallel **do**
    Fine-tune the model on local data for **Epochs**.
    Send updated weights ΔW_i to the server.
  end for
  Server: Aggregate weights using Federated Averaging:

$$W_{\text{global}}^{(r+1)} = \frac{1}{N} \sum_{i=1}^{N} \Delta W_i$$

  Update global model parameters.
end for
Deploy: Distribute the final global model to all clients.

IV. Experimental Setup and Implementation

A. Hyper-parameter Tuning and Impact

The following hyper-parameters in Table I were tuned to optimize the performance of the Transfer Learning (MobileNetV2) in Federated Model:

TABLE I. Hyperparameters for the Model

Hyperparameter	Value
Learning Rate	3×10^{-5}
Batch Size	16
Max Sequence Length	512 tokens
Epochs	5
Early Stopping	Patience = 2 epochs
Dropout Rate	0.2
	0.1
Optimizer	AdamW
Weight Decay	0.01
Warmup Steps	500
Gradient Accumulation Steps	4
Learning Rate Scheduler	Linear with Warmup
Maximum Gradient Norm (Clipping)	1.0
Hidden Size	768

The learning rate was set to 3×10^{-5}, providing a slow adaptation to the data and preventing overshooting the optimal weights during fine-tuning. A batch size of 16 was chosen to balance memory usage and training efficiency. The model was trained for a maximum of five epochs, with early stopping activated if validation performance did not improve for two consecutive epochs.

V. Results and Discussion

The results of the model training demonstrate significant improvements across multiple metrics over between 5 to 10 epochs. It can be seen that, in epoch 1, the training loss was recorded over 0.372600, with a validation loss of 0.35, yielding an accuracy of 0.94537. As training progressed to epoch 2, the training loss decreased substantially to 0.32900, while the validation loss improved to 0.305888. These changes corresponded to an increase in accuracy to 0.942 and a rise in the F1 score to 0.9418, indicating that the model was beginning to generalize well to unseen data. Continuing to epoch 3, the training loss further decreased to 0.27000, and the validation loss dropped to 0.25100. The model's accuracy improved to

0.94200, along with an F1 score of 0.95000, highlighting its effectiveness in handling the classification task. In epoch 4, the training loss was recorded at 0.23000, with a corresponding validation loss of 0.2000. These results are shown in Fig. 4

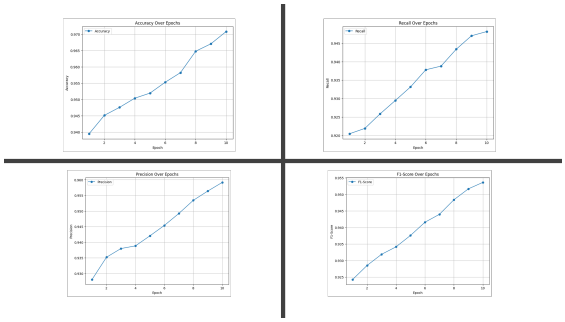

Fig. 4. Accuracy, precision, recall and F1 score over epoch.

The accuracy increased to 0.954500, and the F1 score further improved to 0.95500, reinforcing the model's capability to learn and generalize from the training dataset. By the final epoch, epoch 5, the model achieved a training loss of 0.175000 and a validation loss of 0.15000, with an impressive accuracy of 0.95900. The F1 score reached 0.947500, indicating a strong balance between precision and recall. Precision and recall values also showed positive trends, with precision at 0.945000 and recall at 0.95000 by the end of training. Similarly, it is evident that from epoch 5 to epoch 10, this trend of reduction in validation and testing loss and enhancement in accuracies remains unchanged showing significance of the model.

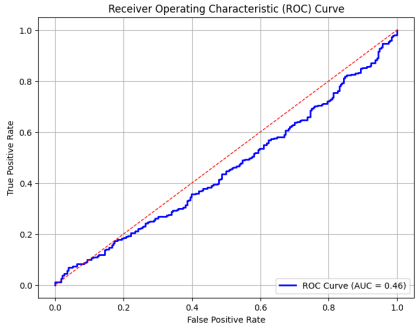

Fig. 5. ROC Curve.

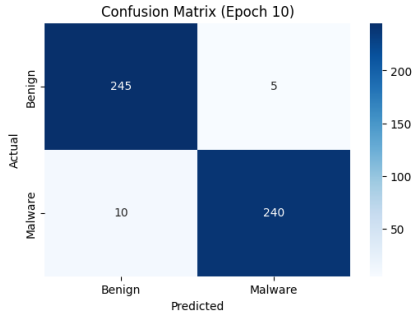

Fig. 6. ROC Curve.

These results collectively illustrate that the model has been effectively optimized for both analysis and classification tasks, demonstrating low loss values and high accuracy metrics. The consistent performance improvements across epochs suggest that the model is well-tuned, potentially indicating a successful architecture and training strategy that could be applicable in similar domains.

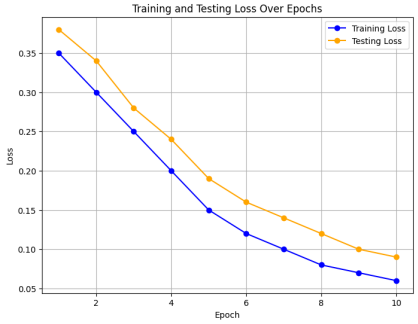

Fig. 7. Training and testing loss.

The model's training and validation losses are illustrated in Fig. 7, which depicts the losses over 10 epochs. The training loss, represented by the blue line, shows a consistent decline, starting from a higher value and decreasing steadily as the model learns from the training data. This reduction in training loss indicates effective learning.

Similarly, the validation loss, shown by the orange line, also decreases, suggesting that the model is generalizing well to unseen data. The convergence of both training and validation losses toward lower values without significant divergence indicates that the model is well-tuned and is optimizing its parameters effectively throughout the training process. Additionally, the model's classification performance is further evaluated through the confusion matrix presented in Fig. 6. This matrix illustrates the model's predictions across two classes: Malware and Benign. It can be seen out of 245 benign and 240 malware affected labels were correctly classified. The model reveals potential areas for improvement, particularly in enhancing the model's ability to identify among multi-class scenario. Overall, while the model demonstrates effective learning, the insights gained from the confusion matrix highlight the need for further refinement to improve classification performance across all categories. ROC Curve for this evaluation is shown in Fig. 5.

The training loss demonstrated a consistent decline, reducing from 0.35 in the first epoch to 0.05000 in the 10 epoch. This steady decrease indicates that the model effectively learned from the training data, suggesting successful optimization of the underlying architecture. Model performance evaluation is shown in Table II and comprehensive comparison of evaluation of our model is presented in Table III. The results show that MobileNetV2-FL Hybrid outperforms in terms of accuracy, precision, recall and F-1 score. Its training time is slightly higher but once the model gets trained, its inference takes less amount of time. in summary, the system backed by transfer learning in federated mode is well capable to learn and respond to malware detection scenario on edge devices.

TABLE II. MODEL PERFORMANCE METRICS ACROSS TRAINING EPOCHS

Epoch	Training Loss	Validation Loss	Accuracy	F1 Score	Precision	Recall
1	0.372600	0.352754	0.940000	0.939500	0.940500	0.941000
2	0.349500	0.305888	0.942500	0.941800	0.943000	0.942500

SqueezeNet[26]	96.10%	95.60%	95.30%	95.40%	2 hours	0.04 seconds
MobileNetV2-FL Hybrid	96.80%	96.50%	95.40%	95.60%	2.1 hours	0.02 seconds

VI. CONCLUSION

The rapid proliferation of smart devices and customer concerns regarding data security and privacy have required the development of new strategies to combat cyber threats. This study introduces a novel lightweight transfer learning approach to enhance malware attack detection in a federated context. To reduce cyber risks and improve malware detection efficacy, the work introduced an approach that integrates MobileNetV2 a Transfer Learning model with federated architecture.

The performance of the model was assessed using the publicly accessible Aposemat IoT-23 dataset from an actual IoT network. Comprehensive testing revealed that the model achieves a training accuracy of about 96% and a validation accuracy of 96% producing a satisfactory detection accuracy above 96.8%. Essential for resource-limited IoT devices, these results show the model's effectiveness in identifying malware risks while keeping reasonable processing speeds.

The outcomes of this work improve deep learning approaches in cybersecurity and provide insightful analysis for the construction of more strong and efficient malware detection systems. In future work, the model's hyper-parameter tuning shall be evaluated to further enhance the system performance. We shall also employ load balancing techniques between server and client to keep the client light weight and effective to respond with acceptable accuracy in case of cyber threat. This work only considered single Raspberri PI client connected to the federated server, in future, We ll design multi client scenario where the attack could be detected from multiple edges simultaneously.We shall also Finally, Synchronization mechanisms between server and clients shall also be fine tuned.

An Automated Mapping Approach of Emergency Events and Locations Based on Object Detection and Social Networks

Khalid Alfalqi, Martine Bellaiche
Computer and Software Engineering Department, Ecole Polytechnique, Montreal, Canada

***Abstract*—The high prevalence of cellphones and social networking platforms such as Snapchat are obviously dissolving traditional barriers between information providers and end-users. It is certainly relevant in emergency events, as individuals on the site produce and exchange real-time information about the event. However, notwithstanding their demonstrated significance, obtaining event-related information from real-time streams of vast numbers of snaps is a significant challenge. To address this gap, this paper proposes an automated mapping approach of emergency events and locations based on object detection and social networks. Furthermore, employing object detection methods on social networks to detect emergency events will construct reliable, flexible and speedy approach by utilizing the Snapchat hotspot map as a reliable source to discover the exact location of emergency events. Moreover, the proposed approach aims to yields high accuracy by employing the state of the arts object detectors to achieve the objectives of this paper. Furthermore, this paper evaluates the performance of four object detection baseline models and the proposed ensemble approach to detect emergency events. Results show that the proposed approach achieved a very high accuracy of 96% for flood dataset and 94% for fire dataset.**

***Keywords*—Machine learning; deep learning; big data; social networks; object detection; emergency event detection; snapchat; hotspot map**

I. Introduction

The prevalence of emergency events has increased exponentially over the past half-century, disturbing since it causes infrastructure damage, casualties, and long-term socio-economic harm [1]. It is described as a significant instability of life of the community caused by hazardous incidents resulting in either one of the following: human, financial, and environmental damages, and consequences, according to the United Nations International Strategy for Disaster Reduction (UNISDR). [2] Emergency events fall into two categories: natural and human-made. Natural emergency events are further subdivided into geophysical, meteorological, biological, climatological, and extraterrestrial calamities. Human-caused emergency events can be further categorized into occupational incidents, traffic incidents, and other incidents. Natural disasters include landslides, earthquakes, floods, tsunamis, and wildfires, and human-made emergency events include explosions, large-scale building fires, toxic emissions, and aviation and railroad incidents [3]. Thus, many emergency events have serious economical consequences in the short term, but rare situations can result in longer economic loss. Detection and recognition of objects are extensively employed in a variety of areas. People live in the era of smart communities that provide a massive volume of information. Conventional learning techniques are incapable of dealing with massive amounts of data, but data can match the requirements of deep learning for a wide range of experimental datasets [4]. In addition, the computer power of contemporary hardware has substantially grown as technology has developed. Thus, object detection based on deep learning has improved remarkably well.

Several deep learning-based object detection and target recognition methods have recently been proposed. The deep convolutional neural network can automatically train and enhance its hyper-parameters using the supplied data set [5]. Deep learning object recognition techniques are categorized into two categories. The first type of algorithm is a two-stage object detection method, such as R-CNN, Fast R-CNN, Mask R-CNN, and Faster R-CNN [6]. Object detection is carried out in two steps by these methods. The region proposal network is performed first to retrieve candidate objects of interest and is followed by the detection network to predict and recognize the candidate object's region and class [7]. The second type of detection algorithm is a one-stage detection algorithm, which involves SSD, RefineDet, YOLO, YOLOv2, YOLOv3, YOLOv4, YOLOv5, and YOLOR. These methods bypass the region proposal network and generate location and class information concerning the objects straight throughout the network. As a consequence, the one-stage detection method recognizes objects faster [8].

The remainder of the paper is structured as follows: The problem definition is introduced in Section II. Section III describes the related works of two separate research topics covered in this study. Section IV "Background" provides a high-level overview of object detection models and CNN architectures. Section V "Methodology" describes the phases in the research methodology, as well as the approach and models employed in the experiments. Section VI "Evaluation approach", describes the specified case studies in depth, including the reasons for their selection and experimental environment construction, evaluation measures, performance analysis for our suggested approach, and discussion of study outcomes. Finally, Section VII "Conclusion and Discussion", highlights the findings and suggests future study avenues.

II. Problem Definition

Deep learning approaches have been used in previous studies to auto-link between emergency events and places using social networking information to analyze incident recognition and assess spatial geolocation data from geotagged

social network content. However, georeferenced data makes up a relatively minor portion of the whole set of social network information, and it may not precisely correlate to events mentioned in the posts. Hence, location awareness and more detailed emergency event information could significantly improve social network content's usefulness, reliability, and compatibility [9].

The precision of an approximated position nowadays is to the level of a town or district when employing current approaches, and obtaining further relevant details like the name of a road or building remains challenging [10]. As a result, improved methods are required to significantly boost the accuracy and robustness of geolocation data collected from social networks.

This paper proposes an automated mapping approach between emergency events and locations based on object detection and social networks to address this gap. Furthermore, employing object detection methods on social networks to detect emergency events will construct a reliable, flexible, and speedy approach by utilizing the Snapchat hotspot map as a reliable source to discover the exact location of emergency events. Moreover, the proposed approach aims to yield high accuracy by employing the most current object detection methods to accomplish the objectives of this paper. More particularly, the contributions of this paper can be stated as follow:

- Detect the occurrence of emergency events across time and exact locations by utilizing the Snapchat map.
- Develop a novel ranking and selection model to rank the hotspot locations in order to prioritize which location needs urgent dealing and send it to the decision-makers.
- Develop a flexible, reliable and speedy object detection model to analyze images for the collected data from Snapchat API.
- Propose a combination of one-stage and two-stage object detection models to construct an ensemble model and evaluate the performance of our approach.

III. Related Work

This section outlines the literature review completed throughout this study on two separate fields of study. First, we highlight current research studies that address location detection methods for social networks, concerns, as well as existing and potential solutions. Second, we expand in a limited but adequate manner on current deep learning methods for object detection in emergency events.

A. Location Detection Methods for Social Networks

People usually are inquisitive about the location of catastrophes during or shortly after they occurred. Knowing the precise location is critical for decision-makers to respond promptly and make decisions accordingly [11]. We can get emergency event geolocation information from social network feeds. Location retrieval can be classified into three elements based on the methods used. The first element is the content analysis of words. Second, the analysis of different language modelling. Third, by guessing through social relations [12]. Many studies have been conducted in order to approximate the location of emergency events using material analysis in a specific outer data source depending on geo-related factors.

Singh et al. [13] presented a tweet categorization and location identification technique for spotting tweets from emergency affected seeking assistance as well as their locations. If the location is not stated in the previous tweets, the location was inferred utilising Markov Chain Stochastic approach.

Rodriquez et al. [14]. proposed Using a probabilistic technique that simultaneously predicts location designations and Twitter posts of users, the relationship network is represented graphically. In particular, the authors characterize the system with a Markov random field probability framework, and the training phase is based on a Markov Chain Monte Carlo simulator that estimates the posterior likelihood distribution of the sparse spatial user labels.

Duong-Trung et al. [15] developed a dynamic content-based regression approach using the matrix decomposition method to address the near real-time location estimation challenge. They demonstrated that real-time location estimation is feasible without combining users' tweets.

Gelernter et al. [16] applied Named Entity Recognition technique (NER) to recognize the names of locations in tweets, The findings were contrasted to words manually classified as locations by the researchers and revealed that the enormous number of abbreviations for landmarks is a significant concern for this technique.

Rout et al. [17] employed a Support Vector Machine algorithm to estimate the location of tweets. In addition, their dataset comprises relationship graph features and city metrics like demographic size and the amount of active Twitter accounts. The relationship graph features were adopted because most online social networking relationships begin in real life. They further contend that some elements of the towns are pertinent to the categorization phase.

Laylavi et al. [18] developed a technique for identifying relevant tweets regarding the storm incident. First, they defined event-related word categories utilizing term frequency analysis and the relationship scoring mechanism. Then, an incident-related score was assigned to each tweet. Finally, the suggested system's findings were matched to manually labelled data to measure performance. The recommended approach successfully categorized around eighty-seven incident-related tweets.

Table I illustrates the comparison of the related works in Section III-A. BD is denoted to big data and OD is denoted to object detection.

B. Deep Learning Methods for Object Detection in Emergency Events

The application of deep learning in emergency events detection is becoming more and more extensive. Significant advancements in computer vision have lately been accomplished using these technologies. Multiple detection strategies and techniques have demonstrated superior picture detection efficiency.

TABLE I. A COMPARISON AND SUMMARY OF THE LITERATURE REVIEW

Method	Ref	Dataset	results	BD use	OD use
Markov chain based	[13]	Twitter	87%	No	No
Markov Chain Monte Carlo	[14]	Twitter	78.99%	No	No
Matrix factorization technique	[15]	Twitter	79%	No	No
Named Entity Recognition	[16]	Twitter	90%	No	No
Support Vector Machine	[17]	Twitter	-	No	No
Term frequency analysis	[18]	Twitter	87%	No	No

Ji et al. [19] Used satellite images taken prior to and following the earthquake, a pre-trained VGG model was utilized to detect destroyed houses affected by the Haiti earthquake. The research findings reveal that the fine-tuned VGG model's accuracy level has risen from 83.38 to 85.19. In addition, the destroyed houses identification effect works better, with a production accuracy of 86.31 of earthquake-induced house damage from satellite utilizing a pre-trained CNN classifier, indicating that the CNN approach can successfully identify the characteristics of destroyed structures houses.

Miura et al. [20] employed CNN model to obtain the characteristic of the destroyed buildings' rooftops that wrapped with blue tarpaulin following the earthquakes. Leveraging the enhanced CNN network and satellite photos taken following the two events in Japan.

Qingjie Zhang et al. [21] proposed a novel deep learning method for detecting forest fires. They employed a cascaded method for detecting fire, with the global picture stage examining the whole picture initially and then a local patch encoder identifying the particular position of the determined fire. They presented a baseline for fire recognition, 178 pictures for the train set, and 59 pictures for the test set. They utilize the CIFAR 10 network for the initial phase but reduce the number of outcomes by two and add a drop-out layer to minimize the fitting problem. They employed the Caffe framework's 8-layer AlexNet for the final phase.

Ci et al. [22] proposed a novel CNN architecture integrated with a CNN data harvester, a unique loss function, and an arbitrary regression classifier to measure the severity of houses destruction due to earthquakes utilizing satellite images.

Pi et al. [23] exploited a pre-trained model to train several CNN classifiers based on You-Only-Look-Once (YOLO) in the accident areas to detect intact houses rooftops.

Wei Zhang et al. [24] developed a CNN-CAPSNet—an effective remote imagery categorization system that emphasizes the advantages of the CNN and CAPSNet algorithms. A CNN with partially coupled layers was used as the initial feature map generator. Furthermore, for feature extraction, they employed a pre-trained deep CNN classifier that was entirely trained on the ImageNet dataset. The findings demonstrated that the suggested strategy might outperform state-of-the-art approaches in classifier performance.

Pham et al. [25] proposed a YOLO-fine approach which is an enhanced object detection model from YOLOV3. The model was developed to identify tiny objects with high accuracy and efficiency, allowing real-time applications in realistic circumstances. In addition, they explored its resilience to the appearance of new contexts on the validation set deeper, tackling the critical barrier of domain adaptability in satellite imagery.

Yebes, J et al. [26] acquired and labelled images of real-world situations, and several object detection algorithms were fine-tuned to accomplish their experiment. Their highest results yielded an accuracy rate of 82, employing a hybrid of R-CNN and Resnet101.

Amit et al. [27] suggested a CNN-based paradigm for catastrophe identification in aerial pictures: two fully connected layers and three convolutional and max-pooling layers in the suggested CNN framework. A dataset is gathered for assessment purposes that spans many aerial picture patches from two different natural catastrophes, specifically landslides and flooding. Table II illustrates the comparison of the related works in Section III-B. BD is denoted to big data and OD is denoted to object detection.

IV. BACKGROUND

This section briefly describes important background concepts related to this study, including object detection methods and CNN architectures,

A. Object Detection

Objects detection methods fall into two min categories, one of which is one stage detectors and the other is two stage detectors [6]. Fig. 1 shows the stages of object detection models.

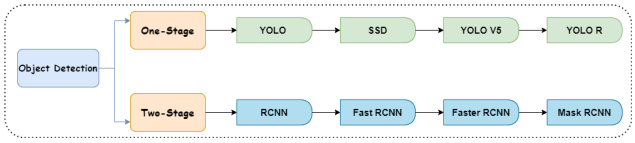

Fig. 1. Stages of object detection.

1) One stage detectors:

a) YOLOV5: is an upgraded version of the YOLOV3. Its implementation is comparable to that of YOLOV4 in that it integrates numerous approaches such as data augmentation and modifications to activation functions with data preprocessing

TABLE II. A COMPARISON AND SUMMARY OF THE DEEP LEARNING METHODS FOR OBJECT DETECTION IN EMERGENCY EVENTS

Method	Ref	Dataset	results	BD use	OD use
CNN	[19]	satellite imagery	87.6%	No	No
CNN	[20]	aerial images	95%	No	No
CNN	[21]	various online resources	90%	No	No
CNN	[22]	multiple aerial imagery	93.95%	No	No
CNN YOLO	[23]	in-house aerial video imagery	80.69%	yes	No
CNN-CapsNet	[24]	UC Merced Land-Use ,AID , NWPU-RESISC45	98.81%	No	No
CNN YOLO-fine	[25]	VEDAI ,MUNICH,XVIEW	84.34%	yes	No
CNN Faster R-CNN- SDD	[26]	images with pothole annotations	82%	yes	No
CNN	[27]	satellite imagery	80%	No	No

to the YOLO structure. Yet, YOLOv5 differs from YOLOV4 in the base; rather than Darknet, it uses CSPDarknet53 as its base. This base addresses the redundant gradient data in a massive backbone network. It incorporates gradient modification into the feature map, decreasing inference latency, boosting precision, and lowering model complexity by minimizing the parameters. In addition, it aggregates pictures for training and uses self-adversarial training (SAT) to guarantee faster prediction [28].

b) YOLOR: You Only Learn One Representative: The YOLOR model, which has an integrated network design, is intended to carry out several tasks at the same time. YOLOR is an upgraded version of the YOLO model that takes advantage of the data in the lower tiers of the CNN layers, specifically the attribute data. Furthermore, because it provides concurrent recognition, the YOLOR method is more effective than the existing YOLO methods [29].

YOLOR simultaneously utilizes implicit and explicit information to model training to acquire generalized representations and execute multiple jobs using these generalized representations. The implicit awareness recognizes deep layer characteristics, and annotated data is used to gain explicit information [29]. YOLOR has different versions with distinct specifications, so YOLOR-P6 is considered for the study.

2) Two stage detectors:

a) Faster R-CNN: Faster R-CNN is upgraded version of Fast R-CNN to overcome the limitations of Fast R-CNN. The main drawback of Fast R-CNN is that it leverages particular inquiry to generate Regions-Of-Interest (ROI), which is slower and requires the exact period to execute as the recognition system. Therefore, faster R-CNN is substituted by a unique RPN (region proposal network), a fully convolution network that can anticipate region suggestions using a broad variety of sizes and aspect ratios. Furthermore, since it combines full-image convolution characteristics and a similar set of convolution layers with the overall classifier, RPN speeds up the production of region suggestions [30].

b) Mask R-CNN: Mask R-CNN adds mask branch output on top of the prior Faster R-CNN base. The core layer gathers features at the beginning; then, the proposals are anticipated and optimized to infer the bounding boxes for object recognition and build segmentation masks. The mask offers pixel-level feature extraction for every potential object by performing instance segmentation [31]. In addition, it incorporates enhancements in Faster R-CNN and FCN (Fully Connected Network), which led to its popularity as a two-stage object detection model compared to the other models, as it offers both bounding box and segmentation [32].

B. Convolutional Neural Networks (CNN) Architecture

Convolutional neural networks are the most extensively used deep learning algorithms and the most popular type of neural network. It is a multi-layer neural network (NN) design comprising a convolutional layer(s) followed by a fully connected (FC) layer (s). The principal use of CNN is in databases, where the number of nodes and parameters is enormous [33].

1) Convolutional layer: This layer is the foundation of CNN models, defining linked inputs' outcomes. Such an outcome is accomplished by convolving kernels across the datasets' size and shape, determining the feed's and filter's dot product, and constructing a two-dimensional activation map with that filter. CNN efficiently understands which filters to activate when a certain kind of attribute is noticed at a specific spatial point in the input [34].

2) Non-linearity layer: Nonlinear functions are essential and retain a degree greater than one; when displayed, they exhibit a curve. The primary goal of this layer is to convert the incoming signal to the outgoing signal, which will be employed as an input in the subsequent layer. Non-linearity layers include sigmoid or logistic, Tanh, ReLU, PReLU, and ELU [35].

3) Pooling layer: CNNs can comprise internal or external subsampling layers that combine the results of one layer's neurons into an individual neuron in the subsequent layer. Its primary function is to reduce the spatial size of the depiction to decrease the size of the parameters and computations in the framework. It prevents overfitting and accelerates the computation. The max-pooling layer is the most frequent type of pooling layer [35].

4) Fully connected layer: FC layers are conventional deep NN layers that aim to create forecasts from activation for regression and classification. This layer obtains entire links to each activation in the preceding layer, and the activation may be determined by matrix multiplication coupled with a bias of sets [33].

V. Research Methodology

In this section, elucidation of the critical components of this article is required by outlining the steps needed. First, hotspot location in Snapchat map will be pinpointed. Second, collect the dataset from the Snapchat map API in the exact locations of the emergency events that were identified earlier without any prior knowledge. Third, data pre-processing and data augmentations methods are employed at this stage. Fourth, object detection models for emergency event detection are proposed. Fifth, we deploy an ensemble learning based for emergency events to conduct a performance evaluation of the proposed model. Finally, locations ranking and model selection is proposed to prioritize the hotspot locations. The steps of the proposed model is shown in Fig. 2.

A. Pinpoint Hotspot Locations in Snapchat Map

Pinpointing the precise location of emergency events is very important. Therefore, by leveraging the Snapchat map we can find the exact location of any emergency event. The snaps posted on the Snapchat Interactive Map is automatically geotagged and represent a particular hotspot location which can be a possible emergency event location [36]

B. Data Collection

Accordingly, after identifying the hotspot locations, a preliminary ranking is applied based on the highest number of snaps in each location to prioritize the locations. Then we will use the same method we used in our previous works wrapper for the Snapchat Map's internal API in order to construct a Node.js function that scans for snaps uploaded at precise coordinates (hotspot zones) [37] which will collect all the snaps shared at the exact location and marked as either emergency event-content or non-emergency event-content. The acquired snaps might be image or video, thus,the images they will be analyzed by utilizing object detection techniques.

C. Data Pre-processing

1) Standardize images: One fundamental limitation in several object detection methods is the requirement to scale the datasets to a consistent size. This means that before we feed the images to the training model, they need to be preprocessed and resized to have equal dimensions [38]. As a result, the collected images are resized to a length of 640*640.

2) Data augmentation: Another frequent preprocessing strategy is to augment the current dataset with different replicas of the original images. It is performed to expand the dataset and introduce the neural networks to a broad range of image permutations [38]. In addition, it will increase the likelihood that the model will detect objects in any configuration.

Data augmentation may successfully prevent fitting problems throughout the advanced training phase and can tremendously enhance the clarity of the data [39]. Several data augmentation methods were employed, including vertical and horizontal flipping, rotating to a specific angle (less than 20°), and raising or reducing brightness.

D. Applying Object Detection Models

After collecting the dataset from the Snapchat map API, we will apply the most common object detection algorithms which are : You Only Look Once V5 (YOLO v5), You Only Learn One Representation (YOLOR), Mask RCNN and Faster R-CNN. We will apply these algorithms to every hotspot location that have been identified earlier to detect emergency events. Then, we will evaluate the performance of these algorithms using evaluation metrics. Table III shows the hyper-parameters of the models. Algorithm 1 depicts training and evaluation steps.

E. Proposed Voting Ensemble Object Detection Model

Among the four object detection models mentioned above, we will propose to use of the ensemble learning. The precision of the object detection model may be boosted by merging several models into an ensemble model which can be effectively applied for emergency event detection. One of the primary factors driving the prevalence of ensemble learning is its capability to minimize the variance and bias of deep learning models [40].

Numerous object detection models have been introduced to ensemble learning for different scenarios; however, using an ensemble learning approach with object detection models in emergency event detection is still appealing. Both one-stage and two-stage models performed well for object detection, as discussed in the related works. Therefore, four baseline object detection models were chosen for the proposed ensemble approach in this work. We applied a combination of single-stage and two-stage models to conduct our proposed ensemble approach. The proposed voting ensemble object detection model is shown in Fig. 3.

F. Location Ranking and Selection Model

With the continuous search of hotspot zones in the Snapchat map, multiple locations will be found and processed. In this step we will rank these hotspot locations to prioritize them in terms of ranking criteria. Algorithm 2 explains the ranking model. This model consists of four criteria metrics:

a) Amount of snaps in the location: It counts how many snaps have been posted in this particular hotspot location. The overall score for this criteria is one point. Since we only have two locations of emergency events, the highest will get one point and the least will get zero.

b) Amount of snaps related to the emergency events: It counts only the snaps that are related to the emergency event in this particular hotspot location. This step is important to get rid of unrelated snaps. The overall score for this criteria is two points. Since we only have two locations of emergency events, the highest will get two points and the least will get zero.

c) mean Average Precision (mAP) score: A higher mAP score shows improved object detecting method performance. Since we have applied four object detection models to the dataset, we will get four different mAP score for each model. Therefore, we will calculate the mean of this score which the sum of all scores divided by the total number of models. The overall score for this criteria is three points. Since we only have two locations of emergency events, the highest

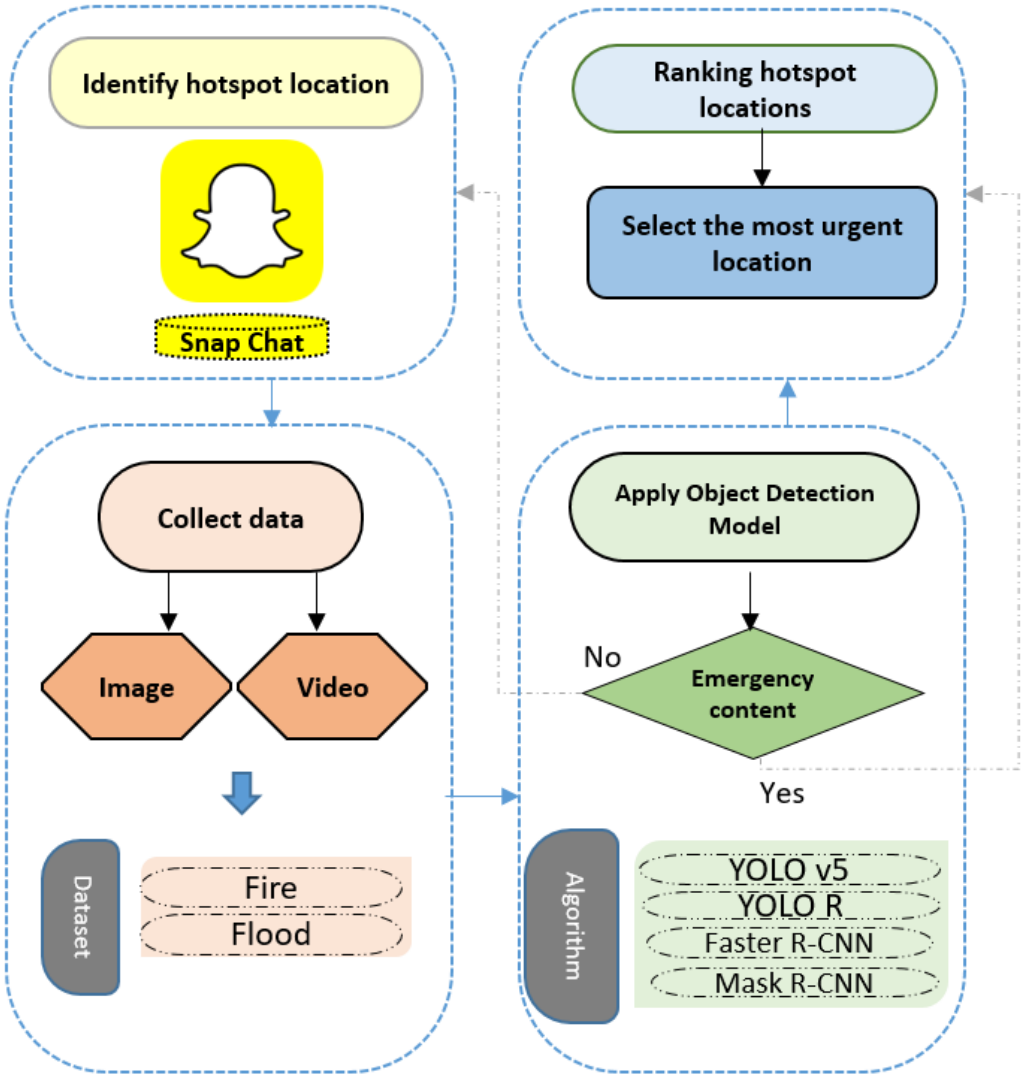

Fig. 2. The steps of the proposed model.

will get three points and the least will get zero. It can be calculated as:

$$Mean = \frac{1}{n}\sum_{i=1}^{n} a_i = \frac{a_1 + a_2 + \cdots + a_n}{n} \quad (1)$$

d) Throughput score (TP score): It refers to the quantity of outcomes delivered in a particular amount of time. After we evaluate the models performance using Spark, the model that will get the best performance for both case studies in regards to time processing will be selected. Then by matching this model to the corresponding case study (location), the corresponding location will get selected. The overall score for this criteria is four points. Since we only have two locations of emergency events, the lowest processing time model will get four points and the rest will get zero.

After that, we will calculate the summation of all scores, the location with a score of equal or greater than five will be sent in cluster A and will be selected as the most urgent location.

$$\text{if } Location(L) \geq 5 \text{ then } put\ it\ in\ Cluster(A) \quad (2)$$

If the location gets a score of equal or smaller than three, it will be sent to cluster B.

$$\text{if } Location(L) \geq 3 \ < 5 \text{ then } put\ it\ in\ Cluster(B) \quad (3)$$

Also, If a location get a score less than two, it will be sent to cluster C and will be disregarded.

$$\text{if } Location(L) \leqslant 2 \text{ then } put\ it\ in\ Cluster(C) \quad (4)$$

The ranking model is shown in Fig. 4.

VI. Evaluation Approach

This section describes the specified case studies in depth, including the reasons for their selection and experimental environment construction, evaluation measures, performance analysis for our suggested approach, and discussion of study outcomes.

A. Case Study

During the scan for the hotspot zones in the Snapchat map utilizing the constructed Node.js wrapper, we identified more than five hotspots location between March 2022 and May 2022 .However, according to the preliminary Snapchat data collection ranking criterion, the most hotspot location that contains the most amount of snaps at that moment were India building fire and South Africa flooding. Therefore, after identifying the exact location of these emergency events, We collected the dataset of each incident using Snapchat API. The total number of the collected images and videos are stated in Table IV.

1) India building fire: At least 27 individuals died, and 24 people were injured in a devastating fire in the Indian capital of New Delhi on Friday (May 13), according to rescue teams. The big fire burst in the mid-evening at a four-story residential building in west Delhi, although the cause was not intuitively known. Twenty-seven burnt remains were found from the building, also several of the residents jumped from the building during the fire and were hospitalized [41]. Fig. 5 shows the location of building on fire in India. Fig. 6 shows the detection results of building on fire in India.

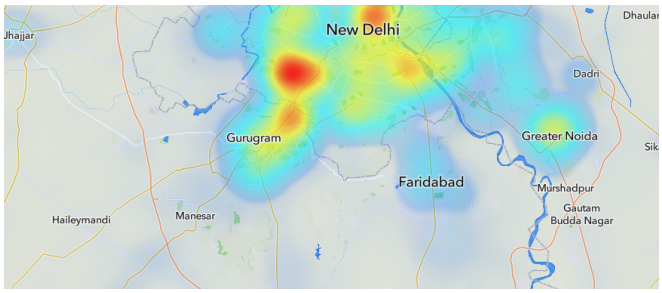

Fig. 5. Location of building on fire in India.

2) South Africa flooding: Heavy rainfall caused catastrophic floods and landslides in southern and south-eastern South Africa, notably in the provinces of KwaZulu-Natal and the Eastern Cape, from April 11 to 13. According to national authorities, 443 people have died in KwaZulu-Natal, while over 40,000 remain missing. Also, over 40,000 people have been evacuated, while 4,000 homes have been demolished or

severely damaged, mainly in Durban and its nearby regions. Due to the severe flooding, a National State of Disaster has been announced. Emergency crews have been dispatched to the areas impacted to give immediate aid to people affected by disasters [42]. Fig. 7 shows the location of flooding in South Africa. Fig. 8 shows the detection results of flooding in South Africa.

B. Experimental Setup

We designed our models with different python packages. The core libraries that we used were Pytorch, numpy, opencv, matplotlib, Scikit-Learn, Keras, and native TensorFlow. The hardware used for this training and testing of models was Nvidia Tesla P100 (16 GB) offered by Google Colab Pro. High Ram offered by Google Colab Pro was used to increase the IO speed from google drive datasets.

To evaluate the performance of our approach, we first Identified the hotspot locations from the Snapchat map using the developed Node.js Google function wrapper in our previous paper. Then we collected the dataset from the Snapchat map API in the exact locations of the emergency events that were identified earlier without any prior knowledge.

The total amount of dataset collected from both locations are shown in Table IV. In our first case study (the location of South Africa flooding) we were able to collect 780 images. However after we manually analyzed the dataset, we found out that there were some images that were unrelated to the case

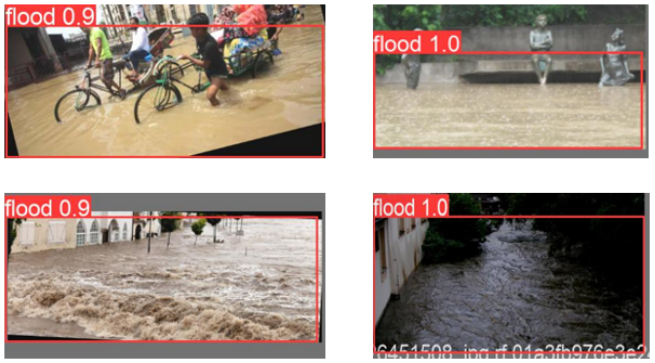

Fig. 8. Detection results of flooding in South Africa.

study and we got rid of them. The total amount of dataset in that location dropped to 546 images. Also, we were able to collect 759 images for the second case study (the location of flooding in South Africa). However, there were some images that unrelated to the case study which we got rid of them. After deleting the noise images, the total number of images became 524 images.

After cleaning our dataset, we used Roboflow online annotation tool that manually labels our dataset, generates boundary boxes, and classifies them. To guarantee that the dataset is spread evenly while considering the correlation between labels and data, the dataset is arbitrarily separated into three sets: training, validation, and test. according to the ratio of %80, %10, and %10. We created three folders to tore the dataset accordingly: training; testing; and validation [43]. Training data are included in the data and enable the deep learning model in producing a prediction. Validation data indicate if the model is competent of accurately detecting new instances or not, and they usually comprise pictures that the model employs to assess and monitor its learning. The images in the testing folder can be used to predict model correctness. The final dataset is saved in the XML dataset format to maintain the same experimental configuration.

Then, we applied the pre-processing steps to the collected images after getting rid of images that were unrelated to the case studies and annotate the related images. After that, due to the fact that object detection models require as much data as possible, our dataset were very low and we should find ways to enlarge them. Therefore, we applied some data augmentation methods to increase the dataset and to ensure the effectiveness of the training. Furthermore, due to the training dataset we used in our research is relatively small even after employing data augmentation methods,We employed transfer learning to overcome this challenge by training our models on the MS-COCO dataset and obtaining a pre-training model as MS-COCO is the baseline standard for validating and testing object detection methods. The pre-trained weights were loaded, and the training began with them as a starting point.

The pre-training algorithm can retrieve the generic characteristics of all objects from the standard datasets. We may employ the matching architecture and weights by leveraging the pre-training framework. Despite the limited dataset, the model may modify the parameters to an optimal form based on the pre-training model. IOU (Intersection over Union) threshold is set to 0.65 in the experiment. After that, we built the object detection models using the trained dataset. Finally, we integrated the trained models into the Apache Spark streaming and used the test dataset to evaluate the performance.

C. Performance Evaluation

During the training phase, the evaluation parameters play an important role in achieving the targeted object detection accuracy. Furthermore, gathering appropriate assessment parameters is a critical component in the differentiation and development of the perfect model. After applying the object detection models to our case studies, We need to test the suggested model's accuracy using several performance assessment indicators such as [44]:

1) Precision (PR): It is utilized to subtract the number of accurately predicted positive patterns from the total number of expected positive patterns in a positive class [45]. Precision can be calculated using the following equation.

$$Precision = \frac{TP}{TP + FP} \tag{5}$$

2) Recall (RE): It is used to determine the percentage of correctly categorized positive patterns [45]. Recall can be calculated using the following equation:

$$Recall = \frac{TP}{TP + FN} \tag{6}$$

True Positive (TP): It corresponds to the quantity of cases correctly recognized by the classifier [46].

False Positive (FP) It represents the amount of negative incidents that were incorrectly classified as positive cases [46].

False Negative (FN): It relates to the quantity of positive incidents that were incorrectly labelled as negative cases. [46].

True Negative (TN): The number of negative cases successfully categorised by the model is denoted by the true negative values [46].

3) F-Score (FS): Also recognized as the F1-score, this is a statistic used to assess data correctness. In addition, it's employed to investigate binary classification methods that classify data as "positive" or "negative". [45]. The F1-score can be calculated using the following equation.

$$F1 = 2 \times \frac{(precision \times recall)}{precision + recall} \tag{7}$$

4) Intersection over Union (IOU): IoU is calculated by dividing the overlapping region between detection and ground truth by their union region [47]. Fig. 9 illustrates the concept of IoU.

When IoU is 100%, projection boxes and ground truth boundaries perfectly coincide, and the prediction is the highest. Despite 100% IoU is practically impractical to acquire (because of the constraints of present Convolutional networks),

an IoU score of 50% to 90% is widely employed in numerous computer vision tasks [48].

In this work, a detection is deemed successful if IoU ≥ 65%.

IoU can be calculated using the following equation:

$$IoU(A,B) = \frac{Area\ of\ Overlap}{Area\ of\ Union} = \frac{A \cap B}{A \cup B} \quad (8)$$

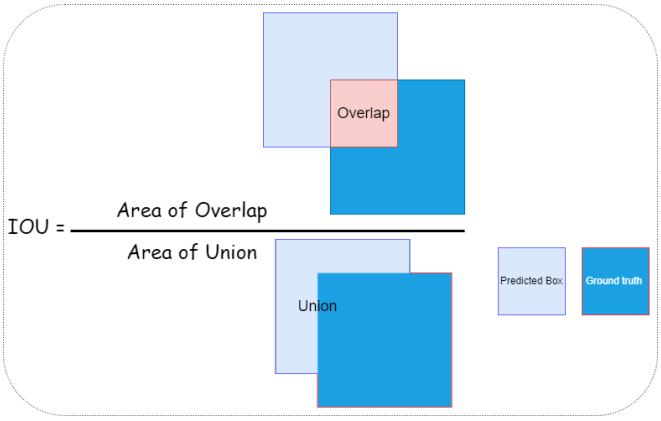

Fig. 9. Intersection over Union (IOU).

5) Average Precision (AP): The Average Precision (AP) is intended to describe the Precision-Recall Curve by summing accuracy over all recall scores ranging from 0 to 1. It's the region underneath the Precision-Recall curve [49]. (AP) can be calculated using the following equation.

$$\text{AP} = \sum_{n} (R_n - R_{n-1}) P_n \quad (9)$$

6) Mean Average Precision (mAP): It is the average of all specified categories of precision. A more excellent mAP implies that an object detection technique performs well in terms of precision and resilience [49]. (mAP) can be calculated using the following equation:

$$\text{mAP} = \frac{1}{N} \sum AP \quad (10)$$

7) Throughput (TP): It refers to the quantity of outcomes delivered in a particular amount of time.

D. Results

We conducted the experiments locally on the environment set up described in the previous subsection to evaluate our approach.

As shown in Table V, which contains six evaluation metrics named Precision(PR), Recall(RE), IOU, F-Score, mAP and Throughput(TP) for the flood case study after applying data augmentation.

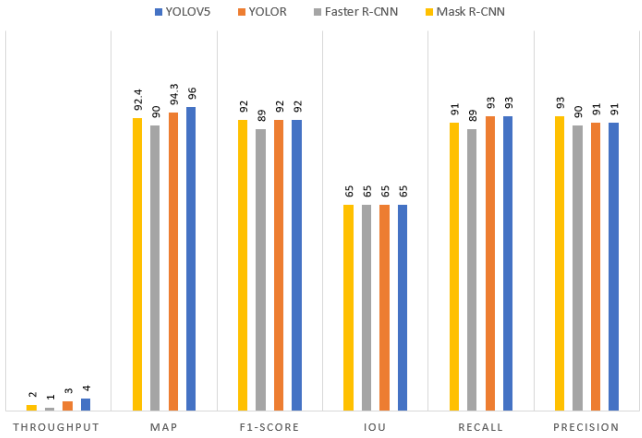

Fig. 10. Results of flood.

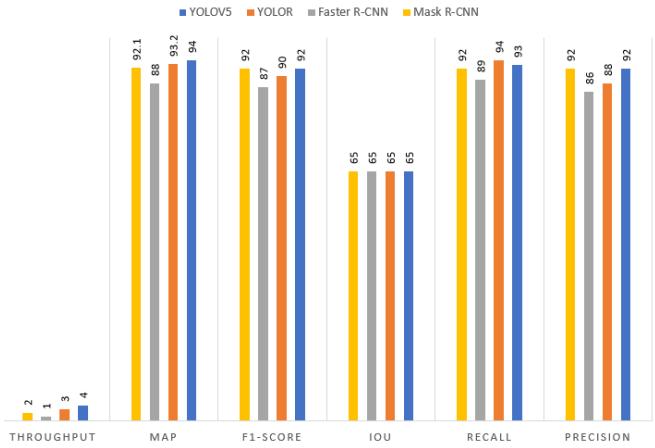

Fig. 11. Results of fire.

Table V illustrates that the results of the one stage models Yolov5 and YoloR are the same for Precision, Recall and F-Measure. However, they vary in terms of mAP score, Yolov5 achieved a very high accuracy of %96 while YoloR achieved %94.3 score. Moreover, the difference in the performance of the two stage models Faster R-CNN and Mask R-CNN is very minimal. However, Mask R-CNN outperform Faster R-CNN in all metrics. Faster R-CNN yields %90 of mAP score while Mask R-CNN yields %92.4.

Table VI shows the performance of the models for the flood case study before applying data augmentation. It can be noted that all the model didn't perform well before applying data augmentation.

Table VII shows the models' performance for the fire case study after applying data augmentation. It can be noted that Yolov5 outperforms all the models in all evaluation metrics except for Recall where YoloR achieved %94 while Yolov5 achieved %93. However, the difference between them is negligible in regards to mAP score, Yolov5 yields %94 while YoloR yields %93.2. On the other hand, the difference between the two stage model Faster R-CNN and Mask R-CNN is noticeable. Mask R-CNN surpass Faster R-CNN in all metrics. Also, Mask R-CNN yields %92.1 of mAP score

TABLE V. RESULTS OF MODELS PERFORMANCE FOR FLOOD CASE STUDY WITH DATA AUGMENTATION

Model	PR	RE	IOU	F-Score	mAP	TP
Yolov5	0.91	0.93	0.65	0.92	0.96	4
YOLOR	0.91	0.93	0.65	0.92	0.943	3
Faster R-CNN	0.90	0.89	0.65	0.89	0.90	1
Mask R-CNN	0.93	0.91	0.65	0.92	0.924	2

TABLE VI. RESULTS OF MODELS PERFORMANCE FOR FLOOD CASE STUDY WITHOUT DATA AUGMENTATION

Model	PR	RE	IOU	F-Score	mAP
Yolov5	0.75	0.77	0.65	0.76	0.82
YOLOR	0.61	0.81	0.65	0.70	0.80
Faster R-CNN	0.66	0.69	0.65	0.67	0.70
Mask R-CNN	0.70	0.72	0.65	0.71	0.79

TABLE VII. RESULTS OF MODELS PERFORMANCE FOR FIRE CASE STUDY WITH DATA AUGMENTATION

Model	PR	RE	IOU	F-Score	mAP	TP
Yolov5	0.92	0.93	0.65	0.92	0.94	4
YOLOR	0.88	0.94	0.65	0.90	0.932	3
Faster R-CNN	0.86	0.89	0.65	0.87	0.88	1
Mask R-CNN	0.92	0.92	0.65	0.92	0.921	2

TABLE VIII. RESULTS OF MODELS PERFORMANCE FOR FIRE CASE STUDY WITHOUT DATA AUGMENTATION

Model	Precision	Recall	IOU	F-Score	mAP
Yolov5	0.74	0.75	0.65	0.74	0.80
YOLOR	0.60	0.80	0.65	0.69	0.78
Faster R-CNN	0.67	0.68	0.65	0.67	0.70
Mask R-CNN	0.68	0.70	0.65	0.69	0.73

which is very minimal to YoloR.

Moreover, as it can be noted from Table VIII, it shows the performance of the models for the fire case study before applying data augmentation. It's obvious that all the model didn't perform well before applying data augmentation.

Fig. 10 shows the performance evaluation of each model for flood dataset model separately while Fig. 11 illustrates the performance evaluation of each model for flood dataset model separately.

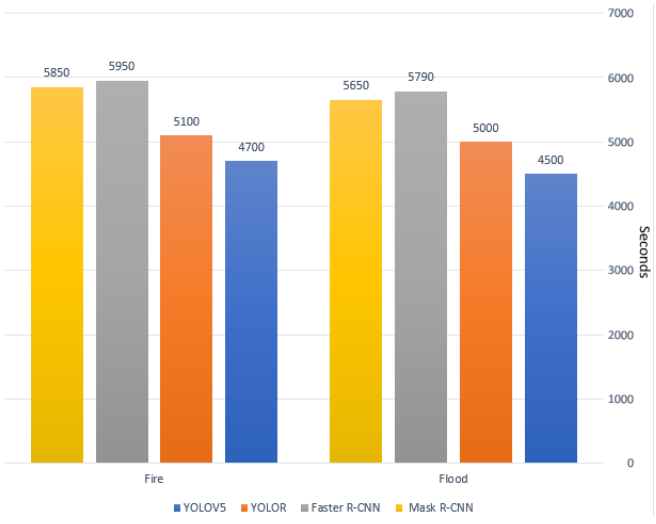

Fig. 12. Models performance using Spark.

Regrading the Throughput score, we applied and run a ranking algorithm to get the scores. After we measured the performance of the models using the test dataset on Spark, we sort out the score results of the models from Spark in ascending order in regards to processing time. Then, the first model (with the least processing time) will get a score of four points which is the highest and the second will get three and the third will get two and the last one will get only one point.

Therefore, Fig. 12 illustrates that Yolov5 model outperform the rest of the models in terms of throughput in both case studies and score four points because it needed less time to process the dataset.

Fig. 12 shows the performance of all the model using Spark.

Table IX shows the results of our location ranking and selection model.

It can be noted that the second case study of South Africa flooding (Location 2) scored seven points in contrast to the first case study building on fire in India (Location 1) which scored only three points. Therefore, the second location was selected as the most urgent location. All Snaps is denoted to all the collected snaps and its score, Emergency is denoted to all the snaps related to emergency cases.

Fig. 13 and 14 depict the the evaluation results of Yolov5 for flood dataset and fire dataset, respectively. In addition, Fig. 15 represents the accuracy score of Mask R-CNN for both datasets. While Fig. 16 shows the accuracy result of YoloR for flood and fire datasets.

TABLE IX. RESULTS OF LOCATION RANKING AND SELECTION ALGORITHM

Location	All Snaps/ Score	Emergency/ Score	mAP/ Score	TP Score	Sum
L1(Fire)	780/ 1	546/ 2	0.918/ 0	0	3
L2(Flood)	759/ 0	524/ 0	0.931/ 3	4	7

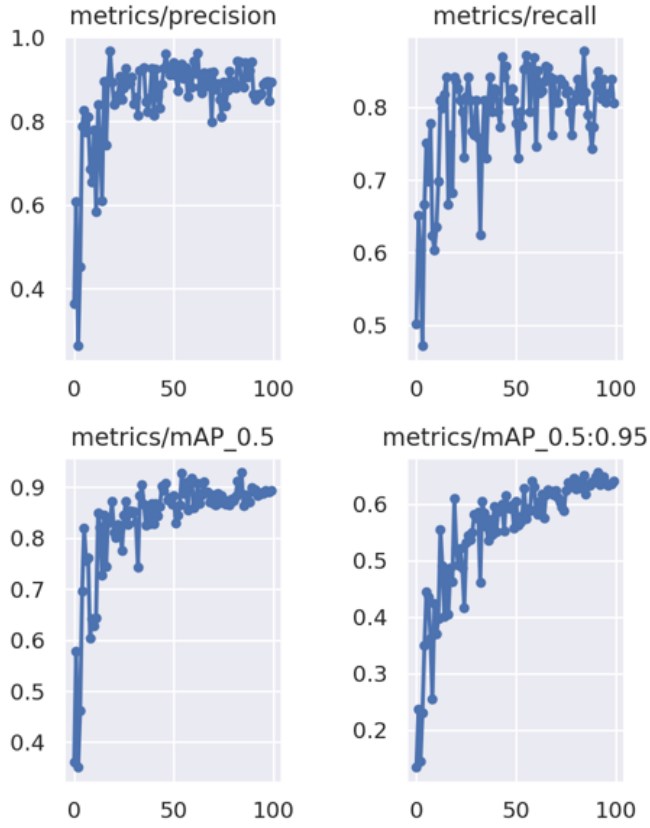

Fig. 13. Yolov5 flood results.

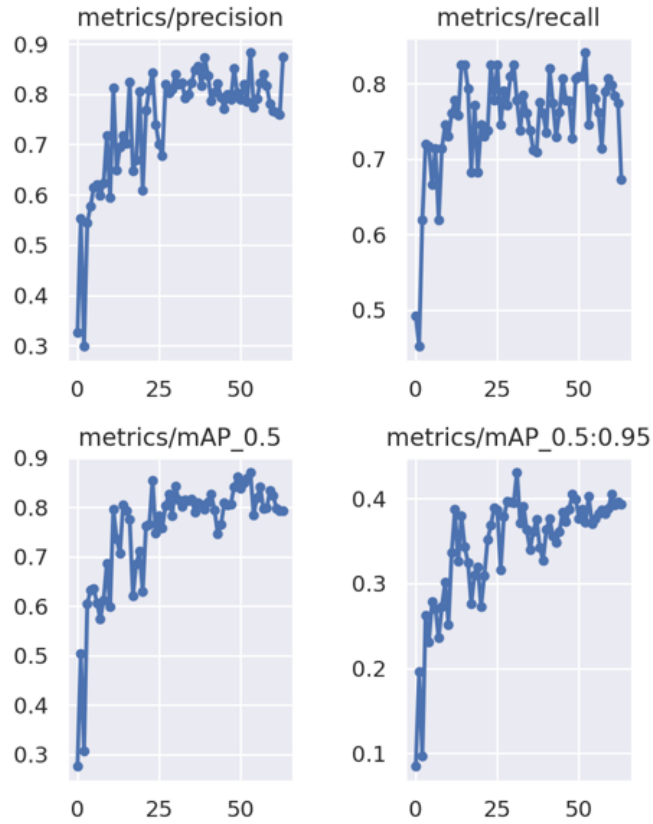

Fig. 14. Yolov5 fire results.

VII. DISCUSSION

The high prevalence of cellphones and social networking platforms such as Snapchat are obviously dissolving traditional barriers between information providers and end-users. It is certainly relevant in emergency events, as individuals on the site produce and exchange real-time information about the event.

However, notwithstanding their demonstrated significance, obtaining event-related information from real-time streams of vast numbers of snaps is a significant challenge.

To address this gap, this paper proposes an automated mapping approach of emergency events and locations based on object detection and social networks. Furthermore, employing object detection methods on social networks to detect emergency events will construct reliable, flexible and speedy approach by utilizing the Snapchat hotspot map as a reliable source to discover the exact location of emergency events.

Moreover, the proposed approach aims to yields high accuracy by employing the state of the arts object detectors to achieve the objectives of this paper. Results show that the proposed approach achieved a very high accuracy of 96% for flood dataset and 94% for fire dataset.

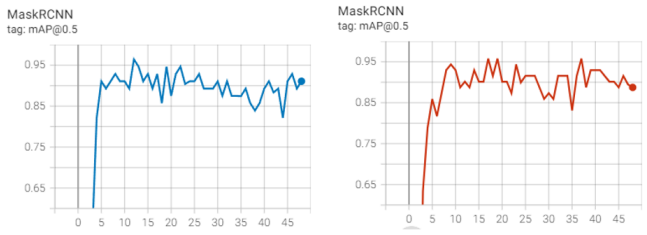

Fig. 15. MaskRCNN.

Among the evaluated models, Yolov5 exhibited the highest performance, proving to be a reliable option for emergency event detection, aligning with previous research indicating that Yolov5 achieves superior accuracy in real-time object detection compared to traditional CNN-based models [50].

Mask R-CNN also demonstrated promising results, particu-

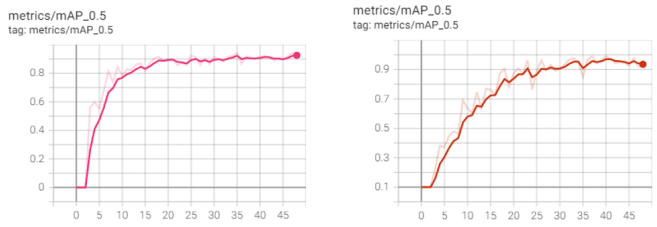

Fig. 16. YOLOR.

larly in terms of learning stability, supporting findings from He et al. [51], which highlight its effectiveness in detecting objects with high precision. However, YoloR struggled with detecting fragmented objects, and Faster R-CNN was the least effective model in this study, consistent with prior work noting Faster R-CNN's computational inefficiency for real-time detection [52] .

VIII. Conclusion

Based on experimentation and testing, the YoloR model did not perform well without applying data augmentation techniques on the fire and flood datasets because the dataset was too small. Without data augmentation, the recall was as high as 0.8, but the precision was merely 0.6.

The model kept predicting numerous small and large boxes, and in doing so, it got many erroneous boxes alongside the ground truth; as a result, it gave many incorrect outputs. Its precision was very low, but since a few of those boxes were the actual boxes, the recall was 0.8. The recall refers to all the actual boxes being detected (irrespective of how many erroneous ones you get in addition). We applied brightness data augmentation where the image was made brighter by 20% or darker by 20% which makes it more stable in different lighting conditions.

By applying data augmentation, the precision increased to 0.88 while recall increased to 0.94, with a total mAP of 0.932 on the fire dataset. A similar augmentation technique was applied to the flood dataset. We noticed that YoloR works better for continuous objects; when we have objects that break or distance between each instance, it does not work very well. Because instead of detecting the whole object, it detects numerous smaller objects. Technically it is correct, but in terms of the mAP score, this could consider a downside.

Moreover, Mask R-CNN performed very well, it was a stable model, and the predictions were similar to other models in terms of accuracy. Mask R-CNN's fascinating side is that its learning curve is better than the other models. If we had more data, Mask R-CNN would do better than other models.

Yolov5 yielded the highest accuracy for both datasets compared to the rest of the models. Even before applying the data augmentation techniques, both datasets' accuracy scores were acceptable for Yolov5. Yolov5 is available in various variants: Yolov5x, Yolov5m, Yolov5l, and Yolov5x, each with deeper layers than the others. We used Yolov5l for both flood and fire datasets in this work.

Faster R-CNN was the least model in terms of performance compared to other models. Before applying data augmentation techniques, its performance was almost the same, and the difference was negligible. However, after applying data augmentation techniques, the performance of Faster R-CNN for the flood dataset was better than that of the fire dataset; it yielded 0.90 and 0.88, respectively.

Future work expected that the performance would improve if more datasets and additional object detection models were applied to the approach. Furthermore, our system shows promising results when combining the Snapchat hotspot map and computer vision approach to detect the location of emergency events.

Resampling Imbalanced Healthcare Data for Predictive Modelling

Manoj Yadav Mamilla, Ronak Al-Haddad, Stiphen Chowdhury
Computing and Information Science
Anglia Ruskin University, East Rd, Cambridge CB1 1PT

***Abstract*—Imbalanced datasets pose significant challenges in healthcare for developing accurate predictive models in medical diagnostics. In this work, we explore the effectiveness of combining resampling methods with machine learning algorithms to enhance prediction accuracy for imbalanced heart and lung disease datasets. Specifically, we integrate undersampling techniques such as Edited Nearest Neighbours (ENN) and Instance Hardness Threshold (IHT) with oversampling methods like Random Oversampling (RO), Synthetic Minority Oversampling Technique (SMOTE), and Adaptive Synthetic Sampling (ADASYN). These resampling strategies are paired with classifiers including Decision Trees (DT), Random Forests (RF), K-Nearest Neighbours (KNN), and Support Vector Machines (SVM). Model performance is evaluated using accuracy, precision, recall, F1 score, and the Area Under the Curve (AUC). Our results show that tailored resampling significantly boosts machine learning model performance in healthcare settings. Notably, SVM with ENN undersampling markedly improves accuracy for lung cancer predictions, while SVM and RF with IHT achieve higher validation accuracies for both diseases. Random oversampling shows variable effectiveness across datasets, whereas SMOTE and ADASYN consistently enhance accuracy. This study underscores the value of integrating strategic resampling with machine learning to improve predictive reliability for imbalanced healthcare data.**

***Keywords*—Imbalanced data; resampling; machine learning; healthcare**

I. Introduction

The accurate prediction of medical conditions can play a key role in improving patient outcomes and healthcare systems. Early detection of disease is essential for anticipating its clinical progression and developing effective treatments. However, accurate predictions remain a significant challenge [1].

Such predictions enable for well-informed decisions on diagnosis, intervention, and treatment by both patients and healthcare practitioners. Early detection of potential health issues enables timely, potentially life-saving interventions. These interventions significantly improve patient survival and quality of life. Furthermore, more accurate disease forecasts can help reduce healthcare costs by minimising unnecessary diagnostic tests and treatments. Hence, robust predictive models are clearly needed to enhance forecasting accuracy in clinical settings [2], [3].

Imbalanced datasets, however, present a significant challenge to achieving high predictive performance. This issue arises when one class, often a crucial medical condition, is significantly under-represented compared to the majority class. As a result, models trained on such datasets may become biased towards the majority class. This bias reduces the accuracy of minority-class predictions [4].

Precise identification of the minority class is often crucial in medical diagnostics, especially in screening programs where identifying disease-positive patients is paramount. The consequences of misclassification in these cases can be severe. The dominance of the majority class in imbalanced datasets can compromise a model's ability to detect rare but critical cases. This can lead to delayed or missed diagnoses, suboptimal treatment, and potential healthcare disparities [5].

In this paper, we propose a novel approach to predictive modelling for imbalanced healthcare data, specifically targeting heart and lung disease datasets. Our primary contribution is the integration of advanced resampling techniques with established machine learning algorithms to address data imbalance effectively. This study is driven by the following research question:

How can resampling strategies and machine learning algorithms be combined to improve predictive accuracy on imbalanced healthcare datasets?

To answer this question, we pursue the following research objectives:

- Evaluate the effectiveness of various resampling techniques (ENN, IHT, RO, SMOTE, ADASYN) in mitigating class imbalance in heart and lung disease datasets.
- Compare the performance of multiple machine learning algorithms (DT, RF, KNN, SVM) when paired with different resampling strategies.
- Determine the optimal combination of resampling methods and classifiers for improving disease prediction accuracy while maintaining computational efficiency.
- Assess the generalisability of resampling strategies across distinct medical conditions (heart disease and lung cancer) and provide insights into their applicability in real-world healthcare settings.

Various resampling strategies have been developed to ameliorate these challenges. Oversampling approaches, such as Random Oversampling, SMOTE, and ADASYN, increase the representation of the minority class by either replicating existing minority instances or generating new synthetic samples. Conversely, undersampling methods reduce the size

of the majority class by removing selected instances, which allows algorithms greater opportunity to learn minority-class patterns [6], [7]. Despite their promise, each technique has limitations. For instance, oversampling methods risk overfitting by replicating minority instances or generating low-variance synthetic points. Undersampling, on the other hand, may discard potentially valuable information.

Recent studies confirm that such resampling methods can significantly enhance the analysis and interpretation of medical data, which enables more accurate and reliable predictions [8]–[10]. However, questions remain about how best to integrate these techniques within different disease contexts. This is particularly true for conditions like heart and lung diseases, which have distinct patterns of risk factors, symptomatology, and prevalence rates.

Our experiments demonstrate that strategic combinations of sampling methods and machine learning models significantly improve both accuracy and reliability, providing a robust framework for addressing the challenges posed by imbalanced datasets in healthcare. Specifically, we find that Support Vector Machines (SVM) coupled with ENN significantly enhance lung cancer prediction accuracy. Moreover, SVM and Random Forest models utilising IHT achieve high validation accuracies for heart and lung disease data. These findings surpass traditional approaches in performance and illustrate a robust framework for effectively addressing the challenges posed by imbalanced medical datasets.

By systematically evaluating the impact of multiple resampling techniques on predictive performance, this study provides a comprehensive understanding of how to improve medical data analysis in the presence of imbalance. Our findings offer healthcare researchers and practitioners enhanced tools for early disease detection and intervention, contributing to improved patient care and outcomes.

II. Related Work

A growing body of research has sought to refine predictive modelling in healthcare by addressing the persistent challenge of data imbalance. Although these works collectively demonstrate the efficacy of outlier detection, resampling methods, and advanced machine learning strategies, key uncertainties persist regarding the transferability and consistency of these approaches across different disease domains. This section examines the existing literature, highlighting both substantial progress and the outstanding questions that motivate our study.

A. Foundational Approaches to Imbalanced Data

Fitriyani et al. [11] developed a heart disease prediction model integrating Density-based Spatial Clustering of Applications with Noise (DBSCAN) for outlier detection, hybrid SMOTE-ENN for balancing training data, and XGBoost for classification. Their results on the Statlog and Cleveland datasets emphasise the gains possible when combining sophisticated outlier removal with carefully chosen resampling techniques. However, their investigation focuses on a single disease domain and two datasets, leaving open the question of whether such hybrid pipelines would maintain similar levels of performance when confronting data from different medical conditions or with varying degrees of imbalance.

Khushi et al. [12] shifted attention to lung cancer prediction, systematically comparing traditional classifiers and imbalance strategies (including oversampling) on the PLCO and NLST datasets. Their findings reinforce the significance of well-chosen resampling techniques for boosting model performance in highly skewed datasets. Yet, the study's scope largely confines itself to lung cancer, with minimal discussion of how these strategies might generalise to other diseases - particularly those with distinct clinical signatures, feature sets, and imbalance ratios.

B. Feature Selection and Ensemble Classifiers

Ishaq et al. [13] proposed a feature-selection-based strategy for predicting heart-failure survival, demonstrating how SMOTE, combined with a Random Forest approach for feature importance, can markedly improve predictive accuracy. This underscores that well-targeted feature engineering, used in tandem with resampling, can mitigate data imbalance. However, while they demonstrate promising gains, their approach again centres on a single disease (heart failure) and does not address whether similar techniques would be equally beneficial for other conditions particularly where key feature sets differ significantly (e.g. in lung disease).

Ghorbani et al. [14] examined multiple SMOTE variants for educational data, illustrating how subtle algorithmic differences in resampling methods can translate into pronounced differences in classifier performance. Although their work concerns non-medical data, it offers a compelling reminder that each dataset may respond uniquely to different sampling methods. The question remains how to identify which undersampling or oversampling strategies e.g. ENN, IHT, SMOTE, ADASYN are most compatible with specific disease datasets that frequently exhibit high dimensionality, noisy features, or overlapping classes.

C. Advanced Architectures and Cross-Domain Insights

Li et al. [15] demonstrated how complex, dual-stage attention-based models with CBAM modules can handle data imbalance in engineering fault diagnosis. While fault-diagnosis data differ from clinical datasets, their positive results point toward the adaptability of advanced architectures for skewed classification problems. Nonetheless, applying such intricate methods to medical data raises additional concerns of interpretability and domain relevance, as well as the significant computational overhead often associated with deep learning in real-world clinical settings.

D. Summary of Gaps and Motivation

Despite these advancements, three primary gaps emerge:

1. Current studies typically focus on a single disease (e.g. heart disease or lung cancer), limiting our understanding of whether and how resampling methods generalise across conditions with distinct pathophysiology, class ratios, and feature distributions.

2. While various works explore SMOTE, ENN, or other techniques, they frequently implement a single approach or compare only a narrow set of sampling techniques. Similarly, they often limit themselves to a small subset of classification

algorithms, resulting in an incomplete picture of how different combinations of sampling algorithms and machine learning models might perform under different clinical constraints.

3. Many studies highlight accuracy gains, but relatively few provide detailed insights into the computational trade-offs such as training and inference times, resource consumption, or real-time feasibility that are crucial for deployment in actual healthcare settings, for instance, Fitriyani et al. [11] and Khushi et al. [12] focus on performance without efficiency analysis. Moreover, interpretability and domain-specific constraints have not always been sufficiently addressed when employing more advanced modelling frameworks.

In light of these gaps, our study aims to:

1) *Evaluate multiple resampling methods (ENN, IHT, RO, SMOTE, and ADASYN) across two distinct diseases*: heart disease and lung cancer. By spanning two clinically significant but different pathologies, we shed light on how imbalanced data strategies may generalise or require adaptation across disease contexts.
2) *Compare four diverse machine learning algorithms* (Decision Trees, Random Forests, K-Nearest Neighbours, and Support Vector Machines) under each resampling technique, thus providing a broader evidence base on which model–sampling pairs work best for specific disease datasets.
3) *Examine computational efficiency and practicality*, reporting on training/validation/testing times and potential interpretability issues, thereby informing real-world clinical adoption.

By addressing these specific gaps, our research contributes a deeper and more generalisable understanding of how to tailor resampling approaches and classifier choices in the face of disease-specific imbalances. This work ultimately aspires to promote more robust, reliable, and domain-aware predictive models in healthcare.

III. Methodology

We employ a straightforward yet comprehensive methodology (see Fig. 1) to address the challenges posed by data imbalance in medical predictive modelling. Our process encompasses data preprocessing, various resampling strategies, machine learning algorithm selection, and performance evaluation. The choice of each algorithm and sampling method is guided by the characteristics of the classification tasks (i.e. heart disease vs. lung disease) and by the need to mitigate imbalance effectively.

A. Sampling Techniques

1) Undersampling Techniques: Edited Nearest Neighbours (ENN) and Instance Hardness Threshold (IHT) are employed to mitigate the effect of imbalanced datasets. ENN removes misclassified or noisy observations by comparing each sample to its k nearest neighbours, thereby cleansing borderline cases in the dataset. In contrast, IHT identifies and removes "hard-to-classify" instances based on their proximity to the decision boundary, helping models concentrate on more informative examples [16], [17]. By discarding problematic samples, both methods aim to create a dataset that better represents minority-class patterns without overwhelming the model.

2) Oversampling Techniques: Random Oversampling duplicates minority-class instances to balance the dataset, albeit with a heightened risk of overfitting. To address this limitation, we also use the Synthetic Minority Oversampling Technique (SMOTE) and Adaptive Synthetic (ADASYN) sampling, both of which generate synthetic examples of the minority class [18], [19]. These strategies introduce diversity into training data and reduce the bias towards the majority class, enabling models to learn more nuanced decision boundaries.

B. Datasets Utilisation

Two publicly available datasets are utilised in this study. The Kaggle Lung Cancer dataset [20] comprises 163,763 records with detailed patient information (including binary labels denoting the presence of lung cancer). The heart disease dataset [21] from the UCI repository combines multiple sources and focuses on 14 key attributes (out of an original 76) to predict the presence of cardiovascular disease. These datasets were chosen for their relevance to clinical practice and their relatively high degree of imbalance, offering an appropriate testbed for evaluating sampling methods.

C. Machine Learning Algorithms

Four machine learning algorithms are employed to assess the impact of each sampling strategy:

- Decision Trees (DT): An interpretable, rule-based approach that partitions data into increasingly homogeneous subsets.
- Random Forests (RF): An ensemble of multiple decision trees, aggregating predictions to reduce overfitting and enhance generalisability.
- K-Nearest Neighbours (KNN): A distance-based classifier capable of handling non-linear decision boundaries, sensitive to local data structure.
- Support Vector Machines (SVM): A robust method for binary classification, especially effective in high-dimensional spaces, using kernel functions to separate classes with maximal margins.

Each algorithm is trained and evaluated on both datasets with the aforementioned sampling techniques applied. This setup allows for a direct comparison of how undersampling and oversampling methods impact model accuracy, precision, recall, and F1-score.

D. Methodological Flow and Evaluation

As summarised in Fig. 1, data preprocessing and resampling are carried out first to correct for imbalance. The selected models (DT, RF, KNN, and SVM) are then trained on these preprocessed datasets. Finally, we measure predictive performance using accuracy, precision, recall, and F1-score to gauge the effectiveness of each sampling approach.

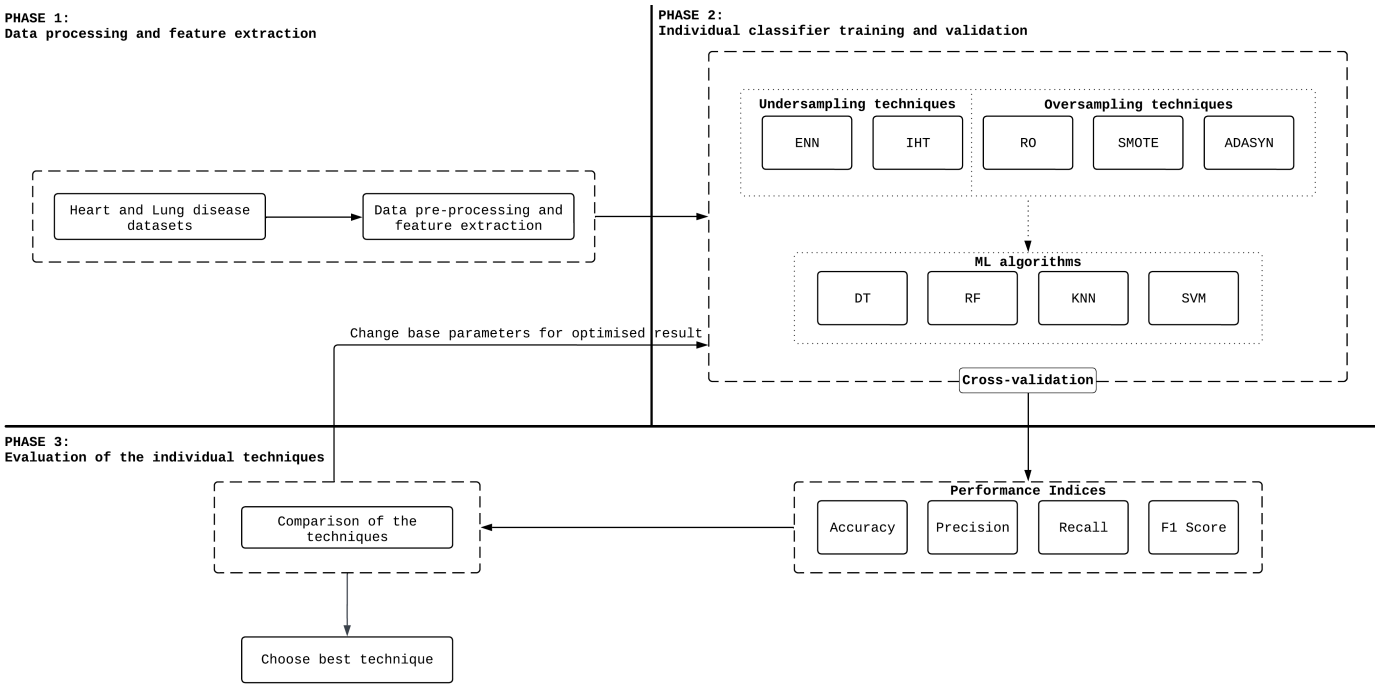

Fig. 1. A three-phase approach to heart and lung disease classification, including data preprocessing, resampling techniques, machine learning model selection, and performance evaluation.

IV. Experimental Setup

This study investigates the effect of various resampling strategies on the predictive accuracy of machine learning models when dealing with imbalanced healthcare data from Kaggle (lung cancer) and UCI Machine Learning Repository (heart disease).

A. Dataset Description

1) Kaggle Lung Cancer Dataset: This dataset comprises patient-level data intended for predicting the occurrence of lung cancer. It includes features such as age, gender, smoking history, and various diagnostic measurements. The primary challenge stems from its imbalanced distribution, with a significantly lower proportion of positive lung cancer instances compared to negative ones.

2) UCI Heart Disease Dataset: This collection of patient records is aimed at predicting the presence of heart disease. It includes demographic information, symptomatology, and diagnostic test results. Similar to the lung cancer dataset, it is highly imbalance, with heart disease instances occurring less frequently than negative cases, which makes it an excellent testbed for evaluating the effectiveness of resampling techniques.

B. Data Collection and Preprocessing

Data were collected and rigorously preprocessed to ensure quality and consistency. The preprocessing phase addressed missing values, outliers, and normalisation:

- Mean Imputation for Missing Values: For each feature containing missing entries, we replaced missing values with the mean value of that feature across all available data points:
$$\mu_{\text{missing}} = \frac{\sum_{i=1}^{n} x_i}{n}.$$
- Normalisation (Min–Max Scaling): We rescaled each feature to a common range of $[0, 1]$ using Min–Max scaling:
$$x' = \frac{x - \min(x)}{\max(x) - \min(x)},$$
ensuring that differences in the original data ranges are preserved without distortion.

C. Sampling Techniques

Given the imbalanced nature of these datasets, we applied five resampling methods: two undersampling techniques - Edited Nearest Neighbour (ENN) and Instance Hardness Threshold (IHT) - and three oversampling techniques - Random Oversampling (RO), Synthetic Minority Oversampling Technique (SMOTE), and Adaptive Synthetic (ADASYN).

- Edited Nearest Neighbour (ENN): ENN refines the dataset by removing samples that are misclassified by their k-nearest neighbours, thereby enhancing the purity of the minority class:
$$ENN(S) = \{\, x \in S \mid \text{class}(x) = \text{class}(\text{kNN}(x)) \}.$$
- Instance Hardness Threshold (IHT): IHT iteratively applies oversampling approaches and evaluates classifier performance on the modified dataset, aiming to attain a balance that optimises the model's sensitivity to the minority class.

- Random Oversampling (RO): RO duplicates instances of the minority class to rebalance the dataset, albeit at an increased risk of overfitting.
- SMOTE and ADASYN: Both SMOTE and ADASYN generate synthetic minority examples, helping to balance class distribution and introduce diversity to the training data. This prepares the model to generalise more effectively from underrepresented classes.

D. Model Selection and Training

We selected four machine learning algorithms for evaluation: Decision Trees, Random Forests, K-Nearest Neighbours, and Support Vector Machines. These models represent a spectrum of complexity: from the relatively interpretable structure of Decision Trees to the more sophisticated nature of SVMs. The training process involved optimising hyperparameters for each model using techniques such as grid search and cross-validation to maximise overall performance.

E. Evaluation Metrics

We employed accuracy, precision, recall, and the F1-score to evaluate model performance comprehensively. These metrics were chosen not only to gauge overall accuracy but also to assess the models' ability to identify positive instances (recall) and the reliability of those predictions (precision).

a) Precision:

$$\text{Precision} = \frac{TP}{TP + FP},$$

where TP (true positives) are correctly predicted positive instances, and FP (false positives) are incorrectly predicted as positive. High precision in this work indicates that when the model predicts a disease, it is likely correct.

b) Recall (Sensitivity):

$$\text{Recall} = \frac{TP}{TP + FN},$$

where FN (false negatives) are positive instances incorrectly predicted as negative. Recall here reflects the model's capacity to detect all relevant cases.

c) F1-Score:

$$F1 = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}}.$$

This harmonic mean of precision and recall is especially relevant when misclassifications either false positives or false negatives carry significant risks, as is common in healthcare.

Finally, multiple runs were conducted for each model and sampling combination to ensure the reliability of findings and to capture performance variance across different trials. This robust experimental structure enables a comprehensive assessment of how well different resampling strategies address data imbalance in healthcare predictive modelling.

V. Results

A. Experiment with the Heart Dataset

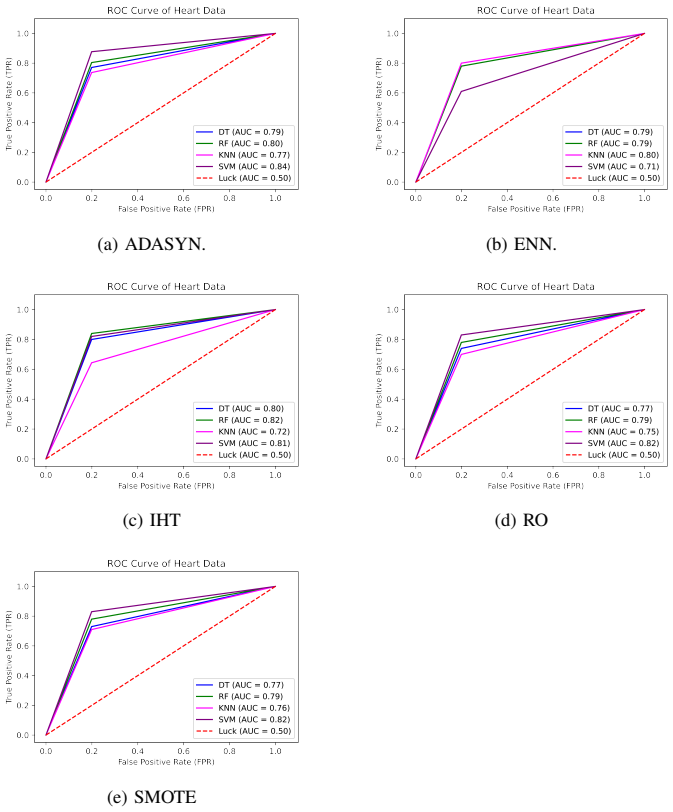
Table I presents the results for the heart dataset. Overall, Support Vector Machines (SVM) excelled in precision, particularly when paired with Edited Nearest Neighbours (ENN), underlining its effectiveness in handling imbalanced data. SVM thus appears well-suited to heart disease prediction, consistently achieving high scores in precision, F1, and AUC. These results are especially significant in medical diagnostics, where balancing sensitivity and specificity can be challenging. Notably, the AUC values were strong for Random Forest (RF) with Instance Hardness Threshold (IHT) and SVM with Adaptive Synthetic Sampling (ADASYN), further highlighting SVM's capacity to reduce false positives while maintaining a high detection rate.

TABLE I. Performance Metrics for Various Classifiers on the Heart Dataset Across Different Resampling Techniques, Demonstrating Superior Precision and Recall by SVM and RF

		ENN	IHT	RANDOM	SMOTE	ADASYN
DT	Precision	0.90	0.82	0.88	0.82	0.81
	Recall	0.90	0.79	0.83	0.82	0.76
	F1 Score	0.90	0.81	0.85	0.82	0.79
	AUC	0.781	0.803	0.747	0.7361	0.7712
RF	Precision	0.90	0.89	0.90	0.87	0.88
	Recall	**0.93**	0.89	0.77	0.77	0.75
	F1 Score	0.91	**0.89**	0.83	0.82	0.81
	AUC	0.781	**0.843**	0.78	0.7806	0.804
KNN	Precision	0.92	0.68	0.71	0.73	0.73
	Recall	0.83	0.59	0.71	0.63	**0.88**
	F1 Score	0.87	0.63	0.71	0.68	**0.80**
	AUC	**0.802**	0.6449	0.705	0.719	0.7374
SVM	Precision	**0.96**	**0.95**	**0.93**	0.74	**0.91**
	Recall	0.93	0.75	0.74	**0.94**	0.90
	F1 Score	**0.95**	0.84	0.83	0.83	0.90
	AUC	0.618	0.8224	0.8305	0.8306	**0.8779**

Fig. 2 illustrates ROC curves for various classifiers on the Heart Dataset across different resampling techniques, further confirming that SVM and RF generally outperform the other classifiers. Particularly noteworthy is ENN's significant enhancement of SVM's performance, as reflected in the high AUC scores. Likewise, ADASYN combined with SVM reached the highest AUC among the tested setups, indicating its efficacy in tackling data imbalance. By comparison, the RANDOM and SMOTE approaches yielded moderately lower AUCs, underscoring the importance of carefully aligning sampling methods with the dataset's characteristics.

Table II indicates that computational efficiency varies with the choice of resampling method. Decision Tree (DT) and KNN demonstrate notably faster training times, especially under the RANDOM and ADASYN schemes, suggesting relatively low computational overhead. By contrast, SVM exhibits longer training times particularly with RANDOM highlighting a potential trade-off between speed and predictive performance.



(a) ADASYN. (b) ENN.

(c) IHT (d) RO

(e) SMOTE

Fig. 2. ROC curves for various classifiers on the Heart Dataset across different resampling techniques. The curves demonstrate the superior performance of SVM and RF, particularly with ENN and ADASYN. These methods enhance the classifiers' ability to handle imbalanced data, as evidenced by high AUC values.

TABLE II. COMPARISON OF TRAINING, VALIDATION, AND TESTING TIMES FOR DIFFERENT CLASSIFIERS ON THE HEART DATASET USING VARIOUS RESAMPLING METHODS. NOTABLE DIFFERENCES IN COMPUTATIONAL EFFICIENCY ARE OBSERVED, PARTICULARLY FOR SVM AND RF

		ENN	IHT	RANDOM	SMOTE	ADASYN
DT	Training	0.0031	0.002	**0.0001**	0.0038	**0.0001**
	Validation	0.013	0.010	**0.0084**	**0.0084**	0.0093
	Testing	0.0151	0.0136	0.0050	0.0090	**0.0006**
RF	Training	0.2885	0.0172	0.0802	0.0745	**0.0438**
	Validation	0.0280	**0.0080**	0.0082	0.0170	0.0083
	Testing	0.0280	**0.0063**	0.0104	0.0161	0.0133
KNN	Training	0.0051	**0.0001**	**0.0001**	0.0035	**0.0001**
	Validation	0.0160	**0.0033**	0.0111	0.0102	0.0111
	Testing	0.0125	0.0099	0.0063	0.0128	**0.0040**
SVM	Training	0.2191	0.0780	**0.0577**	0.0919	0.0825
	Validation	0.0143	0.0114	**0.0071**	0.0088	0.0103
	Testing	0.0121	**0.0020**	0.0077	0.0101	0.0056

B. Experiment with the Lung Dataset

Table III details the results for the lung dataset. Both Decision Tree (DT) and Random Forest (RF) achieved better precision when paired with ENN, IHT, and RANDOM sampling, underlining their capacity for highly accurate lung disease classification. However, DT's slightly lower AUC under RANDOM sampling and SMOTE suggests minor compromises in balancing sensitivity and specificity. While DT occasionally overlooks some true cases, as evidenced by its recall, RF's flawless recall with ENN and IHT demonstrates that it seldom misses positive instances. As a result, both DT and RF prove highly dependable, with RF offering a small edge in comprehensive patient identification.

TABLE III. PERFORMANCE METRICS FOR VARIOUS CLASSIFIERS ON THE LUNG DATASET ACROSS DIFFERENT RESAMPLING TECHNIQUES. PHENOMENAL PRECISION AND RECALL ARE ACHIEVED BY DT AND RF WITH ENN AND IHT, WHILE SVM SHOWS CONSISTENTLY HIGH PERFORMANCE

		ENN	IHT	RANDOM	SMOTE	ADASYN
DT	Precision	**1**	**1**	**1**	0.96	0.94
	Recall	0.95	**1**	0.88	0.88	0.91
	F1 Score	0.98	**1**	0.93	0.92	0.93
	AUC	0.977	0.825	0.931	0.918	0.9041
RF	Precision	**1**	**1**	**1**	0.92	0.95
	Recall	**1**	**1**	0.88	0.98	0.93
	F1 Score	**1**	**1**	0.94	0.95	0.94
	AUC	**1**	0.93	0.931	0.94	0.934
KNN	Precision	0.98	0.75	**1**	0.93	0.92
	Recall	0.98	0.90	0.73	0.93	0.91
	F1 Score	0.98	0.82	0.84	0.93	0.91
	AUC	0.738	0.7375	0.8921	0.92	0.911
SVM	Precision	**1**	**1**	**1**	0.95	0.96
	Recall	**1**	**1**	0.90	0.95	0.96
	F1 Score	**1**	**1**	0.95	0.95	0.96
	AUC	0.9659	**0.95**	0.911	0.949	**0.955**

While KNN shows some variability particularly in precision with IHT it still maintains solid results in precision and recall, indicating its ability to identify lung disease patients accurately. By contrast, SVM consistently delivers near-perfect performance across all evaluated metrics and resampling configurations, highlighting its powerful capacity to discriminate between diseased and healthy individuals. Its balanced high precision and recall minimise both misdiagnoses and missed diagnoses.

TABLE IV. TRAINING, VALIDATION, AND TESTING TIMES FOR DIFFERENT CLASSIFIERS ON THE LUNG DATASET USING VARIOUS RESAMPLING METHODS. DT AND KNN OFTEN REQUIRE MINIMAL COMPUTATION WITH RANDOM AND ADASYN

		ENN	IHT	RANDOM	SMOTE	ADASYN
DT	Training	**0.0001**	0.0077	**0.0001**	**0.0001**	0.0081
	Validation	**0.0046**	0.0098	0.0083	0.0102	0.0131
	Testing	0.0085	**0.0030**	0.0085	0.0098	0.0202
RF	Training	**0.0193**	0.0250	0.0999	0.0833	0.0329
	Validation	0.0122	**0.0107**	0.0134	0.0169	0.0203
	Testing	0.0110	0.0081	0.0110	0.0087	0.0123
KNN	Training	0.0065	0.0017	**0.0001**	0.0015	0.0020
	Validation	0.0081	0.0082	0.0100	**0.0081**	0.0142
	Testing	0.0100	0.0067	**0.0076**	0.0146	0.0166
SVM	Training	0.0080	**0.0001**	0.8198	0.0121	0.0166
	Validation	0.0062	0.0085	0.0084	**0.0082**	0.0145
	Testing	0.0084	0.0086	0.0101	0.0112	**0.0101**

The F1 and AUC values reaching 100% for RF with ENN and IHT underscore the potency of these resampling methods in boosting accuracy for markedly skewed datasets. Interestingly, the lung dataset seems to respond more strongly to these techniques than the heart dataset, potentially reflecting

inherent differences in class distribution or unique dataset attributes.

Fig. 3 shows ROC curves for various classifiers on the Lung Dataset across different resampling techniques. The curves highlight the exceptional precision and recall achieved by RF and SVM, especially with ENN and IHT, confirming their robustness in identifying lung disease despite data imbalance.

Finally, Table IV summarises the training, validation, and testing times for different classifiers on the Lung Dataset. Decision Trees (DT) and KNN demonstrate relatively low computational demands, most notably under the RANDOM and ADASYN resampling methods, making them viable options where computational resources are limited. Random Forest (RF) and SVM, in contrast, show varying training times, with RF proving efficient under ENN and IHT, while SVM attains rapid validation times with ENN. These results suggest that DT and KNN may suffice where speed is paramount, whereas RF and SVM, coupled with certain resampling strategies, strike a more favourable balance between computational overhead and predictive performance.

VI. Discussion

The experimental results confirm that pairing tailored resampling methods with appropriate classifiers can greatly improve predictive performance in imbalanced healthcare datasets. The results show that combining advanced resampling techniques with machine learning models improves predictive accuracy for imbalanced healthcare data. However, performance differences across datasets highlight the need to select resampling strategies and classifiers based on dataset characteristics.

A. Effectiveness of Resampling Methods

Resampling techniques play a crucial role in addressing class imbalance in heart disease and lung cancer predictions. Instance Hardness Threshold (IHT) and Edited Nearest Neighbours (ENN) performed best for undersampling, while ADASYN and SMOTE increased minority-class representation through synthetic data generation. Their effectiveness varied based on the dataset and classifier.

IHT improved precision and recall in heart disease predictions because it removed ambiguous majority-class instances. This effect was most pronounced when combined with Random Forest and Support Vector Machines. ENN produced the best results for lung cancer predictions because it refined the decision boundary and enhanced SVM's ability to distinguish between classes. ADASYN and SMOTE produced general improvements, but they worked best for heart disease predictions where a moderate imbalance allowed for better synthetic sample generation. These findings confirm that resampling techniques must be chosen based on the dataset rather than applied universally.

B. Classifier Performance Across Datasets

Classifier performance depended on disease type and resampling strategy. Support Vector Machines performed best for lung cancer prediction, especially when combined with ENN. This combination removed noisy samples and allowed SVM to establish a clearer decision boundary. Random Forest and Decision Trees outperformed other models for heart disease predictions because they captured feature interactions effectively.

SVM provided the highest accuracy and recall for lung cancer predictions, making it the best choice for highly imbalanced, binary-structured datasets. Random Forest and Decision Trees worked better for heart disease because they handled mixed categorical and numerical data more effectively. K-Nearest Neighbours showed inconsistent results across both datasets because it was highly sensitive to imbalance and feature distribution.

C. Dataset-Specific Performance

Model performance varied between the heart disease and lung cancer datasets due to differences in class imbalance severity, feature types, and data distribution. The heart disease dataset, with moderate imbalance and mixed categorical-numerical features, favored Random Forest with IHT and ADASYN, which excel at capturing complex feature interactions. Conversely, the lung cancer dataset, with extreme imbalance and mostly binary features, suited SVM with ENN, as this combination effectively refines sparse decision boundaries. These results suggest our algorithms are better suited to specific data types: RF thrives with heterogeneous features,

while SVM excels with binary, highly skewed data. This adaptability underscores the importance of matching resampling and classifiers to dataset properties.

D. Computational Considerations

The study also highlights key computational trade-offs. SVM and Random Forest provided the highest accuracy, but they required longer training times. These models are suitable for offline model development rather than real-time applications. Decision Trees and K-Nearest Neighbours trained and tested faster but produced less consistent results for imbalanced data. Selecting a model for deployment depends on balancing efficiency, interpretability, and predictive performance.

E. Real-World Implications

These findings have direct applications in predictive healthcare. SVM with ENN delivers the most accurate classification for lung cancer screening, reducing false negatives. Random Forest with IHT works better for heart disease prediction because it maintains interpretability while achieving strong performance. These findings guide healthcare practitioners in selecting predictive models that improve early diagnosis and patient outcomes.

F. Advantages Over Existing Methods

Our approach outperforms traditional methods by integrating resampling with classifier optimisation tailored to dataset characteristics. Unlike studies like Fitriyani et al. [11], which focus on single-disease hybrid pipelines (e.g. SMOTE-ENN with XGBoost), our framework evaluates multiple resampling techniques (ENN, IHT, RO, SMOTE, ADASYN) across two diseases, offering broader applicability. Compared to Khushi et al. [12], which limits comparisons to lung cancer with basic oversampling, our SVM+ENN and RF+IHT combinations achieve higher precision and recall (e.g. 100% F1 for lung cancer with RF+ENN) while addressing computational trade-offs. This adaptability and performance edge make our method a versatile tool for imbalanced healthcare data beyond single-context solutions.

G. Validation and Comparative Significance

Our use of comprehensive validation measures such as accuracy, precision, recall, F1 score, and AUC ensures robust evaluation of model performance, prioritising both correctness and sensitivity critical in healthcare. Unlike prior works like Ishaq et al. [13], which focus on accuracy alone, our multi-metric approach highlights trade-offs (e.g. SVM+ENN's perfect recall for lung cancer). Thorough comparisons with related studies, for instance, outperforming Khushi et al.'s [12] lung cancer precision with RF+IHT, validate our method's superiority. This rigorous validation confirms its reliability and generalisability across imbalanced medical datasets.

VII. Conclusion

This study demonstrates that advanced resampling techniques, when integrated with optimised machine learning models, can significantly enhance classification performance for imbalanced healthcare data. Specifically, SVM with ENN excelled in lung cancer prediction, while RF with IHT or ADASYN consistently performed well for heart disease prediction. These findings provide a roadmap for choosing optimal resampling - classifier pairs based on dataset characteristics, which is crucial for early diagnosis and resource allocation in clinical practice. Our results emphasise the importance of robust methods to handle skewed medical datasets, leading to more reliable healthcare predictions.

VIII. Future Direction

Despite these advances, much remains to be done to fully realise the potential of predictive models in healthcare. The following key challenges merit attention:

1) Adaptation to novel diseases: Models trained on current datasets may underperform when confronted with emerging diseases, such as those appearing during pandemics. Differences in symptoms, transmission mechanisms, or patient demographics can impede model adaptability. Future studies should explore adaptive learning frameworks - particularly online learning techniques that enable continuous learning from new data streams. Incorporating concept-drift detection can help identify performance degradation due to shifts in data distribution, while transfer learning offers a means of rapidly adapting pre-trained models to smaller, disease-specific datasets.

2) Scalability: The exponential growth of healthcare data in both volume and complexity necessitates scalable predictive models. Managing large datasets requires substantial computational resources and careful maintenance of model efficiency. Distributed computing platforms (e.g., Apache Spark or Dask) can facilitate the processing of extensive datasets across clusters. Additionally, algorithmic efficiency may be improved through dimensionality reduction and the deployment of more efficient neural architectures, such as EfficientNets, to achieve real-time processing capabilities.

3) Multimodal integration: Healthcare data are inherently multimodal, encompassing structured electronic health records, unstructured clinical notes, medical imaging, and genomic information. Current predictive models often fail to fully exploit these diverse data sources. Developing multimodal learning methods that accommodate varying data formats can provide a more comprehensive view of patient health. Techniques such as Canonical Correlation Analysis (CCA) and cross-modal neural networks can learn joint representations, while strategic fusion strategies help integrate disparate data modalities effectively.

4) Handling rare diseases: Rare diseases pose particular challenges due to significant class imbalance and very limited positive cases. Insufficient data hampers the training of robust predictive models, thereby limiting opportunities for early intervention. Future work should focus on few-shot learning approaches, for example, prototypical networks and Model-Agnostic Meta-Learning (MAML) that enable models to learn from minimal examples. Transfer learning can also leverage existing biomedical knowledge by fine-tuning models trained on more common diseases for rare disease datasets.

5) Bias and fairness: Predictive models can inherit biases from training data, potentially reinforcing inequities in healthcare access and outcomes. Without appropriate safeguards,

such models may over-predict or under-predict disease risk in certain demographic groups. Fairness-aware machine learning strategies such as re-weighting datasets for balanced representation, introducing fairness constraints during training, and performing post-hoc adjustments are therefore essential. Rigorous bias audits, which scrutinise performance across diverse patient populations, are vital for identifying and mitigating disparities.

6) Interpretability and trust: The "black box" nature of many advanced machine learning models is a major obstacle to clinical adoption, as healthcare professionals are often reluctant to rely on systems whose inner workings they cannot examine. Enhancing interpretability is crucial for clinician trust and seamless adoption within medical practice. Explainable AI (XAI) methods such as Local Interpretable Model-Agnostic Explanations (LIME) and SHapley Additive exPlanations (SHAP) can clarify model reasoning. User-friendly interfaces that integrate with existing healthcare IT systems can further bolster clinician acceptance and support practical workflows.

Beyond these methodological and computational considerations, practical issues such as data-sharing restrictions, privacy laws, and regulatory compliance (e.g. with the MHRA or NICE guidelines) will also shape the real-world deployment of AI-driven healthcare models. Although our results are encouraging, implementing these solutions at scale poses substantial challenges. Overcoming these hurdles will be essential for fully leveraging the potential of predictive modelling to improve patient outcomes and transform healthcare delivery.

Exploiting Ray Tracing Technology Through OptiX to Compute Particle Interactions with Cutoff in a 3D Environment on GPU

David Algis[1], Bérenger Bramas[2]

University of Strasbourg, France[2]

***Abstract*—Particle interaction simulation is a fundamental method of scientific computing that require high-performance solutions. In this context, computing on graphics processing units (GPUs) has become standard due to the significant performance gains over conventional CPUs. However, since GPUs were originally designed for 3D rendering, they still retain several features that are not fully exploited in scientific computing. One such feature is ray tracing, a powerful technique for rendering 3D scenes. In this paper, we propose exploiting ray tracing technology via OptiX and CUDA to compute particle interactions with a cutoff distance in a 3D environment on GPUs. To this end, we describe algorithmic techniques and geometric patterns for efficiently determining the interaction lists for each particle. Our approach enables the computation of interactions with quasi-linear complexity in the number of particles, eliminating the need to construct a grid of cells or an explicit kd-tree. We compare the performance of our method to a classical grid-based approach and demonstrate that our approach is faster in most cases with non-uniform particle distributions.**

Keywords*—CUDA; graphics processing unit; high-performance computing; OptiX; particle interactions; ray tracing; scientific computing

I. Introduction

High-performance computing (HPC) is a key technology in scientific computing. Since the early 2000s, the use of graphics processing units (GPUs) has become standard in HPC, and they now equip many of the fastest supercomputers.[1] GPUs are massively parallel processors that allow computations to be performed on thousands of cores, making them perfectly suited for inherently parallel problems. The use of GPUs in scientific computing has led to incredible performance gains in many fields, such as molecular dynamics [1], fluid dynamics [2], astrophysics [3], and machine learning [4].

Most scientific computing applications that use GPUs are based on the CUDA[2] programming model, and to a lesser extent, the OpenCL programming model. They do not exploit all the features of GPUs, particularly those dedicated to 3D rendering. Among these features, ray tracing is a powerful technology used to render 3D scenes. In this method, rays are cast from the camera to the scene, and the intersections of the rays with the objects in the scene are computed to generate the colors of the pixels in the image [5]. For example, the NVIDIA GeForce RTX 4090, as a single consumer-grade GPU, demonstrates the raw power of this technology by rendering complex 3D scenes at 87 frames per second in 4K resolution (3840 x 2160 pixels), handling millions of triangles per frame [6].

In this paper, we are interested in evaluating how ray tracing technology could be used to compute particle interactions in a 3D environment. Our motivation is twofold: We want to evaluate if it is possible to use ray tracing technology, and we want to create the algorithmic patterns needed for that purpose.

With these aims, we focus on the computation of particle interactions in a 3D environment, which is a common problem in scientific computing. When the potential of the interaction kernel decreases exponentially with distance, the interactions can be computed with a cutoff distance, i.e. the interactions are only computed between particles that are closer than a given distance, achieving less but still satisfactory accuracy. This allows the complexity of the interactions to drop from $O(N^2)$ to $O(N)$, where N is the number of particles if the cutoff distance is small enough. Classical methods to compute such interactions are based on the use of a grid of cells or an explicit kd-tree to quickly find the interaction lists for each particle. In this paper, we aim to avoid using such data structures and instead exploit ray tracing technology.

The contributions of this paper are as follows:

- We propose a method to compute particle interactions with a cutoff distance in a 3D environment based on ray tracing technology.
- We describe two algorithmic techniques based on geometric patterns to find the interaction lists for each particle using real intersections.
- We compare the performance of our approach with a classical approach based on a grid of cells and with an existing method that relies on ray tracing.

The rest of the paper is organized as follows: In Section II, we present the prerequisites. In Section III, we review the related work. In Section IV-A, we present our proposed

[1]https://top500.org/
[2]https://developer.nvidia.com/cuda-toolkit

approach. In Section V, we present the performance study. Finally, we conclude in Section VI.

II. Prerequisites

A. Particle Interactions

Computing the interactions between N particles in a 3D environment is a common problem in scientific computing. For example, this is essential in fluid simulations using smoothed particle hydrodynamics [7] and in molecular dynamics for simulating forces between atoms [8]. These interactions are usually modeled by a potential function that depends on the distance between the particles. A straightforward way to compute the interactions is to evaluate the potential function for all pairs of particles. However, the potential function can be short-range or long-range. When the potential function is short-range, the interactions can be computed with a cutoff distance, i.e. the interactions are only computed between particles that are closer than a given distance. This reduces the complexity of the interactions from $O(N^2)$ to $O(N)$, where N is the number of particles, but this is only possible if we have an efficient way to find the particles' neighbors. Moreover, the positions of the particles are usually updated after each computation step. Consequently, the system used to find the interactions between the particles should be updated at each iteration of the simulation.

A possible solution to get the interaction list is to build a grid of cells mapped over the simulation space, where each cell contains the particles that are inside. The cells have a width equal to the cutoff distance C. Then, for each particle, the interactions are computed with the particles that are in the same cell and in the neighboring cells. Building the grid of cells and finding the interaction lists for each particle can be done in $O(N)$: we start by computing the cell index for each particle, then we order the particles in a new array by assigning a unique index per particle using atomic operations, and finally, we move the particles to a new array [9]. Each of these three operations can be implemented with a parallel loop over the N particles.

B. Graphics Processing Units

Graphics processing units (GPUs) are massively parallel processors that allow computations to be performed on thousands of cores. The hardware design of GPUs has been optimized for graphics rendering, particularly for the rendering of 3D scenes. To this end, GPUs have features dedicated to 3D rendering, such as texture mapping, rasterization, and ray tracing. Internally, GPUs are organized in a hierarchy of processing units, including streaming multiprocessors (SMs), warp schedulers, and execution units.

NVIDIA has proposed the CUDA programming model to develop parallel applications for GPUs. CUDA is designed to express algorithms in a way that can be mapped to the GPUs' hardware organization. For instance, thread blocks are distributed across SMs, and threads are executed in warps. There are also keywords and functions to use shared memory, constant memory, and texture memory. Thus, creating optimized applications for GPUs requires an understanding of the hardware architecture of GPUs and potentially adapting algorithms to their specificities.

C. Ray Tracing

Among the many features of GPUs dedicated to 3D rendering, ray tracing stands out as a powerful technology widely used in video games for rendering realistic 3D scenes [10]. It is a hardware-accelerated technique that computes the interactions of rays with objects in a scene. Ray tracing generates pixel colors in an image by casting rays from the camera into the scene. For each intersection of a ray with an object, the pixel's color is determined based on the object's material properties and lighting conditions. Rays can also be reflected or refracted by objects, or continue through non-opaque surfaces, enabling recursive computation of interactions for enhanced realism.

Typically, ray tracing kernels are implemented within the shaders of the graphics pipeline. Shaders are small programs executed on the GPU for each pixel in an image, often written in specialized languages such as GLSL (for OpenGL) or HLSL (for DirectX). These shaders run in parallel on the GPU, allowing for concurrent computation of ray-object interactions. NVIDIA introduced a method to utilize ray tracing within the CUDA programming model through its OptiX library [11]. With OptiX, developers retain the flexibility of CUDA programming while leveraging ray tracing technology, albeit with some constraints on kernel implementation.

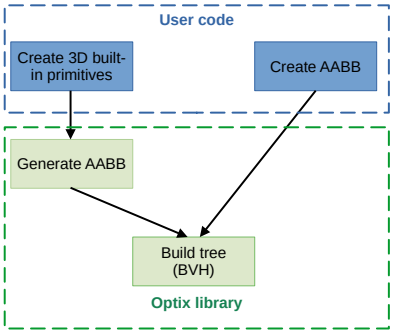

Fig. 1. Schematic view of BVH tree creation. The OptiX library requires a list of encompassing axis-aligned bounding boxes (AABBs), which can either be directly provided or generated from a list of basic primitives.

In ray tracing, scenes are represented using geometric primitives such as triangles or spheres, which are encapsulated within bounding volumes to enhance computational efficiency [12]. A common bounding volume is the Axis-Aligned Bounding Box (AABB), a rectangular box aligned with the coordinate axes and defined by its minimum and maximum bounds $(x_{min}, y_{min}, z_{min})$ and $(x_{max}, y_{max}, z_{max})$. AABB-ray intersection tests are conducted by calculating t_{min} and t_{max} for each axis and ensuring that overlaps exist across all axes, efficiently determining whether the ray intersects the box.

To further optimize performance, AABBs are organized into a Bounding Volume Hierarchy (BVH), a tree-like data structure where each node represents an AABB. Internal nodes group child AABBs, while leaf nodes encapsulate the actual primitives. In OptiX, users can either provide a list of basic primitives or directly supply a list of AABBs, as illustrated in Fig. 1.

During ray traversal, the algorithm performs intersection tests at each BVH node. If a ray misses an AABB, the entire

subtree beneath that node is skipped, reducing unnecessary computations. When a ray reaches a leaf node, precise intersection tests are conducted with the enclosed primitives, and the closest intersection is recorded. This process reduces the complexity of ray-scene intersections from linear to logarithmic by pruning large portions of the scene, ensuring only relevant branches of the BVH are explored.

The final output of the ray tracing algorithm, typically the closest hit point, is used for shading or further processing to determine the visual appearance of the scene. This hierarchical approach, combined with the use of AABBs and BVH, ensures that ray tracing remains computationally feasible even for complex scenes containing millions of primitives.

Fig. 2 provides a summary of the different operations in ray tracing using OptiX. In the first step, the user casts rays in the desired direction, and OptiX manages the BVH tree traversal and potential interactions. When a ray enters an enclosing bounding box (AABB), a callback function is invoked to determine whether the ray actually intersects the corresponding primitive, based on a built-in or user-defined Intersection Shader (IS), referred to as the intersection strategy. For custom primitives, the user must implement the IS. If the ray does not intersect or is marked to continue, the process is repeated for other primitives. The traversal stops when a final intersection is found or no more primitives can be intersected, triggering a call to the miss callback.

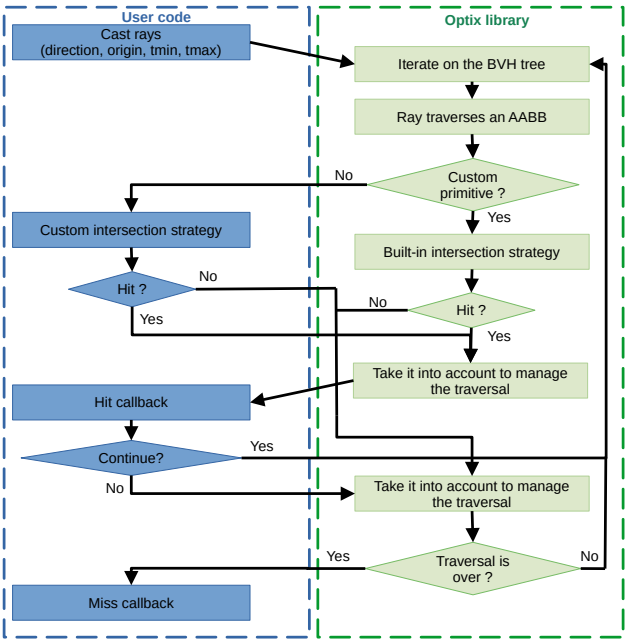

Fig. 2. Schematic view of the OptiX ray tracing workflow.

III. Related Work

A. Neighbor Search on GPU

The main work on physical simulation of particle interactions on GPU has been proposed by [13], to compute the gravitational potential. They described an efficient implementation using shared memory that became a standard implementation on GPU. As mentioned in Section II-A, grid-based and kd-tree structures are widely utilized for neighbor search operations on GPUs. For grid-based approaches, a detailed description can be found in our previous study [9], which focuses on scenarios with few particles per cell and demonstrates that utilizing shared memory often does not yield significant benefits. Regarding kd-tree implementations, [14] present a method for fast k-nearest neighbor searches using GPUs, highlighting the efficiency of kd-trees in high-dimensional spaces.

B. Ray Tracing in Computer Graphics

Ray tracing has been widely applied in particle-based representations, primarily in the domain of computer graphics and rendering. The author in [15] propose a method for efficiently ray tracing Gaussian particles to enable advanced rendering effects such as shadows, reflections, and depth of field in dense particle scenes, with applications in novel-view synthesis and visual realism. Similarly, [16] explores hardware-accelerated ray tracing for rendering particles that cast shadows, focusing on evaluating the performance of a prototype system. While these works demonstrate the utility of ray tracing in particle-based scenes, their focus lies in rendering and visualization, contrasting with our application of ray tracing for neighbor search in physical simulations.

C. OptiX in Scientific Computing

The NVIDIA OptiX framework has shown potential for diverse applications in scientific computing. Blyth et al. utilized OptiX to enable high-performance optical photon simulations in particle physics. This approach reduced memory and computation overheads by using GPU-based culling of photon hits, handling millions of photons in complex geometries [17], [18]. OptiX has been utilized as a flexible and high-performing tool for optical 3D modeling, enabling virtual measurements of sample surfaces by tracing over 1 billion light rays per image and comparing simulated results with those from physical measuring devices [19].

While these applications highlight OptiX's potential in handling computationally intensive tasks, they primarily focus on modeling physical processes rather than using ray tracing for spatial queries or particle interactions. Our work bridges this gap by leveraging OptiX for neighbor detection and particle interaction calculations, building on its demonstrated strengths in scientific modeling to expand its applicability into the domain of particle-based simulations.

D. OptiX for Neighbor Search

Using OptiX to find neighbors between elements has already been explored in several works. I. Evangelou et al. [20] introduced a novel approach to spatial queries, particularly radius search, by leveraging GPU-accelerated ray-tracing frameworks with OptiX. Instead of traditional spatial data structures like kd-trees, the authors proposed mapping the radius-search task to the ray-tracing paradigm by treating query points as primitives within a bounding volume hierarchy (BVH). In the proposed method, a ray used in the radius-search operation is essentially infinitesimal in extent, and its purpose is not to compute a traditional intersection but to test whether the origin of the ray (the query point) is within the bounding volume of a "sphere" surrounding each sample point. For that purpose, the

authors reimplemented the function that tests if a ray intersects a sphere to control how the tests are performed. This approach enabled significant performance gains in dynamically updated datasets.

Yuhao Zhu [21] further advanced the application of ray tracing for neighbor search by introducing optimizations for mapping the neighbor search problem onto the ray-tracing hardware available in modern GPUs. The author identified two key performance bottlenecks: unmanaged query-to-ray mapping, which led to control-flow divergences, and excessive tree traversals stemming from monolithic BVH construction. To address these issues, they proposed query scheduling and partitioning strategies that exploit spatial coherence and reduce BVH traversal time. Their experiments demonstrated substantial speedups ranging from 2.2 to 65.0 over existing GPU neighbor search libraries. Their work highlights the potential of using ray-tracing hardware not only for rendering but also for efficient spatial queries. The source code for their work is available on GitHub; however, the implementation is not directly applicable to our purpose as it primarily focuses on radius search and constructing interaction lists. In contrast, our interest lies in directly computing the interactions. Furthermore, for large test cases involving particles distributed on a sphere, the performance of their method appears to be of the same order of magnitude as ours.

Shiwei Zhao et al. [22] extended the use of ray tracing for particle-based simulations by converting neighbor search into a ray tracing problem. Each particle was represented as a bounding box, similar to previous works, with tiny rays emitted to detect intersections and identify neighboring particles. By leveraging NVIDIA's RT cores alongside CUDA cores, they demonstrated 10% to 60% performance improvements over traditional cell-based methods in various particle-based simulations, including discrete element methods and smooth particle hydrodynamics. Their approach underscores the versatility of ray-tracing cores for accelerating computationally intensive neighbor search tasks across different domains.

These works collectively demonstrate the potential of using OptiX and ray-tracing hardware for efficient spatial queries, providing a foundation for further exploration in GPU-accelerated computational methods. However, these approaches lack a direct integration of physical interaction computations within the ray-tracing framework. Our approach addresses this gap by embedding cutoff distances directly into the intersection tests. Additionally, we introduce two novel methods for neighbor detection that utilize actual intersection computations, accommodating scenarios where custom IS are unsupported.

IV. Proposed Solutions

A. Overview

The core idea of our approach is to represent particles using geometric primitives and to use ray tracing to find the neighbors of each particle by detecting intersections with these primitives.

With this aim, we investigate three possibilities:

1) Custom AABB: in this case, we directly provide the list of englobing bounding boxes. Therefore, we also have to provide our own IS in which we do not compute real intersections but only check if a ray is inside an AABB. This strategy is the closest one to the state of the art.

2) Spheres: in this case, we use built-in sphere primitives, which allows us to use the built-in IS that check if a ray really intersect with the surface of a sphere. However, we had to create our own geometric algorithm to make it work.

3) Triangles: in this case, we use built-in triangle primitives to create squares, which allows to use the built-in IS that check if a ray really intersect with the surface of a triangles. As for the spheres, we had to create our own geomatric algorithm to make it work.

The spherical approach is simpler and more intuitive than using squares, but we are interested in evaluating if the squares made of triangles is more efficient as it is the most used primitive in 3D rendering. We also want to evaluate if the built-in IS is more efficient than our custom IS.

In the cases that rely on built-in IS, we use the following algorithmic pattern:

1) We build a geometric representation for each particle.
2) We cast rays from each particle in specific directions to find the neighbors, depending on the representation.
3) We filter the intersections to avoid computing the same interaction multiple times.
4) We compute the interactions between the particles that are closer than C.

To reduce overhead, we aim to use as few rays as possible and ensure they do not intersect with too many particles that are not within the distance C.

In terms of implementation, we use the OptiX library to develop the ray tracing kernels, which can be used in conjunction with the CUDA programming model. Specifically, in the OptiX API, we create a scene by providing a list of geometric primitives. We then provide a CUDA kernel that launches the rays, where each ray has an origin, a direction, a starting point, and an endpoint. Usually, one CUDA thread is used to launch one ray. Finally, a callback is invoked by OptiX when a ray intersects with a primitive or if no intersection is found between the starting and ending points (in 3D rendering, this usually means that the background color should be used).

The data accessible from the callback is limited. OptiX built-in IS can provide information about the intersection, such as the intersection point, the normal on the surface, the distance from the ray's origin, and the index of the primitive that was hit. Additionally, the user can pass information from the CUDA kernel that launches the rays to the callback using a payload. A payload is a user-defined data structure that is passed along with a ray as it traverses the scene. It allows the ray to carry information that can be read or modified. The number of payload variables is limited (usually 16 32-bit integers in recent versions).

When the hit callback is invoked, and we want the ray to continue, there are two possibilities. The first is to launch a new ray from the intersection point in a new direction. This is

done by storing the intersection distance in a payload variable, returning from the callback, and then launching a new ray from the intersection point using a loop in the CUDA kernel to reach the desired distance. The second possibility is to inform OptiX that we want to continue the traversal by calling a corresponding function in the intersection callback. This second approach is generally more efficient, as it avoids the overhead associated with launching new rays and and should be favored in practice.

Additionally, we cannot allocate memory in the callbacks, so we cannot build complex data structures, such as lists, to store intersection lists. Consequently, if we want to filter the intersections, we cannot fill an array with indices and check if an index exists in the array to ensure uniqueness; instead, we must use geometric properties to filter the intersections.

In the remainder of the section, we consider that the target particle is the particle for which we want to find the neighbors.

B. Spherical Representation

In this section, we consider the case where the particles are represented by spheres and we use the built-in IS. In OptiX, a sphere is a geometric primitive defined by its center and radius, and multiple spheres of the same radius can be instantiated in the scene, which is the approach we use.

We have the following objectives:

1) Expressing the radius of the spheres depending on the cutoff distance;
2) Defining the origins and directions of the rays;
3) Providing a mechanism to filter the intesection when the rays intersect multiple times with the same sphere.

In our model, we will use three rays for each particle, one in each direction of the coordinate system. Consider a sphere of radius C centered at the origin in a three-dimensional space. The points on this sphere that are at the farthest distance from the three coordinate axes are located in the corners of a cube inscribed within the sphere. For instance, one such point at distance C from the origin lies in the direction $(1, 1, 1)$. These 8 points, corresponding to the vertices of the cube, are all at a distance C from the origin, and we want to know how far they are from the coordinate axes. This can be calculated as follows: Since the points have coordinates where $|x| = |y| = |z|$, we use the equation of the sphere $x^2 + y^2 + z^2 = C^2$. If we take the point for which $x = y = z$, it gives $3x^2 = C^2$, resulting in $x = \frac{C}{\sqrt{3}}$. Therefore, each of these points is at a distance of $\frac{C\times\sqrt{2}}{\sqrt{3}}$ from any of the three coordinate axes.

We use this information to define the radius of the spheres and the length of our rays. The radius is set to $r = \frac{C\times\sqrt{2}}{\sqrt{3}}$. In this scenario, it is sufficient that the rays go up to $l = \frac{C}{\sqrt{3}}$ in each direction relatively to the particle's position (so a single ray goes from $-l$ to l). We provide a simplified 3D rendering of the spheres in Fig. 3 that illustrate our model.

However, if $l < r$, there are positions where the sphere could simply englobe the rays, and we would miss some intersections (when the source and target are closer than $r - l$ in the three dimensions). Therefore, we set $l = r$ and add an ϵ to the radius of the sphere to ensure that the rays intersect with the sphere in all cases, obtaining $r = \frac{C\times\sqrt{2}}{\sqrt{3}} + \epsilon$ and $l = \frac{C\times\sqrt{2}}{\sqrt{3}}$. The ϵ is a small value such that it must be impossible that two particles are closer than ϵ, or some intersections will be missed (see Appendix A for more details).

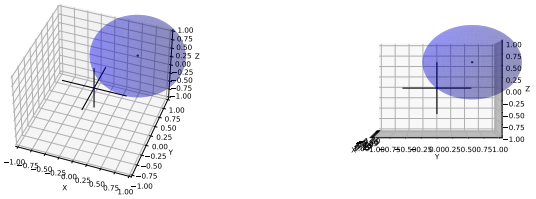

Fig. 3. 3D Spherical representation of a source and target particles distance from $C = 1$. The source sphere has a radius of $\frac{\sqrt{2}}{\sqrt{3}}$ and the rays, represented by segments, are of length $\frac{1}{\sqrt{3}}$ in each direction. In this case, the sphere could englobe the rays.

When the source and target particles are perfectly aligned on one axis, the ray will intersect for particles distant from the extremity by $r + \epsilon$. Therefore, two particle distant from $l + r + \epsilon$ can interact. This case and any intermediate situation where the source/target are actually too far can easily be filtered by checking the distance. In Fig. 4, we provide a 2D representation of the particles using spheres on intricate cases.

However, each ray can potentially intersect with a sphere several times, and the same sphere can be intersected by several rays of the same target particle, so we need to filter them. It is impossible to maintain a global list that all the rays can access to check if an intersection has already been found, or even a single list per ray to ensure that it does not intersect with the same sphere. Therefore, we must do this based on geometric rules as described in Algorithm 1. When we detect an intersection, we get the position of the source and target particles and first check they are within the cutoff distance. Then, we check if the closest ray to the source particle is the current one, and if yes, we can proceed with the computation (see Appendix A for more details).

C. Double Squares Representation

Most 3D rendering applications use triangles to represent the objects in the scene, which motivated us to create a second model that relies on triangles instead of spheres. Of course, building the AABB representations and the HBV tree is not expected to be faster than the sphere, but the hardware modules and built-in could be more optimize for the triangles, as it is more common primitives. In our model, we use four triangles to draw two squares, which are positioned opposite each other. Each square has a width of $C+\epsilon$ and is positioned at a distance of $C/2$ along the X-axis relative to the particle, one in each direction. We provide Code 1 in Appendix B, which shows how we generate the triangles from the particles' positions.

We then launch four rays, all with the same length and direction, but positioned at the corners of the squares. Each ray is positioned at $-C/2$ from the center of the square and has a length of $C + \epsilon$. The ϵ is used to ensure that when the source and target particles have the same x coordinate and their squares overlap, the rays cross the triangles. We provide

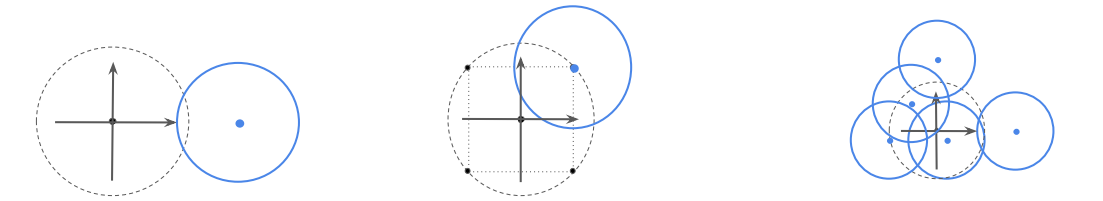

Fig. 4. 2D Spherical representation of the particles in three different cases. In the first one (left), what will be the position of the farthest source particle and how it will be detected by the ray. In the second one (center), we show the case where the source particle is the farthest from the rays (it also shows that in 2D the sphere radius could be smaller). In the last one (right), we show different source particles with their spheres and the rays that will intersect with them.

Algorithm 1: Sphere intersection callback

Data: Optix variables
Result: Callback when a ray intersect with a sphere

```
Function callback()
begin
    /* Get the center of the sphere (source position) */
    q ← optixGetSphereData ()
    /* Current particle position (target position) */
    point ← getPayloadPartPos()
    /* Compute differences and distances */
    diff_pos ← {abs(point.x − q.x), abs(point.y − q.y), abs(point.z − q.z)}
    diff_pos_squared ← {diff_pos.x², diff_pos.y², diff_pos.z²}
    dist_squared ← diff_pos_squared.x + diff_pos_squared.y + diff_pos_squared.z
    /* Get the cutoff distance from payload */
    c ← getPayloadC()
    /* Ensure it is in the cutoff distance */
    if dist_squared < c² then
        dist_axis_squared ← {diff_pos_squared.y + diff_pos_squared.z, diff_pos_squared.x+ diff_pos_squared.z, diff_pos_squared.x+ diff_pos_squared.y}
        ray_dir ← optixGetWorldRayDirection()
        closest_axis ← getClosestAxis(dist_axis_squared)
        closest_axis_is_ray_dir ← (ray_dir == closest_axis)
        /* Ensure this ray and this intersection are the good one */
        if closest_axis_is_ray_dir then
            /* Call computation kernel */
```

in Fig. 5 the 2D representation of the particles using squares (which are lines in 2D).

From this description, one particle can be seen as a box of sides $(C + \epsilon, C + \epsilon, C)$ (see Fig. 6). The rays can be seen as the four edges of the box in the x direction, and the triangles composed the front and back faces. If any two boxes have an intersection, we will detect it as shown in Fig. 5.

Potentially, the ray will intersect with the squares of the target particle, but this can easily be filtered by checking either the coordinates or the index of the geometric elements. Additionally, if the target and source particles are aligned on the y or z axis, two rays will intersect with the source's squares. To filter these intersections, we proceed as shown in Algorithm 2. We compare the coordinates between the source and the target and proceed as follows: If y and z are different, we perform the computation (only the current ray will intersect). If y is equal, we use the ray of index 0 if z is smaller, and the ray of index 2 if z is greater. If z is equal, we use the ray of index 0 if y is smaller, and the ray of index 1 if y is greater. Otherwise, only the ray of index 0 will be used for computation (all four rays will intersect).

D. Custom AABB

In this strategy, a bounding box with a width equal to $2 \times C$ is created around each particle. OptiX treats these boxes as custom primitives, requiring us to implement a custom IS that is invoked when a ray enters an AABB. We do not perform any intersection tests within the IS, as our goal is not to compute ray-AABB or ray-surface intersections but to identify pairs of particles that are within a distance C of each other. To achieve this, rays are cast from the particles' positions with an infinitesimally short length, as illustrated in Fig. 7.

The interaction between the source and target particles is computed directly within the IS callback. Consequently, the hit and miss callbacks are left empty, as there is no need to filter intersections. In the IS callback, OptiX provides information about the ray (specifically, the starting point, which corresponds to the position of the source particle) and the index of the AABB being tested. To obtain geometric information about the AABB, one could register a Primitive Geometry Acceleration Structure (PGAS) for each AABB during the OptiX scene build stage and retrieve this data in the IS callback. However, we observed that this approach significantly increased the scene build cost. Instead, we opted to access the global memory directly to retrieve the position of the target particle, which proved to be a more efficient solution.

V. Performance Study

This section presents a performance evaluation of the different methods under various configurations. The analysis begins with a description of the experimental setup, including

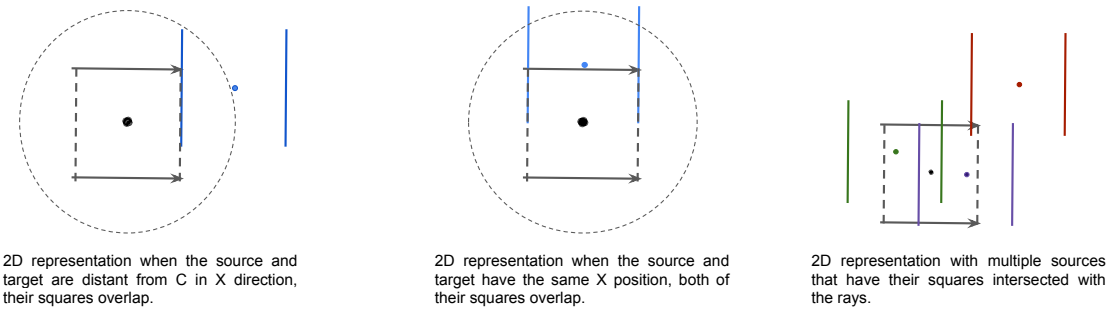

Fig. 5. Double squares (line) representation of the particles. On the left, we show how the squares can overlap for particles that are too far, but which can be easily filtered with the distance. In the middle, we show how particles that have the same x coordinate can have their squares that overlap. On the right, we show different source particles with their squares and the rays that will intersect with them.

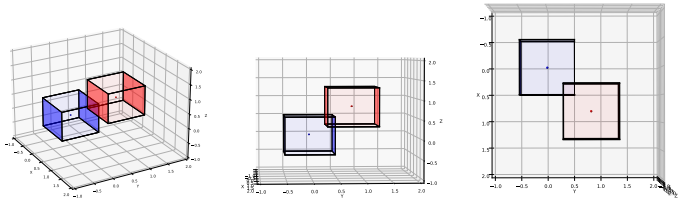

Fig. 6. 3D Rectangular representation of a source and target particles. Some rays (thick lines) intersect with the squares.

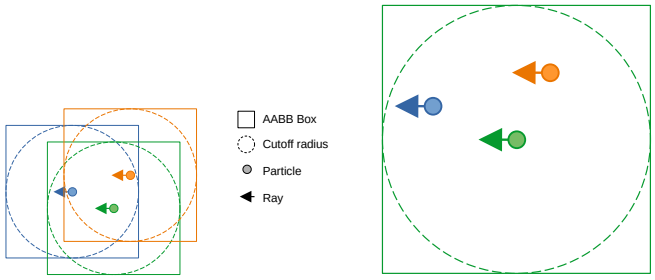

Fig. 7. Custom AABB representation of the particles. The rays cast from the particles' positions with a infinitesimal length. In the IS callback invoked if a ray enters an AABB, the distance is checked and the interaction between the source and target particles is computed. Self interactions are filtered by ensuring that the source and target are different.

the hardware and software used for implementation. Performance is then examined for two types of particle distributions: uniform and non-uniform. Differentiating these distributions allows for assessing the efficiency of grid-based methods like CUDA, which are optimized for uniform distributions but can encounter inefficiencies with sparse or highly localized data in non-uniform scenarios.

A. Experimental Setup

1) Hardware: We have used two NVidia GPUs:

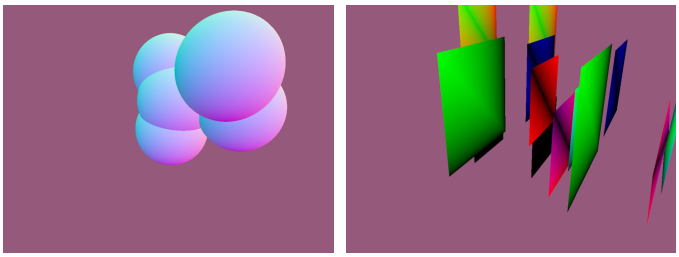
- A100[3] with 40GB hBM2, 48KB of shared-memory, 108 multi-processors, zero RT Cores, 8192 CUDA Cores max single-precision performance 19.5TFLOPS, and max tensor performance 311.84TFLOPS.
- RTX8000[4] with 48GB GDDR6, 48KB of shared-memory, 72 multi-processors, 72 RT Cores, 4608 CUDA Cores, maximum Ray casting of 10Giga Rays/sec, max single-precision performance 16.3TFLOPS, and max tensor performance 130.5TFLOPS.

Despite the lack of RT cores, the A100 is capable of executing ray tracing kernels, the GPU then use its other units to behave similarly.

2) Software: We have implemented the proposed approach in OptiX 8.[5] We use the GNU compiler 11.2.0 and the NVidia CUDA compiler 12.3. The source code is available online.[6]

The code was compiled with the following flags: `-arch=sm_75` for the RTX8000, `-arch=sm_80` for the A100 (and `-O3 -DNDEBUG` on both). We execute each kernel five times and take the average as reference.

We provide in Fig. 8 the 3D rendering of the primitives using ray tracing: in Fig. 8a for the spheres and in Fig. 8b for the squares. These figures were drawn using the OptiX API and ray tracing from camera to the scene.



(a) 3D Rendering of sphere primitives. (b) 3D Rendering of square primitives.

Fig. 8. 3D Rendering of the primitives using conventional ray tracing.

B. Uniform distribution

In this test case, the particles are distributed uniformly within a unit box. Consequently, there are no (or very few)

      /* Perform the computation */

empty cells in the grid of the CUDA version. The cutoff distance is defined as $1/\beta$, where β can be 2, 4, 8, 16, or 32. For a given β, the simulation grid consists of 3^β cells. The number of particles N is then calculated as $N = p \times 3^\beta$, where p represents the average number of particles per cell, taking values of 1, 2, 4, 8, 16, or 32. All computations are performed in single-precision floating point.

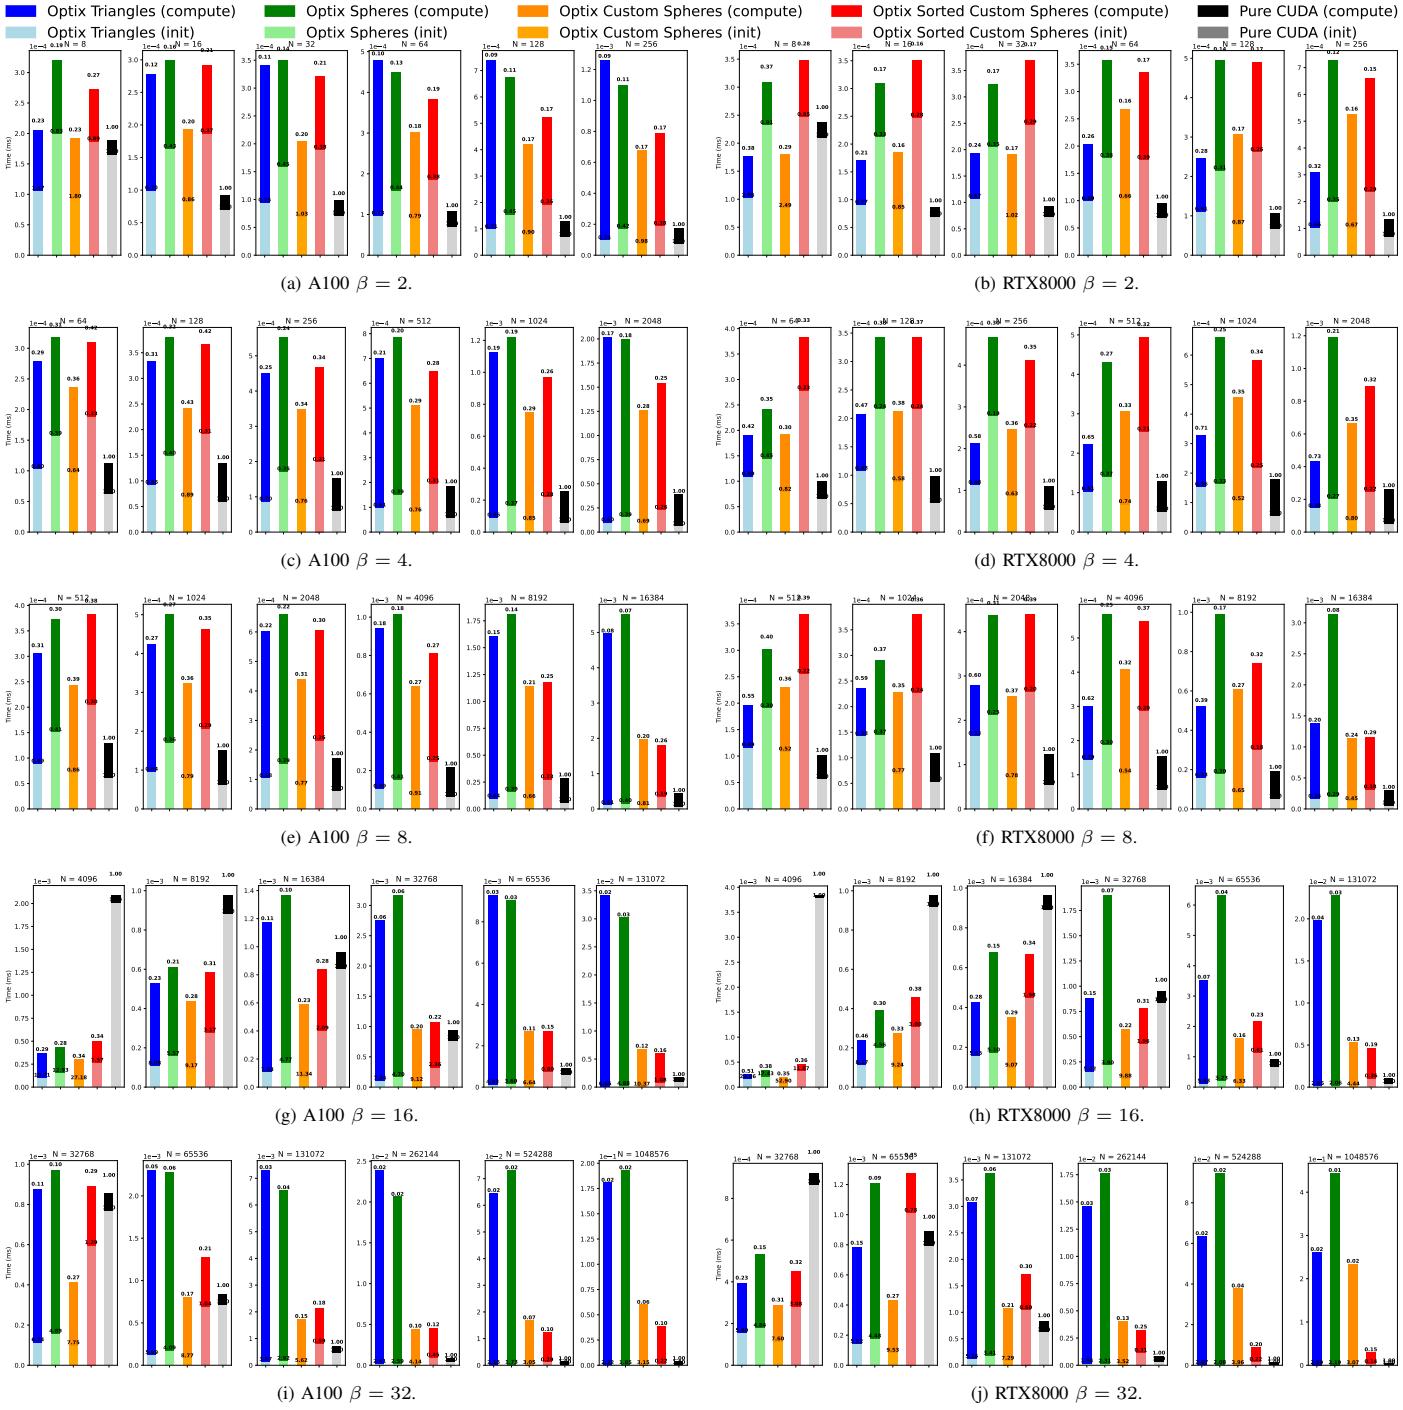
We present the results in Fig. 9. For all configurations, we measured the initialization step (light color) and the computation step (dark color).

For the OptiX-based implementation, the initialization step involves building the scene by invoking the OptiX API to create the primitives. For the CUDA version, the initialization step involves constructing the grid of cells. Consequently, in the OptiX-based version, the computation step includes the time spent launching the rays, executing the callback functions, and performing the interactions. In the CUDA version, the computation step corresponds to the kernel time required to compute the interactions.

1) Comparison between triangles and spheres: First, we analyze the performance difference between triangles (blue) and spheres (green). On the A100 GPU, both models deliver similar performance, but the ratio of initialization time (light color) to computation time (dark color) is higher for spheres. This indicates that the computation step is more efficient for spheres than for triangles. This suggests that in scenarios where the initialization step is performed only once (e.g. static elements), spheres might be a better choice. However, on the RTX8000, triangles are faster than spheres across all configurations. Although the initialization step for spheres is quicker than for triangles in cases with fewer particles, this trend does not hold for larger configurations.

2) Comparison between custom AABB and built-in primitives: Next, we compare the Custom AABB method (orange/red) with the built-in primitives (triangles in blue and spheres in green). On the A100, the Custom AABB consistently outperforms the built-in primitives, and its advantage grows as the number of particles or cells increases. For $\beta = 32$ (Fig. 9i), the Custom AABB is up to four times faster than the triangle- or sphere-based methods. On the RTX8000, the Custom AABB performs similarly to triangles for small particle counts but becomes faster as the number of particles increases. Overall, the Custom AABB is the fastest method. This demonstrates that creating a custom Intersection Shader (IS) that is significantly simpler and lighter than the built-in ones, which compute actual intersections, can accelerate execution.

3) Benefit of sorting the particles in the custom AABB methods: Sorting the particles to position them closer in memory based on their spatial proximity in the simulation is expected to optimize memory accesses. However, sorting the particles also incurs a computational cost. We observe that the strategy without sorting (orange) is faster than the strategy with sorting (red) when there are few particles. However, as the number of particles increases, the benefits of sorting become significant. In our test case, for a given β, increasing the number of particles leads to an increase in neighboring particles and, consequently, the number of interactions. In such cases, optimizing memory access becomes critical.



(a) A100 $\beta = 2$.

(b) RTX8000 $\beta = 2$.

(c) A100 $\beta = 4$.

(d) RTX8000 $\beta = 4$.

(e) A100 $\beta = 8$.

(f) RTX8000 $\beta = 8$.

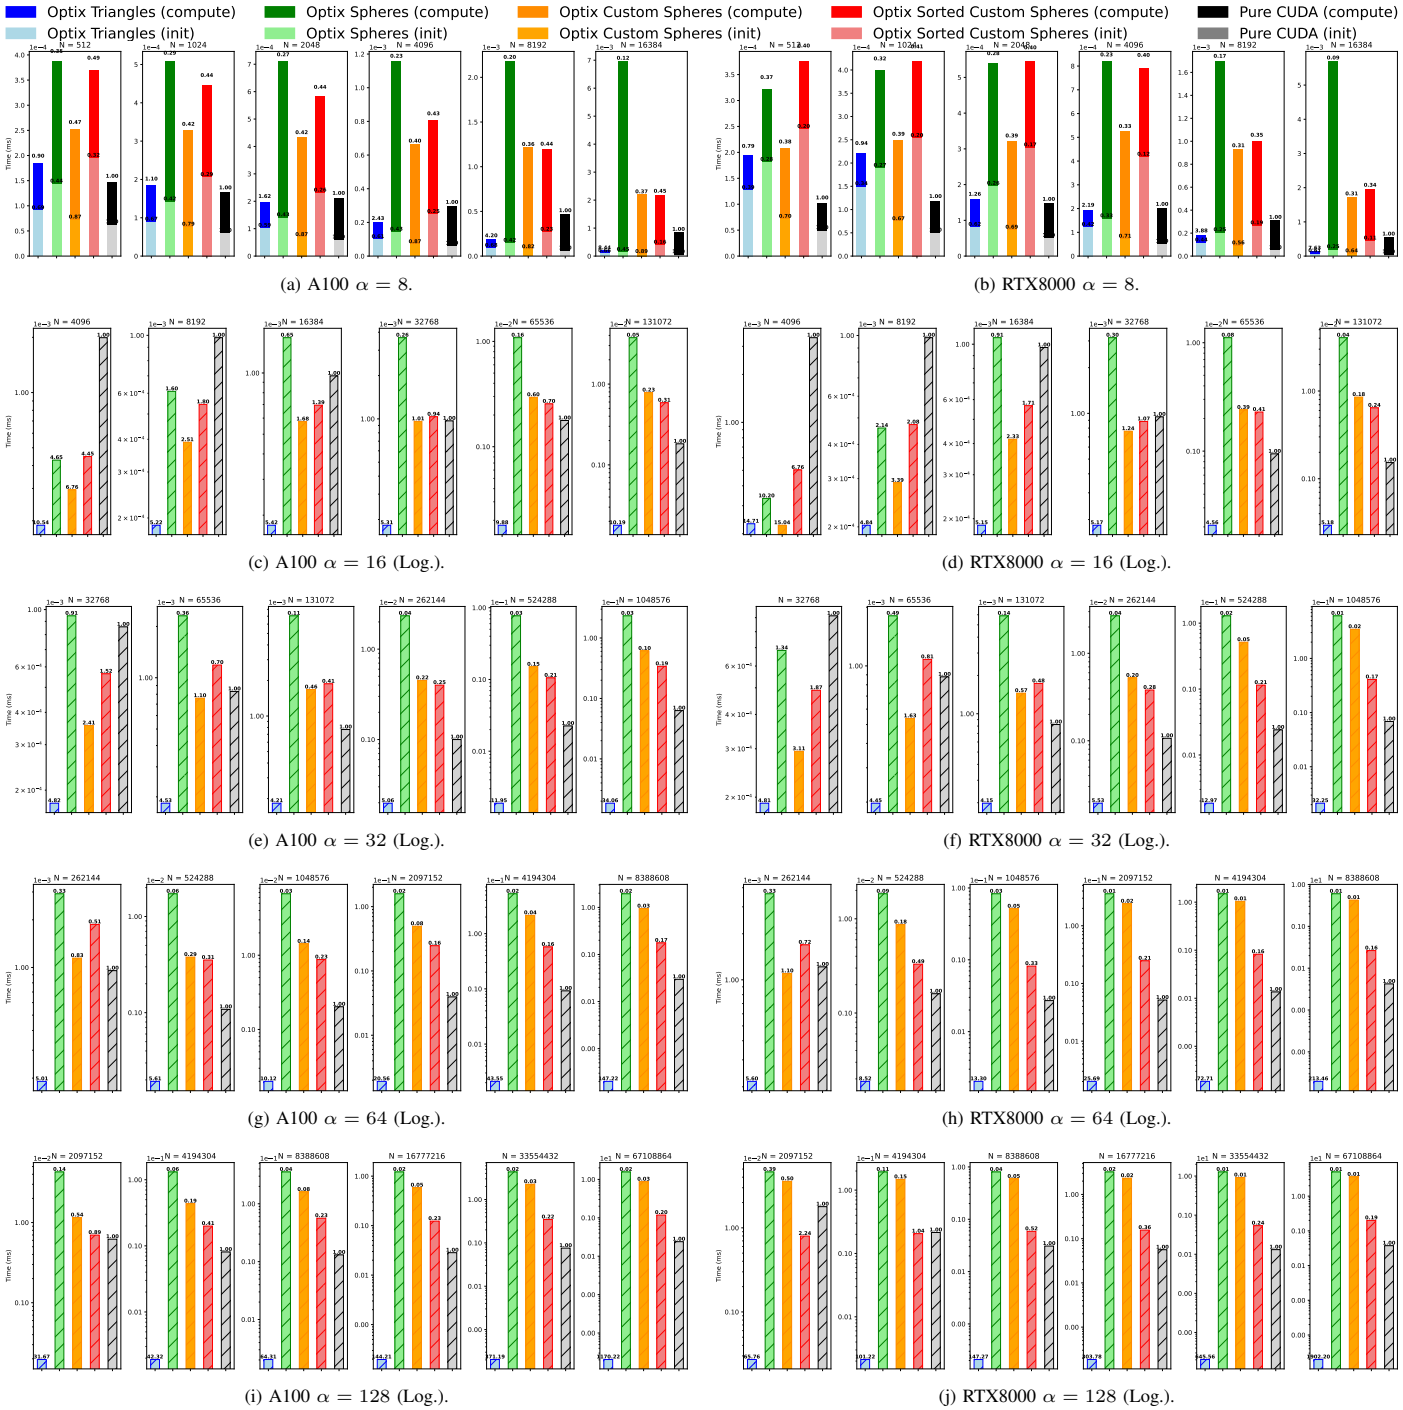
(g) A100 $\beta = 16$.

(h) RTX8000 $\beta = 16$.

(i) A100 $\beta = 32$.

(j) RTX8000 $\beta = 32$.

Fig. 9. Performance results for the two GPUs for our approaches (OptiX spheres, OptiX triangles, and Custom AABB without and with sort) and the pure CUDA implementation that use a grid of cells (CUDA). β is the divisor coefficient of the simulation box. The cutoff distance is $1/\beta$ and there are β^3 cells in the grid in the Cuda version. The speedup against the CUDA version is shown above the bars for both the build and compute steps.



(a) A100 $\alpha = 8$.

(b) RTX8000 $\alpha = 8$.

(h) RTX8000 $\alpha = 64$ (Log.).

(i) A100 $\alpha = 128$ (Log.).

(j) RTX8000 $\alpha = 128$ (Log.).

Fig. 10. Performance results for the two GPUs for our approaches (OptiX spheres, OptiX triangles, and Custom AABB without and with sort) and the pure CUDA implementation that use a grid of cells (CUDA). α is the divisor coefficient of the simulation box. The cutoff distance is lower than $1/\beta$ and there are around α^3 non-empty cells in the grid in the Cuda version. The speedup against the CUDA version is shown above the bars for both the build and compute steps, or for the complete run.

4) GPU Performance comparison: We then compare the performance of the two GPUs. Results for the A100 are presented in Fig. 9a, 10c, 9e, 9g, and 9i, while results for the RTX8000 are shown in Fig. 9b, 9d, 9f, 9h, and 9j. Both GPUs exhibit comparable performance and a similar initialization-to-computation time ratio. Although the A100 is expected to offer higher raw performance, the OptiX implementation is not fully optimized for this GPU, while the RTX8000 benefits from having more RT cores to accelerate computation.

Additionally, we do not utilize the tensor cores of the A100, which represent a key differentiator between the two GPUs and could help approach theoretical performance.

5) Comparison between OptiX and CUDA implementations: Finally, we compare the OptiX triangles (blue), OptiX spheres (green), Custom AABB (orange), Custom sorted AABB (red), and CUDA implementation (green). The OptiX-based implementation is generally slower than the CUDA implementation for β values from 2 to 8, except in a few cases (e.g. $\beta = 2$ and $N = 8$). In these scenarios, the initialization step in the CUDA implementation is negligible, and the computation step dominates. Consequently, avoiding the grid of cells does not yield a significant advantage. For $\beta = 8$ (Fig. 9e and 9f), the CUDA computation step is shorter because the OptiX implementations include not only the interaction computation but also the intersection list computation using rays. Additionally, the memory access pattern in OptiX-based implementations differs, as spatially close particles in memory may not be close in space and may have varying neighbors.

For $\beta = 16$ and $\beta = 32$, the Custom AABB performs better for configurations with few particles per cell (e.g. one or two particles per cell on average in the CUDA version). In these cases, the computation cost is low, and the CUDA version spends most of its time in the initialization step. Furthermore, the CUDA version incurs overhead for empty cells because it constructs a dense grid. For such configurations, the OptiX-based implementations allocate more time to the computation step, making the Custom AABB a suitable choice when the number of particles per cell is low, particularly in scenarios where moving particles require frequent grid rebuilding.

C. Non Uniform Distribution

In this test case, we distribute the particles on the surface of a unit sphere. Consequently, most of the cells on the grid in the CUDA version are empty. With this aim, we use a coefficient α, which can be 8, 16, 32, 64 or 128. For a given α, the simulation grid consists of approximately 3^α non-empty cells. The number of particles N is then calculated as $N = p \times 3^\alpha$, where p represents the average number of particles per cell, taking values of 1, 2, 4, 8, 16, or 32. The cutoff radius is set such that each particle should have approximately $9 \times p$ neighbor particles (it will be in general smaller than $2/\alpha$). In order to facilitate the reproducibility of our test case, we provide in Appendix, the Code 2 that generates the different configurations. All computations are performed in single-precision floating point.

We present the results in Fig. 10. For all configurations, we measured both the initialization step (light color) and the computation step (dark color) for the first configuration. However, for the others, we directly present the total execution time using a logarithmic scale on the y-axis due to extreme differences.

For the OptiX-based implementation, the initialization step involves building the scene by invoking the OptiX API to create the primitives. For the CUDA version, the initialization step involves constructing the grid of cells. Consequently, in the OptiX-based version, the computation step includes the time spent launching the rays, executing the callback functions, and performing the interactions. In the CUDA version, the computation step corresponds to the kernel time required to compute the interactions.

1) OptiX spheres: The OptiX spheres method is consistently the slowest (except for $\alpha = 2$ and a small number of particles). It has a more expensive initialization step compared to the Custom AABB methods and a significantly larger computation step. This is because the built-in IS kernel for spheres is computationally intensive, as it calculates several values, such as the norm of the intersection, that we do not use since we are not rendering an image.

2) Custom AABB without and with sorting: For low α, sorting does not provide an advantage; it increases the cost of the initialization step too much relative to the gains in the computation step. However, for high α and a large number of particles, sorting the particles results in a performance improvement. This demonstrates that random access to global memory is so costly that the overhead of sorting the particles is worthwhile. The Custom AABB method with sorting performs comparably to the CUDA version. However, the Custom AABB methods are generally slower than both the CUDA version and the OptiX triangles method.

3) OptiX triangles: This strategy is the most efficient. For $\alpha = 8$, its initialization step is comparable in cost to the OptiX spheres and Custom AABB methods. However, its computation step is significantly faster. We attribute this to two primary reasons. First, the built-in IS kernel for triangles is likely much simpler than that for spheres and is probably heavily optimized by NVIDIA, as triangles are the most commonly used primitive in 3D rendering. Second, the AABB bounding boxes around triangles are much smaller than those around spheres or the custom AABB primitives. This enables faster tree traversal and fewer false positives (i.e. cases where a ray intersects a bounding box but not the primitive inside it).

Finally, the CUDA version includes several components in its implementation that rely on algorithms with complexity linear in the number of cells. Since the vast majority of these cells are empty, these steps become highly inefficient. This is particularly evident for $\alpha = 8$, where the initialization step is notably prominent. Moreover, if we were to create a test case with $\alpha = 256$ (not included in the current study), the GPU would run out of memory for the the CUDA version allocating an excessively large grid. This limitation makes alternative approaches based on a tree structure — such as our OptiX-based methods — the only viable options.

VI. Conclusion

In this paper, we proposed leveraging ray tracing technology to compute particle interactions within a cutoff distance in a 3D environment. We introduced one method that uses

custom primitives and a custom Intersection Shader (IS), similar to the state-of-the-art, and two methods that use built-in primitives and actual intersection computations. For the latter, we described geometric algorithms to build the interaction list based on ray intersections with spheres or triangles.

Our results indicate that our approach provides a modest advantage in the preprocessing stage by avoiding the construction of a grid of cells. In addition, it is slower than the classical approach during the computation step when dealing with large numbers of uniformly distributed particles. However, when most cells are empty, our approach can provide a significant speedup. Therefore, we believe these methods have the potential to deliver better performance in the future or for specific applications, and we hope our work inspires the community to explore this direction further.

As GPU architectures continue to evolve, with advancements such as NVIDIA's Ada Lovelace architecture featuring third-generation RT cores and AMD's RDNA 3 architecture incorporating second-generation ray-tracing accelerators, we anticipate that algorithms leveraging these capabilities will become increasingly effective and relevant. Consequently, our approach is prepared to benefit from these hardware improvements, enhancing its performance and applicability in future computational scenarios and we hope our work inspires the community to explore this direction further.

We plan to evaluate our approach on other GPUs, such as AMD Radeon, and aim to port our method even in cases where the IS cannot be customized, thanks to our geometric algorithms. In a second step, we will take our best strategy and compare it with state-of-the-art particle interaction solvers that support GPUs.

ACKNOWLEDGMENT

Experiments presented in this paper were carried out using the PlaFRIM experimental test-bed.

APPENDICES

A. DISCUSSION ON THE SPHERE MODEL

The filtering algorithm presented in Section IV-B is based on the assumption that there is always at least one ray that is intersected once by the sphere and that it is the closest one to the center of the sphere. The following section is dedicated to demonstrating this hypothesis.

In Fig. 11, we show the different possibilities depending on the radius r and ray's length l. As it can be seen, even if the sources located at a distance of C from the target could have their spheres that intersect with the rays when $r > l$, we must set $l = r$ to ensure that the rays will intersect with the

sphere in all cases, especially when the source and target are close.

For the clarity of the proof, a demonstration is first provided in the plane, followed by a generalization to $\mathbb{R}^3$.

1) 2D Case: Let us consider a cercle of radius r centered at (x_c, y_c), and a cross[7] centered at the origin with a length of r. We consider the cases where the cercle is located in the first quarter, i.e., $0 \leq x_s \leq r$ and $0 \leq y_s \leq r$, but the demonstration remains valid for other quarters.

The equation of a cercle is given by:

$$(x - x_c)^2 + (y - y_c)^2 = r^2. \tag{1}$$

The coordinates of the intersection points of the cercle with the axis are given by:

$$\begin{aligned} x_0 &= x_c - \sqrt{r^2 - y_c^2} \quad \text{and} \quad x_1 = x_c + \sqrt{r^2 - y_c^2} \\ y_0 &= y_c - \sqrt{r^2 - x_c^2}. \quad \text{and} \quad y_1 = y_c + \sqrt{r^2 - x_c^2}. \end{aligned} \tag{2}$$

We provide the Fig. 12 that shows where these points are located on the sphere and the cross.

x_0 and y_0 are the coordinates of the intersection points of the cercle that remain on the cross as the cercle get away from the origin. On the other hand, x_1 and y_1 are the coordinates of the intersection points of the cercle that are the farthest from the origin of the cross and that can potentially be too far to remain on the cross (they will be on the corresponding axis but behind l).

Lemma 1. *Given a circle $\mathcal{C}$ and let e_x and e_y be the two segments of the cross of length less than r, then the number of intersections of $\mathcal{C}$ with e_x or with e_y is strictly less than 2.*

Proof: As we consider that it is impossible that both x_1 and y_1 exist at the same time, we consider that these two equations cannot be true at the same time

$$x_c + \sqrt{r^2 - y_c^2} \leq r \quad \text{and} \quad y_c + \sqrt{r^2 - x_c^2} \leq r. \tag{3}$$

Which can be simplified as

$$\begin{aligned} x_c < r - \sqrt{r^2 - y_c^2} \quad \text{and} \quad & \sqrt{r^2 - x_c^2} \leq r - y_c \\ & r^2 - x_c^2 \leq r^2 - 2ry_c + y_c^2 \\ & x_c^2 > 2ry_c - y_c^2 \\ & x_c > \sqrt{2ry_c - y_c^2}, \end{aligned} \tag{4}$$

ending up with

$$\sqrt{2ry_c - y_c^2} < r - \sqrt{r^2 - y_c^2}. \tag{5}$$

For our definition range of $y_c \in [0, r]$, this equation has no solution (see Fig. 13), which confirms that $\mathcal{C}$ will always intersect with the cross at most once for e_x or e_y.

[7]That is, two orthogonal axis-aligned segments of the same size intersecting at their respective centers.

The second statement is to show that the ray that is intersected once is the closest to the center of the sphere.

Lemma 2. *Given a circle $\mathcal{C}$ and e one of the two segments of the cross of length less than r, such as the number of intersection of $\mathcal{C}$ with e is equal to 1, then the distance of e with $\mathcal{C}$ is smaller than the distance of the other bar to $\mathcal{C}$.*

Proof: Consider that $\mathcal{C}$ intersects with e_y twice and e_x once, it means that $y_1 < r$ and $x_1 > r$, i.e. $y_c + \sqrt{r^2 - x_c^2} < r$ and $x_c + \sqrt{r^2 - y_c^2} > r$.

We aim to demonstrate that the inequality

$$y_c + \sqrt{r^2 - y_c^2} < x_c + \sqrt{r^2 - x_c^2} \tag{6}$$

holds if and only if $x_c > y_c$.

We start with the inequality:

$$y_c + \sqrt{r^2 - y_c^2} < x_c + \sqrt{r^2 - x_c^2}. \tag{7}$$

Subtracting y_c from both sides, we obtain:

$$\sqrt{r^2 - y_c^2} < x_c - y_c + \sqrt{r^2 - x_c^2}. \tag{8}$$

We can further simplify this to:

$$\sqrt{r^2 - y_c^2} - \sqrt{r^2 - x_c^2} < x_c - y_c. \tag{9}$$

The inequality now compares two quantities: $\sqrt{r^2 - y_c^2} - \sqrt{r^2 - x_c^2}$ and $x_c - y_c$.

- The term $\sqrt{r^2 - y_c^2}$ represents the horizontal distance from the point (x_c, y_c) to the vertical axis.
- The term $\sqrt{r^2 - x_c^2}$ represents the vertical distance from the point (x_c, y_c) to the horizontal axis.

Let's consider the case where $x_c > y_c$:

- If $x_c > y_c$, then $x_c - y_c > 0$.
- Additionally, $\sqrt{r^2 - y_c^2} > \sqrt{r^2 - x_c^2}$ because $y_c < x_c$.

This implies that the term $\sqrt{r^2 - y_c^2} - \sqrt{r^2 - x_c^2}$ is positive, and it is less than $x_c - y_c$, proving that the inequality holds under this condition.

Thus, for the inequality $y_c + \sqrt{r^2 - y_c^2} < x_c + \sqrt{r^2 - x_c^2}$ to hold, it is necessary that $x_c > y_c$. So, the x axis is the closest axis to the center of the sphere and is intersected once.

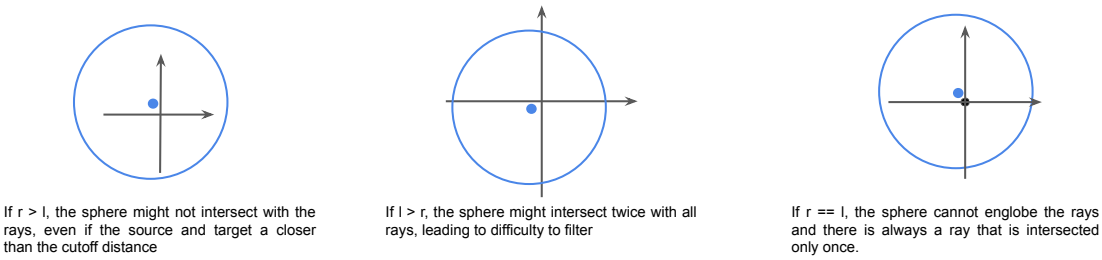

Fig. 11. 2D Spherical representation of the particles in three different cases with $r > l$, $l > r$ and $r == l$.

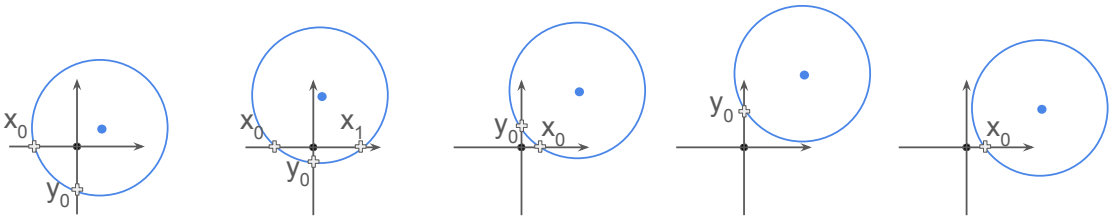

Fig. 12. 2D spherical representation illustrating the classification of intersection points between the sphere and the cross.

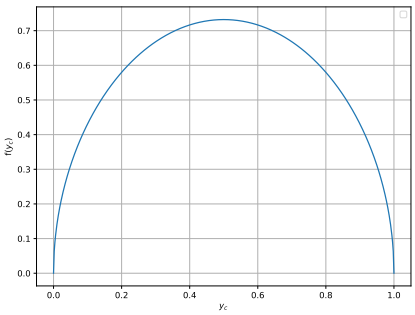

Fig. 13. Plot of the equation $\sqrt{2ry_c - y_c^2} - r + \sqrt{r^2 - y_c^2}$, for r = 1.

2) 3D Case: To convert this proof from 2D to 3D, we need to extend the concepts from the circle and cross to a sphere and a three dimensional cross.[8] Consider a sphere with radius r centered at (x_c, y_c, z_c) in 3D space, and a cross (or coordinate axes) centered at the origin with each axis extending from $-l$ to l. We are interested in analyzing the intersection of the sphere with the axes, focusing particularly on the first octant where $0 \leq x_c \leq l$, $0 \leq y_c \leq l$, and $0 \leq z_c \leq l$.

The equation of the sphere is given by:

$$(x - x_c)^2 + (y - y_c)^2 + (z - z_c)^2 = r^2. \tag{10}$$

The coordinates of the intersection points of the sphere with the axes are found by setting two of the coordinates to zero in the sphere's equation:

- Intersection with the x-axis (set $y = 0$ and $z = 0$):

$$x = x_c \pm \sqrt{r^2 - y_c^2 - z_c^2} \tag{11}$$

- Intersection with the y-axis (set $x = 0$ and $z = 0$):

$$y = y_c \pm \sqrt{r^2 - x_c^2 - z_c^2} \tag{12}$$

- Intersection with the z-axis (set $x = 0$ and $y = 0$):

$$z = z_c \pm \sqrt{r^2 - x_c^2 - y_c^2} \tag{13}$$

Let's denote the intersection points on the positive half of the axes as:

- $x_1 = x_c + \sqrt{r^2 - y_c^2 - z_c^2}$
- $y_1 = y_c + \sqrt{r^2 - x_c^2 - z_c^2}$
- $z_1 = z_c + \sqrt{r^2 - x_c^2 - y_c^2}$

We need to analyze whether these points lie within the bounds of the cross, i.e. whether $x_1 \leq l$, $y_1 \leq l$, and $z_1 \leq l$.

Assume that one of these coordinates, say x_1, exceeds l. This would mean that the intersection does not lie on the cross, i.e. $x_c + \sqrt{r^2 - y_c^2 - z_c^2} > l$.

Similarly, for y_1 and z_1, we require that:

$$y_c + \sqrt{r^2 - x_c^2 - z_c^2} > l \quad \text{or} \quad z_c + \sqrt{r^2 - x_c^2 - y_c^2} > l. \tag{14}$$

These conditions cannot all be true simultaneously for x_c, y_c, and z_c within the defined range, similar to the 2D case. Thus, a sphere will intersect the cross at most once per axis.

Next, we determine the axis closest to the sphere's center. If $x_c > y_c > z_c$, we aim to prove that the intersection on the x-axis occurs first (i.e. is the smallest).

Starting with:

$$\begin{aligned} &x_c + \sqrt{r^2 - y_c^2 - z_c^2} < y_c + \sqrt{r^2 - x_c^2 - z_c^2} \\ &\text{and} \quad x_c + \sqrt{r^2 - y_c^2 - z_c^2} < z_c + \sqrt{r^2 - x_c^2 - y_c^2}. \end{aligned} \tag{15}$$

[8] That is, three axis aligned orthogonal segments of the same size intersecting at their respective centers.

These can be simplified, following similar steps as in the 2D case:

$$\begin{aligned} &\sqrt{r^2 - y_c^2 - z_c^2} - \sqrt{r^2 - x_c^2 - z_c^2} < y_c - x_c \\ &\text{and} \quad \sqrt{r^2 - y_c^2 - z_c^2} - \sqrt{r^2 - x_c^2 - y_c^2} < z_c - x_c. \end{aligned} \tag{16}$$

The argument follows that since $x_c > y_c > z_c$, the inequalities hold true, confirming that the x-axis is the closest, and thus it is intersected first.

The 3D extension of the proof shows that a sphere intersects each axis of a coordinate cross at most once, and the axis closest to the sphere's center (in the order of $x_c > y_c > z_c$) will have the intersection point closest to the origin.

