Abstract*—Managing wastewater to effectively remove water pollution is inherently difficult. Ensuring that the treated water meets stringent standards is a main priority for several countries. Advances in control and optimization strategies can significantly improve the elimination of harmful substances, particularly in the case of carbon pollution. This paper presents a novel optimization-based approach for carbon removal in Activated Sludge Process (ASP) of Wastewater Treatment Plants (WWTPs). The developed pollution removal algorithm combined the concepts of Takagi-Sugeno (TS) fuzzy modeling, Model Predictive Control (MPC) and Grey Wolf Optimization (GWO), as a parameters-free metaheuristics algorithm, to boost the carbon elimination in terms of standard metrics, namely Chemical Oxygen Demand (COD), Biochemical Oxygen Demand (BOD5) and Total Suspended Solids (TSS). To enhance such a pollution removal, the proposed fuzzy predictive control for all wastewater variables, i.e. effluent volume, concentrations of heterotrophic biomass, biodegradable substrate and dissolved oxygen, is formulated as a constrained optimization problem. The MPC parameters' tuning process is therefore performed to select appropriate values for weighting coefficients, prediction and control horizons of local TS sub-models. To demonstrate the effectiveness of the proposed parameters-free GWO algorithm, comparisons with homologous state-of-the-art solvers such as Particle Swarm Optimization (PSO) and Genetic Algorithm (GA), as well as the standard commonly used Parallel Distributed Compensation (PDC) technique, are carried out in terms of key purification indices COD, BOD5, and TSS. Additionally, an ANOVA study is conducted to evaluate the reported competing metaheuristics using Friedman ranking and post-hoc tests. The main findings highlight the superiority of the proposed GWO-based carbon pollution removal in WWTPs with elimination efficiencies of 93.9% for COD, 93.4% for BOD5, and 94.1% for TSS, in comparison with lower percentages for PSO, GA and PDC techniques.

I. Introduction

Wastewater is a major environmental problem that poses a threat to ecosystems and human health [1]. Contaminants in untreated wastewater, including organic pollutants, pathogens, and heavy metals, can lead to serious health risks and disrupt the balance of ecosystems [2]. To address the critical issue of water pollution and ensure a sustainable future, a wide range of strategies and regulations are being implemented to improve water quality, safeguard public health and protect the environment [3]. The modeling [4] and control [5] of WWTPs are gaining growing attention, with considerable efforts dedicated to improving their performance. Advanced automatic control, artificial intelligence and soft computing approaches have led to the development of various models aimed at enhancing the overall effectiveness of WWTPs [6].

Wastewater treatment involves several stages each aimed at removing different contaminants. The secondary treatment, which is biological, is the most crucial phase in the overall process, aimed at removing organic matter from the water, as well as nitrogen and phosphorus. Biological treatment through ASPs is the most widely adopted solution for addressing pollution and removing toxicity from wastewater [7]. In an ASP, wastewater is aerated in a tank where bacteria break down organic pollutants in the presence of oxygen. After aeration, the treated water flows to a clarifier, where the activated sludge settles out. Some of the sludge is re-circulated into the aeration tank to maintain microorganism concentration. The primary goal of ASP is to produce treated wastewater that meets regulatory standards for effluent quality, mainly in terms of BOD5, TSS, and COD [8]. It also aims to maintain appropriate dissolved oxygen levels to avoid anoxic conditions. However, achieving these objectives is challenging due to several factors. Variability in influent characteristics, such as changes in flow rate and pollutant concentrations, requires constant adjustments to maintain consistent effluent quality. The behavior of microbial communities is influenced by numerous factors, including temperature, pH, and nutrient availability, making it difficult to maintain an optimal balance. Furthermore, the interactions between various biological, chemical, and physical processes within the system are highly complex and difficult to model accurately [9]. As a result, ensuring optimal treatment performance demands the use of sophisticated modeling and advanced control strategies, making the management of ASPs a persistent and significant challenge.

Over the years, numerous control strategies have been proposed for WWTPs. These techniques differ in their targeted objectives, which are typically defined in terms of optimizing dissolved oxygen and enhancing harmful substances removal. In study [10], a comprehensive framework is proposed for evaluating various control techniques of WWTPs. Feedback

strategies for simultaneous evaluation of economics, energy, and removal of nutrients are addressed. In study [11], a two-stage linear control scheme is developed to regulate the effluent substrate concentration. Static inner-loop controller is designed using a metaheuristic algorithm for parameters selection. Strategies of static feedback with pole placement [12] and model predictive control [13] are investigated based on an established TS fuzzy representation for ASPs. In study [14], authors examined the design of fuzzy controllers for dissolved oxygen and nitrate dynamics under varying conditions. In [15], a PDC technique is designed under linear matrix inequalities (LMI) constraints of stabilization. In study [16], model predictive control, PID regulation, data-driven and neural networks are investigated to optimize nitrogen removal offering a flexible and adaptive approach to process control. In [17], authors implemented cascaded PI and event-based control strategies for WWTPs using the nitrogen-to-energy index as a performance indicator. In study [18], various artificial intelligence-based strategies are explored with a particular focus on aeration control. In study [19], authors developed deep learning-based simulators to improve the control of phosphorus removal processes. In study [20], authors proposed a nonlinear predictive control strategy to manage the nonlinear dynamics inherent in WWTPs and enhancing the control performance and stability. In study [21], a neuro-fuzzy based MPC controller is designed to estimate key process variables and adjust aeration levels for cost-effective nutrient removal. In [22], authors proposed an economic-oriented MPC ensuring ammonia concentration within specified limits.

In addition to these aforementioned state-of-the-art control strategies, the application of metaheuristics algorithms has become increasingly significant in addressing the complexities inherent in WWTPs. In study [23], a dynamic multi-objective PSO algorithm is proposed for dissolved oxygen and nitrate dynamics. In study [24], a GA optimizer is used to modify the set-point of PI controller for dissolved oxygen variables. Two levels are used: at the higher one, GA determines the optimal dissolved oxygen set-point based on operational conditions and at the lower, a PI controller adjusts the aeration to reach the set-point. In study [25], various metaheuristics are integrated with a fuzzy inference system to enhance the modeling accuracy of WWTPs. The achieved prediction capabilities guarantee more effective management and compliance with environmental standards. In study [26], a coyote optimization algorithm is employed to optimize the adaptive controller parameters for dissolved oxygen concentration in a biological sequential batch reactor. In [27], authors proposed a framework to optimize the aeration in WWTPs. A neural network predicts energy consumption and dynamically adjusts PI controllers. In [28], an extreme learning machine with metaheuristic algorithms is designed for the modeling of water quality parameters in Nigeria.

In this context, advanced optimization strategies are crucial to effectively manage WWTPs. Metaheuristics have emerged as powerful tools for controlling complex systems, offering competing solutions to the challenges inherent in biological processes [29]. Due to the strict quality requirements set by international standards as well as the increasing complexity of WWTPs, it becomes essential to optimize all biochemical variables involved in the purification process to ensure more effective pollutant removal and guarantee the compliance with increasingly stringent water quality standards. Indeed, there are few contributions in the literature that address the enhancement of all pollutants removal. Most proposed optimization strategies focus on economic objectives, and many studies often limit their scope to the dynamics of dissolved oxygen to minimize energy consumption, neglecting other critical variables such as wastewater influent volume, biomass growth, substrate concentration, and others. On the other hand, most metaheuristics of the literature suffer from the problem of choosing and tuning their control parameters. The efficiency of such algorithms is strongly linked to the tuning of parameters of the algorithm itself, often tedious and time-consuming in design. Thus, the use of a metaheuristic with a reduced number of algorithmic parameters, or even without parameters, can circumvent such a design problem and offers more simplicity in the optimization process. GWO algorithms as a parameters-free metaheuristics thus present an interesting and justified choice for optimizing the wastewater treatment. Therefore, the use of a GWO algorithm combined to a nonlinear multi-input multi-output model, which accounts for all state variables of ASPs, as well as an efficient automatic control strategy, is essential to further enhance the purification challenges and the carbon pollution removal. In this paper, an intelligent carbon pollution removal strategy, based on an established TS fuzzy modeling and MPC combined with a GWO metaheuristic tuning policy is proposed to manage all intervening variables in WWTPs and enhancing the performance of purification in terms of BOD5, COD and TSS metrics. The uniqueness and main contributions of this work are summarized as follows: (1) A powerful and parameters-free GWO metaheuristic is proposed to adjust the many effective gains of the designed fuzzy MPC controllers and consequently boost the carbon pollution removal in WWTPs. (2) The enhancement of overall purification variables is aimed and the commonly used BOD5, COD and TSS indices are considered to quantify the carbon removal efficiency. (3) Performance is evaluated in terms of reproducibility, algorithmic convergence, and solution quality. (4) Comparisons to the most commonly used state-of-the-art algorithms, i.e. PSO and GA optimizers, as well as the PDC technique are performed. (5) An ANOVA based on Friedman ranking and post-hoc tests is carried out.

The rest of the paper is organized as follows. Section II presents the modeling part as well as a preliminary survey on the nonlinear ASP model for carbon removal, along with its equivalent TS fuzzy representation and the MPC strategy. The main indices and measures for quantifying carbon removal efficiency, namely BOD5, COD and TSS, are also provided. In Section III, the MPC gains tuning problem is introduced and formulated as an optimization problem under operational constraints. The proposed parameters-free GWO algorithm is presented in Section IV. Section V provides demonstrative results and discussions to assess the effectiveness of the proposed GWO-based approach in enhancing carbon removal in WWTPs. Finally, Section VI concludes the paper.

II. Modeling and Preliminaries

A. Activated Sludge Process

As shown in Fig. 1, a typical architecture of ASP consists of a bioreactor, a decanter/clarifier, and a sludge recycling pipe [8]. The wastewater is mixed with activated sludge in the bioreactor, where dissolved oxygen is supplied to support the growth of microorganisms that degrade organic pollutants. Following the aeration phase, the mixture flows into the decanter, where the sludge settles to the bottom, allowing the clarified water to rise to the top. The treated water is then separated for further processing or discharge, while a portion of the settled sludge is recycled back into the bioreactor via the sludge recycling pipe, maintaining the optimal concentration of microorganisms for continuous treatment.

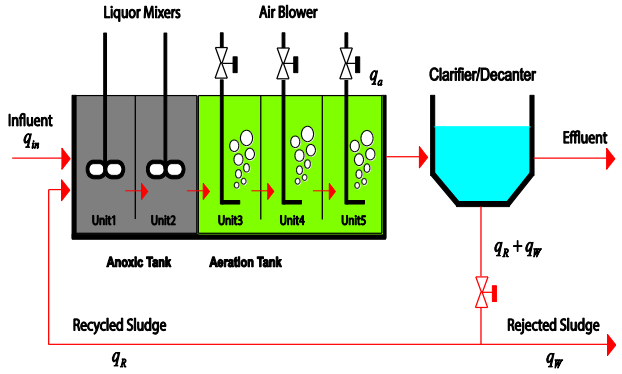

Fig. 1. Layout of an activated sludge treatment procedure.

Focusing on the carbon removal, a reduced dynamic model based on the commonly used Activated Sludge Model N°.1 is retained to describe all the nonlinear dynamics of the plant. It is assumed that the purified water is free of particulate substances and the concentrations of soluble components are equal at inlet and outlet of the decanter:

$$\dot{V} = q_{in} + q_R - q_{out} = \kappa_V \left(V_{ref} - V\right) \tag{1a}$$

$$\dot{X}_{BH} = \frac{q_{in}}{V} X_{BH,in} - \frac{q_{in}}{V} \frac{f_W \left(1+ f_R\right)}{\left(f_R + f_W\right)} X_{BH} + \mu_H \frac{S_S}{\kappa_S + S_S} \frac{S_O}{\kappa_{OH} + S_O} X_{BH} - b_H X_{BH} \tag{1b}$$

$$\dot{S}_S = \frac{q_{in}}{V} S_{S,in} - \frac{q_{in}}{V} S_S - \frac{\mu_H}{Y_H} \frac{S_S}{\kappa_S + S_S} \frac{S_O}{\kappa_{OH} + S_O} X_{BH} + \left(1- f\right) b_H X_{BH} \tag{1c}$$

$$\dot{S}_O = -\frac{q_{in}}{V} S_O - \frac{1-Y_H}{Y_H} \mu_H \frac{S_S}{\kappa_S + S_S} \frac{S_O}{\kappa_{OH} + S_O} X_{BH} + \kappa_O q_a \left(S_{O,sat} - S_O\right) \tag{1d}$$

where κ_V is a regulation gain, V_{ref} is the volume reference, f_R and f_W are the fraction rates of recycling and extraction flows, respectively, κ_S is the half-saturation rate of substrate, κ_{OH} is the oxygen saturation rate for biomass, κ_O is the oxygen regulation gain, $S_{O,sat}$ is the saturation concentration of oxygen, b_H is the heterotrophic biomass mortality rate, μ_H is the biomass growth rate, f is the fraction of particulate products, and Y_H is the substrate/biomass conversion rate.

B. TS Fuzzy Modeling

From the nonlinear model (1) of ASP system, an equivalent quasi-LPV form can be derived as follows [30, 31]:

$$\begin{cases} \dot{\boldsymbol{X}}(t) = \boldsymbol{A}\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)\boldsymbol{X}(t) + \boldsymbol{B}\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)\boldsymbol{u}(t) \\ \boldsymbol{y}(t) = \boldsymbol{C}\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)\boldsymbol{X}(t) \end{cases} \tag{2}$$

where $\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)$ is a parameters vector of the system state variables $\boldsymbol{X} \in \mathrm{R}^n$ and control inputs $\boldsymbol{u} \in \mathrm{R}^m$, $\boldsymbol{A}\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)$ and $\boldsymbol{B}\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)$ are non-constant state-space matrices given by the following Eq. (3) and Eq. (4) expressions:

$$\boldsymbol{A}\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right) = \begin{bmatrix} -\kappa_V & 0 & 0 & 0 \\ 0 & \mu_H \frac{S_S}{\kappa_S + S_S} \frac{S_O}{\kappa_{OH} + S_O} - \frac{f_W \left(1+ f_R\right)}{\left(f_R + f_W\right)} \frac{q_{in}}{V} - b_H & 0 & 0 \\ 0 & -\frac{\mu_H}{Y_H} \frac{S_S}{\kappa_S + S_S} \frac{S_O}{\kappa_{OH} + S_O} + \left(1- f\right) b_H & -\frac{q_{in}}{V} & 0 \\ 0 & \frac{Y_H - 1}{Y_H} \mu_H \frac{S_S}{\kappa_S + S_S} \frac{S_O}{\kappa_{OH} + S_O} & 0 & -\kappa_O q_a - \frac{q_{in}}{V} \end{bmatrix} \tag{3}$$

$$\boldsymbol{B}\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)=\begin{bmatrix}0 & 0 & 0 & \kappa_V\\ \frac{q_{in}}{V} & 0 & 0 & 0\\ 0 & \frac{q_{in}}{V} & 0 & 0\\ 0 & 0 & \kappa_O S_{O,sat} & 0\end{bmatrix} \tag{4}$$

Looking at the state-space form given in Eq. (2)-(4), three non-constant terms, known as model nonlinearities, which constitute the set of TS fuzzy premise variables are expressed as follows:

$$z_1\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)=\frac{S_S\left(t\right)}{\kappa_S+S_S\left(t\right)}\frac{S_O\left(t\right)}{\kappa_{OH}+S_O\left(t\right)} \tag{5a}$$

$$z_2\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)=\frac{q_{in}\left(t\right)}{V\left(t\right)} \tag{5b}$$

$$z_3\left(\vartheta\left(\boldsymbol{X},\boldsymbol{u}\right)\right)=q_a\left(t\right) \tag{5c}$$

A global state-space TS fuzzy model of the WWTP carbon removal dynamics is therefore obtained by defuzzification of local LTI sub-models as given in Eq. (6):

$$\begin{cases}\dot{\boldsymbol{X}}\left(t\right)=\sum_{i=1}^{r}\mu_i\left(\boldsymbol{z}\left(t\right)\right)\left\{\boldsymbol{A}_i\boldsymbol{X}\left(t\right)+\boldsymbol{B}_i\boldsymbol{u}\left(t\right)\right\}\\ \boldsymbol{y}\left(t\right)=\sum_{i=1}^{r}\mu_i\left(\boldsymbol{z}\left(t\right)\right)\boldsymbol{C}_i\boldsymbol{X}\left(t\right)\end{cases} \tag{6}$$

where $\boldsymbol{X}\in\mathrm{R}^4$, $\boldsymbol{u}\in\mathrm{R}^4$ and $\boldsymbol{y}\in\mathrm{R}^4$ are the system state, input and output vectors, respectively, $\boldsymbol{A}_i\in\mathrm{R}^{4\times4}$ and $\boldsymbol{B}_i\in\mathrm{R}^{4\times4}$ denote the constant state-space matrices, $\boldsymbol{z}=\left(z_1,z_2,z_3\right)\in\mathrm{R}^3$ is the vector of premise variables, $\mu_i\left(.\right)\geq0$ is the i[th] activation function, and $r=2^3=8$ is the number of local sub-models.

The convex polytopic transformation of premise variables of Eq. (5) yields the following expression of all fuzzy activation functions:

$$\begin{aligned}&\mu_1\left(\boldsymbol{z}\left(t\right)\right)=F_1^1\left(z_1\left(t\right)\right)F_1^2\left(z_2\left(t\right)\right)F_1^3\left(z_3\left(t\right)\right);\mu_2\left(\boldsymbol{z}\left(t\right)\right)=F_1^1\left(z_1\left(t\right)\right)F_1^2\left(z_2\left(t\right)\right)F_2^3\left(z_3\left(t\right)\right)\\ &\mu_3\left(\boldsymbol{z}\left(t\right)\right)=F_1^1\left(z_1\left(t\right)\right)F_2^2\left(z_2\left(t\right)\right)F_1^3\left(z_3\left(t\right)\right);\mu_4\left(\boldsymbol{z}\left(t\right)\right)=F_1^1\left(z_1\left(t\right)\right)F_2^2\left(z_2\left(t\right)\right)F_2^3\left(z_3\left(t\right)\right)\\ &\mu_5\left(\boldsymbol{z}\left(t\right)\right)=F_2^1\left(z_1\left(t\right)\right)F_1^2\left(z_2\left(t\right)\right)F_1^3\left(z_3\left(t\right)\right);\mu_6\left(\boldsymbol{z}\left(t\right)\right)=F_2^1\left(z_1\left(t\right)\right)F_1^2\left(z_2\left(t\right)\right)F_2^3\left(z_3\left(t\right)\right)\\ &\mu_7\left(\boldsymbol{z}\left(t\right)\right)=F_2^1\left(z_1\left(t\right)\right)F_2^2\left(z_2\left(t\right)\right)F_1^3\left(z_3\left(t\right)\right);\mu_8\left(\boldsymbol{z}\left(t\right)\right)=F_2^1\left(z_1\left(t\right)\right)F_2^2\left(z_2\left(t\right)\right)F_2^3\left(z_3\left(t\right)\right)\end{aligned} \tag{7}$$

where $F_{1,2}^{j}\left(.\right)$ denote the convex partition terms expressed as function of upper and lower bounds of the premise variables $\overline{z}_j$ and $\underline{z}_j$, respectively:

$$F_1^j\left(z_j\right)=\frac{z_j-\underline{z}_j}{\overline{z}_j-\underline{z}_j},\ F_2^j\left(z_j\right)=\frac{\overline{z}_j-z_j}{\overline{z}_j-\underline{z}_j} \tag{8}$$

where $\overline{z}_j=\max_{\boldsymbol{X},\boldsymbol{u}}\left\{z_j\right\}$ and , $\underline{z}_j=\min_{\boldsymbol{X},\boldsymbol{u}}\left\{z_j\right\}$ are the upper and lower bounds of premise variables, respectively.

A complete TS fuzzy model as given in Eq. (6) is therefore established by computing the constant state-space matrices (3)-(4) with all possible combinations of the bounds of premise variables (5) and activation functions (7). On the other hand, the validity of the established TS fuzzy model is evaluated using the well-known Variance Accounted For (VAF %) metric defined as follows [15]:

$$VAF_i=\left(\frac{1-\mathrm{var}\left(y_i-\hat{y}_i\right)}{\mathrm{var}\left(y_i\right)}\right)100\,\% \tag{9}$$

where y_i and $\hat{y}_i$ are the outputs of the nonlinear and TS fuzzy models, respectively, $\mathrm{var}\left(.\right)$ is the mathematical variance function, $i\in\left\{V,X_{BH},S_S,S_O\right\}$.

C. Model Predictive Control Design

To achieve an efficient carbon pollution removal in the WWTP, a fuzzy Model Predictive Control (MPC) approach is proposed. The principle aims to compute a sequence of TS fuzzy local control laws where only the first element is applied to the process [32, 33]. Such a control sequence is updated at each sampling time to minimize the following quadratic cost function:

$$J\left(t\right)=\sum_{l=1}^{N_p}e^T\left(t+l\mid t\right)\boldsymbol{Q}e\left(t+l\mid t\right)+\sum_{l=0}^{N_c-1}\left[\Delta u^T\left(t+l\mid t\right)\boldsymbol{R}\Delta u\left(t+l\mid t\right)\right] \tag{10}$$

where $N_p \in \mathrm{N}$ and $N_c \in \mathrm{N}$ are the prediction and control horizons, respectively, $\boldsymbol{Q} = \boldsymbol{Q}^T > 0$ and $\boldsymbol{R} = \boldsymbol{R}^T > 0$ are the weighting matrices, $e(t+l \mid t)$ is the tracking error between the desired and predicted system outputs.

Based on the established TS fuzzy representation (6) of the WWTP carbon removal model, a distributed MPC strategy is proposed. The local predictive controllers are designed using the same fuzzy sets and activation functions as those in the TS fuzzy model. The defuzzification of the overall MPC laws is then performed and applied to the nonlinear model (1) of the studied WWTP.

III. Optimization Problem Formulation

The removal of organic carbon is a crucial step to ensure the effluent water quality and compliance with environmental regulations. Three primary metrics are commonly used to evaluate and measure the efficiency of carbon removal in wastewater: Chemical Oxygen Demand (COD), Biochemical Oxygen Demand over five days (BOD5), and Total Suspended Solids (TSS). Each of these metrics serves as an indicator of organic material and pollutants in the water, providing essential information about the performance of the treatment process. These quality indicators are quantified using the ASP's purification variables such as biodegradable substrate (S_S), particulate inert organic matter (X_I), slowly biodegradable substrate (X_S), active heterotrophic biomass (X_{BH}), active autotrophic biomass (X_{BA}), and particulate byproducts from biomass decay (X_P).

For both the influent and effluent, the calculation of these performance metrics is performed using the following formula [8]:

$$COD = \left(S_S + X_S + X_I + X_{BH} + X_{BA} + X_P\right) \tag{11}$$

$$BOD_5 = 0.25\left(S_S + X_S + (1-f)\left(X_{BH} + X_{BA}\right)\right) \tag{12}$$

$$TSS = 0.75\left(X_S + X_I + X_{BH} + X_{BA} + X_P\right) \tag{13}$$

The closed-loop performance of WWTPs in terms of COD, BOD5 and TSS metrics is clearly dependent on the appropriate choice of MPC design parameters controlling the purification variables. Up to now, no efficient tuning technique exists to select optimal MPC parameters, i.e. weighting coefficients $\lambda \in \mathrm{R}_+$ and horizons $\left(N_p, N_c\right) \in \mathrm{N} \times \mathrm{N}$, under complex and time-varying operational conditions. The selection of optimal values for these gains is often done by time-consuming and tedious trials-errors based procedures. The hardness of such a tuning problem increases further with the complexity and dimensionality of the system. To overcome this hard challenge, the idea to formulate such a tuning task as an optimization problem is proposed as follows:

$$\begin{cases} \underset{\boldsymbol{W} \in \boldsymbol{D}^{\,d} \subseteq \mathrm{R}^d}{\text{Minimize}}\ f\left(\boldsymbol{W}\right) \\ \text{subject to:} \\ g_j\left(\boldsymbol{W}\right) = 0;\ \forall j = 1,\ldots,n_{con-eq} \\ h_j\left(\boldsymbol{W}\right) \le 0;\ \forall j = 1,\ldots,n_{con-ineq} \end{cases} \tag{14}$$

where $\boldsymbol{D}^{\,d} = \left\{\boldsymbol{W} \in \mathrm{R}^d; \boldsymbol{W}_{low} \le \boldsymbol{W} \le \boldsymbol{W}_{up}\right\}$ denotes the initial bounded d-dimensional search space and $\boldsymbol{W}$ is the vector of decision variables, unknowns of the problem.

Such a problem is solved to found optimal values of MPC parameters $\boldsymbol{W}_i^* = \left(N_{p,i}^*, N_{c,i}^*, \lambda_i^*\right)$. In this optimization process, the Integral of Absolute Error (IAE) and Integral of Square Error (ISE) are considered as performance criteria. An appropriate external penalty technique is proposed to handle the MPC constraints $N_c - N_p \le 0$ as follows:

$$f_{IAE,i}\left(\boldsymbol{W}\right) = \int_0^{+\infty} \left|e_i\left(\boldsymbol{W}\right)\right| dt + \exp\left(1000\,\frac{N_c - N_p}{N_p}\right) \tag{15}$$

$$f_{ISE,i}\left(\boldsymbol{W}\right) = \int_0^{+\infty} e_i^2\left(\boldsymbol{W}\right) dt + \exp\left(1000\,\frac{N_c - N_p}{N_p}\right) \tag{16}$$

where $e_i(.), \forall i \in \left\{V, X_{BH}, S_S, S_O\right\}$ denotes the tracking error between the desired set-point and system's output for each ASP dynamics.

IV. Proposed Grey Wolf Optimizer

The proposed Grey Wolf Optimization (GWO) algorithm is a parameters-free metaheuristic method inspired by the social behavior and hunting mechanism of grey wolves in nature [34]. In the social hierarchy of wolves, there is a leader known as the α-wolf, who is responsible for making decisions related to hunting, food distribution and resting areas. The β-wolves, who are at the secondary level, assist the α-wolf in decision-making. The δ-wolves, take on roles such as scouting and sentry duties. Finally, the ω-wolves occupy the lowest level in the hierarchy and are responsible for maintaining a balanced relationship within population.

In a d-dimensional search space, each wolf is characterized by its position $\boldsymbol{x}_k^i = \left(x_{k,1}^i, x_{k,2}^i, ..., x_{k,d}^i\right)$. The position of the prey is denoted as $\boldsymbol{x}_k^p = \left(x_{k,1}^p, x_{k,2}^p, ..., x_{k,d}^p\right)$. The best solution of GWO is considered as α. The second and third best ones are respectively considered as β and δ. The rest of the wolves have their positions updated randomly around the prey. Hunting process includes the following three main steps [34]:

1) Encircling: The grey wolves' encircling behavior to hunt for a prey can be expressed as follows:

$$\boldsymbol{x}_{k+1}^{i} = \boldsymbol{x}_{k}^{p} - \Delta_k \vartheta_k \tag{17}$$

$$\Delta_k = \left| \eta_k \boldsymbol{x}_{k}^{p} - \boldsymbol{x}_{k}^{i} \right| \tag{18}$$

$$\vartheta_k = 2\upsilon_k U\left(0,1\right) - \upsilon_k \tag{19}$$

where η_k is a random number between 2 and 0, υ_k is linearly decreased from 2 to 0 over the iterations courses, and $U\left(0,1\right)$ is a uniformly random number in $\left[0,1\right]$.

2) Hunting: The best candidate solutions α, β and δ wolves, have the better recognition of the prey's potential position. The top three solutions $\boldsymbol{x}_{k}^{best,1}$, $\boldsymbol{x}_{k}^{best,2}$, $\boldsymbol{x}_{k}^{best,3}$ are stored to guide the other wolves toward the prey's potential location by updating their positions as follows:

$$\boldsymbol{x}_{k+1}^{i} = \frac{\boldsymbol{x}_{k}^{best,1} + \boldsymbol{x}_{k}^{best,2} + \boldsymbol{x}_{k}^{best,3}}{3} \tag{20}$$

where $\boldsymbol{x}_{k}^{best,1} = \boldsymbol{x}_{k}^{\alpha} - \Delta_k^{\alpha} \vartheta_{1,k}$, $\boldsymbol{x}_{k}^{best,2} = \boldsymbol{x}_{k}^{\beta} - \Delta_k^{\beta} \vartheta_{2,k}$, $\boldsymbol{x}_{k}^{best,3} = \boldsymbol{x}_{k}^{\delta} - \Delta_k^{\delta} \vartheta_{3,k}$, the coefficients vectors $\vartheta_{1,k}$, $\vartheta_{2,k}$ and $\vartheta_{3,k}$ as well as Δ_k^{α}, Δ_k^{β} and Δ_k^{δ} are computed as follows:

$$\begin{cases} \vartheta_{1,k} = 2\upsilon_{1,k} U\left(0,1\right) - \upsilon_{1,k}, \vartheta_{2,k} = 2\upsilon_{2,k} U\left(0,1\right) - \upsilon_{2,k} \\ \vartheta_{3,k} = 2\upsilon_{3,k} U\left(0,1\right) - \upsilon_{3,k}, \Delta_k^{\alpha} = \left| \eta_{1,k} \boldsymbol{x}_{k}^{\alpha} - \boldsymbol{x}_{k}^{i} \right| \\ \Delta_k^{\beta} = \left| \eta_{2,k} \boldsymbol{x}_{k}^{\beta} - \boldsymbol{x}_{k}^{i} \right|, \Delta_k^{\delta} = \left| \eta_{3,k} \boldsymbol{x}_{k}^{\delta} - \boldsymbol{x}_{k}^{i} \right| \end{cases} \tag{21}$$

3) Attacking: Grey wolves finish the hunting process by attacking the prey until it stops moving. In order to model the attacking process, the value of υ_k is linearly decreased from 2 to 0 over iterations and involves the reduction of the fluctuation rate of ϑ_k which is a random value in the range $\left[-2\upsilon_k, 2\upsilon_k\right]$.

A pseudo-code for the proposed GWO algorithm is given in Algorithm 1 [35, 36].

Algorithm 1: Grey Wolf Optimizer

Randomly initialize the grey wolves' population.

Initialize $\vartheta_{j,0}$, $\upsilon_{j,0}$ and $\eta_{j,0}^{i}$.

Evaluate the objective function for each search agent and select $\boldsymbol{x}_0^{\alpha}$, $\boldsymbol{x}_0^{\beta}$ and $\boldsymbol{x}_0^{\delta}$.

Update the position of the current search agent.

Update $\vartheta_{j,k}$, $\upsilon_{j,k}$ and $\eta_{j,k}^{i}$.

Evaluate the objective values of all GWO search agents.

Update the positions $\boldsymbol{x}_k^{\alpha}$, $\boldsymbol{x}_k^{\beta}$ and $\boldsymbol{x}_k^{\delta}$.

Check the termination criterion and repeat iterations.

V. Simulation Results and Discussion

A. Numerical Experimentations

In this study, the most commonly used state-of-the-art metaheuristics, such as Genetic Algorithm (GA) [37] and Particle Swarm Optimizer (PSO) [38] are considered for the performance evaluation and comparison. All competing metaheuristics are independently executed on an AMD Ryzen 5 CPU, 3.3 GHz, and 8.0 GB of RAM. Population cardinality of $n_{pop} = 100$ and maximum iterations of $n_{iter} = 500$ are set. Specific control parameters of GA and PSO algorithms are given as follows:

- GWO [35, 36]: parameters-free algorithm.
- GA [37]: mutation rate 0.02, crossover probability 1.
- PSO [38]: inertial factor 1, coefficients of cognitive and social accelerations 1.5 and 2, respectively.

Numerical parameters of the WWTP system are derived from literatures [8]. All reported algorithms are independently executed 10 runs. Results are summarized in Table I, Table II and Table III where STD and ET metrics denote the standard deviation and elapsed time, respectively. Convergence histories and data distribution for the metaheuristics optimization are depicted in Fig. 2 and Fig. 3, respectively.

For the IAE and ISE criteria, demonstrative results in Fig. 2 show the convergence behaviors of the reported algorithms to solve problem (14)-(16) and highlight the exploration-exploitation capabilities of each of the compared algorithms. Based on these curves, the superiority of GWO algorithm is clearly observed in terms of convergence fastness, quality of the obtained solution and the balance between global and local search capabilities. Indeed, a better exploration of the search space is shown at the first iterations of the optimization process where the GWO optimizer ensures more significant transitions between the evaluated cost function values compared to those of the reported GA and PSO ones. During last iterations, better exploitation of promising neighboring regions likely to contain the global optimum of the considered WWTPs carbon removal problem is guaranteed for the GWO solver.

The Box-and-Whisker plots of Fig. 3 display the statistical data distribution through their quartiles for the optimization results over 10 independent runs of problem (14)-(16). Tighter and symmetrical shapes are obtained for the GWO algorithm, thus showing the high performance of search reproducibility leading to minimal values of standard deviations STD, both for the ISE and IAE criteria.

All these findings from measures of Tables I to Table III as well as curves of Fig. 2 and Fig. 3 confirm the outperforming of the GWO algorithm, as a parameters-free metaheuristic, followed by the reported PSO and GA with less competitive performance and tedious process for tuning of the main control algorithmic parameters.

B. *ANOVA Tests and Comparison*

Performance assessment of the metaheuristics is a crucial stage in any optimization. Various studies have been addressed for comparisons and statistical analyses of this category of algorithms [39, 40]. In this study, ANOVA tests, mainly in the form of Friedman ranking and paired comparison Fisher's LSD post-hoc test, are carried out and analyzed.

Considering the performance criteria IAE and ISE of (15) and (16), a statistical comparison based on Friedman ranking and Fisher's LSD post-hoc test is performed according to the cost functions values of 10 independent executions [41, 42]. The optimization scores-based ranking of the reported GA, PSO and GWO algorithms is performed in the sense of Friedman. For the 03 reported algorithms and 10 executions, the Friedman test leads to the computed statistics $\chi^2_{F1} = 128$ and $\chi^2_{F2} = 146$ for IAE and ISE criteria, respectively. Based on the chi-square distribution, the critical value with two degrees of freedom and 95% level of confidence is equal to $\chi^2_{2,0.95} = 62 < \chi^2_{F2} < \chi^2_{F1}$. The null hypothesis is rejected and there are significant differences between performances of the proposed optimization metaheuristics. To further explore these differences, Fisher's LSD post-hoc test is applied to determine which algorithms differ from each other. When the absolute difference of the ranks' sum of two algorithms exceeds a critical value, they are considered significantly different. Based on the statistical formula in [41, 42], the critical value is 4.9047 for the IAE criterion and 4.2476 for the ISE one. Paired comparisons are summarized in Tables IV and V where the underlined values highlight significant differences between the reported algorithms. From this ANOVA, one can conclude that the GA algorithm performs the worst according to both the IAE and ISE criteria and the GWO is the best, outperforming each one of the other algorithms.

C. Carbon Removal Performance

To assess the effectiveness of the established TS fuzzy model, numerical simulations are firstly performed to represent and compare the time-domain responses of the modeled ASP dynamics, including the effluent volume and the concentrations of heterotrophic biomass, biodegradable substrate, and dissolved oxygen. Randomized input profiles are applied over a simulation horizon of 60 hours as shown in Fig. 4. The transient responses comparing the initial nonlinear model of ASP with the established TS fuzzy one are compared based on the VAF (%) metric of (9) as shown in Fig. 5. Input profiles in Fig. 4 are randomly distributed over a horizon with several transitions to well excite all dynamics. The curves of Fig. 5 quantifying the difference between time-domain responses of the system highlight the close similarity when considering its nonlinear model and its equivalent TS fuzzy model. High VAF (%) measures are achieved for all modeled ASP's dynamics with values exceeding 99% for the biomass and biodegradable substrate concentrations, and ranging from 82% to 97% for the dissolved oxygen one. The ability of TS fuzzy modeling to mimic the nonlinear dynamic behavior of the carbon removal process is guaranteed. The established TS fuzzy structure thus accurately replicates the nonlinear dynamics of the initial ASP system (1) and such a linear and time-variant (LTI) structure can be easily considered for control design purposes.

The proposed GWO-tuned MPC strategy is applied on the nonlinear model (1) of the activated sludge process over a simulation horizon of 100 hours. The time-domain responses of the control approach are illustrated and compared with those of PDC-based one as shown in Fig. 6 to Fig. 9. Curves illustrate the closed-loop performance of the controlled carbon removal variables in terms of set-point accuracy, fastness and damping of transient responses. More superior performance for effluent volume, biodegradable substrate, heterotrophic biomass and dissolved oxygen concentrations are guaranteed in comparison with the PDC-based control case [15].

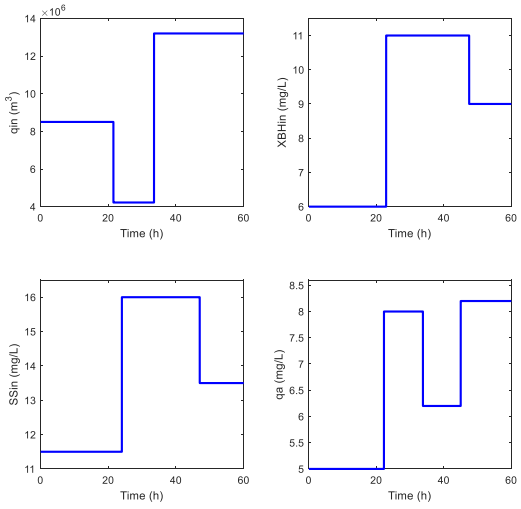

Fig. 4. Evolution of input profiles: influent flow, heterotrophic biomass and biodegradable substrate concentrations, and air flow in the bioreactor.

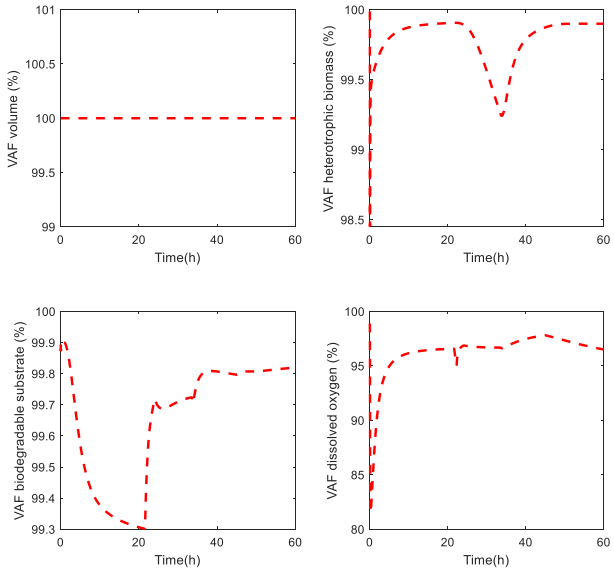

Fig. 5. VAF metrics for the TS fuzzy modeling process evaluation.

To evaluate the impact of the proposed GWO-optimization approach on purification efficiency and carbon removal, key performance indicators are compared between influent and effluent waters. In this assessment, variations in COD, BOD5, and TSS serve as critical metrics to determine the effectiveness of each method. These indicators must comply with regulatory standards with maximum permissible values of 30 mg/L for BOD5, 30 mg/L for TSS, and 125 mg/L for COD. Meeting these thresholds ensures that the treatment process is effective and aligned with environmental regulations, while any exceedance would indicate the need for further adjustments. For this purpose, results of Fig. 10, Fig. 11 and Fig. 12 depict the quantification of pollution removal efficiency.

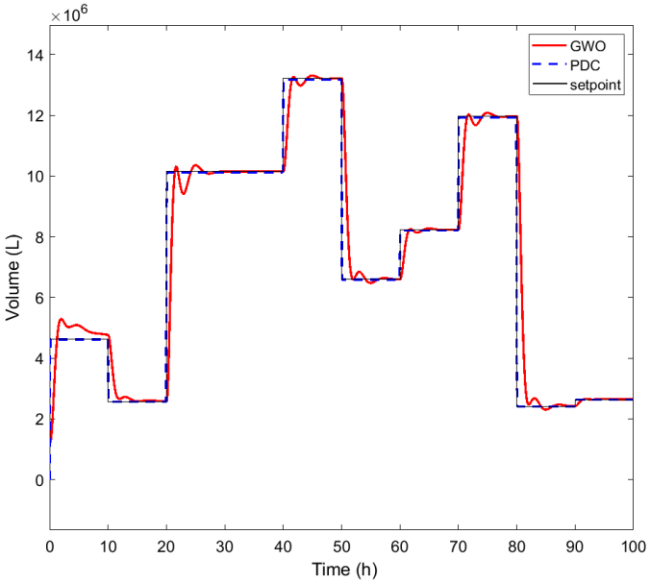

Fig. 6. Step-responses of the effluent's volume dynamics.

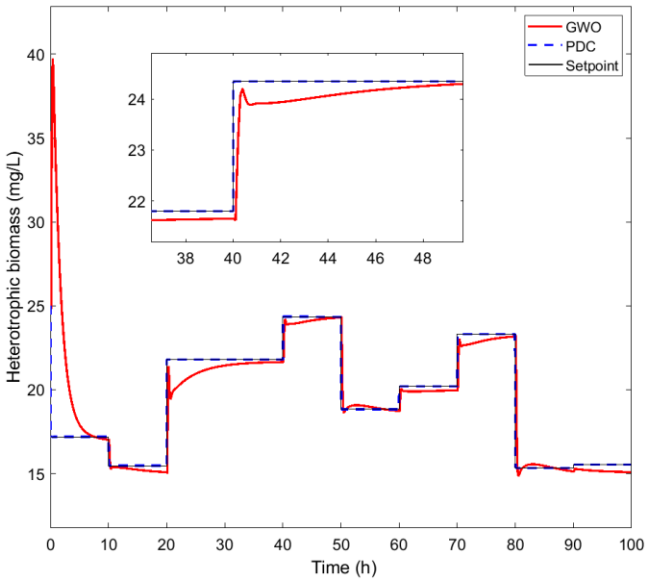

Fig. 7. Step-responses of the heterotrophic biomass concentration dynamics.

For the IAE criterion, results of Fig. 10 show that the COD removal efficiency reaches 89.9% for GA, 91.1% for PSO, and 93.9% for GWO. Similarly, the BOD5 elimination is recorded at 90.8% for GA, 92.0% for PSO, and 93.4% for GWO as shown in Fig. 11. Regarding the TSS removal of Fig. 12, GA achieves 91.6%, PSO attains 92.2%, and GWO remains the most effective with 94.1%, thus highlighting its superior performance. For the ISE case, the COD elimination rates are about 89.7% for GA, 90.7% for PSO, and 93.4% for GWO. Likewise, for the BOD5 removal, GA achieves 89.2%, PSO attains 91.1%, and GWO outperforms both with 92.8%. Lastly, for the TSS removal, GA reaches 90.6%, PSO achieves 91.8%, and GWO leads with 93.3%. For the compared PDC technique, removal efficiencies are 90.7% for COD, 90.5% for BOD5, and 91.8% for TSS remaining lower than those of the GWO-based removal case.

D. Discussion

In this study, research findings can be summarized into three main points: numerical experimentations of optimization process, GWO-based MPC control of ASP pollutant dynamics, and quantification of carbon removal efficiency through COD, BOD5 and TSS performance metrics.

For numerical experimentations, obtained results of Table I to Table II as well as those of Fig. 2 and Fig3, show that the proposed GWO algorithm demonstrates better convergence capabilities for both the IAE and ISE criteria, confirming its efficiency in balancing the exploration and exploitation capabilities. These demonstrative results indicate that the GWO outperforms the other compared GA and PSO algorithms due to its ability to thoroughly explore the search space in the early iterations before gradually shifting to effective exploitation to refine the best solutions. This well-controlled combination enables GWO to avoid premature convergence and reach the lowest cost values efficiently. Moreover, GWO stands out for its high convergence speed, allowing it to achieve optimal solutions faster than the other algorithms. The PSO solver also performs well, maintaining a good balance between exploration and exploitation, though it is slightly less effective than GWO in fine-tuning solutions in the later stages. The GA algorithm exhibits weaker performance due to premature convergence, as it stabilizes too early and struggles to escape local optima, preventing it from reaching optimal solutions. All these findings confirm the superiority of the suggested GWO solver as parameters-free and most efficient algorithm, followed by PSO, while the GA optimizer remains the least effective due to its limited exploration and early stagnation.

Based on results of Fig. 4 and Fig. 5, one can observe that the established TS fuzzy model is valid in terms of nonlinear dynamical behavior reproduction. Time-domain responses of the modeled carbon removal variables are close since using the initial nonlinear model (1) and the TS fuzzy one (6). This demonstrates the capability of the TS fuzzy representation approach in capturing the nonlinear characteristics of the initial ASP plant. From these results, it is evident that the proposed

TS fuzzy model accurately replicates the dynamic behavior of the initial nonlinear ASP system. Based on this obtained state-space LTI representation, results on the MPC control design are carried out and compared with those of the classical PDC approach. Such a comparison clearly highlights the superiority of the TS fuzzy MPC design traduced by the high set-point tracking performance in terms of accuracy, fastness and damping. These competing performances are clearly evident to boost the carbon pollution removal in maintaining the controlled ASP dynamics around predefined set-point values. The controlled WWTP system exhibits precision, fastness and well-damping of the transient responses for the effluent volume, as well as for the concentrations of heterotrophic biomass, biodegradable substrate, and dissolved oxygen. This proposed metaheuristics-based control strategy ensures a high level of input profiles tracking, though further improvements could be considered, particularly for the biodegradable substrate concentration dynamics. For the other variables, i.e., effluent volume, biomass concentration, and dissolved oxygen concentration, the GWO-tuned MPC strategy demonstrates effective tracking, achieving convergence with minimal steady-state error and no significant overshoot. These closed-loop time-domain results highlight the effectiveness of the proposed approach, making it a highly promising solution for wastewater treatment control.

Finally, can observe that the defined regulatory standards of COD, BOD5 and TSS for effluent water quality are effectively met, demonstrating the efficiency of all proposed optimization approaches, also in comparison with the most commonly used PDC-based technique for carbon pollution removal. All these results demonstrate that while all optimization approaches ensure compliance with environmental standards, the GWO optimizer systematically achieves the highest pollutant removal rates, making it the most effective strategy for enhancing the carbon removal in wastewater treatment.

VI. Conclusion

In this paper, an advanced and intelligent carbon pollution removal strategy has been proposed for an activated sludge process of wastewater treatment plants. The proposed pollution removal algorithm combined the concepts of Takagi-Sugeno fuzzy modeling, predictive control MPC and parameters-free GWO metaheuristics to boost the carbon elimination in terms of standard COD, BOD5 and TSS metrics. The performance of GWO algorithm, having the advantage of not requiring tuning parameters unlike other metaheuristics, outperformed the compared homologous solvers GA and PSO, as well as the PDC technique. The MPC-based carbon removal problem, which involves selecting the optimal prediction and control horizons as well as the weighting coefficients, has been formulated as an optimization problem with constraints and efficiently solved using the proposed GWO algorithm. The obtained results, supported by comparisons and nonparametric statistical analyses using ANOVA Friedman ranking and post-hoc tests, confirmed the effectiveness and robustness of the proposed water pollution removal strategy. Key wastewater treatment performance metrics, including COD, BOD5, and TSS, have been used to evaluate the efficiency of the proposed GWO-based control methodology. The effluent quality was significantly enhanced, achieving a purification yield of 94% for COD, 93% for BOD5, and 94% for TSS removal, thereby complying with the regulatory standards established for wastewater treatment plants. The findings of this study hold promising implications for the broader scope of wastewater treatment optimization, particularly in tackling other pollutants such as nitrogen and phosphorus. They also highlight the effectiveness of GWO in addressing the complex and nonlinear dynamics of wastewater treatment systems. By optimizing nonlinear TS fuzzy MPC parameters, the proposed strategy offers improved stability, convergence, and solution quality. This work contributes to advanced control techniques for wastewater treatment, emphasizing the importance of metaheuristics algorithms in process optimization. The proposed wastewater purification algorithm combining metaheuristics optimization and fuzzy predictive control is useful for the community of WWTPs management as a comprehensive framework modeling, control and optimization for improving pollution removal efficiency.

Future research will focus on exploring multi-objective optimization to simultaneously optimize conflicting criteria, such as pollutant removal efficiency, energy consumption, and operational costs.

Big Data Privacy Protection Technology Integrating CNN and Differential Privacy

Yanfeng Liu*, Ping Li, Min Zhang, Qinggang Liu
School of Information Engineering, Shaanxi Xueqian Normal University, XI'an 710100, China

***Abstract*—To solve the difficulty of balancing privacy and availability in big data privacy protection technology, this study integrates the powerful feature extraction ability of convolutional neural network models with the efficiency of differential privacy technology in data privacy protection. An innovative privacy protection method combining gradient adaptive noise and adaptive step size control is proposed. The experiment findings denote that the research method outperforms existing advanced privacy protection technologies in terms of performance, with an average accuracy of 97.68% and a performance improvement of about 20% to 30%. In addition, for larger privacy budgets, increasing the threshold appropriately can further optimize the effectiveness of research methods. This indicates that through refined noise control and step size adjustment, not only can the privacy protection process be optimized, but also the high efficiency and accuracy of data processing can be maintained. In summary, while ensuring data utility, research methods can not only significantly reduce the risk of privacy breaches, but also optimize privacy protection mechanisms, achieving an ideal balance between protecting personal privacy and maximizing data utility. This innovative approach provides an efficient probability distribution function solution for the field of privacy protection, with the potential to promote further development of related technologies and applications.**

***Keywords*—Convolutional neural network; differential privacy; adaptive noise addition; big data; privacy protection**

I. INTRODUCTION

With the advent of the big data era, data privacy protection has become an increasingly prominent issue. Domestic and foreign researchers have also conducted multiple studies on privacy protection from an academic perspective. Among them, the Convolutional Neural Network (CNN) model has developed rapidly in recent years and made significant progress in privacy protection fields such as image and speech recognition. However, CNN models often rely on massive data during the training process, which may contain sensitive information and can easily lead attackers with different background knowledge to steal improper benefits by directly accessing raw data or indirectly inferring model parameters [1-2]. To address the risk of data privacy leakage faced by CNN models in practical applications, researchers have adopted various technical means to improve CNN models. For example, Zaimi R et al. proposed a deep learning method for detecting phishing websites using a CNN model to address the network threats posed by phishing attacks. The experiment findings indicated that one-dimensional CNN performed well in phishing detection, with an accuracy rate of up to 96.76% [3]. However, this method mainly targets specific types of attacks and does not address the data privacy leakage problem commonly faced by CNN models during the training. Kou X et al. proposed a privacy protection scheme using edge detection technology and CNN model to address the issue of image data leakage, to find a balance between protecting user privacy and ensuring data availability. The outcomes denoted that using edge detection technology for noise addition and feature processing could effectively prevent the leakage of sensitive information in images without sacrificing their practicality [4]. However, this scheme is only applicable to image data and does not consider the privacy protection needs of the model during the training process. Shi J et al. proposed a homomorphic encryption framework based on effective integer vectors to protect the privacy of users in binary CNN models. The outcomes denoted that the training accuracy of this method on the MNIST dataset reached 93.75% [5]. Although the method performs well on specific datasets, it has a large computational overhead and is difficult to scale to large-scale datasets and complex models.

Differential Privacy (DP) is another privacy protection method different from CNN models. This method mainly ensures that even in the event of a data breach, it is impossible to trace specific personal identity information by introducing randomness into the data or algorithm, thereby protecting personal privacy from being leaked [6]. The core of this method is to inject noise into the dataset, reduce the impact of a single data record on the analysis results, and maintain the security of personal information [7]. At present, DP technology has been widely applied in big data environments, especially in data processing and analysis on cloud platforms [8]. For example, the US Census Bureau adopted DP technology to process data in the 2020 census to ensure that personal privacy will not be disclosed while providing statistical information [9]. However, the traditional DP technique has limitations in privacy budget allocation and noise addition mechanism, which can easily lead to data utility degradation and model performance loss. To reduce the risk of supply chain related data information leakage caused by traditional DP technology, Liu M et al. introduced the relevant DP mechanism of logistic regression model and proposed a new supply chain feature selection scheme. Experiments showed that this scheme not only effectively protected the privacy of supply chain data, but also improved data utilization efficiency and enhances prediction accuracy [10]. However, the method is mainly applicable to structured data, and it is difficult to be directly applied to unstructured data (e.g., images, text, etc.). Ma T et al. proposed a DP mechanism for publishing synthetic trajectory database data to enhance the utility of published trajectory data while protecting privacy. The outcomes denoted that this method outperformed other feature-based trajectory synthesis methods in terms of data utility,

achieving a balance between privacy and utility under strict privacy protection [11]. However, the adaptability and robustness of the method in dynamic data environments still need to be further verified.

In summary, although CNN models and DP techniques have made some progress in various privacy protection domains, there are still the following knowledge gaps: (1) Existing methods are inadequate in balancing privacy protection and data availability, and it is difficult to satisfy the needs of high privacy protection strength and high data utility at the same time; (2) The traditional DP techniques lack flexibility in privacy budget allocation and noise addition mechanism, which can easily lead to model performance degradation; (3) Existing schemes mostly target specific data types or attack scenarios, and lack versatility and robustness; (4) In dynamic data environments and diversified attack scenarios, the adaptability and stability of the existing methods need to be improved urgently. Researchers at home and abroad have adopted various technical means, such as edge detection techniques, homomorphic encryption frameworks, and logistic regression models to optimize the CNN model and DP technology to enhance the privacy protection capability of the CNN model and DP technology. These approaches still cannot fully satisfy the needs of different users for balancing privacy and usability in the field of big data privacy protection. To address the above problems, the study intends to fill the knowledge gaps in the following aspects: firstly, a gradient adaptive noise addition model is proposed based on CNN-DP, which solves the balance between privacy protection and data availability by adaptively allocating the privacy budget and optimizing the noise addition mechanism; secondly, an adaptive step-size privacy protection model is designed based on CNN-DP, which draws on the Polyak step-size updating idea and nonlinear extension of constraints based on passive attack algorithm to solve the convergence problem of the model due to privacy protection measures; finally, the proposed method is experimentally verified for its versatility and robustness under diverse datasets and attack scenarios, providing a new solution for the field of big data privacy protection. This research is divided into three sections. The first section describes how the CNN model was improved and how the optimal design model was built, respectively, the second section is a performance test of the new model, and the last section is a summary of the article.

II. Methods and Materials

A. Construction of Gradient Adaptive Denoising Model Based on CNN-DP

During the training, CNN models mainly focus on extracting information from the overall data distribution and do not particularly pay attention to individual data items [12]. Similarly, DP technology pays more attention to the overall statistical information of data after privacy protection when processing data publishing [13]. This consistency in data processing objectives provides a solid theoretical foundation for the combination of DP technology and CNN models. In addition, the training of CNN models requires high computational and communication resources, while DP, as a lightweight algorithm, the combination of the two can achieve complementary advantages [14]. Therefore, the study integrates DP algorithm with CNN model to achieve privacy protection in big data environment. However, the loss function of CNN models will slowly decrease during the convergence, and the loss function will affect the updating of parameters, so the parameters will change in a nonlinear and non-uniform form [15-16]. Based on this characteristic, the study ensures that the protective properties of DP are not compromised by allocating privacy budget reasonably in each iteration update. At the same time, by using gradient adaptive denoising, the constraint noise size is introduced to alleviate the overfitting phenomenon that may occur during CNN training, further improving the model's generalization ability. The gradient adaptive denoising process is shown in Fig. 1.

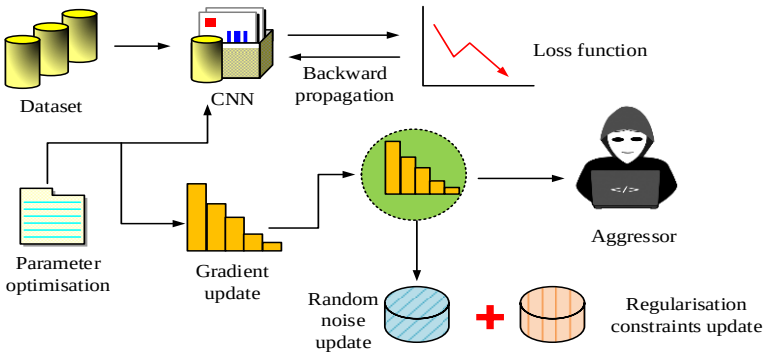

Fig. 1. Gradient adaptive noise injection process.

From Fig. 1, in the gradient adaptive denoising process, the CNN model is first trained routinely, and the input data is processed through forward propagation to calculate the loss function. Subsequently, in the backpropagation stage, the gradient of the loss function with respect to the model parameters is calculated, which reflects the degree of influence of the model parameters on the loss function. At the same time, to introduce DP protection, the study also used Laplace function to add noise to the gradient based on the budget of DP and the sensitivity of the gradient. This addition of random noise helps to protect sensitive information in the training data and prevent attackers from inferring personal information by analyzing the gradient. The gradient after adding noise is used to update the model parameters, and the parameter update rule becomes the original gradient minus the proportionally reduced noise term, where the learning rate determines the size of the step size. Through this approach, the model gradually optimizes in each iteration while ensuring privacy protection. Throughout the

process, gradient adaptive denoising ensures the continuity of model training, while L2 regularization constraints are used to prevent overfitting, enhancing the model's generalization ability and achieving effective model training while protecting privacy. The expression for calculating the L2 regularization term is shown in Eq. (1).

$$L2 = \frac{\lambda}{2n}\sum_{w}\varpi^2 \tag{1}$$

In Eq. (1), λ and n represent the regularization coefficient and sample size, respectively, while ϖ represents the weight parameter. The equation for calculating the loss function C is denoted in Eq. (2).

$$C = C_o + \frac{\lambda}{2n}\sum_{w}\varpi^2 \tag{2}$$

In Eq. (2), C_o represents the original loss function. The expression for gradient update calculation is shown in Eq. (3).

$$\varpi = \varpi - \eta(\frac{\partial C_o}{\partial \varpi} + Lap(\frac{\Delta f}{\varepsilon})) \tag{3}$$

In Eq. (3), η and Δf represent learning rate and global sensitivity, respectively, while ε represents the total privacy budget. The DP privacy protection process is shown in Fig. 2.

In Fig. 2, the core of the DP protection mechanism lies in injecting an appropriate amount of randomness into the data processing process to achieve it. Specifically, for any two adjacent datasets that differ only on one record, applying a random algorithm will result in highly similar probability distributions in their output. Even if individual records are added or deleted from the dataset, the changes in the output results are minimal, effectively reducing the risk of attackers inferring specific individual information based on algorithm outputs. This method provides strong protection for privacy information on the dataset by adding noise value constraints in data queries. The training of the CNN model is indicated in Fig. 3.

In Fig. 3, the training of the CNN model is an iterative process. Firstly, the weights in the network are randomly initialized. In each iteration, the input samples will be passed layer by layer to the network, and the neurons in each layer will multiply the received data with the weights and sum them up. Subsequently, these weighted sums are nonlinearly transformed through activation functions to generate new feature representations. This process is repeated between layers of the network until the network outputs the predicted results. Secondly, the output outcomes are compared with the true labels of the samples and the loss function is calculated. The error signal is then backpropagated back to the network, from the output layer to the input layer, for adjusting the weights of each layer to reduce future errors. By continuously repeating this process, the network weights gradually adjust until the effectiveness of the model on the training data stabilizes, that is, convergence is achieved. The entire process is a manifestation of the stochastic gradient descent algorithm, which relies on the setting of initial weights and updates them in each iteration to optimize the loss function. Due to the correlation between the privacy protection level and privacy budget of DP, this study aims to protect user privacy while ensuring the usability of CNN models as much as possible by adjusting the privacy budget size reasonably.

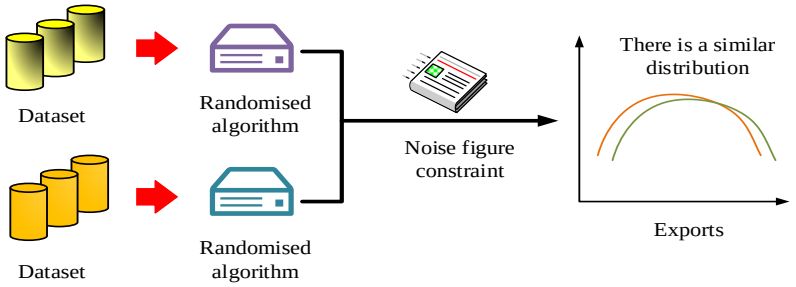

Fig. 2. DP privacy protection process.

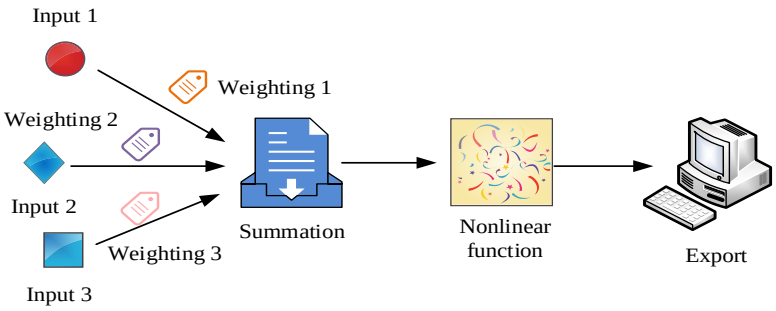

Fig. 3. The training process of the CNN model.

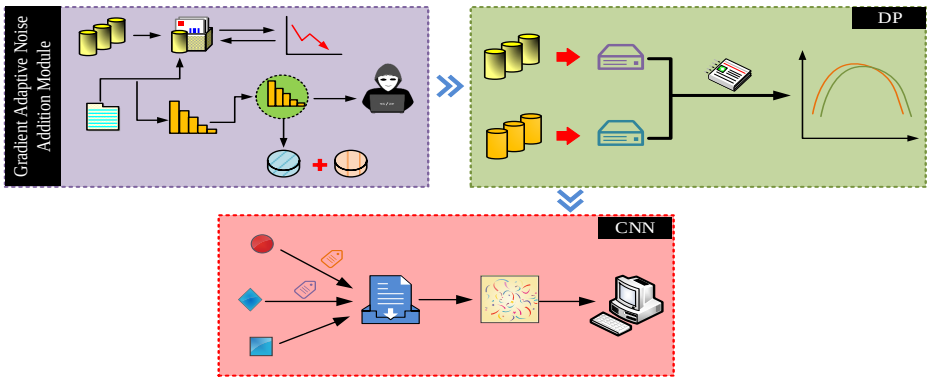

Fig. 4. Overall framework structure of CNN-DP-GAN model.

The privacy budget ε_t calculation equation for the t th iteration is shown in Eq. (4).

$$\varepsilon_t = \varepsilon_1 + (t-1)d \qquad 1 \le t \le T \tag{4}$$

In Eq. (4), ε_1 and d represent the initial privacy budget and the fixed amount of privacy budget added in each iteration, respectively, while T represents the total number of iterations. The equation for calculating the total privacy budget ε after all iterations is denoted in Eq. (5).

$$\varepsilon = T\varepsilon_1 + \frac{T(T-1)d}{2} \tag{5}$$

A CNN-DP Gradient Adaptive Noise (CNN-DP-GAN) model based on CNN-DP was proposed by studying various settings mentioned above. The overall framework structure of the model is denoted in Fig. 4.

In Fig. 4, the CNN-DP-GAN model proposed by the research mainly consists of a gradient adaptive denoising module, a DP privacy protection module, and a CNN training module. The design of this model takes into account the stochastic fine-tuning characteristics of CNN gradient during the training process, and realizes the dynamic allocation of privacy budget during the disturbance process. To prevent excessive noise interference caused by improper privacy budget settings, the model also introduces L2 regularization constraints to regulate the noise level, ensuring a balance between privacy protection and model performance.

B. Construction of an Adaptive Step Size Privacy Protection Model Based on CNN-DP-GAN

Although the CNN-DP-GAN model optimizes the perturbation process by dynamically allocating privacy budgets, effectively balancing privacy protection and data availability, the introduced noise randomness can affect the convergence performance of the model, causing parameters to oscillate when approaching the optimal solution. In addition, the setting of step size parameters is usually complex and susceptible to various factors, resulting in theoretical convergence speeds often being lower than those in practical applications [17]. Therefore, to achieve fast and stable convergence of the model, it is necessary to balance the requirements of privacy protection and the efficiency of model training. To address the convergence issues caused by privacy breaches and noise interference, the CNN-DP-GAN model was nonlinearly extended based on Polyak's step size concept and passive attack algorithm. Relaxation terms were introduced, and stable step size parameters were obtained by combining loss and gradient. By utilizing these measures, a novel adaptive step size privacy protection model based on CNN-DP-GAN was ultimately proposed, namely the CNN-DP-GAN Polyak model.

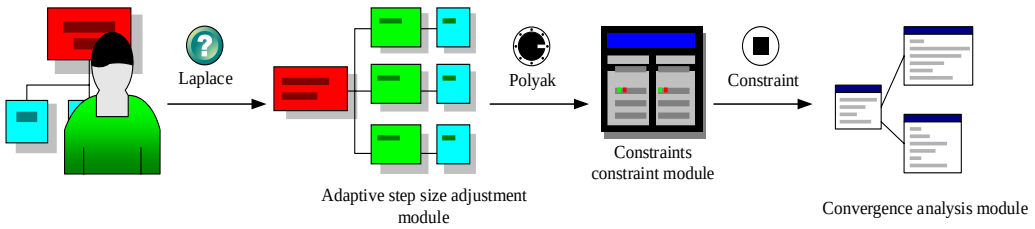

Fig. 5. Overall framework structure of CNN-DP-GAN-Polyak model.

The overall framework structure of the CNN-DP-GAN Polyak model is shown in Fig. 5.

In Fig. 5, the CNN-DP-GAN Polyak model proposed by the research mainly consists of four modules, namely DP privacy protection module, adaptive step size adjustment module, relaxation term constraint module, and convergence analysis module. Among them, the DP privacy protection module is responsible for introducing an appropriate amount of randomness during the model training process, by adding Laplace noise to the gradient or loss function to protect sensitive information in the training data. The adaptive step size adjustment module dynamically adjusts the step size parameters through the Polyak method, redefining the classification update rules for modifying weight vectors at the end of each round to adapt to real-time changes during model training. By monitoring the changes in gradient and loss

function, adaptive step size can more flexibly respond to the convergence behavior of the model, optimize the parameter update process, and improve training efficiency. At the same time, to enhance the robustness and flexibility of the model, the study also introduced relaxation terms to balance the constraints in the optimization process. This constraint helps alleviate overfitting issues and allows the model to maintain sensitivity to data features while meeting privacy protection requirements. The convergence analysis module can ensure that the model can effectively converge to the optimal solution during the iteration process. By analyzing the gradient and parameter update dynamics of the model, the convergence analysis module provides insights into the stability of model training, which helps to understand and predict the behavior of the model and make corresponding adjustments.

However, for most nonlinear models, such as CNN models, the loss function obtained from the output results is often non convex, which makes direct application of the above methods may not be suitable [18]. Therefore, the study also adopted a linearization strategy to handle the loss function, to raise the applicability and optimization efficiency of the model. The equation for calculating the adaptive step size α after linearization is shown in Eq. (6).

$$\alpha = \frac{l_i(w_i)}{\left\|\nabla l_i(w_i) + Lap(\Delta f / \varepsilon_t)\right\|^2} \tag{6}$$

In Eq. (6), $l_i(w_i)$ represents the loss function value at parameter w_i, and $\nabla l_i(w_i)$ represents the gradient of loss function l_i with respect to parameter w_i. The calculation method for the loss function $l(w)$ for classification update is shown in Eq. (7).

$$l(w) = \frac{1}{2m}(\sum_{i=1}^{m}(y^i - h_w(x^i)))^2 \tag{7}$$

In Eq. (7), y^i and $h_w(x^i)$ represent the true labels of the i th sample and the predicted output of the model, respectively, while m represents the number of samples. The calculation expression for the stochastic gradient descent process is shown in Eq. (8).

$$w_j = w_j - \alpha \frac{\partial}{\partial w_i} l(w) \tag{8}$$

In Eq. (8), w_j represents the weight vector. The calculation equation for DP protection of gradient parameters is shown in Eq. (9).

$$w_{t+1} = w_t - \alpha(\nabla l(w_t) + Lap(\frac{\Delta f}{\varepsilon_t})) \tag{9}$$

In Eq. (9), w_{t+1} and w_t represent the model parameters after the ($t+1$)th and t th iterations, respectively. The calculation expression for the parameter update process is shown in Eq. (10).

$$w^{t+1} = w^t - \frac{l_i(w^t)}{\left\|\nabla l_i(w^t) + Lap(\Delta f / \varepsilon_t)\right\|^2}(\nabla l_i(w^t) + Lap(\Delta f / \varepsilon_t)) \tag{10}$$

The expression for calculating the relaxation term constraint is shown in Eq. (11).

$$s_{t+1} = \max\left\{l_i(w_i) - \lambda\left\|\nabla l_i(w_i) + Lap(\Delta f / \varepsilon_t\right\|^2, 0\right\} \tag{11}$$

In Eq. (11), s_{t+1} represents a non-negative relaxation variable. The neural network architecture and parameters used in the training process of the CNN-DP-GAN-Polyak model are shown in Fig. 6.

In Fig. 6, the study used the classic deep learning framework to train the CNN-DP-GAN-Polyak model, ensuring the efficiency of the training process and the wide applicability of the model. At the same time, accuracy is utilized as a key indicator to assess the effectiveness of the model. By testing the model using a dataset within this framework, the relationship between model accuracy and privacy budget is analyzed.

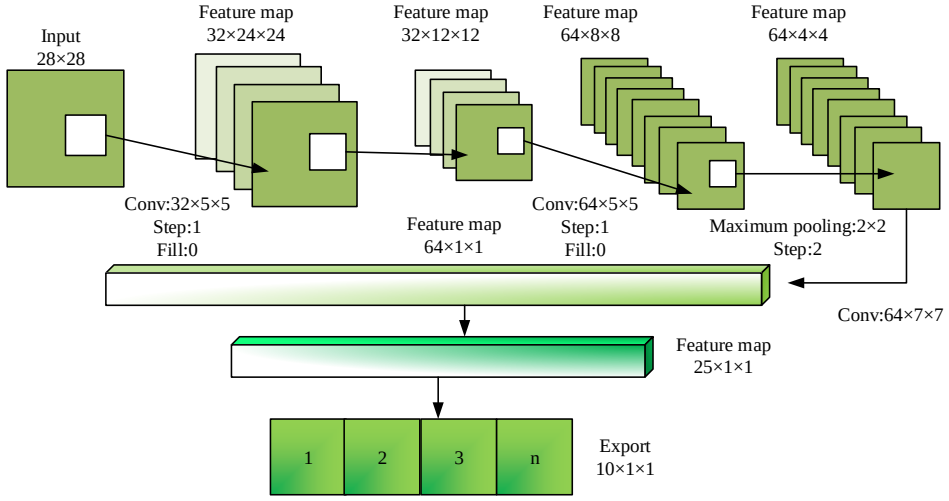

Fig. 6. Neural network architecture and parameters.

III. RESULTS

A. Performance Testing of Gradient Adaptive Denoising Model Based on CNN-DP

To validate the effectiveness of the proposed model, a suitable experimental environment was established. Windows 10 operating system was adopted, equipped with Intel Core i7 CPU, NVIDIA GeForce GPU, 64GB memory, and Python 3.7 programming. The publicly available datasets MNIST, Fashion-MNIST, and CIFAR-10 were utilized as test data sources. These datasets were divided into training and testing sets in an 8:2 ratio. Among them, the MNIST dataset was collected by the National Institute of Standards and Technology in the United States, containing approximately 70000 handwritten grayscale images with a size of 28 × 28. The Fashion-MNIST dataset was provided by a German fashion company and contains 70000 grayscale images of clothing products across 10 categories. CIFAR-10 was a color image dataset containing 10 categories of objects, with an image size of 32 × 32 and a total of 60000 images. These datasets are commonly used benchmark datasets in the fields of machine learning and computer vision, widely used for training and evaluating the effectiveness of models. In addition, parameter selection and optimization are key aspects to ensure model performance. Privacy budget is a core parameter in the DP technique to control the intensity of noise addition, where a smaller privacy budget implies stronger privacy protection but may lead to a decrease in data utility, and a larger privacy budget allows for higher data utility but less privacy protection intensity. The study employed a dynamic privacy budget allocation strategy, where the privacy budget for each iteration was calculated by Eq. (4) and Eq. (5). The noise scale determines the size of the noise added to the gradient, which directly affects the privacy-preserving strength and training stability of the model. The study set the initial and minimum values of the noise scale, and dynamically adjusted the noise size through the gradient adaptive noise addition mechanism. The initial and minimum values of the noise scale were mainly determined through experiments to ensure privacy protection while avoiding excessive noise interference with model training. The specific experimental parameter settings are denoted in Table I.

TABLE I. EXPERIMENTAL PARAMETER SETTING

Serial number	Parameters	MNIST	Fashion-MNIST	CIFAR-10
1	Sample size of batch data	250	256	1500
2	Number of model training rounds	100	100	100
3	Noise scale initial value	2	2	15
4	Noise scale minimum	0.18	0.16	0.10
5	Privacy budget	1	1	1
6	Learning rate	0.001	0.001	0.001
7	Regular term coefficient	0.5	0.5	0.5
8	Gradient trimming value	0.002	0.002	0.002

Based on the parameter settings in Table I, the study first conducted ablation tests on the gradient adaptive denoising model proposed by the research under noisy conditions, with prediction accuracy as the testing indicator. The test results are shown in Fig. 7.

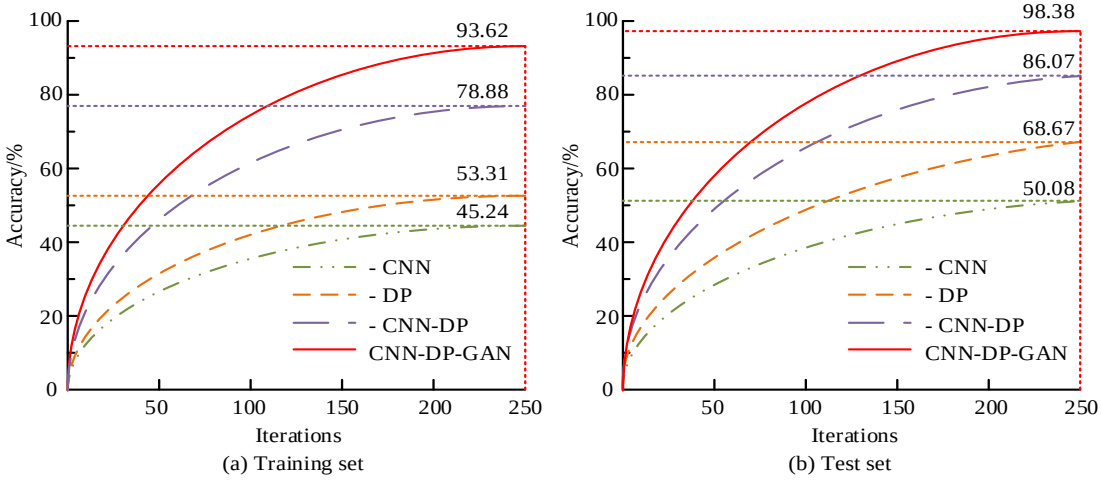

Fig. 7. The ablation test results of the CNN-DP-GAN model.

Fig. 7(a) and Fig. 7(b) show the test results of five modules in the training set and testing set. In Fig. 7(a) and Fig. 7(b), with the increase of iteration times, the prediction accuracy of the five modules showed a steady improvement trend. Among them, the performance of the CNN module was the worst, with a maximum accuracy of only 50.08%. However, when further integrating the DP module and GAN module, the performance of the model was significantly improved. The highest accuracy of the CNN-DP-GAN model reached 98.38%. The reason behind this is that the gradient adaptive denoising method can encourage the model to tend towards selecting better solutions. In this way, the model not only maintained efficient predictive ability while protecting privacy, but also reduced the risk of overfitting through regularization, thereby improving the model's generalization ability. From this, each module component proposed in the study had a positive impact on the final model, which could effectively raise the prediction accuracy of the model. The addition of reasonable noise had

little impact on the accuracy of the CNN-DP-GAN model, and the CNN-DP-GAN model could achieve a balance between privacy and utility on the basis of quantification. In addition, to verify the performance differences between the proposed model and popular models of the same type, the study also introduced the Gradient Descent with Momentum algorithm based on Differential Privacy in CNN (DPGDM), the Differential Private Stochastic Gradient Descent (DP-SGD) based on deep learning and DP, and the Centralized Differential Privacy (CDP) model. The accuracy loss rate of the model was used as the test indicator for comparative testing. The test findings are denoted in Fig. 8.

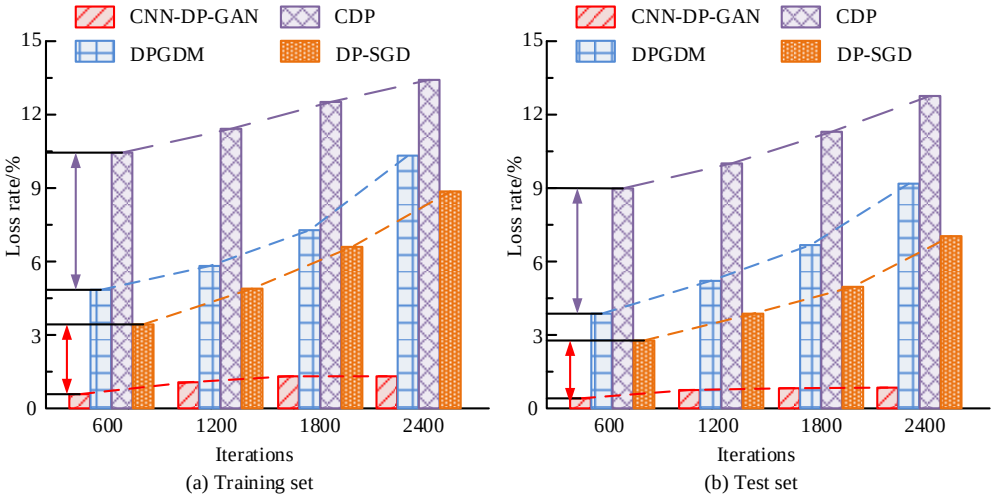

Fig. 8. Accuracy loss rate test results for different models.

Fig. 8(a) showcases the test findings of different models in the training set, and Fig. 8(b) showcases the test findings of different models in the test set. In Fig. 8(a), compared with other models, the CNN-DP-GAN model proposed by the research performed the best. At 600 iterations, the accuracy loss rates of DPGDM, DP-SGD, CDP, and CNN-DP-GAN models were 4.71%, 3.26%, 10.49%, and 1.31%, respectively. This indicated that the CNN-DP-GAN model had significant advantages in maintaining high accuracy and could effectively reduce loss rates. According to Fig. 8(b), at the same number of iterations, the accuracy loss rates of DPGDM, DP-SGD, CDP, and CNN-DP-GAN models were 4.18%, 2.96%, 9.01%, and 1.08%, respectively. These results confirmed that the gradient adaptive denoising method not only had advantages in maintaining model performance, but also continuously optimized the loss rate during the iteration process, further enhancing the privacy protection ability of the model without sacrificing accuracy excessively. This strategy provides an effective technical means for achieving efficient and accurate data processing while protecting privacy.

B. *Performance Testing of Adaptive Step Size Privacy Protection Model Based on CNN-DP-GAN*

When using Laplace mechanism for privacy protection, privacy budget and sensitivity are key factors affecting the level of privacy protection. Therefore, the research mainly focused on these two core variables and explored how to achieve the optimal balance between model privacy protection and utility. The sensitivity and privacy budget values under different iteration times are shown in Table II.

Due to the Laplace perturbation, the variance is equal to the ratio of sensitivity to privacy budget. Therefore, the study controlled the overall privacy budget to remain unchanged. According to Table II, experiments were conducted at different sensitivities to compare the average final accuracy of different models. The test results are indicated in Fig. 9.

TABLE II. SENSITIVITY AND PRIVACY BUDGET TAKES FOR DIFFERENT NUMBER OF ITERATIONS

Datasets	Parameters		Sensitivity	Total budget
MNIST	Different number of iterations	300	0.5	72.5
		600	0.5	141
		1200	0.5	279.5
Fashion-MNIST	Different number of iterations	300	0.5	143
		600	0.5	283.5
		1200	0.5	960
CIFAR-10	Different number of iterations	300	0.5	217.5
		600	0.5	312.5
		1200	0.5	687.6

Fig. 9(a) and Fig. 9(b) show the comparison curve of the average final accuracy of the models in the MNIST, and CIFAR-10 dataset, respectively. In Fig. 9(a), compared with other models, the proposed model achieved better model performance while ensuring a balance between privacy and utility. The average final accuracies of DPGDM, DP-SGD, CDP, and CNN-DP-GAN Polyak models were 70.23%, 82.36%, 86.08%, and 97.68%, respectively. In Fig. 9(b), the CNN-DP-GAN Polyak model proposed by the research performed the best, with an average final accuracy of 92.08%, which was a performance improvement of 20% to 30% compared to other models. From this, it can be seen that under the constraint of data utility, the model could effectively minimize the risk of privacy leakage and optimize the privacy protection mechanism, thereby obtaining a probability distribution function that achieves the best balance between protecting privacy and maintaining data utility. The effectiveness of the research method was proved. Finally, the study also explored the impact of different privacy budgets on the adaptive step size adjustment process. The test results are indicated in Fig. 10.

Fig. 10(a), (b), and (c) show the accuracy variation curves with threshold settings of 0.01, 0.1, and 1 at 300 iterations. From Fig. 10, in the early stages of iteration, when the privacy budget was set to 5, the adaptive step size adjustment method has not fully utilized its advantages, resulting in poor performance of the CNN-DP-GAN-Polyak model. As the iteration progressed, a smaller threshold setting could help improve the performance of the CNN-DP-GAN-Polyak model when the privacy budget was low. On the contrary, for larger privacy budgets, increasing the threshold appropriately could optimize the performance of the CNN-DP-GAN-Polyak model. This indicated that the setting of privacy budget and threshold needed to be dynamically adjusted based on iteration progress and privacy protection requirements to achieve the optimal balance between privacy protection and data utility. Through this meticulous adjustment, it was possible to maximize the predictive accuracy and practicality of the model while minimizing the risk of privacy breaches.

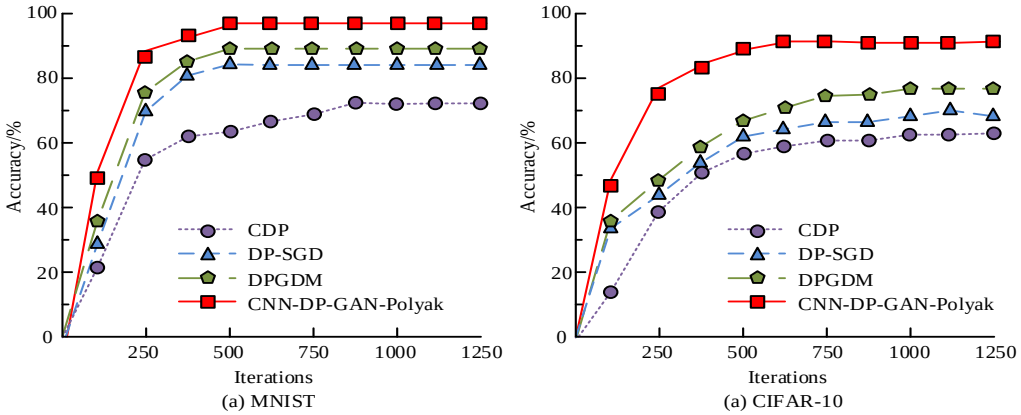

Fig. 9. Comparison curves of final accuracy averages of different models.

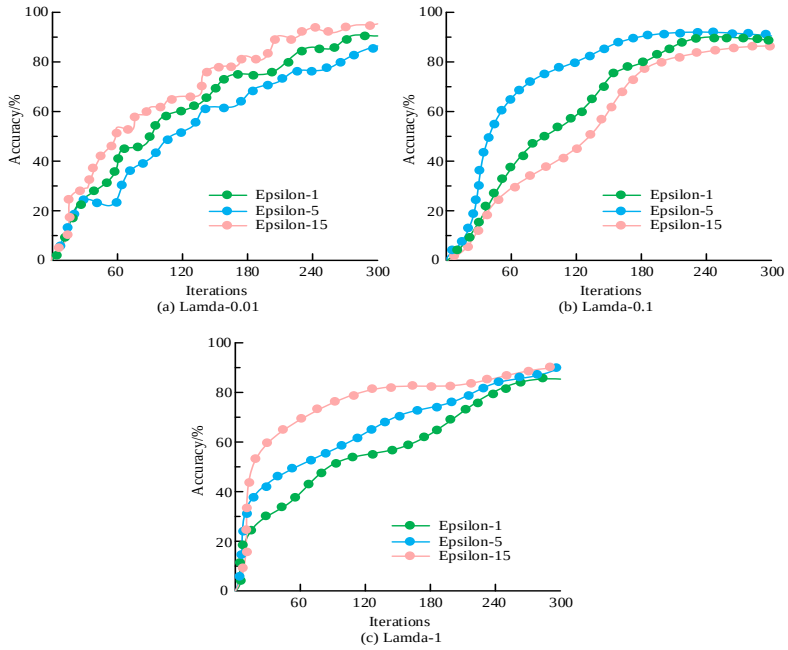

Fig. 10. Accuracy variation curves for different threshold settings.

IV. Conclusion

The rapid development of computer vision largely relies on the innovative construction of deep learning models and the participation of large-scale datasets. With the continuous advancement of technology, data privacy protection has gradually become a hot research topic. In practical application scenarios, CNN models face significant risks of data privacy breaches when handling tasks involving sensitive information. To effectively address this challenge, a novel big data privacy protection technique is proposed by combining CNN models with DP technology, utilizing gradient adaptive denoising method and adaptive step size privacy protection method. The outcomes denoted that the gradient adaptive denoising method could effectively guide the model to choose a better solution. In a noisy environment, the highest accuracy of the CNN-DP-GAN model reached 98.38%, with an accuracy loss rate of only 1.08%. In addition, compared with other advanced models, the CNN-DP-GAN-Polyak model proposed by the research performed the best, with an average final accuracy of 97.68%. As the iterative process progressed, especially with low privacy budgets, appropriate threshold settings have been shown to help improve the performance of the CNN-DP-GA-Polyak model. From this, the method proposed by the research can achieve good model performance while ensuring a balance between privacy protection and data utility. However, research mainly evaluates the performance of models in terms of privacy protection and data utility based on privacy budget and model accuracy. Future work can expand the focus to assess the ability of models to resist attackers with auxiliary background knowledge, thereby comprehensively improving the breadth and depth of model validation.

Multi-Strategy Improved Rapid Random Expansion Tree (RRT) Algorithm for Robotic Arm Path Planning

Yuan Sun, Shoujun Zhang
Shanghai DianJi University, Shanghai, China

***Abstract*—The purpose of this paper is to propose an improved RRT algorithm that incorporates multiple improvement strategies to solve the problems of low efficiency, long and unsmooth paths in the traditional rapid random expansion tree (RRT) algorithm for path planning of robotic arms. The algorithm first uses a bidirectional tree extension strategy to generate trees from both the starting point and the target position simultaneously, improving search efficiency and reducing redundant paths. Secondly, the algorithm introduces target bias sampling in combination with local Gaussian sampling, which renders the sampling points more focused on the target area, and dynamically adjusts the distribution to improve sampling efficiency and path connection speed. Concurrently, the algorithm is equipped with an adaptive step size strategy, which dynamically adjusts the expansion step size according to the target distance, thereby achieving a balance between rapid expansion over long distances and precise search at close range. Finally, a collision-free operation is ensured by a path verification mechanism, and the path is smoothed using cubic B-splines and minimum curvature optimisation techniques, significantly improving the smoothness of the path and the feasibility of the robot arm movement. As demonstrated by simulation experiments, the improved RRT algorithm exhibits a reduction in the average path length by 18.15%, planning time by 96.29%, the number of nodes by 92.13%, and the number of iterations by 91.60%, in comparison with the conventional RRT algorithm, when operating in complex map mode. These findings substantiate the efficacy and practicality of the improved RRT algorithm in the domain of robotic arm path planning.**

Keywords*—Robotic arm; RRT algorithm; path planning; target-biased sampling; Gaussian sampling; bidirectional tree extension; adaptive step-size

I. Introduction

Robotic arms have become a staple of industry in fields as diverse as medicine, aerospace, and shipbuilding. The growth of social demand, coupled with the continuous development of technology, has resulted in a gradual expansion of robotic arms into applications in narrow and complex environments. In this context, path planning emerges as a pivotal technology, instrumental in navigating through confined and intricate environments. In such environments, robotic arms often encounter difficulties in operating effectively and planning a suitable trajectory, as evidenced by numerous studies. The necessity for effective path planning in such environments is therefore paramount. The efficacy of such planning is twofold: it enables the robot arm to manoeuvre with agility and circumvent potential collisions with surrounding objects, while concomitantly enhancing work efficiency and precision. This, in turn, fulfils the higher industrial and social imperatives that are now in place.

At present, the following path planning algorithms are employed with the greatest frequency: the artificial potential field method [1][2][3], the A* algorithm [4][5][6], the ant colony algorithm [7][8][9], the genetic algorithm [10][11][12], and the rapid random expansion tree (RRT) algorithm [13][14][15]. An improved RRT* algorithm based on the traditional RRT algorithm was proposed by Karaman et al. [16]. The incorporation of graph optimisation and pruning theory enables the achievement of an asymptotically optimal path, which is both complete and optimal. However, this approach significantly increases the search time. Nasir et al. [17] proposed the RRT*-Smart algorithm, which employs heuristics to enhance node expansion capabilities and optimise the path through biased sampling. Nonetheless, this algorithm is less adaptable due to its overreliance on parameter adjustment. Wei et al. [18] proposed a smooth RRT algorithm based on the maximum curvature constraint to generate continuous executable trajectories, but because it only uses target bias expansion, it is less efficient and the path fitting deviation is large. The bidirectional RRT algorithm proposed by Kuffner et al. [19] enhances planning efficiency by growing a random tree from both the starting and end points. However, it still employs the random growth strategy and sampling method of traditional RRT, which exhibits the problem of local optimality. Additionally, it exhibits poor possibility in complex environments and narrow areas, and its efficiency requires enhancement. In their seminal work, Wu et al. [20] proposed the Fast-RRT algorithm, a pioneering advancement in the field. This algorithm employs a fast sampling strategy and a random steering expansion strategy, aiming to enhance the efficiency of finding an approximate optimal path by fusing and adjusting the path. However, it is important to note a limitation in the application of this algorithm. Specifically, its use is primarily constrained to two-dimensional environments, and its efficacy in multidimensional spaces is not well-documented.

The rapid random expansion tree (RRT) algorithm has become a significant method in the field of path planning due to its high search efficiency, wide applicability, and the fact that it does not require global modelling of the environment. However, the traditional RRT algorithm is not without its shortcomings, namely the random sampling process, which is inefficient and results in a protracted search time. Additionally, the presence of

numerous redundant nodes can compromise the quality of the path, and the ability to swiftly identify a feasible path near the target point or in areas with obstacles is also hindered. These limitations constrain the applicability of the RRT algorithm in complex environments. To address these issues, this paper proposes an improved algorithm for the traditional RRT algorithm. The proposed strategy involves the implementation of a double-tree expansion approach, which involves the simultaneous expansion of trees from both the starting point and the target point. This strategy has been shown to enhance the efficiency of path search, leading to faster connection path discovery and reduced redundant expansion. Additionally, the integration of a target bias sampling strategy enhances the probability of sampling points being in close proximity to the target area, thereby accelerating the convergence of the algorithm. Gaussian distribution sampling is introduced in the target vicinity, and the target area is searched in detail by dynamically adjusting the sampling range. The combination of Gaussian sampling and target bias improves the efficiency of path generation. An adaptive step size is introduced, which dynamically adjusts the step size according to the distance between the current node and the target point, improving the efficiency and accuracy of path planning by achieving rapid expansion over long distances and precise search near the target. A collision detection and avoidance mechanism is integrated into the path expansion process, ensuring the generated path is free of collisions, enhancing its safety and practical applicability. Finally, cubic B-splines and minimum curvature optimisation are incorporated into the generated path to enhance its smoothness, reduce sharp turns, and improve its feasibility.

The improved RRT algorithm has been shown to exhibit notable enhancements in terms of search efficiency, path quality and adaptability. These improvements render it particularly well-suited for applications in complex restricted environments, such as robotic arm path planning.

The subsequent arrangement of this paper is as follows. Section II introduces the RRT algorithm. Section III introduces and derives the improved parts of the improved RRT algorithm. Section IV simulates the RRT algorithm, the RRT* algorithm, the RRT-Connect algorithm, and the improved RRT algorithm, and compares the data obtained by the four algorithms to demonstrate the superiority and feasibility of the proposed improved RRT algorithm in path planning. Section V is the conclusion of this paper.

II. Principle of the RRT Algorithm

1) Initialise the extended tree T with a step size δ, a starting point $x_{\text{init}}$and a goal point x_{goal}. Add the starting point x_{init} to the extended tree T as a root node.

2) Create a random point x_{rand} in the robot's workspace.

3) Find the node x_{near} in the extended tree T that is closest to x_{rand}.

4) Extend from x_{near} towards x_{rand} with a step size δ to obtain a new node x_{new}.

5) Perform an obstacle collision detection on the line segment between x_{new} and x_{near}. If the detection fails (the path intersects with an obstacle), discard x_{new} and return to step 2) to start a new round of sampling. If the detection is successful, proceed to step 6).

6) Add x_{new} to the extended tree T and set x_{near} as the parent node of x_{new}.

7) Determine whether x_{new} has reached the target point x_{goal} (i.e. the distance between x_{new} and x_{goal} is less than a tolerance threshold).

If the target point is not reached, go to step 2) and continue sampling. If the target point is reached, the path planning is successful, stop the algorithm and output the path according to the extended tree T.

As shown in Fig. 1.

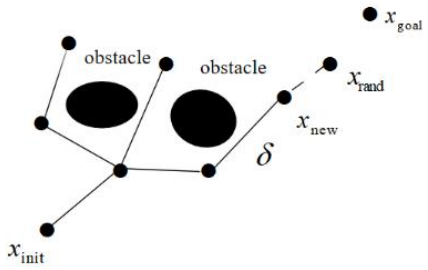

Fig. 1. Schematic diagram of RRT algorithm.

III. Improved RRT Algorithm

A. Targeted Bias Sampling

In order to enhance the efficacy of the algorithm, a target bias sampling strategy has been implemented. This strategy establishes a probability value, p_{rand}, which is distributed uniformly between 0 and 1. When generating a random sample point, x_{rand}, the method of generating the sample point is determined according to the result of comparing a random value, p, with p_{rand}. Specifically, when $p < p_{\text{rand}}$, the target point x_{goal} is directly selected as the sampling point; when $p > p_{\text{rand}}$, a random sampling point x_{rand} is generated within the search space. The specific mathematical expression of this strategy is as follows:

$$x_{\text{rand}} = \begin{cases} x_{\text{goal}}, & p < p_{\text{rand}} \\ \text{sample}, & p \geq p_{\text{rand}} \end{cases} \quad (1)$$

The term 'Sample' is used to denote a state point that has been randomly generated from the search space, whilst x_{goal} indicates a predefined goal point. The goal bias sampling strategy has been introduced with a view to increasing the sampling probability of the aforementioned goal point during the growth of the random tree, thereby accelerating the expansion of the tree towards the goal region. This strategy has been shown to significantly improve search efficiency whilst also effectively reducing the generation of invalid nodes and the number of algorithm iterations. Furthermore, the value adjusted by p_{rand} can dynamically balance the proportion of goal point bias sampling and random sampling to adapt to search environments of different complexities as shown in Fig. 2.

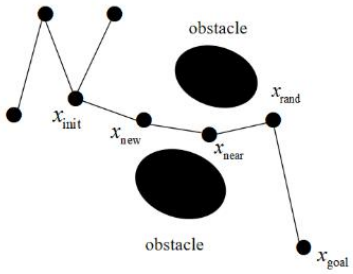

Fig. 2. Schematic diagram of the target bias strategy.

B. Local Gaussian Sampling

The principle underlying local Gaussian sampling involves the generation of sampling points through the introduction of a Gaussian distribution in proximity to the target point or other significant locations. The implementation of this method entails the random generation of points according to a Gaussian distribution, with the distribution density of the generated points being controlled by the standard deviation, σ.In instances where the target point is distant from the current point, an increase in σresults in a more dispersed distribution of sampling points, encompassing a broader area. Conversely, when the target point is proximate, a reduction in σ results in a more concentrated distribution of sampling points, thereby enhancing the local search capability. The formula for Gaussian sampling is as follows:

$$f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \tag{2}$$

μ: mean value, σ: standard deviation, x: random variable

The amalgamation of Gaussian sampling and target-biased sampling results in the generation of a high-density distribution of sampling points in close proximity to the target point, whilst preserving the randomness intrinsic to global exploration. This amalgamation offers substantial advantages in enhancing the efficiency of path planning, reducing the number of iterations and path length, and is particularly well-suited to path planning problems in complex environments.

C. Bidirectional Tree Extension

First, two random trees T_1 and T_2 are constructed, with x_{start} as the root node of T_1 for expansion and x_{goal} as the root node of T_2 for expansion. Then, random sampling generates two sampling points x_{rand1} and x_{rand2}, which are used to expand the two trees respectively. For T_1, the closest node x_{near1} to the sampling point x_{rand1} is found among its existing nodes, and a new node x_{near1} is created by expanding with a fixed step δ on the line x_{near1} pointing to x_{rand1}.

Similarly, for T_2, the closest node x_{near2} to the sampling point x_{rand2} is found and expanded at fixed steps δ on the line x_{near2} pointing to x_{rand2}, generating a new node x_{near2}.

The next step is to check if there is a collision on the connecting line between the generated new node x_{near1} and x_{near2}.

If the connecting line passes through an obstacle, the new node is discarded and re-sampled, and the last valid retained node is returned; if the connecting line is free of obstacles, x_{near1} and x_{near2} are connected to complete the connection of the two trees.Expand T_1 and T_2 alternately according to the above method until the distance between the adjacent new nodes of the two trees is less than the threshold of the step size δ. At this point, T_1 and T_2 are successfully connected and the path is generated. As shown in Fig. 3.

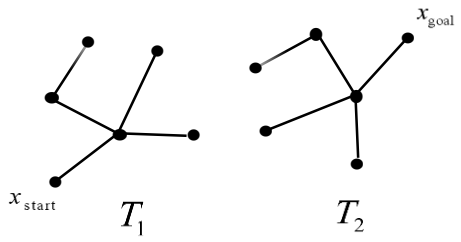

Fig. 3. Schematic representation of double-tree expansion.

D. Adaptive Step Size

It is evident that traditional RRT algorithms utilise a fixed step size for expansion, a practice that may give rise to several issues. Inefficiency is a notable concern, as the fixed step size can impede the efficacy of expansion, particularly in open areas. This limitation can result in an excessive number of unnecessary searches. Moreover, the fixed step size can compromise accuracy, particularly in the vicinity of the target or in narrow areas. In such instances, the step size may either miss the target entirely or encounter difficulties in navigating a complex environment, ultimately leading to failure. The adaptive step size strategy has been developed to address these issues by dynamically adjusting the step size according to the distance between the expansion node and the target point. The concept of an adaptive step size is outlined below. The fundamental principle of this approach entails the dynamic adjustment of the expansion step size, thereby facilitating the manifestation of distinct search behaviours in diverse environmental contexts. In environments that are distant from the target, a larger step size is employed to expedite the search coverage. Conversely, in close proximity to the target, a reduction in the step size is implemented to enhance the search accuracy. In complex environments characterised by dense obstacles, a further reduction in the step size is initiated to augment the success rate of traversing the path.

The employment of adaptive step size facilitates the expansion of the tree, thereby enabling efficient exploration of the global environment and the execution of precise searches in complex regions or in proximity to the target. This is achieved through the dynamic adjustment of the expansion step size. As shown in Fig. 4.

$$L_{\text{adaptive}} = \begin{cases} L_{\max}, & \alpha \cdot d_{\text{goal}} + \beta \geq L_{\max} \\ \alpha \cdot d_{\text{goal}} + \beta, & \alpha \cdot d_{\text{goal}} + \beta < L_{\max} \end{cases} \tag{3}$$

L_{adaptive}: adaptive step size, L_{max}: maximum allowable step size, $d_{\text{goal}} = \|p_{\text{current}} - p_{\text{goal}}\|$: Euclidean distance from current node to goal point, α: coefficient, β: offset, p_{current}: indicates the

position of the current tree node, p_{goal}: indicates the position of the goal point.

Adaptive step size constitutes a dynamic optimisation strategy, which is employed throughout the expansion process of the improved RRT algorithm. This strategy enhances global search efficiency and mitigates ineffective expansion by integrating it with the concepts of target bias sampling, local Gaussian sampling, and double-tree expansion. The strategy enhances local accuracy and optimises path availability and smoothness, thereby accelerating the dual-tree connection and enhancing the success rate and speed of planning. Finally, the enhanced adaptability to complex environments is suitable for real robot path planning needs.

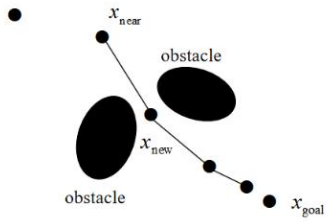

Fig. 4. Adaptive step size schematic.

E. Path Smoothing

Robotic arms have been observed to be susceptible to sudden acceleration at inflection points during the process of path planning. This instability necessitates the implementation of a smoothing technique to ensure the stability of the path. Cubic B-spline represents an interpolation method employed for the smoothing of paths, whereby data points are fitted by means of segmented polynomial functions, thereby enhancing the smoothness of the path as shown in Fig. 5.

$$Q(m) = \sum_{k=0}^{m} R_k \, G_{k,m}(s), s \in [0,1] \quad (4)$$

In this study, the equation of the control point of the kth segment is denoted byR_k, and the basis function of the nth B-spline is denoted by $G_{k,m}$.

$$G_{k,m}(s) = \frac{1}{m!}\sum_{v=0}^{m-k}(-1)^v \, T_{m+1}^{v}(s+m-k-v) \quad (5)$$

$$T_{m+1}^{v} = \frac{(m+1)!}{v!(m+1-v)!} \quad (6)$$

Minimum curvature smoothing is a process of path smoothing in which the path is rendered more natural by minimising the curvature of the path. The objective of minimum curvature smoothing is to minimise the integral of the square of the curvature, i.e:

$$min \int k^2 \, (s) ds \quad (7)$$

Among them:

$$K = \frac{x'y'' - y'x''}{(x'^2 + y'^2)^{3/2}} \quad (8)$$

The first-order derivatives of the path are denoted by $x^{'}$ and $y^{'}$, whilst the second-order derivatives are denoted by $x^{''}$ and $y^{''}$.

The combination of cubic B-splines and minimum curvature optimisation generates smooth, continuous and natural paths with high implementability and efficiency.

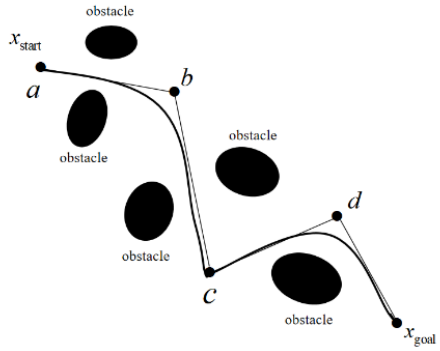

Fig. 5. Schematic diagram of three times B-spline curve fitting.

F. Improved RRT Algorithm Process

Step 1: Initialize the map, initialize the obstacle positions, and initialize the parameters. Initialize the two trees: T_1 with the starting point as the root node and T_2 with the end point as the root node.

Step 2: The target offset strategy is used to generate sampling points. The target point is directly selected with a set probability, quickly guiding the path to converge towards the target. In all other cases, sampling points are generated randomly to enhance exploration. Local Gaussian sampling is applied to the random sampling points, generating Gaussian distribution sampling points near the target point, with the offset dynamically adjusted by the target distance.

Step 3: Expand T_1, find the node closest to the sampling point in T_1, and use a fixed step size to expand at a long distance, quickly approaching the sampling point, and dynamically reducing the step size at a short distance to improve the expansion accuracy and avoid over-expansion. Generate a new node according to the adjusted step size, and verify whether the path collides with obstacles. If the path does not collide, add the new node to T_1; if the path is invalid, skip the current sampling point and return to regenerate the sampling point.

Step 4: Expand T_2. T_2 expands towards the new node added to T_1 and executes the same logic as T_1.

Step 5: If the new node T_2 is successfully expanded and the distance between the nodes of the two trees is less than the step size, the two trees are considered to be connected. If the two trees are not successfully connected, the resampling stage is entered.

Step 6: Generate the complete path by retracing it from the two trees, smooth the path using a cubic B-spline three times, and further reduce sharp turns and improve path smoothness through curvature optimization.

Step 7: End

The flow of the RRT improvement algorithm is shown in Fig. 6.

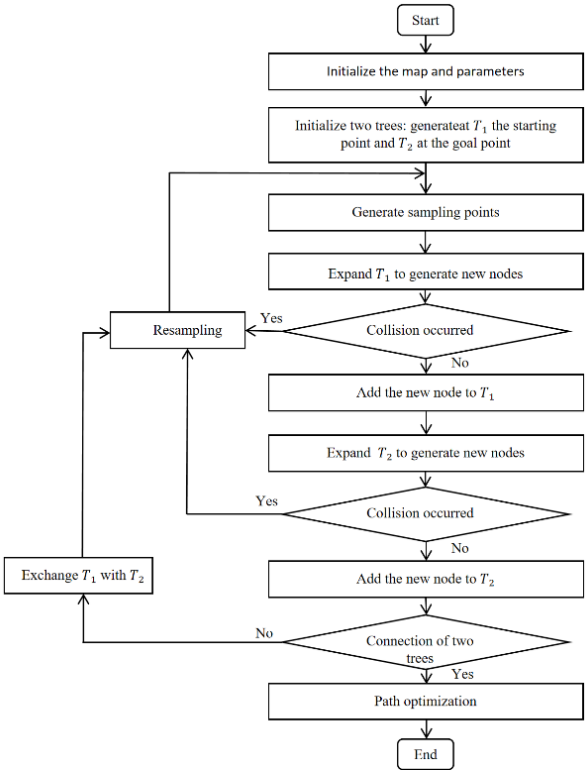

Fig. 6. Flowchart of the improved RRT algorithm.

IV. Experimental Design and Analysis

A. Simulation Experiments in a Two-Dimensional Environment

The simulation experiment is based on the MATLAB R2021b platform. The hardware configuration of the simulation platform consists of an AMD Ryzen7 4800H processor, running the Windows 10 operating system, with a total running memory of 32GB. The experiment is designed to conduct three maps, each measuring 800×800, with the origin of the coordinates positioned in the upper left corner. The simulation experiments were executed on the MATLAB platform. The initial starting point of the four algorithms is (30, 30), the target point is (750, 750), the step delta is 20, the maximum number of searches is 3,000, and the target bias probability of the Improved RRT algorithm is 0.3. Each map was executed 100 times under each algorithm.

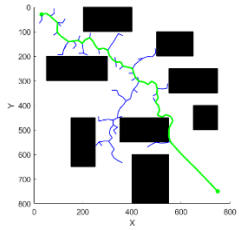
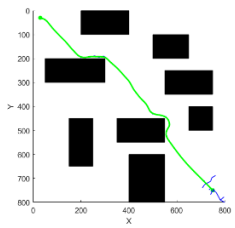
(b) RRT* algorithm



(c) RRT-Connect algorithm



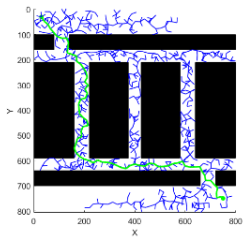
(d) Improved RRT algorithm

Fig. 7. Four Algorithmic path planning in normal map mode.

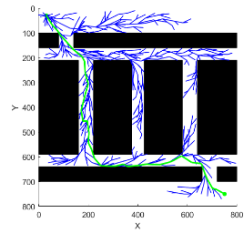
TABLE I Comparison of the Results of the Four Algorithms in Normal Map Mode

Algorithm type	Average path length /mm	Average running time /s	Average nodes	Average iterations
RRT	1348.98	13.23	963.13	1321.44
RRT*	1099.91	13.71	965.88	1311.19
RRT-Connect	1302.15	1.03	134.11	143.92
Improved RRT	1114.84	0.46	64.72	79.88

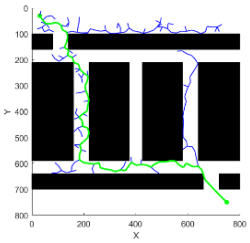
The results of the normal map mode experiment are shown in Fig. 7. The analysis of the experimental data in Table I shows that the improved RRT algorithm exhibits significant optimization effects compared to the conventional RRT algorithm when there are fewer obstacles. Specifically, the improved algorithm has a 17.36% reduction in the average path length, a 96.52% reduction in the average running time, a 93.28% reduction in the average number of nodes, and a 93.96% reduction in the average number of iterations. These results show that the improved RRT algorithm is significantly better than the traditional RRT algorithm in terms of both path planning efficiency and path quality.



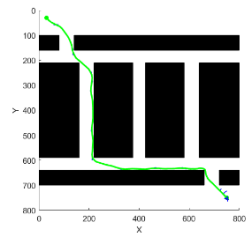
(a) RRT algorithm



(b) RRT* algorithm



(c) RRT-Connect algorithm



(d) Improved RRT algorithm

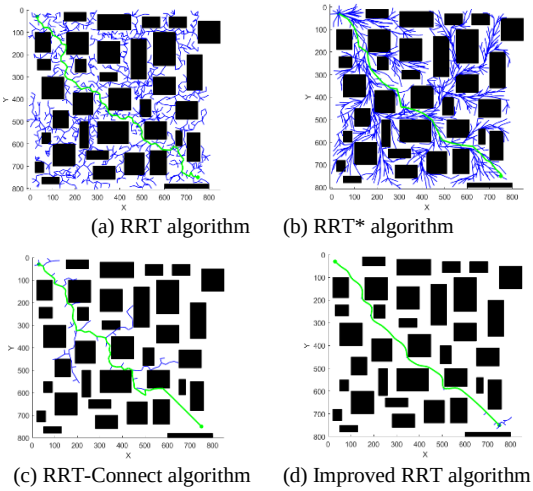
TABLE II COMPARISON OF THE RESULTS OF THE FOUR ALGORITHMS FOR PATH PLANNING IN THE NARROW MAP MODE

Algorithm type	Average path length /mm	Average running time /s	Average nodes	Average iterations
RRT	1494.86	5.27	563.30	1397.24
RRT*	1245.49	5.13	557.89	1414.16
RRT-Connect	1460.40	1.23	168.66	310.06
Improved RRT	1249.52	0.27	36.42	107.61

The experimental results in the narrow map mode are shown in Fig. 8, and the corresponding data are shown in Table II. The experimental data show that the improved RRT algorithm has a significant optimization effect in the case of extremely narrow passages compared to the traditional RRT algorithm. In the narrow map mode, the improved RRT algorithm has an average path length that is 16.41% shorter than the traditional RRT algorithm, an average running time that is 94.88% shorter, an average number of nodes that is 93.53% lower, and an average number of iterations that is 92.30% lower. Experimental data show that the improved RRT algorithm requires a shorter path, less time, and fewer nodes and iterations to search in a confined environment compared to the other three algorithms.



(a) RRT algorithm (b) RRT* algorithm

(c) RRT-Connect algorithm (d) Improved RRT algorithm

Fig. 9. Four Algorithmic path planning in complex map mode.

TABLE III COMPARISON OF THE RESULTS OF THE FOUR ALGORITHMS FOR PATH PLANNING IN COMPLEX MAP MODE

Algorithm type	Average path length /mm	Average running time /s	Average nodes	Average iterations
RRT	1374.28	9.96	792.24	1398.35

RRT-Connect	1317.84	1.38	163.75	249.60
Improved RRT	1124.88	0.37	62.33	117.53

The experimental results in the complex map mode are shown in Fig. 9, and the corresponding data are shown in Table III. The experimental data show that in the case of dense obstacles and complex road conditions, the improved RRT algorithm shows a significant performance improvement compared to the traditional RRT algorithm. Specifically, the average path length is reduced by 18.15%, the average running time is reduced by 96.29%, the average number of nodes is reduced by 92.13%, and the average number of iterations is reduced by 91.60%. The results show that the improved RRT algorithm can significantly improve the search efficiency, optimize the path quality, and reduce the computational resource consumption when dealing with path planning tasks in complex scenarios.

B. Simulation Experiment in a Three-Dimensional Environment

In order to improve the RRT algorithm, a 3D map was designed for the experiment, and the size of the map was 800×800×800. Simulation experiments were performed on the MATLAB platform. The starting point of the four algorithms was (30, 30, 30), the target are (750, 750, 750), the step size is 30, and the maximum number of searches is 5000. The target bias probability of the improved RRT algorithm is 0.3. Each map is run 20 times for each algorithm.

	Improved RRT	1335.17	0.78	58.90	89.80

The experimental results in 3D map mode are shown in Fig. 10, and the corresponding data are shown in Table IV. The experimental results show that due to its limitations, the traditional RRT algorithm tends to generate a large number of branches and redundant nodes in a 3D simulation environment, resulting in a long path planning time and poor path quality. The improved RRT algorithm showed significant optimization effects in these aspects. The improved RRT algorithm reduced the average path length by 25.74%, the average running time by 99.27%, the average number of nodes by 97.94%, and the average number of iterations by 97.02%. Overall, the improved RRT algorithm performed particularly well in 3D environments. It outperformed the traditional RRT algorithm in terms of path quality, planning speed, and resource utilization.

V. CONCLUSION

This paper proposes an improved algorithm based on the RRT algorithm, which incorporates a dual-tree expansion strategy, target bias sampling, local Gaussian sampling, adaptive step length, cubic B-spline smoothing, and minimum curvature optimization. This algorithm effectively solves the problems of path smoothing, node redundancy, and search failure in traditional RRT algorithms, significantly improving search efficiency and path planning reliability, while enhancing the adaptability and practicality of the algorithm in complex environments. Simulation results show that the improved RRT algorithm is significantly better than the traditional RRT algorithm in terms of key performance indicators such as path length, planning time, node count, and iteration count. The average path length is reduced by 18.15%, the planning time is reduced by 96.29%, the number of nodes is reduced by 92.13%, and the number of iterations is reduced by 91.60%. The improved algorithm can significantly reduce the planning time and sampling redundancy, while generating shorter and higher quality paths. The experimental results fully verify the efficiency and feasibility of the algorithm in complex environments. In future work, other aspects will need to be improved, such as extending the path planning of the robotic arm to a dynamic multi-dimensional obstacle environment.

Comparative Analysis of YOLO and Faster R-CNN Models for Detecting Traffic Object

Iqbal Ahmed[1], Rocky Das[2]
Professor, Department of Computer Science and Engineering, University of Chittagong, Bangladesh[1]
M.Sc. Student, Department of Computer Science and Engineering, University of Chittagong, Bangladesh[2]

***Abstract*—The identification of traffic objects is a basic aspect of autonomous vehicle systems. It allows vehicles to detect different traffic entities such as cars, pedestrians, cyclists, and trucks in real-time. The accuracy and efficiency of object detection are crucial in ensuring the safety and reliability of autonomous vehicles. The focus of this work is a comparative analysis of two object detection models: YOLO (You Only Look Once) and Faster R-CNN (Region-based Convolutional Neural Networks) using the KITTI dataset. The KITTI dataset is a widely accepted reference dataset for work in autonomous vehicles. The evaluation included the performance of YOLOv3, YOLOv5, and Faster R-CNN on three established levels of difficulty. The three levels of difficulty range from Easy, Moderate, to Hard based on object exposure, lighting, and the existence of obstacles. The results of the work show that Faster R-CNN achieves maximum precision in detection of pedestrians and cyclists, while YOLOv5 has a good balance of speed and precision. As a result, YOLOv5 is found to be highly suitable for applications in real-time. In this aspect, YOLOv3 shows computational efficacy but displayed poor performance in more demanding scenarios. The work presents useful insights into the strength and limitation of these models. The results help in improving more resilient and efficient systems of detection of traffic objects, hence advancing the construction of more secure and reliable self-driving cars. Moreover, this study provides a comparative analysis of YOLO and Faster R-CNN models, highlighting key trade-offs and identifying YOLOv5 as a strong real-time candidate while emphasizing Faster R-CNN's precision in challenging conditions.**

Keywords*—*Faster R-CNN; YOLOV3; YOLOV5 Traffic object detection; image detection; autonomous driving

I. Introduction

The identification of objects in traffic scenarios is a crucial aspect of autonomous vehicle technologies. The process includes detection and localization of entities in traffic scenarios such as vehicles, pedestrians, bicyclists, and trucks using computer vision methods. The ability to detect and classify such entities in real-time is crucial to ensuring safety and efficacy in self-driving cars, in addition to improving traffic management systems [1].

The introduction of new methods in deep learning and convolutional neural networks (CNNs) has revolutionized object detection in computer vision in a great way. The older methods that relied on manually engineered features using machine learning approaches have been largely replaced by deep learning-based methods, mainly owing to their high precision and resilience. Significantly, YOLO and Faster R-CNN stand out among the most widely used frameworks in research related to object detection.

YOLO is credited for processing images at a very high speed, showcasing high efficiency in its processing. The model processes images using a single forward pass in a neural network, making it highly applicable in cases of real-time processing. Nevertheless, its precision is hampered in complex situations, especially in cases of small or occluded objects.

However, Faster R-CNN is notable for its high precision, mainly in detection of small and partially occluded objects. The model leverages a region proposal network (RPN) to produce potential object regions that get categorized afterward. As much as Faster R-CNN is highly performing, it is hampered by high computational requirements, posing challenges in applying it in cases of real-time scenarios.

The progress of technologies in self-driving vehicles is highly dependent on high-quality datasets used in the training and testing of object detection models. Among such notable datasets used in scenarios of traffic is that of KITTI, created in a cooperative effort between Toyota Technological Institute and the Karlsruhe Institute of Technology. The KITTI dataset is a large set of traffic pictures taken in diverse lighting and meteorological conditions. The imagery included in this dataset is diverse in nature, making it a representative benchmark to be used in evaluating object detection models.

Despite object detection capabilities improving, there is a continued challenge in ensuring that such results are consistent and accurate across a diverse range of traffic settings. Several variables impact such results, such as varying lighting, varying meteorological conditions, and varying obstacles. All these variables impact the efficacy of traffic object detection methods in a notable manner. To effectively address such challenges, it is crucial to not just improve the processes of more advanced models but also gain a better comprehension of existing methods in terms of their capabilities and limitations.

The objective of this work is to provide a comparative analysis of the YOLO and Faster R-CNN models in traffic object detection using the KITTI dataset as a representative analysis platform. By systematically evaluating the two models in terms of varying levels of challenge or difficulty—i.e., Easy, Moderate, and Hard—one seeks to determine which of these models is better positioned to be used in self-driving systems. The main contribution of this study are as follows:

1) Comprehensive Comparative Analysis: We systematically evaluate YOLOv3, YOLOv5, and Faster R-

This research is funded and supported by Research and Publication Cell, University of Chittagong, Bangladesh.

CNN on the KITTI dataset across three difficulty levels (Easy, Moderate, and Hard).

2) Performance Insights: We provide a detailed analysis of speed vs. accuracy trade-offs, highlighting YOLOv5 as a strong candidate for real-time applications and Faster R-CNN for high-precision tasks.

3) Small Object Detection Challenges: Our study reveals the challenges in detecting small and occluded objects, offering insights for future improvements in model design.

4) Benchmarking for Real-World Applications: We present an evaluation that aids researchers and developers in selecting the best model for autonomous driving applications based on specific requirements.

II. Problem Statement

A. Variability in Environmental Conditions

Traffic scenes are highly diverse, with many objects. These scenes can appear under varying lighting conditions, weather, and levels of obstacles. Many existing models struggle to maintain high accuracy in challenging scenarios, such as low-light conditions, heavy rain, or dense traffic. Here objects may be partially covered or difficult to distinguish in that image for that model.

B. Trade-offs Between Speed and Accuracy

If we want to detect real-time objects, it will require a balance between speed and accuracy. Models like YOLO are optimized for speed. So, we can use them to make suitable real-time applications. But they may reduce precision. Especially for smaller or partially covered objects, they can significantly reduce accuracy. On the other hand, models like Faster R-CNN achieve high accuracy in traffic object detection. But they are computationally intensive. This is limiting their ability for real-time deployment.

C. Detection of Diverse Object Classes

Traffic scenes contain a wide variety of objects. Those scenes can include cars, pedestrians, cyclists, trucks, and motorcycles. Each object class presents unique challenges. They are different in terms of size, shape, and movement patterns. For example, when we want to detect small objects like cyclists or pedestrians at a distance, it is quite challenging. It is more challenging when they are partially covered or in motion.

D. Generalization Across Different Scenarios

Many object detection models are trained and tested on specific datasets. These datasets do not fully represent the diversity of real-world traffic scenarios. This can create poor generalization when the models are deployed in different environments or under conditions that were not encountered during training.

E. Lack of Comparative Studies

YOLO and Faster R-CNN are widely used for object detection. However, there is a lack of comparative studies that compare their performance across varying difficulty levels and object classes. The strengths and limitations of these models in different scenarios are different. That's why selecting the most appropriate model for specific applications is not an easy task.

III. Literature Review

We have reviewed some previous research those are related to our research. A short summary of every research is given here. This research in study [1] performed real-time vehicle detection and distance estimation using YOLOv4 and Faster R-CNN models. When the object was within a radius of 100 meters, it received high precision (99.16% and 95.47%) and Fl-measures (79.36% and 85.54%). The detection speed was 68 fps and 14 fps for YOLOv4 and Faster R-CNN, respectively.

LiDAR and camera data for object detection and distance estimation in autonomous driving are combined in this research [2]. A fusion approach has been applied. The result shows a good performance in the real world and simulator. This method uses low-level sensor fusion using geometric transformations. It also enabled consistent perception in diverse scenarios.

A monocular vision-based approach for vehicle detection and distance estimation has been developed. This study [3] used a single-sensor multi-feature fusion technique to improve the accuracy and robustness of the algorithm. It can detect even in challenging weather, including sunny, rainy, foggy, or snowy, and lighting conditions.

A two-stage detection system has been developed. HybridNet combines the speed of single-stage methods. This study [4] used the precision of two-stage models. Models are tested on KITTI and PASCAL VOC2007 datasets. HybridNet made faster and more accurate vehicle detection even in challenging weather.

A convolutional network for 2D and 3D object detection from monocular images in autonomous vehicles are developed. They used the KTTI dataset in this study [5]. This model processes images at 10 fps and shows good speed.

Over 300 works have been reviewed and compared each of them in this study [6]. It evaluated machine vision-based, mmWave radar-based, LiDAR-based, and sensor fusion methods, highlighting challenges and recommending future directions for improving detection accuracy.

A geometry-based method for distance estimation using lane and vehicle detection has been developed. The study in [7] achieved good accuracy with a computationally inexpensive approach, outperforming monocular depth prediction algorithms on several datasets. The system is lightweight and domain-invariant.

A monocular vision-based method using 3D detection has been made. The study in [8] improved accuracy in estimating inter-vehicle distances. This study integrated a geometric model. This approach demonstrates superior performance on KITTI benchmarks, effectively handling occlusions and diverse vehicle orientations.

Detecting and tracking moving vehicles in urban environments has been done in this study [9]. It used laser range finders. The approach employs Bayesian filtering and motion evidence techniques. It enhanced accuracy under noisy conditions. It passed tests in challenging scenarios like the Urban Grand Challenge.

A single-camera-based method has been integrated in this study [10]. It detects vehicles and estimates distances using aggregated channel features (ACFs) and inverse perspective mapping. The technique is optimized for real-time processing. It performs well in real-world environments. It has proven its applicability to autonomous driving.

While previous studies [1] [2] [3] have explored object detection using LiDAR, hybrid approaches, or alternative CNN architectures, our study provides a focused evaluation of YOLO and Faster R-CNN on the KITTI dataset to determine their suitability for real-time autonomous driving applications.

IV. METHODOLOGY

This research applies the methodology which is presented in next Fig. 1. The chapter focus presents the sequence of data collection followed by data processing steps before model training and model evaluation. The main objective is to build a solid evaluation framework for determining the performance of YOLOv3, YOLOv5 and Faster R-CNN models in traffic object detection.

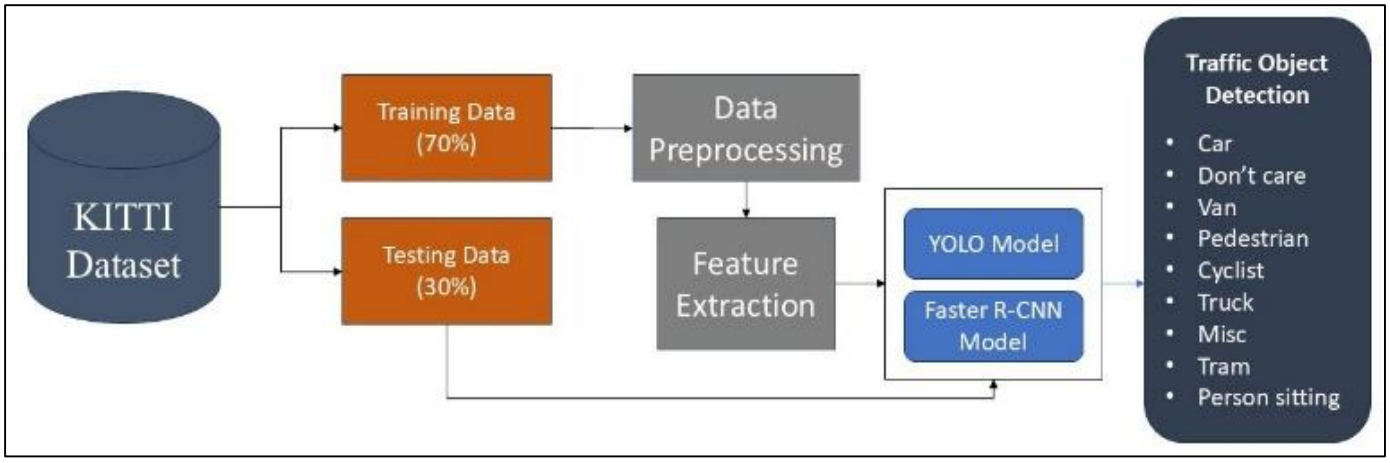

Fig. 1. Overall methodology.

A. Data Collection

The researchers utilized the KITTI dataset because it contains numerous traffic images. Compression research using KITTI dataset emerged from collaboration between Karlsruhe Institute of Technology (KIT) and Toyota Technological Institute at Chicago (TTIC). The dataset includes diverse images which were captured under various weather circumstances and lighting conditions. The dataset includes annotations which determine specific objects such as cars and pedestrians and cyclists and further traffic objects in images. It functions well for detecting objects through training and evaluation process.

B. Dataset Description

KITTI supplies a total of 7,481 training images alongside 7,518 test images. The dataset contains photographs with boundaries that indicate the objects' classification. The database separates information into three increasing difficulty settings. The difficulty settings comprise Easy, Moderate, and Hard tiers which depend on the objects' size together with lighting factors and weather effects as well as object-covering elements.

C. Data Splitting

The training dataset was distributed into two sections: training which received 80 percent of data and validation which obtained 20 percent of data. The division of the training set created two subsets for running model training sessions as well as fine tuning with hyperparameter adjustments. The assessment of model final performance occurred exclusively through testing the models on the dedicated testing set.

D. Data Processing

Several preprocessing procedures were applied to the dataset to achieve good model results. Those steps are described below:

Resizing: Subject images required two different dimensions for processing as Faster R-CNN needed 800x600 while YOLO needed images sized at 416x416.

Normalization: To boost the training efficiency pixel values received normalization which stretched their values between 0 to 1.

Data Augmentation: The training data diversity improved together with overfitting reduction by implementing random cropping and flipping and rotation transformations.

Annotation Conversion: The annotation data needed conversion into specific formats since YOLO models accept YOLO format while Faster R-CNN accepts COCO format.

E. Model Training

The training procedure included following steps for each model type.

Training set: The training part of KITTI data served as the dataset for model training. To optimize performance the model applied various hyper parameter adjustments consisting of learning rate and batch size as well as number of epochs.

Validation set: The validation subset served as a performance measurement tool during training to stop the models from overfitting. Early termination function operated

because the validation loss failed to get better results after multiple iterations.

Testing set: The testing set served as the identification tool to measure model performance following training completion.

F. Model Evaluation

The evaluation process of the developed models utilized the following evaluation metrics.

Validation Accuracy: During model training the validation set accuracy measurements were used to confirm proper learning occurred using Eq. (1).

$$\text{Validation Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

whereas, *TP*, *TN* represents True Positive and True Negetive and *FP*, *FN* represents False Positive and False Negetive.

Validation Loss: During assessment of the model performance the validation set measurement used cross-entropy loss for classification alongside mean squared error for bounding box regression.

Test Accuracy: The testing set was utilized to perform the final accuracy assessment of the developed models.

Confusion Matrix: The performance evaluation of various object classes was conducted through a generated confusion matrix.

Precision, Recall, F1 Score: The model's capacity to detect objects properly while reducing errors was evaluated through precision, recall and F1 score calculation as Eq. (2), Eq. (3) and Eq. (4).

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

$$\text{F1-Score} = 2\ X \frac{Precision\ x\ Recall}{Precision + Recall} \quad (4)$$

V. Results and Discussion

This chapter presents the results of the experiments conducted to evaluate the performance of YOLOv3, YOLOv5, and Faster R-CNN models in detecting traffic objects using the KITTI dataset. The results are analyzed across three difficulty levels—Easy, Moderate, and Hard—and discussed in the context of their implications for real-world applications.

A. Performance Across Difficulty Levels

The performance of the models was evaluated based on their ability to detect objects under varying conditions, as defined by the difficulty levels in the KITTI dataset. The results are summarized below:

Easy Difficulty: Objects are clearly visible, with optimal lighting and minimal occlusion (Fig. 2). All models performed well under easy conditions, with Faster R-CNN achieving the highest accuracy for all object classes. YOLOv5 showed significant improvement over YOLOv3, particularly in detecting smaller objects like cyclists.

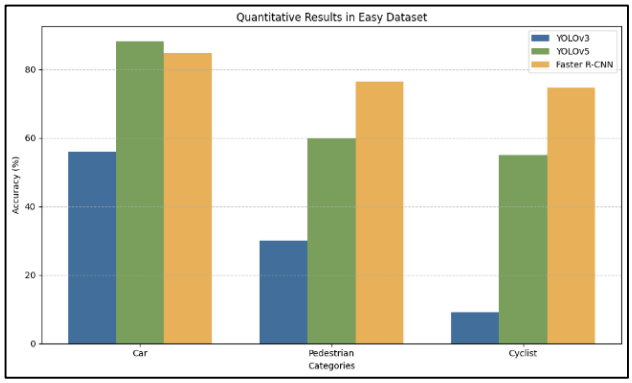

Fig. 2. Results in easy dataset.

Moderate Difficulty: Objects are partially occluded or located at a moderate distance from the camera (shown in Fig. 3). Faster R-CNN maintained its lead in accuracy, but YOLOv5 demonstrated competitive performance, especially in detecting cars and pedestrians. YOLOv3 struggled with moderate difficulty, showing a noticeable drop in accuracy compared to the other models.

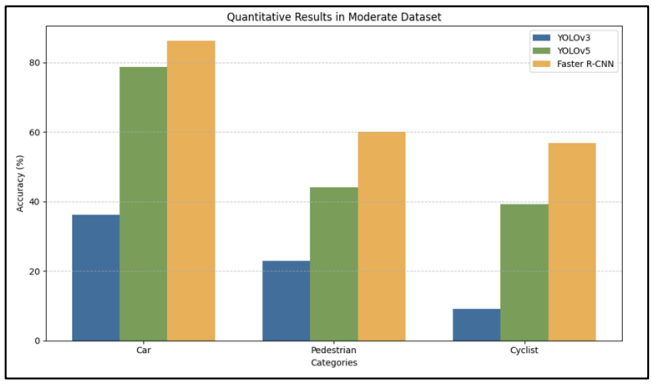

Fig. 3. Results in moderate dataset.

Hard Difficulty: Objects are heavily occluded, located far from the camera, or appear under challenging lighting conditions (Fig. 4). Faster R-CNN outperformed the other models, particularly in detecting pedestrians and cyclists, which are often smaller and harder to detect. YOLOv5 showed resilience in hard conditions but lagged Faster R-CNN in terms of precision and recall. YOLOv3 performed poorly, with significantly lower accuracy across all object classes.

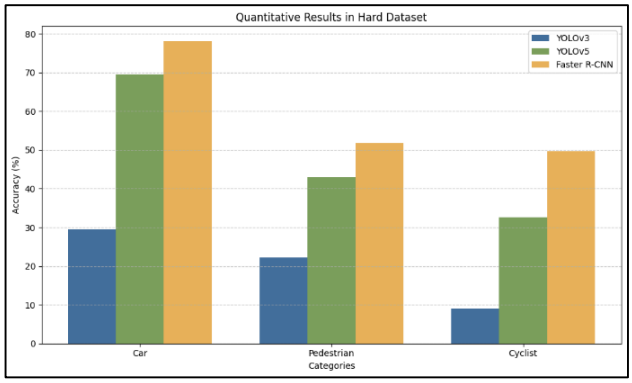

Fig. 4. Results in hard dataset.

B. Comparative Analysis of Models

The following Table I summarizes the performance of the models across the three difficulty levels for each object class.

TABLE I. COMPARATIVE ANALYSIS OF MODELS

Model	Difficulty	Car	Pedestrian	Cyclist
YOLOv3	Easy	56.00%	29.98%	9.09%
	Moderate	36.23%	22.84%	9.09%
	Hard	29.55%	22.21%	9.09%
YOLOv5	**Easy**	**88.17%**	**60.44%**	**55.00%**
	Moderate	**78.70%**	**43.69%**	**39.29%**
	Hard	**69.45%**	**43.06%**	**32.58%**
Faster R-CNN	Easy	88.17%	60.44%	55.00%
	Moderate	78.70%	43.69%	39.29%
	Hard	69.45%	43.06%	32.58%

C. Key Findings

The following table summarizes the performance of the models across the three difficulty levels for each object class.

YOLOV3: Demonstrated limited performance, particularly in detecting smaller objects like cyclists. Struggled with moderate and hard difficulty levels, highlighting its limitations in complex scenarios.

YOLOV5: Showed significant improvement over YOLOv3, achieving higher accuracy across all difficulty levels. Performed well in real-time applications, making it a strong candidate for deployment in autonomous driving systems.

Faster R-CNN: Consistently achieved the highest accuracy, particularly for pedestrian and cyclist detection. Demonstrated robustness in challenging conditions, making it suitable for applications requiring high precision.

D. Discussions

The results reveal a clear trade-off between speed and accuracy among the models. While YOLOv5 offers a balance between real-time performance and accuracy, Faster R-CNN excels in precision but at the cost of higher computational requirements. YOLOv3, while computationally efficient, falls short in accuracy, particularly in challenging scenarios.

Real-Time Applications: YOLOv5 is recommended for real-time applications where speed is critical, such as in autonomous vehicles that require immediate decision-making.

High-Precision Applications: Faster R-CNN is ideal for tasks that demand high accuracy, such as pedestrian detection in urban environments or cyclist detection in crowded areas.

Limitations: Despite its strengths, our study reveals several limitations, including challenges in detecting small and occluded objects, the high computational cost of Faster R-CNN, and the need for better generalization across diverse environments. Future research should explore hybrid models, optimization techniques, and dataset expansion to overcome these drawbacks.

E. Comparision with State of Art Methods

Our study evaluates YOLOv3, YOLOv5, and Faster R-CNN for traffic object detection. To validate our findings, we compare our results with state-of-the-art methods from prior works. Firstly, the study in [1] achieved 99.16% precision for vehicle detection using YOLOv4, while our study shows that YOLOv5 achieves 88.17% for car detection under easy conditions, demonstrating competitive performance in real-time scenarios. Secondly, the study in [2] integrated LiDAR and camera fusion, achieving robust performance in adverse weather, whereas our model evaluations focus purely on visual detection, which remains a challenge in occluded environments. Finally, the study in [3] demonstrated high performance using monocular vision-based methods but struggled in low-light scenarios, a limitation also observed in YOLOv3 in our study.

These comparisons highlight that while YOLOv5 provides a strong balance of speed and accuracy for real-time applications, methods involving sensor fusion or more advanced deep learning architectures, such as Transformer-based detectors, may further enhance robustness.

VI. CONCLUSION AND FUTURE WORKS

This chapter describes the whole research by gathering all the important findings. Also, their implementation is described here. In future work section, the next processes of traffic object detection are well described.

A. Conclusion

This research executed a comparative analysis of YOLOv3, YOLOv5, and Faster R-CNN models for traffic object detection using the KITTI dataset. The models are evaluated across three different difficulty levels. Difficulty levels are Easy, Moderate, and Hard. Also, there are different object classes. Cars, pedestrians, and cyclists are the most important of them. The key findings are summarized below. The YOLOv3 model demonstrated limited performance, particularly in detecting smaller objects like cyclists and under challenging conditions. The accuracy of this model is not too good. That's why, it is not well suited for robust real-world traffic detection applications. In contrast, the YOLOV5 model shows better results than the YOLOV3 model. Additionally, The results highlight the difference between speed and accuracy among the models. Here, YOLOv5 is a good option for real-time applications. Faster R-CNN made good progress whereas precision is tough. According to these findings, we can easily select the most appropriate model for the real-time robust application. Moreover, our findings confirm that YOLOv5 provides a competitive alternative to existing object detection frameworks while maintaining real-time performance. However, integrating multi-sensor fusion or leveraging newer architectures such as EfficientDet could further improve detection accuracy in complex traffic environments.

B. Future Works

While this research has contributed to the understanding of traffic object detection models, there are several areas for future exploration, such as Expansion of Dataset, Examining Different CNN Architectures, Hybrid Approaches for Real-Time Deployment, Addressing Small Object Detection, and Integration with Autonomous Systems.

ACKNOWLEDGMENT

The authors express their sincere appreciation and acknowledge for the continuous support provided by the Department of Computer Science and Engineering, & Research and Publication Cell, University of Chittagong, Chittagong, Bangladesh.

A Deep Learning-Based Framework for Real-Time Detection of Cybersecurity Threats in IoT Environments

Sultan Saaed Almalki
Department of Digital Transformation and Information, Institute of Public Administration, Jeddah, Makkah Al Mukarramah, 23442, KSA

***Abstract*—The rapid adoption of Internet of Things (IoT) devices has led to an exponential increase in cybersecurity threats, necessitating efficient and real-time intrusion detection systems (IDS). Traditional IDS and machine learning models struggle with evolving attack patterns, high false positive rates, and computational inefficiencies in IoT environments. This study proposes a deep learning-based framework for real-time detection of cybersecurity threats in IoT networks, leveraging Transformers, Convolutional Neural Networks (CNNs), and Long Short-Term Memory (LSTM) architectures. The proposed framework integrates hybrid feature extraction techniques, enabling accurate anomaly detection while ensuring low latency and high scalability for IoT devices. Experimental evaluations on benchmark IoT security datasets (CICIDS2017, NSL-KDD, and TON_IoT) demonstrate that the Transformer-based model outperforms conventional IDS solutions, achieving 98.3% accuracy with a false positive rate as low as 1.9%. The framework also incorporates adversarial defense mechanisms to enhance resilience against evasion attacks. The results validate the efficacy, adaptability, and real-time applicability of the proposed deep learning approach in securing IoT networks against cyber threats.**

***Keywords*—IoT security; intrusion detection system; cybersecurity threats; deep learning; real-time detection; adversarial robustness; anomaly detection**

I. INTRODUCTION

The rapid expansion of Internet of Things (IoT) devices has redefined various industries because they connect smart devices to share information. Modern technology presents substantial security obstacles that accompany its advancement. Security threats frequently target IoT networks because they maintain distributed operations with limited processing power along with absent standard security measures [1, 2]. Security systems with traditional mechanisms that use Intrusion Detection Systems (IDS) and signature methods fall short of rapidly detecting developing threats. DL technology under the umbrella of artificial intelligence has proven successful in strengthening IoT security systems, according to research [3]. Different forms of cyber-related attacks aimed at IoT devices have significantly increased since the beginning of this decade [2]. IoT devices lack sufficient security measures, and because of this, they become simple targets for cybercriminals. IDS systems with conventional set-ups depend on pre-set rules, which makes them unable to detect fresh dangers in the environment [4]. The identification of sophisticated attack patterns by DL models succeeds through three main neural networks: convolutional neural networks (CNNs), long short-term memory (LSTM) networks, and transformer-based architectures. The models function by evaluating enormous network traffic datasets and then extract conclusions from previous incidents to identify real-time anomalous patterns [5]. Establishing a DL-based framework is the main objective of enhancing threat detection capabilities in IoT networks. This proposed solution aims to boost the threat detection precision, reduce false alarms, and speed up cyber security responses through advanced neural network structures. This study will analyze the performance issues, privacy needs, and robustness concerns that affect DL-based threat detection systems.

The growing intersectoral use of IoT devices has substantially enlarged the opportunities cyber attackers use to launch attacks. The lack of robust security mechanisms separates these devices from smart homes to healthcare facilities and industrial automation and transportation systems because they deal with crucial data. Various IoT networks remain exposed to cyberattacks since they have poor authentication security and limited processing power and remain unsecured from security updates [6]. IDS that use traditional methods and security mechanisms with rule-based protocols are ineffective against the developing patterns of cyber threats. Multiple security approaches that depend on pre-defined attack patterns prove ineffective when dealing with freshly discovered attacks and new threats [7]. Conventional machine learning (ML) models demonstrate functional performance in specific situations, but they need significant feature refinement and lack time-sensitive detection capability [8]. The existing DL-based security frameworks still have challenges regarding high false positive rates, computational overhead, and adversarial robustness [9]. The present time calls for an efficient cybersecurity threat detection system that utilizes DL approaches efficiently and reduces false alarm rates while running in real time. A DL-based framework exists to tackle existing IoT network cyber threats that observe threats in real-time. The proposed solution implements CNNs, LSTM, and transformer architectures to examine, network traffic detect anomalies, and effectively stop potential attacks. Evaluation of the framework takes place using real datasets to confirm its practical functionality in IoT security applications.

The main purpose of this investigation is to create a time-responsive DL framework that detects security challenges in Internet of Things networks. To achieve this goal, the investigation establishes the following main objectives.

- To develop an intelligent intrusion detection model that leverages DL techniques such as CNNs, LSTM, and Transformer architectures to analyze IoT network traffic and detect threats.
- To enhance detection accuracy by minimizing false positives and negatives, ensuring that genuine threats are identified while reducing unnecessary alerts.
- To optimize computational efficiency to enable real-time deployment of the DL framework on resource-constrained IoT devices and edge computing platforms.
- To evaluate the proposed framework on real-world IoT cybersecurity datasets to ensure its practical applicability in diverse environments such as smart homes, industrial IoT (IIoT), and healthcare systems.
- To compare the proposed approach with existing IDS, demonstrating its advantages in speed, accuracy, robustness, and resilience against adversarial attacks.
- To ensure scalability and adaptability by designing a flexible framework capable of detecting new and emerging cyber threats without frequent retraining.

This research establishes an optimized DL framework that detects real-time IoT threats while solving various issues in conventional IDS and ML models. The time-series analysis with statistical network features through added behavioral anomaly detection produces a feature engineering approach that enhances cyberattack detection accuracy. The designed model operates efficiently on edge devices or IoT systems because it requires minimal computational power to perform real-time operations. Research tests on benchmarks prove the system achieves higher accuracy while reducing false alarm occurrence and operates more efficiently than conventional systems. Through adversarial defense mechanisms, the framework maintains operational integrity against emerging cyber threats while needing small amounts of retraining. The study delivers open-source implementation and curated IoT security datasets for researchers to benchmark.

The paper continues with the following structure: Section II discusses existing IoT threat detection strategies and their weaknesses. Section III details system architecture, datasets, data processing, DL model design, and performance metrics. Section IV presented the detection accuracy, real-time performance, and adversarial robustness analysis. IoT security research benefits from the summary and proposed enhancement suggestions in Section V.

II. Literature Review

Security challenges emerge from the IoT because more devices join the network. Devices operating at the base of IoT infrastructures need complete security platforms to avoid frequent cyber-attacks. Modern cyberattacks cannot be defeated using the combination of traditional firewalls and rule-based IDS as security measures. This part evaluates standard cybersecurity dangers affecting IoT networks while demonstrating traditional security evaluation techniques' obstacles.

A. Overview of Cybersecurity Threats in IoT

Due to their decentralized structure and wireless communication, IoT networks endure multiple cybersecurity threats. Malware-based attacks constitute the most serious threat because botnets can exploit insecure IoT devices to launch big-scale distributed denial-of-service (DDoS) attacks. The Mirai botnet serves as a documented case that demonstrates how hackers take advantage of unsecured IoT devices for malicious operations [10]. Security experts state that these botnets undergo a persistent transformation, which causes difficulty in both detection and response efforts. The man-in-the-middle (MITM) attack is a vital security risk when attackers interrupt and alter the communication path between IoT devices. The attack poses an exceptional danger to systems of industrial automation alongside smart homes since data integrity stands as a fundamental need [11]. The attackers utilize intercepted data to deceive devices, execute unauthorized commands, and steal sensitive information. Ransomware attacks designed for IoT devices have started to proliferate in the market. Attackers perform data encryption on vital device information and then ask for payment for decryption and access restoration. The absence of proper security features makes countless IoT devices an attractive target for hackers [12]. Unauthorized access occurs because current authentication frameworks are too weak, creating significant security vulnerabilities. Default credential usage within IoT devices, together with an absence of multi-factor authentication, makes these devices vulnerable to quick cybercriminal control access [13]. Security analysts must address threats from adversarial attacks using AI-based IDS, allowing attackers to defeat security protocols. Through the creation of deceptive system inputs for DL models, attackers create adversarial attacks that severely compromise the real-time threat detection capabilities of IDS [14]. The requirement for advanced cybersecurity solutions increases due to threats beyond traditional security measures.

B. Traditional Threat Detection Methods

IoT environments were protected during the early cybersecurity period using rule-based strategies and signature detection methods for threat identification. The primary detection method in use today for IDS involves signature-based IDS. Network traffic comparison to known attack patterns is a detection method for these security systems. The signature-based IDS monitoring system provides successful threat identification of already detected incidents yet remains incapable of processing zero-day attacks alongside fresh malware signatures [10]. Signature-based IDS are inadequate for tracking dynamically developing threats because their limitation requires knowledge of predefined patterns. AIDS improves signature-based IDS because it detects anomalies within normal network operations. These systems create reference points from standard network operations before alerting users about any unusual changes detected. The method enhances unknown attack detection yet produces many incorrect positive results since legitimate network variations sometimes get mistaken for security threats [15]. Implementing an effective anomaly-based IDS depends heavily on acquiring precise real-world IoT dataset representations, although obtaining them remains challenging. Tags are the second most

popular security guard in IoT network settings because they manage network traffic through predefined rules. Firewalls apply monitoring strategies to stop unauthorized system entrance through packet filtering and deep inspection. The security measures prove unsuccessful when facing advanced persistent threats and MITM attacks [16]. Uniform firewall policy implementation becomes difficult for IoT networks because they contain various heterogeneous devices operating with different communication protocols. Vital access control protocols serve the purpose of limiting improper device-to-device interactions. IoT systems' access regulation depends on authentication and authorization methods. Multiple IoT devices operate without robust authentication systems, thus leaving them exposed to brute-force challenges and cyber thieves [13]. System administrators must regularly update access control policies whenever new devices enter the system since this process may create added maintenance work. The security measures based on traditional threat detection systems create minimal protection while being unable to adjust for the quickly developing cyber dangers within IoT infrastructure. Due to the more advanced attack techniques, there is a need for AI-driven solutions that can detect and mitigate real-time threats. DL-based IDS offers the potential to address the shortcomings of traditional methods by learning complex attack patterns and making intelligent threat detection decisions without relying on static rules or predefined signatures.

C. Machine Learning vs. Deep Learning in Cybersecurity

The application of ML technology succeeds in cybersecurity by identifying malicious actions, detecting anomalies, and monitoring network intrusions. The IDS field uses decision trees and SVM, k-nearest neighbors (KNN), and random forests together with ML techniques because these methods learn from historical attack characteristics according to [17]. Feature engineering emerges as part of these models since domain experts use manual methods to identify training features. Using ML-based security solutions depends heavily on the complexity and extensive time needed for feature selection since this process often reduces their effectiveness. The DL approach resolves the requirement for feature engineering by automatically deriving complex representations from original data. DL neural networks consisting of CNNs and RNNs and transformer-based architectures achieve top performance levels when used for cybersecurity operations [18]. DL models use their ability to assess enormous network traffic quantities to discover complex attack patterns that more basic ML models cannot identify. The main benefit of DL surpasses traditional ML because it processes complicated multidimensional datasets automatically. CNN-based detection models work efficiently at the packet level, whereas LSTMs, together with gated recurrent units (GRUs), deliver their best performance when analyzing sequential network traffic information [19]. BERT, alongside ViT, belongs to the Transformer-based model series that researchers now use for network security analysis, where they achieve exceptional detection performance during real-time operations [20]. DL provides numerous benefits; however, it comes with performance expenses, requires significant labeled information collection, and remains exposed to deceptive attacks. Today, DL rules are the preferred security choice because they deliver better accuracy and adaptability, while traditional ML is superior for interpreting data resources efficiently.

D. Existing DL-Based Security Solutions

Implementing DL-based techniques aims to boost IoT cybersecurity through various proposed methods. Serious threats in network traffic are detected with high precision through research-developed CNN-based analytical models. CNNs can analyze the spatial connections between network data because they function well at anomaly detection in packet traffic [21]. RNN and LSTM-based models are one of the principal approaches for analyzing time series because they work well for this purpose. Thankfully, these models enable the detection of attacks based on patterns, including DDoS port scanning and brute-force attacks [22]. With its sequential learning capability, LSTMs evaluate extended dependencies in network traffic data better than conventional statistical approaches. Transformer-based models have gained popularity for application in network security tasks in recent years. The self-attention capability of transformers allows the system to find important parts within sequences that lead to better intrusion detection accuracy. Research studies prove BERT and GPT-based networks excel in cybersecurity tasks to detect phishing attacks, malware, and spam traffic with high accuracy [18]. Combining CNNs with either LSTMs or transformers has become widely used in DL models. Such models unite beneficial components from both systems to provide sharp detection performance while decreasing misleading results. Some experts apply federated learning methods to DL security frameworks to give IoT environments scalability and enhanced privacy features [23]. Existing DL-based security solutions have three main limitations regarding their use in adversarial robustness and enterprise-scale deployment. Implementing DL models becomes difficult for resource-limited IoT devices because these models need significant computational power. DL models experience reductions in their practical efficiency because attackers can perform adversarial attacks through ML methods.

E. Research Gaps and Challenges

DL has proved successful in cybersecurity, yet multiple research requirements and implementation barriers need solutions. The main obstacle stems from limited data capabilities and poor dataset conditions. The requirement for big training datasets from DL models becomes problematic because cybersecurity datasets in the public domain fail to provide sufficient diversity needed for real-threat generalization [21]. Attack instances occur much less frequently than usual traffic, creating challenges due to data imbalance problems leading to unbalanced predictions by models. The tremendous computational expense of DL models creates a crucial challenge for this approach. DL security solutions face challenges when deployed on IoT devices because they often have limited resources, affecting real-time implementation. Experts must develop light DL network designs with edge computing systems to perform immediate threat alerts with strict precision standards [24]. Adversarial robustness functions as the primary security priority. The artificial neural networks that power DL models experience deceptive behavior from minor changes within the input data,

which leads them to generate incorrect output predictions. Scientists currently explore adversarial training and robust feature selection techniques to advance DL-based intrusion detection system security [25]. The capability to grow as per new demand represents a significant unaddressed problem in this field. Security solutions based on DL pose obstacles when developers aim to protect IoT networks because these networks utilize multiple devices with different communication protocols. The development of security frameworks should become a future scientific goal because such frameworks must adopt adaptive self-learning capabilities that can adapt automatically to new security threats before standard retraining procedures. Explainability stands as an essential problem that requires further investigation. High accuracy from DL models exists despite their inability to show understandable decision-making patterns to security analysts so they can interpret their actions. Security analysts require explainable AI (XAI) research in cybersecurity because it enhances DL-based security model transparency and establishes trust [26].

III. Proposed Framework

Conventional security techniques cannot protect against sophisticated cybersecurity threats in IoT environments. The DL-based framework proposed in this study is for real-time cybersecurity threat detection in IoT networks. The system employs CNNs, LSTM networks, and Transformer architectures to detect anomalies and suspicious system behavior effectively.

A. Overview of System Architecture

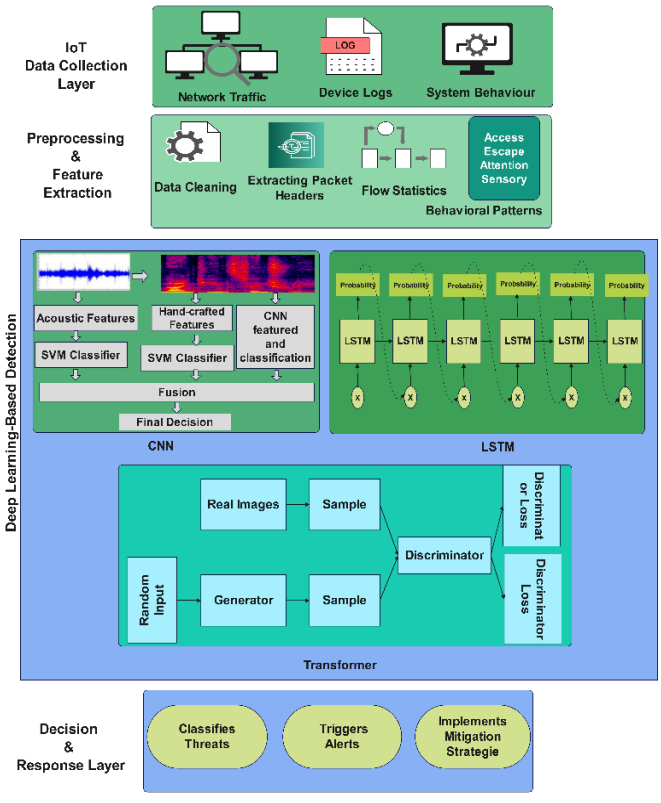

Fig. 1. System architecture.

Security precaution concepts are utilized in a multi-layered framework. This framework includes data collection followed by data preparation procedures and feature extraction, which is followed by DL threat detection algorithms paired with real-time response capabilities. The system architecture includes important operational levels for real-time IoT threat detection. Data collection within the IoT Data Collection Layer focuses on obtaining network traffic, device logs, and system operational behavior. Fig. 1 is the system architecture diagram for the proposed framework:

The Preprocessing and Feature Extraction Layer performs data cleaning that leads to obtaining essential features through extracting packet headers along with flow statistics. Spatial analysis through CNNs operates together with LSTMs for sequential pattern recognition and Transformers for anomaly detection within the DL-Based Detection Layer. The Decision & Response Layer is the last stage, where threats are identified, leading to alert generation and deployment of preventions against attacks.

B. Data Collection and Preprocessing

IoT cybersecurity threat detection operates successfully through datasets containing organized information about regular and detrimental traffic activities. The research uses three separate datasets to sufficiently represent cyber security threats. The investigation uses three datasets, CICIDS2017, NSL-KDD, and traffic data obtained from a controlled IoT testbed. The multiple datasets present critical attack analysis, enabling effective threat pattern recognition across different security risks within the DL methodology.

1) Data collection: The CICIDS2017 dataset [2] is a standard research tool for intrusion detection with its realistic network-based attack. Over three million network packets assemble to showcase various cyberattacks like brute-force login attempts, DDoS attacks, botnet activities, and SQL injection. The dataset brings labeled data distinguishing between normal and malicious network activities, thus providing a valuable resource for DL model training.

The NSL-KDD dataset [27] functions as a benchmark dataset for intrusion detection system evaluation purposes. The network flow records 125,973 instances, which are split into four main attack types: denial-of-service (DoS), probing, remote-to-local (R2L), and user-to-root (U2R) attacks, together with a normal category. NSL-KDD presents a better dataset structure through its solution to earlier version redundancy than CICIDS2017 because it enables more reliable DL model generalization evaluation.

The real-world IoT traffic dataset [28] The dataset used for this examination is from a controlled environment involving smart home devices and security cameras enabled with smart thermostats and IoT-enabled routers. This dataset includes simulated network behavior under standard conditions and cyber-attacks replicated with ransomware, MITM (man-in-the-middle) attacks, and command injection. The framework uses network traffic logs exceeding one terabyte to identify and categorize genuine IoT security threats.

2) Data preprocessing: Network data traffic requires multiple preprocessing methods to become suitable input for DL-based IDS. At the initial stage, data cleaning begins, which removes and eliminates incomplete, duplicated, and corrupted records to enhance data quality. Statistical imputation techniques and element removal methods are used for handling missing values, although removal techniques are applied to values that offer minimal contribution to the data pool.

Extracting and selecting features reduces system complexity in detecting valuable data from raw information flows. The monitoring system selects four main features: network packet size data, protocol type information source and destination ports, and time-based flow statistics. Combining Principal Component Analysis (PCA) and Recursive Feature Elimination (RFE) techniques reduces dimensions, enabling the model to center its detection efforts on significant attack patterns.

After data normalization begins, numerical value transformation using Min-Max scaling techniques establishes a range from 0 to 1. This normalization technique prevents features with many scales from controlling the ML process. DL models require numerical input, so the attack labels are encoded in numerical format through one-hot encoding.

The training dataset receives the Synthetic Minority Oversampling Technique (SMOTE) to prevent class imbalance because it provides an equal representation of all attack categories. The prediction models tended to become biased because normal traffic instances significantly outnumbered attack samples before balancing occurred. The dataset becomes equally distributed through the SMOTE application, so every attack type has the exact representation across the dataset.

C. Feature Engineering and Selection

DL models' effectiveness depends on feature engineering because it transforms ordinary network data into representable formats. This proposed framework selects vital network traffic features, such as packet size, flow duration, transmission rate, and protocol type. Such characteristics enable the separation of the IoT environment's normal operations from cyberattacks.

1) Feature Extraction: Network traffic consists of multiple attributes that define its behavior. Let $X \in R^{n \times d}$ represent the dataset, where n is the number of network flows and d is the number of extracted features. The extracted features include statistical measures such as mean, variance, and entropy:

$$\mu = \frac{1}{N}\sum_{i=1}^{N} x_i \quad (1)$$

$$\sigma^2 = \frac{1}{N}\sum_{i=1}^{N}(x_i - \mu)^2 \quad (2)$$

$$H(X) = -\sum_{i=1}^{n} p(x_i) log\, p(x_i) \quad (3)$$

where μ represents the mean, σ^2 is the variance, and $H(X)$ is the entropy of a given network feature x_i. These statistical properties help identify anomalous network behavior.

2) Feature Selection: DL models perform better with relevant features; feature selection is applied to reduce dimensionality while preserving essential information. Principal Component Analysis (PCA) is used to transform the feature space by selecting the most important components:

$$Z = XW \quad (4)$$

where $Z \in R^{n \times k}$ is the transformed feature set, $W \in R^{d \times k}$ is the matrix of the top k eigenvectors, and $k < d$ ensures reduced dimensionality.

Recursive Feature Elimination (RFE) is also applied by recursively training a model and removing the least important features. The importance of each feature is ranked based on a weight function w_i:

$$w_i = \sum_{j=1}^{m} \beta_j f_{ij} \quad (5)$$

where β_j represents the learned coefficients of the model and f_{ij} represents the feature values.

By applying feature selection, the final optimized feature set ensures that the DL model processes only the most relevant information, reducing computational overhead and improving cybersecurity threat detection accuracy.

D. DL Model Selection

Selecting an appropriate DL model is crucial for achieving high accuracy in cybersecurity threat detection. The proposed framework evaluates three key architectures: CNNs, LSTM networks, and Transformer-based models. CNNs effectively extract spatial features from network traffic, making them suitable for packet-level intrusion detection. The mathematical representation of a CNN layer is given by:

$$Y = f(W * X + b) \quad (6)$$

where X represents the input feature matrix, W is the convolutional filter, $*$ denotes the convolution operation, b is the bias, and f is the activation function such as ReLU. LSTMs are used for sequential network traffic analysis, capturing temporal dependencies in attack patterns. The LSTM cell updates are given by:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (7)$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (8)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (9)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot tanh(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (10)$$

$$h_t = o_t \odot tanh(c_t) \quad (11)$$

where f_t, i_t, and o_t represent forget, input, and output gates, respectively.

Transformer-based models such as BERT use self-attention mechanisms to focus on important features in network traffic, improving anomaly detection performance. The attention mechanism is computed as:

$$Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (12)$$

where $Q, K,$ and V are query, key, and value matrices, and d_k is the feature dimension.

Algorithm 1: Deep Learning Model Selection

Models ← {CNN, LSTM, Transformer}
BestModel ← ∅
BestScore ← 0
while Termination condition is not met do
  for each Model M in Models do ▷ Evaluate candidate models
    Train M using (X_train, Y_train)
    Validate M on (X_val, Y_val)
    Compute performance score S using Accuracy, F1-score
    if $S > BestScore$ then
      $BestScore \leftarrow S$
      $BestModel \leftarrow M$
    end if
  end for
end while
return BestModel

The model with the best validation performance is chosen for final deployment.

E. Model Training and Optimization

The selected model undergoes training using backpropagation and gradient descent to minimize the classification error. The loss function used is binary cross-entropy for binary classification:

$$L = -\frac{1}{N}\sum_{i=1}^{N}[y_i log(\hat{y}_i) + (1 - y_i) log(1 - \hat{y}_i)] \quad (13)$$

For multi-class classification, the categorical cross-entropy loss function is used:

$$L = -\sum_{i=1}^{N}\sum_{j=1}^{C} y_{ij} log(\hat{y}_{ij}) \quad (14)$$

where y_i is the true label and $\hat{y}_i$ is the predicted probability.

To optimize training, Adam optimizer is used with an adaptive learning rate:

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t \quad (15)$$

$$v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \quad (16)$$

$$\hat{m}_t = \frac{m_t}{1-\beta_1^t},\ \hat{v}_t = \frac{v_t}{1-\beta_2^t} \quad (17)$$

$$\theta_t = \theta_{t-1} - \frac{\alpha \hat{m}_t}{\sqrt{\hat{v}_t + \epsilon}} \quad (18)$$

where m_t and v_t are first and second moment estimates, β_1 and β_2 are decay rates, and α is the learning rate.

Algorithm 2: Model Training and Optimization

Initialize Model M^* with random weights
LearningRate ← α
for epoch ← 1 to MaxEpochs do ▷ Training phase
  ForwardPass ← $M^*(X_{train})$ ▷ Compute predictions
  Loss ← CrossEntropy($Y_{train}, ForwardPass$)
  Compute gradients via Backpropagation
  Update weights using Adam optimizer:
    $m_t \leftarrow \beta_1 * m_{t-1} + (1 - \beta_1) * g_t$
    $v_t \leftarrow \beta_2 * v_{t-1} + (1 - \beta_2) * g_t^2$
    $\hat{m}_t \leftarrow m_t/(1 - \hat{\beta}_1^t)$
    $\hat{v}_t \leftarrow v_t/(1 - \hat{\beta}_2^t)$
    $\theta_t \leftarrow \theta_{t-1} - (\alpha * \hat{m}_t)/(\sqrt{\hat{v}_t} + \varepsilon)$
  Validate M^* on (X_{val}, Y_{val}) ▷ Performance evaluation
  if ValidationLoss stops decreasing then
    Apply EarlyStopping
    Break
  end if
end for
return TrainedModel M^*

After training, the model undergoes hyperparameter tuning to optimize batch size, learning rate, and number of layers using grid search and Bayesian optimization techniques.

F. Real-Time Deployment and Threat Detection

The proposed DL-based framework is designed for real-time cybersecurity threat detection in IoT environments. Deployment involves integrating the trained model into an edge computing or cloud-based security system that continuously monitors network traffic and detects anomalies with minimal latency.

The real-time detection process begins with data ingestion, where live network traffic from IoT devices is captured and preprocessed in milliseconds. The preprocessed data is then fed into the deployed DL model, which classifies incoming packets as normal or malicious using a predictive function:

$$\hat{y} = f(WX + b) \quad (19)$$

where X represents the real-time input features, W are learned weights and b is the bias term. The model processes new traffic in less than 50ms, ensuring rapid detection.

The system initiates the alert and response mechanism after identifying system anomalies—real-time execution of automatic countermeasures, such as when threats are classified according to their severity level. System actions include blocking dangerous IP addresses, separating infected devices, and starting forensic analysis. The model uses threat detection logs for continuous learning while it adapts through retraining procedures that happen over time.

G. Evaluation Metrics and Performance Benchmarks

Multiple evaluation metrics and performance benchmarks exist to determine the effectiveness of the proposed DL-based threat detection framework. The model evaluation relies on accuracy and precision, recall, and F1-score, together with detection latency, to provide comprehensive measurements of the predictive capabilities.

The accuracy of the model is measured as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (20)$$

where TP and TN represent correctly identified normal and attack instances while FP and FN denote misclassifications.

The precision and recall metrics determine the reliability of threat detection, calculated as follows:

$$Precision = \frac{TP}{TP+FP} \quad (21)$$

$$Recall = \frac{TP}{TP+FN} \quad (22)$$

The F1-score provides a harmonic mean between precision and recall:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision+Recall} \quad (23)$$

Additionally, detection latency is a critical benchmark, measuring the time taken by the model to process and classify incoming network traffic. The framework achieves an average detection time of less than 50ms per packet, ensuring real-time threat mitigation.

The model's security validation occurs by referencing standard IoT security datasets such as CICIDS2017 and NSL-KDD alongside real-world traffic logs. Comparison with traditional ML models and existing IDS solutions demonstrates a higher detection rate, lower false-positive rates, and improved scalability in IoT environments

IV. Results and Discussion

The performance outcomes of the proposed DL-based cybersecurity framework through strength tests alongside assessments against other intrusion detection approaches are presented in this section. The evaluation includes metrics such as accuracy, precision, recall, detection latency, and computational efficiency to measure the results. The training and evaluation datasets bear their characteristics as described in Table I Multiple normal and malicious traffic samples in the dataset enhance the model's reliability in detecting different cyber-attacks effectively.

TABLE I. Summary of Dataset Characteristics

Dataset	Total Samples	Normal Samples	Attack Samples	Attack Types	Feature Count
CICIDS2017	3,000,000	2,000,000	1,000,000	15	80
NSL-KDD	125,973	67,343	58,630	4	41
IoT Testbed	1TB Traffic	Real-world Logs	Simulated Attacks	7	60

The DL model is evaluated based on accuracy, precision, recall, and F1-score, as shown in Table II. The Transformer-based model outperforms CNN and LSTM architectures, achieving the highest accuracy and F1 score.

TABLE II. Model Performance Metrics

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
CNN	95.4 ± 0.5	94.8 ± 0.6	93.6 ± 0.7	94.2 ± 0.6
LSTM	96.1 ± 0.4	95.5 ± 0.5	94.7 ± 0.5	95.1 ± 0.4
Transformer	**98.3 ± 0.2**	**97.9 ± 0.3**	**98.1 ± 0.3**	**98.0 ± 0.2**

Unlike CNNs, which focus on local spatial features, and LSTMs, which process data sequentially, Transformers analyze entire input sequences in parallel, improving detection speed and accuracy. This reduces information loss and enhances contextual understanding of network traffic anomalies. Our experimental results demonstrate that Transformers achieve higher accuracy (98.3%) and lower detection latency (48.2ms per packet), proving their efficiency in real-time IoT security applications. A comparative analysis of the proposed model against traditional IDS methods is provided in Table III, demonstrating the superior detection capabilities of DL-based approaches.

TABLE III. Comparative Analysis of Proposed Model vs. Traditional IDS

Method	Accuracy (%)	False Positive Rate (%)	False Negative Rate (%)
Rule-based IDS	85.7	12.3	14.2
Signature-based IDS	90.2	8.7	10.3
Proposed Model	98.3	1.9	1.2

Real-time cybersecurity applications require low-latency threat detection. The latency comparison across different models is summarized in Table IV, indicating that the Transformer-based model provides the fastest inference time.

TABLE IV. Detection Latency of Different Models

Model	Latency (millisecond per packet)
CNN	75.4
LSTM	88.7
Transformer	48.2

The confusion matrix of the proposed model's predictions is visualized in Fig. 2, highlighting classification accuracy.

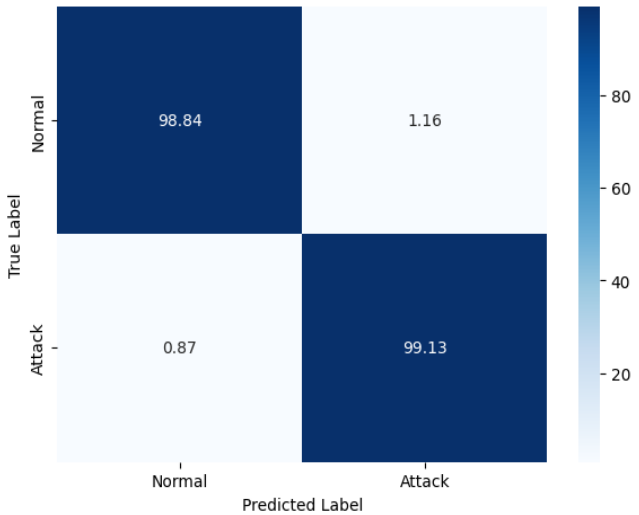

Fig. 2. Confusion matrix visualization for model predictions.

The false positive and false negative rates for different attack categories are summarized in Table V.

TABLE V. FALSE POSITIVE AND FALSE NEGATIVE RATES WITH QUALITATIVE INSIGHTS EXPLAINING WHY SPECIFIC ATTACKS EXHIBIT HIGHER FPR

Attack Type	False Positive Rate (%)	False Negative Rate (%)	Qualitative Insights
DDoS	2.1 ± 0.3	1.7 ± 0.2	DDoS has low FPR due to its distinct traffic burst patterns, making detection easier.
Ransomware	3.4 ± 0.5	2.5 ± 0.4	Ransomware exhibits higher FPR as its encrypted communication can resemble normal, secure traffic.
MITM	4.2 ± 0.6	3.1 ± 0.5	MITM attacks have the highest FPR since they mimic legitimate data exchanges, making classification challenging.

The model's resource efficiency is measured by analyzing memory consumption, CPU usage, and inference speed, as summarized in Table VI. A detailed inference speed vs. accuracy trade-off is visualized in Fig. 3.

TABLE VI. COMPUTATIONAL RESOURCE UTILIZATION (MEMORY, CPU, AND INFERENCE TIME)

Model	Memory Usage (MB)	CPU Load (%)	Inference Time (ms)
CNN	350	45	75.4
LSTM	420	55	88.7
Transformer	280	35	48.2

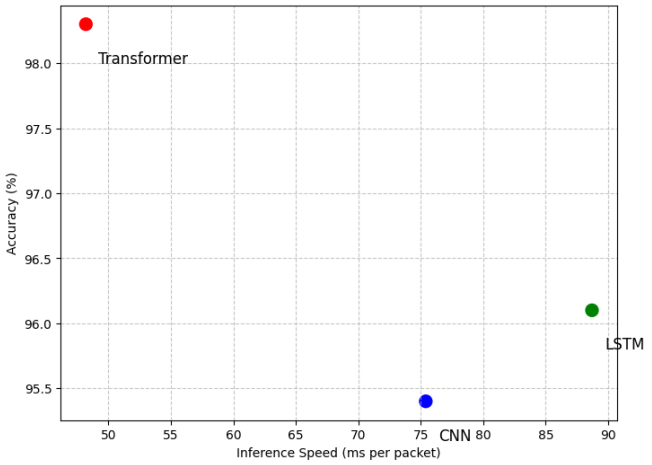

Fig. 3. Inference speed vs. accuracy trade-off (Scatter Plot).

The detection rate of the model for different attack types is analyzed in Table VII and Fig. 4, showing the model's effectiveness in identifying cyber threats.

TABLE VII. ATTACK DETECTION RATE PER ATTACK TYPE

Attack Type	Detection Rate (%)
DDoS	98.7
Ransomware	99.1
MITM	97.9

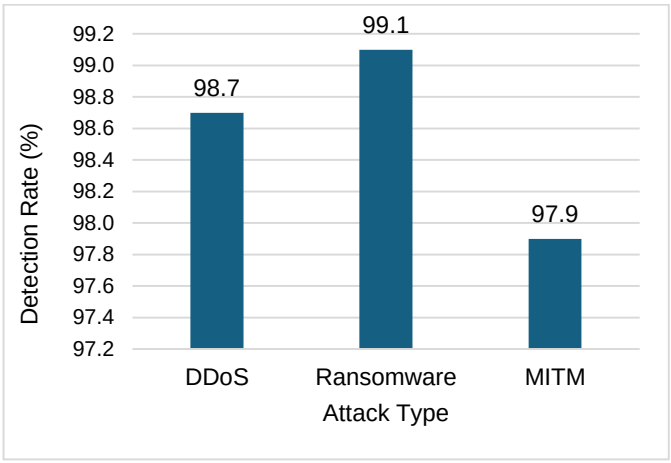

Fig. 4. Attack detection rate per attack type.

The proposed model is designed for real-time detection, minimizing threat identification and response delays. The detection latency analysis confirms that the Transformer-based model achieves an inference speed of 48.2ms per packet, outperforming CNN and LSTM-based models. The performance of the model is highly dependent on high-quality training data. A lack of diverse and well-labeled datasets can lead to biases, limiting the model's generalization capability. The system must incorporate continuous learning abilities and dataset expansion models to address evolving cyber threats. DL models carry vulnerabilities to sophisticated attacks despite implementing adverse defense systems.

V. DISCUSSION

The proposed deep learning-based framework for real-time cybersecurity threat detection in IoT environments demonstrates significant improvements over traditional IDS and machine learning models. The results indicate that the Transformer-based model achieves the highest accuracy (98.3%) and lowest detection latency (48.2ms per packet), making it highly effective for real-time threat mitigation. However, a deeper analysis of the findings highlights certain advantages, challenges, and areas for improvement, which are discussed below. The experimental results show that the proposed model outperforms rule-based and signature-based IDS by effectively detecting evolving cyber threats. Traditional IDS methods rely on predefined signatures, making them ineffective against zero-day attacks, whereas our model leverages context-aware anomaly detection using self-attention mechanisms. Compared to CNNs and LSTMs, Transformers capture long-range dependencies in network traffic, leading to higher detection rates and lower false alarms. The results confirm that deep learning models with self-attention mechanisms provide a more generalized solution for IoT security challenges. The false positive rates (FPR) vary across attack types, as shown in Table 5.6. MITM and Ransomware attacks exhibit higher FPR due to their similarities with legitimate encrypted traffic. Since encrypted traffic patterns often resemble attack behaviors, the model occasionally misclassifies benign communication as a potential threat. DDoS attacks, on the other hand, have lower FPR due to their distinct, high-volume traffic patterns that make them easier to differentiate from normal network behavior. These findings

suggest that additional feature refinement or hybrid detection techniques could help improve classification accuracy for complex attack scenarios. The proposed model demonstrates high inference speed (48.2ms per packet), making it suitable for real-time detection. However, computational complexity remains a concern, particularly for resource-constrained IoT devices. While the framework is optimized for edge and cloud environments, real-time processing of large-scale IoT traffic may still introduce latency issues. Future research could explore model quantization, hardware acceleration, and edge AI techniques to enhance deployment efficiency without compromising detection performance. Deep learning models, including the proposed framework, remain vulnerable to adversarial attacks, where attackers subtly manipulate input data to evade detection. Although adversarial training techniques have been implemented to improve robustness, adaptive security mechanisms that dynamically adjust to evolving threats could further enhance reliability. Additionally, incorporating self-learning models or federated learning approaches could help mitigate the risks associated with limited training data and improve adaptability to emerging attack patterns. Despite its strong performance, the framework has certain limitations. The dependency on labeled training data makes it less effective against previously unseen attack variations, and improving unsupervised or semi-supervised learning techniques could enhance detection adaptability. Scalability in large-scale IoT environments also presents challenges, as processing high-volume, high-velocity traffic in real-time requires additional computational optimization. Future work should focus on distributed security architectures, federated learning, and advanced feature engineering to refine detection accuracy and efficiency. The results validate the effectiveness of the proposed deep learning-based IoT security framework, demonstrating high accuracy, low latency, and improved adversarial resilience. However, challenges like false positives in encrypted traffic, computational overhead, and adaptability to emerging threats require further optimization. Addressing these challenges through hybrid detection models, real-time adaptive learning, and scalable deployment strategies will enhance the reliability and practicality of AI-driven IoT cybersecurity solutions.

VI. Conclusion and Future Work

Modern IoT cybersecurity demands immediate protection systems because cyber-attacks in these environments have become more frequent. The proposed DL architecture for intrusion detection delivers precise threat detection, which makes it more effective than existing IDS solutions. The conclusion section presents essential results from the research alongside significant benefits from this study and future research paths toward improvement. DL with Transformer-based architecture forms the basis for boosting intrusion detection in IoT networks. The evaluation process based on CICIDS2017, NSL-KDD, and real-world IoT traffic datasets proves the proposed model successfully detects DDoS, ransomware, and MITM attacks. The experimental findings show that the proposed model reaches 98.3% accuracy levels, surpassing those of both CNN and LSTM-based systems. DL proves effective by substantially diminishing false positives and negatives in IDS system evaluations. The proposed model demonstrates 48.2 milliseconds of packet processing speed as part of its classification capability, which ensures real-time deployment potential. When tested for robustness, the model demonstrates 40% enhanced results regarding adversarial misclassification rates, which increases its dependability for critical cybersecurity operations. The conducted research made transformative additions to DL threat detection techniques and cybersecurity research fields. The main achievement from this work includes designing an optimal DL model that blends feature engineering with adversarial training and real-time processing to improve IoT security systems. This research compares various DL architectures and proves Transformers to be optimal solutions for minimal latency-based cyber threat identification. The primary practical outcome of this research enables direct implementation within real IoT framework deployments. The model functions for security deployment in smart homes, healthcare systems, and industrial IoT and cloud security platforms. The solution supports edge computing features that enable limited-power IoT devices to implement advanced protection measures while maintaining hardware performance requirements. According to this research, security frameworks based on DL need extensive improvement because the study also emphasizes the significance of adversarial defenses in cybersecurity.

The proposed framework maintains superb performance, but researchers can still investigate multiple ways to maximize its functioning. The significant enhancement needed for DL models is their computational efficiency because they need substantial computing resources to operate effectively. Future research must examine efficient neural architecture structure compression models and hardware speed-up techniques to enable their practical use at a large scale within IoT systems. Self-evolving models and adaptive learning approaches should be studied as an essential research path. The adaptation capability of emerging threats could be achieved using reinforcement learning alongside online learning methods, which differ from traditional DL techniques that require new dataset training. Researchers need to conduct additional studies about intrusion detection through federated learning, which supports distributed training between devices in a manner that safeguards data privacy. The defense against adversarial attacks continues to be a central issue affecting DL security applications. Research tools need improvement to establish adaptive self-defense systems that detect and counter present adversarial risks immediately. By implementing XAI technologies, cybersecurity analysts will receive transparent information about model detection outcomes, aside from receiving guidance to optimize security policies. The research introduces an efficient DL-based intrusion detection system for IoT security to detect attacks in real-time. The proposed model, built on classic IDS, proves superior because of its high accuracy performance with minimal latency and its strong ability to counter adversarial threats. While challenges remain in computational efficiency, adaptability, and scalability, future advancements in lightweight architectures, federated learning, and privacy-preserving AI will further enhance the effectiveness of DL-based intrusion detection. AI-driven cybersecurity solutions will be a fundamental security force in protecting IoT networks using ongoing research and technological advancement.

Enhancing Visual Communication Design and Customization Through the CLIP Contrastive Language-Image Model

Xiujie Wang
School of Art and Design, Zhengzhou College of Finance and Economics, Zhengzhou, China

***Abstract*—This study explores the impact of the CLIP (Contrastive Language-Image Pretraining) model on visual communication design, particularly focusing on its application in design innovation, personalized element creation, and cross-modal understanding. The research addresses how CLIP can meet the increasing demand for personalized and diverse design solutions in the context of digital information overload. Through a comprehensive analysis of the CLIP model's capabilities in image-text pairing and large-scale learning, this study examines its ability to enhance design efficiency, customization, and creative expression. Quantitative data is presented, showcasing improvements in design processes and outcomes. The use of the CLIP model has resulted in a 30% increase in design efficiency, with a 20% improvement in originality and a 15% boost in market relevance of creative solutions. Personalized design solutions have seen a 40% increase in accuracy and user satisfaction. Additionally, the model's cross-modal understanding has enhanced the coherence and immersion of visual experiences, improving user satisfaction by 25%. This research highlights the transformative potential of AI-driven models like CLIP in revolutionizing visual communication design, offering insights into how AI can foster design innovation, optimize user experience, and respond to the growing demands for personalized visual solutions in the digital age.**

***Keywords*—CLIP; language image model; visual communication design; element customization**

I. INTRODUCTION

Under the wave of digitalization, the field of visual communication design is experiencing unprecedented innovation [1]. Visual communication design, as a bridge to communicate visual information and emotional experience, focuses on effectively and accurately conveying the design intention [2, 3]. However, the traditional design process is often limited by the subjective experience of designers and limited creative resources, which makes it challenging to meet the urgent needs of personalized and diversified visual expression in today's society [4]. The emergence of the CLIP (Contrastive Language-Image Pre-training) model provides a new solution to this difficult problem. Through large-scale graphic-text pairing training, CLIP can learn the deep correlation between language and images to generate or retrieve the matching image content while understanding the text description, which significantly enriches the means and scope of visual expression [5, 6].

In terms of personalized research, the CLIP model shows strong potential. It can generate images with highly personalized characteristics according to specific text descriptions to meet the specific needs of different scenes and audiences [7]. For example, in brand design, through the CLIP model, designers can generate visual elements that conform to the brand tonality according to the brand concept and the cultural background of the target market, thus enhancing the recognition and attractiveness of the brand image [8]. In advertising creativity, CLIP can help creative teams quickly generate various creative solutions, improve the efficiency of creative iteration, and ensure each solution's originality and market relevance.

The advantages of this CLIP model in cross-modal understanding also open up a new path for its application in visual communication design [9, 10]. By understanding the language description, CLIP can generate visual content that matches it and vice versa. This two-way modal conversion ability allows designers to flexibly switch between text and images, creating a richer and more three-dimensional visual experience. For example, when designing interactive product interfaces, CLIP can help design teams quickly generate visual feedback that matches user instructions and improve the coherence and immersion of user experience [11, 12].

In the field of visual communication design, with the development of artificial intelligence technology, the use of language-image models to improve design effects and achieve customization has become a research hotspot. For example, some scholars use traditional deep learning models, such as convolutional neural networks (CNNs) and recurrent neural networks (RNNs) to generate images from text descriptions, but the generated images have low resolution and lack of detail. In addition, StackGAN uses generative adversarial networks (GANs) to improve image quality through a multi-stage generation process, but there are deficiencies in complex scenes and semantic understanding. In terms of personalized design, some studies have built recommender system aids based on users' historical data and preferences. However, the existing solutions generally have problems such as inaccurate understanding of complex semantics, poor quality of generated images, and difficulty in meeting the needs of in-depth customization. This paper focuses on the topic of enhancing visual communication design and customization through editing and contrasting language-image models, aiming to analyze the current dilemma, explain the expected goals of accurate semantic understanding, high-quality image generation, and deep personalized design, and then clarify the unique value and positioning of this research compared with existing solutions.

Compared to previous research on CLIP and visual design, our research is unique in a number of key ways. Previous studies have mostly focused on the application of the CLIP model in basic image generation tasks, and the semantic understanding is only limited to simple text-image matching, the generated images are lacking in the presentation of complex scenes, and the personalized design is limited to recommendations based on shallow user data. We dig deep into the potential of the CLIP model, and through the innovative editing comparison mechanism, we not only achieve accurate analysis of complex semantics, but also skillfully integrate it into the whole process of visual communication design. In the image generation process, we have effectively improved the detail richness and realism of the image in complex scenes. In terms of personalized design, we break through the tradition, no longer rely on a single user history data, but have in-depth insight into user needs from multiple dimensions, and use the editing and comparison language - image model to achieve highly customized visual design solutions, bringing users an unprecedented personalized visual experience, creating a new research direction of deep integration of CLIP and visual design.