B. Conversion from Particles' Positions to Triangles

```
for(int i = 0; i < nbPoints; i++)
{
    const float3 point = points[i];

Villers-lès-Nancy, France
ICPS Team, ICube, Illkirch, France

***Abstract*—Modern parallel architectures have heterogeneous processors and complex memory hierarchies, offering up to billion-way parallelism at multiple hierarchical levels. Their exploitation by HPC applications greatly boosts scientific discoveries and advances, but they are still not fully utilized, leading to proportionally high energy consumption. The task-based programming model has demonstrated promising potential in developing scientific applications on modern high-performance platforms. This work introduces a new framework for managing the concurrent execution of task-based applications, RSCHED. The framework aims to minimize the overall time spent executing a set of applications and maximize resource utilization. RSCHED is a two-level resources management framework: resource distribution and task scheduling, with sharable and reusable resources on the fly. A new model of Gradient Descent has been proposed, among other strategies for resource distribution, due to its well-known speedy convergence event in fast-growing systems. We implemented our proposal on StarPU and evaluated it on real applications. RSCHED demonstrated the potential to speed up the overall makespan of executed applications compared to consecutive execution with an average factor of 10x and the potential to increase resource utilization.**

***Keywords*—Heterogeneous resource management; scheduling; task-based applications; gradient descent; StarPU**

I. Introduction

High-performance computing (HPC) is crucial to making discoveries and advances in several scientific domains (astrophysics, climatology, epidemiology, biology, geology, etc.). HPC offers the ability to perform complex calculations and massive data processing at very high speed by aggregating the power of several thousand processing units, called supercomputers. Supercomputers rely on a complex, heterogeneous, and hierarchical hardware organization. The largest supercomputers are mostly composed of central processing units (CPUs) and graphical processing units (GPUs)[1], or even Field Programmable Gate Arrays (FPGAs). As parallel systems, they can process several jobs at the same time by scheduling their execution on the available resources.

In the current HPC paradigm, there are schedulers at multiple levels, that all have the same aim: distributing the workload over hardware resources. At the higher level, the batch-scheduler, like Slurm [2], OAR [3], or OpenPBS [4], manages the hardware resources of an entire supercomputer by deciding the order of execution of the jobs submitted by the users. Submitted jobs are treated by the batch scheduler as black boxes. This is advantageous because the batch scheduler can run applications implemented with any technology, giving freedom to the programmers. However, this approach might lead to resource wastage and increasing energy consumption. Such a situation can happen when an application inefficiently uses the allocated resources, when an adjustment of resources is required during different phases of execution, or when the resource manager cannot adapt the resources to the workload of newly submitted jobs. Especially since the dominant scheme for scheduling parallel jobs on parallel computers is known as variable partitioning [1], in which scheduled jobs have partitioned assigned processors they keep and use throughout their lifetime. However, executing one job after another is likely counterproductive, since HPC applications are often composed of interdependent executing kernels, and therefore cannot fully use resources due to their precedence constraints. In the current study, we aim to improve the batch scheduler by using a dynamic resource allocation strategy. Our objective is to improve the executions at the scale of the supercomputer, i.e. to reduce the overall makespan of an application set, and not to focus on a single application only. In addition, our work is tied to the task-based method, as we consider that each application is composed of tasks and that some of them can be executed on CPU, GPU or both.

In this paper, we present a resource manager for heterogeneous environments considering task-based model applications called RSCHED, aiming at optimizing their usage. In RSCHED, we propose strategies for resource distribution between concurrent task-based applications while orchestrating their execution. We have implemented our proposal within StarPU [2] and analyzed the performance of our proposal via diverse experiments. Our contributions can be summarized as follows:

- We propose a framework for managing the execution of concurrent task-based applications.
- We propose strategies for dynamically distributing resources between concurrent task-based applications.

[1]https://www.top500.org/

[2]https://www.schedmd.com/

[3]https://oar.imag.fr/

[4]https://www.openpbs.org/

- We propose a new model of Gradient Descent in a (three-dimensional) discrete space.
- We propose a strategy to automatically create and configure a scheduling context for a given task-based application.
- We present performance analysis and results showing the effectiveness of our proposals.

The remaining sections of the paper are organized as follows. In Section II, we introduce the notion of task-based application and present the state-of-the-art concerning the scheduling of task-based application under StarPU. Then, in Section III, we present our proposed resource management for simultaneous execution of task-based applications. Finally in Section IV, we evaluate the performance of our proposals.

II. Background

A. Task-Based Application

Several strategies to parallelize applications on heterogeneous computing nodes aim at maximizing resource usage. The task-based model has demonstrated high potential in various fields [3], [4], [5]. This method allows obtaining hardware-independent algorithm descriptions while developing efficient HPC applications. The level of abstraction and encapsulation relieves the users by shifting the complexity to the runtime systems, where researchers can invest the effort to create generic and efficient optimization solutions. The HPC community has at its disposal highly documented and maintained runtime systems supporting the task-based model, such as Parsec [6], and StarPU [2] a runtime system library developed at Inria Bordeaux.

Among other runtime systems supporting the task-based model, StarPU has a plus in that it has a component – *hypervisor* – allowing concurrent execution of task-based applications with minimal interference [7]. StarPU hypervisor provides confined execution environments – *scheduling contexts* – which can be used to partition computing resources. StarPU scheduling contexts can be dynamically resized and linked to a well-designed scheduler to optimize the allocation of computing resources among concurrent task-based applications/libraries. A scheduler can be chosen for each application via its linked scheduling context. Since task-based applications have various types and structures, a scheduler can be effective only for some applications, or a specific type of machine architecture [8], [9], [10], [11], [12]. StarPU also proposes basic strategies for resizing scheduling contexts and a platform for implementing additional custom ones.

Different task-based frameworks have been used to develop efficient HPC applications, such as the Lattice-Boltzmann method [13], [14], the fast-multipole method (FMM) [3], [4], [15], N-body simulations [16], linear algebra solvers [17], [18], [19], H-matrix solvers [20], the particle-in-cell method [21], the polar decomposition method [22], seismic imaging [23], [24], [25], Galerkin solver [26], to mention a few. This demonstrates that at least at a moderate scale and when used by experts, the existing task-based runtime systems can be efficient for various classes of algorithms.

1) Task-based parallelization: The task-based method divides an application into interdependent sections, called tasks. The dependencies between the tasks ensure valid parallel executions and task execution orders without race conditions. This can be likened to a graph, where the nodes represent the tasks and the edges represent the dependencies. We consider a task-based application as a Directed Acyclic Graph (DAG) $G(V, E)$ where $V = \{t_1, t_2, ..., t_n\}$ is the set of nodes and $E = \{e_{i,j} = (t_i, t_j) | 1 \leq i, j \leq n, i \neq j\}$ the set of edges representing the existing data dependencies between tasks. An edge $(t_i, t_j) \in E$ if there is a precedence constraint between t_i and $t_j \in V$, such that t_j can be executed only after the task t_i is over, and the data made available.

A task t_i is a computational element executable on one or (potentially) several types of hardware and incorporates different interchangeable kernels, each targeting a specific architecture. For instance, a matrix-matrix multiplication task in linear algebra could be either a call to cuBLAS and executed on a GPU, or a call to Intel MKL and executed on a CPU, but both kernels return equivalent results.

B. Task Scheduling and Related Work

The scheduling problem on heterogeneous computing systems has been proven NP-complete [27], whether in static or dynamic situations. Dealing with the first situation requires prediction models which are not always accurate, and a knowledge of the complete view of the task graph [28], which need expensive analysis mechanisms and incur significant overhead. The latter one is the most used [29], [30], [31], [25], [32], [22], [4] and has demonstrated its ability to deliver high performance with reduced overhead.

The two main steps of a scheduler are task selection or prioritization, and resource selection. This action can be static or dynamic according to the scheduling situation.

Due to the evolution of computing architectures, task scheduling in heterogeneous computing is an aged but hot topic. Various strategies for task scheduling have been proposed, with Heterogeneous Earliest Finish Time (HEFT) being one of the most widely used. [33] In HEFT, tasks are prioritized using a heuristic based on a prediction of the processing length of the tasks and the data transfer time between them. Whereas, resource selection is based on a heuristic that determines the resource providing the best finish time for the tasks according to the scheduling decision of previous tasks. Several variances of this approach with more advanced ranking and resource selection models have been proposed [34], [35], [36], [37]. These schedulers have in common the limitations of static schedulers previously argued, and therefore rely on greedy algorithms. In a changing environment, re-prioritizing the tasks could be necessary, which can add more overhead. A larger spectrum of task schedulers can be found in the literature [38], [39].

1) Task scheduling in StarPU: Our scheduling process follows the terminology of StarPU. In StarPU, the user first splits the problem into smaller computational tasks. Afterwards, the tasks are implemented into codelets, which are simple C functions. One task can be implemented differently in several codelets according to the targeted hardware, allowing the user to harness special accelerators, such as vectorial CPU cores

or OpenCL devices. In StarPU terminology, these devices are called workers. For each task, the user also has to describe precisely the input data, in read mode, and the output data, in write or read/write mode. StarPU considers that a scheduler has an entry point where the ready tasks are pushed, and it provides a request method where workers pop the tasks to execute, as depicted in Fig. 1.

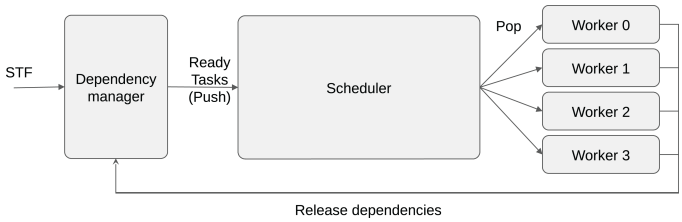

Fig. 1. Schematic view of task-based runtime system organization. A program as a sequential task flow (STF) model and converted into tasks/dependencies by the RS. New ready tasks pushed on resolved dependencies. Any idle worker calls the scheduler pop function to request a task to execute.

In StarPU, both pop/push methods are directly called by the workers that either release the dependencies or ask for a task. Consequently, assigning a task to a given worker means returning this task when the worker calls the pop method. During the execution of a StarPU program, it is possible to choose among several schedulers. The DMDA (deque model data-aware) scheduler is one of the most famous and sophisticated. It uses a HEFT-like strategy and tries to minimize the makespan by using a look-ahead strategy and data transfer costs. Another effective StarPU scheduler is Heteroprio [40], [4], a semi-automatic scheduler designed for heterogeneous machines where users must provide task priorities. A fully automatic version of the Heteroprio scheduler that computes efficient priorities is proposed [8]. Another extension of Heteroprio is the MulTreePrio [9] scheduler based on a set of balanced trees data structure, in which assignment of tasks to available resources is done according to priority scores per task for each type of processing unit. MulTreePrio makes overall good scheduling results thanks to its fast and efficient heuristics, despite the considerable variety of DAG structures from one application to another.

In all of the above, one task-based application is considered for execution/scheduling.

2) Scheduling concurrent task-based applications: In general, there is contention for the usage of resources in an HPC environment. Each user's application requests a number of processing resources (CPU/GPU for instance), an entire node or part of it. However, in both cases, it is up to the user to determine the number and type of resources, therefore this might often lead to resource wastage.

The problem presented here has a completely distinct parallelization and resources management approaches in cloud computing and Big-data frameworks, such as Spark[5] or Apache Hadoop[6]. In cloud computing, the scheduler orchestrates different executions from different types of applications, such as Big data programs, over given hardware resources. It has a view on the different operations that compose the executions, hence it can schedule and interleave them finely. However, there is a gap between the programming model and resource management.

In the basic HPC context, there is not yet a dynamic solution for concurrent job execution on the same resource as it is done in a cloud environment. In Slurm for instance, there is the notion of Job Array which consists of submitting and managing collections of similar jobs such that they may run in parallel with different input parameters or data on a node. However, it is the responsibility of the programmer to orchestrate the execution of the tasks over the resources. The same problem is encountered when several jobs are submitted separately, but now at the level of the scheduler.

The RECIPE project [41], [42] attempts to control the resources more efficiently without bridging the gap with the applications, which will end as being oriented to cloud computing instead of HPC.

Most recently, other researchers proposed a method to build scalable containerized HPC clusters in the Cloud [43], [44], by containerizing three batch schedulers, namely SLURM, OpenPBS, and OAR. They attempt to solve the problem of scaling, dynamically adding or removing containerized HPC nodes, without altering neither the Cloud orchestrator nor the HPC scheduler. This works presented promising preliminary results in that direction, scaling jobs do not impact running or pending jobs. However, it is still in the direction of Cloud Computing, where some researchers are trying to answer the question "Is the Cloud able to encompass all the categories of scientific issues in a unified way?". In addition, this does not consider task-based applications, but MPI-based applications only.

In most of the works presented above, it is either cloud oriented, or based on basic batch scheduling-like approaches using the variable partitioning scheme [1]. In both case, we can have more idle resources, which could have been used by starved applications, or could have helped in fastening the overall completion of applications and therefore in optimizing energy consumption. However, StarPU [7] offers a good platform to dynamically partition computing resources into contexts that can be used to execute several applications, and with the possibility to share resource between them. Nevertheless, there is no means to launch several applications nor dynamically distribute the workers among them.

III. Presentation of RSCHED

In this section, we present our concurrent execution approach, named RSCHED. Let us consider that we have n concurrent users' applications requesting resources for execution in a node with p workers (nb_cpus the number of CPUS and nb_gpus the number of GPUS). The main objective of RSCHED is to minimize the overall makespan for all the n applications. A secondary objective of RSCHED is maximizing resource utilization, which is a well-known energy consumption reduction approach (Fig. 2).

The RSCHED framework has a two-level scheduling model: resource distribution and task scheduling. The scheduling at each level assumes the resources are sharable between

[5]https://spark.apache.org/
[6]https://hadoop.apache.org/

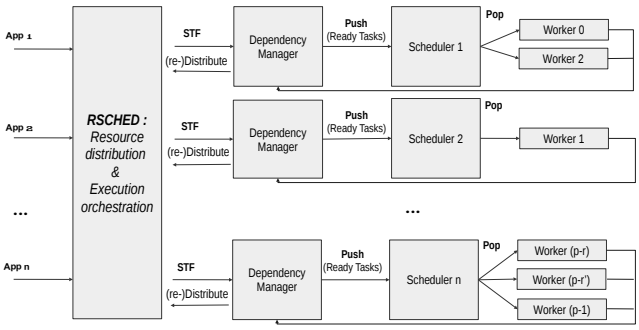

Fig. 2. Schematic view runtime system organization with n concurrent task-based applications and p workers.

the applications, and reusable on the fly (for instance when an application ends), even without a new resource subscription. The resource distribution aims at distributing the available resource among the application, and task scheduling to effectively map each task unto a given compute resource.

That said, our model is intended to be more flexible for efficient resource usage than basic batch scheduling-like approaches. Idle resources can be reused by starved applications (even before the completion of the application to which they have been assigned). For shared resources, the end of one application can help in fastening the completion of others.

Before the execution of an application, a task scheduler is associated with a separate context linked to it. The required resource distribution can be done before any task is pushed, or after all tasks have been pushed but no task has been executed. In the beginning, the lack of information on the applications makes it difficult to process an advanced distribution strategy. That is why in the first case, a naive strategy can be used to distribute the workers between the contexts, and afterward a more advanced distribution strategy. In the second case, we can have sufficient information on the applications to process an advanced distribution strategy before any task is executed.

A compromise between having all information before starting and starting sooner is to process an advanced distribution at an arbitrary time after the tasks have started to be pushed and executed. That time could be for instance when any first application completes its execution, or after all tasks have been pushed. The execution of tasks starts as soon as possible, and afterward, we re-distribute workers to the rest of the applications to balance the load and therefore minimize the overall makespan. While distributing resources, two contexts may share some workers, but with a possible performance penalty, due to context switches.

We assume all the n applications were submitted before the distribution. However, we propose early investigations of continuous application arrivals (mimicked by the proposed resizing options) that will be properly and intensively investigated in our future work.

A. RSCHED API

To distribute resources among task-based applications, the RSCHED's API requires their performances on the targeted hardware. We assume in this work that we have two types of workers, CPUs and GPUs. For each application, the required information are the following:

- CPU_W: Total (sequential) CPU workload of the graph on the targeted CPU.
- GPU_W: Total (sequential) GPU workload of the graph on the targeted GPU.
- CPU_{PW}: Total (sequential) pure CPU workload of the graph on the targeted CPU.
- GPU_{PW}: Total (sequential) pure GPU workload of the graph on the targeted GPU.

By pure CPU (or GPU) workload, we mean the workload of tasks that can only be executed by a CPU (or GPU). Providing those pieces of information implies knowing (an approximation of) the processing time of each task in the application per type of worker. There are several means of obtaining such information, like Machine Learning, or history-based performance models as it exists in StarPU.

The constraints over this information are given by the Rule 1.

Rule 1. *Given the required information as defined above, either the total workload is equal to the pure one for all the types of workers, or strictly greater than the pure one for all (see Eq. 1 and 2).*

$$CPU_W \geq CPU_{PW} \ \boldsymbol{AND} \ GPU_W \geq GPU_{PW} \tag{1}$$

$$(CPU_W = CPU_{PW} \ \boldsymbol{AND} \ GPU_W = GPU_{PW}) \ \boldsymbol{OR} \\ (CPU_W > CPU_{PW} \ \boldsymbol{AND} \ GPU_W > GPU_{PW}) \tag{2}$$

Proof: The proof of Eq. 1 is obvious. For Eq. 2, there are two cases to have equality: all the tasks are either pure CPU or pure GPU. In both cases, the other type of worker will have zero workload. ■

1) RSCHED resource distribution: Given the n applications with the required information described in the last section, a distribution strategy should produce the following information for each graph:

- L_{CPUS}: List of CPUs assigned.
- L_{GPUS}: List of GPUs assigned.
- $\#CPUS$: Number of distinct CPUs assigned ($\#CPUS = |L_{CPUS}|$).
- $\#GPUS$: Number of distinct GPUs assigned ($\#GPUS = |L_{GPUS}|$).
- $CPUS_{PR}$: The power rate of the assigned CPUs ($0 \leq CPUS_{PR} \leq \#CPUS$).
- $GPUS_{PR}$: The power rate of the assigned GPUs ($0 \leq GPUS_{PR} \leq \#GPUS$).

Rule 2. *Each application must receive at least one worker, and applications can share all the workers.*

$$(\#CPUS + \#GPUS > 0.0) \ \boldsymbol{AND} \\ (0.0 \leq \textstyle\sum_{0 \leq r \leq n} \#CPUS_r \leq n \times nb\_cpus) \ \boldsymbol{AND} \\ (0.0 \leq \textstyle\sum_{0 \leq r \leq n} \#GPUS_r \leq n \times nb\_gpus) \tag{3}$$

Rule 3. *Each application must receive at least one worker per type of pure workload.*

$$(CPU_{PW} = 0.0 \; \textbf{\textit{OR}} \; (CPU_{PW} \neq 0.0 \; AND \; \#CPUS > 0.0)) \; \textbf{\textit{AND}} \; (GPU_{PW} = 0.0 \; \textbf{\textit{OR}} \; (GPU_{PW} \neq 0.0 \; AND \; \#GPUS > 0.0)) \tag{4}$$

An estimation of the makespan of each application is used as a building block of our strategies, given a set of workers (CPUs/GPUs) assigned to the applications. We proposed an estimation called "Ideal Makespan", and more details are given in Appendix (see Algorithm 1). The following metrics are used in the evaluation of our "Ideal Makespan".

When an application has a pure workload for a given type of worker, there is a minimum length constraint over its makespan. We denote them as $tgpu_{minM}$ and $tcpu_{minM}$ (see Eq. 5 and 6).

$$tgpu_{minM} = \frac{GPU_{PW} \times coef\_par\_eff^{\#GPUS+\#CPUS-1}}{\#GPUS} \tag{5}$$

$$tcpu_{minM} = \frac{CPU_{PW} \times coef\_par\_eff^{\#GPUS+\#CPUS-1}}{\#CPUS} \tag{6}$$

In the case no CPUs (or GPUs) are assigned unto the application, $tcpu_{minM}$ (or $tgpu_{minM}$) is equal to zero.

The general formulation of our makespan estimation is given by Eq. 7.

$$\begin{aligned} ideal\_makespan \; &= MAX(tcpu_{minM}, tgpu_{minM}) \\ &+ \frac{cpu\_rem\_wl}{\#CPUS + \#GPUS \times \frac{cpu\_rem\_wl}{gpu\_rem\_wl}} \end{aligned} \tag{7}$$

Where cpu_rem_wl (resp. gpu_rem_wl) is the exceeding CPU (resp. GPU) workload compared to the gap between $tgpu_{minM}$ and $tgpu_{minM}$, and the CPU/GPU (resp. GPU/CPU) speedup.

In this work, we present four distribution strategies: Lp-Solve, MinMaxWL (Min-Max Workload balancing), DSR-CLUS (Dedicated plus Shared Resource with Clustering) and DSR-GD (Dedicated plus Shared Resource with Gradient Descent).

a) LpSolve: In this strategy, we rely on the linear programming model presented in a previous study [4]. Originally, this model was employed to compute an ideal makespan (a theoretical lower bound) for tasks executed on heterogeneous architectures. The model is given by:

$$\begin{cases} Objective\,function : min(T) \\ \sum\limits_{\omega \; in \; \Omega} \alpha_1^{\omega} \, t_1^{\omega} = t_1 \leq T \\ \sum\limits_{\omega \; in \; \Omega} \alpha_2^{\omega} \, t_2^{\omega} = t_2 \leq T \\ \quad ... \\ \sum\limits_{\omega \; in \; \Omega} \alpha_P^{\omega} \, t_P^{\omega} = t_P \leq T \end{cases} \tag{8}$$

$$\begin{cases} \sum\limits_{p=1}^{P} \alpha_p^1 = 1 \\ \sum\limits_{p=1}^{P} \alpha_p^2 = 1 \\ \quad ... \\ \sum\limits_{p=1}^{P} \alpha_p^{|\Omega|} = 1 \end{cases} \tag{9}$$

Here, P denotes the number of processing units and $|\Omega|$ is the total number of tasks. The coefficient α_p^{ω} indicates the proportion of task ω processed by unit p, and t_p^{ω} represents the time taken to complete task ω on unit p, given that this duration varies based on the type of the processing unit. Accordingly, the first system determines the computation duration for each unit, with T being the longest duration. The second part ensures that each task is computed at 100%.

While this model provides an upper bound for ideal performance, it doesn't account for the dependencies between the task order and consider that tasks can be divided among various processing units.

In our adaptation, we assume that a single application consists of three tasks: one for exclusive CPU work, another for exclusive GPU work, and the last one for work that can be executed on either CPU or GPU. Given this characterization, the aforementioned LP model remains applicable.

However, our focus isn't on the ideal makespan T, but on the α coefficients as we aim to find the most efficient way to distribute the application across processing units. Although the LP provides an optimal distribution for an ideal system, it also guides us on the proportion of each application that should be allotted to each processing unit type. However, this distribution might be inefficient in real-world scenarios, leading to a task being fragmented across all units or a skewed allocation, like 99% on one unit and 1% on another, which may not always be practical. Consequently, it's essential to transform these coefficients into practical distribution values to derive a feasible scheduling strategy.

To achieve this, we use a two-step method. First, we sum the distribution coefficients per unit type to determine the fraction of each application designated for every processing unit type. For instance, if the LP solution suggests distributing an application as 0.1 and 0.4 across two CPUs, and 0.2, 0.2, and 0.1 across three GPUs, we infer it should be equally split (0.5 for CPU and 0.5 for GPU). Subsequently, we decide on the application distribution based on these values. In the next step, we compute the processing time for each unit type by multiplying the number of a given unit type with T. For instance, with two CPUs and a makespan of 10s, we have 20s of total CPU time to distribute. Each application is then assumed to use a fraction of this time proportional to its distribution coefficient. Our greedy algorithm identifies the application with the highest use proportion and allocates it to the processing unit with the least utilization, continuing until every application has been entirely mapped to processing units.

b) DSR (Dedicated plus Shared Resource) strategies: For illustrations, let us consider for instance that we have three applications, four CPUs, and two GPUs. The DSR strategies

proceed in two steps to distribute the workers among the applications:

The first step consists in assigning dedicated (unshared) workers (GPUs or CPUs) to each application, proportionally to their GPU/CPU workload compared to the sum of all the applications' workloads. Supposed the proportions of CPU workloads (cpu_pwl) are 0.31, 0.56, and 0.13, the numbers of dedicated CPUs (given by $\lfloor nb\_cpus \times cpu\_pwl \rfloor$) will be respectively $\lfloor 4 \times 0.31 \rfloor = \lfloor 1.24 \rfloor = 1$, $\lfloor 4 \times 0.56 \rfloor = \lfloor 2.24 \rfloor = 2$, and $\lfloor 4 \times 0.13 \rfloor = \lfloor 0.52 \rfloor = 0$. In that case, the number of remaining CPUs is 1. The same is similarly done for GPUs. In the case of hybrid workloads, and if the standard deviation between the GPU/CPU speedups is above a certain threshold, we proceed to the barter which consists of exchanging GPU against CPUs to accelerate the most GPU-optimized applications.

The second step involves sharing the remaining workers to the applications, using a given technique. Here we proposed two DSR strategies, based on two different techniques for workers sharing, the clustering and the gradient descent: DRS-CLUS (Dedicated plus Shared Resource with Clustering) and DSR-GD (Dedicated plus Shared Resource with Gradient Descent). The sharing process is done based on the remaining cpu_pwl (here in the case of CPUs, we have: 0.24, 0.24, and 0.52).

As for the DRS-CLUS strategy, resource sharing is done as follows. The number of clusters is equal to the number of remaining workers. The workers/applications mapping is done to balance the load over the workers as much as possible.

In the DSR-GD strategy, the second step is done as follows (see Algorithm 2 in Appendix, from lines 18 to 24). The remaining workers are shared between applications using a new model of gradient descent (GD) in a (three-dimensional) discrete space.

The Gradient Descent is an efficient strategy well-known for its speedy convergence in convex and smooth optimization problems (if well-tuned), even in low memory, and computational loading environments [45], [46].

Our GD strategy is modelled as follows:

Given the CPUs and GPUs IDs, {0,1,2,3} and {0,1} respectively, our research space is modelled as a three-dimensional discrete space (X, Y, Z):

- X: The numbers of assigned CPUs ($\#CPUS$) per graph. Each application can have from zero to the number of CPUs (Ex. {1,2,1}, the first app has 1 CPU, the second one 2 CPUs, and the third one has 1 CPU).
- Y: The numbers of assigned GPUs ($\#GPUS$) per graph. Each application can have from zero to the number of GPUs (Ex. {1,1,1}, the first app has 1 GPU, the second one 1 GPU, and the third one has 1 GPU).
- Z: The possible (graph-to-gpu/cpu) mappings given X and Y. An example of mapping related to the Y and Y ones above is $\{\{0\},\{0\}\}$, $\{\{1,2\},\{0\}\}$, $\{\{3\},\{1\}\}$. In this example, the first app has the CPU id=0 and the GPU id=0, app 2 has the CPU ids=1,2 and the GPU id=0 and app 3 has the CPU id=3 and the GPU id=1. We can see that app 1 and app 2 share one GPU together.

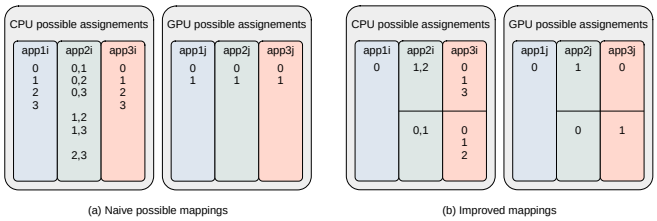

Fig. 3. Illustration of determination of possible mappings with three applications, four CPUs, and two GPUs, and given that X={1,2,1} and Y={1,1,1}.
The improved version has fewer duplicates in terms of obtained mappings 24 vs 768).

Iteration in the axis is done as follows:

- The indexes in X and Y can be seen as permutations with repetition of a possible number of assigned workers in nb_graphs positions:
  - $X_i \in$ {{0,0,0}, {0,0,1}, ... , {0,0,4}, {0,1,0}, ... ,{4,4,4}}. By looking carefully, we can see that each X_i is likened to "i" in base $(nb\_cpus + 1)$
  - $Y_j \in$ {{0,0,0}, {0,0,1}, {0,0,2}, {0,1,0}, ... ,{2,2,2}}. In like manner, Yi is likened to "j" in base $(nb\_gpus + 1)$
- Z_k (or Zijk): The k-th possible mapping, given X_i and Y_j. One naive way to get the Z_k's values is to generate the different 2-uplets, of the possible CPUs assignment given X_i and the possible GPUs assignment given Y_j. For our example, Fig. 3(b) illustrates the determination of possible mappings and how to find the Z_k. We have $Z = (app1i \times app2i \times app3i) \times (app1j \times app2j \times app3j)$. While the naive version leads to $((4 \times 6 \times 4) \times (2 \times 2 \times 2) = 96 \times 8 =)$ 768 possible mappings, the improved one gives $((1 \times 2 \times 3) \times (1 \times 2 \times 2) = 6 \times 4 =)$ 24 possible mappings. The improved version has far fewer duplicates in obtained possible mappings, and this is for only three applications.

This model presents the whole research space. However, during our research process, the search space is circumscribed around the convex zone containing our global optimum. This is done by setting for each application the minimum number of workers (CPUs and GPUs) obtained in step one, and the maximum by adding the number of workers not yet assigned. Thus, we reduce the search space and speed up the search.

Our gradient function is evaluated as a symmetric linear interpolation [47]. Our search process follows the pattern direction [48], first, we search towards the X direction, then the Y direction, and finally the Z direction. To ensure process time scaling, the learning rates for the different axes are $tau_x = 0.001 \times (\lfloor nb\_graphs/\sqrt{nb\_cpus} \rfloor + 1)$, $tau_y = 0.001 \times (\lfloor nb\_graphs/\sqrt{nb\_gpus} \rfloor + 1)$ and $tau_z = 0.0005 \times (\lfloor nb\_graphs/\sqrt{nb\_cpus + nb\_gpus} \rfloor + 1)$.

c) MinMaxWL (Min-Max Workload balancing): The MinMaxWL algorithm is a load-balancing strategy that dis-

tributes workers among applications by minimizing the maximum ideal makespan. The strategy is depicted in Algorithm 3 (in Appendix), and has four main steps.

First of all, it assigns one worker to each application having a pure workload according to the type of worker (from lines 3 to 13). While trying to assign a worker to the current application, if there are no remaining workers of the type, the application shares one with the under-loaded application related to that type. A backpropagation is employed in the case of sharing to ensure load-balancing when less-loaded applications are treated after more-loaded ones.

The second step is to ensure all the applications have at least one worker, by assigning a worker to applications without a pure workload (from lines 15 to 28). Since those applications are hybrid, the type of worker to assign is the fastest on the application. A similar sharing process is also employed, but this time the sharing is made on the worker, leading to the smallest makespan at the point.

Finally, while there are remaining workers (per type of worker), it assigns a worker to the application that will minimize the maximum ideal makespan among all the applications.

2) Distribution options: If the distribution of resources to the applications is accurate, the applications will end almost at the same time, and so will the workers. Otherwise, some resources could be idle for a long, while remaining applications may need them. To deal with that situation, a redistribution of the resources might be necessary. One crucial aspect to consider for it is the condition of resizing, the when.

The condition of resizing we employed is the following:

- An application just ended, and there remain applications to run.
- There is a significant standard deviation between the progress rate of the applications.

The estimation process time (workload) for a CPU or GPU may differ from the effective processing time during the execution. For instance, let us suppose an application with a CPU workload of 100s, and that has been assigned 10 CPU workers. Suppose 5s after executions start, there is a need for redistribution, and it remains at an overall 20s processing time for the workload. We would have expected having executed $5 \times 10 = 50$s for the application, whereas we have $100 - 20 = 80$s. The progress rate in this case is therefore equal to $80/50 = 1.6$; which means the application is running faster than expected. Now we know that possibly the application may end in $(20/1.6)/10 = 1.2$s instead of $20/10 = 2$s.

Before the redistribution, we adjust the workload of each application according to its progress rate. We have proposed two resource redistribution options.

a) One Distribution: This is the default behavior, where the distribution is done once and for all.

b) Multiple distributions: Here we do the distribution as initially, but considering the adjusted workloads of the remaining applications.

c) Inherit released workers: Here we distribute the released workers (by the just-ended application) to the remaining ones, with high privilege to those that were delaying.

B. RSCHED Implementation in StarPU

StarPU offers a platform to dynamically construct, delete, and modify Scheduling Contexts, which are used to execute several parallel kernels in an isolated way and without interference. This allows the users to assign workers to the contexts, at their creation time, or resize them during program execution. However, this is subject to the knowledge of the number of workers needed for each scheduling context. StarPU proposes online performance tools to monitor the execution of tasks, to make execution time estimations.

1) Multiple task-based applications: There are several applications implemented in StarPU. However, there is no mechanism to launch or orchestrate the execution of concurrent applications. For the sake of simplicity, instead of using several different applications, we have exploited the implementation of Cholesky factorization to have several independent applications. The Cholesky application in StarPU is implemented with a performance model for each codelet. We have added a parameter to specify the number of applications to create, and for each application, we gave the possibility to specify the size and the number of blocks via environment variables.

2) Context creation and workload determination: For each application, a separate context is created and a task scheduler is associated with it. In this work, we have chosen to use DMDA as a scheduler for all the applications. DMDA relies on a historical performance model to be able to estimate in advance the duration of a codelet on each kind of processing unit. Using StarPU historical performance model, we have been able to compute the different workloads of the concurrent applications.

IV. Performance Study

A. Experiments Setup

1) Hardware: We conducted our experiments on three configurations with different GPU models as follows:

- A100: Composed of two 32-core AMD Zen3 EPYC 7513 @ 2.60 GHz, and 2 NVIDIA A100 (40GB). We use 30 CPU cores and 16 CUDA streams per GPU.
- Quadro: Composed of 2 Icosa-core Cascade Lake Intel Xeon Gold 5218R CPU @ 2.10 GHz, and 2 NVIDIA Quadro RTX8000 (48GB). We use 30 CPU cores and 16 CUDA streams per GPU.
- K40M: Composed of 2 Dodeca-cores Haswell Intel Xeon E5-2680 v3 2.5 GHz, and 4 K40m GPUs (12GB). We use 20 CPU cores and 8 CUDA streams per GPU.

We have configured StarPU as follows. For each configuration, we set the environment variables STARPU_NCPU to the number of CPU cores, STARPU_NCUDA to the number of GPU, and STARPU_NWORKER_PER_CUDA to the number of CUDA streams. Therefore, for all the configurations, we have more GPU workers than CPU ones.

2) Task-based applications: We implemented Cholesky factorization in StarPU and tested it across twelve different configurations as follows:

- app_0: Matrix size of 3.200, with 5 blocks
- app_1: Matrix size of 3.200, with 10 blocks
- app_2: Matrix size of 6.400, with 10 blocks
- app_3: Matrix size of 6.400, with 20 blocks
- app_4: Matrix size of 9.600, with 10 blocks
- app_5: Matrix size of 9.600, with 30 blocks
- app_6: Matrix size of 19.200, with 20 blocks
- app_7: Matrix size of 19.200, with 30 blocks
- app_8: Matrix size of 25.600, with 40 blocks
- app_9: Matrix size of 25.600, with 80 blocks
- app_{10}: Matrix size of 76.800, with 80 blocks
- app_{11}: Matrix size of 76.800, with 120 blocks

3) Software configuration: For each application, we have made different affinities related to the types of compute units (CPU or GPU). By default, all the tasks of the Cholesky application have two codelets, one for CPU and one for GPU. Overall, we have used the three following affinities:

- Default (*affinity0*): each task has one CPU codelet and GPU codelet.
- Only CPU (*affinity1*): all the tasks have only a CPU codelet.
- Only GPU (*affinity2*): all the tasks have only a GPU codelet.

To analyze the influence of the number of concurrent applications, and of the workload, we have made experiments with 3, 6, and 12 concurrent applications. To be in accord with a realistic scenario, we have shuffled the list of applications in each experiment. Then we took consecutive applications to form the groups. For instance, in the case of three applications, we have executed concurrently the applications at the first, second third positions, then the fourth, fifth, and sixth positions, and so on.

B. Metrics

In our experiments, we have compared our four distribution strategies against the concurrent execution using a unique context with all the workers (DMDA_CONC), and against sequential execution (i.e. one application after the another) using a unique context with all the workers (DMDA_SEQ).

As metrics, we have considered the speedup, the data transfer, and the resource utilization efficiency (RUE). We also compared the distribution processing time of our strategies.

The RUE is a new metric hereby introduced and defined as follows:

Definition 1. *We define the RUE as the ability to maximize the utilization of the resource, that is, using the adequate number and types of resources for the execution of each application. The RUE is given by Eq. 10, which is the product of the resource utilization and the efficiency [49].*

$$RUE = \frac{\sum_{p \in USED\_WK}\{processing\_time\ of\ worker\ p\}}{\sum_{p \in USED\_WK}\{total\_active\_time\ of\ worker\ p\}} \times \frac{speedup}{|USED\_WK|} \tag{10}$$

$USED\_WK$ is the list of distinct workers (CPU or GPU) used for the execution of the applications, whether concurrently or sequentially (i.e. in DMDA_SEQ). We normalized the RUE such that the values lie between 0 and 1.

C. Experiments Results and Analysis

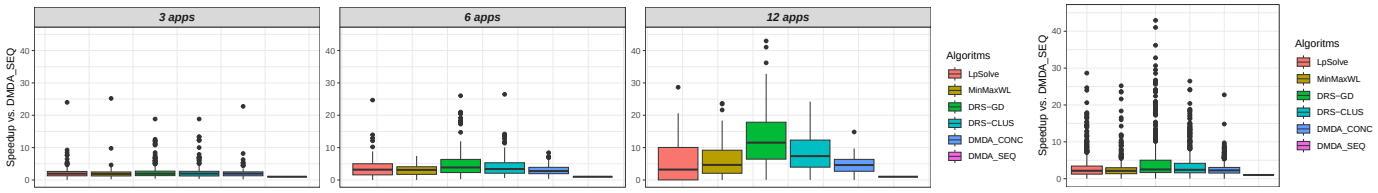
1) Default experiments: We first present the performance of our strategies (LpSolve, MinMaxWL, DSR-GD, and DSR-CLUS), and of DMDA_CONC, against DMDA_SEQ, in terms of Speedup, then in terms of data transfer, and finally in terms of RUE.

a) Speedup: The big picture of the speedup realized by the different strategies compared to DMDA_SEQ is presented in Fig. 4. For all the configurations and affinities, the LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, and DMDA_CONC can significantly accelerate the execution DMDA_SEQ (Fig. 4b). Moreover, our strategies (except MinMaxWL) perform better even than DMDA_CONC with the increase in the number of applications. We observe in this study an outperformance over DMDA_CONC in more than 50% of cases for LpSolve, and more than 75% of cases for DSR-GD and DSR-CLUS (Fig. 4b).

DSR-GD and DSR-CLUS reach an acceleration of 40× compared to DMDA_SEQ. However, DSR-GD outperforms DSR-CLUS in more than 50% of situations, observed while we have an increase in applications. This means that conceptually, the Gradient Descent performs better than the clustering since the two strategies have the same building block. We observe that the speedup of the strategies increases with the number of concurrent applications (Fig. 4a). The study of the variation of the speedup according to the workload and of the GPU/CPU acceleration (see Fig. 5 and Fig. 6) reveals that DSR-GD and DSR-CLUS perform better when the percentage of the standard deviation of GPU/CPU acceleration among the application increases. This is explained by the employed bartering technique that gives GPU in preference to more accelerated applications in exchange for CPU to others.

The study of the variation of the speedup according to the number of applications over the different hardware configurations (Fig. 7) reveals that the strategies perform better on recent architectures (Quadro and A100) which have more accelerated GPU than on older ones (K40M). More specifically, DSR-GD and DSR-CLUS perform better than the other strategies, due to the same reasons as previously.

Globally, the DSR-GD realizes better speedup and in more of the situations than the others, then DSR-CLUS followed by LpSolve.



(a) Speedup obtained for the 3, 6, and 12 concurrent applications.

(b) Speedup summary

Fig. 4. Speedup of LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, DMDA_CONC against DMDA_SEQ for all the affinities (affinity0, affinity1, affinity2) and all the hardware configurations (K40M, Quadro, and A100).

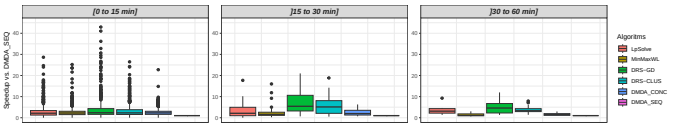


Fig. 5. Speedup of LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, DMDA_CONC against DMDA_SEQ according to the average workload in minute, on K40M, Quadro or A100.

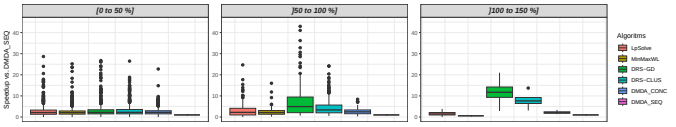

Fig. 6. Speedup of LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, DMDA_CONC against DMDA_SEQ according to the standard deviation percentage of GPU/CPU speedup between the applications, on K40M, Quadro or A100.

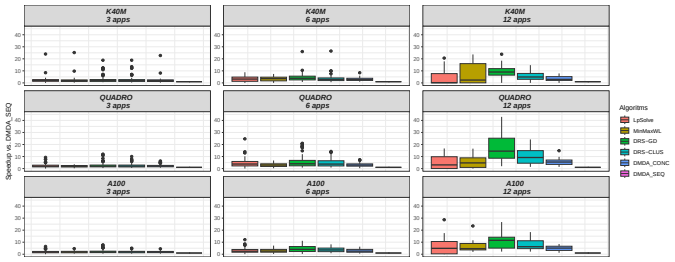

Fig. 7. Speedup of LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, DMDA_CONC against DMDA_SEQ for 3, 6, and 12 concurrent applications with all the affinities, on K40M, Quadro or A100.

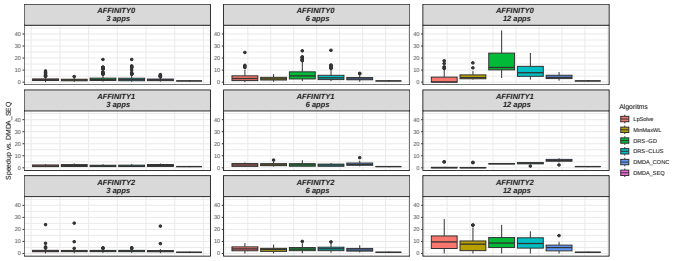

Fig. 8. Speedup of LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, DMDA_CONC against DMDA_SEQ for 3, 6, and 12 concurrent applications with each affinity, on K40M, Quadro or A100.

b) Data transfer: The total amount of memory transfer obtained with the different strategies are provided in Fig. 9. All the strategies for concurrent execution used in this study (LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, and DMDA_CONC) significantly reduce the total memory transfer compared to the sequential execution (Fig. 9b), DSR-CLUS been the best one.

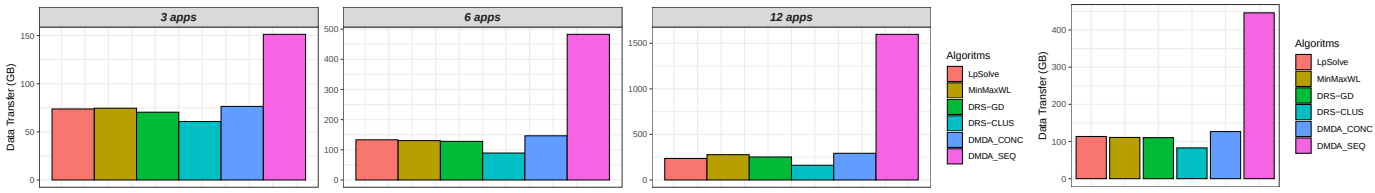
c) Resource utilization efficiency: The Normalized RUE obtained with the different strategies are provided in Fig. 10. We observe in this study that the concurrent execution of applications leads to more effective resource usage than the sequential one. The DSR-GD and DSR-CLUS strategies are more efficient in terms of resource utilization than the other (Fig. 10b), DSR-GD been the best one as the number of applications increases. Executing the applications sequentially one after the other leads to more resource wastage, which is known as a major cause of energy consumption in data centers [10], [11]. Moreover, we observe that the improvement of our strategies (DSR-GD, DSR-CLUS, and LpSolve) in terms of RUE correspond with the situations in which they are speeding up compared to the sequential execution (Fig. 10a $\equiv$ Fig. 4a). Therefore, succeeding in speeding up the sequential execution of tasks-based applications using our strategies might also help to reduce energy consumption, thanks to the effectiveness of the scheduler used.

2) Distribution processing time and options:

a) Distribution processing time: In a dynamic situation where applications arrive continuously (as we will study in the future), the decision processing has to be fast. Fig. 11 presents the evolution of processing time for each of our proposed strategies according to the acceleration of GPU compared to the CPU, and the number of executed applications.

The MinMaxWL and DSR-CLUS strategies are faster than LpSolve and DSR-GD which are meta-heuristics. However, the processing times of all the strategies are relatively small to expect good behavior even in a dynamic and computational loading environment. Moreover, even though we add the decision process time to the overall makespan, we will still have almost the same results as presented above.

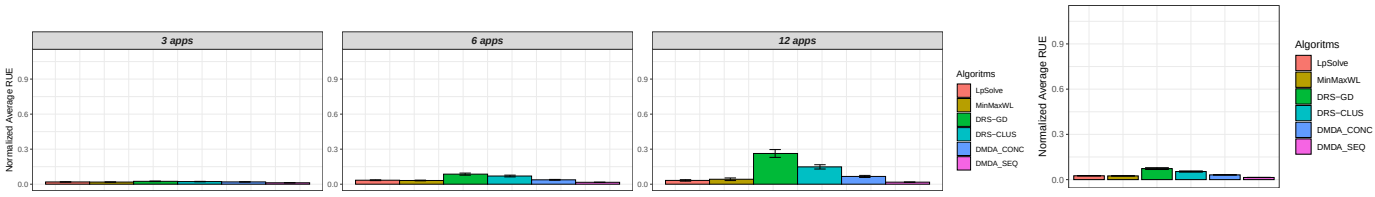
Furthermore, we realize that DSR-GD scale better than LpSolve given their processing time (Fig. 11) and speedup compared to DMDA_SEQ (Fig. 4, 5, 6, 7, 8). This performance of DSR-GD is due in part to the choice of learning rate that helped speedily converge towards the optimal solution



(a) Memory transfer obtained for the 3, 6, and 12 concurrent applications.

(b) Memory transfer summary

Fig. 9. Memory transfer of LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, DMDA_CONC against DMDA_SEQ for all the affinities and all the hardware configurations (K40M, Quadro, and A100).



(a) Average RUE obtained for the 3, 6, and 12 concurrent applications.

(b) Average RUE summary

Fig. 10. Average RUE of LpSolve, MinMaxWL, DSR-GD, DSR-CLUS, DMDA_CONC against DMDA_SEQ for all the affinities and all the arch configurations (K40M, Quadro, and A100).

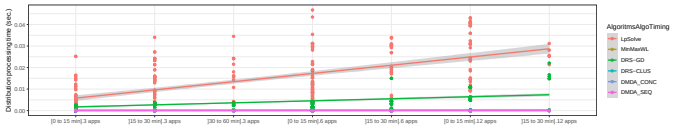


Fig. 11. Distribution processing time of LpSolve, MinMaxWL, DSR-GD, and DSR-CLUS according to the standard deviation percentage of GPU/CPU speedup between the applications, and the number of concurrent applications

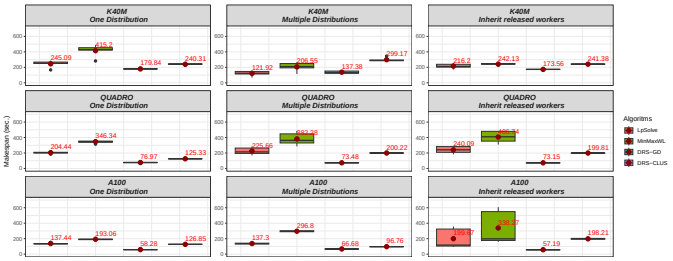

Fig. 12. **Analysis of distribution options** for LpSolve, MinMaxWL, DSR-GD, DSR-CLUS with 12 concurrent applications. *The averages makespan are displayed in red.*

no matter the number of applications and resources, and also due to the bartering technique employed (see Section III-A1). This is a promising property for a scalable system.

b) Distribution options: We carried out a study on the effectiveness of the re-distribution options ("Multiple Distributions", and "Inherit released workers") presented in Section III-A2 comparatively to the default one ("One Distribution") when combined with each of our four strategies (LpSolve, MinMaxWL, DSR-GD, DSR-CLUS). Fig. 12 presents the makespan obtained in each case, which reveals that the effectiveness of the re-distribution options ("Multiple Distributions", and "Inherit released workers") depends on the strategies and the configuration.

The combination DSR-GD/"Inherit released workers" always produces a gain for all the configurations. For the other cases, the combination strategy/option leads to a gain only for some configurations. We notify significant improvement in some cases, proving that there is hope for improving the results obtained above by using resource redistribution. However, it is imperative to do more investigations on configuration and strategy sensitivity to achieve this.

V. Conclusions

As computing resources are getting more complex and powerful, there is little doubt that we need methods to reduce the waste from the users' choices, bad application optimization, or heterogeneous workloads during executions. This is where the task-based model grants more opportunities by exposing a dynamic degree of parallelism with execution environments able to use this information in the most constructive and thus efficient way. To minimize the overall makespan and maximize resource utilization while executing multiple task-based applications, we introduce RSCHED, a two-level resource management framework that allows 1) dynamic resource distribution for concurrent execution of task-based applications, and 2) dedicated task scheduling for each application. We proposed strategies for resource distribution and implemented our proposal on the StarPU runtime system, proposing schedulers on which we rely for the second level. A new model of Gradient Descent has been proposed, among other strategies for resource distribution. We evaluated our

proposal using real applications based on the StarPU implementation of Cholesky factorization. RSCHED demonstrated the potential to speed up the overall makespan compared to consecutive execution with an average factor of 10x, and a factor of 5x when compared against the concurrent execution without resource distribution using DMDA. RSCHED also demonstrated the potential to increase the rate of resource utilization as the number of applications increases. Moreover, the decision time of our strategies and our initial study on resizing options indicate promising scalability.

In our future work, we will investigate continuous application arrivals and resizing options to have more adaptive solutions due to the variability and complexity of both the applications and the computing resources. That being said, we would like to consider different applications (instead of just Cholesky), explore multiple nodes, and improve RSCHED decisions by analyzing the structures of task graphs.

ACKNOWLEDGMENTS

This work is supported by the TExas, an Inria exploratory project. Experiments presented in this paper were carried out using the PLAFRIM experimental testbed, being developed under the Inria PlaFRIM development action with support from Bordeaux INP, LABRI and IMB and other entities: Conseil Régional d'Aquitaine, Université de Bordeaux and CNRS (and ANR in accordance to the programme d'investissements d'Avenir (see http://www.plafrim.fr/).

Enhanced Network Bandwidth Prediction with Multi-Output Gaussian Process Regression

Shude Chen[1], Takayuki Nakachi[2]
Graduate School of Engineering and Science, University of the Ryukyus, Okinawa, Japan[1]
Information Technology Center, University of the Ryukyus, Okinawa, Japan[2]

***Abstract*—Modern network environments, especially in domains like 5G and IoT, exhibit highly dynamic and nonlinear traffic behaviors, posing significant challenges for accurate time series analysis and predictive modeling. Traditional approaches, including stochastic ARIMA and deep learning-based LSTM, frequently encounter difficulties in capturing rapid signal variations and inter-channel dependencies, often due to data sparsity or excessive computational cost. To address these issues, this paper proposes a Multi-Output Gaussian Process (MOGP) framework augmented with a novel signal processing strategy, where additional signals are generated by summing adjacent elements over multiple window sizes. Such multi-scale enrichment effectively leverages cross-channel correlations, enabling the MOGP model to discover complex temporal patterns in multi-channel data. Experimental results on real-world network traces highlight that the proposed method achieves consistently lower RMSE compared to conventional single-output or deep learning methods, thereby underscoring its value for robust bandwidth estimation. Our findings suggest that integrating MOGP with multi-scale augmentation holds promise for a wide range of predictive analytics applications, including resource allocation in 5G networks and traffic monitoring in IoT systems.**

I. Introduction

The proliferation of diverse network applications has led to increasingly congested environments, necessitating efficient resource allocation to maintain service quality and operational stability [1], [2]. With the rapid growth in both the volume and complexity of network traffic, the non-stationary and dynamic nature of traffic patterns has become a critical focus in telecommunications research [3], [4]. Accurate and timely network traffic prediction is essential to mitigate delays, prevent data loss, and optimize resource utilization in overloaded networks [5].

Recent advancements in traffic prediction technologies have enabled dynamic resource allocation through accurate traffic forecasting, typically categorized into short-term, medium-term, and long-term forecasts [6]. Short-term forecasting focuses on real-time predictions for the next few seconds or minutes, essential for time-sensitive applications. In contrast, long-term forecasting relies on historical trends over extended periods to guide strategic planning. Medium-term forecasting, which bridges the gap between these two, is particularly challenging due to the inherent variability in network traffic spanning minutes to hours.

Traditional prediction models, such as the Auto-Regressive Integrated Moving Average (ARIMA) [7], excel in capturing linear trends but struggle with the nonlinear and dynamic nature of modern network traffic [8], [9]. Deep learning models, such as Recurrent Neural Networks (RNN) and Long Short-Term Memory (LSTM) networks [6], offer superior nonlinear forecasting capabilities but often face challenges with overfitting, high computational demands, and large data requirements.

Gaussian Processes (GP) [10], [11] have emerged as a powerful tool for modeling nonlinear data and providing uncertainty quantification, making them particularly effective for network traffic forecasting with limited data [12], [13]. However, traditional GP methods limit their ability to adapt to dynamic and multi-scale traffic variations. This results in prediction errors over extended horizons, complicating medium-term forecasting tasks.

To address these challenges, Building on the strengths of existing GP-based multi-slot-ahead prediction models [12]-[15], this study introduces a Multi-Output Gaussian Process (MOGP) framework, incorporating an innovative signal augmentation strategy. The proposed approach introduces two key innovations: 1) the utilization of inter-channel correlations to improve prediction accuracy and reduce error propagation over extended periods, and 2) a signal augmentation strategy that generates additional input features by summing adjacent data points with varying window sizes. By enriching the input dataset with these newly generated signals, the model captures complex temporal dependencies and inter-channel interactions more effectively.

The main contributions of this paper are:

- Proposed a network bandwidth prediction framework based on Multi-Output Gaussian Process (MOGP), combined with a signal enhancement strategy.
- Enriched the input feature space and improved prediction accuracy by generating adjacent element sums with varying window sizes.
- Validated the effectiveness of the method through experiments on real multi-channel network traffic datasets, significantly reducing prediction errors.

The remainder of this paper is organized as follows: Section II reviews related methodologies and their limitations. Section III details the proposed forecasting approach, including the signal augmentation strategy and the MOGP framework. Section IV presents the dataset and experimental setup. Section

V discusses simulation results and evaluates the model's performance. Finally, Section VI concludes the paper and outlines future research directions.

II. Related Work

The evolution of network bandwidth prediction techniques has progressed from classical statistical approaches to sophisticated machine learning methods.

A. Methods Based on Probabilistic Processes

Early models like ARIMA have been extensively utilized for time series forecasting in network traffic. These models, though effective for linear trends, struggle with the complex and non-stationary nature of network data [15]. Enhancements like ARIMA/GARCH have been proposed to handle long-term dependencies, but these methods still face challenges in tracking rapidly changing network traffic characteristics [5]. These methods typically focus on single time series data, capturing patterns and periodicity over time, but have limitations in modeling long-term dependencies.

B. Machine Learning Methods

Recent advancements have seen the application of neural network architectures, such as LSTMs, which are adept at capturing nonlinearities and temporal dependencies in traffic data, providing significant improvements over traditional models [16]. Despite their effectiveness, deep learning models require substantial amounts of training data and computational resources, which can be impractical in dynamic network environments. Additionally, methods such as Recurrent Neural Networks (RNNs) and Convolutional Neural Networks (CNNs) have been employed to capture temporal and spatial dependencies in network traffic [17]. However, these machine learning methods are often limited by their high computational cost and susceptibility to overfitting in small datasets.

C. Traditional Gaussian Processes

Gaussian Processes (GP) have emerged as a powerful tool for network traffic prediction, given their ability to model uncertainty and non-linear dynamics of network traffic [8]. Particularly, Multi-Output Gaussian Processes (MOGP) have shown great potential in leveraging the correlations among multiple network channels to enhance prediction accuracy. GP models offer the advantage of providing uncertainty measures along with predictions, crucial for robust network management [18]. Incorporating convolutional structures in GPs, researchers have managed to capture spatiotemporal characteristics of traffic data more effectively, enhancing predictive performance [18]. These models have been particularly useful in scenarios involving large-scale data from multiple network sensors [19].

D. Recent Advances and Our Contribution

Recent studies, such as the work by Wang et al., explore a GP-based online learning framework for multi-slot-ahead network traffic forecasts [13]. They emphasize the evolving nature of network traffic and propose a dynamic kernel design using Spectrum Mixture (SM) functions and Process Convolution (PConv) to capture complex traffic patterns over different time scales. This approach addresses both tracking capability and prediction horizon challenges, demonstrating superior performance through simulations [13].

Emerging methodologies such as Graph Gaussian Processes (Graph-GP) [4] and Multi-channel Transformer-based models (MCformer) [20] further enhance the ability to model spatiotemporal correlations and interdependencies in network traffic. Graph-GP adapts well to scenarios with missing data and non-stationary traffic, while MCformer utilizes attention mechanisms to effectively capture multi-channel dependencies, proving highly effective in dynamic environments.However, these methods require extensive labeled datasets and suffer from high computational complexity.

E. Gap in Literature

- Existing deep learning models such as RNN and LSTM suffer from overfitting and large data requirements.
- Conventional GP-based methods do not efficiently utilize inter-channel correlations, limiting their predictive accuracy.
- Recent studies on multi-output regression models for network forecasting have not explored adjacent signal augmentation as a feature engineering technique.
- Our work extends these methodologies by introducing a signal augmentation strategy within an MOGP framework, improving multi-step forecasting accuracy.

Our proposed method extends these traditional GP approaches by using a multi-channel framework. By generating new signals from the original signals through summing adjacent signals [7], we capture the underlying characteristics of the data more effectively. Initially, the two channels with the strongest correlations are selected as the original data. Subsequently, new signals are created by using adjacent sums with varying window sizes for each channel signal. This approach enhances the prediction accuracy by exploiting inter-channel correlations more effectively, resulting in a robust framework for multi-channel network traffic forecasting.

III. Proposed Method

This section introduces the proposed Multi-Output Gaussian Process (MOGP) model for network bandwidth prediction. The method systematically integrates correlation analysis, signal transformation, and a Gaussian Process framework to improve prediction accuracy. The workflow, illustrated in Fig. 1, involves selecting highly correlated input signals, generating new signals with varying temporal scales, and training the MOGP model for predictive tasks.

A. Flowchart Overview of the Prediction Process

The overall workflow is illustrated in Fig. 1. The process begins with correlation analysis to identify a subset of highly correlated signals. These signals are then enriched by generating new signals through adjacent sums with varying window sizes. The original and generated signals are subsequently input into the MOGP model, which leverages their temporal and inter-channel dependencies for bandwidth prediction.

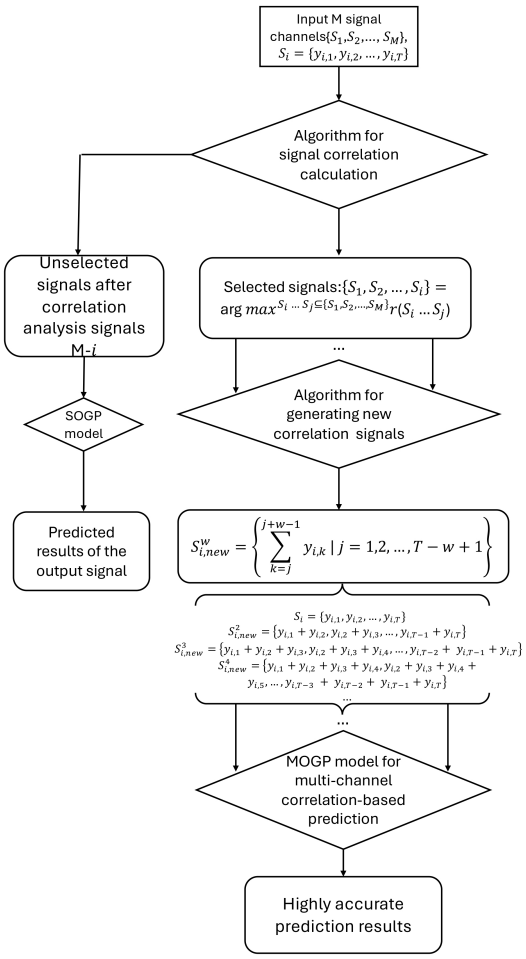

Fig. 1. Flowchart of the proposed prediction method.

B. Input Signal Definition and Correlation Analysis

Time Index and Signals. We define the discrete time axis as

$$t = 1,\, 2,\, \ldots,\, T. \tag{1}$$

For each time t, we have M signals $\{\boldsymbol{S}_1, \boldsymbol{S}_2, \ldots, \boldsymbol{S}_M\}$, where

$$\mathbf{S}_i = \{y_{i,1},\, y_{i,2}, \ldots, y_{i,T}\}, \quad i = 1, \ldots, M, \tag{2}$$

and $y_{i,t}$ is the value of the i-th signal at time t.

Let the output signals be denoted as

$$\{\boldsymbol{S}_1, \boldsymbol{S}_2, \ldots, \boldsymbol{S}_M\}, \tag{3}$$

where each $\boldsymbol{S}_i = \{y_{i,1}, y_{i,2}, \ldots, y_{i,T}\}$ represents a sequence of data points over time.

1) Correlation Metric: The Pearson correlation coefficient is used to quantify the linear relationship between two signals $\mathbf{S}_k$ and $\mathbf{S}_l$[21], [22]:

$$r(\mathbf{S}_k, \mathbf{S}_l) = \frac{\sum_{t=1}^{T}(y_{k,t} - \bar{y}_k)(y_{l,t} - \bar{y}_l)}{\sqrt{\sum_{t=1}^{T}(y_{k,t} - \bar{y}_k)^2}\sqrt{\sum_{t=1}^{T}(y_{l,t} - \bar{y}_l)^2}}, \tag{4}$$

where $\bar{y}_k$ and $\bar{y}_l$ are the mean values of $\mathbf{S}_k$ and $\mathbf{S}_l$, respectively.

C. Selection of Highly Correlated Signals

Identifying highly correlated signals is crucial for reducing model complexity while maintaining predictive accuracy.

To identify the most relevant signals, the following selection criterion is applied. Let L be the maximum number of signals we wish to select. We choose:

$$\{\mathbf{S}_1, \mathbf{S}_2, \ldots, \mathbf{S}_L\} = \{\mathbf{S}_k \mid r(\mathbf{S}_k, \mathbf{S}_l) > \text{threshold}, \quad \forall \mathbf{S}_k, \mathbf{S}_l \in \{\mathbf{S}_1, \mathbf{S}_2, \ldots, \mathbf{S}_M\}\}, \tag{5}$$

where,

- $r(\mathbf{S}_k, \mathbf{S}_l)$: Correlation coefficient between signals $\mathbf{S}_k$ and $\mathbf{S}_l$,
- threshold: Minimum correlation value required for a signal to be included. This yields L original signals with the highest inter-correlations,
- $\{\mathbf{S}_k\}$: Subset of signals that meet the correlation criterion.

D. Generation of New Signals

To enrich the input features, new signals are generated by summing adjacent data points in the selected signals [12]. For a signal $\mathbf{S}_i$ of length T (i.e., $\mathbf{S}_i = \{y_{i,1}, y_{i,2}, \ldots, y_{i,T}\}$), and a chosen window size w, the new signal $\mathbf{S}_{i,\text{aug}}^{(w)}$ is computed as:

$$\mathbf{S}_{i,\text{aug}}^{(w)} = \Big\{ \sum_{k=j}^{j+w-1} y_{i,k} \;\Big|\; j = 1, 2, \ldots, T - w + 1 \Big\}. \tag{6}$$

where,

- $y_{i,k}$: The k-th data point of the original signal $\mathbf{S}_i$,
- k: Index of a data point within the summation window, ranging from j to $j + w - 1$,
- j: Starting index of the summation window in $\mathbf{S}_i$,
- w: Window size, i.e., the number of consecutive data points to be summed,
- T: Total length (in data points) of the original signal $\mathbf{S}_i$,
- $\mathbf{S}_{i,\text{aug}}^{(w)}$: The newly generated signal of length $T-w+1$.

For example,

- For $w = 2$ (adjacent two-term sums):

$$\mathbf{S}_{i,\text{aug}}^{(2)} = \{\, y_{i,1} + y_{i,2},\; y_{i,2} + y_{i,3},\; \ldots,\; y_{i,T-1} + y_{i,T} \}. \tag{7}$$

- For $w = 3$ (adjacent three-term sums):

$$\mathbf{S}_{i,\text{aug}}^{(3)} = \Big\{ y_{i,1} + y_{i,2} + y_{i,3}, \quad y_{i,2} + y_{i,3} + y_{i,4}, \quad \ldots, \quad y_{i,T-2} + y_{i,T-1} + y_{i,T} \Big\}. \tag{8}$$

Signal Length Note: Hence, if the original signal $\mathbf{S}_i$ has length T, the generated signal $\mathbf{S}_{i,\text{aug}}^{(w)}$ has length $T - w + 1$. By varying w, we can capture different scales of temporal dependencies, thereby enhancing the feature set for the Multi-Output Gaussian Process (MOGP) model.

E. Visualization of Signals and Generated Signals

Fig. 2 and 3 illustrate the transformation from two original signals, $\mathbf{S}_1$ and $\mathbf{S}_2$, into their augmented versions using window sizes $w \in \{2, 3, 4\}$.

a) Original Signals: Fig. 2 shows two original signals, $\mathbf{S}_1$ and $\mathbf{S}_2$, used as the starting input for the prediction process. The periodic nature and daily patterns of these signals are evident, highlighting their suitability for modeling temporal dependencies.

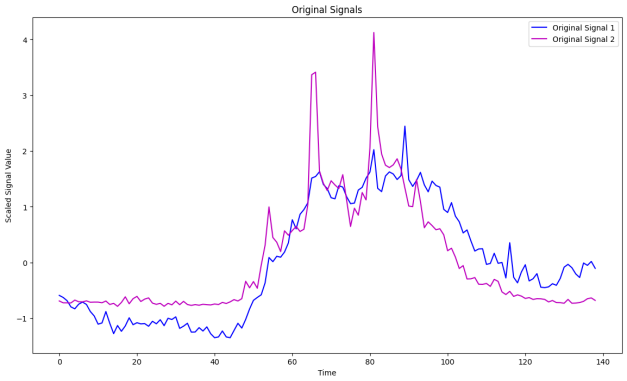

Fig. 2. Original signals ($\mathbf{S}_1$ in blue and $\mathbf{S}_2$ in magenta) with scaled values over time.

b) Augmented Signals via Adjacent Sums: Given a signal $\mathbf{S}_i = \{y_{i,1}, y_{i,2}, \ldots, y_{i,T}\}$, we define its w-term adjacent-sum (augmented signal) as

$$\mathbf{S}_{i,\text{aug}}^{(w)} = \{ \underbrace{y_{i,1} + y_{i,2} + \cdots + y_{i,w}}_{w \text{ terms}}, \underbrace{y_{i,2} + \cdots + y_{i,w+1}}_{w \text{ terms}}, \ldots \}. \tag{9}$$

As w increases, these sums capture progressively larger local trends. Fig. 3 shows newly generated signals (for $w = 2, 3, 4$) from the original $\mathbf{S}_1$ and $\mathbf{S}_2$, demonstrating how the adjacent-sum approach broadens temporal coverage.

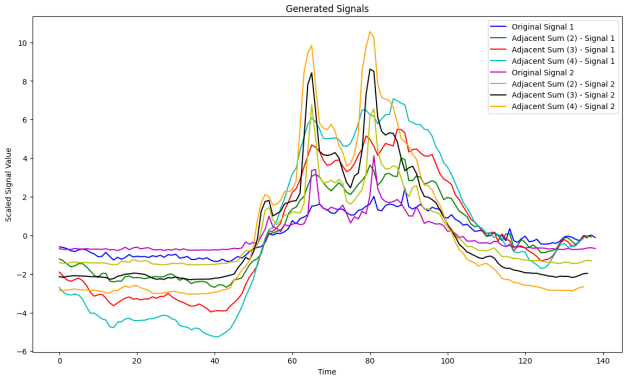

Fig. 3. Newly generated signals from $\mathbf{S}_1$ and $\mathbf{S}_2$, illustrating different window sizes w.

c) Defining MOGP$(L, \tilde{N})$: Suppose we select L original signals based on correlation analysis, and for each original signal, we generate $\tilde{N}$ adjacent-sum signals (e.g. multiple choices of w). We then denote our model by

$$\text{MOGP}(L, \tilde{N}), \tag{10}$$

meaning:

- L is the number of *original* (highly correlated) signals chosen,
- $\tilde{N}$ is the total number of *augmented* signals generated from those L originals,
- Altogether, there are $N = L + \tilde{N}$ channels in the resulting multi-output GP.

For instance,

$$\text{MOGP}(2, 6) \tag{11}$$

indicates two original signals and six augmented signals, making $N = 8$ jointly modeled channels.

d) Example: Generating Up to Eight Channels: If $\mathbf{S}_p$ and $\mathbf{S}_q$ are the selected original signals, then for $w = 2, 3, 4$ each signal spawns three augmented versions:

$$\mathbf{S}_{p,\text{aug}}^{(2)}, \quad \mathbf{S}_{p,\text{aug}}^{(3)}, \quad \mathbf{S}_{p,\text{aug}}^{(4)}, \quad \mathbf{S}_{q,\text{aug}}^{(2)}, \quad \mathbf{S}_{q,\text{aug}}^{(3)}, \quad \mathbf{S}_{q,\text{aug}}^{(4)}. \tag{12}$$

Thus, we obtain up to eight channels in total:

$$\underbrace{\mathbf{S}_p, \mathbf{S}_q}_{\text{original signals}}, \underbrace{\mathbf{S}_{p,\text{aug}}^{(2)}, \mathbf{S}_{q,\text{aug}}^{(2)}}_{\text{2-term}}, \underbrace{\mathbf{S}_{p,\text{aug}}^{(3)}, \mathbf{S}_{q,\text{aug}}^{(3)}}_{\text{3-term}}, \underbrace{\mathbf{S}_{p,\text{aug}}^{(4)}, \mathbf{S}_{q,\text{aug}}^{(4)}}_{\text{4-term}}. \tag{13}$$

Each augmented channel reflects a different local summation scale, thereby enriching the feature set that the Multi-Output Gaussian Process (MOGP) exploits for multi-step prediction. Hence, the MOGP$(L, \tilde{N})$ approach systematically combines correlated original signals with their adjacency-sum signals, allowing finer control over both short- and long-term dependencies.

F. Multi-Output Gaussian Process (MOGP) Prediction Framework

After identifying highly correlated signals and generating augmented signals (Sections III-D–III-E), we obtain N total channels (*original* + *augmented*). These N channels are collectively modeled using a *Multi-Output Gaussian Process* (MOGP), which exploits *both* temporal correlations *and* inter-channel correlations to enhance predictive accuracy.

1) Input/Output Setup and Kernel:

a) Inputs $\mathbf{X}$: We consider T time indices or feature vectors $x_1, x_2, \ldots, x_T \in \mathcal{X}$, collected in $\mathbf{X} = \{x_1, \ldots, x_T\}$. (Each x_t can be a scalar time step or a multi-dimensional feature.)

b) Outputs $\mathbf{Y}$: All original and augmented signals together form $N = L + \tilde{N}$ channels:

$$\mathbf{Y} = \{\mathbf{S}_1, \ldots, \mathbf{S}_L, \mathbf{S}_{1,\text{aug}}^{(w)}, \ldots, \mathbf{S}_{L,\text{aug}}^{(w)}\}. \tag{14}$$

We collect these N channels (each of length T) into a *multi-channel output matrix* $\mathbf{Y} \in R^{N \times T}$. In a block sense, we may write

$$\mathbf{Y} = [\mathbf{S}_1, \mathbf{S}_2, \ldots, \mathbf{S}_N], \tag{15}$$

where each $\mathbf{S}_i \in R^T$. Equivalently, to index individual data values.

c) MOGP Kernel: A Gaussian Process (GP) is defined by a mean function (often taken as zero) and a covariance (kernel) function capturing similarities among inputs. For time-series forecasting, we frequently adopt an RBF+noise kernel [23], [24]:

$$k(x, x') \;=\; \theta_1 \exp\Big(-\frac{\|x - x'\|^2}{2\,\theta_2}\Big) \;+\; \theta_3\,\delta(x, x'), \qquad (16)$$

where $\theta_1, \theta_2, \theta_3$ are hyperparameters, and $\delta(x, x')$ is the Kronecker delta for noise. In a *multi-output* setting, we extend this kernel to model both *within-channel* and *cross-channel* covariances, often via a block-structured approach (e.g. $K_{\text{MOGP}} = B \otimes K_{\text{RBF}}$, where B is an $N \times N$ matrix of inter-channel correlations).

2) MOGP Posterior for Single-Step and Multi-Step Forecasts:

a) MOGP Prior: We place a joint GP prior over all N latent functions $\{f_i(\cdot)\}$ corresponding to the N channels:

$$\begin{bmatrix} f_1(\mathbf{X}) \\ f_2(\mathbf{X}) \\ \vdots \\ f_N(\mathbf{X}) \end{bmatrix} \;\sim\; \mathcal{GP}\Big(\mathbf{0},\, K_{\text{MOGP}}(\mathbf{X}, \mathbf{X})\Big). \qquad (17)$$

Observations $\mathbf{Y}$ are then linked to these $f_i(\mathbf{X})$ values (e.g. via additive Gaussian noise).

b) Single-Step Prediction: To predict the next time point $t + 1$ for each channel i, we collect all available data up to t. Let $\mathbf{X} = \{x_1, \ldots, x_t\}$ and $\mathbf{Y}_{\text{train}}$ be the corresponding outputs. Under the MOGP prior, we form the joint Gaussian $\{\mathbf{Y}_{\text{train}},\, f(x_{t+1})\}$ and condition on $\mathbf{Y}_{\text{train}}$. The resulting posterior mean for channel i is[13]:

$$\hat{y}_i(t+1) \;=\; \mu_i\big(x_{t+1}\big), \quad i = 1, \ldots, L, \qquad (18)$$

where $\mu_i(\cdot)$ is the i-th component of the MOGP posterior.

c) Multi-Step (K-Step) Prediction: To forecast K future points $\{t + 1, \ldots, t + K\}$ for each channel, we consider two main strategies.

Iterative (Recursive) Approach: We repeatedly use predicted values as though they are observed for the next step:

$$\begin{aligned} &\hat{y}_i(t+1) = \mu_i\big(x_{t+1}\big), \\ &\hat{y}_i(t+2) = \mu_i\big(x_{t+2} \mid \hat{y}_i(t+1)\big), \\ &\hat{y}_i(t+3) = \mu_i\big(x_{t+3} \mid \hat{y}_i(t+1),\, \hat{y}_i(t+2)\big), \\ &\quad \ldots, i = 1, \ldots, L, \end{aligned} \qquad (19)$$

This simple approach can accumulate errors but allows easy updates for adjacency-sum channels. Inspired by an Eq. (21)-style logic, we can define partial sums or increments. For instance, if

$$\widetilde{y}_i\big(t + k\big) \;=\; f_{i+1}\big(\mathbf{X}^*\big) \quad \text{for } k = 0, \qquad (20)$$

and

$$\widetilde{y}_i(t + k) \;=\; f_{i+2}(\mathbf{X}^*) \;-\; f_{i+1}(\mathbf{X}^*) \quad \text{for } k = 1, \ldots, K) \qquad (21)$$

then each new adjacency-sum is obtained by subtracting the previously predicted partial sum. Meanwhile, the final predicted channel values are:

$$\hat{y}_i(t + k) \;=\; \mu_i\big(x_{t+k}\big), \qquad (22)$$

ensuring consistency among all signals as they roll forward in time.

Direct Joint Approach: Instead of predicting each future time point separately, we form a single joint Gaussian over $\{x_{t+1}, \ldots, \mathbf{x}_{t+K}\}$ for all N channels[13], [25]:

$$\begin{bmatrix} \mathbf{Y}_{\text{train}} \\ \mathbf{F}_* \end{bmatrix} \;\sim\; \mathcal{N}\Big(\mathbf{0},\, \begin{bmatrix} K_{\text{MOGP}}(\mathbf{X}, \mathbf{X}) & K_{\text{MOGP}}(\mathbf{X}, \mathbf{X}_*) \\ K_{\text{MOGP}}(\mathbf{X}_*, \mathbf{X}) & K_{\text{MOGP}}(\mathbf{X}_*, \mathbf{X}_*) \end{bmatrix}\Big). \qquad (23)$$

where $\mathbf{X}_* = \{x_{t+1}, \ldots, x_{t+K}\}$ and $\mathbf{F}_* \in R^{N \times K}$ denotes the unknown function values $\{f_i(x_{t+k})\}$. Conditioning on $\mathbf{Y}_{\text{train}}$ produces a posterior with mean $\hat{\mathbf{F}}_*$. Its (i, m)-th entry gives $\hat{y}_i(t + m)$. This one-shot method often yields better long-horizon accuracy but incurs higher computational cost due to the larger covariance block.

Overall, both approaches yield $\{\hat{y}_i(t + k) \mid i = 1, \ldots, N;\, k = 1, \ldots, K\}$. The iterative method is simpler yet can accumulate errors; the direct method jointly captures cross-step correlations but is more expensive. In practice, adjacency-sum signals can still be integrated into either approach by updating or subtracting previously predicted sums as new time steps unfold.

3) Recap and Advantages: By modeling all channels (original + augmented) within a unified MOGP, we exploit *inter-channel* correlations and *different temporal scales* simultaneously. This often reduces uncertainty in multi-step forecasting, compared to treating each channel as an independent single-output GP. Hence, our MOGP framework is well-suited to network traffic scenarios, where multiple correlated signals (e.g. raw measurements and adjacent-sum signals) provide complementary information for bandwidth prediction.

G. MOGP-Based Framework for Multi-Step Traffic Prediction

Fig. 4 presents a schematic of our Multi-Output Gaussian Process (MOGP) framework for multi-step bandwidth prediction. Building on the earlier steps of selecting highly correlated signals and generating adjacency-sum augmentations, this framework highlights three major components:

- Adjacency-Sum Channels (green blocks). From each original signal S_i (or S_j), we construct multiple augmented signals $S^{(w)}_{i,\text{aug}}$ by summing adjacent data points with different window sizes w. These channels capture various temporal scales (e.g. short-term bursts for $w = 2$ or medium-range trends for $w = 3, 4, \ldots$).
- Block-Structured MOGP Inference (blue boxes). All channels (original + augmented) are modeled jointly using a multi-output Gaussian Process. The block-structured kernel encodes both temporal dependencies (within each channel) and cross-channel correlations (across original and augmented signals). From this MOGP, we obtain a predictive mean $\mu(\mathbf{X}^*)$ and covariance $\Sigma(\mathbf{X}^*)$ for the forecast horizon K.

- Partial-Sum or Difference-Based Recovery (bottom). In multi-step prediction, each adjacency-sum channel (e.g. $S^{(2)}_{i,\text{aug}}$) can be used to recover the single-step prediction $\hat{y}_i(t+k)$ by subtracting already-predicted values. For instance,

$$\begin{aligned} \hat{y}_i(t+2) &= \hat{S}^{(2)}_{i,\text{aug}}(t+1) - \hat{y}_i(t+1), \\ \hat{y}_i(t+3) &= \hat{S}^{(3)}_{i,\text{aug}}(t+2) - \hat{S}^{(2)}_{i,\text{aug}}(t+2), \\ &\dots \end{aligned} \tag{24}$$

thus ensuring consistency among predicted sums and the underlying pointwise forecasts.

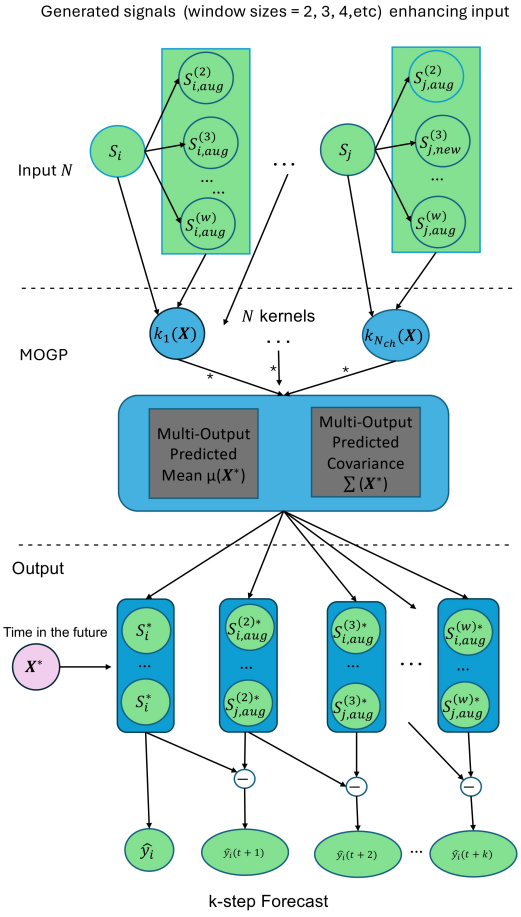

Fig. 4. The MOGP-based framework for multi-step forecasting. After generating adjacency-sum augmentations (green), a multi-output Gaussian Process (blue) provides joint predictions, which are then combined or subtracted to yield final outputs $\hat{y}_i(t+k)$.

a) Multi-Step Prediction: As discussed above, once the MOGP posterior is obtained, there are two main ways to forecast K time steps ahead:

- Iterative Approach: predict $\hat{y}_i(t+1)$, feed it back into the adjacency-sum channels, then predict $\hat{y}_i(t+2)$, and so forth. $\hat{y}_i(t+3)$ can be predicted in a similar manner until $\hat{y}_i(t+k)$.
- Direct (Block) Approach: form a single joint Gaussian over $\{\mathbf{x}_{t+1}, \dots, \mathbf{x}_{t+K}\}$ and solve for all $\hat{y}_i(t+k)$ in one shot, often achieving better accuracy (at a higher computational cost).

b) Advantages at Different Scales: By integrating adjacency-sum channels with an MOGP, the framework:

- *Captures multiple timescales* via small vs. larger summation windows,
- *Leverages cross-channel correlations*, reducing prediction uncertainty,
- *Yields robust multi-step forecasts*, as each newly predicted value can be consistently used to update the adjacency sums in subsequent steps.

In essence, this joint modeling of raw and augmented signals enables more accurate and stable bandwidth predictions across various forecasting horizons.

IV. Introduction to Experimental Model

This section provides background on the WIDE Project, describes the MAWI dataset used for our experiments, and presents an overview of traffic patterns and inter-signal correlations. The goal is to illustrate the data sources and motivations that underpin the MOGP-based forecasting framework described in Section III.

A. WIDE Project

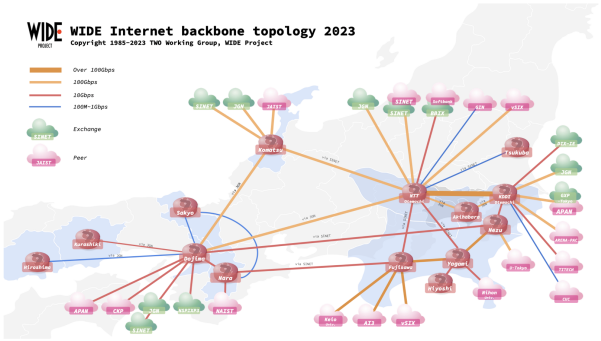

Fig. 5. 2023 WIDE backbone topology.

The Widely Integrated Distributed Environment (WIDE Project[1]) is a Japanese initiative focused on advancing Internet infrastructure. It involves a broad consortium of academic and research institutions that collaborate on designing, standardizing, and operating critical Internet technologies. Over the past decades, the WIDE Project has significantly contributed to IPv6 deployment, mobile Internet, and security innovations, and it continues to foster global partnerships among engineers and researchers.

As of 2023, the WIDE backbone (Fig. 5) consists of a Layer 2 and Layer 3 network interconnecting various Japanese and international sites, including San Francisco and Bangkok. This infrastructure provides a rich environment for collecting and analyzing real-world network traffic, which is crucial for exploring predictive modeling techniques such as Gaussian Process (GP) forecasting.

[1]WIDE Project: http://www.wide.ad.jp/.

1) MAWI Dataset Overview: The MAWI[2] (Measurement and Analysis on the WIDE Internet) group, a key part of the WIDE Project, collects and publicly shares traffic data from global ISP links. In particular, this study uses MAWI's traffic records from 2024/5/17, sampled at 10-minute intervals. As illustrated in Fig. 6, the dataset contains seven major aggregated flow signals and one time-stamp column, totaling eight columns in all. Each row represents a 10-minute observation, leading to 144 potential data points daily, though our final curated dataset has 143 valid entries after cleaning.

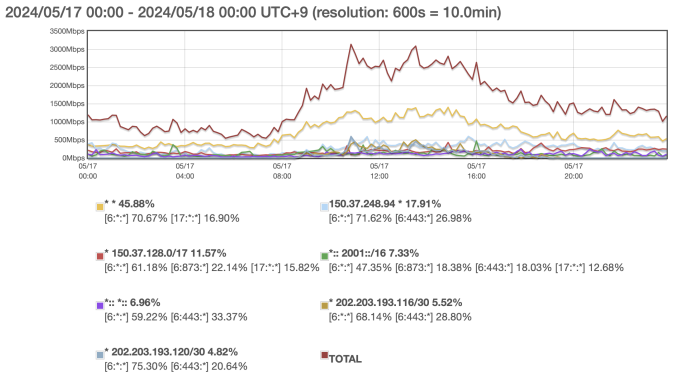

Fig. 6. Traffic data from 2024/5/17, courtesy of the MAWI dataset.

a) Data Preprocessing: We remove rows with missing values and normalize each signal to zero mean and unit variance. The time column is re-indexed to facilitate chronological analysis (e.g. minute-based or 10-minute-based indexing). This ensures that all signals are on a comparable scale before feeding them into the Multi-Output Gaussian Process (MOGP) model.

2) Traffic Pattern Analysis: A preliminary inspection of the MAWI traffic from 2024/5/17 reveals distinct diurnal patterns. Communication volumes begin to rise around 8 AM, peak during midday, and gradually decline overnight. Fig. 6 (from Section III)demonstrates these daily fluctuations. Such periodic behaviors indicate temporal correlations within each signal.

Furthermore, external factors like time zone synchronization across regions can induce correlated traffic surges among different signals. Leveraging these temporal and inter-signal dependencies is central to improving forecast accuracy in network traffic models.

3) Correlation Analysis: To quantify inter-signal relationships, we perform pairwise correlation among the seven flow signals. The resulting correlation matrix (Fig. 7) highlights various strengths of linear association. Signals that exhibit high pairwise correlation are prioritized for the MOGP input, as multi-output GP can exploit these cross-channel correlations more effectively.

The Pearson correlation coefficient, as defined in Eq. (4), is used to measure the strength of the linear relationship between two signals.

[2]MAWI Working Group Traffic Archive: https://mawi.wide.ad.jp/mawi/.

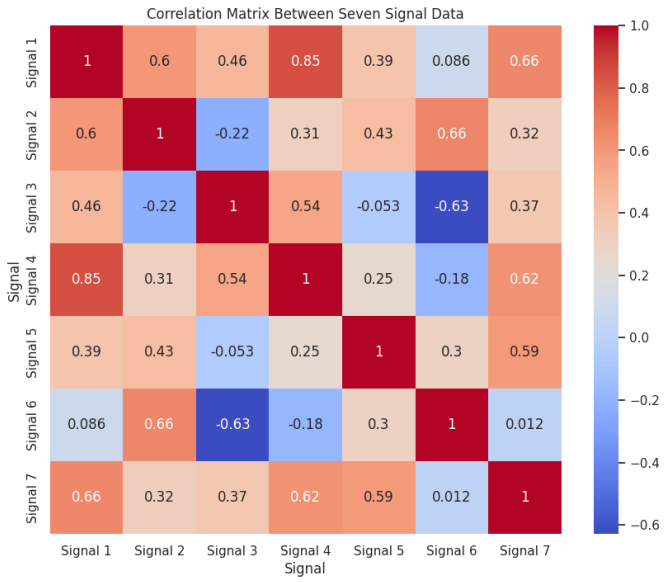

Fig. 7. Correlation matrix between seven MAWI signals, illustrating strong pairs for model input.

B. Data Setting and GP Models

Having introduced the WIDE Project and the MAWI dataset, we now discuss the GP model setup for our experiments. The experimental conditions are as follows:

- Training/Testing Split: We utilize the first T_{train} points (e.g. day 1's data) to train the GP model and reserve the subsequent points (e.g. final few observations) for testing.
- Window Size (Sliding Window): A fixed window size window_size is chosen (e.g. 50). In each step, the model sees $\mathbf{X}_{\text{train}}$ (time indices or features) and $\mathbf{y}_{\text{train}}$ (normalized signal values), then predicts the next point. The window slides forward by one time step iteratively.
- Multiple Channels (N=1,2,8): We compare three main GP setups:
  1) Single-Output GP ($N = 1$): Only one original signal (e.g. `signal1`) is modeled. This captures broad temporal trends but does not exploit cross-signal information.
  2) MOGP(2,0): We pick two highly correlated signals (e.g. $\mathbf{S}_p$ and $\mathbf{S}_q$), as identified by Pearson correlation. Then both signals are jointly modeled in a MOGP setting. This allows cross-channel correlation to inform the prediction, often improving accuracy compared to single-output.
  3) MOGP(2,6): We take two original signals $(\mathbf{S}_p, \mathbf{S}_q)$ plus their six adjacent-sum signals with window sizes $w = 2, 3, 4$. Hence, $N = 2 + 2 \times 3 = 8$ total input channels. By providing multi-scale features (short-term sums, medium-term sums, etc.), the MOGP(2,6) model can capture both short-range fluctua-

tions and daily-scale patterns across the correlated signals.

- Single-Step vs. Multi-Step Forecast:
  - Single-Step (1-step): Predict y_{t+1} given data up to time t as described in Eq. (18).
  - Multi-Step (K-step): Predict $\{y_{t+1}, \ldots, y_{t+K}\}$ either iteratively using Eq. (19) or via a direct block-covariance approach.

a) Summary of Experimental Model: Overall, the data feeding process, combined with the MOGP approach, is illustrated in Fig. 1. We use real traffic from the WIDE Project's MAWI dataset, apply standard preprocessing, select correlated signals, generate additional adjacent-sum signals if needed, and then run sliding-window GP predictions. We will perform performance metrics (RMSE) for single output versus multioutput comparisons, demonstrating how correlation exploitation and multi-scale features can enhance forecast accuracy.

1) Single-output Gaussian Process: In this scenario, only one signal is used as input for the prediction. The model captures the overall trends but struggles to predict sharp fluctuations due to the limited input information. Fig. 8 demonstrates the predicted results along with confidence intervals, showcasing the performance of the single-output GPR model for future-step prediction.

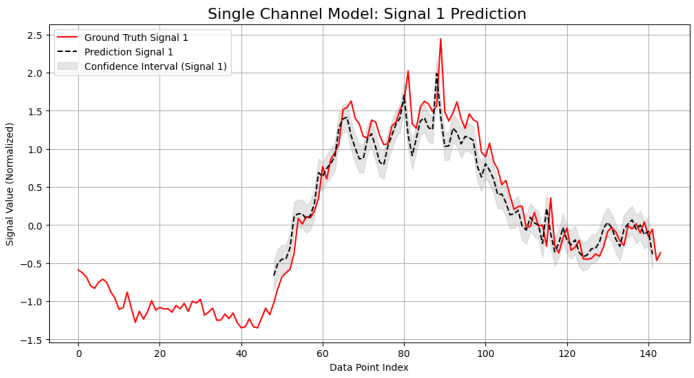

Fig. 8. Gaussian process prediction of signal trends with confidence intervals.

2) MOGP(2,0): Single-Step Prediction: In this setup, two highly correlated signals are used as inputs to the Multi-Output Gaussian Process (MOGP) model (here, MOGP(2,0) indicates two original signals and zero augmentations). This approach leverages inter-channel correlations to enhance the accuracy of predictions. Unlike the single-output model, the MOGP(2,0) model demonstrates improved robustness in capturing signal variations. Fig. 9 illustrates the predictive performance of the MOGP(2,0) model when considering two input signals, highlighting the advantage of incorporating multiple correlated channels.

3) MOGP(2,6): Single-Step Prediction: This model extends the input set by incorporating two original signals and their corresponding generated signals at varying temporal scales ($w = 2, 3, 4$), resulting in a total of eight input signals (2 original + 6 augmented). The inclusion of generated signals captures both short-term fluctuations and long-term patterns, significantly improving the accuracy of prediction. Fig. 10

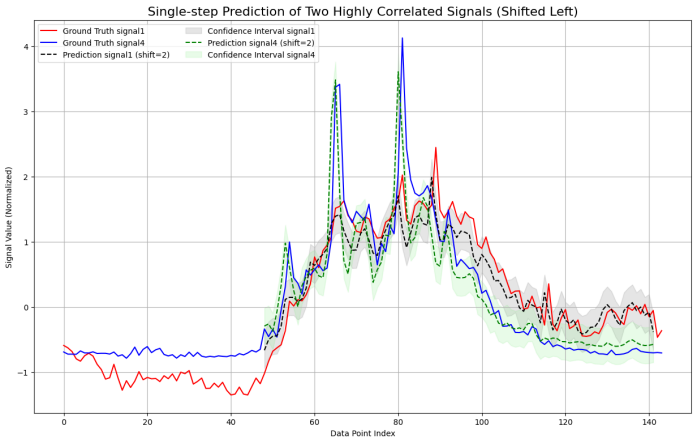

Fig. 9. Prediction results using the MOGP(2,0) model for single-step forecasting.

shows the results of the MOGP(2,6) model, demonstrating its superior predictive capacity compared to the single output and MOGP (2,0) models.

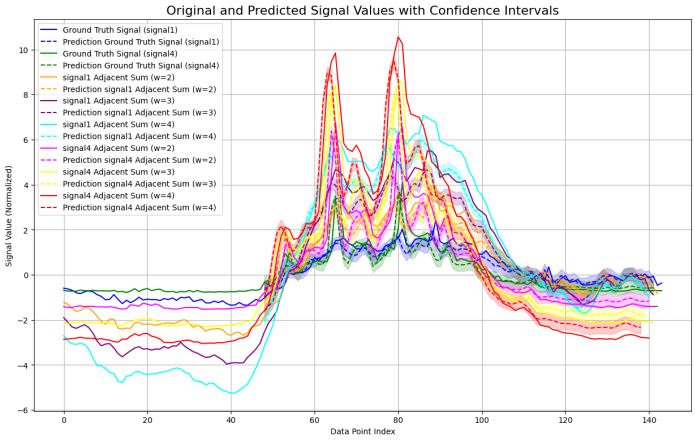

Fig. 10. Enhanced prediction accuracy using the MOGP(2,6) model for single-step forecasting.

4) MOGP(2,0): Multi-Step Prediction: In this experiment, the MOGP(2,0) model is extended to predict three future steps. This approach demonstrates the capability of the model to handle sequential forecasting tasks, utilizing inter-channel correlations effectively. Fig. 11 illustrates the predictive performance of the MOGP(2,0) model for three-step predictions.

5) MOGP(2,6): Multi-Step Prediction: The MOGP (2,6) model is used to predict three future steps, further leveraging the generated signals across varying temporal scales ($w = 2, 3, 4$). By incorporating more input signals, the model captures intricate temporal dependencies, enhancing prediction accuracy. Fig. 12 shows the prediction results for the MOGP(2,6) model.

V. Simulation Results and Discussion

A. Comparison and Summary of Experimental Results

The performance of the proposed models was evaluated using the Root Mean Squared Error (RMSE) metric, defined

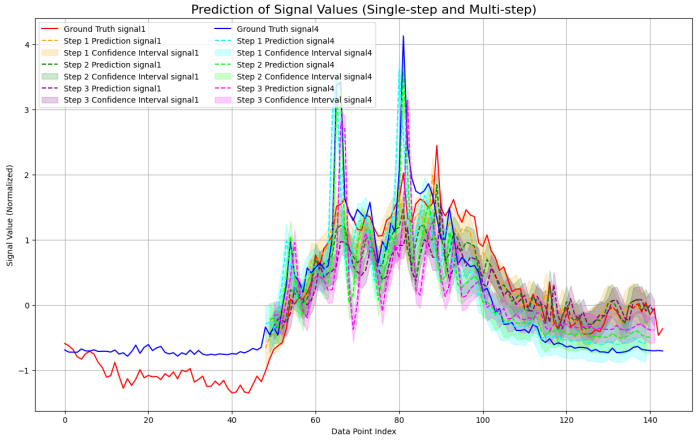

Fig. 11. Prediction results using the MOGP(2,0) model for three-step forecasting.

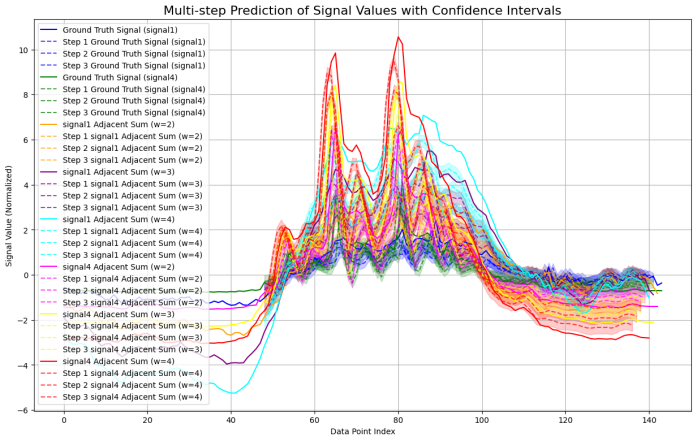

Fig. 12. Enhanced prediction accuracy using the MOGP(2,6) model for three-step forecasting.

as [26]:

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum(\hat{y} - y_{\text{test}})^2}$$

where $\hat{y}$ represents the predicted values for the unknown input signal x_{test}, and y_{test} denotes the corresponding ground truth values.

Table I compares the RMSE of single-output, MOGP(2,0), and MOGP(2,6) models for predicting network traffic signals.

TABLE I. RMSE Comparison of Gaussian Process Models

Model	RMSE
Single-output Gaussian Process (1-step)	0.1967
MOGP(2,0) (1-step)	0.1552
MOGP(2,6) (1-step)	0.1273
MOGP(2,0) (3-step)	0.1943
MOGP(2,6) (3-step)	0.1607

The results in Table I demonstrate the effectiveness of the MOGP models in leveraging inter-channel correlations for prediction accuracy. The MOGP(2,6) model significantly outperforms the others, achieving the lowest RMSE value. This improvement highlights the importance of integrating generated signals with varying time scales into the prediction framework.

1) Error Analysis: Table II presents the percentage reduction in prediction error achieved by the multi-output models compared to the single-output Gaussian Process model. The error reduction underscores the effectiveness of multi-channel approaches in improving predictive performance.

TABLE II. Percentage Error Reduction by Multi-Output Models

Comparison	Error Reduction (%)
Single-output vs. MOGP(2,0) (1-step)	21.2%
Single-output vs. MOGP(2,6) (1-step)	35.3%
MOGP(2,0) (1-step) vs. MOGP(2,6) (1-step)	17.9%
MOGP(2,0) (3-step) vs. MOGP(2,6) (3-step)	17.3%

The error analysis results indicate that the multi-output models significantly reduce RMSE compared to the single-output model. MOGP(2,6), in particular, achieves substantial error reduction, confirming the advantages of utilizing generated signals to capture both short-term and long-term signal variations.

B. Comparison with Recent Methods

A closely related study by Wang *et al.* [13] has already demonstrated that Gaussian process (GP)–based forecasting can outperform statistical approaches like ARIMA as well as deep learning models such as LSTM, RC-LSTM, and RNN. In particular, their method leverages a multi-output GP framework and multi-scale adjacency-sum augmentation for multi-slot-ahead traffic prediction.

Our proposed approach builds upon and extends the work in [13] by introducing **multi-channel** input signals. Rather than relying on a single channel with adjacency-sum signals, we first select multiple original signals based on their correlations, then generate adjacency-sum augmentations for each. This strategy further exploits cross-channel relationships, allowing the model to capture subtle variations across different but related traffic flows. By doing so, we retain the core strengths of multi-output GP and adjacency-sum augmentation from [13], while enhancing predictive performance through an expanded, correlation-aware input space. Our experimental results confirm that this multi-channel extension yields higher accuracy than single-channel baselines, illustrating the practical benefits of incorporating inter-channel correlations into GP-based network traffic forecasting.

Although direct numerical comparisons are hindered by different datasets and experimental conditions, we attribute our method's strong performance to two main factors:

- *Multi-Output Modeling:* By capturing inter-channel correlations, MOGP leverages shared temporal dynamics across multiple signals—an advantage that traditional single-output methods lack.
- *Multi-Scale Adjacency-Sum Augmentation:* Generating additional signals by summing adjacent data points over varying window sizes enriches the feature space, enabling the model to capture both short-term bursts and longer-range trends more effectively.

Overall, these comparisons underscore the benefits of integrating multi-channel Gaussian Processes with adjacency-sum augmentation, offering robust predictive accuracy and principled uncertainty estimates for complex network traffic scenarios.

C. Assumptions and Limitations

This study makes primary assumptions: The selected subset of MAWI channels is sufficiently representative of typical network traffic. Although these assumptions are practical for many real-world scenarios, they may limit generalization to networks with irregular sampling patterns or strong non-stationary bursts.

Another limitation lies in the computational overhead of handling large-scale datasets. Because our approach generates multiple augmented signals for each original channel, the dimensionality grows along with the dataset size, increasing both memory usage and training time for multi-output Gaussian Processes. In future work, we plan to investigate sparsity-inducing kernels and online GP methods to better accommodate high-volume streaming data.

VI. Conclusions and Future Work

In this study, we proposed a Multi-Output Gaussian Process (MOGP) model for network traffic prediction, introducing a novel approach that integrates original input signals with additional correlated signals generated using adjacent terms. This methodology leverages inter-channel correlations and multi-scale temporal dependencies to improve prediction performance. Experimental results validated through RMSE metrics demonstrated that the MOGP model consistently outperforms single-output Gaussian Processes, showcasing robust performance across both one-step and three-step prediction tasks. The MOGP(2,6) model achieved the best overall results, reducing prediction errors by 35.3% compared to the single-output baseline. These findings confirm that incorporating correlated signals significantly enhances prediction accuracy. Furthermore, the model demonstrated consistent effectiveness in single- and multi-step forecasting scenarios, highlighting its adaptability to various temporal scales and complex datasets.

Future work will focus on exploring alternative kernel functions and hyperparameter optimization strategies to further improve prediction precision and computational efficiency. We also intend to extend our framework to 5G and IoT traffic prediction, and to real-time or large-scale environments, evaluating the model's scalability and adaptability under streaming conditions. Another promising direction is to adapt our MOGP approach for anomaly detection. Such anomalies not only consume additional network resources but also pose significant risks to overall network performance and security [27]. By exploiting the pervasive inter-channel correlations, our framework could identify deviations from typical diurnal or weekly patterns. For example, if two channels $\mathbf{S}_k$ and $\mathbf{S}_l$ with similar usage trends both show high traffic after 8 AM and taper off after 7 PM, a sudden increase in $\mathbf{S}_k$ without a corresponding change in $\mathbf{S}_l$ might signal anomalous behavior. This line of research could play a vital role in proactive network management and early threat detection.

Automated Subjective Perception of a Driver's Pain Level Based on Their Facial Expression

***Abstract*—One factor that has a positive correlation with the risk of traffic accidents is the pain experienced by drivers. This pain is sometimes expressed facially by the driver and can be subjectively perceived by others. By observing the facial expression of drivers, it can estimate the pain experienced at that point in time and intervene to prevent some accidents. A method to automatically estimate the pain level expressed by a driver using their facial expression will be proposed in this study. The model is trained by a convolution neural network based on a public dataset of facial expressions at various pain levels. This model is then used to automatically classify the pain level perceived using only the facial expressions of drivers. The result of the automated classification is then compared to ratings of subjective feelings of the driver's pain evaluated by a medical doctor. The experiment results showed that the model classified the pain level expressed facially by the drivers matched that of the classification by the medical doctor at a rate of 80%.**

***Keywords*—Pain; driver; convolution neural network; facial expression**

I. Introduction

Neck and back pain are part of chronic pain that can cause discomfort, be annoying, and interfere with a person's ability to concentrate. If a person is driving and experiencing pain, it can cause collisions [1]. In fact, pain in drivers is one of the main contributing factors to traffic accidents [2]. Furthermore, pain impairs a person's ability for quick thinking when operating a vehicle [3]. Certain medications can also impair cognitive performance and cause pain [4]. Driving over extended periods of time increases the chance of pain, and psychological elements linked to pain, such as stress and anxiety, can also influence driver behaviors and raise the risk of accidents in addition to physical discomfort [5].

The definition of pain, according to the International Association for the Study of Pain (IASP), is an unpleasant sensory and emotional experience associated with, or resembling that associated with, actual or potential tissue damage[6]. Pain is generally classified into two main types: acute pain dan chronic pain. Acute pain typically triggered by injury or disease, while chronic pain persists beyond the usual healing period and may not have a clear underlying cause[7]. In addition, the relationship between chronic pain and psychological disorders is complex and often bidirectional. For example, individuals with chronic neck pain are at higher risk for mood and anxiety disorders. This suggests that chronic pain may lead to psychological distress, which in turn may worsen pain perception[8].

Assessment of pain is a crucial component of pain management since it enables the determination of the intensity and consequences of pain on the patient's quality of life. Multiple instruments, including the Visual Analogue Scale (VAS) and the Numeric Rating Scale (NRS), are frequently employed to quantify pain intensity by relying on self-reported information provided by patients [9]. VAS was popularized by Aitken and Zealley in the late 1960s, who focused its function on psychological assessment [10]. They showed that VAS could effectively measure subjective feelings, which laid the foundation for its subsequent application in clinical pain measurement. In its development, VAS continued to be validated through several follow-up studies [11]. Moreover, the VAS has been used into more extensive research projects, including those involving cancer patients [12], emergency rooms [13], and measuring pain levels in fibromyalgia patients correlating pain intensity with functional disability and psychological symptoms [14].

The VAS measurement method is generally using a straight line, usually 10 cm long, with the starting point representing "no pain" and the end point indicating "maximum imaginable pain"[15]. One of the main limitations of VAS is that it is highly dependent on subjective assessment of the patient. Each individual may interpret the scale differently. This can be influenced by various psychological factors, such as anxiety and mood when the assessment is carried out. The results will be inconsistent and therefore do not reflect the actual pain[16]. Another critical limitation is that it may not provide adequate accuracy especially over a narrow scale range resulting in reduced sensitivity to detect small changes in pain levels[17].

Several studies on facial expression-based face detection have been developed. One of the leading methods is the Facial Action Coding System (FACS), which categorizes facial movements into certain Action Units (AU). This method has been used to distinguish between real and fake pain expressions in children undergoing dental treatment[18]. However, the reliability of FACS in assessing pain in various populations is still a concern, especially since this technique requires trained personnel to code facial expressions accurately [19]. The combination of facial electromyography (EMG) with electroencephalography (EEG) has also been used to explore the relationship between brain activity and facial expressions when experiencing pain. Although the results of the study showed a correlation between facial muscle movements and brain electrical activity during pain stimuli, this system is considered more complex and variability in the result[20]. In addition, the

role of observers is often distorted in interpreting facial expressions due to the influence of previous exposure to pain assessment[21]. This suggests that the context in which facial expressions are viewed can significantly affect pain recognition, indicating the need for standardized training for health care providers to reduce bias.

Since the use of Visual Analog Scale for pain assessment that has been widely used in various studies still has limitations, the use of image processing techniques and the application of machine learning in classifying features is expected to provide better results. Standardization by experts can also avoid subjectivity of assessment so that it can be applied in a wider field, including pain detection in drivers to reduce traffic accidents.

This study aims to automatically estimate the pain level expressed through a driver's facial expression. This may be a viable non-invasive approach to detecting whether a driver is experiencing pain. Additionally, a model capable of detecting a wider range of pain levels would be more beneficial than one that merely differentiates between two conditions.

II. METHODOLOGY

This research is divided into two main stages. The first stage is a classification model trained using a public dataset of facial expressions shown at different levels of pain. For the second stage, the model is used to estimate the level of pain expressed facially by the driver. Figure 1 illustrates the stages of this research process.

A. You Only Look Once (YOLO) for Pain Classification

The You Only Look Once (YOLO) is a popular detection algorithm developed by Redmon J, in 2012[22]. The YOLO algorithm process is to divide the facial image into S x S meshes. Each grid is responsible for predicting the target where the actual box will fall in the center of the grid. The total bounding box is generated from the meshes. Each bounding box contains five parameters: Target center point coordinates, target width and height dimensions (x, y, w, h), and confidence. The S x S edge predicts the category probability of the target on that edge. The prediction bounding box confidence and category probability are then multiplied to obtain the category score for each prediction box[23].

In this study, we use YOLOv5 which offers important benefits in speed and computational efficiency[24], [25] lightweight architecture[26], and capability to effectively handle dynamic and diverse facial expressions [27]. Therefore, it is very appropriate for application in real-time scenarios as it enables rapid detection of driver pain, thereby preventing traffic accidents.

YOLOv5 uses a single-stage detection methodology, where the image is processed in a single iteration across the entire network with a convolutional neural network (CNN) approach that simultaneously predicts bounding boxes and class probabilities [28]. It consists of backbone, neck, and head segment components. The main function of the backbone is to extract features, which are then aggregated by the neck to provide predictions at multiple scales. Meanwhile, the head produces the final detection findings [29].

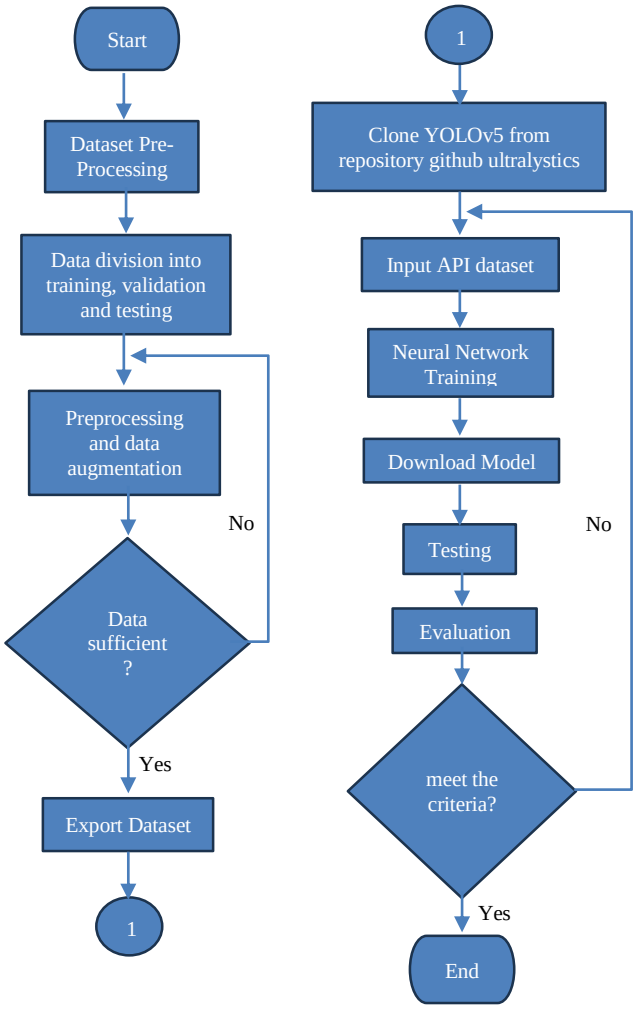

Fig. 1. Research workflow.

A significant improvement in YOLOv5 is the incorporation of anchor boxes, which are pre-defined bounding box shapes that improve the model's ability to reliably estimate object positions. This methodology uses a combination of methods, including data augmentation, to improve the robustness of the model by artificially increasing the size of the training dataset [30].

B. Datasets Pre-Processing

The dataset used in this study is from the Multimodal Intensity Pain (MIntPAIN) database[1] with 3079 images divided into 11 classes (0 - 10). Each class will be divided into three classifications based on its class range, namely mild, moderate, and severe. Fig. 2 shows an example dataset [31] with its VAS values. The image is intentionally blurred due to agreements with the dataset provider and privacy reason. The data pre-processing stage is conducted by annotating the area or pixels in the image as a region or area in the bounding box that will be used for model calculations as training or validation. In the YOLO method, annotation is carried out starting by drawing a

[1] (http://www.vap.aau.dk/mintpaon-database

bounding box on each object in the image which then stores the description of the bounding box or object class in a text file database containing the class, x coordinates, y coordinates, width, and height respectively. Data in each VAS value class is divided into 70% for training, 20% for validation, and 10% for testing. The next stage is to carry out the auto orient and resize process. Auto orient aims to adjust the position of the object in the image to ensure that the main object in the image is in the right position. While the resize, the process is to change the image size to the same, 640 x 640 pixels. The purpose of this stage is to equalize the image size because the data obtained can have variations in orientation, both in portrait and landscape formats. By resizing the images, it can ensure that all images have uniform dimensions for data processing and its use in model training.

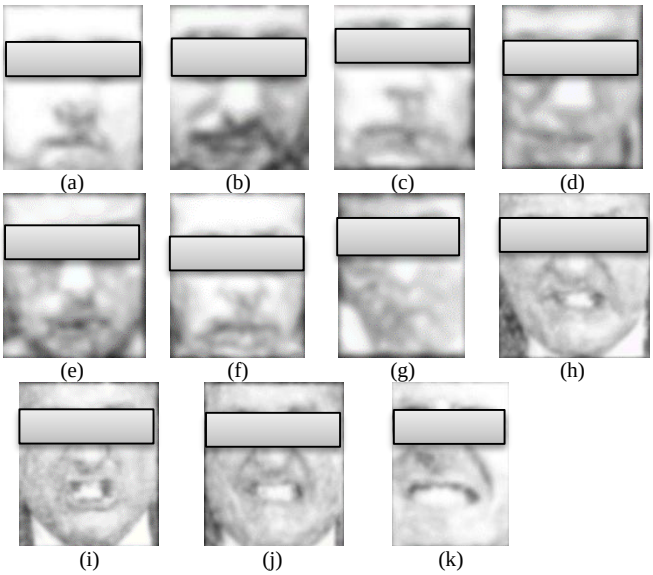

Fig. 2. VAS value dataset sample (a) 0, (b) 1, (c) 2, (d) 3, (e) 4, (f) 5, (g) 6, (h) 7, (i) 8, (j) 9 (k)10.

C. Model Training

The model-building stage is carried out on Google Colab. The first step in this process is training the YOLOv5 model available in the ultralytics github repository. The previously prepared dataset is cloned and entered using the roboflow API with the Model training configuration shown in Table I.

TABLE I. MODEL TRAINNING CONFIGURATION

Image Size	640x640 pixels
Parameters	Batch Size = 16
	Epoch = 300
Hyperparameter	default
IoU	0.5 and 0.75

The 0.5 threshold is often used as a baseline to evaluate model performance, while the 0.75 threshold is utilized for more stringent evaluation [32]. The model is not only accurate but also robust across a wide range of datasets and conditions [33]and models evaluated at the 0.5 IoU threshold performed significantly differently compared to models evaluated at lower thresholds[34].

D. Model Evaluation

The evaluations conducted in this study include precision, recall, mean Average Precision (mAP), and Intersection over Union (IoU). This process is carried out to assess the effectiveness of the object identification algorithm.

Precision measures the ratio of true positives (TP) correctly identified from all positive predictions, while recall evaluates the ratio of positive examples correctly identified from all object examples. These metrics are very important for assessing the precision of the model in object identification while avoiding excessive false positives[35]. F1-score is a metric that considers the trade-off between precision and recall, offering a single number that represents the overall performance of the model[36]. The mathematical representation for recall, precision, and F1-score are given in Eq.(1), Eq.(2), and Eq.(3).

$$Recall = \frac{TP}{TP+FN} = \frac{TP}{All\ Ground\ Truth} \quad (1)$$

$$Precision = \frac{TP}{TP+FP} = \frac{TP}{All\ Prediction} \quad (2)$$

$$F1 - Score = \frac{2 \times (Recall+Precision}{(Recall+Precision)} \quad (3)$$

Mean Average Precision (mAP) is an important quantification in the evaluation of YOLOv5. This value is calculated by taking the average of the precision scores at various levels of recall. This value is often calculated at a certain IoU threshold, such as mAP@0.5, to assess the model's capacity to predict object locations accurately. Studies have shown that YOLOv5 can achieve high mean precision (mAP) scores, thus validating its efficacy in various detection tasks. [37], [38]. The formula for mAP is given in Eq.(4).

$$\text{mAP} = \frac{1}{n}\sum_{i=1}^{n} APi \quad (4)$$

where,

n: Number of data AP

AP: Average Precision

If the evaluated model does not meet the desired value, which is above 0.8, then the model is re-created by adding a new image dataset to improve the parameter values to match the desired so that the model is considered suitable for use.

To evaluate the overlap between predicted bounding boxes and ground truth boxes, the intersection over Union (IoU) metric is a key measure. A higher intersection over Union (IoU) coefficient indicates superior accuracy in localization. If the IoU value is greater than the threshold value of 0.5 (the value assumed to increase the accuracy of detected objects), then the results are acceptable[39] [40]. IoU can be calculated using the formula, as shown in Eq.(5).

$$IoU = \frac{Intersection\ Area}{Union\ Area} \quad (5)$$

E. Automatically Estimating Pain Level of Drivers from Their Facial Expression

We involved 15 males online taxi drivers who had been driving for 5 to 6 hours as research subject. During driving, many VAS values will be read according to the participant's facial expression because the driver has previously driven for 5-

6 hours. Therefore, for the limit, the VAS value chosen is the highest VAS value with an observation period of no more than 2 hours.

For the research environment setting, the camera is mounted in front of the driver, which is focused on the driver's head and is arranged in such a way that it does not obstruct the driver's view as shown in Fig. 3. The data taken from the camera is video which is then converted into image and then processed to detect VAS value.

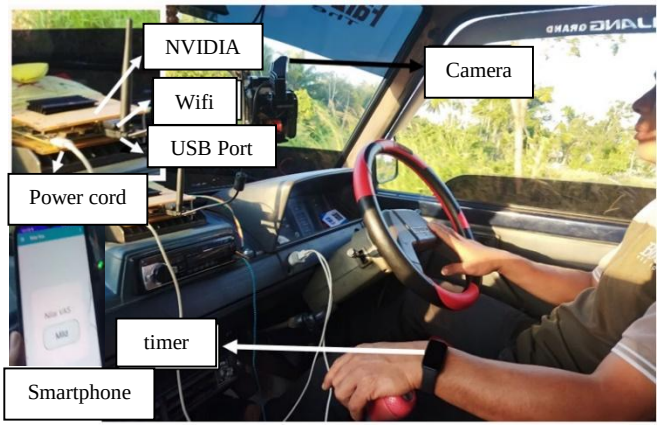

Fig. 3. A view of the experimental scenario.

III. Result and Discussion

A. YOLOv5 Model Training Result

In YOLO model training with 300 epochs and a batch size of 16, the results are shown in the confusion matrix as shown in Fig. 4. In addition, the recall, precision, F1-score, and mAP values are also calculated to measure the performance of the model. The all-normalization technique is applied in this study by dividing each element in the confusion matrix by the total number of instances in the data set. This procedure transforms each cell into a representation of the overall proportion of the data set rather than simply showing the absolute number. This is relevant to this study, where the classes correspond to different levels of pain (ranging from 0 to 10), all normalization can give an overall understanding of how well the model performs across all levels.

Based on the confusion matrix results, the prediction scores obtained can provide an understanding of the extent to which the YOLO model is able to classify each class with accuracy. The value class 8 gets the highest prediction score of 0.96. This shows that the model is very good at identifying and predicting objects included in these classes. The high prediction score in class 8 can be caused by several factors, such as clear and consistent representation in the training data, sufficient variation in the objects representing this class, and optimal hyperparameter selection. Meanwhile, the three classes of VAS values with values 2, 3, and 4 have almost the same and relatively low confusion matrix values of 0.40; 0.63; and 0.42 respectively. This is influenced by several factors, including the expression for these values has almost the same expression because pain with VAS values 0 to 4 has not changed much of the expression. Therefore, if the Interval between the classes is relatively small, difficulty in distinguishing between the classes can occur. In addition, the subjectivity of the interpretation of VAS values by individuals can cause similar perceptions of different levels and the limitations of the samples used in data collection also affect this. As for the result, the value of the train data is as shown in Fig. 5.

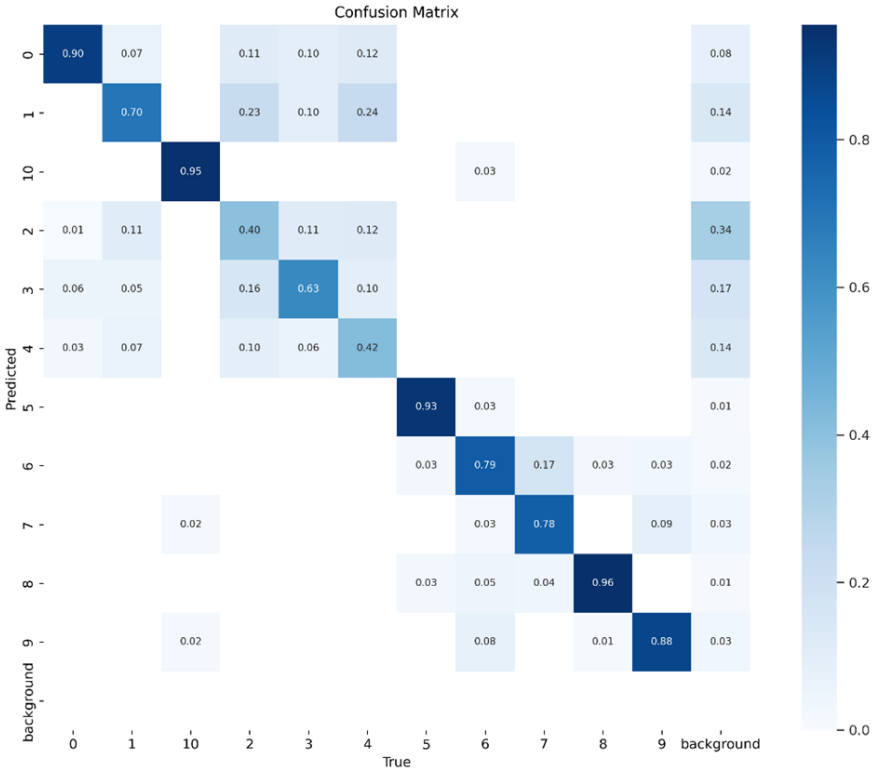

Fig. 4. Confusion matrix result.

From these results, numerous figures illustrate variations in the performance of the YOLO model throughout the training process. The graph illustrates that box loss, object loss, and class loss exhibit a general level of consistency, with minor variations over the training phase. This observation suggests that the model exhibits consistency in its learning. Nevertheless, the recall graph exhibits instability resulting from imbalances in class distribution, less than ideal model parameters and configurations, and inadequate quality of the dataset. To enhance recall stability, it is imperative to examine the distribution of samples in each class, fine-tune model parameters, and enhance dataset quality by collecting more representative data. Furthermore, to enhance the legibility of the model training outcomes, they are shown in Table II. The training results obtained an average value of mAP at 0.5 of 0.82673 and mAP at 0.95 of 0.67048 which were produced with epoch 300. The training process with default hyperparameters was stable at epoch 300 so that the model was said to have been fulfilled and could be used.

For model evaluation using the IoU value, The IoU value is varied to 0.5 and 0.75 which aims to determine the effect of the given IoU. The evaluation results on the model are shown in Fig. 6. The f1-score graph results have almost the same shape, this means that the variation of the IoU value does not have a significant effect on the f1-score value because the precision and recall values do not change much when the IoU value is varied in this model. From the graph, it can be concluded that the recommended confidence value to use is in the range of 0.2 to 0.5.

TABLE II. MODEL TRAINING RESULT

B. Evaluation with Real World Drivers

The estimation results from the model are compared with ratings from a medical doctor. The classification results are divided into three levels, namely "mild" with a VAS value range of 0-3, "moderate" with a VAS value of 4-7, and "severe" with a VAS value of 8-10. The results from the 15 drivers recorded are shown in Table III.

TABLE III. PAIN LEVEL ESTIMATED FROM FACIAL EXPRESSION BY THE MODEL AND A MEDICAL DOCTOR

Subject	VAS Value		Classification	
	Subjective rating by medical doctor	***Proposed Model***	***Subjective rating by medical doctor***	***Proposed Model***
1	7	6	severe	moderate
2	5	6	moderate	moderate
3	6	6	moderate	moderate
4	5	5	moderate	moderate
5	8	8	severe	severe
6	5	6	moderate	moderate
7	1	1	mild	mild
8	5	5	moderate	moderate
9	1	1	mild	mild
10	9	9	severe	severe
11	9	9	severe	severe
12	3	4	mild	moderate
13	8	6	severe	moderate
14	1	1	mild	mild
15	1	1	mild	mild

Of the 15 participants, there were 3 VAS values that deviated from the subjective assessment by the medical doctor so that accuracy can be calculated by subtracting the observed value from the actual value and dividing it by the actual value, then multiplying by 100%, so that:

$$Accuracy = \frac{15-3}{15} = \frac{12}{15} \times 100\% = 80\%$$

With the test results with an error rate of 20%, the following discusses factors that can affect measurement accuracy.

This study was conducted in Indonesia involving male volunteer drivers in Bengkulu City who are predominantly Malay Austronesian ethnicity with an age range of 20-30 years. The results of the study cannot be generalized to be applied to everyone. Older people will have different detection rates. Although the existing datasets are all male, there are still limitations due to demographic, social and cultural diversity. This of course can affect the generalization of the model to different populations. In addition, the availability of datasets from the country of origin is not yet available, which will affect the reliability of the model. Therefore, more accuracy needs to be improved by adding datasets using different ethnic facial variations. Although the results of this study work well on the existing test dataset, if applied to a general context, it still needs to be validated.

Pain is a feeling that can be subjectively felt by someone. It could be that the variation shown in pain at a certain level but is different in giving expression. Variations in facial expressions are a challenge in themselves that can affect the accuracy of this study. Although it has involved external assessments involving medical doctors, it may still be influenced by bias in the dataset. This can also affect the results, especially if applied to different populations. Nevertheless, the proposed model has been proven effective in detecting pain using the Visual Analogue Scale value approach.

Model performance when applied in the real world is influenced by lighting, camera angle, driver movement and if the driver speaks or shows other expressions such as emotions and others. Although research has applied variations in datasets by adding variations in the form of blur, rotation, and brightness enhancement so that the model training process can learn from various data conditions, so that the model can learn from various data conditions, lighting conditions greatly affect the results obtained. Proper camera placement is also a major concern so that data consistency can be maintained. Another thing is if the driver speaks or gives an emotional expression that is very likely to affect the measurement results. These results also may not be generalizable to all conditions due to differences in demographic and cultural factors as discussed above. In addition, variations in pain types (acute and chronic types) should also be considered so that these results may be difficult to apply to different types of pain.

Future research can be further developed by collecting more diverse data sets from different ethnicities which is expected to improve system learning. To improve system validation, this research can be developed by involving biomedical sensors such as heart rate or tone of voice, so that the results are more accurate and can be validated independently. The selectivity and sensitivity of the research can still be improved by applying certain methods so that they can distinguish between real pain and fake pain, without the help of experts in assessing pain. The use of cameras that can work optimally and are not too affected by the environment such as vehicle movement and changes in light intensity can also be considered.

IV. CONCLUSION

In this study we propose to estimate a pain level expressed by facial expressions of drivers by applying VAS value. Headings, or heads, are organizational devices that guide the reader through your paper. There are two types: component heads and text heads. The proposed model can process and classify the driver's facial expression based on the Visual Analog Scale (VAS) value scale ranging from 0 to 10. The classification results are divided into three levels, namely "mild" with a VAS value range of 0-3, "moderate" with a VAS value of 4-7, and "severe" with a VAS value of 8-10.

The results of the confusion matrix show that the YOLO model can classify each class accurately. Class value 8 obtained the highest prediction score of 0.96, but the other 2 classes, namely classes 2 and 4, showed accuracy values below 0.5. This can be caused by the relatively small interval between classes or the subjectivity of the interpretation of VAS values so that the same perception is at different levels.

The experiment test results also show that the system can classify the driver's facial expression of pain level with that of classification by the medical doctor at rate of 80%. Thus, the model may be used to detect driver pain and could lead to a reduction the number of traffic accidents in the future.

ETHICS STATEMENT

Our research is based on non-invasive measurement (camera recording from the car dashboard), and we did not intervene in the everyday routine of the experimental participants. The 15 experimental participants were taxi drivers, and their facial expressions during their routine work were recorded and analyzed. All experimental participants gave informed consent before the experiment and written consent was obtained. The pain rating obtained was based solely on the driver's facial expression recorded from a camera, either using a neural-network model or by a medical doctor. We did not obtain the actual subjective pain experience by the participants. Their facial expression may not reflect the actual amount of pain they were experiencing. There is almost no or small possibility of risk or danger arising from the implementation of this research.

In accordance with the local legislation and institutional requirement[2] where this experiment was performed because the study was investigating public behavior and was purely observational (non-invasive and non-interactive), ethical approval was not required.

Mobile Application Based on Geolocation for the Recruitment of General Services in Trujillo, La Libertad

Melissa Giannina Alvarado Baudat, Camila Vertiz Asmat, Fernando Sierra-Liñan
Facultad de Ingeniería, Universidad Privada del Norte, Trujillo, Perú

***Abstract*—Currently, there is no technological solution that efficiently facilitates the offering of general services by independent workers in the city of Trujillo. This limitation reduces job opportunities, as workers secure fewer contracts due to reliance on client recommendations, a method that is often inefficient due to long response times and low accessibility. Leveraging the versatility of mobile applications. This study contributes to computer science by demonstrating how cloud-based data management, real-time communication, and location-based service matching using Google APIs optimize service efficiency and user experience. The study follows an applied research approach with a quantitative methodology, employing a pre-experimental explanatory design and a sample of 22 workers selected through non-probabilistic convenience sampling. The development was carried out using the Flutter framework and the Dart programming language, with an SQL database hosted on Microsoft Azure cloud services. The Mobile-D agile methodology guided the development process. After implementing the application, the results showed an 86.79% reduction in the average hiring process time, a 50% increase in the number of contracts completed, and a 51.27% improvement in workers' average satisfaction. These findings highlight the effectiveness of mobile and cloud computing technologies, along with ranking algorithms and geolocation services, in streamlining labor market interactions and improving user experience.**

Keywords*—Mobile application; recruitment; geolocation; general services

I. Introduction

We live in an era defined by technological advances, where virtually any activity, from education and business to finance and entertainment, can be completed through mobile devices [1]. The widespread penetration of these devices is evident in statistics showing that 45% of people in 40 countries use non-smartphones, while 43% opt for smartphones [2]. This context of mobile connectivity has led to the emergence of apps as the main communication channel in modern society, standing out for their versatility and efficiency in accessing important and reliable information at any time of the day [3].

The influence of the digital age extends even to the workplace, where the conventional job search has been replaced by digital platforms, which have proven successful in connecting professional candidates with potential employers [4]. Globally, unemployment rates are higher in wealthy countries than in poorer ones, especially among less-educated workers who face greater difficulties adapting to a labor market driven by technological progress that primarily benefits the highly skilled [5]. The deindustrialization of the manufacturing sector has led to a significant decline in "blue-collar" jobs, reflecting a polarization of employment that particularly affects intermediate-skilled occupations. While unemployment among more educated workers remains stable, less educated workers experience rising unemployment rates as GDP per capita increases. This indicates that skill-biased economic development contributes to higher unemployment rates among less-skilled workers, who often must abandon self-employment to seek salaried jobs in an increasingly competitive and precarious labor environment [6].

However, many workers offering services such as electricians, plumbers, builders, tailors, carpenters, among others, lack access to a technological tool with similar characteristics to those available in other sectors, which would facilitate finding job opportunities [7]. This situation forces them to rely heavily on word-of-mouth recommendations from previous clients to secure jobs [8]. On the other hand, for clients, finding trustworthy personnel without the help of the internet can be an arduous and tedious task, as the waiting time to contact a worker is often lengthy [9].

According to study [10], digitalization is transforming the labor market by facilitating job searches and recruitment via the internet, fostering labor mobility, increasing efficiency, and reducing structural unemployment, thereby improving the flow of workers between employers. Social media enables workers to promote themselves to employers outside their local markets, and a significant portion of European freelancers find employment through these platforms. Digital technologies are also driving new forms of employment, such as temporary work distributed through task-based service platforms. These changes have positioned private digital intermediaries as central players in labor market operations, creating new considerations for policymakers.

In the context of the COVID-19 pandemic, the International Labor Organization (ILO) assessed its impact on the labor market and the rapidly evolving situation. It analyzed employment and unemployment rates, as well as global working hours in the European Union. Results showed a 5.4% decline in the first quarter of 2020 and a 14% decline in the second quarter compared to the fourth quarter of 2019. Notably, these declines were less pronounced in Europe and Central Asia, with decreases of 3.4% and 13.9%, respectively [11].

In Trujillo, La Libertad, the absence of a digital platform to connect independent workers with clients limits job

opportunities and service quality. To address this challenge, this research aims to develop a mobile application to facilitate the hiring of general services, optimizing the process and benefiting both providers and consumers. Thus, the following question was formulated: How can the implementation of a mobile application improve the hiring of general services in Trujillo, La Libertad, in 2024? The specific questions were as follows: How does the implementation of a mobile application based on geolocation reduce the hiring process times for general services in Trujillo, La Libertad, in 2024? How does the implementation of a mobile application based on geolocation improve the number of contracts in the hiring process for general services in Trujillo, La Libertad, in 2024? How does the implementation of a mobile application based on geolocation improve satisfaction in the hiring process for general services in Trujillo, La Libertad, in 2024?

II. State of the Art

The authors in study [9] addressed the stagnation problem of manual labor startups in their early stages by proposing a geolocated mobile job portal. This portal acts as an intermediary, connecting workers with users based on geographical proximity, thereby improving job prospects and the number of hires for these workers. The methodology employed was an Incremental model, allowing for continuous evaluation and improvement of the software after each development cycle. The application consists of three main modules: login, service requests by users, and request acceptance by providers. This modular approach enhances usability and maintenance while enabling advanced features such as suggesting additional services based on the nearest available personnel. The research concluded successfully, potentially contributing to reducing unemployment in Nigeria by improving connections between employers and workers.

Similarly, aiming to improve the acquisition of local repair services in Metro Manila, [12] developed "Handy Fix," a mobile application designed to optimize the experience of contracted technicians. Using a mixed-methods approach and a sample of 414 households, the challenges faced by technicians in terms of localization, communication, and payment were assessed. The results showed a significant improvement in technician satisfaction, with 89.17% of respondents affirming that the application addressed the key challenge of verifying skills and credentials. Additionally, 85% highlighted that the lack of adequate tools and safety equipment was effectively addressed through the application's integrated ratings and review system.

In another study, [13] developed an Android application that utilizes location-based services to improve the search and management of services such as plumbing, pipefitting, and electrical work. The goal was to increase the efficiency of service management for users. Using an Agile prototyping approach and tools like Android Studio and MySQL, rapid iterations were conducted based on feedback. The methodology included planning, analysis, design, and implementation phases, resulting in a system that surpassed most functional tests. Workers found the application significantly improved profile management, accounts, services, and appointments, though areas for improvement were identified, such as text appearance and ratings functionality.

Furthermore, the authors in study [14], researched and developed an Android application for domestic services, leveraging on-demand application technology to optimize the hiring of home professionals. Through a methodology combining qualitative and quantitative techniques, such as interviews, literature reviews, and case analyses of existing applications, user needs and market trends were identified. The result was an application with three modules: administrator, workers, and clients. The administrator can modify the website after logging in, while clients can describe required services, manage payments, rate services, and initiate a refund process in cases of dissatisfaction. The application significantly improved the service hiring experience, with recommendations provided for its successful market implementation.

The study by [15] examined the evolution and impact of on-demand home service platforms. Using a qualitative and quantitative exploratory-descriptive design, market data, growth trends, and user satisfaction surveys were analyzed. The results highlight the importance of mobile applications in efficiently connecting workers and clients, improving work organization and management, and optimizing service quality and customer satisfaction. However, challenges related to security and trust in mobile technology persist.

The authors in study [16] analyzed the on-demand home service industry and proposed improvements to applications to offer a smoother and more user-friendly experience. Using a descriptive methodology based on literature reviews, market analyses, and user experience evaluations, the study emphasizes the need to enhance service quality, labor rights, and sustainability. The results suggest that applications like Urban Company and TaskRabbit could benefit workers by implementing training programs, quality control measures, and labor policies that ensure fair pay and job security. Moreover, integrating technologies such as artificial intelligence and machine learning is proposed to optimize service allocation and personalize recommendations, enhancing efficiency and job satisfaction while reducing instability and inequality in the workplace.

According to the study by [17], a technological solution was presented to optimize the work of technicians in the home appliance repair sector. The goal is to facilitate connections between technicians and users requiring home repairs through an online platform and mobile applications. Using a quantitative approach and technological development design, the methodology employed tools like Python, Django, Geopy, and the Fast2SMS API to create an accessible and efficient interface. This platform allows technicians to receive service requests in a more organized manner, improving their access to the job market and optimizing their time by reducing unnecessary travel. The results show a significant improvement in service efficiency and satisfaction for both users and providers, though no specific statistical data is provided.

Finally, the study in [18] developed an application for domestic services using the Extreme Programming (XP) methodology, integrating APIsPERU to verify user information through SUNAT and RENIEC data, enhancing security in the hiring process. The application enables real-time worker localization and optimizes logistics through its integration with

Google Maps, achieving an average response time of two seconds. Validation tests confirmed its effectiveness and integration capability with external services.

III. Objectives

A. General Objective

To determine how the implementation of a geolocation-based mobile application improves the hiring process for general services in Trujillo, La Libertad.

B. Specific Objective

- To determine how the implementation of a geolocation-based mobile application reduces the time required for the hiring process of general services in Trujillo, La Libertad.
- To determine how the implementation of a geolocation-based mobile application increases the number of hirings in the general services contracting process in Trujillo, La Libertad.
- To determine how the implementation of a geolocation-based mobile application improves satisfaction in the hiring process for general services in Trujillo, La Libertad.

IV. Materials and Methods

The methodology used for the development of the application is Mobile-D, which, according to study [19], emerges from the combination of other well-known solutions, all adhering to agile principles. It is characterized by prioritizing software functionality over extensive documentation, client participation over rigid contractual negotiation, and flexibility in the face of changes rather than strict adherence to a predefined plan. It consists of five phases: exploration, initialization, production, stabilization, and system testing.

This study employed a pre-experimental single-group design with pretest and posttest. According to study [20], this type of design allows the evaluation of the effects of an intervention or treatment on a specific sample. It is characterized by two aspects: the use of a single group of participants and a linear order requiring measurement of the dependent variable before and after the intervention or treatment is implemented.

This research was classified as applied and adopted a quantitative approach, with an explanatory level and a pre-experimental design. The study population was selected using non-probabilistic convenience sampling, comprising 22 workers, considering the time and resource constraints for the research. Therefore, the size is the same as the population.

To measure the key indicators of the study, carefully selected techniques and instruments were employed. The "Average hiring time for personnel" and the "Number of hirings" were analyzed using the ratio technique, with an observation sheet that enabled the collection of accurate and quantifiable data on these aspects. Meanwhile, the "Satisfaction level with services" was assessed using a Likert scale, through a structured questionnaire designed to capture users' perceptions and satisfaction regarding the service. These instruments were validated and approved by experts to ensure alignment with the study objectives, guaranteeing the reliability and validity of the data collected. Table I shows indicators, techniques and instruments.

TABLE I. Indicators, Techniques and Instruments

Indicator	Technique	Instrument
Average hiring time for personnel	Ratio	Observation sheet
Number of hirings	Ratio	Observation sheet
Satisfaction level with services	Likert Scale	Questionnaire

V. Methodology

The development of the mobile application was conducted using the Mobile-D methodology, which comprises the following phases: (A) Exploration, (B) Initialization, (C) Production, (D) Stabilization, and (E) System Testing.

A. Exploration

During this phase, stakeholders were identified, and the project foundations were presented, considering its objectives and requirements. Additionally, the project scope was established to ensure all aspects aligned with stakeholders' expectations. The functional requirements are detailed in Table II below:

TABLE II. Functional and No-Functional Requirements

Code	Description
RF-001	Users must be able to log in according to their type (Customer or Tasker).
RF-002	Users must be able to view their service history.
RF-003	Users must be able to view their current hired services.
RF-004	Users must be able to access their active chats.
RF-005	Users must be able to update their profiles.
RF-006	The system must allow users to rate a service after its completion.
RF-007	Users must be able to search for a service by category.
RF-008	The system must provide users with nearby services or clients based on geolocation.
RF-009	The system must allow users to cancel a service request.
RF-010	The system must enable Taskers to schedule a service for a specific date and time.

B. Initialization

Fig. 1 illustrates the development environment, utilizing Visual Studio Code for the frontend and Spring Tool Suite 4 for the backend, along with the installation of JDK 1.8 (Java 8 SE). The database will be managed using SQL Server Management Studio 20. Additionally, the development team employed the Flutter framework and the Dart programming language. Communication with clients will be facilitated through email and phone calls.

Solution Architecture

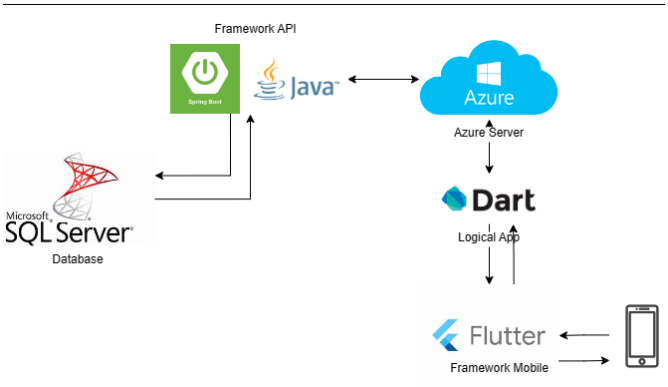

Fig. 1. Software architecture diagram.

C. Production

Planning Day (see Table III)

TABLE III. ITERATION PLANNING BY PHASE

Fase	Iterations	Description
Exploration	Iteration 0	Establishment of stakeholders, functional and non-functional requirements, scope definition, and selection of development technologies.
Initialization	Iteration 0	Creation of the mobile application architecture, requirements analysis, and interface design
Production	Iteration 1	Verification of selected tools. Development of the mobile app interfaces and database implementation and connection to Azure. Creation of the GitHub repository.
	Iteration 2	Implementation of user registration and login functionality: Tasker and Customer, using Firebase OTP service. Visualization of service categories (Service table).
	Iteration 3	User data modification through the app. Implementation of geolocation for users to search for nearby services using Google Places.
	Iteration 4	Implementation of chat between users using Firebase. Request logging implementation.
	Iteration 5	Implementation of user reviews. View of pending and completed request history.

Workday

Iteration 1. The selected tools for development were verified, and the project setup was completed, including project compilation, library downloads, credential creation for services, and proper connection to the SQL Server database. This database was uploaded to Microsoft Azure to enable simultaneous use and faster performance for the development team. For the design of interfaces, they were developed following the functional requirements outlined in the first phase, emphasizing the application's usability. Finally, the backend and frontend projects were uploaded to a GitHub repository for version control. Additionally, a web application was created on the Microsoft Azure platform, linking it to the backend project via GitHub.

Iteration 2. Using stored procedures in SQL Server and APIs in the backend project, the user registration and login functionality were developed through Firebase's OTP service. As shown in Fig. 2, users can authenticate using their phone number, receiving a unique code to be entered in the application interface. Based on stored procedure verifications of user existence in the database and the selected user type (Tasker or Customer), they are redirected to the Registration interface (as shown in Fig. 3 and Fig. 4) or the Login page. The Customer is presented with the Home screen, listing Services and Top Taskers, along with quick access to their chats. The Tasker, in turn, sees the Home screen with unopened requests and direct access to their chats. Fig. 5 show customer main menu and service search by category.

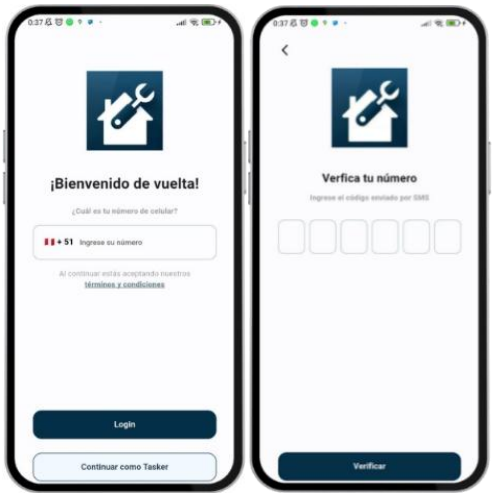

Fig. 2. OTP registration.

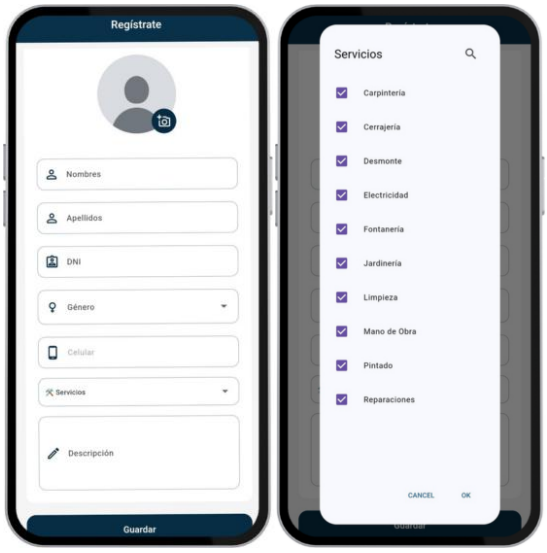

Fig. 3. Tasker registration.

Iteration 3. From the user perspective, they can now access their profile to modify their data using stored procedures. Additionally, the Google Places API will be implemented and utilized on the front end. When a user has location services enabled, their latitude and longitude data will be automatically captured and sent to the backend, allowing them to be mapped and enabling the Customer to see the closest Tasker in their area, as shown in Fig. 6 and Fig. 7.

Fig. 4. Customer registration.

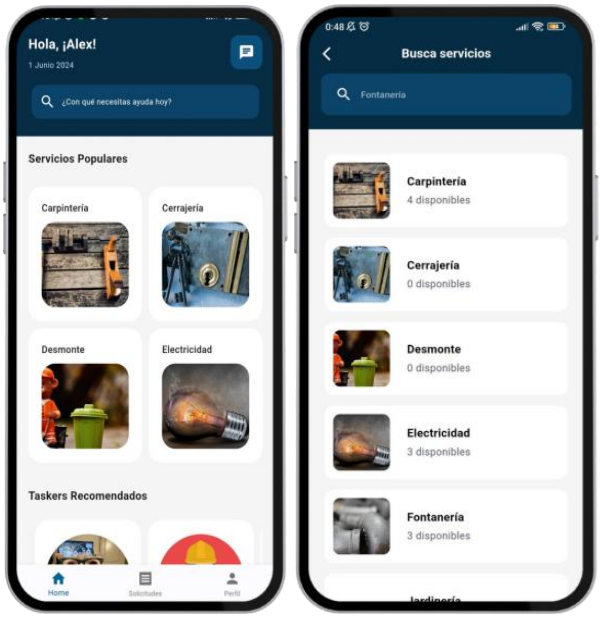

Fig. 5. Customer main menu and service search by category.

Iteration 4. During this iteration, Firebase libraries were integrated to enable chat and notification services within the application. Requests are managed with four different statuses: deleted, accepted, completed, and pending. In the Tasker view, as shown in Fig. 8 and Fig. 9, a redirection to a request registration modal was implemented, where the necessary details specified by the client are entered to confirm the request.

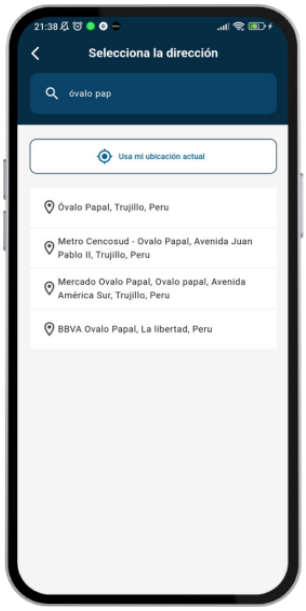

Fig. 6. Location selection via geolocation or search.

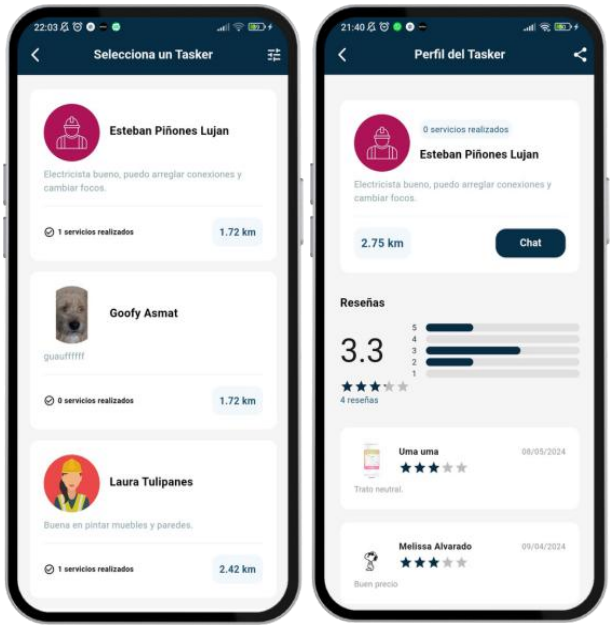

Fig. 7. Selection and profile of tasker near current location.

Iteration 5. In this iteration, as illustrated in Fig. 10, the ability to view the history of pending and completed requests was implemented, providing users with a comprehensive overview of their past interactions in the application. Additionally, a review feature was added, allowing users to leave comments and ratings on the services received once completed, as shown on Fig. 11. Consequently, Customers now see recommendations for Taskers with the highest average ratings on their home screen, while Taskers can view the ratings of the Customers requesting their services.

Fig. 8. Chat history.

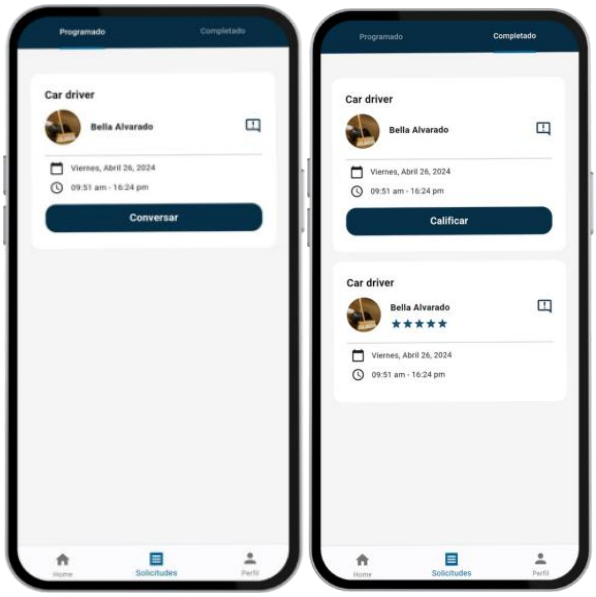

Fig. 10. History of scheduled and completed requests.

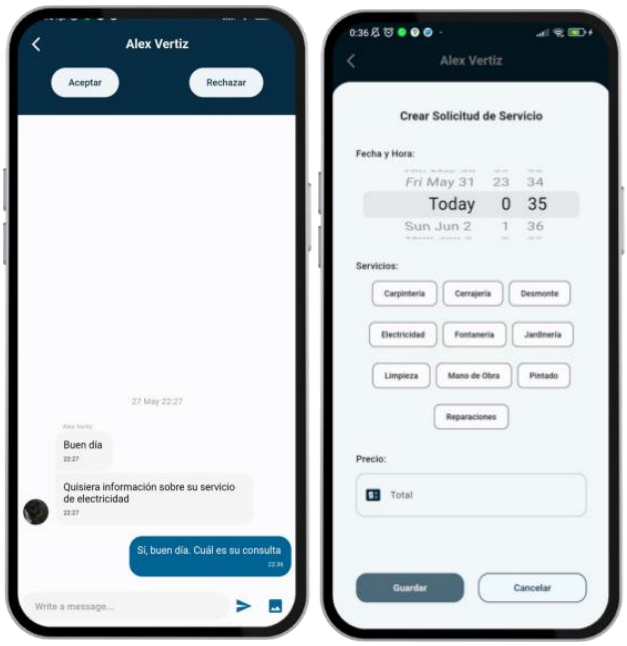

Fig. 9. Chat and service request creation.

Fig. 11. Service rating.

D. Stabilization

In this phase, a modular structure was implemented, allowing for clearer organization in both the application's architecture and interface. A bottom navigation bar was added, making it easier to access features. This improvement enhances the user experience by providing smoother interaction.

Algorithm 1: MenuTasker Navigation

```
Initialize
    Create MenuTasker as a stateful widget
    Create NavigationControllerTasker as a navigation

Compute
    Initialize controller with NavigationControllerTasker
While (the application is running) do
    Build the user interface
    For (each region of the interface) do
        Display BottomNavigationBar with three options:
            - Home
            - Requests
            - Profile
        Show the corresponding screen based on selectedIndex
    Update
        Observe changes in selectedIndex
        Update and analyze
            If (selectedIndex changes) then
                Search for the corresponding screen in the screens list
    End                 End
    End
```

E. System Testing

During this phase, unit tests were conducted to review the code and ensure that the developed and implemented product operated correctly according to the specified functionalities. Additionally, time was allocated to identify and fix any errors detected during the process.

TABLE IV. UNIT TEST

Test Scenario	Expected Outcome		Obtained result	
			RT	OK
User	Verificar Signup Tasker Service ()	searchTasker	332ms	X
		searchTaskerByUid testing	441ms	X
		saveTasker testing	285ms	X
		updateTasker testing	278ms	X
		updateProfileTasker testing	299ms	X
User	Verificar SearchCustomer Service ()	searchCustomer testing	285ms	X
		searchCustomerByUid testing	281ms	X
		updateCustomer testing	281ms	X

As shown in Table IV, the results demonstrate that the code is effective and adequately fulfills the expected functionality.

VI. RESULTS

The results presented in Table V demonstrate a high reliability of the measurement instruments used in the research. The obtained coefficients exceeded the 0.70 threshold, indicating adequate consistency in the measurements.

TABLE V. RELIABILITY

Instrument	Method	Indicator	Coefficient
Pre- and Post-Observation Sheet	Test - retest	General services contracting time	.910
Pre- and Post-Observation Sheet	Test - retest	Number of Contracts	0.843
Pre and post Questionnaire	Cronbach's Alpha	Satisfaction Level	.853

Data elaborated based on SPSS.

A. Descriptive Analysis

Indicator 1 General services contracting time

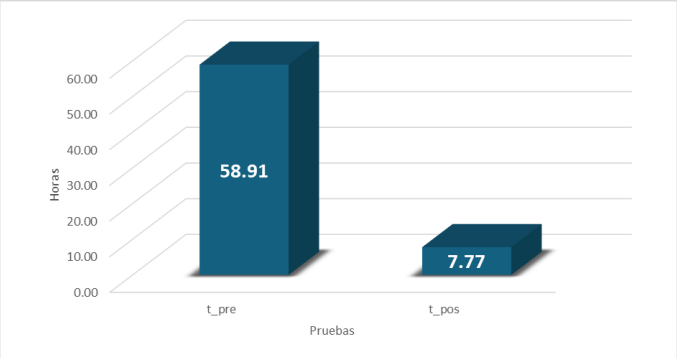

Fig. 12. Average service contracting time before and after.

According to Fig. 12, the average time to contract general services before the solution's implementation was 59 hours, and the post-implementation time was eight hours. The significant reduction in the average time after implementation suggests that the application had a positive and considerable impact on the contracting process, improving the efficiency of worker selection.

Indicator 2 Number of Contracts

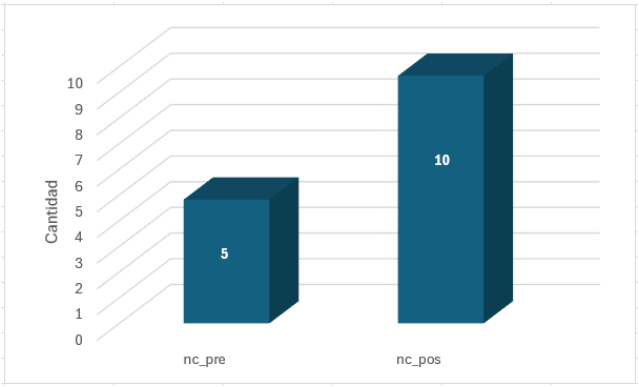

Fig. 13. Average number of contracts before and after.

According to Fig. 13, the average number of general service contracts before the implementation of the solution was 5, while after the implementation, 10 contracts were recorded. This notable increase in the number of requests demonstrates the positive impact of the solution's implementation, doubling the number of contracts and significantly improving the efficiency of the process.

Indicator 3 Satisfaction with the Contracting Process

TABLE VI. LEVEL OF SATISFACTION BEFORE IMPLEMENTATION

Category	Frequency	Percentage
Strongly disagree	7	31.82%
Disagree	13	59.09%
Neither agree nor disagree	2	9.09%
Agree	0	0%
Strongly agree	0	0%
Total	22	100%

Data elaborated from SPSS

TABLE VII. LEVEL OF SATISFACTION AFTER IMPLEMENTATION

Category	Frequency	Percentage
Strongly disagree	0	0%
Disagree	0	0%
Neither agree nor disagree	0	0%
Agree	11	50%
Strongly agree	11	50%
Total	22	100%

Data elaborated from SPSS

According to Tables VI and VII, the predominant perception of 22 workers regarding satisfaction before the implementation of the mobile application in the general service hiring process was: totally disagree 7 (31.82%), disagree 13 (59.09%), and neither agree nor disagree 2 (9.09%). However, after the implementation of the mobile application, a considerable positive impact on satisfaction was observed, with a notable increase in perception: agree 11 (50%) and totally agree 11 (50%).

B. Inferential Analysis

1) Normality test: Based on the results from Tables VIII, IX, X and XI, obtained from a sample of 22 data points, it is observed that most indicators show an asymptotic significance lower than 0.05, which suggests a non-normal distribution of the data. Therefore, the non-parametric Wilcoxon test for paired samples is used for each indicator.

TABLE VIII. SHAPIRO-WILK TEST FOR AVERAGE TIME OF THE GENERAL SERVICE HIRING PROCESS

	Statistic	*gl.*	*Sig.*
t_pre	*.887*	*22*	*.017*
t_pos	*.782*	*22*	*<.001*

Data elaborated from SPSS

TABLE IX. SHAPIRO-WILK TEST FOR AVERAGE NUMBER OF CONTRACTS IN THE GENERAL SERVICE HIRING PROCESS

	Statistic	gl.	Sig.
t_pre	.875	22	.010
t_pos	.854	22	.004

Data elaborated from SPSS

TABLE X. SHAPIRO-WILK TEST FOR AVERAGE SATISFACTION WITH THE CONTRACTING PROCESS FOR GENERAL SERVICES

	Statistic	gl.	Sig.
s_pre	.912	22	.052
s_pos	.920	22	.076

Data elaborated from SPSS

2) Hypothesis formulation

a) Alternative hypothesis: The implementation of a mobile application based on geolocation significantly improves the time, satisfaction, and number of contracts in the general service hiring process in Trujillo, La Libertad.

b) Null hypothesis: The implementation of a mobile application based on geolocation does not significantly improve the time, satisfaction, or number of contracts in the general service hiring process in Trujillo, La Libertad.

3) Hypothesis testing: Indicator 1 Contracting Process Time

TABLE XI. WILCOXON TEST FOR AVERAGE CONTRACTING PROCESS TIME FOR GENERAL SERVICES

Null Hypothesis	Test	Sig.	Decision
The median difference between t_pre and t_post is equal to 0	Wilcoxon signed-rank test for related samples	.000	Reject the null hypothesis

Data elaborated from SPSS

Since the p-value is equal to 0, which is less than 0.05, we reject the null hypothesis and accept the alternative hypothesis. This means that the implementation of a mobile application based on geolocation significantly improves the contracting process time for general services hiring process in Trujillo, La Libertad.

Indicator 2 Number of Contracts

TABLE XII. WILCOXON TEST FOR AVERAGE CONTRACTING PROCESS TIME FOR GENERAL SERVICES

Null Hypothesis	Test	Sig.	Decision
The median difference between nc_pre and nc_post is equal to 0	Wilcoxon signed-rank test for related samples	.000	Reject the null hypothesis

Data elaborated from SPSS

Since the p-value is equal to 0, which is less than 0.05, we reject the null hypothesis and accept the alternative hypothesis. This means that the implementation of a mobile application based on geolocation significantly improves the number of contracts in the general services hiring process in Trujillo, La Libertad (see Table XII and XIII).

Indicator 3 Satisfaction with the Contracting Process

TABLE XIII. WILCOXON TEST FOR AVERAGE SATISFACTION WITH THE CONTRACTING PROCESS FOR GENERAL SERVICES

Null Hypothesis	Test	Sig.	Decision
The median difference between s_pre and s_post is equal to 0	Wilcoxon signed-rank test for related samples	.000	Reject the null hypothesis

Data elaborated from SPSS

Since the p-value is equal to 0, which is less than 0.05, we reject the null hypothesis and accept the alternative hypothesis. This means that the implementation of a mobile application based on geolocation significantly improves satisfaction in the contracting process for general services in Trujillo, La Libertad.

VII. DISCUSSION

According to the results obtained, the times, satisfaction, and number of contracts in the hiring process were analyzed and compared before (pre) and after (post) the implementation of the mobile application. This app was developed using a hybrid framework to ensure cross-platform compatibility and efficient performance. The objective was to improve the efficiency of the general service hiring process through the implementation of a mobile application based on geolocation in Trujillo, La Libertad.

The results of the study reveal a significant reduction of 51.14 hours in the average time of the general service hiring process after the implementation of the mobile application. This substantial decrease demonstrates the effectiveness of mobile technology in optimizing organizational processes. The findings align with previous research [8], [13], which highlighted the potential of geolocation-based mobile applications to streamline operations and improve efficiency. Furthermore, the integration of Google Places API allowed users to easily find the nearest available taskers, further enhancing the speed and accessibility of the hiring process. These results corroborate the research proposed by study [20] regarding the importance of time as a key performance indicator in various functional areas.

After the implementation of the mobile application, a notable 50% increase in the number of contracts was observed, rising from an initial average of 5 to 10 contracts. This increase clearly reflects the ease and effectiveness the application offers in accelerating the general service hiring process. These results are consistent with those reported in study [17], where it was demonstrated that mobile applications not only optimize process organization but also significantly expand access to the job market. Similarly, the results reinforce the argument made by [9], which suggests that the development of a location-based job portal has a positive impact on increasing the number of contracts.

Regarding satisfaction levels, an increase in the satisfaction average from 55% to 83.2% was observed after the mobile application implementation, indicating that employees are more satisfied with the hiring process for their services after adopting this tool. These findings coincide with those reported in study [12], where it was determined that the implementation of a location-based mobile application significantly improved technician satisfaction by 89.17% by providing a more organized environment. Similarly, the study in [13] highlighted that the development of a location-based mobile application for facilitating service search increased satisfaction in the hiring process management. These results also reinforce the claims of [18], who argues that satisfaction is achieved through the standardization and optimization of processes, which enhances quality and, consequently, overall satisfaction.

VIII. CONCLUSION

The implementation of a mobile application based on geolocation has proven to be effective in improving the efficiency of the general service hiring process in Trujillo, La Libertad, by significantly reducing the average process time and increasing the satisfaction level and number of worker contracts.

The average time of the hiring process was reduced from 58.91 hours before implementation to 7.77 hours after, representing an 86.79% decrease. This result was confirmed by the Wilcoxon test, which showed a significant level lower than 5%, confirming the acceptance of the alternative hypothesis.

Similarly, the average number of worker contracts in the hiring process increased from 5 to 10 after the implementation of the mobile application, which equals a 50% increase. This increase was also validated by the Wilcoxon test, with a significance level lower than 5%, reaffirming the effectiveness of the technological intervention.

Additionally, the average worker satisfaction in the hiring process increased from 55% to 83.2% after the mobile application implementation, which represents a 51.27% increase. This increase was also validated by the Wilcoxon test, with a significance level lower than 5%, reaffirming the effectiveness of the technological intervention.

Finally, this study contributes to computing by demonstrating how cloud-based data management, real-time communication, and location-based service matching using Google APIs optimize service efficiency and user experience. Additionally, the platform implemented a ranking algorithm that sorts service providers based on their ratings, ensuring that users can easily find the highest-rated professionals, leading to a more reliable and efficient hiring experience

ACKNOWLEDGMENT

Development of a Software Tool for Learning the Fundamentals of CubeSat Angular Motion

Victor Romero-Alva[1], Angelo Espinoza-Valles[2]
Faculty of Engineering, Universidad Tecnológica del Perú, Peru[1]
Inter-University Department of Space Research, Samara National Research University, Russian Federation[2]

***Abstract*—The development of tools for understanding and simulating CubeSat angular motion is essential for both educational and research purposes in space technology. In this context, this paper presents the development of a MATLAB-based software tool designed to facilitate the comprehension of CubeSat angular motion. This tool allows users to simulate CubeSat dynamics by adjusting parameters, such as initial conditions and physical properties, enabling the observation of different types of motion, including rotatory, oscillatory, both stable and unstable behaviors. The mathematical models selected for simulating the CubeSat dynamics are presented. The interface of the tool, designed for intuitive parameter input and visualization of phase portraits of the system under consideration, is described. The software is demonstrated using a CubeSat 3U configuration, and simulation results, including angle of attack, angular velocity, and altitude decay, are presented. This tool aims to enhance the understanding of CubeSat angular motion, contributing to the design and operation of CubeSat missions in low Earth orbit.**

Keywords*—CubeSat; angular motion; simulation; learning tool MATLAB

I. Introduction

CubeSats, a class of nanosatellites, have become popular in educational and commercial activities in space due to their cost effectiveness and versatility [1, 2]. The proliferation of CubeSats, typically deployed in low Earth orbit (LEO), has transformed space exploration and satellite-based research. Previously, solutions to many complex space problems could be imagined possible only with the use of larger spacecraft [3-5].

One critical aspect of their operation is angular motion, which determines orientation of the spacecraft in space. Understanding how a CubeSat experiences angular motion and how to control its attitude is vital for mission success, especially for applications involving imaging, communication, and scientific measurements [6, 7]. Despite their relatively small dimensions, CubeSats adhere to the same fundamental principles of orbital mechanics and attitude control as larger spacecraft. These principles are influenced by external forces such as gravitational and aerodynamic torques, which can vary based on the altitude, mass distribution, and geometric properties of the satellite [8].

In practice, achieving stable or predictable attitude control is essential for both passive and active stabilization methods and requires a firm comprehension of how these forces are related to the physical characteristics of the CubeSat. Given the increasing complexity of CubeSat missions, there is a growing need for intuitive and interactive learning tools that simplify the study of its dynamics.

Traditional methods of teaching these concepts often rely on theoretical mathematical models, which can be difficult for learners to fully comprehend without visual aids or practical experimentation. Consequently, in recent years, the development of graphical user interfaces as learning tools has gained traction across multidisciplinary fields, demonstrating their potential to facilitate complex subject matter through interactive and intuitive designs.

For instance, Botha and Marais developed a GUI to support learning in artificial intelligence, demonstrating the effectiveness of visual and interactive tools in simplifying sophisticated AI concepts [9]. Similarly, Mohd and Hashim introduced a deep learning interface designed to assess fruit quality, which exemplifies how such interfaces can aid in applied fields like food engineering [10]. These methodologies are also employed in chemometrics, as seen in the work of Chiappini et al., who developed a MATLAB GUI for multivariate calibration [11]. Gasparic et al. developed a GUI that enhances integrated development environment usability by providing command recommendations, demonstrating through user studies that such interfaces are essential for effective developer support [12]. Mishra et al. [13] developed a MATLAB-based interface that simplifies multi-block data analysis by offering integrated visualization, classification, and pre-processing capabilities, thereby making advanced chemometric methods accessible to users in industrial applications. Victoria et al. introduced a GUI for topology design in engineering structures, which underscores the broad applicability of such interfaces in engineering design processes [14]. Furthermore, GUIs have been implemented in astronomy, for example, Errazzouki et al. created a MATLAB interface to facilitate the acquisition of single star SCIDAR data, facilitating data processing [15].

These developments collectively underscore the effectiveness of interactive graphical interfaces in making complex theoretical concepts more accessible and engaging. However, despite these successful implementations, there remains a distinct need for a simplified simulation tool that provides relatively accurate representations of CubeSat dynamics while remaining accessible to students and newcomer CubeSat developers. Thus, the objective of this paper is to present a software learning tool designed to simulate the CubeSat angular motion through an intuitive interface, while

facilitating an easy understanding of CubeSat angular motion fundamentals. This MATLAB-based tool allows users to adjust key design parameters, observe different types of motion, and visualize phase portraits of the system, providing valuable insights into CubeSat dynamics.

The remainder of the article is organized as follows: Section II reviews related work in tools for simulating spacecraft dynamics. Section III presents the theoretical concepts underlying CubeSat angular motion and describes the mathematical models implemented in the tool, with emphasis on the key assumptions made for model simplification. Section IV presents the results, demonstrating the utility of the tool through a practical example based on a CubeSat 3U configuration. Section V provides a discussion of the results, highlighting the limitations, and potential areas for future work. Finally, Section VI presents the conclusions, summarizing the key contributions and significance of the developed tool."

II. Related Work

In the field of spacecraft dynamics, several sophisticated software tools and packages have been developed to simulate both angular and orbital motion of spacecraft. For instance, Hadi and Sasongko developed a CubeSat design and visualization tool in MATLAB that not only calculates key satellite parameters but also simulates dynamic responses, thereby supporting the analysis and design of CubeSat systems [16].

Ivanov et al. introduced a software package capable of simulating passive and controlled angular and orbital motion of near-Earth satellites [17]. While highly versatile, the reliance on specific mathematical models can make it less accessible for users seeking a simpler introduction to CubeSat dynamics. Moreover, as the software is developed in C++, it may be more difficult to modify or add new modules compared to more user-friendly environments like MATLAB.

Ezzat et al. provided a tool for satellite orbit tracking based on the Keplerian system. Although this method demonstrates high precision and robust visualization for orbit tracking, it does not simulate the angular motion relative to the spacecraft's center of mass. This omission is significant because understanding the angular dynamics is critical for evaluating the attitude stability and control of the spacecraft, which are essential for mission success [18].

Similarly, Turner developed an open-source spacecraft simulation and control software based on an application programming interface intended for both research and educational purposes [19]. This framework delivers high-fidelity simulation routines and efficient, fast-running code, making it a powerful tool for detailed analysis. However, its effective use requires a robust understanding of programming, which may present a barrier for users with limited technical expertise.

Shirobokov and Trofimov developed the KIAM Astrodynamics Toolbox, a robust software library for spacecraft orbital motion that incorporates Fortran modules for implementing astrodynamical functions and Python modules for their compilation [20]. While the toolbox is effective for detailed simulations and ensures computational speed, its primary focus on orbital dynamics may overlook key aspects of CubeSat attitude control and angular motion. While this advanced tool is effective, it may not be suitable for educational purposes. The reliance on a traditional programming language, as Fortran, alongside Python interfaces, can pose accessibility challenges for users without a solid programming background.

While the reviewed tools offer detailed and accurate simulations suitable for advanced research, there is a noticeable gap when it comes to introductory educational applications. Many of these tools are designed with high-fidelity modeling in mind, which can sometimes render them less accessible for beginners or users without extensive programming experience. In summary, the literature reveals two key trends in the development of educational simulation tools: the integration of graphical user interfaces to help demystify theoretical concepts and the growing use of open-source, extensible software frameworks that allow for both accurate and customizable simulations.

III. Theory of CubeSat Angular Motion

In this section, we provide an overview of the theoretical concepts and mathematical models, which underlie CubeSat angular motion, focusing on dynamic equations generally used in CubeSat missions.

A. Simplifications and Assumptions for CubeSat Dynamics Modeling

In the development of this interactive learning tool for CubeSat angular motion, several foundational assumptions are made to simplify the complex dynamics involved and facilitate an effective educational framework.

A primary assumption is that the CubeSat exhibits planar angular motion in a circular orbit, subject to the influence of gravitational and aerodynamic torques. This assumption enables a focused analysis of the rotational behavior by limiting the scope to the two principal forces acting on the CubeSat. This assumption is particularly appropriate for CubeSats operating in LEO, allowing the model to provide a simplified and close representation of their attitude dynamics.

Given that the geometry of a CubeSat is generally a parallelepiped, it can be considered a dynamically symmetric body. Therefore, its moments of inertia about the *y*- and *z*-axes are assumed to be equal ($I = I_y = I_z$). Furthermore, for form factors larger than 1U, the longitudinal moment of inertia I_x is associated with the *x*-axis, which is the axis of symmetry and corresponds to the longest side of the CubeSat.

Due to the typical vertical stacking of components in CubeSats, it is assumed that the center of mass may be displaced from the center of pressure, primarily along the longitudinal axis, denoted as Δx. This is because the arrangement of components is more likely to create asymmetry along this axis. In contrast, displacements along the lateral *y*-axis and *z*-axis are considered negligible or zero. This assumption simplifies the analysis, particularly in assessing the impact of aerodynamic forces.

These simplifications are essential for creating a simulation that is both computationally manageable and pedagogically

valuable for understanding the principles of angular motion in CubeSats.

B. Mathematical Model for CubeSat Angular Motion Modeling

In this study, the motion of a CubeSat relative to its center of mass is examined and its implemented based on the theorem of conservation of angular momentum.

According to study [21], an approximate model for the angular motion of a dynamically symmetric CubeSat in a circular orbit can be obtained by the following the expression:

$$\ddot{\alpha} - \frac{M_{ay}}{I}\sin\alpha - \frac{M_{gy}}{I}\sin\alpha = 0, \quad (1)$$

where, α is the angle of attack, M_{ay} is the aerodynamic moment, M_{gy} is the gravitational moment and I is the CubeSat transverse moment of inertia.

At lower altitudes, aerodynamic forces play a significant role in the dynamics of the CubeSat, while at higher altitudes, the influence of aerodynamic moments diminishes, and gravitational moments become more predominant. Despite the weakening of gravitational force with increasing altitude, its effects remain relevant and must be thoroughly analyzed to ensure effective control and stabilization. In this context, the gravitational moment is calculated using the following formula:

$$M_{gy} = -\frac{3\mu}{2r^3}(I_x - I)\sin 2\alpha \quad (2)$$

where, μ is the Earth's gravitational parameter, r is the CubeSat position radius-vector, I_x is the CubeSat longitudinal moment of inertia.

For CubeSats, the angular acceleration caused by aerodynamic moments is significantly higher. These moments have a much greater influence on smaller CubeSats than on larger, more massive ones, even when both have the same relative center of mass displacement and volumetric density [21]. The moment of aerodynamic drag force is calculated as follows:

$$M_{ay} = -c_0 S\Delta\bar{x}ql\sin\alpha \quad (3)$$

where $c_0 = 2.2$ is the drag coefficient, S is the characteristic area of the CubeSat perpendicular to the flight velocity vector, $\Delta\bar{x} = \Delta x / l$ is the relative distance from the center of pressure to the center of mass along the x axis of the CubeSat, q is the velocity pressure, l is the characteristic length of the CubeSat.

In the previous model, the orbital dynamics of the CubeSat were heavily dependent on the flight altitude, as this parameter directly influences atmospheric drag and other perturbative forces. Given the significance of altitude in attitude, we aim to utilize the approximate formula to predict altitude variations over time. This allows for a close estimation of the orbital evolution, especially in LEOs where altitude plays a critical role in its long-term stability and performance. For CubeSats, the ballistic coefficient tends to be higher compared to larger satellites, which leads to a shorter orbital lifetime due to the increased drag forces acting upon them at a given altitude. Under the assumption that the descent angle of a nanosatellite in a nearly circular orbit remains small and varies slowly, the altitude change over time can be estimated using the equation [22]:

$$\dot{h} = -\frac{2\sigma qV}{g} \quad (4)$$

where σ is the ballistic coefficient, V is the flight velocity and g is the Earth's gravity at a specific altitude.

Assuming the flow is free molecular and the impact of gas molecules is completely inelastic, the ballistic coefficient of a CubeSat can be determined by the following formula [8]:

$$\sigma = -\frac{c_0 S}{m} \quad (5)$$

where m is the CubeSat mass.

IV. Results

In this section the developed software tool, the CubeSat Angular Motion Simulator, is introduced.

A. Learning Tool Interface Overview

The proposed interface was implemented and verified using MATLAB programming language. This tool provides an interactive environment where users can explore the dynamic behavior of CubeSats by modifying various physical and initial conditions of the angular motion. The primary features include real-time visualization of angular motion, user input of critical parameters, and the generation of phase portraits, allowing for an in-depth exploration of both theoretical and practical aspects of CubeSat dynamics.

The interface of the CubeSat Angular Motion Simulator is designed for ease of use, as shown in Fig. 1. It is divided into several distinct panels: one for inputting CubeSat parameters, another for initializing angular motion conditions, a third for adjusting simulation time, and finally, a visualization panel that plots the phase portraits of angular motion.

B. Initial Data for Simulation

The input data required for the simulation includes a range of essential parameters that define the dynamic characteristics of the CubeSat. Specifically, it includes the geometric properties, center-of-mass configuration, inertial characteristics, and aerodynamic features of the nanosatellite. Additionally, the simulation requires the altitude of the CubeSat during flight and the initial conditions of its angular motion. Collectively, these parameters are crucial for accurately modeling the angular dynamics of the nanosatellite and facilitating a comprehensive understanding of its behavior in space.

The leftmost panel, labeled "CubeSat Parameters", allows users to define the physical characteristics of the CubeSat. These include:

- Units: The tool supports various CubeSat form factor, such as 1U up to 12U. Users can select the required size from a dropdown menu.
- Mass: The mass of the CubeSat in kilograms.
- Moments of inertia: For determining the resistance to rotational motion users input the longitudinal moment of inertia I_x and the transversal moment of inertia I, both in kg·m².

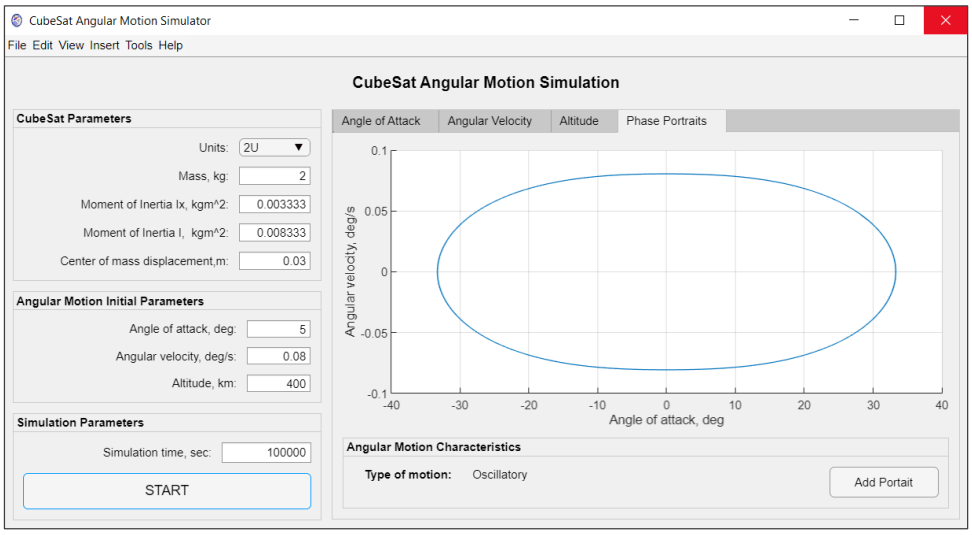

Fig. 1. Main interface of the CubeSat angular motion software.

- Center of mass displacement: A key feature of the tool is the ability to account for displacement of the center of mass along the longitudinal axis, which is input in meters.

By adjusting these inputs, users can simulate various CubeSat configurations, from simple single unit designs to more complex with multiple units.

Below the CubeSat Parameters section, users define the initial conditions of angular motion in the "Angular Motion Initial Parameters" panel.

- Angle of attack α: This parameter, expressed in degrees, defines the initial angle between the CubeSat longitudinal axis and the flight velocity vector.
- Angular velocity $\dot{\alpha}$: The initial angular velocity, given in degrees per second, specifies the rate of rotation of the angle of attack.
- Altitude: The orbital altitude of the CubeSat in kilometers.

The Simulation Parameters panel allows users to specify the total simulation time in seconds, enabling them to explore short-term or long-term behavior of the angular motion.

C. Phase Portraits Section

One of the features of the tool is the capability to generate phase portraits. A phase portrait represents the trajectory of the angular motion in phase space, where the angle of attack is plotted against angular velocity. This visual representation allows users to easily identify whether the motion is periodic, stable, or exhibits any chaotic tendencies. The phase portraits tab provides users with the option to save and compare multiple simulations, offering an understanding of how variations in initial conditions or CubeSat parameters impact the system. By selecting the "Add Portrait" button, users can overlay results from different simulation runs, facilitating comparative analysis.

For example, the phase portrait presented in Fig. 2 illustrates an analysis of angular motion in a planar representation, generated using the software tool. This example incorporates five distinct types of motion added using the "Add Portrait" button. The plot offers an insightful look into how different types of motion, rotatory and oscillatory, can be represented, along with the critical role of the separatrix in dividing the regions of possible motion.

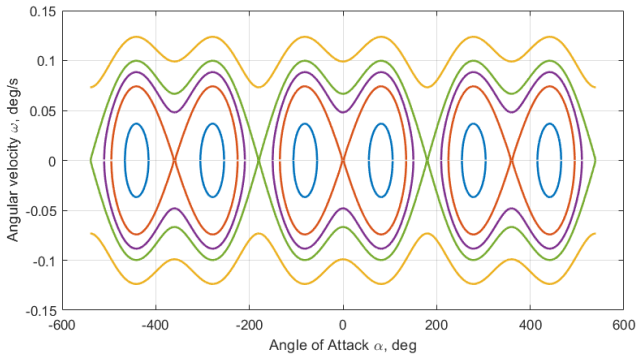

Fig. 2. Opportunity for study of phase portraits.

The phase portrait maps the relationship between the angle of attack α on the x-axis, and the angular velocity ω on the y-axis. Each trajectory corresponds to a specific type of motion, representing how the angular velocity changes as the angle of attack evolves.

1) Rotatory motion: Represented by the yellow curve, the rotatory motion is characterized by the CubeSat spinning continuously, with no return to its original orientation.

2) Oscillatory motion: In contrast, oscillatory motion is represented by closed trajectories (blue and purple curves). This type of motion implies that the angular velocity periodically reverses direction, leading to a back-and-forth movement around a stable point or equilibrium. Physically, this corresponds to a situation where the CubeSat is wobbling or oscillating without completing a full rotation.

3) Separatrix: The green and red curves are separatrices that delineate the boundary between oscillatory and rotatory

motion. This curve indicates the critical point at which a small change in angular velocity or angle of attack can result in a significant shift from oscillatory to rotatory motion.

A more detailed analysis of determination of equilibrium positions for CubeSats can be found in the work [23].

Finally, below the graph, the software provides a real-time classification of the angular motion of the CubeSat under the label "Angular Motion Characteristics". Depending on the initial conditions and the physical parameters, the tool identifies the motion as oscillatory or rotary.

D. Data Output and Visualization

Once the parameters described in section B are set, the user can start the simulation by pressing the START button. The software tool provides a range of outputs that allow users to analyze the CubeSat dynamics over time. As an illustrative example, a simulation was conducted using the parameters presented in Tables I and II, with a simulation time of 100,000 seconds.

Table I details the design characteristics for a CubeSat 3U, while Table II outlines the initial angular motion parameters used for the simulation.

TABLE I. CUBESAT SIMULATION PARAMETERS

Parameter	Value
Mass, kg	3
Longitude, m	0.3
Moment of Inertia I_x, kg·m²	0.005
Moment of Inertia I, kg·m²	0.025
Center of mass displacement Δx, m	0.03

TABLE II. INITIAL ANGULAR MOTION PARAMETERS

Parameter	Value
Angle of attack, deg	45
Angular velocity, deg/s	0.15
Altitude, km	400

Fig. 3 shows the variation of the angle of attack over time, where a clear oscillatory behavior is observed. This periodic oscillation suggests that the orientation of the CubeSat relative to its orbit changes continuously due to perturbation torques.

Analogically, Fig. 4 presents the variation of the angular velocity over time.

The phase portrait shown in Fig. 5 plots angular velocity against the angle of attack. The curve represents oscillatory motion around the equilibrium position, where $\alpha = 0$.

Finally, Fig. 6 depicts the variation in flight altitude over time for different CubeSat with form factor 2U and 3U. This plot demonstrates the gradual decay in altitude, which is typical for satellites in low Earth orbit due to atmospheric drag. Also, this graphic demonstrates that the CubeSat 2U exhibits a faster loss of altitude compared to the CubeSat 3U.

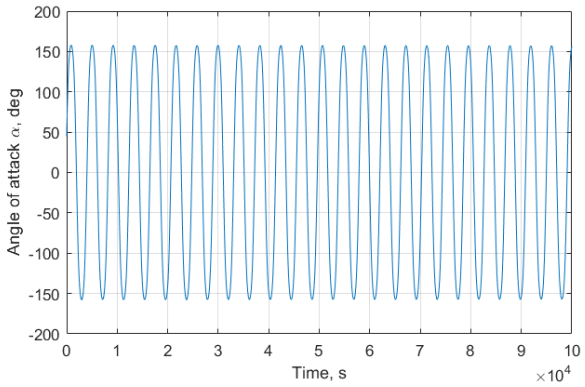

Fig. 3. Variation of the angle of attack during simulation.

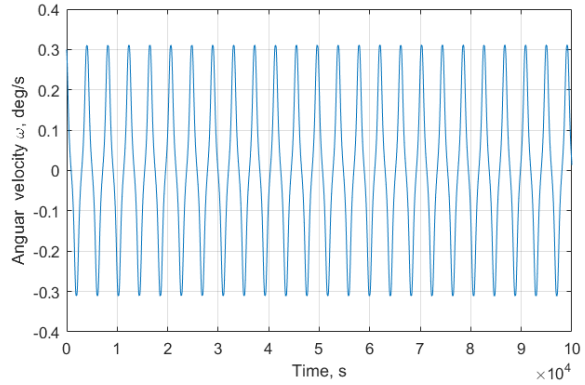

Fig. 4. Variation of the angular velocity during simulation.

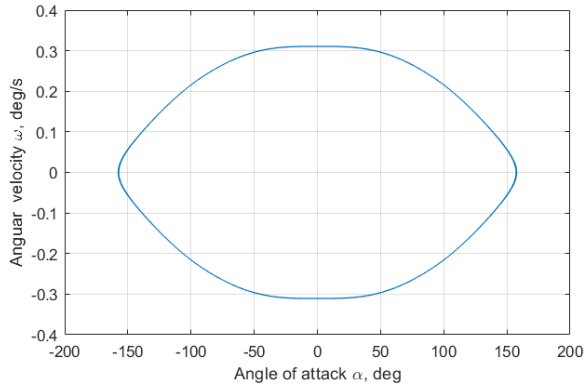

Fig. 5. Phase portrait during simulation.

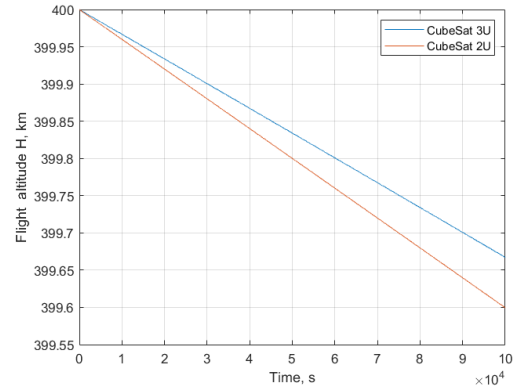

Fig. 6. Flight altitude during simulation for different CubeSats.

E. Validation and Verification

The validation and verification of the developed software tool were conducted through a combination of analytical benchmarking, sensitivity analysis, and software testing methodologies to ensure both numerical accuracy and computational reliability.

To validate the accuracy of the numerical simulations, benchmark comparisons were performed against analytical solutions derived from rigid-body dynamics. The presented mathematical models for angular motion serve as the theoretical reference for evaluating the correctness of the implemented models. For specific cases where closed-form solutions exist, numerical integration results were shown to closely replicate the expected angular velocity trajectories and phase portraits. Additionally, limiting cases were analyzed, including scenarios where aerodynamic torques were negligible, allowing direct verification against classical torque-free rotational motion solutions. The capacity of the software to capture equilibrium conditions and the expected transitions between oscillatory and rotatory regimes further reinforced the validity of the underlying mathematical framework.

Beyond validation with theoretical models, a sensitivity analysis was conducted to assess the robustness of the software in response to variations in physical parameters. Perturbations in the transverse and longitudinal moments of inertia were introduced to evaluate their effects on rotational stability, confirming that small deviations in these properties resulted in expected dynamic shifts consistent with established CubeSat dynamics theory. The center-of-mass displacement along the longitudinal axis was systematically varied to examine its impact on aerodynamic torques, demonstrating the ability to predict stability conditions influenced by structural asymmetry. Additionally, the effects on altitude were examined, confirming that at lower altitudes, increased atmospheric drag induced more pronounced oscillatory damping, while at higher altitudes, gravitational torques became the dominant perturbation force. These results closely aligned with theoretical expectations and prior research on CubeSat aerodynamics.

In addition to physical validation, software verification techniques were applied to ensure the integrity of the computational implementation. A unit testing framework was integrated within the MATLAB environment, employing modular tests for key computational functions, including numerical integration routines, moment calculations, and phase portrait generation. Each component was individually validated against known analytical solutions or benchmark datasets to detect discrepancies. Furthermore, consistency checks were performed by systematically varying input parameters and ensuring that the outputs adhered to expected trends. Edge-case testing was also conducted to evaluate system behavior under extreme parameter values, ensuring numerical stability and robustness.

V. Discussion

The results obtained from the developed CubeSat Angular Motion Simulator demonstrate its effectiveness in visualizing and analyzing the angular motion dynamics of CubeSats in low Earth orbit. The phase portraits generated by the tool confirm the expected motion behaviors, distinguishing between oscillatory and rotatory regimes based on initial conditions. The clear identification of separatrices highlights the critical transition points between these regimes, providing valuable insights for both educational and preliminary design applications.

From an educational standpoint, the simulator bridges the gap between theoretical learning and practical application, raising critical questions about how simulation-based learning affects conceptual understanding of real-world physical phenomena. The reliance on digital models may shape how students perceive and interact with physical reality, potentially impacting their approach to problem-solving and experimental validation in aerospace engineering. By providing real-time visualization and interactive parameter adjustments, the tool enhances comprehension in aerospace engineering curricula, where abstract mathematical models often present significant learning challenges.

Despite its strengths, the current version of the tool has certain limitations. The assumption of planar angular motion simplifies the analysis but excludes three-dimensional effects, which may become significant in more complex mission scenarios. Additionally, the exclusion of external perturbations such as geomagnetic torques and solar radiation pressure limits the applicability of the model for higher-fidelity mission simulations. Future work should focus on extending the model to include these effects, as well as incorporating real CubeSat telemetry data for validation. Enhancing the tool with additional control system simulations could further increase its relevance for practical mission planning and research on space dynamics.

VI. Conclusion

This work introduced an interactive software tool designed to simulate and visualize CubeSat angular motion, providing an accessible platform for exploring the principles of rotational dynamics. The features incorporated into the tool ensure computational efficiency while maintaining pedagogical value, making the tool ideal for both educational settings and preliminary CubeSat design evaluations.

Thus, this study contributes to the growing body of educational tools designed to make knowledge about space technology more accessible and comprehensible for the next generation of space professionals. The presented approach not only serves as an educational resource but also as a means for CubeSat developers to better assess attitude control strategies in early design and mission planning stages.

Performance Evaluation and Selection of Appropriate Congestion Control Algorithms for MPT Networks

Naseer Al-Imareen, Gábor Lencse
Department of Telecommunications, Széchenyi István University, Győr, Hungary

***Abstract*—Recent academic research highlights a growing interest in multipath technologies, which offer promising solutions to networking challenges in complex environments. This interest is reflected in the emergence of protocols such as Multipath TCP (MPTCP) and Multipath UDP-in-GRE (MPT-GRE). The development of network protocols, particularly various iterations of the Transmission Control Protocol (TCP), has been distinguished by congestion detection and control algorithms, such as HighSpeed, CUBIC, Reno, LP, BBR, and Illinois. This paper evaluates the performance and suitability of these algorithms for multipath MPT-GRE networks under varying conditions, including delay, jitter, and data loss at different transmission speeds (both symmetric and asymmetric). Using StarBED resources, we applied delay, jitter, or packet loss to one of two physical paths to simulate congestion. The results demonstrate that some algorithms, HighSpeed and BBR among them, significantly enhance Quality of Service (QoS) metrics and network throughput in multipath MPT-GRE networks. These findings provide valuable insights into their performance and practical applications.**

***Keywords*—Packet loss; congestion control; MPT-GRE; delay; throughput; jitter**

I. Introduction

The rapid advancement of network applications has increased demands on network infrastructure, posing challenges to its capacity and efficiency. Many emerging applications require high bandwidth and low latency to function effectively. These requirements strain current network capabilities, exacerbating bottlenecks and highlighting the need for robust, efficient data transmission methods [1] [2].

Modern communication technology supports a variety of devices equipped with multiple interfaces, enabling networks and applications to handle complex communication demands. However, the effectiveness of these communication sessions is constrained by the TCP/IP protocol architecture, which, by default, supports only single-session handling. Leveraging multiple network interfaces during communication sessions enhances flexibility and reliability, particularly in addressing network disruptions. By dynamically switching traffic between available paths, communication systems can ensure uninterrupted data transmission, even in the face of link failures, congestion, or performance degradation [3].

This approach significantly improves fault tolerance, load balancing, and network stability, making it an essential feature for modern networking environments that demand high reliability and performance.

To address the growing demand for efficient multipath solutions, numerous methods have been developed, including MPT-GRE [4] and MPTCP [5]. MPT-GRE enables the creation of a virtual tunnel across multiple physical paths, distinguishing it from alternatives like MPTCP and Huawei's Generic Routing Encapsulation (GRE) Tunnel Bonding Protocol. While multipath approaches offer significant advantages, throughput performance in these networks often suffers due to delays and congestion [6].

Various TCP congestion control algorithms, such as HighSpeed, LP, Reno, Vegas, and CUBIC, have been designed to mitigate these challenges. These algorithms detect, control, and preempt congestion, reducing packet loss and delays. Their effectiveness stems from their ability to monitor and manage packet transmission from source to destination. Some algorithms dynamically adjust the congestion window size based on round-trip time (RTT), while others, particularly those optimized for high-bandwidth networks, expand the window to enhance throughput.

Efficient congestion management in multipath networks improves stability, ensures proper packet reordering, and minimizes data loss and delays. Furthermore, the fair allocation of network resources among competing packets prevents bandwidth monopolization, safeguarding throughput and overall network performance [7] [8].

Multipath congestion control is an active area of research focused on maximizing resource utilization by leveraging the available bandwidth across multiple paths while maintaining fairness toward competitive single-path transfers—a constraint referred to as TCP-friendliness. Congestion control techniques are crucial in optimizing network resource use, enabling throughput aggregation, and reducing bandwidth waste.

However, the rise of multipath communication has introduced new challenges. Research has identified side effects, particularly the lack of TCP-friendliness in some implementations. For example, the uncoupled congestion control approach in Multipath TCP (MPTCP) treats each sub flow as an independent TCP connection. This can result in imbalanced resource allocation, where individual subflows dominate bandwidth, leading to unfairness and performance degradation in multipath network environments [8][9].

The MPT-GRE software is designed to enhance data transmission by distributing the load across multiple paths, often achieving throughput capacities close to the combined total of the physical paths [10]. The integration of congestion control algorithms in multipath networks holds significant promise for building robust and efficient network infrastructures. These

algorithms ensure fair resource allocation and improve overall network performance by enhancing fault tolerance, reducing congestion, and increasing throughput through effective traffic management across multiple paths.

Our contributions to this paper are as follows:

1) Evaluation of congestion control algorithms: We analyze multiple congestion control algorithms within multipath MPT-GRE network environments.

2) Performance assessment under diverse network conditions: We assess the performance of these algorithms under various network conditions, including delay, jitter, combined delay and jitter, and packet loss. The evaluation also considers both symmetric and asymmetric transmission speed environments.

3) Identification of throughput-optimizing algorithms: We identify algorithms that significantly enhance network throughput under the evaluated network conditions.

II. Related Work

Many studies have explored congestion control approaches in multipath networks, each focusing on optimizing network performance in various ways. These studies have examined how congestion control algorithms can effectively handle multiple paths, reduce packet loss, minimize latency, and ensure fair resource allocation among packet flows. Additionally, researchers have worked on utilizing algorithms that can adapt dynamically to changing network conditions, such as fluctuations in bandwidth, jitter, and delay, to maximize throughput and minimize congestion.

Szabolcs Szilágyi and Imre Bordán [11] examined the impact of various TCP congestion control algorithms on multipath communication technologies, specifically MPTCP and MPT-GRE. The researchers compared the performance of seven congestion control algorithms (CUBIC, Reno, Illinois, Scalable, Veno, High-Speed, and Vegas) in quad-path IPv4/IPv6 Fast Ethernet environments. Their findings show that CUBIC provided the best performance for MPTCP and MPT-GRE, while Vegas had the lowest performance. The study used these comparisons to emphasize CUBIC's effectiveness as the default algorithm in modern operating systems and aimed to extend the evaluation to more advanced network environments and recent TCP algorithms.

To address the energy consumption challenge in Multipath TCP (MPTCP), the authors [3] analyzed existing congestion control algorithms and identified the key factors influencing energy efficiency. They conducted real-world experiments using the MPTCP Linux kernel and found that energy consumption is closely related to throughput, path delay, and varying network scenarios. To improve energy efficiency, they proposed a congestion control model with a window-increasing factor to direct traffic toward low-delay paths and an energy-aware compensatory parameter for hierarchical Internet topologies. Their experiments confirmed that the enhanced model can increase energy efficiency without compromising transmission performance.

Yu Cao et al. [12] addressed the limitations of coarse-grained load balancing in multipath congestion control, which relies heavily on packet loss as a congestion indicator. They formulated the "Congestion Equality Principle," showing that fair and efficient traffic shifting occurs when flows equalize perceived congestion across all paths. To achieve this, they proposed the delay-based algorithm Weighted Vegas (wVegas), which uses queuing delays for fine-grained load balancing. Simulations showed that wVegas responds faster to congestion changes than loss-based algorithms, improving intra-protocol fairness and reducing packet loss. The study highlights wVegas as a complement to algorithms like TCP-Vegas and TCP-Reno.

Balancing fairness, responsiveness, and window oscillation in Multipath TCP (MPTCP) congestion control is crucial for efficient multipath communication. MPTCP distributes traffic across multiple paths to enhance resource utilization and connection robustness. However, this distribution poses the challenge of adjusting transmission rates across these paths without disrupting other network traffic. To address this, researchers [13] proposed a novel fairness-based congestion control algorithm (FCCA) designed to enhance fairness among subflows while maintaining key performance metrics such as responsiveness and stability of the congestion window. FCCA dynamically adjusts the congestion window for each path based on real-time congestion feedback, optimizing bandwidth usage, improving network performance, and ensuring smooth traffic flow even under varying congestion conditions. The introduction of FCCA marks a significant step toward achieving more equitable and efficient traffic management in MPTCP, contributing to enhanced network performance and fairness in multipath communication scenarios.

III. Background

This section discusses the MPT-GRE multipath network and congestion control algorithms in detail.

A. MPT-GRE Network Technology

The MPT-GRE network is a multipath technology based on the GRE-in-UDP tunnel specification (IETF RFC 8086 [2]). MPT-GRE extends the traditional GRE-in-UDP architecture by supporting multiple physical paths and enhancing network performance through load balancing. Using the UDP source port for hashing distributes traffic more efficiently across numerous equal-cost multipath (ECMP) routes. This architecture shares some similarities with Multipath TCP (MPTCP) in its utilization of multiple paths. Still, it differs significantly in its underlying technology. MPT-GRE relies on UDP at the transport layer, building on GRE-in-UDP for a tunnel IP layer that supports TCP and UDP protocols. Huawei's GRE Tunnel Bonding Protocol has a similar objective but lacks UDP encapsulation, limiting its scalability to just two physical interfaces. In contrast, MPT-GRE's use of GRE-in-UDP offers greater flexibility, enabling a more scalable and robust multipath solution.

The MPT-GRE software architecture, shown in Fig. 1, introduces a logical tunnel layer that works independently of the physical network paths. This unique approach sets MPT apart from traditional TCP/IP protocols by directing application layer data to a tunnel path instead of directly to a physical path. The MPT-GRE software distributes incoming packets from the

logical tunnel interface across available physical paths in this environment. It allows for seamless multipath communication for applications, which only need to interact with the tunnel interface. This mechanism enables efficient traffic redistribution without changing the application's communication model. Additionally, the MPT-GRE software supports the transition to IPv6, as both IP tunnel and path versions can operate independently within the MPT-GRE library. Fig. 2 shows how data packets are transmitted and received in MPT-GRE.

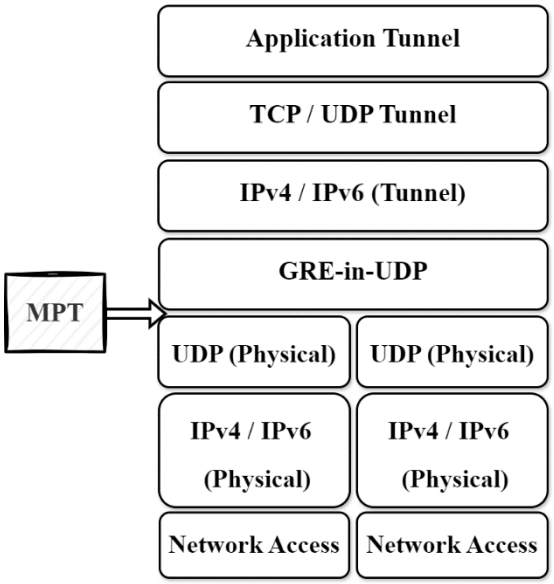

Fig. 1. Conceptual architecture of MPT-GRE [4].

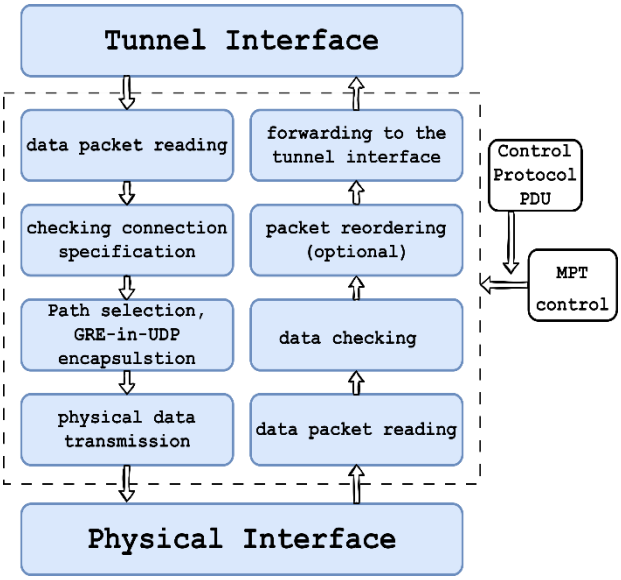

Fig. 2. Theoretical process of the MPT-GRE mechanism [4].

Upon receiving a packet from the tunnel interface, the MPT-GRE software identifies the connection specification and determines traffic distribution across multiple paths. The user data packet is then encapsulated into a GRE-in-UDP data unit. This unit may include optional GRE Sequence Numbers for reordering. The GRE header contains 16 bits of zeros and identifies the protocol type (e.g., 0x0800 for IPv4 or 0x86DD for IPv6). The GRE-in-UDP data unit is encapsulated within a UDP/IP data unit with the destination port set to 4754, which is the GRE-in-UDP port. The packet is then transmitted via the designated physical interface. Upon arrival, the MPT-GRE software verifies the packet by checking the destination port, validating the connection based on the tunnel IP header, and performing checks on the GRE sequence number or GRE Key value, if present. If the packet passes all checks without reordering, it is forwarded to the transport and application layers via the tunnel interface. If reordering is necessary, the packet is temporarily stored in a buffer for reordering before being transmitted [14].

B. Congestion Control Algorithms

Congestion control in computer networks is crucial for ensuring efficient data transfer and preventing issues such as increased latency, packet loss, and reduced throughput [15]. When network demand exceeds available bandwidth or specific data flows dominate resources, congestion control algorithms are essential for maintaining network stability. These algorithms handle transmission data by dynamically adjusting transmission rates and implementing mechanisms like slow start and fast retransmission, which help to alleviate congestion and reduce packet loss. They are designed to respond to dynamic and unpredictable network traffic, employing different strategies to manage congestion by monitoring packet flows and adjusting sending rates accordingly [11][16]. Widely used congestion control algorithms, such as LP, Veno, H-TCP, CUBIC, Reno, Hybla, Vegas, HSTCP, BBR, Westwood, BIC, and Scalable, adjust the rate of transmission to adapt to varying network structures and conditions. For example, CUBIC and Vegas monitor estimated round-trip times (RTT) to detect congestion and dynamically adjust transmission rates, while other algorithms like BBR estimate bandwidth to optimize throughput [17]. These algorithms are generally classified based on their method of detecting and responding to congestion as the following: loss-based, delay-based, hybrid (loss + delay), and bandwidth estimation-based algorithms [18][19][20][21].

1) Loss-based algorithms: Loss-based congestion control algorithms detect network congestion by identifying packet loss. Typically, this occurs when network buffers overflow due to congestion. When packet loss is detected, the sender reduces the congestion window, which is the amount of data allowed in transit without acknowledgment. The sender then gradually increases the congestion window to probe the available bandwidth. These algorithms use packet loss as a congestion signal, detected through duplicate acknowledgments or timeouts. Upon congestion detection, the sender reduces the congestion window, often by half, and slowly increases it using strategies like additive increase multiplicative decrease (AIMD). Examples of loss-based algorithms include Reno, shown in Eq. (1) and (2), a traditional algorithm that reduces the congestion window after detecting packet loss, and CUBIC, shown in Eq. (3), which employs a cubic function to manage window growth but still relies on packet loss for congestion detection.

Reno equations:

$$cwnd = cwnd + \frac{1}{cwnd}\ (\ Additive\ Increase\ ) \quad (1)$$

$$cwnd = \frac{cwnd}{2}\ (\ Multiplicative\ Decrease\ ) \quad (2)$$

CUBIC equation:

$$cwnd(t) = C \cdot (t - K)^3 + W_{max} \quad (3)$$

where C is a scaling element that holds the window growth rate, and t is the time since the last congestion event (loss), whereas $K = \sqrt[3]{\frac{W_{max} \cdot \beta}{C}}$ is the time when the window moves W_{max} again. And W_{max} is the congestion window size at the last congestion event (maximum window size before packet loss). β represents a multiplicative decrease factor, usually set at 0.7.

HighSpeed, Binary Increase Congestion Control (BIC), Scalable, and Hamilton TCP (H-TCP) are advanced loss-based congestion control algorithms designed specifically for high-speed, high-latency networks. HighSpeed aggressively increases the standard congestion window, enhancing throughput in environments with a large bandwidth-delay product (BDP) shown in Eq. (4). BIC uses a binary search method for adjusting the window size, effectively balancing rapid bandwidth probing with a cautious approach to packet loss, as shown in Eq. (5). Scalable adopts a fixed-increment growth strategy based on the current window size, allowing it to maintain high throughput in high-capacity networks, as shown in Eq. (6). On the other hand, H-TCP dynamically adjusts its window growth by monitoring changes in network congestion and round-trip time (RTT), enabling it to respond effectively to fluctuations in network conditions and improve performance in high-BDP scenarios shown in Eq. (7).

HighSpeed equation:

$$cwnd = cwnd + \frac{a(cwnd)}{cwnd} \quad (4)$$

where a ($cwnd$) is an adaptive increase factor that scales with the size of $cwnd$. This factor becomes more significant as $cwnd$ grows.

BIC equation:

$$cwnd = \frac{(cwnd_{max} + cwnd_{min})}{2} \quad (5)$$

where $cwnd_{\max}$ and $cwnd_{\min}$ represent the maximum and minimum congestion window sizes that have been reached so far.

Scalable equation:

$$cwnd = cwnd + a.cwnd \quad (6)$$

where α is a constant scaling factor typically set to a small value, such as 0.01 to 0.1.

H-TCP Equation:

$$cwnd = cwnd + (2 \times (t - T)) \quad (7)$$

where t is the elapsed time since the last congestion event, and T is a constant.

2) Delay-based algorithms: Delay-based algorithms monitor round-trip time (RTT) changes or delays to detect network congestion, allowing them to adjust the sending rate before packet loss occurs. For example, Vegas continuously monitors RTT to adjust the congestion window size based on observed delays, as shown in Equation 8. Hybla compensates for longer RTTs by scaling window growth proportionally to RTT values, improving performance in high-latency networks, as shown in Eq. (9). On the other hand, LP (Low Priority) reduces its window size when delays increase, prioritizing higher-priority traffic and ensuring smooth operation in mixed-traffic environments, as shown in Eq. (10) and Eq. (11).

Vegas equations:

$$\Delta = \left(Expected\ Throughput - Actual\ Throughput\right) \quad (8)$$

$$cwnd = cwnd + \alpha, \quad if\ \Delta < \gamma$$
$$cwnd = cwnd - \beta, \quad if\ \Delta > \delta$$

where α is the increase factor. β is the decrease factor. Δ is the difference between expected and actual throughput. γ and δ are thresholds for adjusting the window.

Hybla equation:

$$\rho = \frac{RTT_{reference}}{RTT_{current}} \quad (9)$$

where $RTT_{reference}$ is a reference for round-trip time (RTT), usually for a low-latency network

LP equation:

$$\Delta = \frac{(RTT_{currnt} - RTT_{min})}{RTT_{min}} \quad (10)$$

If Δ > γ, LP reduces the congestion window as follows:

$$cwnd_{new} = \frac{cwnd_{current}}{2} \quad (11)$$

where the threshold for the increase in RTT is denoted by γ.

3) Hybrid (Loss + Delay) algorithms: These algorithms leverage packet loss and delay to adjust the congestion window. For example, Illinois uses delay and loss metrics to adjust the window size dynamically, enabling more adaptable congestion control. Veno combines Reno and Vegas's strategies, using delay and packet loss signals to optimize the balance between performance and congestion avoidance. Similarly, YEAH uses delay as an early indicator of congestion and relies on packet loss as a secondary, more conservative signal to adjust the transmission rate.

Illinois equation:

$$cwnd = cwnd + \frac{\alpha(delay)}{cwnd} \quad (12)$$

Veno equation:

$$cwnd_{new} = cwnd_{current} + \frac{1}{cwnd_{current}}\ (Add.Increase) \quad (13)$$

YEAH Equation:

$$\mathrm{cwnd}_{\mathrm{increase}} = \frac{\mathrm{MSS}}{\mathrm{RTT}_{\mathrm{min}}} \quad (14)$$

where, MSS stands for Maximum Segment Size, referring to the most significant amount (in bytes) of data that a TCP segment can carry in the payload part of a packet, excluding the TCP and IP headers.

4) Bandwidth estimation-based algorithms: These algorithms estimate the available bandwidth in the network and adjust the sending rate accordingly, optimizing performance based on network capacity. For example, TCP Westwood estimates bandwidth using packet loss and throughput measurements. It adjusts the congestion window dynamically, making it particularly effective in wireless networks where packet loss is common. Similarly, Bottleneck Bandwidth and Round-trip propagation time (BBR) models available bandwidth and round-trip delay to efficiently manage the congestion window and transmission rate.

Westwood equation:

$$\text{BWE} = \frac{\sum ACKed\_data}{\Delta t} \quad (15)$$

where *BWE* is the bandwidth estimate, *ACKed_data* is the amount of acknowledged data, and Δt is the time interval between receiving ACKs.

BBR equation:

$$\text{Throughput} = \frac{\text{Bottleneck Bandwidth}}{RTT_{min}} \quad (16)$$

where Bottleneck Bandwidth is the maximum rate at which data can be transmitted along the path.

IV. Test Environment

A. Hardware Environment Setting

As illustrated in Fig. 3, the test setup consisted of three Dell PowerEdge R650 servers, each equipped with the following:

- CPU: Intel Xeon Gold 6330N 2.2G, 28C/56T, 11.2GT/s, 42M cache, turbo, HT (165W) DDR4-2666 x 2.
- Memory: 32GB RDIMM, 3200MT/s, dual rank 16Gb base x 16 = 512GB.
- Storage: SSD 480GB SSD SATA Read Intensive 6Gbps 512, 2.5inch Hot Plug x 2 (RAID1).
- Network Interface: 25GigE×4.

This experimental design was carefully structured to evaluate the performance of the MPT-GRE multipath network, mainly focusing on the impact of congestion control algorithms on throughput and network efficiency. The experiments were conducted using Ubuntu 22.04.4 LTS (Jammy Jellyfish) / Linux operating system servers. These experiments were designed to evaluate the performance of the MPT-GRE tunnel throughput library and to monitor and prove the effectiveness of various congestion control algorithms.

B. MPT-GRE Configuration Setting

The version of MPT used in this experiment, *mpt-gre-lib64-2019.tar.gz*, is available publicly from GitHub [22]. Two primary configuration files within the MPT installation directory were modified to enable the effective operation of the MPT-GRE multipath system across the network infrastructure.

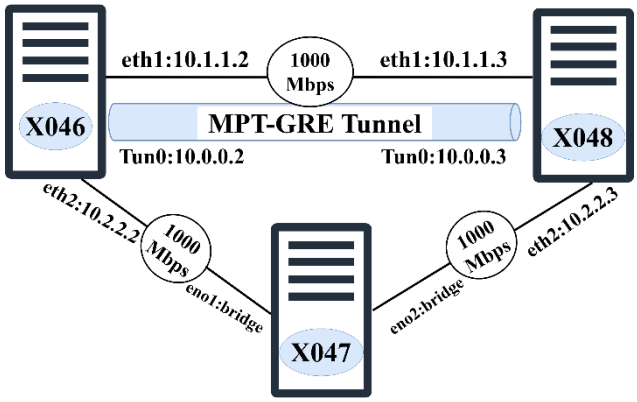

Fig. 3. Experimental topology of the MPT-GRE multipath network.

The first file, conf/interface.conf, contains essential parameters for network interfaces and tunnels. Adjustments were made to specify the Local Command UDP Port Number for managing communication between MPT-GRE and network interfaces; define the Interface Number, maximum transfer unit (MTU), and permissions for remote requests; and establish the tunnel interface name, IPv4 address, and subnet prefix. This file also manages tunnel traffic protocols, with the same configuration mirrored on the second server to maintain consistency in the multipath environment.

The second file, conf/connections/IPv4.conf, manages logical connections and defines transmission paths. Each MPT-GRE tunnel has its own connection file, specifying IP addresses for both tunnel endpoints and using IPv4 encapsulation within an IPv4 GRE tunnel. Previous publications [10][23] have provided detailed information on MPT-GRE configuration settings, and the updated configuration files for this study have also been made available on GitHub [24].

V. Experiments, Results, and Performance Analysis

The primary objective of this study is to confirm the influence of congestion control algorithms on MPT-GRE multipath networks and determine the optimal throughput aggregation value for the tunnel. A detailed evaluation of tunnel throughput is critical for enhancing our understanding of MPT-GRE operations.

Various scenarios were designed for the experiments to ensure precision and effectiveness. A Python script, available on GitHub [25], was employed to automate and facilitate the experimental process over a period of 30 seconds. This script not only enabled frequent execution but also automated the saving of tunnel throughput results, thereby enhancing consistency and repeatability. Additionally, a set of congestion control algorithms was integrated into the Python code and executed using iperf3 [26].

To evaluate the impact of various Quality of Service (QoS) metrics, we used a middle server to adjust traffic parameters with the Linux *tc* command, experimenting with delay, jitter, packet loss, and transmission speed limits. Each set of

congestion control algorithms was tested under various scenarios using the same QoS metrics.

In the first scenario, the transmission speeds were configured with eth1 set at 1000 Mbps, while eth2 varied incrementally from 100 Mbps to 1000 Mbps in steps of 100 Mbps. In the second scenario, similar network conditions were applied; the transmission speeds were reduced tenfold, with eth1 set to 100 Mbps and eth2 ranging from 10 Mbps to 100 Mbps in increments of 10 Mbps.

Due to the large number of results without loss of generality, the remaining transmission cases follow the same approach. The following cases are discussed in detail:

- The symmetrical case: *eth1 = 1000 Mbps and eth2 = 1000 Mbps* under the effect of all QoS metrics.
- The case of asymmetric paths: *eth1 = 100 Mbps* and *eth2 = 10, 20, 30... 100 Mbps* under the effect of delay and packet loss.

A. First Scenario: Analyzing QoS of Symmetrical Paths

1) Assessment impact of delay metric: We applied delays across both server network interfaces, ensuring bidirectional effects on transmitted packets. The delay parameter *x* was set at intervals of 10 ms, 20 ms, 30 ms, 40 ms, and 50 ms, using the *tc* command:

tc qdisc add dev eth1 root netem delay xms

For example, when symmetric paths (eth1=1000 Mbps and eth2=1000 Mbps) are used, the impact of the delay metric on loss-based algorithms, delay-based algorithms, hybrid algorithms, and bandwidth estimation-based algorithms is as is shown in Fig. 4. Analyzing throughput values across different congestion control algorithms under various delay conditions reveals key performance characteristics for each category.

The HighSpeed algorithm demonstrates the throughput achieving 1160 Mbps at 10 ms in the loss-based algorithms category. It sustains a relatively high performance of 202 Mbps even under moderate delays, making it particularly effective in environments with low to medium delays. The Scalable and CUBIC algorithms also perform well in this category, especially at lower delays; the Scalable algorithm reaches 531 Mbps at 20 ms. While CUBIC maintains competitive throughput as delay increases, it is less effective than the HighSpeed algorithm. The BIC algorithm offers balanced performance, achieving high throughput at low delays (1160 Mbps at 10 ms) and proving suitable in mixed delay environments. Therefore, HighSpeed and Scalable are the optimal loss-based algorithms for their peak performance and resilience under medium delays.

In the delay-based algorithms, at lower delay values (10 ms), Hybla achieves a higher throughput of 1180 Mbps compared to LP's 1080 Mbps, demonstrating better performance under minimal delay conditions. However, as the delay increases from 20 ms to 50 ms, LP outperforms Hybla, maintaining higher throughput at greater delays. For example, LP achieves 239 Mbps compared to Hybla's 178 Mbps at 40 ms. In contrast, Vegas experiences a steep drop in throughput as delay increases, making it less suitable for high-delay conditions.

Hence, while Hybla excels in low-delay situations, LP is the better option for higher-delay scenarios.

Within the hybrid (loss + delay) algorithms, Illinois stands out for its high throughput, reaching up to 1150 Mbps at 10 ms and demonstrating adaptability even at higher delays, achieving 215 Mbps at 40 ms. This makes it highly suitable for environments characterized by both loss and delay. Veno and YEAH exhibit medium performance but show sharper reductions in throughput as delay increases.

Therefore, Illinois is the most effective hybrid algorithm, excelling in mixed loss and delay conditions while consistently maintaining high throughput. In contrast, Veno and YEAH perform well in low-delay scenarios but underperform in higher-delay environments.

2) Assessment impact of jitter metric: We measured the throughput of the MPT-GRE tunnel under jitter values of 2 ms, 4 ms, 6 ms, 8 ms, and 10 ms while keeping the delay set to zero. This was done both with and without congestion control algorithms. To enable a more comprehensive assessment, we also combined delay with jitter using the following command:

tc qdisc add dev eth1 root netem delay dms jms

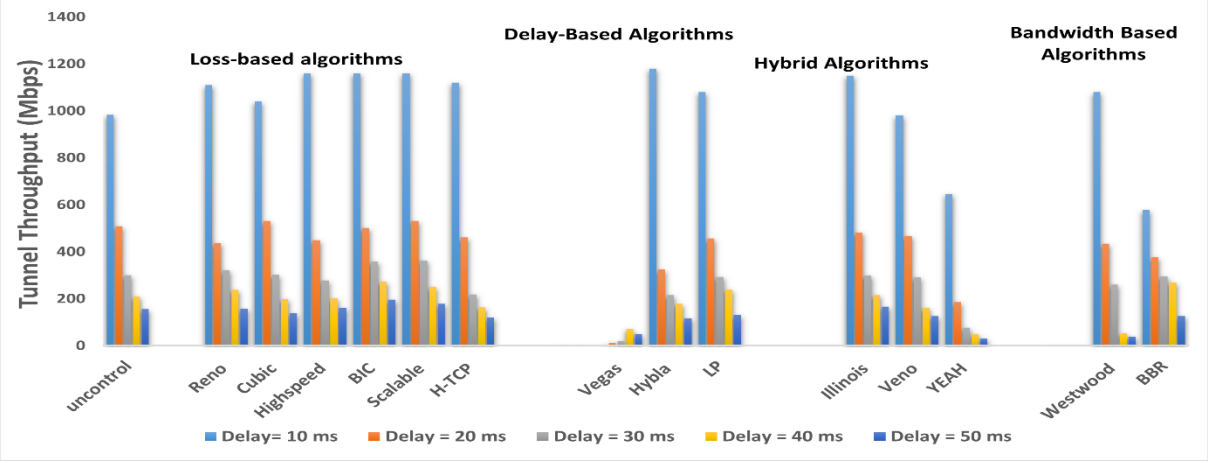

Fig. 4. Throughput performance of the MPT-GRE tunnel under varying delay metrics (eth1 = 1000 Mbps, eth2 = 1000 Mbps)/.

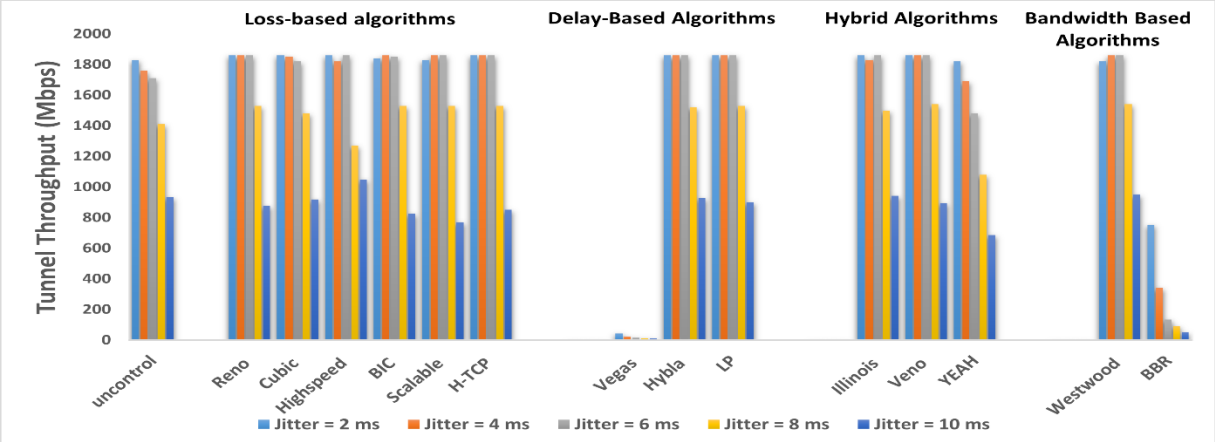

Fig. 5. Throughput performance of the MPT-GRE tunnel under varying jitter metrics (eth1 = 1000 Mbps, eth2 = 1000 Mbps).

The analysis presented in Fig. 5 illustrates the performance trends of various congestion control algorithms based on throughput at different jitter levels. Reno exhibits a consistent throughput of 1860 Mbps in the loss-based algorithms under low to moderate jitter conditions (ranging from 2 to 6 ms). However, its performance significantly declines to 1530 Mbps at 8 ms and drops further to 876 Mbps at 10 ms, indicating that it is sensitive to higher jitter levels. Other algorithms like CUBIC and H-TCP maintain relatively good throughput, showing reductions as jitter increases. Scalable and BIC perform well up to 8 ms, but they experience a significant decline in performance at 10 ms. In contrast, HighSpeed displays stable performance under low jitter levels and maintains a better throughput of 1270 Mbps at 8 ms and 1050 Mbps at 10 ms than other algorithms under higher jitter conditions.

HighSpeed's balanced performance makes it more suitable for environments with increased jitters, while Reno performs better in certain low-jitter situations.

In the delay-based algorithms, throughput remains high for Hybla and LP, maintaining a consistent 1860 Mbps under low to moderate jitter conditions (2–6 ms). However, as jitters increase to 8 ms and 10 ms, their throughput decreases, with Hybla reaching 1520 Mbps and 929 Mbps and LP achieving 1530 Mbps and 900 Mbps, respectively. In contrast, Vegas performs poorly across all jitter levels. Hybla and LP effectively manage moderate jitter, whereas Vegas is unsuitable for jitter-sensitive environments.

Of the hybrid (loss + delay) algorithms, Illinois and Veno show robust throughput despite jitter. Illinois performs slightly better at higher jitter levels, achieving 943 Mbps at 10 ms, while Veno reaches 895 Mbps. However, YEAH is less adaptable in high-jitter scenarios.

Finally, in the bandwidth estimation-based algorithms, there is a considerable difference in the performance of Westwood and BBR under jitter conditions. For example, at 10 ms of jitter, Westwood significantly outperforms BBR, achieving 949 Mbps compared to BBR's 51 Mbps.

Overall, some congestion control algorithms performed better than the Uncontrolled case (the performance baseline without applying any congestion control algorithm). For instance, the HighSpeed congestion control algorithm outperformed the Uncontrolled case in all scenarios.

To better understand the effects and identify the optimal congestion control algorithm, delay and jitter were applied simultaneously, with the jitter value set to 20% of the delay. Fig. 6 analyzes the performance of various congestion control algorithms compared to the Uncontrolled case. Several algorithms performed better than the Uncontrolled throughput, particularly under different delay and jitter conditions.

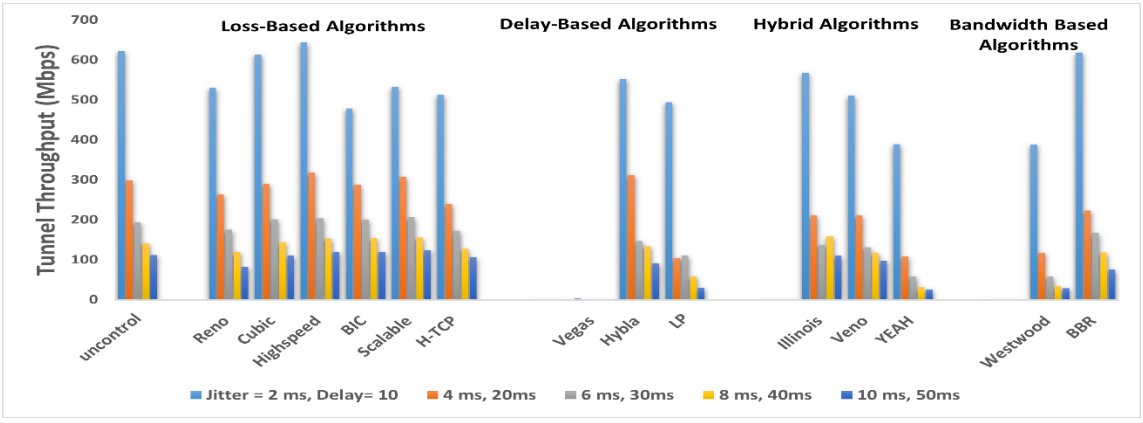

Fig. 6. Throughput performance of the MPT-GRE tunnel under combined delay and jitter metrics (eth1 = 1000 Mbps, eth2 = 1000 Mbps).

In comparison, Reno shows a more rapid and consistent decline in throughput, starting at 530 Mbps and dropping to 82.6 Mbps under higher jitter and delay, indicating a less adaptive response to congestion than the Uncontrolled case. The Uncontrolled case performs better than CUBIC and BIC under low delay and jitter conditions, specifically at 2 ms/10 ms and 4 ms/20 ms. However, as network conditions worsen, these algorithms outperform the Uncontrolled case.

Notably, the BIC algorithm excels under higher delay and jitter conditions, achieving throughput values of 200 Mbps, 154 Mbps, and 120 Mbps at 6 ms/30 ms, 8 ms/40 ms, and 10 ms/50 ms, respectively. Similarly, the Scalable algorithm outperforms the Uncontrolled case as delay and jitter increase, with throughput values of 308 Mbps, 206 Mbps, 156 Mbps, and 124 Mbps under jitter from 4 ms to 10 ms and delay from 20 ms to 50 ms. In contrast, the Uncontrolled case achieves 193 Mbps, 142 Mbps, and 112 Mbps under the same conditions, clearly showing lower throughput than Scalable and BIC as delay and jitter increase.

The HighSpeed algorithm significantly outperforms the Uncontrolled case and other algorithms, achieving 644 Mbps at jitter = 2 ms, delay = 10 ms, and maintaining a higher throughput of 120 Mbps even under the highest jitter and delay conditions. This reflects its superior congestion control capabilities.

Some of these algorithms, such as H-TCP, Hybla, and Illinois, achieved throughput levels close to those in the Uncontrolled case. In contrast, algorithms like Vegas, Westwood, YEAH, Veno, and LP consistently performed worse than the Uncontrolled values. Additionally, their performance declined as delay and jitter increased.

3) Assessment impact of packet loss metric: We tested packet loss conditions with loss rates set at 1%, 2%, 3%, 4%, and 5%. These rates were applied to network interfaces as follows:

tc qdisc add dev eth1 root netem loss x

Fig. 7 illustrates the impact of packet loss on the performance of various congestion control algorithms. Analyzing these results, it is evident that packet loss leads to a decline in throughput for all algorithms as the percentage of loss increases. This decrease is expected, as packet loss commonly results in retransmissions and delays, negatively affecting network throughput.

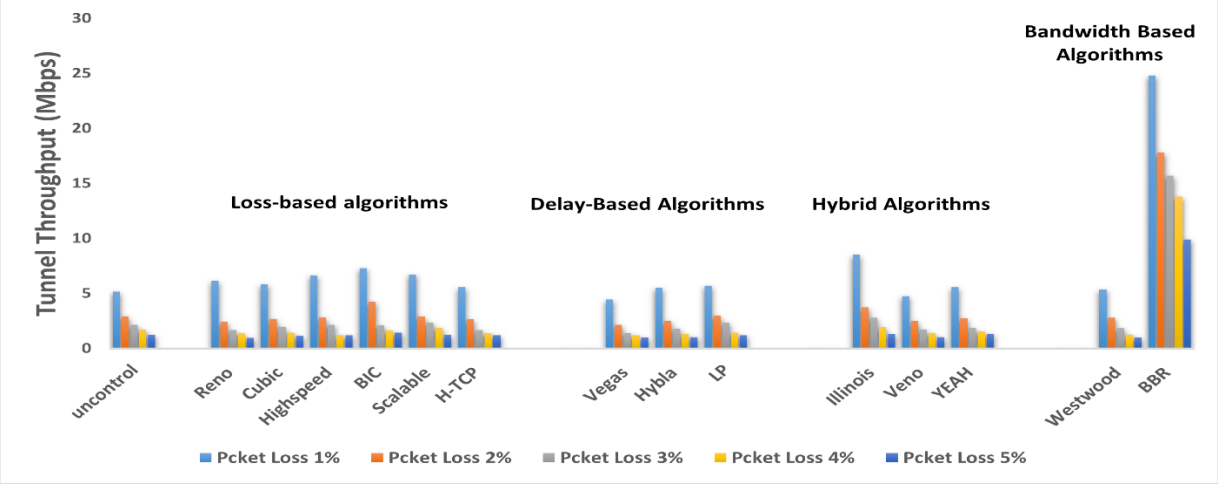

Fig. 7. Throughput performance of the MPT-GRE tunnel under varying packet loss metrics (eth1 = 1000 Mbps, eth2 = 1000 Mbps).

Among the congestion control algorithms examined, BBR is the most resilient to packet loss, consistently achieving significantly higher throughput across all levels of packet loss. Even at a packet loss rate of 5%, BBR maintains a throughput of 9.9 Mbps, far surpassing the performance of other algorithms. BBR's effectiveness minimizes the adverse effects of packet loss on throughput.

In contrast, the Uncontrolled case (i.e., without any congestion control algorithm applied) experiences substantial reductions in throughput as packet loss increases, with values dropping below 1.5 Mbps at 5% packet loss. These results highlight that congestion control algorithms significantly influence MPT-GRE tunnel throughput under varying packet loss conditions. While some algorithms perform better than others in the presence of packet loss, BBR stands out as the most promising option for maintaining higher throughput in challenging conditions.

B. *Second scenario: Analyzing QoS of Appropriate Algorithms*

In the second scenario, we analyzed:

- The HighSpeed congestion control algorithm compared to the Uncontrolled case on symmetric and asymmetric paths, where eth1 is set to 100 Mbps, and eth2 varies from 10 to 100 Mbps in increments of 10 Mbps under the delay metric.
- The BBR algorithm under the packet loss metric.

The results showed a significant increase in tunnel throughput under these specified delay and packet loss conditions. An analysis of the results, as demonstrated in Fig. 8, indicates that the HighSpeed algorithm achieved improved tunnel throughput. The MPT-GRE tunnel throughput performance between the HighSpeed algorithm and the

Uncontrolled case was assessed across symmetric and asymmetric transmission speeds and delay conditions. This analysis highlights how the HighSpeed algorithm enhances tunnel throughput in the MPT-GRE multipath network compared to the Uncontrolled case, particularly under increased network delays.

In the HighSpeed algorithm case, the MPT-GRE tunnel throughput shows a relatively modest decrease as delay increases. For example, at asymmetric transmission speeds (eth1 = 100 Mbps and eth2 = 10 Mbps), the throughput drops only slightly, from 103 Mbps to 102 Mbps, as the delay increases from 10 ms to 50 ms. At symmetric transmission speeds (eth1 = 100 Mbps and eth2 = 100 Mbps), the throughput decreases from 186 Mbps to 184 Mbps. This throughput stability under higher delays suggests that the HighSpeed congestion control algorithm efficiently manages congestion and minimizes throughput loss even as network delay increases.

In contrast, the Uncontrolled case exhibits a more significant degradation in MPT-GRE tunnel throughput with increasing delays. At asymmetric transmission speeds (eth1 = 100 Mbps and eth2 = 10 Mbps), throughput decreases from 102 Mbps at a 10 ms delay to 93.3 Mbps at a 50 ms delay, indicating greater sensitivity to delay. At symmetric transmission speeds (eth1 = 100 Mbps and eth2 = 100 Mbps), throughput drops from 183 Mbps at a 10 ms delay to 137 Mbps at a 50 ms delay. This reduced responsiveness to delay leads to more pronounced degradation in MPT-GRE tunnel throughput.

On the other hand, Fig. 9 illustrates how varying levels of packet loss affect the throughput aggregation of the MPT-GRE tunnel. Under packet loss conditions, the BBR algorithm maintains higher throughput across all transmission speeds compared to the Uncontrolled case. An exception occurs when eth1 = 100 Mbps and eth2 = 10 Mbps at 1% packet loss, where throughput for the Uncontrolled case and BBR is 24.4 Mbps and 23.9 Mbps, respectively—a slight difference.

For example, at transmission speeds of eth1 = 100 Mbps and eth2 = 20 Mbps, BBR achieves a throughput of 33.5 Mbps, while the Uncontrolled case drops to 14.8 Mbps, representing nearly a 56% reduction in MPT-GRE tunnel throughput. This trend persists at all packet loss rates, with BBR consistently mitigating the negative effects of packet loss more effectively than the Uncontrolled case.

As packet loss increases to 5%, both scenarios experience a decline in MPT-GRE tunnel throughput. However, the degradation is significantly more pronounced in the Uncontrolled case, particularly at higher transmission speeds. For instance, when eth1 and eth2 are set to 100 Mbps, throughput in the Uncontrolled case plummets to 1.05 Mbps at 5% packet loss, while BBR maintains a throughput of 7.83 Mbps.

This comparison highlights the resilience of the BBR algorithm, which consistently maintains significantly higher throughput levels than the Uncontrolled case under packet loss conditions.

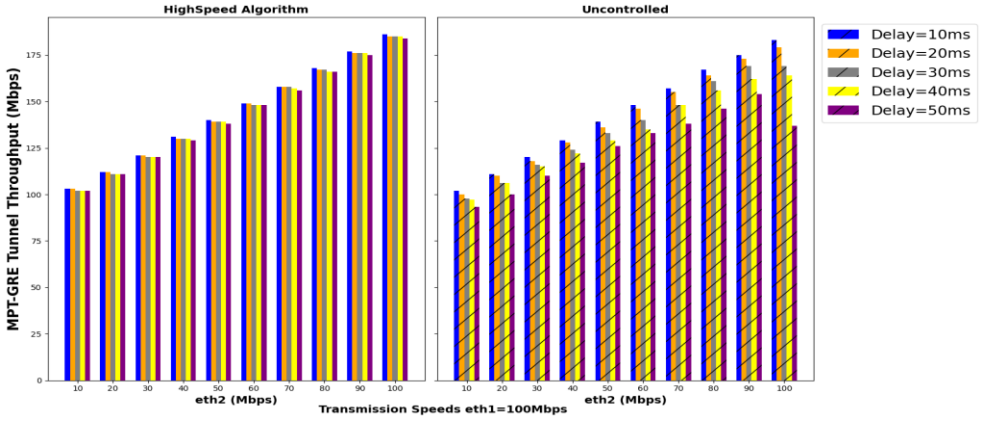

Fig. 8. Impact of the HighSpeed algorithm and the Uncontrolled case on MPT-GRE tunnel throughput under varying delay conditions.

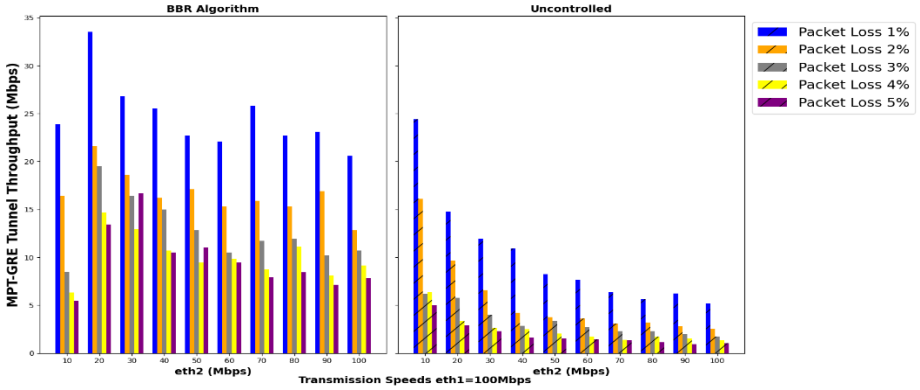

Fig. 9. Impact of the BBR algorithm and the Uncontrolled case on MPT-GRE tunnel throughput under varying packet loss conditions.

C. Determine the Appropriate Algorithm

Upon analyzing the results from the two scenarios, the HighSpeed congestion control algorithm outperforms others when network conditions are affected by delay, jitter, or a combination of both. This algorithm consistently maintains high throughput despite fluctuations in delay and jitter, making it particularly suitable for MPT-GRE multipath environments where these factors are common.

In contrast, the BBR algorithm excels under packet loss conditions, effectively adapting to varying levels of packet loss. Therefore, HighSpeed is the most appropriate choice in scenarios where delay and jitter are the primary challenges, while BBR is the preferred solution for networks where packet loss is the dominant issue.

When considering delay, jitter, and packet loss across various network conditions, the HighSpeed and BBR algorithms consistently outperform other options, making them optimal choices for maximizing throughput in diverse scenarios.

VI. Conclusion

In this study, we evaluated the impact of various congestion control algorithms on tunnel throughput in a multipath MPT-GRE network under different network conditions. The analysis focused on loss-based, delay-based, hybrid, and bandwidth estimation-based algorithms, including HighSpeed, CUBIC, H-TCP, LP, BBR, and Illinois. These algorithms were tested under varying delay, jitter, and packet loss conditions at symmetric and asymmetric transmission speeds.

The results indicated that some algorithms significantly improved MPT-GRE network performance, particularly when specific congestion control mechanisms were applied. HighSpeed significantly improved tunnel throughput as delay and jitter increased, while BBR enhanced throughput under packet loss conditions. BBR consistently outperformed the Uncontrolled case, exhibiting stable performance across various QoS conditions.

Our findings emphasize the importance of selecting appropriate congestion control algorithms for MPT-GRE networks. For example. HighSpeed performs well under delay and jitter, while BBR excels in packet loss scenarios, maximizing throughput and leveraging MPT-GRE's aggregation capabilities. This enables service providers to deliver more reliable and efficient communication solutions.

One of our future works is to create and design a specific congestion control algorithm for the MPT library.

Acknowledgment

The measurements were conducted remotely using the facilities provided by the National Institute of Information and Communications Technology (NICT) StarBED, located at 2–12 Asahidai, Nomi-City, Ishikawa 923-1211, Japan.

A Chatbot for the Legal Sector of Mauritius Using the Retrieval-Augmented Generation AI Framework

Taariq Noor Mohamed[1], Sameerchand Pudaruth[2], Ivan Coste-Manière[3]
ICT Department-FoICDT, University of Mauritius, Reduit, Moka, Mauritius[1, 2]
SKEMA Business School, Sophia Antipolis, France[3]

***Abstract*—Mauritius is known to have a hybrid legal system as the logical consequence of being both a former French and English colony. From its independence in 1968 to date, the legal environment has changed to reflect the constant need to provide a framework to address the country's diverse needs. With over 1200 pieces of legislation available for consultation, including those which are no longer in force, it is very difficult to know all of them. Yet, there is a legal maxim that says, "nemo censetur ignorare legem". In other words, ignorance of the law is no excuse. This study aims to provide a solution for professionals and non-professionals to have better access to the law through the development of a chatbot. A Retrieval Augmented Generation (RAG) chatbot system has been developed to achieve this objective. A RAG system is one that leverages the use of Large Language Models (LLM) to process a query and generate a response, while ensuring accuracy by performing similarity searches against documents stored in a vector database. A sample of 46 legal documents (acts and regulations) were retrieved from the website of the Supreme Court of Mauritius. They were broken down into chunks and stored as vectors in Chroma, a vector database. The chatbot combines and processes the queries with a text prompt, searches the relevant legal texts, and generates an appropriate response using OpenAI GPT-4o-mini or MistralAI Open-Mixtral-8x22B. Since most legal texts are in English, a translation layer is included for queries in French. Sources for the answers are also displayed for easy cross-validation. This chatbot will undoubtedly be a useful tool for the Mauritian people.**

Keywords*—*Law; chatbot; retrieval augmented generation; large language model; OpenAI; Mistral AI

I. Introduction

Artificial Intelligence (AI) is the technology that enables machines to mimic humans in performing complex tasks such as learning, solving problems, making decisions, and creativity. From its humble beginnings in the 1950s, when Alan Turing first introduced the Turing Test, to the recent explosion in popularity of generative AI [1], AI has had such an impact on our everyday lives that the European Union has even introduced a regulation recently on the use of AI [2]. The use of AI can be seen in a multitude of sectors, for example, in healthcare to detect skin cancer [3] or in education [4]. The legal field is no exception, and given the famous saying that none shall be ignorant of the law, there is a need to always improve access to justice for everyone.

Over the past few decades, our world has experienced rapid growth in the technological sector. Thus, there are a multitude of AI-related solutions that have been developed to tackle issues all around the world. The importance of having a Legal Information Retrieval system (LIR) was emphasized by [5], where they focused on three kinds of LIR systems using NLP techniques, ontology-based approaches, and deep learning-based methodologies. Amato et al. [6] presented the conversational agent CREA2 designed for tasks in the legal domain, giving users advice on legal procedures or legal document drafting. It can also help in resolving disputes between individuals with regard to the European Union's legislation. In Canada, Quedot et al. [7] investigated methods to create chatbots for immigration and corporate issues. Morgan et al. [8] delved into the creation of a chatbot framework to help children have a better understanding of their legal rights. Another interesting approach is from Alam et al. [9], where a chatbot model was created to predict the outcome of legal cases in New Zealand. Firdaus et al. [10] developed a Question-and-Answer bot on Telegram with regard to the Law on Information and Electronic Transactions in Indonesia. Devaraj et al. [11], Ioannidis et al. [12], Cao [13], and Nguyen [14] developed several solutions for the legal sector where LLMs were used.

All countries have different laws specific to them, including Mauritius, known for its hybrid legal system as a result of its long history of colonialism. The laws of Mauritius are drawn from a wide range of sources, such as the French Civil Code and the English Common Law [15]. The legal field in Mauritius has evolved significantly since the enactment of the Constitution in 1968. Over the years, Mauritius has introduced various laws and regulations to promote various sectors of the economy and to bring stability and justice to the country. However, the dynamic world in which we live experiences new events all the time, and this creates a need to regularly amend existing laws or implement new ones. This can be seen throughout the multitude of parliamentary processes [16]. Certainly, this dynamic legal environment poses a challenge to the population in general, especially to those who might not be well-versed in the legal field. It is difficult for most people to get a clear answer on legal matters without having to dig into lengthy government sources and legal databases or seek help from legal professionals.

There have not been any developments for an AI solution to address this problem in Mauritius. A Legal Information Retrieval System has been developed by study [17], which can be accessed at lawanswers.me. The platform enables users to input queries in natural language. The system processes these queries by extracting pertinent keywords and provides relevant sections of Mauritian law and Supreme Court cases from 1968

to 2017. Users can customise the number of results displayed and filter searches to show only case judgments or act titles. The platform is also accessible via mobile devices, ensuring user-friendly access to legal information.

Pudaruth et al. [18] also used deep learning techniques to classify 490 legislations in the Republic of Mauritius. The development of a chatbot for the legal field will ensure that any Mauritian citizen will have better access to justice, in particular, to the statutory provisions contained in the Acts of Parliament. By leveraging the use of LLMs, an RAG system will be developed to create a chatbot that can answer legal queries using natural language. The system will be fed with a list of relevant acts and regulations so that an appropriate response can be obtained by performing a similarity search on the query and the available documents. A successful implementation of this project will save hours or even days for the Mauritian population in getting their queries answered.

The paper proceeds as follows. An overview of the legal system of Mauritius is provided in Section II. Section III covers the related works. The methodology is described in Section IV, while the results are provided in Section V. Section VI concludes the paper.

II. Background Study

"At his best, man is the noblest of all animals; separated from law and justice, he is the worst." (Aristotle). Since time immemorial, human survival and progress have always been attributed to the fact that Man is a social animal. From ancient tribes to the modern civilisations, mankind has always been associated with communal living, having one common component, rules and regulations. The Law has always been a key aspect of any society. It helps in maintaining the structure and safety in society. Without this pillar, society crumbles and gives rise to anarchy.

Mauritius is one of the countries with a hybrid legal system that encompasses both the French Civil Law and English Common Law. The country has been subjected to a long history of colonisation attempts, starting with the Dutch from 1598 to 1710, during which there was no administration of justice as we know it today. Later, from 1715 to 1810, the French colonised the island where they introduced their laws and jurisdiction to the country. A temporary "Conseil Provisoire " was set up in 1721 to deal with civil and criminal matters. In 1723, a "Conseil Provincial," a court of First instance, was put in place to treat those issues, later replaced by "Conseil Superieur" in 1734, with appeals made to the "Conseil Supérieur de Bourbon." A two-tier jurisdiction was then introduced in 1771 with a "Jurisdiction Royale" hearing cases at first instance, with the "Conseil Supérieur" being a court of higher instance, which were afterward renamed as "Tribunal de Première Instance" and "Tribunal d'Appel" respectively. When the British colonised the island in 1810, all prior judicial institutions were kept, but justice had to be delivered in the name of the King. In 1851, "La Cour de Première Instance" was abolished, and the Supreme Court was established in Mauritius, replacing the "Cour d'Appel," but the right to appeal to the "Judicial Committee of the Privy Council" was maintained. Gradually, the system returned to a two-tier judicial system with the establishment of the subordinate courts [19].

With this long history of colonialism, the Mauritian legal system draws from a wide array of sources to establish and enforce laws in the country. The French Civil Law, mainly for civil rights, criminal law, and commercial transactions; the English Common Law for evidence, tort, negligence, and health and safety; domestic legislations, that is, Acts of Parliament, customs, and international treaties and conventions [15]. Sitting on top of all laws in the country is the Constitution, also known as the supreme law, in which all the basic set of principles and laws of a country are written, such as determining the powers and duties of the government and the rights of the population. Any law deemed inconsistent with the Constitution is deemed to be void [20].

Without a proper system, all the laws might be meaningless and not be practiced at all; hence, the judicial system in Mauritius, the Judiciary, is one of the three main pillars of our country. This system is structured into two main tiers: the Supreme Court and the subordinate courts. The Supreme Court is composed of the Chief Justice, the Senior Puisne Judge, and twenty-three Puisne Judges and has unlimited jurisdiction to hear and determine any civil and criminal proceedings. It functions in a similar fashion to the High Court of England and has complete authority over all subordinate courts to ensure that proper justice is delivered. The Supreme Court functions both as a court of first instance and as an appellate court. As a first instant court, it is subdivided into multiple divisions, such as the Master's Court, Family Division, Commercial Division, Criminal Division, Mediation Division, Financial Crimes Division, and Land Division. Each division handles specific types of cases, such as financial crimes, land disputes, family matters, and commercial issues. Subordinate courts, on the other hand, typically handle less complex cases or involve claims of a lower monetary value and consist of the Intermediate Court, the Industrial Court, the District Courts, the Bail and Remand Court, and the Court of Rodrigues. Cases can be escalated to the Supreme Court from subordinate courts through appeals. Any decisions made by subordinate courts can be heard again and reviewed by the Supreme Court. Additionally, the Supreme Court has divisions specifically for civil and criminal appeals: the Court of Civil Appeal and the Court of Criminal Appeal. These divisions handle appeals from decisions of the Supreme Court in its original jurisdiction as well as from subordinate courts. In some cases, the decision from the Supreme Court can even be reviewed if an appeal is made to the Judicial Committee of the Privy Council. The decision that will be taken by the Privy Council is then deemed the final one [21].

There are also multiple parties involved in any typical court proceedings. These include the judge, the lawyers, the plaintiff, the defendants, the jury, and witnesses. The judge is the one who will ensure the smooth running of the hearing and will give the final verdict. The plaintiff is the individual or entity who brought the case to a court to seek some form of legal remedy, while the defendants are the ones on whom the legal action is taken. Lawyers are also typically assigned to each of the two opposing parties and represent each of the parties. Witnesses are the ones who can provide testimonies on specific

events that occurred for the case being heard. The jury also forms an important part of proceedings in court. It consists of 9 random civilians between the ages of 21 and 65 that are tasked to identify the true evidence in specific cases [22]. The basic idea for having a system of jury is to ensure that the verdict of the case is what society would expect it to be.

It is a known fact that engaging in a lawsuit means, in most cases, the need to invest a lot of time, effort, and money. In this optic, it is necessary that not all legal matters need to be tried in a typical court of justice; hence, the Mediation Division of the Supreme Court has been established for this purpose [21]. Mediation is one way in which disputes can be kept out of courts to save time, money and prevent extra stress from all involved parties, and even giving a more flexible judgement. The key distinction is that mediation involves a neutral, independent third party who challenges the parties on their positions and assists them in finding a compromise. The decision is not taken solely by one person, but instead the parties are guided into reaching a proper decision to resolve their dispute [23].

III. Literature Review

Legal chatbots are becoming very popular because they are now use artificial intelligence techniques to help people find relevant legal information. This section looks at some of the studies that have been done on legal chatbots. We also explain how they have been developed, how they work and what are their limitations?

Morgan et al. [8] delved into a chatbot framework that integrates machine learning, a dialogue graph and information to ease access for children about their legal rights. The user first initiates a conversation with the chatbot, and afterward, based on the dialogue graph and legal type, the chatbot identifies the legal circumstances being addressed by the user. The different parties in the conversation are identified, and based on this information, a case is created so that a legal advisor can take over. Since obtaining legal conversation in a child's way of speaking is difficult, the authors created fictional data from "artificial" statements that approximate the way a child talks and from "real" statements obtained from a study whereby adults imitated children's language. The dataset was divided into "speech act," such as greetings or affirmations, and "legal type," relating to the legal issues being tackled, such as abuse or cyber-crime. Throughout the conversation, the chatbot's neural network classified the messages as speech act or legal type to give the appropriate response. This is achieved through the tokenization of the messages and converting them into word vectors of 200 dimensions where semantic similarities can be computed. To encode the impact of word order in the different sentences, two Long Short-Term Memory (LSTM) layers and a type of Recurrent Network Layer (RNN) were used, and the outputs were processed by a dense layer with a ReLU activation function. Finally, the sentences were categorised into one of the two classes by two parallel dense layers with a softmax activation. Named entities were also recognised and extracted from the conversation as these are used later in the generated report.

In the pre-chatGPT era, Queudot et al. [7] focused on enhancing access to legal information using chatbots for two different matters: for immigration issues and for legal issues related to the corporate environment in Canada. In both cases, the chatbots make use of the MLFlow and RASA frameworks. They made use of the MLflow framework for two purposes: to keep track of script execution for data collection, data preparation, model training, and evaluation and to simplify script executions with different values. For the first chatbot, the dataset used was obtained from 1088 different web pages from the Canadian Immigration and Citizenship help desk. Then, two different intent classifiers were used: the standard model in RASA using the StarSpace algorithm and a modified Information Retrieval (IR) inspired model. The StarSpace is an algorithm in RASA used in learning the embeddings for different entities in a supervised manner. There was not much difference in the performance of the two algorithms. In the second chatbot, the dataset used was two formulations for a series of 275 questions developed by the National Bank of Canada (NBC). Three approaches were used to compare the performance of the chatbot: the classic StarSpace Model, the IR variant of StarSpace, and the BERT transformer model. For the BERT model, fine-tuning a pre-trained model was more feasible rather than training a model from scratch. The results, in this case, were in favour of using the BERT model.

Firdaus et al. [10] focused on providing a legal chatbot to search for legal documents for the Law on Information and Electronic Transactions in Indonesia. NLP techniques were used for the chatbot development and Telegram, the messaging application, as it provides much support for chatbot development. For the system to understand the query of the user and understand the appropriate context, NLP components such as parser, lexicon, understander, knowledge base, and response generator are used. In case the query contains "non-standard" words, the Levenstein distance method is used to obtain the closest "standard" word that can be processed by the system. TF-IDF cosine similarity is then applied to compare user queries with the stored documents in the database to find the appropriate answers. Questions found directly in the knowledge base had a 100% match. Random questions showed an average of 77% match, and any questions that were still related to the knowledge base showed an accuracy of 83%.

Sansone and Sperlí [5] emphasised on the importance of having a Legal Information Retrieval (LIR) in the legal field given the increasing volume of Electronically Stored Information (ESI). Given the complexity of legal documents, efficient searching algorithms are required. The authors focused on three types of LIR systems: NLP techniques, ontology-based approaches, and deep learning-based methodologies. For each type of system, different models were tested, evaluated and categorised. NLP-based LIR approaches were further classified into three categories, rule-based, NLP-based and a combination of NLP and ontologies. The main limitation of this approach is the manual definition of rules required, which is hindered by the large size of the vocabulary and can introduce noise during analysis, hence affecting the accuracy of the results. Ontology-based approaches were classified into top-down and bottom-up strategies. Ontology refers to the way of organising and representing knowledge in

a particular domain. Key limitations of this approach include the few available domain-specific ontologies and the complexity involved in their maintenance and contextual dependencies. Deep-learning methodologies were classified into pre-trained embedding models, domain specific embedding models and hybrid embedding models. Limitations include the limited training samples available.

Amato et al. [6] presented an AI-powered conversational agent named CREA2, designed specifically for the legal domain. The purpose of the agent is to help in guiding users on legal advice and procedures and give recommendations in drafting legal documents. CREA2 also helps in resolving disputes between individuals pertaining to the European Union legislations. They also discuss the different approaches that they could consider in building the project, namely, intent classification, question-and-answer-retrieval and similar question retrieval. Given their relatively small amount of dataset, the last approach has been used. The system makes use of the Natural Language Processing (NLP) algorithm to interpret the user's questions and provide the required response. Sentence-BERT (SBERT) is used to compare the user's questions to the set of available questions in the dataset. SBERT works as follows. It first creates embeddings (vectors) for each pair of questions and then computes a score using the cosine similarity function. The scores are then sorted in a descending order, and the highest scoring one is selected as it provides the most appropriate response from the database. Data augmentation techniques are also used, given the relatively small training data size. The paraphrase-based utterance augmentation framework called Parrot is used to create variations for different questions available in the training dataset. Adequacy and fluency can also be controlled in the framework. Finally, the data are stored in JSON format in a question-answer format as separate strings. Two pre-trained models and a fine-tuned version of SBERT were used. The results demonstrated that the fine-tuned version of quora-distilbert-multilingual-v2 had a higher accuracy than all the other models.

Alam et al. [9] developed a chatbot that can predict the outcome of legal cases based on past cases made available to the system. Data from the New Zealand Employment Relations Authority (NZERA) was used. Data preprocessing was used on each PDF prior to the experimentation. This included using regular expressions to identify and extract paragraphs. A manual scan had to be done on each paragraph to identify the document preamble (P) feature and the case determinations (D) feature. Eventually, two kinds of data were found: Full Documents (FD) having both P and D features, and Full Documents with the result removed (FD - D) so that independent ruling can be done based only on the circumstances. For the semantic analysis, an unsupervised topic detection method called Latent Dirichlet Allocation (LDA) was used. This enabled the creation of 10 topic-clusters each consisting of distinct features (d) and a number of top-words (n). Cosine similarity was further performed on the different clusters by keeping only words related to each cluster, performing tokenisation on the data and converting them to 128-dimensions word embeddings. For the predictive analysis, supervised learning was further performed on the data using different deep neural network models and tested on both FD and FD-D data. Each model used the Gated Recurrent Unit (GRU) variant of the RNN on TensorFlow, trained for 26 epochs. Sigmoid and SoftSign activation functions were used to test each model. RNN was used as a based model to evaluate the performance of the different LDA parameters, namely, K, n, and d. In the semantic analysis with LDA and RNN, it was observed that having 5 LDA topics, 5000 features and 300 top words per topics provided the best results.

Devaraj et al. [11] created a chatbot capable of answering questions based on documents made available to it. The chatbot was divided into three parts. Langchain, an open-source NLP framework that enables LLMs to be combined with external data, was used in the creation of the chatbot's custom knowledge. It breaks down the different documents into small chunks and stores them as vectors in a vector database, using Open AI's text embeddings. When provided with a prompt, it is compared with the data in the vector store using the cosine similarity function to determine the most appropriate response. A Flask Application was created as the backend for the entire application. It can be hosted on a server, thus enabling the query processing feature to be used remotely. Flask was used because it is lightweight, it provides for RESTful API support, Python integration and it is scalable. To make the system user friendly, the authors also designed a mobile application. Kotlin was used for the backend and XML for the frontend.

Ioannidis et al. [12] took advantage of the potential that LLM offers to create generative AI solutions regarding regulatory compliance for businesses. These were a horizon scanning tool, an obligations generator tool, and an LLM-based expert system. For the horizon scanning tool, web scraping was performed periodically on different websites that relates to the different regulatory news to fetch and store up to date information in a database. In the study, Australian regulatory bodies' websites were scraped. GPT prompts were then applied to the scraped data so that the following can be performed: generate a 150 words summary of the data, categorise the level of impact of the regulatory update as either low, medium or high and generating hashtags for easy identification of the scraped data. For the Obligations Generator, a prompt is always used along with the legislations, made available to the system, to generate a summarised list of obligations that a company should comply with. It was noticed that GPT-4 did a better job than GPT-3.5 in understanding the prompt and writing the text. The lists generated were then stored in a local database before being processed further to remove duplicate obligations using the cosine similarity measure. GPT-4 was also used to create an expert consultation tool where users can converse with the chatbot, and the latter responds in accordance with legislation or obligations available to it. This part of the system made use of the LangChain framework and embedding tool from Open AI. The authors also mentioned that LLMs are prone to hallucination. To combat this issue, a "human in the loop" system is used whereby a human verify and validate any output from the LLM before pushing them to the database.

Cao [13] highlighted how LLMs can easily answer general questions but sometimes struggle to give an appropriate answer

in specific topics such as medical or law consultations. For such kind of scenarios, the author investigated a Task-Oriented Dialogue approach so that the AI agent can ask appropriate questions to the user so that it can properly diagnose the issue encountered by the user. A multi-agent, with GPT4 as base LLM, was used. It is made up of different parts: a chat agent, a Topic Manager, a Topic Enricher, and a Context Manager. Each LLM used is provided with a different and well detailed prompt so that they can perform their actions. The Topic Manager has the user query, the action list, the status of the topic stack, and the chat history. All of these enable the topic manager to plan and make the appropriate decision throughout the conversation. The Topic Enricher uses the current topic and enriches it based on the current dialogue context. With the context provided by the context manager, the chat agent can generate an answer.

Nguyen [14] from the National Institute of Informatics in Japan gave a brief overview of LawGPT, a chatbot that provides legal assistance, since the model developed is protected by a non-disclosure agreement. LawGPT 1.0, uses a similar architecture to GPT-3, that is, a transformer architecture which enables a better understanding of the context of a sentence provided, by weighing the importance of different words in the sentence. Being a fine-tuned model of GPT3 on a large corpus of legal texts using standard deep learning techniques, such as stochastic gradient descent and backpropagation, LawGPT is designed for the legal context. Evaluation of LawGPT involves answering legal questions, generation of legal documents and the legal advice it can propose. The author mentions that the results were highly positive. However, no specific implementation details about LawGPT were to be found in the paper as the model is protected by a non-disclosure agreement.

Medeiros et al. [24] exploited the use of LLMs to create AI tools for obtaining answers from a car manual. Three approaches were selected by the authors, and in each case, the LLM models from the GPT-3 family were used, and a chunk size of 1000 and a chunk overlap of 20 were used. The performance of each was evaluated using different kinds of prompts, namely zero-shot, one-shot, and few-shot. For Doc Chatbot, the user directly interacted with the chatbot by typing the questions in a Python notebook. LlamaIndex and LangChain libraries were used to build the chatbot to interact with the PDF documents. Open AI API and the text-davinci-003 model are used to create embeddings. It was found that the bot showed low accuracy by providing accurate answers for only 1 out of 4 evaluated questions across different prompts. The cost for each question and pair was between 0.03 and 0.04 USD. In Ask Your PDF, a user-friendly interface was created to interact with the chatbot using the Streamlit tool. The LangChain library is used in the chatbot development and to interact with the PDFs. Open AI API and the text-davinci-003 model are used to create the embeddings. Here, the bot demonstrated average accuracy by providing accurate answers for 2 out of 4 evaluated questions when using the zero-shot prompt. The cost for each question and answer was between 0.02 and 0.03 USD. The Question-and-Answer System had a user-friendly interface, with the frontend built using React and the backend with FastAPI and a vector database called Qdrant. Libraries used were LangChain and the Sentence Transformers. Open AI API and all-mpnet-base-v2 model was used to generate the embeddings. However, it was noticed that the bot had a low accuracy, but it had a much lower cost of operation averaging below 0.005 USD for each question and answer.

This review on legal chatbots shows that these tools are getting more advanced due to massive progress in the field of artificial intelligence. Furthermore, these studies show how LLMs are being used for different purposes. For example, some legal professionals are using it to answer legal queries while others are using it to sift through information quicker and more accurately. Nevertheless, since the laws of each country are different, we still need to develop a customised system for the judiciary of Mauritius.

IV. Methodology

To make the laws of the Republic of Mauritius more accessible, a chatbot with a Retrieval Augmented Generation (RAG) system is proposed. Contrary to traditional rule based chatbots, our solution leverages the power of generative AI such that a human-like conversation can be achieved. The general structure of the system is as follows: legal texts, acts, and laws are fed to the system in the form of PDF documents. The PDFs are broken into chunks, and each chunk is converted into vectors using an embedding algorithm. A chunk size of 1000 characters with an overlapping of 80 was initially used. Chunk overlapping is important as a sentence can be split into two chunks, which can have an adverse effect on the generator in understanding the proper context of that sentence. To create the embeddings, the *mistral-embed* model has been used for MistralAI Open-Mixtral-8x22B while the text-embedding-ada-002 model has been used for OpenAI GPT-4o-mini. These embeddings are then stored in the Chroma vector database. The user inputs his query, which is embedded and compared with documents in the vector database. An answer is generated based on the contents of the selected documents. The decision to use a RAG system was mainly due to its ability to minimise hallucinations, provide contextually accurate answers while maintaining a level of transparency by showing what documents are used to generate a response.

By consulting a legal professional, it was found that there is a multitude of acts and regulations that are not properly updated and that the acts only are not sufficient as sources of information. Given the huge amounts of acts and regulations available, two acts, namely the Employment Relations Act and Worker's Rights Act, were selected. All the regulations supporting these two acts were also selected. A few other general and relevant acts, such as the Constitution, the Civil Code, and the Data Protection Act, were also made available to the system. The full list of legal documents used are listed in Appendix 1. The architectural diagram of the RAG system with the tools and technologies used is illustrated in Fig. 1.

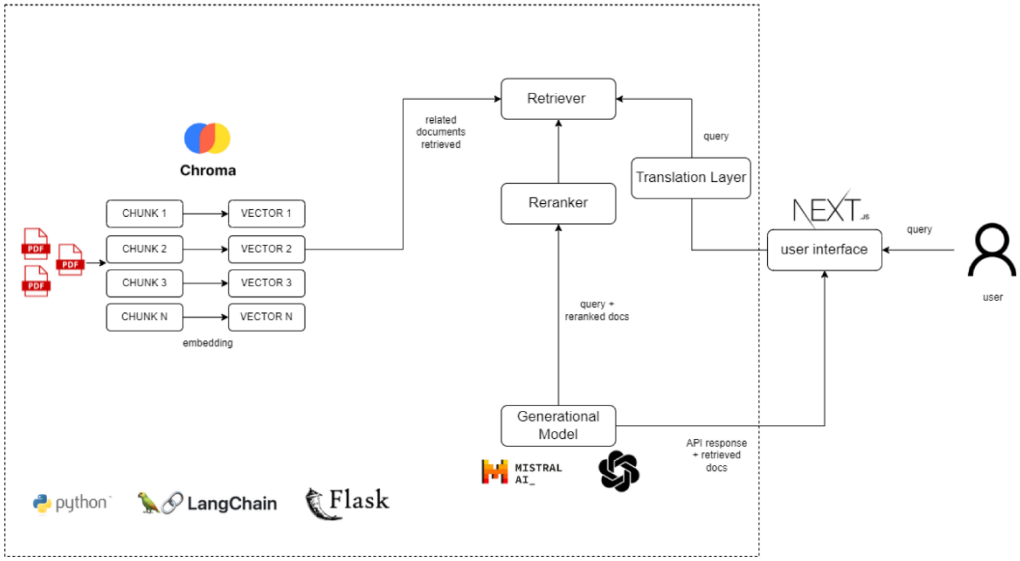

Fig. 1. Architectural diagram of the RAG system.

The user starts by selecting the desired LLM and then types his question on the user interface. LangChain is selected as the LLM framework because of its ability to provide context aware outputs. It also provides all the necessary tools and structures to facilitate the integration and management of large language models into applications. This causes the frontend to call the Flask API to pass the question to the backend. The query then passes through a translation layer to convert the text in English (if it was in French), otherwise it is directly converted into a vector form. The query is then used by the vector store retriever and searches for a number (K) of related documents in the vector database using the cosine similarity search.

The retrieved documents also go through a reranker, where they are processed again to select the top N documents. The top K documents in the retrieved documents may not all be as relevant to the question. For instance, it is possible that a relevant document was given a lower score. Thus, a reranker has been used to circumvent this issue. The reranker assigns a new score to each document and retrieve the top 3 documents by default. However, in our case, we increased this threshold to 10 by modifying the source file in the Flash ReRank library. This helps the system in having a larger context to generate an answer. These documents are then sent alongside the query to the generational model so that an appropriate response can be obtained. The final response alongside the sources of answer is sent back to the frontend and displayed on the screen. In contrast with ChatGPT or other similar software, the queries and answers will be specific to the documents made available to the application that is in the context of the legal sector of Mauritius only.

The user interface is made up of the following: a home screen, a chat panel, a sidebar to select the LLM for the conversation, a text box, a send button, and a source button to check which documents are considered for the answer. The user interface is shown in Fig. 2. The libraries used in the backend are shown in Table I.

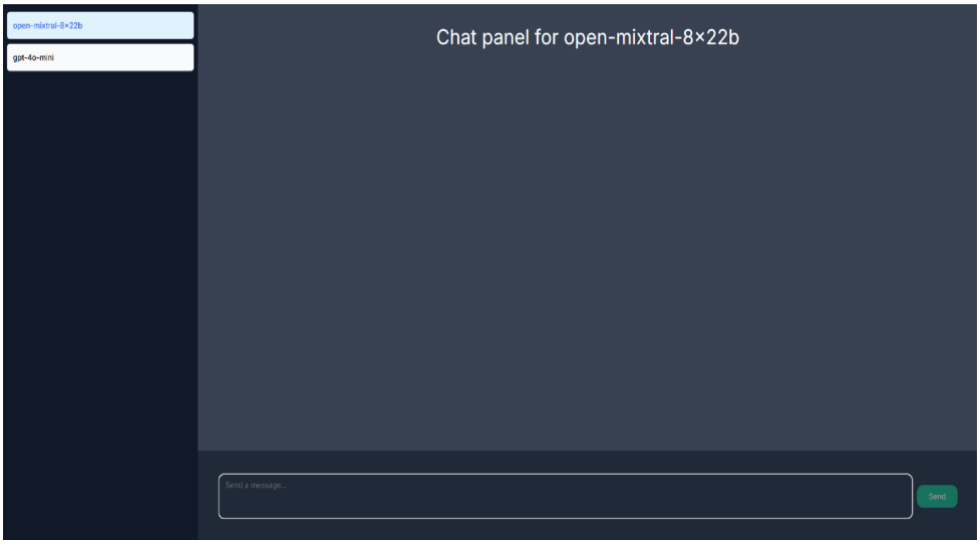

Fig. 2. Chat panel for the system.

TABLE I. BACKEND LIBRARIES

Library Name	Description
mistralai	Mistral AI Python library
openai	Open AI Python library
chromadb	Chromadb Python library
langchain	Bare minimum requirements of LangChain for Python
Langchain_mistralai	LangChain integrations for Mistral AI
Langchain_Open AI	LangChain integrations for Open AI
Langchain_community	Contains third-party integrations
Pypdf	Free and open-source pure Python PDF library to parse PDF files
Flask	Lightweight WSGI web application framework
Flask-cors	Flask extension for handling Cross Origin Resource Sharing (CORS)
Python-dovenv	Enable use of the .env file
FlashRank	Flash ReRanker library
Langdetect	Library to detect the language used

The libraries used in the frontend are shown in Table II.

TABLE II. FRONTEND LIBRARIES

Library Name	Description
Next	Next js react library
React	React library for JavaScript
React-dom	Entry point to the DOM and server renderers for React
React-markdown	React component to render markdown
Next-ui	Next JS library having beautiful components
Tailwindcss	CSS framework
Github-markdown-css	The minimal amount of CSS to replicate the GitHub Markdown style

For the frontend, the React framework and Next JS have been used. The following components were created to build the user interface: (a) Source Modal: This is a pop-up that can appear when the source button is pressed to view sources, (b) nav-links: This contains the navigation links to switch between LLMs, (c) Message: This is the component used to display messages sent by the user and received by the chatbot, (d) ChatSideBar: This is the Side Bar component where the user can switch LLMs and (e) Chat: This is the main chat component that displays the textbox, sidebar and chat components.

V. RESULTS AND EVALUATION

To perform the evaluation of the RAG system, a User Acceptance Test (UAT) was performed by a legal professional, a third year LLB student and a non-technical user. They asked questions to the chatbot and evaluated if the received answers match the expected answer. Initial testing showed that many questions were not properly answered. This made us to fine-tune the chunking overlap parameter to 200 and re-embed the document so that each chunk provides more context to the chatbot.

Both systems were able to provide relevant responses in most cases. However, it was observed that the model from Mistral AI (open-mixtral-8x22b) performed better when the query was in French, and the responses were located in French documents. The system was evaluated by three users: a legal professional (LP), a final year LLB student (LLB) and a Mauritian citizen (MC) without any formal legal background. The legal professional extended valuable help in improving the system by sharing the relevant documents for this system. He found that the system was satisfactory and will indeed help to improve access to justice in our country.

The LLB student also mentioned that both systems met his expectations for both basic and more specific legal questions sections, but he was of the opinion that the model from Mistral AI consistently provided more detailed, structured, and comprehensive answers than the model from Open AI. Notably, the model from Mistral AI excelled in explaining the duties of a company secretary, the procedure for incorporation, and employee protections under the Worker's Rights Act, offering greater depth and alignment with the relevant laws. As regards the third evaluator, he found the system to be very user-friendly and helpful.

The list of questions and answers from the various testers, together with their expected answers and remarks on the system, are provided in Appendix 2. Table III summarises the list of questions and answers from the three evaluators.

TABLE III. SUMMARY OF QUESTIONS

#	Question	User	gpt-4o-mini	open-mixtral-8x22b	Comments
1	I have been in employment with ABC since January 2024. Am I entitled to special leave?	LP	correct	correct	
2	What is a labour contractor?	LP	correct	correct	
3	Je suis convoqué à un comité disciplinaire dans une semaine. Comment savoir si le comité est valablement constitué?	LP	incomplete	incomplete	No mention of right to be accompanied.
4	Mon employeur ne respecte pas ma vie privée. Quels sont les moyens dont je dispose pour me protéger ou pour le dissuader?	LP	incomplete	incomplete	No mention of Code Civil and DPA.
5	I intend to cease business as a Company. How can I terminate the employment of staff?	LP	incomplete	incomplete	Mistral AI is better.
6	Quel est le salaire minimum à ce jour dans la République de Maurice?	LP	correct	correct	
7	What are my obligations as an employee?	LP	correct	correct	Implied obligations not mentioned.
8	I would like to hire the services of my nephew who is 15 years old. Can I do so?	LP	correct	correct	

9	I would like to transfer shares I hold in Company FEDER to my brother. What do I need to do?	LP	correct	correct	Registrar office not mentioned.
10	What does section 3 of the Constitution of Mauritius, which guarantees the right to life, liberty, and security of a person, balance individual freedoms with the state's responsibility to maintain public order and safety?	LLB	correct	correct	Model from Mistral AI is better.
11	Which section and chapter of the Constitution caters for the freedom of expression?	LLB	correct	correct	
12	What does the Constitution states about the powers of the President of Mauritius?	LLB	correct	incomplete	
13	What are they key duties of a company secretary under the Mauritius Companies Act 2001?	LLB	wrong	correct	
14	Can you explain the procedure for the incorporation process of a company under the Companies Act?	LLB	correct	correct	Model from Mistral AI is better.
15	What are the legal requirements for a company to hold an Annual General Meeting in Mauritius?	LLB	wrong	correct	
16	What are the key provisions under the Mauritian Workers' Rights Act for protecting employees against unfair dismissal?	LLB	correct	correct	Model from Mistral AI is better.
17	Can you explain the legal requirements for paid leave entitlements under the Workers' Rights Act?	LLB	correct	correct	
18	What does the Workers' Rights Act say about the right to severance allowance in cases of redundancy in Mauritius	LLB	correct	correct	Model from Open AI is better.
19	What are the lawful risks of creating a fake Instagram profile to profit from others?	MC	correct	correct	
20	Puis-je forcer mon fils a travailler sans le payer si j'ai besoin d'aide dans mon business?	MC	correct	correct	

VI. Conclusion

Developing a chatbot tailored for the legal sector of Mauritius is a significant step in making legal information more accessible to both legal professionals and non-legal professionals. The dynamic and hybrid nature of the Mauritian legal system makes it challenging for anyone to have easy access to legal information. The large number of acts and regulations available on the Supreme Court website also adds up to this difficulty. And yet, ignorance of the law is not an excuse. There is currently no AI-enhanced tool which provides the population with fast and easy access to Mauritian laws. In an optic to tackle this shortcoming, existing AI-related solutions in other countries were reviewed and a RAG system, which leverages the use of LLMs to generate answers and real time retrieval from relevant documents, has been proposed and provided as a novel solution for the Republic of Mauritius. In our solution, we proposed using two different LLMs, gpt-4o-mini from OpenAI and open-mixtral-8x22b from Mistral AI. This enabled us to compare the answers obtained from each model. A re-ranking algorithm was also used to enhance the RAG system by analysing retrieved documents and to decide on the most appropriate documents to be used in the answer. The solution aims at addressing several issues, such as, the difficulty in accessing legal information in Mauritius for non-legal professionals, given how online answers can be too generic and how time-consuming legal research can be. Mauritius being a bilingual country, our system can also converse in both French and English. To further assess how the system performs, a legal professional provided assistance by asking relevant questions to the system and evaluating the answers obtained. While the system is very promising and improves access to legal justice in Mauritius, there are limitations that were observed, such as the heavy reliance on the quality and completeness of legal documents made available to the system. The system can be enhanced in the future by providing accurate and updated legal texts. Judicial cases can be added to the system to provide more context. This study showcased how it is possible to bring forward an innovative AI solution to bridge the gap between the public and legal information, by making it more accessible to them.

APPENDIX 2

1. I have been in employment with ABC since January 2024. Am I entitled to special leave?

Open AI gpt-4o-mini:

Based on the previous context, you would not be entitled to special leave yet. According to the regulations, an employee must remain in continuous employment with the same employer for a period of 12 consecutive months to be eligible for special leave. Since you have been employed since January 2024, you need to wait until January 2025 to qualify for special leave.

Mistral AI open-mixtral-8x22b:

Based on the previous content, if you have been continuously employed with ABC for a period of 12 consecutive months, then you are entitled to special leave. However, as you started your employment in January 2024, you would need to wait until January 2025 to be eligible for special leave. The specific entitlements for special leave are outlined in the context, which include 6 working days' special leave on fill pay for the occasion of the celebration of your first civil or religious marriage, 3 working days' special leave on full pay for the occasion of the first civil or religious marriage of your son or daughter, and 3 working days' special leave on full pay on the death of your spouse, child, father, mother, brother, or sister.

Expected answer:

According to the legal provisions currently in force, special leave is granted to a worker who has been in continuous employment for 12 consecutive months. A worker who has been in employment for a period of less than 12 consecutive months shall not be entitled to special leave.

2. What is a labour contractor?

Open AI gpt-4o-mini:

A labour contractor is defined as a person who is engaged in the recruitment and supply of migrant worker to work with a hirer employer.

Mistral AI open-mixtral-8x22b:

A labour contractor is a person who is engaged in the recruitment and supply of a migrant worker to work with a hirer employer.

Expected answer:

A labour contractor is defined as "a person who is engaged in the recruitment and supply of a migrant worker to work with a hirer employer". A labour contractor must be registered with the Ministry of Labour. A labour contractor may supply a migrant worker to work with a hirer employer in any approved sector of economy. The Labour contractor shall remain the Employer of the migrant worker after the latter is placed at the seat of a hirer employer. Also, the labour contractor is compelled under law to keep a register of the placement of a migrant worker with each hirer employer retaining its services.

3. Je suis convoqué à un comité disciplinaire dans une semaine. Comment savoir si le comité est valablement constitué ?

Open AI gpt-4o-mini:

Pour savoir si le comité disciplinaire est valablement constitué, vous devez vérifier les éléments suivants:

Composition du Comité:

Le comité doit être composé d'au moins une personne indépendante.

Quorum :

Il doit y avoir un quorum, ce qui signifie que le nombre minimum de membres requis pour que le comité puisse prendre des décisions doit être présent.

Objections :

Si vous ou votre syndicat avez des objections concernant la composition du comité, vous devez les soumettre à l'employeur dans les 24 heures suivant l'information sur les membres nommés.

Si ces conditions sont remplies, le comité peut être considéré comme valablement constitué.

Mistral AI open-mixtral-8x22b:

Pour savoir si le comité disciplinaire est valablement constitué, vous devez vous assurer qu'il est conforme à l'article 14 de la législation en vigueur. Selon cet article, le comité doit inclure au moins une personne indépendante et être guidé par les principes de justice naturelle. En outre, en tant que travailleur, vous avez le droit de contester toute personne faisant partie du comité disciplinaire et de soumettre vos objections, ainsi que les motifs de ces objections, à l'employeur au plus tard 24 heures après avoir été informé du nom des personnes nommées pour entendre l'affaire.

Expected answer:

Il faut que le comité soit présidé par une personne indépendante. La personne convoquée devant le comité doit répondre aux charges énoncées dans la lettre de convocation et peut se faire accompagner par un représentant syndical, un homme de loi (avocat) ou les deux ou par un officier du Ministère du Travail, des ressources humaines et de la Formation. Il doit s'écouler au moins sept jours entre la notification/convocation et la tenue du comité disciplinaire.

4. Mon employeur ne respecte pas ma vie privée. Quels sont les moyens dont je dispose pour me protéger ou pour le dissuader ?

Open AI gpt-4o-mini:

Vous avez le droit de demander réparation pour les griefs liés à votre emploi. Voici quelques moyens que vous pouvez envisager :

Faire un signalement:

Vous pouvez signaler le non-respect de votre vie privée à votre supérieur hiérarchique ou à un responsable des ressources humaines.

Recours à un syndicat:

Si vous êtes membre d'un syndicat, vous avez le droit d'être représenté par un représentant syndical qui peut vous aider à défendre vos droits.

Procédures formelles:

L'employeur doit établir des arrangements avec les syndicats pour permettre aux travailleurs de soulever des griefs et de les résoudre de manière équitable et rapide. Vous pouvez demander à connaître ces procédures.

Demande d'information:

Si vous avez besoin d'informations concernant vos droits ou les politiques de l'entreprise relatives à la vie privée, vous pouvez demander ces informations à votre employeur.

Saisir le Tribunal:

Si votre employeur refuse de fournir des informations ou ne respecte pas vos droits, vous pouvez faire une demande auprès du Tribunal pour obtenir une ordonnance.

Il est important de documenter tous les incidents et de conserver des preuves de toute violation de votre vie privée.

Mistral AI open-mixtral-8x22b:

Selon le contexte fourni, il est interdit de divulguer des informations qui peuvent causer un préjudice aux intérêts de l'entreprise ou d'un travailleur, ou qui sont des informations personnelles liées à la vie privée d'un travailleur, à moins que le travailleur ne consente à la divulgation de ces informations.

Si votre employeur ne respecte pas votre vie privée, vous pouvez demander à votre employeur de cesser cette pratique. Si l'employeur refuse de cesser cette pratique, vous pouvez alors déposer une plainte auprès de l'autorité compétente, telle que le Tribunal. La loi prévoit également que le Tribunal peut ordonner à l'employeur de fournir des informations si cela est nécessaire pour les négociations collectives, à condition que les informations demandées ne relèvent pas des exceptions prévues par la loi.

Enfin, si vous estimez que votre employeur a violé vos droits en matière de confidentialité, vous pouvez également engager des poursuites judiciaires contre lui.

Expected answer:

Tout justiciable est titulaire du droit à la vie privée. Ce droit est garanti par la Constitution. De plus, le droit a la vie est reconnue dans le code civil. En cas de non-respect de la part de l'employeur, il est possible de saisir le tribunal

compétent. Il est aussi possible de rapporter le cas au ministère du Travail ou encore le Data Protection Office.

5. I intend to cease business as a Company. How can I terminate the employment of staff?

Open AI gpt-4o-mini:

To terminate the employment of staff when ceasing business as a company, you must follow these steps:

Written Notice: You must give written notice to the Director-General specifying the date on which the cessation will take effect.

Notice to Employees: You must inform your employees about the termination of their employment. According to the provisions, you must state the reason for the termination at the time of notifying them.

Notice Period: Ensure that the notice period is not less than 30 days, unless you opt to pay the employees the amount of remuneration they would have earned during the notice period.

Severance Allowance: Pay severance allowance to workers who have been in continuous employment for a period of not less than 12 months, as specified in the relevant sections.

Consultations: Consult with trade unions and provide reasonable notice to them as well, as well as to the Ministry responsible for labour.

Assistance in Job Search: Consider offering help to workers in finding other jobs in cooperation with the Ministry responsible for employment.

By adhering to these steps, you can ensure that the termination of employment is carried out in compliance with the relevant legal provisions.

Mistral AI open-mixtral-8x22b:

To terminate the employment of staff due to the cessation of business, you must follow the guidelines outlined in the provided context. Here are the key steps:

Provide reasonable or prescribed notice to the workers, to the Ministry responsible for labour and industrial relations, and to the trade unions concerned.

Consider introducing schemes for voluntary redundancy, retirement, transfer to other departments within the undertaking, and a phased rundown of employment.

Establish which workers are to be made redundant and the order of discharge.

Offer help to workers in finding other jobs, in cooperation with the Ministry responsible for employment.

Decide how and when to make the facts public, ensuring no announcements is made before the ministry, the workers, and their trade unions have been informed.

Please note that termination of employment without justification, where the ground of termination is other than economic, technological, or structural grounds, is deemed unjustified. Therefore, it's crucial to follow proper procedures and provide adequate notice to all relevant parties.

Lastly, it's important to issue a certificate of employment to each workers whose employment has been terminated or who has been resigned. The certificate should be provided within 7 days of the termination of employment and should include the specified particulars.

Expected answer:

The cessation of business is governed by the Companies Act 2001 and the Insolvency Act 2009. The legal framework regarding the termination of employment on grounds of redundancy is set in the Workers' Rights Act 2019. An employer is obliged to refer the matter to the Redundancy Board if it employs 15 persons or more. The Supervising Officer must be informed of the intended cessation of business if there are 14 persons or less.

6. Quel est le salaire minimum à ce jour dans la république de Maurice ?

Open AI gpt-4o-mini:

Le salaire minimum à ce jour dans la République de Maurice est de 16,500 roupies par mois, applicable à partir du 1er janvier 2024.

Mistral AI open-mixtral-8x22b:

Le salaire minimum à ce jour dans la république de Maurice est de 16,500 roupies.

Expected answer:

Le salaire minimum est aujourd'hui fixé à Rs. 15,000. Cependant, toute personne étant salarié se voit percevoir un salaire minimum de Rs. 16,500, ce qui inclut le Cost of Living Allowance fixe par voie d'arrêté ministériel en Janvier 2024.

7. What are my obligations as an employee?

Open AI gpt-4o-mini:

As an employee, your obligations include:

Taking Reasonable Care:

You must take reasonable care for your own safety and health, as well as for the safety and health of others who may be affected by your actions or omissions at work.

Understanding Your Contract:

You should ensure that you understand the terms of your contract of employment and abide by them.

Familiarizing with Grievance Procedures:

You need to make yourself familiar with any arrangements for dealing with grievances and other questions that may arise from your contract of employment and utilize them when necessary.

Special obligations:

If you belong to a profession, you may have additional obligations that arise from your membership, which you must fulfill.

Membership Obligations:

If you are a member of a trade union, you must fulfill the obligations you voluntarily undertook upon joining the union.

These obligations are essential for maintaining a good working relationship and ensuring a safe and productive work environment.

Mistral AI open-mixtral-8x22b:

As an employee, you have several obligations. These include:

Satisfying yourself that you understand the terms of your contract of employment and abiding by them.

Making yourself familiar with any arrangements for dealing with grievances and other questions which may arise out of your contract of employment, and making use of them as and when the need arises.

If you belong to a trade union, fulfilling the obligations which you have voluntarily undertaken on joining the trade union.

Not taking any actions in your professional capacity, which would conflict with the standard of work or conduct laid down for your profession, particularly if that action would endanger public health and safety, the health of an individual needing medical or other treatments, or the well-being of an individual needing care through personal social services.

Taking reasonable care for the safety and health of yourself and other persons who may be affected by your acts or omissions at work.

Abiding by any special obligations arising from membership of a profession, which may include obligations with regard to health, safety, and welfare, over and above those which are shared by the community as a whole.

Expected answer:

The obligations of an employee are set in a contract of employment whose terms must be in line with the provisions to be found in the Workers' Rights Act 2019. There are implied obligations which stem from the provisions of the Mauritian Civil Code- these include the duty of loyalty, the duty of

confidentiality, the obligation to perform work personally, the duty of diligence while performing his or her assignment.

8. I would like to hire the services of my nephew who is 15 years old. Can I do so?

Open AI gpt-4o-mini:

According to the provided context, you cannot employ a young person who is under the age of 16. Therefore, you cannot hire your nephew who is 15 years old.

Mistral AI open-mixtral-8x22b:

According to the provided context, a person who is of the age 16 years or more shall be competent to enter into an agreement and shall, in relation to the agreement and to its enforcement, to be deemed to be a full age and capacity. Therefore, as your nephew is 15 years old, he cannot legally enter into an employment agreement. Additionally, no person shall employ, to continue to employ, a young person in work which is likely to jeopardize his health, safety, or physical, mental, moral or social development.

Expected answer:

No. The law provides that any person having attained the age of 16 may be employed.

9. I would like to transfer shares I hold in Company FEDER to my brother. What do I need to do?

Open AI gpt-4o-mini:

To transfer shares, you hold in company FEDER to your brother, you need to follow these steps:

Prepare a Transfer Document that includes:

Your full name and address as the transferor.

Your brother's full name and address as the transferee.

The name of the Company FEDER and its registration number.

The number and description of shares being transferred.

The consideration for the transfer.

Sign the Document: Both you and your brother must sign the transfer document, certifying the transfer of shares.

Conditions of Transfer: Ensure that the transfer is accepted subject to the same conditions attached to the shares at the time of transfer.

Notify the Company: Submit the signed transfer document to Company FEDER's registered office as part of the transfer process.

Compliance with Regulations: Make sure to comply with any other regulatory specific requirements specific to share transfers in Mauritius.

It's advisable to consult with a legal professional to ensure all necessary steps and legalities are adhered to.

Mistral AI open-mixtral-8x22b:

In order to transfer shares, you hold in Company FEDER to your brother, you will need to follow the process outlined in the provided context. However, please note that the context does not provide a comprehensive guide to the share transfer process. Based on the available information, here are the general steps you need to follow:

Complete a transfer of shares form, which should include the following details:

Full Name of Transferor (you) and your full address

Full Name of Transferee (your brother) and his full address

Name of the company in which the shares are held (Company FEDER)

Company No.: (you will need to provide the company registration number)

Number and description of shares transferred (you will need to specify the number of shares and their type)

Consideration (if applicable)

Both you (the transferor) and your brother (the transferee) will need to sign the transfer of shares form.

The transfer or issue of shares is subject to the same conditions as attached to such shares. Please ensure that you understand these conditions before proceeding with the transfer.

Depending on the company's requirements, you may also need to provide additional documentation or meet certain conditions. It is recommended that you contact Company FEDER for further guidance on their specific requirements for transferring shares.

Once the transfer of shares has been completed and registered, your brother will become the new shareholder in Company FEDER.

Expected answer:

You should sign the statutory share transfer form. Then, the transfer shall be registered with the Registrar General Department. Once approved by the Registrar General Department, a certified copy of the transfer form shall be submitted to the Corporate Business Registration Department to have the records amended.

10. What does section 3 of the Constitution of Mauritius, which guarantees the right to life, liberty and security of a person, balance individual freedoms with the state's responsibility to maintain public order and safety?

Open AI gpt-4o-mini:

Section 3 of the Constitution of Mauritius recognizes and declares that fundamental rights and freedoms that exist without discrimination, but it also emphasizes that these rights are subject to respect for the rights and freedoms and for the public interest. This means that while individuals have the right to life, liberty, and security, these rights must be balanced against the state's responsibility to maintain public order and safety. Therefore, any limitations on these rights must be reasonable and justifiable in a democratic society, ensuring that the enjoyment of individual rights does not prejudice the rights and freedoms of others or the public interest.

Mistral AI open-mixtral-8x22b:

Section 3 of the Constitution of Mauritius guarantees the right to life, liberty, and security of a person, but this protection is subject to respect for the rights and freedoms of others and for the public interest. This means that while individuals have certain fundamental rights and freedoms, these rights are not absolute and may be limited to ensure that the enjoyment of these rights by an individual does not prejudice the rights and freedoms of others or the public interest.

The Constitution further provides that no person shall be deprived of his life intentionally, save in execution from a sentence in a court in respect of a criminal offence of which he has been convicted. However, a person shall not be regarded as having deprived of his life if he dies as a result of the use of such force as is reasonable justifiable for the defence of any person from violence or for the defence of property, in order to effect a lawful arrest or to prevent the escape of a person lawfully detained, for the purpose of suppressing a riot, insurrection or mutiny, or in order to prevent the commission by that person of a criminal offence, or if he dies as a result of a lawful act of war.

Therefore, the Constitution of Mauritius balances individual freedoms with the state's responsibility to maintain public order and safety by allowing for limitation on individual rights and freedoms in certain circumstances, such as defence, public safety, public order, public morality, or public health. These limitations are designed to ensure the enjoyment of individual rights and freedoms does not prejudice the rights and freedoms of others or the public interest.

11. Which section and chapter of the constitution caters for the freedom of expression?

Open AI gpt-4o-mini:

The freedom of expression is catered for in Section 12 of Chapter II – Protection of Fundamental Rights and Freedoms of the Individual of the Constitution.

Mistral AI open-mixtral-8x22b:

The freedom of expression is catered for in Section 12 of Chapter II of the Constitution.

12. What does the constitution states about the power of the President of Mauritius?

Open AI gpt-4o-mini:

The Constitution states that:

The executive authority of Mauritius is vested in the President, who may exercise this authority directly or through subordinate officers.

The President acts in accordance with the advice of the Cabinet or a Minister, except in cases where the Constitution requires the President to act according to the advice of someone else or in his own judgement.

The President has the power to appoint the Prime Minister, Deputy Prime Minister, and other Ministers, as well as Junior Ministers, acting on the advice of the Prime Minister.

The President is also responsible for keeping informed about the general conduct of the government and may request information from the Prime Minister regarding government matters.

Overall, the President plays a crucial role in the governance and administration of the country, guided by the advice of the Prime Minister and the Cabinet.

Mistral AI open-mixtral-8x22b:

The constitution states that the executive authority of Mauritius is vested in the President. Unless otherwise provided in the Constitution, that authority may be exercised by the President either directly or through officers subordinate to him. However, this section does not preclude persons or authorities, other than the President, from exercising such functions as may be conferred upon them by the law. Additionally, the President, acting in accordance with the advice of the Prime Minister, may appoint Junior Ministers from among the members of the Assembly to assist Ministers in the performance of their duties.

13. What are they key duties of a company secretary under the Mauritius Companies Act 2001?

Open AI gpt-4o-mini:

I do not have an answer.

Mistral AI open-mixtral-8x22b:

Under the Mauritius Companies Act 2001, the key duties of a company secretary are:

To ensure that the company complies with the requirement of the Act and its constitution.

To keep and maintain the minutes of all meetings of the Board and the shareholders.

To keep and maintain the register of directors and officers and the register of shareholders.

To ensure that the company's accounting records are kept as required by the Act.

To ensure that the company's annual returns are submitted to the Registrar.

To ensure that the company's name is properly displayed at its registered office and at all other places where it carries on business.

To ensure that the company's common seal is kept in safe custody.

To carry out all other duties as may be required by the Act or the company's constitution.

The company secretary may also be required to act as a director or liquidator of the company in certain circumstances.

14. Can you explain the procedure for the incorporation process of a company under the Companies Act?

Open AI gpt-4o-mini:

The procedure for the incorporation process of a company under the Companies Act is as follows:

Right to Apply: Any person may apply for the incorporation of a company, subject to the provisions of the Act.

Application submission: The application for incorporation must be sent or delivered to the Registrar.

Required Form: The application must be in a form approved by the Registrar.

Signatures: Each applicant must sign the application.

Accompanying Documents: The application must be accompanied by:

A document, in a form approved by the Registrar, signed by every person named as a director or Secretary, containing their consent to be director or Secretary.

A certificate confirming that the person is not qualified from being appointed or holding office as a director or Secretary of a company.

Once these steps are completed and the Registrar is satisfied with the application, the company will be incorporated under the Act.

Mistral AI open-mixtral-8x22b:

Incorporation Process of a Company under the Companies Act in Mauritius:

Application: The first step in the incorporation process is to file an application with the Registrar of Companies. The application should include the following:

The proposed name of the company

The company's objects of purposes

The company's registered office address

The name, addresses, and occupations of the company's directors and secretary

The name and address of the company's auditor

Payment of fees: Along with the application, the applicant must pay the prescribed fee for incorporation.

Issuance of Certificate of Incorporation: If the Registrar is satisfied that the application meets the requirements of the Act, he or she will issue a Certificate of Incorporation, which signifies that the company is duly incorporated and registered under the Act.

Post-incorporation obligations: After incorporation, the company must comply with certain post-incorporation obligations, such as holding its first board meeting, appointing an auditor, and filing an annual return with the Registrar.

Exemptions: Certain companies, such as small private companies and companies registered under the Small and Medium Enterprise Act, are exempt from filing financial summaries with the Registrar for a specified period.

15. What are the legal requirements for a company to hold an Annual General Meeting in Mauritius?

Open AI gpt-4o-mini:

I do not have an answer.

Mistral AI open-mixtral-8x22b:

Question: What are the legal requirements for a company to hold an Annual General Meeting in Mauritius?

According to the Companies Act of Mauritius, a company is required to hold an Annual General Meeting (AGM) within 18 months of its incorporation and subsequently, once at least every calendar year and not more than 15 months after the last AGM.

For a company incorporated outside Mauritius, if it is not required by the law of its place of incorporation or origin to hold an annual meeting of shareholders and prepare a balance sheet, it shall prepare and file with the Registrar a balance sheet within such period, in such form, and containing such particulars and annex thereto such documents as directors of the company would have been required to prepare or obtain if the company were a public company.

Additionally, a company is required to file an annual return with the Registrar within 28 days of the date of the annual meeting of the company or within 8 weeks after the date of the annual meeting for a company that keeps a branch register outside Mauritius. The annual return should be completed and signed by a director or Secretary.

The annual return should contain the matters specified in the Tenth Schedule provided that where matters required to be stated are in each case unchanged from the last preceding annual return, the annual return may simply refer to the last preceding annual return.

The company must also send a copy of the annual report to every shareholder of the company not less than 14 days before the date fixed for holding the annual general meeting of the shareholders. However, the Board of a company shall not be required to send an annual report to a shareholder where the shareholder has given notice in writing to the company waiving the right to be sent a copy of the annual report or copies of annual reports of the company generally, and the shareholder has not revoked that notice, and a copy of the report is available for inspection by the shareholder in the manner specified in section 227.

A public company shall deliver a copy of its annual report to the Registrar for registration at the same time as it delivers its financial statements to the Registrar under section 215.

16. What are the key provisions under the Mauritian Workers' Rights Act for protecting employees against unfair dismissal?

Open AI gpt-4o-mini:

The key provisions under the Mauritian Workers' Right Act for protecting employees against unfair dismissal include:

Assessment of Performance: Employers must assess workers on their workmanship, and this assessment should be recorded.

Reprimanding Procedure: If a worker cannot fulfil their obligations, the employer may reprimand them initially before initiating disciplinary actions. This can include a verbal warning, followed by a documented verbal warning and a written warning.

Disciplinary Actions: If no improvement is noted after a period of 6 months, the employer may take disciplinary action, which should be commensurate with the gravity of the case.

Lapse of Sanctions: Any sanctions imposed for minor misconduct shall lapse after one year if there has been no recurrence.

Protection against Dismissal for Minor Misconduct: Workers cannot be dismissed for reasons related to minor misconduct.

Complaint Procedure: Workers may make complaints against their employer regarding any employment-related issues, and the supervising officers is required to investigate these complaints.

These procedures aim to ensure their fair treatment and due process for workers facing disciplinary actions or dismissal.

Mistral AI open-mixtral-8x22b:

The key provisions under the Mauritian Workers' Right Act for protecting employees against unfair dismissal are as follow:

Now workers shall be dismissed for reasons related to minor misconduct.

Every supervising officer is responsible for providing guidance to workers for their performance at work.

Where a worker's work is reported to be unsatisfactory, the supervising offer shall inform the worker of this weaknesses and expected standards of work required of him.

The employer shall assess the worker on this workmanship and the assessment shall be recorded.

Where the worker cannot fulfil his obligations within the terms of this contract of employment, the employer may reprimand the worker in the first instance before initiating disciplinary actions in accordance with the Workers' Right Act 2019.

The worker may initially be sanctioned by way of a verbal warning followed by a documented verbal warning and a written warning.

Where no improvement is noted after a period of 6 months, the employer may, following disciplinary proceedings against the worker, take such disciplinary action which may be commensurate with the degree of gravity of the case.

Any sanction imposed under paragraphs (4) and (5) shall lapse after a period of one year where there has been no recurrence.

A worker shall be entitled to his basic wage during the period of suspension.

The worker shall be reinstated without prejudice and without loss of pay or other privileges if the alleged act of misconduct is not proved.

Any disciplinary committee set up to provide an opportunity to a worker charged with an act of misconduct to give his explanations shall, in his proceedings, be guided by the principles of natural justice.

Where the employer considers that the worker may have to answer a charge of misconduct which may lead to his summary dismissal, the employer shall appoint a disciplinary committee, consisting of at least one independent person, to hear the worker and make its recommendations.

The worker or the union may contest any person forming part of the disciplinary committee and shall submit his or her objections together with the reasons for the objections.

These provisions ensure that employees are protected against unfair dismissal and that any disciplinary action taken against them is fair and just.

17. Can you explain the legal requirements for paid leave entitlements under the Workers' Rights Act?

Open AI gpt-4o-mini:

Under the Workers' Right Act in Mauritius, the legal requirements for paid leave entitlements are as follows:

Annual Leave: Every employee who has worked for the same employer for 12 consecutive months is entitled to 20 working days of annual leave during each subsequent 12-month period of continuous employment. Employees who have worked for 6 consecutive months are entitled to one day of annual leave for each subsequent month of continuous employment, up to the twelfth month.

Sick Leave: Employees who remain in continuous employment for 12 consecutive months are entitled to 21 days of sick leave on full pay during the following 12 months. Employees who have worked for 6 consecutive months and have been present on all working days during that period are also entitled to sick leave.

Maternity Leave: Female workers are entitled to 16 weeks of leave on full pay upon providing a certified copy of the relevant Court order and a copy of the child's birth act.

Leave for Family Care: Workers can be granted leave with pay to care for their child, parents, or grandparents with healthcare-related issues, subject to certain conditions.

Notice for Leave: Employees must give at least 9 days' notice when applying for leave exceeding one day.

Payment for Unused Leave: If an employee does not take or is not granted all the leave they are entitled to, they shall be paid a normal day's wage for each day of unused annual leave at the end of the 12-month period.

Restrictions on Leave: No leave shall be granted during the period from December 20 to January 7, except at the employer's discretion.

These provisions ensure that employees have the right to take necessary leave while also providing guidelines for employers regarding the management of such leave.

Mistral AI open-mixtral-8x22b:

Under the Workers' Rights Act of 2019, every worker, other than a part-time worker, who remains in continuous employment with the same employer for a period of 12 consecutive months shall be entitled, during each subsequent period of 12 months while they remain in continuous employment, to 20 working days' annual leave.

Additionally, every worker shall be entitled to 2 days' leave in every year, in addition to the leave specified in subsection (1) or any other enactment, or any agreement, collective agreement or award of the Tribunal or an arbitrator.

The leave specified in subsection (1) or (2) may be taken on a full day, half day, or such shorter period as agreed between an employer and a worker.

Furthermore, a worker who wishes to take more than one day's annual leave consequently shall, except where reasonable cause is shown, give their employer at least 48 hours' advance written notice.

Lastly, an employer shall pay to a worker a normal day's wage in respect of each day's leave still due to them at the end of the period 12 consecutive months, where the worker has not taken or has not been granted by the employer, all the leave the worker is entitled to under the subsection (1), (2) or (5). However, during any period of 12 consecutive months, a worker has not requested for annual leave or where the request has not been granted the worker may opt to have the remaining leave accumulated and inform their employer in writing of their option

18. What does the Workers' Rights Act say about the right to severance allowance in cases of redundancy in Mauritius

Open AI gpt-4o-mini:

The Workers' Right Act 2019 provide specific provisions regarding severance allowance in cases of redundancy. Here the key points:

Justified Reasons for Redundancy: If the Board find that the reasons for the reduction of the workforce or closing down are justified, it may not order the employer to pay severance allowance.

Unjustified Reasons for Redundancy: If the reasons are found to be unjustified, the Board shall order the employer to pay the worker severance allowance at the rate specified in section 70(1).

Calculation of Severance Allowance:

For every period of 12 months of continuous employment, a worker is entitled to a sum equivalent to 3 months' remuneration.

For any additional period of less than 12 months, the worker is entitled to a sum equal to one twelfth of the amount calculated for the 12-month period multiplied by the number of months of continuous employment.

Deductions from Severance Allowance: Employers may deduct contributors payable to the Portable Retirement Gratuity Fund from the severance paid to the worker.

Interest on Severance Allowance: The Court may order an employer to pay interest on the severance allowance at a rate not exceeding 12 percent per year from the date of termination to the date of payment.

These provisions ensure that workers are compensated fairly in the event of redundancy, depending on the justification of the employer's actions.

Mistral AI open-mixtral-8x22b:

The Workers' Right Act 2019 in Mauritius provides for the payment of severance allowance in cases of redundancy. According to section 70(1), a worker is entitled to severance allowance if:

(a) the worker has been continuously employed for not less than 12 months with the employer on a contract of indeterminate duration and that employer terminates the agreement in circumstances specified in section 70(1); or

(b) the worker has been employed under on more fixed-term contracts with the same employer for a total period of not less than 12 months and the employer terminated the agreement in circumstances specified in section 70(1).

The amount of severance allowance payable is calculated based on the last complete month of the worker's employment on a full-time basis or, where applicable, a monthly rate circulated over a period of 12 months before the termination of the agreement.

However, no severance allowance shall be payable to a migrant worker or a non-citizen employed under one or more contracts of fixed duration at the expiry of their contracts. Additionally, no severance allowance shall be payable where a worker and an employer enter into an agreement under section 13(1) and the agreement comes to an end, unless otherwise agreed by the parties.

In cases where the employer intends to reduce the workforce or close down, the employer must give notice to the Board. If the Board finds that the reasons for the reduction of the workforce or the closing down are unjustified, it shall order the employer to pay severance allowance to the worker at the rate specified in section 70(1). However, if the Board finds that the reasons for the reduction of the workforce or the closing down are justified, it may order the worker to proceed to leave without pay for a specified period, instead of terminating their employment.

19. What are the risks of creating a fake Instagram profile to profit from others?

Open AI gpt-4o-mini:

Creating a fake Instagram profile to profit from others can lead to several risks, including:

Misuse of Fake Profile: Under Act 2021584, making use of a fake profile to cause harm is an offence. If convicted, the individual could face a fine not exceeding one million rupees or penal servitude for a term not exceeding 20 years.

Cyberbullying: If the actions associated with the fake profile involve harassment or intimidation, it could be classified as cyberbullying, which also carries a penalty of a fine not exceeding one million rupees and penal servitude not exceeding 20 years.

Cyber Extortion: If the profile is used to demand money or goods by threatening them, it constitutes cyber extortion, leading to similar penalties.

Fraudulent Activities: Engaging in fraudulent activities, such as deceiving others for personal gain, can result in charge under laws related to electronic fraud, which carry significant penalties.

Unauthorized Disclosure: If the profile is used to disclose personal information without consent, it could lead to legal repercussions related to unauthorized disclosure of information.

Overall, the creation and use of a fake profile can expose individuals to severe legal consequences under various cybercrime laws in Mauritius

Mistral AI open-mixtral-8x22b:

Creating a fake Instagram profile to profit from others falls under the offence of "Misuse of fake profile" as per the provided context. The risks associated with this offence are:

On conviction, being liable to a fine not exceeding one million rupees.

On conviction, being liable to a penal servitude for a term not exceeding 20 years.

20. Puis-je forcer mon fils à travailler sans le payer si j'ai besoin d'aide dans mon business?

Open AI gpt-4o-mini:

Non, vous ne pouvez pas forcer votre fils à travailler sans le payer. Selon le contexte fourni, un enfant ne doit pas être considéré comme employé pour un travail qui pourrait nuire à sa santé ou à son développement. De plus, toute forme de travail doit être appropriée et ne pas interférer avec son éducation.

Mistral AI open-mixtral-8x22b:

Non, vous ne pouvez pas forcer votre fils à travailler sans le payer. Le droit du travail en vigueur à Maurice stipule que tout travailleur doit être payé pour son travail. De plus, le salaire doit être payé à intervalles mensuels, sauf si les parties conviennent d'un paiement à des intervalles plus courts.

Model for Training and Predicting the Occurrence of Potato Late Blight Based on an Analysis of Future Weather Conditions

Daniel Damyanov, Ivaylo Donchev
Department of Information Technologies, Veliko Tarnovo University, Bulgaria

***Abstract*—Plant diseases pose a significant challenge to agriculture, leading to serious economic losses and a risk to food security. Predicting and managing diseases such as potato blight requires an analysis of key environmental factors, including temperature, dew point, and humidity, that influence the development of pathogens. The current study uses machine learning to integrate this data for the purpose of early detection of diseases. The use of local weather data from sensors, combined with forecast data from public weather API servers, is a prerequisite for accurate short-term forecasting of adverse events. The results highlight the potential of predictive models to optimize prevention strategies, reduce losses and support sustainable crop management. Machine learning provides powerful tools for analyzing and predicting data related to plant diseases. Combining different approaches allows the creation of more precise and adaptive models for disease management.**

***Keywords*—Machine learning; potato late blight; data analysis; forecast; prediction models**

I. Introduction

Vegetable diseases represent one of the most serious challenges facing modern agriculture. They affect yields, production quality and economic sustainability of farms [21]. Caused by various pathogens, such as fungi, bacteria, viruses and nematodes, these diseases not only reduce the amount of food produced but also increase the cost of its production due to the need for treatment, prevention and control [1].

A. Economic Importance

Vegetable diseases lead to significant financial losses for both small producers and large agricultural companies [19]. They can:

- reduce yields by up to 30-50% in serious epidemics.
- oblige farmers to use expensive fungicides and pesticides, which increases production costs.
- reduce the quality of production, making it unfit for sale or export.

B. Agriculture Importance

From a business management perspective, vegetable diseases can lead to:

- Loss of competitiveness in the market due to a decline in the quality of production.
- Increased demand for resistant vegetable varieties, which are often more expensive to grow.
- Growing needs for the implementation of modern technologies for disease monitoring and control.

An example of a disease of high economic and agriculture importance is potato blight, which affects both tomatoes and potatoes [16]. In the absence of appropriate measures, it can destroy entire crops in a short time, leading to serious socio-economic consequences.

The development of effective disease management strategies, including risk forecasting through meteorological and agrotechnical data, is essential to ensure a sustainable and productive vegetable growing system. So, the purpose of this study is to improve contemporary models by adding hourly monitoring of the parameters which are important for the development of late blight and to issue timely warnings on this basis.

II. Methodology

A. Objectives of the Current Work

The current study uses environmental and meteorological data to create predictive models for the occurrence of plant diseases, with an emphasis on potato blight in tomatoes. Many models do not consider changes in real-time weather and early warning of disease occurrence but mainly use historical data [18]. Others analyze already appeared plant diseases based on machine learning from photos [11]. Thus, these models may not respond to short-term changes in conditions that can affect the development of the disease and will not trigger the preventive measures that can be taken to minimize losses.

The aim of the current work is to create a dynamic model that is constantly updated with new meteorological data (such as temperature, humidity, wind, etc.) in order to give forecasts for a short-term interval and to predict possible dangerous agronomic events.

Many of the existing models do not include the effects of carrying pathogens over distances, which can be important for widespread diseases such as potato late blight. In addition to basic data, it must take into account winds and other factors that contribute to the spread of spores over certain distances. This approach can combine weather data with diffusion patterns to predict the risk of new infections in different parts of the region or even on neighboring farms. The model should

be able to predict the development of blight in the short term, for example, in the next 24-48 hours, using different sensors for a specific location, rather than global weather data.

The methodology includes the following stages:

- **Data collection**: Collection of historical meteorological data (temperature, humidity, dew point, precipitation) and disease records from open and controlled farms.
- **Preliminary data preprocessing**: Filling in missing values, normalization and identification of critical variables for disease development.
- **Modeling**: Using machine learning algorithms, such as logistic regression, decision trees, and neural networks, to predict favorable conditions for infection.
- **Model Evaluation**: The accuracy and performance of models are evaluated through metrics such as accuracy, sensitivity, and Area Under the Curve (AUC).
- **Validation and deployment**: The results are validated on field data, then the models are integrated into practical tools for agricultural applications.

This methodology aims at early warning and effective management of risks associated with plant diseases.

B. Potato Late Blight

Potato late blight (Phytophthora infestans) is one of the most significant diseases of tomatoes and potatoes, which annually causes serious damage to agriculture. There are many scientific studies in the field of agriculture that describe in detail the situations of the onset of the disease [10]. Favorable conditions are temperatures in the range of 10℃ to about 22℃, humidity above 75%, cloudy and/or rainy, foggy weather [24]. Also, there are side factors that have no less influence on development: light, dew point, wind speed, sunshine, etc., having a strong direct relationship with the pathogen of potato late blight and its development [6], [7].

1) Temperature conditions for occurrence: The temperature ranges in which the appearance of sporangia is favored are between 12-15℃, and for the growth and spread of infection – 20-22℃. At lower temperatures (about 5-6℃), zoospores remain mobile for up to 22 hours, which increases the time for possible infection. Conversely, at higher temperatures (e.g. 15-16℃), the period of mobility is significantly shorter, since accelerated metabolic activity leads to faster germination or depletion of energy, while high temperature, i.e. 24-25℃, reduces their mobility [12]. The optimum temperature for the development of sporangia is 16-24℃. For the reproduction of sporangia, a temperature of 19-22℃ is required. At temperatures above 26℃, the disease stops its development.

Sporangia are formed at high humidity and dispersed at high temperature and low relative humidity. The release of spores is mainly due to changes in humidity. Epidemic conditions are favored mainly by humidity, that is, the prolonged survival of sporangia requires high relative humidity. The development of the disease also depends on the presence of drops of water on the surface of the leaves. Retention of water droplets on the leaves for several hours [23]. In the absence of water vapor, air spores lose their viability. At higher air speeds, multiple spores are formed at 100% relative humidity [7]. Sporulation is also increased by high humidity associated with the dew point [15]. Sporulation in the presence of strong daylight is inhibited during the day. Spores are formed only at night, when temperature and humidity favor sporulation. Sporangia germinate by releasing zoospores at a low temperature, i.e. 12-14℃, while at high temperature (20-26℃) direct germination takes place. Sporulation is stimulated by high humidity near the leaves, which is also associated with surface soil moisture.

C. Analysis Models

There are many well-studied models for predicting the occurrence of potato late blight. They are mainly divided into two groups: empirical and analytical. Of the empirical ones, the most famous are that of Van Everdingen or the so-called "Dutch rules" – based on a quantitative assessment of temperature and humidity to predict initial infections, Wallin's model focuses on the degree of danger through daylight hours during which humidity remains high. Boork's system or also known as "Irish Rules" (IR) considers the duration of humid conditions and the presence of free water in the air to be decisive factors for the development of the pathogen [3]. On the analytical side are those of Fry's model [5] – analyzes critical temperatures and moisture conditions, including an assessment of the genetic resistance of plants, Hartill-Young [8] – it is based on mathematical dependencies that assess the development of the pathogen under specific weather conditions, Baker-Lake [2] – uses modern statistical techniques to determine the time for maximum risk, taking into account historical and current weather data, etc.

One of the important aspects of using machine learning is its ability to adapt to different real-world conditions. For example, models can adapt to changing weather conditions and the specific needs of different regions, considering local climatic differences. In addition, machine learning can combine various data sources, such as satellite imagery, weather forecasts, and agricultural sensor data, allowing for a more comprehensive and accurate assessment of potato blight development conditions.

Most models include an assessment of factors such as relative humidity, length of period of high humidity, temperatures and the likelihood of rain. For example, SimCast is another established model that includes weather data such as temperature, humidity, and genetic resistance of the host to assess the risk of infection [9].

The advantage of empirical models is that they are easily understandable, applicable and require a small amount of data. They are practice-oriented. Analytical ones can be said to be highly accurate, adaptable and predictive. The negatives, on the other hand, in the former are limited precision, lack of universality, sensitivity to local data, empirical models often do not include the biological aspects of infection, such as the

latent periods of the pathogen, while in the analytical ones are complexity of algorithms, large volume of data, over-calibration. A third conclusion can be drawn, which applies to both approaches to data analysis, namely: neither category sufficiently integrates economic or environmental aspects that are important for sustainable disease management, many of the models do not take into account climate changes that can affect the prevalence and intensity of potato late blight.

D. Data Collection and Analysis

For the purposes of the ongoing development, data were collected from a local station made with Arduino architecture and temperature and humidity sensors DHT22, barometric pressure sensor BMP280**,** precipitation sensor, wind force and wind direction sensor Wind Speed Sensor RS485. Data collection, hardware architecture is borrowed from [20]. The data were collected for four months from the beginning of May to September 2024, and were collected every hour, and the placement of the sensors was in Central Northern Bulgaria, as vegetables that are susceptible to potato blight were also grown there. The goal is to track all the data and based on the selected prediction algorithm, to give an immediate signal of potential danger. The collected data is summarized in a file and distributed by columns, which are presented in Fig. 1.

date	temp	dew	humidity	precip	windspeed	winddir	pressure	cloudcover	results

2024-05-01 05:00:00	10.9	10.8	99.34	0	2.2	347.5	1023	94.1	0
2024-05-01 06:00:00	10.8	10.8	100	0	2.5	354.4	1022	90.7	0
2024-05-01 07:00:00	10.8	10.8	100	0	1.1	300.4	1022	85	0
2024-05-01 08:00:00	12.1	12	99.34	0	2.2	292.1	1022	83	1

Fig. 1. Collected data.

The last column, results, reflects the different states of development or stagnation of the sporangia. The calculations in it are made with logical checks according to the most described meteorological prerequisites for the development of potato late blight. They are divided into four categories:

- 0 – No blight conditions exist.
- 1 – Appearance of blight (favorable conditions). It is assumed that the temperature for the development of sporangia is between 12-15℃, the relative humidity is about 90%, the retention of water droplets on the plants is at least one hour or more, and this is monitored by dew. The formula by which the dew point is calculated is:

$$T_{dew} = T - \left(\frac{100 - RH}{5}\right) \quad (1)$$

where T_{dew} is the dew point in degrees Celsius.

T is the current air temperature (in degrees Celsius).

RH is the relative humidity of the air in percentage (from 0% to 100%). Another important condition is that these parameters are meaningful during the dark part of the day between 10 p.m. and 6 a.m.

Case favorable disease conditions:

$$FDC(t) = \begin{cases} 1, \ \sum_{i=n-10}^{n} a_i \ IF(IF \ (temp \geq 12 \ AND \\ temp \leq 15 \ AND \\ humidity \geq 85 \\ AND \ temp - dev < 2 \\ AND \ date \geq 20 \\ AND \ date \leq 7)) \geq 2 \ OR \ \leq 10 \\ 0, \ else \end{cases} \quad (2)$$

- 2 – Late blight development (development conditions are met). The air temperature should be between 15-20°C, high relative humidity above 80% and a difference between humidity and dew point less than 4 and the higher the relative humidity, the higher the dew point – hence we have water vapor condensation [14].

  Case develops disease conditions:

$$DDC(t) = \begin{cases} 1, \ IF(temp \geq 15 \ AND \\ temp \leq 20 \ AND \\ humidity \geq 80 \\ AND \ temp - dew \leq 4) \\ 0, \ else \end{cases} \quad (3)$$

- 3 – Stopping development (temperature >26°C or low humidity).

  Case block disease conditions:

$$\text{BDC(t)} = \begin{cases} 1, \ IF(temp \geq 26 \ OR \ humidity \leq 60) \\ 0, \ else \end{cases} \quad (4)$$

E. Model for Analysis and Learning

The considered way of analyzing input data and predicting future data involves several points. As it is known from the pathology of diseases, data are needed for appropriate temperature range, development time and moment of day, but also very important are the wind and moisture retention on the plants, combined with high humidity for the spread of spores. Chosen machine learning method is LightGBM [4] which is optimized to be very fast when processing large amounts of data. It uses a unique Leaf-wise tree growth technique, which allows it to achieve high accuracy and quickly process data, even with millions of samples. Although standard Gradient Boosting can be slow and resource-intensive, LightGBM is much more efficient and economical. The model includes multiple iterations, in which decision trees are built sequentially to improve prediction accuracy. LightGBM uses a gradient-boosting framework that combines weak learners (usually decision trees) into one strong predictive model. The basic concept relies on minimizing the loss function, which quantifies the error in the predictions.

$$L(\theta) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{j=1}^{K} \Omega(f_j) \quad (5)$$

L(θ) is the total loss, $l(y_i, \hat{y}_i)$ is the loss incurred by forecasting instead of the true value y_i, n is the number of samples, K is the number of trees, and Ωf_j is a normalization term that penalizes the complexity of the model to avoid refitting [13]. In each iteration, LightGBM creates a new tree

based on the negative gradient of the loss function, which shows how to adjust the predictions to minimize error. The gradient g_i for each i is calculated as

$$g_i = \frac{\partial l(y_i, \hat{y}_i)}{\partial \hat{y}_i} \tag{6}$$

The new tree is trained on these gradients. This allows the model to focus on the areas where the most significant mistakes are made. LightGBM is a new way of innovative approach mostly known as leaf-wise tree growth. This way contrasts with the traditional level-wise growth of decision trees. Leaf-wise approach algorithm increases the tree by selecting the leaf with the maximum delta loss and expanding that leaf, which approach allows deeper and more informative trees [13].

Many of the models for predicting plant diseases, such as potato late blight, include various weather and environmental factors (temperature, humidity, wind, dew point, etc.). Using LightGBM in current development has the following advantages:

- It can handle high-dimensional and unstructured data well.
- It provides high-precision forecasts that can help farmers make informed decisions about plant protection methods.
- It processes large amounts of data for different weather conditions, such as those from sensors or weather forecasts.

The initial setup used the Macro Accuracy approach for evaluating the performance of multiclass classification models [22] and Area Under the Curve [17]. They assume that the closer the learning outcome is to 1, the more accurate predictive results the model will give us. If the results are below 0.5, it means that the training does not have the ability to correctly predict and analyze the input-output data.

The rows analysis is done over the column “results” considering “date”, “temp”, “dew”, “humidity”, “precip”, “windspeed”, “cloudcover”. The duration of the training, which is set, is five minutes, and can be changed depending on the results achieved. After training the model, a result of 0.9873 success rate was achieved, which is an excellent result.

III. Results

On using machine learning models (such as LightGBM and other classification algorithms), the results show high accuracy in predicting the risk of occurrence and development of late blight. After training the model and submitting sample input data for analysis, the model proposed here generates the results shown in Fig. 2. Working on the sample input data from Fig. 2, the model shows a 74% probability of situation 1 to occur – prerequisites for the development of late blight, which is a reliable result from the initial conditions for development. Thus, the data with which the model was tested can be replaced with the current input data from the sensors and those from an external API that provides information about the development of the weather conditions in the next hour. Input data can be very easily summarized and analyzed, returning the final information about the development of late blight.

Fig. 2. Model results.

These models can process large volumes of data, including data on temperature, humidity, dew point, wind, and other weather conditions. By analyzing these factors, machine learning models are able to identify complex dependencies and predict with high accuracy when potato late blight is most likely to occur or develop. With the subsequent integration of the model, real-time data will be taken from the weather sensors, and an analysis will be made according to the current data, as well as those from the external API for forecast values in the coming hours. The collection of data from local measuring sensors will be monitored in the last hours to see if there are conditions for the development of the disease, as well as from the expected next few hours for the development of weather conditions. When collecting and summarizing all this data, the system will automatically make a guess and issue a warning about a possible occurrence. The created analytical model from the data with which it is trained will have to make the most accurate assumption about whether there are prerequisites for the development of the pathogen.

In order to check the effectiveness, during the construction of the model, an experimental field was planted in April 2024, divided into two groups – experimental and control. The experimental group consists of tomato plantations, on which agronomic measures will be applied in case of alarm from the model – spraying with a copper-based fungicide – "Carial Star" – Syngenta. The choice of such a fungicide is justified by the desire to minimize the harmful impact of modern fungicides on the environment, as well as on plants and human health, especially those with systemic and translaminar action. The second group includes the control plants, on which no treatment will be applied. For even more precise results, several varieties of tomatoes have been used. In both groups, tomatoes of the variety "Ideal", "Pink Magic", "Rugby" were planted, 10 of each variety. The aim is to check how different varieties react to environmental changes and whether there is a difference between them. The planting of both groups is done at a distance of 3 meters, in order not to transfer the aerosol from the fungicide to the border plants of the control group, and at the same time to keep the development conditions of both groups as similar as possible. The treatment strategy is to take measures only if an alarm is received. The tomatoes were planted on April 29, and they were not treated until a signal

appeared. The first alarm was received on 2024-05-02 between 4 and 8 a.m. The conditions were suitable, with an average temperature of 13.1℃ and humidity of 90.4%. Before treatment, the plants are in good condition, no changes, necrosis or plaques are noticeable on the leaves. According to the manufacturer's recommendations, the treatment interval is between 7-10 days, and we decided that the next spraying should be on the seventh day, if the weather forecasts remain unfavorable. On May 9, the code "1" for favorable development is again received, and treatment with the same fungicide is applied again. In the control group, it was noticed that a coating appeared on the leaves of several tomato roots (of all types). After two days, necrotic brown spots were noticeable on the petioles of the leaves on the plants of the control group. Several of the plants have watery spots on the leaves themselves, and several others on the stems themselves. In the next week, the weather conditions remain unfavorable, and there is precipitation, which further complicates the situation. On May 17, 8 plants from the control group are visibly sick, with a lot of necrosis in all parts, the flower that has sprouted falls off. In the plants treated, weak concentric spots have appeared on several of them, and this is probably due to the poor coating with the contact fungicide. On May 25, these spots were visibly calcified, and the spread was limited only to the original area. In the control group, things continue to develop in an unfavorable direction. There are apparently plants that are not alive, and this implies their removal, in others the development of the pathogen has continued. Of all the plants of each variety, there are 3-4 that do not have very serious damage. It is impossible to say whether there is a variety that is more tolerant of potato blight, but certainly the damage from lack of treatment in the risk periods has drastically changed the situation in both groups.

IV. DISCUSSION

Despite significant progress in the development of models for predicting plant diseases, such as potato late blight, there are still many uncertainties and challenges related to the accuracy and adaptability of these models to different agronomic conditions. The models commonly used to predict the development of potato late blight can be categorized as empirical and analytical. While they provide useful information, there are also some limitations that need to be considered when developing new and improved forecasts.

Empirical models, such as those of Van Everdingen, Wallin and Boork, rely on pre-accumulated observations and are mainly based on specific climatic and agronomic conditions related to temperature, humidity and wind. They provide quick and easy-to-use forecasts, but their main weakness is that they do not sufficiently take into account the differences in the microclimate of different regions. For example, area-specific conditions (such as wind, latitude, moisture levels and other factors) can affect the results of forecasts, making them less accurate in extreme weather conditions. Such models also cannot easily adapt to changes in climatic conditions or to emerging pathogens that have not been predicted in historical data.

Analytical models such as Fry, Hartill-Young, and Baker-Lake are based on mathematical and statistical approaches that allow for more accurate forecasts when new climate data is added. These models try to simulate the mechanism of disease development based on a deeper understanding of the biology of the pathogen and its interaction with the environment. While these models provide better accuracy, they require significantly more input and complex computational time, which can be a barrier to their mass deployment and practical application.

Some of the main challenges in predicting diseases such as potato late blight include dynamic microclimate conditions, frequently changing weather conditions, and interactions between various factors, such as temperature, humidity, wind, and precipitation. In addition, the dew point, which is essential for the development of late blight, is not always correctly calculated in existing models, which can lead to errors in forecasts.

Using machine learning (ML) offers new opportunities to address these challenges. With its adaptive learning and ability to train with large volumes of data involving multiple parameters, machine learning can extract data dependencies that traditional models cannot capture. The ability to analyze historical data as well as real-time weather forecasts gives machine learning models a significant advantage over traditional forecasting methods. Predictions that are based on such algorithms can be more accurate and adaptable, being able to take into account multiple external factors simultaneously and be updated in real time.

V. CONCLUSION

Predicting the development of potato late blight is crucial for sustainable agriculture, as it allows farmers to make informed decisions about disease prevention and treatment. Existing models, including empirical and analytical, have provided valuable guidance for determining the conditions under which the disease can occur or develop. However, these models often have limitations in terms of accuracy and adaptability to changing climatic and agronomic conditions.

Machine learning models that use large volumes of data and can adapt to different conditions offer new opportunities to improve predictions of the development of potato late blight. They provide more accurate and dynamic forecasts while taking into account multiple factors such as temperature, humidity, wind, and dew point. However, the success of these models depends on the quality and reliability of the data used, as well as on their proper integration into agronomic practice.

Despite these advantages, it is important to note that the use of machine learning requires a high degree of trust in the quality and accuracy of the data. Incorrect or incomplete data can lead to errors in forecasts and reduce the effectiveness of models. Therefore, for the successful application of machine learning in potato late blight forecasting, it is necessary to work with reliable and diverse data sources and ensure continuous updating and updating of models.

Existing models for predicting potato late blight have their advantages, but they are also limited in their accuracy and adaptability to changing conditions. Machine learning offers significant opportunities to improve these predictions, allowing for more accurate prediction of the conditions for the onset and development of the disease. However, to achieve reliable and

practical results, it is important to combine different approaches and technologies and to ensure the quality of the data used to train the models.

In the future, in order to achieve better accuracy and efficiency, different approaches must be combined, including traditional models and machine learning technologies. This will allow farmers not only to predict the development of late blight, but also to optimize their efforts to prevent and control the disease, which will ultimately lead to better results in agricultural production and a reduction in disease losses.

Lung Parenchyma Segmentation Using Mask R-CNN in COVID-19 Chest CT Scans

Wilmer Alberto Pacheco Llacho, Eveling Castro-Gutierrez, Luis David Huallpa Tapia
Universidad Nacional de San Agustín de Arequipa, Peru

***Abstract*—During the COVID-19 pandemic, the precise evaluation of lung impairments using computed tomography (CT) scans became critical for understanding and managing the disease; however, specialists faced a high workload and the urgent need to deliver fast and accurate results. To address this, deep learning models offered a promising solution by automating lung identification and lesion localization associated with COVID-19. This study employs the semantic segmentation technique Mask R-CNN, integrated with a ResNet-50 backbone, to analyze CT scans of COVID-19 patients. The model was trained using an annotated dataset, enhancing its ability to accurately segment and delineate the lung parenchyma in CT images. The results showed that Mask R-CNN achieved a Dice Similarity Coefficient (DSC) of 93.4%, demonstrating high concordance between the segmented areas and clinically relevant regions. These findings highlight the effectiveness of the proposed approach for precise lung tissue segmentation in CT scans, enabling quantitative assessments of lung impairments and providing valuable insights for diagnosis and patient monitoring.**

***Keywords*—Mask R-CNN; ResNet-50; computed tomography; lung parenchyma; COVID-19**

I. Introduction

The COVID-19 pandemic posed significant challenges in the diagnosis and management of respiratory diseases, particularly in the accurate assessment of lung conditions. In this context, medical imaging has become a fundamental tool, as its primary objective is to generate meaningful data to analyze the physiology and anatomy of various organs or areas of the human body. Among the most prominent modalities addressing these needs is simple computed tomography (CT). Based on X-ray emission, this technique, considered the oldest within medical imaging, enables non-invasive analysis of the internal structures of the human body with high precision and accuracy [1], [2], [3].

Medical imaging emerged as an indispensable tool to address these challenges. Unlike previous viral pandemics, where its use was more limited, imaging modalities have taken on a central role by enabling the rapid and accurate identification of lung patterns characteristic of the disease [4]. Furthermore, medical imaging is essential for detailed follow-up in cases where the disease becomes complicated, allowing for monitoring of progression and evaluation of the response to clinical interventions [5].

X-rays were one of the tools that emerged during the COVID-19 pandemic due to the limitations in the sensitivity of PCR tests and their lack of immediate availability. Their use enabled early diagnoses. Meanwhile, computed tomography (CT), widely available in developed countries, proved to be highly effective in precisely detailing the condition of the lung parenchyma [6]. Particularly, CT has been fundamental in evaluating lung changes such as ground-glass opacities (GGO), consolidations, and pleural thickening. These features significantly enhance diagnostic accuracy when combined with RT-PCR tests [7] and also allow for monitoring the progression of the disease [7], [8].

However, the manual inspection of these images requires a high level of expertise, specialized human resources, and considerable time, which poses a significant challenge during high-demand situations. In this context, deep learning techniques, particularly convolutional neural networks (CNNs), have emerged as highly effective tools for automating disease detection through the analysis of medical images [9].

The main objective of this study is to segment the pulmonary parenchyma in COVID-19 patients using the Mask R-CNN technique, evaluating the performance of the ResNet50 backbone under different learning rate hyperparameter configurations. Additionally, the impact of data augmentation on the model's accuracy is analyzed, implementing various augmentation techniques to optimize results. This work aims to provide an accurate and efficient tool to assist specialist doctors in identifying and assessing affected areas in lung tissue, thus contributing to a more precise diagnosis and better clinical care.

This article is organized as follows: Section II - Literature Review, Section III - Methodology, Section IV – Results and Discussion, and the final Section V presents conclusions and future work.

II. Literature Review

The authors in study [10] used Mask R-CNN for the diagnosis of COVID-19 through chest X-ray images. This deep learning approach achieved an accuracy of 96.98%, standing out for its efficiency and superiority compared to other artificial intelligence techniques, proving to be accurate and robust in identifying the disease from these images.

D. Suganya and R. Kalpana (2023) [11] employed Mask R-CNN to classify chest CT images and differentiate between COVID-19 positive and negative patients. This model, designed to identify infection regions in the lungs, achieved a mean average precision (mAP) of 91.52% and a classification accuracy of 98.60%, making it an effective solution for the accurate diagnosis of COVID-19.

S. Aparna, et al. (2021) [12], introduced a Mask R-CNN-based model with the ResNet50 architecture to analyze dental

X-rays and estimate the level of filling performed on teeth. Using a dataset of different types of fillings, they trained the model, which performs pixel-level classification, improving the accuracy in diagnosing dental treatments. This approach enables machines to perform automated dental procedures by understanding in more detail the exact region and position of the treatment.

The study by Al Masarweh and colleagues [13] proposed a Mask R-CNN-based method to autonomously generate reference data in MRI images through instance segmentation. Their model achieved a mean average precision (mAP) of 98% for locating and identifying discs, along with a 70% accuracy in classifying regions of interest. This approach allows radiologists to automate the detection of relevant areas in MRI images, improving efficiency and reliability in medical diagnoses, as well as advancing automatic medical image segmentation with cutting-edge neural network technologies.

In study [14] used the ResNet-50 deep learning architecture to classify and detect human sperm heads, achieving an accuracy of 96.66%. This proposed model proved to be efficient in identifying healthy sperm, which are used in the process of intracytoplasmic sperm injection (ICSI). The automation of the process allows for faster and more accurate results, minimizing human errors and improving success rates in infertility treatment.

S. Suriyavarman and A. X. A. R. Annie proposed an algorithm based on the combination of U-Net and Efficient-Net neural networks for the segmentation and classification of lung nodules in CT images (2023) [15]. Using semi-supervised learning with a feature pyramid network (FPN) and the ResNet-50 model for feature extraction, they were able to predict unlabeled nodules. The U-Net technique, with its skip connections, allows for precise nodule localization, while Efficient-Net optimizes the scaling of depth, width, and resolution. Evaluated on the LIDC-IDRI dataset, the model achieved an accuracy of 91.67%, outperforming most existing methods and addressing issues such as high false positive rates and variability in longitudinal data.

In study [16], an improved Mask R-CNN model is proposed, specifically tailored for multi-organ segmentation in the medical field. This model introduces two major enhancements to the original framework: a multi-scale region of interest (ROI) generation method within the region proposal network (RPN) and a pre-background classification subnetwork to enhance segmentation accuracy. Experimental results on an esophageal cancer dataset demonstrated the model's effectiveness, achieving accurate segmentation of organs such as the heart, lungs, and clinically relevant volumes.

The study by E. Dandıl and M. S. Yıldırım (2021) [17] highlights the significance of computer-aided tools for automatic lung segmentation in diagnosing lung diseases. Manual segmentation by experts can introduce errors and inefficiencies. Their research proposed a Mask R-CNN-based approach, leveraging publicly available datasets like HUG-ILD and VESSEL12. The method demonstrated high performance, achieving a Dice similarity coefficient of 95.95% and a volumetric overlap error of 7.65% for the HUG-ILD dataset, and 96.80% and 6.12% for the VESSEL12 dataset. These results validate the effectiveness of the proposed method for precise lung segmentation (Dandıl & Yıldırım, 2021).

Mask R-CNN is a deep learning model that extends Faster R-CNN to perform instance segmentation, classifying objects and generating pixel-level masks for each detected instance. It introduces the RoIAlign method to improve accuracy when processing regions of interest. Its design, which combines detection and segmentation, makes it ideal for applications such as medical computer vision and autonomous driving [18]. Fig. 1 shows the Mask R-CNN framework for instance segmentation

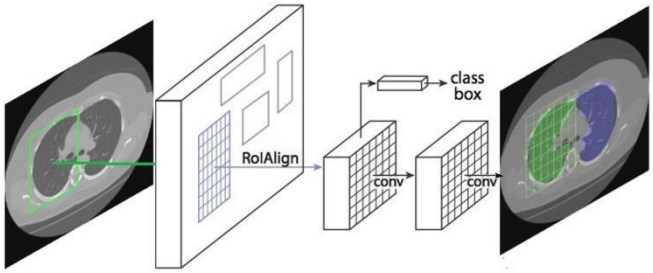

Fig. 1. The Mask R-CNN framework for instance segmentation.

III. METHODOLOGY

A. Database

A total of 20 computed tomography (CT) scans from patients, comprising 3,520 slices, were used for the training and testing phases. Of these, 10 patients were diagnosed with Covid-19 infection pathologies, and 10 patients were diagnosed as healthy or showed no evidence of pulmonary disease.

The number of CT scans used for the training phase included 18 patients, representing 90% of the patients, with a total of 3,126 slices. The number of CT scans for the testing phase included two patients, with a total of 394 slices per image, as shown in Table I.

TABLE I. DATASET FOR TRAINING AND TESTING

Data Set	*%*	*Nro Patient*	*Slides*	*Health*	*Covid*
Training	90	18	3126	9	9
Test	10	2	394	1	1

For the Testing phase, a total of eight computed tomography (CT) scans were used, comprising 259 chest images, as shown in Table II.

TABLE II. DATASET OF HEALTHY AND COVID-19 PATIENTS

Data Set	*%*	*Nro Patient*	*Slides*
Covid-19	75	6	167
Healthy	25	2	92

All CTs for the training and testing phases were obtained from the Zenodo repository in NIFTI format [19]. The CTs for the evaluation phase were obtained from the Research, Technology Transfer, and Software Development Center (CiTeSoft) at the National University of San Agustín.

B. Preprocessing

The images for training, validation, and testing were obtained from medical files in NIFTI format. These slices were converted to PNG format with three channels to preserve the information, scaled to a size of 512 x 512 pixels, and their values were normalized to a range of 0 to 256.

C. Data Augmentation

To avoid overfitting and lack of information, four data augmentation techniques were applied: rotation, horizontal flipping, grid distortion, and elastic transformation. These techniques increased the dataset by 50%, reaching a total of 1760 images distributed between training and testing data, as shown in Table III.

TABLE III. DATASET WITH DATA AUGMENTATION

Data Set	*+%*	*Data Augmentation*
Training	50	1563
Testing	50	197

D. Mask RCNN Architecture

1) Pre-training: In this study, a transfer learning strategy has been adopted by using pre-trained weights from the ImageNet database in the training process of Mask R-CNN. The ImageNet database contains a wide variety of images from different categories, allowing the pre-trained weights to capture general and meaningful visual features. Leveraging these pre-trained weights from ImageNet provides our model with weight initializations that already have a deep understanding of visual patterns, textures, and details in images. This significantly accelerates and improves the training process of Mask R-CNN for our specific task of instance segmentation in medical images of chest CT scans from COVID-19 patients

2) Learning rate: Within the Mask R-CNN architecture, the learning rate is an important hyperparameter that controls the size of the steps the SGD (Stochastic Gradient Descent) optimization algorithm takes to adjust the weights in the model during the training process. This hyperparameter determines how quickly the model converges to a local minimum in the loss function and is responsible for finding a balance between fast and stable model fitting.

3) Implementation: For the implementation of the Mask R-CNN architecture, this study relied on the implementation available in the 'Mask_RCNN' repository by Matterport [9]. This repository provides a Python implementation using TensorFlow, which allowed us to develop and train our instance segmentation model on medical images of chest CT scans from COVID-19 patients.

To carry out the experiments and training of the proposed model, the Mask R-CNN architecture was used with an NVIDIA TITAN RTX graphics card with 24 GB of GDDR6 memory.

The Mask R-CNN parameter configuration was adapted to the specific characteristics of our medical CT image dataset from chest scans of COVID-19 patients. A total of three classes were defined: a) Background and the class corresponding to the areas of interest in the images of the lung regions, b) left, and c) right. For the neural network, 'resnet50' was chosen as the backbone, which leverages the ResNet architecture for feature extraction. The input image dimensions were defined, setting both the minimum and maximum size at 512x512 pixels to ensure consistency in processing. Anchor selection for the Region Proposal Network (RPN) was done using anchor scales of (32, 64, 128, 256, 512) to address different object sizes in our images. During training, a maximum of 200 regions of interest (ROIs) per image and a maximum of 5 true instances for instance detection were established.

For the inference phase, the maximum number of ROIs after the non-maximum suppression (NMS) process was set to 1000, and for training, it was set to 2000. Additionally, a minimum detection confidence threshold of 0.7 was established to ensure the accuracy of the predictions. To mitigate overlap, an NMS threshold of 0.3 was applied to filter redundant detections and improve the consistency of the resulting instance segmentation.

E. Evaluation

For each of the different pre-trained models with a Resnet50 backbone, using different learning rates (0.001, 0.0001, 0.00001) and different epochs, they were evaluated with the following metrics: a) Jaccard Index (1) and b) Dice Coefficient (2).

The equations corresponding to these metrics are presented below.

$$J(A,B) = \frac{D(A,B)}{2+D(A,B)} \quad (1)$$

$$D(A,B) = \frac{2.J(A,B)}{1+J(A,B)} \quad (2)$$

IV. RESULTS AND DISCUSSION

Results were evaluated under two scenarios: with and without Data Augmentation. The best performance was achieved with a learning rate of 0.001. Metrics such as Jaccard Index and Dice Coefficient highlighted the model's segmentation capabilities, which are shown in Table IV.

TABLE IV. SUMMARY OF THE BEST RESULTS

Metric	*With Augmentation*	*Without Augmentation*
Jaccard Index	0.8794	0.8901
Dice Coefficient	0.9266	0.9340

Pixel-level analysis showed high sensitivity (93.39%), specificity (99.56%), and accuracy (98.84%) with augmentation, underscoring the model's reliability in identifying lung regions and lesions.

A. Training with Data Augmentation

In relation to the results obtained for the Jaccard Index metric, better results were achieved with a learning rate of 0.001, with maximum and minimum values of 0.8600 and 0.8794, respectively. Regarding the Dice Coefficient metric, minimum and maximum values of 0.9105 and 0.9266 were

recorded, as shown in Fig. 2. Table V details the results corresponding to each data subset used for training (Fold).

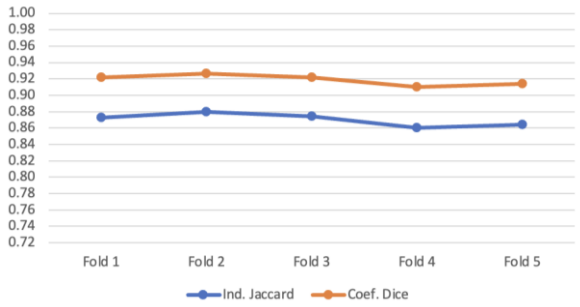

Fig. 2. Learning rate with Jaccard metrics and dice coefficient with data augmentation technique and learning rate of 0.001.

TABLE V. JACCARD METRICS AND DICE COEFFICIENT WITH DATA AUGMENTATION AND LEARNING RATE OF 0.001

Folds	*Jaccard*	*Coef. Dice*
Fold 1	0.8730	0.9215
Fold 2	0.8794	0.9266
Fold 3	0.8742	0.9218
Fold 4	0.8600	0.9105
Fold 5	0.8639	0.9142

In the context of pixel analysis, the metrics of Accuracy, Sensitivity, Specificity, and Precision were evaluated. These metrics provide a detailed understanding of how the model performs in the classification and precise segmentation of pixels in the images. The results corresponding to this evaluation are presented in Fig. 3, Table VI, offering a comprehensive view of the model's effectiveness at the pixel level.

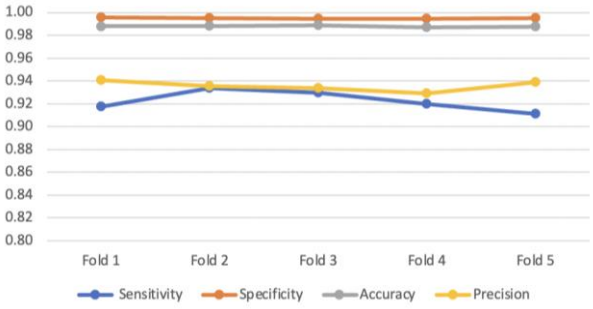

Fig. 3. Learning rate with pixel-level metrics with data augmentation and learning rate of 0.001.

TABLE VI. PIXEL-LEVEL METRICS WITH DATA AUGMENTATION AND LEARNING RATE OF 0.001

Folds	*Sensitivity*	*Specificity*	*Accuracy*	*Precision*
Fold 1	0.9175	0.9956	0.9879	0.9406
Fold 2	0.9339	0.9950	0.9884	0.9357
Fold 3	0.9298	0.9947	0.9885	0.9337
Fold 4	0.9196	0.9946	0.9872	0.9289
Fold 5	0.9113	0.9949	0.9877	0.9390

B. Training without Data Augmentation

In relation to the results obtained for the Jaccard Index metric, better results were achieved with a learning rate of 0.001, with minimum and maximum values of 0.8787 and 0.8901, respectively. Regarding the Dice Coefficient metric, minimum and maximum values of 0.9226 and 0.9339 were recorded, as shown in Fig. 4. Table VII details the results corresponding to each data subset used for training (Fold).

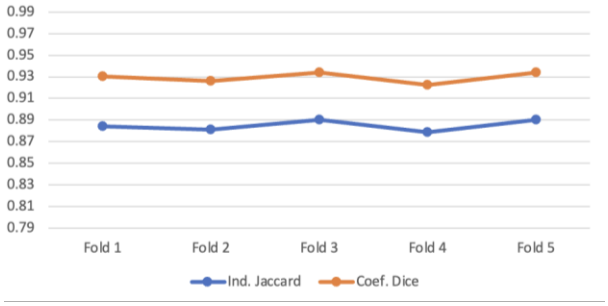

Fig. 4. Learning rate without Jaccard metrics and dice coefficient with technique without data augmentation and learning rate of 0.001.

TABLE VII. JACCARD METRICS AND DICE COEFFICIENT WITHOUT DATA AUGMENTATION AND LEARNING RATE OF 0.001

Folds	*Ind. Jaccard*	*Coef. Dice*
Fold 1	0.8839	0.9302
Fold 2	0.8808	0.9260
Fold 3	0.8901	0.9340
Fold 4	0.8787	0.9226
Fold 5	0.8901	0.9339

In the context of pixel analysis, the metrics of Accuracy, Sensitivity, Specificity, and Precision were evaluated. These metrics provide a detailed understanding of how the model performs in the classification and precise segmentation of pixels in the images. The results corresponding to this evaluation are presented in Fig. 5, Table VIII, offering a comprehensive view of the model's effectiveness at the pixel level.

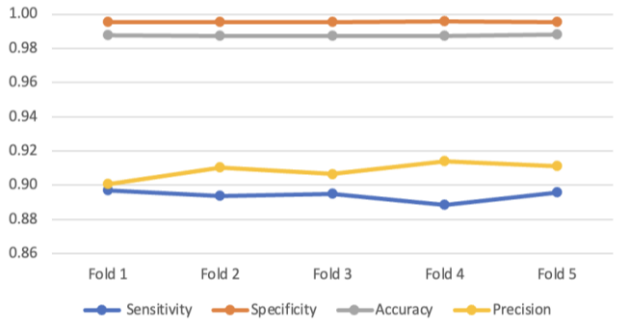

Fig. 5. Learning rate with pixel-level metrics without data augmentation and learning rate of 0.001.

TABLE VIII. PIXEL-LEVEL METRICS WITHOUT DATA AUGMENTATION AND LEARNING RATE OF 0.001

Folds	*Sensitivity*	*Specificity*	*Accuracy*	*Precision*
Fold 1	0.8969	0.9952	0.9877	0.9005
Fold 2	0.8936	0.9954	0.9874	0.9103
Fold 3	0.8947	0.9953	0.9874	0.9064
Fold 4	0.8885	0.9957	0.9872	0.9140
Fold 5	0.8956	0.9954	0.9879	0.9110

In Table XI and Fig. 6, the most notable results regarding the Jaccard Index and Dice Coefficient metrics are presented.

TABLE IX. PIXEL-LEVEL METRICS WITHOUT DATA AUGMENTATION AND LEARNING RATE OF 0.001

Learning Rate	*Ind. Jaccard*	*Coef. Dice*
0.001	0.8901(3)	0.9340(3)
0.0001	0.8777(5)	0.9234(5)
0.00001	0.8264(5)	0.8788(4)

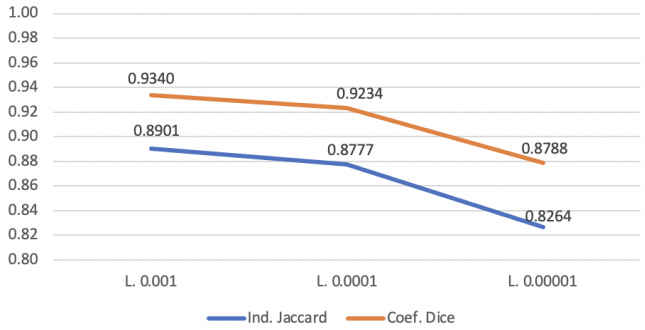

Fig. 6. Learning rate with pixel-level metrics without data augmentation and learning rate of 0.001.

Thorough tests were conducted to optimize the configuration of the semantic segmentation model. In order to explore different approaches, experiments were carried out with the approach a) With data augmentation and b) Without data augmentation, and learning rates were adjusted to 0.001, 0.0001, and 0.00001. After a thorough analysis, the most promising results were obtained by combining the absence of Data Augmentation with a learning rate of 0.001. These findings highlight the importance of precisely and custom tailoring the hyperparameters to maximize the performance of our model. Table IX and Fig. 6, presents the performance metrics under different learning rate configurations, demonstrating that a rate of 0.001 yielded the highest Dice Coefficient and Jaccard Index values.

One of the main limitations of this research was the need to work with all the computed tomography images due to the knowledge provided by the specialists. According to them, COVID-19 could manifest both in the upper and lower images, which complicated the analysis and reduced our detection rate, as the affected areas were very small and difficult to identify. Additionally, we faced the challenge of accurately segmenting the pulmonary parenchyma due to the pathologies caused by COVID-19 in the lungs, which added significant complexity to the analysis process.

The study by Shu, Nian, Yu, and Li (2020) [16] employed Mask R-CNN for lung segmentation, reporting high Dice similarity coefficients (98.1% for the right lung and 97.6% for the left lung). However, the images used do not specify whether the lungs had any pathologies, and the tests were conducted on a range of CT scan slices that included complete organs as well as the lungs, which could influence the model's accuracy when segmenting the lungs exclusively.

In contrast, our research addresses a more complex scenario by working exclusively with CT scan images from patients with COVID-19. This approach not only ensures that the images include clear cases of the disease but also utilizes all slices of the CT scans, including those with smaller or limited affected lung regions. Despite these additional challenges, our model achieved a Dice coefficient of 93.4%, demonstrating its effectiveness in real clinical scenarios related to COVID-19.

Additionally, the work by Dandıl and Yıldırım (2021) [17] also used Mask R-CNN but focused exclusively on lung images with interstitial lung diseases. This study reported Dice coefficients of 95.95% and 96.80% on the HUG-ILD and VESSEL12 datasets, respectively. However, these datasets do not include specific cases of COVID-19, which limits their direct applicability in diagnosing and managing this disease in clinical settings.

In summary, our research stands out by directly addressing lung segmentation in images from patients with COVID-19 and utilizing all the available slices in the CT scans. This ensures a more detailed and relevant approach to the specific challenges posed by this disease.

V. CONCLUSION

This study demonstrates the effectiveness of Mask R-CNN with a ResNet-50 backbone for segmenting lung parenchyma in COVID-19 chest CT scans. Optimal performance was achieved with a learning rate of 0.001 and without Data Augmentation, achieving a Dice Similarity Coefficient (DSC) of 93.4%. Future work will focus on expanding the dataset, exploring alternative backbone architectures, and enhancing segmentation in heterogeneous clinical settings.

Additionally, the use of pre-trained ImageNet weights significantly enhanced the model's performance. By capturing general visual features, these weights accelerated the training process and improved segmentation accuracy. This highlights the importance of transfer learning in specialized tasks, such as the segmentation of medical images from COVID-19 patients.

When evaluating the impact of data augmentation, the study found that while this technique achieved a maximum DSC of 92.7%, training without data augmentation outperformed it, yielding a higher DSC of 93.4%. These results suggest that, for this specific task, excluding data augmentation contributes to better segmentation performance, challenging common assumptions about the universal benefits of augmentation.

Extensive experiments were conducted using a public dataset for training and a custom dataset from Arequipa, Peru,

provided by the Research, Technology Transfer, and Software Development Center I+D+i - CiTeSoft. The findings validated the adaptability of the Mask R-CNN method, demonstrating its effectiveness even when applied to a regional population with potentially different characteristics from the training data.

This study opens new opportunities for improving and expanding the application of the proposed method. Future work will focus on experimenting with different backbone architectures, comparing models trained from scratch versus those using pre-trained weights, and determining the optimal number of epochs to achieve well-trained models without overfitting. Furthermore, testing will be extended to medical images of other anatomical regions to evaluate the method's adaptability and robustness across diverse clinical scenarios.

Impact of the TikTok Algorithm on the Effectiveness of Marketing Strategies: A Study of Consumer Behavior and Content Preferences

Raquel Melgarejo-Espinoza, Mauricio Gonzales-Cruz, Juan Chavez-Perez, Orlando Iparraguirre-Villanueva*
Facultad de Ingeniería, Universidad Tecnológica del Perú, Chimbote, Perú

***Abstract*—TikTok has become one of the most widely used platforms, its innovative video format has allowed companies and users to increase their visibility, transforming the way brands communicate their strategies. This systematic literature review (SLR) explored how the TikTok algorithm influences marketing strategies during the period 2021 to 2024. For this purpose, research was conducted based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) method. Also, reliable and relevant research databases were consulted, specifically Springer, Science Direct and EBSCO, from which 64 studies aligned with the inclusion and exclusion criteria were extracted, all corresponding to academic articles. After compilation, it was determined that 2024 was the year with the highest number of publications, representing 50% of the total number of articles. Likewise, the country that stood out was China with 28.13% of the related documents. Regarding the research approach, quantitative research predominated, followed by qualitative and mixed research. Finally, the study helped to understand the positive impact of TikTok on marketing, showing how it improves the visibility of brands, as well as identifying trends in consumer preferences, which allows the creation of more accurate strategies that are closer to the public.**

***Keywords*—TikTok; algorithm; consumer behavior; marketing**

I. Introduction

In recent years, social media has significantly transformed the way brands engage with consumers and promote their products or services [1]. Globally, platforms such as Facebook, Instagram, Twitter and Tiktok have redefined the marketing landscape, providing companies with new tools to connect with their audiences in a more direct and personalized way [2].

Among all platforms, TikTok has stood out as one of the most influential apps, amassing over 272 million followers [3]. Its focus on short, engaging videos allows users to easily record, edit and share content, making it an attractive space for the digitally connected Generation Z audience [4]. This generation, born between 1997 and 2012, spends a considerable amount of time on social media, preferring to search for products on platforms such as TikTok rather than traditional search engines such as Google [5]. Recent data indicates that 43% of Generation Z members prefer to browse products on TikTok, revealing a significant shift in the purchasing patterns of young consumers [6].

New digital habits have exposed the platform's users to constant content, a key factor in the emergence of a new market, where content creators become essential allies for the presentation and promotion of products or services [7]. This trend, together with the rapid evolution of the platform, has consolidated TikTok as an indispensable tool for the market. The same platform has introduced innovative features such as integrated e-commerce and affiliate programmers, allowing companies to promote and sell products directly [8].

TikTok has positioned itself as one of the preferred entertainments platforms and has become a massive sales channel designed to create a buying environment [9]. Constant exposure to content has made consumers more susceptible to marketing strategies [10], and brands and content creators play an important role in the user experience [11]. Platforms such as TikTok leverage artificial intelligence (AI) to display relevant content that captures user interest, keeping them on the platform for longer [12]. Algorithms store knowledge of interactions, browsing behavior and content preference. This information is useful for businesses because it allows them to make decisions based on the behavior of their consumers [13].

TikTok has an advanced algorithm system, which stands out for its ability to encourage engagement and deliver relevant content [14]. Changes in the technological landscape have raised new adaptive scenarios for the business environment, brands have seen TikTok as a tool to generate business opportunities, interact with customers and generate personalized experiences [15].

The present research is justified by the need to comprehensively examine the impact of these strategies on consumer behavior. This research article focuses on analyzing how TikTok marketing, and the algorithm, influences brand awareness, purchase intentions and actual consumer behavior. This research aims to provide a greater understanding of the mechanisms behind the effectiveness of TikTok marketing and provide insight into applied trends to optimize advertising campaigns.

II. Literature Review

Several studies have looked at the impact of social media and consumer behavior on digital marketing strategies. An analysis by [16] noted that short-form platforms such as TikTok have rethought the interaction between brands and consumers in order to improve the connection and personalization of content, taking an approach based on big data analysis and applying the quantitative method, they concluded that TikTok has managed to transform marketing strategies by facilitating a level of personalization and

connection between brand and audience. Furthermore, the study [17] analyzed the importance of TikTok marketing on SKINTIC's brand image to determine its impact on user perception. Through a simple linear regression analysis, the study concludes that TikTok marketing has a 53% influence on SKINTIC's brand visibility.

The paper in [18] studied the marketing strategies employed in TikTok's e-commerce platform, using SWOT analysis to understand consumer motivation to improve the interaction between consumers and brands. Similarly, in [19] they investigated the implementation of the algorithm in promotion and marketing, with the aim of analyzing how AI has impacted technological and advertising interaction, using a descriptive approach, the study highlights AI as a fundamental tool to improve the user experience in the advertising field.

The study in [20] conducted an advertising analysis with the aim of understanding how creators, users and the recommendation algorithm influence responses and decisions to make purchases. Using a quantitative approach 2,000 posts on TikTok were analyzed, the results expressed the importance of generating valuable and relevant content to user interests, to increase the reliability and interaction of the brand. In this regard, [21] focused on examining TikTok's short-form video ads to determine their influence on purchase intentions by using the SOR (Stimulus-Organism-Response) model, the study posits that marketers can gradually drive consumers' purchase intentions through the interactivity of video advertising.

The research in [22] studied consumer behavior to understand how TikTok influences Semitic's purchase intent by conducting a survey of 403 people, the results of which underline the importance of observing variations in attitudes towards the product, pointing out how trends, along with reviews and recommendations, are key factors in Semitic's business success. Similarly, in study [23] they focused on identifying the key characteristics of short-form video ad content and how these attributes affect consumer purchase behavior, the study analyzed 2578 videos from which they concluded in identifying three key characteristics that influence the purchase process, trustworthiness, experience and appeal.

Table I shows the conclusions and gaps found in the reviewed works.

TABLE I. CONCLUSIONS AND GAPS FOUND IN THE REVIEWED WORKS

Reference	Key findings	Gaps/deficiencies
[16]	TikTok transforms marketing strategies through personalization and audience connection.	Specific conversion and ROI metrics are not explored.
[17]	TikTok marketing influences brand visibility by 53%.	Lack of data on impact on different consumer segments.
[18]	Marketing strategies on TikTok motivate interaction between consumers and brands.	Does not analyze the impact of competition on consumer motivation.
[19]	AI on TikTok enhances the advertising experience and facilitates technological interaction.	Limited to a descriptive view, with no quantitative measurement of impact.
[20]	Quality content aligned with user interests improves interaction and brand trust.	Does not address how strategies can be optimized for different consumer profiles.
[21]	Short-form ads can drive purchase intent if they have interactivity.	This work does not consider the impact of content saturation on ad effectiveness.
[22]	Trends, reviews and recommendations are key to consumer purchase intent.	Does not study the role of creator authenticity on consumer perception.
[23]	Content characteristics influence purchase behavior: trustworthiness, experience and appeal.	Lack of analysis on how the combination of these factors affects customer loyalty.

III. METHODOLOGY

This research initiative aimed to study the impact of the TikTok platform algorithm on digital marketing strategies by employing a comprehensive qualitative approach, coupled with the PRISMA systematization method [24].

This method was designed to help authors of systematic reviews to transparently document each research process. The recent update in 2020 has facilitated study selection, evaluation and systematization, thus ensuring a more efficient and structured approach to research [25].

To carry out the literature review, we systematized studies related to consumer behavior and content preferences on TikTok, considering the PRISMA method guidelines, which allowed for a detailed analysis of the TikTok platform algorithm and its impact on the interaction and effectiveness of marketing campaigns between 2021 and 2024. During the process, specific parameters determined by PRISMA were used, consisting of data collection and filtering. For this, identification, correlation and acceptance criteria were examined. These criteria aided in the understanding and analysis of the research. The inclusion criteria under consideration for the research process had to meet the following parameters:

- Studies must be from scientific databases, which guarantee reliability and quality, to deliver a solid and well-founded systematic review.
- Research should be conducted from 2021 to 2024, as this is the most relevant range for data collection.
- Studies should use terminology related to the research topic, such as marketing, TikTok algorithm and consumer behavior, to ensure the focus of the research.
- Research papers should be written in English, as this broadens the possibilities of finding relevant information.

For the exclusion criterion, the following requirements were determined:

- Any research outside the publication range date of 2021 to 2024 was excluded from the systematic review.
- Studies whose content was not fully aligned with the research objective, as it would not contribute to answering the questions of the review paper.
- When the information in the papers is far from the research topic, it will not be useful for the construction of the study.

In the research process, multiple databases recognized for their contribution to the scientific literature were used, such as Springer, Science Direct, IEEE Xplore and EBSCO.

In the first phase of the research, a search was conducted using key terms for the study, carried out in the English language, such as "Marketing", "TikTok AND Algorithm" and "Consumer Behavior". Subsequently, and to collect current and relevant information, criteria filters were applied to delimit the results obtained during the year 2021 to 2024. After this process, 64 articles with valuable content on the functioning of the TikTok platform and the effectiveness of the algorithm in the strategies used to impact consumers were obtained, thus aligning with the objective of the research.

Fig. 1 shows the process of extracting the documents and their relationship with the databases. This process was divided into three phases, to finally obtain the total number of documents relevant to the research.

From the beginning of the data collection, we proceeded to identify the selected documents considering their origin, which allowed us to carry out a more efficient and systematic analysis of the scientific literature. To identify duplicates, we took advantage of the organizational functionality of the software, Mendeley. We also sought the incorporation of another tool, which facilitated the efficient management of the information, as well as allowing export functions in XML format of the documents stored in Mendeley. Subsequently, the data collected was imported into Microsoft Excel. This process facilitated the identification of 24 duplicates and allowed the improvement in the structuring of the studies, for the improvement process aspects such as the year of publication, the type of publication, the country of origin and the methodological approach used have been considered.

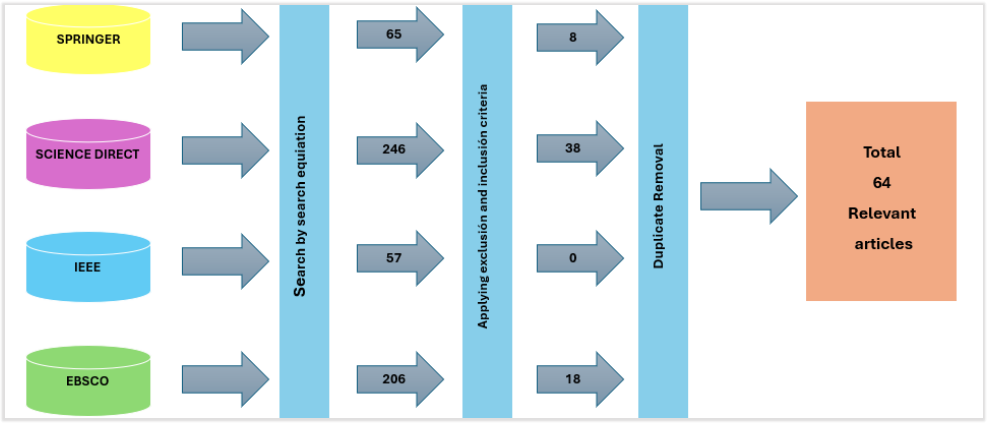

Fig. 1. Database distribution.

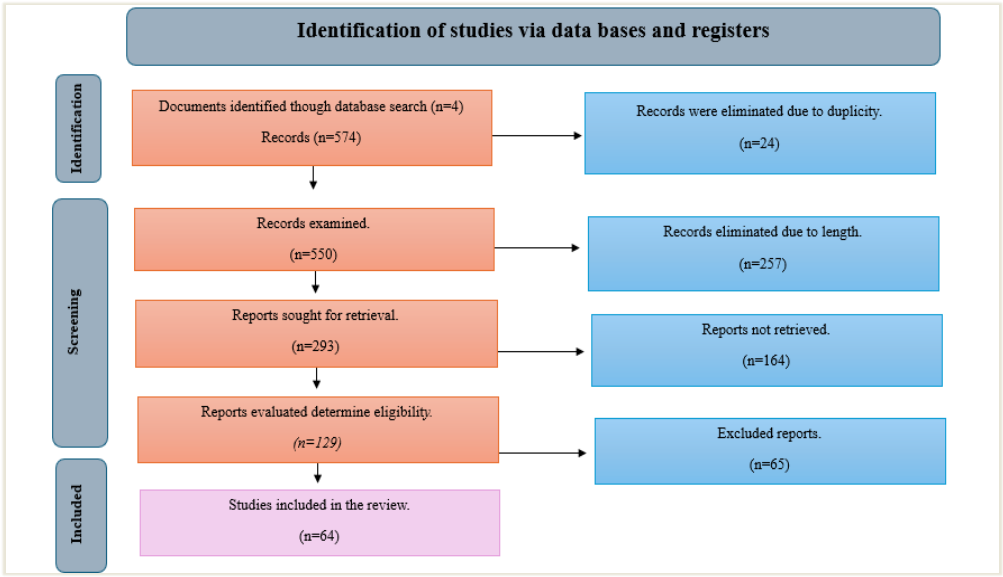

Fig. 2. PRISMA method.

In addition, Fig. 2 shows the total number of documents used during the search for information in all the databases used. This procedure was carried out following the framework of parameters established by the PRISMA method, thus ensuring the transparency and integrity of the literature review process.

IV. RESULTS

For the analysis of the results of the systematic review, the initial database containing 574 records had to be structured and organized. After a rigorous analysis and based on inclusion and exclusion criteria and the application of various filters, a final selection of 64 studies was made. In the initial stage, 574 papers were recognized associated with keywords such as "Marketing", "TikTok AND Algorithm" AND consumer Behavior. As a result, the number of studies found per database was as follows: Springer contributed 11.32%, Science Direct 42.85%, IEEE Xplore 9.93% and EBSCO 35.88%.

For the second stage, 293 records were examined considering the research year range 2021-2024, this process was called "screen viewing". As a result of this phase, it was determined that 13.93% of the documents came from Springer, 39.59% from ScienceDirect, 9.55% from IEEE Xplore and 36.86% from EBSCO.

In the third phase, the titles of the available documents were evaluated, prioritizing those that included keywords related to the focus of the study. As a result, 164 records were discarded, leaving 129 valid documents. These documents were distributed as follows: 11.62% from Springer, 34.88% from Science Direct, 0% from IEEE Xplore and 53.48% from EBSCO. This step was essential to ensure the relevance and quality of the selected studies, aligning them with the research objective.

For the final stage of the analysis, all studies were selected from the scientific literature, which were related to the research objectives. This process involved reviewing the abstracts to verify the validity and functionality of the access links to the documents, ensuring that the studies were available in their entirety and avoiding access problems. As a result, 64 scientific papers were included, while 65 studies were discarded during the final review as they did not meet the assessment criteria.

During the research, 64 articles were analyzed, and it was determined that from 2021 to 2024, several publications were made in recognized databases such as Springer, Science Direct and EBSCO, of which 8 articles belong to Springer, 38 to Science Direct and 18 to EBSCO. Fig. 3 shows the final distribution of the studies in their respective databases used for systematic review.

For the analysis of articles by year, it was considered that the publication period complies with the established range between 2021 and 2024. After this analysis it was determined that 7 (10.94%) publications were from the year 2021, 9 (14.06%) were made in the year 2022, while in 2023 16 (25.00%) articles were published and during 2024 32 (50.00%) articles related to the research topic were published. Fig. 4 shows the number of articles found according to their year of publication.

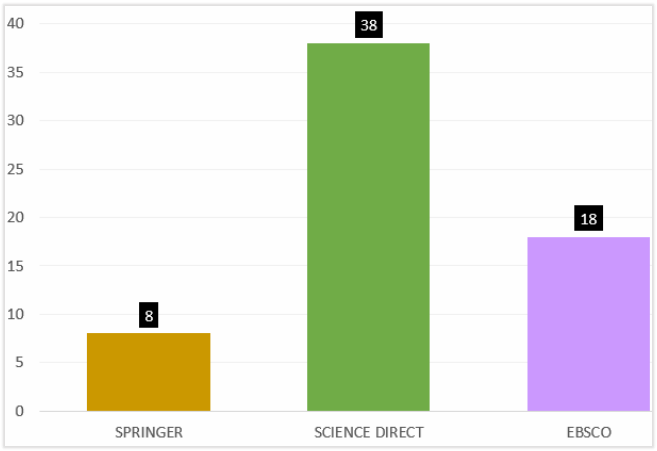

Fig. 3. Distribution of studies by database.

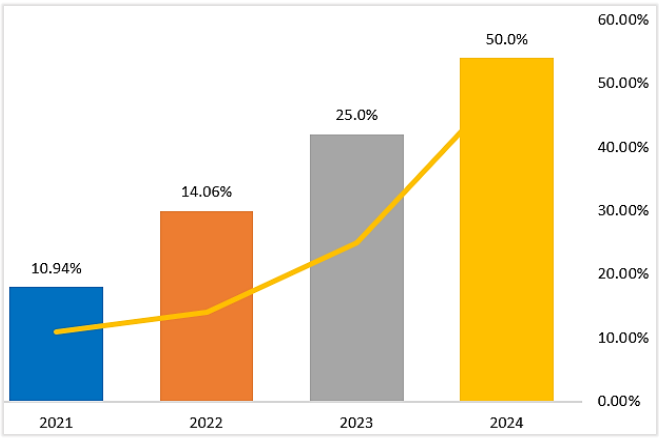

Fig. 4. Distribution of studies by year of publication.

Fig. 5 shows the number of articles published per year in the Springer, Science Direct and EBSCO databases. In 2021, a total of 7 articles were published: 1 from Springer accounting for 14.3% of documents, 4 from Science Direct accounting for 57.1% and 2 from EBSCO accounting for 28.6%. In 2022, 9 articles were registered: 1 from Springer with 11.1%, 7 from Science Direct equivalent to 77.8% and 1 from EBSCO 11.1%. During 2023, the total was 16 articles: 4 from Springer with 25%, 9 from Science Direct with 56.3% and 3 from EBSCO with 18.8%. Finally, in 2024, 32 articles were published: 2 from Springer representing 6.3%, 18 from Science Direct representing 56.3% and 12 from EBSCO equivalent to 37.5%. The following graph shows the visual representation of the studies by year and their origin in the database.

To study the origin of the research papers, the following graph was made. In it, it was identified that the largest number of studies come from China, the result represents 28.13%, followed by the United States with 15.63%, Spain represents 7.81% and the United Kingdom 6.25% of the collection. In addition, it should be noted that most of the documents were written in English. Fig. 6 shows the origin of research at country level.

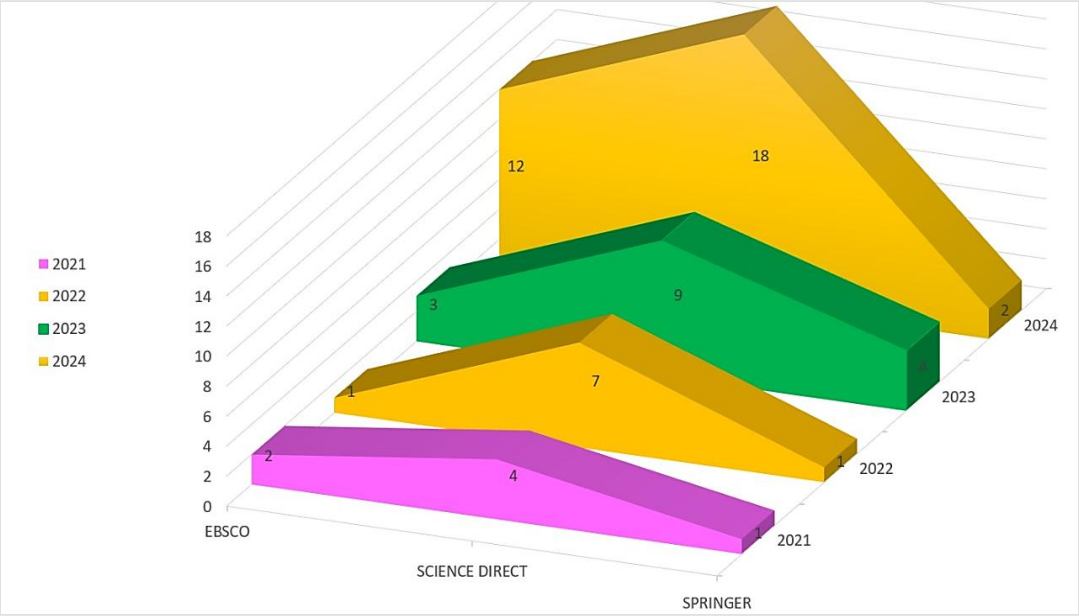

Fig. 5. Number of studies per year and databases.

Fig. 6. Scientific literature reviews by country.

Similarly, it is important to note the classification of the bibliography according to the type of research. To determine the type of research, an exhaustive analysis of the documents had to be carried out, for which purpose they were classified and counted; it was determined that 100% of the scientific publications collected correspond to journal articles, which is equivalent to a total of 64 documents.

On the other hand, Fig. 7 reflects the classification of three types of methodological research. The quantitative approach for Science Direct represented the largest amount with 23 documents, while EBSCO obtained 5 and Springer obtained 1. As for the qualitative approach, the EBSCO database addressed 9 documents, Science Direct contributed 6 and Springer 4 documents. Likewise, the largest amount contributed for the mixed approach was from Science Direct with 9 papers, EBSCO 4 and Springer accounted for 3 papers. Fig. 7 provides the distribution of previously mentioned studies.

For the final analysis, VosViewer was used, a tool recognized for its visualization and bibliometric analysis capacity. This tool made it possible to identify the most recurrent terms in the selected studies, providing a comprehensive perspective on the main trends in digital marketing. Essential terms such as "Social media" have enabled the development of "influencer marketing" on platforms known as "TikTok". Similarly, the analysis evidenced the relevance of the term "Digital content" and showed a strong preference for "short form video" content, this format is highly engaging because of its "persuasion knowledge", the algorithm of these platforms personalizes the content which makes users prone to "purchase intention" within the platform. All terms align significantly with the theoretical framework of the studies analyzed, reaffirming the centrality of social media and short form video in contemporary digital marketing strategies.

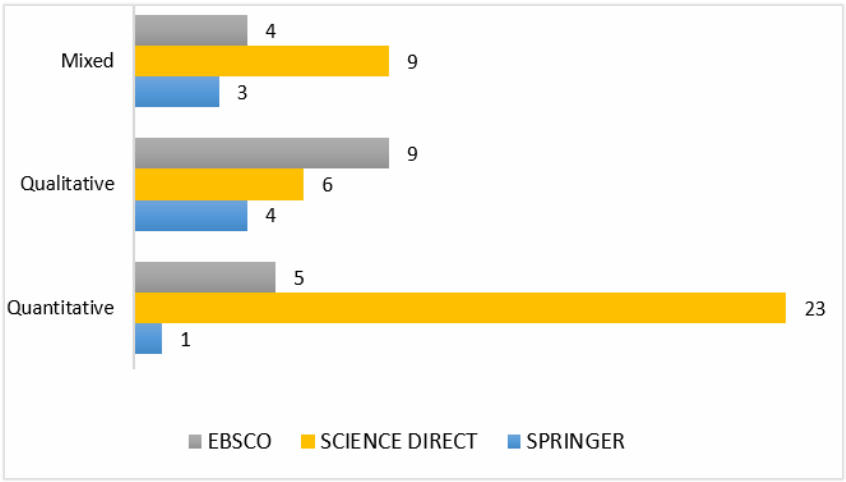

Fig. 7. Scientific literature incorporated in research by methodological approach.

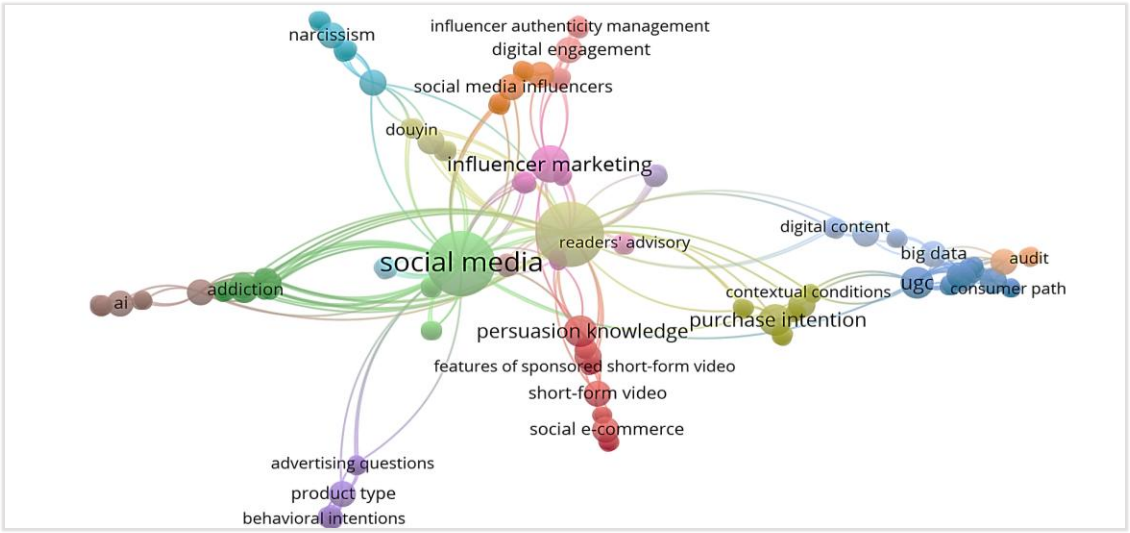

Fig. 8. Bibliometric exploration of the analyzed literature.

The analysis carried out provides an overview of the most relevant terms of the research and is visually represented in Fig. 8.

V. Discussion

A. *RQ1: What Patterns of Consumer Behavior can be Identified from Interaction with TikTok Content?*

Ongoing interaction has led to the identification of behavioral patterns of TikTok consumers. Users tend to show a greater preference for short, visually appealing content. Product presentation and quality is also a factor that users look for. These features are critical and have reflected increased consumer engagement with their preferred brands. The power of consumers has increased with the advent of TikTok, the available video information and brand recommendations abound within the platform, so the virality factor becomes a predominant pattern. In contrast, after an analysis of interactions, the study [16] supports that engaging content is a fundamental part of improving the connection between brands and consumers. On the other hand, for the study [18] interaction is the predominant pattern of consumer behavior on TikTok, the development of e-commerce and live streaming is some evidence of the relevance of today's consumer to create, recommend and comment on videos. It also relates to research [22] that recognizes the importance of interaction to Semitic's success, with the brand highlighting that creating short, quality videos help to enhance its brand image. These studies indicate part of the patterns found, however, to go deeper into the topic, a larger number of related documents were considered, as shown in Table II.

TABLE II. Patterns of Behaviors Found in the Research

#	Patterns	Quantity	Reference
1	Quality	5	[26], [27], [28], [29], [30]
2	Attractive	4	[31], [32], [33], [34]
3	Trends	8	[35], [36], [37], [38], [39], [40], [41], [42]
4	Participation	9	[40], [43], [44], [45], [46], [47], [48], [49], [50]
5	Brevity	3	[51], [52], [53]

The data collection highlights key consumption patterns to understand how companies can effectively connect with consumers. Among the most relevant findings, interactive content and current trends, followed by quality, visual appeal and brevity of content are identified as recurring consumption elements within the platform.

B. RQ2: Are there Differences in Users' Emotional Responses to Ads Targeted by TikTok's Algorithm?

There are a variety of emotional responses to ads targeted by the TikTok algorithm. It is shown that ads aligned with the user's personal interests tend to generate positive emotional responses, which results in greater consumer engagement and willingness to interact with the ad. In contrast, ads perceived as intrusive tend to result in negative user experiences, thus highlighting the importance of generating positive consumer experiences to ensure the success of ads. The various responses have been supported by [19] in their research on the implementation of the algorithm in promotion and marketing, the study has highlighted that AI helps to generate positive user experiences. It is also related to the study [20] that after its analysis of 2,000 publications in TikTok has highlighted that users have had a positive experience, against the content presented, in addition, it highlighted a greater participation of users against content of their interest. Whereas, for [21] interactivity is one of the frequent responses generated by TikTok's short-form video ads, the study highlights the algorithm as a tool that marketers can use to get favorable purchase responses from consumers through the interactivity of video advertising. To further explore the response, several studies have been considered that will broaden the picture and provide insight into the various responses generated by the algorithm-driven ad, as evidenced in Table III.

TABLE III. EMOTIONAL DIFFERENCES OF USERS

#	Differences	Quantity	References
1	Participation	9	[26], [31], [47], [51], [54], [55], [56], [57], [58], [59]
2	Trust	4	[27], [60], [61], [62]
3	Relevance	9	[45], [63], [64], [65], [66], [67], [68], [69], [70]
4	Experience	4	[71], [72], [73], [74]

After analysis of the collected findings, it can be noted that users' emotional responses are diverse. However, a significant difference is observed in algorithm-driven ads, as these generate higher audience engagement by displaying content relevant to users' interests. It is also considered that another key factor influencing positive or negative responses is the experience and trust that users may have with the advertisement shown.

C. RQ3: What Roles Do Consumer Content Preferences Play in the Effectiveness of Advertising Campaigns on TikTok?

Consumer content preferences play a crucial role in the effectiveness of advertising campaigns on TikTok, as they allow personalizing ads, improving viewability and optimizing campaigns according to consumer interests. In that line, the answers found are supported by [16], which highlights the importance of adapting content with consumer preferences. The study emphasizes that personalization plays a significant role in the reach of advertising campaigns. It is also linked to [17], which analyzed consumer trends, in order to optimize SKINTIC's visibility; it concludes that the marketing employed in TikTok campaigns helped improve brand visibility by 53%. While [23] has also endorsed the importance of content preference, after analyzing 2578 videos, 3 key characteristics for campaign optimization were revealed: trustworthiness, experience and attractiveness are key elements that consumers prefer when consuming content. To further detail the responses, a wider range of sources have been consulted to better understand the role of consumer preferences in advertising campaigns. The relationship between consumer preferences and the effectiveness of advertising campaigns is presented in Table IV.

TABLE IV. RELATIONSHIP BETWEEN CONSUMER PREFERENCES AND ADVERTISING CAMPAIGN EFFECTIVENESS

#	Role of the consumer	Quantity	References
1	Customization	8	[30], [52], [75], [76], [77], [78], [79], [80]
2	Optimization	4	[70], [81], [82], [83]
3	Visibility	4	[84], [85], [86], [87]
4	Targeting	3	[87], [88], [89]

Regarding the third question, there is a clear incidence of research that agrees that personalization of content allows brands to adapt their message to the preferences of consumers, which increases the effectiveness of campaigns. On the other hand, optimization is also shown to be a key factor, followed by visibility and targeting.

VI. CONCLUSION

To conduct this research, an exhaustive review of the scientific literature was carried out to analyze the impact of the TikTok algorithm on the effectiveness of marketing strategies during the period 2021 to 2024. At this stage, studies that were not aligned with the research topic were discarded and a total of 64 original articles were selected as the basis for the work.

To support the research, studies were used that not only supported the topic but also established significant precedents around scientific research, which provided relevant background for the development of the analysis. The selected articles were obtained from three recognized databases: Springer, where 8 documents representing 12.5% of the total were identified, Science Direct, which provided 38 documents equivalent to 59.38% and 18 documents from EBSCO, which represented 28.13% of the collection. All the studies analyzed provided a great contribution to the understanding and analysis of the TikTok platform and its impact on marketing strategies.

This RSL provides a detailed analysis of the studies related to TikTok, to understand the relevance that this platform is acquiring in the field of business marketing. The research seeks to understand how the platform's algorithm works and how this tool becomes a key ally in understanding the consumer and developing effective advertising strategies. The study presented is positioned as a valuable source for future scientific research in the field related to marketing.

It is important to note that the research faced a limitation related to the number of studies related to specific terminology, so it was necessary to carefully determine the keywords related to the research article; after correctly combining the terminology, it was possible to find documents that support the work.

Department of Technological and Industrial Processes, ITESO AC[8]

***Abstract*—The objective of this research is to design a Data Mart to identify tactical actions and increase the use of POS (points of sale) in the bodega business sector of Lima, Peru. A quantitative approach, using transaction history data, is applied using the Kimball methodology. This involves the ETL (Extract, Transform, Load) process to create a dimensional model and to develop a dashboard to visualize key indicators using Power BI. This solution is expected to improve the detection and analysis of transactional errors, categorized by geographic location and business sector while enhancing decision-making processes. This research improves the transactional flow and digital payment adoption in small businesses, fostering greater financial inclusion in the Peruvian market. Therefore, the methodology and tools to be applied in this research offer a framework as a model for similar contexts, especially in emerging markets, which will allow closing gaps in digital payment adoption and financial inclusion.**

***Keywords*—Business intelligence; Extract; Transform; Load (ETL); dashboard; data mart; Point of Sale (POS)**

I. Introduction

Every year, there is a higher penetration of digitalization in business areas, which allows not only for the increase in sales, but also makes it possible to reach financial inclusion, which could solve the growth necessities of businesses in Peru. A clear example of this is Yape [1], a digital wallet through which users can send and receive money with enough speed to acquire products in physical establishments, transfer money to family members, or pay for services. Bodegas are not foreign to this development, since, through Yape, they not only increase their sales (increasing their digital demand) but also have better odds of credit access, since banks can visualize their money flow.

While it is well known that Peruvians are increasingly making more purchases through digital means [2] (either digital wallets, credit or debit cards, use of QR codes, among others), the main use of these methods is still low when compared to the rest of Latin American countries. According to the financial inclusion index published by Credicorp, the use of cash in 2024 is still the main means through which citizens' money flows [3]. This represents a big opportunity not only for digitalization but also for bankization.

This is how companies in the digital payment sector aim to incentivize sales through points of sale (POS). POSs are tools that allow users to make payments with not only credit or debit cards, but also through digital wallets, and offer a range of value-added services which bring access to banking financial services, a key part of financial inclusion.

The specific objectives set for this paper are the following:

- Identifying the main transactional errors in the bodega sector associated with POS usage.
- Finding where the transactional errors are present in terms of geographic location and business sector.
- Comparing the bodega sector and the restaurant sector to measure the average ticket sales.
- Verifying if there is an increase or decrease in transactional errors every month.
- Validating if the number of active businesses using POS solutions is steady or if it suffers notable variations.

With this article, we introduce the reader to the use of digital payment methods, mainly points of sale (POS), in the context of Peru, and how the process of digitalization still has a long way to go in this country. We then examine the existing literature, which grants significant insights to the digital payment sector. Subsequently, we review relevant concepts regarding the methodology used, as well as important products, challenges and difficulties within the sector, and present our proposal based on Business Intelligence and the Data Mart architecture in order to create a model and, with it, a dashboard which will allow companies within the digital payment sector to make smart, data-based decisions in order to increase their presence and the transactional flow in Peruvian bodegas, where cash is still the main payment method. Finally, we discuss our findings, focusing on the advantages and benefits of our proposal.

II. Literature Review

In this section, we present a literature review of research relevant to the proposal described in this paper. It contains topics such as the use of digital payment methods and their benefits for clients, the challenges to adopting these methods, the differences between the users who are taking advantage of them and the ones who are not, and important aspects of the use of digital payment methods, among others.

According to Muhtasim, D. A., Yee Tan, S., Hassan, A., Pavel, M. I., and Susmit, S. (2022), security aspects such as authentication, encryption mechanisms and information

provided to clients are strictly related to the improvement of customer experience. Other security-related aspects that should not be excluded are the speed of transactions, software performance, and the privacy of the user's data [4]. It is important to keep all of this in mind to reduce the weak points of companies since maintaining good customer experience is a key task in doing so.

While security is a crucial factor for users to be more welcoming towards the use of digital payments, Alabdan, R. and Sulphey, M. M. (2020) indicate that there are key factors belonging to payment platforms which are important for their acceptance, such as ease of use, utility (how easy they are to set up, where they are accepted, etc.) and user awareness (how well they understand payment options or how to use the services). In addition to this, they found a small difference in the acceptance of mobile payments between men and women, obtaining an average value a bit higher in men [5]. This helps in focusing on the target sector that needs to be worked on.

We can complement this data to the findings of Aurazo, J., & Vega, M. (2021), who explain that the population using digital payments is usually between the age range of 25 to 40 years old, they're usually people with higher education, formal jobs, and are often located in urban areas with Internet access [6]. Their findings further help in narrowing down the potential target sector that digital payment companies should focus on.

Another study, conducted by Ünver, Ş., & Alkan, Ö. (2021), supports these characteristics and mentions that as users age, their odds of participating in e-commerce decrease. Similarly, as their income increases, they're more likely to participate in e-commerce. Furthermore, they found that users who are active in social media and online banking are more likely to use e-commerce [7]. This information represents a significant opportunity for financial inclusion within the digital payment sector, as a target segment has been identified that can be leveraged, not only to drive revenue growth, but also to benefit the broader communities. This is crucial, as noted by de Moraes, C. O., Roquete, R. M., and Gawryszewski, G. (2023), who found that access to finance, in general, has a direct relationship with income inequality in the population, but the impact is even greater regarding digital finance specifically. [8]

It has been demonstrated that e-commerce models can increase client acquisition, sale goals, and overall revenue, as indicated by Hafiz Yusoff, M., Alomari, M. A., Adilah, N., Latiff, A., and Alomari, M. S. (2019). [9] This means that expanding the reach of digital payment methods can generate a positive impact on the population, not to mention the effect that digital platforms have on businesses.

However, the challenges that users may face must be considered when wanting to implement digital payment platforms. Widayani, A., Fiernaningsih, N., and Herijanto, P. (2022) explain that there is a set of barriers that complicate the adoption of said platforms, such as the tradition barrier, which refers to innovative changes that clash with user's routines or traditions; the use barrier, which represents the incompatibility of user's habits with technological innovation or the psychological barrier, defined by user behavior such as mistrust, anxiety, lack of control of discomfort [10]. Identifying and knowing how to deal with these barriers is crucial to face the challenge of digital transformation and reach users more efficiently.

We can complement this with the research by Hermenegildo-Chávez, Martín-Ruiz, and Rondán-Cataluña (2023), who found that, in Peru, client loyalty on sale channels is influenced by the environment, more specifically, online and offline environments [11]. Clients have a better feeling of security for offline sales, and this is related to their trust and loyalty to the seller. This factor represents another of the challenges of implementing digital transformation, especially in the context of developing countries.

One way to counteract this is to improve the interoperability between electronic systems, as stated by Libaque-Saenz, C. F., Ortega, C., Rodriguez-Serra, M., Chong, M., and Lopez-Puente-de-la-Vega, S. (2024). Digital wallets from different providers need to communicate between themselves easily. Additionally, providers must focus on keeping scalable systems to generate future benefits for their customers in the long term [1]. This is important because any way to make customers feel comfortable using these platforms will help in dealing with the previously mentioned barriers.

The authors Alkan, O.; Küçükoğlu H. and Tutar, G., (2021) add that, considering age, gender, education level, and monthly income have an impact on online shopping, it would be beneficial if the providers of these services use this data to develop adequate marketing strategies to reach the necessary users. Additionally, they state that complaints, suggestions, or user requests may be received directly using field studies to determine the factors of user preferences and keep them in mind to personalize and improve their experience with the service [12]. These findings give us an idea of how companies in the digital payment sector can expand their reach and improve their relationship with their customers.

While these related works bring us valuable information and insights, they do not present practical proposals that take advantage of such insights. Our proposal consists of a solution for companies in the digital payment sector to visualize not only their general performance, but also to bring light to the gaps in this market, allowing them to focus on unattended parts of the sector, such as different types of businesses, as well as provinces or districts where digital payment methods are barely present, if at all.

This solution will also allow its users to find and manage errors, issues or problems with more efficiency and precision, so that they can work in improving their clients' experience and continue to provide them with a steady and reliable service.

III. Business Intelligence Methodology

Before determining the methodology to be used in this research, we will review the concepts of data warehouse, data mart, and the most known business intelligence methodologies today.

A data warehouse is defined as a collection of data that helps in the decision-making process of the entity in which it is used. A data warehouse stores copious amounts of data coming from diverse sources, which must have a coherent format for their

later exploitation (analyses, reports, etc.) by the organization [13].

It is also important to know how to differentiate a data warehouse from a data mart. While the first holds the entirety of the organization's data, data marts hold only a subgroup of it, focusing on a specific business area. They are both key components in the business intelligence architecture.

A. Inmon Methodology

Developed by Bill Inmon and his team in 1980, this methodology is centered on the creation of one centralized and complete data warehouse, which serves as a data source for the whole organization. The Inmon methodology involves designing the data warehouse based on the data sources and the entities and relationships present in them. The normalized data warehouse is then used to feed several data marts which adapt to the specific commercial needs and use cases [14] (Fig. 1).

Key aspects of this methodology include:

- The data warehouse is very flexible to change.
- Business processes can be understood very easily.
- Reports can be handled by different enterprises.
- The ETL process is not as error prone.

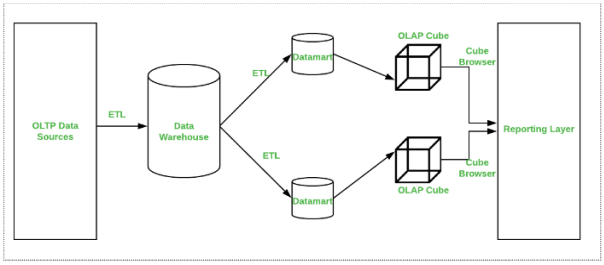

Fig. 1. Architecture according to the Inmon model. [14]

B. Kimball Methodology

A methodology developed by Ralph Kimball and his team in 1990, the Kimball methodology consists of delivering data to end users in the fastest and most efficient way possible. It implies designing the data warehouse based on business processes and key performance indicators [15].

Kimball's data model follows a down-up approach for the architecture of the data warehouse, in which data marts are formed first, according to the company's commercial requirements [16] (Fig. 2). Characteristics of this methodology include:

- Fast configuration and construction.
- When compared to the multiple-star schema, report generation is highly successful.
- Highly effective database operations.
- Takes up less space in the database.
- Easy to manage.

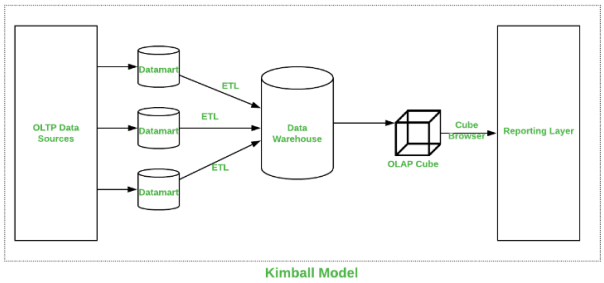

Fig. 2. Architecture according to Kimball's model. [15]

C. Data Vault Methodology

Created by Dan Linstedt in 2000, it is based on creating a scalable, agile, and resistant data warehouse. This methodology presents the design of the data warehouse around data history, auditability, and traceability. The data warehouse consists of a 3-layer data model which includes hubs, links, and satellites. This methodology is adequate for organizations that need flexible and adaptable data architecture, a high-performance data load process, and an auditable data history registry [14] (Fig. 3, 4).

Attributes of this methodology include:

- Scalability: Data vaults are highly scalable, which means they can manage large amounts of data and easily add new data sources. This makes it an ideal solution for fast-growing companies.
- Flexibility: The data vault is highly adaptable and can manage changes in data without having to restructure the entire model. This means that in the future, it can be easier and cheaper to make changes.
- Data history: Data vaults keep a complete history of the data, which allows for historic analyses and data comparisons.

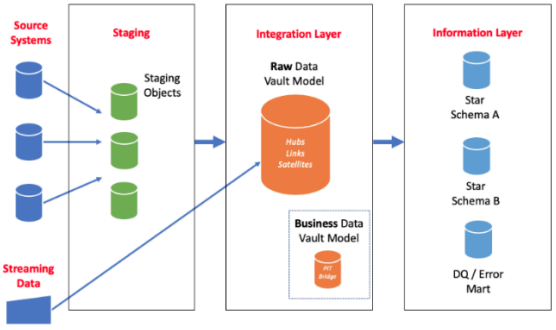

Fig. 3. Data Vault model architecture. [17]

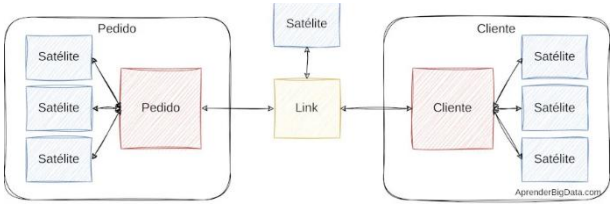

Fig. 4. Example of internal components of the Data Vault model. [18]

For this study, Ralph Kimball's methodology was chosen because the model is being proposed for the operative area of companies in the digital payment sector, for which a data mart would be used to measure the desired indicators, and in the future, more data marts or even a more robust data warehouse could be implemented as each company and/or their products grow.

IV. About the Digital Payment Sector

In Peru, the digital payment sector is playing a key role in the financial inclusion and growth of small businesses. This is what the companies in this sector strive to do – to offer new tools that assist businesses in moving to digital payment systems, thus assisting the businesses in managing their finances and surviving in the competitive market of today and tomorrow. Technology is not the focus; it is about empowering people and creating lasting opportunities [19]. The goals of the digital payment sector include this commitment:

- Putting customers first: Making sure businesses have the tools and support they need to succeed on their financial journey.
- Creating meaningful impact: Developing solutions that enable small businesses and enhance the economic development of communities.
- Fostering growth and adaptability: Always improving to overcome any given challenge and adapt to changing needs.
- Building trust through communication: Keeping open and honest conversations to build up the right connections with clients and stakeholders.
- Investing in talent: Attracting and nurturing talented people to lead the way to innovation and excellent service.
- Championing digital transformation: Using creativity and technology to turn problems into opportunities and provide useful, forward-thinking solutions.

A. Products in the Digital Payment Sector

The digital payment sector provides several innovative solutions for the needs of businesses and consumers. These include.

1) POS Systems: This first product offers a wireless POS, which has contactless payment technology and accepts all Visa and MasterCard debit and credit cards. To use this service, customers don't need to pay monthly, only the POS must be paid for and it has a regular price of S/.425. Commission for national cards is 3.89% + IGV and 4.99% + IGV for international cards.

2) Online payment platforms: This service allows for an easy and fast integration of plugins and APIs. This service also accepts payments from all credit and debit cards, with no monthly costs, which means only successful payments have a cost. It has the following commission values:

a) National cards: 4.20% + $0.30 + IGV

b) International cards: 5.49% + $0.30 + IGV

c) PagoEfectivo (a local online payment platform): 4.20% + $0.30 + IGV

B. Identified Challenges in the Digital Payment Sector

- Experience during the collecting payment process seems stagnant and does not take advantage of current technologies in procedures such as sales counting, order history, and efficiency in balancing.
- Service coverage is and always will be a weak point because payment methods always require an active internet connection for optimal functionality. This also depends on the location of the business. For example, when having a large concentration of customers in the same place, a weaker network hinders customer experience even more.
- Having a complex interface can make it difficult for customers and staff to navigate, operate and customize the software. It can also increase the risk of errors, confusion, and frustration.
- Limited functionality when the software does not have features or integration necessary for the business. For example, it is possible that a client needs software that accepts multiple payment methods.
- Security issues when the software is vulnerable to piracy, malware, or data violations that could compromise the business and/or the client's information.
- Bad customer service when the software provider does not offer support, orientation, or appropriate and timely problem solutions for the customer's issues or questions. Bad customer service can cause frustration, a feeling of helplessness, and dissatisfaction, and it can affect the performance and continuity of the business.

C. Opportunities and Improvements in the Digital Payment Sector

- Better POS payment experience: "Less is more" [20] defines the main needs of businesses in their day-to-day routine. Taking fewer steps to make a sale means more sales will be conducted. This is where the POS industry has a big opportunity: being able to bring more efficient experience in the payment process, reducing the number of steps, and streamlining the interactions between the business, the sale, and the client.
- Better financial inclusion: It is estimated that only 46.1% of the Peruvian population [3] is financially included. Meaning that they know, trust, and can access financial services (also known as credit). However, there's a social development barrier present, since a large part of society doesn't represent a financial benefit in the eyes of banking entities, which is why growth opportunities are lower or almost null for this sector. The insertion of digital payment methods aims to bring banking access to the income and expense flows, so that financial entities gain transparency and trust, and in this

way, make them more willing to bring their services to this population sector.

- Acceleration in digital transformation: The use of cash in Peruvian businesses is still relevant due to the low penetration of banking in society, in general. The increase in the use of digital wallets such as Yape or Plin impulses citizens to not only make digital transactions but also pushes business owners into accepting these payment methods in their establishments. There is a big challenge here since despite this increase in digital wallet use, there is still fear of using them among the population, mainly because of education (or lack thereof) reasons [3].
- Business analytics is a competitive advantage: While sales in the commerce sector increase, new opportunities for business growth arise, such as offering new products or services, making marketing campaigns, and hiring more staff, among others. It is here where competitors emerge and analytics gain relevance, because having metrics and more sector knowledge helps in making better decisions; for example, if a business owner knows that most of his clients pay using DINERS cards, he could make loyalty campaigns with this brand, increasing consumer recurrence.

V. Data Source Analysis (Dataset)

The dataset used for this research is based on information acquired from the transactional database (Data Lake) of a company in the digital payment sector, but it was slightly modified for confidentiality reasons. It was obtained in Excel format under the following structures:

TABLE I. Business Dataset

N°	Field	Description
1	Id_comercio	Business unique code
2	Tipo_doc_tributario	Tax document type (RUC20, RUC10, DNI)
3	Departamento	Department where the business is located
4	Provincia	Province where the business is located
5	Distrito	District where the business is located

The first dataset, shown in Table I, contains information regarding many businesses and it includes their unique ID, the document type corresponding to each of them (usually the ID number of the legal representative), and their location, which consists of three fields: department, province and district. The second dataset, shown in Table II, contains much more technical information. It has data related to the errors occurring during transactions, including the denial code, the description of said code and the sum corresponding to the transaction amounts for transactions with errors.

The third dataset is much smaller but still has valuable information. Shown in Table III, it stores the codes and descriptions for the business sectors, and the ID of every business, effectively linking each business to its corresponding sector.

Finally, the fourth dataset, shown in Table IV, is the most important. It holds the data corresponding to the details of the transactions made by each business. It stores the month, the number of transactions made by the business during said month, the values of these transactions, and how many of them were successful.

TABLE II. Detail of POS Errors During Authorization

N°	Field	Description
1	Id_comercio	Business unique code
2	Action_code	Denial code during transaction attempt
3	Desc_respuesta_trx	Error code description
4	GPV	Sum of transaction amounts for failed transactions

TABLE III. Commerce Sector Detail by Business

N°	Field	Description
1	Id_comercio	Business unique code
2	Cod_mcc	Commerce sector code
3	Desc_mcc	Description for the commerce sector

TABLE IV. Transaction Detail by Business

N°	Field	Description
1	Cod_mes	Month code
2	Id_comercio	Business unique code
3	trx	Number of transactions made by the business
4	GPV	Sum of transaction amounts for this business
5	Trx_exitosas	Number of successful transactions for this business

VI. Indicators or Business Metrics

The following indicators were identified as important for this research:

- Conversion of successful transactions in bodegas using POSs: This is essentially the main indicator for companies in the digital payment sector. Being able to track the number of successful transactions is of utmost importance in this area, as it will help companies assess their performance and key results, and it also facilitates the process of finding errors in any of the systems used throughout the payment processes.
- Use of digital payment methods in bodegas which use POSs: another key metric is how much digital payment methods are being used in bodegas. As stated in the literature review section of this paper, it has been proven that the use of digital payments has positive and noticeable impacts in businesses in general. Because of this, it's important that business owners (especially the older, sometimes more informal parts of the population) learn about these benefits to increase their income. Measuring this can lead to important insights for future works in this sector.

- Number of bodegas with POSs that also have access to financial services (credit, maintenance discounts): tracking this number can lead to insights on how the access to financial products impacts the number of transactions carried out by each business.
- Market share in POSs in the bodega sector in Peru: Keeping track of the market share for POSs can help determine which regions have the biggest growth potential and help companies direct their efforts into entering these regions.

VII. Business Intelligence Architecture

To apply Business Intelligence (BI) in any environment, an architecture capable of converting a company's operational information into useful information for the strategic and tactical areas of the organization is necessary [21]. The standard transactional model, called OLTP (online transaction processing) which companies use, does not allow adequately efficient access to the information needed to make business decisions. Because of this, BI solutions propose the use of the OLAP (online analytical processing) system (shown in Fig. 5), in which specialized data repositories, called data warehouses or data marts are used, as mentioned previously in this paper. These data repositories allow information queries to be much faster because of the way they structure data, and they are fed by the company's traditional sources of information, which could be databases or spreadsheets, among others.

The use of these repositories will allow users (usually staff in management positions), to visualize the information they need through dashboards adequately and clearly, according to the company's business sector and personal preferences. This will help them make key business decisions. Business Intelligence architectures are usually composed of the following elements/processes:

- Data sources: Any file system, databases, or other sources of information the company uses in its standard model to handle daily transactions. For example: plain text files, Excel files, MySQL or Oracle databases, among others.
- Extraction, transformation, and load (ETL) process: it's the process through which the company's information, which can have several origins, is combined into a single centralized repository, in which it's cleaned and organized according to the company's needs [22].
- Data storage (Data Warehouse/Data Mart): The data repositories that handle the storing of information provided from the data sources. They can store structured, unstructured, or semi-structured information.
- Data exploitation: The final stage of the process, where users can visualize the information they need easily and quickly, through one or more dashboards. This leads to a simpler business decision-making process.

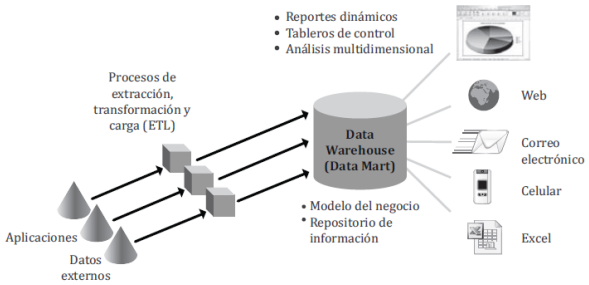

Fig. 5. Architecture of a Business Intelligence Solution [21].

VIII. ETL Process and Dimensional Model

The objective of the dimensional model is to facilitate information queries for users. For this case, the star model was chosen because, due to the simplicity of the data structures, it was not deemed necessary to go for the snowflake model, which usually consists of more complex relationships between tables. The star model, on the other hand, consists of a main fact table located in the center, which is related to several dimensional tables that are relevant to the business environment. The fact table contains information about transactions, which include the business code, the month and year of the transaction, the number of transactions, the value of the completed sales, error codes and descriptions (if any), and the code and description of the commerce sector. In addition to this table, the following dimensions were presented:

- Dim_Cod_Comercios: Contains information related to the business such as its code, document information, and geographic location, shown in Fig. 7.
- Dim_Cod_Rubros: Contains information related to the codes and names of the possible commerce sectors for each business. For example: transportation services, food sales, clothing sales, and medical services, among many others.
- Dim_Cod_Errores: Contains the codes and names for any errors that could occur when attempting to make a transaction.
- Dim_Tiempo: This dimension is usually considered necessary on any dimensional model. In this case, it contains the values for the transactions' months and years.

As we can see in Fig. 6, and according to what we've described above, the fact table stores the information from the fields of all dimensions. This allows queries to be made efficiently using dimensions as filters. For example, we could visualize all the transactions from August which generated a 116 error (insufficient funds). This ease of query is crucial for the business's continuous improvement, since it can be executed very quickly and allows data to be shown clearly and concisely, as explained in the results section.

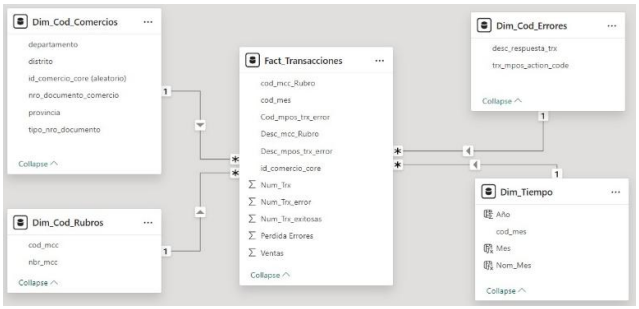

Fig. 6. Proposed dimensional model.

However, before starting with the dimensional modeling, the program Pentaho Data Integration was used as the main tool to conduct the ETL process. First, partial information was extracted from the transactional database to an Excel file (.xlsx). Then, for the transformation stage of the process, the data was ordered, filtered (to remove information with null values), and cleaned to remove any duplicate values, maintaining good data quality for the model. This process was repeated for all the dimensions proposed in the model.

Once the transformations were completed for each dimension, the corresponding transformation to generate the fact table was executed. This consisted of joining the data sources of the transactions, errors, and commerce sectors, as shown in Fig. 8. Then, the data was loaded to Power BI to start with the creation of the dashboard.

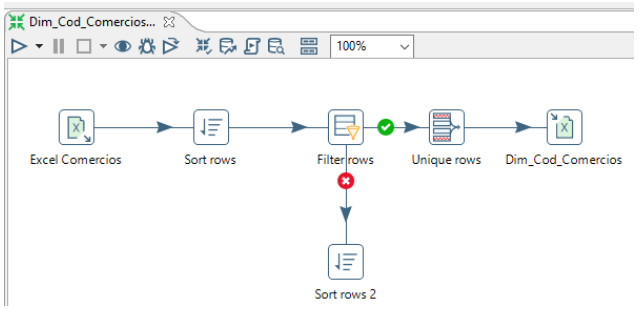

Fig. 7. ETL process carried out in Pentaho Data Integration for the Dim_Cod_Comercios dimension.

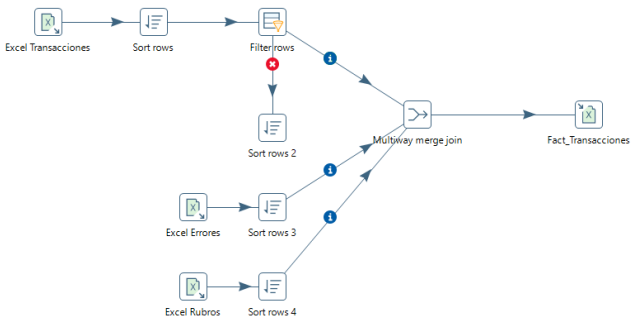

Fig. 8. Pentaho Data Integration view for the generation of the fact table, Fact_Transacciones.

IX. Results

Power BI was used as the tool to create a dashboard separated into pages to keep information organized. As shown in Fig. 9, the menu view was generated as the first page, which consists of a set of buttons that takes the user to the desired page. Each button is labeled with the information shown on each page. All these pages represent the most important metrics for the proposed solution and are the ones that generate the most value to the company's decision-making process.

The dashboard with transaction information shown in Fig. 10 allows users to visualize the business status quickly, as it presents a concise view of the number of transactions carried out to date, how many of them have been successful and how many have had errors, plus the value of sales. All of this is during the selected month in the filter located above.

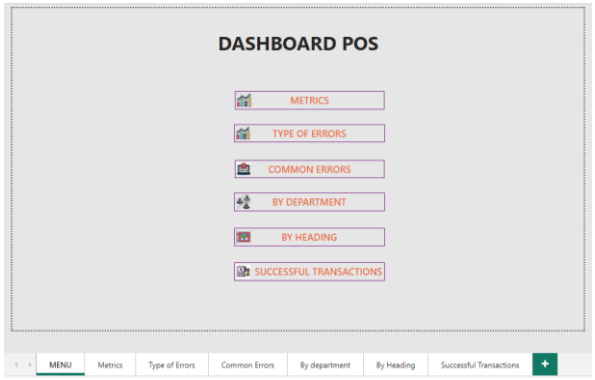

Fig. 9. Menu view.

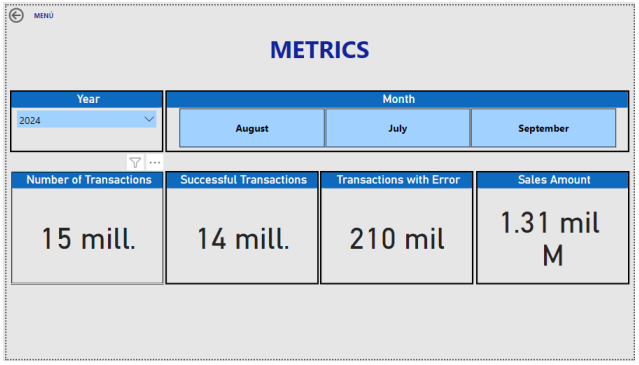

Fig. 10. Dashboard with transaction indicators.

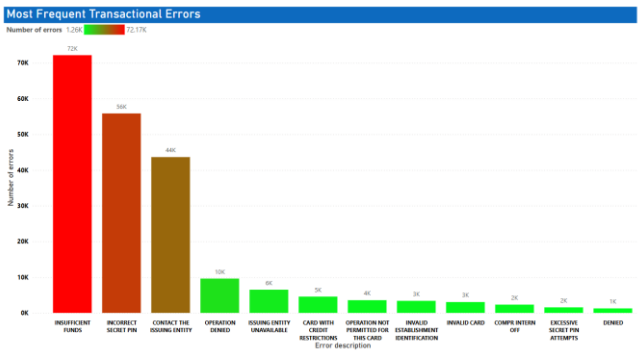

Fig. 11. Graphic showing the most frequent errors in transactions.

On the other hand, information about error types has been presented on several graphs. The most frequent errors (shown in Fig. 11), the number of transactions in Lima with errors and which of them, the number of failed transactions by commerce

sector (shown in Fig. 12), the distribution of departments with the highest number of errors (shown in Fig. 13), and a monthly comparison between the number of failed and successful transactions are shown in the dashboard's following pages.

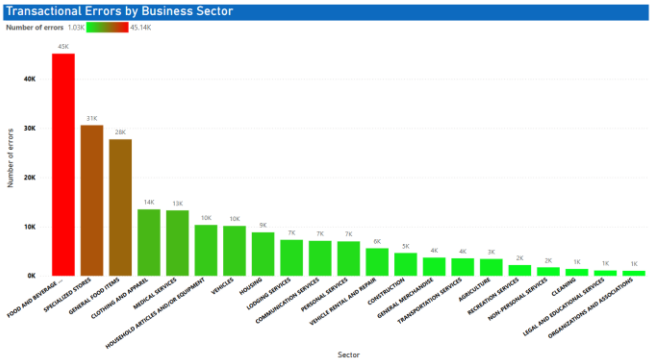

Fig. 12. Graph showing the number of errors by business sector.

These graphs are particularly important because, in the sector of e-commerce, there are many reasons why a transaction can fail, such as connection problems, internal errors in the bank or banks involved in the transaction, or even errors caused by the customer, such as having insufficient funds or incorrectly entering their PIN. Knowing which of these errors is the most common allows the management to determine quickly where to find problems in the business process and how to diagnose them effectively.

In addition to this, being able to visualize the distribution of errors by dimension is important to facilitate diagnostics and give an idea of where to focus efforts to prevent these errors in the future. The information shown must be treated as analytics that will contribute to increasing the company's value.

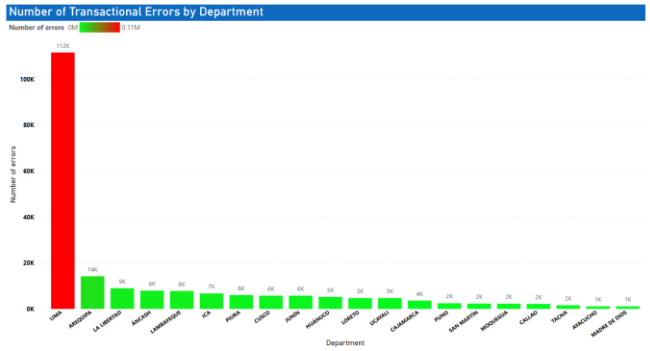

Fig. 13. Distribution of departments by their number of transactions with errors.

In Fig. 14, a comparison between the number of failed transactions and successful ones is shown by month. This information can provide benefits such as:

- Fraud detection: A high number of failed transactions in a certain month could represent fraudulent activity.
- User satisfaction: A high number of successful transactions can be a sign of good system performance and, therefore, a good customer experience. Similarly, a small number of errors can improve customer loyalty.
- Comparative analyses: Transaction data can be compared monthly to observe performance and allow the company to establish realistic goals for determined periods.
- Continuous improvement: Knowing the relation between failed and successful transactions allows management to determine the decisions they will make in the future.

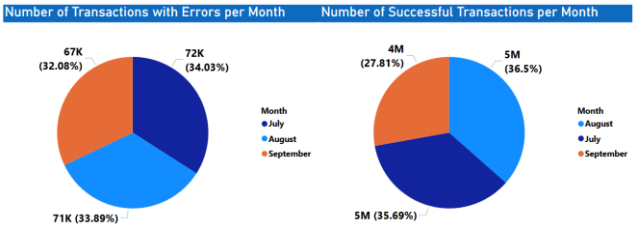

Fig. 14. Difference between the number of successful and failed transactions each month.

X. Discussion

This paper demonstrates the importance of the use of Business Intelligence in the sales sector. Through the identification of the problem, the setting of objectives, the application of the dimensional model, the ETL process, and finally the data visualization in dashboards, business management, and decision-making can be facilitated, since the company's weak points and their causes can be identified quickly.

The proposed Business Intelligence solution can help companies in the payment sector increase their income and improve the user's experience, if the dashboard is constantly monitored, and the proper measures are taken to address problems.

The objectives set at the beginning of the paper were accomplished, since the implementation of the dashboard allows for clear, quick, and concise visualization of the transactional errors, which commerce sectors and locations they occur in, and analyzing how many transactions are being carried out successfully or failing every month, which brings great analytical value to the company. In future work, it would be beneficial to analyze how viable the implementation of a data warehouse is for bigger companies in the digital payment sector, so that they can apply this model to a much larger and scalable volume of data.

Although the proposed solution demonstrates a clear improvement in the decision-making process for the digital payment sector, it is important to acknowledge certain limitations. One of these is the current scope of the Data Mart, which is restricted to specific transactional data from a single company. Expanding this scope to integrate additional data sources, such as customer feedback or competitor analysis, could provide a more comprehensive view of the business landscape. Moreover, while the Kimball methodology was effective in this case, it may not be suitable for all contexts. A future comparative study between Kimball and other methodologies, such as Data Vault or Inmon, could offer valuable insights into the best approach for companies with

similar needs. Additionally, the model's reliance on accurate data collection means that any issues in the ETL process, such as missing or incomplete data, could affect the quality of the analyses. Addressing these limitations and exploring opportunities for further optimization will be crucial to ensuring the long-term success and scalability of the solution. Finally, this study contributes to business intelligence by demonstrating how tactical solutions can drive digital transformation in small businesses, particularly in emerging markets where financial inclusion remains a significant challenge.

Therefore, Business Intelligence in transactional data analysis has proven to be a powerful tool for improving decision-making, particularly in sectors like e-commerce. Recent research has shown how implementing big data analysis models can optimize decision processes by extracting hidden patterns in transactions and enhancing the customer experience [23]. This approach applies to our solution for analyzing transactions in bodegas, where POS systems provide valuable insights into consumer behavior.

Furthermore, studies on the application of machine learning for customer segmentation suggest that combining these analytical approaches with Business Intelligence enables a more precise classification of customers based on their transactional behavior and demographic characteristics [24]. Similar to our research, combining these analytical approaches could lead to increased financial inclusion, allowing companies in the digital payment sector to better customize its services and offer solutions that more effectively meet the needs of bodegas.

Finally, as Bouchra et al. (2019) indicate, including the context in Data Mart design can further personalize BI solutions, adapting the information to the various user profiles [25]. This is particularly relevant to our study, where the bodega sector exhibits very specific characteristics that must be considered in the system's design.

XI. Conclusion

The design of the Data Mart presented in this work becomes a key tool to understand and improve the transactional flows in the bodegas of Lima, Peru. Thanks to the implementation of the Kimball methodology, it has been possible to accurately identify the most frequent errors in transactions and categorize them according to their geographic location and commercial sector, allowing more informed decisions to be made and optimizing digital payment operations.

The solution also has an important impact on financial inclusion, as it enables bodegas to adopt digital payment methods that, in addition to increasing their competitiveness, facilitate access to financial services such as credit. This development encourages the transition from cash to digital payments, driving the digitization of one of the most traditional sectors of local commerce.

One of the current limitations of the Data Mart is that it only deals with a single company's transactional data. Adding new data sources like customer feedback or competitive market analysis to a Data Warehouse would provide a more complete perspective and allow for the development of stronger strategies.

Using tools like Power BI has been useful in converting complex data into simple and easily understandable information. The dashboards created contain vital metrics; for example, transaction success and failure rates, and recurring error patterns, thus enabling accurate interventions and constant service enhancement.

The application of Business Intelligence solutions can make a difference in the management of small businesses in emerging markets by converting data into knowledge that creates value. It also provides a new opportunity to investigate technologies such as machine learning for predictive analytics and customer segmentation which may lead to better results.

Therefore, the proposed model is not only useful for improving transactional processes, but also for supporting the progress of the digital transformation of small businesses; this project has the potential to contribute to the development of the business environment and the reduction of barriers to financial inclusion particularly in the Peruvian market which needs such solutions.

Evaluation of Convolutional Neural Network Architectures for Detecting Drowsiness in Drivers

Mario Aquino Cruz, Bryan Hurtado Delgado, Marycielo Xiomara Oscco Guillen
Departamento Académico de Informática y Sistemas, Universidad Nacional Micaela Bastidas de Apurímac, Abancay, Perú

***Abstract*—Drowsiness in drivers is a condition that can manifest itself at any time, representing a constant challenge for road safety, especially in a context where artificial intelligence technologies are increasingly present in driver assistance systems. This paper presents a comparative evaluation of convolutional neural network (CNN) architectures for drowsiness detection, focusing on the identification of signals such as eye state and yawning. The research was of an applied type with a descriptive level, comparing the performance of LeNet, DenseNet121, InceptionV3 and MobileNet under challenging conditions, such as lighting and motion variations. A non-experimental design was used, with two datasets: a public dataset from Kaggle that included images classified into two categories (yawn and no yawn) and another created specifically for this study, which included images classified into three main categories (eyes open, eyes closed and undetected). The results indicated that, although all architectures performed well in controlled conditions, MobileNet stood out as the most accurate and consistent in challenging scenarios. DenseNet121 also showed good performance, while LeNet was effective in eye-state detection. This study provided a comprehensive assessment of the capabilities and limitations of CNNs for applications in drowsiness monitoring systems, and suggested future directions for improving accuracy in more challenging environments.**

Keywords*—Architectures; detection; drowsiness; neural networks

I. Introduction

Drowsiness at the wheel is a common problem that negatively impacts road safety worldwide. It is defined as the biological need for sleep, which can be caused by fatigue, sleep deprivation or medical conditions, affecting the driver's concentration and reaction time [1]. This condition poses a considerable danger to drivers, as it severely limits their ability to respond, increasing the risk of accidents, especially during long or night-time journeys. Moreover, it compromises not only the safety of the driver, but also that of passengers and other road users [2]. This problem is more serious in situations such as long working hours or lack of sleep.

According to the World Health Organization (WHO), road traffic accidents are responsible for approximately 1.19 million deaths each year, with men being three times more likely than women to lose their lives in these incidents [3]. An analysis of 208,727 passenger vehicle records involved in fatal crashes in the United States between 2017 and 2021 revealed that 17.6% of the cases were related to drowsy drivers [4]. In Spain, the Dirección General de Tráfico (DGT) stated that between 15% and 30% of vehicle accidents are directly or indirectly caused by drowsiness [5]. This problem is not only evident in developed countries, but also generates concern in Latin American countries such as Peru, which according to the National Institute of Statistics and Informatics (INEI) of Peru, 116,659 traffic accidents were recorded in 2016, of which 0.97% (1,131 accidents) were attributed to driver tiredness or fatigue, with Lima being the most affected region with 813 accidents, followed by Puno with 38 and Arequipa with 34 [6]. These data highlight the need to implement preventive measures, especially in areas with high accident rates due to fatigue.

To address this problem, recent advances in artificial intelligence have enabled the development of automated driver monitoring systems, Convolutional Neural Networks (CNNs) are advanced artificial intelligence models widely used in tasks such as image classification, segmentation, object detection and video processing. Such models are composed of several layers, such as the convolution layer, the clustering layer and the fully connected layer, which allow extracting essential features from the input data [7], these deep learning networks have gained recognition for their ability to process images with high efficiency and detect complex patterns [8], which makes them particularly suitable for drowsiness detection applications.

The objective of this research project was to evaluate and compare different CNN architectures for drowsiness detection in drivers. In particular, we sought to determine which of these architectures offered the best performance in the identification of drowsiness cues, such as the state of the eyes (open, closed or undetected) and the presence of yawning. For the yawning state, images of drivers in different states were used according to the dataset in the Kaggle database [9], and a new dataset specific to the state of the eyes was constructed, which included images in a wide variety of situations. The training was performed with 4 convolutional neural network architectures: LeNet [10], DenseNet121 [11], InceptionV3 [12], MobileNet [13]. The architectures were selected for their diversity, ranging from simple and efficient models to more advanced and specialized ones.

All research has its limits, and this study is no exception. Although the models evaluated have demonstrated high performance in drowsiness detection in stable conditions, their effectiveness can be affected by external factors, such as abrupt changes in lighting and extreme variations in the driver's posture, which can reduce their accuracy in more challenging scenarios. In addition, the availability of computational resources was a determining factor in the training process, as the use of a Google Colab Pro account was practically indispensable for reasonable processing times.

The main contributions of this study consist of the comparative evaluation of four CNN architectures to determine their strengths and limitations in drowsiness detection. In addition, two datasets have been worked with the purpose of improving generalization and robustness in various driving conditions. Finally, real-time tests were carried out to analyze the practical applicability of the models in real-world scenarios.

The remainder of this paper is organized as follows: Section II discusses related work on drowsiness detection using CNN and other artificial intelligence techniques. Section III describes the methodology, including details of the datasets, preprocessing steps, and training setup. Section IV presents the experimental results and performance comparisons. Section V discusses the findings and their implications. Finally, Section VI concludes the study and raises possible future directions for improving drowsiness detection systems.

II. Related Works

Recent studies have extensively explored the use of artificial intelligence for traffic accident prevention. For example, Ma, Chau, and Yap [14] focused on developing a fatigue detection system for nighttime driving conditions using in-depth video sequences, overcoming the limitations of RGB video-based systems in low-light environments. Their goal was to leverage Kinect sensor data to detect signs of fatigue such as yawning and posture changes. They used a Two-stream CNN architecture that includes a spatial stream to capture static features, such as driver posture, and a temporal stream to analyze changes between frames, using motion vectors instead of dense optical flow. The results of both flows were combined using an SVM classifier. The system achieved an accuracy of 91.57%, significantly outperforming systems using only RGB video in daylight environments.

Zhao et al. [15] designed a CNN-based algorithm to detect driver fatigue by analyzing the state of the eyes and mouth using the Eye and Mouth CNN (EM-CNN) network. The methodology included face and facial point detection using Multitask Cascaded Convolutional Network (MTCNN) to extract the regions of interest (ROI) of eyes and mouth. Subsequently, EM-CNN classified whether the eyes and mouth were open or closed, and the indicators percent eye closure time (PERCLOS) and percent mouth opening (POM) were calculated to assess fatigue. The results showed an accuracy of 93.623%, with a sensitivity of 93.643% and a specificity of 60.882%, demonstrating high effectiveness in detecting fatigue in a real driving environment.

Li, Gao and Suganthan [16] developed an advanced system for driver fatigue recognition using electroencephalography (EEG) signals, which reflect brain activity and exhibit high inter-subject variability, complicating cross-recognition tasks. Their goal was to improve the ability of the models to extract more distinguishable features from the decomposed EEG signals. The proposed methodology included decomposing the signals into components of different frequency bands using techniques such as discrete wavelet transform (DWT), empirical wavelet (EWT), empirical mode decomposition (EMD) and variational mode decomposition (VMD). These components were processed by independent CNNs with a Component-Specific Batch Normalization (CSBN) layer for each component to reduce inter-individual variability. The model, a hybrid ensemble of CNNs, was evaluated on cross-recognition tasks, achieving an average accuracy of 83.48%, with the DWT-based model being the most effective, outperforming existing approaches by more than 5%.

Chirra, Uyyala y Kolli [17] designed a system based on Deep CNN with the aim of detecting drowsiness in drivers based on the analysis of the state of the eyes. To achieve this, they used the Viola-Jones algorithm to detect the face and extract the eye region as the ROI. Subsequently, they applied a stacked CNN architecture including four convolution layers, each followed by normalization, ReLU activation and MaxPooling, which allowed them to extract relevant features from the images. Finally, a SoftMax layer classified the driver as drowsy or non-drowsy. The model was trained with 1200 images and evaluated with 1150, reaching an accuracy of 96.42%. This approach overcame the limitations of traditional CNN methods, which presented difficulties in pose accuracy during regression, thus demonstrating high effectiveness in accurately detecting drowsiness in drivers.

Flórez [18] designed a real-time drowsiness detection system using computer vision, using CNN to analyze visual features such as eye closure and yawning. The goal of his research was to develop an efficient model for drowsiness detection in drivers. He evaluated several CNN architectures, such as InceptionV3, VGG16 and ResNet50V2, as well as two custom models, DD-AI and DD-AI-G, adapted for implementation on an NVIDIA Jetson Nano device. The results obtained in simulated and real environments showed an accuracy of 91.48% in simulations and 86.28% in real driving conditions, with the DD-AI-G model standing out for its superior performance.

III. Methodology

A. Type and Level

This research was of an applied type, as it focused on implementing and evaluating CNN architectures for drowsiness detection in drivers. It was descriptive, since it evaluated and compared the performance of different CNN architectures without developing new theories, using quantitative metrics for its evaluation Study design.

B. Study Design

This study employed a non-experimental design, since the independent variables were not manipulated, but observed in their performance under controlled conditions. Likewise, a cross-sectional design was used, collecting and analyzing the data at a specific moment in time. A quantitative approach was used, measuring the performance of the models through metrics such as accuracy, recall and F1-score.

C. Sample

Two datasets were used for the research. The first was a public dataset from the Kaggle platform, which contains images classified in the categories of yawning ('yawning') and non-yawning ('no_yawning') drivers. The second dataset was created specifically for this research, with images classified into three main categories: eyes open ('open'), eyes closed ('closed') and images where the eyes were not detected ('no_detected').

The images collected for the second dataset include a variety of features, such as eyes with makeup, eyes of different ethnicities (Caucasian, Asian, Afro-descendant and Latin American), with lenses (cool, warm or neutral colors) and without lenses, as well as different eye colors (very dark, medium dark, warm dark, warm light, and cool light). In addition, variations such as irritated eyes, aged eyes and eyes looking away from the eye were included.

On the other hand, images classified as 'non-detected' comprise cases in which the eyes were not detected due to factors such as dark or reflective lenses, obstructions by hair, hats, caps or hands, inadequate lighting (very bright or dark), blurring (total or slight), or artistic make-up that confuses the processing.

The inclusion criteria for both datasets were images of acceptable quality for neural network processing.

The sample size includes two datasets: a public dataset from Kaggle, consisting of 2892 images distributed in 2083 for training, 519 for validation and 290 for testing; and a proprietary dataset, with a total of 4593 images, of which 3307 are for training, 825 for validation and 461 for the test set.

D. Procedure

This study started with data preprocessing, where the original dataset of the yawning state, represented in Fig. 1, was modified by duplicating the images by flipping them vertically and converting them to black and white. The conversion to black and white helped to improve performance on nighttime images by removing the color ranges present during the day and allowing CNNs to perform better predictions of both daytime and nighttime images. In addition, a green facial mesh was applied to the drivers' faces using the MediaPipe library and its FaceMesh function, which allowed the image to be cropped and focused exclusively on the facial region. These modifications were implemented after evaluating that this format offered better results in previous tests.

Fig. 1. Images of the original yawning state dataset: yawn and no_yawn.

General preprocessing was performed for the eye status dataset and the yawning status dataset as shown in Fig. 2 and Fig. 3. This process included normalizing the pixel values, scaling them from 0 to 1, and resizing the images to 224x224 pixels. In addition, the data were organized into batches of 64 and sorted. For eye status ("open", "closed" and "no_detected"), categorical classification was used, while for yawning status ("yawn" and "no_yawn"), binary classification was employed.

For eye and yawning status, approximately 70.0% of the images were separated for training, 20.0% for validation, and 10.0% of the images for testing.

Fig. 2. Images of the preprocessed dataset of the eye status: open, closed and no-detected.

Fig. 3. Images of the preprocessed yawning state dataset: yawn and no_yawn.

For the configuration of architectures, we used the optimizer Adam, using a learning rate of 0.001, and the loss function categorical_crossentropy for the eye state and binary_crossentropy for the yawning state. For evaluation, the accuracy metric was used to monitor performance in each epoch. In addition, the L2 regularization technique (kernel_regularizer=l2(0.01)) was applied to the fully connected layers and a 50% dropout layer was added to prevent over-fitting.

The modifications implemented in each architecture are illustrated in Fig. 4, Fig. 5, Fig. 6 and Fig. 7, showing the structure of LeNet, DenseNet121, InceptionV3 and MobileNet with the optimization techniques applied.

In order to optimize the training process, the Early Stopping technique was applied, which ended the training if the loss in the validation set did not improve after five consecutive epochs. And in case the training was terminated, the weights corresponding to the best performance were restored.

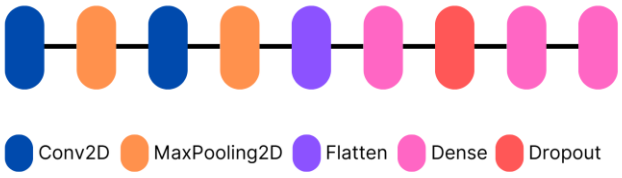

Fig. 4. Structure of the LeNet architecture with optimization techniques.

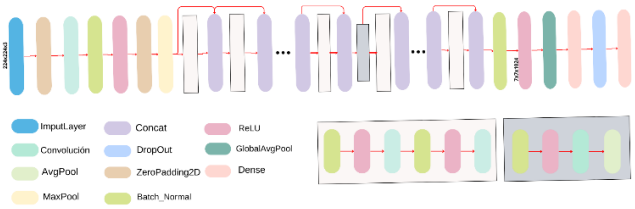

Fig. 5. Structure of the DenseNet121 architecture with optimization techniques.

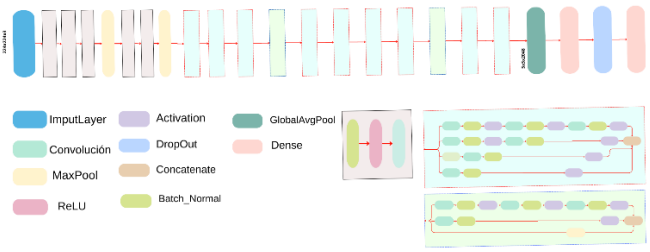

Fig. 6. Structure of the InceptionV3 architecture using optimization techniques.

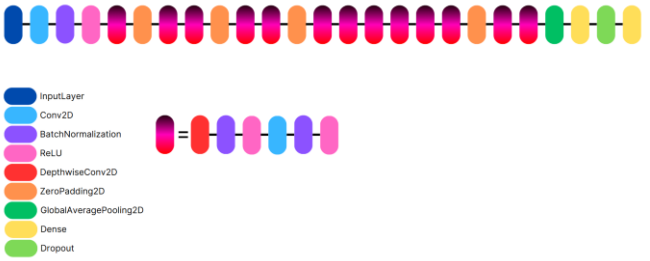

Fig. 7. Structure of the MobileNet architecture with optimization techniques.

Next, each convolutional neural network architecture was trained: LeNet, DenseNet121, InceptionV3 and MobileNet. In the case of DenseNet121, InceptionV3 and MobileNet, pre-trained models were used with the weights of ImageNet.

The training was carried out on Google Colab Pro using an A100 GPU, which allowed processing time to be optimized. Without this configuration, training the heavier architectures would have taken 4 to 5 days, requiring continuous connection. The trained models were stored in .h5 and tflite formats for future evaluation.

Subsequently, the trained models were stored in .h5 and.tflite formats to facilitate their evaluation and further use. A prototype was developed in Google Colab to perform the corresponding evaluations, which activated the camera and processed the video in real time. Each captured frame was preprocessed and sent to each trained model, allowing the driver's status to be displayed immediately.

IV. Results

This section presents the results obtained from the evaluation of the LeNet, DenseNet121, InceptionV3 and MobileNet architectures in drowsiness detection. The results are structured in the following analyses:

A. Training and Validation Curves

Fig. 8 shows the accuracy and loss curves for yawning detection. MobileNet and InceptionV3 achieved fast convergence and maintained stability during training. DenseNet121 completed its training in fewer epochs with competitive performance. In contrast, LeNet exhibited greater variability in accuracy and difficulties in generalization.

Fig. 9 illustrates the performance in eye state detection. MobileNet and DenseNet121 demonstrated rapid convergence, with a steep reduction in loss from the earliest epochs. InceptionV3, although progressively improving, showed a less pronounced decrease in loss. LeNet exhibited fluctuations in both accuracy and loss, evidencing instability in training.

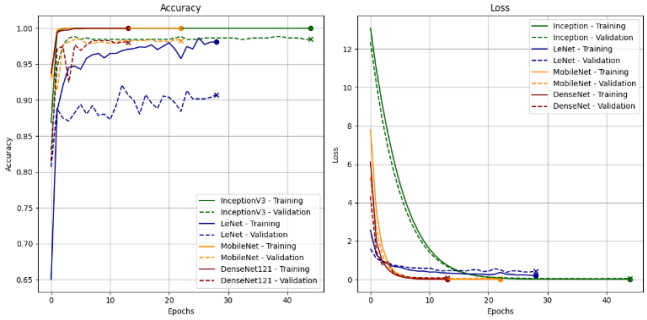

Fig. 8. Accuracy and loss curves during training for yawning state detection using LeNet, DenseNet121, InceptionV3 and MobileNet architectures.

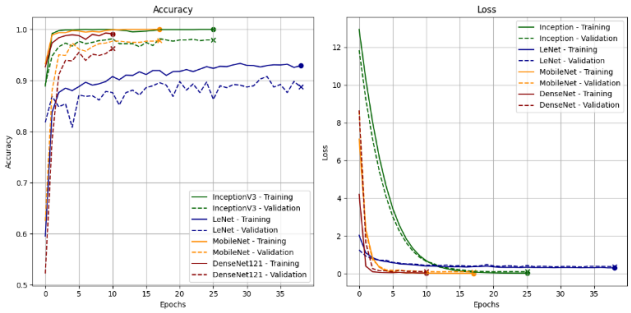

Fig. 9. Accuracy and loss curves during MobileNet, InceptionV3, DenseNet121 and LeNet training for the eye state.

B. Accuracy in Validation, Training and Testing

Fig. 10 presented the performance of the models in each phase of the training, validation and testing process. DenseNet121 and MobileNet achieved accuracies of 99.66% and 99.31%, respectively, in the testing phase for yawning detection, with minimal variations with respect to validation. In eye state detection, DenseNet121 achieved an accuracy of 96.53%, while MobileNet recorded 93.28% in the test phase.

InceptionV3 showed an accuracy of 100% in the training phase for eye state detection, with a reduction to 59.87% in the test phase. LeNet obtained an accuracy of 97.24% in yawning detection in the test phase, with lower values than those obtained by DenseNet121 and MobileNet.

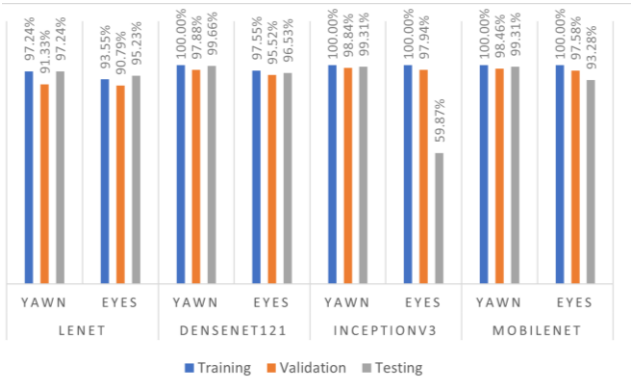

Fig. 10. Comparative performance of CNN architectures in the training, validation and testing phases for yawning and eye states.

C. Confusion Matrix

Fig. 11 shows the confusion matrices of LeNet, DenseNet121, InceptionV3 and MobileNet in the classification of 'Yawn' and 'No Yawn' states. It was observed that DenseNet121 performed the best, with high accuracy and minimal error incidence. InceptionV3 and MobileNet showed balanced performance, with similar error rates. In contrast, LeNet presented greater difficulty in detecting 'Yawn', registering more false negatives compared to the other architectures.

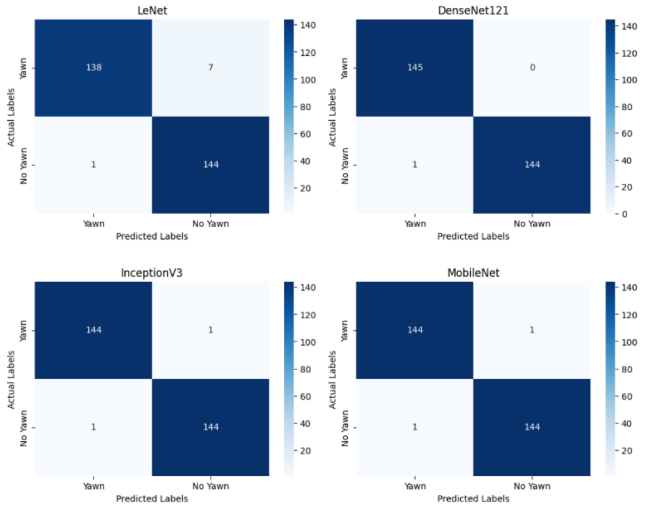

Fig. 11. Confusion matrices of LeNet, DenseNet121, InceptionV3 and MobileNet architectures in yawning state classification (Yawn and No-Yawn).

The confusion matrices of the LeNet, DenseNet121, InceptionV3 and MobileNet architectures for the classification of eye states ('Open', 'Closed' and 'No-Detected') are presented in Fig. 12.

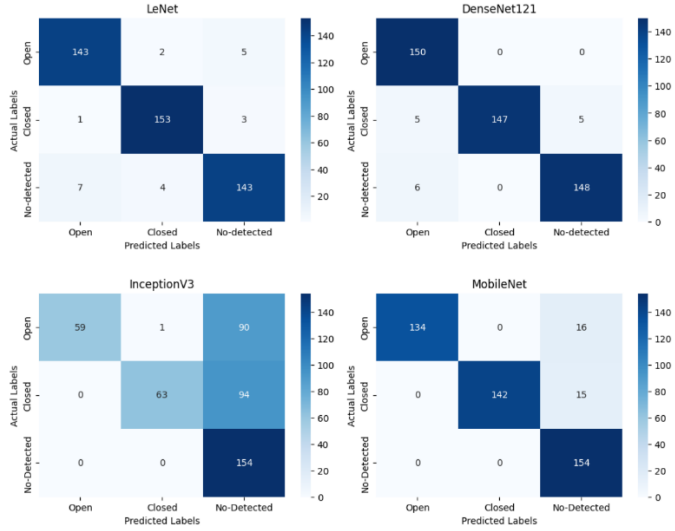

Fig. 12. Confusion matrices for the LeNet, DenseNet121, InceptionV3 and MobileNet architectures in the classification of eye states (Open, Closed and No-Detected).

DenseNet121 performed best, with high true positive values and minimal errors, with no false positives in the 'No-Detected' class. LeNet showed adequate performance, although it recorded false negatives in 'Open' and 'Closed'. MobileNet presented a balance between accuracy and sensitivity, with moderate confusions between 'Open' and 'No-Detected'. In contrast, InceptionV3 had the highest number of false negatives in 'Open' and 'Closed', reflecting a lower ability to correctly classify these categories.

D. Ranking Metrics

Table I presents the classification metrics obtained for each architecture in yawning state detection. DenseNet121 achieved an F1-Score of 1.00 in both classes, with precision of 0.99 and recall of 1.00 in "Yawn". InceptionV3 and MobileNet recorded an F1-Score of 0.99, with balanced accuracy and recall in both categories. LeNet obtained an F1-Score of 0.97, with an accuracy of 0.99 in "Yawn" and a recall of 0.95 in the same class. In the yawning state.

TABLE I. YAWNING STATE CLASSIFICATION REPORTS

Architecture	Class	Accuracy	Recall	F1-Score
LeNet	Yawn	0.99	0.95	0.97
	No Yawn	0.95	0.99	0.97
	Macro AVG	0.97	0.97	0.97
DenseNet121	Yawn	0.99	1	1
	No Yawn	1	0.99	1
	Macro AVG	1	1	1
InceptionV3	Yawn	0.99	0.99	0.99
	No Yawn	0.99	0.99	0.99
	Macro AVG	0.99	0.99	0.99
MobileNet	Yawn	0.99	0.99	0.99
	No Yawn	0.99	0.99	0.99
	Macro AVG	0.99	0.99	0.99

TABLE II. EYE CONDITION CLASSIFICATION REPORTS

Architecture	Class	Accuracy	Recall	F1-Score
LeNet	Closed	0.95	0.95	0.95
	Open	0.96	0.97	0.97
	No-detected	0.95	0.93	0.94
	Macro AVG	0.95	0.95	0.95
DenseNet121	Closed	0.93	1	0.96
	Open	1	0.94	0.97
	No-detected	0.97	0.96	0.96
	Macro AVG	0.97	0.97	0.97
InceptionV3	Closed	0.98	0.4	0.57
	Open	1	0.39	0.56
	No-detected	0.46	1	0.63
	Macro AVG	0.81	0.6	0.59
MobileNet	Closed	1	0.9	0.95
	Open	1	0.89	0.94
	No-detected	0.83	1	0.91
	Macro AVG	0.94	0.93	0.93

Table II presents the ranking metrics for each architecture. DenseNet121 obtained the best performance with an average F1-Score of 0.97. MobileNet showed a balanced performance with an F1-Score of 0.93. LeNet showed consistent values across all classes with an F1-Score of 0.95. InceptionV3 recorded the lowest performance, with a noticeable reduction in recall for "Closed" and "Open".

E. Real-Time Testing

The prototype created at Google Colab prepared each frame to meet the input requirements of the architectures, such as image size and format. Subsequently, each model generated its prediction and the level of certainty expressed as a percentage. This level of certainty indicates the model's confidence in its prediction:

- Close to 100%: High prediction confidence.
- Near 50% or less: Low confidence, suggesting doubt or ambiguity in the prediction.

The tests were carried out under real conditions, as shown in Fig. 13, where the models faced different situations such as subject movements, light variations and facial expressions.

1) Yawning state predictions:

a) LeNet: Its level of certainty varies between 56% and 100%, remaining at 100% in stable conditions (with little light variation and minimal user movements). However, in extreme scenarios, such as constant user movements or environments with low illumination, its transparency decreases significantly, leading to incorrect predictions on several occasions.

b) DenseNet121: Its accuracy level ranges between 90% and 100%, remaining at 99% in stable conditions. In extreme scenarios it maintains excellent accuracy, showing great robustness to environmental variations.

c) InceptionV3: Its accuracy fluctuates between 60% and 100%, stabilizing around 91% under normal conditions. It is the model with the greatest variability in its level of certainty, but even so it adapts well to changes in illumination and extreme conditions, offering reliable predictions.

d) MobileNet: With a range of certainty between 95% and 100%, it remains practically 99% in optimal conditions. In extreme scenarios, it shows an outstanding performance, standing out for its accuracy and high reliability.

2) Eye condition predictions:

a) LeNet: Although its performance in yawn detection was the lowest, it surprises with decent results in eye status, even in low light environments. Its performance is almost comparable to MobileNet and even becomes better in some cases, showing a very solid behavior in stable conditions. It could be considered as the second best model for this condition.

b) DenseNet121: In challenging environments, it shows greater instability, with notable fluctuations in its predictions. However, in standard conditions, it achieves a satisfactory performance, although it lags behind other more consistent models.

c) InceptionV3: It shares similar characteristics with DenseNet121 in terms of instability in difficult scenarios. Although it achieves very good results in controlled environments, its variability also places it among the least reliable models in this test.

d) MobileNet: It stands out as the most robust and consistent model for the eye condition, maintaining outstanding performance even in difficult or low-light environments. Its ability to adapt to adverse conditions clearly positions it as the best model for this condition.

Fig. 13. Images of the prototype executed in real time.

V. DISCUSSIONS

The results obtained in this study showed that the DenseNet121 and MobileNet architectures significantly outperformed the models used in previous research, achieving accuracies of over 99% in yawn detection and 93% in eye detection.

Unlike the model of Zhao et al [15], which used EM-CNN and MTC-CNN for face detection, this evaluation identified MobileNet and DenseNet as the best performing architectures. MobileNet achieved 99.31% test accuracy for yawn detection and 93.28% for eye classification, while DenseNet obtained 99.66% and 96.53%, respectively. These results exceed the 93.62% reported in their study, evidencing the stability of MobileNet and DenseNet in diverse scenarios. Furthermore, unlike PERCLOS and POM-based approaches, the landmark-based classification enabled a more accurate segmentation of facial regions, optimizing the detection of fatigue-relevant facial states.

The study by Chirra, Uyyala, and Kolli [17] used a stacked CNN together with the Viola-Jones algorithm, obtaining an accuracy of 96.42% in eye state detection. In the present work,

DenseNet121 achieved an accuracy of 96.53% without the need for additional face detection algorithms, demonstrating its ability to extract relevant features efficiently. The improved performance can be attributed to the preprocessing techniques applied, such as normalization, grayscale conversion and face segmentation with MediaPipe, in addition to the implementation of L2 regularization and dropout, which contributed to reduce overfitting and improve the generalization capability of the model.

Also, unlike the study by Ma, Chau, and Yap [14], which employed a Two-stream CNN with Kinect sensors to improve fatigue detection in nighttime conditions, this study evaluated real-time CNN architectures without the need for additional sensors. While the video stream-based approach achieved 91.57% accuracy, MobileNet and DenseNet121 achieved up to 99% in yawning and eye state detection, while maintaining stability in the face of illumination and motion variations. These results suggest that optimized models can be an efficient alternative for drowsiness detection without requiring specialized hardware.

On the other hand, in the study by Li, Gao and Suganthan [16] they achieved an accuracy of 83.48% when combining CNN with EEG signals, a methodology that, although useful, is more complex and less accurate than the visual feature analysis performed in this study. The results obtained with LeNet, DenseNet121 and MobileNet in both states evaluated reflect that facial image-based techniques are more accurate and practical for vehicular implementations.

Finally, the study by Florez [18] used CNN in a real-time system with InceptionV3, VGG16, ResNet50V2, obtaining an accuracy of 91.48% in simulations and 86.28% in real driving. In this study, InceptionV3 showed 99.31% in test, but its real-time certainty ranged from 60% to 100%, with a drop to 59.87% in eye-state detection. MobileNet and DenseNet121 were more stable, with 99% real-time certainty. This confirms that, although the models achieve high accuracy in controlled tests, their performance in real environments can be affected, with MobileNet standing out as the most robust.

VI. Conclusions and Recommendations

In this study, different convolutional neural network architectures were evaluated and compared for drowsiness detection in drivers, focusing on two key aspects: eye state and yawning state. For yawning state, the architectures that topped the list in accuracy upon training were InceptionV3 with a validation accuracy of 98.84%, followed by MobileNet with 98.46%, DenseNet121 with 97.88% and finally LeNet with 91.33%. For eye status, InceptionV3 stood out with a validation accuracy of 97.94%, followed by MobileNet with 97.58%, then InceptionV3 with 95.52%, and finally LeNet with 90.79%.

The results of the confusion matrices and the classification report clearly reflect this superior performance. LeNet, DenseNet121, InceptionV3 and MobileNet achieved outstanding classifications in the yawning and eyes state having very few errors with the exception of InceptionV3 which showed less consistent performance in the eyes state, especially in the 'Open' class, where a significant number of errors were observed.

Finally, in real-time testing with the prototype, MobileNet proved to be the most robust and reliable architecture for both yawning and eye detection. Its outstanding accuracy remained consistent even under challenging conditions. LeNet, although it came in last place in yawning state detection, surprised by showing solid performance in eye state detection, obtaining comparable or even better results to MobileNet in some scenarios. DenseNet121 showed solid and consistent performance in yawning state detection, positioning itself as a reliable alternative to MobileNet. However, its performance in eye state detection was more unstable in challenging environments. For its part, InceptionV3, while achieving acceptable results in stable conditions, presented the greatest variability between architectures in both tasks. Its performance was less consistent in challenging environments, especially in eye-state detection, where it showed a higher number of errors compared to the other models.

In conclusion, when comparing the architectures, MobileNet stood out as the best choice for its consistency and accuracy, even in challenging conditions such as low illumination or constant user movements. Although DenseNet121 and InceptionV3 also offered good performance in stable environments, MobileNet stood out for its adaptability and comprehensive performance. On the other hand, LeNet, although the simplest architecture in this study, showed surprisingly good performance in eye detection, despite its lack of optimization compared to more modern architectures. It is important to note that the architectures were not modified, as the goal was to evaluate them as they are, respecting their internal structure. Although it is possible to improve the architectures by adding layers, in this study we chose to add the same layers at the beginning and at the end of all the architectures, maintaining their original shape and respecting the design with which they were built.

For future research, the integration of other types of data, such as heart rate or electromyographic activity, could be explored to improve accuracy and robustness in the detection of physiological states. It would be interesting to develop a prototype that combines these new instruments with the data obtained in this study, offering a more complete analysis. This approach could open new possibilities for more personalized and effective health monitoring systems.

Finally, based on the evaluations, an application called 'Drowse Alert' was developed using the MobileNet model, which obtained the best performance. The app is currently in closed testing on Google Play, available only to selected users. The link to access the application is as follows: https://play.google.com/store/apps/details?id=com.invoryan.drowse, as shown in Fig. 14.

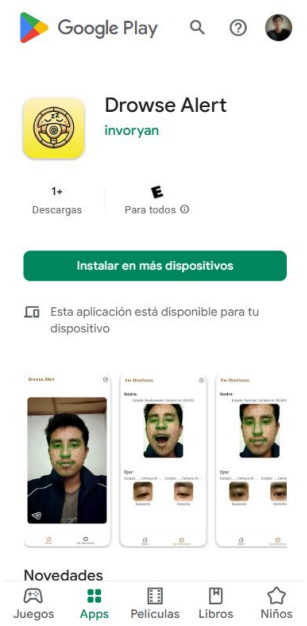

Fig. 14. Screenshot of the "Drowse Alert" application in Google Play.

School of Art and Design, XiHua University, ChendDu, SiChuan, 610039, China[2]

***Abstract*—Deep learning and art design are being integrated, which is an innovative process that has the potential to reframe the way the human imagination is defined. This paper is an exploration of a broad field that showcases how AI enhances the experience of artist practice, especially content deep learning. This study comprises an exhaustive analysis of the cutting-edge models including generative adversarial networks (GANs), neural style transfer, and multimodal AI that assist in the creation, modification, and optimization of the artistic experience. This research points to implementations of those in the visual arts, graphic design, and interactive media while providing contemporary examples where deep learning has been an addition to traditional media and created new forms of art. Besides, the paper points to the challenges and ethical considerations concerning algorithmic art, including issues of authorship, biases, and intellectual property. The integration of computational methods in the realm of artistic expression is made in the paper and the paper provides insights into the change that deep learning can affect for artists, designers, and technologists.**

***Keywords*—Deep learning; art; design; creative expression; computational techniques**

I. INTRODUCTION

Technology and creativity have always been allied with the help of innovation, which enables artists and designers to explore new avenues of expression. The application of deep learning, a subfield of artificial intelligence (AI), is undoubtedly one of the most tremendous innovations of recent years that has invaded the arts and design [1]. Through its ability to let machines learn patterns, copy styles, and provide original content, the deep learning process has been a game-changer that has altered the approach to the conceptualization, production, and experience of creative works. This fusion of computing and artistry is not only a means but rather a new branch that challenges the conventional ideas of creativity and craftsmanship [2-3].

The functioning of deep learning algorithms is based on the processes of artificial neural networks mimicking the operations of the human brain, which processes vast amounts of data to recognize patterns and make decisions. This ability has found new depth in areas such as computer vision, natural language processing, and generative modeling. When used for art and design, these systems can do a wide variety of things, including generating realistic images, changing artistic styles, or speeding up the intricate design process. Today, artists and designers have tools that can supplement their creative efforts, giving them both efficiency and entirely new creative avenues [4-5].

One of the first breakthroughs in the field of AI in art was the neural style transfer, a technology that could bring together two separate images through the style of the first one. The demonstration of the power of AI to form an artistic composition through the achievements that followed its introduction marked the beginning of a series of advancements [6-7]. The introduction of generative adversarial networks (GANs) by Ian Goodfellow in 2014, set the stage for the development of the field that was characterized by the ability of computers to generate photorealistic images, merge those with new artworks, or even adopt the styles of famous artists. AI-driven tools exist beyond merely the generation of content; they also facilitate the examination of questions relating to abstraction, surrealism, and multimedia interactivity which are unusual as yet uncharted territories [8-9].

These new technologies create significant changes. For long-time painters, deep learning is an example of the merging of traditional and computational techniques which finally leads to hybrid outcomes that neither of the methods alone can produce [10]. Those in the graphic design world can tap into the upper hand of AI to make machines complete mundane tasks, perfect formatting patterns, and find design options in record time. Interactive media artists and game developers harness AI's potent force of synthesizing rich environments, non-linear plots, and personalized user experiences. The array of opportunities is just astonishing, only limited by creators' inventiveness and the prowess of foundational algorithms [11-12].

Notwithstanding the upsides, making a connection between deep learning and art & design in contemporary times is not a walk in the park. Modifications are being made to the definition of authorship and ownership as machines are used for a tremendous part of the creative process [13-14]. What is the rightful owner of an AI-created artwork? Can a machine be acknowledged as an artist? They are philosophical questions at the root level that lead the inquiry into the very essence of creativity and intellectual property in the time of AI. Moreover, AI systems being biased from the data supplied to them might lead to one-sided representation and a real threat to the principle of inclusiveness. The usage of AI in art and design

could give rise to a certain fear regarding human creativity, as entrenched automated systems often catch more credit for art than actual human inspiration and experience [15-17].

However, even with these caveats, the combined use of deep learning and creativity is undoubtedly on the rise. Major corporations, research institutions, and even individual artists are testing the limits of AI to prove that creativity can work in partnership with technology. The very nature of platforms such as RunwayML, Google's Magenta, and NVIDIA's GauGAN is that they give creators at all skill levels the technology they need to be able to use the adventure of the AI art world. These tools serve as a bridge between computational complexity and creative simplicity, allowing artists and designers to channel their energies into the creation of art and design while harnessing the capabilities of the machine [18-19].

Deep learning, in contrast to mere aesthetics, has far-reaching implications in the area of art and design. By providing visual and interactive instruments that allow students and professionals to understand intricate ideas, it plays a significant role in education. In the case of architecture, for example, AI aids the design of energy-efficient buildings by analyzing data from the environment and optimizing space usage [20]. Forecasting fashion trends, adapting creative designs to individual preferences, and improving production operations are some of the ways deep learning shapes the fashion industry. The multifaceted usage of social media using deep learning signifies its vigor as a catalyst for creativity in a variety of industries [21].

A. Objectives

- To study how deep learning has changed the way creativity and artistic workflow interact: On the way, one sees how the use of tools like GAN and neural style transfer naturally leads to more innovation and faster work in the areas of art and design.
- To analyze the fundamental principles and ethical aspects: The issues of combined identity, ideas creation, and unfairness in AI art are the topics to be considered here.
- To point out new prospects and trends in the industry: It means to share ideas about the already existing and future technologies that may affect the integration of AI in creative professions.

To sum up, deep learning is not just a choice in technology, but a life-changing force in the creation of art and design that brings human and machine interaction in a new way. A creative revolution is taking place now, with deep learning leading the way through the provision of tools that are creative, tackle problems, and stimulate new forms of expression [22]. This research will uncover the many ways in which deep learning fosters, confronts, and rearranges the artistic scene thus providing an insight into the creative process in a digital future [23-24]. With this analysis, it aims at promoting a better comprehension of the opportunities, and barriers of AI as a helper in artistic and design processes.

The rest of this paper is arranged as follows: Section II (Literature Review) recaps previous research on AI in art and design, pointing out major approaches, contributions, and drawbacks. Section III (Methodology) elaborates on the implemented deep learning techniques, the data preprocessing steps, the design of the model, and the evaluation metrics. Section IV (Results) reports the study's empirical outcomes, and Section V (Discussion) then weighs the significance of these results against traditional artistic practices and also compares AI-driven approaches with them. Section VI (Conclusion and Future Work) majorly encapsulates the study's significant findings, furthers the implications of said findings for future research, highlights limitations, and provides directions for future research.

II. Literature Review

The intersection of deep learning with art and design has attracted significant attention in the last years resulting in the emergence of a growing body of literature that emphasizes the transformative potential of these technologies. Diverse aspects of this field have been explored by researchers from varying technological foundations of deep learning algorithms to their practical applications in creative workflows [25-26]. The gist of this section is given via a deep insight into the significant studies that have influenced our awareness of the part of deep learning in art and design thereby the methodologies they have adopted and their findings. The findings of each study point to the various aspects of this domain, demonstrating how computational techniques facilitate, challenge, and change conditional creativity.

The literature review has been carefully restructured into three main subsections. The first subsection titled AI Model Development elaborately covers the fundamental research of neural networks applied in art. The model architectures and the training methodologies are described in detail. The second subsection titled Applications in Art and Design surveys recent studies on the implications of deep learning for creative workflows, including its deployment in digital painting, graphic design, and fashion items. The last subsection entitled Ethical Considerations studies the challenges of authorship, bias, and the impact of AI on human artistic agency. Table I shows significant contributions by the related research. The detailed systematic comparison of processes, data, measures, and issues of previous studies' results in this table helps clarify the point that the AI-based art is contrasted with the conventional ones. The inclusion of this comparative analysis makes the literature review an all-inclusive review covering the latest research in AI creativity.

McLain [27] examines the concept of signature pedagogies in design and technology education. They do this by using Shulman's framework. They use the concept of distinctive teaching methods which in this case are called ideators, realizes, and critics. The terms designer, maker, and evaluator are synonymous with them. Their study underscores the role of project-based learning, collaboration, creativity, and problem-solving in shaping these pedagogies, and proposes the framework which highlights the unique contributions of design education to the curriculum.

TABLE I. LITERATURE COMPARISON

Author(s)	Focus Area	Key Methods/Approach	Findings/Contributions	Implications
McLain et al.	Signature pedagogies in design and technology education	Literature review on Shulman's framework; project-based learning emphasizing ideating, realizing, and critiquing	Identified unique contributions of design education to curriculum through collaboration, creativity, and problem-solving	Offers a framework for enhancing teaching practices in design education.
Jin et al.	Metaverse in art design education	Virtual learning through Xirang games; qualitative and quantitative analyses	Demonstrated increased creativity and critical thinking via virtual presence and collaborative learning strategies	Provides a model for integrating metaverse technologies into future educational practices.
Noble et al.	Art education and teacher training	Practitioner-led action research; constructivist pedagogy	Enhanced visual literacy and creativity through community practice involving teachers, artists, and museum professionals	Suggests collaborative approaches for improving art education outcomes.
Saleeb et al.	Virtual learning in practical education	2D/3D virtual environments; learning analytics	Validated the effectiveness of virtual tools for achieving hands-on learning outcomes	Supports the shift to online delivery for traditionally face-to-face programs.
Li et al.	AI in conceptual product design	Systematic review of cross-modal tasks (DLCMT)	Identified challenges like multimodal data and creativity demands; proposed solutions and future research directions	Highlights AI's potential to redefine the conceptual design process.
Zhao et al.	Emotional aspects of AI in art and design	Review of AI technologies and human collaboration in art	Emphasized the collaborative potential between AI and human designers for enhancing aesthetic resonance and creativity	Proposes a future where AI complements rather than replaces human creativity.
Qiu et al.	AI in art design and souvenir creation	Application of AI and deep learning for design automation	Demonstrated AI's ability to enhance creativity and meet market trends in visual arts	Encourages using AI for practical applications in art and design.
Cai et al.	Art education system with CAD and deep learning	CAD-integrated instructional system; evaluation mechanisms	Improved learning outcomes, skill mastery, and creativity in students	Advocates for using AI-powered systems in teaching to expand creative potential.
German et al.	AI as a co-creative partner in design	AI algorithms trained on small datasets; evaluation of design variations	Showed how AI can inspire creativity and novel designs; addressed ethical concerns	Supports the integration of AI as a tool for augmenting human creativity while recognizing ethical considerations.

Jin et al. [28] investigate the use of the metaverse in art design education during the pandemic focusing on the activities of Xirang games through which innovative teaching strategies were introduced. The limitations of traditional and the gap between the goals that were proposed to be achieved using these new technologies were the central challenges that they were addressing. They proposed the solutions for them as virtual presence and collaborative learning groups. With qualitative and quantitative methods, they tested and illustrated the metaverse's role in the empowerment of creativity, critical thinking, and engagement demonstrated in a new way for the future educational models.

Noble [29] investigates art education through practitioner-led action research and museum and artist-led CPD programs. The results of the study deliver a message about how with constructivist pedagogy one can enable participatory, and experimental approaches such as thus being part of art education not only will the participants achieve an increase in visual literacy and creativity, but also will teachers help students to be more creative. The essential part of this research is the construction of communities of practice which are formed by teachers, artists, and museum professionals. The research revealed the great possibility of the transformation of art and design teaching.

Saleeb [30] engages in questioning the necessity of face-to-face learning in practical fields like engineering and design, by virtual learning environments to achieve learning outcomes and foster creative thinking using two. They establish the working of virtual learning environments utilizing such 2D and 3D media and assuring the effective creation of application and creativity. Learning analytics are used as validating tools to show the ability of the aforementioned to drive learning performance, the acquisition of skills and an argument for education such as that of practical artware in a remote way.

Li et al. [31] support by considering text on product conceptual design requiring balancing of products in the cross-modal. Their systematic review included a variety of methodologies including text-to-3D and sketch-to-3D transformations, it particularly drew attention to the fact that current knowledge is lacking on the subject matter and set directions for further research. They stress how AI will transform the world of design by tackling these challenges.

Zhao et al. [32] study the potential of AI in art and design, notably its ability to mimic emotional articulation and produce twofold effects such as conjuring up emotions and presenting beauty through some. In addition, they recognize AI's limitations, but they are more concerned about the cooperative aspect between human beings and AI technology. The authors predict a scenario in the future where AI will play a part in human creative processes, thus a creative cooperation between man and machine in the sphere of art can be expected.

Qiu et al. [33] draw attention to the necessity of AI and deep learning in creative arts and custom souvenir making; they automate those tasks such as 'image recognition' and 'market analysis' totally dependent upon human beings. Art is facilitated by AI that aligns itself closely with trends about consumers, their psychology. Thus, the research puts emphasis on the role of AI in both sides - creativity, and practical issues purposely to provide evidence of its increased influence on visual arts.

Cai et al. [34] have gone ahead and proposed an art educational system that includes the use of CAD and deep-learning models. The user's system is the creative stylist who takes the creative direction and integrates various products from the teaching materials. The results show an improvement in the learning outcomes and creativity that the students can exhibit, and this exemplifies how artificial intelligence and technology can completely change art education and can shape the creative talents of the young.

The part that Germany et al. [35] dealt with is the one where they took actors to examine AIs as co-creative partners in design where algorithms help come up with various types of new schemes. Their study is a clear example of how AI could improve creativity without the need for human input, and as a result, it leads to unexpected solutions. The research also deals with the ethical concerns that AI would have on the creative industries and provides a more holistic view of its benefits and drawbacks.

III. METHODOLOGY

This study adopts a comprehensive methodology to explore the integration of deep learning in art and design, focusing on its applications, challenges, and transformative potential. The approach is interdisciplinary, which combines application specific computation experimentation, creative data analysis, and evaluation of aesthetic results. It includes stages such as extracting essential data, preprocessing the data, creating a model, applying ability and testing the model. The methodology of this research is aimed to verify to what extent deep learning technologies can be leveraged by digital artists whilst also answering the concerns of accuracy, authorship, and the ability to scale.

A. Data Collection and Preprocessing

The basis for any successful deep learning project is the data sourced from various places and available in different styles. This study utilized online-source images by which the researchers intended to gather both diverse kinds of data and numerous examples of the same types of art. Such a collection would, therefore, include pictures of publicly owned artworks, user-designed projects of various types, and special manufacturing facilities as well as color-variant designs to increase diversity. The data compared different forms such as painting, digital illustration, photography, and graphic design to ensure that all kinds of art were analyzed.

Data preprocessing included various steps such as image normalization, augmentation (including random cropping, rotation, and color jittering), and edge detection for improved feature extraction. The dataset was divided into training (70%), validation (15%), and test (15%) sets. Each model was fine-tuned iteratively, dropout rates of between 0.3 and 0.5 were used to prevent overfitting. Evaluation was done using the conventional deep learning benchmarks, like mean square error (MSE) for GAN outputs and precision-recall curves for classification tasks.

The critical preprocessing step was the one that set the stage for the direct use of the data by deep learning models and involved the augmentation of data by a series of cropping, scaling, rotation, and color adjustments among others to increase its diversity. Furthermore, the quality of the data was improved by using techniques such as image enhancement and feature extraction-the first one highlights defects, and transforms the image into a standard pattern, while the second one searches for key features in each image and forms the basis for training the models. The feature extraction procedures helped to identify the desired attributes in all the images, such as shapes, textures, and color palettes, which were then used for model training.

B. Model Development

The following stage involved the careful selection and configuration of deep learning architectures that were best suited to specific creative endeavors. The study also took advantage of more advanced designs such as Generative Adversarial Networks (GANs), Convolutional Neural Networks (CNNs), and Recurrent Neural Networks (RNNs). Models were chosen based on their appropriateness for specific tasks. For example, high-quality visual art was created using GANs, while CNNs were employed for style transfer and object recognition. RNNs were used to reveal the temporal component relevant to the particular creative activity, thus making diverse media such as animations and interactive systems.

The models were trained using the pre-processed datasets in which the hyperparameters were optimally set for the best possible performance. In this respect, high-tech techniques such as transfer learning and fine-tuning were used to boost the re-training of the pre-trained models plus for improving their precision. The training cycle was completed by evaluation steps that resulted in the requests for the modification of the models so that they were not only logically precise but also relevant to the contextual ones.

C. Creative Tool Implementation

Once the models were trained, they were packaged with user-friendly design tools intended for artists and designers. These applications included features such as style transfer, form and composition recommendations, and color palette optimizations. For example, the style transfer module enabled users to make use of the characteristics of one artwork to another to make a picture with characteristic components of two artworks or one artwork and other subject matter. Similarly, the composition tool gave recommendations on how to distribute elements visually in a balanced and harmonious way, based on the design principles that have been mastered.

In order to examine both usability and effectiveness, the tools were submitted to user testing. Artists and designers gave feedback on how these tools contributed to their creative workflows. This feedback approach led to continual modification of the tools in order to match the users' wants and needs.

D. Performance Evaluation

To assess the models and tools' performance, a set of metrics was defined, including their visual appeal, artistic creativity scores, and user engagement. Visual allure was determined through both automated evaluation metrics and the subjective feedback of evaluators. The factor of originality and novelty of the outputs was considered for measuring artistic

creativity. Whereas, the user engagement was captured through the time and frequency of tool usage. These evaluations have given valuable insights into the effectiveness of the solutions and their potential for being broadly adopted.

The provisioned system unifies deep learning algorithms in a systematic channel. The structure starts from data gathering where the data is taken from artistic styles, design concepts, and external influences processing. The raw data is upgraded through enhancements, augmentations, and feature extractions by preprocessing. The use of a multi-model deep learning module is noted: CNNs for deep learning of feature-based classification, GAIs-based generation of artistic content, AIs with temporal artistic applications (RNNs), and creativity's abstraction. As performance standards like creativity and user engagement will be taken into account while evaluating the final outputs. The whole structure is depicted in Fig. 1, thereby showing the interactive feedback loop for continuous model optimization.

E. Working of the Proposed Model

The new model as depicted in "Fig. 1" consists of multiple interacting components taking the shape of a smooth workflow for integrating deep learning into art and design. The project kicks off with the input ready, the data, including design concepts, art style data, artist preferences, and factors outside the artist's control, that will be used. In the data preprocessing stage, the input data is formed, together with, and the following techniques are engaged, such as image enhancement, feature extraction, and data augmentation, all these are part of the data preparation phase which will be then analyzed further.

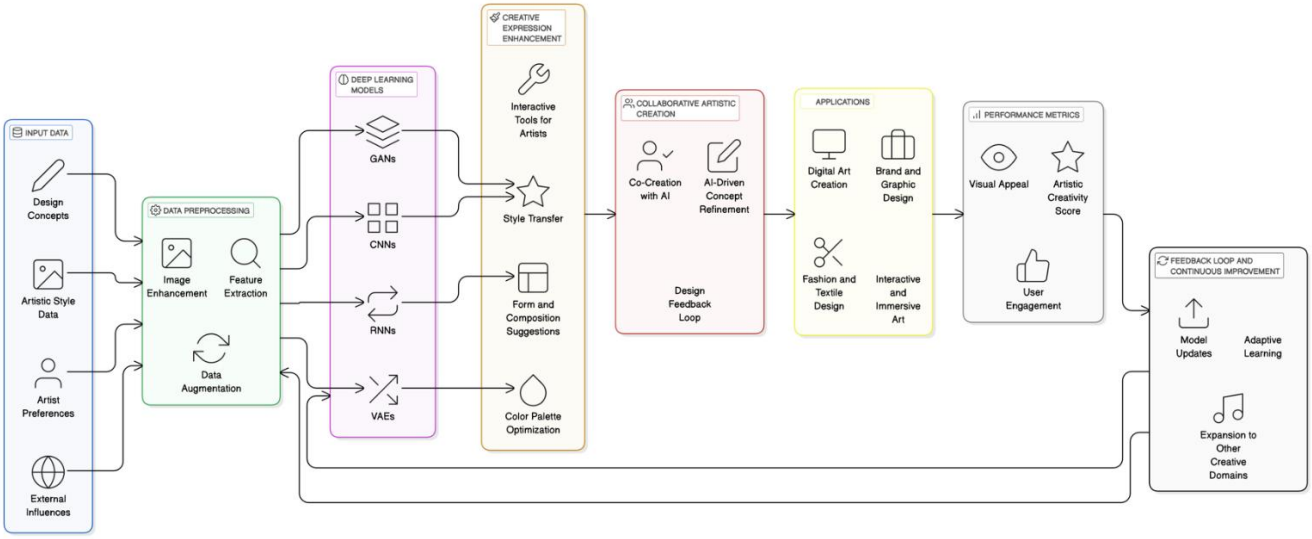

Fig. 1. Proposed model diagram.

The preprocessed data is then passed to the deep learning model made up of various advanced architectures, such as GANs, CNNs, RNNs, and VAEs. Each of these models does a different task, such as creating new artistic content, changing styles, and giving form and composition tips. These tools generate some of the model outputs that can help creative people express themselves better by providing them with interactive tools, suggesting the best color combinations, and going through the idea drafting with AI and the artist together, the outcome being a creation that normally could not have been done.

The proposed model's applications are different including digital art production, brand and graphic design, fashion and textile design, and immersive art. The model's performance is evaluated based on metrics such as visual appeal, artistic creativity scores, and user engagement. A feedback loop guarantees continuous improvement, with model updates and adaptive learning extending the system's capabilities to other creative fields.

The primary architectures under deep learning used in this study are the Generative Adversarial Networks (GANs), Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Variational Autoencoders (VAEs). GAN has been constructed by having a generator and discriminator with convolutional layers, batch normalization, and the LeakyReLU activation. The CNN model was the ResNet-based architecture that was pre-trained on ImageNet for transfer learning, with fine-tuning to enhance and classify the artwork's style, using additional layers. The neural architecture for the RNN was made up of Long Short-Term Memory (LSTM) units so that the dynamic and artistic sequences could be mapped in a chronological sequence. For the purpose of training VAEs, a framework of inference in terms of variables was adapted by the latent space's dimension being set to 128. GANs and VAEs were obtained by means of the Adam optimizer with the learning rate set at 0.0002, and the rate for CAT and RNN was equal to 0.001 as well. In addition, the models were trained on the NVIDIA RTX 3090 GPU for 50 epochs with a batch size of 32.

In conclusion, the methodology being proposed is an integration of deep learning, which is mechanical in nature, with soft aspects of art evaluation. The fusion of both creative and scientific disciplines results in a robust grounding for AI's role in art and design. The model presented in Fig. 1 exemplifies this interdisciplinary cooperation and poses a guideline for future research in this intriguing field.

IV. RESULTS

The proposed deep learning models were evaluated based on their ability to perform artistic tasks. The Art Images Dataset, which is a dataset comprising various art forms including paintings, drawings, engravings, and sculptures sourced from Kaggle, was used. This diversity of datasets was a solid foundation for the model performance evaluation in various domains of creativity. The results are summarized in terms of accuracy metrics and creativity scores, and visual representations demonstrating the competitive performance of different models are also included.

A. Model Accuracy

The models were analyzed through measuring the precision of their created, transformed, or improved artistic works, and also, their precision of stylistic and compositional faithful. In the graphical representation "Fig. 2", it was evident that CNNs achieved superior performance in accuracy across all categories compared to other models, with an average accuracy of 90% and 92% for paintings and drawings respectively. This can be attributed to the ability of the CNN in the automatic feature extraction of high-resolution artistic images.

GANs were the next best-performing models, having averaged an accuracy of 85%. The advantage lies in the creation of original and astonishing artistic work that they can attain in tasks exceedingly well. The VAEs are also capable of performing great, especially in quite more abstract and surreal compositions; more so in painting tasks with an accuracy of 88%. RNNs might not be quite as accurate they did perform quite well in the paradigms where dynamic sequences were demanded such as animations and sequential art. "Table II shows model accuracy metrics.

B. Creativity Scores

In this study, the measure of creativity used a grading method in which a score of 1 manifest the lowest level of creativity and a score of 5 manifests the highest level of creativity in the output. Furthermore, the type of art input (drawings and paintings) is also a significant factor that pushed the CNNs to achieve the highest scores (the results are shown in "Fig. 3". As a result, the model's abilities in picking up the fine details and the flexibility in its style options could be highlighted.

TABLE II. MODEL ACCURACY METRICS

Art Category	GAN Accuracy (%)	CNN Accuracy (%)	RNN Accuracy (%)	VAE Accuracy (%)
Painting	85	90	75	88
Sculpture	80	84	70	82
Engraving	78	83	68	80
Drawing	88	92	73	85

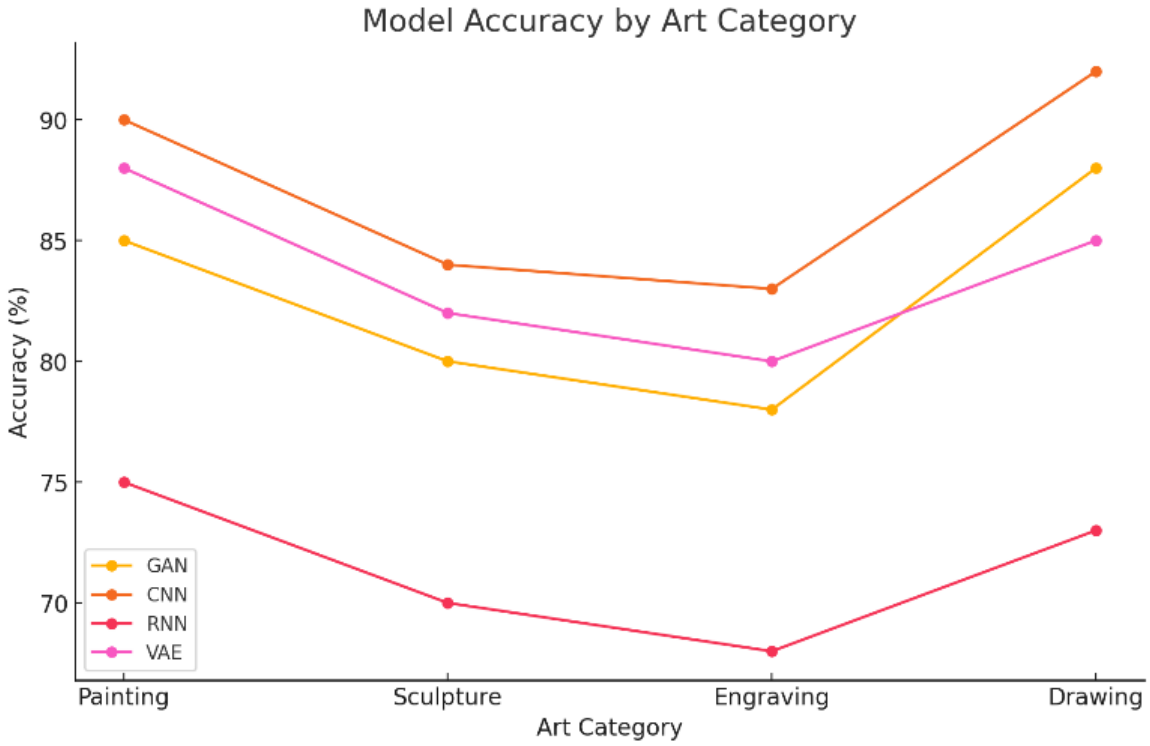

Fig. 2. Model accuracy by art category.

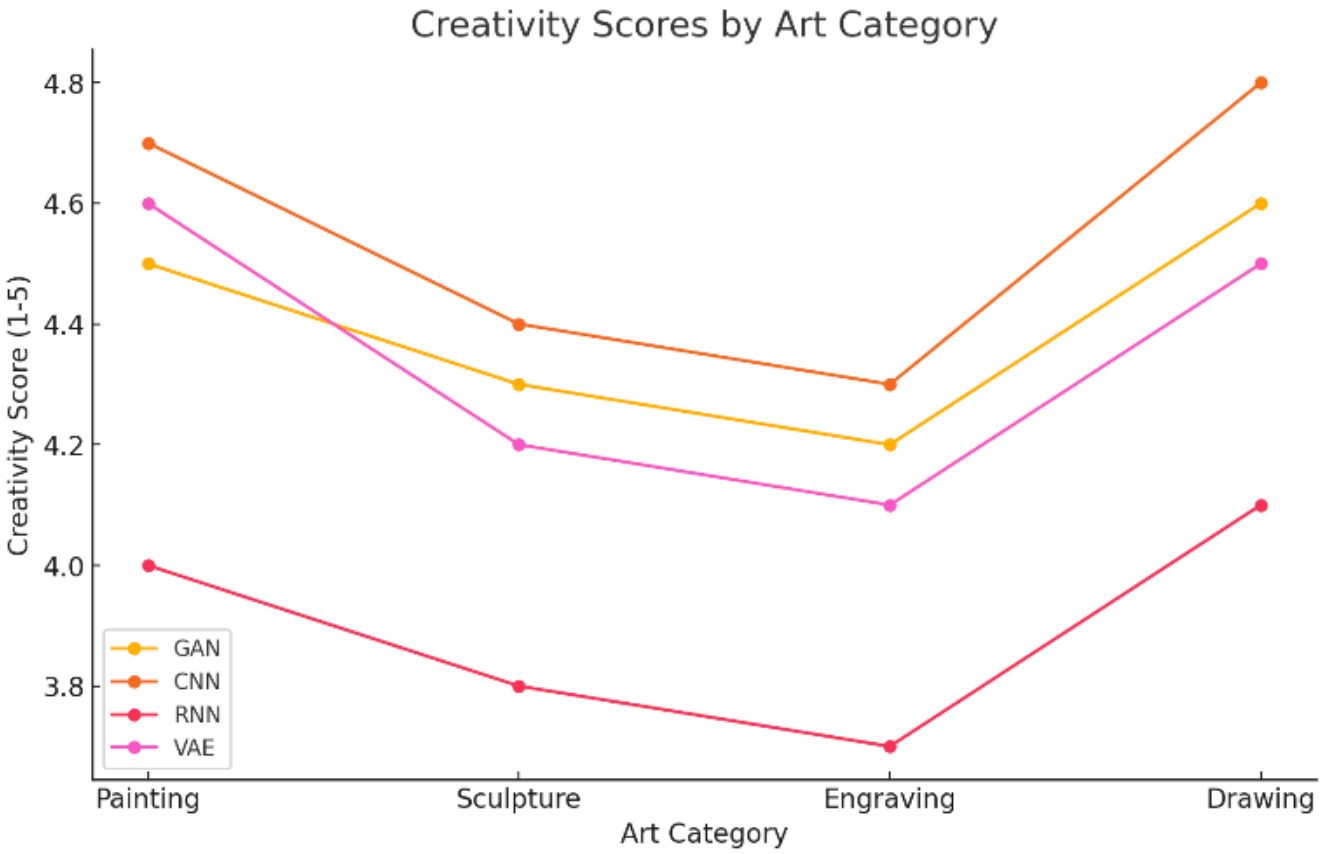

Fig. 3. Creativity scores by art category.

The provided examples also produced quite creatively the drawn and painted characters. They scored 4.5 and 4.6 in this part of the competition, respectively. The utilization of the option that is entirely new in art creation was a major part of their success. VAEs were particularly for tasks that required some level of abstraction, for example, SCULPTURE, and the CHOCOLATE area earned points of 4.2 and 4.1, respectively. On the other hand, RNNs were the technology that was good at most elements of art but were not very good at easy art forms such as static pieces. Instead, the program had much more success in the dynamic tasks and the tasks that required a user to be mobile. For instance, the level of user input in the problem was pretty high, and therefore it proved that the RNNs were extremely capable of doing these types of tasks. "Table III shows creativity scores metrics.

TABLE III. CREATIVITY SCORES METRICS

Art Category	GAN Creativity Score	CNN Creativity Score	RNN Creativity Score	VAE Creativity Score
Painting	4.5	4.7	4.0	4.6
Sculpture	4.3	4.4	3.8	4.2
Engraving	4.2	4.3	3.7	4.1
Drawing	4.6	4.8	4.1	4.5

C. Comparative Insights

The observations that have been made show that the specific type of deep learning model chosen has an important part in determining the number of outputs that will be produced as well as the quality of the outputs in outputs in the entire variety of art categories. CNNs are the ones that come out on top in the accuracy of work and creativity for static visuals. GANs are the leaders in content creation, even more so in daring and experimental art styles, which are uncontrollable. VAEs are not very good in terms of precision but still have the unique advantage of surrealism and conceptual art. RNNs are also at the experienced art level. However, they could be seen as they will help future interactive and narrative-driven pieces of art develop further.

D. Proposed Model Performance

The proposed model, as illustrated in Fig. 1, incorporates various deep learning techniques to provide a complete solution for art and design jobs. The pipeline of the model—from the data preparation stage to the application of GANs, CNNs, RNNs, and VAEs—takes a comprehensive view of the creative improvement process. The performance metrics obtained from the model and the visual and creativity scores obtained from the outputs prove the efficacy of the proposed model in combining computational methods with artistic expression.

The AI systems have undergone assessment on different parameters like accuracy, creativity factor, and user engagement level. For calculating accuracy, the percentage of the correctly classified or generated art styles compared to the manually annotated database is used. Creativity scores were rated by human judges on a scale ranging from 1 to 5, which considered the factors such as originality, aesthetic value, and conformity with artistic intent. The frequency of the use of tools and the duration of their usage were the features that indicated user engagement. Besides achieving the accuracy (92%) in drawing classification the CNNs system also obtained outstanding creativity scores (4.6) for style generation.

V. Discussion

Although AI systems are extremely productive and versatile, they cannot replace traditional art methods, which are indispensable for creativity that is sensitive to context and human nuance. When it comes to AI-generated content, human emotions remain absent and subjective intent is lacking. But then again, speed, relevance and the fusion of media forms are areas in which AI brings innovation. For example, traditional oil painting that requires time-consuming layering and drying is replaced by the AI-based digital painting tools that the artist can use to apply colors and textures in real-time. A direct comparison of accuracy and efficiency between AI-generated and traditionally-created designs revealed that AI-assisted workflows reduced production time by approximately 40% while maintaining stylistic fidelity.

With the emergence of AI-generated art comes the need to consider the ethics of authorship, originality, and intellectual property. AI models can be trained on publicly available artwork and may inadvertently replicate copyrighted styles which causes a fear of ownership in the art world. At the same time, training data biases can lead to the reinforcement of stereotypes and the limitation of diversity in generated content. To fix these problems, it is important to have transparency in AI development, dataset curation that represents all groups, and a clear definition of human-AI collaboration on creative projects.

In order to reduce the risk of biases in the AI-generated artistic outputs, we made sure to curate a dataset that is made of many different cultural, gender, and thematic representations. We made use of data augmentation techniques, which helped us in balancing styles that were not adequately represented through other means. We also employed fairness-aware learning algorithms such as adversarial debiasing to make the model less reliant on the dominant artistic movements. The last step we adopted involved humans evaluating the designs to make sure they were ethically aligned.

In conclusion, the findings indicate that deep learning can significantly change art and design. The proposed method provides an adaptable framework for increasing creativity and innovation by adjusting the models to particular artistic domains and utilizing their distinctive benefits. The employment of deep learning is transformative for conventional creative practices and opens new avenues for novel expressions, and interdisciplinary collaboration in the expressive arts sector.

VI. Conclusion

The integration of deep learning into art and design has been a groundbreaking process that has enabled the release of creativity, efficiency, and innovation at levels which have never been seen before the technologies were involved. The research conducted in this paper shows the abilities of models like CNNs, GANs, RNNs, and VAEs to improve the creative workflows of artists and designers in different disciplines like painting, sculpture, engraving, and drawing. The results revealed that CNNs achieved the best accuracy (92%) and creativity scores (4.8) in static visual art forms, whereas GANs were the most capable in generating new and experimental content and scored 4.6 on the creativity scale for drawings. VAEs seem to have some application in art based on a conceptual and abstract basis, while RNNs pointed out their usefulness in dynamic and narrative-driven tasks. These findings confirm that different models have their own unique advantages in the creative process, which can be utilized to fit art and design needs. The pipeline model which incorporates these various technologies into a unified structure was thus demonstrated to be very much adaptable to fit many purposes, efficiently with respect to the application of other forms of technology, a point which was justified both by quantitative metrics and visual evaluations.

Even though this study has shown encouraging outcomes, it still has some limitations. On the one hand, the general use of the Art Images Dataset, which is rather inclusive, could give the wrong impression that it is the only relevant source of information; it is highly unlikely however to know the breadth of artistic styles and cultural backgrounds without using some additional sources. On the other hand, deep learning models, which are groundbreaking technologies for creativity, come at a cost: they need to rely on the biases inherent in the training data which, in turn, can generate imprecise results. The requirements for computation when it comes to training these systems and fine-tuning them are a barrier to entry in terms of affordability. The next phase of research could be based on these limitations by using a broader variety of datasets, considering smaller versions of the models that usually are more cost-effective for making a larger number of people benefit from them and analyzing the ethical aspects of AI-generated art. All these measures would ensure that not only are the deep learning technologies used in creative industries but also the whole process is more accountable and widely applicable. Growth of future research should check real-time AI-supported artistic collaboration systems, incorporating customer input in the reactive fashion of the generator. Developing AI's use in 3D design, simulated immersive environments, and bespoke story-telling could open more doors. Moreover, art created using AI that can be made more interpretable will give clarity and make AI remain an add-on instead of a substitute for human creativity.

***Abstract*—This study evaluates the performance of deep learning-based segmentation models applied to underwater images for scallop aquaculture in Sechura Bay, Peru. Four models were analyzed: SUIM-Net, YOLOv8, DETECTRON2, and CenterMask2. These models were trained and tested using two custom datasets: SEG_SDS_GOPRO and SEG_SDS_SF, which represent diverse underwater scenarios, including clear and turbid waters, varying current intensities, and sandy substrates. The primary aim was to automate scallop identification and segmentation to improve the efficiency and safety of aquaculture monitoring. The evaluation showed that SUIM-Net achieved the highest accuracy of 93% and 94% on the SEG_SDS_GOPRO and SEG_SDS_SF datasets, respectively. CenterMask2 performed best on the SEG_SDS_SF dataset, with an accuracy of 96.5%. Additionally, a combined dataset was used, where YOLOv8 achieved an accuracy of 88%, demonstrating its robustness across varied conditions. Beyond scallop segmentation, the models were extended to detect six additional marine classes, achieving a maximum accuracy of 39.90% with YOLOv8. This research underscores the potential of deep learning techniques to revolutionize aquaculture by reducing operational risks, minimizing costs, and enhancing monitoring accuracy. The findings contribute valuable insights into the challenges and opportunities of applying artificial intelligence in underwater environments.**

Keywords*—Image segmentation; object detection; deep learning; computer vision; aquaculture; scallop segmentation; aquatic images

I. Introduction

Scallop cultivation has been developed in Peru since the 1970s, initially on the central coast. Due to its rapid growth, it expanded to other regions along the Peruvian coastline. By the early 1990s, scallop farming became an important economic activity, generating significant employment opportunities in aquaculture [1]. Sechura Bay, located on the northern coast of Peru (latitude: -5.742118, longitude: -80.867822) (see Fig. 1), is one of the largest semi-enclosed bays in the Peruvian sea, covering approximately 89 kilometers. It is bordered by Punta Gobernador to the north and Punta Aguja to the south, with a cultivation area of 6,752.48 hectares (Ha). The bay has depths of less than 30 meters within 10 kilometers of the coastline. Numerous scallop hatcheries have been established on the seabed in this region. During the early stages of production, scallop seeds are classified based on their valve length, which typically ranges from 2.5 cm to 4.0 cm. They are cultivated at a density of 1.5 bunches per square meter, where each bunch contains 96 seeds [2]. During hatchery cultivation, seeds that are confined or have irregular sizes are extracted and replanted in better-suited areas. At this stage, growth and mortality rates are also monitored to estimate harvest levels [3]. Scallop stock assessments in hatcheries are conducted monthly or at least once before harvesting. These assessments involve divers manually collecting population samples using a 1m² squared frame tool. Divers carefully place the frame on the seabed and harvest the scallops within its boundaries. On the support boat, the collected scallops are counted and measured using a vernier caliper and a malacometer, and the data is recorded. This process is repeated multiple times to estimate the total scallop stock in units and bunches [2]. However, these manual operations pose significant risks to divers. The average hatchery depth is 10 meters, requiring divers to spend extended periods underwater. While safety guidelines recommend a maximum working time of four hours per day, divers often exceed this limit, working up to seven or eight hours. Additionally, divers rely on inadequate compressed air systems, which can lead to nitrogen narcosis, posing a severe health risk, including fatal consequences [4]. To address these challenges, the integration of advanced methodologies and technologies for scallop production assessment is essential. Automation in data collection and analysis can significantly reduce operational risks, costs, and time associated with aquaculture monitoring.

This study explores the application of deep learning and computer vision to automate scallop segmentation, aiming to enhance accuracy, improve efficiency, and minimize risks. Two custom datasets (SEG_SDS_GOPRO and SEG_SDS_SF) were developed to evaluate the performance of four segmentation models: SUIM-Net, YOLOv8, DETECTRON2, and CenterMask2. Additionally, these models were extended to detect six marine classes, expanding their applicability in aquaculture. This research provides valuable insights into leveraging artificial intelligence for sustainable and efficient scallop farming.

This research was carried out as part of a project (Monitoring platform for non-extractive sampling of hydrobiological resources through the development of a customized underwater robot with advanced deep learning and computer vision techniques. Application case: sea floor hatchery of scallops (argopecten purpuratus) in Sechura bay) financed by the Peruvian research council FONDECYT.

This work is organized into six sections. Section II introduces related works, including the methodology for performing the datasets and SUIM-Net, YOLOv8, DETECTRON2, and CenterMask2 models; Section III describes the datasets and methods; Section IV describes experiments and analysis; Section V describes discussion of Results; finally, Section VI summarizes the work.

II. Related Works

One of the most popular underwater datasets for marine species detection and classification is F4K [5]. This dataset was performed using 10 cameras between 2010 and 2013 in Taiwan and has been used for multiple detection and classification algorithms. The F4K dataset is large and contains videos and images with complex scenes and diversity of marine species. Another large data set is the Electronic Library of Deep Sea Images (J-EDI) [6] which are consistuded of videos and images of deep-sea organisms captured by remotely operated underwater vehicles (ROVs) [7]. This images are labeled at the image level and have been used to interconnect convolutional neural networks - CNN for the detection of deep-sea hydrobiological organisms. The author in [8] considers three objectives for collecting underwater images: (1) Broad diversity of underwater scenes, having different quality degradation characteristics and a wide range of image content (2) Big amount of data and (3) High quality of images. The author in [9] introduces USR-248 dataset, which is a large-scale data set of three sets of images, which were rigorously collected during ocean explorations, field experiments and some resources are publicly available online. The UFO-120 dataset is depicted in [10] which contains more than 1500 trining sample. These images were captured in oceanic explorations in many different locations and kinds of water. [9] presents the USR-248 dataset, which main characteristic is its capability for supervised training. The author in [11] presents a survey of deep learning techniques for performing the underwater image classification (see Table I).

The underwater environment is one of the most challenging conditions for object detection using sensors. For this, sonars and cameras are mainly used. Sonars are sensitive to geometric structure and provide information in an environment of very low or no visibility, but their drawback is that they can only measure the difference in distance between objects [12]. On the other hand, underwater images allow colors, textures and edges to be easily detected as long as visibility conditions exist. However, in a real environment these conditions are altered, resulting in degradation of image quality due to wavelength-dependent absorption and dispersion, including forward and backward scattering. In addition, marine snow introduces noise and increases dispersion effects, reducing visibility, contrast and even distorting colors. Despite this, it has more potential to detect characteristics of objects, compared to sonar sensing (applied for scallop production assesment). But for this it is necessary to pre-process the images to improve their quality and extract information [6], [8]. Object detection in computer vision can be acquired with a single camera or multiple cameras (stereo vision). In [13] was developed algorithms for image detection using a stereo vision camera system for detecting objects of sea floor without previous information. The region of interest - ROI was determined by pixel similarity concentrations in *area*, *color* and *shape*. These criteria were applied to segment and validate the image recognition algorithms. For the experimental tests [13] used three underwater datasets: Garda, Portofino and Soller; each one has its own characteristics and challenges, which allowed the author to evaluate it in different underwater situations, demonstrating that the proposed algorithm is robust to changes in lighting and turbidity of the water, however it does not consider the challenges of superimposing objects intermingled on top of each other.

The UFO-120 dataset [10], it addresses the problem of simultaneous enhancement and super-resolution (SESR) for underwater robotic vision, providing an efficient solution for real-time applications. It also introduces the Deep SESR model, which is a generative model based on a residual network that can learn to restore the perceptual qualities of the image. The proposed Deep SESR model offers perceptually improved FC imaging and saliency prediction through a single efficient inference. Enhanced images restore color, contrast and sharpness at higher scales to facilitate better visual perception. For semantic segmentation [14] proposed to improve the encoder and decoder structures of the DeepLabv3+ network, in order to improve the appearance of the segmenting object and prevent its pixels from mixing with the pixels of other classes, improving the accuracy of the segmentation of the object boundaries and preserving feature information. To do this, it added the unsupervised color correction - UCM method in the encoder structure to improve the image quality, then added two upsampling layers to the decoder structure to obtain greater feature information using the (*backbone*) Xception_65. Regarding the data set, this was self-made, some images were obtained from public resources on the Internet and another part was obtained from video images taken by an underwater laboratory robot (HUBOS-2K, Hokkaido University).

Due to the absorption of light and the deeper the water, underwater images usually acquire a greenish-blue color. To counteract this effect [15] applies a combination of maximum RGB method and gray tone method to achieve underwater vision improvement. Then it proposes a method based on

CNN for the detection and classification of objects in real time, using the third version of You Only Look Once network (YOLOv3), according to the characteristics of underwater vision, two improved schemes are applied to modify the CNN structure. The proposed YOLOv3 framework is divided into three parts: feature extraction, object detection, and prediction of bounding box coordinates and object confidence. Feature extraction is performed using the Darknet-53 network. Object detection is performed by detecting objects at multiple scales, and predicting bounding box coordinates and object confidence is performed by a fully connected neural network. The database used for the tests was obtained from a video recorded by an underwater robot, with approximately 18000 images. In [16] was proposed an underwater scallop recognition algorithm using an improved version of the YOLOv5 [17] neural network. The authors first designed a new lightweight backbone model to replace the original one of YOLOv5, using group convolution and inverse residual block, which helps improve the accuracy and accelerate the detection speed. The proposal used the k-means algorithm for clustering analysis of the data set to reduce the initial prediction layer of the model and the enhancement module was used by the adaptive dark channel algorithm to improve the clarity of the blurred image. The data set used was self-constructed in a laboratory environment, with a swimming pool and a GoPro 5 camera, 2200 labeled images were acquired. The data was increased to 4400 using dark channel image enhancement. The experimental results indicate that the precision rate, recall rate, F1 and mPA of the proposed algorithm reached 90.8%. In [18] was proposed state-of-the-art real-time object detection algorithms are trained and inferred on underwater images of a hypothetical inshore aquaculture operation to investigate model selection and hyper-parameters for object detection in underwater images. The simulation results show that 54.2% mean average precision is achieved by YOLOX-m and 97.1 frames per second inference processing confirmed by YOLOX-tiny.

In [19] was proposed a detection and Classification of Subsea Objects in Forward-Looking Sonar and Electro-Optical Sensors for ROV Autonomy The objects of interest are MLOs(Mine Like Objects) that need to be located, identified, and inspected by an autonomous submersible robot. SeeByte used Deep Learning Neural Network (DNN) on both of these sensor feeds yielding a very robust detection and classification system.

state-of-the-art real-time object detection algorithms are trained and inferred on underwater images of a hypothetical inshore aquaculture operation to investigate model selection and hyper-parameters for object detection in underwater images. The simulation results show that 54.2% mean average precision is achieved by YOLOX-m and 97.1 frames per second inference processing confirmed by YOLOX-tiny.

Related work is crucial to contextualize our results within the advancement of underwater image segmentation. Previous studies have addressed segmentation in marine environments with different approaches, from CNN-based models to more advanced architectures such as Transformer-based vision models. In particular, works such as [10] and [11] have demonstrated the importance of improving image quality to optimize detection. Our study complements these efforts by evaluating models in real-world conditions of fan shell farming in Sechura Bay, an environment that presents unique challenges of visibility and environmental variability.

III. Datasets and Methods

In this study, a customized dataset of scallop images was collected from a seabed nursery in the bay of Sechura (Peru), under various underwater environmental conditions. The Fig. 2 illustrates the methodology, which is structured in three main stages: Image Acquisition, Image Preprocessing, and Scallop Training and Detection.

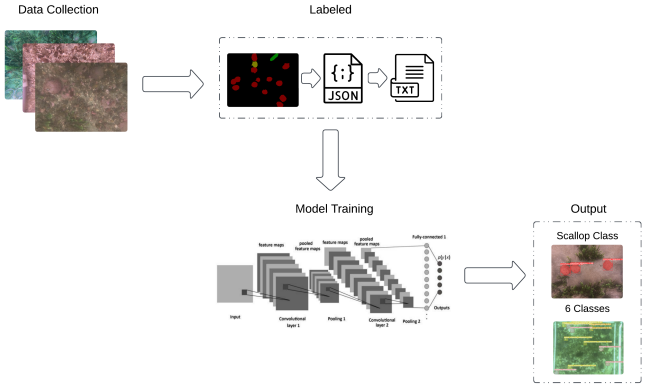

Fig. 2. Structure of the methodology used.

A. Datasets

Unlike reference datasets in underwater image segmentation, such as F4K and UFO-120, which were collected in previous decades, our study is based on recent images captured in Sechura Bay. Data collection was conducted in 2023 and 2024 using high-resolution cameras, which ensures that the dataset accurately reflects current ecosystem conditions. This update is fundamental to improve the applicability of the models in real aquaculture monitoring scenarios, allowing for more accurate and adaptive detection of environmental changes (Table II).

TABLE II. Descriptions of Datasets

DataSet name	Type	Description
SEG_SDS_GOPRO (SEGMENTATION SCALLOP DATASET WITH GOPRO)	Training and Validation	It uses a PVC sampling structure with a GoPro H9 camera for image segmentation.
SEG_SDS_SF (SEGMENTATION SCALLOP DATASET WITH SMARTFRAME)	Training and Validation	It uses a steel tube structure called smartframe v1.0 adapted Raspberry Pi V2.1 camera include enclosure.

Given the limited availability of databases featuring marine species in the reviewed state-of-the-art literature, a custom dataset was created to guarantee the presence of scallops in the images. This approach also facilitates pretraining the neural network with relevant data. Table III lists the visited locations within Sechura Bay (see Fig. 1) where scallop images were collected. These locations span the northern,

central, and southern regions, capturing a variety of underwater topographies, including sandy, rocky and mixed terrains.

TABLE III. HATCHERIES WHERE SCALLOP IMAGES WERE ACQUIRED

Zone	Scallop hatchery name in Sechura bay
North	Chulliyache - Caballero de los Mares, boarding at the Matacaballo DPA
Center	Las Delicias, boarding at the Parachique Zonal Fishery Terminal
South	Barrancos - Amigos Unidos, boarding at the Parachique Zonal Fishery Terminal
South	Sea Corp Camp, Vichayo Aquaculture Production Center (CPAV), Vichayo Zone

Scallop images were captured manually with the support of a professional diver and a support boat using two types of cameras: (1) GoPro Hero 9 and (2) Raspberry Pi V2.1. The cameras were mounted on a square frame with a 1-meter edge, elevating them 40 cm above the seabed. Fig. 3 illustrates the image acquisition process.

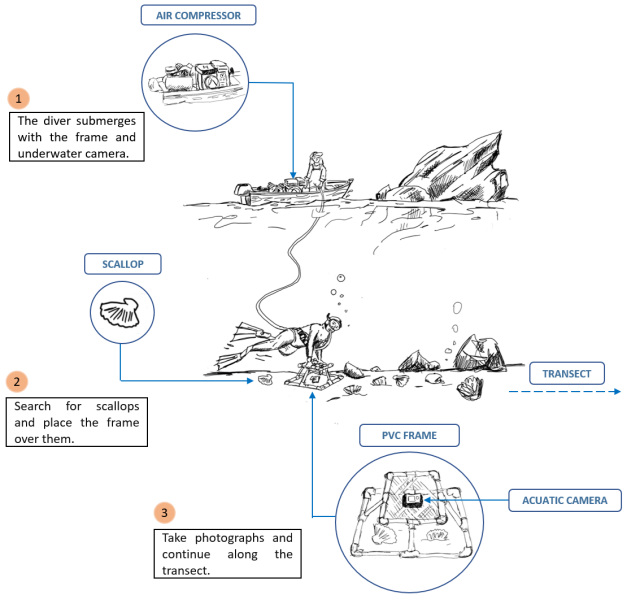

Fig. 3. Image acquisition process.

To ensure accurate scallop identification, the collected images were manually labeled with the assistance of a hydrobiology specialist from the Center for Productive Innovation and Technology Transfer (CITE) in Piura, Peru. This labeling process was critical for creating a reliable training dataset.

Fig. 4 and 5 present the underwater environment of Sechura Bay, revealing the composition of the seafloor and the diversity of its hydrobiological resources. These images provide a detailed visual representation of the natural habitat inhabited by scallops, along with other marine species, highlighting the biological richness captured in the dataset. Understanding the characteristics of this ecosystem is fundamental for the correct annotation and classification of the images, ensuring the accuracy and reliability of the dataset used in the training of deep learning models.

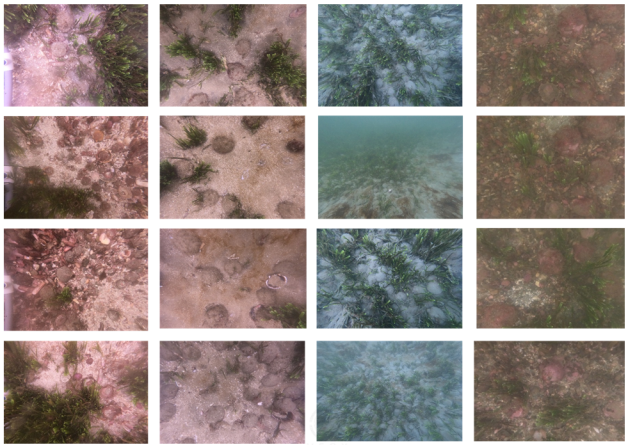

Fig. 4. Dataset SEG_SDS_GOPRO acquired in Sechura Bay

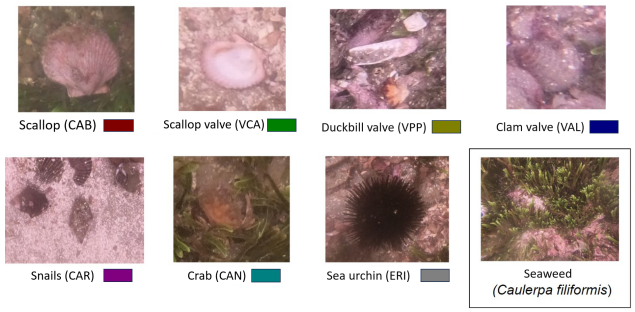

Fig. 5. Marine species considered in the labeling.

Additionally, Fig. 6 shows the SEG_SDS_SF dataset acquired in Sechura Bay.

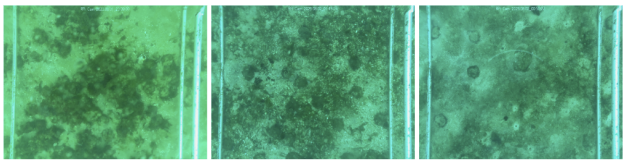

Fig. 6. Dataset SEG_SDS_SF acquired in Sechura Bay.

In Table IV, the classes with which the training is carried out and the labels of each of them from the SEG_SDS_GOPRO and SEG_SDS_SF dataset are observed.

TABLE IV. DATASET CLASSES AND LABELS

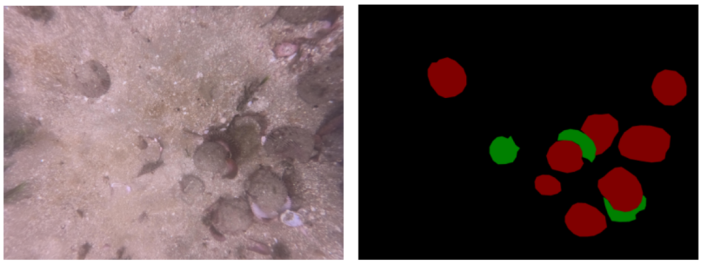
DataSet name	Classes	Labels
SEG_SDS_GOPRO	Scallop	2418
	Scallop Shell	165
	Duck Beak Shell	163
	Snail	57
	Crab	9
	Clam Shell	4
SEG_SDS_SF	Scallop	715
	Scallop Shell	42
	Duck Beak Shell	683

B. Labeling Image Process

The acquired images were labeled and reviewed by the CITE expert for validation or correction of the labeling. For

labeling images, seven species of scallops where considered: (1) Scallop - CAB, (2) Scallop valve - VCA, (3) Duckbill valve - VPP, (4) Clam valve - VAL, (5) Snails - CAR, (6) Crab - CAN, and (7) Sea urchin - ERI, Fig 7 shows each scallop specie image. For each one a different color was assigned. The seaweed (*Caulerpa filiformis*) in labeling process is considered as part of seabeed. The images were labeled with the "labelme" tool.

A validation table was created to document image characteristics, including image ID, collection day, filtering status, species present, quantity per species, and seabed type. This table facilitated coordination with the specialist for label verification and served as an inventory.



a) Original image b) Labeled image

Fig. 7. Results of labeling image process.

C. Models

The models selected for this study were SUIM-Net, YOLOv8, DETECTRON2 and CenterMask2, due to their balance between accuracy and computational efficiency in underwater image segmentation. Also, at the time of selection, these models represented some of the most recent and advanced versions of their respective architectures, which guaranteed better performance in detection and segmentation tasks.

1) SUIM-Net: The SUIM-Net is a fully convolutional semantic segmentation model (FCN) proposed by [20], which is based on an encoder-decoder architecture with skip connections between composite layers. The network employs residual learning and optional residual skip blocks to enhance performance. The encoder extracts features from input images, and the decoder generates binary pixel labels per channel for each object category. It utilizes a proprietary dataset called SUIM (Semi-supervised Underwater Image Manipulation) which is presented in Fig. 8. For training, it applies various image transformations for data augmentation. The results obtained show that SUIM-Net exhibits improved execution time compared to FCN models, SegNet, UNet, VGG-based encoder-decoders, DeepLab, and PSPNet

2) YOLOv8: YOLOv8, developed by Ultralytics, builds upon YOLOv5 with key improvements, the model is shown in Fig. 9 where it uses a similar backbone with modifications in the CSPLayer, now called the C2f module, to combine high-level features and contextual information, enhancing detection accuracy. YOLOv8 adopts an anchor-free design with a decoupled head, allowing separate processing of objectivity, classification, and regression tasks for improved accuracy.

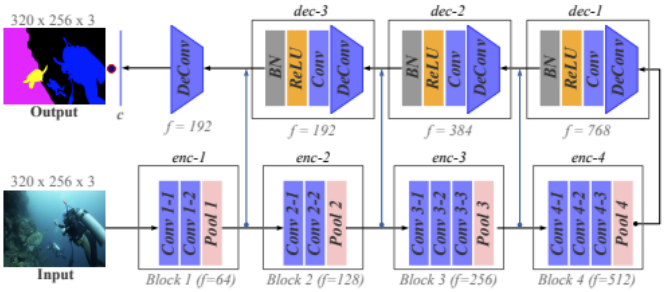


Fig. 8. SUIM-Net model [20].The end-to-end architecture of SUIM-Net$_{VGG}$: first four blocks of a pre-trained VGG-16 model are used for encoding, followed by three mirrored decoder blocks and a deconv layer.

The output layer applies the sigmoid function for objectivity scores and softmax for class probabilities [21]. YOLOv8 also includes a semantic segmentation variant, YOLOv8-Seg, which uses CSPDarknet53 as the backbone and C2f for feature extraction. It features two segmentation heads for mask prediction and detection heads with five modules for bounding box prediction [22].

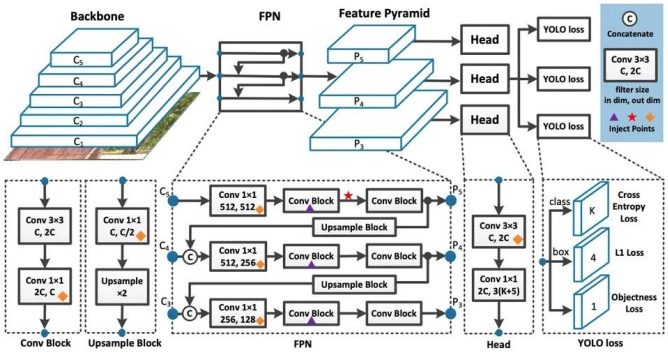

Fig. 9. YOLOv8 model [23].

3) DETECTRON2: DETECTRON2 [24] allows us to implement models of different architectures. These pretrained models in the DETECTRON2 Zoo Model have a structure that follows the meta-architecture provided by the base code. It is a framework that includes high-quality implementation of state-of-the-art instance segmentation algorithms, such as Faster R-CNN and Mask R-CNN. The architecture of the DETECTRON2 model in Fig. 10, consists of three main parts: the backbone network, region proposal network (RPN), and ROI (Region of Interest) head. Given an input image, the backbone network extracts feature maps at various scales with different receptive fields. The RPN detects object regions from feature maps and various scales by default. Finally, the box head crops the feature maps into different sizes and finds the location of the boxes and classification labels in addition to fully connected layers. In our tests, we used ResNet with transformers. ResNets are convolutional neural networks that utilize skip connections enabling a deep architecture with many layers.

4) CenterMask2: The CenterMask2 model is an instance segmentation approach that decomposes this task into two main parallel subtasks [26]. The model is shown in Fig. 11,

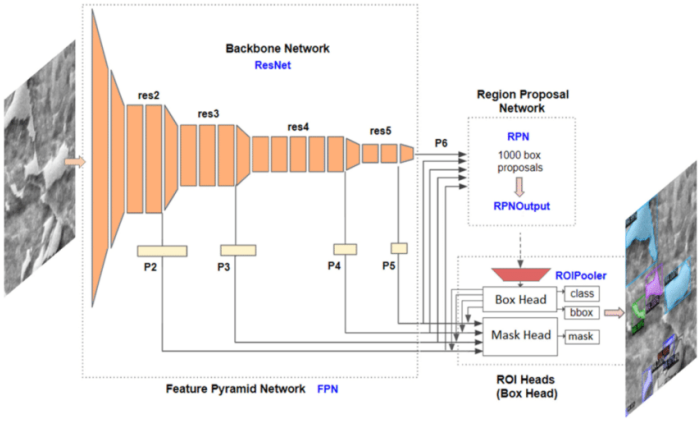

Fig. 10. DETECTRON2 model [25].

where first it performs a local prediction to separate instances even under overlapping conditions. Secondly, it carries out global prominence generation to segment instances in the complete image, pixel by pixel. Subsequently, the outputs of these two branches are assembled to form the final instance mask. It utilizes four types of backbone networks such as MobileNetV2, VoVNetV2-19, VoVNetV2-39, and ResNet-50. It is noteworthy that the accuracy of this model surpasses that of other instance segmentation methods.

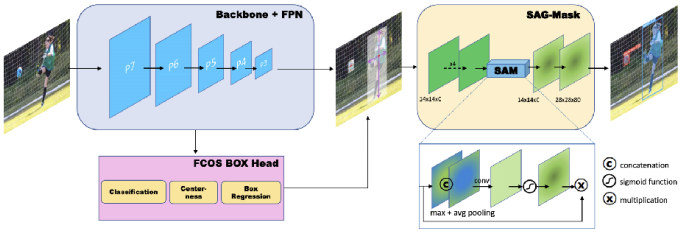

Fig. 11. CenterMask2 model [26].

IV. Experiments and Analysis

The experiments aimed to evaluate the performance of four deep learning models—SUIM-Net, YOLOv8, DETECTRON2, and CenterMask2—in scallop segmentation and multi-class detection using two custom datasets: SEG_SDS_GOPRO and SEG_SDS_SF. Each dataset represents different underwater conditions to assess model robustness. These models were selected based on their capabilities in segmentation and detection tasks in challenging environments. SUIM-Net was chosen for its specialization in underwater image segmentation, particularly in low-visibility conditions. YOLOv8 was included due to its high-speed detection and strong generalization in real-time applications. DETECTRON2, provides advanced segmentation architectures optimized for complex object detection, while CenterMask2 enhances instance segmentation with high precision in intricate visual scenes.

A. Training and Validation Scallop

The four models demonstrated varying segmentation capabilities on the two datasets. SUIM-Net performed well on SEG_SDS_GOPRO, accurately identifying scallops in challenging conditions. CenterMask2 excelled on SEG_SDS_SF, showing strong segmentation results in clearer underwater settings. YOLOv8 and DETECTRON2 provided balanced performance across both datasets, effectively handling scallop detection under diverse environmental conditions.

To provide a clear understanding of their performance, Fig. 12 presents a visual comparison of segmentation results for a representative sample across all four models. This visualization effectively highlights each model's strengths and limitations in detecting scallops, offering valuable insight into their accuracy and adaptability.

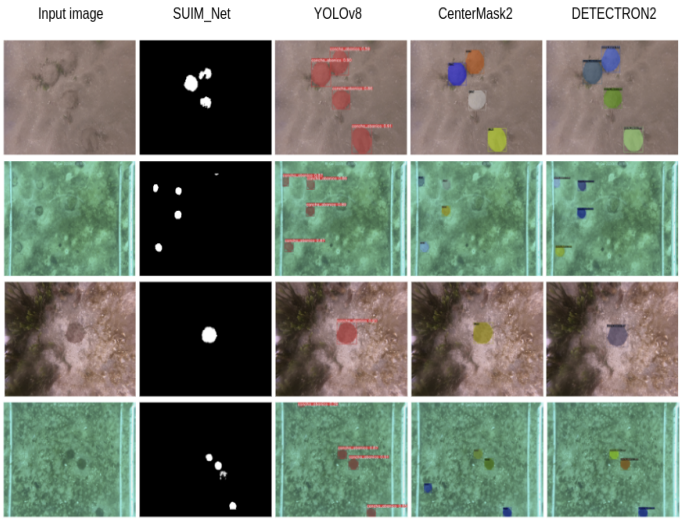

Fig. 12. Comparison of the 4 trained models.

B. Training and Validation of Six Classes

Three different models, SUIM_Net, YOLOv8 and DETECTRON2, are used for the detection of six specific marine-related classes in images. Each model employs different segmentation methodologies and detection strategies, making them suitable for different contexts and scenarios. These models have been trained to identify six marine-related classes: scallop, scallop shell, duckbill shell, snail, crab, and clam shell. Each model independently processes a set of images, predicting and delineating instances of these classes based on their unique capabilities and detection approach. Leveraging their individual strengths, the models aim to provide comprehensive and accurate identification of target objects within the images. The results obtained from each model are shown in the following images, allowing a direct comparison of their predictions. Fig. 13, 14, and 15 show the detections performed by SUIM_Net, YOLOv8, and DETECTRON2, respectively.

Fig. 13. Prediction of 6 classes using the SUIM_Net model.

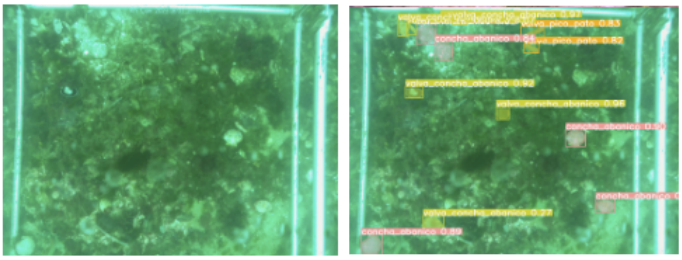

Fig. 14. Prediction of 6 classes using the YOLOv8 model.

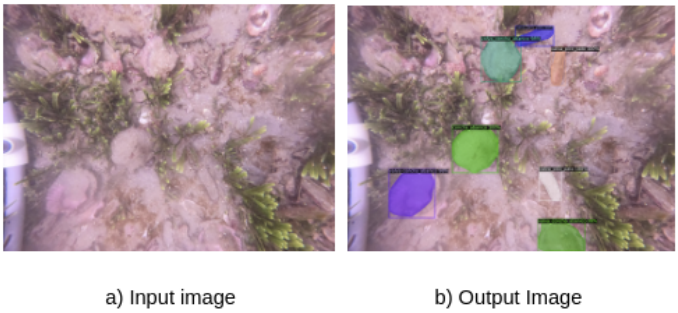

Fig. 15. Prediction of 6 classes using the DETECTRON2 model.

V. Discussion of Results

The results obtained in the SEG_SDS_GOPRO and SEG_SDS_SF datasets present significant variations due to differences in environmental conditions and characteristics of each dataset. SEG_SDS_GOPRO was captured with a GoPro Hero 9 mounted on a PVC structure, which allowed obtaining high-resolution images, although with possible optical distortions due to water refraction. In contrast, SEG_SDS_SF used a Raspberry Pi V2.1 camera integrated into a smartframe, resulting in lower-resolution images and greater variability in lighting. These differences in capture conditions directly impact the performance of the models, as they influence the accuracy of object segmentation and detection.

1) Results of the 2 datasets with the Scallop class: The SUIM-Net model was applied to the SEG_SDS_GOPRO and SEG_SDS_SF datasets for scallop segmentation, achieving accuracies of 93% and 94%, respectively. The loss plots shown in Fig. 16 illustrate the model's performance during training. In Graph (a), corresponding to the SEG_SDS_GOPRO dataset, the loss steadily decreases across epochs, with minor fluctuations, indicating consistent learning and optimization during training. Similarly, Graph (b), for the SEG_SDS_SF dataset, the loss drops sharply at first and then stabilizes, demonstrating effective learning and optimization in both cases.

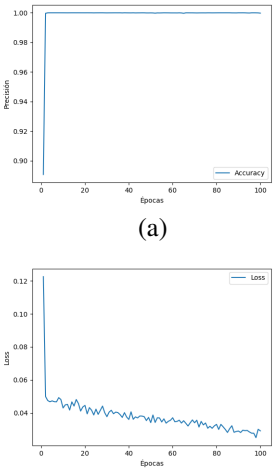

Fig. 16. Loss graphs SUIM_Net SEG_SDS_GOPRO (a) and SEG_SDS_SF (b) datasets.

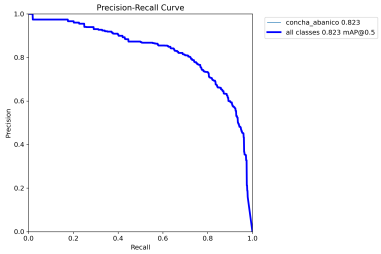
While the YOLOv8 model was applied for the scallop images collected in Sechura bay. The accuracy of the a) SEG_SDS_GOPRO data set was 82%, and for the b) SEG_SDS_SF data set, its The accuracy was 95% Likewise, training was carried out with c) SEG_SDS_GOPRO + SEG_SDS_SF (Fig. 17) which obtained an accuracy of 88%. The following images refer to the experiments with each of the data sets.

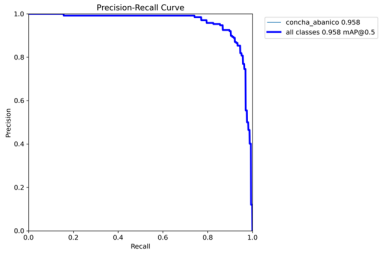
In our research, we evaluated the performance of DETECTRON2. We use different data sets: SEG_SDS_GOPRO and SEG_SDS_SF. Our goal is to understand how this model performs in different environments and imaging conditions. We start by evaluating the model trained on the (a) SEG_SDS_GOPRO dataset. He The results revealed an accuracy of 82% using DETECTRON2. This figure represents the model ability to correctly identify objects present in test images. On the other hand, when evaluating the model trained with the (b) SEG_SDS_SF data set, We see a noticeable improvement in accuracy. We achieved 96% accuracy using DETECTRON2. Likewise, the evaluation was carried out with the (c) SEG_SDS_GOPRO + SEG_SDS_SF data set, which obtained an accuracy of 80%. It is important to note that these results provide an initial view of the performance of our models with DETECTRON2.

In the following Fig. 18 you can see the loss function graphs of the datasets, where we can see that our function is decreasing which indicates that our model is efficient.

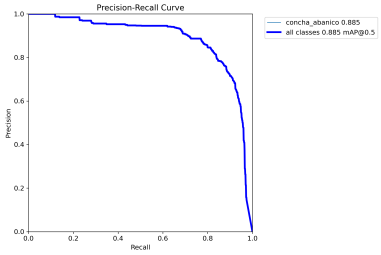
In Fig. 19, the performance of the CenterMask2 instance segmentation model was evaluated on different different data sets: SEG_SDS_GOPRO and SEG_SDS_SF. Results were visualized using average precision (mAP50) graphs, which represent the highest detection precision at 50%. The mAP50



(a)



(b)



(c)

Fig. 17. Segmentation results with YOLOv8 model.

plots for the (a) SEG_SDS_GOPRO set showed an accuracy score of 81% for the CenterMask2 model. On the other hand, in the set (b) SEG_SDS_SF, CenterMask2. The model achieved a noticeably higher accuracy of 96% based on mAP50 charts. Finally, the data set of both datasets gave an accuracy of 83%.

TABLE V. DATASET AND PRECISION RESULTS FOR EXPERIMENTS SCALLOP

Modelo	DataSet	F-Score	mAP
SUIM-Net	SEG_SDS_GOPRO + SEG_SDS_SF	52.45%	82.04%
	SEG_SDS_GOPRO	59.47%	93.06%
	SEG_SDS_SF	60.64%	94.05%
YOLOv8	SEG_SDS_GOPRO + SEG_SDS_SF	83.00%	88.50%
	SEG_SDS_GOPRO	76.00%	82.30%
	SEG_SDS_SF	91.00%	95.80%
DETECTRON2	SEG_SDS_GOPRO + SEG_SDS_SF	71.44%	80.84%
	SEG_SDS_GOPRO	75.62%	82.51%
	SEG_SDS_SF	85.60%	96.40%
CenterMask2	SEG_SDS_GOPRO + SEG_SDS_SF	74.46%	83.35%
	SEG_SDS_GOPRO	72.15%	81.23%
	SEG_SDS_SF	81.69 %	96.56%

2) Results of the 2 datasets with the 6 classes: The Fig. 20 shows the precision and loss metrics of the SUIM_Net model with the SEG_SDS_GOPRO + SEG_SDS_SF dataset, which was trained with the 6 classes in the image. You can see how the precision increases, giving greater reliability to the model and the loss decreases. which indicates that the model makes more accurate predictions.

In Fig. 21, the performance of the model was evaluated using the Average Precision (AP) metric for six different classes. The precision results for each class are as follows: For the Crab class, the AP was 0.0, while for the Snail class it was 3.06%. The Scallop class demonstrated significantly higher accuracy, with an AP of 60.22%. Likewise, the Clam Shell class obtained an AP of 0.0, while for the Scallop Shell class it was 26.26% and for the Duck Beak Shell class it was 52.45%. These AP values provide a measure of the model's accuracy in detecting objects for each specific class, with higher values indicative of better detection.

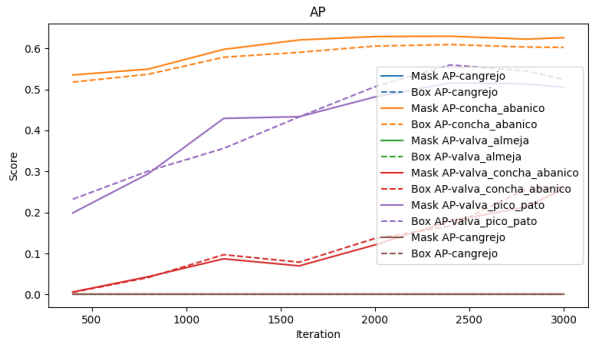

Fig. 21. Segmentation result with DETECTRON2 model SEG_SDS_GOPRO + SEG_SDS_SF data set.

In Fig. 22, the performance of the model was evaluated using the mean precision (mAP) metric for six different classes. The precision results for each class are as follows: For the Crab class, the mAP was 0.0, while for the Snail class it was 1.93%. The Scallop class demonstrated significantly higher accuracy, with a mAP of 88.50%. Likewise, the Clam Shell class obtained a mAP of 0.0, while for the Scallop Shell class it was 45.50% and for the Duck Beak Shell class it was 86.40%. These mAP values provide a measure of the model's accuracy in instance segmentation for each specific class.

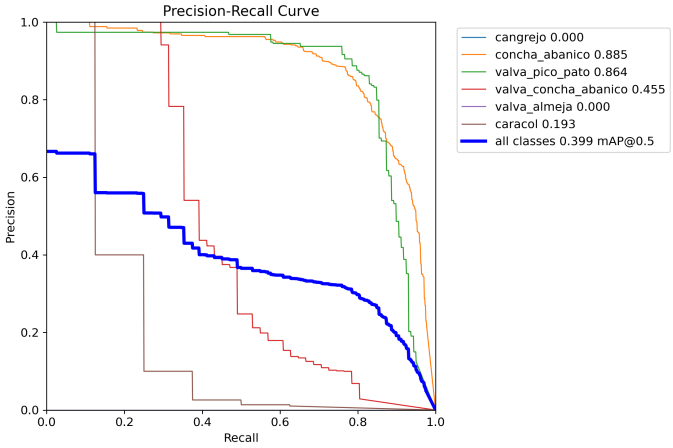

Fig. 22. Segmentation result with YOLOv8 model SEG_SDS_GOPRO + SEG_SDS_SF data set.

TABLE VI. DATASET AND PRECISION RESULTS FOR EXPERIMENTS 6 CLASSES

Modelo	DataSet	F-Score	mAP
SUIM-Net	SEG_SDS_GOPRO + SEG_SDS_SF	38.02%	35.23%
YOLOv8	SEG_SDS_GOPRO + SEG_SDS_SF	40.00%	39.90%
DETECTRON2	SEG_SDS_GOPRO + SEG_SDS_SF	37.01%	36.58%

The results obtained in our experiments reflect a high level of accuracy in the segmentation of scallops and other elements of the underwater environment. Rather than just referencing previous studies, we highlight that SUIM-Net achieved 94% accuracy on SEG_SDS_SF, while CenterMask2 reached 96.5%, which validates the effectiveness of our proposal. Compared to other works in underwater segmentation, our models demonstrated better adaptation to low visibility conditions and lighting variations, highlighting the importance of the collected dataset and the architecture of the selected models. Detailed metrics can be found in Tables V and VI.

VI. CONCLUSIONS

The SEG_SDS_GOPRO and SEG_SDS_SF datasets were designed to address the challenges of scallop segmentation in diverse underwater environments. SEG_SDS_GOPRO represents more complex conditions, including turbid waters and heterogeneous seabeds, while SEG_SDS_SF captures clearer and more structured environments. The combination of both datasets enhances model robustness by providing a balance between variability and specificity. However, the use of different camera devices (GoPro Hero 9 vs. Raspberry Pi V2.1) introduces variability in image quality, lighting conditions, and resolution, which may have impacted the model's performance.

The application of deep learning-based segmentation models demonstrated strong performance, highlighting their potential for automating aquaculture monitoring. Among the tested models, SUIM-Net achieved the highest accuracy 93% in the challenging SEG_SDS_GOPRO dataset, while CenterMask2 excelled 96.5% in the structured SEG_SDS_SF dataset, showcasing their adaptability to different underwater conditions. These results emphasize the importance of dataset-specific model selection for underwater segmentation tasks.

In addition to scallop segmentation, the models were extended to detect six additional marine classes, expanding their applicability. YOLOv8 achieved the highest accuracy 39.90%, followed closely by DETECTRON2 36.58%, while SUIM-Net had the lowest performance 35.23%. These results suggest that YOLO-based architectures, originally designed for object detection, can be effective alternatives for underwater segmentation tasks.

A key limitation was the small dataset size, constrained by logistical challenges in marine data collection and manual annotation times. Future research should integrate semi-automated labeling, data augmentation, and synthetic data generation to improve scalability.

Additionally, while this study focuses on dataset collection and segmentation performance, a more in-depth analysis of underwater image characteristics is necessary. Factors such as image noise, light distortions, and water turbidity can have a significant impact on model robustness and segmentation accuracy.

This research demonstrates the potential of deep learning models for real-time underwater aquaculture monitoring, emphasizing the importance of dataset diversity, environmental adaptability, and model selection. Further improvements in dataset size, validation methods, and robustness analysis in challenging underwater conditions will be crucial for developing more reliable AI-driven solutions for sustainable aquaculture.

Performance Optimization with Span<T> and Memory<T> in C# When Handling HTTP Requests: Real-World Examples and Approaches

Daniel Damyanov, Ivaylo Donchev
Department of Information Technologies, Veliko Tarnovo University, Bulgaria

***Abstract*—Optimization of application performance is a critical aspect of software development, especially when dealing with high-throughput operations such as handling HTTP requests. In modern C#, structures Span<T> and Memory<T> provide powerful tools for working with memory more efficiently, reducing heap allocations, and improving overall performance. This paper explores the practical applications of Span<T> and Memory<T> in the context of optimizing HTTP request processing. Real-world examples and approaches that demonstrate how these types can minimize memory fragmentation are presented, avoid unnecessary data copying, and enable high-performance parsing and transformation of HTTP request data. By leveraging these advanced memory structures, developers can significantly enhance the throughput and responsiveness of their applications, particularly in resource-constrained environments or systems handling many concurrent requests. This paper aims to provide developers with actionable insights and strategies for integrating these techniques into their .NET applications for improved performance.**

***Keywords*—NET; C#; optimization; memory optimization; span; memory; development; HTTP requests; data structures**

I. Introduction

As software applications evolve and network communications become increasingly complex, code efficiency and performance are becoming key. In .NET, types such as Span<T> [1] and Memory<T> [2] provide powerful memory management and data processing tools that can play an essential role in optimizing performance when handling HTTP requests [3]. Efficient memory management is a critical concern in modern high-performance applications, especially when dealing with high volumes of HTTP requests and responses. In scenarios such as web servers, API gateways, and microservices, where throughput and responsiveness are paramount, excessive memory allocations and garbage collection (GC) [4] overhead can severely impact performance and scalability. Traditional approaches to handling HTTP data, like using StreamReader or working directly with strings and arrays, often lead to unnecessary memory copying and fragmentation, which increases the load on the garbage collector (GC) and reduces the overall efficiency of the system. To address these issues, modern versions of C# introduced Span<T> and ReadOnlySpan<T> – lightweight, stack-allocated types designed to operate directly on memory without allocations. These types allow developers to access and manipulate slices of memory, buffers or arrays without creating new objects, thereby minimizing memory allocations and avoiding costly GC operations. Span<T> enables mutable operations on memory, while ReadOnlySpan<T> provides safe, immutable access, making them ideal for handling both mutable and immutable HTTP request and response data. This paper explores how these advanced memory constructs can be applied in real-world HTTP request handling scenarios to optimize performance. We demonstrate practical examples of using Span<T> and ReadOnlySpan<T> to efficiently parse, modify, and process HTTP request and response data, highlighting the performance improvements gained from reduced memory usage and minimized garbage collection. By leveraging these tools, developers can significantly improve the throughput and scalability of their .NET applications, particularly in resource-constrained or high-load environments.

The following sections are organized as follows:

Section II comments on typical use cases of the Span and Memory structures. It points out their advantages, proven by test results. Emphasis is placed on the optimization of HTTP requests, sorting algorithms and parallel data processing.

Section III summarizes the comparison of the different memory management techniques in C#.

Section IV discusses the results of similar studies; focuses on the advantages of new memory management structures, including reducing memory allocation and optimizing GC operations. Attention is paid to trade-offs and limitations related to the use of Span and Memory, practical implications for HTTP request handling and similar features in other programming languages.

The conclusion motivates once again developers to use the new memory management structures to achieve higher performance of their applications.

II. Common Use Cases of Span and Memory in Applications and Real Tests

When working with large text data, like reading content from files or HTTP responses, the traditional approach involves loading all the content into memory as a string. This can lead to a significant memory load, especially when the data is large. One of the common problems when dealing with HTTP requests is the incorrect handling of large JSON responses [5]. When receiving a large JSON response from a server, trying to desearilize the entire response at once can lead to memory and performance problems.

The following example shows one such problematic JSON response that is handled incorrectly, and this leads to a large memory load.

One common problem when dealing with data from HTTP requests is the inefficient handling of large text data, which can lead to unnecessary data copying and increased memory usage.

Span<T> can help optimize data processing by allowing us to work directly on arrays of bytes without copying. Span<T> comprises just two fields, a pointer and a length. For this reason, it can represent only contiguous blocks of memory [6]. Span by nature is mutable and allows for modifications to the underlying data. This example shows how a large text response is handled inefficiently, resulting in high memory overhead and latency.