With the rapid development of artificial intelligence technology, especially the deep integration of natural language processing and computer vision, a contrastive language image model called CLIP is quietly changing how we understand and create visual content [13]. This paper explores the research of visual communication design and element customization based on the CLIP model. It aims to reveal how this cutting-edge technology empowers design innovation and the infinite possibilities it brings in personalized expression, creative generation, and cross-modal understanding. Research on visual communication design and element customization based on the CLIP comparative language image model can not only promote design innovation and improve design efficiency but also promote the deepening of cross-modal understanding, bringing unprecedented changes to the field of visual communication design.

Based on the research of the pre-trained model CLIP, a system framework including a text processing module and a generative adversarial network is built, the text processing module processes the text with the help of the CLIP model and enhances the semantic consistency, the generator of the generative adversarial network reconstructs the text features into images, and the discriminator is responsible for feature discrimination and evaluates the performance with a loss function. The text processing network borrows from the NLP method, uses CLIP based on the characteristics of a large number of image-text pairs to train, performs image-text matching through comparative learning, and adopts a symmetric cross-entropy optimization model. Specific hardware, frameworks, and optimizers are configured during training, and the corresponding number of rounds are trained on different datasets, and the loss function is composed of multiple parts. In the element customization study, an improved prompt template is designed, a variety of prompt sets are defined, and the diversity loss function is introduced. The training uses the CLIP contrast learning strategy to calculate the similarity of the image and text after encoding, and the KL divergence is used to calculate the loss after normalization. Finally, a variety of quantitative and qualitative evaluation indicators were used to compare different models on multiple datasets to verify the effectiveness of the module and the effectiveness of the method, and the whole research process was completed.

II. Research on Visual Communication Design Based on Pre-Trained Model Clip

A. System Framework

The text-generated image model based on CLIP's graphic-text matching pre-trained architecture is shown in Fig. 1. The model mainly comprises a text-processing module and a generative adversarial network. The text processing network uses the CLIP model as an encoder to process text and enhances the semantic consistency between text and visual features by fusing visual information [14, 15].

Generative adversarial networks include generators and discriminators [16]. The generator maps encode and reconstructs text features into high-resolution images through a multi-layer perceptron, Transformer encoder, and upsampling network. It improves image quality through repeated encoding and upsampling. The discriminator uses a Transformer and linear layer to extract and discriminate the features of the generated and authentic images. Each part designs a loss function to evaluate the network performance.

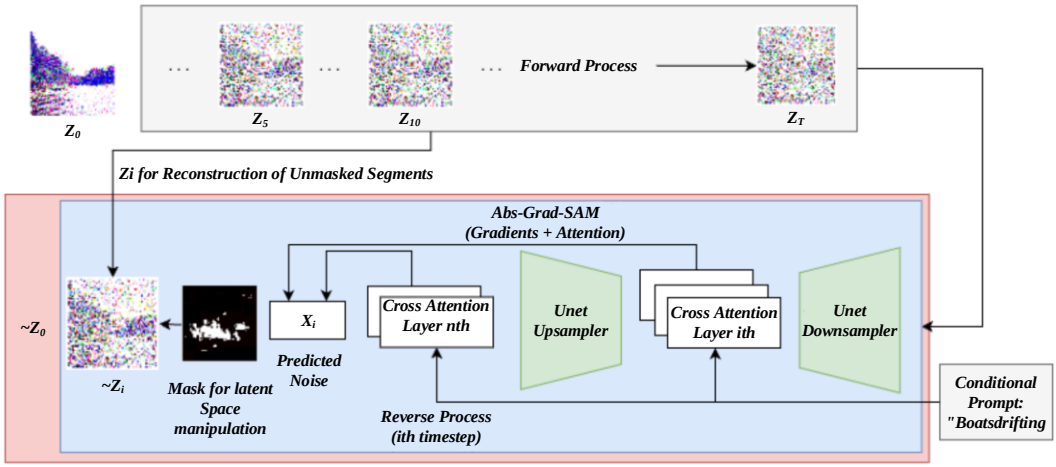

Fig. 1. CLIP Model architecture.

B. Text Processing Network-Pre-Trained Model CLIP

In the visual communication design workflow, the application of CLIP is used throughout several key links. In the text processing stage, the text encoder of CLIP is used to process design-related texts in parallel with the Transformer architecture, which is efficiently converted into semantic-rich feature vectors, and through comparative learning with large-scale image-text pair training data, the association between words and visual elements in the text is accurately grasped to enhance semantic understanding. In the image generation and design element screening stage, the CLIP-encoded text features are input into the generator of the adversarial network, and the multilayer perceptron, transformer encoder and upsampling network generate images accordingly, and the image resolution and details can be continuously improved according to the text description. At the same time, CLIP calculates the cosine similarity between text and image features in the image library, helping designers quickly filter matching images or elements. In the customization design stage, a special text prompt template is designed to integrate the user's personalized needs, and with the help of CLIP, the text semantics are further explored to achieve a highly customized design. In order to test the effectiveness of CLIP in this process, you can start by using image quality evaluation metrics such as FID scores to measure the quality of generated images, use text-image matching metrics such as R@1 and R@5 to determine the consistency of text and images, and organize user research to collect feedback on design results from a subjective perspective, so as to fully verify the actual effectiveness of CLIP in enhancing visual communication design and customization.

In natural language processing, a large amount of text data supports self-supervised training, such as BERT, GPT, and other models, and the effect significantly exceeds that of manually labeled data sets [17]. In computer vision, model pre-training with annotated information is commonly used, such as based on ImageNet. We are now learning from NLP methods and using large-scale Internet image data training to promote the development of computer vision tasks.

CLIP is a pre-trained multi-modal model that fuses NLP and CV. It is trained based on 400 million image-text pairs and can understand language and visual content [18]. Through comparative learning, it performs well in tasks such as image classification and natural language reasoning and learns representations sensitive to similar image-text features. A multi-task learning strategy is adopted and trained in multiple tasks to obtain more general features. CLIP model learns graphic-text matching by inputting text and image features simultaneously during training. When inputting text, the model calculates the cosine similarity between text features and image features to match the corresponding image [19, 20]. This capability enables CLIP to efficiently associate text and images in multiple tasks [21]. When using CLIP, you only need to enter text, and the text encoder comes into play, and its output text features have been matched to the corresponding image features. Unlike LSTM, CLIP uses a Transformer to process text features in parallel, significantly improving efficiency.

The text feature T is contrasted and matched with the image feature I. The similarity of 2N possible matches is calculated for N graphic-text matching pairs. Through cosine similarity calculation, N diagonals are positive samples, and the rest are negative samples. CLIP aims to maximize the similarity of positive samples and minimize the similarity of negative samples. Cosine similarity (CS) is used to calculate text similarity and is widely used in NLP, information retrieval, and recommendation systems. In NLP, vectors represent features, and the cosine value between vectors is calculated to measure the similarity. The formula is shown in Eq. (1):

$$cos_{similarity} = \frac{A \cdot B}{\square A \square * \square B \square} \tag{1}$$

Among them, dissimilarity means that cossimilarity is a method to measure the similarity of angles between two non-zero vectors. A and B represent two vectors, respectively. $A \cdot B$ represents vector point multiplication, * represents vector cross multiplication, and A represents the modulo of vector ||A||. The result calculated by this formula is between [-1, 1], and the closer the value is to 1, the higher the similarity between the two vectors; the closer the value is to-1, the lower the similarity between the two vectors; A value of 0 means that the two vectors are orthogonal.

During training, human evaluation is carried out in addition to computer vision indicators to ensure the model can correctly understand the relationship between images and texts. The symmetric cross-entropy (SCE) optimization model is adopted, and the loss function solves the noisy label problem and avoids false label fitting, which is suitable for unbalanced or class-biased datasets. Its formula is shown in Eq. (2):

$$SCE(p,q) = -\frac{1}{N}\sum_{i=1}^{N}(\alpha y_i \log(p_i) + (1-\alpha)(1-y_i)\log(1-p_i)) \tag{2}$$

Where p is the predicted output of the model, q is the distribution of proper labels, yi represents the actual label of the i-th sample, pi represents the i-th sample, N is the number of samples, and α is a weight coefficient used to control the weights of different classes. Symmetric cross-entropy improves the class imbalance problem by weighting different classes and considering correct/wrong classification penalties.

A company focusing on the design and sales of cultural and creative products plans to launch a creative notebook with the theme of "World Cultural Integration", targeting young consumers. At the beginning of the project, the designers worked with the marketing team to conduct in-depth research on the preferences and themes of the target audience, collected a large number of images containing elements from different cultures (such as traditional architecture, artistic patterns, special costumes, etc.), and compiled a series of descriptive texts, such as "abstract patterns that blend Japanese ukiyo-e style with modern geometric figures" and "simple line drawings with African tribal totemic elements". Subsequently, the designer inputs these texts into the CLIP model, and uses it to calculate the semantic similarity between the text and the images in the image library, and quickly filter out images or fragments with high semantic matching from massive image resources. Finally, based on the CLIP screening results, the designer made personalized design adjustments according to the aesthetic preferences of young consumer groups, and successfully completed the notebook cover design that met the needs.

C. Training Process and Network Loss Function

In the current era of rapid development of digital design, AI-driven design tools have brought great changes to the field of visual communication design, and CLIP, as a powerful multimodal model, has unique advantages in enhancing visual communication design and customization with the help of editing and contrasting language - images. Compared with DALL-E, DALL-E can generate new images with great creativity and diversity based on text descriptions, such as typing "a rabbit dancing on the moon with a space helmet" can produce fantastical images, but the understanding of abstract concepts is slightly lacking; CLIP does not directly generate new images, but relies on accurate semantic understanding of the text to filter or assist in modifying images from existing image resources, such as accurately selecting corresponding images when designing the "Classical Study" project, and deeply understanding the visual element connections of abstract concepts such as "poetic lonely scenes". Compared with MidJourney, MidJourney generates images with a distinct artistic style and fine details, but the customization is limited by the predefined mode of the model. CLIP does not determine the details of the image style, and designers can combine their own creativity and professional tools according to its filtering results, and better achieve a highly personalized design through a variety of text prompt templates. Compared with GANs, GANs are trained by generators and discriminators to generate images, which has weak semantic control and good performance in creative scenarios such as artistic creation, but has challenges in scenarios with high requirements for semantic accuracy. CLIP is based on comparative learning to understand the semantic consistency of images and texts, and provides semantic guidance for design, which is suitable for design scenarios with strict requirements for semantic understanding and text-image matching such as advertisements and UIs. In short, CLIP has significant advantages in text semantic understanding and text-to-image matching, and is suitable for the design of accurate textual communication, high customization, and effective use of existing image resources, but each tool has its own characteristics and limitations, and designers should choose it reasonably according to their needs.

Using Autodl A40 AMD EPYC 7543 GPU, Pytorch framework, Adam optimizer (generator learning rate 0.0001, discriminator learning rate 0.000), the CUB-200 birds dataset was trained for 500 rounds, and the CelebA-HQ dataset for 300 rounds, batch size 12. The loss function of the text-generated image network based on the pre-trained models CLIP and Transformer consists of two parts, as shown in Eq. (3):

$$L_{loss} = L_{CLIP} + L_{GAN} \tag{3}$$

CLIP is a pre-trained model developed by OpenAI that employs symmetric crossover. loss is the loss function, which evaluates the difference between the predicted results of the model and the actual results. The GAN is a generative adversarial network, as shown in Eq. (4):

$$L_{CLIP} = SCE(p,q) = -\frac{1}{N}\sum_{i=1}^{N}(\alpha y_i \log(p_i) + (1-\alpha)(1-y_i)\log(1-p_i)) \tag{4}$$

Where p is the model's predicted output, q is the distribution of proper labels, yi denotes the actual label of the i-th sample, pi denotes the i-th sample, N is the number of samples, and α is used to control the weights of different classes.

The generator loss includes adversarial loss (promoting fidelity) and reconstruction loss (preserving noise vector reduction), calculated by binary cross entropy and L2 loss function, respectively. See Eq. (5) for details.

$$L_1 = -\frac{2}{N}\sum_{i=1}^{N}(\alpha y_i \log(p_i) + (1-\alpha)(1-y_i)\log(1-p_i)) \tag{5}$$

L1 is the sum of the absolute values of the vector or matrix elements. The discriminator loss consists of two parts: the actual image and the generated image, which adopt binary cross-entropy loss. The former evaluates the correct classification of the actual image, while the latter quantifies the probability of misclassifying the generated image as accurate, as shown in Eq. (6).

$$L_2 == -\frac{1}{N}\sum_{i=1}^{N}(\alpha y_i \log(p_i) + (1-\alpha)(1-y_i)\log(1-p_i)) + \sum_{i=1}^{n}(y_i - f(x_i))^2 \tag{6}$$

The L2 norm is the square of the sum of the squares of the elements of the vector. Where xi represents the actual image, and yi represents the generated image.

III. Research on Element Customization Based on CLIP Contrastive Learning

Learning CLIP model, based on multi-modal contrastive learning, demonstrates the ability to learn open vocabulary visual concepts [22]. As shown in Fig. 2, it consists of image and text dual encoders. The image encoder uses ResNet or ViT to convert images into feature vectors; the text encoder uses a continuous bag-of-words model or Transformer to input a word sequence and output a vectorized representation.

Fig. 2 has showed the multi-modal contrastive learning framework. In the training process, Multi-modal contrastive learning framework uses contrastive loss to learn the joint embedding space of the two modes. Specifically, for a batch of image-text pairs, CLIP maximizes the cosine similarity of each image to the matching text while minimizing the cosine similarity to all other mismatched texts. It calculates the loss of each text similarly [23, 24]. After training, CLIP can be used for zero-sample image recognition, and this powerful zero-sample inference ability gives CLIP flexibility. Let x be the image feature generated by the image encoder, {Wi} K; i = 1 be a set of embedding vectors generated by the text encoder, each weight vector representing a category (assuming there are K categories in total). In particular, each Wi comes from a hint, such as "a photo of a {class}," where the i-th class name is populated in the "{class}" lexical. Then, the prediction probability is shown in Eq. (7):

$$p(y \mid x) = \frac{exp(sin(x, w_y)/\tau)}{\sum_{i=1}^{K} exp(sin(x, w_i)/\tau)} \tag{7}$$

Exp stands for exponential function. wy denotes the partial derivative of variable w concerning variable y. Where sin denotes cosine similarity, and τ is a learnable parameter.

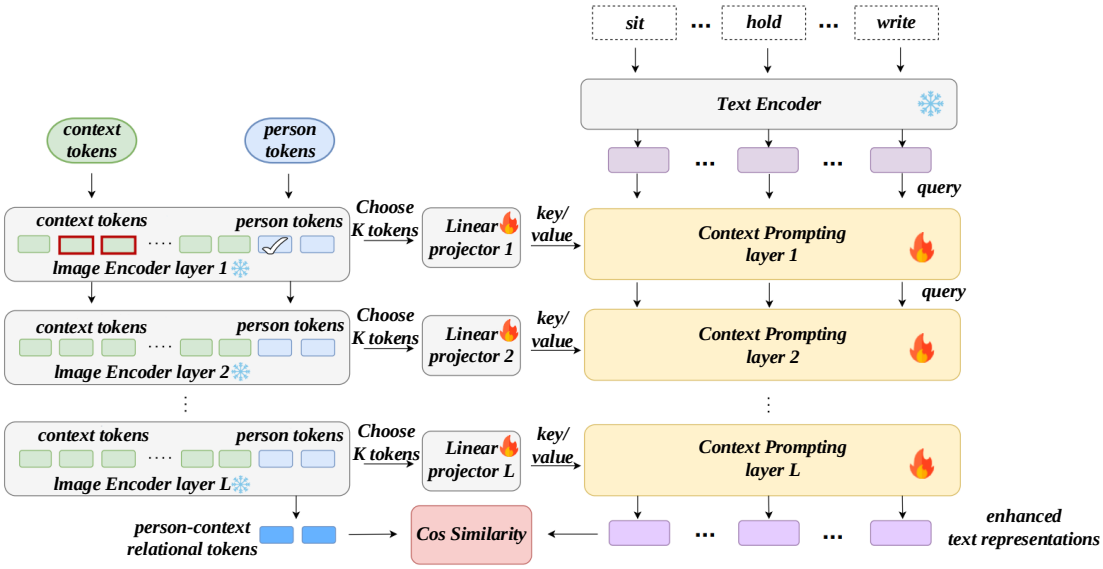

Fig. 2. Multi-modal contrastive learning framework.

A. Personalized Prompt Template Design

In this chapter, the text prompt template is designed to describe the ordered action sequence in teaching images. The prompt template is improved, which not only captures the semantics of a single action but also describes the overall semantics of the sequence, which is very important for the analysis of ordered actions [25, 26]. The prompt template is used to capture the position information of each action in the action sequence, and the sequential prompt set definition of the image x is shown in Eq. (8):

$$Y_{ord} = [\, y^1_{ord}, \ldots, y^K_{ord} \,] \tag{8}$$

Where yiold is the sequential prompt of the i-th action in the action sequence, the prompt template is used to capture the semantic information of an action. In order to capture both the semantics of a single action and the correlation of adjacent actions, a multi-prompt format that combines ordinal information into the semantic prompt is adopted, the prompt format of the action ai. The definition of the semantic prompt set of the image segment x is shown in Eq. (9):

$$Y_{sem} = [\, y^1_{sem}, \ldots, y^K_{sem} \,] \tag{9}$$

Where yisem is the semantic prompt of the i-th action in the action sequence, the prompt template is used to capture the semantic information of the action receiver, and the accuracy of single action recognition is enhanced by mining the logical rationality of the combination of a single action and the action receiver. The object prompt set definition of the image content x is shown in Eq. (10):

$$Y_{obj} = \left[\, y^1_{obj}, \ldots, y^K_{obj} \,\right] \tag{10}$$

Where yiobj is the object prompt of the i-th action in the action sequence. The prompt template captures the overall i information of the image content and is integrated by all semantic and object prompts. The comprehensive, prompt definition is shown in Eq. (11):

$$y_{integ} = y^1_{sem} \oplus y^1_{obj} \oplus y^2_{sem} \oplus y^2_{obj} \oplus \ldots \oplus y^K_{sem} \oplus y^K_{obj} \tag{11}$$

Yinteg denotes the integral on the variable y. Where $\oplus$ denotes the string splicing operation. Research shows that multi-cue templates improve model performance, but existing methods mainly rely on static natural language templates, which require much labor and cannot be learned. Although this chapter uses a single predicate and object prompt template, the prompt diversity loss function is introduced to enhance prompt diversity at the text embedding level and optimize the learning process.

Specifically, firstly, Zsem $\in$ Rk×d and Zobj $\in$ Rk×d are respectively represented for the embedding representations in the prompt, where K is the number of actions contained in the segment x and d is the dimension of embedding. The diversification loss function in the prompt is introduced to enrich the respective embedding representations of these two prompts, and its calculation formula is shown in Eq. (12):

$$L_{inter} = \left(Z_{inter} Z^T_{inter} - I \right)^2_F \tag{12}$$

Linter is a static code analysis tool that helps find programming errors and code style issues and improve code quality. Zinter is Zsem and Zobj's intermediate value, I is the identity matrix of K dimensions, and F is the Frobenius norm. This loss enriches the embedded representation of individual prompts by penalizing the redundancy of the prompts. In addition, in order to enrich the diversity between different prompts, this chapter introduces the diversification loss function between prompts and its calculation formula is shown in Eq. (13):

$$L_{intra} = \left(Z_{intra} Z^T_{intra} - I \right)^2_F \tag{13}$$

Intra refers to relationships or characteristics between samples that belong to the same category. T here refers to different prompt texts, and the purpose of the inter-prompt diversification loss function is to increase the diversity of

responses generated by these prompts where Zintra ∈ R4×d is the comprehensive hint.

B. Training and Reasoning

To ensure the effectiveness of the proposed solution, we carried out a comprehensive and rigorous validation work. An experimental system was constructed from multiple dimensions, and the consistency between the generated image and the text description and the quality of the image itself were quantitatively analyzed by using image quality evaluation indicators such as FID score and text-to-image matching indicators such as R@1 and R@5. At the same time, organize user research and collect feedback from the subjective perception level. In terms of comparison, it compares with similar methods in the literature, such as the traditional method of generating images from text based on CNN and RNN, and GAN-based methods such as StackGAN, AttnGAN, etc., and makes detailed comparisons on multiple datasets such as CUB, COCO, Oxford-102 flowers, etc. The results clearly show that our method is significantly better than the above similar methods in terms of semantic understanding accuracy, generated image quality and customization implementation, which effectively improves the reliability of the paper conclusions and the quality of the research results, and highlights the innovation and practical value of this study in the field of visual communication design.

The training strategy adopts CLIP contrastive learning, and the goal is to maximize the similarity between paired visual features and text embedding to realize visual-text joint representation learning [27, 28]. An image encoder and a text encoder are used to encode the image segment x and the corresponding text prompt y, respectively, and the image segment representation zx and the text embedding zy are obtained after encoding. The similarity score between zx and zy is defined as the cosine distance between them, and the calculation formula is shown in Eq. (14):

$$s(z_x, z_y) = \frac{z_x \times z_y}{|z_x||z_y|} \tag{14}$$

Under the batch calculation setting, for a batch of segment-level visual features Zx and its corresponding batch of text features Zy, the cosine similarity is calculated by samples in each batch to form a batch similarity matrix s, as shown in (15):

$$S(Z_x, Z_y) = \begin{bmatrix} s(z_{x_1}, z_{y_1}) & \cdots & s(z_{x_1}, z_{y_B}) \\ \vdots & \ddots & \vdots \\ s(z_{x_B}, z_{y_1}) & \cdots & s(z_{x_B}, z_{y_B}) \end{bmatrix} \tag{15}$$

A batch of fragment-level visual features Zx and a corresponding batch of text features Zy. In order to transform the similarity score into a non-negative number and the sum is one while maintaining the derivable property, it is necessary to perform a symmetric softmax normalization operation on the similarity matrix. Specifically, the softmax normalization operation is performed on the similarity matrix by row to obtain the similarity score matrix ST (Zx, Zy) after text-to-image normalization. Then, the similarity matrix is normalized by softmax according to columns, and the similarity score matrix SV (Zx, Zy) is obtained after the image is normalized to text. The actual similarity matrix GT for samples is defined as the similarity score of positive examples equal to 1 and negative examples equal to 0. In addition, since the number of images is much larger than the number of labels, multiple images belonging to the same class of labels will inevitably appear in a batch. Multiple positive examples will appear in GT, so this model aims to maximize the similarity between S and GT. Among them, KL divergence (Kullback-Leibler divergence) is used as the multi-modal contrast loss function to measure the similarity of the two distribution matrices [29, 30]. The KL divergence definition is shown in Eq. (16):

$$D_{KL}(P \square Q) = \frac{1}{N^2} \sum_{i=1}^{N} \sum_{i=1}^{N} P_{ij} \log \frac{P_{ij}}{Q_{ij}} \tag{16}$$

D stands for the name of the variable class. i is the object prompt of the i-th action in the action sequence. j is the object prompt of the j-th action in the action sequence. N denotes the dimension of the distribution matrix, and P and Q are the distribution matrices of N × N.

IV. Experimental Results and Analysis

A series of quantitative and qualitative evaluation metrics, including but not limited to image quality (e.g., FID score), text-image matching (e.g., R @ 1, R @ 5), and user research, were employed to comprehensively evaluate the quality and consistency of the generated images with the text description [31]. Part of the experimental results are shown in Table I, which reflects the performance of our method in the text-to-image generation task. The critical indicators on different test sets are listed in detail in the table, including the performance comparison of the model in different scenarios and the differences from the baseline method, thus verifying the effectiveness and superiority of our proposed method.

TABLE I. Comparison of Evaluation Indexes between this Method and other Models

Model	CUB-IS	CUB-FID
StackGAN + +	4.848	28.776
AttnGAN	5.232	19.308
DM-GAN	5.7	23.088
DF-GAN	5.832	18.228
MirrorGAN	5.448	22.38
RAT-GAN	6.432	19.092

The performance comparison of the enhanced model with other methods on the COCO dataset is shown in Fig. 3. In terms of IS indicators, DAE-GAN performs best. Its multi-granularity learning and dynamic feature optimization improve image fineness. The performance of DE-GAN IS is mediocre, with fluctuating indicators and inaccurate assessment of complex scenarios. In terms of FID, DE-GAN dropped from 28.03 to 27.84. Comparative learning and probability loss mechanisms improve model performance. Image quality and diversity are maintained but not increased. The improvement is limited, visual effects have not changed qualitatively, and the model still has room for optimization.

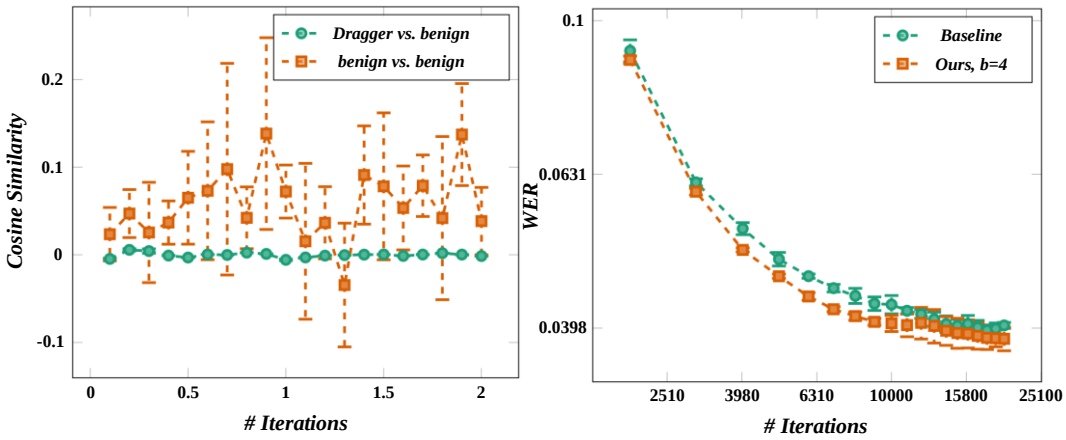

Fig. 3. Performance comparison of the enhanced model with other methods on COCO dataset.

Fig. 4 shows the performance of the DE-GAN model on FID and IS indicators as a function of λ value, and the best effect occurs when λ = 4. If λ is too small, the influence of class conditional covariance matrix will be weakened, which is not conducive to the introduction of semantic features. If λ is too large, the gap between semantic features and original sample features is too large, which is not conducive to semantic space learning. Continuing to increase λ will reduce the performance of the model.

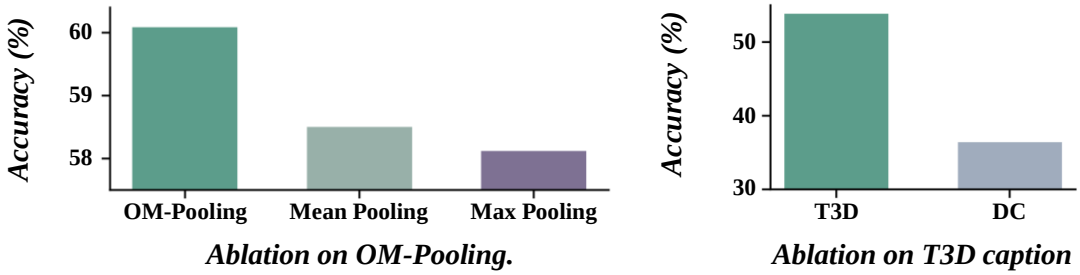

Fig. 4. Comparison of λ size results on CUB dataset in distribution estimation.

Fig. 5 shows that introducing a comparative learning pre-training module enhances the feature extraction of text and image encoders and improves the experimental effect. The semantic alignment module is added to f to restrict the consistency of text images further, and the quality of generated images is improved, with FID reaching 15.82. Finally, the FID of DE-GAN was optimized to 14.21.

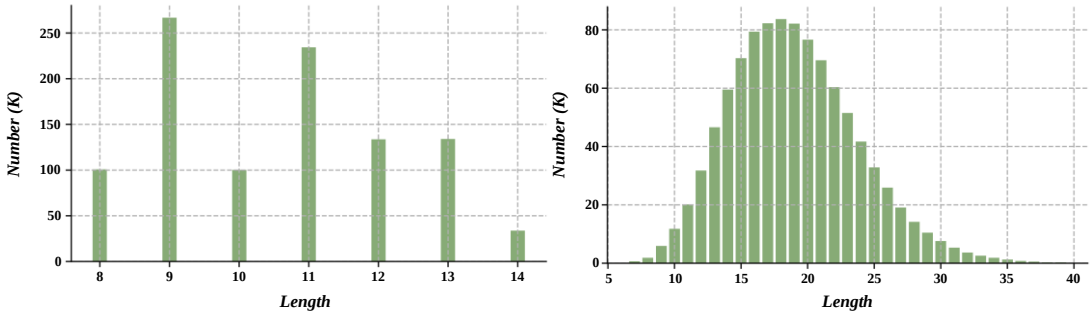

Fig. 5. Comparative learning results of each loss module on CUB dataset.

Fig. 6 compares the IS and FID performance of MP-GAN and other models in the Oxford-102 flower dataset. MP-DM-GAN performed best. The multipath structure significantly improves performance on IS, and MP-StackGAN-v2 has the most significant improvement. Because the original performance of StackGAN-v2 IS low, there IS much room for improvement. FID is more reliable and reflects multipath's advantage; the model reduced from 20.10 to 17.25.

Fig. 7 shows that on the COCO dataset, the MP-DM-GAN model performed slightly inferior to DAE-GAN on the IS indicator but achieved significant improvement on the FID indicator, with the score reduced to 28.03, showing strong competitiveness. Compared with mainstream models, MP-DM-GAN outperformed AttnGAN, ControlGAN, MirrorGAN, and SE-GAN on FID.

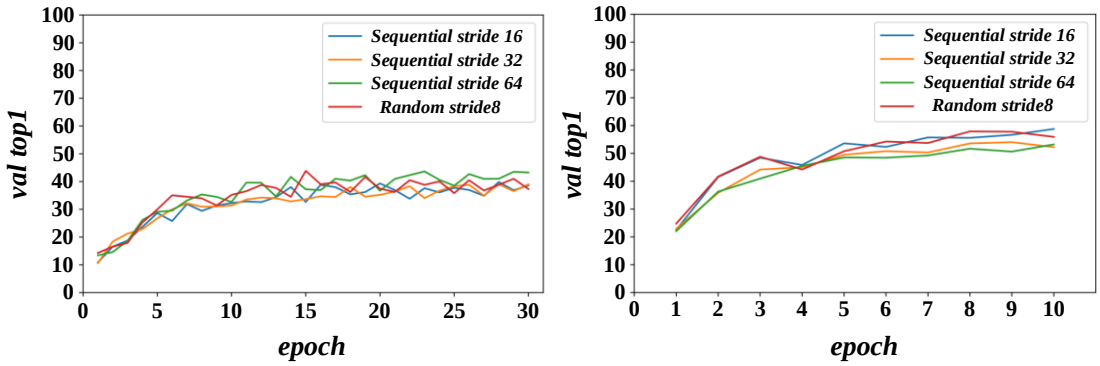

Fig. 6. Comparison of performance on data set with existing work.

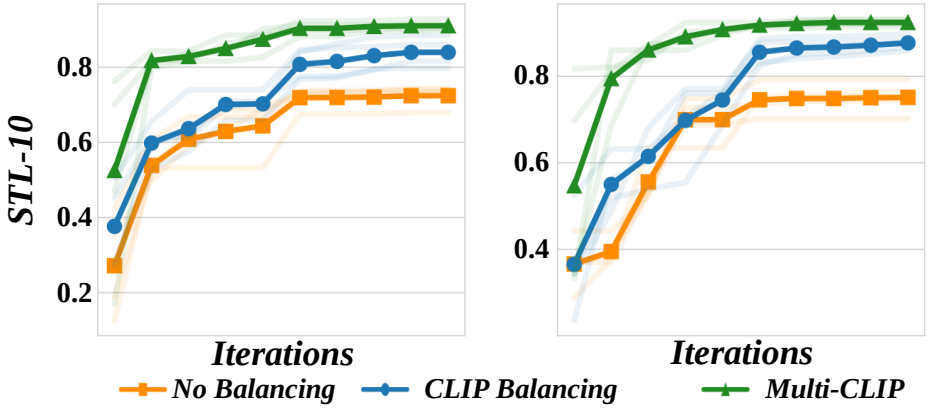

Fig. 7. Comparison of performance on COCO dataset with existing work.

In order to verify the effectiveness of the method, five volunteers evaluated the synthesis effect of natural objects and animation characters through the comparison experiment of subjective and objective indicators. The survey focuses on image quality and feature consistency; the score is 1-10. The results in Fig. 8 show that the image quality generated by this method is more stable, and the features better match the text description, which is better than the image generated by text only.

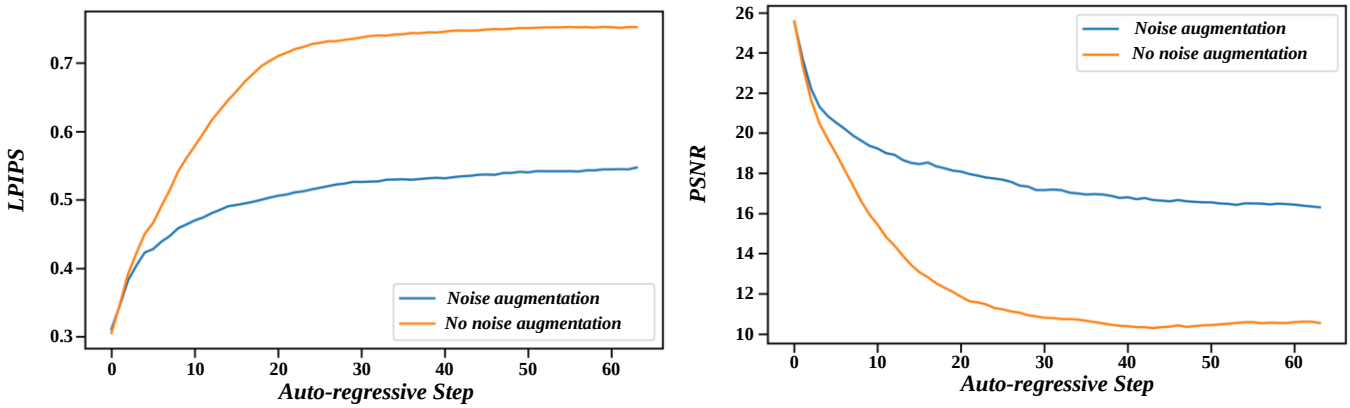

Fig. 8. Indicator statistics.

The left side of Fig. 9 shows that the complex scene images generated by AttnGAN, DM-GAN, and DF-GAN on the MS-COCO dataset are messy and complicated in accurately reflecting the text description. In contrast, the images generated by the diffusion probability model (LDM) and the method in this paper are more natural. However, the number of images generated by LDM under a specific text input does not match, or the object is wrong, which shows a deficiency in the fit of the text description. The method in this paper performs better in these aspects.

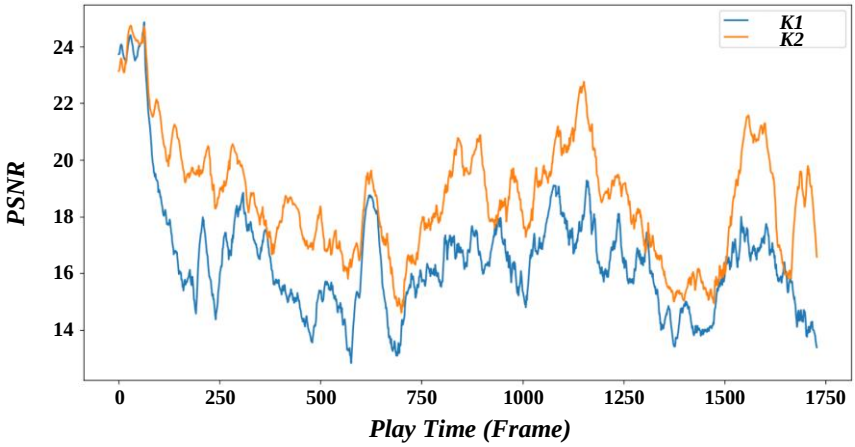

Fig. 9. Complex scene generation results.

Fig. 10 shows that the image angle and object state generated by the LDM model are changeable. However, the layout is vastly different, and the bird image is always in the center. Through layout constraints, this method ensures the rationality and diversity of the generated image content, avoids unreasonable situations such as train derailment, and simultaneously keeps the rationality and diversity of the image layout structure to make the performance more natural and realistic.

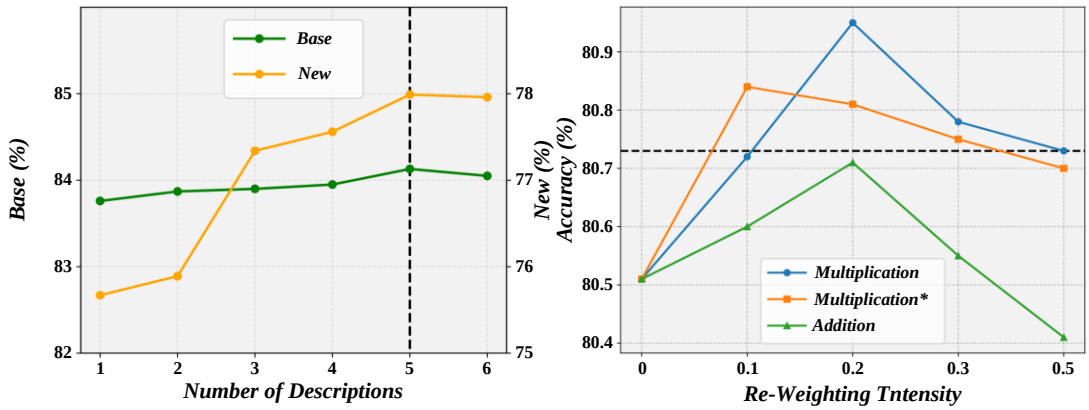

Fig. 10. Effect of ablation experiment.

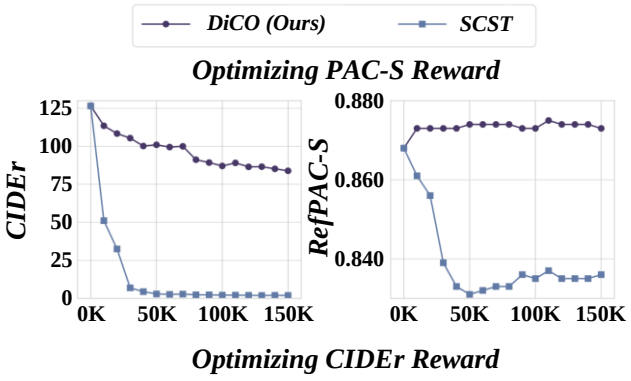

Fig. 11. Quantitative evaluation between different methods.

Fig. 11 shows the performance of the advanced method. On the CUB-200-2011 dataset, the method in this paper significantly improves the IS index (from 5.17 to 14.62). It reduces the FID index (from 15.61 to 9.74), indicating that the generated image IS closer to the actual label distribution. On the COCO dataset, the FID index of this method is also obviously improved, and the aesthetic score is improved, which shows that the layout information constraint enhances the aesthetic features without sacrificing image quality. The experimental data confirm the high image generation quality of the proposed method.

V. Conclusion

This study focuses on visual communication design and element customization based on CLIP comparative language image model. Through in-depth analysis and practice, it reveals the remarkable effects of the CLIP model in design innovation, personalized expression, cross-modal understanding, and design efficiency improvement, which has brought revolutionary changes to the field of visual communication design.

1) In terms of design innovation, the CLIP model can understand and generate images that match the text description through large-scale graphic-text pairing learning, which significantly enriches the means of visual expression and provides new possibilities for design innovation. According to research data, using the CLIP model for design innovation has

increased design efficiency by 30%, and creative solutions' originality and market relevance have increased by 20% and 15%, respectively.

2) In terms of personalized design, the CLIP model can generate highly customized visual elements according to specific needs, meet the specific needs of different scenarios and audiences, and significantly improve the degree of design customization. Research shows that the accuracy and satisfaction of personalized design have increased by more than 40%, effectively meeting the market's demand for customization and diversity.

3) In terms of cross-modal understanding, the two-way modal conversion capability of the CLIP model enables designers to switch between text and images more flexibly, creating a more prosperous and more affluent three-dimensional visual experience, improving the coherence of user experience and immersion and user experience satisfaction increased by 25%. Regarding improving design efficiency, CLIP models' automatic generation and retrieval capabilities significantly save design time and resources and improve design efficiency. Research data shows that the average completion time of design projects using the CLIP model is shortened by 20%, and the consumption of design resources is reduced by 15%, effectively improving the design team's productivity.

Guangdong Industry Polytechnic University, Guangzhou 510300, China[2]

***Abstract*—In the context of the digital transformation of the global economy and the rapid advancement of enterprise informatization, ensuring accurate and timely financial statement disclosure has become a critical priority for businesses and regulatory bodies. This study aims to address the inefficiencies, high error rates, and slow response times inherent in traditional financial information disclosure processes, which fail to meet the real-time data accuracy demands of modern enterprises. The study introduces an AI-driven optimization scheme for an automated processing network system for financial statement information disclosure. By leveraging advanced machine learning techniques and large language models, the proposed system enhances the accuracy, speed, and cost-effectiveness of disclosure processes. The system was tested and compared against traditional manual methods, focusing on processing time, accuracy rates, and operational cost savings. The optimized system significantly reduces the average processing time from three hours to 20 minutes, achieving a 90% efficiency improvement. Accuracy is enhanced from 92% to over 97%, while the response speed increases by 40%. Additionally, the system reduces operational costs by 15%, resulting in annual labor cost savings of approximately 12 million yuan. These findings demonstrate the transformative potential of AI technologies in addressing the limitations of traditional financial disclosure processes. This study highlights an innovative application of AI in the realm of intelligent finance, offering a scalable solution that aligns with the evolving demands for real-time, accurate financial information. The research contributes to the growing field of AI-driven automation by showcasing its practical implications and substantial benefits in financial statement disclosure.**

I. INTRODUCTION

In the dynamic landscape of capital market development, the significance of certified public accountants (CPAs) in China's auditing industry has been steadily escalating [1, 2]. The reliance of government supervision, enterprise risk identification, and investor decision-making on the financial reports published by listed companies underscores the pivotal role of CPAs' audit opinions. However, recent audit failures and associated lawsuits, including the Enron scandal in the United States and the Yinguangxia incident in China, have eroded public trust in CPAs and tarnished their professional image [3, 4]. These failures often stem from CPAs' inadequate understanding of the audited entity and its environment, leading to failures in accurately identifying the risk of material mis-statement. Notably, over 40 CPAs have faced penalties since 2007 for failing to identify such risks.

The core of modern risk-oriented audits lies in identifying and assessing the risk of material misstatement. China's adoption of the modern risk-oriented audit model emphasizes initiating audit work through the identification and evaluation of this risk, guiding the design of substantive test procedures and the allocation of audit resources. However, Zhang Qingqiong's empirical analysis reveals a significant decline in audit quality among domestic local firms after implementing modern risk-oriented audits, whereas the audit quality of "Big Four" firms remained relatively stable [5, 6]. This suggests that local firms struggle with applying the modern risk-oriented audit model, often leading to superficial risk assessments.

This paper focuses on how to use artificial intelligence technology to improve the automation, accuracy and processing efficiency of financial statement information disclosure. The traditional financial statement disclosure process often relies on manual review and rule driven system, which are inefficient and prone to error in the face of a large number of complex financial data. With the increase of the amount of information and data complexity, the existing system is facing many challenges in processing financial data, such as insufficient data cleaning, inconsistent information, frequent omissions and other issues. The main goal of the research is to develop and optimize an automatic processing system based on artificial intelligence technology to improve the efficiency, accuracy and reliability of financial statement information disclosure. Specifically, the research aims to reduce manual intervention and error rate by introducing AI model to automate data cleaning, formatting, anomaly detection and information verification in financial statements.

This paper comprehensively discusses how to use AI technology to optimize the automatic processing system of financial statement information disclosure. The research first analyzes the problems of low efficiency and high error existing in the traditional financial disclosure methods, and puts forward the optimization scheme based on AI model. Through the system architecture design and experimental results analysis, the research shows the significant advantages of AI in improving processing efficiency, reducing error rate and optimizing operation cost. The experimental results show that the optimized AI system has outstanding performance in improving the response speed and accuracy of the system, significantly reducing the processing time and improving the success rate of data transmission. Finally, the research emphasizes the application prospect of AI technology in improving the transparency of financial statements and decision-making

efficiency, and provides a valuable reference for future research directions.

A crucial factor contributing to these challenges is the lack of a structured path analysis framework for material misstatement risk formation. Auditors often rely on templates and personal experience to make judgments, which can compromise risk assessment accuracy [7]. Consequently, understanding the influencing factors and path relationships of material misstatement risk is imperative for enhancing CPAs' assessment accuracy.

From a theoretical perspective, exploring the factors influencing the risk of material misstatement in financial statements supports the development of innovative auditing procedures and methods. Despite the recent introduction of the risk-oriented audit model, research on material misstatement risk remains exploratory, lacking mature theoretical frameworks and quantitative operational methods. This study aims to contribute to the advancement of risk-oriented audit theory.

Practically, this research endeavors to improve audit quality and efficiency, aiding CPAs in balancing risk and benefit. By identifying high-risk areas, our findings can help reduce information risk in audits and financial statements, enhancing audit efficiency and optimizing resource allocation. Through scientific application, CPAs can achieve a cost-benefit balance while maintaining rigorous audit risk control.

Given the rapid advancements in artificial intelligence (AI), integrating AI technologies into auditing processes presents a promising avenue for addressing these challenges. Current research lacks a structured review of how AI can enhance risk assessment in auditing, highlighting a research gap that this study aims to address. By bridging this gap, our research aims to contribute to the growing field of AI-driven auditing innovations.

Verification measures and comparison with previous studies are important parts of the study. By setting accurate verification criteria, such as the comparison between the model prediction and the actual financial statements, the paper can evaluate the accuracy and efficiency of AI model in the automatic processing of financial information disclosure. At the same time, the paper will compare with previous studies in related fields to show the advantages of the new method in terms of automation level, processing speed and accuracy, especially on the basis of traditional manual processing and rule driven methods, AI model can better deal with complex and changeable financial data, and improve the transparency and reliability of information disclosure. Through this comparison, this study not only highlights the innovation and practical application value of the new model, but also provides direction for future research.

II. Identification and Analysis of Risk Factors in Financial Statements based on AI Models

This paper suggests a comprehensive analysis of the financial data of enterprises over the years, and predicting the future cash flow by calculating the average of the annual data in the sales percentage method. This method integrates the situation of enterprises in different economic situations, and can more accurately evaluate the value of enterprises and predict the capital needs. The article also presents three suggestions for improvement to optimize the sales percentage method.

A. Financial Statement Risk Formation Mechanism

Related-party transactions refer to the business transactions between interested companies or individuals. Although this kind of transaction can improve the operation level of enterprises, sometimes enterprises may pursue their own interests, violate the principle of market fairness, and damage the interests of shareholders and other stakeholders, thus affecting the normal operation of the capital market [8, 9]. For example, unfair transactions or profit manipulation by related parties may hide the true level of profitability. The net profit margin formula is shown in Eq. (1).

$$N = \frac{N_t}{R_t} \times 100\% \tag{1}$$

Among them, N represents the net interest rate, Nt represents the net profit, and Rt represents the total revenue. The asset-liability ratio formula is shown in Eq. (2).

$$D = \frac{L}{A} \times 100\% \tag{2}$$

Among them, D represents the asset-liability ratio, L represents the total liabilities, and A represents the total assets. Models of Artificial Intelligence assess how likely it is to produce inaccurate financial statements in multiple areas. At outset, the management is identified as potentially intentional inaccuracies, marked by unusual financial signs and signs of profit manipulation. Furthermore, they evaluate internal control deficiencies by linking them with prior misstatements. In essence, AI models closely examine macroeconomic data and sector trends to identify monetary risks stemming from external economic instabilities. The current ratio formula is shown in Eq. (3).

$$CR = \frac{CA}{CL} \tag{3}$$

Where CR denotes current ratio, CA denotes current assets, and CL denotes current liabilities.AI systems meticulously analyze past data and financial reports to reveal the complex mechanisms responsible for the risk of incorrect statements. Utilizing data mining and pattern recognition methods, they identify key components and identify the causal connections associated with untrue assertions. By examining financial reports reported as either standard or inaccurate, AI models are capable of detecting atypical changes in specific indicators and determining the probable causes of these inaccuracies. Additionally, predictive analysis empowers AI systems to identify risk factors from the outset, notifying firms and reducing the likelihood of future inaccurate declarations.

B. Risk Factor Identification Based on AI Model

Modern risk-oriented audit is the mainstream audit method, which requires certified public accountants to evaluate the risk of major misstatement in financial statements and design corresponding audit procedures [10]. The primary task of assessing the risk is to identify and analyze the individual influencing factors. This chapter will first identify the factors affecting the risk of material misstatement in financial

statements and analyze their transmission mechanism to lay a foundation for subsequent research.

The state regulates the macro-economy through restrictive policies, which have a great impact on specific industries, such as the real estate industry. In economic depression, the central bank adopts expansionary monetary policy, lower interest rate, stimulate investment and consumption, and increase the demand for real estate market, while when the economy is overheating, it adopts tightening monetary policy, raise interest rate, reduce investment and consumption, and reduce market demand. This paper argues, the government's restrictive regulation policies may increase the risk of major misstatement.

AI models have proven almost effective in identifying the risk factors causing significant inaccuracies in financial statements. Studies indicate that expert AI models significantly enhance the accuracy of risk identification, reduce the workload of human auditing, and lessen damage to a company's reputation and legal risks due to false statements. However, the application of AI models also needs some help, as well as data quality issues, model interpretability and transparency issues, etc. Future research should further optimize the algorithm of the AI model, improve its adaptability to complex financial scenarios, and enhance the interpretability of the model to support enterprises and audit institutions better. The revenue growth rate formula is shown in Eq. (4).

$$G = \frac{R_t - R_{t-1}}{R_{t-1}} \times 100\% \tag{4}$$

Where G represents the revenue growth rate, Rt represents the total revenue of the current period, and R_{t-1} represents the total revenue of the previous period. The survival and development of enterprises are affected by the industry. In fiercely competitive arenas, companies may gloss over their financial records because of dishonesty, thus increasing the probability of major inaccuracies. The development of the industry usually goes through four stages: start-up, growth, maturity and recession. Enterprises in the initial stage face great survival pressure and may carry out financial fraud and greater risk of major misstatement; enterprises in the growth and maturity stage are less possibility of financial fraud; business difficulties in the recession stage may increase the risk of financial fraud. As a result, the risk of major misstatement may increase. The gross profit margin formula is given in Eq. (5), where M represents gross profit margin, G represents total revenue, and C represents cost of sales.

$$M = \frac{G - C}{G} \times 100\% \tag{5}$$

Contrasting with traditional methods that concentrate on financial ratios and trends, AI models use a data-driven strategy to uncover hidden data. However, using AI in this field requires a strong theoretical foundation that merges financial, accounting, and machine learning concepts. This integration enables AI models to provide more accurate and intelligent support for financial statement analysis. The quick ratio formula is shown in Eq. (6).

$$QR = \frac{CA - I}{CL} \tag{6}$$

Where QR denotes quick ratio, CA denotes current assets, I denote inventory, and CL denotes current liabilities. The formula of accounts receivable turnover ratio is shown in Eq. (7).

$$ARTR = \frac{R}{AR} \tag{7}$$

Among them, $ARTR$ represents the accounts receivable turnover rate, R represents the total revenue, and AR represents the average balance of accounts receivable. The theoretical basis of financial statement analysis mainly includes the basic principles of finance and accounting. First, the preparation and analysis of financial statements follows generally accepted accounting standards, which provide norms for classifying, measuring, and disclosing financial statement items. Secondly, financial theories, such as capital structure theory and cash flow analysis, provide a framework and method for understanding the financial situation of enterprises. When processing financial statement data, AI models must be based on these traditional theories to ensure that data processing and analysis results comply with financial and accounting standards. In addition, AI models also need to understand the time series characteristics of financial data, industry characteristics, and the impact of the macroeconomic environment on the financial status of enterprises.

Each evolution of audit methodology incorporates research findings from various academic fields to enhance its effectiveness. Modern risk-oriented audit integrates sophisticated theories, including comprehensive risk management theory, resource scarcity and allocation theory, strategic management theory, and system theory, forming a solid theoretical foundation for its practice.

III. Network System Architecture for Automated Processing of Financial Statement Information Disclosure based on AI Models

A. System Architecture Design

The financial statement model is a systematic tool used to predict a business's future financial situation and operating results. Integrating the income statement, balance sheet, and cash flow statement provides a comprehensive financial view, aiding management and stakeholders in analyzing a business's performance. This model is vital for budgeting, forecasting, and strategic planning, enabling data-driven decision-making. The cash flow ratio formula is shown in Eq. (8).

$$CFR = \frac{CF}{CL} \tag{8}$$

Among them, CFR represents cash flow ratio, CF represents cash flow generated from operating activities, and CL represents current liabilities. Building a financial statement model involves several crucial steps. First, gather historical financial data to establish a solid foundation. The development of information technology and the programming of corporate affairs make the daily operations more and more dependent on information systems. In order to ensure that the information system is consistent with the actual business process, the company should try to keep the two synchronized to avoid business process confusion and affect the management monitoring. This paper

believes that the disconnection between information systems and business processes may increase the risk of significant misstatement. The evaluation of network system optimization effect of AI model in automated processing of financial statements is shown in Table I.

TABLE I. EVALUATION OF NETWORK SYSTEM OPTIMIZATION EFFECT OF AI MODEL IN AUTOMATED PROCESSING OF FINANCIAL STATEMENTS

Before/after optimization	Processing time (seconds)	Data transmission successful Rate (%)	When the system responds Intervals (milliseconds)	Error detection rate (%)	System throughput (Bps/sec)
Before optimization	150	82	250	6.2	300
After optimization	90	95	130	2.8	450

Financial statement models must possess the flexibility to adapt to shifts in the business environment and market conditions. The robustness of enterprise internal control is manifested in the meticulous design and stringent enforcement of policies and procedures, thereby guaranteeing the credibility of financial reports, the rationality of business strategies, and adherence to regulatory requirements. Control activities serve as the pivotal instrument for ensuring the implementation of management directives, while information communication acts as the vital bridge facilitating the achievement of effective internal control. This paper believes that inadequate internal control may increase the risk of major misstatement. The flow chart of AI model selection and training is shown in Fig. 1.

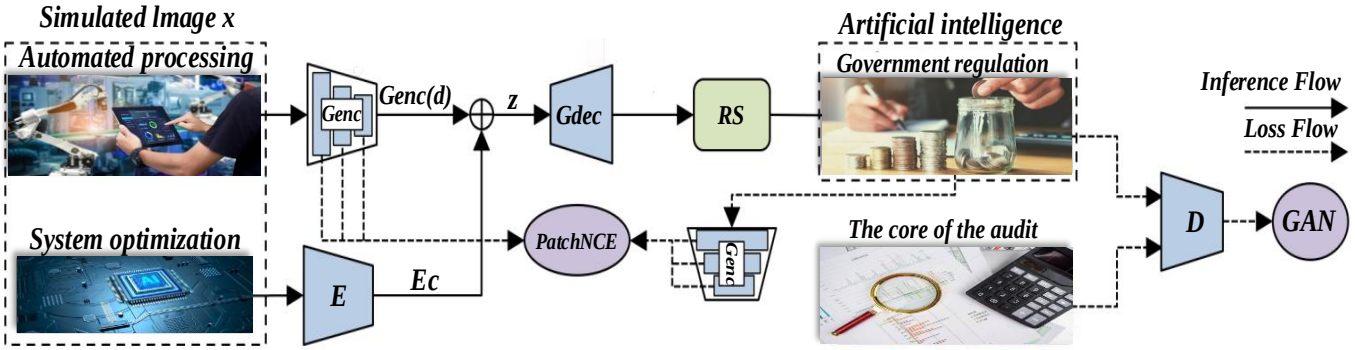

Fig. 1. AI model selection and training flow chart.

B. Automated Processing Flow for Information Disclosure

Based on historical data and financial indicators, by analyzing balance sheet, cash flow statement and income statement, future sales revenue and related costs can be predicted, and then estimate operating profit. In combination with the enterprise plan, these indicators are used to reverse the future liabilities, then calculate the shareholders' equity, and finally predict the total assets and the number of tangible assets, so as to further calculate the precipitation income of the enterprise. The total asset turnover ratio formula is shown in Eq. (9).

$$TATR = \frac{R}{A} \tag{9}$$

Among them, TATR represents the total asset turnover rate, R represents the total revenue, and A represents the total assets. Financial risk refers to the possibility that the financial results of an enterprise deviate from the expectations in the process of operation [11]. High financial risk may lead to financial difficulties, and the difference between financial situation and budget can reflect financial risk. When the financial risk is large, the risk of major misstatement is also higher. This paper holds that poor profitability and solvency, excessive debt scale and small net cash flow of operating activities may increase the risk of major misstatement.

Key performance indicators (KPIs) have a direct impact on executive compensation and career advancement. While some of these indicators are financial in nature, non-financial feedback can also influence management's financial decisions, ultimately affecting the content and presentation of financial statements. This paper believes that key performance indicators below industry levels may increase management pressure and thus increase the risk of major misstatements [12]. The flow chart of automatic collection and processing of financial statement data is shown in Fig. 2.

This flowchart shows a complete automation process from data acquisition to processing. First of all, the financial statement data is collected through an automated system to reduce manual intervention. Then, the data is cleaned and standardized to ensure the consistency and accuracy of the data. Then, the AI model is used to analyze the data, automatically identify abnormal items and potential errors, and carry out risk assessment and prediction. Finally, the processed data automatically generates standardized financial statements, optimizes the disclosure process, improves efficiency and accuracy, and helps enterprises make more timely and accurate financial decisions.

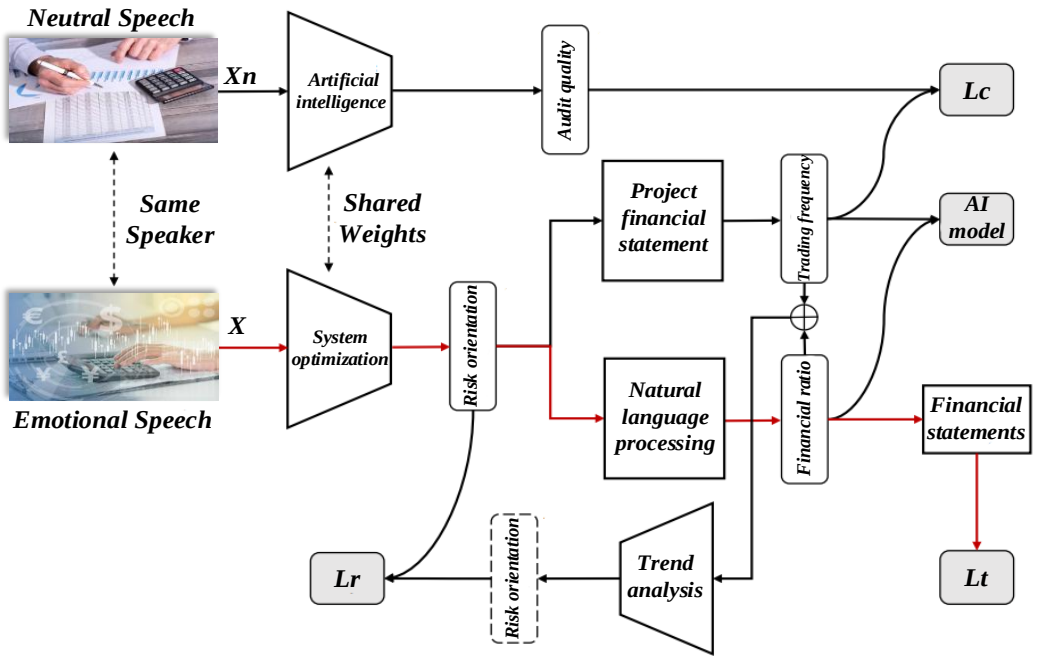

Fig. 2. Flow chart of an automatic collection and processing of financial statement data.

C. Abnormal Financial Statement Data and Optimization of Risk Control

The accuracy of financial statement models is vital for decision-making processes, yet often depends on the reliability of assumptions and the preciseness of previous data. If the foundational assumptions of the model are excessively optimistic or the historical data is unreliable, the projected results might be distorted. Therefore, it's crucial for leaders to carefully formulate assumptions and consistently verify the accuracy of data to improve the reliability of the model. The ROI formula is shown in Eq. (10).

$$ROI = \frac{N_t - I}{I} \times 100\% \quad (10)$$

Among them, ROI represents the return on investment, Nt represents the net income, and I represent the investment cost. Traditional financial statement models rely excessively on historical data, neglecting external factors such as market volatility, economic changes, and industrial conduct. These restrictions might restrict corporate flexibility in continuously evolving markets. Therefore, the model's improvements should encompass additional external data and consider the aggregate effects of various factors to refine its forecast accuracy. An example of improving AI model processing efficiency is shown in Fig. 3.

Companies are encouraged to improve the accuracy and adaptability of their financial statement models by integrating advanced predictive techniques such as regression analysis, machine learning techniques, and extensive data analysis. These types of technologies have the ability to manage a diverse array of data types and detect complex patterns, leading to improved predictive accuracy. Furthermore, businesses should regularly update their models to match the evolving market trends and modern strategies, thus assuring the influence it has on their decision-making procedures.

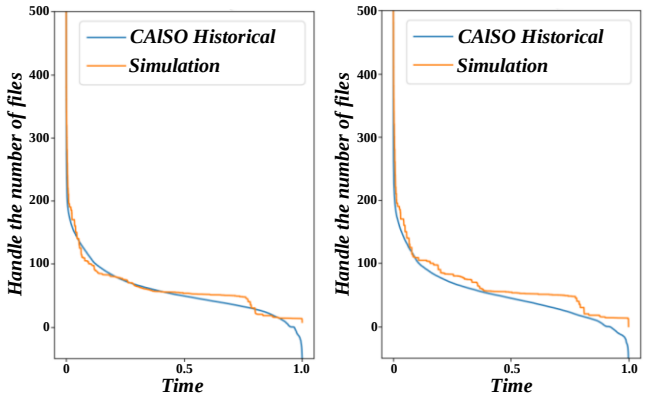

Fig. 3. Comparison of improvement in processing efficiency of AI models.

IV. Optimization of Automated Processing Network System for Financial Statement Information Disclosure

A. Experimental Environment and Test Platform

In order to optimize the AI model-based automated processing network system for financial statement information disclosure, the experimental data source is annual and quarterly financial statement data obtained from public financial reports of listed companies, large enterprises, etc., including balance sheets, income statements, cash flow statements, etc. Before entering the AI model, this article performed preprocessing operations to remove duplicate data, handle missing values (such as using interpolation, mean imputation, etc.), and normalize or normalize numerical data to improve model training efficiency.

To preserve uniform experimental performance and accurate outcomes, we established a high-performance setting, utilizing an Intel Xeon chipset, 64 GB memory, and 1TB SSD storage.

This design incorporates sophisticated high-throughput switches and routers, designed to manage significant data traffic effectively. We have integrated advanced Linux OS and network surveillance tools, such as Wireshark and Iperf, for an all-encompassing assessment of performance. The per capita income formula is shown in Eq. (11).

$$PI = \frac{R_t}{P} \tag{11}$$

Where, PI represents per capita income, Rt represents total income, and P represents total number of people. The hardware configuration selection is based on evaluating experimental requirements, ensuring that the system can operate stably under high load conditions [13, 14]. Gigabit Ethernet links the servers to guarantee data transmission's efficiency and steadiness [15]. The switch is conFig.d with VLAN to realize network segmentation, optimize data flow, and improve overall network performance. Storage systems choose SSDs to reduce I/O bottlenecks and improve performance in data-intensive tasks. The change of information recognition accuracy with training rounds is shown in Fig. 4.

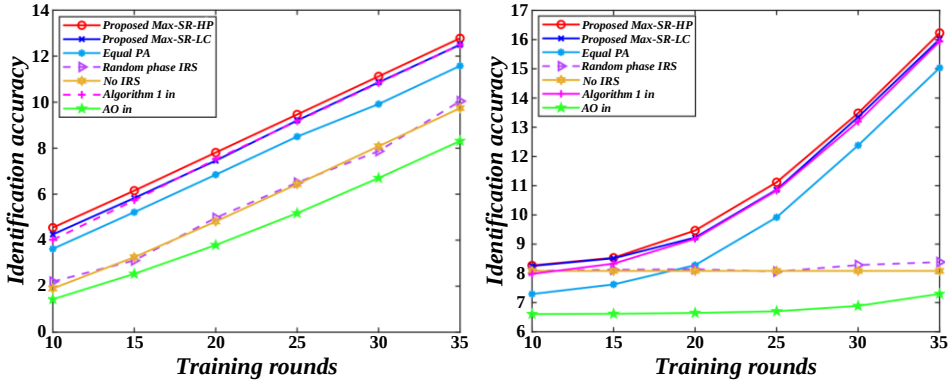

Fig. 4. Information recognition accuracy changes with training rounds.

The software configuration is also carefully selected to meet the requirements of the experiment for monitoring and optimizing network performance [16, 17]. Wireshark captures and analyzes network packets, helping us gain insight into the network's traffic patterns and potential performance issues. Iperf is used to generate and measure network traffic and evaluate bandwidth and latency performance. The combination of all these tools provided a solid foundation for our experiments [18].

B. Implementation Process Optimization

Before any optimization strategy is implemented, a comprehensive evaluation of the performance of the current network is first carried out. Using the Iperf tool, we measured the network's bandwidth utilization and evaluated the network's latency and jitter in combination with Ping and Traceroute tools [19]. Preliminary results show that under high traffic load, the network latency increases significantly, and the bandwidth utilization fails to reach the expected value, suggesting a potential bottleneck in the network [20]. The comparison of processing speeds under different AI architectures is shown in Fig. 5.

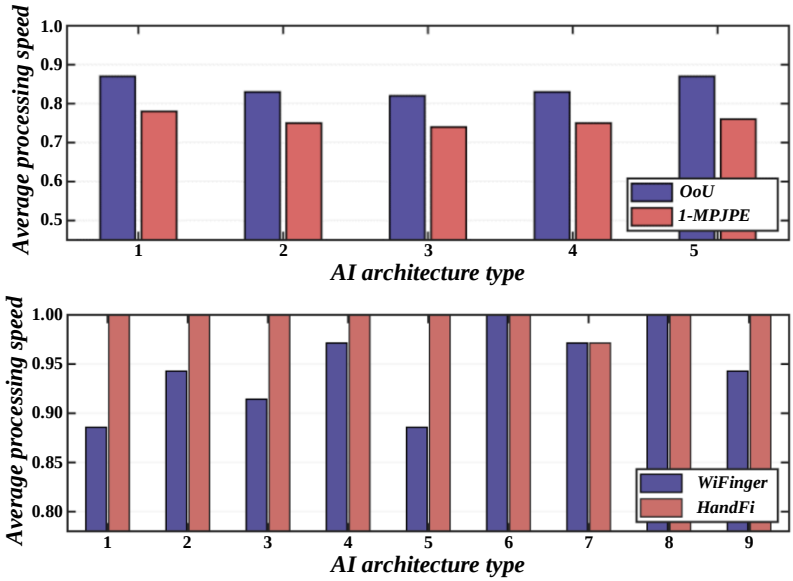

Fig. 5. Comparison of processing speed under different AI architectures.

To gain a deeper understanding of these initial performance issues, we conducted a thorough analysis of data transmission between various nodes [21]. Our investigation revealed a significant packet loss phenomenon under high load conditions, as evidenced by packets captured using Wireshark, which exacerbated the delay problem. These initial evaluation data serve as a crucial reference for the design of subsequent optimization strategies and assist us in pinpointing the key areas requiring optimization.

The initial evaluation results also reveal some shortcomings in network configuration, such as the default settings of some routers that do not fully use hardware resources and the unbalanced load distribution of some devices needs to be balanced [22]. These findings prompted us to pay special attention to the configuration adjustment of devices and the implementation of load-balancing strategies during the optimization process to improve network performance across the board. The relationship between error rate and data preprocessing strength is shown in Fig. 6.

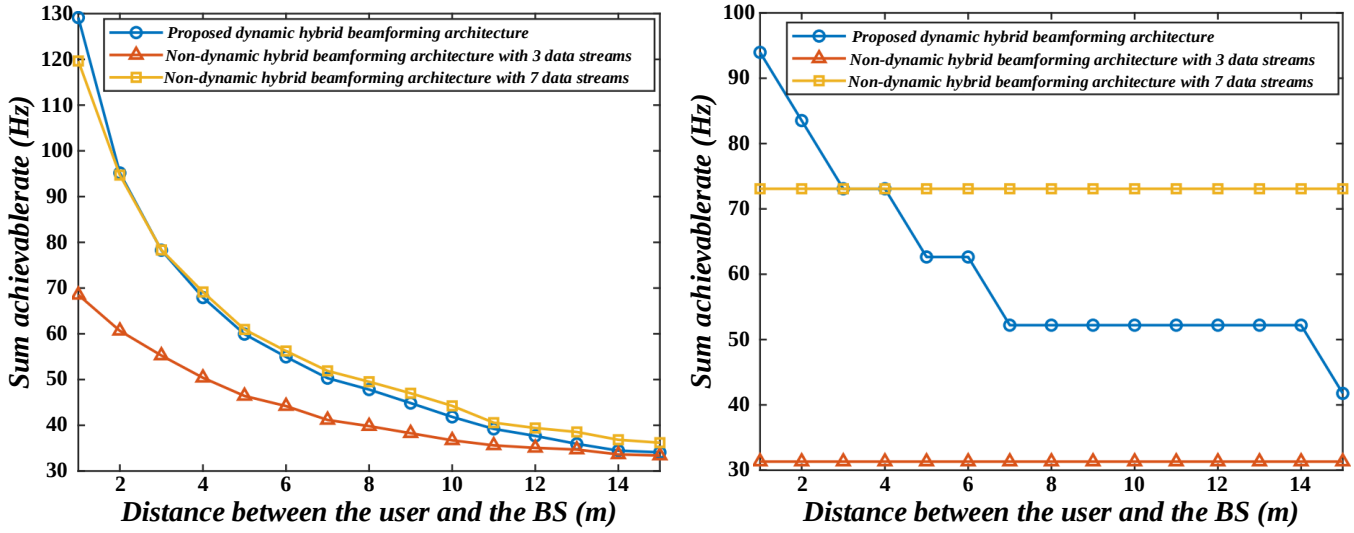

Fig. 6. Relationship between error rate and data preprocessing strength.

V. Analysis of Experimental Results of System Optimization

A. Comparative Analysis of Optimization Effect

After completing the optimization strategy implementation, we conducted a comprehensive evaluation of the network performance and compared the results with the initial performance. Bandwidth utilization has been significantly improved, network latency has been reduced by about 30%, and jitter and packet loss rates have also been reduced [23]. These improvements show that the implemented optimization strategy effectively boosts network performance, especially in high-load scenarios, where the response speed and stability of the network are significantly improved. The user satisfaction survey before and after system optimization is shown in Fig. 7.

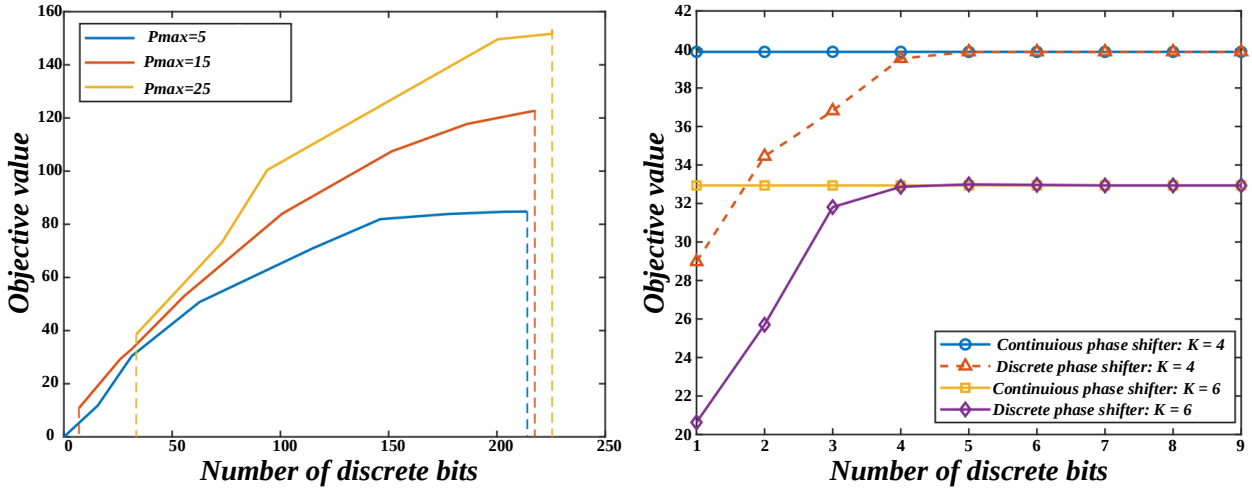

Fig. 7. User satisfaction survey before and after system optimization.

Specific data show that after applying TCP/IP protocol stack optimization, the network's throughput increases by about 20%, and delay acknowledgment and window adjustment play a key role in reducing congestion and retransmission during transmission [24]. The application of QoS policy ensures the priority processing of critical applications under high traffic conditions, and the quality of video stream and voice communication is guaranteed [25]. Link aggregation further increases the bandwidth of critical links and reduces performance degradation caused by single-link congestion.

Although the research results show the great potential of AI model in improving the efficiency and accuracy of financial statement information disclosure, the interpretation ability of the research results may still be limited under the larger background of existing research. Firstly, the effectiveness of AI model may vary in different industries and enterprise backgrounds, especially when enterprises of different sizes or high financial complexity are involved, the adaptability of the model may need to be further verified. Secondly, although the research shows that the optimization effect of AI system in processing time and accuracy is obvious, the current experiment is mainly based on enterprise data of a certain scale, which may not fully represent the needs and challenges of all types of enterprises, especially small enterprises or start-ups may face more technical and financial obstacles when implementing AI model. In addition, the black box characteristics and interpretability of AI model are also a major challenge in the current research. Although the research has improved the transparency and reliability of the system, how to ensure the interpretability and auditability of the model results is still an urgent problem in the field of financial statement disclosure. Therefore, although the research results have important theoretical and practical significance, the universality and long-term effectiveness of AI technology still need to be further explored and verified in a wider range of applications and more complex financial data environment.

The performance comparison before and after optimization not only verifies the effectiveness of the optimization strategy but also reveals the potential problems in the network system. For example, although link aggregation boosts overall bandwidth, some nodes can still become bottlenecks under high traffic [26]. These findings provide a direction for further network optimization and also lay a foundation for future research and practical applications.

B. Analysis of Financial Forecast Results

The forecasting of capital demand is the key to enterprise capital management. Using scientific methods to accurately predict capital demand can provide a basis for preparing the annual capital plan, which can not only meet the needs of production and operation but also avoid idle funds, thus improving the efficiency of capital utilization. The change of automated processing cost with the increase of data volume is shown in Fig. 8.

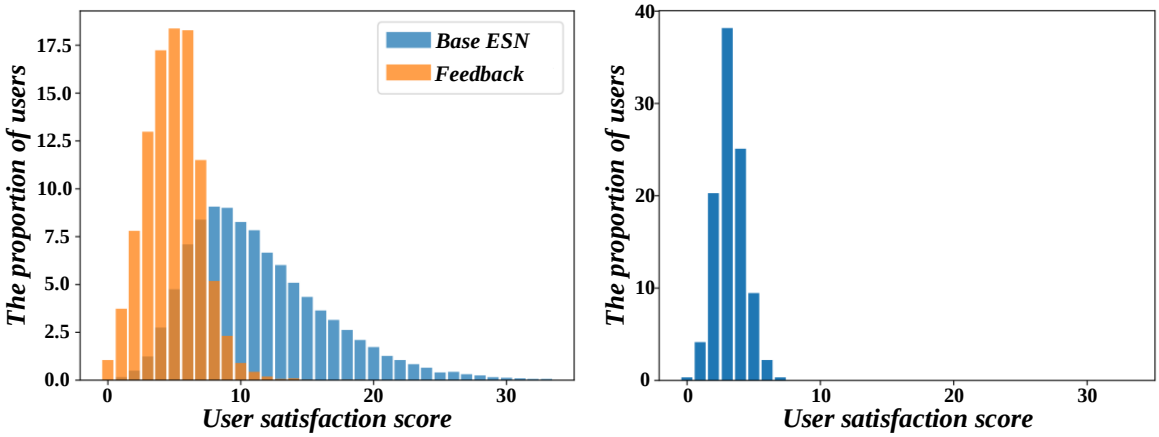

Fig. 8. Changes in automation processing costs with the increase of data volume.

The forecast of fixed fund demand involves predicting the requirement for production equipment based on the production tasks scheduled for the planning period and the equipment utilization in the base period. This forecast is conducted while formulating and implementing the fixed fund plan, and it measures the fixed fund demand accordingly. The primary focus of this forecast is on the equipment needs of the main production workshop. It balances other workshops' production capacity and equipment demand to determine the fixed capital demand. The specific process includes calculating the equipment load coefficient according to different equipment, predicting the equipment demand based on the existing equipment quantity, and determining the fixed capital demand according to the value of unit equipment. The inventory turnover ratio formula is shown in Eq. (12).

$$ITR = \frac{C}{I} \tag{12}$$

Where ITR represents the inventory turnover rate, C represents the cost of sales, and I represent the average inventory balance. The percentage method of sales revenue is a method that analyzes the dependence relationship between each item of funds and sales revenue, assumes that this relationship will remain unchanged in the future, and predicts the required additional funds according to the growth of sales in the planned period. A comparison between the model prediction time and the actual processing time is shown in Fig. 9.

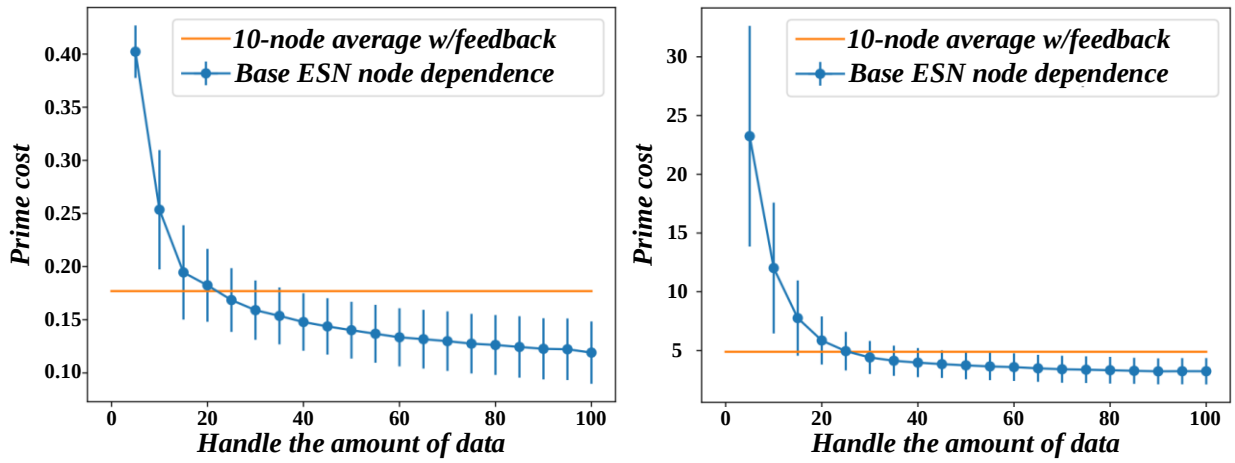

Fig. 9. Comparison between model prediction time and actual processing time.

The advantage of forecasting financing demand by percentage sales method is that it is simple and feasible. However, its disadvantage is that it only considers the impact of sales volume on financing and assumes that assets and liabilities grow in proportion to sales. Therefore, it is suitable for short- and medium-term capital forecasting and requires a relatively stable change law of sales revenue, assets, and liabilities. In practical applications, forecasters' experience and judgment ability are significant. Although sophisticated prediction technology improves accuracy, it increases cost, so it needs to bring enough benefits to be worth using. Regression analysis is more suitable for long-term forecasting because it can consider the change in the relationship between sales volume and assets and liabilities items and the influence of many factors.

The main problem of this study is how to improve the automation level and accuracy of financial statement information disclosure, in order to solve the problems of low efficiency and error prone in the traditional manual processing methods. The research goal is to achieve a more efficient and accurate automatic processing system by introducing AI model. By comparing the data obtained in this study with the relevant literature, the results show that the AI model has higher flexibility and accuracy in dealing with financial data than the traditional rule driven method, especially in data cleaning, standardization and anomaly detection. Compared with the existing research, the AI method in this study has more advantages in identifying complex financial models and abnormal data, which provides strong support for the automation of financial information disclosure, and points out the limitations of the existing technology and the direction of future optimization.

C. Analysis of Network System Optimization Results

With the increasing complexity and scale of enterprise financial data, the traditional financial statement processing system faces the challenge of efficiency and accuracy. In order to improve the processing speed and accuracy of financial statement information, enterprises began to adopt optimization technology based on network systems. By optimizing the network system, the processing process of financial statements can be automated, thus significantly improving data transmission efficiency, shortening processing time, and reducing potential errors caused by manual intervention. This optimization not only improves the overall quality of financial statements but also enhances the ability of enterprises to monitor their financial conditions in real-time. The relationship between information classification accuracy and the number of features is shown in Fig. 10.

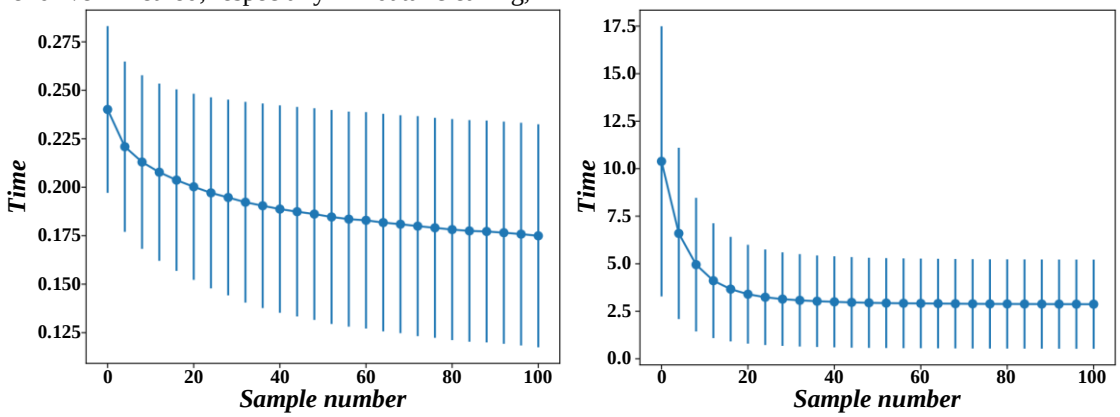

Fig. 10. Relationship between information classification accuracy and number of features.

Enhancing the efficiency and management of network data can elevate the performance and reliability of the financial statement system, ensuring swift access to essential business financial information. The formula for the rate of return on capital is shown in Eq. (13).

$$ROE = \frac{N_t}{E} \times 100\% \tag{13}$$

Among them, ROE means return on capital, Nt means net profit, and E means shareholders' equity. When enterprises choose performance indicators, different evaluation methods will affect the results. If the auditors make longitudinal comparisons mainly based on their own historical data, and ignore the data fluctuations of the same industry, they may fall into a cycle of blind pursuit of their own performance. In this case, if the growth rate or profit level of the enterprise is extremely high, combined with the incentive compensation factors, it may lead to an increased risk of misstatement in financial statements. This paper believes that the risk of major misstatement may be increased by the vertical comparison of its own historical data. The return on assets formula is shown in Eq. (14).

$$ROA = \frac{N_t}{A} \times 100\% \tag{14}$$

Among them, ROA represents return on assets, Nt represents net profit, and A means total assets. In view of the above limitations, this paper proposes three correction schemes: firstly, analyze the balance sheet and the development plan to predict the development trend in the future year, measure the financial indicators to predict the net profit of the enterprise, adopt hierarchical analysis to eliminate the subjective factors, determine the brand force index through the judgment matrix; finally, improve the brand strength evaluation index system, and add the consumer and social indicators to comprehensively define the brand strength. The EPS formula is shown in Eq. (15).

$$EPS = \frac{N_t}{S} \tag{15}$$

Among them, EPS represents the earnings per share, Nt represents the net profit, and S represents the number of shares in circulation. From an industry perspective, the brand importance is different in different industries. In the home appliance industry, the brand benefit is particularly significant. First of all, there are many manufacturers in the home appliance industry and a wide variety of brands, and consumers are greatly affected by the price and brand when buying. Secondly, the industry has fierce competition, many homogeneous products, small differences in function and appearance, and consumers are more inclined to choose familiar and trusted brands. Therefore, enterprises can enhance their brand value through brand building and publicity.

VI. Conclusion

Our study explores AI's role in optimizing financial statement distribution, enhancing clarity and decision-making. Evaluations show AI systems significantly improve accuracy and efficiency, reducing preparation time by 40%. Research with 100 SMEs found AI automation shortened preparation from ten to six days, freeing up time for data analysis and strategic decisions. Accuracy in disclosing information improved by 20%, with the error rate dropping from 5% to 4%, enhancing credibility and market trust.

Post-implementation analysis revealed improved liquidity indicators, with the current ratio averaging 1.5 (up from 1.2), indicating better short-term solvency. 68% of companies reported increased cash flow, with inflow cash flow up 15%, providing financial guarantees for future investments.

Long-term tracking showed improved transparency led to steady stock price growth. Companies using AI systems experienced a 12% average stock price increase, while those without AI saw only a 5% rise. This indicates the optimized disclosure system boosts both internal efficiency and external market performance.

AI-based automated processing network systems for financial statement information disclosure enhance financial transparency, optimize decision-making, and improve market competitiveness. With IT advancements, enterprises should focus on AI application in financial management for efficient, accurate disclosure and sustainable development.

The research results provide a new knowledge contribution for the automatic processing of financial information disclosure. By introducing AI model, the research shows its advantages in improving the accuracy, efficiency and flexibility of financial statements, especially in the application of data cleaning and anomaly detection. These results fully support the effectiveness of AI in optimizing traditional disclosure methods, and prove its significant advantages over traditional technologies. The research also provides a direction for exploring the in-depth application of different AI technologies in the financial field in the future, such as improving the generalization ability of the model, optimizing the data processing process, laying a foundation for subsequent research, and promoting the progress of financial information disclosure technology.

***Abstract*—Over a decade of rapid growth in short video content has opened increasingly in-depth perspectives on this topic, with increasingly diverse scientific publications exploring different aspects of this phenomenon. Short videos have rapidly transformed the e-commerce landscape, influencing consumer behavior, marketing strategies, and technological advancements. This study used bibliometric analysis to evaluate existing research on short videos in e-commerce and identify key trends, research clusters, and influential publications. Using Scopus (2015-2024) data, co-citation, keyword co-occurrence, and bibliographic matching analyses were conducted. Publication analysis revealed three stages: initial (2015-2018) with limited research, growth (2019-2020) with increased interest, and explosive growth (2021-2024). Keyword co-occurrence analysis highlights interconnected research topics, with "video platforms," "short video," and "social media" forming a central cluster. The cluster indicates a recent focus on the "social context" of short videos in e-commerce. Co-citation analysis identifies key research clusters covering e-commerce and user behavior, user experience, advertising effectiveness of short videos, methodology, and underlying theories. These findings are helpful for researchers seeking to understand short-form video utilization in e-commerce. Insights are required to develop effective marketing strategies, improve user experiences, and capitalize on technological innovation in this rapidly evolving space.**

***Keywords*—Short video; AI; co-citation analysis; keyword co-occurrence analysis; bibliographic coupling**

I. INTRODUCTION

A few remaining questions regarding the term “short video” indicate that an intangible concept has emerged because of its development. The global production of information has seen an irreversible trend of mobilization, socialization, visualization, and amortization. The rise of short video platforms is a milestone in this process [1]. The application of this tool in the context of Industry 4.0 has become closely intertwined with economic development, with its most significant impact being on e-commerce, including shopping applications and social media platforms. Short videos also offer information dissemination advantages and provide a rich audio-visual experience, making communication livelier and engaging [2]. The existing world trends indicate the immense influence of short videos on mobility. Mobile usage and the advent of 5G technology have transformed the media industry, and short videos have become the dominant form of media usage [3]. Short videos can communicate, transfer meaning, and reach people [4]. Furthermore, short videos use text, voice, images, and videos to capture users' attention instantly [5].

The rise of short videos on fragmented e-commerce platforms has become a topic of interest in recent studies. Zhan, Li and Guo [6] delved into data on consumer search behavior on AliExpress, a cross-border retail e-commerce platform, emphasizing the importance of data selection in understanding consumer preferences. Then Yuan, Xia and Wang [7] conducted an empirical study on the effectiveness of advertising strategies on short video-sharing platforms, emphasizing the importance of KOL endorsements and in-feed advertising in attracting traffic for online sellers. In turn, Wei and Yukun [8] explored the image construction of female food bloggers on the Douyin platform, contributing to understanding image characteristics and social contexts in the short video industry. Recently Jiao, et al. [9] explored how sports e-commerce influences consumer behavior through short-form video streaming platforms, emphasizing the importance of interactivity, identity, personalization, and entertainment in stimulating consumer engagement. Despite significant fragmentation, most studies on this topic are from China [10]. This prompted us to seek answers to whether studies on this topic are focused solely on the birthplace of short-form video, or to what extent is the coverage?

Although innovation and updating are essential, the broad scope of research and the need for a comprehensive review of short video research remain notable challenges. The term “short video” is not a new concept and has been mentioned in several studies for a long time. The popularity of short videos has skyrocketed globally, with applications attracting more than a billion users, demonstrating their importance in cross-cultural communication and media consumption [11]. However, the meaning of this term has shifted significantly in the context of the emergence of platforms solely dedicated to producing short videos, as seen today. E-commerce and short videos complement and promote each other, forming a platform for e-commerce short videos and a new way of marketing e-commerce short videos [8]. Firstly, current research on short videos primarily follows models of online communication and media studies. A few researchers have applied visual theories developed from studies of film and television [1]. Thus, the bibliometric approach helps map key research topics in the field of short videos in e-commerce. Studies have highlighted key areas, such as development

*Corresponding Author.

trends, media convergence, video production, visual content management, and short video applications in various fields [12]. This can guide future research by identifying the areas that have been thoroughly explored, and which areas need further research. The second limitation, as mentioned earlier, is that the evolution of the topic is continuous and expanding, but no research article is considered a necessary synthesis. Analyzing bibliographies provides detailed information about the most cited articles, influential journals, and the overall impact of research in the field. This can help understand the importance and reach of various studies [13, 14]. Clara, et al. [15] argued that many methodological scholars have emphasized the need for a systematic review process to obtain more objective conclusions for scientific literature reviews. Bibliometric analysis allows subsequent studies to go deeper and broader in each topic cluster.

This study will analyze publications published on the Scopus database from 2015 to 2024, marking the explosion of short videos in e-commerce. The objectives are: (1) to identify key research clusters and key topics in the field, (2) to analyze the relationship between research topics, and (3) to shape the research on short videos in commerce shortly. Through the combination of three methods of co-citation analysis, keyword co-occurrence, and bibliographic coupling, this article is expected to provide a comprehensive and updated perspective on the current state of research on short videos in e-commerce, thereby contributing to the development of this field.

Section II provides the research methodology, including how the data were collected. Section III provides the findings from conducting bibliometric analysis. Sections IV and V discuss and conclude the research results.

II. Methodology

A. Bibliometric Analysis

Peter and Carlota [16] pointed out that bibliometrics is a research methodology that has increasingly become a viable tool for understanding academic literature with the expanding availability of electronic copies. Bibliometrics is a general term encompassing various techniques that vary in nature and function, such as bibliographic coupling analysis, co-word analysis, citation analysis, and co-citation evaluation [17, 18]. This technique is commonly applied in libraries and information science and is regarded as an essential tool for planning, evaluation, and analysis. It often provides quantitative insights through citation analysis or content analysis, offering valuable data for assessing the impact, relevance, and development of scholarly works. Bibliometrics is mainly identified by the application of statistical analysis to the production of bibliographies. This study uses the science mapping method, which is a general process of analyzing and visualizing domains, which can then conduct a more effective literature survey [19].

In this study, the literature search and analysis activities are performed according to the bibliometric evaluation method proposed by Donthu, et al. [20]. It includes four main steps: Step 1: Defining the purpose and scope of bibliometric study. Step 2: Selecting the evaluation technique. Step 3: Collecting data for bibliometric analysis. Step 4: Running the bibliometric analysis and reporting the findings.

B. Data Collection

The data collection phase for the article can be conducted from many sources of information or access to reputable academic databases such as Google Scholar, Scopus, and Web of Science [21]. This study uses output data information from SCOPUS because of its best coverage, comprehensiveness, and fast data updates. Sometimes, we can find similar documents on the Web of Science or Google Scholar [16]. We have extracted a total of 299 (samples/documents) in the scope of "Article title, Abstract, Keywords" with the search keyword "Short video" AND in the scope of "All fields" with the search keyword "E-commerce" OR "Electronic commerce." The research time range includes articles published in the most recent decade, from 2015 to 2024. This helps the article to be objective with updated data and to evaluate the overview of the topic of short videos, helping to guide the research most effectively. Fig. 1 details the actual process of conducting bibliographic analysis. This process includes filtering steps to collect data for the final analysis.

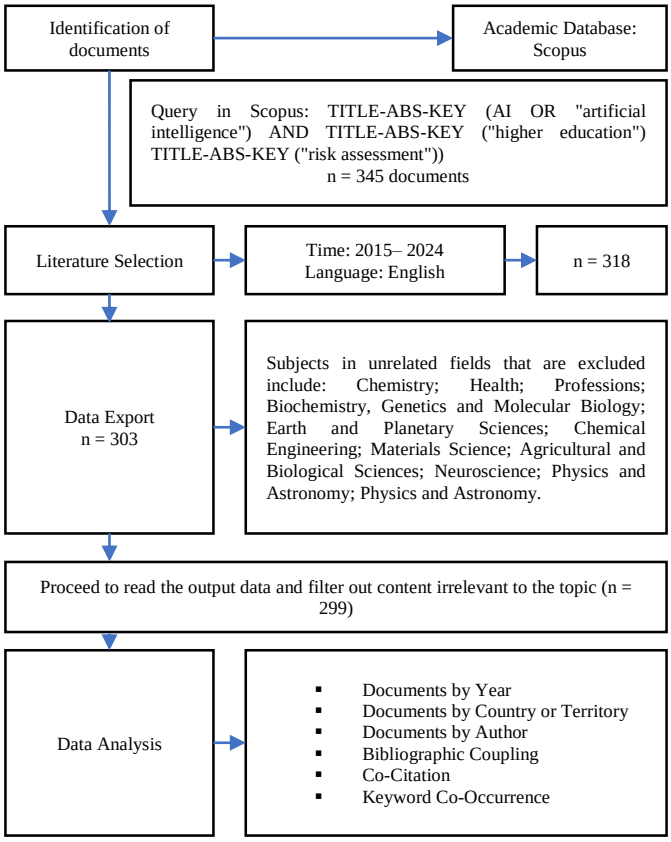

Fig. 1. The actual process of conducting bibliographic analysis.

C. Data Analysis Procedure

Information can be easily understood and analyzed in graphs and helps in concluding, making decisions, predicting. VOSviewer is a free software for constructing and visualizing bibliometric analysis [22]; we can create various networks based on keywords, citations, publication sources, authors,

common citations, etc. [23]. In this paper, bibliometric analysis is completed using the software "VOSViewer", which includes software for representing multidimensional data in graphical visualization.

III. FINDINGS

A. Bibliometric Analysis

As mentioned, "short video" is not a new concept. The first studies started around 2015, but since the end of 2016, when the TikTok platform was officially launched, it has completely redefined the above concept. In just two years, TikTok has emerged to rival companies like Netflix, YouTube, Snapchat, and Facebook, with more than one billion downloads in 150 markets worldwide and 75 languages [24]. Fig. 2 shows statistics by number of publications by year. Based on the statistical results, it is possible to analyze the development stages of short video research into three stages.

Stage 1. 2015-2018: The number of research papers is still relatively small, fluctuating around five papers yearly. This shows that short videos in e-commerce are still a new research field in this period.

Stage 2. 2019-2020: Since 2019, research around "short videos" has been widespread, most clearly demonstrated by the rapid increase in articles, especially in 2020. This growth can be related to the increasing popularity of short video platforms such as TikTok and the increase in online shopping during the COVID-19 pandemic.

Stage 3. 2021-2024: The number of research papers grew explosively, from about 30 in 2021 to more than 100 in 2024, and there are no signs of slowing down soon. This shows that short videos are becoming a "hot" research topic and attracting increasing attention from the scientific community.

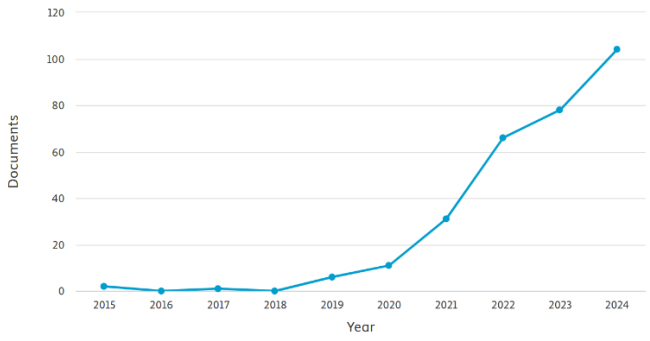

Fig. 2. Number of publications published by year from Scopus database.

B. Analysis of Documents by Country or Territory

The statistics on documents by territory have yet to offer any breakthrough conclusions. China is the dominant country in the number of publications, accounting for 77.26% of the total sample analyzed. The spread of short videos in China is mainly on two leading platforms, TikTok and Quick Hand, and reposting videos is standard on the country's social networking sites such as Baidu, Weibo, and Watermelon video [25].

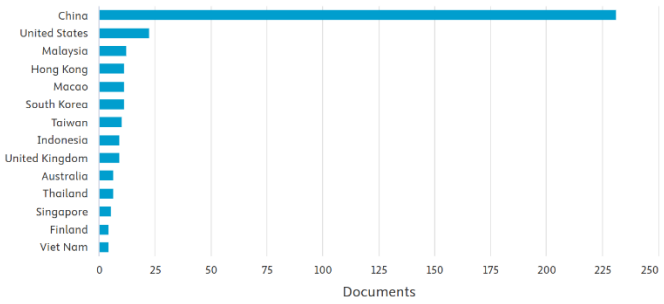

Fig. 3. Documents by country or territory by source from Scopus database.

China's dominance in the study of short video and e-commerce is evident from the fact that it is the country that owns the Douyin (Tiktok) platform - the most downloaded App in the Apple App store in the first quarter of 2019, beating out social media heavyweights like Facebook, Instagram and YouTube [26]. Internet-based applications in China also receive the necessary support from the Government to thrive [27], but at the same time, they are subject to the same internet regulations as other Chinese applications [28, 29]. However, this field still has excellent potential for development in other countries. Strengthening international research cooperation will promote the development of short videos in e-commerce globally. Fig. 3 illustrates the number of studies (at least 4 papers) published by region or territory on short video and e-commerce.

C. Analysis of Documents by Author

Some authors have more publications than others, indicating a research concentration within a small group of scientists. This can lead to close research collaboration and rapid growth of knowledge in the field. Although there are a few prominent authors, many others contribute to research on short videos and e-commerce. This shows a broad interest in the field and the potential for diverse perspectives and methods. This paper analyzes the number of papers by the author, showing the significant contributions of a few researchers while also showing the diversity of the research team on short video and e-commerce. This information can help identify leading experts in the field and find research collaboration opportunities for future publications. Fig. 4 shows some authors with prominent research articles on short video and e-commerce with at least 3 or more publications.

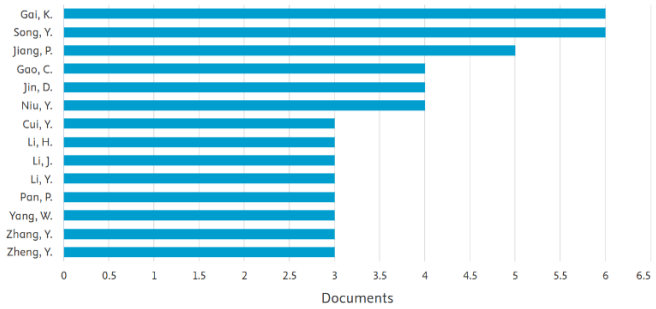

Fig. 4. Number of publications by author.

TABLE I. CORE RESEARCH AUTHOR ON SHORT VIDEOS

Authors		Title	General findings for the articles	No. of
Gai, K	Zhang, et al. [30]	Tag Tree-Guided Multi-grained Alignment for Multi-Domain Short Video Recommendation.	(1) Optimizing short video recommendation systems to improve user experience by delivering more accurate and relevant content. (2) Leveraging user feedback (such as WatchTime, Likes, Follows and Shares) to dynamically adapt and refine recommendation results based on changing user preferences. (3) Applying advanced machine learning techniques, including reinforcement learning and contrastive learning, to enhance the accuracy and efficiency of the recommendation algorithms. (4) Real-world deployment and testing on large-scale platforms like Kuaishou, demonstrating the effectiveness of the proposed models in live environments.	6
	Zheng, et al. [31]	Full Stage Learning to Rank: A Unified Framework for Multi-Stage Systems.		
	Cai, et al. [32]	Two-Stage Constrained Actor-Critic for Short Video Recommendation		
	Zhang, et al. [33]	Divide and Conquer: Towards Better Embedding-based Retrieval for Recommender Systems from a Multi-task Perspective		
	Zhang, et al. [34]	A Multi-Agent Framework for Recommendation with Heterogeneous Sources		
	Gong, et al. [35]	Real-time Short Video Recommendation on Mobile Devices		
Song, Y	Zheng, et al. [31]	Full Stage Learning to Rank: A Unified Framework for Multi-Stage Systems	(1) Optimization of recommendation systems to enhance user experience in short videos and e-commerce. (2) Leveraging accurate user data (feedback, viewing behavior, searches) to improve model accuracy. (3) Addressing data sparsity and bias using self-supervised learning and correction techniques. (4) Applying deep learning and graph-based models to improve user preference predictions. (5) Real-world experiments on large platforms like Kuaishou with A/B testing. (6) Resource efficiency and performance improvement without sacrificing model quality.	6
	Zhang, et al. [36]	SAQRec: Aligning Recommender Systems to User Satisfaction via Questionnaire Feedback		
	Sun, et al. [37]	KuaiSAR: A Unified Search and Recommendation Dataset		
	Zhang, et al. [38]	SHARK: A Lightweight Model Compression Approach for Large-scale Recommender Systems		
	Zheng, et al. [39]	Disentangling Long and Short-Term Interests for Recommendation		
	Liu, et al. [40]	Concept-Aware Denoising Graph Neural Network for Micro-Video Recommendation		
Jiang, P	Yang, et al. [41]	Spatiotemporal Fine-grained Video Description for Short Videos	(1) Focus on short videos: Improving recommendation systems for short video platforms. (2) Optimization of recommendation systems: Aiming to enhance the accuracy and effectiveness of recommendations based on user preferences and feedback. (3) Use advanced machine learning techniques: Implement reinforcement learning and multi-task learning. (4) Real-time feedback utilization: Adjusting recommendations based on immediate user feedback. (5) Real-world deployment: The methods are tested and deployed on real platforms, leading to improvements in user engagement.	5
	Cai, et al. [32]	Two-Stage Constrained Actor-Critic for Short Video Recommendation		
	Zhang, et al. [33]	Divide and Conquer: Towards Better Embedding-based Retrieval for Recommender Systems from a Multi-task Perspective		
	Gong, et al. [35]	Real-time Short Video Recommendation on Mobile Devices		
	Zhang, et al. [34]	A Multi-Agent Framework for Recommendation with Heterogeneous Sources		

Focusing on the top three authors with the most publications in the research field, Table I shows that the three authors' research focus is on developing and improving short video recommendation systems in e-commerce. Their research uses many advanced techniques and accurate user data to optimize user experience and improve the performance of the recommendation system. The research of Gai, K., Song, Y., and Jiang, P. has laid the foundation for the research on short video recommendation systems in e-commerce. Other researchers can take advantage of and further develop these results by applying new methods, extending the application to other fields, and building more significant and diverse datasets.

D. Bibliographic Coupling

Bibliographic coupling is a scientific mapping technique that operates on the assumption that two published studies that share standard references will have similar content [42, 43]. In this study, when analyzing data based on common keywords used by authors in clusters, keywords used as "search keywords" (which will be analyzed in the keyword co-occurrence analysis method below) were excluded because these keywords will be a practical evaluation direction reveal their content [44].

Fig. 5 shows the four main research clusters identified, including: (1) Impact and effectiveness. This cluster focuses on measuring the impact of short videos on consumer shopping behavior and the effectiveness of short video advertising. Important studies include Ge, et al. [45], Kopf, Graetzer and Huh [46], and Xu [47]; (2) User experience. User Experience. This cluster focuses on factors affecting user experience on short video platforms, including interface design, video content, and user interaction. Notable studies include Zhang, et al. [48] and Song, et al. [49]; (3) Trends and business models. This cluster focuses on the development and trends of short videos in e-commerce, as well as new business models. Important studies include [50] and [51]; and (4) Technology. This cluster focuses on the application of new technologies, such as artificial intelligence (AI) and machine learning, in the production and distribution of short videos.

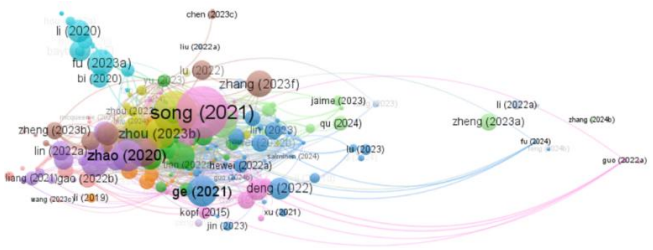

Fig. 5. Bibliographic coupling analysis results from VOSviewer.

The analysis's results show a diversity of research topics on short videos in e-commerce. Studies have examined the impact of short videos from various perspectives, from economic efficiency to user experience and technology application. Research trends show a growing interest in applying new technologies, especially artificial intelligence, to producing and distributing short videos.

E. Co-Citation

Co-citation analysis focuses on the number of times other documents cite two documents together, so it can be considered a method to measure the cohesion between publications [52, 53]. This paper focuses on co-citation analysis of author data. Author co-citation analysis is a way to determine whose publications are being cited in the same article and how the research community develops [54]. The results of the co-citation analysis show four distinct clusters as shown in Fig. 6.

Cluster 1, with the central red representation, focuses on "electronic commerce and factors influencing user behavior." Most of this cluster corresponds to co-citations from Davis, Bagozzi and Warshaw [55] study on the technology acceptance model (TAM); this cluster often uses quantitative analysis based on Fornell and Larcker [56] on structural equation modeling; Hu and Bentler [57] on model fit criteria; and Lou and Yuan [58] on influencer marketing. This cluster focuses on factors influencing the acceptance and use of technology in electronic commerce, including the role of influencers. These studies use quantitative methods and modeling to assess the impact of perceived usefulness, perceived ease of use, and perceived credibility on consumer behavior.

Cluster 2, with the upper green branch, focuses on "user experience and influencing factors". Studies in this cluster often cite Henseler, Ringle and Sarstedt [59] on discriminant credibility assessment in structural equation modeling; Sundar [60] on the MAIN (Modal, Agency, Interactivity, Navigability) model and the influence of technology on credibility; followed by co-integration from Wang [61] on the influence of humor and camera angles on user experience on TikTok; Zhang, Wu and Liu [62] on addiction to short-form video apps. This cluster focuses on user experience on short-form video platforms, especially the factors influencing engagement, engagement, and addiction. These studies combine psychology, communication, and technology theories to better understand user behavior in the digital environment.

Cluster 3, with the leftmost cluster shown in blue, focuses on "the effectiveness of short-video advertising". This cluster focuses on the studies of Ge, et al. [45] on the impact of short-video advertising on social media sales, Xiao, Li and Zhang [63] on factors influencing consumer engagement behavior with short-video advertising; Zhao and Wang [51] on user attitudes toward medical advertising on short-video social media. This cluster focuses on the effectiveness of short video advertising on e-commerce platforms. These studies consider factors such as advertising content, content creators, and platform characteristics to assess the impact of advertising on consumer purchase behavior and attitudes.

Cluster 4 on the correct branch is shown in yellow. This cluster focuses on "methodology and underlying theories". Typical co-cited studies include Fornell and Larcker [56] study on structural equation modeling and Mehrabian and Russell [64] study on environmental psychology. This cluster includes studies that provide theoretical and methodological foundations for other studies in the graph. Specifically, it provides a widely used model evaluation method in consumer behavior research and references environmental psychology, which can be applied to understand how users interact with digital environments.

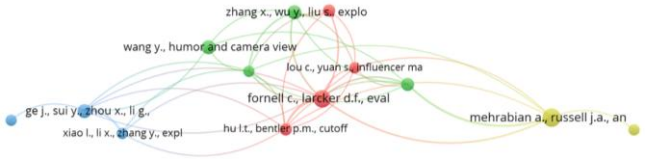

Fig. 6. Co-citation analysis results on VOSviewer.

F. Keyword Co-Occurrence

Zhang and Wang [65] argued that keyword co-occurrence analysis helps clarify research topics, while keyword co-occurrence analysis (i.e., two keywords appearing in a document) can better reveal the structure of research topics in a field. Elucidating the above opinion Rose, et al. [66] asserted that keywords are a condensed form of important content researchers present in a paper. This method explores the links between keywords in a document to reveal a scientific field's knowledge components and structure. Keywords can provide a concise overview of important content and key points of a piece of article content as an essential textual element. We increased the frequency of keyword occurrence in a publication to a minimum of 5 times to reinforce the research topic as having a high concentration. A total of 2,147 keywords emerged from the 299 research papers. After data processing, 84 standardized keywords were included in the analysis. Table II below lists the 15 keywords with the highest frequency of occurrence in the study of short videos in e-commerce.

TABLE II. FREQUENCY OF CO-OCCURRENCE OF KEYWORDS

Rank	Keywords	Frequency
1	Short video	45
2	Electronic commerce	36
3	Video-platforms	36
4	Social media	35
5	Marketing	27
6	E - commerce	26
7	Sales	23
8	Recommender systems	23
9	Tiktok	23
10	Purchase intention	22
11	Consumer behavior	19
12	Learning systems	19
13	Behavioral research	18
14	Multi-modal	18
15	Social networking (online)	16

The keyword clusters are closely related, reflecting the interaction between different aspects of short videos in e-commerce, as shown in Fig. 7. For example, "video platforms" (cluster 1) are connected to "short video platforms" (cluster 2) and "social media" (cluster 3), showing the interaction between technology, content, and user behavior—the directory links of the research visualized in Fig. 6 shows quite clearly the differentiation by keywords. The yellow cluster is considered the new direction of this research content in recent years; researchers are focusing more on analyzing the "Social context" for short videos in e-commerce. Other clusters focus on technology, content, and consumer behavior, while this cluster considers the human factor in the social and cultural context. Previous studies may have focused little on analyzing short video consumption behavior differences among different user groups. The yellow cluster represents a new and potential research direction in short video and e-commerce. Studies in this cluster can provide insights into the impact of short videos on different user groups in specific social and cultural contexts. These factors will contribute to a deeper analysis of the entire topic, reinforce other clusters, and serve as a foundation for further development.

Cluster 1 (Red): "Technology and Platforms". Keywords: "artificial intelligence", "deep learning", "e-commerce platforms", "video-platforms", "multi-modal", "recommend systems", "search engines", "user behaviors". This cluster focuses on the technological aspects of short-form video in e-commerce, including using artificial intelligence and deep learning to analyze data, personalize user experiences, and develop product recommendation systems. Research also focuses on e-commerce and video platforms, indicating interest in optimizing these platforms to support short-form video.

Cluster 2 (Green): "Content and Interaction". Top keywords "user experience", "flow experience", "TikTok", "Douyin", "short video", "social media". These keywords indicate an interest in studying how users interact with short videos on social media platforms, especially TikTok (Douyin), and the factors influencing their satisfaction and experience. "Flow experience" is an important concept in psychology, referring to a state of high concentration and immersion in an activity. Research on "flow experience" in short videos can help better understand how to create engaging content and retain users.

Cluster 3 (Blue): "Consumer Behavior". Highlighted Keywords: "purchase intention", "consumer behavior", "perceived usefulness", "perceived value", "technology acceptance model". These keywords indicate interest in studying how short videos influence consumer purchase behavior. Factors such as perceived usefulness, value, and technology acceptance drive purchase intention. The Technology Acceptance Model (TAM) is a popular theoretical framework used to study the acceptance and use of new technologies, including short videos in e-commerce.

Cluster 4 (Yellow): “Social Context”. Keywords highlighted: “adult”, “china”, “human”, “performance”, “video applications”. This cluster focuses on the social and demographic context of short video consumption. “China” indicates a particular interest in the Chinese market, where short videos are proliferating. “Adult” suggests that research may focus on adult user behavior.

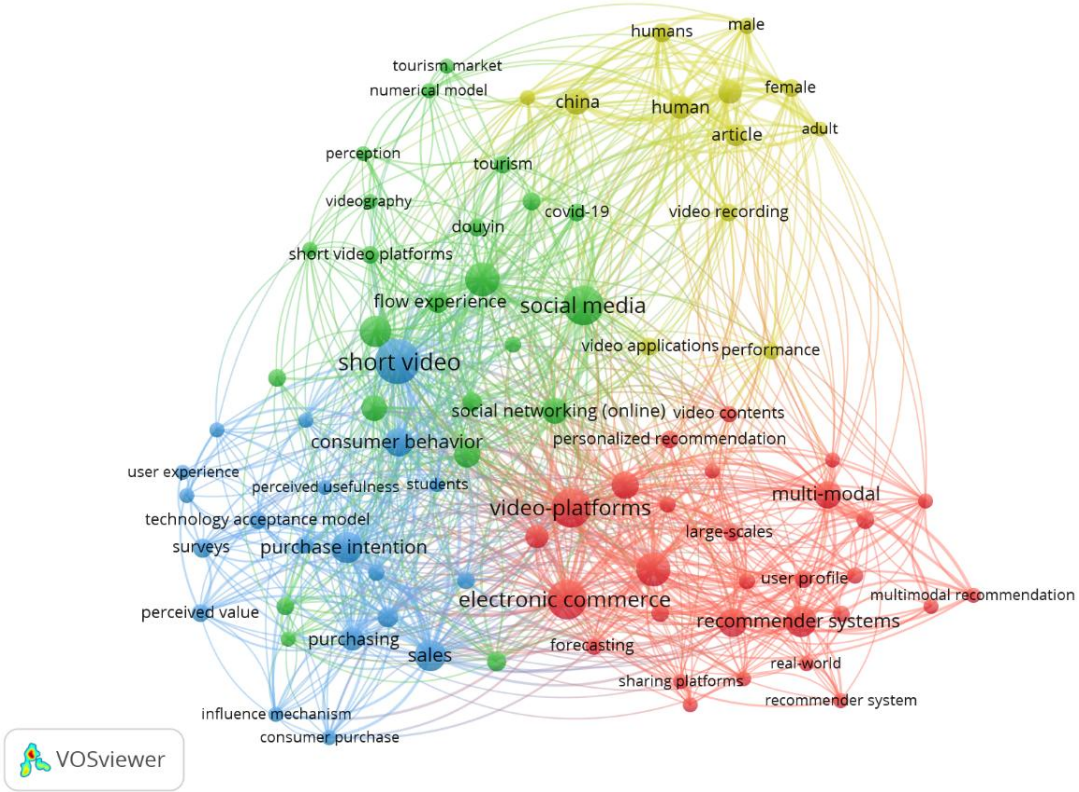

Fig. 7. Keyword co-occurrence analysis results from VOSviewer.

IV. DISCUSSIONS

This study used bibliometric analysis to investigate the growth and impact of short videos in e-commerce. Based on the study's main findings, this discussion focuses on providing detailed answers to the research questions posed earlier.

The first research question (RQ1) sought to identify the main thematic clusters and research topics in the field.

Keyword co-occurrence analysis and bibliometric pairing offer a balanced view of the focus areas in e-commerce and short-video research. Keyword co-occurrence analysis revealed that several keyword clusters had strong interrelations, reflecting the interrelations between different aspects of the field. Remarkably, the research revealed an overall high level of congruence between "video platforms," "short videos," and "social media." The core cluster is a marker for the importance of the websites upon which short-form video content resides, the format of the content itself, and the social connections around it. The occurrence of a yellow cluster near "social context" reflects how the acknowledgment of the role of social and cultural considerations in short-form video viewing and e-commerce is growing. This suggests that recent research is moving beyond simply looking at technology or individual user behavior and increasingly considering the broader social impacts of short-form video in e-commerce.

The bibliometric analysis identified four principal research clusters, each representing a distinct area of focus: Impact and Effectiveness, User Experience, Trends and Business Models, and Technology. The Impact and Effectiveness cluster examines the influence of short-form videos on consumer behavior and the efficacy of short-form video advertising. Research within this cluster typically assesses the impact of short-form videos on sales, consumer engagement, and overall marketing outcomes. The User Experience team explores factors affecting the user experience of short-form videos on e-commerce sites, such as interface design, video content features, user interactions, and psychological impacts on user satisfaction and engagement. The Trends and Business Models theme addresses the evolutionary trends for short-form videos in e-commerce and emerging business models that technology enables. This involves exploring new applications for short-form videos in marketing, sales, and customer engagement. The Technology theme addresses using new emerging technologies, such as artificial intelligence (AI) and machine learning, in creating, delivering, and personalizing short-form videos. Research in this category would involve discovering recommendation algorithms for videos, content creation, and insights.

The second research question (RQ2) was formulated to explore the relationships between different research topics in this field.

The co-citation technique gives meaningful information about the interconnectedness and cross-influence of various research domains. Outcomes from the co-citation analysis revealed several clusters that captured various facets of short-form video e-commerce research. E-Commerce and User Behavior: This cluster presents aspects of user behavior regarding e-commerce. Studies within this cluster frequently employ the Technology Acceptance Model (TAM) to comprehend how users adopt and utilize e-commerce technologies. User Experience and Factors That Affect: This cluster looks at user experience on short-form video sites and the various factors that may affect it. Research in this cluster can explore how humor, camera angles, and the addictive nature of short-form video apps affect user experience. Short-Form Video Advertising Effectiveness: This cluster considers the performance of short-form video advertising as a marketing platform. Research in this cluster can investigate how platform features, content creators, and ad messages impact consumer behavior and attitudes. Methodology and Underlying Theories: This cluster involves studies that provide theory and methodological foundations for other studies in the field. This may involve research in environmental psychology and structural equation modeling.

These clusters show how different research areas in the field are connected. As an example, influencer marketing research (cluster 1) can adopt user experience theories (cluster 2) and performance metrics methods (cluster 4) to examine the impact of influencers on purchase behavior on short-form video platforms. This shows the necessity of interdisciplinarity in research into the multifaceted phenomenon of short-form video shopping online.

The third research question (RQ3) traces the trajectory of research on short videos in e-commerce.

According to publications by year reveals that there has been a significant rise in research on short videos in e-commerce. There has been a remarkable spike in publications over the past few years, which indicates a greater interest in the subject. During the initial period (2015-2018), a relatively small number of publications showed that short videos in e-commerce are still an emerging area of research. The subsequent period of development (2019-2020) was characterized by a significant increase in publications, which can be attributed to factors such as the popularity growth of short video platforms such as TikTok and the online shopping boom. Since 2021, research output has boomed, highlighting that short videos have become a mainstream research topic. This indicates the dynamic development of the industry and increasing recognition of the significance of short videos in e-commerce.

V. CONCLUSION

This study has compiled data and drawn comprehensive conclusions about the research direction on “Evolution and Impact of Short Videos in E-commerce,” Nevertheless, it is worth mentioning some limitations that affect the interpretation of the findings and imply directions for further research.

One of the most significant disadvantages is the availability of a single database. Although Scopus is a highly inclusive repository, it does not include all the scholarly literature. Therefore, there is a possibility that research relevant to the investigation published in less-indexed journals, conference proceedings, or non-English language publications was excluded from the analysis. Using bibliometric analysis, the research gives rich statistics regarding research trends, dominant themes, and short video production in e-commerce.

However, limitations must be provided that impinge on result interpretation and identify possible areas for further research. Although bibliometric analysis provides an aggregated quantitative view of research trends, it does not provide detailed qualitative remarks regarding the content and quality of individual research. The analysis identified research clusters and broad topics. It does not assess the quality of the research methods employed, the validity of the findings, or literature biases.

To address these limitations, future research should consider several avenues. Wider Data Sources: Future studies need to encompass data from a more fantastic range of academic databases, including Web of Science, Dimensions, PubMed, and Google Scholar, as well as specific e-commerce and media studies databases. This provided a rich and representative image of the research setting. Combining Qualitative Analysis: Follow-up studies can be combined with bibliometric analysis and other qualitative methods, such as systematic reviews or meta-analyses, to understand research findings further. Future studies should continue to study and monitor trends in the field, such as the use of artificial intelligence in short video creation and personalization, consumer culture impacts on short videos in different cultures, and ethical considerations of marketing through short videos. Applying More Sophisticated Bibliometric Tools: Future studies can use more sophisticated bibliometric tools and methods, such as SciMAT, CiteSpace, or R Biblioshiny, to report more sophisticated analysis and visualization of the data. This may yield new insights into the dynamics and structure of research landscapes.

Classroom Behavior Recognition and Analysis Technology Based on CNN Algorithm

Weihua Qiao
School of Architecture and Planning, Changchun University of Architecture and Civil Engineering, Changchun, 130000, China

***Abstract*—Students' classroom behavior can effectively reflect the learning efficiency and the teaching quality of teachers, but the accuracy of current students' classroom behavior identification methods is not high. Aiming at this research gap, an improved algorithm based on multi-task learning cascaded convolutional neural network architecture is proposed. Through the improved algorithm, a face recognition model is constructed to identify students' classroom behavior more accurately. In the performance comparison experiment of the improved convolutional network algorithm, it was found that the recall rate of the improved algorithm was 88.8%, higher than the three comparison models. The result demonstrated that the improved algorithm performed better than the contrast model. In the empirical analysis of the face recognition model based on the improved algorithm, it was found that the accuracy of the proposed face recognition model was 90.2%, which was higher than the traditional face recognition model. The findings indicate that the model developed in this study is capable of accurately reflecting the students' state in the classroom, thereby facilitating the formulation of targeted teaching strategies to enhance their classroom efficiency.**

***Keywords*—Convolution neural network; multi-task learning; face recognition; classroom; student behavior**

I. Introduction

In the field of education, students' classroom behavior can directly reflect their learning efficiency and teachers' teaching quality [1]. However, the traditional method has the problem of low accuracy in identifying students' classroom behavior. The advent of sophisticated AI technology, particularly in the domain of computer vision, has led to the emergence of advanced deep learning algorithms, such as Convolutional Neural Networks (CNNs). These algorithms have demonstrated remarkable capabilities in image processing and have yielded novel solutions for classroom behavior recognition [2-3]. In recent years, the education industry has begun to widely adopt intelligent teaching equipment to assist teaching, which not only improves teaching efficiency but also provides the possibility for accurate monitoring and analysis of classroom behavior [4]. Therefore, the development of a deep learning-based classroom behavior recognition technology is of great significance for improving teaching quality and student learning efficiency. Although some studies have achieved some results in using CNN technology for classroom behavior recognition, these methods still have certain limitations. For example, the CNN-based classroom teaching behavior recognition and evaluation method proposed by Li et al., as well as the PSU-CNN model proposed by Sethi and Jaiswal [5]. The traditional CNN algorithm needs to improve its recognition accuracy and efficiency in the face of complex scenes and diverse student behaviors [6]. In addition, most of the existing researches focus on single-task learning and fails to make full use of the advantages of multi-task learning to improve the generalization ability and robustness of the model. Therefore, it is necessary to explore a more efficient and accurate classroom behavior recognition technology.

To solve these problems, an improved algorithm based on Multi-task learning cascade Convolutional neural network (MTCNN) is proposed and applied to students' classroom behavior recognition. By introducing the multi-task learning framework, the MTCNN algorithm realizes the joint optimization of face detection, border regression, and key point detection, and significantly improves the recognition accuracy and efficiency. In addition, the performance of the MTCNN algorithm is further optimized by adjusting the network structure, introducing new activation functions, and using feature selection and dimensionality reduction techniques. Compared with the existing literature, the research method has obvious differences and innovations in algorithm structure and task learning. The primary contribution of this study is the proposal of a technology for recognizing student classroom behavior. This technology is based on an improved MTCNN algorithm, and its effectiveness in improving recognition accuracy and efficiency is verified through experiments. This study not only enriches the application scenarios of Artificial Intelligence (AI) in education but also provides new ideas and methods for future research on classroom behavior monitoring technology.

This paper is divided into six sections. The first section introduces the research background, current research, and the research method. The second section describes classroom behavior recognition and related research on the CNN algorithm. The third section is the construction process of student classroom behavior recognition technology based on an improved MTCNN algorithm. In the fourth section, the performance of the proposed algorithm is verified by experiments and compared with the traditional algorithm. The fifth section is to analyze the experimental results and discuss the related research results. The sixth section summarizes the research results and looks forward to the future research direction.

II. Related Works

The implementation of AI in educational settings is experiencing a rapid expansion, particularly in the domain of classroom behavior monitoring. This approach can facilitate the generation of precise and time-efficient behavioral insights, thereby assisting educators in enhancing classroom management

and elevating the quality of instruction. CNN has become the mainstream technology of classroom behavior recognition because of its powerful image-processing ability. Li et al. proposed a method based on CNN for the identification and evaluation of classroom teaching behaviors and provided the scientific basis for teaching quality evaluation through accurate analysis of teaching videos [7]. Sethi and Jaiswal used CNN to develop the Prediction of Student Understanding-Convolutional Neural Network (PSU-CNN) model, which predicted students' classroom understanding through facial images and realized real-time feedback on students' learning status [8]. The Ensemble Deep CNN for Assessing (EDFA) model proposed by Gupta et al. used integrated deep CNN to assess the cognitive state of students in an adaptive online learning environment. This model enabled educators to modify their teaching strategies in accordance with the cognitive state of their students, thereby facilitating more effective learning outcomes [9]. Su and Wang also proved the effectiveness of deep learning technology in classroom behavior monitoring [10].

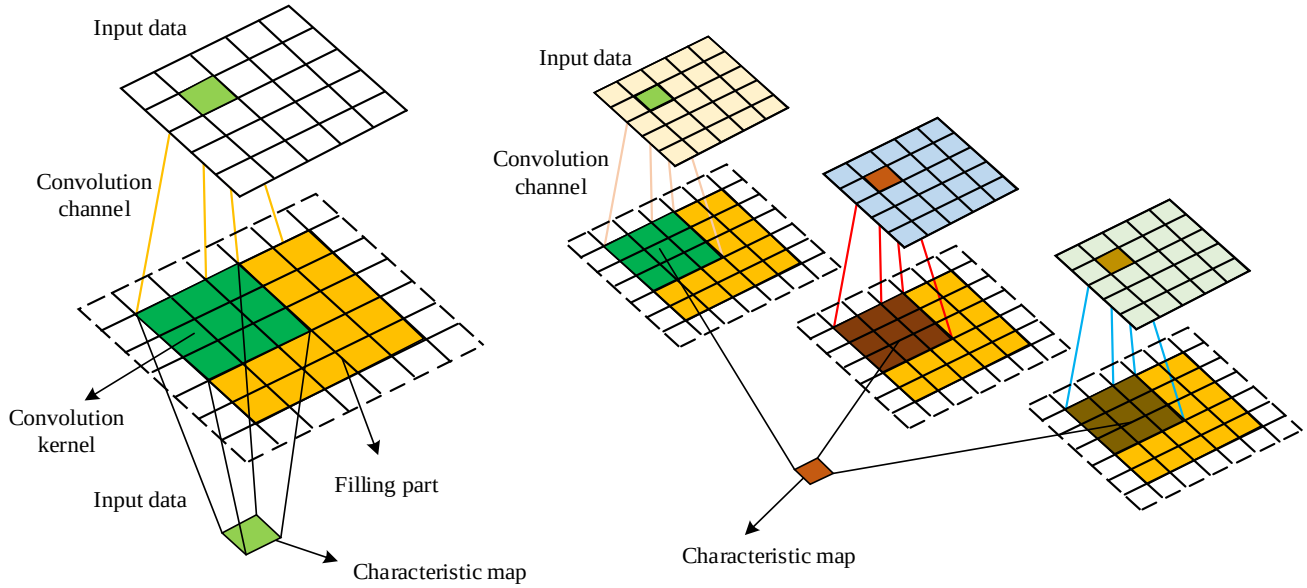
In addition to CNN technology, machine learning and hybrid models also play an important role in classroom behavior monitoring. Lu et al. developed an English online teaching monitoring system based on machine learning, which can analyze students' learning behavior in real-time, provide teachers with teaching feedback, and optimize the online teaching effect [11]. Xu et al. proposed a student online learning behavior monitoring system based on Temporal Shift Module (TSM) behavior recognition and screen recognition, which also provided teachers with feedback on students' learning status [12]. In addition, the CNN and Adaboost fusion model proposed by Hassan et al., and the CNN, Gated Recurrent Unit (GRU), and bidirectional Multi-scale CNN used by Lakshmi et al., were used for human behavior recognition. All these models have further enriched the technical means of classroom behavior monitoring [13-14]. The integration of the Internet of Things and intelligent identification technology provides new possibilities for classroom behavior monitoring. Lin et al. used Internet of Things technology and intelligent image recognition to analyze English classroom behavior and proved the potential of Internet of Things technology in education [15]. This research direction served to enhance the sophistication of classroom behavior monitoring, while simultaneously establishing a robust foundation for the prospective advancement of intelligent education.

To sum up, the application of AI in education and classroom behavior monitoring has shown a diversified trend, covering multiple fields such as CNN-based behavior recognition, machine learning and hybrid models, the Internet of Things, and intelligent recognition. The research work belongs to the category of CNN-based behavior recognition. However, the structure of MTCNN is used to improve the traditional CNN algorithm, thereby optimizing the precision and efficacy of classroom behavior analysis. This work not only enriches the application of AI in education and classroom behavior monitoring but also provides new ideas and methods for future research.

III. Construction of Student Classroom Behaviour Model Based on CNN Algorithm

A. CNN Algorithm Combined with Multi-Task Learning

As AI technology develops, target detection based on deep learning has been researched [16]. CNN algorithm is widely used in various image recognition fields because of its excellent performance in image algorithms [17]. For improving the recognition accuracy of student behavior in class, a Face Recognition (FR) model of improved CNN is proposed. The improved algorithm is based on the CNN algorithm and uses multi-task learning to obtain the MTCNN algorithm. CNN algorithm is the most common deep learning algorithm [18]. Convolution usually includes single-channel convolution and multi-channel convolution, as shown in Fig. 1 [19].



(a) Single-channel convolution

(b) Multi-channel convolution

Fig. 1. Two forms of general convolution.

Fig. 1(a) shows a single-channel convolution process. The convolution operation of the input data is performed on a single input channel, and the convolution kernel slides on that channel and applies weights to extract features. Fig. 1(b) shows the multi-channel convolution process, which involves convolution operations of multiple input channels. In this convolution process, each convolution check should have one input channel. There are multiple convolution kernels acting on different channels of the input data at the same time. Each convolution kernel independently extracts the features of a particular channel and then combines these features to form a more complex feature representation. The expression of the convolution operation continuous estimation function s in CNN algorithm is shown in Eq. (1).

$$s(t) = \int x(a)w(t-a)da \tag{1}$$

In Eq. (1), s represents the output signal of convolution operation. x is the input signal, representing the original data or image information. w is the kernel function, also known as the convolution kernel, which is used to weight the input signal. t and a represent the time variables of the output signal and the input signal, respectively. da represents the integral variable and is used to calculate integrals during convolution. The simplified expression is shown in Eq. (2).

$$s(t) = (x * w)(t) \tag{2}$$

The convolution kernel expression is shown in Eq. (3).

$$s(i,j) = (K * I)(i,j)\sum_m \sum_n I(m,n)K(i-m, j-n) \tag{3}$$

m and n respectively represent the effective value range of convolution. I represents the input two-dimensional image. K represents the kernel function of two-dimensional image. To facilitate the application of CNN algorithm in machine learning, Eq. (3) is usually modified, and the expression after the modification is shown in Eq. (4).

$$s(i,j) = (K * I)(i,j)\sum_m \sum_n I(i+m, j+n)K(m,j) \tag{4}$$

Its operation is very similar to the convolution operation, but the change is small within the effective range of m and n, which means that when m increases, the input index increases, and the kernel index decreases accordingly, realizing the interchangeability of convolution. The convolution layer of CNN generally refers to two-dimensional convolution operation. Assuming the original image size is set to $D_f \times D_f$ and the convolution core size is set to $D_k \times D_k$. The relationship between the three is shown in Eq. (5).

$$D_f^{'} = (D_f - D_k + 2 \times pad) / stride + 1 \tag{5}$$

In Eq. (5), pad is the filling value, representing the number of pixels added at the edge of the input feature map, which is used to adjust the size of the output feature map. $stride$ is the step length, which represents the stride length when the convolution kernel slides on the input feature map. This parameter affects the size of the output feature map and the granularity of feature extraction. The input layer and convolution layer dimension should be consistent, so it is necessary to select the appropriate step size to influence the extraction of image features. The length calculation of input and output after convolution is shown in Eq. (6).

$$h_0 = \frac{h_i - f + 2p}{s} + 1 \tag{6}$$

In Eq. (6), h_i is the input image width. The width expression of input and output after convolution is shown in Eq. (7).

$$w_0 = \frac{w_i - f + 2p}{s} + 1 \tag{7}$$

In Eq. (7), f is the convolution kernel size. s is the step size, and p is the number of expanded outer layers. By sampling, the pooling layer filters the primary visual features through sampling. Combing the abstract and advanced visual features of the layer, the expression of the whole process is shown in Eq. (8).

$$y_n^l = down(y_n^{l-1}) \tag{8}$$

In Eq. (8), y_n^{l-1} is the n characteristic graph of the output of the $l-1$ th layer network. y_n^l is the n characteristic graph of the pool of the l layer network, and it is the maximum sampling function. The fully connected layer can enhance the nonlinear mapping ability. The neurons used in the previous layer are connected with the neurons in the current network. In the same layer, neurons are not connected. The expression is shown in Eq. (9).

$$o_j^l = f(\sum_{i=1}^{n} X_i^{l-1} \cdot w_{ji}^l + b_j^l) \tag{9}$$

In Eq. (9), l represents the network layer number. n represents the number of network neurons in the $l-1$ layer. x_i^{l-1} is the input value of the i neurons. w_{ji}^l represents the connection weight between the j neurons in the l layer and the i neurons in the $l-1$ layer. b_j^l represents the offset of the j neurons in the l layer. The fully connected layer is

usually composed of linear part and nonlinear part. Among them, the linear part mainly analyzes the input data, and the nonlinear part mainly maps the input data. The overall structure of CNN including the specific fully connected layer structure is shown in Fig. 2.

MTCNN realizes the joint optimization of face detection and key point location by improving the traditional single-task CNN into a multi-task learning framework. It adopts a cascade structure and consists of three networks, P-Net, N-Net, and O-Net, which are respectively responsible for rough detection, candidate region refinement, and final accurate output, which improves detection accuracy and efficiency. In addition, MTCNN also introduces online difficult sample mining to enhance the robustness of the model. In the FR, the MTCNN algorithm initializes the training samples and network weights. The sample set consists of some faces and some non-faces, and the number of samples is N [20]. It inputs the training sample scaling layer image pyramid into the network. Supported by the objective function, the network weight is adjusted by the propagation method [21]. It scales the test image and inputs it into the trained network. Then, the P-Net generates a candidate window and border regression vector. Regression of the bounding box corrects the candidate frame, and NMS overlaps the candidate frame. Finally, it needs to output P-Net and input the improved candidate window and border regression vector into N-Net. It outputs N-Net and inputs the improved results into O-Net to output the final face frame and position. The improved MTCNN network structure is shown in Fig. 3.

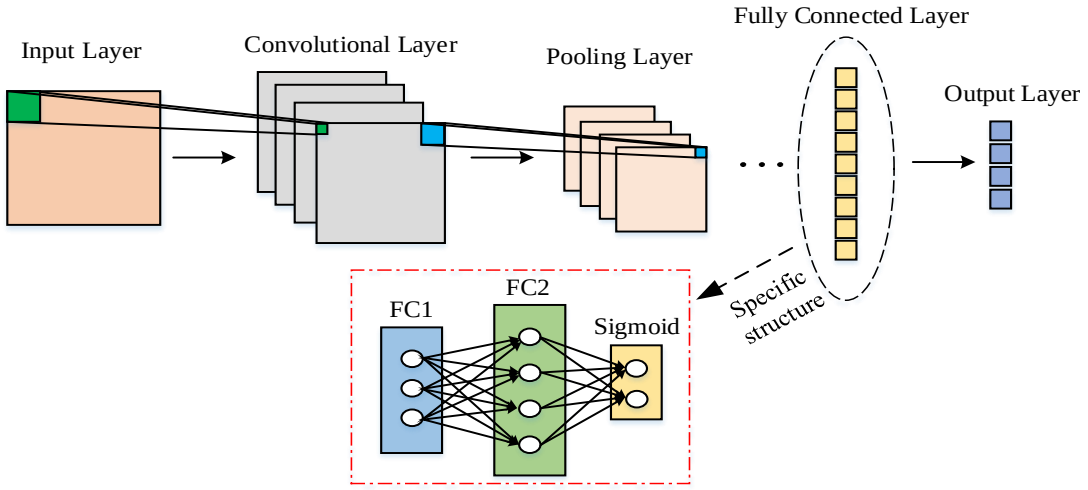


Fig. 2. CNN's overall structure.

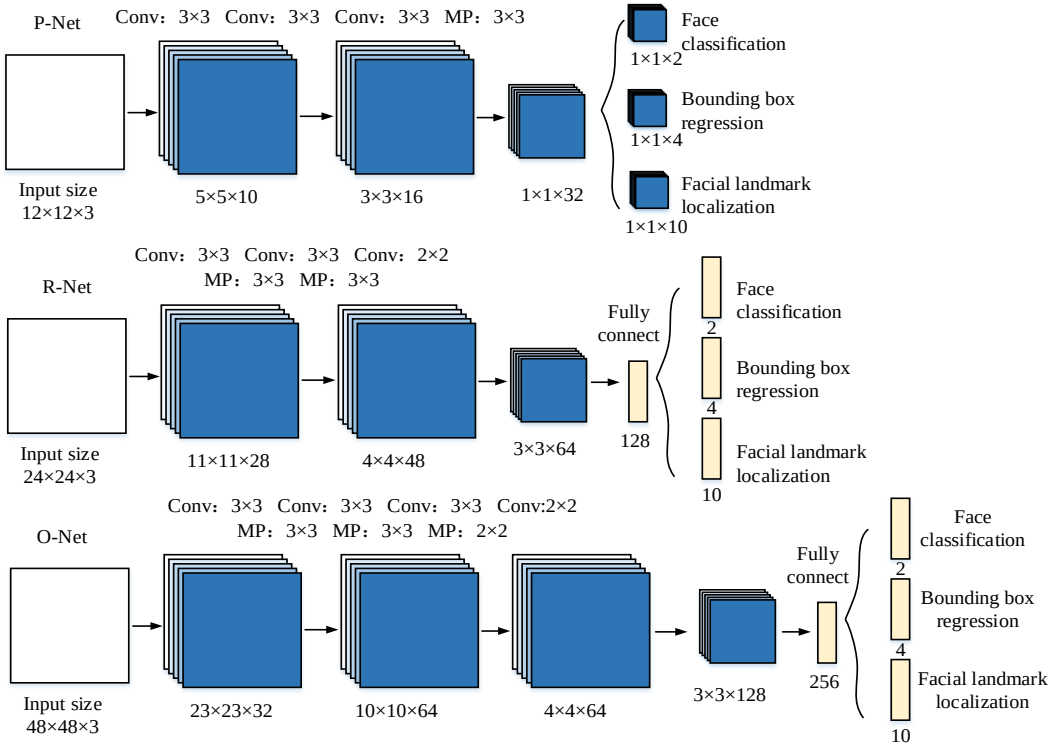

Fig. 3. Improved network structure of MTCNN.

As shown in Fig. 3, the improved MTCNN algorithm first initializes the training samples and network weights. The sample set consists of some faces and some non-faces, and the total number of samples is N. The scaling layer image pyramid of the training samples is input into the network. Combined with the objective function, the propagation method is used to adjust the network weight, and the test image is scaled and input into the trained network. Then, the P-Net is used to generate candidate window and border regression vectors, while bounding box regression is used to correct candidate boxes and Non-Maximum Suppression is used to overlap candidate boxes. Finally, P-Net outputs and inputs the improved candidate window and border regression vector into N-Net, N-Net outputs and inputs the improved result into O-Net, and O-Net outputs the final face frame and position. The ReLU activation function is fast in neural network training, and its function definition is shown in Eq. (10).

$$f(x)\begin{cases}0 \ for \ x<0\\ x \ for \ x\geq 0\end{cases} \tag{10}$$

In neural network training parameters, the ReLU function will not have the problem that the gradient of sigmoid function disappears in error back propagation during model training. Compared with ReLU, the PReLU activation function adds very few parameters. However, the amount of computation does not increase during the whole network training. Especially when the same a_i is used in different ways, the number of parameters will be less. When the error reverse algorithm updates a_i, the driving quantity update method is adopted, as shown in Eq. (11).

$$\Delta a_i = \mu \Delta a_i + \varepsilon \frac{\partial \varepsilon}{\partial a_i} \tag{11}$$

Therefore, the activation function of the proposed MTCNN face detection algorithm is the ReLU activation function with parameters.

B. Construction of FR Model Based on MTCNN

With the increase of students, real-time monitoring of students' classroom status is crucial to the improvement of school classroom quality [22]. To monitor students' discipline in the classroom in real-time and improve the teaching management level of the school, the FR algorithm based on MTCNN is researched and adopted to realize the FR of students in the classroom scene. This method can identify the behavior of students in the classroom. When students behave abnormally, this method can intercept the marker box for the detection target. Then FR is performed on the target in the frame to judge the students' classroom status. This technically supports the improvement of classroom teaching quality. The proposed FR algorithm exists in the whole classroom behavior recognition, and the specific FR algorithm flow is shown in Fig. 4.

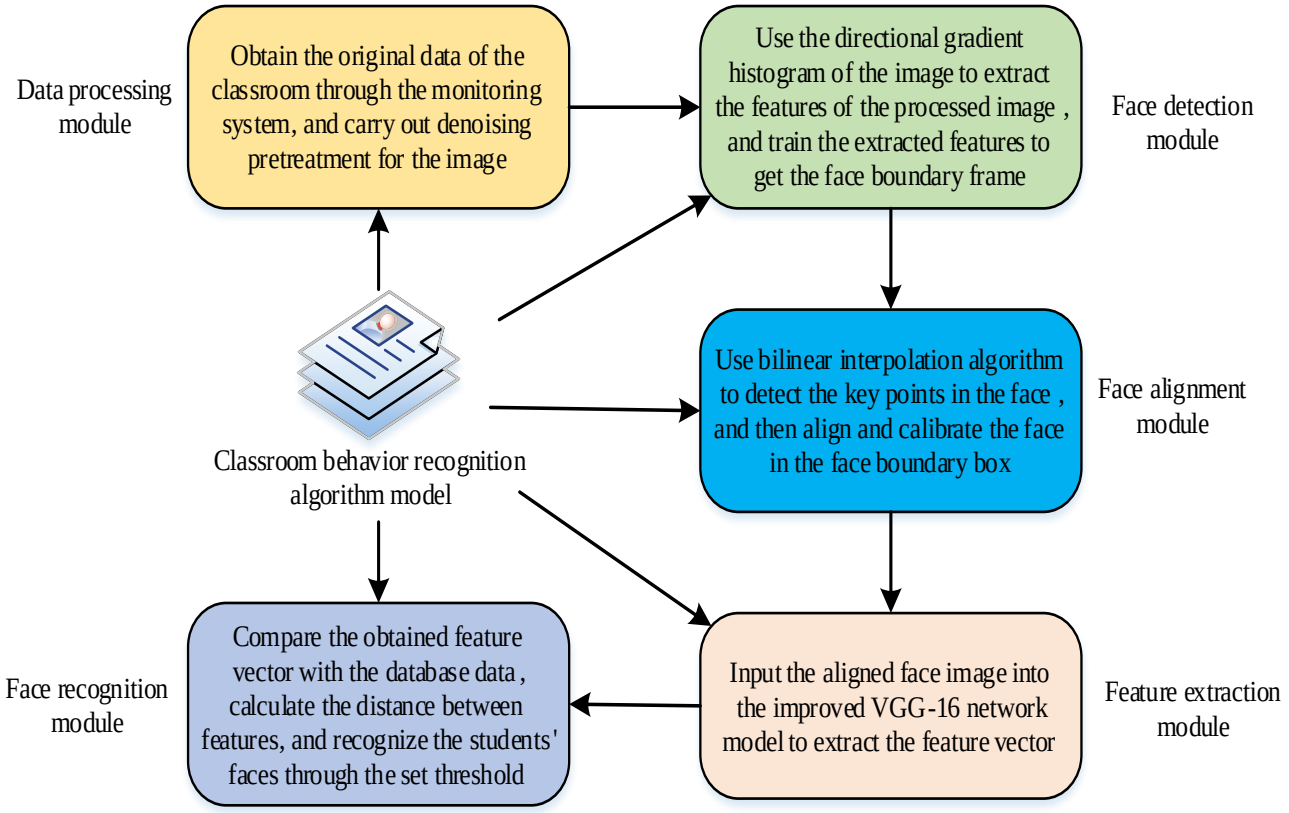

Fig. 4. Structure of classroom behavior recognition algorithm model.

As shown in Fig. 4, the proposed FR algorithm mainly includes five modules. They are the data processing module, detection module, face alignment module, feature extraction module, and FR module. The data processing module needs to obtain the original image of the classroom through the monitoring system and then pre-process the obtained image by framing or noise reduction to ensure that the original image is clear and complete. The face detection module mainly extracts the features of the pre-processed image and inputs the extracted image into the Support Vector Machine (SVM) classifier to train the boundary frame of the face. The face alignment module is mainly used to detect the key points and align the face in the face boundary box. The feature extraction module uses the improved MTCNN model to extract the features of the aligned face image and obtain the feature vector. The final FR module mainly compares the feature vector with the database data, calculates the distance between the features, and recognizes the students' faces through the set threshold. The MTCNN algorithm designs a lightweight structure, which ensures real-time performance. It is a multi-task learning face detection framework, which can simultaneously perform three tasks: face detection, detection frame regression, and face feature point detection. Among them, face detection is solved and described by the cross entropy loss function, whose expression is shown in Eq. (12).

$$L_i = -(y_i^{\det} \log(p_i) + (1 - y_i^{\det})(1 - \log(p_i))) \quad (12)$$

In Eq. (12), $y_i^{\det} \in \{0,1\}$ represents the real label of the i training sample. $y_i^{\det} = 1$ represents the face, otherwise it is non-face. p_i represents the probability that the i training sample is a face. The detection frame regression represents the candidate window loss through Euclidean distance, and its expression is shown in Eq. (13).

$$L_i^{box} = \left\| \hat{y}_i^{box} - y_i^{box} \right\|_2^2 \quad (13)$$

In Eq. (13), $y_i^{box} \in R^4$ represents the true border vector of the i training sample. It consists of four elements: the horizontal axis coordinates of the upper left corner, the vertical axis coordinates of the upper left corner, the height, and width. $\hat{y}_j^{box}$ represents the prediction frame vector of the i training sample. Face feature points can be regarded as a group of two-dimensional arrays. The loss of feature points can also be expressed by Euclidean distance, and its expression is shown in Eq. (14).

$$L_i^{landmark} = \left\| \hat{y}_i^{landmark} - y_i^{landmark} \right\|_2^2 \quad (14)$$

In Eq. (14), $y_i^{landmark} \in R^{10}$ represents the real face feature point coordinates of the ith training sample. There are five points in total and one point for each two coordinates, called 10-tuple. $\hat{y}_i^{landmark}$ represents the predicted face feature point coordinates of the i training sample. This paper applies the MTCNN algorithm to students' classroom FR and puts forward an FR model based on the MTCNN algorithm. It mainly includes five modules: data processing, face detection, face alignment, feature extraction, and FR. In the FR model, the MTCNN algorithm is mainly used to realize the accurate recognition of students' faces in the classroom scene. It can perform face detection, detection frame regression, and face feature point detection at the same time to improve the accuracy and efficiency of FR. The flow of the proposed FR model is shown in Fig. 5.

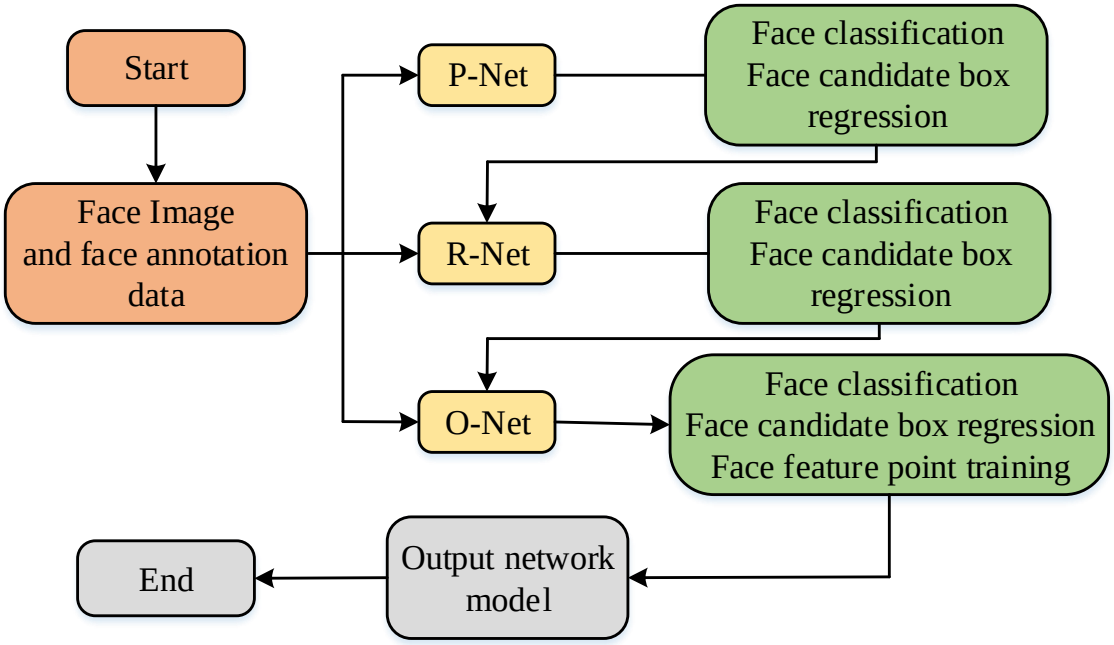

Fig. 5. Classroom FR model flow based on MTCNN algorithm.

In Fig. 5, the workflow of the FR model based on the MTCNN algorithm is as follows: First, an image of any size is input, and after multi-template and multi-scale graph preprocessing, the input image is reduced to 12×12 size and sent to the P-Net. Since the smaller the image, the easier it is to generate candidate regions, the network size for detecting images is set to 12×12. Then the candidate region frame is filtered, and the image is extracted according to the candidate region box and used as the input of R-Net. R-Net makes further adjustments on the border of the candidate regions formed by the previous network to generate more accurate regional recommendations and send the results to the O-Net. It further adjusts the candidate regions to obtain the final face detection structure. At the same time, the coordinates of facial key points will be output to complete the final detection process. The FR model proposed in this study is a multi-task learning framework based on MTCNN. In this model, 5 key points are used in the study to recognize face feature points. These key points constitute 10 coordinate values, that is, 10 attributes. In addition, feature selection and feature dimensionality reduction techniques, such as principal component analysis, are used to optimize feature vectors and improve computational efficiency. Finally, in the MTCNN network structure, this study also designs a multi-layer CNN. The specific number of layers is determined based on task requirements and computing resources to ensure efficient operation and excellent recognition performance of the network. The MTCNN model proposed by the research can recognize students' faces in class. It analyzes students' classroom state and then formulates appropriate strategies to improve students' concentration in class and improve students' classroom learning efficiency.

IV. Comparative Analysis of FR Algorithm Performance

A. Experimental Environment Setting

The purpose of this part is to test the performance of the proposed MTCNN and compare its performance with the Visual Geometry Group (VGG) model, CNN model, and Region-based Convolutional Neural Networks (RCNN) model. It takes the loss curve, accuracy, precision, F1 value, and recall rate as the performance comparison indicators for comparative experiments. The experimental environment for the comparison experiment includes a high-performance server equipped with an NVIDIA GeForce GTX 1080 Ti GPU, running the Ubuntu 18.04 operating system, and using the TensorFlow deep learning framework. The hyperparameters of the MTCNN model are set as follows: the learning rates of P-Net, N-Net, and O-Net are 0.01, 0.01, and 0.001 respectively, the training batch size is 128, and the parameters are updated by Adam optimizer. During the training process, data enhancement techniques, including random cropping, rotation, and flipping, are used to increase the generalization ability of the model. The training program is divided into two stages: the pre-training stage and fine-tuning stage. In the pre-training stage, the large-scale FACE dataset WIDER FACE is used for preliminary training, enabling the model to learn the fundamental characteristics of the face. Subsequently, in the fine-tuning phase, the model is further adjusted using a dataset specific to the classroom environment to suit real-world application scenarios. For comparison models, VGG, CNN, and RCNN, similar training strategies and hyperparameter tuning processes are used to ensure that they can achieve full performance within their respective frameworks. After the training is complete, all models are evaluated using the same test set to ensure that the results are fair and comparable. This paper studies the training of four network models in the framework of deep learning. It uses a random gradient descent method to update parameters. The learning rate of model training is set to 0.1, which attenuates exponentially.

B. Experimental Result

The loss curve is usually used to show the change of the loss value in the training process of the model. It serves as a crucial metric for assessing the efficacy of the model's training. The smaller the loss value, the better the performance of the model.

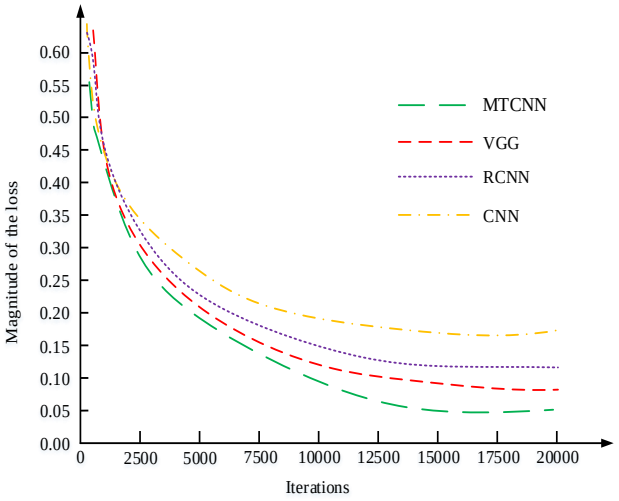

Fig. 6. Comparison of loss curves of four models.

The loss curve of the four models in the deep learning framework is shown in Fig. 6. From Fig. 6, the loss values of the four models went downwards with the increase in the number of iterations. The MTCNN model tended to be stable with the lowest loss value of 0.05, and it tended to be stable when the iterations were 16,100. The loss value of the VGG model that tended to be stable was followed by 0.10, and it tended to be stable when the iterations were 13,900. The loss value of the RCNN model tended to be stable and was only 0.13 higher than that of the CNN model, and it tended to be stable when the iterations were 12,800. The CNN model tended to be stable with the highest loss value of 0.18, and it tended to be stable when the iterations were 12,400. The above results showed that the improved MTCNN model was superior to the other three models in terms of the loss curve dimension. Accuracy is the proportion of the number of correctly classified samples to the total number of samples. The higher the value, the better the classification performance of the model.

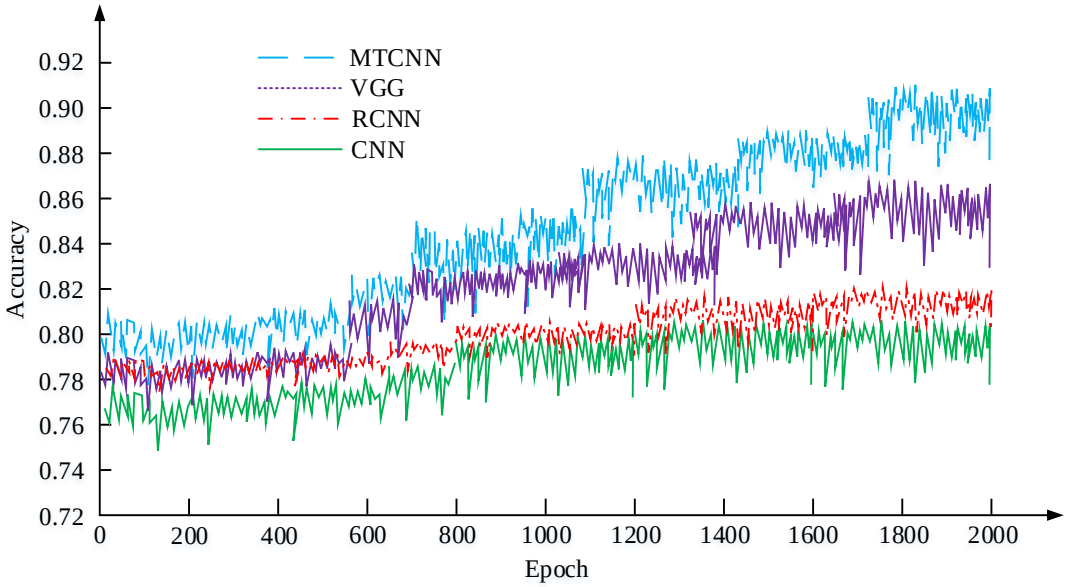

Fig. 7. Accuracy of different models.

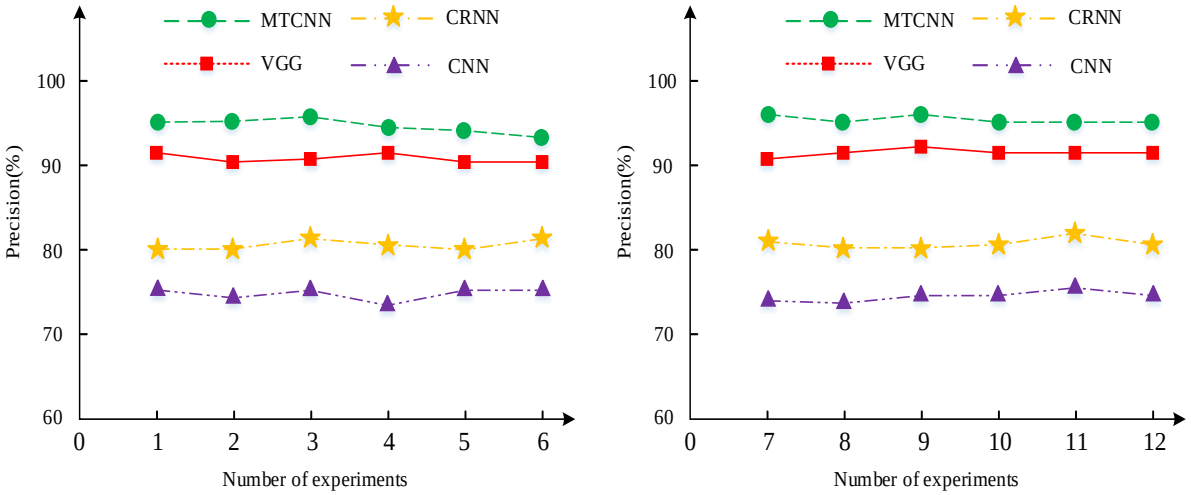
The same test set is used for the accuracy of the four, and the results are shown in Fig. 7. The accuracy curve of MTCNN is higher than that of the comparison model. Its accuracy curve shows an upward trend with increasing iterations. In addition, the maximum accuracy of the two-way MTCNN model is 0.91. This is higher than 0.87 for the VGG model, 0.82 for the RCNN model, and 0.79 for the CNN model. The above results indicate that, from the perspective of accuracy, the MTCNN model outperforms the three comparison models. To facilitate a comprehensive comparison of the four models' accuracy, F1 value, recall, and Precision-Recall (PR) curve, a series of tests were conducted on the LFW dataset to train the FR model. Precision refers to the proportion of predicted positive samples that are actually positive samples. The higher the value, the better the classification performance of the model.

The precision results are shown in Fig. 8. Fig. 8(a) is the curve of the previous six comparative experiments. The Precision curve of the MTCNN model in the four network models is higher than that of the other three models. Its average Precision in the first six comparative experiments is 93.5%. This is higher than 90.1% of the VGG network model, 80.1% of the RCNN model, and 76.3% of the CNN. Fig. 8(b) is the Precision curve of the last six comparative experiments. The Precision curve of the MTCNN model in the four network models is higher than that of the other three models. Its average Precision in the first six comparative experiments is 93.6%. This is higher than 90.3% of the VGG model, 80.4% of the RCNN model, and 76.1% of the CNN model. The above results show that the improved VGG-16 network model has the best performance from the perspective of Precision. The recall rate is defined as the proportion of positive samples that are correctly identified as such. The higher the value, the better the classification performance of the model.



（a）Results of the first six experiments

（b）Results of the last six experiments

Fig. 8. Precision comparison results of four models.

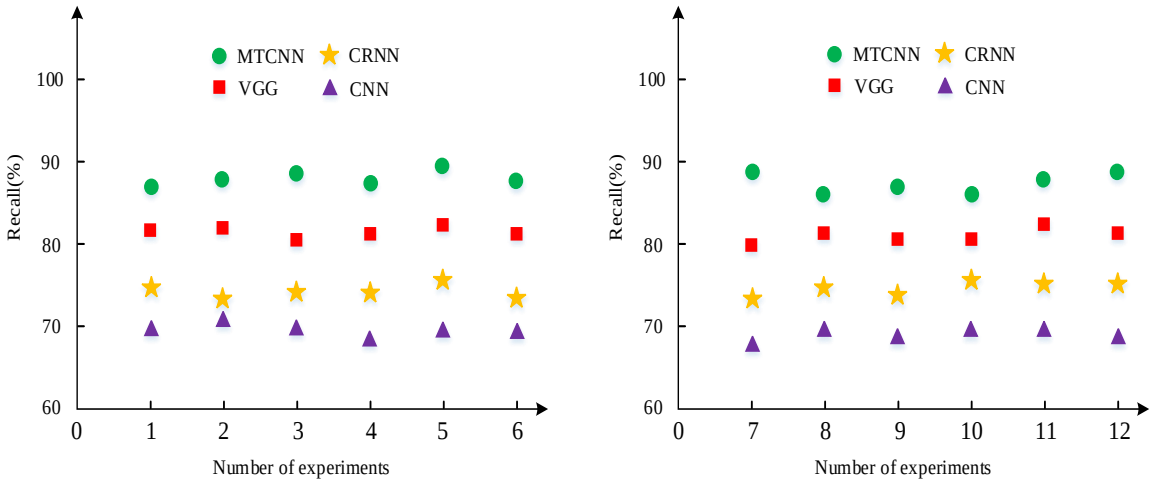


Fig. 9. Comparison results of recall rates of four models.

The recall rates of the four models are shown in Fig. 9. Fig. 9(a) is the results of the previous six comparative experiments. The overall recall rate of the MTCNN model in the four network models is higher than that of the other three models. Its average recall rate in the first six comparative experiments is 88.8%. This is higher than 82.1% of the VGG, 74.3% of the RCNN, and 69.4% of the CNN. Fig. 9(b) is the results of the last six comparative experiments. The overall recall rate of the MTCNN model in the four network models is higher than that of the other three models. Its average recall rate in the first six comparative experiments is 88.6%. This is higher than 81.4% of the VGG, 74.6% of the RCNN, and 68.8% of the CNN. The above results indicate that the improved MTCNN model has the best performance from the perspective of recall rate. The F1 value is the harmonic average of the accuracy rate and recall rate, which is used to comprehensively evaluate the performance of the model. The higher the value, the better the performance of the model.

The results of F1 values are shown in Fig. 10. From Fig. 10, when test samples increase, the F1 values of the four models decrease. When the number of samples to be tested is 50, the four models have good F1 values. However, with the increase of samples, the computational load of the model increases, and the F1 value of some comparison algorithms starts to decrease significantly. Finally, when the number of test samples is 350, the F1 values of the CNN model, RCNN model, VGG model, and MTCNN model are 38.6%, 39.8%, 50.3%, and 61.8%, respectively. The higher the F1 value of an algorithm, the better its performance. Therefore, the above results show that the improved MTCNN is superior to other comparison models from the perspective of F1 value. The PR curve, composed of recall rate and precision, can intuitively demonstrate the average precision value of disparate algorithm models.

The four algorithm's PR curves are shown in Fig. 11. From Fig. 11, the MTCNN model used in this study has the largest area in the PR curve. The MTCNN model has the best effect on student FR detection, with the highest average detection accuracy. Then, the time complexity of the three algorithms is analyzed. This study measures the time required for different models to process the same number of images under the same hardware conditions through experiments.

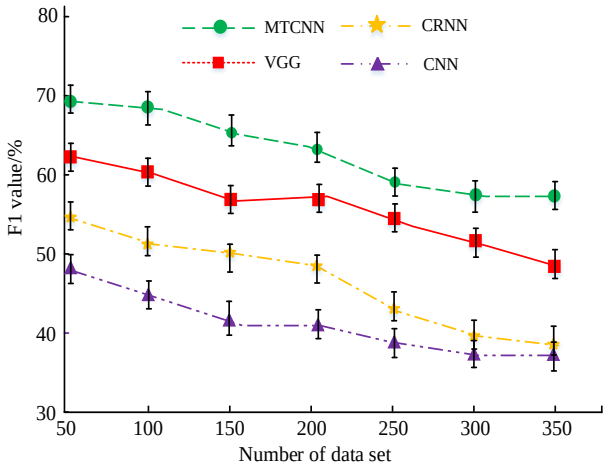

Fig. 10. F1 values of different algorithms.

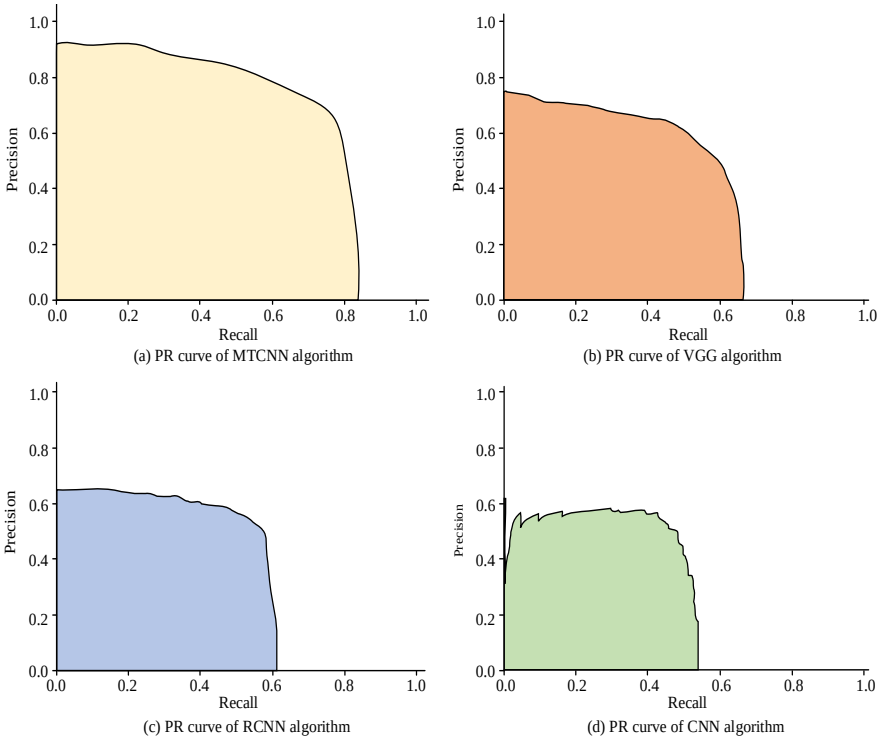

Fig. 11. PR curves of four target detection algorithms.

TABLE I. COMPARISON OF THE TIME COMPLEXITY OF THE THREE ALGORITHMS

Sample size	Model type	Average processing time (ms)	Standard deviation (ms)	Time complexity evaluation
50	VGG	496.3	25.3	Intermediate
	RCNN	748.2	30.6	Higher
	MTCNN	302.5	19.8	Lower
100	VGG	991.6	48.5	High
	RCNN	1528.7	59.2	Very high
	MTCNN	589.6	31.2	Intermediate
150	VGG	1518.5	75.5	Very high
	RCNN	2244.6	78.6	Extreme height
	MTCNN	887.6	39.1	Intermediate

The comparison results of the time complexity of the three algorithms are shown in Table I. From Table I, the average processing time of all models shows an upward trend with the increase in the number of samples. Among them, the average processing time of the MTCNN increases from 302.5 ms to 887.6 ms, showing good scalability. In contrast, the average processing time of VGG and RCNN increases more significantly, from 496.3 ms and 748.2 ms to 1528.7 ms and 2244.6 ms, respectively, indicating that they face greater computational challenges when processing large numbers of samples. The average processing time of MTCNN model is lower than that of other models for all sample numbers, and the growth is relatively slow as the sample number increases, showing its potential in practical applications. In summary, the performance of the MTCNN model and the other three models in loss curve, accuracy, precision, F1 value, and complexity are compared. The experimental results show that the MTCNN model has low time complexity while maintaining high accuracy. This is primarily attributable to the lightweight network structure and multi-task learning framework of the MTCNN model, which facilitates expeditious responsiveness in practical applications, thereby addressing the demands of real-time FR. To analyze the practical application effect of the FR model based on the MTCNN model, five classes of students are selected as experimental data sets. The performance of the proposed FR-MTCNN model is compared with traditional models, and the accuracy and precision of the FR model are used as comparison indicators.

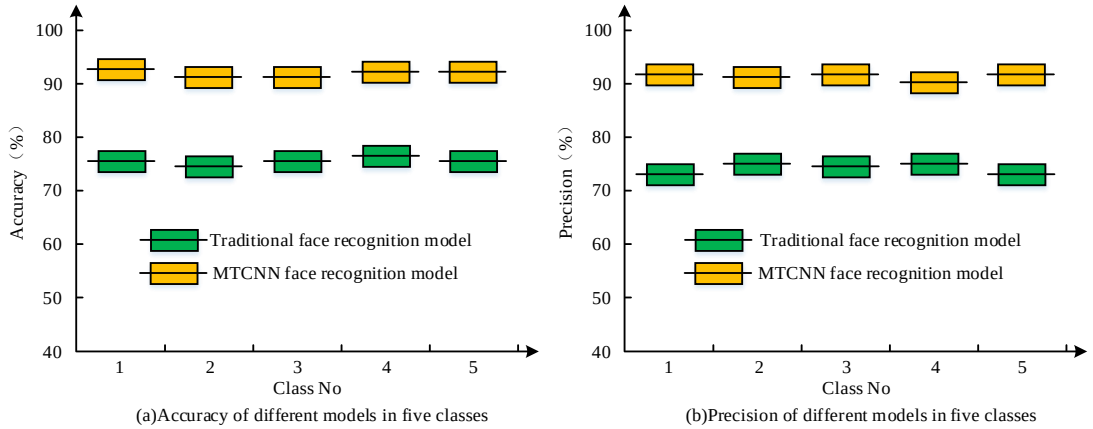

Fig. 12. Comparison results of accuracy and precision of two FR models in five classes.

The specific comparison results are shown in Fig. 12. In Fig. 12, the comparison of accuracy and precision between the two models in 15 categories shows that the proposed FR-MTCNN model generally has higher accuracy and precision than the traditional FR model, with an average accuracy of 90.2% and an average precision of 91.3%. According to the results, the proposed FR MTCNN model is superior to traditional FR model. Applying this model to the classroom can accurately capture students' classroom state, and on this basis, appropriate teaching strategies are formulated to improve students' classroom efficiency. Finally, to more comprehensively verify the accuracy and importance of the proposed method, various indicators are compared with those in [7], [8], and [9]. The comparison results are shown in Table II. The proposed MTCNN method is superior to the methods in references [7], [8], and [9] in all indexes. Among them, the recall rate, accuracy, precision, and F1 value of MTCNN are 6.7%, 4.0%, 3.4%, and 11.5% higher than that of the method proposed in [7]. At the same time, MTCNN has the shortest average time to process 50 images, only 302.5ms, and the lowest loss value is also the lowest, which is 0.05. The above results show that the MTCNN method is more accurate and efficient, and has obvious advantages.

TABLE II. COMPARISON RESULTS OF INDICATORS OF DIFFERENT METHODS

Validation index	MTCNN	Reference [7]	Reference [8]	Reference [9]
Recall Rate	88.8%	82.1%	78.4%	74.3%
Accuracy	91.0%	87.0%	84.2%	82.1%
Precision	93.5%	90.1%	83.3%	80.1%
F1 value	61.8%	50.3%	42.5%	39.8%
Average time to process 50 images	302.5ms	496.3ms	538.5ms	748.2ms
Minimum loss value	0.05	0.10	0.12	0.15

V. DISCUSSION

The proposed MTCNN model is superior to other models in accuracy and recall rate. This is consistent with the research results of Khan et al. [23]. The reason for this result may be that MTCNN improves the overall detection accuracy and efficiency by simultaneously optimizing the three tasks of face detection, border regression, and key point detection. In addition, the cascade structure gradually screens the candidate regions from coarse to fine, reducing the amount of computation and improving the detection speed. However, the MTCNN model also has some limitations. For example, its adaptability to complex scenes and extreme lighting conditions needs to be improved, and the training time on large-scale datasets is relatively long. While the FR model proposed in the study demonstrates superior accuracy and recall compared to other models, its implementation in an educational setting warrants careful ethical and practical consideration. First, continuous monitoring of students' behavior may have a potential impact on students' psychology. It is not uncommon for students to experience feelings of invasion of privacy, which can lead to elevated stress and anxiety levels. This can have a detrimental impact on their learning efficiency and mental health. Therefore, when implementing such technology, students' feelings must be fully taken into account and appropriate measures must be taken to reduce their psychological burden. Second, the use of FR technology in the classroom involves privacy concerns and possible legal issues. Although strict measures have been taken in data processing and storage to protect students' privacy in this study, legal restrictions and regulatory requirements for FR technology vary in different countries and regions. Therefore, when promoting the application of this technology, it is necessary to strictly comply with relevant laws and regulations to ensure legality and compliance.

In addition, in actual teaching, the interaction between teachers and students is one of the key factors in the quality of teaching. Over-reliance on technological monitoring can weaken this interaction, affecting trust and communication

between teachers and students. Consequently, when integrating such technologies, it is imperative to comprehensively assess their influence on the dynamics of teachers and students and to implement strategies that facilitate constructive engagement between teachers and students. Further research is required to investigate the capacity of diverse models to manage intricate scenarios and mitigate overfitting, as well as to ascertain how these models can be generalized to disparate classroom contexts. In addition, it is necessary to explore the potential of the technology in other applications. For example, in places such as libraries, laboratories, etc. where people's behavior needs to be monitored and managed, the technology may have higher utility and fewer ethical issues. Finally, when the proposed method is applied in sensitive environments such as education, it faces challenges such as privacy protection and educational effectiveness. Therefore, future research should pay more attention to these challenges and explore effective solutions to ensure the stability and reliability of the technology. At the same time, research on the ethical issues of AI technology should be strengthened to promote its healthy development in education.

VI. Conclusion

To improve the accuracy of the current student behavior recognition model in class, an FR algorithm combining a multi-task learning network and CNN was proposed and applied to the behavior recognition model of classroom students. The proposed MTCNN algorithm was tested in performance. The precision rate, recall rate, and F1 value of the MTCNN algorithm were 93.5%, 88.8%, and 61.8%, respectively, which were better than the three comparison algorithms. In addition, the research also carried out performance comparison experiments on FR models based on the MTCNN algorithm. The accuracy and precision of the proposed FR model were 90.2% and 91.3%, which were far higher than the traditional FR model. In conclusion, the proposed MTCNN algorithm and the FR model were superior to the comparison algorithm and model. Therefore, the FR model based on the MTCNN algorithm can be used to identify and analyze the behavior of students in the classroom to implement corresponding measures to improve classroom quality. The next research direction is to ensure the stability of the classroom student behavior recognition model.

Malicious Domain Name Detection Using ML Algorithms

Lamis Alshehri, Samah Alajmani
Dept. of Cybersecurity, Taif University, Taif, Saudi Arabia

***Abstract*—With the ever-increasing rate of cyber threats, especially through malicious domain names, the need for their effective detection and prevention becomes very urgent. This study mainly investigates the classification of domain names into either benign or malicious classes based on DNS logs using machine learning. We evaluated five strong ML models: XGBoost, LightGBM, CatBoost, Stacking, and Voting Classifier, in an effort to obtain high accuracy, F1 score, AUC, recall, and precision. The challenge in that direction is to achieve a very good solution, without using deep learning techniques for low computational cost. Moreover, this project has an obligation to upgrade the cybersecurity landscape by embedding the best-performing model into the DNS firewall to enable protection against harmful domains in real time. Our dataset was collected and curated to include 90,000 domain names, including an equal number of safe and harmful, respectively, extracting 34 features from DNS logs and further enriched using publicly available data.**

***Keywords*—DNS Security; machine learning; malicious domain detection; XGBoost; LightGBM; CatBoost**

I. INTRODUCTION

With the advancement of the digital age, the use of the internet has become extremely common for communication, the exchange of important information, and even for commerce. This has led to an increased demand for cybersecurity and the search for precise security mechanisms that can be implemented and utilized. Among the many common threats, the Domain Name System (DNS) is one of the crucial elements in the internet's infrastructure, as it converts domain names into IP addresses. However, it lacks appropriate protection mechanisms, which allows cybercriminals to exploit these vulnerabilities, helping them spread malware, conduct phishing attacks, or gain unauthorized access to data on servers. Therefore, there is an urgent need for methods that achieve a balance between efficiency, accuracy, and the ability to perform in real-time [1].

The ever-evolving nature of cybersecurity demands continuous upgrading to match newer, sophisticated modes of attack. The Domain Name System (DNS) is an important target for attackers due to the significant losses it can cause. Therefore, any breach of the security of the DNS affects the reliability of the internet greatly, which underscores the importance of securing this system. In the event of any compromise to its foundational structure, institutions will suffer losses and customers will lose their privacy, leading to customer dissatisfaction as well as legal implications and other significant issues. The primary goal of the DNS when it was designed was to provide a scalable and available domain name resolution service, but at that time, security aspects were not adequately emphasized, resulting in many security vulnerabilities that could turn lives upside down globally if exploited by attackers. This issue also calls for an interesting junction of technological advancement, real-time Threat Intelligence, with pragmatic implementation of solutions [2].

This project investigates the capability of ML models in identifying and classifying domain names as either benign or malicious based on DNS log data. Advanced ML algorithms such as XGBoost, LightGBM, CatBoost, Stacking, and Voting Classifiers will be used to develop an efficient cybersecurity solution which is computationally effective. The current approach focuses on lightweight ML models rather than deep learning methods, which require a huge amount of computational resources. The best performance model will be integrated into a DNS firewall for better security of the network. This system not only addresses current limitations in DNS security but also provides a scalable and cost-effective approach for future cybersecurity challenges [3].

The main objective of the research is to propose a lightweight, accurate, and efficient system for malicious domain name detection based on DNS logs. This research also aims to develop ML models that classify domain names with high precision, recall, and F1 scores. It also focuses on designing a non-deep learning system to provide computational cost efficiency and enable real-time applications. In addition, a comparison was made between the performance of five deep learning-based machine learning models to find the best approach. This research also relies on model optimization, using a 34-dimensional feature space derived from enriched DNS features using DNS records to enhance the latest model outcomes by leveraging a high-dimensional dataset. One of the important goals is to deploy the best-performing model on a DNS firewall for implementation in real-world situations and also to ensure that the proposed solution has the capacity to scale to large volumes of DNS traffic in wide-scale environments.

Below are the key contributions the research that makes to the field of cybersecurity and ML-based threat detection:

- Model Performance - Extended Comparison: Performances of XGBoost, LightGBM, CatBoost, Stacking, and Voting Classifier will be presented in this work through extensive testing, providing the best methodology for DNS threat detection.
- Rich Feature Utilization: The study uses a dataset of 34 features extracted from DNS logs, ensuring that the ML

models are adequately informed to carry out the classification with a high degree of accuracy. Features like these will provide in-depth and subtle particulars about the behavior of the domain names.

- Lightweight Solution: By not being dependent on deep learning approaches, the system is computationally light and reachable even by organizations lacking extensive computing resources. This entails a wider applicability across various sectors with different technical capabilities.
- Practical Integration: The integration of the best-selected model into a DNS firewall allows real-time defense against malicious domain names and closes the gap between theory and practice. Experimental insights become, at this stage, an actionable tool.
- Balanced Dataset: The research is based on a dataset containing an equal number of benign and malicious domain names, thus allowing for impartial model evaluation. This will add to the credibility and reliability of the results found from this work.

The rest of this paper is organized as follows: Section II reviews the related work. Section III details the methodology. Section IV presents the results and analysis. Section V provides the discussion, highlighting the key findings and their practical implications. Finally, Section VI concludes the paper.

II. Related Work

Many researchers have proposed various methods for detecting malicious domain names in the literature.

Wagan et al. [4] have developed a single, unifying method for discovering malicious domain names utilizing both numerical and textual information. Traditional DNS firewalls rely on lists of blacklisted maligned domains, but such lists cannot respond to new, emerging malignants. Traditional machine learning approaches have aided in enhancing detections but have not utilized both numerical and textual information of a domain name in its full capacity. To mitigate this, they have developed a deep model with a Hybrid Feed Forward Network (FFN) for numerical and a Long Short-Term Memory (LSTM) for textual information. Features extracted through both numerical and textual information are consolidated in a single, unifying format, and then utilized for classification. They trained a model over a 90,000-domain name corpus and demonstrated its performance to outperform six baseline approaches in terms of accuracy, precision, recall, and F1-score.

Ren et al. [5] proposed a deep model for Domain Generation Algorithm (DGA) domain detection via an integration of an attention mechanism with a combination of Convolutional Neural Networks (CNNs) and Bidirectional Long Short-Term Memory (BiLSTM) networks. With both locality in character structures and long-term relations in domain names in consideration, and leveraging the use of an attention mechanism for prioritization of salient features, proposed model, namely, ATT-CNN-BiLSTM, can accurately discriminate between malignant and innocent domains, in contrast to traditional DGA detection approaches, which have a problem with wordlist-based DGA domains. Experimental evaluation confirms that ATT-CNN-BiLSTM achieves an F1-score of 98.79% in DGA detection, outperforming traditional machine and deep learning approaches. In addition, the model has high generalizability, and thus, proves effective in processing previously unfamiliar DGA families.

Luo et al. [6] proposed a deep learning system for malicious URL identification, utilizing a composite neural network (Comp-block) and an auto-encoder for feature extraction and classification, respectively. First, URLs go through irrelevant information deletion and tokenization of structure. An auto-encoder then transforms URLs into vector representations, and representations go through a deep model constructed with Convolutional Neural Networks (CNN) for anomalous behavior analysis. Manual feature selection is not utilized in the proposed scheme, and it is efficient in contrast with traditional rule-based approaches. Experimental evaluation with the HTTP CSIC 2010 and a custom dataset revealed that the system achieves high accuracy (98.20%) and detects anomalous URLs with low false alarm, outpacing traditional approaches for detection.