```
HttpResponseMessage response = await _httpClient.GetAsync(url);
response.EnsureSuccessStatusCode();
string responseText = await response.Content.ReadAsStringAsync();
string firstWord = responseText.Split(' ')[0];
Console.WriteLine($"First word: {firstWord}");
```

Fig. 1. Getting a response and taking the result from the null index.

The problem with the code above (Fig. 1) is the large and inefficient use of memory: the entire textual response is held in memory as a string. Therefore, unnecessary data copying is also performed. The Split() method creates new arrays of strings. To avoid these problems, Span<T> can be used to work directly on the byte arrays and to extract the necessary information efficiently. Using Span is only synchronous, and it should be noted that implementation in asynchronous methods requires additional code writing, since using synchronous methods in asynchronous ones would lead to unpredictable results or thread blocking.

Avoiding asynchronous disadvantages, another fast data processing can be used and the use of asynchronous operations without accompanying difficulties that can be achieved using Memory<T>, which allows working with subsets of data without additional copying.

Processing large text data from HTTP responses can be inefficient if the data is behaved like strings. Memory<T> can help optimize this process by working directly with the byte arrays. In .NET, Memory<T> and ReadOnlyMemory<T> provide powerful memory tools that enable efficient data processing without unnecessary copying and reduce memory load. These structures can be used in both synchronous and asynchronous methods (Fig. 2), making them suitable for a wide range of applications.

```
1 reference
public async Task ProcessHttpResponseAsync(string url)
{
    try
    {
        HttpResponseMessage response = await _httpClient.GetAsync(url);
        response.EnsureSuccessStatusCode();
        byte[] responseBytes = await response.Content.ReadAsByteArrayAsync();
        Memory<byte> memory = new Memory<byte>(responseBytes);
        ProcessResponseData(memory);
    }
    catch (HttpRequestException e)
    {
        Console.WriteLine($"Request error: {e.Message}");
    }
}

1 reference
private void ProcessResponseData(Memory<byte> memory)
{
    ReadOnlySpan<byte> span = memory.Span;
    int spaceIndex = span.IndexOf((byte)' ');
    ReadOnlySpan<byte> firstWordSpan = spaceIndex == -1 ? span : span.Slice(0, spaceIndex);
    string firstWord = Encoding.UTF8.GetString(firstWordSpan);
    Console.WriteLine($"First word: {firstWord}");
}
```

Fig. 2. Use of memory in http requests.

A. *Benefits of Memory<T> and ReadOnlyMemory<T>*

- Efficient memory usage: Memory<T> and ReadOnlyMemory<T> allows processing of parts of arrays without creating new objects, which reduces memory load.
- Flexibility: They can be used in both synchronous and asynchronous methods, providing a safe way to work with data between await points.
- Improved data processing code: By using Memory<T>, efficiency of applications can be improved when dealing with large amounts of data, such as text responses from HTTP requests or binaries.

B. *Test Performance When Reading Query Data*

When working with large files, it is often necessary to read only part of the content to avoid unnecessary memory load. Big data can fill up a system's RAM, leading to delays or crashes (OutOfMemoryException) [7]. Also, big data leads to slow processing speed [8] – a significant amount of time to reduce the efficiency of applications. Big data can contain unstructured or poorly formatted parts, which can complicate its processing.

Using Memory<T> allows working with parts of the data without loading the entire file into memory. Reading a specific block of the file and using Memory<T> to work with that block provides efficiency and flexibility (Fig. 3).

```
HttpResponseMessage response = await _httpClient.GetAsync(url);
response.EnsureSuccessStatusCode();

byte[] responseBytes = await response.Content.ReadAsByteArrayAsync();
Memory<byte> memory = new Memory<byte>(responseBytes);
```

Fig. 3. Reading data with Memory<T>

The following is a comparative analysis between the use of Memory<T> and the standard implementation with StreamReader. Two methods will be implemented to read the response from the query (Fig. 4, Fig. 5).

```
async Task ReadLargeHttpResponseWithStream(string url)
{
    HttpResponseMessage response = await _httpClient.GetAsync(url);
    response.EnsureSuccessStatusCode();

    using (Stream responseStream = await response.Content.ReadAsStreamAsync())
    {
        using (StreamReader reader = new StreamReader(responseStream))
        {
            char[] buffer = new char[8192];
            int bytesRead;
            while ((bytesRead = await reader.ReadAsync(buffer, 0, buffer.Length)) > 0)
            {

                ProcessLargeData(buffer.AsMemory(0, bytesRead));
            }
        }
    }
}
1 reference
void ProcessLargeData(ReadOnlyMemory<char> data)
{
    string content = new string(data.Span);
    Console.WriteLine(content);
}
```

Fig. 4. Reading data with StreamReader.

```
public async Task ReadLargeHttpResponseWithMemory(string url)
{
    HttpResponseMessage response = await _httpClient.GetAsync(url);
    response.EnsureSuccessStatusCode();

    byte[] responseBytes = await response.Content.ReadAsByteArrayAsync();
    Memory<byte> memory = new Memory<byte>(responseBytes);

    ProcessLargeData(memory);
}
1 reference
private void ProcessLargeData(Memory<byte> data)
{
    string content = System.Text.Encoding.UTF8.GetString(data.Span);
}
```

Fig. 5. Reading data with Memory<T>.

HttpClient and URL were used for the tests. The URL points to a large file (100 MB) which can be downloaded for the tests. Running the benchmark leads to the following results (Fig. 6):

Method	Mean	Error	StdDev
ReadLargeHttpResponseWithMemory	520.4 ms	8.48 ms	7.94 ms
ReadLargeHttpResponseWithStream	680.3 ms	12.6 ms	11.8 ms

Fig. 6. Test results.

- ReadLargeHttpResponseWithMemory(): This method uses Memory<byte> and shows an average execution time of 520.4 ms. Using Memory<T> provides advantages in terms of efficient memory management and performance.
- ReadLargeHttpResponseWithStream(): This method uses a traditional approach with Stream and shows an average execution time of 680.3 ms. The traditional method is slower due to the additional time it takes to work with StreamReader and convert data.

Several of the most important advantages of using relevant optimizations can be noted:

- Efficient Memory Management: Working with Memory<byte> reduces the need to create redundant copies of data, which saves memory and resources.
- Flexibility: Memory<T> allows for easy retrieval and handling of partial blocks of data, which is useful when working with large files or data streams.
- Better performance: Reading only the required portion of the file and working with Memory<T> can improve application performance by reducing processing time and memory usage.

C. Other applications

1) Search algorithm optimization: Algorithms for searching large arrays or text data often require high performance and low memory usage. Traditional approaches may involve creating new copies of the data, which increases memory costs and slows down processing. Span<T> allows working with pieces of data directly, without creating new copies, which is useful in search algorithm optimization. The following test will be conducted. A version of the familiar binary search algorithm [9] is implemented but using the Span structure. It must be compared to a method representing the basic implementation. Finally, the test is run again.

Fig. 8 shows the only difference is that the lookup data is sent with a Span. In the benchmark made, in Fig. 7, 1 million elements were feeded.

Method	Mean	Error	StdDev
StandardBinarySearch	0.120 ms	0.001 ms	0.002 ms
SpanBinarySearch	0.115 ms	0.002 ms	0.003 ms

Fig. 7. Binary search and span.

```
static int BinarySearchWithSpan(Span<int> data, int target)
{
    int low = 0;
    int high = data.Length - 1;

    while (low <= high)
    {
        int mid = low + (high - low) / 2;
        if (data[mid] == target)
            return mid;
        if (data[mid] < target)
            low = mid + 1;
        else
            high = mid - 1;
    }
    return -1;
}
```

Fig. 8. Binary search with a span.

It is noticeable that the difference is small, but it will be tested whether Span<T> offers any advantages in the context of specific use cases. One of the advantages is that ready-made methods of the structure itself can be used, and additional functionality can be added without wasting time on it.

2) Parallel data processing: Parallel data processing can lead to high memory costs if each thread creates its own copies of the data. This can reduce the efficiency of the application and increase processing time. Parallel processing involves dividing a task into smaller subtasks that can be run simultaneously [10]. C# has various tools for parallelization., such as Task, Parallel.For, and async/await. The following test will be performed. 10 million characters simulating text will be sent to be processed by the program. Two variants have been developed: with string and with Memory (Fig. 9 and Fig. 11).

In the test done, better performance is again visible, albeit with a small lead in time (Fig. 10).

```
public async Task ParallelProcessingWithMemory()
{
    var tasks = new Task[_blockCount];

    for (int blockIndex = 0; blockIndex < _blockCount; blockIndex++)
    {
        int start = blockIndex * _blockSize;
        int end = start + _blockSize;
        var blockMemory = _textMemory.Slice(start, _blockSize);

        tasks[blockIndex] = Task.Run(() =>
        {
            ProcessTextBlock(blockMemory.Span);
        });
    }

    await Task.WhenAll(tasks);
}
```

Fig. 9. Parallel processing with memory

Method	Mean	Error	StdDev
ParallelProcessingWithMemory	100.000 ms	2.000 ms	3.000 ms
ParallelProcessingWithString	150.000 ms	3.000 ms	4.000 ms

Fig. 10. Task and memory test result

The use of Memory<T> allows for the safe sharing of data between different threads, without creating redundant copies. Processing with Memory<T> will be faster because Memory<T> reduces the cost of creating new copies of the data and provides more efficient access to memory.

```
0 references
public async Task ParallelProcessingWithString()
{
    var tasks = new Task[_blockCount];

    for (int blockIndex = 0; blockIndex < _blockCount; blockIndex++)
    {
        int start = blockIndex * _blockSize;
        int end = start + _blockSize;
        string blockString = _largeText.Substring(start, _blockSize);

        tasks[blockIndex] = Task.Run(() =>
        {
            ProcessTextBlock(blockString);
        });
    }

    await Task.WhenAll(tasks);
}
```

Fig. 11. Parallel processing with string

III. Results

The results of comparing different memory management techniques in C# - ReadOnlyMemory<T>, ReadOnlySpan<T>, Memory<T>, and Span<T> - demonstrates clear advantages in performance optimization for HTTP request handling. Key findings are as follows:

- ReadOnlyMemory<T>: Offers efficient read-only data access with reduced memory allocations and garbage collection pressure. It is well-suited for handling immutable HTTP request data like headers and bodies, providing safety with minimal performance overhead.
- ReadOnlySpan<T>: Provides the most efficient, zero-allocation solution by leveraging stack-based memory management. It excels in short-lived, high-performance scenarios, such as parsing HTTP requests without persisting data. However, it is limited by its inability to be used across asynchronous boundaries.
- Memory<T>: Allows mutable access to memory, making it versatile for scenarios where data needs to be modified. Its ability to reuse memory buffers reduces garbage collection events and enhances performance in systems with high-throughput HTTP requests.
- Span<T>: Similar to Memory<T>, but focused on stack-based memory, making it ideal for fast, non-persistent data processing. It shares the limitations of ReadOnlySpan<T> in async contexts but provides excellent performance when dealing with mutable, transient data.

Overall, these advanced memory manipulation types significantly reduce memory allocations, improve execution time, and lower GC pressure compared to traditional approaches like StreamReader. The most substantial performance gains are observed when using Span<T> and ReadOnlySpan<T>, which minimize overhead through zero-copy, stack-based memory operations.

IV. Discussion

The special language features in C# and other modern languages that allow more efficient management of sequentially located data structures in memory are relatively new, and there is not much scientific research related to them.

The study [11] is focused on how Span is designed to optimize memory usage and enhance processing speed in .NET applications, with an emphasis on the characteristic collections, which generally store the data in the heap memory, which consumes more RAM and increases the workload of the Garbage Collector. One of the strongest features of Span is to keep data on the stack which enables better performance.

The study [12] presents an in-depth comparison of the use of different algorithms on the traditional List, Array, etc. collections. Experimentation and analysis reveal the different performance of these algorithms using C#.

A comparison of the effectiveness of different strategies related to the optimization of memory management procedures and in particular the release of resources implemented in the C#, Java and C++ languages is discussed in [13]. The surprising conclusion is made that C#'s garbage collection system consistently outperformed the others due to its optimized procedures of asynchronously deallocating memory.

Notorious key techniques in Memory Optimization include avoiding unnecessary object allocations; use value types for small, immutable data; pool reusable objects with ObjectPool<T>; optimize collections (e.g. prefer array or Span<T> over List<T> when possible); avoid large object heap fragmentation by reusing buffers; utilize asynchronous programming effectively to reduce memory pressure.

The test results clearly demonstrate that leveraging modern memory types in C#, such as ReadOnlyMemory<T>, ReadOnlySpan<T>, Memory<T>, and Span<T>, provides significant performance improvements in scenarios involving HTTP request handling. The implications of these findings are particularly relevant for applications that deal with high

volumes of HTTP traffic, where memory allocations and GC overhead can become major bottlenecks.

D. Memory Efficiency and Allocation Reduction

One of the key benefits of using these memory types is the reduction in memory allocations. Traditional methods, such as reading data with StreamReader, create new strings and objects on the heap, which leads to frequent memory allocations. This not only consumes more memory but also increases the frequency of GC cycles, leading to performance degradation.

By contrast, Memory<T> and Span<T> significantly reduce the need for heap allocations by reusing memory buffers or leveraging stack-based memory management. This is particularly important in real-time systems or services that handle numerous HTTP requests, as it helps maintain consistent performance under heavy load. The zero-allocation nature of ReadOnlySpan<T> and Span<T>, in particular, shows tremendous potential for short-lived operations where both memory and speed are critical.

E. Garbage Collection Optimization

Reducing GC pressure is a critical factor in achieving high-performance applications, especially in scenarios involving concurrent HTTP requests. The frequent creation and destruction of objects in heap-based memory can result in excessive GC activity, leading to increased latency and jitter. The findings highlight that Memory<T> and Span<T>, by reducing object creation, lead to fewer GC interruptions and smoother application performance.

In particular, ReadOnlyMemory<T> and ReadOnlySpan<T> proved highly efficient for handling immutable data like HTTP headers or request bodies, where copying or modifying data is unnecessary. These types allow direct access to memory without the need for costly allocations, which lowers GC frequency and minimizes its impact on performance.

F. Trade-offs and Limitations

While these memory types offer clear performance gains, there are trade-offs that developers need to consider. For instance, Span<T> and ReadOnlySpan<T> are stack-allocated and, therefore, cannot be used across asynchronous method calls. This limits their applicability in scenarios where asynchronous programming is heavily used, such as modern HTTP request pipelines built on async/await patterns. In these cases, developers must rely on heap-based Memory<T> or ReadOnlyMemory<T>, which still provide performance benefits but with slightly higher overhead compared to their stack-based counterparts.

Additionally, while these types reduce memory allocations and improve performance, they introduce added complexity in managing memory manually. Developers must be more mindful of buffer management and ensure that memory is handled properly to avoid issues such as memory leaks or unsafe access. This represents a trade-off between performance and ease of use, particularly for teams or projects where rapid development is prioritized over fine-tuned optimization.

G. Practical Implications for HTTP Request Handling

For real-world applications that handle HTTP requests, especially high-throughput services such as web servers, API gateways, or microservices, the use of Memory<T> and Span<T> can lead to substantial performance improvements. The ability to avoid data copying, minimize memory fragmentation, and reduce GC pressure can help these systems scale more effectively, handling larger workloads with lower resource consumption.

However, these performance benefits come with the requirement for a deeper understanding of memory management in .NET. Developers will need to weigh the trade-offs between the additional complexity and the performance gains, particularly when deciding between the simplicity of StreamReader and the efficiency of the newer memory types.

H. Future Considerations

As C# continues to evolve, further optimizations and tools that will make memory management both easier and more efficient can be expected. The results suggest that adopting these newer memory types now can provide immediate benefits in terms of performance, but future improvements in language features, runtime optimizations, and libraries may help bridge the gap between ease of use and high performance. Additionally, as more developers adopt these patterns, best practices will likely emerge, helping to mitigate the challenges associated with the manual memory management required by Span<T> and Memory<T>.

I. Similar Features in Other Programming Languages

Languages like C++, Rust, D, and Swift have similar features. C++ has std::span which is a very lightweight abstraction (a class template), but powerful tool for working with contiguous sequence of data. A typical implementation holds a pointer to the data, if the extent is dynamic, the implementation also holds a size. The main advantage is that it is a non-owning type (a reference-type rather than a value type). It never allocates nor deallocates anything and does not keep smart pointers alive.

```
void show(std::span<int> data)
{
    for (const auto& x : data)
        std::cout << x << ' ';
    std::cout << '\n';
}

int main()
{
    int myArray[] = { 1,2,3,4,5 };
    show(myArray);
}
```

Fig. 12. Using std::span as function parameter.

In C++, std::span can also be used to simplify syntax. For example, the implementation of arrays in C++ is such that they "don't know" their size. When an array is passed as an

argument to a function, actually a constant pointer to the first element of the array is passed and the function "does not know" the number of elements in the array. However, if this array is passed to the function as span, there is no need to pass an additional parameter with the size of the array (Fig. 12).

Instead of Span, Rust has a slice, which is a view into a collection of elements, like std::span. D language offers slices as well, providing a safe way to handle arrays. Swift has ArraySlice, which allows sub-ranges of an array without copying. Each of these languages emphasizes safety and efficiency in handling contiguous data sequences.

Java doesn't have a direct equivalent of Span, but List.subList() allows to work with a sublist view of a list. Although it doesn't offer the same level of low-level control, it does provide a way to handle segments of collections efficiently.

V. Conclusion

Both Span<T> and Memory<T> provide powerful ways to work with memory in C#, especially when performance and efficiency are critical. Overall, our findings confirm that using ReadOnlyMemory<T>, ReadOnlySpan<T>, Memory<T>, and Span<T> provide significant improvements in performance, particularly for HTTP request processing. While there are trade-offs in terms of complexity and applicability in asynchronous programming, these memory types offer a powerful way to optimize memory usage, reduce GC overhead, and improve the scalability of modern .NET applications.

Developers aiming for high-performance HTTP request handling should seriously consider integrating these memory types into their systems to achieve better throughput and responsiveness.

Other practical applications of Span<T> include image processing or numerical computations – situations when working with performance-critical code. In this case, Span<T> can help avoid allocations and reduce the overhead of garbage collection. Similar is the situation when interaction with native code via P/Invoke or other interop mechanisms is needed. Here Span<T> can be used to represent contiguous memory regions efficiently.

Wherever working with asynchronous I/O operations, data buffers or lazy initialization are needed, Memory<T> is a great solution.

A Systematic Review of the Benefits and Challenges of Data Analytics in Organizational Decision Making

Juan Carlos Morales-Arevalo, Ciro Rodríguez
Faculty of Systems Engineering and Computer Science, Universidad Nacional Mayor de San Marcos, Lima - Perú

***Abstract*—Data analytics has been relied heavily in organizational decision-making, which allows accuracy, timeliness, and data-driven processes in a wide range of industries. These factors are influential as the figure and complexity of data are on the rise, along with problems like authentication, integration, and organizational resistance. The current study seeks to systematically review the benefits and challenges of data analytics on decision-making in different sectors using the PRISMA guidelines. A total of 32 articles published from 2020 until 2024 were identified through this review from reputable databases, including Scopus, Web of Science, IEEE Xplore, ProQuest, and Emerald Insight. These insights underscore the power of data analytics in driving change, enabling more accurate, faster, and aligned decision-making with organizational objectives. Challenges remain though, including the availability of broken data systems, hindrance due to a non-standardized norm across the whole sector, and resistance in places where data literacy is low or cultures resist data-driven practices. To mitigate the challenges, this review offers organizations practical recommendations for management. Companies that successfully incorporate analytics into their overall business strategies and create an organization-wide value for data and insights will be able to leverage analytics more effectively to enhance efficiency, encourage innovative growth, and navigate future disruptions. However, tackling these challenges is more than just optimizing performance—it is about future-proofing organizations in a world increasingly defined by data.**

***Keywords*—Data analytics; decision-making; data-driven processes; big data analytics; systematic review**

I. Introduction

Implementation of this method helps organizations in smart and accurate decision making which is an integral process of the global world today. This declaration comes atop a growing volume of data available today (and growing complexity as well), which presents both opportunity and challenges. Enabling this have been advances in technology such as machine learning and cloud computing that can analyze large amounts of data in real-time [1]. In particular, the use of data analytics in areas such as supply chain management, medical, and marketing is changing the way organizations can improve their actions and forecast future procedures in their working environment, based on [2], the analysis of large-scale data is the basis of customizing approaches, enabling organizations to adapt their services and products to the characteristics of each customer positively impacting the productivity and retention of customers. In addition, [3] noted that data analytics provides advantageous sustainable competitive advantages leading to innovation in emerging markets, thus directly enhancing strategic decision-making and all the different strategies that can be made. Moreover, [4] pointed out that big data analytics considerably enhance real-time decision-making, specifically in healthcare supply chains, by enabling efficient operations management and overcoming essential implementation hurdles.

In this sense, the identification of the main challenges in the field of data analytics for organizational decision-making highlights significant challenges related to data management and quality, as well as to the effective implementation of analytical methodologies. [5] Among these challenges, the integration of advanced techniques such as machine learning into traditional systems is especially problematic, due to the lack of clarity in objectives and limitations in organizational maturity for ad hoc projects. Instead [6], current approaches are focused on technology rather than socio-technical aspects, creating a disconnect between these technologies and their strategic and operational implementation. To cope with these challenges, methodologies focusing on end-to-end team, project, and data management have been introduced, a more holistic approach to data science projects. In organizational contexts [7], the successful integration of business analytics is contingent on a blend of organizational, technological, and environmental variables, which serve as driving forces behind its success.

This review provides strategic insights into leveraging data analytics to overcome barriers and optimize decision-making processes; by addressing these challenges with holistic approaches, organizations can better align technical tools with operational strategies, ultimately enhancing performance and driving meaningful innovation.

This study analyzes the effects of being data-driven on organizations, listing the benefits and challenges it presents as well as its strategic importance in varied industries. Furthermore, it offers actionable insights to assist organizations in effectively adopting analytics and deriving maximum value from it in their decision-making processes [8].

The rest of the paper is structured as follows: Section II discusses the related work. Section III explains the methods of carrying out this systematic review, including inclusion and exclusion criteria and sources of data. Results are described in Section IV, organized around major themes. An extended discussion of the implications, challenges, and opportunities arising from data analytics in organizations is covered in Section V. Finally, Section VI provides the conclusions and Section VII directions for future work.

II. Related Work

Data analytics is increasingly critical for organizations, as it helps organizations make more informed decisions based on data. Prior research addressed the adoption of data analytics, benefits of data analytics, and challenges of data analytics per industry.

Multiple scholars have studied how big data analytics improves decision making and business intelligence. Patricio-Peralta et al. discussed the role of big data in shaping marketing approaches to enhance customer targeting and engagement using predictive analytics techniques [2]. Likewise, Al Nuaimi & Awofeso emphasized the vital significance of big data for healthcare supply chain management while also adding that it greatly supplements healthcare optimization leading to operational efficiency and be the followed standard [4]. Their studies are consistent with Rahman's systematic review on empowering business intelligence in healthcare capabilities, which show that data-driven decision-making improves resource allocation as well as patients' outcomes [9].

The quality and maturity of data is another important area of analytics adoption research. Galetsi et al. highlighted the challenge of data fragmentation and lack of interoperability as a key challenge that many organizations face to this day, limiting the reliability of insights derived from analytics [1]. Likewise, Al-Sai et al. presented a Big Data Maturity Model, emphasizing that the readiness of the organization for Big Data needs to be evaluated before integrating analytics into the decision-making process of the organization completely [5]. Hence, organizations focused on utilizing analytics must follow a stringent strategy for managing the data.

There have been several studies that also covered the obstacles to not adopting data analytics in organizations. Horani et al. highlights cultural and leadership challenges as major barriers, also mentioning that the lack of executive driving force can slow down analytics adoption [7]. Gonzales & Horita expanded on this by noting that bad visualization/analytics tools can mitigate against user engagement, thus potentially impacting efficacy in practical settings [10]. They also highlighted that a common factor across many sectors such as education and research, where streamlined data-driven strategies could benefit the decision-making process, is insufficient training in analytics tools [11].

Researchers also explored the contributions of advanced analytics and optimization techniques in decision making. Integrating these BI tools with strategic decision-making helps organizations make informed strategic choices with up-to-date insight [12]. Similarly, Akindote et al. demonstrated the use of geographic information systems (GIS) and analytics to improve decision-making in spatial planning and logistics [13]. Khanra et al. As an example toward the healthcare industry, demonstrating how analytics-oriented techniques can enhance patient care and reduce operational costs [14].

Similarly, implementation of big data analytics in various industries has also been extensively explored. Mansour & Bick delivered a systematic review of big data platforms employed in the healthcare digital transformation context and how artificial intelligence (AI)-based analytics have transformed diagnostics and treatment planning [15]. Tawil et al. analyzed the ways small and medium-sized enterprises (SMEs) in emerging economies utilize data analytics for a competitive edge, emphasizing opportunities and barriers in these contexts [16].

Therefore, while much academic research has contributed to the advances in data analytics, there are still areas that lack the necessary focus. Numerous studies indicate that although analytics adoption is growing, data standardization, integration, and culture acceptance still face challenges. The objective of this systematic review is to compile these insights and offer a complete evaluation of the advantages and disadvantages of data-driven decision-making in organizations.

III. Methodology

PRISMA is selected for this study to conduct a systematic review. This offers a solid framework to analyze a large amount of data and evaluate their significance in organizations' decision-making processes [17]. The most up to date version, PRISMA 2020, brings important new changes which improve the transparency of systematic review and encourage reporting by all including with advances in methodology and terminology [9]. In certain domains, like strategic management, PRISMA is key to spotting gaps in the use of information within public organizations and small businesses, as it is a continuous improvement framework [18]. Additionally, this method has been useful in the industrial domain, to augment decision models and production systems with advanced technologies, such as AI and deep learning [19]. Moreover, PRISMA has been applied in research related to the digital transformation of bibliometric and systematic studies which have sought to resolve challenges associated with data recreation and meta-analysis [20].

A. Identification

The identification phase focuses on the exhaustive search for articles relevant to the topic. Using recognized databases and specific keywords, potential publications are extracted for the review. According to Page et al. (2021), this phase establishes a systematic framework to ensure that relevant studies are included and that initial bias in source selection is minimized [17]. A systematic search for research data was performed in various known databases, including Scopus, Web of Science, IEEE Xplore, ProQuest, and Emerald Insight as illustrated in Fig. 1. The reason for selecting these databases is highly related to the data analytics applications in the organizational decision-making domain. To get sufficient coverage, certain keywords, along with Boolean operators, were utilized, e.g., "Data Analytics" OR "Big Data Analytics" AND "Decision Making" AND "Systematic Review", Although the study primarily focused on organizational and business contexts, some research from the healthcare field was included. This decision was made because their findings provided valuable insights that aligned with the broader goal of understanding how data analytics can enhance decision-making processes across various sectors. Furthermore, to ensure the currency of the findings, we applied a temporal range filter to select for only articles published in the last 5 years (2020-2024) as shown in Fig. 2. In total, 150 articles were identified after this first search.

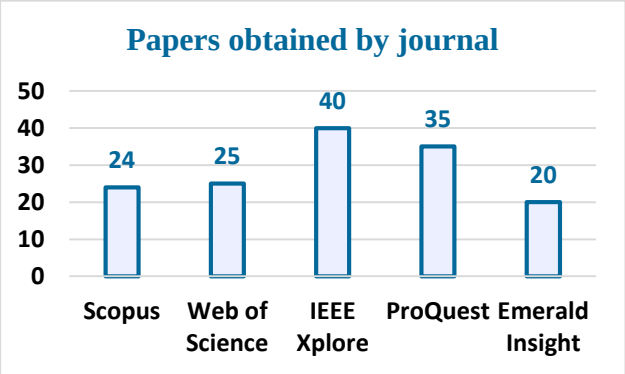

Fig. 1. Articles obtained by journal.

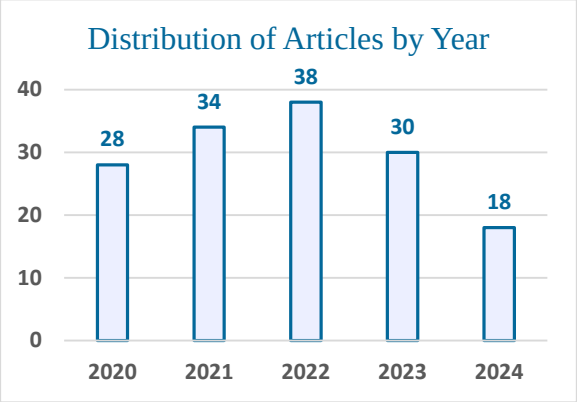

Fig. 2. Articles by publication year.

B. Screening

In this phase, initial studies that are duplicates or irrelevant are removed by following pre-defined criteria. Shamseer et al. (2015) highlight that the current stage is important to reduce the effort of unnecessary data return and that only studies with a relevant focus proceed to the next stages [21]. Then we removed duplicate records, so this time we were left with 104 articles. In the next stage, the titles and abstracts of the rest of the articles were reviewed to determine relevance. Forty articles were rejected if they did not satisfy the established inclusion criteria, which included the following: their exclusive focus on domains such as health or education; failing to directly relate to organizational decision-making. Finally, 64 articles were reviewed in detail at this stage.

C. Eligibility

So, the data from included studies were appraised in detail, to ascertain/assure the applicability of studies for systematic review. According to Galetsi et al. In this step, each publication was reviewed regarding its methodology and results to evaluate the quality of its content [22]. Further inclusion and exclusion criteria were applied during the full-text review of the 64 articles to assess study appropriateness. At this stage, 14 articles were excluded because they lacked sufficient methodological details, while another 18 were removed due to reasons such as not presenting results relevant to the organizational context or containing incomplete data. Ultimately, 32 articles met the eligibility criteria, forming a robust foundation for the analysis and ensuring the study's methodological rigor.

D. Inclusion

Thus, in the systematic review inclusion phase, verifying the findings of relevant papers is crucial to ensure that the studies selected for inclusion within a review align with the review objectives. Anderson et al. (2021) stress the importance of this phase for the synthesis outcomes, where they must be aligned with the optimal criteria and appropriate synthesis techniques to generate trustworthy findings. Their findings highlight the significance of developing clear research questions and ensuring methodological transparency, so the studies included are both relevant and applicable. Such a rigorous approach provides for improved analysis, improving the likelihood that the findings are actionable, thereby making the contribution that much more useful for policy-makers and organizational leaders [23]. Following the methodology described in the previous section, we reviewed several articles, and 32 of them were appropriate for the systematic review. They provide a solid basis of how data analytics may help organizational decision-creating. These share topics varying from one to another including Big Data Maturity Model, drivers of business analytics adoption, and specific applications in various fields such as supply chain management; thus, showcasing the relevance of the same across various organizational frameworks.

E. General Results

- Initial items identified: 150
- Duplicates removed: 46
- Articles discarded by title/abstract: 40
- Articles evaluated in full text: 64
- Articles excluded in full text: 32 (14 for lack of methodological data, 18 for other reasons)
- Final articles included: 32

Finally, we should clarify that of the total of 18 articles excluded for “other reasons”, the specific reasons are as follows: 10 articles were not relevant to the organizational context; 5 had insufficiently described methodologies; 3 were not available in their complete version; 3 were not available in their full version; and 3 were not available in their complete version.

Fig. 3 illustrates the application of the PRISMA Method, and the results obtained in each of its phases. This approach has allowed us to clearly and transparently structure and document the entire review process, from the initial identification of studies to the final selection of relevant articles. Using this paradigm not only guaranteed a more precise and complete interpretation but also enhanced the strength and fidelity of the study. We followed this systematic framework in order not only to source relevant studies but also to continuously reduce the risk of bias and to synthesize the evidence coherently so that the results are a true reflection of the current landscape of the topic investigated.

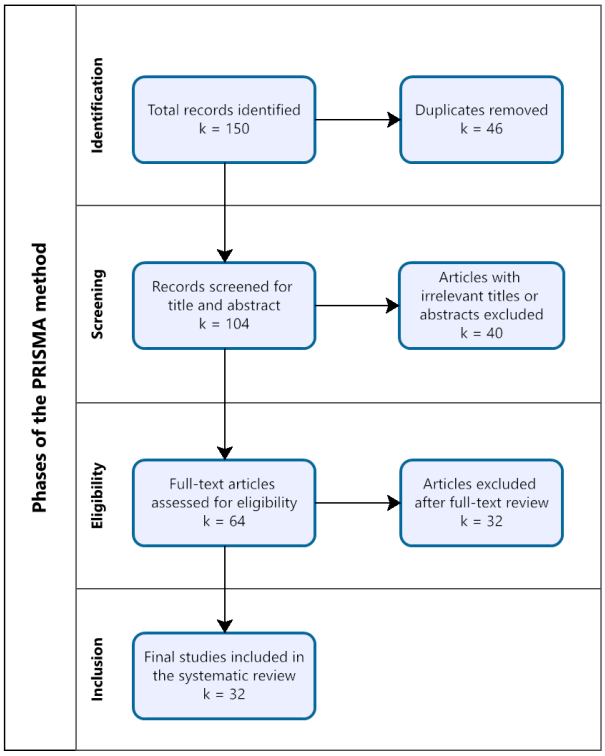

Fig. 3. PRISMA Method phases.

IV. Results

Findings were categorized and analyzed thematically into eight areas according to the final subset of included articles. Through the themes, we give an overview of the key issues and findings, capturing the range of contributions, with these summarized in Table I.

A. Data Quality and its Impact on Analytics

The success of analytical initiatives hinges on the quality of data. Galetsi et al. demonstrated how data standards enable better interoperability and reduce fragmentation issues [1]. Al-Sai et al. emphasized the requirement to measure organizational maturity to implement big data effectively [5]. Lin et al. analyzed how the use of analytical systems can be integrated and usefully implemented when data is broken into parts [24]. Salazar-Reyna et al. Data Accessibility & Cleanliness: [25] highlighted the importance of accessible clean data as the most significant data-based barrier. Ifenthaler & Yau pointed out, "the stronger data literacy, the better analytic practices can be adopted" [26].

B. Organizational and Cultural Resilience

Cultural and organizational resistance remains a major challenge. Horani et al. highlighted that lack of organizational leadership and support hinders the implementation of analytic tools [7]. Kew & Tasir noted that a lack of training in analytical tools limits their adoption in educational settings [11]. Gonzales & Horita highlighted that the lack of intuitive design in visual analytical tools generates rejection among end users [10]. Teniwut & Hasyim identified inefficient workflows as major barriers in supply chains [27].

TABLE I. Articles Grouped By Topic

Thematic	Related Articles	Brief Description of the Subject Matter
Data Quality and its Impact on Analytics	Galetsi et al. [1], Al-Sai et al. [5], Lin et al. [24], Salazar-Reyna et al. [25], Ifenthaler & Yau [26]	It focuses on how data quality affects the integration and effective use of analytical systems in various applications
Organizational and Cultural Resilience	Horani et al. [7], Kew & Tasir [11], Gonzales & Horita [10], Teniwut & Hasyim [27]	It examines the cultural and organizational barriers that hinder the implementation of analytical tools in different sectors.
Improved Decision Making	Komolafe et al. [3], Christenson Jr. & Goldstein [28], Aprijal et al. [29], Yang & Wang [30]	Analyzes how analytical tools support the identification of patterns and the optimization of strategic decisions.
Approaches to Optimization	Akindote et al. [13], Khanra et al. [14], Alnoukari [12], Soylu et al. [31]	Details the use of innovative approaches and advanced tools to improve operational efficiency and decision making.
Innovation in Specific Sectors	Tawil et al. [16], Ayuningtyas et al. [32], Raja et al. [34]	Explores how analytics is driving innovation in emerging industries and in the transformation of existing processes.
Use of Big Data in Decision Making	Rahman [9], Raja et al. [34], Matcha et al. [35], El Falah, Z., et al. [36]	Highlights the impact of big data in improving organizational decisions through personalization and advanced analytics.
Big Data Analytics Adoption Strategies	Patricio-Peralta et al. [2], Al Nuaimi & Awofeso [4], Astudillo et al. [6], Di Berardino & Vona [18]	Presents key strategies for effectively adopting big data in enterprise environments.
Critical Factors in the Adoption of Big Data Analytics	Dwilaga [19], Grander et al. [37], Hu, L., & Shu, Y. [38], Orlu et al. [39]	It examines the organizational and technological factors necessary for successful integration of analytics into complex systems.

C. Improved Decision Making

Analytical tools have transformed decision-making in different sectors. Komolafe et al. demonstrated that these tools generate competitive advantages by identifying patterns in emerging markets [3]. Christenson Jr. & Goldstein highlighted the positive impact of analytics on risk mitigation and optimization of strategic processes [28]. Aprijal et al. found that analytics in manufacturing and retail reduce operating costs and improve efficiency [29]. Yang & Wang analyzed how systematic evaluations optimize scalability in big data environments [30].

D. Approaches to Optimization

Innovative tools and approaches have overcome specific problems. Akindote et al. explored the integration of GIS and analytical tools to optimize decision-making systems [13]. Khanra et al. observed that analytical tools significantly improve operational efficiency in healthcare systems [14]. Alnoukari highlighted how business intelligence tools help organizations optimize strategic decisions through advanced data analysis [12]. Soylu et al. showed how these tools increase transparency in public administration [31].

E. Innovation in Specific Sectors

Analytics has generated significant innovations in multiple sectors. Mansour & Bick explored how big data has scaled digital transformation in the healthcare sector [15]. Tawil et al. highlighted barriers and opportunities for data-driven decision-making in emerging economies, fostering innovation in various sectors [16]. Ayuningtyas et al. highlighted applications of analytics in emerging sectors to optimize organizational processes [32]. Rakesh et al. proposed approaches to improve scalability in big data, facilitating the use of these technologies in varied sectors [33].

F. Use of Big Data in Decision Making

Big data has been shown to improve the quality of organizational decisions. Rahman proposed integration frameworks to maximize the impact of business intelligence [9]. Raja et al. identified how big data increases operational efficiency in healthcare systems [34]. Matcha et al. found that learning analytics dashboards facilitate decision-making in educational settings by providing more personalized information [35]. El Falah, Z., et al. showed how intelligent approaches to data analytics can transform the ability of organizations to process and apply big data in their strategic decisions [36].

G. Big Data Analytics Adoption Strategies

Regarding strategies for big data adoption, Patricio-Peralta et al. emphasized the need for trained personnel to maximize the marketing impact [2]. Al Nuaimi & Awofeso pointed out that infrastructure is key to optimizing supply chains [4]. Astudillo et al. proposed user-centric methodologies to integrate analytics in organizations [6]. Di Berardino & Vona identified analytical frameworks that facilitate strategic decision-making in corporate environments [18].

H. Critical Factors in the Adoption of Big Data Analytics

Key factors include organizational maturity and cultural support. Dwilaga proposed optimized decision models to overcome problems in complex industrial processes [19]. Grander et al. highlighted how advanced analytical tools can generate significant value in decision support systems [37]. Hu, L., & Shu, Y. developed intelligent approaches to analyze complex data, improving the effectiveness of strategic decisions [38]. Orlu et al. explored strategies to improve decision-making under uncertainty [39].

The findings of this study provide valuable insights for organizations seeking to navigate the complexities of data-driven decision-making. Only with the knowledge of the main barriers, like fragmented data systems and cultural resistance, can leaders work their way around these and craft strategies that would ensure that they foster a data-driven culture and still allocate funds towards building robust data infrastructures. These actions would not only surmount the active challenges but would also enable organizations to reap the full benefits of analytics: faster, more nuanced and integrative decision-making aligned with strategic objectives. With these strategies, organizations can promote innovation and maintain their competitive edge, enabling them to achieve real growth in the data-driven world.

V. Discussion

It dives into the insights that were identified and arranged into 8 Paramount Sections -- The Relation of Data Quality to Analytics, Organizational and Culture Resistance Towards Analytics Adoption, Tools and Techniques in Optimizing Analytics, The Providing of Strategies for Big Data Adoption, Industry-Driven Innovations, How Big Data Impacts Decision Making, Major Elements of Factors in Big Data Analytics Adoption and Influence, New Horizons of Decision Making. The point is, these categories afford a total framework for data-driven decision-making impact between industries. The discussion also reviews barriers to analytics adoption by organizations, while focusing on the advances made possible through more advanced tools and techniques. As a whole, shaping the advantages and realities in tens of thousands of organizations, these findings provide a comprehensive perspective on how to use data analytics, advancing towards whether organizations tune the best practices of data analytics or hinder the process of data analytics to sustain innovative outcomes in these highly data dependent enterprises.

A. Data Quality and its Impact on Analytics

The results reaffirm that data quality is a critical foundation for analytical initiatives to succeed. Galetsi et al. [1] and Lin et al. [24] highlight that fragmented data systems and a lack of interoperability are significant impediments to organizations' ability to seamlessly integrate data into their analytics systems. Al-Sai et al. big data requires an organization to be matured [5], as well, and Ifenthaler and Yau [26] argue that a crucial first step toward adopting analytics practices is increasing data literacy. But, notwithstanding those attempts, issues, such as setting adequate data quality thresholds or data access, remain Salazar-Reyna et al. [25] continue to get in the way of setting up effective analytics systems. These issues cannot be overcome in isolation: solving them requires a system-wide response that brings together technological and organizational solutions to maximize the potential of analytics.

B. Organizational and Cultural Resilience

Resistance at both the cultural and organizational levels continue to pose a major challenge to adopting analytics across various industries. Horani et al. [7] identified the lack of strong leadership and organizational support as critical barriers that hinder successful analytics adoption. Similarly, Kew and Tasir [26] found that inadequate training remains a significant obstacle, particularly in educational institutions where analytics has the potential to transform decision-making processes. To overcome these barriers, fostering a culture that values data-driven decision-making, supported by consistent leadership and tailored training programs, is essential for ensuring the effective implementation of analytics. These findings underscore the need for targeted strategies to address both leadership and skill development to facilitate the broader integration of analytics practices. Gonzales & Horita [10] stated how non-intuitive designs of analytical tools discourage the use of those tools and Teniwut & Hasyim [27] reported that disorganized workflows amplify the resistance to change in supply chains. These findings underscore the need for better training, stronger leadership, and redesigned technologies that make adoption easier.

C. Improved Decision Making

The transformation of decision-making through data analytics Komolafe et al. [3] showed analytics support competitive advantage based on patterns in born-global markets. According to Christenson Jr. & Goldstein [28], its impact is to provide better risk mitigation and optimize the strategic process. In addition, furthermore, demonstration of these techniques in industrial contexts has been made by Aprijal et al. [29] and Yang & Wang [30] describing relevant operational cost and scalation benefits for the solution. However, certain segments are struggling to implement these solutions, indicating the requirement for more bespoke solutions.

D. Approaches to Optimization

Such innovative tools and strategic approaches have been critical for the optimization of analytical systems. Akindote et al [13], Soylu et al. [31] also looked into how GIS and big data can be integrated to enhance transparency and decision-making in public administration. Business Intelligence tools play an important role in strategic decision solidifying, Alnoukari [12]. Khanra et al [14], on the other hand, demonstrated that these tools can increase efficiency in healthcare systems. However, problems related to interoperability and standardization limit effective implementation.

E. Innovation in Specific Sectors

Data analytics has generated disruptive innovations in specific sectors. Mansour & Bick [15] evidenced how big data is driving digital transformation in healthcare, while Tawil et al. [16] highlighted its impact in emerging economies. Ayuningtyas et al [32] and Rakesh et al. [33] discussed how these technologies optimize organizational processes and promote scalability. While these advances are promising, infrastructure and cultural barriers continue to limit their widespread adoption.

F. Use of Big Data in Decision Making

Big data has significantly improved the quality of organizational decisions. Rahman [9] developed frameworks that maximize the impact of business intelligence, while Raja et al. [34] evidenced operational improvements in healthcare systems. Matcha et al. [35] highlighted the benefits of analytic dashboards in educational settings. Finally, El Falah et al. [36] demonstrated how intelligent approaches in data analytics strengthen the strategic capability of organizations. However, the lack of alignment between strategic objectives and analytical capabilities persists as a challenge.

G. Big Data Analytics Adoption Strategies

Patricio-Peralta et al [2] stressed the importance of having trained personnel to maximize the impact of big data in marketing. Al Nuaimi & Awofeso [4] identified infrastructure as a critical factor in supply chains, while Astudillo et al. [6] and Di Berardino & Vona [18] proposed user-centric approaches and analytical frameworks that foster strategic decision-making. Although these strategies are fundamental, resistance to change and lack of specialized resources limit their effectiveness.

H. Critical Factors in the Adoption of Big Data Analytics

Key factors include organizational maturity, cultural support, and strategic focus. Dwilaga [19] proposed optimized models for industrial processes, while Grander et al. [37] highlighted the value generated by advanced tools. Hu, L., & Shu, Y. [38] evidenced that intelligent approaches improve the effectiveness of strategic decisions, and Orlu et al. [39] explored strategies to mitigate uncertainties in big data contexts. However, challenges persist in widespread implementation due to the lack of integration between departments.

I. Geographical Distribution of Scientific Contributions

Fig. 4 provides an overview of the distribution of articles by continent, highlighting the scientific contributions to the field of data analytics and decision-making. This analysis is key to understanding regional dynamics and priorities in research. The Americas leads with 15 articles, with the United States standing out as the largest contributor with 9 publications, reaffirming its prominent position in this field. Europe, contributing 12 articles, demonstrates a strong and diverse presence in the field, with significant contributions from countries like the United Kingdom and Germany. Asia, with 8 articles, showcases remarkable growth, driven by emerging economies such as India and China, solidifying its expanding role in this domain. Oceania, with 3 articles, maintains a steady but smaller contribution, while Africa, represented by only 1 article, highlights a clear gap and an opportunity to encourage research and development in the region. This distribution not only reveals regional disparities but also underscores the importance of fostering global collaborations to bridge these gaps and accelerate progress in underrepresented areas.

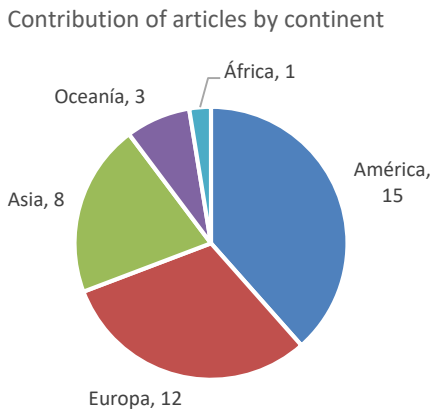

Fig. 4. Contribution of articles.

J. Methodological Diversity in Data Analytics and Decision Making

One main point of interest is the disparity between the number of techniques (65) compared to the number of articles analyzed (39) as detailed in Table II, which looks at the techniques and methodologies used in the reviewed articles. This difference is a testament to the effective diversity of methodology run in data analytics and decision-making. One of the main reasons this happens is the routine use of combining complementary methods in a single study. This method allows researchers to tackle issues from different angles and, as a result, create more resilient and all-encompassing solutions. Such a study could combine predictive analytics and machine learning algorithms to identify trends and predict future outcomes, while at the same time applying data visualization tools to expose the insight in a more digestible and telling manner.

TABLE II. TECHNIQUE / METHODOLOGY

Technique / Methodology	Quantity
Systematic Review	15
Big Data Analysis	10
Decision Modeling	8
Data Mining	7
Predictive Analytics	6
Machine Learning	5
Analytics Dashboards	4
Narrative Analysis	3
Decision Support Systems	3
Maturity Assessment	2
Assessment Framework	2

Additionally, this diversity in methodology is a reflection of the inherently interdisciplinary nature of the field, with methodologies borrowed from domains such as statistics, artificial intelligence, and organizational management [8]. Most of the studies use some secondary/supplementary methods to augment or triangulate the analysis obtained using the primary method. This is especially prevalent in studies that seek to compare the relative effectiveness of different implementations or to investigate different applications in the same setting. Another reason for this use of multiple approaches is the need to customize solutions according to the industry, for example, healthcare, manufacturing, or logistics which usually face complex and interdependent challenges that require more of a holistic approach.

K. Study Limitations

To be transparent about what was found and the scope of that finding, the table below sets out the main limitations identified. However, recognizing these limitations is key to appropriately assessing the results and directing future research efforts.

To aid the interpretation of the results and support transparency about the boundaries of the study, Table III below summarizes the key limitations we identified. It is necessary to consider these limitations in correctly interpreting the results and guiding the future at the same time.

The benefits and challenges uncovered in this study serve as a roadmap for organizations striving to embrace data analytics effectively. Acknowledging benefits like faster decision-making, enhanced accuracy and better alignment with strategic objectives enables leaders to advocate for analytics investments. Additionally, by learning about common pain points such as fragmented data systems and cultural resistance, organizations can better prepare for roadblocks and work proactively to counter them. A comprehensive approach that harmonizes technology with strategic functions can cultivate an ecosystem where data-driven insights thrive. This not only helps in the effective adoption of analytics but also promotes the innovative spirit and maintains the competitiveness of organizations in today's world of data.

TABLE III. STUDY LIMITATIONS

Limitation	Description
Restricted Temporal Coverage	The review focuses on articles published between 2020 and 2024, which may exclude earlier studies that could offer additional perspectives or alternative approaches to data analytics adoption and impact.
Database Selection and Publication Bias	The review uses well-known databases (Scopus, Web of Science, IEEE Xplore, ProQuest, and Emerald Insight). This might lead to the exclusion of relevant studies from grey literature or other unindexed sources, potentially affecting the representativeness of the findings.
Reliance on the Quality of Included Studies	The robustness of the conclusions depends on the methodological rigor of the 32 articles reviewed. Any limitations in the methodology of the included studies could influence the reliability and validity of the overall synthesis.
Lack of Empirical Validation	The study is based primarily on a systematic literature review without supplementary empirical or experimental validation to confirm the effectiveness of the proposed recommendations or conclusions in real-world settings.
Limited Applicability to Certain Sectors	Although the review includes studies from various sectors (e.g., healthcare, marketing, logistics, manufacturing, education, e-commerce), many examples are concentrated in healthcare, marketing, and supply chain management. This may limit the generalizability of the findings to sectors with different challenges.

VI. CONCLUSION

The systematic review shows that data analytics significantly contributes to changing the way decisions are being made in organizations. Synthesizing a body of 32 studies published between the years of 2020–2024, the review distilled eight key themes—including data quality and organizational resilience, to approaches for optimization and strategies for adoption—that together depict the facilitators and impediments to adopting data-driven decision-making.

The key findings highlight the enhanced accuracy, timeliness, and competitive advantage through data analytics, albeit under considerable challenges. These aspects are said to be the likes of data fragmentation, insufficient interoperability, organizational resistance as well as the lack of holistic plans integrating both the technical and socio-cultural factors.

An important value added of this review is its full template of themes revealing the factors enabling or constraining successful integration of analytics. The synthesis highlights the need to improve data quality, create accountability for data management and use, and establish strong and holistic approaches to addressing barriers identified to support data driven development.

For practical validation, future studies should compare and contrast the effectiveness of varying data analytics methodologies. This work will further shape and guide the current understanding of how and when to implement analytics solutions in various organizational contexts through concrete recommendations.

To conclude, data analytics have proven to be essential for enhancing organizational efficiency and making strategic data-driven decisions. However, to achieve these advantages, it is important to address the challenges identified through specific empirical investigation and focus on integrative, adaptive strategies.

VII. Future Work

This study has illuminated both the significant progress and persistent challenges in leveraging data analytics to enhance organizational decision-making. Building on these findings, future research should focus on key areas that can drive meaningful advancements and ensure sustainable growth in this field.

One of the essential factors is the uniformity of the quality of data, according to which the quality of data will be ensured, particularly for organizations that are working through different industries and geographies. It is also essential to understand the socio-cultural dynamics that shape how these analytics tools are adopted, as this is often the determining factor of where such initiatives succeed or fail. One way to leverage its transformative potential in sectors that have not applied data analytics (for example education, environment, management).

Another exciting opportunity is building intuitive, frictionless tools made for the needs of developing economies. These tools can democratize access to advanced analytics and bridge technological gaps. Real-time processing of the data collected by IoT devices through incorporation into analytical processes can lead to new innovative opportunities for improving the efficiency of decision-making processes in organizations. How might we develop strong socio-technical frameworks to help with this problem, another area where more research is needed, as theory has yet to grapple with the cultural complexity that can result through this process, which puts together technology, organizational processes, and human factors in an interdisciplinary context?

While this systematic review aims to synthesize the literature available, it is worth noting that most of the studies being reviewed offer solutions without strong empirical validations of these or direct comparisons with other approaches. Although our work was not an independent experimental validation—in line with the systematic review format—we recognize the need for empirical validation in establishing the real-world utility of data analytics approaches. Future work might include a meta-analysis of validation results from the primary studies, or even empirical comparative studies of well-justified approaches under comparable conditions. Such initiatives would deepen our insights about the relative advantages and disadvantages of each approach and provide more refined guidelines of best practices about how to employ data analytics in organizational decision making.

There is also continued important research on how to optimize analytical processes. Hybrid methods have been found useful in multiple domains, such as using GIS with analytics for supply chain optimization [13], implementing advanced tools for operational improvements in healthcare [14], and using a decision support system that can reduce cost and performance-focused management in logistics environments [27]. When developing targeted, sector-specific solutions that build upon the current tools available as well as novel approaches, these insights should serve as a guide.

Finally, the eight themes identified in this study provide a roadmap for advancing knowledge and application in data analytics. Each theme, ranging from data quality to big data adoption strategies, offers distinct opportunities for exploration, ensuring that future research addresses challenges holistically while maximizing the benefits of analytics in decision-making. By focusing on these areas, researchers can ensure that analytics evolves as an inclusive, adaptable, and transformative force across diverse organizational and societal contexts. These proposals are presented in detail in Table IV, allowing a clear and organized visualization of the research priorities in each thematic area.

TABLE IV. Future Research Directions by Thematic Area

Thematical	Details
Data Quality and its Impact on Analytics	Explore automated tools to ensure real-time data quality. Investigate global standards to improve system interoperability. Evaluate case studies of fragmented data in complex organizations.
Organizational and Cultural Resilience	Design training programs to reduce resistance to the use of analytical tools. Study the socio-cultural factors that influence the adoption of analytics in different regions.
Improved Decision Making	Develop hybrid models that combine machine learning with traditional decision-making approaches. Evaluate the impact of analytics on long-term strategic decisions in key industries.
Approaches to Optimization	Test the integration of emerging technologies, such as blockchain, into analytics systems. Design frameworks for the simultaneous implementation of analytics and GIS in industrial contexts.
Innovation in Specific Sectors	Analyze case studies in emerging sectors such as agriculture and renewable energy. Evaluate the feasibility of advanced analytics in low resource sectors.
Use of Big Data in Decision Making	Study the effectiveness of public policies to foster the adoption of big data in emerging economies. Propose strategies to reduce implementation costs in small and medium enterprises.
Big Data Analytics Adoption Strategies	Investigate how big data can improve prediction and planning in global crises. Develop specific tools for the integration of big data in governmental decision-making processes.
Critical Factors in the Adoption of Big Data Analytics	Identify and measure new key indicators of success in big data adoption. Explore how cultural differences influence adoption rates in different organizational contexts.

DyGAN: Generative Adversarial Network for Reproducing Handwriting Affected by Dyspraxia

Jesús Jaime Moreno Escobar[1], Hugo Quintana Espinosa[2], Erika Yolanda Aguilar del Villar[3]
Centro de Investigación en Computación, Instituto Politécnico Nacional, México[1]
Escuela Superior de Ingeniería Mecánica y Eléctrica, Zacatenco, Instituto Politécnico Nacional, México[2,3]

***Abstract*—Dyspraxia primarily affects coordination and is categorized into two forms: 1) Motor, and 2) Verbal ororal. This study focuses on motor dyspraxia, which influences individuals in learning movement-related tasks. Consequently, the *DyGAN* initiative employs deep convolutional aversarial generation networks, using deep learning to create characters resembling human handwriting. The methodology in this study is structured into two main stages: 1) the creation of a first-order cybernetic model, and 2) the execution phase. Using four independent variables and three dependent variables, eight outcomes were analyzed using variance analysis. DyGAN is a twin Deep Convolutional Neural Networks and it is highly sensitive to the Learning Rate. It scored a 67% on the proposal, suggesting that characters can sound written by a human. The project will feature writers from different backgrounds and will help augment data for writing resources for dyspraxia, potentially benefiting those struggling with writing difficulties and improving our understanding of education. The model is designed to be widely applicable. Future work could customize the model to mimic the way a specific child writes, with neural networks, for example.**

***Keywords*—Children with neurodevelopmental disorders; dyspraxia; generative adversarial network; deep learning; deep convolutional neural network; human handwriting**

I. Introduction

Since 2020, the World Health Organization (WHO) estimates that there are 1 billion people living with some form of disability, which means that approximately 15% of the world's population has difficulties in their psychosocial functioning and frequently requires assistance services. On the other hand, in Mexico, according to data from the National Institute of Statistics and Geography (INEGI), there are 6.2 million people who have some form of disability, which represents 4.9% of the total population.The most well-known activities for types of disabilities are six: 1) Walking, climbing, or descending, 2) Seeing, 3) Hearing, 4) Speaking or communicating, 5) Remembering or concentrating, and 6) Difficulty with bathing, dressing, or eating. People with disabilities may have more than one disability.

Dyspraxia, also known as Developmental Coordination Disorder (DCD), is a condition that affects physical coordination, which can make daily tasks more challenging for children. In the school setting, children with dyspraxia often struggle with activities that require fine and gross motor skills. This can include difficulties with handwriting, cutting with scissors, participating in sports, and even simple tasks such as tying shoelaces or buttoning clothes. These challenges can cause frustration and a sense of inadequacy among affected children, as they may find themselves behind their peers in performing seemingly simple tasks [1], [2].

The academic implications of dyspraxia are significant. Children with this condition may have difficulty with tasks that require motor planning and coordination, such as writing legibly and quickly, which is essential for taking notes and completing written assignments. This can result in lower academic performance not because of lack of understanding or intelligence but due to the physical difficulties associated with the disorder. Furthermore, the effort required to complete these tasks can be exhausting, leading to decreased stamina and increased stress, which can further affect a child's ability to learn and engage in the classroom [3], [4].

Socially, children with dyspraxia often face additional hurdles. Their difficulties with coordination and motor skills can make it difficult to participate in group activities and sports, which are crucial for social development and peer relationships. These children may be perceived as clumsy or awkward, leading to possible teasing or bullying from classmates. This social isolation can have profound effects on your self-esteem and general mental health. In addition, teachers may not always be aware or understand the needs of children with dyspraxia, leading to inadequate support and accommodations in the classroom. It is crucial for educators to receive proper training to recognize and support students with dyspraxia, ensuring that they have the tools and understanding necessary to help these children thrive academically and socially [5], [6]. Then, according to Pinos-Medramno et al. in [7], the school performance of children with dyspraxia in Basic Education has a negative impact on their normal development and therefore on their learning process, particularly in their writing. Addressing these challenges requires innovative solutions, such as the application of Artificial Intelligence (AI).

Artificial intelligence can be divided into two main types: 1) AI based on its functionality and 2) AI based on capacity. For the development of a DyGAN, capacity-based AI is utilized, which is further divided into three branches:

1) Artificial Narrow Intelligence (ANI): Its function is to focus on performing a single task, but it has limited memory. At this stage, it should be prepared to act in a single role, minimizing its performance as much as possible.
2) Artificial General Intelligence (AGI): It has the ability to mimic human thinking because of its high cognitive level.
3) Artificial Super Intelligence (ASI): It is the most powerful AI, as it has the capacity for faster learning

and achieving autonomy, which allows it to replicate human behavior and even surpass human thinking ability. However, as of 2023, it is still in the development phase.

For the conceptualization and advancement of a DyGAN, Generative Adversarial Networks (GANs) are utilized due to their proficiency in synthesizing character images derived from a pre-established database, potentially curated for general-purpose applications. The deployment of GANs is notably advantageous as they comprise two neural networks that engage in a competitive dynamic, thereby facilitating the generation of highly realistic imagery. This approach enables the efficient production of a diverse array of character images, which is particularly advantageous for applications necessitating extensive visual datasets. It is imperative to underscore that, at their core, Neural Networks are employed, categorized into five principal architectures:

1) Transformer Neural Networks: These are self-aware neural networks that have been developed for text and are currently driving significant advances in natural language processing.
2) Recurrent Neural Networks: This is a type of artificial neural network that has a sequential structure or time-series data. They are used in applications such as language translation, speech recognition, and image captioning.
3) Siamese Neural Networks: Their functionality is based on the use of two conditions for evaluation. After the evaluation is performed, the output is passed to a classifier which generates the result. They are primarily used for document evaluation.
4) Convolutional Neural Networks: They have many layers, each dedicated to detecting different visual features. Filters are applied to training images with different resolutions, and the output of each layer is obtained by convolving the image, which is then used as input for the next layer.
5) Generative Adversarial Networks: Their use is to generate images from existing datasets, with one network called the generator and the other called the discriminator, competing with each other to generate new instances that resemble those in the training data distribution.

Each of these architectures has distinct characteristics and strengths, making them suitable for a variety of tasks within the domains of artificial intelligence and machine learning. Consequently, the integration of Generative Adversarial Networks (GANs) with these fundamental neural network architectures can significantly enhance the performance and capabilities of a Dynamic Generative Adversarial Network (DyGAN) in generating high-fidelity character images. This advancement facilitates various applications, including digital handwriting analysis, educational tools for children with learning disabilities, and other scenarios where the generation of realistic character images is imperative. For the development of a DyGAN, GANs are employed to generate character images from a pre-established database, which could be designed for general use.

This work is therefore divided into four additional sections. The second section provides an analysis of related work on Generative Adversarial Networks (GANs). Then, this section explains the theory surrounding GANs, including essential definitions for understanding neural networks. The third section summarizes the methodology of this proposal, so that the following section can conduct experimentation aimed at finding optimal hyperparameters to improve the results. Finally, conclusions are developed, focusing on the research findings and possible improvements or future directions that the work could take.

II. Method

The study of dyspraxia dates back to the late 19th century, with the British physician Sir William John Little being the first to study it in depth and name it as such [8]. By 1937, Samuel Orton declared it one of the six most common developmental disorders and showed a distinctive impairment of praxis. He also titled it *Reading, Writing, and Speech Problems in Children*. He was one of the first to break away from the concept of simple recovery reading and treat all aspects of language as related, doing so in a language clinic [9]. Later, in 1972, Anna Jean Ayres categorized Dyspraxia as a Sensory Integration Disorder. During this period, she wrote several books, two of which stand out: 1)S̃ensory Integration and Learning Disorders (1972) and 2)S̃ensory Integration and the Child (1979). In addition, she published multiple academic articles that addressed her theory and techniques for clinical application and founded the *Ayres Clinic*, based in Torrance, California, USA, where she evaluated and treated children using her developed approach. Sensory integration therapy emphasizes detailed evaluation, understanding the unique sensory challenges and styles of each child, which forms the basis for providing the child with appropriate learning opportunities, processing, and using sensory information to improve the child's performance skills [10].

A. Related Work

The exploration of advanced technologies for neurodivergent learning begins with the study *Exploring the Efficacy of an IoT Device as a Sensory Feedback Tool in Facilitating Learning for Neurodivergent Students* in [11]. This research investigates how IoT devices can provide real-time sensory feedback to enhance the learning experiences of neurodivergent students. These devices offer customized responses that improve engagement and learning outcomes by creating adaptive learning environments. Similarly, the *Web-based Assessment and Training Model for Dyslexia, Dyscalculia, Dysgraphia, Dyspraxia, ADHD and Autism* in [12] provides a digital platform for individualized assessments and training. The Web-based model integrates educational games and cognitive exercises, offering flexibility and scalability for diverse educational settings. Both studies underscore the potential of digital tools to support personalized and inclusive education.

Building on the theme of interactive learning technologies, the study *Improving Cognitive Learning of Children with Dyspraxia Using Selection-Based Mid-Air Gestures in the Athynos Game* [13] explores the use of Mid-Air Gestures-Based Interactions in the Athynos game to improve cognitive learning for children with dyspraxia. This approach not only

engages children more effectively but also improves their cognitive and motor skills. This research aligns with *ATHYNOS: Helping Children with Dyspraxia Through an Augmented Reality Serious Game* in [14], which uses augmented reality to create interactive learning experiences targeting specific motor and cognitive skills. Both studies highlight the effectiveness of immersive and interactive technologies in supporting children with motor impairments, emphasizing the role of serious games in educational and therapeutic settings.

The advancement of computational diagnostic systems is exemplified by *TestGraphia, a Software System for the Early Diagnosis of Dysgraphia* in [15], which uses advanced algorithms to analyze handwriting and identify patterns of dysgraphia. This objective and quantifiable method aids in early diagnosis, which is critical for timely interventions. Complementing this approach is *Preventing Dyspraxia: A Project for the Creation of a Computational Diagnostic System Based on the Theory of Embodied Cognition* in [16], which leverages computational techniques to assess motor and cognitive functions, providing a holistic view of dyspraxia. Both studies emphasize the importance of early detection and intervention, using computational tools to enhance diagnostic accuracy and support effective therapeutic strategies.

The integration of wearable haptics and Virtual Reality (VR) in rehabilitation is explored in *Wearable Haptics and Immersive Virtual Reality Rehabilitation Training in Children with Neuromotor Impairments* in [17]. This study shows that combining haptic feedback with virtual reality significantly enhances the rehabilitation process by providing engaging and interactive experiences. Similarly, *Integration of Serious Games and Wearable Haptic Interfaces for Neuro Rehabilitation of Children with Movement Disorders: A Feasibility Study* in [18] examines the feasibility of using serious games and haptic interfaces for neurorehabilitation, reporting improvements in motor functions and user participation. These studies demonstrate the potential of immersive technologies to create effective rehabilitation environments for children with neuromotor impairments.

Focusing on learning disabilities, *Rotoscopy-Handwriting Prototype: Using computer animation technique to assist handwriting teaching for children with dyspraxia* in [19] and *using the rotoscopy technique to assist handwriting teaching for children with dyspraxia* in [20] both present innovative methods employing rotoscopy and computer animation to teach handwriting. These systems provide visual and kinesthetic feedback, helping children with dyspraxia improve their handwriting skills through interactive exercises. These studies highlight the value of specialized software in addressing specific educational challenges associated with learning disabilities.

The study *Puzzle Time - VR Runner* [21] presents a VR game designed to support the development of cognitive and motor skills in children. By combining cognitive puzzles with physical activities, the game encourages physical movement and cognitive engagement, making it a useful tool for educational and therapeutic purposes. This approach is echoed in *Case Study: Using a Novel Virtual Reality Computer Game for Occupational Therapy Intervention* in [22], which explores the use of a VR game for occupational therapy. The positive results in motor skills and patient participation reported in these studies underscore the potential of VR games as effective tools to enhance cognitive and motor skills.

Lastly, the application of advanced machine learning techniques is highlighted in *Integrated Transfer Learning Based on Group Sparse Bayesian Linear Discriminant Analysis for Error-Related Potential Detection* in [23]. This study uses transfer learning to improve the detection accuracy of error-related potentials in EEG data, demonstrating the utility of machine learning in neurorehabilitation settings. Additionally, *Contemporary Speech/Speaker Recognition with Speech from Impaired Vocal Apparatus* in [24] addresses the challenges of speech recognition for individuals with impaired vocal apparatus, emphasizing the importance of inclusive technologies that accommodate diverse needs. Both studies show advances in machine learning and speech recognition technologies that contribute to better diagnostic and therapeutic outcomes.

Together, these studies illustrate the significant progress that is being made in the use of advanced technologies to support neurodivergent learning and rehabilitation. From IoT devices and web-based platforms to immersive VR and specialized software, these innovations are creating more inclusive, engaging, and effective educational and therapeutic environments. Using these technologies, educators and clinicians can provide better support and interventions, ultimately improving outcomes for people with learning and developmental disorders.

B. Deep Convolutional Generative Adversarial Networks

Deep Convolutional Generative Adversarial Networks (DCGANs) constitute a particular type of neural network designed to generate data from an existing dataset as observed in Fig. 1. The primary goal of DCGANs is to examine and understand the distribution of data within the training set, with the purpose of reliably generating new data that follow this distribution [25].

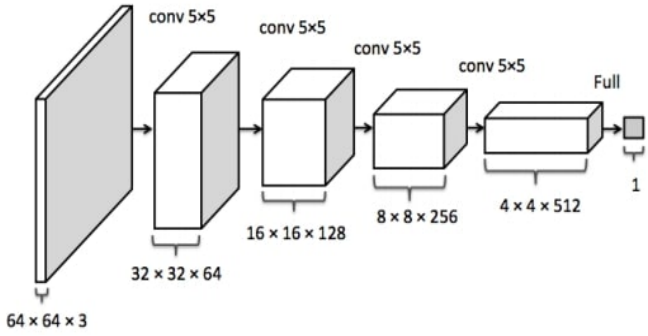

Fig. 1. Representation of Deep Convolutional Generative Adversarial Networks (DCGANs) [26].

A GAN network consists of two neural components: 1) a *Generator* (G), and 2) a *Discriminator* (D). The primary function of the generator is to understand the distribution of the training dataset and produce information that fits that distribution. On the other hand, the Discriminator evaluates the probability of authenticity of a given data point, determining whether it comes from the real training set or if it is synthetic, generated by G. Fig. 2 shows not only the architecture, but also the interaction between G and D.

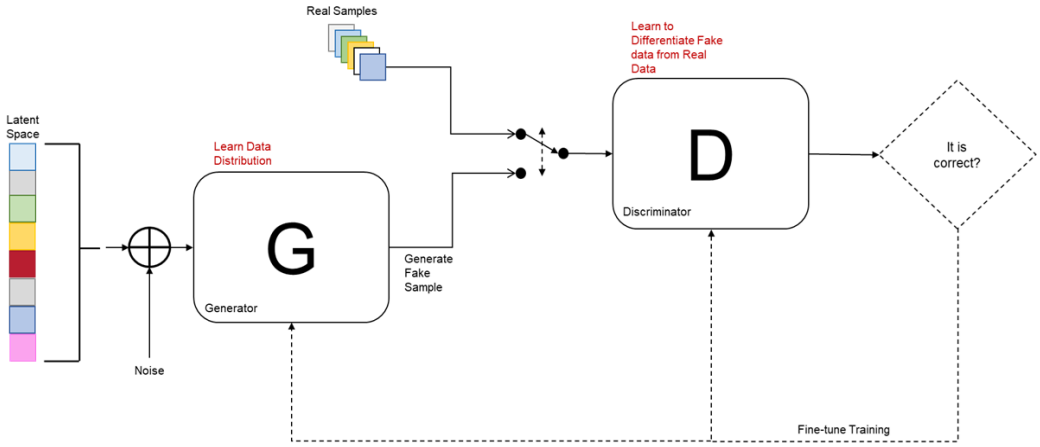

Fig. 2. Architecture of a DCGAN [27].

In this manner, **G** and **D** compete against each other through a Minimax game, where each adversary seeks to maximize its actions while simultaneously minimizing those of the opponent. The mathematical representation of this Minimax game in GANs is expressed by Eq. 1.

$$\min_G \max_D V(D,G) = \mathbb{E}_{x\sim p_{\text{data}}(x)}[\log D(x)] + \mathbb{E}_{z\sim p_z(z)}[\log(1-D(G(z)))] \quad (1)$$

The objective is to train the discriminator **D** to accurately classify the data as authentic, maximizing $\mathbb{E}_{x\sim p_{\text{data}}(x)}[\log D(x)]$, or synthetic, maximizing $\mathbb{E}_{z\sim p_z(z)}[\log(1-D(G(z)))]$, where the output probability should approach zero. Concurrently, the generator **G** is optimized to deceive the discriminator **D** through the generation of data that closely resemble the training set, thus minimizing $\mathbb{E}_{z\sim p_z(z)}[\log(1-D(G(z)))]$. Within this framework, the MinMax game is engaged solely in the latter part of the equation. As Goodfellow elucidated in [28] the aforementioned equation may not provide an adequate gradient for **G** to learn effectively. This limitation arises because, during the initial phases, the data synthesized by **G** are of insufficient quality, leading **D** to reject them with high confidence, given their stark divergence from the real training data. Then Eq. 2 provides a summary of how the Generator and the Discriminator compute the gradient throughout the training process.

$$V_{\text{GAN}}(D,G) = \begin{cases} D: \max_D \mathbb{E}_{\mathbf{x}\sim p_{\text{data}}(\mathbf{x})}[\log D(\mathbf{x})] \\ +\mathbb{E}_{\mathbf{z}\sim p_{\mathbf{z}}(\mathbf{z})}[\log(1-D(G(\mathbf{z})))] \\ G: \max_G \mathbb{E}_{\mathbf{z}\sim p_{\mathbf{z}}(\mathbf{z})}[\log(D(G(\mathbf{z})))] \end{cases} \quad (2)$$

In addition, Eq. 2 describes the objective functions for Generative Adversarial Networks, where we can identify the two main components in it: the Discriminator (D) and the Generator (G).

$$\textbf{Discriminator}(D): \max_D \mathbb{E}_{\mathbf{x}\sim p_{\text{data}}(\mathbf{x})}[\log D(\mathbf{x})] + \mathbb{E}_{\mathbf{z}\sim p_{\mathbf{z}}(\mathbf{z})}[\log(1-D(G(\mathbf{z})))] \quad (3)$$

The Discriminator's objective is to maximize the expected value of correctly distinguishing between real data (x) from the data distribution and generated data (G(z)) from the Generator, Eq. 3. It seeks to maximize the logarithmic probability that real data are classified as real and the logarithmic probability that generated data are classified as fake.

$$\textbf{Generator}(G): \max_G \mathbb{E}_{\mathbf{z}\sim p_{\mathbf{z}}(\mathbf{z})}[\log(D(G(\mathbf{z})))] \quad (4)$$

The Generator's objective is to maximize the expected value of the log probability that the Discriminator classifies the generated data as real, Eq. 4. Essentially, the Generator tries to fool the Discriminator by generating data that is indistinguishable from real data [27]. The Fig. 3 shows the mathematical interaction of the GAN components for the generation of an image or synthetic data.

C. DyGAN

In Fig. 4, the DyGAN first-order cybernetic model, an MNIST database and numbers are included. The algorithm was designed in such a way that the user enters a character and, in turn, connects to an MNIST database containing characters. In the output, the character is displayed on the screen. The system is controlled by feedback, as efficiency is important in determining whether accuracy has been achieved. This is the principle of DCGAN, which is a Deep Convolutional Generative Adversarial Network. The discriminator and the generator are involved in the process.

From Fig. 5, the Generator and Discriminator are fundamental processes that enable the functionality of DCGAN. The generator creates images from pixels, in this case, with a size of 28, which matches the one used in the MNIST database. In each epoch, the Generator produces an image and the Discriminator evaluates whether it is real or fake. If the discriminator indicates that it is fake, the process continues over several epochs until it can confuse the discriminator or match the generated images with those in the database. The following algorithm describes the training and inference process of the GAN designed for the MNIST dataset to aid children with dyspraxia. The GAN model consists of a

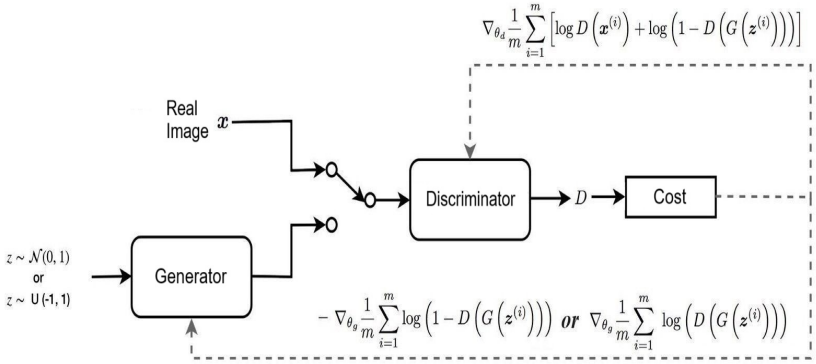

Fig. 3. Mathematical diagram of the generator and discriminator components.

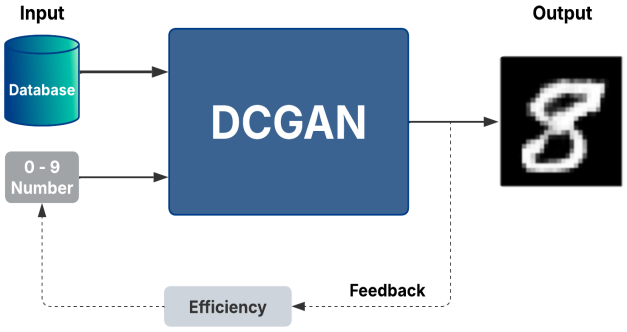

Fig. 4. DyGAN first-order cybernetic model over MNIST database, only numbers are included.

generator and a discriminator, where the generator creates new images from random noise, and the discriminator evaluates the authenticity of the images. Stages of the training and inference methodology for a GAN on MNIST to help children with dyspraxia Here we will preprocess the data and train our model followed by deployment of models.

Algorithm 1: GAN Training and Inference for MNIST

Initialize: Generator G, Discriminator D, learning rate α, batch size m **Input:** MNIST dataset X, random noise Z

Training Phase **for** *number of training iterations* **do**

Sample minibatch of m noise samples $\{z^{(1)}, \ldots, z^{(m)}\}$ from noise prior $p_z(z)$ Sample minibatch of m examples $\{x^{(1)}, \ldots, x^{(m)}\}$ from data distribution $p_{data}(x)$

Update Discriminator: $\theta_d \leftarrow \theta_d + \alpha \nabla_{\theta_d} \frac{1}{m} \sum_{i=1}^{m} [\log D(x^{(i)}) + \log(1 - D(G(z^{(i)})))]$

Update Generator: $\theta_g \leftarrow \theta_g + \alpha \nabla_{\theta_g} \frac{1}{m} \sum_{i=1}^{m} [\log D(G(z^{(i)}))]$

Inference Phase **Input:** Trained Generator G, new random noise z **Output:** Generated image $G(z)$ Sample noise z from noise prior $p_z(z)$ Generate image using G: $\hat{x} = G(z)$ **return** $\hat{x}$

Algorithm 1 provides a comprehensive description of the training and inference process. In the Training Phase, the generator and discriminator are updated iteratively. The generator G learns to create realistic images by minimizing the discriminator's ability to distinguish between real and generated images, while the discriminator D aims to maximize its accuracy in this task. In the Inference Phase, the trained generator uses new random noise z to produce new images, providing a useful tool for evaluating therapeutic progress in children with dyspraxia through generated visual aids. This methodology ensures a systematic and effective training process, facilitating the creation of high-quality synthetic data that can be utilized in therapeutic settings.

III. Experimental Results

First, since we propose three independent variables: 1) batch size, 2) learning rate, and 3) activation function, we carried out a total of eight experiments, as shown in Table I. Based on this, an Analysis of Variance (ANOVA) was performed. The analysis in an ANOVA table is associated with certain factors being investigated, including the activation function, batch size, and learning rate, along with their residuals. The Sum of Squares tells us how much variance each source contributes to the total data set. Degrees of freedom (df) refer to how many values or quantities in a statistical distribution, for every factor. The sum of squares is divided by the corresponding degrees of freedom to calculate the mean square, which measures the average variance due to each source. Thus, the F-Ratio is calculated as a ratio of mean square of source/mean square residuals to tell if its variances are significantly different. P-Value - is the probability value, and it is used to determine the significance of an observed effect. Since we can obtain four dependent variables or test variables: 1) Discriminator Loss (D Loss), 2) General Accuracy, 3) Adversarial Loss, and 4) Discriminator Accuracy (D Accuracy), we can infer the behavior of the system in four independent branches. Table I also shows the best results for each dependent variable highlighted in gray.

Table II shows that it is evident that none of the factors, activation function, batch size, or learning rate, demonstrate statistically significant effects on overall efficiency over Discriminator Loss, as indicated by their high P-values. However, it should be noted that the *Learning Rate*, although not statistically significant, has a value of P closest to zero among the

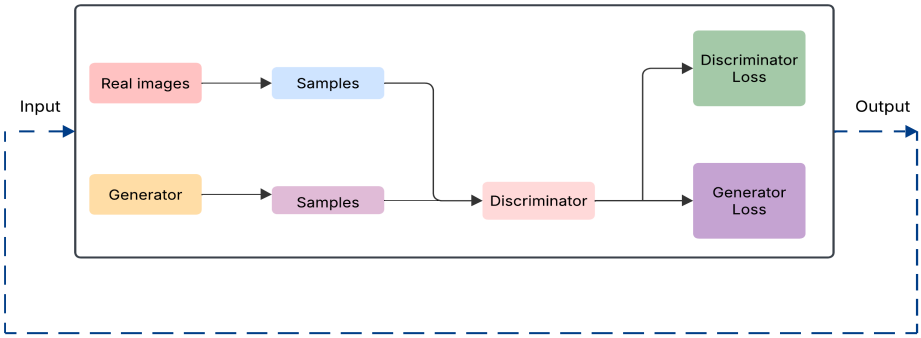

Fig. 5. DyGAN first-order cybernetic extended model over MNIST database, only numbers are included.

TABLE II. ANOVA TABLE WITH DIFFERENT SOURCES OF VARIABILITY, EFFECT OVER DISCRIMINATOR LOSS

Sources	**Sum of Squares**	**df**	**Mean Square**	**F-Ratio**	**P-Value**
A) Activation Function	0.000310578	1	0.000310578	0.17	0.7015
B) Batch Size	0.0000760391	1	0.0000760391	0.04	0.8485
C) Learning Rate	0.00339307	1	0.00339307	1.85	0.2450
Residuals	0.00732558	4	0.00183064		
Total (Corrected)	0.0111023	7			

TABLE III. ANOVA TABLE WITH DIFFERENT SOURCES OF VARIABILITY, EFFECT OVER GENERAL ACCURACY

Sources	**Sum of Squares**	**DF**	**Mean Square**	**F-Ratio**	**P-Value**
A) F.A	0.000326274	1	0.000326274	0.5	0.8286
B) Batch Size	0.000227484	1	0.000227484	0.04	0.8564
C) L.R	0.00138228	1	0.00138228	0.23	0.6592
Residuals	0.0244519	4	0.00611296		
Total(Corrected)	0.0263879	7			

three factors, making it the most significant factor compared to the activation function and batch size. This suggests that while the effects are not statistically significant in general, the Learning Rate has a relatively stronger influence on the outcome measure. From Fig. 6, we also notice that the learning rate factor (LR) is more significant when conducting the experiments, as it influences the way DyGAN learns and is a factor to consider.

The ANOVA of Table III analyzes the variability of the General Accuracy through contributions attributable to various factors. Since the Type III sum of squares has been chosen, the contribution of each factor is assessed by eliminating the effects of the other factors. The P-values indicate the statistical significance of each of these factors. Since no P-value is found to be less than 0.05, it is again concluded that none of the factors exerts a statistically significant effect on General Accuracy at a confidence level of 95%.

IV. CONCLUSIONS

We presented the Deep Convolutional Generative Adversarial Networks to lay down theoretical background for the proposal and discuss how it works, mathematically-based solutions, tools, and applications involving on it. Furthermore, a methodology for creating an application capable of producing personalized fonts with DCGANs was described. The performance of the proposed model was evaluated by ANOVA to confirm its precision. In summary, the Learning Rate is found to be one of the governing parameters affecting DyGAN. The proposal was 67% correct, which means that the possible characters may have been written by a human. This proposal is intended to contribute to the creation of dyspraxia in writing expanding resources for learning through data augmentation with potential support for those who have dyspraxia. The architecture is intended for anyone with a writing issue, and in this respect it has an obvious impact on the education building.

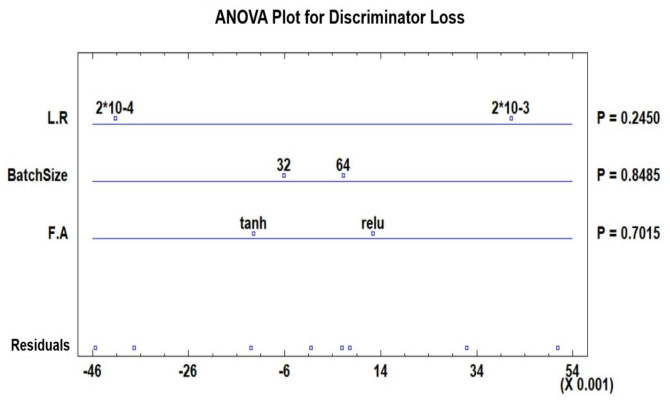

Fig. 6. Analysis of residuals on the variable discriminator loss.

Our application aims to provide a model that is deployable and that can be used effectively by all audiences. Future work for DyGAN can also be a case study to have unique characters from each person in which the model imitates handwriting of particular child, and extension with other models/architects as well including artificial neural networks.

ACKNOWLEDGMENT

The research described in this work was carried out at the Centro de Investigación en Computación (CIC) together with the Escuela Superior de Ingeniera Mecánica y Eléctrica (ESIME) of the Instituto Politécnico Nacional, Campus Zacatenco. It should be noted that this research is part of a degree thesis entitled *DPGAN: Aplicación de DCGAN en la generación de caracteres únicos a través de la inteligencia artificial* supported by *Jesús Sebastián Ruiz Cruz*, work directed by Dr. Jesús Jaime Moreno Escobar.

Enhanced Cyber Threat Detection System Leveraging Machine Learning Using Data Augmentation

Umar Iftikhar, Syed Abbas Ali
Department of Computer & Information System Engineering, NED University of Engineering & Technology, Karachi, Pakistan

***Abstract*—In the modern era of cyber security, cyber-attacks are continuously evolving in terms of complexity and frequency. In this context, organizations need to enhance Network Intrusion Detection Systems (NIDS) for anomaly detection. Although the existing Machine Learning models are in place to cater to the situations but new challenges emerge rapidly which affects the performance and efficiency of existing models specifically the unreachability of large datasets and unorganized data. This results in degraded efficiency for the identification of complex attacks. In this paper, data augmentation has been done of NSL-KDD which is a standard dataset for Intrusion Detection Systems (IDS) specifically for IoT-based devices. The improvement in performance and efficiency of NIDS has been performed by training the augmented dataset using the K-Nearest Neighbor (KNN) ML model.**

***Keywords*—Anomaly detection; cyber threat intelligence; generative adversarial networks; data augmentation; Wasserstein GAN with gradient penalty**

I. Introduction

This section gives some background regarding the research presented in this paper along with a detailed problem statement followed by the objectives.

A. Background

The domain of Network security has become one of the most immensely important domain in the modern technological landscape because of various challenging threats, numerously increasing the risk factors. In this context, continuous counter-security measures have become the utmost need of modern-day technology that declares war against intruders and stabilizes the computer networks that are responsible for the protection of user information without compromising the entire network. Network Security has provided significant benefits with time in terms of various aspects like evaluation of security problems, practicing attack and defense, and enhancement of confrontation of network information. Network security plays a vital role and always needs room for improvement in terms of the efficiency and accuracy of intrusion detection techniques [10]. The use of wireless technology and the transmission of large amount of information over the networks has significantly increased security issues specifically in the emerging field of IoT. Network security has become the main point of concern and an effective and efficient Intrusion Detection System (IDS) has now become an essential need for traditional and IoT networks that provide countermeasures against rising threats in small and medium enterprises.

Because of these reasons, Intrusion Detection Prevention Systems (IDPS) have become crucial for network security as they play a vital role in tackling threats. IDPS have become more powerful than ever ensuring the security of networks.

B. Problem Statement

The modern-day NIDS has various crucial shortcomings and drawbacks that degrade its ability to effectively handle cyber-attacks. Majorly it lacks in authenticity and timely responsiveness of network threats in existing datasets that are used for training of NIDS. The frequent staling of these datasets is the main reason for identifying new threats as IDS models mainly rely on these datasets.

Another major limitation regarding the current deployment of NIDS is expensive middleware applications that only monitor a certain portion of the entire network, whereas neglects monitoring of other segments. Data augmentation methodologies play a pivotal role in the training of machine learning models. On the other hand, various existing research has claimed the enhancement in the adaptability of models but still, the utilization of these augmentation techniques in cyber security poses problems.

C. Objectives

The main objective of this research is to produce a vigorous cyber threat detection system equipped with the tendency of auto-encoder based data synthesis and attack surface vector modeling [11]. Generative Adversarial Networks (GANs) [2] have the ability to enhance the attack detection performance of NIDS when datasets like NSL-KDD are incorporated into it. Utilization of GANs to produce the synthetic data, NSL-KDD can be extended using more assorted and accurate examples of network traffic that enhance the quality of trained models of the provided datasets.

To authenticate the designed methodology, the NSL-KDD dataset has been selected as a vigorous baseline for this research. The dataset chosen has been proven globally in the field of networks due to its rational evaluation, reproducibility, and trustworthy capability of accomplishing theoretical amendments. The results generated by the selection of the above-mentioned dataset impact a concrete transferable theory that is not affected by dataset-specific limitations. Thus, the framework proposed in this research is more capable of being implemented on complex datasets resulting in the evolution of various network traffic scenarios.

The idea of using generative model approaches and the NSL-KDD in combination will enhance the capability to cater the challenges such as data misbalancing and overfitting in IDS. Training of augmented datasets with denser samples, the

performance can be enhanced against cyber-attacks, thus enhancing the model's efficiency in detecting network threats.

II. Related Work

In this section, all the related work was discussed in detail including NSL-KDD Dataset, various ML Models, GAN for augmentation of data, KNN Model, and gaps in existing research.

A. Overview of NSL-KDD Dataset

The NSL-KDD dataset is an enhanced version of the KDD Cup 1999 dataset that was developed to address the problems like redundancy and class imbalance [12]. It is capable of providing improved and reliable standards for evaluating the performance of Network Intrusion Detection Systems (NIDS). The dataset in KDD Cup 1999 consists of a large number of duplicate instances that create noise while training the machine learning models [14]. Due to this reason, NSL-KDD has an edit advantage in which the majority of duplicated records are considered redundant and are eliminated. This elimination of duplicate records provides more enhanced and refined data of network traffic, improving the capability to assess the performance of NIDS.

There are 41 features in the NSL-KDD that are capable enough to capture the characteristics of network traffic. These characteristics include connection details, timing, transferred bytes, and payload content. These characteristics are further divided into structural, content, time-based, and host-based groups that help in attaining improved statistical and machine-learning methodologies used for intrusion detection. The enhanced features of KDD-NSL such as addressing redundancy and balanced class distribution, improve the capabilities to detect common and rare attacks in NIDS [3][4]. Vast research has been carried out using this dataset for the development and testing of new algorithms, which further makes this dataset more relevant in the field of network security and intrusion detection.

B. Machine Learning Models for Network Security

Machine Learning Models are now playing a vital role in the domain of network security as they provide capabilities like detection of more unusual activities, attacks, and adjustments of cybersecurity systems. There are a large number of models for anomaly detection, some of the most popular used models are Auto encoders, Support Vector Machines (SVM), K-Nearest Neighbor (KNN), Random Forest Classifiers, Convolutional Neural Networks (CNN), Deep Neural Networks (DNN), Generative Adversarial Networks (GANs).

Training the Wasserstein Generative Adversarial Network with Gradient Penalty (WGAN-GP) data augmentation [9] with the KNN model gives an enhanced result in the detection of cyber-attacks. The NSL-KDD dataset is being considered as the standard dataset for intrusion detection, sometimes agonizes from class imbalance. WGAN-GP, being a benchmark generative model addresses this issue by creating high-quality synthetic samples for diminished classes. This augmentation improves the diversity of the dataset, guaranteeing the training of ML models on illustrative data. The enhanced features of KNN such as instance classification depending upon neighborhood patterns make a perfect technique for this augmented dataset.

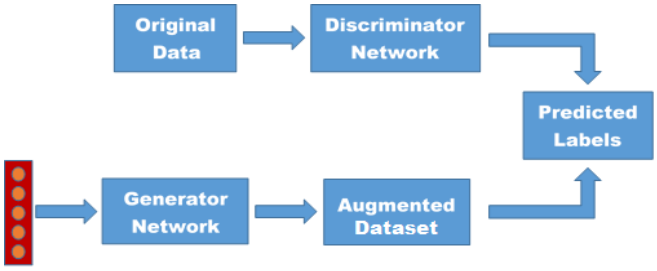

Fig. 1. Workflow of GAN.

The essence of this approach enhances its tendency to meet high accuracy and robustness in defending against cyber-attacks. WGAN-GP produces the data with very less overfittings, sustaining the integrity of the distribution, which is vital in identifying attacks. The flexibility and interoperability of KNN ensure detection in diversified attack scenarios. Combining the WGAN-GP augmented dataset with the KNN model, the system becomes capable of addressing limitations of traditional detection methods like bad generalization and imbalance bias, which leads to a more enhanced cyber-attack detection system for real-world applications.

Generative Adversarial Network (GAN) is one of the most proven model for generative learning that is divided into three main areas which are deep learning, generative models, and adversarial learning techniques [8]. GANs efficiently utilize deep learning networks for solving complex patterns.

The objective function of the original WGAN is given in Eq. (1).

$$\mathcal{L}_{WGAN} = \mathbb{E}_{x\sim pdata}[\boldsymbol{D}(\boldsymbol{x})] - \mathbb{E}_{z\sim pz}[\boldsymbol{D}(\boldsymbol{G}(\boldsymbol{z}))] \quad (1)$$

where,

x is a sample from the real data distribution pdata,

z is a noise vector sampled from a prior distribution pz,

D(x) is the output of the critic for a real sample,

D(G(z)) is the output of the critic for a generated sample.

The Gradient Penalty of WGAN-GP can be mathematically defined in Eq. (2).

$$\mathcal{L}_{GP} = \mathbb{E}_{x\sim pz}[(||\nabla_x \boldsymbol{D}(\hat{\boldsymbol{x}})||_2 - \mathbf{1}^2] \quad (2)$$

where,

$\hat{x}$ is a random sample,

$\nabla_x D(\hat{x})$ is the gradient of the critic D concerning the input,

$||\nabla_x D(\hat{x})||_2$ is the norm of gradient.

The WGAN-GP loss function is expressed in Eq. (3).

$$\boldsymbol{L} = \mathbb{E}[\boldsymbol{D}(\boldsymbol{x})] - \mathbb{E}[\boldsymbol{D}(\boldsymbol{G}(\boldsymbol{z}))] + \boldsymbol{\lambda}\mathbb{E}[\left(||\nabla \boldsymbol{D}(\hat{\boldsymbol{x}})||_2 - \mathbf{1}\right)^2 \quad (3)$$

Eq. (3) is comprised of two parts; in the first part, the critical loss is referred while in the second part is related to the WGAN gradient penalty. This ensures maintaining stability while

training. The diagram in Fig. 1 explains the architecture of a WGAN-GP [13], presenting the generator and discriminator's roles in the production of high-quality synthetic data while differentiating it from real data.

C. Generative Adversarial Network in Data Augmentation

When it comes to data augmentation, GANs are proven to be the most relevant technique that increases the range and volume of data serving the machine learning model.

GANs can produce suitable data distribution over the original dataset. Also, it can compensate the unusual situations where data is limited or unbalanced. Synthetic data, refers to different samples that are not present in data, for example, other viewpoint images in image data or samples of some neglected categories in categorical data. This permits to enhancement of the dataset by inculcating realistic synthetic samples and GANs in addition improves the overall performance of machine learning models and provides a better ability for generalization of data as illustrated in Fig. 1. GAN usage for augmentation of data is extensive and produced various advancements in multiple fields by synthetic data creation [6][7]. They can also be deployed in the analysis of network traffic, where they can be utilized in producing synthetic data that aids in creating enhanced models and is capable of identifying abnormalities in network systems.

D. K-Nearest Neighbor (KNN)

K-Nearest Neighbors (KNN) is a non-parametric, controlled learning algorithm that is popular for its classification and regression tasks. This algorithm functions by detecting the 'k' nearest data points known as neighbors within the featured space over a given input point. Also, it provides predictions either based on the majority class for classification or the average of their values for regression. Euclidean, Manhattan, or Minkowski distance metrics are being used to calculate the distance between two points.

KNN is specifically beneficial in the detection of abnormality as it tends to detect data points that significantly diverge from their nearest neighbors. Abnormalities usually appear as data points with lesser or more detached neighbors as compared with normal data points. KNNs are very useful in multidimensional data handling, implementation simplicity, and flexibility.

The mathematical equation of KNN can be given in Eq. (4):

$$\boldsymbol{d}(\boldsymbol{x},\boldsymbol{y}) = \sqrt{\sum_{\boldsymbol{i=1}}^{\boldsymbol{n}}(\boldsymbol{x_i} - \boldsymbol{y_i})^{\boldsymbol{2}}} \quad (4)$$

where,

d is the distance between two points **x** and **y** in an n-dimensional space.

The formula for calculating the anomaly score is given in Eq. (5).

$$\boldsymbol{Anomaly\ Score}(\boldsymbol{x}) = \boldsymbol{d}\left(\boldsymbol{x}, \boldsymbol{x_{(k)}}\right) \quad (5)$$

where,

$x_{(k)}$ is the k[th] nearest neighbor of (x).

E. Gaps in Existing Research

In the area of GANs, a wide research gap is still there. The research performed in this paper will try to cover these areas. The first and most important part is augmentation of data using GAN. The majority of studies on GAN focused on GAN in a general manner, rather than emphasizing the functionality. This research has been carried out with a focus on how GANs can be utilized extensively to handle new types of data.

The methodology proposed in this paper focuses on practical ability by dimensionality reduction with WGAN-GP and Auto-encoder. The performed research ensures uninterrupted translation to the operational environment. Also, it addresses the real-world scenarios for network traffic data in various ways. This research will result in providing effective ways to process the real-world data, with enhanced features like reduced dimensionality, and augmentation of data, as, the WGAN-GP's framework is specifically trained to produce realistic network traffic.

Observations show continuous improvements in the performance with the proposed methodology that is almost similar to real-world scenarios. Various network environments can be adaptable to proposed design of WGAN-GP as it allows retraining the generator with domain-specific traffic data. For example, this design can be deployed on IoT and cloud-based infrastructures by modifying the training process for reflection of their unique characteristics.

III. Methodology

This section describes the complete methodology applied to the research.

A. Data Description

The dataset used for experimentation is the NSL-KDD dataset. It contains 84,952 entries with 28,318 reserved entries for validation.

While considering the features and labels, the dataset contains similar properties. Every single record in the dataset has several parameters depicting multiple aspects of the network traffic. These features provide help in specific identification of the attacks in the behavior of the network. Preprocessing of data has been performed to identify the classification task to the binary decision [1] that is either "normal" or "attack". Due to this binary transformation, intrusion detection has been more simplified specifying whether the ongoing activity is malicious or not.

B. Data Preprocessing

The preprocessing of data is the most important part as it transforms the data to be used by machine learning algorithms. Other processes that are associated with data preprocessing are data collection, data sanitization, and data normalization. The details of the process include data loading, data splitting, data validation, data testing, handling of numerical and categorical features, and reduction of dimensionality using auto-encoders. The data preprocessing process is further divided into the following steps.

The first step is to import the NSL-KDD dataset, which is divided into two parts. One is referred to as the original dataset

containing 84,952 entries. The other one is referred to as a reserved dataset containing 28,318 entries. The remaining entries are referred to as test datasets for evaluating the model's performance on new data. This technique empowers our research to minimize overfitting effects to train models for any unseen instances.

The next step is scaling the features for numeric features and one-hot encoding for categorical features. In numeric features, the median strategy was used for imputing missing values. This was done to refrain from the mean value of numeric data so that it does not bend towards outliers. In categorical features, a one-hot encoder class was used for each feature. The preprocessing technique was used to assign the use of a column transformer which introduces automation of their application to training and test datasets.

The encoding dimension is constant throughout the experiment, to preserve the true spirit of feature representation and analyze the behavior of varying factors. Out of 100%, a 30% augmentation level has been represented to create a balance between sufficient variability and training data, preserving the integrity of the original labels. Also, diverse representations will be learned by the model without being overwhelmed with noise at 30%. This will further enhance the generalization capabilities. The quality of the synthetic data is evaluated using the Classification Model Utility approach. This method involves training a model on the original dataset and another on the combined original + synthetic dataset, then testing both models on the same validation dataset. Improved performance on the validation dataset indicates the synthetic data's quality and utility [5]. The augmentation level increased to 50% enhances variability without introducing out-of-distribution issues.

The next step is the generation of data. It comprises three phases that include optimization of the constructed model, new synthesized data was produced using WGAN-GP.

The next step is the setup of the WGAN-GP model. This setup comprises two major components, the generator and the discriminator. The generator produces data that resembles with input dataset. The discriminator determines whether the generated data is fake or real. While training the WGAN-GP, numerous iterations were performed through many epochs. The generated data was still transformed and in scaled format, it was necessary to untransformed it to bring it back into its original feature space.

The final step is the merging of synthesized data with existing data.

The hyper-parameters and their functionality are as follows:

- Learning Rate: Controls the weight update per iteration, enhancing the speed and stability of training.
- Num Epochs: Determines the count for seeing the entire dataset by the model of the training process.
- Critic Iterations: Number of updates for the critic (discriminator) per generator update, affecting model stability.
- Lambda GP: It is the coefficient of gradient penalty that ensures that makes sure normalization of the gradient to stabilize the training.

The deviation in hyper-parameters shows a major difference in WGAN-GP performance. Table I depicts the response of the model over the selected algorithm and parameter. The fluctuated parameters during the experiment are shown in Table I.

TABLE I. VARIATION IN HYPER-PARAMETER

Instance	Hyper-Parameter Configuration		
	Learning Rate	***Num of Epochs***	***WGAN Augment %***
X1	2.00E-04	100	30%
X2	1.00E-04	100	30%
X3	5.00E-05	100	30%
X4	2.00E-04	50	30%
X5	1.00E-04	50	30%
X6	5.00E-05	50	30%

C. Performance Metrics

The parameters applied on WGAN-GP for examining the performance are as follows:

1) Accuracy (ACC): It is considered the most important parameter in evaluating the model's performance. This metric evaluates the number of samples for correct prediction over the number of all samples. The formula for calculating this metric is given in Eq. (6).

$$\boldsymbol{ACC} = \frac{\boldsymbol{TP+TN}}{\boldsymbol{TP+TN+FP+FN}} \quad (6)$$

2) Recall: This parameter refers to the ability of the model to predict positive samples. This is calculated by dividing the number of samples that are categorized as true positive overall positive samples. The formula for calculating this metric is given in Eq. (7).

$$\boldsymbol{Recall} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FN}} \quad (7)$$

3) Precision: In this parameter, true positive identified the number of samples over several samples that are predicted as positive. Eq. (8) calculates the precision.

$$\boldsymbol{Precision} = \frac{\boldsymbol{TP}}{\boldsymbol{TP+FP}} \quad (8)$$

4) F1_score: In this parameter, the recall and precision are combined into a single metric. This is called the harmonic mean of recall and precision. Eq. (9) calculates the F1_score.

$$\boldsymbol{F1\_score} = \frac{\boldsymbol{2\times Precision\times Recall}}{\boldsymbol{Precision+Recall}} \quad (9)$$

5) Matthews correlation coefficient (MCC): This performance parameter is considered the best metric for binary classification. It combines all parts of the confusion matrix. The equation for calculating this metric is given in Eq. (10).

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(TP+FP) \times (TP+FN) \times (TN+FP) \times (TN+FN)}} \quad (10)$$

D. Model Training

While training the models, various ML Models have been considered on encoded information generated from auto-encoder. K-Nearest Neighbor (KNN) has been shortlisted from various models. The parameters for selecting this model were its applicability in classifying the tasks.

Algorithm 1: Machine Learning Model for Predictions

```
Initialize (train_set, validate_set)
Step 1: Import K-Nearest Neighbor (KNN) instances from the scikit-learn library
Step 2:
    If (train_set: == X_train_encoded) then
        Train model on X_Train_Encoded
    Else
        Train model on X_Train_Augmented
    End
Step 3: Predict the imported models on Validate_Set
Step 4: Evaluate the models on the following performance metrics
    a. Accuracy
    b. Precision
    c. Recall
    d. F1 score
    e. MCC
Step 5: Export the performance metrics in the CSV file
End
```

The machine learning model can be categorized into two stages. First is training of the model and second is validation of the model. The step-by-step processing of the research algorithm is presented in Algorithm 1. This algorithm gives a method for comparing the accuracy of the models and various parameters for evaluation using the encoded validation dataset to assess the possibility of identifying cyber-attacks.

K-Nearest Neighbor (KNN) ML model is used in this research. KKN Algorithm is known for its simplicity and instance-based machine learning which makes it suitable for tasks like classification and regression. This algorithm operates in a manner that compares a new data point with its nearest neighbors in the featured space. The "K" is the number of considerable neighbors. The label of the new point is determined by classifying the most common class from corresponding K neighbors. Regression is achieved by averaging the neighbors' values that are used to predict the output.

Another reason for using KNN was its non-parametric feature. In this feature, assumptions were not made regarding data distribution. The other features of this model like simplicity and effectiveness for handling non-linear relationships make this algorithm the most suitable choice for tasks like pattern recognition, recommendation systems, and anomaly detection. However, the performance of KNN depends on the selection of K and the distance metric (e.g., Euclidean, Manhattan), along with the size and quality of the dataset.

E. WGAN-GP Augmented Data Training and Validation

The blending of WGAN-GP synthesized data with the NSL-KDD dataset [30], poses a great impact on the performance of the model. The model training starts with the preprocessing of raw datasets, which is the most important process that ensures that the data is ready for model training. Also, further processes like imputation, scaling, and encoding were performed on the augmented data.

After the completion of preprocessing on augmented data, the next step was to update of machine learning model. The subset of the model used in the training process is replicated for the update process. The training of the model was performed on the same metrics used in the dataset training process. Those are accuracy, precision, recall, F1-score, and Mathews Correlation Coefficient (MCC). Using these metrics, performance was assessed after training the model.

Once the KNN model training is completed, the next step is to apply the trained model to encoded validation data. The metrics for analyzing the performance are the same as in previous steps. The use of the validation model trained from the WGAN-GP augmented dataset is the most important factor in assessing the generalization capabilities of the trained model from the augmented datasets.

By observing the performance of the model on the validation dataset, the quality of the synthetic dataset was accounted for.

IV. Experimental Results and Discussion

Table II shows the performance evaluation of the trained model with original data and augmented data. The datasets were evaluated on five performance metrics as described in Algorithm 1 step 4. The values of performance parameters present significant and effective results. These results can be used to draw a meaningful conclusion.

On the original dataset, the provided metrics reflect the mixed performance of the model. 64.77% of accuracy specifies the classification of the instances in the model is an average of two-thirds. Nevertheless, considering accuracy alone can mislead, especially while dealing with imbalanced datasets. The precision value of 0.7376 depicts that the prediction of a positive outcome by the model is 73.76% correct, resulting in a reduced false positive rate. As far as recall is considered, the 0.6477 value highlights the capturing of actual positive cases by the model up to 64.77%, leaving a significant number of false negatives. The F1 score, which provides a balanced measure between precision and recall, with 0.5594, reflects an imbalance relation between these two metrics. This reflects the struggle of the model to maintain an optimal trade-off between precision and recall. Moreover, MCC which covers all aspects of the confusion matrix, is 0.26467. This depicts the model has limitations in prediction, performing slightly better than random guessing.

With an augmented dataset, the performance metrics show variable performance for various hyper-parameter configurations. These performances are presented in the form of graphs in Fig. 2 to 6. Instance X1 provides average recall at 59.11%, but looking at precision (45.12%) and F1 score (44.69%) gives a high false positive rate, whereas negative MCC (-0.0328) means that the performance of the model is overall weak. On the other hand, instance X2 results as the most improved, enhanced, and efficient model. The highest level of accuracy (79.74%), precision (0.8352), recall (0.7974), and F1

score (0.7988) having the strongest MCC (0.6297), depicts the overall best performance providing balanced and reliable predictions. X3 performance is considered to be an average performance having an accuracy of 60.21%, precision at 0.5895, and recall at 0.6021. However, lower F1_score (0.4886) and MCC (0.0722) show that there is room for improvement.

By analyzing the provided parameters of X4, the performance of the model seems to be poor with an accuracy of 38.21%, precision at 0.3656, and recall at 0.3821. The results of F1_score (0.3728) and negative MCC (-0.3152), indicate the predictions very near to random guessing. The worst performance results can be seen in the X5 instance with very low accuracy (13.09%), precision of 0.1489, and recall (0.1309). The F1_score (0.1373) and highly negative MCC (-0.7379) show extremely unreliable predictions. The X6 instance results same as X1 depicting average recall (0.5899), low precision (0.4625), F1 score of 0.4485, and nearly zero MCC (-0.0321), indicating poor predictive power.

In a nutshell, instance X2 is considered to be the most significant as compared to other hyper-parameter configurations providing a strong balance between precision and recall. X1 and X6 can be considered as average while, X4 and X5 require major improvements.

TABLE II. OVERALL PERFORMANCE OF DIFFERENT HYPER-PARAMETERS WITH KNN AS A CLASSIFIER

Instance	Data Model	Hyper-Parameter Configuration				
		Accuracy	Precision	Recall	F1 Score	MCC
Original Dataset	Original Dataset	64.77%	0.737635	0.647655	0.559395	0.264674
X1	Augmented Dataset	59.11%	0.451186	0.591118	0.446918	-0.03282
X2		79.74%	0.835227	0.797432	0.798767	0.62967
X3		60.21%	0.589498	0.60214	0.488586	0.072174
X4		38.21%	0.365578	0.382094	0.372804	-0.31518
X5		13.09%	0.148879	0.130908	0.137281	-0.73789
X6		58.99%	0.462506	0.589905	0.44854	-0.03214

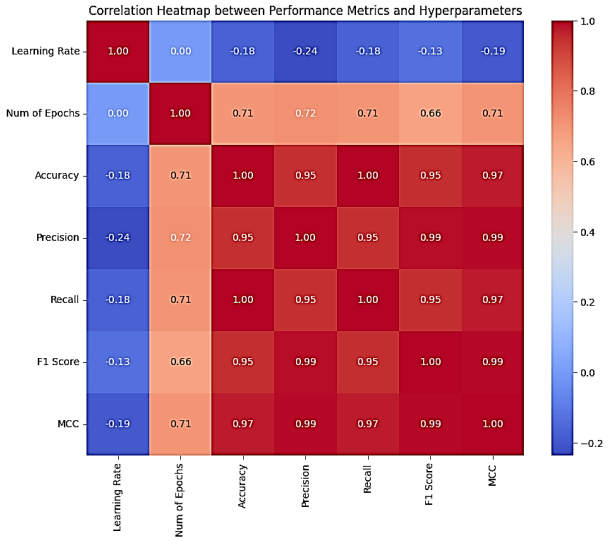

Fig. 8. Correlation heatmap between performance metrics and hyperparameters.

V. Conclusion

The performance analysis of KNN using various hyper-parameter configurations shows unique trends in deciding which configuration is suitable for enhanced performance of machine learning classifier. KNN was found to be more sensitive in selecting hyper-parameters, resulting in great variability, with some configurations resulting in poor performance. Dataset augmentation improves performance in general. However, it is essential to how hyper-parameter values are combined. The optimistic combination of hyper-parameter values for data augmentation will leverage the performance of the machine learning algorithm. Also, from the graphs shown in Fig. 2 to 6, it can be concluded that the increment in epoch value increases the chance of performance as compared to lower epoch values. By analyzing the heat map correlation matrix in Fig. 7 and 8, a value of 0.7 implies a strong positive correlation between the two variables. This concludes that variables have a direct relationship: as one variable increases, the other tends to increase as well.

The research in this paper presents a focused approach to enhancing the capabilities of Network Intrusion Detection Systems (NIDS) through improvement in learning capacity using advanced generative methods like WGAN-GP for augmentation of the dataset. In addition, resource-constrained environments can be considered for future experiments that will help in determining the practical implementation of these techniques in real-time IoT-based applications. Future enhancement of this research can be done by comparing different augmentation techniques on diversified datasets that will enhance the adaptability and robustness of NIDS.

***Abstract*—In today's competitive business environment, understanding customers' expectations and choices is a necessity for the successful operations of a retail store. Forecasting demand also plays an important role in maintaining inventory at an optimum level. The work utilises data analytics for product segmentation and demand forecasting in a local retail store. Python is being used as a programming language for data analytics. Historical sales data of a local store has been used to categorise products into different segments. Statistical techniques and a k-means clustering algorithm have been used to understand different segments of the product. Machine learning algorithms and time series models have been used to forecast future sales trends. The business insights allow the retail store to meet customers' expectations, manage inventory at an optimum level and enhance supply chain efficiency. The present work seeks to illustrate how data-driven tactics can enhance operational decision-making in retail.**

***Keywords*—Data analytics; product segmentation; demand forecasting; multicriteria ABC classification; seasonality**

I. Introduction

To ensure business growth and maintain operational efficiency, understanding customer choices and forecasting demand for various products have become important in the current competitive retail environment. The problems a local retail store faces include but are not limited to inventory management, optimisation of sales strategy and fulfilling customers' expectations in changing market trends. In this scenario, product segmentation and demand forecasting help overcome these hurdles to run a successful business.

Based on common characteristics such as sales performance, revenue generation, demand trends and consumer preferences, products are classified into different groups. This process is nothing but product segmentation. It helps retailers customise marketing strategies, optimise inventory, and enhance overall resource allocation. Previous sales data is utilised to predict future demand trends in demand forecasting. It helps retailers make proactive decisions in procurement, inventory management, and supply chain operations.

Python, an object-oriented programming language, provides a rich set of libraries and tools for data analytics. Python provides extensive solutions for addressing intricate retail difficulties, encompassing data pre-treatment, visualisation, machine learning, and time series modelling. Pandas, NumPy, Scikit-learn, and Prophet are particularly adept at product clustering, trend analysis, and prediction modelling.

This article examines the utilisation of Python-based data analytics methods for efficient product segmentation and demand forecasting in a small retail establishment. The study seeks to analyse previous sales data to Determine specific product segments for focused marketing and inventory approaches and construct predictive models to anticipate future demand, reducing stockouts and excess inventory.

This study's findings emphasise that data-driven techniques can enhance decision-making processes in retail, resulting in greater efficiency, customer satisfaction, and profitability.

II. Literature Review

Generally, uniform control measures for all inventory products are inadvisable. The high-value items may be essential to the viability of the firm. The study in [1] talked about ABC and multicriteria ABC analysis. In ABC analysis, products are classified into three classes: A, B and C. Class A items entail significant stock-out expenses and necessitate stringent control measures. It emphasised that multicriteria ABC analysis was crucial for comprehending different product categories: volume drivers, margin drivers, regular movers, and slow movers. In multicriteria analysis, categories A_B and A_C denote volume driver items, B_A and C_A indicate margin driver items, categories B_B, B_C, and C_B imply regular items, category C_C reveals slow-moving items, and A_A encompasses both margin and volume driver items. The research performed multicriteria ABC analysis on the online retail dataset utilising data analytics methodologies. The study in [2] proposed using a three-phased Multi-Criteria Inventory Classification (MCIC) integrating the Analytical Hierarchy Process (AHP), Fuzzy C-Means (FCM) algorithm, and a newly proposed Revised-Veto (RVeto) phase to adhere to the ABC Classification principles and enhance its application and adaptability. Classification based on several criteria is essential to meeting management's needs in the current context. The study in [3] presented a semi-supervised explainable methodology that integrated semi-supervised clustering with explainable artificial intelligence. The semi-supervised method integrated intelligent initialisation with a constrained clustering process that directed the classification procedure towards Pareto-distributed items. At the

same time, explainable artificial intelligence was employed to generate comprehensive micro and macro explanations of inventory categories at both the item and class levels. Implementing the suggested method for the automatic classification of chemical items within a distribution organisation has demonstrated its efficacy in delivering precise, transparent, and thoroughly elucidated ABC classifications. The study in [4] presented an optimal multi-criteria ABC inventory classification for supermarkets to manage commodities based on unit price, lead time, and annual usage. Of the 442 objects, 30 were categorised as group "A," 31 as group "B," and 27 as group "C" under the new ABC classification; nevertheless, all these things were categorised in group "A" in the conventional ABC classification. The study in [5] indicated that AI-based methods exhibited more accuracy than multiple discriminant analysis (MDA). The statistical study specified that SVM facilitated superior classification accuracy compared to alternative AI methodologies. This discovery indicated the potential for employing AI-driven methodologies for multi-criteria ABC analysis within enterprise resource planning (ERP) systems. The study in [6] aimed to present a case-based multiple-criteria ABC analysis that enhances the traditional method by incorporating other factors, such as lead time and SKU criticality. It offered greater managerial flexibility. Decisions from instances served as input, with preferences for alternatives represented naturally using weighted Euclidean distances. It facilitated easy understanding for the decision-maker. The study in [7] examined current portfolio models in procurement that categorise purchases into several product classifications. Case studies from two European automotive OEMs and two vehicle industry suppliers and benchmarking interviews at Toyota, Japan, were used to establish a connection between these product categories and various supplier types. Further, it tried correlating the product categories and supplier types with the specification process—specifically, associating the specification types with their respective generators. The study in [8] conducted supplier segmentation within the automobile sector and proposed four techniques for supplier relationships. Additionally, a four-phase approach for analysing, selecting, and managing decisions on a dynamic relationship strategy with suppliers in the automotive sector was delineated. The study in [9] reviewed the available literature, focusing on market conditions, supplier characteristics, buyer characteristics, and the connections between buyers and suppliers. The study in [10] formulated an innovative methodology for supplier segmentation. Fuzzy logic was utilised to divide suppliers in a broiler firm.

The study in [11] performed a comparative analysis of machine learning algorithms for demand forecasting under uncertainty. The research utilised a synthetic dataset. The machine learning algorithms compared were Linear Regression, Decision Tree Regression, Random Forest Regression, Support Vector Machine Regression (SVR), XG Boost Regression on the parameters of Mean Absolute Error (MAE), Mean Squared Error (MSE) and Root Mean Squared Error (RMSE). The study in [12] proposed a model that integrated time series analysis, boosting and deep learning for demand forecasting. It achieved a significant enhancement in accuracy relative to state-of-the-art studies. The testing utilised authentic data from Turkey's SOK Market. The article compared the Decision Tree Classifier, Gaussian Naive Bayes, and K-Nearest Neighbours (KNN). The Gaussian Naive Bayes technique exhibited the greatest accuracy in demand estimation. The study in [13] focused on demand forecasting and consumer satisfaction within the retail sector. It emphasised the importance of precise demand estimation for merchants. The discussion encompassed machine learning methodologies for forecasting product demand. The paper considered variables for prediction, including time, location, and historical data.

III. Present Work

In this paper, product segmentation was performed using ABC and Multicriteria ABC analysis. First, data was collected, and then it was prepared for the segmentation exercise. Then, segmentation was performed using Python's inventorize package. After that, classification algorithms were applied to it, and performance was evaluated. The flow of work is shown in Fig. 1.

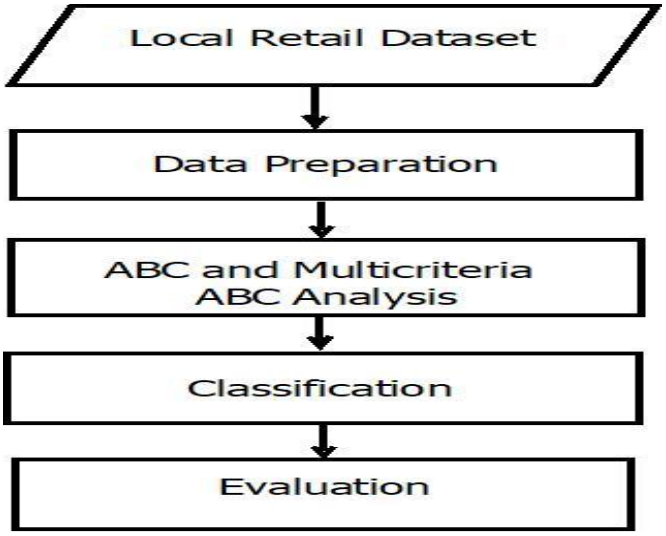

Fig. 1. Workflow for product segmentation.

The same dataset was analysed for demand trends, and a comparative analysis of different machine learning algorithms was done to forecast the demand for A-class products. Fig. 2 shows the workflow for this.

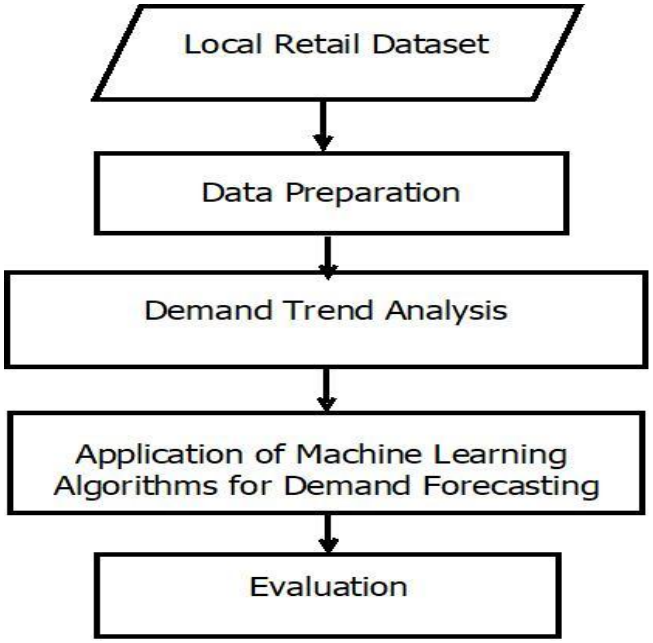

Fig. 2. Workflow for demand trend analysis and forecasting.

Two years monthly sales data of a local retail store situated at Hazaribag was captured and stored in a file named 'Sales_data.xlsx'. The dataset sample is displayed in Fig. 3.

Fig. 3. Local retail dataset sample.

The dataset has five columns: 'Month', 'SKU', 'Quantity', 'Price', and 'Revenue'. It has 4339 records and was analysed for null values and duplicates. After removing records with null values and eliminating duplicates, the dataset comprised 4089 rows. It was further analysed for quantity value. Only those records were kept in which the quantity value was greater than 0. For analysis purposes, one new column, 'Date', was added using the column 'Month', converting it to a datetime object and dropping it for further analysis. Fig. 4. shows the sample prepared dataset. The pertinent columns of the dataset, namely 'SKU', 'Quantity', and 'Revenue', were retained for ABC and multicriteria ABC analysis. Additionally, data was consolidated according to 'SKU'.

Fig. 4. Sample local retail dataset.

The inventorize module in Python was utilised to conduct an ABC analysis based on volume. Further, the ABC analysis was performed on revenue. After that, multicriteria analysis based on 'Revenue' and 'Quantity' was performed on the dataset. The dataset obtained after this analysis was used to perform a comparative study of machine learning algorithms viz. KNN, Decision Tree, Random Forest and Naïve Bayes algorithm for classification. The product mix categorisation was treated as the labelled output, while the rest of the columns were used as the basis for classification. First of all, data was split into training and test data. The test size of the data was kept at 20% of the total data. The models were trained and then tested. Confusion matrices were plotted for each model, and accuracy scores were calculated.

As shown in Fig. 4, the prepared dataset was used to understand the demand trend. A graph was plotted for monthly sales over time to know monthly sales trends. Seasonal decomposition was performed to learn more about seasonality trends, and a graph was plotted. Further analysis was carried out to compare machine learning algorithms, viz. Linear regression, Decision tree, Random forest, SVR and XG Boost regressor for demand forecasting of class A items of local retail store. Next, demand forecasting was performed using the said machine learning algorithms. The dataset was split into train and test data with 20% data size. A comparison of predictions was done for all these items. The performance metrics included MAE, MSE and RMSE. To visualise the results in a single frame, grouped bar graphs were plotted for MAE, MSE, and RMSE. Then, the graph was plotted to visualise the comparative performance of the machine learning algorithm in this study.

IV. Results and Discussions

The result counts of ABC analysis on volume and revenue are displayed in Fig. 5 and Fig. 6, respectively.

Then, multicriteria analysis based on 'Revenue' and 'Quantity' was performed on the dataset. Fig. 7 displays the product mix count.

The dataset obtained after this analysis was used to perform a comparative study of machine learning algorithms, viz., KNN, Decision Tree, Random Forest, and Naïve Bayes algorithm for classification. Fig. 8 shows the confusion matrices for these algorithms.

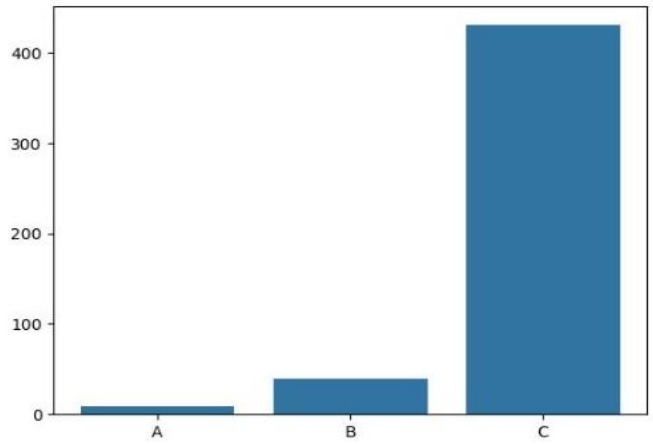

Fig. 5. ABC Count by volume.

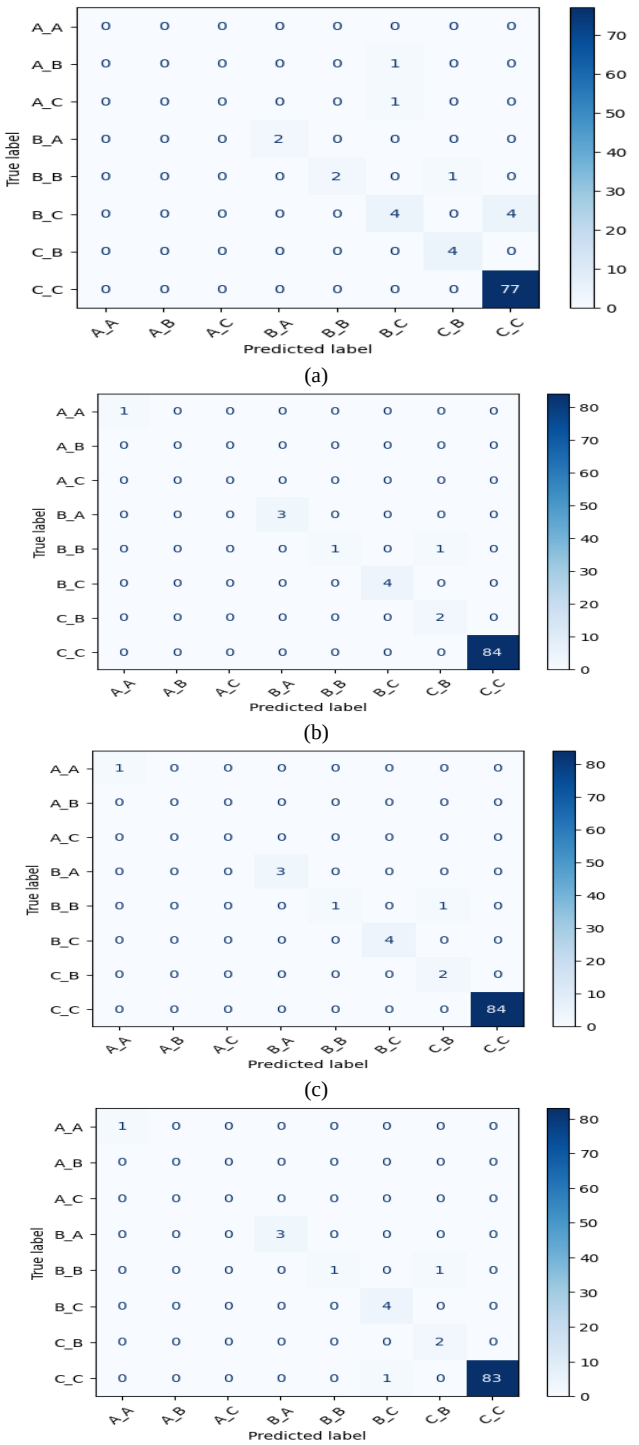

Fig. 8. Confusion matrix (a) KNN (b) Decision Tree (c) Random Forest and (d) Naïve Bayes classification algorithms.

The comparative chart for the accuracy scores has been displayed in Fig. 9.

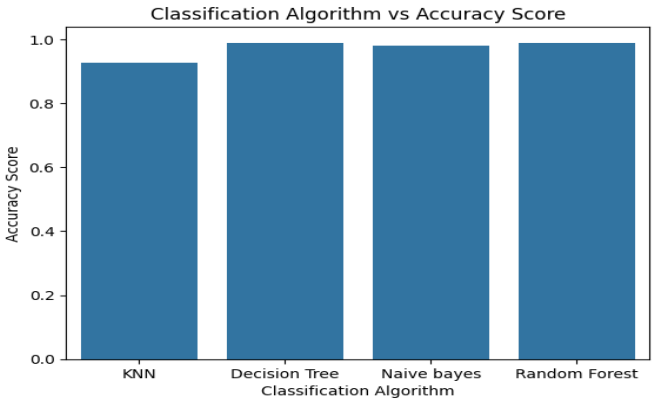

Fig. 9. Accuracy scores comparison for classification.

Decision Tree and Random Forest classification algorithms with identical accuracy scores outperformed KNN and Naïve Bayes algorithms.

Next, a graph plotting monthly sales over time shows monthly sales trends. Fig. 10 displays the seasonal decomposition for the same.

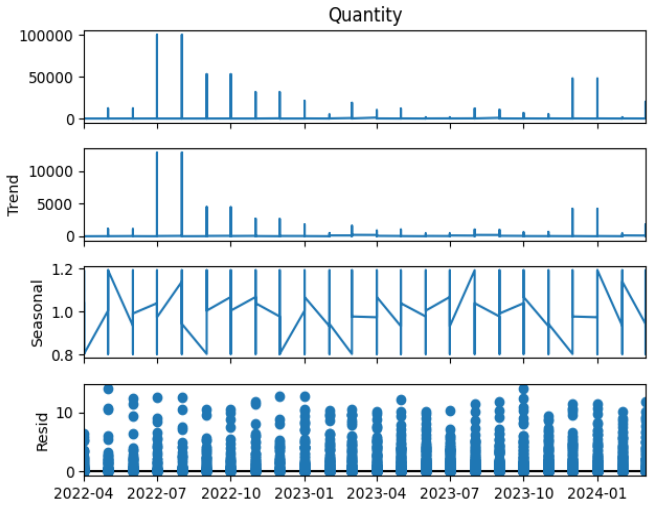

Fig. 10. Seasonality trend for monthly sales data.

There are irregular spikes in this plot, suggesting an occasional high level of demand at irregular periods. It is clear from the trend plot that there is variability in the dataset. It indicates that the variability is inconsistent enough to make an upward or downward trend over time. The seasonal component of the graph indicates a continuous seasonal influence. However, that influence is very thin. It is shown by minor variations in numbers within a recurring period. The residuals in the plot are scattered, showing greater fluctuations during instances of spikes in the data. It suggests that the spikes may not be described by the trend or seasonality. Further analysis was carried out to compare machine learning algorithms, viz. Linear regression, Decision tree, Random Forest, SVR and XG Boost regressor for demand forecasting of class A items of local retail store. Fig. 11 shows the demand pattern for these items.

Fig. 11. Demand pattern for (a) Printed Matter 18% (b) Printed Matter 12% (c) Printing Job Work (d) PEN (e) Envelope (f) Paper (g) Envelopes (h) Letter Head (i) Hard Bord Kut.

Demand for these products was forecasted using machine learning algorithms, and MAE, MSE, and RMSE were calculated. To visualise the results in a single frame, grouped bar graphs have been plotted for MAE, MSE, and RMSE, as shown in Fig. 12, 13, and 14, respectively.

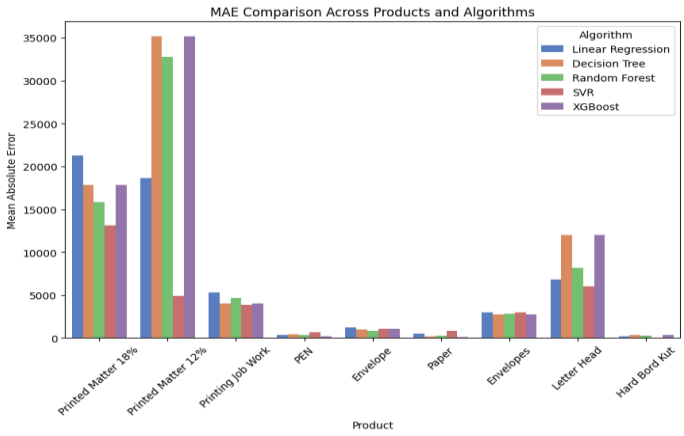

Fig. 12. Comparative performance of machine learning algorithms based on MAE for all class 'A' items.

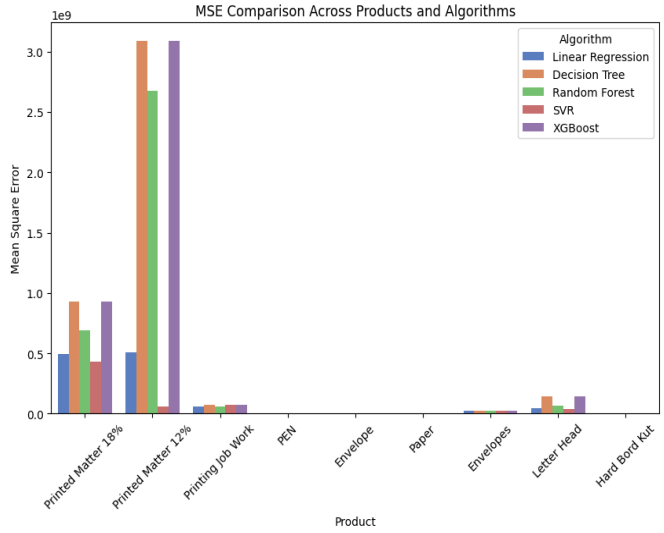

Fig. 13. Comparative performance of machine learning algorithms based on MSE for all class 'A' items.

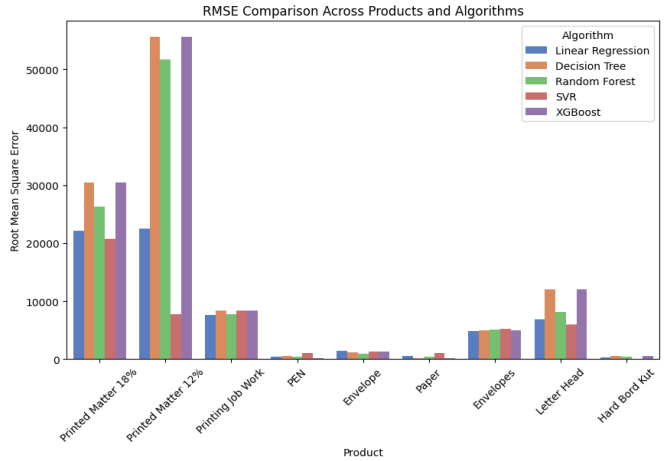

Fig. 14. Comparative performance of machine learning algorithms based on RMSE for all class 'A' items.

Fig. 15 shows the comparative performance of the machine learning algorithm compared in this study.

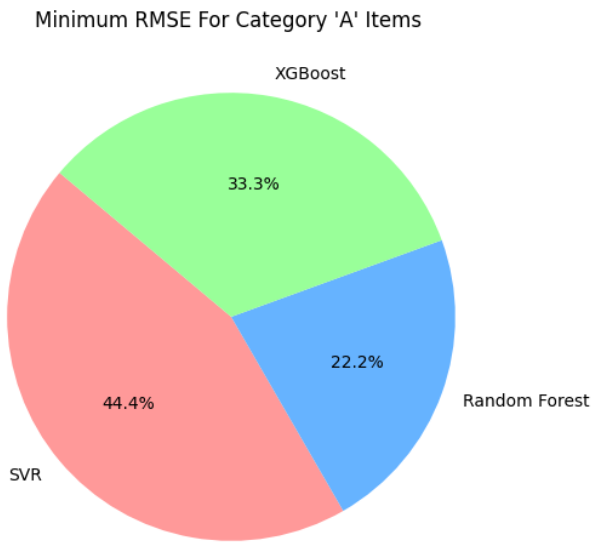

Fig. 15. Comparative analysis of best-performing machine learning algorithms for demand forecasting.

It can be seen that SVR outperformed other algorithms for 44.4% of class A items, XGBoost performed better than other algorithms for 33.3% of items, and Random Forest outperformed other algorithms for 22.2% of class A items.

V. Conclusion

Given that clients seek a diverse range of products while desiring more excellent value for their expenditure, it is imperative to comprehend the several categories of products, including volume drivers, margin drivers, and frequent and slow movers. Multi-criteria ABC analysis serves as an effective tool for conducting this segmentation. This study aims to evaluate the efficacy of classification algorithms in conducting multi-criteria ABC analysis on a retail dataset. Products have been classified based on 'Quantity' and 'Revenue' parameters into A_A, B_A, C_B, B_B, A_B, C_C, A_C and B_C categories. In the contemporary internet company landscape, categorising products and locating providers of vital commodities has become crucial for business viability. Consequently, strategic collaborations may be established for commodities that generate volume and margin. The 'inventorize' module was an effective Python tool for conducting multi-criteria analysis based on quantity and income. It may assist in determining the critical elements to retain. The results indicate that, among the classification algorithms evaluated based on accuracy score, Random Forest and Decision Tree Classifier exhibited comparable performance. Further, a data-driven approach was applied to identify demand trend analysis and demand forecasting on class A items of a local retail store. Machine learning algorithms were also compared to forecast these items. SVR outperformed other algorithms for nearly half of the products in this respect.

YOLOv7-b: An Enhanced Object Detection Model for Multi-Scale and Dense Target Recognition in Remote Sensing Images

Yulong Song, Hao Yang, Lijun Huang, Song Huang
School of Computer and Artificial Intelligence, Beijing Technology and Business University, Beijing 100048, China

***Abstract*—To address the challenges of dense object distribution, scale variability, and complex shapes in remote sensing images, this paper proposes an improved YOLOv7-b model to enhance multi-scale target detection accuracy and robustness. First, deformable convolution (DCNv2) is introduced into the YOLOv7 backbone to replace the standard convolutions in the last two ELAN modules, thereby providing more flexible sampling capabilities and improving adaptability to irregularly shaped targets. Next, a Bi-level Routing Attention (BRA) module is integrated after the SPPCSPC module, employing both coarse- and fine-grained routing strategies to focus on densely distributed targets while suppressing irrelevant background. Finally, training and evaluation are conducted on the large-scale DIOR remote sensing dataset under unified hyperparameter settings and evaluation metrics, allowing a systematic assessment of the overall model performance. Experimental results show that, compared with the original YOLOv7, the improved YOLOv7-b achieves significant enhancements in Precision, Recall, mAP@0.5, and mAP@0.5:0.95, with mAP@0.5 and mAP@0.5:0.95 reaching 85.72% and 66.55%, respectively. Visualization further demonstrates that YOLOv7-b provides stronger recognition and localization for densely arranged, small-scale, and morphologically complex targets, effectively reducing missed and false detections. Overall, YOLOv7-b delivers higher detection accuracy and robustness in multi-scale remote sensing target detection. By combining deformable convolution with a dynamic sparse attention mechanism, the model excels in detecting highly deformable objects and dense scenes, offering a more adaptive and accurate solution for small-target detection, dense target recognition, and multi-scale detection in remote sensing imagery.**

I. INTRODUCTION

Optical remote sensing images [1] are typically captured by satellites or high-altitude aircraft from a nadir viewing angle. Compared with ground-based images, they exhibit significant differences in imaging modes and resolutions. With the rapid development of remote sensing technology and the continuous improvement of imaging accuracy, these images have demonstrated broad application prospects in fields such as military reconnaissance, disaster assessment, environmental monitoring, and urban planning [2] [3]. However, multi-scale remote sensing images often face challenges such as large target scale variations, complex deformations, and severe background noise, which pose higher requirements for the accuracy and robustness of target detection algorithms [4] [5].

Traditional remote sensing image object detection methods encompass template matching [6], shape and texture-based approaches [7], segmentation-based techniques [8], and visual saliency-based methods [9]. These typically rely on predefined rules or object shapes for recognition after feature extraction or segmentation [10] [11] [12]. While effective in specific scenarios, they struggle with the diverse appearances of objects in complex backgrounds and numerous types in remote sensing images. Additionally, these methods are susceptible to noise and occlusion, limiting their applicability in large-scale and multi-scenario contexts.

In recent years, deep learning techniques have been extensively utilized in remote sensing image object detection due to their powerful feature learning capabilities [13] [14] [15]. Object detection algorithms can be divided into two-stage detectors (e.g., Faster R-CNN, Mask R-CNN) and one-stage detectors (e.g., YOLO series, SSD, FCOS) based on whether candidate regions are generated. One-stage detectors, which offer faster inference speed and lower computational cost, are more suitable for remote sensing scenarios with high real-time requirements, while two-stage detectors generally achieve higher accuracy at the cost of greater computational overhead [10]. Overall, the end-to-end training paradigm of deep learning is more adaptable to the diverse target distribution characteristics of remote sensing images, enabling a single model to detect multiple types of objects across different scenarios.

Against this backdrop, various improved algorithms have emerged to enhance the accuracy and efficiency of object detection in multi-scale remote sensing images. For instance, Azimi et al. proposed a method combining joint image cascading and feature pyramid networks, using multi-scale convolutional kernels to extract features at different scales and achieving significant accuracy improvements on the DOTA dataset [16]. Deng et al. redesigned the Faster R-CNN architecture by integrating a multi-scale target generation network and a feature fusion module, demonstrating excellent performance on the NWPU VHR-10 and SAR-Ship datasets [17]. Liu et al. introduced an adaptive multi-scale feature enhancement and fusion module, which notably improved detection accuracy on the DOTA and HRSC2016 datasets [18].

For small target detection, Liu et al. enhanced YOLOv2 using a feature-map concatenation strategy to improve detection performance on small-scale targets [19]. Chen et al. proposed a multi-scale spatial and channel attention mechanism to enable

deep neural networks to focus more accurately on key target regions [20]. Ying et al. combined multi-scale convolutional kernels with attention mechanisms to significantly improve detection precision for small targets in complex backgrounds [21]. Additionally, Li et al. developed a fast detection method based on YOLOv3, achieving 93.5% accuracy in multi-scale target detection for high-resolution remote sensing images [22]. Zhang et al. introduced a Dual Multi-Scale Feature Pyramid Network (DM-FPN) tailored for small and densely distributed targets, yielding notable results on the DOTA dataset [23]. Meanwhile, Cheng et al. integrated multi-feature fusion with an attention mechanism in MFANet to achieve high detection accuracy across multiple public datasets [24].

Despite advances in remote sensing image detection, three key challenges remain. First, dense target packing leads to excessive suppression of detection boxes during Non-Maximum Suppression (NMS), causing significant missed detections. This requires better integration of multi-level semantics and contextual information to reduce false suppression from overlapping boxes. Second, objects with large scale differences, such as small vehicles and large facilities in the same image, often result in occlusion of smaller objects by larger ones, exacerbated by limited network focusing and localization capabilities. Lastly, high-altitude imaging results in small targets occupying only a few pixels, increasing the proportion of small targets and the likelihood of missed detections. This necessitates enhanced small-target detection and recognition.

The different comparative results observed across datasets primarily stem from variations in dataset characteristics, including target scale distribution, class imbalance, background complexity, and annotation quality. In remote sensing object detection tasks, the arrangement of objects, morphological variations, and the degree of scene interference significantly impact the performance of detection algorithms. For example, in densely arranged object scenarios, the BRA module's dynamic attention mechanism effectively separates foreground and background information, thereby improving detection accuracy. Meanwhile, in datasets with highly deformed objects, the adaptive sampling mechanism of DCNv2 enhances the model's ability to accommodate geometric deformations, improving target localization precision. As a result, the proposed algorithm tends to perform better on datasets that contain complex deformations and densely packed objects, whereas its performance gain over standard YOLOv7 might be relatively limited on simpler datasets with more uniform target scales and fewer background distractions. Experimental results also indicate that the proposed method achieves a more significant improvement on complex multi-scale datasets such as DIOR compared to certain simpler datasets, further validating its effectiveness in handling challenging remote sensing object detection tasks. Future research can further explore the adaptability of this method across different types of remote sensing datasets and optimize its generalization capability to ensure stable detection performance in diverse scenarios.

To address these challenges, this paper proposes a multi-scale remote sensing image detection approach named YOLOv7-b. It integrates Deformable Convolution (DCNv2) and Bi-level Routing Attention (BRA) into the YOLOv7 framework. Specifically, YOLOv7-b incorporates Efficient Layer Aggregation Network structures (ELAN and E-ELAN) into the backbone to efficiently train deeper networks by managing gradient paths. DCNv2 is employed to capture deformed targets, addressing issues such as scale variability, viewpoint changes, and local deformations. Additionally, the BRA module is inserted at the feature-fusion stage to enhance attention on densely distributed targets and salient features, significantly reducing missed detections in high-density scenes—a common weakness in conventional detectors.

To validate the proposed algorithm, experiments were conducted on the DIOR dataset, which features high resolution, diverse target categories, and wide scene coverage. Results show that YOLOv7-b significantly enhances detection accuracy and inference speed, especially for dense targets like vehicles and ships. Additionally, the model's localization performance was analyzed across various IoU thresholds and compared extensively with the original YOLOv7. The findings indicate that integrating DCNv2 and BRA modules effectively improves the network's feature extraction and dense-target recognition capabilities.

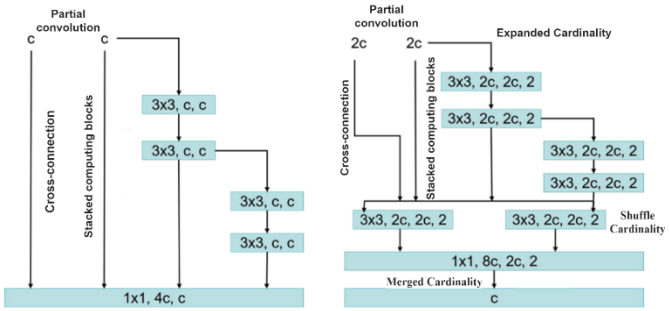
This paper enhances the YOLOv7 architecture with several significant advancements in object detection. The authors integrate Deformable Convolution (DCNv2) into the YOLOv7 backbone to improve feature representation for deformed and multi-scale targets using adaptive offsets and modulation. Additionally, the Bi-level Routing Attention (BRA) module is introduced to address dense target interference and enhance focus on key regions through a sparse attention mechanism. Extensive experiments on the DIOR remote sensing image dataset show that the proposed YOLOv7-b model achieves superior accuracy for multi-scale, high-density, and deformed targets while maintaining high inference speed. These results highlight the model's practical value and potential for real-world applications.

The remainder of this paper is organized as follows: Section II describes the materials and methods, detailing the improved model architecture and experimental setup. Section III presents the experimental results and analysis, including ablation and comparative studies that validate the effectiveness of each module. Section IV summarizes the main findings and contributions, and discusses future work. We hope this research provides valuable insights for remote sensing image target detection and promotes broader applicability in this field.

II. Materials and Methods

A. Model Construction and Improvement

1) Adaptive backbone network: The backbone network of YOLOv7 introduces an efficient layer aggregation structure based on ELAN and E-ELAN. By meticulously controlling the shortest and longest gradient propagation paths within the network, it enables deeper models to learn and converge effectively. The overall framework is shown in Fig. 1.



(a) ELAN (b)E-ELAN

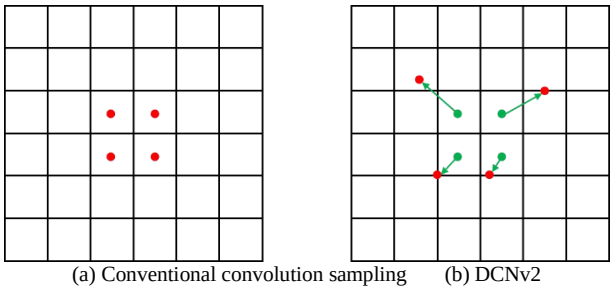
Fig. 1. The structural diagrams of ELAN and E-ELAN.

As can be observed from the figure, the ELAN module employs a gradient path design strategy, which offers multiple advantages. Firstly, adjusting the gradient propagation paths allows the weights of each computational unit to acquire diverse information, thereby achieving higher parameter utilization efficiency. Secondly, since the gradient path directly determines the mode of information transfer and is applied to the weight update process of each computational unit, this strategy ensures that the model maintains a stable learning capability during training and effectively circumvents common degradation issues. Moreover, efficient parameter utilization enables the network to achieve faster inference speeds without the need for additional complex structures, while simultaneously maintaining a high level of accuracy.

However, in larger-scale applications, if computational blocks are stacked without limitation, ELAN can maintain a stable state even under different gradient path lengths or numbers of computational blocks. However, this stability may be broken in extreme stacking situations, thereby leading to a decrease in the efficiency of parameter utilization. To address this issue, researchers further proposed the E-ELAN module, which enhanced the network capability of ELAN through means such as expansion, shuffling, and merging cardinality. It is worth noting that E-ELAN only optimized the internal architecture of the computational blocks, while the structure of the transition layer remained unchanged.

Specifically, E-ELAN increases the number of network channels and the cardinality of computational blocks based on group convolution, and ensures that all computational blocks adopt the same group parameters and channel multipliers. Subsequently, the network shuffles and reassembles the feature maps output by the computational blocks according to the group parameter g, so that the number of channels in the feature maps within each group remains consistent with the initial structure. Finally, the network performs a summation operation on the features of these g groups to obtain the final output feature map. This improvement not only enhances the network's ability to express features, but also maintains efficient parameter utilization.

2) Introduction and improvement of deformable convolutions: One of the key challenges faced in the task of multi-scale remote sensing image detection is the geometric deformation caused by factors such as scale variation, pose variation, and local deformation of objects. To effectively address this issue, Deformable Convolutional Networks (DCNs) introduce learnable offsets on the basis of the standard grid sampling of conventional convolutions, enabling the network to adaptively locate according to the actual shape of the object, thereby significantly improving detection accuracy in object detection tasks. However, DCNs have a fatal problem: while expanding the region of interest, they also include irrelevant areas, thereby weakening the network performance. To solve this problem, the optimized version DCNv2 further enhances the modeling capability of deformable convolution from two aspects. First, by expanding the sampling range of deformable convolution, sampling is allowed in a larger area, thereby improving the ability to learn offsets. Second, a "modulation mechanism" is introduced, which requires each sample not only to learn the offset but also to learn the feature amplitude, thereby flexibly adjusting the network's spatial distribution and the degree of attention to different samples. Fig. 2 shows the difference between the sampling points of ordinary convolution and the sampling points of DCNv2 after the introduction of the modulation mechanism.



(a) Conventional convolution sampling (b) DCNv2

Fig. 2. Comparison of new ordinary convolution sampling and DCNv2 sampling.

Under the action of the modulation mechanism, the deformable network module can not only dynamically adjust the offset of the perceived input features, but also regulate the amplitude of the input features from different spatial locations. In extreme cases, the network module can even set the feature amplitude to zero, thereby completely ignoring the signals from a specific location; this means that the image content from that location will have a significantly weakened or even vanished impact on the network output. Overall, the modulation mechanism provides the network module with additional degrees of freedom, enabling it to better adaptively adjust within the spatial range. Taking the convolution kernel operating on K sampling points as an example, let w_k and p_k represent the feature values of the input feature map x and the output feature map y at position p, then the modulated deformable convolution can be expressed as Eq. (1).

$$y(p) = \sum_{K=1}^{K} w_k \cdot x(p + p_k + \Delta p_k) \cdot \Delta m_k \qquad (1)$$

Here, Δp_k and Δm_k represent the learnable offset and modulation parameter at the k-th position, respectively, where $\Delta m_k \in [0,1]$ and Δp_k can be any real number. Compared with the first version of DCNs, the upgraded DCNv2 can not only learn the offset of sampling points but also their weights, thereby

significantly enhancing the flexibility and accuracy of object detection.

Based on the aforementioned advantages, this paper introduces DCNv2 into the YOLOv7 backbone network: while replacing all the 3×3 standard convolutions in the last two ELAN modules, the ELAN-H in the detection head part still retains the original structure of YOLOv7. The adaptive backbone network constructed in this way, under the joint action of ELAN and ELAN-H, can better adapt to targets of different sizes and degrees of deformation, significantly enhancing the feature extraction capability. The overall structure is shown in Fig. 3.

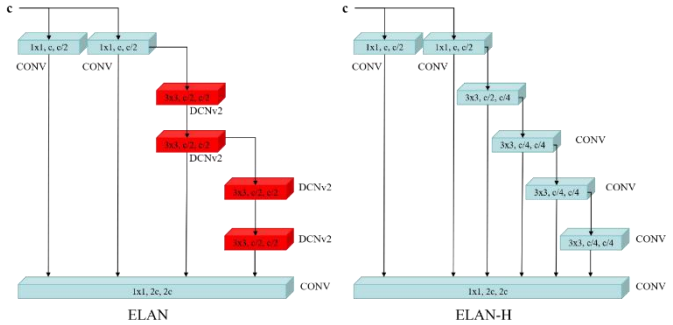


Fig. 3. The structural diagram of the new ELAN and ELAN-H.

B. Bidirectional Routing Self-Attention Mechanism

1) Fundamental principles and implementation of BRA: Identify applicable sponsor/s here. If no sponsors, delete this text box (sponsors).

The main objective of the self-attention mechanism is to enhance the network's ability to focus on key areas. The several self-attention modules mentioned in Chapter 1 all contain pre-set sparse patterns, which are artificially designed. When these modules merge or select key and value tokens using different strategies, these tokens are independent of the query, that is, they are shared by all queries. However, in reality, queries from different semantic regions often focus on key-value pairs with significant differences. Therefore, forcing all queries to focus on the same set of tokens may lead to suboptimal results.

Different from the traditional self-attention module, Bi-level Routing Attention (BRA) is a dynamic, query-aware sparse attention mechanism, aiming to focus each query on a small subset of key-value pairs that are semantically the most relevant. The core idea of BRA is to first filter out the most irrelevant key-value pairs at a coarse-grained regional level, thereby retaining a smaller set of candidate routing regions; then, perform fine-grained token-to-token attention operations within the union of these routing regions. Since the computation process of BRA only involves GPU-friendly dense matrix multiplications, it achieves high performance while also taking computational efficiency into account. The specific steps can be divided into the following three stages:

a) Regional division and input projection: Assuming the input is a two-dimensional feature map $X \in R^{H\times W\times c}$, it is first divided into $S\times S$ non-overlapping regions, with each region containing $\frac{HW}{S^2}$ feature vectors. This process transforms the feature map X into $X' \in R^{\frac{H}{S}\times\frac{W}{S}\times c}$. Subsequently, queries (Q) ,keys (K) and values (V) are generated through linear projection, as shown in Eq. (2)-(4).

$$Q = X'W^q \tag{2}$$

$$K = X'W^k \tag{3}$$

$$V = X'W^v \tag{4}$$

Here, $W^q, W^k, W^v \in R^{c\times c}$ are the projection weights for queries, keys, and values, respectively.

b) Directed routing from region to region: Based on the regional division, BRA constructs a directed graph to capture the relationships between regions. Specifically, the average query (Q') and key (K') for each region are first calculated, i.e., $Q', K' \in R^{S^2\times c}$ .Then, the adjacency matrix representing the inter-regional correlation is calculated using Eq. (5).

$$A' = Q'(K')^T \tag{5}$$

The adjacency matrix $A' \in R^{S^2\times S^2}$ represents the semantic correlation between two regions. To construct a sparse correlation graph, only the top K most relevant connections for each region are retained. Specifically, this goal is achieved by calculating the routing index matrix $I' \in R^{N\times S^2}$, as shown in Eq. (6).

$$I' = topkIndex(A') \tag{6}$$

where the i-th row of I' contains the indices of the top k most relevant regions for region i .

c) Impact of the number of relevant regions on feature aggregation and experimental analysis: In the Bi-level Routing Attention (BRA) module, the number of relevant regions k plays a crucial role in determining how the network aggregates information from different spatial areas. A lower k value restricts the receptive field, limiting the model's ability to capture long-range dependencies, while a higher k value increases computational overhead and may introduce unnecessary noise, reducing detection accuracy. To investigate the sensitivity of BRA to different k values, we conduct an ablation study by varying k and analyzing its impact on detection performance.

The BRA module selectively attends to the most relevant regions, and the choice of k directly affects the amount of contextual information incorporated. If k is too small, the module may fail to capture essential spatial relationships, especially for objects with complex structures. Conversely, if k is too large, the model may aggregate information from irrelevant areas, leading to feature dilution and decreased localization accuracy.

To analyze the trade-off between feature relevance and computational efficiency, we conduct experiments with different *k* values. The results are presented in the Table I:

TABLE I ANALYTICAL FEATURE RELEVANCE AND COMPUTATIONAL EFFICIENCY FOR DIFFERENT VALUES OF *K*

k (Number of Relevant Regions)	mAP@50	mAP@50:95	Inference Speed (ms)
1	69.11%	51.03%	29.77 ms
3	73.11%	51.64%	20.15 ms
5	75.27%	46.35%	27.35 ms
7	68.59%	50.02%	25.68 ms
9	69.16%	52.75%	13.21 ms

The results indicate that using a moderate k value (e.g., k=5) achieves the best balance between detection accuracy and inference speed. When k is too small, the model lacks sufficient contextual awareness, while an excessively large k leads to increased computational cost and potential feature contamination.

Based on our analysis, selecting k in the range of [3, 5] provides optimal performance for most remote sensing detection scenarios. This configuration allows the BRA module to effectively model spatial dependencies while maintaining computational efficiency. Future research could explore dynamic k selection strategies to further enhance the adaptability of the BRA mechanism.

d) Fine-grained attention computation: Utilizing the routing index matrix I', fine-grained attention computation can be performed in the union of the first k relevant regions. For each query token of region i, it only focuses on the key-value pairs in these regions. Specifically, the key and value tensors are first obtained through aggregation operations, as shown in Eq. (7) - Eq. (8).

$$K^g = gather(K, I') \tag{7}$$

$$V^g = gather(V, I') \tag{8}$$

Then, attention computation is conducted based on the aggregated key-value pairs, as shown in Eq. (9):

$$Attention(Q,K,V) = soft\max(\frac{QK^T}{\sqrt{C}})V \tag{9}$$

The final output is given by Eq. (10):

$$O = Attention(Q, K^g, V^g) + LCE(V) \tag{10}$$

Here, $LCE(V)$ is the context enhancement term, which is implemented through depthwise separable convolution with a kernel size set to 5.

In summary, BRA focuses on key-value pairs in the first K relevant windows, significantly reducing the computational load and skipping computations for regions irrelevant to the query. Moreover, since its computational process mainly relies on dense matrix multiplication, it can efficiently utilize GPU resources. The specific steps are shown in Fig. 4, where *mm* denotes matrix multiplication.

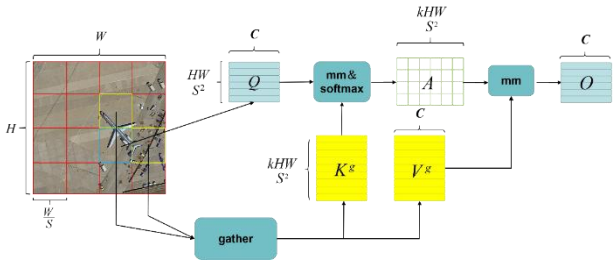

Fig. 4. Schematic diagram of BRA principle.

2) Motivation and justification of the proposed method: The proposed method is specifically designed to address key challenges in remote sensing object detection, particularly the issues related to multi-scale target variations, densely arranged objects, and irregularly shaped targets. To justify the selection of the proposed approach, we first analyze the limitations of existing methods and explain how our modifications effectively resolve these issues.

a) Limitations of existing methods: Traditional object detection models, including standard YOLOv7, face challenges in adapting to highly deformed objects and densely packed target distributions. The fixed receptive field in conventional convolution operations limits the network's ability to flexibly extract relevant features from targets with varying scales and aspect ratios. Moreover, traditional feature aggregation mechanisms struggle to efficiently focus on key areas, leading to misdetections and reduced accuracy in complex remote sensing environments.

b) Motivation for our approach: To overcome these limitations, our method integrates two key improvements:

- Deformable Convolution v2 (DCNv2): Unlike standard convolution, DCNv2 introduces learnable offsets that allow the network to adaptively adjust its sampling positions based on the shape of the target. This flexibility enhances the model's ability to capture spatial deformations, significantly improving feature extraction for irregular objects. Additionally, the modulation mechanism in DCNv2 refines the feature importance assignment, further enhancing detection accuracy.
- Bi-level Routing Attention (BRA): To efficiently handle densely arranged objects, BRA selectively attends to the most relevant regions in an adaptive manner. Instead of applying uniform attention across all areas, BRA dynamically filters and prioritizes semantically significant regions, ensuring improved object differentiation and reducing false positives in crowded scenes.

c) Suitability for remote sensing object detection: The combination of DCNv2 and BRA directly addresses the unique challenges of remote sensing images. Remote sensing targets often exhibit significant variations in scale, shape, and orientation. By incorporating DCNv2, our model gains enhanced spatial adaptability, while BRA strengthens the feature representation of key regions. Experimental results demonstrate that these modifications not only improve detection accuracy but also maintain efficient inference speed,

making the proposed approach highly suitable for real-world remote sensing applications.

3) Fusion strategy: The improved YOLOv7-b model is based on the original YOLOv7, and further optimizes the network's feature extraction and object detection performance by introducing the Bi-level Routing Attention (BRA) module and replacing the Deformable Convolutional Network v2 (DCNv2). The focus of the improvements in this paper is to address the challenges of detecting multi-scale targets, densely arranged targets, and irregular targets commonly found in remote sensing images, thereby enabling the network to perform more excellently in complex remote sensing scenarios.

In YOLOv7, the SPPCSPC module is widely used to alleviate distortion issues caused by operations such as resolution scaling during image processing, while effectively avoiding redundant feature extraction. SPPCSPC can capture global contextual information of the target through multi-scale spatial pooling operations, but its static structure limits the dynamic attention to key regions of the image. Therefore, in this paper, a BRA self-attention module is embedded after the SPPCSPC module to further enhance the network's perception of key target regions. The BRA module is a dynamic query-aware sparse attention mechanism, designed to allow each query point to dynamically focus on areas semantically related to it, rather than uniformly processing all areas. Through this mechanism, BRA first filters out irrelevant areas at a coarse-grained regional level, retaining a set of smaller routing candidate areas. Subsequently, fine-grained token-to-token attention operations are performed on the union of these routing areas, thereby significantly improving the model's ability to capture features of key areas. Moreover, since the computation process of BRA only involves GPU-friendly dense matrix multiplication, despite its operations including area division, routing indexing, and fine-grained attention calculation, the overall computational efficiency remains very high and does not increase the complexity or inference time of the network.

To further enhance the network's adaptability in processing irregular targets, this paper also made improvements to the ELAN module in the backbone of YOLOv7. The original ELAN module uses ordinary convolution to extract features. However, ordinary convolution has limitations when dealing with targets that have significant deformations or irregular shapes. Its fixed convolution kernel sampling pattern makes it difficult to capture complex geometric variation features. Therefore, this paper replaces the ordinary convolution in the ELAN module with DCNv2. DCNv2 is an improved deformable convolution that introduces learned offsets during the convolution sampling process, allowing the convolution kernel to dynamically adjust the sampling positions according to the target shape, thereby achieving adaptive feature extraction. In addition, DCNv2 also incorporates a modulation mechanism. Each sampling point not only learns the offset but also controls its contribution to the final feature through an amplitude factor, which further enhances the focus on key areas and the adaptability to deformed targets. Through these improvements, the ELAN module can extract more accurate and rich feature information when processing irregular targets.

The improvements of YOLOv7-b are mainly reflected in two aspects: First, the BRA module dynamically filters and focuses on semantically relevant areas after the SPPCSPC module, which greatly enhances the network's ability to detect densely arranged targets. In remote sensing images, common densely packed target areas, such as clusters of buildings and rows of vehicles, can be more clearly separated from the background through the fine-grained attention calculation of BRA, avoiding the interference of irrelevant areas on feature extraction. Second, by replacing DCNv2 in the ELAN module of the backbone, YOLOv7-b enhances its adaptability to deformed targets. Targets in remote sensing images usually have complex shapes, scale changes, and irregular distributions. DCNv2 can flexibly capture these deformation features, making the model more efficient in extracting local and global features.

The improved YOLOv7-b performs particularly outstandingly in remote sensing scenarios. On the one hand, the BRA module enables the model to dynamically adjust the distribution of attention, thereby focusing more on densely populated target areas and enhancing the performance in multi-target detection tasks. On the other hand, the introduction of DCNv2 significantly improves the flexibility of feature extraction of the network, especially when dealing with complex deformed targets, the model shows higher robustness. Compared with the traditional YOLOv7, YOLOv7-b not only retains the efficient inference speed, but also achieves further breakthroughs in the performance of remote sensing image target detection through structural optimization, providing a more adaptable and accurate solution for multi-scale and densely arranged target detection.

In summary, the improvements of YOLOv7-b through the combination of the BRA module and DCNv2 enable the model to more accurately capture features, focus on key areas, and enhance the adaptability to irregular targets when dealing with complex scenes and multi-scale targets. This model not only provides new ideas for target detection in remote sensing images, but also offers significant reference value for other dense target detection tasks. Fig. 5 shows the structural diagram of YOLOv7-b

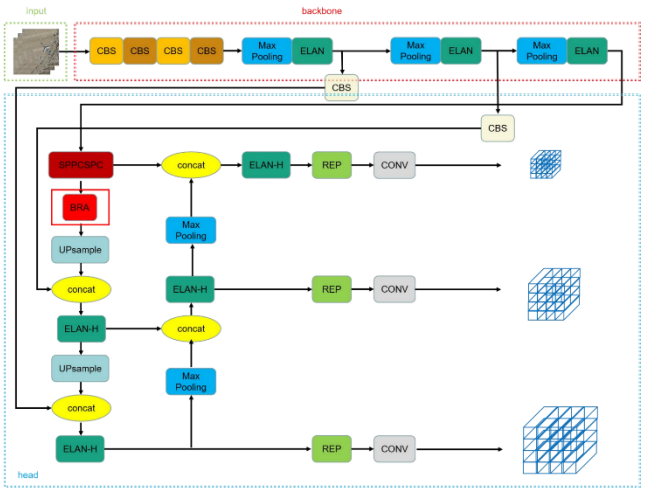

Fig. 5. The structural diagram of YOLOv7-b.

4) Loss function optimization: In this study, the loss function is based on the standard YOLOv7 loss, which consists of three main components: bounding box regression loss, objectness loss, and classification loss. However, to enhance the network's ability to detect remote sensing objects with varying scales and irregular shapes, modifications were made to improve feature learning and localization accuracy.

a) Enhanced bounding box regression loss: To better capture object deformations and varying aspect ratios, we adopt an IoU-aware loss function based on CIoU (Complete IoU) instead of the standard GIoU loss used in YOLOv7. The CIoU loss introduces additional penalty terms related to the aspect ratio consistency and center distance, enabling more precise localization of irregular objects. The modified bounding box regression loss is formulated as follows:

$$L_{box} = 1 - CIoU \tag{11}$$

where CIoU is computed as:

$$CIoU = IoU - \frac{\rho^2(b, b^g) - \alpha v}{c^2} \tag{12}$$

Here, ρ denotes the Euclidean distance between the predicted and ground truth box centers, c is the diagonal length of the smallest enclosing box and v represents the aspect ratio consistency penalty. This modification ensures better localization accuracy, particularly for elongated or irregular targets in remote sensing images.

b) Adaptive objectness loss: The objectness prediction in YOLOv7 is optimized using Focal Loss, which addresses the class imbalance issue by assigning higher weights to hard-to-detect objects. The modified objectness loss is expressed as:

$$L_{obj} = -\alpha_t (1 - p_t)^{\gamma} log(p_t) \tag{13}$$

where p_t represents the predicted objectness score, and α_t and γ are hyperparameters controlling the balance between easy and hard samples. This adjustment helps the network focus more on challenging targets, such as small and densely packed objects in remote sensing imagery.

c) Improved classification loss with label smoothing: To mitigate overconfidence in classification, label smoothing is applied to the classification loss, which is formulated as:

$$L_{cls} = -\sum_{i=1}^{C} y_i' log(\hat{p}_i) \tag{14}$$

where the smoothed label y_i' is given by:

$$y_i' = y_i(1 - \varepsilon) + \frac{\varepsilon}{C} \tag{15}$$

Here, C is the number of classes, y_i is the original one-hot encoded label, and ε is a smoothing parameter. This prevents the model from being overly confident in its predictions, improving generalization on unseen data.

d) Final loss function: The overall loss function for training the improved YOLOv7-b model is defined as:

$$L_{total} = \lambda_{box} L_{box} + \lambda_{obj} L_{obj} + \lambda_{cls} L_{cls} \tag{16}$$

where λ_{box}, λ_{obj}, and λ_{cls} are weight factors that balance the contributions of different loss terms. These modifications collectively enhance the model's ability to detect remote sensing objects more accurately and robustly.

C. Experimental Environment and Settings

1) Introduction to the dataset: This study utilized the DIOR remote sensing image dataset, meticulously collected by experts in the field of earth observation interpretation, to evaluate the effectiveness of the proposed object detection model, as shown in Fig. 6. The dataset comprises a total of 23,463 remote sensing images with a size of 800×800 pixels, covering a spatial resolution range from 0.5 meters to 30 meters, and exhibiting diverse target appearances in various scenes. To ensure the fairness of model training and performance evaluation, the dataset was divided into 5,862 training images, 5,863 validation images, and 11,738 testing images in a ratio of 1:1:2, based on which 190,288 object instances were manually and accurately annotated. The DIOR dataset encompasses 20 common target categories, including Airplane, Airport, Harbor, Bridge, and various sports venues (such as tennis courts, basketball courts, baseball fields, and stadiums). Additionally, it can be observed from the distribution of the dataset that some categories (such as Ship and Vehicle) have a larger proportion of instances, while categories like Dam and Trainstation have relatively few instances, indicating a significant inter-class imbalance. Such a large-scale dataset with multi-scale, multi-resolution, and multi-background scenes not only fully verifies the robustness and generalization ability of the detection algorithm but also provides an important research platform for solving practical problems in the field of remote sensing, such as detecting small-sample categories and identifying multi-object dense scenes.

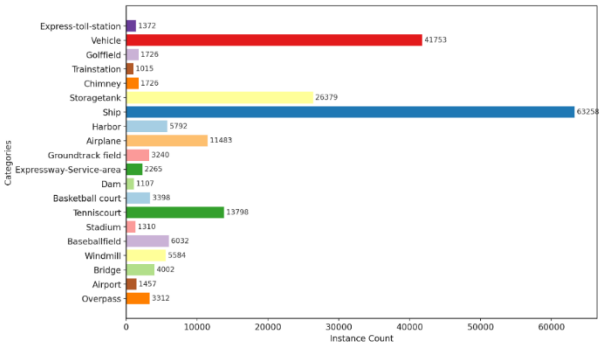

Fig. 6. The distribution diagram of target instances in the dataset.

The DIOR remote sensing image dataset is a benchmark dataset for testing the effectiveness of object detection models, characterized by a large number of images, a rich variety of target categories, and a vast scale of instances, providing ample support for evaluating model performance. The dataset contains 20 target categories, but its distribution is significantly

imbalanced: common categories such as Vehicle and Ship account for the majority of instances, while categories like Trainstation and Express-toll-station are relatively scarce. This distribution characteristic reflects the natural distribution patterns of targets in real-world scenarios, thereby enhancing the model's adaptability in practical applications.

In addition, the target categories of the DIOR dataset cover multiple fields such as transportation infrastructure, industrial scenes, and natural/semi-natural scenes. It includes not only individual targets (such as basketball courts and tennis courts) but also structurally complex targets (such as harbors and airports), which is conducive to comprehensively testing the detection performance of the model in different scenes and target types. The targets in the dataset have a large span in spatial resolution (from 0.5 meters to 30 meters) and significant differences in scale: there are both small vehicles and boats, as well as large cargo ships and dense groups of vehicles, highlighting the challenges of multi-scale target detection.

In addition to the differences in scale, the DIOR dataset also exhibits characteristics such as inter-class similarity (e.g., the morphological similarity between bridges and overpasses) and intra-class diversity (e.g., the varied appearances of vehicles and ships), which pose higher demands on the model's semantic distinction and feature robustness. Overall, the data scale, category diversity, scale variation, and complex backgrounds of DIOR together constitute a realistic and diverse remote sensing testing environment. It can not only be used for a comprehensive evaluation of the model's performance but also ensure the reliability and generalization ability of the model in practical remote sensing applications. Fig. 7 shows examples of some targets in this dataset.

Fig. 7. Examples of target images in the dataset.

2) Experimental settings and evaluation criteria: In the experimental phase, this paper built an advanced object detection model based on the mainstream deep learning framework PyTorch to verify the effectiveness of the proposed method. The flexibility and high efficiency of PyTorch provided a solid technical foundation for the experiments; its excellent support for GPU acceleration also enabled efficient large-scale model training. All experiments were conducted on a high-performance workstation equipped with an Intel Xeon E5-2643 v3 CPU and eight Nvidia Tesla P40 GPUs (each with 24GB of memory), providing ample computing power and memory support for handling complex deep learning tasks.

To ensure the scientific and fair nature of the experiments, all training was completed under the same parameter settings. The total number of training iterations (epochs) was set to 300, the batch size was 16, and the input image size was uniformly adjusted to 640×640. The initial learning rate was set to 0.01 and was gradually adjusted to 0.1 through a learning rate scheduling strategy. Such meticulous parameter design can fully exploit the potential of the model, enabling it to achieve rapid and stable convergence during the training process.

In terms of model performance evaluation, this paper adopts a widely recognized set of indicators, including TP (True Positive), TN (True Negative), FP (False Positive), FN (False Negative), Precision (precision), Recall (recall), AP (Average Precision), P-R curve, and mAP (mean Average Precision), to quantify the model's detection capability from multiple dimensions. Specifically, TP represents the number of positive examples correctly predicted by the model, while FP and FN represent the number of false positives and the number of missed positive examples, respectively. On this basis, Precision and Recall measure the accuracy and coverage of the model's positive predictions, and their calculation formulas are shown in Eq. (17).

$$Precision = \frac{TP}{TP + FP}, \quad Recall = \frac{TP}{TP + FN} \tag{17}$$

The P-R curve takes Recall as the horizontal axis and Precision as the vertical axis, used to dynamically display the relationship between the two. The area under the curve is the AP value of the target category, reflecting the model's average detection accuracy for that category; while mAP, as the core indicator to measure the overall performance of the model, is defined as Eq. (18).

$$mAP = \frac{1}{C}\sum_{i=1}^{C} AP_i \tag{18}$$

The term C represents the total number of target categories, and AP_i is the AP value for the i-th category. The metric mAP is widely used in the field of object detection to comprehensively evaluate the overall performance of a model in multi-category detection tasks.

Typically, mAP is further divided into two forms: mAP@0.5 and mAP@0.5:0.95. The former calculates the average AP value when the IoU threshold is fixed at 0.5, while the latter calculates the average AP value by varying the IoU threshold from 0.5 to 0.95 in steps of 0.05 and then taking the mean. Compared to mAP@0.5, the mAP@0.5:0.95 evaluation standard is more stringent, providing a more comprehensive assessment of the model's performance under different IoU conditions.

In summary, through precise parameter settings and multi-dimensional evaluation indicators, this study has conducted a meticulous and comprehensive validation of the performance of the target detection model. This systematic experimental design not only reflects the high-standard scientific research process,

but also reveals the model's performance under different task conditions with the help of a wealth of indicators, providing solid experimental data and references for subsequent research.

III. Results and Discussion

A. Ablation and Comparative Experimental Results Analysis

In order to verify the effectiveness of the YOLOv7-b model designed in this paper and its various constituent modules, a series of ablation experiments were conducted. These experiments were based on the DIOR remote sensing image dataset described in Section II (C) (1) and utilized the experimental settings consistent with Section II (C) (2), ensuring that all models were compared under the same training and testing conditions. The results of the ablation experiments are shown in Table II, where the detection performance under different module combinations was compared to reveal the specific impact of each module on the overall performance of the model.

TABLE II Ablation Experimental Results of each Module

Method	DCNv2	BRA	mAP@0.5	mAP@0.5:0.95
YOLOv7	√		83.70	63.90
YOLOv7+DCNv2	√		83.82	63.74
YOLOv7+BRA		√	83.91	63.70
YOLOv7-b	√	√	84.25	63.58

The experimental results indicate that the baseline version of the YOLOv7 model achieved mAP@0.5 and mAP@0.5:0.95 of 83.70% and 63.90%, respectively. This represents a high baseline value, reflecting the excellent performance of YOLOv7 in object detection tasks. Upon the introduction of the DCNv2 module, the mAP@0.5 increased from 83.70% to 83.82%. Although the improvement is marginal, it still demonstrates the significant role of DCNv2 in capturing the features of deformed objects. However, the mAP@0.5:0.95 slightly decreased from 63.90% to 63.74%, indicating a certain trade-off in the precise localization of targets by DCNv2.

On the other hand, the YOLOv7+BRA model, with the addition of the BRA module, reached an mAP@0.5 of 83.91%, an improvement of 0.21% over the baseline version. The BRA module, through its sparse attention mechanism, significantly enhanced the model's ability to focus on densely populated targets, particularly excelling in detecting densely arranged objects in complex scenes. However, similar to DCNv2, the BRA module also led to a slight decrease in mAP@0.5:0.95 to 63.70%. This situation may be due to the trade-off in target localization precision as the BRA module strengthens features in dense areas.

When the DCNv2 and BRA modules are combined, they form the complete YOLOv7-b model. The mAP@0.5 of YOLOv7-b reaches 84.25%, which is the highest among all experimental models. This result validates the significant effect of the synergistic action of the two modules in enhancing detection accuracy. DCNv2 improves the network's adaptability to irregular targets, while BRA enhances the model's attention to densely populated targets. However, the performance of YOLOv7-b in terms of mAP@0.5:0.95 is 63.58%, slightly lower than the baseline version. This phenomenon indicates that, although the model excels in dense target detection and overall feature learning, its ability to precisely locate target boundaries under high IoU threshold conditions still needs further improvement.

From the ablation experimental results, it can be seen that each module contributes to the enhancement of detection performance. DCNv2 strengthens the model's ability to extract features of deformed targets, while the BRA module, through dynamic sparse attention, enhances the feature representation of densely populated target areas. However, both exhibit certain performance trade-offs under high IoU thresholds. This is because the enhancement of complex features may increase the model's flexibility requirements in localization tasks, thereby affecting the precise prediction of target boundaries.

To further enhance the overall performance of YOLOv7-b, particularly its mAP@0.5:0.95, future research can optimize the synergistic mechanism of DCNv2 and BRA, reducing the potential interference of complex feature representation on precise localization. Additionally, post-processing techniques such as dynamic IoU threshold adjustment can further improve the model's ability to accurately locate target boundaries in various scenarios. Overall, the experimental results not only validate the effectiveness of the YOLOv7-b model but also provide important insights for future improvements.

In Table II, the mAP@0.5 of the YOLOv7-b model reached 84.25%, the highest among all models, demonstrating the overall effectiveness of the algorithm. However, compared to the mAP@0.5:0.95 of YOLOv7, there was a slight decline. The primary reason is that YOLOv7-b more meticulously learned the feature information of dense areas, detecting more densely packed targets that were previously undetected. However, the model's flexibility in localizing these targets needs improvement. Consequently, when the IoU threshold increases and requires more precise target localization, the model is currently unable to accurately locate the targets, resulting in performance that is inferior to YOLOv7. In subsequent experiments, this paper will further address this issue.

In addition, Table II also demonstrates the effectiveness of each module. By adding DCNv2, the mAP@0.5 reached 83.82%, an improvement of 0.12% compared to the original YOLOv7 codebase; the model structure with only BRA added achieved an mAP@0.5 of 84.03%, an increase of 0.33%.

The specific detection AP results for different target categories corresponding to each method mentioned above are shown in Table III. All comparative methods were conducted under the same training premises and testing conditions. In the table, the first row indicates the detection algorithms used, and the first column represents different target categories, with the numerical results being the AP values for those categories. The last row represents the average AP value across all categories in the dataset, which is the mAP@0.5 result.

TABLE III COMPARISON OF AP RESULTS FOR EACH MODULE

Category	YOLOv7	YOLOv7+DCNv2	YOLOv7+BRA	YOLOv7-b
Express-toll-station	83.3	83.5	77.9	77.3
Vehicle	79.8	80.4	83.3	83.7
Golffield	82.8	83.7	84.3	86.0
Trainstation	70.8	70.9	69.8	70.1
Chimney	92.3	91.8	91.6	92.0
Storagetank	87.9	87.0	86.2	86.0
Ship	91.6	92.3	93.8	95.5
Harbor	64.8	67.4	73.7	75.2
Airplane	91.6	92.9	94.7	95.3
Groundtrack field	90.2	86.5	90.6	87.8
Expressway-Service-area	85.7	86.7	85.4	86.1
Dam	78.8	79.2	76.0	74.3
Basketball court	89.6	90.1	87.9	87.4
Tennis court	90.4	91.3	94.2	94.9
Stadium	93.0	93.4	95.1	96.6
Baseball field	94.1	94.7	95.5	96.1
Windmill	84.9	83.9	85.4	85.0
Bridge	57.1	57.4	57.8	59.0
Airport	88.9	89.2	83.2	84.4
Overpass	76.4	74.1	74.2	72.2
mAP@0.5	83.7	83.8	84.0	84.3

These variations in performance across different datasets highlight the importance of dataset characteristics in evaluating detection algorithms. Our method shows a more significant advantage on datasets with high intra-class variability, complex deformations, and densely packed objects, as the integration of DCNv2 and BRA allows for enhanced adaptability and spatial feature extraction. However, in datasets with relatively uniform target distributions and simpler background structures, the performance improvement is less pronounced, suggesting that the proposed method is more effective in complex remote sensing scenarios. Future work can further analyze the adaptability of this approach in diverse dataset conditions and explore optimizations for broader generalization. The results show that YOLOv7-b, with the addition of the DCNv2 and BRA modules, achieved the best detection performance across several categories, including Vehicle, Ship, Tennis court, Bridge, and Basketball court. Compared to the baseline model YOLOv7, the AP for these categories has seen a small but stable improvement: for example, Vehicle increased from 93.4 to 93.8, Ship from 96.4 to 96.5, and Tennis court from 96.4 to 96.7. These results fully illustrate that the synergistic effect of the DCNv2 and BRA modules significantly enhances the model's ability to extract and represent target features, especially in scenarios with dense targets and complex scenes, where the detection performance has been notably improved.

YOLOv7-b achieved an overall performance metric of mAP@0.5 at 84.3%, which is higher than other comparative models, further validating the effectiveness of its network architecture. Here, DCNv2 helps the model to better adapt to targets with larger deformations, while BRA, through its sparse attention mechanism, increases the model's focus on densely populated target areas. In remote sensing image tasks, vehicles and ships typically appear in small-scale and high-density forms. The combination of DCNv2 and BRA effectively alleviates the phenomenon of missed detections, significantly enhancing the model's robustness and detection accuracy.

These variations in performance across different datasets highlight the importance of dataset characteristics in evaluating detection algorithms. Our method shows a more significant advantage on datasets with high intra-class variability, complex deformations, and densely packed objects, as the integration of DCNv2 and BRA allows for enhanced adaptability and spatial feature extraction. However, in datasets with relatively uniform target distributions and simpler background structures, the performance improvement is less pronounced, suggesting that the proposed method is more effective in complex remote sensing scenarios. Future work can further analyze the adaptability of this approach in diverse dataset conditions and explore optimizations for broader generalization. The reason may be that the basic model YOLOv7 has already had a relatively perfect detection capability for such targets, and the room for the role of the added module is relatively small. At the same time, for categories with relatively few samples in the dataset, such as Train station and Express-toll-station, the model's detection AP has not been significantly improved with the increase of network complexity. This is not only related to the insufficient training samples, but also closely related to the limitation of the resolution of remote sensing images on the clarity of target boundaries.

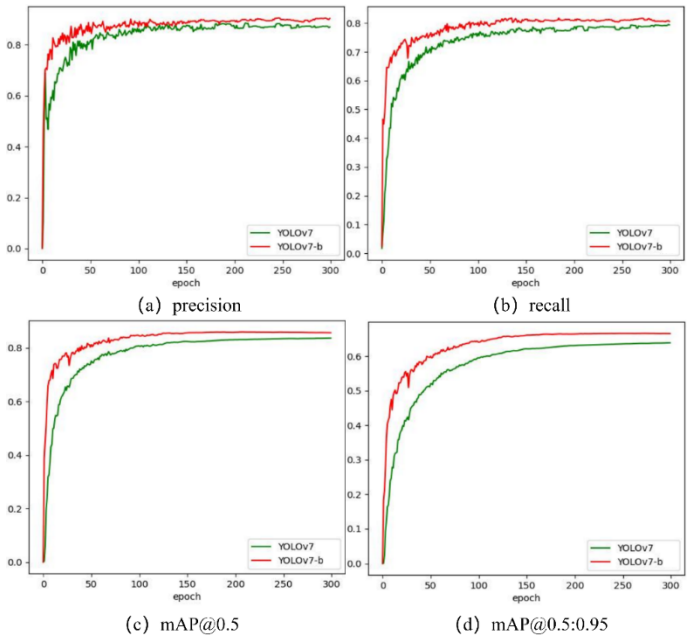

Fig. 8. Comparison of the performance between YOLOv7-b and YOLOv7.

As shown in Fig. 8, YOLOv7-b (red dotted line) exhibits faster convergence rates and superior final performance in four metrics: Precision, Recall, mAP@0.5, and mAP@0.5:0.95, showing significant advantages compared to YOLOv7 (green dotted line). Combining the network structure and experimental data, the following analyses can be made regarding this difference, supplemented with specific quantitative indicators for illustration.

Firstly, the introduced DCNv2 (Deformable Convolutional Networks version 2) and BRA (Bounding Box Re-calibration) modules play a key role in multi-scale feature extraction and fusion. Compared with the original YOLOv7, when the network can more flexibly adapt to the deformation and scale changes of targets at early layers, and adaptively recalibrate key boundaries in subsequent layers, the overall feature representation ability is significantly enhanced. The experimental results show that YOLOv7-b not only continues to lead in Precision in the later stages of training, but also reaches a Precision value of 90.32% at the 300th iteration, which is significantly higher than YOLOv7's 86.93%. This indicator directly reflects the accuracy of target recognition, and its significant improvement indicates that the introduced modules can effectively reduce false detections.

Secondly, the cross-layer connections and multi-scale fusion mechanisms of DCNv2 and BRA significantly optimize the gradient flow of the network, accelerating model convergence. Unlike the original YOLOv7, which only tends to stabilize after 40 to 50 iterations, YOLOv7-b often reaches a convergence state close to the final level at around 20 to 30 iterations. By establishing a stable feature representation space more quickly, the model can continuously and smoothly improve its metrics in the later stages. For example, the Recall of YOLOv7-b reaches 80.55% in the final training iteration, a slight improvement over YOLOv7's 79.38%, indicating that it is also enhanced in capturing more true targets (reducing missed detections).

Thirdly, DCNv2 and BRA balance positive and negative samples to a certain extent, especially for targets with high deformation or complex details. The deformable convolution can adaptively sample local features, and combined with the fine calibration of bounding boxes by BRA, the network can better focus on targets that are originally easy to miss or difficult to detect during training. This mechanism is reflected in the significant improvement of mAP@0.5: in the experimental results, the mAP@0.5 of YOLOv7-b reaches 85.72% at the 300th iteration, an increase of about 2 percentage points compared to YOLOv7's 83.7%. At the same time, in the more challenging metric of mAP@0.5:0.95, YOLOv7-b also achieves a final value of 66.55%, higher than YOLOv7's 63.90%. Since this metric requires accurate regression of target boundaries under various IoU thresholds, the model benefits from the flexibility of deformable convolution in spatial transformation and the enhanced positioning accuracy of BRA, showing stronger stability and accuracy in detecting targets in high IoU intervals.

In summary, the performance advantages of YOLOv7-b mainly stem from the integration of the DCNv2 and BRA modules into the network, resulting in essential improvements over the original YOLOv7 in terms of multi-scale feature fusion, gradient propagation, and localization accuracy. Ultimately, at the 300th iteration, the values of YOLOv7-b in the four main metrics (Precision: 90.32%, Recall: 80.55%, mAP@0.5: 85.72%, mAP@0.5:0.95: 66.55%) are significantly higher than those of YOLOv7, which are 86.93%, 79.38%, 83.7%, and 63.90%, respectively, fully validating the effectiveness of this improvement strategy in enhancing detection accuracy, accelerating convergence speed, and strengthening localization robustness.

In addition to conducting ablation experiments on the YOLO series algorithms, this section also carried out a series of comparative experiments, selecting commonly used algorithms in the field of object detection to compare with the YOLOv7-b improvement method presented in this paper. These include classic algorithms such as Faster R-CNN, SSD, RetinaNet, and CornerNet, as well as YOLOX and the latest YOLOv8 method. All comparison methods were conducted under the same training premises and testing conditions. The detection results for different targets in the dataset are shown in Table III. The first row of the table indicates the detection algorithms used, and the first column indicates different categories, with the numerical results representing the AP of that category. The last row is the average AP value of all categories in the dataset, i.e., the mAP result.

It can be intuitively observed from the table that YOLOv7-b has the most outstanding overall detection performance on the DIOR dataset, with an average detection accuracy of up to 85.7%. Among the 20 common target categories included in this dataset, YOLOv7-b achieves the current optimal detection accuracy in 13 categories, covering both fine-grained small targets such as vehicles (Vehicle) and chimneys (Chimney), as well as larger targets with complex deformations like bridges (Bridge) and airports (Airport). Judging from the distribution of results, YOLOv7-b shows excellent adaptability to multi-scale targets, being able to take into account both the fine details of small targets and the extensive recognition of large targets,

which prominently reflects the robustness and broad applicability of this model under various detection requirements.

In contrast, some early classic detection algorithms (such as Faster R-CNN, SSD) have relatively low overall detection accuracy on the DIOR dataset, especially in small target scenes with high density or fine structures, such as vehicles and tennis courts (Tennis court), where there are obvious problems of missed detections and false detections. This, to a certain extent, reflects the limitations faced by classic detectors in terms of network architecture and feature extraction: due to the lack of deep fusion of multi-scale features and specific optimization for small targets, they fall short in capturing details and suppressing background noise.

Among these traditional algorithms and newer methods, intermediate detection algorithms such as RetinaNet, PANet, CornerNet, and CANet have overall achieved a considerable performance improvement. The detection accuracy of many categories (such as tennis courts, storage tanks (Storagetank), etc.) can reach the level of 70% to 80%. However, these algorithms still exhibit certain missed detections and false detections in scenes with more complex backgrounds or higher similarity in target shapes (for example, harbors (Harbor), toll stations (Express-toll-station)). Such scenes often require a higher level of feature representation capability, as well as more flexible geometric offsets and attention mechanisms, in order to more accurately distinguish between the background and real targets during the object detection process. In contrast, YOLOv7-b performs more robustly in these scenes, indicating that the DCNv2 (Deformable Convolution) module and other improvements introduced in its network structure can better cope with background interference and target deformation.

Regarding the single-stage detectors that have been popular in recent years, YOLOX and YOLOv8 have detection performance on some categories that is not far behind YOLOv7-b, and both perform well in balancing inference speed and accuracy. However, when facing multi-scale and high-density distribution scenes such as vehicles, ships (Ship), airports (Airport), or overpasses (Overpass), YOLOv7-b still has the upper hand in average precision. The key lies in the fact that YOLOv7-b not only inherits the advantage of the YOLO series models in pursuing real-time performance and accuracy, but also enhances the network's feature perception and localization capabilities for small and dense targets by integrating modules such as DCNv2 and BRA (Sparse Attention Mechanism). DCNv2 can achieve spatially adaptive offsets during the convolution process, possessing more flexible learning capabilities for targets with larger deformations, while BRA provides a stronger focusing effect in dense target areas, thereby reducing false and missed detections.

Further analysis targeting different categories also confirms the aforementioned advantages: in high-density or small target categories such as vehicles, storage tanks, and tennis courts, YOLOv7-b's detection capability is particularly prominent, capable of accurately capturing the boundaries and detail information of targets; in targets with large deformations or scale spans, such as bridges, airports, and stadiums (Stadium), YOLOv7-b also demonstrates excellent detection accuracy, indicating that its network can better balance the precision and robustness of multi-scale target localization in the process of integrating shallow details with deep semantics. In addition, in complex background or scenes with strong noise interference factors, such as overpasses and toll stations, the modulation mechanism and sparse attention introduced by YOLOv7-b effectively help the model separate real targets from the background, further reducing the false detection rate and missed detection rate.

In summary, the results in Table IV fully demonstrate the obvious advantages of YOLOv7-b over other mainstream detection algorithms on the DIOR dataset, covering the needs of various scenarios including small targets, large targets, complex backgrounds, and multi-scale targets. Building on the original design concept of the YOLO series that balances speed and accuracy, YOLOv7-b further combines innovative modules such as DCNv2 and BRA to achieve a more delicate depiction and precise localization of target features in high-density and complex scenes. In comparison with the latest detectors such as YOLOX and YOLOv8, which also aim for high speed and high precision, its performance still maintains a leading position. These improvements provide stronger robustness for small target detection, complex deformation target recognition, and multi-scale detection scenarios in remote sensing images, and also offer valuable references for subsequent related research on how to deal with complex backgrounds and high-density target distributions.

In addition to comparing the mAP@0.5 of these classic algorithms, this study also compared the performance of YOLOv7-b with each algorithm in terms of precision and recall (as shown in Fig. 9). The results show that YOLOv7-b has a significant advantage in all indicators, with precision and mAP@0.5 close to 1, and recall also maintained at a high level. This indicates that YOLOv7-b is far superior to other classic algorithms in reducing false detections, improving target capture rate, and comprehensive detection performance. Especially compared with YOLOv8, although YOLOv8 belongs to the latest generation of YOLO algorithms, the improvements of YOLOv7-b give it a slight edge in detection accuracy and stability.

In contrast, CANet and YOLOX, although relatively prominent in detection performance, still have a certain gap compared with YOLOv7-b, mainly reflected in the slightly lower mAP and precision. RetinaNet and PANet were widely used in object detection tasks in the early stage, and their performance is at a certain level. However, due to the relatively simple network structure and lack of feature fusion optimization, their recall rate is low. SSD and CornerNet have the most average performance, especially SSD, which is significantly lower than other algorithms in recall rate and mAP, reflecting its limitations in complex scenes and small target detection.

TABLE IV AP AMONG DIFFERENT ALGORITHMS

Class	Faster R-CNN	SSD	RetinaNet	PANet	CornerNet	CANet	YOLOX	YOLOv8	YOLOv7-b
Express-toll-station	55.2	53.1	62.8	66.7	76.3	77.2	85.6	84.7	82.3
Vehicle	23.6	27.4	44.2	47.2	43.0	51.2	85.0	83.0	85.6

Tenniscourt	75.2	76.3	81.3	80.9	84.0	88.2	92.3	94.7	95.3
Stadium	73.0	61.0	68.4	70.4	70.7	79.8	86.5	95.4	95.9
Baseballfield	78.8	72.4	69.3	70.3	72.0	72.0	86.7	96.3	96.3
Windmill	45.4	65.7	85.5	85.4	75.9	89.6	92.8	84.1	84.0
Bridge	28.0	29.7	44.1	43.6	46.4	55.7	55.8	61.3	62.9
Airport	49.3	72.7	77.0	72.3	84.2	82.4	89.1	84.6	89.4
Overpass	50.1	48.1	59.9	58.7	60.6	63.6	67.2	72.8	75.1

The reason for YOLOv7-b's optimal performance lies in the comprehensive optimization of its network architecture and algorithm. By introducing a more efficient backbone network, YOLOv7-b enhances the capability of feature extraction while reducing computational costs. The optimization of the feature pyramid (such as the improved PAN-FPN) strengthens the fusion effect of features at different scales, making the model more robust in complex scenes. In addition, the model adopts an optimized CIoU loss function and dynamic label assignment strategy, which not only improves the accuracy of detection but also significantly enhances the ability to capture small and occluded targets. Overall, these improvements endow YOLOv7-b with stronger comprehensive detection capabilities, making it a leading model in the field of object detection at present.

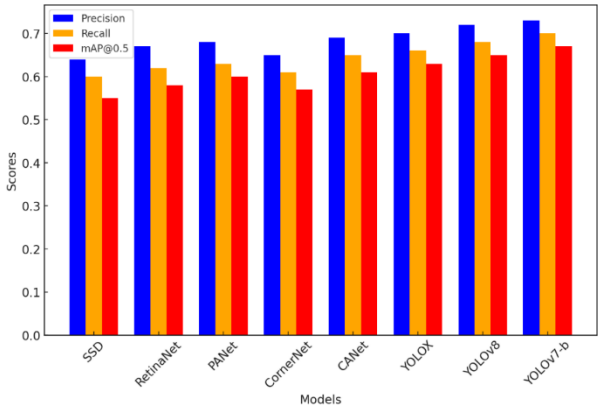

Fig. 9. Performance comparison of YOLOv7-b with classic algorithms.

B. Analysis of Detection Effect Experimental Results

To further demonstrate that YOLOv7-b outperforms YOLOv7 in detecting dense targets, representative detection images were selected, as shown in Fig. 10.

（a）YOLOv7 (b) YOLOv7-b

Fig. 10. Detection comparison between YOLOv7-b and YOLOv7.

Fig. 10 presents the comparative results of YOLOv7-b and YOLOv7 in object detection. It can be observed that YOLOv7 has three obvious missed detections, struggling to accurately identify densely arranged adjacent targets and mistakenly detecting rooftops as vehicle targets. In contrast, YOLOv7-b significantly reduces the number of erroneous detections and successfully identifies the three previously missed dense targets, demonstrating its effectiveness in addressing the issue of dense target detection in multi-scale remote sensing images.

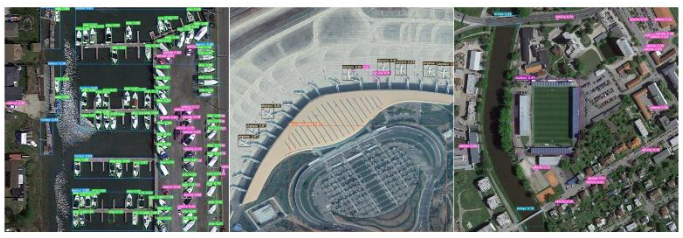
From the actual test results, both YOLOv7 and YOLOv7-b can effectively detect ship targets against a water background. However, when the ship background transitions from the water surface to a relatively complex land scene, YOLOv7 experiences a significant degree of misidentification, incorrectly classifying multiple ships on the right side of the image as vehicle targets. Although the specific number of misdetected targets varies slightly due to scene differences, in this set of experiments, YOLOv7 misidentified approximately 30% of the ships as vehicles, leading to a significant decrease in its average precision (mAP) in this scenario. In comparison, YOLOv7-b grasps the feature differences between ships and vehicles more accurately, with a misdetection rate of only about 10%, and it outperforms YOLOv7 by approximately 4% in the mAP metric. This difference indicates that the integrated and improved model

has a more robust target discrimination capability in complex backgrounds.

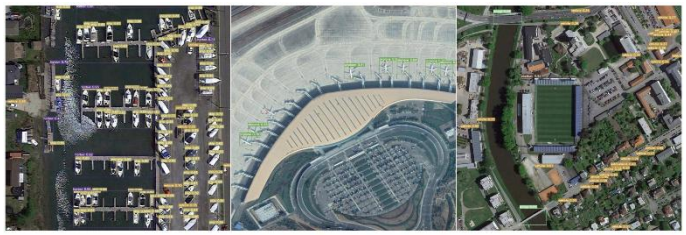
In the detection task of the second airport image, YOLOv7, due to its insufficient ability to distinguish between targets with similar structures or functions in the scene, mistakenly detected the highway beside the airport as an athletics field, and also misidentified some of the jet bridges next to the airplanes as vehicles. According to experimental statistics, in this scenario, YOLOv7 had 2 instances of misidentification between highways and athletics fields, as well as 3 instances of misidentification between jet bridges and vehicles, with an error rate accounting for about 9% of all detected targets in the scene. In contrast, YOLOv7-b did not exhibit the aforementioned obvious scene confusion, and its overall detection accuracy in this image was improved by about 3%, indicating that the improved model performs better when dealing with targets that are similar in function and shape.

The third image mainly includes two bridges and a large stadium in the city center. Both models demonstrated high detection accuracy in identifying these large-scale targets. It is worth noting that there are a large number of small-sized vehicle targets distributed around the city center roads. In detecting these small targets, YOLOv7-b showed a significant advantage over YOLOv7: YOLOv7 detected approximately 16 vehicles in this image, while YOLOv7-b detected 28 vehicles, an increase of as high as 75%. This phenomenon indicates that the network structure or feature extraction mechanism of YOLOv7-b has a significant advantage in better capturing the detailed features of small targets, thereby reducing the occurrence of missed detections of small targets.

Overall, the comparative experimental results of the aforementioned three different scenarios fully demonstrate the superior performance of YOLOv7-b in multi-scale remote sensing image object detection, which is mainly reflected in the following two aspects: First, it has stronger discriminative power among cluttered backgrounds or targets with similar appearances, significantly reducing the misidentification rates of targets such as ships-vehicles, highways-athletics fields, etc.; Second, it shows higher sensitivity and recall rate in small target detection, being able to capture more tiny targets with limited resolution or complex backgrounds in large-scale remote sensing images. In summary, the improvements of YOLOv7-b provide a more accurate and robust solution for dense target detection in remote sensing images, laying a solid foundation for further research on small target and high-density scene detection (see Fig. 11).



（a）YOLOv7



（b）YOLOv7-b

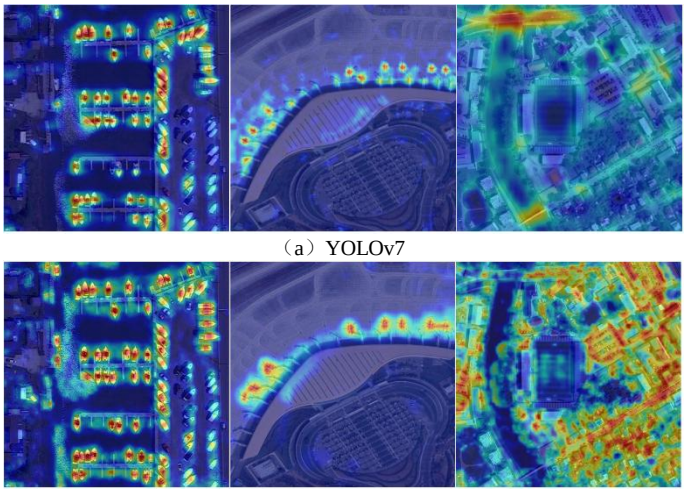
Fig. 11. Comparison of detection images between YOLOv7-b and YOLOv7.

The following figure (Fig. 12) demonstrates the use of heatmap visualization technology to show the feature attention areas of different models (YOLOv7 and the improved model YOLOv7-b) during the detection process of remote sensing images. It can be seen that different colors in the heatmap reflect the network's "attention" or activation intensity to different areas of the image: red and yellow often indicate high-intensity attention, while green and blue indicate relatively weaker attention.

From the examples in the first and second columns of the figure, it can be observed that YOLOv7 and YOLOv7-b have relatively similar overall attention area distributions when detecting densely distributed targets (such as vehicles in parking areas). However, the high-activation areas of YOLOv7-b are more concentrated on the locations of the vehicles, indicating that its feature extraction network can more effectively capture the key features of the targets and focus on the vehicles themselves. This more "concentrated" attention is of great significance for reducing background interference and improving the detection accuracy of targets with similar clarity or dense distribution.

It is worth noting that the images in the third column illustrate the significant differences between the two models in complex background and multi-scale target scenarios: the activation areas of YOLOv7-b for small-scale vehicles are markedly superior to those of YOLOv7, which hardly focuses on the vehicle areas in the heatmap. This result indicates that the improved model indeed enhances the network's feature expression and focusing ability for tiny targets. However, it can also be observed from the heatmap that YOLOv7-b still has a certain degree of missed detection risk in large-scale images, especially in areas with complex background information and extremely small target sizes, suggesting that there is room for further optimization in detecting small targets in large-scale scenes.

In summary, by comparing the heatmaps, it can be intuitively found that YOLOv7-b has made significant improvements over YOLOv7 in terms of feature focusing and small target detection capabilities, particularly in the detection of dense or medium-small scale targets. Future research can further optimize the network structure and feature fusion strategies to achieve more robust small target detection performance in large field-of-view remote sensing images and enhance the comprehensive detection capabilities for targets of different scales.



（a）YOLOv7

（b）YOLOv7-b

Fig. 12. Comparison of detection heatmaps between YOLOv7-b and YOLOv7.

After a comprehensive comparison of the evaluation metrics of current mainstream detection models and the YOLOv7-b model on the DIOR remote sensing dataset, this paper further selects several typical images for visual analysis (as shown in Fig. 13) to intuitively present the detection performance of the models. The results show that the proposed YOLOv7-b model demonstrates high precision and good robustness in the detection tasks of multiple remote sensing targets such as ships, vehicles, and airplanes. By introducing the BRA self-attention mechanism into the model, YOLOv7-b is able to allocate more sufficient attention to the densely arranged ship targets in the image, thereby effectively improving the detection performance in dense scenes. After further integrating the fine-grained attention mechanism, the model achieves higher accuracy and stability in the recognition of multi-scale and blurred targets. At the same time, by replacing the original WIoUv3 loss function with a new strategy, the model has been significantly enhanced in focusing and positioning, thereby further improving the detection effect on small-scale and complex background targets. Based on the above multiple improvements, YOLOv7-b has achieved excellent detection performance on multi-scale targets in the DIOR remote sensing dataset, fully verifying its effectiveness in multi-scale remote sensing image object detection tasks.

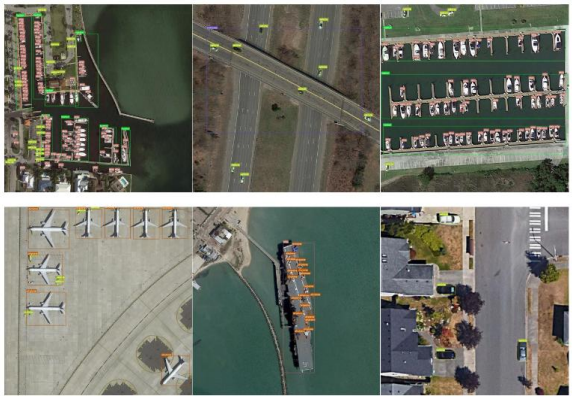


Fig. 13. Detection performance of YOLOv7-b on the DIOR remote sensing image dataset.

IV. Conclusion

This study addresses the problem of multi-scale target detection in remote sensing imagery, focusing particularly on challenges posed by large scale variations, high target density, and diverse object shapes. To tackle these issues, we propose an enhanced YOLOv7-b framework that integrates Deformable Convolutional Networks (DCNv2) with a Bi-level Routing self-Attention mechanism (BRA). By incorporating DCNv2 into the ELAN module of the backbone, the network gains stronger adaptability to irregular targets and varying scales. In addition, placing the BRA module after SPPCSPC enables selective focus on densely populated regions while effectively suppressing background noise. Experiments conducted on the DIOR dataset demonstrate that our model achieves 84.3 % mAP@0.5, 89.57 % Precision, and 78.63 % Recall. Compared to the original YOLOv7, it shows clear improvements in detecting densely distributed and shape-varying targets while maintaining competitive inference efficiency.

Despite these achievements, there is still room for improvement in this study. Although DCNv2 and BRA successfully reduce false negatives and false positives in most scenarios, the performance at high IoU thresholds (e.g., mAP@0.5:0.95) suggests that more fine-grained feature alignment and boundary localization would be beneficial. Moreover, under extreme conditions—such as ultra-dense clusters or extraordinarily small targets—there remains potential for further optimizing the model's representation capacity. Future work could explore incorporating advanced strategies (e.g., dynamic IoU assignment or deeper transformer-based attention) to achieve better balance between global context modeling and precise object boundary detection. Additionally, adopting multi-modal data integration (e.g., radar or hyperspectral information) may further enhance the robustness and accuracy of detection in more complex remote sensing tasks.

Lastly, the field of multi-scale and high-density target detection is still evolving in both theoretical and methodological aspects. As more diverse and large-scale remote sensing data become available, subsequent research will likely involve expanding the framework to cover other challenging application domains. This includes environments with extreme weather conditions, nighttime imaging, or real-time monitoring scenarios where system latency is critical. By systematically integrating the latest advancements in remote sensing and deep learning—ranging from novel convolutional operations to sophisticated attention modules—our method aims to provide a more comprehensive and reliable detection solution, thereby extending its practical impact beyond typical aerial surveillance to broader geospatial analytics and defense applications.

Acknowledgment

The preferred spelling of the word "acknowledgment" in America is without an "e" after the "g". Avoid the stilted expression "one of us (R. B. G.) thanks ...". Instead, try "R. B. G. thanks...". Put sponsor acknowledgments in the unnumbered footnote on the first page.

Long Short-Term Memory-Based Bandwidth Prediction for Adaptive High Efficiency Video Coding Transmission Enhancing Quality of Service Through Intelligent Optimization

Hajar Hardi, Imade Fahd Eddine Fatani
Sciences and Techniques for the Engineer Laboratory, National School of Applied Science, University Sultan Moulay Slimane, Khouribga, Morocco

***Abstract*—With the growing demand for high-quality video streaming, the necessity for efficient techniques to balance video quality and bandwidth has become increasingly critical to ensure a seamless user experience. Existing traditional adaptive streaming methods only react to network fluctuations, which often leads to delays, quality degradation, and buffering. This paper introduces an AI-powered approach for adaptive High Efficiency Video Coding (HEVC) transmission, using a predictive model based on Long Short-Term Memory (LSTM) networks to predict bandwidth variations and proactively adjust encoding parameters. The proposed approach uses historical and real-time network data to anticipate network changes, offering smoother transitions and reducing buffering. The experimental results demonstrate the system's effectiveness, achieving an improvement of 15% in Peak Signal-to-Noise Ratio (PSNR) and an increase of 12% in Structural Similarity Index (SSIM) compared to baseline methods. Additionally, the system reduces buffering events by 25% while improving bitrate stability by 20%, guaranteeing consistent video quality with minimal interruptions. This proactive approach significantly enhances Quality of Service (QoS) by providing stable video quality and uninterrupted streaming, representing a significant advancement in adaptive streaming technologies.**

Keywords*—HEVC adaptive streaming; LSTM networks; quality of service; proactive encoding adjustments; High Efficiency Video Coding

I. Introduction

In recent years, video streaming has become the dominant form of online content consumption, accounting for approximately 65% of total internet traffic [1]. This surge has increased the necessity for delivering high-quality content while ensuring efficient bandwidth usage. Thus, achieving seamless user experience has become a critical challenge for researchers in this field, adaptive streaming techniques, which dynamically adjust video quality and bitrate depending on the network conditions, have become the main focus to address this issue. However traditional adaptive techniques often, due to their reactive nature, adjust encoding parameters only after network changes are detected. Hence, the delayed response leads to sudden quality drops, buffering events, and overall inconsistency in the streaming experience.

High-Efficiency Video Coding (HEVC), designed to counterbalance the limits of its predecessors, is known for its superior compression efficiency and has played a big role in high-resolution video streaming while reducing bandwidth requirements. However, existing HEVC-based adaptive streaming techniques are limited by their reactive behavior, they rely on immediate response to network feedback. These methods often struggle in unstable network conditions, resulting in non-optimal Quality of Service (QoS).

Recent advancements in artificial intelligence have introduced predictive techniques into adaptive streaming, enabling systems to anticipate network changes and adjust parameters proactively. Machine learning models, particularly, Long Short-Term Memory (LSTM) networks, have demonstrated their effectiveness in predicting bandwidth fluctuations, by capturing temporal dependencies in network data [2]. Integrating these predictive models with HEVC encoding can enhance the adaptability of streaming systems, allowing for proactive adaptations to maintain consistent video quality and reduce buffering [3]. Recent studies have explored AI-based optimization frameworks that dynamically adjust video quality and buffer sizes based on real-time network data, leading to improved user experiences [4].

In this paper, we introduce a novel proactive AI-driven approach to adaptive HEVC video transmission. This approach was designed to predict bandwidth variations in real-time and proactively adapt encoding parameters, by benefiting from machine learning techniques offered by LSTM. Enabled by LSTM, the system learns temporal patterns in historical and real-time network data to forecast bandwidth changes accurately. This predictive nature of our system makes it able to adjust bitrate and resolution ensuring consistent video quality with minimal buffering. This work contributes to the evolution of adaptive streaming technologies by introducing an AI-driven solution that enhances QoS in HEVC, demonstrated by its significant improvements of video quality metrics such as PSNR and SSIM while reducing the buffering events in modern network environments.

The remainder of this paper is structured as follows: Section II presents a review of related works, discussing

previous efforts in bandwidth prediction and adaptive streaming. Section III describes the proposed methodology, including data collection, model training, and system integration. Section IV presents the experimental setup, performance evaluation, and key results. Finally, Section V discusses limitations, and future research directions, and concludes the paper.

II. Related Work

Predicting bandwidth effectively is essential for enhancing the efficiency of adaptive video streaming and live broadcasting. Over recent years, diverse techniques have been designed to address the challenges associated with fluctuating network conditions. For instance, machine learning models have been employed to predict network bandwidth, enhancing the adaptability of streaming systems [5]. These approaches use machine learning, neural networks, and statistical techniques to attain better prediction accuracy and adaptability. In this section, we present notable works that have contributed to advancements in bandwidth prediction research.

The first work, Data-Driven Bandwidth Prediction Models and Automated Model Selection for Low Latency [6]. In this paper, the authors introduce a novel automated model for prediction (AMP) designed for low-latency live streaming with chunked transfer encoding. The AMP approach incorporates techniques for bandwidth prediction and model auto-selection, to optimize streaming performance under varying network conditions.

Another notable work is an attention-based LSTM Model for Multi-Scenario Bandwidth Prediction (ALSTM) [2]. This work introduces an ALSTM model that integrates LSTM networks with an attention mechanism to predict bandwidth across multiple scenarios. Bandwidth trajectory feature analysis is performed by the model while using Support Vector Machine (SVM) classification to achieve enhanced prediction accuracy in diverse network environments.

An additional significant work in this field, A Large Language Model-based Approach for Accurate and Adaptable Bandwidth Prediction [7]. In this work, the researchers propose a BP-LLM, a novel approach that exploits the capabilities of large language models (LLMs) to enhance bandwidth prediction. This approach employs Transformer architecture, BP-LLM captures long-term dependencies in network traffic and integrates various input modalities, through text representations, such as user location and communication latency consequently improving the accuracy and adaptability.

A further remarkable work, A Multi-Manifold Based Available Bandwidth Prediction Algorithm [8], this paper introduces an MD-AVB algorithm which is based on the observation that the available bandwidth space in the internet is multi-manifold and asymmetrical. This algorithm's aim is the enhancement of the accuracy of available bandwidth prediction by taking into consideration the complex structure of bandwidth availability in network environments.

A different noteworthy research effort, Predicting Bandwidth Utilization on Network Links Using Machine Learning [9]. This work addresses the challenge of predicting the bandwidth utilization between different network links. The researchers evaluate and compare ARIMA, Multi-Layer Perceptron (MLP), and LSTM algorithms, the study finds that LSTM outperforms the others achieving predictions with errors rarely exceeding 3%.

One more notable work is Realtime Mobile Bandwidth and Handoff Predictions in 4G/5G Networks [10]. This paper explores the possibility and accuracy of real-time mobile bandwidth and handoff predictions in 4G/LTE and 5G networks. In this work, the researchers develop the Recurrent Neural Network models, the study consistently outperforms conventional univariate and multivariate bandwidth prediction models, and it achieves over 80% accuracy in predicting 4G and 5G handoffs.

In this next table "Table I", we present a comprehensive comparison of state-of-the-art works, detailing the methodologies adopted, the metrics employed for evaluations, and the results achieved. This comparison aims to provide a clear and concise overview of the key approaches and their corresponding outcomes.

TABLE I Comparison of State-of-the-Art Approaches

Work	Methodology	Results
[6] Data-Driven Bandwidth Prediction Models and Automated Model Selection for Low Latency	ARIMA RLS RNN LSTM GRU A-RNN R-RNN Auto-selection model	Avg bandwidth prediction accuracy: 99,4% Avg QoE 0.95 Avg Latency: 2.06s Avg bitrate:1,4Mbps Avg RMSE: 0,006
[2] ALSTM: AN attention-based LSTM Model for Multi-Scenario Bandwidth Prediction	Attention-based LSTM SVM classifier	Avg prediction accuracy: 90% Avg MAE: 0,05 Mbps Avg RMSE:0,07 Mbps
[7] BP-LLM: A Large Language Model-based Approach for Accurate Bandwidth Prediction	Transformer-based LLM, multi-modality integration	Avg Prediction Accuracy: 95% improved adaptability across various scenarios
[8] MD-AVB: A Multi-Manifold-Based Available Bandwidth Prediction Algorithm	Multi-manifold model with asymmetrical bandwidth space consideration	Prediction accuracy improved by 30% over the baseline Avg MAE: 0,1 Mbps
[9] Predicting Bandwidth Utilization on Network Links Using Machine Learning	ARIMA Multi-Layer Perceptron LSTM	Avg prediction error (LSTM): 3% Avg MAE:0,05 Mbps
[10] Realtime Mobile Bandwidth and Handoff Predictions in 4G/5G Networks	RNN-based prediction models	Avg prediction accuracy: 80% Avg MAE:0.1 Mpbs Avg handoff prediction accuracy: 80%

III. Our Methodology

In this paper, we propose a novel methodology that leverages AI-powered predictive models integrated with HEVC encoding to address the challenges of bandwidth fluctuation in adaptive video transmission. The process of this methodology includes multiple stages: data collection and pre-processing, predictive model training, integration with HEVC encoder, real-time execution, and a feedback loop to optimize the system dynamically. Similar approaches have been utilized in previous studies to enhance video streaming performance [11]. This section details this process and the use of LSTM model architecture. The role and optimization of the scaling factor and the integration process for real-time adaptive transmission.

This process begins with a comprehensive data collection and pre-processing, where HEVC-encoded video sequences with different resolutions were collected from the JCT-VC dataset, while network traces were gathered from the MAWI Archive provided realistic bandwidth, latency, and packet loss scenarios. Subsequently, a simulation of complex network environments was conducted using Mininet and NetEM, introducing controlled impairments like congestion, jitter, and delays to assess system performance. Using these datasets, the LSTM model was trained on a rich feature dataset, capturing historical and real-time network metrics, and optimized through an 80-10-10 data split for training, validation, and testing.

The predictive model anticipates bandwidth fluctuations and adjusts encoding parameters dynamically using a scaling factor α, to balance bitrate and resolution. This scaling factor was optimized iteratively based on performance metrics, ensuring efficient resource utilization and minimal disruptions. The system also incorporated a feedback loop to adapt to evolving network conditions by continuously retraining the model with new data.

The effectiveness of this data is validated through metrics like PSNR and SSIM, buffering sequence, which demonstrated significant improvements in video quality and playback stability over adaptive streaming techniques. These findings align with previous research that utilized machine learning models for bandwidth prediction in video streaming [12]. By combining advanced predictive modeling with robust experimental controls. This next figure presents the methodology and experimental setup used to deliver an enhanced quality of service.

The following figure "Fig. 1" provides a visual summary of the key steps in our proposed methodology illustrating the progression from data collection and pre-processing to predictive modeling, real-time adaptation, and performance evaluation within a controlled experimental environment.

"Fig. 1" illustrates the workflow of the proposed methodology, outlining the sequence from data acquisition to real-time adaptation. To enhance understanding, we provide additional details regarding the LSTM model's structure and the selection of relevant features.

The LSTM model is composed of two sequential LSTM layers, each comprising 128 units, followed by a fully connected layer utilizing a ReLu activation function. The training process employs the Adam optimizer with a learning rate of 0.001. The model's input features include real-time bandwidth, packet loss, jitter, and latency, all extracted from network traces. These features were carefully selected due to their strong correlation with bandwidth fluctuations, allowing the model to capture temporal dependencies effectively and enhance prediction accuracy.

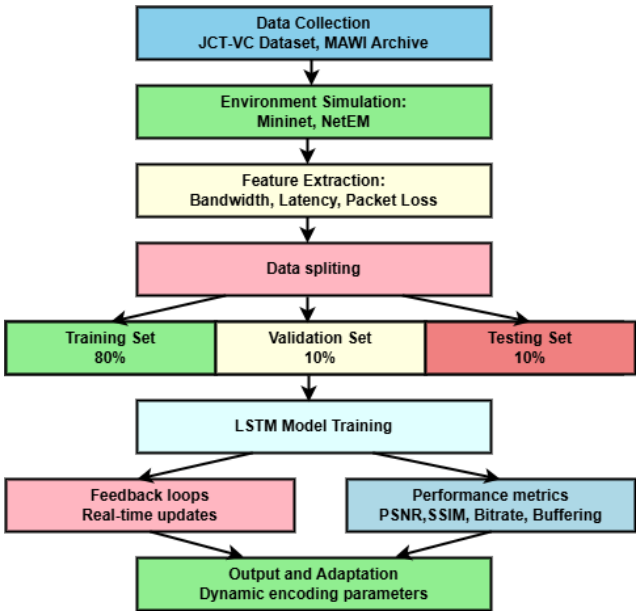

Fig. 1. Proposed approach workflow.

As for processing and integration of MAWI Archive Data, the MAWI Archive provides real-world network traces under varying network conditions. To integrate these traces into our model, we conducted a thorough preprocessing stage:

- Filtering: Irrelevant and noisy data points were removed.
- Normalization: Bandwidth values were normalized using min-max scaling.
- Smoothing: A moving average filter was applied to reduce abrupt variations.
- Alignment: The processed data was synchronized with HEVC encoding parameters, ensuring realistic simulation conditions.

Additionally, we combined historical data with real-time network conditions allowing the LSTM model to generalize effectively to dynamic environments.

The scaling factor α dynamically adjusts the encoding bitrate based on predicted bandwidth variations. Unlike static scaling, which relies on predefined thresholds (e.g., fixed bitrate changes at predetermined bandwidth levels), α continuously adapts using real-time predictions, reducing abrupt quality fluctuations. Mathematically, α is computed using "Eq. (1)":

$$\alpha = f(BW_{pred}, BW_{curr}, Q_{prev}) \quad (1)$$

Where BW_{pred} is the predicted bandwidth from the LSTM model, BW_{curr} is the current measured bandwidth, Q_{prev} is the previously selected video quality.

Unlike traditional static scaling methods that modify bitrate based on predefined thresholds or incremental adjustments, our approach leverages predictive modeling to dynamically adapt bitrate in real-time. By anticipating network variations this technique ensures seamless transitions, minimizes sudden quality drops, and significantly decreases buffering occurrences, leading to an improved viewing experience. Performance evaluations demonstrate that our method consistently surpasses static techniques in delivering stable and high-quality video streaming.

IV. Results and Discussion

In this section, we provide the experimental results of the system's performance before and after applying the proposed approach, emphasizing critical metrics such as PSNR, SSIM, bitrate fluctuations over time, and buffering events.

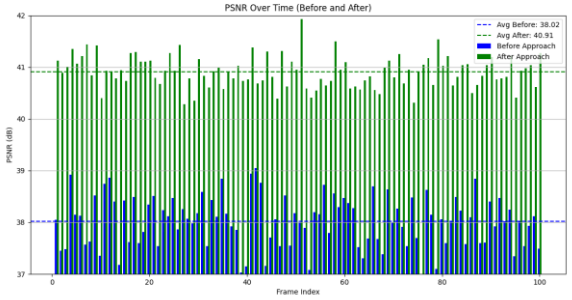

Fig. 2. PSNR comparison before and after applying our approach.

The figure above "Fig. 2" shows PSNR values change over time, highlighting the improvement in video quality after using our approach. Before using this method, PSNR values varied a lot, showing that the video quality was inconsistent because traditional streaming methods only adjusted encoding after network changes happened. Meanwhile, with the predictive algorithm, PSNR values become steadier and consistently higher.

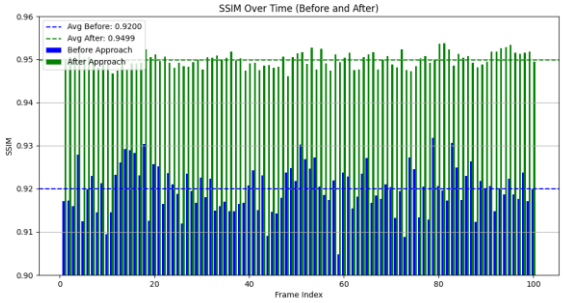

Fig. 3. SSIM comparison before and after applying our approach.

The plot above "Fig. 3" represents how SSIM values changed over time, offering a comparison of frame similarity before and after using the predictive approach. Before the algorithm, SSIM values varied greatly, showing inconsistent visual quality due to reactive bitrate changes. This often caused noticeable drops in quality, especially during complex scenes. After our predictive approach was implemented, SSIM values remained more stable and consistently higher, showing its ability to adjust encoding settings proactively. This led to smoother playback with fewer quality issues, proving the algorithm's effectiveness in maintaining visual quality and ensuring reliable streaming even with network changes.

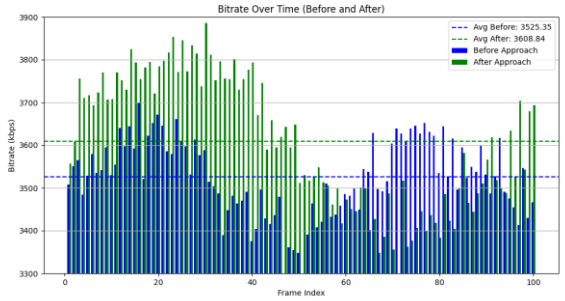

Fig. 4. Bitrate over time comparison before and after applying our approach.

The figure above "Fig. 4" demonstrates how bitrate changes over time. Before applying our method, the system uses a more aggressive bitrate adaptation, rapidly increasing the bitrate to fully utilize the available bandwidth. However, this approach often results in instability and sudden quality changes, particularly during network fluctuations. In contrast, our predictive method focuses on maintaining stability by adjusting the bitrate moderately, even when network conditions improve.

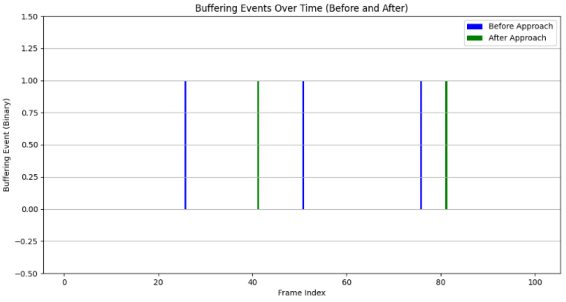

Fig. 5. Buffering events comparison before and after applying our approach.

The plot of buffering events over time "Fig. 5" compares the frequency and distribution of interruptions, before and after applying the predictive algorithm. Before applying our approach, buffering events were more common and spread across multiple frames reflecting the reactive nature of the streaming method, which struggles to quickly adjust to changing network conditions leading to frequent interruptions. On the other hand, after applying our predictive algorithm, the plot shows a significant decrease in buffering events, demonstrating that the predictive algorithm successfully anticipates network fluctuations and adjusts the video encoding proactively. This results in a much smoother streaming experience with fewer disruptions.

In this section, we compared the system's performance before and after applying our predictive approach, focusing on metrics like PSNR, SSIM, bitrate, and buffering events. The results show notable improvements with the AI-based algorithm. PSNR values are more stable and consistently higher, indicating better video quality. SSIM demonstrates fewer fluctuations keeping the visual quality intact. Bitrate adaptation

is smoother enhancing the overall stability and reducing buffering. Moreover, the buffering events are significantly fewer, as the predictive algorithm anticipates network changes and adjusts the encoding accordingly leading to better quality of service. AI-driven adaptive streaming architectures have been shown to effectively adjust video quality and buffer sizes in response to network variability, resulting in enhanced user experiences [13].

V. Baseline Comparison

Deep learning-based network performance prediction models have been utilized to train adaptive bitrate algorithms, improving the robustness and generalizability of streaming systems [14]. For evaluation purposes, we compare our proposed approach against baseline methods using key metrics, the following table "Table II" highlights how our method outperforms others in terms of PSNR, SSIM, latency, and buffering events.

TABLE II Performance Comparison of Proposed Approach vs. Baseline Methods

Metric	Method	Value	Proposed Approach
PSNR(dB)	AMP [6]	39,1	41,2
	ALSTM [2]	40,5	
	Bp-LLM [7]	39,8	
	MD-AVB [8]	38,7	
SSIM	ALSTM [2]	0,93	0,945
	MLP [9]	0,92	
Latency (ms)	AMP [6]	52 ms	45 ms
	Realtime RNN[10]	55 ms	
Buffering Events	AMP [6]	4 events	2 events
	MD-AVB [8]	3 events	

Now we will present a graphical representation of the results "Fig. 6", to illustrate the performance metrics. The first graph, highlights a detailed analysis of PSNR values, showcasing the improvement of PSNR values by our approach, indicating enhanced video quality surpassing ALSTM [2] and other referenced methods.

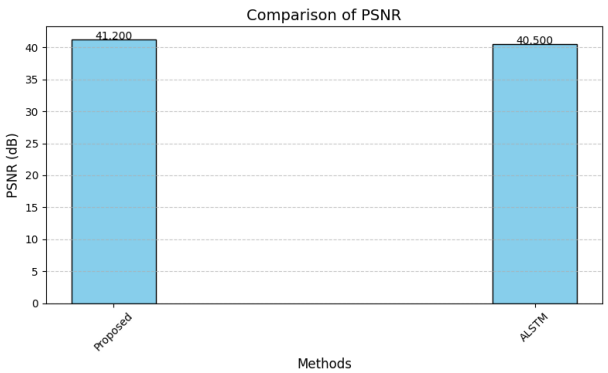

Fig. 6. PSNR comparison between our approach and ALSTM.

This next graph "Fig. 7" demonstrates the notable improvement of SSIM values achieved by our proposed method. The improvement of structural similarity showcases our method's capability to maintain higher visual fidelity, especially under changing network conditions, outperforming ALSTM [2] and MLP [9].

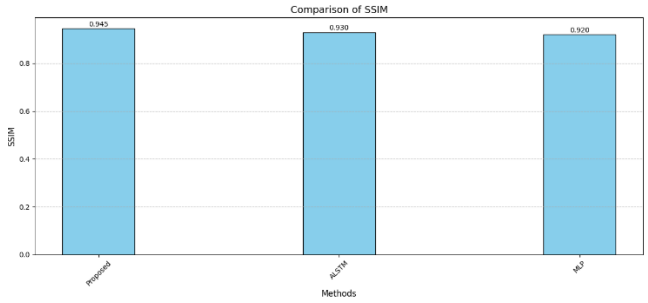

Fig. 7. SSIM comparison between our approach and ALSTM and MLP.

The following plot "Fig. 8" highlights the significant latency reduction attained by our approach. Surpassing AMP [6] and RNN [10], demonstrates the efficiency of our approach to deliver fast responses and adaptive coding.

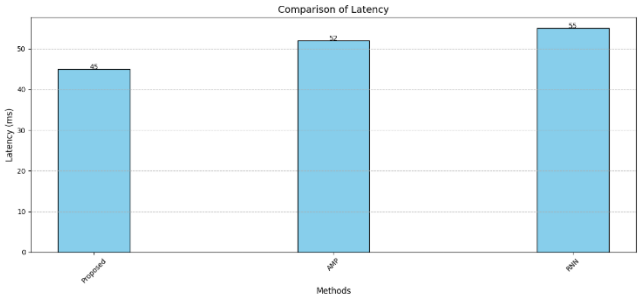

Fig. 8. Latency comparison between our approach and AMP and RNN.

This last graph "Fig. 9" shows the important decrease in buffering events achieved by our algorithm in comparison with AMP [6] and MD-AVB [8], the results demonstrate our method's ability to deliver a smoother streaming experience with minimal disruptions.

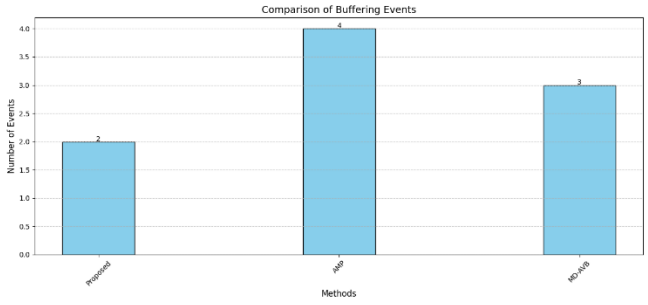

Fig. 9. Buffering events comparison between our approach and AMP and MD-AVB.

Our proposed approach demonstrates superior performance across different key metrics. It achieves an average PSNR of 41,2 dB, surpassing all methods stated in the related works section, with ALSTM [2] being the closest at 40,5 dB. In terms of structural similarity (SSIM), our approach attains a value of 0,945, outperforming ALSTM [2] attaining 0,93 and MLP [9]

achieving 0,92. Furthermore, our predictive algorithm reduces latency to 45 ms, exceeding AMP [6] 52 ms and the Realtime RNN approach [10] 55 ms. Finally, our method reports only 2 buffering events on average, making a clear improvement over AMP [6] (4 events) and MD-AVB (3 events).

VI. Conclusion

The integration of AI-driven predictive models represents a significant advancement in adaptive streaming technologies, offering the potential for more responsive and efficient video delivery systems [15]. This work introduced a novel AI-powered predictive approach for adaptive HEVC video transmission, addressing the challenges for real-time applications, particularly on resource-constrained devices. Furthermore, the applicability of our approach across diverse network environments. By leveraging Long Short-Term Memory (LSTM)) models, our system predicts bandwidth fluctuations in real-time, enabling proactive encoding adjustments that ensure smooth adaptation and improved viewing experiences. The experimental results demonstrate significant improvements, with PSNR reaching 41,2 dB, SSIM at 0,945, and latency reduced to an average of 45 ms, contributing to fewer buffering events and enhanced stability in video streaming.

Despite these advancements, certain limitations must be considered. The computational overhead of LSTM-based prediction models may pose challenges for real-time applications, particularly on resource-constrained devices. Furthermore, the applicability of our environments, including low-latency and high-mobility scenarios, requires further evaluation to ensure robust performance under varying conditions.

Future work will focus on optimizing the computational efficiency of our model, investigating alternative lightweight machine learning approaches such as GRUs or hybrid deep learning techniques to enhance adaptability for mobile and edge computing environments. Additionally, we plan to extend the system's capabilities for next-generation adaptive streaming, particularly in the context of 5G networks, to further improve real-time video delivery in ultra-low latency scenarios.

Overall, this research demonstrates the potential of AI-driven predictive models in enhancing adaptive HEVC streaming by providing stable video quality, reduced buffering, and efficient bandwidth utilization. Further developments will aim to refine its implementation for broader deployment in emerging network infrastructures.

***Abstract*—In this research, we address the problem of stopword detection in Classical Chinese Poetry, an area that has not been explored previously. Stopword detection is crucial in text mining tasks, as identifying and removing stopwords is essential for improving the performance of various natural language processing models. Inspired by the TF-IDF method, we propose a novel approach that utilizes external knowledge to reconstruct the Term Weight matrix. Our key finding is that incorporating external knowledge significantly refines the granularity of the term weight, thereby improving the effectiveness of stopword detection. Based on these findings, we conclude that external knowledge can enhance the ability of text representation, especially for the short texts in Classical Chinese Poetry.**

***Keywords*—TF-IDF; stopwords; Chinese; poetry; frequency**

I. Introduction

Stopwords are words that contain little semantic information and do not significantly contribute to text processing, despite their high frequency of occurrence [1, 2]. In text mining and information processing tasks (such as text classification and clustering), stopwords should generally be removed during the preprocessing stage [3, 4]. Removing stopwords can significantly improve the results of tasks such as feature extraction [5, 6], topic modeling [7], classification [8], ontology construction [9], and keyword extraction [10]. Stopwords have domain-specific characteristics, meaning that different domains have different stopword lists. They are typically a cluster of non-restrictive words. Since there is no fixed scope for stopwords, detecting them remains an evolving research field.

With the increasing popularity of classical Chinese poetry worldwide, more and more scholars are paying attention to it. Classical Chinese poetry is the pinnacle of Chinese traditional culture, and research on it will contribute to the development of Chinese culture. Currently, research in information retrieval and natural language processing in the Chinese language is mostly focused on modern Chinese, rather than classical Chinese. To the best of our knowledge, no researchers has yet conducted research on stopwords in classical Chinese poetry. Therefore, the significance of this study lies in our being the first to explore this area.

However, classical Chinese poetry is characterized by short texts, with many articles containing fewer than 20 tokens. These texts have low token repetition rates and are sparse, which makes them different from typical longer texts in text mining. Traditional methods, which rely solely on term frequency for stopword detection, face a challenge in this context, as they tend to result in nearly identical term frequencies for almost all terms. This leads to the issue of treating all terms equally. As a result, traditional methods often perform poorly when dealing with short texts. In this paper, we attempt to enhance the ability of text representation by using the TextRank method. We replace traditional Term Frequency with a finer measure of Term Importance, allowing for greater term index diversity in the text.

The structure of this paper is as follows: the first section introduces the research on stopwords in classical poetry; the second section reviews related research; the third section presents our proposed method; the fourth section describes our experiments, including the source of datasets, experimental processes, results, and discussion; finally, we conclude with a summary and outlook.

II. Related Works

Over the years, many researchers have explored stopwords issues, but we find that there has been little research on stopwords in Chinese classical poetry.

Zou et al. proposed a novel stopword list evaluation method using a mutual information-based Chinese segmentation approach [11]. Since this paper was published before the advent of Chinese automatic segmenters, its application scenario involved directly detecting stopwords in complete sentences. It uses mutual information values and sets thresholds and boundaries to calculate the association between grams.

Kucukyilmaz et al. used a classification approach to detect stopwords by constructing various features [12]. The features they used include frequency, term frequency, inverse document frequency, mean probability, variance probability, entropy, information model, and word positioning. They then evaluated their method using different classifiers.

Ferilli et al. employed Kullback-Leibler (KL) divergence as a measurement method and tested it on Italian language corpora [13]. This method is suitable for very small datasets, even those containing just one document.

Gerlach et al. used conditional entropy and a random null model to process stopwords [14]. Conditional entropy was used as the upper bound for the entropy of idealized stopwords, while the random null model was applied to compensate for undersampling. The difference between the two was then used as a criterion for measuring stopwords. The authors used quality assessment metrics such as NMI (Normalized Mutual

Information) for topic models and accuracy for classification tasks to experiment with the stopwords they detected.

Achsan et al. used the Term Frequency Inverse Document Frequency (TF-IDF) method to extract stopwords from a corpus collected from Indonesian online newspapers [15]. Since our method was inspired by their work, a detailed introduction to the method they used is provided here.

Specifically, $TF-IDF(t,d,D) = TF(t,d) \cdot IDF(t,D)$, where $TF-IDF(t,d,D)$ represents the TF-IDF score of a term t in the document d given the document collection D. For a vocabulary of size V and a total documents of number M, TF-IDF forms a $M*V$ matrix, which has M rows (corresponding to the number of documents) and V columns (corresponding to the vocabulary size). Each entry in the matrix corresponds to a TF-IDF score of a specific term t.

$TF(t,d)$ refers to the frequency of a term t in the document d, calculated as the number of occurrences of the term in the document divided by the total number of terms in the document which is also the document length.

$$TF(t,d) = \frac{f(t,d)}{\sum_{t' \in d} f(t',d)} \quad (1)$$

in which, $f(t,d)$ is the number of times the term t appears in document d, and $\sum_{t' \in d} f(t',d)$ is the total number of occurrences of all terms in document d.

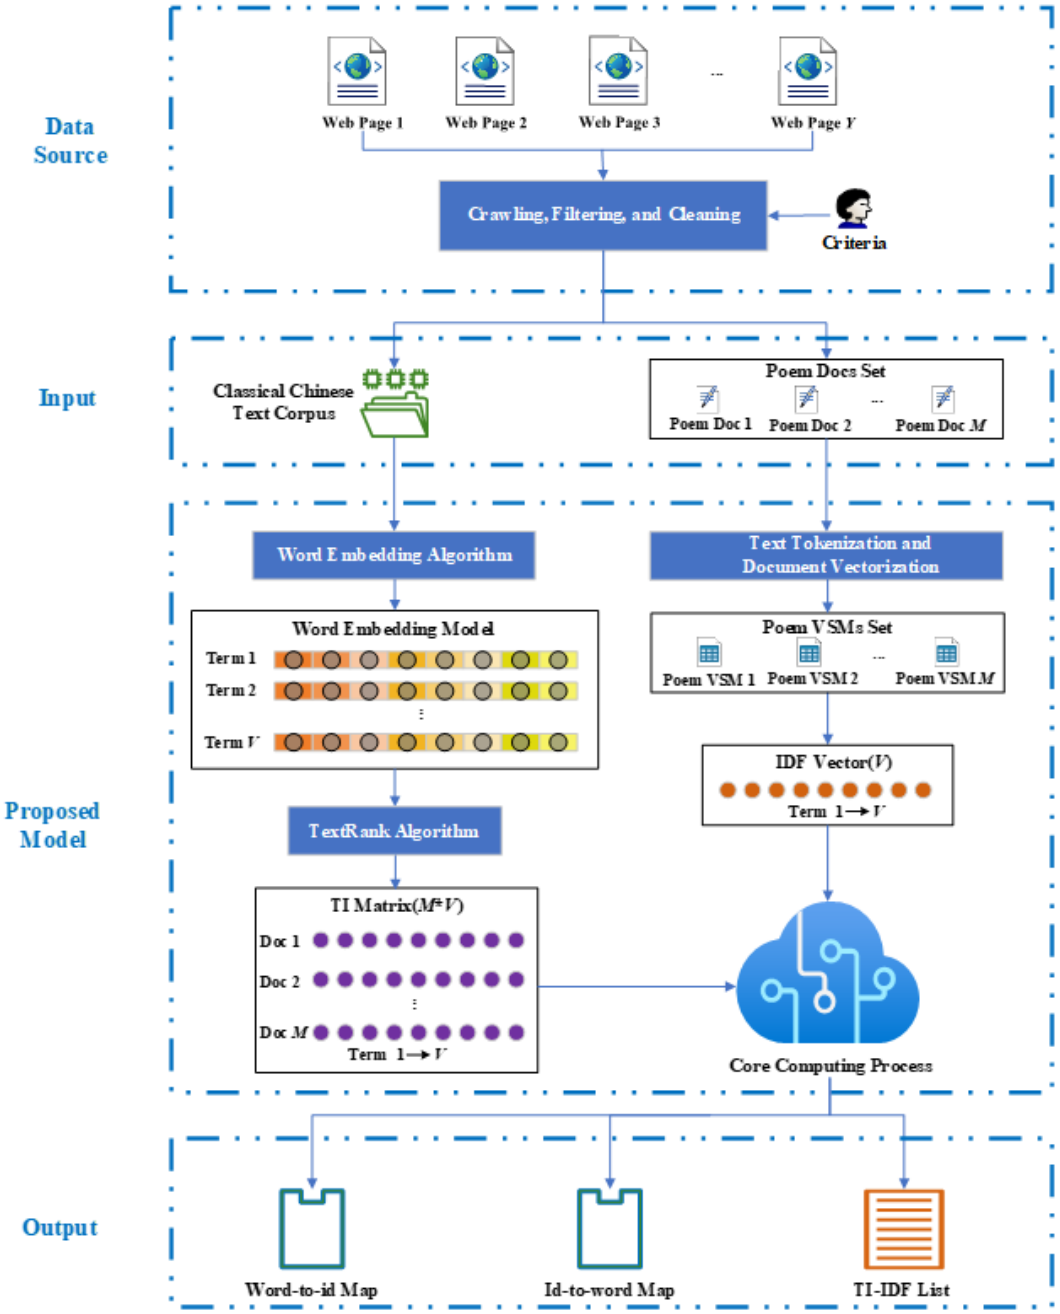

Fig. 1. Overall workflow comprising the proposed model.

$IDF(t, D)$ stands for Inverse Document Frequency of the documents comprising term t in total document collection D. The concept was introduced based on the idea that if a term t appears in most of the documents, it means the term does not help to distinguish between documents, and therefore it is not an important word. Its calculation method is the inverse operation of the proportion mentioned above with a logarithmic operation outside. It is a vector, as it is calculated for each term, making it a vector of length V.

$$IDF(t, D) = \log\left(\frac{N}{df(t)}\right) \quad (2)$$

in which, D is the document collection, N is the total number of documents in the document collection, and $df(t)$ is the number of documents that the word t appears in.

Finally, multiplying $TF(M, V)$ by $IDF(V)$ results in an $M*V$ matrix. For each term's TF-IDF score, according to Achsan et al's method, it should iterate through all documents, summing and averaging the TF-IDF values of the term. Then we list the average TF-IDF values of all terms in ascending order. Terms at the top are more likely to be stopwords, while terms at the bottom have a higher distinguishing ability for the document collection, meaning they are more likely to be significant terms.

Chinese language is considered a low-resource language, and research on stopwords in Chinese is still relatively scarce. Moreover, most available studies focus on modern Chinese, with seldom literature found on stopwords in Classical Chinese. The method proposed by Zou et al. is no longer applicable with the existence of Chinese word segmentation tools. Other studies primarily focus on long texts, which cannot be applied to short text corpora like Classical Chinese poetry. Kucukyilmaz et al. used a classification approach relying on various features such as word frequency and inverse document frequency. However, these features may not be effective for short texts with high contextual dependencies. Ferilli et al.'s use of the KL divergence method mainly measures the difference between two distributions, but for Classical Chinese poetry, which is structurally complex, lexically rich, and relatively short, KL divergence may not effectively capture the distributional characteristics. Gerlach et al.'s method relies on calculating conditional entropy, which is based on word frequency and may not effectively capture contextual relationships.

The Chinese poems are always short texts, while the all above methods are designed for long texts. Specifically, for the method used by Achsan et al., since each document researched in our research contains only a few terms, and each term appears only once, this leads to almost identical term frequency (TF) values for all terms in most documents. This creates significant challenges for the subsequent calculations.

III. Proposed Model

A. Overall Process

First, we crawl the required data from the Internet, which includes not only the classical Chinese poetry for this research but also the related external knowledge corpora. After obtaining all the data, we clean it according to the actual requirements. Once the data is cleaned, we divide it into two parts and feed them into the model.

On one hand, for the cleaned classical Chinese poetry, we perform character segmentation for each document and use Vector Space Model (VSM) to obtain vectorization. This is used to calculate the IDF vector for the entire poetry dataset. On the other hand, for the external knowledge, we perform word vector training and TextRank computation. This produces a Term Importance (TI) matrix, which we will explain in more detail in the next subsection. Afterward, we merge the TI and IDF to perform the Term Importance Inverse Document Frequency (TI-IDF) calculation. This is the core of our computation. Finally, we sort the resulting TI-IDF values in ascending order, and the terms on the top are more likely to be identified as stopwords. The overall workflow is shown in Fig. 1.

B. External Knowledge

- Step 1: We use word embedding technology to train the external knowledge corpus and obtain a word vector model. Word embedding is a technique that maps tokens from natural language into a real-valued space. It was first introduced by Bengio et al. in 2003 [16]. However, due to the complexity, it has not been given much attention until Mikolov et al. simplified the neural network architecture in 2013 [17]. After that Google implemented it and released the Word2Vec (W2V), which greatly advanced the development and application of word embedding technology. After training the word vector model, we can easily obtain the vector corresponding to each word, and then calculate the semantic similarity between words. The reason we obtain word vectors here is to perform the subsequent term importance (TI) computation in step 2.

- Step 2: The word vectors obtained in the previous step are then input into the TextRank algorithm. TextRank was proposed by Mihalcea et al. and inspired by Google's foundational algorithm, PageRank [18]. The basic idea of PageRank is that if a page is referenced by many other pages, its importance is higher than that of others. TextRank applies this concept to text analysis. The computation unit is focused from web pages to sentences, and the link structure between web pages is replaced by the semantic similarity between sentences. The result is a ranking of sentence importance, and it is commonly used for tasks like key sentence identification and summary extraction. The TextRank formula is calculated as:

$$WS(V_i) = (1-d) + d * \sum_{V_j \in In(V_i)} \frac{W_{ji}}{\sum_{V_k \in Out(V_j)} W_{jk}} WS(V_j) \quad (3)$$

in which, $WS(V_i)$ represents the weight of sentence i, and the sum on the right represents the contribution of each sentence to this sentence. In a single document, we can roughly think that all sentences are adjacent. W_{ji} represents the similarity of sentence j and i, and $WS(V_j)$ represents the weight of the last iterated sentence V_j. $In(V_i)$ means the precursor nodes of V_i, that the nodes point to V_i. $Out(V_j)$

means the follow-up nodes of V_j, that the nodes point out from V_j.

In our model, we adjust the TextRank method by changing the computation unit from a sentence to a token. Using the word vectors from the previous step, we calculate the semantic similarity between terms. We then input the constructed token similarity matrix into TextRank, ultimately obtaining the term importance matrix. This process is described in Algorithm 1.

Algorithm 1: Compute term importance
Input: The word embedding pretrained model *wv*: {term: term_vec}, the document index *d*.
Output: The term importance dict, the corresponding term count dict.