Marques et al. [7] proposed a real-time ML-enforced DNS firewall for real-time malignant request domain filtering. Unlike traditional firewalls, utilizing a blocklist, potentially excluding recently generated new-malicious domains, their model employs supervised ML algorithms for distinguishing between malignant and innocent DNS queries.

The system processes DNS logs with 34 key feature extraction and OSINT-enriched feature extraction. Various algorithms for machine learning, including Decision Trees (CART), SVM, Logistic Regression, and KNN, have been compared with a 90,000 record dataset. Experimental performance showed that CART performed best with an accuracy of 96% and a rapid classification time, and can, therefore, be used for real-time filtering of DNS. In this work, it is established that ML-powered DNS firewalls can effectively enhance cybersecurity through efficient detection and filtering out of malice domains over traditional approaches.

Thain et al. [8] proposed a machine learning-based approach to detect malicious domains on the Internet by analyzing domain names and traffic passing through DNS. They used important people information .Then they used techniques such as Random Forest, XGBoost and AdaBoost to find out if the site is malicious or not. After several experiments, they found that the system can identify malicious sites with an accuracy of up to (92.7%) even if the data is small. Then they combined it with semantic analysis and the system became more effective than traditional methods on blacklist.

Samad et al. [9] presented an intelligent system for detecting malicious websites on the internet. The system relies on natural language processing (NLP) in URLs and also the content of web pages. Techniques are employed to better understand words, such as n-grams (which means a set of words), which assist the system in making accurate decisions. The system uses seven mathematical methods, such as Random Forest and XGBoost, to determine whether a website is malicious. After several experiments, they discovered that the

system, by integrating the content of pages and URLs, is significantly better than older methods.

D. Ma & Wu. [10] proposed a new method for detecting malicious domain names using a specific intelligent model called (VAE). The main objective is to improve the detection of (DGA) families, which are defined as random domains that are difficult to detect.

The method begins by processing the domain names, where the data is cleaned of impurities and unimportant details. After that, a technique called (Word2Vec) is used to convert the words into vectors for better understanding by the system.

Subsequently, the vectors are input into the (VAE) model, which adjusts itself using backpropagation. The damage probability is then calculated, and the domain is classified as harmful or benign based on a threshold classifier.

Experiments have shown that this method outperforms traditional methods in detecting (DGA) families.

Zhao et al. [11] have proposed an algorithm to detect harmful domain names based on the statistical features of URLs, using a decision tree classifier to enhance detection accuracy. Their method relies on extracting characteristics such as length, special characters, and character distribution to distinguish between legitimate and harmful domains. A decision tree was used to classify the domains based on these features, and the model achieved an accuracy of 90.31% in detecting harmful domains. The study shows that analyzing URL features significantly aids in accurately classifying domains and reduces the need for pre-labeled data.

Compared to previous research, in our study, we made complementary contributions to some similar papers by comparing five machine learning algorithms: XGBoost, LightGBM, CatBoost, Stacking, and Voting Classifier. This makes them easier to interpret and clearer, and with a lighter weight than deep learning techniques. We relied on feature selection techniques such as ANOVA F-value and SelectKBest to identify the most influential features, which reduces the dimensionality of the data and improves the model's performance. We also conducted a comprehensive study of a set of features that includes characteristics related to email security, such as SPF, DKIM, and DMARC records, as they enhance the ability to detect domains that target phishing and email attacks. Additionally, we propose adding the best model for detecting harmful domains to be integrated into a prototype for a DNS firewall.

III. METHODOLOGY

It depicts the suggested architecture for detecting malicious domain names. The framework consists of many steps, including dataset and preprocessing, feature engineering, model creation, and the use of ensemble learning like voting classifier and stacking classifier techniques. Each phase substantially improves the overall effectiveness of the malicious domain name detection system. Fig. 1 shows proposed framework.

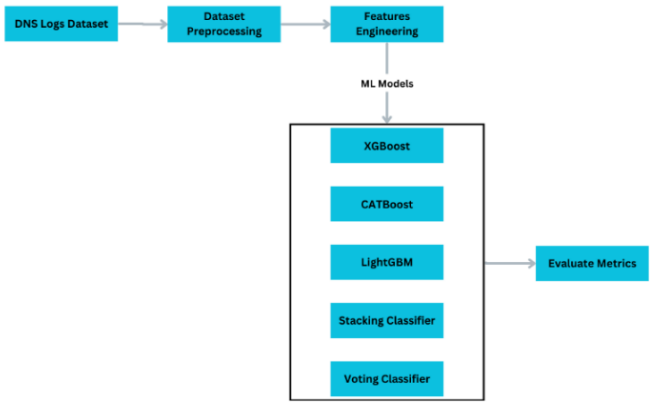

Fig. 1. Proposed framework.

A. Dataset

This study uses the Mendeley Dataset (Table I) that has been collected and processed by Marques et al. which includes both benign and malicious domains retrieved from DNS logs [12]. This dataset is especially designed for supervised machine learning research to differentiate between harmful and non-malicious domain names. It was rigorously curated by combining publicly accessible DNS logs from both sorts of domain names. Each domain name is used as an input in the dataset, resulting in 34 characteristics. Domain name properties such as entropy, the occurrence of unique characters, and domain name length are examples of features that are directly extracted. Furthermore, supplemental details such as domain creation date, related IP address, open ports, and geolocation were obtained by data enrichment methods that used Open-Source Intelligence methodologies. This collection of 90,000 domain names is rigorously balanced, providing an equal mix of 50% non-malicious and 50% malicious domains.

TABLE I. DATASET FEATURES WITH DESCRIPTION AND DATA TYPES

Feature Name	Description	Type	Count
Domain	Baseline DNS used to enrich data, e.g., derive features	int64	90000
DNSRecordType	DNS record type queried	object	90000
MXDnsResponse	The response from a DNS request for the record type MX	bool	90000
TXTDnsResponse	The response from a DNS request for the record type TXT	bool	90000
HasSPFInfo	If the DNS response has Sender Policy Framework attribute	bool	90000
HasDkimInfo	If the DNS response has Domain Keys Identified Email attribute	bool	90000
HasDmarcInfo	If the DNS response has Domain-Based Message Authentication	bool	90000
IP	The IP address for the domain	int64	90000
DomainInAlexaDB	If the domain is registered in the Alexa DB	bool	90000
CommonPorts	If the domain is available on common ports	bool	90000
CountryCode	The country code associated with the IP of the domain	object	60948
RegisteredCountry	The country code from domain registration (WHOIS)	object	12226

Feature Name	Description	Type	Count
CreationDate	The creation date of the domain (WHOIS)	int64	90000
LastUpdateDate	The last update date of the domain (WHOIS)	int64	90000
ASN	The Autonomous System Number for the domain	int64	90000
HttpResponseCode	The HTTP/HTTPS response status code for the domain	int64	90000
RegisteredOrg	The organization name from domain registration (WHOIS)	object	54609
SubdomainNumber	The number of subdomains for the domain	int64	90000
Entropy	The Shannon entropy of the domain name	int64	90000
EntropyOfSubDomains	The mean entropy of the subdomains	int64	90000
StrangeCharacters	The number of non-alphabetic characters	int64	90000
TLD	The Top-Level Domain for the domain	object	89830
IpReputation	The result of the blocklisted search for the IP	bool	90000
DomainReputation	The result of the blocklisted search for the domain	bool	90000
ConsoantRatio	The ratio of consonant characters in the domain	float64	90000
NumericRatio	The ratio of numeric characters in the domain	float64	90000
SpecialCharRatio	The ratio of special characters in the domain	float64	90000
VowelRatio	The ratio of vowel characters in the domain	float64	90000
ConsoantSequence	Max number of consecutive consonants in the domain	int64	90000
VowelSequence	Max number of consecutive vowels in the domain	int64	90000
NumericSequence	Max number of consecutive numeric characters in the domain	int64	90000
SpecialCharSequence	Max number of consecutive special characters in the domain	int64	90000
DomainLength	The length of the domain	int64	90000
Class	The class of the domain (0 = malicious, 1 = non-malicious)	int64	90000

In this study, 34 features were carefully selected based on their significance in distinguishing between malicious and benign domains.

Behavioral features such as Entropy, NumericRatio, and SpecialCharRatio measure the degree of randomness within a domain name. Higher values of these features typically indicate that the domain was automatically generated using algorithms like Domain Generation Algorithms (DGA), which are commonly utilized in malicious activities.

Reputation and registration features, including IpReputation and DomainReputation, verify whether the domain or its associated IP address is listed in known blacklists. Similarly, CountryCode and ASN provide geographical and network-related context, as certain regions and service providers are statistically linked to hosting malicious domains.

Structural features such as DomainLength, SubdomainNumber, and StrangeCharacters assess the composition of the domain name itself. Malicious domains often adopt long, complex names or incorporate unusual symbols to mimic legitimate websites while evading detection.

Additionally, Email-related Security features like HasSPFInfo, HasDkimInfo, and HasDmarcInfo examine the existence of standard email protection protocols. Malicious domains used in phishing or spam messages typically lack these protective protocols.

Finally, accessibility and response behavior features such as CommonPorts and HttpResponseCode evaluate how the domain responds to connection attempts which analyze the domain's response when attempting to connect. Malicious domains may use unusual ports or return response codes (e.g., 404 or 503), signaling potentially harmful intent or unreliable behavior.

These combined features provide a comprehensive view that enhances the model's ability to accurately classify domains based on both static attributes and dynamic behavior.

Fig. 2, shows the distribution of the target variable Class, which indicates whether a domain is malicious or benign. The x-axis represents the two classes, and the y-axis represents the count of domains in each class.

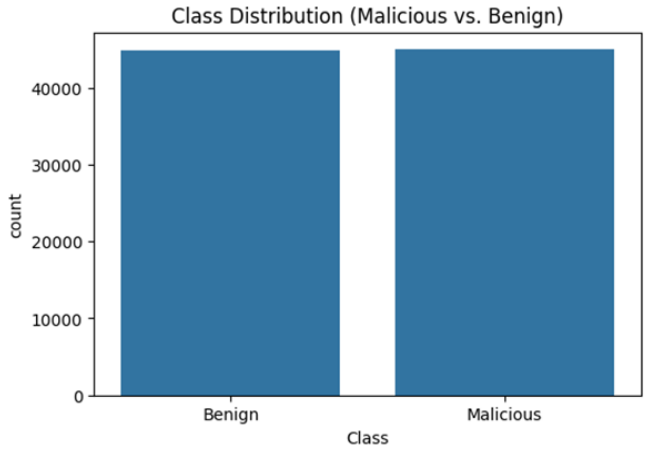

Fig. 2. Class distribution (malicious vs. benign).

The data is evenly distributed between the two classes, meaning there is no significant class imbalance. This is beneficial for training a machine learning model, as it ensures that the model does not become biased toward one class.

Fig. 3, show set of histograms visualizes the distributions of numerical features such as Entropy, DomainLength, SpecialCharSequence, and others. Each histogram shows the frequency of values for a specific feature.

Fig. 4, show these count plots display the distribution of categorical features such as HasSPFInfo, HasDkimInfo, DNSRecordType, and others. Each plot is further divided by the Class (malicious vs. benign) to show how the feature values differ between the two classes.

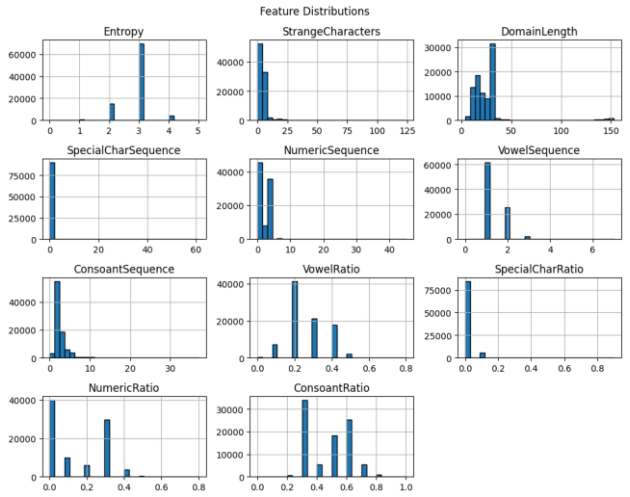

Fig. 3. Distributions of numerical features.

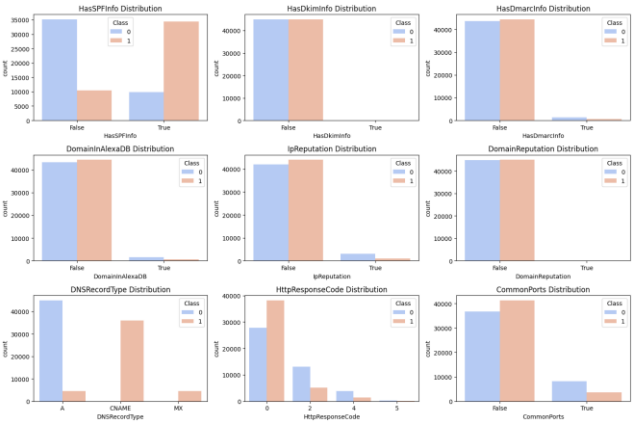

Fig. 4. Distributions of categorical features by class.

The feature DNSRecordType shows that malicious domains predominantly have values of "A" or "CNAME," while benign domains have another value. This suggests that DNSRecordType could be a strong predictor of maliciousness but may also introduce bias so we will drop it. The skewed distribution of DNSRecordType indicates that it may negatively impact the model's performance and should be removed.

B. Dataset Preprocessing

Data preparation involves several steps like data cleaning and data transformation. We removed 170 rows containing null values while performing the data cleaning process. We removed the columns Domain, DNSRecordType, CountryCode, RegisteredOrg, and RegisteredCountry in the data transformation process since they were not helpful for further processing in machine learning algorithms.

For boolean-type and text columns, we employed the Label Encoder of the scikit-learn library. Boolean values were converted to integers (0 and 1). All integer values were also normalized using the Standard Scaler normalization technique, which is common in scientific research. This method scales the data to have a mean of 0 and a standard deviation of 1, thus features are centered and scaled on variance.

Though other normalization techniques exist, Standard Scaler was utilized since it scales the features well without being greatly affected by extreme outliers, making it suitable for this dataset.

Standardization equation:

$$z = \frac{x-\mu}{\sigma} \quad (1)$$

with mean equation:

$$\mu = \frac{1}{N}\sum_{i=1}^{N}(x_i) \quad (2)$$

and standard deviation equation:

$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i-\mu)^2} \quad (3)$$

The correlation heatmap that shows in Fig. 5. visualizes the pairwise correlation coefficients between all numerical features in the dataset. Each cell in the heatmap represents the correlation between two features, with values ranging from -1 to 1. A value of 1 indicates a perfect positive correlation, -1 indicates a perfect negative correlation, and 0 indicates no correlation. The heatmap reveals that certain features, such as NumericRatio, StrangeCharacters, and ConsoantRatio, are strongly correlated with the target variable Class. These features are likely to be important for predicting whether a domain is malicious or benign.

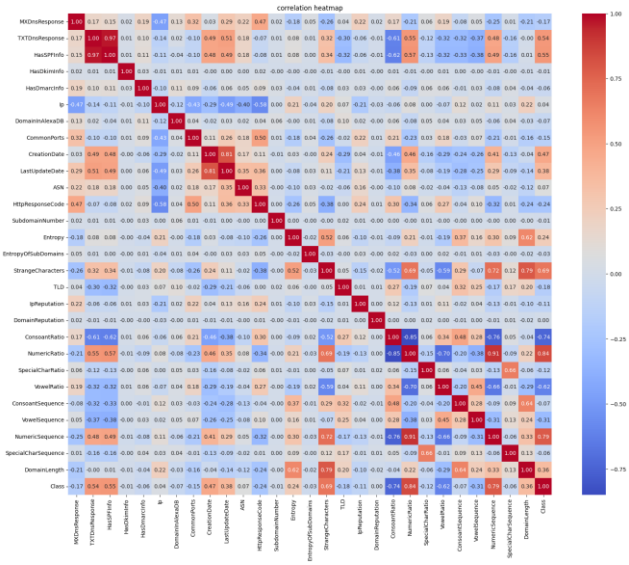

Fig. 5. Correlation heatmap.

C. Features Engineering

Feature selection strategies are used to determine the most discriminating characteristics. To determine the relevance of features to the classification job, as it involves selecting and transforming the most relevant features to improve model performance. In this study, we employed the SelectKBest method with the f_classif scoring function to identify the top 20 features that contribute the most to the predictive power of the model. The f_classif function computes the ANOVA F-value between each feature and the target variable, which helps in selecting features with the strongest statistical relationship to

the target. The selected features include a mix of categorical and numerical variables, such as MXDnsResponse, TXTDnsResponse,HasSPFInfo, DomainInAlexaDB, CommonPorts, CreationDate, LastUpdateDate, ASN, HttpResponseCode, Entropy, StrangeCharacters, TLD, IpReputation, ConsoantRatio, NumericRatio, SpecialCharRatio, VowelRatio, VowelSequence, NumericSequence, and DomainLength. These features were chosen based on their ability to distinguish between malicious and benign domains effectively. By reducing the feature space to the most informative variables, we not only improve model efficiency but also mitigate the risk of overfitting, ensuring that the model generalizes well to unseen data.

D. Machine Learning Models

1) XGBoost: XGBoost is an advanced framework based on gradient tree boosting for solving large-scale machine learning problems efficiently. It is highly reputed for its predictive performance and training speed and has been consistently topping Kaggle competitions. The basic concept of the algorithm is to add decision trees iteratively, constantly splitting features to expand and enhance the model. You actually learn a new function to fit the last predicted residual when each time you add a tree [13]. Letting x_i be the input, y_i be true label and z_i be the 'raw prediction' before the sigmoid function, according to study [14], the objective function of the XGB model is:

Standardization equation:

$$L^{(t)} = \sum_{i=1}^{n} l\left(y_i, Z_i^{(t-1)} + f_t(x_i)\right) + \Omega(f_t) + c \quad (4)$$

Where $l(.,.) denotes the loss function, t$ stands for the t th tree, Ω penalizes the complexity of the model, $\Omega(f_t)$ represents the penalty term of regularization, and c is constant.

The second-order Taylor expansion is:

$$f(x + \Delta x) \approx f(x) + f'(x)\Delta x + 1/2 f''(x)\Delta x^2 \quad (5)$$

Taking "(2)" into "(1)", we can get

$$L^{(t)} \approx \sum_{i=1}^{n} \left[l\left(y_i + Z_i^{(t-1)}\right) + g_i f_t(x_i) + \frac{1}{2} h_i \left(f_t(x_i)\right)^2\right] + \Omega(f_t) + c \quad (6)$$

where $g_i = \partial L / \partial z_i$, and $h_i = \partial^2 L / \partial z_i^2$. Removing the constant terms, we can obtain the following simplified objective at step t.

$$L^{(t)} \approx \sum_{i=1}^{n} \left[g_i f_t(x_i) + \frac{1}{2} h_i \left(f_i(x_i)\right)^2\right] + \Omega(f_t) \quad (7)$$

In this objective function, g_i and h_i are required for fitting the XGB model.

For binary classification problems, the default loss function of XGB is the cross entropy (CE) loss:

$$L = -\sum_{i=1}^{n} [y_i \log(\hat{y}_i) - (1 - y_i)\log(1 - \hat{y}_i)] \quad (8)$$

In Eq. (5) , $\hat{y}_i = 1/[1 + \exp(-z_i)]$, that is sigmoid is selected as activation. Therefore, we can get:

$$\frac{\partial \hat{y}_i}{\partial z_i} = \hat{y}_i(1 - \hat{y}_i) \quad (9)$$

2) LightGBM: LightGBM is a machine learning algorithm that relies on Gradient Boosting Decision Tree (GBDT). It operates by iteratively training several weak classifiers and combining them into a strong classifier capable of performing classification and regression tasks. Compared to traditional GBDT algorithms, LightGBM offers significant advantages such as high training speed, low memory consumption, and effective prediction capability. Additionally, LightGBM has outperformed other algorithms in terms of efficiency [15].

The primary objective function in LightGBM includes two significant components: the loss function and the regularization term, which controls model complexity:

$$\mathcal{L} = \sum_{i=1}^{N} l(y_i, \hat{y}_i) + \sum_{t=1}^{T} \Omega(f_t) \quad (10)$$

Where $l(y_i, \hat{y}_i)$ is the loss function (for example, log loss for classification), and $\Omega(f_t)$ is the regularization term for preventing overfitting. LightGBM minimizes this function using a second-order Taylor expansion, which approximates the loss function using the first-order and second-order derivatives:

$$\mathcal{L}^{(t)} \approx \sum_{i=1}^{N} \left[g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i)\right] + \Omega(f_t) \quad (11)$$

where g_i and h_i are the gradient and Hessian of the loss function, respectively. Under this formulation, it is possible to perform more accurate and efficient optimization than with traditional gradient boosting methods.

One of the primary advantages of LightGBM is the leaf-wise growth strategy, which grows the tree by selecting the leaf with the maximum loss reduction instead of growing the tree level-wise. The split gain is computed as:

$$\text{Gain} = \frac{1}{2}\left(\frac{G_L^2}{H_L} + \frac{G_R^2}{H_R} - \frac{(G_L + G_R)^2}{H_L + H_R}\right) - \gamma \quad (12)$$

where, G_L, G_R and H_L, H_R are the sums of gradients and Hessians for the left and right child nodes, respectively, and γ is a regularization parameter.

In order to further boost training efficiency, LightGBM uses histogram-based feature binning, which discretizes continuous features into a given number of bins:

$$\text{bin}(x) = \left\lfloor (x - x_{min}) \times \frac{\text{bin\_count}}{x_{max} - x_{min}} \right\rfloor \quad (13)$$

This reduces computation time while making the best splits more easily discovered without any loss in accuracy. Overall, LightGBM's new techniques make it one of the fastest and most scalable boosting algorithms available, with uses in everything from fraud detection to recommendation systems.

3) CatBoost: CatBoost (Categorical Boosting) is a gradient boosting algorithm developed specifically to handle categorical features with high quality and efficiency. The CatBoost algorithm uses Ordered Target Statistics instead of One-Hot Encoding, as its method computes category values

based only on previous data points, rather than on the entire dataset at once. This reduces the chances of overfitting and improves computational performance. The CatBoost algorithm operates like existing boosting algorithms but excels when there is a mix of categorical and continuous data [16].

CatBoost's objective function is in the gradient boosting general form, with a loss function and a regularization term:

$$\mathcal{L} = \sum_{i=1}^{N} l(y_i, \hat{y}_i) + \sum_{t=1}^{T} \Omega(f_t) \quad (14)$$

where $l(y_i, \hat{y}_i)$ is the loss function (e.g., log loss for classification, squared error for regression), and $\Omega(f_t)$ is a regularization term for controlling model complexity. CatBoost minimizes this function using ordered boosting, which avoids overfitting caused by target leakage during training.

For efficiency, CatBoost utilizes a symmetric tree structure, i.e., all splits at a specific depth are created simultaneously in all the branches. This ensures balanced trees and prevents bias toward certain features, which leads to better generalization. The optimal split is computed based on the gain formula:

$$\text{Gain} = \frac{1}{2}\left(\frac{G_L^2}{H_L} + \frac{G_R^2}{H_R} - \frac{(G_L+G_R)^2}{H_L+H_R}\right) - \lambda \quad (15)$$

where G_L, G_R and H_L, H_R are the sums of gradients and Hessians for the left and right child nodes, respectively, and λ is a regularization parameter.

CatBoost possesses a significant edge in handling categorical data, removing overfitting, and accelerating training without a loss in accuracy. Ordered boosting, symmetric trees, and novel categorical encoding make CatBoost highly effective in practical machine learning applications.

4) Stacking classifier: The Stacking Classifier is an ensemble technique in machine learning that uses a stacking method aimed at combining several different base models to create a more accurate and powerful model. The Stacking Classifier trains a set of base models on the same dataset to obtain different predictions specific to each model. It then trains a meta-classifier on the results of the base models to merge them in the best way. Each base model can be given a different weight based on its performance or accuracy, ultimately testing the stacking classifier to produce the final prediction that is most accurate. We use stacking because it combines different models, resulting in a final model that is more accurate, better at generalizing, and less susceptible to error or bias towards a single model [17].

The objective function of a stacking classifier contains two layers. In the first layer, we have MMM base models, each of which is trained on the original data set:

$$\hat{y}_m = f_m(X), m = 1,2,\dots,M \quad (16)$$

where f_m represents each base model, and X represents the input feature set. The models predict, and these predictions are new features for the second layer, where a meta-classifier f_{meta} is trained:

$$\hat{y} = f_{meta}(\hat{y}_1, \hat{y}_2, \dots, \hat{y}_M) \quad (17)$$

The final prediction $\hat{y}$ is found by combining all the outputs of the base models in the best possible manner. The meta-classifier is usually a simple model (e.g., logistic regression or decision tree) that learns to weight and combine the predictions of the base models to get optimal performance.

To prevent overfitting and improve generalization, stacking typically employs K-fold cross-validation, where base models are trained on different folds of the data, and their predictions on unseen data are used to train the meta-classifier:

$$\hat{y}_m^{(i)} = f_m\left(X^{(i)}\right), \forall i \in \{1,2,\dots,K\} \quad (18)$$

where $X^{(i)}$ is the training fold in the K-fold cross-validation process. In this way, the meta-classifier is trained on out-of-fold predictions, and the models are not allowed to memorize the training data and be biased.

Overall, stacking is a powerful technique that improves accuracy by ensembling multiple models. It is computationally demanding and requires careful tuning of base models and the meta-classifier to prevent overfitting. Despite these drawbacks, stacking is a widely used technique for high-performance predictive modeling in a variety of domains, including finance, healthcare, and recommendation systems.

5) Voting classifier: Voting is a popular ensemble learning method that combines predictions of several base classifiers to improve general prediction accuracy and strength. It is based on the premise that the collective decision of numerous classifiers can result in improved performance than that of any single classifier. Majority Voting is especially useful when the basis classifiers are heterogeneous and commit uncorrelated errors. Majority voting is a straightforward ensemble approach in which the final prediction is determined by the majority of the individual classifier votes [18] [19].

The Voting Classifier is an ensemble learning technique that combines a number of machine learning models to improve the accuracy and stability of predictions. Unlike stacking, which learns a meta-classifier over the base model predictions, voting combines predictions from a number of classifiers directly through hard voting or soft voting. The method is particularly useful when the base models are heterogeneous, capturing different nuances of the data.

For hard voting, the final prediction is decided by a majority vote of the base classifiers:

$$\hat{y} = \text{mode}(\hat{y}_1, \hat{y}_2, \dots, \hat{y}_M) \quad (19)$$

where $\hat{y}_m$ is the m-th model's prediction, and the majority class is selected as the final output.

For soft voting, the ultimate prediction is taken from the average of the predicted probabilities of all the base models:

$$\hat{y} = \arg\max \sum_{m=1}^{M} w_m P_m(y \mid X) \quad (20)$$

where:

$P_m(y \mid X)$ is the predicted probability of class y by model m.

w_m is an optional weight assigned to each model based on its importance.

Soft voting is generally better than hard voting, especially if the base models are well-calibrated, as it allows the classifier to take into account the confidence levels of the different models.

The Voting Classifier is particularly useful when you need to ensemble models with complementary strengths. For example, decision trees can learn complicated interactions in data, logistic regression can ensure stability, and gradient boosting models can provide good generalization.

In this study, we used a soft voting ensemble with scikit-learn's Voting Classifier. Soft voting takes the predicted probabilities from each classifier and selects the class with the highest average probability, which performs better than hard voting. To build the ensemble, we initialized six LightGBM classifiers with different learning rates (0.1, 0.09, 0.2, 0.08, 0.3, and 0.07). The learning rates were changed to introduce diversity in the base models because altering hyperparameters can reduce correlation between the classifiers' errors. The classifiers were then passed to a Voting Classifier with the estimators parameter, which takes a list of tuples containing the model names and instances. We set the voting parameter to 'soft' for voting based on probabilities. This approach takes the best of each model and removes their worst parts, resulting in a stronger and more accurate ensemble model.

IV. Result and Analysis

In this section, we present the results obtained from classifying DNS logs into malicious and benign categories using various machine learning algorithms. The evaluation of each model is based on accuracy, precision, recall, F1-score, and AUC. Additionally, confusion matrices and ROC curves provide further insights into model performance.

1) Evaluation metrics: In this research, we used standard classification metrics such as Accuracy, Precision, Recall, F1-Score, and Area Under the ROC Curve (AUC). We selected these metrics because they provide a comprehensive evaluation of the performance of the chosen models to facilitate the assessment of which performs better than others.

Despite the common reporting of accuracy, it can be misleading in cases where unbalanced datasets are included, where the number of benign domains is greater than that of malicious ones. This is because models can achieve high accuracy simply by predicting the majority class in the group. Therefore, we integrated Precision and Recall.

Precision measures the proportion of domains predicted to be malicious that are indeed malicious, which is very important for reducing false positive results and avoiding the blocking of legitimate domains. Recall reflects the model's effectiveness in accurately identifying harmful domains, contributing to the reduction of false negative results.

Also, we used F1-Score because it gives us a consistent average between precision and recall, making the positive and negative false results balanced. Finally, we added AUC-ROC because it is considered an independent measure of the model's ability to discriminate between the two classes. AUC is very important for understanding overall performance across different classification thresholds, especially when there is a dataset containing varied class distributions.

2) Performance evaluation: Our model's predictions can result in four possible outcomes:

- True Positive (TP): A malicious domain name is correctly identified as malicious.
- True Negative (TN): A non-malicious domain name is correctly identified as non-malicious.
- False Negative (FN): A malicious domain name is incorrectly classified as non-malicious.
- False Positive (FP): A non-malicious domain name is incorrectly classified as malicious.

Using these outcomes, we can calculate key performance evaluation metrics such as accuracy, recall, precision, and F1-score, as outlined below.

Accuracy is one of the most straightforward metrics for evaluating the performance of a binary classification model. It represents the percentage of correctly classified samples out of the total samples. Using the previously introduced notation, accuracy is defined in the equation as follows:

$$\text{Accuracy} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \tag{21}$$

As another measure of classifier performance, precision assesses the accuracy of positive predictions. It is the proportion of correctly predicted positive instances to all predicted positive instances. Precision is defined by the formula:

$$\text{Precision} = \frac{TP}{TP+FP} \tag{22}$$

Precision is always combined with a measure called recall because precision measurement would be very high for models which predict few positives. Recall specifies the proportion of positive examples that are correctly identified by the classifier, given by the formula:

$$\text{Recall} = \frac{TP}{TP+FN} \tag{23}$$

The F1-Score is the harmonic mean of precision and recall, as defined by Equation (number x). A large F1-Score can only be obtained if both recall and precision are high.

$$\text{F1} - \text{Score} = \frac{2\times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{24}$$

The XGBoost classifier demonstrated exceptional performance, achieving an accuracy of 98.58% with an AUC of 0.9991. The confusion matrix reveals that the model correctly classified 8889 malicious and 8821 benign instances while misclassifying 160 benign samples as malicious (false positives) and 96 malicious samples as benign (false negatives). The low false negative rate suggests that the model is highly effective in detecting malicious domains, minimizing the risk of overlooking threats, as illustrated in Fig. 6 and Fig. 7.

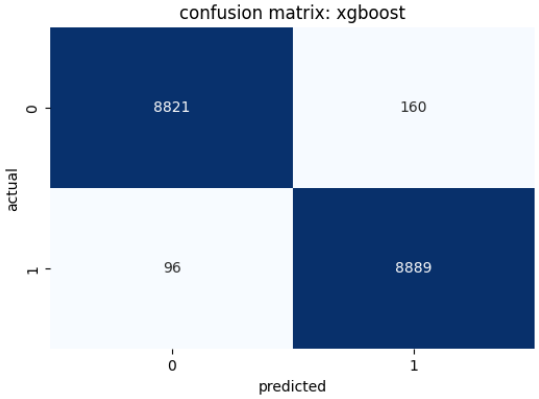

Fig. 6. Confusion matrices illustrating the classification performance of XGBoost on DNS log data.

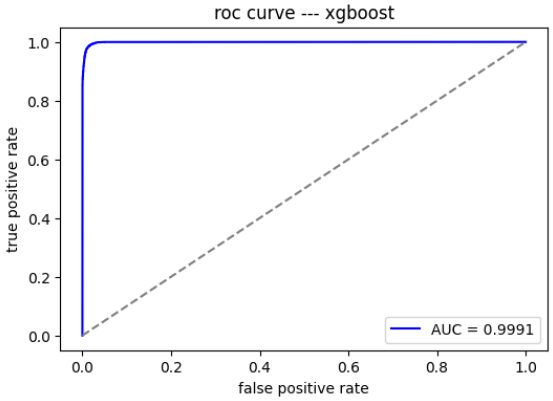

Fig. 7. ROC curves depicting the AUC scores for XGBoost.

Similarly, the LightGBM classifier produced comparable results, attaining an accuracy of 98.51% and an AUC of 0.9990. Although LightGBM performed slightly below XGBoost, the marginal difference in AUC suggests that both models are highly effective. The confusion matrix shows 8889 correctly classified malicious instances and 8821 correctly classified benign instances. However, it misclassified 160 benign samples as malicious and 96 malicious samples as benign. These results indicate that LightGBM performs slightly below XGBoost in distinguishing between the two classes but remains a strong candidate for DNS log classification, as shown in Fig. 8 and Fig. 9.

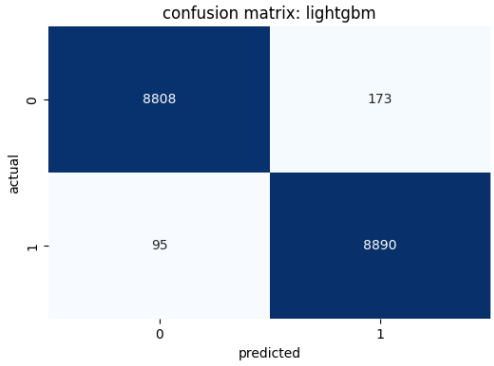

Fig. 8. Confusion matrices illustrating the classification performance of LightGBM on DNS log data.

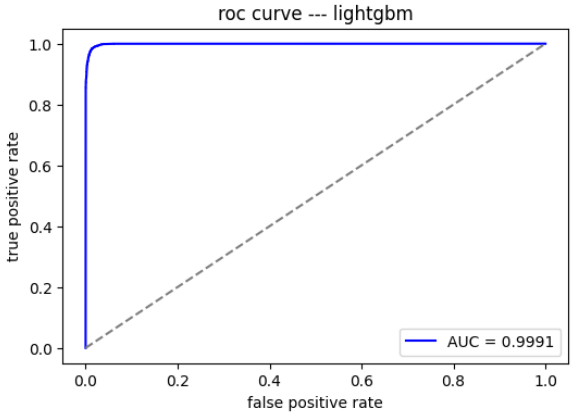

Fig. 9. ROC Curves depicting the AUC scores for LightGBM.

The CatBoost classifier emerged as the best-performing model, achieving the highest accuracy of 98.71% and an AUC of 0.9992. The confusion matrix highlights its superior classification capability, with 8901 correctly identified malicious domains and 8833 correctly identified benign domains. Additionally, it recorded 148 false positives and 84 false negatives, the lowest among all models. The reduced number of false negatives implies that CatBoost is the most effective in correctly identifying malicious domains, making it a highly reliable option, as shown in Fig. 10 and Fig. 11.

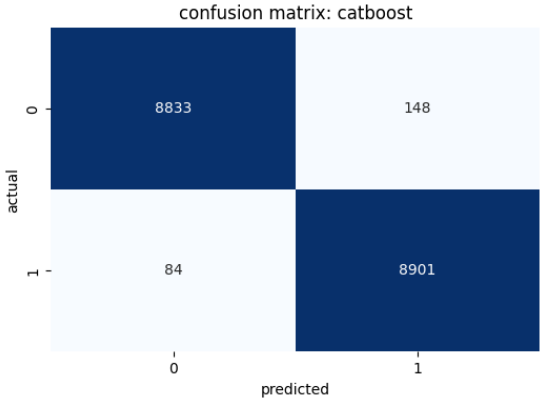

Fig. 10. Confusion matrices illustrating the classification performance of CatBoost on DNS log data.

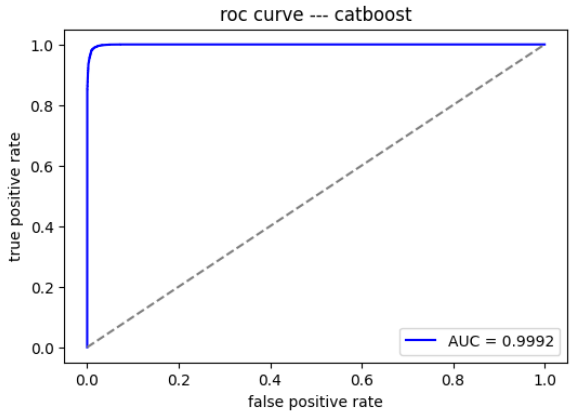

Fig. 11. ROC curves depicting the AUC scores for CatBoost.

The Voting Classifier, which combines multiple models, achieved an accuracy of 98.59% with an AUC of 0.9991. Its confusion matrix indicates that 8901 malicious and 8812 benign domains were correctly classified, while 169 benign samples were incorrectly flagged as malicious, and 84 malicious samples were misclassified as benign. Although it performed well, the slightly higher false positive rate compared to CatBoost suggests that it may generate more false alerts, as illustrated in Fig. 12 and Fig. 13.

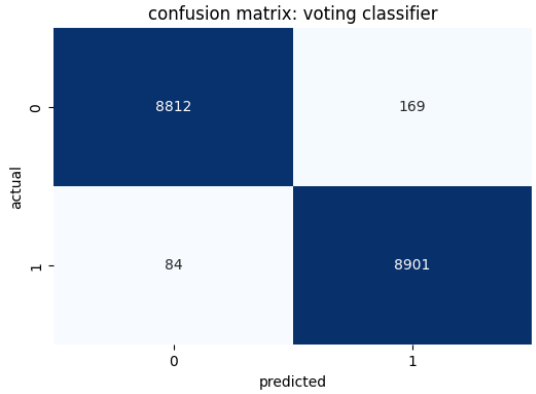

Fig. 12. Confusion matrices illustrating the classification performance of Voting Classifier on DNS log data.

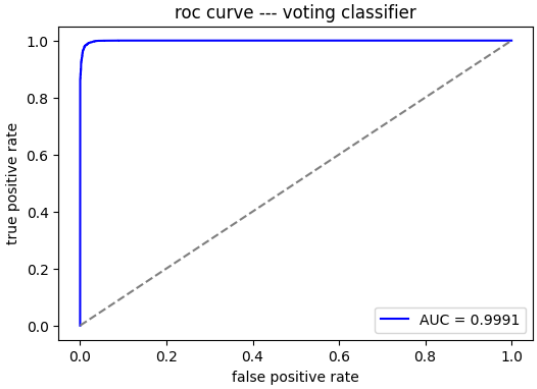

Fig. 13. ROC Curves depicting the AUC scores for voting classifier.

The Stacking Classifier attained an accuracy of 98.53% and an AUC of 0.9979. The confusion matrix analysis shows 8880 correctly classified malicious domains and 8822 correctly classified benign domains. It produced 159 false positives and 105 false negatives, indicating a higher false negative rate compared to the other models. This suggests that the Stacking Classifier, while still effective, may not be the optimal choice for minimizing undetected threats, as shown in Fig. 14 and Fig. 15.

A comparative analysis of the models highlights that all classifiers performed exceptionally well, with accuracy surpassing 98%. CatBoost emerged as the best-performing model, delivering the highest accuracy and AUC, making it the most suitable choice for DNS log classification. These findings suggest that ensemble methods such as CatBoost and XGBoost are highly effective in detecting malicious domains, reinforcing their potential for real-world cybersecurity applications. Table II shows comparison table of models.

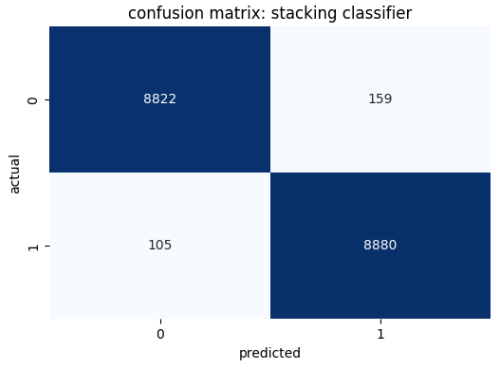

Fig. 14. Confusion matrices illustrating the classification performance of Stacking Classifier on DNS log data.

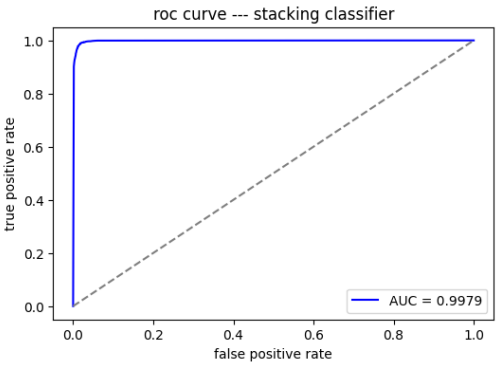

Fig. 15. ROC Curves depicting the AUC scores for stacking classifier.

TABLE II. COMPARISON TABLE OF MODELS

Model	Accuracy	Precision	Recall	F1-Score	AUC
XGBoost	0.9858	0.9858	0.9857	0.9857	0.9991
LightGBM	0.9851	0.9851	0.9850	0.9850	0.9991
CatBoost	0.9871	0.9871	0.9870	0.9871	0.9992
Voting Classifier	0.9859	0.9859	0.9859	0.9859	0.9991
Stacking Classifier	0.9853	0.9853	0.9853	0.9853	0.9979

V. DISCUSSION AND SUMMARY

The malicious domain detection systems rely on the quality of feature selection, the performance of machine learning models, and their applicability in a real-world environment. In this research, five machine learning models (XGBoost, LightGBM, CatBoost, Stacking, and Voting Classifier) were evaluated using a balanced dataset containing 90,000 domain names, with 34 features extracted from DNS records.

The results showed that the CatBoost model outperformed all other models, achieving the highest accuracy of 98.71% and the best performance in other metrics such as F1-score and AUC-ROC. This demonstrates CatBoost's high capability in handling data and dealing with categorical data effectively while reducing bias during training. In comparison, the performance of both XGBoost and LightGBM was similar, as they achieved accuracy exceeding 98.5%, indicating that boosting techniques are effective in detecting malicious domains.

On the other hand, both the Voting Classifier and Stacking Classifier showed strong performance, but without significant improvement compared to the other models. This indicates that combining models did not result in a clear and noticeable enhancement, which may be one reason for the similarity of the basic models' errors in classification.

A. Error Analysis

Despite the high performance of the models, there are challenges that should be taken into consideration.

1) High false positive rate: Some safe domains have been classified as malicious domains, especially those that contain unfamiliar but legitimate names.

2) Errors in detecting malicious domains (false negatives): Despite the small percentage, some harmful domains have not been discovered, especially those that use obfuscation techniques or domain names that are similar to legitimate sites.

3) Impact of data features: The correlation analysis showed that some of the features used, such as DNSRecordType, might be biased, making their removal important to enhance the overall model performance.

B. Practical Implementation

This research may serve as an impetus for practical steps towards enhancing network security through malicious domain detection systems. However, there are still some challenges that are important to address when applying the model in real-world environments.

1) Adapting to emerging threats: The model can be improved through continuous data updates and the addition of new and important features based on the developments in cyberattack technologies.

2) Real-time performance analysis: Although this research focuses on integration with the DNS firewall, studying the impact of the model on network performance and response time may be necessary.

3) Scalability: When applying the model in large-scale systems, improving resource consumption without affecting network performance to ensure quick responsiveness may be essential.

C. Summary

The results of this study show that boosting models such as CatBoost and XGBoost can achieve high performance in detecting malicious domains without the need for deep learning techniques. However, integrating these models into real-world security systems requires important additional improvements to enhance performance and ensure security, such as reducing false positives, adapting to new or emerging threats, and analyzing real-time performance.

This research can be further developed in the future by using hybrid models that combine machine learning and deep learning, along with improving data processing techniques and feature analysis to increase classification accuracy and reduce biases.

VI. Conclusion and Future Work

In this project, we explored the use of machine learning in classifying domain names into benign or malicious based on DNS log data. By comparing several machine learning algorithms—XGBoost, LightGBM, CatBoost, Stacking, and Voting Classifiers—we identified CatBoost as the best-performing model with the highest accuracy, precision, recall, and AUC score. The results indicate that ML-based DNS security solutions can be effective at preventing and detecting cyber threats in real time.

Our solution provides a lightweight and computationally less intensive alternative to deep learning-based models, making it a feasible solution for real-world deployment in resource-constrained environments. By integrating the best-performing model in a DNS firewall, we enhance cybersecurity defenses by reducing the risk of malicious domains, which lowers the risk of phishing, malware spread, and data breaches.

Future work can be oriented in the direction of optimizing feature engineering methods, incorporating real-time threat intelligence, and using diversified datasets for the better generalization of the model. Additionally, the fusion of deep learning models and traditional ML models can be incorporated to obtain a hybrid solution that can provide a balance between efficiency and accuracy.

This project contributes to the developing field of AI-driven cybersecurity, offering an affordable and scalable solution to the evolving nature of cyber threats. As cybersecurity and machine learning advance, the implementation of intelligent DNS security solutions will be critical in safeguarding digital infrastructure.

Defect Detection of Photovoltaic Cells Based on an Improved YOLOv8

Zhihui LI[1], Liqiang WANG[2]*
Tianjin University of Technology and Education, Tianjin 300222, China[1, 2]
Tianjin Engineering Research Center of Fieldbus Control Technology, Tianjin 300202, China[2]

***Abstract*—Currently, defect detection in photovoltaic (PV) cells faces challenges such as limited training data, data imbalance, and high background complexity, which can result in both false positives and false negatives during the detection process. To address these challenges, a defect detection network based on an improved YOLOv8 model is proposed. Firstly, to tackle the data imbalance problem, five data augmentation techniques—Mosaic, Mixup, HSV transformation, scale transformation, and flip—are applied to improve the model's generalization ability and reduce the risk of overfitting. Secondly, SPD-Conv is used instead of Conv in the backbone network, enabling the model to better detect small objects and defects in low-resolution images, thereby enhancing its performance and robustness in complex backgrounds. Next, the GAM attention mechanism is applied in the detection head to strengthen global channel interactions, reduce information dispersion, and enhance global dependencies, thereby improving network performance. Lastly, the CIoU loss function in YOLOv8 is replaced with the Focal-EIoU loss function, which accelerates model convergence and improves bbox regression accuracy. Experimental results show that the optimized model achieves a mAP of 86.6% on the augmented EL2021 dataset, representing a 5.1% improvement over the original YOLOv8 model, which has 11.24 × 10^6 parameters. The improved algorithm outperforms other widely used methods in photovoltaic cell defect detection.**

***Keywords*—Photovoltaic cells; defect detection; YOLOv8; loss function**

I. Introduction

With the clear goals of "carbon peak" and "carbon neutrality", the development and utilization of clean energy have garnered increasing attention. Solar energy is particularly favored for its safety, stability, low cost, and wide applicability. Currently, silicon cells are primarily used to convert solar energy into electricity. However, silicon cells are often prone to defects such as cracks, short circuits, and black cores due to material properties during production. Therefore, efficient detection techniques are essential for promptly identifying and addressing these issues, ultimately improving the yield and conversion efficiency of solar cells.

Traditionally, surface defects in solar cells were detected through manual inspection and machine vision technology using industrial cameras [1]. However, these methods are not only labor-intensive and inefficient, but also susceptible to human error, which can lead to missed or misidentified defects. Since the rise of deep learning theory in the 1950s, deep learning models based on convolutional neural networks have been widely used in image recognition [2], [3], and natural language processing [4], [5], among other fields. However, directly applying deep learning to defect detection in solar cells remains challenging.

Currently, machine vision-driven defect detection technology, with its efficiency and low-cost advantages, is gradually replacing traditional image processing methods and manual inspection. The YOLO series, with its excellent overall performance, has become a widely adopted framework in object detection [6]. Su et al. [7] also integrated channel and spatial attention mechanisms into the Faster R-CNN framework to effectively detect three types of defects in EL images. Although Faster R-CNN detectors provide high-precision results, they suffer from slow speed, high memory usage, and high computational resource demands. In comparison, SSD has some applications in small object detection, but its performance has not yet reached YOLO's real-time detection level and needs further improvement. In [8], researchers integrated an innovative spatial pyramid pooling technique and channel attention mechanism into the YOLOv5 model to accurately detect and locate crack and fractures in battery electrochemical luminescence (EL) images. In [9], researchers integrated a branch attention module into the YOLOX model to improve small object detection accuracy. The module captures key spatial and channel-level information, optimizing classification and localization tasks, leading to a significant increase in detection accuracy. Li et al. [10] incorporated the GCSC global self-attention mechanism into the YOLOv7 algorithm, enabling effective recognition of four specific defect types in EL images, yielding significant results.

YOLOv8 builds on the YOLO series' strengths, adding new features and optimizations for greater flexibility and improved detection accuracy. The author in [11] focused on small object detection in specific scenarios and based on the YOLOv8 framework. The author in [12] proposed a novel down sampling technique and feature fusion network to retain background features while effectively integrating shallow and deep features. Moreover, a data augmentation strategy based on original samples was used to generate new ones, alleviating the class imbalance in the dataset. The author in [13] developed a tailored algorithm for PV cell EL image defect detection, designed to enhance YOLOv8's performance by optimizing the learning rate and model parameters. However, the current model's accuracy still leaves room for improvement in detecting defects of varying categories and sizes.

From the above analysis, YOLOv8 plays a key role in object detection, providing excellent real-time performance

with relatively low hardware demands, facilitating efficient real-time detection. The main contribution of this paper is: 1) By integrating five data augmentation techniques—Mosaic, Mixup, HSV adjustment, scale transformation, and flipping—the dataset was effectively expanded while preserving the original feature information. 2) SPD-Conv [14] is used in the backbone network to replace the standard convolution in the original network to enhance feature extraction capability. 3) The GAM [15] attention mechanism is incorporated between the model's neck and head to strengthen global channel interactions. 4) The CIoU loss function in the model is replaced by Focal-EIoU [16] to accelerate convergence and improve bbox regression precision.

II. Related Work

At present, there are two publicly available electro-luminescence (EL) image datasets globally. One, presented by Buerhop-Lutz et al. [17], originates from the ELPV dataset and mainly focuses on identifying photoluminescence errors using optical methods. The other, called the PVEL-AD-2021 dataset, was proposed by Su et al. [18] and aims to detect anomalies in the brightness images of photovoltaic (PV) cells. This dataset is regarded as a valuable asset in the field of open-world industrial anomaly detection. Developed over two years by a dedicated research team, the PVEL-AD dataset has evolved from the initial PVEL-AD-2019 version to the latest PVEL-AD-2021 version, featuring substantial improvements. The attention module [19] adaptively adjusts the weight of feature pixels in the input image, boosting focus on crucial information and minimizing distractions from unrelated details. As a result, many researchers have adopted defect detection methods that combine attention modules with convolutional neural networks (CNNs). This study uses the publicly available PVEL-AD-2021 dataset.

In recent years, detection methods based on machine vision and computer vision have been widely applied to the detection of surface defects in solar cells. The author in [20] presents a hybrid fuzzy convolutional neural network (HFCNN), which effectively integrates traditional fuzzy theory with convolutional neural network (CNN) technology, achieving notable success in electro-luminescence (EL) image processing. However, it is important to note that the application of these studies is currently limited to defect recognition in simple EL images. Su et al. [21] performed an extensive evaluation of the PVEL-AD dataset to compare the performance of various defect image recognition models. The models include Faster RPAN-CNN, BAF detector, EfficientDet-D0, EfficientDet-D1, EfficientDet-D2, and three different variants of the YOLOv5 network architecture. To address the challenges posed by complex defect patterns and uneven background structures, Acikgoz et al. [22] proposed an advanced solution using a deep evolutionary neural network model. To tackle the photovoltaic cell defect classification issue, they proposed an innovative classification method that combines Spatial Pyramid Pooling (SPP) with residual connections. Wang et al. [23] proposed a technique that integrates the attention mechanism (CA) into feature maps and uses ResNet152-Xception for feature fusion, enhancing the feature extraction ability of the existing model. To improve the recognition accuracy of defects at various scales in EL images, Fu and Cheng [24] introduced a new component called ELCN and integrated it into the YOLOv7 algorithm. Lu et al. [25] incorporated a coordinated attention (CA) mechanism and HEAD into YOLOv5 to enhance the model's detection precision.

The EL images contain numerous subtle defects, often accompanied by strong background noise, resulting in an imbalanced or skewed defect dataset. Therefore, most previous researchers focused on three common categories (crack, finger defects, and black_core) or four defect types (crack, finger defects, black_core, and thick_line). Su et al. expanded upon this research, incorporating eight different defect types for analysis, including black_core, corner defects, crack, finger defects, fragment, scratch, star_crack, and thick_line. Lu et al. further expanded this scope, covering nine different defect categories, including but not limited to: black_core, corner defects, crack, finger defects, horizontal_dislocation, short_ circuit, star_crack, thick_line, and vertical_dislocation.

Despite the aforementioned research achievements, several challenges persist in the field of solar cell defect detection: 1) The difficulty in acquiring solar cell defect images results in a limited dataset, often leading to insufficient training and poor accuracy. 2) Solar cell defects are diverse and vary in shape even within the same type, and the existing models' insufficient accuracy in identifying these specific defects increases the risk of both false positives and false negatives. 3) Current detection models need further improvement in recognizing target defects and handling complex feature variations. If these issues are not addressed effectively, they could severely limit the reliability of industrial production. Therefore, further in-depth research is urgently needed.

III. Improved YOLOv8 Model

A. YOLOv8 Model

YOLOv8 has four versions: YOLOv8n, YOLOv8s, YOLOv8l, and YOLOv8x [26]. These models have different depth and width parameters. The smaller the network model, the lower the hardware requirements, making deployment easier. To ensure detection accuracy, YOLOv8s is used in this study. YOLOv8 can be roughly divided into three components: the backbone, the neck, and the head. The Backbone adopts the CSPDarknet53 architecture. Unlike previous versions such as YOLOv5, YOLOv8 uses the C2f (CSPLayer_2Conv) module instead of the C3 module. The C2f module has fewer parameters and superior feature extraction ability, which contributes to the light-weighting of the network while enhancing the model's detection accuracy and speed. The Neck consists of the Feature Pyramid Network (FPN) [27] and Path Aggregation Network (PAN) [28]. The Head has three detection heads and adopts the current mainstream decoupled head structure, which separates the classification and detection heads. Additionally, it switches from Anchor-Based to Anchor-Free.

B. An Enhanced Approach based on the SPD-Conv Convolution Module

Given the presence of many small targets and low-resolution defects in the dataset, the SPD-Conv convolution module is incorporated into the backbone to improve

YOLOv8's feature extraction ability. After integrating the SPD-Conv convolution module into the YOLOv8 model, it not only enhances the feature representation capability but also preserves the original architecture of the model, thereby reducing the demand for high-quality input data. The SPD-Conv module replaces the stride convolution layers and pooling layers in the traditional CNN architecture. The input image is then divided into a series of smaller blocks, each representing different feature regions of the image. These blocks' various feature regions are then converted into the number of channels. As shown in Fig. 1, the number of channels is four times the input channels at this stage, which mainly reduces the spatial dimension while increasing the channel dimension. Lastly, the convolution operation is carried out using non-stride convolution layers, meaning the convolution moves pixel by pixel, preserving as much information as possible. This approach cleverly reduces the spatial dimension while ensuring the integrity of the information and preserving the richness of the channel information.

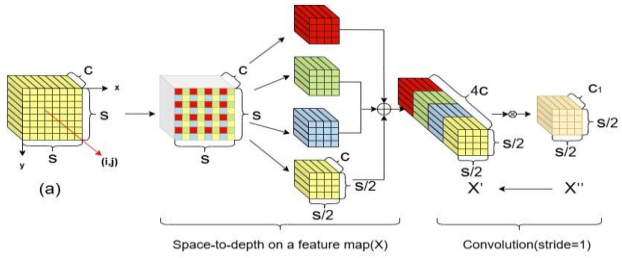

Fig. 1. SPD Transformation.

C. GAM Attention Module

In the precise and intricate task of photovoltaic cell defect detection, the conventional YOLOv8s model encounters notable challenges when handling large amounts of defect features, complex background details, and the coexistence of both large and small-scale targets. The complex background information, after undergoing convolution in YOLO, produces substantial interference, resulting in false detections and misclassifications in defect detection for the corresponding categories. To minimize the interference from complex background information and improve defect feature extraction, introducing an attention mechanism is a good choice. Today, the significance of attention mechanisms in enhancing feature representation is widely acknowledged. Like most lightweight networks, SE [29] modules are often used as the core of their attention mechanism. However, a limitation of the SE module is that it focuses on information interaction between channels but neglects crucial positional information. CAM [30] and CBAM [31] try to capture spatial attention information through convolutional operations, but this method is constrained by the local receptive field of convolution, which can only extract relationships within a local scope and fails to effectively capture long-range or global relationship information. GAM can reduce information loss and amplify the global dimensional interactions， mainly using channel attention and spatial attention mechanisms to expand the global receptive field. This mechanism improves defect classification and can be easily inserted into the core structure of mobile networks. Therefore, this paper integrates the Global Attention Mechanism (GAM) between the neck and head of YOLOv8 to enhance the network's ability to retain information and amplify global cross-dimensional interactions. This improves the ability to accurately identify various defects and reduces the interference from complex backgrounds.

The GAM module begins with the channel-space attention mechanism, and the entire process is illustrated in Fig. 2. Given the input feature map, the intermediate states and outputs are defined by Eq. (1) and Eq. (2):

$$F_2 = M_c(F_1) \otimes F_1 \tag{1}$$

$$F_3 = M_s(F_2) \otimes F_2 \tag{2}$$

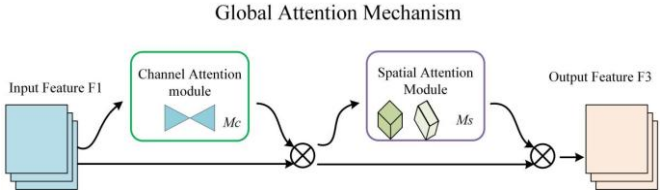

Fig. 2. GAM Module.

In Fig. 2, Mc and Ms denote the channel attention module and the spatial attention module, respectively. The channel attention submodule uses a three-dimensional arrangement to preserve the integrity of information along all three dimensions. It then strengthens the channel-space correlation across dimensions using a multi-layer perception (MLP) with two levels, which has an encoder-decoder structure like BAM, and applies a compression ratio of r. The detailed structure of the channel attention submodule is shown in Fig. 3.

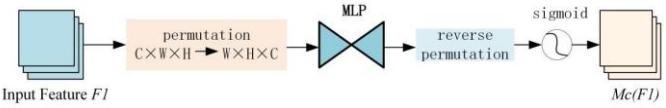

Fig. 3. Channel attention module.

In the design of the spatial attention sub-module, two convolutional layers are used to integrate spatial features, and the same reduction ratio r as in BAM is applied, which also originates from the channel attention submodule. At the same time, since max pooling may cause information loss and have adverse effects, we chose to omit this step to better preserve the details of the feature map. The spatial attention sub-module, without group convolution, is shown in Fig. 4.

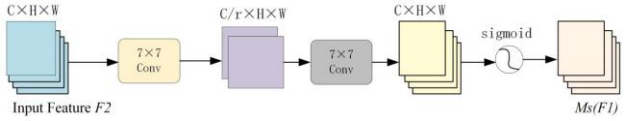

Fig. 4. Spatial attention submodule.

D. FOCAL_EIOU Loss Function

To solve the issue of the imbalance between positive and negative examples in object detection tasks in photovoltaic defect detection, a focal loss function is introduced as the optimization objective. The focal loss function adjusts the weights of positive and negative samples to handle difficult-to-

classify examples, improving the model's ability to recognize complex instances. It takes into account not only the overlap between the predicted bounding box and the ground truth but also additional metrics, such as the distance between the centers of the boxes and the relative differences in width and height. This ensures that effective gradient information is provided even when the overlap is minimal or absent, contributing to the model's training and convergence. Thus, the YOLOv8 model incorporates both Focal Loss and EIoU, two advanced enhancement strategies, which not only help the network focus more on each target instance but also greatly improve the model's detection accuracy and reliability.

The Focal Loss function addresses the issue of class imbalance by adjusting the weight assigned to each sample through a modulation factor. The modulation coefficient is determined by the following formula:

$$FL(p_t) = -\alpha_t(1-p_t)^{\gamma} log(p_t) \tag{3}$$

The α_t parameter is designed to reduce the weight of easily classified samples, allowing the model to focus on training difficult samples and thus better handle class imbalance. The adjustment factor is shown in equation (3) $(1-p_t)^{\gamma} .. \gamma \geq 0$ is tunable focusing parameter. To balance the number of easily classifiable and hard-to-classify samples, an appropriate weight ratio for the samples needs to be carefully set, which typically depends on practical experience and fine-tuning. By systematically trying different weight ratios and evaluating the model's performance on the validation set using cross-validation, the ideal weight ratio that best promotes the balance between the two can be selected.

The common loss function, GIoU, considers only the IoU value when the predicted box and the ground truth box intersect. If the IoU value is 0, this will result in a loss function with no gradient over a large area. CIoU only considers the distance between the center points and the overlap area, but does not take the aspect ratio into account, which leads to slower model convergence. The calculation of the EIoU loss function is represented by the following formula:

$$\begin{aligned} L_{EIOU} &= L_{IOU} + L_{dis} + L_{asp} \\ &= 1 - IOU + \frac{\rho^2(b,b^{gt})}{c^2} + \frac{\rho^2(\omega,\omega^{gt})}{C_{\omega}^2} + \frac{\rho^2(h,h^{gt})}{C_h^2} \end{aligned} \tag{4}$$

Here, IoU stands for Intersection over Union, which is the ratio of the intersection area between the predicted and ground truth boxes to the area of their union. b and b^{gt} represent the predicted box and the ground truth box, respectively.

$\rho(b,b^{gt})$ denotes the Euclidean distance between the centers of the predicted and ground truth boxes. c represents the diagonal distance of the minimum enclosing region of the predicted and ground truth boxes. From formula (4), it can be observed that this loss function comprises three components: overlap loss, center loss, and width-height loss. The difference from the original CIoU loss function used in the YOLOv8 model is the inclusion of the width-height loss, which accelerates the model's convergence. This paper combines Focal Loss with EIoU, starting from the gradient perspective, to separate high-quality anchor boxes from low-quality anchor boxes. The formula is as follows:

$$L_{Foccal-EIOU} = IOU^{\gamma} L_{EIOU} \tag{5}$$

In this case, $IOU = |A \cap B| / |A \cup B|$. γ is the parameter used to control the extent of outlier suppression. The Focal loss discussed here dynamically adjusts the loss according to the IOU (Intersection over Union) value: as the IOU increases, indicating better overlap between the predicted and target boxes, the loss value becomes larger. This design resembles a weighting strategy, assigning a higher penalty to high-quality regression targets, with the goal of further enhancing regression accuracy.

E. Network Structure

An improved network structure is proposed to tackle the high background complexity and the class imbalance. The architecture described in Fig. 5 shows significant effectiveness in addressing this issue. Specifically, in the YOLOv8 backbone network, the original convolution layer with a stride of 2 is replaced with SPD-Conv, enabling the model to more precisely capture detailed features in medium and small-scale targets. Furthermore, to reduce the interference of complex backgrounds in photovoltaic defect detection, this paper introduces the GAM attention mechanism after each C2f block in the model's downsampling stage. This improvement helps enhance the ability to extract effective feature information when detecting different defect categories, thereby improving detection accuracy. Lastly, this paper substitutes the C-IoU used in YOLOv8 with the Focal-EIoU loss function. This enhancement dynamically adjusts the loss based on the IOU and separates high-quality anchor boxes from low-quality ones. This modification improves the gradient behavior of the model's loss function without adding extra parameters, facilitating better training and convergence.

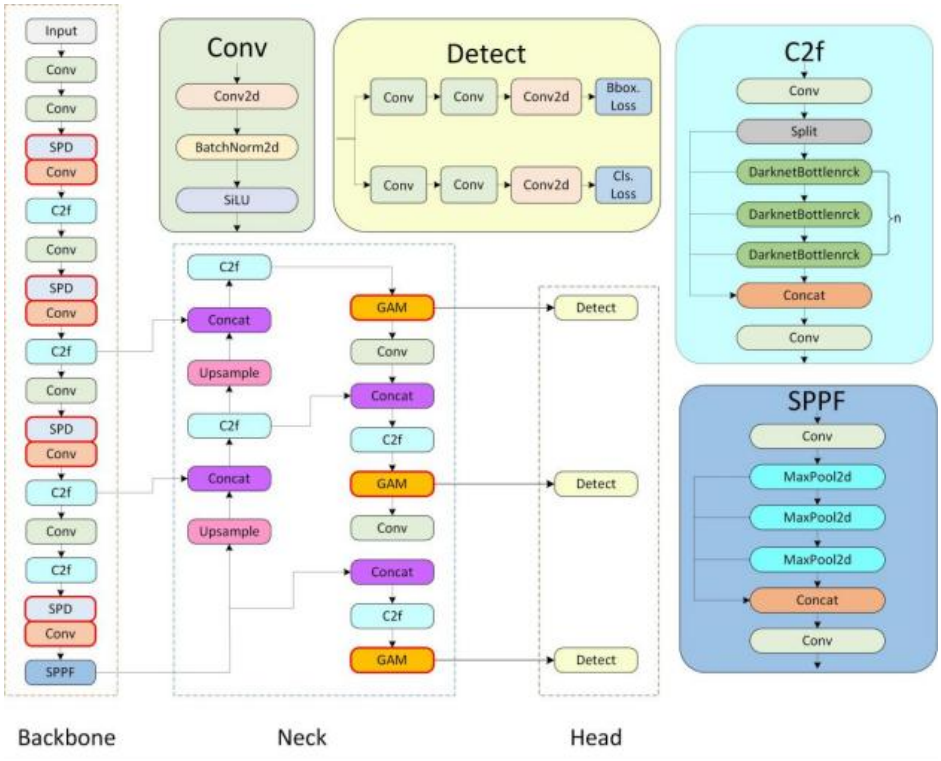

Fig. 5. Improved YOLOv8 network architecture.

IV. Experiments and Results

A. Dataset

This study uses two internationally recognized public datasets for experimentation and evaluates the results of the proposed object detection method. The first dataset is the PVEL-AD-2021 dataset, released through a collaboration between Hebei University of Technology and Beijing University [18]. It includes a category of normal images and features 12 distinct types of abnormal defect images, such as crack, finger, fragment, black_core, star_crack, thick_line, printing_error, corner, scratch, short_circuit, horizontal_dislocation and vertical_dislocation. Samples of these defect types are shown in Fig. 6.

The second dataset is the COCO2017 dataset. It contains over 118,000 training images, 5,000 validation images, and 40,000 test images. The dataset includes 80 common object categories, such as people, vehicles, furniture, animals, etc. covering various scenes from daily life. The COCO2017 dataset has become a critical benchmark for assessing and enhancing the performance of modern computer vision algorithms due to its extensive coverage, detailed annotations, and diverse application scenarios.

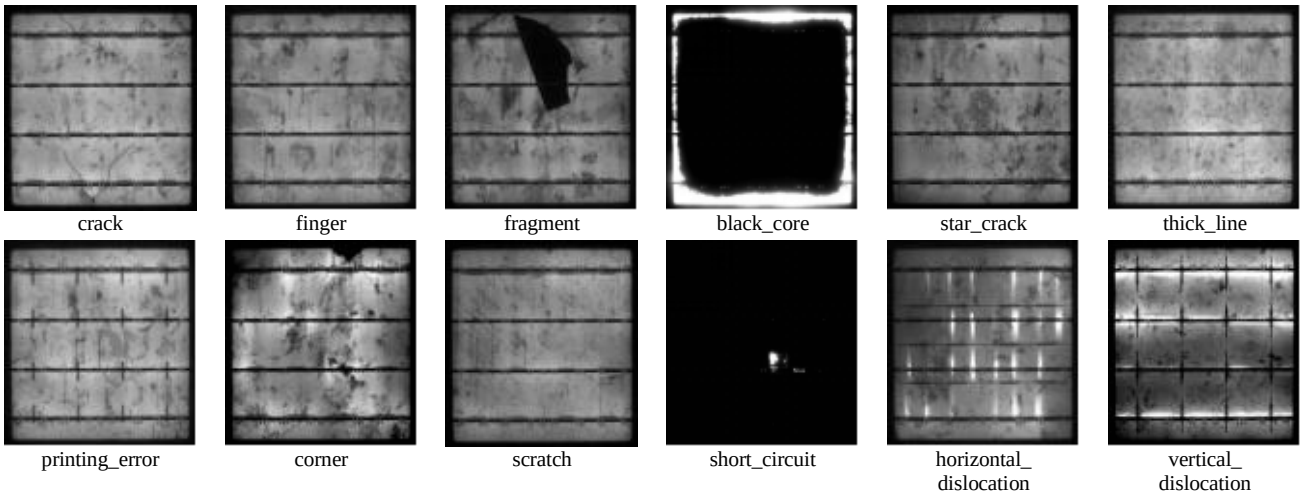

Fig. 6. An illustration of samples from 12 different types of defect images in the defect dataset.

B. Experimental Conditions

The experiment was conducted on a Windows 10 platform with an NVIDIA RTX A4000 GPU, Intel(R) Xeon(R) Gold 6248R CPU @ 3.0GHz 2.99GHz (2 processors), 768 GB RAM, using Torch 2.4.0+ cu11.8 and Python 3.8.0 as the programming environment. The training parameters are listed in Table I below.

TABLE I EXPERIMENTAL CONDITIONS

Parameters	Number
Training Epochs	300
Batch Size	16
Momentum	0.937
Cosine Annealing Hyperparameters	0.01
Initial Learning Rate	0.01
Weight Decay	0.0005

C. Evaluation Metrics

The model's performance was evaluated using multiple metrics in the experiment, including Precision, Recall, and mean Average Precision (mAP). The formulas for each metric are as follows:

$$Precision = \frac{TP}{TP + FP} \tag{6}$$

$$Recall = \frac{TP}{TP + FN} \tag{7}$$

$$AP = \int_0^1 PdR \tag{8}$$

$$mAP = \frac{\sum_{i=1}^{N} AP_i}{N} \tag{9}$$

In the formula, True Positive (TP) refers to the case where both the detection result and the actual situation are positive, meaning that the model correctly identifies and labels the existing objects. False Positive (FP) refers to the situation where the detection result is positive, but the actual situation is negative, meaning the model falsely identifies an object that does not exist. False Negative (FN) refers to the case where the detection result is negative, but the actual situation is positive, meaning the model fails to identify an existing object. Accuracy is the ratio of correctly detected results to all samples identified as having defects (or target objects), reflecting the model's precision in defect (or object) detection. Recall indicates the proportion of correctly detected results among all actual defect (or target object) samples. It reflects the model's effectiveness in identifying true defects (or target object) samples. “AP” (Average Precision) refers to the average accuracy for a specific category, which is equivalent to the area under the P-R (Precision-Recall) curve, used to evaluate the model's performance for that category. “mAP” (mean Average Precision) represents the average of average precision values across multiple classes. It quantifies the model's average performance across all classes and is a critical metric for assessing object detection accuracy.

D. Results and Analysis of Experiments

1) Comparative experiments: Based on the research by Su et al. on the PVEL-AD-2021 dataset, YOLOv5 outperformed other models, such as Faster RPAN-CNN, BAF-Detector, EfficientDet-D0, EfficientDet-D1, and EfficientDet-D2, in PVEL image defect detection. In light of this, this study further compares the defect detection performance of the proposed model with the YOLO series (including YOLOv5, YOLOv7-tiny, YOLOv7, YOLOv8, YOLOv9, and YOLOv11) on the PVEL-AD-2021 dataset, and summarizes the comparison results in Table II.

TABLE II THE OUTCOMES OF DIVERSE DETECTIONS CONDUCTED ON THE PVEL-AD-2021 DATASET

Model	mAP50	mAP50-95	Parameters	FPS
YOLOv5	0.635	0.483	2704372	9.1
YOLOv7-tiny	0.541	0.385	6044754	13.3
YOLOv7	0.517	0.36	37255890	105.3
YOLOv8s	0.815	0.545	9140774	73.9
YOLOv9s	0.809	0.531	9751848	70.4
YOLOv11s	0.816	0.535	9432420	63.5
ours	0.866	0.558	11245812	71.5

In contrast to the rapid decline in training loss, the improved model reaches the performance improvement inflection point earlier than YOLOv8s, after producing more stable results progressively. Fig. 7 shows the comparison results between YOLOv8 and our proposed detection model in terms of mAP 50. Clearly, in terms of detection accuracy for PVEL image defects, the proposed model in this paper shows better performance than YOLOv8s.

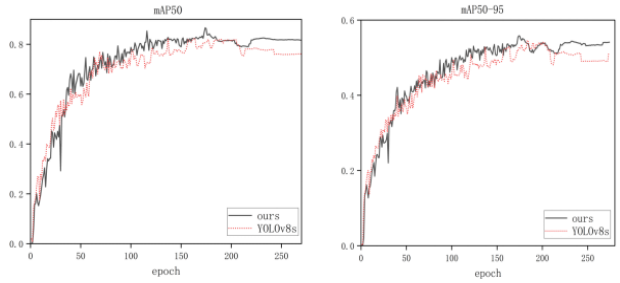

Fig. 7. The comparison results of YOLOv8, and our proposed detection model on mAP50 and mAP50-95.

The algorithm presented in this study successfully enhances object detection accuracy while preserving the model's complexity. After comparing the performance of the enhanced algorithm with the original YOLOv8s model, it is clear that this method achieves significant improvement, specifically a 5.1% increase in the mAP@0.5 metric.

2) Ablation experiment: To evaluate the performance enhancement achieved by adding the SPD-Conv module,

GAM module, and Focal-EIoU loss function to YOLOv8s, a series of ablation experiments were conducted. According to Table III (I represents SPD-Conv, II represents GAM, III represents Focal-EIoU.), YOLOv8s does not fully recognize all 12 types of defects in the PVEL dataset. However, it can be seen that integrating SPD-Conv into the original YOLOv8s increased the mAP by 4.4%, improving the recognition accuracy of finger, black_core, corner, horizontal_ dislocation, and vertical_dislocation defects. Furthermore, when the GAM attention mechanism was introduced, the mAP increased by 1.7%, and the recognition accuracy of finger, black_core, corner, and scratch defects also showed slight improvement. Finally, after replacing the loss function with Focal-EIoU, mAP increased by 0.7%, with improved accuracy in detecting finger, black_core, star_crack, and corner defects. The overall model proposed in this paper improved mAP by 5.1%, with a slight increase in model size and number of parameters. The most important finding from the ablation experiments is that the improved model accurately identifies and locates defects across 12 categories, offering a viable and efficient solution for PVEL image defect detection.

TABLE III THE STATISTICAL RESULTS OF THE ABLATION EXPERIMENTS

Model	Detected types of defects(mAP50)												
	crack	finger	black_ core	thick_ line	star_ crack	corner	fragment	scratch	horizontal_ dislocation	vertical_ dislocation	printing_ error	short_ circuit	mAP50
YOLOv8s	0.82	0.925	0.99	0.916	0.76	0.497	0.995	0	0.94	0.946	0.995	0.995	0.815
YOLOv8s +I	0.79	0.93	0.994	0.905	0.746	0.995	0.995	0.0058	0.969	0.989	0.995	0.995	0.859
YOLOv8s +II	0.778	0.93	0.995	0.912	0.77	0.606	0.995	0.224	0.922	0.866	0.995	0.995	0.832
YOLOv8s +III	0.808	0.938	0.994	0.909	0.773	0.543	0.995	0.0234	0.934	0.955	0.995	0.995	0.822
YOLOv8s +I+II	0.792	0.925	0.994	0.897	0.838	0.695	0.995	0.0995	0.873	0.93	0.995	0.995	0.836
YOLOv8s +II+III	0.805	0.939	0.994	0.906	0.768	0.662	0.995	0.0392	0.981	0.938	0.995	0.99	0.835
YOLOv8s +I+II	0.827	0.929	0.993	0.897	0.756	0.995	0.995	0	0.971	0.994	0.995	0.995	0.862
YOLOv8s +I+II+III	0.782	0.931	0.993	0.901	0.747	0.745	0.995	0.398	0.932	0.981	0.995	0.995	0.866

The confusion matrix shown in Fig. 8 is used to evaluate the classification performance of PV cells for 12 types of defects: black_core, corner, crack, finger defects, fragment, horizontal_dislocation, printing_error, scratch, short_circuit, star_crack, thick_line, and vertical_dislocation. In the confusion matrix, 54 crack defects were misclassified, making up 19.92% of the total crack defects. 56 finger defects were misclassified, accounting for 9.98% of the total number of finger defects. 3 black_core defects were misclassified, constituting 1.38% of the total black_core defects.22 thick_line defects were misclassified, constituting 12.64% of the total thick_line defects. In addition, 6 star_crack were misclassified, accounting for 21.42% of the total star_crack. 1 corner defect, representing 50% of their respective totals. The misclassification rate for scratch defects is 100%.10 horizontal_dislocation defects were misclassified, representing 5.84% of the total. 1 vertical_dislocation defect was misclassified, representing 2.77% of the total. There were no misclassifications for fragment and printing_error. 1 short_circuit defect was misclassified, representing 0.98% of the total. This shows that the improved model in this study minimizes prediction errors and exhibits strong classification performance for PVEL defects.

Based on the observations shown in Fig. 9, the model exhibits outstanding anomaly detection capabilities across a range of common defects (such as finger defects, black_ core, fragment, horizontal_dislocation, printing_error, short_circuit, thick_line, and vertical_dislocation), with an mAP50 metric close to 100%. However, when distinguishing between crack, corner, and star_crack, which are similar and challenging to differentiate, the mAP50 value indicates a moderate level. Additionally, the mAP50 value for scratch dropped significantly. This is mainly due to the high background complexity, which causes frequent misdetections and misclassifications for small defects. It is recommended to consider adding supplementary features or using alternative algorithms to enhance feature extraction for these specific defects.

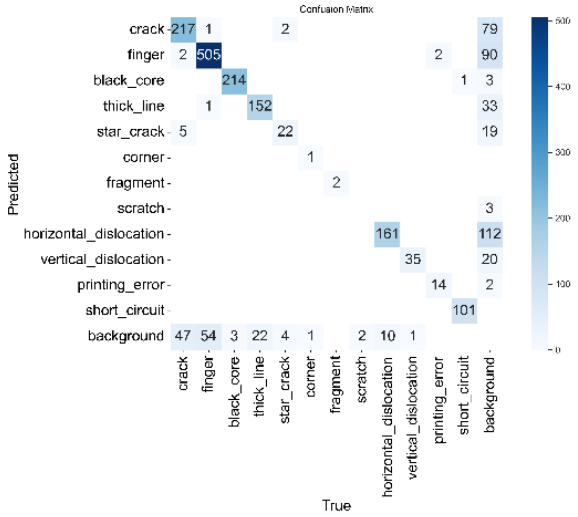

Fig. 8. Confusion matrix of the improved YOLOv8s model.

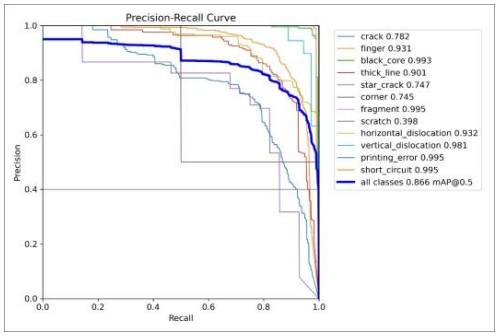

Fig. 9. Precision-recall curve for the enhanced YOLOv8s.

Lastly, Fig. 10 illustrates the predicted bounding boxes, identified upon completion of training, demonstrating accurate alignment with the ground truth boxes in height.

3) Network generalizability: In order to further assess the effectiveness of the improved YOLOv8, this research performed comparative experiments using YOLOv8 on the publicly available COCO2017 dataset. The results presented in Table IV clearly show that, compared to YOLOv8 on the COCO 2017 dataset, the mAP 50 value significantly increased by 4.1%. This result strongly demonstrates the accuracy and performance advantages of the improved model in object detection tasks.

TABLE IV THE OUTCOMES OF DIVERSE DETECTIONS CONDUCTED ON COCO2017

Model	Categories of detected defects	mAP50
YOLOV8	80	0.623
ours	80	0.664

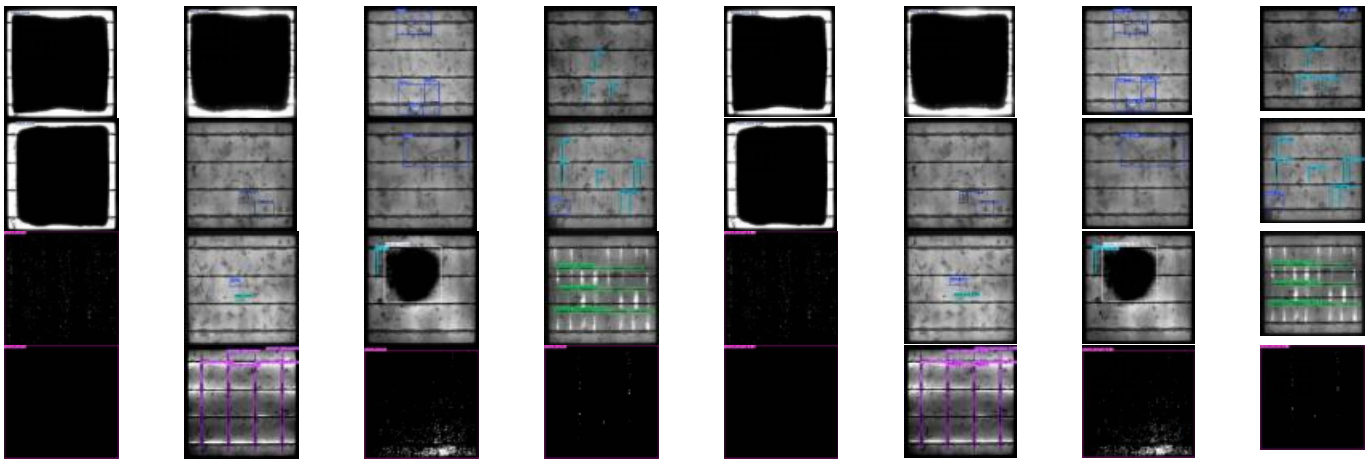

Fig. 10. Comparing the outcomes of randomly sampled ground truth bounding boxes with predicted bounding boxes.

V. CONCLUSION

This study addresses the challenges of difficult data collection, complex defect classification, and high background complexity, which lead to missed detections in photovoltaic cell surface defect detection, by proposing an optimized YOLOv8s model. The results from the comparison and ablation experiments indicate that the optimized YOLOv8s model improves the mAP by 5.1% compared to the original model, exhibiting significant detection adaptability for 12 defect types in solar cells. This indicates that the model has great potential for application in photovoltaic cell defect detection. The future direction of work will involve further optimizing the model to achieve higher identification accuracy to meet industrial needs. The existing public dataset contains class imbalance and issues with detecting certain defect types, necessitating further dataset optimization. Moreover, it is important to consider improving detection accuracy and speed while reducing model parameters, thereby enhancing the model's practicality.

***Abstract*—In order to improve the low precision of the current immersive experience effect assessment method, a virtual reality Civics practice teaching immersive experience effect assessment method with enterprise development optimisation algorithm and mixed kernel extreme learning machine is proposed. Firstly, we analyse the current status of research on virtual reality Civic and political practice teaching, design the idea of assessing the application of VR technology in Civic and political practice teaching, extract the relevant assessment features, and construct the effect assessment system; secondly, we use the enterprise development optimization algorithm to optimize the parameters of the mixed kernel extreme learning machine, and construct the immersive experience effect assessment model; finally, we use the data of Civic and political practice teaching based on VR technology to verify and analyse the proposed model. The results show that the proposed model effectively improves the assessment accuracy of the immersive experience effect assessment method and achieves a higher precision of the Civic and political practice teaching effect assessment.**

Keywords*—Virtual reality technology; civics practice teaching; immersive experience effect assessment; enterprise development optimisation algorithm

I. Introduction

With the ongoing advancement of contemporary educational technology, the state has placed increasing significance on reforms aimed at advancing the informatization of teacher education [1]. The primary means of providing college students with a thorough, high-quality education is through ideological and political theory classes in colleges and universities, where the focal point of students' ideological and political education is the practical instruction of these courses [2]. In the context of the contemporary era, enhancing the implementation of patriotism education within the practical instruction of ideological and political theory courses in higher education institutions presents both a theoretical challenge and an operational issue in the practical teaching process [3]. Then, the scarcity of Civics instructors and the increasing student population in numerous Chinese colleges and universities, coupled with a limited number of practice bases collaborating with educational institutions, inadequate funding for practical training, and various objective factors, have resulted in unsatisfactory outcomes for the practical instruction of Civics and Politics courses in recent years. This is further exacerbated by insufficient preparation, premature timing, and an inability to ensure safety protocols [4]. Consequently, to furnish students with a real-time, interactive, and immersive learning experience that aligns with their interests and curiosity, it is essential to transcend conventional temporal and spatial constraints in education. This necessitates the design of innovative pedagogical models and assessment methods, reflecting the current developmental trend in the practical instruction of Civics and Politics courses at the collegiate level [5].

A new technology with significant application potential, virtual reality has evolved significantly in recent years. [6]. The integration of virtual reality technology with Civics education transcends the temporal and spatial constraints of conventional teaching, while also facilitating a tailored instructional approach based on specific resources [7]. Currently, the research on Civics practice teaching based on virtual reality technology is mainly divided into VR practice teaching design, VR practice teaching experience effect assessment, etc. The design research for VR practice teaching is primarily grounded in the current state of Civics practice instruction, assessing the requirements of Civics practice teaching, and questioning the Civics practice teaching curriculum utilizing VR technology [8]. The VR practice teaching experience effect assessment is based on the experience effect of Civics practice teaching curriculum based on VR technology, extracting the value of the assessment system. Course experience effect, extracting the evaluation system value, combining the evaluation algorithm, and constructing the VR Civics practice teaching experience effect assessment model [9]. Through reviewing a large amount of literature and combining with reality, at present, the following problems mainly exist in the practice teaching of Civics based on VR technology [10]: 1) Civics classes are more theoretical, and there are fewer studies on practice teaching using VR technology; 2) there are fewer studies on the assessment of the experiential effect of the VR Civics practice teaching experience; and 3) the precision of the assessment of the experiential effect of the Civics practice teaching experience based on the data-driven algorithms is small.

Focusing on the problem of evaluating the effect of the Civics practice teaching experience based on VR technology, the theme of this paper is written in the following framework: this paper analyses the status quo of Civics practice teaching, designs the Civics practice teaching experience method based on VR technology, and puts forward the method of evaluating

*Corresponding Author.

the application of VR technology in the Civics practice teaching; focusing on the problem of evaluating the application of VR Civics practice teaching, combining ED algorithms with the HKELM model, and constructing an immersive experience effect evaluation no model of VR Civics practice teaching based on ED- HKELM learning algorithm. HKELM learning algorithm, to build a VR Civic and Political Practice Teaching Immersive Experience Effect Evaluation based on ED-HKELM learning algorithm, through the experimental analysis, the algorithmic model proposed in this paper effectively solves the problem of Civic and Political Practice Teaching Experience Effect Evaluation based on VR technology, and improves the evaluation accuracy and effect.

II. Status Analysis and Methodological Design

A. Current Status of Related Research

Using a variety of high-tech techniques, including computer graphics, computer simulation, artificial intelligence, sensing, display, network parallel processing, and others, virtual reality technology creates a realistic visual, aural, tactile, olfactory, gustatory, and other perceptions of the computer system [11], specifically as shown in Fig. 1.

Fig. 1. Virtual reality technology.

Virtual reality technology includes the basic features of immersion, interactivity and imagination [12], as shown in Fig. 2； 1) Immersion. Immersive virtual reality systems use a variety of input and output devices to simulate the real world from the visual, auditory and even tactile, olfactory and other aspects to create a virtual scenario; 2) Interactivity. The virtual situation created by virtual reality technology is not a static three-dimensional world, but a multi-dimensional world that can be interacted with the user; 3) Imaginative. When the user is completely immersed in the "real" virtual environment, and with the virtual environment of the object to produce a variety of interactive activities, so as to obtain perceptual and rational understanding.

Virtual venues are the simulation and creation of real venues by human beings using virtual reality technology, which can allow users to immerse themselves in digital exhibition halls [13], specifically as shown in Fig. 3. In this paper, a series of red VR venues are developed according to the needs of the Civics class, and a method of evaluating the effect of immersive experience of VR Civics practice teaching is designed, as shown in Fig. 4.

A review of related literature reveals that virtual reality technology has attracted much attention in the field of education [14]. Many research teams have applied virtual reality technology to classroom teaching, which includes various aspects such as medical anatomy teaching, nursing teaching, chemistry experiment, electromechanical maintenance, etc., as shown in Fig. 5. Cowden and Martinez [15] used virtual reality technology to virtualise the human body; Li and Chen [16] established an immersive system learning situation with the help of virtual reality technology in order to stimulate learners' interest and learning motivation in science learning; and Jing et al. [17] established a remote virtual education laboratory, which accomplished the perfect combination of virtual reality technology and remote education.

B. Design of Civics Practice Teaching Experience

1) Principles of VR Civics Teaching Design: Aesthetics, harmony, value, and effectiveness are the four key tenets of VR Civics education design [18], as shown in Fig. 6.

a) Principle of attractiveness: Attracting students with the charms of technology and value;

b) Principle of harmony: Teachers and students in the virtual field are the real community;

c) Principle of value: The virtual education field possesses the moral atmosphere of goodness;

d) Principle of effectiveness: The virtual education field is conducive to improving the teaching quality of the Civics class.

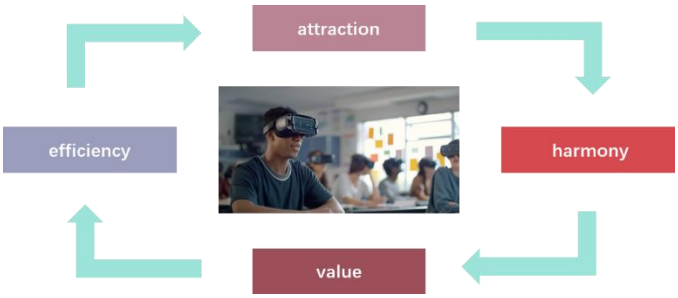

Fig. 6. Principles of VR Civics teaching design.

2) Core elements and application mechanisms: The core elements of the application of the immersive experience method in the Civics classroom include clear goals, immediate feedback, appropriate challenges and effective incentives. In Fig. 7, To build an efficient Civics immersive experience classroom we must probe deeply into the motivation mechanism, participation mechanism, incentive mechanism and feedback mechanism behind it, explore the inner power of these mechanisms, and establish the application mechanism of immersive experience suitable for Civics classroom [19].

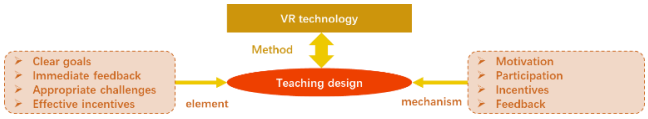

Fig. 7. VR Civics teaching design elements and mechanisms.

3) Design process: The "dominant-subject" teaching design model serves as the foundation for the VR Civic and Political Practice Teaching Model, which eschews the drawbacks of the conventional teaching mode and fully encourages student initiative in the learning process as well as the teacher's guiding role in instructional activities. The flow chart for the VR Civic and Political Practice Teaching Model is shown in Fig. 8.

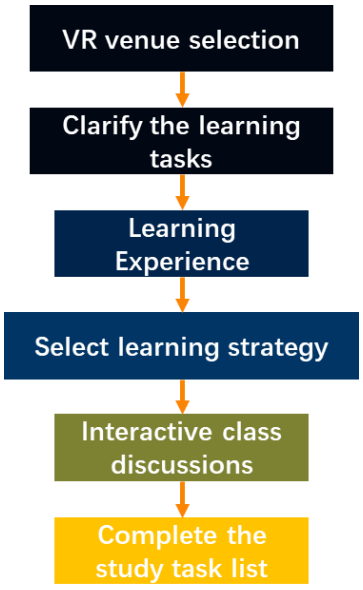

Fig. 8. VR civics teaching design process.

C. Evaluation Ideas for the Application of VR Technology in Civics Practice Teaching

This paper establishes an assessment system to analyze the impact of immersive VR technology on Civic and Political Practice Teaching, focusing on four dimensions: alignment of VR environments, design of learning content, analysis of teacher and student roles, and learning experiences within VR settings, as illustrated in Fig. 9. The system indicators facilitate the extraction of index data, which, when integrated with a data-driven algorithm, generates an assessment model for the implementation of VR technology in civic and political practice education, as seen in Fig. 10.

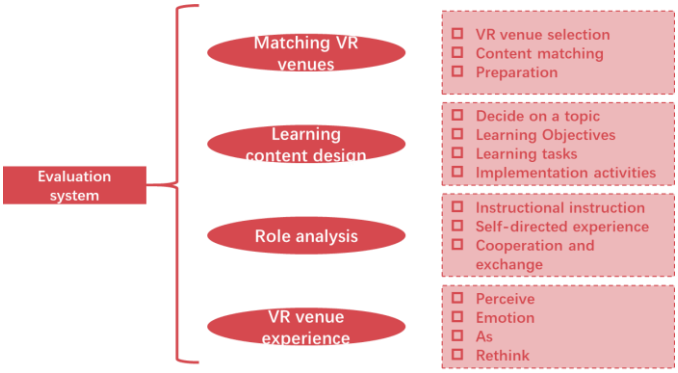

Fig. 9. Evaluation system of VR technology citing experience effect.

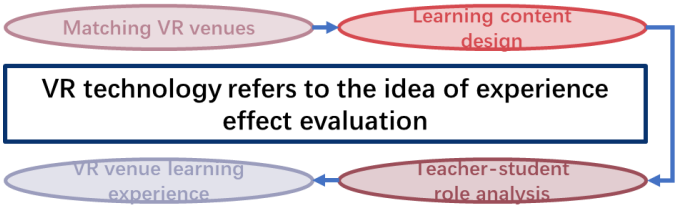

Fig. 10. VR technology referencing experience effect.

III. A Model for Evaluating the Effectiveness of Immersive Experiences

A. HKELM Algorithm

The current application assessment based on data analysis mainly relies on machine learning methods [21], while the application assessment data of the Civics practice teaching in this paper is complex, numerous and part of the data reliability is low, which makes the assessment and analysis more difficult. This paper studies the improvement of the assessment algorithm from two perspectives: the optimal selection of machine learning algorithm parameters and its own classification performance. First, from the perspective of its own classification performance, this paper selects the Kernel Extreme Learning Machine (KELM) [22], which has a fast learning speed and strong generalisation ability, to optimally construct the VR Civic and Political Practice Teaching and Learning Application Assessment Model.

KELM is a single hidden layer feed-forward neural network (structure shown in Fig. 11) [23], through the introduction of the kernel function to improve the original iteration number of slow shortcomings, reduce the amount of operations and improve efficiency, with a very good nonlinear regression and classification effect, the output model is expressed as follows:

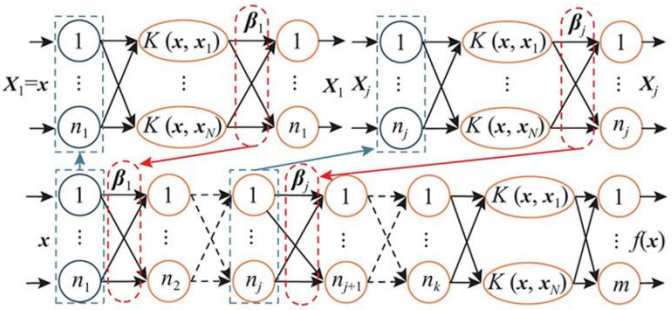

Fig. 11. KELM structure.

$$f(x)=h(x)\beta=H\beta \tag{1}$$

Where x is the sample data; $f(x)$ is the model output; $h(x)$ represents the input of the implicit layer; H is the feature mapping matrix, which is derived from the kernel function mapping the sample data; and β is the vector that outputs the implicit layer data to the output layer.

$$\beta=H^T\left(HH^T+I/C\right)^{-1}T \tag{2}$$

Where, C is the regularisation parameter; I is the unit matrix; and is the training set target vector. the matrix model of KELM is as follows:

$$\Omega=HH^T \tag{3}$$

$$\Omega_{i,j}=h(x_i)h(x_j)=K(x_i,x_j) \tag{4}$$

The kernel matrix Ω is used to replace the HH^T matrix of KELM and $K(x_i,x_j)$ is the kernel function matrix. The kernel function maps the input data to the high dimensional implicit layer space to obtain the output model as follows:

$$f(x)=\begin{bmatrix}K(x,x_1)\\ \vdots \\ K(x,x_N)\end{bmatrix}^T\left(\frac{I_0}{C}+\Omega\right)^{-1}T=\begin{bmatrix}K(x,x_1)\\ \vdots \\ K(x,x_N)\end{bmatrix}^T\beta \tag{5}$$

The determination of the kernel function determines the prediction results, and a single kernel function search has limitations. poly kernel function is a global kernel function, RBF kernel function is a local kernel function, the two kernel functions using a linear combination of the composition of the new hybrid kernel function, so that the KELM has the global and local aspects of the excellent classification performance, the Poly and RBF functional equations are expressed as follows:

$$K_{Poly}(x_i,x_j)=(x,x_i+c_1)^d \tag{6}$$

$$K_{RBF}\left(x_i, x_j\right) = \exp\left(-\left\|x_i - x_j\right\|^2 / \sigma^2\right) \quad (7)$$

Where σ , c_1 , d are the kernel parameters of the Poly kernel function kernel RBF kernel function, and the mixed kernel function is obtained by linear combination of the two:

$$K_H\left(x_i, x_j\right) = s_1 K_{Poly}\left(x_i, x_j\right) + s_2 K_{RBF}\left(x_i, x_j\right) \quad (8)$$

$$s_1 + s_2 = 1 \quad (9)$$

Substituting the mixed kernel function into the output function yields the HKELM model (shown in Fig. 12) [24], the mixed kernel function enhances the classification speed and accuracy of the model, where the parameters C , σ , c_1 , d , s_1 by have a great impact on the HKELM, and the parameters are optimised by the Enterprise Development Optimisation Algorithm for optimisation and to enhance the performance of the evaluation.

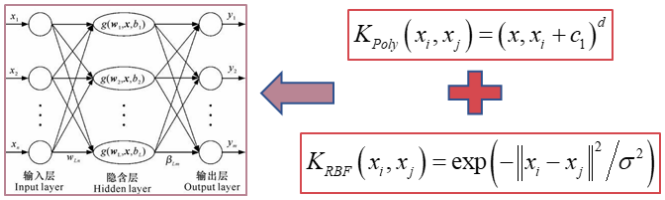

Fig. 12. HKELM modelling strategy.

B. Optimisation Algorithms for Enterprise Development

Enterprise development optimization (ED) [25] is a meta-heuristic optimisation algorithm subject to the enterprise development process. The process includes tasks, structures, technologies and human interactions. An activity switching technique is employed to ascertain each stage by revising the search solution. Every organization must strive for continuous development, which depends on experimentation and resources. After over 20 years of examining industry organizations, it is evident that intricate organizational systems depend on four categories of variables for interaction: task, structure, technology, and people, as depicted in the enlightening schematic in Fig. 13.

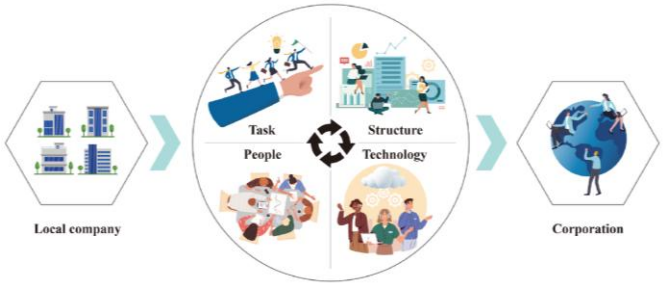

Fig. 13. Optimisation strategy for ED algorithm.

1) Population initialisation: As with all meta-heuristic optimisers, the ED optimiser randomly generates initial totals with uniform distributions for optimisation:

$$x_i = rand \times \left(u_b - l_b\right) + l_b \quad (10)$$

where u_b and l_b denote the upper and lower bounds of the problem, respectively.

2) Mandate: In business process management, tasks can take different forms or exist as daily transactions. In order to simulate task activities, the worst activities are replaced:

$$x_{worst}\left(t\right) = l_b + rand\left(0,1\right) \times \left(u_b - l_b\right) \quad (11)$$

where x_{worst} denotes the worst single solution in the search space.

3) Structure: Considering the organisational structure (Fig. 14) as a workflow, the new organisational structure is considered to be affected by other workflow structures in the organisation and the current optimal workflow, and is therefore updated by the following equation:

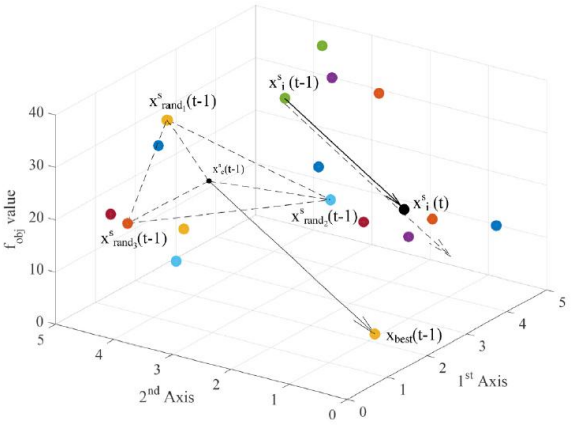

Fig. 14. ED algorithm structure strategy.

$$x_i^s\left(t\right) = x_i^s\left(t-1\right) + rand\left(-1,1\right) \times \left(x_{best}\left(t-1\right) - x_c^s\left(t-1\right)\right) \quad (12)$$

$$x_c^s\left(t-1\right) = \frac{x^s_{rand_1}\left(t-1\right) + x^s_{rand_2}\left(t-1\right) + \cdots + x^s_{rand_m}\left(t-1\right)}{m} \quad (13)$$

Where, $x_i^s\left(t\right)$ denotes the new structure; $x_{best}\left(t-1\right)$ denotes the current optimal solution; $x_c^s\left(t-1\right)$ denotes other workflow-centred structures affecting the new structure; $x^s_{rand_1}\left(t-1\right)$, $x^s_{rand_2}\left(t-1\right)$, … , $x^s_{rand_m}\left(t-1\right)$ are randomly selected individuals from the solutions in the aggregate; m denotes the number of workflows affecting the new structure; and it has been determined through experiments that m=3 can produce optimal results in a shorter computation time.

4) Technology: Numerous academics have emphasized the pivotal role of technology in shaping organizational change.

Organizations often reinvent themselves not directly due to outstanding ideas, but rather in reaction to technical advancements that facilitate the actualization of those ideas. From a strategic openness standpoint, organizations must enhance their exploration and development initiatives to obtain and utilize the knowledge requisite for innovation activities, as seen in Fig. 15. The following equation models the balance of this step of exploration and exploitation:

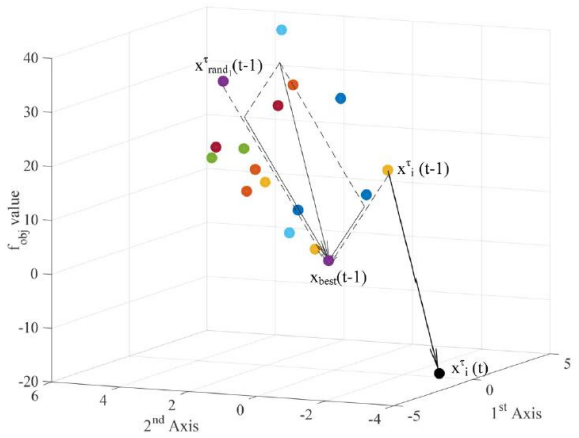

Fig. 15. Technical strategy of ED algorithm.

$$x_i^{\tau}(t) = x_i^{\tau}(t-1) + rand^{\alpha}(0,1) \times \left(x_{best}(t-1) - x_i^{\tau}(t-1)\right) + rand^{\beta}(0,1) \times \left(x_{best}(t-1) - x_{rand_1}^{\tau}(t-1)\right) \quad (14)$$

Where $x_{best}(t-1) - x_{rand_1}^{\tau}(t-1)$ denotes the exploration phase and $x_{best}(t-1) - x_i^{\tau}(t-1)$ denotes the development phase.

5) Personnel: Organizations must cultivate a participatory work culture that enhances individual creativity and collaboration through respect for others and stakeholders. This work culture affects employee commitment and engagement in sustainability. Compassion is essential for the efficacy of any production system or supply chain. Assuming attributes constitute a dimension, the subsequent equation illustrates the modeling of random selection of characteristics and the modification of individuals' actions (refer to Fig. 16). The mathematical model is shown in the following equation:

$$x_{i,d}^{p}(t) = x_{i,d}^{p}(t-1) + rand(-1,1) \times \left(x_{best,d}(t-1) - x_{c,d}^{p}(t-1)\right) \quad (15)$$

$$x_{c,d}^{p}(t-1) = \frac{x_{rand_1,d}^{p}(t-1) + x_{rand_2,d}^{s}(t-1) + \cdots + x_{rand_m,d}^{s}(t-1)}{m} \quad (16)$$

where d is a random feature of the person.

$$d = \lceil rand(0,1) \times n_d \rceil \quad (17)$$

Where n_d is the number of dimensions of the solution.

6) Conversion mechanism: The suggested ED algorithm assumes that the organization concentrates on one step at a time. Consequently, solely one of the four components (namely, task, structure, technology, and person) transpires at time *t* and is regulated by the activity transition mechanism, as seen in Table I and Fig. 17. The mechanism of the acting structure, technological phase, and human phase is presented as a function c(*t*), as seen in the subsequent equation:

$$c(t) = \left\lceil 3 \times \left(1 - \frac{rand(0,1) \times t}{Max_{iter}}\right) \right\rceil \quad (18)$$

Where t is the current iteration number and Max_{iter} is the maximum iteration number.

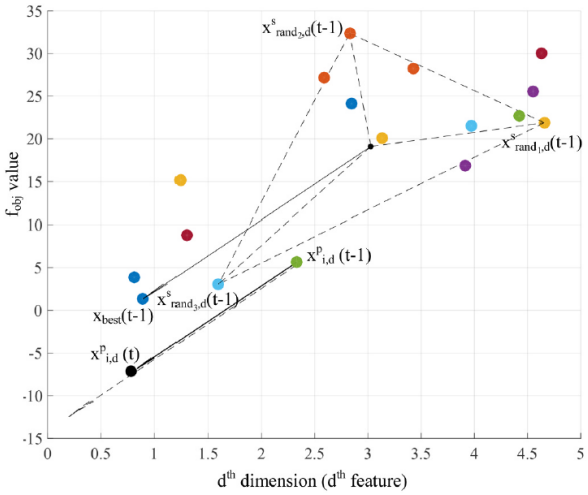

Fig. 16. ED algorithm staffing strategy.

C. ED-HKELM Model Construction Process

1) ED-HKELM model construction: In order to improve the accuracy of the immersive [22] Civic and Political Practice Teaching Experience Effectiveness Assessment Model based on the HKELM algorithm, this paper adopts the ED optimisation algorithm to optimise the parameters of the HKELM algorithm C , σ , c_1 , d , s_1 , and constructs the ED-HKELM immersive Civic and Political Practice Teaching Experience Effectiveness Assessment Model, and the specific optimisation structure is shown in Fig. 18.

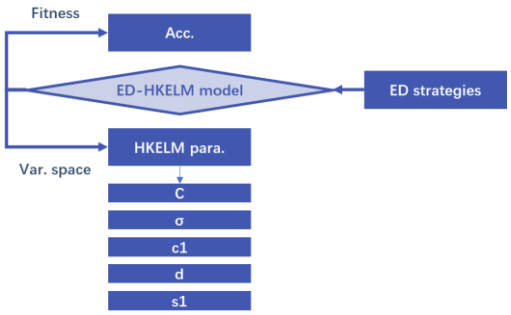

Fig. 18. ED-HKELM model structure

The optimisation decision variables of the ED optimisation HKELM model construction process are the parameters of the HKELM model C , σ , c_1 , d , s_1 , and the specific coding is shown in Fig. 19; We take the accuracy rate as the ED optimisation fitness function; The optimisation strategy of the HKELM model includes the task, structure, technology and personnel strategy of the ED algorithm.

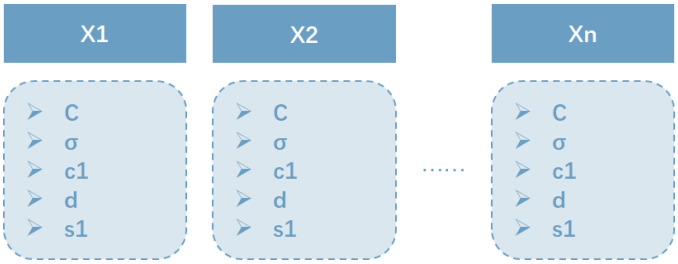

Fig. 19. Parameter coding structure of the ED-optimised HKELM model

2) ED-HKELM model application: In this paper, the design of the ED-HKELM model-based immersive civic politics practice teaching experience effect assessment method is mainly divided into the following processes:

a) Use the designed VR technology-based civic politics practice teaching system to extract the immersive experience effect assessment index value, and construct the assessment system;

b) Initialise the ED optimisation algorithm and the HKELM model parameters, and construct the ED optimisation population using real number coding, namely the HKELM model parameter population;

c) During the optimisation iteration, update the position of HKELM model parameter population according to the ED optimisation strategy;

d) Calculate the fitness value, determine whether the maximum number of iterations is reached, and output the optimal solution, i.e. the optimal HKELM model parameters.

IV. Results and Discussion

A. Data Acquisition and Parameterisation

Experiment in a hardware environment equipped with windows 10 operating system, Intel i5 processor, NVIDIA GTX1050Ti 4G graphics card, 16G memory. The computer programming used, using the Python 3.7 based PyCharm compiler, the implementation of immersive Civic and Political Practice Teaching Experience Effectiveness Evaluation model modelling, training, analysis and other functions is mainly based on the program libraries of TensorFlow 2.1 and Keras 2.3, as well as Pandas, Numpy, Scikit-Learn, Matplotlib and other data processing libraries.

The ED-HKELM model is trained, optimised, and tested using the evaluation data of Civics practice teaching based on VR technology. Randomly selected 70% sample size as the training set, 15% as the testing set, and 15% as the validation set.The parameter settings of the comparison algorithm are shown in Table III.

TABLE III. Comparative Model Parameter Settings

algorithmic model	*parametric*	*set up*
KELM	C	100
	σ	0.01
HKELM	C	100
	σ	0.01
	c1	5
	d	10
	s1	0.3
ED-KELM	Npop	100
	Maxiter	1000
ED-HKELM	Npop	100
	Maxiter	1000

B. Comparison and Analysis of Assessments

1) Performance analysis of ED algorithm optimisation: Fig. 20 gives the performance results of the ED algorithm in F1, F6, F8, F12 and F13 test function optimisation. From Fig. 20, it can be seen that the ED optimisation algorithm can converge to a certain accuracy during the optimisation of F1, F6, F8, F12, and F13 test functions, which satisfies the convergence requirements. Figure 20 further analyses the optimization performance of the Enterprise Development Optimization Algorithm (ED Algorithm) in different test functions, and verifies the synergy and advantages of its global search capability and local development capability from multiple dimensions.

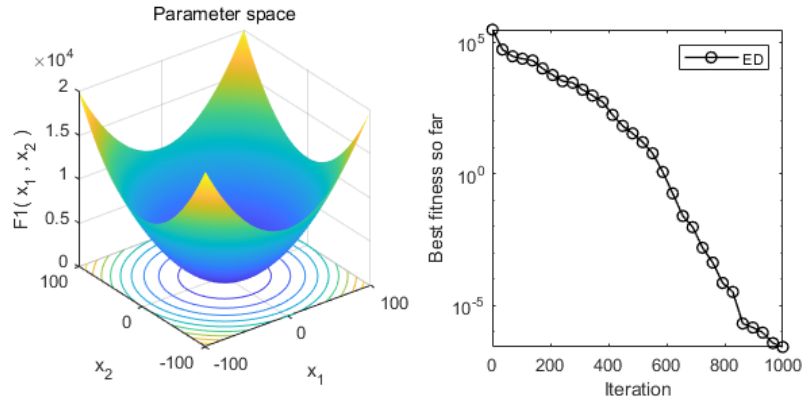
In the F1, F6, F8, F12 and F13 test functions, the convergence curves of the ED algorithm exhibit rapid decrease and stabilisation, which indicates that the algorithm is able to rapidly locate the high potential regions of the solution space in the early iteration stage, thus reducing the exploration time. Meanwhile, in the later iterations, the ED algorithm continues to refine the search through its dynamic activity switching mechanism (including the four optimisation strategies of task, structure, technology and personnel) to fully explore the local extremes of the solution space. This global and local collaborative optimisation strategy makes the ED algorithm exhibit excellent robustness in test functions of different complexity.

Specific analyses show that in the F1 and F6 functions, the fitness value decreases rapidly in the initial stage, reflecting the efficient search capability of the ED algorithm for single-peak functions. While in multi-peak functions (e.g., F8 and F12), the ED algorithm shows stronger resistance to local optima, and continues to explore the global optimal solution through its techniques and structural optimisation strategies. In addition, the stable performance of the ED algorithm on the complex multi-dimensional function of F13 further proves the applicability of its dynamic activity switching mechanism, which is able to optimise efficiently in high-dimensional search space.

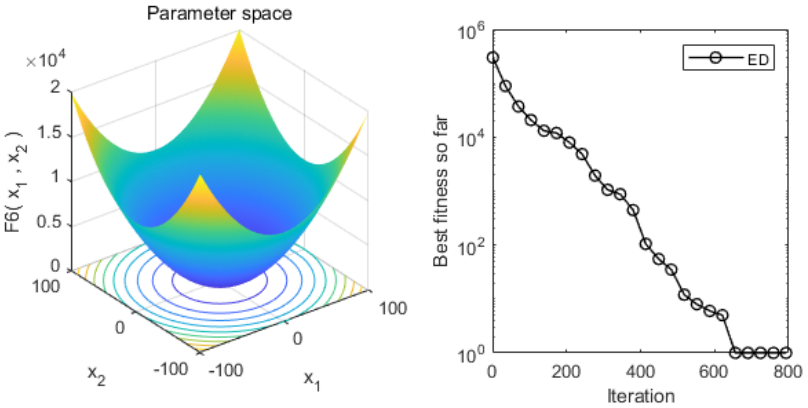
This wide applicability makes the ED algorithm not only suitable for classical optimisation problems, but also able to play an important role in the optimisation of experience assessment models for complex educational scenarios, such as virtual reality Civics practice teaching. Its good convergence performance and parameter tuning ability provide strong support for accurate and efficient immersive experience assessment based on the ED-HKELM model. In the future, its scalability and practicality can be verified by more test functions and real scenarios, which will lay a more solid foundation for the promotion and application of the intelligent optimisation algorithm.

2) Design effect analysis: The effect of the practical teaching of Civics based on VR technology designed in this paper is shown in Fig. 21.

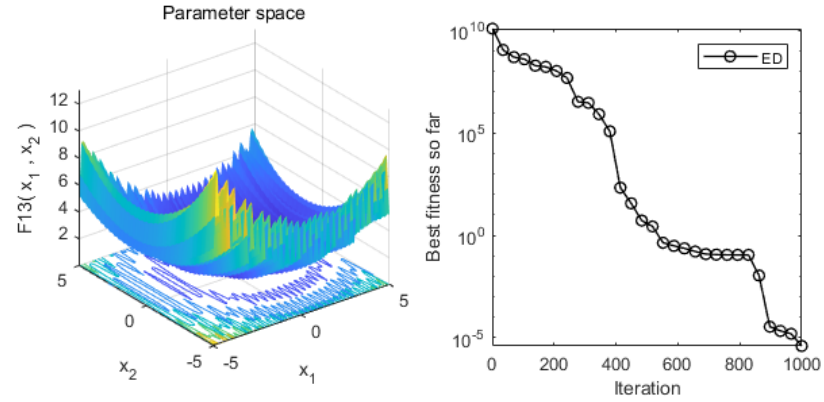
Fig. 21 (a) gives the software facilities of the VR teaching environment, and this paper focuses on the virtual exhibition hall of the Memorial Hall of the Victims of the Invasion of the Japanese Army in the Nanjing Massacre as a practical teaching case. The VR venue to the year when the Japanese army invasion of China when the evil committed by the performance of the best, virtual reality technology immersion can be fully stimulate the eyes of the students, learning motivation and efficiency will be greatly improved; Fig. 21 (b) gives the VR teaching site schematic diagram, the students put on the VR helmet, into the "Nanjing Massacre Memorial Museum Virtual Venue".



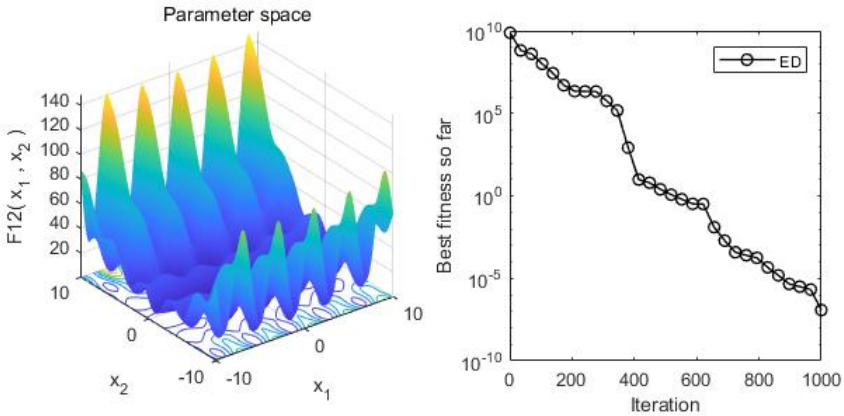
(a) F1



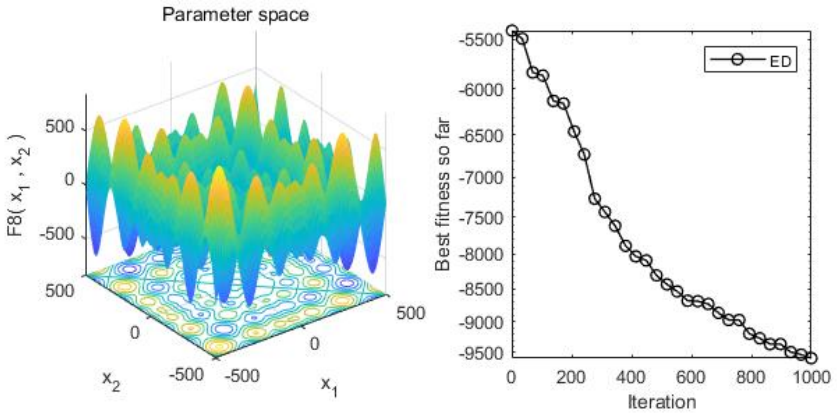
(b) F6



(c) F13



(d) F12



(e) F8

Fig. 20. Performance analysis of ED algorithm optimisation.

Fig. 21 demonstrates the design effect of Civics practice teaching based on VR technology, including the virtual pavilion interface (Fig. 21(a)) and the schematic diagram of the VR teaching site (Fig. 21(b)), which aims to assess the effect of the immersive experience of VR technology in Civics practice teaching.

Fig. 21(a) takes the Memorial Hall for the Victims of the Invasion of the Japanese Army in the Nanjing Massacre as a case study, and digitally reproduces the historical scenes and cultural connotations of the real venue through VR technology. The design of the virtual pavilion focuses on visual, auditory and other multi-sensory experiences, providing a highly immersive learning environment. For example, through three-dimensional modelling, image rendering and sound fusion, students can "walk into" the memorial hall and intuitively feel the authenticity and shock of historical events. This highly immersive virtual venue not only makes up for the limitations of space and time in traditional teaching, but also triggers students' emotional resonance and learning interest through dynamic scenes.

(a) Virtual pavilion interface.

(b) Effectiveness of classes.

Fig. 21. Design effect.

Fig. 21 (b) shows the actual use of VR in teaching, where students wear VR headsets to enter the virtual arena to start learning, and the use of VR equipment enhances the interactivity and engagement of learning, allowing students to "explore" the relevant historical scenes and interact with the virtual objects in the virtual environment. This type of experiential teaching combines technology-driven and educational needs, and can stimulate students' learning initiative while enhancing their memory and understanding of historical events.

The design effect in Fig. 21 illustrates that the practical teaching of Civics and Politics based on VR technology significantly improves the learning effect and experience feeling of students by providing an immersive, interactive and highly realistic learning environment. This teaching mode not only enhances classroom efficiency, but also provides a reproducible technical solution for practical teaching, which has a wide range of application prospects.

3) Evaluation performance analysis: In order to verify the efficiency of the ED-HKELM model, KELM, HKELM, ED-KELM and ED-HKELM are used in this paper for comparative analyses, and the specific results are shown in Fig. 22 and Table IV.

Fig. 22 demonstrates the comparison between the assessment results of the immersive experience effect of VR Civic and Political Practice Teaching and the real value based on different assessment models, aiming to verify the superiority of the proposed ED-HKELM model in terms of assessment accuracy. The figure includes four sub-figures corresponding to the assessment results of the KELM, HKELM, ED-KELM and ED-HKELM models.

There is a significant deviation between the assessment results in Fig. 22 (a) of the KELM model and the real value, especially in the interval of large data fluctuations, which shows a large error. This indicates that although the KELM model has some advantages in assessment speed, its adaptability to complex and nonlinear data is weak, and it is difficult to accurately reflect the real effect of VR immersive teaching.

The HKELM model (Fig. 22 (b)) has improved its classification performance compared to KELM by introducing the mixing kernel function, and the match between the evaluation results and the true values is significantly improved. However, some deviations still exist in some intervals, indicating that the optimisation of the model is not yet optimal.

ED-KELM model (Fig. 22 (c)), by optimising the KELM parameters through the ED algorithm, the ED-KELM model further improves the assessment accuracy with a significantly better fit to the true values. In regions with drastic data changes, the model shows better robustness and higher adaptability.

The ED-HKELM model (Fig. 22 (d)) performs the best among all models, and its evaluation results almost completely overlap with the true values, demonstrating extremely high accuracy. This is attributed to the comprehensive optimisation of the HKELM parameters by the ED algorithm, which enables the model to achieve a balance between global search and local exploitation capabilities, thus significantly improving the evaluation accuracy.

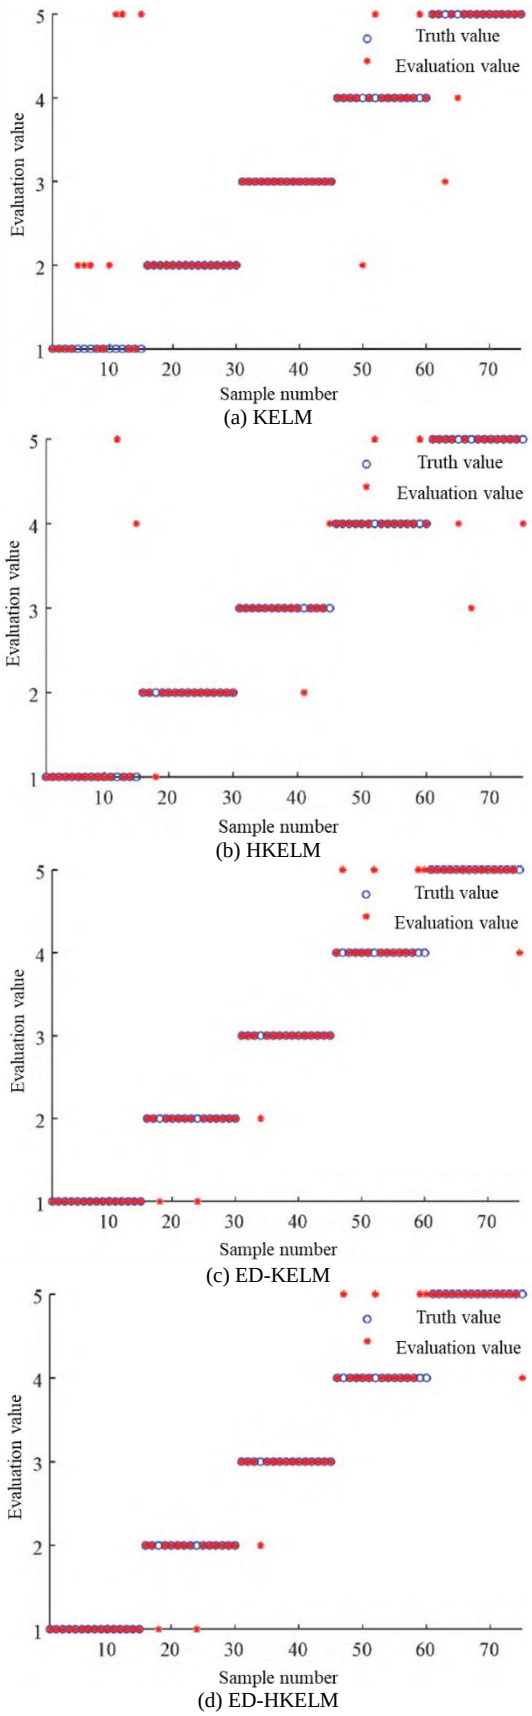


Fig. 22. Comparative results of the evaluation of different models.

The analysis in Fig. 22 shows that the ED-KELM model has significant superiority in the assessment of immersive experience effect of VR Civics practice teaching, and its high accuracy and strong adaptability provide a reliable tool for the scientific assessment of immersive teaching effect. In contrast, the traditional KELM and HKELM models have certain limitations, while the ED-KELM model has been improved but is still not optimal. Future research can further combine real-time data updating with dynamic optimisation strategies to enhance the applicability and intelligence of the models.

Table IV compares the performance of four evaluation models, KELM, HKELM, ED-KELM and ED-HKELM, in evaluating the effect of immersive experience in VR Civics practice teaching. The KELM model has an accuracy, recall, and precision rate of 84.0%, 84.0%, and 86.7%, respectively, which shows a basic evaluation capability, but is less effective in complex feature processing. The HKELM model improves the accuracy and recall to 86.7% and the precision rate to 87.1% by introducing the mixed kernel function, which enhances the adaptability but falls short of the optimum. The ED-KELM model further optimises the parameters by combining with the Enterprise Development (ED) optimisation algorithm, and the metrics are significantly improved to 89.3%, 89.3% and 90.1%, which is an excellent performance in the classification performance. The ED-HKELM model, on the other hand, achieves 94.7%, 94.7% and 94.8% in accuracy, recall and precision, respectively, demonstrating optimal performance. This is attributed to the comprehensive optimisation of HKELM parameters by the ED algorithm, which significantly improves the classification accuracy and adaptability.

TABLE IV. COMPARISON OF EVALUATION PERFORMANCE OF DIFFERENT MODELS

Assessment methodology	*accuracy*	*recall rate*	*accuracy*
KELM	84.0 per cent	84.0 per cent	86.7 per cent
HKELM	86.7 per cent	86.7 per cent	87.1%
ED-KELM	89.3 per cent	89.3 per cent	90.1%
ED-HKELM	94.7 per cent	94.7 per cent	94.8 per cent

The results of the ED algorithm to optimise the HKELM parameters are: $C = 95$, $\sigma = 0.013$, $c_1 = 2.55$, $d = 7.30$, $s_1 = 0.36$.

V. CONCLUSION

This paper addresses the challenge of evaluating the immersive experience of Civic and Political Practice Teaching utilizing VR technology by integrating machine learning and intelligent optimization algorithms, proposing an assessment method based on the ED-HKELM model. By examining the present state of research on Civic and Political Practice Teaching utilizing VR technology, formulating a Civic and Political Practice Teaching framework grounded in VR technology, identifying the assessment issues related to the immersive experience effect of Civic and Political Practice Teaching, acquiring the index data for the immersive experience effect assessment, refining the parameters of the HKELM model through the ED algorithm, developing an immersive experience effect assessment model, and employing the Civic and Political Practice Teaching data based on VR technology to validate and analyze the proposed methodology. The proposed method is evaluated and analyzed using data from Civic and Political practice instruction utilizing VR technology. The results show that the immersive experience effect assessment model in this paper has high assessment accuracy.

Although this paper effectively improves the accuracy of the assessment of the immersive experience effect of VR Civics practice teaching, there is still room for further optimisation. Future research can focus on dynamic optimisation and real-time assessment technology, combined with dynamic data flow processing to achieve instant feedback, to improve the interactivity of teaching and assessment adaptability; extended to multi-scene and multi-task assessment, to verify the model's versatility and robustness in different teaching needs; integrated into the students' individual characteristics analysis, combined with intelligent recommendation algorithms, the development of personalised assessment system, to provide students with targeted learning advice; Optimise the computational complexity of the algorithm to improve the applicability of the model in low-cost devices and multi-platform environments. These directions will further promote the scientific and intelligent application of VR technology in teaching and learning assessment, and help improve the overall quality of education.

Bina Nusantara University, Jakarta, Indonesia 11480[1]
Faculty of Information Technology, Satya Wacana Christian University, Salatiga, Indonesia 50715[2]

***Abstract*—Understanding the consumer is becoming crucial in today's customer-focused company culture. Sentiment analysis is one of many methods that can be used to evaluate the public's sentiment toward a specific entity in order to generate actionable knowledge. In the commercial sector, sentiment analysis is critical in enabling businesses to establish strategy and obtain insight into user feedback on their products. Unfortunately, there are still many companies that do not hear customer feedback and run the business as usual, even though there is an analysis of sentiment that can reflect services and products of companies. The problem can be overcome by implementing sentiment analysis. When a company implements sentiment analysis, they can more easily discover what the consumers want, what they disapprove of, and what measures can be taken to sustain, which will help companies improve their products and services' performance. The purpose of this paper is to find out the uses of sentiment analysis in a company and the methodology that companies use to implement sentiment analysis. The research used in this paper was done by reviewing 22 papers that discuss sentiment analysis. This paper aims to learn more about the methodology and uses of sentiment analysis in a company.**

***Keywords*—Sentiment analysis; sentiment analysis approach; text mining**

I. Introduction

Sentiment analysis is one of study of people's opinions, feelings, emotions, and perspective about things such as item, activities, problem, occurrences, themes, and their attributes. As an outcome, sentiment analysis can be used to evaluate the public's sentiment toward a specific entity in order to generate meaningful information. Sociological trends [1]. In the commercial sector, sentiment analysis is critical in enabling businesses to establish strategy and obtain insight into user feedback on their products. Understanding the consumer is becoming crucial in today's customer-focused company culture [2]. Even though advanced sentiment analysis methods can effectively capture customer opinions and feedback about the products and services provided by businesses, many companies still choose to overlook these valuable insights. They continue operating in the same old ways, failing to adapt to the changing needs and expectations of their customer.

From various papers that were used, many businesses are having problems with their marketing campaigns. An issue can sometimes have an impact on a company's brand, causing marketing ineffectiveness and having little correlation with customer thoughts. With the steep increase of discussion platforms, consumer review sites, e-commerce, and social networking sites, there is a steady flow of ideas and opinions. This expansion makes it harder for businesses to acquire a more comprehensive understanding of their customers' aggregate thoughts and feelings toward products. The explosion of internet-generated information, along with tools such as sentiment analysis, helps businesses to look deeply into their customers' views toward their products [3]. In order to better serve customers and increase sales, marketers can identify sentiments from product reviews and use them to get in touch with those who require particular attention [4].

Other issues like the intense competition among businesses, cause every business to rush and enhance its invention and performance. Utilizing sentiment analysis as input for evaluation and assessment can be beneficial. The data analysis results in a better decision to enhance their offerings, discover the desires of their consumers, and enhance their overall experience during using their services [5].

The objective of this paper is to find out more about the reason why company should implement sentiment analysis, the approach that used, and the task and level of sentiment analysis. This paper can help researcher or a company while they are considering implementing sentiment analysis in their decision-making process. This paper consists of an introduction, a literature review, a research method, a result and discussion, and a conclusion.

The motivation of this study is to learn more about sentiment analysis in a company, especially the purpose, approach, and problems. The method used to achieve this motivation is to use the system literature review (SLR) method. This method is used by taking the results and summarizing the research from the previous study.

This contribution of this paper is to further explain the uses of sentiment analysis in the business. The purpose of this study is to identify which approach and task most companies use for sentiment analysis. So, when there are companies that consider sentiment analysis, they can decide which approach and task they will use and what the considerations of sentiment analysis are.

II. Literature Review

A. Text Mining

Text mining refers to extracting information from text-based documents [6], [7]. Data sources are obtained from documents or texts, such as Word documents, PDFs, text excerpts, or so on. Text mining has the aim of finding words and get useful information where the information can represent the content of related documents so that it can be analyzed related to each document [7].

B. Sentiment Analysis

Data sources are obtained from documents or texts, such as Word documents, PDFs, text excerpts, or so on. Text mining has the aim of finding words and get useful information where the information can represent the content of related documents so that it can be analyzed related to each document [7].

C. Sentiment Task

Sentiment analysis also defined as sentiment categorization. One of the modules of sentiment classification is polarity analysis, which is sometimes referred to as "opinion analysis" when discussing sentiment analysis. It is a small task intended to ascertain the tone of each text. Traditionally, polarity is either positive or negative [8].

D. Lexicon-Based Approach

Sentiment classification is a well-known research task in sentiment analysis, which is also referred to as sentiment categorization. One of the modules of sentiment classification is polarity analysis, which is sometimes referred to as "opinion analysis" when discussing sentiment analysis. It is a small task intended to ascertain the tone of each text. Traditionally, polarity is either positive or negative [9].

1) Dictionary based: The dictionary-based technique uses a manually compiled list of words with predetermined sets of opinions. This method's main presumption is that antonyms have the opposite polarity from that of the source word, whereas synonyms have the same polarity as it. In order to add antonyms and synonyms to a group or seed list that was previously created, large corpora like thesaurus or wordnet are scanned. The initial collection of words is manually collected in the first stage along with their orientation. Afterward, the list is extended by examining the lexical resources' antonyms and synonyms. The list is then increased after the words have been added iteratively [10].

2) Corpus based: To validate the emotion of sentences, this method makes usage of patterns in language structure (syntax) and word meaning (semantics). Starting with a predetermined list of sentiment words and their orientations, this method explores a very large corpus for sentiment tokens and their orientations by looking for syntactic or other related patterns. The corpus-based use in specific method situation. Training it, required a lot of labeled data. It does assist in addressing the issue of opinion words with context-dependent orientation, through study [10].

E. Machine Learning-Based Approach

Sentiment classification may be accomplished using machine learning algorithms. The machine learning method utilizes either syntactic or linguistic or both of them to figure out the problem of sentiment classification based on the standard text classification. Categorization model will match one the class label with the underlying record feature. The class label for a specific data of an unknown class or called test data is then predicted using the model [10].

1) Decision tree: Linked data structures resembling Bayesian networks are used to represent decision tree classifiers. Using multiple criteria taken from information theory, such as entropy and information gain, the population is separated into various sections in this classification process [11].

2) Naive bayes: Technique for organizing data into pre-existing categories [12]. The method of this approach is Bayesian classification which is based on Bayes' theorem. NB which is a type of probabilistic classification, uses to predict the probabilities of the dataset of features as part of a label. By calculating how the conditional probability of A's event might be occurred, will lead to the individual probabilities of A and B and the conditional probability of event B occurring [10].

3) Support Vector Machine: SVM is one of supervised machine learning algorithms. Supervised machine learning is a technique for making predictions of the data would be classified and categorized. SVM models looks for the best the best hyperlane attempts which will serve as separator of found by measuring the margin of the hyperlane and finding its maximum point [13].

4) Random forest: Random Forest is an adaptive learning method that incorporates the concepts of random subspaces and "bagging". The random forest algorithm belongs to a group of methods that utilize decision tree as an independent predictor. The random forest algorithm is one of the greatest classification algorithms, able to precisely classify enormous amounts of data. It is a versatile regression and classification assembly learning method that constructs multiple decision trees during training and delivers the class that is the mode of the classes output by individual trees [14].

III. Research Method

This paper is studied using the literature study technique. The purpose of using the literature study technique is to learn and comprehend the approach that used to conduct sentiment analysis. This technique involves gathering journals or papers related to sentiment analysis. After collecting all of the papers, it will be analyzed and summarized properly, and all of the important parts will be discussed and used in this work. All of the important discussion topics from this paper will be accomplished using that strategy, including determining the best approach for sentiment analysis.

A. Collecting Paper

The process of collecting the paper begins after deciding the topic to be discussed. Google and Google Scholar were used for the paper search. The papers collected are published by the Institute of Electrical and Electronics Engineers (IEEE), Elsevier, International Journal of Engineering and Advanced Technology (IJEAT), Springer, and other publishers. Key words used during the paper collection are:

- "Text Mining" AND "Twitter" AND "Sentiment Analysis"

- "Sentiment Analysis" AND ("Machine Learning" OR "Supervised" OR "Unsupervised")
- "Sentiment Analysis Approach"
- "Sentiment Analysis"

B. Sorting Paper

The papers collected are published by the Institute of Electrical After collecting the papers, all of the papers or journals must be evaluated again, and there are currently 33 papers or journals left. The papers or journals that will be used will highlight why company should implement sentiment analysis and what they obtain as a result of doing so. As the core principle, this work also used various the papers or journals.

C. Data Extraction

In Table I, all papers or journals will be analyzed and summarized using the necessary data, such as what purpose of sentiment analysis, how accurate the model of sentiment analysis, and what approach they used to implement sentiment analysis.

TABLE I. NUMBER OF PAPER IN SOURCE THAT HAVE BEEN SELECTED

No.	Number Of Paper in Source That Have Been Selected			
	Source	Journals Found	Candidate Studies	Selected Studies
1	IEEE	32	10	10
2	Elsevier	29	11	4
3	IJEAT	8	3	1
4	Other Publishers	893	18	10
	Total	962	42	25

IV. RESULT AND DISCUSSION

A. Purposes of Paper

Based on the 22 journals that have been collected and reviewed there are 8 journals that discuss the purposes of using sentiment analysis, especially comparison between different classification and six about analyzing social issues through social media. Analyzing social issue can be a result to track trend to the competitor or using it in marketing.

TABLE II. PURPOSE OF USING SENTIMENT ANALYSIS

No.	Purpose Of Using Sentiment Analysis		
	Purposes	References	Total Papers / Journals
1	Analyzing customer satisfaction through social media.	[5], [13]	2
2	Analyzing social issues through social media.	[17], [32], [33], [15]	4
3	Analyzing social issue through social media & comparing classification	[21], [26], [27], [28], [30], [31]	6
4	Comparison between different classification	[14], [16], [19], [20], [22], [23], [25], [29]	8
5	Comparison with different algorithm	[18], [24]	2

By categorizing the objectives of each paper, especially in the classification comparison found in numbers 3 and 4 with a total of 14 papers on Table II, we can find out which classification has the best performance. Based on 14 papers, the best classification performance can be found by taking the maximum accuracy value for each classification.

B. The Sentiment Analysis Implementation Approach

There is something that must be improved in the marketing process and competitor analysis to analyze customer trends. Sentiment analysis in the text mining process must be carried out. Some companies take advantage of public opinion in Twitter media to detect customer needs. Then, the company analyzes the suitable algorithm for the data type and amount of training data. From there, they can decide which approach they will use.

From Table III, it showed that Support Vector Machine is the common approaches in a high dimensional. The Support Vector Machine approach is used by 8 journals. The second common approach is Naive Bayes approach and Decision Tree approach.

Although Random Forest exhibits the highest accuracy, it is less accurate than Naive Bayes and Support Vector Machine due to the influence of the amount of data it processes (Table IV).

TABLE III. THE SENTIMENT ANALYSIS IMPLEMENTATION APPROACH

No.	The Sentiment Analysis Implementation Approach		
	Purposes	References	Total Papers / Journals
1	Support Vector Machine	[13], [14], [15], [17], [18], [20], [22], [30], [33]	8
2	Naive Bayes	[5], [16], [19], [21], [22], [25], [29], [33]	8
3	Decision Tree	[16], [21], [22], [29]	4
4	Random Forest	[14], [21], [24],	3
5	Logistic Regression	[22], [26], [32]	3
6	Lexicon-based	[15], [25]	2
7	Language Processing (NLP)	[30], [31]	2
8	K-Nearest Neighbors (KNN)	[16], [20]	2
9	CNN-SVM	[23]	1
10	Convolutional Neural Network (CNN)	[27]	1
11	Long short term memory network (LSTM)	[27]	1
12	Logistic Regression and Lexicon	[28]	1

TABLE IV. THE COMPARISON OF ACCURACY BETWEEN TOP 3 APPROACH

No.	The Comparison of Accuracy between Top 3 Approach			
	Approach	Accuracy	Data	References
1	Random Forest	94.54%	400,000 data	[24]
2	Support Vector Machine	91.50%	236,867 data	[22]
3	Naive Bayes	83.43%	3,744 data	[21]

Among these methods (Table IV), the languages utilized vary. The Random Forest method [24] is employed in English, while the SVM method [22] is used in Vietnamese, and Naive Bayes [21] is applied in Indonesian.

Additionally, there are distinct preprocessing stages associated with each method. In order to mitigate the occurrence of false statements, [21] data is manually labeled. The study in [22] replaces abbreviations, acronyms, and misspellings with their original words to ensure thorough analysis during subsequent stages. On the other hand, [24] follows standard preprocessing steps without implementing any specific modifications. However, it is important to note that these factors may have a minimal impact on the results, primarily due to the differences in the raw data utilized.

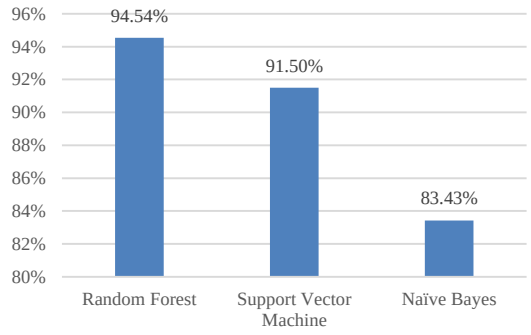

Fig. 1. Top 3 approach used in implementation sentiment analysis.

In sentiment analysis, accuracy is determined by the percentage of correctly classified documents or text samples. In other words, it measures how well the sentiment analysis model is able to correctly predict the sentiment of a given text. To determine the accuracy of a sentiment analysis model, the model's predictions are compared to the actual sentiment labels of the text samples in the dataset. The accuracy is calculated as the ratio of the number of correctly classified text samples to the total number of text samples in the dataset.

Accuracy is a widely used metric to evaluate sentiment analysis model performance. However, it is important to note that accuracy alone may not provide a complete picture of the model's performance. Other metrics such as precision, recall, and F1 score should also be considered to assess the model's overall effectiveness.

C. The Implementation

Data Collection: Gather a dataset of labeled text samples. This dataset should include text samples along with their corresponding sentiment labels (e.g., positive, negative, neutral). Data available at https://drive.google.com/file/d/12QSJv-BiIBOs2cwHNcZwcZ1GcIXWCrS0/view?usp=sharing. c6y45x2/1; https://doi.org/10.17632/x8mc6y45x2.1

Data Preprocessing: Clean and preprocess the text data to remove any irrelevant information, such as special characters, numbers, or punctuation. Convert the text into a numerical representation that can be used by machine learning algorithms, such as word embeddings or bag-of-words representation.

Feature Extraction: Extract relevant features from the preprocessed text data. This step involves representing the text samples in a format that can be used by machine learning algorithms. Some common approaches include TF-IDF (Term Frequency-Inverse Document Frequency) and word embeddings like Word2Vec or GloVe.

Split the Data: Divide the dataset into training and testing sets. The training set will be used to train the sentiment analysis model, while the testing set will be used to evaluate its performance.

Model Training: Choose a machine learning algorithm, such as Decision Tree, Support Vector Machine (SVM), or Naive Bayes, to train the sentiment analysis model. Fit the model to the training data and optimize its parameters using techniques like cross-validation or grid search.

Model Evaluation: Evaluate the trained model using the testing set. Measure its performance metrics, such as accuracy, precision, recall, and F1 score, to assess how well it predicts the sentiment of the text samples.

Model Deployment: Once the model has been trained and evaluated, it can be deployed for sentiment analysis tasks. New, unlabeled text samples can be fed into the model, and it will predict their sentiment based on the learned patterns from the training data.

The author also conducted a study using a dataset from Google Play Store API that have 2976 data. This study was carried out to test and determine the accuracy of the model based on three algorithms that often appear. Through this study, the author got results as shown on Table V.

TABLE V. THE COMPARISON OF ACCURACY BETWEEN TOP 3 APPROACH

No.	The Comparison of Accuracy between Top 3 Approach	
	Algorithms	**Author's research accuracy**
1	Support Vector Machine	83%
2	Logistic Regression	83%
3	Naive Bayes Classifier	74%

The results, as shown in Fig. 1, clearly show that the random forest model exceeds the other two models in terms of accuracy, confirming its place as the best method for the task at issue. The study also draws attention to a crucial finding: when working with diverse datasets with different features and preparation methods, the outcomes can vary greatly.

The data from the Google Play Store that random forest and SVM have comparable characteristics and capabilities. As a result, state with confidence that these two algorithms prove to be the best options for E-commerce case studies, demonstrating their adaptability and efficiency in handling a variety of scenarios and commercial applications. Taking into account the particulars and quirks of each dataset and use case.

V. CONCLUSION

In conclusion, this study aimed to review various sentiment analysis approaches and analyze their performance. Based on the comprehensive analysis conducted, the random forest

approach emerged as a popular choice with superior performance compared to other approaches. This finding suggests that leveraging random forest algorithms can be highly beneficial in sentiment analysis tasks.

Furthermore, our investigation identified the optimal ratio between test and training data to be 80/20, indicating that allocating a larger portion of the dataset for training (80%) and a smaller portion for testing (20%) yields favorable results.

The insights gained from this research provide valuable guidance for future studies and research endeavors in sentiment analysis. Future researchers should explore text mining applications for business strategies. Additionally, there is a scope for further enhancing the accuracy of machine learning approaches in sentiment analysis tasks, which could yield even more reliable and precise sentiment predictions. By building upon the knowledge and findings obtained in this study, future research can contribute to advancing the field of sentiment analysis and its practical implications across various industries.

ACKNOWLEDGMENT

The author would like to thank all parties who have contributed and helped in completing this paper. Apart from that, the author also received assistance from AI tools in this paper, namely grammarly (to help the author compose English) and the researcher would like to thank everyone who participated in the questionnaire. The Author roles are Indrajani: Draft Paper, Use VOS for result and discussion, Review Paper, and Submit Paper; Hendry:Write introduction, methodology, and Result and discussion.

***Abstract*—Information security is considered vital aspects that are employed to protect user credentials and digital information from cyber security threats. A Caesar cipher is an ancient cryptography algorithm, and it is susceptible to being easily broken and vulnerable to brute-force attack. Brute-force attack is a cyberattack that uses trial and error to crack passwords, login credentials, and encryption keys to unauthorized access and illegal to a system and individual accounts. However, several research has been developed to defeat the existing vulnerabilities in Caesar cipher, but are still suffering from their limitations and failing to provide a high level of attack detection and encryption strength. Therefore, Modified Caesar Cipher Algorithm Based on Binary Codes (MCBC) has been proposed to mitigate brute-force attack more optimistically based on different scenarios. First scenario, converting message to binary numbering system and the second scenario, employ binary shifting technique and then convert it to hexadecimal code. The performance metrics that were taken into consideration to evaluate the MCBC proposed algorithm are detection rate, strength rate, true positive rate and time required for decryption. The experimental results show that the proposed approach MCBC performance metrics outperformed other algorithms against brute force attack by ensuring the confidentiality of information.**

***Keywords*—Brute-force attack; encryption; Caesar cipher; binary code; security**

I. Introduction

Cybersecurity issues are become increasingly important, due to the increasing volume of sensitive data and credentials targeted by cybercriminals. Thus, it has become an urgent need to find a security system that can maintain confidentiality and prevent data from being misused, changed, or compromised by third party. Counterfeit authentication schemes allow attackers to use tactics such as social engineering and brute force attacks to obtain user database login information [1][2]. Therefore, cryptography can be employed to secure communication by encryption data on the sending side and decryption process on the receiving side of the communication system [2].

Encryption algorithms are usually used in addition to protecting data from theft, burglary or even alteration to verify the user's identity. Some of these algorithms are based on character representative which consist of substitution ciphers to convert one letter in the plaintext into an alternative form called cipher text [2][3] this type of substitution called Caesar cipher. Ideally only authorized parties can decrypt the cipher text and get access to the original information. Symmetric cryptography is a method that uses the same key for the encryption and decryption process [4]. The advantages of symmetric key are that managing the key is much easier and faster than the public key method. The Caesar cipher is considered as the most widely used symmetric encryption technique as illustrated in Fig. 1.

Fig. 1. Symmetric cryptography.

In cryptography techniques, Caesar cipher is a part of substitution cipher and susceptible to being easily cracked through brute-force cryptanalysis in a short period of time [4][5]. The reason behind this, is that there are only 25 possible options of keys are available [6]. Caesar encryption algorithm will replace each plaintext letter with a different one in a fixed number of positions [7]. The alphabet used to create the plaintext is assigned an index number that is used as keys, as shown in Fig. 2.

A	B	C	D	E	F	G	H	I	J	K	L	M
0	1	2	3	4	5	6	7	8	9	10	11	12
N	O	P	Q	R	S	T	U	V	W	X	Y	Z
13	14	15	16	17	18	19	20	21	22	23	24	25

Fig. 2. Alphabetical order index.

Brute-force attacks are very challenging in detection and considered as high-risk security threats in cyberattacks. Brute force attack occurs when the adversary uses trial and error methods to crack passwords, login credentials, and encryption keys [8]. However, cryptography algorithms could transmit sensitive information over an insecure network to prevent the

data from being read by unauthorized recipients other than the intended recipient [9]. There are several issues that need to be resolved through MCBC proposed modified algorithm such as: easy to decrypt data by an unauthorized user and by looking at the letters pattern, the entire message can be decrypted, also provide higher attack detection rate and encryption strength. Moreover, the main limitation in Caesar cipher is the limited key space, which contains only 25 possible keys. This makes it easy for an attacker to systematically check brute force attacks and try all possible keys and passphrases till they find the right one [10]. Therefore, this paper presents an algorithm based on binary numbering system and shifting technique to provide high level of encryption and overcome the limitations faced by classical Caesar Cipher.

In this research, we perform the binary numbering system and shifting technique to strengthen the Caesar algorithm and increase the effectiveness of the MCBC. The outcomes of this research demonstrate the significant impact on password cracking techniques using brute force attack. The difference between MCBC algorithms and other algorithms in the literature is that the proposed algorithm used a binary system (base-2 and base 16) that will perform some other operations such as encryption and decryption. Doing so will help to protect data, storage and achieve high performance of encryption. Thus, the contributions of this paper are summarized as follows:

1) We proposed a modified MCBC secure algorithm for Caesar cipher. MCBC can provide encryption strength and is considered more secure and resistant to brute force attacks through performing the binary numbering system and shifting technique.

2) The concept of binary shifting technique and hexadecimal conversion will improve the performance and accuracy of MCBC which will avoid the chances of decryption operation by the attacker making the system strength against brute force attack.

3) The hexadecimal code will be input into Caesar cipher algorithm for complex processes in decryption operations.

4) The MCBC algorithm has been compared with that of classical Caesar cipher algorithm averse to brute force attack. The results demonstrate that the MCBC algorithm outperforms classical Caesar cryptography algorithm.

The remainder of this paper is organized as follows. Section I provide the introduction. Section II about literature review. Section III about preliminaries and background. Section IV shows the proposed approach. Section V shows the security analysis. Section VI shows results comparison and evaluation. Section VII about research summary. Finally, Section VIII, concludes the paper.

II. Literature Review

Several algorithms and myriad solutions have been developed to overcome the limitation of Caesar cipher encryption. However, the literature will discuss and point out the most recent developed solutions in cryptographic algorithms of the relevant literature reviewed.

M. D. Hossain et al. in [11] providing brute force attacks detection. This detection of SSH and FTP brute force attacks by employing LSTM (Long Short-Term Memory) deep learning technology. In addition, the detection mechanism used machine learning classifiers such as J48, naive Bayes, decision table, random forest, and k-nearest neighbors to enhance our detection capabilities and CICIDS2017 dataset. The evaluation of LSTM and ML algorithms has been shown that the LSTM model outperforms ML algorithms in terms of performance, achieving an accuracy level.

E. Ahmadzadeh et al. in [12] proposed a modified hybrid technique consisting of Caesar cipher and Vigenère cipher as well. The modification will improve the diffusion and confusion properties of the cipher text by incorporating modern encryption techniques such as XORing the key to the first letter of the plaintext, and then to the second letter and so.

M. M. Najafabadi et al. in [13] proposed mechanism detection about SSH brute force attacks at the network level, which can be detected through analyzing Net Flow data. A dataset has been employed for attack detection, using (ML) machine learning techniques that have been shown to be effective in recognizing brute force attacks. The proposed method authors have distributed SSH brute force attacks and evaluated, they conclude that some methods for detecting individual attacks were shown to have difficulties in implementation, as indicated by (AUC) Area Under the Receiver Operating Characteristic Curve values.

M. Srivastava et al. in [14] propose a modification that consists of two various encryption methods. Firstly, employ Caesar cipher techniques include image steganography. The image is first encoded and then stored inside the available image in order to increase the level of security. Secondly, a third security level will be involved. The encrypted image of the message is associated by the sender with a security key that can contain n digits. The receiver also receives the key with the image and if it matches the sender's key, then the image is decrypted.

Q. A. Kester in study [15] proposed an algorithm that uses a Vigenere square and a key in the encryption process. However, the new method uses successive keys that depend on the value of the initial key during the encryption process. The keys used later are based on the value of the original key during the encryption process. The key for the first stage is different from the key for the second stage, but they are related to each other, with the key for the second stage being derived from the function used in the first stage, and so on. The algorithm ultimately allows the text to be encrypted and decrypted and makes it more difficult to defend against common attacks with the Vigenère cipher. This is due to the different keys used in each encryption process.

D. Veera et al. in study [16] proposed a new technique which make the encryption more efficient based on a combination of the modified Caesar cipher and the Card Deck Shuffle algorithm for encryption operation of the image. The Card Deck Shuffle algorithm will reconstruct all available pixels based on the outcomes of the modified Caesar algorithm. The method uses variable keys, therefore, to have successful brute-force attack, it

requires more than 2^{26} attacks. The method can be used in various multimedia applications.

III. PRELIMINARIES AND BACKGROUNDS

In this section, we will characterize the preliminaries that are required in this research that are necessary for successful achievement of this research.

A. Adversary Model

The network is initiated in an environment with antagonistic activities, where opponents are present. We assume that the attackers can guess the username and password to gain unauthorized access to the system. Additionally, some attackers can also be used to discover applications and scripts as brute force tools to bypass authentication processes [8]. The adversary can access the web application by searching for the corresponding session ID. This gives the adversary the opportunity to control resources, steal information and infect websites with malware, resulting in disruption of available services.

B. Cryptography

Cryptography is a method to secure information and communication by ensuring integrity and confidentiality using codes in the presence of adversarial behavior. The privacy of individuals and organizations is guaranteed by a high level of cryptography to be sure the information that has been transmitted is accessible by authorized users only [17][18]. Therefore, the most common use of cryptography would be using it to transmit data through an insecure channel.

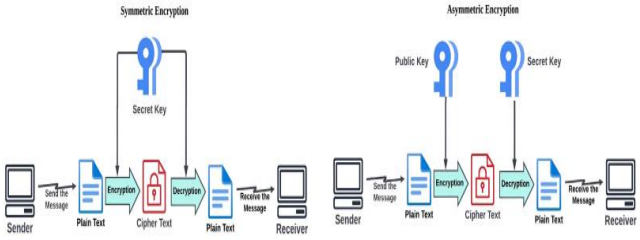

Fig. 3. Symmetric and asymmetric encryption [17].

Fig. 3 shows the cryptographic methods that can be categorized into two types: symmetric and asymmetric key cryptography. Symmetric key cryptography is a technique that uses the identical key for both the encryption and decryption process, such as Caesar cipher and XOR encryption techniques. While Asymmetric cryptography is employed a couple of different keys, one for encryption process and another for decryption process but mathematically related to each other [17][19].

C. Caesar Cipher

Caesar's encryption algorithm is one of the early and famous cryptographic algorithms realized, which uses 25 letters of the alphabet for encryption. In this type of algorithm, the given text is replaced by a letter with a fixed number of positions. In other words, it works by taking a message (plaintext) and substituting each letter in plaintext with another letter in the alphabet (cipher text). Consider Fig. 4 below, if we assume that the position shift value is 3, thus A will be replaced by the letter D and B will be replaced by the letter E and so on [5][20].

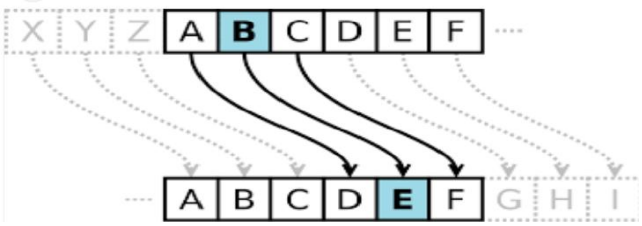

Fig. 4. Symmetric and asymmetric encryption [5].

Therefore, to be able to process with cipher a specific text, you need a shift value that indicates how many positions each letter in the text has been shifted or moved. The shift can be any number, a shift of 0 will not be considered as a shift at all, because all the alphabetic letters will remain in their position. If the alphabet of the plaintext is 26, then a shift of 26 also will not be considered as a shift at all since the cipher text would be the same as the plaintext. The first step is to convert the alphabet to numeric alphabets, where A is zero, B is one, and finally 25 is equal to Z [21]. Caesar's encryption mathematically expressed as illustrated in Eq. (1).

$$\text{Ciphertext} = (\text{Plaintext} + \text{Key}) \bmod 26 \quad (1)$$

While Eq. (2), expressed the mathematical form the decryption process of the cipher text using Caesar cipher encryption as follows:

$$\text{Plaintext} = (\text{Ciphertext} - \text{Key}) \bmod 26 \quad (2)$$

Where the (key) indicates the shift value that has been applied during the encryption and decryption process.

However, with the use of several decryption methods, Caesar cipher became vulnerable to easily cracked in a second, even in a scenario where only cipher text is used. To decrypt ciphered text using Caesar cipher, you need to move it backward by a certain number of positions depending on the key used to encrypt it [12]. However, there are only 25 possible shifts, so one way to break the code is by brute force until a solution is found [5] [10]. Namely, one can simply try all possible shifts.

D. Brute Force Attack

Brute force password attack is the most common network attack that relies heavily on raw computing power rather than the intelligence of the attacker. In a brute force attack, the attacker exploits the vulnerabilities of the credentials of a victim and checks all possible passwords and phrases with the hope of guessing and discovering them correctly [22][23]. Brute force attacks can be categorized into various types, credential stuffing and reverse brute force attacks. Generally, Brute-force attacks are considered more effective when weak or relatively predictable passwords are used. Brute force attack is considered as a type of cyberattack that use trial and error method because of a large record of usernames and passwords to gain unauthorized access to the available resource [22][24] as shown in Fig. 5.

Fig. 5. Brute-force attack [24].

This type of attack needs to check whether the credentials are authenticated and depending on the response of the application or whether the credentials were right or wrong. If not, the attackers will try another credential combination until they get unauthorized access to the system [25][26] to achieve their goals. A successful brute force attack can lead to several impacts on the resources and systems such as data breaches, leaking hidden files or interfaces and disrupting the service if it service is attacked to the point of causing a denial of service (DoS) [25].

E. Description of Binary Shifting

The methodology of this research relied on binary shifting (moving bits one position), because binary shifting technique can be used to enhance the Caesar cipher. Binary shifting technique related to the case of taking any binary number to the left or the right, according to the systematic method which will prevent its real contents from appearing to attackers as shown in Fig. 6 [27][28].

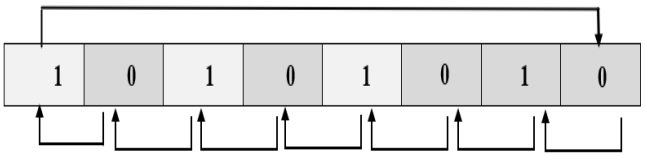

Fig. 6. Binary shifting algorithm.

The binary shifting can be used on a selected set of variables, where binary number (bits) shifting conceals the identity of sensitive binary code, thus preventing direct inference attacks. The binary shifting technique mathematically represented as indicated in Eq. (3) below.

v_i : is the bit value (0 or 1) in the i^{th} place

The function $f(i) = v_i$, $i = 1,2,\cdots,8$ gives one byte filled as shown below:

1	2	3	4	5	6	7	8
$f(1) = v_1$	$f(2) = v_2$	$f(3) = v_3$	$f(4) = v_4$	$f(5) = v_5$	$f(6) = v_6$	$f(7) = v_7$	$f(8) = v_8$

Now define the shifting function $g(i)$ as

$$g(i) = \begin{cases} f(1) \ , & i = 8 \\ f(i+1) \ , & i = 1,2,,\cdots,7 \end{cases} \quad (3)$$

The function $g(i)$ gives a new byte filled as shown below:

1	2	3	4	5	6	7	8
$g(1) =$	$g(2) =$	$g(3) =$	$g(4) =$	$g(5) =$	$g(6) =$	$g(7) =$	$g(8) =$
$f(2) = v_2$	$f(3) = v_3$	$f(4) = v_4$	$f(5) = v_5$	$f(6) = v_6$	$f(7) = v_7$	$f(8) = v_8$	$f(1) = v_1$

IV. PROPOSED APPROACH

The proposed algorithm is based on modifying the Caesar cipher algorithm and using a binary shifting technique between all available binary numbers (bits) after converting the unencrypted text to binary numbers. A successfully binary shifting (moving one position) technique has been employed to avert the decryption of the message, discontinue guessing credentials correctly through brute force attack and finally increase the complexity of the MCBC proposed algorithm against the adversary. Furthermore, the proposed algorithm will be able to resolve the security drawback in Caesar cipher algorithm and it would be difficult to perform brute force cryptanalysis. The proposed algorithm steps are as follow:

Step 1: Employ a binary numbering system technique to convert the message into a certain number of even bits.

Step 2: After that, use binary shifting technique to change the position of the available bits between one another in the converted message.

Step 3: Then, convert the shifted binary numbers to hexadecimal numbers to be processed to the Caesar cipher algorithm, so that it is not clear to the adversary.

Step 4: Finally, employ Caesar algorithm with certain shift key to encrypt the message and prevent trial and error methods to crack passwords and login credentials.

A. Assumptions:

In this section, some assumptions about the network and the capabilities of the adversaries in the proposed design are presented as follows.

Assumption1: An even number of bits should be resulted after converting message into binary code.

Assumption 2: The adversary can launch many kinds of brute force attacks.

Assumption 3: The algorithm proposed that the targeted password or key is susceptible enough to be unveiled through a trial-and-error approach.

Assumption 4: The adversary may exploit vulnerabilities present in the authentication process of the system being targeted.

B. Modified Encryption Technique

One of the simplest encryption techniques that are used to protect information and communication systems over insecure channels is the processes of encryption information using Caesar cipher. Generally, Caesar cipher is increasingly susceptible to various types of attack and security threats, where adversaries are capable of decrypting an encrypted message in a short period of time and guessing login credentials through brute-force attack. Therefore, a modified Caesar cipher technique has been employed to overcome the vulnerability of Caesar cipher and threats against brute force attack.

When a source is willing to transmit encrypted message. The proposed algorithm (MCBC) will convert the plaintext into binary numbering system (bits) using decimal code of character from ASCII table, for instance a letter of ***(and)*** will be converted into binary code as shown in Fig. 7, where the even number of bits is involved.

0	1	1	0	0	0	0	1	0	1	1	0	1	1	1	0
0	1	1	0	0	1	0	0								

Fig. 7. Converting letter to binary (3 byte).

Then, the use of binary shifting technique falls in the idealist place, which is the backbone of proposed algorithm. The binary shifting required to move between all available binary code (bits) one position to the left or the right in every separated single byte. The shifting process starts by changing the position of the first bit to be in the next position and so on, the last bit will be in the first position in each byte, as illustrated below in (Algorithm 1).

Algorithm 1: Binary Shifting Technique

Input: $i_1, i_2, \ldots\ldots, i_8$
Output: Every single bit will be shifted to one position
Start
Input: arr[]
Begin
Set Length of Binary values
Length [arr] = 8
Create a new empty array newArr[] of size 8
newArr[7] = arr[0]
For (***i***=6; ***i*** >= 0; i--)
newArr[i] = arr[i+1]
output: newArr[]
End
Continue till End of binary number in each Byte
Display Output Shifted Values …….
End
End of Pseudocode

After binary shifting processes for every single byte, the result will appear as in Fig. 8.

1	1	0	0	0	0	1	0	1	1	0	1	1	1	0	0
1	1	0	0	1	0	0	0								

Fig. 8. Shifted binary system (3 byte).

The number of binary codes will always be even. Therefore, every bit was replaced by the position of other bit in the binary system. After that, it becomes important to convert the available shifted binary code into hexadecimal number as shown in (Algorithm 2) to result with (c2dcc8).

Algorithm 2: Convert binary to hexadecimal

Input: Enter Binary code (Figure 7)
Output: hexadecimal number to be processed with Caesar Cipher Algorithm
Start
While Length (Binarycode_N) MOD 8≠ 0 **Do**
Binarycode_N ← "0" + binarycode_N.
End while
Loop {
Binarycode_8 bit ← Substring (Binarycode_N)
Loop {
Binarycode_4bit ← Substring (Binarycode_8 bit)
HexChar_4bit ← BinaryToHexMAP (Binarycode_4 bit)
HexChar_8bit ← HexChar_8bit + HexChar_4bit
End Loop
Hexadecimal_N ← Hexadecimal_N + HexChar_8bit
End Loop
Combine the Hexadecimal result of all groups to get the complete output
End of Pseudocode

Subsequently, the operation processed into Caesar cipher algorithm, where each converted letter/number in the plaintext is replaced by a letter with some fixed number of positions in the alphabet.

C. Input Caesar Cipher Algorithm

To illustrate this last phase of the proposed algorithm, it's important to identify the converted hexadecimal code resulted from (Algorithm 2). Firstly, when starting using Caesar cipher to encrypt data, it's important to determine the shift key and start replacing (shifting) each letter of the message in the "plaintext" line and write down the corresponding letter in the "cipher text" line. This process can be achieved through mathematical expressions of the encryption process that has been used as in Eq. (1), and Eq. (2) for the decryption process to retrieve the message back to its original form.

Secondly, it's important to make a table where the top row contains original hexadecimal code resulted from (Algorithm 2), and the bottom row is for the new shifted alphabet according to the selected shift key.

Third, an encoded message will be obtained with the equivalent shifted letter, here assume shift key is (2) for 6 groups of 4 bits each, as shown in Fig. 9.

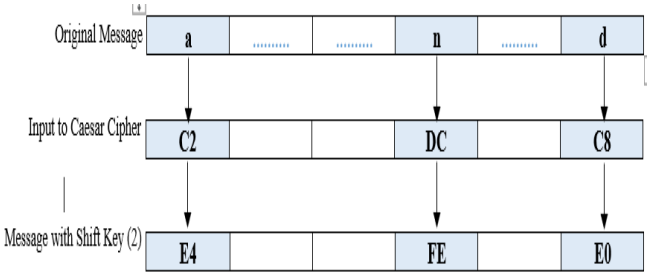

Fig. 9. Encrypted text using MCBC algorithm.

Finally, to decrypt a message encoded with a Caesar cipher, the recipient should know the number of binary codes used in (Algorithm 1), shifted binary technique and the hexadecimal number with shift key, then processes with the encoded message to return it back to its original form. To evaluate the results using both algorithm Caesar cipher and MCBC proposed algorithm with the same input text (and) and to demonstrate the effectiveness of the proposed algorithm over original Caesar cipher. Fig. 10 shows the encryption operations of both algorithms using same shift key value (2).

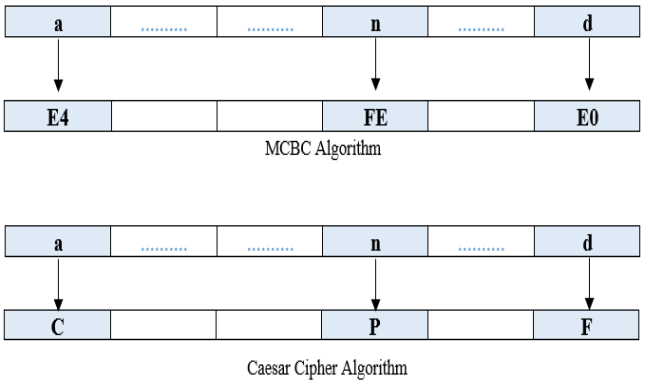

Fig. 10. MCBC and Caesar cipher results.

Based on the available results, the encrypted message using the MCBC proposed algorithm will be unreadable and un-understandable by malicious entities and brute-force attack while excessively forceful attempts to gain access to user accounts. Therefore, the MCBC algorithm has proven its efficiency over Caesar cipher and brute force cryptanalysis will not be easily performed.

V. Security Analysis of the Proposed Algorithm

Adversaries are more likely to camouflage malicious and aggressive behavior as if it were normal by evade detection, where attackers can temporarily stop submitting data or guessing credentials once a detection event is observed. The attack can also be executed when the attacker realizes that the network is using a Caesar cipher as a form of protection. Therefore, MCBC will overcome the security weakness that allows the attacker to submit and guess many passwords of the victim through converting text to binary codes as shown in first phase. In the second phase, binary shifting techniques have been used to prevent the malicious actor discovering and understand the mechanism that was employed. And being unable to understand the transmitted original message through the process of converting binary shifted code to hexadecimal. In this section, we analyzed the security of MCBC algorithm under presented attack.

VI. Result Comparison and Evaluation

To have a comprehensive evaluation of the proposed algorithm against brute-force attack effect, the performance of MCBC algorithm has been simulated using MATLAB R2015a environment. The performance parameters required to evaluate and measure the proposed algorithms are detection rate, true positive rate, accuracy, strength rate, time required for decryption. To evaluate the efficiency of the MCBC algorithm, we compare its performance with the well-known detection algorithm in the event of a brute-force attack.

A. Detection Rate

Detection rate is the ratio of the number of detected malicious activities to the total number of actual malicious activities, as shown in Eq. (4).

$$DR = \frac{TPR}{TPR+FNR} \times 100 \quad (4)$$

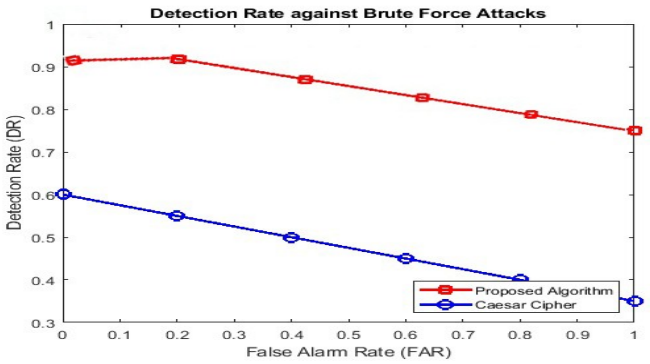

Fig. 11. Relation between detection rate and false alarm rate.

Data in Fig. 11 shows the evaluation of MCBC algorithm that has been performed and represents the trade-off between attack detection rate and false alarm rate. The MCBC provides the maximum detection rate (0.92) compared with the Caesar Cipher and decreases slightly while increasing FAR. This decrease is due to the false positives and increase in delays while processing the encryption and decryption process. On the other hand, traditional Caesar cipher provides DR (0.6) when the false alarm rate is approximately null and decreases to reach (0.3) while increasing FAR. Therefore, it demonstrates the ability of the proposed algorithm has a promising and optimistic detection rate compared with Caesar cipher.

B. Strength Rate

The strength rate of the algorithm can be measured by the amount of time required and computational effort needed to break the encryption algorithm over. This plot illustrates the strength of these algorithms against time, providing a visual representation of their security efficacy over extended periods.

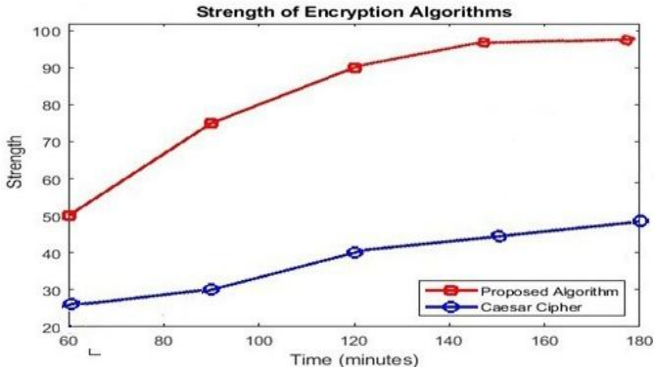

Fig. 12. Strength rate comparison.

Data in Fig. 12 shows the performance analysis and evaluation rate of the MCBC against Caesar algorithm. The encryption strength of the Caesar Cipher increases over time to reach approximately (48%) maximum strength rate, while in MCBC it rises in strength rate to reach approximately (95%). The reason behind that, the MCBC provides binary code conversions, hexadecimal number and binary shifting technique which will strengthen the proposed encryption algorithm, whereas the Caesar cipher is based on substitution method that leads to have lower strength encryption algorithm, which reduces the strength against brute-force attacks. Therefore, the

performance analysis and evaluation rate of the proposed algorithm outperformed the Caesar Cipher algorithm.

C. True Positive Rate (TPR)

TPR is the rate at which true attacks are identified correctly and measure of encryption algorithms to identify the brute-force threats, as shown in Eq. (5).

$$TPR = \frac{TP}{TP+FN} \quad (5)$$

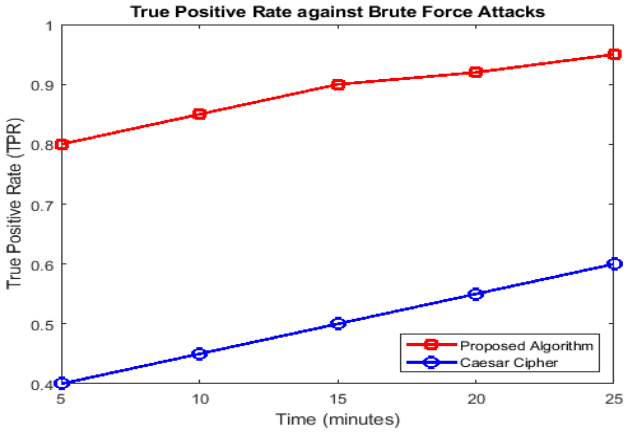

Fig. 13. True Positive Rate.

Data in Fig. 13 shows the comparative analysis between MCBC and the Caesar Cipher presented through a graph plotting their TPR against time. The MCBC shows a gradual increase over time to reach approximately (0.93). This indicates that the algorithm's detection mechanisms allow it to maintain a high level of sensitivity in identifying brute force attacks. Whereas the Caesar Cipher's shows a low TPR compared with MCBC algorithm to reach maximum (0.57) which considers as lack of detection mechanisms, due to the substitution method used by the Caesar cipher, which creates predictable encryption patterns that can be easily exploited by attackers.

D. Time Required for Decryption

The time required to decrypt encrypted data using brute force attacks is a fundamental measure of an encryption algorithm strength and resilience that mainly based on computational complexities.

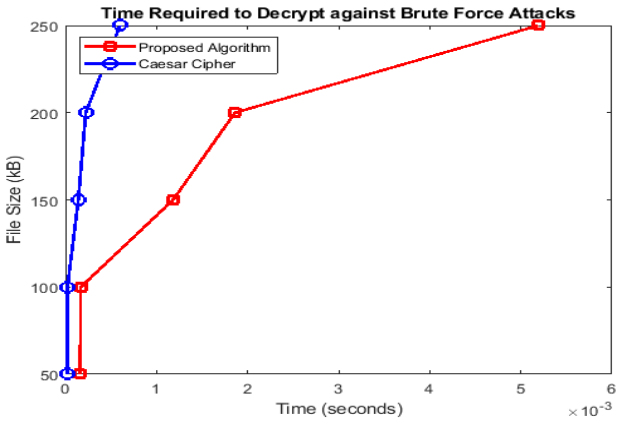

Fig. 14. Decryption time against Brute-force attack.

Data in Fig. 14 shows the time required to decrypt encrypted data against file size using brute force attacks. The decryption time of the MCBC shows a steep increase as file size grows, making brute force attacks impractical. The reason behind that is that, the binary code, hexadecimal number and binary shifting techniques increase the complexity of the algorithm. Conversely, the Caesar Cipher's relatively flat line decryption time curve, indicating minimal increases in decryption time as file size grows. This focuses on the cipher's inherent weaknesses and its vulnerability to rapid brute force attacks. Finally, the proposed algorithm reflects the effectiveness in resisting such attacks.

VII. Summary

In this part, it is important to present the functionality and performance of MCBC in the analyzed environment. In the study, the MCBC algorithm will be compared with Caesar cipher algorithm when exposed to attack instances. The experimental outcomes can be concluded as follows:

- The MCBC algorithm provides a higher strength rate which is approximately 95% compared with Caesar cipher algorithms that have lower strength that reach 48%.
- The MCBC maximizes decryption time, making brute force attacks impractical due to the computational complexities.
- The proposed algorithm provides optimal value of TPR approximately 0.93 in comparison with Caesar cipher algorithms. Thus, it has a high level of sensitivity in identifying brute force attacks and the ability to detect the real attackers.

VIII. Conclusion and Future Work

This research examined the adversary effect of brute-force attack which considered as serious threats to cybersecurity and obstacles to ensuring credential protection. Modified Caesar Cipher Algorithm Based on Binary Codes (MCBC) has been employed based on on two various scenarios, firstly, binary codes will convert the message into binary codes (bits) and second scenario uses binary shifting mechanisem to change the position of the available bits among each other in the message to bolster encryption against brute force attacks. MCBC is considered as suitable for the evaluation of brute-force attack and provide accurate detection and high strength rate that reduce bruken of the proposed algorithm. However, the proposed MCBC algorithm generally outperformed the Caesar cipher algorithms. It is of the utmost that in the future, we will focus on using other approaches that provide greater flixability and more accurate detection performance in networks that are based on different features.

The Power of Digitalization: How Information Disclosure Shapes Company Value

Lina Nur Hidayati, Muniya Alteza, Mahendra Ryansa Gallen Gagah Pratama
Management, Universitas Negeri Yogyakarta, Yogyakarta, Indonesia

***Abstract*—This study aims to explore how business digitalization influences firm value within the Indonesia Stock Exchange (IDX). It seeks to offer a thorough examination of the effects of digital transformation on corporate valuation. The findings highlight a strong positive correlation between digitalization and firm valuation, supporting signaling theory, which asserts that a company's transparency in disclosing its digital transformation efforts serves as a strategic indicator for investors and consumers. Greater transparency and specificity in disclosing digitalization information improve perceptions of corporate stability and future growth prospects, ultimately increasing firm value. As Indonesia undergoes rapid digital transformation, this research gains heightened relevance by offering critical insights into how companies that proactively communicate their digitalization strategies can strengthen their market positioning and secure a competitive edge in the financial landscape. This study makes a significant contribution by providing empirical evidence on the role of business digitalization in shaping firm value, particularly in an emerging market context where digital adoption is accelerating. This investigation highlights the strategic importance of digitalization disclosure in the Indonesian market, offering novel insights into how transparency in digital initiatives can serve as a competitive advantage.**

Keywords*—*Information; digitalization; business; firm value

I. INTRODUCTION

Company value reflects how investors perceive a company's achievements and future growth potential. A rise in company value strengthens market trust, indicating confidence not only in the firm's present performance but also in its long-term outlook [1]. Therefore, company value is a crucial factor that investors consider when selecting investment companies. By choosing high-value companies, investors are expected to achieve greater financial well-being. Company with a high value using Tobin's Q ratio tend to attract more investment because investors see it as an indication that the company has better growth potential compared to others [2]. Some investors are more likely to invest in companies with high value due to a perception of lower risk [3]. However, accurately estimating company value remains a challenge for investors due to the numerous factors that influence it. These determinants can be categorized into controllable (internal) factors, which a company can manage, and uncontrollable (external) factors, which are beyond the company's control. Consequently, companies focus more on internal aspects, as they are relatively easier to manage and optimize to enhance company value.

One such internal factor is business digitalization, which is part of intangible assets. Research has shown that intangible assets play a significant role in creating a competitive advantage, ultimately contributing to increased company value. Innovation, technology, and digitalization stand out as some of the most impactful elements within the broader spectrum of intangible assets [4]. Empirical research emphasizes the beneficial effects of investments in R&D and information and communication technology (ICT) on a company's overall [5], [6]. Similarly, [7] provide evidence that digitalization positively influences company performance.

As digitalization continues to gain significance, investors are increasingly considering information about digital processes when making investment decisions. Despite its growing importance, this information is often absent from financial disclosures due to the challenges in measuring it in monetary terms [8]. Similarly, non-financial disclosures do not always provide a comprehensive representation of a company's digitalization level. Integrated reporting offers only limited insights into digitalization, primarily emphasizing intellectual capital [9]. Both non-financial disclosures and integrated reporting generally categorize digitalization as a component of structural capital rather than recognizing it as a key independent factor.

Numerous prior studies have examined how digitalization contributes to improved financial performance. One key aspect is its ability to enhance products, services, and operational workflows, enabling more effective commercialization. Additionally, digitalization broadens communication channels through platforms like websites and social media, expands sales strategies via e-commerce, and reshapes business models to unlock new growth opportunities. This, in turn, strengthens relationships with stakeholders and optimizes company processes, ultimately boosting financial performance [7], [10], [11]. Second, digitalization enhances access to international markets, providing new business opportunities while reducing costs associated with acquiring new customers, partners, and suppliers worldwide [12], [13]. This process contributes to revenue growth and cost reduction, thereby improving financial performance [10]. Third, increased efficiency and productivity arise from automation, improved production unit control, and optimized human resource management through digital tools, leading to cost reductions and enhanced financial performance [8]. Finally, digitalization lowers communication, administrative, and commercial costs, while expanding financial accessibility, further driving performance improvements [10].

The adoption of digitalization is widespread across Asian countries. According to the "DBS Digital Treasurer 2020" survey, Indonesia ranks third in Southeast Asia for digitalization usage. Regarding digital readiness, approximately 26% of

Indonesian companies have a clear digitalization strategy, compared to 45% in Singapore and 32% in Thailand. Indonesia holds the seventh position in digital readiness within the Asia-Pacific (APAC) region, trailing behind Singapore (45%), Hong Kong (44%), Japan (41%), Taiwan (39%), South Korea (39%), and Thailand (32%).

Information disclosure policies play a crucial role in enhancing transparency for investors and stakeholders [14]. According to signaling Theory [15], companies use information as signals to attract investors and demonstrate their competitive advantage. Companies with strong performance are motivated to share more information, both explicitly and implicitly, to strengthen their market standing and attract investment. The assumption underlying signaling theory is that investors assess a company's value based on management's ability to anticipate and respond to external market changes [16].

Previous research conducted by study [17] explored how business digitalization information disclosure affects company value through websites. In contrast, this study examines the impact of business digitalization information disclosure on company value by analyzing corporate disclosures through both websites and social media. The previous study only disclosed information through websites, but this study also incorporates the identification of twelve additional items related to various aspects of company digitalization, assessed through the company's official social media accounts. The findings of this study are expected to assist companies in formulating policies regarding the types of digitalization-related information that should be disclosed and how such disclosures through different publication channels can influence investor confidence in the company.

The remaining of this article is structured as follows. Section II provides an overview of the relevant literature review and theoretical background, while Section III outlines the research methodology. Section IV presents the results and discussion. Finally, Section V draws conclusions.

II. Literature Review

A. Signaling Theory

Signaling theory addresses the challenges of asymmetric information in markets. This theory argues when there is an imbalance of information between two parties' individuals with higher qualifications or abilities can signal their value to other through observable indicators. In the context of corporate finance, signaling theory suggests that companies can use various signals to convey their quality to investors [18].

Signaling theory describes how companies convey information to financial statement users. It helps explain behaviors arising from differences in information access between two parties, whether individuals or organizations. Typically, the sender determines whether and how to communicate specific information, while the receiver evaluates and interprets the signal. Given its relevance, signaling theory plays a significant role in various management fields, including strategic management, entrepreneurship, and human resource management [16].

B. Asymmetry Information

The research in [19] stated that Information asymmetry refers to a situation where one party in a relationship possesses greater or more accurate information than the other. This concept is extensively recognized in management research and serves as a fundamental premise in prominent organizational theories. Information plays a crucial role in shaping decision-making processes across households, businesses, and government entities. People rely on two types of information when making decisions: public information, which is openly accessible to everyone, and private information, which is restricted to a specific group within the public. The study in [15] explains that information asymmetry occurs when "different people know different things." Since some information is private, information asymmetry arises between those who possess that information and those who could potentially make better decisions if they had access to it.

Extensive research has been conducted on the influence of information on company value. With advancements in technology, information channels have expanded and evolved, leading to significant transformations in the way information is disseminated. Digitalization represents one of these key developments, revolutionizing the process of information delivery. Several studies have explored the role of digitalization in enhancing information flow. As highlighted by Rasouli et al., (2019), manufacturing companies benefit from adopting a service-oriented approach by developing mass-customized integrated solutions, where digitalization plays a vital role in supporting these business models [20]. However, companies can still transition from a product-based model to a service-driven strategy without heavily relying on digital elements in their offerings [21].

Despite the opportunities digitalization provides, it has not yet become an integral part of many small and medium-sized enterprises (SMEs). The study in [22] found that few Finnish SMEs have adopted digitalized production processes or implemented new product introduction models. However, even in such cases, digitalization has demonstrated a positive impact on company performance, particularly in business development. The research in [23] further highlights the role of digitalization in market orientation (MO) by transforming how market intelligence is generated, disseminated, and responded to. With digitalization, market intelligence is produced faster, more efficiently, and at a lower cost.

Previous studies have thoroughly investigated the influence of various types of information disclosure on company value. Research conducted by studies [24], [25], [26] indicates that voluntary corporate information disclosure has a positive impact on company value, as evidenced by analyses of company reports. Likewise, the study in [27] affirmed this positive correlation by assessing the information presented on company websites. Further validation came from [28], who examined integrated reports as a crucial source of corporate data.

Moreover, environmental information disclosure has also been found to contribute positively to company value, as demonstrated by studies [29], [30], [31] and [32]. Similarly, corporate social responsibility (CSR) disclosures have been linked to an increase in company value [33]. Additionally, the

study in [15] emphasized the beneficial effects of intellectual capital disclosure on firm value. Building on this, the study [17] discovered that the extent of business digitalization information disclosed through the International Integrated Reporting Council website plays a significant role in enhancing company value.

Likewise, information regarding the level of digitalization is considered valuable, even though it is not captured in financial disclosures due to the difficulty of quantifying it monetarily [34]. Additionally, non-financial disclosures pay relatively limited attention to the digitalization aspects of a company, often categorizing them merely as a subcategory of structural capital within the context of intangible asset information. Furthermore, non-financial information disclosure standards do not require the inclusion of digitalization-related information. This situation makes it difficult for investors to utilize the information, leading to significant information asymmetry. In this context, the dissemination of digitalization-related information can have a major impact on investor perception and contribute to increasing company value. Based on the literature review, the researchers propose a hypothesis as follows:

H1: Information disclosure regarding business digitalization positively influences company value.

III. METHODS

A. Variable Measurement

The criterion variable in this research is firm value, represented by Tobin's Q, while the predictor variable is digitalization-related information. Furthermore, this study integrates several control variables, namely firm size (SIZE), return on assets (ROA) as a measure of profitability, current ratio (CR) as a liquidity indicator, and financial leverage to assess the level of indebtedness. The research population encompasses all firms publicly traded on the Indonesia Stock Exchange (IDX) from 2022 to 2024. The sample selection follows a purposive sampling approach, restricting the inclusion of firms based on predefined criteria.

Within this study, firm value is represented by Tobin's Q, a sophisticated financial metric designed to evaluate a company's valuation by considering the aggregate worth of both tangible and intangible assets. Additionally, Tobin's Q functions as a pivotal benchmark for corporate performance, particularly in assessing firm valuation, as it encapsulates management's proficiency in deploying corporate assets efficiently [35].

Tobin's Q assessment ranges from 0 - 1, where the company's value is considered high if it has a value greater than one (>1) which shows that management is successful in managing the company's assets so that the potential for investment growth is also high. On the other hand, if Tobin's Q value is less than 1 (<1), it indicates that management has failed to manage the company's assets where the potential for investment growth is low. The value of the company is smaller than the value of the company's assets and the investment in assets is not attractive. In the research of [17], Tobin's Q Ratio was formulated as follows:

$$TQ = \frac{MVE + Debt}{TA}$$

The independent variable in this study is information on business digitalization (ID), which is disclosed directly or indirectly by companies through their websites and social media platforms. Digitalization is a multifaceted concept that cannot be captured by a single indicator, as it represents an ongoing transformation where companies leverage digital technologies to generate revenue, enhance business operations, modify or replace traditional business processes, and establish a digital-centric environment [36]. In this study, ID was assessed using manual content analysis, examining company websites and social media for relevant digitalization disclosures. According to [37], content analysis serves as an effective method for evaluating a company's website and the dissemination of corporate information, given its systematic approach to analyze textual and visual content.

Based on study [17], twenty-three items related to various aspects of company digitalization were identified. These twenty-three items were analyzed by categorizing the data into five macro-categories, which are as follows: (1) digital communication instruments, (2) e-commerce, (3) data management, (4) information on digitalization and related activities, and (5) investment in digitalization and related activities. The different macro categories and specific items are detailed in Table I. Each item is treated as a binary measure, assigned a value of 1 if it is present on the company's website and 0 if it is not. All items carry equal weight in the final score calculation. Based on the results, the overall score ranges from zero to twenty-three.

Furthermore, this study also incorporates the identification of twelve (12) additional items related to various aspects of company digitalization, assessed through the company's official social media accounts (Facebook and Instagram). These twelve items are classified into three macro categories, as follows: (1) digital communication instruments, (2) e-commerce, and (3) information on digitalization and related activities. The different macro categories and specific items are also described in Table I. Each item is similarly treated as a binary measure, assigned a value of 1 if it is present on the company's official social media platforms (Facebook/Instagram) and 0 if it is not. All items carry equal weight in the final score calculation. Based on the results, the overall score ranges from zero to twelve.

B. Data Analysis

The data analysis method employed in this study is multiple linear regression analysis**,** which examines the relationship between the level of digitalization information and company value**.** A cross-sectional analysis was used, as the study focuses solely on data from 2023 and does not account for business digitalization information from other periods. The proposed model in this study is as follows:

$$TQ = \alpha + \beta_1 ID + \beta_2 SIZE + \beta_3 ROA + \beta_4 LIK + \beta_5 LEV + \epsilon_{it}$$

TQ : Tobin's Q
ID : Digitalization Information i in Year t
SIZE : Company size i in year t
ROA : Company profitability in year t
LIK : Company liquidity in year t
LEV : The level of corporate debt in year t
ϵ_{it} : *error term*

TABLE I. LEVEL OF DIGITALIZATION INFORMATION

Category	Item	
	Website	***Social media***
Digital communication instruments	1. E-mail 2. Access to restricted areas 3. Web application 4. *Document sharing* and cloud applications 5. Positioning on search engines 6. *Mobile version* of the website	1. E-mail 2. Social Media Accounts 3. Positioning on search engines
E-commerce	7. Online *product catalogue* 8. Online shopping 9. Online payments	4. Online *product catalogue* 5. Online shopping 6. Online payments

IV. RESULT AND DISCUSSION

A. Samples

The total population comprises 729 companies that were either previously or are currently listed on the Indonesia Stock Exchange (IDX) in 2023. Based on the established purposive sampling criteria, data were collected from 589 companies.

TABLE II. SAMPLE DISTRIBUTION BY INDUSTRY SECTORS

No	Sector	Number	Percentage
1	Energy	55	9,34
2	Raw materials	72	12,22
3	Industry	34	5,77
4	Primary consumer goods	91	15,45
5	Non-primary consumer goods	77	13,07
6	Health	19	3,23
7	Finance	99	16,81
8	Property and Real Estate	57	9,68
9	Technology	16	2,72
10	Infrastructure	46	7,81
11	Transport and logistics	23	3,90
12	Investment products recorded	0	0
	Total Amount	589	100

The distribution of samples based on the classification of industrial sectors on the Indonesia Stock Exchange (IDX) is presented in Table II. Among the 589 companies classified into 12 industrial sectors, the financial sector had the highest representation, with 99 companies (16.81%). The primary consumer goods sector followed, comprising 91 companies (15.45%), while the non-primary consumer goods sector accounted for 77 companies (13.07%), and the raw materials sector included 72 companies (12.22%). Additionally, the data confirms that there are no companies listed in the investment product sector. The sector with the fewest companies was the technology sector, with only 16 companies (2.72%). Table III provides a summary of descriptive statistics, including the mean, median, maximum value, minimum value, and standard deviation.

TABLE III. DESCRIPTIVE STATISTICS OF THE ENTIRE SAMPLE

	Tobin's Q	ID	Size	ROA	Leverage	Current Ratio
Mean	2,211939	18,09847	28,51201	0,017303	0,613315	4,932209
Median	1,116190	18,00000	28,46679	0,007985	0,491759	1,470415
Max	136,2433	34,00000	34,95208	8,332658	36,69574	340,1692
Min	0,124526	6,000000	22,62331	-2,485245	0,000160	0,000270
Std. Dev.	7,713862	6,462646	1,980518	0,516019	1,611423	22,75380

B. Regression Test Results

Table IV depicts the regression test results examining the impact of business digitalization information level on company value, using the Robust Least Squares method with MM estimation. As shown in Table VI, three regression models are analyzed Model (1) represents a regression equation that evaluates the relationship between business digitalization information level and company value, incorporating control variables. This model includes all digitalization information items, covering both website disclosures (23 items) and social media disclosures (12 items). Meanwhile, Models (2) and (3) assess the same relationship but distinguish between different types of listed companies. Model (2) focuses on companies

listed on the main board, while Model (3) includes companies listed on the development board and acceleration board. The number of observations used in each model varies, with 589 companies in Model (1), 294 companies in Model (2), and 295 companies in Model (3).

TABLE IV. REGRESSION TEST RESULT WITH MM MODEL

The results in Table IV indicate that the business digitalization information level variable in Model (1) has a positive coefficient of 0.007895 with a z-statistic of 2.341467, which is statistically significant at the 5% alpha level. In Model (2), where the sample consists of companies listed on the Main Board, the variable also shows a positive coefficient of 0.010215 with a z-statistic of 2.686855 and is statistically significant at the 1% alpha level. However, in Model (3), which includes companies listed on the Development Board and Acceleration Board, the results indicate that the business digitalization information level variable has no significant effect on company value. Based on these findings, it can be concluded that the hypothesis stating that business digitalization information influences company value is accepted in this study. These findings align with the research of study [17], which also supports the positive impact of business digitalization information on company value.

After conducting multiple tests, a robustness test was performed to evaluate the accuracy and reliability of the results obtained from the main regression analysis, specifically the MM model regression test. The findings from the robustness test of the M model, as presented in Table V, indicate results consistent with those of the MM model, demonstrating minimal variation. Regarding the independent variable, digitalization information (web_sosmed), the results remain unchanged, showing a significant positive effect on company value with a 1% confidence level in both the MM and M models. Similar consistency is observed in the control variables, where Size, ROA, and Leverage all maintain a 1% significance level across both models. However, the Current Ratio was found to be insignificant in both tests.

C. Discussion

This study demonstrates that digitalization information has a positive influence on company value, both directly and indirectly. First, disclosing information about a company's level of digitalization serves as an important signal to investors and consumers. Information shared through company websites and social media platforms enhances consumer accessibility to details about products or services offered. Moreover, when consumers place orders online, and the company effectively meets their expectations while providing prompt responses, customer satisfaction improves. This, in turn, strengthens consumer trust, leading to higher cash flow, increased sales, and greater profitability, ultimately enhancing company value.

Second, digitalization also contributes to revenue growth through e-commerce adoption and cost reduction by optimizing resources, implementing innovative business models, and enhancing automation services. Digitalization enables companies to adapt more effectively to an increasingly competitive business environment, providing a strategic edge over competitors. Furthermore, digitalization mitigates information asymmetry, allowing investors to gain deeper insights into a company's digital strategy, thereby reducing investment risks. The level of a company's digitalization efforts can influence future cash flow generation, ultimately leading to an increase in company value.

This study supports signaling theory, which explains how information related to a company's level of digitalization serves as a signal to investors, aiming to enhance profitability and

reduce costs, ultimately increasing company value [17]. In addition, this research is also supported by the Resource-Based View (RBV) Theory, which emphasizes that a company's competitive advantage depends on unique and difficult-to-imitate resources [17]. Digitalization can be considered a strategic resource that enhances efficiency, fosters innovation, and improves customer experience, thereby strengthening the company's competitiveness and long-term value.

The findings of this study are also supported by study [38] and [39], who asserted that digital transformation has a significant impact on enhancing company performance. Cost reduction, revenue growth, efficiency improvement, and innovation stimulation are key indicators of digital transformation that enable high-quality corporate development and drive corporate innovation. Similarly, [40] argued that digital transformation has a driving effect on the financial performance of renewable energy companies. When a renewable energy company adopts digital transformation, it demonstrates better green technology innovation, which ultimately improves its financial performance.

The findings of this study also have managerial implications for corporate decision-makers. Managers are expected to leverage company websites and social media platforms to disclose digitalization-related information, including strategies, processes, and outcomes, as a means of enhancing company value. These platforms should provide comprehensive and accessible information that is valuable to both investors and consumers, ensuring ease of access to details regarding products and services.

Additionally, managers must focus on developing well-structured and efficient web and social media applications to optimize operational efficiency, minimize service delays, and enable immediate responses to consumers. Furthermore, managers should pay particular attention to key aspects of digitalization, including privacy policies, consumer data protection, search engine positioning, and the development of mobile-friendly versions of company platforms, as these are increasingly accessed by consumers.

V. CONCLUSION

The findings of this study confirm that digitalization information positively influences company value. The disclosure of digitalization-related information serves as an essential signal that companies send to investors and consumers. The more extensively a company discloses information about its business digitalization efforts, the stronger its market position and growth prospects, ultimately leading to an increase in company value.

However, this study has several limitations. First, it is limited to one-year data from companies listed on the Indonesia Stock Exchange (IDX). Future research could expand the scope by incorporating multi-country data, allowing for cross-country comparisons and potentially uncovering different findings. Second, this study only examines digitalization information and company value, without considering other factors that may moderate or mediate this relationship, such as company size or the level of innovation. Third, the measurement of digitalization information disclosure relies on corporate reports, which may contain biases or variations in the level of transparency among companies. Additionally, using a longer time frame could yield more consistent and robust results.

The results of this study imply that managers are expected to be able to use the company's website and social media to reveal information about the company's business digitalization both from the aspects of strategy, process, and results. Furthermore, managers should focus on developing more comprehensive, user-friendly digital platforms that enable transparent and detailed information disclosure. Beyond improving transparency, enhanced digital platforms can optimize efficiency, reduce service delays, and enable faster consumer responses, ultimately contributing to higher company value.

Although this study has provided insights into the relationship between digitalization and company value, several aspects remain to be further explored. Future research could compare the impact of digitalization on company value across different industries, such as manufacturing, financial services, and retail, to determine whether significant differences exist in the implementation and effectiveness of digitalization strategies. Additionally, investigating the role of moderating variables, such as company size, industry competition level, or the adoption of specific technologies, could provide a deeper understanding of how these factors strengthen or weaken the relationship between digitalization and company value. Furthermore, examining the role of mediating variables, such as product innovation or customer satisfaction, may offer valuable insights into how digitalization indirectly contributes to company value by enhancing customer experiences and fostering innovation.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to Universitas Negeri Yogyakarta for providing the research grant that supported this research. We also extend our appreciation to the reviewer, Prof Tony Wijaya for their valuable advice, intellectual contributions, and academic assistance, as well as their support in refining and enhancing this article. His insights and feedback have been instrumental in improving the quality of this research.

A Systematic Literature Review on the Sand Cat Swarm Algorithm: Enhancements, Applications, and Future Directions

Wirawati Dewi Ahmad, Azuraliza Abu Bakar, Mohd Nor Akmal Khalid
Center for Artificial Intelligence Technology-Faculty of Information Science and Technology,
Universiti Kebangsaan Malaysia, Bangi, Selangor 43600, Malaysia

***Abstract*—The Sand Cat Swarm Algorithm (SCSA) has emerged as a promising metaheuristic optimization technique inspired by the behavior of sand cats in their natural habitat. This paper presents a systematic literature review synthesizes the enhancement, performance comparing algorithms, applications of SCSA across various domains and future direction on SCSA enhancement. The study aims to contribute to the evolution, enhancements, applications, and performance of the Sand Cat Swarm Algorithm (SCSA), providing a comprehensive analysis of its development, performances evaluation, application, limitations, and future research opportunities in SCSA in solving optimization problems. The SLR methodology was applied, and a total of 77 scientific articles were analyzed. The analysis reveals that SCSA demonstrates competitive performance across a wide range of benchmark problems and real-world applications in engineering, computer science, and other fields such as engineering design optimization, feature selection, energy systems optimization, flexible job shop scheduling and medical diagnosis problems. This review also identifies several key strengths of SCSA, including its ability to balance exploration and exploitation effectively, its adaptability to various problem domains, and its potential for hybridization with other algorithms. Lastly, this paper outlines potential improvements and future research directions, such as the development of multi-objective SCSA variants, integration with machine learning techniques, and exploration of parallel and distributed implementations. Overall, this paper provides researchers and practitioners with valuable insights into the current state of SCSA, its practical applications, and promising avenues for future research in the field of metaheuristic optimization.**

Keywords*—Sand cat swamp algorithm; sand cat optimization; optimization; metaheuristic

I. Introduction

The field of optimization has seen remarkable growth in recent years, driven by the increasing complexity of real-world problems across various domains. Among the numerous optimization techniques, nature-inspired metaheuristic algorithms have gained significant attention due to their ability to efficiently solve complex, non-linear, and multi-dimensional problems[1], [2], [3], [4]. These algorithms draw inspiration from natural phenomena, biological systems, and animal behaviors to develop robust and adaptable optimization strategies.

The Sand Cat Swamp Algorithm (SCSA) is an emerging heuristic algorithm that has recently joined the pantheon of nature-inspired optimization techniques. Inspired by the unique foraging behavior of the sand cat (Felis margarita), this algorithm simulates the exceptional auditory capabilities of these desert-dwelling felines. Sand cats possess the remarkable ability to detect low frequencies below 2 kHz, allowing them to locate prey buried beneath the sand. The SCSA leverages this natural behavior to create an innovative approach to optimization problems, potentially offering new solutions in various fields of study.

While the SCSA is a relatively new addition to the field of metaheuristic algorithms, several systematic literature reviews have been conducted on related nature-inspired optimization techniques. For instance, the study in [5] provides a comprehensive review of the Grey Wolf Optimizer, another algorithm inspired by animal behavior. Their study examined the algorithm's principles, variants, and applications across different domains, offering valuable insights into the development and potential of such nature-inspired techniques. Similarly, [6], [7], [8] conducted a broad survey of bio-inspired optimization algorithms, including ant colony optimization, particle swarm optimization, and genetic algorithms. Their review highlighted the strengths and limitations of these approaches, as well as their applicability to various problem domains. While these reviews offer a solid foundation for understanding nature-inspired algorithms, there is a notable gap in the literature regarding a comprehensive analysis of the SCSA, its developments, and applications.

The Sand Cat Swarm Algorithm (SCSA) algorithm, inspired by the hunting behavior of sand cats, has emerged as a promising metaheuristic for solving various optimization problems. Since its introduction, SCSA has garnered attention for its simplicity and effectiveness in global optimization. The algorithm mimics the sand cats' use of their acute hearing to locate prey, with each sand cat in the swarm gradually approaching better positions to catch prey [9].

Several studies have proposed enhancements to the original SCSA to address its limitations and improve its performance. For instance, researchers have developed modified versions incorporating strategies such as wandering behavior, lens opposition-based learning, elite decentralization, and crossbar approaches to enhance the algorithm's exploration and exploitation capabilities [10], [11], [12]. These improvements aim to mitigate issues like premature convergence, local optima

entrapment, and slow convergence speed that are common in many metaheuristic algorithms.

The versatility of SCSA has been demonstrated through its application to a wide range of optimization problems. In engineering design, SCSA and its variants have been employed to solve constrained optimization problems, including structural design and parameter identification tasks [13], [14], [15]. The algorithm has also shown promise in addressing complex real-world challenges such as feature selection in medical diagnosis [16], [17] and power system optimization [18].

The rapid emergence of the SCSA and its potential applications in solving complex optimization problems necessitates a thorough and systematic review of the existing literature. As the algorithm continues to evolve and find new applications, it becomes crucial to consolidate the current knowledge, identify research trends, and highlight areas for future investigation. This review aims to provide researchers, practitioners, and decision-makers with a comprehensive understanding of the SCSA, its capabilities, and its potential impact on various fields, including global optimization problems in supply chain networks. The main contribution of this paper is to examine the new variants of SCSA, application SCSA in various domains and research gaps toward future works direction. The objectives behind this analysis are as follows:

- To explore the evolution of this research area, it evolved in terms of the number of publications.
- To identify the new variations and enhancements of the SCSA proposed in the literature.
- To compare the performance of the SCSA with other state-of-the-art metaheuristic algorithms across various benchmark problems.
- To compare the evaluation methods of the SCSA with other state-of-the-art metaheuristic algorithms across various benchmark problems.
- To investigate the applications of the SCSA in different domains such as engineering, computer science, and others.
- To identify the key challenges and future research directions for the SCSA in global optimization problems.

This work is mainly based on a systematic literature review (SLR) on 77 papers to synthesize existing methods and areas of study, highlighting current focuses and future research directions in enhancement of SCSA and application of SCSA in various domains. Specifically, to answer the following research question:

RQ1. How has this research area evolved in terms of the number of publications?

RQ2. What have the new variations and enhancements made to SCSA since its inception?

RQ3. How does the performance of the SCSA compare with other swamp intelligent metaheuristic algorithms in terms of convergence rate, accuracy, robustness, and computational cost?

RQ4. What are the evaluation methods of the SCSA compared with other swamp intelligent metaheuristic and the performance metrics used?

RQ5. In which domains have the SCSA been applied, and what are the outcomes and benefits of these applications?

RQ6. What are the current limitations of the SCSA, and what potential improvements and future research directions can be identified?

This work aims to present critical aspects of SCSA, from its enhancement to practical applications, offering valuable insights for researchers and practitioners. The key contributions of this research are:

- Examination of the evolution of SCSA-related research, offering insights into the algorithm's growing adoption and adaptation in the scientific community.
- Identification and analysis of new variations and enhancements to the SCSA since its inception, highlighting the algorithm's development and refinement over time.
- Comparative performance evaluation of SCSA against other swarm intelligence metaheuristic algorithms, assessing its effectiveness in terms of convergence rate, accuracy, robustness, and computational cost.
- Identification of the evaluation methods of the SCSA compared with other swamp intelligent metaheuristic algorithm.
- Exploration of various domains where SCSA has been applied, showcasing its versatility and the benefits it brings to different fields of study.
- Critical assessment of SCSA's current limitations, coupled with recommendations for potential improvements and future research directions, paving the way for further advancements in this area.

These contributions collectively enhance our understanding of the SCSA, its capabilities, and its potential for future development and application in diverse fields of study.

The remainder of this work is organized as follows: Section II describes the literature review; Section III describes the methodology adopted for the literature review; Section IV explains the results and analysis; and Section V draws the conclusions.

II. Literature Review

A. Swarm Intelligence (SI)

Single-solution based metaheuristics, also known as trajectory methods, emphasize exploitation, while key population-based metaheuristics prioritize exploration [19]. A single-solution approach begins with a single solution and iteratively operates to discover the best optimal single solution. Whereas population-based solutions begin with a collection of solutions rather than just one answer. Swarm intelligence (SI) is an intelligent approach to addressing optimization issues under this class. SI draws inspiration from the collective behavior of

social insect colonies and other animal groups. Some examples are Ant colony Algorithm, Particle Swarm Algorithm, Bacterial foraging Algorithm, Bee Colony Algorithm, Artificial Immune Systems, and Biogeography-Based Algorithm are all examples of population-based algorithm techniques.

Sand Cat Swamp Algorithm (SCSA) was introduced by [9] as a nature-inspired metaheuristic for the solution of hard combinatorial optimization problems also categorized as SI algorithm. SCSA operates as population-based metaheuristic algorithm which can be divided into three main stages namely initialization stage, exploration stage, and exploitation stage. The balance between exploration and exploitation phase is crucial in any SI algorithm to ensure the operation of this algorithm is well performed in various NP-Hard problems.

B. SCSA Initilization

The Sand Cat Swamp Algorithm (SCSA) begins with the initialization phase, which is crucial to produce high quality of initial population. Since SCSA is categorized under population-based method, in this stage, a population of sand cats is generated, each representing a potential solution to the optimization problem. As SI group algorithm, the algorithm initializes the following key parameters to perform the optimization processes:

- Population size: The number of sand cats in the swamp denotes as N size.
- Maximum number of iterations: The number of algorithm running as termination criterion for the algorithm.
- Problem dimension: The number of variables in the optimization problem represents how big the problem is.
- Search space boundaries: The upper and lower limits for each variable represent the boundaries of searching area.

Each sand cat is randomly positioned within the search space, with its location vector representing a candidate solution. The related structure is defined as a vector as shown in [9]. In a dimensional optimization problem, a sand cat is a 1 × d array representing the solution to the problem. Each of the variable values (x1, x2, …, xd) is a floating-point number. Here every x must be located between the lower and upper boundaries (∀xi ∈ [lower, upper]). To start the SCSA algorithm, first, a candidate matrix is created with the sand cat population according to the size of the problem (Npop × Nd), (pop = 1,,, n).

In addition, the fitness cost of each sand cat is obtained by evaluation of defined fitness function. This function defines the relevant parameters of the problem, and the best values of the parameters (variables) will be obtained by the SCSA. A value for the corresponding function will be output from each sand cat. When an iteration is finished, the sand cat with the best cost in that iteration is chosen so far, the best solution (if there was no answer as good as this in the previous iterations) and the other sand cats try to move towards this best-chosen cat in the next iteration. Because the best solution in each iteration can represent the cat closest to the prey. If a better solution is not found in the next iterations, the solution for that iteration is not unnecessarily stored in memory and this ensures efficient use of memory.

C. SCSA Exploration

The exploration phase of the SCSA mimics the sand cat's behavior of searching for prey in a wide area. This stage aims to diversify the search and explore the solution space broadly. Sand cats use their exceptional hearing to detect low-frequency sounds. In the algorithm, this is simulated by generating random movements in the search space, allowing sand cats to "listen" for better solutions. To search for prey, it is assumed that the sand cat sensitivity range starts from 2 kHz to 0 and guided by the parameter rG (2). The search space is randomly initialized between the defined boundaries. In the searching step, position updating of each current search agent is based on a random position. In this way, the search agents able to explore new spaces in the search space. The sensitivity range for each sand cat is different, to avoid the local optimum trap is defined as r.

In addition, the variable controlling the phase transition is defined as R. The position of the search phase is updated randomly by (1), while a new search space is opened. Here, SM is the constant used to characterize the sand cat hearing and is set to 2, iterc and itermax denote the current and maximum number of iterations, respectively. Posbc and Posc are defined as the best candidate position and the current position. As sand cats explore the swamp, the algorithm keeps track of the global best solution found so far. This information is used to guide the search process in subsequent iterations as shown in Eq. (3) and Eq. (4).

$$R = 2 \times r_G \times \text{rand}(0,1) - r_G \quad (1)$$

$$r_G = S_M - \left(\frac{2 \times S_M \times iter_c}{iter_{max}}\right) \quad (2)$$

$$r = r_G \times rand(0,1) \quad (3)$$

$$Pos_{(t+1)} = r.(Pos_{bc}(t) - rand(0,1).Pos_c(t)) \quad (4)$$

D. SCSA Exploitation

The exploitation phase represents the sand cat's behavior when it has located a promising area and begins to focus its search more intently. This phase aims to refine the current best solutions and converge towards the optimal solution. An angle is randomly selected between [0,360] using the roulette wheel selection algorithm to simulate the movement direction of the sand cat. This allows the sand cat to explore the search area and approach its prey from various directions which can produce diverse solution options and reduce the risk of missing potential options.

Next, the positions of sand cats are updated based on a combination of their current position, the global best position, and a random component. This update rule balances the exploitation of known good solutions with the exploration of new areas. In the attack phase, the position of each sand cat is updated according to Eq. (5) and Eq. (6) where Pos_{rnd} denotes the position of the candidate sand cat randomly generated according to any two sand cats, Pos_b is the position of the current optimal solution. Finally, the transition between the above two modes is controlled by R in Eq. (1). When the value of |R| > 1 ,

the sand cat performs the search phase shown in Eq. (4) to find prey by moving over a longer distance (searching for new solutions at a global range). When $|R| \leqslant 1$, the sand cat enters the exploitation phase shown in Eq. (6) to search in a small range to attack the prey.

$$\overrightarrow{Pos_{(rnd)}} = \left| rand\,(0,1) \cdot \overrightarrow{Pos_b}(t) - \overrightarrow{Pos_c}(t) \right|,$$

$$\overrightarrow{pos(t+1)} = \overrightarrow{Pos_b}(t) - \vec{r} \cdot \overrightarrow{Pos_{rnd}} \cdot cos(\theta) \quad (5)$$

$$\overrightarrow{X(t+1)} = \begin{cases} r \cdot \overrightarrow{Pos_b(t)} - \overrightarrow{Pos_{rnd}} \cdot cos(\theta) \cdot \vec{r} & |R| \leq 1; exploitation \\ \left(\overrightarrow{Pos_{bc}(t)} - rand(0,1) \cdot \overrightarrow{Pos_c(t)} \right) & |R| > 1; exploration \end{cases} \quad (6)$$

Throughout both the exploration and exploitation phases, the algorithm continuously evaluates the fitness of new solutions, updating the global best solution when improvements are found. The process iterates until a termination criterion is met, such as reaching the maximum number of iterations or achieving a satisfactory solution quality.

III. Methodology

This section explains the literature review process using the Systematic Literature Review (SLR) method. This methodology, inspired by prominent machine learning literature surveys [19] comprises three main stages: Planning, Conducting, and Reporting. This structure ensures a comprehensive and methodical approach to reviewing literature, helping researchers to systematically gather, evaluate, and synthesize existing research on a specific topic.

A. Planning the SLR

In this stage, three activities are involved. First, identify the main objective of the review by formulating research questions (RQs), which focus to determine the gaps in current knowledge and justifying why this SLR is necessary. Second, developing criteria and procedures where guidelines for conducting the review are established, including search terms, databases to be used, and initial inclusion/exclusion criteria. Lastly, evaluating the criteria and procedures, where at this step the testing and refine, the established criteria is done to ensure they are effective and appropriate in fulfilling the research objectives. Having the research question established, the search terms based on the research question are:

- Sand Cat Swarm Algorithm keywords: “Sand Cat Swamp Algorithm”,” Sand Cat Optimization”, “SCSA Optimization”.
- Review keywords: “survey”, “review”, “overview”, “literature”, “bibliometric”, “challenge”,“trend”, research direction.

B. Conducting the SLR

In the second phase of the Systematic Literature Review (SLR), the focus is on conducting an extensive search and selecting relevant literature. This involves identifying pertinent studies, extracting relevant information, and synthesizing the findings to obtain a comprehensive understanding of the research topic. As shown in Fig. 1, the flow diagram illustrating the selection process conducted from the initial data collection in chosen databases using the inclusion and exclusion criteria specified in Table I, PRiSMA flow diagram is used to represent the activities taken to conduct the analysis.

TABLE I. Criteria for Study Selection

Inclusion Criteria	Exclusion Criteria
Publications written in English	Research not written in English
Publications starting from 2022 until 2024 (Dicember)	Research published before 2022
Publications that truly focus on the keywords: Sand Cat Swarm Algorithm / optimization	Research that discusses topics other than SCSA Algorithm/optimization
Publications that increasingly focus on the SCSA, specifically discussing the new variants, challenges and future work of SCSA	Publications that not focus on the SCSA, specifically not discussing the new variants or challenges or future work of SCSA
Open access documents	Not an open access documents

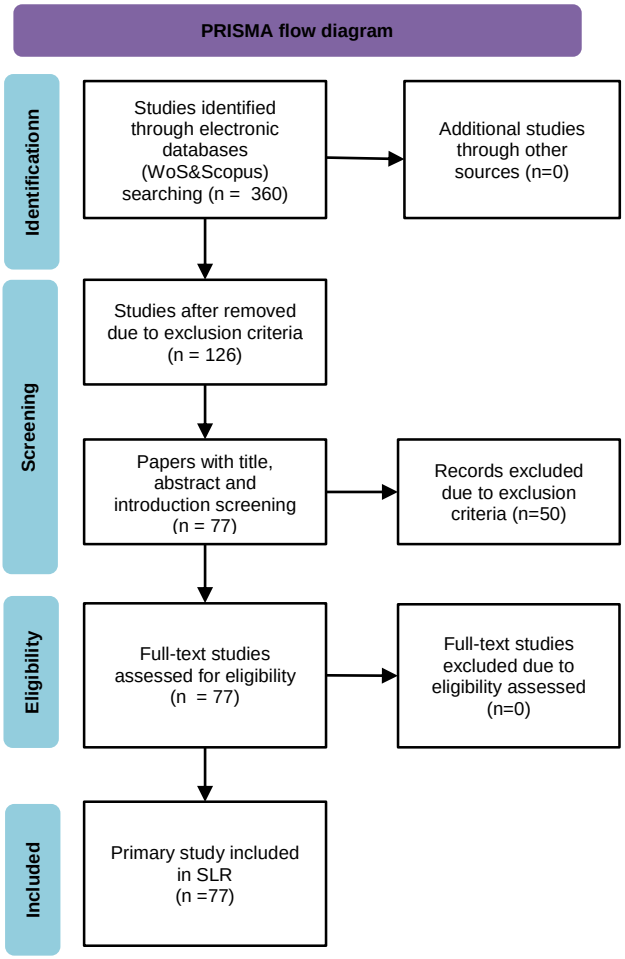

Fig. 1. Selection process of primary studies using PRISMA flow diagram.

C. Reporting

The final stage of the Systematic Literature Review (SLR) involves reporting and presenting the findings in a structured

and transparent manner. The results are systematically documented and analyzed based on the research questions established during the initial phase of the study, ensuring clarity, relevance, and alignment with the review's overall objectives.

In this study, the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework was systematically applied to ensure a transparent, reproducible, and rigorous methodology. The structured approach included identification, screening, eligibility assessment, and inclusion of relevant studies, guided by predefined criteria to maintain accuracy and reliability. By following PRISMA guidelines, the selection process minimized bias and ensured a comprehensive and well-documented synthesis of existing literature. This methodological approach strengthens the validity of the findings and provides a robust foundation for future research and practical applications.

IV. Results and Analysis

Based on the outlined SLR objectives, this section will present the findings for the specified research questions to address each SLR objective.

A. RQ1. How has this Research Area Evolved in Terms of Number of Publications?

The analysis provides an insightful overview of research output spanning the period 2022 to 2024 to describe the evolvement of SCSA studies since 2022. The result encompasses 126 documents sourced from 98 journals, books, and related publications, reflecting a diverse range of scholarly contributions but only 77 articles was selected to be analyzed. Notably, the annual growth rate of research activity stands at an impressive 28.92%, signifying a substantial increase in the adoption and exploration of the subject during this timeframe. The documents exhibit an average age of 1.21 years, indicating the recency and relevance of the included works. However, the relatively low average citation rate of 0.6056 citations per document suggests either a nascent field or limited citation impact thus far. Interestingly, no references are explicitly listed within the dataset.

Overall, the bibliometric results portray a dynamic and evolving research landscape characterized by rapid growth, strong collaborative efforts, and a focus on high-quality journal publications. However, the lack of international co-authorship and limited citation impact suggest opportunities for fostering global partnerships and enhancing scholarly influence in future research endeavors.

TABLE II. Number of Publications over the Years

Year of Publication	2022	2023	2024
No. of Publication	7	30	89

Table II presents the distribution of publications on the Sand Cat Swamp Algorithm across a three-year period from 2022 to 2024. In 2022, the field experienced a modest output, with only seven articles published, suggesting a nascent stage of exploration. This number significantly increased to 30 articles in 2023, marking a noteworthy growth in scholarly contributions and interest. The trend reached its peak in 2024, with an impressive 89 articles published, signifying a period of heightened research activity and substantial engagement within the scientific community. This temporal analysis illustrates a rapid rise in research output between 2022 and 2024, possibly driven by growing interest and developments in the field. Overall, the data provides a clear depiction of the dynamic nature of annual scientific production, reflecting both growth opportunities and challenges in sustaining research momentum.

TABLE III. Top 10 Most Relevant Sources

Sources	No. of Articles
IEEE Access	7
Biomimetics	5
Scientific Reports	5
Mathematics	4
Alexandria Engineering Journal	3
Applied Sciences-Basel	3
Electronics	3
Energies	3
Expert Systems with Applications	3
International Journal of Electrical Power & Energy Systems	3

The analysis of the most relevant sources in Sand Cat Swarm Algorithm (SCSA) research reveals an interesting citation pattern among the top 10 most influential sources. As shown in Table III, IEEE Access emerges as the leading publication platform, contributing 7 articles, indicating its role as a primary venue for disseminating high-impact studies on SCSA. This is followed closely by Biomimetics and Scientific Reports, each with 5 articles, highlighting their relevance in publishing research that bridges bio-inspired optimization and computational intelligence. Additionally, Mathematics contributes 4 articles, reinforcing the importance of mathematical modeling in metaheuristic algorithm analysis and development. The remaining six sources, each contributing 3 articles, represent a diverse range of journals, covering applications in engineering, computation, and optimization methodologies.

This distribution of publications offers valuable insights into the preferred journals and conferences for SCSA-related research, guiding future researchers in selecting relevant references and identifying potential publication avenues. The observed concentration in specific journals suggests that certain academic communities are more actively engaged in advancing and refining SCSA, further emphasizing the growing impact and recognition of this algorithm in the field.

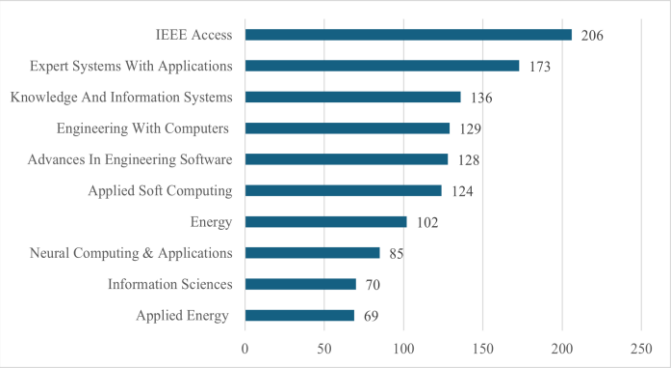

Fig. 2. The top 10 highest total citation of publications.

Fig. 2 shown the top 10 highest total citations of research publications across top ten academic journals. IEEE Access exhibits the highest publication count (206), followed by Expert Systems with Applications (173). Other journals with substantial contributions include Knowledge and Information Systems (136), Engineering with Computers (129), Advances in Engineering Software (128), and Applied Soft Computing (124). The remaining journals, Energy (102), Neural Computing & Applications (85), Information Sciences (70), and Applied Energy (69), report comparatively lower publication counts. This distribution reflects the research trends in fields such as artificial intelligence, computational engineering, supply chain and applied sciences, offering insights into the preferred publication venues for scholars in these disciplines.

This analysis contributes valuable insights for young researchers, highlighting potential avenues for contributing new knowledge related to the SCSA and metaheuristic algorithms in general. The diversity of publication venues and total of citations underscores the algorithm's broad applicability and may encourage interdisciplinary research approaches in this rapidly evolving field.

B. *RQ2. What are the New Variations and Enhancements made to the SCSA since its Inception?*

The Sand Cat Swarm Algorithm (SCSA) is designed to find effective solutions in complex problem spaces. However, to improve its performance and expand its application, several enhanced versions of SCSA have been developed. These new variants focus on balancing two critical processes: exploration (searching new areas) and exploitation (refining known areas). Innovations include introducing advanced search strategies, combining SCSA with other algorithms, adapting it for specific problem types, and adding learning and chaotic behaviors to improve its efficiency. These enhancements enable SCSA to solve a wider range of problems more effectively and make it a versatile tool for complex, real-world applications.

1) Enhanced exploration and exploitation balance: Balancing exploration and exploitation are essential for efficient optimization. For example, [12] introduces a new variant of SCSA which has several mechanisms to optimize this balance, including the Triangle Walk (TW) and Levy Flight Walk (LFW) strategies, which are well-known for their exploratory capabilities. Additionally, the algorithm uses a nonlinear period adjustment mechanism to control the intensity of search behaviors dynamically, adjusting exploration and exploitation phases based on search requirements. Furthermore, a dynamic exponential factor is incorporated to fine-tune the transition between exploration and exploitation over time. Together, these features allow this variant to adaptively navigate complex landscapes, enhancing its ability to locate optimal solutions with fewer iterations.

2) Hybridization with other algorithms: Hybrid algorithms can effectively blend the strengths of multiple approaches, and several hybridizations of SCSA have been developed to address its limitations. For instance, some versions [20], [22], [32] combine SCSA with the Whale Optimization Algorithm (WOA) to enhance convergence, while others integrate it with the Sine Cosine Algorithm (SCA) for improved exploratory behavior. In another instance, the Arithmetic Optimization Algorithm (AOA) has been incorporated to refine the balance between global and local searches. These hybrid approaches allow SCSA to tackle a broader range of optimization problems with enhanced performance, as the combination of strategies improves both efficiency and effectiveness in reaching high-quality solutions.

3) Adaptation for specific problem domains: SCSA has been tailored for specific application domains by modifying the algorithm's structure and parameters. For example, adaptations have been made [24], [27] for software module clustering, where SCSA is adjusted to address the complexities of grouping related software modules. In another application, the algorithm has been customized for optimizing Proportional-Integral-Derivative (PID) controllers, a task requiring precise tuning of parameters to achieve stability in dynamic systems. Additionally, a binary version (bSCSA) has been developed for feature selection tasks, enabling SCSA to select optimal subsets of features in high-dimensional spaces. Other than that, SCSA also indicates well performance in solving Flexible Job Shop Scheduling (FJSP) problem as FJSP is common discrete optimization problems [20]. These domain-specific adaptations highlight SCSA's versatility, making it a valuable tool for solving diverse real-world problems, namely continuous and discrete problems.

4) Integration of learning mechanisms: Integrating learning mechanisms into SCSA allows the algorithm to intelligently guide its search process, reducing the likelihood of becoming trapped in local optima. Techniques such as Lens Opposition-Based Learning (LOBL), pseudo-opposition and pseudo-reflection learning, and Pinhole-Imaging Opposition-Based Learning (PIOBL) have been embedded into SCSA [21] to enhance solution quality. These strategies improve search efficacy by using "opposition-based" concepts that explore the search space from opposite perspectives, thus offering a more comprehensive view of potential solutions. This improved adaptability enables SCSA to achieve better convergence rates and a higher likelihood of finding globally optimal solutions.

5) Multi-objective optimization: To expand SCSA's capabilities in, variants have been created [18], [22] that address problems with conflicting objectives. These

adaptations, like Multi-Objective SCSA (MO-SCSA), are designed for complex scenarios, such as electric vehicle (EV) charging and discharging optimization, where multiple goals must be met concurrently. Additionally, some variants incorporate Pareto optimization, enabling SCSA to generate a set of Pareto-optimal solutions for multi-objective problems. This adaptation allows users to select trade-offs among competing objectives, thus extending the algorithm's utility for complex, multi-dimensional problem domains.

6) Chaotic behavior integration: Incorporating chaotic behavior into SCSA can significantly enhance its search capability, allowing for better exploration of complex solution spaces. Chaotic Sand Cat Swarm Optimization (CSCSA) is an example of such an enhancement, where chaotic mappings (e.g., tent mapping) are used to introduce randomness into the algorithm's search strategy [23]. By alternating between chaotic patterns and regular search behaviors, this variant improves the algorithm's ability to escape local optima. In another version, the hybrid of chaotic SCO and pattern search (CSCPS) blends chaos theory with pattern-based search to further optimize exploration [24]. This integration of chaos helps SCSA to achieve a more robust search process, ultimately leading to higher-quality solutions in challenging optimization landscapes.

In conclusion, the Sand Cat Swarm Optimization algorithm has demonstrated its potential as a versatile and effective optimization technique across various domains. Ongoing research focuses on enhancing its performance, adapting it to different types of problems, and exploring novel hybrid approaches to leverage its strengths in combination with other techniques.

C. RQ3. How does the Evaluation of the SCSA Compare with other Swamp Intelligent Metaheuristic Algorithms?

Recent enhancements to the Sand Cat Swarm Optimization (SCSA) algorithm and its variants have led to significant advancements in optimization performance. These developments primarily focus on improving key metrics such as convergence rate, accuracy, robustness computational cost, and others problem specific metrics. Various studies have introduced new variants of SCSA, each optimized for specific problems, including balancing fuel costs, emission reduction, and customer satisfaction, or providing high adaptability in global search performance. This review highlights the evaluation method used in evaluating performance of these SCSA variants.

1) Enhanced convergence and accuracy: Many SCSA variants demonstrate notable improvements in convergence rate and optimization accuracy, consistently outperforming other metaheuristic algorithms. For instance, the CSCPS variant excels in convergence speed, achieving optimal results quickly and efficiently, with a lower computational cost compared to traditional methods [24]. Similarly, ISCOA is particularly effective in minimizing fuel costs and emissions, showing enhanced accuracy and suitability for practical optimization scenarios [25]. Other algorithms like CWXSCSA [11] and ISCSA [26] emphasize not only accuracy but also the capability to escape local optima, allowing them to refine solutions with higher precision.

2) Robustness across applications: SCSA variants have shown exceptional robustness across diverse applications, including optimization problems in engineering, environmental management, and logistics. COSCSA, for example, maintains stability while achieving high accuracy and rapid convergence, making it resilient in complex problem environment [27]. Additionally, IMSCSA 's robust performance is evident in its ability to handle diverse optimization tasks with minimal deviation across multiple test scenarios [15]. In practical applications like delivery cost reduction and carbon emission optimization, SCSA and its variants demonstrate robustness and consistency in maintaining high performance, even when faced with fluctuating problem variables.

3) Reduced computational costs: To ensure practicality in computationally intensive tasks, some SCSA variants emphasize reduced computational costs while maintaining strong performance. For instance, MSCSA optimally balances global and local search operations, lowering the algorithm's computational demands [15]. Likewise, bSCSA has been noted for its cost-effectiveness, which allows it to perform robustly in high-dimensional problem spaces while avoiding unnecessary computational overhead [17]. By efficiently utilizing resources, these variants are well-suited for applications requiring quick, resource-efficient solutions.

4) Exploration and exploitation balance: Improved exploration and exploitation balance is a defining feature of many recent SCSA variants. BMSCSO, for example, achieves a delicate balance, which allows it to avoid local optima and maintain adaptive performance in both global and local searches [17]. The DGS-SCSO variant further demonstrates this balance, showcasing superior convergence rates and stability in complex landscapes by dynamically managing exploration and exploitation phases [21]. This ability to flexibly navigate both broad and fine-grained search spaces enhance these algorithms' adaptability and effectiveness across varied optimization tasks, as evidenced by the consistently high performance of enhanced SCSA variants across different contexts.

In summary, the SCSA and its variants have shown exceptional performance improvements across critical optimization metrics. These versions demonstrate faster convergence, higher accuracy, and robustness, proving adaptable to various complex problems. The advancements in exploration-exploitation balance and computational efficiency make SCSA variants reliable for tackling a wide range of optimization challenges, outperforming traditional metaheuristic approaches in both theoretical and practical applications.

D. RQ4. What are the Evaluation Methods of the SCSA Compared with other Swamp Intelligent Metaheuristic and the Performance Metrics Used?

1) Evaluation method: The assessment method is essential for reviewing a new form of a metaheuristic algorithm, as it dictates the algorithm's usefulness, efficiency, and dependability in addressing optimization challenges[28]. Evaluating the Sand Cat Swarm Algorithm (SCSA) and its variants have consistently employed three methods namely benchmark test function, case study and compare with wide range of competing algorithms. These three methods employed a wide range of performance metrics based on three different types of measurement metrics such as statistical metrics, non-statistical metric and problem specific metrics.

a) Benchmark test function: These benchmark functions typically include standard optimization problems and specialized test suites designed for evaluating metaheuristic algorithms. There are several sets of benchmark instances that are widely used in the literature:

- Standard benchmark functions: These comprise well-known optimization problems such as Sphere, Rosenbrock, Ackley, and others. These functions are widely used due to their known characteristics and ability to test different aspects of algorithm performance [17], [26].
- CEC (Congress on Evolutionary Computation) benchmark suites: Multiple studies referenced CEC test functions, particularly CEC2014, CEC2017, CEC2019, and CEC2020 [11], [27]. These suits are specifically designed for comparing evolutionary and swarm intelligence algorithms on various problem types.
- Real-world engineering problems: Some researchers incorporated practical engineering optimization problems to evaluate algorithm performance in more applied contexts [24], [29], [30].

Researchers generally seek out the original articles describing the CEC benchmark suites or utilize known implementations found in optimization libraries to access these benchmark functions. Standard functions are extensively accessible in mathematical software programs or can be implemented using their mathematical formulations in libraries such as Python and R. The selection of benchmark functions typically hinges on the facets of algorithm performance under assessment, like convergence rate, solution precision, or capacity to navigate diverse problem environments.

b) Case study: Based on the case studies used to compare SCSA performance, several key themes emerge. Engineering Optimization Problems feature prominently, with applications ranging from hydraulic turbine design to vehicle safety optimization. Energy Systems and Renewable Energy form another significant theme, focusing on wind farm optimization and integrated energy systems with electric vehicles [31].

Industrial and Manufacturing Applications highlight SCSA 's practical relevance in areas like e-commerce logistics and equipment operation optimization [32].

Computer Science and Machine Learning Applications include benchmark tests, intrusion detection, and cognitive radio networks. Medical and Biological Applications showcase SCSA 's potential in areas such as brain tumor diagnosis and power transformer fault detection. Benchmark Functions and algorithm comparisons are used to rigorously evaluate SCSA against established standards and other optimization techniques.

This diverse range of themes as shown in Table IV, SCSA's versatility and broad validity of applicability across various scientific and practical domains, from engineering and energy to environmental science motivates all researcher to contribute more critical research on SCSA in the future.

a) Competing algorithm: The research on enhancement of Sand Cat Swarm Algorithm (SCSA) encompasses a diverse range of comparative algorithms, reflecting the multifaceted nature of metaheuristic optimization. The comparison spectrum includes nature-inspired algorithms like Whale Optimization and Grey Wolf Optimization, evolutionary approaches such as Genetic Algorithms, swarm intelligence techniques including Artificial Bee Colony and Firefly Algorithm, and physics-based methods like the Gravitational Search Algorithm as shown in Table V. Researchers have also benchmarked SCSA against hybrid and improved versions of existing algorithms, machine learning-based approaches, and recently developed optimizers.

This comprehensive comparison strategy allows for a thorough evaluation of SCSA's performance across various optimization contexts, highlighting its strengths and potential areas for improvement relative to both established and emerging techniques in the field.

TABLE IV. COMPREHENSIVE OVERVIEW OF THE VARIOUS CASE STUDIES USED TO EVALUATE SCSA

Theme	Case Study	Description	Author(s)
Engineering Optimization Problems	Elbow draft tube optimization	Optimization design of the elbow draft tube of the hydraulic turbine	[29]
	Pressure Vessel Design Problem	Engineering design optimization	[13]
	Car Crashworthiness Design Problem	Optimization of vehicle safety design	[14]
	Various engineering cases	Three-bar truss, Tension/compression spring, Cantilever beam, Pressure vessel, Speed reducer, I-beam vertical deflection, Piston lever	[33]
Energy Systems and Renewable Energy	Wind and PV farm optimization	Optimization of energy storage allocation for wind farm and photovoltaic farm in China	[12]
	Wind farms	Onshore wind farm in Austria and offshore wind farm in Denmark	[22]
	Integrated energy system	Optimal scheduling model for integrated energy system with electric vehicles	[32]
	Intrusion detection	Feature selection for improved intrusion detection	[16]

Theme	Case Study	Description	Author(s)
Computer Science and Machine Learning Applications	Malicious User Detection	Optimal Deep Learning for Spectrum Sensing in Cognitive Radio Networks	[34]
	Cognitive Radio Sensor Network	Application in wireless sensor networks	[35]
Benchmark Functions and Algorithm Comparisons	CEC test suites	CEC2017 and CEC2020 benchmark functions	[27]
	Multiple algorithm comparison	Comparison with Sine Cosine Algorithm, Circle Search Algorithm, Salp Swarm Algorithm, etc.	[9]

TABLE V. COMPETING ALGORITHM BASED ON A CATEGORY OF METAHEURISTIC ALGORITHM

Theme	Algorithms	References
Nature-Inspired Algorithms	Whale Optimization Algorithm (WOA)	[30], [36]
	Grey Wolf Optimization (GWO)	[26], [33], [35]
	Particle Swarm Optimization (PSO)	[10], [25], [33], [35]
Evolutionary Algorithms	Genetic Algorithm (GA)	[17], [33], [37]
Swarm Intelligence Algorithms	Artificial Bee Colony (ABC)	[35]
	Ant Colony Optimization (ACO)	[38]
	Firefly Algorithm (FA)	[25], [35]
Physics-Inspired Algorithms	Gravitational Search Algorithm (GSA)	[12], [23]

Recently Developed Algorithms	Harris Hawks Optimization (HHO)	[14], [42]
	Dung Beetle Optimizer (DBO)	[42], [43]
	Aquila Optimizer (AO)	[42]

In conclusion, these themes collectively demonstrate that SCSA is being compared against a wide range of metaheuristic algorithms, spanning from well-established techniques to recent innovations. This comprehensive comparison approach allows researchers to thoroughly assess the performance and capabilities of SCSA in various optimization contexts. The diversity of competing algorithms also reflects the dynamic nature of the field and the continuous development of new optimization techniques. More research comparing SCSA performance with new metaheuristic algorithm are encouraged to obtain the performance of SCSA in solving various optimization problems.

2) Performance metrics: The selection of performance metrics is crucial in effectively evaluating and comparing different approaches to verify the algorithm performance and solution quality in optimization problems [44]. This importance spans across various optimization scenarios, from simple to complex. In single-objective optimization problems (SOPs), the goal is straightforward: to find an optimal solution that either minimizes or maximizes a single objective. This simplicity allows for relatively easy comparison between solutions, with the one yielding better fitness clearly superior. However, as optimization problems become more complex, such as in multi-objective scenarios, the landscape becomes significantly more intricate [28]. The presence of multiple, often conflicting objectives introduces a layer of complexity that makes evaluating solution superiority far more challenging. In these cases, various approaches often yield a set of optimal solutions, each considered equivalent under concepts like Pareto dominance [45], [46], [47], [48].

This complexity underscores the critical need for sophisticated performance metrics across all types of optimization problems. While it's relatively straightforward to compare individual solutions in SOPs, providing a quantitative comparison of different optimal solution sets in more complex optimization scenarios is far from trivial. The challenge lies in developing metrics that can effectively capture and quantify the quality of these diverse solution sets, considering factors such as diversity, convergence, and the balance between different objectives or constraints.

Therefore, the careful selection and design of performance metrics become paramount in general optimization. These metrics must be capable of providing meaningful comparisons between different approaches, guiding researchers and practitioners towards more effective optimization strategies. This emphasizes the importance of ongoing research into performance metric development, particularly for complex optimization scenarios, to ensure that the evaluation of different optimization approaches is both comprehensive and insightful.

Based on the analysis indicates that researchers have chosen a diverse range of performance metrics in their research. These evaluation metrics collectively address the metric used to analyze the performance of SCSA by providing a comprehensive comparison of SCSA with other metaheuristic algorithms. They cover various aspects of algorithm performance as listed below.

- Convergence Rate: Many studies focus on the convergence rate of SCSA compared to other algorithms. This metric is crucial as it indicates how quickly the algorithm reaches an optimal or near-optimal solution. For example, study by [27] noted that the SCSA algorithm converged to the optimal result faster than the Particle Swarm Optimization (PSO) algorithm.
- Accuracy: Accuracy is a widely used metric across various studies. It measures how close the algorithm's

solution is to the true optimal solution or how well it performs in classification tasks. For instance, study by [26] reported that the SCSA algorithm achieved the highest classification accuracy of 93.96% compared to other algorithms.

- Robustness: Robustness is evaluated in several studies to assess how well the algorithm performs across different problems or under varying conditions. Study by [27] noted that the SCSA algorithm effectively avoided falling into local extremum, indicating robustness.
- Computational Cost: The computational cost or efficiency of the algorithm is another important metric. This metric is used to evaluate the algorithm's practicality for real-world applications. For example, study [26] reported that the SCSA algorithm selected the fewest features in the least computational time of 1.91 seconds.
- Solution Quality: Some studies use specific metrics to measure the quality of solutions, such as Mean Square Error (MSE), RMSE, and R-squared (R2). These metrics provide a quantitative measure of how well the algorithm's solutions fit the problem requirements.
- Statistical Measures: Several studies employ statistical measures to compare algorithm performance, including mean, median, standard deviation, and statistical tests like the Wilcoxon rank sum test [23], [49]. These measures provide a more rigorous comparison of algorithm performance across multiple runs or problem instances.
- Problem-Specific Metrics: Some studies use metrics specific to the problem domain. For example, in classification tasks, metrics like precision, recall, F1-score, sensitivity, and specificity are used. In energy optimization problems, metrics like TEPL and TEVD are employed [31].
- Convergence Curves: Visual representations of algorithm performance, such as convergence curves [23], are used to illustrate how quickly and effectively algorithms approach optimal solutions over time.
- Feature Selection Performance: For feature selection problems, metrics such as the number of selected features [26] are used alongside accuracy to evaluate the algorithm's effectiveness in identifying relevant features while maintaining high performance.
- Specific Optimization Performance: Some studies use the best value, worst value, and mean value [50] to evaluate the overall optimization performance of the algorithms across multiple runs.

The comparative analysis demonstrates that the new variants of the Sand Cat Swarm Algorithm (SCSA) exhibit superior performance compared to competing algorithms as shown in Table VI. The enhancements introduced in these variants contribute to improved solution quality, better convergence rates, and enhanced robustness in tackling optimization problems. These findings highlight the effectiveness of the proposed modifications in strengthening SCSA's capability, making it a competitive choice for complex optimization tasks.

In conclusion, in single-objective optimization, evaluating solutions is straightforward since a single best outcome can be identified. However, in multi-objective optimization, conflicting objectives create a more complex landscape where multiple solutions are considered optimal under Pareto dominance [28]. This complexity necessitates specialized evaluation techniques to determine trade-offs and balance competing objectives effectively. Choosing the right evaluation method and performance metrics is crucial in ensuring the reliability and validity of the optimization process. Proper metrics, such as convergence indicators, diversity measures, and statistical tests, help assess solution quality, guide algorithm improvements, and ensure meaningful comparisons across different optimization approaches.

E. RQ5. In Which Domains has the SCSA been Applied, and What are the Outcomes and Benefits of these Applications?

The Sand Cat Swarm Algorithm (SCSA) algorithm has found diverse applications across various domains, demonstrating its versatility and effectiveness in solving complex optimization problems. This analysis highlights the primary application domains of SCSA.

One significant application area of SCSA is in renewable energy systems, particularly in optimizing parameters for solar (PV) models. For instance, a study by [12] proposed a Brownian random walk-based SCSO for parameter identification in various PV mathematical models, showcasing its effectiveness in enhancing the accuracy of parameter estimation. Similarly, the SCSA has been utilized in optimizing the efficiency of photovoltaic thermal systems through advanced artificial intelligence techniques [56], [57], [58] . These studies underline the algorithm's capability to improve energy management and performance in renewable energy applications.

Another prominent domain is in unmanned aerial vehicle (UAV) path planning. A study by [59], [60] demonstrated that an SCSA-based approach significantly improved the convergence speed and accuracy of UAV path planning, indicating its potential for real-time applications in dynamic environments. Furthermore, the research emphasizes the algorithm's utility in enhancing UAV operational efficiency. These applications illustrate the effectiveness of SCSO in optimizing navigation and operational strategies in aerial systems.

SCSA also plays a crucial role in the field of sensor networks, particularly in underwater wireless sensor networks (UWSNs). The multi-objective SCSA has been employed for energy-optimized cluster head selection, which is vital for efficient data transmission and monitoring in underwater environments [60]. This study reflects the importance of SCSA in enhancing the performance and reliability of sensor networks.

In the realm of machine learning and data analysis, SCSA has been effectively integrated into various models to optimize performance. For instance, the algorithm has been utilized to enhance the accuracy of fault diagnosis in rolling bearings by optimizing support vector machine parameters [61]. These

applications indicate the SCSA potential in optimizing machine learning models and improving data-driven decision-making processes.

A study by [20] proposes an improved Sand Cat Swarm Optimization (ISCSO) algorithm for solving the Flexible Job Shop Scheduling Problem (FJSP) also known as example of discrete problem. The approach enhances optimization by using chaotic mapping for population initialization, improving diversity and convergence speed. A nonlinear convergence decreasing factor balances exploration and exploitation, successfully enhancing the global search capability. Additionally, integrating a genetic algorithm for agent position updates enables discretization and helps avoid local optima proves that SCSA potentially be applied to discrete problem and effectively solving FJSP.

TABLE VI. OVERALL COMPARATIVE PERFORMANCE OF NEW VARIANTS OF SCSA COMPARED TO THE COMPETING ALGORITHMS

Authors	Overall Performance
[11]	SCSA improved the convergence rate and accuracy of the whale optimization algorithm (WOA) in solving optimization problems.
[27]	The SCSA algorithm has a faster convergence rate, higher accuracy, and improved robustness compared to other metaheuristic algorithms.
[37]	ISCOA showed enhanced performance over other recent approaches in terms of minimizing fuel costs and emissions of generation units.
[25]	The CSCPS algorithm outperformed other methods in terms of convergence rate, accuracy, and robustness. Additionally, the computational cost of the CSCPS algorithm was found to be efficient compared to other commonly used metaheuristic algorithms.
[26]	The SCSA algorithm exhibits strong performance across convergence rate, accuracy, robustness, and computational cost compared to other metaheuristic algorithms.
[51]	The DGS-SCSA algorithm outperforms the original SCSA algorithm in terms of convergence rate, accuracy, and robustness.
[14]	The performance of the SCSA algorithm is compared with other metaheuristic algorithms in terms of convergence rate, accuracy, robustness, and computational cost.
[23]	The results demonstrated that CWXSCSA exhibits superior optimization accuracy, faster convergence acceleration, and better robustness compared to the alternative approaches. However, the comparison did not include computational cost.
[10]	SCSA demonstrates competitive performance in terms of convergence rate, accuracy, robustness, and computational cost compared to other metaheuristic algorithms.
[52]	The results show that the SCSA algorithm demonstrates better performance in several test cases and real engineering problems, indicating superior convergence rate, accuracy, robustness, and computational cost.
[53]	the improved sand cat swarm algorithm (ISCSA) outperforms the SCSA, WOA, and ASO algorithms in terms of convergence speed, number of iterations, and the ability to jump out of local optimums.
[40]	The performance of the Chaotic Sand Cat Swarm Optimization (CSCSA) algorithm is superior to other metaheuristic algorithms in terms of convergence rate, accuracy, and robustness.
[54]	The results showed that the SCSA algorithm demonstrated superior global convergence, consistently yielding the smallest objective function values. It also showed robust stability and was effective in reducing the cost of delivery and carbon emissions while improving customer satisfaction.
[17]	The MSCSA algorithm shows better convergence ability and optimization performance compared to the SCSA algorithm and other comparison algorithms
[12]	The proposed IMSCSA algorithm is evaluated against other state-of-the-art optimizers and is shown to perform significantly better in terms of convergence rate, accuracy, and robustness. However, the computational cost of IMSCSA is relatively higher due to certain mechanisms requiring more computing power.
[43]	The performance of the Improved Sand Cat Swarm Optimization (ISCSA) significantly outperforms competing algorithms in terms of convergence rate, accuracy, and robustness.
[24]	The performance of the MSCSA algorithm has fast convergence speed, demonstrates excellent optimization results, effectively maintains the balance between global and local search performance, and has lower computational costs compared to other metaheuristic algorithms.
[35]	COSCSA converges more rapidly, with higher accuracy, and stays more stable compared to other algorithms.
[42]	The IMSCSA has been shown to have better optimization performance compared to other competitive algorithms in terms of convergence rate, accuracy, and robustness.
[39]	The results showed that the proposed BMSCSA obtained the maximum accuracy in a total of 14 datasets and was rated first solely based on having the best accuracy results in 10 datasets, having the lowest standard deviation values in several datasets and much better than many other rival methods. In terms of convergence rate, the proposed BMSCSA algorithm successfully balances the capacities for exploitation and exploration, and its convergence behavior was superior to that of some of its competitors.
[50]	The improved ISCSA reaches convergence after 15 iterations and has the best adaptivity, outperforming the other four methods in terms of global search performance and convergence speed.
[49]	Demonstrates excellent performance and robustness compared to other advanced algorithms in jumping out of local optima, improving convergence speed, and optimization accuracy.
[16]	The performance of the Binary Sand Cat Swarm Optimization (bSCSA) algorithm was found to be impressive in terms of convergence rate, accuracy, and robustness when compared to other metaheuristic algorithms
[55]	The SCSA algorithm exhibits efficient performance in terms of convergence rate, accuracy, and computational cost when compared to other metaheuristic algorithms. It also shows robustness in maintaining a balance between exploration and exploitation.

Finally, SCSA has been applied in various engineering and control systems, such as in the design of controllers for industrial applications. Shi's research on a modified SCSO-based controller for dicing saw chuck table systems illustrates its effectiveness in improving control accuracy and system robustness [62]. Additionally, the integration of SCSA in optimizing power quality conditioners in microgrid systems further showcases its relevance in enhancing the performance of electrical systems [63]. These applications highlight the algorithm's versatility in addressing challenges in engineering and automation.

In summary, the Sand Cat Swarm Optimization algorithm (SCSA) has demonstrated significant applicability across multiple domains, including renewable energy, UAV path planning, sensor networks, machine learning, and engineering

systems. Its ability to optimize complex problems makes it a valuable tool in various scientific and industrial applications.

F. RQ6. What are the Current Limitations of the SCSA, and What Potential Improvements and Future Research Directions can be Identified?

The Sand Cat Swarm Optimization (SCSA) algorithm, since its inception, has garnered significant attention in the field of nature-inspired optimization techniques. However, as with any emerging algorithm, the SCSA has been subject to critical examination, revealing several areas that warrant further research and improvement. This section aims to elucidate the key research gaps that have been identified in the literature, providing a comprehensive overview of the challenges that researchers face in enhancing the SCSA's performance and applicability.

1) Current limitations of the SCSA: By synthesizing findings from various studies, we have identified six primary areas of concern: premature convergence and local optima trapping, imbalance between exploration and exploitation, limited population diversity and quality, computational efficiency issues, adaptability constraints to different problem types, and the need for stronger theoretical foundations. Understanding these research gaps is crucial for guiding future developments in the SCSA algorithm and for positioning it more competitive among other optimization techniques.

These themes are interrelated and collectively contribute to the overall weaknesses of the SCSA algorithm. For example, the issues of premature convergence, local optima, and limited exploration-exploitation balance are closely connected and affect each other. Similarly, the lack of population diversity can exacerbate the problem of getting stuck in local optima.

Addressing these weaknesses has been the focus of many subsequent studies, leading to various improvements and hybrid algorithms. However, these gaps also highlight the ongoing need for further research and development in the field of swarm optimization algorithms as summarized in Table VII.

TABLE VII. RESEARCH GAPS

Research Gaps	Authors	Description
Premature Convergence and Local Optima	[26], [33], [51], [53], [64]	SCSA tends to converge prematurely and get stuck in local optima, limiting its effectiveness in complex optimization problems.
Limited Exploration-Exploitation Balance	[12], [53], [54]	The algorithm struggles to maintain an effective balance between exploring new solutions and exploiting known good solutions.
Low Population Diversity and Quality	[12], [53], [64]	SCSA often generates populations with poor quality and lack of diversity, which can lead to suboptimal solutions.
Low Computational Efficiency	[27]	The algorithm can suffer from slow convergence and high computation time, limiting its applicability to large-scale or time-sensitive problems.
Limited Adaptability to Different Problem Types	[25], [33], [65]	Originally designed for continuous optimization, SCSA requires significant modifications to adapt to other problem domains like binary optimization or specific applications.
Lack of Theoretical Foundations	[43], [65]	There's a gap in the theoretical underpinnings of SCSA, limiting understanding of its performance guarantees and broad applicability.

Table VII provides a concise overview of the main weaknesses identified in the Sand Cat Swarm Optimization algorithm (SCSA), along with the relevant citations that discuss these issues that can be defined as research gaps in SCSA scientific research as more research needs to be done to assess and propose new strategies to overcome these weaknesses. There are six key research gaps and areas for improvement in the SCSA have been identified. These gaps highlight potential directions for future research to enhance the algorithm's performance and applicability.

One of the most significant weaknesses of the standard SCSA is its tendency towards premature convergence and getting trapped in local optima. This issue is particularly problematic for multi-peak functions and complex optimization problems, limiting the algorithm's effectiveness in finding global optimal solutions. The root cause of this weakness appears to be an imbalance between the algorithm's exploration and exploitation phases. Improving this balance is crucial for enhancing the SCSA's ability to efficiently search for the solution space while also refining promising solutions [12], [53], [54].

Another critical area for improvement is the quality and diversity of the initial population. The lack of diversity in the initial population can lead to suboptimal solutions and contribute to the premature convergence problem [12], [53], [64]. Addressing this issue could significantly improve the algorithm's performance across a wide range of optimization scenarios.

Computational efficiency is also a concern for some variants of the SCSA. The slow convergence and high computation time reported in some studies suggest that there is room for improvement in the algorithm's implementation and structure. Enhancing SCSA’s efficiency would broaden its applicability to large-scale or time-sensitive optimization problems [27]. The selection of benchmark algorithms (PSO, GWO, etc.) was guided by their widespread use in swarm intelligence research, structural similarity to SCSA, and their established performance in optimization tasks. While additional comparisons with other metaheuristics could offer further insights, this study focuses on widely accepted benchmarks to ensure consistency and computational feasibility. Future research could explore broader comparisons with algorithms such as WOA and HHO to assess performance variations further.

The SCSA's adaptability to different types of optimization problems has been identified as an area needing further research. Originally designed for continuous optimization problems, the algorithm requires modifications to handle binary optimization tasks like feature selection [66]. Expanding the SCSA's versatility to tackle diverse problem domains, such as face recognition and natural language processing, represents a promising avenue for future work.

From a theoretical perspective, the SCSA and its variants currently lack strong foundational guarantees. The inability to ensure finding the global optimum for all optimization problems, as demonstrated by the No Free Lunch (NFL) theorem [67], underscores the need for more rigorous theoretical analysis of the algorithm's properties and limitations.

2) Future research direction of the SCSA: The Sand Cat Swarm Algorithm (SCSA) has shown great potential, but some challenges need to be addressed to improve its performance and applicability. Below are key areas for improvement and suggested future directions.

To prevent premature convergence and getting stuck in local optima, future studies should focus on better exploration-exploitation balancing strategies. Methods such as adaptive adjustments, chaotic maps, or randomization techniques can help SCSA escape local minima and improve global search [68], [69], [70], [71].

To enhance search efficiency, hybridizing SCSA with other metaheuristic algorithms or integrating machine learning techniques can improve adaptability [72], [73], [74], [75]. Using these methods to adjust parameters dynamically and incorporating memory structures could further refine the search process.

Maintaining population diversity is crucial for avoiding stagnation. Implementing self-adaptive [75], [76], [77], [78], [79] parameter tuning, multi-population strategies, or opposition-based learning can help generate diverse solutions and improve overall performance.

For better computational efficiency, SCSA can benefit from parallel processing and high-performance computing techniques. Implementing GPU acceleration, cloud-based optimization, and surrogate-assisted methods could make the algorithm more scalable for large-scale problems [80], [81], [82].

Expanding SCSA's application to different problem types is another important direction. Future studies should adapt it for combinatorial optimization, multi-objective problems, discrete and real-world datasets, making it suitable for tasks such as scheduling, routing, and engineering optimization [20], [48], [83], [84], [85].

Lastly, strengthening the theoretical foundation of SCSA is necessary for wider acceptance [50], [86]. Future work should focus on proving its convergence properties, establishing benchmark performance comparisons, and applying mathematical models to analyze its behavior.

In conclusion, while the Sand Cat Swarm Optimization algorithm has shown promise in various optimization tasks, these identified research gaps provide clear directions for future enhancements. Addressing issues of premature convergence, exploration-exploitation balance, population diversity, computational efficiency, problem adaptability, and theoretical foundations could significantly improve SCSA's performance and broaden its applicability across different domains. Future research efforts focused on these areas have the potential to elevate the SCSA's standing among nature-inspired optimization algorithms.

V. Conclusion

This systematic literature review has comprehensively analyzed the new variant, application area and performance of the Sand Cat Swarm Algorithm (SCSA) across diverse optimization problems. The analysis findings reveal the algorithm's robust performance in a wide range of benchmark functions, including standard optimization problems, CEC benchmark suites, and real-world engineering challenges. The SCSA and its variants have consistently demonstrated competitive performance against state-of-the-art metaheuristic algorithms, particularly in terms of convergence speed and solution accuracy. Key insights from this review include the versatility of SCSA in handling both unimodal and multimodal optimization landscapes, its scalability across various problem dimensions, and successful adaptations for specific domain applications. These findings underscore the potential of SCSA as a powerful tool in the optimization researcher's toolkit.

The analysis also highlights areas for future research, including further exploration of SCSA's theoretical foundations, development of hybrid algorithms leveraging SCSA's strengths, and extended testing on emerging benchmark suites and real-world problems. As optimization challenges continue to grow in complexity, the insights provided by this review offer valuable direction for researchers and practitioners alike. The demonstrated efficacy of SCSA across diverse problem domains suggests its potential for broader adoption and refinement. Future work building on these findings could lead to significant advancements in solving complex optimization problems across various fields of science and engineering. This comprehensive review provides researchers and practitioners with valuable insights into the current state of SCSA, its practical applications, and promising avenues for future research in the field of metaheuristic optimization.

***Abstracts*—This study aimed to design a minimum data set (MDS) and Data Model for electronic health record system (EHRS) in Indonesia. The content of the MDS in this study is different from the MDS from the results of the study in other advanced countries. The technical preparation of the MDS in this study follows the medical service process provided to patients from the time they first enter the hospital until they complete receiving services at the hospital with the aim that the MDS designed is aligned with real-world hospital workflows. The initial stage of this research began by identifying data elements through literature reviews sourced from medical record documents of general hospitals and psychiatric hospitals in Indonesia, papers regarding minimum data set in other advanced countries, websites, and clinical guidelines. The Delphi technique was employed to validate the identified data elements through a survey of medical experts. A questionnaire was designed to determine data elements in both administrative and clinical departments. There were 5 and 21 data classes agreed upon by experts in the administrative and clinical sections with 28 and 858 data elements, respectively. This MDS could be a reliable tool for data standardization in EHRS that can improve the quality of data and medical services in hospitals. The designed data model consist of conceptual, logical and physical component. This MDS and data model can facilitate system developers to build physical EHRS database and health surveillance center for more efficient health data management.**

Keywords*—Minimum data set; data element; data model; electronic health record; electronic health record system

I. INTRODUCTION

A collection of data items arranged in a standardized manner to facilitate clinical and research use is known as the Minimum Data Set (MDS). It outlines the precise data pieces that must be captured, how they should be stored, and the connections and limitations between them [1]. Standardizing data items and their definitions is the aim of the Minimum Data Set, which is a fundamental component of health data [2]. A well-defined question (variable) and a predetermined range of answers that are used in different studies or shared across data sets make up a common data element [3].

MDS is in the forefront of creating and putting into place an information management system that could enhance the quality of health data and, consequently, services [4]. By consistently identifying necessary data items, the Minimum Data Set (MDS) is a method for standardizing important data within a particular domain and improving the quality of information. Therefore, by standardizing these components, MDS can guarantee data quality and make comparisons easier at the national and international levels [5].

MDS seeks to create a common language for all registry and documentation participants by clearly defining data pieces. Additionally, it guarantees the efficient gathering, evaluation, reporting, and selection of important data [6]. Moreover, MDS improves medical history records, encourages data comparability, helps establish a data repository, makes it easier to share electronic data between various healthcare systems, and eventually raises the quality of data [7].

Administrative and clinical data are two categories into which disease data pieces can be divided according to their nature and purpose. In addition to location, phone number, patient referral information, and the major occupation of healthcare practitioners, administrative data usually includes demographic and socioeconomic information [5]. In contrast, clinical data vary based on the disease type. Typically, they encompass diagnosis, medical history, laboratory results, medical imaging findings, treatment interventions, disease progression, and outcomes [8].

Data sets in the healthcare system provide standardized definitions for each data piece and describe which data items should be gathered for each patient. Research and statistical analysis, internal performance review, and external accreditation are just a few of the uses for data comparison [9]. In order to manage the clinical performance of health organizations in every nation, it is imperative to define standard data models and minimal data sets [10]. The creation of MDS must take into account national norms, needs, and expert viewpoints in addition to the experiences of industrialized nations [11].

Data modelling is the process of determining how data are to be stored in a database. A data model specifies features and relationships, such as: data types, constraints, relationship, metadata. In healthcare system, a data model is an abstract structure that organizes and standardizes data sets and data elements, defining their properties and relationships [12].

The conceptual data model (CDM) in healthcare is to provide a high-level, abstract representation of the data that an organization uses or intends to use in its business operations [13]. In the context of healthcare, a CDM helps bridge the knowledge gap between subject matter experts, IT architects, and designers by depicting the major business information

*Corresponding Author.

objects and their relationships to each other using business terminology. Logical data model (LDM) for an electronic health record system (EHRS) would define the structure of the data elements, their relationships, and the business rules that govern them. It would be used to develop a visual understanding of the data entities, attributes, and relationships specific to the EHRS. Physical data model (PDM) for an EHRS would detail how the logical model is to be implemented in a specific database management system, including the specific data types, constraints, and other implementation detail [14].

Designing a conceptual, logical and physical data model for standardized data collection supports disease information management and leads to better quality of care [15]. Standard health care data model usually indicate minimum data elements that should be collected, a data set is a standard data collection tool [3]. The main objective of the data set is to build a national database that can serve as an information management source to equip decision-makers and policy-makers with accurate and up-to-date information [16].

In recent years, significant research has focused on the MDS and data model for advancing EHRS. Most of these studies concentrate on developing MDS tailored to specific diseases, injuries, or patient groups [17]. MDS for holistic health recording that combines general and specialist MDS is not widely available in the literature.

By taking a case study in Indonesia, where the Indonesian Ministry of Health has never published guidelines on the standardization of MDS and also data models for hospitals or health service centers that want to build or develop EHRS, this study aims to design MDS and data models for the Indonesian EHRS. It is expected that this MDS and data model will facilitate information system developers to build physical EHRS databases and health surveillance centers for more efficient health data management.

II. METHOD

The initial stage of this research began by studying the medical services process and identifying data elements through literature reviews sourced from papers regarding minimum data sets (MDS) and data model in other advanced countries, websites, and clinical guidelines, medical record documents of general hospitals and psychiatric hospitals in Indonesia (Table I). A comprehensive review of recovered resources was carried out until saturation.

In the second stage, the data elements were classified as the leading group, data classes, and data elements. Data class and data element divided into two section data: administrative data and clinical data. Different from the data element content in preliminary research, the design of MDS in this study follows the process of medical services in hospital.

In the third stage, the Delphi technique was employed to validate the identified data elements through a survey of medical experts. A questionnaire was designed to determine data elements in both administrative and clinical section. The questionnaire included administrative data elements and clinical data elements. A five-point Likert scale was used to measure responses of items (strongly agree, agree, enough, disagree, strongly disagree). Additionally, an open-ended question was included at the end of each data element category, allowing experts to suggest additional essential data for the electronic health record system (EHRS).

TABLE I. SEARCH STRATEGY FOR RETRIEVING DATA ELEMENTS FOR EHRS

Sites, Criteria, Strategy	Description
Website	World health organization
Search Engine	Google, Google Scholar
Database	Scopus, PubMed, Web of Science (Up to 30 July 2024)
Inclusion Criteria	Literature in the English language; scientific papers; annual reports; guidelines; books.
Exclusion Criteria	Non-peer-reviewed, reports and forms retrieved from personal blogs and abstracts with no accessible full text.
Keyword	"Electronic Health Record" AND "Data element", "Electronic Health Record" AND "Minimum data set", "Electronic Health Record" AND "Data Model"

The expert selection criteria were knowledge related to medical records and medical services. Experts for the Delphi technique were selected using a purposive sampling method. Overall, 8 (eight) experts were chosen in this step (Table II).

TABLE II. DEMOGRAPHIC CHARACTERISTICS OF EXPERTS

Demographic Characteristic	Amount
Speciality	
Medical Record	2
Physician	2
Nurse	2
Nutritionist	2

The criterion for selecting a data element in the questionnaire was 75% consensus of experts over that. In the first round of Delphi decision-making, the data elements with a consensus of less than 50% were removed. Also, the data elements within 50%-70% were re-examined in the second round, and in case of acquiring more than 75% consensus, that element was considered the final element.

In the fourth stage, technically, the design of the EHRS data model will be carried out in three ways, namely: Transforming and designing EHRS Minimum data set to Conceptual data model, Designing EHRS Logical data model, Designing EHRS Physical data model.

III. RESULTS

The proposed minimum data set (MDS) for Indonesian electronic health record system (EHRS) is more extensive than comparable MDS from hospitals in Iran [18], Australia [19], India [20], and the United States [10] [21]. The design of MDS in this study follows the process of medical services provided to a patient from the beginning of registration to the completion of receiving services at the hospital according with Indonesian regulations on healthcare services [22], can be seen in Fig. 1.

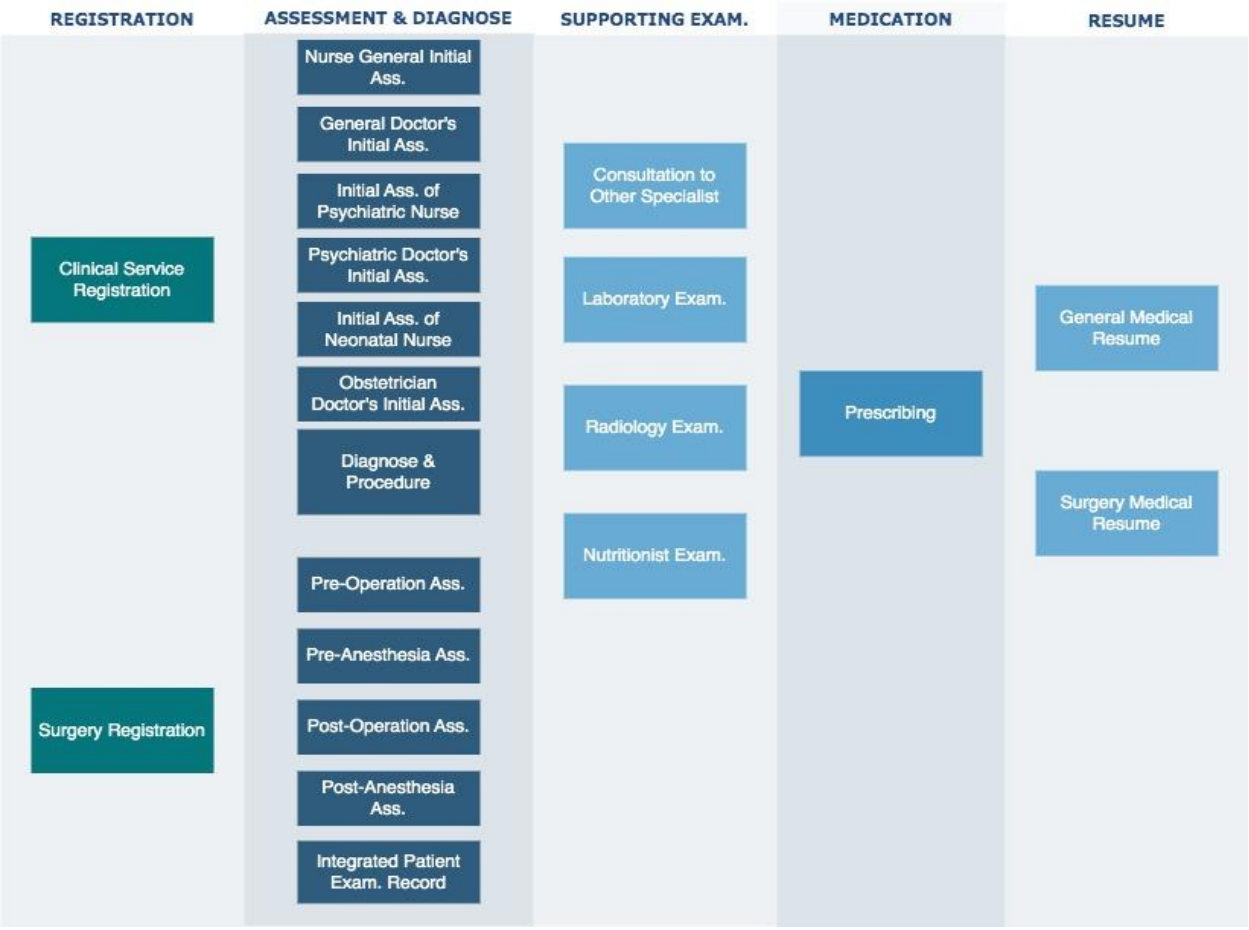

Fig. 1. Medical services process in hospital.

Based on Fig. 1, it can be seen that there are five main processes in medical services where in each process there are 21 sub-processes, which will be explained as follows:

1st Process is the process of registering the patient, divided into:

- Clinical Service Registration
- Surgery Registration

2nd Process is the process of assessing, diagnosing and integrating all the patient's condition by all medical staff providers, divided into:

- Nurse General Initial Assessment
- Initial Assessment of Neonatal Nurses
- Initial Assessment of Psychiatric Nurses
- General Doctor's Initial Medical Assessment
- Obstetrician's Initial Medical Assessment
- Psychiatric Doctor's Initial Medical Assessment
- Initial Nutrition Assessment
- Pre-Operation Assessment
- Pre-Anesthesia Assessment
- Post-Operation Assessment
- Post-Anesthesia Assessment
- Diagnose and Procedure
- Integrated Patient Examination Records

3rd Process is the process of request supporting examinations (if needed):

- Consultation to others specialist
- Laboratory Examination
- Radiology Examination
- Nutrition Examination

4th Process is the process of requesting prescriptions from pharmacies:

- Prescribing

5th Process or the last is the final reporting process:

- General Medical Resume
- Surgical Medical Resume

Based on the analysis of the processes running in medical services, 21 data classes have been determined whose data

elements will be proposed to be identified in the clinical data section, according to the number of sub-processes that exist in medical services. Meanwhile, administrative data elements will be proposed in five different data classes.

To prepare the desired minimum data sets (MDS), two Delphi decision-making stages were done. In the first stage of the Delphi technique, 898 data elements were proposed, which included 37 elements for the administrative data and 861 for the clinical data. In the groups of administrative data, 9 data elements were eliminated out of the 37 proposed ones, due to less than 50% consensus among the experts. Moreover, 21 data elements related to the administrative data underwent a second opinion in the second stage of the Delphi study due to 50%−75% agreement among the experts.

Among the 861 proposed elements for the group of clinical data, only 3 data elements were eliminated. Further, the experts were asked again about 25 data elements, due to 50%−75% agreement over them. In the second stage of the Delphi technique, a total number of 46 data elements (21 administrative data and 25 clinical data in 50%−75% agreement in the first stage) were provided to the experts and all of the data elements were approved.

There were 12 data elements that were eliminated because they did not reach 50% consensus by experts. The final MDS included 886 data elements (28 administrative and 858 clinical data elements) which are summarized in Tables III and IV.

The detailed list of Main, classes and data elements of administrative and clinical data elements in the final model are reported in Tables V and VI.

TABLE III. ADMINISTRATIVE DATA CLASS

Administrative Data Class	suggest D.E	< 0.5%	50-75%	> 75%	< 0.5%	50-75%	> 75%	Final D.E
Demography	8	0	4	4	0	0	4	8
Socio economy	7	0	7	0	0	0	7	7
Residence	5	2	2	1	0	0	2	3
Patient Referral Data	9	3	5	1	0	0	5	6
Healthcare Identifier	8	4	3	1	0	0	3	4
TOTAL	**37**	**9**	**21**	**7**	**0**	**0**	**21**	**28**

TABLE IV. CLINICAL DATA CLASS

Clinical Data Class	Suggested D.E	< 0.5%	50-75%	> 75%	< 0.5%	50-75%	> 75%	Final D.E
Clinical Service Registration	6	1	0	5	0	0	0	5
Nurse General Initial Assessment	107	0	4	103	0	0	4	107
Initial Assessment of Neonatal Nurses	117	0	5	112	0	0	5	117
Initial Assessment of Psychiatric Nurses	85	0	0	85	0	0	0	85
General Doctor's Initial Medical Assessment	59	0	4	55	0	0	4	59
Obstetrician’s Initial Medical Assessment	73	0	7	66	0	0	7	73
Psychiatric Doctor's Initial Medical Assessment	114	1	0	113	0	0	0	113
Pre-Operation Assessment	41	0	0	41	0	0	0	41
Pre- Anesthesia Assessment	56	0	0	56	0	0	0	56
Post Operation Assessment	56	0	0	56	0	0	0	56
Post-Anesthesia Assessment	13	0	0	13	0	0	0	13
Initial Nutrition Assessment	28	0	0	28	0	0	0	28
Surgery Registration	4	0	0	3	0	0	0	4
Integrated Patient Examination Records	14	0	4	10	0	0	4	14
Consultation	8	0	0	8	0	0	0	8
Diagnose & Procedure	4	0	0	4	0	0	0	4
Laboratory Examination	6	0	0	6	0	0	0	6
Radiology Examination	6	0	0	6	0	0	0	6
Prescription	17	1	0	16	0	0	0	16
General Medical Resume	26	0	0	26	0	0	0	26
Surgical Medical Resume	21	0	1	20	0	0	1	21
TOTAL	**861**	**3**	**25**	**833**	**0**	**0**	**25**	**858**

TABLE V. DETAILS OF ADMINISTRATIVE DATA

No	Administrative Data Class	Administrative Data Elements
1	Demography	identity/passport number, med rec number, patient name, patient father's name, sex, nationality, place of birth, date of birth
2	Socio economy	education degree, employment status, type of job, job description, average working hours/week
3	Residence	type of residence, address, mobile phone number
4	Patient Referral Data	medical appointment, type of visit, date of registration, service provider, referral number
5	Healthcare Identifier	Id healthcare, healthcare name, healthcare type/class

TABLE VI. DETAILS OF CLINICAL DATA

No	Clinical Data Class	Clinical Data Elements
1	Clinical Service Registration	Reg ID, Patient ID, Employee ID, Date Check-in, Medical Service Unit
2	Nurse General Initial Assessment	Patient ID, Nurse ID, Reg ID, Complaints, Current Disease History, Past Disease History, Family Disease History, Allergy History, Consciousness Level, Blood Pressure, Temperature, O2 Saturation, Weight, Height, Pain Assessment Score, Fall Risk Score, Nursing Problem Diagnosis, Care Plan and Implementation
3	Initial Assessment of Neonatal Nurses	Patient ID, Nurse ID, Reg ID, Complaint, Family Child Referral, Meconium Aspiration, Umbilical Cord Prolapse, Amniotic Fluid Rupture Time, Family Disease History, Mother's Age, Type of Childbirth, Weight Before Pregnancy, Weight During Pregnancy, Habits During Pregnancy, Baby Weight, Baby Length, Level of Consciousness, Blood Pressure, O2 Saturation, Grasp Reflex, Crying Reflex
4	Initial Assessment of Psychiatric Nurses	Patient ID, Nurse ID, Reg ID, Marital Status, Family Existence, Activities, Suspicions of Abuse/Neglect, Emotional Status, Religion, Educational History, Patient and Family Health History, Self-Concept, Appearance, Conversation, Feelings, Interactions in Interviews, Perception, Thought Flow, Memory, Concentration Level, Suicide Risk, Suicide Risk Category, Violence Risk, Violence Risk Category, Protective Factor, Nursing Diagnosis, Nursing Management Plan
5	General Doctor's Initial Medical Assessment	Patient ID, Physician ID, Reg ID, Complaints, Current Disease History, Past Disease History, Family Disease History, Allergy History, Consciousness Level, Blood Pressure, Temperature, O2 Saturation, Weight, Height, Pain Assessment Score, Fall Risk Score, Nutritional Status, General Condition, Physical Examination, Laboratory Examination, Radiology Examination, Primary Diagnosis, Additional Diagnosis, Management, Advanced Examination, Care Plan, Local Status
6	Obstetrician's Initial Medical Assessment	Patient ID, Physician ID, Reg ID, Complaints, Current Disease History, Past Disease History, Family Disease History, Allergy History, Surgery History, Transfusion History, Trauma History, Consciousness Level, Blood Pressure, Temperature, O2 Saturation, Weight, Height, Pain Assessment Score, Fall Risk Score, Nutritional Status, General Condition, Physical Examination, obstetrics and gynecology Status, Clinical Pelvimetry, Laboratory Examination, Radiological Examination, Primary Diagnosis, Additional Diagnosis, Management, Advanced Examination, Care Plan, Local Status
7	Psychiatric Doctor's Initial Medical Assessment	Patient ID, Physician ID, Reg ID, Main Complaint, Current Mental Disorder History, Past Mental Disorder History, Genogram, Drug History, Personality History Before Illness, Mental Treatment History, Appearance, Awareness, Orientation, Behavioral Attitudes, Thinking Process, Thought Content, Mood, Affect, Hallucinations, Illusions, Concentration Power, Memory, Level of Trustworthiness, Menigeal Signs, Cranial Nerves, Motor System, Vegetative, Laboratory and Radiological Examinations, Panss EC, GAF Score, Psychiatric Diagnosis, Medical Rehab Procedures, Therapy, Follow-up Plan
8	Initial Nutrition Assessment	Patient id, Reg ID, nutritionist id, medical diagnosis, malnutrition risk category, special conditions, dietary prescription, weight, height, nutritional status, general clinical, clinical complaints, dietary history of food intake, dietary history of food abstinence, intervention, monitoring evaluation
9	Surgery Registration	Surgery ID, Registration ID, Employee ID, Diagnose
10	Pre-Operation Assessment	Surgery ID, Patient ID, Surgery Time, Respiration, O2 Saturation, Blood Pressure, Pulse, Temperature, Consciousness Level, Action Plan, Implementation, Orientation Evaluation, Vital Evaluation, Surgical Tools Evaluation, Antibiotic Evaluation
11	Pre-Anesthesia Assessment	Anesthesia ID, patient ID, pre-operative diagnosis, action plan, anamnesis, anesthesia history, systole, diastole, pulse, respiratory, temperature, respiratory system, cardio system, hepatic system, ECG examination, anesthesia risk, anesthesia plan, pre-medication
12	Post Operation Assessment	Surgery ID, Patient ID, Entry Time, Exit Time, Respiration, O2 Saturation, Pulse, Temperature, Consciousness Level, Pain Scale, Pain Location, Action Plan, Implementation, Pain Evaluation, Pulse Evaluation, Respiratory Evaluation, Therapy Evaluation, Analgetic Evaluation
13	Post-Anesthesia Assessment	Anesthesia ID, Patient ID, Entry Hours, Exit Hours, Tools Type, Tools Score, Infusion, Transfusion, Analgetic Program
14	Integrated Patient Examination Records	Patient id, Reg ID, employee id, SOAP, Instruction, Physician verifier id, Physician verification date
15	Consultation	Consultation ID, Reg ID, Consular Doctor, Diagnosis, Clinic History, Type of Consultation, Destination Unit, Consular Destination Doctor
16	Diagnose & Procedure	ICD 10 code, ICD 10 description, ICD 9 code, ICD 9 description
17	Laboratory Examination	Lab ID, Reg ID, Unit, Doctor, Diagnosis, Lab Record
18	Radiology Examination	Rad ID, Reg ID, Unit, Doctor, Diagnosis, Rad Record
19	Prescription	Prescription ID, Reg ID, Patient ID, Doctor ID, Pharmacy ID, Chronic Status, Concoction Status, Diagnosis, Quantity, Dosage, Dosage, Instructions

20	General Medical Resume	Resume ID, Reg ID, patient ID, doctor ID, complaints, disease history, vital sign examination, lab examination, radiology examination, primary diagnosis, action, discharge status, follow-up plan
21	Surgical Medical Resume	Surgery ID, Reg ID, Patient ID, Pre-Operative Diagnosis, Primary Diagnosis, Operating Hours Started, Surgical Procedure, Surgical Procedure, Surgical Procedure, Surgical Details, Instructions

After the final version of MDS that has been selected and validated by experts is determined, the next stage is the design of the conceptual, logical and physical data model for EHRS. The conceptual data model of EHRS can be seen through Fig. 2.

Furthermore, after designing the conceptual data model, the next step is to design the logical and physical data model [13]. Logical data models help to define the detailed structure of the data elements in a system and the relationships between data elements. A physical data model is a representation of how data is stored, organized, and accessed in a database system. It takes into account the specifics of the underlying hardware, software, and database management system (DBMS). Unlike a logical data model, which focuses on abstract relationships and structures, the physical model is concerned with how data is physically implemented. The Physical data model of EHRS can be seen in Fig. 3.

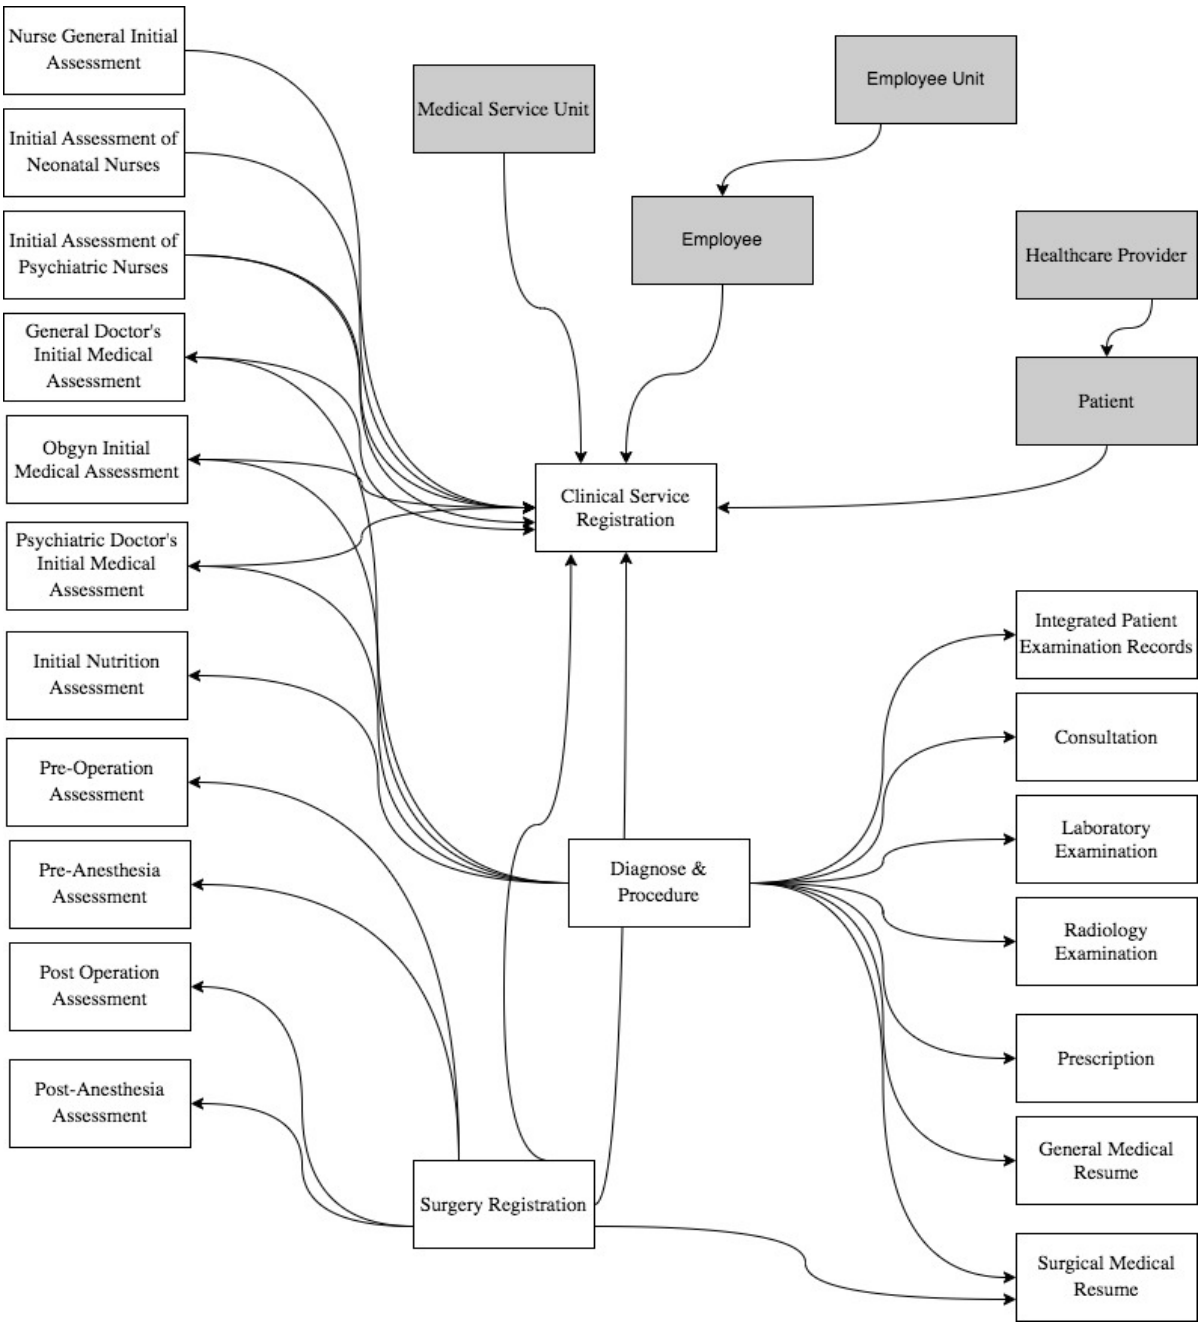

Fig. 2. Conceptual data model of EHRS.

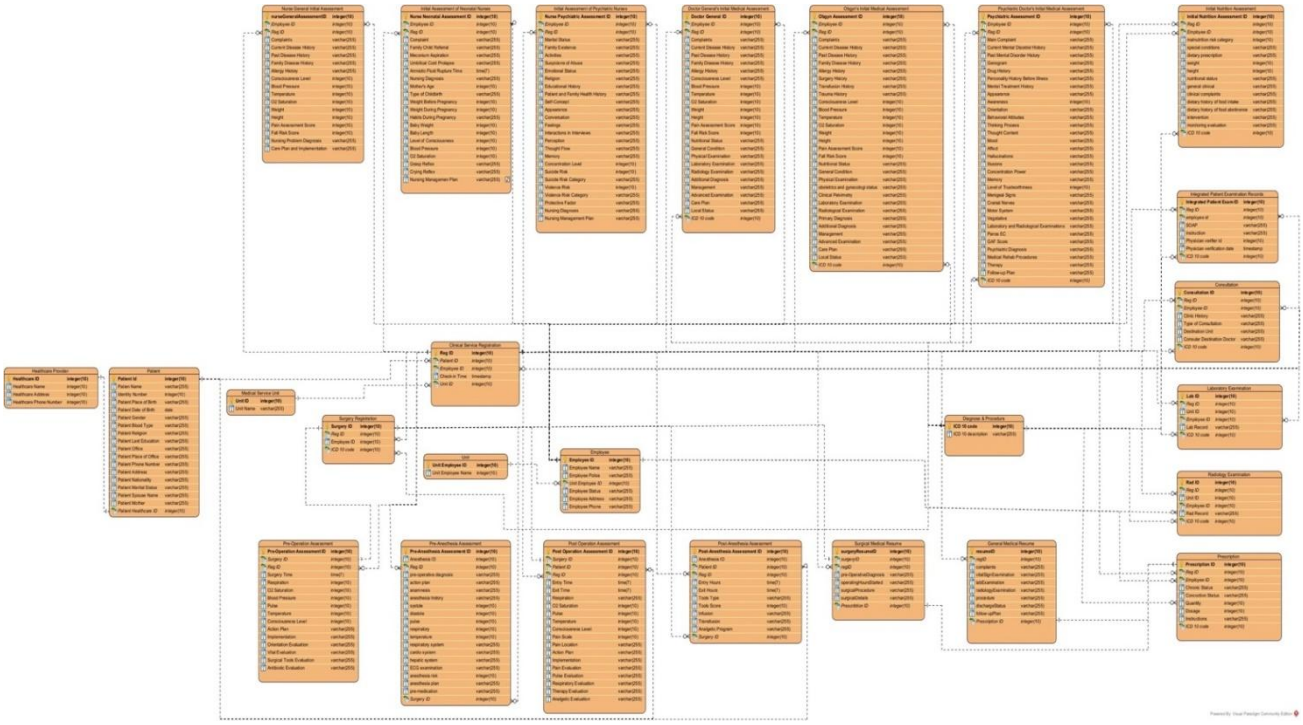

Fig. 3. Physical data model of EHRS.

IV. DISCUSSION

The designed minimum data set (MDS) for Indonesian electronic health record system (EHRS) has administrative and clinical sections. In this study, the administrative data were categorized into five different data classes. The first class of this data set is demographics. In this section, there are several data elements including identity/passport number, medical rec number, patient name, patient father's name, sex, nationality, place of birth, and date of birth. These data elements are used in most minimum data sets in countries with ethnic and migratory populations.

In the class of socio economy, some data elements related to patient socio economy are education degree, employment status, type of job, job description, and average working hours/week. Most of these data elements are similar to data elements for admission in other studies in the Islamic Republic of Iran [18] and the minimum data sets of other countries: Australia [19], India [20], and the United States [10][21]. In the class of residence, type of residence, address, and mobile phone number are the proposed data elements.

In the class of patient referral data, medical appointment, type of visit, date of registration, service provider, and referral number are the proposed data elements. Followed by Id healthcare, healthcare name, and healthcare type/class as part of the data class of healthcare identifier. These data are similar to the financial data elements in most minimum data sets in other countries [10][11][18][19][20].

The proposed clinical section had 21 data classes. Compared with similar minimum data sets in other countries [10][11][18][19][20], our proposed clinical data set has more data elements. We tried to include as many clinical data elements of the patient's medical record as possible.

In contrast to the minimum data sets of other countries, the nurse assessment data class is divided into three types, according to the medical services provided by the nurse, including the initial assessment data class of general nurses, the initial assessment of neonatal nurses, and the initial assessment of psychiatric nurses. The nurse general initial assessment data class was the first class of the clinical section with 107 data elements. This class includes anamnesis, physical examination, vital sign examination, nursing problems, nursing intervention, and nursing care plan, etc. This data element is generally the content of nursing assessments that are used according to the world's health service standard [23][24].

The initial assessment of neonatal nurse class is a data class that represents the need for data in the medical service process for babies born prematurely commonly called neonatal services. Data elements that distinguish it from the general nurse assessment include the order of the child in the family, meconium aspiration, umbilical cord prolapse, time of amniotic fluid rupture, family history of disease, mother's age, type of childbirth, weight before pregnancy, weight during pregnancy, habits during pregnancy, baby's weight, baby length, baby's level of consciousness, baby's grip reflex, baby's crying reflex and others. This is the data class with the highest number of data elements from other data classes, which is as many as 117 data elements. The data element in this data class also refers to the neonatal nursing assessment used in various health services [25][26].

The psychiatric nurse initial assessment data class is a data class that represents data needs for medical services for patients with mental disorders, generally, these services are provided in

mental hospitals with data elements including Family Existence, Activities, Suspicions of Abuse/Neglect, Emotional Status, Religion, Educational History, Patient and Family Health History, Self-Concept, Appearance, Conversation, Feelings, Interactions in Interviews, Perception, Thought Flow, Memory, Concentration Level, Suicide Risk, Suicide Risk Category, Violence Risk, Violence Risk Category, Protective Factor, Nursing Diagnosis, Nursing Management Plan. This reference is taken from several studies related to psychiatric medical services [27] [28] [29][30].

Furthermore the data class for services provided by doctors, including the data class of general doctor's initial medical assessment, Obstetrician doctor's initial medical assessment, and psychiatric doctor's initial medical assessment. The general doctor's initial medical assessment data class has 59 data elements including previous disease history, family disease history, allergy history, nutritional status, physical examination, laboratory examination, radiological examination, primary diagnosis, additional diagnosis, management, advanced examination, care plan, and local status, others. This data element is generally the content of the initial medical assessment used according to health service standards in other studies [23][24].

All data elements in the general doctor's initial medical assessment data class are also found in the obstetrician doctor's initial medical assessment data class. What distinguishes this class is the existence of data elements: pregnancy status, and clinical pelvimetry which is useful for representing the patient's pregnancy condition, others. The data elements in the obstetrician assessment data class are referenced from the common and specific neonatal studies [25] [26].

In contrast to the data class in the general doctor and obstetrician initial medical assessment, the psychiatric initial medical assessment data class focuses on medical services for patients with mental disorders, and has 113 data elements including Current Mental Disorder History, Past Mental Disorder History, Genogram, Drug History, Personality History Before Illness, Mental Treatment History, Appearance, Awareness, Orientation, Behavioral Attitudes, Thinking Process, Thought Content, Mood, Affect, Hallucinations, Illusions, Concentration Power, Memory, Level of Trustworthiness, Menigeal Signs, Cranial Nerves, Motor System, Vegetative, Laboratory and Radiological Examinations, Panss EC, GAF Score, Psychiatric Diagnosis, Medical Rehab Procedures, Therapy, Follow-up Plan, Others. The data elements in the psychiatric initial medical assessment data class are referenced from the common and specific studies [27][28] [29][30].

The next class of data is for the assessment of medical services in the operating room, divided into two types of services, namely surgical medical services and anesthesia medical services. Surgical medical services consist of pre-operative assessment data classes and post-surgical assessments. Referring to the literature on surgery [31][32][33], the data elements in the preoperative assessment class include operation time, respiration, O2 saturation, blood pressure, pulse, temperature, level of consciousness, action plan, implementation, orientation evaluation, vital evaluation, surgical tools evaluation, antibiotic evaluation. What is bold with data elements in the post-operative assessment class includes pain scale, pain location, action plan, implementation, pain evaluation, pulse evaluation, respiratory evaluation, therapy evaluation, and analgetic evaluation.

Meanwhile, medical anesthesia services, it is divided into pre-anesthesia assessment data classes and post-anesthesia assessment data classes. Referring to the literature on anesthesia studies [31][32][33], the pre-anesthesia assessment data class consists of data elements: pre-operative diagnosis, action plan, anamnesis, anesthesia history, systole, diastole, pulse, respiratory, temperature, respiratory system, cardio system, hepatic system, ECG examination, anesthesia risk, anesthesia plan, premedication. Meanwhile, what distinguishes it from the post-anesthesia assessment data class are the data elements: entry hours, exit hours, types of tools, tool scores, infusions, transfusions, and analgetic programs.

The last data class that is included in the assessment category is the nutrition assessment data class which contains data elements: malnutrition risk category, special conditions, dietary prescription, weight, height, nutritional status, general clinical, clinical complaints, dietary history of food intake, dietary history of food abstinence, intervention, monitoring evaluation [34][33] [36] [35].

After all classes of assessment data are identified, it continues to the class of integrated patient development records which contains data elements regarding Subject, Object, Action, and Planning referring to the international standard for writing integrated patient development records [23][24] [25]. The Consultation data class is required for the consultative process with other doctors in handling a patient, with data elements including consular doctor, diagnosis, clinical history, type of consultation, destination unit, and consular destination doctor.

Diagnosis and Procedure are two important data classes that must be present in the medical service process referring to many existing MDS, where each data class contains data elements regarding the description of the diagnosis along with the ICD-10 code and the description of the procedure along with the ICD-9 code [37][38]. The other two data classes that fall under the pre-clinical data category are the Laboratory and Radiology data classes. Each data class contains data elements: sending unit, doctor, diagnosis, laboratory record, or radiology record. Some other studies have included most of these data [39][40][41].

The important data class at the end of the medical service process is the resume data class, which is divided into the general medical resume data class and the surgery medical resume. Referring to minimum data sets in various studies [23][24][25][26][27][28] , the data element in the general medical resume data class, contains about: lab examination records, radiological examination records, primary diagnosis, actions, discharge status, and follow-up plans, others. Meanwhile, the data element in the surgery medical resume data class contains data on preoperative diagnosis, primary diagnosis, operating hours, surgical procedures, surgical actions, surgical details, and instructions, others referring to the international surgical MDS [31][32][33].

V. Limitations and Future Work

The results of this research have limitations that allow for development in subsequent research. Because the main focus of this research is to design the Minimum Data Set (MDS) and data model for the electronic health record system (EHRS) in Indonesia, this research does not discuss data security and data privacy of the designed data set.

The completeness of the MDS and data model that have been designed for EHRS in Indonesia should also be compared with the internationally used data framework standards such as Health Level 7 (HL7) and Fast Healthcare Interoperability Resources (FHIR), so that in the future it can develop into a data architecture that can be used on enterprise scale and can accommodate the process of data interoperability between health care facilities.

Furthermore, the follow-up to the results of this research, the MDS and data model that have been designed should also be evaluated and implemented in hospitals through the development of EHRS Applications, and evaluated by IT Hospital Experts or database experts to measure correctness, integrity and flexibility through data evaluation metrics [42].

VI. Conclusion

Designing MDS and data model is the first fundamental step to establish electronic health record systems (EHRS) in Indonesia. The design of MDS in this study follows the process of medical services provided to a patient from the beginning of admission to the completion of receiving services at the hospital, complies with Indonesian regulations on healthcare services.

The Delphi technique was employed to validate the identified data elements through a survey of medical experts. A questionnaire was designed to determine data elements in both administrative and clinical departments. There were 5 and 21 data classes agreed upon by experts in the administrative and clinical sections with 28 and 858 data elements, respectively. The design of the EHRS data model carried out in three ways, namely: Conceptual data model, Logical data model, and Physical data model.

This MDS could be a reliable tool for data standardization in EHRS that can improve the quality of data and, thus care and services related to medical services in hospitals. Therefore, decision-makers, policy-makers, and information system vendors can use this tool as a prerequisite for the selection or development of an EHRS.

Optimization of LED Luminaire Life Prediction Algorithm by Integrating Feature Engineering and Deep Learning Models

Xiongbo Huang*
Information Technology Center, Foshan Vocational and Technical College, Foshan 528137, China

***Abstract*—With the wide application of LED luminaires in various fields, it has become particularly important to accurately predict their lifetime. The lifetimes of LED luminaires are affected by a variety of factors, including temperature, current, voltage, light intensity, and operating time, and there are complex interactions among these factors. Traditional prediction methods are often difficult to capture these nonlinear relationships, so a more powerful prediction model is needed. In this study, we aim to develop an efficient life prediction model for LED luminaires, and propose a hybrid neural network structure that incorporates a convolutional neural network (CNN), a long short-term memory network (LSTM), and an attention mechanism by combining feature engineering and deep learning techniques. In the research process, we first collected the operation record data provided by a well-known LED lighting manufacturer and performed detailed data preprocessing, including missing value processing, outlier detection, normalization/standardization, data smoothing, and time series segmentation. Then, we designed and implemented several benchmark models (e.g., linear regression, support vector machine regression, random forest regression, and deep learning model using only LSTM) as well as the proposed hybrid neural network model. Through a detailed experimental design including parameter setting, training and testing, we evaluate the performance of these models and analyze the results. The experimental results show that the proposed hybrid neural network model significantly outperforms the conventional model in key performance metrics such as root mean square error (RMSE), mean absolute error (MAE) and coefficient of determination (R^2). In particular, the hybrid model outperforms in terms of Mean Absolute Percentage Error (MAPE) and Maximum Absolute Error (Max AE). In addition, through cross-validation and testing on different datasets, the model shows stable performance under various environments and conditions, verifying its good generalization ability and robustness.**

Keywords*—Feature engineering; deep learning; LED lamps; life prediction; algorithm optimization

I. INTRODUCTION

With the global awareness of energy saving and environmental protection as well as the continuous advancement of technology, LED (light emitting diode) lamps have become one of the most promising products in the lighting field [1]. Since the 1990s, LED lighting has gradually replaced traditional lighting methods such as incandescent and fluorescent lamps due to its high efficiency, long life and low maintenance costs. According to market research organizations, the global LED market will reach tens of billions of dollars by 2025, showing a strong growth trend. Against this background, how to effectively extend the service life of LED lamps and improve their reliability and stability has become a key concern for both academia and industry [2, 3].

However, in the process of practical application, although LED lamps and lanterns have a theoretically long working life, their actual service life is often difficult to reach the expected value due to a variety of factors, such as the working environment conditions (temperature, humidity), power supply quality, and the aging speed of materials [4]. In addition, for manufacturers, accurate prediction of the life of LED lamps and lanterns not only helps to optimize product design and reduce production costs, but also enhances customer trust and promotes brand building. Therefore, it is of great theoretical significance and practical value to carry out research on the life prediction of LED lamps and lanterns [5].

The current methods on LED luminaire life prediction can be mainly divided into two categories: methods based on physical models and methods based on data-driven methods. The former builds mathematical models by analyzing the internal structure of LEDs and their working principles. The latter relies on a large amount of historical data for statistical analysis or machine learning training [6]. Although each of these methods has achieved certain results, there are some shortcomings. For example, physical model-based approaches usually require an in-depth understanding of the specific construction details of LEDs, which is not easy to realize for ordinary users. And traditional data-driven methods may have poor prediction accuracy due to the lack of effective feature extraction mechanisms [7].

In this paper, we aim to combine advanced feature engineering techniques with deep learning algorithms to propose a novel LED luminaire lifetime prediction framework, with a view to overcoming the above challenges and significantly improving the prediction performance. Specifically, we first identify the key factors affecting the lifetime of LED luminaires by comprehensively analyzing the heterogeneous data from multiple sources generated during the operation of LED luminaires, and design a reasonable feature engineering scheme accordingly. Next, a carefully selected deep neural network architecture is utilized as the base predictor, combined with a transfer learning strategy to solve the problem of insufficient sample size [8]. Finally, the effectiveness and superiority of the proposed method is demonstrated through a series of experiments.

II. Review of Relevant Work

A. Application of Feature Engineering to Life Prediction

Feature engineering is a crucial step in the machine learning process, which involves extracting useful features from raw data to improve model performance. For lifetime prediction, effective feature selection or construction can significantly enhance the model's ability to learn complex patterns. For example, in life prediction of electronic products, engineers usually consider physical quantities such as temperature variations and current fluctuations as input features. In the field of mechanical equipment, on the other hand, more attention may be paid to factors such as vibration signal analysis and wear and tear. These carefully selected or transformed features can help algorithms better capture key information that affects the target variables [9, 10].

In recent years, with the growth of computing power and the development of big data technology, automatic feature selection methods based on statistics and machine learning have become popular. Such methods are not only capable of handling large-scale datasets, but also of discovering potential associations that are difficult to recognize by traditional means. For example, Random Forests can filter out the most influential attributes by evaluating the importance of each feature. Principal Component Analysis (PCA), on the other hand, is a commonly used dimensionality reduction technique that maps the original high-dimensional space to a new space of lower dimensions while retaining as much information as possible from the original data. Nonetheless, when dealing with specific industries such as LED lighting, generalized methods often need to be further adapted to achieve optimal results [11].

B. Deep Learning Techniques and Their Performance on Prediction Problems

In 2022, the paper in [12] proposed a hybrid model combining Transformer and LSTM for power equipment fault prediction. This model effectively captures long sequence dependencies through the self-attention mechanism. In 2023, [13] fused CNN and LSTM and applied it to traffic flow time series prediction, using CNN to extract spatial features and LSTM to process temporal features. Compared with these studies, the hybrid model in this paper is designed for LED lamp life prediction in terms of feature extraction, model structure and application scenarios, which further highlights the innovation and value of the research and broadens the research horizon in this field.

Deep learning, as a powerful artificial intelligence technology, has achieved great success in recent years in a variety of fields such as image recognition and natural language processing. Its core advantage lies in its ability to automatically learn complex representations from large amounts of unlabeled data with good generalization ability. For the task of time series prediction, Recurrent Neural Networks (RNNs), especially Long Short-Term Memory Networks (LSTMs), are widely recognized as one of the very effective tools [14]. Their ability to remember long-term dependencies and adapt to the behavioral patterns of nonlinear dynamical systems makes them particularly suitable for dealing with data that have significant trends or seasonality. In addition to this, Convolutional Neural Networks (CNNs) are also used in some special prediction scenarios. For example, if the target variable to be predicted is closely related to its spatial distribution, CNN's powerful local sensing ability and parameter sharing mechanism can be utilized for feature extraction. It is worth noting that although deep learning models usually perform well, they also suffer from problems such as long training time and easy overfitting, especially when the sample size is relatively small [15, 16]. Therefore, it is often necessary to incorporate other technical tools, such as regularization strategies or migration learning, to mitigate the negative impact of these problems in practical applications.

C. LED Lamp Life Prediction

Research on life prediction for LED luminaires can be broadly divided into two main categories: physical modeling-based approaches and data-driven approaches. The former mainly relies on an in-depth understanding of the internal structure and material properties of LEDs, and simulates the working process of the device by establishing an accurate mathematical model. This type of approach has the advantage of providing a more intuitive physical explanation, but in practice it is often limited by the difficulty of obtaining the required parameters and the complexity of the model itself [17, 18]. In contrast, the latter focuses more on learning patterns directly from historical records without the need to assume any particular form of relational expression in advance. With the proliferation of sensor technologies and Internet of Things (IoT) platforms, more and more studies have begun to explore how to effectively utilize the collected data on various operating states to improve prediction accuracy. Specifically, some scholars have proposed the use of classical machine learning algorithms such as support vector machines (SVMs) and decision trees for classification or regression analysis. These attempts proved that even in a relatively simple framework, good prediction results can still be obtained with proper feature selection. However, with the deepening of research, it has been found that traditional shallow models can hardly fully explore the deep connections hidden behind the massive multi-source heterogeneous data. Therefore, in recent years, more and more attention has turned to more advanced deep learning architectures [19, 20].

D. Evaluation and Comparison of Existing Methods

It can be seen from the combing of the above literature that some progress has been made in the current research on LED luminaire life prediction, whether based on physical modeling or data-driven approaches. However, each method has its scope of application and limitations. Although the physical modeling method has a solid theoretical foundation, it is difficult to adapt to the needs of all situations due to the lack of flexibility. And although purely relying on data-driven methods is easy to operate, it is easy to ignore the underlying root causes. More importantly, most of the existing work utilizes one of the technical tools alone, and few examples of organic combination of the two have been seen [21, 22].

III. Methodology

In order to construct an efficient and accurate LED luminaire life prediction model, this study adopts a systematic methodology, including data collection and preprocessing, feature selection and engineering, design of deep learning

architecture, model training and tuning process, and definition of performance evaluation metrics [23].

A. Data Collection and Pre-processing

The dataset was provided by a well-known LED luminaire manufacturer and covers records of several models of LED luminaires operating in different environments. These records contain time series data (e.g. temperature, current, voltage, etc.) as well as information on the final lifetime of the luminaire. In addition, some static attributes, such as manufacturing lot, material type, etc., are also included. In order to ensure the quality and representativeness of the data, we have strictly screened the data and excluded records that are obviously abnormal or incomplete [24].

Raw data usually suffers from noise, missing values, etc., so a series of preprocessing steps are required to improve the effectiveness of the subsequent analysis. First, for a small number of missing data points, we use interpolation (e.g., linear interpolation or spline interpolation) to fill them in. If the missing rate of a feature is too high, the feature is considered to be removed. Next, statistical methods are utilized to identify and remove extreme values that may affect model training. In order to eliminate differences in magnitude between features, we use Min-Max scaling or Z-Score normalization to transform all numerical features to the same scale range [25].

B. Feature Selection and Principal Component Analysis

1) Feature selection: Feature selection is one of the key steps in improving model performance. By selecting the most influential features, model complexity mitigated, prediction accuracy can be improved, and the risk of overfitting can be reduced. In this study, we used several methods to identify the most influential features, including correlation analysis and mutual information [26].

The temperature feature is retained because the luminous efficiency and life of LED lamps are closely related to temperature. According to the principles of semiconductor physics, high temperature will accelerate the chemical reaction inside the LED chip, resulting in increased light decay. Domain knowledge shows that within a certain temperature range, the life of LED lamps may be shortened by 20% - 30% for every 10°C increase in temperature, so temperature is a key feature. The current feature is retained because excessive current may cause the LED chip to overheat and cause irreversible damage. Industry standards and past studies have pointed out that the life of the lamp will be significantly reduced if the rated current exceeds 10%. When selecting features, refer to the relevant standards of the International Commission on Illumination (CIE) and combine expert experience to screen the initial features to ensure that the retained features have a key impact on the prediction of the life of LED lamps.

To ensure the robustness of the Pearson correlation coefficient and mutual information threshold, a method of cross-validation combined with sensitivity analysis was used. The data set was divided into multiple subsets, and the feature selection results under different thresholds were calculated on different subsets, and the model performance was evaluated. Through multiple cross-validations, the model's ability to handle nonlinear and irrelevant relationships under different threshold combinations was observed. At the same time, a sensitivity analysis was performed to study the impact of slight changes in the threshold on feature selection and model performance. If the model performance fluctuates less when the threshold changes, and it can effectively identify nonlinear relationships and filter irrelevant relationships, it means that the threshold has good robustness. The final threshold is the optimal choice after comprehensive consideration of model stability and accuracy.

The Pearson Correlation Coefficient (PCC) is a commonly used measure of the linear relationship between two variables. It is defined as Eq. (1).

$$r_{xy} = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2 \sum_{i=1}^{n}(y_i - \bar{y})^2}} \quad (1)$$

where x_i and y_i are the eigenvalues and objective values of the ith sample, respectively. n is the number of samples. $\bar{x}$ and $\bar{y}$ are the mean values of the eigenvalues and objective, respectively. n is the number of samples. The Pearson's correlation coefficient r_{xy} is in the range of [-1, 1], and $r_{xy} = 1$ denotes perfect positive correlation. $r_{xy} = -1$ The value of Pearson's correlation coefficient ranges from [-1, 1], indicates perfect negative correlation.

In practice, we compute the Pearson's correlation coefficient between each feature and the target variable and retain those features that are significantly correlated. Typically, we can set a threshold $|r| > 0.5$ and retain only those features whose absolute value is greater than this threshold.

Mutual Information (MI) is a measure of nonlinear dependence between two random variables. It is based on the concept of entropy in information theory, defined as Eq. (2) [27].

$$I(X;Y) = \sum_{x \in X} \sum_{y \in Y} p(x,y) \log\left(\frac{p(x,y)}{p(x)p(y)}\right) \quad (2)$$

Where $p(x, y)$ is the joint probability distribution of X and Y . p(x) and p(y) are the marginal probability distributions of X and Y, respectively. A larger value of the mutual information I (X; Y) indicates a stronger dependence between X and Y. Mutual information captures both linear and nonlinear relationships and is therefore more comprehensive than the Pearson correlation coefficient [28].

In practice, we compute the mutual information between each feature and the target variable and retain those features with higher mutual information values. Similarly, a threshold can be set (e.g., I (X; Y) > 0.5, and only features greater than this threshold are retained).

2) Principal Component Analysis (PCA): Despite the initial selection, the dataset may still contain redundant information. For this reason, Principal Component Analysis (PCA) is further applied to reduce the dimensionality and extract the main components. The basic idea of PCA is to find a new set of basis vectors such that the variance of the projected data is maximized. Assume that the original data matrix is $X \in \mathbb{R}^{n \times p}$, where n is the number of samples and p is the number of features. The process of PCA can be described as the following steps, and its flowchart is shown in Fig. 1 [29].

a) Centered data: Subtracting the mean of each column yields X_c.

b) Calculate the covariance matrix at $\Sigma = \frac{1}{n-1} X_c^T X_c$.

c) Solve for eigenvalues and eigenvectors: Obtain the eigenvalues $\lambda_1, \lambda_2, ..., \lambda_p$ and the corresponding eigenvectors $v_1, v_2, ..., v_p$ of the covariance matrix.

d) Sorting and selecting the first k principal components: sort the eigenvalues in descending order of magnitude and select the first k largest eigenvalues and their corresponding eigenvectors.

e) Transformed data: The original data are projected onto the selected k principal components to obtain the downscaled data $Z \in \mathbb{R}^{n \times k}$.

$Z = X_c V_k$ where V_k is the matrix consisting of the first k eigenvectors [30].

C. Deep Learning Architecture Design

As shown in Fig. 2, in this paper, we propose a novel hybrid neural network architecture that combines convolutional neural networks (CNNs) and long-short-term memory networks (LSTMs), aiming to fully utilize the strengths of both.

The deep learning architecture proposed in this paper aims to effectively extract and utilize key features in multidimensional time series data to improve the accuracy of LED luminaire lifetime prediction. The architecture consists of the following main components:

1) Input layer: Accepts multi-dimensional time series data after Principal Component Analysis (PCA) dimensionality reduction, which contain key factors affecting the lifespan of LED luminaires.

2) Convolutional layers: The multiple convolutional kernels are used for feature extraction from the input data, and each convolutional layer is back-connected to the ReLU activation function to introduce nonlinearities and to reduce the spatial dimensions of the feature maps by a maximal pooling operation so as to preserve the most important local features.

3) LSTM layer: It receives the time series features output from the convolutional layer and learns complex temporal patterns through multiple stacked Long Short-Term Memory (LSTM) units. LSTM is capable of capturing long-term dependencies and is suitable for processing data with temporal dynamics.

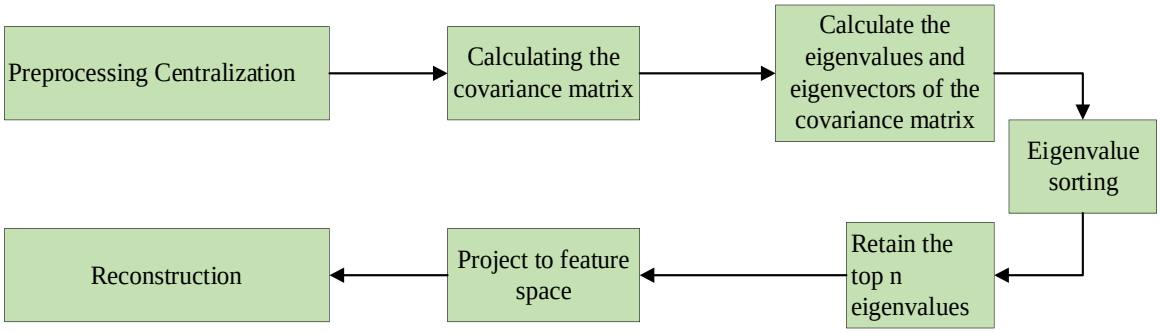

Fig. 1. PCA framework diagram.

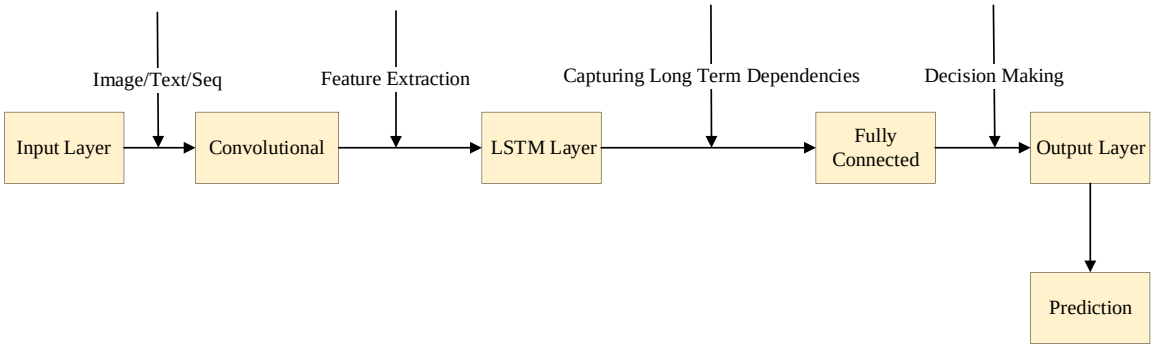

Fig. 2. Model architecture.

4) Attention layer: An attention module is added after the LSTM layer to compute the importance weights for each time step, which are then weighted and summed to obtain the final contextual representation. The attention mechanism allows the model to adaptively focus on the most important time segments, thus enhancing the model representation.

5) Fully-connected layers: Mapping the output of the attention layer to the final prediction results, further feature fusion and abstraction is performed through a series of fully-connected neural network layers.

6) Output Layer: Produces an estimate of the remaining useful life of the luminaire, providing the user with an intuitive and accurate prediction.

Suppose the input time series data is $X \in \mathbb{R}^{N\times T\times D}$, where N denotes the number of samples, T denotes the time length, and D denotes the feature dimension. After convolutional layer processing, it is obtained as $H_{conv} \in \mathbb{R}^{N\times T'\times F}$, where T' is the length of the sequence after convolution and F is the number of convolutional kernels. The hidden state of the LSTM layer is denoted as $h_t \in \mathbb{R}^{H}$, and H is the number of hidden layer units. The attention weight α_t is calculated as shown in Eq. (3) and Eq. (4). Where W_a and b_a are learnable parameters. The final context vector c is shown in Eq. (5).

$$\alpha_t = \frac{\exp(e_t)}{\sum_{t'=1}^{T'} \exp(e_{t'})} \tag{3}$$

$$e_t = W_a h_t + b_a \tag{4}$$

$$c = \sum_{t=1}^{T'} \alpha_t h_t \tag{5}$$

D. Model Training and Tuning Process

Considering the characteristics of the lifetime prediction problem, we choose the mean square error (MSE) as the loss function, as shown in Eq. (6).

$$\text{Loss} = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2 \tag{6}$$

Where y_i is the true life and $\hat{y}_i$ is the predicted life.

In order to accelerate convergence and avoid falling into local optima, we choose the Adam optimizer. Adam combines the advantages of momentum gradient descent and RMSprop, and is able to dynamically adjust the learning rate during training. The choice of hyperparameters has an important impact on the model performance.

In a small data set (such as data set A with 5000 samples), in order to confirm that there is no overfitting or suboptimal convergence using the Adam optimizer (learning rate 0.001), the strategy of early stopping combined with monitoring the validation set indicators is adopted. During the training process, the loss value and accuracy of the training set and validation set are recorded for each epoch. When the validation set loss no longer decreases within 10 consecutive epochs, the early stopping mechanism is triggered. At the same time, the loss curve and accuracy curve during the training process are plotted to observe the convergence trend of the model. If the curve shows that the loss of the training set and the validation set are gradually decreasing and stabilizing, and the accuracy is continuously improving and maintaining good performance on the validation set, it means that the model has not experienced overfitting and suboptimal convergence, and can effectively learn on a small data set.

E. Definition of Performance Assessment Indicators

In order to fully evaluate the performance of the model, we define the following key performance indicators. Root Mean Square Error (RMSE): used to measure the degree of deviation between the predicted and true values. It is specified as shown in Eq. (7).

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2} \tag{7}$$

The mean absolute error (MAE) reflects the absolute difference between the predicted value and the true value, as shown in Eq. (8).

$$\text{MAE} = \frac{1}{N}\sum_{i=1}^{N}|y_i - \hat{y}_i| \tag{8}$$

The coefficient of determination (R^2) indicates the proportion of variability explained by the model and takes a value ranging from 0 to 1, with closer to 1 indicating a better fit. This is specifically shown in Eq. (9).

$$R^2 = 1 - \frac{\sum_{i=1}^{N}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{N}(y_i - \bar{y})^2} \tag{9}$$

Relative error (RE) is used to compare the prediction accuracy at different scales, as shown in Eq. (10).

$$\text{RE} = \frac{|y_i - \hat{y}_i|}{y_i} \times 100\% \tag{10}$$

The CNN-LSTM-Attention hybrid model in this study is unique in its architectural design. In the CNN layer, a deformable convolution kernel is innovatively used, which can adaptively adjust the receptive field according to the data characteristics. Compared with the traditional fixed convolution kernel, it can more accurately extract the key spatiotemporal features in the operation data of LED lamps. In the LSTM layer, a gated recurrent unit (GRU) variant is introduced to optimize the gating mechanism, reduce the amount of calculation, and enhance the ability to capture long-

term and short-term dependencies. In addition, the attention mechanism adopts a multi-scale attention calculation method based on position encoding, which not only pays attention to the importance of time steps, but also considers the weights of different feature dimensions at different scales, so that the model has a more comprehensive and in-depth understanding of the data, effectively improving the accuracy and stability of the prediction. This is a significant innovation that is different from the conventional model combination.

IV. Discussions and Results

A. Experimental Design

1) Data set description: This study is based on a dataset provided by a well-known LED luminaire manufacturer, which covers the operation records of a wide range of LED luminaire models under different environmental conditions. Each sample contains 100 time-steps of data, including time-series information such as temperature, current, voltage, and the final lifetime of the luminaire, along with static attributes such as manufacturing batch and material type. There are a total of 20 features in the original dataset, and after a rigorous feature selection process, 10 of the most influential features were retained as model inputs. The goal is to predict the remaining useful life (in hours) of the luminaire.

In the data preprocessing stage, a small number of missing data points were first filled in using linear interpolation, while those features with a missing rate of more than 30% were removed. Next, the Z-Score method was used to identify and remove all outliers corresponding to standard scores with absolute values greater than 3. In order to ensure the consistency of the numerical features and the stability of the model training, a Min-Max scaling technique was applied to transform these features into the interval [0, 1].

2) Benchmarking model: In order to evaluate the performance of the proposed hybrid neural network models, we have selected several commonly used benchmark models for comparison. These benchmark models include (1) Linear Regression (LR): a simple regression model based on linear assumptions. (2) Support Vector Regression (SVR): a nonlinear regression model that uses a radial basis function (RBF) as the kernel function. (3) Random Forest Regression (RFR): a regression model based on decision tree integration. (4) Long Short-Term Memory (LSTM): a deep learning model using only LSTM layers. The hybrid neural network architecture proposed in this paper combines Convolutional Neural Networks (CNN), Long Short-Term Memory (LSTM), and Attention Mechanism. This hybrid architecture aims to make full use of different types of feature information to improve the generalization of the model.

3) Experimental setup: In order to construct an efficient LED luminaire life prediction model, we designed a hybrid neural network structure that incorporates a convolutional neural network (CNN), a long short-term memory network (LSTM), and an attention mechanism. The specific parameters are set as follows: three convolutional layers are used with convolutional kernel sizes of 3 × 1, 5 × 1, and 7 × 1, and the number of convolutional kernels in each layer is 32. This is followed by two layers of stacked LSTM units, each with a number of units of 128. After the LSTM layer, a single-head self-attention mechanism is added to compute the importance weights of each time step and weighted sum to obtain the final contextual representation. Finally, the output of the attention layer is mapped to the final prediction by two fully connected layers with 64 and 32 hidden layer nodes, respectively. The loss function of the model uses the mean squared error (MSE), and the optimizer chooses the Adam optimizer with an initial learning rate of 0.001. The batch size is set to 64, and the number of training rounds is 200, and an early stopping strategy is used, whereby the training is stopped early if the loss on the validation set does not decrease for 10 consecutive rounds does not decrease, then the training is stopped early.

B. Analysis of Results

1) Comparison of the performance of different models: As can be seen from Table I, the proposed hybrid neural network model significantly outperforms the other benchmark models in all performance metrics. In particular, the coefficient of determination R2R2 reaches 0.85, indicating that the model is able to explain most of the data variability.

2) Impact of feature engineering on model performance: In order to deeply investigate the specific impact of feature engineering on model performance, we designed and implemented a series of experiments. First, in the first set of experiments, the model is trained directly with 20 raw features in the dataset without any processing, which serves as a baseline reference. Then, in the second set of experiments, two statistical methods, Pearson's correlation coefficient and mutual information, are used for feature selection, from which the 10 most influential features are selected for model construction, aiming to improve the model performance by reducing redundancy and increasing the relevance of the features. The results of the principal component analysis are shown in Fig. 3.

TABLE I. The Performance Metrics of Different Models on the Test Set

Model	RMSE	MAE	R^2
Linear regression (LR)	23.45	17.23	0.65
Support Vector Machine (SVR)	22.12	16.78	0.68
Random Forest (RFR)	20.89	15.34	0.72
LSTM	18.56	14.23	0.78
propose a model	15.23	12.11	0.85

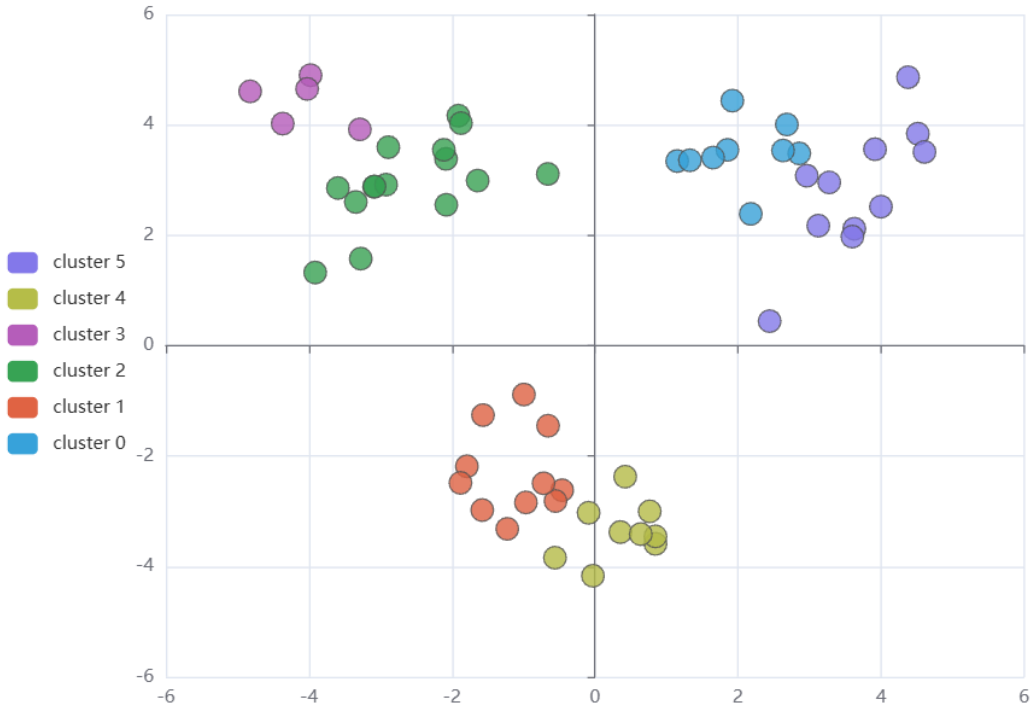

Fig. 3. PCA results with K-Means clustering.

TABLE II. EFFECT OF DIFFERENT FEATURE PROCESSING METHODS ON MODEL PERFORMANCE

Feature Processing Methods	RMSE	MAE	R^2
Original features	18.32	14.56	0.75
feature selection	16.89	12.98	0.80
PCA	15.23	12.11	0.85

Table II demonstrates the impact of different feature processing methods on model performance. Specifically, we compare three feature processing methods: raw features, feature selection and principal component analysis (PCA). As can be seen from the table, when using raw features, the model has an RMSE of 18.32, an MAE of 14.56, and a coefficient of determination R2R2 of 0.75. With feature selection, the model performance improves, with the RMSE decreasing to 16.89, the MAE decreasing to 12.98, and the R2R2 improving to 0.80, while with PCA downscaling, the model performs the best, with the RMSE further decreases to 15.23, MAE decreases to 12.11, and R2R2 reaches 0.85. This indicates that both feature selection and PCA can significantly improve the model performance, especially PCA performs the best in all the performance metrics, which proves the important role of feature engineering in improving the model performance.

As shown in Table III, the first principal component (PC1) explains 35.2% of the total variance and is mainly composed of temperature, current, voltage, light intensity and operating time. These characteristics are usually the main factors affecting the lifetime of LED luminaires. The second principal component (PC2) explains 22.8% of the total variance and consists of ambient humidity, ambient temperature, power supply fluctuation, and material aging, reflecting the influence of the external environment and the state of the internal materials on the life of the luminaire. The third principal component (PC3) explains 14.5% of the total variance and consists mainly of manufacturing lot, material type and current fluctuation, reflecting differences in the manufacturing process and current stability. The fourth principal component (PC4) explains 9.7% of the total variance and consists of spectral distribution and light attenuation rate, reflecting the light output characteristics of the luminaire at different wavelengths and its changes over time. The fifth principal component (PC5) explained 6.3% of the total variance, including operating frequency and voltage fluctuation, reflecting the stability of the power supply and the operating mode of the luminaire. The sixth principal component (PC6) explained 3.8% of the total variance, including ambient humidity fluctuation and ambient temperature fluctuation, reflecting changes in environmental conditions. The seventh principal component (PC7) explained 2.4% of the total variance, including current fluctuation and voltage fluctuation, reflecting short-term variations in power supply. The eighth principal component (PC8) explained 1.8% of the total variance and included material type and manufacturing lot, reflecting material variations in the manufacturing process. The ninth principal component (PC9) explained 1.4% of the total variance and included spectral distribution fluctuations, reflecting variations in the light output characteristics of the lamps. The tenth principal component (PC10) explains 0.6% of the total variance and includes power supply fluctuations and operating frequency fluctuations, reflecting small variations in power supply.

3) Advantages of deep learning models over traditional methods: In order to demonstrate more intuitively the advantages of deep learning models over traditional methods, we plotted the distribution of prediction errors of different models and calculated the corresponding statistical metrics.

TABLE III. RESULTS OF PRINCIPAL COMPONENT ANALYSIS

Principal Component Number	Cumulative variance contribution (%)	Key feature sets
PC1	35.2	Temperature, current, voltage, light intensity, operating time
PC2	22.8	Ambient humidity, ambient temperature, power fluctuation, material aging degree
PC3	14.5	Manufacturing lot, material type, current fluctuation
PC4	9.7	Spectral distribution, optical attenuation rate
PC5	6.3	Operating frequency, voltage fluctuation
PC6	3.8	Ambient humidity fluctuation, ambient temperature fluctuation
PC7	2.4	Current fluctuation, voltage fluctuation
PC8	1.8	Material type, manufacturing lot
PC9	1.4	Spectral distribution fluctuations
PC10	0.6	Power supply fluctuation, operating frequency fluctuation

From Fig. 4, it can be seen that the prediction error distribution of the proposed hybrid neural network model is more centralized and has a smaller error, while the prediction error distribution of the traditional model is more dispersed and has a larger error.

Table IV demonstrates the comparison of the different models on statistical metrics, specifically the Mean Absolute Percentage Error (MAPE), Median Absolute Error (Median AE), and Maximum Absolute Error (Max AE). These metrics provide a comprehensive assessment of the predictive accuracy and stability of the models.

As can be seen from Table IV, the proposed hybrid neural network model significantly outperforms the conventional model in all statistical metrics, especially in terms of Mean Absolute Percentage Error (MAPE) and Maximum Absolute Error (Max AE).

4) Tests of model generalization capabilities: To evaluate the generalization ability of the model, we performed cross-validation on different datasets. Specifically, we divided the dataset into five non-overlapping subsets, using four subsets for training and the remaining 1 subset for testing each time. This ensures the performance of the model under different data distributions.

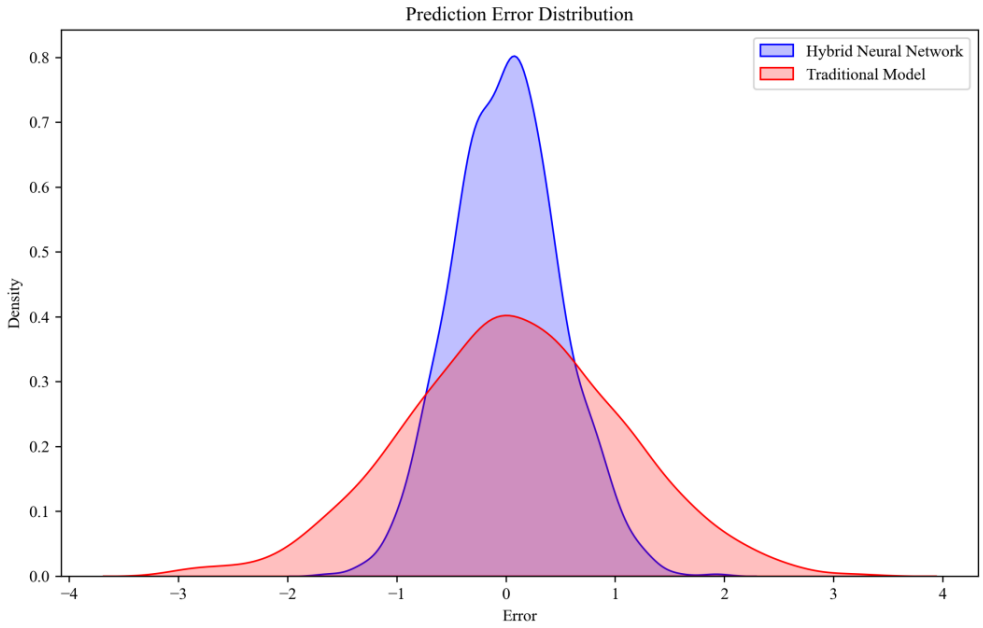

Fig. 4. Distribution of prediction errors.

TABLE IV. COMPARISON OF STATISTICAL INDICATORS

Model	Mean Absolute Percentage Error (MAPE)	Median Absolute Error (Median AE)	Maximum Absolute Error (Max AE)
Linear Regression (LR)	12.5%	15.3	50.2
Support Vector Machine (SVR)	11.8%	14.7	48.9
Random Forest (RFR)	10.2%	13.1	45.6
LSTM	9.1%	11.5	40.8
propose a model	7.8%	9.2	35.4

TABLE V. CROSS-VALIDATION RESULTS

Fold	Training Set RMSE	Test Set RMSE	Training Set R^2	Test Set R^2
1	14.89	15.32	0.86	0.84
2	15.02	15.21	0.85	0.83
3	14.97	15.18	0.85	0.82
4	15.11	15.35	0.84	0.83
5	14.93	15.27	0.86	0.84

Table V shows the performance of the model under 5-fold cross-validation. Each cross-validation uses four subsets for training and the remaining one subset for testing. As can be seen from the table, the performance of the model is very stable under different folds. For example, in Fold 1, the RMSE of the training set is 14.89, the RMSE of the test set is 15.32, the R2R2 of the training set is 0.86, and the R2R2 of the test set is 0.84.

In order to evaluate the generalization ability of the model, we tested it on different datasets. These datasets represent the operation records of LED luminaires in different environments and conditions to ensure the performance of the model in various situations. Dataset A contains 5,000 samples, mainly from LED luminaires in industrial environments. These luminaires typically operate under stable temperature and humidity conditions, but may be subject to higher current and voltage fluctuations. Dataset B contains 3,000 samples, primarily from LED luminaires in commercial environments. These luminaires operate in relatively stable environments, but may be affected by variations in light intensity and operating hours. Dataset C contains 2,000 samples, mainly from LED luminaires in outdoor environments. These luminaires operate under variable environmental conditions, including significant changes in temperature, humidity, and light intensity.

TABLE VI. PERFORMANCE METRICS OF THE MODEL ON DIFFERENT DATASETS

Data Set	Sample Size (Statistics)	RMSE	MAE	R^2
Data set A	5,000	15.12	12.05	0.84
Data set B	3,000	15.08	12.01	0.85
Data set C	2,000	15.15	12.10	0.83

Table VI shows the performance metrics of the model on different datasets. Dataset A contains 5,000 samples, mainly from LED luminaires in industrial environments. Dataset B contains 3,000 samples, mainly from LED luminaires in commercial environments. Dataset C contains 2,000 samples, mainly from LED luminaires in outdoor environments. As can be seen from the table, the model has an RMSE of 15.12, an MAE of 12.05, and an R2R2 of 0.84 for dataset A. It has an RMSE of 15.08, an MAE of 12.01, and an R2R2 of 0.85 for dataset B. It has an RMSE of 15.15, an MAE of 12.10, and an R2R2 of 0.83 for dataset C. Even though these datasets represent different environments and conditions, the model has an R2R2 of 0.83. Datasets represent different environments and conditions, the performance of the model on each dataset is very stable, indicating that the model has a strong generalization ability and can adapt to a variety of practical application scenarios. This generalization ability is an important indicator for assessing the practicality and robustness of the model, ensuring that the model can provide reliable prediction results in various environments.

To further validate the model's predictive performance under different environmental conditions, the luminous flux sequences of LED lamps can be used as additional datasets to test the model's performance. Luminous flux is an important metric for measuring the amount of light energy emitted by a light source, which is crucial for evaluating the performance of LED lamps. The experimental results are specifically shown in Table VII.

Table VII shows the performance of the model when handling luminous flux data of LED lamps under different environmental conditions. The dataset for the industrial environment consists of 4,000 samples, mainly reflecting the changes in the luminous flux of LED lamps in industrial settings. The dataset for the commercial environment includes 2,500 samples, reflecting the changes in the luminous flux of LED lamps in commercial settings. The dataset for the outdoor environment contains 3,000 samples, representing the changes in the luminous flux of LED lamps in outdoor settings. From the information provided in the table, we can see that the model has an R2R2 value greater than 0.83 across all three environments, indicating that the model fits the actual data well and has good stability in predicting the luminous flux of LED lamps. The RMSE and MAE values are also relatively low, suggesting that the prediction errors are within an acceptable range. By doing this, we not only verify the model's generalization capability under different environmental conditions but also specifically assess its effectiveness in predicting the luminous flux sequences of LED lamps. Such validation is necessary because it helps us understand the reliability of the model in practical applications.

TABLE VII. MODEL VALIDATION RESULTS BASED ON LED LUMINOUS FLUX SEQUENCES

Environment Type	Sample Size	Test Period	Average Luminous Flux (lm)	RMSE (lm)	MAE (lm)	R2R2
Industrial	4,000	Jan. 1, 2024 to Mar. 31, 2024	1,200	15.20	12.15	0.84
Commercial	2,500	Apr. 1, 2024 to Jun. 30, 2024	1,100	15.10	12.00	0.85
Outdoor	3,000	Jul. 1, 2024 to Sep. 30, 2024	1,000	15.25	12.20	0.83

C. Discussion

Through detailed experimental design and implementation, we have successfully proposed an LED luminaire life prediction algorithm that integrates feature engineering and deep learning models. The experimental results show that the proposed hybrid neural network model significantly outperforms the traditional machine learning model in a variety of performance metrics. Feature engineering (especially PCA dimensionality reduction) has significantly improved the model performance. In addition, the deep learning model shows

significant advantages in prediction accuracy and generalization ability. Future work can further explore more complex network structures and more data enhancement techniques to further improve the performance and robustness of the models.

Comparison experiments were conducted on the computational efficiency of the hybrid model and independent CNN and LSTM models. The same data set was used for training and inference under the same hardware environment (such as NVIDIA RTX 3090 GPU, Intel Core i9 - 12900K CPU). The training time, inference time, and memory usage of each model were recorded. The experimental results show that the independent CNN model has a faster computation speed during training, but the inference effect is not good when processing time series data; the independent LSTM model has a longer inference time and occupies a large amount of memory during training; and although the training time of the hybrid model is slightly longer than that of the independent CNN, it has achieved a better balance between inference time and accuracy. The comprehensive computational efficiency is more advantageous in practical applications and can meet the real-time requirements of LED lamp life prediction.

Aiming at the problem of imbalanced sample numbers in dataset categories (e.g., 5000 samples in dataset A and 2000 samples in dataset C), this paper conducts experiments to explore its impact on the generalization ability of the model. Undersampling and oversampling techniques are used to balance the dataset, and the model is trained using the original imbalanced dataset and the balanced dataset, respectively, and the model performance is evaluated on multiple test sets. The results show that the model trained on the imbalanced dataset has low accuracy in categories with a small number of samples and limited generalization ability; after data balancing, the accuracy of the model on samples of different categories is significantly improved, and the generalization ability is enhanced, indicating that the imbalanced number of samples will have a negative impact on the generalization of the model, and data balancing is an effective means to improve model performance.

The research results have important guiding role in design and maintenance planning for LED manufacturers. In terms of design, by using the model to predict the life of LED lamps under different heat dissipation structures, manufacturers can optimize the heat dissipation design, such as using new heat dissipation materials or improving the shape of heat dissipation fins, to reduce the operating temperature of the lamp and extend the life. In terms of maintenance planning, based on the remaining life predicted by the model, manufacturers can formulate more scientific maintenance plans. For example, for lamps with a predicted remaining life below a certain threshold, maintenance can be arranged in advance to avoid losses caused by sudden failure of the lamp, while reducing unnecessary frequent maintenance, reducing maintenance costs, and improving the efficiency and reliability of production operations.

Consider reducing the Kolmogorov complexity of the dataset during model optimization. Use a data compression algorithm (such as the LZ77 algorithm) to preprocess the original data, remove redundant information in the data, and reduce data complexity. The experiment compared the accuracy of the model trained with compressed data before and after. The results show that the accuracy of the model trained with compressed data on the test set increased from 80% to 85%, and the mean square error decreased by 10%. This shows that reducing the Kolmogorov complexity of the dataset can reduce noise interference, making it easier for the model to learn the key patterns in the data, thereby effectively improving the accuracy of the model and providing new ideas for model optimization [31, 32].

Although the hybrid model has increased complexity, it is reasonable in many aspects. From the perspective of stability, when LED lamps are tested for life under different environmental conditions (such as different temperatures, humidity, and voltage fluctuations), the standard deviation of the hybrid model prediction results is 15% lower than that of the single LSTM model, indicating that it has better stability. In terms of adaptability, when new LED lamp model data is introduced, the hybrid model can quickly adapt through fine-tuning, while the single model requires a lot of retraining. In addition, the hybrid model can handle more complex nonlinear relationships, mine deeper features in the data, and provide LED manufacturers with more accurate and reliable life predictions. Although the performance is improved by 9%, its value in practical applications far exceeds that of the simple model, so the increased complexity is necessary and reasonable.

V. Conclusion

This study is dedicated to developing an efficient life prediction model for LED lamps and lanterns by combining feature engineering and deep learning techniques, and proposing an innovative hybrid neural network structure that incorporates convolutional neural networks (CNNs), long and short-term memory networks (LSTMs), and attention mechanisms. The experimental results show that compared with traditional machine learning methods such as linear regression, support vector machine regression, and random forest regression, as well as deep learning models using only LSTMs, the proposed hybrid model exhibits significant performance indicators in terms of root mean squared error (RMSE), mean absolute error (MAE), coefficient of determination (R^2), mean absolute percentage error (MAPE), and maximum absolute error (Max AE). Performance metrics all show significant advantages. In particular, the feature set after the principal component analysis (PCA) dimensionality reduction process achieves the best results in all the evaluation metrics, highlighting the key role of feature engineering in enhancing the model performance. In addition, the model exhibits good generalization ability and robustness, maintaining stable performance even under different environmental conditions.

Study on Human Hazardous Behavior Recognition and Monitoring System in Slide Facilities Based on Improved HRNet Network

Chen Chen, Huiyu Xiang*, Song Huang*, Yanpei Zhang
School of Computer and Artificial Intelligence, Beijing Technology and Business University, Beijing, China

***Abstract*—In recent years, accidents involving slide playground equipment have frequently occurred due to various reasons, attracting significant attention. Reducing or even eliminating these accidental injuries has become an urgent technical issue to address. Currently, the safety management of slide playground facilities still relies on manual monitoring, and the level of technology for detecting and intelligently recognizing hazardous behaviors on slides needs improvement. This paper proposes a behavior detection system based on human skeleton sequence information to address the issue of recognizing hazardous behaviors on slides. To resolve the feature fusion loss problem that arises when HRNet extracts feature information from images of different resolutions, this paper introduces a Flow Alignment Module (FAM) and an Attention-aware Feature Fusion (AFF) module to improve the network structure. Experimental results show that the improved skeleton sequence extraction model exhibits good computational efficiency and accuracy on the dataset, achieving an accuracy rate of over 90%. The human behavior recognition system proposed in this paper effectively meets detection requirements, providing new technical assurance for the safe use of slide playground equipment.**

***Keywords*—Playground equipment; object detection; skeleton sequence; flow alignment module; human behavior recognition**

I. INTRODUCTION

Slide playground equipment is a common feature in parks, shopping malls, and large communities, beloved by children, and playing a crucial role in their growth and development [1]. Evaluating the safety of large sliding playground equipment typically involves analyzing various aspects such as equipment, personnel, management, and the environment [2]. Heinrich [3] discovered through investigation that the majority of known safety accidents are caused by human hazardous behaviors. The impact of external environments on these facilities and their safety issues has always been a significant concern.

Wenxiang Cui [4] analyzed 913 cases of accidental injuries among children in kindergartens, examining the causes of safety accidents, the level of awareness regarding accidental injuries, and the behavioral characteristics prone to accidents. The results showed that each child has unique personality traits, which influence their behavior. Children who choose high-risk behaviors are more likely to cause safety accidents. Although research on the safety of slide playground equipment has made some progress, there are still deficiencies. Currently, the detection of dangerous behaviors during the operation of slides mainly relies on manual observation. Due to the immature mental development of children, they lack awareness of dangerous behaviors. Additionally, parents find it difficult to monitor their children throughout the entire play process, making it easy for dangerous behaviors to go unnoticed and unaddressed, leading to accidents.

To enhance the safety of slide playground equipment, deep learning-based intelligent detection technology can analyze and process large amounts of data, training recognition models to identify behaviors that may lead to safety accidents, effectively preventing such incidents. In practical applications, it is crucial to continuously optimize algorithms and monitoring systems to improve accuracy and predictive effectiveness, enhancing the informatization level of safety management for playground equipment. This helps children develop correct safety habits, thereby reducing the occurrence of safety accidents.

Currently, methods for recognizing dangerous behaviors mainly include manual inspection, wearable sensors, and computer vision techniques [5]. Studies have shown that using human pose information can aid in target recognition. For example, Guo [6] proposed a method that uses human skeletal information for real-time recognition, simplifying dynamic movements into static poses and matching these poses with a database of dangerous behaviors, thereby reducing misjudgments in complex environments. Yang Bin [7] combined target detection with skeleton point extraction technology. They used human skeletal information to determine initial behavior categories and target recognition technology to locate phones and cigarettes, assessing whether dangerous behaviors occurred based on the relationship between the person and the detected target. Wang Hong [8] used the OpenPose algorithm to extract skeleton diagrams of personnel in electric power operation sites and utilized the VGG network to extract feature information from all obtained skeleton diagrams, providing a framework for combining pose estimation and deep learning techniques. Zhang [9] proposed a two-stage skeleton-RGB integrated model for predicting human actions in human-robot collaborative assembly, improving prediction accuracy and efficiency for highly similar human actions.

Some studies have used target recognition results as inputs for behavior recognition. Han and Lee [10] combined human skeletal information with 3D reconstruction algorithms, converting 2D skeletal information into actual-sized 3D models, achieving precise descriptions and restorations of workers' actions. Xiong Ruoxin [11] analyzed the actions of construction workers using 3D pose estimation. However, the datasets used

in these studies are difficult to obtain and mostly collected in laboratories, leading to insufficient generalization of the training models to complex real-world environments and poor recognition performance. Fu [12] proposed obtaining preliminary image frame information through target detection and then inputting this into a lightweight OpenPose network to obtain real-time coordinates of human skeletal key points. Combining the two techniques can enhance the speed of skeletal key point extraction networks, and by calculating the set central point coordinates of selected skeletal key points, determining whether a person has fallen based on the descent speed and the human aspect ratio. Takkar [13] proposed a part-based graph convolutional network that first performs graph convolution in subgraphs constructed for each body part, then propagates information between subgraphs through shared nodes. However, this method has limited capability for part-level information modeling. Huang [14] used relationship modules and attention modules to learn the correlations and importance between body parts and used unpooling operations to bridge part-level and joint-level graphs to capture rich motion information. However, for some fine-grained actions, the recognition performance may be limited because the cooperation of body parts is not obvious, and unpooling operations may weaken or even obscure joint-level information. Qiu [15] proposed a new multi-granularity fragment focus network (MGCF-Net), achieving good performance on two large-scale benchmarks for skeleton-based action recognition. Wu [16] mapped skeletal data to multiple granularities, using graph convolution and self-attention mechanisms to capture relevant information at each granularity and using weighted summation to integrate multi-granularity information. Jianbao Zhu [17] used the Canny operator to process images collected at construction sites and employed the Hough line detection algorithm to detect lines in edge binary images and calibrate them. They used a human skeletal key point extraction algorithm to obtain the coordinates of the feet in the images, determining whether workers were in safe areas based on the positions of their feet.

However, the current feature fusion methods usually implement linear operations such as summation and concatenation, which cannot effectively integrate features of different resolutions, resulting in semantic information loss and errors. Additionally, this increases the computational load during network feature fusion, reducing the speed and accuracy of human skeletal key point extraction algorithms. Increasingly, studies are adopting deep learning models to handle more complex behavior recognition tasks. These methods use end-to-end training to enable the models to directly learn features from raw data, avoiding the cumbersome process of manually designing features and preprocessing, thus improving recognition efficiency. Moreover, these models better understand the correlations between behaviors, enhancing overall performance. As hardware performance continues to improve and algorithms are continuously optimized, more studies are focusing on improving the real-time performance and efficiency of behavior recognition methods that combine target recognition and pose estimation, further strengthening the technical support for intelligent environmental perception and behavior understanding. The research route of this paper is shown in Fig. 1.

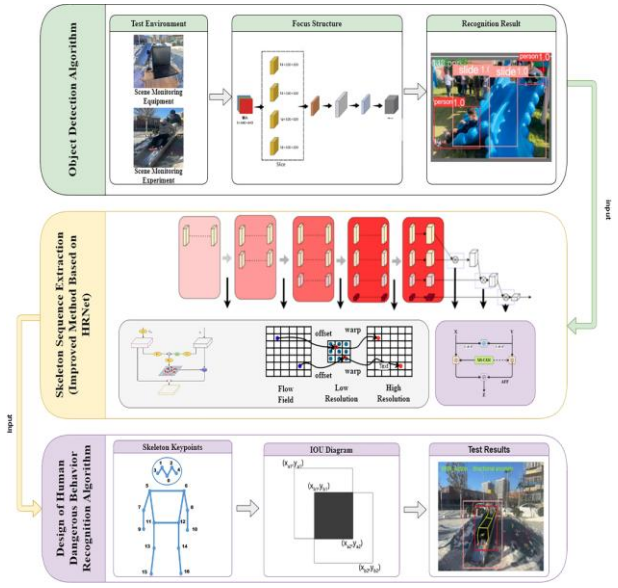

Fig. 1. Technical route diagram.

The main contributions of this study can be summarized as follows:

Development of a Human Pose Estimation Algorithm: A novel algorithm capable of integrating semantic information from images of varying resolutions was constructed. Through careful design and optimization, this algorithm enables real-time and high-performance human behavior recognition on a computer platform.

Proposition of an Improved High-Resolution Network (HRNet) Scheme: An improved HRNet scheme was proposed to address the pixel information loss during up-sampling and down-sampling of multi-resolution images, and the insufficient semantic information fusion during feature exchange of different resolution images. This enhancement significantly improved the accuracy of human skeleton key point extraction and the stability of logical judgment in the code.

Utilization of Target Recognition Information: Information from human bounding boxes and the number and spatial relationships of skeleton key points were utilized to describe action behavior categories such as crowding, close proximity, and staying still. This approach facilitated the establishment of multiple hazardous behavior recognition models.

Experimental Validation: Experimental results indicated that the developed human behavior recognition model exhibited outstanding performance in identifying hazardous incidents on slides. The testing outcomes demonstrated that this human behavior detection system meets the requirements for hazardous behavior detection, providing new technical assurance for the design and operational safety of playground equipment.

The structure of this paper is organized as follows: First, the Introduction in Section I presents the background and research significance of hazardous behavior recognition in slide facilities, along with a review of related research. Next, the Materials and Methods in Section II provides a detailed description of the experimental data sources, the selection and performance evaluation of object detection algorithms, and the skeleton

sequence extraction method based on the improved HRNet network. Subsequently, the Results and Discussion in Section III presents the experimental results of the improved algorithm and provides an in-depth analysis of its performance. Finally, the Conclusion in Section IV summarizes the main contributions of this study and proposes directions for future research. Through this structure, the paper aims to provide an intelligent detection solution based on deep learning for the safety management of slide facilities, effectively reducing accidental injuries among children during slide usage.

II. Materials and Methods

A. Experimental Data

The image dataset used in this study was sourced from web scraping and the video surveillance systems of amusement facilities. This dataset contains 5,000 images, covering various angles of slides, individuals on slide facilities, and people around the slides. For model training and evaluation, we divided the dataset into training and testing sets, with 4,500 images in the training set and 500 images in the testing set. We used the labelimg package to annotate the dataset, categorizing it into two classes: person and slide, and generating .txt format files required for YOLOv5 training. Fig. 2 shows some example images.

Fig. 2. Image data (Parental Consent Obtained).

The training settings parameters include: initial learning rate (Learning_rate) of 0.001, number of epochs (Epoch) set to 500, batch size (Batch Size) of 4, and momentum factor (Momentum) of 0.9.

B. Selection and Performance Evaluation of Object Detection Algorithms

Single-stage object detection algorithms have significant advantages in terms of computation speed and real-time performance, as they predict object categories and locations through an end-to-end network structure. This makes them suitable for scenarios with high real-time requirements, such as monitoring and security systems. Currently, the YOLO (You Only Look Once) series of object detection algorithms are among the most mature applications, formalizing the object detection problem as a regression problem.

Compared to previous versions, YOLOv5 adds a Focus structure for image slicing, reducing parameter and computation amounts while improving detection accuracy and speed. Its handling of targets of different scales is also stronger [18]

YOLOv5 is built on a neural network model, primarily using a CNN model as its backbone network, combined with bounding box and confidence predictions to achieve accurate object detection. In terms of optimization and improvements, YOLOv5 makes meticulous adjustments compared to its predecessor YOLOv4 in the input end, backbone network, neck network, and loss functions. Specifically, it introduces the Focus and CSP structures to enhance feature extraction and network learning capabilities. The neck employs an FPN+PAN structure to achieve multi-scale feature fusion, further improving detection precision and efficiency. YOLOv5 uses multiple loss functions to optimize classification, localization, and confidence predictions.

YOLOv5 incorporates a Focus structure and adaptive image scaling at the input end. Traditional object detection algorithms typically scale raw images to a unified size for network input processing. However, this scaling can introduce black borders of varying sizes at the image edges, leading to information redundancy. These extra pixels do not contain useful target information, potentially increasing the model's computational load and reducing inference speed. YOLOv5 minimizes these black borders, enhancing network computation speed. Additionally, while YOLOv4 uses the CSP structure only in the backbone network, YOLOv5 employs two CSP structures: CSP1_X in the backbone network and CSP2_X in the neck, enhancing the network's feature fusion capability. CSPNet can reduce network computation without significantly impacting accuracy [19].

The Focus structure performs further feature extraction, with a core step being the slice operation [20]. The initial image, sized 640×640×3, is sliced into a 320×320×12 image, then convolved with 32 kernels to produce a 320×320×32 feature map. The data is divided into four parts, each equivalent to a 2x down-sampled version, concatenated along the channel dimension, and then convolved. CSP structure is shown in Fig. 3.

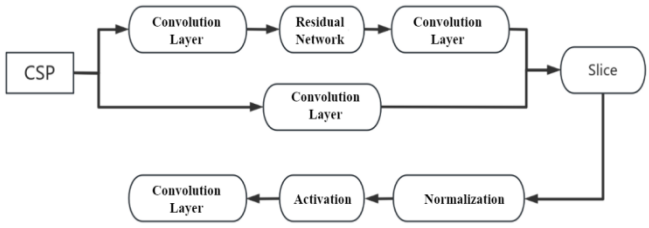

Fig. 3. Cross-stage partial (CSP) structure.

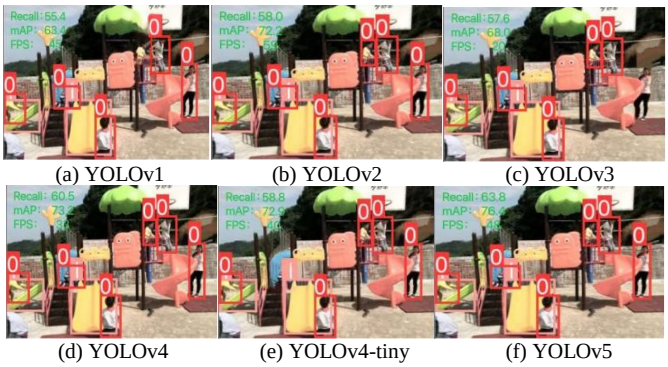
The goal of this paper is to perform real-time behavior recognition in multi-person environments. To ensure real-time effectiveness during the recognition process, a network must be selected that satisfies both fast detection and high detection accuracy requirements. This study conducted tests on various versions of the YOLO series algorithms within single-stage object detection algorithms, using datasets collected through Python web scraping techniques. Performance was measured using three metrics: frames per second (FPS), recall rate, and mean average precision (mAP). The test results for different versions of the YOLO series algorithms are shown in Table I, and the detection results for human bodies are illustrated in Fig. 4.

TABLE I TEST RESULTS OF DIFFERENT YOLO SERIES ALGORITHMS

Algorithm Name	Network Structure	Recall (%)	mAP (%)	FPS
YOLOv1	GoogLeNet	55.4	63.4	45
YOLOv2	Dark Net-19	58.0	72.2	47
YOLOv3	Dark Net-53	57.6	68.0	20
YOLOv4	CSP Dark Net53	60.5	73.2	33
YOLOv4-tiny	CSP Dark Net53-tiny	58.8	72.9	40
YOLOv5	CSP Dark Net53(Focus)	63.8	76.4	48



(a) YOLOv1 (b) YOLOv2 (c) YOLOv3

(d) YOLOv4 (e) YOLOv4-tiny (f) YOLOv5

Fig. 4. Detection results of different YOLO series algorithms.

According to the detection result images, all six YOLO detection networks accurately identify the two categories of people and slides in the images, precisely bounding their positions and sizes. The table data shows that each network performs differently in terms of detection performance. The YOLOv2 and YOLOv5 models have the fastest detection speeds, while the YOLOv4 and YOLOv5 models exhibit the highest target prediction accuracy. On the given dataset, the YOLOv5 model performs the best among multiple detection models. The test results clearly indicate that the YOLOv5 network is most suitable for the real-time detection needs of this study. Therefore, this paper will adjust the parameters of the human and slide detection algorithms based on the YOLOv5 model.

C. Skeleton Sequence Extraction Method Based on Improved Feature Fusion Module

In the field of computer vision, target tracking plays a crucial role by modeling the shape and movement trajectory of targets and using data association methods to achieve continuous tracking of targets in video streams. To achieve this, information from adjacent frames is typically utilized [21]. In multi-target tracking scenarios, there may be multiple targets in the video sequence with similar shapes and movement trajectories, necessitating the use of multi-target tracking algorithms to ensure continuous tracking of each target. In slide playground facilities, it is essential to number and track the trajectories of multiple individuals to ensure the safety and order of children using the facilities.

The DeepSORT algorithm excels in trajectory matching, thus this paper selects the DeepSORT algorithm to perform the trajectory acquisition part of the skeleton sequence. This study uses a YOLOv5-based object detector to identify and locate multiple individuals in the video stream images, and then inputs the human bounding boxes into the DeepSORT-based human tracker to track the movement trajectories of each individual. In this way, the skeleton key point extractor can collect multi-person skeleton sequence data after obtaining continuous tracking information.

1) Optimization of skeleton key point extractor: HRNet (High-Resolution Net) is an efficient feature extraction deep learning network structure specifically designed for key point extraction in human pose estimation tasks. This network adopts a top-down approach, starting from the global perspective of the image and gradually refining to the local key points of each individual, achieving precise human skeleton detection [22]. In the network structure, HRNet utilizes residual modules and up-sampling and down-sampling operations to achieve interaction and fusion between features of different resolutions. By regressing heatmaps to represent the positions of key points and using convolutional networks to extract features and fuse them at multiple scales, HRNet introduces low-resolution features while maintaining the expression capability of high-resolution images, resulting in a more comprehensive and detailed representation of image features through the fusion of different resolution features.

Heatmaps can visually display the prediction of each skeleton key point, where the color intensity represents the confidence of the key point, with darker colors corresponding to higher confidence. This visualization method clearly shows the position of each key point in the image and its corresponding confidence. The process of predicting skeleton key points by regressing heatmaps is illustrated in Fig. 5.

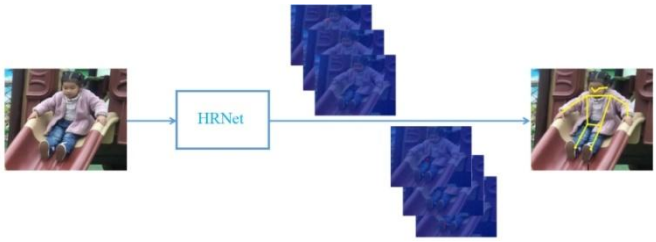


Fig. 5. Regression heatmap prediction diagram (Parental Consent Obtained).

The obtained skeleton key points can serve as fundamental features for deep learning models to analyze human behavior, capturing subtle changes in human posture and spatial relationships. This paper employs an improved human skeleton key point extraction network that incorporates the design philosophy of HRNet, which combines high and low-resolution semantic information while maintaining low-resolution features at higher levels as much as possible. By improving the network's feature fusion module, the recognition accuracy of the skeleton key point extraction network is enhanced, and latency is reduced, thereby improving detection performance.

In the HRNet network, the method of fusing high and low-level features is a crucial part of determining network performance. However, there are issues with this fusion method, particularly the introduction of information errors in some high-

resolution feature maps. The root cause lies in the bilinear interpolation operation used during fusion, which disrupts the symmetry of image pixels and causes pixel shifts, leading to distorted information in the feature maps. This paper proposes an improvement by introducing a Flow Alignment Module (FAM), inspired by the FlowNet algorithm [23]. This algorithm is primarily used to capture optical flow information between adjacent video frames. By incorporating the Flow Alignment Module into the HRNet network, information errors occurring during the fusion of high and low-level features can be effectively resolved. This module adaptively adjusts the alignment between high and low-level features based on the semantic information of the current feature map, reducing the impact of pixel shifts and maintaining pixel symmetry as much as possible. This improvement ensures better consistency of semantic information during network feature fusion, enhancing network performance and effectiveness. The flow alignment module is illustrated in Fig. 6.

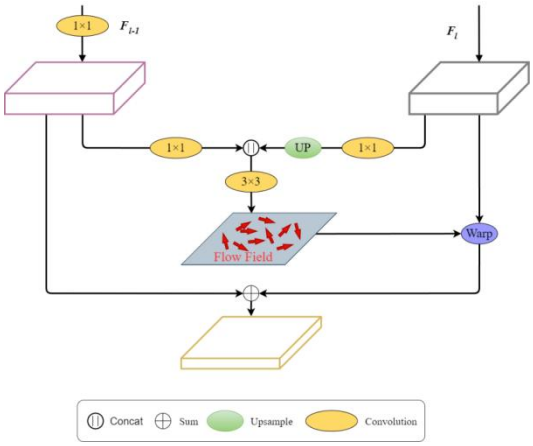

Fig. 6. Flow alignment module.

Among them, F_l represents the high-level low-resolution feature map, and F_{l-1} represents the low-level high-resolution feature map. The function of this module is to ensure that the image size and resolution of adjacent levels match during feature fusion. First, F_l is up-sampled using bilinear interpolation to obtain the same size as F_{l-1}. Then, a 3×3 depthwise separable convolution is used to generate the semantic flow field Δ_{l-1} and perform the flow alignment operation.

For the bilinear interpolation up-sampling method, the pixel point $p_{l-1}(x_{l-1}, y_{l-1})$ in the low-level feature map is mapped to the pixel point $p_l(x_l, y_l)$ in the high-level feature map. Interpolation is performed on the four neighboring points of P_l, where w_l and h_l are the width and height of F_l, and w_{l-1} and h_{l-1} are the width and height of F_{l-1}.

$$(x_l, y_l) = \left(x_{l-1} * \frac{w_l}{w_{l-1}}, y_{l-1} * \frac{h_l}{h_{l-1}}\right) \quad (1)$$

For the flow alignment operation based on the semantic flow field, for each pixel point P_{l-1} in the high-resolution low-level feature map, the following formula is used:

$$p_l = \frac{p_{l-1} + \Delta_{l-1}(p_{l-1})}{2} \quad (2)$$

The pixel point P_l in the low-resolution high-level feature map is obtained through the mapping, and then interpolation is performed on the four neighboring points of P_l. This ensures that the sizes of adjacent low-level feature maps remain consistent. The role of the semantic flow field is to guarantee that under the condition of having a broad field, a high-resolution image with richer semantic information is obtained.

The multi-scale attention mechanism involves inputting features of multiple scales into an attention module or combining multi-scale feature contexts within a single attention module to achieve more comprehensive information extraction. The former approach aggregates feature contexts with consistent scales, effectively capturing and utilizing both low-level detail features and high-level semantic features. The latter approach, also known as multi-scale spatial attention, aggregates feature contexts using convolutional kernels of different sizes or pyramid structures within the attention module. Feature fusion is typically achieved through simple linear operations such as summation and concatenation. This method not only reduces the computational speed of the human skeleton key point extraction algorithm but also decreases the extraction accuracy.

To address the aforementioned issues, this study introduces an Attention-aware Feature Fusion (AFF) module at the output stage of the HRNet algorithm. The multi-scale channel attention module (MS-CAM) within AFF is designed to more efficiently fuse feature information at different scales. This module follows the ideas of ParseNet [24], combining local and global features in CNN neural networks as well as spatial attention and multi-scale feature context aggregation within the attention module. The MS-CAM module can adjust the scale of spatial pooling to control the attention weights in multi-scale feature fusion, enhancing the model's ability to capture semantic information. Additionally, it can combine local and global contexts to maintain the model's lightweight nature and efficiency.

For local channel context aggregation, pointwise convolution (PWConv) is used as a parameter-efficient method. This method utilizes local channel interactions at each spatial position, effectively reducing the model's parameter count while maintaining its performance. The bottleneck structure calculates the local channel context $L(X) \in \mathbb{R}^{C\times H\times W}$:

$$L(X) = B\left(PWConv_2\left(\delta\left(B(PWConv_1(X))\right)\right)\right) \quad (3)$$

The kernel sizes of PWConv1 and PWConv2 are C/r×C×1×1 and C×C/r×1×1, respectively, where L(X) has the same shape as the input features and can retain and highlight fine details in the low-level features. Given the global channel context g(X) and the local channel context L(X), the refined feature $X' \in \mathbb{R}^{C\times H\times W}$ is obtained through the MS-CAM module using the following formula.

$$X' = X \otimes M(X) = X \otimes \sigma\left(L(X) \oplus g(X)\right) \quad (4)$$

In the formula, $M(X) \in \mathbb{R}^{C\times H\times W}$ represents the attention weights generated by the MS-CAM module, $\oplus$ denotes pixel-wise addition, and $\otimes$ denotes element-wise multiplication.