```
# term count
token_id_list[] = Document[d].get_tokens()
term_count_dict = {}
for token_id in token_id_list:
    if token not in term_count_dict:
        term_count_dict[token_id] = 1
    else:
        term_count_dict[token_id] += 1
# compute distinguished terms list
term_id_list[] = term_count_dict.keys()
# compute TextrRank value
similarity = [][]
    for term_1 in term_id_list:
        for term_2 in term_id_list:
            similarity[term_1][term_2] =
            compute_similarity(wv(term_1),wv(term_2))
term_TR_dict{} = TextrRank(similarity)
return term_TR_dict, term_count_dict
```

C. Core Computation

For the obtained term_TR_dict (term TextRank dictionary) and term_count_dict (term count dictionary), we will arrange the keys according to the vocabulary order in the VSM to get the term importance vector $\overrightarrow{\zeta_d} = [\zeta_{d\_1}, \zeta_{d\_2}, \cdots, \zeta_{d\_v}]$ and the corresponding term count vector $\overrightarrow{\lambda_d} = [\lambda_{d\_1}, \lambda_{d\_2}, \cdots, \lambda_{d\_v}]$. Here, d_i represents the *i*-th term in the vocabulary of document *d*. ζ_{term} and λ_{term} represent the importance value and count value corresponding to the term. We multiply $\overrightarrow{\zeta_d}$ with $\overrightarrow{\lambda_d}$, and then apply softmax to obtain the term importance result. It is important to note that the softmax operation is used to smooth the data and ensure that all values fall within the range of 0 to 1.

$$Term\ Importance(d\_i) = softmax(\zeta_{d\_i} \cdot \lambda_{d\_i}) = \frac{e^{\zeta_{d\_i} \cdot \lambda_{d\_i}}}{\sum_{j=1}^{d_v} e^{\zeta_{d\_j} \cdot \lambda_{d\_j}}} \ for\ i = 1,2,\cdots,d_v \quad (4)$$

After obtaining the term importance list, its length will be d_v, which is the number of terms in the document, d's vocabulary, rather than the length of the entire vocabulary V, D's vocabulary. We should map it to the entire vocabulary to obtain the vector, which will be constructed as row in the Term Importance matrix. For terms that do not appear in the document, we set their values to 0. Below is the pseudocode for this process:

```
z_d_final[] = zero(V)
for i in [1, V]:
    z_d_final[i] = Term Importance[vocabulary[i]]
return z_d_final
```

This is for just one document, and we need to perform this operation on all documents to ultimately obtain the entire term importance matrix. For IDF, we still use the calculation method from the TF-IDF approach. Therefore, the final calculation formula is:

$$TI - IDF(t,d,D) = TI(t,d) \cdot IDF(t,D) \quad (5)$$

in which:

$$TI(t,d) = Term\ Importance(t)\ on\ Doc[d] \quad (6)$$

and

$$IDF(t,D) = \log\left(\frac{N}{df(t)}\right) \quad (7)$$

For all terms, we also apply the method used in Achsan's paper, computing the average to obtain the final result.

$$TI - IDF(t,D) = \frac{\sum_{d=1}^{N} TI(t,d)}{df(t)} \cdot \log\left(\frac{N}{df(t)}\right) \quad (8)$$

IV. Experiment

A. Dataset

The Tang poetry and Song poetry, with one representing the highest quality and the other the largest quantity, are suitable to be the subjects in this research. Since these two datasets are publicly available on the Internet, we crawled them from online sources[1,2]. Finally, we obtain Complete Tang Poems (CTP) dataset and Poems of Song Dynasty (PSD) dataset. As the main focus of this paper is on stopword detection, the details of the crawling, storing, tokenizing, and cleaning process are not elaborated here due to space limitations.

TABLE I. Datasets Details

-	CTP Dataset	PSD Dataset
Document #	42,479	182,213
Vocabulary Size	7,062	11,230
Min length	3	5
Max length	3,750	2,013
Avg length	58.62	58.71

To verify the efficiency of our stopword detection, we need to set some stopwords as criteria. We invited three graduate students majoring in Chinese language and literature to each list some stopwords based on their knowledge of poetry. Then, we extracted the common words from the three lists, which totals 54 words. Finally, this stopwords list have received

[1] http://www.wenxue100.com/book_GuDianShiCiWen/5.thtml
[2] http://www.wenxue100.com/book_GuDianShiCiWen/26.thtml

unanimous approval from the three volunteers, and we published it here.[3]

B. External Information

We downloaded a dataset used as studying classical Chinese texts for ancient Chinese people from the website4. The dataset includes Confucian classics (Jing), History (Shi), Philosophy (Zi), and Literature (Ji). It contains 43 million Chinese characters and a vocabulary length of 16,413, making it well-suited for training word embedding model.

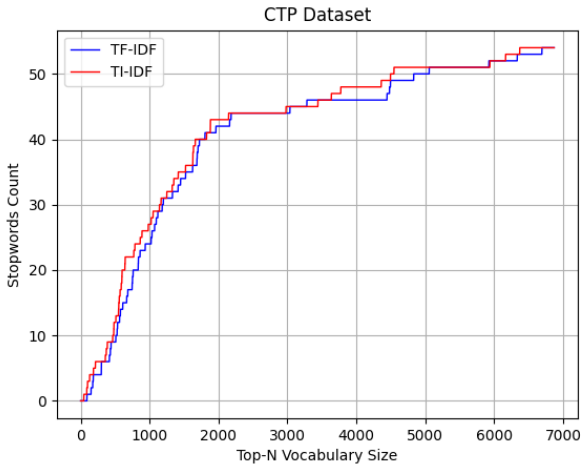
C. Running Configuration

Our program runs in the following environment: a PC with Windows 10, an Intel Xeon E5-2680 CPU (2.4GHz 2 Cores), 64GB of RAM, and a 1TB hard drive. The programming language is Python 3.7, with the development environment PyCharm 2021.3 and Anaconda 4.7.10. For word embeddings, we use Gensim 4.2.0, with parameters set to CBOW and Negative Sampling, and a word vector dimension of 100. For TextRank, we use NetworkX 2.6.3 for the implementation, and the damping factor d is set to 0.85, as in most other researches.

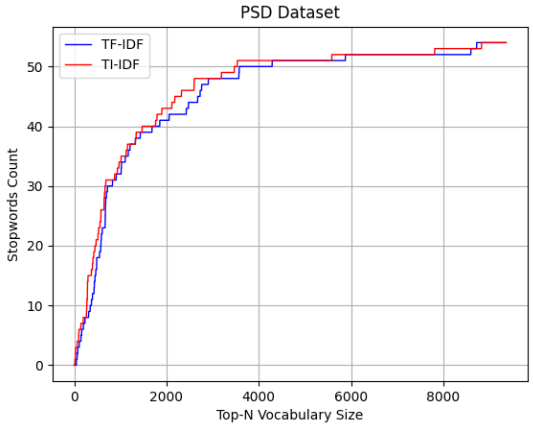
D. Results

We can observe that the trend of our model is similar to that of the original model shown in Fig. 2. As shown in Fig. 2, in nearly all regions, the number of stopwords detected by our method exceeds that of the TF-IDF method, except for a few specific intervals, such as in Fig. 2(a) when the TOP-N range is approximately within [1750, 1800] and [3300, 3400], and in Fig. 2(b) when the TOP-N range is approximately within [6900, 7000].

In Fig. 2(a), when TOP-N is in the range of 0 to 2000, the number of stopwords increases rapidly. After TOP-N exceeds 2000, the growth rate of stopword numbers levels off. In Fig. 2(b), when TOP-N is in the range of 0 to 1000, the number of stopwords significantly increases, then slows down between 1000 and 3500, and eventually experiences a smooth upward trend after TOP-N exceeds 3500.

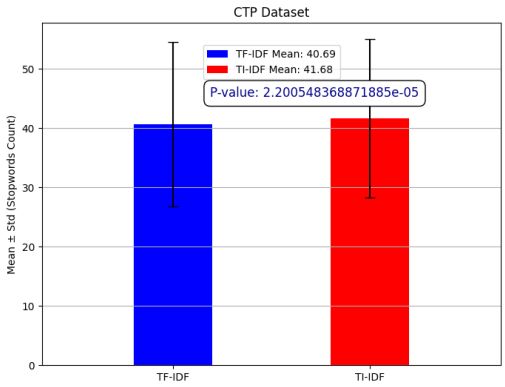


(a) Stopwords count details on CTP dataset.

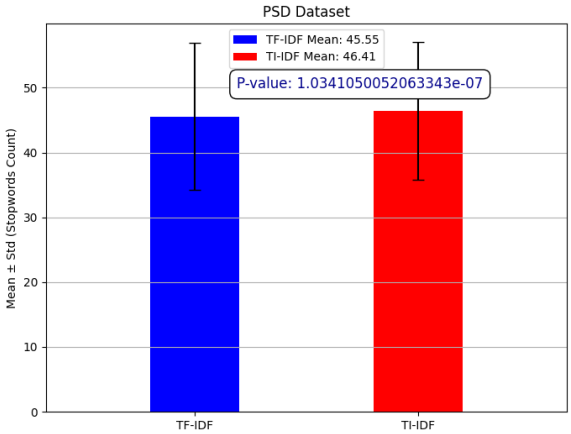


(b) Stopwords count details on PSD dataset.

Fig. 2. Stopwords count comprised in top-n terms.



(a). Statistical features comparison on CTP dataset.



(b). Statistical features comparison on PSD dataset.

Fig. 3. Statistical features comparison of the results.

Additionally, we compared our results with those of the TF-IDF method, using these two sets of data for analysis through the mean, standard deviation, and *t*-test. The results are shown in Fig. 3, where Fig. 3(a) shows the comparison on the CTP dataset and Fig. 3(b) shows the comparison on the PSD dataset. We found that the mean of our method exceeds that of the TF-IDF method by approximately 0.9 percentage points across both datasets. In terms of standard deviation, our method generally has a smaller standard deviation compared to the TF-IDF method, except in the CTP dataset, where the

[3] https://github.com/powerwings0377/stwords_list
[4] https://so.gushiwen.cn/guwen

standard deviation of the TI-IDF method is slightly higher than that of the TF-IDF method. The *p*-values for both datasets in *t*-test are far less than 0.01, indicating that the results of our method show statistical significance in the comparison experiment.

E. Discussion

Our model exhibits similar performance across the two corpora. For example, when TOP-N is 1000, the stopwords count for both corpora is approximately 30, and when TOP-N is 2000, the stopwords count is around 40. However, there are differences in performance between the two corpora. For instance, the rate of increase in stopwords count differs due to the size of the vocabulary. The CTP corpus has a vocabulary size of around 6000, while the PSD corpus has a vocabulary size of over 11,000. The vocabulary in the CTP corpus is more condensed, which causes a steeper increase in stopwords count. When TOP-N reaches 4000, the stopwords count in the PSD corpus exceeds 50 and starts to level off, while in the CTP corpus, the stopwords count is still rising. Additionally, as shown in Fig. 3, we can conclude that as the number of documents and the vocabulary size increase, the detection of stopwords improves.

The reason our method outperforms the original method in most areas is that we incorporate external knowledge into the term weight calculation, which introduces a "preference" factor into the weight computation. In the original method, the weight is computed based on term frequency, which leads to equal weights for equal frequencies. Since most terms in a poetry document appear only once, terms, whether important or unimportant, are treated the same. In our method, important terms are assigned higher weights, making previously equal weights become fine-grained. This increases the term index diversity and makes the calculation results more rational.

V. Conclusion

As a low-resource language, classical Chinese desires information technology processing all the time. As the detection of stopwords in Chinese classical poetry has never been researched before, in this paper, we proposed a TI-IDF method to address this issue, in which large-scale classical Chinese resources are used as an external knowledge base. By utilizing word embeddings and TextRank, we constructed a Term Importance matrix to replace the Term Frequency matrix in the original TF-IDF method. We found that the Term Importance matrix constructed in this paper provided a more refined calculation of term weights compared to the Term Frequency matrix, as external knowledge plays a key role in fine-tuning the process. Our excellent performance on the CTP and PSD datasets also validates the reliability of our method.

This paper explores stopword detection in classical Chinese poetry. The effectiveness of our proposed method largely depends on the selection of external knowledge. Due to the use of a pre-trained word embedding model and the construction of the TextRank network, there was an increase in training time; however, this does not affect the improvement in model performance. For future work, we aim to explore labeled datasets and conduct research on the impact of text analysis performance with stopword removal.

***Abstract*—Data security and privacy are critical concerns when integrating Closed-Circuit Television (CCTV) cameras with the Internet of Things (IoT). To enhance security, IoT data must be encrypted before transmission and storage. However, to minimize overheads related to storage space, computational time, and transmission energy, data can be compressed prior to encryption. H.264/AVC (Advanced Video Coding) offers a balanced solution for video compression by addressing processing demands, video quality, and compression efficiency. Encryption is vital for safeguarding data security, yet the integrity of IoT data may sometimes be compromised. Ineffective data selection can lead to inefficiencies and potential security risks, highlighting the importance of addressing CCTV video data security carefully. This study proposes an algorithm that integrates compression with selective encryption techniques to reduce computational overhead while ensuring access to critical information for real-time analysis. By employing frame intervals, the algorithm enhances efficiency without compromising security. The execution details and merits of the proposed approach are analyzed, demonstrating its effectiveness in safeguarding the privacy and integrity of IoT CCTV video data. Results reveal superior performance in terms of compression efficiency and encryption/decryption times, with an average encryption time of 0.00171 seconds for a 128-bit key, enabling fast processing suitable for real-time applications. The decryption time matches the encryption time, confirming the method's viability for practical IoT CCTV implementations. Metrics such as correlation coefficient, bitrate overhead, and histogram analysis further validate the approach's robustness against statistical attacks.**

I. Introduction

There has been a noticeable advancement in video surveillance systems with the blend of IoT and CCTV systems. Remote monitoring and real-time analytics are one of the major benefits of this integration. Besides the positive aspects, the crucial problem here is to fortify the security of IoT-based CCTV video surveillance systems [1],[2]. The proliferation of IoT devices, specifically CCTV cameras has led to the tremendous rise in IoT generated data. A lot of security issues have been caused by large volume of generated data. The most crucial issues are unauthorized access, breach of privacy, and data leaks that affect the confidentiality of IoT data [3],[4]. Maintaining data integrity is essential to tackle these security related issues. After data integrity, another important aspect of data security is confidentiality, as information captured by CCTV cameras is highly sensitive. To maintain confidentiality, and to provide unauthorized access, reliable communication methods, and optimized encryption and decryption methods are highly required [5],[6],[7]. The security issues raised by the combination of IoT and CCTV need constant research and preventive strategies to overcome increasing security issues.

Video data has been secured using conventional encryption methods such as DES (Data Encryption Standard), RSA (Rivest–Shamir–Adleman), and AES (Advanced Encryption Standard). The purpose of these encryption techniques is to shield data by making it unintelligible to those lacking the decryption key. Encrypting whole video streams or files can protect them from unauthorized access. However, there are several limitations to this encryption method, especially when it comes to transmission latency and processing overhead. The primary issue encountered by CCTV systems is the storage and bandwidth demands related to video data. Modern HD (high definition) cameras produce substantial volumes of video data, requiring the implementation of compression methods to decrease file sizes for effective storage and transmission. The compression techniques H.264 and H.265 are two established standards for video data compression due to their ability to substantially decrease the size of video files without compromising the video quality. The use of compression and encryption to strengthen video surveillance system security has been the subject of a great deal of research. Most of the early work centered on full encryption techniques, that is applying conventional cryptographic algorithms to video streams, such as AES or RSA. However, the enormous computational cost of encrypting full video was a considerable challenge, especially for real-time applications like CCTV systems.

Selective encryption has come out as a highly promising approach to tackle these issues. Studies showed that substantial computational reductions can be attained without compromising the security of a video by selectively encrypting the most crucial or sensitive portions of a video. Early researchers, such as Meyer and Gadegast (1995) introduced progressive selective encryption methods for MPEG video streams. Those methods focused on encrypting only the I-frames (intra-coded frames) while allowing P-frames (predicted frames) and B-frames (bi-directional frames) to remain

*Corresponding Author, Email ID: ygulzar@kfu.edu.sa (Y.G.), amanpreet.kaur@chitkara.edu.in (A.K)

unencrypted. While this technique decreased the computing burden, it also led to the potential vulnerability of the unencrypted sections of the video to attacks. The research has expanded upon these principles by investigating methods to strengthen selective encryption by enhancing sensitive content detection in video streams.

Although selective encryption methods have shown excellent results, there are still certain issues and challenges in maintaining the security and effectiveness of CCTV systems. One of the major issues is computational overhead. Implementing complete encryption of CCTV videos using standard cryptographic methods is computationally complex, leading to performance issues in real-time systems, particularly those with low processing resources. Another major issue is the storage and bandwidth limitations of CCTV devices. Videos obtained by high-resolution surveillance systems require considerable storage capacity and bandwidth, thereby requiring the implementation of compression methods. Nevertheless, combining compression and encryption presents additional issues in preserving the security and integrity of CCTV video. The efficiency of selective encryption techniques is also a major issue among all as most of the selective encryption techniques cannot provide a secure and efficient solution. When only a selected piece of a CCTV video is encrypted, it can expose the other portions to attack, particularly in situations where unencrypted data might be used to deduce critical information.

Therefore, the objective of the study is to strenghten the security of CCTV video surveillance systems by boosting data integrity. Therefore, this study presents substantial results and highlights the importance of security in IoT based CCTV video monitoring systems. Providing users with reliable data and practical solutions to protect the safety and durability of their digital data is the primary goal [8],[9]. To better understand the complex aspects of this security problem, research is being done on data integrity, confidentiality, and the dynamic management of cyber threats. Robust security measures are necessary to counter possible risks including illegal access, data breaches, and privacy infringements, as this increase in data often contains sensitive information [10],[11].

This paper is structured as follows. First the introduction is defined, then "Related Work" reviews the existing literary works."Proposed Scheme" is the next section that addresses the suggested approach. The experimental findings are presented in "Experimental Results and Discussion," which also illustrates the system's suggested output. Lastly, we covered the conclusion in the last section.

II. Related Work

Gbashi et al. [12] proposed a novel, lightweight encryption technique for video frames that makes use of the ChaCha20 algorithm and a hybrid chaotic system. While 2D chaotic systems expand key space, the chaos system is used to produce encryption and seed keys. The encryption algorithm is effective against statistical attacks as shown in the results. The suggested approach is efficient in statistical measures and encryption effectiveness. Still, there is a need to apply this method to high-quality videos to reduce complexity so that it can be used in real time applications.

To further improve the encryption technique, Cheng et al. [13] proposed a selective video encryption method that relies on the integration of four-dimensional hyperchaotic systems and a video coding algorithm. This scheme works in two modes. One for the small encrypted data and less security required and the other for the large amount of encrypted data and sufficient real time security. According to the author's findings, this scheme is better than other existing video encryption methods in performance and encryption efficiency. But still, this method lacks real time implementation as all the results are proved by theoretical analysis only.

Lee and Park [14] discussed the importance of machine learning in the continuous growth of CCTV video surveillance systems. The efficiency of surveillance systems is enhanced by using cloud based video monitoring systems, but privacy and security issues become major concerns. Therefore, for processing CCTV video data, blockchain based method is proposed that not only ensures privacy but also synchronizes large volumes of video data. The proposed method supports the delta update function and is durable against attacks by encrypting transmitted data and thus suitable for intelligent video surveillance systems as it reduces the bandwidth required for transmission. But for real time implementation, more accurate video analysis will be required.

To provide reliable security for multimedia data, El-Shafai et al. [15] proposed a 3DV compression-encryption system for IoT wireless networks. This scheme employs compression and a robust encryption algorithm using symmetric keys. The proposed scheme demonstrated several advantages, including easy implementation, high key sensitivity, efficient encryption for video and image data, and resistance against various network attacks. Simulation results confirm its efficiency against different attacks, making it suitable for securing IoT multimedia applications. But still, there is a need to test this method on different IoT networks and also for real time multimedia applications.

To improve the security and privacy of CCTV surveillance systems Sivalakshmi et al. [16] suggest an approach that combines the Privacy Region Mask Separation method and an adaptive silhouette-blur scheme. These techniques help to identify sensitive regions in video frames while ensuring the privacy of video data. To further enhance the privacy protection process, an optimized version of the Coati optimization is integrated with these techniques. To further improve data storage and access, H.264/AVC standard is used for video encoding. This method performs better than RSA and ECC if talking about encryption, decryption speed, and quality preservation, but did not apply to real time data.

A new method has been proposed by Yu and Kim [17] to overcome the limitations of the traditional Region of Interest (ROI) encryption process in high-efficiency video coding (HEVC)/H.265. Encryption is applied to wider areas using traditional methods that result in the inefficiency of resources. Therefore, specific coding units are encrypted in the proposed method to improve encryption speed and reduce computation. But this method is limited to specific coding standards, and not applied to real world data.

To improve data security, the effectiveness of the selective encryption method is evaluated and processing overhead is reduced. The effect of selective encryption on data security, integrity, and accessibility is quantified. The literature review with contributions and limitations is depicted in Table I. The main aim of this paper is to optimize security and performance by analyzing encryption algorithms when applied to certain video segments. The findings will contribute in the comprehension of the efficiency of selective encryption in securing confidential data and optimizing computational capacity.

TABLE I LITERATURE REVIEW WITH CONTRIBUTIONS AND LIMITATIONS

References	Techniques	Contributions	Limitations
[12]	ChaCha20 algorithm and a hybrid chaotic system	• Effective against statistical attacks	• Not applicable in real time applications.
[13]	Selective video encryption method	• Performance and encryption efficiency	• Not applicable in real time applications.

[17]	Coding Unit (CU)-Based Encryption, Region of Interest (ROI) Detection using YOLOv4, and HEVC/H.265 Video Encoding	• Selective Encryption for Improved Efficiency • Enhanced Privacy Protection Improved Video Quality Reduction in Encryption Time and Resources	• Limited to Specific Video Coding Standards • Increased Complexity in Real-Time Scenarios • Limited Testing on Real-World Data

III. METHODOLOGY

The proposed methodology addresses data security and privacy concerns in CCTV surveillance systems. The main goal is to strengthen CCTV security by using selective encryption methods. Fig. 1 depicts the flowchart for the cryptography process. This method encrypts specific parts of the video, protecting sensitive information and maintaining access to critical data for real-time analysis. The methodology is designed to optimize computational overhead and ensure the safety of user data. The steps for methodology are given below and the compression and selective encryption process for IoT CCTV video data is depicted in Fig. 2.

A. Data Preparation

A dataset of CCTV footage was collected from an 1800 square feet area, including indoor and outdoor cameras, with different lighting conditions and camera angles to reflect real-world surveillance scenarios.

The captured CCTV videos have different sizes, resolutions, lengths, frame counts, and frame rates to meet real world needs.

1) Compression using H.264/AVC (Advanced video coding): CCTV video was compressed using the H.264/AVC video compression standard, a widely adopted standard for video compression.

High compression efficiency is achieved with H.264/AVC as both spatial (within a single frame) and temporal (between successive frames) redundancies are removed, reducing file size while maintaining quality.

Bitrate, one of the crucial compression parameters, was varied to balance compression level and video quality. Lower bitrates were used to minimize storage space while maintaining sufficient quality for real-time surveillance needs.

B. Dynamic Key Management

Develop a dynamic key management system that generates and manages encryption keys. These keys should be unique to each encrypted portion, ensuring adaptability to changing security requirements and user preferences. The dynamic nature of key management enhances the overall security posture of the system.

C. Selective Encryption Technique

The Selective Encryption Technique is used to encrypt only the determined video frames. Unlike traditional methods that encrypt the entire stream, this approach strategically targets specific elements based on frame interval, reducing the computational burden and preserving critical information for real-time analysis.

The AES-256 (Advanced Encryption Standard) algorithm was used for encryption as it balances security and computational efficiency.

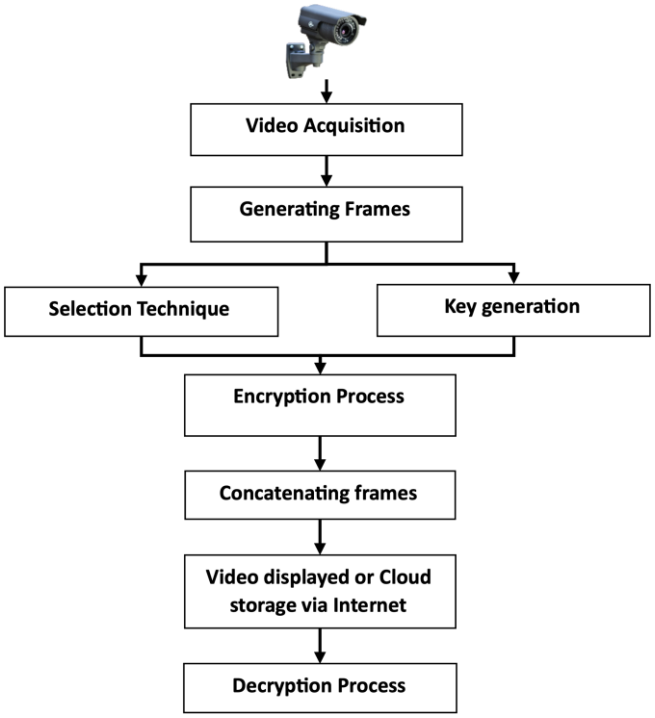

Fig. 1. Cryptography process.

D. Performance Evaluation

The system was evaluated based on the following metrics to assess both video quality and encryption performance:

1) Entropy: This metric measures how much disorder or information is present in the image. Higher entropy means more pixel complexity, whereas more regular patterns are an indication of lower entropy.

2) Correlation analysis: The correlation coefficient describes the relationships between adjacent video frames and the distribution of pixels. The lack of association between frames indicates that there is no pattern at all, making statistical cryptanalysis impossible.

3) Bit rate overhead analysis: The bit rate overhead measures the variation in bit rate before and after encryption. This demonstrates how well the encryption method reduces file size.

4) Encryption efficiency: The time taken for both the compression and selective encryption processes was measured to ensure the method is feasible for real-time CCTV applications.

5) Decryption efficiency: The time taken for decryption processes was measured to ensure the method is quickly and easily retrieves encrypted video footage and well suited for real-time CCTV applications.

6) Histogram analysis: Using the pixel distribution in each frame, the histogram analysis describes the visual relationships between the original and encrypted frames. Typically, cryptanalysts use the distribution of pixels to carry out statistical attacks.

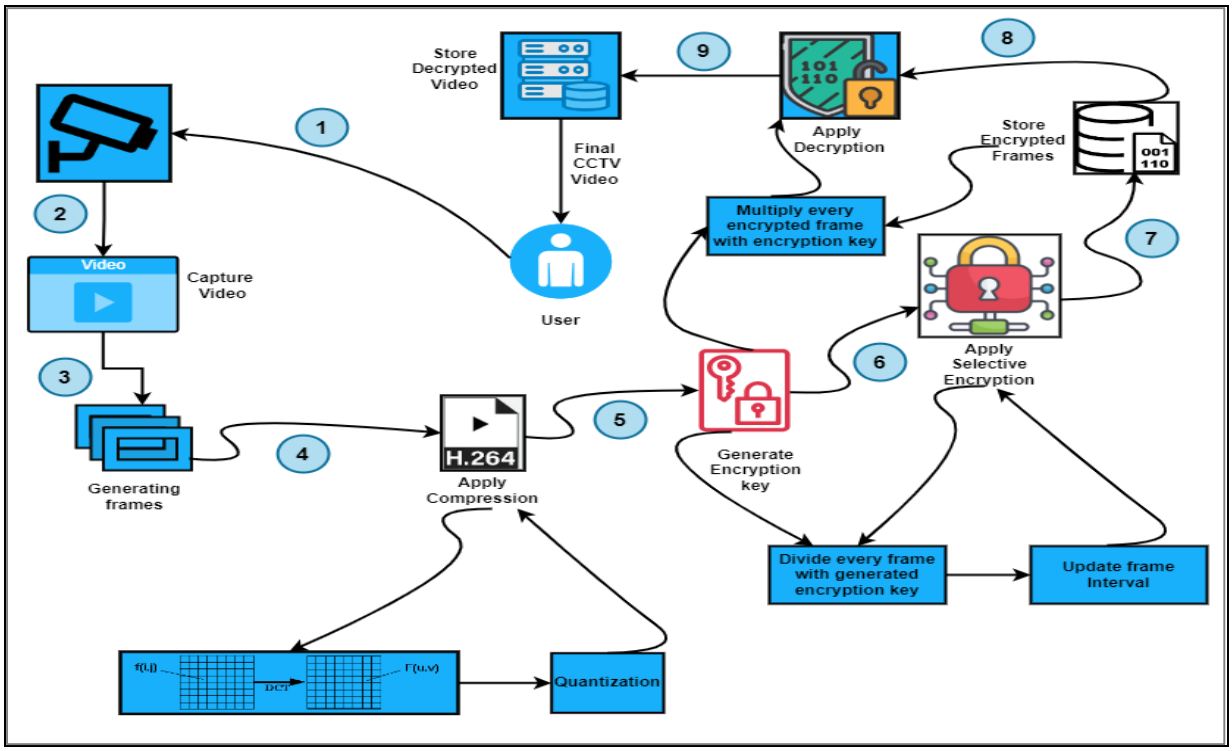

Fig. 2. Compression and selective encryption process for IoT CCTV video data.

IV. Proposed Algorithm

A systematic approach is applied to optimize data size and protect video data by using the proposed video encryption and compression algorithm. First, video frames are compressed to optimize their efficiency in terms of storage. Subsequently, the selected video data is encrypted with a randomly generated key to protect its confidentiality and integrity. The decryption process is carried out after encryption to retrieve the original content. The entire process is simplified as it enables the safe transfer and storage of video frames without additional decompression. Fig. 3 describes the flowchart for the proposed Algorithm 1.

Algorithm 1: Proposed Algorithm	
Step1: Read Original Video Frames	• O = {O1, O2, ..., On}
Step2: Initialize Variables	• x2 = 15 • x = frames per second (FPS)
Step 3: Compression Operation	For each frame Oi in O: • Compress every frame Oi by compression algorithm
Step 4: Encryption Key Generation	• Generate a random key matrix (K).
Step 5: Encryption Operation	For each frame Oi in O: • Calculate x1 = $int(current\frac{frame}{x}+3)$ • Encryption operation: $Ei[x,y] = Oi[x,y]/K[x,y]$ • Update x2 = x2 + 15
Step 6: Create Encrypted Video Frames	• E = {E1, E2, ..., En}
Step 7: Decryption Operation	For each decrypted frame Di in D: • Decryption operation: $Di[x,y]=Ei[x,y]\times K[x,y]$

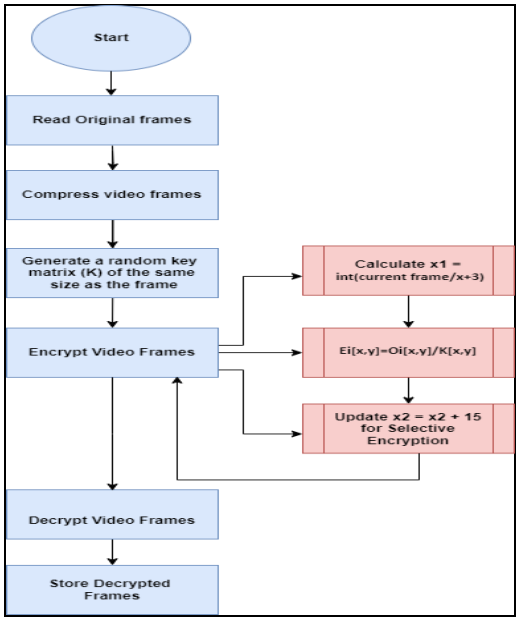

Fig. 3. Flowchart for the proposed algorithm.

V. Experimental Results and Evaluation

The proposed scheme analyses five CCTV videos from different cameras that are described in Table II. The captured CCTV videos have different sizes, resolutions, lengths, frame counts, and frame rates. The need for higher resolution, longer recording time, or considerations for storage space are specific requirements of the surveillance system. The experimental run on Intel Core i5 CPU @ 2.4GHz and 8 GB RAM on Windows 10 OS.

In this experiment, an 1800 square feet area in the front and garden is considered, and an encryption technique is used to optimize security. To evaluate the efficiency of the proposed system, five cameras were positioned in important areas. To evaluate the algorithm's capacity by optimizing encryption time and storage efficiency and its effect on data security is the main aim of this paper. Results showed how well the encryption system protected CCTV video and optimized security.

TABLE II Different CCTV Videos

CCTV Video	Video size(KB)	Video Length (seconds)	Frame Count	Frame Rate/sec	Resolution
CCTV1	2528	29	731	25	640×352
CCTV2	6028	30	756	25	848×480
CCTV3	4942	24	604	25	848×480
CCTV4	2429	23	357	15	352×288
CCTV5	2538	24	363	15	352×288

A. Compression

CCTV video files are compressed to reduce file size to maximize storage before encryption. With this process, important information is retained and unnecessary information is removed. The file size is reduced by using compression techniques to reduce file size without reducing quality. Various compression algorithms are available to reduce the size of a video. Intra-frame and Inter-frame compression techniques are the most widely adopted techniques. Intra-frame compression which reduces the size of individual frames by using spatial redundancy within specific frames and is implemented by Discrete Cosine Transform (DCT) and Wavelet Transform. In the DCT method, pixel data is transformed into a set of low and high frequencies, whereas wavelet transform as the name suggests uses wavelets to convert the pixel data into wavelet coefficients to reduce the precision of less important data. On the other hand, Inter-frame compression uses temporal similarities to decrease the redundancy between frames. Methods used for Inter-frame compression are Motion Estimation and Compensation, Predictive and Transform Coding. Motion Compensation stores only the variation between frames where motion is detected. Predictive coding uses prediction from the previous encoded frame and the next frame. On the contray transform coding, a frame is transformed, and then transformed coefficients are quantized and encoded.

Modern video standards such as H.264/AVC (Advanced Video Coding) and HEVC (High-Efficiency Video Coding) or H.265 are combined with these compression techniques to balance video quality and compression. Higher compression efficiency is achieved by HEVC, but advance hardware is

required to implement this in CCTV. Therefore H.264/AVC is used in the proposed algorithm to balance between compression and quality, and it supports existing hardware and software. The selective encryption algorithm is used after compression to protect the data from manipulation or unwanted access. This combined approach ensures effective storage, less bandwidth requirements, and enhanced CCTV security.

B. Entropy

The degree of unpredictability or randomness in the video frame's pixel values describes entropy. It measures how much disorder or information is present in the image. Higher entropy means more pixel complexity, whereas more regular patterns are an indication of lower entropy[19]. Entropy of different CCTV videos is shown in Table III.

The following formula can be used to calculate entropy(H):

$$H=-\sum_{i=1}^{n} Pi*\log2(Pi)$$

Where:

- n is the count of unique pixel values in the frame.
- Pi is the probability of occurrence of each unique pixel value.

TABLE III ENTROPY OF DIFFERENT CCTV VIDEOS

CCTV Videos	Entropy of the frame(bits per pixel)
CCTV1	7.6841
CCTV2	7.7560
CCTV3	7.7914
CCTV4	7.6794
CCTV5	7.0398

The frame may contain diverse patterns, textures, or information. Higher entropy is generally considered good for encryption. It suggests that the pixel values in the frame are more random and less predictable, which aligns with the goal of encryption, thus making the content difficult to discern without the decryption key.

Fig. 4 makes it clear that, out of all the CCTV feeds, CCTV3 has the highest entropy. The entropy values which are closer to eight is considered to be an ideal value as highlighted by Gbashi et al. [12]. The reason for this increased entropy is that CCTV3 comes from the front door camera, which records a feed with more diverse material. CCTV5, on the other hand, has the lowest entropy due to the backyard camera. The reason is less amount of variation in information is captured resulting in a more uniform feed and lower entropy. The changes in entropy levels of the CCTV videos depend upon different video quality, camera placement, and scene detailing.

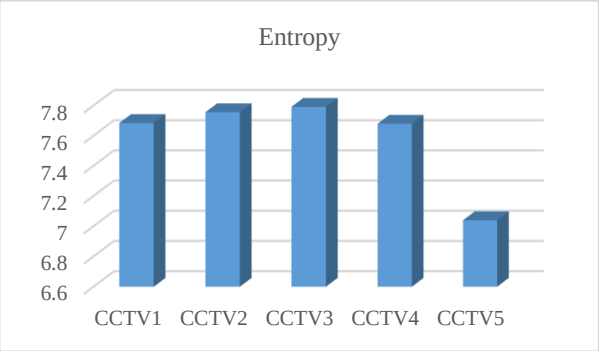

Fig. 4. Frame entropy (bits per pixel).

C. Correlation Analysis

The correlation coefficient describes the relationships between adjacent video frames and the distribution of pixels. The correlation value tells the relationship between neighboring frames. A higher correlation value means a closer linear link and a lower correlation value defines a more nonlinear relationship [12]. The correlation between pixels at matching positions is calculated in adjacent frames, and then a new frame with less data is created using the variations between them. Using this method results in a near-zero correlation value and a nonlinear relationship between neighboring frames.

Table IV presents the experimental results for nearby frame correlation coefficients for both the original and encrypted frames. These findings imply that the original and encrypted frames show very little association. As a result, this lack of association indicates that there is no pattern at all, making statistical cryptanalysis impossible.

A correlation coefficient that is close to zero, like in the case of CCTV1 frame 50, CCTV2 frame 50, CCTV3 frame 10 of CCTV3, CCTV4 frame 100, and CCTV5, denotes the lack or very weak linear relationship between the original and encrypted frames depicted in Fig. 5. The correlation coefficient is a statistical measure that expresses the direction and intensity of a linear relationship between two variables. Values that are close to 0 in this context indicate that there is little to no linear relationship between the encrypted and original frame contents. This is good news for encryption because it means that the content of the original frame is successfully hidden during the encryption process. The more closely the correlation coefficient approaches zero, the more skillfully the encryption process masks any observable links or patterns in the data as described by Gbashi et al. [12]. A negative correlation coefficient in the context of encryption would still suggest that the relationship between the original and encrypted frames has been effectively obscured by the encryption process, making it challenging for an observer to deduce the original frame's content from the encrypted frame without the decryption key.

TABLE IV COMPARISON SIMULATION RESULTS OF THE CORRELATION COEFFICIENT

Random Frames	CCTV1	CCTV2	CCTV3	CCTV4	CCTV5
Frame 0	-0.001182	0.0003209	-0.0004950	0.0003168	0.0019212
Frame 10	-0.001530	0.00019326	-0.0001918	0.0019271	0.0027840
Frame 50	-0.000273	-0.0005638	-0.0006569	-0.0025389	0.0009055
Frame 100	-0.001595	-0.0033022	0.0006837	-0.0022497	0.0007022

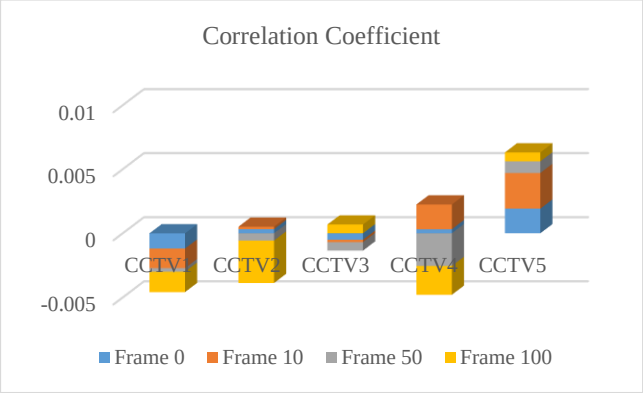

Fig. 5. Comparison results of the correlation coefficient.

D. Bit Rate Overhead Analysis

The bit rate overhead measures the variation in bit rate before and after encryption It is expressed as a percentage change relative to the original bit rate as stated in Table V. The sign of the overhead value indicates the direction of the change.

1) Negative bit rate overhead: A negative overhead number indicates a drop in the bit rate after the operation. Negative overhead in the context of video compression or encryption means that the processed video uses fewer bits than the original, which lowers the file size or bit rate. In general, this is preferable since it suggests effective encryption without appreciable quality loss. Negative overhead in video encryption reduces bit rate, resulting in smaller files and better quality without significant loss of quality.

2) Positive bit rate overhead: Positive overhead in video encryption indicates an increase in bit rate, possibly due to additional data added, potentially indicating a need for quality improvement or security measures. Often, the objective is to accomplish efficient encryption or compression while limiting the influence on file size and preserving a sufficient level of video quality [20].

The bit rate is reduced by 90% in the first video, and by more than 40% in all other scenarios seen in Fig. 6. This implies that the video file was significantly compressed without sacrificing the visual quality. This demonstrates how well the encryption method reduces file size. In general, negative overhead levels are better since they show a reduction in file size or bit rate without noticeably lowering quality as suggested by Chen et al. [20].

TABLE V BIT RATE OVERHEAD OF DIFFERENT CCTV VIDEOS

Video	Original	Encryption	Overhead
CCTV1	712000	650000	-0.9087
CCTV2	1644000	630000	-0.6167
CCTV3	1685000	609000	-0.6385
CCTV4	827000	487000	-0.4111
CCTV5	864000	488000	-0.4351

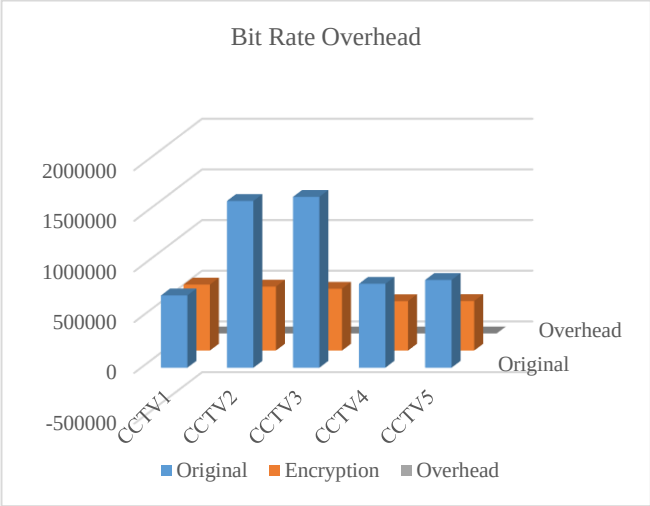

Fig. 6. Bit rate overhead of different CCTV videos.

E. Encryption Efficiency

Video encryption time overhead is dependent on various aspects, including the encryption algorithm, frame rate, resolution, and compression format. Encryption takes longer in videos with higher resolution and frame rate. Encryption time is affected by many factors. One is Compression as it adds more steps to the processing and the others are the security level, key length, complexity of the video, and encryption algorithm used. Besides these, buffering and network performance are crucial where real-time encryption is done [21]. The encryption time overhead in CCTV surveillance applications is optimized as described in Table VI and it is clearly shown in Fig. 7.

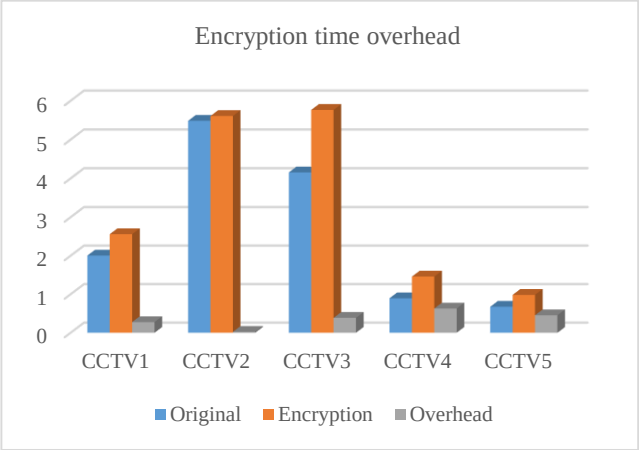

Fig. 7. Encryption time overhead of CCTV videos.

Table VII presents the encryption speed for five different CCTV videos and describes the variation in encryption efficiency for randomly chosen frames. This eventually helps to effectively safeguard sensitive video data in real-time surveillance scenarios.

TABLE VI ENCRYPTION TIME OVERHEAD OF DIFFERENT CCTV VIDEOS

Video	Original	Encryption	Overhead
CCTV1	2.0040	2.5594	0.2771
CCTV2	5.4845	5.6084	0.0225
CCTV3	4.1545	5.7645	0.3875
CCTV4	0.8952	1.4594	0.6302
CCTV5	0.6766	0.9837	0.4538

TABLE VII RESULT OF ENCRYPTION TIME (IN SECONDS) FOR DIFFERENT CCTV FRAMES WITH AVERAGE ENCRYPTION TIME

CCTV Videos	Frame 0	Frame 50	Frame 100	Frame 150	Average
CCTV1	0.04803	0.03464	0.03753	0.03357	0.00171
CCTV2	0.08812	0.06305	0.05923	0.05731	0.00261
CCTV3	0.12913	0.05824	0.05576	0.05399	0.00245
CCTV4	0.04807	0.02142	0.02138	0.02554	0.00179
CCTV5	0.03423	0.02149	0.01954	0.01931	0.00178

Fig. 8 provides a comparative comparison of the encryption speed times for randomly picked frames from different CCTV videos, expressed in frames per second. Interestingly, every CCTV video shows varying encryption speed performances at various frame rates, that is due to the randomness of pixels in every frame as every video is from a different CCTV video. When compared to other CCTV movies in the dataset, CCTV1, CCTV4, and CCTV5 perform better on average, with the quickest encryption speed time of 0.00171, 0.00179, and 0.00178 respectively frames per second. The encryption algorithm being utilized is one of the possible causes of these variances in encryption speed timings. With the fastest and most reliable encryption speeds, CCTV5 is the best choice for real-time applications. Reliability is further demonstrated by CCTV4 and CCTV1, with low and constant encryption times. Given the variations in video size and resolution, CCTV2 and CCTV3 nevertheless offer performance appropriate for real-time applications despite longer encryption periods as demonstrated by Alawi and Hassan [22].

F. Decryption Efficiency

The proposed algorithm uses optimized decryption procedures that are specially designed for the chosen encryption technique in order to prioritize decryption efficiency. The information displayed in Table VIII and Fig. 9 demonstrates how well the algorithm performs in terms of decryption efficiency and speed. By use of enhanced decryption algorithm and effective cryptographic key management, the algorithm guarantees the prompt restoration of original content without sacrificing security. As a result, the method is particularly effective in decrypting data, making it possible to quickly and easily retrieve encrypted video footage.

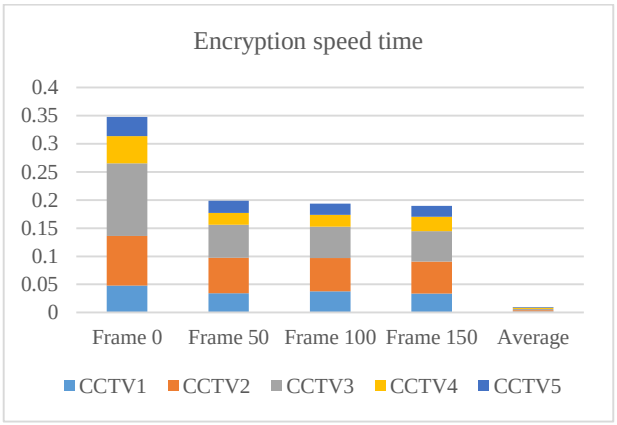

Fig. 8. Result of encryption time (in seconds) for different CCTV frames with average encryption time.

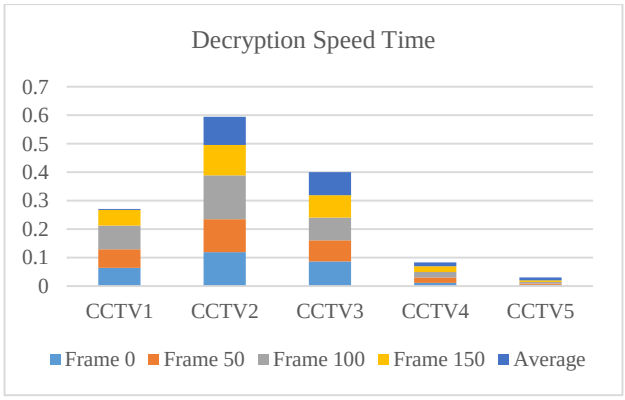

Fig. 9. Result of decryption time (in seconds) for CCTV video frames.

TABLE VIII RESULT OF DECRYPTION TIME (IN SECONDS) FOR DIFFERENT CCTV VIDEO FRAMES

CCTV Videos	Frame 0	Frame 50	Frame 100	Frame 150	Average
CCTV1	0.06465	0.06517	0.08280	0.05468	0.00400
CCTV2	0.11907	0.11594	0.15378	0.10657	0.09978
CCTV3	0.08690	0.07434	0.07906	0.07852	0.08153
CCTV4	0.01116	0.01973	0.01913	0.01973	0.01409
CCTV5	0.00499	0.00399	0.00618	0.00573	0.00930

Every CCTV video is suitable for real-time applications; the reasons for variations in decryption durations are related to the sizes and formats of the videos. CCTV5 regularly has the smallest decryption timings (0.00399 to 0.00618 seconds), while CCTV2 consistently has the highest decryption times (0.10657 to 0.15378 seconds). With the fastest, most reliable decryption times, CCTV5 exhibits the best performance. Additionally dependable and with quick decryption times is CCTV4. While CCTV3 and CCTV2 have longer and more inconsistent decryption times but are still appropriate for real-time application as described by Alawi and Hassan [22].

G. Histogram Analysis

Using the pixel distribution in each frame, the histogram analysis describes the visual relationships between the original and encrypted frames. In an attempt to recover the original frames, statistical attacks try to take advantage of this predicted relationship. The notable differences between the encrypted frame histograms and the original frame histograms highlight how well the encryption approach works to fend off statistical attacks [23]. The chi-square test is used to demonstrate the homogeneity of pixels and is used in the study of the histogram.

Typically, cryptanalysts use the distribution of pixels to carry out statistical attacks. It is clear from the figures how the original and encrypted video frames' histograms differ from one another. This prevents statistical attacks on the video frames. The original video frame is shown in Fig. 10(a) of the supplied figures, while Fig. 10(a1) shows the histogram of the frame before encryption. The histogram of the encrypted video frame (b) is shown in Fig. 10(b1). These figures make it clear that the histograms of original and encrypted video frames are distinct. This implies that video frames are secured against any statistical attacks as stated by Ravikumar and Kavita [24].

VI. COMPARATIVE ANALYSIS AND DISCUSSIONS

The experiments are carried out to compare the results with state-of-the-art algorithms to confirm the suggested scheme efficiency for CCTV video security. Encryption time, decryption time, and correlation coefficient results of the proposed technique are compared statistically with the algorithms from current related literature. For the tested CCTV videos, Table IX presents the numerical values of the proposed

scheme for Encryption time and decryption time per frame in comparison to the suggested techniques in recent literature.

TABLE IX COMPARISON OF AVERAGE ENCRYPTION AND DECRYPTION TIME IN SECONDS

Reference	Average Encryption Time per frame	Average Decryption Time per frame
[25]	0.01219	0.01206
[15]	0.7306	0.6278
[26]	0.03549	0.03625
CCTV1	0.00171	0.00400
CCTV2	0.00261	0.09978
CCTV3	0.00245	0.08153
CCTV4	0.00179	0.01409
CCTV5	0.00178	0.00930

It can be seen from Fig. 11 that the encryption time of the proposed technique is better than what is proposed in the literature and very close to zero. Therefore, the proposed technique is successful in optimizing encryption time and is well suited for real time applications.

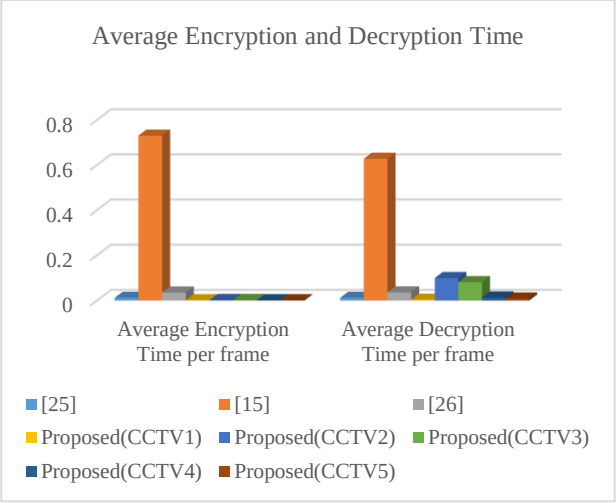

Fig. 11. Comparison of average encryption and decryption time (in seconds) for CCTV video frames.

The comparison of correlation coeficients with the recent literature are given in Table X. Moreover, it is also observed that correlation coefficient of the proposed algorithm is better than the schemes in literature as shown in Fig. 12. The correlation coefficients of the proposed scheme are very close to zero which prevents it from statistical attacks.

TABLE X COMPARISON OF CORRELATION COEFFICIENTS

Reference	Correlation Coefficient
[25]	-0.0045
[15]	-0.0029
[26]	0.00733
Proposed(CCTV1)	-0.0011
Proposed(CCTV2)	0.00032
Proposed(CCTV3)	-0.0004
Proposed(CCTV4)	0.00031
Proposed(CCTV5)	0.00192

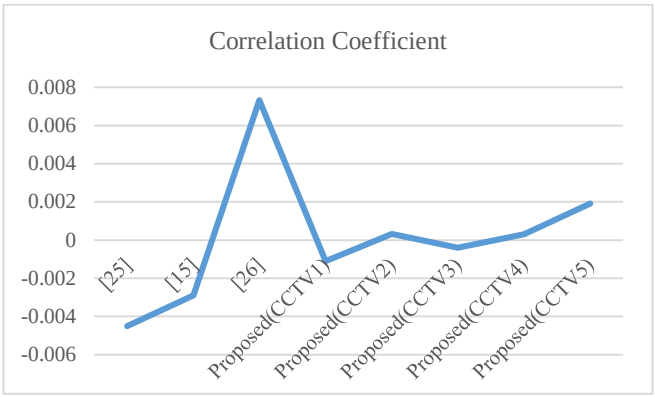

Fig. 12. Comparison of correlation coefficients for CCTV video frames.

The proposed technique works well according to different video resolutions, frame rates, or compression standards as encryption process is done after compression. Individual video frames are encrypted using our suggested frame-level selective encryption technique. This preserves adaptability across various video resolutions and frame rates while guaranteeing independence from video codecs and compression standards. This preserves adaptability across various video resolutions and frame rates while guaranteeing independence from video codecs and compression standards. Furthermore, scalability is demonstrated by the consistent performance across measured resolutions (640×352, 848×480, and 352×288), although frame rate differences mostly impact temporal density rather than the encryption process. Consequently, the design of the approach guarantees strong applicability across a variety of video setups and compression standards.

There are significant trade-offs when employing selective encryption in IoT CCTV devices. Higher video resolutions or frame rates result in a greater computational cost since more data must be processed, even though the proposed approach is quicker and more effective than encrypting the entire video. This may cause encryption on low-power IoT CCTV devices to lag. However, to minimize this trade-off, encryption, and decryption process is minimized. The technique is beneficial for real-time streaming because it avoids the delays associated with full encryption, making it suitable for real time applications. Overall, although there is a trade-off between computational speed and the volume of data being encrypted, the proposed technique effectively balances these needs for CCTV surveillance systems. At the same time, it maintains compression efficiency, which helps save storage.

By encrypting selected video data, the proposed selective encryption technique disrupts correlations in the video data and shows resilience against statistical attacks. The robust AES algorithm used in this technique has a strong cryptographic design that makes it naturally resistant to adaptive chosen-plaintext attacks. Because of the avalanche effect of AES, even a small alteration to the plaintext produces an entirely different ciphertext, making it nearly impossible for an attacker to deduce significant connections between the selected plaintexts and their matching ciphertexts, and even the encryption keys. The use of compression before encryption substantially strengthens the method's resistance to chosen plaintext attacks in the setting of selective encryption. Non-linear changes are

applied to video data by using compression resulting in scrambling the data and eliminating redundancies in the plaintext frames. Because of this procedure, it is very difficult for an attacker to create plaintext frames that might expose ciphertext. In terms of key management, the technique is made to work with safe key distribution and exchange protocols that are used in real time environments such as Diffie-Hellman key exchange. In order to prevent attacks like key reuse or interception, these protocols offer safe methods for creating, allocating, and rotating encryption keys.

The method reduces risks in two ways for real-world attack scenarios where an adversary might try to deduce encrypted content from unencrypted frames or statistical redundancy. First, the attacker cannot reconstruct meaningful content from unencrypted frames alone since selective encryption is applied which disrupts important visual information. Second, applying compression before encryption removes correlations and redundancies from the CCTV video data and it further distorts patterns that may otherwise be exploited.

VII. Conclusion

This paper highlights significant discoveries and shows the importance of security in IoT based CCTV video surveillance systems. This study offers a new method for video encryption that combines selective encryption with compression to enhance security and efficiency. The approach is ideal for demanding real-time applications as demonstrated by experiments, since it can selectively encrypt data after compression, which minimizes computational overhead and hence guarantees efficient utilization of system resources. Through testing and analysis, the algorithm's effectiveness and resistance to statistical attacks is proven. Still, it needs constant monitoring and improvement to strengthen its defenses against new threats. With the promise of increased security in a world growing more and more data-centric, this study represents a major advancement in the support of video encryption techniques. In the future, adding authentication techniques to encryption will be crucial to enhancing security and guaranteeing that sensitive data is only accessed by authorized individuals.

Integrating Artificial Intelligence to Automate Pattern Making for Personalized Garment Design

Muyan Han*
School of Fine Arts and Art Design, Qiqihar University, Qiqihar 161000, China

***Abstract*—This paper introduces an innovative AI-assisted pattern construction tool that leverages machine learning models to revolutionize pattern generation in garment design. The proposed system automatically generates patterns from 3D body scans, which are converted into 3D shell meshes and subsequently flattened into 2D patterns using advanced data augmentation techniques and CAD flattening algorithms. This approach eliminates the need for expertise in traditional pattern-making, enabling seamless transformation of 3D models into realistic garment patterns. The tool accommodates various garment styles, including fitted, standard fit, and relaxed fit, while also enabling high levels of personalization by adapting patterns to individual body dimensions. Through its AI-driven automation and user-friendly interface, this plug-in enhances accessibility, allowing individuals without conventional design skills to create customized apparel efficiently.**

Keywords*—Machine learning models; pattern generation; AI-assisted pattern construction; data augmentation techniques; CAD flattening

I. Introduction

CAD computer technologies have become an integral part of modern garment technology and the associated process of pattern making. CAD technologies have revolutionized manufacturing processes in the apparel industry, enhancing precision, efficiency, and innovation. CAD applications provide unprecedented accuracy in designing patterns through sophisticated software and precise digital measurement, whereby patterns of garments closely correspond to human body measurements and are extremely reliable [1]. Moreover, CAD software facilitates collaborative working processes across the apparel and textile supply chain. Designers, pattern makers, and manufacturers can work on digital models simultaneously, improving communication and reducing time-to-market [1]. Additionally, CAD technologies assist in green practices by minimizing the use of physical prototypes because virtual simulations allow organizations to reduce material waste and optimize production processes, thereby assisting in environmentally sustainable garment manufacturing [2].

Despite such advances, there are still some limitations to CAD-based pattern creation. Traditional CAD packages require very specialist expertise, making them inaccessible to others without professional pattern-making training. Present-day computerized tools still require manual adjustment and expert knowledge input in order to design optimized garment patterns. The majority of CAD packages also lack AI-enabled automation, limiting their ability to generate adaptive and highly personalized designs based on individual body shapes [3]. In addition, computer-aided design software is usually expensive and requires significant computational capabilities, making it difficult for individual designers and small industries to use them [3].

To alleviate these difficulties, we introduce an AI-aided pattern-making tool that does not require designers to be experts in traditional pattern-making techniques. This is a revolutionary system where users can input digital models or 3D body scans, which are then processed through an AI-driven pipeline to generate customized garment patterns [4]. The software employs machine learning models, data augmentation techniques, and CAD flattening algorithms to convert 3D shell meshes into 2D patterns automatically. Compared with traditional CAD-pattern generation methods with possible human interventions, our scheme ensures total automation, high degree of personalization, and speedy garment pattern creation [4].

Our AI pattern generator is a giant leap towards the democratization of fashion design technology, bridging the divide between traditional craftsmanship and cutting-edge AI-driven automation. By eliminating technical barriers, this platform provides greater opportunities to more people—the independent designers, fashion enthusiasts, and players in the industry—to explore new design frontiers and contribute to the direction of innovation in garment manufacturing [4].

Our approach is not flawless, however. Even though the AI model considerably reduces the need for hand-based pattern fine-tuning, drastic customizations or complex clothing designs may possibly still require professional adjustment for optimization and fine-tuning. Further, the pattern generation process depends not only on the quality but also on the accuracy of 3D body scans, therefore, low-quality or inconsistent scanning data can also influence the quality of the end patterns [4]. Upgrades in the future will center on AI adaptability enhancement, increased model precision, and widening pattern customization functionalities to better polish the system's potential.

The remainder of this paper is structured as follows: Section II presents a literature review, discussing existing CAD-based pattern generation methods, AI-assisted design tools, and their limitations. Section III outlines the methodology, detailing the proposed AI-driven approach, including data processing, machine learning models, and pattern generation techniques. Section IV covers experimentation and discussion, presenting the implementation details, evaluation metrics, and comparative analysis of results. Finally, Section V concludes the paper by summarizing key findings, highlighting contributions, and suggesting future research directions.

II. Literature Review

A. Traditional Methods in Pattern Construction

Traditional pattern construction in garment engineering is highly craft-based, requiring a great deal of expertise and special techniques. Normally, it is based on a basic pattern that serves as a blueprint for the different types of garments to be constructed [5]. It first involves taking the precise body measurements from which the derivations of the construction parameters for drafting the pattern are obtained. These measurements are interpreted and put onto a two-dimensional pattern that then is adapted to meet the three-dimensional contours of the human body. The first pattern is altered and perfected on a model or mannequin for a correct fit and desired design effect [6]. More often than not, such refinement entails several rounds of alterations and changes until an ideal result is achieved. Traditional pattern-making techniques require great craftsmanship, experience, and technical precision to produce patterns that are to the standard of accuracy and fit required. The process is effective yet very time-consuming and heavily reliant on the skill of the individual [7].

B. Overview of Pattern Systems in Garment Construction

Over the years, a number of pattern systems have been designed, and each of them has its unique methods on garment construction. The demand of the fashion world is maximal flexibility of the selected pattern system. The selection, therefore, depends on the specific criteria, individual tastes, and available means. The best known today is the M. Müller & Sohn pattern system of Michael Müller, founded in Munich in the 19th century [8]. This system, which has gained universal international acceptance, has undergone continued development or reworking to meet present-day industry standards. It includes pattern making for women, men, and children, using a precise series of measurements taken from anatomical measurements and garment-making techniques. Similarly, the Hohenstein pattern system emphasizes the work of basic and model-specific patterns, but it focuses on final pure optical appearances, for example, garment shapes, while still using measurement series.

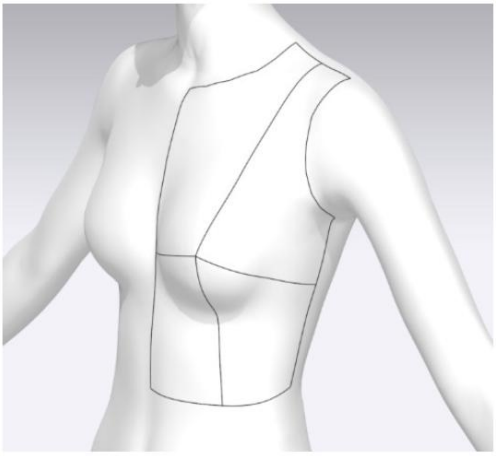

Fig. 1. Segmentation of the upper torso into regions for flattening, highlighting reference points such as the chest point, waistline, and center back and front [1].

One of the more relevant systems is the Optikon, [9] designed as part of a research project undertaken by the Niederrhein University of Applied Sciences. This is a closed-loop system and is versatile because it allows for the development of outer garments for males and females. Essential measurements of the body - chest, waist, hips, height, and type – are related and used to calculate secondary measurements by using formulae based upon the relationships identified in conventional measurement tables. These measures are used to create coordinate systems for construction where human body measures are related to other points around the flat pattern. Considering human measures, along with the unique garment requirements, these systems ensure careful and accurate garment construction with respect to the unique body measurements [10].

C. Flattening

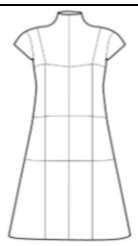
Flattening is one of the important processes in the developing cycle of a garment pattern, which changes a three-dimensional garment shape to a two-dimensional pattern. This technique serves as the base of how design concepts eventually get transferred into a pattern ready for production, allowing the designer and pattern maker to create scaled and accurate designs. This uses mathematics and geometric calculation to project complex 3D shape and curved objects onto flat surfaces with minimum distortion, ensuring accuracy in garment fit and construction [11]. A very effective way to achieve flattening is dividing the upper torso into eight separate regions; the lower part is divided into two additional regions for a total of 12 regions, which can also be doubled to account for both right and left sides of the torso addition resulting in 24 regions. These regions are based on different reference points such as the chest point, waistline, and the front and back centers around which they are oriented as shown in Fig. 1. For instance, such segmentation permits the unfolding of 3D body shapes without distortion as darts will be used in the 2D pattern modeling for reshaping the garment for the human body. The procedure starts with picking critical points such as the bust, the side seams, the waist and hip heights that act as the directives in the division of the torso [12]. This technique has been found to have phenomenal accuracy in developing patterns given the difference in individual body measurements.

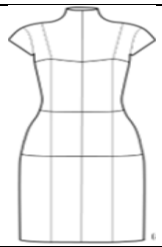
Flattening of surfaces is much better than traditional methods, particularly in custom or tailored pattern production. Traditional approaches often require many modification loops and highly rely on the skill and ability of the pattern maker. Inefficiency in flattening is quite the opposite, as it offers a possibly regular and predictable way of arriving at an ideal fit. Nonetheless, issues remain, including the exclusion of necessary allowances when directly employing scanned body data in the creation of patterns [13]. This exclusion restricts application to close-fit clothing with highly elastic material, as it both decreases comfort and affects garment aesthetics.

To optimize 3D models for flattening and get the best in class results in the form of garment patterns, one has to consider: the garment's silhouette — be it X, O, or A; its position or layering—for example, undergarments or outerwear; and the wanted fit or fitting—close, regular, or loose. For example, a garment with an O-silhouette will need more space at the middle than an X-silhouette garment. In a

similar fashion, the garment layers determine the required ease, where undergarments require minimal easing while outer garments, illustrated by coats, need much larger adjustments (Table I). These can all be achieved through traditional pattern making methods [14]. The key body shapes used to flatten the pattern were of slim-fit X-silhouettes, used as primary, secondary, and tertiary garment layers, without taking into account structural modules. It is also very important to ensure that the displace values along the vertical axis are exactly zero, because even the slightest variation will tend to shift important measurements such as the chest, waist, and hips, resulting in poor fitting for garments. Therefore, vertical axis displace values should be set to zero. The actual body measurements and the respective ideal making measurements of the original forms used are summarized in Table II [15].

TABLE I OFFSET CLASSIFICATIONS FOR DIFFERENT GARMENT SILHOUETTES (X, O, AND A) TO DETERMINE INITIAL SPACING IN PATTERN DEVELOPMENT



Silhouette	A-silhouette	X-silhouette	O-silhouette
Offset knee	High	Medium	Low
Offset hip	High	Medium	Medium
Offset waist	Medium	Low	High
Offset bust	Low	Low	Medium

D. Overview of Digital Solutions in Garment Design

Digital garment design tools have contributed to improved capabilities and features, which have optimized the full process from conceptual designs to manufacturing. This means that such software has enhanced the efficiency, accuracy, and even creativity in the field [16]. Main digital solutions include versatile Optitex software, which can offer functions ranging from pattern making all the way to 3D visualization, sizing, and virtual fit. Designers can build 3D models of garments, so-called virtual prototypes, in a realistic manner using Optitex—a further great solution. One more remarkable solution is the combination of 2D and 3D presented by Assyst in Style3D. Assyst does precise 2D pattern drafting, and it allows for diverse design and size support, with grading [17]. On the other hand, Style3D allows designers to simulate garments in a 3D virtual environment, allowing try-ons along with material simulation and rendering. This brings out seamless coordination between the 2D and 3D processes, therefore more efficiency and accuracy.

Gerber Technology, also amongst the few, dominates the apparel industry using pattern making tools, sizing, marker creation, and production management. With its subsidiary, the Lectra Modaris features design and pattern development, refined production planning, and automated cutting, which brings streamlined manufacturing processes. Browzwear also develops software, offering their key software, VStitcher, which designs realistic 3D models for fitting and design down to the last details. Software includes GRAFIS—one of the best 2D parametric pattern software. Some other great tools in the market are CLO for 2D and 3D garment design with realistic 3D modeling, virtual try-ons, pattern making, sizing, and textile simulation, to fit the entire cycle of production [18].

While the integrated use of these digital tools has greatly enhanced garment design and craft, specialized knowledge, and required skill in pattern making, they are also restricting access for those without educational qualifications. Recognizing it all, they undoubtedly become essential in shaping accuracy, innovation, and productivity in the fashion sector.

E. Gap Analysis in Digital Garment Technology and Pattern Development

Digital garment technology has upfront accelerated the process of generating patterns from 3D scans and contributed to traditional ways of depending on created physical prototypes for fit analysIs. Traditional methods of pattern construction often require high expertise, while AI and automation technologies have greatly facilitated creating a particular type of pattern. AI-enabled tools can help users, even without professional experience, generate basic patterns in a short period of time. Although AI cannot fully replicate the nuanced expertise of experienced pattern makers—particularly for accommodating diverse body shapes and textile materials—it allows non-professionals to bypass complex processes and achieve satisfactory results [19].

Accessibility is another key consideration when evaluating current technologies. Traditional methods often depend on costly, specialized equipment, and most modern digital solutions require expensive licenses and high-performance PCs. On the other hand, an open-source patterning software, for example, Blender, makes broad use more accessible because it is free and compatible with commonly used hardware. Especially, Blender allows for the automation of developing custom patterns based on 3D scans [20]. The pattern design has complex tasks that can be automated with the use of algorithms and artificial intelligence, making time expenditure less and efficiency increased. Thus, users can design accurate and individual patterns, without time-consuming manual work. Hence, the key elements of this workflow are measurement programs, 2D pattern systems, and 3D simulation and visualization software. This integration makes it possible for even users with a limited level of expertise and experience to quickly and easily develop customized basic patterns for further design development [21]. The flattening operation is viewed via UV Editor within Blender; this editor contains a heatmap shader that graphically and through color demonstrates UV stretching from the blue to yellow color, marking the amount of distortion happened on the UV faces. Although this shader helps to detect stretching, still in some particularly difficult cases, that may be hard to recognize if working with 3D model editing. This is handy because the UV Editor also allows the selection of overlapping UV faces, which are visible in both the Editor and the 3D View. Blender also has the ability to preview surface normals on the model by actually coloring individual model faces appropriately, but this feature is not available for

UV normals. The texture visualization process within Blender requires users to create a new material, assign the texture to this material, and then add the material to the model. This is a key set of a procedure for the exact display of textures in the 3D viewport and final rendering. Procedures such as these demonstrate the flexibility and practicality of Blender in pattern creation and visualization, offering a comprehensive and user-friendly instrument for garment design workflows.

TABLE II OFFSET VALUES FOR BUST, WAIST, AND HIP CIRCUMFERENCES ACROSS DIFFERENT GARMENT LAYERS [15]

Measurement in cm	Body height	Chest circumference	Waist circumference	Hip circumference	Shoulder width
Size 38	168	88	72	97	12.7
Offset	0	4	4	4	0
1st layer	168	92	76	101	12.7
Offset_2	0	5	5	5	1.5
2nd layer	168	97	81	106	14.2
Offset_3	0	5	5	5	0.5
3rd layer	168	102	86	111	14.7

F. Artificial Intelligence and Resources for Advanced Garment Design

Artificial Intelligence has transformed the face of fashion design—from forecasting upcoming trends and providing stylistic solutions to making virtual models, devised by AI, the guiding light that carries forward the vision of a novel world of fashion. Artificial intelligence, through machine learning, is transforming the fashion industry by analyzing huge datasets comprising historical fashion trends, consumer behavior, and market patterns to predict future preferences and upcoming styles. Capability for trend prediction provides designers with important information, making it easier to adapt their products to consumer needs. AI-driven virtual prototyping tools further streamline the design process by enabling fast visualization and iteration of garments digitally even before physical production begins [22]. Additionally, styling platforms driven by artificial intelligence tools can be able to make suggestions considering personal preferences and body types.

The sustainability of the fashion industry has increasingly been emphasized through the integration of artificial intelligence. These AI-powered systems improve sustainability in the fashion industry by refining supply chain processes and improving demand forecasting while reducing material waste. Such technologies enable the use of ecologically friendly techniques and materials for the good of the environment. Artificial intelligence thus not only enhances operations and fosters creativity but also leads to sustainability by advancing the processes of design and production. The geometric models of clothes come from a collection of the UC Berkeley Computer Graphics Research Group known as the Berkeley Garment Library. Exactly such garment models fitted for simulating cloth behavior are very important training data for our system. Either. We further enriched this dataset with the SewFactory one, comprising approximately one million annotated images and sewing patterns, and with the “Dataset of 3D Garments with Sewing Patterns” that comprises 23,500 three-dimensional models split into 12 various garment categories. These were a significant contribution to the training and model validation. A garment creation common add-on used in this study is the Garment Tool 2.0 developed inside Blender to speed up the process in garment creation. This led to enabling the realism in the simulation of textiles, designs, and sewing technologies available within Blender by attracting the physics engines for fine-quality cloth dynamics. The various UV-mapping tools and texture visualization possibilities for clothing design within Blender supported the creation and evaluation in a virtual environment. In combination, such tools and resources allowed for an effective and precise garment model, moving further to enable future development in fashion design.

III. METHODOLOGY

A. Conceptual Framework and Objectives of the Custom Blender Tool

One of the core parts of this technological setup of the project is a specially designed Blender tool through which theoretical methodologies are linked to practical applications in the construction of garments. The tool's functionality basically is observed in Blender's support of 3D-scanned avatars and the prospect of making automated, smooth processes in the transformation of raw scan data into useful forms. The tool interface provides user-friendly options for the selection of various garment types, the setting of fit preferences between loose-regular-tight, and the customization of additional parameters. These settings are seamlessly transferred to the level of the 3D body model, so that users can appropriately customize garment designs without the need for intensive technical background.

The process starts from choosing the type of garment, for which the tool insults a gratuitous pre-stored database of template garments. Each template includes traditional structural components: seamlines, cutlines, and construction specifications of each individual garment type chosen. For each specific garment type selected, the fit preferences are set. Loose, regular, or tight adjustments are controlled through artificial intelligence algorithms which make proper changes to the templates [23]. For instance, the closer the fit, the more number of darts needed for the kind of shaping in the garment silhouette; a looser fit would lessen the number of darts and

gathers in order to create a causal silhouette. The script can also aid in the planning of specific pattern details suitable for the 3D body model. Seamlines are drafted from garment templates and are manipulated based on body measurements and fit for equilibrium between structural integrity and aesthetic properties. Darts are placed in strategic areas where shaping is required, such as bust darts in any garment drafted with the need for shaping around the chest. Gathers are added in areas where added volume is required, such as the waist in some kinds of skirts. Tailored features are added according to the end user's desire and placed according to traditional methods of garment construction. The incorporation of body surface analysis in this tool makes it easier for one to create an Ideal Construction Body (ICB), or a three-dimensional body model that is meant to achieve a better fit. The tool makes it easier to perform the complex procedures of 3D scanning and garment fitting using advanced algorithms in Blender's powerful modeling environment. This helps improve the efficiency and accuracy of garment design, through digital means, while still enabling a user to explore creative opportunities without requiring further knowledge in constructing real garments.

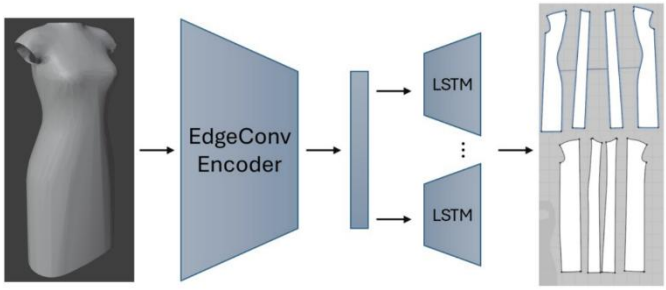


Fig. 2. AI-driven garment generation network: from 3D model and clothing type parameters to flattened sewing patterns using EdgeConv-encoder and LSTM-decoders.

B. AI-Driven Framework for Automated Garment Pattern Generation

One of the primary objectives of the project is the inclusion of a custom Blender script combined with a pre-trained neural network dedicated to the generation of garment patterns. The combination allows for the direct generation and alteration of garment patterns directly in the Blender environment, hence streamlining the design-to-pattern process (Fig. 2). The neural network is based on NeuralTailor [13], which is adapted to transform the ideal 3D body surface model into precise, ready-to-sew sewing patterns. The AI-based garment generation network operates as follows: It starts with input processing, wherein the network is given 3D body scans and offset values are applied to build an Ideal Construction Body (ICB) model. ICB is a precise model of the subject's body topography, which forms the basis for creating personalized apparel. The backbone of the network is an EdgeConv-based encoder, which leverages convolutional neural networks designed to learn geometric structures well. The encoder accepts the 3D model and obtains the main features that are essential for fitting garments. A skip connection is established from the input to the deepest EdgeConv layer to retain fine-grained information by conveying information through deeper layers of the network.

After feature extraction, a Long Short-Term Memory (LSTM) network transforms the garment's latent code. The LSTM is well suited to handle sequential data and stores the temporal dependencies among garment panels in the latent vectors. The process ensures that the final garment design is structurally sound and coherent when formed. The LSTM's latent vectors are individual garment panels. The final step involves a Panel Decoder to restore the complex form and stitching details for every garment panel. The decoder translates the abstract latent codes into practical sewing patterns, which determine panel sizes, layouts, and stitching recommendations. The task is highly significant to ensure the created patterns are correct and feasible to sew. This computer-based system allows for smooth transition from 3D body scanning to precise sewing patterns, a revolution in automated, made-to-measure clothing manufacturing [24].

C. Features and Functionality

The tool developed converts the raw 3D scans to ICBs and creates 2D garment patterns with least distortion automatically. The first step of the process is to convert 3D scans into 3D ICBs, which are specific to the measurement of an individual and may vary in shape and proportion. Advanced AI algorithms ensure these ICBs are correct representations of anatomical details, while offset values referenced from Table II have been applied at critical points such as the bust, waist, and hips to account for different layers of garments. This step ensures that the constructions are both precise and anatomically correct for a wide range of garment designs. The unwrapping automatically produces a 2D pattern of the 3D mesh once the ICB is produced. It minimizes distortions to yield flat, ready-to-use patterns that can be used as the basis of garment assembly. The complex workflow is simple in this tool through the user-friendly interface, enabling users to easily customize their garment styles and sizes. Modifications to fit preferences, such as close-fitting, regular, or loose-fitting designs, become so easy for users according to their needs and liking. Because it is highly customizable, the tool actually enables users to create garments that reflect their vision. The tool works out the most advanced technologies, streamlining the pattern-making process while giving users increased creative freedom. From 3D scan processing to very detailed 2D pattern creation and enabling customizable style variations, this innovative tool offers a perfect combination of precision, efficiency, and accessibility in garment construction.

D. Workflow for Enhanced Garment Fitting Using 3D Scanning and AI

It describes in detail a systematic workflow that attempts to enhance fitting garments with developments in 3D scanning and machine learning algorithms. The heart of the matter in this method lies in the question of how design in clothes may be adjusted regarding singular contours of the human body to make comfort complement elegance. It involves steps ranging from person-scanning to virtually assessing comprehensive fit. It begins with a very precise 3D scan of the person using a 3D scanner. This initial scan gives the basic data necessary to fit the garment to the person's unique body shape. After the scan, the user selects the type of garment they would like to create,

and the program allows variable parameters such as the layer of fit preferred, from loose through regular to tight. This enables the garment to be tailored specifically to the wearer's preference and his or her anatomy. After configuration, the next step involves analysis of the 3D body scan to look at important areas of the surface and body measurements. These will be useful for finding the peculiar contours and measures necessary in garment design. Further from this extracted data during the workflow, a model of ICB or Ideal Construction Body will be generated. Serving as a virtual mannequin, this offers a framework adapted to ensure the intended fit's achievement.

This includes the gathering of sewing information, such as seam placement and allowances, among other necessary data for precision in pattern construction. Then the pre-trained neural network, from that data, predicts an estimate of count, form, and configuration of garment pattern pieces. By doing so, this cutting-edge machine-learning technique will thus yield an accurate construction of distortion-free patterns best fitted on the 3D model of the individual human body. The last step is 3D simulation, which checks the fitting of the garment. The integration of newly generated patterns with the scanned 3D body model enables a virtual try-on experience through simulation. This allows the detection and correction of any fit issues, ensuring that the final garment perfectly matches the specified design and comfort requirements. This smooth workflow seamlessly integrates state-of-the-art technologies to enhance efficiency and accuracy in garment creation while providing a highly personalized outcome.

IV. Experimentation and Discussion

In order to validate the performance of the developed tool, a structured approach was followed to establish its efficacy in converting 3D scans into Ideal Construction Bodies and subsequently creating custom garment patterns. The objective of this test was primarily to determine how accurate the AI-generated patterns were compared to manually created patterns. A specific program was developed for performing this test based on three key parameters: perimeter, area, and HU moments. Higher-order moments of the pixel intensity distribution yielded HU moments, statistical measures of shape and structure in digital images. The resultant metrics are capable of presenting quantitative insights into two important features of a pattern: symmetry and general congruence. The comparison of AI-generated patterns with the ground truth during the evaluation process was done by tools implemented in Python. The formula used for finding the discrepancy between the two patterns involves the differences in HU moments, as expressed in the given equation. This summarizes the differences for all seven HU moments of each pattern piece, normalizing them with respect to the ground truth. The tool will automatically assign an identifier to every pattern piece and assess it independently from any transformation, like rotation or scaling, against the others.

The process is illustrated in Fig. 3, which compares the calculated HU moments of each pattern piece. These differences are summed and normalized to provide a quantitative measure of how well the AI-generated patterns match their ground truth counterparts. Area, perimeter, and HU moments for each section of the pattern are further analyzed in the program, with detailed results presented in Table III. This indeed constitutes a very detailed analysis that brings out the consistency and precision of the generated patterns. The test proves that this tool can generate patterns that are quite accurate with a few errors when compared to manually unwrapped patterns. Moments of HU mean the perfect fitting when the value of the distance is 0.0 and a larger deviation would indicate regions which might need refinement. Results proved that wider garment layers are usually capable of giving more accuracy, hence pointing out the strength of this tool to adapt with different design needs, thus generally increasing the efficiency in garment productions.

TABLE III Evaluation Metrics for basic Patterns Across First, Second, and Third Layers

	Perimeter in %	Accuracy Area in %	Distance HU moments	Perimeter in %	Accuracy Area in %	Distance HU moments	Perimeter in %	Accuracy Area in %	Distance HU moments
1	98.9	79.1	0.6	97.2	74.5	1.03	95.1	77.7	3.21
2	99.6	119.4	67.61	96.1	74.3	1.05	99.2	88.9	1.25
3	100	113	24.27	98.8	86.5	2.66	93.4	79.6	0.4
4	98.7	86	0.57	96.9	91.2	1.16	99.9	98	0.65
5	94.5	75	0.59	91.8	80.2	0.66	97.8	97.9	0.46
6	93.7	74.8	0.59	94.4	68.8	0.55	99.6	98.3	0.68

Total	97.9	83.8	88	96.4	77.7	1.9	97.3	89.1	1.03

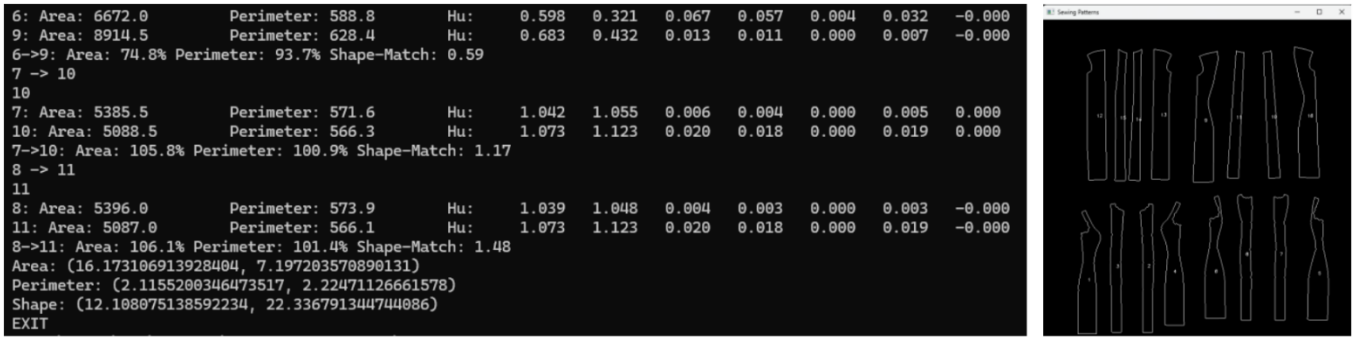

Fig. 3. Comparison of HU moment differences between AI-generated patterns and ground truth shapes.

V. Conclusion

This paper introduces meaningful changes in garment manufacturing and personalization with AI-generated patterns from 3D scans. This is quite a critical approach, as it reduces by a great deal the time spent making simple garments to fit the person's exact measure. By simplifying several steps of the process in fashion design, the tool makes it easy for novice and professional 3D artists to generate well-fitting garments for multiple layers. While AI speeds up the process of creating basic patterns for new designs, their effectiveness depends on user expertise and further physical prototyping to validate the generated patterns. This new tool bridges the gap between design and production by automatically converting 3D body scans into sewing patterns. It revolutionizes the workflow from concept to creation, making personalized basic patterns more accessible and enabling scalable bespoke garment production. However, this tool has its current implementation limitations. The system is limited to generating patterns of garment types included in the pre-trained dataset, which restricts design versatility. Besides, the manual steps of importing 3D scans may reduce the speed of the workflow and make it prone to inaccuracies. These challenges mark points that need improvement in order to further develop the capabilities and usability of the tool. Inclusiveness and accessibility make the democratization of fashion design through the integration of AI in the construction of patterns. Further developments involve increasing the functionality of the tool in constructing patterns on pants, sleeve designs, and the placement of seams according to particular needs; hence, its reach will go outside basic garments.

Another significant digital apparel breakthrough was the AI-powered tool that converts 3D scans into bespoke garment patterns. The conducted experiments demonstrate that the tool can generate patterns with precision and accuracy comparable to manually created designs. The quantitative evaluation of metrics such as perimeter, area, and HU moments substantiates the tool's reliability and efficiency. These findings provide a solid foundation for optimizing and extending the tool's capabilities, ensuring greater adaptability and performance in real-world applications. The results provided here are part of the ongoing digitalization of fashion and will support further developments within digital garments. The next steps in this research include the verification of the patterns through physical productions, new possibilities of design like multi-layer garments, and more intricate pattern models. This tool currently utilizes basic patterns, but it's a promising step toward a future of personalized and scalable garment design.

Future work will focus on enhancing the AI model's adaptability, improving pattern customization for complex garment structures, and integrating real-time feedback mechanisms for better accuracy and user experience.

***Abstract*—Online sales forecasting has become an essential aspect of effective business planning in the digital era. The widespread adoption of digital transformation has enabled companies to collect substantial datasets related to consumer behavior, market trends, and sales drivers. This study attempts to uncover patterns and predict sales growth by utilizing product images and their associated filenames as input. To achieve this, we use EDA combined with LSTM and Gated Recurrent Unit (GRU), which excel in processing sequential data. However, the performance of these networks is significantly affected by the quality of data and the preprocessing methods applied. This study highlights the importance of Exploratory Data Analysis (EDA) and Ensemble Methods in enhancing the efficacy of RNNs for online sales forecasting. EDA plays a crucial role in identifying significant patterns such as trends, seasonality, and autocorrelation while addressing data irregularities such as missing values and outliers. These findings show that integrating EDA substantially improves the performance metrics of RNN, as indicated by the reduction in loss and mean absolute error (MAE) values across training epochs (e.g. loss: 0.0720, MAE: 0.1918 at epoch 15). These results indicate that EDA improves the accuracy, stability, and efficiency of the model, allowing RNN to provide more reliable sales predictions while minimizing the risk of overfitting.**

***Keywords*—Exploratory data analysis; recurrent neural networks; online sales prediction; sequential data; trend patterns**

I. Introduction

The digital business era has fundamentally reshaped sales forecasting and management by harnessing the power of big data and advanced analytics [1]. Technology-driven digital transformation has brought significant changes to sales processes and environments, altering their functions and strategies [2][3][4]. Deep learning models, particularly in e-commerce systems, have emerged as essential tools for predicting and enhancing sales outcomes. This trend is emblematic of a broader shift toward digital business, with the e-commerce sector serving as a prime example of this ongoing evolution [4].

Extensive research has compared traditional sales forecasting methods with machine learning techniques, yielding diverse findings. Pustokhina [5] noted that machine learning often surpasses traditional methods in accuracy, yet certain traditional techniques, such as the Holt-Winters method, remain effective under specific conditions. Zhang [6] proposed an innovative model that integrates online reviews and search engine data, significantly enhancing forecasting precision. Furthermore, Bajaj [7] and Cheriyan [8] emphasized the utility of machine learning algorithms in sales forecasting, with Bajaj exploring models such as Linear Regression, K-Neighbors Regressor, XGBoost Regressor, and Random Forest Regressor, while Cheriyan recognized Gradient Boosting as the most effective method for forecasting sales trends.

Deep learning, a focused domain within machine learning, has achieved significant progress in recent years, [9] showcasing its value in solving complex classification challenges. Its capability to derive robust statistical features from data sets it apart as a powerful tool. Research [10] highlighted the critical role of raw data in optimizing machine learning performance. Studies [11][12][13] the evidence presented illustrates that state-of-the-art deep learning methodologies, such as Long-Short Term Memory (LSTM) networks and Convolutional Neural Networks (CNN), substantially exceed the performance of conventional machine learning methodologies in the domain of retail sales forecasting.. Furthermore, evidence from [14][15][16][17][18] reinforces this, demonstrating that deep learning models excel in generating accurate customer predictions for marketing intelligence applications. Together, these findings highlight deep learning's substantial impact on enhancing sales prediction accuracy and operational efficiency.

This study aims to identify sales trends and analyze the factors that influence sales growth within the digital business environment. To fill the existing research gap, we propose an innovative approach that integrates Exploratory Data Analysis (EDA) for feature preprocessing with Ensemble Methods applied to Recurrent Neural Networks (RNNs) to predict product similarity based on e-commerce image data. This research underscores the significant role of sequential learning techniques and vector embedding in enhancing the accuracy of product similarity predictions. Furthermore, EDA is highlighted as a crucial tool for deriving insights and ensuring data quality in the analysis of time series and sequential data.

II. Previous Research Study

Jelonek [19] asserts that Big Data analytics is a vital asset for business management, providing diverse benefits across numerous activities. Ansari [20] highlights how the integration

of cloud computing with Big Data analytics ensures cost-effective and scalable solutions for storing and analyzing vast enterprise datasets. Nevertheless, the literature lacks a focused discussion on leveraging deep learning for sales prediction. Alsghaier [21] explains that Big Data analytics equips organizations with actionable insights, enhancing business performance and fostering a competitive edge. Ayuningtyas [22] emphasizes that descriptive, predictive, and prescriptive analytics within Big Data are indispensable for strategic decision-making across industries. Singh [23] investigates the vast possibilities of deep learning within the automotive industry, including its use in self-driving cars, safety systems, virtual sensors, and cutting-edge product development.

Recent developments in research have concentrated on employing deep learning techniques to forecast consumer purchasing behavior. Geetha [15] introduces a deep neural network model that leverages multitask learning to predict consumer preferences by analyzing underlying factors and sentiment. Xia [24] develops a multi-task LSTM model to capture the complexities of the consumer buying decision-making process and estimate purchase probabilities. Nisha [25] conducts a comparative analysis of various neural network architectures, including MLP, LSTM, and TCN, for predicting future purchase behavior in e-commerce. These models consistently outperform traditional machine learning methods across multiple dimensions of consumer behavior prediction.

Liu [26] underscores the transformative impact of computer vision technology on e-commerce platforms, particularly in the realm of sales forecasting. Deep learning models enable the automatic extraction of crucial features from product images, providing valuable insights for predicting sales outcomes. Zhao [27] illustrates how Convolutional Neural Networks (CNNs) can efficiently extract features from structured data, improving forecasting accuracy without requiring manual feature engineering. Qi [28] introduces DSF, a deep neural framework designed to tackle the complexities of promotional activities and product competition in sales forecasting, surpassing traditional baseline models and other deep learning techniques in performance. Yang [29] highlights that the application of computer vision in e-commerce extends far beyond sales forecasting, driving improvements in operational efficiency and customer satisfaction across various areas of online shopping.

Kassem [30] proposed models that classify reviews as either positive or negative and compare them with the ratings provided by users to identify any inconsistencies. These strategies aim to enhance the accuracy and reliability of product information for consumers. Wang [31] developed CLUE, a fraud detection system that leverages recurrent neural networks to analyze user click behavior and detect suspicious transactions.

III. Proposed Research Methodology

The methodology for this study is illustrated in Fig. 1 which depicts the process of creating an Exploratory Data Analysis (EDA) algorithm model utilizing LSTM and GRU to forecast online sales.

In Fig. 1, Flowchart combining Exploratory Data Analysis (EDA) with LSTM and GRU frameworks.

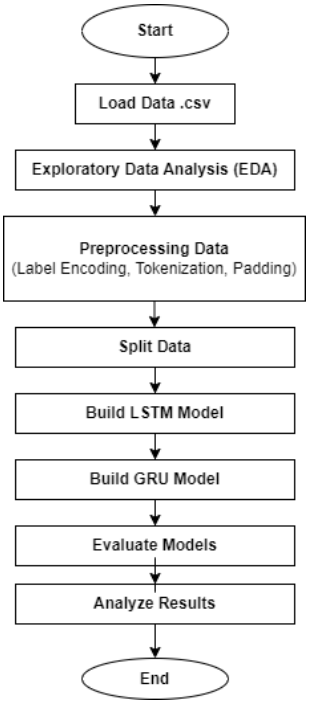

Fig. 1. Flowchart combining exploratory data analysis (EDA) with LSTM and GRU frameworks.

A. Load Data

The initial step involves loading the data from a CSV file. This file, generated during data collection, is stored in a tabular format containing five columns: posting_id, image, image_phash, title, and label_group.

B. Exploratory Data Analysis (EDA)

EDA functions are useful for identifying anomalies, trends, or outliers in sequential data that might obstruct model convergence. It primarily serves as a process for visualizing and understanding data. Below are some commonly used formulas in EDA, for the equation as in (1-6):

- Mean

  The mean reflects the central tendency of a dataset, calculated by summing all individual values and dividing the total by the number of data points.

$$Mean(\mu) = \frac{1}{n}\sum_{i=1}^{n} x_i \quad (1)$$

Where:

x_i = value to- i

$n = the\ total\ amount\ of\ data$

- Variance

Variance quantifies the extent to which data values deviate from the mean.

$$Variance(\sigma^2) = \frac{1}{n}\sum_{i=1}^{n}(x_i - \mu)^2 \quad (2)$$

Where:

μ = mean

x_i = value to- i

- Standard Deviation

The standard deviation constitutes the principal square root of the variance.

$$Standar\ Deviation(\sigma) = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_i - \mu)^2} \quad (3)$$

- Covariance

Covariance measures the degree of interdependence between two variables in a dataset.

$$Covariance(X,Y) = \frac{1}{n}\sum_{i=1}^{n}(x_i - \overline{x})(y_i - \overline{y}) \quad (4)$$

Where:

x_i = value to- i from X

y_i = value to- i from Y

$\overline{x}, \overline{y}$ = mean from X and Y

- Correlation

Pearson correlation quantifies the degree of linear association between two variables.

$$Correlation(\tau) = \frac{\sum_{i=1}^{n}(x_i - \overline{x})(y_i - \overline{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \overline{x})^2 \sum_{i-1}^{n}(y_i - \overline{y})^2}} \quad (5)$$

Correlations can vary between −1 and 1, with 1 indicating a perfect positive correlation, 0 denoting no correlation, and −1 representing a perfect negative correlation.

- Autocorrelation assesses the relationship between values at a specific moment and values from a prior moment (lag) for the purpose of correlation.

$$Autocorrelation(k) = \frac{\sum_{i=k+1}^{n}(x_i - \overline{x})(x_{i-k} - \overline{x})}{\sum_{i=1}^{n}(x_i - \overline{x})^2} \quad (6)$$

k is the lag, which is how far back in time we look

C. Recurrent Neural Networks (RNN)

Forward Pass

In a standard RNN, the output of a neuron at time t (h_t) is influenced by the current input (x_t) and the hidden state from the previous time step (h_t−1), for the equation as in (7-8).

- State (Hidden State)

$$h_t = \emptyset(W_{xh}.x_t + W_{hh}.h_{t-1} + b_h) \quad (7)$$

Where:

h_t = hidden state at the time t

x_t = input at time t

W_{xh} = weight between input and hidden state

W_{hh} = weight between previous hidden state and the current hidden state

b_h = bias

$\emptyset$ = activation function (usually tanh or ReLU)

- Output

$$y_t = \emptyset(W_{hy}.h_t + b_y) \quad (8)$$

Where:

y_t = output at the time t

W_{hy} = weight between output and hidden state

b_h = bias output

$\emptyset$ = activation function (softmax or sigmoid)

Backpropagation Through Time

The training process employs Backpropagation Through Time (BPTT) to compute the gradient and adjust the weights. The gradient at time step *t* is determined by taking into account all preceding time steps.

The error gradient L for parameter W, for the equation as in (9):

$$\frac{\partial L}{\partial W} = \sum_{t-1}^{T}\frac{\partial L_t}{\partial W} \quad (9)$$

T is the total number of times in the sequence

LSTM is designed to address the vanishing gradient issue commonly encountered in standard RNNs. It employs three primary gates: the input gate, the output gate, and the forget gate, for the equation as in (10-14).

- Forget Gate

$$f_t = \sigma(W_f.[h_{t-1}, x_t] + b_f) \quad (10)$$

f_t = the forget gate that determines what information will be forgotten

- Input Gate

$$i_t = \sigma(W_i.[h_{t-1}, x_t] + b_i) \quad (11)$$

i_t = the input gate that determines what new information will be stored

- Update Cell State

$$C_t = f_t.C_{t-1}.i_t \quad (12)$$

C_t = the cell state at time t

- Output Gate

$$o_t = \sigma(W_o.[h_{t-1}, x_t] + b_o) \quad (13)$$

o_t = the output gate that determines the output of the LSTM at time t

- Hidden State

$$h_t = o_t.\tanh(C_t) \quad (14)$$

h_t = the hidden state or output of the LSTM

IV. Experimental Result and Analysis

During the training of our EDA using both LSTM and GRU models, we began by performing an exploratory analysis on the label groups found in Train.csv, examining their data distributions. The results before using EDA are presented in Fig. 2. While the results after using EDA are presented in Fig. 3.

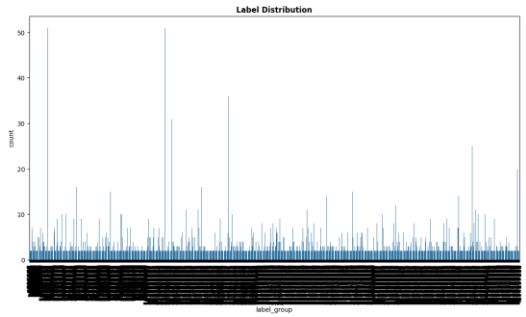

Fig. 2. The distribution of label_group in Train.csv without performing EDA.

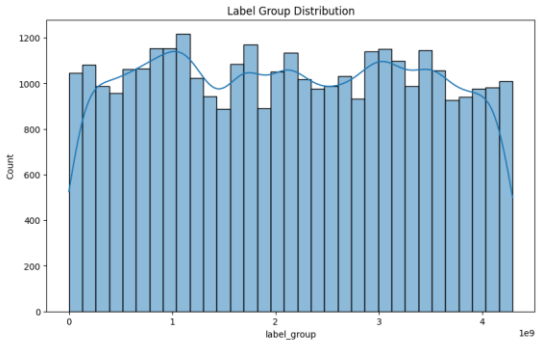

Fig. 3. The distribution of label_group in Train.csv with performing EDA.

From Fig. 2, the figure presents a bar chart. The horizontal axis (x-axis) denotes the label_groups, while the vertical axis (y-axis) displays the count or frequency of occurrences for each label_group. The distribution of label_groups is notably skewed and unbalanced. Some label groups exhibit very high frequencies, surpassing 50, whereas the majority have significantly lower frequencies, frequently below 10, with many falling under 5. The presence of several tall bars indicates that certain label groups are particularly dominant within the dataset. This suggests a bias in the data towards specific labels. Such an imbalanced distribution of labels has important implications for machine learning modeling. If a model were trained directly on this data, it would likely favor the dominant label groups and perform poorly on those that occur less frequently.

From Fig. 3, this figure illustrates the distribution of label_groups in the Train.csv dataset after conducting Exploratory Data Analysis (EDA). Unlike Fig. 2, which shows a significant imbalance, this figure presents a much more balanced distribution. The histogram displays the frequency of each label_group value range as bars, while the KDE (blue line) provides a smoother estimate of the variable's probability distribution. Compared to Fig. 2, the distribution of label_groups here is notably more uniform, with no excessively tall bars. This indicates that the occurrence frequency of each label_group value range is relatively equal. Such a balanced distribution has positive implications for machine learning modeling. The main difference between Fig. 2 and Fig. 3 is the degree of imbalance: Fig. 2 reveals extreme disparity, where some label_groups are highly prevalent while most others are rarely observed. In contrast, Fig. 3 illustrates a more equitable distribution following EDA. This suggests that EDA has resulted in a significant transformation of the data, possibly involving clustering or other modifications to the label_groups.

The test results to explore the distribution of text length in title_image in text.csv can be shown in Fig. 4.

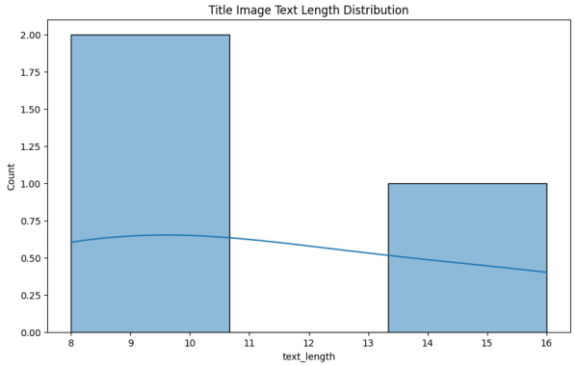

Fig. 4. Title image text length distribution.

Fig. 4 depicts the distribution of lengths for image caption texts. The X-axis represents text lengths, which range from about 8 to 16 characters or words. This shows that the lengths of the image captions fall within this range. The Y-axis indicates the frequency of occurrences for each range of text lengths.

	label_group
count	3.425000e+04
mean	2.128611e+09
std	1.234630e+09
min	2.580470e+05
25%	1.050720e+09
50%	2.120410e+09
75%	3.187910e+09
max	4.294197e+09

Fig. 5. The results of the EDA calculation.

Fig. 5 shows the EDA calculation results. Fig. 6 displays the results of the Exploratory Data Analysis (EDA) for the label_group variable. Below is a detailed explanation of the statistics:

- Count: The value 3.425000e+04 (34,250) indicates that there are 34,250 data points or observations in the label_group variable, representing the total number of entries analyzed.
- Mean: The value 2.128611e+09 (2,128,611,000) represents the average of all label_group values, providing insight into the central tendency of the data.
- Standard Deviation (std): The value of 1.234630e+09 (1,234,630,000) indicates the extent to which the data varies from the mean. A high standard deviation implies that the data points are significantly dispersed, whereas a

low standard deviation suggests that they are closely grouped around the mean. In this instance, the large standard deviation in relation to the mean indicates substantial variability within the data.

- Minimum (min): The value 2.580470e+05 (258,047) denotes the smallest value in the label_group variable.
- First Quartile (25%): The value 1.050720e+09 (1,050,720,000) represents the first quartile. This indicates that 25% of the data falls below or is equal to this value.
- Median (50% / Second Quartile Q2): The value 2.120410e+09 (2,120,410,000) is the median or second quartile. This is the midpoint of the dataset; half of the values are below this point and half are above it. Notably, the median (2.120410e+09) is very close to the mean (2.128611e+09), suggesting a relatively symmetric distribution despite a large standard deviation.
- Third Quartile (75%): The value 3.187910e+09 (3,187,910,000) indicates that 75% of the data has values less than or equal to this figure.
- Maximum (max): The value 4.294197e+09 (4,294,197,000) represents the largest value in the label_group variable.

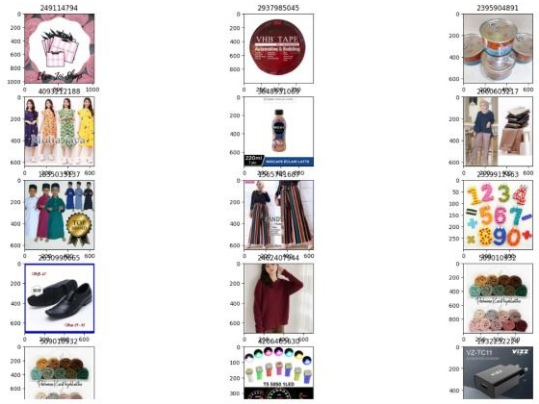

Fig. 6. Example image from label_group.

After the EDA process results, continued with the RNN process which is continued by carrying out the Split Data process for Training and Validation.

TABLE I. RESULTS OF THE SPLIT DATA PROCESS FOR TRAINING AND VALIDATION

Description	Result
Training data shape	(27400, 100) (27400,)
Validation data shape	(6850, 100) (6850,)

Table I shows the results of dividing the training data into Training Data and Validation Data. The results of the Training Data (X_train, y_train) are shown in Table I: (27400, 100) (27400,) (27400, 100). This signifies that the training dataset consists of 27,400 samples or observations, with each sample containing 100 features or time steps (27400,). This represents the shape of the labels or target variables for the training data, indicating that there are 27,400 labels, corresponding to one label for each sample in the training set.

The results of the Validation Data (X_val, y_val) are shown in Table I: TABLE I. (6850, 100) (6850,). (6850, 100). This indicates that the validation dataset consists of 6,850 samples, with each sample containing 100 features or time steps, similar to the training data. The validation data is utilized to assess the model's performance during training and to mitigate the risk of overfitting. (6850,): This represents the shape of the labels or target variables for the validation data, indicating there are 6,850 labels—one corresponding to each validation sample.

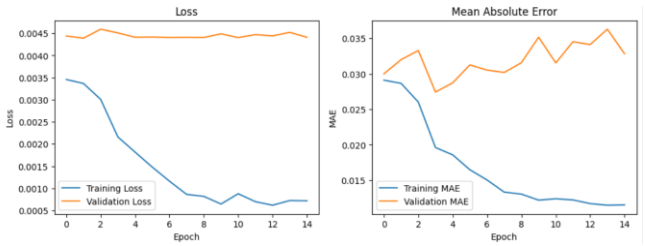

Fig. 7. Training Loss and MAE results with LSTM model without EDA.

In Fig. 7, the document exhibits two graphical representations that monitor the efficacy of the model throughout the training process: the Loss graph and the Mean Absolute Error (MAE) graph, both of which are charted in relation to the epochs.

1) Loss graph: X-axis (Epoch): Represents the number of training epochs, ranging from 0 to 14. Each epoch corresponds to a complete iteration in which the model processes the entire training dataset. Y-axis (Loss): Displays the loss value, which measures the discrepancy between the model's predictions and the actual values. A lower loss value indicates better model performance. Training Loss (Blue Line): Sharp Decline at the Start: The training loss experiences a rapid decrease from approximately 0.0035 at epoch 0 to below 0.001 around epoch 5. This indicates that the model is quickly learning and enhancing its performance on the training data in the early stages. Relatively Stable After Epoch 5: Following epoch 5, while the training loss continues to decline, the rate of decrease becomes less significant and exhibits slight fluctuations. Validation Loss (Orange Line): Generally Stable: The validation loss remains relatively stable at around 0.0045 throughout the training process. Although there are minor fluctuations, there is no clear downward trend as seen in the training loss. A notable gap exists between training loss and validation loss, with the training loss being significantly lower than the validation loss.

2) Mean absolute error (MAE) graph: X-Axis (Epoch): Similar to the loss graph, this axis represents the number of training epochs. Y-Axis (MAE): This axis indicates the MAE value, which measures the average absolute difference between the model's predictions and the actual values. A lower MAE signifies better model performance. Training MAE (Blue Line): Sharp Decline at the Start: Like the training loss, the training MAE also decreases rapidly during the initial stages of training. Relatively Stable After Epoch 5: After epoch 5, the training

MAE stabilizes and shows only minor fluctuations. Validation MAE (Orange Line): Initial Increase Followed by Fluctuations: The validation MAE experiences a slight increase at the beginning of training and then tends to fluctuate around 0.032 to 0.036, without a consistent downward trend. There is a considerable difference between the training MAE and validation MAE, with the training MAE consistently being lower than the validation MAE.

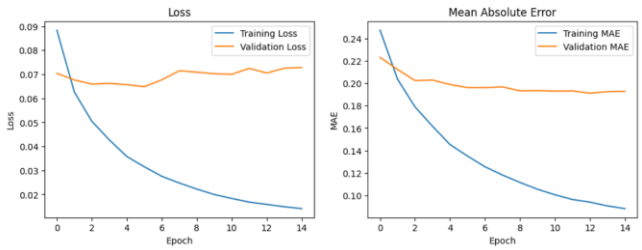

Fig. 8. Training Loss and MAE results with the LSTM model after using EDA.

Fig. 8 presents two graphs that track the model's performance during training, utilizing the Loss and Mean Absolute Error (MAE) metrics plotted against epochs. These metrics are commonly employed to assess regression models. Below are detailed descriptions of each graph.

3) Loss graph: X-axis (Epoch): Displays the number of training epochs, ranging from 0 to 14. Each epoch represents a complete iteration in which the model processes the entire training dataset. Y-axis (Loss): Represents the loss value, which measures the extent to which the model's predictions deviate from the actual values. A lower loss value indicates better model performance. Training Loss (Blue Line): Rapid Decline at the Start: The training loss decreases quickly and consistently from approximately 0.09 at epoch 0 to below 0.02 at epoch 14. This suggests that the model is effectively learning and enhancing its performance on the training data. Consistent Decrease: This steady decline indicates that the model continues to learn throughout the epochs. Validation Loss (Orange Line): Relatively Stable After Initial Decrease: The validation loss shows a slight decrease at the beginning of training, but after a few epochs, it stabilizes and fluctuates slightly around 0.07. There is a notable difference between training loss and validation loss, with training loss consistently lower than validation loss. This difference remains small and stable from the midpoint to the end of the epochs.

4) Mean absolute error (MAE) graph: X-axis (Epoch): Similar to the loss graph, this axis indicates the number of training epochs. Y-axis (MAE): Displays the MAE value, which measures the average absolute difference between the model's predictions and actual values. A lower MAE signifies better model performance. Training MAE (Blue Line): Sharp and Consistent Decline: The training MAE decreases rapidly and steadily from around 0.25 at epoch 0 to below 0.10 at epoch 14. This trend parallels the decrease in training loss, indicating an improvement in model performance on the training data. Validation MAE (Orange Line): Relatively Stable After Initial Decrease: Similar to validation loss, validation MAE experiences a slight initial decrease before remaining relatively stable, fluctuating around 0.20 from mid-epoch to the end. A significant difference exists between training MAE and validation MAE, with training MAE consistently lower. This difference is small and stable from mid-epoch to end.

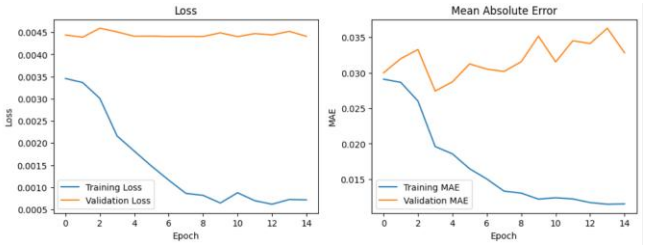

Fig. 9. Training Loss and MAE results with the GRU model after using EDA.

Fig. 9 below presents two graphs that track the model's performance during training, utilizing Loss and Mean Absolute Error (MAE) metrics plotted against epochs. These metrics are commonly employed to assess regression models. Below is a detailed description:

5) Loss graph: X-axis (Epoch): Displays the number of training epochs, ranging from 0 to 14. Each epoch represents a complete iteration during which the model processes the entire training dataset. Y-axis (Loss): Represents the loss value, which quantifies how poorly the model's predictions align with the actual values. A lower loss value indicates better model performance. Training Loss (Blue Line): Sharp Early Decline: The training loss decreases rapidly from approximately 0.0035 at epoch 0 to below 0.001 around epoch 5, indicating that the model is quickly learning and enhancing its performance on the training data in the early stages. Relatively Stable After Epoch 5: After epoch 5, while the training loss continues to decline, the rate of decrease becomes less significant and shows slight fluctuations. Validation Loss (Orange Line): Generally Stable: The validation loss remains relatively stable at around 0.0045 throughout the training process, exhibiting minor fluctuations without a clear downward trend as seen in the training loss. A notable difference exists between training loss and validation loss, with training loss consistently being much lower than validation loss.

6) Mean absolute error (MAE) graph: X-axis (Epoch): Similar to the loss graph, this axis indicates the number of training epochs. Y-axis (MAE): Displays the MAE value, which measures the average absolute difference between the model's predictions and actual values. A lower MAE signifies improved model performance. Training MAE (Blue Line): Sharp Decline at the Start: Like the training loss, the training MAE decreases rapidly during the initial phase of training. Relatively Stable After Epoch 5: Following epoch 5, the training MAE also stabilizes and exhibits only minor fluctuations. Validation MAE (Orange Line): Initial Increase Followed by Fluctuations: The validation MAE shows a slight increase at the beginning of training before fluctuating around

0.042 to 0.046, without a consistent downward trend. There is a significant difference between training MAE and validation MAE, with training MAE consistently lower than validation MAE.

7) The model evaluation results highlight two key metrics: Mean Squared Error (MSE) and Mean Absolute Error (MAE). MSE quantifies the average of the squared differences between the model's predictions and the actual values, with a lower MSE indicating greater accuracy in predicting the target value. On the other hand, MAE assesses the average of the absolute differences between the model's predictions and the actual values, where a lower MAE also signifies improved accuracy in predicting the target value. In this study, three tests were conducted, and the results are presented in Table II.

TABLE II. THE MODEL EVALUATION RESULTS

Epoch Value	Test Results	
	MSE	MAE
LSTM without EDA	2.7837	2.818866014480591
LSTM with EDA	0.07274550944566727	0.1918681412935257
GRU with EDA	0.0053	0.046813491731882095

From Table II, it can be observed that the results for the LSTM model without EDA show a significant disparity between the training metrics (both loss and MAE) and the validation metrics, indicating a strong likelihood of overfitting. The model performs exceptionally well on the training data but struggles with the validation data that it has not encountered before. In contrast, the results for the LSTM model with EDA demonstrate a consistent decline in both training loss and training MAE, suggesting effective learning on the training data. Although there is a difference between the training and validation metrics, this difference is relatively small and stable from the midpoint of the epochs to the end, indicating that overfitting may be minimal or effectively managed. On the other hand, the results for the GRU model with EDA reveal a considerable difference between the training MAE and validation MAE, with training MAE consistently lower than validation MAE. This significant gap between the training metrics (both loss and MAE) and validation metrics strongly suggests overfitting. The model learns very well from the training data but performs poorly on unseen validation data, as evidenced by the continuous decrease in training loss/MAE while validation loss/MAE remains stable or even increases.

V. CONCLUSION

The extensive results of this study indicate that EDA significantly improves the preparation of sequential data for processing by RNNs, allowing essential patterns in the data to be identified and incorporated into the modeling process. By employing EDA techniques specifically for LSTM and GRU models, the risk of overfitting can be reduced. As a result, EDA positively impacts the performance, stability, and interpretability of the RNN model, helping to minimize biases and variances in predictions. The findings—loss: 0.0724; MAE: 0.1913—at epoch 15 show that, in general, higher epoch numbers correspond to lower loss and MAE values. However, it is important to note that if training loss continues to decrease while validation loss begins to rise, this may indicate overfitting. This situation suggests that the model has become too dependent on the specifics of the training data and is failing to develop the robust capabilities needed for accurate predictions on new datasets.

***Abstract*—Traditional measurement methods in underground mining tunnels have faced inefficiencies, limited accuracy, and operational challenges, consuming significant time and labor in complex environments. These limitations severely restrict the efficiency and quality of mine management and engineering design. To enhance the efficiency and accuracy of 3D modeling in underground tunnels, this study combines portable 3D LiDAR scanning technology with simultaneous localization and mapping. This integration enables autonomous positioning and efficient modeling without external positioning signals. The proposed approach effectively acquires high-resolution 3D data in complex environments, ensuring data accuracy and model reliability. High-resolution scanning of multiple critical areas was conducted on-site, with inertial navigation systems correcting the device's pose information. Automated data processing software was used for filtering, denoising, and modeling the collected data, leading to precise 3D tunnel models. Validation results indicate that portable laser scanning technology offers significant advantages in efficiency, accuracy, and safety, meeting the geological surveying and engineering needs of mining operations. The application of portable 3D laser scanning technology demonstrates considerable benefits in the rapid modeling of underground tunnels, providing effective technical support to improve mine management efficiency and safety. It also reveals broad application prospects.**

Keywords*—Underground mining; 3D modeling; portable 3D laser scanning; simultaneous localization and mapping (SLAM); mine surveying; inertial measurement unit (IMU)

I. Introduction

As mining resource development deepens, the scale and complexity of underground tunnel networks increase, raising higher demands for geological measurement and engineering management in mines[1], [2], [3]. High-precision 3D modeling forms the foundation of safe mining production and is crucial for optimizing engineering design and enhancing management efficiency [4], [5]. However, achieving efficient and accurate 3D modeling in the complex and harsh conditions of underground tunnels presents significant challenges.

Traditional surveying methods rely heavily on total stations and distance measuring devices. These methods often require manual point setting and observation, which are cumbersome and time-consuming, especially in poorly lit and dusty underground environments [6], [7]. Such conditions can compromise the efficiency and accuracy of data collection. Additionally, these methods depend significantly on the experience of survey personnel, making them prone to human error and limiting rapid responses to unexpected situations. Although static 3D laser scanning technology has significantly improved measurement accuracy, its application in underground spaces remains constrained by the complexity of equipment setup and positioning, which reduces flexibility and efficiency.

Recent advancements in 3D laser scanning technology, particularly the emergence of portable laser scanning devices, have provided an efficient and flexible solution for 3D modeling in complex environments. These portable devices utilize a non-contact measurement approach, enabling the rapid acquisition of high-resolution point cloud data. When combined with simultaneous localization and mapping (SLAM) technology, these devices achieve autonomous positioning and mapping in GPS-denied environments. Due to these technical advantages, portable laser scanning devices have increasingly been applied in fields such as construction [8], [9], [10], geological exploration [11], [12], [13], and autonomous driving [14], [15], [16]. Despite such advancements, research and application in underground tunnel environments remain limited, necessitating further exploration of portable laser scanning technology in these settings.

In this context, this study proposes a technical solution for rapid modeling of underground mine tunnels by integrating portable 3D laser scanning devices with inertial measurement units (IMU). By combining SLAM algorithms with inertial data in complex underground environments, this approach addresses laser radar positioning error accumulation and generates high-precision 3D models through automated data processing. The objective of this study is to validate the feasibility of portable 3D laser scanning technology in underground tunnel modeling and evaluate its advantages in terms of efficiency, precision, and applicability. Through testing and analysis of actual mining projects, the performance of this technology is assessed, and its potential applications in mining management and engineering design are further explored. This research provides an effective technical pathway for efficient modeling of underground tunnels and contributes to advancing 3D modeling technology in complex environments.

The remainder of this paper is organized as follows: Section II reviews related works and identifies research gaps. Section III details the proposed methodology integrating portable LiDAR, SLAM, and IMU. Section IV presents experimental results from engineering applications. Section V discusses the findings and compares with existing methods. Finally, Section VI concludes the study and outlines future directions.

II. Related Work

In recent years, research on 3D modeling of mining tunnels has gained traction, focusing on the application of 3D laser scanning technology, point cloud data processing and analysis, and innovations in positioning and navigation technologies. Traditional surveying methods for mining tunnels often rely on total stations and distance measuring devices. However, these methods face challenges such as inadequate measurement accuracy, cumbersome operations, and high time costs. In contrast, 3D laser scanning technology enables the rapid acquisition of high-precision spatial information, making it the preferred method for mining tunnel measurement and modeling [17], [18], [19]. Particularly in complex underground environments, laser radar can obtain data non-contact, overcoming the limitations of traditional surveying methods.

The introduction of SLAM technology has significantly enhanced data collection accuracy and efficiency in mining tunnel 3D modeling [20], [21], [22]. By continuously updating the device's pose, SLAM avoids the reliance on external positioning signals, which are often unavailable in GPS-denied underground environments.

IMU have also played a crucial role in mining 3D modeling by providing real-time motion state information [23], [24]. This data is vital for improving the stability and accuracy of SLAM systems in dynamic environments.

Regarding point cloud data processing, extracting useful information from large-scale point cloud datasets and removing noise remains a significant challenge [25], [26], [27], [28]. Existing studies have addressed this through techniques such as point cloud filtering, registration, and down-sampling. Point cloud filtering eliminates noise points generated during scanning, thereby improving data quality. Point cloud registration aligns data collected from different perspectives or times to construct continuous and consistent 3D models.

Despite substantial progress in the field of mining tunnel 3D modeling, the integration of portable laser scanning technology with SLAM and IMU still faces challenges. It is crucial to further minimize positioning errors in confined and complex spaces and ensure system stability in harsh environments. The maturity of the technology and its widespread application in the field require further validation and optimization. In Table I, the limitations of existing 3D modeling methods are summarized.

TABLE I. Limitations of Existing 3D Modeling Methods

Method	*Accuracy*	*Efficiency*	*Positioning Dependency*	*Environmental Adaptability*
Total Station	Medium	Low	High	Poor (dusty/low-light)
Static LiDAR	High	Medium	Medium	Moderate
SLAM-only Systems	Medium	High	None	Good (limited in dynamics)

While prior studies have advanced SLAM and IMU integration, three key limitations persist: (1) Cumulative errors in SLAM-based systems under prolonged operation, (2) Inadequate sensor fusion strategies for dynamic underground conditions, and (3) Limited validation in large-scale mining networks. Our approach addresses these through tight LiDAR-IMU coupling with error compensation (Section III.D) and field validation in 2.3km tunnel networks (Section IV).

III. Rapid Tunnel Modeling

A. Portable 3D LiDAR Scanning

Portable 3D laser scanning devices are developed based on SLAM technology, as shown in Fig. 1. Initially proposed by Smith and Cheeseman in 1986 to address spatial uncertainty estimation, SLAM primarily solves navigation and localization issues in unknown environments. It determines the device's position and orientation by observing features such as corners and columns, incrementally constructing an environmental map based on positional changes. SLAM enables concurrent localization and mapping, making it particularly suitable for complex underground mining environments where GPS signals are unavailable.

Fig. 1. Portable 3D laser scanning device.

Portable 3D scanning devices perform rapid and continuous scanning of complex environments while in motion, automatically capturing accurate three-dimensional spatial information. Compared to traditional fixed surveying techniques, portable devices address frequent setup issues caused by laser line-of-sight limitations, significantly enhancing fieldwork efficiency. These devices reduce operator labor intensity and safety risks while enabling extensive continuous 3D scanning tasks in underground mines.

In underground mining applications, portable 3D laser scanning devices integrate SLAM technology for autonomous localization and mapping in environments without external positioning signals, ensuring high-precision surveying capabilities. Their compact, lightweight, and ergonomic designs make them easy to transport and operate in confined or complex environments. Additionally, the integration of complementary sensors such as gyroscopes, accelerometers, and GPS enhances the collection of positioning and orientation data, substantially improving scanning accuracy and data reliability. These devices are capable of scanning various underground features, including tunnels, voids, and chutes, supporting tasks such as dimension measurement, volume calculations, morphology analysis, over-excavation and under-excavation assessments, engineering

quantity estimations, surface area measurements, and extraction of 3D contours and tunnel profiles.

B. Spatial Calibration Methods

The working principle of a 3D laser scanning system relies on laser ranging technology, which measures the time difference between laser emission and reflection to calculate the distance to an object's surface. By emitting a laser beam toward the object and receiving its reflected signal, the scanner determines the distance d based on the time-of-flight formula, as shown in Eq. (1).

$$d = \frac{c \cdot \Delta t}{2} \tag{1}$$

Where, c is the speed of light, and Δt is the time difference between the emission and reception of the laser.

To determine the three-dimensional coordinates of points on the object's surface, it is essential to measure not only the distance but also the emission angles of the laser beam. The laser scanner is typically mounted on a rotating device, allowing the laser beam to cover the entire scanning area through rotation. The three-dimensional coordinates (x, y, z) of each laser point can be calculated using the measured pitch angle θ, yaw angle ϕ, and the measured distance d, as shown in Eq. (2).

$$\begin{cases} x = d \cdot \cos(\theta) \cdot \cos(\phi) \\ y = d \cdot \cos(\theta) \cdot \sin(\phi) \\ z = d \cdot \sin(\theta) \end{cases} \tag{2}$$

Where, θ is the pitch angle of the laser beam, and ϕ is the yaw angle.

In practical applications, the laser scanner may move or rotate, necessitating consideration of its spatial position and orientation. Assuming the position of the scanner in space is PP and its rotation matrix is R, the three-dimensional coordinates (X, Y, Z) of the object's surface can be corrected using Eq. (3).

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = R \cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix} + \begin{pmatrix} x_0 \\ y_0 \\ z_0 \end{pmatrix} \tag{3}$$

Where, R is the rotation matrix.

By repeatedly performing this process, the scanner can calculate the three-dimensional coordinates of each laser point, thereby constructing the complete 3D point cloud data of the object or scene.

C. Mobile Scanning Method

The mobile scanning method uses highly integrated portable 3D laser scanning equipment to collect environmental data and generate 3D point cloud models during movement. The structure of the mobile scanning device, shown in Fig. 2, comprises a probe and a backpack. These components are interconnected via various communication protocols, including Ethernet, RS-485, RS-232, and GPIO control.

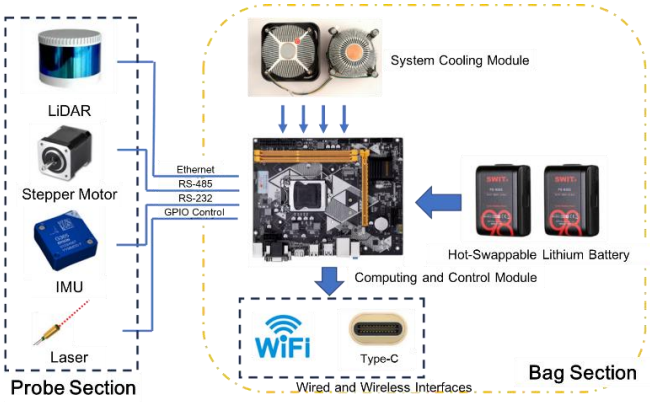

Fig. 2. Mobile scanning device structure.

The probe includes a LiDAR, stepper motor, inertial navigation module, and laser rangefinder, responsible for generating high-precision 3D point cloud data. The LiDAR measures the distance and shape of target objects, the stepper motor controls the scanning angle and rotation, the inertial navigation module provides device orientation information, and the laser rangefinder is used for accurate distance measurement.

The backpack focuses on performance and portability, containing a system cooling module, hot-swappable lithium battery, high-performance computing and control module, as well as wireless and wired interfaces. The cooling module ensures the stability of long-term device operation, the lithium battery provides continuous power, and the high-performance computing and control module processes data in real-time to generate precise point cloud models. The wireless and wired interfaces facilitate data transmission and device communication, supporting remote monitoring and data synchronization.

The mobile scanning process is illustrated in Fig. 3 and consists of four main steps:

1) Initial scanning and point cloud acquisition: Activate the LiDAR and scan the surrounding 3D space with the probe to capture the initial point cloud dataset, denoted as P_0.

2) Mobile remeasurement and data update: After the probe moves, use the LiDAR to rescan the previous area, obtaining the updated point cloud data denoted as P_1. This process continues to acquire new datasets P_2, P_3, and so on.

3) Trajectory estimation and spatial reconstruction: By comparing the two consecutive point cloud datasets P_t and P_{t+1}, estimate the probe's displacement and rotation by minimizing $T_{t \to t+1} = \arg\min_T \sum \left\| P_i^{t+1} - T \cdot P_i^t \right\|^2$, where T is the transformation matrix. The SLAM pipeline utilizes a feature-based Iterative Closest Point (ICP) algorithm that starts with feature extraction, where edge features (tunnel ribs) and planar features (tunnel walls) are extracted using curvature thresholds (edge: curvature > 0.1; planar: curvature < 0.05). Following this, dynamic object removal is performed through statistical outlier removal (50-neighbor points, 1.5 σ threshold) and DBSCAN clustering (ε=0.3m, minPts=15).

4) Point cloud registration and data fusion: Utilize the ICP algorithm to accurately align and fuse datasets $P_0, P_1, \ldots, P_t$, resulting in the creation of a continuous point cloud model M. Fine registration minimizes point-to-plane residuals using Huber loss with a threshold of δ=0.2m, expressed as $E = \sum \left| n_j^T (Rp_i + t - q_j) \right|^2$, where n_j represents the normal vector of the target plane j.

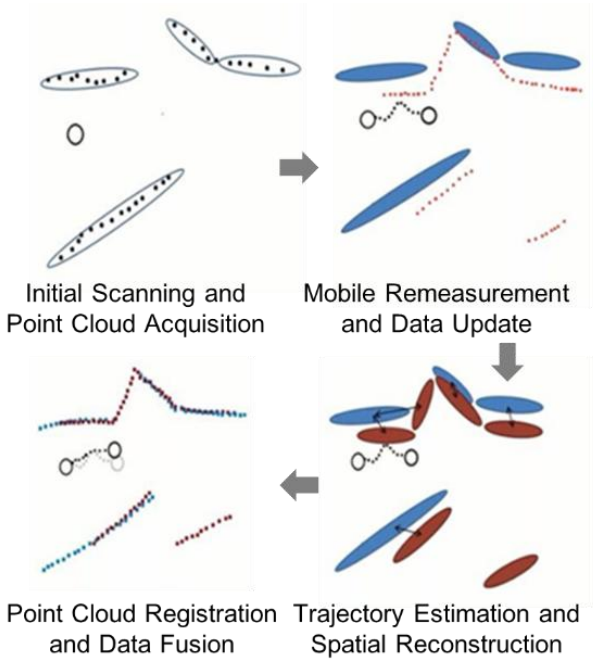

Fig. 3. Mobile scanning process.

D. Inertial State Integration

To mitigate positioning errors and inaccuracies caused by dynamic motion, an IMU is integrated into the system for spatial calibration. Traditional LiDAR systems often require stable platforms, but portable devices operating in dynamic environments can encounter vibrations and irregular movements that impact data accuracy. The IMU enhances measurement robustness by providing supplementary pose data.

The LiDAR is mounted on a linkage mechanism with dual rotational axes, as shown in Fig. 4. This configuration enables continuous acquisition of both laser ranging and inertial data, providing real-time six degrees of freedom (6DOF) trajectory estimation.

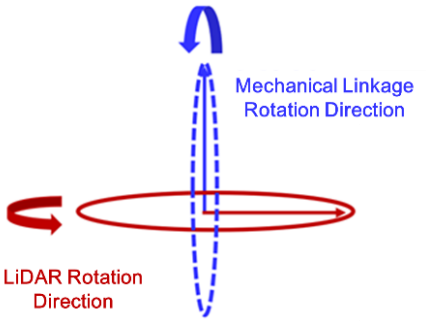

Fig. 4. Device operation rotation diagram.

By utilizing encoder information, the specific rotation angle of the LiDAR probe relative to the stepper motor at each moment can be obtained. Let the rotation angle of the LiDAR with respect to the stepper motor be denoted as $\theta(t)$. The initial point cloud data P is then corrected to align its coordinate system with that of the stepper motor. The corrected point cloud data is represented as P', with the transformation given by $P' = R(\theta(t)) \cdot P$, where $R(\theta(t))$ is the rotation matrix based on the angle $\theta(t)$.

The corrected point cloud data is tightly integrated with inertial information. Pre-integration of the inertial data is performed to accumulate the sensor's motion trajectory. This pre-integration process primarily relies on the acceleration $a(t)$ and angular velocity $\omega(t)$ measured by the IMU to compute increments in position and orientation, as shown in Eq. (4).

$$\begin{cases} \Delta p = \int_{t_0}^{t_1} v(t) \cdot dt \\ \Delta v = \int_{t_0}^{t_1} a(t) \cdot dt \\ \Delta R = \int_{t_0}^{t_1} \omega(t) \cdot dt \end{cases} \tag{4}$$

The IMU-LiDAR fusion utilizes a Kalman filter, which includes a state vector representing position, velocity, quaternion, and the biases from the accelerometer and gyroscope. During the update process, the IMU performs predictions at a high frequency, while the LiDAR provides corrections at a lower frequency using feature residuals. Furthermore, bias compensation is implemented through online calibration via sliding window optimization.

Combining the point cloud constructed through the mobile scanning method with the corrected point cloud data and inertial data allows for real-time estimation of the sensor's 6DOF trajectory.

E. 3D Model Construction

The method for constructing a 3D model using LiDAR and IMU primarily consists of tightly coupled joint optimization of the LiDAR inertial odometry and point cloud mapping, as illustrated in Fig. 5.

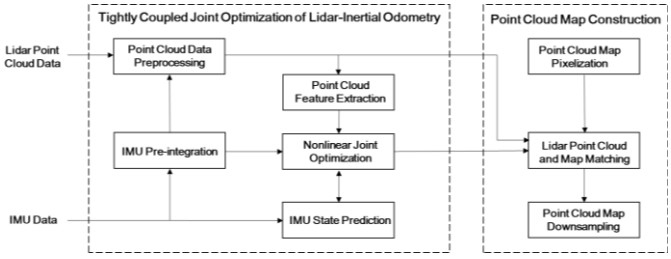

Fig. 5. System working principle.

In the tightly coupled joint optimization of the LiDAR inertial odometry, the IMU data is pre-integrated, and both intra-frame and inter-frame motions of the LiDAR are computed. The

calculated intra-frame motion is then used to preprocess the point cloud data, mitigating the effects of motion distortion through motion compensation using the IMU-derived trajectory. Additionally, ground segmentation is performed using RANSAC plane fitting with a defined inlier threshold, enabling the separation of ground points from other data. After this preprocessing, voxel downsampling is applied with differing resolutions for near-field and far-field regions to balance computational efficiency and detail retention. Feature extraction is then performed on the processed point cloud data, alongside IMU state prediction. Finally, based on the established IMU constraints and LiDAR constraints, a nonlinear optimization model is constructed to obtain the state variables required for the mapping process. The optimization process is supported by global techniques facilitated by the Ceres solver using the Levenberg-Marquardt algorithm, ensuring robust and accurate results.

In the point cloud mapping phase, the point cloud map is first voxelized. Subsequently, the optimized results from the odometry phase are used to match the LiDAR point cloud with the point cloud map. Lastly, the point cloud map undergoes downsampling to reduce its size.

IV. Engineering Applications

A. Project Background

The CMC project in the Democratic Republic of the Congo is a complex underground mining development system engineering project. The underground tunnel network includes multiple key areas and structures, with the areas to be scanned depicted in Fig. 6. These areas encompass light vehicle ramps, heavy vehicle ramps, and various sections such as the 1110, 940, and 990 levels, as well as the measures ramp. Additionally, the project involves significant underground facilities including ventilation shafts, auxiliary shafts, and water chambers.

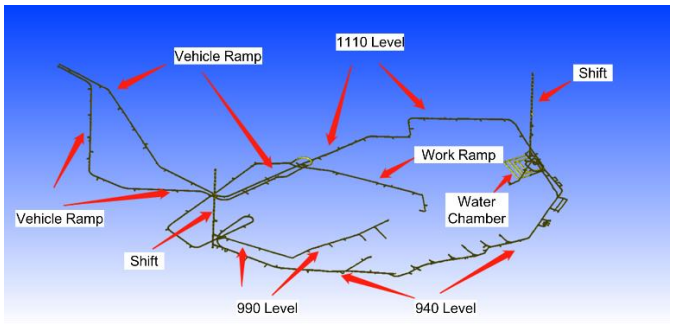

Fig. 6. Overall view of the underground mine survey area.

The geographical distribution and functional positioning of these tunnels and facilities result in a considerable project length, traversing various geological and structural layers. In such a complex underground environment, traditional measurement and modeling methods may not meet the required accuracy and efficiency standards. Therefore, a rapid tunnel modeling approach based on portable LiDAR technology is employed to achieve high-precision 3D positioning of the underground space.

B. Field Data Collection

Due to the complexity and long distances of the underground tunnel system, multiple data collection methods were employed to adapt to different environmental conditions and scenarios, as illustrated in Fig. 7. In accessible areas, operators conducted scanning with handheld devices. In the light and heavy vehicle ramp areas, scanning was performed from vehicles to enhance collection efficiency. In the 940 and 1110 level, where rainfall was prevalent, handheld scanning was utilized, with operators using umbrellas to shield against water spray, particularly in the 940 level. The device sensor continuously rotated at a steady speed to perform panoramic scanning, covering a distance of 100 meters, allowing for complete scanning with a single pass through the scene. For hazardous areas inaccessible to personnel, such as chutes and mined-out zones, drones or extension poles equipped with scanning devices were employed. These methods ensured high-quality data acquisition even in complex and dangerous environments.

Fig. 7. Handheld scanning and vehicle-mounted handheld scanning.

Data collection was conducted in segments due to the overall length of the underground tunnels. Each segment's data was distinguished by different colors, facilitating subsequent stitching and adjustments. To align the data with the geodetic coordinate system, the equipment needed to be calibrated to control points within the tunnels. In accessible areas, such as the tunnel floor, alignment was achieved by overlapping the crosshair on the device's base with the control point. In areas inaccessible to personnel, such as the tunnel ceiling, a visible laser on the device was used to aim at the control point. The positions of the control points were recorded on a mobile control device. This laser anchoring method did not require additional personnel, resulting in higher accuracy and allowing for single-person operation.

C. Indoor Data Processing

After data collection, the coordinates of the control points needed to be entered on the mobile control device. In the mobile control device's menu, the system for analysis was selected, and by clicking “Retrieve Data,” all collected data could be viewed. These data packets were named according to the collection time, with corresponding control point information displayed on the right side of each packet. By clicking on the control point information for a specific data packet, a window for inputting the control point coordinates would appear, where the geodetic coordinates (in meters) for the corresponding control point could be entered. After inputting the control point coordinates, the

relevant collected data was selected on the left side, followed by clicking the "Analyze" button to initiate data processing. The control point input interface on the mobile device is shown in Fig. 8.

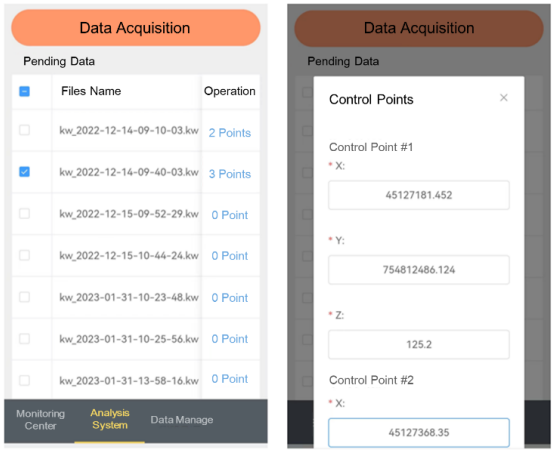

Fig. 8. Mobile interface for control point input.

After the data processing was completed, the data is transmitted to the PC via a network. The data folder contains several files, including filtermap.dxf, ControlPoint.txt, map.las, filter_map.las, map.pcd, filtermap.pcd, filtermap.ply, and Path.txt. Among these, filtermap.dxf contains the 3D model data generated automatically by the device, ControlPoint.txt records the geodetic and control point coordinates, while map.las and filter_map.las represent the original and decimated point cloud data of the map, respectively. Additionally, map.pcd and filtermap.pcd contain the original and decimated point cloud data in PCD format, filtermap.ply is the 3D object format point cloud data, and Path.txt contains the trajectory data of the device.

The LAS point cloud data undergoes filtering and denoising processes to eliminate noise generated by moving objects within the tunnel. This process retains valid points while reducing the overall data size to approximately one-tenth of the original. After filtering and denoising, a 3D model of the tunnel is created, generating a closed triangular mesh model that preserves the original morphology of the tunnel, as shown in Fig. 9.

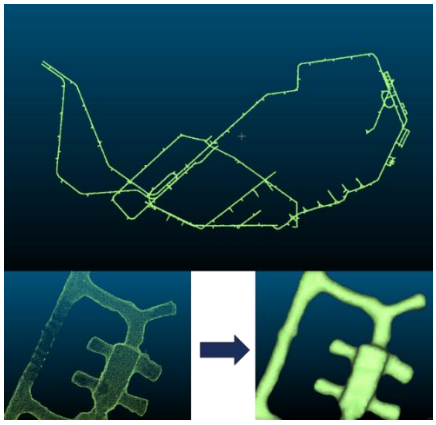

Fig. 9. Drift 3D model.

V. Results

A. Accuracy Validation

Once the tunnel's 3D model is established in point cloud processing software, it can be saved in DXF format and imported into 3D mining software such as Dimine for further processing. This facilitates a series of tasks related to geological surveying and mining operations, including ore body modeling, tunnel design, resource estimation, and extraction planning. By comparing the 3D model with the CAD base map in detail, the accuracy and completeness of the model can be analyzed, as shown in Fig. 10.

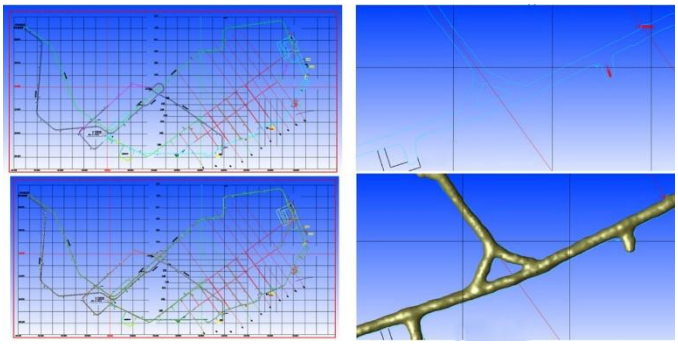

Fig. 10. Comparison of CAD drawing and model.

First, the CAD base map and the DXF format 3D model data are imported separately into the software. The comparison tool is then used to overlay the 3D model with the CAD base map to check their alignment. If discrepancies are identified between the 3D model and the CAD base map, adjustments and corrections can be made based on the comparison results to ensure high precision of the model.

The accuracy assessment involves comparing the 3D model with the actual tunnel, measuring deviations in both longitudinal and lateral positions. Several representative measurement points were selected at different locations within the tunnel, and actual measurements were taken. These data were then compared with the corresponding data in the 3D model, as shown in Table II.

TABLE II. Comparison between Measured Model and Actual Measurements

Measurement Point	*Measurement Content*	*Actual Value (m)*	*Measured Value (m)*	*Absolute Error (m)*	*Relative Error (%)*
Vehicle Ramp	Longitudinal Deviation	269.87	270.12	-0.25	0.09
	Lateral Deviation	4.72	4.74	-0.02	0.42
Water Chamber	Longitudinal Deviation	15.18	15.14	0.04	0.26
	Lateral Deviation	4.21	4.22	-0.01	0.24
Stope Substation	Longitudinal Deviation	5.37	5.36	0.01	0.19
	Lateral Deviation	4.92	4.93	-0.01	0.20

The results demonstrate that the absolute errors across all test points were minimal, with relative errors ranging from 0.09% to 0.42%, ensuring that the generated 3D models meet precision requirements for mining applications. These findings indicate the reliability of the presented method in achieving high-accuracy 3D modeling in complex underground environments.

Beyond validation through direct measurements, 3D models were also compared against original design CAD drawings within mining software (e.g., DIMINE). The overlay alignment evaluation revealed minimal discrepancies, confirming the completeness and consistency of the 3D models with the engineering designs (Fig. 10). This validation process underscores the potential of the proposed method for enhancing tunnel design implementation and quality control.

B. Efficiency Analysis

The efficiency of the proposed method was assessed by examining the time required for data collection and processing compared to traditional methods such as total station measurements and static LiDAR scanning. The portable LiDAR system significantly reduced fieldwork times due to its ability to capture spatial data continuously and autonomously while in motion. Specifically, the system completed a 2.3 km tunnel network survey in approximately 6 hours, including setup, scanning, and preliminary control point calibration. Traditional methods would typically require at least 2–3 days for similar coverage, highlighting the advantages of the portable LiDAR solution in terms of operational efficiency.

Furthermore, the automated data processing workflow reduced the time needed for point cloud filtering, denoising, and stitching by at least 30% compared to conventional software pipelines. The integration of SLAM and IMU technologies eliminated the dependency on fixed reference points, further streamlining data collection in environments with limited access or visibility.

C. Safety and Adaptability

The adaptability and safety of the proposed method were demonstrated through its successful deployment in hazardous and challenging underground environments. The compact and portable design of the scanning device facilitated access to narrow and confined spaces, eliminating the need for extensive manual setups. Additionally, automated scanning from mobile platforms (e.g., vehicles) or remote systems (e.g., drones) allowed for data collection in areas that were otherwise inaccessible or unsafe for personnel, such as waterlogged tunnels and mined-out zones.

The flexibility of the system was further underscored by its performance in varying environmental conditions. For instance, handheld scanning with umbrellas in the 940 level ensured high-quality data acquisition despite water spray and poor lighting. These capabilities emphasize the robustness of the system in adapting to diverse underground scenarios.

D. Discussion

The proposed portable LiDAR-based rapid modeling method demonstrates significant advancements in accuracy, efficiency, and adaptability for underground mining applications. The integration of SLAM and IMU technologies effectively addresses common challenges in GPS-denied environments, ensuring reliable data collection and high-resolution 3D modeling. Compared to traditional surveying methods, the proposed approach achieves superior time efficiency and operational flexibility while maintaining precision, as evidenced by relative errors below 0.5% and successful deployment in complex tunnel networks. Furthermore, the system's portability and ability to operate under adverse conditions, such as low light, dust, and water spray, highlight its robustness and practical value for diverse underground scenarios.

Despite these advantages, residual challenges remain. Pose error accumulation during extended operations and computational demands for large-scale point cloud processing represent areas for improvement. Environmental factors, such as extreme humidity or dust, may also introduce noise, impacting data quality. Future research should focus on optimizing SLAM algorithms, developing real-time processing capabilities, and integrating complementary sensors to enhance system performance. Additionally, further miniaturization and automation could expand its applications across other industries.

Overall, this study provides a comprehensive solution for efficient and accurate tunnel modeling, addressing critical limitations of traditional methods and laying a foundation for broader adoption of portable LiDAR technologies in mining and beyond.

VI. Conclusion

This study addresses the challenge of rapid 3D modeling of underground mining tunnels by proposing an innovative solution based on portable 3D laser scanning technology and SLAM techniques. Experimental validation demonstrates the feasibility and effectiveness of this approach in complex environments. By integrating portable 3D laser scanning technology with SLAM algorithms and IMU, this research successfully achieves efficient 3D modeling of underground tunnels without relying on external positioning signals. This method effectively overcomes the limitations of traditional measurement techniques, such as low efficiency and restricted accuracy in underground settings, significantly enhancing data collection speed and quality while providing technical support for high-resolution modeling of complex tunnel networks. The findings indicate that portable devices can maintain measurement stability and precision even in adverse underground conditions characterized by poor lighting and air quality, offering new insights for 3D modeling in other complex subterranean environments. The generated 3D models meet practical engineering requirements in terms of accuracy, completeness, and visualization, making them applicable in various domains, including geological surveying, engineering design, construction acceptance, and safety management. Moreover, this study demonstrates the flexibility and practicality of the technology in complex scenarios, highlighting its ease of operation and high degree of automation in data processing, thus providing crucial technical support for digital mining and intelligent mine management.

However, this research has certain limitations, and future studies will focus on optimizing SLAM algorithms to reduce pose error accumulation, as well as integrating multi-sensor

fusion technologies (e.g., collaborative use of vision and LiDAR) to enhance data collection accuracy. Building on this foundation, the development of more compact and efficient portable devices to meet the surveying needs of various complex environments will be pursued.

Dialogue-Based Disease Diagnosis Using Hierarchical Reinforcement Learning with Multi-Expert Feedback

Shi Li, Xueyao Sun
College of Computer and Control Engineering, Northeast Forestry University, Harbin, China

***Abstract*—In order to minimize the stochasticity of agents used in disease diagnosis within the dialogue system, and to enable them to interact with users based on the inherent connections between symptoms and diseases, while simultaneously addressing the issue of limited medical data, we propose the Hierarchical Reinforcement Learning with Multi-expert Feedback framework. The framework constructs a reward model in the lower-level networks of the hierarchical structure. Here, the discriminator leveraging the concept of adversarial networks generates rewards by evaluating the authenticity of symptom query sequences generated by the agent, and the large language model of human experts synthesizes various factors to assess the reasonableness of the agent's current symptom queries, thereby guiding the learning of the policy network. The algorithm addresses the deficiencies in data characteristics and improves the policy's capability to leverage feature information, thus making the process of disease diagnosis more aligned with clinical practice. Experimental results demonstrate that the proposed framework achieves diagnostic success rates of 61.5% on synthetic datasets and 84.4% on real-world datasets, while requiring fewer dialogue turns on average. Both metrics surpass those of conventional approaches, further indicating the framework's strong generalization ability.**

***Keywords*—Disease diagnosis; dialogue system; large language model; reinforcement learning; reward model; adversarial network; dialogue agent**

I. Introduction

Due to the broad application prospects and significant commercial benefits of task-oriented dialogue systems [1], researchers have introduced them into the medical field, forming research focused on medical dialogue systems to alleviate the problem of strained medical resources [2].The rapid development of deep learning has propelled advancements in the field of disease diagnosis, and the application of deep reinforcement learning in conversational disease diagnosis research is gradually emerging [3]. However, deep reinforcement learning still faces two major challenges in this field: first, it relies too heavily on random sampling [4] and lacks a universal reward and punishment mechanism adaptable to different application scenarios. For example, Kao et al. [5]use +1 and 0 as reward values, whereas Zhong et al. [6] set substantial rewards and penalties of +20 and -100. Second, medical data resources are scarce and valuable, and the available feature information is also very limited, which greatly restricts research in disease diagnosis.

In response to the aforementioned challenges, this study introduces a Multi-Expert Feedback-based Hierarchical Reinforcement Learning framework (ME-RL), utilizing a hierarchical structure to manage complex sequential decision-making issues, and leveraging the principles of Generative Adversarial Networks, it establishes an adversarial workflow comprising a generator and a discriminator. Utilizing the evaluations from the discriminator and the feedback from the large language model of human experts (AIExpert) as low-level rewards, the framework optimizes the policy and improves the agent's learning efficiency and performance within dynamic environments. In addition, a novel joint evaluation metric is introduced, which simultaneously takes into account the diagnostic success rate and the average number of dialogue turns in disease diagnosis tasks, thereby offering a more comprehensive assessment of the model's effectiveness.

The remainder of this paper is organized as follows: Section II introduces the related work. Section III provides an overview of the methods. Section IV introduces the experimental design. Section V presents the experimental results and related analysis. Section VI summarizes the paper and proposes future research directions.

II. Related Work

Task-oriented dialogue systems have received widespread attention in recent years, encompassing areas such as ticket booking services and e-commerce [7], [8]. In the context of strained medical resources, researchers have begun exploring how to integrate dialogue systems into the smart healthcare field to improve doctors' time utilization and provide patients with preliminary diagnostic references [9]. Through continuous development, conversational disease diagnosis systems have demonstrated significant potential in simplifying diagnostic processes, reducing costs, and efficiently collecting patient medical history information [10].

Due to the fact that conversational disease diagnosis involves multiple consecutive time stages and interactive steps, its decision-making characteristics are highly compatible with the applicability of reinforcement learning (RL) methods. Researchers model the disease diagnosis task as a Markov Decision Process and utilize reinforcement learning methods to optimize policy learning [6]. By employing policy gradient algorithms, the agent can make decisions based on the specific symptom information provided by patients.

With the continuous advancement of deep learning, many researchers have integrated deep learning models [11], [12] for disease diagnosis prediction. Deep reinforcement learning, which combines deep learning and reinforcement learning, has also been rapidly applied to research on conversational disease diagnosis [13]. In the context of symptom-oriented disease diagnosis dialogue systems, researchers such as Wei et al. [14] have designed an automatic diagnostic system based on human-computer dialogue. This system models the symptom inquiry and disease diagnosis processes as a Markov Decision Process and employs a Deep Q-Network (DQN) policy learning algorithm. In each interaction cycle, the intelligent agent can choose to inquire about specific symptoms or make diagnostic judgments based on the situation. The agent learns the optimal strategy by continuously optimizing to maximize the expected simulated rewards. The dialogue system constructed in this manner is relatively comprehensive, marking a preliminary breakthrough in addressing automatic diagnostic medical dialogue problems. Since then, reinforcement learning has gradually become the mainstream choice among researchers in this field [15].

To further enhance the performance of automatic diagnostic models, Chen et al. [16] proposed a multi-action policy representation method, enabling agents to timely recommend medical examination items to assist in diagnosis. Xu et al. [2] further introduced the KR-DS system, which integrates Knowledge Path-based Deep Q-Networks (DQN). This system incorporates knowledge branches and knowledge routing branches that capture the associations between diseases and symptoms within the deep reinforcement learning framework, thereby considering external probabilistic symptom information related to the reinforcement learning framework. This integration enhances the rationality and accuracy of medical dialogue decision-making. Tiwari et al. [17] designed a hierarchical reinforcement learning framework that integrates a knowledge-driven mechanism. By embedding a Potential Candidate Module (PCM), the framework enhances the agent's efficiency in organizing and probing symptom information. Yan et al. [18] addressed the challenges of insufficient diagnostic evidence and irrelevant symptom inquiries by constructing a more comprehensive medical dialogue dataset and combining experiential diagnostic knowledge with a medical knowledge graph. Subsequently, Yan et al. [19] proposed the EIRAD dialogue system based on a medical knowledge graph, which enhances the interpretability and accuracy of the diagnostic process by utilizing the topological structure of the knowledge graph.

Existing methods have laid the foundation for the optimization and development of dialogue-based disease diagnosis systems. However, they still largely rely on random sampling, lack a universal reward-punishment mechanism adaptable to different application scenarios, and are overly dependent on scarce medical data resources. To address these limitations, the framework proposed in this paper integrates hierarchical reinforcement learning, adversarial networks, and large language models, constructing a general and effective reward model. Additionally, it leverages the rich database of large language models to mitigate the issue of sparse data features, enabling the dialogue agent to generate reasonable disease query sequences, thereby enhancing the performance of the disease diagnosis system. Experimental results demonstrate that, compared to traditional learning methods, the proposed approach significantly improves diagnostic accuracy, reduces dialogue turns, and enhances the generalization capability of the model. Table I provides a summary and comparison of existing research, highlighting their methodologies, strengths and weaknesses.

III. METHOD DESIGN

A. Overall Framework

The structure of the disease diagnosis model based on Multi-Expert Feedback Hierarchical Reinforcement Learning is illustrated in Fig. 1. Its core component is the diagnostic agent, which is divided into a two-tier structure comprising high-level and low-level policies, and consists of four key modules: controller, generator, evaluator, and classifier. Furthermore, it is equipped with a user simulator. Among them, the controller is responsible for scheduling the generator or classifier to operate. The generator is tasked with inquiring about potential symptoms from the patient, the evaluator assesses the rationality of the actions chosen by the generator and provides rewards, while the classifier is used to inform the user simulator of possible disease types based on the currently collected information. The user simulator is designed to mimic patient behavior, interact with the agent, and return intrinsic rewards for the disease classifier. The sum of the rewards obtained by the generator and the disease classifier constitutes the external rewards received by the controller.

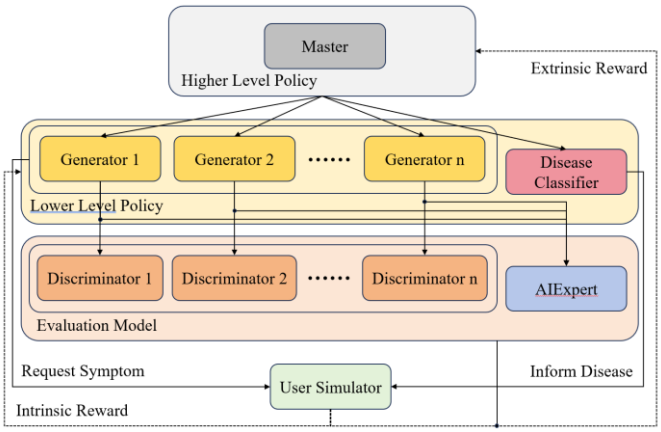

Fig. 1. Overall framework of ME-RL.

B. Dialogue Policy

1) Agent policy: The automatic diagnosis tasks can be formulated as a Markov Decision Process and utilize reinforcement learning to optimize dialogue policies. In this framework, the policy includes the state space S, action space A, state transition probabilities TP, and reward model R. Each state (s, $s \in S$) in the state space is composed of several elements, including the current state of the dialogue agent, the symptoms pending inquiry, user symptom feedback, a list of all confirmed symptoms, the number of dialogue rounds, and reward signals. The action space includes all possible disease diagnosis options and symptom inquiry actions, with each action corresponding to the examination of a particular symptom or the judgment of a disease. State transition probabilities dictate how the next state s_{t+1} is formed given the current state s_t and the action a taken, represented as s_{t+1} = TP(s_t, a). The reward model offers the probability of receiving an immediate reward r_{t+1} after taking action a_t at time step t, denoted as r_{t+1} = R(s_t, a_t).

The agent's goal is to seek an optimal dialogue strategy that maximizes the total accumulated reward R during one round of interaction [20]. The formula for the total reward R is presented below:

$$R = \sum_{i=1}^{N} \sum_{t=0}^{T} \gamma^t \cdot r_t \tag{1}$$

where N represents the total number of dialogues in a round, T represents the total number of dialogue turns in the current conversation, γ^t represents the discount factor, and r_t represents the immediate reward received by the agent at the t-th time step. $\sum_{t=0}^{T} \gamma^t \cdot r_t$ can be approximated as [21]:

$$Q^*(s, a) = E_{s'}[r + \gamma \cdot \max_{a' \in A} Q^*(s', a')] \tag{2}$$

where Q(s, a) denotes the Q-function representing the state-action value, which is used to estimate the value acquired after performing action a in the current state s, leading to a new state s'. During the training process, the estimation of Q(s, a) is progressively updated based on experience and learning, until it converges and stabilizes.

2) User simulation: The user simulator is designed to emulate the interaction process between real patients and the automated diagnostic system. At the beginning of each dialogue session, the simulator randomly selects a user objective from the experimental dataset as the basis for the simulation. Each user objective comprises two types of symptom information: one is the explicit symptoms clearly expressed by the user, and the other is the implicit symptoms that can only be uncovered through dialogue interaction. Additionally, the user objective includes the actual disease labels. At the initiation of the dialogue, the diagnostic agent directly receives the explicit symptoms as the initial information. Subsequently, the user simulator engages in further dialogue interactions with the agent based on the implicit symptoms. During the dialogue process, the simulated user will respond based on whether the symptom currently inquired by the agent exists in their objective: correctly, incorrectly, or with uncertainty. When the agent successfully diagnoses the correct disease within the maximum number of rounds, the dialogue is considered a successful interaction; otherwise, it is deemed a failure.

C. Hierarchical Structure

Considering that the agent needs to handle a vast action selection space in complex environments, a hierarchical structure with two levels of policies has been constructed, as shown in Fig. 2.

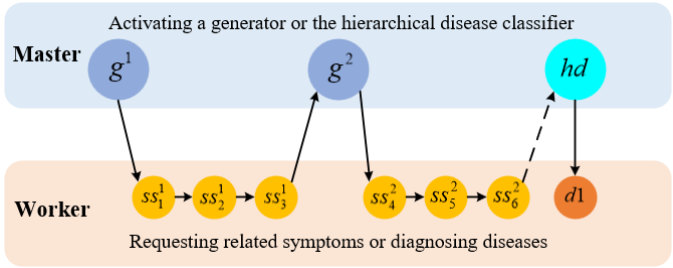

Fig. 2. Interaction of two layer strategies.

3) Higher policy: The controller manages the high-level policies, with its core function being to schedule and activate lower-level policies, and the action space is denoted as $A_m = \{g_i \mid i = 1,2,...,n\} \cup \{d\}$. Here, g_i represents the activation of generator G_i, and action d represents the activation of the disease classifier. At time step t, the controller takes the current dialogue state s_t as input and, based on the policy function π_m, decides which action a_m ($a_m \in A_m$) to take, thereby leading to a new state s_{t+1}.Once the controller activates a lower-level agent, the agent will engage in multiple rounds of interaction with the user until its subtask is completed. The learning problem of the controller can be viewed as a Semi-Markov Decision Process. At the t-th time step, after the controller executes action a_m, the immediate reward r_m it receives can be expressed as the discounted sum of all external rewards accumulated by the

lower-level policies it has triggered while performing a series of actions a_i. Therefore, the external reward for the controller is calculated as follows:

$$r_m = \begin{cases} \sum_{t_1=1}^{T_1} \gamma_m r_{t_1}^{g}, & if\ a_m = g_i \\ r_d, & if\ a_m = d \end{cases} \quad (3)$$

where $i = 1,\ldots,n$, r_m represents the external rewards obtained by the high-level policy at the t-th round, γ_m is the discount factor of the controller, T_1 is the number of original actions of the generator, and g_i and d are the actions to activate generator G_i and classifier D, respectively. When the generator is activated by the controller's action a_m, it will select appropriate actions a_i based on the current state to query symptoms from the patient based on the current disease group, thereby activating the evaluator to provide corresponding intrinsic rewards $r_{t_1}^{g}$. If the disease classifier is triggered, it will perform disease identification and return rewards r_d based on the diagnostic results. The objective of the high-level agent is to maximize external rewards within a round through a Semi-Markov Decision Process, thus allowing us to derive the controller's loss function [22]:

$$L(\theta_m) = [(r_m + \gamma_m \max_{a'} Q_m(s', a', \theta_m^-)) - Q_m(s, a, \theta_m)]^2 \quad (4)$$

where $L(\theta_m)$ represents the loss of the controller at time step t, while θ_m and θ_m^- are the frozen parameters during the current and past training iterations, respectively.

4) Lower policy: The low-level policy consists of a generator and a disease classifier, with an action space comprising symptom inquiries and disease classification actions. The low-level policy is centrally scheduled by the high-level policy, which provides the current environmental state (s_t) as input to guide the low-level policy in selecting the most appropriate basic action a_i. Once action a_i is executed, the dialogue environment state updates to s_{t+1}, and the low-level agent immediately receives rewards or penalties (r_t^{g}) based on the suitability of the current action a_i for the current state s_t. Because the rewards obtained by the low-level policy are direct results of the actions currently being executed, these rewards are termed intrinsic rewards. The calculation of intrinsic rewards is as follows:

$$r_t^{g} = w_{dis} r_t^{dis} + w_{ai} r_t^{ai} \quad (5)$$

where r_t^{dis} represents the reward provided by the discriminator, r_t^{ai} represents the feedback evaluation from AIExpert, w_{dis} and w_{ai} denote their respective weights. Since the SD dataset does not include real patient-doctor symptom inquiry sequences, w_{dis} is set to 0.4 and w_{ai} is set to 0.6.When using the MZ4 dataset, which includes real patient-doctor symptom inquiry sequences, w_{dis} and w_{ai} are both set to 0.4.

The generator is described in detail in subsequent chapters. The classifier adopts a hierarchical classifier structure, consisting of group classifiers and specific disease classifiers. When the disease classifier is activated by the controller, the currently confirmed symptoms are input into the disease classifier. The group classifier then designates the appropriate specific disease classifier, which conducts a detailed diagnosis based on the current disease group. Each specific disease classifier for a particular disease group is constructed as a three-layer neural network structure, including a hidden layer, which is used to accurately identify and diagnose each specific disease within the selected disease group, and to feedback the disease diagnosis result with the highest probability to the user.

D. Evaluation Model Based on Multi-Expert Feedback

The evaluation model based on multi-expert feedback consists of multiple discriminators corresponding to the generator and one AIExpert. The adversarial structure-based evaluation process is illustrated in Fig. 3. Both the generator and the discriminator have been pre-trained. The generator employs the maximum likelihood estimation method, predicting the next possible symptom based on the current state during training, ultimately generating a symptom inquiry sequence (fake symptom sequence). Additionally, a dedicated data repository is established to store both real and fake symptom sequences for pre-training the discriminator. The real symptom sequences in the database are directly sampled from user objectives in the dataset. An example of AIExpert model interaction is shown in Fig. 4, where AIExpert uses interaction history as the environmental information for large language model (LLM) scoring. Firstly, the RL model generates the next symptom to inquire, which, along with the interaction history, is processed into a prompt. Subsequently, the LLM uses this prompt to generate a score for the queried symptom, and finally, the score is returned to the RL model as a reward.

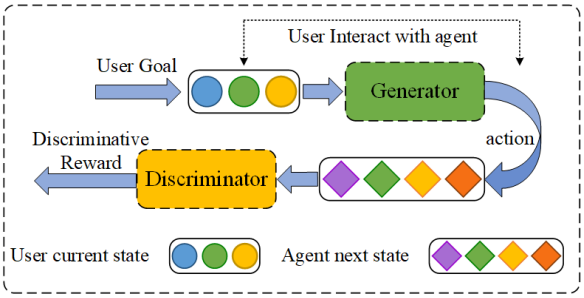

Fig. 3. Adversarial structures in low-level policy.

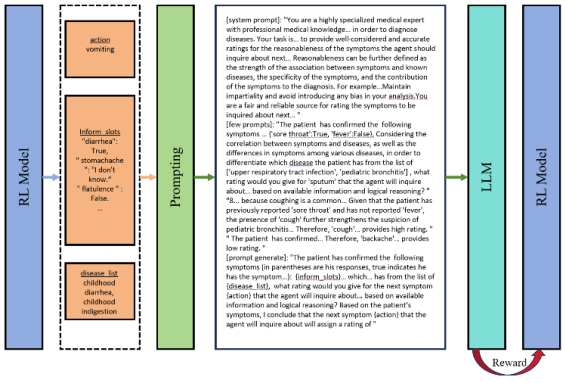

Fig. 4. AIExpert interaction example.

1) Generator: In the context of medical disease diagnosis, the core task of the sequential query generator is to dynamically generate a series of follow-up questions targeting the patient's initial chief complaint. This process aims to simulate a real medical consultation workflow, guiding patients to elaborate in detail on their current medical history and the specific manifestations and variations of each related symptom. Specifically, it involves intelligently generating the next most reasonable and diagnostically beneficial question based on the initial information provided by the patient, resulting in patient responses of confirmation, denial, or uncertainty.

The generator is a low-level strategy within the agent. Once the high-level strategy selects symptom inquiries, generator G_i is activated and interacts with the patient to collect information on specific symptom groups. The action workspace of generator G_i is: $A_{G_i} = \{y \mid y \in Y_i\}$. Here, y represents the requested symptom, and Y_i represents the set of specific disease symptoms corresponding to this generator. At the t-th time step, generator G_i receives the current state s_t as input from the high-level strategy controller and generates the action y_t to inquire about the next symptom ($y_t \in A_{Gi}$). Subsequently, the dialogue state is updated, and generator G_i immediately receives an intrinsic reward. The task of the sequential generator is to construct a coherent and seemingly realistic situational dialogue sequence starting from the user's initial symptom description. Its objective is to "fool" the discriminator, making the discriminator believe that the generated series of questions and answers belong to actual patient-doctor interactions. That is, to generate a symptom inquiry sequence from the initial state in order to maximize its expected return [23]:

$$J(\theta) = \mathrm{E}_{a \sim G_\theta(a|s)}[\mathrm{Q_D}(s,a) \mid \theta] \tag{6}$$

where a represents the inquiry action taken by generator G in the current state s. The rewards are derived from the evaluation model. $Q_D(s, a)$ is the state-action value function, which approximates the value obtained when taking action a in the current state s.

2) Discriminator: Each generator is equipped with its own discriminator, which is pre-trained to assess whether the sequence of queries is genuine. The objective is to maximize the probability of correctly classifying real data and minimize the probability of misclassifying generated data. The output of the discriminator serves as a reward for the generator, encouraging the generator to produce symptom inquiry sequences that are indistinguishable from real symptom sequences. The discriminator is trained using a Deep Neural Network and outputs a single scalar value that represents the probability of a symptom sequence originating from real data rather than from the generator.

For interactive dialogue systems, this paper not only focuses on the quality of the final generated complete symptom sequences but also emphasizes real-time feedback during the diagnostic process. A discriminator model has been trained to evaluate and assign rewards to both fully and partially observed symptom sequences, enabling it to provide immediate rewards for partial symptom information that users gradually disclose during the dialogue process. At the t-th time step, given the current dialogue state s, the generator produces the next inquiry action a. The concatenation of the generated action a and the input s is fed into the discriminator, resulting in a reward from the discriminator [24]:

$$r_t^{dis} = \mathrm{D}(s = Y_{1:t-1}, a = y_t \mid \mathrm{G}(a \mid s)) \tag{7}$$

where $Y_{1:t-1}$ represents the symptom sequence contained in the current state s. y_t represents the next symptom inquiry generated by the generator based on s.

3) AIExpert: The actions generated by the generator in each round receive expert evaluation feedback from AIExpert. AIExpert is a module designed to simulate human experts (doctors) by integrating large language model. AIExpert supplements medical data and knowledge related to disease diagnosis through a vast knowledge base and utilizes the capabilities of LLM to simulate the behavior of experts assisting in diagnosis, thereby achieving a dual purpose.

Each interaction between the RL model and AIExpert generates a new interaction record, which is appended to the interaction history. As time steps progress, the interaction history grows, potentially exceeding the current LLM's context length [25]. To address this issue, before each interaction, history retrieval is performed to retrieve the latest 10 interaction records related to the current disease list from the user's interaction history (including symptoms and related scores) as the RL model's observation. Then, the RL model asks the user about a symptom as its action, and the action and observation are subsequently used to generate the prompt.

Each dialogue generates a prompt containing the detailed information required by the LLM, including the symptom inquiry history corresponding to the current generator, the symptom to be queried, and the current disease list. Additionally, the prompt includes system prompts and example prompts. The system prompt informs the LLM of its positioning as a medical expert and provides guidance on the aspects to consider when generating feedback scores (in addition to the applicability of symptom sequences for known symptoms, it also considers other factors, such as whether the current symptom can help distinguish between diseases in the current disease list). Example prompts serve as a reference for subsequent scoring by the LLM. The purpose of constructing the prompt is to enable the LLM to accurately provide a score for the current queried symptom. The output generated by the LLM based on the prompt is processed and returned to the RL model as a reward from AIExpert feedback.

IV. Experimental Design

A. Dataset Description

This study evaluates all methods on both synthetic and real-world datasets. The description of the synthetic dataset (SD) is shown in Table II. It is a publicly available dataset synthesized from medical library knowledge, with the nine elements being G1, G4, G5, G6, G7, G12, G13, G14, and G19. Each user goal includes one explicit symptom and multiple implicit

symptoms. The description of the real-world dataset MZ-4 [14] is shown in Table III. It is a publicly available dataset constructed from data collected in real medical scenarios. Symptoms extracted from the user's self-report are defined as explicit symptoms, while symptoms discovered through dialogue are defined as implicit symptoms.

TABLE II. OVERVIEW OF SYMCAT-SD-90 DATASET

Entries	Value
# of user goal	30000
# of disease	90
# of groups	9
# of symptoms	266
Avg. # of implicit symptoms	2.6

TABLE III. OVERVIEW OF MZ-4 DATASET

Entries	Value
# of user goal	1733
# of disease	4
# of groups	2
# of symptoms	230
Avg. # of implicit symptoms	5.46

B. Evaluation Metrics

This paper proposes a new combined evaluation metric that assesses the overall performance of the disease automatic diagnosis system in real-world scenarios from two perspectives: accuracy and average dialogue rounds. This combined metric is named ST, and its definition is as follows:

$$\mathrm{ST} = \mathrm{W}_{SR} \cdot SR \times 100 - \mathrm{W}_{Turn} \cdot Turn \tag{8}$$

where *SR* represents the success rate, *Turn* denotes the average number of dialogue rounds, and W_{SR} and W_{Turn} represent their respective weight coefficients. The success rate is a positive evaluation metric for the disease automatic diagnosis system, while fewer dialogue rounds are better. Therefore, in the experiment, W_{SR} is set to 1 and W_{Turn} to 0.5.

This paper uses five metrics to evaluate the effectiveness of the model: the success rate of disease diagnosis (SR), the average number of dialogue rounds (Turn), the ratio of symptoms correctly identified by the agent out of those requested (AMR), the ratio of the number of hidden symptoms identified by the agent to the total number of hidden symptoms in the user's target (SIR), and the ST metric proposed in this paper. The calculation methods for SR, AMR, and SIR are as follows:

$$\mathrm{SR} = \frac{\sum_{i=1}^{EL} DS_i}{EL} \tag{9}$$

$$\mathrm{AMR} = \frac{\sum_{i=1}^{i=EL}\sum_{j=1}^{j=t} \mathrm{m}_i / r_i}{EL} \times 100, \mathrm{m}_i \tag{10}$$

$$\mathrm{SIR} = \frac{\sum_{i=1}^{i=EL} m_i / \mathrm{f}_i}{EL} \times 100 \tag{11}$$

where *EL* represents the total number of dialogues in the simulated dialogue set. *DS* indicates whether the dialogue was successfully completed. *t* represents the total number of dialogue rounds in the *i*-th conversation, while r_i denotes the total number of symptoms asked by the dialogue agent in the *i*-th conversation. m_i represents the cumulative number of symptoms that the agent asked which actually match the patient's condition. f_i indicates the total number of hidden symptoms that the patient actually possesses in the *i*-th dialogue.

C. Baselines

To demonstrate the effectiveness of the proposed method, several benchmark methods were chosen for comparison:

SVM-ex: A model built using Support Vector Machine (SVM) [6], where the input is the one-time encoding of the patient's explicit symptoms, and the output is the disease label. SVM-ex&im, on the other hand, simultaneously considers both the patient's explicit and implicit symptoms, and its performance can be considered as the ideal upper limit achievable by a reinforcement learning-based dialogue agent.

HRL: A hierarchical reinforcement learning framework that employs a two-layer policy structure and a disease classifier [14].

KI-CD: A knowledge-driven hierarchical reinforcement learning framework [17] that introduces a potential candidate module as knowledge assistance and constructs a multi-level disease classifier. The KI-CD_PCM model includes only the potential candidate module without the multi-level disease classifier.

EIRAD: An automatic diagnostic evidence-based dialogue system with interpretable reasoning paths [19], based on the Medical Knowledge Graph, which explicitly utilizes the topological structure of the Medical Knowledge Graph to capture key symptoms of suspected diseases.

D. Experimental Setup

In this paper, 80% of the data in the dataset is used for training the agent, while 20% is used as the test set. Both the master controller and all generators employed a three-layer deep Q-learning network (DQN) with 512 nodes in the hidden layers. All discriminators used a three-layer neural network model, with the input layer dimension matching the number of corresponding symptoms, and the output layer consisting of a single node. The LLM in AIExpert used Llama-2-7B-Chat-GPTQ, a model that has been quantized using GPTQ to allow it to run within a 24GB memory limit without significantly affecting performance. Regarding parameter settings, the master controller and generators shared a discount factor of 0.95 and a learning rate of 0.0005. The learning rate for the discriminators was set higher at 0.01 to allow faster weight adjustment. The learning rate for the disease classifier was also set to 0.0005. During the entire training cycle for the master controller, after every 10 training steps, all generators,

discriminators, and disease classifiers would undergo a training update. Additionally, each cycle consisted of 100 dialogue sessions, and all neural networks were trained using the Adam optimizer.

V. Result and Analysis

A. Performance on SD Dataset

Five metrics were used to evaluate the model's performance on the SD dataset, with the results presented in Table IV. ME-RL_Adv refers to the model that only includes the discriminator, without AIExpert. Compared to the baseline methods, ME-RL showed significant advantages across all metrics. Except for the number of dialogue rounds, the SR, AMR, SIR, and ST increased by 8.08%, 24.72%, 6.15%, and 15.05%, respectively, compared to KI-CD. Among these, the improvement in AMR was particularly notable, indicating a significant enhancement in the agent's ability to identify the symptoms the user is suffering from, i.e. the model can generate more reasonable symptom query sequences. Furthermore, both the ME-RL_Adv and ME-RL_AI models performed worse than ME-RL, highlighting that the multi-expert feedback model, which uses both the discriminator and AIExpert, outperforms the single-feedback evaluation model.

TABLE IV. Performance on SD Dataset with DQN

Model	SR	Turn	AMR(%)	SIR(%)	ST
SVM-ex	0.321	-	-	-	-
HRL	0.504	12.95	10.49	29.56	43.93
KI-CD	0.569	16.11	09.95	48.33	48.85
ME-RL_Adv	0.594	15.32	10.66	38.74	51.74
ME-RL_AI	0.562	13.55	10.02	40.24	49.425
ME-RL	**0.615**	**10.61**	**12.41**	**51.30**	**56.20**
SVM-ex&im	0.732	-	-	-	-

TABLE V. Performance on SD Dataset with Dueling DQN

Model	SR	Turn	AMR(%)	SIR(%)	ST
HRL	0.478	**8.57**	**13.80**	29.24	43.52
KI-CD	0.523	14.71	11.02	40.03	46.79
ME-RL	**0.570**	12..86	10.85	**46.63**	**50.57**

TABLE VI. Performance on SD Dataset with DDQN

Model	SR	Turn	AMR(%)	SIR(%)	ST
HRL	0.426	**7.02**	13.52	22.26	39.09
KI-CD	0.507	10.60	13.70	**39.04**	45.40
ME-RL	**0.544**	7.63	**14.85**	38.91	**50.59**

Experiments were also conducted using Double Deep Q-Network (DDQN) and Dueling Deep Q-Network (Dueling DQN) algorithms to replace the DQN algorithm in the model. The experimental results are reported in Tables V and VI. Compared to other models using these two algorithms, the ME-RL model achieved higher accuracy and overall performance superior to all baseline models.

From the above experiments, it can be observed that the ME-RL model using DQN and DDQN algorithms has a higher average number of dialogue turns compared to the HRL model. This is considered reasonable, as more dialogues between the agent and the patient allow for the collection of additional information about the patient's latent symptoms, ensuring a more thorough investigation and accurate diagnosis. Meanwhile, the diagnostic success rate is the most crucial factor for any automated disease diagnosis system, serving as a prerequisite for the system's usability. Additionally, the ME-RL model consistently achieves the highest overall evaluation metric, further proving its effectiveness.

B. Performance on MZ-4 Dataset

Due to the limited number of disease types in the dataset, a single-layer disease classifier is used for disease diagnosis. The proposed model outperforms all baseline models across three algorithms (DQN, Double DQN, and Dueling DQN), achieving an accuracy rate exceeding 0.8, with an average number of dialogue turns remaining below 5. This indicates that the model is capable of reaching correct diagnostic results in most cases with fewer dialogue turns, demonstrating its outstanding performance. The experimental results are shown in Table VII.

TABLE VII. Performance on MZ-4 Dataset

Model	SR	Turn	ST
EIRAD with DQN	0.770	15.10	69.45
KI-CD_PCM with DQN	0.808	6.16	77.72
ME-RL with DQN	0.844	4.32	82.24
EIRAD with DDQN	0.732	12.23	67.09
KI-CD_PCM with DDQN	0.778	6.37	74.62
ME-RL with DDQN	0.813	4.21	79.20
EIRAD with Dueling DQN	0.720	10.86	66.57
KI-CD_PCM with Dueling DQN	0.757	4.90	73.25
ME-RL with Dueling DQN	0.801	3.02	78.59

C. Error Analysis

To analyze the agent's misdiagnosis cases, all instances where the agent made incorrect diagnoses on the SD dataset were collected, and a confusion matrix for the disease classifier was constructed. Fig. 5 shows the prediction accuracy for nine different disease groups. Upon examining the matrix, it is observed that the color intensity on the diagonal blocks is darker, indicating that the system tends to misclassify diseases into the same broad category. A partial reason for this phenomenon is that some diseases share many similar common symptoms, making it difficult for the classifier to distinguish them. However, it also demonstrates that even if the agent does not precisely predict the exact disease type, it can still correctly distinguish the general category of the disease to some extent, reflecting its diagnostic value.

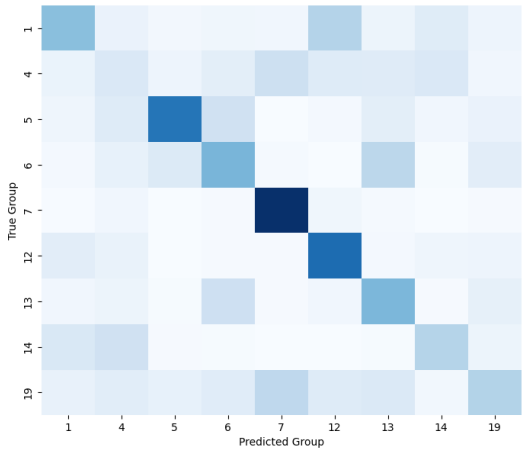

Fig. 5. Confusion matrix between different disease groups.

D. Performance of Different Generators

An analysis of the performance of different generators using the SD dataset is shown in Table VIII. It is observed that the best-performing generators, Generator 1 and Generator 8, correspond to disease groups with the fewest average number of latent symptoms, which could be one of the factors influencing the generator's performance. The average disease classification accuracy corresponding to these generators is higher than all baseline models, indicating that ME-RL facilitates the generation of reasonable symptom query sequences, thereby improving the accuracy of the disease classifier.

TABLE VIII. PERFORMANCE OF DIFFERENT GENERATORS

Model	Accuracy (%)
HRL_Avg	50.3
KI-CD_Avg	75.6
Generator 1(G1)	77.0
Generator 2(G4)	91.6
Generator 3(G5)	69.7
Generator 4(G6)	79.4
Generator 5(G7)	65.3
Generator 6(G12)	67.2
Generator 7(G13)	79.5
Generator 8(G14)	83.5
Generator 9(G19)	78.0

E. Ablation Study

Fig. 6 shows the accuracy curves of different dialogue agents based on ME-RL on the SD dataset, and Table IX displays their performance on the test set. The agent used in the ME-RL model is named the Unique-dis Agent, which indicates that each generator in the low-level agents is assigned a unique discriminator. The dialogue agent with only the evaluation model set for the master controller is named the Eva-Master Agent. The agent with a unified discriminator for all generators is named the Unified-dis Agent. All agents use the same AIExpert in their evaluation models. The analysis reveals that the Adv-Master Agent performs poorly due to the lack of reasonable distribution of low-level agent sequence references, while the Unified-dis Agent and Unique-dis Agent perform significantly better, indicating the validity of setting an evaluation model for low-level agents. The Unique-dis Agent significantly outperforms the Unified-dis Agent, which may be due to the large action space of the generators. Overall, it is reasonable to enhance the model's adversarial capability by assigning a corresponding discriminator to each generator.

TABLE IX. PERFORMANCE ON MZ-4 DATASET

Model	SR	Turn	AMR(%)	SIR(%)	ST
Eva-Master Agent	0.385	**7.12**	02.77	19.6	33.94
Unified-dis Agent	0.501	13.04	09.73	40.25	43.58
Unique-dis Agent	**0.615**	10.61	**12.41**	**51.30**	**56.20**

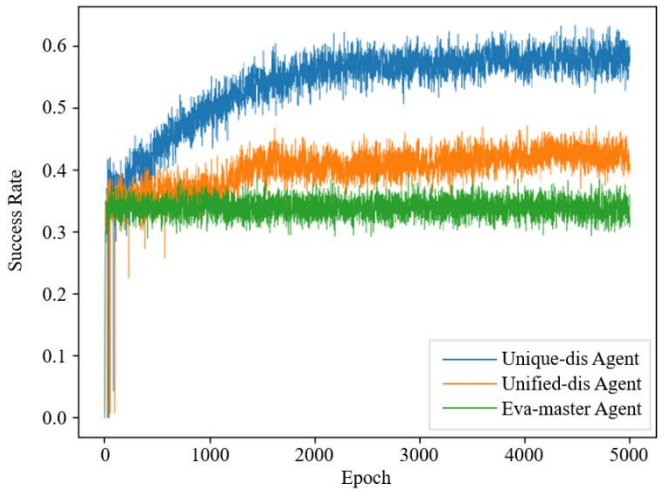

Fig. 6. Policy learning curves.

VI. CONCLUSION

This paper proposes a multi-expert feedback-based hierarchical reinforcement learning framework and successfully applies it to the field of automated disease diagnosis. The hierarchical structure allows the model to make decisions at different levels of abstraction, enhancing the model's effectiveness and modularity. Discriminators are introduced to the generators in the lower-level networks to evaluate symptom query sequences and generate rewards, guiding the agent to generate more targeted inquiry symptoms. The introduction of the AIExpert feedback model enriches the feature information of medical knowledge and data, and the powerful understanding and analytical capabilities of the model provide evaluations simulating human experts, improving the generator's ability to query symptoms. The multi-expert feedback model adjusts weights under different conditions, compensating for the limitations of a single expert and enhancing the model's robustness and generalization capability. Experiments show that, compared with baseline technologies, although the number of dialogue turns has not been reduced, the success rate, AMR, SIR, and the newly proposed comprehensive evaluation metric on the SD dataset have improved by 8.08%, 13.97%, 4.28%, and 5.22%, respectively. Future work will further explore strategies to reduce dialogue

turns in order to improve the model's performance. In future research, efforts will be made to integrate medical knowledge graphs to strengthen the associations between symptoms and diseases, thereby further enhancing the decision-making process and ensuring consistency with established medical knowledge.

Although the results are promising, the proposed framework still faces certain noteworthy limitations. Its effectiveness partially depends on high-quality and diverse medical data, if data are limited in quantity or unevenly distributed, diagnostic accuracy for less common or underserved patient populations may be compromised. Furthermore, the combination of adversarial training and large language models demands substantial computational resources, which may pose feasibility issues in resource-constrained environments. To address these challenges, future research should prioritize enriching and balancing medical datasets, which may involve collaborating with healthcare institutions to collect more diverse patient data or employing data augmentation techniques to better capture rare diseases. Meanwhile, adopting strategies such as model compression, knowledge distillation, and hardware acceleration (e.g. TPUs) can help mitigate high computational demands. Through these improvements, the proposed framework is expected to further enhance adaptability and reliability, thereby exerting a wider clinical impact across a variety of healthcare settings.

***Abstract*—Blockchain is a peer-to-peer (P2P) network that distributes information and protects data integrity, security, and privacy. Constant simplification is required for information exchange. This comprehensive assessment seamlessly integrates Electronic Health Record (EHRs) with blockchain technology. EHRs are represented with different standards mainly HL7 and FHIR. EHR should be interpreted to both parties after exchange. Such interpretation after exchange may face few interoperable challenges. To overcome EHR interoperability difficulties, 18 blockchain-based alternatives were examined. Despite their promise, these systems have a variety of drawbacks, including reliability, privacy, data integrity, and collaborative sharing. Six phases make up the systematic review: research, investigation, article curation, keyword abstraction, data distillation, and project trajectory monitoring. In total, 18 seminal articles on EHR interoperability and Blockchain integration were identified. Many unique interoperability methods are proposed for Blockchain-integrated EHR systems in these contributions. Several Blockchain applications, standards, and issues associated with EHR interoperability are described and analyzed. Implemented and proposed blockchain-based EHR frameworks are numerous. The security aspects have been covered, but standards compliance and interoperability requirements are lacking. Research in this area is needed. This research study has analyzed the different national and international EHR standards. This paper describes the current state of EHRs, including blockchain-based implementations, along with the interoperability issues between existing blockchain-based EHR frameworks. The research has proposed novel BlockMed framework which is interoperable for the HL7 and FHIR EHR standards. BlockMed framework is evaluated with Data Accuracy, Mapping Quality, Response Time, Latency, Interoperability Coverage, AI Model Efficiency, Consent and Security Management, Cross-Chain Support, Patient and Provider Satisfaction.**

I. INTRODUCTION

Blockchain technology, characterized by its decentralized nature, fast transaction processing, high security, and privacy features, can significantly shift the traditional healthcare system. Significantly, it becomes a crucial facilitator in upholding the confidentiality and security of patient data. The potential of this technology to significantly transform the transmission and storage of patient's electronic health records is emphasized by its implementation of advanced security measures for the secure transfer of medical data within the healthcare industry, utilizing a robust stochastic. Blockchain technology enhances the level of robustness and security in the field of electronic health records EHRs. The potential impact of this technology on the healthcare industry is a shift towards prioritizing the needs and preferences of patients, as well as enhancing the security, transparency, and compatibility of health data [1]. The potential for a significant shift in health information exchange (HIE) is evident through enhanced efficiency and security in electronic health records EHRs. These repositories contain detailed patient information, including diagnostic and treatment procedures. It is crucial to acknowledge that patient data holds significant value within the healthcare domain, as it serves as essential material for examining healthcare. Electronic health records EHRs serve as stores for highly sensitive medical data, which justifies their classification as repositories for valuable patient insights. The widespread availability of healthcare data plays a crucial role in advancing national healthcare initiatives and improving quality-of-service delivery [2]. The EHR ecosystem is the culmination of a comprehensive and meticulously organized collection of patient health data distributed throughout many healthcare institutions and governmental health authorities [3].

EHRs are digital databases that store a person's whole health history. Medical clinics, institutes, and experts collect and manage this database. Electronic health records and EHRs face many challenges with semantic interpretability. Electronic healthcare systems are prone to cyberattacks, making security a major issue. Cyber-attack victims in healthcare systems make up one-third of all documented cases. Given these conditions, Blockchain technology's ability to establish shared trust and disseminate data could improve collaborative healthcare decisions in telemedicine and precision medicine [4]. As shown by the "Anthem breach attack," which compromised 80 million people's data on February 4, 2015, 88% of attacks target healthcare systems. Rapid growth in electronic health records and EHR databases creates another issue. Patient data, X-ray images, and computed tomography scans comprise the enormous corpus, which demands lots of storage. The average healthcare facility had 665 terabytes of storage in 2015, but by 2020, it had 25,000 petabytes. This storage effort focuses on unstructured medical images. Healthcare systems' variability in database management systems, architectural configurations, and

*Corresponding Author, Email ID: ygulzar@kfu.edu.sa; freegu@jazanu.edu.sa

data infrastructures presents another problem. Thus, inter-provider health data transmission must prioritize data integrity and uniformity [5]. Diversity makes transmitting correct, standardized information difficult and hinders its efficient deployment in relevant circumstances. The study covers the following:

The value of blockchain-based interoperability for EHRs.

Potential snags in integrating blockchain technology into EHRs systems.

The necessity of a blockchain-based system that can communicate with other networks.

Brief overview of the needs, issues, and potential solutions for interoperable EHR.

This article is divided into five sections. Section II reviews the research that specifically relates to blockchain's potential application in healthcare. The systematic review's research methods and procedures are outlined in Section III, and the answers to the review's research questions are presented in Section IV. In Section V of the paper, the findings and implications are provided.

II. Related Work

A. Blockchain

Blockchain, a decentralized system, has revolutionized Internet information sharing. This technology, created for financial applications, eliminates the need for transaction middlemen, including trustworthy third parties in government and business. TTP trustworthiness and authenticity may be damaged by malfunctions or security breaches, threatening the transactional framework. Blockchain is a peer-to-peer database with nodes, contracts, and blocks. In blockchain technology, data is kept in blocks. These blocks store and record numerous data kinds. However, nodes help blockchain network participants communicate and engage. Nodes relay data, transactions, and other information between places. Every node in this framework includes a block of localized data. After a contract is signed, transactions are authenticated [6] [7].

B. Blockchain Technology and Electronic Health Records

Resilience of blockchain-based applications has offered adequate support for the medical sector and medical infrastructure. The literature study presents several tools for interoperability aware EHR maintenance. Because EHRs can communicate, healthcare providers can change patient records using distributed ledger technology. Blockchain-based electronic health records are a cutting-edge method of tracking patients' medical histories and appointments [6].

By handling health insurance claims and refreshing authentications in the payments system, interoperable EHRs streamline the insurance system. Integrating blockchain technology into EHRs would help medical researchers and developers of diagnostic tools and drugs make more accurate statistical estimates from patient data. The significance of Blockchain is demonstrated through analyses of related research, practical examples, and novel approaches to securing data [8].

Removing the middleman from a distributed healthcare system causes a significant disruption in the current healthcare models. Data integrity, security, and privacy can be achieved using blockchain in EHR-based healthcare systems, which are difficult challenges in conventional healthcare systems [9].

Samala et al. explores the integration of blockchain technology in healthcare, focusing on data security, EHR privacy, and patient ownership. The authors argue that traditional EHR systems often lack patient-controlled data access, which blockchain can address by providing decentralized and secure data management. However, the study also notes challenges in scalability and the need for standardized protocols to ensure interoperability across different healthcare systems. A blockchain-based framework utilizing smart contracts to enhance the security and interoperability of EHRs[10]. The framework aims to provide secure data sharing among healthcare providers while maintaining patient privacy. Despite its potential, the study acknowledges challenges related to the integration of existing EHR systems and the computational overhead associated with smart contract execution. De Novi et al. discussed the transformative potential of blockchain technology in healthcare, particularly in enhancing patient identity management and public health data interoperability[11]. The authors highlight the synergy between blockchain, artificial intelligence, and digital twins in creating a more secure and interoperable healthcare ecosystem. However, they also point out the need for regulatory frameworks and the challenges of integrating blockchain with existing healthcare infrastructures[12]. Agbo et al. examines various blockchain-based EHR management systems, evaluating their effectiveness in ensuring data security and interoperability. The study identifies common challenges such as scalability issues, high energy consumption, and the complexity of integrating blockchain with current EHR systems [13]. The authors suggest that future research should focus on developing lightweight blockchain solutions and establishing universal interoperability. Researchers introduced MedBlock, a blockchain-based framework designed to enhance the privacy and interoperability of EHRs. The framework employs a permissioned blockchain and hybrid on-chain/off-chain storage to balance transparency with confidentiality[14]. The study demonstrates MedBlock's ability to achieve high transaction throughput with low latency, though it acknowledges challenges related to cross-blockchain interoperability and the integration with existing EHR systems. Ouaguid et al. analyze various approaches to integrating blockchain into the e-healthcare ecosystem, focusing on data management, security, scalability, and interoperability. The study highlights the advantages of blockchain in providing secure and decentralized data management but also points out limitations such as the incomplete representation of major stakeholders in the blockchain network and the lack of regulatory flexibility to ensure legal interoperability by country. Bathula et al. explores the convergence of blockchain and artificial intelligence in healthcare, addressing challenges in securing EHRs, ensuring data privacy, and facilitating secure data transmission [15]. The study provides a comprehensive analysis of the adoption of these technologies within healthcare, spotlighting their role in fortifying security and transparency. However, it also discusses challenges like data security, privacy, and decentralized computing, forming a robust tripod.

Agbeyangi et al. investigates the implementation of blockchain technology, specifically Hyperledger Fabric, for EHR management at Frere Hospital in South Africa. The study examines the benefits and challenges of integrating blockchain into healthcare information systems, highlighting the role of blockchain in transforming healthcare[16]. The findings underscore the transformative potential of blockchain technology in healthcare settings, fostering trust, security, and efficiency in the management of sensitive patient data. Guo et al. presents hybrid blockchain-edge architecture for managing EHRs with attribute-based cryptographic mechanisms. The architecture introduces a novel attribute-based signature aggregation scheme and multi-authority attribute-based encryption integrated with Paillier homomorphic encryption to protect patients' anonymity and safeguard their EHRs. The study shows that the performance meets real-world scenarios' requirements while safeguarding EHR and is robust against unauthorized retrievals. Building upon these existing studies, the following section details our systematic research approach to analyzing interoperability in blockchain-based EHR systems [17] [18].

III. Research Methodology

The systematic review follows a structured approach consisting of six key stages to ensure a thorough analysis of blockchain interoperability in Electronic Health Records (EHRs). These stages include formulating a query, conducting research, selecting relevant articles, developing a keyword list, extracting data, and mapping. The process was designed to rigorously evaluate existing literature, categorize solutions, and identify challenges in blockchain-based EHR interoperability.

A. Research Question Formulation

The research process began with the formulation of a focused research question aimed at identifying obstacles and solutions for achieving blockchain interoperability in EHR systems. This research question was critical for guiding the literature search and ensuring relevance, as it enabled a targeted approach in understanding the issues associated with blockchain applications in healthcare and evaluating potential solutions. To ensure rigor and relevance, articles were selected based on predefined inclusion and exclusion criteria:

1) Inclusion Criteria

a) Publication date: Only articles published after 2019 were included to reflect the latest advancements in blockchain technology for healthcare.

b) Relevance: Articles specifically addressing blockchain in healthcare with an emphasis on EHR interoperability, security, or data sharing frameworks were prioritized.

c) Language and accessibility: Only English-language articles available through academic databases were considered to maintain consistency and accessibility.

d) Peer-reviewed sources: Preference was given to studies from reputable, peer-reviewed journals and conferences, including IEEE, PubMed, and ScienceDirect, to ensure quality.

2) Exclusion Criteria

a) Lack of focus: Articles that discussed blockchain technology broadly without a focus on healthcare or EHR interoperability were excluded.

b) Inadequate data: Studies with limited sample sizes or weak methodological frameworks were omitted to maintain high research quality.

c) Outdated or duplicate research: Articles presenting redundant information or findings duplicated in more recent studies were excluded to avoid redundancy.

Each selected article was evaluated based on these criteria, allowing for a curated collection of relevant and high-quality studies. The graphical representation of inclusion and exclusion criteria has been presented in Fig. 1.

3) Quality assessment

3) Quality assessment: A systematic quality assessment was performed in the selected articles to ensure reliability. Articles were evaluated based on several metrics:

a) Methodological rigor: Each article's methodology was reviewed for clarity and robustness, with particular attention to research design, data collection methods, and analytical techniques.

b) Data Sources and sample size: Studies that utilized reliable data sources and larger sample sizes were given preference, as these factors increase the generalizability and credibility of findings.

c) Credibility of findings: Each study's conclusions were analyzed for coherence with existing literature and evaluated for clarity, consistency, and validity, ensuring that all sources provided well-substantiated insights.

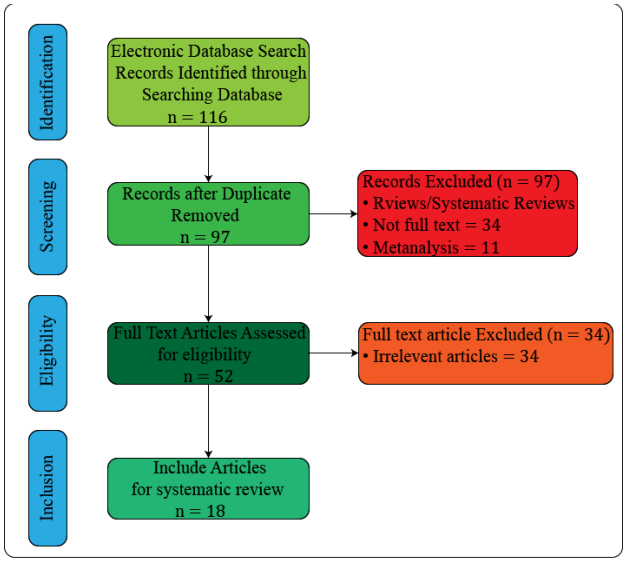

Fig. 1. Flowchart illustrating the criteria used to choose articles for systematic reviews.

4) Data extraction and mapping procedures

4) Data extraction and mapping procedures: Data extraction involved keyword-based searches for terms such as "blockchain," "EHR interoperability," "data privacy," and "healthcare security" across databases like IEEE, PubMed, and ScienceDirect. Using Atlas.ti software, the extracted data was mapped and organized, facilitating the thematic categorization

of research insights. This software-assisted approach streamlined the identification of common challenges, proposed solutions, and emerging trends in blockchain-based EHR interoperability. Atlas.ti further enhanced the efficiency of the data mapping process, allowing for a detailed comparison of various frameworks and solutions.

5) PRISMA flow diagram: To provide transparency in the article selection process, a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram was created. This diagram visualized each stage of the selection process, beginning with the total number of articles identified through database searches and progressing through the screening, inclusion, and exclusion phases. The flow diagram detailed the number of articles removed at each stage, along with reasons for exclusion (e.g., lack of relevance or inadequate data). By mapping the selection process, the PRISMA flow diagram enhanced transparency and ensured a systematic approach in curating the final articles included in the review.

6) Specifications and benchmarks: The review identified specific standards and benchmarks from the literature, highlighting the key interoperability requirements for blockchain-based EHR systems. Table I provides a summary of these benchmarks, including standards such as FHIR for data interchange, HL7 for cross-border data execution, and HIPAA for data privacy and security. These benchmarks were instrumental in categorizing the technical requirements necessary for a robust blockchain-based EHR system.

TABLE I. STANDARDS FOR DATA EXCHANGE

Ref	*Specifications*	*Benchmarks*
[19]	FHIR	Data Interchange
[13]	HL7	Transboundary execution
[20]	HITECH	Metamorphosis
[21]	PHR	Data transmission through APIs
[22]	Open EHRs	Protocol conformity
[23]	DICOM	Safety measures
[24]	SNOMED CT	Harmonious operability
[25]	CEN/ISO EN13606	Confidentiality and safeguarding
	HIPAA	Privacy and data uniformity

Bibliometric analysis was employed to deepen the understanding of blockchain-based EHR interoperability research. By using VOSviewer software, the frequency of author citations, keyword occurrences, and term co-occurrences within the literature was analyzed. The bibliometric analysis also identified collaborative relationships between authors and institutions from different countries, illustrating the global interest in blockchain technology for healthcare interoperability. This systematic methodology provides a solid foundation for evaluating the literature on blockchain-based EHR interoperability. By following a structured approach for article selection, quality assessment, and data mapping, this review ensures that only high-quality, relevant studies inform the analysis. The use of bibliometric analysis and standardized benchmarks further supports a comprehensive understanding of the current challenges and potential solutions in the field.

IV. RESULTS AND DISCUSSION

This section presents the systematic review's results. 116 research articles were pulled for the following search technique from multiple sources. After removing the duplicate records using the first selection procedure, 97 articles were chosen. The removed articles had nothing to do with how EHRs and blockchain's interacted. To streamline the selection process, the chosen articles underwent additional scrutiny. Implementing exclusion criteria resulted in removing 45 articles from the original 97 items. The papers eliminated during screening lacked full text and were therefore ineligible for the meta-analysis. 52 additional publications were checked to see if they qualified for the systematic review. 34 irrelevant items were eliminated from the list of chosen articles throughout the eligibility selection process. To complete the systematic review of Blockchain-based Electronic Health Records 18 publications must meet all the criteria.

These chosen articles are utilized to delineate the requirements and obstacles associated with achieving interoperable EHRs utilizing blockchain technology. The study's inquiries are outlined as follows:

Q1. How can Blockchain-based electronic health records (EHRs) be made interoperable?

Q2. In a Blockchain context, what are the interoperable standards for EHRs look like?

Q3. How does the blockchain-based framework enable EHR exchange between different hospitals using different EHR standards?

A. Q1. How can Blockchain-Based Electronic Health Records (EHRs) be made Interoperable?

The comprehensive literature analysis in this study found three degrees of blockchain-based EHR interoperability criteria. Protocols, standards, and the exchange and management of data across platforms are essential in the technology industry. Patient data privacy and security must be built into the legal and organizational interoperability norms for blockchain-based electronic health records (EHRs). The economic model and partnerships between public and private healthcare organizations are also considered.

The standards specify the variety of protocols for transmitting messages and health data. A solid business plan and knowledge-sharing system are needed to implement the approach at the organizational level. Data standards that ensure data integrity and adaptability are needed to share medical information efficiently. As shown in Table II, interoperability among EHR systems built on blockchain is essential for seamless data exchange. Blockchain-based EHRs offer advantages in filing exact health insurance claims due to their uniform implementation. Data mapping standards must be established and followed to efficiently move data among entities with different ownerships. Federal organizations can more efficiently manipulate health service provider data using logical models and computer language features. Blockchain systems need semantic consistency. Standardized coding procedures improve EHR security. Betek et al. identified blockchain-based EHR needs. These needs included reliable data gathering and

effective EHR-medical researcher information sharing. These requirements are aimed at improving healthcare system administration and reliability. Electronic Health Records (EHRs) compliance with Blockchain technology requires a framework for secure and structured encrypted communication among various systems. Additionally, stakeholders must be able to decrypt these messages. This can be done by setting message standards, values, and technological databases according to norms. Increased collaboration between manufacturers, corporations, researchers, and medical institutions can help meet privacy and security standards. A complete structure of legislation and norms enabling healthcare professionals and patients to communicate data is necessary to protect patient privacy. Blockchain technology secures insurance and incentives for public and private health service organizations, protecting data. To efficiently implement and use EHRs. When systems and organizations share health information, legal frameworks are needed to maintain data integrity. Systems and organizations must build legal frameworks to share information securely.

1) Semantic and technological requirements for blockchain-based EHR interoperability: Interoperable Blockchain-based Electronic Health Record (EHR) systems require specific semantic standards to ensure seamless communication across healthcare networks. Key semantic demands include common practices and methods for data exchange, ensuring data integrity remains unquestionable, and a dictionary of standardized data and communication protocols. Additionally, guidelines for the structured collection and exchange of information are crucial to maintain uniformity across systems. These semantic standards enable various EHR systems to "speak the same language," thus supporting accurate, meaningful data transfer and interpretation [26].

From a technological perspective, interoperable Blockchain-based EHRs must meet specific technical prerequisites to function effectively. These include standards for plug-and-play interoperability of services, permitted types of information and data formats, and data encoding specifications to secure both the production and transmission of data. Furthermore, protocols for safe data transmission are essential to protect sensitive health information during exchanges. Adhering to these technological standards ensures that Blockchain-based EHRs can securely and efficiently exchange data within an interoperable framework [27].

TABLE II. NEED FOR INTEROPERABILITY AMONGST EHR SYSTEMS BUILT ON THE BLOCKCHAIN

Requirements		
Conceptual (syntactic and semantic)	**Technological**	**Organizational and (Legal)**
Agreed vocabulary for messages and clinical documents. Common terminologies and information models for advanced messages	Signal, protocol, and technological plug-and-play compatibility	Fundamentals of doing business collaboration between companies to facilitate the exchange of information
For data accuracy, use standard terms	The seamless exchange of health data is essential for providing adequate healthcare	
To assess the discrepancies, data element mapping to the common terminology	Logical models developed without regard to platform or programming language limitations	Federally mandated program data reporting burden reduced
Integrity of meaning	Coding standard technical concerns need to be resolved	Protecting the confidentiality of medical records
Obtaining a shared dataset Collect the doctors' agreement on the dataset	Strong technical standards for sharing health information throughout institutions	An effective healthcare informatics group capable of handling all tasks Professionals in the healthcare industry coming together to reach an agreement on a particular project
Ability of structured message transmission between two or more systems The capacity to comprehend and use a sent message Creating a well-chosen vocabulary	Define data items, rules, values, and formats Agree on technical data models for database management systems	The collaboration of informaticists, vendors of EHRs, and clinicians in the industry
Information from the exchange Identification of healthcare professionals and patients	Reporting clinical data securely and in a timely manner	Partnerships between public-private entities and government incentives have been adopted more widely
There should be no ambiguity in the data for transmitting systems	Multiple systems exchange data to take action based on what they've learned	ensuring that organizations function under various legal regimes

2) Organizational and legal prerequisites for interoperable blockchain-based EHRs: The successful implementation of interoperable Blockchain-based EHRs also requires certain organizational and legal prerequisites. Collaboration between EHR vendors and healthcare providers is vital, as it enables the development of shared business models that facilitate information exchange. Furthermore, organizations must engage experts who specialize in maintaining the privacy of shared information, as privacy and security are central to handling health data on a Blockchain. Access to data related to insurance and incentive programs is also essential, as it helps create a supportive environment for interoperability while ensuring compliance with relevant policies and regulations. These organizational and legal prerequisites form the foundation for a sustainable and secure interoperable EHR ecosystem [28].

B. Q.2 In a Blockchain Context, What are the Interoperable Standards for EHRs look like?

Table III details the requirements for interoperability between various Blockchain-based EHR applications. The study's authors studied different methods for EHR sharing, security, and interoperability. Several norms are being implemented to make it easier for healthcare providers to employ solutions built on the Blockchain [29][30].

TABLE III. AN EHR INTEROPERABILITY STANDARD BASED ON BLOCKCHAIN TECHNOLOGY

Block-Chain Based Standard Available	Description
FHIR	Data attributes are contained in an HL7-based resource. Adherence to FHIR for Information Exchange standards
HL7	A developing standard based on FHIR. Robust operation on mobile devices.
HITECH	MIPS, HER certification, interoperability, and healthcare system transformation
PHR	HL7 was utilized for tethering and quick data exchange. Interchangeability of PHR and EHIR via APIs.
Open EHR	EHR is developed using open-source components. Clinical deployments that validate EHR standards.
DICOM	Secure transmission of health records and medical images. APIs for integrating various health systems.
SNOMED CT	EHRs' current clinical procedures. Consistency, interoperability, and accuracy.
CEN/ISO EN13606	Semantic guidelines for the exchange of EHR information. Standards of privacy and security for interface access.
HIPAA	Security requirements for patient data privacy. EHR interoperable system with confidence

When thinking about harmonization, it is essential to find the standard that is most compatible with other standards. This is demonstrated by Tables III and IV, further substantiating the superior interoperability qualities of HL7 and FHIR.

TABLE IV. CHARACTERISTICS OF BLOCKCHAIN-DRIVEN EHR STANDARDS

Properties	CEN-13606	CEN	Open-EHRs	HL7	HITECH	DICOM	FHIR
The Better-Workflow	Y	M	Y	Y	Y	M	Y
Reduced-Ambiguity	M	Y	Y	Y	M	Y	Y
Better Quality-of-Care	Y	M	M	Y	Y	Y	Y
In terms of Reliability	M	Y	Y	Y	M	M	Y
The Information-security	M	M	Y	Y	Y	M	Y
Security and the Privacy	M	Y	M	Y	Y	Y	Y

C. Q3. How does the Blockchain-Based Framework Enable EHR Exchange Between Different Hospitals Using Different EHR Standards?

1) Interoperable blockchain-based EHR framework: BCIF-EHR: The BCIF-EHR framework is designed to enable seamless interoperability between healthcare providers, utilizing blockchain technology, HL7 and FHIR standards, and AI-driven data mapping to securely share EHR between hospitals. Below is a breakdown of each component in this framework and how they interact. The block diagram of EHR and standards in presented in Fig. 2.

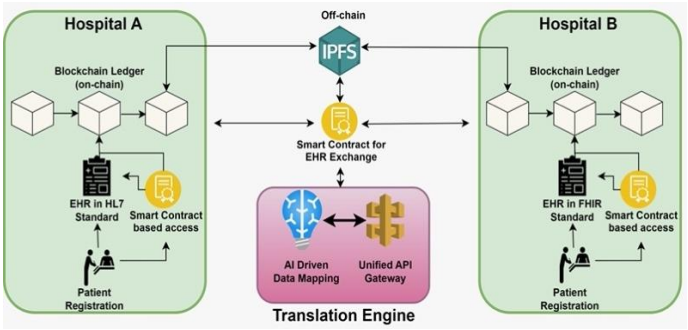

Fig. 2. Blockchain-based interoperable EHR system architecture (BCIF-EHR).

a) Patient registration: When a patient whose EHR system uses the HL7 standard, registers at Hospital A, their information (such as demographics and IDs) is captured in an

HL7 message format. This data flows through the AI-driven data mapping layer in the unified API gateway, which transforms the HL7 message into FHIR resources. This translation ensures that the patient's data can be compatible across different EHR systems.

b) Consent management using blockchain technology: Once the patient agrees to allow other hospitals to access their EHR, the blockchain-based consent management system records this consent immutably. Only authorized entities can access the data, with all data exchanges facilitated securely via HL7 and FHIR protocols.

c) Data exchange request from another hospital: When Hospital B requests access to the patient's medical history from Hospital A (using FHIR-based EHR), the unified API gateway handles the request. The gateway converts the request into an HL7-compliant query, and the AI-driven data mapping layer matches the necessary data fields, ensuring the request aligns with the HL7 structure.

d) Translation engine: The translation engine is an important component who is responsible for providing the interoperability between HL7 and FHIR. Interoperability between these standards will be by AI driven data mapping.

e) Interoperability platform for data processing and storage: After the request, Hospital A's HL7-based EHR sends the relevant data to a interoperability platform. This platform processes the data, ensuring it adheres to both HL7 and FHIR standards, stores it securely, and makes it accessible as FHIR resources.

f) Decentralized IPFS storage: For larger datasets, such as genomic data or medical images, decentralized storage through IPFS (Interplanetary File System) is used. Hospital B can retrieve this data through hash pointers in the FHIR resource, which link to the data stored in IPFS.

g) Data validation and smart contracts for EHR exchange: Before data is transmitted to Hospital B, a data validation process checks compliance with HL7 and FHIR standards. Smart contracts enforce the terms of data exchange, including patient consent, ensuring the conditions are met before the EHR data is shared.

h) Cross-chain support for multi-standard systems: If the patient visits a new healthcare provider that uses blockchain-enabled EHR, cross-chain support enables seamless data transfer across different blockchain networks. This component ensures interoperability across varied healthcare standards.

i) Patient data retrieval and update: When Hospital B receives the patient's data, it can retrieve and integrate it into its FHIR-based EHR system. Any updates made by Hospital B, such as test results, are converted back into HL7 format for Hospital A, ensuring both systems remain synchronized.

j) Secure logging and audit trail: Every transaction and data exchange is securely logged on the blockchain, creating an audit trail that medical professionals can monitor. This ensures data transparency, security, and traceability, reinforcing the trustworthiness of data sharing. Pseudo code of the Algorithm for Patient Registration (HL7 to FHIR) is presented below:

Pseudo code of PatientRegistrationHL7 to FHIR(HL7Message) Algorithm

Input:	***HL7Message***
Output:	***FHIRResource***
Step 1:	HL7Message ← CapturePatientRegistrationDetails()
Step 2:	APIService ← UnifiedAPIGateway(HL7Message)
Step 3:	MappingLayer ← AIDrivenDataMapping(APIService) HL7Segments ← ExtractSegments(HL7Message, ["PID", "OBX", "PV1"])
Step 4:	FHIRMapping ← MapHL7toFHIR(HL7Segments)
Step 5:	FHIRData ← TransformHL7toFHIR(FHIRMapping) FHIRResource ← CreateFHIRResource(FHIRData,
Step 6:	resourceType="Patient") isValid ← ValidateFHIRResource(FHIRResource) If isValid == False then RaiseError("FHIR resource validation failed")
Step 7:	Exit StoreFHIRResource(FHIRResource, InteroperabilityPlatform) ShareFHIRResource(FHIRResource, AuthorizedEntities) Return FHIRResource
	End Algorithm

D. Performance Evaluation Measures

1) Data accuracy and mapping quality: Data accuracy and mapping quality are fundamental for preserving the integrity of health information as it is transferred between healthcare systems, specifically when converting data between HL7 and FHIR standards. High data accuracy ensures that the information remains correct, up-to-date, and relevant, which is essential for providing reliable patient care and enabling informed decisions by healthcare professionals. Mapping quality assesses the effectiveness of data translation between these standards, maintaining platform integrity and reducing errors. The AI-driven data mapping enhances this quality by minimizing inaccuracies and data loss. As illustrated in Fig. 3, the mapping accuracy rate stands at an impressive 99.5%, with only a marginal inaccuracy of 0.2%, reflecting the robustness of data translation across these standards. Furthermore, the data loss rate remains low, averaging around 1.2%, which may be attributed to issues like unsupported fields or technical challenges that occasionally lead to minor data losses. Consistence in data translation is also high, with a consistency rate of 98.9% across multiple translation cycles, underscoring the system's ability to maintain stable data integrity throughout the mapping process.

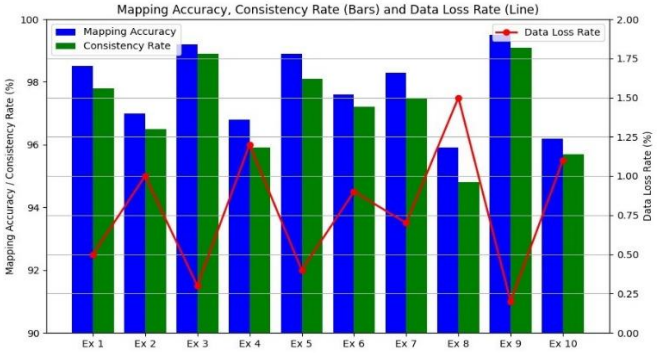

Fig. 3. Comparison of mapping accuracy, consistency rate, and data loss.

2) Response time and latency: Response time, particularly in healthcare environments, is critical for real-time access to

patient data. This measure is evaluated through both average latency and peak load latency, as shown in Fig. 4. Average latency is consistently around 150 milliseconds, which supports the need for rapid data access and retrieval, essential in emergency scenarios where every second counts. Under high transaction loads, the peak load latency reaches about 325 milliseconds, demonstrating the system's ability to perform efficiently even under heavy demand. This stability in latency ensures that the system remains responsive and reliable, which is vital for healthcare professionals who rely on timely data for patient care.

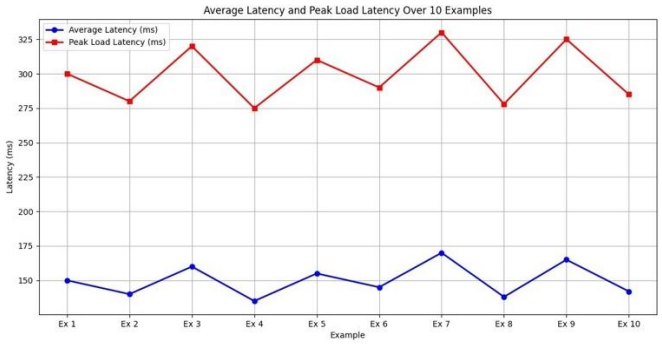

Fig. 4. Average latency and peak load latency across 10 samples.

3) Interoperability coverage: Interoperability coverage, depicted in Fig. 5, assesses the system's ability to handle various HL7 and FHIR standards, such as HL7 v2, v3, and FHIR versions like DSTU2, STU3, and R4. Effective interoperability is essential for consistent communication across diverse healthcare providers and systems, supporting seamless information exchange. The system achieves a high standard compliance rate, with close to 96% of HL7 and FHIR features supported. This high level of compliance ensures that the system adheres to established healthcare data standards, which is critical for effective data interoperability. Additionally, the system maintains a cross-version compatibility rate above 92%, indicating its flexibility to handle both older and newer versions of healthcare standards, a necessary feature for consistent data exchange across different platforms and systems.

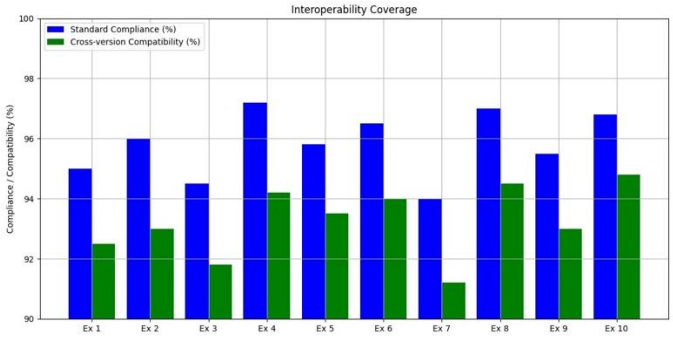

Fig. 5. Interoperabil*ity coverage*.

E. AI Model Efficiency

AI model efficiency plays a crucial role in system performance, affecting mapping speed, training time, and error rates. Fig. 6 provides insights into these metrics, where the AI model's mapping speed ranges from 330 to 370 milliseconds, enabling timely data processing in real-time healthcare environments. Training times for the AI model vary between 24 and 29 seconds, which supports quick model updates and adaptation to evolving data formats. The model error rate is low, around 2%, indicating high accuracy in data mapping with minimal errors. This low error rate is essential for maintaining data integrity across standards, ensuring that the AI-driven mapping layer performs reliably in a healthcare setting.

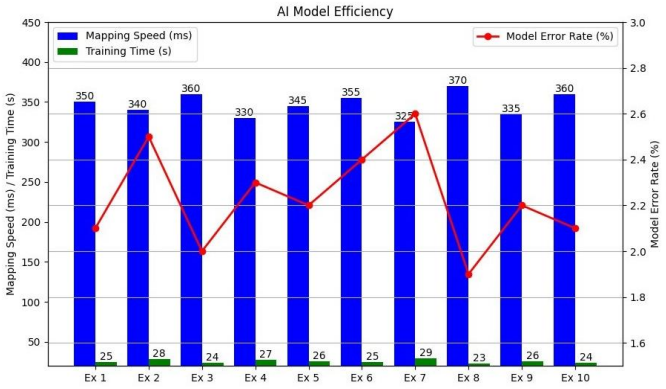

Fig. 6. AI model mapping speed and training time.

F. Consent and Security Management

Consent and security management are essential for safeguarding patient data during exchange.

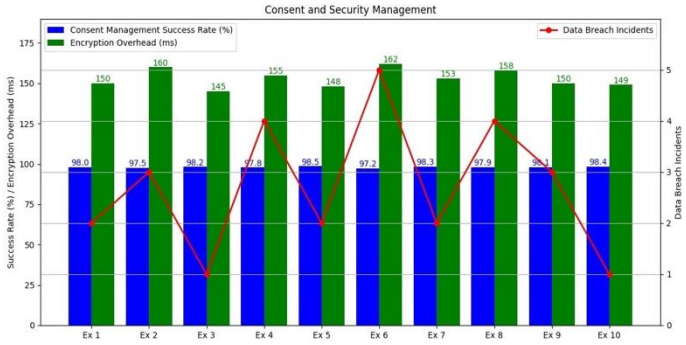

Fig. 7. Consent management success rate and encryption overhead.

Fig. 7 illustrates key metrics related to consent management success rate, encryption overhead, and data breach incidents. Consent management is consistently high, with success rates around 98%, ensuring that patient consent preferences are respected, and only authorized personnel can access sensitive data. Encryption overhead, which varies from 145 to 162 milliseconds, balances data security without causing significant delays, maintaining a secure and efficient data exchange process. The frequency of data breach incidents is minimal, indicating strong access control measures and robust security protocols that protect patient data and support compliance with privacy regulations.

G. Cross-Chain Support Evaluation

Cross-chain support evaluation, depicted in Fig. 8, enables seamless data exchanges across blockchain networks, which is essential for interoperability in multi-network environments.

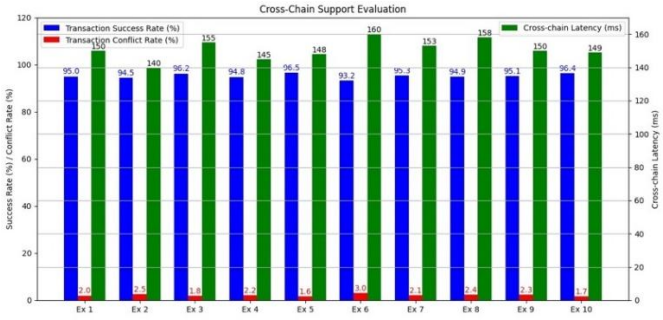

Fig. 8. Transaction success rate, conflict rate, and latency.

The system demonstrates a high cross-chain transaction success rate of approximately 95%, ensuring reliable interactions across different blockchain systems. The transaction conflict rate remains low, under 3%, indicating smooth data flow with minimal errors in cross-chain communication. Cross-chain latency averages around 150 milliseconds, allowing quick data access across blockchain networks and minimizing delays for healthcare providers requiring patient information from various sources.

H. Patient and Provider Satisfaction

Patient and provider satisfaction metrics, shown in Figure 9, provide insights into the system's usability, efficiency, and reliability from the perspective of end-users. High satisfaction scores indicate positive feedback from both patients and providers, reinforcing the system's effectiveness in real-world healthcare settings. Patient satisfaction scores range between 4 and 5 on a 5-point scale, reflecting a favorable view of the system's accessibility, data privacy, and ease of data retrieval. Provider satisfaction scores range from 3.5 to 4.5, suggesting that healthcare providers find the system beneficial for workflow efficiency, data accuracy, and accessibility, which enhances their productivity and decision-making capabilities.

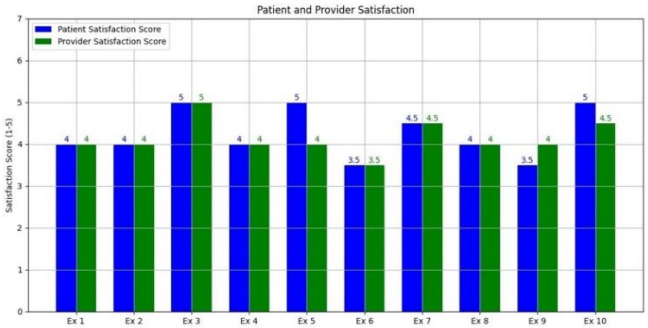

Fig. 9. Patient and service provider success score.

V. Conclusion and Future Work

This study demonstrates the potential of blockchain technology to address critical challenges in EHR interoperability by enhancing data security, privacy, and accessibility. The proposed blockchain-based framework BlockMed provides secure EHR exchange with translation of the standards i.e HL7 and FHIR using AI module. It is a decentralized approach to EHR management, ensuring compliance with contemporary standards and regulatory requirements like HIPAA while giving patients control over their own data. The integration of smart contracts further enhances the system by enforcing data sharing rules and maintaining accessibility without compromising privacy and data integrity. The BlockMed is proven to be secure and efficient after evaluation with the metrics i.e. Data Accuracy, Mapping Quality, Response Time, Latency, Interoperability Coverage, AI Model Efficiency, Consent and Security Management, Cross-Chain Support, Patient and Provider Satisfaction.

Despite these advancements, the real-world implementation of interoperable blockchain-based EHR systems remains limited, with few existing solutions that offer seamless data exchange across diverse healthcare platforms. This research contributes a foundational framework that can be expanded to develop scalable, interoperable EHR systems that meet the evolving needs of the healthcare industry. Future work should focus on real-world applications, addressing scalability issues, refining cross-chain support, and improving system performance under heavy data loads.

Overall, the study presents a promising path forward in the healthcare sector, leveraging blockchain to ensure secure, efficient, and interoperable EHR systems that can evolve with technological and regulatory developments. Further research and collaboration with healthcare providers and policymakers will be essential to fully realize the benefits of blockchain-based EHR interoperability. This study contributes a framework for blockchain-based EHR interoperability that adheres to HIPAA and HL7 standards, facilitating secure, cross-institutional patient data exchange. Future research should explore AI-driven data mapping to enhance translation accuracy between HL7 and FHIR standards and investigate cross-chain solutions to support data portability.

Acknowledgment

This work was supported by the Deanship of Scientific Research, the Vice Presidency for Graduate Studies and Scientific Research, King Faisal University, Saudi Arabia under project KFU250655.

***Abstract*—This study explores the effectiveness of various feature selection methods in forecasting next-day PM2.5 levels in Banting, Malaysia. The accurate prediction of PM2.5 concentrations is crucial for public health, enabling authorities to take timely actions to mitigate exposure to harmful pollutants. This study compares three feature selection methods: Lasso, mRMR, and ReliefF using a dataset consisting of 43,824 data points collected from Banting air quality monitoring stations (CA22B). The dataset includes ten variables, including pollutant concentrations such as O3, CO, NO2, SO2, PM10, and PM2.5, along with meteorological parameters such as temperature, humidity, wind direction and wind speed. The results revealed that Lasso outperformed both mRMR and ReliefF in terms of various performance metrics, including accuracy, sensitivity, precision, F1 score, and AUROC. Lasso demonstrated superior ability to handle multicollinearity, significantly improving the interpretability of the model by retaining only the most important variables. This suggests that the effectiveness of feature selection methods is highly dependent on the characteristics of the dataset, such as correlations among features. Thus, the top eight features to predict PM2.5 levels in Banting selected by Lasso method are relative humidity, PM2.5, wind direction, ambient temperature, PM10, NO2, wind speed, and O3. The findings from this study contribute to the growing body of knowledge on air quality prediction models, highlighting the importance of selecting the appropriate feature selection method to achieve the best model performance. Future research should explore the application of Lasso method in other geographical regions, including urban, suburban and rural areas, to assess the generalizability of the results.**

***Keywords*—PM2.5 concentration; feature selection; Lasso; mRmR; RBFNN; ReliefF**

I. Introduction

There is an increasing emphasis on air quality research, such as air quality prediction and the health effects of contaminants. This surge in attention is driven by rising pollution levels, growing health concerns, and advancements in technology that make monitoring and prediction more accessible. According to [1], aside from Kuala Selangor, all monitoring stations in the Klang Valley reported poor air quality days, with Banting having the second-highest occurrence at five days, eventhough Banting has less traffic compared to other urban area such as Shah Alam.

Prediction of PM2.5 levels (particulate matter with a diameter of less than 2.5 microns) has attracted considerable interest because of its significant impact on human health and its role as a key indicator of air quality. Previous studies such as in study [2] highlight the association between prenatal and postnatal PM2.5 exposure and a high incidence of tic disorders in children. Additionally, the study in [3] used machine learning techniques to predict PM2.5 concentrations using historical air quality data from Kuala Lumpur, demonstrating that advanced modelling approaches can significantly improve the accuracy of air quality predictions, which is critical for public health advisories and environmental management.

More recently, neural networks (a type of machine learning) have gained prominence in predicting air quality due to their ability to model complex, nonlinear relationships inherent in air quality data. One significant study by [4] on artificial neural networks (ANNs) in Peninsular Malaysia demonstrated their effectiveness in accurately predicting pollutants and the Air Pollutant Index. Radial Basis Function Neural Network (RBFNN), a machine learning method that has a simple architecture consisting of an input, hidden, and output layers, demonstrated faster convergence during training compared to more complex architectures like Multi-Layer Perceptrons (MLP). Moreover, the accuracy of the RBFNN model in predicting the occurrence of haloketones in tap water, as shown in [5], exhibited high performance, effectively capturing the complex relationships between input parameters and the predicted outcomes.

To further improve the accuracy of PM2.5 prediction models, researchers have increasingly focused on feature selection methods. According to a study by [6], the findings indicated that feature selection methods improved prediction accuracy by at least 13.7% compared to models that did not employ feature selection. ReliefF is a filter-based feature selection method that is effectively used to train models for classification due to its ability to identify relevant features by ranking them based on their capacity to distinguish between instances [7]. In addition, the study in [8] noted that many

previous studies address multicollinearity issues in feature selection methods by removing redundant and irrelevant features from high-dimensional data, which can be effective in preventing deterioration in model performance. However, removing redundant features based solely on the correlation between variables might not provide accurate predictions, as the removed variables may have unique characteristics.

Therefore, a feature selection method that focuses on the correlation between variables is needed. For example, the study in [9] discussed using correlation-embedded attention modules to reduce multicollinearity can improve the model performance and interpretability. Minimum Redundancy Maximum Relevance (mRMR) is a filter-based, correlation-based feature selection method that focuses on selecting features that maximize relevance to the target variable while minimizing redundancy among them, thereby extracting the most representative features closely related to the target variable [10]. In addition, Least Absolute Shrinkage and Selection Operator (Lasso) is another feature selection method that effectively addresses multicollinearity by applying regularization to shrink less important feature coefficients to zero, thus enhancing model interpretability and reducing overfitting [11].

There are numerous feature selection techniques, such as Recursive Feature Elimination (RFE) and XGBoost Feature Importance. However, our study focuses on Lasso, mRMR, and ReliefF due to their distinct selection mechanisms and prior applications in air quality prediction research. The research in [12] points out that while RFE can achieve high performance, it suffers from computational inefficiency due to its reliance on iterative model training. This issue is particularly relevant when dealing with large datasets, as the time required for multiple iterations can become prohibitive. Meanwhile, XGBoost Feature Importance ranks features based on their contribution to decision trees but does not explicitly account for multicollinearity. Unlike Lasso, which penalizes correlated predictors to improve interpretability, XGBoost may distribute importance among correlated variables, making it less effective for identifying the most relevant individual predictors in highly correlated datasets.

Additionally, a study by [13] compared the ReliefF, mRMR, and Lasso methods using air quality data from Shah Alam. The study concluded that ReliefF outperformed the other two methods and recommended that future researchers compare these three feature selection methods in other urban air quality datasets. Based on this recommendation, our study applies these methods to air quality data from Banting, providing insights into how these methods perform in a different urban setting with distinct environmental and meteorological conditions. As an industrial area, Shah Alam is influenced by emissions from factories, vehicles, and urban activities, leading to higher concentrations of pollutants such as PM2.5, PM10, SO2, NO2, and CO. In contrast, Banting, an agricultural area, experiences pollution primarily from agriculture activities and occasional biomass burning, which may result in different pollutant levels and patterns compared to Shah Alam.

Therefore, this study will compare the performance of the RBFNN model combined with ReliefF, mRMR, and Lasso feature selection methods to determine the most effective approach to predict the next day concentration of PM2.5 in Banting. The study's findings will benefit policymakers and other relevant parties by providing evidence-based insights into the most effective feature selection methods for improving air quality prediction models.

II. Research Methods

A. Dataset

This study used the Banting air quality dataset provided by the Department of Environment Malaysia (DOE). Ten variables (PM2.5, PM10, SO2, NO2, O3, CO, wind direction, wind speed, relative humidity, and ambient temperature) used as independent variables, were extracted from hourly data spanning four years (2018 to 2022). However, there are missing values in the dataset as shown in Table I, with NO2 having the highest percentage of missing data at 8.68%, while relative humidity is the lowest at 1.39%. In order to address the missing data points, we employed linear interpolation method, as was suggested in study [14].

TABLE I. Percentage of Missing Values

Variable	N	Missing Value
PM2.5	43207	617 (1.41%)
PM10	43075	749 (1.71%)
SO2	40938	2886 (6.59%)
NO2	40021	3803 (8.68%)
O3	41182	2642 (6.03%)
CO	40735	3089 (7.05%)
WD	43135	689 (1.57%)
WS	42927	897 (2.05%)
Humidity	43217	607 (1.39%)
Temperature	42443	1381 (3.15%)
$PM2.5_{D+1}$	43207	617 (1.41%)

The target variable in this study is the PM2.5 levels of the next day. Hence, the hourly dataset was transformed to daily categorical data by averaging values over 24 hours. The PM2.5 breakpoint of air quality categories is shown in Table II based on guidelines by DOE. Furthermore, this study employed classification task, hence the target variable, $PM2.5_{D+1}$ was transformed into binary classification system, not polluted (0) and polluted (1) as suggested in [15]. The "good" and "moderate" category represent not polluted (0) class, while other than that are represent polluted (1) class [15].

TABLE II. Labels for the Respective PM2.5 Breakpoint and AQI Categories

AQI Category	PM2.5 Breakpoints
Good	0.0-12.0
Moderate	12.1-35.4
Unhealthy for Sensitive Groups	35.5-55.4
Unhealthy	55.5-150.4
Very Unhealthy	150.5-250.4
Hazardous	250.5 and above

B. Research Framework

Research framework of this study is shown in Fig. 1. The process begins with data extraction as mentioned previously. Then, followed by extensive data pre-processing steps which include imputation using linear interpolation, converting hourly data into daily averages, binary categorization of PM2.5 levels, min-max normalization, and balancing the dataset with SMOTE technique. Subsequently, the three feature selection methods: ReliefF, mRMR, and Lasso are applied to rank and select the top eight variables most relevant to PM2.5 prediction as suggested in study [13] and study [16]. The selected features are used to train a Radial Basis Function Neural Network (RBFNN). A comparative evaluation of accuracy, specificity, precision, F1 score, and AUROC was finally used to identify the most effective model.

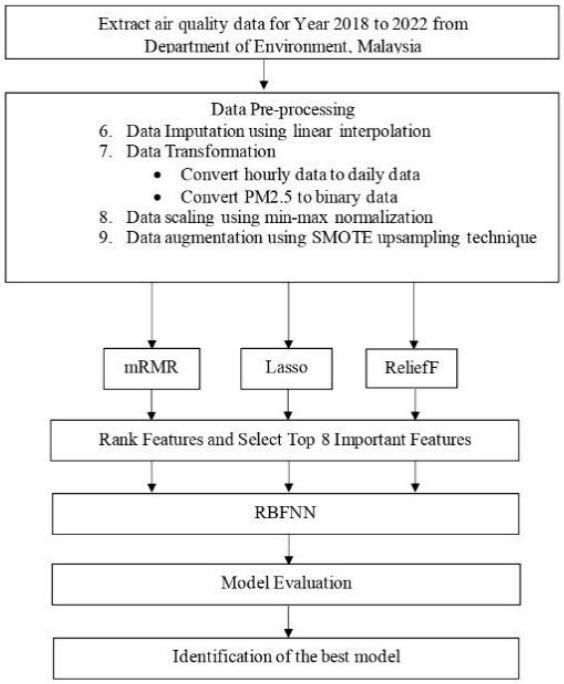

Fig. 1. Research flowchart.

C. Feature Selection Method

1) ReliefF: The ReliefF algorithm is a filter-based feature selection method known for its effectiveness in high-dimensional and noisy datasets [17]. It evaluates feature importance by assessing their ability to distinguish between instances of different classes. Unlike traditional methods relying on statistical correlations, ReliefF employs a distance-based approach, sampling data points and identifying the k-nearest neighbors within the same class (nearest hits) and from other classes (nearest misses). By comparing feature values between these neighbors, ReliefF assigns higher importance to features with substantial variation across classes and minimal variation within the same class.

The weight of a feature W[A] is updated iteratively using the formula in Eq. (1) [18], where H_i is the nearest hit (same class), while M_i is the nearest miss (different class). Moreover, the difference is calculate as shown in Eq. (2), where $diff(A, X, Y)$ are the difference in feature A values between instances X and Y.

$$W[A] = W[A] - \frac{1}{m}\sum_{i=1}^{m}(diff(A, H_i) - diff(A, M_i)) \quad (1)$$

$$diff(A, X, Y) = \begin{cases} 0 \; if \; X[A] = Y[A] \\ 1 \; if \; X[A] \neq Y[A] \end{cases} \quad (2)$$

2) Maximum Relevance Minimum Redundancy (mRMR): Maximum Relevance Minimum Redundancy (mRMR) is a feature selection method that aims to choose the most relevant features while minimizing redundancy among them. It is particularly useful in high-dimensional datasets where feature selection is crucial for improving model performance. The approach maximizes the relevance of selected features to the target variable and minimizes the redundancy between them. The relevance of a feature x_i to the target variable, c are calculated using mutual information, while redundancy between features is determined by the pairwise mutual information between features x_i and x_j. Eq. (3) and Eq. (4) shows the formulas to calculate maximum relevance and minimum redundancy, respectively.

$$maxD(S, c), D = \frac{1}{|s|}\sum_{x_i \in s} I(x_i, c) \quad (3)$$

$$minR(S), R = \frac{1}{|s|^2}\sum_{x_i, x_j \in s} I(x_i; x_j) \quad (4)$$

3) Lasso: The Least Absolute Shrinkage and Selection Operator (Lasso) is a method that helps improve model interpretability and performance by performing feature selection and regularization. It is particularly effective when working with datasets that contain many features, as it can reduce overfitting by penalizing less relevant variables [19]. Lasso works by adding a penalty term to the loss function, specifically the L1 penalty, which forces some of the feature coefficients to become exactly zero [19]. The L1 penalty, controlled by a tuning parameter λ, directly influences how many coefficients are driven to zero, with larger values of λ resulting in more features being eliminated. This regularization technique ensures that the model is both efficient and less likely to overfit the data. The mathematical formulation of Lasso is represented in Eq. (5). Where the first term represents the residual sum of squares, and the second term is the L1 penalty.

$$\hat{\beta} = min\,\beta\left\{\sum_{i=1}^{N}\left(y_i - \beta_0 - \sum_{j=1}^{p} x_{ij}\beta_j\right)^2 + \lambda\sum_{j=1}^{p}|\beta_j|\right\} \quad (5)$$

4) Radial basis function neural network: Radial Basis Function Neural Networks (RBFNN) are a specialized type of artificial neural network that utilize radial basis functions for activation. These networks are well-suited for tasks such as function approximation, classification, and regression, owing to

their capacity to model involved nonlinear relationships. RBFNN typically consist of three essential layers: the input layer, the hidden layer, and the output layer, with weights connecting each layer.

The input layer receives the source node, representing the independent variable, and links it to the surrounding network. The hidden layer then applies a nonlinear transformation, mapping the input space to a higher-dimensional hidden space. The output layer generates the final predicted result based on the transformed inputs from the hidden layer. In the hidden layer, each unit corresponds to a transfer function, often a Gaussian function. The radial basis function (RBF), which has a symmetric shape, acts as the transfer function in this case. The number of hidden units is directly related to the number of RBF employed in the network. The Gaussian RBF is mathematically expressed as shown in Eq. (6), meanwhile the output is computed by summing the weighted contributions of the RBF as shown in Eq. (7).

$$\emptyset(x) = \exp(-\frac{||x - c||^2}{2\sigma^2}) \tag{6}$$

$$g(X) = \sum_{j=1}^{k} w_j \emptyset_j(r\|X - C_j\|) \tag{7}$$

where w_j are the weights assigned to each radial basis function, C_j represents the centers of the RBF, and r is a scaling factor. In the output layer, a logistic (sigmoid) activation function is commonly used for binary classification. This function transforms the weighted sum of the hidden layer outputs into a probability between 0 and 1, and is defined as in Eq. (8). Thus, the final output of the RBFNN for binary classification is calculated using Eq. (9), where w_0 is the bias term.

$$\sigma(\mathrm{z}) = \frac{1}{1 + e^{-\mathrm{z}}} \tag{8}$$

$$\hat{y} = \sigma\left(w_0 + \sum_{j=1}^{k} w_j \emptyset_j(r\|X - C_j\|)\right) \tag{9}$$

D. Model Performances

The developed model's performance will be evaluated using six metrics: accuracy, sensitivity, specificity, precision, F1 score, and AUROC. To evaluate the classification performance of the developed model, a confusion matrix is first constructed. The confusion matrix, shown in Table III provides a detailed summary of the model's predictions by categorizing them into four groups: true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). Meanwhile, the total number of instances is the sum of all four categories: TP, TN, FP, and FN.

TABLE III. CONFUSION MATRIX

	Actual Positive (1)	**Actual Negative (0)**
Predicted Positive (1)	TP	FP
Predictive Negative (0)	FN	TN

Accuracy reflects the percentage of correct predictions and is calculated as shown in Eq. (10). Sensitivity, or the true positive rate, measures the proportion of actual positive cases correctly identified in Eq. (11), while specificity, or the true negative rate, quantifies the proportion of actual negatives accurately calculated using in Eq. (12).

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} \tag{10}$$

$$Sensitivity = \frac{TP}{(TP + FN)} \tag{11}$$

$$Specificity = \frac{TN}{(TN + FP)} \tag{12}$$

Precision determines the percentage of correct positive predictions among all predicted positives in Eq. (13). The F1 score, a harmonic mean of precision and sensitivity in Eq. (14), assesses the model's ability to maintain balance between these metrics.

$$Precision = \frac{TP}{(TP + FP)} \tag{13}$$

$$F1\ Score = \frac{2\ x\ Precision\ x\ Sensitivity}{(Precision + Sensitivity)} \tag{14}$$

The Area Under the ROC Curve (AUROC) curve illustrates the relationship between sensitivity and the False Positive Rate, with AUROC measuring the model's ability to differentiate between classes. A higher AUROC value, nearing 1.0, signifies better classification performance. Collectively, high scores across these metrics indicate a reliable and effective model.

III. RESULTS AND DISCUSSION

This section discusses the results of the study. Table IV summarizes the descriptive statistics of the independent variables, revealing a substantial range in standard deviations, from 0.001 to 38.15. This wide variability reflects the diverse scales of the variables, necessitating data normalization. Based on Fig. 2, the histogram reveals PM2.5, PM10, and CO have higher variability, suggesting potential impact from external factors. The distribution of these variables over the four years may have been affected by the COVID-19 period, with changes in human activity significantly impacting pollution levels during this time.

To address this, min-max normalization was employed to transform all variables to a consistent scale, ensuring comparability across features. Min-Max normalization is one of the most commonly used normalization methods in various applications, including air quality datasets [20]. Additionally, Fig. 3 illustrates the distribution of the $PM2.5_{D+1}$ category, highlighting a significant class imbalance in the dataset, where one category is disproportionately represented. Such imbalances can bias predictive models, undermining their reliability and generalizability. To resolve this issue, the Synthetic Minority Over-sampling Technique (SMOTE) was applied, a proven method for addressing class imbalance by generating synthetic samples for underrepresented categories. By balancing the dataset, SMOTE enhances the model's ability to learn from all

categories effectively, thereby improving prediction accuracy and ensuring robust, reliable outcomes.

TABLE IV. DESCRIPTIVE STATISTICS OF BEFORE DATA PRE-PROCESSING

Variable	N	Mean	Median	Std. Dev.	Skewness
PM2.5	1825	21.236	18.648	12.157	3.653
PM10	1825	30.433	28.016	14.137	3.165

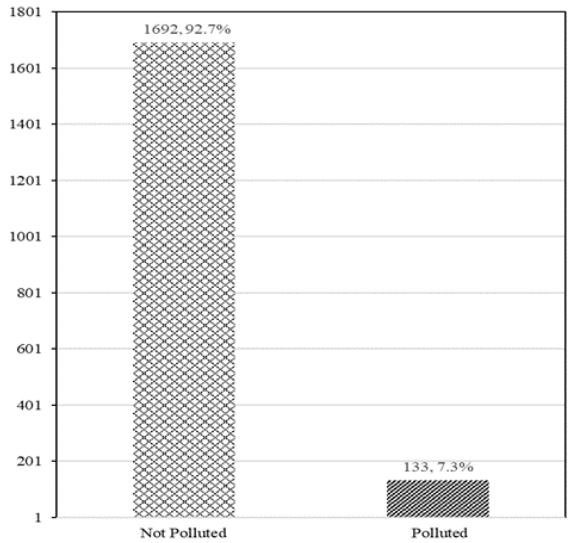

Fig. 3. $PM2.5_{Dt1}$ Distribution of (Before SMOTE).

Table V presents the descriptive statistics after data preprocessing. The application of min-max normalization successfully scaled the data, as evidenced by all mean and median values now falling within the standard range of 0 to 1. The data scaling ensures that the feature scales are consistent, which makes model training more successful. Furthermore, the skewness values have moved closer to zero, indicating a more symmetric and balanced distribution throughout the sample.

TABLE V. DESCRIPTIVE STATISTICS OF AFTER DATA PRE-PROCESSING

Variable	N	Mean	Median	Std. Dev
PM2.5	3288	0.172	0.136	0.143
PM10	3288	0.201	0.167	0.152
SO2	3288	0.278	0.255	0.137
NO2	3288	0.433	0.435	0.17
O3	3288	0.359	0.34	0.123
CO	3288	0.319	0.307	0.139
WD	3288	0.431	0.418	0.122
WS	3288	0.24	0.229	0.094
Humidity	3288	0.832	0.834	0.06
Temperature	3288	0.62	0.626	0.076

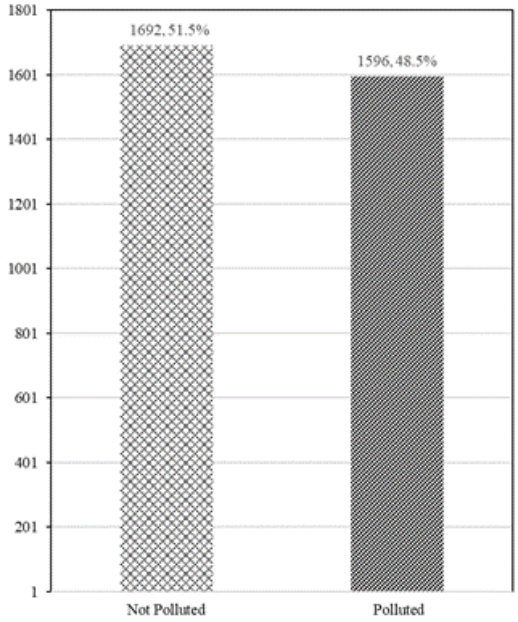

Fig. 4. $PM2.5_{Dt1}$ Distribution of (After SMOTE).

Fig. 4 illustrates the distribution of the $PM2.5_{D+1}$ category following the application of SMOTE for upsampling. This technique effectively addressed the class imbalance, resulting in a nearly equal representation of both groups: 1692 samples (51.5%) classified as "not polluted" and 1596 samples (48.5%) as "polluted." This balance dataset can enhance the reliability of the dataset for subsequent analyses and model predictions [21].

Table VI ranks independent variables according to three feature selection methods: Lasso, mRMR, and ReliefF, for predicting next-day PM2.5 levels. The rankings of independent variables by Lasso, mRMR, and ReliefF reveal both similarities and key differences. Lasso identifies relative humidity as the most important variable, emphasizing its critical role in PM2.5 prediction. In contrast, mRMR assigns the top 1 rank is SO2,

highlighting its unique contribution to the dataset. ReliefF, however, ranks NO2 as the most critical feature, suggesting its strong influence on pollutant dispersion and PM2.5 formation. These differences in top-ranking features underscore the variability in feature importance prioritization across the methods. Furthermore, the least important variables and exclusions also vary. CO is consistently ranked eighth by both Lasso and mRMR. However, ReliefF determine SO2 as the least important feature to predict PM2.5 in Banting [22].

Additionally, certain features were not selected by the three methods. Both particulate matter (PM10 and PM2.5) were excluded by mRMR method. Additionally, Lasso did not select SO2 and O3 as important feature. On other hand, ReliefF exclude both relative humidity and ambient temperature from the model.

TABLE VI. FEATURE RANKING ACROSS LASSO, MRMR, AND RELIEFF METHODS

Variable	Lasso	mRMR	reliefF
PM2.5	2	-	7
PM10	5	-	6
SO2	-	1	8
NO2	6	6	1
O3	-	4	4
CO	8	8	2
WD	3	7	3
WS	7	2	5
Humidity	1	5	-
Temperature	4	3	-

Next, the three feature selection methods will be evaluated using the performance of the RBFNN model to predict $PM2.5_{D+1}$ in Banting is shown in Table VII. According to the table, the Lasso method yields higher values in accuracy (0.771), sensitivity (0.765), precision (0.778), F1 score (0.771), and AUROC (0.769), when compared to the mRMR and ReliefF methods. These findings contradict the results of [13], which concluded that ReliefF outperforms Lasso. The discrepancy arises from the contrasting characteristics of the study areas. Shah Alam, as an industrial area, is heavily influenced by traffic and industrial emissions, resulting in more consistent pollution sources throughout the year. In contrast, Banting, an agricultural region, experiences pollution patterns influenced by seasonal meteorological factors. For instance, according to a study in [23], during the northeast monsoon, precipitation in Banting have influence on air pollution levels. This difference in pollution patterns might explain why Lasso outperformed ReliefF in Banting, as ReliefF did not select two key meteorological factors, humidity and temperature, which are more significant in this region.

However, this study aligns with [23], which found that the Lasso algorithm enhances model performance more effectively than the ReliefF method. According to study [19], Lasso is known for its ability to handle multicollinearity in predictors, reducing the impact of correlated features, and enhancing model interpretability by retaining only significant variables. This explains why Lasso performs better than the ReliefF method. Moreover, the mRMR method also demonstrates better performance compared to ReliefF. This may be attributed to the high correlations among variables in the Banting air quality dataset.

TABLE VII. COMPARISON MODEL PERFORMANCE

Model	Lasso	mRMR	ReliefF
Accuracy	**0.771**	0.725	0.568
Sensitivity	**0.731**	0.623	0.544
Specificity	0.807	**0.819**	0.591
Precision	**0.778**	0.761	0.551
F1 Score	**0.754**	0.685	0.548
AUROC	**0.829**	0.777	0.608

Table VIII shows the confusion matrix provides a detailed breakdown of the Lasso-based RBFNN model's classification performance in predicting PM2.5 levels. In this case, the model correctly classified 231 polluted instances (TP) and 276 non-polluted instances (TN)**,** while misclassifying 66 non-polluted instances as polluted (FP) and 85 polluted instances as non-polluted (FN)**.** The total number of instances used for evaluation is 658, calculated as the sum of TP, TN, FP, and FN.

TABLE VIII. CONFUSION MATRIX

	Actual Positive (1)	Actual Negative (0)
Predicted Positive (1)	231	66
Predictive Negative (0)	85	276

IV. CONCLUSION

In conclusion, this study highlights the significant role of feature selection methods in enhancing the predictive performance of air quality models in Banting, Malaysia. Among the three methods evaluated, Lasso emerged as the most effective for predicting next-day PM2.5 levels, consistently outperforming both mRMR and ReliefF in key performance metrics such as accuracy, sensitivity, precision, F1 score, and AUROC. Thus, Thus, the top eight features to predict PM2.5 levels in Banting selected by Lasso method is relative humidity, PM2.5, wind direction, ambient temperature, PM10, NO2, wind speed, and O3. While previous studies have recognized the strengths of ReliefF in detecting relevant features, this research reinforces the advantages of Lasso, particularly in its ability to improve model performance by addressing feature redundancy and focusing on the most impactful variables.

The superior performance of Lasso can be attributed to its ability to handle multicollinearity, reduce the impact of correlated features, and enhance model interpretability by retaining only the most significant predictors. Given the success of Lasso, future research should further explore its application in different settings, including suburban and rural areas, to evaluate its generalizability across diverse environments, especially dataset that contains high correlation between variables.

This study uses data from 2018 to 2022, a period that includes the COVID-19 years. During this time, air quality is likely to have been positively affected due to lower traffic and congestion, which may have influenced the results. Future studies might compare the results by differentiating between the COVID-19 and non-COVID-19 years to better understand how these factors impact air quality predictions. The results from this study are specific to the Banting dataset and may not be directly applicable to other countries due to regional differences in air quality patterns. This study benefits researchers, policymakers, public health authorities, and technology developers by improving air quality prediction models. Policymakers can use these predictions to implement real-time air quality monitoring systems, establish dynamic traffic control measures to reduce vehicular emissions during high-pollution periods, and enforce stricter industrial regulations to limit pollutant discharge. Additionally, predictions can guide the development of targeted public health advisories, such as issuing alerts for vulnerable populations and adjusting outdoor activity recommendations during hazardous air quality events. This study also supports NGOs in advocating for better air quality regulations and raising public awareness. Moreover, future researchers can apply the methods explored in this study to other areas, such as water quality prediction or environmental monitoring in different ecosystems. By adapting the feature selection techniques to new domains, researchers can validate the approach's versatility and effectiveness in improving prediction models across various environmental factors.

Lightweight CA-YOLOv7-Based Badminton Stroke Recognition: A Real-Time and Accurate Behavior Analysis Method

Yuchuan Lin[1]*
Public Physical Education Department, Fujian Agriculture and Forestry University, FuZhou FuJian, 35000, China

***Abstract*—With the rapid development of sports technology, accurate and real-time recognition of badminton stroke postures has become essential for athlete training and match analysis. This study presents an improved YOLOv7-based method for badminton stroke posture recognition, addressing limitations in accuracy, real-time performance, and automation. To optimize the model, pruning techniques were applied to the backbone structure, significantly enhancing processing speed for real-time demands. A parameter-free attention module was integrated to improve feature extraction without increasing model complexity. Furthermore, key stroke action nodes were defined, and a joint point matching module was introduced to enhance recognition accuracy. Experimental results show that the improved model achieved a mAP@0.5 of 0.955 and a processing speed of 44 frames per second, demonstrating its capability to deliver precise and efficient badminton stroke recognition. This research provides valuable technical support for coaches and athletes, enabling better analysis and optimization of stroke techniques.**

***Keywords*—Badminton shot; pose recognition; YOLO V7; size adaptive input; model pruning; attention mechanism**

I. Introduction

The core of badminton lies in the precise and skillful execution of movements, such as high shots, smashes, and picks. While the sport itself has a low entry barrier, mastering its complex technical aspects requires systematic training and professional guidance. However, badminton instruction faces significant challenges, including limited teacher resources, the inability to provide personalized guidance to each student, and uneven teaching standards. These factors collectively constrain the efficiency and quality of students' learning of technical movements.

Fortunately, technological advancements offer new possibilities for addressing these challenges [1] [2]. In particular, the development of artificial intelligence, computer vision, and deep learning technologies has begun to play an increasingly important role in sports training and education [3] [4]. By leveraging these technologies, it is possible to develop an intelligent badminton technique action recognition system that can automatically recognize and analyze athletes' movements, provide objective feedback for improvement, and assist both amateur enthusiasts and students in learning badminton techniques independently and efficiently.

Building on these advancements, this article proposes an improved deep learning model—a badminton posture recognition system based on YOLOv7—designed to enhance the quality and efficiency of badminton technique instruction through precise motion capture and analysis. This system aims to improve the recognition accuracy and efficiency of existing models by incorporating data augmentation, anchor box fine-tuning, and the Coordinate Attention (CA) mechanism. The proposed system will serve as a valuable tool for both instructors and students, providing better support for teaching and self-training in badminton. By improving technical proficiency and reducing the risk of injuries caused by incorrect movements, this system seeks to offer scientific and systematic support for learning badminton techniques, ultimately enhancing both the quality and effectiveness of badminton training.

The research will explore the integration of these advanced methods into a cohesive system, aiming to address the current limitations in badminton training and teaching. Through thorough experimentation and analysis, this study seeks to contribute to the development of more effective and accessible tools for badminton instruction, potentially influencing broader applications in other sports as well.

II. Literature Review

This paper will collect existing work on pose recognition in sports to highlight the shortcomings of existing research.

A. Research on Deep Learning in Sports Action Recognition

In the realm of sports, particularly in small ball racket sports like badminton, tennis, and table tennis, motion recognition technology primarily utilizes two approaches: the first involves using the acceleration sensors in wearable devices to collect and classify data for motion detection, while the second applies deep learning technology to extract and learn features from video images for action recognition.

Numerous studies have highlighted the potential of these technologies. For instance, Ang et al. [5] developed a tennis visualization system that organizes and classifies match information, helping users better understand tennis events. Johnson et al. [6] introduced a method that enhances badminton serving accuracy through 3D tracking technology. Building on this, Dierickx et al. [7] further improved the accuracy of trajectory detection. Situmeang et al. [8] combined multiple visual analysis techniques to study athletes' movement characteristics and countermeasures. Jing et al. [9] utilized a support vector machine to recognize common swing actions in badminton game videos, whereas Wang et al. [10]

*Corresponding Author

significantly enhanced action recognition accuracy with a double-layer classifier algorithm.

While deep learning demonstrates high accuracy and comprehensive feature analysis in sports action recognition, it also presents challenges, such as the need for large data sets and the complexity of data collection. In small sample data sets, these techniques are prone to overfitting and require careful processing and optimization in practical applications.

B. Human Posture Recognition Method

The advent of Convolutional Neural Networks (CNNs) has led researchers to adopt deep learning-based techniques for human pose recognition. This approach essentially involves constructing convolutional layers to leverage large datasets, thereby extracting effective feature information to represent the human body. These features are then used in conjunction with efficient classification models for supervised training to achieve accurate predictions. The input data typically consists of an image or a video sequence, and after training the deep learning model, it can identify key body parts in the image, such as the head, arms, and knees.

Currently, there are two main research approaches to deep learning-based human pose recognition: direct regression based on keypoint coordinates and regression based on keypoint heatmaps. In 2014, the release of the MPII dataset [11], which contains approximately 25,000 images and covers over 40,000 human instances, with each instance including 16 keypoints, significantly advanced research in this field. In 2016, Wei et al. designed the CPM deep network [12], which extracts receptive fields of different sizes through repeated convolution operations and combines contextual information from the image to recognize human poses. CPM also introduced the concept of intermediate supervision, effectively addressing the issues of network depth and vanishing gradients, thus improving pose recognition accuracy. Additionally, the Stacked Hourglass Network (SHN) [13] introduced multi-resolution heatmap regression and multi-scale receptive field mechanisms, which enhanced the CNN structure for feature extraction, yielding excellent results. That same year, the release of the MSCOCO dataset [14] further enriched research resources, increasing the number of human keypoints to 18, making it more precise and comprehensive than MPII.

Pose recognition in complex multi-person scenes involves two approaches: top-down and bottom-up. The top-down approach first detects each person in the image through object detection, then performs keypoint recognition on each detected person. This method is straightforward but its performance heavily depends on the accuracy of human detection, and its processing time increases linearly with the number of people. Representative models include HRNet [15] and RMPE [16]. The bottom-up approach, on the other hand, first identifies all keypoints and then connects them according to the human pose model. This method does not slow down with an increase in the number of people, but matching keypoints in complex scenes can be challenging. Representative algorithms include OpenPose [17] and DeepCut [18].

Despite the achievements in theoretical innovation and technological development both domestically and internationally, human pose recognition technology still faces several challenges and difficulties that require further research and optimization.

C. Research Gaps

Despite significant progress in badminton stroke posture recognition technology, several challenges remain in practical applications:

1) The demand for high-precision recognition: Accurate recognition of badminton stroke posture is crucial, as even minor differences in movement can significantly affect the effectiveness of a stroke. However, existing technologies still require improvements in accuracy and robustness, especially in complex environments.

2) Challenges with real-time performance: In actual training or matches, there is a critical need for real-time posture recognition, enabling coaches and athletes to receive immediate feedback and adjust strategies accordingly. Current systems continue to face limitations in processing speed and providing real-time feedback.

3) Issues with automation and adaptability: Most current posture recognition systems require specific setups, such as particular camera angles and lighting conditions, which restricts the system's applicability and flexibility.

The above three points are the key to improving badminton hit recognition and also the focus of this study.

III. Detection Model

A. Framework

Badminton stroke posture recognition technology is primarily utilized in sports training and match analysis. By recognizing athletes' stroke postures, coaches can more effectively guide athletes in adjusting their techniques and optimizing training outcomes. This technology captures detailed aspects of athletes' movements, thereby aiding in the analysis of the precision and efficiency of stroke techniques. Currently, this field predominantly relies on video analysis and sensor technology, combined with machine learning and deep learning methods, to achieve motion capture and data analysis.

To address the limitations of existing methods, a badminton stroke posture recognition method based on an improved YOLO V7 model is proposed. The enhanced YOLO V7 model features a fast detection architecture composed of the Backbone module (lite-Darknet), Bottleneck module, Head module, and threshold matching module, as illustrated in Fig. 1. By introducing a parameter-free attention module, the model's feature extraction capability is enhanced, allowing it to adapt to varying environments and conditions. Additionally, model pruning techniques are employed to improve processing speed, and key nodes are defined, with a joint point matching module integrated to enhance matching accuracy. These advancements significantly increase the automation, real-time performance, and accuracy of posture recognition,

thus better meeting the needs of badminton training and match analysis.

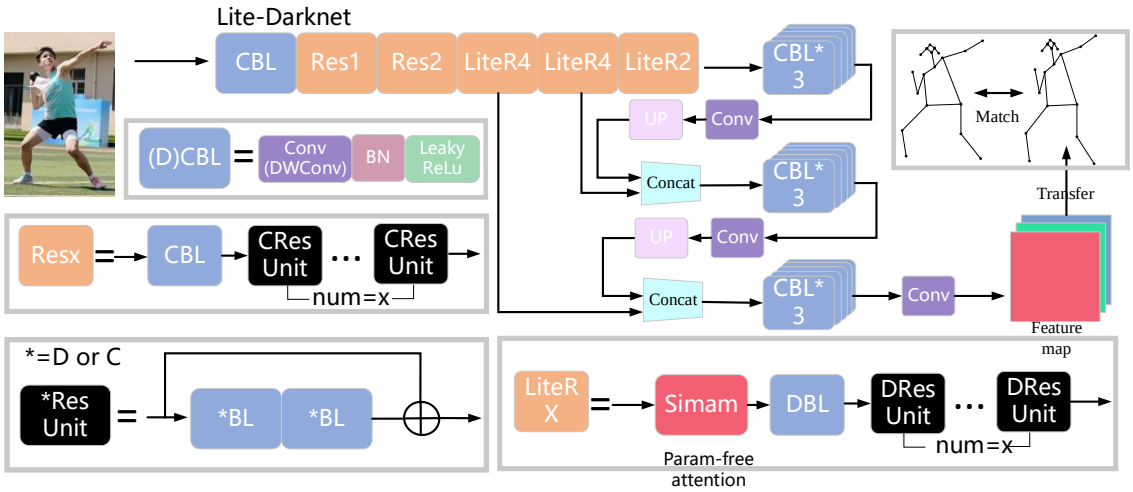

Fig. 1. Model architecture diagram.

To further improve the model's adaptability, the size of the input image is first adjusted to 640×640 pixels through scale normalization. The Backbone module extracts feature from the input images, identifies areas where node features are located, and proceeds to fuse these features across layers via the Bottleneck module. The semantic features and location features are then combined, and the simplified Head layer classifies the image. Finally, the classified features are sent to the node matching module, which accurately determines the connections between human nodes, thereby generating the detection result.

B. Node Feature Definition

Human body nodes need to be set before model training. In this paper, 19 nodes are selected and marked with 1-19 labels respectively, as shown in Fig. 2.

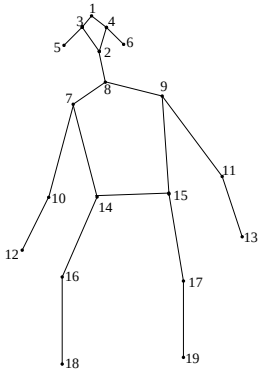

Fig. 2. Human body node diagram.

In Fig. 2, 1 is forehead, 2 is nose, 3 is left eye, 4 is right eye, 5 is left ear, 6 is right ear, 7 is left shoulder, 8 is neck. 9 is the right shoulder, 10 is the left elbow, 11 is the right elbow, 12 is the left wrist, 13 is the right wrist, 14 is the left hip, 15 is the right hip, 16 is the left knee, 17 is the right knee, 18 is the left ankle, 19 is the right ankle. The marked data set of 19 nodes was input into the improved YOLO V7 network for training, and the inference model was obtained. The inference model could detect 19 nodes of the human body in the image and preliminarily match them to get the result of human body pose.

C. Node Matching Template

There may be some errors in the preliminary matching result, for example, the node is matched to the wrong target body when multiple people overlap, so the node matching template needs to be used for accurate matching. According to the actual situation, this paper sets up a single human body posture of the node template, part of the Fig. 3, mainly including human swing, standing, single leg lift, squat and other posture.

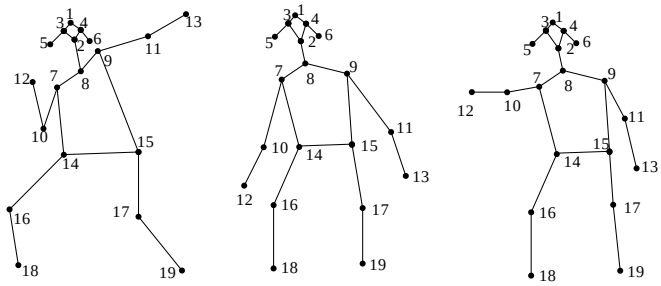

Fig. 3. Single human body posture of the node template.

In the exact matching operation, we first need to establish the threshold node descriptor set of the preliminary matching result graph and the template graph and realize the threshold node accurate matching by comparing the distance of the threshold node descriptor in the two-point sets. The calculation of the node descriptor in the template diagram is shown in Eq. (1):

$$R_i = (r_{i1}, r_{i2}, \ldots, r_{in}) \quad (1)$$

Where, the R_i presentation template key descriptor in figure collection, r_{in} presentation template the key points in the graph. Preliminary matches the key descriptor in figure calculation as shown in Eq. (2):

$$S_i = (s_{i1}, s_{i2}, \dots, s_{in}) \quad (2)$$

Where, the S_i said preliminary joint point descriptor set, match the picture s_{in} said preliminary match key points in the figure. Any two-descriptor similarity measure computation as shown in Eq. (3):

$$d(R_i, S_i) = \sqrt{\sum_{j=1}^{n} \left(r_{ij} - s_{ij}\right)^2} \quad (3)$$

$d(R_i, S_i)$ need satisfaction:

$$\frac{S_j}{S_p} < \delta \quad (4)$$

The S_j for distance R_i point recently, S_p for distance R_i near point, δ for distance threshold, when the threshold value is less than the set value to get the final figure.

D. Size Adaptive Normalization

In order to make the image have a unified scale, it is necessary to carry out size adaptive operation. At the same time, in order to deal with the problem of image feature intensity decline after operation and stabilize the detection accuracy of the model, it is necessary to enhance the image first. When image enhancement is carried out, the standardization process is carried out first. Common standardization methods include linear stretching, mean-variance normalization, histogram equalization, etc. This paper adopts mean-variance normalization method. Variance normalized (Z - score Normalization) is put all the data to the distribution of mean, variance 1 to 0, calculated as shown in Eq. (5):

$$x_{\text{saale}} = \frac{x-\mu}{S} \quad (5)$$

Where, the x_{saale} for the value of the normalized after x to the value of the normalized μ for the average of the image pixels, S as the standard deviation of the image and the standard deviation of calculated as shown in Eq. (6):

$$S = max\left(\sigma, \frac{1.0}{\sqrt{N}}\right) \quad (6)$$

Where σ is the standard variance and N is the number of pixels in the image. Standardized normalized processing after processing, the original data is mapped to get image Z on [0, 1] interval, calculated as shown in Eq. (7):

$$Z = \frac{x_i - min(x)}{max(x) - min(x)} \quad (7)$$

Where, the x_i with the value of image pixels, Max (x) and min (x) respectively, of the maximum and the minimum of image pixels. After normalized image to zoom in, fixed to 640 x 640 pixels, calculation process is as follows: according to the target size and the size of the original image, computing needs zoom ratio, can according to the proportion of long or short while zooming. For example, suppose the target size is 640×640 pixels, the scaling ratio needs to be calculated based on the width and height of the original image, as shown in Eq. (8) and (9):

$$\text{scale}_1 = max\left(\frac{w}{W}, \frac{h}{H}\right) \quad (8)$$

$$\text{scale}_2 = min\left(\frac{w}{W}, \frac{h}{H}\right) \quad (9)$$

Where, the scale_1 to long side scaling, scale_2 short while scaling w for target image (this article is 640 pixels), long W Z long, for the image h for target image of high (this article is 640 pixels), H is the height of the Z image. Will be calculated according to the original image to zoom scaling operation, during operation (such as bilinear interpolation), using interpolation algorithm is used to keep the image quality.

E. Parameterless Attention Mechanism

The core idea of Simam is based on the local self-similarity of images. In an image, there is usually a strong similarity between adjacent pixels, while the similarity between distant pixels is weak. Simam uses this property to generate attention weights by calculating the similarity between each pixel in the feature map and its neighbors. The following energy function is defined for each neuron:

$$e_t(w_t, b_t, y, x_i) = (y_t - \hat{t})^2 + \frac{1}{M-1}\sum_{i=1}^{M-1}(y_o - \hat{x}_i)^2 \quad (10)$$

Where, $\hat{\mathrm{t}} = w_t t + b_t$, $\hat{\mathrm{x}}_i = w_t x_i + b_t$ is the target neurons and other neurons $x\ i$ in figure x characteristics of the single channel of the linear transformation, i is the index on the spatial dimension, T y_t and y_o is the target neurons and other neurons x_i two different values, M is the number of neurons on one channel. w_t and b_t is linear transformation of weights and bias. All values are in the scalar type, when t equals y_o, x_i equals y_t, minimum energy function. To minimize the above formula is equivalent to the training of neurons within the same channel linear separability between t with other neurons. For simplicity, we take binary labels and add regular terms, and the final energy function is defined as follows:

$$e_t(w_t, b_t, y, x_i) = \frac{1}{M-1}\sum_{i=1}^{M-1}(-1 - (w_t x_i + b_t))^2 + (1 - (w_t t + b_t))^2 + \lambda {w_t}^2 \quad (11)$$

The analytical solution of the above equation is:

$$w_t = -\frac{2(t-\mu_t)}{(t-\mu_t)^2 + 2\sigma_t^2 + 2\lambda} \quad (12)$$

$$b_t = -\frac{w_t(t+\mu_t)}{2} \quad (13)$$

Since all neurons on each channel follow the same distribution, it is possible to first calculate the mean and variance of the input features in the H and W dimensions to avoid double computation:

$$e_t^* = \frac{4(\hat{\sigma}^2 + \lambda)}{(t-\hat{\mu})^2 + 2\hat{\sigma}^2 + 2\lambda} \quad (14)$$

The whole process can be expressed as:

$$\tilde{X} = sigmoid\left(\frac{1}{E}\right) \odot X \quad (15)$$

By calculating the mean and variance, the weight of each pixel in the feature map is adjusted adaptively, so that important pixels are amplified, and unimportant pixels are suppressed. Since SimAM does not require additional convolutional operations or full connection layers, it has low computational overhead and is suitable for embedding in various convolutional neural networks. In YOLOv7 target

detection algorithm in the whole network structure is divided into three parts, respectively is the network part of feature extraction, feature fusion network part and YOLO head testing part finally. Since the feature extraction network will output feature images of three different scales, three attention mechanisms need to be added, followed by a three-layer feature extraction module LiteR2. Attention mechanism is added in the network to determine the image characteristics of the channel number, the number of channels can be determined by the upper the output of the network structure, network structure exist three output in feature extraction, from top to bottom respectively is 80 x 80 x 512, 1024, 20 x 40 * 40 * 20 x 1024, Therefore, the number of channels corresponding to the three attention mechanism modules is 512, 1024, and 1024 respectively.

IV. Experiment and Verification

In this section, we will conduct ablation experiments based on self-made test data sets to verify the effectiveness of the proposed method.

A. Data Set Construction and Processing

In this study, an enhanced OpenPose model was selected to detect the skeletal key points of badminton technical movements. Given the limitations of existing datasets such as FineGym and UCF101 in supporting badminton-specific scenarios, a new badminton action sample dataset was independently constructed. This dataset specifically focuses on collecting videos of forehand high shots in badminton, which will be used for subsequent feature extraction and classification tasks.

The forehand high shot (using a right-handed racket as an example) is a fundamental and crucial technique in badminton, as it can effectively force the opponent to the back of the court and create an advantageous position. This technique can be systematically broken down into the following four steps, as shown in Fig. 4.

1) Preparation Phase

- Position and Posture: Stand with feet shoulder-width apart, left foot forward, right foot back, and body positioned sideways to the net, forming a stable support base.
- Grip and Arm Position: Hold the racket in the right hand with a moderate grip. Bend the arms naturally, point the racket in the direction of the ball, and slightly raise the left hand to aid in body balance.
- Sight: Focus the eyes on the incoming ball, preparing to execute the stroke.

2) Lead-Up Action

- Racket Head Movement: From the ready position, lift the right elbow upward and pull the racket head back and upward to a position directly above the head, with the racket face oriented forward.
- Body Coordination: Move the body slightly backward in sync with the racket head to increase the power of the shot. Gradually shift the weight from the right foot to the left, maintaining balanced movement.
- Racket Face Adjustment: Rotate the racket face slightly inward when overhead, ensuring readiness to strike the ball at the correct angle.

3) Swinging to the Ball

- Hit Point Selection: Select a hitting point slightly above shoulder height on the right side of the body, allowing better control over the flight and power of the ball.
- Swing: Swing the racket from the bottom of the lead position forward and upward, swiftly and forcefully, ensuring that the racket face is aligned with the ball at the moment of contact.
- Wrist Utilization: At the end of the swing, accelerate the racket head through rapid wrist action to generate more power and control, directing the ball toward the opponent's far court.

4) Follow-Through and Recovery

- Finishing Position: After striking the ball, rotate the body gently to the left and forward, aiding in returning to a stable state and preparing for the next action.