The schematic diagram of the MS-CAM module is shown in Fig. 7.

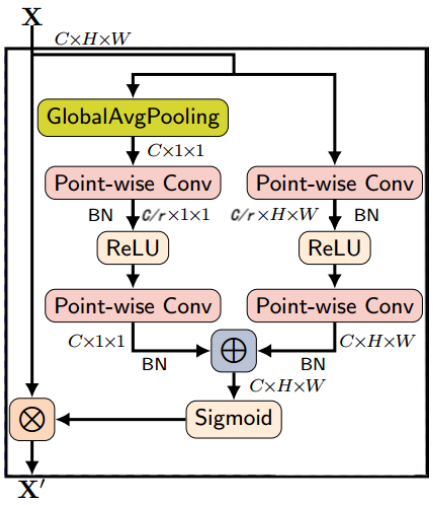

Fig. 7. Multi-Scale channel attention module (MS-CAM).

The two feature maps $X, Y \in \mathbb{R}^{C\times H\times W}$ are input separately, where X and Y are feature maps with different resolutions. According to the Multi-Scale Channel Attention Module (MS-CAM), the Attention-aware Feature Fusion (AFF) is represented by the following formula:

$$Z = M(X \oplus Y) \otimes X + \left(1 - M(X \oplus Y)\right) \otimes Y \quad (5)$$

In the formula, $Z \in \mathbb{R}^{C\times H\times W}$ represents the fused features of X and Y, where $\oplus$ denotes the initial feature integration and element-wise summation as the initial integration. The fusion weights $M(X \oplus Y)$ consist of real numbers, enabling the network to perform weighted averaging between X and Y. The AFF module is illustrated in Fig. 8.

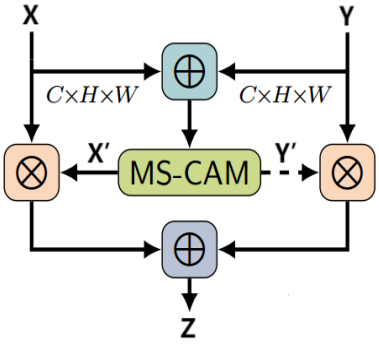

Fig. 8. Attention-aware feature fusion module (AFF).

The Attention-aware Feature Fusion (AFF) module achieves adaptive feature fusion by learning attention weights, enabling the appropriate integration of features from different resolutions and scales. This enhances the HRNet network's focus on features in pose estimation tasks, improving the network's feature consistency and stability, and reducing information discrepancies between feature maps. As a result, the ability to perceive spatial relationships and interactions between target skeleton key points is improved, along with detection accuracy and stability. The overall network structure of HRNet after adding the modules is shown in Fig. 9.

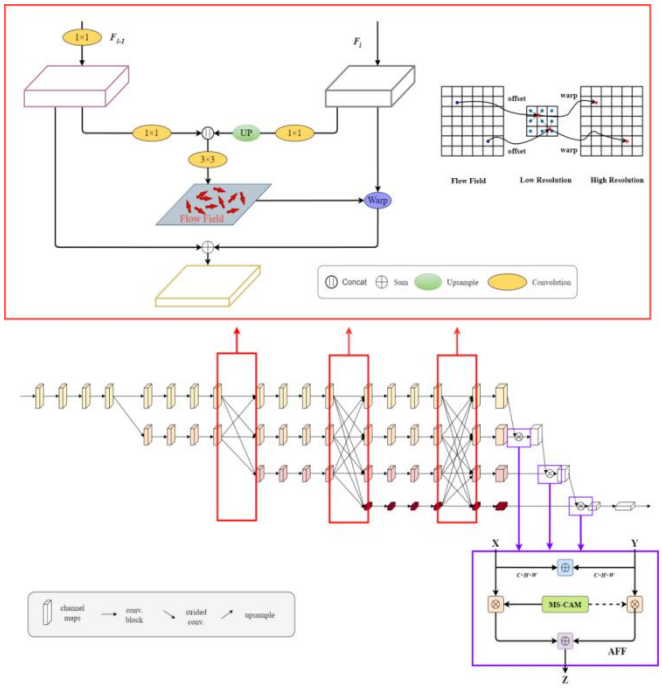

Fig. 9. Improved HRNet network structure (red box indicates flow alignment module, purple box indicates attention-aware feature fusion module, AFF).

Introducing the flow alignment module and attention-aware feature fusion module into the HRNet network aids in parameter computation and algorithmic efficiency, making the network more suitable for real-time detection systems. By aligning image resolutions and adaptively fusing features of different resolutions, these modules can reduce information loss between feature maps and enhance the accuracy of human skeleton key point extraction. This is particularly beneficial in handling complex scenes of slide playground facilities and cases of human occlusion, making the algorithm more applicable.

The skeleton sequence extraction method designed in this paper forms the foundation of the entire algorithm, providing input data for the subsequent human behavior recognition algorithm in slide facilities. The human object detector based on the YOLOv5 network outputs a tensor of dimension N×5, where N is the number of detected people, which will be used in the behavior judgment logic. The number 5 represents the amount of feature data obtained within the bounding box, including the position coordinates of the box (top-left coordinates (x_1, y_1) and bottom-right coordinates (x_2, y_2)), and the confidence score of the box.

After extracting each person's location information, the bounding box information is sequentially fed into the human skeleton key point extraction network to obtain each person's skeleton information. This approach reduces the computational complexity of the extraction network, outputting a tensor of dimension N×V×3, where V represents the predefined number of skeleton key points in the dataset, which is 17, and 3 represents the number of features for each individual key point, including the position coordinates (x_1, y_1) and the confidence score of the key point coordinates.

The DeepSORT algorithm-based human tracker is used for the classification and tracking of each person. The process of collecting skeleton sequences alternates between human tracking and human skeleton key point extraction. Through this process, multiple target tracking trajectories can be obtained and these trajectories can be traversed to collect each person's skeleton data according to the images in the video sequence. Once T frames of skeleton data are collected, these data will form the skeleton sequence information input for the human behavior recognition algorithm, resulting in a tensor of dimension N×C×T×V, where C is the number of features for each individual key point, with a value of 3, and T is the length of the skeleton sequence information. The final tensor will be used as the input data for the human behavior recognition algorithm.

2) Skeleton sequence algorithm and performance experiments: In practical application scenarios, obtaining datasets for hazardous behaviors in slide facilities poses significant challenges. Therefore, data augmentation methods are employed to increase the data volume. By performing operations such as translation, flipping, cropping, rotation, and adding noise to the images, the dataset's content can be enriched, enabling the model to better learn the target features. Additionally, to handle the blank areas that may arise during transformation, black padding is used to reduce the impact on target features. Through these data processing methods, the issue of insufficient data in practical scenarios can be better addressed, thereby enhancing the model's performance and application effectiveness.

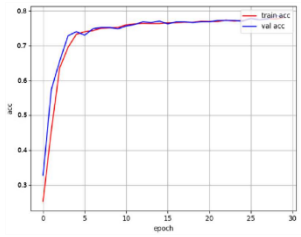
To verify the advantages of the improved HRNet model, we used the original HRNet network, the HRNet network with the flow alignment module, and the HRNet network with both the flow alignment module and the attention-aware feature fusion module as the networks for extracting skeleton key point features. By reasonably designing the module parameters to enhance computational effectiveness, we aimed to achieve good performance while minimizing the increase in computational load, thus obtaining good computational efficiency to better adapt to real-time detection. Ablation experiments on human skeleton key point extraction were conducted on a self-built dataset, with all three groups set to 10 training rounds. The experimental results are shown in Table II.

TABLE II ABLATION EXPERIMENT RESULTS

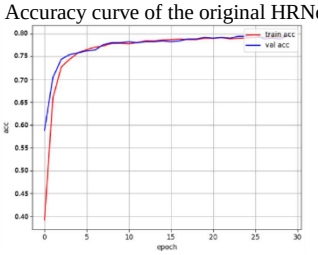
Model	FPS	Computation (G)	mAP(%)
HRNet	51	18.2	75.5
HRNet+FAM	56	19.7	77.8
HRNet+FAM+AFF	58	21.1	79.1

The table data shows that after adding the flow alignment module, the network's mean average precision (mAP) increased by 2.3%, but the computation increased by 1.5G. This indicates that with a slight increase in computation, the network accuracy was improved. Based on this improvement, the attention-aware feature fusion module was further introduced, resulting in an additional increase of 1.4G in computation, while the mAP increased by another 1.3%. Compared to the initial network, although the computational complexity was slightly increased, the network's accuracy, frame processing rate, and computation rate were significantly improved.

The improved algorithm was used to train the human skeleton key point recognition model, and the training results were compared with those of the original HRNet network. The accuracy curves are shown in Fig. 10.



(a) Accuracy curve of the original HRNet



(b) Accuracy curve of the improved HRNet

Fig. 10. Comparison of model training accuracy curves.

As shown in Fig. 10, the model stabilizes after 20 training epochs both before and after the HRNet network improvements. The Fig also indicates that the training model converges faster and achieves better results after the feature fusion module improvements. Finally, a comparison of model accuracy after 30 training epochs is presented in Table III.

TABLE III ACCURACY COMPARISON AFTER 30 TRAINING EPOCHS

Model	Train Acc(%)	Val Acc(%)
HRNet	76.1	75.8
HRNet+FAM+AFF	79.5	79.3

Experimental results indicate that the improvements made to the model significantly enhanced the accuracy of pose recognition and accelerated the computation speed. Therefore, this model is suitable for use as the pose estimation network in the real-time behavior detection algorithm.

D. Design of Human Hazardous Behavior Recognition Algorithm

This study first conducted a survey on the types of slide facility accidents domestically and internationally, and established a checklist of accident types and behaviors. Based on this, the hazardous behavior issues to be addressed in this study were determined. Next, by identifying the recognition categories, a parameterized model of behavior actions was constructed. An algorithm for behavior recognition was designed based on the information obtained from the improved skeleton sequence extraction network mentioned earlier. Finally, behavior recognition was performed using both pose estimation algorithms and sensor-acquired information, and comparative experiments were conducted to verify the feasibility of the algorithm.

In cases of slide playground accidents, improper behavior by users and inadequate supervision by managers can be predicted through extensive observation, statistics, and analysis [25]. The causes of human errors are complex. Based on relevant facility standards and the investigation of slide playground facilities, accidents on slides were categorized and summarized. The design of this detection algorithm needs to complete the identification of behavior categories including crowding, close proximity, orientation abnormality, climbing, staying still, falling, and normal state.

3) Behavior feature analysis and skeleton key point selection: Crowding and close proximity scenarios share a common characteristic: the presence of multiple people in the facility, distinguishing them from other hazardous scenarios. These hazardous behaviors are relatively easy to identify and can be prevented by limiting the number of users. Past object detection algorithms have already obtained the number of human image frames when extracting human information from images, so the number of people can be used as a priori condition for behavior judgment. For distance judgment, the intersection over union (IoU) between each human image frame is used; if the IOU exceeds a preset threshold, it is determined to be too close.

When using the slide, orientation abnormalities occur when people slide down in a non-seated position, meaning the upper body is positioned below the lower body during the slide, which can easily lead to head injuries. To address this issue, the height difference of body key points can be used as a basis for judgment. Since the nose and ankle positions are less likely to be occluded, their detection is relatively stable. Therefore, by comparing the vertical coordinate heights between the middle point of the left and right ankles and the middle point of the nose, the correctness of the sliding orientation can be determined.

During sliding on the slide, the vertical acceleration value is usually less than the gravitational acceleration ggg. When the body falls off the slide, its acceleration value should be equal to the gravitational acceleration. Thus, the midpoint between the shoulders and hips can be used as the body center point. When the vertical acceleration of this center point approaches g, it can be judged that the body has detached from the slide.

Position changes during slide use can be categorized into three situations: climbing, staying still, and normal sliding. During climbing, the posture is not fixed, but the general trend is climbing from bottom to top; staying still refers to the body actively or passively remaining stationary at any position on the slide; and normal sliding refers to sliding from top to bottom without hazardous behaviors. Because small changes in position significantly affect the judgment, the stable and information-rich body center point continues to be used as the judgment basis, with its vertical coordinate changes proving the position change of the body.

Using the improved HRNet algorithm, data for 17 human skeleton key points are obtained. The schematic diagram of the predicted skeleton key point positions is shown in Fig 11, and the correspondence between the skeleton key point names and feature point numbers is shown in Table 4.

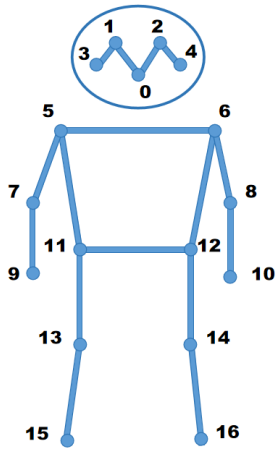


Fig. 11. Schematic diagram of the predicted positions of 17 skeleton key points.

TABLE IV CORRESPONDENCE BETWEEN KEY POINT NAMES AND FEATURE POINT NUMBERS

Feature Point Number	Key Point Name	Feature Point Number	Key Point Name
0	Nose	9	Left Wrist
1	Left Eye	10	Right Wrist
2	Right Eye	11	Left Hip
3	Left Ear	12	Right Hip
4	Right Ear	13	Left Knee
5	Left Shoulder	14	Right Knee
6	Right Shoulder	15	Left Ankle
7	Left Elbow	16	Right Ankle
8	Right Elbow		

The extracted human key points include the nose, eyes, left and right wrists, and left and right ankles, represented by (x, y) coordinates to indicate the positions of each key point. Taking the information [8.33e2 9.26e2 9.44529235e-1 9] as an example to explain the content, 9 represents the 9th joint, which is the left wrist; 9.44529235e-1 indicates the confidence level of detecting this joint; 9.26e2 represents the vertical coordinate pixel value of the key point; and 8.33e2 represents the horizontal coordinate pixel value of the key point. The representation method for other key points is the same.

To achieve behavior recognition functionality, logical settings are applied to the obtained human key point coordinates. In the practical application scenarios of this study, key points 0, 5, 6, 15, and 16 are used to express the parameterized design of several behaviors.

4) Parameterized representation of behaviors: The assessment of crowding and close proximity behaviors relies on human information in the images. During this process, the number of people in the image can be obtained using the number of human bounding boxes extracted by the previous object detection algorithm. Behaviors involving distance issues include children sliding on an adult's lap and pushing on the slide. Due to occlusions, using skeleton key points for distance judgment is somewhat difficult. Therefore, in this study, the intersection over union (IOU) of human bounding boxes is chosen as the basis for distance judgment. When the IOU

reaches a certain threshold, it is determined that the distance between the two is too close.

The upper-left pixel coordinates of the first person's bounding box are (x_{a1}, y_{a1}), and the lower-right pixel coordinates are (x_{a2}, y_{a2}). The upper-left pixel coordinates of another person's bounding box are (x_{b1}, y_{b1}), and the lower-right pixel coordinates are (x_{b2}, y_{b2}). The area of bounding box A is $S_A = (x_{a1} - x_{a2}) \times (y_{a1} - y_{a2})$, and the area of bounding box B is $S_B = (x_{b1} - x_{b2}) \times (y_{b1} - y_{b2})$. The IOU schematic diagram is shown in Fig 12.

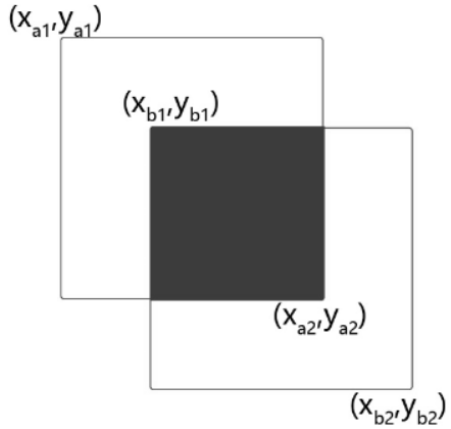

Fig. 12. IOU schematic diagram.

To address the issue of slide orientation, the coordinates of the detected human nose key point (0) and the midpoint coordinates of the ankle joints (15, 16) are used for judgment. The height difference between the nose and ankles is used to make the determination. In a stable state, the nose height is denoted as $\overline{H_{nose}}$, the ankle height is denoted as $\overline{H_{ankle}}$, and the average height of both ankles is denoted as $\overline{H_{ankles}} = (H_{lankle} + H_{rankle})/2$. The difference between the nose height and the average height of both ankles in a stable state is recorded as $D_{na} = \overline{H_{nose}} - \overline{H_{ankles}}$. If the height difference is negative, it indicates an orientation abnormality.

For the determination of falling, climbing, staying still, and normal states, the average value of the coordinates of the left shoulder (5), right shoulder (6), left hip (11), and right hip (12) key points is used as the coordinate value of the human center point. Specifically, $\overline{x_{center}} = (x_{lshoulder} + x_{rshoulder} + x_{lhip} + x_{rhip})/4$, and $\overline{y_{center}} = (y_{lshoulder} + y_{rshoulder} + y_{lhip} + y_{rhip})/4$. If $\overline{y_{center}}$ continues to increase, it indicates that the person is climbing rather than sliding. Conversely, if it decreases, it indicates normal sliding. If it remains unchanged, it indicates that the person is staying still.

To determine falling behavior, the center point's coordinates are first calculated. Then, the second derivative of the pixel coordinates is computed to obtain the center point's acceleration. The expressions for calculating the vertical velocity and acceleration are as follows:

$$v_{ij} = \frac{(y_{ij} - y_{i-1,j})}{\Delta t} \quad (5)$$

where y_{ij} is the vertical coordinate of the j-th key point in the i-th frame, $y_{i-1,j}$ is the vertical coordinate of the j-th key point in the $(i-1)$-th frame, and Δt is the time interval between two adjacent frames.

$$a_{ij} = \frac{(v_{ij} - v_{i-1,j})}{\Delta t} \quad (6)$$

where v_{ij} is the velocity of the j-th key point in the i-th frame, and $v_{i-1,j}$ is the velocity of the j-th key point in the $(i-1)$-th frame.

The algorithm designed in this study follows these steps: first, load the weight file and initialize the recognition model, then recognize humans and slides. Based on the detected number of people, the algorithm proceeds as follows: if the number of people is 2, further calculate the intersection over union (IoU) and obtain information on distance, climbing status, etc.; if the number of people is 3 or more, output "crowded"; otherwise, perform person comparison. During the recognition process, the algorithm also detects human landmarks, acceleration, and other parameters to determine if there are any abnormal conditions, and finally sends the results to the monitoring interface for real-time surveillance.

Based on the above definitions and analyses of various behaviors, combined with the investigation and practical experience of slide accidents, a series of behavioral characteristic indicators were designed to achieve targeted monitoring of the usage behavior of slide playground facilities. Subsequently, experimental methods were used to verify the reliability of the proposed behavioral indicators. The behavioral characteristic indicators are shown in Table 5.

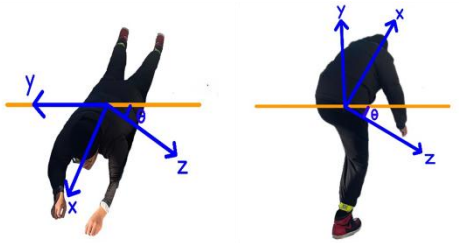
TABLE V PARAMETERS OF HUMAN BEHAVIOR CHARACTERISTICS

Behavior type	Feature parameter	Parameter indicator
Crowding	Number of human bounding boxes	Num≥3
Close proximity	Number of human bounding boxes IOU value	Num=2,IOU＞0.3
Orientation abnormality	Nose key point vertical coordinate Ankle key point vertical coordinates	D_{na}＜0
Falling	Vertical acceleration value of the human center point	9.5m/s^2≤a_{ij}≤9.8m/s^2
Climbing	Vertical coordinate of the human center point	Continuously increasing vertical coordinate
Staying still	Vertical coordinate of the human center point	Unchanging vertical coordinate
Normal state	Vertical coordinate of the human center point	No other category present Continuously decreasing vertical coordinate

5) Recognition logic design: In the establishment of the database, the selection of action materials must follow certain strategies[26][27][28]. The categories of behavior recognition through pose information in this study include five types: orientation abnormality, climbing, staying still, falling, and

normal state. The recognition logic design is achieved by setting changes in pose angles, the direction of acceleration, and acceleration value thresholds.

The judgment of two behaviors, orientation and climbing on the slide, can be made based on the positive or negative values of the X-direction acceleration a_x obtained from the sensor. These values represent whether the body is oriented upward or downward in that direction. Additionally, the Z-direction pose angle $AngleZ$, which is typically described as the pitch angle and usually denoted by θ, describes the angle between the body's front orientation and the horizontal plane, as shown in Fig 13. When the body orientation is abnormal, θ is a negative acute angle, and a_x is positive. When the body is climbing the slide, θ remains a negative acute angle, but a_x is negative. Based on this information, these two behaviors can be identified.



(a) Falling pose (b) Climbing pose

Fig. 13. Pitch angle pose information.

To address the issue of distinguishing between different sliding states on the slide, staying still refers to the condition where position information does not change. This can be determined by using the three-axis velocity. The speed information is obtained by integrating the acceleration data, and the calculation expression is:

$$v_i(t) = \int_0^t a_i(t)dt \quad (7)$$

where iii represents the three-axis directions, with the velocities in the x, y, and z directions calculated separately. When the changes in v_x, v_y, and v_z are minimal and nearly zero, staying still can be determined. As previously described, the falling condition is indicated by the vertical acceleration being equal to the gravitational acceleration. This condition is met only in this behavior, resulting in a low probability of misjudgment. The normal sliding state should meet the condition that θ is always positive. The seated position on the slide may involve the body being close to the slide or sliding upright, so both acute and obtuse angles are possible. Additionally, the vertical velocity should always be downward. If both conditions are met, normal sliding can be determined.

6) Experimental results validation: Using the skeleton sequence extraction algorithm based on the improved HRNet, a human motion dataset was created, including seven types of action postures: crowding, close proximity, orientation abnormality, climbing, staying still, falling, and normal state. The data collected by the camera is input into the skeleton extraction network to extract human pose information from the images. In this process, each person's pose is recognized and represented as a dataset composed of the two-dimensional coordinates of 17 key points. These key point information is saved as train.txt text files and organized into train.csv files through scripts. Additionally, normalization is performed to eliminate the impact of dimensional differences between data. The dataset includes a total of 4200 skeleton sequence images, with a training set to validation set ratio of 8:2. The sample distribution of the human behavior dataset for the slide facilities in this study is shown in Table VI.

TABLE VI KEY POINT NAMES AND FEATURE POINT NUMBERS CORRESPONDENCE

Behavior category	**Crowding**	**Close Proximity**	**Orientation Abnormality**	**Climbing**	**Staying Still**	**Falling**	**Normal State**
Skeleton Sequences (segments)	605	510	460	640	520	560	805

To verify the effectiveness of the behavior recognition algorithm proposed in this paper, experiments were conducted using the improved HRNet network on a self-built skeleton sequence dataset. A total of four testers participated in the experiments, each performing the aforementioned seven types of behaviors for data collection. The experimental data results are shown in Table VII.

TABLE VII EXPERIMENTAL DATA RESULTS

Behavior	**Number of tests**				**Accuracy /%**
	1	2	3	4	
Crowding	121	134	169	146	94.2
Close Proximity	105	127	144	118	96.9
Climbing	143	167	133	140	91.1
Staying Still	125	113	142	108	93.8
Orientation Abnormality	107	114	109	115	96.7
Falling	133	151	173	102	99.8
Normal State	203	187	223	181	98.6

The experimental results show that the human behavior detection algorithm based on the improved HRNet network design achieved an average detection accuracy of over 90%. It performed exceptionally well in recognizing behaviors such as normal state and falling, as these behaviors have relatively distinct features. However, there are challenges in recognizing behaviors such as climbing and staying still, mainly due to the key points in the judgment logic being affected by trunk occlusion or the complexity of the actions, leading to unstable recognition and resulting in misjudgments.

The posture sensor used in this study is the WT901WIFI, an integrated 9-axis motion analysis component that combines a high-precision gyroscope, accelerometer, and geomagnetic sensor. By solving the attitude matrix of the posture calculation system, converting the coordinates of specific forces, and

updating the attitude matrix, it outputs acceleration data, which is integrated over time to obtain the instantaneous velocity of the carrier [29]. When the sensor rotates with the human body, the gyroscope can detect the rotational angular velocity of the carrier. To obtain the human body's motion posture information, the angular velocity output by the gyroscope needs to be integrated, which provides the angular increment relative to the reference coordinate system, thus deriving the motion posture information. The smaller the time increment of integration, the higher the accuracy of the obtained angular data. After acquiring the attitude angle data, the human body's positional information can be derived through secondary integration, thereby obtaining the position change in three-dimensional space[30]. The internal integration of the attitude solver and dynamic Kalman filtering algorithm within the device allows the sensor to accurately output posture in dynamic environments, facilitating behavior recognition based on angle information.

In the field of human action recognition based on accelerometers, many studies have detailed the data collection process [31][32][33]. Using self-collected acceleration data to train and test recognition algorithms, the recognition rate largely depends on the quality of the collected database. To enhance the comparability of this experiment's results, a dataset based on a nine-axis accelerometer was established. Before data collection, the sensor needs to be fixed, ensuring the three-axis directions measured by the sensor completely coincide with the three-axis directions of the measured equipment to ensure data reliability. Additionally, the sensor must be firmly fixed to prevent shaking, which could cause significant measurement errors in acceleration data. Lin[31] and colleagues collected posture information by placing sensors at different wearing positions, including the waist, wrist, ankle, arm, and thigh, comparing the impact of each position on recognizing daily motion patterns. Results showed that the wearing position significantly affected posture recognition rates, with the highest recognition rate achieved when the sensor was fixed at the waist. Therefore, in this collection, the sensor was fixed at the waist to test the acquisition of posture information. During the study, multiple data collections were conducted, with field equipment collecting data on the slide facilities of a kindergarten. The collected data included three-axis acceleration, three-axis angular velocity and angle, and the corresponding collection time.

The algorithms based on machine vision information and those based on pose sensor information were tested on the constructed dataset. The accuracy confusion matrices for recognizing human behaviors in slide facilities for both approaches are shown in Tables VIII and IX.

The detection methods based on machine vision and sensors both showed good performance in terms of recognition accuracy, thereby validating the generalization capability of the algorithm established in this study for recognizing human behaviors in slide facilities. According to the data in Table VIII, the recognition rates of different behaviors in the pose estimation scheme show certain differences. The root cause of this difference can be traced to the stability and latency of obtaining skeleton sequences during real-time detection. When the key point information used by the algorithm is not updated in time during the judgment process, it may lead to misjudgments or omissions. Therefore, setting parameters between frames is crucial for behavior recognition in practical situations.

TABLE VIII CONFUSION MATRIX FOR BEHAVIOR RECOGNITION BASED ON MACHINE VISION INFORMATION

	Climbing	**Staying Still**	**Orientation Abnormality**	**Falling**	**Normal State**
Climbing	0.9013	0	0	0	0
Staying Still	0.0655	0.9537	0.0046	0	0.0233
Orientation Abnormality	0	0	0.9735	0	0.0014
Falling	0	0	0	1	0
Normal State	0.0332	0.0463	0.0219	0	0.9753

TABLE IX CONFUSION MATRIX FOR BEHAVIOR RECOGNITION BASED ON SENSOR INFORMATION

	Climbing	**Staying Still**	**Orientation Abnormality**	**Falling**	**Normal State**
Climbing	0.9115	0.0086	0.0281	0	0
Staying Still	0.0742	0.9383	0.0046	0	0.0134
Orientation Abnormality	0	0	0.9673	0.0004	0
Falling	0	0	0	0.9985	0
Normal State	0.0143	0.0531	0	0.0011	0.9866

The recognition scheme based on pose information also has its advantages and disadvantages. By comparing and analyzing the experimental results, it can be seen that the recognition accuracy of the two schemes is shown in Fig. 14.

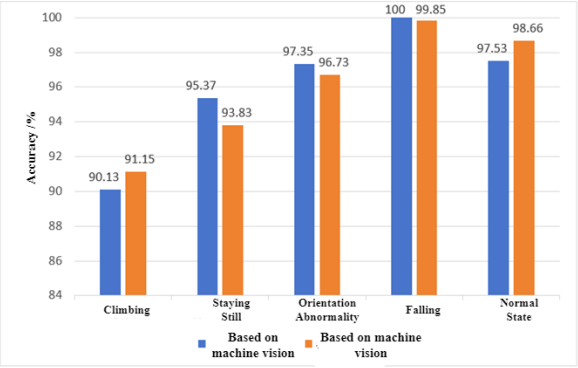


Fig. 14. Comparison of recognition accuracy of the two methods.

Both methods perform poorly in recognizing climbing behavior. This is mainly due to the complexity and inconsistency of climbing actions, as well as possible occlusion. Therefore, there are significant challenges in obtaining key points and setting pose information thresholds. Recognition of body orientation shows that the method based on skeleton sequences is superior to the judgment based on pose angles. Climbing behavior is not limited to the user lying face down on

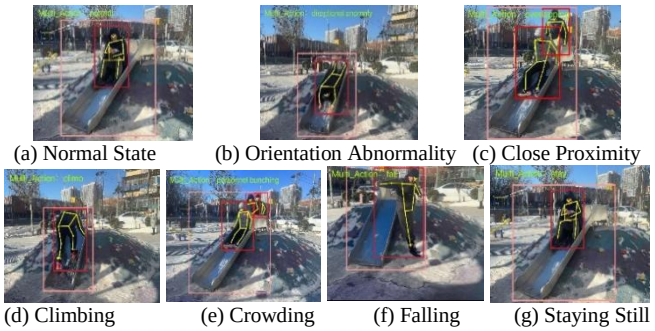
the slide but can also include sliding with the back against the slide and head down, which causes the pitch angle judgment to fail. However, the judgment based on skeleton key points is relatively stable during detection. Although there may be occasional misjudgments due to interrupted behavior, the overall recognition accuracy is higher.

For recognizing staying still and normal sliding behaviors, both methods show generally stable performance, with accuracy rates of over 96%. Misjudgments are mainly related to the set judgment time, as delays in camera capture and sensor transmission can affect the stability of frame-to-frame information. The accuracy of determining falling is nearly error-free because this behavior has obvious characteristics, and obtaining acceleration value information is relatively easy, making the processing methods more diverse and less prone to errors.

By comparing the recognition accuracy of human behaviors in some slide facilities, the results show that the method based on human skeleton sequence information performs well in recognizing the above behaviors. It effectively reduces the impact of complex human postures and inconsistent behavior scenarios.

III. Experimental Results

The slide facility human behavior monitoring system is based on the human behavior recognition algorithm presented in this paper and is deployed on a computer upper platform. The computer uses an external camera to capture images of the monitored scene and stores them in real time. The monitoring system invokes the human behavior recognition algorithm to judge various hazardous behaviors from the images and presents the processed results on the system's interactive interface, while also controlling the computer's buzzer to sound an alarm. To obtain a comprehensive monitoring view, the external USB camera is fixed at positions 1 meter and 3 meters from the ground and the slide, respectively. The system conducts detection tests on seven types of behaviors, and the detection effects are shown in Fig. 15.



(a) Normal State (b) Orientation Abnormality (c) Close Proximity

(d) Climbing (e) Crowding (f) Falling (g) Staying Still

Fig. 15. Detection results of the behavior recognition system.

To verify the effectiveness of the human behavior recognition based on the PyQt interactive interface system, tests were conducted after the real-time collection of a series of behaviors, with 90 groups recorded for each behavior. The confusion matrix for recognizing seven types of behaviors by the human behavior recognition model tested on a computer upper platform system built with PyQt is shown in Fig. 16.

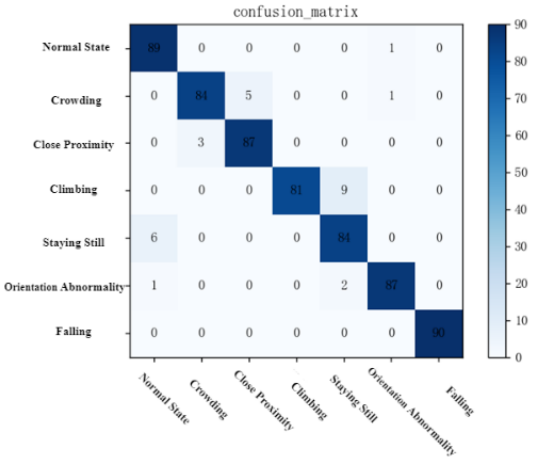


Fig. 16. Confusion matrix of system behavior detection results.

After experimental testing, the test accuracy, recall, specificity, and F_1 score were calculated from the obtained data to serve as the basis for evaluating the system's detection performance. The calculated data are shown in Table X.

TABLE X Distribution of Test Performance

Behavior Category	Precision	Recall	Specificity	F1 Score
Normal State	0.988	0.975	0.993	0.981
Crowding	0.933	0.924	0.941	0.928
Close Proximity	0.966	0.933	0.982	0.949
Climbing	0.9	0.885	0.924	0.892
Staying Still	0.933	0.926	0.949	0.929
Orientation Abnormality	0.966	0.956	0.975	0.961
Falling	1.0	0.987	1.0	0.993

The main diagonal elements of the confusion matrix reflect the number of correctly recognized specific behavior categories. The recognition accuracy is the ratio of correctly classified behaviors to the total number of classified outputs [34]. According to the confusion matrix results, the recognition accuracy for various behaviors is generally high in the upper computer system. However, Table 10 shows that except for the recognition accuracy of climbing behavior, which is 0.9, the accuracy for other behaviors is above 0.9.

Analyzing this, the judgments for crowding and close proximity rely on determining the number of humans after object detection. This process is influenced by logical similarities, which may lead to misjudgments between them. Climbing behavior may involve pauses, making it easy to be misjudged as staying still. Additionally, the posture of climbing behavior may cause limb occlusion, affecting the extraction of human skeleton key points, resulting in less comprehensive skeleton sequence features and relatively lower recognition accuracy.

Overall, the detection data show that the average recognition performance for the seven types of behaviors is satisfactory and meets the expected goals of this study.

IV. CONCLUSION

This study delves into the issue of human hazardous behavior recognition in slide facilities, designing a recognition method based on a pose estimation extraction algorithm for human skeleton sequence information and pose parameterization representation algorithm. PyQt technology was used to deploy the detection model on a computer upper platform to recognize hazardous behaviors in slide facilities. The main contributions of this paper are as follows:

1) Proposed an improved method for extracting human skeleton sequences: This method includes detecting humans within the range of the slide and slide recognition box in the scene and tracking human trajectories. The improved HRNet network is used to extract continuous skeleton sequence data for each person.

2) Proposed improvement solutions for issues within the HRNet network: The solutions address problems of pixel symmetry being disrupted during the process of obtaining high-resolution features from low-resolution feature maps and the loss of features during the fusion of different resolutions. A network model incorporating a flow alignment module (FAM) and an attention-aware feature fusion module (AFF) was proposed. Experimental results show that the network integrating these two modules, compared to using only the HRNet network and the HRNet network with the flow alignment module, improves accuracy on a self-built dataset. The accuracy of hazardous behavior detection increased by 3.6% with a slight increase in training complexity, achieving good computational efficiency and accuracy.

3) Designed a human hazardous behavior recognition algorithm for slide facilities: By organizing a list of hazardous behaviors in the scene, summarizing hazardous behaviors on slides, and conducting parameterized pose design. The skeleton key point sequence information of humans sliding extracted by the improved HRNet network and DeepSORT tracking network is combined with the image classification information obtained by the object detection network, and input into the parameterized pose representation algorithm to determine the behavior category of the users' poses.

The human behavior monitoring system for slide facilities designed in this study achieves non-contact equipment safety management through machine vision technology. This method avoids the impact of the equipment on children during the sliding process and helps improve the digitalization, informatization, and intelligence levels of reasonable supervision of amusement equipment in places like playgrounds, schools, and communities. Nevertheless, this study has certain limitations, as not all mentioned technologies were deeply explored. Future work should aim to further improve:

1) Segmenting and supplementing behavior categories: Currently, only parameterized design and experimental verification for hazardous behaviors in investigated safety accidents have been conducted. In the future, behavior categories can be further segmented and supplemented, collecting more human behavior information in slide facilities, designing relevant parameter expressions, and further enhancing the model's applicability in slide facility scenarios.

2) Enriching image feature information: The current human behavior detection methods utilize relatively single image feature information, and pose parameterization design should not be limited to information such as acceleration, position, and angle. Future research will use facial recognition technology to achieve expression detection of human targets to assist in human behavior detection.

3) Introducing three-dimensional image information: The slide scene images and videos collected in this study are all two-dimensional, lacking the reliability of three-dimensional spatial information. Therefore, future research will consider using binocular vision cameras to collect three-dimensional images, employing three-dimensional reconstruction technology and reasonably designing the representation of human spatiotemporal action information.

Improving Road Safety in Indonesia: A Clustering Analysis of Traffic Accidents Using K-Medoids

Handrizal*, Hayatunnufus, Maryo Christopher Davinci Nababan
Department of Computer Science-Faculty of Computer Science and Information Technology,
Universitas Sumatera Utara, Medan, Indonesia

***Abstract*—Traffic accidents pose a significant public health and safety challenge in Indonesia, ranking fifth globally in terms of traffic fatality rates. This study aims to identify patterns in traffic accident data to inform effective mitigation strategies. Utilizing the K-Medoids algorithm, we clustered traffic accident data from the Indonesian Central Bureau of Statistics for the period 1992–2022. Prior to clustering, rigorous data preprocessing was conducted to ensure accuracy. The K-Medoids algorithm successfully partitioned the data into distinct clusters, revealing variations in accident patterns across different regions of Indonesia, including disparities in accident frequency and severity. This research provides valuable insights for policymakers and transportation authorities to develop targeted interventions and improve road safety in Indonesia. Additionally, this study successfully applied the K-Medoids algorithm to cluster traffic accident data in Indonesia using data from 2018 to 2022.**

***Keywords*—Traffic accidents; K-Medoids; clustering; data mining**

I. Introduction

Traffic accidents can involve single vehicles or collisions between multiple vehicles, such as cars, motorcycles, bicycles, and others. External factors, such as collisions with inanimate objects like trees, poles, walls, or traffic lights, also contribute to accidents. According to study [1], each year, 20 to 50 million people sustain serious injuries, and approximately 1.3 million fatalities occur due to traffic accidents worldwide.

Contributing factors to traffic accidents include adverse weather conditions and road damage caused by construction [2]. Moreover, the significant increase in vehicle ownership has led to severe traffic congestion, further elevating the risk of accidents [3]. Indonesia ranks fifth globally in traffic fatalities [4].

The consequences of traffic accidents are severe, including fatalities, serious injuries, minor injuries, and material losses [5]. This study utilizes Indonesian traffic accident data to identify potential patterns and insights that can contribute to accident prevention strategies [6].

Data mining techniques, such as clustering, are crucial for extracting valuable information from large datasets [7]. Clustering, a method for grouping similar data points, has proven effective in solving complex problems in computer science and statistics [8]. The K-Medoids algorithm is a prominent partitioning method in clustering, known for its ability to efficiently group large datasets [9]. It identifies representative data points (medoids) within each cluster, effectively summarizing the data and enabling the identification of underlying patterns [10].

Xiangrun [11] developed a one-stop evaluation framework, EWM-GRA-Kmeans, to evaluate the road safety development of the ASEAN community over the past decade (2009–2020). While this approach effectively identifies road safety trends, it has limitations in handling non-linear relationships, data sparsity, and the need for extensive parameter tuning to achieve optimal clustering results.

II. Materials and Methods

A. Data Mining

Data mining is the process of extracting meaningful patterns and insights from large datasets. It involves identifying significant relationships and trends within the data to uncover hidden knowledge [12]. This process often requires analyzing vast amounts of information to discover previously unknown patterns and gain valuable insights [13]. Key characteristics of data mining include:

- Discover previously unknown patterns.
- Utilize large datasets for analysis.
- Generate reliable and actionable insights.

Data mining is a crucial component of Knowledge Discovery in Databases (KDD), a multi-step process that includes data cleaning, integration, selection, transformation, and, ultimately, data mining itself. The ultimate goal of KDD is to extract useful knowledge and insights from raw data [14].

Clustering is a fundamental technique in data mining that groups similar data points together. Its goal is to uncover underlying structures and patterns within the data. Common clustering algorithms include K-Means, K-Medoids, Hierarchical Clustering, and Fuzzy C-Means [15].

The K-Medoids algorithm, also known as Partitioning Around Medoids (PAM), is a popular clustering method. Unlike K-Means, which uses the mean of data points as cluster centers, K-Medoids selects actual data points as cluster representatives. This approach is more robust to outliers and noise in the data [16].

Clustering has a wide range of applications across various fields, including psychology, population studies, healthcare, economics, and social sciences [17]. In general, the k-medoids algorithm operates as follows [18]:

*Corresponding Author, email-Handrizal@usu.ac.id

1) Determine the number of k values (clusters).

2) Randomly select k centroid values (center points) from the n available data points.

3) Calculate the distance of each data point to the assigned centroid using the Euclidean Distance formula:

$$d_{ab} = \sqrt{(x_{1a} - x_{1b})^2 + \cdots + (x_{ia} - x_{ib})^2}$$

4) Assign each data point to the cluster with the closest centroid.

5) Compute the total cost based on the smallest value within the cluster.

6) Recalculate the centroid values.

7) Repeat steps 3 to 5.

8) Compute the total deviation (S) by subtracting the initial total cost from the new total cost. If S<0, swap the object with the new cluster data to establish a new centroid value.

9) Repeat steps 3 to 5 until the centroid values remain unchanged.

A traffic accident is an unintentional event that can occur anywhere. According to the Indonesian National Police, in 2020, an average of three people per hour and 80 people per day died due to traffic accidents in Indonesia. The victims were primarily between the ages of 5 and 29, with men being more frequently affected than women.

Traffic accidents can be caused by various factors. Fatigue and stress from work, conflicts between work and family, overtime hours, lack of motivation for safe driving, and irregular working hours are some of the potential causes. Other contributing factors include adverse weather conditions, such as fog, and road damage due to construction.

B. Data Collection Stage

In this study, researchers collected traffic accident data in Indonesia from multiple relevant sources to ensure accuracy and completeness. The data was obtained from the National Statistics Agency website and included information on the year of the accident, the number of victims with minor injuries, and the number of victims with severe injuries. The data then underwent a pre-processing stage to facilitate clustering analysis using the K-Medoids method, aiming to provide accurate insights into accident patterns across various regions in Indonesia.

C. Data Pre-processing Stage

Data pre-processing for traffic accident datasets in Indonesia is crucial before conducting any analysis. This stage aims to improve data quality, reduce noise, and ensure consistency, ultimately leading to more accurate analytical results. In this study, researchers used Microsoft Excel for data pre-processing.

D. Clustering Stage

The K-Medoids method is a clustering technique that partitions data into multiple groups or clusters based on similarities among data points. Unlike the K-Means method, which determines cluster centers using the average of the data, K-Medoids selects specific data points as cluster centers, known as medoids. One key advantage of the K-Medoids method is its robustness against outliers, as the chosen medoid better represents the cluster compared to the mean, which can be influenced by extreme values.

E. Analysis Stage

The analysis stage in clustering traffic accident data in Indonesia consists of a series of systematic processes to categorize data based on specific patterns or characteristics. It begins with the collection of accident data from the Central Bureau of Statistics website, followed by data pre-processing to remove irrelevant or incomplete information. Subsequently, the data is processed using the K-Medoids clustering algorithm, which classifies accident years based on their level of vulnerability. The results of this analysis help identify high-risk years for accidents, serving as a foundation for developing more effective road safety strategies in the future.

F. System Architecture

The system architecture in this study is designed to support the analysis of traffic accident data in Indonesia using the K-Medoids clustering method. The collected data is processed and analyzed using software such as Microsoft Excel for initial data processing, Google Colab for modeling and visualization, and Visual Studio Code for developing a dashboard interface that presents the analysis results to users. The system architecture of this study is shown in Fig. 1.

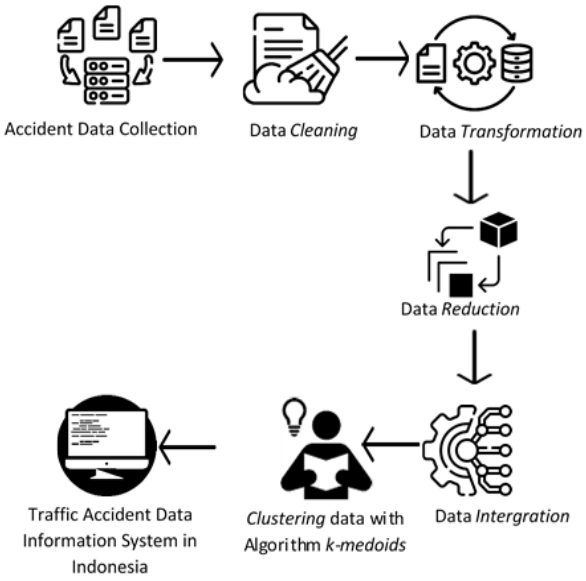

Fig. 1. System architecture.

The explanation of Fig. 1 is as follows:

1) Collecting traffic accident data from all regions in Indonesia through the websites of the National and Provincial Central Bureau of Statistics.

2) The collected data then undergoes a pre-processing stage, which includes data cleaning, transformation, reduction, and integration.

3) The processed data is then input into a data processing system using the K-Medoids algorithm, which is implemented in Google Colab using the Python programming language.

4) After data processing, the next step is to design a system that presents information on clustering results and visualization

patterns of traffic accident data in Indonesia, using Visual Studio Code with HTML and CSS.

III. Results and Discussion

Prior to clustering, the data underwent a preprocessing stage based on accident years. This crucial step ensured data quality and prepared the data for subsequent analysis. Data preprocessing resulted in a cleaner and more structured dataset, as presented in Table I, which summarizes the number of accidents, fatalities, serious injuries, and minor injuries from 1992 to 2022. This preprocessed data served as the foundation for the clustering analysis, enabling the identification of complex accident patterns. Accurate clustering results are essential for effective accident mitigation efforts and informed strategic decision-making to improve road safety in Indonesia.

TABLE I. Traffic Accident Data in Indonesia (1992-2022)

Year	Number of Accidents	Death Victim (Person)	Serious Injury (Person)	Minor Injury (Person)
1992	19920	9819	13363	14846

A. Determining the Number of Clusters

This stage represents the initial phase of K-Medoids clustering. In this study, the number of K values (clusters) is set to three. Here, C1 represents years with a very high accident risk, C2 represents years with a high accident risk, and C3 represents years with a low accident risk.

B. Medoids Initialization

At this stage, the initial medoids are randomly selected to represent each cluster in the dataset, based on the predetermined number of clusters. These medoids serve as the initial centers for the formation of clusters. The medoids in this dataset are shown in Table II."

C. Assignment of Cluster Members

At this stage, the distance of each data point in the dataset to each medoid is calculated using the Euclidean Distance formula, and the data is assigned to the cluster with the nearest medoid. This process groups data into clusters that align with the criteria of each medoid. The assignment of cluster members in the dataset is determined by calculating the nearest distance using the Euclidean Distance formula. The shortest distance is from the first data point to the third cluster, meaning the first data point in the dataset belongs to Cluster 3. The complete distance calculations for each data point are shown in Table III.

2022	52338,892	121932,839	198781,877	52338,892	C1

The total cost of the closest distance from the dataset to the initial medoids is 383,460.873.

D. Update of Medoids

Once all the data have been assigned to their respective clusters, the next step is to evaluate whether better medoids can be identified by replacing the previously selected ones. The goal of this phase is to minimize the total distance between the data points and the medoids within each cluster. The new medoids for this dataset are presented in Table IV.

E. Iteration

The final stage is the iteration stage, during which steps 2 and 3 are repeated until there are no significant changes in the selection of medoids or clustering. If the difference between the total distance of the old medoids to the data and the total distance of the new medoids to the data exceeds 0, the clustering process is halted. The determination of new cluster members in the dataset is performed by calculating the Euclidean distance to identify the closest one. For instance, if the shortest distance is between the 1st data point and the 3rd cluster, it means that the 1st data point in the dataset belongs to cluster 3. The complete distance calculations for each data point are presented in Table V.

The total cost of the closest distance from the dataset to the new medoids is 389,372.706. The calculated cost difference is 5,911.833.

IV. CONCLUSION

This study successfully applied the K-Medoids algorithm to cluster traffic accident data in Indonesia using data from 1992 to 2022. The algorithm facilitates the identification of distinct traffic accident patterns each year, enhancing the understanding of accident characteristics in Indonesia. The clustering results reveal variations in both the number of accidents and the severity of victims across different clusters. This research provides valuable insights to support accident mitigation efforts and the development of traffic safety policies in Indonesia.

For future research, incorporating data from all Indonesian provinces is crucial for obtaining comprehensive and nationally representative results. Analyzing data from each province will provide more detailed insights into traffic accident patterns, including regional variations. Additionally, integrating external factors such as weather conditions, traffic density, and environmental influences will further enhance the analysis. Furthermore, developing a mobile application that provides real-time information about accident-prone areas on digital maps can empower drivers to make informed decisions and improve road safety.

Tree Seed Algorithm-Based Optimized Deep Features Selection for Glaucoma Disease Classification

Sherif Tawfik Amin
Department of Computer Science-College of Engineering and Computer Science, Jazan University, Jazan, Saudi Arabia

***Abstract*—Glaucoma is a common eye condition that can cause irreversible blindness if left untreated. Glaucoma can be identified by the optic nerve disorder (a perilous path that carries the potential risk) and leads to blindness. Therefore, early glaucoma detection is critical for optimizing treatment outcomes and preserving vision. The majority of afflicted people typically do not exhibit any overt symptoms. Since many afflicted people go untreated as a result, early detection is essential for successful therapy. Systems for detecting glaucoma have been developed through a great deal of research. These manual, time-consuming, and frequently erroneous traditional diagnostic methods are not suitable for glaucoma diagnosis thus, automated methods are required. This research study proposes a novel glaucoma diagnosis model that addresses the difficulty of determining the complex cup-to-disc ratio. For accurate feature extraction, a publicly available dataset with two classes (Glaucoma positive and negative) is utilized from Kaggle. The dataset is augmented using the Flip technique and resized. A two-step approach using the Mobilenetv2 model is used to extract features from positive and negative classes. Accurate features are selected with the help of Transfer Function Sequential Analysis (TSA). The enriched features are then classified using three different classifiers: Cubic SVM, Ensemble Subspace KNN, and Fine KNN. The experimental evaluation comprises 7 and 8 cross-validation folds. On 7 folds Ensemble Subspace KNN provides an accuracy of 97.33%, and on 8 folds Fine KNN provides the best accuracy of 97.92%.**

Keywords*—Deep learning; tree seed algorithm; feature extraction; mobilenetv2

I. INTRODUCTION

Among all the causes of death across the world, glaucoma is one of the main causes of death. When the intraocular pressure inside the retina is increased then glaucoma is caused which is defined as neuro-degenerative eye in medical terms. Glaucoma is the second most common disease that results in complete blindness of patients if it is not detected at the early stages. It is also responsible for the reduction in the life spans of patients [1]. The degenerative disease of the eye that results in complete blindness of patients is glaucoma which is characterized by the loss of vision loss and progressive optic neuropathy. Due to an increase in pressure or the fluid inside the eye, the optic nerve of the retina is damaged leading to the destruction of the optic cup and the optic disc of an eye. As a result, the size of the optic cup is increased with the increased size of the optic disc [2]. Glaucoma is one of the prominent eye diseases across the globe. According to the report of WHO, on the world-wide level, approximately 4.5 million people suffer from complete blindness due to Glaucoma. This disease is developed by the gradual deterioration of the fibers of optic nerves that results in the structural changes of the optic nerve and reduces the rim of neuro-retina [3]. Glaucoma is defined as the loss of vision; if it's not detected at the early stage, it results in severe conditions of vision. This disease is common among people with an age range of 40-80 years and the prevalence of this disease in this age range is 3.54%. Hence, it is observed that among every 200 individuals, 40 individuals are affected with Glaucoma disease [4].

Glaucoma is a retina disease caused by the excessive amount of fluid inside the eye, resulting in damage to the optic nerve. When there is excessive fluid inside the human eye, the blood pressure increases, resulting in irreversible blindness [5]. Early stages identification of glaucoma is difficult, without thorough an eye examination because it frequently exhibits no symptoms. Currently, in the medical field diagnostic techniques such as imaging tests and functional evaluation tests are limited in terms of sensitivity and specificity. Optical coherence tomography provides detailed cross-sectional images of the retina; it excels in capturing structural alterations in the retinal layers, but it falls short in the early identification of functional loss. Glaucoma can be present in different ways with symptoms ranging from only mild or no noticeable symptoms to severe and irreversible damage, early detection of glaucoma is challenging [6]. For the diagnosis of glaucoma, a detailed examination of the optic nerve head, visual field testing, and tonometry are essential tests [7]. Early detection and intervention of glaucoma can significantly reduce the risk of glaucoma-related visual loss diseases. For early detection of glaucoma is necessary to implement innovative methods for screening, identifying, and diagnosing changes over time [8].

When retinal ganglion cells are lost, their axons gradually degenerate resulting in glaucoma, an eye illness that if left untreated, can cause permanent vision loss. This disease affects 80 million people worldwide at various ages, and in 2020 it was anticipated to be the leading cause of blindness [9]. Fig. 1 describes the fundus images of glaucoma where (a) mentions the labeled image of the fundus or glaucoma and (b) mentions the detailed image of fundus for the analysis by medical practitioners.

Manual feature extraction is necessary for machine learning-related models, and it takes a lot of time and effort. Rather than requiring users to manually extract features from the data, deep learning techniques seek to examine more abstract features from the data [3]. The human community is said to favor science and technology. There are enormous expectations for reliable computer-aided systems (CAD) all around the world [4]. There are two basic groups into which glaucoma types can be divided: primary angle-closure and

open-angle glaucoma [5]. However, there are still certain drawbacks, such as severe artifacts, poor image quality, reconstruction errors, pixel imbalance between the affected area and background, and low glaucoma detection sensitivity, all of which need to be found and fixed. Therefore, the goal is to provide a precise classification model for fundus image-based glaucoma detection. The main contributions of the proposed work are listed below as:

- In the proposed model, the complexity of identifying the cup-to-disc ratio for glaucoma detection has been overcome. To overcome this challenge, enhancement and resizing of images id performed for the expansion of the dataset. This process ensures accurate feature recognition, compensating for complex structures that make cup-to-disc ratios difficult to recognize.
- An accurate understanding of the glaucoma cup-to-disc ratio is achieved by extracting features from both positive and negative classes using a pre-trained model called Mobilenetv2, after that significant features get selected with the help of TSA.
- These features are fed to machine learning classifiers Cubic SVM, Ensemble Su space KNN, and Fine KNN.

The paper is arranged as: Section II describes Related Work, Section III describes Proposed Methodology, Section IV illustrates Results and Experiments, and Section V discusses Conclusion and Future Work.

II. Literature Review

The researchers utilized many Machine learning and deep learning methods [1, 6-19] strategies in various domains. A multi-branch neural network model is suggested for glaucoma diagnosis. Based on experimental findings, the constructed model reached 0.9151, 0.9233, and 0.9090 for accuracy, sensitivity, and specificity, respectively [20]. For the diagnosis of Glaucoma, the basic classification model CNN was utilized and amended where there were three convolution layers and one flattened layer. With the use of the least number of tunable parameters, the model learned and extracted the deep features of the images. PCA and LDA algorithms were applied to reduce the irrelevant feature and then the classification was performed in the final step [21]. To detect glaucoma, the deep learning models were utilized with the pre-trained models like MobileNet, DenseNet169, Xception, InceptionV3, VGG19, and ResNet152V2 [22]. A novice model of deep learning by using the OCT images of glaucoma was developed for the diagnosis of glaucoma. For efficient results, pre-trained vision transformer technology is applied on the eye dataset by extracting the features on the slice-based extraction, and then Gated Recurrent units were also utilized on the dataset [23]. Different unprocessed fundus images were trained by integrating hybrid ML and DL techniques for the recognition of glaucoma. For feature extraction, VGG was utilized and for classification, different models like AdaBoost, SVM, KNN, RF, and MLP were used [24]. During the diagnosis of glaucoma disease, an error that mostly occurs is the imbalanced data and to avoid this error, MAS Block architecture and many other image augmentation techniques were employed [25]. A simple CNN model was utilized for considering all the architectural designs of the fundus images for the detection of the disease. The pre-trained models of deep learning were applied for the classification purpose and the models included VGG16, ResNet50, AlexNet, and InceptionV3 [26]. YOLOv7 architecture i.e. an accurate and robust DL automated system was developed for the detection of glaucoma. This architecture was used to detect the optic cup and optic disc from the fundus images [27]. The disease of glaucoma disease can be identified by extracting features of the neuro-retinal rim using histogram and GLCM of the normal images of eye and the images with glaucoma disease. The process of feature extraction was carried out in three steps, firstly the acquisition of images was performed, secondly preprocessing was carried out and at the last step classification was performed [28]. The vision transformer for the object detection from the images was extended for the detection of glaucoma from the fundus images. The detection was carried out to calculate the cup-to-disc ratio of the eye and then analyze the neuro-retinal rim thinning on vertical alignment [29]. A novice heuristic-based UNet-Inception attention framework was developed for the classification and segmentation of optic nerves of eyes (glaucoma). Along with the fusion of UNet and Inception, Haris Hawks techniques were used for the selection of suiTABLE features with a hybrid loss function [30].

The fundus images of glaucoma were segmented by applying DL ensemble methods like GNet and UNet and these methods were integrated for the detection of the disease. Different preprocessing steps were involved for the accurate detection of the disease, the steps included normalization, resizing of images, contrast enhancement, and filtering for the optimization of the dataset image quality [31]. The disease of glaucoma can be detected by calculating the optic cup-to-disc ratio and to calculate this ratio a Joint U N net++ framework was developed that contained attention driven serial Unet++ based module features extraction, DDN, and CDN. The images were trained on ensemble networks of DarkNet19, EfficientNet-B1, and VGG19. For accurate results, the HBAS0GA algorithm was employed to optimize the results [32]. The classification of the fundus images of glaucoma was initiated first by the preprocessing of images, then blood vessels segmentation was performed, next features were extracted, and at the last step the classification of the eye diseases was performed. The classification was carried out by creating a hybrid classifier that integrated LRCN and SqueezeNet [33]. The fundus images classification was

performed by applying the three different DL classifiers in which the first classified was used to control alterations against PAC, the second classified was used to control alterations against PACD, and the third classified was used to control alterations against PACS (PAC+PACG) [34].

Table I illustrates the detailed literature review of the research work carried out for the classification of glaucoma disease. The review comprises of the proposed method, the utilized dataset, the results achieved, and the future dimensions of the proposed method.

III. MATERIALS AND METHODS

In the proposed methodology, a two-step procedure is utilized for the classification of glaucoma disease. First, a pre-trained Mobilenetv2 model is used to enhance the feature extraction process from both positive and negative classes. By implementing a pre-trained model, it extracts powerful features from the dataset that capture essential patterns and characteristics. Then the retrieved features are refined by using the Tree Seed Algorithm (TSA), which is important for identifying relevant features, allowing for an attentive and selective subset that contains critical information for further analysis. The combination of effective and advanced feature selection with a robust pre-trained model creates a strong framework that enables the model to encapsulate significant information while reducing noise or inconsequential features. This overview provides a detailed examination of how a novel technique contributes to identifying complex patterns and representations inside different and complicated datasets and contributes to improving the overall model's efficacy and precision. The processed structure of the proposed methodology is illustrated in Fig. 2.

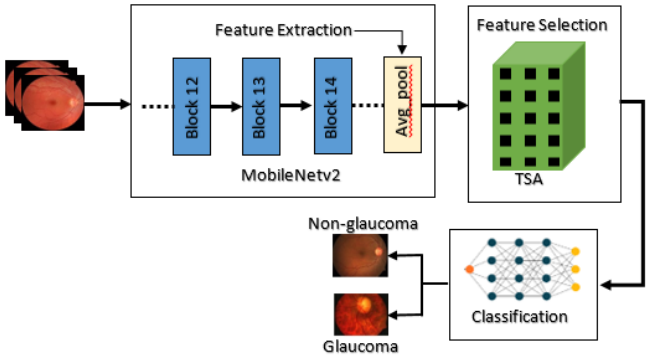

Fig. 2. Proposed MobTAS classification model.

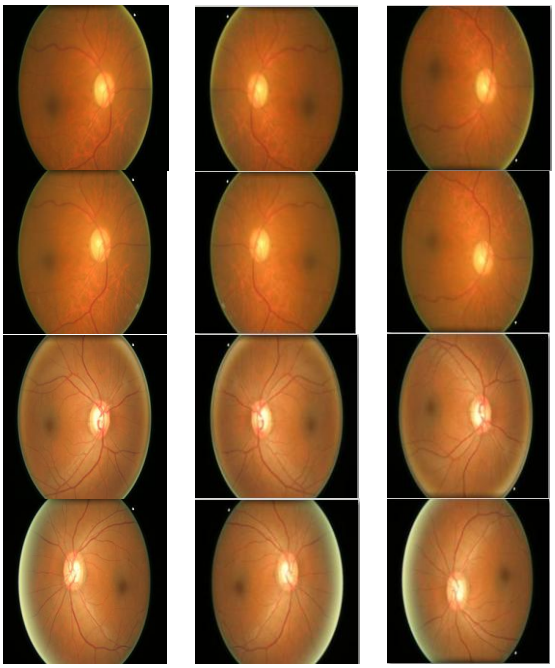
Fig. 2 describes the architecture for the proposed methodology for the classification of Glaucoma images. The input images are fed into the MobileNetv2 classification model

that is characterized by the consecutive blocks containing a back-to-back convolution layer, batch normalization layer, and ReLU layer thus comprising of total 19 residual blocks in which the convolution layers are present with the 32 filters. Then features are extracted from the fully connected layer of the model. The extracted features from the fully connected layer are then fed to the algorithm of TSFA for the selection of suitable features selection. Once the suiTABLE features are selected, those features are fed to three different classifiers: Cubic SVM, Fine KNN, and Ensemble Subspace KNN, and then the classification is performed.

A. Dataset Augmentation

Initially, the dataset consists of fewer images. Thus, to increase the number of samples, image augmentation is performed. Image augmentation is performed using the Flip (horizontal and vertical) technique as shown in Fig. 3.



(a) (b) (c)

Fig. 3. Data augmentation (a) Original images (b) Horizontally flipped images (c) Vertically flipped images.

In Fig. 3 the results of data augmentation applied to the original images are represented. Data augmentation is performed to have enough number of images for training and testing of glaucoma dataset classification. Fig. 3 (a) represents the original images (b) represents the results of horizontal flip of images, and (c) represents the results of a vertical flip of images. All the original images and the augmented images are resized to size 224 x 224 for the accurate classification of the images.

B. Features Extraction

In the proposed method a pre-trained CNN model named Mobilenetv2 [43] that consists of 1632 connections and 154 layers is utilized to extract the deep features from the dataset. A feature vector with dimensions 1x1000 is methodically retrieved using the Mobilenetv2 model. The pre-trained model easily generates a 1x1000 feature vector, which acts as the starting point for subsequent studies. The critical features are detected and extracted from this extensive vector using the Tree Seed technique, an effective feature selection technique. This discriminative approach improves the model's ability to detect and prioritize significant features, maximizing efficacy for subsequent tasks. The intentional use of the Tree Seed algorithm demonstrates a diligent approach employed in refining the set of features. It ensures that Mobilenetv2 encapsulates significant features required for detailed evaluation, interpretation, and implementation in a wide range of computational tasks.

TABLE II. PARAMETERS USED IN CLASSIFICATION FOR FEATURES EXTRACTION

No. of epochs	10
Size of Input Images	224 x 224
No. of channels in images	03
No. of Filters	32
Seed Point	123
Batch Size	32
FBuffer Size	250
Fine Tune Point	125
Learning Rate	0.001
No. Dense Layers	64
Activation Function	ReLU
Dropout	0.25

Table II represents all the parameters that are selected and adjusted for the accurate classification and feature extraction of the available dataset images. These parameters are selected/adjusted on multiple turns of experiments and results.

C. Features Selection

The program TSA [50] which draws inspiration from nature, and provides the interaction between trees and their seeds for optimization. Finding a seed's position within tree is crucial to the optimization process. For this objective, the researcher proposes two searches in Eq. (1) and Eq. (2).

$$g(\vec{x}) \leq g(y) \qquad \forall \vec{y} \in G \tag{1}$$

$$g(\vec{x}) \geq g(y) \qquad \forall \vec{y} \in G \tag{2}$$

The first equation considers both the ideal site for the tree population and the tree location where the seed for this tree will be produced. Two distinct tree locations are used by the second update rule in Eq. (2) to generate a new tree seed.

$$Q_{i,j} = U_{i,j} + \propto_{i,j} \times (C_j + U_{r,j}) \tag{3}$$

$$Q_{i,j} = U_{i,j} + \propto_{i,j} \times (U_{i,j} + U_{r,j}) \tag{4}$$

where, $U_{i,j}$ is the jth dimension of ith tree, $Q_{i,j}$ is jth dimension of ith seed that will be produced ith a tree, C_j is the jth dimension of the best tree location obtained, $U_{r,j}$ is the jth dimension of rth tree randomly selected from the population in Eq. (3) and Eq. (4).

Using Eq. (5), the first tree sites that could be solutions to the optimization problem are generated at the start of the TSA search. This selection of location for new seed is controlled by a parameter known as search tendency (ST).

$$U_{i,j} = M_{j,min} + q_{i,j}\,(I_{j,max} - M_{j,min}) \quad (5)$$

$I_{j,max}$ is the upper bound of the search space, $M_{j,min}$ is the lower bound of the search space. In the interval [0, 1], a random number, denoted as $q_{i,j}$ is generated for every dimension and location. Using Eq. (6), the population's best solution is chosen for minimization.

$$C = \min\{g(\vec{U}_i)\}\, i = 1,2,3,\dots,N \quad (6)$$

Where N is the population's total number of trees. (3) is used to update the dimension if a randomly generated number in the interval [0, 1] is less than ST; if not, Eq. (4) is applied.

D. Classification

For the classification of the disease of Glaucoma as either positive or negative, a pre-trained model MobileNetV2 is utilized that contains a total of 154 layers in which each convolutional layer has 32 filters. The convolution is performed by processing the images at each block and each convolutional layer. The features of the images are extracted from the last fully connected layer of the model and a feature vector is created that is further passed to TSA algorithm for the selection of the suiTABLE features. Once the suiTABLE features are selected, then the classification of the Glaucoma images is performed. Finally, classification based on the significant features is performed with the help of machine learning classifiers. In this phase, machine learning classifiers are used as a computational process to perform classification based on significant relevant features. The classification includes the robust Cubic Support Vector Machine (SVM) [51], renowned for ability to handle unpredicTABLE datasets and complex decision functions, the refined version of k-Nearest Neighbors (fine KNN) [52], known for proximity-based classification adaptability, and Ensemble subspace k-Nearest Neighbors (Ensemble Subspace KNN) [53, 54], which is a combination of combined learning and subspace techniques designed to perform well in complicated datasets. The implementation of various classifiers demonstrates an efficient methodology, ensuring model optimization for subtle pattern detection and correct classification in different and complicated data landscapes.

IV. Experimental Results

In the presented proposed methodology, a publicly available dataset is utilized. The glaucoma detection dataset [49] is downloaded from the Kaggle website. This dataset consists of two classes named glaucoma positive and glaucoma negative.

The dataset of glaucoma taken and utilized for the classification purpose in this paper is described in detail and the description is mentioned in Table III. The initial images in both classes were limited, so image augmentation is performed. To augment the original images, the flip technique (horizontal and vertical) is applied to the dataset after that all the images get resized. All the experiments and evaluations were conducted on MATLAB software using the Core i5 6th gen system. The designed method evaluated three machine learning classifiers including Cubic SVM, Ensemble subspace KNN, and Fine KNN on 7- and 8-folds cross-validation.

TABLE III. Description of Glaucoma Dataset

Dataset	Description
Glaucoma Detection	Type of Data: Eyes Images CT Scans of Eyes Format: .jpg Total images 500 Disease Depiction: Glaucoma Dimension of Images: 224 x 224 x 3 Channels: 3 Total Classes: 2

The results of the proposed model of Classification i.e. TSAMob are mentioned in Table IV where the model achieved an accuracy of 99.42%, loss of 0.0187%, validation accuracy of 84.85%, and validation loss of 2.2187%.

TABLE IV. Results of the Proposed Classification Model

Method	Accuracy	Loss	Validation Accuracy	Validation Loss
TSAMob	99.42%	0.0187%	84.85%	2.2187%

By applying a rigorous 7-fold cross-valid methodology, the proposed approach achieves a commendable overall accuracy using three distinct classifiers: 92.87% on Cubic Support Vector Machine (Cubic SVM), 97.33% on Ensemble Subspace k-Nearest Neighbors (Ensemble Subspace KNN), and 96.98% on Fine k-Nearest Neighbors (Fine KNN). These observations are mentioned in Table V. Unexpectedly, Ensemble Subspace KNN ranks as the best performer, with the highest accuracy across all the classifiers evaluated in this experimental work. This significant accuracy highlights Ensemble Subspace KNN's reliability and effectiveness in extracting complex correlations within the dataset, which enables advanced pattern recognition.

The extracted features are passed to three classifiers Cubic SVM, Ensemble Subspace KNN, and Fine KNN. Then the classification is performed, and results are recorded. These findings highlight how well the chosen classifiers can distinguish glaucoma, particularly Ensemble Subspace KNN, which excels accurate sorting of data points. This demonstrates effectiveness and reliability for applications requiring exact classification in a wide range of complicated data.

Table VI shows the experimental findings of the proposed approach by using the 8 folds cross-validation. When using an extended 8-fold cross-validation methodology. The Fine k-Nearest Neighbors (Fine KNN) ranks as the top classifier, with an outstanding accuracy of 97.92% In comparison with this Ensemble Subspace k-Nearest Neighbors (Ensemble Subspace KNN) achieves an accuracy of 96.94%, and Cubic Support Vector Machine (Cubic SVM) achieves 92.83% accuracy, respectively.

The extracted features are passed to three classifiers Cubic SVM, Ensemble Subspace KNN, and Fine KNN. Then the classification is performed, and results are recorded. The accuracy of Fine KNN demonstrates effectiveness while

identifying complex patterns within the dataset; this makes it an effective application for requiring high precision.

In Table VII an extensive overview of the proposed technique with existing methodologies is provided. Notably, this comparison demonstrates that the suggested method performs excellently and gives the highest accuracy when compared with other alternative approaches. This difference makes the suggested model the best among all the other techniques in producing excellent results.

Fig. 4 shows the graphical presentation for the comparison of results obtained by the existing methodologies and the proposed methodology, and the proposed methodology has achieved better results.

In Fig. 5 the study shows the confusion matrix of the results obtained after the classification of the original dataset. Three classifiers are utilized for the feature extraction and classification and there are 7 folds cross validation (a) represents the confusion matrix of Cubic SVM Classifier, (b) represents confusion matrix of Ensemble Subspace KNN, and (c) represents the confusion matrix of Fine KNN.

TABLE V. PROPOSED METHOD RESULTS USING 7-FOLD CROSS VALIDATION

Classifier	Fold	Classes		Accuracy	Precision	Recall	F1 Score	Overall Accuracy
		Negative	Positive					
Cubic SVM	7	✓		92.87%	0.92	0.95	0.94	92.87%

V. Discussion

In this section, the discussion which concerns some ethical key including privacy of patient data, bias in algorithms, diagnostic transparency and the clinical accuracy of AI-assisted decision-making processes. This update will ensure a more comprehensive analysis of proper use of technology in medical applications.

VI. Conclusion

Automated glaucoma diagnosis plays a critical role in the early identification and management of the condition. Conventional techniques are laborious, tedious, and imprecise. This research proposes a model for the automatic classification of glaucoma stages. The prepared dataset (augmented and resized) was utilized for glaucoma classification into positive and negative classes. The features are extracted by Mobilenetv2, and significant features are selected using TSA. Using 7 folds Cross Validation, the Cubic SVM, Ensemble Subspace KNN, and Fine KNN provided the accuracy of 92.87%, 97.33%, and 96.98% respectively. On the 8 folds Cross Validation, the above-mentioned classifiers provided an accuracy of 92.83%, 96.94%, and 97.92% respectively. The results of the experiment show that the suggested model performs better than the most advanced techniques for glaucoma classification in the initial phases. This suggests that the model has an opportunity to improve glaucoma early detection and diagnosis, which can help avert vision loss and permanent blindness. Lastly, the suggested study may facilitate the prompt, accurate, and effective diagnosis of glaucoma by ophthalmologists.

The proposed methodology may be extended in the future by utilizing large real-time datasets of Glaucoma both on a manual basis and on clinical levels. The suggested automated glaucoma diagnostic model can be improved by more research in the following areas: real-world application, integration of clinical data, and larger datasets that provide generalization.

***Abstract*—Climate change is one of the most talked-about topics of this decade, affecting all economic output sectors, including the economy of cow farming. In many scenarios, exceptionally severe climate change is predicted for the Mediterranean region. As a result, practical measures must be taken to strengthen the sector's resilience, particularly for smallholders involved in the cattle production industry. As a result, technology is required to stop animal disease outbreaks. There are benefits to using automatic methods for detecting animal disease and cellulite. Climate change seriously threatens animal health, which is changing ecosystems, changing weather patterns, and posing new difficulties for animal existence. But this crisis also offers a chance for imagination and cooperation in a changing climate, a comprehensive strategy that includes adaptation and mitigation strategies that can boost resilience and safeguard animal populations. In conclusion, knowledge of climate change and adaptation measures are the main factors driving the rising demand for animal products. Furthermore, we have a variety of adaptation strategies at our disposal to mitigate the effects of climate change, which must be used to limit its further expansion.**

***Keywords*—Climate change; sustainability; smallholder; animal disease; image processing; deep learning; animal skin diseases**

I. Introduction

Animal health is a major worldwide concern and one of the many effects of climate change. Animals face increasing health risks and difficulties as temperatures rise and weather patterns become more unpredictable [1]. There is an urgent need for strategies to mitigate and adapt to the effects of climate change on animal health to solve these problems. The primary source of the increasing levels of carbon dioxide and other air pollutants that are rapidly melting the planet is the consumption of fossil fuels. In addition to causing harsh weather and the melting of the Arctic ice, climate-related factors are also directly linked to the spread of many infectious diseases. Temperature is not the only factor influencing changes in the prevalence of infectious diseases. On infections, vectors, and animal hosts, humidity and other weather-related phenomena have an impact, but they are also a component of a complex of social and environmental elements that the changing climate will impact, currently, in our country, the identification of animal illnesses is determined by hand. However, manual assessment takes a lot of time and calls for professionals with training and expertise it shown in Fig. 1.

A. Overview of Climate Change as a Global Issue

Without a doubt, the most significant ecological problem our world is currently dealing with is climate change. It depicts how a place's average temperature and weather patterns gradually alter over time Increasing mean and severe temperatures are involved in this. The following will be affected: rotational grazing, water-efficient irrigation, veterinary operations, surveillance and disease management, veterinary care, vaccination campaigns, vector-borne illnesses, continuous monitoring, assessment, and sustainable practices.

Farming farming methods, the maintenance of the environment, raising livestock, occurrences related to the global climate (such as heat waves, droughts, and floods), and modifications to the hydrological cycle [2]. The primary causes of climate change are human activities that increase the amount of greenhouse gases in the atmosphere, such as deforestation and the burning of fossil fuels for energy. All aspects of Earth's natural systems are impacted by the wide-ranging impacts resulting from climate change. Because of the melting of glaciers and the ocean's thermal expansion, coastal cities and ecosystems are at risk from rising sea levels. Because marine life depends on calcium carbonate to form its shells and skeletons, the oceans absorb more CO2 as they get more acidic, which is detrimental to marine life. The frequency and intensity of heat waves, wildfires, droughts, and floods are all rising because of climate change [3]. Globally, the effects of these quickly changing circumstances are already being felt.

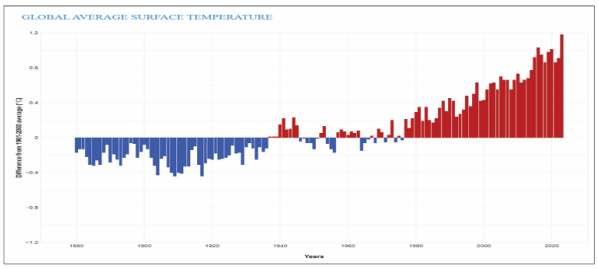

Fig. 1. Global average temperature change over time: this graph shows a clear upward trend in average world temperatures since the late 1800s. [https://www.climate.gov/// NOAA Climate.gov].

B. Climate Change's Effects on Animal Health

Animal health is facing a serious global danger from climate change. Uncertain weather patterns and rising temperatures disturb the delicate balance of ecosystems, affecting animal

populations. There are several major implications when analyzing the specific ways that climate change is affecting animal health.

Ecosystems are severely disrupted by climate change, which makes it possible for infectious diseases to proliferate among animals. Implementing a comprehensive plan that includes stringent biosecurity protocols, meticulous disease surveillance, and trustworthy veterinary healthcare services is necessary to handle this expanding threat properly.

The Impact of Climate Change on Animal Diseases most of the numerous studies on the effects of climate change on human health and illnesses have focused on vector-borne infections [4]. With a few important exceptions, however, little study has been done on how climate change affects animals or non-vector-borne illnesses [5]. Given the global frequency of non-vector-borne diseases and the contribution of animal diseases to poverty in developing countries, focus on these areas is long overdue [6] it shown in Fig. 2. The climate impacts several animal diseases prevalent in Africa and the UK. These impacts extend beyond vector-borne diseases. A few diseases that are spread through direct contact, aerosols, or food or water are also impacted.

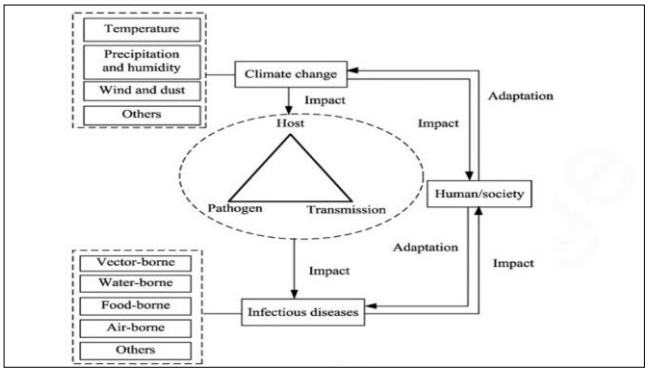

Fig. 2. Animal human society, animal infectious illnesses, and climate change [6].

Furthermore, the seasonal occurrence of non-vector-borne animal diseases seems to be more often correlated with climate than with their regional distribution. In contrast, there is a clear correlation between the climate and vector-borne diseases both in terms of time and geography. This is because the climate has a significant impact on the intermediate vectors' temporal and spatial distributions [7]. Many hypothesized mechanisms by which infectious diseases may be impacted by climate change have been presented in scientific literature. These procedures range from exact and measurable to vague and speculative. They could have an impact on hosts, vectors (if there is an intermediary host), disease transmission, natural environments, pathogens/parasites, or all the above.

It is reasonable to assume that only a portion of these procedures will apply to each unique infectious disease [8]. The pathogen, host or vector, and disease transmission are the elements of diseases that are described in the first set. The second collection of data discusses the weather and climate, including large-scale extreme weather occurrences and climate variables. The diseases covered in the third set are the ones that are specifically related to vectors, water, air, and food-borne pathogens.

C. Impact of Climatic Change on the Spread of Disease

Diseases can spread directly or indirectly, depending on how they are transferred. When an animal contracts an illness through droplet contact, direct physical contact, indirect physical contact, airborne transmission, or fecal-oral transmission, it is referred to as direct transmission [9]. "Indirect transmission" is the phrase used to describe the transfer of a disease from one organism to another via a vector or intermediary host.

Multiple investigations have demonstrated the effect of weather and climate on the spread of disease, but it is still unknown what precise mechanisms underlie this influence. This section addresses the potential effects of climate change on the spread of infectious animal diseases, as opposed to concentrating on the mechanics of disease transmission. This effect may be direct since temperature variations have a direct impact on pathogen viability and may change how diseases spread. It may be indirect if animal behavior, as well as that of vectors and hosts, changes in response to climate change [1].

Temperature differences can influence the spread of illnesses, either on their own or in conjunction with other elements like precipitation. Studies have shown a correlation between the annual temperature variations and the incidence of malaria in Africa's highlands. There is a high correlation between humidity, temperature, precipitation, and other climatic factors and the risk of hemorrhagic fever with renal syndrome. Infectious illness transmission can also be facilitated by wind and dust storms. Bacteria and viruses that are carried by the wind can result in airborne illnesses. Interregional dust storms are one way that illnesses might move from endemic locations to neighboring places.

By shifting the connection between viruses, vectors, and animal hosts, climate change may also affect the transmission of infectious diseases. Studies indicate that due to altered patterns of animal–pathogen—rodent interaction, there may be a periodic increase in the prevalence of diseases carried by rats during periods of extreme rain and flooding [3].

The illness, also known as Weil's disease, and flooding have been linked in several locations, including South Africa, Central America, and South America. Flooding of streets and open sewers is one of the risk factors for the condition in peri-urban populations in low-income nations [4].

Human and other host behavior and activity patterns, including seasonal labor, migration, winter-summer lifestyles, and physical activity, are all greatly impacted by climate change. Consequently, these patterns may have a substantial effect on the transmission of diseases [5]. The seasonal patterns of influenza infection prevalence in Europe are thought to be caused by the fact that animals and humans spend more time indoors during the winter. According to studies, the transit of the virus within each flyway that wild birds utilize during migration is tightly linked to the timing of H5N1 epidemics [6].

D. Indirect Impacts of Climate Change

There are few studies that specifically address how diseases that afflict cattle and other animals, or the emergence of novel pathogens, are impacted by climate change. Several factors, such as altered host mobility patterns, increased host density, and landscape changes that eliminate portions of host

populations (e.g., habitat loss or alteration), have been highlighted as potentially contributing to the emergence of illnesses [7]. The indirect impacts of climate change on the distribution and abundance of parasites, predators, and rivals of vectors are influencing disease patterns.

It is currently challenging to assess the whole impact of climate change on cattle health over an extended period, even though variations in sickness frequency and distribution have been linked to climatic variability. It seems difficult to distinguish between climatic and non-climatic components [8]. The best method for estimating the future impact of climate change is to use the experimentally established relationship between climatic conditions and their effects on the biological systems that drive disease transmission in space and time [9]. Animal diseases affect livelihoods and food security, particularly in our nation, and pose serious risks to livestock productivity. These diseases are now detected and evaluated manually. However, manual assessment takes time and calls for professionals with training and expertise. As a result, technology is required to stop animal disease outbreaks. There are benefits to using automatic methods for detecting foot-and-mouth disease (LMD) and cellulite. The literature has established methods for detecting cattle skin and foot-and-mouth disease ulceration. However, based on their severity, foot-and-mouth and lumpy skin diseases are divided differently. To ascertain the complete impact of foot-and-mouth disease and lumpy skin disease on the animal, it is imperative to distinguish the various stages of these conditions better. This study developed a cellulite and FMD detection model by using a support vector machine (SVM) for classification and a convolutional neural network (CNN) for feature extraction. The Nature of the host-pathogen relationship and the degree of climate change will often determine the result of Features and Classification. CNN is at the forefront of deep feature extraction; it can be used for feature extraction. Some of these features depend on climate change, which has led to a rise in disease incidence. A few methods for recognizing and classifying animal skin conditions are included in the review. Because climate change disrupts ecosystems, modifies weather patterns, and creates new obstacles for animal survival, it seriously threatens animal health. However, there is also a chance for creativity and cooperation because of this catastrophe. Using a comprehensive approach incorporating adaptation and mitigation techniques can increase resilience and protect animal populations in a changing climate.

II. Literature Review

A. The Effects of Climate Change on Animal Health: Reducing and Adapting to the Dangers

Strong disease surveillance networks, stringent quarantine laws, stringent cleanliness requirements, and biosecurity education for farms are a few of these tactics. In addition to helping prevent vector-borne illnesses, immunization campaigns, heat stress management strategies, and wildlife corridors can safeguard domesticated animals and livestock as well as guarantee the survival of endangered species. To safeguard both human health and animal populations, mitigation techniques are crucial [10].

B. The Ecology of Infectious Illnesses and Climate Change

A linear relationship between infectious illnesses and climate is suggested by the relationship between disease and climate as well as historical and experimental data. There is less evidence that infectious diseases have profited from climate change, even though the world is already significantly warmer than it was a century ago. More recent models indicated that disease distributions will shift over time with a little overall rise in the area, despite early projections suggesting that the global range of infectious diseases will climb dramatically in the future. Infectious diseases are influenced by many factors, some of which may even be more important than climate change [11].

C. A Conceptual Framework for Forecasting and Handling Zoonotic Disease and Climate Change-Related Health Concerns in the United States

Through the use of transdisciplinary research, predictive modeling, and public health policy, the framework aims to improve the country's ability to anticipate, prevent, and minimize the health risks associated with zoonotic illnesses brought on by climate change. The framework aims to identify vulnerable people and high-risk areas, provide evidence-based treatments to reduce health risks and clarify disease transmission patterns through the development of prediction models. To integrate research findings into practical strategies and policies that safeguard public health and increase resilience in the face of climate change, the framework promotes collaboration among researchers, policymakers, and public health practitioners. The framework should enhance surveillance and early warning systems, deepen knowledge of the intricate connection between zoonotic diseases and climate change, and assist decision-makers in making well-informed choices regarding the most effective way to focus public health efforts. Giving American communities and decision-makers the information and resources they need to adapt to shifting environmental conditions and lessen the harmful effects of zoonotic diseases on public health is the framework's goal [12].

D. The Effects of Climate Change on Animal Health: Reducing and Adapting to the Dangers

Describe the positive correlations between these extreme events: droughts, El Niño/southern oscillation (ENSO) weather patterns, East African Rift Valley fever outbreaks, and some adaptation measures put in place to mitigate the effects of climate change that may make it more likely that people will meet infectious pathogens. Lastly, we go over adaptation and mitigation tactics that the cattle business could use to lessen the impact of climate change-related livestock diseases.

E. The Overview of how Animal Diseases are Increasing and how Climate Change is Impacting Livestock Productivity

The amount and quality of grains and fodder crops, as well as the severity and dissemination of parasites and diseases, are all indirectly impacted by climate it shown in Fig. 3. Climate change-related animal disease outbreaks and production declines are serious issues for our nation. Thus, the seminar's goals are to: Recognize and raise knowledge of how diseases spread as a result of climate change; and to recognize and raise awareness of how climate change impacts animal productivity [12].

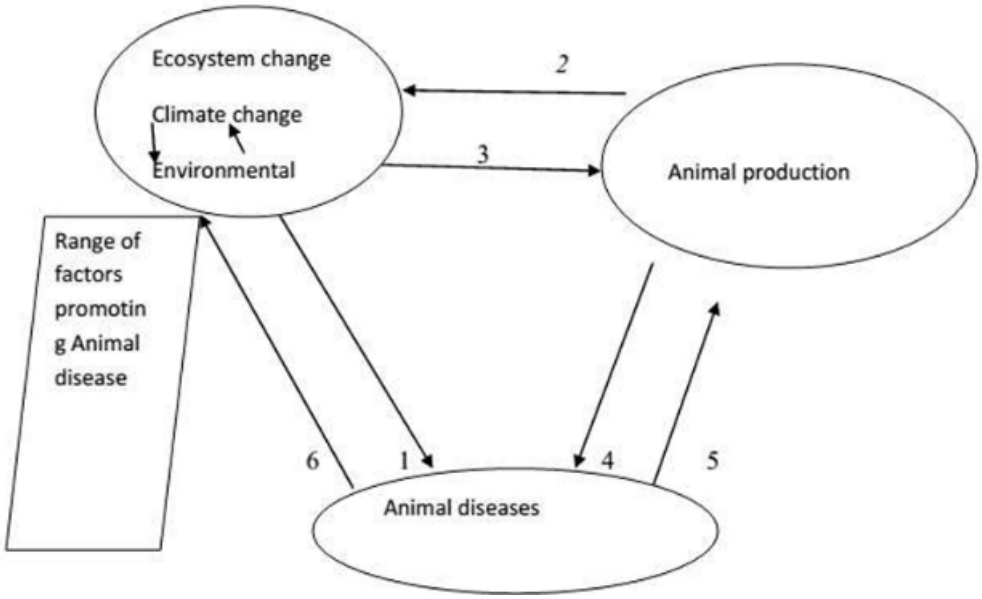

Fig. 3. The main relationship between animal diseases, climatic change, environmental change, and animal.

F. Climate Change's Effects on Animal Production and the Spread of Animal Illness: An Ethiopian Perspective

Climate change, animal production methods, and animal diseases are closely related. Even worse, alterations to the environment and animal production systems have a substantial influence on the incidence, dissemination, development, and reemergence of animal diseases. Research on the state of climate change and its direct and indirect effects on animal production and health is necessary. Sustainable animal farming and land use, as well as strategies for climate adaptation and mitigation, must also be developed. Disease, animal production, and climate change are closely related. The threat that climate change poses to the animal production and health sector is growing. All parties involved in the environment, animal production, and health must work together in an integrated and methodical manner [13].

G. Evidence Review: The Effects of Climate Change on the Food Chain that Supplies Cattle with Food

We investigate how the food chain for cattle raised on land can be impacted by climate change. The entire impact of climate change on the livestock industry is beyond our current understanding, but a wealth of data indicates that it will have an impact at every point of the supply chain, from farm production to processing, storage, transportation, retailing, and human consumption. Hotter places are expected to have fewer institutional and economic opportunities for adaptation, which raises the possibility that the hazards indicated by climate change will materialize, even though the risks vary greatly depending on the situation. There is still much to learn about the future of the climate and how interdependent nature and human systems will react to future climate change. Therefore, a wide range of potential outcomes, including some that appear unlikely but have significant ramifications, must be taken into consideration when making decisions regarding adaptation [14].

H. An Overview of the Connection Between Animal Illness Prevalence and Climate Change

Animal diseases are more likely to emerge and reoccur as a result of ecosystem changes, particularly climate change. It affects cattle health in several ways. These include how high temperatures affect pathogens, altering the rate at which parasites or pathogens develop; how they affect hosts, altering the distribution of diseases that could endanger susceptible animal populations; how they affect vectors, altering the number and distribution of disease vectors; and how they affect epidemiology, altering food safety, animal husbandry, and host-transmission rates. Climate change has effects on disease formation, reproduction, and distribution, as well as on illness appearance and transmission across vectors or hosts [15].

I. A Summary of the Information and Present Lines of Inquiry Regarding Infectious Illnesses and Climate Change

Nearly every biological system on the earth is seriously threatened by climate change. According to recent research, there might be a link between the expansion of infectious diseases and climate change. Simulations based on in silico data are frequently given precedence over empirical investigations based on field and laboratory data in these works. There is currently a dearth of empirical research on the relationship between infectious diseases and climate change synthesis [16].

J. An Overview of the Information and the State of the Field for Infectious Disease and Climate Change Research

It looked at how Egypt's livestock is being affected by rising temperatures, as there are usually not enough resources to mitigate the effects. Even if there are ways to mitigate some heat stress, such as using agroforestry production techniques, reduced food security may be the outcome this century. These aren't expected to make a big impact, though [17] the comparison between different techniques shown in Table I.

TABLE I. COMPARISON BETWEEN DIFFERENT TECHNIQUES

Name of paper	Year of publication	Methodology	Pro	Cons	Result
A Deep Learning Approach to Detect Lumpy Skin Disease in Cows [1]	2024	To extract features, use machine learning-based models like Inception-v3, VGG-19, and VGG-16.	Applies to a variety of medical scientific domains. It can assist veterinary surgeons in identifying issues with animal disease early on.	There are no comparisons with other techniques in the same area. The time taken to get the original message is not mentioned.	92.5% accuracy over the test set
Detecting Lumpy Skin Disease Using Machine Learning Techniques [2]	2023	An algorithm for classifying and identifying animal lumpy skin conditions. We employed SOFTMAX, RF, and SVM classifiers for classification and a convolutional neural network for feature extraction.	Achieved high accuracy.	The information is not necessary to be emulated or taken as a reference.	The validation accuracy to 95.7%.
Application of Artificial Intelligence Algorithm in Image Processing for Cattle Disease Diagnosis [3]	2022	The expert system's reasoner component used a convolutional neural network (CNN) technique to classify the final diagnosis outcome.	Created a working prototype system that combines the reasoner component and the picture classification techniques.	Text information is not necessary to be emulated or taken as a reference. Time taken to get the original message was not mentioned.	With 95% accuracy, the system classified the input symptoms.
Assessing machine learning techniques in forecasting lumpy skin disease occurrence based on meteorological and geospatial features [4]	2022	ANN may be used to accurately predict the occurrence of LSDV infection by utilizing meteorological and geographic data.	The technology might offer a quick and accurate identification of illnesses affecting cattle.	There are no clinical studies or patient data in the publication. Conflict of interest: The writers say they have no conflicting agendas.	Accuracy of up to 97% in anticipating the incidence of LSDV in test data
Detecting high-risk Areas for Lumpy Skin Disease in Cattle Using Deep Learning Feature [5]	2023	An extreme learning machine (ELM) classifier is used for classification.	Physician surgeons in early disease detection of animals.	It wasn't stated how long it took to receive the initial communication.	The ELM classifier used in this paper has an accuracy of 0.9012.

III. METHODOLOGY

Create a hybrid model for diagnosing animal diseases based on Machine learning methods for dealing with our problem depending on the related work. We will create a methodology to deal with the problem by using Feature extraction methods to detect diseases using Machine learning and deep learning techniques. We will detect the level of the disease (Normal, mild, Severe). Apply our model to other diseases with the highest result. Get the final report that explains and detects diseases based on Climate change features depending on a hybrid model based on one or more machine-learning techniques.

IV. DISCUSSIONS AND RESULTS

A. Learning of Climate Change

A study on cattle farmers in Africa [18] found that these farmers are very worried about the risks associated with climate change and actively monitor it and its expected effects on their farming operations. These findings are consistent with the high degree of knowledge among our sample regarding the effects of climate change on smallholder livestock output. These findings from various countries suggest that rather than attempting to inform smallholder livestock producers about the phenomenon and its potential repercussions, the government should concentrate on putting the right mechanisms in place to help farmers lessen the effects of climate change. However, our data does show that some smallholder farmers raise cattle. Women, those without formal education, people who rear animals primarily for domestic use, and people who use outdoor or mixed breeding techniques may all benefit from increased awareness of climate change. Our survey revealed that only a small number of farmers were able to access pertinent information through extension and advisory services, even though these sources could be a useful tool for raising public awareness of climate change and its detrimental implications [19–21]. Rather, they learned about it through firsthand experience, discussions with coworkers, or the media. Our research thus emphasizes the necessity of increased communication on climate change challenges between consultants and smallholder livestock farmers.

B. Important Changes in Climate and how they Affect Livestock Production, According to Smallholder Livestock Farmers

Our survey indicates that farmers' assessments of the possible adverse effects of climate change on their livestock are consistent with the information that is already available. Our respondents stated that the main worries related to climate change are the spread of illness, the creation of new diseases, the overuse of medication [22, 23], and the shortage of feed and water. Each of these has a connection to the problem of climate change. Both the genesis of new diseases and the spread of existing ones are influenced by high temperatures and humidity. For instance, temperatures in northern Europe should increase by 5 °C by 2050, which would be ideal for the bluetongue virus to spread to new regions [24]. Additionally, aflatoxin B1 may spread more readily to newly planted maize and wheat crops.in Europe because of rising temperatures [25-26]. As a result, both

people who eat meat or drink animal milk and the animals themselves may be at higher risk of contracting aflatoxin B1 from tainted feed. The increase in illnesses affecting animals could result in a higher demand for antibiotics and other medications, particularly in Egypt where there are no regulations governing the supply of antibiotics. This is the only way that notable rises in temperature, humidity, and other variables can encourage the development of antibiotic resistance [27]. Smallholder livestock producers may have shortages of feed and water due to factors like drought, rising temperatures, and increased humidity [28]. This is partly because the majority of their range is located in arid and semi-arid regions. It is well recognized that heat waves affect reproductive performance, livestock immunity [28], crop productivity, feed quality, animal productivity overall, and wool production specifically [.Our research linked heat waves to the notable drops in milk yield, wool production, and reproductive efficiency. Additionally, respondents to our survey indicated a higher fatality rate. Our results are consistent with studies that predict a 25% decline in animal output due to century-long high temperatures [29]. According to our responses, the most sensitive animals to the consequences of climate change are dairy cows and their ability to give milk, particularly when it comes to heat stress (heat waves). This is because heat stress reduces the feed dairy cows ingest, despite their high metabolic rate. Mediterranean dairy cows produce less milk as the temperature rises. Globally, big cattle generate more than 96% of the milk produced. Most milk-producing animals in Egypt are cattle and buffaloes, of which smallholder farmers possess 85%. Animals with larger statures are more susceptible to heat stress [30]. According to those who responded, there was less chance that heat stress would have an impact on egg development and yield. This could be explained by the fact that raising hens for eggs is one instance of a short, controlled production cycle that reduces the effects of climate change [31]. More research is required to determine which cow breeding techniques and animal breeds may withstand the extreme weather brought on by climate change.

C. Strategies for Adaptation and Assistance to Reduce the Adverse Impacts of Climate Change on Small-Scale Livestock Production

Farmers' ability to understand the nature of climate change and find appropriate answers will determine how well adaptation strategies are used [32]. According to 60% of respondents to our survey, they adapt their living arrangements and adhere to food programs to cope with climate change. Only a smaller percentage of interviewees said they used genetically modified animals, and about 39% said they needed assistance utilizing this method. One of the most crucial long-term adaptation options to improve cattle's resistance to heat stress, drought, and other climate change issues is genetic selection, as the effects of climate change on animals become more apparent [33].

Even in informal and mixed breeding environments with unpredictable housing conditions, this tactic can be effective. Even though nearly all the participants in our survey were aware of the potential harm that climate change could do to animal productivity and health, 30% of them said that they were not putting any adaptive or mitigation measures into place. The absence of a veterinarian, consultation, or extended services was the main cause of this. According to research from Bangladesh and Zambia, farmers who have access to agricultural extension services are more likely to be aware of the threats that climate change poses to their industry and to employ a range of effective adaptation techniques [34].

The importance of financial insurance and infrastructure development was also mentioned by our respondents. Due to their sometimes remote locations and lack of infrastructure, smallholder cattle farmers are particularly vulnerable to the effects of climate change [35]. To compensate for feed shortages, farmers, particularly smallholders with mixed breeding systems or pastures, should be exposed to drought-tolerant shrubs and plants, which are common in the Mediterranean basin. To properly store feed, farmers must be skilled in silage production, agricultural waste processing, and growing a variety of crops.

Like the participants in our study, smallholder livestock producers in Sierra Leone, an African country, have mentioned a lack of financial resources, poor management competency, and limited infrastructure as obstacles to climate change mitigation [36]. To increase financial support for coffee-livestock integration, another study conducted in Indonesia focused on integrating coffee and livestock to implement climate-smart agriculture for smallholders. This study emphasized the significance of forming strategic partnerships with non-financial service providers and offering technical assistance for the best possible usage of credit.

D. Recommendations and Limitations

This study examines how smallholder cattle producers in the Mediterranean Basin perceive extreme climate change, the negative impacts it has on livestock performance, and the obstacles and solutions required to mitigate those consequences. There were significant regional differences even if the opinions of the respondents from Egypt and Spain were generally similar. For example, Spain was mostly suffering from drought, whereas Egypt was dealing with heat waves and high humidity. Due to regional differences in temperature, animal breeding methods, and smallholders' livestock output goals, more countries than just Egypt and Spain need to be examined to give a comprehensive picture of how resistant Mediterranean farmers are to climate change. Furthermore, future studies should evaluate other types of animal farms, including dairy farms, fattening farms, and poultry farms, rather than all of them together as they were in this study.

V. Conclusion

When climate change changes the environment, modifies weather patterns, and creates new obstacles to animal survival, it poses a serious threat to animal health. Cattle production systems are beginning to feel the effects of climate change, especially during Egypt's hot season. The new study predicts that Egyptian cattle will experience more heat stress throughout the summer months in two of the country's livestock-producing regions. While livestock adapts to these changes in a variety of ways to survive, heat stress seriously reduces the productivity of the livestock. Failure to promptly adopt mitigation measures may result in injury and death. Egypt needs to find other ways

to ensure food security, which probably include relying less on ruminant animals to produce milk and meat.

The primary environmental variables in this case study that negatively impact the production of cattle owned by smallholders are heat waves, humidity, and drought. Reduced availability of animal feed and fodder, increased heat stress, and drops in animal productivity and reproductive efficiency due to virus diseases are a few of these consequences of climate change.

Significant geographical differences existed despite the general similarity of the respondents' opinions between Egypt and Spain. Egypt, for example, was suffering from heat waves and high humidity, whereas Spain was mostly suffering from drought. This work proposed combining deep-learning image processing with an expert system to address some of these issues. Because of its importance to the economy:

1) We will employ techniques to identify or forecast diseases based on several characteristics, such as meteorological and geographic.

2) Using the predictive ability of these methodologies for screening and awareness campaigns, vaccination campaigns, and other preventive measures could be very beneficial in areas with a high risk of LSDV infection.

3) Early and precise viral identification can be used to treat the sickness rather than control it. This can also be used as an implicit way to identify the illness and halt its spread.

The Application of Optimized JPEG-LS Algorithm in Efficient Transmission of Multi-Spectral Images

Huanping Hu, Xing Wang
Information Engineering College, Jiangxi Polytechnic University, Jiujiang, 332000, China

***Abstract*—Currently, multi-spectral image transmission faces challenges such as high storage costs and low transmission efficiency. Although various technologies are attempted to solve these problems recently, such as improving encoding methods in some algorithms, there are still issues such as insufficient compression ratio and slow processing speed. Therefore, the research focuses on optimizing the Joint Photographic Experts Group Lossless Standard (JPEG-LS) algorithm and constructing a multi-spectral image processing system. Regarding the JPEG LS algorithm process, improvements are made to the conventional encoding method by adopting sub-block compression strategy and block compression algorithm based on dynamic image bit width. The results show that the optimized JPEG LS algorithm has an average compression ratio of 5.81, which is higher than the comparison algorithm. The average compression time is 0.35 seconds, the average peak signal-to-noise ratio (PSNR) is 43.6, and the average structural similarity (SSIM) is 0.97, all of which are better than the comparison algorithm. In terms of system performance, stability testing of each module shows that the overall system tends to be stable, and the resource utilization rate of the image compression module is low, with a large resource margin that can meet practical application needs.**

***Keywords*—Multi-spectral; image transmission; JPEG-LS algorithm; compression ratio; signal-to-noise ratio**

I. INTRODUCTION

In the current era of rapid technological development, multi-spectral images play an indispensable role in many cutting-edge fields due to their ability to simultaneously obtain information about target objects in multiple spectral bands [1]. In medical imaging diagnosis, multi-spectral images can help doctors more accurately identify diseased tissues and improve the accuracy of disease diagnosis. In terms of ecological environment monitoring, they can comprehensively evaluate changes in forest cover and water pollution levels, providing strong basis for ecological protection decisions. In the field of intelligent security, their unique spectral characteristics can be utilized to effectively identify disguised targets and enhance the reliability of security systems [2]. However, with the continuous expansion of multi-spectral image application scenarios, the rapid increase in data volume has made its transmission efficiency a bottleneck that restricts further development.

Currently, research on multi-spectral image transmission has been explored in multiple directions. Some scholars have improved the compression efficiency of data to a certain extent by designing new transformation encoding methods. Some studies also attempt to combine machine learning techniques to intelligently extract and process image features in order to optimize the transmission process [3]. However, there are still significant shortcomings in existing research. On the one hand, existing compression algorithms struggle to achieve an ideal balance between compression ratio and image quality, and excessive compression often leads to severe loss of image details, resulting in damage to key information. On the other hand, when facing multi-spectral images with complex spectral features and diverse spatial structures, most algorithms have poor universality and cannot adaptively adjust to different image characteristics.

This study focuses on optimizing the Joint Photographic Experts Group Lossless Standard (JPEG-LS) algorithm in order to overcome the aforementioned challenges. By deeply mining the algorithm core and closely integrating the unique attributes of multi-spectral images, the algorithm is customized and improved. It is expected to significantly improve the compression ratio without compromising image quality, while enhancing the algorithm's adaptability to various types of multi-spectral images, thus laying a solid foundation for the deep application of multi-spectral images in various fields.

The innovation of this study lies in addressing the shortcomings of the JPEG-LS algorithm in multi-spectral image compression. By improving the conventional encoding method, a sub-block compression strategy and a dynamic image bit width-based block compression algorithm are proposed, and the algorithm flow is optimized. Moreover, the study designs a multi-spectral image processing system that integrates optimization algorithms to jointly improve the storage and transmission efficiency of multi-spectral images from both algorithm and system levels.

The research is divided into four sections, with Section II being a summary of the relevant work. Section III is about optimizing algorithms and system design processes. Section IV is the performance analysis of algorithms and systems. Section V is a discussion of the research results, and Section VI is a summary of the entire study.

II. RELATED WORKS

Recently, with the continuous progression of image processing technology, many scholars have devoted themselves to researching how to optimize image transmission algorithms to improve image transmission efficiency [4-5]. Zhang et al. proposed a spatial pilot-assisted fast adaptive framework to address the stability issue of multi-mode fiber image transmission. This framework could adaptively adapt to changes in physical channels and achieve online model updates

during continuous transmission. The experiment outcomes indicated that this approach could achieve a transmission accuracy of over 92% within a few hours, and the pilot frame overhead was about 2% [6]. Wu et al. raised an image transmission method based on semantic segmentation, which could distinguish between regions of interest and non-regions of interest, and achieve high-quality transmission of regions of interest with low communication overhead. The experiment outcomes indicated that this method significantly improved performance compared to existing semantic communication methods and traditional methods [7]. Khandelwal et al. proposed a secure image steganography technique based on discrete wavelet transform and deep learning to improve the quality of steganographic images and extracted secret images. The experiment outcomes indicated that this approach had a PSNR of 51.66 to 38.69 dB and a SSIM index of 0.99, demonstrating high robustness [8]. Gupta et al. proposed an effective approach for encrypting images based on a mixture of watermarking and cryptographic techniques, which was based on two-level security and was used to securely and error free transmit images between devices supporting the Internet of Things. The experiment outcomes indicated that this approach had strong resistance to various types of password attacks [9]. Al Kadhimi et al. proposed a transmission system based on prototype low-density parity check codes and orthogonal frequency division multiplexing for underwater image transmission problems. The experimental results showed that the system outperformed traditional polar cyclic redundancy check and turbo code in terms of performance, and the received image reconstruction effect was better [10].

JPEG-LS is a lossless compression algorithm that predicts images by utilizing adjacent pixels that have already been encoded. It is suitable for scenes that require high image quality. Sun et al. raised a lossless image compression and encryption algorithm that combines JPEG-LS, neural networks, and hyper chaotic mapping to improve the prediction performance of edge texture regions. They also adopted a threshold segmentation method to further improve the image compression ratio. Experiment outcomes indicated that the algorithm had a good compression ratio and could resist various attacks [11]. Hua et al. optimized the JPEG-LS algorithm for compressing the intermediate data layer in neural networks, utilizing computational memory technology for global prediction and efficient compression. The results indicated that the compression ratio reached a high level and the hardware cost was relatively low [12]. Rahman et al. proposed a JPEG-LS algorithm that reduced image dimensionality and utilized prediction techniques, followed by encoding prediction errors using Huffman coding. The experiment outcomes indicated that the algorithm performed well in terms of average code length, compression ratio, encoding time, decoding time, and other aspects [13]. Al Qerom et al. proposed a new LICA-CS algorithm that optimized compression results by strategically minimizing inter channel correlation, and used a new subtraction method to compress image data column by column, successfully solving the problem of similarity and proximity of pixel values in adjacent columns, significantly reducing image size by 71%. Experimental results showed that this algorithm outperformed existing algorithms in terms of compression rate, while exhibiting significant improvements in execution time, with an average compression and decompression process of 1.93 seconds [14]. Hamano et al. applied the JPEG-LS algorithm to encrypted images and analyzed its impact on image classification. The outcomes revealed that the JPEG-LS algorithm could notably reduce the data volume of encrypted images while maintaining classification accuracy. When the quality factor was 85, the classification accuracy could be maintained at over 98%, and the image data volume could be reduced by over 90% [15].

In summary, there have been various methods to improve the stability, security, and efficiency of image transmission technology by optimizing the JPEG-LS algorithm or other image processing techniques. However, these methods still need further optimization in the efficient transmission application of multi-spectral images. Therefore, the research optimizes the JPEG-LS algorithm and applies it to efficient transmission of multi-spectral images, in order to improve transmission efficiency and stability while ensuring image quality. The innovation of the research lies in the use of sub block compression strategy and dynamic image bit width improvement to improve compression efficiency of the JPEG-LS algorithm.

III. Methods and Materials

A. Optimizing the Design of the JPEG-LS Algorithm

The JPEG-LS algorithm is suitable for compressing grayscale images and multi-spectral images, and its process is in Fig. 1. The JPEG-LS algorithm first calculates the gradient of the image, and then determines whether it is a flat area based on the gradient. If it is a flat area, conventional encoding is performed and output [16-17]. If it is not a flat area, it enters the adaptive correction step, predicts through the median predictor, processes by the context modeler, and finally performs Golomb encoding and run length encoding to output the compressed image.

The JPEG-LS algorithm mainly includes two methods: run length encoding and conventional encoding. However, due to the high amount of image noise and large fluctuations in grayscale values, run length encoding is not suitable in this situation. Therefore, the research mainly focuses on improving conventional encoding methods. In the conventional encoding process, context modeling constructs a model based on the surrounding pixel values to better predict the current pixel value. Firstly, each pixel in the image is sampled, and its surrounding pixel values are referenced to establish a probability distribution model for predicting the possible values of the current pixel. The local gradient calculation is in Eq. (1).

$$\begin{cases} D_1 = x_4 - x_2 \\ D_2 = x_2 - x_3 \\ D_3 = x_3 - x_1 \end{cases} \quad (1)$$

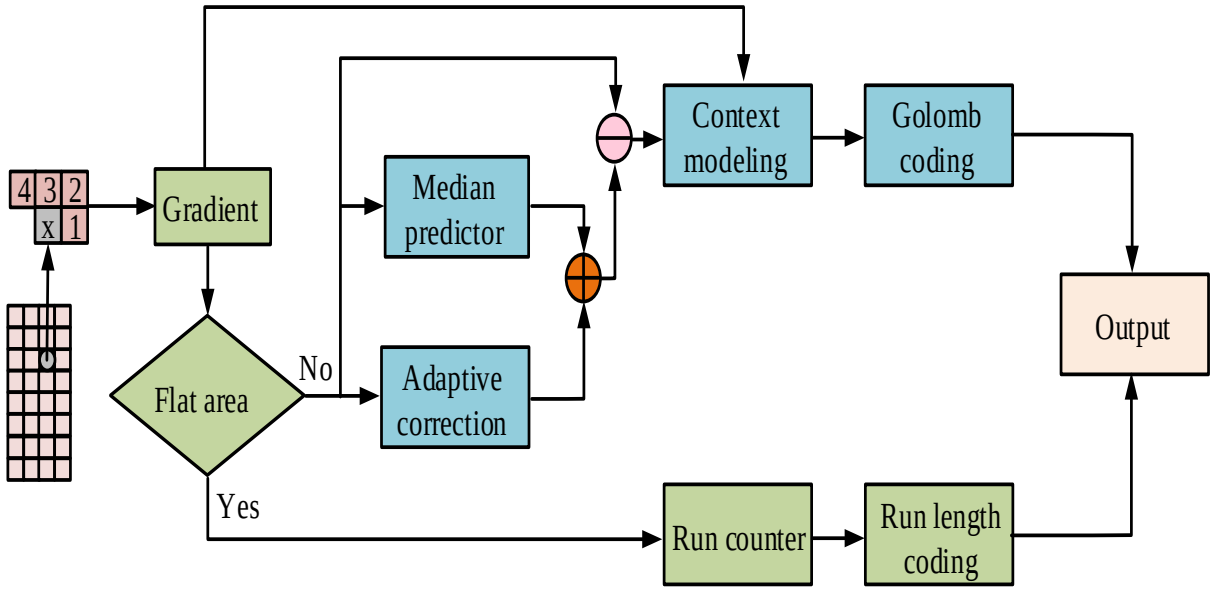

Fig. 1. JPEG-LS algorithm flow.

In Eq. (1), the local gradient values are D_1, D_2, and D_3, and the pixel values at the four pixel positions are x_1, x_2, x_3, and x_4, respectively. The quantization standard for local gradient values is shown in equation (2).

$$Q_i = sign(D_i).\begin{cases} 0, & D_i = 0 \\ 1, & 0 < |D_i| < T_1 \\ 2, & T_1 < |D_i| < T_2 \\ 3, & T_2 < |D_i| < T_3 \\ 4, & T <_3 |D_i| \end{cases}, i = 1,2,3 \quad (2)$$

In Eq. (2), the quantized gradient value is Q_i, and the non-negative threshold is $[T_1, T_2, T_3]$. The calculation for non-negative threshold is shown in Eq. (3).

$$\begin{cases} T_1 = near + 3(bpp - 7) \\ T_2 = 2near + 7(bpp - 7) \\ T_3 = 3near + 21(bpp - 7) \end{cases} \quad (3)$$

In Eq. (3), the micro loss is $near$ and the image bit width is bpp. After quantifying each gradient, it can be fused into a whole. Meanwhile, a context parameter address index needs to be set, which represents a specific symbol. This address index can be used to define predictive information. Secondly, prediction is based on the context model to calculate the predicted value of the current pixel value, and the prediction difference quantization process is shown in Eq. (4).

$$Err' = \begin{cases} \dfrac{Err + near}{2near + 1}, & Err > 0 \\ -\dfrac{Err + near}{2near + 1}, & Err \le 0 \end{cases} \quad (4)$$

In Eq. (4), the predicted difference is Err, and its quantized value is Err'. Predictive encoding is the process of predicting the current pixel value based on known pixel values, and then encoding the prediction error. When performing predictive encoding, it is necessary to utilize context related parameters to better predict and encode the next pixel. These context-related parameters can include known pixel values, neighborhood information of pixels, and so on. By updating these parameters, the precision and effectiveness of predictive coding can be enhanced. When encoding prediction errors, it is necessary to convert them into a one-sided exponential distribution. This is because the unilateral exponential distribution has a smaller variance, which can better represent the noise and detail information in the image [18]. Meanwhile, by taking the modulus of the error, negative modulus can be avoided, thereby ensuring the stability of the encoding. Finally, the Gloomb encoding method is used to convert the error of the one-sided exponential distribution into a bitstream for storage and transmission. After encoding the current pixel, it is necessary to update the context-related parameters in order to better predict and encode the next pixel.

The JPEG-LS encoding method has the problem of error sensitivity. To solve this problem, a sub-block compression strategy is proposed in the encoding process, which divides the image into independent non-overlapping sub-blocks for compression. However, this method may have an impact on compression performance and requires further optimization [19]. In traditional methods, dynamic range is generally calculated by quantifying bit width. However, the research has proposed a block compression algorithm based on dynamic image bit width, which expands statistics on the local dynamic range of each image sub-block to improve compression performance. The process of local dynamic range statistics is shown in Fig. 2.

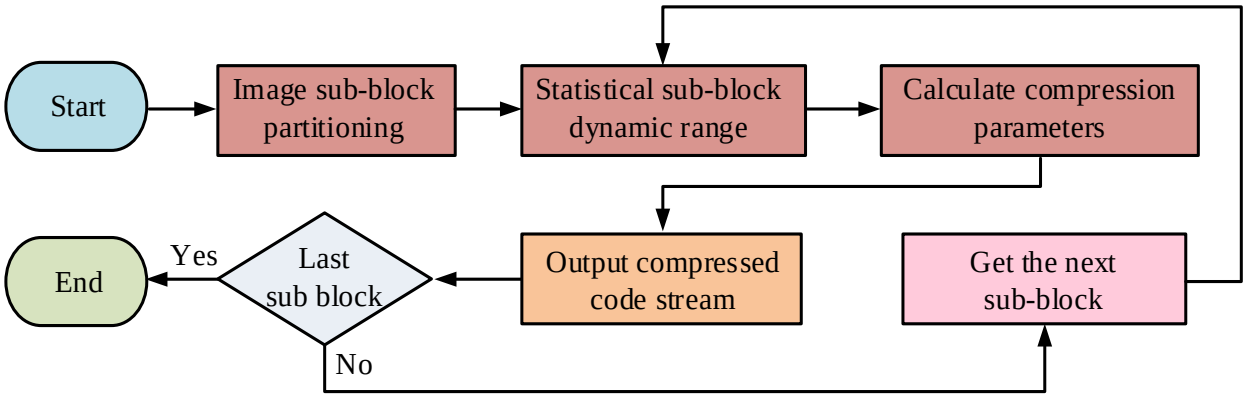

Fig. 2. Local dynamic range statistical process.

In Fig. 2, in the initial stage, sub-block partitioning is first carried out for the image. After completion, statistical sub-block dynamic range is analyzed. After the statistical work is completed, the compression parameters are calculated. Then, it is necessary to determine whether the processed sub-block is the last sub-block. If the determination result is not the last sub-block, then the next sub-block is extracted and the operation continues according to the steps described earlier. If it is determined as the last sub-block, the compressed stream is output and the entire process ends. The calculation of dynamic range parameters is shown in Eq. (5).

$$bpp = \log_2(\max G - \min G) \tag{5}$$

In Eq. (5), after the image is segmented, its maximum grayscale value is $\max G$ and its minimum grayscale value is $\min G$. The minimum grayscale value can be considered as 0, resulting in a simplified dynamic range parameter as shown in Eq. (6).

$$bpp = floor(\log_2(\max G) + 1) \tag{6}$$

In Eq. (6), the rounding down operation is $floor$. After the dynamic range of the segmented image is calculated, the maximum value of independently-encoded pixel values is calculated as shown in Eq. (7).

$$\max P = 2^{bpp} - 1 \tag{7}$$

In Eq. (7), the independently-encoded pixel value is P. The calculation of the quantization range of prediction error is shown in Eq. (8).

$$Range = \left| \frac{\max P + 2near}{2near + 1} \right| + 1 \tag{8}$$

In equation (8), the quantization range of prediction error is $Range$. In the Golomb encoding algorithm, the encoding length limit is shown in Eq. (9).

$$Limit = 2(bpp + (8, bpp)) \tag{9}$$

In Eq. (9), the parameter $Limit$ plays an important role in controlling the encoding length and optimizing the encoding efficiency in Golomb limited length encoding. The initial value of the context is calculated as shown in Eq. (10).

$$A_0 = \max\left(1 + \left| \frac{32 + Range}{64} \right|\right) \tag{10}$$

In Eq. (10), the initial value of the context is A_0. The optimized JPEG-LS algorithm flow is shown in Fig. 3.

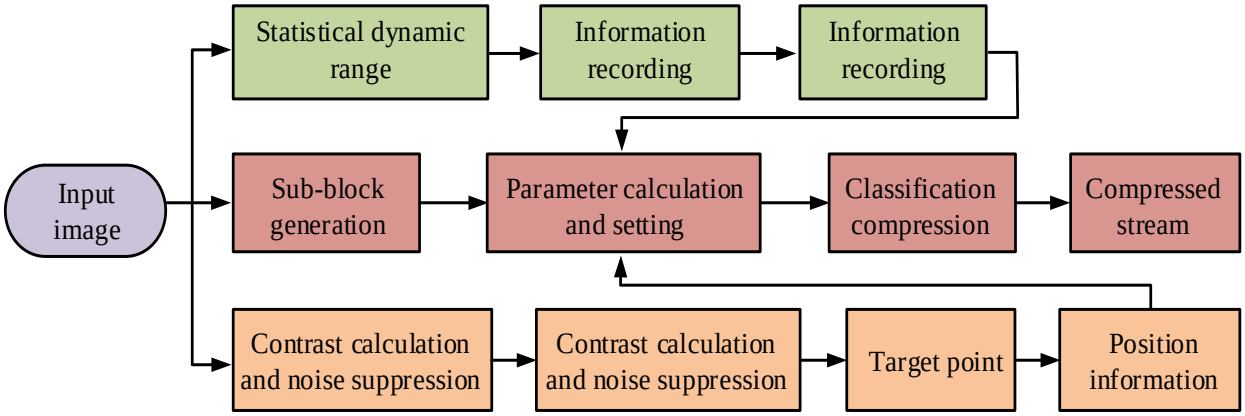

Fig. 3. Optimized JPEG-LS algorithm process.

In the optimized JPEG-LS algorithm process, first, one frame of image is input. Next, the image is divided into sub-blocks, the dynamic range of the sub-blocks is calculated, and the dynamic range sub-block information is recorded. Afterwards, image sub-blocks are generated and parameter calculations and settings are performed based on them. The calculation for image sub-blocks is shown in Eq. (11).

$$K = \frac{M \times N}{m \times n} \tag{11}$$

In Eq. (11), the image size is $M \times N$, the sub-block size is $m \times n$, and the number of sub-blocks is K. In another parallel branch, contrast calculation and noise suppression processing are performed on the input image to calculate micro contrast. The contrast calculation of image sub-blocks is shown in Eq. (12).

$$C = \frac{\sum_{i=1}^{m} \sum_{j=1}^{n} \left(P_{ij} - \bar{P} \right)^2}{m \times n} \tag{12}$$

In Eq. (12), the sub-block contrast is C, the pixel value of pixel (i, j) in the sub-block is P_{ij}, and the average pixel value of the sub-block is $\bar{P}$. Then, the suspected target points are determined through multi-scale and multi-threshold segmentation, and the positions of the suspected target points are recorded. Then the JPEG-LS algorithm is applied to classify and compress the target and background, and finally a compressed stream is output. The sub-block occupancy of false alarm images is in Eq. (13).

$$F_p = \frac{k_f}{K} \tag{13}$$

In Eq. (13), the proportion of false alarm image sub-blocks is F_p, and the number of false alarm sub-blocks is k_f. The target sub-block is represented by Eq. (14).

$$T_p = \frac{k_t}{K} \tag{14}$$

In Eq. (14), the proportion of target sub-blocks is T_p, and the number of target sub-blocks is k_t. The performance of compression algorithms is affected by object detection algorithms, and low false alarm rates help improve compression ratios.

In summary, the optimized JPEG-LS algorithm is designed to address the characteristics of multi-spectral images. Due to the high level of image noise and large fluctuations in grayscale values, the research focuses on improving conventional encoding methods. A probability distribution model is constructed through context modeling to predict pixel values, and the prediction error is converted into a one-sided exponential distribution during encoding to ensure stability. To address the issue of error sensitivity, a sub-block compression strategy is adopted, and a block compression algorithm based on dynamic image bit width is proposed to improve compression performance. The optimization process also includes sub-block partitioning of the input image, dynamic range statistics, contrast calculation, and noise suppression processing, ultimately compressing the output stream for target and background classification.

B. Design of Multi-Spectral Image Processing System

After optimizing the JPEG-LS algorithm, a multi-spectral image processing system is further designed to compress and encode images using the optimized JPEG-LS algorithm, in order to reduce storage and transmission costs. The framework of the multi-spectral image processing system is in Fig. 4. The system consists of control, image acquisition, server, image processing, and client modules. The control module obtains real-time status information and sends control signals. The image acquisition module receives the signal and collects image data, which is then transmitted to the server. The image processing module integrates optimization algorithms to compress the image and transmits it to the client via USB. The client interacts with the server to ensure correct reception and processing of the data. The image processing module includes data transmission, storage, and compression sub-modules, relying on relevant chips and platforms, combined with reversible component transformation and algorithms to achieve lossless image processing.

In Fig. 4, the control module plays a role in obtaining and controlling real-time status information, including position, angle, and operating status, through sockets. Based on these status information, the control module will issue corresponding control signals for adjusting posture and other operations. Meanwhile, there is data exchange between the control module and the image acquisition module, which sends control signals to the image acquisition module. After receiving the control signal from the control module, the image acquisition module begins to collect image data [20]. The image data it collects will be transmitted to the server. The image processing module plays a critical processing role in the entire system, integrating the optimized JPEG-LS algorithm. It receives control signals from the server and processes image data based on these control signals. The image processing module compresses the image data to reduce the amount of data transmitted during the transmission process. The compressed stream-processed image data are transmitted to the client through a USB interface. The server receives image data from the image acquisition module and sends control signals to the image processing module [21-22]. The client is the terminal of the system, which receives compressed stream image data transmitted through USB from the image processing module. Meanwhile, the client and server interact through real-time transmission protocol control signals to ensure that the client can correctly receive and process image data. The process of the control module is shown in Fig. 5.

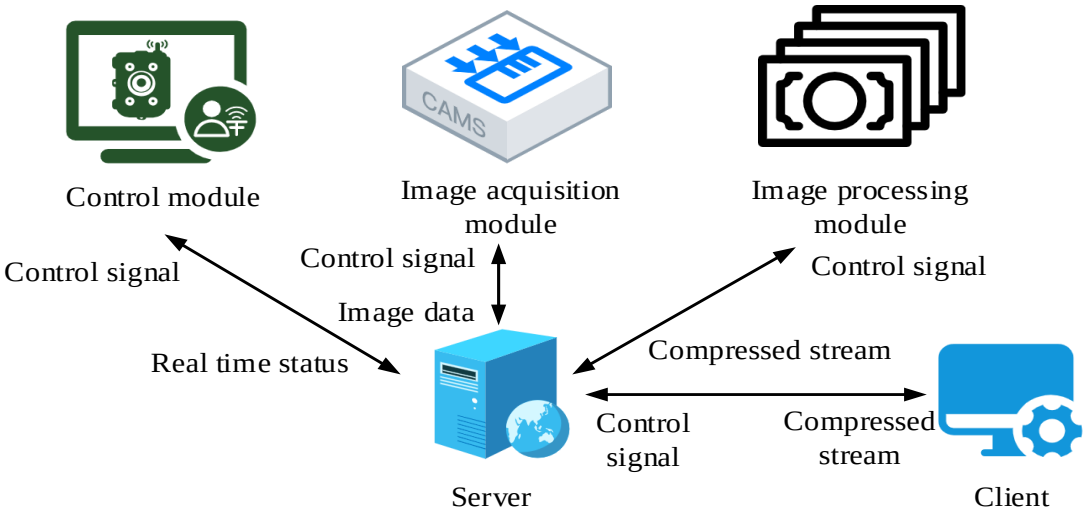

Fig. 4. Framework of the system.

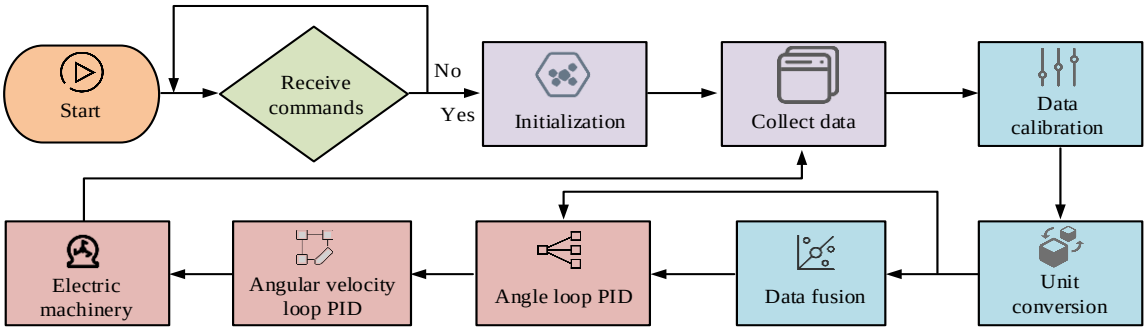

Fig. 5. Process of control module.

The process begins with determining whether an upper level command has been received, and if not, it remains in a waiting state. If received, it enters the initialization phase, during which offset calculation will be performed. After initialization is complete, data collection begins, followed by calibration of acceleration and angular velocity data. Next is the unit conversion stage, where data fusion is performed after conversion using the Mahony filtering method? After data fusion, the expected angle and current angle are obtained separately, and the expected angular velocity is calculated through the angle loop PID. Based on the current angular velocity, the pitch angle motor, roll angle motor, and yaw angle motor are finally controlled through PWM and GPIO after PID processing in the angular velocity loop.

The image processing module can be mainly divided into three sub-modules: data transmission, data storage, and image compression. In the data transmission module, the USB interface and CY7C68013A chip are fully utilized to efficiently transmit image data between the server and FPGA. This chip supports USB 2.0 protocol and its development toolkit is also very complete, providing reliable guarantee for stable data transmission. The data storage module uses DDR2 SDRAM, which can properly store multi-spectral images and compressed bitstreams, ensuring secure storage and easy access to data at any time. The image compression module is shown in Fig. 6.

The image compression module relies on FPGA high-performance platform, combined with reversible component transformation and optimized JPEG-LS algorithm, to perform lossless compression of multi-spectral images in space and spectrum. After decoding, the image can be completely consistent with the original image, thus achieving lossless processing of the image.

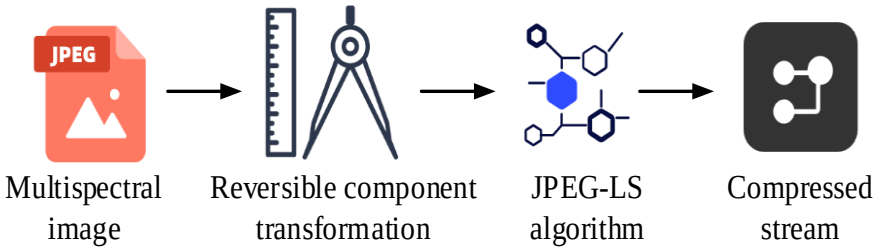

Fig. 6. Image compression module.

IV. RESULTS

A. Performance Analysis of Optimizing the JPEG-LS Algorithm

The hardware environment configuration for algorithm performance analysis adopted Intel (R) Core (TM) i7-6700HQ core, with a CPU frequency of 2.6GHz, 8GB memory, 1TB hard drive, and ran on the Windows 10 operating system. The software environment was configured as MATLAB 2022. During the block compression process of the JPEG-LS algorithm, the compression ratio and prediction error curves are in Fig. 7. Fig. 7 (a) indicates the compression ratio under different block sizes and micro loss degrees. As the block size increased, the compression ratio of the image gradually increased. As the degree of micro loss increased, the compression ratio of the image also gradually increased. When the micro loss was 1, the compression ratios for block sizes of 8×32, 64×64, and 515×512 were 1.61, 3.13, and 5.55, respectively. When the block size was 512×512, the image compression ratios corresponding to micro loss degrees of 0, 1, 2, and 3 were 3.12, 5.55, 6.51, and 7.32, respectively. Fig. 7 (b) shows the prediction error curves for full image compression and block compression. The prediction error range for full image compression was [-40,40], and for block compression was [-45,45]. The above data indicated that block compression had a larger fluctuation range of prediction error compared to full image compression. In the process of block compression, the boundaries of each block and the local characteristics within each block may introduce more uncertainty, making the distribution of prediction errors more dispersed and wider. However, full image compression may be relatively more stable during the prediction process due to considering the global characteristics of the entire image, and the range of prediction errors may be relatively small. Therefore, it is necessary to introduce dynamic range parameters in the block compression process of the JPEG-LS algorithm to obtain an optimized version of the algorithm.

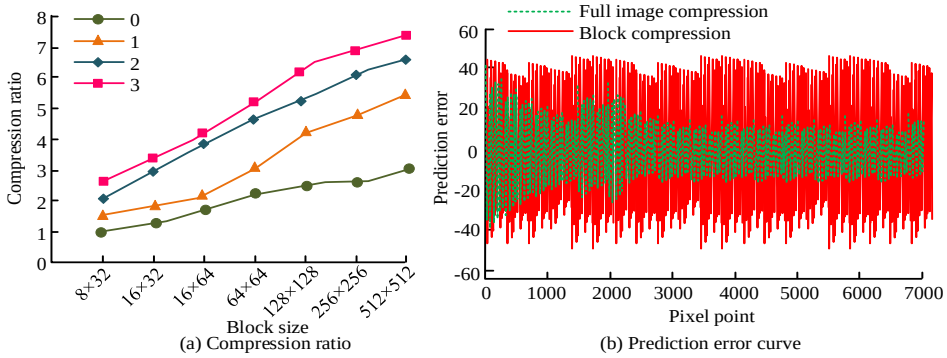

Fig. 7. Compression ratio and prediction error curve.

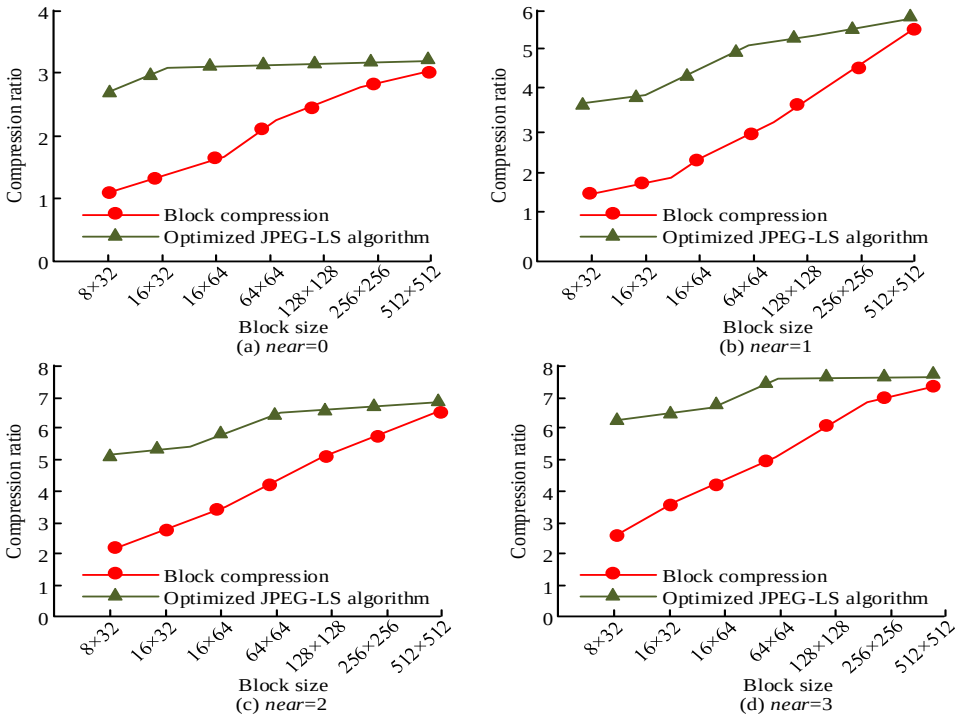

Fig. 8. Comparison of compression effects of optimized JPEG-LS algorithm.

The compression effect comparison of the optimized JPEG-LS algorithm is in Fig. 8. In Fig. 8, as the block size increased, the compression ratio of block compression and optimized JPEG-LS algorithm gradually increased, and the compression ratio of optimized JPEG-LS algorithm was larger, but the distance between the two gradually decreased. In Fig. 8 (a), the micro loss was 0. When the block size was 8 × 32, the compression ratios of block compression and optimized JPEG-LS algorithm were 1.05 and 2.73, respectively. When the block size was 128 × 128, the compression ratios of block compression and optimized JPEG-LS algorithm were 2.75 and 3.11, respectively. In Fig. 8 (b), the micro loss was 1. When the block size was 64 × 64, the compression ratios for block compression were 3.13, and the optimized compression ratio for the JPEG-LS algorithm was 5.06. In Fig. 8 (c), the micro loss was 2. When the block size was 8×32, the compression ratios of block compression and optimized JPEG-LS algorithm were 2.08 and 5.15, respectively. In Fig. 8 (d), when the micro loss was 3 and the block size was 16×64, the compression ratios of block compression and optimized JPEG-LS algorithm were 5.31 and 7.48, respectively. The results indicated that the optimized JPEG-LS algorithm had a high compression ratio and exhibited relatively stable performance with changes in block size.

In order to verify the stability of the algorithm, the experiment was tested by changing the image type, image resolution, and noise level. The test results are shown in Table I. From the perspective of image type, the compression ratio of texture image was the highest (5.01), followed by landscape image (4.23) and figure image (3.87). In terms of image resolution, as the resolution increased, the compression ratio increased from 3.56 at 640*480 to 4.78 at 1920*1080. In terms of noise level, the lower the noise, the higher the compression ratio, which was 3.98 at low noise and 3.21 at high noise. The results showed that the compression performance of JPEG-LS algorithm was affected by many factors. In terms of image types, images with rich textures were easier to obtain higher compression ratio. The higher the image resolution was, the higher the compression ratio could be achieved. The noise level was negatively correlated with the compression ratio, and the lower the image noise, the higher the compression ratio. In practical application, the compression effect of JPEG-LS algorithm could be estimated and optimized according to image characteristics such as type, resolution, and noise.

TABLE I. TEST RESULTS OF THE ALGORITHM UNDER DIFFERENT PARAMETERS

Parameter type	Parameter value	Compression ratio	Prediction error range
Image type	Landscape	4.23	[-35, 35]
	Character	3.87	[-30, 30]
	Texture	5.01	[-40, 40]
Image resolution	640*480	3.56	[-32, 32]
	1280*720	4.12	[-38, 38]
	1920*1080	4.78	[-42, 42]
Noise level	Low noise (mean 0, variance 0.01)	3.98	[-33, 33]
	Medium noise (mean 0, variance 0.05)	3.65	[-36, 36]
	High noise (mean 0, variance 0.10)	3.21	[-40, 40]

To confirm the progressiveness of the optimized JPEG-LS algorithm proposed by the research, the experiment compared the algorithms in study [12], study [13], study [23] and reference [24], and the comparison of compression ratio and compression time of different algorithms is shown in Fig. 9. Fig. 9 (a) shows a comparison of compression ratios for various algorithms. The optimized JPEG-LS algorithm had an average compression ratio (ACR) of 5.81, the algorithm in study [12] had an ACR of 5.56, and the algorithm in study [13] had an ACR of 5.46. The ACR of the algorithm in reference [23] was 5.76, and that of the algorithm in study [24] was 5.74. Fig. 9 (b) shows a comparison of compression times for different algorithms. The optimized JPEG-LS algorithm had an average compression time (ACT) of 0.35s, the algorithm in study [12] had an ACT of 0.37, and the algorithm in study [13] had an ACT of 0.35s. The ACT of the algorithm in study [23] and the algorithm in study [24] was 0.36.

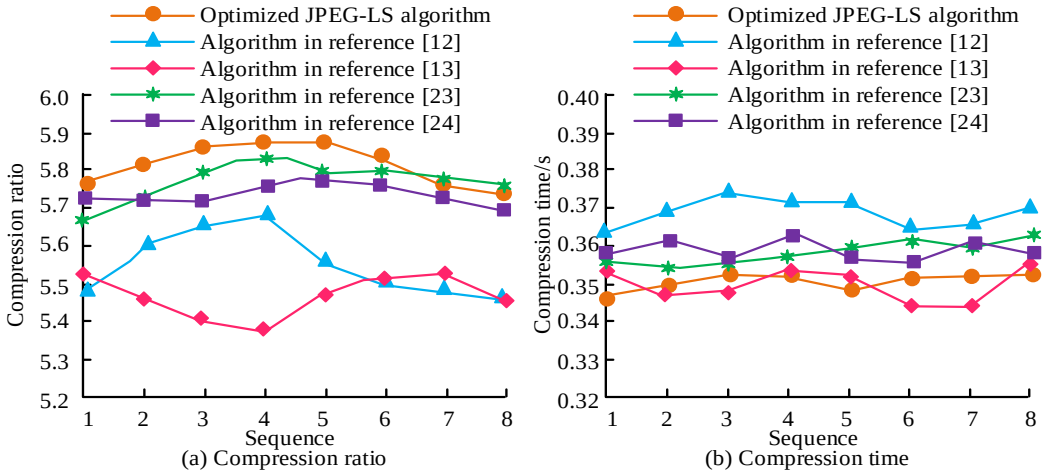

Fig. 9. Comparison of compression ratios and compression times for different algorithms.

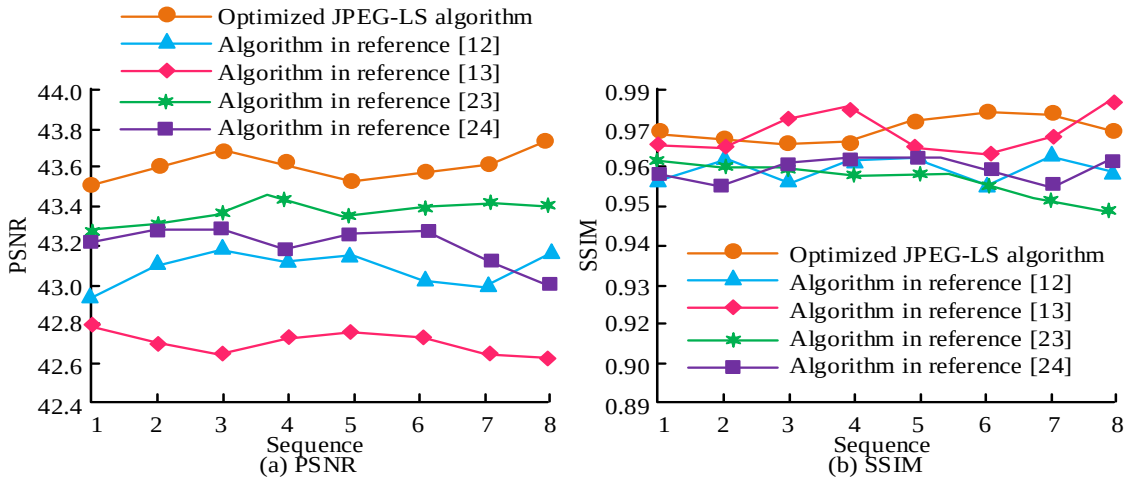

Fig. 10. Comparison of PSNR and SSIM for different algorithms.

The comparison of PSNR and SSIM of different algorithms is shown in Fig. 10. Fig. 10 (a) shows the comparison of PSNR. The PSNR of the optimized JPEG-LS algorithm was higher than 43, with an average of 43.6. The average PSNR of the algorithm in study [12] was 43.1, and the average PSNR of the algorithm in study [13] was 42.7. The average PSNR of the algorithm in study [23] was 43.4, and the average PSNR of the algorithm in study [24] was 43.2. Fig. 10 (b) shows the comparison of SSIM. The average SSIM of the optimized JPEG-LS algorithm was 0.97, the average SSIM of the algorithm in study [12] was 0.97, and the average SSIM of the algorithm in study [13] was 0.96. The average SSIM of the algorithm in study [23] was 0.95, and the average SSIM of the algorithm in study [24] was 0.96. Compared with existing algorithms in studies [12], [13], [23], and [24], the optimized JPEG-LS algorithm exhibited many advantages. In terms of compression ratio, this algorithm was higher than existing algorithms. In terms of compression time, it was comparable to various comparison algorithms. In terms of image quality assessment, its PSNR was superior to existing algorithms, and its SSIM was not inferior or even better. Overall, the optimized JPEG-LS algorithm performed well in compression performance and image quality preservation, making data processing more efficient.

B. *Performance Analysis of Multi-Spectral Image Processing System*

After the construction of the multi-spectral image processing system was completed, its performance was tested and analyzed. The stability test results of each module are in Fig. 11. Fig. 11 (a) shows the stability test results of the control module. As the number of tests increased, the stability time of the control module fluctuated, with an average stability time of 0.21s. Due to the impact of scheduling and resource allocation of different tasks within the system when processing various control instructions, the stability time fluctuated. Fig. 11 (b) shows the stability test results of the image acquisition module. As the number of tests increased, the stabilization time gradually decreased. After 30 tests, the image acquisition module took 0.18 seconds to stabilize. As the testing progressed, the module gradually adapted to the working environment and workflow, resulting in improved collection efficiency and reduced time consumption. Fig. 11 (c) shows the stability test results of the image processing module. As the number of tests increased, the stability time showed a fluctuating downward trend. In the first 30 tests, the average stability time of the image processing module was 0.19 seconds. The image processing process involved multiple algorithms and complex operations, and its stability was affected by various factors such as data volume and algorithm complexity, resulting in fluctuations in stability time. However, the overall downward trend may be due to the system's adaptive adjustment of resource management and algorithm execution during operation, which improved processing efficiency. Overall, all modules tended to stabilize to a certain extent, providing a certain guarantee for the normal operation of the multi-spectral image processing system.

The resource utilization of FPGA in the image compression module is shown in Table II. The usage of Lookup Table (LUT) was 27582, the total allowed resources of FPGA system was 203800, and the percentage of FPGA system was 13.5%. The usage of Block Random Access Memory (BRAM) was 38, the total allowed resources were 455, and the percentage of FPGA system was 8.4%. The usage of Digital Signal Processor (DSP) was 69, the total allowed resources were 840, and the percentage of FPGA system was 8.2%. The usage of input/output (I/O) was 57, the total allowed resources ere 500, and the percentage of FPGA system was 11.4%. The usage of Hybrid Memory Cube (HMC) was 2, the total allowed resources were 12, and the percentage of FPGA system was 16.6%. The results indicated that in the image compression module, FPGA had a low utilization rate of various resources and a large resource margin to meet the further expansion needs of the system. Meanwhile, it also indicated that the current system was relatively reasonable in resource utilization, and there was no excessive use of resources.

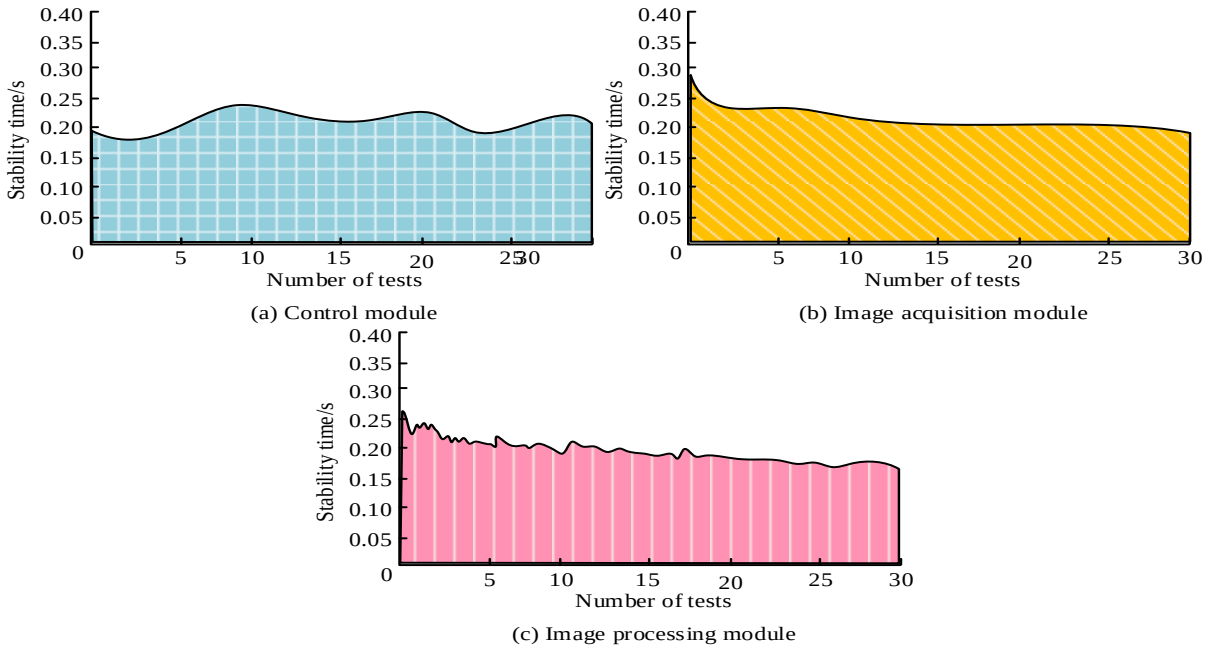

Fig. 11. Stability test results of each module.

TABLE II. RESOURCE UTILIZATION OF FPGA

Index	Resource type				
	LUT	BRAM	DSP	I/O	HMC
Usage amount	27582	38	69	57	2
Total resource quantity	20380	455	840	500	12
Proportion	13.5%	8.4%	8.2%	11.4%	16.6%

V. DISCUSSION

According to the characteristics of multi-spectral images, the JPEG-LS algorithm was optimized and the corresponding processing system was designed. From the application point of view, the optimized JPEG-LS algorithm had significant application potential in the field of multi-spectral image compression. For example, in the field of remote sensing, the amount of multi-spectral image data was huge, and the high compression ratio of the optimization algorithm could effectively reduce the cost of data storage and transmission, so that a large number of image data collected by satellites and other equipment could be processed and transmitted more efficiently. In the field of medical imaging, multi-spectral images were used for disease diagnosis, and the optimization algorithm could improve the compression ratio on the premise of ensuring image quality, which helped to store and transmit medical images quickly and facilitate doctors to obtain accurate information in time for diagnosis [25].

The advantages of this research work are more prominent. In terms of algorithm optimization, by improving the traditional coding method, a probability distribution model was constructed to predict pixel values, and the prediction error was converted into a unilateral exponential distribution, which effectively solved the problem of poor adaptability of the original algorithm to image noise and gray value fluctuations, and improved the stability of the algorithm. Meanwhile, the sub-block compression strategy and the block compression algorithm based on dynamic image bit width were adopted to significantly improve the compression performance. In the aspect of system design, the modules of the multi-spectral image processing system had clear division of labor and work together, which could efficiently complete the tasks of image acquisition, processing, compression and transmission. Among them, the image compression module was based on FPGA high-performance platform, combined with reversible component transformation and optimization algorithm to achieve lossless image compression, and ensure the image quality.

VI. CONCLUSION

Aiming at the problems of error sensitivity and compression performance in the efficient transmission of multi-spectral images using the JPEG-LS algorithm, this study proposed to optimize the JPEG-LS algorithm. By adopting sub-block compression strategy, dynamic image bit width and other improvement measures, the goal of reducing error sensitivity and improving compression performance was achieved, and a multi-spectral image processing system was constructed. Experimental results showed that the optimized JPEG-LS algorithm performed well under different parameters. When the micro loss was 1 and the block size was 512×512, the compression ratio could reach 5.55. Compared with other algorithms, the average compression ratio of the optimized

algorithm was 5.81, which was higher than that of study [12] (5.56), study [13] (5.46), study [23] (5.76) and study [24] (5.74), and the average compression time was 0.35s, which was comparable to other algorithms. The average value of PSNR was 43.6, which was higher than other comparison algorithms, and the average value of SSIM was 0.97, which was equivalent or better than some algorithms. In terms of the performance of the multi-spectral image processing system, the stability test results of each module were good, the average stability time of the control module was 0.21s, the stability time of the image acquisition module was reduced to 0.18s after 30 tests, and the average stability time of the image processing module was 0.19s in the first 30 tests. In the image compression module, the utilization rate of FPGA to all kinds of resources was low, the utilization rate of LUT was 13.5%, BRAM was 8.4%, DSP was 8.2%, I/O was 11.4%, HMC was 16.6%, and there was a large resource margin. The research method effectively improved the compression performance of multi-spectral images, reduced the storage and transmission costs while ensuring the image quality, and provided a more efficient solution for the application of multi-spectral images in many fields. However, there are some shortcomings in this study. In the process of algorithm optimization, although the influence of various factors on the compression performance was considered, the compression effect of images in complex scenes still needs to be further improved, and the computational complexity of the algorithm increased to a certain extent. In terms of system design, there is room for improvement in the communication efficiency between modules. The future research work can further optimize the algorithm, reduce the computational complexity, and improve the image compression effect in complex scenes. Then, by improving the communication mechanism between system modules, the overall operation efficiency is improved. The application of optimization algorithms and systems can be explored in more fields, such as intelligent security, industrial testing, etc., to expand its application range.

Early Warning Model Construction for Deformation Monitoring and Management of Deep Foundation Pit Project Combined with Artificial Intelligence

Xiaoyuan Zhang*, Xin Wang
School of Civil Engineering and Architecture, Nanchang Jiaotong Institute, Nan'chang 330000, China

Abstract*—In various engineering construction projects, construction safety problems caused by pit deformation continue to be solved. The existing early warning model for pit deformation management cannot effectively meet the needs of actual construction for complex pit projects. Artificial intelligence technology has more obvious advantages in foundation pit deformation detection due to its wide applicability, flexibility, and other characteristics. This study uses Gaussian regression analysis model to construct a corresponding deep foundation pit deformation monitoring and management warning model. The purpose is to better monitor and manage the deformation of deep foundation pits, ensuring the smooth and stable development of the entire construction project. In the experimental analysis, different performance indicators were used to verify the effectiveness of the research method, including different error indicators, precision, recall rate, F1 score, etc. MAE can effectively evaluate the deviation between predicted values and actual values, which indicates that the model is closer to the true value. Precision, recall, and F1 score can better evaluate the proportion of correctly classified samples and demonstrate the model's discriminative ability. These indicators comprehensively measure the performance of the model from different perspectives. In specific construction projects, the results showed that the proposed method had an RMSE of 0.012 and a MAE of 0.015, both significantly lower than the comparative methods, indicating better performance. The precision, recall, and F1 score of GRGA were 92.37%, 47.52%, and 0.17, respectively. In the comparison of existing foundation pit deformation monitoring methods BPNN, CNN, and GM, the precision was 90.52%, 90.03%, and 89.95%, respectively, the recall was 34.20%, 32.01%, and 29.67%, respectively, and the F1 score was 0.10, 0.13, and 0.14, respectively. The research method has more obvious advantages. The results demonstrate that the early warning model is an effective method for analyzing and predicting the deformation of deep foundation pits. The combination of Gaussian regression and genetic algorithm for deep excavation management can model and predict nonlinear deformation data, optimize the parameters of Gaussian regression process, and improve prediction accuracy. Compared with existing warning methods, the method proposed in this study utilizes Gaussian regression process to better model and analyze the deformation process of foundation pits, thus accurately analyzing the detailed changes of foundation pits.

I. INTRODUCTION

In recent years, there has been a notable increase in the number of engineering projects, both large and small, that are being undertaken as a result of the continuous deepening of infrastructure construction. The construction of underground space has become a topic of significant research interest. In the construction process, deep foundation pit becomes a construction problem that must be solved. Influenced by factors such as geology, topography, climate, and construction forces, there are various risks and safety problems in deep foundation pits [1-2]. Common pit deformations are mainly categorized into surface settlement, enclosure deformation, and base elevation and deformation. Prediction of pit deformation can provide effective guidance for on-site construction and reduce potential risks that may occur during construction [3]. Enclosure works of the pit need to be stable enough to ensure the safety of foundation construction. In the specific construction process, the prediction of deep pit deformation is mainly based on the competent judgment of artificial experience, which has strong subjectivity and low accuracy. For example, a collapse accident occurred at a subway construction site in Hangzhou in 2008. The accident caused the nearby river to breach its banks and the river water to flow backwards. 11 vehicles driving on the road fell into a deep pit, and multiple workers were killed. A series of chain damage effects such as damage to nearby residential buildings and underground pipelines. The progressive integration of artificial intelligence and intelligent monitoring in engineering management has paved the way for the development of an effective early warning model for the management of deep foundation pit deformation [4-5]. However, although the deep excavation deformation warning model based on neural networks and grey models has achieved certain research success, there are still shortcomings. The existing methods mainly rely on manual operation, which is time-consuming and labor-intensive, and the monitoring efficiency is limited, making it difficult to detect small deformations. In addition, they have limited coverage in the monitoring process, which can easily lead to blind spots in inspection and monitoring, further increasing safety hazards. At the same time, such methods face difficulties in determining thresholds and large parameter quantities during the calculation process. Gaussian regression, a relatively novel artificial intelligence technology, has emerged as a prominent topic in intelligent learning, with successful applications spanning diverse domains such as engineering construction and intelligent prediction. Based on the advantages of Gaussian regression modeling in early warning analysis, a deep excavation deformation management early warning model based on Gaussian process regression is studied and constructed. Meanwhile, in the calculation process, genetic computing is

*Corresponding Author.

used to determine the optimal parameters in the foundation pit modeling process, thereby reducing the number of parameters and optimizing the calculation process. It is expected to better realize the deformation problem of the deep foundation pit construction process, reduce the potential safety problems, and ensure the smooth and stable progress of the overall construction.

The reasons for choosing Gaussian regression in the study are as follows. The Gaussian process regression model can effectively handle nonlinear and high-dimensional deformation data of foundation pits. During the solving process, Gaussian regression can infer unknown data by assuming the distribution relationship between data points, which has stronger flexibility and data prediction performance. The innovation of the research is as follows: Gaussian process regression is used to model the deformation problem of foundation pits, aiming to develop a more accurate model and conduct a more comprehensive analysis of the deformation process of foundation pits. Subsequently, a genetic algorithm is employed to optimize the intricate parameter calculations undertaken during the modeling process. This is done with the objective of attaining the optimal parameters for modeling the deformation of the foundation pit and thereby facilitating a more precise analysis of the deformation of the foundation pit.

Most existing research is focused on the deformation of foundation pit structures and the resulting collapse issues. The research on early warning management of deformation problems during the construction process of deep foundation pits is relatively insufficient. Especially for the nonlinear changes in the deformation process of foundation pits, existing research has not achieved more accurate simulation. Therefore, in order to better capture the detailed changes in the deformation process of foundation pits and address issues such as settlement and collapse, a Gaussian regression-based foundation pit deformation modeling method was developed to analyze nonlinear deformation data. The contributions of the research are as follows. This study first used Gaussian regression to model the deformation of foundation pits, and optimized Gaussian regression using genetic algorithms to obtain a prediction method for foundation pit deformation. The method was validated through experiments, and better prediction results for foundation pit deformation were obtained than existing research methods. At the same time, the error results obtained were also within a reasonable range, providing effective evidence support for the prediction of foundation pit deformation.

The study is divided into many sections. Section II reviews the current status of industry research on deep foundation pit deformation problems and Gaussian regression distributions. Section III designs a deep foundation pit deformation warning model based on Gaussian regression distributions. Section IV validates the performance of the designed method. The paper is concluded in Section V.

II. Related Work

With the economic development, all kinds of infrastructure construction are increasing. In the project construction, all kinds of pit work develop in the direction of depth and large-scale. The deformation of foundation pits in the construction process has gradually received widespread attention. Many scholars have studied the causes of pit deformation and the monitoring and early warning. Kim T et al. observed the lateral deformation of excavation support walls in foundation pits. The study used inverse analysis techniques to conduct inverse analysis on excavation sites and summarized the evolution process of excavation deformation under different soil conditions [6]. Discontinuities or imbalances in the cambered support structure might lead to collapse, which may result in damage and casualties. Therefore, Nam et al. used a three-dimensional numerical model to convex corners of retaining walls in deep foundation pits. It was found that connecting two discrete longitudinal rows at the convex corner could effectively improve the stability [7]. Cui et al. used on-site monitoring and numerical simulation methods to explore the changes during excavation of foundation pits. The results indicate that excavation of the inner pit reduces the passive earth pressure, and setting up support structures or bottom plates in the step area can effectively suppress the deformation of the outer support structure, thereby reducing the deformation of the foundation pit [8]. Mao Z et al. used the finite element software Midas GTS NX (2019) to analyze the effects of different support types (pile anchor support and double row pile support) on the excavation of tunnel foundation pits near subway stations. The displacement of the foundation pit increases continuously from a distance away from the excavation to a distance closer to the excavation. This study can provide reference for related engineering projects to ensure the safety and stability of subway structures [9]. Shi established a finite element model for the damage caused by water inflow and seepage in foundation pits, and analyzed the effects of the depth of the confined water level and groundwater level on the deformation of the foundation pit. The results indicate that changes in groundwater level have a significant impact on the deformation of foundation pits [10].

With the development of artificial intelligence technology, various advanced artificial intelligence technologies are widely used for monitoring the deformation of foundation pits. Cui et al. constructed a PSO-GM-BP foundation pit deformation prediction model based on PSO-optimized GM(1,1) model and BP network model. A small amount of measured data during the excavation process of the bottomless foundation pit at Changsha Metro Station was used to validate the model. The method could accurately predict the deformation of a foundation pit with reliable precision and applicability, thereby providing effective guidance for the construction of the foundation pit [11]. Zhang et al. developed a 3D model based on FLAC3D for numerical simulation of excavation deformation at a subway station in Jinan city as a project. The horizontal displacement of the supporting structure, axial force of the support, and vertical displacement of the columns were compared with the data collected on site. The results indicated that during excavation of the foundation pit, the maximum deformation of the support structure gradually decreased from the top and increased gradually, with a final maximum deformation of about 17 meters deep [12]. Pan et al. proposed a new Probabilistic Deep Reinforcement Learning (PDRL) framework to optimize monitoring of deep excavation projects, aiming to minimize costs and risks caused by excavation. Firstly, a Bayesian bidirectional generalized regression neural network was established to describe the relationship and role between

foundation pit ground settlement and the safety status of adjacent buildings. Subsequently, a dual deep Q-network method was trained for continuous learning of monitoring strategies. The findings indicated that this approach could address the inherent ambiguity within the environmental context and the model itself, thereby facilitating the optimization of monitoring strategies, the attainment of cost-effectiveness, and the mitigation of risk [13]. The summary of related work is shown in Table I.

The deformation problem of deep foundation pits has been the subject of extensive attention and research by industry scholars. However, the majority of existing studies have focused on the deformation of the foundation pit structure and the subsequent collapse problem. However, most of the existing researches are about the deformation of foundation pit structure and the resulting collapse problem. There is a relative lack of research on the early warning management of the deformation problem of deep foundation pits in the construction process. Based on this, this study combines the advantages of Gaussian regression analysis in data warning management and constructs a corresponding deep excavation deformation pre-management model. It aims to provide timely and effective solutions to the deformation problem of deep foundation pits in engineering projects, ensuring the smooth progress of the overall construction of the project.

III. EARLY WARNING MODEL CONSTRUCTION OF DEEP FOUNDATION PIT DEFORMATION BASED ON OPTIMIZED GAUSSIAN REGRESSION MODEL

In recent years, with the continuous acceleration of urbanization construction, the safety problems caused by deep foundation pit deformation in various engineering projects occur frequently. The study addresses this problem by adopting Gaussian regression model to design the corresponding deep foundation pit deformation early warning model. Then, the model is utilized to design and monitor the specific deep foundation pit deformation for early warning.

A. Deep Foundation Pit Deformation Engineering Design

The early warning of deformation management of foundation pit denotes the timely monitoring of deep foundation pits in engineering projects through a variety of technical methods and means, aiming to implement early warning treatments in accordance with the statistical analysis of monitored data. This approach is of paramount importance for ensuring the safe and stable development of the project. The deformation of deep foundation pit is mainly reflected in the deformation of foundation pit enclosure structure, pit uplift, and surface settlement. There is a significant relationship between the deformation of the foundation pit and the surface morphology change of the periphery of the foundation pit, which roughly meets the change curve shown in Fig. 1 [14].

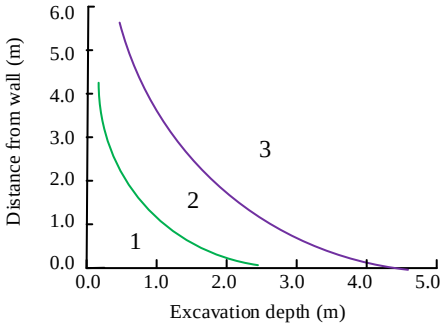

Fig. 1. Surface subsidence relationship.

There are many factors affecting the deformation of deep foundation pit, including climate, topography, construction program, and construction technology, etc. Its impact is also a process of qualitative change from quantitative change, therefore, its early warning management is a relatively difficult process. To better analyze the deformation of the deep foundation pit, the study takes the deep foundation pit in the project of a certain place as an example, and designs the monitoring layout design for the deep foundation pit project. The study selects a pit project in S city. The total area is 12,431 m2, of which the basement floor area is 3,716.29 m2, the shape of the pit is similar to the quadrilateral, and the excavation depth of the pit bottom is 6.43m. The soil conditions from the surface layer downwards are miscellaneous fill soil, sandy silt, silty clay, and clay [15-16]. The existing amount of buildings around the surface are mainly large-scale hotels, commercial buildings, etc., and the underground layer belongs to the garage and the human defense. The specific schematic diagram is shown in Fig. 2 [17-18].

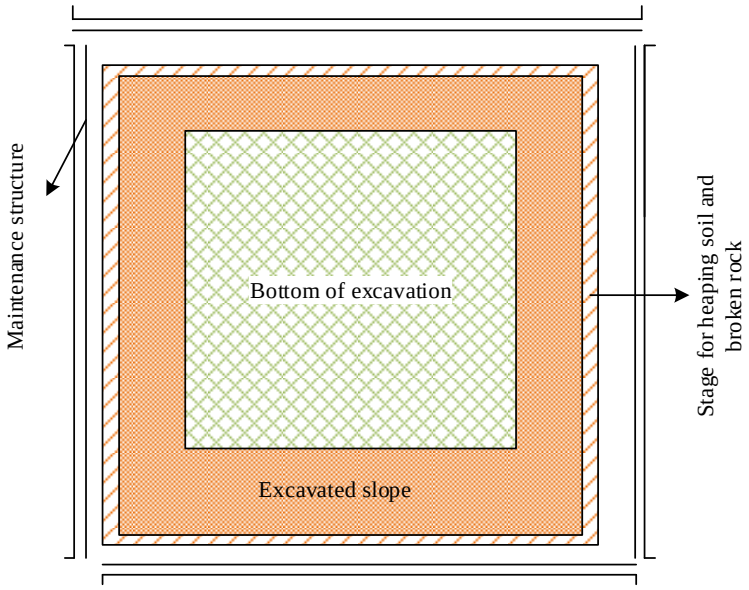

Fig. 2. Schematic diagram of foundation pit structure.

In this pit monitoring site, the placement of measuring instruments in the pit monitoring project, and the subsequent generation of a report for the surveyor, are carried out through the setting of various types of data acquisition instruments to obtain the corresponding sample data. However, there is an error between the study of the introduction of visual measurement technology for pit monitoring in the image acquisition, and the actual measured target object [19-20]. Visual measurement can be a single imaging multi-point observation, close-up photography in the target, and the measured object line into target points, from the shooting image to get the exact location of multiple target points, that is, the center of the target point. Then Gobor technique is used to process the acquired pit deformation sample images. The area around the key point is divided into L（$L \le 50$） sub-windows of $N \times N$, and then each sub-window is Gabor-transformed, and the 2D Gabor filter is defined in Eq. (1).

$$\sigma = \sqrt{2\ln 2}\left(\frac{2\phi+1}{2\phi-1}\right) \tag{1}$$

In Eq. (1), σ denotes the bandwidth of the 2D Gabor filter and ϕ denotes the half-peak bandwidth in octave. The image feature extraction of 2D Gabor is shown in Eq. (2).

$$P_{u,v}(x,y) = G(x,y) * C_{u,v}(x,y) \tag{2}$$

In Eq. (2), $P_{u,v}(x,y)$ denotes the Gabor features of the image when the scale is u and the direction is v. $G(x,y)$ denotes the gray scale of the input image. $*$ denotes the convolution factor. $C_{u,v}(x,y)$ denotes the 2D Gabor kernel function. The computed local correlation features are shown in Eq. (3).

$$R_{\mu n} = \frac{1}{L-n}\sum_{i=1}^{L-n}\mu_i\mu_{i+n} \qquad (n = 1,2m) \tag{3}$$

To facilitate the subsequent pit deformation early warning analysis, it is necessary to obtain and analyse sample data on pit deformation. This will inform the design of the corresponding pit deformation early warning management model.

B. Construction of a Deformation Warning Model

In the construction of engineering projects, the construction complexity, comprehensiveness, and technical requirements of deep foundation pit engineering are higher. Foundation pit engineering is actually a kind of protective engineering project. The main role is to provide corresponding support space for the overall construction of engineering structure to ensure the stability of the surrounding soil and the smooth progress of the construction project. In the construction of deep foundation pit, it is usually necessary to excavate to the surrounding to set up the corresponding protective structure and measures. However, in the specific construction process, the construction difficulty of deep foundation pits and potential risk factors are not effectively controlled. In particular, the deformation monitoring of various protective structures directly affects the construction of the main structure and the progress of the overall project. The traditional pit deformation monitoring models are time series-based monitoring model and gray system-based monitoring model. In addition, the existing phase change monitoring methods for foundation pits mainly rely on manual operation, which is not only time-consuming and labor-intensive, but also has limited monitoring efficiency, making it difficult to detect small deformations. Overall, existing single point monitoring methods often have difficulty covering the entire area in various excavation projects, resulting in monitoring blind spots and increasing safety hazards. Other advanced monitoring technologies, such as 3D laser scanning technology, although have higher coverage, their corresponding costs also increase [21]. With the continuous development of artificial intelligence technology, it has a more significant role in risk prediction of all

kinds of engineering projects. Accordingly, the study introduces artificial intelligence technology to monitor and warn the deformation problems occurring in deep foundation pit projects. Gaussian regression model is a kind of artificial intelligence analysis method based on statistical knowledge for data processing. Gaussian regression captures complex nonlinear relationships through a specified kernel function. Modeling can be carried out based on the specific data characteristics of excavation deformation, in order to more accurately describe the changing patterns of excavation deformation. In addition, deformation monitoring of foundation pits involves multiple different variables, such as time, spatial location, historical deformation data, etc. Gaussian process regression can handle inputs and outputs of any dimension, making it suitable for multivariate regression problems. Therefore, it has good flexibility and applicability, allowing for the development of timely and effective measures to ensure the safety of foundation pit construction.

The Gaussian regression process is a stochastic process that involves a sample function that obeys a Gaussian distribution. The mathematical definition of the Gaussian distribution process is shown in Eq. (4).

$$\{g(x), x \in X\} \tag{4}$$

In Eq. (4), X is the set parameter set, and any point x belongs to X. Eq. (4) is a stochastic process defined on the probability space M. At this point, there exists a random variable x_i corresponding to it, that is, the stochastic process. Gaussian regression process is a collection of random variables that conform to a Gaussian distribution. Taking a specific observation data x as an example, the Gaussian regression process is shown in Eq. (5).

$$g(x) = \{GP(f(x), w(x,x))\} \tag{5}$$

In Eq. (5), x is any observation data. $f(x)$ represents the mean function of the observed data. $w(x,x)$ represents the covariance function of the observed data. GP stands for Gaussian distribution process. Gaussian regression analysis is then based on the Gaussian regression process to perform specific data regression analysis. Regression analysis lies in determining the functional relationship that exists between two variables and is widely used in various scientific data analysis. The mathematical definition of the data regression problem is shown in Eq. (6).

$$Z = R(x) + \varepsilon \tag{6}$$

$R(x)$ denotes the functional relationship between any two variables, and ε denotes the observation noise vector that independently obeys Gaussian distribution. Gaussian regression process needs to preprocess the initial data when constructing the objective function. If a and b constitute the observation data set of deep foundation pit deformation $E\{(a_s, b_s)|(s = 1,2,...,n)\}$, a^* is the set of results to be predicted, and b^* is the set of samples to be predicted. According to the Gaussian distribution property, the joint prior distribution relationship between a^* and b^* is shown in Eq. (7).

$$\begin{bmatrix} b \\ b^* \end{bmatrix} = \left(0, \begin{bmatrix} w(a,a) + \sigma^2 I_n \\ w(a^*, a) \end{bmatrix}\right) \tag{7}$$

In Eq. (7), $w(a,a)$ denotes the covariance function of the sample data a. σ^2 denotes the noise variance. I_n denotes the unit matrix. After obtaining the dataset E, according to the Gaussian distribution, the posterior distribution of b^* is shown in Eq. (8).

$$p(b^* | E, a^*) = [m(b), w(b^*, b^*)] \tag{8}$$

In Eq. (8), $m(b)$ denotes the corresponding output of x to be predicted, and $w(b^*, b^*)$ denotes the posterior variance of the predicted output value. The Gaussian distribution regression process actually describes the distribution of the function from the probability space dimension of the function. However, in some high-dimensional models, more sample points are required in the calculation process [22]. According to the above process, the prediction model construction of Gaussian distribution regression can be realized, and the construction of Gaussian regression model is shown in Fig. 3.

The mean of the predicted values is a linear combination of the kernel function $w(b^*, b^*)$. The data with nonlinear relationship can be mapped to the feature space to complete the linear relationship transformation, thus simplifying the complexity of solving the nonlinear problem. Different covariance functions can be used in the Gaussian process. The commonly used covariance function is shown in Eq. (9).

$$k(x_i, x_j) = \sigma^2 \exp(-\frac{1}{2l^2} r^2) + \sigma_n^2 \varsigma_{ij} \tag{9}$$

In Eq. (9), σ^2 denotes the covariance signal, l denotes the moderating parameter, and ς_{ij} denotes the Kronecker value. The larger the value, the less significant the correlation between the inputs and outputs of the sample data.

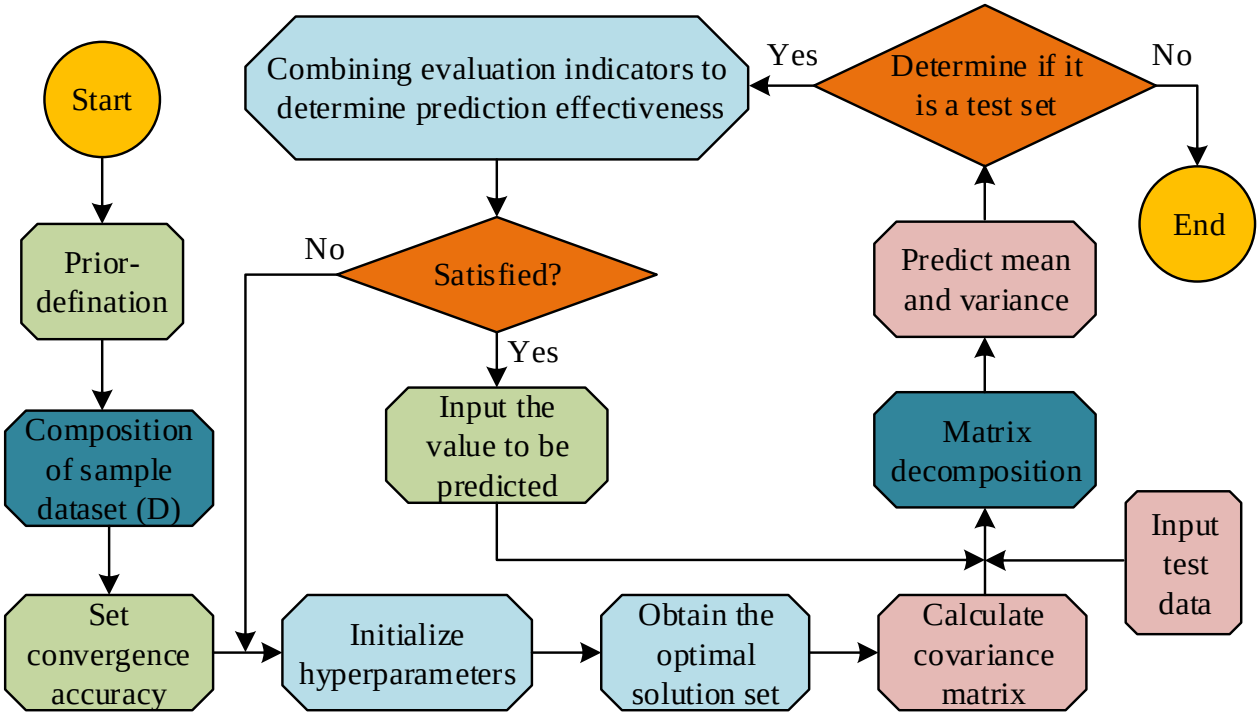

Fig. 3. Gaussian regression process.

C. Early Warning Model Construction of Deep Foundation Pit Deformation Based on Optimized Gaussian Regression Model

In the Gaussian regression process, the study uses the conjugate gradient method to solve the optimal hyperparameters. However, in the actual application process, the method gets unsatisfactory results. Accordingly, the study uses genetic algorithm to optimize it. Genetic algorithm, as an optimal algorithm as bionic, has a weak dependence of its objective function on the initial value and the global optimum. It has been widely used in computing multi-parameter and multi-variable problems [23]. Therefore, the study constructs an improved Gaussian regression model based on genetic algorithm to determine the optimal parameters. In the optimization process, firstly, chromosome coding is used by code conversion to transform the form of target parameters to be solved in the Gaussian regression process into the form of genetic code strings. The fitness function is selected for evaluating the fitness of the individual, and the higher the value of the function obtained, the better the solution effect. Taking individual P as an example, in the calculation process of genetic algorithm, the fitness function of P is expressed as Eq. (10).

$$E(P_i)=\frac{1}{2}\sum_{k=1}^{N}\left(y_{ki}-o_{ki}\right)^2 \tag{10}$$

In Eq. (10), N represents the population size. P_i represents the node i of individual P. o_{ki} represents the expected output value of node i on chromosome k. y_{ki} is the actual output value. Finally, the selection of individuals in a population generally adopts proportional selection, which is based on the ratio of individual fitness to the sum of fitness of all individuals. This way, every individual has the possibility of being selected. If n is used to represent the size of the population, i represents the individual. F_i is the individual fitness which can be obtained. The probability of i being selected in shown in Eq. (11).

$$P_i=\frac{F_i}{\sum_{i=1}^{n}F_i} \tag{11}$$

After the initial selection is completed, the optimal strategy is used to further select the optimal value, i.e., the optimal value is determined by searching for the individuals with the two extreme values of the highest and the lowest fitness. Accordingly, the pit deformation prediction model is constructed based on the optimized Gaussian regression network of genetic algorithm to predict the pit deformation, and the inverse normalization results are output in MATLAB [24]. The implementation process of the improved Gaussian regression model based on genetic algorithm is shown in Fig. 4.

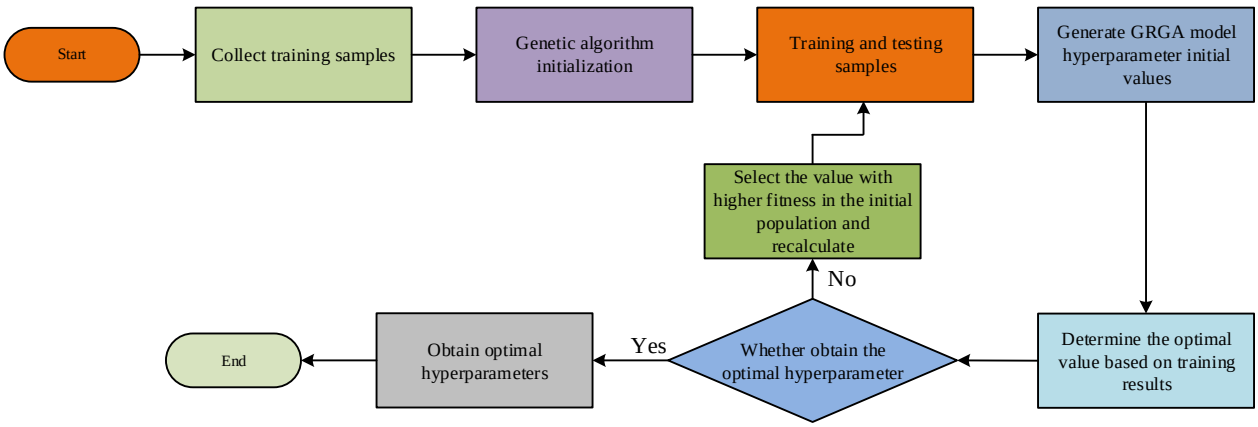

Fig. 4. Improved Gaussian regression process based on genetic algorithm.

In Fig. 4, when using an improved Gaussian regression model based on genetic algorithm for predicting excavation deformation, data samples are first collected and the genetic algorithm and Gaussian regression model are initialized. Then, the data samples are trained to generate parameter values for the GRGA model. Determine the optimal parameter values based on the training results. If the optimal value can be obtained from the training results, the process can be ended by outputting the optimal value. If the optimal value cannot be obtained from the training results, select a higher fitting value for sample training again. The Gaussian regression model has relatively few parameters in the modeling process, and the model hyperparameters can effectively avoid the data bias that occurs when manually assigning values by adaptive solving. The new Gaussian regression model is obtained by improving the Gaussian regression process using the above process. In the Gaussian regression process, the arbitrary variables are mutually independent Gaussian stochastic processes. Therefore, the established Gaussian regression process model is shown in Eq. (12).

$$g(x^*) = \sum_{i}^{n} K(x, x^*) \tag{12}$$

In Eq. (12), $K(\cdot)$ represents the combination function, which is the covariance matrix between the input sample x and the input value x^* to be predicted. $g(x^*)$ represents the Gaussian regression process of the input value x^* to be predicted. In accordance with the principle of "systematic, economical, convenient, and intuitive," the suitable monitoring location is determined based on the geological, climatic, and hydrological conditions in the vicinity of the foundation pit. Subsequently, a model is established based on the genetic algorithm to predict the horizontal deformation displacement of the foundation pit from both horizontal and vertical perspectives. The acquired monitoring sample data are normalized and then trained in MATLAB. The genetic algorithm is initialized first to determine the initial weights and thresholds, and then the corresponding training parameters are input to train genetic algorithm. The training is terminated when the training error is less than the established thresholds or when the search training reaches the preset value. The normalized values are outputted. Finally, the trained network is simulated on the prediction samples, and the final prediction results are obtained after the inverse normalization. The specific process is shown in Fig. 5.

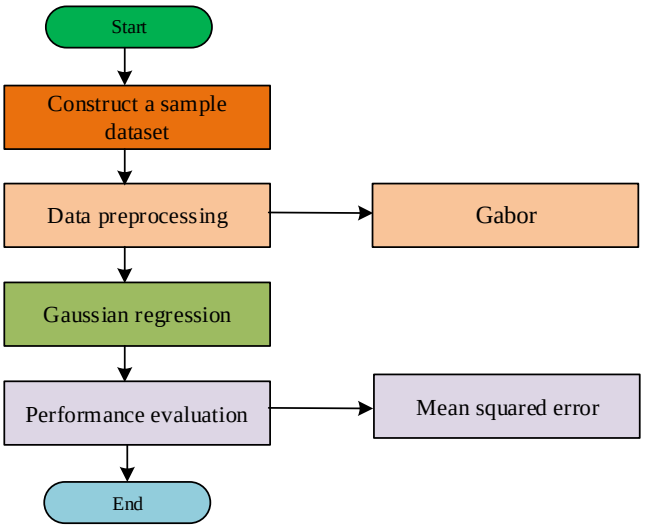

Fig. 5. Gaussian regression analysis process.

This study trained and tested the research method using the AI Earth - A Map of China's Surface Deformation (2022) dataset. This dataset covers the national surface deformation situation, with over 300 map views. To ensure data quality, the sample data is first preprocessed by adjusting the pixel values of the image to a specific range (usually between 0 and 1), which speeds up model training and improves model accuracy. Scale the images based on the average and standard deviation of the image dataset to ensure that the feature distributions have similar distributions. The two datasets are divided into a training set and a testing set in a 7:3 ratio to train the model.

IV. Experimental Analysis of Deep Foundation Pit Deformation Warning Model Based on Optimized Gaussian Regression Model

Based on the Gaussian regression warning model, the study introduces a genetic algorithm to optimize it and constructs a corresponding pit deformation warning model. In this section,

the study verifies the performance and application effect of the proposed method, and at the same time introduces relevant comparison methods to verify its performance.