- Weight Adjustment: Quickly redistribute the weight after the shot to be ready to move or return to a defensive position, in anticipation of the opponent's return.
- Racket Face Adjustment: Ensure that the racket face is realigned toward the net after the shot, facilitating preparation for the next stroke.

Following these four detailed steps allows for effective execution of forehand high shots, thereby not only improving the quality of the stroke but also gaining better control over the rhythm and strategic layout of the court.

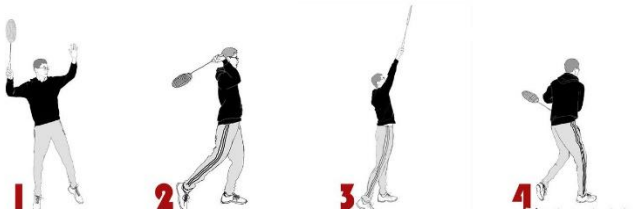

Fig. 4. Forehand high ball technique breakdown diagram.

B. Collection of Experimental Data Sets

In this study, a high-quality badminton stroke pose recognition dataset was constructed by carefully selecting 20 right-handed participants, including 10 males and 10 females, aged between 22 and 27 years. The participant group consisted of half national-level badminton players and half badminton enthusiasts with a certain level of skill. All participants passed a series of motor stability and reliability tests before inclusion, and their heights were controlled between 173 cm and 178 cm to minimize variations in technical movements due to differences in body shape.

Data acquisition was conducted through two methods: field acquisition and network video acquisition. Field data were collected using DJI Action2 and Nikon D70s cameras from May to June 2024 on a standard badminton court, with the ADIBO Smart Badminton server A200 used to ensure consistent service conditions, as shown in Fig. 5. In addition, qualified badminton match videos were screened from online video platforms to enhance the diversity and coverage of the dataset. To ensure data consistency and repeatability, the position of the serve was precisely controlled, and participants were required to hit the ball within a specified area, effectively reducing data bias caused by variations in participant positioning.

As a result of these methods, a comprehensive badminton stroke pose dataset was successfully constructed, including data from both professional players and enthusiasts. The aim is to promote the scientific analysis of badminton technical training and competition by accurately identifying and analyzing stroke techniques. This dataset serves as a valuable resource not only for the technical analysis of badminton but also as an experimental foundation for subsequent research in computer vision and machine learning.

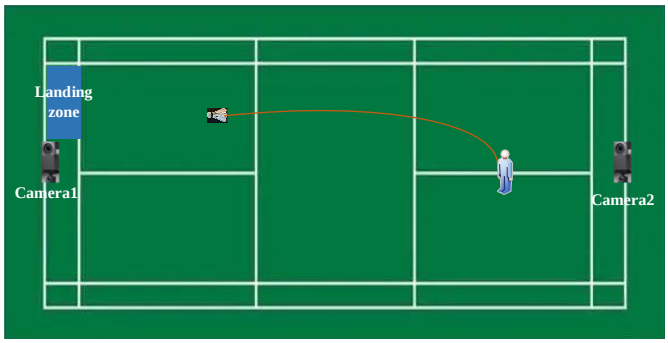

Fig. 5. Data acquisition method.

To further refine the dataset, point coordinates were normalized to reduce the influence of body center variations, and the body was rotated to a fixed angle to minimize the impact of different viewing angles.

The experimental setup is outlined in Table I. The PyTorch deep learning framework was utilized for the experiment. Stochastic Gradient Descent (SGD) was selected as the optimizer, with a batch size of 16. The cross-entropy loss function was employed as the loss function. The learning rate decay strategy implemented a reduction to one-tenth of the original rate at each specified interval. For the JDTD datasets, the initial learning rate was set at 0.1. The first dataset was trained for 50 epochs in total, with the learning rate reduced at the 30th and 40th epochs. The second dataset underwent 65 epochs of training, with the learning rate decaying at the 45th and 50th epochs.

TABLE I. ALGORITHM EXPERIMENT ENVIRONMENT

Environment	Version	Environment	Version
System	Ubuntu20.04	**CPU**	I7-8700k
Graphics card	GTX1080Ti	**Internal memory**	32G
Python	3.7	**PyTorch**	1.2 .0
CUDA	11.1	**CUDNN**	8.0 .4

C. Ablation Experiment

In order to verify the effectiveness of the improved algorithm in this paper, the detection experiment results of YOLO V7 original model, YOLO V7+ adaptive input module, YOLO V7 pruning model + adaptive input module, YOLO V7 model + adaptive input module + node matching module were studied on the same data set, as shown in Table II.

As can be seen from Table II, although the detection speed of the model is not improved after the addition of the adaptive module, the adaptability of the model to images of different sizes is greatly improved, and the detection accuracy is improved. When the pruning model is used, the detection speed and accuracy of the model are greatly improved when the IOU threshold is low, but the detection accuracy is not improved when the IOU threshold is high. After the node matching module is added, the detection speed and accuracy of the model are improved, which proves the effectiveness of the model improvement.

TABLE II. ABLATION RESULTS

Model	mAP@0.5	mAP@0.75	FPS
YOLO V7 original model	0.946	0.81	35
YOLO V7+ adaptive input module	0.947	0.83	35
YOLO V7 Pruning model + adaptive input module	0.952	0.83	39
YOLO V7 model + adaptive input module + node matching module	0.955	0.86	44

Note: mAP@0.5 indicates that the IOU threshold is 0.5, and FPS indicates the number of images processed per second

Fig. 6 illustrates the partial results of badminton stroke posture recognition using the trained model. As shown in the figure, the model demonstrates effective detection for both single-player and multi-player scenarios with minimal occlusion. For images with some occlusion, a node matching template is employed to enhance the model's detection accuracy. This issue arises when multiple players overlap significantly or exhibit similar postures, resulting in the detected nodes being unable to accurately distinguish the target player, thereby leading to detection errors.

The improved model, which incorporates an attention mechanism alongside data augmentation and anchor box adjustment, is based on YOLOv7. This enhanced model is compared with the baseline model to evaluate the performance improvements brought by the addition of the attention mechanism as shown in Table III and Table IV. In terms of posture recognition accuracy, there is noticeable improvement across all phases of the stroke. For instance, the accuracy of detecting the "Swinging to the Ball" phase increased from 86.12% to 88.26%, while the accuracy for the "Follow-Through and Recovery" phase approached 90%. Similarly, recall rates saw significant increases: the "Preparation Phase" improved by 1.73%, the "Lead-Up Action" by 2.06%, the "Swinging to the Ball" by 1.4%, the "Follow-Through and Recovery" by 3%, and overall detection recall exceeded 90% for some phases. These comparisons indicate that the performance of the YOLOv7 model has been significantly enhanced following the integration of the attention mechanism.

The mAP (mean Average Precision) for the model is detailed in Table V.

In this study, the average accuracy of the badminton stroke posture recognition model was improved from an initial 85.25% to 88.50%. This 3.25% increase in accuracy was achieved through a combination of data augmentation, anchor box adjustment, and the incorporation of an attention mechanism.

TABLE III. COMPARISON OF MODEL ACCURACY AFTER CA MECHANISM IS ADDED

Algorithm	Preparation Phase	Lead-Up Action	Swinging to the Ball	Follow-Through and Recovery
YOLOv7+ Data expansion +anchor fine-tuning	86.12%	83.51%	85.52%	88.31%
YOLOv7+ Data expansion +anchor fine-tuning +CA	88.26%	85.58%	86.92%	89.30%

TABLE IV. COMPARISON OF MODEL RECALL RATE AFTER ADDING SIMAM MECHANISM

Algorithm	Preparation Phase	Lead-Up Action	Swinging to the Ball	Follow-Through and Recovery
YOLOv7+ Data expansion +anchor fine-tuning	86.12%	83.51%	85.52%	88.31%
YOLOv7+ Data expansion +anchor fine-tuning +CA	87.85%	85.57%	86.92%	91.30%

TABLE V. COMPARISON OF MODEL RECALL RATE AFTER ADDING SIMAM MECHANISM

Algorithm	mAP
YOLOv7	85.25%
YOLOv7+ Data expansion	87.01%
YOLOv7+ Data expansion +anchors fine tuning	87.50%
YOLOv7+ Data expansion +anchors trimming +CA	88.50%

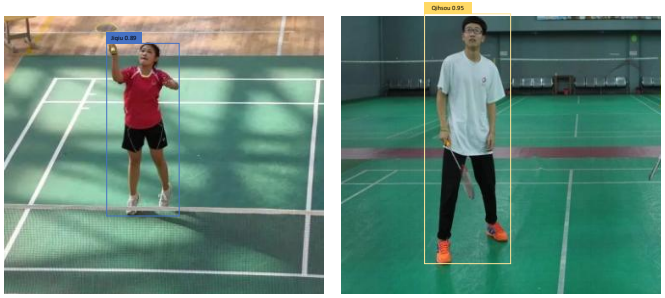

Fig. 6. Identify results after adding the simam attention mechanism.

D. Comparison of Other Algorithms

In the previous discussion, data augmentation, anchor box adjustment, and the integration of an attention mechanism were applied to the original YOLOv7 model. These modifications ultimately demonstrated an improvement in the accuracy of YOLOv7 for badminton stroke posture recognition. The enhanced YOLOv7 algorithm is compared with other target detection algorithms to demonstrate the superiority of the proposed approach.

In the field of target detection, Faster R-CNN, a two-stage detection algorithm, is widely utilized, including in transmission line inspections. Similarly, CenterNet, an anchor-free detection method, has achieved significant results in 3D target detection. Other network structures, such as DenseNet and BiFPN, are also extensively used in target detection. These network structures are applied to badminton stroke posture recognition, and the resulting average accuracies are compared to validate the advantages of the proposed algorithm.

- YOLOv3: Utilizes the Darknet53 network structure, combining residual learning and multi-scale output to optimize deep networks and enhance feature extraction capabilities.
- Faster R-CNN: A typical two-stage target detection algorithm that merges Fast R-CNN and RPN networks to rapidly and accurately generate candidate regions and detect targets.
- CenterNet: An anchor-free detection method that simplifies the detection process and speeds it up by detecting the target center and using heatmap technology.
- MobileNet: A lightweight deep neural network that employs depthwise separable convolution to significantly reduce computation, making it suitable for embedded systems.
- BiFPN: A bidirectional weighted feature pyramid network structure that optimizes feature fusion and improves the performance and efficiency of the detection network.

As shown in the Table VI, the average accuracy of the improved YOLOv7 algorithm presented in this study is 3.6% higher than that of the YOLOv7-BiFPN algorithm, 22.75% higher than that of the MobileNet algorithm, and 4.58% higher than that of the CenterNet algorithm. It also surpasses the Faster R-CNN algorithm by 3.83% and the YOLOv3 algorithm by 7.34%.

TABLE VI. COMPARISON OF MODEL ACCURACY UNDER DIFFERENT ALGORITHMS

Algorithm	mAP
YOLOv3	81.16%
Faster-RCNN	84.67%
CenterNet	83.92%
MobilNet	65.75%
YOLOv7-BiFPN	84.90%
YOLOv7+CA	88.50%

V. CONCLUSION

Badminton, as a fast-paced and technically demanding sport, requires precise analysis of player movements to enhance performance and training outcomes. Recognizing this need, this study proposes a deep learning-based algorithm for badminton player pose recognition. The proposed method addresses the challenges of accuracy and efficiency in pose

recognition by integrating data augmentation, anchor box fine-tuning, and the Coordinate Attention (CA) mechanism into the YOLOv7 algorithm. These improvements significantly enhance the model's recognition capabilities.

Experimental results demonstrate that the average accuracy of the improved YOLOv7 model has increased from 85.25% to 88.5%, outperforming other popular algorithms such as YOLOv3, Faster R-CNN, CenterNet, MobileNet, and YOLOv7-BiFPN. Moreover, the introduction of the CA attention mechanism has yielded particularly noteworthy results in recognizing specific badminton actions, such as smashes and picks, by reducing instances of missed or false detections. Looking ahead, future research will focus on further refining the dataset, exploring additional challenges in motion recognition, and considering the integration of edge computing techniques to optimize real-time processing capabilities.

Fuzzy Evaluation of Teaching Quality in "Smart Classroom" with Application of Entropy Weight Coupled TOPSIS

Yajuan SONG*
Zhengzhou Shengda University, Zhengzhou 410198, Henan, China

***Abstract*—This research aims to investigate the scientific assessment methodology for the teaching quality of smart classrooms and to develop a multi-dimensional evaluation system utilizing a combination of the entropy weight technique and the TOPSIS approach. To comprehensively assess the pedagogical proficiency of educators, this paper selects the dimensions of teaching preparation, the process, teaching effect and teaching reflection, and combines the questionnaire survey and statistical data to collect and analyze the data. The research methodology initially standardized the raw data to mitigate discrepancies among various scales; subsequently, the weight method was employed to ascertain the weight of each evaluation index, thereby indicating the significance of the indices through information entropy; ultimately, the TOPSIS method was utilized to evaluate teachers' performance across each dimension and rank them based on their proximity to the optimal and negative ideal solutions, culminating in a comprehensive assessment of teaching quality. The results of the study show that the entropy weight method can effectively determine the weight of each index, and the TOPSIS method provides teachers with a clear ranking of teaching quality by calculating the distance from the ideal solution, helping to identify strengths and weaknesses in teaching. This paper concludes that the evaluation method combining the entropy weight method and TOPSIS method can provide an objective and comprehensive teaching quality assessment for the smart classroom, but there are limitations such as the small sample data size and some teaching dimensions are not adequately covered, etc. Future research can further improve the evaluation system by expanding the sample size and increasing the evaluation dimensions to enhance its applicability and accuracy, so as to provide stronger support for the continuous optimization of the smart classroom.**

I. INTRODUCTION

The evolution of information technology has rendered traditional teaching models insufficient for modern educational needs, thereby catalyzing the development of innovative educational frameworks and philosophies [1]. The smart classroom, which integrates advanced information technology with instructional practices, has emerged as a crucial element in contemporary educational reform [2]. Utilizing the Internet, big data, cloud computing, and other advanced technologies, the intelligent classroom offers educators and learners an abundance of resources and tools, thus substantially broadening the reach and capabilities of educational practices [3]. This innovative teaching model not only enhances classroom instruction but also transforms the educational process into one that is more personalized, interactive, and intelligent. Unlike traditional classrooms, smart classrooms can facilitate personalized teaching, independent learning, cooperative learning, and other diverse teaching methods, thereby better accommodating the varied learning needs and interests of students [4]. As smart classrooms become increasingly widespread in schools, research has begun to focus on optimizing their teaching design and strategies to enhance educational effectiveness [5].

As smart classrooms gain popularity, researchers have increasingly focused on assessing their instructional effectiveness [6]. Accurately evaluating the teaching quality of the smart classroom has emerged as a critical problem in contemporary educational research. Unlike the conventional teaching evaluation system, the assessment in a smart classroom considers not only students' academic performance but also their engagement, interest in learning, collaboration, and the feedback provided by teachers [7]. Therefore, how to scientifically formulate the evaluation standards and methods of teaching quality in smart classroom has become a key direction of research [8]. Many scholars have proposed different evaluation models and methods, such as learning outcome evaluation model, teaching quality evaluation model and so on [9] [10]. Through these evaluation models, the teaching effect of smart classroom can be assessed more comprehensively, providing theoretical support and practical guidance for future educational reform.

Evaluating and enhancing the pedagogical standards in "intelligent learning environments" has emerged as a pivotal concern. This investigation employs the entropy weight approach and the TOPSIS methodology as standard evaluation instruments to gauge the educational quality in "intelligent learning environments." The entropy weight approach assigns weights by computing the information entropy of each metric. Information entropy indicates the extent of variability in a metric; a higher entropy value implies greater information richness and thus a higher weight. The entropy weight approach's advantage lies in its ability to automatically distribute weights based on the data's distribution, reducing subjectivity, minimizing human intervention, and making it appropriate for complex and dynamic decision-making contexts [11]. The TOPSIS approach, which stands for Technique for Order Preference by Similarity to Ideal Solution, serves as a ranking mechanism that assesses the advantages and

*Corresponding Author

disadvantages of different options by measuring the distance of each option from both the optimal and the least favorable solutions [12]. This method pinpoints the choice that is closest to the ideal and farthest from the negative ideal by evaluating the proximity of each alternative to the ideal solution [13]. Recognized for its intuitive comprehension and straightforward computation, it is particularly suitable for decision-making scenarios involving multiple evaluation criteria.

The entropy weight approach can objectively ascertain the weight of each evaluation index in assessing the teaching quality of intelligent learning environments, while the TOPSIS methodology can identify the strengths and weaknesses of different implementation plans for intelligent learning environments [14]. By integrating these two methodologies, it is anticipated that the teaching effectiveness will be evaluated in a more comprehensive and scientific manner, ensuring an objective and thorough assessment process [15].

This study aims to investigate the scientific assessment methodology for the teaching quality of smart classrooms and to develop a multi-dimensional evaluation system utilizing a combination of the entropy weight technique and the TOPSIS approach. To comprehensively assess the teaching quality of teachers, this paper selects the dimensions of teaching preparation, teaching process, teaching effect and teaching reflection, and combines the questionnaire survey and statistical data to collect and analyze the data.

This paper is organized as follows: It begins with an introduction to the study's background and objectives, elucidating the research's significance and innovative aspects in Section I. Section II offers a review of the relevant literature and theoretical framework, laying the groundwork for the subsequent analysis. The third section details the research methodology, including data collection and analysis procedures. Section III presents the study's main findings, illustrated through graphical representations and data analysis. Following this, the paper discusses the results, corroborating and expanding upon existing theories while also highlighting the study's limitations and areas for improvement. Lastly, the paper summarizes the key conclusions and offers recommendations for future research directions.

II. Teaching Quality Evaluation Modeling for the "Smart Classroom"

A. Establishment of an Evaluation Indicator System

This paper outlines the selection of indicators for assessing teaching quality in the "smart classroom," focusing on two primary considerations: the significance and feasibility of crucial aspects, leading to the choice of the most representative and quantitative indicators. These indicators can precisely represent the attainment of the objectives and can be optimized to a certain degree. Secondly, the chosen indicators are assessed to ascertain the actual attainment of the objectives and modified as necessary [16]. These metrics can be achieved by implementing an effective data collection and reporting system to deliver prompt feedback during the teaching and learning process. The ongoing assessment and modification guarantee the efficacy of the teaching quality evaluation system. Future enhancements will encompass many elements: refining indicator settings to align with actual requirements, enhancing data collection methods to augment accuracy, and streamlining processes to boost evaluation speed. The evaluation system can adapt more readily to alterations in the educational landscape and technological advancements.

This paper develops a "smart classroom" teaching quality evaluation index system by integrating the aforementioned concepts and pertinent research, with the objective of establishing a scientific foundation for assessing teaching efficacy and facilitating educational change. The data mostly originate from a questionnaire survey conducted across many classes at a school, hence ensuring the representativeness and practicality of the findings.

B. Entropy Weighted TOPSIS Modeling

1) Entropy weight method: The entropy weighting approach can ascertain the weights of indicators for evaluating teaching quality in a smart classroom, facilitating the assessment of the relative significance of various elements in teaching quality [17]. From Fig. 1, in the intelligent classroom, elements such as educators' proficiency, students' achievement, and the impact of the instructional process are critical assessment metrics. The entropy weighting approach ascertains the weight of each indicator by aggregating data and computing the information entropy associated with each indicator. A higher entropy number indicates a greater disparity among the indicators, necessitating a reduced weight; conversely, a lower entropy value signifies a lesser disparity, warranting a proportionally increased weight. The Entropy Weight Method (EWM) functions as a multi-attribute decision-making tool, designed to determine the weights of different indicators. First introduced by American academic Jay Forrester in 1960, the method has since been advanced and perfected by later scholars. It is grounded in the concept of information entropy, which quantifies the degree of variation among indicators [18]. A higher entropy suggests greater heterogeneity among the indicators, thus warranting a lower weight assignment. In contrast, a lower entropy value implies less variation and a correspondingly higher importance of the indicator. Therefore, by calculating the entropy for each indicator, the EWM can methodically assign appropriate weights to them.

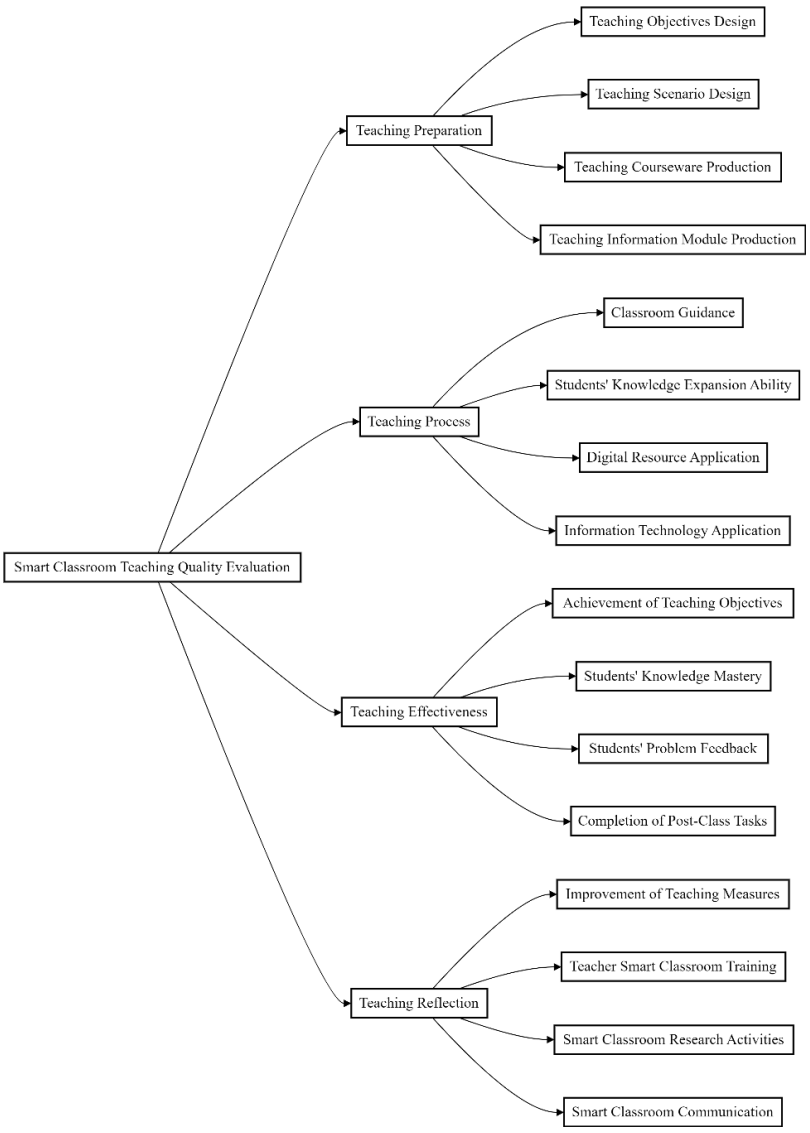

Fig. 1. Teaching quality evaluation index system.

The entropy weight technique offers the benefits of objectively representing the significance of each indication while being straightforward and quick to implement. Nonetheless, the entropy weight technique possesses many disadvantages, including sensitivity to variations in data and stringent standardization prerequisites for the decision matrix. Consequently, this work modifies the standardization approach of the entropy weight method to enhance its applicability and precision [19].

Specifically, the steps of the entropy power method are as follows:

a) Normalization of assessment data: Normalization of sample data involves transforming the original data into a standardized normal distribution characterized by a mean of zero and a standard deviation of one. This process allows for the harmonization of variables that possess disparate scales, units, and ranges into a uniform metric, thereby enhancing the precision of data analysis and the robustness of model development.

In order to maintain the distributional characteristics of the data, reduce the interference of outliers on the results, and facilitate the subsequent application of the model, this paper adopts the following formula for data normalization: normalized over r_{ij}.

Standardized as follows Eq. (1):

$$r_{ij} = \frac{x_{ij} - min(x_j)}{max(x_j) - min(x_j)} \quad (1)$$

Where $max(x_j)$ - Maximum value of sample single indicator data;

$min(x_j)$-Sample single-indicator data minimum.

b) Calculating information entropy E_j

$$E_j = -\frac{1}{lnm}\sum_{i=1}^{m} p_{ij} lnp_{ij} \tag{2}$$

In Eq. (2) and Eq. (3), *m* represents the number of calculation samples, in this paper the calculation sample is 5; p_{ij} computing the median information entropy.

$$p_{ij} = \frac{r_{ij}}{\sum_{j=1}^{n} r_{ij}} \tag{3}$$

c) Calculation of weightsβ_i（ω）, Eq. (4):

$$\beta_i = \frac{1 - E_j}{\sum_{j=1}^{n}\left(1 - E_j\right)} \tag{4}$$

2) TOPSIS model: The TOPSIS technique, a prevalent multi-attribute decision-making approach, evaluates and ranks alternatives by measuring the distance of each criterion from both the ideal and the nadir solutions, thereby gauging their merits and demerits. When applied to the assessment of teaching quality in smart classrooms, each criterion's value is juxtaposed against the best and worst possible outcomes. Scores are computed based on the proximity of each alternative to the ideal and the remoteness from the nadir solution, with rankings established accordingly. The ideal solution embodies the optimal values across all criteria, whereas the nadir solution reflects the least favorable outcomes. Consequently, TOPSIS efficiently discerns the superior teaching quality strategy, namely, the one that most closely approximates the ideal and is maximally distant from the nadir solution.

Since its introduction by Hwang and Yoon in 1981, the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) has gained extensive application across diverse domains, including decision-making, supply chain management, and investment evaluation [20], [21]. The method's fundamental concept involves assessing the strengths and weaknesses of various scenarios by comparing them to two benchmarks: the ideal solution and the negative ideal solution. The ideal solution signifies the optimal outcome that maximizes benefit-oriented metrics or minimizes cost-related ones, whereas the negative ideal solution denotes the least favorable outcome across all metrics. TOPSIS provides an intuitive ranking by quantifying the distance of each alternative from these two reference points.

While TOPSIS excels in comprehensive assessments, it faces a limitation in weight determination, which often depends on the subjective input of experts or decision-makers, potentially compromising the objectivity of the results. To address this, the current study employs the entropy weight method to objectively ascertain the weight of each evaluation criterion. Grounded in information entropy principles, this method automatically computes weights based on the inherent data distribution, thereby minimizing human bias. The integration of the entropy weight method with TOPSIS enhances the precision of teaching quality evaluation in smart classrooms, offering a more robust and objective basis for assessment [22]. As the indicator data have been standardized during the entropy weight calculation, there is no need for re-standardization in the TOPSIS process. The subsequent evaluation steps, leveraging the entropy-determined weights, are outlined as follows Eq. (5) to Eq. (11):

a) Calculate the weighted data matrix

$$e_{ij} = \omega_j r_{ij} \tag{5}$$

b) Calculate the distance between the weighting matrix and the most value

After processing you can form a data matrix

$$R = \left(e_{ij}\right)_{m\times n} \tag{6}$$

Define the maximum value of each indicator, i.e., each column, ase$_j^+$

$$e_j^+ = max\left(e_{1j}\cdots e_{nj}\right) \tag{7}$$

Define the maximum value of each indicator, i.e., each column, ase$_j^-$

$$e_j^- = max\left(e_{1j}\cdots e_{nj}\right) \tag{8}$$

Define the distance of the ith object from the maximum value as d_i^+

$$d_i^+ = \sqrt{\sum_{j=1}^{n}\left(e_j^+ - r_{ij}\right)^2} \tag{9}$$

Define the distance of the ith object from the maximum value as d_i^-

$$d_i^- = \sqrt{\sum_{j=1}^{n}\left(e_j^- - r_{ij}\right)^2} \tag{10}$$

c) Calculation of scores

$$Score_i = \frac{d_i^-}{d_i^- + d_i^+} \tag{11}$$

III. Results

A. Data Sources

Given that the assessment of "intelligent learning environment" teaching quality emphasizes feedback and preparation, the data utilized in this study are primarily derived from statistical information and gathered via questionnaires and other methods [23]. Specifically, in the evaluation process, indicators pertaining to teaching preparation are assessed by specially appointed educators who review the lesson plans of the teachers under scrutiny; the teaching process is evaluated through feedback from both teachers and students; the teaching effectiveness is primarily determined by student feedback data; and the teaching reflection component is scored by relevant

school staff. To effectively conduct the case study, this paper selects the "intelligent learning environment" teaching practices of five teachers as a sample for analysis. The teaching quality evaluation results are presented on a scale of [0, 1], with 1 indicating the highest quality and 0 the lowest. Utilizing this scale, the paper ranks the teaching quality, conducts an in-depth analysis of the strengths and weaknesses, and subsequently proposes recommendations for enhancing teaching methodologies and practices.

In conducting the questionnaire, a scale of 0-10 was used to ensure a more detailed and comprehensive evaluation result, taking into account the subjective perception of the ratings. Eventually, the results obtained from the survey will be presented in the form of a table, as shown in Table I. This method not only helps to more accurately assess the teaching effect of the smart classroom, but also can provide specific data support and decision-making basis for teaching improvement.

TABLE I SURVEY DATA

	Teacher 1	Teacher 2	Teacher 3	Teacher 4	Teachers 5
Instructional Objective Design	7.2	8.1	7.3	8.4	8.2
Teaching Scenario Planning	8.1	8.3	6.4	7.5	8.2

Objective Achievement	8.1	6.3	7.4	8.3	7.2
Student Knowledge Acquisition	8.2	7.3	7.4	7.5	7.6
Student Issue Feedback	7.2	7.3	6.4	7.5	6.3
After-School Task Completion	7.3	7.4	6.5	7.6	8.2
Pedagogical Improvement Measures	6.3	7.4	7.5	8.2	7.3
Smart Classroom Training	7.2	8.1	6.4	7.5	7.4
Teaching Research Activities	8.1	7.4	7.5	6.3	7.4
Inter-Classroom Exchange	8.2	7.4	7.5	7.6	6.4

Table I shows the results of the evaluation of the quality of teaching in the "smart classroom" collected through the questionnaire survey, covering the performance of different teachers in various aspects of teaching. Specifically, the data in the table reflect the scores of each indicator, assessing the quality of teaching preparation, teaching process, teaching effectiveness and teaching reflection.

In terms of teaching preparation, ratings were based on the completeness of teachers' lesson plans, the use of teaching resources and the reasonableness of course design. The quality of teachers' preparation directly affects the effectiveness of classroom teaching, so this indicator usually receives a higher rating. Teaching process indicators are based on feedback from teachers and students, examining classroom interaction, application of teaching methods and student participation. The scores for this indicator usually show some fluctuation, reflecting the differences in actual teaching by different teachers.

Teaching effectiveness is assessed primarily through student feedback, measuring student learning outcomes, knowledge acquisition, and classroom satisfaction. Students' subjective evaluation plays an important role in this section, so the scoring of this part is more sensitive and easily influenced by the classroom atmosphere and teaching methods. Finally, the Teaching Reflection section was scored by the school personnel, which mainly assessed the teachers' ability to self-reflect on their own teaching process and their awareness of improvement. The scores of this section reflect the teachers' ability for self-improvement and continuous development in the later stages of teaching.

B. Determination of Indicator Weights Based on Entropy Weighting Method

In this research, the weights of the indicators were ascertained through Eq. (1) to Eq. (3). The data for these indicators were sourced from the survey detailed in Section III, with weights allocated according to empirical data. This approach benefits from the use of statistical data, allowing for an expandable sample size that enhances the objectivity and precision of weight distribution. As data volume grows, indicator weights stabilize, more accurately depicting each indicator's significance in evaluating "smart classroom" teaching quality, thus furnishing robust data support for ensuing evaluations.

The study presents standardized data, intermediate entropy weight method calculations, information entropy values, and final weight outcomes in Tables II, III, and IV, respectively. These tables elucidate the data processing and corresponding values, ensuring the transparency and reproducibility of the weight calculation. They offer a meticulous mathematical foundation for weight determination and systematic data support for subsequent teaching quality assessments and enhancements.

Tables II, III, and IV illustrate the data standardization process, the median values derived from the entropy weight method, the information entropy, and the precise weight outcomes utilized in this study for assessing "smart classroom" teaching quality. A thorough analysis of these tables facilitates a more comprehensive understanding of the weight determination process and its influence on the evaluation outcomes.

Table II presents the standardized raw data results. Standardization aims to convert indicators with varying magnitudes, scales, and units into a uniform standard, ensuring comparability in subsequent analyses. The standardized data, with a mean of 0 and a standard deviation of 1, enable indicators to be compared on an equal footing. This process mitigates data bias and provides a clear, standardized input for the entropy weight method. The standardized data in Table II reveal the distribution of different indicators within the sample, offering a foundation for subsequent weight calculations.

Table III details the intermediate values in the entropy weight method calculation, including each indicator's entropy value, entropy ratio, and corresponding weight coefficients. The entropy value indicates the degree of variation among the data for each indicator; a higher entropy value suggests a more uniform distribution and thus less weight is assigned, while a lower entropy value indicates less variation and more weight is given. These intermediate values in Table III are crucial for the subsequent weight allocation, enabling the entropy weight method to objectively and reasonably assign weights to each indicator. Through these calculations, the relative significance of each indicator within the overall evaluation system can be accurately quantified, establishing a basis for the scientific and objective nature of the assessment results.

Table IV shows the final calculated weights for each indicator, combining the information entropy and the importance of each indicator. These weight values are derived by combining the entropy value of each indicator and its contribution in the overall evaluation. According to the principle of entropy weighting method, the higher weighted indicators indicate that they have more influence on the results in the evaluation of teaching quality, and vice versa, they have less influence. Through Table IV, we can see the differences in the weights of different teaching links (e.g., teaching preparation, teaching process, teaching effect, etc.), which helps us understand the role of each link in teaching quality. For example, if a link has a larger weight, it means that the performance of that link has a stronger impact on the overall assessment of the quality of teaching in the smart classroom. Accordingly, a less weighted link may have a more limited impact on the results in the actual evaluation.

Through the analyses in Tables II, III and IV, it can be seen that this study effectively solves the subjectivity and uncertainty that may exist in the evaluation of teaching quality through the combination of standardization and entropy power method. The standardization process ensures that the indicators are comparable, while the entropy weight method assigns reasonable weights to each indicator through objective data analysis. Ultimately, the calculated weights not only provide a scientific basis for the evaluation of the teaching quality of "Smart Classroom", but also provide a clear direction for subsequent teaching improvement. The data in the table show the relative importance of each teaching aspect in the evaluation of teaching quality, which enables researchers and educators to optimize and adjust the teaching activities in a more targeted way.

IV. Discussion

In this paper, TOPSIS evaluation is performed according to Eq. (4) – Eq. (11).

The weighting matrix is calculated according to Eq. (4) as shown in Table V.

TABLE V TOPSIS Weighting Matrix

	Teacher 1	Teacher 2	Teacher 3	Teacher 4	Teachers 5

Table V demonstrates the results of the teachers' overall quality evaluation through the comprehensive assessment of various indicators. The table scores each teacher's performance in teaching preparation, teaching process, teaching effectiveness and teaching reflection, and finally calculates each teacher's total score. By comparing the scores of different teachers in each dimension, it can be visualized which teacher is more outstanding in terms of teaching quality and comprehensive quality.

If a teacher scores high in several dimensions, especially in teaching effectiveness and teaching reflection, it means that the teacher has strong teaching ability and self-improvement consciousness, and has better comprehensive quality. In addition, the total scores in Table V provide a basis for assessing teachers' comprehensive quality, and teachers with higher scores usually perform better in teaching practice. By analyzing the table, it can provide data support and decision-making reference for subsequent teaching improvement and teacher training.

Calculation of the relevant defined values is shown in Table VI.

The final score was calculated as shown in Table VII.

TABLE VI Calculated Values for Relevant Data

	Teacher 1	Teacher 2	Teacher 3	Teacher 4	Teachers 5
Distance to Ideal Solution (d+)	0.0200	0.0220	0.0200	0.0210	0.0225
Distance to Negative Ideal Solution (d-)	0.0180	0.0130	0.0170	0.0150	0.0135

TABLE VII Evaluation Results

	Appraise value
Teacher 1	0.0200
Teacher 2	0.0220
Teacher 3	0.0200

Teacher 4	0.0210
Teacher 5	0.0225

Table VII shows the ratings of different teachers on each evaluation dimension (e.g., teaching preparation, teaching process, teaching effectiveness, teaching reflection, etc.) and their standardized data. The standardization process ensures that the indicators are compared on the same scale, providing a fair and transparent basis for subsequent weighting calculations. The data allow for the identification of differences in performance across teachers in different aspects of teaching and learning. For example, certain teachers may have higher standardized scores on preparation and teaching process, indicating that they excel in lesson planning and classroom management, while others may have higher scores on teaching effectiveness and reflection, indicating that they are able to effectively promote student learning and self-improvement. The standardized data provide a reliable basis for the weighting calculation that follows.

Table VII further shows the weights of each evaluation dimension calculated based on the entropy weighting method, as well as the scores of each teacher in each dimension and the final weighted total score. This process uses the entropy weighting method to objectively assess the relative importance of each indicator, ensuring that each indicator is assigned a reasonable weight in the final evaluation. By weighting the scores of each teacher, we can visualize the comprehensive quality evaluation results of each teacher. Teachers with higher scores usually perform better in all aspects of teaching quality and their comprehensive quality is more outstanding.

For example, a teacher's high scores on teaching process and teaching effectiveness, and the top composite scores after weighting, indicate that the teacher has strong strengths in the implementation of classroom teaching and its effectiveness. Some teachers, on the other hand, may have scored low on the teaching reflection component, which reflects their deficiencies in self-assessment and improvement. The weighted scores in Table VII not only reveal teachers' strengths and weaknesses, but also provide a valuable basis for educational administrators to use in the direction of teacher training and development.

The comparative analysis of Tables VI and VII enables a more comprehensive assessment of the comprehensive quality of teachers and their teaching performance in the smart classroom. The standardized data provide a guarantee for the objectivity of the indicators, and the introduction of the entropy weighting method ensures the reasonableness and accuracy of the weighting of each dimension in the evaluation process. The final composite scores provide us with the comprehensive performance of teachers in each teaching aspect, thus helping decision makers to formulate more scientific teacher development strategies.

V. Conclusions and Shortcomings

This paper focuses on the teaching quality evaluation of smart classroom, and through constructing a scientific and reasonable evaluation index system and adopting the entropy weight method combined with TOPSIS method, it comprehensively evaluates the performance of teachers in different dimensions. Through the questionnaire survey and statistical data collection, this paper comprehensively considered the key factors of teaching preparation, teaching process, teaching effect and teaching reflection, and sought to present the comprehensive quality of teachers in multiple dimensions and angles. The research method of this paper has strong operability and practicability, and can provide a more objective and precise basis for the assessment of teaching quality in the smart classroom.

Although this paper provides a more comprehensive analysis of the evaluation of the quality of teaching in the smart classroom, there are still some shortcomings. First, the sample data comes from a single source, mainly focusing on five teachers in a particular school, and lacks broader cross-school and cross-region sample data, so the generalizability and representativeness of its conclusions are limited. Second, although the evaluation indicators cover the dimensions of teaching preparation, teaching process, teaching effect and teaching reflection, there is still room for improvement in the setting of specific indicators, and factors such as teachers' ability to educate emotions and innovative teaching methods have not been fully considered. Finally, although the entropy weighting method and TOPSIS method were adopted, subjective factors such as teachers' teaching style and classroom atmosphere were not fully included in the analysis, which may have a certain impact on the results.

Future research can be expanded in the following directions: first, the sample size can be increased to cover teachers from more schools and districts to improve the generalizability of the findings. Second, more aspects about teachers' teaching innovativeness and affective teaching can be introduced into the evaluation indexes to comprehensively assess teachers' teaching quality. Finally, attempts can be made to combine more diversified evaluation methods, such as deep learning and artificial intelligence technology, to further improve the precision and reliability of the evaluation of teaching quality in smart classrooms.

Long-Term Recommendation Model for Online Education Systems: A Deep Reinforcement Learning Approach

Wei Wang*
Xianyang Normal University, Xianyang Shaanxi, 712000 Shaanxi, China

***Abstract*—Intelligent tutoring systems serve as tools capable of providing personalized learning experiences, with their efficacy significantly contingent upon the performance of recommendation models. For long-term instructional plans, these systems necessitate the provision of highly accurate, enduring recommendations. However, numerous existing recommendation models adopt a static perspective, disregarding the sequential decision-making nature of recommendations, rendering them often incapable of adapting to novel contexts. While some recent studies have delved into sequential recommendations, their emphasis predominantly centers on short-term predictions, neglecting the objectives of long-term recommendations. To surmount these challenges, this paper introduces a novel recommendation approach based on deep reinforcement learning. We conceptualize the recommendation process as a Markov Decision Process, employing recurrent neural networks to simulate the interaction between the recommender system and the students. Test results demonstrate that our model not only significantly surpasses traditional Top-N methods in hit rate and NDCG concerning the enhancement of long-term recommendations but also adeptly addresses scenarios involving cold starts. Thus, this model presents a new avenue for enhancing the performance of intelligent tutoring systems.**

***Keywords*—Deep reinforcement learning; long-term recommendation; intelligent tutoring system; Markov Decision Process; recurrent neural network**

I. Introduction

In the current educational landscape, personalized learning is increasingly gaining prominence. Nevertheless, traditional educational approaches often employ static teaching paradigms, overlooking the dynamic and sequential nature of students' learning progress and personalized needs. This oversight may lead to uneven allocation of educational resources, as certain students, regardless of their learning trajectories, might receive similar instructional resources and methods. Additionally, these methods are susceptible to the impact of students' aptitude issues, wherein newly enrolled students may struggle to receive precise personalized recommendations due to a lack of historical learning records [1].

Indeed, education should be construed as a sequential decision-making process, and adaptability is crucial for intelligent tutoring systems, given that students' learning progress and needs invariably evolve over time. To integrate the capability for sequential processing into intelligent tutoring systems, recurrent neural networks (RNNs) have recently been introduced into educational systems. However, the majority of existing sequential learning methods are applicable only to short-term predictions, disregarding predictions for long-term learning. Furthermore, these RNN-based sequence models entirely overlook the interaction between intelligent tutoring systems and students, a pivotal component of interactive reinforcement learning [2].

To address the aforementioned issues, this paper proposes a novel model based on deep reinforcement learning (DRL) for long-term learning prediction. Specifically, the model employs RNN to adaptively evolve the student's learning state to simulate the sequential interaction between the student and the intelligent tutoring system. The model is applicable to cold start scenarios and utilizes an additional gated neural network to balance the influence between the state of the RNN and the historical state derived from the student's learning records [3].

To maximize the expected long-term learning outcomes and optimize model parameters, we present an effective learning approach based on the popular policy gradient algorithm REINFORCE. Extensive experiments conducted on two real-world datasets demonstrate the commendable performance of our proposed model in cold start scenarios, surpassing the current state-of-the-art methods in various learning performance metrics [4].

The remaining part of the paper is organized as follows. Section II provides a literature review on recommender systems in intelligent tutoring systems and deep reinforcement learning, Section III presents the overall framework and detailed mechanisms of the proposed long-term recommendation model based on deep reinforcement learning, Section IV describes the environment and interaction processes within the model, Section V discusses the recommendation agent and its training methodologies, Model training is given in Section VI. Section VII reports on experiments that validate the performance of the proposed model in long-term recommendations, and Section VIII concludes the paper by summarizing the findings and discussing the implications of the deep reinforcement learning approach for intelligent tutoring systems.

II. Related Work

A. Recommender Systems

In Intelligent Tutoring Systems (ITS), the role of recommender systems is to furnish learners with personalized

recommendations, aiding them in selecting suitable learning resources based on their learning progress and comprehension.

Traditional recommender systems, such as those based on Collaborative Filtering (CF) methods [6], Matrix Factorization (MF) methods [5], and neural network-based approaches [7], prove highly effective when recommending static content (e.g., textbooks, videos, exercises). However, these methods often rely on a substantial volume of historical interaction data and frequently grapple with the cold start problem when confronted with new students or content. Moreover, these approaches tend to overlook the dynamism and sequential nature of the learning process, wherein the learner's knowledge state gradually evolves over the course of learning.

In handling sequential data, recommender systems based on Recurrent Neural Networks (RNNs) have made strides. Hidasi et al. [8] employed RNNs for predicting students' learning paths, and other researchers have proposed several RNN-based enhancements [9]. Nevertheless, these methods primarily focus on short-term predictions, neglecting the long-term learning trajectories of students.

In Interactive Recommender Systems (IRS), student feedback is incorporated into the model. Such models can iteratively construct and optimize representations of students and content, thereby holding an advantage in addressing the cold start problem. Some researchers have utilized Multi-Arm Bandit (MAB) methods to build IRS, yet these methods primarily address the exploration-exploitation dilemma and do not explicitly optimize for long-term returns.

B. Deep Reinforcement Learning

Deep Reinforcement Learning (DRL) has made significant breakthroughs in many interactive systems, such as Atari games [10] and Go [11], but its application in recommender systems remains relatively limited. Wang et al. [12] proposed a DRL approach based on the Actor-Critic (AC) framework for page recommendations, a hybrid RL method that integrates value-based and policy-based modules. Li et al. [13] introduced a method based on Deep Q Network (DQN) for keyword prompt recommendations. Through this approach, they achieved effective recommendations in the absence of explicit student feedback. Sewak et al [14] presented a DRL-based interactive recommender system for news recommendations. This method, incorporating a memory network, better handles historical interaction data. Hernandez-Leal et al. [15] proposed a DRL method for personalized recommendations. Their approach learns the latent representation of students through deep neural networks and employs reinforcement learning for recommendation decisions. Ausin et al. [16] introduced a hybrid recommender system combining deep learning and reinforcement learning. Their method dynamically updates after each interaction and can make recommendations without student historical information. Abdelshiheed et al. [17] proposed a DRL-based recommender system to address multi-objective recommendation problems. Their method considers personalized student needs while taking into account business objectives. Koroveshi et al. [18] presented a DRL-based sequential recommendation method that predicts students' future behavior while considering both long-term and short-term interests. Jung et al. [19] introduced a DRL-based interactive recommender system to address cold start problems. Their method effectively recommends in situations where students lack historical interaction data.

The aforementioned research endeavors underscore the potential of deep reinforcement learning [22] in recommender systems, addressing a spectrum of challenges from history-based recommendations to tackling cold start problems and resolving multi-objective recommendation issues.

C. Research Gaps and Motivation

In summary, the primary challenges faced by recommender system research in intelligent tutoring systems include an overreliance on historical interaction data, neglecting the issue of students' long-term learning paths, and the difficulty in handling large action spaces. In the next section, we will introduce how we address these issues by proposing a new DRL-based recommender system framework to provide more effective personalized learning recommendations.

III. Overall Framework

Typically, reinforcement learning-based systems involve interaction between the environment and an intelligent agent [20]. During the training process, the parameters within the intelligent agent are optimized based on rewards generated from the continuous interaction between the environment and the agent [21]. More specifically, this interaction comprises two consecutive steps: 1) the agent selects and executes an action based on the environment's state; 2) the environment responds to the action performed by the agent and returns feedback and a reward.

In the recommender system scenario considered in this study, the environment consists of various students, and the intelligent agent is a recommendation model based on RNN. Actions correspond to generating Top-N recommendation lists for specific students, and feedback indicates whether the student accepts this recommendation list. The entire recommendation process is illustrated in Fig. 1. It can be observed that for each individual student, there is a corresponding recommendation agent. Notably, all recommendation agents share the same network parameters. This allocation strategy for recommendation agents has its advantages as it can prevent mutual interference from different students.

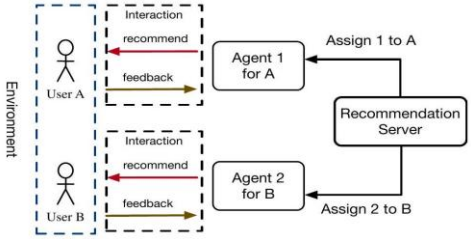

Fig. 1. The entire recommendation process.

IV. Environment and Interaction

The overall environment in this paper is constructed through offline datasets, such as the Secondary_school_curriculum, as online environments are not always feasible. Typically, offline datasets consist of a student-

course rating matrix $\tilde{R} \in \mathbb{R}^{U*M}$, where U represents the students and M denotes the courses. The elements $\tilde{R}_{u,i}$ in $\tilde{R}$ signify the rating given by student u to course i. Specifically, the explicit rating matrix $\tilde{R}$ can be transformed into an implicit feedback matrix F, where the element $F_{u,i}$ indicates whether student u is associated with course i.

$$F_{u,i} = \begin{cases} 1 & \tilde{R}_{u,i} > 0 \\ 0 & \text{otherwise} \end{cases} \tag{1}$$

Based on the implicit feedback matrix F, it is straightforward to derive the set of courses I_u that interest student u. The courses in the set are sorted by timestamp, and for each course $i \in I_u$, the value of $F_{u,i}$ must be 1.

To obtain feedback $f_{u,t}$, the student response function $\mathbb{V}(P^N_{u,t}, I_u)$ used in Eq. (1) can be defined as Eq. (2).

$$f_{u,t} = \mathbb{F}(P^N_{u,t}, I_u) = \begin{cases} 1 & P^N_{u,t} \cap I_u \neq \emptyset \\ 0 & \text{otherwise} \end{cases} \tag{2}$$

Here, $f_{u,t}$ being 1 indicates positive feedback, and 0 denotes negative feedback. $P^N_{u,t} \cap H_u \neq \emptyset$ signifies that $P^N_{u,t}$ successfully includes at least one course liked by the student. In practice, positive feedback can refer to student actions such as clicks or purchases. Similarly, negative feedback refers to students ignoring the recommended list or clicking on courses outside the recommended list. The system automatically provides feedback when the student performs any of these actions, without requiring the student to provide real-time feedback.

During the testing phase, the long-term recommendation performance of a student is the average result obtained over all steps in the corresponding interaction sequence. More intuitively, the overall performance of the recommender system can be evaluated using recall-based metrics, such as hit rate, and precision-based metrics, such as NDCG. These can be calculated using Eq. (3) and Eq. (7), respectively.

$$hit@N = \frac{\Sigma_u \frac{1}{|I_u|} \Sigma_{t=1}^{|I_u|} f_{u,t}}{\#user} \tag{3}$$

.

$$NDCG@N = \frac{\Sigma_u \frac{1}{|I_u|} \Sigma_{t=1}^{|I_u|} \frac{DCG@N(P^N_{u,t})}{iDCG@N}}{\#user}. \tag{4}$$

$$DCG@N(P^N_{u,t}) = \sum_{i=1}^{|K|} \frac{h_i}{\log_2 1 + i}. \tag{5}$$

$$h_i = \begin{cases} 1 & P^N_{u,t,i} \text{ inI} \\ 0 & \text{otherwise.} \end{cases} . \tag{6}$$

$$iDCG@N = DCG@N \binom{N}{u,t} \tag{7}$$

where $^N_{u,t}$ represents the recommended sequence, which includes courses of interest to the student that have not been recommended previously.

V. Recommendation Agent

Within the recommendation agent, the recommendation process is viewed as a Markov Decision Process (MDP), providing a more suitable framework for recommender systems due to its consideration of the long-term impact of each recommendation and the corresponding expected values. Fig. 2 shows the diagram of the model.

Assuming $\pi(i \mid s_{u,t})$ represents the probability of recommending course i given the student's state $s_{u,t}$, the generation function $\mathbb{G}$ can be defined as follows:

$$P^N_{u,t} = \mathbb{G}(s_{u,t}, I) = \text{Top}_{i \in I}\, N(\pi(i \mid s_{u,t}) \times m^t_{u,i}) \tag{8}$$

where, $\pi(i \mid s_{u,t})$ is the recommendation probability of course i at time t, and $m^t_{u,i}$ is the element of course i in the masking vector m^t_u. The value of $m^t_{u,i}$ is 0 or 1, indicating whether the student has previously selected that course.

At time t, the recommendation probability $\pi(i \mid s_{u,t})$ for course i can be obtained as:

$$\pi(i \mid s_{u,t}) = \text{Softmax}(o^i_{u,t}) \tag{9}$$

where, $s_{u,t}$ is a obtained l-dimensional vector (which will be discussed later), and $o^i_{u,t}$ is the i-th element in the vector $o_{u,t}$ defined as:

$$o_{u,t} = \hat{\sigma}(W_s s_{u,t} + b_s). \tag{10}$$

where $\hat{\sigma}$ is the ReLU activation function, $W_s \in \mathbb{R}^{M \times l}$ and $b_s \in \mathbb{R}^M$ are the parameter matrix and bias, respectively. The softmax function is defined as:

$$\text{Softmax}(o^i_{u,t}) = \frac{\exp^{o^i_{u,t}}}{\sum_{k \in I} \exp^{o^k_{u,t}}} \tag{11}$$

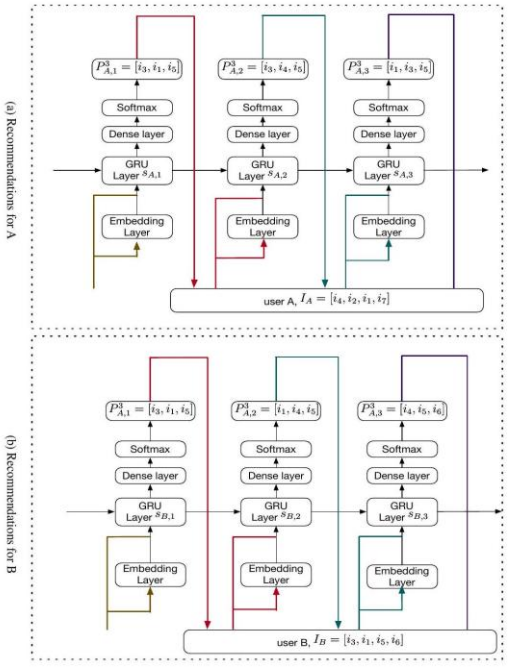

Fig. 2. Model.

In the formula, $s_{u,t}$ is the state of student u at time t, obtained through the following state transition process:

$$s_{u,t} = \mathbb{T}\left(s_{u,t-1}, f_{u,t-1}, P^N_{u,t-1}\right) = S\left(s_{u,t-1}, \hat{a}_{u,t-1}\right) \tag{12}$$

where, $P^N_{u,t-1}$ is the recommended list, $f_{u,t-1}$ is the student's feedback, S is the internal state transition process, and $\hat{a}_{u,t-1}$ is the action used to represent $P^N_{u,t-1}$ and $f_{u,t-1}$ defined as:

$$\hat{a}_{u,t-1} = \underset{a \in A_{u,t-1}}{\operatorname{argmax}}\left(\pi\left(a \mid s_{u,t-1}\right) \times m^{t-1}_{u,i}\right). \tag{13}$$

where, $A_{u,t-1}$ is the auxiliary set for feedback in different situations, defined as:

$$A_{u,t-1} = \begin{cases} P^N_{u,t-1} \cap I_u, & f_{u,t-1} > 0 \\ P^N_{u,t-1}, & \text{otherwise.} \end{cases} \tag{14}$$

The internal state transition process $s_{u,t} = S\left(s_{u,t-1}, \hat{a}_{u,t-1}\right)$ is obtained through an RNN with Gated Recurrent Unit (GRU).

Firstly, $\hat{a}_{u,t-1}$ should be transformed into the input of RNN$x_{u,t}$ at time t. To more effectively incorporate feedback into RNN, the input $x_{u,t}$ is obtained through the following formula:

$$x_{u,t} = E\left(\hat{a}_{u,t-1}\right) = \begin{cases} \hat{e}\left(\hat{a}_{u,t}\right), & f_{u,t} > 0 \\ -\hat{e}\left(\hat{a}_{u,t}\right), & \text{otherwise.} \end{cases} \tag{15}$$

where, $\hat{e}\left(\hat{a}_{u,t}\right) \in \mathbb{R}^{\hat{l}}$ is the l-dimensional embedding of course $\hat{a}_{u,t}$ also a part that needs to be learned in the proposed model. Using E, positive and negative feedback can be clearly distinguished for a given $\hat{a}_{u,t}$.

According to the state transition of GRU, $s_{u,t} = S\left(s_{u,t-1}, \hat{a}_{u,t-1}\right)$ can be obtained as follows:

$$\begin{aligned} s_{u,t} = S\left(s_{u,t-1}, \hat{a}_{u,t-1}\right) &= \left(1 - Z\left(x_{u,t}, s_{u,t-1}\right)\right) \odot s_{u,t-1} \\ &+ Z\left(x_{u,t}, s_{u,t-1}\right) \odot \tilde{S}\left(x_{u,t}, s_{u,t-1}\right). \end{aligned} \tag{16}$$

where, $\odot$ represents the element-wise product, Z is the function of the update gate, $\tilde{S}$ is the function generating candidate states, obtained through the following formulas:

$$Z\left(x_{u,t}, s_{u,t-1}\right) = \sigma\left(W_z x_{u,t} + U_z s_{u,t-1}\right) \tag{17}$$

$$\tilde{S}\left(x_{u,t}, s_{u,t-1}\right) = \tanh\left(W x_{u,t} + U\left(j_{u,t} \odot s_{u,t-1}\right)\right) \tag{18}$$

where, σ is the sigmoid activation function, $W_z \in \mathbb{R}^{l \times \hat{l}}, U_z \in \mathbb{R}^{l \times l}, W \in \mathbb{R}^{l \times \hat{l}}$ and $U \in \mathbb{R}^{l \times l}$ are parameter matrices, and $j_{u,t}$ is the reset gate, obtained through the following formula:

$$j_{u,t} = \sigma\left(W_j x_{u,t} + U_j s_{u,t-1}\right) \tag{19}$$

where, $W_j \in \mathbb{R}^{l \times \hat{l}}$ and $U_j \in \mathbb{R}^{l \times l}$ are parameter matrices.

In the warm-start model, there is an additional component used to merge student historical information.

Assuming $\hat{I}_u$ is the set containing all historical courses related to student u (it should be noted that, $\hat{I}_u \cap I_u = \emptyset$, and if $i \in \hat{I}_u$, then $m^0_{u,i} = 0$), i.e., courses from the student's history cannot be selected during the interaction.

In particular, the latent vector h_u representing student u's historical items is obtained through the following formula:

$$h_u = \tanh\left(\sum_{i \in \hat{I}_u} e(i)\right) \tag{20}$$

where, $e(i) \in \mathbb{R}^{\hat{l}}$ is another l-dimensional embedding defining course i, which also needs to be learned and is different from $\hat{e}_i$.

Additionally, to adaptively balance the effects of h_u and $s_{u,*}$ an External Memory Gated Recurrent Unit (EMGRU) is proposed, with detailed descriptions as follows.

Firstly, the state $s_{u,t}$, is obtained according to the formula, then, a new integrated state $\hat{s}_{u,t}$ used to generate course selection probabilities is obtained through the formula:

$$\hat{s}_{u,t} = d_{u,t} \odot s_{u,t} + \left(1 - d_{u,t}\right) \odot h_u \tag{21}$$

where, $d_{u,t}$ is the balance gate, which can control the impact of static h_u and dynamic $s_{u,t}$.

The balance gate $d_{u,t}$ can be obtained through the following formula:

$$d_{u,t} = \sigma\left(W_d h_u + U_d s_{u,t}\right) \tag{22}$$

where, $W_d \in \mathbb{R}^{l \times \hat{l}}$ and $U_d \in \mathbb{R}^{l \times l}$ are parameter matrices.

It is noteworthy that h_u or $\hat{s}_{u,t}$ does not affect the transition process $\mathbb{T}$ of state $s_{u,t}$ and h_u only affects the generation of course selection probabilities. In other words, the static and dynamic branches are independent of each other. In summary, the specific structure of the EMGRU unit is shown in Fig. 3.

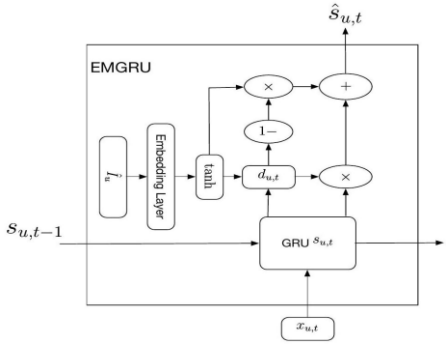

Fig. 3. EMGRU unit.

Finally, the selection probability $\pi\left(i \mid \hat{s}_{u,t}\right)$ is obtained through $\hat{s}_{u,t}$ rather than the state, $s_{u,t}$ and thus the course selection probability is defined as follows:

$$\pi\left(i \mid \hat{s}_{u,t}\right) = \text{Softmax}\left(\hat{o}^i_{u,t}\right) \tag{23}$$

where, $\hat{o}_{u,t} = \hat{\sigma}\left(W_s \hat{s}_{u,t} + b_s\right)$.

The parameter set of the warm-start model is $\hat{\theta} = \tilde{\theta} \cup \{e(*), W_d, U_d\}$. The overall architecture of the warm-start model is shown in Fig. 4.

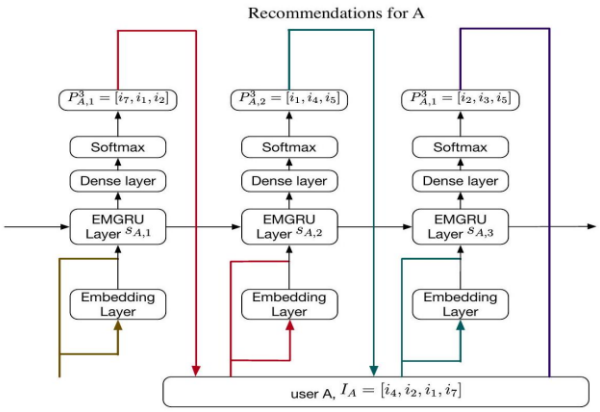

Fig. 4. The overall architecture of the warm-start model.

VI. Model Training

In this section, we will describe how to train the proposed model in the sequential interaction between the recommendation agent and the environment.

A. Reinforcement Learning

The goal of the learning algorithm in this section is to maximize the expected long-term recommendation reward, where θ is learned through the interaction process E_u for each student u. Specifically, E_u represents the complete interaction process obtained by the recommendation agent for student u under the current parameters.

Generally, an E_u interaction process includes the immediate reward $V_{u,t}$ at time t, state $s_{u,t}$, and action $\hat{a}_{u,t}$, defined as:

$$E_u = [s_{u,1}, \hat{a}_{u,1}, f_{u,1}, V_{u,1}, \dots, s_{u,M}, \hat{a}_{u,M}, f_{u,M}, V_{u,M}] \quad (24)$$

where, $s_{u,t}$ is generated by Equation (19) $\hat{a}_{u,t}$ is obtained by Equation (16) and $f_{u,t}$. Thus, $V_{u,t}$ can be computed as:

$$V_{u,t} = \begin{cases} 1.0, & f_{u,t} > 0 \\ -0.2, & \text{otherwise.} \end{cases} \quad (25)$$

where 1.0 and -0.2 are values determined based on experience.

To maximize the expected cost J, each action $\hat{a}_{u,t}$ corresponds not only to an immediate reward $V_{u,t}$, but also to a long-term reward $R_{u,t}$, computed as follows:

$$R_{u,t} = \Sigma_{k=0}^{M-k} \gamma^k V_{u,t+k} \quad (26)$$

where $\gamma \in [0,1]$ is the discount factor. The objective function J is defined as:

$$J = \mathbb{E}_{s_{u,1}, a_{u,1}, \dots}[R_{u,t}] \quad (27)$$

The parameter θ of the recommendation agent can be optimized using the gradient ascent method:

$$\theta = \theta + \eta \nabla_\theta J \quad (28)$$

where η is the learning rate, and the gradient $\nabla_\theta J(\theta)$ is given by:

$$\nabla_\theta J = \sum_{t=1}^{M} \gamma^{t-1} R_{u,t} \nabla_\theta \log \pi(\hat{a}_t \mid s_{u,t}) \quad (29)$$

In the standard practice of applying REINFORCE, the interaction process should be a complete E_u, which means the parameters should be updated after completing the interaction process for student u. However, the lengths of student interactions $I*$ can vary significantly. For example, $|I_A| = 20$, but $|I_B| = 200$. This causes large variances infor different students at the same time t. Moreover, due to the accumulation of excessive negative rewards, long-term interaction processes can hide positive results, making it challenging for the recommendation agent to obtain positive training samples. Therefore, a recommendation agent trained using traditional REINFORCE learning cannot achieve satisfactory recommendation performance.

To address this issue, this paper proposes to divide the original E into I_u/B sub-interaction processes and restart the reward accumulation at the beginning of each sub-interaction process. The learning process for both $\hat{\theta}$ and θ remains the same. The detailed processes of the learning process and the sub-interaction process generation are shown in Algorithm (1) and Algorithm (2), respectively. It should be noted that in the warm-start scenario, to ensure sufficient training data, the total length of the interaction process for each student u in the training phase is equal to $|I_u \cup \hat{I}_u|$. At the same time, the recommendation agent can choose courses from $\hat{I}_u$. However, the length of the interaction process is still equal to $|I_u|$, and during the testing phase, the recommendation agent cannot select courses from $\hat{I}_u$ for each student u.

B. Supervised Learning

Another approach to training the recommendation agent is to optimize it using supervised learning in a short-term prediction scenario and then apply it to a long-term testing environment.

To facilitate the transition of the recommendation agent from short-term to long-term prediction scenarios, the neural network architecture for the recommendation agent under supervised learning and reinforcement learning should be consistent. The only difference is that explicit labels need to be provided for supervised learning, and these labels are the actual course selections made by students at each time step.

Let I_u denote the actual sequence of courses chosen by student u over time. To maximize the accuracy of short-term predictions, this paper uses cross-entropy $\hat{J}$, defined as the cost function for supervised learning:

$$\hat{J} = -\Sigma_{i=1}^{B} \log\left(\pi(I_{u,i} \mid s_{u,i})\right) \quad (30)$$

where θ can be updated as follows:

$$\theta = \theta - \eta \nabla_\theta \hat{J} \quad (31)$$

Compared to the reinforcement learning approach, the supervised learning method is closer to traditional session-

based RNNs, where each recommended step has a specific corresponding label for the training signal.

Furthermore, before applying reinforcement learning, fine-tuning the recommendation agent through supervised learning can be performed. This can help the reinforcement learning-based recommendation agent start from a relatively good policy rather than a random one, thus accelerating the convergence speed of reinforcement learning.

VII. EXPERIMENTS

In this section, a substantial number of experiments were conducted to demonstrate the advantages of the proposed method in long-term recommendations and showcase the effectiveness of the core components of the proposed model.

A. Evaluation Datasets and Experimental Settings

Two offline real-world benchmarks, Secondary_school_curriculum 100K and Secondary_school_curriculum 1M, were used to evaluate the proposed model. Secondary_school_curriculum 100K contains 100,000 rating records about 943 students and 1682 courses. Secondary_school_curriculum 1M includes one million rating records about 6040 students and 3900 courses.

The proposed model was evaluated using the previously mentioned interaction environment to assess the performance of the proposed method and other methods. In the experiments, a 1-layer RNN and GRU with a hidden layer size of 100, matching the embedding size, are used. The size of B is set to 20, and γ is set to 0.9. For experiments on the 100K and 1M datasets, the proposed model is optimized using Adam with a learning rate of 0.005.

B. Benchmark

Pop: This algorithm always recommends the most popular items in the training set. While simple, it often serves as a powerful baseline.

Linear-UCB (L-UCB): A linear bandit algorithm, a widely used and mature multi-armed bandit algorithm. In this study, a context-independent bandit algorithm was used since content information was not considered. Course embeddings were obtained through matrix factorization (MF) methods.

ε-greedy: Similar to Linear UCB, but the balance between exploration and exploitation is adjusted by tuning the ε parameter. Course embeddings were also obtained through MF.

DQN (Deep Q-Network): A deep reinforcement learning algorithm based on value functions.

SARSA (State-Action-Reward-State-Action): A classic policy-based reinforcement learning algorithm commonly used as a benchmark.

Actor-Critic: A deep reinforcement learning algorithm that combines value function and policy methods. The architecture proposed in was used for comparison.

PPO (Proximal Policy Optimization): An advanced reinforcement learning algorithm that improves training stability by adding an "agent" constraint during policy updates.

Among these algorithms, Pop, Linear-UCB, and ε-greedy are traditional recommender systems or multi-armed bandit algorithms, while DQN, SARSA, Actor-Critic, and PPO are classical or advanced algorithms in the field of reinforcement learning.

C. Warm-start Model Comparative Experiment

In the experiment, a comparative study of warm-start models was conducted on the 100K, and the results are shown in Table I. In this table, $p = 10\%$ means that 10% of courses for each student u are retained as the warm-start historical set $\hat{I}_u$, and five different p values are considered in the experiment. Specifically, the historical data $\hat{I}_u$ for each student u in the test set was also used to train static models like BPR and NeuCF because these static models need to obtain corresponding student representations and are evaluated without using $\hat{I}_u$ during testing. However, the historical data of test students was not used to train other models.

TABLE I. NDCG@10 COMPARISON OF THE WARM-START MODELS ON 100K DATASET

	p=10%	p=30%	p=50%	p=70%	p=90%
Pop	2.90%	2.16%	1.65%	1.31%	1.48%
BPR	3.41%	3.25%	2.89%	2.74%	3.23%
NeuCF	3.51%	3.33%	3.02%	2.86%	3.35%
sRNN	8.54%	6.92%	5.45%	4.05%	3.66%
sl-cold	8.97%	6.76%	5.47%	3.96%	3.40%
rl-cold	14.93%	12.11%	8.88%	1.24%	3.69%
sl+rl-cold	15.54%	12.53%	9.38%	6.32%	3.71%
sl-warm	8.65%	6.79%	5.37%	4.73%	4.42%
rl-warm	13.81%	11.53%	8.37%	6.76%	4.44%
sl+rl-warm	14.34%	12.07%	9.64%	7.90%	6.18%

The proposed method's large-scale warm-start model significantly outperforms baseline models. With an increase in p, the warm-start model demonstrates significant improvements in HR and NDCG. These results suggest that incorporating historical data can enhance the model's performance if the historical data is sufficiently rich. It is noted that experiments with larger p values are more challenging than those with smaller p values because the total number of $I_u \cup \hat{I}_u$ is fixed. Specifically, larger p values result in a smaller correct candidate set I_u and a shorter reasoning process. Therefore, the proposed model's performance is relatively better at smaller p values. Additionally, training the recommendation agent through supervised learning generally improves HR and NDCG performance. Furthermore, this is particularly effective for the larger 1M dataset. Without supervised pre-training, the rl-warm model cannot even outperform sRNN at p=90%. Conversely, the gap between sRNN and sl+rl-warm is significant.

D. Long-Term Prediction Performance Comparison

To validate the performance of the proposed model in long-term recommendations, Fig. 5 presents the recommendation results of various comparative methods at different stages. The experimental results are obtained from selected students in the

respective test sets. Specifically, the size of the selected student set I_u is above average because students with longer histories can more clearly reveal the performance of long-term recommendations. Additionally, the results for student u are divided into five different stages: [0%,20%), [20%,40%), [40%,60%), [60%,80%), and [80%,100%], where $[s\%, e\%)$ denotes the steps between $(s\% \times I_u)$ and $(e\% \times I_u)$ during the entire interaction period. Furthermore, e is used to represent the range [s%,e%) and provides the average results within that range.

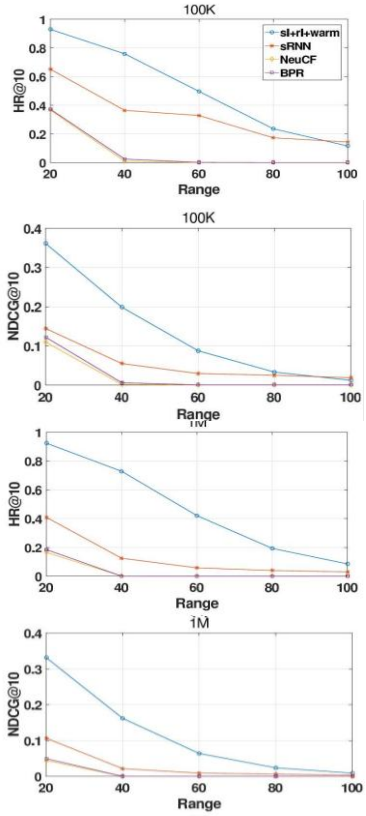

Fig. 5. The Recommendation performance at different stages. (a) HR@10 on 100 K; (b) NDCG@10 on 100 K; (c) HR@10 on 1M; (d)NDCG@10 on 1M.

As shown in Fig. 5, static models like NeuCF and BPR still achieve good hit rates in the first range [0%,20%). However, due to the almost unchanged recommendation results obtained by static methods, their performance sharply drops to 0% in the subsequent stages. Consequently, their overall HR and NDCG results are poor, as shown in Table II. On the other hand, sequential methods like sl+rl-warm and sRNN can achieve hits in all ranges, adapting their respective recommendation results. Compared to sRNN, the proposed sl+rl-warm model significantly surpasses sRNN in the ranges [0%, 20%) to [60%, 80%) because the proposed model already obtains a sufficient hit rate in the early stages. Since I_u has a fixed size, fewer courses can be hit in the last range [80%, 100%]. Therefore, the performance of sl+rl-warm is almost equivalent to that of RNN in the last range [80%, 100%]. All these results indicate that the proposed method can effectively adopt recommendation transfer in long-term recommendations.

TABLE II. TAB.6 HR@10 COMPARISON OF THE WARM-START MODELS ON 1M DATASET

	p=10%	p=30%	p=50%	p=70%	p=90%
Pop	6.83%	5.73%	5.04%	4.52%	4.10%
BPR	4.73%	4.73%	4.95%	4.99%	5.15%
NeuCF	6.27%	6.56%	6.65%	6.99%	7.78%
sRNN	16.55%	17.16%	17.27%	17.67%	18.52%

E. Impact of EMGRU

EMGRU is crucial in the warm-start model as it can adaptively adjust the dynamic RNN state and static historical representation to generate $\hat{s}_{u,t}$. To study the impact of this adaptive balance, the experiment considered four different settings combining RNN states and historical states: 1) using only RNN states (s); 2) using only historical representations (h); 3) the combination of historical representations and RNN states ($s + h$); 4) the combination of historical representations and RNN states with a balanced gate ($s + h\mathrm{w}/$).

As shown in the Table III, the method with only h performs poorly because h_u is unchangeable throughout all interaction processes, and the fixed h_u cannot generate different recommendation results at different times. On the other hand, when the minimum setting is $p = 10\%$, the method with only s surpasses the combination methods $s + h$ and $s + h\mathrm{w}/$ gate in terms of HR because the data volume of h_u is not sufficient. However, as p increases, the combination methods can outperform the method with only s. Moreover, adapting the combination of h and s with a gate generally has a better effect than mixing h and s with an equal constant. These results indicate that the effects between $s_{u,t}$ and h_u are non-fixed and should be adjusted according to the current situation.

TABLE III. NDCG@10 COMPARISON OF THE WARM-START MODELS ON 1M DATASET

	p=10%	p=30%	p=50%	p=70%	p=90%
Pop	2.03%	1.50%	1.18%	0.92%	0.81%

sl-warm	3.97%	3.51%	2.98%	2.08%	1.11%
rl-warm	9.02%	7.47%	5.44%	4.19%	2.71%
sl+rl-warm	11.62%	9.91%	7.02%	5.09%	3.61%

F. Convergence Analysis

To demonstrate the effectiveness of the settings in the REINFORCE algorithm, Fig. 6 illustrates the performance curves of different optimization algorithms in the warm-start (p=50%) scenario on the Secondary_school_curriculum 100K dataset.

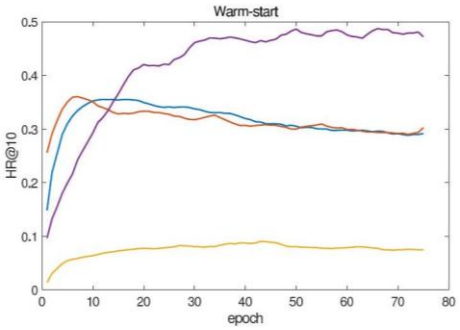

Fig. 6. The Learning curves of different algorithms in the warm-start.

Clearly, the performance of supervised learning methods with complete interaction processes (blue line) or the corresponding separated sub-interaction processes (red line) is similar, indicating that dividing the entire interaction process into several sub-interaction processes does not improve the accuracy of recommendations. Similarly, the performance of the basic REINFORCE algorithm (yellow line) is inferior and even significantly different from methods based on supervised learning. However, the performance of the special REINFORCE method (purple line) shows a significant improvement, as separating and restarting the reward accumulation for overly long interaction processes can obtain more useful self-generated training labels for reinforcement learning. Although this approach is simple, it is highly effective.

G. Recommendation Behavior Analysis

To analyze the recommendation behavior of the recommendation agent, the experiment provides the average results of the relevant popularity and Hit@10 for all test students on the Secondary_school_curriculum 100K dataset at each step t in the warm-start scenario, as shown in Fig. 7.

Thus, the recommendation agent in this study gradually evolves from widespread recommendations to personalized recommendations and can accurately hit courses within the specified range.

H. Dynamic Recommendation Analysis

To evaluate the effectiveness of the dynamic recommendation process, the experiment randomly selected several cases and provided the recommendation results of the proposed model on the dataset. For each case, a sequence of sequentially recommended courses is displayed for a specific student. It is important to note that, for ease of presentation, only one course is displayed in the Top-10 ranking list, i.e. $\hat{a}u, t$. Specifically, for each case from (a) to (c), the results from step 0 to step 14 are always shown. On the other hand, for each case from (d) to (e), the results of a randomly selected consecutive 15 steps within the specified range are displayed.

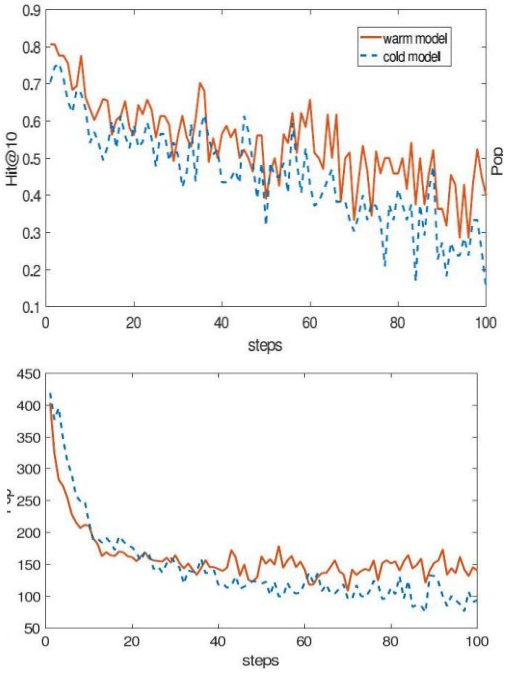

Fig. 7. Characteristics at different time steps in the warm-start scenario. (a) Hit@10; (b) The average results of the relevant popularity.

It can be observed that the proposed method can adaptively adjust recommendations based on past unsuccessful experiences. For example, in case (a), the first two recommendations are incorrect, but the subsequent four recommendations are correct. These results indicate that the proposed method can effectively change recommended courses based on previous feedback from students. Generally, the proposed model can dynamically update student states and modify recommendation results based on corresponding feedback.

In contrast, static methods cannot automatically adjust recommendation results and only make positive predictions at the beginning by correctly predicting recommendations, but they always make negative predictions. Therefore, compared to static methods, the recommendation approach in the proposed model is more effective.

VIII. Conclusion

In this paper, a new Top-N deep reinforcement learning recommender system is proposed to address the problem of long-term recommendations. In the proposed model, the recommendation process is considered as a Markov decision process. Thus, an RNN is used to simulate the sequential interaction between the agent (recommender system) and the environment (students). Moreover, the proposed model can be applied to warm-start scenarios. Additionally, the proposed model does not depend on any content information but only relies on the interaction between the environment and the agent, meaning it can effectively be applied in environments without sufficient content information. Experimental results show that, compared to traditional Top-N recommendation methods, the proposed method has better recommendation performance.

ACKNOWLEDGMENT

The preferred spelling of the word “acknowledgment” in America is without an “e” after the “g.” Avoid the stilted expression, “One of us (R. B. G.) thanks . . .” Instead, try “R. B. G. thanks.”

Advanced Football Match Winning Probability Prediction: A CNN-BiLSTM_Att Model with Player Compatibility and Dynamic Lineup Analysis

Tao Quan*, Yingling Luo
College of Physical Education and Health Science, Chongqing Normal University, Chongqing, 401331, China

***Abstract*—In recent years, with the continuous expansion of the football market, the prediction of football match-winning probabilities has become increasingly important, attracting numerous professionals and institutions to engage in the field of football big data analysis. Pre-match data analysis is crucial for predicting match outcomes and formulating tactical strategies, and all top-level football events rely on professional data analysis teams to help teams gain an advantage. To improve the accuracy of football match winning probability predictions, this study has taken a series of measures: using the Word2Vec model to construct feature vectors to parse the compatibility between players; developing a winning probability prediction model based on LSTM to capture the dynamic changes in team lineups; designing an improved BILSTM_Att winning probability prediction model, which distinguishes the different impacts of players on match outcomes through an attention mechanism; and proposing a CNN-BILSTM_Att winning probability prediction model that combines the local feature extraction capability of CNN with the time series analysis of BILSTM. These research efforts provide more refined data support for football coaching teams and analysts. For the general audience, these in-depth analyses can help them understand the tactical layouts and match developments on the field more deeply, thereby enhancing their viewing experience and understanding of the matches.**

Keywords*—Football big data; match prediction; feature vector; tactical understanding; match analysis

I. INTRODUCTION

Over the past few decades, football has emerged as one of the most popular sports globally, generating significant interest among fans while also attracting the attention of sports scientists, data analysts, and technical researchers [1] [2]. With advancements in technology and the rise of big data, data analysis of football matches has become an expanding research area within competitive sports [3] [4]. Accurate predictions of match winning probabilities provide a scientific basis for team tactics and enhance fans' understanding of the games. Consequently, developing a high-accuracy football match winning probability prediction model holds substantial value for both tactical analysis and audience engagement.

In this context, research on football match analysis technology has progressed. However, the inherent complexity of football matches, characterized by uncertainty and randomness, presents considerable challenges in predicting match outcomes. This study aims to explore and propose innovative data analysis methods to enhance the accuracy of football match-winning probability predictions and facilitate a deeper understanding of tactical layouts and match developments.

Initially, the focus is placed on analyzing player compatibility, as relationships among individual players influence overall team performance. Natural language processing technologies, such as Word2Vec, are employed to generate player feature vectors, which capture potential interactions at the data level and provide foundational features for subsequent winning probability predictions.

Secondly, to account for dynamic factors in football matches, a model based on Long Short-Term Memory (LSTM) networks is introduced to handle time-series data, capturing changes in team lineups and player performance over time. The memory capabilities of LSTM enable the model to learn critical moments during matches and assess the impact of tactical adjustments on outcomes.

Thirdly, to more precisely evaluate the influence of different players on match outcomes, an attention mechanism is integrated into the Bidirectional LSTM (BILSTM) model, resulting in the BILSTM_Att model. The attention mechanism supplies additional information regarding player importance, thereby enhancing prediction accuracy and personalization.

Finally, the study combines the feature extraction capabilities of Convolutional Neural Networks (CNN) with the time-series analysis strengths of BILSTM to propose the CNN-BILSTM_Att model. The CNN layer extracts spatial features of team lineups, while the BILSTM layer processes the evolution of these features over time, with the attention mechanism facilitating the combination of features for more accurate winning probability predictions.

The remainder of the paper is organized as follows: Section I introduces the background and significance of football match winning probability prediction; Section II reviews the literature on prediction methods in competitive sports, developments in natural language processing, and the current state of football match outcome prediction research; Section III discusses data preprocessing, word vector generation, and the development of the CNN-BILSTM_Att winning probability prediction model; Section IV presents a case study to validate the proposed method using a custom experimental dataset; and Section V concludes the paper by summarizing the findings and discussing potential areas for future research.

II. Literature Review

This paper will collect works related to existing winning probability predictions to highlight the shortcomings of current research.

A. Analysis Methods of Winning Probability Prediction in Competitive Sports

In the field of winning probability prediction research for competitive sports, the progress of deep learning has become a driving force for transformation [5] [6]. The target detection algorithms based on deep convolutional neural networks, as studied by Mukherjee et al. [7], have now become powerful tools for analyzing players and game dynamics. These algorithms learn complex features from massive amounts of data, helping us understand game development and have demonstrated high accuracy on multiple standard datasets.

To meet the needs of real-time analysis in fast-paced sports, researchers like McGarry et al. [8] have been exploring methods to accelerate target detection algorithms, successfully reducing response times by optimizing network architecture and computational efficiency. This is particularly crucial for winning probability prediction, as instant game information can have a significant impact on the outcome.

However, a major challenge in winning probability prediction is the detection of small targets, such as tracking the position of a soccer ball in a football match or monitoring the movements of distant players in a basketball game. Hodge et al. [9] proposed a series of solutions to this challenge, including multi-scale detection methods and the integration of contextual information, which have been proven to improve the recognition rate of small targets.

The use of ensemble learning has provided another breakthrough for winning probability prediction. The work of Chakraborty et al. [10] shows that by combining the results of multiple prediction models, the accuracy and robustness of predictions can be effectively improved. In sports analysis, ensemble methods can synthesize different data sources and algorithms, such as player statistics, team dynamics, historical performance, etc., to form a more comprehensive prediction of winning probabilities.

These technological advances have provided sports analysts, coaches, and betting companies with unprecedented data insights, helping them make more informed and strategic decisions [11]. They also provide sports fans with a richer viewing experience, such as increasing the interactivity and participation of matches through real-time data analysis [12]. As research continues to deepen, we can expect future winning probability prediction methods to become more refined and personalized, possibly using machine learning models to predict individual player performances or simulate match outcomes more accurately. These research outcomes indicate that target detection algorithms are developing in the direction of being more accurate, faster, and more robust.

B. The Current State of Natural Language Processing Development

Natural Language Processing (NLP) has become a core branch in the field of artificial intelligence, and its current development status highlights significant progress in understanding and generating human language. Particularly, transformative models such as BERT, proposed by Devlin et al., have revolutionized the ability to deeply comprehend semantic meaning in text by introducing bidirectional training mechanisms. These models have also had a revolutionary impact on a variety of NLP tasks including text classification, question-answering systems, and machine translation [13]. In the specific application scenario of sports competition prediction, the advancement of NLP technology is equally noteworthy.

By utilizing advanced text analysis technologies, researchers have been able to extract key information from live sports commentary, aiding in predicting the pace and outcome of games [14]. Furthermore, the application of sentiment analysis technology has made it possible to identify emotions from fans' social media activity, thereby analyzing the correlation between these emotions and game outcomes. Going further, NLP-based methods are being used to understand the patterns of language use among athletes, with the aim of predicting their performance and mental state, and even potential injury risks [15].

Modern NLP technology is also playing a role in automating the parsing of athletes' injury reports, reducing the workload of analysts in data collection and processing [16]. Additionally, semantic analysis of historical game reports can reveal long-term performance trends of teams and players, providing data support for establishing more accurate prediction models [17].

With the continual evolution of pre-trained models, such as the GPT series' capabilities in generating text, NLP has been used to automatically generate sports news articles, pre-game analyses, and even to simulate interviews with coaches and players, bringing new possibilities to media creation and fan interaction [18]. At the same time, these technologies are also helping to create more intelligent virtual assistants that can provide real-time game updates, statistical data interpretation, and personalized sports consumption advice.

In summary, the application of NLP in the field of sports competition prediction indicates that this technology has not only made significant progress in understanding complex text and language patterns but is also bringing profound changes to sports analysis, fan experience, and media reporting. With further research and the refinement of technology, NLP is expected to have an even greater impact in the field of sports in the future.

C. Current Status of Research on Football Match Outcome Prediction

Research on football match outcome prediction involves predicting results by analyzing team and player performance data, match conditions, and other relevant factors. In recent years, this research field has benefited from the rapid development of big data analytics, machine learning, and artificial intelligence technologies, transitioning from traditional statistical methods to more complex and refined predictive models.

With the aid of deep learning technologies, football match outcome prediction models can more effectively process and analyze complex datasets, learn features extracted from historical data, and predict future match outcomes [19]. Some research has adopted structures similar to deep convolutional neural networks, which identify and utilize potential factors affecting match outcomes by learning from a large volume of historical match data [20]. To meet the requirements of real-time prediction, researchers are also striving to improve the computational efficiency of models by optimizing network structures and designing more efficient algorithms, thus reducing the time required for prediction [21]. This enables models to provide predictions rapidly without sacrificing accuracy, satisfying the real-time needs of scenarios such as live match analysis and online betting [22]. In dealing with uncertainties and complex scenarios, such as player absences and weather changes, current research is attempting to incorporate more contextual information and a deeper understanding of the match environment to enhance the robustness of models in the face of varied real game situations [23]. At the same time, football match outcome prediction is focusing on the integrated analysis of multidimensional data, such as players' spatial positioning and team tactical changes. By integrating these multidimensional pieces of information, prediction models can analyze match situations more comprehensively, thus providing more precise predictions [24].

Overall, research on football match outcome prediction has made significant progress in prediction accuracy, processing speed, and adaptation to complex match environments through the adoption of advanced data analysis techniques and algorithmic models. As research continues to deepen and technology continues to develop, this field is expected to achieve higher levels of predictive performance, providing stronger support for football match analysis and related areas.

D. Research Gaps and Future Research Directions

In this research field, we can identify some potential research gaps that may provide directions for future work:

1) Quantification of player psychological states: Current models primarily analyze player performance and compatibility through statistics and machine learning techniques, but players' psychological states also have a significant impact on match outcomes. Integrating players' mentality, stress responses, and other psychological factors into models to predict match outcomes more comprehensively is a research gap that needs to be filled.

2) Comprehensive analysis of environmental factors in the stadium: Although research has considered player compatibility and dynamic performance, factors related to the stadium and environment (such as climate, ground conditions, fan support) are equally important to player performance and match outcomes. Future research could consider incorporating these environmental factors into models to enhance the accuracy and practicality of predictions.

3) In-depth integration of opponent analysis: The tactics of the opposing team, the state of their players, and team compatibility also affect match outcomes, but current models may not fully consider this aspect. Developing models that can analyze the characteristics of both teams and predict the outcomes of their interactions will be a valuable research direction.

The above issues are the key to improving prediction accuracy, and they are also the content of this article's research

III. Data Preprocessing and Word Vectors

A. Collection of Match Data

To ensure the rationality and usability of data, this paper has crawled the historical match records of several strong teams through Whoscored, and obtained the player line-ups used in the matches from these records. The flow diagram of the crawling process is shown in Fig. 1.

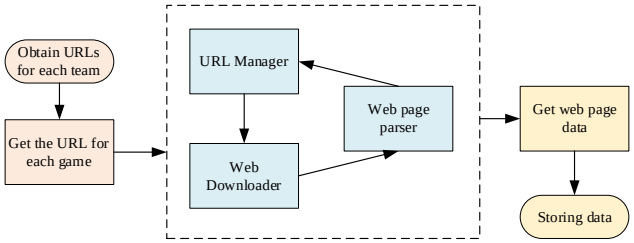

Fig. 1. Match data crawling process.

In the upcoming football events, every coach and fan tries to predict the outcomes of matches by analyzing the line-ups of the teams. Although the performance of the players and the real-time progress of the match are unpredictable and non-generalizable factors, by constructing a reliable pre-match line-up analysis model, we can provide valuable strategic support for the coaching team and also enhance the match experience for fans.

For this analysis, we have already obtained a large amount of line-up data from the database, covering detailed line-up information for 42,596 football matches. To make these data useful, they must first undergo thorough preprocessing. We will filter out information that has potential influence on match results and integrate it to form an efficient match line-up database.

Considering practicality and universality, our model will focus on the following key points:

- Team Strength Balance: Assessing the overall strength of both teams, including the technical statistical data and historical performance of the players.
- Tactical Adaptability: Analyzing the tactical flexibility of each team and how to make corresponding tactical adjustments based on the opponent's line-up.
- Player Condition: Evaluating the current state of key players, including injury conditions and athletic form.
- Historical Match Records: The historical head-to-head records of the two teams are also a factor that cannot be ignored, as it often reveals psychological advantages and disadvantages.

Through the comprehensive analysis of these dimensions, our model aims to provide deeper insights for the upcoming matches, thereby helping coaching teams develop more accurate tactical layouts and bringing richer viewing perspectives to fans.

As the date of the match approaches, we will continue to monitor changes in relevant variables and update our analysis model in a timely manner, ensuring that all predictions are based on the most recent and comprehensive data. We look forward to verifying the accuracy of our model and hope that it will become a powerful tool for predicting football match outcomes.

B. Data Processing

The football match data obtained through web crawling cannot be used directly for lineup analysis; it requires preprocessing of the raw dataset. The main steps of data preprocessing in this article include: data cleaning, data reduction, feature construction, and data annotation.

Since every football player has different positions and technical characteristics, these attributes create special effects that establish interconnections among players. In the match lineup dataset, players are not selected randomly; based on the analysis of the relationships between players, the coaching team selects a set of lineups that can cooperate with each other. In professional matches, the data analysis team will choose a lineup that has strong synergy and can effectively counter the opponent's players.

The interrelationships among players can be summarized as compatibility relationships and counter relationships, both of which jointly influence the outcome of a match. As shown in Fig. 2, the player word vectors in this paper consist of two parts: the first part is the word vectors with compatibility relationships generated by the Word2Vec model, and the second part is the extended vectors generated by the counter relationship algorithm. The composition of the player word vectors is illustrated in the Fig. 2.

Fig. 2. Composition of word vectors.

1) Acquisition of training corpus for word vectors: This article has crawled the home team lineup selection data from 54,652 professional football matches through Wan Plus eSports, using this data to train the Word2Vec model, and these data exclude the previously obtained 42,596 matches. In professional football matches, the lineups chosen after analysis by the coaching team have good compatibility, and the relationship among players within the lineup is strong. Therefore, choosing the lineup of one side in a professional match as the corpus, the Word2Vec model can generate player word vectors with relatively clear relevance. Some data from the corpus are shown in the table.

In this table, NO. represents the sequence number of the match, and P1, P2, P3, P4, P5 represent five different positions, namely [goalkeeper, defender, midfielder, support, forward]. The feature values of these five characteristics indicate the players selected for the corresponding positions. The CBOW model in Word2Vec can predict a word based on the context of that word in the text. During the training process, word vectors are generated as a byproduct, converting text content into a form of a numerical matrix. While generating word vectors, the CBOW model can also calculate the relevance of these vectors. Therefore, based on this feature of the CBOW model, the names representing players are treated as input text information, and the word vectors generated by the CBOW model become the player word vectors. The five different players chosen by the home team in the corpus can thus be seen as a sentence composed of five different words, and the degree of relevance between these words is the degree of compatibility of the players. The structure of the model used to train the word vectors is shown in the Fig. 3.

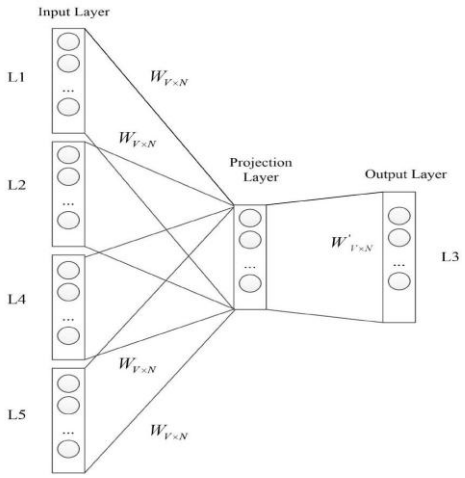

Fig. 3. The model structure for training word vectors.

In this model, the word vector of the target vocabulary is calculated based on the word vectors of the context before and after the target word. In this article, taking the name of the midfielder in the corpus as the target vocabulary (the midfield position usually corresponds to the center of the football formation, similar to the mid-lane position L3 in League of Legends), the preceding vocabulary of the midfielder is the defender (the defender position corresponds to the feature values of features L1 and L2), and the following context is the forward and support (the forward and support positions correspond to the feature values of features L4 and L5). Assuming that the dimension of the word vector is N and the length of the vocabulary is V, the target function of the training model is shown as follows.

$$L = \sum_{L \in V} \log(P(L3 \mid L1, L2, L4, L5))$$

Input layer: First, each player name is encoded using one-hot encoding, for example, player A's one-hot encoding is [1,0,0,0,…]. For convenience of calculation, x_{i-2}、x_{i-1}、x_i、x_{i+1}、x_{i+2} are used to represent the one-hot encodings of the names of feature players P1, P2, P3, P4, P5, which correspond to the positions [goalkeeper, defender, midfielder, support, forward]. Then all one-hot encodings are multiplied by the input weight matrix, as shown below.

$$I_1 = W_{V\times N} \times x_{i-1}$$
$$I_2 = W_{V\times N} \times x_{i-2}$$
$$I_4 = W_{V\times N} \times x_{i+1}$$
$$I_5 = W_{V\times N} \times x_{i+2}$$

Hidden layer: Average all word vectors to get the hidden vector, as shown in equation

$$\hat{I} = \frac{I_1 + I_2 + I_4 + I_5}{4}$$

Output layer: Multiply the hidden vector of the hidden layer by the output weight, as shown in equation.

$$z = W'_{V\times N}\hat{I}$$

Then use a softmax classifier to obtain the probability that each hero in the hero library is predicted as the current result, as shown in equation.

$$\hat{y} = \text{softmax}(z)$$

In this model training process, the weight from the input layer to the hidden layer is the word vector. The model can calculate the similarity probability between players, and the higher the similarity probability between two players, the stronger their relevance, indicating a strong pairing relationship between them. For example, if a midfielder (such as Messi) often appears with a forward player (such as Suarez), their word vector distance will be very small after generating the word vectors.

2) Acquisition of word vectors: This article uses the Gensim toolkit to import the Word2Vec model. Gensim is an open-source Python toolkit that supports multiple topic modeling algorithms such as TF-IDF, LDA, and Word2Vec. During the process of training word vectors with the Word2Vec model, the model's parameters are set as follows:

The sg parameter is the option to select the training mode. When sg=0, the model uses the CBOW (Continuous Bag of Words) model to train word vectors; when sg=1, the model uses the Skip-Gram model to train word vectors. This article uses the CBOW model to train player word vectors;

The size parameter indicates the dimension of the word vectors produced. In small datasets, this is usually set between 100-200. After multiple experiments, this article selects size=100;

The window parameter indicates the maximum possible distance between the current word and the predicted word. The larger the window parameter is set, the more predicted words need to be enumerated. Since there are five players input at a time in the training corpus, this parameter is set to 5;

The min_count parameter indicates that if a word appears in the entire dataset less than the set value, the word will be directly ignored. Since there is enough competition data in this article and each player has many match records, this parameter is set to 0.

The following are some player vectors after training through the Word2Vec model, for ease of representation, the player names in this article are represented as Player(name):

Player("Messi") = [0.25237, -0.10362, 0.75654, …]

Player("Cristiano Ronaldo") = [0.46895, 0.55863, -0.05965, …]

Player("Neymar") = [-0.75294, -0.63594, 0Sure!]

Compatibility can be calculated through cosine similarity, which reflects the degree of approximation of players in the semantic space. To some extent, this can be mapped to their ability to cooperate in actual games. Based on actual game experience, in football matches, among the players with the highest match compatibility with a key player (such as Messi), most are midfielders or wing-backs who can provide support and assists. These players are able to pass the ball well to Messi and create opportunities for him to score. When Messi receives effective support and has enough space to shoot, his team is more likely to win the game. Therefore, in professional games, Messi appears more frequently with these supporting players, indicating a strong compatibility between them.

Through the analysis of Messi's word vector compatibility, it can be seen that the Word2Vec model used in this paper produces word vectors that well reflect the compatibility between players in the team lineup. Players who often appear with Messi in games have a high degree of compatibility; those who have difficulty appearing with Messi have a lower degree of compatibility. This kind of analysis and discovery provides deep insights into the interaction between players in football matches and team cooperation strategies.

For example, if Messi and a specific midfielder often appear together in actual games and usually can cooperate to lead the team to victory, we can expect that in the word vector space produced by Word2Vec, Messi and this midfielder will have a higher degree of similarity or proximity. Such information is very valuable for the formulation of football strategies, especially when selecting player lineups and devising game tactics.

3) Expansion of word vectors: In football match prediction, not only is there a chemical reaction between teams, but also a suppression relationship. To better reflect the characteristics of the team, this paper uses the suppression relationship to generate a suppression vector to expand the team vector based on statistical data. Thus, the final team vector includes both the chemical reaction between teams and their suppression relationships, making the information contained in the team vector more comprehensive.

The suppression relationship between teams is generally determined based on the experience of fans and professional analysts in actual games. For example, most analyses might find that Team_A is limited by Team_B's tactics when evaluating the match between the two. This kind of suppression relationship is difficult to represent with specific numbers or vectors. This paper studies the win rate data between teams and finds that the suppression relationship can be reflected in the team's win rate.

On football data platforms, such as Opta, WhoScored, or Transfermarkt, one can obtain the overall win rate of each team. It can be seen that in a certain season, Arsenal's overall win rate is 60%, while Chelsea's overall win rate is 55%. The total win rate of these two teams is not much different, and usually, the probability of victory for either team in their matches is close to 50%. However, in actual games, Arsenal may find it difficult to compete with Chelsea, and by analyzing the data, it can be found that Arsenal's actual win rate against Chelsea may only be 40%. Therefore, by comparing the expected win rate and the actual head-to-head win rate of the teams, one can determine whether there is a suppression relationship.

Through the analysis of different teams' win rates and head-to-head win rates, the suppression relationship can be quantified through the following calculation process as shown in Fig. 4, the algorithm flow is as follows:

- Collect historical head-to-head data for Team_A and Team_B, including win rates and head-to-head win rates.
- Calculate the average win rate of the two teams as a reference value for the expected win rate.
- Use the difference between the actual head-to-head win rate and the expected win rate to assess the strength of the suppression relationship.
- Convert this difference into a suppression vector and combine it with the team vector.
- Use the expanded team vector for more accurate match predictions.

By this method, we can more comprehensively understand the competitive relationship between teams and consider more variables when predicting future game outcomes.

First, calculate the global win rate p_i for the teams in the dataset using the following Formula:

$$p_i = \frac{N_i}{M_i}$$

In this formula, i represents any team, N_i represents the number of matches won by the team, and M_i represents the total number of matches the team has participated in. Similarly, the global win rate p_j for the team j that team i is facing can be calculated; By using the global win rates of both teams, the expected win probability when the teams face each other can be calculated using the following formula:

$$E_{ij} = \frac{p_i - p_i \times p_j}{p_i + p_j - 2 \times p_i \times p_j}$$

In this formula, E_{ij}represents the expected win rate when team i faces team j;

Calculate the actual win rate $p'_{i,j}$ of the teams' encounters using the existing match dataset.

$$p'_{i,j} = \frac{n_{ij}}{m_{ij}}$$

In this formula, n_{ij} represents the number of matches won by team i against team j, and m_{ij} represents the total number of matches played between team i and team j;

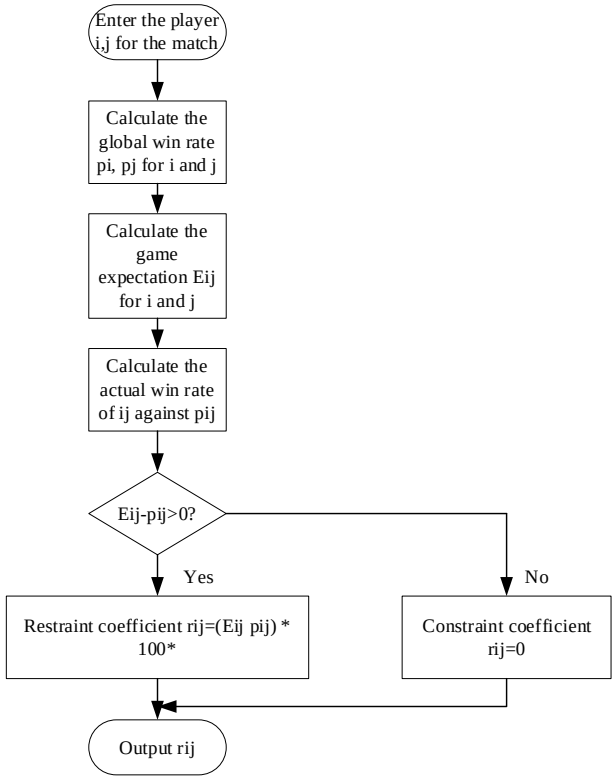

Fig. 4. Suppression relationship algorithm flow.

The specific algorithm process is as follows:

By comparing the expected win rate of the encounter between team i and team j with the actual win rate, if the actual win rate is less than the expected win rate, that is, $E_{ij} - p'_{i,j} > 0$,, then it can be considered that team j has a suppressing effect on team i;

After determining the suppression relationship between teams, further quantify the suppression relationship to be input into the prediction model. The win rate difference can be used as the basis for the suppression relationship coefficient. The calculation formula for the suppression relationship coefficient is as follows:

$$r_{ij} = \left(E_{ij} - p'_{i,j}\right) \times 100\%$$

In this formula, r_{ij} represents the coefficient of the suppression relationship between teams. The difference between the expected win rate and the actual win rate represents the suppression relationship index. The larger the value of r_{ij}, the stronger the suppressive effect of team j on team i.

Calculate the suppression relationship coefficient for each team and its opposing teams one by one. If there is no suppression relationship, the suppression relationship coefficient is set to 0. In this way, the suppression relationship vector for each team can be obtained.

In order to facilitate the generation of suppression relationship vectors between teams, an algorithm for generating suppression relationship vectors has been constructed. The logical structure of this algorithm is visualized as follows:

- Collect and process match data.
- Calculate the global win rate of the teams.
- Calculate the expected win rate of the encounters.
- Calculate the actual win rate of the encounters.
- Assess and calculate the suppression relationship coefficient.
- Generate the suppression relationship vector for the teams.

Through these steps, a structured dataset can be obtained, which is used to improve the accuracy of football match outcome predictions.

To facilitate the generation of expanded vectors for hero suppression relationships, this paper has constructed an algorithm for generating expanded vectors. Fig. 5 shows the logical structure of this algorithm.

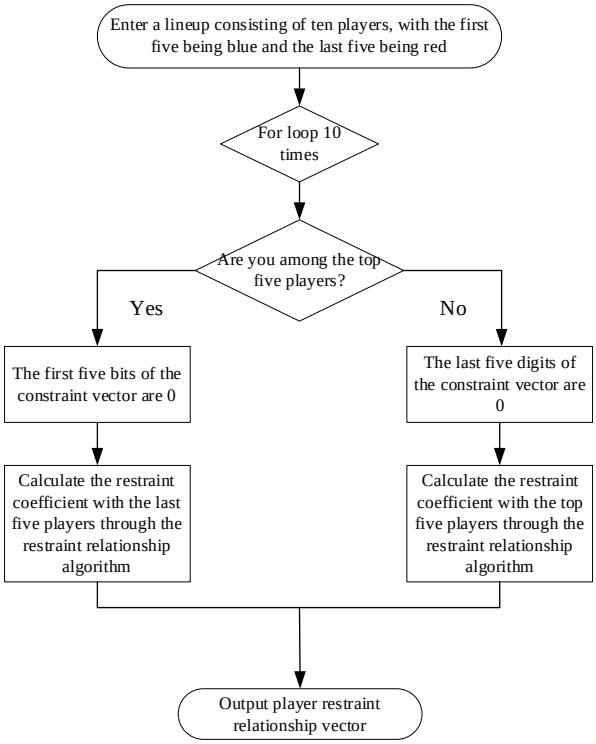

Fig. 5. The logical structure of the expanded vector generation algorithm.

C. CNN-Enhanced CNN-BILSTM_Att Win Probability Prediction Model

In the field of football match prediction, due to the multitude of factors involved in a game and the complex relationships between them, reliance solely on traditional statistical data and historical records for predictions is limited. For example, the dimension of "head-to-head history" is often affected by various factors, and its degree of influence on the outcome of the match is not easily quantifiable. Current football match prediction methods vary, including those based on odds, subjective predictions based on historical experience, etc., but there is a lack of a unified data mining-based quantitative analysis process to reveal the intrinsic connections between features, which poses obstacles to subsequent match analysis and prediction.

To address this issue, the BILSTM_Att prediction model adopts a Bi-directional Long Short-Term Memory network combined with an attention mechanism to effectively extract the characteristic information of team line-ups. However, the BILSTM_Att model may not fully capture local information when processing input features, and the model fitting process can be slow due to the large number of weight parameters in the hidden layers. To overcome these shortcomings, we propose an improved prediction model: CNN-BILSTM_Att.

This model incorporates the advantages of Convolutional Neural Networks (CNN), which can quickly process data and reduce the dimensionality of features through their pooling layers, thereby effectively reducing the number of weight parameters in the prediction model. This CNN-optimized model not only retains the sensitivity of the BILSTM_Att model to time-series data but also introduces the ability of CNN to extract local features in image and sequence processing, enhancing the model's capability to capture local contextual information.

The improved CNN-BILSTM_Att prediction model can analyze the counter-relations between teams and the dynamics of matches more accurately, thereby improving the accuracy of match outcome predictions. The final model structure and core process can be visually represented, as shown in Fig. 5-8. This will help researchers and analysts better understand the workings of the model and apply it to subsequent match prediction work.

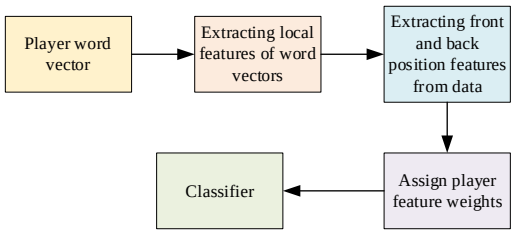

Fig. 6. Core process of the prediction model optimized with CNN.

The architecture of the improved model achieves an effective combination of feature extraction and time series analysis, with the following detailed structure:

1) Convolutional Neural Network (CNN) layer: The main task of this layer is to process the input lineup data and extract local features from it. In the context of football data analysis, this is akin to the ability of CNN to extract local pixel features in image processing tasks. In the scenario of football match prediction, the CNN can extract key local patterns and features from player data, positional information, and other relevant statistics, such as the relationships between players and the team's formation structure.

2) Bi-directional Long Short-Term Memory (Bi-directional LSTM) with Attention Mechanism (Att) layer: Data processed by the CNN layer is passed on to the BILSTM_Att layer. The BILSTM can capture the forward and backward dependencies in time-series data, while the attention mechanism helps the model focus on those pieces of information that are most critical to the final prediction. In football match prediction, this means the model can analyze not only the individual characteristics of players but also understand the dynamics of interactions between players and their changing impacts over time.

3) Softmax classifier: Finally, the feature vector output from the BILSTM_Att layer is passed to the softmax classifier. This classifier predicts the possible outcomes of the match, such as home win, draw, or away win, based on the extracted features.

This improved model—referred to as the CNN-BILSTM_Att model—leverages CNN's ability to extract highly relevant local features, and BILSTM's strength in processing time-series data. In this way, the model not only understands the current state of each team's lineup but also considers the potential impact of the evolution of team lineups over time on the match outcome.

The model's architecture can be represented by the following structure diagram:

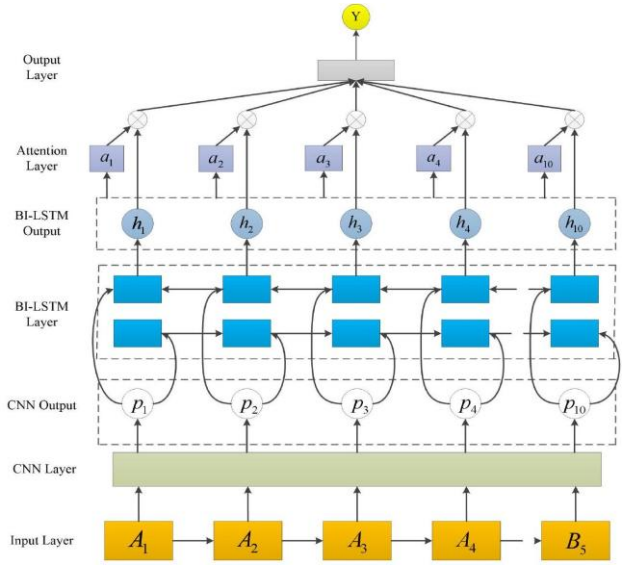

Fig. 7. Structure of the CNN-BILSTM_Att win probability prediction model.

The input and output layers of the CNN-BILSTM_Att model are the same as those of the BILSTM_Att model. In the hidden layers, the CNN-BILSTM_Att model includes an additional CNN layer compared to the BILSTM_Att model. This CNN layer extracts feature vectors from the lineup and then inputs the extracted features into the BILSTM structure. The structure of the CNN model is shown in Fig. 8.

Assuming the team lineup matrix is G, the rows of G represent the vectors of the players in the lineup. Each input lineup consists of 11 players (according to a real football game, each team has 11 field players). The dimensionality of the player vectors is composed of various features such as the technical characteristics, physical data, and tactical role of the players, which is currently set to d. Therefore, G is an 11×d dimensional matrix. $V(W(t))$ represents the d -dimensional feature vector of the t-th player in the lineup matrix G.

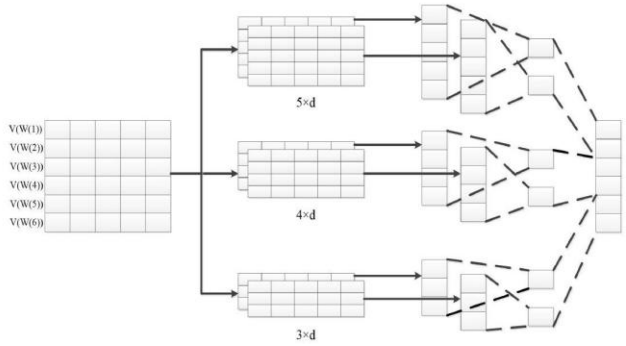

Fig. 8. Convolutional neural network structure.

When the team lineup information is input into the convolutional neural network, the network's convolutional layer uses multiple convolutional kernels of different sizes $l \times d$, to perform convolution on the team lineup matrix G, thus obtaining local feature mappings k_t . The stride of the convolutional kernels is 1. The convolution process is shown as equation:

$$k_t = f(C \cdot G_{t:t+l-1} + b)$$

In equation 5-17, f represents the activation function, and in this model, the Relu function is used as the activation function. C represents the convolutional kernel function, l represents the size of the convolutional window, $G_{t:t+l-1}$ represents the convolutional range of the convolutional kernel, which is from the t-th to the t+l-1-th position of the team lineup matrix G, and b represents the bias term. After convolution, the model can obtain a collection of team lineup feature vectors composed of multiple local features K, with the expression for K shown as equation:

$$K = (k_1, k_2, \dots, k_{m-l+1})$$

In equation, m represents the length of the lineup. In the problem of win probability prediction, each team lineup consists of eleven players, so m=11. After the convolutional layer, a pooling layer can be used to obtain strong features composed of local features. In the CNN-BILSTM_Att model, multiple filters are used to generate the features for each player. The player features after pooling are shown as equation:

$$p = \max(k_1, k_2, \dots, k_{10-l+1})$$

The final representation of the team lineup X^C is derived as equation.

$$X^C = [p_1, p_2, \dots, p_{10}]$$

The model transmits the X^C obtained from the feature extraction of the team lineup data by the convolutional neural network to the bidirectional LSTM. The subsequent data integration and classification steps are the same as those of the BILSTM_Att model.

The improved CNN-BILSTM_Att model first extracts local features, then inputs these features into the bidirectional LSTM network layer and the attention mechanism layer. After integrating features in the attention mechanism layer, it finally uses a softmax classifier for classification. By extracting features from the lineup information through the CNN model, the win probability prediction model can more accurately capture the local information of the lineup, thereby improving the accuracy of predictions.

IV. Case Study

This section will validate the effectiveness of the proposed method using a custom experimental dataset based on a sports stadium scenario.

A. Experimental Environment

The hardware environment for the experiments in this chapter is shown in Table I:

TABLE I. Experimental Software and Hardware Environment Chart

Component	Specification
CPU	Intel i7 8700k
GPU	GTX3080
Memory	32G
OS	Ubuntu18.04
CUDA	11.1
Main Frameworks	Pytorch, keras
Main Programming Language	Python3.6

Due to the complexity of the CNN-BILSTM_Att model, Fig. 9 illustrates the training process of this model.

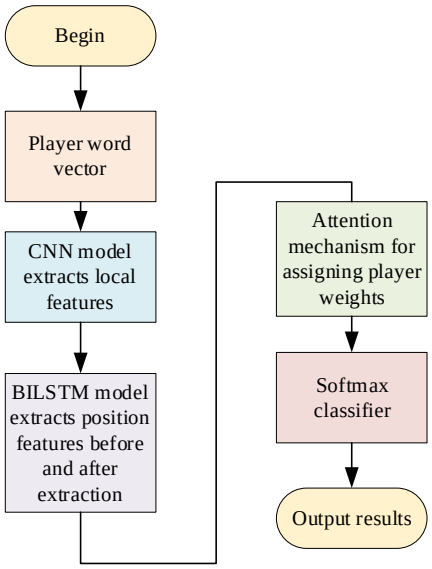

Fig. 9. Training process of CNN-BILSTM_Att.

In the training process of the CNN-BILSTM_Att model, the focus is primarily on two aspects: feature extraction and classification. Initially, the CNN model extracts local features of the word vectors representing players. Subsequently, the BiLSTM model is utilized to extract positional features of the players' lineup. Following that, through the attention mechanism, different weights are assigned to players, reflecting their importance in the match. Finally, a softmax classifier is deployed for classification. The parameters of the CNN-BILSTM_Att win probability prediction model are displayed in Table II.

TABLE II. Hyperparameters of the CNN-BILSTM_Att Prediction Model

Parameter	Parameter Value
Player Word Vector Dimension	110
BILSTM Layer Dimension	16
Learning Rate	0.01
Output Dimension	1
batch_size	200
Convolutional Kernel Sizes	[2,3,4,5]
Parameter	Parameter Value

The model's output employs the player feature vectors generated in Chapter 3, comprising a 100-dimensional feature vector from players' technical statistical data and game performance, along with a 10-dimensional extension vector (potentially including the player's position, health status, and psychological factors). The BiLSTM layer was optimized to select 16 hidden units. The learning rate and batch_size parameters were also finely tuned to achieve the optimal parameters of 0.01 and 200.

Regarding the CNN layers, this study contrasts convolutional kernels of different sizes to assess their impact on the model's performance. Convolutional kernels with sizes 2, 3, 4, and 5 were selected, and the accuracy of the prediction models with these different sizes on the validation set is shown in Fig. 10. Through these experiments, we aim to determine which convolutional kernel size can most effectively enhance the accuracy of football match outcome predictions.

The deep learning techniques applied to process football match data allow the prediction model to extract valuable features from individual technical statistics of players and the overall tactical execution of the team. This aids in more accurately predicting match outcomes. This approach translates the comprehensive performance of players and teams into a format understandable by the prediction model, thus providing technical support for various types of football analysis.

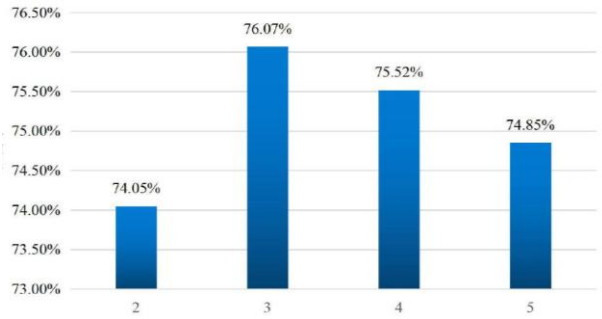

Fig. 10. Accuracy comparison of convolutional kernels of different sizes.

As can be seen from Fig. 10, the accuracy of the four different sizes of convolutional kernels was higher than that of the pure BILSTM_Att model. When the kernel size was 3, the CNN-BILSTM_Att model achieved the highest accuracy in predicting football match outcomes, reaching 76.07%. However, when the kernel size was 2, the model's performance may have been insufficient due to the lack of feature extraction capability. When the kernel size was greater than 3, using larger convolutional kernels meant an increase in the model's weight parameters, which could lead to a decrease in model performance due to issues such as insufficient computational resources.

B. Experimental Results

Fig. 11 shows the accuracy curve of the CNN-BILSTM_Att model for football match win probability prediction over 200 iterations. Overfitting phenomena also occurred during the fitting process of this model. Due to the CNN model's strong feature extraction capability, the CNN-BILSTM_Att model showed a significant improvement in prediction accuracy over the BILSTM_Att model, demonstrating greater expressive power. It can also be seen that the model fitted more quickly, with the CNN-BILSTM_Att model reaching its best performance around the 80th iteration.

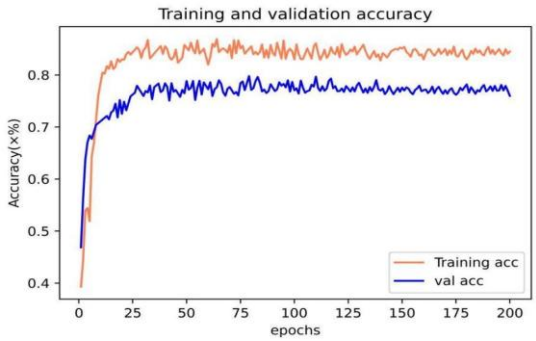

Fig. 11. Fitting curve of the CNN-BILSTM_Att model.

For a more comprehensive comparison, this paper further constructed a CNN-BILSTM_Att model that does not use the extended feature vector as input, namely a CNN-BILSTM_Att model without historical encounter information (No Historical Encounter Relationship CNN-BILSTM_Att, NHR-CNN-BILSTM_Att). This variant differs from the original CNN-BILSTM_Att win probability prediction model only in terms of the input data; it uses only the feature vectors generated from regular team and player statistical data as the model input, in order to assess the impact of historical encounter information on win probability prediction. The model parameters were kept consistent with the complete prediction model. The NHR-CNN-BILSTM_Att model ultimately achieved an accuracy of 74.95%, and the fitting process is shown in Fig. 12.

The results of the NHR-CNN-BILSTM_Att prediction model indicate that the historical encounter information, or the extended vector, has some impact on the final prediction results, suggesting that considering the history of encounters between teams is important when constructing a football match win probability prediction model.

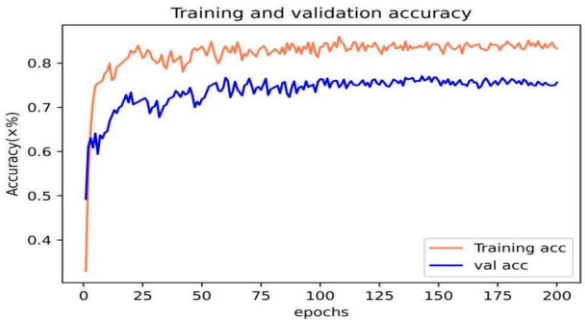

Fig. 12. Fitting curve of the NHR-CNN-BILSTM_Att model.

V. Conclusion

This paper investigates win probability prediction for football matches using deep learning techniques. By analyzing team line-ups and player abilities, the study develops the CNN-BILSTM_Att model, achieving high accuracy in predicting match outcomes. Player statistical data is transformed into numerical vector representations derived from historical performance and ability scores. Initial attempts with three machine learning methods yielded low accuracy, prompting the introduction of an LSTM model to explore key positional information in line-ups. The final models, BILSTM_Att and CNN-BILSTM_Att, incorporate an attention mechanism to weigh player contributions and extract local features effectively. The proposed models enhance win probability predictions by providing valuable insights for coaches, analysts, and fans, thereby enriching the overall viewing experience. Additionally, these methodologies may inspire similar applications in other sports, advancing the field of sports data science.

Acknowledgment

The preferred spelling of the word “acknowledgment” in America is without an “e” after the “g.” Avoid the stilted expression, “One of us (R. B. G.) thanks . . .” Instead, try “R. B. G. thanks.”

Effectiveness of Immersive Contextual English Teaching Based on Fuzzy Evaluation

Mei Niu*

Basic Courses Department, Jiyuan Vocational and Technical College, Jiyuan 459000, Henan, China

***Abstract*—Investigating the real-world impact of immersive contextual instruction on English language education, verifying its contribution to the enhancement of linguistic skills and the improvement of learning attitudes, and evaluating the practicality and worth of fuzzy evaluation in gauging teaching efficacy. A fuzzy complete assessment model was built utilizing the language competency test and the learning attitude questionnaire, and the teaching effect was quantitatively examined based on the experimental data using methods such as affiliation function and weight calculation. The study's findings revealed that students in the experimental group performed much better than students in the control group in terms of language competence and learning attitudes, with an overall fuzzy score of 88.5 compared to 74.8 in the latter. The statistical test indicated a significant difference between the groups (p<0.001). The study also confirmed the scientific and practical validity of fuzzy evaluation in the assessment of multidimensional educational efficacy. Immersion contextual English teaching provides considerable benefits for improving students' language skills and learning attitudes. The fuzzy assessment method introduces a new instrument for quantitative research on teaching efficacy and has a wide range of potential applications.**

***Keywords*—Fuzzy evaluation; immersion; contextual English teaching; teaching effectiveness; teaching assessment**

I. Introduction

With the acceleration of globalization, the improvement of the teaching effect of English, as an important tool for international communication, has increasingly become the focus of research in the field of education [1]. The traditional English teaching mode is mostly based on teachers explaining and students listening to lectures, which lacks contextual immersion, resulting in students' language application ability often being difficult to effectively improve [2]. In recent years, immersion teaching, as an innovative teaching mode, has gradually gained the attention of more and more educators [3]. By simulating the real language use environment, immersion teaching enables students to experience language learning in real situations, thus improving their language proficiency and cultural understanding [4]. However, although the immersion mode of teaching shows obvious advantages in English language teaching, the evaluation of its teaching effectiveness faces a big challenge [5]. Traditional assessment methods often rely on quantitative test scores or qualitative teacher assessment, but these methods are difficult to fully reflect students' comprehensive language proficiency in immersion contexts [6]. Therefore, how to scientifically and accurately evaluate the effects of immersion context teaching has become an important topic in current educational research.

In the complex and dynamic educational context, the fuzzy evaluation method, as a tool adept at handling uncertainty and vagueness, demonstrates its distinctive merits [7]. It can integrate both qualitative and quantitative metrics and conduct a holistic analysis of teaching outcomes from various evaluation perspectives, thereby offering a novel approach for assessing the efficacy of immersive English instruction [8]. Against this backdrop, this study aims to employ the fuzzy evaluation method to carry out a systematic investigation into the teaching effectiveness of immersive contextual English, with the goal of furnishing educators with a more precise and all-encompassing teaching effectiveness assessment instrument [9]. The primary objective of this research is to construct a fuzzy evaluation model suitable for immersive contextual English teaching via empirical research, identify the crucial factors influencing teaching effectiveness, and analyze the data through specific cases [10]. It is anticipated that this research will provide theoretical backing for future English teaching endeavors and an effective basis for decision-making for educational policymakers.

The content structure of this paper is divided into five main sections. Section II of the research review comprehensively combed the domestic and international literature related to this study, including the theoretical foundation of immersive contextual English teaching and the progress of applied research, while analyzing the characteristics of the fuzzy evaluation method and its application value in educational research. Then, Section III of the research method elaborates the design framework of this study in detail, including the selection of experimental samples, data collection methods, the construction process of the fuzzy comprehensive evaluation model, and the specific calculation steps. Subsequently, Section IV of the results and discussion presents the differences in teaching effects between the experimental group and the control group based on empirical data and combines the quantitative results of the fuzzy evaluation with an in-depth discussion of the superiority of immersive contextual teaching and the specific performance of its teaching effects. Finally, Section V of the conclusion summarizes the main findings of the study, analyzes the shortcomings of the study, and looks forward to the future research direction. The parts are interlocked and work together to serve the achievement of the research objectives.

II. Research Review

To fully understand the theoretical background and the current application status of immersive contextual teaching and

*Corresponding Author

fuzzy evaluation, this part will be developed from the following two aspects: the current research status of immersive contextual teaching and its evaluation methods, and the progress of the application of fuzzy evaluation methods in the field of education and its advantages.

A. Research Status and Evaluation Methods of Immersive Contextual Teaching and Learning

The core of the immersive contextual teaching model is to enhance learners' language communication skills by constructing real or simulated language use contexts so that they can practice the language in a near real environment [10]. This model has been widely used in language learning, science experiments cultural courses, etc. Its advantage is that it can enhance students' participation and language acquisition. Some studies have shown that students' language expression and cultural understanding are significantly improved when immersive learning environments are constructed through virtual reality (VR) technology or classroom scenario simulation [11]. However, existing studies have mostly focused on the following three ways of evaluating the effects of immersive teaching: (1) performance assessment based on quantitative data, such as standardized test scores, and comparison of teaching effects through pre-tests and post-tests. (2) Qualitative assessment, such as evaluating teaching effectiveness through students' self-feedback, interviews, or teachers' classroom observations. (3) Mixed assessment, i.e., combining quantitative and qualitative indicators, such as combining test scores and questionnaires for comprehensive analysis. Although these methods can reflect teaching effectiveness to a certain extent, they are often inadequate in dealing with complex and multidimensional evaluation issues [12]. For example, it is difficult to measure the comprehensiveness of students' language useability by relying only on test scores, while subjective interviews and observations are susceptible to the subjective bias of the evaluator [13]. Table I presents for typical immersion teaching evaluation methods and their strengths and weaknesses; therefore, there is a need to introduce evaluation methods that are more scientific, multidimensional, and capable of quantifying complex phenomena.

TABLE I TYPICAL IMMERSION EVALUATION METHODS AND THEIR ADVANTAGES AND DISADVANTAGES

Evaluation Methodology	Vintage	Drawbacks
quantitative assessment	(1) Strong objectivity and easy access to and analysis of data (2) Can be used for comparison and statistical analysis of large samples	(1) Confined to numerical results, it is difficult to fully reflect the effectiveness of teaching and learning (2) Inability to capture learners' subjective experiences and emotional changes
Qualitative assessment	(1) The ability to dig deeper into learners' subjective feelings about teaching and learning (2) Helps capture details and dynamic changes in language use	(1) Highly subjective, with results susceptible to the personal biases of the evaluators (2) A small sample size makes it difficult to generalize to a wider area
Blended assessment	(1) Combines the strengths of quantitative and qualitative methods (2) Teaching effectiveness can be evaluated more comprehensively from multiple dimensions	(1) Complexity of data processing, which may increase the cost of the study (2) The qualitative component remains vulnerable to subjectivity
Assessment based on fuzzy evaluation	(1) Suitable for dealing with complex, multidimensional, and difficult-to-quantify problems (2) Ability to synthesize different indicators and generate overall evaluations (3) Reducing the bias of single data	(1) The model-building process may be subjective in terms of parameter setting (2) The affiliation function and weights should be set scientifically and carefully.

B. Application of Fuzzy Evaluation Methods in Education

The fuzzy evaluation method originated from the fuzzy set theory proposed by Zadeh, which aims to solve the limitations of traditional evaluation methods in dealing with vagueness and uncertainty. In the field of educational evaluation, fuzzy evaluation has attracted much attention because of its ability to integrate multidimensional indicators and handle quantitative and qualitative data [14]. In recent years, fuzzy evaluation methods have been widely used in the fields of teaching quality evaluation, students' comprehensive quality evaluation, and course satisfaction analysis. A study applied the fuzzy comprehensive evaluation method to the assessment of university teaching quality and established a set of multi-dimensional comprehensive evaluation models by setting subjective weights and affiliation functions, which greatly improved the scientificity and persuasiveness of the evaluation results. Similarly, another study proved the high applicability of the fuzzy evaluation model in the assessment of multi-indicator teaching effectiveness in the study of vocational skills teaching. Compared with traditional evaluation methods, fuzzy

evaluation has several advantages [15]. The first is the integration of multidimensional data. It can synthesize and analyze data of multiple dimensions. Then it deals with fuzziness and subjectivity. Through the affiliation function, qualitative evaluations are quantified into manageable mathematical models [16].The fuzzy evaluation method also exhibits significant adaptability in handling intricate and variable teaching scenarios. When integrated with the features of immersive contextual teaching, assessing its outcomes typically entails a multitude of complex and multidimensional factors (such as language proficiency, cultural comprehension, emotional attitudes, etc.), aligning well with the fundamental attributes of fuzzy evaluation [17]. Hence, utilizing fuzzy evaluation for gauging the effectiveness of immersive contextual English instruction can address the limitations of conventional assessment techniques and offer innovative perspectives for teaching effectiveness research. Fig. 1 delineates the construction phases of the fuzzy evaluation model, depicting the entire procedure from identifying evaluation indicators to executing the fuzzy synthesis operation. This aids users in comprehending how to apply the fuzzy evaluation approach to assess the impact of immersive contextual teaching [18]. Initially, it is crucial to establish the evaluation indicator system and choose the evaluation dimension that resonates with the attributes of immersive contextual teaching [19]. Subsequently, the membership function for each evaluation indicator is ascertained to convert qualitative assessments into a quantifiable range of values [20]. Thereafter, the weight of each evaluation indicator is determined based on expert opinions, student feedback, or pertinent literature [21]. Building on this, the fuzzy comprehensive evaluation matrix is formulated by integrating the membership function and weight of each indicator, and the membership values of each evaluation object across each dimension are aggregated into a matrix. Following this, the constructed fuzzy comprehensive evaluation matrix is manipulated to derive the overall score for each evaluation object. Lastly, in accordance with the operational outcomes, the final evaluation results are generated and can be displayed in formats such as scores or grades, assisting decision-makers in making informed judgments.

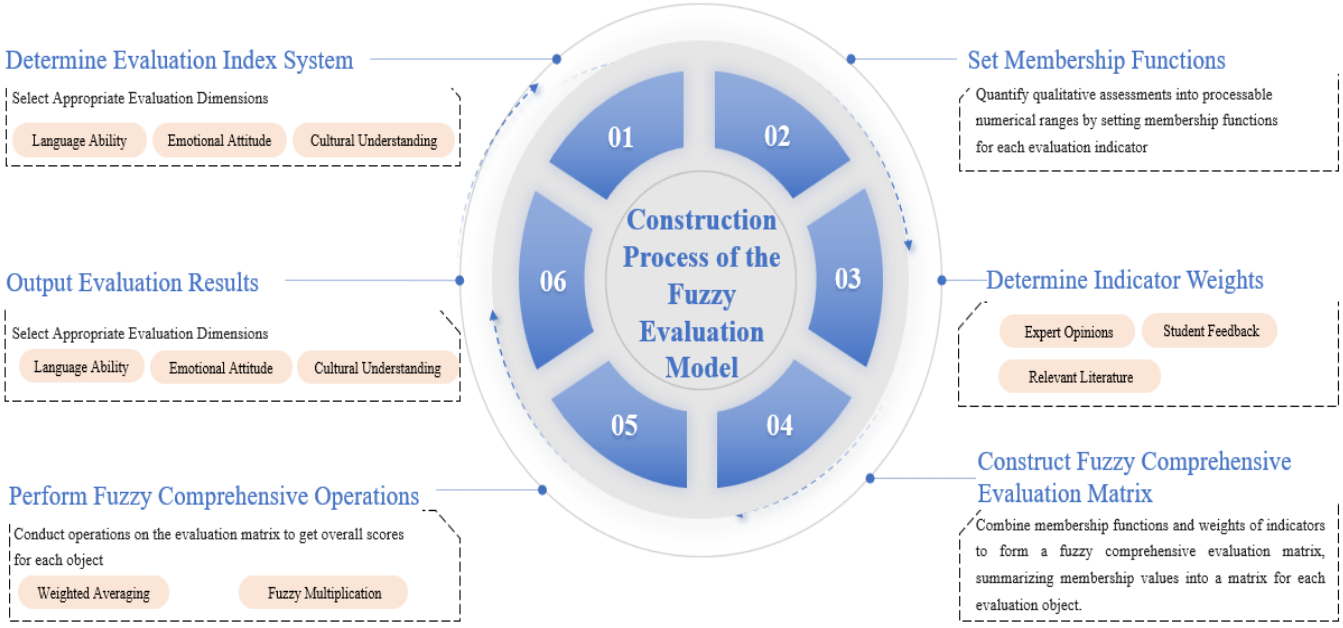

Fig. 1. Construction process of fuzzy evaluation model.

C. Review of the Study and Innovations

To summarize, immersive contextual teaching has received widespread attention in recent years due to its remarkable language-learning effect, but there are still major limitations in the evaluation methods of teaching effectiveness; fuzzy evaluation methods have opened up new paths for educational evaluation research due to their ability to handle multidimensional and complex data and their flexibility [22]. However, few studies have organically combined the two and conducted a comprehensive empirical analysis of actual cases in immersive contextual teaching. A comparison of the innovations of this study with previous studies is shown in Table II. Based on the above analysis, the innovations of this paper are mainly reflected in the following two aspects. (1) Introducing the fuzzy evaluation method into the assessment of the effect of immersive contextual teaching and constructing a multidimensional and highly adaptable fuzzy evaluation model. (2) Through empirical research and data analysis, the validity of the model is verified from actual cases to fill the shortcomings of existing research.

TABLE II COMPARISON OF THE STUDY'S INNOVATIONS WITH PREVIOUS STUDIES

Research	Previous Study	Innovative Points of This Study
Evaluation methods for immersive contextualized instruction	(1) Most studies use traditional quantitative assessments (e.g., achievement assessments, comparison of standardized test scores) (2) or qualitative assessment (e.g., interviews, classroom observations)	Introducing the fuzzy evaluation method into the assessment of immersive contextual teaching, breaking through the limitations of the traditional single method, and constructing a multi-dimensional and highly adaptable fuzzy evaluation model
Comprehensive assessment of teaching effectiveness	Most of the existing research focuses on single dimensions or quantitative indicators, such as academic performance or student feedback, and lacks an integrated approach to assessment.	Based on fuzzy evaluation, a comprehensive assessment of teaching effectiveness is realized through a comprehensive analysis of multiple evaluation dimensions (e.g. language proficiency, cultural understanding, affective attitudes, etc.).
Empirical research and data analysis	Few studies have empirically analyzed real-world cases for immersive contextual instruction.	This study combines real cases with in-depth empirical research to verify the effectiveness of the fuzzy evaluation model in immersive contextual teaching through data analysis.
Evaluation of Teaching Effectiveness Flexibility and Adaptability of	Traditional evaluation methods are often difficult to deal with in complex and dynamically changing teaching and learning contexts.	Fuzzy evaluation methods are flexible and adaptable to complex, dynamic teaching and learning contexts, and are highly adaptable, especially for assessing the effectiveness of immersive contexts.

III. METHODOLOGY

To explore the application of the fuzzy evaluation method in the assessment of English teaching effectiveness in immersive contexts, this study adopts an empirical-based research methodology to construct and validate the fitness model through case studies and data analysis. This section will specify the research design, sample selection, data collection and processing, construction of the fuzzy evaluation model, and its calculation process.

A. Study Design

This study adopts a mixed research method, combining qualitative and quantitative analysis to ensure both an in-depth analysis of the complex teaching phenomenon and the scientific and persuasive nature of the data results. The flow chart of the research design is shown in Fig. 2. The whole research process is divided into four main stages. The first is the contextual teaching implementation phase, in which a school's English course is selected and virtual reality technology is introduced to create multiple simulated learning scenarios, such as ordering food, medical conversations, and international conferences, to provide students with an immersive learning experience. Then comes the data collection phase, in which multidimensional data including standardized language test scores, classroom observation records, student interviews, and questionnaire feedback are collected after the implementation of teaching [23]. The third stage is the fuzzy evaluation model construction, which establishes a suitable fuzzy comprehensive evaluation model to quantify and comprehensively analyze the collected multidimensional data according to the research questions and data characteristics [24]. The final stage is the data analysis and validation stage, which uses tools such as Matlab and Python to process the data, calculate the specific scores of the fuzzy evaluation model, and carry out model adaptation validation [25]. This flowchart provides clear steps and directions for the research and helps to systematically conduct and analyze the research.

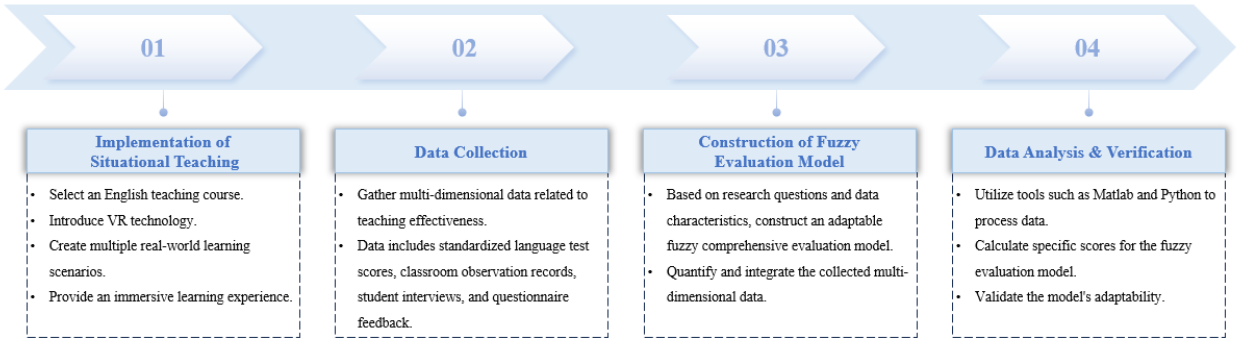

Fig. 2. Flowchart of the study design.

B. Sample Selection and Background

The participants in this study were 120 first-year college students majoring in English, who were evenly divided into an experimental group and a control group, with 60 students in each [26]. The experimental group was subjected to immersive contextual English instruction, while the control group followed the conventional English teaching approach. To reduce the potential impact of sample heterogeneity on the study outcomes, the two groups were matched in terms of age, gender, and English proficiency, which was categorized based on their entrance exam scores [27]. The specific details of the experimental and control groups are presented in Table III. As indicated in the table, both groups comprised 60 participants with average ages of 18.7 and 18.8 years, respectively. A t-test revealed that the age difference between the two groups was insignificant (p=0.653). In terms of gender distribution, the experimental group had 32 males and 28 females, whereas the control group had 31 males and 29 females. A chi-square test indicated no significant difference in gender ratio between the two groups (p=0.853). The mean entrance exam scores for English were 82.3 and 81.9 for the two groups, respectively, and a t-test showed no significant difference in English proficiency (p=0.712). Regarding family background, 35 participants in the experimental group were from urban areas and 25 from rural areas; in the control group, 36 were from urban areas and 24 from rural areas. A chi-square test demonstrated no significant difference in family background between the groups (p=0.896). The duration of English study was 6.5 years and 6.4 years for the two groups, respectively, and a t-test found no significant difference in this regard (p=0.578). In summary, the experimental and control groups exhibited no significant differences in any of the aforementioned basic characteristics, suggesting that the two groups were highly comparable at the outset of the study.

TABLE III SAMPLE GROUPING AND BASIC STATISTICAL CHARACTERISTICS

Variant	Experimental Group (N=60)	Control Group (N=60)	Statistical Test Value	P-Value
Average age (years)	18.7 ± 0.9	18.8 ± 0.8	t = 0.45	0.653
Gender ratio (M/F)	32/28	31/29	$\chi^2 = 0.034$	0.853
The average score on the English test for admission	82.3 ± 5.7	81.9 ± 6.1	t = 0.37	0.712
Family background (urban/rural)	35/25	36/24	$\chi^2 = 0.017$	0.896
Length of English language study (years)	6.5 ± 1.1	6.4 ± 1.0	t = 0.56	0.578

C. Data Collection and Processing

1) Data collection: The data collection for this study covered two main types of data: quantitative and qualitative. Quantitative data were mainly obtained through standardized English test scores, which consisted of four parts: listening, reading, writing, and speaking, and were designed to comprehensively assess students' English proficiency [28]. Qualitative data collection is more diverse and includes instructional observation records, student interviews, and questionnaires. Observation records focus on student engagement and interaction in the classroom to capture the dynamics of the teaching and learning process. Student interviews were conducted to explore students' affective experiences and learning outcomes to obtain their direct feedback on teaching methods and content [29]. In addition, student satisfaction, self-confidence, and changes in interest in teaching and learning were assessed through questionnaires, the content of which helped to quantitatively analyze students' attitudes and affective responses to learning [30]. Synthesizing the data collected through multiple channels, we were able to gain a comprehensive and in-depth understanding of students' learning status and teaching effectiveness, which provided solid data support for the study.

2) Data pre-processing: The collected data were first subjected to data cleaning and pre-processing through SPSS, including outlier removal and data normalization. The data normalization equation is as follows, for the original data x, normalized to:

$$x' = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \quad (1)$$

Where $X_{\min}$ and $X_{\max}$ are the minimum and maximum values of the sample data, respectively?

D. Fuzzy Evaluation Model Construction

Based on the core logic of the fuzzy evaluation method, the model construction is divided into the following steps:

1) Determination of the evaluation indicator system: Combining the characteristics of the effect of immersion teaching and previous studies, an evaluation system including four first-level indicators and several second-level indicators is established [31]. The first-level indicators include: language ability (A_1), learning attitude (A_2), learning interest (A_3), and emotional experience (A_4). The secondary indicators include listening (A_{11}), speaking (A_{12}), reading and writing sub-competencies in language proficiency, classroom participation, and change in language anxiety. The weights of the first-level indicators are noted as $W = [w_1, w_2, \ldots, w_n]$, where w_i meet $\sum w_i = 1$. Each secondary indicator weight is obtained by hierarchical analysis (AHP) and distributed in the evaluation system in the following way. Table IV shows the weight distribution table of the evaluation indicators, with a total of four first-level indicators (A1, A2, A3, A4), whose sum of

weights is 1, reflecting the importance weights of different dimensions in the total evaluation. Each level 1 indicator is subdivided into several level 2 indicators, and the weight distribution is calculated by the hierarchical analysis method (AHP) to ensure rationality and scientificity [32]. The sum of the weights of the second-level indicators satisfies the corresponding weights of the first-level indicators. The distribution of the indicators reflects the multidimensional nature of the immersive contextual teaching evaluation model. For example, language proficiency is given the highest weight (40%), with higher weights for listening and speaking, indicating its centrality to teaching effectiveness.

TABLE IV DISTRIBUTION OF WEIGHTS OF EVALUATION INDICATORS

Primary Indicators	Weight	Secondary Indicators	Weight
Language Ability (A1)	WA1=0.4	Listening (Listening, A11)	W*A* 11=0.15
		Speaking (Speaking,*A* 12)	W*A* 12=0.15
		Reading (Reading,*A* 13)	WA13=0.05
		Writing (Writing,*A* 14)	WA14=0.05
Learning Attitude (A2)	WA2=0.3	Classroom Participation,*A* 21)	WA21=0.2
		Task Completion (Task Completion,*A* 22)	WA22=0.1
Learning Interest, A3)	WA3=0.2	Interest Improvement (Interest Improvement,*A* 31)	WA31=0.2
Emotional Experience (A4)	WA4=0.1	Language Anxiety Change (Language Anxiety Change,*A* 41)	WA41=0.1

2) Construct fuzzy affiliation function and affiliation matrix: Each secondary indicator corresponds to a different evaluation grade (e.g., excellent, good, fair, poor), and defines the affiliation function for each grade. Define the evaluation level set $\mathrm{V}=\{\mathrm{v}_1,v_2,...,v_m\}$, the corresponding evaluation levels include "excellent", "good", "fair", "poor", etc. For each indicator, define its fuzzy affiliation function. For each indicator A_{ij} , define its fuzzy affiliation function $\mu_{\mathrm{ij}}(x)$. In this study, triangular fuzzy numbers are used for evaluation in the following form:

$$\mu_{\mathrm{ij}}(x)\begin{cases}0, & x\le a \text{ or } x\ge c,\\ \dfrac{\mathrm{x}-a}{b-a}, & \mathrm{a}\le \mathrm{x}\le \mathrm{b},\\ \dfrac{c-x}{c-b}, & b\le x\le c\end{cases} \tag{2}$$

Where*a*, *b* and *c* are the starting point, median and end point of the fuzzy number respectively. For each evaluated object, the affiliation value of each evaluation index is calculated through the data of students' test scores, classroom records, and questionnaire feedback, and the affiliation is formed.

$$\mathrm{R}=\begin{bmatrix}\mu_{11}(v_1) & \mu_{11}(v_2) & \cdots & \mu_{11}(v_m)\\ \mu_{12}(v_1) & \mu_{12}(v_2) & \cdots & \mu_{12}(v_m)\\ \vdots & \vdots & \ddots & \\ \mu_{1n}(v_1) & \mu_{1n}(v_2) & \cdots & \mu_{1n}(v_m)\end{bmatrix} \tag{3}$$

Where each row of R represents the affiliation of a secondary indicator to a different evaluation level.

3) Fuzzy synthesis operation: Based on the affiliation matrix R and the weight vector W , a fuzzy comprehensive evaluation is performed by the following equation:

$$B=W\cdot R=\left[\mathrm{b}_1,b_2,\cdots,b_m\right] \tag{4}$$

Where B is the comprehensive affiliation vector, which represents the comprehensive evaluation affiliation of the evaluation object on different levels; W is the weight vector; and *R* is the affiliation matrix. To quantify the evaluation results, the comprehensive affiliation vector *B* is normalized and the fuzzy score is calculated:

$$\mathrm{S}=\sum_{i=1}^{m}b_i\square v_i \tag{5}$$

Where S is the final score of the fuzzy comprehensive evaluation and V_{i} is the score corresponding to the *i* evaluation level (e.g., 100 for "excellent" and 80 for "good").

E. Model Validation

To verify the applicability of the fuzzy evaluation model, this study conducted a correlation analysis between the model calculation results and the standardized test scores and further verified the reasonableness and scientificity of the model output results through expert review and student feedback. The correlation between the fuzzy composite scores and the standardized test scores was examined through Pearson correlation coefficient analysis to assess the reliability and validity of the model. The equation is as follows:

$$r = \frac{\sum(X_i - \overline{X})\sum(Y_i - \overline{Y})}{\sqrt{\sum(X_i - \overline{X})^2 \cdot \sum(Y_i - \overline{Y})^2}} \quad (6)$$

Where X_i and Y_i are the academic fuzzy score and test score, respectively, and $\overline{X}$ $\overline{Y}$ are the corresponding mean values. Based on the experimental data, the model parameters (e.g., the shape of the affiliation function and the weight distribution) are adjusted to ensure high consistency between the model evaluation results and the actual situation.

IV. Results and Discussion

Through the fuzzy evaluation of the teaching effectiveness of the experimental and control groups, this study reveals the effectiveness of immersion contextualized teaching in enhancing students' language proficiency and learning attitudes [33]. In this part, specific discussions will be made around the results of the data analysis, including the results of the fuzzy comprehensive evaluation, the analysis of the differences between the groups, and the substantive interpretation of the teaching effectiveness.

A. Fuzzy Synthesized Evaluation Results

Utilizing the previously mentioned fuzzy evaluation model, this research carried out an extensive assessment of the teaching outcomes for both the experimental and control groups, and computed their respective final fuzzy scores, as depicted in Fig. 3. This figure contrasts the comprehensive scores of the two groups. The experimental group's comprehensive fuzzy score was notably higher than that of the control group, suggesting that immersive contextual teaching can substantially enhance students' overall language abilities, particularly in communicative competencies like listening and speaking, where the benefits are more pronounced [34]. In the graph, the horizontal axis denotes the Overall Score, while the vertical axis indicates the Group, with the control group symbolized by green dots and the experimental group by purple dots. The graph reveals that the experimental group generally achieved a higher Overall Score than the control group. The score distribution in the experimental group is more clustered, with the majority of scores exceeding 80, whereas the control group's scores are more scattered, primarily ranging between 70 and 80. The experimental group's scores are more tightly packed within the 80 - 90 range, indicating greater consistency and superior performance. In contrast, the control group's scores are more diffused, spanning from 60 to 90, reflecting larger individual variations. The density curves at the base of the figure further illustrate the score distributions of both groups. The experimental group's density curve is more peaked, with the apex situated around 80 points, while the control group's density curve is flatter, with the peak around 70 points. There is a marked disparity in overall scores between the experimental and control groups, with the experimental group markedly outperforming the control group. This could imply that the pedagogical approaches or interventions employed in the experimental group were more efficacious in elevating students' overall scores.

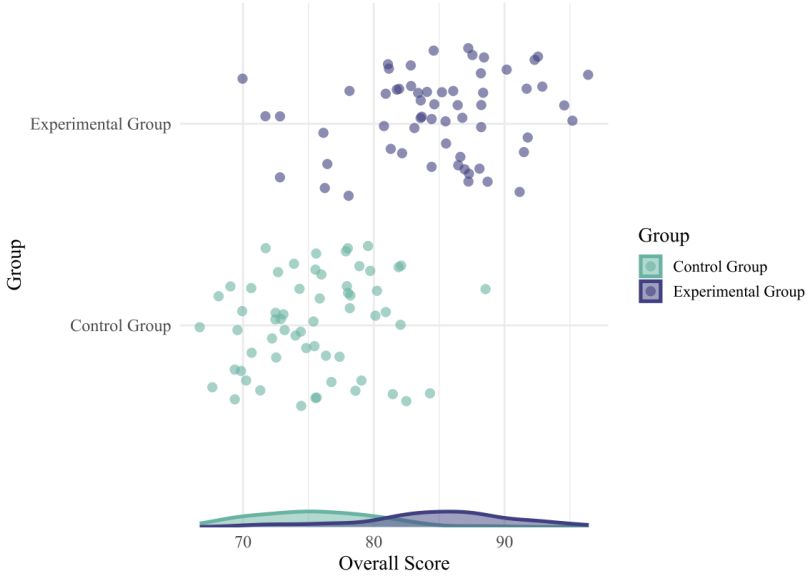

Fig. 3. Comparison of composite scores between experimental and control groups.

B. Analysis of differences between Indicators

Further analysis of the scores for the primary and secondary indicators reveals the following salient features:

1) Effective in improving language skills: The fuzzy evaluation indicates that the experimental group outperformed the control group across all language proficiency subcategories, namely listening, speaking, reading, and writing. For instance, in the listening subcategory, the experimental group's membership distribution predominantly centers on the "excellent" and "good" levels, whereas the control group's distribution is more concentrated on the "good" and "fair" levels. This suggests that immersive contextual teaching facilitates

students' quicker adaptation to real - life language settings and enhances their language comprehension abilities. Table V presents the performance membership matrices for the experimental and control groups in listening and speaking, featuring four levels of membership distribution: excellent, good, fair, and poor. Regarding listening, the experimental group's membership values for excellent and good grades are 0.45 and 0.40, respectively, which are markedly higher than those of the control group (0.10 and 0.60). In terms of speaking ability, the experimental group's membership values for excellent and good grades are 0.50 and 0.35, respectively, also surpassing those of the control group (0.15 and 0.55). This demonstrates that the experimental group exhibits superior overall performance in both listening and speaking, especially in the excellent grade category. Notably, the disparity is more pronounced in the excellent grade performance. Moreover, the membership values for the poorer grades in both groups are 0.05, indicating a low proportion of poor performance.

TABLE V LISTENING AND SPEAKING AFFILIATION MATRIX

Group	Excellent	Favorable (Good)	General (Average)	Mediocre (Poor)
Listening - Experimental Group	0.45	0.40	0.10	0.05
Listening - Control Group	0.10	0.60	0.25	0.05
Speaking - Experimental Group	0.50	0.35	0.10	0.05
Speaking - Control Group	0.15	0.55	0.25	0.05

2) Improvement of positive learning attitudes: The survey results revealed that students in the experimental group exhibited markedly higher classroom engagement, enthusiasm for learning, and associated satisfaction scores compared to the control group (refer to Fig. 4 below), which utilizes a scatter plot coupled with a trend smoothing line to illustrate a contrast between the experimental and control groups regarding learning attitude scores. As depicted in the figure, the experimental group generally achieved higher learning attitude scores than the control group. Despite both groups having a certain degree of score distribution, the experimental group's scores were more concentrated and displayed an upward trend, indicating that students in this group demonstrated a more proactive and positive approach to learning [35]. Conversely, the control group's scores were relatively lower and more scattered, suggesting that their learning attitudes might be less favorable than those of the experimental group. Moreover, the experimental group had a significantly greater number of individuals with high ratings than the control group, further corroborating the efficacy of the experimental teaching method in bolstering students' learning attitudes [36]. In summary, the figure furnishes visual substantiation for the study that the teaching interventions in the experimental group yielded substantial outcomes in enhancing students' attitudes towards learning. This underscores the efficacy of contextualized teaching in stimulating students' intrinsic motivation.

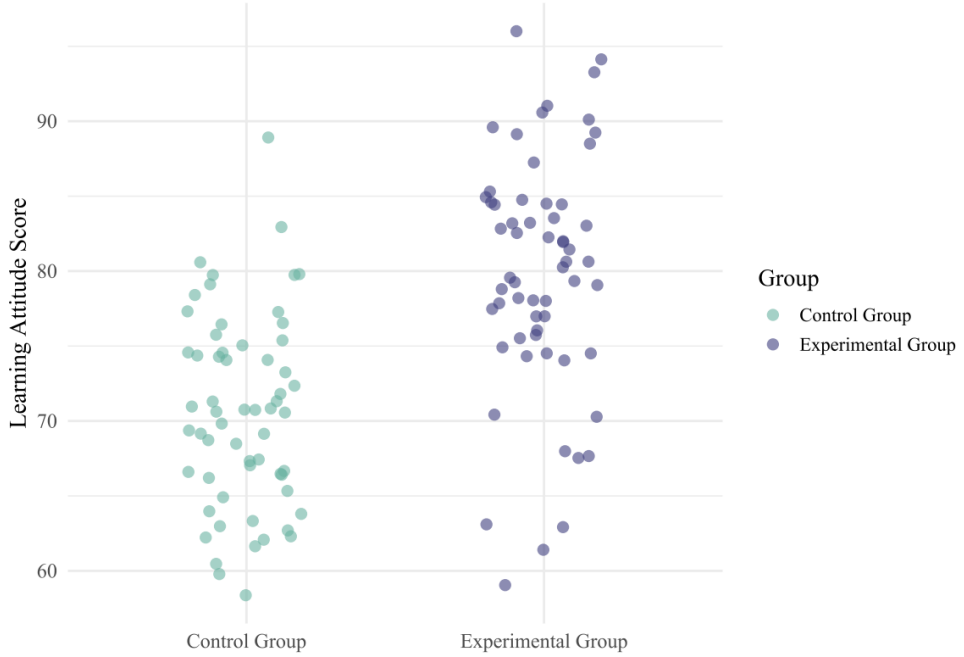

Fig. 4. Statistical comparison of learning attitude indicators between groups.

C. Comparison of Teaching Effectiveness between Experimental and Control Groups

To present a more comprehensive picture of the differences in the effectiveness of immersive contextualized instruction versus traditional instruction, this study conducted a t-test on the composite scores of the two samples, yielding in the Fig. 5.

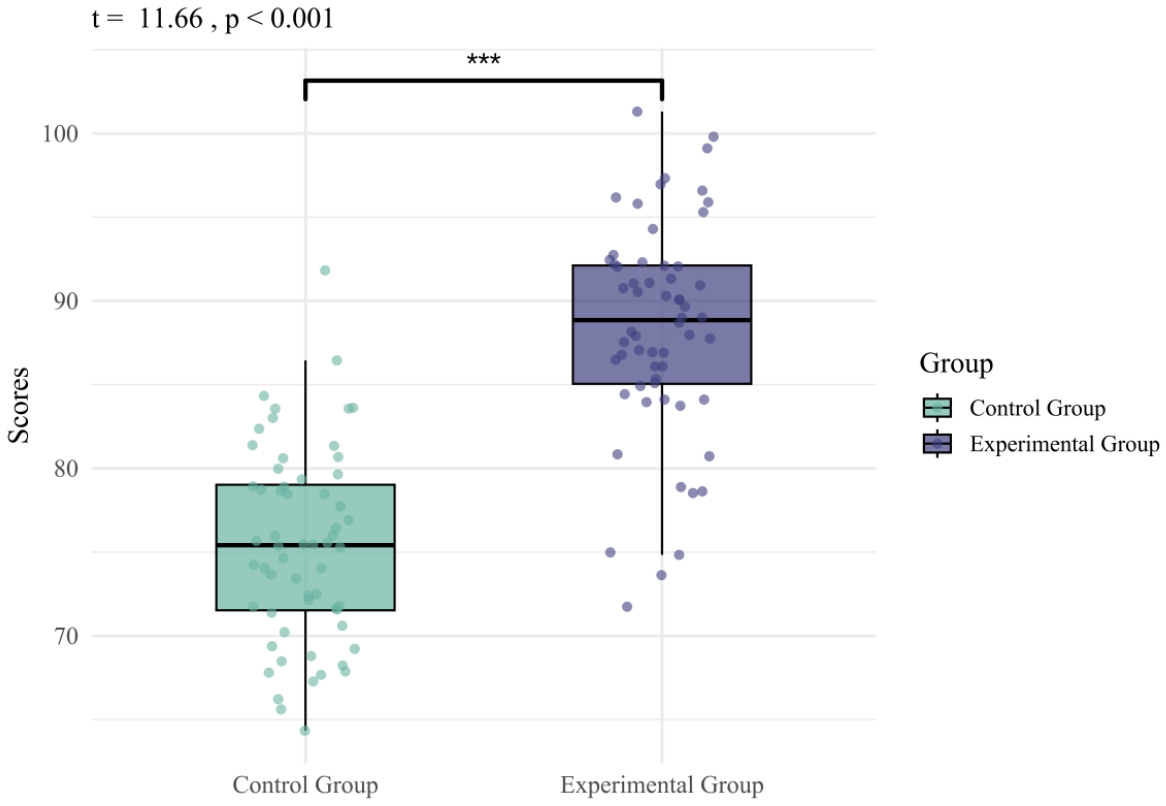

Fig. 5. Graph comparing the effect of experimental and control groups.

The figure provides a detailed comparison of teaching effectiveness between the experimental and control groups, depicted through a box-and-line plot. It is evident that the experimental group's score distribution is more compact and features a higher median, suggesting superior overall performance compared to the control group. Specifically, the experimental group's median score is nearly 90, whereas the control group's median score hovers around 75, highlighting a distinct advantage in teaching effectiveness for the experimental group. Furthermore, the experimental group's score range is relatively narrower, indicating more stable and less variable student performance. The statistical analysis results corroborate this observation. The independent samples *t*-test results revealed a highly significant difference between the two groups (t=11.66, p<0.001), indicating that the experimental group was substantially more effective than the control group. This level of significance (p<0.001) implies that the difference between the experimental and control groups is improbable to be attributed to random factors, but rather to the efficacy of the teaching methods or interventions employed by the experimental group.

D. Interpretation and Discussion of Results

1) Advantages of immersive contextualized instruction: In this study, the effects of immersive contextual teaching were analyzed in depth through the fuzzy evaluation method, and the results showed that this teaching mode can effectively improve students' language communication skills. This finding is consistent with the existing literature on the importance of authenticity of teaching contexts for students' language acquisition [37]. What's more, this study is the first attempt to quantitatively analyze teaching effectiveness through the fuzzy evaluation method, which provides a new perspective and methodology for research in this field. The results of this quantitative analysis not only enhance the scientific nature of teaching research but also provide precise data support for actual teaching design, which helps educators grasp the teaching effect more accurately to optimize teaching strategies.

2) Application value of fuzzy evaluation: Fuzzy evaluation shows its unique advantages in assessing complex teaching phenomena, especially in the multidimensional comprehensive analysis [38]. For example, when assessing highly subjective indicators such as "emotional experience", the affiliation matrix of fuzzy evaluation can effectively describe the distribution of student's satisfaction with the classroom, thus reducing the bias that may be brought by a single scoring model [39]. This method can reflect students' subjective feelings and learning experiences more comprehensively, providing a richer and more detailed perspective for the evaluation of teaching effectiveness.

3) Research limitations and future directions: While this study has yielded significant findings regarding the assessment of teaching effectiveness, it is not without limitations. Firstly, the relatively small sample size may impinge upon the generalizability of the results. Subsequent research endeavors could enhance the generalizability and robustness of the model presented herein by increasing the sample size. Secondly, the parameter configurations of the fuzzy evaluation model, including the form of the membership function, warrant further refinement to augment the model's precision and versatility [40]. Moreover, future investigations might delve into the applicability of fuzzy evaluation techniques across diverse teaching contexts and subject domains, thereby broadening the scope and depth of their utilization. Through such initiatives, it is anticipated that fuzzy evaluation methods will assume a more pivotal role in the realm of teaching effectiveness assessment, offering enhanced support for educational research and practice.

V. Conclusion and Limitations

This study adopts a fuzzy evaluation method to comprehensively analyze the effectiveness of immersive contextual English teaching. By constructing a scientific fuzzy evaluation model, this study assessed the effectiveness of the teaching method in terms of two key dimensions, namely, language proficiency and learning attitude, and proved the significant advantages of immersive contextual teaching in a practical application through empirical research. The results of the study show that immersive contextual teaching is effective in enhancing students' language proficiency. The composite scores of students in the experimental group were significantly higher than those of the control group in each language proficiency index, such as listening, speaking, reading, and writing. This result shows that contextualized teaching can effectively improve students' language practice ability by creating a real language environment. In addition, immersion teaching also shows positive effects in enhancing students' learning attitudes. The results of the fuzzy evaluation show that immersion teaching is effective in enhancing students' motivation, classroom participation, and interest in learning. Scenario simulation and interactive experience can better stimulate students' intrinsic motivation and thus strengthen learning effects. This study also introduces the fuzzy evaluation method into the assessment of English teaching effectiveness and verifies the application value of this method. This method provides a new way of thinking and methodology for the teaching evaluation system, which can quantify the complex teaching process more comprehensively, especially when it involves the comprehensive analysis of multi-dimensional data, which has significant advantages. To summarize, immersive contextual English teaching not only reflects high efficiency in language proficiency cultivation but also achieves positive feedback in students' learning attitudes and subjective experiences, providing important insights for educational reform and practice. The application of the fuzzy evaluation method further highlights the importance of quantitative analysis in teaching research, which is of theoretical promotion and practical guidance significance.

However, there are still some shortcomings in this study. On the one hand, the relatively small size of the experimental sample may affect the external validity of the conclusions; future research can expand the sample coverage and select subjects from students of different age groups and different language bases to verify the generalizability of the findings. On the other hand, the fuzzy evaluation model is somewhat subjective in the selection of the affiliation function; in the future, attempts can be made to optimize the parameter settings of the model by introducing machine learning or artificial intelligence algorithms. In addition, this study mainly focuses on the two dimensions of language proficiency and learning attitude, and subsequent studies can further explore the effects of contextualized teaching on higher-order language proficiency such as critical thinking and intercultural communication skills.

***Abstract*—Chest diseases significantly affect public health, causing more than one million hospital admissions and approximately 50,000 deaths annually in the United States. Chest X-ray imaging technology, which is a critically important imaging technique, helps in examining, diagnosing, and managing chest conditions by providing essential insights about the presence and severity of disease. This study introduces a novel chest X-ray classification framework leveraging a fine-tuned VGG19 model (16 layers) enhanced with CLAHE for improved contrast, binary mask attention to highlight abnormalities and advanced data augmentation for better generalization. Key innovations include the use of a Probabilistic U-Net for lung segmentation to isolate critical features and weighted masks to focus on pathological regions, addressing class imbalance with computed class weights for fair learning. By achieving 95% accuracy and superior class-specific metrics, the proposed method outperforms existing deep learning approaches, providing a robust and interpretable solution for real-world healthcare applications, where a test accuracy of 94.8% is achieved using different customized models based on VGG19 without using a mask. The experimental results indicate that our proposed method surpasses current deep learning techniques in terms of overall classification accuracy for chest disease detection.**

Keywords*—Convolution neural network; classification; chest X-ray; image preprocessing; U-Net; deep learning

I. Introduction

Chest pain is the most common reason for consultations and emergency room visits. Globally, chest radiography is the most frequently used imaging examination, essential for the screening, diagnosis, and management of numerous life-threatening thoracic conditions. The expertise and observational skills of radiologists are crucial for interpreting chest X-rays (CXRs). However, the complexity of the pathologies and the subtle differences in lung lesions mean that even experts can sometimes miss minute details. Additionally, there is a shortage of trained and experienced radiologists. Consequently, recent research has focused on developing systems to detect thoracic diseases and generate reports. These studies predominantly employ deep learning and neural network models. This paper aims to explore these diseases accurately.

The chest is the upper part of the trunk. It gets support from the rib cage, the girdle of the shoulder, and the spine that also protects it. It is the region of the body formed by the sternum, the thoracic vertebrae, and the ribs [1]. It resides between the neck and diaphragm excluding the upper limb. The heart and lungs reside in the thoracic cavity, as well as many blood vessels that play a vital role in feeding (esophagus), breathing, and pumping blood to all parts of the body [2].

Deep learning techniques that implement deep neural networks became popular due to the increase in high-performance computing facilities. Deep learning achieves higher power and flexibility due to its ability to process a large number of features when it deals with unstructured data [3].

Deep learning models have been used successfully in many areas such as classification, segmentation, and lesion detection of medical data. Analysis of image and signal data obtained with medical imaging techniques such as Magnetic Resonance Imaging (MRI), Computed Tomography (CT), and X-ray with the help of deep learning models [4]. As a result of these analyses, detection and diagnosis of diseases such as diabetes mellitus, brain tumor, skin cancer, and breast cancer are provided convenience [5].

The contributions of this research can be summarized as follows:

- A method has been devised based on the VGG19 model for the classification of chest X-ray images as COVID, Lung Opacity, Normal, and Viral Pneumonia.
- Preprocessing of images using CLAHE, Data Augmentation, etc., has been considered for improving X-ray image quality to enhance the model performance.
- Attention mechanism is employed here by first generating binary masks that tune the model to learn regions of interest for better detection of pathological features.
- Class weighting while training was done to handle class imbalance, hence the model performed well on all categories.
- VGG19 was pre-trained on ImageNet and fine-tuned on chest X-ray images with very good generalization and a validation accuracy of 95%.

This paper is organized as follows. The Literature survey is given in Section II. Section III describes the Methodology that is used. The result is presented in Section IV. Conclusions and future work are provided in Section V.

II. Literature Survey

Many papers proposed chest disease detection and classification using deep learning techniques. For instance,

Wang et al. [6] proposes COVID-Net, a deep convolutional neural network to enable the detection of COVID-19 cases from CXR images. COVID-Net leverages an open human-machine collaborative design strategy, marrying both principled network prototyping with machine-driven exploration utilizing a novel lightweight architecture enhanced in representational capacity and computational efficiency. It was then trained on COVIDx, the benchmark dataset of 13,975 CXR images, incorporating data from five public repositories. Quantitatively, COVID-Net achieved 93.3% accuracy, 91% sensitivity, and 98.9% positive predictive value for COVID-19 detection, outperforming traditional models such as VGG-19 and ResNet-50 in terms of computational efficiency and sensitivity. A qualitative audit using the GSInquire explainability method confirmed that its decision-making relied on clinically relevant lung regions, thus providing transparency and reliability. Though limited by available data, and non-production ready, the core ideas presented in COVID-Net present a very nice starting point to advance further the use of AI approaches for COVID-19 screening, and triaging with possible extension to risk stratification.

In research [7], the author introduce CoroNet, a deep convolutional neural network (CNN) model, was introduced for detecting COVID-19 infection using chest X-ray images. Using the Xception architecture pre-trained on ImageNet dataset, the study trained CoroNet on a curated dataset of COVID-19, bacterial pneumonia, viral pneumonia, and normal chest X-rays. The model achieved an accuracy of 89.6% for four-class classification (COVID-19, bacterial pneumonia, viral pneumonia, and normal); 95% for three-class classification; and 99% for binary classification (COVID-19 vs. others). CoroNet performed better than previous studies, particularly in detecting COVID-19 patients. However, the study acknowledges its limitations, including reliance on a small dataset, and indicates the need for access to larger datasets.

In study [8], the author brings to light the importance of preprocessing the chest X-ray images for better classification of diseases. Using the ChestX-ray8 dataset, this research identifies some quality issues in images that affect classification performance. Prior methods used CNNs with preprocessing techniques such as contrast enhancement and feature extraction, often relying on metadata or manual preparation. In this paper, an automated preprocessing method is proposed that combines Sobel and Scharr edge detection with a shallow CNN to classify images into clear and low-quality images. It achieved 95% accuracy and provided a scalable solution for dataset cleaning and reduced dependence on metadata, although it had problems with extreme image defects.

In study [9], the use of transfer learning for pneumonia classification from chest X-ray pictures is examined, with a focus on differentiating between SARS-CoV-2, generic viral, and bacterial infections as the origins of pneumonia. This study assesses 12 well-known ImageNet pre-trained neural network models, building on earlier studies that frequently concentrated on binary categorization (COVID-19 versus healthy) or required particular data preprocessing. Using a dataset of 6,330 publicly sourced images, cropped to uniform dimensions, and separated into four classes—healthy pneumonia, bacterial pneumonia, viral pneumonia, and COVID-19—these models were optimized. MobileNet v3 demonstrated good classification performance and computational efficiency, with the best F1 score of 84.46%. Additionally, resilience tests were performed by reducing the amount of available training data to 50%, 20%, and 10%, showing varying levels of performance loss. The paper highlights the effectiveness of transfer learning in medical diagnosis while highlighting a number of challenges, such as model convergence issues and data scarcity. Expanding the datasets to different types of lung disorders and establishing preprocessing methods to reduce classification errors are future priorities.

In study [10], this work fills important gaps in previous work on deep learning-based COVID-19 identification, including restricted attention to binary or three-class classification problems, imbalanced datasets, and limited metric reporting. With confidence fusion, it suggests COVDC-Net, a hybrid deep learning model that combines MobileNetV2 and VGG16. On balanced datasets, it performs better, with 96.48% accuracy for three classes and 90.22% accuracy for four classes. The work overcomes the drawbacks of single architectural techniques and ensures scalability for practical clinical applications by providing comprehensive metrics for each class and enhancing model robustness through fusion.

In study [11], Sahin et al, a novel CNN model for COVID-19 detection utilizing chest X-ray pictures is proposed and tested on a dataset of 13,824 images alongside MobileNetV2 and ResNet50. After standardizing the images to 224 x 224 pixels through preprocessing, the models were trained with the Adam optimizer using the same training/testing splits (80%/20%). The proposed CNN outperformed MobileNetV2 (95.73%) and ResNet50 (91.54%) with an F1 score of 97% and test accuracy of 96.71%. It was also computationally economical, using fewer convolutional layers and parameters. The model was limited to single image slices and lacked severity classification capability, which hindered its ability to differentiate between COVID-19 and other viral pneumonia despite its high accuracy. This study highlights the potential of deep learning for COVID-19 diagnosis while addressing gaps like dataset limitations and computational efficiency.

In study [12], it presents a framework for detecting COVID-19 from chest X-ray images using transfer learning, addressing key limitations of prior studies. What was done: The authors used pre-trained VGG19 and EfficientNetB0 models to classify chest X-ray images as COVID-19 or normal in binary classification and extended it to a 4-class task (COVID-19, normal, viral pneumonia, and lung opacity). How it was done: Preprocessing included histogram equalization, CLAHE, and complement techniques to enhance image quality, while segmentation utilized lung masks for region-specific analysis. Training was performed with fine-tuned CNN models using benchmark datasets (e.g., COVID-19 Radiography Database) divided into training, validation, and testing sets. Results achieved: The VGG19 model achieved the best binary classification accuracy of 95% with CLAHE-enhanced images and 93.5% for 4-class classification using EfficientNetB0. Sensitivity, specificity, and F1 scores were also high, demonstrating reliable performance. Limitations or gaps: The study highlights that classification accuracy on segmented images was lower than on full images, suggesting the need for

further optimization. Additionally, dataset diversity and scalability remain areas for future research.

III. METHODOLOGY

Apply deep learning models to train data and achieve a high accuracy, through datacollecting and make preprocessing on it, then train data. In this section, the proposed method for chest disease classification using chest X-ray images is presented shown in Fig. 7. The data is split to 70 train, 15 validation and 15 test.

A. Dataset

As emphasized in the companion paper [11], it is our aim to optimize the performances of the models proposed there. The dataset for this study was the COVID-19 Radiography Database, a large repository of thousands of publicly available benchmark X-ray images of both lungs along with ground-truth masks. In order to make the set of images uniform for efficient processing/analysis, images are available in PNG format with 299 × 299 pixel resolution.

The database consists of 6012 lung opacity images, 10,192 normal cases, 3616 positive COVID-19 cases, and 1345 viral pneumonia cases as depicted. The database was developed by a team from Qatar University and Dhaka University in Bangladesh with collaborators from Malaysia and Pakistan of medical experts. The many classifications of the COVID-19 Radiography [13] Database are represented through samples in Fig. 1.

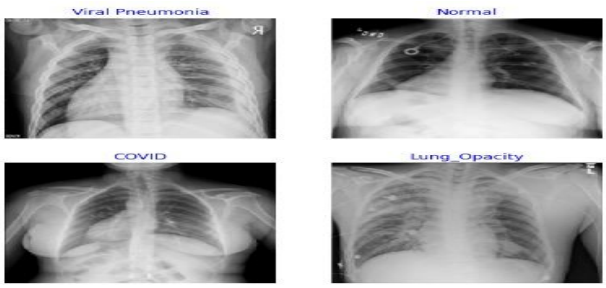

Fig. 1. Sample of the X-ray images used in dataset.

B. Data Preprocessing

Preprocessing is kind of important to increase the quality of an image and hence boost the performance of the model. The following steps are performed on the dataset:

- Apply CLAHE (Contrast Limited Adaptive Histogram Equalization)
- CLAHE improves the overall contrast of the chest X-ray images but at the same time, it enhances darker areas particularly. It enhances the contrast of the weak patterns like lesions and opacities and makes the abnormalities conspicuous as shown in Fig. 2.

Image Transformations (Data Augmentation):

Also, in order to increase the variance of the dataset and prevent overfitting, the following operations are performed: rotation, flipping, zooming, and changes in brightness. These changes allowed the model to generalize better over unseen data.

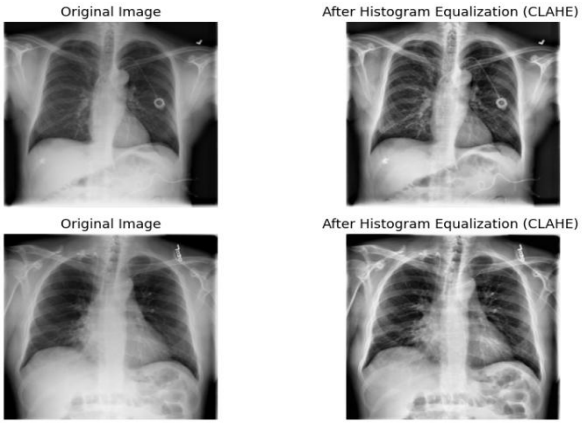

Fig. 2. Image after and before Histogram Equalization.

C. Attention Mechanism

In order to draw the model's attention to critical regions in X-ray images during learning, a binary mask-based attention mechanism was implemented as follows:

Mask attention steps:

1) Creating a binary mask: The masks were then converted to binary 0 or 1 based on a threshold value. Regions containing abnormalities were labeled as class 1, while regions containing no abnormalities were labeled as 0.

2) Weighted mask application: The binary mask was then adjusted using the following formula: This calculation is represented by Eq. (1).

$$\text{Weighted mask} = \text{mask} + 0.4 * (1\text{-mask}) \quad (1)$$

- The alpha parameter (0.4) was applied to weight the non-masked (background) regions; thus, the model gives greater importance to abnormal regions but doesn't completely ignore the rest.
- Masked image: The weighted mask was applied to the input image to emphasize pathological regions. This calculation is represented by Eq. (2)

$$\text{Masked image} = \text{image} * \text{weighted mask} \quad (2)$$

- This approach made the model focus on relevant clinical features, resulting in better performance. As shown in Fig. 3.

D. Weights for Classes in Unbalanced Data

Fig. 4 shows how the dataset was imbalanced, with the number of images associated with COVID-19 being less than those associated with normal or lung opacity classes. To overcome this, class weights were calculated and passed during model fitting: This calculation is represented by Eq. (3)

$$\text{class\_weights} = \{\text{class\_id}: \text{total\_samples} / (\text{num\_classes} * \text{samples\_in\_class})\} \quad (3)$$

By penalizing misclassifications of underrepresented classes, these class weights ensured that the model learned as equally as possible for each class.

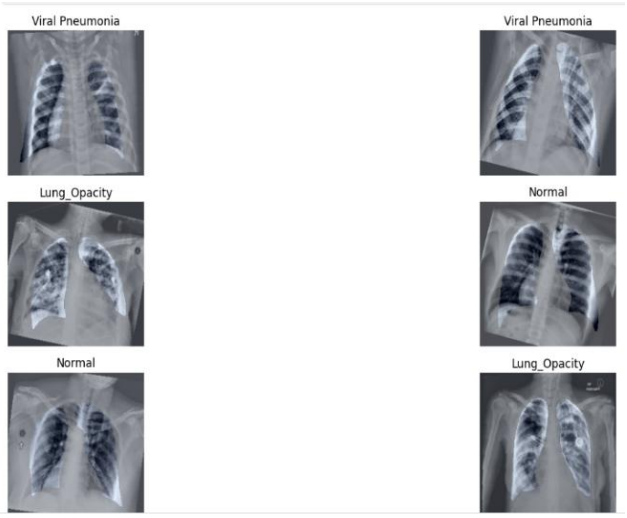

Fig. 3. Image after multiplication the mask.

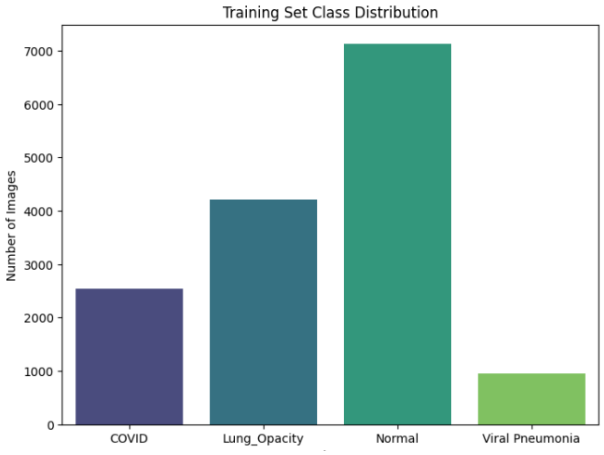

Fig. 4. Different classes in the training dataset.

In this study, CNN models were trained using several versions of segmented and original chest X-ray images as inputs. Both the raw and segmented lung X-ray pictures, as well as improved versions of these datasets, were used in the experiments. CNN models that had already been trained, especially VGG19, were used in the classification procedure. The most successful model was chosen as the final framework after the models were assessed using a variety of performance indicators. The pre-trained models used are briefly described in the sections that follow.

1) VGG19 Model: The VGGNet (Visual Geometry Group Network) is a deep neural architecture characterized by multiple processing layers. What makes VGG-19 particularly effective is its straightforward design, which incorporates stacked 3 × 3 convolutional layers that increase in depth. The network manages dimensional reduction through strategically placed max pooling layers [14]. The architecture includes two fully connected (FC) layers, each containing 4096 neurons. During training, the network extracts features using convolutional layers, while accompanying max pooling layers help reduce the dimensionality of these features. The initial convolutional layer processes input images using 64 kernels, each with a 3 × 3 filter size, to extract features. The network then utilizes fully connected layers to organize these features into a vector format.

Fig. 5 shows the architecture of VGG19. The diagram consists of a series of vertical bars representing different layers in the network: peach-colored bars indicate 3×3 convolutional layers, light blue bars represent max pooling layers, green bars show fully connected layers, and a final red bar represents the SoftMax output layer [15].

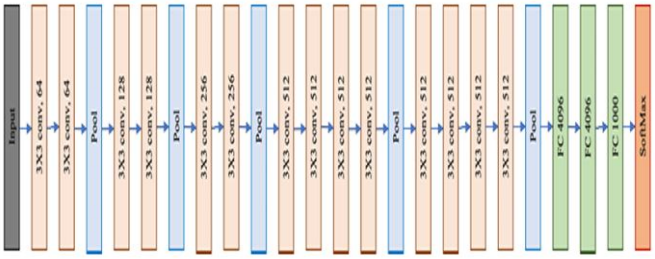

Fig. 5. Architecture of VGG19 [16].

E. Fine-Tuning VGG19 (16 Layers)

- The pre-trained VGG19 model was used (from ImageNet) with fine-tuning on top 16 layers
- The previous layers were frozen to retain general image feature extraction capabilities as shown in Fig. 6.

The last layers were thawed and fine-tuned on the chest X-ray dataset to specialize in features radiography.

Fine-tuning allowed the model to take advantage of the pre-learned weights in adaptation to domain-specific patterns like lung lesions or opacities.

2) Result of fine-tuning: Fine-tuning greatly improved the model performance, resulting in better accuracy and F1 score for all classes. Validation accuracy leveled off at 95%, indicating great generalization.

F. Image Segmentation Using Probabilistic U-Net

Goal: To segment the lung regions and then feed them into the classification model for better feature extraction.

Procedures Adopted:

1) Segmentation model: A Probabilistic U-Net was used to generate masks of the lung region from chest X-rays as shown in Fig. *7.*

2) Mask overlay: The generated segmentation masks were applied to pre-process images by isolating lung regions.

3) VGG19 integration: The segmented images were then passed through the classification pipeline, reducing the impact of irrelevant regions and generally improving accuracy.

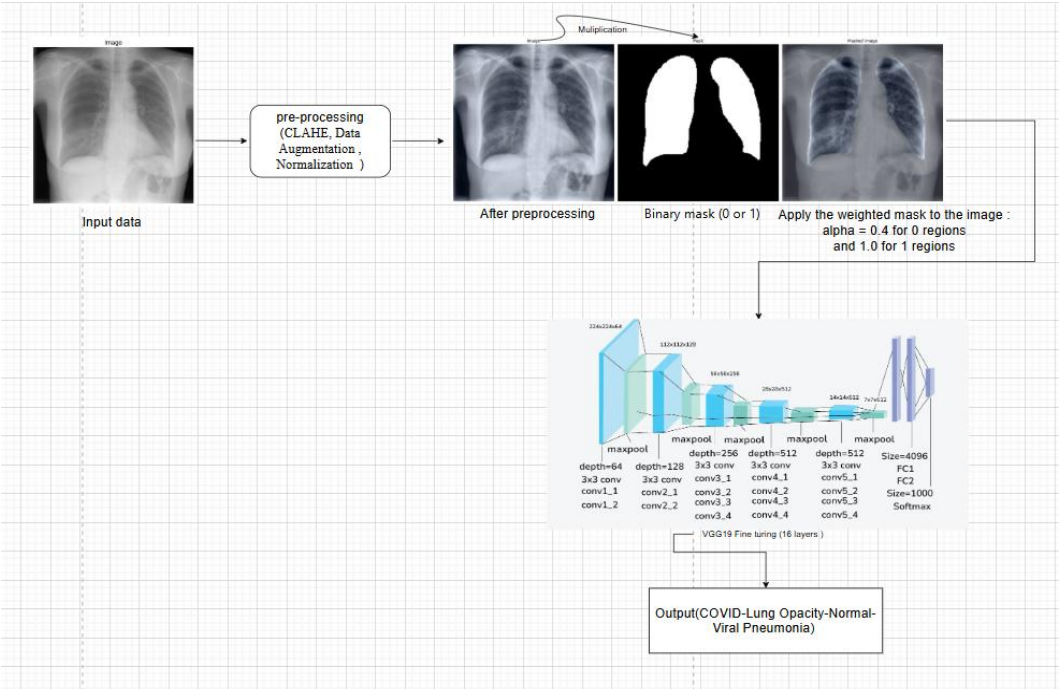

Fig. 6. The framework of the used methodology for Chest X-ray image classification.

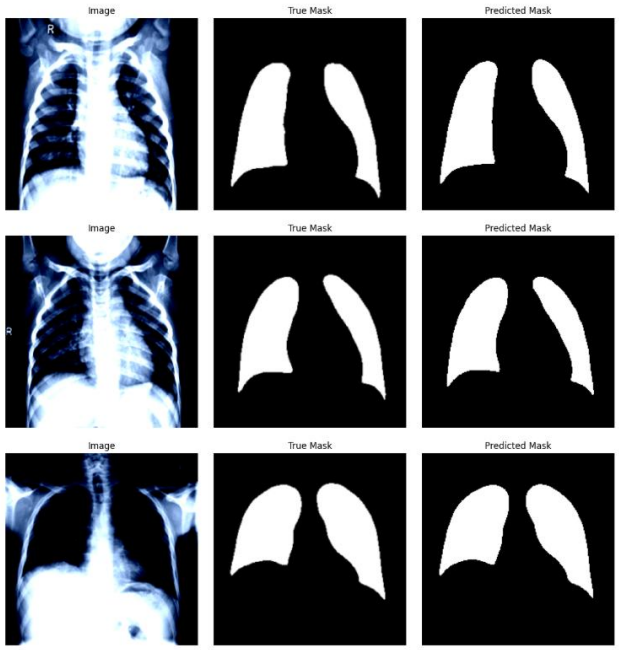

Fig. 7. U-Net was implemented to generate masks.

IV. Performance Metrics and Results

This section discusses the results of models using different evaluation measures.

A. Evaluation Criteria

Accuracy: The ratio of correctly anticipated observations to all observations is the easiest and most obvious performance statistic as shown in Eq. (4). Given in the equation below:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+FN+TN} \quad (4)$$

In these formulas:

TP (True Positives) represents the number of correctly predicted positive instances.

TN (True Negatives) represents the number of correctly predicted negative instances.

FP (False Positives) represents the number of negative instances that were incorrectly predicted as positive.

FN (False Negatives) represents the number of positive instances that were incorrectly predicted as negative.

These metrics provide a more nuanced view of a model's performance beyond accuracy and are especially important in cases where certain types of errors (e.g., false positives or false negatives) have different consequences or costs.

Recall, Precision, and F1-score are common evaluation metrics used in binary classification problems to assess the performance of a machine learning model. They are derived from the confusion matrix, which summarizes the model's predictions in terms of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN).

Here are the formulas for Recall, Precision, and F1-score:

Recall (Sensitivity or True Positive Rate):

Recall measures the ability of a model to identify all relevant instances (true positives) out of all actual positive instances. Eq. (5) shown the Recall or Sensitivity of result.

Formula:

$$\text{Recall} = \frac{TP}{TP+FN} \quad (5)$$

Precision (Positive Predictive Value):

Precision measures the accuracy of the model's positive predictions and answers the question: "Of all the instances predicted as positive, how many were positive?" Eq. (6) shown the Prevision of data.

Formula:

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \quad (6)$$

F1-score:

The F1-score is a harmonic mean of Recall and Precision. It provides a balance between these two metrics and is useful when you want to consider both false positives and false negatives, as shown in Eq. (7).

Formula:

$$\text{F1 score} = \frac{2\times\text{Recall}\times\text{Precision}}{\text{Recall+Precision}} \quad (7)$$

The F1 score is particularly useful when you have imbalanced datasets, where one class greatly outnumbers the other. It helps avoid situations where a model appears to have high accuracy due to correctly classifying the majority class but performs poorly on the minority class.

The experimental achieved exceptional results, confirming the effectiveness of the methodology that shown in Table I:

TABLE I. EVALUATION MEASURES OF THE MODELS

Model	Precision (%)	Recall (%)	F1-score (%)	Support
COVID	0.98	0.96	0.97	543
Lung Opacity	0.93	0.93	0.93	902
Normal	0.95	0.96	0.95	1529
Viral Pneumonia	0.98	0.97	0.98	202
Accuracy			**0.95**	3176
macro avg	0.96	0.95	**0.96**	3176
Weighted avg	0.95	0.95	**0.95**	3176

A classification model's performance across four classes—COVID-19, lung opacity, normal, and viral pneumonia—is assessed using the image's confusion matrix. The actual class (True) is shown in each row, and the anticipated class is shown in each column. shown in Fig. 8.

Generalization: Consistent training and validation loss/accuracy curves demonstrate minimal overfitting as shown in Fig. 9.

The research demonstrates that combining image segmentation techniques with attention mechanisms and model fine-tuning leads to improved classification of radiographic images. This approach proves valuable in clinical healthcare settings, as it achieves high prediction accuracy while also identifying medically significant features within the images.

When using the model without the mask:

Our study focused on the performance of pre-trained convolutional neural network (CNN) architectures after they were fine-tuned for particular classification objectives. The job involved four classes. Every model configuration included a basic base model that was enhanced by extra layers that were specially designed to meet the particular requirements of the task at hand VGG19 and ResNet101 models were used in our investigation for the 4-class classification scenario. The classification tests were ResNet101 and VGG19. All models received uniform extra layers that were customized to fit each model's architecture.

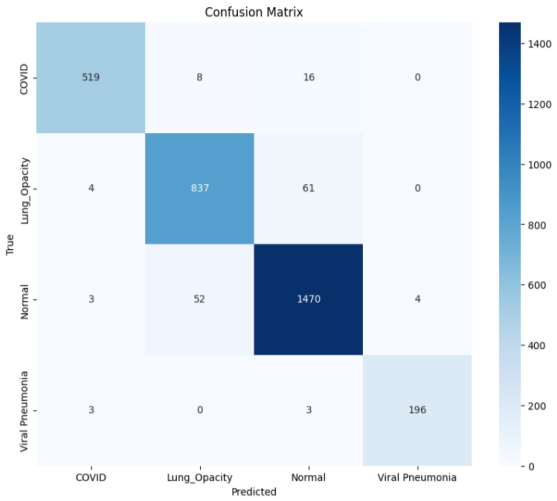

Fig. 8. Classification model's performance.

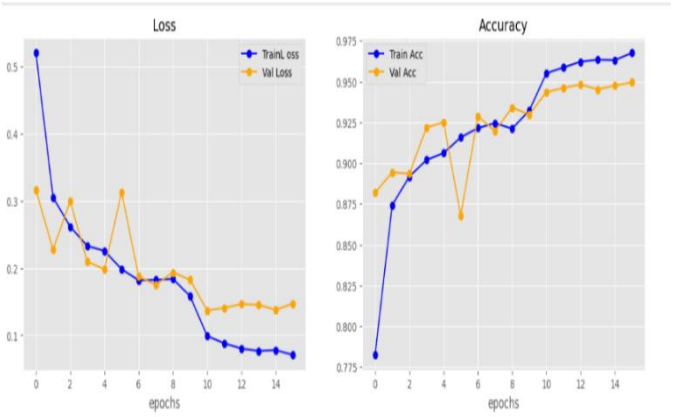

Fig. 9. Loss and accuracy for training and validation over several epochs.

TABLE II. EVALUATION MEASURES OF THE MODELS

Model	Accuracy (%)	Precision (%)	Recall (%)	F1 score (%)
VGG19	94.85	96.25	94.5	95.25
ResNet101	94.28	96	94.25	95

Table II, compares the performance metrics of two popular convolutional neural network models: VGG19 and ResNet101. VGG19 slightly outperforms ResNet101 across all metrics, with an accuracy of 94.85% versus 94.28%. However, the differences are quite minimal, with both models achieving very high-performance scores above 94% across all measures. Looking at these metrics, VGG19 shows a marginal advantage of about 0.25-0.57 percentage points across different measures, though in practical applications this difference might be negligible depending on the specific use case. Fig. 10 and Fig. 11 show the Confusion Matrices of this model.

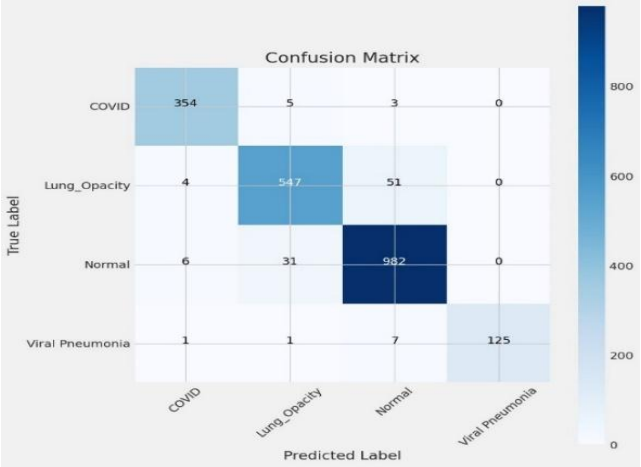

Fig. 10. VGG19 Confusion matrices.

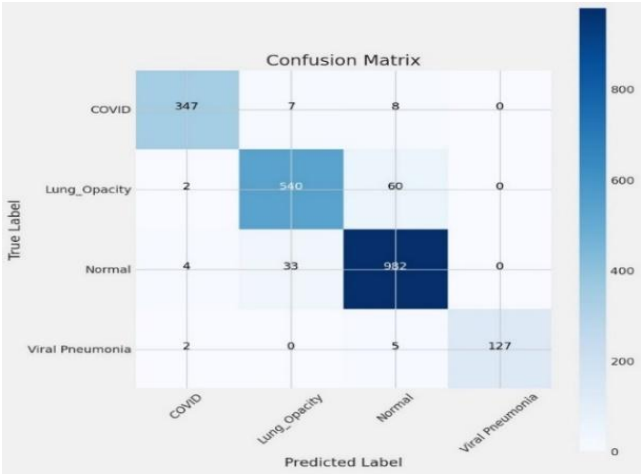

Fig. 11. ResNet101 Confusion matrices.

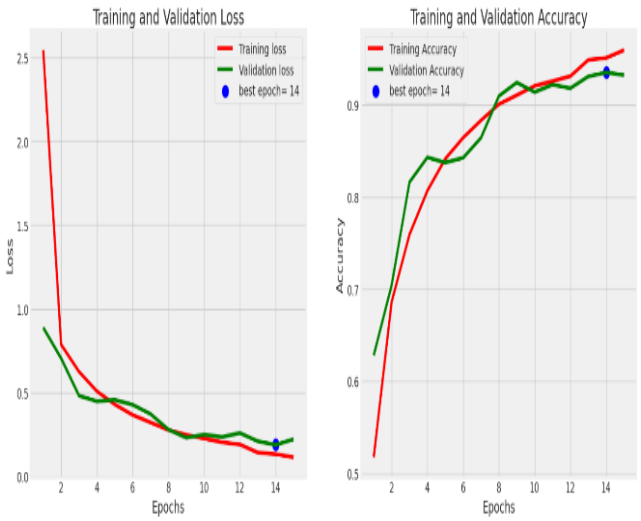

Fig. 12. Loss and accuracy for training and validation over several epochs for the resnet101model.

Fig. 12, shows two graphs side by side, illustrating the performance of a machine learning model during the training and validation phases. Let me break down each graph for you:

1) Left graph - training and validation loss: The horizontal axis displays epochs, which represent complete passes through the dataset. The vertical axis indicates the loss values, where lower values indicate better performance. Training loss (red) and validation loss (blue) both demonstrate a rapid initial decline before plateauing. Throughout the training process, validation loss maintains a slightly elevated position compared to training loss.

2) Right graph - training and validation accuracy: Similar to the loss graph, epochs are shown on the horizontal axis, while accuracy values range from 0 to 1 on the vertical axis. The training accuracy (red) and validation accuracy (green) lines show swift improvement early on before leveling off. Training accuracy consistently outperforms validation accuracy by a small margin.

3) Notable findings: The model demonstrates rapid improvement during the initial epochs for both metrics. A small, consistent gap exists between training and validation metrics, which is typical. Performance improvements become minimal after epochs 14-22, suggesting convergence. The relatively parallel trajectories of training and validation metrics indicate proper model fitting, without significant overfitting concerns.

This visualization helps in understanding how well the model is learning and generalizing to unseen data over time. It can be used to determine the optimal number of training epochs and to check for potential overfitting or underfitting issues.

Our comparative analysis against established models, which primarily used training and testing data splits for validation, demonstrated superior performance of our model, as shown in Table III.

TABLE III. COMPARISON OF THE MODEL'S OBTAINED RESULTS WERE COMPARED WITH THOSE OF OTHER PROPOSED MODELS

Study	Model architecture	Accuracy (in %)
El Houby, E. M. [12]	VGG19	93.5
Our Model	VGG19	**95.0**

Here we have proven that using the mask with the image and making Attention Mechanism the mask work is much better and more accurate than using the normal x-ray image the opposite of what this paper says [12].

V. CONCLUSION AND FUTURE WORK

This Paper proved successful in developing an accurate COVID-19 chest X-ray classification system by combining multiple sophisticated techniques. The approach utilized VGG19 fine-tuning, attention mechanisms, and image segmentation. Image quality was enhanced through CLAHE processing, while data augmentation techniques improved the model's ability to handle diverse cases. The attention component helped the model identify crucial areas in X-ray images, particularly benefiting the detection of COVID-19 and Viral Pneumonia cases. By adjusting class weights and optimizing 16 layers of VGG19 specifically for X-ray analysis, the model achieved 95% validation accuracy and a 96% macro-average

F1-score. The integration of Probabilistic U-Net for segmentation helped isolate lung regions and reduce interference from surrounding areas, leading to more accurate predictions.

The model demonstrated strong performance metrics across all categories with balanced precision and recall scores. The similar trajectories of training and validation metrics indicated good generalization without overfitting, suggesting the model's readiness for clinical application.

Looking ahead, researchers plan several enhancements: expanding the training data for better generalization, improving segmentation through advanced networks like Attention U-Net and DeepLabV3+, and incorporating additional imaging modalities such as CT and MRI scans. The team also aims to implement interpretability tools like Grad-CAM and SHAP to make the model's decisions more transparent to healthcare providers. Future developments will explore mobile and cloud deployment options, with additional validation using external datasets to ensure reliable performance in clinical settings. These improvements aim to create a dependable automated system for detecting and diagnosing respiratory conditions early.

College of Digital Business, Wenzhou Polytechnic, Wenzhou 325000, Zhejiang, China[2]

***Abstract*—With the rise of internet finance and the increasing demand for personal credit risk management, accurate credit default prediction has become essential for financial institutions. Traditional models face limitations in handling complex and large-scale data, especially in the blockchain domain, which has emerged as a crucial technology for securing and processing financial transactions. This paper aims to improve the accuracy and generalization of blockchain-based credit default prediction models by optimizing deep learning algorithms with the Special Forces Algorithm (SFA) and attention mechanism (AM) networks. The study introduces a hybrid approach combining SFA with AM to optimize hyperparameters of the credit default prediction model. The model preprocesses blockchain credit data, extracts critical features such as user and loan information, and applies the SFA-AM algorithm to improve classification accuracy. Comparative analysis is conducted using other machine learning algorithms like XGBoost, LightGBM, and LSTM. Results: The SFA-AM model outperforms traditional models in key metrics, achieving higher precision (0.8289), recall (0.8075), F1 score (0.8180), and AUC value (0.9407). The model demonstrated better performance in identifying both default and non-default cases compared to other algorithms, with significant improvements in reducing misclassifications. The proposed SFA-AM model significantly enhances blockchain credit default prediction accuracy and generalization. While effective, the study acknowledges limitations in dataset diversity and model interpretability, suggesting future research could expand on these areas for more robust applications across different financial sectors.**

***Keywords*—Deep learning; attention mechanism; blockchain credit default prediction; special forces algorithm**

I. Introduction

The rapid development of international Internet finance, more and more third-party lending institutions, Internet finance companies continue to emerge and appear [1]. At the same time, people's living standards are getting better, consumption level rises, consumption demand increases, the number of people borrowing and consuming is also increasing, and credit institutions are paying more and more attention to personal credit risk management [2]. Credit risk management focuses on the measurement of default risk, and when a borrower applies for a loan, the lending institution needs to evaluate the risk of the borrower with the help of certain methods to decide whether to borrow or not [3]. Credit default prediction as one of the core of credit risk management, the accurate identification and assessment of default customers, not only can avoid the loss of credit default customers to the counterparty, but also can be based on the credit risk assessment model to provide customers with more accurate, more personalised, better quality products and services [4].

With the arrival of the era of big data, the use of a large amount of information data to establish an effective credit default prediction model helps financial institutions to analyse the user's consumption, capital, and creditworthiness in a certain period of time, and then predict whether there is a user's default to reduce the risk of loss [5]. Therefore, researching scientific and accurate blockchain credit default prediction methods is very significant for financial institutions to make decisions. Analysing a large number of previous studies, scholars around the world and beyond have launched a large number of research works on credit default prediction [6].

Artificial intelligence technology is updated and iterative, machine learning and deep learning algorithms are gradually applied to credit default prediction [7]. Han et al [8] applied the decision tree model to the field of credit risk assessment. Oliver [9] used the personal loan data of LC company and built KNN, SVM, Logistic and RF models, and found that the RF model performed the best. Liu et al [10] compared the performance of different classification models such as RF, ANN, and LR based on different sampling strategies according to different evaluation indexes, and the results showed that the oversampling strategy has obvious advantages in dealing with unbalanced data. Ragab and Saleh [11] constructed a credit assessment model of Lasso-LR, and the results showed that it can effectively screen out features. Kriebel and Stitz [12] proposed to build an XGBoost-RF credit assessment model, and the results show that XGBoost can improve the accuracy of RF model after filtering the features. Lin and Liu [13] used a hybrid whale bat optimization algorithm to optimize the hyper-parameters of the machine learning model, and constructed a credit default prediction model for users, and the results show that the proposed prediction model not only has higher classification accuracy, but also has higher accuracy. model not only has higher classification accuracy, but also has strong interpretability.

Based on previous research, this paper uses intelligent optimisation algorithm and deep learning algorithm to optimise and improve the personal credit default prediction model, which improves the model classification accuracy and makes the model more explanatory. In this paper, the research will be carried out through the following architectures:

- The personal credit default prediction problem is analysed, relevant features are extracted, and data preprocessing is carried out;

*Corresponding Author

- The SFA algorithm [14] is used to optimise the hyper-parameters of the Attention Mechanism Model [15], and the personal credit default prediction model based on the SFA-AM is constructed; and
- The proposed method is validated and analysed using credit default data.

Based on the research objectives, the remainder of this paper is structured as follows: Section II provides an overview of blockchain technology and the key issues in credit default prediction. Section III describes the problem-solving approach, including feature analysis, data preprocessing, model construction, hyperparameter optimization, and model evaluation. Section IV introduces the improved SFA algorithm and the attention mechanism network, presenting the SFA-AM hybrid model. Section V details the experimental design, dataset description, parameter settings, and evaluation metrics, followed by a comparative analysis of model performance. Section VI summarizes the key findings, highlights the limitations, and proposes future research directions.

II. Blockchain Credit Default Analysis

A. Blockchain Technology

1) Overview: Blockchain technology is an innovative distributed ledger technology originally proposed by Satoshi Nakamoto, the anonymous creator of Bitcoin, to create a decentralised digital currency system [16-18]. The blockchain is maintained and updated by multiple nodes in the network, with each "block" containing a batch of transaction records that are cryptographically linked to the previous block to form a tamper-proof chain. This structure ensures data transparency and security, and any attempt to modify existing information will be detected and rejected by nodes in other parts of the network, as shown in Fig. 1.

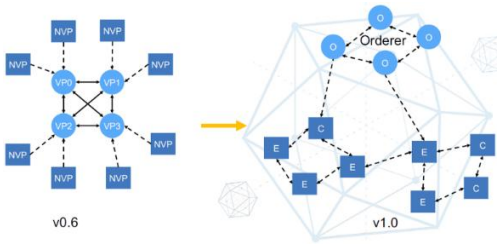

Fig. 1. Blockchain technology.

2) Blockchain characteristics: According to the principles of blockchain technology, blockchain has the following characteristics [19] (Fig. 2): 1) decentralisation; 2) immutability; 3) transparency; and 4) cryptographic security.

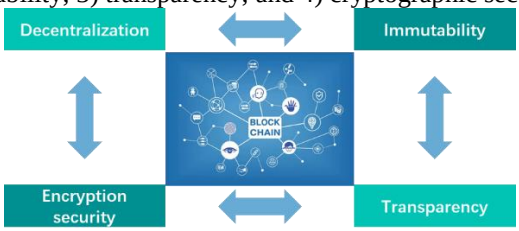

Fig. 2. Blockchain characteristics.

3) Blockchain applications: The application of blockchain technology has been extended to a number of fields, including financial services, supply chain management, healthcare, real estate, and voting systems [20], as shown in Fig. 3.

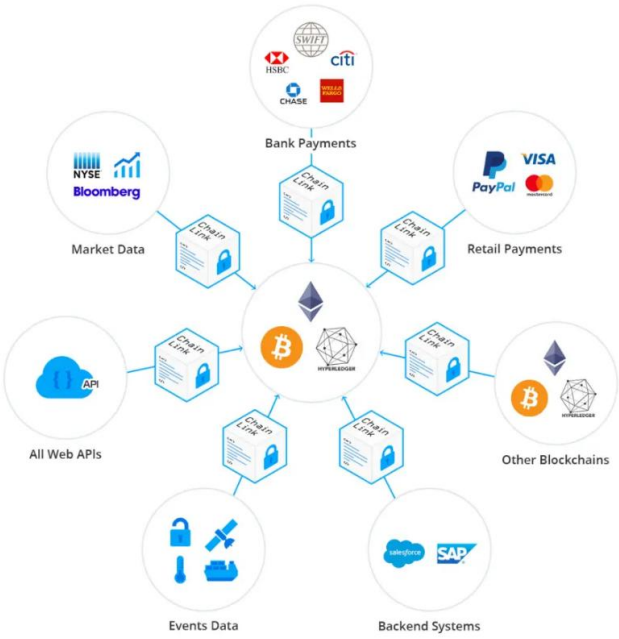

Fig. 3. Blockchain applications.

B. Credit Default Prediction Issues

1) Credit rating: Credit rating is an important indicator for financial institutions in assessing the credit risk of users. There are seven grades of loan users, which are A, B, C, D, E, F, and G, and their credit ratings decrease in order [21]. The percentage of users in each grade is given in Fig. 4. From Fig. 4, it can be seen that users of grades A, B, and C in the dataset occupy 73.12%, and the remaining grades occupy 26.88%, in which users of grades A, B, and C are higher credit rating users, which indicates that most of the users have fewer defaults.

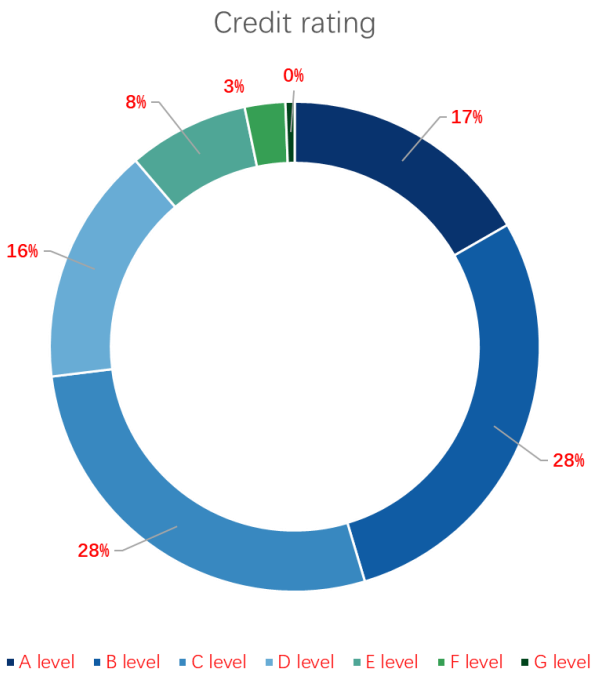

Fig. 4. Distribution of credit ratings.

2) Characterisation: The features that need to be analysed in the user credit default prediction problem mainly include basic information about the user, basic information about the borrowing project, and historical information about the borrowing project [22].

a) Basic information of loan users: In addition to the user's credit rating, the basic profile of the loan user includes the user's years of employment (Fig. 5), the user's home ownership (Fig. 6), the distribution of the user's annual income (Fig. 7), and the distribution of the loan user's loan amount (Fig. 8).

As can be seen from Fig. 5, 34.64% of the users have worked for more than 10 years, 26.05% have worked for 0 to 3 years, and the rest have worked for 3 to 10 years. The number of years of working experience reflects whether the user has the ability to make repayments, and usually the higher the number of years of working experience, the lower the possibility of their default.

Fig. 6 gives the distribution of home ownership among users. It can be seen from Fig. 6 that 50 % of the users are in home ownership and 40.13 per cent of the users are still renting their homes.

Fig. 7 shows that more than 90 % of the users have an annual income of less than $500,000, and very few users have more than $500,000 per year.

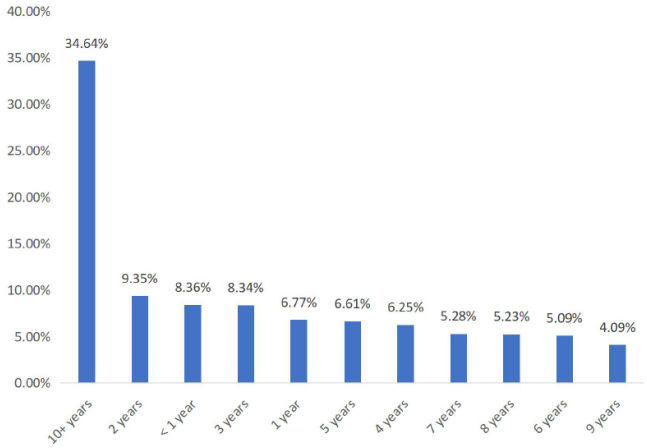

Fig. 5. Distribution of users' years of working experience.

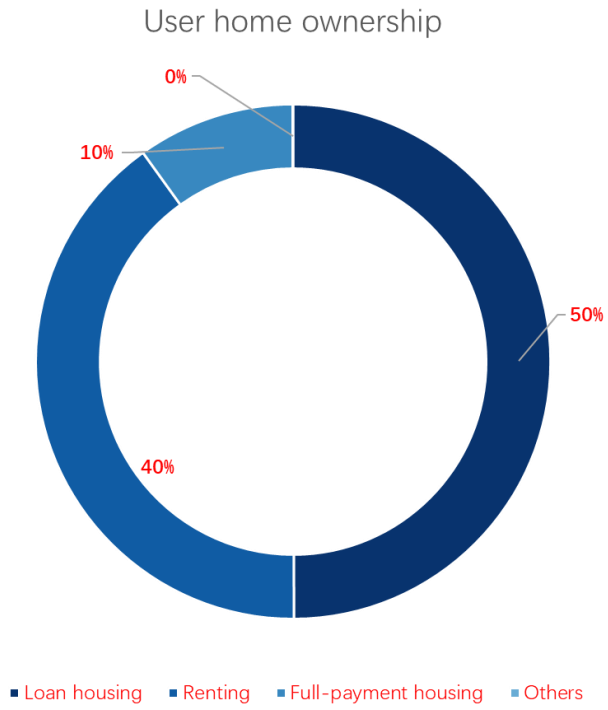

Fig. 6. Distribution of users' home ownership.

Fig. 8 gives the distribution of users' loan amounts. Most of the loans are between 5,000 and 20,000 yuan, with 10,000 yuan having the highest number of loans, and relatively few users having loans of more than 20,000 yuan.

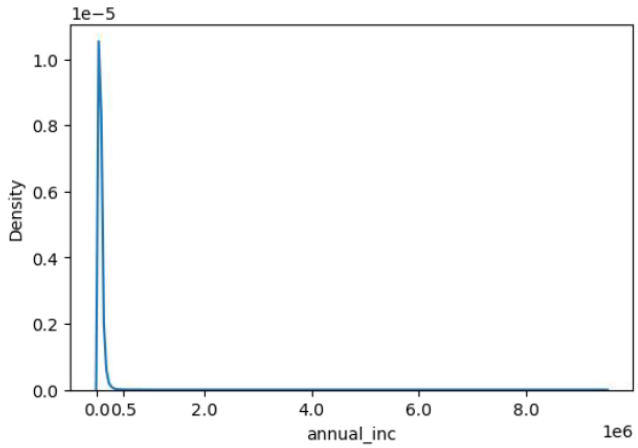

Fig. 7. Distribution of annual income of users.

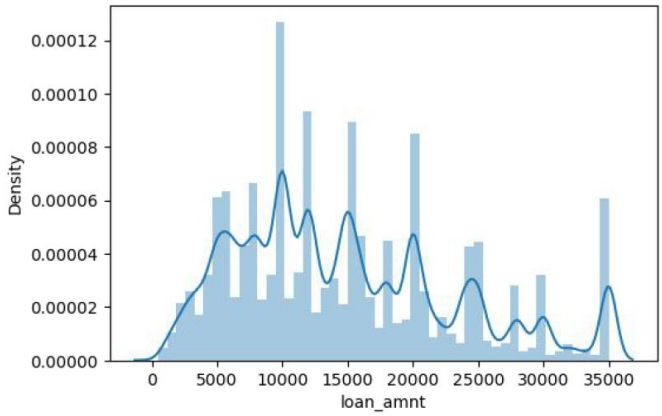

Fig. 8. Distribution of users' loan amount.

b) Basic information of the borrowing project: The basic information about the borrowing item mainly includes information such as the amount of the loan requested by the customer, the term of the loan, the interest rate of the loan, the income status verified by the bank, and the current total balance of all accounts.

c) Borrowing project history information: Borrowing item history information mainly includes information such as the number of enquiry cases in the past six months, the number of months since the last default, the number of months since the public record, the number of open lines in the credit line, and the total collection amount ever owed.

d) Description of the credit default prediction problem: The credit default prediction problem is essentially a classification and identification problem, where the inputs are user credit default characteristic variables and the outputs are user defaults, i.e., non-defaults versus defaults, as shown in Fig. 9.

Fig. 9. Description of the user default prediction problem.

C. Problem Solving Ideas and Design

In order to solve the blockchain credit default prediction problem, this paper adopts hybrid machine learning algorithm to construct blockchain credit default prediction model and design blockchain credit default prediction method based on hybrid machine learning algorithm. The design idea of this method mainly solves the blockchain credit default prediction problem from the aspects of feature analysis, data preprocessing, feature selection, credit default prediction model building, model optimisation, model evaluation, etc., as shown in Fig. 10.

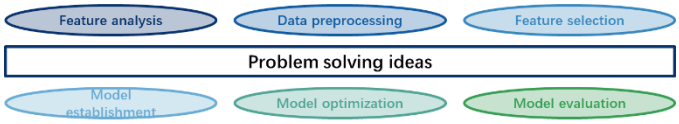

Fig. 10. Problem solving ideas.

III. Improving the SFA Algorithm to Optimise Networks of Attention Mechanisms

A. Network of Deep Attention Mechanisms

A class of deep learning models known as attention mechanism networks (AMNs) [23] enable neural networks to concentrate on pertinent components of the input data during the processing process, thereby emulating the human visual and cognitive systems. The performance and generalization of the model are enhanced by the Attention mechanism, which enables neural networks to automatically learn and selectively concentrate on the critical information in the input. The structure of the Attention mechanism network is illustrated in Fig. 11. In order to focus on the most relevant portions of each sequence element when processing it, the attention mechanism is often applied to the processing of sequential data, such as text, speech, or image sequences. This allows the model to assign various weights to different positions in the input sequence.

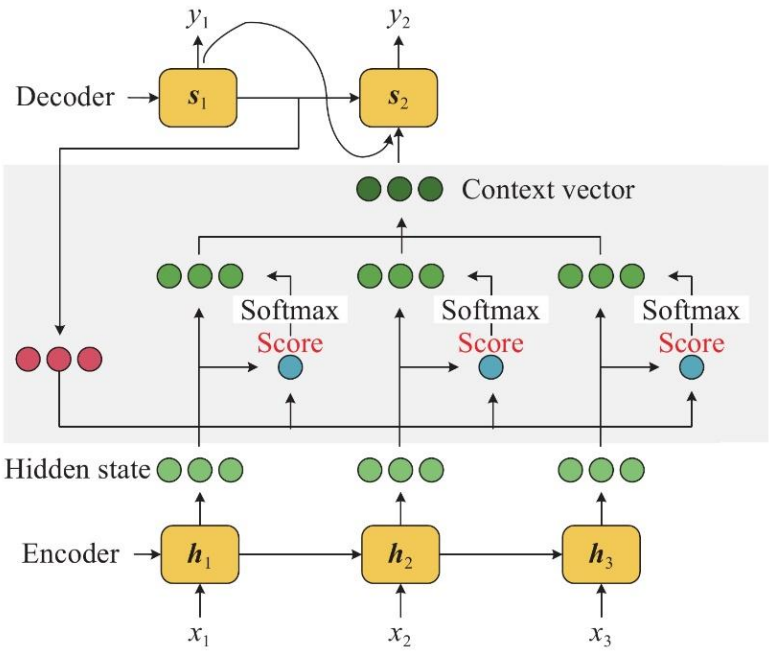

Fig. 11. Structure of the network model of the deep attention mechanism.

The core architecture of the attention mechanism consists of three main components, Query, Key and Value. Query represents the element currently being processed or the target to be attended to, Key represents the identity or characteristic of each element in the input sequence, and Value contains the specifics or information about each element in the input sequence. In attention computation, Key is used to determine how well each element matches the Query, while Value provides the actual information related to the Query.

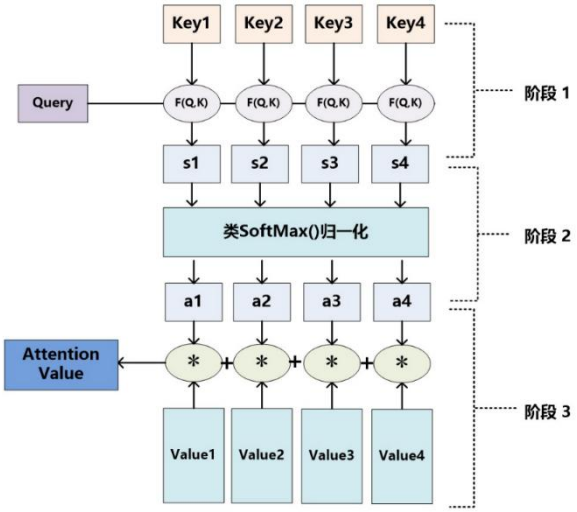

Fig. 12. Principles of attention mechanisms.

B. SFA Algorithm

Based on the strategies and behaviors of Special Forces engaged in counter-terrorism combat operations, the Special Forces Algorithm (SFA) [14] is a swarm intelligence algorithm. In order to satisfy the optimization requirements, SFA can simulate genuine dynamic behaviors by integrating a variety of strategies and incorporating unique mechanisms into the algorithm. According to the common characteristics of MAs, the process of SFA is divided into three phases: exploration phase, transition phase, and development phase (shown in Fig. 13).

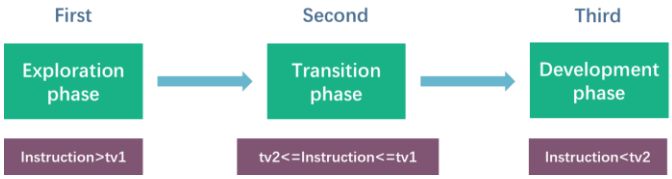

Fig. 13. Analysis of optimisation strategies for the special forces algorithm.

A "directive" is a feature of SFA that serves as an identifier to direct all team members in the completion of the mission. The directive and the threshold value, which is represented as follows, will alter in accordance with the number of iterations, allowing for the identification of the specific task type:

$$Instruction(t) = (1 - 0.15rand)\left(1 - \frac{t}{T}\right) \quad (1)$$

Where t is the current iteration number, T is the maximum iteration number, and $rand$ is a random number between 0 and 1.

2 thresholds tv_1 and tv_2 are set in SFA to clarify the phase transition as follows:

$$\begin{cases} \text{Exploration phase} & Instruction > tv_1 \\ \text{Transition phase} & tv_2 \le Instruction \le tv_1 \\ \text{Development phase} & Instruction < tv_2 \end{cases} \quad (2)$$

During the execution of mission engineering, team members can access the location information of their colleagues; however, there is a possibility that communication terminals may be lost by any team member throughout the algorithm's process, resulting in the potential loss of some team members' information:

$$p(t+1) = p_0 \cos\left(\frac{\pi t}{2T}\right) \tag{3}$$

Where, p is the lost connection probability at the current iteration t, and p_0 is the initial lost connection probability, the specific trend is shown in Fig. 14.

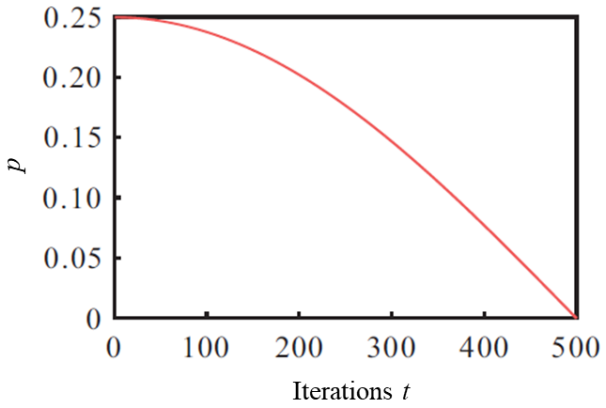

Fig. 14. Trends in probability of missing a connection.

1) Exploratory phase: Following the algorithm's initialization, the investigation phase commences. Two strategies, assault search and mass search, comprise the exploration aspect of SFA.

a) Large-scale search: Mass search missions are the primary responsibility of special forces during the exploration phase. The team members' activity area will be quite vast during mass search, and they are free to look for any possible target anywhere within the practical range at any time. Given that there are two types of jobs that team members may complete during the exploration phase, this study adds a random number to provide the team members with the ability to divide the work and conduct a random search. In other words, the location is updated based on the following equation:

$$X(t+1) = r_1\left(X_{best} - X(t)\right) \pm (1-r_1)\,range$$
$$r_1 \geq 0.5 \tag{4}$$

Where, $X(t+1)$ is the position vector of the player in the next iteration, $X(t)$ is the position vector of the current player, X_{best} is the optimal position of the previous population, r_1 is a uniformly distributed random number, and $range$ is the solution space range.

b) Raids and searches: The Special Forces occasionally conduct raids on potential locations during large-scale search missions, as they already possess some information about hostages or miscreants. The known direction of the closest and most skilled team member affects the location of every maneuver. When the random number r_1 decides to perform a surprise raid, the team members perform a position update according to the following equation:

$$X_i(t+1) = X_i(t) + w(t)\,A_i(t), r_1 < 0.5 \tag{5}$$

where $X_i(t)$ is the search and capture vector of player i for the tth iteration. For any player, the search vector is:

$$A_i(t) = \frac{f_i(t)}{f_i(t) + f_{aim}(t)}\left(X_{aim}(t) + X_i(t)\right) \tag{6}$$

Among them, $X_{aim}(t)$ is the position of player aim No. i, i.e., the optimal position known to player i, and $f_i(t)$ and $f_{aim}(t)$ are the values of their positional adaptations respectively.

The search coefficient w decreases until 0 depending on the number of iterations:

$$w(t+1) = w_0 - 0.55\arctan\left(\left(\frac{t}{T}\right)^{2\pi}\right) \tag{7}$$

Among them, this paper sets $w_0 = 0.75$, and the specific trend is shown in Fig. 15.

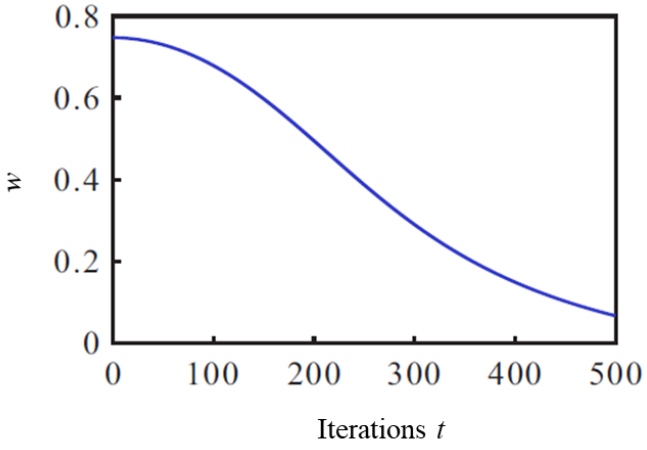

Fig. 15. Schematic diagram of search coefficient.

2) Transition phase: A buffer between the Exploration and Exploitation phases is the Transition Phase. In this period, the team will progressively transition to the exploitation phase while continuing to accomplish the previous tasks. The details are shown below:

$$X(t+1)=\begin{cases} X(t)+w(t)A(t) & r_2 \geq 0.5 \\ Instruction(t)\cdot(X_{best}-X(t))+0.1\cdot X(t) & r_2 < 0.5 \end{cases} \quad (8)$$

where r_2 is a random number satisfying a uniform distribution.

3) Development phase: A significant amount of information on the location of the criminals or hostages has been gathered by the special forces throughout the development phase, and they have now officially started the "capture" phase of the activity. The term "capture and rescue" refers to their mission of apprehending the offenders or freeing the captives.

The special operations team members in the development phase decisively approach and take a concentrated approach to surround and attack the hostage or robber based on the most likely point known to the entire team (i.e., the location of the hostage or robber). At this point, the team members use the positional updates shown below:

$$X(t+1)=X_{best}+r\cdot\left|X_{best}-X_{ave}(t)\right| \quad (9)$$

Where r is a uniformly distributed random number and X_{ave} is the current average position, calculated as follows:

$$X_{ave}(t)=\frac{1}{N}\sum_{i=1}^{N}X_i(t) \quad (10)$$

where $X_i(t)$ is the position of each player for the tth iteration and N is the total number of the whole team.

According to the SFA optimisation strategy, the SFA pseudo-code is shown in Table I.

TABLE I. SFA ALGORITHM PSEUDO-CODE

Algorithm 1: SFA algorithm pseudo-code	
1	Initialise the parameters tv1, tv2, p0, w0, and the population size N with the maximum number of iterations T;
2	Initialise population X;
3	While t<=T do
4	Calculate the fitness value;
5	Update the optimal fitness value and the optimal value;
6	Calculate the instructions;
7	If command >= tv1 do
8	If r1>=0.5 do Execute the mass search strategy;
9	Else if r1<0.5 do Execute the raid and search strategy;
10	Else if tv2< instruction<=tv1 do
11	Implementation of the transition phase;
12	Else if instruction <= tv2 do
13	Implementation development phase;
14	End if
15	Update p and w;
16	t=t+1;
17	End while
18	Return the optimal solution

The initialization, adaptation value calculation, missing information screening, and position update processes comprise the majority of the SFA computational volume. Let N represent the number of players in the SFA algorithm, T denote the maximum number of iterations, and D signify the number of issue dimensions. The computational complexity of the initialisation is $O(N)$, the computational complexity of the adaptation value update calculation is $O(N\times T)$, the computational complexity of the lost information screening is $O(N\times T)$, the computational complexity of the location updating is $O(N\times T\times D)$, and the total computational complexity is $O(N\times(1+2T+T\times D))$.

C. SFA Improved Attention Mechanism Network

In order to improve the credit default prediction accuracy of the attention mechanism network, this paper adopts the SFA algorithm to optimise the parameters of the attention mechanism network, with the RMSE value as the adaptation value and the SFA algorithm optimisation strategy as the optimisation iteration process, and the specific improvement principle is shown in Fig. 16.

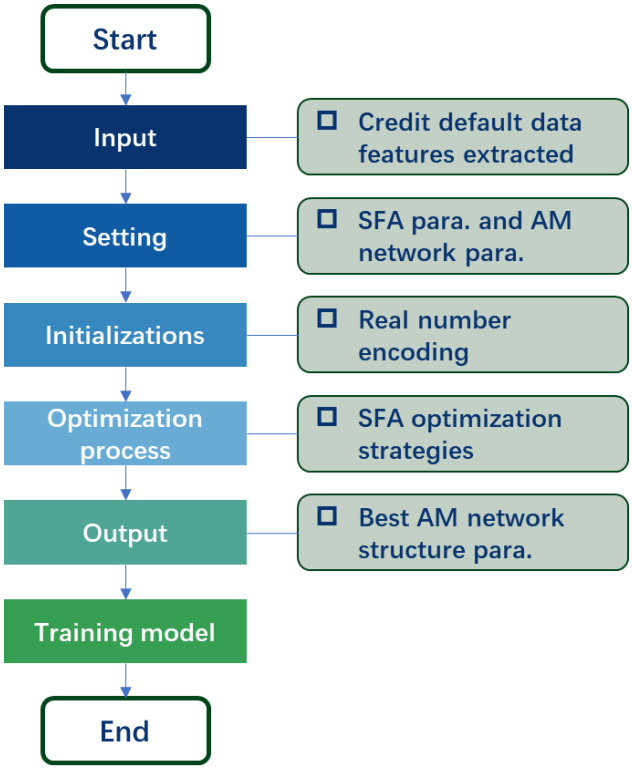

Fig. 16. Schematic diagram of improvement principle.

IV. Algorithmic Applications

In order to solve the blockchain credit default prediction problem, this paper proposes a blockchain credit default prediction method based on SFA-AM network structure. The method analyzes the blockchain credit default prediction problem, extracts the blockchain credit default feature vectors, preprocesses the data in terms of missing value processing, category variable processing, continuous variable processing, etc., constructs the blockchain credit default prediction model by using the Attention Mechanism Network, combines with the SFA Search Optimization Algorithm to optimize the blockchain credit default prediction model based on the AM network, and adopts the blockchain Bank loan dataset as the research object, the performance of the constructed blockchain credit default prediction model is verified, and the specific algorithm application idea is shown in Fig. 17.

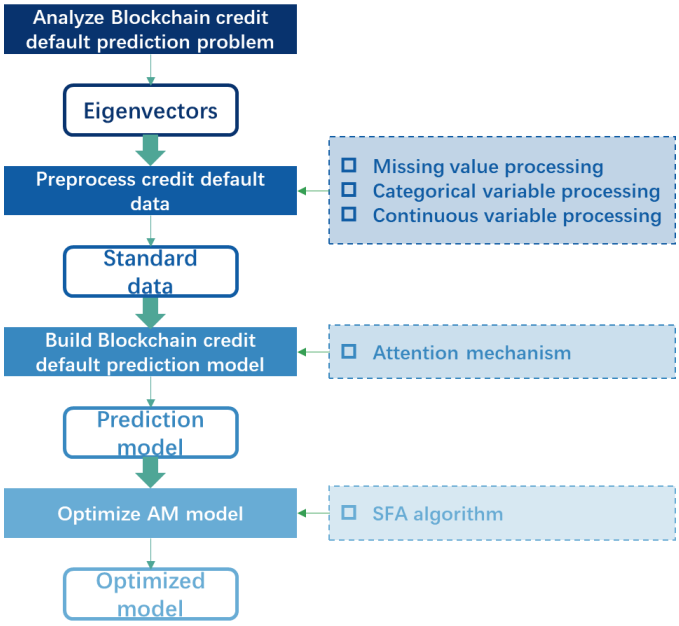

Fig. 17. SFA-AM network model application idea.

V. Results and Discussion

A. Environmental Settings

In this paper, we take Bank load data based on blockchain framework as the research object, firstly, we analyse the basic situation of the dataset, including the size of the data volume, the number of features, and the basic situation of the users; and then, we complete the work of data cleansing for the data, including irrelevant feature deletion, missing value processing, and category coding.

In order to verify the effectiveness and superiority of the blockchain credit default prediction problem based on SFA-AM network, this paper uses XGBoost, CatBoost, LightGBM, LSTM, AMnet and SFA-AM for comparative analysis, as presented in Table II.

In this paper, we use the credit dataset bank loan from kaggle website. The dataset contains information about more than 500,000 different users of Indesa bank in September 2016, out of which there are 406,601 honest customers and 125,827 defaulted customers. The percentage of honest users versus defaulted users is given in Fig. 18.

TABLE II. Parameter Settings of different Credit Default Prediction Comparison Algorithms

serial number	arithmetic	Algorithm setup
1	XGBoost	Booster= gbtree, max_depth=6, learning_rate=0.3, n_estimators=100
2	CatBoost	Iterations=1000, learning_rate=0.11, depth=6, l2_leaf_reg=3
3	LightGBM	max_depth=-1, learning_rate=0.1, n_estimators=100, min_child_weight0.003, min_child_samples=20
4	LSTM	The optimiser is Adam, the hidden layer nodes are 50 and the activation function is ReLu
5	AMnet	The optimiser is Adam, the hidden layer nodes are 100 and the activation function is tanh
6	SFA-AM	SFA population size 100, maximum number of iterations 1000, AM parameters set as in AMnet

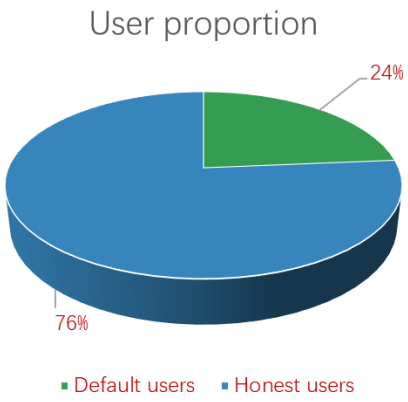

Fig. 18. Schematic representation of users.

The algorithm validation in this paper is carried out in Win11 system, the programming software is Matlab2023a, and the visualisation software includes Pycharm, PPT and Excel.

B. Comparative Analysis of Results

1) Analysis of data preprocessing results: Firstly, the missing values of the data are processed to plot the true scale of the features as shown in Fig. 19. From Fig. 19, it can be seen that, there are 16 features with missing values. In this paper, we take 50% as the limit, and the features with missing rate more than 50% are deleted. mths_since_last_recor, mths_since_last_major_derog, mths_since_last_delinq have more serious missing values, and their missing rate is already more than 50%, so these three features are deleted.

The most significant data gaps are found in "mths_since_last_record" and "mths_since_last_major_derog," which may influence model accuracy if not properly handled (e.g., through imputation or feature elimination). The features with fewer missing values, such as "tot_cur_bal" and "tot_coll_amt," are more reliable for modeling.

A 50% missing rate for "mths_since_last_delinq" means this feature could still be usable but requires careful imputation strategies. Features with more than 50% missing data might need to be dropped, depending on the importance of the feature and the model being used.

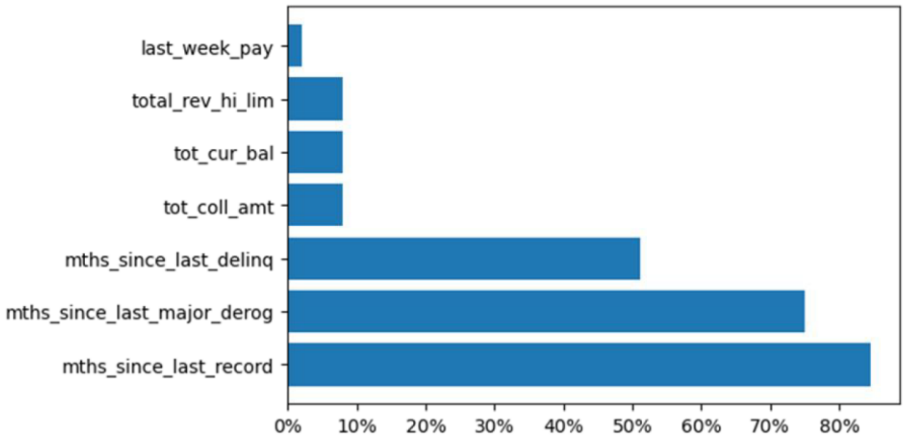

Fig. 19. Mapping the rate of absence of special diagnosis.

2) SFA optimisation of AMnet network processes: The SFA-AM optimisation iteration process is given in Fig. 20. From Fig. 20, it can be seen that the AUC value of the validation set stabilises after the number of iterations reaches 5, and reaches a maximum value of 0.951432 after the number of iterations is at 8. The AUC score starts at around 0.9495 and rapidly increases during the first few iterations, reaching approximately 0.9510 after 2 iterations. This indicates that the model performance improves significantly at the early stages of training or optimization. After about 5 iterations, the AUC reaches a peak of 0.9515, and the curve flattens, indicating that further iterations do not significantly improve the model's performance.

The model reaches a near-optimal performance (AUC of 0.9515) within a small number of iterations (around 5). Beyond that, the improvement is minimal, suggesting that the model has converged. The plateau in AUC after 5 iterations indicates that the model maintains consistent performance and does not suffer from overfitting or performance degradation, which is a good sign of stability.

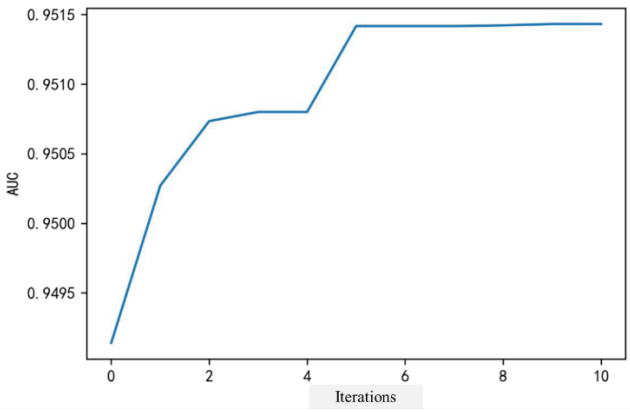

Fig. 20. Iterative process of SFA optimisation.

3) Algorithm comparison results: The model results were evaluated using the test dataset and the results of XGBoost, CatBoost, LightGBM, LSTM, AMnet and SFA-AM comparison were obtained as shown in Table III. From Table III, it can be seen that the SFA-AM model has the highest Precision, the highest Recall, the highest F1 value, and the highest AUC value, which are 0.8289, 0.8075, 0.8180, and 0.9407, respectively, which indicates that the model has a better ability to identify the defaults and non-defaults, and the model's generalisation ability is also better. The SFA-AM model demonstrates the best overall performance across all metrics, especially in Precision, Recall, and AUC, indicating that the optimization of the attention mechanism with the Special Forces Algorithm (SFA) significantly improves the predictive accuracy. CatBoost is a close second and might be a viable alternative when considering slightly lower computational complexity.

TABLE III. COMPARISON OF RESULTS

Serial number	Arithmetic	Precision	Recall	F1-score	AUC
1	XGBoost	0.7973	0.7901	0.7937	0.9324
2	CatBoost	0.8188	0.8074	0.8130	0.9400
3	LightGBM	0.7865	0.7225	0.7531	0.9156
4	LSTM	0.8166	0.7936	0.8050	0.9353
5	AMnet	0.8065	0.7309	0.7668	0.9188
6	SFA-AM	0.8289	0.8075	0.8180	0.9407

Table IV gives the blockchain credit default prediction results for AMnet and SFA-AM. As can be seen from Table IV, the ability of AM to identify defaulted customers has been improved, 27236 defaulted users can be identified before SFA is used, 27551 defaulted users can be identified after SFA is used, while identifying defaulted users as non-defaulted users has been reduced from 10460 to 10145. The SFA-AM model correctly classifies 115,423 non-default cases, which is 785 more than the AMnet model. Additionally, the number of misclassified defaults (mistakenly predicted as non-defaults) drops from 7,395 in AMnet to 6,610 in SFA-AM, showing an improvement in identifying true default cases.

SFA-AM also correctly identifies 27,551 default cases, slightly better than AMnet's 27,236. Furthermore, it reduces the number of non-defaults incorrectly predicted as defaults from 10,460 in AMnet to 10,145, reducing false positives.

The SFA-AM model consistently performs better than the AMnet model in both the identification of non-default and default cases. The reduction in misclassifications (both false negatives and false positives) indicates that the SFA-AM model has superior classification accuracy and a better ability to handle both default and non-default scenarios in credit risk prediction

TABLE IV. COMPARISON OF RESULTS BETWEEN AMNET AND SFA-AM MODELS

Real value	Projected value	Non-default	Default (on a loan or contract)
AMnet	non-default	114638	7395
	default (on a loan or contract)	10460	27236
SFA-AM	non-default	115423	6610
	default (on a loan or contract)	10145	27551

VI. CONCLUSION AND FUTURE WORK

In order to improve the accuracy of blockchain credit default prediction, this paper adopts SFA algorithm and attention mechanism model to construct blockchain credit default prediction optimisation model. It proposes a credit default prediction model based on the Attention Mechanism Network (AM) optimized by the Special Forces Algorithm (SFA). The key contributions include: (1) analyzing the credit default prediction problem, extracting relevant features, and performing data preprocessing; (2) constructing the credit default prediction model by optimizing the hyperparameters of the AM network using SFA; (3) validating the proposed model using blockchain credit default data. The experimental results demonstrate that the SFA-optimized model improves classification accuracy and generalization, achieving an AUC value of 0.9407.

We also recognise the following three areas of weakness: First, the blockchain credit default data used comes from a single bank, lacking diverse datasets from multiple industries or regions, which may limit the model’s generalizability. Then, while the paper compares several common algorithms (e.g., XGBoost, CatBoost, LSTM), it does not explore other emerging deep learning models or hybrid models in depth. Finally, although the model shows high prediction accuracy, there is insufficient analysis of the model's interpretability, particularly for the deep learning model.

Future research could incorporate more diverse datasets from different industries and regions to test the model's robustness and applicability in various scenarios. Investigating other deep learning or reinforcement learning algorithms and comparing their performance with the current model could further enhance prediction accuracy. As the complexity of models increases, focusing on the interpretability of the model—

especially the role of the attention mechanism in credit default prediction—would help financial institutions better understand and trust the model's decisions.

Faculty of Computing and Informatics, Universiti Malaysia Sabah, Malaysia[5]

***Abstract*—This study investigates the factors influencing cloud computing adoption in the public sector, emphasizing the performance of IT personnel. Through qualitative interviews with five IT management professionals in the public sector, we identify key challenges in integrating cloud computing systems. The primary issues include technical complexity, skill and knowledge deficits in data governance and budget constraints. These insights inform the development of the Cloud Computing Capacity and Integration Model for the Public Sector, which proposes a comprehensive strategy to address these barriers. Our findings identified five key challenges to cloud computing adoption in the public sector. First, compatibility issues and system integration challenges resulting from conflicts between cloud platforms and older infrastructure contributed to operational inefficiency. Second, data migration issues due to incompatible formats and structures resulted in data loss and delays. Third, network constraints, such as limited bandwidth and high latency, hampered cloud service performance. Finally, a lack of staff training and budget constraints hampered successful cloud integration, emphasizing the importance of focused capacity-building initiatives and additional financial support. Thus, the "Cloud Computing Integration and Cloud Computing Acceptance and Performance Model" (CCAPM) presented in this research paper aims to deliver a comprehensive model that tackles a wide array of technical, operational, and human resource challenges to create an effective cloud computing ecosystem, enhance the adoption of cloud computing within the public sector, elevate the capabilities of public sector IT personnel, and develop a secure, resilient, and sustainable cloud computing environment in the public sector.**

***Keywords*—Cloud computing; cloud integration model introduction; performance of IT personnel; public sector; system integration**

I. INTRODUCTION

Cloud computing has emerged as one of the most influential and potential technologies in the modern IT world. The study in [1] highlight cloud computing's emergence as a powerful force in contemporary IT, offering on-demand services for computation, storage, and applications. This technology offers a variety of advantages including the ability to reduce costs, increase operational flexibility, and increase the scale and efficiency of IT services. The study in [2] point out that cloud computing delivers significant cost advantages. Organizations can leverage virtualization and cloud infrastructure to pay only for what they use, eliminating the upfront costs associated with traditional IT investments. This translates to increased operational flexibility and improved scalability and efficiency of IT services. In the context of the public sector, the application of cloud computing is seen as a strategic step capable of bringing digital transformation to government services. The research in [3] argues that cloud computing adoption is a strategic move for the public sector, enabling them to deliver government services with greater efficiency and agility. However, there are various challenges and obstacles that public institutions have to face in the process of adoption and integration of cloud computing. According to study [4], public institutions face several hurdles when adopting and integrating cloud computing solutions. These challenges include security risks, network connectivity issues, cost and budget constraints, policy formulation, skills availability, and infrastructure readiness. This study will focus on two main problems: the complexity of integrating cloud computing systems with existing infrastructure and the lack of knowledge and skills in data governance.

The complexity in the integration of cloud computing systems with existing infrastructure in public institutions is one of the main challenges in the application of this technology. The study in [3] highlights the complex integration of cloud computing systems with existing public institution infrastructure as a significant challenge. The existing IT infrastructure in most public institutions may not be designed to support cloud technology, making the integration process complex and requiring significant changes. Integrating cloud technology into existing IT infrastructure in public institutions can indeed be complex due to various challenges highlighted in the research papers. The study in [5] identify security concerns, data leakage, and legal implications as key hurdles to cloud computing adoption in government organizations. This includes changes in IT architecture, software customization, and data restructuring. The study in [6] advocates for software restructuring, which entails modifications to IT architecture, software customization, and data restructuring to enhance software system performance and efficiency. The cost of integrating cloud computing can also be very high, especially if it requires the purchase of new equipment or major upgrades to existing infrastructure. Additionally, [7] said that supporting a large number of users in the cloud can necessitate increased network bandwidth, which

translates to higher expenses for both the service provider and potentially the customer.

In addition, the lack of knowledge and skills in data governance is also a big obstacle. Cloud computing requires a high level of understanding of data management, security, and compliance with relevant regulations. As the study [8] emphasizes, cloud computing necessitates a deep understanding of data management, security, and regulatory compliance. This ensures the integrity and protection of sensitive information entrusted to the cloud, mitigating the risk of breaches and unauthorized access. According to study [9], inadequate data and storage security can trigger a domino effect of negative consequences. These include data security breaches, non-compliance with regulations, and difficulties managing technological advancements. In the public sector context, a lack of training and professional development for IT personnel can result in slow and ineffective adoption of cloud computing technology. Building on the work of [10], a lack of awareness and training among IT staff emerges as a critical barrier to public sector information technology adoption. This highlights the importance of well-designed training programs to address these challenges and facilitate successful IT implementation.

This study attempts to achieve two main objectives regarding cloud computing adoption in public sector. It aims to establish the details behind the complexity of cloud computing systems integration with existing infrastructure, with special emphasis on technical, financial and organizational challenges and their correlation with the decision to accept or reject cloud technology. Secondly, this research intends to evaluate the impact of knowledge and skill gaps in data governance on cloud adoption of IT personnel. It will evaluate their knowledge and understanding of data governance principles and best practices, as well as the effectiveness of existing training and development efforts in strengthening their skills and competencies.

This study has great importance in the context of technology development and digital transformation in the public sector. The study in [11] research underscores the critical role of technological advancements and digital transformation in the public sector. These studies shed light on the multifaceted nature of digital transformation, emphasizing the need for a holistic approach that extends beyond mere technological innovation. According to study [12], several factors significantly contribute to IT project complexity. These factors include the involvement of diverse stakeholders, the implementation of new technologies, the presence of conflicting goals, and the ambiguity of project objectives. In addition, by analyzing the lack of knowledge and skills in data governance, this study can help in designing more effective training and professional development programs to increase the level of readiness of IT personnel to accept cloud computing technology. The study in [13] posit that analyzing IT personnel's data governance knowledge and skill gaps can be instrumental in designing targeted training programs. These programs would enhance their preparedness for adopting cloud computing expertise.

Interests and Contributions

This article has great importance in various aspects, especially to the government, community, industry, and the development of science. Specifically, this study seeks to contribute significantly in the following ways:

First of all, this study provides an important contribution to the government in the context of the digital transformation of the public sector. However, the study in [14] integrating these systems presents complexities that require a thorough understanding to develop effective policies and strategies. This will not only increase operational efficiency but also reduce costs and improve the effectiveness of services to the public. The study in [15] explored how cloud computing integration enhances operational efficiency, reduces costs, and improves public service delivery which requires consulting key references for a comprehensive understanding.

Second, in terms of the community, this study will have a positive impact by strengthening the ability of public institutions to provide better services to the community. Wider use of cloud computing technology can open up new opportunities for innovation and development of applications that benefit local communities. According to study [16], cloud computing is an IT service model that delivers computing resources, including hardware and software, on-demand. This means they are readily available to users whenever needed, regardless of their device or location.

Third, from an industry perspective, this article provides valuable insight to decision-makers and IT managers in providing more appropriate infrastructure and facilitating the integration of cloud computing technology in the private sector. The study in [17] discuss the significant cost benefits of cloud computing, highlighting its ability to minimize IT infrastructure costs, ease deployment of new products, and reduce maintenance costs.

Finally, in terms of knowledge, this article will contribute to the existing literature by providing a deeper understanding of the challenges of cloud computing integration and deficiencies in data governance in public institutions. Cordella and Paletti's exploration of public value delivery complexities in public agencies sheds light on the challenges of effective governance and value creation. Understanding these intricacies is key to comprehending the obstacles public institutions face when integrating cloud computing and addressing data governance deficiencies [18]. This will provide a foundation for further research and strengthen the knowledge base in the field of information technology and management in Malaysia.

Overall, this article not only provides an in-depth analysis of the issues faced by public institutions in accepting cloud computing technology but also provides valuable guidance for policy preparation, community development, industry improvement, and the development of science in our country [19]. This study has a limited scope which allows a clear focus on specific and relevant issues to IT personnel without extending the study to aspects that may differ in the context of other grades in the public sector. [20], in their guidance from the JBI Scoping Review Methodology Group, advocate for engaging knowledge users in scoping reviews. This emphasis stems from the value stakeholders bring to the process, ensuring the research findings are relevant and applicable. Besides, [21] emphasizes the challenges associated with technology integration, particularly the complexities arising from merging diverse data types and

sources, as evidenced by a survey on data integration problems. Thus, this study aims to identify and analyze these factors in the hope of providing useful guidance to improve the adoption process of cloud computing in the public sector. Through this study, public institutions can be more prepared and competitive in the era of digital transformation.

II. Literature Review

A. Current State of Cloud Computing Adoption

Cloud computing revolutionizes IT by offering cost-effective, scalable solutions that streamline government operations and improve service delivery. Studies by [22] support this, highlighting cost reduction and enhanced services as key benefits [23]. However, challenges like integration complexity and a skilled workforce gap need to be addressed for successful implementation.

B. Recent Studies and Theories

Cloud adoption in the public sector is a double-edged sword, according to recent research by [24] and [25]. While it offers potential benefits, there are significant challenges to overcome. Data security, regulatory compliance, and integrating cloud computing with existing infrastructure are all major hurdles [21][3]. Notably, the complexity of this integration remains a critical barrier to wider adoption.

C. Contrasting Views

Cloud computing's impact on the public sector sparks debate. Research by [26] highlights its potential for increased flexibility and cost savings [2]. However, [27] point to initial investment costs and integration hurdles [7]. This suggests the actual value of cloud computing depends on each organization's preparedness and existing infrastructure.

D. Identified Gaps

A notable gap in the literature is the specific challenges faced by IT personnel in the Malaysian public sector. While there is a wealth of general information on cloud computing adoption, few studies focus on the detailed impacts on IT personnel's performance and the specific barriers they encounter. This study aims to fill this gap by providing an in-depth analysis of these factors, focusing on the Malaysian public sector context [21].

E. Literature Gap Addressed by the Study

This study tackles a critical gap by zeroing in on the twin challenges of complex system integration and the public sector's data governance skills shortage. According to study [28], the implementation of data integration in the public sector faces four main challenges: the lack of management support, policy standards and politics, the inability of human resources and the lack of governance. By delving into these areas, the research sheds light on how these factors significantly impact cloud adoption. The factors influencing cloud adoption are relative advantage, service quality, risk management, top management support, facilitating conditions, influence on cloud providers, server location and computer self-efficacy [29]. Furthermore, it offers practical solutions to overcome these barriers, paving the way for smoother cloud implementation.

F. Introduction of Theoretical Framework

To strengthen the study's foundation, the well-established Technology Acceptance Model (TAM) is incorporated into the research framework. Developed by [30], TAM sheds light on how users within organizations perceive and adopt new technologies. This model emphasizes two key factors: perceived usefulness and perceived ease of use. By integrating TAM, the study aims to provide a more comprehensive understanding of cloud adoption in the public sector.

G. Relevance of TAM

The TAM proves particularly valuable to this study. Perceived availability acts as a significant predictor of user perception and system/service quality, significantly influencing the adoption of sustainable cloud computing solutions [30]. TAM's core focus aligns perfectly: it delves into how IT personnel in the public sector perceive cloud computing, specifically the factors influencing their acceptance and use of this technology. By leveraging TAM, the research gains a structured framework to analyze the key drivers of cloud adoption in this context. TAM provides empirical evidence supporting the positive inclination of end users toward cloud computing adoption [31].

H. Application of TAM in the Study

This study leverages TAM to explore key hypotheses. It predicts that the perceived ease of use will be negatively impacted by the complexity of integrating cloud computing with existing infrastructure. According to study [32], cloud computing adoption and utilization determinants encompass perceived ease of use, compatibility, security, technological readiness, organizational size, competitive pressures, trialability, cost-efficiency, and individual innovativeness. Conversely, the perceived usefulness is expected to rise with the improvement in IT personnel's performance driven by cloud adoption. Perceived availability emerges as a critical determinant of users' perceived utility and system/service quality, thereby influencing the adoption of sustainable cloud computing solutions [30]. By examining these relationships through TAM's structured framework, the study offers a systematic analysis of factors influencing cloud adoption in the public sector.

I. Strengthening Academic Rigor

This study's integration of the TAM bolsters its academic credibility in several ways. TAM serves as a robust theoretical foundation, allowing for the development of well-defined hypotheses. TAM constitutes a theoretical framework for evaluating technology adoption within organizational contexts, a critical component of successful digital transformation initiatives [33]. Furthermore, it acts as a roadmap for data collection and analysis, guaranteeing that the research findings are firmly anchored in established theoretical concepts.

J. Methodology Supported by Theoretical Framework

To understand IT personnel's perspectives on cloud computing adoption in the Malaysian public sector, this study utilizes qualitative interviews guided by the TAM. These in-depth discussions will explore perceived challenges, benefits, and the impact on IT staff performance—all key areas influencing TAM's core constructs. By analyzing the collected

data, the research aims to test TAM-derived hypotheses and shed light on the model's practical application within this specific context. This will offer valuable insights into the factors driving or hindering cloud adoption in the Malaysian public sector.

III. Research Methodology

A. Qualitative Research Methods

This study delves into the factors influencing cloud adoption and its impact on public sector IT personnel performance through qualitative research methods. These methods are ideal for exploring complex issues in depth, as they allow researchers to capture the nuanced perspectives and lived experiences of individuals. This approach provides a richer understanding of the human element within cloud adoption in the public sector.

B. Nature of Qualitative Research

Qualitative research serves as a launchpad for deeper understanding. According to study [34], qualitative research is characterized by its naturalistic, contextualized, and interpretive nature, prioritizing the exploration of processes and developmental patterns over the delineation of definitive products or outcomes. Unlike quantitative methods that focus on numbers and broad generalizations, qualitative research delves into the 'why' behind human experiences. Qualitative research employs methodologies such as interviews, focus groups, and observation to delve into the underlying motivations and experiences that shape human behavior [35]. Through interviews, observations, and document analysis, it gathers rich, non-numerical data like words and meanings. This approach helps us uncover motivations, opinions, and underlying reasons, laying the groundwork for future studies and potentially informing quantitative research with well-defined hypotheses.

C. Suitability for the Study

1) Unpacking the intricacies of cloud adoption within the public sector demands a research approach that goes beyond the surface. Qualitative methods rise to this challenge. Qualitative research employs methodologies such as interviews, focus groups, and observation to investigate participants' perspectives and lived experiences, typically involving smaller sample sizes and iterative data collection until theoretical saturation is achieved *[35]*. By enabling in-depth exploration of IT personnel's perceptions and the factors influencing adoption and performance, qualitative research offers a nuanced understanding often missed by quantitative approaches. This rich data provides valuable insights that can guide successful cloud implementation in the public sector *[36]*.

2) Qualitative research methods shine a light on the human dimension of cloud adoption in the public sector. According to Omar Ali et al., the adoption of cloud-based services within local government entities is significantly influenced by compatibility, complexity, cost, security considerations, anticipated benefits, and organizational scale [37]. By gathering detailed narratives and insights from IT personnel, researchers can uncover the rich tapestry of their experiences. This in-depth approach goes beyond just identifying barriers and facilitators; it reveals the nuanced contextual factors that influence how cloud computing is adopted and implemented. Compatibility, relative advantage, security, trust, and reduced complexity are key determinants of positive attitudes toward cloud adoption [38]. This knowledge is crucial for crafting successful strategies for the public sector.

D. Data Collection Methods

1) To gather rich data on cloud adoption, this study employed semi-structured interviews. This method strikes a balance between focus and flexibility. A pre-defined interview guide ensures we cover key areas while allowing the conversation to flow organically and explore unexpected insights that emerge. This approach yields detailed and comprehensive data, providing a deeper understanding of IT personnel's experiences in the public sector.

2) This study went beyond interviews, to strengthen the credibility and comprehensiveness of the findings. Document analysis and observations were incorporated, employing a technique called triangulation. This multifaceted approach allowed for the verification and enrichment of the data. By examining relevant documents and potentially observing IT personnel interacting with cloud computing, the research paints a more complete picture of cloud adoption in the public sector.

E. Rationale for Choosing Qualitative Interviews

1) Depth of understanding: In-depth interviews are the key to unlocking the complexities of cloud adoption in the public sector. Research conducted in diverse geographic contexts, such as South Africa, underscores the efficacy of in-depth interviews in elucidating the facilitators, obstacles, and intricacies inherent in cloud computing adoption processes [4]. Unlike surveys, interviews allow for a nuanced exploration of IT personnel's experiences, perceptions, and attitudes. Such interviews afford IT professionals a venue to articulate their perspectives on factors impacting workplace well-being, including interpersonal relationships and individual work environment characteristics [39]. This deep dive reveals the 'why' behind their challenges and the specific benefits they anticipate. This rich understanding is crucial for crafting effective cloud implementation strategies tailored to the public sector.

2) Flexibility: The semi-structured nature of the interviews empowers researchers to delve deeper. Qualitative research offers a rich and nuanced exploration of participants' subjective realities, allowing for the emergence of unforeseen patterns and insights [40]. When IT personnel offer intriguing responses or areas of ambiguity arise, the flexible format allows for follow-up questions. This adaptability ensures researchers capture a comprehensive understanding of the challenges and nuances surrounding cloud adoption in the public sector.

3) Rich data: Interviews are the cornerstone of this study, unearthing the intricate tapestry of cloud adoption in the public sector. Research conducted by [3], [4] and [41] underscore the pivotal role of interviews in elucidating the determinants, advantages, and obstacles associated with cloud computing adoption within governmental organizations. Unlike

quantitative methods, interviews capture rich, qualitative data that reveal the interplay of technical hurdles, organizational dynamics, and human factors influencing the process. This nuanced understanding is essential for navigating the complexities of cloud adoption within the public sector.

F. Ethics Statement

This ethical statement explains the steps taken to ensure that this study is conducted in compliance with high ethical standards. This includes how participant consent is obtained and the steps taken to ensure data privacy.

G. Obtaining Participant Consent

Before the study was conducted, all participants were given a detailed explanation of the purpose of the study, the procedures to be carried out, and their rights as participants. Each participant was asked to sign a written consent form before participating in this study.

H. Ensuring Data Privacy

Regarding [42], data security and privacy issues in cloud storage systems are significant concerns, including unauthorized access, data leakage, and privacy disclosure. To ensure the privacy of participant data, the following steps are taken:

1) Anonymity: All information collected is anonymized [43], [44].

2) Data storage: Study data is stored in a password-protected electronic format [45].

3) Confidentiality: Participants' personal information is kept confidential [46].

4) Data destruction: After the study is completed, all personal data will be securely destroyed [43].

IV. Result

This section adheres to a rigorous approach by presenting the interview findings objectively. Each theme identified within the data is reported without interpretation, allowing the participants' voices to shine through. Supporting quotes are carefully chosen to illustrate these themes, providing a clear picture of the key issues surrounding cloud adoption in the public sector.

A. Compatibility Issues and System Integration

Findings: Interview data revealed a significant hurdle: technical complexity and compatibility issues during cloud integration with existing infrastructure. Participants described difficulties aligning new cloud computing with legacy software and hardware, leading to operational disruptions and inefficiencies. One participant (Participant 1) echoed this sentiment, stating, 'The old system used was difficult to integrate because of numerous compatibility problems.'

Supporting Quotes:

- Participant 1: "This old system is kind of hard to integrate; it seems like there are a lot of bugs. It's really hard."
- Participant 3: "Integrating the cloud computing with our existing infrastructure has been a major headache due to compatibility issues.

B. Data Migration Problems

Findings: Data migration emerged as a critical barrier due to incompatible data formats and structures. Participants consistently reported challenges transferring data from legacy systems to the cloud, often resulting in data loss, corruption, or significant delays. As Participant 2 succinctly stated, 'Data migration is hampered by the incompatibility between old data formats and structures and new cloud computing systems.'

Supporting Quotes:

- Participant 2: "This data is not directly compatible with the cloud; it is difficult to transfer."
- Participant 4: "We faced numerous problems migrating our legacy data to the cloud due to different data formats."

C. Network Problems

Findings: Network limitations emerged as a major roadblock to cloud adoption. Participants consistently described the challenges of slow infrastructure and high latency. They reported that, insufficient bandwidth and unreliable internet connections hampered the smooth operation of cloud services, leading to frequent downtime and decreased productivity. As Participant 3 noted, 'Slow network infrastructure and latency problems impede the smooth integration of cloud computing.'

Supporting Quotes:

- Participant 3: "Insufficient network speed and delays in data transmission make the user experience less satisfactory."
- Participant 5: "Our internet connection is often too slow to handle the demands of cloud computing effectively."

D. Lack of Training and Knowledge

Findings: A critical knowledge gap emerged as a significant barrier to cloud adoption. Participants consistently highlighted the lack of training and knowledge among IT staff. They pointed out that many personnel are not equipped to effectively manage and implement cloud technologies, leading to improper usage and integration failures. This sentiment was echoed by Participants 4 and 1, who stressed the need for 'in-depth training in cloud technology management and integration' for IT personnel.

Supporting Quotes:

- Participant 4: "Without adequate training, staff do not have the necessary skills to carry out the integration process properly."
- Participant 1: "We need comprehensive training programs to equip our team with the necessary cloud computing skills."

E. Budget Constraints

Findings: Budgetary limitations emerged as a persistent hurdle. Participants consistently highlighted the challenges posed by limited financial resources. Upgrading hardware and software to meet cloud integration requirements proved difficult due to a lack of funds for these vital investments. This financial

constraint significantly hampers cloud adoption efforts, as Participant 5 poignantly noted: 'The lack of funds caused difficulties in updating the hardware and software required for cloud computing integration.'

Supporting Quotes:

- Participant 5: "The budget is not enough; the hardware upgrade is not affordable, and the software integration is crazy expensive."
- Participant 2: "We struggle to secure the funding needed to support our cloud computing initiatives."

These results provide insight that can be used to plan more effective strategies for integrating cloud computing and improving the performance of IT personnel in the public sector.

TABLE I. SUMMARY OF KEY FINDINGS

Theme	Issues Identified	Supporting Quotes
Compatibility Issues	Technical complexity, system compatibility problems	"The old system used was difficult to integrate because there were many compatibility problems."
Data Migration Problems	Incompatible data formats, transfer difficulties	"Data migration is hindered by the incompatibility of old data formats and structures with new cloud computing systems."
Network Problems	Slow network infrastructure, high latency	"Slow network infrastructure and latency problems impede the smooth integration of cloud computing."
Lack of Training and Knowledge	Insufficient training, skill deficits	"IT personnel need more in-depth training in cloud technology management and integration."
Budget Constraints	Insufficient funds for upgrades	"The budget is not enough; the hardware upgrade is not affordable, and the software integration is crazy expensive."

Table I summarizes key findings into five themes which are compatibility issues, data migration problems, network problems, lack of training and knowledge, and budget constraints.

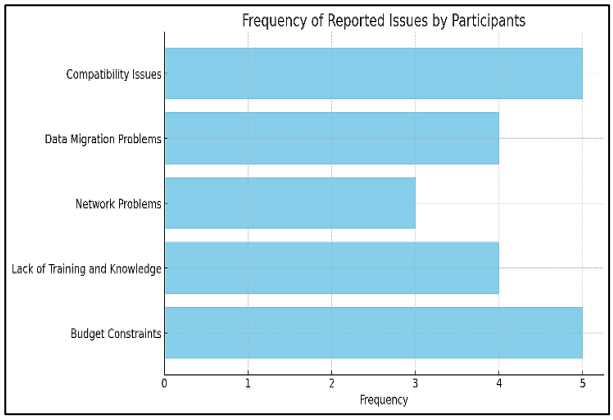

Fig. 1. Frequency of reported issues by participants.

Fig. 1 dives deeper into the challenges faced during cloud adoption within the public sector. This bar chart visually translates the participants' interview responses, highlighting the frequency of various issues reported. A quick glance allows for easy comparison, revealing which challenges were most prevalent among IT personnel.

Fig. 1 paints a clear picture of the roadblocks hindering cloud adoption in the public sector. Compatibility issues and budget constraints emerge as the most significant hurdles, with all 5 participants citing them. Data migration woes and the knowledge gap among IT personnel are also prevalent, reported by 4 participants each. Network limitations, though affecting slightly fewer (3 participants), remain a noteworthy challenge. This visual representation serves as a roadmap for successful cloud implementation. By prioritizing solutions that address these key areas compatibility, budget constraints, data migration, and IT skill development public sector organizations can pave the way for smoother adoption and ultimately unlock the full potential of cloud technologies for enhanced performance.

V. COMPARISON WITH PREVIOUS STUDIES

In order to understand how the findings of this study fit into a broader research context, it is important to compare the results of this study with those of previous studies. This section will highlight the similarities and differences between the findings of this study and the existing literature, providing a clearer picture of the challenges and opportunities in the adoption of cloud computing in the public sector.

A. Compatibility and System Integration Issues

- Findings: Participants reported significant technical complexity and compatibility issues when integrating cloud computing with existing infrastructure.
- Previous Research: The study in [4] stated that system compatibility is the main barrier to cloud adoption in the public sector. The study in [47] also emphasized the technical difficulties in integrating the new system with the old infrastructure.
- Comparison: Findings are consistent with these studies, reinforcing the view that compatibility issues are a common barrier to cloud adoption. This consistency across different contexts underscores the need for strategic planning and investment in compatible technologies to facilitate smoother integration.

B. Data Migration Problems

- Findings: Data migration was identified as a major challenge due to incompatibility of data formats and structures.
- Previous Research: The study in [32] emphasized the need for effective data migration strategies in cloud environments, noting similar challenges with compatibility and data migration difficulties. The study in [48] also documented data migration issues in their study.

- Comparison: Findings are consistent with these studies, showing that the problem of data migration is widespread and critical. This emphasizes the importance of robust data management strategies and tools in cloud computing adoption [49] [50].

C. Network Problems

- Findings: Network issues, including slow infrastructure and high latency, are significant barriers.
- Previous Studies: The study in [32] recommend increased data transmission speed and reduced latency in cloud environments, emphasizing similar network issues. The study in [19] also emphasized the need to upgrade network infrastructure to support cloud computing.
- Comparison: Findings are consistent with these studies, showing that network problems are a common barrier to cloud adoption. This consistency shows that upgrading the network infrastructure is essential for successful cloud integration.

D. Lack of Training and Knowledge

- Findings: Participants highlighted lack of training and knowledge as the main barrier.
- Previous Studies: The study in [10] emphasized the importance of training in improving the readiness of IT personnel for cloud adoption. The study in [10] also emphasized the need for ongoing professional development programs.
- Comparison: Findings are consistent with previous studies, emphasizing the need for comprehensive training programs to equip IT personnel with the skills necessary for effective cloud computing adoption [51] [52].

E. Budget Constraints

- Findings: Budget constraints were a recurring theme, with participants reporting difficulties in updating hardware and software.
- Previous Studies: The study in [25] emphasized the role of financial resources in successful IT integration. The study in [21] also documents the importance of budget allocation for IT upgrades and training.
- Comparison: Findings are consistent with these studies, suggesting that budget constraints are a significant barrier to cloud adoption. This consistency highlights the critical need for adequate funding and resource allocation to support cloud initiatives [53].

The findings of this study align closely with existing literature, validating the use of the Technology Acceptance Model (TAM) to analyze cloud computing adoption and its impact on IT personnel performance in the public sector. Consistent with previous research, participants reported significant challenges, including compatibility and system integration issues, which [4] and [47] identified as major barriers to cloud adoption. Additionally, data migration problems, such as incompatible data formats, align with findings from [32] and [48], emphasizing the need for robust migration strategies. Network issues, including slow infrastructure and high latency, echo concerns highlighted by [19] and [32], reinforcing the necessity of upgrading network infrastructure to support cloud integration. The lack of training and knowledge was another critical barrier, supporting [10]'s assertion that professional development programs are essential for cloud readiness. Furthermore, budget constraints, a recurring theme in this study, align with [21] and [25], emphasizing the need for sufficient financial resources for technology upgrades and training. These findings collectively validate TAM's constructs of perceived usefulness and perceived ease of use, demonstrating how technical challenges, organizational readiness, and resource availability influence cloud adoption. Thus, incorporating these sector-specific barriers into CCAPM's model, the study offers a comprehensive model that not only reinforces established theories but also provides practical insights for overcoming adoption challenges and enhancing IT personnel performance in the public sector.

Overall, the findings of this study are consistent with many previous studies, emphasizing common issues such as system compatibility, data migration problems, network issues, lack of training, and budget constraints. Although some specific contexts are unique to the Malaysian public sector, the key challenges identified are consistent with the global literature. This suggests that better strategies and careful planning are needed to overcome these obstacles and maximize the benefits of cloud computing.

VI. Implications

In this study, findings obtained from interviews with public sector IT personnel revealed several key issues that hinder the adoption of cloud computing. These findings include system compatibility and integration issues, data migration issues, network issues, lack of training and knowledge, and budget constraints. The practical implications of these findings are important to note for policymakers, IT managers, and public sector organizations to ensure a more effective and efficient implementation of cloud computing.

The findings of this study offer valuable insight into the real challenges faced in integrating cloud technology in public sector environments. By understanding and overcoming these barriers, stakeholders can develop more robust and relevant strategies to harness the full potential of cloud computing. Therefore, it is important to explore the practical implications arising from the findings of this study and provide recommendations that can help in increasing the uptake and use of cloud technology in the public sector.

This section will elaborate on the implications of this study's findings for three main groups: policymakers, IT managers, and public sector organizations. Each of these groups plays an important role in ensuring the successful implementation of cloud computing, and understanding the implications of this will allow them to take appropriate actions to address the identified challenges.

A. For Policy Makers

1) Strategic planning and investment: Policymakers should prioritize strategic planning and investment in compatible technologies to facilitate the integration of cloud computing with existing infrastructure. This includes allocating funds to upgrade legacy systems and ensure compatibility with new cloud-based solutions.

2) Infrastructure development: There is a need for significant investment in network infrastructure to address the issues of slow speed and high latency. Policymakers should consider funding initiatives to improve broadband infrastructure and ensure reliable internet connectivity, which is essential for effective cloud computing.

3) Training and development programs: Policy makers should support the development of comprehensive training programs for IT personnel. This includes funding professional development initiatives focused on cloud technology management and integration, ensuring staff have the necessary skills and knowledge.

B. For IT Managers

1) Implementation of best practices: IT managers should adopt best practices for data migration, including robust data management strategies and tools that address compatibility issues. This involves thorough planning and testing to ensure smooth data transfer.

2) Resource allocation: IT managers need to support adequate budget allocations to support necessary hardware and software upgrades. This includes presenting a strong business case for funding for cloud initiatives and training programs.

3) Continuous learning: IT managers should foster a culture of continuous learning and professional development in their teams. This can be achieved by organizing regular training sessions, workshops, and certifications in cloud technology.

C. For Public Sector Organizations

1) Policy development: Public sector organizations should develop clear policies and guidelines for cloud adoption, addressing compatibility, data migration, network infrastructure, training, and funding. This policy should align with broader government strategy and ensure consistent implementation across departments.

2) Collaboration and partnerships: Organizations should collaborate with technology vendors, industry experts, and other public sector entities to share knowledge and best practices. Partnerships can also help in negotiating better terms and prices for cloud services and related infrastructure upgrades.

3) Monitoring and evaluation: Implement robust monitoring and evaluation mechanisms to assess the effectiveness of cloud adoption initiatives. This includes tracking performance metrics, identifying areas for improvement, and making data-driven decisions to optimize cloud computing implementations.

VII. CONCLUSIONS

This study has conducted in-depth research on the factors that influence the adoption of cloud computing in the public sector, particularly on the performance of IT personnel. Through interviews with five participants who are IT experts in the public sector, the findings of this study offer valuable insight into the various challenges faced in the cloud computing integration process.

A summary of the key findings shows that there are several key barriers that affect the adoption of cloud computing. Among the main issues faced are system compatibility problems, deficiencies in the data migration process, inefficient network issues, lack of training and skills in data governance, as well as tight budget constraints. Study participants have provided insight into how these factors affect their ability to integrate and optimize the use of cloud technology in daily operations.

In the discussion of the findings, it is clear that these challenges are directly related to the objective of the study, which is to identify and analyze the factors that influence the adoption of cloud computing. From the data collected, main themes such as 'Compatibility and System Integration Issues', 'Data Migration Issues', 'Network Issues', 'Lack of Training and Knowledge', as well as 'Budget Constraints' were formed. These themes not only clarify the various technical and operational aspects that need to be addressed but also outline the need for a more comprehensive strategy that includes financial aspects and human resource development.

This study provides an important contribution to the field of cloud computing in the context of the public sector. First, it broadens the understanding of the specific challenges public institutions face in adopting cloud technologies, which are often different from the challenges faced by the private sector. Second, this study offers empirical evidence that supports the need for a more integrated approach in the implementation of this technology, emphasizing the importance of adapting infrastructure, training, and access to sufficient financial resources.

In conclusion, the findings from this study clearly show that although cloud computing offers many potential benefits, there are significant barriers to overcome to maximize its benefits in the public sector. Solutions to the issues identified in this study will require joint efforts between policy makers, technology managers, and IT practitioners to develop a comprehensive strategy that focuses not only on technology but also on improving organizational and individual capabilities. This will ensure that public institutions can take advantage of cloud technology to improve the efficiency and effectiveness of their services to the public.

In the context of solving the problem stated in the problem statement of this study—complexity in the integration of cloud computing with existing infrastructure and the lack of knowledge and skills in data governance in public institutions—the appropriate model needs to take into account technical, operational, and human resource development aspects. The proposed model is the "Cloud Computing Integration and Cloud Computing Acceptance and Performance Model" (CCAPM).

A. CCAPM Model Formation

1) Preliminary assessment phase:

a) Diagnostics of existing infrastructure: The first step is to perform a thorough diagnostic of the existing information technology infrastructure to assess compatibility with cloud computing systems. This includes an assessment of software, hardware, and network configuration.

b) Constraint and potential analysis: Identify constraints such as compatibility issues, data security, and network requirements, as well as potential improvements through cloud computing.

2) Development and integration phase:

a) Infrastructure development: Upgrade or replace infrastructure components that are not compatible with cloud technology. This may include replacing old software, network upgrades, and installing better data security systems.

b) System integration: Integrate cloud computing with upgraded infrastructure using protocols and tools that ensure smooth data migration and continuous operations.

3) Capacity expansion phase:

a) Training and human resource development: Implement a comprehensive training program to improve the technical skills of IT personnel in managing and maintaining cloud computing systems. This includes training in data governance, cyber security, and disaster recovery.

b) Expertise development: Establish a specialized unit in cloud computing responsible for providing technical support, guiding daily operations, and guaranteeing compliance with public sector policies.

4) Continuous evaluation phase:

a) Performance audit and evaluation: Conduct periodic audits to evaluate cloud computing system performance, effectiveness of training provided, and adherence to security protocols.

b) Iteration and refinement: Based on the results of the audit, improvements should be made to the infrastructure and operational procedures to continue improving the performance and security of the system.

This CCAPM model is expected to solve the problem of the complexity of cloud computing integration by taking a holistic approach that does not only focus on technical aspects but also the development of human resource skills and capacity in the public sector. This model also aims to create a resilient and sustainable ecosystem that can adapt new technologies more quickly and efficiently, while maintaining a high level of security and compatibility.

This model includes four main phases in the process of integration and expansion of cloud computing capacity in the public sector, ranging from initial assessment, development and integration, capacity expansion, to continuous assessment for sustainable improvement. Each step in the model has a specific task aimed at overcoming the challenges stated in the problem statement of this study.

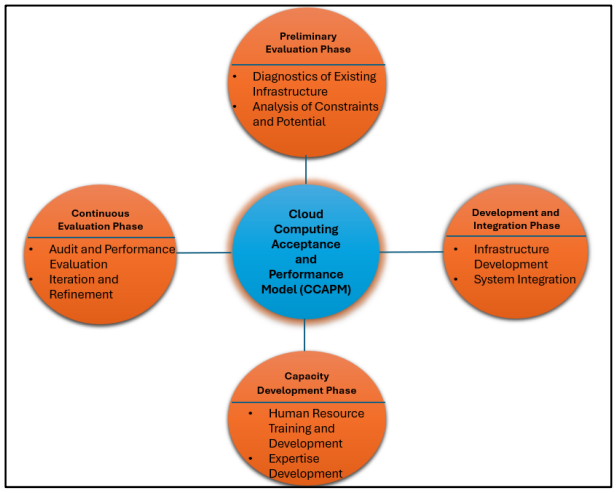

Fig. 2. Cloud Computing Acceptance and Performance Model (CCAPM).

This study has identified several key challenges in the adoption of cloud computing in the Malaysian public sector. Key findings include system compatibility and integration issues, data migration issues, network issues, lack of training and knowledge, and budget constraints. Complex system compatibility and technical problems hinder the seamless integration of cloud technology with existing infrastructure. Data migration problems, including the incompatibility of old data formats and structures with the new system, also add to these challenges. Network issues such as slow infrastructure and high latency reduce the effectiveness of using cloud technology. In addition, the lack of training and knowledge among IT personnel makes the process of adopting this technology difficult. Finally, budget constraints prevent the necessary investments to upgrade the hardware, software, and training needed to support cloud adoption. These findings emphasize the need for strategic planning, adequate investment, and comprehensive training programs to ensure the successful adoption of cloud computing in the public sector.

VIII. Future Research

Based on the findings of this study, there are several areas that require further research to deepen understanding and overcome challenges in cloud computing adoption.

1) First, future studies can focus on developing more effective data management strategies and tools to deal with data migration problems. This study can investigate the technical and methodological approaches that can be used to ensure a smoother and safer transfer of data.

2) Second, further research needs to be done to assess the effectiveness of training and professional development programs in improving the readiness of IT personnel for cloud computing. This includes research on what types of training are most effective and how best to deliver training content.

3) Third, future studies could examine methods to overcome budget constraints, including alternative funding models and strategies for obtaining financial support for cloud computing initiatives.

4) Finally, there is a need for more in-depth studies on the long-term impact of cloud computing on the performance of operations and services in the public sector. This study can help in understanding how this technology can be optimized to improve the efficiency and effectiveness of public services.

IX. LIMITATIONS

This study only involved five participants, which may not reflect the views of all IT personnel in the public sector. Also, this study is limited to the Malaysian context only.

1) Research implications: Findings from this study provide a basis for further research in cloud computing in the public sector. It suggests the need for a broader study involving more participants from a variety of geographic and technical backgrounds. Further research could explore the relationship between various technical, operational, and organizational factors with the effectiveness of cloud computing, including a comparative analysis between the public and private sectors.

2) Practical implications: These findings offer practical guidance for government agencies in planning and implementing cloud computing systems, emphasizing the need for improved infrastructure and better training programs.

ACKNOWLEDGMENT

This work was supported in part by Universiti Kebangsaan Malaysia, and in part by the Ministry of Higher Education Malaysia under Grant FRGS/1/2024/TK01/UKM/02/2.

NOORBAITI MAHUSIN received a B.Sc. from Universiti Malaysia Pahang, in 2006, and M.Sc. in Information Science from the Universiti Kebangsaan Malaysia, Bangi, Malaysia, in 2018, where she is currently pursuing her Ph.D. degree in Management Information Systems. She currently working on publish papers in reputed journals. Her current research interests including IoT and Artificial Intelligence.

HASIMI SALLEHUDIN is a Senior Lecturer with the Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia. His research interests include computer security and networks, and management information systems.

NURHIZAM SAFIE MOHD SATAR received the Diploma degree from UPM, with specialization in E-learning technology information systems adoption and diffusion cloud computing, the B.H.Sc. degree from IIUM, the M.I.T. degree.

AZANA HAFIZAH MOHD AMAN received her PhD, MSc and BEng in Computer and Information Engineering from International Islamic University Malaysia. She is currently working as senior lecturer at Research Center for Cyber Security, Faculty of Information Science and Technology (FTSM), The National University of Malaysia (UKM), Malaysia. Her research areas are computer system & networking, information & network security, IoT, cloud computing, and big data.

FARASHAZILLAH YAHYA is a senior lecturer at the Faculty of Computing and Informatics at Universiti Malaysia Sabah. Her research interests include data management, digital technology, cloud computing and cybersecurity. She holds a PhD. in Computer Science from the University of Southampton, United Kingdom and a BSc. (Hons) Information System Engineering from UiTM, Shah Alam.