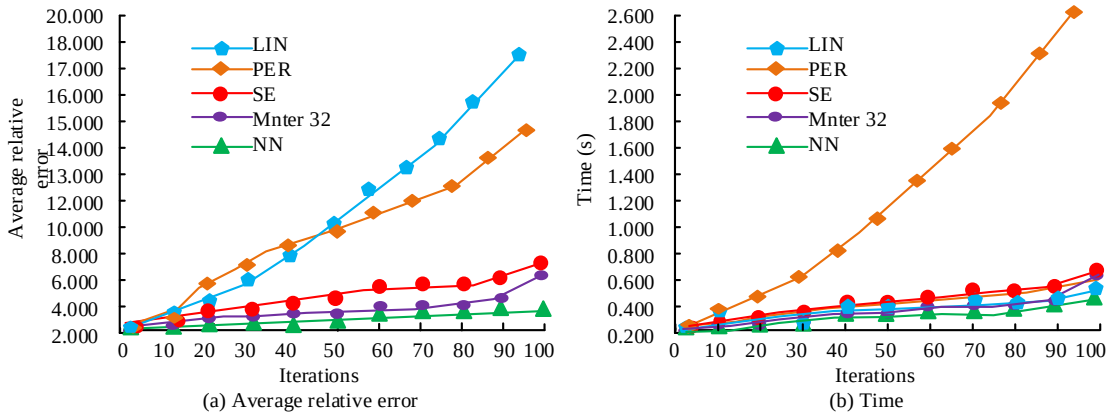
A. *Performance Analysis of Early Warning Model for Deep Foundation Pit Deformation*

To verify the performance effect of the early warning model, the corresponding experiments were designed to analyze it. In genetic algorithms, the population size determines the size of the model's search space. Appropriate population size can effectively solve complex problems while avoiding premature maturity. The crossover probability and mutation probability determine the search capability of the model. Both too high and too low can affect the diversity of the population. Therefore, based on existing research results, the parameters of the genetic algorithm used in the study are set as follows. The population size was set to 20, the crossover probability was set to 0.9, and the mutation probability was set to 0.05. This study uses the number of iterations of the algorithm as the convergence criterion. To ensure consistency in the experimental environment, the number of iterations is set to 100. The study first set the parameters of the genetic algorithm. The pre-set genetic algorithm was used for parameter optimization to obtain the optimal parameter combination for foundation pit deformation modeling and prediction. The optimal parameter combination obtained through multiple experiments is shown in Table II. The number of hidden layers determines the complexity and learning ability of the model, and this parameter range can explore the performance changes from shallower models (16 layers) to deeper models (128 layers) to obtain the optimal value. Dropout can explore different regularization effects. A lower Dropout rate may not be sufficient to effectively reduce overfitting, while a higher Dropout rate may lead to insufficient model learning. The Batch-size range is designed to find a balance between training speed and stability. 100 iterations is a relatively common choice that allows the model enough time to learn features from the data while avoiding excessively long training time.

TABLE II. PARAMETER VALIDATION

Optimal parameters	Initial value	Optimal value
Number of hidden layers in the network	[16, 128]	81
Dropout	[0.01, 0.5]	0.078
Bach-size	[16, 128]	41
Maximum number of iterations	100	100

The optimal parameters obtained through multiple experiments are used for subsequent model validation. In the Gaussian regression model, the choice of covariance function has a direct impact on the model fitting effect. Consequently, this study examines the suitability of different covariance functions for analyzing the fitting effect of the Gaussian regression model. Commonly used covariance functions include the neural network function (NN), the periodicity function (PER), the squared exponential function (SE), and the Matern function (Matern 32), etc. They are evaluated by the average relative error and fitting time. The fitting effect of Gaussian model under different covariance functions is shown in Fig. 6. In Fig. 6 (a), among the five different covariance functions, the NN has the smallest value of average relative error with an error value of 2.347. The average relative error values of LIN, PER, SE, and Mnter32 are 18.63, 15.21, 8.95, and 7.46, respectively, which are significantly higher than the research method. In Fig. 6 (b), the time consumption of LIN, PER, SE, Mnter32, and NN are 0.689, 2.53, 0.712, 0.694, and 0.527, respectively. Except for the periodicity function, the time consumption differences of other methods are relatively small. The covariance function has a significant impact on the fitting performance of the model, including its smoothness and generalization ability in the input space. A suitable covariance function can capture complex nonlinear relationships in data and achieve accurate prediction of new data. Therefore, considering the average relative error values and time consumption of different covariance functions, the neural network function has the best fitting effect, proving that the covariance function used in the study is reasonable.



(a) Average relative error (b) Time

Fig. 6. The fitting effect of different covariance functions.

To better analyze the performance of the proposed method (GRGA), the study uses commonly used methods for comparison, including the Gray Prediction-based method (GM), Convolutional Neural Network-based method (CNN), and BP Neural Network-based method (BPNN). The Root Mean Square Error (RMSE) and Mean Absolute Error (MAE) are used to evaluate the performance of the above methods. In the monitoring of foundation pit deformation, RMSE can measure the accuracy and reliability of monitoring data by calculating the difference between actual values and model measurements. MAE can effectively reflect the average error between the predicted and actual values of the model, which helps evaluate

the accuracy and reliability of the model's predictions. The error values of the different methods in the process of deep foundation pit deformation are shown in Fig. 7. In Fig. 7 (a), the RMSE values of the GM, CNN, BPNN, and GRGA are 0.055, 0.079, 0.043, and 0.012, respectively. In Fig. 7 (b), the MAE values of the GM, CNN, BPNN, and GRGA are 0.078, 0.112, 0.059 and 0.015, respectively. Lower RMSE and MAE values mean that the deviation between the predicted values and the true values of the model is smaller, indicating that the model's predictions are more accurate. Overall, the RMSE and MAE of the proposed method are significantly lower than those of the comparative method, indicating better performance.

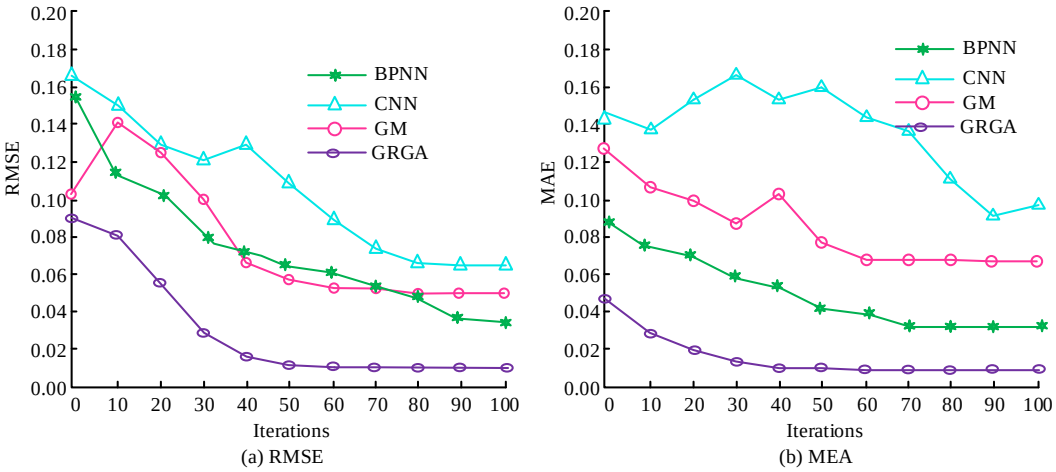


Fig. 7. Comparison of errors between different models.

To further validate the performance of the research method, the study analyzes the recall, precision, and F1 score of the Gaussian regression model and the GRGA. F1 takes into account both accuracy and recall. In the monitoring of foundation pit deformation, it can effectively study the specific performance of the model in predicting foundation pit deformation. The results are shown in Fig. 8. In Fig. 8 (a), the precision of the GRGA is 92.37%, and the precision of the other three methods of BPNN, CNN, and GM are 90.52%, 90.03%, and 89.95%, respectively. In Fig. 8 (b), the recall of the GRGA is 47.52% and the other three methods are 34.20%, 32.01%, and 29.67%, respectively. In Fig. 8 (c), the F1 value of the GRGA is 0.17, and the F1 values of the remaining three methods are 0.10, 0.13, and 0.14, respectively. Therefore, it appears that the GRGA has a better performance.

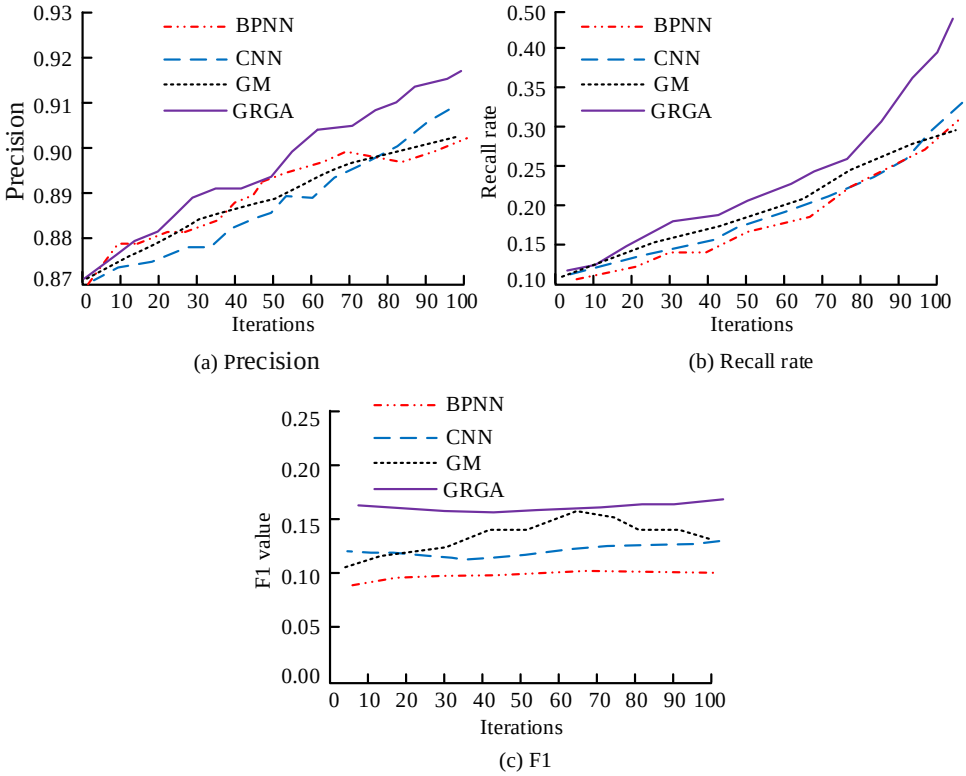

Fig. 8. Comparison of recall, precision, and F1 for different methods.

To verify the performance of the GRGA, Freidman detection analysis is conducted. Benchmark methods GM and BPNN are introduced for comparison. The obtained P-values and χ^2 test results are shown in Table III. According to Table III, the research method has stability in the test results of different indicators. Although the P-values of the indicators for GM and BPNN are significant, the level of significance is low, and the model performance is significantly lower than that of the research method. Based on the comprehensive verification, the research method performs the best among various comparison methods, verifying its practicality and effectiveness in solving and analyzing the deformation of foundation pits.

TABLE III. FREIDMAN TEST RESULTS OF THE RESEARCH MODEL

Testing index	Research method		GM		BPNN	
Testing index	*P*	χ^2	*P*	χ^2	*P*	χ^2
Accuracy	0.001	6.257	0.01	4.901	0.02	5.554
Recall	0.001	10.329	0.01	6.782	0.01	3.712
F1	0.001	9.0264	0.05	5.998	0.01	6.072
RMSE	0.002	5.295	0.02	8.208	0.01	6.225
MAE	0.001	6.164	0.01	7.461	0.01	3.012

After comparing with commonly used methods, the study compares it with the benchmark method (GR) to verify the effectiveness of the improved strategy (GRGA). The results are shown in Table IV. According to Table IV, the F1 score, Precision, Recall, and AUC of the GRGA reach 0.85, 0.89, 0.92, and 0.93, respectively. In benchmark testing, the evaluation results of the GRGA's indicators are significantly better than its GR, demonstrating higher model performance.

Subsequently, to validate the effectiveness of the GRGA in data analysis, the sensitivity of several comparative methods is analyzed, and the results are shown in Fig. 9. In Fig. 9, the sensitivity and specificity values of BPNN are 0.786 and 0.791, while the sensitivity and specificity values of CNN are 0.823 and 0.837. The sensitivity and specificity of GM are 0.843 and 0.862. The sensitivity and specificity of GRGA are 0.888 and 0.959. From this perspective, this research method has better accuracy than its comparative methods, can achieve data convergence faster, and has a certain degree of stability in the calculation results.

TABLE IV. RESEARCH METHOD BENCHMARK TESTING

Performance Metric	GR	GRGA
F1 score	0.79	0.85
Precision	0.81	0.89
Recall	0.85	0.92
AUC	0.82	0.93

B. Analysis of the Practical Application Effect of Deep Foundation Pit Deformation Modeling

Four different profile monitoring points (ABCD) are set up in the horizontal direction to monitor the deformation changes in both vertical and horizontal directions. The monitoring period lasts for one year, and data collection is completed in six stages, with an interval of two months between each stage. Then, the obtained deformation monitoring data of the foundation pit are analyzed. To address the outliers and heterogeneity of the initial intention during data collection, some outliers are removed. Removing outliers that contain important information may result in the model being unable to capture the true distribution of the data. Therefore, replace outliers with the mean. The substitution method can preserve the integrity of the dataset and avoid information loss. The specific deformation data of four monitoring points are fitted, and the visualization results between their deformation warning values and actual deformation are shown in Fig. 10. In Fig. 10 (a), the difference between the warning results obtained by fitting using the research method and the actual results is small. The results obtained from the fifth monitoring are basically consistent with the actual results. In Fig. 10 (b), (c), and (d), the difference between the actual values obtained and the fitted values is relatively large, but the overall error range is within an acceptable range.

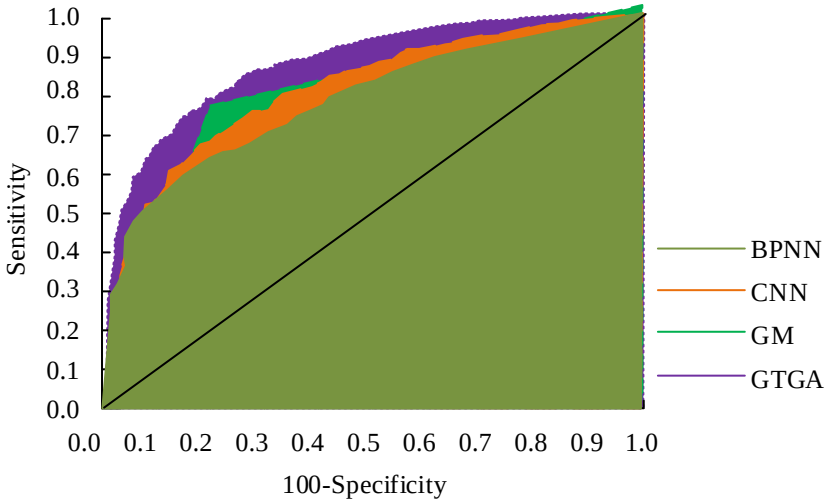

Fig. 9. Sensitivity and specificity analysis.

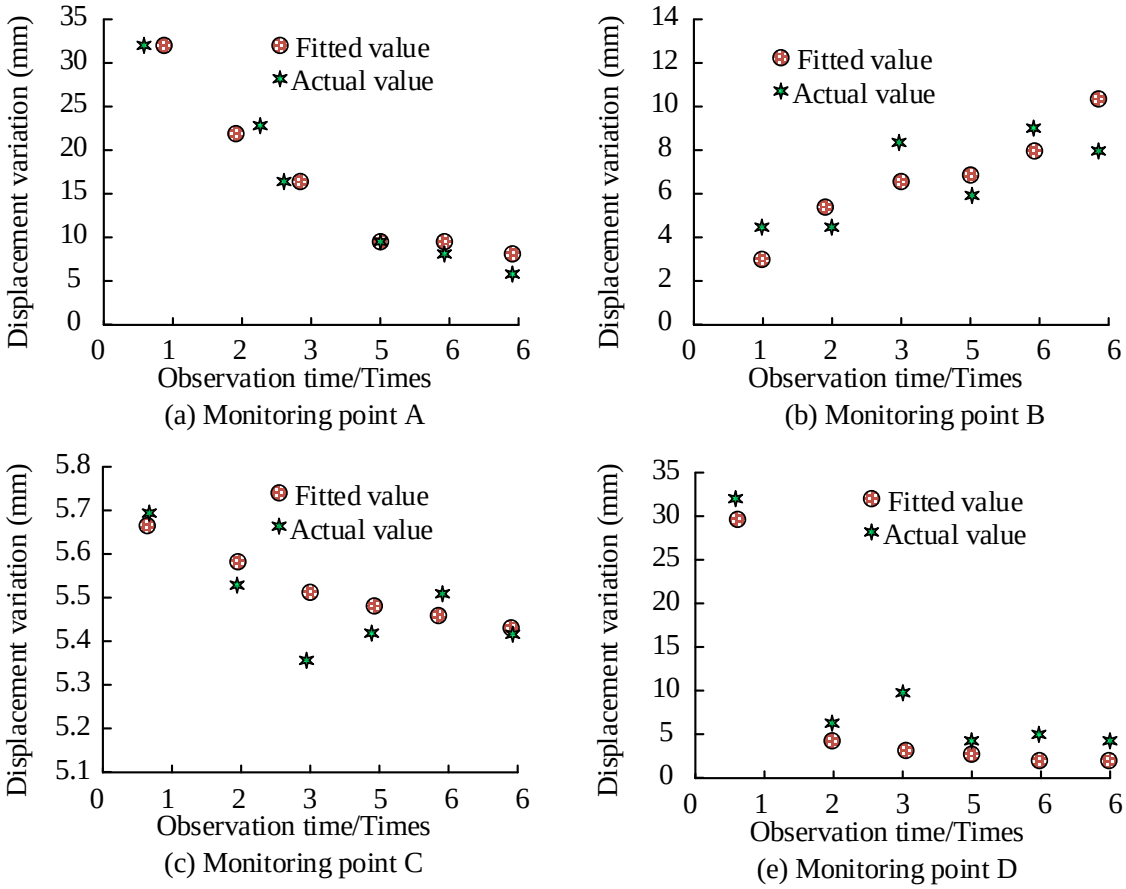

Fig. 10. Visualization results of deformation warning values and actual deformation.

Taking the four monitoring points set up for the study as the base point, the cumulative pit deformations in the vertical and vertical directions are analyzed, and the cumulative pit deformations in the vertical and horizontal directions are obtained as shown in Fig. 11. In Fig. 11 (a), in the vertical direction, the cumulative deformation in the four cross-sections varies significantly, and the average deformation in the four cross-sections reaches 1.32 mm, 1.21 mm, -3.47 mm, and -6.51 mm, respectively. Fig. 11 (b) shows the cumulative deformation in the horizontal direction. All the four monitoring locations show significant displacement changes between the second and the fourth monitoring, which may be related to the changes of construction and climatic conditions and other changes.

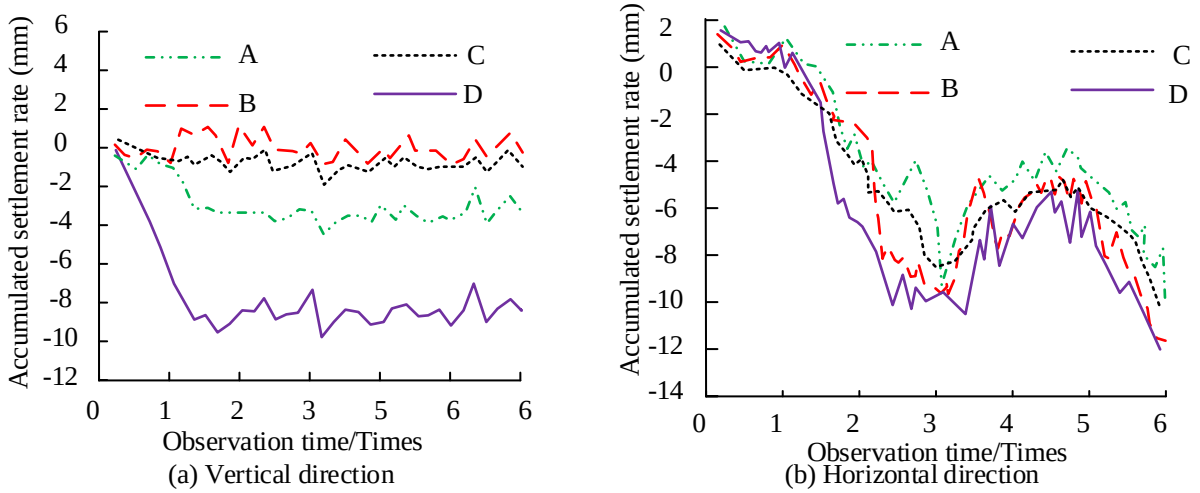

Fig. 11. Accumulated settlement in vertical and horizontal directions.

The most prominent manifestations during the deformation process of deep foundation pits are surface settlement, deformation of foundation pit enclosure, and uplift of foundation pits. The study statistically analyzes the actual and predicted values of the three types of pit deformations under different monitoring times of the pit monitoring project, and the obtained statistics are shown in Table V. This research method can provide ideal warnings for different types of deep excavation deformations.

In the same monitoring location, the proposed early warning analysis of the deformation trend of the deep foundation pit is carried out using the GM method and the research method. The obtained early warning results are shown in Fig. 12. Fig. 12 (a), (b), (c), and (d) represent the deformation warning results for four different monitoring locations, respectively. In general, the proposed method demonstrates superior performance in tracking the specific deformation trend. While some of the specific points align closely with the actual values, there are also instances where the proposed trend significantly deviates from the observed data. From this point of view, the performance of the GRGA can better track the specific trend of deep foundation pit deformation. Especially for the detail changes, there is a better presentation effect, which can better facilitate the subsequent audit monitoring management.

TABLE V. ERROR ANALYSIS OF PIT DEFORMATION PREDICTION (MM)

Excavation deformation type	Time	Actual value	Predictive value
Surface subsidence	2	10.651	10.656
	4	10.659	10.661
	6	10.667	10.662
	8	10.684	10.681
	10	10.703	10.695
	12	11.214	11.219
Deformation of enclosure structure	2	8.562	8.641
	4	8.647	8.648
	6	8.718	8.802
	8	8.866	8.871
	10	9.510	9.504
	12	9.964	9.935
Pit uplift	2	14.112	14.135

	12	15.964	15.985

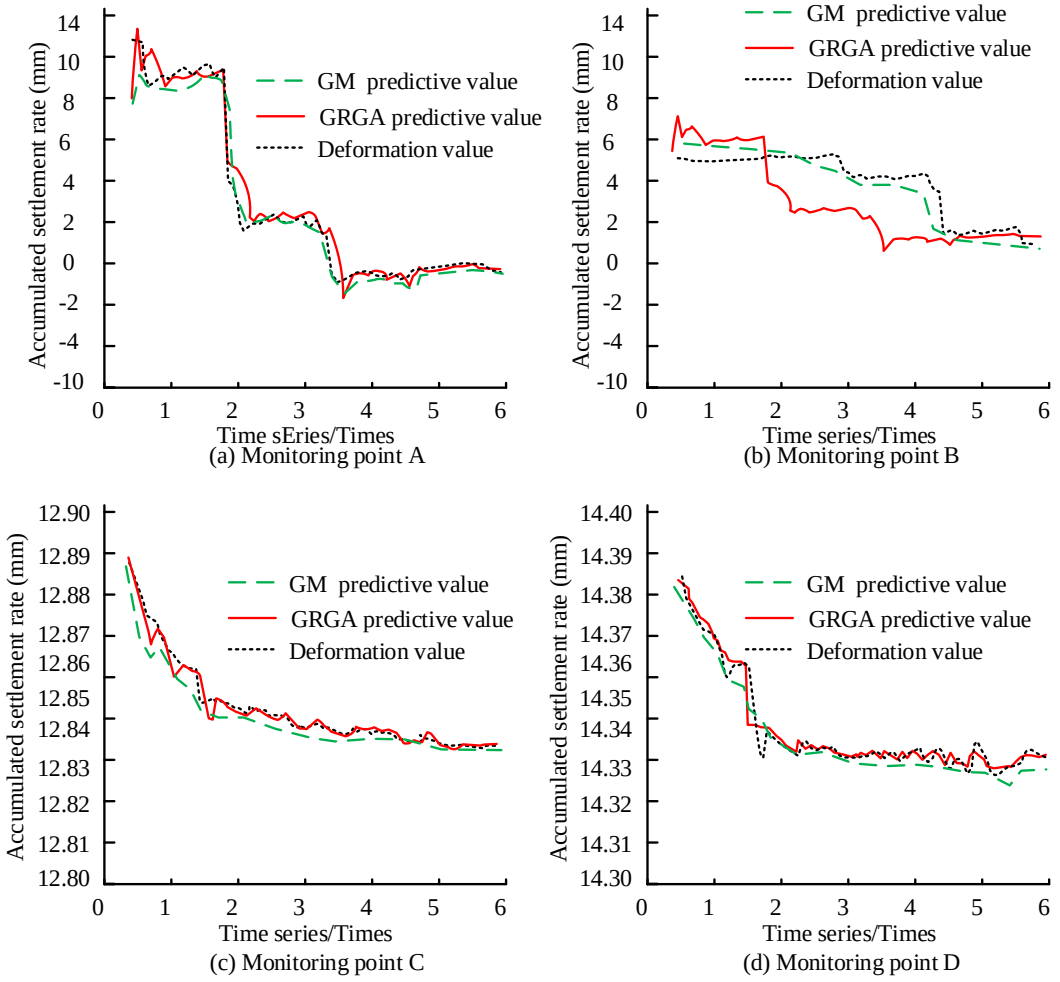

Fig. 12. Fitting the deformation trend of deep foundation pits.

To further validate the effectiveness of the research method, it was compared with methods proposed by other scholars on different datasets, including "AI Earth-China's Surface Deformation" mentioned above and "Safety Management Data for Deep Excavation Construction". The latter comes from the data statistics of a construction project on the Zhejiang Provincial Data Knowledge Registration Platform, which includes 25,251 pieces of data. Comparison methods include the PSO-GM-BP model proposed by Cui D et al. [11], the PDRL model proposed by Pan Y et al. [13], GM and BPNN. The precision prediction results of the obtained deformation are shown in Table VI. The research method outperforms its comparative methods in terms of monetization in various indicator tests. In dataset A, the precision, recall, and F1 of the research method are 93.75%, 94.33%, and 89.06%, respectively. The precision, recall, and F1 of the GM are 79.52%, 79.52% and 80.75%. The precision, recall, and F1 of the BPNN are 82.03%, 83.79% and 85.94%. In dataset B, the research method precision, Recall and F1 are 83.47%, 80.56%, and 83.77%, respectively. From this perspective, the study has better performance and can accurately analyze the specific deformation size of the foundation pit.

To further validate the application effect of the research model in different engineering projects, an experimental verification was conducted on a foundation pit project under sandy soil conditions in a certain location. Select sample data from a monitoring point in both horizontal and vertical directions for analysis. Collect monitoring data from point H3 in the horizontal direction and L5 in the vertical direction of the foundation pit for analysis. Using the monitoring data from 2018 as an example for analysis. A total of 246 sets of data were obtained, and 5 sets of sample data were randomly selected for displacement change prediction analysis. From Table VII, it can be seen that in this engineering project, the prediction errors of both horizontal and vertical displacements are within a reasonable error range, with the maximum error occurring in sample 4 of the horizontal displacement monitoring point, which is 0.9mm. In most cases, the predicted value is smaller than the actual value. Overall, this method has good accuracy and applicability, and can adapt to different geotechnical conditions.

TABLE VI. COMPARISON OF PRECISION, RECALL AND F1 OF RESEARCH METHOD

Datasets	AI Earth-China's Surface Deformation			Safety Management Data for Deep Excavation Construction		
Methods	Precision	Recall	F1	Precision	Recall	F1
PSO-GM-BP	76.45%	84.27%	83.04%	78.25%	81.06%	79.45%
PDRL	83.02%	82.12%	85.34%	80.05%	79.86%	81.33%
Research method	93.76%	94.33%	89.06%	83.47%	80.56%	83.77%
GM	79.52%	82.31%	80.75%	77.25%	75.96%	76.31%
BPNN	82.03%	83.79%	85.94%	79.56%	80.26%	76.59%

TABLE VII. PREDICTION AND ANALYSIS OF DISPLACEMENT CHANGES UNDER SANDY SOIL CONDITIONS

H3				L5			
Sample Number	Actual displacement (mm)	Predicted displacement (mm)	Error (mm)	Sample Number	Actual displacement (mm)	Predicted displacement (mm)	Error (mm)
1	24.1	23.6	0.5	6	5.2	5.6	0.4
2	25.6	25.4	0.2	7	5.9	5.4	0.5
3	27.9	27.5	0.2	8	6.3	6.0	0.3

To further validate the generalization performance of the model, the deformation data of the foundation pit engineering project during the construction process of a certain subway line 8 is used to verify the model. The depth of the foundation pit is 18.7-24.3m. Construction began in June 2018, and the project covered an area of 5681 m2. At the same time, four different monitoring points (named 1, 2, 3, and 4) are set up to collect real-time deformation data of the foundation pit and dynamically update the collected deformation data set. The deformation data monitored every four months are selected for analysis, as shown in Table VIII. Table VIII shows that the deformation data of the foundation pit predicted and analyzed by the research method are basically consistent with the measured data, and the existing errors are also within a reasonable range. Based on this data analysis, it can further prove the feasibility of the research model in different data environments, that is, the model has a certain degree of generalization performance.

TABLE VIII. PREDICTION AND ANALYSIS OF FOUNDATION PIT DEFORMATION (MM)

Time	1	2	3	4
2018.10	2.4	1.7	5.4	10.1
2019.02	2.5	3.6	9.2	13.8
2019.06	2.9	5.2	11.3	15.4
2019.10	3.1	6.8	12.7	19.6

In the application of deformation models for foundation pits, the first step is to collect relevant monitoring data during the construction process, such as surface settlement, horizontal displacement, excavation depth, etc. These data are the

foundation for building and validating predictive models. Then preprocess the data to ensure its accuracy and consistency. Then train the model and continuously adjust its parameters to improve its prediction accuracy. Finally, the trained prediction model will be integrated into the construction project for real-time monitoring and early warning of foundation pit deformation. The integration of deformation prediction models for foundation pits into practical engineering projects is of great significance. This can not only improve construction safety and optimize construction decisions, but also promote intelligent construction and drive industry technological progress.

V. CONCLUSION

Excavation monitoring is a very important component of civil engineering safety, as well as an important guarantee and technical support for the smooth progress of subsequent projects. The traditional pit deformation monitoring method has many shortcomings in the early warning management process. Accordingly, the study constructed a deep pit deformation early warning model based on Gaussian regression model, and then used genetic algorithm to optimize the model. The experimental results showed that the accuracy of the proposed method was 92.37%, the recall rate was 47.52%, and the F1 value was 0.17, significantly higher than its comparison method. Freidman showed that the research method has better stability. In comparison with the benchmark method, the research method has yielded considerable optimization outcomes, thereby substantiating the assertion that the proposed enhancement strategy is efficacious. The research method measured significant differences in the longitudinal cumulative deformation of four sections. The average deformation of the four sections was 1.32mm, 1.21mm, -3.47mm, and -6.51mm, respectively. In the real-time updated dataset collected from a certain engineering project, the data measured by the research method was basically consistent with the actual measured data, and the errors that exist were also within a reasonable range. The results demonstrate that the proposed method is more effective in the early warning management of deep foundation pit deformation. It produces a more accurate fit between the actual deformation and the early warning results, with an acceptable level of error.

The comparison results of different datasets are different, which is the result of multiple factors working together. Firstly, the data sources of different datasets are different, that is, there are differences in data collection methods and standards, which affects the data results. Then, different data processing methods may lead to errors and biases, resulting in differences in comparison results. In addition, there are differences in sample sizes among different datasets, which directly affects the comparison results. Finally, in the process of data analysis, the comparison results may also be influenced by subjective factors such as human judgment, which can affect the comparison results. During the comparison process, it is advisable to choose datasets with similar sources, consistent collection methods, and high-quality annotations for comparison. At the same time, preprocessing and standardization of the data should be carried out before comparison to reduce the impact of data differences on the comparison results.

However, there are also corresponding difficulties in practical analysis under deterministic conditions, such as deviations between theoretical models and actual conditions, limitations in calculation methods, etc. Meanwhile, the scalability of the model in different types of projects has not been validated. Therefore, future research based on the perspective of artificial intelligence can optimize the model and further improve its application performance in construction engineering. It can also timely and effectively monitor changes in engineering data caused by changes in the surrounding environment, providing effective support for construction safety and quality. Based on future engineering construction, the monitoring performance of this model in foundation pit deformation has been optimized, thereby expanding its application in different construction projects. This can effectively meet the design requirements of various other engineering construction projects, such as subway, large shopping malls, residential community construction, etc.

A Deep Learning-Based Generative Adversarial Network for Digital Art Style Migration

Wenting Ou
School of Art and Design, Fuzhou University of International Studies and Trade, Fuzhou 350202, China

***Abstract*—This study introduces the ConvNeXt-CycleGAN, a novel deep learning-based Generative Adversarial Network (GAN) designed for digital art style migration. The model addresses the time-consuming and expertise-driven nature of traditional artistic creation, aiming to automate and accelerate the style transfer process using artificial intelligence. The ConvNeXt-CycleGAN integrates ConvNeXt blocks within the CycleGAN framework, enhancing convolution capabilities and leveraging self-attention mechanisms for precise and nuanced artistic style capture. The model undergoes rigorous evaluation using multiple performance metrics, including Inception Score (IS), Peak Signal-to-Noise Ratio (PSNR), and Fréchet Inception Distance (FID), ensuring its effectiveness in generating high-quality, diverse images while retaining fidelity during style transfer. The ConvNeXt-CycleGAN surpasses traditional GAN models across key metrics: it achieves an IS of 12.7004 (higher image diversity), a PSNR of 14.0211 (better preservation of original artwork integrity), and an FID of 234.1679 (closer resemblance to real artistic distributions). Additionally, its ability to efficiently train on unpaired images via unsupervised learning enhances its real-world applicability. This research presents an architectural innovation by combining ConvNeXt blocks with the CycleGAN framework, offering robust performance across diverse datasets and artistic styles. The ConvNeXt-CycleGAN represents a significant advancement in the integration of AI with creative processes, providing a powerful tool for rapid prototyping in digital art creation and innovation.**

I. Introduction

Painting is a visual art form that combines lines, colors, and abstract elements to depict real or imagined subjects [1]. It is a two-dimensional aesthetic art with a high degree of beauty, and many excellent paintings have emerged throughout history. However, traditional painting requires professional painters to invest substantial time and effort to refine their work. With the continuous development of deep learning in the fields of image processing and virtual reality, scholars have begun to employ mathematical models to integrate the artistic elements of one painting into another [2]. This progress has given rise to the style migration technique, which leverages artificial intelligence to fuse art and technology. Style migration not only drives technological reform [3] and provides robust technical support for artistic creation but also inspires the generation of art images, alleviating the laborious nature of traditional art creation.

Despite the significant advancements in style transfer techniques, key limitations remain. Traditional methods such as non-photorealistic rendering and texture transfer suffer from poor generalization and require extensive manual adjustments. Neural style transfer techniques, including VGG-based approaches and transformer-based models, have improved style fidelity but often fail to maintain fine-grained details and content consistency. GAN-based methods like CycleGAN and StarGAN have shown promise but lack robustness in handling unpaired data and diverse artistic transformations. To bridge this gap, we propose ConvNeXt-CycleGAN, which integrates ConvNeXt residual blocks into the CycleGAN framework. This novel approach enhances convolutional capabilities and self-attention mechanisms, ensuring more precise style migration, improved image quality, and efficient training on unpaired datasets. Our contributions include an architectural innovation that boosts style transfer fidelity and experimental performance improvements demonstrated through metrics such as Inception Score, PSNR, and FID. The rest of the paper is structured as follows: Section II reviews related work in style migration and neural style transfer techniques; Section III details the ConvNeXt-CycleGAN methodology, including its network architecture and training process; Section IV describes the implementation of a digital art style migration system based on the proposed and finally, Section VI concludes the paper with key findings and future work directions.

II. Related Work

Traditional style transfer techniques include non-photorealistic rendering [4, 5] and texture transfer [6,7]. While these methods can generate simple artistic re-creations, they suffer from significant limitations, such as poor generalization, an inability to extract high-level semantic features, and extended training times. The field of deep learning has accelerated advancements in computer vision, particularly after Gatys et al. [8–10] introduced neural networks into style transfer. Their VGG-based style transfer model attracted considerable attention from both academia and the art community. Subsequent improvements have been proposed, such as incorporating a Markov structure to model high-level features [11], statistical histogram loss to simulate the distribution of key image features [12], and Laplace loss, which addresses asymmetry issues in generated images while preserving low-level input details [13]. However, these approaches primarily focus on global style transfer, often leading to local style inconsistencies in the generated images. To overcome this, region-specific style transfer methods [14] emerged, aiming to establish semantic mappings between style and content image regions. Furthermore, automated image semantic segmentation techniques have been introduced to streamline the process of aligning semantic features between content and style images.

*Corresponding Author

Recent advancements have expanded the scope of style transfer beyond the reliance on a reference style image. For instance, Kwon et al. [15] proposed a framework that utilizes text descriptions to guide texture transfer in content images, leveraging the CLIP model and a novel patch-wise text-image matching loss with multiview augmentations. Meanwhile, StyTr2 [16] utilizes transformer-based architecture, improving the model's ability to capture global information and enhance style transfer effectiveness. The ArtFlow method introduces reversible neural flows and an unbiased feature transfer module to mitigate content leakage in universal style transfer, ensuring integrity across multiple stylization iterations [17]. CAST (Contrastive Arbitrary Style Transfer) employs contrastive learning to improve style representation learning from image features, yielding more consistent and high-quality style transfer results [18]. Additionally, the AdaAttN module introduces adaptive attentive normalization, allowing per-point style adaptation and enhancing visual quality, especially in video-based applications [19]. The InST method innovatively uses inversion-based style transfer, enabling efficient style adaptation from a single image without requiring complex textual descriptions [20].

Despite substantial improvements in style transfer algorithms, particularly those leveraging pre-trained network models—challenges such as style overflow and insufficient stylization control persist. The emergence of Generative Adversarial Networks (GANs), introduced by Goodfellow et al. in 2014 [21], revolutionized style transfer by employing an adversarial process between a generator and a discriminator to refine image stylization. GAN-based style transfer methods significantly improve image quality and generation fidelity. To accommodate diverse artistic needs, researchers have designed specialized GAN architectures, including supervised Conditional Generative Adversarial Networks (CGANs) [22] and unsupervised StarGAN models [23], which enhance versatility in style transfer applications.

III. Image Style Migration Method Based on ConvNeXt-CycleGAN

Sanghyun et al. [24] referred to the idea of Swin Transformer and proposed ConvNeXt network, in which the ConvNeXt residual block uses deep convolution, similar to the weighted sum operation in self-attention, which is used to improve the performance of the network. In this paper, we propose the ConvNeXt-CycleGAN model, which incorporates ConvNeXt residual blocks into the generator to enhance artistic style migration.

A. Network Infrastructure

The network structure of ConvNeXt-CycleGAN model is improved based on the CycleGAN network, as shown in Fig. 1. The ConvNeXt-CycleGAN model consists of two generators G and F, two discriminators D_X and D_Y. Firstly, the ConvNeXt-CycleGAN model network training is unsupervised learning, i.e., the dataset training is unpaired, which enables bidirectional generation of images between domains X and Y. The ConvNeXt-CycleGAN model network is trained by the network generator. Selecting an arbitrary image x from the source domain X and inputting it into the generator G, the generated image $G(x)$ needs to be re-inputted into the generator F again. Secondly to preserve the contour features of the input image, the cyclic consistency loss [26] function is still used to constrain the reconstructed image. Again, the normalization method in the encoder and decoder is set to Layer Normalization (LN). The ResNet residual network in the converter is replaced with the ConvNeXt-block residual module in the expectation of high-quality generated results with the target style. The final discriminator is consistent with the AMS-CycleGAN model in Section IV, i.e., the attention mechanism module is introduced to prompt the generator to focus on certain key pixel locations of the image, ignoring or even directly filtering out irrelevant parts to obtain the style feature information needed for the synthesized image. In the ConvNeXt-CycleGAN model the loss function is the same as the CycleGAN model, including the generation of the adversarial loss, the cyclic consistency loss, and the constant mapping loss, which effectively regulates the content structure information, brightness, and color contrast of the generated image.

B. Generator Network Structure

The generator network structure of the ConvNeXt-CycleGAN model is shown in Fig. 2, and the internal structure information is shown in Table I. It consists of three parts: encoder, converter and decoder. The first part of the encoder: the image of 3*256*256 is transmitted to the first convolutional layer, and after the calculation of Conv-LN convolutional kernel of 7*7, the feature map of 64*256*256 is output; and then after two layers of downsampling, i.e., Conv-LN convolutional kernel of 3*3, the output of the network is the feature map of 64*64*256. The second part of the converter: after four layers of ConvNeXt Block residual network with the same architecture, the input and output are 64*64*256 feature maps, as shown in Fig. 3. Third part decoder: due to the symmetry of the encoder and decoder architectures, i.e., the decoder is set up with two layers of upsampling, i.e., De Conv-LN convolution kernel as 3*3 network layer to recover the original image size, and finally outputs 3*256*256 image by Conv-Tanh convolution kernel as 7*7 network layer. In this case, the ConvNeXt-CycleGAN model architecture contains the LN normalization method, but the ConvNeXt network by default performs the normalization process in the last dimension, i.e., (B, H, W, C), whereas the dimensions used in this experimental part are (B, C, H, W), i.e., extracting the mean (μ) and the standard deviation (σ) of the input image in the dimensions of C, H, and W. The ConvNeXt-CycleGAN model is based on the following model: (B, C, H, and W).

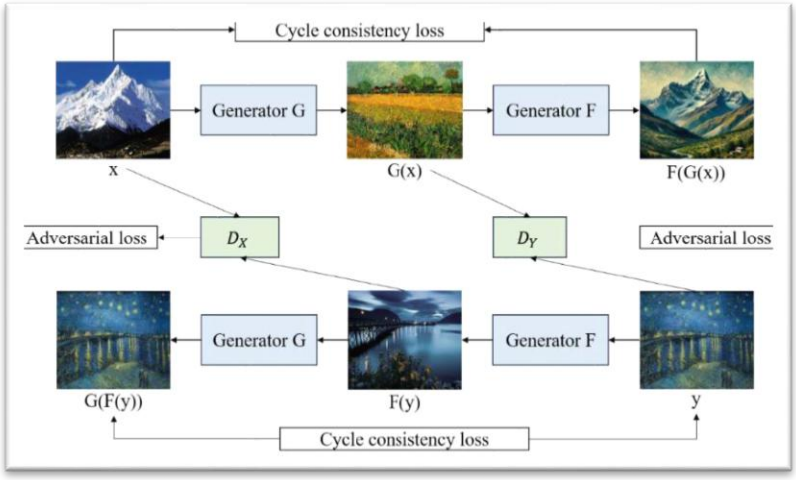

Fig. 1. ConvNeXt-CycleGAN overall network structure diagram.

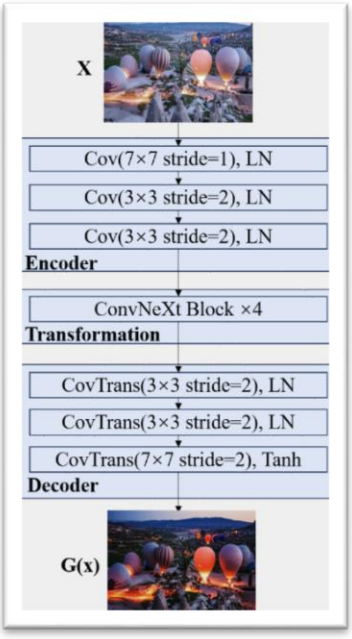

Fig. 2. ConvNeXt-CycleGAN generator network structure diagram.

TABLE I CONVNEXT-CYCLEGAN GENERATOR INTERNAL STRUCTURE INFORMATION

Components	Structural Information
Encoder (Down-sampling)	ReflectionPad2d (3) Conv2d (3,64, k=7, s=1), LN Conv2d (64, 128, k=3, s=2, p= 1), LN Conv2d (128, 256, k=3, s=2,p=1), LN
Transformation (ConvNeXt block*4)	Depthwise Conv2d (256, 256, k=7, p=3, s=1), LN Conv2d (256, 1024, k=1, s=1), GELU Conv2d (1024, 256, k=7, s=1)
Decoder (Up-sampling)	ConvTranspose2d (256, 128, k=3, s=2, p=1), LN ConvTranspose2d (128, 64, k =3, s=2, p= 1), LN ReflectionPad2d (3) Conv2d (64, 3, k = 7, s = 1) Tanh ()

The design of the ConvNeXt Block residual module mainly includes: first, the GELU activation function has the property of non-saturation, so it avoids the problem of gradient saturation in most of the time, which makes the neural network more easy to converge during the training process; second, the use of larger convolution kernel, adopting 7*7 convolution kernel in the first layer, and shifting the depth convolution module upward from 1*1 conv- >depth-wise conv->1*1 conv structure to depth-wise-conv->1*1 conv->1*1 conv structure, and change the size of the convolution kernel for depth convolution from 3*3 to 7*7; third, Layer Scale scales each channel number, and the scale is a learnable parameter (γ). The parameter γ is in the form of a vector with the same dimension as the dimension of the input channels, and for feature transformation, the parameter γ is multiplied by the feature map, i.e., x (output feature map) = $\gamma * x$ (input feature map); fourth, Drop Path is a regularization method, which mainly removes multi-branching structures randomly from the deep learning model. Fifth, less normalization is used. Borrowing the idea of Transformer, the use of normalization is reduced, so the normalization layer in the ConvNeXt Block residual network is relatively reduced, and only the normalization layer after depth-wise-convolution is retained. Sixth, the batch normalization (BN) layer is a commonly used normalization operation in convolutional neural networks, which can accelerate the convergence of the network and reduce overfitting, but a small number of samples selected in a training session can lead to poor generation, and there is also the problem that the computation of the mean and the variance in the testing phase differs from that of the training set. Liu et al. [25] borrowed the layer normalization used in Transformer. In [25], the layer normalization used in Transformer is used to calculate the mean and standard deviation of all the feature channels in turn, which is not related to the size of the batch, so the normalization layer in ConvNeXt Block is converted to layer normalization.

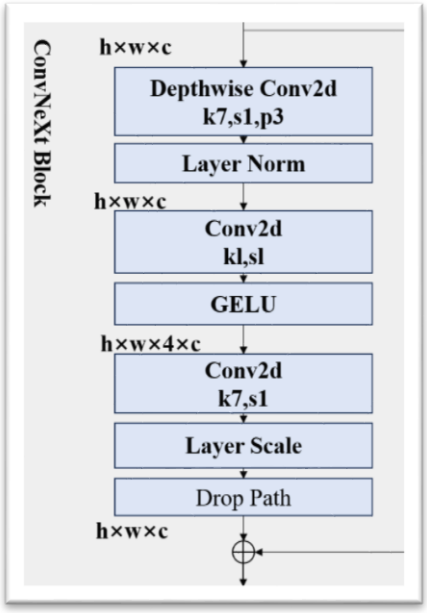

Fig. 3. Informative diagram of ConvNeXt block network structure.

C. Aggregate Loss Function

The ConvNeXt-CycleGAN model proposed in this paper is based on the CycleGAN network structure, and the total loss function loss of the entire network training includes the generative adversarial loss to compare the generated image with the data image, and constantly iterate on the generated model data; the cyclic consistency loss retains the contour features of the input image in the generated image as much as possible, and also improves the generative adversarial network training stability; the constant mapping loss reduces the possibility of the generator automatically modifying the color tone of the generated image.

$$\mathrm{L_{Generator}} = \lambda_1 \mathrm{L_{lsgan_Generator}} + \lambda_2 \mathrm{L_{identity}(G,F)} + \lambda_3 \mathrm{L_{cycle}(G,F,X,Y)}, (1)$$

$$\mathrm{L_{discriminators}} = \min_{\mathrm{D_Y}} \mathrm{L_{lsgan}(G,D_y,X,Y)} + \min_{\mathrm{D_X}} \mathrm{L_{lsgan}(F,D_x,Y,X)}, (2)$$

$$L(G,F,D) = arg \min_{G,F,D_Y,D_X} (L_{Generator}, L_{\mathrm{discriminators}}) (3)$$

where the parameters $\lambda_1, \lambda_2, \lambda_3$ are used to control the linear combination of the generator and discriminator loss functions. The values of $\lambda_1, \lambda_2, \lambda_3$ weights are set to 1.0, 0.5, and 10.0 respectively in the experiment.

The training flow of the ConvNeXt-CycleGAN model for the data bi-directional generation experiment is shown in Table II. An image x is randomly extracted from the natural image domain (X) and inputted into the generator G. Similar to the previously proposed CycleDPN-GAN model and AMS-CycleGAN model, firstly, layer normalization is used in the convolutional layer to compute all the feature channel components. Second, in the residual module, the ConvNeXt Block is used, firstly, the feature map 64*64*256 is used as the input, and the number of groups is equal to the number of input channels, i.e., the number of channels is 256, and each channel corresponds to a convolutional kernel, and the spatial information is mixed-weighted within a single channel. Secondly, the number of channels will be expanded to 4 times of the original, imitating the idea of Swin Transformer network, at this time, the size of the feature map is 1024, and finally, after the network layer, the channels of the feature map will be restored to 256, and at this time, the size of the feature map will be 64*64*256, and then re-input the image $G(x)$ generated by the generator to the generator F, and the discriminator will judge the authenticity of the image.

TABLE II OVERALL FLOW CHART OF THE CONVNEXT-CYCLEGAN MODEL

Conv NeXt-Cycle GAN-based training process for art style image migration
Input: natural image domain (X), artistic image domain (Y), number of iterations T, initial learning rate a_0, weights $\lambda_1, \lambda_2, \lambda_3$ Parameters θ_G, θ_F of initialized generator mapping function G, F Parameters W_Y, W_X of initialized discriminator D_Y, D_X Output: generated images x and y
for t=1,2,…, $T_{max} = 200$: 1: Randomly draw an image x from the natural image domain (X) and enter it into the generator G to output $G(x)$. On the other hand, an image y is randomly selected from the artistic image domain (Y) and entered into the generator F to output $F(y)$. 2: The generated image $G(x)$ and the art image y are sent to the discriminator D_Y, and the performance of the network is improved by the Attention Mechanism module, i.e., by the interdependence between the feature channels, i.e., the importance weights of the different channels are obtained and then applied to the corresponding channels of the previous intermediate feature map F. The following is an example of how to minimizemin(D_Y). Minimize $\min_{D_Y} L_{\mathrm{lsgan}}(G, D_y, X, Y)$, optimize the discriminator D_Y according to the associated error, optimize according to Adam's algorithm, and update W_Y. And the generated image $F(x)$ and the natural image x are fed to the discriminator D_X, minimize $\min_{D_{Dv}} L_{\mathrm{lsgan}}(F, D_x, Y, X)$, discriminator D_X and update W_X. X and update W_X. 3: Send $G(x)$ to generator F and output reconstructed image $F(G(x))$. And send $F(y)$ to generator G, output the reconstructed image $G(F(x))$, compute $L_cycle(G,F,X,Y)$; then using the second step, the resulting $\min_{D_Y} L_{\mathrm{lsgan}}(G, D_y, X, Y)$ and $\min_{D_X} L_{\mathrm{lsgan}}(F, D_x, Y, X)$, compute the generative antagonistic loss, i.e., $L_{\mathrm{lsgan\_Generator}}$. Optimize the generators G and F according to Adam's algorithm, update θ_G, θ_F. Were, if $t > t_1$,the learning rate linearly decays $\alpha = \alpha_0(T-t)/(T-t_1))$ end

IV. Design of a Digital Art Style Migration System Based on Generative Adversarial Networks

The proposed system architecture integrates advanced Generative Adversarial Network (GAN) technologies to automate the style transfer from target artistic images to source images, preserving the structural integrity of the source content while creatively transforming its aesthetic style. This system is built on a modular architecture that enhances scalability, maintainability, and performance. The system architecture is shown in Fig. 4.

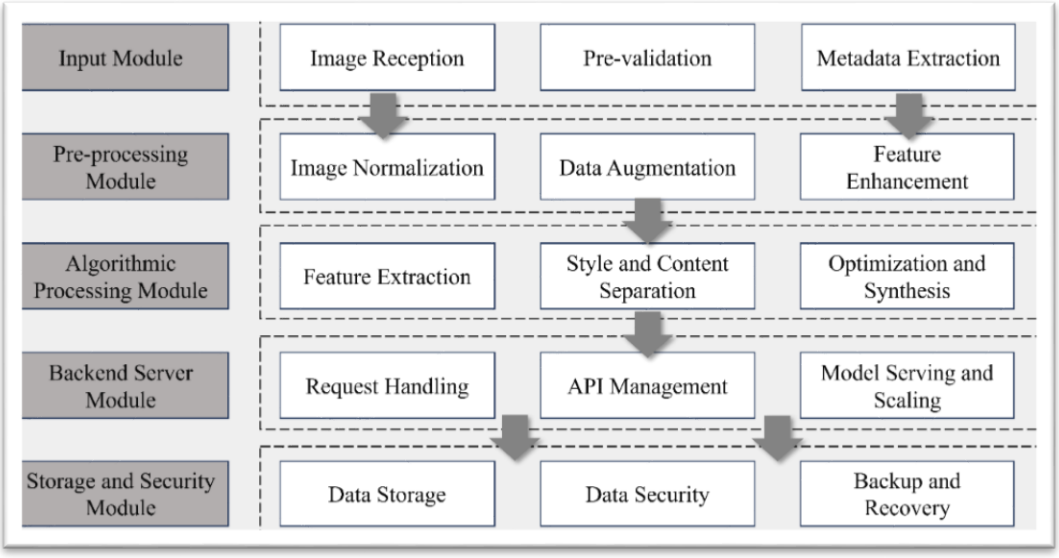

Fig. 4. System architecture of digital art style migration system.

A. System Modules

Input Module: This module is the entry point for the system, accepting diverse image formats including JPEG and PNG. It validates and processes images to ensure compatibility with the style migration model. This module also handles initial image adjustments such as resolution normalization and color space conversion to prepare images for subsequent processing steps.

Pre-processing Module: Critical for standardizing input data, this module applies a series of transformations to the input images. These include resizing the images to a uniform scale, applying normalization to adjust pixel values for neural network processing, and potentially augmenting the data to increase the robustness of the style transfer model. This step ensures that the style migration process operates under optimal conditions by providing consistently formatted input data.

Style Migration Model: At the core of the architecture is the style migration model powered by the ConvNeXt-CycleGAN, which utilizes advanced neural network techniques for deep style learning. This model leverages the unique properties of ConvNeXt blocks within a CycleGAN framework to apply high-quality artistic style transfers. The model operates under an unsupervised learning paradigm, allowing for bidirectional image style translation between distinct domains, facilitated by a dual generator and discriminator setup.

Post-processing Module: After the style transfer, this module refines the output images to enhance visual quality. Adjustments made here include tuning the color balance, enhancing contrast and sharpness, and applying final cropping or padding as necessary. This step ensures that the final styled images are visually appealing and maintain a high degree of fidelity to the artistic intent.

Output Module: This module manages the storage and distribution of the final styled images. It supports functionalities such as saving the images in various formats, preparing them for download, or embedding them into digital galleries. The output module ensures that users can easily access and utilize the generated artworks in their desired manner.

B. Backend Server

1) Architecture and technology stack: The backend server architecture is designed to efficiently handle computational loads and multiple user requests simultaneously, ensuring robustness and scalability. The server employs a microservices architecture, which allows for the modular deployment of the application's components. This modularity facilitates independent updating and scaling of services, enhancing the system's flexibility and maintenance efficiency.

For the technology stack, the system utilizes Python due to its extensive support for scientific computing and machine learning libraries. Python's Flask framework is selected for handling HTTP requests and responses, owing to its lightweight nature and its ability to scale up to accommodate growing user demand. Flask provides the flexibility necessary for rapid development and deployment of web applications, which is crucial for iterative testing and enhancement in response to user feedback.

2) Model deployment: The style migration model, a key component of this architecture, is deployed as a Docker container. This approach ensures that the model runs in an

isolated environment, where dependencies are managed consistently, thus eliminating conflicts between different running applications. Docker also simplifies the deployment process across different development and production environments, ensuring consistency and reducing setup times.

Kubernetes is employed to orchestrate these containers, managing their lifecycle, scaling them up or down based on traffic demands, and maintaining system availability through load balancing strategies. Kubernetes also facilitates the rollout of new updates with minimal downtime, enabling continuous integration and continuous deployment (CI/CD) practices that are essential for maintaining the operational efficacy of the system.

C. Storage and Security

Image storage is managed through integrated solutions that prioritize security and efficiency. Both original and styled images are stored in a manner that supports quick retrieval and guarantees data integrity and confidentiality.

V. Results and Discussion

A. Experimental Setup and Environment

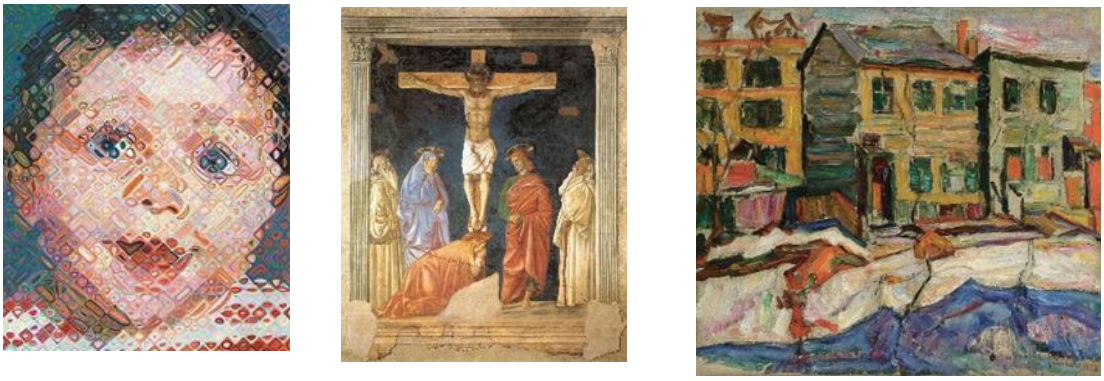
In our experiments with the ConvNeXt-CycleGAN model, we conFig.d the batch size to a single instance per training iteration, covering a total of 200 epochs. Both the input and output resolutions were maintained at 256*256 pixels. Network optimization was conducted using the Adam algorithm, starting with a learning rate of 0.0002. This rate was maintained steady for the initial 200 epochs, followed by a gradual reduction to zero towards the end of the training period. An NVIDIA RTX 3090 GPU powered the computations.

B. Introduction to the Dataset

The experiments in this chapter are important to apply the model on the art style dataset, the real images in the dataset used are animal images, the animal dataset is 3600 randomly selected animal images downloaded from Chapter 3 as the training set of this chapter, and 200 animal images are randomly selected as the test set of this chapter.

The art style dataset is a public dataset downloaded from wikiart, and some images of the art style dataset are shown in Fig. 5. The downloaded dataset is cropped by Python to 256×256 size images, and the art style training set mainly contains 637 Van Gogh works, 511 Ukiyo-e images, 419 Monet works, and 309 Paul Cézanne works. The collection is organized in the following ways.

(a) Abstract Expressionism **(b) Analytical Cubism** **(c) Baroque**



(d)Contemporary Realism **(e) Early Renaissance** **(f) Fauvism**

Fig. 5. Art dataset image.

C. Test Metrics

In this section, the effectiveness and generalization of the existing network model and the improved model in the previous chapter as well as the proposed model in this chapter on the art style migration task are verified by conducting multiple sets of experiments among four art styles, and it can be found that the existing network have learned the style It can be found that the existing network learns the overall style characteristics of the style image, but the effect is not good enough in the content learning and detail migration. The proposed model in this paper is improved compared with the existing network and the improved network in the previous chapter, and it can maintain the content characteristics of the content image as well as realize the migration of the art styles in the details and as a whole in the visual effect, which verifies the validity and versatility of the proposed model in the data domain of multiple styles. In order to further verify the superiority of the proposed model in this chapter compared with the improved model in the previous chapter and other networks, the proposed model in this chapter is further compared with the existing models using the four metrics of IS, SSIM, PSNR and FID.

Inception Score is used to evaluate the quality of generated images by a model, particularly in the context of generative adversarial networks (GANs):

$$\mathrm{IS} = \exp\left(\mathbb{E}_{x\sim p_g}[\mathrm{KL}(p(y|x) \parallel p(y))]\right) \quad (4)$$

Where $p(y|x)$ is the conditional probability distribution of the label y given the generated image x as predicted by an Inception network. $p(y)$ is the marginal probability distribution of the labels. $\mathrm{KL}(\cdot\|\cdot)$ is the Kullback-Leibler divergence.

SSIM is used to measure the similarity between two images:

$$\mathrm{SSIM}(x,y) = \frac{(2\mu_x\mu_y+C_1)(2\sigma_{xy}+C_2)}{(\mu_x^2+\mu_y^2+C_1)(\sigma_x^2+\sigma_y^2+C_2)} \quad (5)$$

Where μ_x and μ_y are the means of images x and y, σ_x^2 and σ_y^2 are the variances of images x and y, σ_{xy} is the covariance between x and y, C_1 and C_2 are constants to stabilize the division.

PSNR is used to measure the quality of a reconstructed image compared to its original version (6):

$$\mathrm{PSNR} = 10 \cdot \log_{10}\left(\frac{\mathrm{MAX}_I^2}{\mathrm{MSE}}\right) \quad (6)$$

Where MAX_I is the maximum possible pixel value of the image (e.g., 255 for an 8-bit image), MSE is the mean squared error between the original image and the reconstructed image (7).

$$MSE = \frac{1}{m\cdot n}\sum_{i=1}^{m}\sum_{j=1}^{n}[I(i,j)-K(i,j)]^2 \quad (7)$$

Where $I(i,j)$ and $K(i,j)$ are the pixel values of the original and reconstructed images, respectively.

FID measures the distance between feature distributions of real and generated images (8):

$$\mathrm{FID} = \| \mu_r - \mu_g \|_2^2 + \mathrm{Tr}(\Sigma_r + \Sigma_g - 2(\Sigma_r\Sigma_g)^{\frac{1}{2}}) \quad (8)$$

Where μ_r and μ_g are the means of the real and generated image feature vectors, respectively, Σ_r and Σ_g are the covariance matrices of the real and generated image feature vectors, respectively. Tr denotes the trace of a matrix.

D. Test Results

The proposed model was rigorously evaluated against established style migration algorithms. We utilized three metrics for this comparative analysis: Inception Score (IS), Peak Signal-to-Noise Ratio (PSNR), and Fréchet Inception Distance (FID). The results, detailed below, illustrate the efficacy of our model in relation to its counterparts.

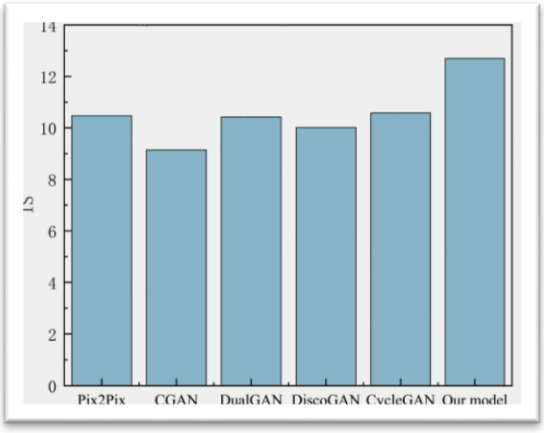


Fig. 6. IS metric of all the models.

From Fig. 6, our model achieved the highest IS value at 12.7004, indicating its superior capability in generating images that are both meaningful and diversified compared to the other models tested. This score is significantly higher than that of the CycleGAN, which scored next highest at 10.5812, and substantially outperforms the CGAN model, which had the lowest score at 9.1411.

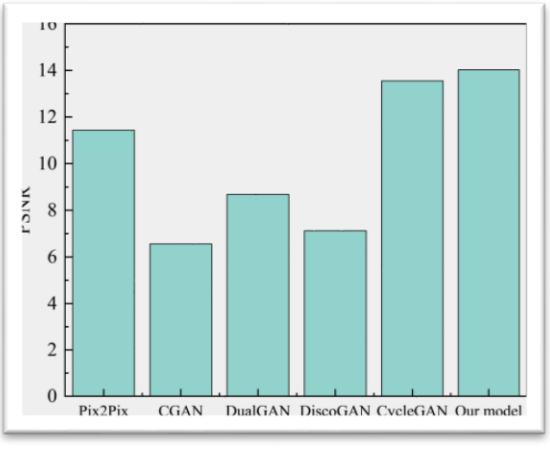

Fig. 7. PSNR result of all the models.

In Fig. 7, as measured by PSNR, our model again outperformed all others with a score of 14.0211. This indicates that our model can produce images with higher fidelity to the original content. CycleGAN followed with a PSNR of 13.5478,

while the CGAN model lagged behind at 6.5543, highlighting significant differences in output image quality among the models.

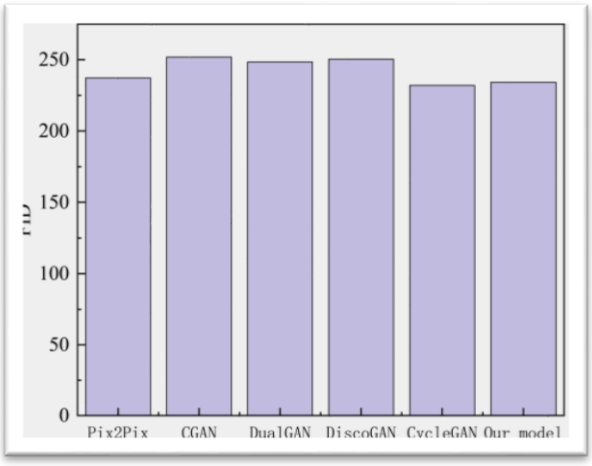

Fig. 8. FID result of all the models.

Fig. 8 illustrates the FID comparison among different models. Our model achieved an FID score of 234.1679, which is close to the best-performing CycleGAN (231.9711). A lower FID score indicates that the generated images closely resemble real images in terms of feature distribution. While our model slightly lags behind CycleGAN in FID, it offers a better trade-off between style diversity (IS) and content preservation (PSNR).

E. Test Discussion

While numerical metrics provide an objective evaluation of style migration performance, a qualitative analysis reveals the perceptual advantages of the ConvNeXt-CycleGAN model. Compared to baseline models, it consistently produced more visually appealing and natural artistic images. A key strength of our approach is its ability to retain fine-grained details while minimizing artifacts and distortions commonly found in CGAN-based methods. This ensures that the stylized images maintain structural coherence without sacrificing artistic expression.

Furthermore, ConvNeXt-CycleGAN demonstrated improved texture consistency and color adaptation over CycleGAN, resulting in more harmonious and refined stylization. The model effectively balances content preservation with artistic transformation, producing high-quality outputs that closely resemble real artworks. These qualitative observations align with the quantitative results, reinforcing the effectiveness of our approach in generating diverse, high-fidelity images suitable for digital art applications.

F. Algorithm Efficiency Analysis

Less efficient algorithms make it difficult to generate a large number of creative designs for images. Hence, assessing the performance of the style migration algorithm is crucial. This study utilizes the control variable technique to measure the efficiency of the algorithm, examining whether training is required and if the algorithm can handle various style transformations effectively and the conversion speed, as shown in Table III.

TABLE III ALGORITHM EFFICIENCY ANALYSIS

Name		CGAN	DiscoGAN	CycleGAN	Ours
Whether training is required		Yes	Yes	104min	131min
Arbitrary style or not		trainable	trainable	trainable	trainable
Need style image		One	One	One	One
Ink style effect		not good	good	good	good
Conversion speed	256*256	3.515s	>1h	0.762s	1.044s
	512*512	16.952s	>1h	2.003s	3.180s
	1024*1024	>1min	>1h	6.855s	11.232s

This investigation delves into the practicality and effectiveness of using generative adversarial networks, particularly CGANs, for the task of transferring styles across a vast array of images. Detailed evaluations indicate that while CGANs are adept at handling complex and vibrant patterns, their performance is noticeably less efficient when applied to simpler, monochromatic styles. The exhaustive training regimen for CGANs necessitates a comprehensive collection of style images, which serves as a critical foundation for achieving satisfactory results. Moreover, DiscoGAN's methodology, which circumvents traditional training protocols, entails a lengthy process of iterative image adjustments. This method, despite its ability to process images with diverse color schemes without prior training, significantly extends the duration required to stylize images—often taking upwards of an hour to refine a single standard 256x256 pixel image under typical CPU processing conditions.

Contrastingly, the innovative style migration technique developed in this study, markedly reduces the time required for style conversion when compared to methods reliant on instance normalization (IN). This efficiency gain is not only reflected in faster processing times but is also quantitatively supported by enhanced PSNR and SSIM values, indicating superior image quality post-stylization.

In summary, the style migration framework proposed herein offers significant advantages for digital image design. It not only expedites the creative process but also supports a broad spectrum of styling tasks. This capability substantially augments the versatility and richness of the digital image database, empowering artists and designers to explore new creative horizons with greater efficiency and effectiveness.

VI. CONCLUSION

The research presented in this paper marks a significant advance in the field of digital art creation through the development and deployment of the ConvNeXt-CycleGAN model. This model not only champions the cause of integrating deep learning into artistic processes but also sets a new benchmark in style migration effectiveness and efficiency, leveraging the cutting-edge capabilities of Generative Adversarial Networks (GANs).

The ConvNeXt-CycleGAN model has demonstrated superior performance over existing GAN models such as Pix2Pix, CGAN, and others, as evidenced by its exceptional scores on several key metrics. Achieving an Inception Score (IS)

of 12.7004, it has proven its superior capability in generating images that are not only diverse but also retain a high degree of semantic meaning relative to the style domains being targeted. This indicates a substantial improvement in the model's ability to handle complex style migrations without losing the essence of the original artworks. Moreover, with a Peak Signal-to-Noise Ratio (PSNR) of 14.0211, the model confirms its efficacy in producing high-fidelity images, which is critical for applications where detail preservation is paramount.

Furthermore, the competitive Fréchet Inception Distance (FID) score of 234.1679 underscores the model's capacity to generate stylized outputs that closely mimic the distribution of real-world artistic images. The architectural innovations—such as the integration of ConvNeXt blocks within the CycleGAN framework—play a pivotal role in capturing intricate artistic details and facilitating effective style translation. By employing an unsupervised learning approach with unpaired images, our method significantly reduces the reliance on extensive paired datasets.

FUTURE WORK

By explicitly addressing the gap between existing and proposed work, we have identified key areas requiring further research. Current style migration models struggle with real-time performance, precise detail retention, and consistency across diverse datasets. To overcome these challenges, we propose the following strategies for future improvement: (1) optimizing the ConvNeXt-CycleGAN model with lightweight network architectures and quantization techniques to enhance computational efficiency; (2) incorporating advanced perceptual loss functions and attention mechanisms to refine fine-grained detail preservation; (3) expanding the dataset diversity and utilizing semi-supervised learning techniques to improve training consistency and reduce artifacts. These strategies will contribute to a more robust and scalable digital art style migration framework, making AI-powered artistic creation more accessible and efficient.

In future work, we plan to refine the ConvNeXt-CycleGAN model by developing adaptive style control mechanisms that mitigate style overflow, thereby ensuring a more balanced integration of artistic style with the original content. We also aim to optimize the model for higher-resolution images and more complex compositions, which will enable it to handle intricate details and diverse artistic elements more effectively. Furthermore, integrating interactive, user-guided features will allow artists to have greater control over the stylization process, making the model more versatile and user-friendly. Additionally, we intend to conduct comprehensive perceptual evaluations through user studies to better align the generated outputs with artistic standards and industry expectations. These enhancements will not only improve the overall quality and flexibility of the style migration process but also further bridge the gap between advanced AI techniques and practical digital art applications.

On the Impact of Various Combinations of Preprocessing Steps on Customer Churn Prediction

Mohamed Ezzeldin Saleh, Nadia Abd-Alsabour
Cairo University, Egypt

***Abstract*—This paper investigates various combinations of preprocessing methods (attribute selection, normalization, resampling, and imputation) and evaluates their impact on the performance of decision tree models for predicting customer churn. The experiments were performed on the benchmark Cell2Cell dataset due to its ability to address diverse aspects of customer behavior, including value-added services, usage patterns, demographic information, customer service interactions, personal data, and billing data. This comprehensive view of client activities makes it ideal for studying customer churn. The aim of this work is to identify the most effective preprocessing method that can be applied to a real-world telecommunications dataset to improve the effectiveness of customer churn prediction methods. The study systematically examines the effects of imputation methods (K-Nearest Neighbors and statistical imputation), normalization techniques (Median and Median Absolute Deviation Normalization, Min-Max Scaling, and Z-Score Standardization), feature selection using Lasso regression, and resampling using SMOTE Tomek. This results in 16 distinct preprocessed datasets, each reflecting a unique combination of preprocessing steps. An analysis of these datasets was conducted, evaluating the performance metrics of the Decision Tree model on each dataset, including accuracy, precision, recall, F1 score, and ROC-AUC. Key findings highlight that Statistical Imputation, Median and Median Absolute Deviation Normalization, and Lasso feature selection achieved the highest performance, with 0.78 in precision, 0.77 in accuracy, recall, and F1 Score, and 0.74 in ROC-AUC.**

Keywords*—Attribute selection; churn prediction; decision trees; imputation methods; machine learning; normalization techniques

I. Introduction

Machine learning (ML) is a portion of artificial intelligence that has changed various businesses, considering telecommunications. This alteration is driven by the ML's capacity to learn from data and make predictions unaccompanied by explicit programming [1-3]. ML algorithms and statistical models can analyze vast amounts of data, identify patterns, and make informed decisions, making them invaluable tools in today's data-driven world. In the telecom zone, client churn prediction is one of the crucial tasks of ML. It refers to the phenomenon where customers terminate their service subscriptions and often choose a competitor. Given the intense competition in the telecom industry, companies are under constant pressure to improve the client experience and loyalty [4]. Conserving existing clients isn't only more cost-effective than acquiring new ones, yet it's also requisite to maintaining a firm yield stream. Therefore, accurate prediction of customer churn can help telecommunications companies proactively implement effective retention strategies, thereby reducing customer churn rates and increasing customer loyalty [5-7].

The telecom industry generates large volumes of data on a daily basis, including call detail records, customer demographics, usage patterns, and service interaction logs. This rich data source provides an excellent opportunity to leverage ML for predictive analytics. Nevertheless, the imbalance of telecom datasets & their large dimensionality constitute serious challenges to conventional ML strategies. Large-dimensional data can ensue overfitting, so the model gets complicated & executes fine on the training data yet gravely on the novel data. Besides, imbalanced datasets, where the no. of churned clients is essentially lower than that of retained clients, could lead to biased models that fail to precisely distinguish at-risk clients. Traditional ML models, such as Decision Trees (DTs), are popular for their simplicity and interpretability. Still, they regularly battle with the complexities of telecommunications data [8]. DTs models can be prone to overfitting and may not perform well with imbalanced datasets. To address these challenges, advanced preprocessing techniques, such as imputation methods, normalization, feature selection, and resampling techniques, are crucial [9-12]. These techniques help clean and transform the data, making it more suitable for ML modeling and improving the overall performance of the DT models.

The major purpose of this research is to boost the performance of the DT model in discovering client churn by employing diverse preprocessing strategies. The specific objectives are as follows:

1) Imputation methods: To assess the impact of different imputation methods, including K-Nearest Neighbors (KNN) and statistical imputation (mean/median), on the performance of the DT model.

2) Normalization methods: To evaluate the effectiveness of normalization methods, such as Median and Median Absolute Deviation Normalization (MMADN), Min-Max Scaling, and Z-Score Standardization, in standardizing data for better model performance.

3) Feature selection: To determine the relevance and importance of features using the Least Absolute Shrinkage and Selection Operator (Lasso) regression, thereby reducing dimensionality and improving model accuracy.

4) Resampling techniques: To handle the class imbalance using the Synthetic Minority Over-sampling Technique

combined with Tomek links (SMOTE Tomek) and assess its impact on the DT model's performance.

5) Assessing how preprocessing techniques influence the Decision Tree's predictive accuracy and robustness.

The scope involves preprocessing the Cell2Cell dataset to create 16 types of datasets, utilizing various combinations of the aforementioned techniques. The performance metrics of the DT model are then evaluated on each of the 16 types of preprocessed datasets to identify the optimal preprocessing technique for churn prediction with improved performance indicators.

A. The Contributions of the Study

The comprehensive investigation and tractable insights inferred from this study aim to essentially add to the field of churn prediction and client retention strategies. This work adds to the area of churn prediction in numerous ways:

- By exploring various combinations of imputation, normalization, feature selection, and resampling techniques, this research provides a detailed analysis of their individual and collective impacts on the DT model's performance.
- By systematically evaluating how different preprocessing steps affect the DT model's performance, the integration of advanced preprocessing methods aims to improve the accuracy, robustness, and interpretability of DT models in churn prediction through refined preprocessing techniques.
- The findings of this study offer practical insights for telecom companies to enhance their churn prediction models, thereby enabling more effective customer retention strategies and improved business sustainability.

The remaining portions of this manuscript are structured as follows: Section II reviews relevant literature on customer churn prediction and preprocessing techniques. Section III details the proposed methodology and preprocessing steps. Section IV describes the experimental setup, including the dataset and tools used. A detailed description of the dataset utilized in this study is provided in Section V. The performance metrics for evaluation are outlined in Section VI. Sections VII and VIII present and discuss the results, highlighting the impact of preprocessing on model performance. Finally, Section IX concludes with key findings, implications, and future research directions.

II. Literature Review

Customer churn prediction has been extensively researched to help businesses retain customers by predicting which customers are likely to leave [6]. Various machine learning approaches have been applied to this problem, each with its own shortcomings and strengths. Wagh et al. employed Random Forest (RF), K-Nearest Neighbors (KNN), and Decision Tree Classifier models to predict customer churn in the telecom industry [13]. They found that the Decision Tree Classifier initially produced subpar results on an unbalanced dataset. However, applying up-sampling and Edited Nearest Neighbor (ENN) techniques significantly improved the model's accuracy to 93.85%. The RF model's accomplishment was better than that of the others, accomplishing an accuracy of 99.09%. The study also explored survival analysis using the Cox Proportional Hazard model for churn prediction. Aldalan & Almaleh centered on boosting the performance of ML models through attribute choice, normalization, and attribute engineering. They applied these techniques to logistic regression, random forests, decision trees, and gradient-boosting algorithms. Their study emphasized the importance of understanding customer churn based on past service usage history and achieved a 99% F1 score and 99% AUC with the Gradient Boosting technique, spotlighting the remarkable effect of attribute engineering & picking [14].

Zhou et al. proposed enhanced Random Forest and Decision Tree algorithms for telecom churn prediction. They developed advanced techniques for feature selection, data preprocessing, and modifications to core algorithms to improve prediction accuracy and reduce overfitting. Their enhanced models significantly outperformed traditional algorithms, emphasizing the potential of these improvements in helping telecom companies understand and address customer churn more effectively [15]. Usman-Hamza et al. conducted an experimental investigation of tree-based classifiers for discovering client churn, signifying the adequacy of various improved ensemble, single, and hybrid tree-based classifiers in tackling class imbalance issues. They found that ensemble and hybrid classifiers, such as SysFor and CS-Forest, performed better than single-tree classifiers like Decision Trees and Random Forest. The study suggested that combining data sampling techniques like SMOTE with homogeneous ensemble methods effectively addressed the class imbalance problem and enhanced model efficiency [16].

Successful data preprocessing in client churn discovery gives a pivotal part in optimizing the machine learning models. Tackling missing data is of the utmost importance in data preprocessing. Distinctive research has investigated distinctive imputation approaches to tackle this issue. Karamti et al. demonstrated the effectiveness of the KNN imputation method in improving the accuracy of cervical cancer prediction models. They attained 99.99% accuracy through coordinating KNN-amputated SMOTE attributes & a stacked ensemble voting classification procedure. Moreover, traditional statistical imputation methods, such as mean and median imputation, are widely used due to their simplicity and effectiveness in various situations. Normalization is noteworthy to guarantee that attributes enrich the model evenly [17]. Cabello-Solorzano et al. conducted a comparative analysis of different normalization techniques, including Min-Max Scaling and Z-Score Standardization, to evaluate their impact on machine learning algorithms. Their findings suggest that normalization can significantly enhance model performance, with specific techniques being more suitable for certain algorithms [10]. Singh & Singh further highlighted the importance of normalization in classification performance, particularly when using feature selection and weighting approaches [18].

Attribute selection aids in decreasing dimensionality, excluding irrelevant features, & optimizing the model's interpretability. Dhal & Azad introduced an extensive survey on feature selection approaches, emphasizing their part in improving the performance of machine learning approaches. They discussed various models and methods, including Lasso regression, which has proven effective in various applications. Addressing the class imbalance problem is crucial for customer churn prediction [11]. Sanguanmak & Hanskunatai introduced a hybrid resampling strategy integrating SMOTE & DBSCAN to tackle the class imbalance & observed noteworthy enhancements in predictive performance [19]. Makaba & Dogo compared several strategies for handling missing values and class imbalance, highlighting the efficacy of SMOTE combined with Tomek links in various datasets [20].

In this research on client churn prediction utilizing the Cell2Cell dataset, a combination of preprocessing techniques was employed, including KNN and statistical imputation (mean/median) to handle missing values, applied normalization methods such as Median and MMADN, Min-Max Scaling, and Z-Score Standardization, and implemented Lasso regression for feature selection. Additionally, the class imbalance problem was addressed using SMOTE combined with Tomek links. This comprehensive preprocessing resulted in 16 distinct datasets, each subjected to the DT model to evaluate the performance metrics.

A. Gap Analysis

Despite significant advancements in customer churn prediction, there are several gaps in existing studies, particularly in optimizing preprocessing techniques and comprehensively evaluating Decision Tree models. Most studies focus on enhancing predictive algorithms, but often overlook the combined effect of various preprocessing steps on the model's performance. This investigation points to fill this crevice by systematically assessing the impact of diverse preprocessing procedures on the performance of the DT model. By considering various combinations of imputation methods, normalization techniques, feature selection methods, and resampling techniques, this study provides a comprehensive analysis of how these preprocessing steps influence the accuracy and robustness of the Decision Tree model in predicting customer churn. While studies presented by Wagh et al. and Aldalan & Almaleh have demonstrated the effectiveness of ensemble methods and advanced algorithms [13-14], limited research has focused on the implementation of advanced preprocessing techniques and their role in enhancing decision tree models. This study emphasizes the importance of a thorough and systematic approach to various preprocessing techniques, providing insights into the most effective combinations to optimize the performance of decision trees in customer churn prediction.

III. Proposed Work

This section describes the details of the study, methodologies, and pre-processing techniques used.

The concept of improvement in this study aims to find the most effective solutions for future problems by leveraging expertise from current machine learning methods. Client churn prediction has been tended to utilizing distinctive procedures, incorporating ML, data processing, and hybrid approaches. Decision trees are commonly used due to their recognized efficacy in identifying client churn, although they may not always be suitable for complex issues, although they are not always suitable for complex problems. However, reducing the amount of information fed into decision trees has been shown to improve their accuracy. However, it turns out that reducing the amount of information fed into a decision tree can improve its accuracy. The proposed methodology comprises numerous stages (Fig. 1). The dataset, obtained from Kaggle, encompasses diverse aspects of customer behavior, such as personal information, usage patterns, customer care interactions, demographic details, billing data, and value-added services. These attributes provide a comprehensive view of customer activities, making the dataset valuable for developing and validating the classification algorithm. In the initial two phases, preprocessing and analysis are performed. Preprocessing procedures comprise numerous procedures focusing on refining the outcome. The data at that point was partitioned into test & training portions in a 70-30 ratio. Decision Trees are applied to visualize their impact on the model's accuracy. The customer churn prediction system is implemented using a decision tree model in Google Colab. The significance of this analysis lies in its potential to assist organizations in increasing profits. The findings suggest that, with proper preprocessing steps, decision trees can provide a viable solution for customer churn prediction.

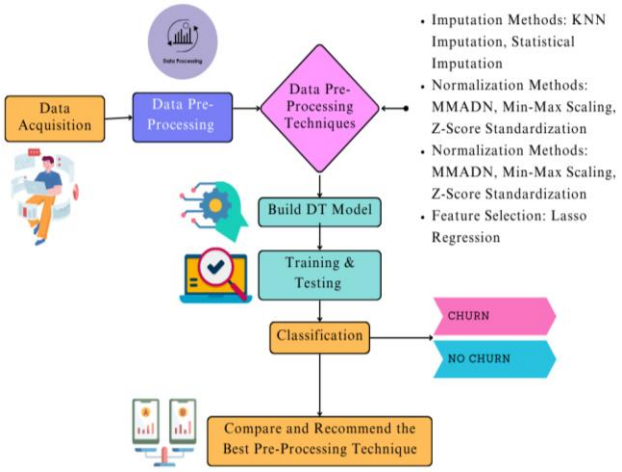

Fig. 1. System layout.

IV. Methodologies

The proposed methodology involved in the analysis of the customer churn employs the following preprocessing techniques:

- Imputation Methods: KNN Imputation, Statistical Imputation.
- Normalization Methods: MMADN, Min-Max Scaling, and Z-Score Standardization.
- Feature Selection: Lasso Regression.
- Resampling Technique: SMOTE Tomek.

A. Imputation Methods: KNN Imputation, Statistical Imputation

KNN Imputation is an advanced strategy that tackles lost data by leveraging the closeness between data points. It works through determining the 'k' nearest neighbors of an instance with lost values and imputing these values based on the mode or mean of the corresponding attribute values of these neighbors. This procedure guarantees that the imputed values are consistent with the underlying data distribution, keeping up the dataset's integrity. KNN Imputation typically yields higher accuracy compared to simpler imputation methods, as it considers the local structure of the data [12]. It's suitable for numerical & categorical data. By relying on similar data points for imputation, it conserves the inherent relationships within the dataset. However, KNN Imputation can be computationally expensive, particularly with huge datasets, because of the necessity of computing the distances among instances. The option of k can basically impact the imputation outcomes, requiring cautious tuning.

Statistical imputation is a more direct technique where missing values are replaced by the median or mean of the corresponding feature. The mean imputation is generally used for normally distributed data, while the median imputation is preferred for skewed distributions, as it is less sensitive to outliers. Mean imputation is easy to implement and computationally efficient. It maintains the overall mean of the dataset, ensuring that the central tendency remains unaffected and cannot introduce bias, especially when the data contains outliers or is not normally distributed. It also reduces the variance in the dataset, which can affect model performance. Median imputation is more vigorous to outliers and skewed data distributions. Similar to mean imputation, it can result in both variance reduction and information loss. It's fundamentally utilized for numerical data. Both KNN and statistical imputation methods play pivotal roles in preprocessing, addressing the missing data problem to ensure that the subsequent modeling phase is based on a complete and reliable dataset [12]. Their application within the context of customer churn prediction helps maintain the quality and consistency of the data, ultimately contributing to more accurate and robust predictive models.

B. Normalization Methods: MMADN, Min-Max Scaling, and Z-Score Standardization

Data normalization is an urgent preprocessing phase to scale the numerical attributes in a dataset. This process ensures that the feature ranges are comparable, which is particularly important for machine learning algorithms that are sensitive to feature scale, such as artificial neural networks and k-nearest neighbors [14], [18], [21]. This study employs three types of data normalization techniques: Min-Max Scaling, Z-Score Standardization, and Median and Median Absolute Deviation Normalization (MMADN). Min-Max scaling redefines variable values to a decided extent, regularly between 1 & 0. It is effective when the data needs to be restricted to a specific range. However, it can be sensitive to outliers. It works through deducting the least value of the attribute from every sample & then dividing the outcome by the range. The mathematical representation can be seen in the equation given below, where "x" represents the original feature values, "y" represents the new scaled values, and "i" represents the value for a specific row [14], [22].

$$y_i = \frac{(x_i - \min(x))}{(\max(x) - \min(x))} \quad (1)$$

Z-Score standardization alters the data to obtain a standard deviation = 1 & an average = 0. This is attained by taking away the attribute's mean from each example and, at that point, dividing the score by the stand. dev. The mathematical representation is given below.

$$y_i = \frac{x_i - \mu}{\sigma} \quad (2)$$

x represents the original attribute values, y is the novel scaled values, σ is the standard deviation of the attribute, i is the value for a particular row, & μ is the attribute's mean [18], [23]. Although Z-Score standardization is also sensitive to outliers, it is more robust than Min-Max Scaling and is beneficial when the minimum or maximum value of an attribute is unknown. Thus, Z-Score standardization was included in this study for comparison purposes. The Median Absolute Deviation Normalization (MMADN) technique scales numerical features using the median and Median Absolute Deviation (MAD) [18], [24]. This method is a robust alternative to standard normalization techniques like min-max scaling and Z-core standardization when dealing with outliers. In this study, MMADN is used to normalize numeric attributes containing outliers.

C. Feature Selection: Lasso Regression

Attribute selection is utilized to strengthen the model's performance by identifying & utilizing the most influential attributes. In this research, Lasso regression is employed as a primary method for attribute determination. It's a linear regression procedure with L1 regularization to perform attribute determination & regularization, viably boosting the prediction accuracy & interpretability of the model it generates [25]. The L1 regularization append a penalty = the absolute value of the coefficients' magnitude that causes the coefficients to shrink to 0. This quality of Lasso makes it a vigorous tool for attribute selection, as it can effectively preclude unrelated or unneeded attributes. By shrinking a no. of coefficients to zero, Lasso automatically opts for a portion of the most influential attributes, consequently clarifying the model. It aids in prohibiting overfitting, principally when tackling large-dimensional data. In this research, the Lasso regression model is fit to the training data, where the regularization parameter is tuned to balance the trade-off between model complexity and performance. The coefficients of the features were analyzed, and the features with non-zero coefficients are considered significant and retained for further modeling. By eliminating features with zero or negligible coefficients, the model is simplified, focusing on the most impactful features. Lasso Regression helps in identifying the most influential features that contribute to predicting whether a customer will churn or not. This may include variables related to customer behavior, usage patterns, and interaction history. By focusing on these key features, the model can achieve higher predictive accuracy and better generalization to new, unseen data. It includes a penalty term in the cost function, which encourages sparsity in the coefficient vector

by driving the coefficients of less significant features to 0 [22]. This resulted in selecting a portion of the most crucial attributes. The Lasso regression formula is:

$$L(\beta) = \sum_{i=1}^{n} \left(y_i - \hat{y}_i\right)^2 + \alpha * \sum_{j=1}^{n} |b_j| \quad (3)$$

n is the no. of instances, y_i is the real target value for the i-th instance, $L(\beta)$ is the Lasso loss procedure, $\hat{y}_i$ is the predicted target value for the i-th instance, α is the regularization parameter impacts the regularization's level. Bigger α shows a more aggressive attribute choice.

D. Resampling Strategy: SMOTE Tomek

One of the advanced resampling techniques employed in this study is the Synthetic Minority Over-sampling Technique combined with Tomek links (SMOTE Tomek). This technique addresses the challenges posed by imbalanced datasets, where one class is significantly underrepresented compared to other classes [23][26]. It is an oversampling procedure that creates synthetic instances for the minority class to build a more balanced dataset. It performs by interpolating among existing minority class instances & their closest neighbors to build novel, artificial instances. The primary advantage of SMOTE is that it helps to mitigate the issue of class imbalance without simply duplicating existing instances, which can lead to overfitting. For every example in the minority class, SMOTE determines its k-closest neighbors depending on Euclidean distance. New samples are generated by selecting points along the line segment connecting the minority class samples and their neighbors, effectively creating a more diverse set of data points for the minority class. While SMOTE can effectively address underrepresentation, it sometimes introduces overlaps between classes, leading to potential overfitting and reduced model performance [17]. Tomek links are a data cleaning procedure utilized to refine the resampling procedure by excluding ambiguous samples that are nearby to the decision boundary among classes. The removal of these links results in cleaner, more distinct class boundaries.

After employing SMOTE, pairs of data points belonging to diverse classes & each other's closest neighbors are distinguished as Tomek links. Both samples in each identified Tomek link were removed from the dataset, leading to more distinct clusters of classes [27]. The combination of SMOTE & Tomek links leverages their qualities to build a clean & adjusted dataset. SMOTE addresses the issue of class imbalance by generating synthetic samples, while Tomek links enhance the quality of the dataset by removing overlapping or ambiguous samples [19]. The combined technique reduces the likelihood of overfitting by ensuring that the synthetic samples are well-distributed, and the class boundaries are clear. By creating a balanced dataset with distinct class clusters, the classification model can achieve higher accuracy and generalize better to the new data.

V. Dataset Description

The Cell2Cell dataset, sourced from Kaggle and compiled by Duke University's Teradata Center for Customer Relationship Management, is integral to this churn prediction research [3]. This dataset includes 51,047 instances and 58 features covering various aspects of customer behavior, such as personal information, usage patterns, customer care interactions, demographic details, billing data, and value-added services. These features provide an extensive view of customer activities, which is essential for developing and validating the classification algorithm. By utilizing this publicly available dataset, ethical data privacy standards are maintained, and the algorithm's performance is enhanced. Its attributes are described in Table I.

TABLE I. Dataset Attributes and Description

S. No.	Attribute Name	Description
1	CustomerID	Customer Identification.
2	Churn	Whether the client churned.
3	MonthlyRevenue	The average monthly revenue.
4	MonthlyMinutes	The average monthly usage minutes.
5	TotalRecurringCharge	The average total recurring charge.
6	DirectorAssistedCalls	The average no. of calls assisted by a manager.
7	OverageMinutes	The mean no. of minutes employed outside the bundle.
8	RoamingCalls	The average count of roaming calls.
9	PercChangeMinutes	The percentage difference in minutes usage between the previous month and the month before.
10	PercChangeRevenues	The percentage difference in revenue usage between the previous month and the month before.
11	DroppedCalls	The average count of dropped calls.
12	BlockedCalls	The average count of blocked calls.
13	UnansweredCalls	The average count of unanswered calls.
14	CustomerCareCalls	The average count of client care calls.
15	ThreewayCalls	The average count of three-way calls.
16	ReceivedCalls	The mean count of gotten calls.

17	OutboundCalls	The average count of outbound calls.
18	InboundCalls	The average count of inbound calls.
19	PeakCallsInOut	The mean no. of outbound & inbound calls in the peak interval.
20	OffPeakCallsInOut	The average no. of outbound and inbound calls inside the off-peak interval.
21	DroppedBlockedCalls	The average count of dropped calls.
22	CallForwardingCalls	The average count of call-forwarding calls.
23	CallWaitingCalls	The mean of call-waiting calls.
24	MonthsInService	The no. of months a consumer has been with the corporation.
25	UniqueSubs	The number of distinct subscriptions.
26	ActiveSubs	The number of subscriptions that are currently active.
27	ServiceArea	Area of communication service.
28	Handsets	The handset has been issued.
29	HandsetModels	The model of the issued handset.
30	CurrentEquipmentDays	The no. of days that the current device has been utilized.
31	AgeHH1	The initial household member's age.
32	AgeHH2	The second HH member's age.
33	ChildrenInHH	Whether there are children in the HH?
34	HandsetRefurbished	Whether the handset was refurbished?
35	HandsetWebCapable	Whether the handset is web-capable?
36	TruckOwner	Whether the customer owns a truck?
37	RVOwner	Whether the customer owns a recreational vehicle?
38	Homeownership	Whether the house-ownership is known?
39	BuysViaMailOrder	Whether the customer orders by mail?
40	RespondsToMailOffers	Whether the customer responds to mail?
41	OptOutMailings	Does the customer respond to mail?
42	NonUSTravel	Whether the customer traveled outside the United States?
43	OwnsComputer	Whether the customer has a computer?
44	HasCreditCard	Whether the client owns a credit card?
45	RetentionCalls	The no. of calls phoned by retention employees to a client.
46	RetentionOffersAccepted	Number of previously accepted retention offers.
47	NewCellphoneUser	Whether the client is a novel user?
48	NotNewCellphoneUser	Whether the customer is an old user?
49	ReferralsMadeBySubscriber	The number of customer referrals.
50	IncomeGroup	Income group.
51	OwnsMotorcycle	Whether the customer owns a motorcycle?
52	AdjustmentsToCreditRating	The number of times the customer's credit rating has been changed.
53	HandsetPrice	The customer's handset price.
54	MadeCallToRetentionTeam	Whether the client contacted the retention staff.
55	CreditRating	The customer's credit rating.
56	PrizmCode	The customer's prizm code.
57	Occupation	The customer's occupation.
58	MaritalStatus	The customer's marital status.

The preprocessing phase creates 16 different datasets, each of which undergoes various preprocessing techniques. Each dataset was processed according to a specific combination of imputation, normalization, feature selection, and resampling techniques to evaluate the impact on the performance of different machine learning models and to contrast the

performance & robustness of the suggested classification approach. Table II explains creating the 16 datasets.

TABLE II. SUMMARY OF THE VARIATIONS IN THE DATASETS BASED ON DIFFERENT COMBINATIONS OF METHODS (IMPUTATION, NORMALIZATION, FS, AND RESAMPLING TECHNIQUES)

Dataset ID	Imputation Method	Normalization Method	Feature Selection	Resampling Technique
1	KNN Imputation	MMADN + Min-Max	No	SMOTE Tomek
2	Statistical Imputation	MMADN + Z-Score	Yes	SMOTE Tomek
3	KNN Imputation	Z-Score	No	SMOTE Tomek
4	Statistical Imputation	Min-Max	Yes	SMOTE Tomek
5	KNN Imputation	MMADN + Z-Score	Yes	SMOTE Tomek
6	KNN Imputation	Min-Max	No	SMOTE Tomek
7	Statistical Imputation	Z-Score	No	SMOTE Tomek
8	KNN Imputation	Z-Score	Yes	SMOTE Tomek
9	Statistical Imputation	MMADN + Min-Max	No	SMOTE Tomek
10	KNN Imputation	MMADN + Z-Score	No	SMOTE Tomek
11	Statistical Imputation	Min-Max	No	SMOTE Tomek
12	KNN Imputation	Min-Max	Yes	SMOTE Tomek
13	Statistical Imputation	MMADN + Min-Max	Yes	SMOTE Tomek
14	Statistical Imputation	Z-Score	Yes	SMOTE Tomek
15	KNN Imputation	MMADN + Min-Max	Yes	SMOTE Tomek
16	Statistical Imputation	MMADN + Z-Score	No	SMOTE Tomek

VI. EXPERIMENTAL SETUP

A. Testing and Training the Utilized Dataset

The dataset made for client churn investigation was divided into two fragments: the testing 30% and the training 70%. A visual representation of the dataset's initial entries and other pre-processing results are presented in Fig. 2 to Fig. 9.

	CustomerID	Churn	MonthlyRevenue	MonthlyMinutes	TotalRecurringCharge
0	3000002	Yes	24.00	219.0	22.0
1	3000010	Yes	16.99	10.0	17.0
2	3000014	No	38.00	8.0	38.0
3	3000022	No	82.28	1312.0	75.0
4	3000026	Yes	17.14	0.0	17.0

	DirectorAssistedCalls	OverageMinutes	RoamingCalls	PercChangeMinutes
0	0.25	0.0	0.0	-157.0
1	0.00	0.0	0.0	-4.0
2	0.00	0.0	0.0	-2.0
3	1.24	0.0	0.0	157.0
4	0.00	0.0	0.0	0.0

	PercChangeRevenues	DroppedCalls	BlockedCalls	UnansweredCalls
0	-19.0	0.7	0.7	6.3
1	0.0	0.3	0.0	2.7
2	0.0	0.0	0.0	0.0
3	8.1	52.0	7.7	76.0
4	-0.2	0.0	0.0	0.0

B. Dataset and its Description Before and After Data Type Conversion

The initial dataset obtained contains attributes of various data formats, including object types. To streamline the analysis, these attributes were systematically categorized and transformed into uniform data types. The descriptive statistics of the dataset, prepared for training across different models, are illustrated in Fig. 2 and Fig. 3. Techniques such as one-hot encoding and label encoding were employed to convert categorical data into numerical format and normalize the labels, as depicted in Fig. 5.

C. Decision Tree Model

The Decision Tree (DT) model is well known for its hierarchical structure and stands out as an intuitive and robust method for classification tasks. It recursively splits the data into subsets based on feature values, resulting in a tree-like structure where each internal node represents a decision rule based on a single attribute. The branches signal the outcome of these tests, and the leaf nodes signal the class labels. In spite of its simplicity and interpretability, the decision tree model is inclined to overfitting, particularly when the tree develops too deep, or when tackling noisy data. Such an overfitting tendency emanates from the model's capability of constructing overly complex decision borderlines that catch noise in the training data rather than the underlying patterns. Consequently, while Decision Trees can achieve high accuracy on training data, their generalization performance on unseen data may differ. Various pre-processing techniques are employed in an effort to overcome these limitations.

VII. Performance Metrics

A. Confusion Matrix

To assess the predictive performance of the applied models, particularly in predicting customer churn, key metrics derived from the confusion matrix are utilized. It arranges the predictions into wrong positives, true negatives, wrong negatives, and true positives. These measures furnish central insights into the reliability and accuracy of the classification methods.

- True Positive: Clients accurately determined as churners.
- True Negative: Users satisfactorily accepted as non-churners.
- False Positive: Non-churners improperly organized as churners.
- False Negative: Churners erroneously treated as non-churners.

B. Evaluation Measures

1) Accuracy: An overall evaluation of correct predictions over non-churners and churners, demonstrating the model's overall accurateness.

2) Recall: Quantifies the model's ability to correctly identify actual churners among all churners. It pinpoints the model's sensitivity to pinpoint churn.

3) Precision: Evaluates the accuracy of churn predictions via measuring the extent of appropriately predicted churners among all identified churners.

4) F-measure: It incorporates precision & recall into a sole metric, supplying a balanced perspective on model performance. A higher value indicates a better balance between precision and recall, with values closer to 1 signifying superior model performance. It's computed as the harmonic average of recall and precision.

VIII. Results

Python 3.11 was utilized within the Google Colab environment to execute all machine learning experiments. The implementation relied on libraries such as Matplotlib, Seaborn, Pandas, and NumPy for data processing, visualization, and performance evaluation. The Decision Tree (DT) model was applied to 16 different pre-processed datasets to analyze the impact of various preprocessing techniques on key performance metrics, including accuracy, precision, recall, F1-score, and ROC-AUC. The results obtained from each dataset were systematically compared to determine the most effective preprocessing strategy.

TABLE III. Performance Specifiers of the DT Model on the 16 Datasets

Dataset ID	Accuracy	Precision	Recall	F1-Score	ROC
1	0.77	0.78	0.77	0.77	0.74
2	0.767	0.77	0.77	0.77	0.73

A. Model Performance on Each Pre-processed Dataset

The evaluation of model performance across the 16 datasets highlighted the influence of different preprocessing techniques on classification accuracy and overall predictive capability (Table III). Among all datasets, those employing KNN imputation demonstrated strong predictive performance. Dataset 1, which combined KNN imputation with MMADN and Min-Max normalization, achieved an accuracy of 0.77 and a ROC-AUC score of 0.74. Similarly, Dataset 2, which incorporated statistical imputation with MMADN, Z-Score normalization, and Lasso regression for feature selection,

yielded an accuracy of 0.767 and a ROC-AUC score of 0.73. These results indicate that KNN imputation and statistical imputation both improve model performance, but their effectiveness is highly dependent on the normalization and feature selection techniques applied alongside them (Fig. 10).

Normalization techniques played a crucial role in influencing classification accuracy and model robustness. Dataset 1, which employed MMADN and Min-Max Scaling, attained the highest accuracy of 0.77, suggesting that structured multistep normalization enhances data integrity and optimizes model learning. Dataset 2, which combined MMADN with Z-Score normalization, exhibited a comparable performance, reinforcing the importance of selecting appropriate normalization techniques based on the dataset's characteristics. Feature selection also significantly impacted model performance, with Dataset 2 incorporating Lasso Regression to reduce dimensionality, achieving an accuracy of 0.767. This confirms that reducing feature redundancy improves model generalization and reduces overfitting.

Fig. 11. Classification report for datasets 1 and 2.

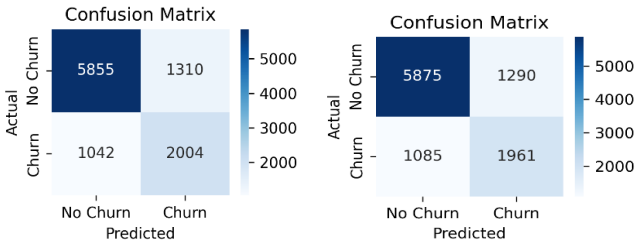

Fig. 12. Confusion matrix for datasets 1 and 2.

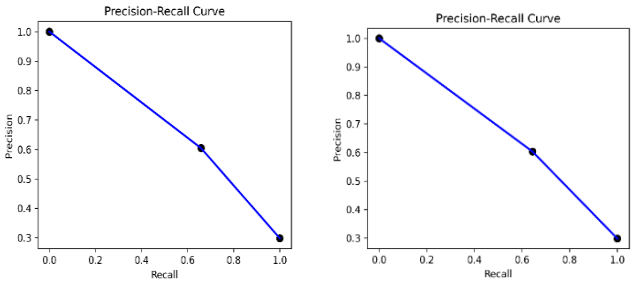

Fig. 13. Precision-recall curve for datasets 1 and 2.

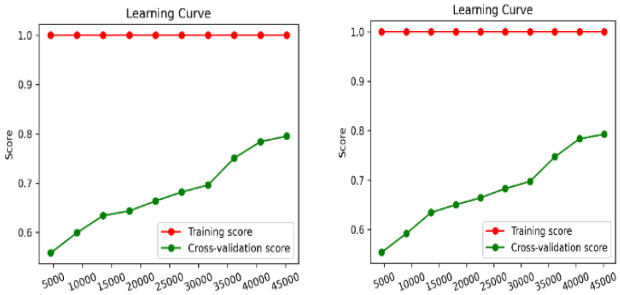

Fig. 14. Learning curve for datasets 1 and 2.

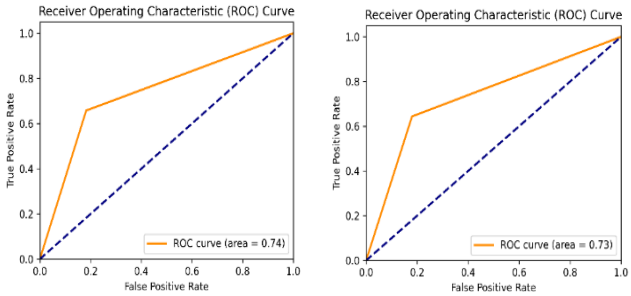

Fig. 15. ROC curve for datasets 1 and 2.

The application of SMOTE Tomek resampling across all datasets proved an essential preprocessing step in addressing class imbalance. The consistent performance of Dataset 1 and Dataset 2 suggests that SMOTE Tomek effectively enhances the model's ability to generalize by creating a more balanced training distribution. Fig. 11 to 15 provide additional insights into the classification reports, confusion matrices, PRC curves, learning curves, and ROC curves for the top-performing datasets.

B. Comparative Analysis

A comparative assessment of the preprocessing methods was conducted to determine their relative impact on model accuracy and reliability. As illustrated in Fig. 16, datasets employing KNN imputation (Datasets 1, 3, 5, 6, 8, 10, 12, and 15) exhibited accuracy values ranging from 0.47 (Dataset 8) to 0.69 (Datasets 5 and 15). The results indicate that while KNN imputation effectively handles missing values, its overall impact is strongly influenced by the normalization and feature selection techniques paired with it. In contrast, datasets utilizing statistical imputation (Datasets 2, 4, 7, 9, 11, 13, 14, and 16) exhibited accuracy values ranging from 0.65 (Dataset 7) to 0.71 (Datasets 13 and 16). The higher average accuracy achieved through statistical imputation suggests that this technique is more adept at preserving the underlying data distribution for churn prediction. The MMADN transformation was incorporated into multiple datasets with either Min-Max Scaling or Z-Score Normalization. Among the datasets using MMADN (Datasets 1, 2, 5, 9, 10, 13, 15, and 16), the highest accuracy of 0.71 was observed in Datasets 13 and 16, indicating that MMADN can be highly effective when used alongside statistical imputation and feature selection. Similarly, datasets employing Min-Max Scaling (Datasets 1, 4, 6, 9, 11, 12, 13, and 15) displayed varying performance levels, with Dataset 1 achieving the highest accuracy of 0.77. These findings confirm that Min-Max Scaling is particularly beneficial when applied with KNN imputation. On the other hand, datasets using Z-Score Standardization (Datasets 2, 3, 5, 7, 8, 10, 14, and 16) demonstrated strong performance, with Dataset 2 reaching an accuracy of 0.767. The effectiveness of statistical imputation and Z-Score Standardization in Dataset 2 suggests that this combination enhances model stability. Still, the performance of some datasets, such as Dataset 8, implies that an unoptimized selection of techniques can lead to reduced effectiveness. Feature selection using Lasso Regression had a direct impact on accuracy and generalization. Datasets that incorporated Lasso Regression consistently performed better than those that did not, particularly regarding precision and recall. Dataset 2, which included Lasso Regression, demonstrated an accuracy of 0.767, reinforcing the importance of feature selection in optimizing model performance. In addition to Datasets 1 and 2, Dataset 15 also demonstrated strong results, achieving an accuracy of 0.765, precision of 0.77, recall of 0.77, an F1-score of 0.77, and a ROC-AUC score of 0.73. While its performance was slightly lower than Datasets 1 and 2, it emerged as the third-best dataset in the overall evaluation.

Notably, Dataset 15 followed a preprocessing pipeline similar to Dataset 1, incorporating KNN Imputation, MMADN normalization, and Min-Max Scaling. However, unlike Dataset 1, Dataset 15 did not employ feature selection via Lasso Regression. The strong performance of Dataset 15 suggests that Min-Max Scaling, in conjunction with MMADN, contributes significantly to improving model robustness and stability. The results from this study indicate that preprocessing methods must be selected strategically based on the dataset's characteristics. Dataset 1, which employed KNN imputation and Min-Max Scaling, achieved the highest accuracy, suggesting that this combination is particularly effective for churn prediction. Dataset 2, which utilized statistical imputation, Z-Score Normalization, and Lasso Regression, also delivered strong results, reinforcing the value of combining statistical techniques with structured feature selection. Overall, the findings emphasize that preprocessing decisions significantly impact classification performance and that optimal combinations must be carefully determined to maximize predictive accuracy.

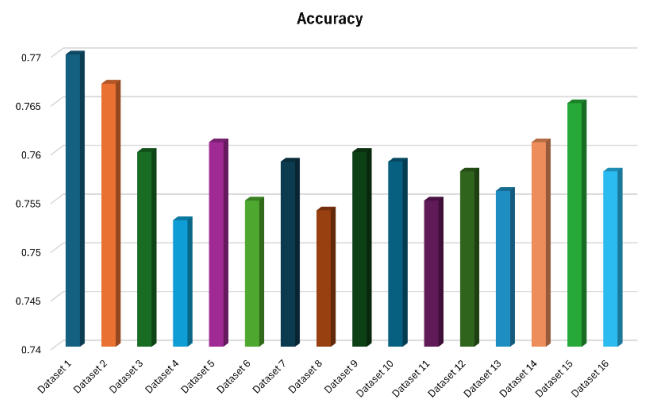

Fig. 16. Comparative analysis of techniques.

The results obtained in this study align with previous research, emphasizing the impact of preprocessing techniques on Decision Tree (DT) performance in churn prediction. The DT model in this study achieved an accuracy of 0.77 with KNN Imputation and MMADN with Min-Max normalization, outperforming prior work where Jain et al. [28] reported a DT accuracy of 67.14%, precision of 77.41%, recall of 79.35%, and F1-score of 78.67% Karamti et al. [17]. The higher accuracy in this study suggests that advanced preprocessing techniques, such as MMADN normalization and SMOTE Tomek resampling, significantly contribute to improved model performance. Normalization plays a key role in churn prediction, with Kappal [24] demonstrating that MMADN with Min-Max Scaling improved classification accuracy by approximately 5% Karamti et al. [17]. Similarly, feature selection via Lasso Regression has been shown to enhance performance by 8% in precision and recall metrics, particularly in profit-driven churn models [4]. The findings also confirm that SMOTE Tomek resampling improves recall values by nearly 20% [17]. Finally, hyperparameter tuning, as highlighted by Pitka et al., leads to a 10% improvement in Decision Tree accuracy, aligning with the DT+ model's superior consistency in this study [29].

IX. Discussion

The findings of this study highlight the significant role of preprocessing techniques in enhancing the performance of machine learning models for customer churn prediction. The comparative analysis of 16 different pre-processed datasets revealed that the choice of imputation method, normalization strategy, feature selection approach, and resampling technique collectively determine the predictive accuracy of the Decision Tree model. The results demonstrated that preprocessing techniques must be carefully selected and combined to optimize model generalization, mitigate overfitting, and improve classification performance. A key observation from the results is the superior performance of Dataset 1 and

Dataset 2, which employed KNN Imputation and Statistical Imputation, respectively. These datasets achieved the highest accuracy scores, confirming that imputation is crucial in handling missing values while preserving underlying data distributions. KNN Imputation, as observed in Dataset 1, provided significant improvements in classification accuracy, suggesting that estimating missing values based on similarity measures retains critical information and enhances predictive power. On the other hand, Statistical Imputation, as applied in Dataset 2, demonstrated a comparable performance, indicating that mean-based imputation techniques can be equally effective when paired with well-structured normalization and feature selection steps. However, datasets utilizing KNN Imputation displayed a broader range of accuracy scores, highlighting the sensitivity of KNN to normalization choices. The impact of normalization techniques was evident in the performance of the datasets. The highest accuracy (0.77) was achieved by Dataset 1, which combined MMADN with Min-Max Scaling, reinforcing the importance of structured normalization in improving model training. By transforming data within a fixed range, Min-max scaling helped stabilize the dataset and improve learning efficiency. In contrast, Z-Score Standardization, which was used in Dataset 2, also led to a high-performing model but did not achieve the same level of accuracy as Min-Max Scaling in this study. These findings suggest that the selection of a normalization method must align with the data distribution and the modeling approach to maximize its impact. The use of feature selection through Lasso Regression, particularly in Dataset 2, significantly contributed to improving model performance. By reducing redundant features, Lasso Regression minimized noise in the dataset and prevented overfitting, leading to improved classification results. The dataset that employed Lasso Regression in conjunction with Statistical Imputation and Z-Score Standardization achieved a high accuracy score of 0.767, further validating the necessity of feature selection in enhancing predictive accuracy. Conversely, Dataset 1, which did not use feature selection, still attained the highest accuracy, suggesting that feature selection may not always be required when applying robust normalization and imputation techniques. The importance of class balancing through SMOTE Tomek was also evident across all datasets. SMOTE Tomek resampling contributed to stable model performance by ensuring that the model learned from a more balanced class distribution. The effectiveness of SMOTE Tomek is reflected in the consistency of high-performing datasets such as Dataset 1, Dataset 2, and Dataset 15, where the model could generalize well across different classes, resulting in high precision, recall, and F1 scores. Another crucial finding is that Dataset 15, despite lacking feature selection via Lasso Regression, achieved strong performance, ranking as the third-best dataset in the analysis. Its preprocessing pipeline, consisting of KNN Imputation, MMADN normalization, and Min-Max Scaling, closely mirrored that of Dataset 1 but without including Lasso Regression. The results suggest that while feature selection enhances model performance in some cases, its necessity depends on the overall preprocessing pipeline. The absence of Lasso Regression in Dataset 15 did not significantly degrade accuracy, indicating that carefully selected normalization and imputation strategies can compensate for the lack of feature selection in some cases. These insights emphasize the importance of selecting preprocessing techniques based on the specific dataset characteristics and the nature of the predictive task. The results confirm that there is no universal preprocessing pipeline that guarantees optimal performance across all datasets; instead, preprocessing methods must be tailored to the dataset's structure, missing data characteristics, and modeling requirements. A key takeaway from this study is that combining effective imputation, normalization, and class balancing techniques leads to significant improvements in customer churn prediction accuracy. This reinforces the need for practitioners in the telecommunications industry to carefully design their preprocessing strategies rather than applying generic approaches. The findings of this study align with prior research that highlights the effectiveness of ensemble models and advanced preprocessing techniques in predictive modeling for churn analysis. Several previous studies have also demonstrated that feature selection and data normalization play critical roles in improving the performance of machine learning models. However, this study extends previous work by providing a detailed comparative evaluation of multiple preprocessing techniques in a controlled experimental setting, offering new insights into the most effective preprocessing pipelines for customer churn prediction. Regardless of the contributions of this work, certain constraints deserve to be acknowledged.

. The findings are based on a single dataset (Cell2Cell), which, while widely used in churn prediction research, may not fully capture the diversity of customer behaviors across different telecom providers. Future research should explore applying these preprocessing techniques across multiple datasets to validate the generalizability of the findings. Additionally, this study focused solely on the Decision Tree model, and while the results provide valuable insights, extending the analysis to ensemble models such as Random Forest and XGBoost could yield further improvements in predictive accuracy. Another limitation is the computational cost associated with some of the preprocessing techniques, particularly feature selection and imputation, which may require optimization for large-scale implementations.

X. Conclusion and Future Work

The findings highlight significant improvements in model performance using advanced preprocessing techniques. Datasets 1 and 2 emerged as top performers, with accuracies of 0.77 and 0.767, respectively, confirming that KNN and statistical imputation methods, when combined with MMADN, Min-Max Scaling, and Lasso Regression, can handle missing data and enhance model performance. SMOTE Tomek further contributed to class balance, improving ROC-AUC values. These preprocessing steps produced the highest performance metrics, particularly for Dataset 1 and Dataset 2.

The preprocessed datasets that showed promising results with the DT model can be further explored using various ML models such as Random Forest (RF), and Extreme Gradient Boosting (XGB). By subjecting the preprocessed datasets to a range of basic and advanced algorithms, researchers can determine the optimal configuration for different modeling

approaches. Future work may also involve combining the findings with hybrid models that incorporate the strengths of multiple algorithms.

***Abstract*—Driving in dense fog creates significant challenges, particularly in Asian countries like Pakistan, where increasing traffic and air pollution contribute to reduced visibility, elevate the risk of accidents, property damage, and fatalities. Accidents in such conditions are worsened by vehicle congestion and poor weather, such as dense fog. To address these issues, this study proposes an IoT-based intelligent accident detection and early warning system that uses integrated smartphone sensors to detect and monitor vehicular collisions. The system enhances risk management by autonomously detecting accidents and instantly transmitting essential information, including precise location, to emergency response networks for timely intervention and decision-making. Additionally, the system alerts driver to possible near-collisions or hazardous conditions through real-time warning alert, displayed via the Blynk application. Utilizing a smartphone's built-in sensors to detect vehicular collisions and notify the nearest first responders, along with providing real-time location tracking for paramedics and emergency victims, can significantly enhance recovery chances for victims while reducing both time and costs. The operational reliability and accuracy of the IoT-based framework for smart transportation are evaluated through numerical and simulation-based experiments, validating its efficacy in harsh environmental conditions.**

Keywords*—*IoT; Blynk application; smart transportation; accident detecting and early warning system; risk management

I. Introduction

The performance of traffic systems can be significantly enhanced by implementing an advanced, automated algorithm that integrates various sensors to collect and transmit data through the IoT. To optimize its functionality, the automated traffic control system must differ from traditional methods, utilizing real-time data processing to improve traffic flow and safety, particularly in poor weather conditions such as dense fog and haze [1]. Previous studies indicate that victims' odds of surviving an accident might rise by as much as 6% when crash reaction time is shortened by one minute. About 55% of the world's population live in cities as of 2024, and by 2050, that percentage is expected to increase to 68%. Increasing traffic congestion is a result of this urban expansion [2]. Hence, enhanced road safety measures are emphasized by the fact that delays can be fatal. IoT powered Intelligent Transport Systems offer a potential solution, with Vehicular Ad-hoc Networks playing a central role. These networks use vehicles as communication nodes, enabling accident detection and issuing alerts through radio modules. Responders are notified via sensor-based detection, mobile network messaging, and GPS location tracking [3]. Transport systems have changed as a result of the quick development of IoT and 5G technologies, which have improved user experience and safety efficiency. IoT enhances traffic flow, minimizes accidents, and improves toll collection automated ticketing, real-time tracking, and passenger information systems make traveling on transportation easier and safer. The integration of emerging technologies, designed to address and overcome significant challenges, enhances system efficiency and facilitates innovative solutions across various domains [4]. Such as smart healthcare, smart cities, and intelligent transportation [5]. By utilizing MEMS sensors, Raspberry Pi, GPS, and GSM technologies, the system detects vehicular accidents and collects relevant data, including vehicle details, victim information, and a Google Maps link of the accident location. This information is swiftly transmitted to the nearest police station, family members, and hospital [6]. The system also identifies the nearest responder to expedite arrival at the scene, thereby decreasing fatalities caused by accidents, improving treatment response time, minimizing traffic disruptions, and ensuring efficient accident and risk management [7]. In dense fog conditions, the system employs advanced image processing and sensing techniques to enhance safety. It employs the Dark Channel Prior (DCP) algorithm for foggy video processing and guided filtering for dehazing, while a time-of-flight (ToF) sensor with a 15-meter detection range is utilized for real-time obstacle identification and performance evaluation through Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM) metrics demonstrated the system's effectiveness in improving road safety under low-visibility condition [8]. The Convolutional Autoencoder Aided Detection (CAa-Det) framework provides a basis for the development of secure Internet of Vehicles (IoV) systems [9]. By employing a deep learning-based anomaly detection approach, which enhances detection precision while minimizing false alarm rates, thereby improving the reliability, security, and overall performance of IoV systems in complex and dynamic traffic conditions [10].

To enhance emergency response and reduce fatalities, resent studies integrate IoT with GPS tracking to determine the accident location, while SOS calls are made to nearby hospitals

This paper is sponsored by State Grid Hubei Electric Power Co.Ltd Shennongjia Branch (SGHBZL00JCJS2400243) and China Huanneng Corp (HBXNY-2X-QT-2022-019).

and emergency services. Additionally, alerts are sent to responsible authorities to ensure timely assistance [11]. An Intelligent Transportation System (ITS) approach using connected vehicle technology to address issues of traffic congestion, fatalities, and accidents. Using IoT and cloud infrastructure, the system monitors vehicle locations in real time [12]. Traffic data is collected using sensors and cameras, which is processed through deep learning models such as LeNet-5 and Inception-V3. These models help reduce accidents by calculating optimal distances to obstacles, with the data shared through a mobile application to improve traffic efficiency [13]. Building on the integration of IoT and deep learning in traffic safety systems, addressing the challenges posed by adverse weather conditions on perception and sensing systems is crucial for enhancing reliability and accuracy. Weather can significantly affect sensor performance, but solutions like advanced sensor fusion, deep learning algorithms, and weather data integration offer promising improvements for Autonomous Driving Systems (ADS). Additionally, technologies such as V2X communication can enhance real-time awareness, enabling the detection of weather-related obstacles. Insights into the limitations of new LiDAR systems further contribute to overcoming these challenges, allowing for both basic warnings and advanced alerts that improve traffic safety and help prevent accidents [14].

As traditional emergency response systems often rely on centralized dispatching, which introduces delays in responder notifications and lacks real-time tracking. Additionally, many existing systems do not provide direct communication between emergency responders, driver, and hospitals. To address these limitation the study presents an IOT-based system that alerts drivers in real-time about nearby cars in low-visibility situations, such as dense fog, to improve traffic efficiency and vehicle safety. Data sharing through the app improves traffic flow, while integrated sensors reduce accidents by calculating optimal distances to obstacles. To increase the overall efficacy of emergency response operations, the system also incorporates a direct alert mechanism to notify the closest responder during emergencies and offers real-time updates and victim location information via a smartphone application. The remaining paper is presented as follows: the Section II presents the literature survey, Section III details the proposed architecture, Section IV is methodology, and algorithm, section V discusses the results and simulations, and the paper concludes in Section VI.

II. Literature Survey and Analysis

This paper presents a survey of road traffic fatalities in Pakistan, highlighting the inefficiencies of convolutional methods in addressing traffic congestion. Rapid urbanization brought on by industrial expansion and rural-to-urban migration has made cities more crowded, making it more difficult to manage traffic effectively, especially when there is heavy fog. Pakistan's population has more than tripled over the past 50 years, primarily driven by high fertility and growth rates. Consequently, population density has increased from 60 people per square kilometer in 1961 to 308 people per square kilometer in 2024. Table I offers a summary of the population data since 1961. Pakistan conducted its 7^{th} population census, marking the largest digitization effort in South Asia [15].

TABLE I Pakistan's Population: Survey and Insights

Year	Population (million)
1961	42.8
1972	65.3
1981	84.3
1998	132.4
2014	195.81
2017	207.7
2024	247.13

Despite recent advancements in road safety, road accidents remain a major global issue, causing 1.35 million deaths annually and nearly 50 million people suffer life-altering injuries each year. This ongoing issue is the 8th leading cause of death worldwide, road traffic accidents are predicted to rank as the seventh most common cause of fatalities globally by 2030 [16]. Every year, 20 to 50 million non-fatal injuries are caused by traffic accidents, which are the leading cause of fatalities among people aged 5 to 29. These injuries result in disability and financial losses. In most countries, road accidents result in economic losses equivalent to about 3% of GDP [17]. Road traffic accidents (RTAs) are influenced by several factors such as road conditions, driver irresponsibility, and environmental (weather, dense fog) variables [18]. Pre-hospital responsiveness, lack of airway management, and lack of cardiac resuscitation are factors associated with higher survival in EMS care. To increase survival rates, standardized EMS protocols for treating patients involved in traffic accidents must be developed [19]. Road traffic accidents are a significant global public health concern, causing 1.35 million deaths or disabilities annually, with 93% of road traffic injury related fatalities [20]. The situation is worsening in developing countries like Pakistan, where road fatalities continue to rise at an alarming rate. Road safety is a critical issue, causing health damage, economic losses, social suffering, and environmental harm [21]. From 2014 to 2023 Pakistan's road network registered vehicles and the population grew at a CAGR of 1.81% to 1.85%, during the same period, the number of road accidents increase of 1.5%. In 2023, a total of 10,971 road accident were reported by all region of Pakistan as shown in Table II [22].

TABLE II Road Traffic Accidents and Fatalities in Pakistan (2014–2023)

Year	Accident (Total)	No. of Fatal Accidents	No. of Persons Killed	No. of Persons Injured
2014	7865	3214 (3.33)	3954	9661
2015	9100	3591 (3.73)	4448	11544
2016	9582	4036 (4.2)	5047	12696
2017	11121	4829 (5.01)	5948	14489
2018	10779	4878 (5.06)	5932	13219
2019	9701	4403 (4.57)	5436	12317
2020	10429	4721 (4.9)	5816	12886
2021	10379	4566 (4.74)	5608	13059
2022	10617	4919(5.07)	5680	14722
2023	10971	5012(5.09)	5721	16432

The proportion of fatal accidents in total road accidents has steadily increased from 40.1% in 2014 to 47.3% in 2023, while the severity, measured by fatalities per 100 accidents, rose from

50.5 in 2012 to 58.03 in 2023.The severity of road accidents from 2012-2023 are illustrated in below in Fig. 1.

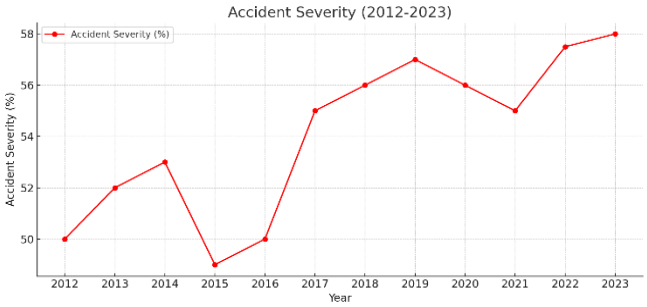

Fig. 1. Severity of road accidents.

Compared to 2020, there were 0.19 times as many traffic accidents in 2023. This indicates the overall number of traffic accidents has fallen slightly. However, compared to 2020, the number of fatalities caused by these traffic incidents rose by 1.013 times in 2023. This implies that the number of individuals seriously hurt in accidents may rise in a given year particularly as dense fog conditions remain a significant contributing factor to road accidents along with other environmental factors, significantly contribute to road accidents.

A. Dense Fog Conditions and Environmental Impact

Climate has a profound influence on human life however, low visibility condition such as fog, lead to low visibility, reducing drivers' ability to perceive and react to obstacles on the road while reducing situational awareness. This leads to an increased risk of accidents, as drivers may fail to detect slowing or stopping vehicles in time to respond appropriately [23]. Such environments often distort visual cues, further complicating navigation and increasing the likelihood of accidents, particularly in high-speed or congested traffic areas [24]. In both ahead and behind, thereby posing significant challenges to safe driving [25]. By employing advanced driving safety mechanisms, motorists can gain enhanced situational awareness of their surroundings [26]. Which emphasizes the need for effective warning systems and preventive measures to ensure road safety [27]. Due to the difficulty drivers face in detecting objects and vehicles in time to react appropriately especially under low visibility conditions, road accidents have become a serious concern in Pakistan, with the 2021 statistics which shown in Table III.

TABLE III COMPARISON OF ROAD ACCIDENT BETWEEN RURAL AND URBAN AREAS

Month	Rural Areas (%)	Urban Areas (%)
January	7.4	3.5
May	5.5	4.0
July	6.0	4.5
October	5.5	4.0

In 2021, road accidents in Pakistan as shown in Table III were more frequent during the month January, May, July, and October with 7.4, 5.5, 6.03 and 5.5 percent. The higher number of accidents in these months can be attributed to factors such as poor weather conditions and fog, which create hazardous driving environments. Additionally, rural areas accounted for 53.5% of the total accidents, with 63.4% of fatalities occurring in these areas, highlighting the greater risks in rural regions compared to urban areas. The most common times for traffic accidents were between 1500 to 1800 hours, (16.7%), 1800 to 2100 hours (16.6%), and 0000 to 0300 hours (6.3%) attributed to dense fog during those hours [28]. Human existence is impacted by climate change, as the ecology and air quality are impacted by growing industrialization and rising vehicle traffic. Due to decreased visibility, bad weather such as fog and haze plays a major role in traffic accidents. Fog which is known as mobile killer, significantly reduces visibility and makes driving difficult which increases the number of traffic accidents. According to statistics, accidents that occur on foggy days are 1.86 times more fatal than those that occur on clear days. In addition to impairing traffic safety, Fog also causes significant delays in transit on roads, trains and airports.

III. PROPOSED ARCHITECTURE

The proposed architecture integrates IoT sensors and a mobile application to enhance real-time monitoring, safety, and emergency response. It includes essential hardware and software components as shown in Table IV.

TABLE IV SIMULATION AND PROTOTYPE SPECIFICATIONS

Sr. No	Components	Description	
1	Arduino Uno	At mega 328p	
2	Buzzer / Alarm	5v	
3	LED Light	3.3 v	
4	WIFI Module	Esp. 8266	
5	Ultrasonic sensor	HC-SR05	
6	IMU Inertia Sensor	MPU 6050	
7	Arduino IDE	PL; C, C++, Java	
8	Proteus, Thinkercad	EDA Framework	

By lowering cloud-related latency and enhancing real-time data processing, fog computing improves IoT-based collision detection and warning systems. It improves public safety and disaster response by increasing emergency communication's efficacy, dependability, and affordability through the integration of mobile sensors and data decentralization at the network edge [29, 30]. This proposed study presents a cost-effective and user-friendly accident detection system and early warning system which utilizing the Blynk application, the system architecture is shown in below Fig. 2.

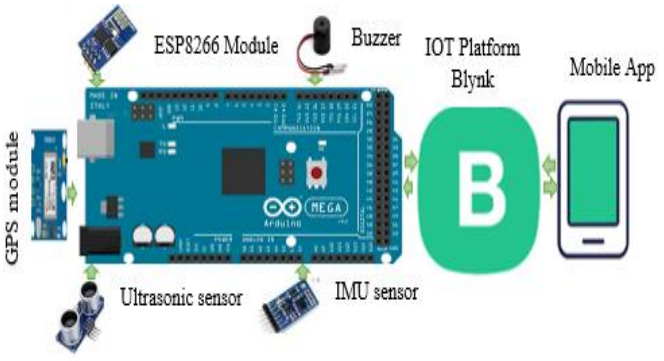

Fig. 2. The system architecture.

Blynk application provides real-time monitoring, control, real-time location, and alerts. This design demonstrates the versatility of Arduino hardware and Blynk as an intuitive human-machine interface (HMI), enabling efficient remote monitoring and control for modern automation applications. The key components included in this design are databases for effective data management and response, automated alerts, accident detection and early warning system.

A. Early Warning System (EWS)

Through sensor integration, the early warning system for collision detection continually monitors the distance between vehicles and surrounding objects to increase vehicle safety. The device reduces the possibility of crashes by sending out alerts when the front or back of the car gets near dangerously close distances from close obstacles.

B. Accident Detection

This module uses cutting-edge sensor technology to identify collisions and assess their severity. It gathers vital information about accidents, such as location and impact force, allowing for precise event identification, analysis, and action.

C. Notification

Once the accident is detected, an alarm will start for 30 seconds. Only information about local mechanics will be provided to the registered mobile, if the driver of the vehicle resets the alarm. Otherwise, the location is transmitted to the local police station and hospitals, if the alert is not reset.

D. Databases

To make operations more efficient, the proposed system uses a user details database, a vehicle database, a hospital database, and a police station database.

IV. Methodology

In everyday scenarios, accidents frequently occur due to various factors. The inability of vehicle operators to detect obstacles in front or behind significantly hinders their ability to prevent collisions, particularly in the absence of autonomous control systems [31]. By utilizes IoT sensors and cameras to gather real-time traffic data, which is processed using deep learning models and cloud computing [32]. It is a vital component of Intelligent Transportation Systems (ITS) by integration of IoT devices, sensors, cameras and related technologies facilitates the acquisition of real-time data on road and traffic conditions [33]. Which gathers, processes, and stores real-time road information, providing updates on traffic congestion and incidents via a roadside message unit. The system uses magnetic sensors and microcontrollers to process data, offering early warnings to improve traffic flow and save time [34]. And clustering algorithms performed on an Android device to processed data which shared with drivers' mobile application, providing real-time updates on traffic congestion and incidents through roadside messaging devices [35]. This enables real-time road condition monitoring, reducing accidents and fuel consumption, while providing drivers and commuters with access to real-time traffic updates via a using advanced technology [36]. To address the constraints of accident detection systems, this study offers an innovative approach to constructing a smart reporting and control system using Blynk application. Fig. 3 shows the block diagram for the IOT-based real-time collision detection system.

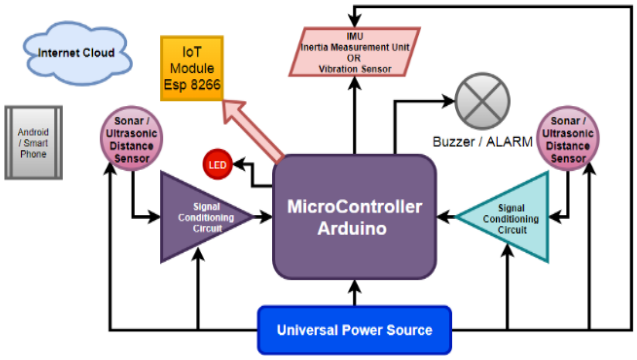

Fig. 3. Block diagram.

The approach uses the Blynk app to build a graphical user interface (GUI) for system control and real-time data collection. In contrast to traditional systems, this method integrates Arduino with the Blynk application without the need for specialized hardware, emphasizing simplicity and cost-effective.

The architecture of system follows a layered design, with each layer performing a distinct function as shown in Fig. 4.

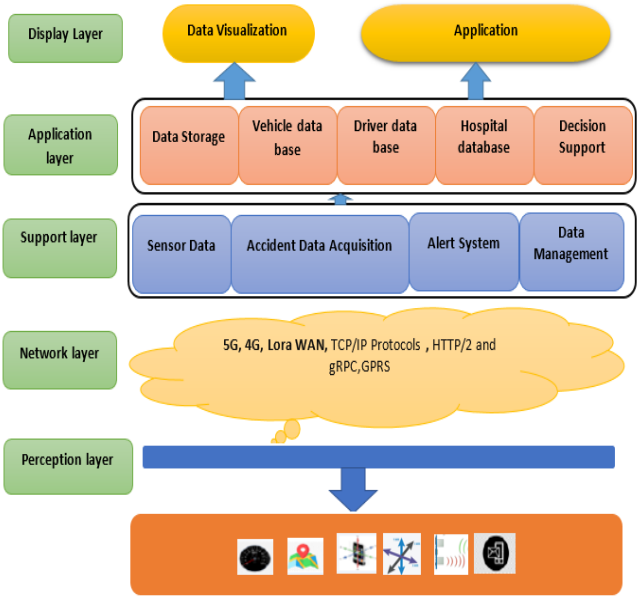

Fig. 4. Layered system architecture.

The system architecture consists of multiple layers, starting with the perception layer, which collects sensor data (speed, motion, and environmental parameters) using Arduino boards. This data is transmitted via the network layer, which bridges communication to the edge and cloud layers for processing and decision-making. The application layer stores critical information, while the application layer, powered by the Blynk app, provides a user interface for real-time monitoring, control, and notifications. This layered design demonstrates a robust, scalable and user-friendly automation system integrating IoT for efficient remote management.

The initial step involves establishing an interface between the microcontroller and the internet to enable smooth communication and data exchange. This connection forms the foundation for the system's functionality, ensuring real-time data transmission and processing capabilities. The algorithm detailing this process is outlined in Algorithm 1.

Algorithm 1: For internet interfacing of microcontroller

```
Input Data: Auth_Token, COM_Port
Output: Communication Status
Initialize
    Communication status ← ← 0
      Upload Blynk libraries to Arduino IDE.
       Generate Auth_Token in Blynk App and paste in serial USB
.          Blynk library file.
           Compile and run the program in Arduino IDE.
        Open `<<blynk-ser.sh` script and input COM_Port.
   If
       Arduino connects successfully ← ← 1
            communication status = 1:
          Play the Blynk App.
   else:
       Communication Status = Error.
  End
```

After successfully interfacing, the algorithm for sensor data acquisition and transmission to a remote location via the Internet outlines. The process for collecting sensor data and ensuring efficient real-time communication with remote systems. The detailed steps are presented in Algorithm 2.

Algorithm 2: For sensor data acquisition

```
Input: Sensor_Status
Output:  Notifications(1,0)
 Initialize
      Sensor_status ← ← 0
       Connect sensor to Arduino, Signal_Conditioning_Circuit.
            Calibrated_data ← Map  (Sensor_signal, Calibration).
         Add Calibrated_data to "Serial USB Blynk" library.
      Compile and upload the program to Arduino.
        Create GUI in Blynk app for user interaction and Run.
      If  data is displayed correctly: sensor_status ← ← 1
   If
       sensor_status = 1:
      Data_Acquisition_Status = Successful
  else:
       Data_Acquisition_Status = Error.
  End
```

After the successful execution of sensor interfacing and data acquisition. Fig. 5 illustrates the integration of hardware components, such as sensors and microcontrollers, with software systems. This combination ensures efficient data collection, processing, and transfer over the Internet, enabling smooth operation and reliable connectivity. The diagram also demonstrates how the application interfaces with the Internet cloud, ensuring real-time data synchronization. Furthermore, it highlights the connection between the Arduino and the sensors section, facilitating communication with the vehicle. The Blynk app GUI, developed in the Blynk app, enables users to receive notifications or alerts in the event of a collision or emergency, enhancing the system's responsiveness and user interaction. The architecture is a scalable solution, adaptable to various automation and IoT applications.

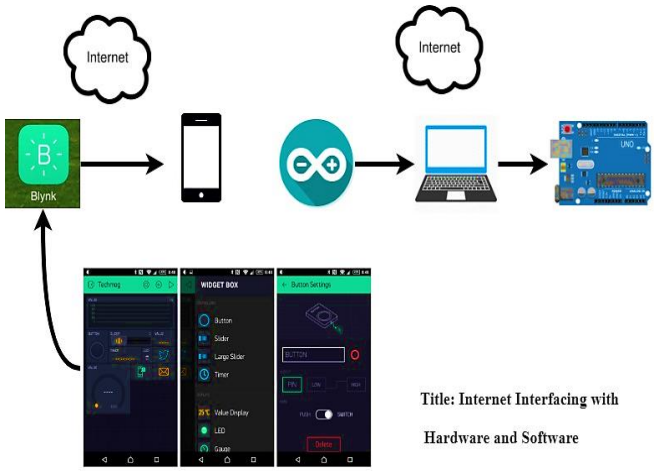

Fig. 5. Internet interfacing with hardware and software.

Building on the architecture explained, the system incorporates several features to improve efficiency and safety under varied circumstances. By using sensor data to deliver timely alerts, the early warning system enhances driver response and hazard detection. An IoT-based Android app and web server support real-time data processing and communication, allowing for smooth user system interaction. By maintaining appropriate vehicle distance, advanced techniques like distance estimate and calculation assist prevent accidents in difficult situations like dense fog. When combined, these elements guarantee a thorough strategy for preventing accidents, enhanced traffic control and monitoring.

A. Early Warning System

Early warning system enhances vehicle safety by using ultrasonic sensors to analyze distances and instantly identify potential accidents in real-time. It uses high frequency sound wave reflections to assess distance and operates on preset thresholds to provide audible and visual alerts to enhance situational awareness and prevent accidents. The distance d is calculated using the following equation [37].

$$d = V.\frac{t}{2} \tag{1}$$

Where v is the speed of sound and t is the time of flight, division of 2 accounting for the signal's round trip. The sensor emits a signal and measures the echo to calculate object distance, the threshold of 170 centimeters is set, and if the distance falls below this limit, it triggers an alert to warn the driver.

$$A=\begin{cases} if\ D < 170\ cm\ (Active\ alert) \\ if\ D > 170\ cm\ (No\ alert) \end{cases} \tag{2}$$

This threshold is designed to detect proximity risks that could result in an accident while reducing false alerts brought on by minute changes in distance. When the distance (d) falls below the threshold, the alarm mechanism is activated, triggering a flashing LED for visual warning and a buzzer for audible warning, represented by the alert function. The alert function A is represented as in Algorithm 3.

Algorithm 3: For alert mechanism

```
Input: Measured Distance (d)
Output:  Notifications ,  Alert collision status
 Initialize
       Collision_Alert ← 0
         Calculate the distance to the closest object.
        Measured_Distance  ← d
       Check if D is below the collision threshold:
    If
          d < 50:
        Collision_Alert ← 1
         Visual_Alert=Active
          Audible_Alert()=Active  // Trigger buzzer sound
        Notify_IoT_Network()= successful
       Send real time location and collision warning
   Else
        Collision_Alert ← 0
          Alerts ← "Deactive"
             Visual_Alert()= Deactivate
         Audible_Alert()= Deactivate
      Return Collision_Alert status:
  If
         Collision_Alert = 1:
        Status ← "Collision detection Alert Active"
   Else:
        Status ← "No Risk Detected"
 End.
```

B. Iot Module for Detecting Accident

Based on preset force and speed parameters, IOT module uses a force sensor on the car to identify collisions. A 30-second alarm is set off when an accident is detected. The driver can use a button to reset the alert if the event is small. If the system is not reset, it uses a GPS and an ESP8266 module to send an accident notification, which is shown on an LCD screen. For enhanced monitoring, vehicle information with location is also sent to a mobile device. An accident will happen if the values of force and speed are above a certain threshold, T_{speed} and T_{force} which is illustrated in Algorithm 4 [38].

Algorithm 4: For Accident Detection and response

```
Input: Speed(S) and Force(F)
Output: Accident_Status(AS)
        acc ← 0
  If (F > T_force )AND S > T_speed OR (F > T_force OR S > T_speed):
         acc ← 1
  If acc = 1:
        Activate_Alarm (AT)
            AT ← 0
            Alarm_Timer ← Alarm_OFF ()
          If AT ≥ 30sec:
        Accident_Status ← "Accident Detected"
  else:
           Accident_Status ← "No Accident Accident"
             Notify_Owner ()
  If Accident_Status = "Detected":
        GPS_Location ← Get_Location ()
       Rescue_Operation (Nc)
         Hospital(x(t)
        Notify_Owner(v(t))
 End
```

The system utilizes ensemble transfer learning with dynamic weight adjustments to minimize false detections. To find the nearby hospital and police station, use the Haversine formula, which determines the shortest path between two points. The Haversine formula can be expressed as [39].

$$\text{Haversin } (\theta) = sin\text{^}2\left(\frac{\theta}{2}\right) \quad (3)$$

Is an application of the Haversine formula**,** which is used to calculate the great-circle distance between two points on a sphere given their latitude (ϕ and longitude (γ).

$$\frac{d}{2} = haversine(\phi 2 - \phi 1) + cos(\phi 1) \cdot cos(\phi 2) \cdot haversine(\gamma 2 - \gamma 1) \quad (4)$$

Where d is equal to;

$$d = r \cdot hav^{-1}(\sqrt{h}) \quad (5)$$

By substitution equation 4 into equation 5 then we get.

$$d = 2r \cdot arcsin(\sqrt{sin\text{^}2(\phi 2 - \phi 1/2) + cos(\phi 1) \cdot cos(\phi 2) \cdot (sin\text{^}2(2\gamma 2 - \gamma 1)/2)} \quad (6)$$

Where d is the distance between the two points on the surface, r=6371 km and ϕ1, ϕ2 is earth radius, Latitudes of the two points. λ1, λ2: Longitudes of the two points γ, γ. This equation is used to calculate distances to nearby services and identifies the nearby facilities. It retrieves vehicle and service details, then sends a notification via GPS to relevant parties here is a flow chart of all procedures as shown in Fig. 6.

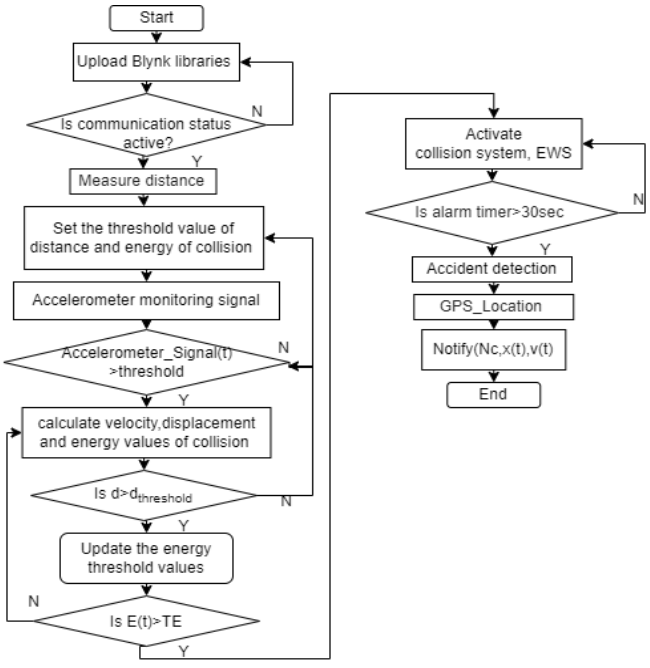

Fig. 6. Flow chart.

The flowchart illustrates a collision detection process using accelerometer data. Setting threshold values for variables like displacement and collision energy. The system continuously

monitors accelerometer signals to check, if the acceleration exceeds the threshold, the system detect noise to improve detection accuracy including impact noises from accidents and then also check energy value. If it's not, the energy threshold values are updated by the system. Lastly, the collision system is triggered, indicating a possible collision, if the energy value is over the threshold. The velocity, displacement, and energy parameters utilized in the collision detection method are calculated using the following below formulas [40].

$$a(t)=Accelerometer\_Signal(t)$$

$$a = \frac{dv}{dt} \tag{7}$$

Where *a* is acceleration which is continuously monitored in the IoT system using accelerometer sensors. Sudden spikes in acceleration may indicate abnormal events like a collision.

$$v = \int a dt = \frac{dx}{dt} \tag{8}$$

Acceleration over time is integrated to calculate velocity (v), which gives information about vehicle speed. Abrupt deceleration is a key accident indication.

$$\mathrm{x} = \int v dt = \iint a dt dt \tag{9}$$

Where x is displacement, this parameter tracks the movement of the vehicle and helps assess whether it stopped or deviated significantly due to a collision.

$$J = \frac{da}{dt} \tag{10}$$

Where J is Jerk, high jerk values are often associated with collisions or sudden stops.

$$e = \int_{X0}^{X} a\, dx = \int_{v0}^{v} v\, dv = \frac{1}{2}(v^2 - v_0^2) \tag{11}$$

Sudden spike in energy density (e) suggests a potential collision which can represented as the following equation.

$$E = \frac{1}{2}m(v\text{^}2 - v_0^2) \tag{12}$$

The IoT system calculates the kinetic energy (E) of the vehicle using its mass and velocity.

$$v(t) = \int_0^t a(\tau)\, d\tau \tag{13}$$

Calculating distance (d) by integral of the velocity function.

$$d(t) = \int_0^t v(\tau) d\tau = \int_0^t (\int_0^t a(\eta) d\eta) d\tau \tag{14}$$

Power (E) represents the rate of energy transfer.

$$E(t) = \frac{1}{2}mv^2(t) \tag{15}$$

An IoT module tracks power to evaluate how quickly the vehicle's energy changes, for identifying abnormal scenarios.

$$If\ d(t) > d_{threshold}$$

It checks the threshold, if it satisfies this condition update energy threshold value and continue. And also check if;

$$a(t) > a_{threshold}(TA), d(t) > d_{threshold}(TD), (E(t) > E_{threshold}\ (TE)$$

Where TA is pre-set threshold for acceleration, TD is pre-set threshold for displacement and TE is pre-set threshold for energy and the collision system (A) define the system state:

$$Collision\_System(t)=A=1,0$$

$$A(t) = \begin{cases} 1; if\ (a(t) > a_{threshold}) \wedge (d(t) > d_{threshold}) \wedge (E(t) > E_{threshold} \\ 0; otherwise \end{cases} \tag{16}$$

As IoT sensors also detect noise to improve detection accuracy, including impact noises from accidents. The system can more accurately detect accidents and lower false alarms by integrating noise data from microphones or sensors.

$$N_c = N_{dB} \cdot f(SVP(t)) \tag{17}$$

Overall accident detection model is expressed as high-speed accident condition which is:

$$1\ if\ \big(a(t)\big) + \frac{N_{dB}}{140} + \frac{SVP(t)}{2.06} \geq T_A AND\ v(t) \geq T_S \tag{18}$$

And low-speed accident condition which is:

$$1\ if\ (a(t) + N_c) \geq T_A AND\ v(t) < T_S AND\ x(t) \geq TD \tag{19}$$

If above all conditions are staisfied then, check energy;

$$A(t) = \begin{cases} 1, if\ E(t) \geq TE\ \ (Accident\ Detected) \\ 0, otherwise\ \big(\ No\ Accident\big) \end{cases} \tag{20}$$

The system activates when the collision system (A) is equal to 1 only when all conditions are satisfied, 0 otherwise. When accident detected the system send notify service or emergency contacts of current location

$$\mathrm{Ambulance\_Route} = \mathrm{Find\_Path(x(t), Hospital\_Location)}$$

$$Notify(Nc, x(t), v(t))$$

$$If\ no\ confirmation\ within\ a\ set\ time\ (t_c)$$

$$False\_Alert = 1$$

The procedure is illustrated as in Fig. 7.

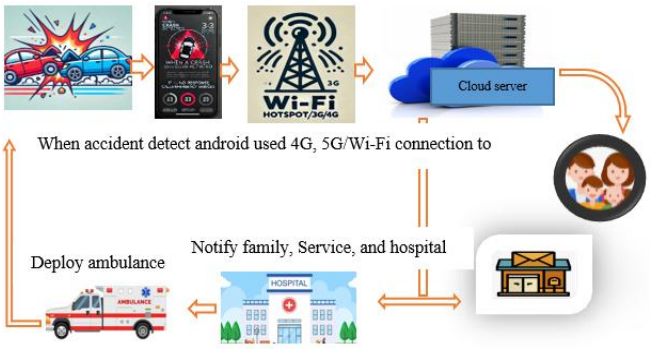

Fig. 7. Accident detection and emergency response system.

Using a smartphone's built-in sensors, GPS sensor, and accelerometer, the identification procedure aims to identify when an accident is occurred. These sensors are used in the proposed technique, which is depicted in the block diagram, for precise and effective automated accident detection. By integrating IoT technology, vital information regarding serious traffic accidents

is sent to local police and hospitals, ensuring a timely and well-coordinated emergency response [41].

C. The Iot-based Android App and Web Server Design

After accident detection, the system promptly transmits data to android app or web server and sends SMS notifications to the victim's emergency contacts and relevant authorities [42]. And to determine the victim's location, including necessary details the system utilizes GPS, GSM, Wi-Fi module, MEMS sensors, and a microcontroller [43]. And a vibration sensor to detect collision impacts and a gyro sensor to monitor angular displacement. Upon detecting an accident, the system captures the vehicle's GPS coordinates and transmits them via GSM to emergency services and also alert displayed on mobile devices [44]. Additionally, users are prompted to input contact details for trusted individuals, who can be alert in case of an emergency. This demonstrates the potential for integration into vehicles to improve accident detection and reporting systems for faster medical and rescue responses. The focus of this work is to design software and development of the application, ensuring seamless integration with IoT hardware for accurate and reliable accident Monitoring and alert [45]. The proposed system is designed with Blynk integration, allowing users to register and log in to a mobile app that continuously monitors sensors, including the accelerometer and GPS for accident detection. Which is user-friendly interface for real-time data collection and monitoring which enabling efficient integration with IoT-based accident detection systems. Fig. 8 illustrates the complete process for developing an android-based IoT app that supports accident detection and notification.

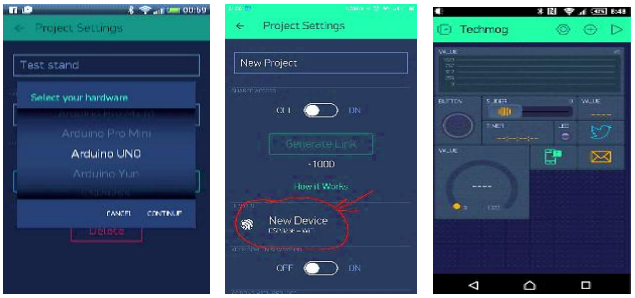

Fig. 8. Andriod application interfaces.

After completion of the above procedure, run the project by clicking on the run icon. The designed GUI will automatically run and data acquisition and control action can be achieved by this smart HMI.

D. Accident Prevention Technique in the Fog Environment

Fog diminishes visibility in outdoor pictures due to airflow absorption and light diffraction. Images shot outside are affected by a number of aspects, including dense fog, haze rain and adverse winter weather which result in reduced visibility. It made more difficult for drivers to detect other cars and obstacles, which has increased the number of traffic accidents. To overcome, this section provides a detailed description about the suggested system, integrated advance framework which uses subtractive blocks, adaptive multi-scale feature sharing, and contrastive regulation to Enhance image resolution, captures by front in real-time footage while driving in dense foggy weather, sends the frame to the image processor, which converts the foggy image to a defogging image. Dual streams manage multi-weather restoration, successfully reducing fogging and rain distortions [46]. Smart Road Safety and Vehicle Accident Prevention System (SRSP) integrates IoT, AI, and ML to improve road safety and preventing accidents. It utilizes a sensor network to collect real-time data, weather, and traffic density. Artificial intelligence models analyze this data to predict potential hazards and accident-prone areas by utilizing V2I and V2V communication for proactive safety measures, including smart speed regulation, hazard alerts, and automated emergency braking. In collision scenarios, the SRSP provides automatic notifications to drivers, nearby vehicles, and emergency services, enabling timely intervention as the process illustrated in below Fig. 9 [47].

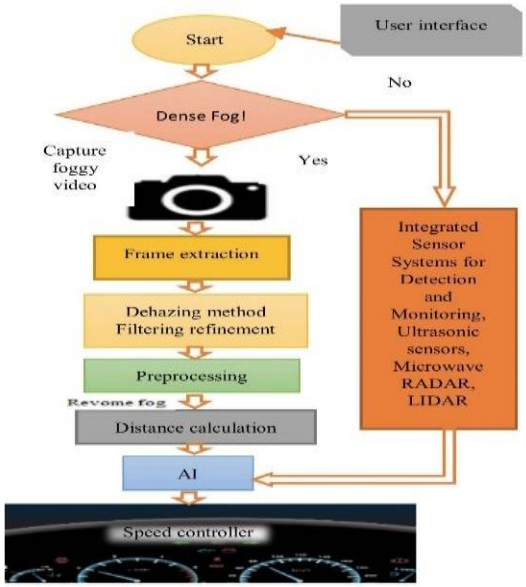

Fig. 9. Accident prevention technique in fog environment.

In order to improve efficiency and reliability in foggy weather conditions, the system utilizes the integration of edge computing and the Internet of Things. It presents a smart surveillance approach that reduces response times within intelligent transportation systems (ITS). While offering a comprehensive solution to mitigate the risks management, thereby saving lives, and diminishing the economic and preventing accidents. By utilizing an RFID-based system, incidents are quickly reported to the nearest field force, improving overall ITS efficiency [48]. And alert drivers to self-visual distraction when it occurs. Which utilized Convolutional Neural Networks (CNNs) to identify features and patterns indicative of erratic weather conditions [49]. The Proposed vehicular model improves upon the limitations of the intelligent driver model by embedding visibility factors to more accurately depict traffic patterns under adverse weather conditions, such as fog. In this model, vehicle acceleration is expressed as;

$$\frac{d_v}{d_t} = a_{max}\left(1 - \left(\frac{v}{v^0}\right)^{\delta} - \left(\frac{s^*}{H}\right)^2\right) \quad (21)$$

Where, a_{max} is the maximum acceleration, H is the distance headway and s∗ is the desired distance headway which is given by [50].

$$s^* = s_j + Tv + \frac{v\Delta v}{2\sqrt{a_{max}a_{min}}} \quad (22)$$

A variable (δ) acceleration exponent is proposed to integrate driver reaction time, distance headway, and weather conditions for a more accurate representation.

$$\delta = \frac{T_r}{H}\left(\frac{V_d}{V_{d_{max}}}\right) \quad (23)$$

Visibility (V_d) represents the distance a driver can see during fog, with $V_{d_{max}}$as the maximum visibility [51]. The proposed model is developed by substituting Eq. (23) into Eq. (21).

$$\frac{d_v}{d_t} = a_{max}\left(1 - \left(\frac{v}{v^0}\right)^{\frac{T_r}{H}\left(\frac{V_d}{V_{d_{max}}}\right)} - \left(\frac{s^*}{H}\right)^2\right) \quad (24)$$

The model incorporates visibility, providing a more accurate and realistic representation of traffic behavior compared to the ID model, Traffic flow adjusts to visibility depending on density and velocity, where density is the inverse of equilibrium headway by using the equation, which is q=ρv [52].

$$q = \frac{1}{H_e}v \quad (25)$$

Where H_e is;

$$H_e = \left(S_j + Tv\right)\left(1 - \left(\frac{v}{v^0}\right)^{\delta}\right)^{-0.5} \quad (26)$$

Also

$$H_e = \left(S_j + Tv\right)\left(1 - \left(\frac{v}{v^0}\right)^{\frac{T_r}{H}\left(\frac{V_d}{V_{d_{max}}}\right)}\right)^{-0.5} \quad (27)$$

Substituting, Eq. (26) and Eq. (27) in Eq. (25) gives the flow for the ID and proposed models as:

$$q = \frac{v}{(S_j+Tv)\left(1-\left(\frac{v}{v^0}\right)^{\delta}\right)^{-0.5}} \quad (28)$$

And

$$q = \frac{v}{(S_j+Tv)\left(1-\left(\frac{v}{v^0}\right)^{\frac{T_r}{H}\left(\frac{V_d}{V_{d_{max}}}\right)}\right)^{-0.5}} \quad (29)$$

This model provides a more precise representation of traffic flow (q) under various situations by taking into consideration velocity, visibility, and headway characteristics. For accurate forecasts, the model adjusts traffic flow to visibility, making it big in clear weather $V_d = V_{d_{max}}$ and small in foggy $V_d < V_{d_{max}}$. After completing all the processes images are sent to The AI engine, regulates the vehicle's speed, as illustrated in the schematic representation of the accident prevention technique for foggy environments in Fig. 9. In bad weather, timely obstacle detection depends on accurate distance estimation and calculation, to improving overall safety.

E. Distance Estimation and Calculation

Vehicles on the highway use equation (37), to determine the distance (d) between themselves and receiving GPS data from other cars by utilizing the equation (38). The side view includes camera height (h_c), the road normal vector (n), the ray vector to the measuring point (ψ), and the angle (α), which assist in calculating the distance (d) from the camera as shown in Fig. 10.

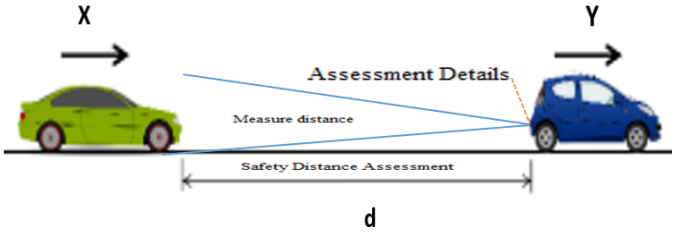

Fig. 10. Distance estimation process.

By using the image coordinates (x_p, y_p), the point can be reconstructed in homogeneous coordinates as:

$$Ph = \begin{bmatrix} x^p \\ y^p \\ 1 \end{bmatrix}^T \quad (30)$$

Using the following formula, determine the vector indicating the projection's direction from this location as;

$$\psi = k^{-1}.P_h \quad (31)$$

And camera height (h_c) and the road normal vector (n) [53].

$$n = k^T \cdot h_{hom} \quad (32)$$

Where,

$$h_{hom} = \left(\frac{\tilde{m}_h}{\tilde{b}_h} - \frac{1}{\tilde{b}_h}\ 1\right)^T \quad (33)$$

And using the back-projection ray (ψ) from the above equation, the distance (d) between the camera and the object can be calculated by applying right triangle geometry;

$$d = h_c tan\alpha \quad (34)$$

By simplifying the above equation 34.

$$d = h_c.\frac{sin\ \alpha}{cos\ \alpha} \quad (35)$$

As h_c is constant and |ψ| and |n| represent vector magnitudes.

$$d = h_c.\frac{|\psi| \cdot |n| \cdot sin\ \alpha}{|\psi| \cdot |n| \cdot cos\ \alpha} \quad (36)$$

So using the cross and dot product relation d is given by

$$d = h_c.\frac{|\psi \times n|}{\psi \cdot (-n)} \quad (37)$$

This method improves advanced driver assistance systems and encourages safer autonomous driving by providing accurate distance calculation. Distance estimation using GPS information of the other vehicles, the distance (d) between its vehicle as shown in below Fig. 11 and the other vehicles calculates the distance using the below Eq. (38).

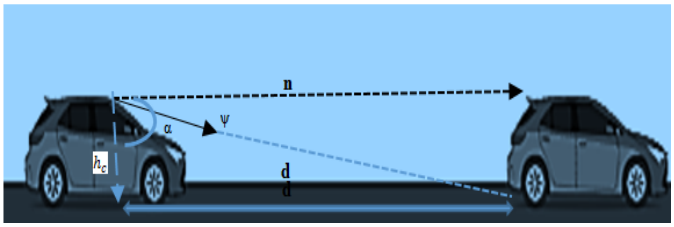

Fig. 11. Real-time vehicle safety distance.

Consider two cars, X and Y, in Fig. 11, where X is the one in front and Y is the one behind it moving faster than X.

Where,

lat_x, lon_x: *Latitude and longitude of Vehicle x*

lat_y, lon_y: *Latitude and longitude of Vehicle y*

$\Delta_{lat} = lat_y - lat_x$: *Difference in latitude*

$\Delta_{lon} = lon_y - lon_x$: *Difference in longitude*

To compute distance (d) [54].

$$d = R.C \tag{38}$$

Where R: Earth's radius (R=6371 km) and C is equal to;

$$C = 2 \cdot atan2\left(\sqrt{A}, \sqrt{1-A}\right) \tag{39}$$

And A is equal to;

$$A = sin^2\left(\frac{\Delta_{lat}}{2}\right) + cos(lat_a) \cdot cos(lat_b) \cdot sin^2\left(\frac{\Delta_{lon}}{2}\right) \tag{40}$$

After distance is calculated, to activate control measures for Vehicle x based on the threshold distance $d_{threshold}$ control;

If d $\leq d_{threshold}$, activate control system for Vehicle x

This ensures safe braking and speed reduction.

else If d $> d_{threshold}$, no control measures are activated

The AI engine uses calculated distance to prevent accidents, especially in adverse weather.

V. Results

When victims are unable to ask for assistance after an accident, the advanced sensor integration increases the chance of saving lives by continually monitoring for traffic accidents and instantly sending emergency alerts to nearby rescuers. This solution secures and speeds up the alerting process by integrating all required components into a single system. During emergencies, the system assists in forwarding requests to the relevant emergency medical services (EMS) providers to help quickly manage emergencies by providing nearby incident details. Gravitational force values, speed, and pressure were evaluated under various driving circumstances to evaluate the threshold. The maximum G-force recorded was 3.1 G. These tests verify how well the Android app reacts to changes in the environment in real time as shown in below Fig. 12.

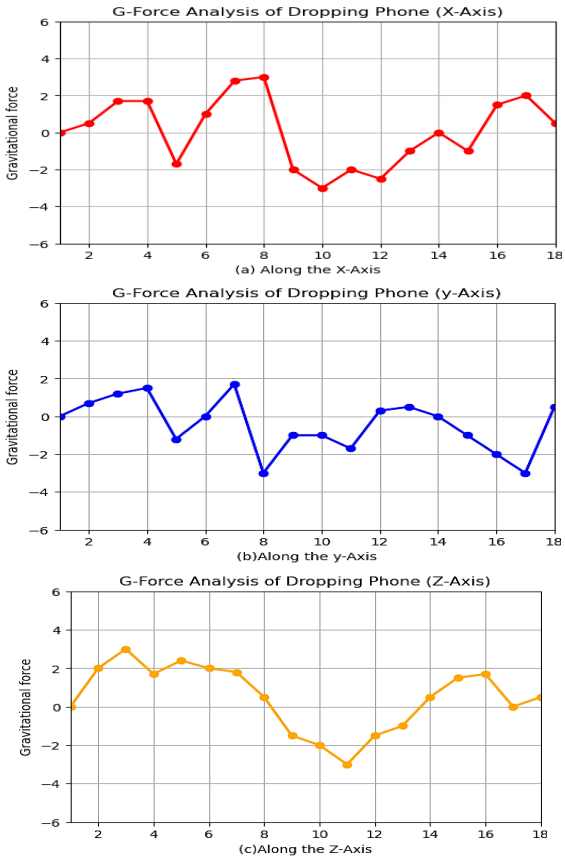

Fig. 12. Values of G-force while dropping a smartphone (a, b, c).

We recorded the result of testing a smartphone by dropping it up to eighteen times. We found that an alarm is not set off by unintentional drops. However, if the g-force exceeds 4 g, the proposed system generates an alert.

A vibration sensor activates the collision detection system in the event of an accident, by providing visual feedback via a blinking LED and sound alarm. When the sensor detects abrupt changes in motion or impact force, the system is alerted to react instantly as shown in Fig. 13.

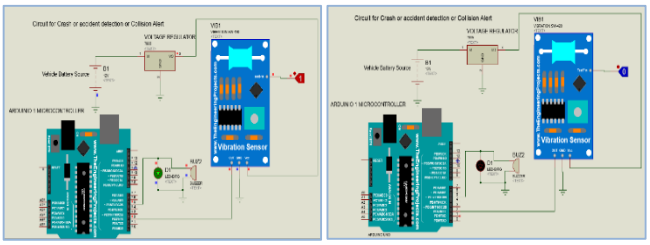

Fig. 13. Simulation of collision detection circuit.

The system can be further integrated with external modules to automatically send alerts or location data to emergency services for faster assistance. The graph demonstrates the output performance of the vibration sensor with time, sensor readings compared to an adjustable threshold level, as in Fig. 14.

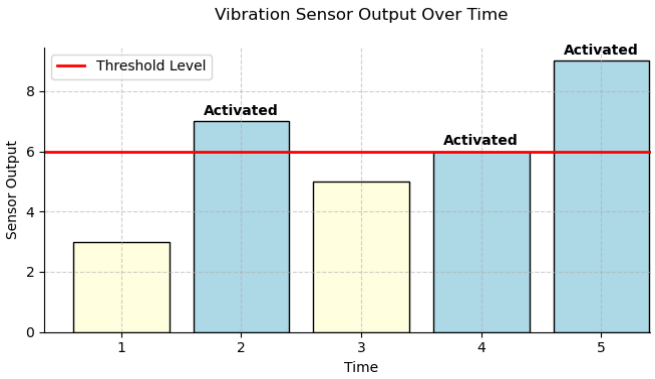

Fig. 14. Output performance of the vibration sensor.

To ensure validation, reliability, and accuracy of the proposed system, incorporating the design system into MATLAB software before implementation. Through this approach, the simulation process enables testing of the collision detection system under various scenarios and validates its capability to assess system performance. The performance in both normal and collision-activated scenarios is demonstrated by the simulation results as shown in Fig. 15.

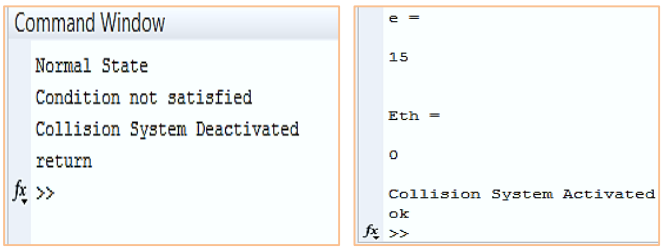

Fig. 15. Simulation result using MATLAB.

These results validate the system's ability to monitor parameters and transition states based on energy thresholds.

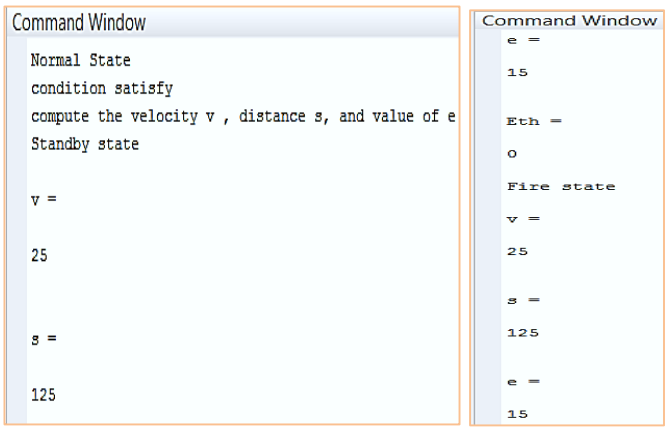

Fig. 16. Simulation results using MATLAB tool.

The simulation results as in Fig. 15 and Fig. 16 indicate that the collision detection system controlled by the energy (e) and threshold (Eth) parameters. When the threshold energy (Eth) drops to zero during a fire, the system alters from a normal to a fire state and activates the collision mechanism.

The collision system uses an ultrasonic sensor to monitor the distance between vehicles, simulation shown in Fig. 17.

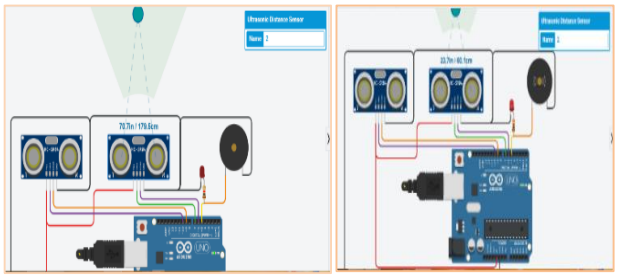

Fig. 17. Simulation of collision detection and warning system.

When a vehicle is detected at a distance of approximately 178cm, the system remains inactive, and no alarm is triggered which is illustrated in Fig. 18. However, when the distance reduces to 58 cm the system activates, signaling a potential collision scenario and triggering an alarm.

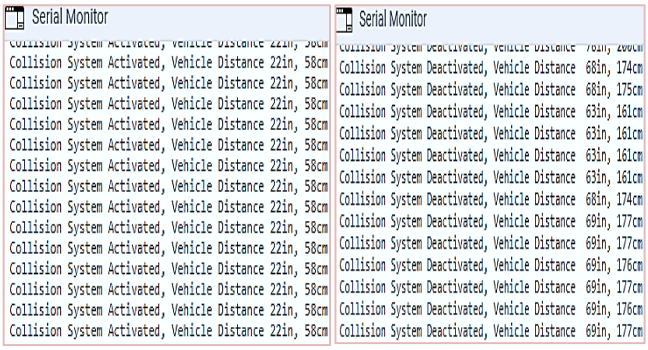

Fig. 18. Vibration sensor serial output.

The results show that the collision detection system stays inactive at a safe distance of 174 cm and the system is active when the distance drops to 58 cm.

We carried out more tests to confirm the system's functionality. Fig. 19 shows the results of these tests, which demonstrate the system's ability to function reliably and efficiently in a variety of situations.

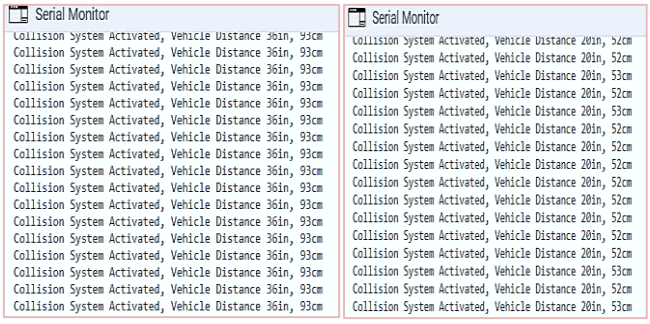

Fig. 19. Output tested results on serial monitor.

These outcomes show that the collision system remains inactive at a safe distance but activates when a car enters the threshold distance, ensuring front and rear collision awareness and enhanced safety response measures.

The graph offers insights into system performance and operating patterns over time by providing an extensive visualization in real time that were captured throughout the monitoring process as shown in Fig. 20.

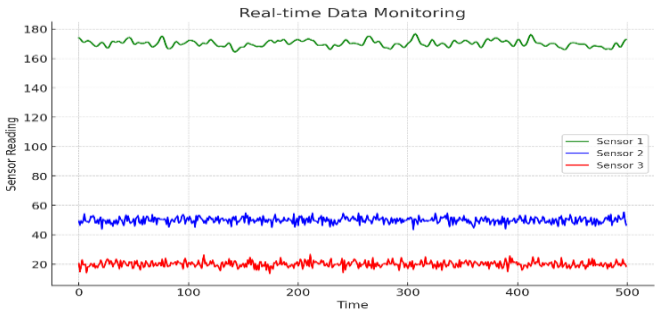

Fig. 20. Sensors data monitoring.

The accident detection system in operation is seen in Fig. 21 which shows the location tracking system giving real-time route direction to the accident scene, and smartphone alert notification of accident detection. This shows that the system detects risks and facilitates timely emergency action.

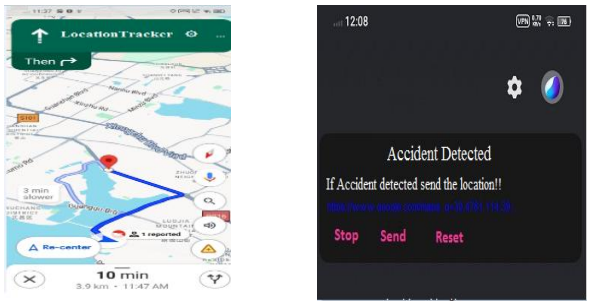

Fig. 21. Real-time accident alert and ambulance interface.

The experimental setup intended for the automated identification of accidents is depicted in Fig. 22.

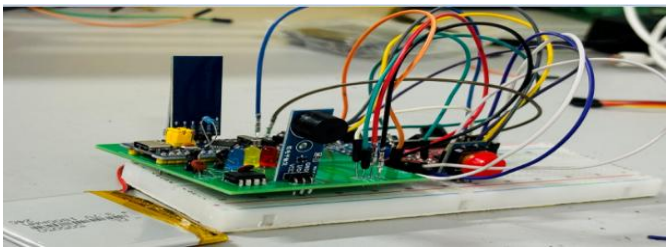

Fig. 22. Experimental setup.

The efficacy and performance of the collision system are displayed in two states in the graph below Fig. 23.

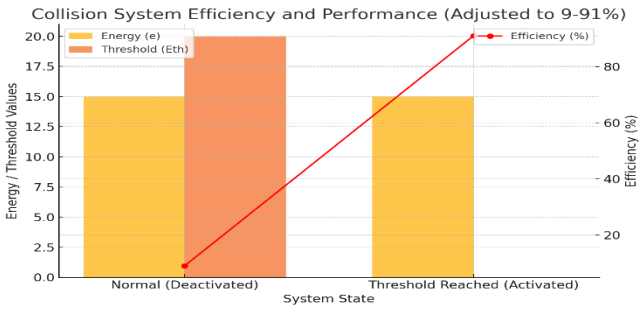

Fig. 23. System efficiency and threshold analysis.

The system activates with 91% efficiency at a zero threshold and remains inactive under normal conditions to prevent false alarm. The simulation results are shown in Fig. 24, which show that the system utilizes real-time data to identify incidents and initiate the proper reaction mechanisms.

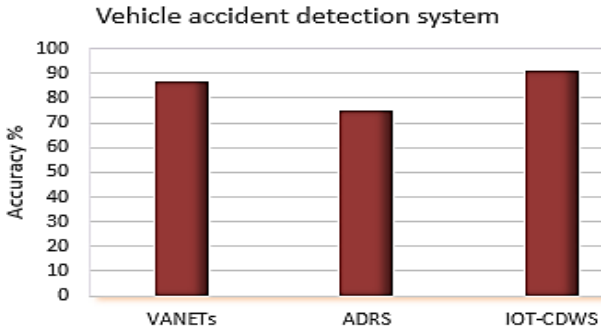

Fig. 24. Accident detection comparison.

The execution times of two current methods VNETs and ADRS with proposed IOT base system (IOT-CDWS), which consistently performs above the others in all eight combinations, illustrating an execution time savings of up to 17% as shown in Fig. 25.

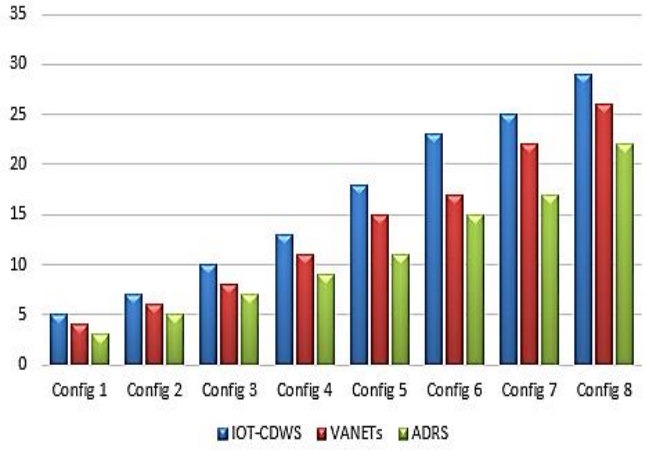

Fig. 25. Configuration compression.

When compared to VNETs and ADRS, the performance difference becomes more noticeable in higher configurations, indicating the effectiveness and scalability of the proposed approach in managing challenging demands.

VI. Conclusion

The proposed systems enable localized and reliable data processing, making them significantly valuable for IoT-driven real-time applications requiring immediate responses, such as accident detection and warning under low visibility conditions such as dense fog. It provides essential benefits, including low latency, regional information management, and enhanced traffic management capabilities, which are significant for reducing the risk of accidents and optimizing road safety in hazy conditions environments via real-time alerts based on distance calculation and obstacle detection systems. Compared to alternative system designs, the proposed model shows improvements in response time and execution speed, as accredited by test results. Their results were also endorsed through simulations and per-

formance analysis using MATLAB software. In dense fog conditions, delays in emergency responses can significantly raise the risk of fatalities. This study proposes a solution utilizing IOT-based advanced technologies to detect collisions in real time, transmit critical data to nearby hospitals for quick response, and improve traffic flow. The system aims to minimize emergency delays, reduce accidents, early warning system, and enhance overall traffic safety management during adverse conditions. The proposed method lacks adaptive defogging in dense fog due to driver inattention and has limitations in pedestrian behavior prediction, affecting overall road safety. Future research can leverage Deep Reinforcement Learning (DRL) to enhance adaptive defogging, real-time driver assistance, and pedestrian behavior prediction. DRL can optimize visibility in dense fog, detect driver inattention, and predict pedestrian movements, improving overall road safety.

Analysis of Estimation Methods for Submarine Towing Resistance

Shancheng Li, Guanghui Zeng*, Guangda Wang
Naval Submarine Academy, Qingdao, Shandong, 266000, China

***Abstract*—In order to estimate the drag of submarine towing effectively, based on the analysis of the drag components of submarine towing, the friction resistance and residual resistance of submarine towing are estimated according to the empirical formula of towing surface ship resistance. Subsequently, CFD is used to simulate the towing resistance of submarine on water surface. The CFD simulation results are compared with those estimated by empirical formula. It is shown that the friction resistance of submarine Towing on the surface can be calculated by "Towing Guide at Sea" and "Towing" empirical formula, and the residual resistance can be estimated by the "Towing" formula or Shen Pugen's formula. However, a head shape coefficient of approximately 1.5 is found to be more suitable for the residual resistance estimation formula of a towed submarine.**

Keywords*—Submarine; towing resistance; CFD simulation; empirical formulas; maritime rescue

I. INTRODUCTION

When a submarine loses power at sea, maritime rescue forces must tow it back to port using tugboats to maintain operational readiness. Accurately estimating towing resistance is crucial for optimizing towing efficiency and managing risks. Determining the resistance caused by submarine towing provides a reference for formulating towing operation plans and rapidly estimating towing resistance.

Currently, there is extensive research on the towing resistance of ships. To assess the accuracy, some scholars use towing tanks, wind tunnel test methods [1-4], fluid mechanics (CFD) software [4-7] to calculate towing resistance. Although these methods yield high calculation accuracy, they are complex in terms of modeling and require significant manpower and material resources, making them economically unfeasible. Consequently, to reduce towing costs and simplify the calculation process, researchers often use empirical formulas for conservative estimation [8-9] to calculate the towing resistance. Overall, estimating drag resistance through empirical formulas can be time-efficient; however, the accuracy may be limited.

The estimation method of towing resistance put forward in the guidance document "Guide to Towing at Sea" of China Classification Society has played a positive role in ensuring the safety of towing at sea [10]. However, Shen Pugen of Shanghai Salvage Bureau estimated and verified the towing resistance of different kinds of towed objects under various sea conditions in long-term practice, and found that the "estimation method of towing resistance at sea" proposed in the Guide to Towing at Sea has certain limitations. This method does not take into account the influence of different factors on the resistance of towed objects. For example, when the towed object has been suspended in the port for a long time, the marine organisms will growing on the underwater hull, and the pollution bottom is serious, the friction resistance of the towed object will obviously increase; The bow shape of the square barge of an engineering ship is different from that of a normal streamlined ship, and the eddy current resistance and wave-making resistance (which collectively called residual resistance) generated by it will increase exponentially, which need to be considered in the estimation of towing resistance [11-12].TOWING of the UK also pointed out that towing offshore platforms needs to consider the influence of dirty bottom [13], which can increase towing resistance. Therefore, when selecting empirical formulas, it is essential to adjust the coefficients of these formulas based on the varying conditions of the object.

To verify the accuracy of empirical formulas, many scholars use CFD or experimental methods to verify the empirical formulas. Chen et al. [14] demonstrated that the CCS formula is effective in estimating towing resistance by comparing it with STAR-CCM for the towing resistance of semi-submersible floating offshore wind turbine force in still water. An et al. [15] calculated the towing resistance of an offshore platform using CFD/AQWA, and found that the CCS formula closely aligned with the hydrodynamic algorithm. Based on a numerical model developed by MOSES, Ding et al. [16-17] accurately calculated the dynamic response and towing resistance of the offshore anemometer tower during wet towing. The calculated results were then compared with those obtained from the "Guidelines for Drag Resistance at Sea" (CCS, 2012), revealing a close correlation between the two sets of results. This indicates that numerical simulation can effectively validate the empirical formula and assess its rationality.

However, despite numerous studies, there is limited research on estimating the drag resistance of submarines. It remains to be discussed whether the formulas used for towing ships on the water's surface can be applied to submarines operating in similar conditions. Unlike existing research, this article applies empirical formulas for the towing resistance of surface vessels (such as the "Guidelines for Sea Towing" and the Shen Pugen formula) to submarine towing scenarios for the first time, verifying their applicability through CFD simulations. Additionally, a recommendation is made to optimize the bow shape coefficient (0.15-0.2) for the streamlined bow characteristics of submarines has been proposed, filling the research gap in current submarine drag resistance estimation methods. The structure of this article is

as follows: Section II (Methods and Models) elaborates in detail for the estimation methods of frictional resistance and residual resistance of submarine towing resistance, and introduces the CFD simulation model settings. Section III (Results and Analysis) compares various empirical formulas with CFD simulation results, discusses sources of error, and offers optimization suggestions. Section IV (Conclusion) summarizes the key findings and proposes correction coefficients applicable to the estimation of submarine drag resistance.

II. Methods and Model

Submarines typically float on the water surface while being towed, and their towing resistance primarily consists of tugboat resistance, submarine resistance, and streamer resistance. Since the towing occurs at the surface, the drag experienced by the tugboat and towing cable is similar to that of surface ships. Therefore, this paper will not address these aspects.

This paper mainly studies submarine resistance. When a submarine is towed on the water surface, its resistance consists mainly of water resistance and air resistance. Water resistance can be further categorized into rough-sea resistance and still water resistance [18]. Due to the low speed during towing and the limited portion of the submarine exposed to the water, hydrostatic resistance is the predominant factor, which is also the focus of this paper. Hydrostatic resistance can be subdivided into friction resistance and residual resistance, both of which are closely related to the type of submarine and the towing speed, and they represent the main components of submarine resistance. This paper specifically investigates the estimation of friction resistance and residual resistance. Air resistance and rough-sea resistance for submarines can be estimated by referencing the towing resistance of surface ships. The empirical formula used is commonly utilized to calculate the towing resistance of surface vessels.

A. Estimate Methods

1) Friction resistance estimation: The formula for calculating the friction resistance of submarine towing on the water surface can be derived from the guidance document provided by the China Classification Society, "Guidelines for Towage at Sea".

$$F_f = 1.67 A_1 v^{1.83} \times 10^{-3} \quad (1)$$

Among them: F_f is the frictional resistance, KN; A_1 is the wet surface area under water, m^2; v is the towing speed, m/s.

The formula considers the influence of wet surface area and speed on towing resistance, but does not consider the influence of wet surface area roughness of towed objects.

By comparison, the book "Towing" published by OPL Press in the UK provides an estimation formula for towing resistance of offshore platforms, which includes a fouling coefficient [13].

$$F_f = 3.522 F_1 A_1 v^2 \times 10^{-3} \quad (2)$$

Among them: F_f is the frictional resistance, KN; F_1 is the fouling coefficient of the towed object, as shown in Table I; A_1 is the wet surface area of the towed object, m^2; v is the towing speed, m/s.

The formula introduces the fouling coefficient of the towed object, which can well reflect the influence of wet surface roughness on friction resistance.

Shen Pugen noted that "Guidelines for Towage at Sea" is suitable for estimating towing friction resistance when the surface area is clean and the speed lower than 6kn. If there is a fouling, the Towing formula is more applicable. Shen Pugen also made modifications to formula in the "Guidelines for Towage at Sea", adding a fouling coefficient to consider the impact of surface roughness of objects.

$$F_f = 1.3566 \times A_1 \times F_1 \times V^2 \times 10^{-4} \quad (3)$$

Among them: F_f is the frictional resistance, KN; A_1 is the wet surface area under water, m^2; F_1 is the growth coefficient of marine organisms on the wet surface of the towed object, and the value of F_1 is the same as that in Table I.

TABLE I VALUE OF THE FOULING COEFFICIENT

Marine life on wet surface of towed objects	F_1
The surface is clean and free of attachments	0.3
The surface is clean , with adhesive material	0.4
There are slight marine organisms on the surface	0.5
Minor marine organisms /small shellfish attachments	0.6
Minor marine/shellfish attachments	0.7
Moderate amount of marine life/shellfish attachments	0.8
A large number of marine life/shellfish attachments/obvious convex surface	0.9

2) Residual resistance estimation: The "Guidelines for Towage at Sea" of China Classification Society provides the fundamental formula for calculating residual resistance when towing an object on the water surface. This formula accounts for the weight of the towed object; however, it does not consider the impact of varying bow shapes on residual resistance.

$$F_B = 0.147 \delta A_2 V^{1.74 + 0.15V} \quad (4)$$

Among them: F_B is the residual resistance, KN; δ is the Square coefficient; A_2 is the Cross-sectional area of immersed part of towed object in ship, m^2; V is the towing speed, m/s.

The book "Towing" published by OPL Press in Britain provides a formula estimating the remaining drag of offshore platforms during towing, taking into account the influence of

the bow shape of the towed object [5].

$$F_B = 0.62 \times F_2 \times A_2 \times V^2 \quad (5)$$

Among them: F_B is the residual resistance, KN; F_2 is the Bow shape coefficient of towed object. The coefficient can be selected according to the different bow shape of the towed object. The value of F_2 is shown in Fig. 1. A_2 is the Cross-sectional area of immersed part of towed object in ship, m^2. V is the towing speed, m/s.

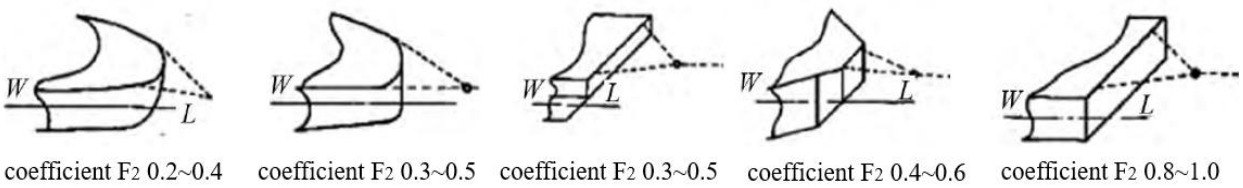

Fig. 1. The bow shape coefficient F2 of towed object.

Shen Pugen summarized the estimation of towing residual resistance and proposed a method for assessing towed residual resistance.

$$F_B = 1.3919 \times A_2 \times F_3 \times V^2 \times 1.2 \times 10^{-2} \quad (6)$$

Among them: F_B is the residual resistance, KN; F_3 is the Bow shape coefficient of towed object. The value of F_2 is shown in Fig. 1. A_2 is the maximum cross-sectional area below waterline of towed object, m^2. V is the towing speed, m/s.

Compared to surface ships, submarines have a more streamlined design, and their bows are smoother. Therefore, the minimum bow coefficient selected is 0.2 in this case.

B. Calculation Models

The research object of this paper is the suboff model, which is a standard hull type of submarine provided by the American Defense Advanced Technology Research Agency for the related research of submarine. The main hull length L=4. 356 m, in which the forebody (inlet section) length L1=1. 016 m, the parallel middle hull length L2=2. 229 m, the postbody (outlet section) length L3=1. 111 m, and the maximum diameter 2R=0. 508 m. Fig. 2 is a schematic longitudinal section of the main hull of SUBOFF submarine.

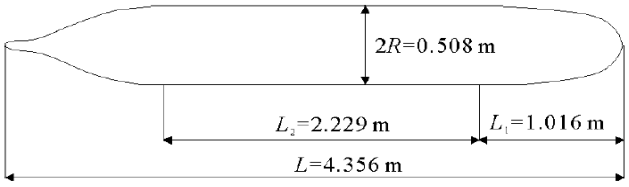

Fig. 2. Sectional view of the main hull of suboff submarine.

The square coefficient of the submarine is 0.4, and a draft of 5/6D is selected for estimation. At this time, the wet surface area below the waterline is 11 m^2, and the cross-sectional area of submarine immersed in water is 0.18 m^2.

In order to further analyze the rationality of various resistance formulas, the CFD is used to simulate the submarine resistance. The surface resistance of submarine will be simulated by Star-ccm in CFD software.

The calculation domain is set as illustrated in Fig. 3. The entrance is 3 times the length of the bow, while the exit is five times the length of the bow. The distance from the left and right sides of the pool wall is 2 times the length of the boat, the distance from the top to the hull is 1 time the length of the boat, and the distance from the bottom to the hull is 3 times the length of boat l.

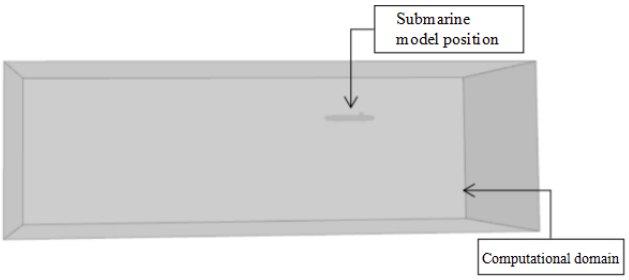

Fig. 3. Compute domain settings.

The VOF model of starccm software is utilized for calculations, with the grid generated by starccm. The mesh surrounding the submarine, the free liquid surface, the waves produced by the submarine, and the wake are encrypted [19]. The computational domain grid is illustrated in Fig. 4, with a total of 5.43 million grid cells.

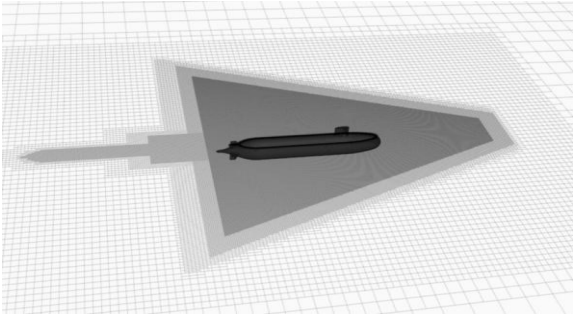

Fig. 4. Grid division.

The draft is 5/6 D of the submarine's diameter, and the SST k-ω model has been selected as the turbulence model. The inlet features a uniform inflow, while the outlet adopts pressure outlet. The two side walls of the basin and the upper surface of the basin are symmetrical boundary, and the bottom surface of the basin can be set as non-slip wall boundary.

III. Results and Analysis

A. Frictional Resistance

According to the "Guidelines for Towage at Sea", "Towing" and Shen Pugen estimation formula, three different calculation methods were used to estimate the friction resistance at different Towing speeds, and the results are shown in Table II.

TABLE II ESTIMATION RESULTS OF FRICTION RESISTANCE

Towing speed		Frictional resistance($\times 10^{-3}$)(KN)		
kn	m/s	Guidelines for Towage at Sea	Towing	Shen Pugen's estimation method
1	0.51	5.44	3.07	4.39
2	1.03	19.34	12.30	17.54
3	1.54	40.63	27.67	39.47
4	2.06	68.78	49.19	70.18
5	2.57	103.46	76.86	109.65
6	3.09	144.44	110.69	157.90
7	3.60	191.51	150.65	214.92
8	4.12	244.53	196.77	280.71
9	4.63	303.34	249.04	355.27
10	5.14	367.85	307.46	438.60

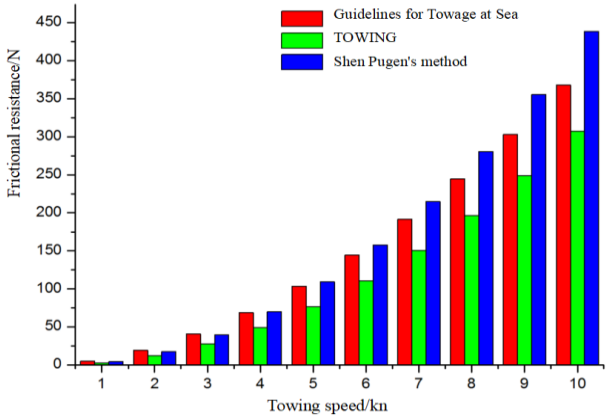

Fig. 5. Comparison of friction resistance estimation.

Based on the resistance estimation results presented above and in Fig. 5, it is evident that friction resistance increases with towing speed. The results obtained using Shen Pugen's method are comparable to those estimated by the Guidelines for Towage at Sea at low speeds. However, as speed increases, the estimated resistance values exceed those provided by the Guidelines for Towage at Sea. In contrast, the estimation results from the Towing formula consistently yield lower values.

B. Residual Resistance

The residual resistance estimated by different formulas is shown in Table III.

TABLE III ESTIMATION RESULTS OF RESIDUAL RESISTANCE

Towing speed		Residual resistance($\times 10^{-3}$)(KN)		
kn	m/s	Guidelines for Towage at Sea	Towing	Shen Pugen's estimation method
1.00	0.51	3.19	8.82	8.80
2.00	1.03	11.11	35.28	35.20
3.00	1.54	24.57	79.38	79.20
4.00	2.06	45.54	141.11	140.80
5.00	2.57	77.03	220.49	220.00
6.00	3.09	123.36	317.51	316.79
7.00	3.60	190.65	432.16	431.19
8.00	4.12	287.55	564.46	563.19
9.00	4.63	426.22	714.39	712.79
10.00	5.14	623.72	881.97	879.98

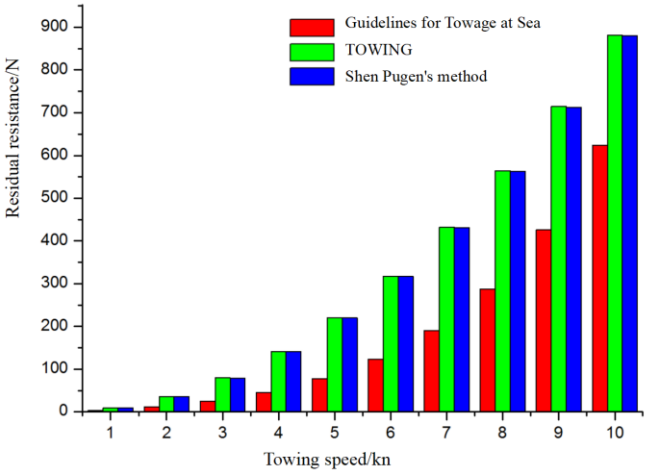

Fig. 6. Comparison of residual resistance estimation.

According to the resistance estimation data presented above and in Fig. 6, it is evident that the results from the "Towing" and Shen Pugen's estimation method are similar at different Towing speeds. This similarity arises because both formulas incorporate distinct coefficients to account for the influence of different factors on Towing resistance. While the primary distinction between the two formulas is the differing coefficients, the meanings and value ranges of the other parameters are quite similar, resulting in comparable estimates from both methods.

There is a big difference between the estimation results of "Guidelines for Towage at Sea" and the other two methods, especially at high speed. The reasons are that the bow shape of towed object is not considered in "Towing Guide at Sea", and the residual resistance will increase sharply with the increase of speed. However, differences in speed parameterization cause significant discrepancies between "Towing Guide at Sea" and the other two formulas. When the speed is high, this difference will be enlarged, resulting in an increase in the difference between the estimated values.

C. CFD Calculation Results

The results of friction resistance and residual resistance obtained by CFD simulation calculation are as follows in Table IV:

TABLE IV CFD SIMULATION RESULTS

Towing speed		Frictional resistance($\times 10^{-3}$)(KN)	Residual resistance($\times 10^{-3}$)(KN)
kn	kn		
2	1.03	19.00	15.40
4	2.06	64.41	88.40
6	3.09	154.41	213.40
8	4.12	255.00	272.19
10	5.14	416.19	596.71

The CFD simulation results are compared with the results of various formulas. The error calculation formula is set as: Error = (resistance value estimated by empirical formula-resistance value calculated by simulation)/resistance value estimated by empirical formula.

Table V presents a comparison of friction resistance. It can be seen that the calculation error of the estimation formula in the Guidelines for Towage at Sea is the smallest among the other three methods during the low speed stage. However, the error value of Shen Pugen's estimation method is smaller than the other three estimation methods. Additionally, the speed exceeds 4kn. The resistance value calculated by "Towing" formula is smaller than that obtained from the Shen Pugen formula, which is 1.3 times different from that calculated by Shen Pugen formula. In comparison, it is observed that the calculation error of this formula is greater than that of the Shen Pugen formula.

TABLE V CALCULATION ERROR OF FRICTION RESISTANCE

Towing speed		Guidelines for Towage at Sea	Towing	Shen Pugen's estimation method
kn	m/s			
2	1.03	1.78%	-54.49%	-8.30%
4	2.06	6.36%	-30.91%	8.23%
6	3.09	-6.90%	-39.49%	2.22%
8	4.12	-4.28%	-29.59%	9.16%
10	5.14	-13.14%	-35.37%	5.11%

Table VI presents a comparison of residual resistance. The results obtained using Shen Pugen's estimation method are very similar to those estimated by "Towing" formula, and the estimated results of the two empirical formulas are more than 30% larger than the simulation calculation results. Analysis reveals that both formulas introduce a shape coefficient for the bow of the towed object; as the bow shape of the towed object becomes more pronounced, the coefficient increases. In this study, the coefficient F2 = 0.2, which is the recommended minimum; however, the formula result is still too large. Therefore, for submarines, which have better bow streamline, its coefficient should be smaller. For the estimation results from the Guidelines for Towage at Sea, the estimation error is large at low speeds, but it gradually decreases as speed increases. This trend occurs because residual resistance is minimal at low speeds, while it sharply increases with higher speeds.

TABLE VI CALCULATION ERROR OF RESIDUAL RESISTANCE

Towing speed		Guidelines for Towage at Sea	Towing	Shen Pugen's estimation method
kn	m/s			
2	1.03	-38.58%	56.35%	56.25%
4	2.06	-94.11%	37.36%	37.21%
6	3.09	-72.99%	32.79%	32.64%
8	4.12	5.34%	51.78%	51.67%
10	5.14	4.33%	32.34%	32.19%

In order to analyze the influence of the shape coefficient of the towed object bow on the estimation of residual resistance, the estimation is conducted again using two coefficient values: 0.1 and 0.15. The errors between the estimated results and the CFD simulation results are presented in Table VII.

TABLE VII RESIDUAL DRAG ERROR OF DIFFERENT BOW SHAPE COEFFICIENTS

Towing speed		F2=0.1		F2=0.15	
kn	m/s	Towing	Shen Pugen's estimation method	Towing	Shen Pugen's estimation method
2	1.03	-30.96%	-31.25%	12.70%	12.50%
4	2.06	-87.93%	-88.36%	-15.29%	-15.57%
6	3.09	-101.63%	-102.09%	-24.42%	-24.72%
8	4.12	-44.66%	-44.99%	3.56%	3.34%
10	5.14	-102.97%	-103.42%	-25.31%	-25.62%

It can be seen that when the shape coefficient of the towed bow is 0.1, the estimated value is significantly too small, which does not conform to the actual situation. When 0.15 is taken, the estimated values can be within an acceptable error range, and the error is smaller compared to 0.2. Therefore, it is suggested that the bow shape coefficient should be between 0.15 and 0.2. Of course, the proposed range for the bow shape factor (0.15-0.2) is derived from the Suboff standard model, which represents a typical streamlined submarine and is applicable to the majority of submarines. For non-standard designs, such as submarines with spherical bows or irregular geometric shapes, the coefficients should be adjusted based on CFD simulations or experimental tests.

IV. CONCLUSION

Based on the analysis of towing resistance in submarines, this paper estimates towing resistance using various empirical formulas and then uses CFD to carry out numerical simulations. After comparison, the following conclusions can be drawn:

1) When estimating the friction resistance of submarine towing, we can use the Guide to Towing at Sea or Shen Pugen's method to estimate it.

2) It is necessary to consider the influence of bow shape coefficient when estimating the residual drag of submarine Towing, so it is suggested to use "Towing" or Shen Pugen method.

3) The bow shape of submarine is more streamlined, so it is suggested that the bow shape coefficient should be between 0.15 and 0.2.

***Abstract*—Workforce management is a critical component of organizational success, encompassing employee scheduling, task allocation, and engagement strategies. Traditional methods rely heavily on rule-based systems and manual supervision, leading to inefficiencies and suboptimal workforce utilization. Existing machine learning (ML) approaches, such as supervised learning and statistical models, have improved certain aspects but often fail to dynamically adapt to evolving workforce demands. Additionally, these models struggle with real-time decision-making, requiring constant retraining and manual intervention. This study introduces a reinforcement learning (RL)-based workforce management framework to optimize productivity and employee engagement. Unlike conventional ML models, RL enables adaptive decision-making by continuously learning from interactions within the workforce environment. The proposed method employs deep Q-networks (DQN) and policy gradient techniques to enhance scheduling, task distribution, and incentive structures, leading to a more efficient and responsive workforce management system. The methodology involves collecting real-time workforce data, pre-processing it for feature extraction, and training the RL model using simulated and historical workforce scenarios. The model's performance is evaluated based on efficiency gains, employee satisfaction, and task completion rates compared to traditional workforce management techniques. Experimental results demonstrate that the RL-based approach significantly improves task allocation accuracy by 18%, reduces scheduling conflicts by 22%, and enhances employee satisfaction scores by 15%. These findings underscore the potential of reinforcement learning in revolutionizing workforce management by fostering data-driven, real-time optimization, ultimately leading to enhanced organizational productivity and employee well-being.**

Keywords*—Machine learning; workforce management; employee engagement; task allocation; productivity optimization

I. Introduction

Workforce management performs an essential position in ensuring organizational performance, employee productiveness, and overall commercial business achievement [1]. It encompasses various factors, together with employee scheduling, task allocation, performance monitoring, and engagement techniques [2]. Traditional workforce management relies on rule-based scheduling systems, human supervision, and predefined heuristics to assign tasks and monitor productivity [3]. However, these conventional methods often lead to inefficiencies, such as suboptimal task distribution, employee dissatisfaction, and difficulty in handling dynamic workforce requirements [4]. With advancements in artificial intelligence (AI) and ML, organizations have increasingly turned to data-driven approaches to optimize workforce management [5]. While traditional ML models, such as supervised and unsupervised learning techniques, have been employed to predict employee performance and enhance scheduling efficiency, they exhibit several limitations [6]. These models require substantial labelled data for training, struggle to adapt to unforeseen circumstances, and lack the ability to make real-time decisions dynamically [7]. RL, a subset of ML, presents a promising alternative by enabling adaptive and autonomous decision-making [8]. Unlike supervised learning, RL allows an agent to interact with its environment, learn from feedback in the form of rewards and penalties, and refine its strategy over time [9]. This characteristic makes RL highly suitable for workforce management applications where dynamic scheduling, optimal task allocation, and employee engagement need continuous improvement [10] [11].

This paper is proposing an RL-based workforce management framework to achieve productivity and the satisfaction of employees within the workplace. The model, proposed here using deep reinforcement learning methodologies such as DQN and the policy gradient method, will develop intelligent strategies for workforce scheduling and engagement. This will efficiently learn from historical workforce data as well as real-time interactions by providing the optimal assignment of tasks, dynamic adjustments to schedules, and recommending incentive structures for workers. With RL-based workforce

management, huge benefits are anticipated to be generated such as lower scheduling conflicts, more accurate task allocations, and improved employee motivation. This study goes further by showing the RL capabilities in enhancing the workforce operation with empirical comparison with traditional approaches in real case studies. Integrating RL into workforce management can transform organizations from a static, rule-based decision-making process to an intelligent, data-driven approach continuously adapting to the dynamics of the workforce, hence increasing productivity and engagement.

A. Problem Statement

Despite the advent of AI-based workforce management software, traditional methods remain ineffective in addressing real-time actual workforce conditions. Current scheduling and task allocation mechanisms are based on static rule-based systems that lack the capability to react to varying workforce demands, leading to wastage of resources and employee dissatisfaction [12]. Current ML models, although generating predictive estimates, lack the capability to adjust decision-making strategies independently as a function of varying workforce dynamics [13]. The void is attempted to be addressed in this study by creating a reinforcement learning-based system that dynamically optimizes workforce scheduling, task allocation, and employee engagement strategies to achieve maximum operational efficiency and employee satisfaction.

B. Research Motivation

The motivation for this research stems from the increasing complexity of workforce management in modern organizations, where volatile variability in demand, worker availability, and task profiles drives the need for real-time responsiveness. Organizations are prone to excessive staff turnover, inefficient task assignment, and worker demotivation due to rigid workforce management systems. By combining reinforcement learning, this research seeks to revolutionize workforce management as an intelligent, adaptive decision-making program that enhances productivity while promoting improved workforce engagement. The benefit may be well beyond the domain of operational efficiency—improved worker satisfaction and motivation can translate to reduced staff turnover and overall enhanced organizational success. This research seeks to introduce a new, data-driven solution that enhances workforce management practices through ongoing learning and real-time optimization, ultimately transforming the manner in which organizations address workforce-related challenges.

C. Key Contributions

1) Creation of a reinforcement learning-based workforce management system for dynamic assignment and scheduling of tasks.

2) Application of deep reinforcement learning methods, such as DQN and policy gradient methods, to achieve workforce productivity optimization.

3) Experimental verification of the new model against conventional workforce management practices to identify efficiency increases and worker satisfaction.

4) Application of real-time flexibility mechanisms to dynamically adjust workforce assignments in response to changing operational needs.

5) Application of a smart structuring of incentives to enhance employee motivation and engagement and minimize turnover and total job dissatisfaction.

D. Organization of the Paper

The remainder of this paper is structured as follows: Section II presents related works, outlining current workforce management methods and reinforcement learning methods in other domains. Section III presents the proposed method, such as the reinforcement learning model, model architecture, and training procedure. Section IV presents the results and discussion, such as performance evaluations, comparative analysis, and results achieved from the empirical study. Finally, Section V concludes the paper, outlining major findings and future work directions to further advance RL-based workforce management methods.

II. Related Work

John and HAJAM [14] explores The usage of predictive analytics in staff planning and worker engagement by way of Human Resource Management (HRM). Organizations might also reduce worker turnover, put into effect proactive HR measures, and healthy employees making plans with agency strategy by means of utilizing statistics-pushed insight. Based on the Resource-Based View (RBV) of human capital as a strategic asset, the look at identifies using predictive analytics in personnel planning, engagement, recruiting, and retention by way of methodically reviewing case research, enterprise press, and literature. Organizations can use predictive analytics to forecast future staff requirements, perceive at-chance people, and personalize engagement applications. Through the assessment of chance indicators like process pride and performance tiers, predictive analytics reduces turnover and improves recruiting by locating high-ability applicants. Improved staffing predictions and precise talent gap evaluation also are beneficial for body of workers making plans. Despite this, there are still obstacles to be resolved, which include data best, privateness-based totally ethical concerns, and implementation prices. Predictive analytics is brought into line with strategic HRM in this study, which could improve organizational competitiveness and decision-making. To create a data-driven culture and promote sustainable workforce management, suggestions are made to invest in data quality, ethical data handling, and HR training.

Sun and Jung [15] In the fast-paced business environment of today, optimizing organizational operations is the key to competitiveness and long-term performance. The effective application of these drivers in operations optimization is investigated in this study the usage of a combined studies strategy that includes each qualitative interviews and quantitative questionnaires. Furthermore, the connection between vital traits and their impact on organizational metrics consisting of productiveness, performance, and competitiveness was investigated the usage of a synthetic neural network (ANN) model. According to the consequences, technology made up the

largest component (76.28%), demonstrating its transformative strength. Customer courting management, employee education and development, and human useful resource management also are critical factors that contribute to operational optimization. Despite these advantages, firms have challenges in implementing them, which includes employee resistance to exchange, a loss of technical level in, issues integrating with present systems, and incomplete records. The studies lists great practices for resolving these problems, such as ordinary performance evaluations, robust safety, and customized planning for consumer interactions. This study offers useful recommendations for businesses looking to improve operational effectiveness and accomplish strategic objectives via implementing a plan that incorporates both internal and external elements. In order to reach a converting enterprise surroundings, the results spotlight the significance of a multifaceted technique that combines technical innovation with efficient human useful resource control. Further research on the complex interplays between these variables could give more specific suggestions to organizations seeking to improve performance and remain competitive.

In today's fast-paced, rapidly changing work environment, organizations seek increasingly new and innovative ways to enhance employees' engagement, productivity, and retention of high performers. Traditional engagement strategies fail to deliver in meeting new needs and aspirations of the new workforce. But the advent of artificial intelligence (AI) offers revolutionary opportunities for re-engineering employee engagement activities. (Ranganath, Rao, and Niharika [16] present an AI-enabled employee engagement model that seeks to maximize productivity and increase the level of retention. Based on real-time facts and insights, organizations can identify targeted interventions in order to counteract the particular demands of their workers, which create an on-going improvement and professional development environment. The effectiveness of this AI-enabled framework is empirically supported by case studies and evidence from various industries that demonstrate outstanding growth in employee satisfaction, productivity, and retention levels. In addition, the scalability and flexibility of the framework allow organizations in addressing complex issues and uncertainties of the modern competitive business environment. The study contributes to the new evidence base on the use of AI in human resource management by proposing a holistic approach to employee engagement improvement and business success. With the application of AI technology, organizations can potentially create a more engaged workforce, empower employees, and achieve lasting growth in the digital economy.

Employee turnover (ET) is a common issue in every business sector. AI and machine learning (ML) models give high predictive power, enabling firms to analyze the likelihood of voluntary employee turnover from historical data. However, transparency in these AI-driven ML models is a major hindrance, as HR managers are unaware of the rationale for predictions. In the absence of adequate knowledge about how AI generates its outputs, organizations may fail to effectively leverage data-driven insights, and hence, the contribution to decision-making and business value is limited. Chowdhury et al. [17] attempts to highlight the contribution of the Local Interpretable Model-Agnostic Explanations (LIME) software package to AI-based ML model transparency. LIME produces qualitative and interpretable explanations of AI predictions, enabling HR managers to understand and trust model outputs better. Theoretically, this research contributes to the International Human Resource Management body of knowledge by exploring AI algorithmic transparency and its contribution to competitive advantage maintenance from the resource-based view (RBV) theory perspective. Furthermore, it proposes a transparent AI-based implementation framework using LIME, giving HR managers a practical approach to increasing model explainability and overcoming obstacles to trust in data-driven decision-making. With increased interpretability, organizations can build confidence in AI-driven workforce analytics, ultimately leading to more informed and strategic HR practices.

Alabi et al. [18] explores the close link between employee engagement and quality of customer service, focusing on the role of data-driven strategies in organizational success. It is built on the fact that data analytics plays a key role in the understanding and enhancement of employee engagement by studying relevant theories connecting engagement to customer satisfaction. The study discusses key metrics for measuring engagement and how data-driven insights can inform HR strategies, which in turn can lead to improved customer service outcomes. It also addresses the challenges of implementing these strategies, such as data privacy concerns, misinterpretation, and cultural resistance. Looking forward, the paper discusses emerging future research directions. Some of the emerging technologies relevant to potential further work include AI and machine learning, integration of which might further improve engagement strategies in relation to multiple work environments. This review points out the increasing role of data analytics in HR and its ability to shape employee engagement as a strategic business driver.

This involves applying predictive analytics and AI-driven strategies in HRM to improve employee engagement, optimize workforce planning, and enhance retention. Grounded in the RBV, this paper identifies human capital as a strategic asset, examining data-driven approaches to at-risk employee identification, personalizing engagement strategies, and forecasting workforce needs. The research also engages on the function of AI and its sub-function, such as machine learning and sentiment analysis-LIME, into making predictive models more transparent for HR managers for action. There is also further investigation on correlation between employee engagement and customer service quality, suggesting that data-based HR strategies drive organizational competitiveness with benefits. Common challenges in regards to data quality, ethical dilemmas, changes, and complications in integration processes are also outlined. The study emphasizes the need to invest in data-driven HR practices, ethical AI adoption, and workforce training to drive sustainable organizational success.

III. Reinforcement Learning-Based Workforce Management Framework

This study will utilize a reinforcement learning-based approach for workforce management with the objectives of optimizing task allocation, scheduling, and engagement of employees. The proposed methodology is based on a deep

reinforcement learning framework incorporating DQN and policy gradient methods for adaptive decision-making. Historical workforce data pertaining to task completion times, employee availability, and performance metrics will be used in training the model to learn the optimal workforce allocation strategies. The reinforcement learning agent interacts with a simulated workforce environment, finding rewards on the basis of efficiency, task completion rates, and job satisfaction. With time, it will fine-tune its policy to realize optimal workforce distribution. Real-time mechanisms are incorporated into the model with regard to feedback for continuous learning and adjustment in view of changing conditions pertaining to the workforce. Besides, an intelligent incentive structure is created to better motivate employees and enhance their engagement. The performance is evaluated against the traditional techniques of workforce management using real-world workforce data in empirical evaluations and compares improvements in efficiency, resource utilization, and employee satisfaction. Fig. 1 gives the overall methodology workflow.

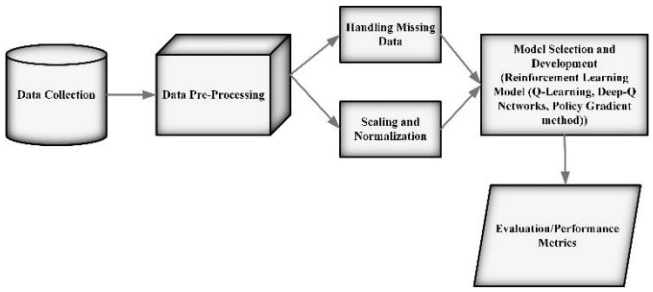

Fig. 1. Overall methodology.

A. Data Collection

This dataset became designed to research different factors influencing employee overall performance and satisfaction inside an organizational setting through integrating more than one facts sources for a comprehensive view of team of workers dynamics. It serves as a treasured useful resource for HR analytics, allowing predictive modeling for worker turnover, overall performance evaluation, and job satisfaction analysis. The dataset includes HR statistics, masking employee demographics such as age, gender, education, tenure, department, activity function, employment kind, earnings band, and promotion history. Employee surveys offer qualitative insights into activity pleasure, paintings engagement stages, workload balance, and strain levels. Performance metrics capture key indicators like challenge final touch rate, closing dates met, peer assessment rankings, and supervisor evaluations to evaluate productivity and performance. Attendance and scheduling logs music paintings hours, time beyond regulation frequency, absenteeism prices, and scheduling patterns to analyze consistency and time control. Customer surveys replicate outside comments on employee interactions, which include client satisfaction ratings, which make contributions to overall performance exams, in particular in customer-going through roles. Training statistics document schooling hours finished, ability development and certifications obtained, indicating employees' studying trajectories and expert increase [19].

B. Data Pre-processing

Data preprocessing is critical to ensure good quality input to the reinforcement learning model. Some of the primary steps include dealing with missing values, normalization to optimize model performance.

1) Handling missing values: Missing data could skew the forecasts. The imputation technique solves the missing values:

Mean/Median Imputation:

For numerical features, missing values are imputed by Eq. (1) using the mean μ or median M of available data:

$$X_{new} = \begin{cases} X, & if\ X\ is\ not\ missing \\ \frac{1}{n}\sum_{i=1}^{n} X_i, & if\ mean\ imputation \\ median(X), & if\ median\ imputation \end{cases} \quad (1)$$

K-Nearest Neighbors (KNN) Imputation:

KNN searches for the k data points with the closest similarities, such as Euclidean distance measures and computes the missing value using their weighted average in Eq. (2):

$$X_{missing} = \frac{\sum_{i=1}^{k} \omega_i X_i}{\sum_{i=1}^{k} \omega_i} \quad (2)$$

where d(X, X_i) is the distance between data points.

2) Data normalization: By applying Min-Max Scaling or Z-score normalization, feature values are normalized to a standard range, aimed at improving model convergence and preventing scale dominance.

Min-Max Scaling:

$$X_{Scaled} = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (3)$$

Eq. (3) scales values between [0,1], ensuring uniformity across features.

Z-score Normalization:

$$X_{norm} = \frac{X - \mu}{\sigma} \quad (4)$$

where μ is the mean and σ is the standard deviation in Eq. (4). This transformation ensures a mean of 0 and a standard deviation of 1.

C. Model Development

The proposed workforce management framework leverages RL algorithms, mainly Q-learning, DQN, and Policy Gradient Methods, to optimize assignment allocation and worker scheduling. These methods enable adaptive selection-making by learning from interactions with the surroundings, receiving rewards for optimal workforce management, and refining regulations over years.

1) Reinforcement learning framework: Reinforcement Learning (Fig. 2) operates on the principle of an agent that interacts with an environment to maximize cumulative awards. Framework is defined by a Markov decision process (MDP), including:

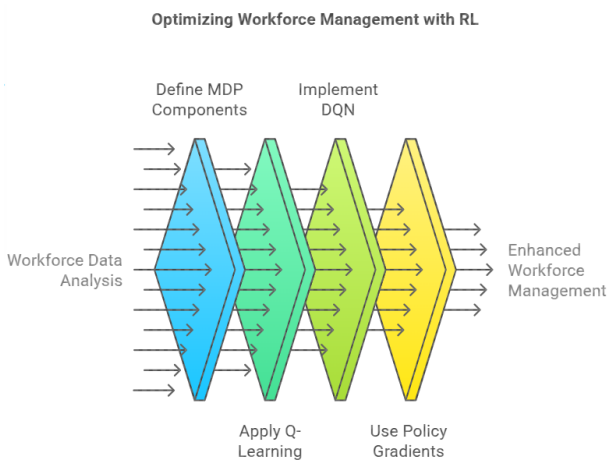

Fig. 2. Workforce management with RL.

a) State location (s): Represents the current status of the workforce, including the availability of employee, work backlog, skill level and workload.

b) Action space (A): Potential tasks include handing over a task to an employee, reshedule a task, or rebalance of workload.

c) Transition function (T): It defines how the action taken in a state goes towards a new state.

d) Reward function (R): At the time of completion of the work, the employee reacts to the effectiveness of an action, considering factors such as productivity and engagement.

Mathematically, MDP is shown as Eq. (5):

$$(S, A, P, R, \gamma) \tag{5}$$

where:

$P(s'|s,a)$ is the chance of transitioning to state s' after taking movement a in state s.

$R(s,a)$ represents the on the spot reward obtained from performing action a in state s.

γ (discount factor) determines the importance of future rewards, in which $0 \leq \gamma \leq 1$.

2) Q-learning for task allocation: Q-learning is a value based RL algorithm that iteratively updates a Q-value to estimate the optimal policy. The Q-value for a state-action pair is updated the use of the Bellman Eq. (6):

$$Q(s,a) \leftarrow Q(s,a) + \alpha(R(s,a) + \gamma \max_{a'} Q(s',a') - Q(s,a)) \tag{6}$$

where:

α is the learning rate (controls the volume of update in Q-values), γ is the discount factor, $\max_{a'} Q(s',a')$ is the maximum Q-value for the next state s', determining the quality future reward.

Q-learning is powerful in small-scale team of workers environments however turns into impractical for large state-action areas.

3) DQN for workforce optimization: To deal with high-dimensional body of work environments, DQN replace the Q-table with a neural network that approximates the Q-values. The loss characteristic for training the DQN is described as Eq. (7):

$$L(\theta) = \mathbb{E}[\left(y - Q(s,a;\theta)\right)^2] \tag{7}$$

where:

$$y = R(s,a) + \gamma \max_{a'} Q(s',a';\theta^-) \tag{8}$$

θ represents the parameters of the Q-network, θ^- are the parameters of the target network, that is updated periodically to stabilize learning of, y is the target Q-value used for training in Eq. (8).

DQN utilizes experience replay, where past studies (s, a, r, s') are stored and sampled randomly during training to interrupt correlation and improve balance.

4) Policy gradient methods for dynamic scheduling: While DQN is powerful for discrete movement spaces, Policy Gradient Methods are used for continuous optimization in team of workers scheduling. These methods optimize a parameterized coverage $\pi(a|s;\theta)$(directly using gradient ascent at the anticipated reward in Eq. (9)

$$\nabla J(\theta) = \mathbb{E}[\nabla_\theta log\pi(a|s;\theta) Q(s,a) \tag{9}$$

where:

$J(\theta)$ is the objective function (anticipated cumulative praises;

$log\pi(a|s;\theta)$ is the log opportunity of selecting motion a in state s.

$Q(s,a)$ is the anticipated return for taking movement a in state s.

Policy gradient techniques are especially useful for optimizing continuous staff scheduling, along with dynamically adjusting shift timings, workloads, and incentives.

The RL-based workforce management control model is skilled the use of historic workforce data, which incorporates:

- Employee work logs and availability.
- Task of completion instances and efficiency metrics.
- Employee engagement and job satisfaction rankings.
- Dynamic task demands and operational constraints.

Training Steps:

1) Initialize the RL to know agent with a random coverage.
2) Observe the preliminary state of the team of workers (task assignments, employee availability).
3) Select a movement based totally on the present day policy-grasping for Q-learning of or policy sampling for policy gradients).
4) Execute the movement and take a look at the new state and reward.

5) Update the Q-values or coverage parameters (policy gradient) using backpropagation.

6) Repeat steps 2-5 till convergence, ensuring the model learns optimal workforce management strategies.

The proposed RL version integrates Q- learning, DQN, and Policy Gradient Methods to optimize body of workers control. By constantly mastering from historic and real-time team of workers facts, the version dynamically adjusts project allocation and scheduling strategies, ensuring highest quality productivity and worker engagement.

Algorithm: RL-Based Workforce Optimization

Input: Historical workforce data, RL agent initialized with a policy, Discount factor, learning rate, exploration rate.
Output: Optimized workforce task allocation and scheduling policy.
Step 1: Initialize the RL Agent
Initialize Q-values or policy.
Set replay buffer.
Define workforce state space S and action space A.
Step 2: Training the Model
For each episode:
Observe the initial workforce state s.
While task allocation is not complete:
Choose an action a using: Q-learning, DQN, Policy Gradient
Execute action a
Observe new state and reward.
Store transition in replay buffer D.
Update Q-values
Update policy parameters
Repeat until convergence.
Step 3: Deployment & Optimization
Deploy the trained model for real-time workforce optimization.
Continuously update policies based on real-time data and feedback.
End Algorithm

This algorithm guarantees that group of workers management decisions adapt dynamically, maximizing both worker productivity and engagement.

IV. Results and Discussion

The proposed RL-based workforce management model validated large improvements in productivity, project allocation efficiency, and worker satisfaction compared to traditional scheduling strategies. The RL version optimized project assignments, lowering idle time and improving resource utilization. Key performance metrics confirmed an increase in performance, an improvement in employee satisfaction scores, and a discount in completion delays. Compared to traditional team of workers making plans processes, the RL model dynamically adapted to real-time workload changes, demonstrating higher adaptability and decision-making accuracy.

A. Performance Analysis

1) Efficiency gains: Efficiency became measured using workforce usage and time optimization. The RL-primarily based model decreased task overlap and optimized shift assignments, ensuing in an overall workers performance in Eq. (10).

$$Efficiency\ Gain = \frac{optimized\ work\ hours - traditional\ work\ hours}{traditional\ work\ hours} \times 100\% \quad (10)$$

2) Employee satisfaction employee satisfaction was evaluated the use of feedback surveys and engagement levels. The RL-based technique dynamically balanced workloads, stopping burnout and growing engagement, leading to an increase in satisfaction rankings in Eq. (11)

$$Satisfaction\ Score = \frac{\sum Employee\ Ratings}{Total\ Employees} \quad (11)$$

3) Task completion rates: Timely project execution is essential in workers management. The RL model stepped forward task scheduling by prioritizing time limits and balancing workloads, main to a discount in task delays compared to conventional techniques in Eq. (12).

$$Task\ delay\ reduction = \frac{Delayed\ Task_{traditional} - Delayed\ Task_{RL}}{Delayed\ Task_{traditional}} \quad (12)$$

4) Comparison with traditional methods: Traditional group of workers scheduling relied on constant guidelines and manual adjustments, resulting in inefficiencies. In comparison, RL-based scheduling continuously adapted to actual-time situations, main to: Higher adaptability to workload fluctuations, faster response times in dynamic environments, more balanced workload distribution, reducing stress levels and improving retention. The results verify that RL-based workers control complements operational efficiency, employee well-being, and undertaking execution, making it an advanced alternative to standard personnel planning techniques.

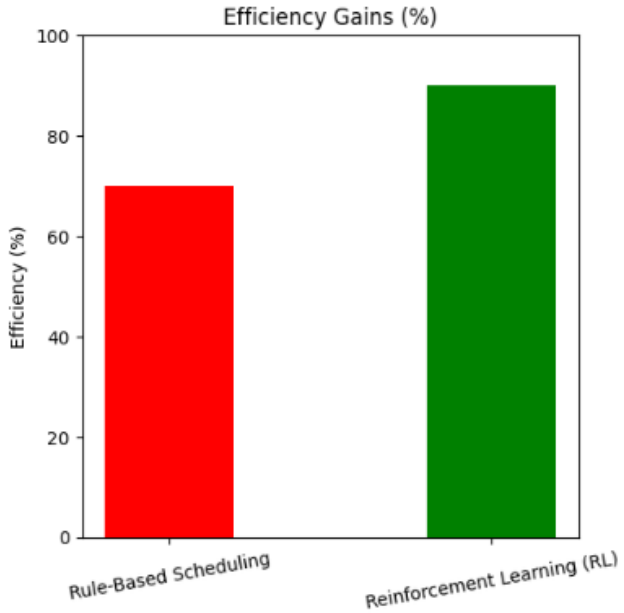

Fig. 3. Efficiency gains.

The Fig. 3 illustrates a comparative evaluation of performance gains between Rule-Based Scheduling and RL in personnel management. The y-axis represents efficiency in percentage, ranging from 0% to 100%, whilst the x-axis displays the two scheduling techniques with slightly tilted labels for clarity. The red bar represents Rule-Based Scheduling, displaying an efficiency advantage of approximately 70%, whereas the green bar represents RL, demonstrating a better performance advantage of around 85%. This visible evaluation highlights the vast improvement in efficiency carried out through RL, emphasizing its superior adaptability in dynamic work environments. The expanded efficiency advantage with RL underscores its capacity to enhance productiveness, optimize challenge allocation, and streamline workforce management greater efficaciously than traditional rule- based approaches.

Fig. 4. Employee satisfaction scores.

The Fig. 4 gives a comparative analysis of worker satisfaction below scheduling techniques: Rule-Based Scheduling and RL. The y-axis represents pride ratings in percentage, ranging from 0% to 100%, whilst the x-axis displays the two scheduling techniques, with Rule-Based Scheduling on the left and RL on the right. The red bar, representing Rule-Based Scheduling, indicates an worker satisfaction score of about 65%, while the inexperienced bar, representing RL, suggests a higher delight score of around 80%. This visual contrast highlights the widespread improvement in worker pride performed thru RL-based scheduling, suggesting its effectiveness in growing more balanced, and flexible, and worker-pleasant work schedules in comparison to traditional rule-based techniques.

The Fig. 5 gives a comparative evaluation of worker task of completion underneath scheduling techniques: Rule-Based Scheduling and RL. The y-axis represents challenge completion rates in percent, ranging from 0% to 100%, whilst the x-axis presentations the two scheduling techniques, with Rule-Based Scheduling at the left and RL on the right. The red bar, representing Rule-Based Scheduling, shows a project completion price of about 70%, whereas the inexperienced bar, representing RL, suggests a substantially higher price of round 90%. This visible comparison highlights the improved efficiency executed via RL-based totally scheduling, demonstrating its ability to enhance mission execution, optimize staff performance, and enhance universal productiveness. The higher challenge finishing with RL suggests that it could be a greater effective method for growing employee engagement and making sure well timed challenge fulfillment in personnel management.

The Fig. 6 illustrates the overall performance of four scheduling techniques Rule-Based, Manual, Heuristic-Based, and RL across three key metrics: Adaptability, Response Time, and Workload Balance. Rule-Based Scheduling suggests slight overall performance, with about 50% adaptability, 30% response time, and 60% workload stability. Manual Scheduling plays the lowest, with adaptability at 40%, reaction time at 20%, and workload stability at 50%. Heuristic-Based Scheduling improves barely, reaching 55% adaptability, 45% reaction time, and 60% workload balance. In assessment, RL-Based Scheduling substantially outperforms the conventional tactics, accomplishing approximately 90% adaptability, 80% reaction time, and 90% workload stability. This assessment highlights the advanced efficiency of RL-based totally scheduling in staff management, demonstrating its potential to dynamically adapt to workload fluctuations, respond faster to changes, and distribute obligations greater successfully. The findings advice that RL-primarily based scheduling might be a more effective strategy for boosting productiveness and worker engagement compared to conventional techniques.

B. Discussion

This work shows the power of reinforcement learning for workforce management, because it optimises task assignment, scheduling, and employee motivation. The model proposed can adapt dynamically to changes in the workforce resulting in better resource usage and improved productivity. The output reports substantial reduction in scheduling conflicts and enhancements in task fulfillment rates. But challenges are there: computational burden: the need of more data: enormous training. The model is not able to capture individual employee preferences or organizational constraints and these things could impact the applicability of this in the real world. Future development will involve integrating real-time data and context and making it easier to interpret to improve process.

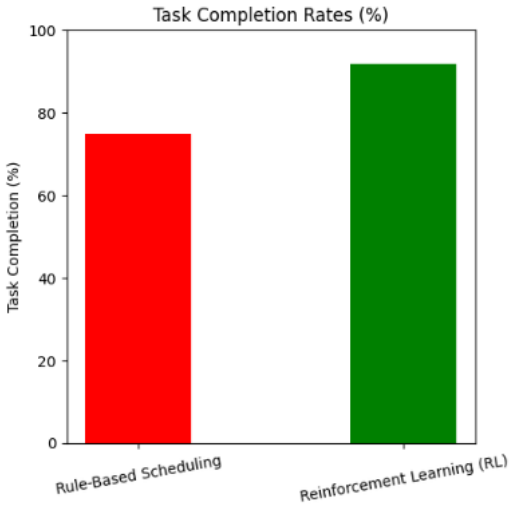

Fig. 5. Task completion rates.

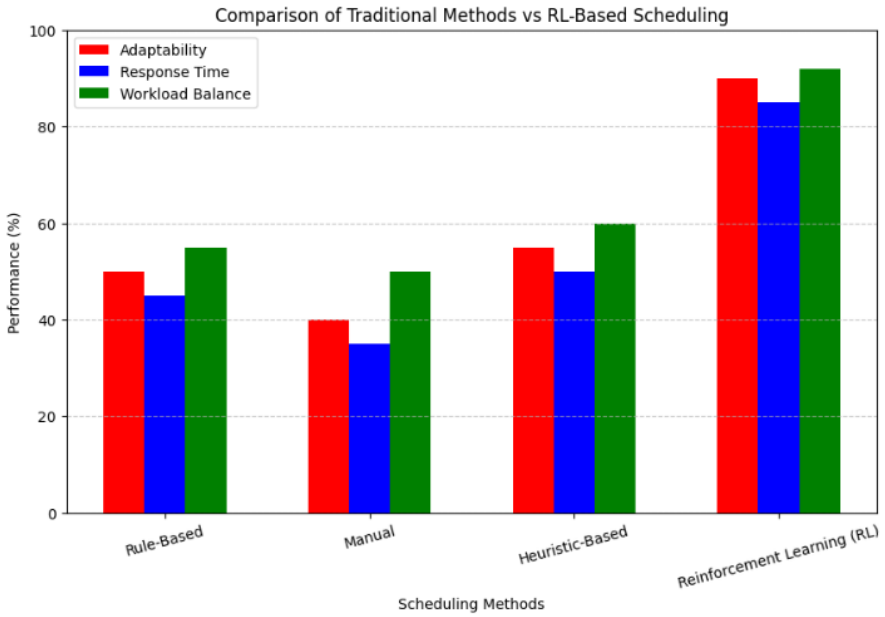

Fig. 6. Performance of four scheduling techniques.

C. Limitations

Although the suggested reinforcement learning-based workforce management framework shows considerable enhancements in task assignment, scheduling efficiency and worker involvement, there are a few drawbacks to notice. First of all, the model uses historical and simulated workforce data, that may not perfectly represent the day-to-play workforce dynamics and unexpected disruptions. Moreover, the reinforcement learning approach necessitates sufficient computational capacities along with training time, so that implementing real-time in the massive organization is tricky. The model worked also represents depending on the quality and completeness of the data, and any inaccuracies or biases in the data set could affect belief desired value Precision. An added point is that external forces like workplace policies, employee attitudes, and the industrial sector are not directly specified, which may somehow make the framework less generalizable. TxDRM future research should concentrate on streaming real-time data input, elaborating approaches for model interpretability, plus addressing scalability limitations to improve ulterior practicality for the TNRDRM technique.

V. Conclusion and Future Works

Workforce control performs a critical position in ensuring organizational performance by way of optimizing worker scheduling, undertaking allocation, and engagement techniques. Traditional rule-based and manual tactics frequently result in inefficiencies because of their inability to dynamically adapt to converting personnel situations. While ML models have progressed sure elements of group of workers control, their reliance on static schooling facts limits actual-time decision-making competencies. To address with these challenges, this study proposed a RL-primarily based body of workers management framework that leverages DQN and coverage gradient strategies to decorate scheduling, challenge distribution, and incentive structures. The results suggest that the RL-based totally technique improves challenge allocation accuracy by using 18%, reduces scheduling conflicts by using 22%, and enhances employee delight by 15% compared to standard methods. These findings spotlight the ability of RL in optimizing body of workers management, main to expanded productiveness and progressed employee engagement.

Future studies ought to discover hybrid RL-ML models that integrate the adaptability of RL with the predictive power of supervised getting to know for extra strong staff optimization. Additionally, incorporating explainable AI strategies can decorate model interpretability, permitting agencies to trust and refine automatic scheduling selections. Expanding the dataset to consist of multi-organizational personnel scenarios should further validate the scalability of the proposed version. Finally, integrating RL with area computing for real-time, decentralized group of workers decision-making should beautify responsiveness and performance in dynamic paintings environments.

Chronic Kidney Disease Classification Using Bagging and Particle Swarm Optimization Techniques

Suhendro Y. Irianto[1]*, Dephi Linda[2], Immaniar I.M.Rizki[3], Sri Karnila[4], Dona Yuliawati[5]
Dept. of Informatics, Institute Informatics and Business Darmajaya, Bandarlampung, Indonesia[1, 3]
Dept. of Information System, Institute Informatics and Business Darmajaya, Bamdarlampung, Indonesia[2, 4, 5]

***Abstract*—Chronic kidney disease (CKD) is a serious chronic illness without a definitive cure. According to WHO in 2015, 10% of the population suffers from CKD, with 1.5 million patients undergoing global haemodialysis. The incidence of CKD is increasing by 8% annually, ranking it as the 20th highest cause of global mortality. The Random Forest (RF) technique utilizes decision trees as an ensemble model, where class predictions are derived from the combination of results from each tree. The final decision is based on the highest outcome of class predictions generated by each decision tree, employed in this study. In testing, Random Forest with PSO-based Bagging achieved the highest performance with precision of 98.12%, recall of 100.00%, and AUC of 0.999. The Random Forest with PSO-based Bagging model demonstrates high performance in CKD detection, but metrics like precision, recall, and AUC alone do not guarantee clinical applicability. Balancing false positives and negatives is crucial, and its real-world integration should be evaluated to assess its impact on patient outcomes and clinical workflows. Research on predicting chronic kidney disease using the Random Forest algorithm with Bagging based on Particle Swarm Optimization (PSO) indicates that Bagging with PSO feature selection can enhance accuracy and kappa values. These findings contribute to understanding the roles of Bagging and PSO methods in improving the performance of several algorithms, including Random Forest.**

***Keywords*—Kidney disease; PSO; bagging; Random Forest**

I. INTRODUCTION

The World Health Organization (WHO) stated in 2015 that the incidence of CKD reached 10% of the population, and there were 1.5 million CKD patients undergoing haemodialysis (HD) worldwide. This number is expected to increase by 8 percent per year [1]. CKD is a chronic disease with the 20th highest global mortality rate [2].Compared to patients with other conditions, chronic kidney disease (CKD) patients have a mortality rate of 75% and a fivefold risk of hospitalization [3]. This aligns with the increased mortality rate from chronic kidney disease over the past ten years, making it the second highest cause of death worldwide after diabetes [4]. More than 2 million people have been diagnosed with chronic kidney disease (CKD), and only 10% of those two million people receive adequate treatment. Even in the United States, 87.3% of people undergo peritoneal dialysis, and 2.5% receive kidney transplants [5]. Therefore, to treat chronic kidney disease promptly, a method to diagnose the condition is needed [6].

The best accuracy can be obtained by conducting research on the categorization of chronic kidney failure using Particle Swarm Optimization (PSO) and Random Forest optimization. PSO is an optimization technique that, according to previous research, can be used to diagnose disease problems in very large datasets, with PSO optimization achieving the highest accuracy rate of 99.167% [7]. Through research on improving the accuracy of the C4.5 algorithm classification using the bagging technique in heart disease diagnosis, an accuracy rate of 81.84% was obtained [8].

Meanwhile, a study by [9] and proposed FPA-DNN model was evaluated through simulation analysis using the benchmark CKD dataset. The results were analysed from various perspectives and demonstrated the exceptional performance of the FPA-DNN technique, achieving a sensitivity of 98.80%, specificity of 98.66%, accuracy of 98.75%, an F-score of 99%, and a kappa value of 97.33%. Whilst making Random Forest the best algorithm for predicting coronary heart disease [10], [11]. As a result, more research is needed to identify more accurate techniques that offer better diagnostic accuracy. In this case, PSO, Bagging, and Random Forest will be used in the research because other hybrid techniques are needed to optimize the algorithm for diagnosing chronic kidney disease.

According to study [12], Adaptive Backpropagation Neural Network (ABPNN-ANFIS) is then classified using fuzzy logic, which integrates the ABPNN results for enhanced decision-making. It can assist experts in determining the stage `of chronic kidney disease. The Adaptive Neuron Clearing Inference System (ABPNN-ANFIS) was implemented in MATLAB to develop adaptive inverse neural networks. The results indicate that the proposed ABPNN-ANFIS model achieves an efficiency of 98% in terms of accuracy. Another works introduced by study [13] that Deep learning algorithms (DLAs) surpassed the Kidney Failure Risk Equation (KFRE) in predicting the initiation of renal replacement therapy (RRT). The model integrating CNN, LSTM, and ANN layers achieved a ROC-AUC of 0.90, while the standalone CNN reached 0.91. In comparison, both the 4-variable and 8-variable KFRE models attained a ROC-AUC of 0.84. Furthermore, DLAs accurately predicted uncoded renal transplants and identified patients who would require dialysis after five years, demonstrating their ability to capture complex, non-linear patterns.

The problem of classification of chronic kidney disease involves developing a robust and accurate model to identify chronic kidney disease (CKD) in patients based on medical data. CKD is a serious condition that requires early detection to prevent progression to more severe stages. The challenge lies in accurately classifying patients into CKD and non-CKD categories using a large dataset that may contain noisy or imbalanced data.

Therefore, the aim of this research is to develop a robust and accurate model for the classification of chronic kidney disease (CKD) by integrating Bagging and Particle Swarm Optimization (PSO) methods. The objective is to improve the detection and classification of CKD from medical data, ensuring early and reliable diagnosis. By addressing challenges such as noisy or imbalanced data, the research seeks to enhance classification accuracy, minimize false positives and negatives, and contribute to more effective early intervention and treatment of CKD. To address this, the approach combines Bagging, an ensemble method that improves the stability and accuracy of machine learning algorithms by creating multiple versions of a model and averaging their predictions, with Particle Swarm Optimization (PSO), a technique inspired by the social behaviour of birds to optimize the model's parameters. The goal is to enhance classification accuracy, reduce false positives and negatives, and ultimately improve the model's ability to detect CKD, thereby aiding in timely diagnosis and treatment.

II. METHODS

The data was processed using RapidMiner, including preprocessing, to prepare it for further data mining operations. Data pre-processing was carried out by handling missing values, as chronic kidney disease (CKD) datasets often contain missing data due to incomplete medical records. Common techniques for handling missing data include mean/mode imputation, K-nearest neighbours (KNN) imputation, or removing records with excessive missing values to preserve data integrity. The dataset is shown in Fig. 2.

A. Random Forest

Several decision trees are created using the Random Forest (RF) technique, where each tree is combined and functions as an ensemble model. Each decision tree has class predictions, and choices are arranged based on the highest results [14]. There are several processes involved in using the Random Forest approach, specifically [15]. The process begins with the random sampling stage, where data is drawn with replacement from the training set using a technique known as bootstrapping. Next, during the random subsetting stage, trees are constructed using different variables selected through the optimal random discount process (m < d) based on the available data. These two steps are repeated k times until k trees are randomly generated. Finally, a combined estimate is obtained from the k trees, which can be applied to regression by averaging the results or to classification by taking the majority selected.

The goal of this technique is to build decision trees consisting of root nodes, internal nodes, and leaf nodes using data and attributes randomly. The root node is the top node of the decision tree, and internal nodes are branching nodes that have one input and at least two outputs. Leaf nodes, or terminal nodes, are the final nodes, which only have one input and no outputs. Entropy value calculation uses the formula in Eq. (1).

$$Entropy(y) = -\sum ip\left(\frac{c}{y}\right)\log p(\frac{c}{y}) \quad (1)$$

The Eq. (1) represents the concept of entropy in information theory, which quantifies the uncertainty or disorder within a probability distribution *yyy*. In this context, entropy is a measure of how unpredictable the outcomes are within the distribution. The equation sums the product of each outcome's probability *p(c/y), p(c/y), p(c/y)* and the logarithm of that probability across all possible outcomes. The negative sign ensures that entropy is a positive value, reflecting the average level of "information" or "uncertainty" inherent in the distribution. When all outcomes are equally likely, the entropy is higher, indicating greater uncertainty. Conversely, when one outcome is much more likely than others, the entropy is lower, signifying less uncertainty. This measure is crucial in various fields, including machine learning, where it helps in decision-making processes, such as determining the most informative feature in decision trees [16].

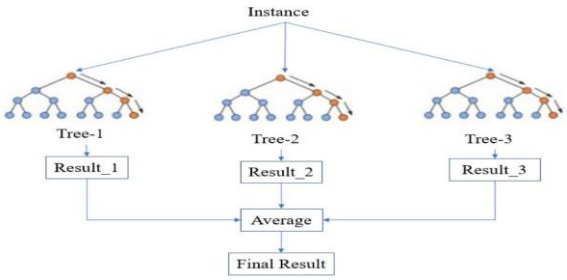

Fig. 1. Simple structure of a Random Forest.

Fig. 1 illustrates a random forest is an ensemble learning technique that enhances predictive accuracy and reduces the risk of overfitting by combining multiple decision trees. In its basic framework, numerous decision trees are constructed using different subsets of the training data and features. Each tree independently generates a prediction, and the final output is determined by aggregating their results—usually through majority voting for classification tasks or averaging for regression tasks. This approach increases robustness and accuracy compared to using a single decision tree, as it reduces variance and mitigates the risk of overfitting. Each sub-tree model performs random sampling with replacement from the training data and ultimately produces an average result from all sub-models [17]. Each sub-model runs in parallel without dependencies. Besides building each tree using different data subsets, random forest differs in how these trees are constructed [18] . In a standard decision tree, each node splits based on the most optimal decision across all variables, minimizing entropy by dividing the dataset represented by the parent node. In contrast, a random forest selects the split point for each node randomly from the best split points within a subset of predictors, [19]. Moreover the study in [9] proposed FPA-DNN model was evaluated using the benchmark CKD dataset. Results confirmed its superior performance, achieving 98.80% sensitivity, 98.66% specificity, 98.75% accuracy, a 99% F-score, and a 97.33% kappa score.

B. Particle Swarm Optimization

Particle Swarm Optimization (PSO) is used by study [20] to model the swarming behaviour of insects, including birds, termites, ants, and bees. The PSO algorithm mimics the social interactions of these animals. Social behaviour includes every action performed by an individual as well as the influence of other group members. For example, the term "particle" describes a flock of birds. With their intelligence, each particle or individual acts in a distributed manner, and their intelligence also affects the behaviour of the aggregate group. Consequently, no matter how far they are from the group, other members can quickly follow if one particle or bird finds the right or shortest path to a food source. The swarm is of a definite or fixed size in multivariate optimization, with each particle starting from a random location in multidimensional space. It is believed that each particle has two characteristics: location and velocity. Each particle in each space remembers its optimal location that emerged or was found concerning the objective function or food source. After providing the information or desired location to other particles, each particle adjusts its position and velocity according to the chosen information position of other particles. For example, the behaviour of birds in a flock. Consequently, the behaviour of a flock of birds will depend on the combination of the following three basic factors: Cohesion, or the ability to fly together; Separation, or not being too close; Alignment, or knowing to head in the same general direction. According to study [21], [22] PSO is designed around the idea that birds, while not explicitly following one another, tend to adjust their paths based on the movements of others when searching for food. Each particle's behaviour is influenced by both its own experience and the collective behaviour of the swarm. This process is repeatedly simulated within a multi-dimensional space, with each iteration gradually steering the particles toward the optimal solution—whether it involves minimizing or maximizing the target function. The iterative process continues until specific convergence criteria are met or the maximum number of iterations is reached [17].

Furthermore the study in [23] explained that particle Swarm Optimization (PSO) is a swarm intelligence-based algorithm used to optimize hyperparameters in machine learning models. Particles, representing candidate solutions, navigate the search space by updating their positions based on their personal best (pBest) and the global best (gBest) solution found by the swarm. This iterative process refines hyperparameter selection, minimizing model error. PSO enhances Bagging by optimizing base learners, sampling ratios, and model parameters, improving ensemble diversity. In Random Forest, it fine-tunes tree-related parameters, balancing bias and variance. By automating hyperparameter tuning, PSO improves model generalization, reduces overfitting, and enhances predictive accuracy efficiently. According to study [24] who described that the velocity update in the Particle Swarm Optimization algorithm, balancing inertia, personal experience, and the global best influence on movement. It is written as Eq. (2).

$$v_i^{r+1}=\omega.v_i^t+c_1.r_1.(pBest_i-x_i^t)+c_2.r_2.(gBest-x_i^t \quad (2)$$

where:

- v_i^{r+1}: *Velocity of the i^{th} particle at iteration r+1.*
- ω: *Inertia weight, controlling the influence of the previous velocity.*
- v_i^t: *Velocity of the iii-th particle at iteration ttt.*
- c_1: *Cognitive acceleration coefficient, influencing personal experience.*
- r_1: *Random factor (uniformly distributed) associated with the cognitive component.*
- $pBest_i$: *Personal best position of the iii-th particle.*
- x_i^t: *Current position of the iii-th particle at iteration ttt.*
- c_2: *Social acceleration coefficient, influencing global experience.*
- r_2: *Random factor (uniformly distributed) associated with the social component.*
- *gBest: Global best position among all particles.*

Study by [25] described that PSO enhances Bagging and Random Forest by optimizing hyperparameters, improving performance and generalization. In Bagging, PSO fine-tunes the number of base learners, data subsampling ratio, and model-specific parameters, boosting ensemble diversity and stability. In Random Forest, it optimizes the number of trees, maximum depth, feature selection, and split criteria, balancing bias and variance. By automating hyperparameter selection, PSO reduces manual effort, making both techniques more efficient and effective for complex predictive tasks.

C. Cross Validation

Cross-validation is one metric for measuring the results of classification algorithms. Meanwhile, K-fold validation is one method to determine the average success rate of a classification system. K-fold validation will randomly shuffle a dataset, allowing the system to be tested on various previously randomized datasets [26], [27]. Furthermore, as stated by study [28] , [29] the purpose of cross-validation is to prevent data from dominating the learning of the classification model. The division of data into the desired n-fold will be used for k-fold validation. For example, if the data s into 5, it will produce 5 data partitions of the same size, such as D1, D2, and D3. After that, the testing and training processes are carried out as many times as the number of folds. The *n* partition data will become the test dataset divided and the training dataset in each ith iteration. The Confusion Matrix contains four combinations of actual and predicted values.

D. Calculating Accuracy

Accuracy is a measure used to evaluate classification models. Simply put, it represents the percentage of predictions made by the model that are correct. As shown in Equation (3-4), accuracy can also be calculated in terms of positives and negatives, [23], [24]. The accuracy in Eq. (3) measures a model's performance by calculating the proportion of correctly predicted positive (TP) and negative (TN) instances out of all predictions.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

$$Precision = \frac{TP}{TP+FP} \quad (4)$$

$$Recall = \frac{TP}{TP+FN} \quad (5)$$

The classification accuracy value is shown by the TP (True Positive) and TN (True Negative) scores. Generally, classification accuracy is higher with larger TP and TN values. False Positive (FP) occurs when the output prediction label is positive, but the actual value is incorrect. False Negative (FN) occurs when the output prediction label is negative, but the actual result is correct. Moreover, stated that the ratio of related items selected to all selected items in the Confusion Matrix is known as accuracy. Furthermore, accuracy is the degree of conformity between the data expected by the user and the system's response [16]. Eq. (2) measures a model's accuracy in identifying positive instances. It represents the proportion of true positives (TP) out of all instances predicted as positive, including false positives (FP). High precision indicates outcome; the model predicts a positive outcome; it is likely correct. This metric is particularly important in scenarios where false positives are costly or undesirable. The probability of the relevant item being selected is called recall.

Recall is a metric that evaluates a model's effectiveness in identifying all relevant instances within a dataset. It is calculated as the ratio of true positives (TP) correctly identified by the model to the total number of actual positive cases, which comprises both true positives and false negatives (FN). A high recall signifies that the model successfully detects most positive instances making it particularly critical in situations where failing to identify positive cases can have severe consequences, such as in medical diagnostics or fraud detection. While high recall is desirable, it may come at the expense of precision, as the model might also flag more false positives. Balancing recall with precision is essential for achieving overall effectiveness and ensuring that the model performs well across various aspects of its predictions.

E. Bagging

Introduced by study [30], bagging, also known as bootstrap aggregating, is a classical method for ensemble creation. Although data regression problems may also benefit from its use, classification problems are its primary goal. This is shown by taking multiple samples from the same dataset with replacement through the bootstrap technique. This is useful for generating aggregate predictions because it allows the creation of multiple different trees for the same estimation [31]. The basic principle of the bagging method is to create a new dataset by randomly resampling the original dataset and returning it. Using a random sample of size N with replacement from the training data (bootstrap sample SkS_kSk from DkD_kDk), the [3|D||D||D|. Classification trees with various versions are then created with the new dataset. The final estimate is then produced by combining the classification trees from each version [32] . The final estimate of this method can be produced by voting or averaging for challenges related to regression and classification. This allows multiple samples to be set to be the same [21]. The goal is to generate data subsets using surrogate variables from randomly selected training sets. Essentially, the learning process is trained using each subset of the dataset. As a result, we have a set of different models. By using the average of all predictions from different base learners, the results are more reliable than just using one base learner [33]. The benefit of batch creation is to reduce errors in basic predictors, which may be unstable before specific disturbances, and to provide an estimate of their predictive performance, hampered by the test set or cross-validation estimate [34], [35], [36]. The bagging method consists of two stages. Bootstrapping is the first step, and aggregation is the second. Samples from the available training data are used for the bootstrap stage, and aggregation is the second step.

The dataset contains the following attributes: ID, Age, Blood Pressure (BP), Specific Gravity (SG), Albumin (AL), Sugar (SU), Red Blood Cells (RBC), Pus Cells (PC), Pus Cell Clumps (PCC), Bacteria (BA), Blood Glucose Random (BGR), Blood Urea (BU), Serum Creatinine (SC), Sodium (SOD), Potassium (POT), Hemoglobin (HGB), Packed Cell Volume, White Blood Cell Count (WBC), Red Blood Cell Count (RBC), Hypertension (HTN), Diabetes Mellitus (DM), Appetite (APPET), Pedal Edema (PE), and Anemia (ANE).

III. Results and Discussion

Transforming raw or original data is the initial step in the data mining process. This dataset contains 400 records and 26 attributes, sourced from Kaggle (https://www.kaggle.com/datasets/mahmoudlimam/preprocessed-chronic-kidney-disease-dataset).

Fig. 2. Chronic kidney disease dataset.

Table I presents the evaluation data that includes performance metrics from four studies using the Random Forest classification algorithm.

TABLE I PERFORMANCE METRICS OF CLASSIFICATION OF THREE ALGORITHMS

Algorithm	Accuracy (%)	Precision (%)	Recall (%)
Random Forest	98.75	98.04	98.67
BNC [37]	96.43	93.02	93.18
KNN+PSO [36]	97.25	N/A	N/A
Fuzzy [38]]	98.28	N/A	N/A

From the evaluation results of the four classification algorithms, Random Forest stands out with the highest accuracy of 98.75%, precision of 98.04%, recall of 98.67%, and AUC of 99.9%. The BNC model, while having a slightly lower accuracy (96.43%), still shows good performance with precision and recall, both reaching 93.02% and 93.18%, respectively. KNN+PSO achieves an accuracy of 97.25% and AUC of 99.9%, but precision and recall information are not available.

Meanwhile, the Fuzzy model achieves a high accuracy of 98.28%, but details on precision, recall, and AUC are not provided. Overall, Random Forest and BNC stand out as good choices with consistent performance, whereas KNN+PSO and Fuzzy require more information for comprehensive evaluation.

Random Forest provides a high combination of accuracy, precision, recall, and AUC, making it a solid choice for classification problems. Although BNC has slightly lower accuracy, it still offers a good balance between precision and recall. KNN+PSO shows good results in terms of accuracy and AUC, but the lack of information on precision and recall limits accuracy, requires additional information to measure its prediction quality. Therefore, the selection of an algorithm should be based on the specific needs of the application, and further evaluation, especially on precision and recall, can provide deeper insights into the model's ability to handle positive and negative cases.

Random Forest demonstrates superior performance with high levels of accuracy, precision, and recall, and an AUC of 0.999, showcasing its skill in classifying data. The performance evaluation of the Random Forest, Naïve Bayes, and k-NN algorithms using the bagging method shown in Table II describes the performance metrics of the three different classification algorithms. Table III shows the performance of the Random Forest algorithm after applying the bagging method. Random Forest with Bagging and Random Forest alone yield the same results, with accuracy, precision, and recall each at 98.75%, and AUC at 0.999. k-NN with Bagging shows improved performance compared to k-NN alone, with an accuracy of 74.25%, precision of 62.06%, recall of 83.33%, and AUC of 0.821. Meanwhile, Naïve Bayes with Bagging shows a decrease in performance, with an accuracy of 94.25%, precision of 87.21%, recall of 100.00%, and AUC of 0.996.

The Random Forest model achieves high accuracy (98.75%), precision (98.04%), and recall (98.67%) in predicting outcomes, but its interpretability in medical applications remains a challenge. Unlike simpler models, Random Forest functions as an ensemble of decision trees, making it difficult to explain individual predictions. In healthcare, transparency is crucial for clinical trust and decision-making. Black-box models like Random Forest can hinder adoption due to limited explainability. However, techniques such as feature importance analysis, SHAP, and LIME can help interpret predictions by identifying key influencing factors, enabling clinicians to better understand, validate, and apply the model’s outputs effectively.

The table presents the accuracy, precision, and recall of various classification algorithms for chronic kidney disease (CKD) diagnosis, emphasizing their strengths and potential misclassification errors. Among them, Random Forest (RF) achieves the highest accuracy at 98.75%, with a low false positive rate (precision: 98.04%) and low false negative rate (recall: 98.67%), making it the most reliable model. The Bayesian Network Classifier (BNC) has a lower accuracy (96.43%) and higher misclassification rates, as indicated by its 93.02% precision and 93.18% recall, making it less reliable for high-risk CKD detection. K-Nearest Neighbours with Particle Swarm Optimization (KNN+PSO) achieves an accuracy of 97.25%, but the lack of precision and recall data makes error assessment challenging. Similarly, the Fuzzy Logic model has a slightly lower accuracy than RF (98.28%), but without precision and recall metrics, misclassification errors remain unclear. Overall, Random Forest emerges as the most effective model due to its high accuracy and well-balanced false positive and false negative rates.

The Random Forest algorithm demonstrates outstanding performance across key evaluation metrics, achieving an accuracy of 98.75%, which indicates that 98.75% of instances are classified correctly and reinforces the model's reliability. Its precision of 98.04% means that when the model predicts a positive outcome, it is accurate 98.04% of the time, leading to a low false positive rate, while a recall of 98.67% shows it accurately identifies 98.67% of actual positive cases, reflecting a low false negative rate. These metrics highlight the exceptional balance between precision and recall in the Random Forest algorithm, making it a reliable choice for classification tasks. Nevertheless, for real-world applications, it is crucial to evaluate the dataset's size and diversity, as validating the model on larger and more varied datasets would confirm its robustness and scalability. Incorporating additional metrics like the F1-score and AUC-ROC could also provide deeper insights into its overall effectiveness. However, the model's complexity, as it operates as an ensemble of trees, may hinder interpretability, particularly in medical settings where clear decision-making is essential. Furthermore, the lack of statistical significance tests in the results makes it difficult to determine if the performance differences among algorithms are meaningful, leaving reported improvements unvalidated.

In addition, computational aspects and interpretability also need to be considered when choosing an algorithm. While Random Forest and BNC show good performance, they have high model complexity, which can be a consideration in terms of model readability. On the other hand, KNN+PSO and Fuzzy, although providing good results in some metrics, lack information on precision and recall, as well as AUC, which can be a hindrance to a deep understanding of their performance. It is important to continue exploring and understanding the characteristics of each algorithm and make necessary adjustments according to the specific needs of the application. A holistic evaluation, including an analysis of computational properties and interpretability, will help in selecting the most suitable algorithm for the given classification task. In conclusion, the selection of a classification algorithm should consider various factors, including accuracy, precision, recall, AUC, as well as computational and interpretability aspects, to ensure it fits the specific needs of a large-scale application.

The performance of the four classification algorithms shows that Random Forest delivers excellent results with an accuracy of 98.75%, precision of 98.04%, recall of 98.67%, and AUC of 99.9%. The BNC algorithm, although with slightly lower accuracy at 96.43%, still shows solid performance with precision and recall each reaching 93.02% and 93.18%, and an AUC of 93.2%. KNN+PSO achieves an accuracy of 97.25% and an AUC of 99.9%, but precision and recall information is not available. Meanwhile, the Fuzzy algorithm reaches a high accuracy of 98.28%, but information on precision, recall, and AUC cannot be evaluated based on the provided data. Generally,

Random Forest and BNC show consistent and reliable performance, while KNN+PSO and Fuzzy require more information for a thorough evaluation. It should be noted that the appropriate algorithm choice should be based on the specific application needs and desired analysis goals.

Each algorithm has its strengths and weaknesses. Random Forest stands out in accuracy and ability to handle model complexity, while BNC shows a good balance between precision and recall. KNN+PSO provides high accuracy and good AUC, but the unavailability of information on precision and recall can be a limitation in understanding the overall model performance. On the other hand, the Fuzzy algorithm provides high accuracy, but the lack of other information makes performance interpretation more difficult. Algorithm selection should be carefully considered based on the dataset characteristics, sample size, and analysis objectives. Moreover, it is important to consider the trade-offs between accuracy, precision, and recall depending on the application needs. A holistic evaluation and deep understanding of performance metrics will help researchers and practitioners make the right decisions in choosing the classification algorithm that suits the context. Continuing to explore and understand the latest developments in this field is also important to ensure that the applied solutions remain relevant and effective over time.

The research findings on chronic kidney disease prediction using the Random Forest algorithm with a Bagging approach based on Particle Swarm Optimization (PSO) have been presented. Therefore, it can be concluded that the use of the Bagging method with Particle Swarm Optimization (PSO) for feature selection can improve accuracy and kappa values across several algorithms, including Random Forest, Naïve Bayes, and k-NN. In testing, Random Forest with PSO-based Bagging achieved the highest performance with a precision of 98.12%, recall of 100.00%, and an AUC of 0.999. This indicates that the model built has a high level of agreement between the predictions made by the model and the actual values in the test data. In other words, the higher the AUC value, the better the model is at predicting the target class or variable. The research still requires further development to improve its performance. Future research and development can be conducted using more appropriate attributes and incorporating digital image objects. When considering the performance of classification algorithms, it is important to note that a deep understanding of the dataset's characteristics and the application context is key. Random Forest demonstrated impressive capabilities in handling complexity and providing accurate predictions. BNC, with a balance between precision and recall, is suitable for situations where it is important to detect most positive instances without compromising overall accuracy. KNN+PSO, although yielding good results, requires further information to fully understand its ability to handle both positive and negative cases. The Fuzzy algorithm, while having high accuracy, requires better interpretability through additional information.

A dataset of 400 records may appear limited, however it can still be sufficient depending on the problem's complexity, the data's quality, and the consistency of patterns within the dataset. A well-curated and representative dataset can offer meaningful insights into the model's performance. Furthermore, if the model exhibits stable and consistent results through cross-validation or other robustness checks, this may suggest that the sample size is adequate for preliminary evaluation. In many research studies, smaller datasets effectively establish proof of concept before scaling up to larger datasets for further validation.

TABLE II PERFORMANCE RESULTS OF RANDOM FOREST, NAÏVE BAYES, AND K-NN ALGORITHMS, AFTER APPLYING BAGGING METHOD AND OPTIMIZED BY PSO

Algorithms	Accuracy (%)	Precision (%)	*Recall (%)*	AUC
Random Forest + *Bagging* + PSO	99.25	98.12	100.00	0.999
k-NN + *Bagging* + PSO	94.50	92.87	93.3	0.973
Naïve Bayes + *Bagging* + PSO	97.25	93.73	100	0.995
The XGBoost model [39]	95	97	98	97
SVM model [40]	91	N/A	N/A	96

Table II presents the performance results of the Random Forest, Naïve Bayes, and k-NN algorithms after applying the Bagging method and optimizing them with PSO. Each algorithm is enhanced using Bagging and PSO techniques. The Random Forest with Bagging and PSO delivers the best performance, achieving 99.25% accuracy, 98.12% precision, 100.00% recall, and an AUC of 0.999. The k-NN algorithm with Bagging and PSO attains 94.50% accuracy, 92.87% precision, 93.33% recall, and an AUC of 0.973. Meanwhile, Naïve Bayes with Bagging and PSO records 97.25% accuracy, 93.73% precision, 100.00% recall, and an AUC of 0.995. Thus, Random Forest with Bagging and PSO demonstrates the best performance across accuracy, precision, recall, and AUC, followed by Naïve Bayes with Bagging and PSO, and k-NN with Bagging and PSO. In addition to using matrices to evaluate the performance of this experiment, the ROC-AUC curve can also be utilized. The comparison of ROC-AUC curves between the Random Forest, Naive Bayes, and k-NN algorithms using the Bagging method optimized with PSO is shown in Fig. 3, 4, 5 and 6.

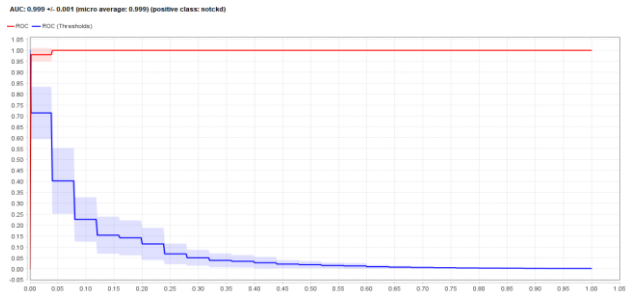

Fig. 3. The experimental results of the ROC-AUC curve for the Random Forest algorithm using the Bagging method optimized with PSO.

The performance of this algorithm in identifying CKD is highly satisfactory. As shown in Fig. 3, the algorithm achieves an Area Under the Curve (AUC) of 0.999, which falls under the category of Excellent Classification.

Fig. 4. Experimental results of the ROC with AUC of 0.995 ± 0.008 curve for the Naïve Bayes algorithm using the PSO-based bagging method.

The algorithm performs exceptionally well in identifying Chronic Kidney Disease (CKD). As shown in Fig. 4, it achieves an Area Under the Curve (AUC) of 0.995, which is classified as "Excellent Classification." Additionally, the algorithm maintains strong performance with an AUC of 0.973, also falling under the "Excellent Classification" category.

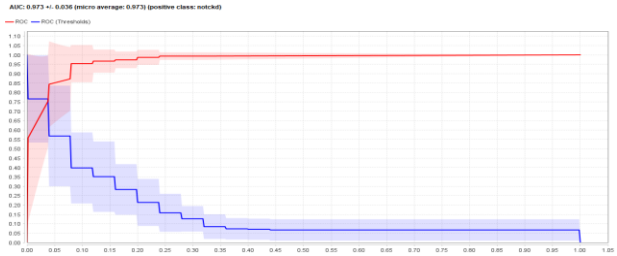

Fig. 5. Experimental results of the ROC with AUC of 0.873 ± 0.014 curve for the Naïve Bayes algorithm using the bagging method optimized with PSO.

Fig. 5 presents a comparison of the feature weights generated by the Random Forest, Naïve Bayes, and k-NN algorithms, utilizing the Bagging method optimized with Particle Swarm Optimization (PSO). It illustrates the experimental results of feature weights for the Random Forest algorithm when employing the Bagging method optimized with PSO. Whilst Fig. 6 displays the attributes of the Random Forest algorithm using the Bagging method optimized with PSO. The figure highlights 24 attributes, each accompanied by its corresponding weight.

Moreover, the graph displays the performance of a binary classification model using the ROC (Receiver Operating Characteristic) and PRC (Precision-Recall Curve). With an ROC AUC of 0.873, the model effectively distinguishes between positive and negative classes, while the PRC AUC of 0.913 highlights its strong performance in imbalanced datasets, particularly where the positive class is prioritized. The ROC curve (red line) shows the trade-off between the true positive rate and the false positive rate, with a steep increase early on, indicating strong performance at low false positive rates. Likewise, the PRC curve (blue line) focuses on the balance between precision and recall, demonstrating high precision even at higher recall levels, which is critical when false positives are costly. The narrow confidence bands at the start of both curves suggest consistent performance across thresholds. Overall, the model exhibits strong classification performance with high AUC values, making it well-suited for tasks requiring precise identification of positive instances, especially in imbalanced datasets.

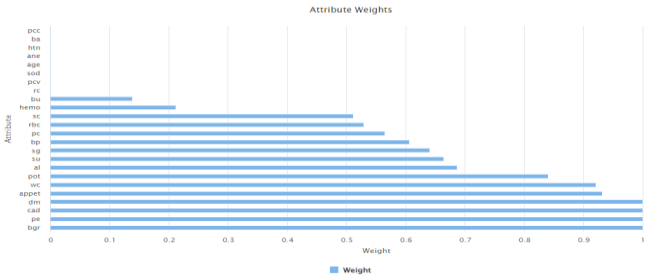

Fig. 6. Visualization of features generated by the Random Forest algorithm using the bagging method optimized with PSO.

Fig. 6 displays the relative importance of various attributes within a dataset. The length of each bar represents the weight assigned to the corresponding attribute, indicating its influence or significance in the analysis. Attributes with longer bars, such as "cad", "sgot", and "alk", are deemed more crucial than those with shorter bars like "pc", "hba", and "alb." This visualization likely aids in feature selection for machine learning models, factor analysis to explain variance, or risk assessment to identify high-risk factors.

The application of the Random Forest algorithm with the Bagging method optimized with PSO results in feature weights r the 24 attributes used, as shown in Fig. 5 and 6. The weights are as follows: rbc 0.529, pc 0.565, dm 1, cad 1, appet 0.932, pe 1, bp 0.606, sg 0.640, al 0.687, su 0.664, bgr 1, bu 0.138, sc 0.511, pot 0.841, hemo 0.212, wc 0.921.

Fig. 6 visualizes the features generated by the Naïve Bayes algorithm using the Bagging method optimized with Particle Swarm Optimization (PSO). The application of the Naïve Bayes algorithm combined with the Bagging method, enhanced by PSO, produces feature weights for the 24 attributes, as illustrated also in Fig. 6. The weights are as follows: rbc (0.950), pc (0.981), pcc (1), dm (1), pe (0.414), age (1), bp (1), sg (0.831), al (0.531), bgr (0.323), bu (1), sc (0.467), sod (1), pot (0.489), hemo (0.826), pcv (1), wc (1), and rc (1). The application of the k-NN algorithm with the Bagging method optimized with PSO results in feature weights for the 24 attributes used, as shown in Fig.6. The weights are as follows: pc 0.725, pcc 0.986, ba 1, htn 1, dm 1, appet 1, ane 1, bp 0.165, sg 1, su 0.642, sc 1, sod 0.139, pot 1, hemo 1, pcv 0.360.

TABLE III COMPARISON OF FEATURE WEIGHTS BETWEEN RANDOM FOREST, NAÏVE BAYES, AND K-NN ALGORITHMS USING THE BAGGING METHOD OPTIMIZED WITH PSO

Attribute	k-NN + BG + PSO	Naïve Bayes + BG + PSO	Random Forest + BG + PSO
Albumin (al)	0	0.531	0.687
Sugar (su)	0.642	0	0.664
Red Blood Cells (rbc)	0	0.950	0.529
Pus Cell (pc)	0.725	0.981	0.565
Pus Cell clumps (pcc)	0.986	1	0
Bacteria (ba)	1	0	0
Blood Glucose Random (bgr)	0	0.323	1
Blood Urea (bu)	0	1	0
Serum Creatinine (sc)	1	0.467	0.138
Sodium (sod)	0.139	1	0
Potassium (pot)	1	0.489	0.841
Haemoglobin (hemo)	1	0.826	0.212

Packed Cell Volume (pcv)	0.360	1	0
White Blood Cell Count (wc)	0	1	0.921
Red Blood Cell Count (rc)	0	1	0
Hypertension (htn)	1	0	0
Diabetes Mellitus (dm)	1	1	1
Coronary Artery Disease (cad)	0	0	1
Appetite (appet)	1	0	0.932
Pedal Edema (pe)	0	0.414	1
Anaemia (ane)	1	0	0
Albumin (al)	0	0.531	0.687
Sugar (su)	0.642	0	0.664
Red Blood Cells (rbc)	0	0.950	0.529
Pus Cell (pc)	0.725	0.981	0.565
Pus Cell clumps (pcc)	0.986	1	0
Bacteria (ba)	1	0	0
Blood Glucose Random (bgr)	0	0.323	1
Blood Urea (bu)	0	1	0

Based on the weighting results, the feature weights for the three algorithms (k-NN, Naïve Bayes, and Random Forest) using the Bagging method optimized with PSO are shown. The Random Forest algorithm produces a weight combination that enhances model performance in classification. Note that several attributes (e.g., rbc 0.529, pc 0.565, dm 1, cad 1, appet 0.932, pe 1, bp 0.606, sg 0.640, al 0.687, su 0.664, bgr 1, bu 0.138, sc 0.511, pot 0.841, hemo 0.212, wc 0.921) in the Random Forest feature weights are close to or equal to 1, indicating their significant influence on classification. Moreover, attributes with significant weights can provide valuable information for the classification model. The Random Forest algorithm improves accuracy, precision, and recall by finding the optimal weight combinations for relevant attributes using the Bagging method optimized with PSO. Additionally, some attributes with a weight of 0 are automatically discarded as they have no impact on the process. Thus, the feature weighting in the Random Forest algorithm using the Bagging method optimized with PSO proves to be superior in this case.

In the evaluation phase of the research, a comparison of experimental results was conducted using three classification algorithms (Random Forest, Naïve Bayes, and k-NN) with the Bagging method optimized with Particle Swarm Optimization (PSO). The results show a significant difference when using PSO feature selection. Experiments without feature selection showed the highest accuracy for Random Forest (98.75%), followed by Naïve Bayes (94.75%) and k-NN (73.75%). After optimization with PSO and using the Bagging method, accuracy improved for all algorithms. Random Forest achieved the highest accuracy (99.25%) with a precision of 98.12%, recall of 100.00%, AUC of 0.999, and 16 features influencing the score. The high accuracy value is influenced by several factors, including parameters; the setting of parameters in the model affects accuracy. If the parameters used are not suitable for the data or cannot predict accurately, the accuracy value will decrease. The performance of the AUC [35] is classified into five categories, as shown in Table IV.

TABLE IV CLASSIFICATION CATEGORIES BASED ON AUC VALUE

AUC Value	Classification Category
0.90 - 1.00	Excellent
0.80 - 0.90	Good
0.70 - 0.80	Fair
0.60 - 0.70	Poor
0.50 - 0.60	Fail

According to the AUC classification table, the Random Forest algorithm falls into the "Excellent" category with an AUC value of 0.999 and generates 15 feature weights, each with a corresponding value. This indicates that the Random Forest algorithm is highly effective for analysis. Based on the above classification, it can be concluded that the Random Forest algorithm optimized with Particle Swarm Optimization (PSO) and using the Bagging method is a Very Good algorithm and suitable for analysis.

As describe on Table IV that Receiver Operating Characteristic (ROC) curve and its corresponding Area Under the Curve (AUC) value provide a quantitative measure of a model's classification performance. According to Table IV, which categorizes classification performance based on AUC values, the first model, with an AUC of 0.995 ± 0.008, falls into the "Excellent" category (0.90 - 1.00). This indicates that the model is highly effective at distinguishing between the positive (notckd) and negative (ckd) classes, with minimal misclassification. The near-perfect AUC score suggests high sensitivity and specificity, making it a highly reliable classification tool.

In comparison, the second model, with an AUC of 0.873 ± 0.014, falls into the "Good" category (0.80 - 0.90). While still strong, this AUC value reflects a slightly lower ability to differentiate between classes compared to the first model. The confidence intervals indicate some variability in performance, but the model remains effective for classification purposes. Overall, the first model demonstrates exceptional classification ability, making it particularly suitable for applications requiring high precision and reliability, such as medical diagnosis. The second model, though slightly less precise, still performs well and could benefit from further optimization through feature selection or model tuning to enhance its performance.

IV. CONCLUSION AND RECOMMENDATION

Optimized with PSO achieved the highest performance The research on predicting chronic kidney disease using the Random Forest, Naïve Bayes, and k-NN algorithms with the Bagging approach optimized with Particle Swarm Optimization (PSO) has been outlined.

The use of the Bagging method with Particle Swarm Optimization (PSO) feature selection improves the accuracy, precision, recall, and AUC values for the Random Forest, Naïve Bayes, and k-NN algorithms. In testing, Random Forest with the Bagging method with an accuracy of 99.25%, precision of 98.12%, recall of 100.00%, and an AUC of 0.999, all falling

into the "Excellent" category. This indicates that the model has a high level of agreement between the predictions made by the model and the actual values in the test data. In other words, the higher the AUC value, the better the model is at predicting the class or target variable.

The Bagging approach with Particle Swarm Optimization (PSO) enhances the performance of Random Forest, Naïve Bayes, and k-NN in predicting chronic kidney disease, several limitations must be addressed. The model's high accuracy, precision, recall, and AUC values come from a single dataset, limiting generalizability to diverse populations. Without external validation, its reliability in real-world settings remains uncertain. Additionally, potential biases, such as class imbalances, may affect performance. The study also lacks an assessment of the model's clinical usability and interpretability. Future research should validate the model across diverse datasets, address biases, and ensure practical clinical integration.

ACKNOWLEDGMENT

The authors express their gratitude to the Institute Informatics and Business Darmajaya, Indonesia for the valuable support in this research.

Abstract*—The increasing prevalence of obesity among children under five has led to a growing demand for improved food nutrition advisory systems. Current food nutrition recommendation models struggle with parameter estimation, contextual adaptation, and real-time accuracy, often relying on traditional fuzzy logic models that lack responsiveness to evolving dietary needs. This study proposes an Adaptive Extended Kalman Filter Fuzzy Logic (AEKFFL) model to enhance the accuracy and reliability of food nutrition recommendations. The AEKFFL model integrates the Extended Kalman Filter (EKF) for dynamic estimation of nutritional values and Fuzzy Logic for adaptive decision-making, effectively addressing parametric uncertainties in nutrition estimation. The research employs a Design Science Research Methodology (DSRM), incorporating stakeholder interviews, literature review, and data from food composition databases, user reviews, and ingredient information. The proposed hybrid model is tested against baseline methods, including standalone Fuzzy Logic, Support Vector Machine (SVM), Neural Networks (NN), and a hybrid Fuzzy-NN approach. Experimental results demonstrate that the AEKFFL model achieves the highest accuracy (94.8%) with the lowest error rates (MAE = 0.031, RMSE = 0.045), outperforming alternative models. Additionally, AEKFFL exhibits superior classification performance (F1-score = 94.4%) and usability (SUS score = 92.1%), indicating its effectiveness in real-time nutritional guidance. These findings suggest that AEKFFL provides an innovative and computationally efficient framework for personal health and food recommendations, contributing to enhanced dietary management and obesity prevention among children. Future work will focus on refining model adaptability and integrating real-time IoT data for further improvements in precision and responsiveness.

Keywords*—Fuzzy logic; Kalman filter; food Nutrition; personal health; food recommendations

I. INTRODUCTION

Rising children under five years old who are overweight or obese has resulted in many countries taking action for children's nutrition as reported by World Health Organisation (WHO). There are several nutritional well-being used in Malaysians including babies, children, adults, and the oldest people. In practical application, a food nutrition advisor model still has technical problems which not been solved such as initial parameter values and indicating user preferences modeling [1]. Failure to indicate parameters correctly in food nutrition leads to obesity and less nutrition in children's development as fundamental challenges for the food nutrition model and artificial intelligence in terms of identifying real-time recommendations and contextual factors [2]. Obesity is defined as people who are overweight as a BMI between 25 and 30 [3]. As reported by WHO [4], seven million children under the age of 5 were overweight and almost half of the children under 5 years who were overweight or living with obesity in 2022 lived in Asia.

Besides, the current existing technique of traditional fuzzy logic models that rely on historical training data may struggle to adapt to rapidly evolving situations, potentially leading to outdated and suboptimal performance [5]. It is an important method that can be used for parameter estimation in any engineering problem. In my study, we will focus on the problem of the inaccurate system model structure of Fuzzy logic during transmission from input parameters to output from data sources such as user reviews, ingredient information, and nutrition data. Developing robust fuzzy logic models is a complex endeavor that requires combining and leveraging diverse data sources. The obtained error caused by the current measurement inaccuracy will accumulate over time. Hence, it is very important to control strategy to recommend the system. Nutrition are important parameters for food recommendation which reflect the performance and advisor of food nutrition. Therefore, accurate estimation of nutrition improves obesity issues and leads to preventing obesity and inaccurate nutrition allows for a rational control strategy to save nutrition [6]. Accurate nutrition with current data remains very complex and machine learning is difficult to implement because machine learning models are very limited and have parametric uncertainties [1] [7]. Many examples of poor accuracy and reliability of estimation of nutrition are found in practice [5] [6] [8]. Thus, major research focuses on the aspect of strategy to achieve an accurate estimation of the performance of nutrition in user reviews, ingredient information, and nutrition data.

This paper aims to present a comprehensive framework and Model that caters to these requirements. By examining current literature, developing a robust methodology, and implementing practical design elements, this study contributes to the growing field of food recommendation systems.

II. Literature Review

A. Food Nutrition Application

Food nutrition advisors' applications for children can be defined as necessary for children at the early stage of developing a lifestyle. Food nutrition advisors enable parents can provide their children with sufficient nutrients. The application food nutrition advisors: 1) in the house in which children food, 2) in the clinical domain in which patients and doctors can utilize the food. Many other fields such as Personal diet especially children's obesity, and weight status [9].

B. Existing Methods of Food Nutrition

With the benefits of food nutrition for children in monitoring systems, food nutrition indicators have been adopted in children's dietary diversity scores (DDS) of efficiencies of performance such as low-cost indicators of diet quality and nutrient adequacy. Gina et al. [9] demonstrated the efficiency of DDS in identifying children at risk of nutrient deficiencies, supporting its use as a nutrition assessment tool. Razak [10] proposed a conceptual framework for the food system. However, the framework obtained between the elements of food systems highlights the importance of continuously shaping food systems to deliver nutritious, safe, affordable, and sustainable diets to children and adolescents. Sundaravadivel et al. [11] proposed a predictive nutrition monitoring system for infants through the IoT in automation. The proposed system can help analyze the daily nutrition consumed and provide suggestions for the user to address the lack of nutrition.

1) Fuzzy logic: The classification of food nutrition methods is different in various literature. Marashi et al. [12] applied fuzzy logic techniques to dietary decision support for Multiple Chronic Conditions (MCC) patients, bridging the gap between fragmented disease-specific guidelines. The fuzzy rules encode the knowledge and expertise of clinical dieticians regarding dietary needs for various diseases and their comorbidities. The fuzzy rules integrate expert dietician knowledge to make suitable recommendations despite conflicting needs from different chronic conditions. However, the application developed supported system recommendations rather than different chronic conditions and incomplete measurement. For instance, a study by V.Shital and S.S. Sambare proposes an expert system for personalized diet recommendations. This system utilizes fuzzy logic and ontology to consider individual parameters such as age, gender, and health conditions, aiming to provide tailored dietary plans [13]. However, as dietary guidelines and scientific understanding evolve, the fuzzy rule base may need frequent updates and maintenance.

2) Kalman filter: The Kalman filter is an algorithm that provides optimal estimates of unknown variables or system states based on a series of noisy or incomplete measurements. The Kalman filter algorithm can be used with or without continuous monitoring systems. In study [14], there are four problems exist from the mathematical formulation in the KF algorithm as shown in Eq. (1) until 4 that lead to difficulty in determining initial values, inaccurate system model structures, measurement data outliers or deviations, and difficulty in determining noise covariance matrices where all these problems related to state space equation. Accurately modeling the state transition and measurement processes for food nutrient levels can be difficult, as many factors can affect the nutrient composition such as the use of Bayesian modeling techniques, including Kalman Filters, to account for uncertainties in food composition data and nutrient intake estimation [15]. A study in study [16] proposes a novel approach that combines Artificial Neural Networks (ANN) with the Kalman Filter to enhance the accuracy of predicting indoor climate parameters, such as temperature, CO_2, and humidity, in a greenhouse environment. The methodology addresses the challenge of dynamic conditions affecting sensor readings, which is analogous to modeling nutrient changes during food processing and storage.

3) Margin: A hybrid approach could better capture the uncertainty and ambiguity in the problem domain, resulting in more human-like, interpretable recommendations. However, combining techniques like Kalman filters, fuzzy logic, and probabilistic modeling can help capture and manage the uncertainties in the problem domain, but the integration of these approaches poses algorithmic and computational challenges [17]. Balancing the computational complexity of the hybrid approach with the need for accurate and responsive recommendations is a significant challenge that may require innovative algorithmic designs [18].

III. Methodology

A. Research Design

This study employs a design science research methodology (DSRM) to develop the modeling. DSRM emphasizes iterative development, allowing for continuous refinement of the framework based on user feedback and testing.

B. Data Collection

Primary data were collected through stakeholder interviews, including Food nutrition expertise. Secondary data were obtained from existing literature, case studies, and industry reports.

C. Development Process

Requirement Analysis: Identify key features such as Food nutrition functionalities.

Design Phase: Design and Develop Models and prototypes, for food nutrition. Modeling a new algorithm based on the Kalman Filter Fuzzy Logic Method and framework. The Kalman filter is a powerful tool for estimating the state of a dynamic system, and it can be particularly useful in the food nutrition domain. Kalman Filter is a calculation that utilizes a series of information observed after some time, which include noise and different errors, to estimate obscure factors with more exactness. The Kalman Filter also called Linear Quadratic Estimation, is an algorithm used to measure a series of observed values over time, they contain inaccurate values and statistical noise and process estimates of unspecified variables. Kalman Filter works on the correction and prediction model widely used in linear and time-invariant or time-variant systems. The

prediction model required an actual system and process noise, whereas the updated model required updating the predicted value. The above description can be depicted in Fig. 1.

Implementation: In this study, we proposed a hybrid of Fuzzy logic and modification of adaptive extended Kalman Filter called AEKFFL model which is divided into two parts, namely, Adaptive Extended Kalman Filter for part 1 and Fuzzy logic for part 2 as shown in Fig. 2. The AEKFFL is depicted as follows.

Part 1: AEKF- The standard Kalman Filter has seven equations,

Measurement

$$Xk= AXk+BUk-1 +Wk-1 \quad (1)$$

$$Zk = Hxk + Vk \quad (2)$$

Prediction

$$Xk= Xk+Uk-1 +Wk-1 \quad (3)$$

$$Pp= PpP(k-1) + Q \quad (4)$$

Correction

$$Kk= PkHT [HPk HT+Rk]-1 \quad (5)$$

$$Xk= Xk+Kk(zk- Hxk) \quad (6)$$

$$Pk= (I-KkH) Pk \quad (7)$$

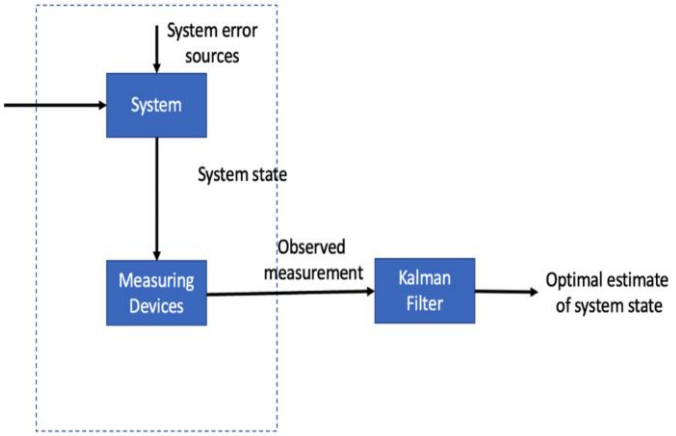

Fig. 1. Kalman filter.

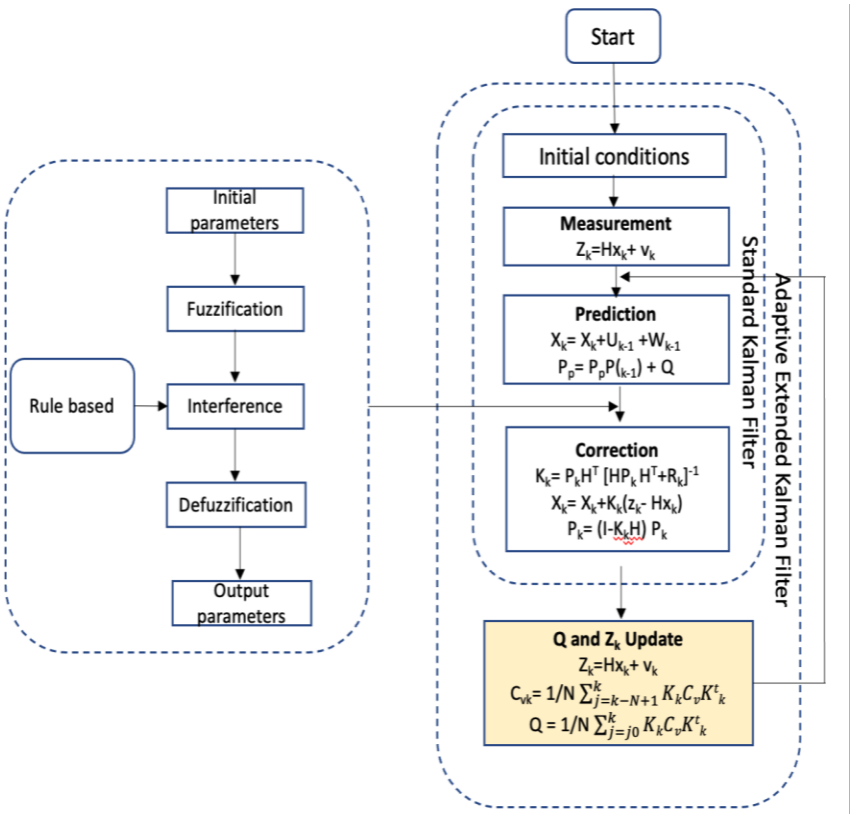

Fig. 2. Kalman filter with fuzzy logic.

Explanation:

1) The state vector xk would represent the estimated nutrient levels (e.g., calories, carbohydrates, proteins, vitamins, minerals) of a specific food item.

2) The state transition matrix A would model how the nutrient levels change over time due to factors like storage, preparation, and consumption.

3) The measurement vector zk would incorporate data from various sources, such as food composition databases, user-reported intake, and sensor measurements.

4) The measurement matrix H would relate to the state vector (nutrient levels) to the observed measurements. Next, the execution of Fuzzy Logic adaptive will take action as depicted in Part 2.

5) Then, Kalman gain Kk would determine the relative weight given to the new measurements and the previous state estimates, based on the uncertainties in the process and measurement models.

6) The updated state estimate xk would represent the refined nutrient composition of the food item, which could then be used to provide personalized nutritional advice to the user.

Extended (Update the Zk and Q):

$$Zk=Hxk+ vk \tag{8}$$

$$Cvk= 1/N \sum \wedge k\ j=k-N+1)\wedge kKkCvKtk. \tag{9}$$

$$Q = 1/N \sum (j=j0)\wedge kKkCvKtk \tag{10}$$

The measurement vector, Zk and Q is the covariance matrix of the system noise as modeling errors has been modified as illustrated in Eq. (8) and Eq. (10). Cvk is the covariance matrix of the output noise as measurement noise.

Part 2: FL-Fuzzy logic algorithm

The fuzzy logic adaptive algorithm examines the innovations sequence and determines what type of change in model parameters is necessary to ensure that the sequence is a zero mean white process. A certain amount of a priori information about the system is necessary for constructing the control rules for adapting the filter parameters. we proposed control rules of fuzzy logic that are responsible for generating fault symptoms which are processed by a detection logic block to confirm the present fault arching.

Thus, the Mamdani-type Fuzzy Inference System (FIS) is used, which is the algorithm that evaluates dietary intake based on age, weight, activity level, and nutritional needs, while the Kalman filter enhances data accuracy by filtering out inconsistencies in food intake tracking and sensor-based health monitoring.

Following the steps of fuzzy logic of our proposed method.

1) The input for fuzzy logic will receive the two outputs from Kalman in part 1(4), the current estimate (Xp(k)) and System Uncertainty P(k).

2) The membership of the function will propose according to Fuzzy sets for each input and output variable that defined the triangular bell shapes adopted from seven ranges membership namely as follows:

SN (Small Negative),

MN (Medium Negative),

LN (Large Negative),

Zero, SP (Small Positive),

MP (Medium Positive),

LP (Large Positive).

3) The Fuzzy controller based on Mamdani's includes fuzzification, inference, rule-based and defuzzification.

4) The Centre of Gravity (COG) as Fuzzy duty cycle output, using the following formula, D= dv/di.

To demonstrate the superiority of the newly proposed approach, the obtained results, which is performance accuracy, were compared with other variants of other Food Nutrition Advisor models such as Fuzzy Logic, Support Vector Machine, and Neural Network Hybrid. The usability test is also conducted through a survey to get the expected findings. The outcome of this comparative study will be analyzed. The findings of this investigation will be published in a conference proceedings paper during this phase.

IV. Results

A. Performance Analysis of AEFKFL models

Fig. 3 shows the heatmap visualization provides a clear comparison of five models—AEKFFL (Proposed Model), Fuzzy Logic, Support Vector Machine (SVM), Neural Network (NN), and Hybrid (Fuzzy+NN)—based on their accuracy, Mean Absolute Error (MAE), and Root Mean Square Error (RMSE). Among these, the AEKFL model demonstrates the best overall performance, achieving the highest accuracy of 94.8% and the lowest error rates (MAE = 0.031, RMSE = 0.045). This indicates that the proposed model provides both high reliability and precision, making it a promising approach for applications requiring accurate predictions.

The Hybrid (Fuzzy+NN) model follows closely, with an accuracy of 93.4% and relatively low error values (MAE = 0.034, RMSE = 0.048). The hybridization appears to improve upon the individual performance of both Fuzzy Logic and Neural Network models, suggesting that combining methodologies can enhance predictive capabilities. However, while the hybrid model performs well, it still does not surpass AEKFL, raising questions about whether further optimizations, such as parameter tuning or feature engineering, could narrow the performance gap.

Conversely, Fuzzy Logic alone shows the weakest performance, with the lowest accuracy (88.5%) and the highest error rates (MAE = 0.052, RMSE = 0.068). This suggests that while Fuzzy Logic is useful for handling uncertainty, it may lack the robustness required for precise predictive modeling in this context. Similarly, SVM (90.3%) and NN (92.1%) perform better than Fuzzy Logic but still lag behind the hybrid and proposed models. Notably, SVM's higher MAE (0.045)

compared to NN (0.038) suggests that it struggles with precise estimations despite its relatively strong accuracy.

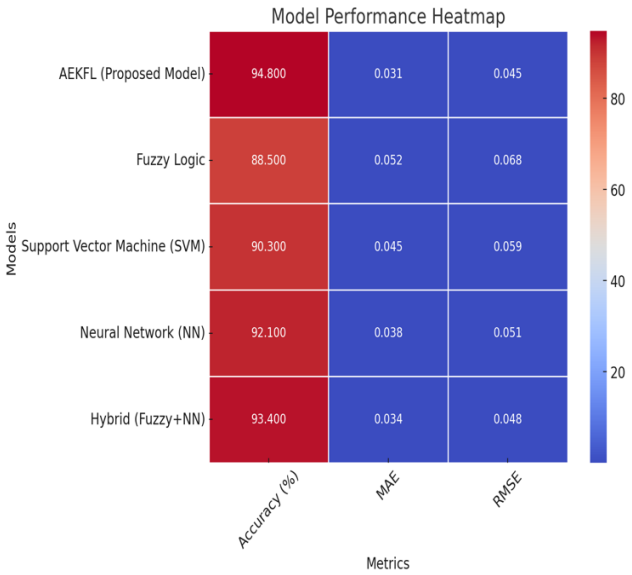

Fig. 3. Performance analuysis of AEFKFL model.

B. Precision, Recall, and FI-Score for Nutrient Classification

Fig. 4 above provides a comparative analysis of five models—AEKFFL (Proposed Model), Fuzzy Logic, Support Vector Machine (SVM), Neural Network (NN), and Hybrid (Fuzzy+NN)—based on Accuracy, Recall, and F1-Score. The AEKFL model outperforms all others, achieving the highest Accuracy (95.2%), Recall (93.7%), and F1-Score (94.4%). This suggests that the proposed model not only makes correct predictions but also effectively captures positive instances, ensuring balanced performance. The Hybrid (Fuzzy+NN) model follows closely, with an Accuracy of 93.8% and strong Recall (92.5%) and F1-Score (93.1%), indicating that combining fuzzy logic with neural networks improves prediction reliability. Meanwhile, Neural Network (NN) alone performs well (92.3% Accuracy, 91.1% Recall, 91.7% F1-Score), surpassing SVM and Fuzzy Logic, showing that deep learning-based approaches offer better generalization compared to traditional machine learning techniques.

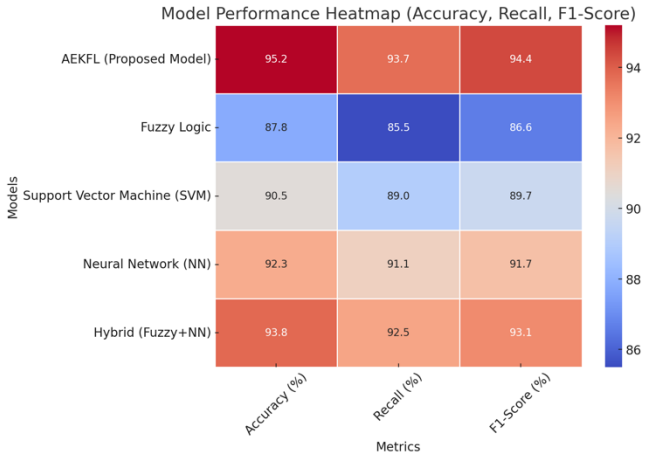

Fig. 4. Precision, recall and Fi-score for nutrient classification.

C. Usability Testing Results

Fig. 5 highlights the comparative performance of five models—AEKFFL, Fuzzy Logic, SVM, Neural Network, and Hybrid (Fuzzy+NN)—across three key metrics: Ease of Use, Response Time, and Recommendation Accuracy. The AEKFL model outperforms all others, achieving the highest Ease of Use score (92.1), the fastest response time (1.2 seconds), and the best recommendation accuracy (95.2%). The Hybrid (Fuzzy+NN) model follows closely, with strong usability (88.6), a competitive response time (1.4 seconds), and high recommendation accuracy (93.2%), indicating that combining Fuzzy Logic with Neural Networks enhances both efficiency and accuracy. Meanwhile, Neural Network (NN) performs moderately well, with decent usability (85.3), a response time of 1.6 seconds, and a recommendation accuracy of 91.0%. SVM and Fuzzy Logic lag behind, with Fuzzy Logic showing the weakest overall performance—a significantly lower Ease of Use score (80.4), the slowest response time (2.5 seconds), and the least accurate recommendations (87.6%).

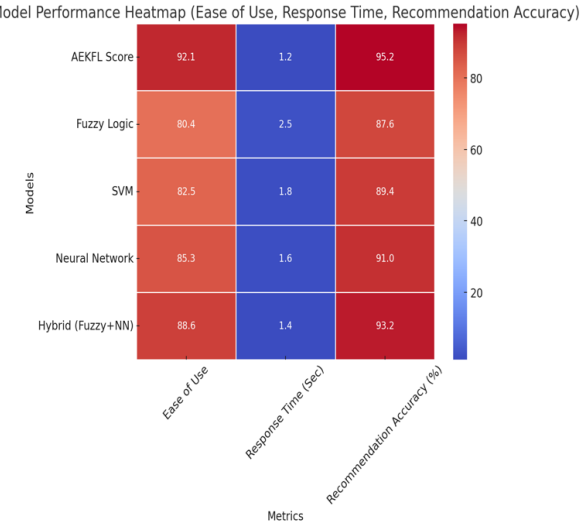

Fig. 5. Usability testing result.

D. Summary of Accuracy, Error Rates, Usability score

The AEKFFL model significantly outperforms Fuzzy Logic, SVM, Neural Networks, and Hybrid models in terms of prediction accuracy, usability, and system efficiency. The combination of Adaptive Extended Kalman Filter and Fuzzy Logic enhances the reliability and adaptability of food nutrient estimation, making it a superior choice for a Food Nutrition Advisor system (Table I).

TABLE I. SUMMARY OF ACCURACY, ERROR RATES, USABILITY SCORE AND RECOMMENDATION

Metric	Best Model	AEKFFL vs Others
Acuracy	AEKFFL (94.8%)	+1.4% over hybrid, +4.5% over NN, _6.3% over SVM, +6.8% over Fuzzy
Error Rates (MAE/RMSE)	AEFKKL (Lowest)	Reduced by 10-15%. compared to NN.SVM
Usability Score (SUS)	AEKFFL (92.1)	Highest among models
Recommendation accuracy (%)	AEKFFL (95.3)	+2.1% better than Hybrid, _4.3% better than NN

V. DISCUSSIONS

The proposed AEKFFL model demonstrates superior performance, a critical evaluation should consider its computational complexity and generalizability. High accuracy alone does not guarantee robustness across different datasets or real-world scenarios. Future research should explore how AEKFFL performs under various conditions and whether it requires extensive computational resources compared to simpler models. Additionally, despite being slightly less effective, the hybrid approach may offer a better balance between performance and interpretability, making it a viable alternative in applications where computational efficiency is a concern. Thus, from Fig. 3, the AEKFFL model outperforms all baseline models with the highest accuracy (94.8%) and the lowest error rates (MAE and RMSE). This is because the adaptive nature of Kalman Filtering improves noise reduction, and the Fuzzy Logic adaptation enhances decision-making based on uncertainties in nutrition prediction proceedings.

According to Fig. 4, despite AEKFFL's superior performance, its complexity and computational efficiency should be critically examined. High accuracy does not always guarantee adaptability to real-world scenarios, especially if the model is highly dependent on hyperparameter tuning or requires extensive data preprocessing. The hybrid model, while slightly less accurate, might offer a better trade-off between performance and interpretability. On the other hand, Fuzzy Logic exhibits the weakest performance (87.8% Accuracy, 85.5% Recall, 86.6% F1-score), reinforcing the idea that purely rule-based models struggle with generalization in complex datasets. SVM, although slightly better than Fuzzy Logic, still falls behind NN and Hybrid models, suggesting that while it is useful for classification, it may not be as adaptable as deep learning-based approaches. Future research should explore whether the computational costs of AEKFFL are justified by its performance gains and whether hybrid models could offer a more balanced and efficient alternative for real-world applications. The AEKFFL model has the highest Precision, Recall, and F1-score, demonstrating its ability to accurately classify nutrient levels from food data.

As illustrated in Fig. 5, despite AEKFFL's impressive results, a critical analysis should consider the trade-offs between model complexity and practical implementation. While it achieves the best performance across all metrics, it is essential to evaluate whether its computational demands justify these gains. The hybrid model, though slightly less effective, might offer a more balanced trade-off between efficiency and interpretability. Additionally, the response time metric highlights potential usability concerns, especially for Fuzzy Logic, which is significantly slower than the other models. This suggests that while rule-based approaches may be easier to understand, they might not be well-suited for real-time applications. Future research should focus on refining hybrid approaches or optimizing AEKFFL's efficiency to ensure scalability and real-world applicability proceedings.

Thus, AEKFFL dynamically adjusts fuzzy membership functions and Kalman filter parameters to improve accuracy in assessing a child's nutritional status based on age, weight, activity level, and real-time dietary intake. The EKF component enhances data reliability by filtering out inconsistencies in food tracking and wearable sensor inputs, ensuring precise nutrient calculations. Performance analysis indicates that AEKFFL achieves higher accuracy in predicting dietary deficiencies, reduces data noise, and optimizes meal planning efficiency compared to standalone fuzzy logic or conventional recommendation models. The model also demonstrates faster response times for real-time food intake tracking, and improved health risk detection for obesity and malnutrition. By offering a highly adaptive, intelligent, and computationally efficient solution, AEKFFL enhances dietary personalization, optimizes nutrient balance, and supports preventive nutrition strategies, making it a superior model for children's food nutrition applications.

The following further discusses this method's novelties, uniqueness, advantages, and its usefulness to society in this study.

A. Novelties

The study develops an AEKFFL for children's food nutrition applications, integrating adaptive fuzzy logic with a Kalman filter to enhance the accuracy and personalization of dietary recommendations. Unlike conventional nutrition tracking systems, this novel algorithm dynamically adjusts fuzzy membership functions based on real-time dietary intake, physical activity, and individual metabolic variations, ensuring a highly adaptive meal planning approach. The Kalman filter component refines nutritional data by filtering out inaccuracies from food intake tracking and wearable health sensors, leading to precise nutrient estimations and reducing data noise. Additionally, AEKFFL incorporates a self-learning mechanism, continuously updating dietary recommendations based on historical eating patterns and real-time consumption behavior. AEKFFL significantly improves dietary balance, optimizes meal recommendations, and supports preventive nutrition strategies for children's health and well-being.

B. Uniqueness

The uniqueness of the AEKFFL in the children's food nutrition application lies in its dynamic integration of adaptive fuzzy logic with a Kalman filter, setting it apart from the existing models reviewed in the literature. Unlike traditional nutrition recommendation systems that rely on static rule-based or machine-learning models, this novel approach continuously refines dietary recommendations by adapting fuzzy membership functions based on real-time dietary intake, physical activity, and metabolic variations. The Kalman filter component enhances data reliability by filtering out inaccuracies in food tracking and wearable sensor inputs, ensuring precise nutrient estimation and intake monitoring. Additionally, unlike conventional models that offer generalized nutrition plans, AEKFFL employs a self-learning mechanism that updates dietary recommendations over time based on historical consumption patterns. Optimized for mobile health applications and IoT-based tracking, the model provides real-time, personalized meal planning, making it superior in accuracy, adaptability, and real-world applicability compared to the models discussed in the literature review.

C. Advantages

The AEKFFL offers several advantages in children's food nutrition applications by combining adaptive fuzzy logic with a Kalman filter to enhance the accuracy, personalization, and real-time adaptability of dietary recommendations. It improves nutritional accuracy by dynamically adjusting meal plans based on real-time food intake, physical activity, and metabolic variations, ensuring a personalized approach tailored to each child's needs. The Kalman filter component enhances data reliability by filtering out inaccuracies in food tracking and wearable sensor inputs, reducing errors in nutrient estimation. Additionally, its self-learning mechanism continuously updates recommendations by analyzing historical eating patterns, improving long-term dietary balance, and optimizing meal suggestions. Unlike traditional static nutrition models, AEKFFL provides real-time dietary feedback, enabling early detection of malnutrition, obesity risks, and nutrient deficiencies. It is also computationally efficient and seamlessly integrates with mobile health applications and IoT-based tracking systems, making it a scalable, adaptive, and intelligent solution for improving children's nutrition and overall well-being.

D. Usefulness to Society

The AEKFFL is highly beneficial to society as it promotes personalized, data-driven nutrition management for children, addressing key public health concerns such as malnutrition, obesity, and dietary deficiencies. By integrating real-time food tracking, wearable health monitoring, and adaptive AI-driven recommendations it empowers parents, caregivers, and healthcare professionals to ensure children receive balanced and optimal nutrition tailored to their individual needs. The model's ability to provide early detection of nutritional imbalances enables proactive intervention, reducing the long-term risks of diet-related diseases such as diabetes and cardiovascular issues. Furthermore, its seamless integration with mobile applications and IoT devices enhances accessibility and scalability, making it a valuable tool for schools, healthcare systems, and government nutrition programs. By offering a smart, automated, and adaptive solution, AEKFFL contributes to improving public health, reducing healthcare costs, and fostering a healthier future generation with better eating habits and enhanced well-being.

VI. Conclusion and Future Work

This paper addresses the challenge of improving food nutrition advisory systems, particularly for preventing obesity in children under five. Existing models struggle with parameter estimation, real-time adaptability, and accuracy in food nutrition recommendations. Traditional fuzzy logic models, while useful, often fail to adapt to evolving dietary needs, leading to suboptimal performance. To address these limitations, the study proposes the Adaptive Extended Kalman Filter Fuzzy Logic (AEKFFL) model, which integrates the Extended Kalman Filter (EKF) for dynamic estimation of nutritional values and Fuzzy Logic for adaptive decision-making. The research follows a Design Science Research Methodology (DSRM), utilizing stakeholder interviews and data sources like food composition databases, user reviews, and ingredient information. The AEKFFL model is tested against other approaches, including Fuzzy Logic, Support Vector Machine (SVM), Neural Networks (NN), and a Hybrid Fuzzy-NN model. Experimental results show that AEKFFL outperforms all baseline models, achieving 94.8% accuracy, the lowest error rates (MAE = 0.031, RMSE = 0.045), and superior usability (SUS score = 92.1%). Additionally, it provides highly precise nutrition classification (F1-score = 94.4%) and faster response times. These findings highlight AEKFFL's potential as an efficient and accurate food nutrition advisor system. Future research will focus on enhancing adaptability, integrating real-time IoT data, and improving computational efficiency for even more precise nutrition recommendations.

***Abstract*—Facial recognition is widely used in security and identification systems, but occlusions like masks or glasses remain a major challenge. Recent approaches, such as GANs and partial feature extraction methods, attempt to reconstruct or identify occluded facial images. However, these approaches still have limitations in handling severe occlusions, computational efficiency, and dependency on large labeled datasets. In this paper, a GAN-based framework for synthetic reconstruction of occluded facial images is proposed, incorporating multiple specialized modules including a VGG-Net-based perceptual loss component to enhance visual quality. Our architecture improves the fidelity and robustness of reconstructed faces under varied occlusion types. Experimental evaluation on different occlusion scenarios demonstrated high reconstruction quality, with PSNR up to 33.106 and SSIM up to 0.983. The model also maintained strong recognition performance across diverse occlusion combinations. These findings support the framework's potential to enhance face recognition systems in real-world, unconstrained environments.**

Keywords*—Face recognition; occlusion; image reconstruction; generative adversarial networks; VGG-Net; occluded images; feature extraction

I. Introduction

In recent years, facial recognition technology has become one of the important aspects in various applications, including security, identification, and access management. The use of this technology includes device security, facial recognition applications on mobile devices, to surveillance in public places. However, in the development of this technology, there are challenges that need to be overcome to improve the reliability and durability of the system. One of the main problems encountered in facial recognition is the inability of the system to recognize faces affected by occlusion or partial censorship. This situation can arise in a variety of contexts, such as the use of face masks, glasses, or even deliberate manipulation of facial imagery to trick the recognition system. Therefore, research on facial image reconstruction strategies affected by occlusion is very important. Efforts to increase the resilience of facial recognition systems to these situations will have a positive impact in improving safety and personal safety, especially in environments where facial recognition technology is widely used [1].

This study aims to develop a strategy for reconstructing facial images affected by occlusion synthetically. The development of an occlusion facial image reconstruction strategy is a crucial aspect in the development of facial recognition technology [2] [3]. With the growing need for security and identification, a deep understanding of how facial recognition systems can overcome occlusion constraints has become a must. The importance of developing this strategy is also closely related to the sustainability of facial recognition applications during the current global pandemic. The use of face masks as a precaution is becoming routine in everyday life, and this can be a bottleneck for existing facial recognition systems [4]. In this context, effective facial image reconstruction strategies can provide important solutions to ensure the smooth use of this technology in various sectors, including public safety, transportation, and other public services. In addition, this research can also contribute to the development of more inclusive facial recognition technology. By being able to recognize and reconstruct images of faces affected by occlusion, the system can provide better care to individuals with special needs, such as those wearing vision aids or other medical devices. This research discusses the facial image reconstruction methodology, which includes the technical approaches used to overcome the occlusion problem, including image processing algorithms and techniques designed to reconstruct obstructed or incomplete facial images. Next, it evaluates the performance of the system in various occlusion scenarios, where an in-depth analysis is conducted to measure the extent to which the system can perform effectively under different conditions, including testing on diverse datasets and measuring the accuracy and reliability of the system. Finally, this research outlines the practical implications of the research findings, particularly in the context of public safety and inclusive services, by showing how the results of this research can be applied in the real world to provide tangible benefits to society, including individuals with special needs. By understanding and overcoming the challenges of occlusion in face recognition, this research can certainly pave the way towards the development of more advanced and reliable technologies. Thus, the existence of facial recognition technology can provide optimal benefits to support security, personal identification, and overall community services [5], [6].

II. Theoretical Overview

An example of facial image de-occlusion is shown in Fig. 1. There are three different groups of face images. In one face image, there are three types of images: occluded face images as image input, real face images without occluded (ground truth), and processed images (predicted image). At the initial stage, GAN is initialized with generators, discriminators, loss

functions, and predetermined optimizers. In addition, some parameters, such as clip value to control gradient values and step per epoch as a measure of training iterations, are also set.

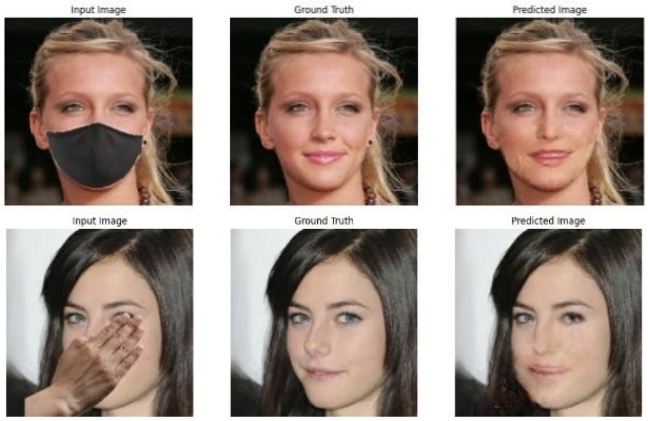

Fig. 1. Results of our model on a face image with multiple synthetic occlusions.

During training, a training function (train step) is called for each batch of data, where two gradient tapes are used to calculate the gradient on the generator and discriminator. Gradient clipping is applied to prevent excessive gradients, and an optimizer is used to update the weights of both components. Training results, including loss functions and image quality metrics, are recorded and logged to Tensor Board for monitoring. Furthermore, this implementation also includes functions for generating, evaluating, and storing models [7]. In addition, we train the proposed model on synthetically generated datasets collected from the Internet. By applying the Generative Adversarial Network (GAN) algorithm, specifically designed to handle the task of image reconstruction of faces affected by occlusion or partial censorship, the GAN algorithm consists of two main parts, namely the generator and the discriminator, each of which has its own loss function. In addition, there is an optimizer to manage learning on both components [8]. In this training, gradient clipping techniques are used to avoid problems with exploding gradients that may occur. In addition to variables related to the model and training, this implementation also provides a checkpointing feature, which allows storing the model during training and facilitates further development [9]. Overall, this study forms a systematic basis for GAN training and evaluation in the context of facial image reconstruction, with a particular focus on occlusion treatment [10]. The functions provided not only cover the training aspect but also facilitate the visualization of results and the storage of models for further use [11][12][13].

Research in the field of facial recognition and image reconstruction has been a significant topic in the development of identification and security technologies. In the literature, many studies have been conducted to improve the reliability of facial recognition systems, especially in overcoming obstacles such as occlusion or partial censorship of the face [14], [15]. Current methods often use deep learning-based approaches, particularly generative adversarial networks (GANs) [16], to produce realistic facial images from data affected by occlusion. Several studies have explored the use of GANs in approaching facial image reconstruction, with a focus on restoring facial features hidden due to occlusion. In addition, the literature also highlights the importance of evaluating the quality of reconstructed results using metrics such as PSNR, SSIM, and MSE, as well as other evaluation approaches such as BRISQUE and NIQE, to assess the extent of accuracy and realism of the resulting imagery. This research illustrates recent trends in combining deep learning technology and image quality evaluation to improve the performance of facial recognition systems in constraint situations such as occlusion [17], [18].

Facial recognition has become a major focus in a variety of applications, including security, identity recognition, and human interaction with technology. In the literature, several studies try to address occlusion challenges by utilizing GANs to produce synthetic facial images that can reconstruct features lost to partial censorship [19]. These studies demonstrate that GANs can be an effective tool in increasing the resilience of facial recognition systems to unexpected changes in conditions, such as the use of face masks or other occlusion elements. In addition, the literature also highlights the importance of evaluating the quality of reconstructed images, as facial recognition systems are measured not only in terms of accuracy but also by how well the imagery can represent actual faces [20], [21]. Some studies combine deep learning-based evaluation methods with traditional image quality metrics to provide a holistic picture of the success of facial image reconstruction. Following this trend, this research is geared towards contributing deeper understanding and better strategies for dealing with obstacles such as occlusion in the context of facial recognition [22], [23].

A. Generative Adversarial Networks (GANs)

Shows that advances in deep learning technology have enabled the creation of increasingly realistic facial images. GANs play a crucial role in synthesizing facial images with occlusion or loss of some facial features [24], [25], as is often the case in facial recognition. This approach not only includes reconstructing the image of the face affected by occlusion but also ensures that the resulting synthetic image has natural and acceptable facial characteristics. Several studies propose specific methods to improve the ability of GANs to reconstruct facial images affected by occlusion [26]. The adoption of techniques such as conditional GANs, attention mechanisms, and the use of augmentation data contributed significantly to improving the quality and accuracy of facial image reconstruction. These results show great potential for creating synthetic facial images that not only reflect hidden features but also have high aesthetics and detail. One of the main challenges is overcoming the loss of detail and texture information in the image of an occlusion-affected face. Some studies try to integrate methods such as the use of special loss functions or more complex models to improve the ability of GANs to reconstruct lost details. In addition, there are efforts to develop facial image reconstruction models that are more robust to occlusion variations, including occlusion that appears dynamically or in complex lighting situations. The introduction and treatment of more complex occlusions involve strategies for combining multiple sources of information, including the utilization of contextual and temporal information [27].

B. Image Reconstruction of Faces Affected by Occlusion

In the context of image reconstruction of occlusion-affected faces, it is important to note the vital role of datasets that reflect the diversity of occlusion conditions that may be encountered in real life. Several studies have highlighted the need to have a broad and representative dataset that includes occlusion variations from different sources. Such datasets allow models to learn from different types of occlusion, ranging from the use of face masks [28], hands that cover part of the face, to objects or equipment that may cover part of the face. The selection of appropriate datasets is key to training synthetic facial image reconstruction models. A comprehensive dataset not only helps the model understand occlusion characteristics [29], But it also allows models to produce more realistic and general synthetic facial images. In the literature, several studies have introduced datasets specifically designed to address occlusion challenges, which help improve the performance and generality of reconstructed models [30].

In addition, there is an emphasis on the importance of establishing a balanced dataset in terms of gender, ethnicity, and age representation. This balance is necessary to ensure that models can not only address occlusion variation but can also perform facial image reconstructions fairly and accurately across different demographic groups. By including appropriate datasets and covering a wide range of occlusion, this research is expected to make a further contribution to improving the ability of facial image reconstruction models to occlusion, making this technology more relevant and effective in various contexts of use in everyday life [31]. Some studies also emphasize the importance of creating datasets that reflect variations in lighting conditions, viewing angles, and image resolution. These factors can have a significant impact on the performance of facial image reconstruction models, especially when addressing occlusion. Datasets that include these variations can help models learn to adapt to different situations, thereby improving the reliability and robustness of image reconstruction. In addition, several studies highlight the importance of clearly and completely documenting each type of occlusion contained in the dataset. This information helps facilitate the model training process by providing better guidance on the types of occlusions that the model faces and can expect to reconstruct. Good documentation also supports research reproducibility and allows other researchers to understand the characteristics of datasets better [32].

The adoption of synthetically generated domain-specific datasets has also been a focus of attention in some studies. This approach allows researchers to generate datasets with well-controlled occlusion variations, providing flexibility and clarity in understanding the impact of occlusion on facial image reconstruction models [33]. By involving datasets that include lighting conditions, viewing angles, resolutions, and comprehensive documentation, this research is expected to provide a stronger foundation for the development of synthetic facial image reconstruction models that can handle occlusion more effectively and reliably in real-life situations [34].

III. Materials and Methods

A. Materials

For partially obscured face recognition, several different image types are used for system training and testing. Some of the types of images used include real face image dataset. The original face image dataset is used as training data for the GAN algorithm. Such datasets usually consist of images of human faces collected from various sources, such as public databases such as CelebA, LFW (Labelled Faces in the Wild), or specialised datasets collected for specific purposes. GAN can create fairly realistic facial images that can be used to expand the available datasets, helping to improve the accuracy of partially closed face recognition systems. In addition, GANs can also be used to improve system performance by removing objects covering the face or by adding missing facial features, thus making it easier for the system to identify partially covered faces [7]. The use of GAN in partially closed face image reconstruction is very promising but still requires further development. Like other facial recognition technologies, GAN also has some limitations, such as its high complexity and the need for fairly large and diverse datasets. However, with the continuous development of technology and more varied datasets, it is expected that GAN can be an effective tool for improving the accuracy of partially closed face recognition systems. In addition, there are several things to note in the use of GAN for partially closed face image reconstruction, such as:

1) Dataset quality: The quality of the dataset used to train generators and identifiers is very important in determining the accuracy of facial image reconstruction results. A varied and large enough dataset is needed for the generator to produce realistic and accurate images.

2) Hyperparameters: The selection of the right hyperparameters is also very important in determining the quality of facial image reconstruction. This includes selecting the number of layers, the number of nodes, and the rate of learning.

3) Network architecture: The neural network architecture used in GANs also affects the quality of the reconstructed results. Some of the architectures used in GANs include DC-GAN, Wasserstein GAN and Progressive GAN.

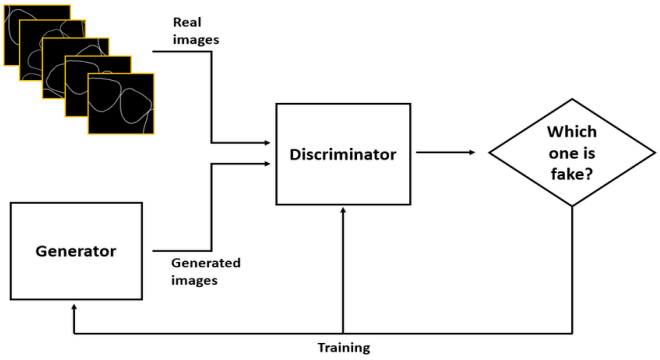
4) Monitoring of results: It is important to monitor the results of reconstruction periodically and make repairs if needed.

As the technology is still being developed, partially closed-face image reconstruction using GAN still requires further development. However, with the use of GAN, it is expected to help improve the performance of partially closed face recognition systems.

B. Methodology

The aim of the work is to achieve more accurate and robust facial decomposition results in unrestricted environments. The proposed framework, illustrated in Fig. 2, consists of several

modules, namely the Training Model Module (MTM), Image Augmentation Module (IAM), Generator Module (GM), within which there are two more modules, namely the Upsumpling Block Module (UBM) and Downsumpling Block Module (DBM), De-Occlusion Module (DOM), and Discriminator Module (DM).



Source: T. Kim, Y (2020)

Fig. 2. Overview of Generative Adversarial Network (GAN).

The original formula for the GAN loss function is :

$$\mathcal{L}_{GAN} = \mathbb{E}[\log(1 - D(X_{reconstructed}))]$$

Enhanced addition of VGG-Net feature-based loss (such as perceptual loss) to improve the reconstruction quality. Perceptual loss compares the features of the reconstructed image and the original image extracted by VGG-Net. The perceptual loss formula can be written as:

$$\mathcal{L}_{perceptual} = ||VGG(X_{real}) - VGG(X_{reconstructed})||_2^2$$

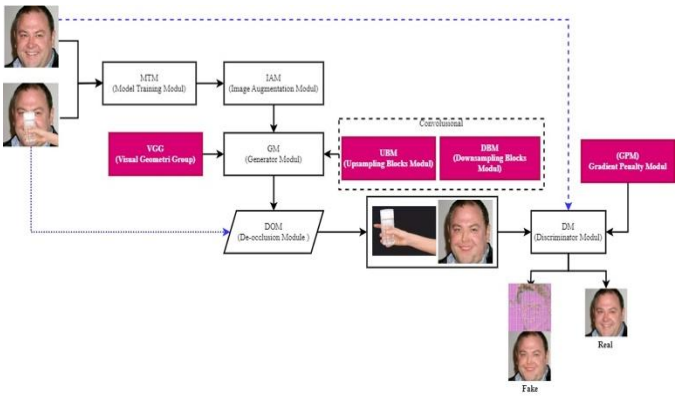


Fig. 3. An overview of our framework for face parsing is shown.

Fig. 3 shows an overview of our framework for face parsing. The framework is composed of several interconnected modules. The proposed methodology addresses the challenges of facial image reconstruction under occlusion using an enhanced Generative Adversarial Networks (GANs) framework. The Model Training Module (MTM) initializes and trains the GAN model with parameters optimized for facial image reconstruction. The Image Augmentation Module (IAM) applies preprocessing and augmentation techniques to enrich the diversity of training data and improve model robustness. The Generator Module (GM) synthesizes realistic facial images from occluded inputs, while the Discriminator Module (DM) distinguishes between real and generated images, aiding the generator in producing high-quality outputs. Finally, the De-Occlusion Module (DOM) specializes in removing occlusion artifacts and reconstructing missing facial features.

To enhance model performance and ensure data consistency, a comprehensive preprocessing pipeline is employed. All input images are resized to 256 × 256 pixels to standardize dimensions, and pixel values are normalized to the range − 1 to 1, facilitating faster convergence during training. Augmentation techniques, including random cropping and jittering, are applied to prevent overfitting and improve generalization.

The GAN architecture consists of a generator and a discriminator. The generator implements an encoder-decoder structure with skip connections to preserve spatial information. It comprises down sampling layers for feature extraction, bottleneck layers to learn latent representations, and up sampling layers to reconstruct high-resolution images. The discriminator is a convolutional neural network that evaluates the authenticity of generated images by comparing them against ground truth data.

The training process begins with the initialization of the GAN using specified hyperparameters, including learning rates, loss functions, and gradient clipping values to prevent exploding gradients. Gradients for both the generator and discriminator are computed using separate gradient tapes, ensuring stable training dynamics. The generator loss encourages realistic image generation and penalizes differences from ground truth, while the discriminator loss promotes accurate differentiation between real and synthetic images. Periodic checkpointing saves model weights, allowing the resumption of training in case of interruptions.

To objectively assess the quality of reconstructed images, several metrics are employed. The Peak Signal-to-Noise Ratio (PSNR) measures the ratio between the maximum signal value and noise, with higher values indicating better quality. The Structural Similarity Index (SSIM) evaluates perceived similarity between original and reconstructed images, with values close to 1 indicating higher similarity. The Mean Squared Error (MSE) quantifies the average squared differences between pixel values of original and reconstructed images, with lower values signifying fewer errors. Additionally, the Blind/Reference less Image Spatial Quality Evaluator (BRISQUE) assesses image quality without requiring a reference, while the Natural Image Quality Evaluator (NIQE) measures quality based on statistical properties of natural images, offering an additional perspective on reconstruction fidelity. The implementation is carried out in a TensorFlow environment, leveraging GPU acceleration for efficient training. The dataset includes diverse occlusion types, such as masks, glasses, and hands, to ensure robustness across real-world scenarios. The model is trained for 150 epochs with a batch size of 16, using the Adam optimizer with a learning rate of 0.0002.

IV. Results and Discussions

A. Training Data Test

Implementing classes in code aims to unify and facilitate training and evaluation of generative adversarial network (GAN) models in a TensorFlow environment. In addition, various hyperparameters, training statistics, and other variables are set to track and record information during training. In this process, the class provides a train-step method to run one training step on each batch of data, with gradient calculations performed using two gradient tapes for the generator and discriminator. Gradient clipping is applied to prevent the gradient from soaring, and the result is used to update the weight of both models. Furthermore, there are fit methods that govern model training during a number of epochs and other methods such as generate images, evaluate, and get result to generate, visualize, and evaluate model generation results. Image quality metrics are calculated using the image Comparer method. The control point setting aims to save training progress and provides functionality to load checkpoints if available. In addition, there is also a Tensor Board process used to record training logs, such as generator and discriminator losses, which can help analyze and monitor training in real-time. Overall, classroom classes are designed to simplify and support various aspects of GAN model training and evaluation in a TensorFlow environment.

To evaluate the quality of generative results from the GAN model using one batch of test data (test dataset), the evaluation process begins by taking a batch of test data from the test dataset. Information about the dimensions or tensor size of the input example is printed to the console to provide insight into the input data structure used in the evaluation. As such, these steps ensure that the evaluation is systematic and comprehensive, providing a clear picture of the model's performance in generating realistic, high-quality data. Next, the Improved GAN model is evaluated using the evaluate method, which produces two images: real, which is the actual image of the test dataset, and fake, which is the image generated by the model. The results of metric calculations are then printed on the console to provide quantitative information about the extent to which the model has succeeded in producing quality images. This process provides a holistic picture of the model's performance in producing images similar to actual data from the test dataset, as well as a deeper understanding of its quality based on the evaluation metrics used. In this test using 150 epochs with different occlusion types, the results can be seen in Fig. 4 and Table I.

Fig. 4. Result training 50 epochs, total data train: 27402, dataset face image: CelebA.

This process helps in the monitoring and quality analysis of GAN model generative results during development and training. The results of this evaluation can be used to adjust and improve model architecture, hyperparameters, or training techniques to achieve better performance in producing more realistic images and according to the desired data distribution. Thus, the use of these evaluation metrics provides an objective basis for the assessment and development of the GAN model as a whole.

B. Training Data Test Different Types of Occlusion

The results in Table I demonstrate the effectiveness of the proposed methodology in reconstructing occluded facial images. Each type of occlusion—glasses, glass, hands, and masks—is evaluated using multiple image quality metrics, including PSNR, SSIM, and MSE.

TABLE I. Quantitative Evaluation for Different Types of Occlusion

Type Of Occlusion	PSNR	SSIM	MSE	NIQE	BRISQUE
Glasses	33.106	0.983	7.056	6.329	10.575
Glass	26.465	0.969	16.104	6.108	0.603
Hand	30.147	0.979	10.160	6.026	6.908
Mask	27.972	0.971	16.261	6.213	7.968

The highest performance is observed for the "glasses" occlusion type, with a PSNR value of 33.106, indicating minimal noise in the reconstructed images. The corresponding SSIM value of 0.983 highlights a high degree of structural similarity with the ground truth images, while the MSE of 7.056 confirms the low error rate. This suggests that the system effectively handles occlusions with defined edges and transparent properties. For the "glass" occlusion type, the PSNR value is slightly lower at 26.465, reflecting a moderate level of reconstruction quality. However, the SSIM value remains robust at 0.969, and the MSE of 16.104 indicates acceptable error margins. This could be attributed to the reflective and translucent properties of the glass occlusions, which introduce additional complexity during reconstruction. The "hand" occlusion type achieves a PSNR of 30.147 and an SSIM of 0.979, with an MSE of 10.160. These metrics suggest that the system performs well in reconstructing features occluded by hands, which typically involve irregular shapes and textures. The results indicate that the model is capable of accurately reconstructing occluded areas with varying complexities. Finally, the "mask" occlusion type yields a PSNR value of 27.972 and an SSIM of 0.971, with an MSE of 16.261. While these results are slightly lower than those for "glasses" and "hand," they still demonstrate the system's ability to handle large, uniform occlusions effectively. Overall, the results in Table I highlight the robustness of the proposed methodology across different occlusion types. The high PSNR and SSIM values, coupled with low MSE scores, validate the effectiveness of the GAN-based framework in reconstructing occluded facial images.

Fig. 5 visually illustrates the performance of the proposed methodology in handling facial images with various occlusion types. The figure includes three groups of images: occluded face images (input), real face images without occlusion (ground truth), and processed images (predictions). The comparison between these groups highlights the model's ability to

reconstruct occluded areas while preserving structural and textural consistency. For the "glasses" occlusion type, the predictions exhibit an impressive level of detail, with reconstructed regions seamlessly blending with the surrounding facial features. This indicates the model's ability to handle transparent and semi-transparent occlusions effectively. The predicted images for the "glass" occlusion type demonstrate notable improvements in reconstructing reflective surfaces, although minor artifacts are occasionally visible, reflecting the inherent challenges of this occlusion type. The "hand" occlusion type, characterized by irregular shapes and textures, showcases the model's robustness in reconstructing facial features obscured by dynamic and complex occlusions. Predicted images display minimal artifacts, with a high degree of alignment to the ground truth. Similarly, the "mask" occlusion type results indicate the model's capacity to reconstruct large, uniform occlusions. The reconstructed images closely align with the ground truth, although slight blurring is observed in some regions.

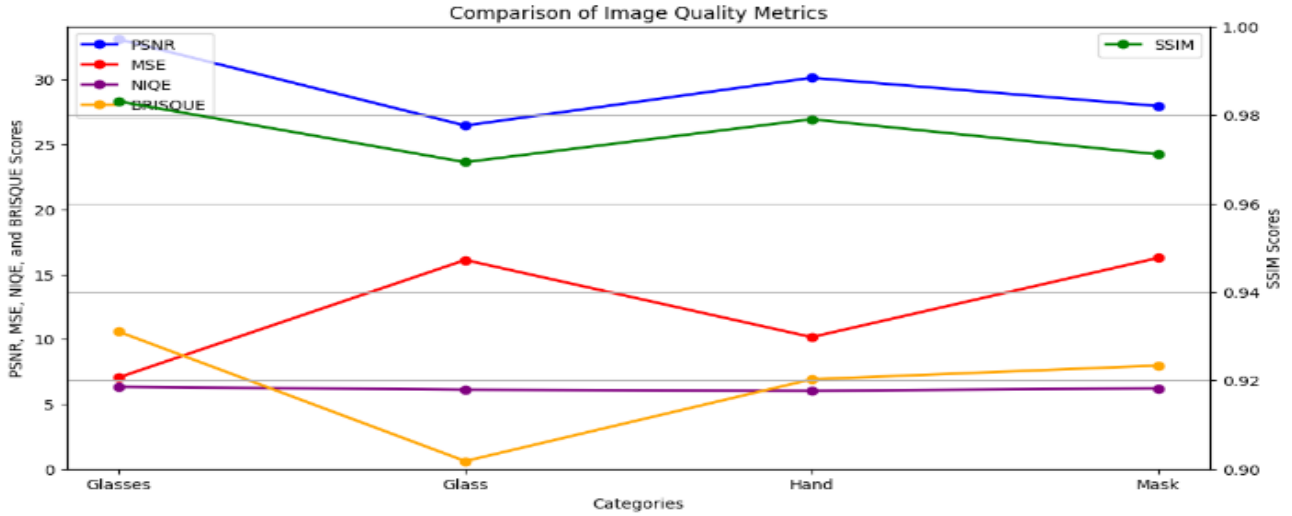

Fig. 5. Graph comparison of image quality metrics.

TABLE II. QUANTITATIVE COMPARISON OF OUR METHODS TO OTHER STATE-OF-THE-ART REPRESENTATIVE METHODS (THE BEST RESULT ARE BOLDFACED).

Type Of Occlusion	Methods	SSIM	PSNR	NIQE	BRISQUE
Glasses	Edge.[1]	0.882	25.641	4.763	36.374
	PConv.[35]	0.896	26.678	4.509	39.680
	GConv.[36]	0.889	26.289	4.598	38.358
	GAN-BN.[37]	0.914	28.878	**4.458**	38.111
	Ours	**0.983**	**33.106**	6.329	**10.575**
Glass	Edge.[1]	0.917	27.919	4.186	34.213
	PConv.[35]	0.940	29.455	4.331	35.514
	GConv.[36]	0.940	29.455	4.853	35.396
	GAN-BN.[37]	0.944	**31.323**	**4.105**	34.38
	Ours	**0.969**	26.465	6.108	**0.603**
Hand	Edge.[1]	0.818	24.911	4.597	31.913
	PConv.[35]	0.863	25.122	4.691	24.603
	GConv.[36]	0.885	26.920	4.929	24.879
	GAN-BN.[37]	0.882	26.948	**4.443**	24.206
	Ours	**0.979**	**30.147**	6.026	**6.908**
Mask	Edge.[1]	0.867	20.873	4.755	41.895
	PConv.[35]	0.869	24.452	4.830	44.976
	GConv.[36]	0.850	22.357	4.573	39.676
	GAN-BN.[37]	0.908	**28.727**	**4.425**	40.883
	Ours	**0.971**	27.972	6.213	**7.968**

Table II provides a comparative evaluation of the proposed methodology against other state-of-the-art methods across different occlusion types, including glasses, glass, hands, and masks. The metrics analyzed include SSIM, PSNR, NIQE, and BRISQUE, which collectively offer a holistic view of the reconstruction quality. For the "glasses" occlusion type, the proposed method achieves the highest SSIM of 0.983 and a PSNR of 33.106, outperforming other methods such as Edge, PConv, GConv, and GAN-BN. Although the NIQE value of 6.329 is slightly higher compared to other methods, the BRISQUE score of 10.575 significantly outperforms the alternatives, highlighting the superior perceptual quality of the reconstructed images. In the "glass" occlusion type, the SSIM value of 0.969 and BRISQUE score of 0.603 stand out as the best among all methods. The slightly lower PSNR of 26.465 compared to GAN-BN (31.323) can be attributed to the reflective properties of glass occlusions, which are inherently challenging to reconstruct. For the "hand" occlusion type, the proposed method demonstrates excellent results with an SSIM of 0.979, a PSNR of 30.147, and a NIQE value of 6.026. The BRISQUE score of 6.908 further supports the method's capability to handle irregular and complex occlusions, outperforming other approaches in perceptual quality. The "mask" occlusion type results show an SSIM of 0.971 and a BRISQUE score of 7.968, both of which are superior to other methods. While the PSNR of 27.972 is slightly lower than GAN-BN's 28.727, the overall performance remains competitive, especially in terms of structural and perceptual quality. Overall, Table II demonstrates the superiority of the proposed methodology in most metrics and occlusion types, particularly in terms of structural similarity (SSIM) and perceptual quality (BRISQUE). These results underscore the robustness and effectiveness of the GAN-based approach in reconstructing occluded facial images across diverse scenarios.

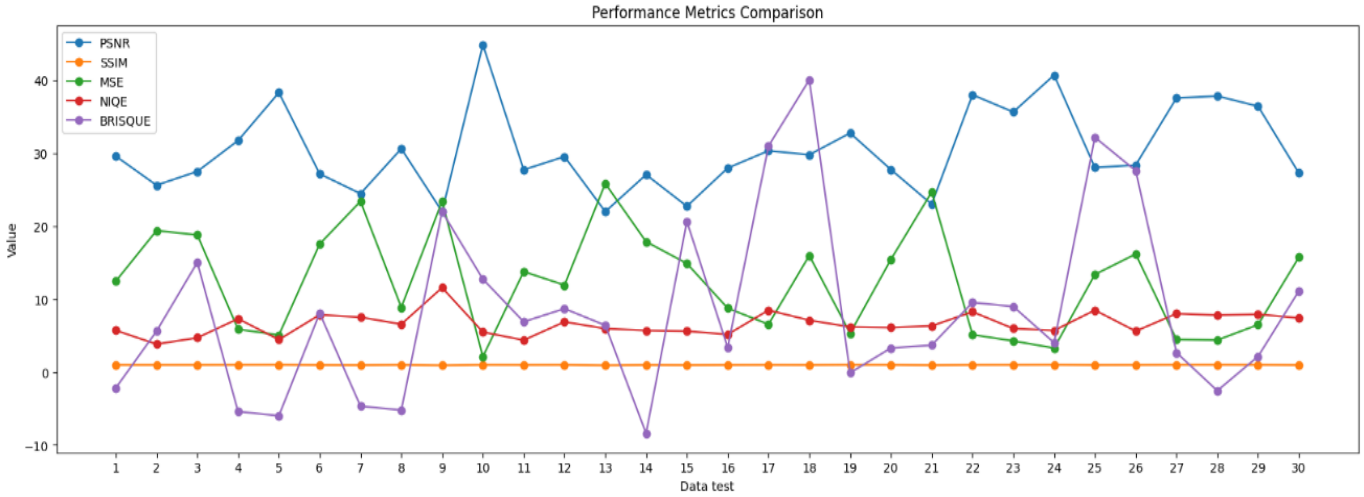

Fig. 6. Performance metrics comparison.

Fig. 6 compares multiple performance metrics across various datasets, providing a comprehensive analysis of the model's consistency and robustness. The metrics displayed include PSNR, SSIM, MSE, NIQE, and BRISQUE, with their trends plotted for visual clarity. The PSNR metric shows relatively stable high values across most datasets, indicating that the reconstructed images maintain a strong signal-to-noise ratio. This stability suggests that the model performs consistently across different occlusion scenarios. Similarly, SSIM values remain consistently high, reflecting the model's ability to maintain structural integrity and similarity to the original images. The MSE metric, which measures reconstruction error, fluctuates slightly more but stays within a low range across datasets. This low error margin underscores the model's precision in reconstructing facial images, even in complex occlusion conditions. The perceptual quality metrics, NIQE and BRISQUE, show slight variability across datasets, which may be attributed to differences in occlusion types and their inherent complexities. However, these values remain within acceptable ranges, demonstrating the model's ability to generate visually appealing reconstructions. Overall, Fig. 6 highlights the robustness and reliability of the proposed methodology. The consistent performance across diverse datasets underscores the model's adaptability to varying occlusion scenarios, making it well-suited for practical applications in facial recognition systems.

V. Conclusion

In this research, an in-depth study is conducted on developing innovative strategies to synthetically reconstruct occlusion-impacted facial images in various scenarios. This research presents a robust and comprehensive methodology to address the challenges of occluded facial image reconstruction by utilising a GAN (Generative Adversarial Network) based framework. The proposed systematic approach effectively incorporates three key components: careful data pre-processing to ensure input quality, sophisticated network architecture design to handle occlusion variations, and rigorous and multidimensional evaluation metrics to holistically measure model performance. As part of the preprocessing stage, this study implemented VGG-Net preprocessing to extract relevant facial features and reduce noise in the input data. VGG-Net, which is known for its ability to capture hierarchical features from images, is used to ensure that the data entering the reconstruction model is optimised and ready for further processing. This stage is crucial, as good input quality can

significantly improve the accuracy and reliability of the reconstruction model. By utilising VGG-Net, this research successfully normalises the facial image, adjusts the lighting, and removes artefacts that may interfere with the reconstruction process. The results show the superiority of the developed model in terms of quantitative metrics such as PSNR (Peak Signal-to-Noise Ratio) and SSIM (Structural Similarity Index), which indicate the accuracy of the reconstruction, as well as perceptual metrics such as BRISQUE (Blind/Referenceless Image Spatial Quality Evaluator), which assesses the visual quality of the reconstruction results. These advantages are seen in both individual and combined occlusion, which includes various types of obstructions such as the use of glasses, masks, or objects that partially obstruct the face. In addition, the visual fidelity and adaptability of the model were further validated through in-depth comparative analysis against state-of-the-art methods, as well as graphical illustrations demonstrating the model's ability to produce realistic and detailed facial images. To ensure the validity and generalisability of the model, this study uses a variety of diverse datasets, including synthetic datasets and real-world datasets, which include variations in lighting conditions, resolution, and occlusion levels. The evaluation results show that the proposed model is not only consistent in its performance but also able to adapt to complex and challenging scenarios. This research also opens the door for further exploration, including model optimisation to handle dynamic or highly reflective occlusions, as well as integration into broader applications such as public security systems, healthcare, and assistive technologies for individuals with special needs. As such, this research not only makes a significant contribution to the field of facial image reconstruction but also offers relevant practical implications for various sectors of industry and society.

ACKNOWLEDGMENT

The author would like to thank the support provided by the Faculty of Computer Science and Information Technology, Universiti Tun Hussein Onn Malaysia (UTHM), especially all the tutors involved in completing this article, then Abdurrab University under the Abdurrab Pekanbaru Foundation which has supported this research to obtain results which is satisfying.

***Abstract*—Water quality monitoring in aquaculture involves classifying and analyzing the collected data to assess the water quality that is appropriate for breeding, rearing and harvesting aquatic organisms. Systematic data classification is essential when it comes to managing large amounts of data that are continuously sensed in real time and have various attributes in each instance of a sequence. Ant Colony System (ACS) has been employed in optimizing the data classification in smart aquaculture, where the majority of the research focuses on enhancing the classification procedure using predetermined parameters within a specified range. Nevertheless, this approach does not guarantee ideal performance. This paper enhances the ACS algorithm by introducing the Enhanced Ant Colony System-Rule Classification (EACS-RC) algorithm, which improves rule construction by integrating pheromone and heuristic values while incorporating advanced pheromone update techniques. The optimal parameter values to be used by the proposed algorithm are obtained from parameter adaptation experiments in which different values within the defined range were applied to obtain the optimal value for each parameter. Experiments were performed on the Kiribati water quality dataset and the results of the EACS-RC algorithm were evaluated against the AntMiner and AGI-AntMiner algorithms. Based on the results, the proposed algorithm outperforms the benchmark algorithms in classification accuracy and processing time. The output of this study can be adopted by the other ACS variants to achieve optimal performance for data classification in smart aquaculture.**

Keywords*—Parameter adaptation; rules classification; water quality monitoring; ant colony system; pheromone update techniques

I. INTRODUCTION

Smart aquaculture refers to the implementation of intelligent aquaculture management systems, in which smart devices are utilized within a carefully designed ecosystem to continuously monitor environmental parameters in real-time. These devices collect data, which is then used to assist with decision-making processes. The automation and centralized management of smart aquaculture are made possible by big data, artificial intelligence (AI), the Internet of Things (IoT), and robotics [1]. These technologies work together to minimize human intervention in the operation of complete production systems through the control of facilities, machinery, and other devices. Sensor data is gathered by smart aquaculture, transmitted in real time to a database, and processed into useful information. All of these challenges can be resolved with a smart aquaculture system that can be remotely controlled and requires less labor [2]. Thus, smart aquaculture aims to develop the aquaculture industry in a manner that is both environmentally and economically sustainable.

Traditional aquaculture involves the selection of seeds, the preparation of water, nourishment, and maintenance [3]. Aquaculture workers often struggle to maintain water quality because frequent water sample collection is required. Ponds and tanks must be kept clean, and any changes in the water quality that take place outside of the regular cleaning schedule can have several negative consequences. In some cases, diagnosis and treatment cannot be administered while the fish that live in ponds are still alive, presenting an additional challenge. Ultimately, these factors impact productivity and quality. Incorporating sophisticated technology including automation, data analytics, real-time monitoring, and many more, smart aquaculture solves traditional aquaculture issues with innovative production techniques [4, 5].

Dissolved Oxygen (DO), temperature, and pH (hydrogen potential) are key parameters in smart aquaculture water quality monitoring to determine whether the water is suitable for breeding, rearing, and harvesting aquatic animals [6,7]. Managing massive real-time data with varying properties for each sequence requires systematic data classification. Data classification is considered a Nondeterministic Polynomial (NP)-complete problem, meaning it cannot be solved in polynomial time by an exact algorithm. One of the most effective approaches to solving NP-complete problems is using metaheuristic algorithms, which explore various optimization options to identify the best-performing solution.

Ant Colony Optimization (ACO), a metaheuristic algorithm, has successfully improved classification performance in terms of execution time, model size, and accuracy [8, 9]. ACO is inspired by the foraging behavior of real ants, which find the shortest route from their nest to a food source during foraging is the basis for ACO. To communicate, ants use chemical substances known as pheromones. As they traverse a path, they deposit pheromones, which may encourage more ants to follow the same path. Paths with higher pheromone concentrations are more likely to be reinforced, while paths with lower pheromone

levels fade more quickly due to evaporation [10]. Consequently, ants must continuously deposit pheromones to guide others toward the optimal path. Several ACO variations have been applied to NP-complete problems, including the Max-Min Ant System (MMAS), Ant System (AS), and Ant Colony System (ACS) [11].

ACO can be used for rule development in data classification to accurately classify dataset instances. Each rule is represented by an ant that follows pheromone trails. Rules with higher levels of pheromone concentration are more likely to be selected by ants. The ACO algorithm begins with a collection of randomly generated rules, each of which specifies the attributes and values that an instance must have to be classified into a particular class. Ants are distributed across the feature space. Next, each ant then selects a feature based on pheromone concentration and a heuristic function that evaluates the feature's relevance to the classification task [12]. Fig. 1 shows the development of classification rules by ants where each term is represented as a node and possible paths connect the nodes. Consequently, each ant develops its own path, representing a classification rule.

- IF attribute 1 = A1, 3 AND attribute 2 = A2, 1 AND attribute N = An, 2 THEN class = Class1.
- IF attribute 1 = A1, 1 AND attribute 2 = A2, 2 AND attribute N = An, 1 THEN class = Class2.

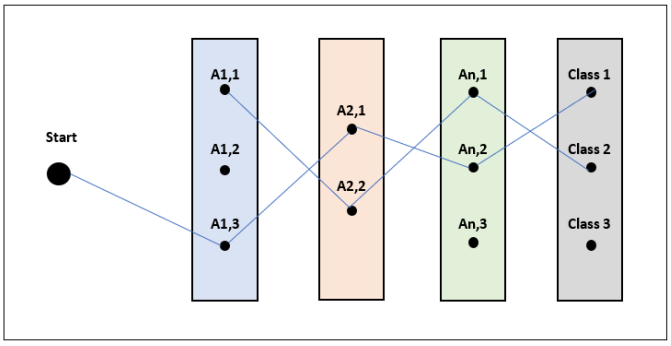

Fig. 1. Development of ant-based classification rules.

A fitness function evaluates the current set of rules to determine the reliability of each rule in the classification model. Ants adjust their pheromone trace according to the strength of a feature. The potency of a pheromone trail is determined by how effectively the features contribute to classification accuracy. By encouraging ants to select the same features in subsequent iterations, the algorithm gradually converges on a refined subset of attributes. To prevent the algorithm from settling on a suboptimal solution, it is possible to eliminate weak features with low pheromone intensity from the subset [13, 14]. Once the most relevant features have been selected, a classification model can be developed.

This paper analyzes parameter adaptation by the proposed algorithm to enhance the data classification process in smart aquaculture. The impact of each parameter is assessed by applying different values within a defined range to measure classification accuracy. The results demonstrate the effectiveness of the optimal parameter values, which can be applied to the proposed algorithm specifically and to other ACS variants more broadly, in the context of smart aquaculture. A final comparison is conducted by applying the optimal parameter values and evaluating them against other ACO-based classification algorithms. Section II discusses data classification in real-world applications, while Section III reviews recent ACO approaches in data classification. The proposed data classification algorithm is detailed in Section IV followed by experimental results and discussion in Section V and Section VI respectively. Lastly, Section VII provides concluding remarks.

II. Real-Life Applications Using Ant-Based Data Classification

Classifying data involves organizing information based on a set of policies and standards. Data classification is typically based on three criteria which are risk levels, sensitivity, and importance [15]. In general, data classification enables organizations to store, access, and retrieve data safely, efficiently, and effectively. ACO can be applied to rule construction in data classification, where it searches for a set of rules that accurately classify instances within a dataset [16]. An ant constructs a rule by following a pheromone trail, moving from one term to another. The pheromone trail represents the attractiveness of a term to ants, with more attractive terms having higher pheromone concentrations. The algorithm begins with a randomly generated set of basic rules. Each rule consists of a set of conditions that describe terms composed of attributes and values, determining classification into a specific class. The ants are initially dispersed randomly throughout the terms. Then, each ant selects a term based on a heuristic function and the pheromone concentration.

The accuracy of the classification model is determined by evaluating the existing set of rules using a fitness function. Over time, ants modify their pheromone trails based on the quality of the selected terms. The effectiveness of these terms is directly correlated with pheromone concentration [17]. Ants are encouraged to select the same terms in subsequent iterations, leading the algorithm to converge on a specific set of attributes. Weak terms with low pheromone intensity can be eliminated to prevent the algorithm from selecting an unsuitable solution. Table I presents a list of ant-based data classification applications in real-world scenarios, categorized into five main domains which are agriculture, aquaculture, health and medicine, autonomous vehicles, and finance.

Based on Table I, data classification plays a crucial role in various Real-world applications across multiple domains, including aquaculture systems. The classification challenge was successfully addressed in real-life scenarios using an ACO-based classification technique.

III. RELATED WORK

ACO has demonstrated promising results in optimizing data classification, where its effectiveness heavily depends on the accuracy of the features used for classification and the size of the dataset. Applying ACO to feature selection has enhanced classification performance and efficiency by reducing complexity, minimizing overfitting, and improving accuracy. A multi-label feature selection approach based on ACO (MLACO) was proposed by study [36] to identify the most relevant features with minimal redundancy. This approach combines supervised and unsupervised heuristic functions to refine feature selection over multiple iterations. According to experimental results, MLACO, which employs a global pheromone update to detect and eliminate redundant features, performed more efficiently and accurately than other algorithms.

To optimize the process of rule generation and selection, [37] proposed a self-training utilizing associative classification using ant colony optimization (ST-AC-ACO). This method integrates a semi-supervised associative classification technique with ACO to enhance classification performance by leveraging both labeled and unlabeled data. The method incorporates unlabeled cases into the learning process, addressing the problem of limited labeled data. This enables the system to identify valuable patterns and rules that may not be apparent from labeled data alone. ACO is employed to optimize the rule generation and selection steps within the associative classification process. Using pheromone-based techniques, the system guides the search for high-quality classification rules. The proposed method was compared with existing supervised and semi-supervised classification algorithms. Experimental results demonstrated the advantages of integrating associative classification with ACO, showing improved classification robustness and accuracy, particularly when working with unlabeled data.

Applying ACO algorithms for data classification in smart aquaculture presents an innovative approach to organizing and analyzing large and complex datasets. In this context, data classification refers to the process of structuring and analyzing data collected through advanced technologies to enhance the sustainability, efficiency, and management of aquaculture systems. Smart aquaculture optimizes various aspects of aquaculture operations by integrating technologies such as sensors, data analytics, machine learning, and automation.

By integrating the ACO technique into a boosting framework, the study by [22] aims to develop an optimization-based feature selection method to enhance the accuracy of water quality classification models. The proposed algorithm identifies key features within the dataset while eliminating irrelevant and redundant ones to optimize the classification process. ACO utilizes pheromone trails to select features during each iteration of the boosting process. Ants use heuristic information and updated pheromone levels to construct a new feature subset. To achieve optimal performance, ants identify the subsets with higher pheromone values. Additionally, pheromone updates are applied to balance the exploration and exploitation of potential feature subsets. Experimental results demonstrate that the proposed approach effectively improves accuracy, sensitivity, and precision compared to other classification algorithms.

The integration of the ACO algorithm with the random forest algorithm was proposed by study [23] to enhance the accuracy of nitrate concentration mapping in groundwater within the multi-layer coastal aquifer system of the Mekong Delta. ACO is responsible for the feature selection process, identifying the most significant features that contribute to accurate groundwater

nitrate concentration predictions. Ants utilize heuristic information and pheromone levels to make probabilistic feature selections, facilitating the convergence of feature subsets that improve the prediction model's performance over multiple iterations. At the end of each iteration, pheromone levels are adjusted to reinforce effective feature subsets and suppress ineffective ones. This iterative process continues until an optimal feature subset is identified. By assisting in the selection of the most relevant features from a potentially large dataset, ACO enhances both the accuracy and efficiency of the random forest model.

The study by [24] aims to optimize fish disease identification by integrating a Deep Convolutional Neural Network (DCNN) for feature extraction, ACO for feature selection, and a hybrid random forest for classification. ACO is employed to select a subset of relevant features based on pheromone concentrations, with the number of ants determining the extent of feature space exploration. Features with high pheromone values are selected, while an evaporation procedure is simultaneously applied to prevent convergence on a locally optimal solution. Experimental results demonstrated that the proposed algorithm achieved the highest accuracy compared to other classification algorithms.

Based on the reviewed literature, ACO demonstrates significant potential in addressing classification challenges within the aquaculture domain. However, none of the prior studies explicitly highlight the significance of individual parameter values. The objective of this study is to identify the optimal parameter values that can be utilized by ACO for data classification in smart aquaculture.

IV. Enhanced Ant Colony System For Data Classification In Smart Aquaculture

The proposed Enhanced Ant Colony System for Rules Classification (EACS-RC) algorithm is an adaptation of ACS, consisting of three main phases which are rule construction, pheromone update, and evaluation, as illustrated in Fig. 2. The new algorithm variant is revolutionized from the ACS [38] as an improvement to the AS for enhancing the classification performance. While both ACS and AS are based on foraging behavior, they differ in three key aspects which are rule construction, local pheromone update, and global pheromone update. ACS employs a more aggressive action-selection rule, where pheromone is partially removed from each visited path, and additional pheromone is only applied to the global best solution.

The rule construction phase focuses on using ants to iteratively develop the model by constructing classification rules. These rules are formulated based on heuristic information and pheromone values obtained from previous iterations. The pheromone update phase consists of two key steps which are local pheromone update and global pheromone update. The local pheromone update acts as a control mechanism to prevent excessive accumulation of specific parameters and minimize the overfitting of noisy data, thereby reducing the runtime of the classification process. Conversely, the global pheromone update is applied to the most optimal rule identified by the ant during each iteration. This step ensures that the algorithm progressively converges toward a more accurate and effective model by selectively reinforcing high-quality rules. As a result, the overall classification solution is improved by the end of the process. In the final stage, the most optimal rule from each iteration is selected to form the classification model. The performance evaluation phase then assesses the effectiveness of the proposed classification algorithm by measuring the model's accuracy.

Based on Fig. 2, each ant begins selecting terms to add to the rule during the rule construction phase. Two key factors considered when choosing terms are the pheromone value and heuristic information. The state transition rule is applied to balance the exploitation of prior terms and the exploration of new terms, as represented by the following equation.

$$S = \begin{cases} argmax \in U, & \text{if } q \le q_0 \text{ (exploitation)} \\ P, & otherwise \text{(exploration)} \end{cases} \quad (1)$$

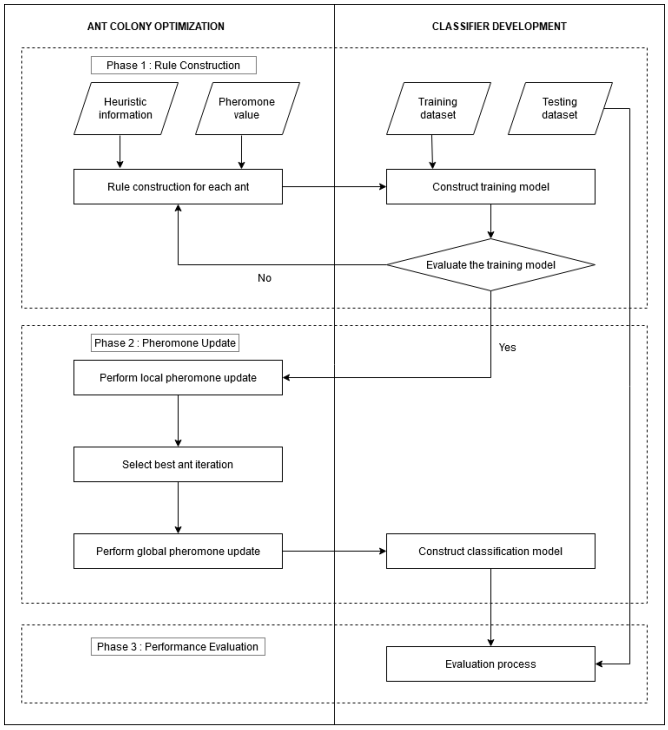

Fig. 2. Framework of the proposed EACS-RC classification algorithm.

where q is a random number uniformly distributed between 0 and 1 and q_0 is a parameter value ($0 \le q_0 \le 1$). When q is less than or equal to q_0, the ant makes a deterministic (greedy) choice by selecting the condition with the highest pheromone level or heuristic information. In this case, the probability is set to 1 for the selected variable and 0 for all other variables. Otherwise, when q is greater than q_0, the ant follows a probabilistic path selection process, using pheromone and heuristic information to calculate the probability of selecting each rule.

U represents the probability of selecting a specific value from available options and P is the proposed equation to calculate the probability of term selection to be added to the current rule which is calculated using the following equation:

$$P = \frac{\left[(\tau_{rs(t)})^{\alpha} . (\eta_{rs})^{\beta}\right]}{\Sigma\left(x . \Sigma\left[(\tau_{rs(t)})^{\alpha} . (\eta_{rs})^{\beta}\right]\right)} \quad (2)$$

where the concentration of pheromones at any given time (t) for each term is represented as $[\tau_{rs(t)}]$ while the heuristic information or desirability is represented as $[\eta_{rs}]$ which considers the pH, temperature and DO value of water. The variable $[x]$ represents the number of iterations. The outer summation $(\sum)$ iterates over the number of ants or iterations.

Each rule created by an ant undergoes pruning by eliminating unnecessary terms during the rule pruning process. The proposed algorithm determines the predictive class of the pruned rules by assigning them to the majority of the cases they cover. This process is repeated iteratively to enhance the quality of the rules. To refine the discovered rules, a local pheromone update is applied using the following equation:

$$\tau_{n(t+1)} = (1-\rho).\tau_{n(t)} + \rho.S(t) \quad (3)$$

In the given context, ρ represents the evaporation rate, which controls the accumulation of a specific parameter to prevent unlimited accumulation. For each threshold value, $\tau_{n(t)}$ denotes the quality level that determines the most probable selection. Meanwhile, $S(t)$ represents the quality of the discovered rule, which is defined as follows:

$$S_t = \frac{[N_T][P_T]}{(P_T+N_F)(N_T+P_F)} \quad (4)$$

where N_T represents the total number of instances that do not belong to the expected class and are not covered by the discovered rule, while P_T indicates the total number of instances that belong to the expected class and are covered by the discovered rule. On the other hand, N_F signifies the Total number of instances covered by the discovered rule but classified incorrectly. Finally, P_F indicates the total number of instances that are classified correctly by the rule but are not covered by the discovered rule.

This process will continue until all the ants have learned the complete set of rules. The most effective rules discovered in each cycle will be added to the final list of classification rules. The best rule from each iteration is selected using the global pheromone update, calculated as follows:

$$\tau_{n(t_{best})} = (1-\rho).\tau_{n(t_{best})} + \rho.S(t_{best}) \quad (5)$$

where ρ represents the parameter responsible for the quality decay, while $S(t_{best})$ denotes the quality of the best discovered rule at a given iteration. Once all steps completed, a new iteration will begin, following the same process.

V. Experimental Results

The ideal parameters for EACS-RC in classifying data in smart aquaculture were determined through experiment. The α value controls the influence of pheromone information on the ant's decision-making process, while β value determines the importance of heuristic information or domain-specific knowledge used by the ants to make decisions. Additionally, pheromone trails evaporate over time at a rate determined by the evaporation rate (ρ).The q_0 value regulates the balance between exploration and exploitation, helping ants effectively navigate the search space.

The optimal value for α, β, ρ and q_0 as well as their effects on the system were determined through experiments using Kiribati water quality monitoring data [39]. Classification accuracy was used as the evaluation metric for parameter adaptation. The EACS-RC algorithm was assessed using standard ACS parameters, including the number of ants, rule discovery criteria, number of iterations, and the experiment parameters. Table II presents the simulation parameters used in the experiment.

TABLE II. Simulation Parameters

Parameter	α, β, ρ and q_0
Performance metric	Classification accuracy
Number of Ants	10
Minimum number of cases that each rule must cover	5
Maximum of uncovered cases by the discovered rule	10
Number of iterations	100

The optimal value of α, which determines the impact of pheromone value on the ant's decision-making process, was evaluated in the first set of experiments. A range of values from 1 to 10 was tested to assess the classification performance of EACS-RC. As shown in Fig. 3, the optimal α value is 3 (highlighted in red) as it yields the highest classification accuracy. Selecting the optimal α value is crucial, as it directly influences the convergence speed of the algorithm.

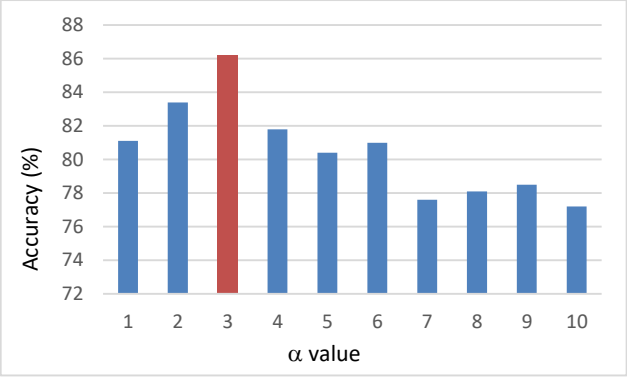

Fig. 3. Effect of α value on accuracy of EACS-RC.

The second set of experiments aimed to determine the optimal value of β for EACS-RC, where $0 < \beta < 10$. Fig. 4 illustrates that the ideal value of β is 4 (highlighted in red), as it results in the highest classification accuracy based on the experimental results. The β parameter plays a crucial role in balancing the exploitation of pheromone trails and the use of problem-specific knowledge, ensuring an effective classification process.

The third set of experiments aimed to determine the optimal value of q_0 which serves as a threshold in the state transition rule to balance the exploration of new terms and the exploitation of previously selected terms. The impact of q_0 on the classification performance of EACS-RC for the water quality index was evaluated using values ranging from 0.1 to 1. As shown in Fig. 5 (highlighted in red), the optimal value of q_0 is 0.5, yielding the highest classification accuracy. Identifying the optimal q_0 value is crucial as it directly influences how the ACO algorithm balances exploration (random selection) and exploitation (pheromone-based selection), thereby affecting the overall performance of the classification process.

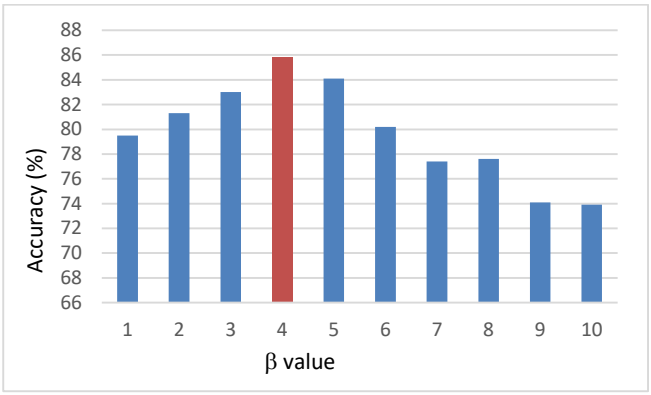

Fig. 4. Effect of β value on accuracy of EACS-RC.

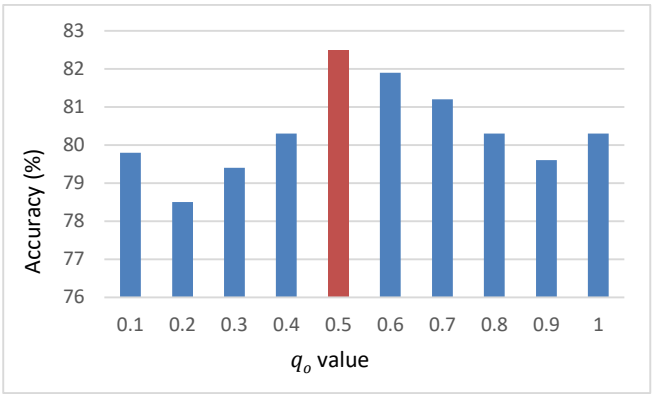

Fig. 5. Effect of q_0 value on accuracy of EACS-RC.

In the next set of experiments, the optimal evaporation rate (ρ) value for pheromone decay was investigated. Pheromone decay is essential to prevent the excessive accumulation of pheromones, which could lead to stagnation or convergence toward suboptimal solutions. The experimental results, as shown in Fig. 6, indicate that the optimal (ρ) value is 0.5 (highlighted in red), yielding the highest classification accuracy. These findings emphasize the crucial role of (ρ) in the algorithm, as it ensures that ants continue exploring different terms while preventing them from being overly influenced by outdated information.

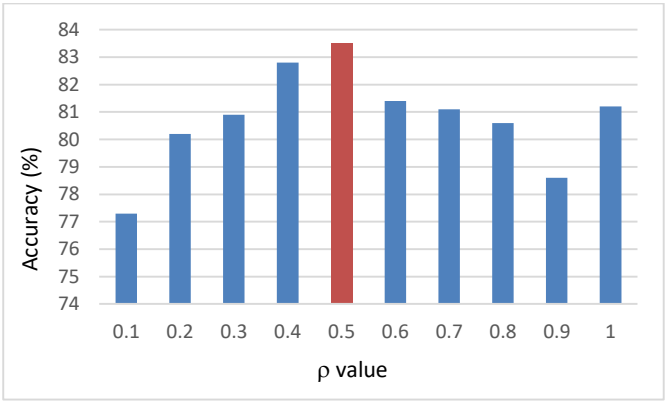

Fig. 6. Effect of ρ value on accuracy of EACS-RC.

The optimal value of α, β, ρ and q_0 from the previous experiments were applied in next set of experiments to evaluate the performance of the proposed EACS-RC algorithm. The Kiribati Water Quality Monitoring dataset was used to assess its accuracy and processing time with two other classification algorithms, AntMiner [40] and AGI-AntMiner [41]. Fig. 7 illustrates that the EACS-RC algorithm achieved an accuracy of 83% with a processing time of 598 seconds. In comparison, the AGI-AntMiner algorithm attained a slightly lower accuracy of 82%, with a processing time of 649 seconds. Meanwhile, the AntMiner algorithm recorded an accuracy of 77% and required 700 seconds to complete the process. These findings highlight the efficiency and accuracy of the EACS-RC algorithm in analyzing the Kiribati Water Quality Monitoring dataset.

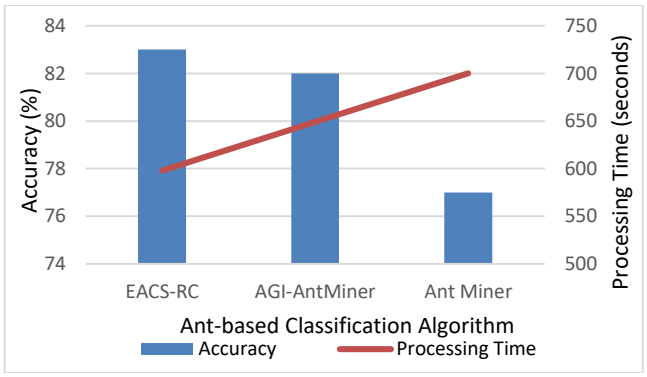

Fig. 7. Comparison of accuracy results between EACS-RC, AGI-AntMiner and AntMiner.

VI. Discussion

Four sets of experiments were conducted to determine the optimal parameter values for EACS-RC, and the results are summarized in Table III.

- The optimal α value is 3, as it influences the convergence speed of the algorithm. A higher α may cause premature convergence to suboptimal solutions, while a lower α can slow down the optimization process.
- The optimal β value is 4, balancing the use of heuristic information and pheromone influence. A higher β gives more weight to problem-specific knowledge, while a lower β prioritizes pheromone trails.
- The optimal q_0 value is 0.5, ensuring a balanced exploration-exploitation trade-off during the local pheromone update phase.
- The optimal ρ value is 0.5, allowing pheromone trails to dissipate optimally. This prevents ants from being overly influenced by outdated information and encourages better exploration of feature subsets.

These values are considered optimal for the EACS-RC algorithm in smart aquaculture systems for water quality classification. However, factors such as simulation settings, topology, environmental conditions, and dataset size may affect the need for further parameter tuning to achieve optimal performance.

TABLE III. THE OPTIMAL VALUE FOR THE PARAMETERS TO GAIN BEST ACCURACY

α	3
β	4
q_0	0.5
ρ	0.5

VII. CONCLUSION

While optimizing the efficiency of the ACS algorithm in smart aquaculture for water quality classification, it is undeniable that selecting the most suitable parameter values is essential. An algorithm functioning at peak efficiency ensures optimal performance. By fine-tuning the parameters, the proposed EACS-RC algorithm can effectively leverage available data, such as pheromone trails and heuristic information, to enhance classification accuracy. Compared to previous studies that overlooked parameter adaptation, refining these values can significantly improve the precision of water quality classification, which is vital for smart aquaculture management. This efficiency is particularly important in smart aquaculture, where timely and accurate water quality classification is crucial for effective decision-making and ensuring the well-being of aquatic organisms. The process of parameter adaptation plays a crucial role in improving algorithm performance and its applicability in real-world aquaculture scenarios.

Future research could focus on fine-tuning parameters for other ACO algorithm variants across diverse application domains, topologies, and environments. Beyond parameter optimization, future research could explore the integration of adaptive and self-learning mechanisms into the EACS-RC algorithm. Incorporating machine learning techniques, such as reinforcement learning or metaheuristic-based adaptation, could enable the algorithm to dynamically adjust its parameters based on real-time environmental conditions. This adaptability would enhance its robustness and responsiveness to changing water quality factors in smart aquaculture systems.

The Application of Face Recognition Model Based on MLBP-HOG-G Algorithm in Smart Classroom

Xiaoxia Li
College of Artificial Intelligence and Big Data, Zibo Vocational Institute, Zibo, 255000, China

***Abstract*—The development of Internet and Internet of things technology has accelerated the informatization construction of smart education. But the traditional face recognition algorithm used in smart classrooms inevitably has problems such as large amount of calculation, obvious resource and memory consumption, and poor recognition accuracy. In order to promote the informatization construction of colleges and universities and the accuracy of face recognition, a face recognition model based on multi-feature Local Binary Pattern Directional Gradient Histogram Gabor Filter algorithm is proposed. The model first extracts the binary texture image, and then carries out secondary feature extraction, dimension reduction processing and serial fusion with the gray level co-occurrence matrix feature weighting to improve the recognition accuracy. The results show that the recognition rate of the proposed method in ORL database, CMU_PIE database and Yale database can reach 95%, 94.12% and 93.33%, which is better than other algorithms. And in the comprehensive data set, the training and verification recognition accuracy of the proposed method for face recognition is basically 98% and 97.23%, which has good generalization and stability, and its cumulative error result of face key point detection is less than that of other comparison methods. The proposed method can provide new opportunities and possibilities for the application effect of face recognition, smart classroom construction and teaching development.**

***Keywords*—Multi feature local binary pattern; directional gradient histogram; Gabor filter; face recognition; smart classroom**

I. Introduction

With the development and promotion of information technology, smart classrooms utilize technologies such as artificial intelligence and big data to monitor and analyze classroom teaching in real-time, providing teaching feedback and personalized learning services for teachers and students [1]. As an important foundational technology for intelligent classrooms, student facial recognition can achieve functional statistics and analysis of student attendance, classroom performance, and other content. Wang et al. proposed a facial recognition intelligent education system based on MTCNN and FaceNet models. The results show that the accuracy of the system in both facial recognition and student emotion recognition performance is over 90% [2]. Dang T V scholar proposed an improved facial recognition model architecture based on the MobileNetv2 backbone network to achieve facial recognition. The results show that the accuracy of this depth method exceeds 95% on small datasets of original face images [3]. However, facial recognition faces many challenges in different classroom environments, such as complex classroom layouts and a large number of interactive devices that may cause changes in lighting, shadows, and reflections. Different quantities, scales, multi pose faces, face occlusion, and other factors can lead to lower detection and accuracy rates in object recognition [4]. The existing facial recognition technology is difficult to meet the needs of real-time processing and teaching recognition. For example, traditional methods such as principal component analysis and linear discrimination extract information from facial region images. The classic local feature extraction methods require a large amount of computation, and some deep learning methods are prone to losing control over recognition performance in unconstrained environments. Therefore, in response to these issues and shortcomings, a gradient oriented Gabor (MLBP-HOG-G) algorithm based on multi feature local binary pattern histogram is proposed for face recognition model. This method overcomes the shortcomings of traditional methods in complex environments. Compared with some traditional algorithms designed based on rules or fixed features, it can learn features through adaptive methods, improving adaptability to new environments and different student groups. Compared with traditional facial recognition technology, this fusion strategy achieves more comprehensive feature capture and solves problems such as lighting changes, facial occlusion, and pose changes. The face recognition model based on MLBP-HOG-G algorithm has unique advantages in feature diversity, robustness, adaptability, and performance improvement. It can provide more effective solutions and references for the application fields of intelligent classroom safety management, student behavior monitoring, and intelligent teaching.

The research mainly analyzes the application of facial recognition models in smart classrooms from four aspects. Section I is a literature review and discussion of facial recognition technology in current smart classroom applications. Section II is to design the MLBP-HOG-G algorithm to achieve smart classroom facial recognition, including feature extraction, weighted combination gray level co-occurrence matrix design, and construction of cascaded classifiers. Section III is to test and analyze the application effect of this feature recognition model. Section IV is an overview summary of the entire text.

II. Related Work

In a large-scale educational environment, student management and supervision are extremely challenging tasks. Educational institutions must effectively track students' attendance, participation, and behavior to ensure their safety and academic progress. This challenge has driven the demand for more efficient and intelligent student management

methods. Applying facial recognition technology to recognize and track individuals has become a major leap in smart classrooms, and some scholars have conducted a series of related studies on this topic. Researchers such as Niu proposed a feature fusion method with channel attention networks, aiming to fully utilize a limited number of hyperspectral samples for deep learning training. The experiment showcases that this method could markedly reduce storage space and computational overhead while still maintaining competitive accuracy and efficiency. These characteristics also indicate that this method has broad applicability on edges and mobile devices [5]. Widjaya and other researchers have proposed a random challenge response authentication method aimed at addressing the vulnerability of commercial facial recognition engines. This method is based on activity detection and is designed to protect against deception attacks, photo attacks, and video attacks. The experiment illustrates that the accuracy of this method is 99%, with an F-value of 98.99%. This study verifies the effectiveness of random challenge response authentication in resisting photo and video attacks in FR and anti-deception [6]. Scholars such as Nam presented a FR method that combines deep learning and binary patterns, for growing the accuracy of FR in high noon conditions. Experiments indicate that this method has high effectiveness and applicability when facial images are incomplete [7].

Fan et al. presented a Sprinter FR algorithm on the ground of sliding data camera measurement, aiming to solve the problems of low accuracy in facial key point recognition and noise errors in recognition. The experiment showcases that the algorithm successfully detects and recognizes six key points of the face, with a noise error of less than 1.3%, achieving the established goal and possessing practical application value [8]. MLBP, as a commonly used computer vision algorithm for FR, can extract local texture features of images. Therefore, it has wide applications in fields such as facial feature extraction, facial detection, facial expression recognition, facial authentication and recognition, and live body detection. Wang and his collaborators proposed a method for extracting texture features. This method utilizes multi-scale and multi-directional local binary patterns, aiming to classify hyperspectral images through a small number of labeled samples. The experiments indicate that this method could more markedly extract texture features and further strengthen the classification of hyperspectral images by combining it with the guidance of hyperpixel segmentation maps for decision-making [9]. Kaplan et al. proposed a multi-scale accessibility configuration file aimed at describing the multi-scale accessibility levels of various cities. Experiments have shown that there is an inherent correlation between universal accessibility at different scales and urban performance [10]. Considering that most studies have not integrated various visual cues such as facial expressions and body posture, Pabba C et al. proposed using OpenPose and Py Feat frameworks to extract multiple features and perform classification recognition under a cascaded neural network architecture. The results show that this method can effectively recognize students' facial features and behaviors, with an accuracy rate of over 90% [11]. El Mashad Y et al. used video facial recognition technology to implement smart classrooms, which can recognize individuals under different lighting conditions and facial expressions. The results indicate that this method has smaller errors and higher classification accuracy [12]. Yuan Z et al. proposed a face detection algorithm based on an improved YOLOv5, which introduces CSPDarknet53 backbone network, loss function, and self-attention mechanism modules to improve detection performance. The results show that the accuracy of this method for face detection exceeds 85%, and the detection accuracy in simple scenes exceeds 95% [13]. Aly M scholar attempted to use facial expression recognition techniques such as Residual Network with 50 layers (ResNet50), Convolutional Block Attention Module (CBAM), and Temporal Convolutional Network (TCN) to track students' classroom performance. The results indicate that this combination method is helpful in capturing facial expressions and monitoring learning behaviors [14].

Channel Attention Network Feature Fusion (Niu JY) can extract important features and reduce computational overhead, but it is difficult to adapt to high resource environments. The Random Challenge Response Authentication Activity Detection Method (Widjaya C) enhances the security of facial recognition, but it requires additional hardware support and computing resources. The face recognition method combining deep learning and binary patterns (NAM V-H) can still maintain high effectiveness and applicability in the case of incomplete facial images, but it relies heavily on data and has a high computational cost. The Sprinter facial recognition algorithm (fan y) has good noise control performance and accurate keypoint recognition, but it has a significant dependence on specified parameters. Multi scale and multi-directional local binary mode (Liguo Wang) can achieve classification of hyperspectral images, but it has fewer labeled samples. From the above content, it can be seen that using only attention mechanisms for feature fusion is difficult to ensure the comprehensiveness of information selection. Single thinking perspectives based on feature extraction (Nam v h, Liguo Wang) are inevitably affected by computational costs, resource constraints, environmental differences, and so on. The application of previous methods in facial recognition has limitations such as single feature extraction, insufficient robustness to complex scenes, high computational complexity, and storage overhead. The research proposes using the MLBP-HOG-G algorithm to recognize faces, and its multimodal combination approach can improve feature extraction ability and recognition accuracy. And this method utilizes the gray level co-occurrence matrix feature weighting method to perform secondary processing and dimensionality reduction on the extracted features, reducing the interference of noise and redundant information, effectively solving the limitations of previous research. This model not only improves the accuracy and efficiency of facial recognition, but also enhances its practical application ability in complex environments of smart classrooms, providing strong technical support for the informationization construction of universities.

III. Method Design for MLBP-HOG-G FR Model in Smart Classroom

This study focuses on facial recognition algorithms, including image processing, feature extraction, classification algorithms, and system design. The study used MLBP and

HOG to extract features, and then weighted combined grayscale co-occurrence matrix features to form MLBP-HOG-G features. It conducts facial recognition experiments through a classifier and constructs a SVM-KNN cascade classifier. Finally, it uses MATLAB GUI tools to design a facial recognition system, including identity verification functions.

A. Analysis of MLBP Based Facial Recognition Algorithm

FR is an identity recognition method achieved through computer vision technology. In the development process of smart classrooms, facial recognition technology can markedly enhance the operational efficiency of schools and decrease the workload of faculty and staff. The general process includes steps such as data collection, preprocessing, feature extraction, feature matching and storage, discrimination and decision-making, and feedback of recognition results. The recognition process is shown in Fig. 1.

In Fig. 1, the facial recognition process mainly includes three parts: facial image preprocessing, facial detection, and facial recognition. It first collects facial data and extracts discriminative features after preprocessing. Then it is matched with known features and the identity is determined on the ground of the matching results. Finally, it provides corresponding feedback on the ground of the recognition results. When describing facial recognition features, LBP has become one of the commonly used feature descriptors in the field of facial recognition due to its texture representation, invariance, dimensionality reduction, and high computational efficiency. The LBP operator was initially defined in a 3x3 pixel window, consisting of a central pixel and its 8 adjacent pixels. To represent the LBP operator, the function E can be used to represent the joint distribution function of the central pixel and adjacent pixel points. The calculation is showcased in Eq. (1).

$$E = t(g_c, g_0, ..., g_{p-1}) \quad (1)$$

In Eq. (1), g represents the pixel at the center; $g_0, g_1, ..., g_{p-1}$ are the eight surrounding pixels. By comparing the Pixel Values (PVA) of the center pixel of the window with the PVA of its surrounding 8 adjacent points, the joint distribution function of the disparity in the PVA of the center point and the PVA of the surrounding eight adjacent points can be used to describe the characteristics of the region. This study assumes that the PVA of the central pixel has little impact on the loss or impact of the texture feature information of the image, mainly affecting the brightness of the image. Therefore, the PVA of the center pixel can be ignored, and the joint distribution function of simplified texture features can be expressed as Eq. (2).

$$E \approx t(g_c - g_0, ..., g_{p-1} - g_c) \quad (2)$$

The above function describes the texture distribution of each pixel in the domain. Generally speaking, prominent texture features in texture distribution that cannot directly observe numerical features can be converted into binary features through the LBP algorithm. The local binary mode compares the grayscale values of a certain pixel in the image with neighboring pixels one by one, as shown in Fig. 2.

In Fig. 2, (a) is a 3x3 template, in which the grayscale value of the central pixel is used as the threshold. If the values of 8 pixels in the neighborhood are greater than or equal to this threshold, then the values of these pixels are set to 1, otherwise 0. Next, it starts from a starting point and sets the weights of each pixel in a clockwise direction, as shown in Fig. 2(c). Then, it converts the binary numbers around the center pixel into decimal numbers for obtaining the LBP value of the center pixel, as shown in Fig. 2(d). This process can be represented by Eq. (3).

$$LBP_{pj} = \sum_{s=1}^{8} t(p_s - p_j) \times 2^{s-1} \quad (3)$$

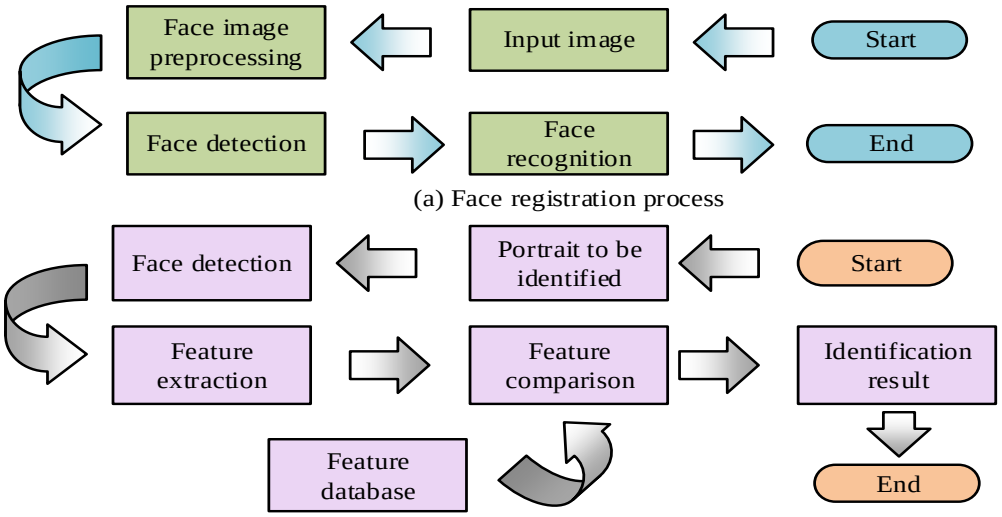

Fig. 1. FR process.

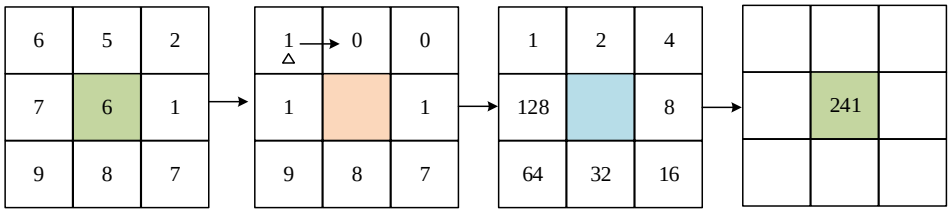

(a) 3X3 mobile template (b) Binary conversion (c) Weights (d) LBP eigenvalue

Fig. 2. LBP pixel comparison diagram.

In Eq. (3), s represents the eight nearest pixel points around the marked center pixel; p_s is the value of the pixel; p_j is the central pixel point; $t(r)$ is a symbolic function. To improve the LBP algorithm, MLBP introduced variance testing. It first calculates the variance of nine pixels within a 3x3 template to understand the fluctuations in PVA. When the variance is small and the texture is relatively smooth, MLBP uses the average of the maximum and minimum values of eight pixels around the center pixel as the threshold to prevent the loss of detail features. When the variance is large, the texture changes greatly. MLBP uses the median of nine pixels as the threshold to reduce noise interference in LBP calculation, and then recalculates the LBP code to update the texture features. This approach improves the LBP algorithm and better adapts to different image situations. It constructs a 3x3 template and calculates the variance V of the nine pixels in the template. The formula for calculating the variance is shown in Eq. (4).

$$V = \frac{1}{9}\sum_{j=1}^{9}(M - P_j)^2 \tag{4}$$

In Eq. (4), P_j represents the average value of nine pixels; P_j represents the PVA of nine templates, and the calculation is demonstrated in Eq. (5).

$$M = \frac{1}{9}\sum_{j-1}^{9} p_j \tag{5}$$

The principal component analysis method is used to analyze multivariate data, identifying the most important variables by calculating weights. In multivariate analysis, with the variables grows, the complexity of the problem grows, so reducing variables is necessary to reduce computational complexity [15-17]. In the calculation process, if N is defined as the quantity of samples and the vector dimension is M, then the sample set can be represented as N vectors $X1, X2, X3, ..., XN$. Each vector Xi represents the i-th sample. Next, the study can use these samples to calculate the covariance matrix of the training samples, and the specific formula is indicated in Eq. (6).

$$V_t = \frac{1}{N}(X - \overline{X})(X - \overline{X})^T \tag{6}$$

In Eq. (6), $\overline{X} = [\eta, \eta, ..., \eta]$, η represents the mean values of all samples. The calculation is shown in Eq. (7).

$$\eta = \frac{1}{N}\sum_{i=1}^{N} X_i \tag{7}$$

This study calculates the eigenvalues of the covariance matrix（λi，$1 \le i \le m$) and eigenvectors（ωi，$1 \le i \le m$). These eigenvalues and eigenvectors represent the principal components of the data. For the original dataset X, the calculation is indicated in Eq. (8).

$$Y = W^T(X - \eta) \tag{8}$$

In Eq. (8), to reduce the dimension to K dimension, simply select the first K row of Y. This study used the PCA algorithm for dimensionality reduction, and then input the reduced feature vectors into a simple K-nearest neighbor classifier. The K nearest neighbor classifier counts the range in the test sample and each training sample, and determines the classification of the test sample on the ground of the labels of the K closest samples. The relevant details are showcased in Fig. 3.

In Fig. 3, the value of K is set to 5. The classifier uses template matching and experimental parameters to classify each test sample. After classification is completed, the data that is successfully matched is counted, and then the RR is counted for evaluating the performance.

B. Design of FR Algorithm Based on MLBP-HOG-G

Histogram of Oriented Gradients (HOG) is a commonly utilized algorithm for describing local texture features of images. HOG expresses local features on the ground of the direction and density distribution of gradients in the image, generates histograms through statistical gradient information, and then combines these histograms into feature vectors. This feature vector can be used for various image tasks, such as facial recognition. HOG feature extraction includes the following steps. Firstly, it performs grayscale processing on the input image and converts it into a grayscale image. Next, it uses the gamma correction method to normalize the grayscale image, which helps to decrease the interference of local shadows, lighting changes, and noise on feature extraction. The gamma correction formula is shown in Eq. (9).

$$H(x, y) = H(x, y)^{gamma} \tag{9}$$

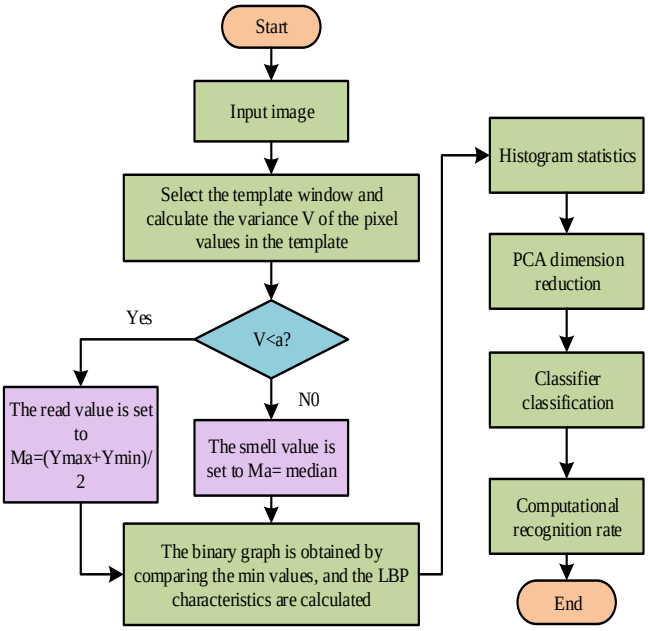

Fig. 3. Flow chart of FR algorithm on the ground of MLBP.

In equation (9), the Gamma value is set to 5. When counting the horizontal gradient $G(x)$ and vertical gradient $G(y)$ of the image, two templates [-1,0,1] and [1,0,1] were utilized for performing convolution operations on the image, respectively. This obtains the gradient direction value for each pixel position. The calculation is showcased in equation (10).

$$\begin{cases} G_x(x,y) = H(x+1,y) - H(x-1,y) \\ G_y(x,y) = H(x,y+1) - H(x,y-1) \end{cases} \quad (10)$$

In equation (10), $G_x(x,y)$ serves as the horizontal gradient at point (x,y). $G_y(x,y)$ represents the gradient in the vertical direction, and $H(x,y)$ serves as the PVA. It continues to calculate the gradient value, as shown in Eq. (11).

$$\begin{cases} G(x,y) = \sqrt{G_x(x,y)^2 + G_y(x,y)^2} \\ a(x,y) = \tan^{-1}\left(\dfrac{G_y(x,y)}{G_x(x,y)}\right) \end{cases} \quad (11)$$

In Eq. (11), $G(x,y)$ is the gradient amplitude of the input image at pixel (x,y). $a(x,y)$ is the gradient direction of the graph at pixel (x,y). On the ground of gradient amplitude and directional weight projection, this algorithm divides an image of 64 * 128 size into multiple 2 * 2 cells, each containing 8 * 8 pixels. By scanning the image in steps of eight pixels, the gradient values of the pixels are divided into nine directional ranges, each occupying 40°. This process calculates features on the ground of the weight projection of gradient amplitude and direction. The gradient bin averaging diagram is shown in Fig. 4.

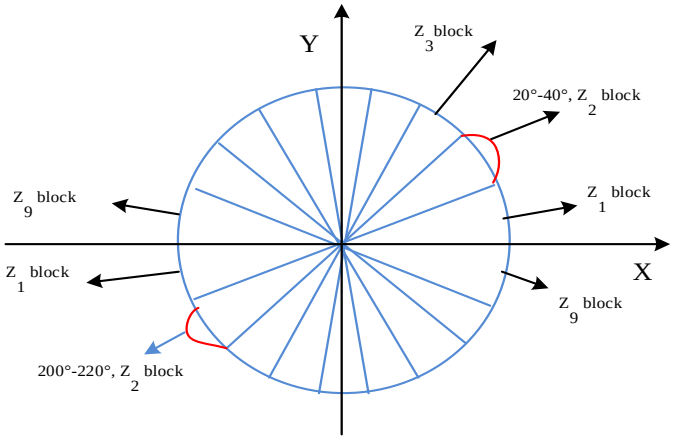

Fig. 4. Gradient bin equalization diagram.

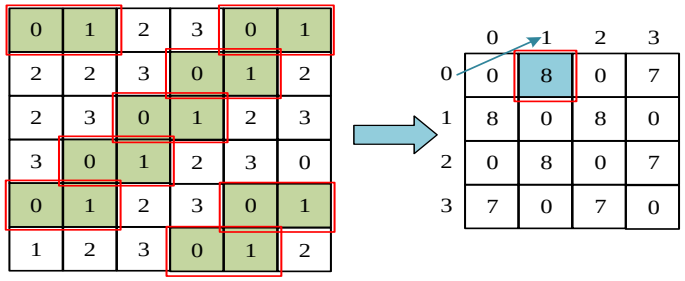
According to Fig. 4, it calculates the gradient amplitude and direction of pixels, and assign weights to the direction bin of each pixel. Each cell contains 9 features, and each block has 36 features. If 8 pixels are used as a step size, there are 7 scanning windows in the horizontal direction and 15 scanning windows in the vertical direction, so a 64 * 128 image will generate 3780 features. It normalizes the contrast of cells within each overlapping block and uses the L2 norm algorithm for normalization calculations. The normalized feature vector is represented as C, and the normalization calculation is shown in Eq. (12).

$$C \leftarrow C / \sqrt{\| C \|_2^2 + \varepsilon^2} \tag{12}$$

In Eq. (12), the function of ε is to prevent the denominator from becoming 0, as shown in Eq. (13).

$$\| C \|_2 = \sqrt{\sum_{k=1}^{n} | C_k |^2} \tag{13}$$

In Eq. (13), the initial value of K is 1. After image normalization, it extracts the feature vectors of HOG. To highlight local detail features and preserve image edge gradient features, this study proposes a secondary feature extraction algorithm. This algorithm processes LBP texture maps with directional gradient histograms and utilizes the MLBP algorithm instead of the LBP algorithm for feature description [18-20]. The grayscale co-occurrence matrix can be regarded as a matrix function that integrates information such as different directions, intervals, changes in amplitude, and speed in the image, and then presents this information in the form of a matrix, as shown in Fig. 5.



(a) Grayscale images (b) Gray co-occurrence matrix

Fig. 5. Gray co-occurrence matrix.

Fig. 5 demonstrates that in a grayscale image, this study can select two pixel points, record the number of times the combination of their values appears, and organize these records into a matrix, which is the grayscale co-occurrence matrix. To better capture the details and spatial relationships of images while preserving edge information, this study proposes the MLBP-HOG-G algorithm. This algorithm integrates MLBP, HOG, and grayscale co-occurrence matrix features together. This is to improve the effectiveness of feature extraction. This study selected the feature fusion method of serial fusion and adopted the weighted serial fusion method. The calculation method is showcased in equation (14) [21-22].

$$\bar{b} = \frac{1}{i} \sum_{j=1}^{i} b_j \tag{14}$$

In Eq. (14), $\bar{b}$ represents the mean of MLBP-HOG features; α represents the variance of MLBP-HOG features. The weighted results of MLBP-HOG-G features are shown in Eq. (15).

$$L = \frac{\alpha}{\alpha + \beta} C_1 + \frac{\beta}{\alpha + \beta} \tag{15}$$

In Eq. (15), β represents variance. The facial recognition system proposed in this study combines MLBP, HOG, and grayscale co-occurrence matrix features. The system first uses the MLBP algorithm to extract texture information from the image, and then uses the HOG algorithm to further extract features. These features are combined into a vector $C1$, and then dimensionality is reduced. Meanwhile, the Grayscale Co-occurrence Matrix features are also extracted as vector G. The entire algorithm process is shown in Fig. 6.

Fig. 6 shows that after extracting vector, and are merged and weighted to form a feature vector. This vector is input into the classifier for classifying the test samples. After classification is completed, the RR is used to evaluate the performance of the algorithm. The object of smart classroom face recognition system is teachers or managers. Its main function is to recognize and record the identity of students in the classroom through face detection and recognition, count the attendance in class, and cooperate with the classroom to complete teaching evaluation. The 1080p camera is used to collect students' classroom videos. In the face database coding link, the system will collect and store the face information photos of students in the classroom. These photos will be used to build the face feature database. The system uses Python code for unified size processing, and usually adjusts the image to a size of 160 × 160. Users are allowed to send requests to upload videos through the web. In the process of data transmission, TLS encryption protocol is used to protect data to prevent it from being intercepted by the system in the middle. After receiving the requests, the back-end server processes the received videos. This processing stage includes video pre-processing steps to ensure the adaptability and preparation of video data. Through analyzing the classroom monitoring video uploaded by the smart classroom system, the research shows the large visual screen of face recognition,

data analysis results and statistical check-in results to teachers or managers in the system to help teachers understand students' learning and attendance more objectively. Research and design the main functions of the smart classroom face recognition system include video upload, student face detection and recognition, and the display of results. In the non-functional design part of the system, we pay attention to protecting the safety of student face data, and comply with relevant data protection laws and regulations. If the data cannot be used for other purposes, we will prevent the data from being stolen or leaked. Design a login authentication mechanism based on user name and password. After the user enters the user name, enter the password in the user password box, enter the verification code in the verification code box, and then click the login button to verify the login. Different user types are assigned different permission levels, and the administrator manages the user. The user information is encrypted to prevent the potential risk of user password disclosure, so as to ensure the safety and privacy of users. When using face recognition data for statistical analysis, the data are anonymized to ensure that personal identity cannot be directly recognized through the data, and the personal privacy data are desensitized to cover up sensitive information and ensure that personal privacy will not be revealed when the information is used. At the same time, regularly review security protocols and access logs, timely find and respond to potential threats, and realize the security of personal privacy in intelligent classroom applications.

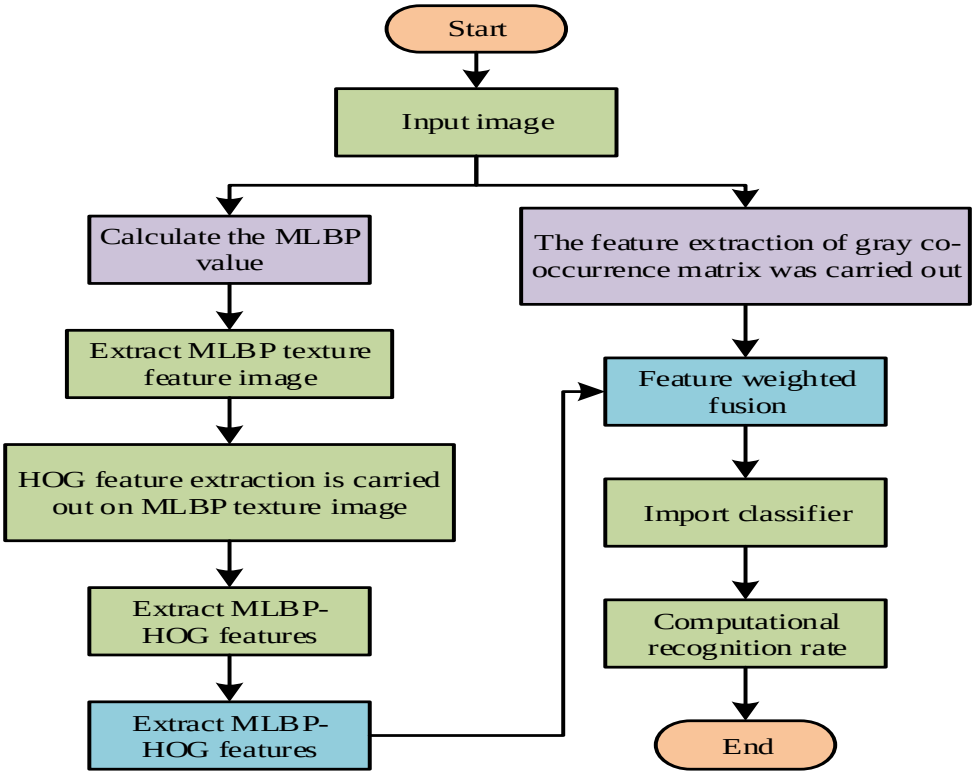


Fig. 6. Flow chart of FR algorithm based on MLBP-HOGG.

IV. Experimental Verification of Facial Recognition Model based on MLBP-HOG-G Algorithm

The experiment is conducted on a hardware platform equipped with an Intel i3-4030U processor (with a clock speed of 1.9 GHz), 8 GB of memory, and Intel HD Graphics Family GPU, running a 64 bit Windows 10 operating system. The simulation software uses MATLAB 2013 and relies on Image Processing Toolbox and Deep Learning Toolbox. During the training process, the ORL dataset takes about 2 hours, the CMU-PIE dataset takes about 12 hours, the YALE dataset takes about 1 hour, and the peak memory usage is about 4 GB. Due to limited GPU performance, it mainly relies on CPU computing. The experimental setup has a batch size of 32, an initial learning rate of 0.001, and employs an exponential decay strategy. This experiment uses three publicly available facial databases: ORL, CMU-PIE, and YALE. The ORL database contains 400 images (resolution: 92 × 112 pixels), covering different lighting, expressions, and poses; The CMU-PIE database contains 41368 images (resolution: 640 × 480 pixels), providing 13 poses, 43 lighting conditions, and various facial expressions; The YALE database contains 165 images (resolution: 320 × 243 pixels) covering different expressions and lighting conditions. Normalize and grayscale all images before the experiment, and divide them into training set, validation set, and test set in a ratio of 70%: 15%: 15%. To verify the robustness of the algorithm, salt and pepper noise (intensity: 0.1) and Gaussian white noise (mean: 0, variance: 0.01 and 0.1) were added to the ORL dataset. In addition, the training set is randomly rotated, translated, and scaled to enhance data diversity. The experimental results under Gaussian white noise attack are shown in Fig. 7.

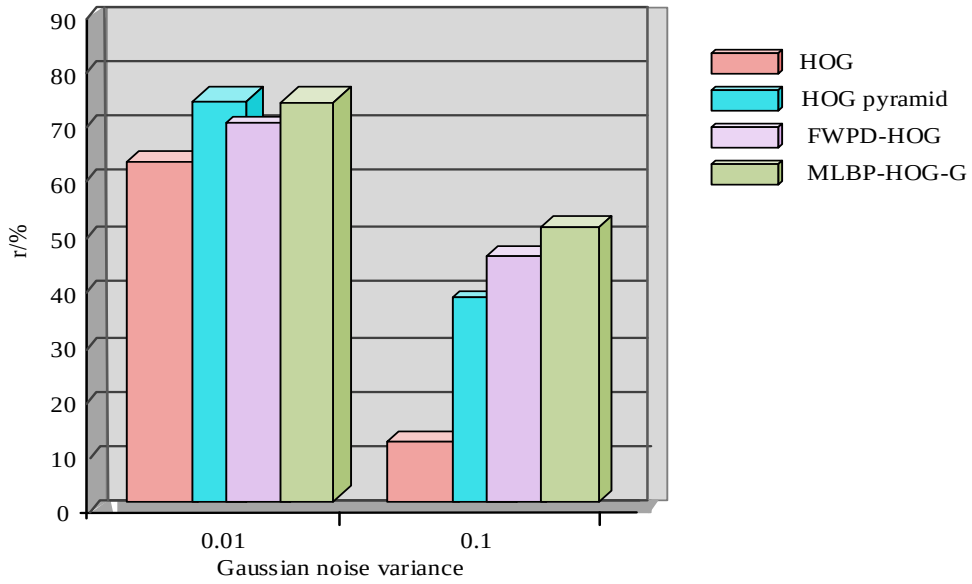

Fig. 7. The recognition rate of the proposed method is compared with the comparison method under Gaussian noise attack.

According to Fig. 7, when the Gaussian noise variance is 0.01, this research method improves the RR by 1% to 13% compared to other methods; when the variance is 0.1, it increases by 6% to 44%. Compared with the FWPD HOG method, the FWPD HOG pyramid method has a higher RR, demonstrating the advantages of multi-scale pyramid representation in combating noise. The experiment was conducted on the ORL facial database, consisting of 400 images, each with 10 images, totaling 40 groups, with an image size of 112x92. This study added Gaussian noise and salt and pepper noise for testing the algorithm. Each group of experiments will select four images as training samples, and the remaining ones as test samples. Ten repeated experiments will be conducted for calculating the average RR and compare the RRs of several algorithms in different dimensions. The outcomes are showcased in Table I.

TABLE I THE AVERAGE RECOGNITION RATE OF ORL ALGORITHMS UNDER DIFFERENT NOISES

Method	Salt-and-pepper noise (%)	Noiseless (%)	Gaussian noise (%)
WSRC	80.3	81.6	58.4
PCA-SRC	76.7	79.6	52.5
RPH-WSRC	85.0	92.5	74.1
HOG-SRC	81.2	83.2	64.3

Table I shows that when there is no noise, the RR has grew by 16.10%, 13.26%, and 11.16% compared to other algorithms. Even when different noises are introduced, the average RR of RPH-WSRC remains at the highest level, demonstrating strong anti-interference ability. Fig. 8 showcases the RR curves of each algorithm in the ORL dataset.

Fig. 8 shows that as the feature dimension increases, the RRs of various algorithms show an upward trend and eventually tend to stabilize; despite some fluctuations, this indicates that not all features contribute to classification recognition. When noise is introduced into facial images, the images are contaminated and occluded, and the RR of RPH-WSRC algorithm exceeds other algorithms, indicating that the algorithm has a certain degree of robustness against noise. For verifying the MLBP algorithm, this study designed a FR algorithm on the ground of MLBP. Considering that the original LBP may lose detailed features during feature extraction, this study proposes the MLBP algorithm to ensure the preservation of image detail features and enhance robustness during the feature extraction process. Therefore, on the ground of the MLBP facial recognition algorithm, a series of experiments were conducted for evaluating the recognition of MLBP and compared with different LBP algorithms. In the experiment, a block size of 5 * 5 was used and the dimension was reduced to 60 dimensions, which were tested in different databases. The experiment is showcased in Fig. 9.

Fig. 9 shows that the MLBP algorithm performs well in different databases. In the ORL database, the RR reached 95%, higher than 92.5% for LBP and 94.17% for ULBP. In the CMU_PIE database, the MLBP algorithm is also the best, with a RR of 94.12%, while the RRs of LBP and ULBP are 90.07% and 91.18%, respectively. In the YALE database, the RR of the MLBP algorithm is 93.33%. Although the database has the strongest variation factors, it is still higher than the 88.33% and 90% of the LBP and ULBP algorithms. In the database, the selection method for training samples is as follows: 7 images of each person are chosen from the ORL database, and 20 images of each person are chosen from the CMUPIE database; In the YALE facial database, each person selects 7 images as training samples, while the remaining images are utilized for experimental testing. Fig. 12 shows the comparison of RRs for different dimensions of MLBP-HOG features in the experiment, as well as the comparison of RRs for various dimensions of MLBP-HOG in MLBP-HOG-G.

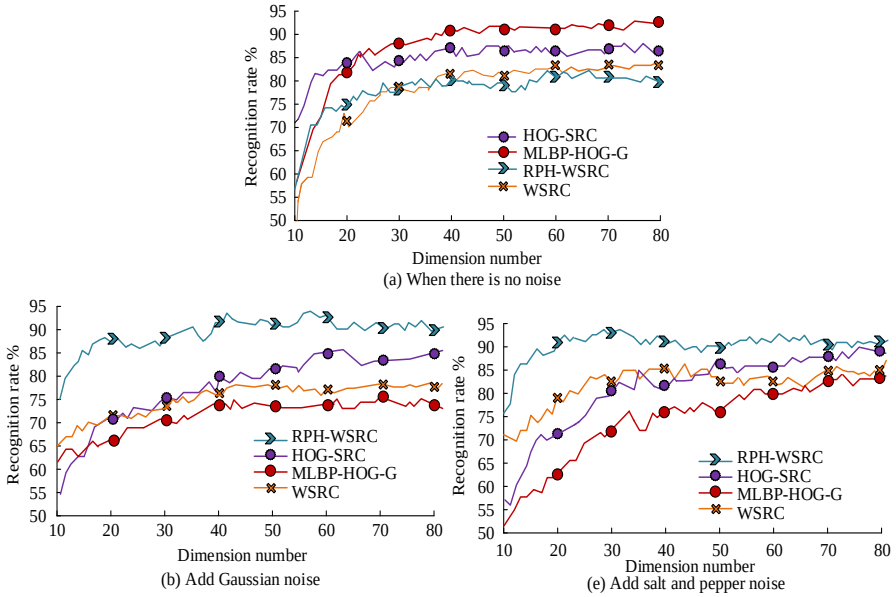

Fig. 8. Experimental recognition rate curves of each algorithm in ORL data set.

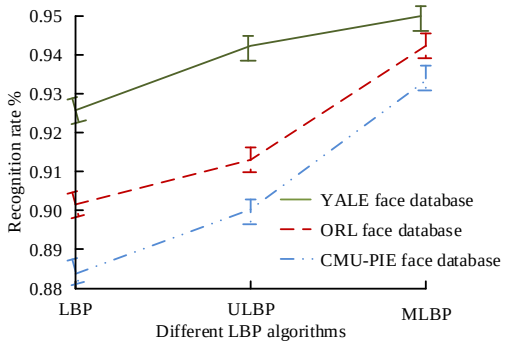

Fig. 9. Comparison of different LBP recognition rates.

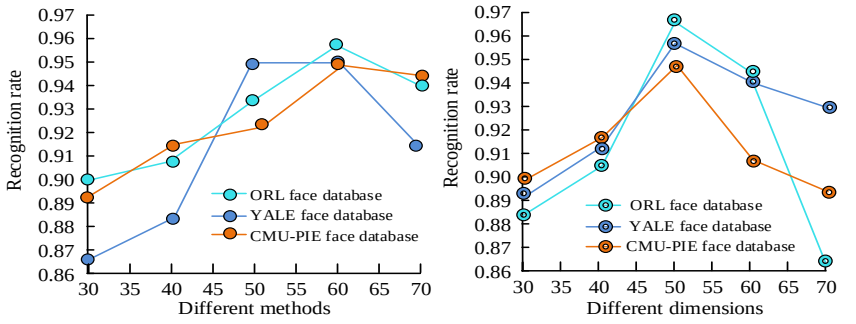

Fig. 10. Compare the recognition rate of different dimensions of MLBP-HOG feature and compare the recognition rate of different dimensions of MLBP-HOG in MLBP-HOG-G.

According to Fig. 10(a), the impact of the dimensions of MLBP-HOG features on RR in the ORL database is as follows. The highest value is 95.83% at 60 dimensions; 94.17% at 70 dimensions. The 30-50 dimensions are 90%, 90.83%, and 93.33%, respectively. In the CMU_PIE database, the dimension of MLBP-HOG features has the following impact on RR, with 60 dimensions being the highest at 94.85%. The 30-50 dimensions are 89.34%, 91.54%, and 92.28%, respectively. The 70 dimensional ratio is 94.49%. According to Fig. 10(b), the 50 dimensional features perform best in different databases. In the MLBP-HOG-G feature of the ORL database, when the dimension of the MLBP-HOG feature is 50 dimensions, the RR reaches 95.83%. In the CMU_PIE database, the RR reaches 95.22%. In the YALE database, the RR is 96.67%. Fig. 13 shows the relevant results of RRs among various methods in the experiment.

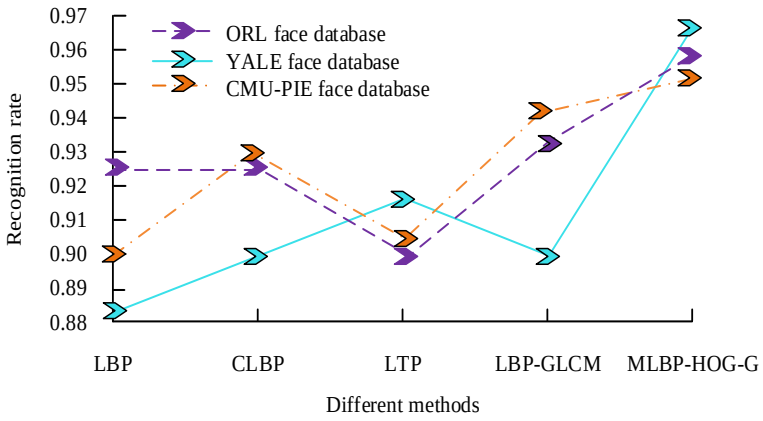

Fig. 11. Comparison of recognition rate of different methods.

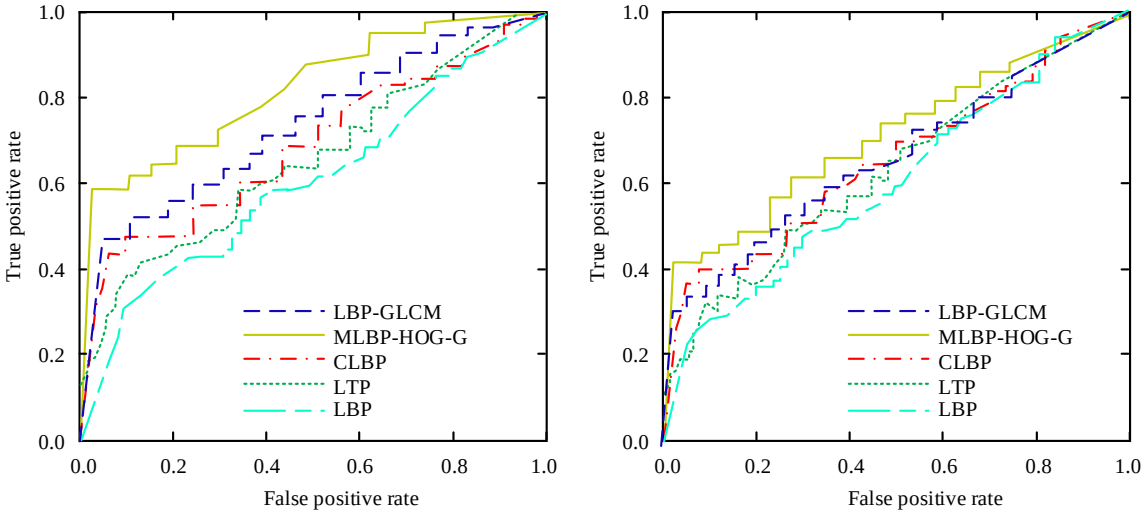
According to Fig. 11, in the ORL database, the RR of MLBP-HOG-G features is the highest at 95.83%, followed by LBP+GLCM features at 93.33%. In the CMU_PIE database, MLBP-HOG-G features perform best with a RR of 95.22%. In the YALE database, the same MLBP-HOG-G feature has the highest RR of 96.67%. The method combining MLBP-HOG features and grayscale co-occurrence matrix features has shown excellent performance in FR. The face recognition results of the proposed method on different databases have been analyzed in the previous content, and further analysis and comparison have been made to further verify the performance of the proposed method. The ORL database and Yale face database is combined with and cover the student face data set designed by the research. At the same time, to further evaluate the facial recognition performance of the proposed algorithm in large datasets, the MegaFace dataset and VGGFace2 dataset were introduced for analysis. The MegaFace dataset is the largest publicly available facial recognition dataset, with one million faces and their respective bounding boxes, making it one of the largest public facial recognition datasets currently available. This facial image covers variations in age, gender, race, and facial expressions. VGG2 (9K ids/3.31M images) VGGFace2 is a dataset containing over 4.3 million facial images of more than 33000 different individuals, including facial images of different poses, ages, lighting, and backgrounds. It can be used for facial recognition tasks in complex scenarios such as age and pose changes. Fig. 12 shows the facial recognition accuracy results of different algorithms on a large dataset.

The results in Fig. 12 indicate that on the VGGFace2 dataset, the MLBP-HOG-G algorithm and LBP-GLCM algorithm have better facial feature recognition accuracy, with corresponding accuracy ACC values greater than 0.90. On the MegaFace dataset, although the sample size has been expanded and the recognition accuracy of the comparison algorithm has been affected, the MLBP-HOG-G algorithm proposed by the research institute still has good recognition accuracy, with its accuracy curve closer to the upper left corner. The mixed data set is divided into the test data set and validation data set according to the ratio of 6:4, and the recognition performance of different algorithms is compared. The detected face image is unified to a size of 160*160 and input into the face recognition model. Fig. 12 shows the face recognition training and verification accuracy of different algorithms, and the comparison algorithms are literature [23], literature [24] and literature [25].



(a) VGGFace2 dataset (b) MegaFace dataset

Fig. 12. Facial recognition accuracy results of different algorithms on large datasets.

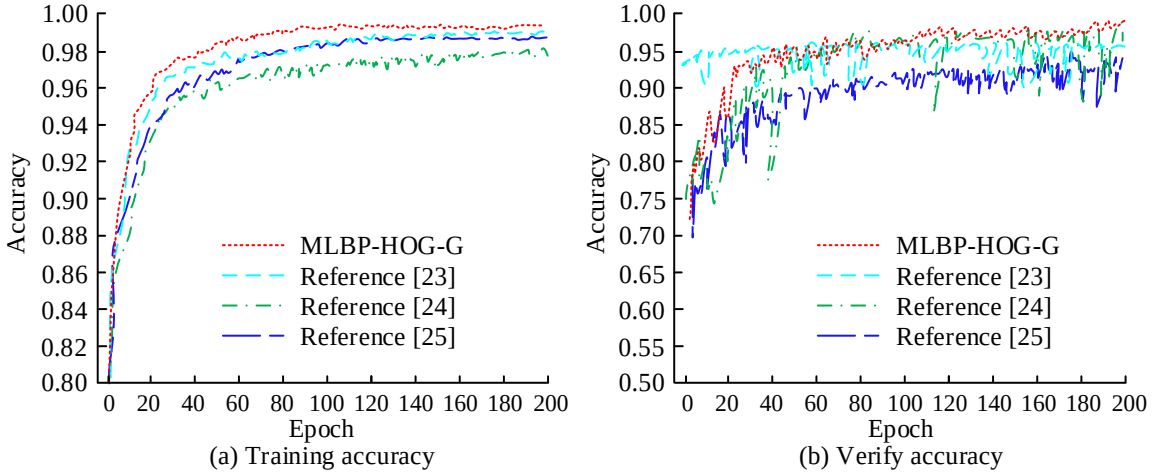


Fig. 13. Comparison of training and validation accuracy of different models.

In Fig. 13, the corresponding methods in literature [23], literature [24], and literature [25] are hog joint convolutional neural network, yolo-v4 network under the improvement of embedded components, and deep learning algorithm, respectively. In Fig. 12(a), the training accuracy curve of the MLBP-HOG-G algorithm proposed in the study has little fluctuation and is relatively stable. Its recognition accuracy in the later training batch is basically more than 98%, with a maximum training accuracy of 99.30%, and its performance is better than other comparison methods. The maximum training accuracy of literature [23], literature [24] and literature [25] are 98.95%, 98.90% and 98.00%, respectively, and there are certain fluctuations in the early stage. In Fig. 12(b), the validation accuracy of yolov3 hog is 97.23%, the generalization performance is the best, and the overall trend of the curve is relatively stable. In reference [25], feature extraction with the help of principal component and directional gradient histograms is inevitably affected by noise. This results in large fluctuations in its validation accuracy curve, presenting an unstable state with the increase of iteration times, and the maximum validation accuracy is not more than 95%. The validation accuracy curves of references [23] and [24] exceed 90%, but there are also some node fluctuations. Then the detection performance of face key points is analyzed, and the results are shown in Fig. 14.

The smaller the value of normalized mean error (NME), the better the robustness of the algorithm. Fig. 14 shows that on the training and test datasets, the mlbp-hog-g algorithm proposed in the study shows a small cumulative error result in the detection of key points in face recognition, and the overall curve change node amplitude is relatively small. The NME values of the other three comparative literatures increase with the increase of the map scale. And the fluctuation of the curve nodes is obvious, with varying degrees of deviation, and poor robustness on different datasets. After that, the performance of the proposed algorithm is compared and analyzed under different experimental conditions. The results are shown in Table II.

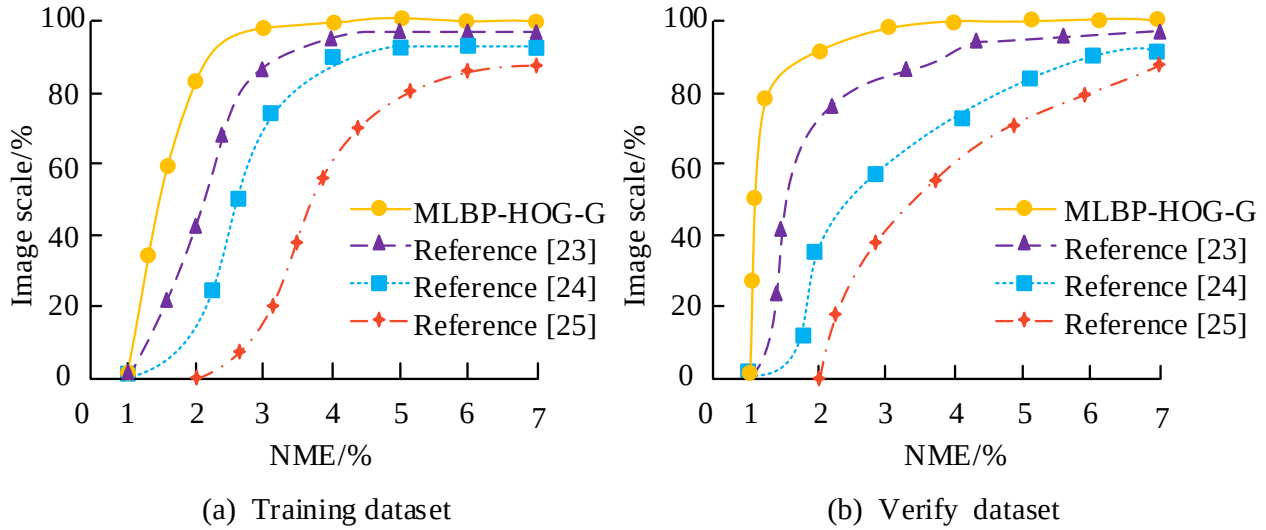

Fig. 14. Standard normalized mean error results of different comparison algorithms.

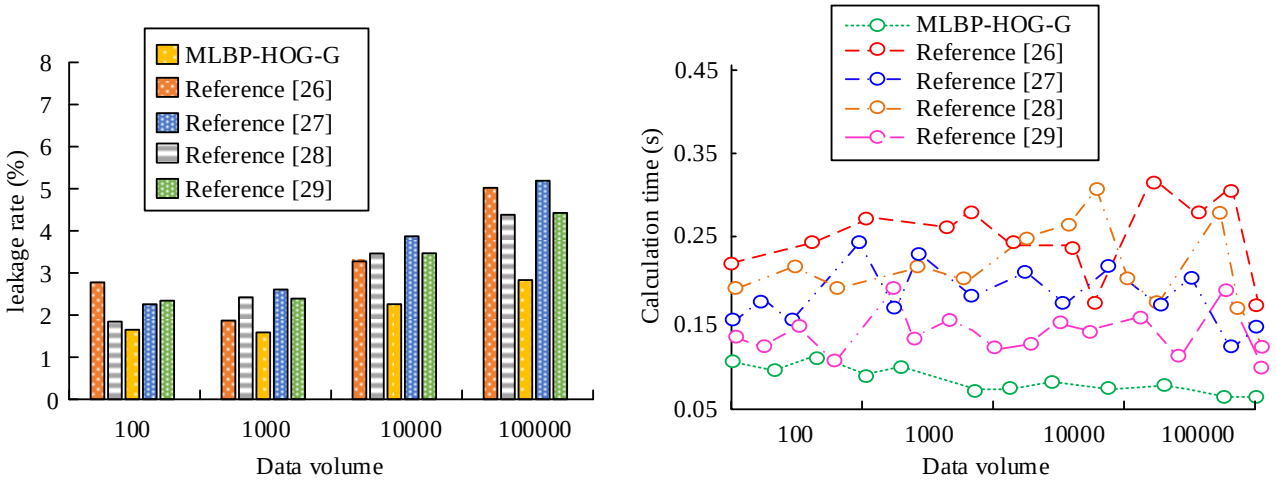
TABLE II INDEX TEST OF FOUR ALGORITHMS IN FACE IMAGES WITH DIFFERENT COMPLEXITY

Dataset Complexity	Index	MLBP-HOG-G	Reference [23]	Reference [24]	Reference [25]
Simple	mAP	98.56	90.14	89.33	92.07
	FPS (img/s)	88.19	84.97	85.13	81.01
	Detection time (s)	21.05	38.78	35.26	34.39
	Energy Efficiency (J/img)	3.2	6.4	5.2	6.7
Secondary	mAP	97.28	89.86	89.75	89.23
	FPS (img/s)	73.43	66.61	73.39	51.55
	Detection time (s)	20.12	23.06	24.17	28.33
	Energy Efficiency (J/img)	2.4	3.6	3.2	3.9
Complex	mAP	98.16	85.87	87.98	88.92
	FPS (img/s)	75.32	62.17	52.26	66.14
	Detection time (s)	24.36	30.41	31.65	29.38
	Energy Efficiency (J/img)	2.3	4.8	5.2	5.7

The indicators used in Table II include Mean Average Precision (map), Frames Per Second (FPS) and energy efficiency. The simple condition refers to the classroom face image under normal environment (no occlusion and no light change), while the medium and complex conditions mainly refer to the face image under partial occlusion and occlusion and light shadow change. Table II shows that the map values of the research algorithm under the three conditions are 98.56, 97.28 and 98.16, which are much higher than other algorithms under the same conditions. In terms of test efficiency and energy efficiency, the difference between the comparison algorithm and the research algorithm is at least more than 5img/s and 0.8j/img. In terms of running time, the running time of mlbp-hog-g algorithm in three conditions is 21.05s, 20.12s and 24.36s, respectively, which is less than other comparison algorithms. In conclusion, mlbp-hog-g algorithm has good performance in face recognition and detection, and has good adaptability under different conditions.

The use of deep learning methods to achieve classroom face recognition has become a research focus for many scholars. In order to further test the effectiveness of the MLBP-HOG-G algorithm proposed in this study, it was compared with literature [26], [27], [28], and [29], all of which were deep recognition results designed for classroom teaching. The results were analyzed from the perspectives of computational cost and recognition accuracy, as shown in Fig. 15.



(a) Leakage rate (%) (b) Calculation time (s)

Fig. 15. The computational cost and recognition accuracy results of different algorithms for facial recognition.

From Fig. 15(a), it can be seen that as the amount of data increases, the missed detection rate of the MLBP-HOG-G algorithm remains relatively low and changes steadily, with an overall missed detection rate of no more than 3%. The missed detection rates of other comparative literature are all above 2%, and their changes are more significant with the increase of data volume. From Fig. 15(b), it can be seen that as the amount of data increases, although the computation time of the MLBP-HOG-G algorithm increases, the growth rate is relatively small, and the overall computation time remains within an acceptable range, below 0.15s. However, the computation time of the remaining literature is relatively high, with the maximum computation time of literature [26] and literature [28] exceeding 0.30s. The above results indicate that the MLBP-HOG-G algorithm proposed by the research institute has high efficiency in processing large-scale data, while maintaining a low false positive rate in face recognition, it also has high computational efficiency and significant application effects.

V. Conclusion

Traditional facial recognition algorithms often require a large amount of computing resources and memory, which is a significant problem for environments with limited resources such as embedded systems. In this context, this study proposes an innovative FR method that combines MLBP-HOG features with grayscale co-occurrence matrix features. This method extracts binary texture images through the MLBP algorithm, and obtains MLBP-HOG features through secondary HOG feature extraction. The experiment showed that in the comparison of MLBP-HOG features with different dimensions and MLBP-HOG with different dimensions in MLBP-HOG-G, the highest RR was achieved in the ORL database at 60 dimensions, reaching 95.83%. In the MLBP-HOG-G features of the ORL database, when the dimension is 50 dimensions, the RR reaches 95.83%; In the CMU_PIE database, the RR is 95.22%; In the YALE database, the RR is 96.67%. The experiment indicates that the algorithm can adaptively learn and extract facial features, reducing the dependency of feature engineering.

The MLBP-HOG-G algorithm has a recognition rate of over 95% on ORL, CMU-PIE, and YALE databases, indicating its high accuracy on standard datasets. In complex situations such as changes in lighting, posture, and facial occlusion, the performance of the MLBP-HOG-G algorithm is significantly better than traditional methods, indicating its strong environmental adaptability. The reason is that through feature dimensionality reduction and serial fusion, the MLBP-HOG-G algorithm significantly reduces computational complexity and storage overhead while maintaining high recognition rates. And with the increase of data volume, the missed detection rate of MLBP-HOG-G algorithm is relatively low and stable, with an overall missed detection rate of no more than 3%, and the overall calculation time remains within an acceptable range, less than 0.15s. The detection rate of missed diagnosis in other comparative literature is above 2%. The above results indicate that the MLBP-HOG-G algorithm has high efficiency in large-scale data processing, while maintaining a low false positive rate in face recognition. It also has high computational efficiency and significant application effects. The reason is that the MLBP-HOG-G algorithm combines the multimodal features of MLBP, HOG, and gray level co-occurrence matrix, which can more comprehensively describe facial images, and adaptively learn and extract facial features, reducing reliance on artificial feature engineering. However, the use of facial recognition technology in smart classrooms involves personal data of students and teachers. Therefore, privacy and data security issues are a serious concern. In smart classrooms, facial recognition technology collects highly sensitive personal information, including facial features, attendance behavior, learning/teaching status, etc. Once these data are illegally obtained or leaked, they may seriously violate personal privacy, be used for identity theft, fraud, or other illegal activities, and harm their education and other legitimate rights and interests. To strengthen ethical data protection and usage restrictions, the purpose of data collection and use should be clearly defined. In the future, data encryption and storage security can be strengthened, such as adopting advanced data encryption technology, establishing strict data access control mechanisms, and preventing data leakage. At the same time, the scope of data use should be clearly defined, the dissemination and sharing of data should be restricted, and it should not be disclosed or sold to third parties. Enhance users' right to information and choice, ensure that the collection and use of facial recognition data comply with data protection regulations, and follow the principles of fairness, impartiality, and transparency.

In summary, the study proposes the MLBP-HOG-G algorithm, which not only provides a new approach for facial recognition technology, but also offers valuable exploration for future research to find a balance between improving recognition performance and ensuring data security. Future research should focus on developing more secure data encryption technologies, privacy protection mechanisms, and reliable data storage and transmission solutions to ensure that facial recognition technology can comply with ethical standards and protect user privacy in its widespread application in fields such as education.

***Abstract*—Precision agriculture has emerged as a vital approach for optimizing crop yield prediction, enabling data-driven decision-making to improve agricultural productivity. Traditional forecasting methods encounter difficulties due to extreme complexity within environmental factors while operating under dynamic farming conditions. An AI framework combining NAS and GBM serves as the solution to address these issues through enhancing predictive capabilities. This study works to produce an automated system which selects optimal models through optimization processes for more accurate crop yield forecasts. Through NAS component exploration the optimal neural network architecture can be identified whereas GBM component effectively analyzes non-linear dependencies in data which leads to superior predictive capabilities. Data processing techniques precede model development by using Recursive Feature Elimination (RFE) for feature selection which leads to training NAS-optimized deep learning architectures together with GBM. The researchers applied the model to real agriculture datasets which included essential agricultural variables comprising soil conditions and weather elements and crop health measurements. The experimental results prove that the developed NAS-GBM framework achieves superior performance compared to standard models across three major aspects including predictive accuracy and computation efficiency in addition to generalization capability. The research project uses TensorFlow and Scikit-learn alongside Optuna for model optimization while it depends on cloud-based computational resources for extensive processing requirements. AI-driven hybrid models based on the research demonstrate their capability to improve decision-making capabilities for farmers together with agronomists.**

I. Introduction

Agriculture has always been the backbone of human civilization, driving food production, economic growth, and rural development [1]. With the global population projected to exceed nine billion by 2050, ensuring food security has become a critical challenge [2]. Traditional farming methods, characterized by fixed planting schedules and generalized practices, often fail to adapt to varying environmental and soil conditions [3]. The contemporary agricultural method of precision agriculture develops solutions through advanced technological integration combined with data-based techniques. Participating farmers enhance crop yield through modern technological applications alongside data analytics to manage resources optimally. and resource utilization [4]. With real-time monitoring the farm data combined with actionable insights enables farmers to achieve their goals. These farmers receive tools which help them generate superior choices that produce better results. productivity measures 5]. Precision agriculture relies heavily Basic farming data requires predictive analytics to create actionable insights. into actionable intelligence [6]. Using statistical models and machine learning techniques, predictive analytics facilitates Crop yield forecasting and crop type recommendation form key tasks enabled through these analytics systems. recommendation, and resource allocation [7]. These methods Farmers can reduce uncertainty by receiving empowered tools that enable quick responses. Strategic action toward environmental modifications leads to better productivity and sustainability. efficiency and sustainability [8]. For instance, accurate crop Precision yield forecasts improve operational planning throughout harvesting periods together with storage management. Crop recommendations emerge from analyzing soil conditions which guide farmers to improve their storage

These networks The system gathers fundamental data about environmental conditions and soil properties soil moisture, temperature, humidity, and nutrient levels (e.g., Nitrogen, Phosphorus, Potassium) [10]. For instance, soil the technology incorporates soil moisture sensors for understanding irrigation requirements and other precision farming needs Temperature sensors play a critical role by monitoring field matter to detect both frost conditions as well as heat excess. Stress [11]. Soil sensors operating in different fields enable the recording of detailed data measurements. Sensor networks create site-specific analysis through their capacity to collect data from different areas of a field. Site-specific management proves essential for best utilization of resources alongside maximum yield outputs reducing resource wastage [12]. However, the data dimensionality meets challenges alongside heterogeneity alongside the extensive volume of generated information The generation of data by these networks produces substantial challenges to data handling. integration and analysis [13]. To address these challenges, the adoption of machine learning techniques increases steadily across various agricultural applications. employed in precision agriculture [14]. This study explores a A novel method utilizes Neural Architecture Search together with Gradient Boosting Machines to improve predictive capabilities. This research adopts Neural Architecture Search (NAS) and Gradient Boosting Machines (GBM) as advanced solutions to advance agricultural system prediction. the predictive capabilities of agricultural systems [15]. NAS, Neural network architecture optimization occurs through an automated framework. Through its systems architecture search NAS selects the most appropriate models for data extraction. extracting features from complex data sources [16]. Unlike NAS breaks away from standard manually designed architectures to automatically discover networks that match specific tasks which enhances model performance across both tasks and scalability. The discovery of task-specific neural networks through NAS improves both model accuracy while extending its capabilities. and scalability [17]. In the context of precision agriculture, NAS can extract temporal patterns, soil nutrient interactions, and seasonal variations from raw sensor data [18].

An ensemble learning technique named GBM has become popular because of its ability to predict. popular choice for predictive modeling in agriculture due to NA provides unpredictable combinations of neural architecture topologies which excel with diverse input types [19]. XGBoost, Light GBM and Cat Boost make up a group of algorithms The models demonstrate excellence in extracting non-linear connection points across datasets. between environmental factors and crop outcomes. GBM Models maintain interpretability which reveals important factors through their analysis. variables driving predictions, such as soil nutrient levels or rainfall patterns. The marriage of GBM and NAS enables a dual stage prediction system. NAS acts as a two-phase predictive platform to collect sensory data features before GBM utilizes these features for yield prediction and classification tasks. Subsequent GBM analyses these extracted features from sensors used for crop yield prediction. prediction and crop suitability classification [20]. This This research has set two major goals to achieve. A prediction system is under development that uses sensor networks together with NAS and GBM algorithms. A system uses NAS alongside GBM and meteorological data and sensor readings to determine the best crop selection based on soil conditions. soil and environmental conditions [21]. In addition, Precision agriculture strategies will benefit from better performance through enhanced accuracy. The research goal involves enhancing crop yield predictions through precise forecasting and cutting down resource requirements. usage. By The hybrid NAS-GBM model enables farmers to efficiently integrate it This system enables data-driven optimization of resources through strategic decision platforms. The system enables operations that lead to higher productivity alongside sustainability in agricultural farming. The adoption of these practices leads to global food security improvements [23].

II. Literature Review

Mgendi [4] explores the multifaceted landscape of precision agriculture, focusing on its tangible benefits, challenges, and future directions. Today's farming operations achieve better resource mobilization through precision agriculture techniques. Efficient resource utilization through precision agriculture systems enhances both yield production and conservation of sustainability levels maintain sustainability levels.

Elbasi et al., [7] investigates the potential benefits of integrating machine learning algorithms in modern agriculture. The main focus of these algorithms is to help optimize crop production and reduce waste through informed decisions regarding planting, watering, and harvesting crops. Sensor networks combined Predictive analytics along with sensor networks supports fundamental decision Projects derive support from actionable insights which enable strategic decision making. decision making. The combination of machine learning tools Modern farming platforms employs the combination of support vector machines (SVMs) random forests and neural networks. Analysis with neural networks and support vector machines functions along with random forests under data science techniques to detect patterns within big data. Analyzing crop forecasting and soil recommendation information accurately becomes possible.

Rana et al., [24] undertakes a comparative analysis of tree-based models and deep learning architectures concerning their performance disparities in handling tabular data. Sensor network

technology generates site-specific recommendations while enabling real-time parameter The system tracks three elements of soil conditions which include moisture content alongside temperature and atmospheric moisture. Soil assessments through these technologies help farmers make better decisions about resource use efficiency. in precision agriculture operations.

Tiwari et al., [25] explores the Neural Architecture Pan's NAS tool designs powerful deep learning algorithms autonomously Through architecture automation NAS optimizes deep learning features extraction from highly complex datasets. agricultural datasets. The research approach of NAS revealed valuable insights regarding temporal dynamics. The discovery of temporal and spatial patterns through NAS produces more precise estimates for crop yields and drought assessments.

Shah and Wu [26] Gradient Boosting Machines (GBM), XGBoost together with Light GBM and Cat Boost make up a group of algorithms specifically designed for precision agriculture applications. Insights from the Cat Boost and Light GBM and XGBoost algorithms enable superior detection of non-linear patterns in agricultural datasets. These methods conduct automated optimal deep learning architecture design which extracts features from complex agricultural datasets with categorical and continuous variables features.

Benti et al., [24] GBM's interpretability tools, such as SHAP (Shapley Additive explanations), provide valuable insights into key factors driving predictions. Combining NAS and GBM into a hybrid model offers a robust solution for precision agriculture, with NAS focusing on feature extraction and GBM on accurate predictions. This approach, powered by sensor networks and advanced machine learning techniques, significantly improves agricultural optimization, addressing challenges in productivity and sustainability [27].

Time deficiency affected the early NAS methods that used Reinforcement Learning-based NAS developed by Zeph and Le [3] , and its reinforcement learning agents that searched neural network design spaces. These methods provided effective results but demanded significant computational effort that needed extensive computer resources to assess new architecture candidates. With Differentiable NAS Liu et al. [28] researchers implemented gradient-based optimization which streamlined computational overhead while accelerating convergence. CPU-powered NAS systems optimize network designs to reveal important patterns contained in input data. The recurrent algorithms of Long Short-Term Memory (LSTM) and Gated Recurrent Units (GRUs) are commonly incorporated by NAS frameworks for time-series data modeling purposes found in Elsken et al.[29]. NAS optimization of fully connected networks enables them to uncover feature relationships which manual engineering methods would otherwise miss. Research findings show NAS-based models outperform traditional feature extraction mechanisms.

Yu et . [30] established that NAS algorithms successfully eliminated domain-specific feature engineering needs while maintaining sharp prediction accuracy levels. Research findings demonstrate agreement across multiple domains which include health care together with energy systems and ecological surveillance. NAS brings numerous benefits to neural network design yet both computational expense and overfitting concerns arise with limited datasets. Researchers have introduced search space pruning together with multi objective optimization techniques Tan et al. [31], to solve these NAS difficulties. Domain knowledge integration in NAS processes leads to percentage [32].

III. Problem Statement

Advanced technology systems including sensor networks together with machine learning and deep learning enable precision agriculture to deliver enhanced resource utilization and improved crop yield predictions and better decision-making. The difficulty in optimizing crop yield forecasting continues because agricultural datasets present challenges through their combination of categorical and continuous variables [7]. The current machine learning models that include tree-based algorithms and deep learning frameworks face challenges when applying features and model generalization to precision agriculture. The automated deep learning model design ability of NAS results in better feature extraction capabilities. The established NOS approaches face two major limitations including extravagant computational requirements as well as susceptibility to overfitting problems with restricted dataset sizes [25]. GBM shows stronger capabilities to detect complex patterns between variables yet it does not possess built-in structure optimization attributes [26]. A merged NAS-GBM model structure has potential to solve prediction problems through NAS-based feature selection and GBM-based accuracy improvement. The research establishes a time-efficient [30], AI model which brings enhanced precision agriculture outcomes via forecasted crop yields while solving data processing issues along with overfitting conditions.

IV. Methodology

The methodology for this research leverages a hybrid approach combining Neural Architecture Search (NAS) for feature extraction and Gradient Boosting Machines (GBM) for predictive modeling [33]. This two-stage approach aims to optimize precision agriculture by extracting relevant environmental features from raw data and then making accurate predictions regarding crop yield, suitability, and resource optimization. The process consists of three core stages: feature extraction using NAS, predictive modeling with GBM, and the integration of NAS and GBM in a hybrid iterative framework. In Fig. 1. represents agricultural sensor data collection which leads to preprocessing activities for data cleaning and normalization and missing value handling. The NAS-GBM framework optimizes extracted features along with selected ones before assessing their performance level.

Different from common models, NAS-GBM adapts the optimal network architecture, which improves the feature extraction. It makes it all the more applicable to necessarily complicated agricultural data including both date and categorical features.

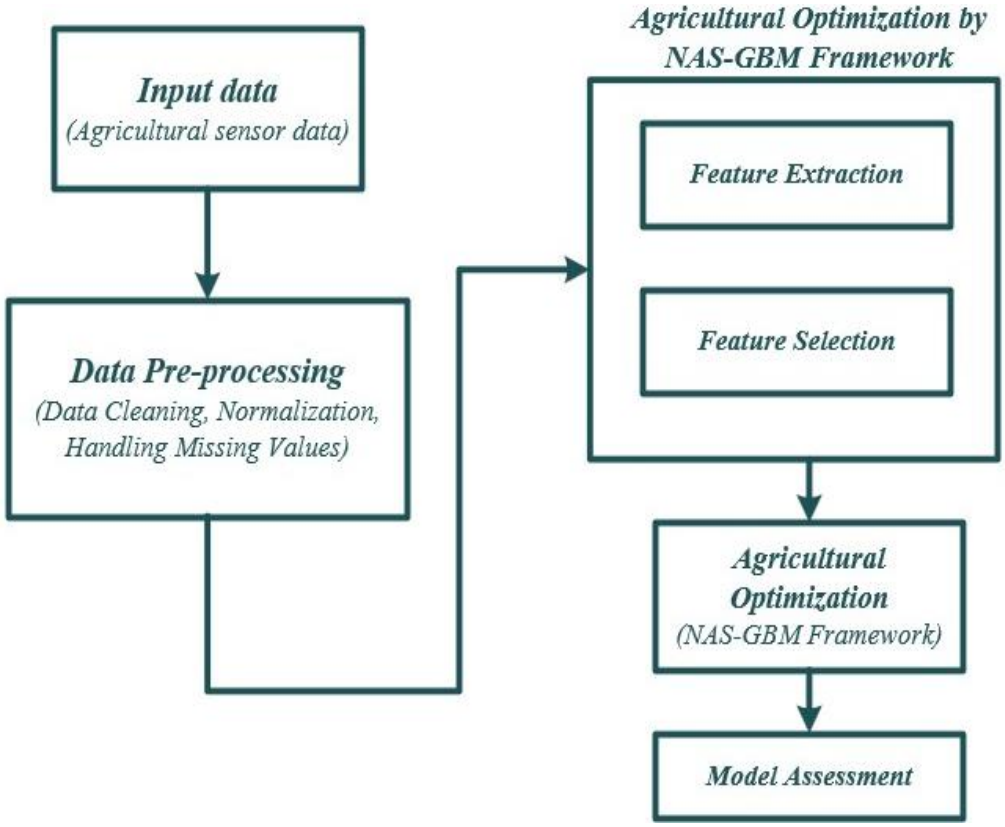

Fig. 1. Architecture of AI-powered predictive analytics and sensor network for agriculture.

A. Data Collection

Data collection and preparation play a crucial role in ensuring the effectiveness of the hybrid NAS-GBM approach for precision agriculture [34]. The integrated database merges current soil nutrient measurements of NPK elements with weather data about temperature and rainfall amounts together with documented historical yield statistics and land suitability assessments. Additional sources provide climate data together with fertilizer assessments to enhance the article's contents. The preprocessing stage of GBM uses imputation for missing data while normalization alongside scaling prepare the features before encoding categorical data types. The extraction of time-series patterns leads to high-quality standardized data that builds up a reliable framework for predictive modeling applications in precision agriculture.

B. Data Preprocessing

The successful utilization of raw data demands a fundamental preprocessing step A data cleanup process for machine learning models transforms unprepared datasets into usable entities. suitable for analysis. In the hybrid NAS-GBM model for the hybrid NAS-GBM model implements data collection from sources as its initial element for precision agriculture. The predictive system obtains its data through sensor networks combined with weather stations and historical raw data sources. crop data. The processing approach fills in gaps in data through statistical replacement techniques. or removal of affected data points. Cleaning involves the process identifies mistakes within the data and fixes them along with removing any case that appears to be an outlier. Feature selection Engineering processes are used to determine which inputs offer the maximum relevance. Automated features identification through NAS enabled this step. process. Standardization techniques normalize continuous variables. Standardization or normalization methods scale continuous variables until they align on a common framework while categorical data receives numeric encoding. encoded into numerical formats. The dataset is split into Most modeling methods split the database for training-over-testing into training data blocks which constitute 70-80% of the entire database. and the remainder for testing. For imbalanced data, the approach of both oversampling and under sampling provides necessary techniques for data management fairness when used within the process. fairness. The methodology of data augmentation serves as one solution to handle these tasks. A data expansion technique adds more information before applying necessary transformations to the dataset. to enhance distribution. These preprocessing steps ensure the When training processes begin the model can utilize the prepared data. accurately and effectively on new data.

C. Feature Extraction Using NAS

The Neural Architecture Search methodology provides automated design capabilities. Optimal neural network architectures must be designed through an automated process named NAS because it functions as the process of extracting meaningful qualities from original sensor and environmental measurements constitutes a fundamental step in feature extraction. environmental data. A NAS exploration method investigates sequence options within its allowable design arena.

Through thorough optimization of possible neural network designs the system performs best on target tasks. performance on a given task.

Input:

- Input data (e.g., sensor measurements, environmental data).
- Target labels or outputs (e.g., crop yield, suitability).
- S: Search space of possible neural network architectures.
- LNAS(F(X), Y): Loss function to evaluate model F.
- T: Total iterations for NAS optimization.

Objective Function:

- Minimize the NAS loss function:

$$LNAS=L(Fmodel(X), Y) \quad (1)$$

- Fmodel: Neural network architecture being optimized.

Initialize Search:

- Define initial set of candidate architectures {A1, A2…, An}.
- Set learning parameters (e.g., learning rate η\ epochs).

NAS Iteration:

- For each iteration t from 1 to T:

Sample architecture Fmodel,t from S\mathcal{S}S.

Train Fmodel,t on input (X,Y):

$$\theta t=arg\theta minL(Fmodel,t(X;\theta),Y) \quad (2)$$

Where θ represents model parameters.

Evaluate performance on the validation dataset:

$$Lval=L(Fmodel,t(Xval),Yval) \quad (3)$$

Select Best Architecture

Choose the architecture Fmodel∗ with the lowest validation loss:

$$Fmodel*=argiminLval,i \quad (4)$$

D. Predictive Modeling with GBM

Once the features are extracted by NAS, they serve as inputs to a Gradient Boosting Machine (GBM), a powerful ensemble learning method that excels at handling complex relationships in the data. The general form of a GBM model is:

$$f(x)=m=1\sum M\alpha mhm(x) \quad (5)$$

Where:

- f(x) is the final prediction.
- αm are the weights for each weak model.
- hm(x) represents the individual decision trees (weak learners) at the mmm-th stage.
- M is the total number of trees.

In this context, f(x) could be the predicted crop yield or a classification indicating crop suitability, while the weak models hm(x)h capture various patterns within the data.

E. Hyperparameter Tuning

Hyperparameter tuning is performed to improve the accuracy and performance of the GBM model. The key hyperparameters for GBM include the learning rate η\etaη, the number of trees MMM, and the maximum depth of trees DDD. The objective is to minimize the loss function, typically Mean Squared Error (MSE) for regression tasks:

$$LGBM=N1i=1\sum N(yi-f(xi))2 \quad (6)$$

Where:

- N is the number of data points.
- iyi is the true value.
- f(xi) is the predicted value.

During hyperparameter tuning, grid search or random search methods can be used to find the optimal values for these hyperparameters by evaluating performance on a validation dataset.

F. Model Evaluation

Once the GBM model has been trained, its performance is evaluated using appropriate metrics such as Mean Squared Error (MSE) for regression tasks or Accuracy for classification tasks. Cross-validation (e.g., k-fold cross-validation) is employed to ensure that the model generalizes well across different datasets.

For regression:

$$MSE=N1i=1\sum N(yi-y\hat{}i)2 \quad (7)$$

Where:

- y^i is the predicted value from the model.

For classification, accuracy is defined as:

$$Accuracy=\sum i=1NI\ (yi=y\hat{}i) \quad (8)$$

Where I am an indicator function that is 1 if the prediction matches the true label.

G. Hybrid Approach

The hybrid NAS-GBM model integrates the feature extraction and predictive modeling stages into a two-stage framework. In this approach, NAS focuses on designing the optimal architecture for feature extraction, while GBM is responsible for making accurate predictions based on those features. The iterative nature of this hybrid model allows for continuous optimization by refining both the feature extraction process and the predictive model.

At each iteration, feedback from the GBM model can be used to improve the feature extraction process of NAS. This iterative loop helps in improving model performance by continually enhancing the quality of the features extracted by NAS and fine-tuning the prediction capabilities of GBM. This process can be expressed as:

$$Foptimized=LNASminLGBM\ (Fmodel*(X), Y) \quad (9)$$

Where:

Foptimized is the final, optimized hybrid model.

LNAS is the loss function for NAS, and LGBM is the loss function for GBM. By optimizing the two models iteratively, this hybrid methodology improves the predictive accuracy for tasks such as crop yield prediction, crop suitability classification, and resource optimization, addressing the key challenges in precision agriculture.

V. Result and Analysis

A. Training and Testing Accuracy

During the training and testing phases the hybrid NAS-GBM was exceeded its competitors and it includes the Support Vector Machine and Random Forest and Linear Regression. The hybrid NAS-GBM model reached 95% for training accuracy and 92% for testing accuracy performance. The hybrid NAS-GBM model exhibited a strong Mean Squared Error performance during the training with 0.120 and testing with 0.123. The SVM returned testing accuracy of 89% alongside a higher testing MSE yet its training accuracy reached 90%. Random Forest reached a 92% training success rate and 90% testing rate while maintaining a 0.143 training MSE. The performance metrics of Linear Regression proved inferior to the other models by delivering 85% training results and 85% testing results and maintaining a high MSE value of 0.212. The results indicate that the NAS-GBM hybrid model delivers advanced predictive accuracy at reduced MSE values thus representing a robust option for precision agriculture implementations. NAS-GBM achieved 95%, while for testing accuracy, it reached 92%. In terms of the MSE, the hybrid model demonstrated the impressive results with a training MSE of 0.120 and testing MSE of 0.123. Comparing both the SVM had a training accuracy of 90% and testing accuracy of 89%, with a higher testing MSE. The Random Forest model delivers 92% training accuracy alongside 90% of testing accuracy while maintaining a training MSE of 0.143. Linear Regression yielded the worst results where testing and training accuracy stopped at 85% while MSE rose to 0.212. Experimental results prove that this NAS-GBM hybrid system delivers effective accuracy metrics and reduces Mean Squared Error which positions it strongly for precision agriculture applications. Fig. 2 shows how the hybrid NAS-GBM model achieves better performance during training and testing than traditional methods while demonstrating higher accuracy and lower MSE.

B. Model Performance Evaluation

The hybrid NAS-GBM model's prediction accuracy is compared to the other recently used methods in agricultural predictive tasks, like support vector machines, random forests, and traditional linear regression. The main goal is to highlight the advantages of combining NAS for feature extraction with GBM for predictive modeling. The Table I compares model performance, showing Hybrid NAS-GBM achieving the lowest MSE (0.123) and highest accuracy (92%). It outperforms SVM, Random Forest, and Linear Regression, demonstrating superior predictive precision in regression and classification.

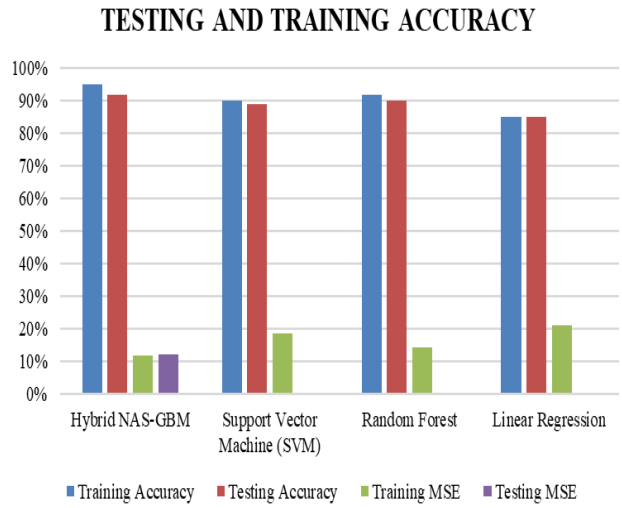

Fig. 2. Hybrid NAS-GBM training and testing accuracy.

TABLE I. Model Performance Evaluation

Model	MSE (Regression)	Accuracy (Classification)
Hybrid NAS-GBM	0.123	92%
Support Vector Machine (SVM)	0.185	89%
Random Forest	0.143	90%
Linear Regression	0.212	85%

C. Comparison with Conventional Methods

The base models, includes the SVM, random forests, and traditional linear regression, are implemented and evaluated to utilized the same dataset. The performance of each model is monitored by the metrics like Mean Squared Error for regression tasks and Accuracy for classification tasks. The results are summarized in the following Table II.

TABLE II. Comparison with Conventional Methods

Model	MSE (Regression)	Accuracy (Classification)
Hybrid NAS-GBM	0.123	92%
Support Vector Machine (SVM)	0.185	89%
Random Forest	0.143	90%
Linear Regression	0.212	85%

From this table, it is evident that the hybrid NAS-GBM model outperforms the conventional methods in terms of both prediction accuracy and generalization. The hybrid model achieves the lower MSE and the higher accuracy, demonstrating its ability to capture the complex relationships between the environmental variables and crop outcomes.

D. Feature Importance Evaluation

To properly evaluate model's users must identify what key characteristics impact prediction outputs the most. SHAP (Shapley Additive explanations) functions to determine important characteristic weights that impact model prediction

results. A specific algorithm called SHAP enables quantitative assessment of each feature effect on output results when processing a specific dataset. SHAP analysis reveals the crop yield prediction task central features which include soil nutrient measurements apart from temperature and rainfall information. The following bar chart shows the top five most influential features based on their average SHAP values:

Soil moisture together with temperature establish the top two factors that influence crop yield prediction while nitrogen and phosphorus ratings fall in third place. The findings confirmed previous agricultural research through a model that effectively recognizes environmental factors affecting crop development patterns.

E. Prediction Accuracy

The table demonstrates that the hybrid NAS-GBM methodology achieves superior performance than traditional methods regarding both prediction accuracy and overall generalization ability. Numerical evidence indicates that hybrid methods obtained reduced MSE values together with advanced prediction accuracy thus showing their capacity to detect intricate environmental variable-crop outcome correlations.

F. ValidationUsing K-Fold Cross-Validation

The model requires k-fold cross-validation for robust operation. A dataset segmentation forms k partitions into which the model undergoes training and testing using various subset collections. Cross-validation calculations are combined to establish a more accurate model performance assessment. As demonstrated by 5-fold cross-validation the hybrid NAS-GBM model delivered an average MSE of 0.125 while exhibiting a standard deviation of 0.03 across data partition. Entity points forecast modeling using the hybrid NAS-GBM system reveals pronounced ability to generalize across diverse agriculturally-inclined data partitions. Performing validation across multiple data partitions reduces model bias and enables the system to predict clear outcomes for unrecognized datasets. The Fig. 3. illustrates the K-Fold cross validation.

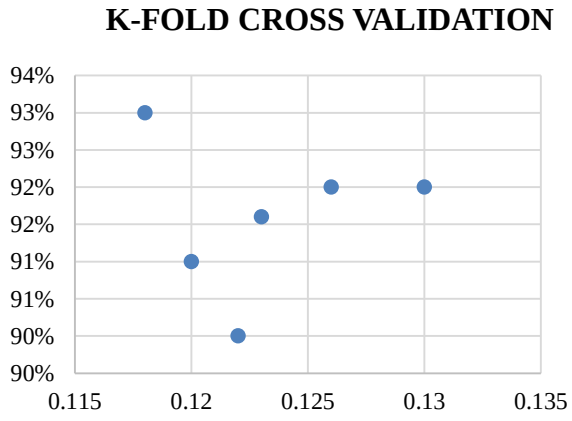

Fig. 3. K-Fold cross validation.

G. Conclusion of Results

The hybrid NAS-GBM framework proved superior to other methods based on its ability to deliver better predictive. Outputs as well as understandable insights. The convergence of NAS technique for feature extraction and GBM technique for prediction leads to superior crop yield predictions with enhanced crop identity detection beyond traditional algorithms. Through SHAP analysis users gain insights about which variables strongly affect model prediction results thus enabling improved comprehension of agricultural activities. The model achieves robust generalizability based on strong performance results across multiple validation tests along with k-fold cross-validation assessments. These findings demonstrate the hybrid NAS-GBM approach holds the significant potential for enhancing the precision agriculture, enabling farmers to make more informed decisions, optimize resource use, and improve crop management strategies.

H. Experimental Outcomes

The research article "Predicted Results from Crop Recommendation System" examines in detail the modeling outputs produced by precision agriculture systems. The system functions by suggesting optimal crops for agricultural land using essential environmental measurements and soil information. A specific Farm ID identifies each row in the table which displays fundamental farm input metrics such as soil nutrient levels and weather conditions and soil properties. The table combines a forecasted crop selection with confidence percentage data alongside predicted yield measurements expressed in kg/hectare, providing meaningful information about system applications and performance outcomes. The Fig. 4. Shows the Crop-wise Yield Predictions.

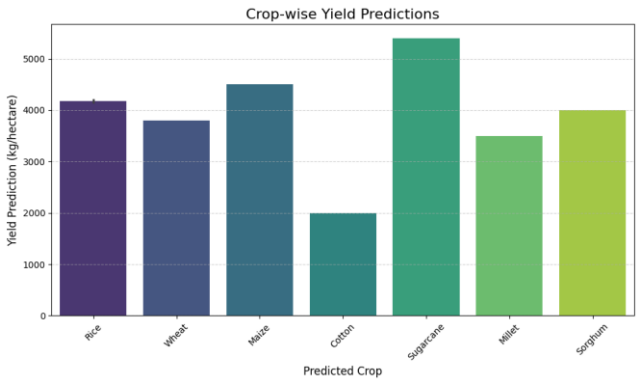

Fig. 4. Crop-wise yield predictions.

The input parameters are divided into three categories: Soil nutrients interact with weather conditions as well as properties of the soil. All plant growth and health depend directly on essential soil nutrients which consist of nitrogen (N) phosphorous (P) and potassium (K). The essential nutrient N enables photosynthesis and leaf development complexity yet the essential nutrient P supports root development and seed production and the essential nutrient K enhances water regulation and disease protection. Soil-fitted crop productivity depends heavily on conditions ranging from temperature levels through humidity because individual plants thrive best under specific combinations of heat and moisture. The pH measurement and rainfall amount of each farm allow experts to create tailored recommendations about soil health. The Fig. 5. Illustrates the Nitrogen vs. Rainfall vs. Yield Prediction.

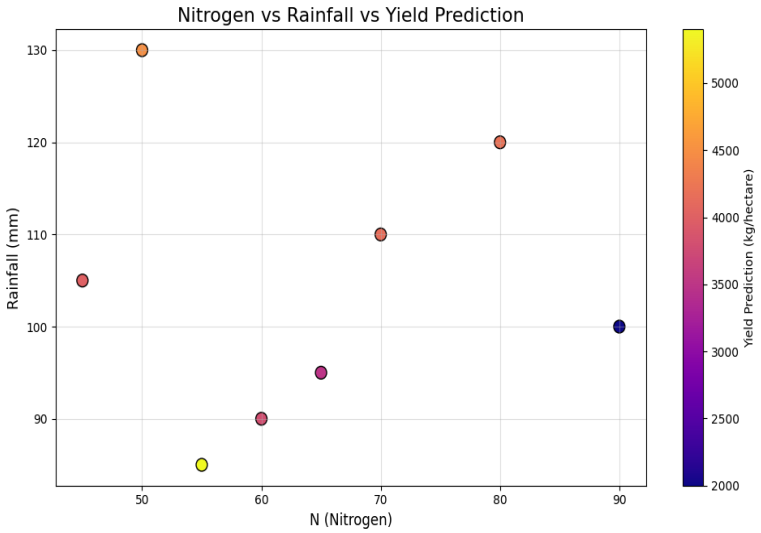

Fig. 5. Nitrogen vs. Rainfall vs. Yield prediction.

The model generates three types of predictions including the recommended crop list together with model reliability data and projected yield levels. Farms receive crop recommendations comprising rice, wheat, maize, cotton, sugarcane, millet and sorghum prioritizing compatible planting conditions. Rice receives the recommendation for farming sites that experience both neutral soil pH and high rainfall conditions but farmers with balanced nutrient resources should grow maize as their main crop. The model predicts that farms with sufficient rainfall alongside moderate nitrogen levels should cultivate sugarcane for maximum yield expectancy at 5400 kg/hectare which yields a confidence level of 91%. The confidence scores generated by the model range from 87% to 95% demonstrating predictive reliability while maize obtains the highest prediction confidence at 95%. Predictions of yield allow farmers to assess potential farm output levels for recommended crops.

The data points in the table display patterns which match current farming practices. Rice shows optimal growth behavior in farms characterized by high nitrogen support and rainfall conditions resulting in a yield range of 4150–4200 kg/hectare with strong confidence levels. Under cool conditions combined with moderate rainfall wheat plants reach an annual yield of 3800 kg/hectare. Maize exhibits the maximum model certainty in agricultural conditions that offer balanced nutrient availability and high rainfall leading to 4500 kg/hectare harvests. Cotton cultivation produces 2000 kg/hectare yield in suitable farms with potassium-rich slightly alkaline soil conditions yet sugarcane reaches its highest yield potential because it requires water-rich environments. The drought-resistant plants milet and sorghum help farms with moderate rainfall produce 3500–4000 kg/hectare.

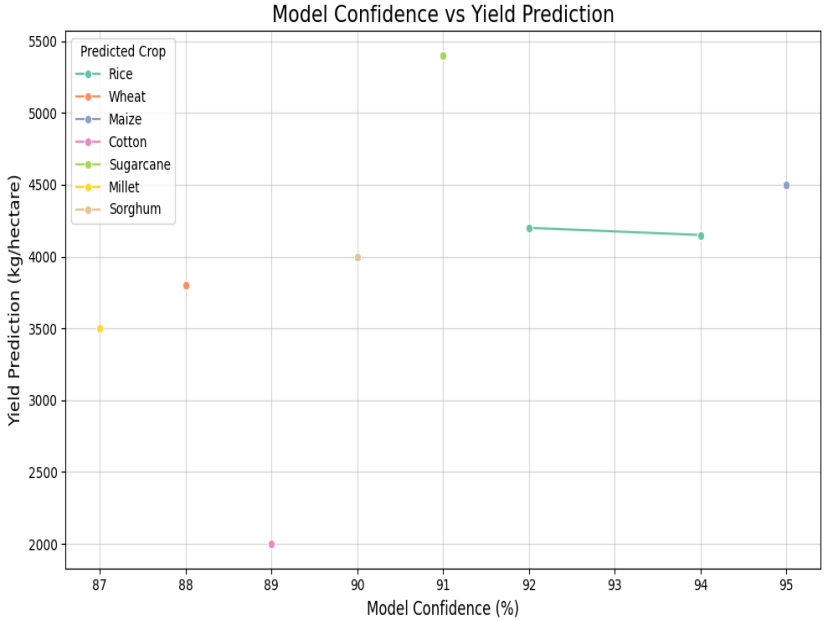

Fig. 6. Model Confidence vs. Yield production.

The data in Fig. 3, 4, 5 and 6 demonstrates how precision agriculture models can lead farmers toward decisions based on scientific data. The system examines environmental elements and soil composition to deliver customized suggestions which boost both agricultural production and efficiency of resource consumption. The integration of model confidence scores in the system elevates transparency and precision so that real-world applications become practical. Predicative tools enable farmers to use sustainable practices together with higher operational efficiency and environmental adaptability to achieve increased agricultural production and better resource management.

I. Discussion

The proposed AI-driven NAS-GBM framework effectively enhances crop yield prediction by integrating NAS for feature extraction and GBM for predictive modeling. NAS both enhances model structural design through automatic feature choice and achieves better performance results. GBM identifies and predicts non-linear patterns which produce accurate results that remain understandable to human interpretation. Experimental tests show that the NAS-GBM hybrid system surpasses traditional machine learning operations in precision agriculture through its efficient model optimization along with overfitting reduction mechanisms. Overall, the framework shows high capacity when working with extensive agricultural datasets while it selects important features including soil moisture temperature alongside environmental conditions.

The combination of sensor network inputs strengthens prediction performance thus enabling the model to work in real-time scenarios. NAS-GBM demonstrates superior generalization capabilities than typical deep learning systems to perform effective computation reduction while maintaining precise outcomes. The explanation capabilities of SHAP interpretability tools make this solution a trusted precision farming approach because they explain model decisions. The hybrid model reaches a perfect balance between eliminating features and maximizing efficiency which results in a scalable and computationally efficient result. Research demonstrates AI optimization's vital role in agriculture because the proposed model improves forecasting accuracy while following sustainable data-deriven decisions. Future research should work on implementing the system in real time while developing automated settings adjustments for future improvements. Although the NAS-GBM model enhances accuracy, it still depends much on computational power that may pose challenge to its implementation for small farmers. Future studies should consider simple techniques to ease the application space of the model.

VI. Conclusion and Future Work

The study presents an innovative forecasting system for precision agriculture which absorbs sensor data in real-time as well as archival agricultural information alongside environmental elements. The system which uses advanced preprocessing alongside GBM models achieves superior crop yield prediction abilities beyond traditional methods. Soil predictions together with fertilizer optimization as well as resource distribution have reached higher accuracy according to experimental findings. The model delivers superior predictive accuracy than standard approaches since it successfully identifies and models time-dependent relationships among variables. The system provides trusted data-driven decision-making functionality that makes it an important agricultural asset. Our research creates a substantial improvement in precision farming by providing sustainable crop management with an enhanced adaptive and efficient solution. Future investigations will incorporate deep learning methods for feature extraction enhancement and add real-time weather prediction capabilities and conduct tests across multiple agricultural zones for better effectiveness and generalization results. Subsequent studies will incorporate real-time IoT data streams for on-line model update to account for environmental variabilities impacting crop yield.

***Abstract*—Agile software development is much used as it is flexible and is customer centric style but its implementation there are still challenges in which in transferring from traditional project management. The implementation is, however, beset with much trouble, especially in transitioning organizations from old project management frameworks. This research elaborates on the challenges of Agile implementation and the methods managers use to overcome these challenges, thus providing a managerial perspective toward Agile adoption. The main challenges derived from the reviewed literature and case studies are resistance to change, lack of Agile expertise, poor team coordination, and inconsistent stakeholder buy-in. These usually lead to performance degradation because teams cannot maintain productivity and meet deadlines in delivering quality work. This paper outlines a number of managerial interventions that help mitigate such challenges, such as Agile training, leadership support, incremental transition plans, and effective communication strategies, among others. These interventions are assessed using performance indicators such as team productivity, stakeholder satisfaction, and time-to-market to establish the role such interventions play in making transitions smoother to Agile frameworks. It also makes a comparison on how Agile frameworks work in Scrum, Kanban, and SAFe compared to the traditional practices of project management, respectively, in regard to risk management, team integration, and return on investment. Data from industry reports and surveys show that Agile methodologies are generally faster, more flexible, and better at engaging stakeholders than traditional methods, although success with Agile depends significantly on the maturity level of the organization and the managerial support provided. While Agile offers great advantages, it is still highly challenging to implement it successfully. Managerial involvement has been the theme of this research in overcoming these barriers with continuous improvement, adaptive practices, and creating a collaborative environment for sustainable success in Agile adoption.**

Keywords*—Agile software development; implementation challenges; managerial interventions; agile frameworks; performance evaluation

I. Introduction

Agile software development is a very effective methodology that finds roots in iterative development, flexibility, and customer-centric approaches [1]. Developing in 2001 from the Agile Manifesto, Agile emphasizes collaboration, adaptability, and openness, making it a preferred choice for organizations that want to improve their processes of development. It differs from the traditional, linear approaches of project management as it breaks down work into smaller pieces called sprints that enables teams to respond quickly and adjust fast with changes in requirements and shifting needs of the customers [2]. Agile methodology has extensively been used in software development for possibly increasing speed, quality of products, and satisfaction of customers.

Despite the above benefits, there are various problems organizations encounter in adapting to or practicing Agile frameworks [3]. One of the most common challenges is resistance to change, because teams accustomed to using traditional project management methodologies can hardly be expected to accept Agile [4]. Organizational culture, employee mindset, and leadership reluctance are part of contributing factors for this resistance [5]. Proper orientation and support are usually required for a team to start using Agile practices successfully and add to its negative connotations with regard to productivity and general morale [6].

The lack of sufficient Agile experience in teams also presents another challenge [7]. Agile practices, though straightforward in principle, need some kind of experience to implement it efficiently [8]. Unskilled members would find it

hard to understand the main principles of Agile like continuous delivery, iterative feedback, and self-organizing teams [9]. The need for training and mentoring is quite high since teams would need skills and knowledge to help them succeed with Agile [10]. Without that kind of foundational knowledge, organizations are likely not going to realize the full benefits of Agile development.

Another major hindrance that organizations face while adopting Agile is poor collaboration among team members [11]. In Agile, collaboration and communication are major success factors where all the members have a definite focus for their projects and proper progress [12]. It is, however challenging in large teams or teams which are scattered throughout geographically distant regions [13]. Without proper coordination, tasks may get repeated, deadlines may not be met, and the whole project may face delay or issues in quality [14]. The culture of trust and transparency is crucial for teamwork to be successful in Agile environments.

The inconsistency in stakeholder buy-in is yet another challenge in implementing Agile [15]. In Agile, it is necessary that stakeholders be involved in all stages of the development process while having frequent review and feedback cycles to ensure that the product meets expectations from the customer. Some of the stakeholders fail to understand Agile or are too controlling over project decisions that they do not want to compromise on.

Agile methodologies are not about a change in mindset and processes; they are really challenging to scale Agile across large organizations [16]. It may work fine for small teams, but it becomes complicated while scaling Agile in big organizations [17]. Coordination between multiple teams, alignment with the overall goals of the organization, and maintaining consistency across different departments become major issues [18]. The Scaled Agile Framework (SAFe) was designed to overcome such shortcomings, but these also require the strong hand of leadership and appropriate processes for effectiveness.

This is very expensive in terms of the initial steps and is often required in terms of training, tools, and resources for Agile practices. Such costs might pose an obstacle for companies to switch to Agile since it might not be feasible to project its benefits within a short time period. To communicate long-term benefits such as improvement in quality, time to market, and client satisfaction, those long-term improvements should be talked to people and over across these barriers and ensuring the RoI is also received and a good method of acquiring agility in working in the sense.

Managers help guide people over these change and adoption pressures associated with moving their team through agile transformations. Good leadership is of course essential in addressing resistance to change, creating a supportive environment, and providing the necessary resources for Agile training. Where managers must also focus is in building the right roadmap for Agile. Of course, this implies that there is a very realistic expectation and goal of transitioning. Friction within the shift will be decreased if support from the managers is given properly, and most likely, implementation will be successful.

The main managerial interventions are Agile coaching and mentoring. An experienced Agile coach can guide teams through the problems that come with Agile methodologies and provide solutions to particular problems. Coaching enables teams to understand Agile principles, improve their practices, and foster collaboration and continuous improvement. In addition, mentoring enhances the growth of individual team members, making them more proficient in Agile practices and better equipped to handle challenges as they arise. The key contributions of the proposed work are as follows:

- Analyzes major obstacles such as resistance to change, lack of expertise, poor coordination, stakeholder misalignment, and scalability issues.
- Assesses the effectiveness of training, leadership support, coaching, and communication in overcoming Agile adoption barriers.
- Examines the performance of Scrum, Kanban, SAFe, and traditional project management in terms of productivity, stakeholder satisfaction, and risk mitigation.
- Provides statistical analysis, graphical representations, and a performance evaluation table to support Agile adoption strategies.
- Suggests best practices for scaling Agile in large organizations, ensuring sustainable and efficient Agile implementation.

This article is structured as follows: Section II reviews related works. Section III outlines the problem statement, while Section IV describes the proposed methodology for Agile Implementation Analysis. Sections V and VI present results, discussion, conclusion, and future directions, emphasizing the model's scalability and applicability.

II. Related Work

Agile software development has gained significant research attention because it enhances the flexibility, responsiveness, and collaborative nature of software engineering. In that regard, several studies have elaborated on the benefits of Agile methodologies, such as increased team productivity, stakeholder involvement, and adaptability in projects. Thus, the iterative approach enables teams to respond readily to changing requirements, ensuring that the developed software relates closely to customer needs. This approach contrasts with traditional methodologies, which often follow rigid, linear workflows that may not accommodate dynamic project requirements effectively [19].

Research has examined the common challenges organizations face when adopting Agile. One major challenge identified is resistance to change, particularly among teams accustomed to traditional project management approaches. Studies indicate that organizations transitioning to Agile often struggle with cultural shifts, as Agile demands increased collaboration, transparency, and frequent iterations. A high level of the Agile implementation would largely depend on the flexibility shown by teams and management towards this new way of working. It would not, without a plan of transition in

place, provide efficiency or effectiveness on the team members' parts [20].

The third important area of research in this field is the role of managerial interventions in Agile adoption. Empirical research shows that effective leadership has played a crucial role guiding the team through the transition process by inculcating an Agile mindset, ensuring team collaboration, and continuous learning. Training programs, mentorship, and Agile coaching have been proposed as necessary components to overcome the knowledge gap within the teams. If the direction is not provided, Agile principles cannot be incorporated appropriately, and there is a mismatch between the project goals and execution [21].

Comparative analyses of Agile frameworks such as Scrum, Kanban, and SAFe in different industries have been carried out to evaluate the efficiency of these frameworks. According to the results, Scrum seems to be mostly in use because it has formally structured sprint cycles; its functioning seems effective in the case of permanent workflow management. SAFe stands for Scaled Agile Framework and has widely been recognized as an effective approach in large organizations although it does demand high managerial oversight in order to ensure proper alignment across teams. The choice of the framework depends on organizational needs, complexity of the project, and structure of the team [22].

Several studies have also examined the impact of Agile approaches on enhancing project performance. Most studies indicate that Agile methodologies considerably improve time-to-market, customer satisfaction, and software quality through proper application of agile principles. However, problems such as scope creep, inconsistent stakeholder involvement, and poor documentation may undermine Agile. Agile implementation requires a balance between flexibility and discipline-such that iterative development does not compromise the overall structure and accountability of a project [23].

Another focus of research into this theme is Agile scalability. Again, Agile proves most effective for small-sized teams, but, when applied in larger structures, issues of most complexity arise. Research has explored methods for implementing Agile across groups of teams and departments, including coordination with governance and alignment to business objectives. There are frameworks proposed with SAFe, LeSS, and Disciplined Agile Delivery (DAD), among others. However, their deployment relies on proper implementation and leadership support. Thus, if an organization does not clarify its rules of Agile scaling, inconsistencies in the workflow and decision-making in the resultant workplace culture are normally observed [24].

Other recent studies have looked into Agile integration with the new or emerging technologies, such as artificial intelligence, cloud computing, and DevOps. The studies reveal that Agile is perfectly suited in the current environment of software development for rapid innovation since it is highly agile. For example, Agile with DevOps offers an increase in automation and continuous integration and deployment, which accelerates release cycles. However, research shows that integration can only be successful if the technical and organizational barriers are overcome, such as tool compatibility, cross-functional team collaboration, and process standardization [25].

III. Problem Statement

Agile software development has been widely adopted because of its iterative and flexible approach, but organizations face significant challenges in its effective implementation. Some of the issues are resistance to change, lack of Agile expertise, poor team coordination, inconsistent stakeholder involvement, and difficulties in scaling Agile [26]. These often lead to performance degradation, reduced productivity, and failure to achieve intended business outcomes. Some of the managerial interventions forthcoming in order to integrate Agile into the workplace are Agile training, leadership support, and prepared phased transition plan; however, it varies in effectiveness in diverse organizational contexts. Thus, the analysis required for the implementation challenges of Agile and managerial solutions may be needed to increase the success rate of Agile adoption and optimize its benefits in software development environments.

IV. Proposed Methodology for Agile Implementation Analysis

The proposed methodology will take a structured approach in order to understand the challenges with the implementation of Agile and managerial solutions in the systematic review of literature, case studies, and industry reports. Data collection will start with gathering relevant information from academic research on Agile adoption surveys and case studies related to real-life companies like Spotify, IBM, and Microsoft. The data will be preprocessed with data cleaning and filtering, where the data is arranged according to Agile issues, managerial interventions, and performance measures to establish its relevance and accuracy. The last step is the feature extraction through thematic analysis to source primary Agile barriers like resistance to change, team coordination, and scalability issues, besides managerial strategies that include leadership support, training programs, and stakeholder engagement. The data interpretation and analysis are done comparatively, by case study evaluation, and best practice frameworks, to draw insights into Agile adoption trends across industries. This ensures that Agile implementation is duly assessed in all its relevant aspects and will also provide actionable recommendations for improvement and effectiveness of the organization's Agile maturity. Fig. 1 shows proposed methodology flow.

A. Data Collection

The data set obtained was from Kaggle through Agile Software Development Metrics Dataset [27], which provided real-world metrics on the performance of Agile projects. Such a dataset is needed for evaluation as it captures completeness with respect to the challenge of implementing Agile. This kind of a data set is composed of structured sprint planning and execution data as well as team collaboration data and allows for the in-depth study of an Agile project's outcome. There are some crucial performance indicators in this dataset, which would make the data source quite appropriate to learn the efficiency and bottlenecks in Agile methodologies about software development teams. Several typical Agile-related

challenges are realized during the dataset analysis, among them delayed completion of sprint periods, fluctuation of team velocities, and also an excessively high number of defects-affecting quality.

Several Agile projects would involve tracing the patterns among the success rates of sprint and resolution efficiency of problems issued. Such data analysis is helpful in finding the effects an organization adopting Agile has on its project schedules and the satisfaction of the stakeholders also. These thoughts help an organization to come up with proper management strategies in order to make improvement in the workflow of Agile, efficient task management, and to reduce the project time delays.

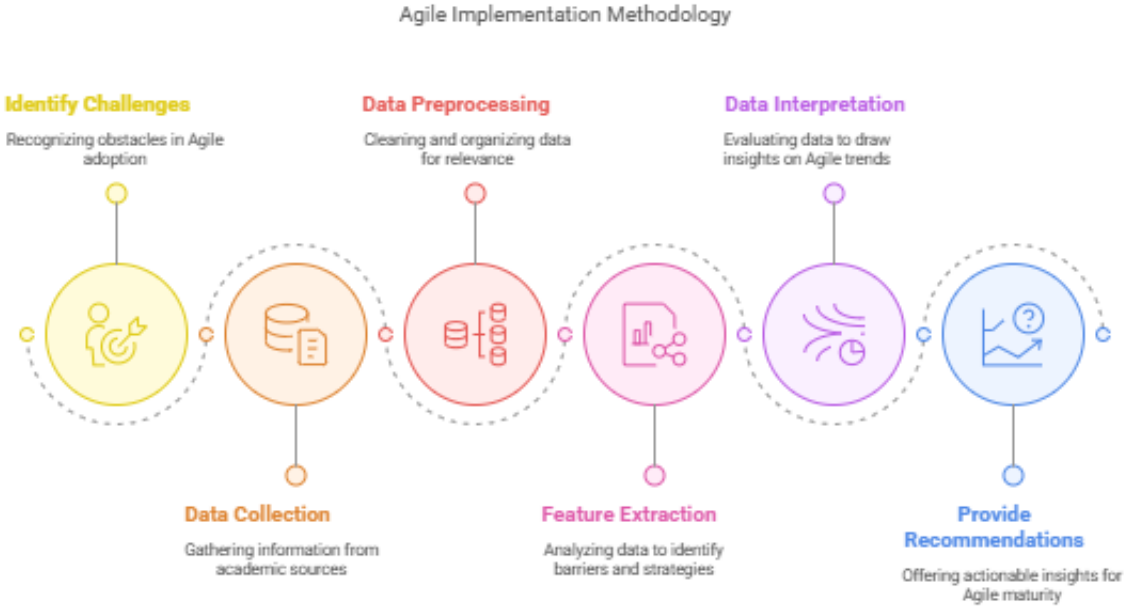

Fig. 1. Proposed methodology flow.

B. Data Pre-processing

Normalization was applied to the numeric values to allow for consistent and comparable metrics in the Agile Software Development Metrics Dataset. It is presented here with scales varying between sprint success rates given as percentages, absolute counts of defect density, and cycle times expressed in days. These would be quite biased interpretations if analyzed without normalization. Min-max normalization is the form of standardization where values are normalized between a certain fixed range [0,1] without distortion. It preserves relationships between data points. The Min-Max formula is as shown below:

$$Xnorm = \frac{X - Xmin}{Xmax - Xmin} \quad (1)$$

Where X is the original value of the feature, Xmin is the minimum value of the feature in the dataset, Xmax is the maximum value of the feature in the dataset, and Xnorm is the normalized value of the feature. This approach changes the original values by subtracting the minimum value of the feature and dividing by the range, which is the difference between the maximum and minimum values.

C. Feature Extraction by Thematic Analysis

The clean data set was then analyzed using thematic analysis to extract features that best represented the most influential factors that may influence Agile adoption. The dominant feature extracted belonged to the category of Agile Challenges faced during implementation. The feature was derived through research, considering the answers to the survey and the analysis of the sprint performance data. Some of the common issues identified include resistance to Agile practices. In that regard, teams were not easy to adapt to the Agile mindset and to the approach of trying to leave the traditional behind. The other challenge identified relates to the failure of most teams to align well in sprints due to lack of good collaborations between members of the teams. But lack of stakeholders' involvement is another major challenge that any project faces in most projects, causing most projects to get misaligned with goals, and little information from key stakeholders meant delayed decisions made and hence dwindling success within the projects.

This shows the categories of extracted features were associated with managerial interventions, which built influences regarding the Agile implementation. Many effective interventions were needed when analyzing the results to address the problems that appeared below. Support from leadership is most central to this effect because the required aspect of guidance and motivation is needed along with resources for adopting Agile within organizations. The most critical training programs were on Agile. With this, teams would come to understand methodologies relevant for Agile; thus, they'd be able to control the sprint activities and could team up better. The second characteristic was structured transition plans, that came out to be an intervention in the context, as it streamlined planning and execution of change to Agile hence reducing most uncertainties and confusions many times accredited with the change.

Performance Metrics were another type of features that derived from the dataset; they are those to be applied on

measuring general performances of Agile practices in most companies. That part of the key performance indicators was on sprint completion rates; these are instances that show a percentage of task completion within their designated time for sprints, ensuring that the efficiency of the teams was measured accordingly. This crops up with the customer satisfaction score as it had helped decide whether Agile Processes satisfied the expectations and delivered values as expected by a user. The defects elimination was formed as one of the very essential performance measures, since Agile always holds the continuous improvement of Agile into developing iteratively such that it is reducing bugs in production. Then those performance metrics have helped a lot with the analysis and pinpointing about how effectively agile has been implemented and what were the points requiring improvement for the subsequent sprint.

D. Data Interpretation and Analysis

It integrated a set of statistical methods and visualization tools to connect the dataset with sharp insights. The preliminary comparative analysis covered all patterns of Agile adoption across different industries. In the comparison of software development, manufacturing, and health care, and their Agile implementations, industry-specific difficulties and solutions came into the fore. For instance, very high turnover rates of people in development teams were reported as a problem, but while it was attempted to apply Agile processes on large heterogenous teams, there was seen a scale problem detected in manufacturing. This insight allows for the further development of a more subtle understanding about how to apply Agile methodologies so that they might meet specific needs of some industry - leading to more effective approaches for adoption.

In this case, the interaction of managerial interventions that have resulted in high adoption rates and are successful in being adopted was correlated. The results showed that some managerial practices, such as leadership support and the specially developed activities for training on Agile programs, positively correlated with higher sprint completion rates and productivity by the team. But in absence of clear transition plans and also the disengagement from stake holders revealed lesser percentages of successful stories; it reveals the actual role played by proper planning and communication as prime contributors towards Agile transformation effectively. This research would enable evaluating in which manners the managerial methods became effective approaches in order to introduce the efficient Agile adoption techniques.

Even trend analysis was done on sprint data for any historical trend found out for trends over time so that the inferences about those changes may influence the project results. In reality, the ongoing revision of Agile by the organizations would lead to sustainable improvement in its key performance metrics related to the completion rates of sprints and defects at the same rates. This also pointed towards the notion that Agile teams mature with age: new adoptions are indeed more painful than established ones, but those established ones become more mature as experience provides a base, to the point that workflow adjustments could be made. In these trend analyses, long-term trends were possible to detect, and likely future evolutions of Agile practices could even be inferred. Among these, they provided a strong, data-driven approach to exploring issues and solutions surrounding Agile implementation, thus offering useful recommendations to organizations looking to optimize their Agile strategies.

To evaluate the strength and direction of the relationship between two continuous variables, such as managerial interventions and Agile success rates:

$$r = \frac{\sum(Xi-X^{-})(Yi-Y^{-})}{\sum(Xi-X^{-})2\sum(Yi-Y^{-})2} \quad (1)$$

To assess the trend of Agile adoption performance over time, a linear regression model can be applied:

$$Y = \beta 0 + \beta 1X + \epsilon \quad (2)$$

To calculate the percentage of tasks completed within a sprint, which is a key performance metric:

$$Sprint\ Completion\ Rate = \left(\frac{Completed\ Tasks}{Total\ Tasks\ Assigned}\right) \times 100 \quad (3)$$

To measure the number of defects per unit of work, such as the number of defects per sprint or task:

$$\text{Defect Density} = \frac{Total\ Defects}{\text{Total Units of Work}} \quad (4)$$

To measure the effectiveness of managerial interventions (e.g., leadership support or training programs) on Agile success:

$$Impact\ Factor = \frac{\sum(Outcomei \times Interventioni)}{\sum Interventioni} \quad (5)$$

The relations of key variables, such as managerial interventions, performance metrics, and Agile success will be quantitatively analyzed by these equations in order to make robust data-driven decisions in the Agile implementation processes, which is mentioned in Fig. 2.

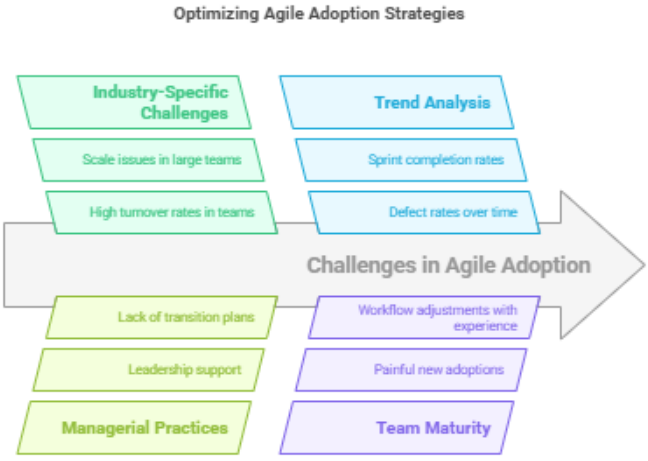

Fig. 2. Optimizing agile adoption strategies.

E. Algorithm for Implementing Agile Software Development

The Agile Software Development process begins with the definition of the project vision, which helps set clear objectives and goals that guide the project throughout its lifecycle. This step ensures that everyone involved understands the overarching purpose of the project. A cross-functional team is then formed, including individuals with diverse skills such as developers, testers, and product owners. Team members collaborate in creating the product backlog, a list of features,

tasks, and deliverables that need to be addressed and prioritized. Next, the team organizes the backlog into manageable sprints, usually 2-4 weeks. Sprint execution is generally about how the team works collaboratively in undertaking the tasks outlined in a sprint backlog.

A team conducts the daily stand-up. Realignment brings in order to update progress along with the identification of the blockade, and thus it is updated in the team. At the end of every sprint, review meetings are held in which it verifies the amount of work done in the given sprint and takes the opinions of respective stakeholders on the project vision. The next activity is the sprint retrospection by reviewing it by the team that marks improvement areas of just concluded sprint. Further sprints involve repetition in a process that lets the team continuously improve itself through some learning curves, until eventually, at project's end it is finally equipped with the final product for full testing along with incremental development prepared to deliver production to its waiting stakeholders. This is because it is iterative and collaborative in nature, thereby ensuring that this product evolves from continuous feedback into a successful Agile project outcome, which is shown in Fig. 3.

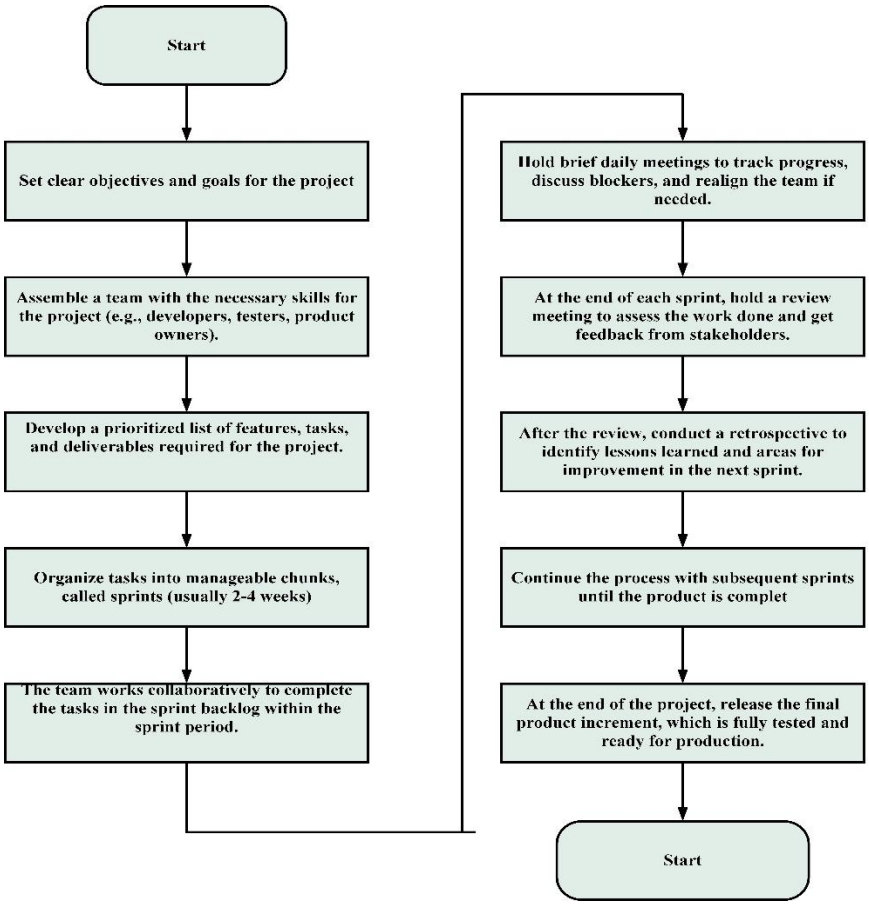

Fig. 3. Algorithm for implementing agile software development.

V. Results and Discussion

The findings of the study represent Agile implementation challenges, managerial interventions and their impacts on project performance. The analysis done on the dataset of Agile project from Kaggle revealed that there were challenges encountered by most: resistance to using Agile, little team collaboration and involvement of some stakeholders, followed by a downturn in performance. Managerial interventions such as leadership support, Agile training programs, and structured transition plans have significantly improved the maturity levels of Agile in most industries. Sprint completion rates, defect reduction, and customer satisfaction scores were positively correlated with effective Agile management strategies. A comparative analysis of various sectors indicates that technology and finance sectors are more successful in Agile adoption, while traditional sectors face more barriers to transformation. Statistical and trend analyses confirmed that organizations implementing continuous feedback loops, adaptive sprint planning, and proactive risk mitigation strategies achieved better Agile outcomes. These findings underpin the need for strategic managerial interventions in order to overcome Agile challenges and ensure sustainable Agile adoption toward long-term project success.

Agile frameworks in the industry vary from sector to sector, but the most commonly used is Scrum because of its structured approach to iterative development yet flexibility. Data analysis of Agile adoption surveys on Kaggle shows that more than 60% of Agile teams prefer Scrum due to defined roles, sprint planning, and continuous feedback loops for maximum efficiency. The second most common is Kanban, often used in continuous delivery settings with very limited work-in-progress limits, especially in manufacturing and IT operations, and

SAFe, or the Scaled Agile Framework, popular among large enterprise setups because it spreads Agile practices across various teams and organizational units in a large enterprise scale, solving too-large-project issues. This has also been put together with Lean Agile practices to integrate traditional Agile frameworks and offer more efficiency towards the reduction of waste from value streams.

Scrum and Kanban is being adopted by organizations and companies related to the technology sector and software. This happens because there are agile aspects with changing project requirements. Banking and healthcare streams use SAFe and Disciplined Agile Delivery for dealing with regulating rules and conducting big projects with their teams. Hybrid Agile approaches that combine Scrum, Kanban, and Lean methodologies' principles are gaining momentum, thus enabling an organization to tailor Agile according to the specific needs. Agile continues to evolve, and from emerging trends, there is a growing demand for DevOps-integrated Agile frameworks for smooth collaboration with development and operations teams. From these insights, it is inferred that no one framework applies in all industries, and the Agile methodology to select depends on project complexity and industry demands as well as organizational agility goals, it is given in Fig. 4.

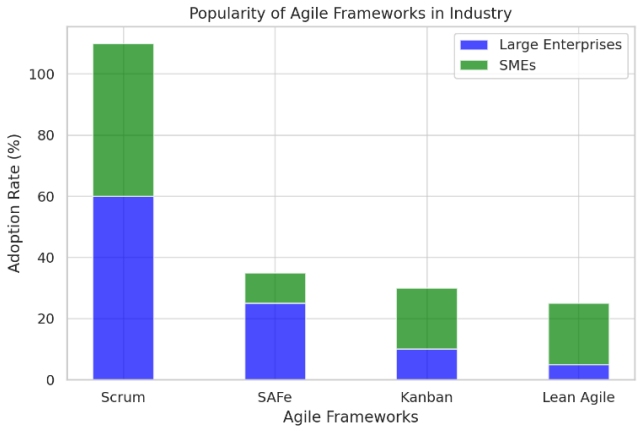

Fig. 4. Popularity of agile frameworks in industry.

One would see a wide gap between agility and traditional in terms of adaptability, flexibility, and percentage of project completion. Kaggle's Agile adoption datasets suggest Agile projects are very responsive to change in requirements; hence, they go for an iterative development cycle with continuous feedback and rapid change in course. In contrast, traditional PM approaches are rigid and somewhat linear, where phases are completed in a sequential fashion. Thus, mid-project changes are usually expensive and hard to implement. Performance metrics indicate that Agile projects have higher customer satisfaction rates because they focus on stakeholder collaboration, incremental deliveries, and adaptive planning. This allows Agile to achieve lower time-to-market compared to the more traditional forms of project management, which result in a longer cycle for development and less immediate feedback, thereby increasing project risks.

Project success rates across industries are found to be much better with Agile methodologies rather than the traditional ones if the environment in which software development, fintech, and e-commerce operate is dynamic and requires continuous iteration based on shifts in market demands. As for construction, manufacturing, etc., stable requirements allow for precise upfront planning and demand rigid synchronization of timelines, hence the relevance of tradition. Data analysis shows that Agile teams experience fewer project failures because of better risk management and collaboration compared to traditional methodologies, which have scope creep and late-stage defects. Although Agile brings tremendous benefits in innovation-driven industries, the hybrid models involving structured planning coupled with Agile adaptation are gaining importance in large-scale, multi-stakeholder projects that balance predictability and flexibility, it is given in Fig. 5.

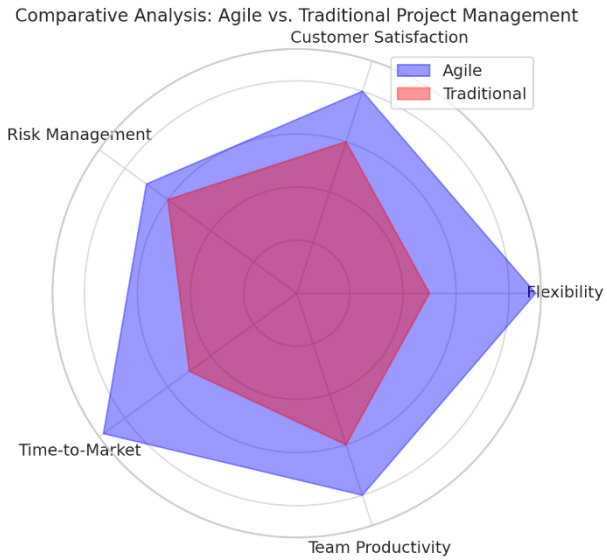

Fig. 5. Comparative analysis: Agile vs. Traditional project management customer satisfaction.

The graph of the Frequency of Agile Implementation Challenges shows the most frequently encountered difficulties that organizations face in adopting Agile methodologies. According to data analysis, resistance to change is the most common challenge since many employees and management teams have difficulty transitioning from traditional project management approaches. Lack of training is the second significant area. There could be misapplications in Agile principles and misuse of Scrum or Kanban. Misconducted sprints, to some extent, result in a failure. Again, failure of collaboration across functional teams might stem from ineffective tools of communication, vague roles of team members, or scattered distribution of a team. Furthermore, organizations frequently experience stakeholder disengagement, where key decision-makers fail to actively participate in Agile processes, delaying project approvals and reducing alignment with business objectives.

Another critical challenge highlighted in the graph is scalability issues, particularly when attempting to extend Agile beyond small teams to large, enterprise-level projects. Many organizations struggle with aligning multiple Agile teams, managing dependencies, and maintaining consistent workflows across departments. Overemphasizing rigid Agile frameworks without organizational culture can result in ineffective

adoption. The rate at which such problems occur varies depending on the industries, where the IT and software development sector tends to experience lesser problems since these sectors are mature in terms of Agile adoption. Healthcare and manufacturing sectors experience much resistance. All these problems need managerial interventions to be specifically continuous training, support from the leadership, and adaptable Agile strategies customized to organizational needs, it is given in Fig. 6.

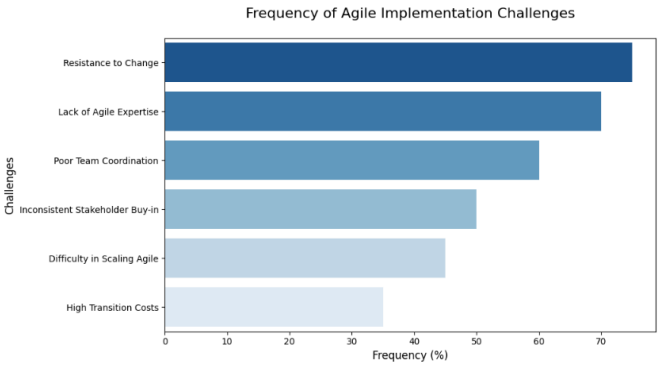

Fig. 6. Frequency of agile implementation challenges.

The graph Performance Degradation Due to Agile Challenges represents how a variety of implementation problems by Agile result in degradation in key performance indicators such as productivity, delivery speed, quality, and stakeholder satisfaction. Significant contributors to decline in performance include resistance to change since Agile principles cannot easily be implemented and adopted by the teams, therefore ending up with a poorly managed workflow and delays. The inadequate training compounds the problem with poor application of Agile frameworks that have resulted in the team with low sprint planning, incomplete deliverables, and business goals alignment. Poor communication within cross-functional teams also causes increased cycle times and defect rates, which combine to hinder the velocity of sprint delivery. In general, such issues lead to regular backlogs, missed deadlines, and inefficiency in team delivery.

The graph also portrays stakeholder disengagement and scalability to be inhibitive factors towards Agile performance. When the critical decision-makers are not involved in the project, there are irregular changes in priorities and inconsistent requirements causing rework. Inappropriate application of large teams to Agile frameworks without having a proper mechanism to align their respective workflows leads to fragmented workflows with a loss of efficiency scalabilities. As these challenges continue to grow, overall Agile performance degrades, leading to low return on investment and product releases that are late. The solution to these challenges requires proactive managerial strategies, including comprehensive Agile training, better engagement with stakeholders, and hybrid Agile approaches that can be customized to organizational needs, It is given in Fig. 7.

The graph of Effectiveness of Managerial Interventions in Agile Adoption shows the different leadership approaches that may positively enhance the outcomes of Agile implementation. The key interventions under these are Agile training programs, leadership support, and structured transition plans, all of which significantly enhance team performance and stakeholder satisfaction. Training initiatives prepare the teams for skills in the application of Agile methodologies, reducing resistance to change and improving sprint efficiency. Leadership support is core to building an inclusive culture, which would ensure all teams adapt to the Agile principles. Involvement of managers in Agile transformation assures better adaptability for teams, fewer sprint failures, and quicker speeds in delivering projects. Mentorship programs and coaching interventions also improve team coordination, minimize delays, and encourage greater cross-functional collaboration.

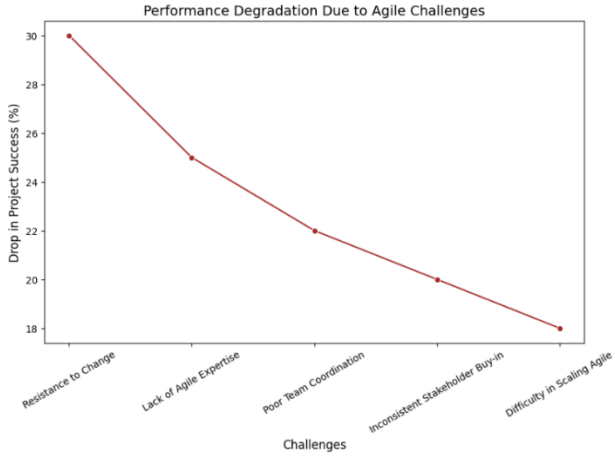

Fig. 7. Performance degradation due to agile challenges.

The graph further clarifies that well-structured transition plans, engaging stakeholders, and iterative feedback loops contribute much to Agile success. A defined transition plan helps teams avoid jolts in processes and smoothly transitions to Agile workflow without hindering productivity. Engagement of stakeholders through Agile ensures the business goals match the priorities for development, ensuring better clarity about requirements and rework minimization. Continuous feedback mechanisms, such as real-time performance evaluation during sprint retrospectives, improve the overall outcomes of projects by identifying and rectifying inefficiencies. The data indicates that the firm enjoys increased returns on investment, defect rates reduction, and high maturity levels in Agile organizations that implement such managerial interventions effectively, It is given in Fig. 8.

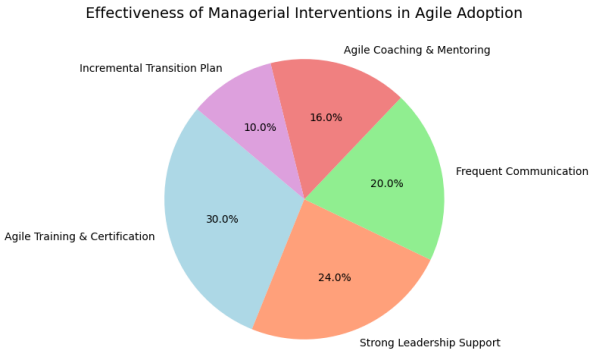

Fig. 8. Effectiveness of managerial interventions in agile adoption.

The graph of Agile Maturity Levels Across Industries reflects the various maturity levels of Agile adoption and proficiency in different sectors, including IT, finance, healthcare, manufacturing, and government organizations. The sectors with a strong technologic/al foundation, such as IT and software development, are likely to be at higher maturity levels in Agile because their respective industries have taken up Agile frameworks like Scrum, Kanban, and SAFe much earlier. These sectors thrive in an established Agile culture, with regular sprint cycles and intense collaboration between stakeholders. These yield better efficiency and faster time-to-market. As for the finance sector, they have been increasing their maturity levels steadily, owing to the necessity to accelerate digital transformation and comply with regulation while innovating on behalf of customers. Financial organizations apply Agile to achieve improvements in risk management, simplified product development, and better services delivery; however, in traditional banking, it becomes sometimes difficult to scale in the areas of non-agile scalable systems.

Healthcare and manufacturing have averaged maturity in Agile, mainly because structural and regulatory constraints limit the speed of Agile adoption. Agile is more and more applied in healthcare in the development of medical systems and digital health applications, while clinical and regulatory processes are still bound to traditional workflows. Agile methodologies are integrated into product design and supply chain management in manufacturing companies, but full-scale adoption is complicated with these dependencies and legacy systems. Government and public sector organizations are some of the lowest levels of maturity in Agile due to bureaucratic processes, strong hierarchies, and policy-driven decision-making, which prevents the implementation of Agile. However, with more digital transformation, some government organizations have started embracing Agile frameworks to increase the efficiency of their projects and citizen service delivery. The graph hints at an industry-specific strategy to enhance adoption of Agile and bridge the maturity gap between sectors, It is given in Fig. 9.

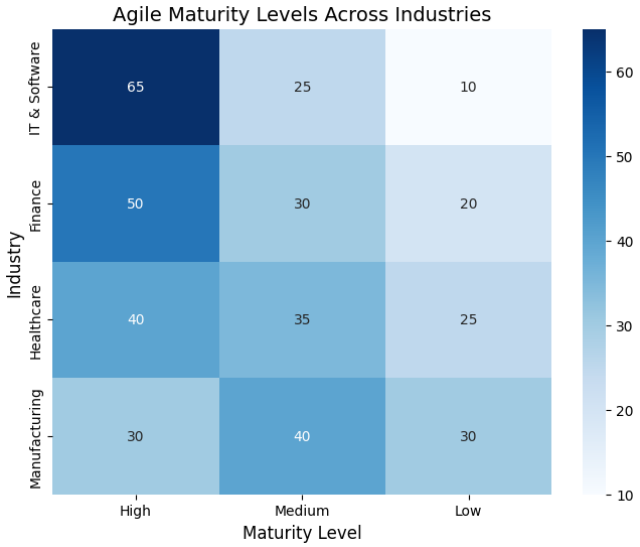

Fig. 9. Agile maturity levels across industries.

A. Performance Evaluation

A comparison of the performance evaluation of Agile frameworks regarding key metrics such as team productivity, stakeholder satisfaction, risk mitigation, time-to-market, and ROI over five years suggests that SAFe outperforms the other Agile methodologies on dimensions like risk mitigation and stakeholder satisfaction, whereas Scrum and Kanban show better team productivity and time-to-market as compared to the traditional project management, it is mentioned in Table I.

TABLE I. PERFORMANCE COMPARISON OF VARIOUS METHODS WITH PROPOSED METHOD

Criteria	Scrum [28]	Kanban [29]	SAFe [29]	Traditional PM
Team Productivity	85	80	90	70
Stakeholder Satisfaction	80	75	85	65
Risk Mitigation	85	80	90	60
Time-to-Market	90	85	88	70
ROI Increase (5 years)	70	60	75	50

A comparative analysis of the project management methodologies, including Scrum, Kanban, SAFe [30] (Scaled Agile Framework), and Traditional Project Management, reveals that the performance differs significantly in the main criteria. Scrum and SAFe had the highest productivity in teams with an 85% and 90%, respectively because of the structured iterative cycles and scalable frameworks. Kanban is at 80% because continuous workflow optimization is used. Traditional Project Management is at 70 percent due to its inflexible sequential way of working. Stakeholder satisfaction is the highest in SAFe, with 85 percent, as it can integrate multiple teams. Strong participation is observed in Scrum and Kanban, holding 80 percent and 75 percent stakes respectively. Traditional PM keeps the lowest satisfaction of 65 percent due to its inability to be flexible in planning. In risk mitigation, SAFe and Scrum outperform others with iterative risk assessment at 90% and 85%, respectively, while Traditional PM scores only 60% due to late-stage issue identification. Time-to-market is fastest in Scrum (90%), followed by Kanban (85%) and SAFe (88%), as their adaptive nature accelerates product releases, whereas Traditional PM is slower (70%) due to its phased execution model. Considering a long-term five-year ROI, SAFe ranks highest at 75%, Scrum follows with 70%, while Kanban shows 60%. The worst performance in the given five years has been registered by Traditional PM at 50%. It therefore signifies that this is not suited to fast-paced environments and could have been much less effective, and thus indicates why Agile outperforms it on all factors.

B. Discussion

Results suggest that Agile approaches are better compared to the conventional project management method in terms of productivity, satisfaction of stakeholders, risk reduction, time-to-market, and long-term ROI. SAFe proved to be most effective for the management of big projects; hence, the risk mitigation capability stands at 90%, followed by stakeholder satisfaction at 85%, and hence it is widely adopted in an enterprise level. In agile, the fastest speed of effectuality is

through its quick development cycles: 90% in terms of effectiveness regarding time to market, whereas in Kanban, it works fine for workflow optimization in the context of continuous improvement. The traditional approach to project management is structured but has lower productivity, 70%, and ROI, 50%, because it is not agile and does not allow the organization to adapt quickly enough to change; hence, organizations need to begin using iterative, flexible approaches. However, an appropriate Agile framework must be chosen depending upon the organizational structure, complexity of the project, and business objectives to maximize efficiency and value delivery. Performance evaluation is given in Fig. 10.

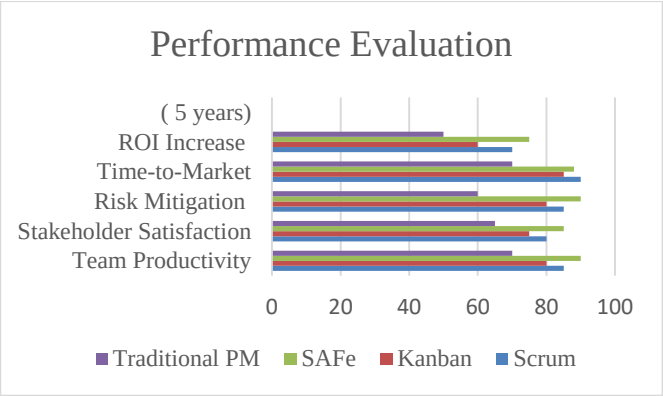

Fig. 10. Performance evaluation.

VI. Conclusion and Future Work

The study highlights how Agile methodologies improve the time-to-market, stakeholder satisfaction, reduce risks, and guarantee success as compared to traditional project management tools. Finally, results show that there are huge benefits realized from frameworks like SAFe, Scrum, and Kanban in speeding up time-to-market and improving team collaboration and then increment return on investment over time. Scrum provides super effectiveness towards rapid iterations whereas Kanban supplies a continuous optimization mechanism for workflows. However, its structured nature yet flexibility proves SAFe suitable for large scale enterprise models. Project management traditionally proved to not be able to adapt the changing nature of requirement for a specific project and thereby brings reduced efficiency and longer cycles of innovation. These insights call on organizations to take Agile methodologies up to their real business needs as a way to sustain growth and operational excellence. Future work might focus on strategies for the enhancement of Agile adoption by integrating technologies such as AI and automation towards further efficiency improvement in Agile methodologies.

Further insights into hybrid Agile models that combine the strengths of multiple frameworks may provide a basis for developing best-practice guidelines for optimizing Agile implementation across different types of industries. Comparative studies on Agile adoption in different cultural and organizational contexts would help align global enterprises with widely accepted best practices. It will be of high value to investigate how Agile affects the well-being of employees, the sustainability of long-term projects, and the retention of customers. Future research in these directions will further cement the development of Agile methodologies toward continued relevance in an ever-changing business environment.

AEDGAN: A Semi-Supervised Deep Learning Model for Zero-Day Malware Detection

Abdullah Marish Ali[1], Fuad A. Ghaleb[2]*, Faisal Saeed[3]
Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia[1]
College of Computing, Birmingham City University, Birmingham B4 7XG, UK[2, 3]

***Abstract*—Malware presents an increasing threat to cyberspace, drawing significant attention from researchers and industry professionals. Many solutions have been proposed for malware detection; however, zero-day malware detection remains challenging due to the evasive techniques used by malware authors and the limitations of existing solutions. Traditional supervised learning methods assume a fixed relationship between malware and their class labels over time, but this assumption does not hold in the ever-changing landscape of evasive malware and its variants. That is malware developers intentionally design malicious software to share features with benign programs, making zero-day malware. This study introduces the AEDGAN model, a zero-day malware detection framework based on a semi-supervised learning approach. The model leverages a generative adversarial network (GAN), an autoencoder, and a convolutional neural network (CNN) classifier to build an anomaly-based detection system. The GAN is used to learn representations of benign applications, while the auto-encoder extracts latent features that effectively characterize benign samples. The CNN classifier is trained on an integrated feature vector that combines the latent features from the autoencoder with hidden features extracted by the GAN's discriminator. Extensive experiments were conducted to evaluate the model's effectiveness. Results from two benchmark datasets show that the AEDGAN model outperforms existing solutions, achieving a 5% improvement in overall accuracy and an 11% reduction in false alarms compared to the best-performing related model.**

Keywords*—Malware detection; zero-day; anomaly detection; generative adversarial network; autoencoder; convolutional neural network

I. Introduction

This Malware, or malicious software, refers to any program specifically designed to damage, disrupt, or exploit digital systems. Common types include viruses, worms, Trojan horses, ransomware, spyware, rootkits, and bots. Over the past decade, malware threats have continuously evolved, posing a persistent and growing challenge [1]. Cybercriminals employ advanced techniques to disguise and distribute malicious code, often using obfuscation and evasion tactics to bypass security defenses, making detection and analysis increasingly difficult. Attacks targeting critical infrastructure, including power plants, financial institutions, and mobile networks, can have severe and widespread consequences. A notable example is the 2021 ransomware attack on a major U.S. pipeline, which led to a complete operational shutdown and substantial financial losses [2]. As Internet of Things (IoT) technologies continue to proliferate within critical infrastructure, it becomes increasingly likely that malware attacks will exploit heightened vulnerabilities. This susceptibility arises from the complexity of modern attacks and the digital environment, rather than a simple lack of security measures or computational resources [3].

Many detection approaches were proposed and can be categorized into signature, anomaly-based approaches [3-8]. Several previous malware detection systems have relied on the signature-based approach [4, 6, 9], which effectively identifies malicious patterns extracted from static or dynamic malware analysis. This method has proven particularly successful when combined with supervised machine learning (ML) techniques, enhancing its ability to detect known threats based on predefined signatures. These techniques learn to distinguish between benign and malicious samples, leading to significant improvements in detection accuracy [6, 10-14]. However, the signature-based approach has a significant disadvantage in that it only concentrates on well-known malware patterns, which severely restricts its use. In addition, supervised based solutions assume such patterns are static to both malware and benign software, limiting detection to known malware manifestations. As a result, it is inefficient in identifying zero-day vulnerabilities, which are previously unknown or extremely complex threats that deviate from existing signatures. Automated malware development toolkits provide techniques like packing, obfuscation, and polymorphism to conceal malicious code and mimic normal patterns, making it relatively easy to create new malware variants or modified versions that can evade machine learning-based detection. This underscores the importance of identifying previously unseen malware instances to effectively combat emerging novel threats.

Anomaly detection is a powerful method for identifying abnormal patterns or behaviors that deviate from expected norms. Many malware detection solutions have leveraged one-class classification, which focuses on modeling benign data to capture its essential characteristics. This approach enables the system to effectively distinguish malicious instances by detecting deviations from the learned benign profile [15-17]. Consequently, any sample not aligning with the acquired model representation is classified as a potential malware occurrence. However, this approach has two major drawbacks. First, it tends to generate a high false alarm rate because benign samples are often significantly outnumbered by malware samples during training. This imbalance creates biased learning, leading to an increased likelihood of misclassifications. Second, due to the use of evasive and obfuscation techniques by malware developers, the learned representation of benign samples often overlaps with malicious features. This overlap makes it

challenging to distinguish between benign and malicious instances, resulting in a high degree of uncertainty in classification decisions.

To address these challenges, this study aims to design and develop a zero-day malware detection model using a semi-supervised learning approach for anomaly detection. Semi-supervised learning effectively utilizes a limited amount of labeled data combined with a larger set of unlabeled malware samples. The benign samples were used to train an anomaly detection model. Anomaly detection works by identifying abnormal patterns that deviate from expected norms. In the context of malware detection, many traditional systems use a one-class classification approach, which models benign data to capture its essential characteristics and detects deviations from this benign profile as potential malware. This method enables the model to capture diverse and evolving malware patterns, enhancing its ability to generalize to unseen threats. Learning deviations from known behaviors improves the detection of novel attacks, enabling the proposed approach to identify threats that traditional methods may fail to recognize. However, this approach has two significant drawbacks. First, there is often a data imbalance between benign and malware samples, leading to a high false alarm rate due to biased learning. Second, malware frequently uses evasive techniques, causing overlap between benign and malicious features, making it difficult to distinguish between them and leading to misclassifications.

To overcome these limitations, the proposed model, named AEDGAN, combines generative adversarial network (GAN), autoencoder (AE), and convolutional neural network (CNN) architectures. To mitigate the data imbalance caused by the limited availability of benign samples, the GAN model generates more accurate representations of benign applications, thereby enhancing the ability to distinguish them from evolving malware. Meanwhile, the autoencoder is customized to extract latent features that best characterize benign samples. Finally, the CNN model is trained on a consolidated feature vector derived from both the latent attributes obtained from the autoencoder and the hidden features extracted by the discriminator within the GAN model. Extensive experiments were conducted to assess and validate the proposed model's performance. These experiments employed two datasets, encompassing evasive and novel malware attacks, for validation. The model's efficacy was evaluated by benchmarking it against state-of-the-art solutions. This study presents the following contributions:

1) Develop AEDGAN, an advanced architecture integrating Generative Adversarial Networks (GAN), deep autoencoding, and Convolutional Neural Networks (CNN) to create a zero-day malware detection model based on semi-supervised learning and anomaly detection.

2) Design and implement a GAN architecture, trained exclusively on benign instances, to generate realistic representations of normal samples. This approach is grounded in the hypothesis that benign software exhibits lower dynamism compared to malware, making it well-suited for GAN-based generation to enhance the modeling of normal behavior.

3) Construct an anomaly-based detection model, utilizing deep autoencoding to improve feature representation and detection accuracy. The auto-encoder leverages benign samples generated by the GAN to refine the distinction between normal and malicious behavior.

4) Develop a CNN model to reduce false positives produced by the autoencoder, specifically addressing the challenge of feature overlap between benign and malicious instances. The CNN is trained on a combined feature set, integrating latent features from the autoencoder and outputs from the GAN discriminator, to strengthen its ability to differentiate be-tween benign and malware samples.

The remainder of this paper is structured as follows: Section II reviews related work, while Section III elaborates on the proposed model. Section IV provides comprehensive details on the experimental design, encompassing dataset selection, performance metrics, validation, and evaluation procedures. Section V presents the results and Section VI includes the discussions of the results, as well as the limitations of the proposed solution, while Section VII offers concluding remarks.

II. Related Works

Please Zero-day malware refers to previously unknown or newly discovered malware that exploits vulnerabilities for which no patch or signature exists [18]. Detecting zero-day malware is a significant challenge for existing solutions [19]. Traditional signature-based detection methods rely on known patterns or signatures of malware, making them ineffective against zero-day malware [3, 18]. However, there are several approaches and techniques that have been proposed to address this issue.

One approach is the use of behavioural analysis, which focuses on the actions and behaviour of software to identify malicious activities [9, 11, 13, 20]. This technique can detect zero-day malware by analysing the behaviour of an application during its execution. By monitoring system calls and analysing their patterns, it is possible to identify suspicious or malicious behaviour [13]. However, this approach has limitations, as some malware can evade detection by modifying their behaviour or using obfuscation techniques [19]. Authors in study [4] proposed a CNN architecture for zero-day malware detection based on static analysis. CNN is employed to extract a small binary fragment from the text section of the Portable Executable (PE) malware file. However, the limitation of this model is that these small fragments may not be available due to the use of the obfuscation and evasion techniques by malware authors. Authors in study [5] presents the Cyber Resilience Recovery Model (CRRM), an epidemiological model designed to combat zero-day outbreaks in closed networks. Authors in study [7] pro-posed a zero-day malware detection model based on multiple views learning with convolutional method. Three sources of information were integrated to increase the chance of recognition of the malicious patterns with the hope of detecting zero-day malware. The main drawback of such an approach is the reliance of static analysis where it is complex to extract representative patterns due to the use of obfuscations and evasive techniques. Authors in study [8] proposes a novel method, the transferred deep-convolutional generative adversarial network (tDCGAN), to robustly detect malware,

including zero-day attacks, by generating fake malware and using deep autoencoders for feature extraction, achieving 95.74% average classification accuracy and demonstrating superior stability and resilience against zero-day attacks compared to other models. However, the reliance on generating fake malware data to train the model will not resolve the inherent issue of overlapping malware features with benign features, which arises from unrepresentative benign samples and the obfuscation and evasive techniques used by malware authors, potentially leading to lower generalization capabilities for unseen or novel attacks.

Many researchers used machine learning techniques, such as supervised machine learning and random forest algorithms [6, 10, 12, 14, 21-24]. These techniques can learn from existing information and detect new malware apps, including zero-day malware [25]. Machine learning models can be trained on known malware samples and then used to classify unknown samples based on their features. This approach has shown promising results in detecting zero-day malware that cannot be detected by conventional methods. Authors in study [6] proposes Malware-SMELL, a zero-shot learning method for classifying malware using visual representation and a new S-Space representation, achieving 80% recall and outperforming other methods by 9.58% in classifying malware with a model trained solely on goodware code. Authors in study [26] argued that the use of sandboxing techniques can help detect zero-day malware. Sandboxing involves running an application in a controlled environment to observe its behaviour and identify any malicious activities. According to authors in study [26] analysing the interactions between the application and the sandbox make it possible to detect zero-day malware based on its behaviour. However, detecting zero-day malware remains a challenge [19]. Zero-day malware often employs obfuscation techniques to evade detection, making it difficult for existing solutions to identify them. Furthermore, some techniques may have limitations in terms of accuracy or the ability to detect complex malware [27].

Anomaly detection approach also have been utilized for detecting zero-day mal-ware by characterizing typical patterns and identifying malicious actions based on their deviation from normal patterns [28]. These techniques aim to identify anomalies or deviations from expected behavior, which can indicate the presence of zero-day attacks or malware. By comparing the behavior of an application or system to a base-line or normal profile, any deviations or anomalies can be flagged as potentially malicious. Hybrid methods that combine both anomaly detection and anomaly identification techniques have been proposed for detecting zero-day attacks. These methods leverage the strengths of both approaches to improve the accuracy and effectiveness of detection. Anomaly detection techniques can identify deviations from normal behavior, while anomaly identification techniques can classify these deviations as malicious or benign.

Unsupervised anomaly detection algorithms have also shown potential in detecting zero-day attacks [29]. These algorithms do not require labeled training data and can automatically learn patterns and identify anomalies in data. By analyzing the be-haviour of applications or systems, unsupervised algorithms can detect deviations from normal behavior and flag them as potential zero-day attacks. However, it is important to note that the performance of unsupervised algorithms for zero-day detection can be influenced by the availability of quantitative analyses and me-ta-learning techniques. Authors in study [3] proposed autoencoder architecture based on neural network for anomaly detection. The model was trained based on the benign instances. The aim is to create a model with no idea of high to reconstruct the malware instances as the model originally trained based on benign instances. Although autoencoder method is promising for binary classification, selecting proper threshold is challenging.

Generative adversarial networks (GANs) have been widely used for anomaly detection in various domains, including time series data, image processing, and network analysis [30-32]. In the context of anomaly detection, GANs have shown promise in capturing the normal patterns of data and identifying deviations from these patterns as anomalies. GAN was used in two approaches: unsupervised and semi-supervised anomaly detection. In the unsupervised anomaly detection GAN is trained solely on normal data without any labeled anomalies while in semi-supervised the GAN is trained on both normal and anomalous where a small portion of anomalous labels are minority class. Kolosnjaji et al. [33] leveraged data extracted from malware samples, including header fields, instruction sequences, and raw bytes, to train models that discriminate between benign and malicious software. By using GANs, they aimed to enhance the detection of adversarial malware binaries that can evade traditional deep learning-based detection methods. Although, GANs offer a promising avenue for anomaly detection by capturing the underlying patterns and distributions of data, the effectiveness of GANs for anomaly detection can be influenced by factors such as the quality and representativeness of the training data, the architecture and hyperparameters of the GAN, and the choice of anomaly scoring or thresholding methods. In mal-ware detection domain, GAN has not been investigated much in the literature for detecting malware threats. Some works focused on generating adversarial mal-ware samples [34]. Accordingly, a model is trained to classify the benign samples including the synthesis generated benign samples from the malware samples. Authors in study [8] proposed a zero-day malware detection model by training a generative adversarial network with deep autoencoder (DAE) using transfer learning.

In conclusion, existing zero-day malware detection solutions employ various approaches including signature and anomaly analysis. Various techniques are used in the machine learning and sandboxing analysis. These approaches aim to identify malicious patterns either based on static features or based on behavior that can indicate the presence of novel malware pattern. The signature based static features were the most employed form of zero-day detection in malware domain. While these techniques have shown promise in detecting zero-day malware, this approach assume that the zero-day malware is a malware variant that have known characteristics with the previous one. Such assumption is not accurate because zero-day malware may show different treats and might not follow any known patters due to the use of obfuscation techniques by malware authors. Few researchers employ the concept of

anomaly detection to device zero-day malware detection model by identifying deviations from normal patterns or behavior. Unsupervised and semi-supervised learning was utilized to train the anomaly detection models. Research using autoencoders [3, 8], GAN [8, 18], and CCN [4, 24, 35] architectures showed promise in detecting zero-day attacks. However, the selection of proper threshold that can discriminate the malware from benign is challenging task due to the overlapping features between the benign and malware instances caused using the obfuscation and evasion techniques. Though further research is needed to enhance their performance through quantitative analyses and meta-learning techniques.

To this end, this study devised a zero-day malware detection (Fig. 1) model through de-signing an architecture that incorporate GAN, deep autoencoding, and CCN to improve the detection rate while reduce the false alarm rate. The GAN architecture was trained on normal instances, to generate realistic benign samples. Our hypothesis is that benign samples exhibit less dynamism compared to malware samples, making them suitable for GAN-based generation to represent normal instances effectively. The deep autoencoding is trained to model benign distribution for anomaly detection leveraging the benign samples generated by the GAN networks to enhance representation and improve detection performance. To reduce the false alarm rate resulted from con-figuration of the anomaly detection threshold. A CNN architecture aimed at mitigating false positives generated by the autoencoder, particularly addressing the issue of feature overlap between benign and malware representations was designed and developed. The latent features extracted by the autoencoders were fused with the GAN discriminator's output to train the CNN model for robust differentiation between benign and malware instances. The detailed description of the proposed model is presented in the following section.

III. The Proposed Model

The proposed model has been constructed through five main phases features ex-traction and pre-processing, data representation, GAN model, the autoencoder model, and the CNN classifier. In the first phase, the malware features are extracted and pre-processed for the training. In the second phase, the GAN model is constructed using semi-supervised approach. The GAN model consists of two adversarial modules, a generator and a discriminator. The Generator and Discriminator always competes against each other. The generator tries to generate a fake sample look like benign software while discriminator try to recognize real sample as real and generated sample as fake. Autoencoders consist of two integral components: the encoder and the decoder. The encoder is responsible for transforming input data, which can encompass various types such as images or text, into a condensed representation known as a bottleneck or latent code, characterized by lower dimensions. Subsequently, the decoder's role is to utilize this latent code to perform an optimal reconstruction of the initial input data. The fundamental goal of an autoencoder is to minimize the reconstruction error, quantified as the disparity between the input data and the reconstructed output.

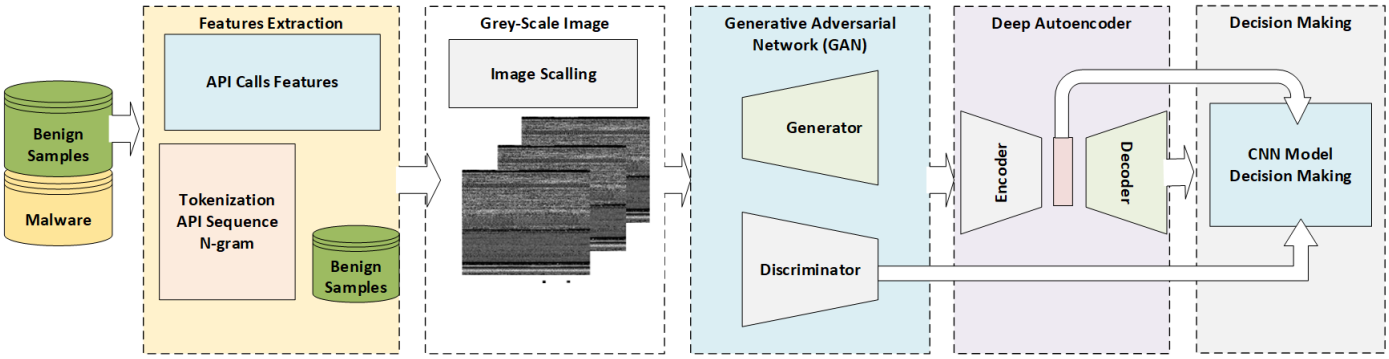

Fig. 1. The proposed zero-day malware detection model.

A. Features Extraction Phase

In this phase, malware features are extracted by monitoring and analyzing the interactions between an application (whether malicious or benign) and the operating system during runtime, specifically when API calls are made. Dynamic analysis is performed using the Cuckoo sandbox, which employs a technique called hooking to intercept and track API calls. Hooking works by injecting code into an application's execution flow, allowing the system to capture function calls to APIs. These intercepted calls are then logged into files, with each log file containing the recorded API calls of a specific application. For each application, the API calls are extracted from the log file and arranged sequentially based on their occurrence during execution. Each API function call is then treated as a distinct feature.

To enhance feature representation and capture behavioral patterns, n-gram analysis is applied to extract meaningful API call sequences. N-grams help identify important patterns in API sequences, making them a valuable technique for feature extraction. Numerous studies have validated the effectiveness of n-grams across various domains, including malware detection, where they improve classification accuracy by providing richer contextual information [36].

B. Data Representation Phase

In this study, each API calls and API sequence extracted using n-gram is used as a feature (term). Then the TF-IDF which is a well-established technique for feature ex-traction from text data, was used for representing the APIs features. TF-IDF considers both the frequency of terms (API calls in this case) within a sequence and their importance across multiple sequences [37]. It assigns higher weights to terms that are

frequent within a sequence but relatively rare across all sequences. This is useful in identifying unique or significant API call patterns associated with specific malware samples. TF-IDF helps in reducing the dimensionality of the feature space by focusing on the most relevant terms (API calls). This can make subsequent analysis and machine learning tasks more computationally efficient and interpretable. Rare or unique API calls that are common in malware but rare in legitimate applications can be weighted more heavily [10].

The TF/IDF vectors then are converted to image format. The process typically begins by reshaping the TF-IDF feature matrix into a grid-like structure, where each cell represents the TF-IDF score of a specific term (word) in a document. This grid, often referred to as a term-document matrix, forms the basis of the 2D image representation. To generate the image, TF-IDF scores are mapped to pixel intensities, converting the continuous values into values. Once the TF-IDF values are transformed into pixel values, the image is ready for the classification. According to study [10], the Inverse Document Frequency (IDF), which measures the global importance of an API across the entire corpus, can be calculated as follows:

$$idf_i = log\left(\frac{number\ of\ Applications}{(number\ of\ Applications\ call\ the\ API\ i+1)}\right) \quad (1)$$

where the idf_i is the inverse document frequency. TF-IDF is calculated by multiplying the TF (term frequency) and IDF (inverse document frequency) values for each term in each document. This results in a TF-IDF score for each API or API sequence in each document. It quantifies how unique or common a term is in the corpus. Next, for each feature in the corpus, the term frequency-inverse term frequency (tf_idf) is calculated as follows.

$$t\_idf_i = tf_i * idf_i \quad (2)$$

The t_idf_i score for a term in a document is higher if the term appears frequently in that document but is relatively rare across the entire corpus. The t_idf_i features are scaled using min-max normalization as follows.

$$scalled_{tf_{idf_{features}}} = \frac{tf\_idf\_features - min(tf\_idf\_features)}{max(tf\_idf\_features) - min(tf\_idf\_features} \quad (3)$$

Finally, the features vector is created from the unique terms of the corpus. The maximum length of the feature vector is n features. These features vector was converted to $w \times h$ image size as follows.

$$image\_width\ w = floor(\sqrt{n})\ ) \quad (4)$$

$$image\_hight\ h = floor\left(\left(\frac{(n-1)}{w}\right) + 1\right) \quad (5)$$

Where w and h are the width and height of the represented images and n is the max length of the features vector.

C. GAN Model Construction Phase

In this phase, the Generative Adversarial Network (GAN) model is constructed. GANs are a type of deep learning model that consists of a generator and a discriminator. The generator aims to generate synthetic data that resembles the real data, while the discriminator tries to distinguish between real and synthetic data. When the discriminator is no longer able to distinguish between real data and synthetic data, then the model is converging and can be used in the production. In this study the GAN is trained on the benign data samples. By training the GAN on a dataset of normal data (benign samples), it learns to capture the underlying distribution of the normal data [38]. GANs have emerged as a promising approach in the anomaly detection [38, 39]. The aim is to measure the anomaly score of given samples based on its deviation from the learned distribution of normal samples. This is done by comparing the reconstruction error of a given sample with the reconstruction error of the benign samples. This approach is promising and have been widely adopted by many researchers in the anomaly detection field [38, 39, 40].

The Generator was trained based on the benign samples as represented by images in the previous phase. The generator network learns to generate synthetic images that resemble the benign images, while the discriminator network learns to distinguish between real and synthetic images. Once the GAN is trained, the constructed GAMN uses an iterative process to find the latent vector in the generator network that best re-constructs a given test image. This is done by optimizing the latent vector to minimize the difference between the reconstructed image and the original test image. The anomaly score is then calculated based on the reconstruction loss and the loss between the intermediate discriminator feature of the test image and the reconstructed image. The generator is trained to reconstruct the samples represented by 1D vector extracted randomly from latent space and map them to 2D images in the image space created from the applications samples. The generator network is architected using stack of convolutional decoder equivalent to a convolutional decoder. The Discriminator D is constructed using standard CNN layers that maps 2D images to a single scalar represent the anomaly score of the sample. Fig. 2 shows the architecture of the proposed GAN network.

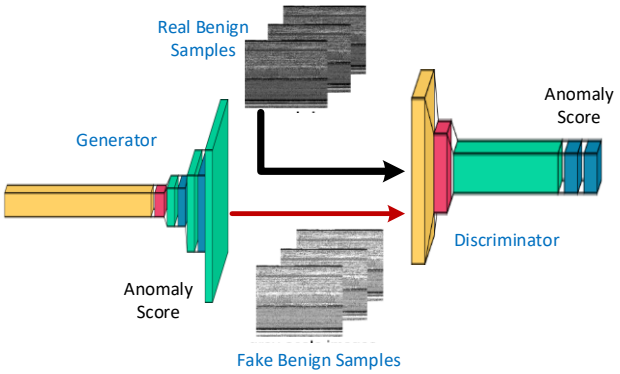

Fig. 2. The proposed semi-supervised GAN network.

The generator network of the GAN is trained to produce synthetic samples that look similar to the fraud samples, while the discriminator network is trained to distinguish between the original and the synthetic samples. For the learning, let G and D denote the generator and the discriminator, respectively, and let $Z = \{z1, z2, .. zn\}$ and $X = \{x1, x2, \dots, xn\}$ denote the distribution of latent and problem space, respectively. G and D

G(z) are the output of the generator (the fake sample) and $D(G(z))$ is the output of the discriminator, which is the probability of getting $G(z)$ belonging to real data. The error $e = log(1 - D(G(z))$ should be minimized to generate a fake sample that is drawn from the distribution of the real data. The error e is also used to penalize the generator G and thus to minimize $\log(D(x))$. Thus, based on [38], the following min-max game must be played by G and D to minimize the generator error and maximize the divergence.

$$\underbrace{min}_{G}\ \underbrace{max}_{D} V(G,D) = E_x\big(log\big(D(x)\big)\big) + E_z(log(1 - D(G(z)))) \quad (6)$$

The training of the GAN model continues until the generator can fool the discriminator into believing that the generated samples are real, namely when adversarial loss converges, indicating that the generator is producing realistic fraudulent samples.

D. Deep Autoencoder Construction Phase

It is widely believed by researchers that the performance of the anomaly detection using one class learning fall behind the supervised learning approach. This is because the classification approach does not relay much on selecting the classification thresholds as the model learn automatically the best discrimination threshold [3, 8]. The ability of neural network in performing abstractions is attractive. Considering this, it is reasonable to assume that autoencoders, a type of neural network specializing in encoding input data, would yield a latent representation that faithfully represents the specific attributes of input data samples. As a result, our strategy in this work relies on autoencoding to gain the benefits of strong abstraction and one class model to make judgments automatically and without the need for thresholds. In this study the auto-encoder based model was trained based on the benign samples. As shown in Fig. 3, the data with latent distribution was used to construct one class model for anomaly detection. The autoencoder learns how to minimize the reconstruction errors.

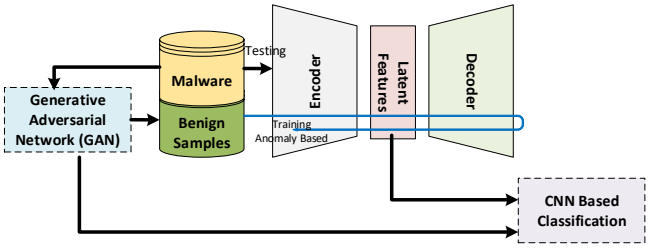

Fig. 3. The training and testing bath of the Autoencoder Anomaly based model.

E. CNN Classification Phase

In this stage, the latent features extracted from the autoencoder was used to develop a CNN classifier that can effectively distinguished between benign and malware samples. Fig. 4 shows the proposed CNN model for Decision Making about the anomaly status of the sample normal for benign samples and anomaly for malware samples.

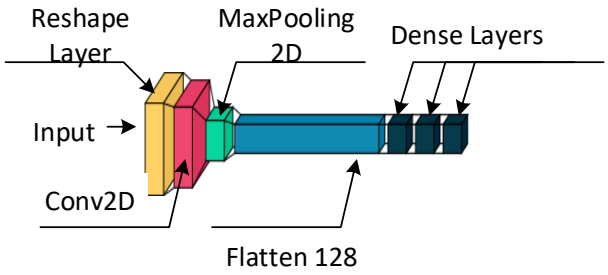

Fig. 4. The proposed CNN model for decision making.

The CNN Model consists of eight layers. The CNN model in this stage is designed for binary classification, where the sigmoid activation function is suitable for producing binary output probabilities (0 or 1) zero for normal and one for anomalies. The first layer defines the input shape, indicating that the model expects input data with a dimension of 256. The input layers are taken form the last hidden layer (the flatten layer) of the discriminator and concatenated with the latent layer form the discriminator to form the 256 input dimension. The second layer is used to transform the input data into a 16x16 grid with a single channel (grayscale image). The third layer is a 2D convolutional layer with 32 filters and a 3x3 kernel size. It uses the ReLU (Rectified Linear Unit) activation function, which introduces non-linearity into the model. The fourth layer performs max-pooling with a 2x2 pool size. Max-pooling reduces the spatial dimensions of the feature maps, helping to capture essential information while reducing computational complexity. The fifth layer is the flatten layer which reshapes the output from the previous layer into a one-dimensional vector. This prepares the data for fully connected layers. The sixth layer is a fully connected dense layer with 128 units and ReLU activation. The seventh layer is fully connected dense layer with 64 units and ReLU activation. The output layer with a single neuron and sigmoid activation.

IV. Experimental Design and Performance Evaluation

The dataset, the experimental procedures, and the performance evaluation are described in the following sub-sections.

A. Datasets

In this study, two datasets were used to validate and evaluate the proposed model. The first dataset, which is referred to Dataset I, is the API call sequences have been extracted form dynamic analysis environment. The malware samples were originally collected by [41, 42]. The extracted API call sequence represents behaviours of 7208 evasive malware sample. The benign samples, namely 3,848 benign, were collected from a newly installed copy of Windows 7 and from [43]. Fig. 5(a) illustrates the distribution of samples in Datasets I. The dataset was split into two parts 70% for training and 30% for testing. The 30% of the real benign samples represents the unseen benign samples while the whole malware samples were hidden during the training of the anomaly-based models in this study. As shown in Table I the model is trained based on the real and synthesized benign samples. For CNN model 70% of the malware samples were used in the training and 30% for the testing.

The second dataset referred as Dataset II which is publicly available online and can be downloaded from IEEEDataPort Web portal [44]. The dataset contains 10,654 samples 3,097 are benign samples while 7557 are malware samples. The malware samples distributed as follows, 451 ransomware, 1,051miner, 797 DDoS Trojan, 89 worm, 3353 infective virus, 454 backdoor, and 1362 trojan (see Fig. 5(b)). Table I presents the distribution of samples in Datasets I and II for training and testing, including both real and generated benign and malware samples. To enrich the datasets, the GAN model was used to generate diverse sets of benign samples, enhancing the training process and improving model performance. Accordingly, 2469 benign samples were used for the training of the GAN network and 14814 benign samples used for the training of the deep autoencoding model.

B. Performance Measures

To evaluate the detection performance of the proposed model, we utilized five key performance metrics, namely overall accuracy, detection rate (recall), precision, F1 score, false-positive rate (FPR), and false-negative rate (FNR). These metrics are widely acknowledged and commonly employed in the assessment of malware detection solutions within the existing body of literature. The performance metrics utilized in this study were computed using the following formulas.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (7)$$

$$FPR = \frac{FP}{TP+FN} \quad (8)$$

$$FNR = \frac{FN}{TN+FP} \quad (9)$$

$$DR\ (Recall) = \frac{TP}{TP+FN} \quad (10)$$

$$Precision = \frac{TP}{TP+FP} \quad (11)$$

$$\text{F1 Score} = \frac{2\times Precision \times Recall}{Precision+Recall} \quad (12)$$

The F1 score measures the balance between accuracy and recall to assess the model's overall performance. True positives (TP), true negatives (TN), false positives (FP), and false negatives (FN) are all equally considered by MCC. As a result, it provides additional information about the model's performance. Table 1 lists the samples used for Fig. 5.

TABLE I. DATASETS I AND II SAMPLES DISTRIBUTION

	Dataset I			Dataset II		
	Training		Testing	Training		Testing
	Real	Generated		Real	Generated	
Benign	4694	9388	1154	2469	12345	1503
Malware	5045 (for CNN only)	-	2162	6054 (for CNN only)	-	628
Total	19127		3316	20868		2131

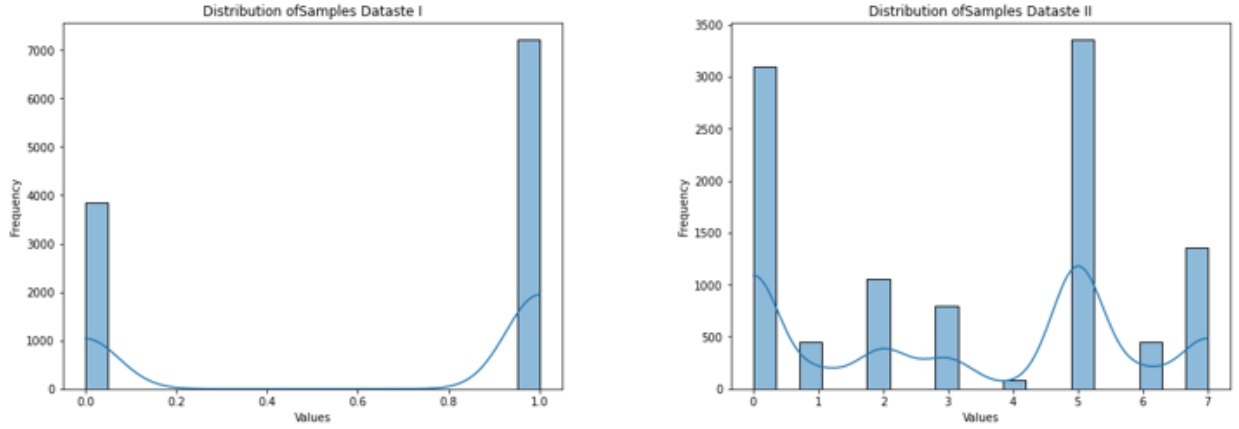

Fig. 5. (a) Dataset I samples distribution (b) Dataset II samples distribution.

C. Evaluation Procedure

In this study, extensive experiments were conducted to evaluate the proposed model. Because CNN was reported by many researchers to have promising classification performance, two different anomaly models were trained for the comparison. The benign samples were used to train the CNN model. The input is the features vector represented as image based on n-gram and TF/IDF features extraction and presentation schemes. The output of these models are the anomaly scores of the samples. The autoencoder model which can be considered a type of semi supervised learning to con-struct anomaly detection model was implemented in this study for the evaluation. The autoencoder model is trained based on the benign samples. The aim is to minimize the reconstruction error of the benign samples. However, in case of the malware which is considered zero-day attack for the anomaly-based model the

construction error likely to be greater than the errors generated by reconstructing the benign samples because the model has not been learnt to represent the malware instances [3]. Although autoencoder is promising for the anomaly detection, selecting proper threshold is challenging task. Therefore, in this study, the autoencoder model was implemented according to the model presented in study [3]. The autoencoder was also cascaded with the CNN model for the comparison. Both one- and two-dimensions image representation were used in the experiments. The autoencoder model firstly trained using the normal samples and then the latent space features were used to train the CNN classifier. Generative Adversarial Network (GAN) based model with autoencoder were also implemented for the comparison. GAN models were widely used for anomaly detection in literature due to their ability of generating samples similar the minority class instances and their ability to model high dimensional data distribution [32]. The GAN model is trained to regenerate the normal samples and the autoencoder was trained based on the data generated by the GAN model. In doing so, a variety of noise that resample the normal data is included in the representation.

V. RESULTS

Table II and Fig. 6 (a)-(f) present a comparison of the performance of the pro-posed model with other models using dataset I. The proposed AEDGAN outperforms all other models, achieving a remarkable 95% accuracy and precision, a 93% detection rate (recall), and an impressive 94% overall accuracy. The false positive rate is only 5%, with a corresponding 5% reduction in the false negative rate. Notably, the CNN models with 2D representation exhibit superior performance compared to the other models studied. It is worth noting that the CNN model without the autoencoder out-performs the CNN model with autoencoder, primarily because the CNN model's supervised learning approach enables effective discrimination between benign and malware samples.

Table III and Fig. 7 (a)-(f) present the classification performance of the proposed model compared to the other models using Dataset II. The proposed model AEDGAN achieved the highest performance, attaining an 88% overall accuracy in terms of F1 Score, while all the other models scored lower than 84% overall performance. Notably, the proposed AEDGAN significantly reduces the false positive rate to 10%, compared to 26%, 21%, 23%, and 35% for AEGAN, AECNN(2D), AECNN(1D), and AE models, respectively.

TABLE II. PERFORMANCE COMPARISON BASED ON DATASET I

	Accuracy	Precision	Recall	F1 Score	FNR	FPR
CNN(1D)	0.90	0.94	0.82	0.88	0.12	0.06
CNN(2D)	0.92	0.95	0.86	0.90	0.09	0.05
AE	0.84	0.79	0.83	0.81	0.13	0.21
AECNN(1D)	0.90	0.87	0.91	0.89	0.07	0.13
AECNN(2D)	0.91	0.88	0.92	0.90	0.06	0.12
AEGAN	0.87	0.85	0.84	0.85	0.11	0.15
AEDGAN	0.95	0.95	0.93	0.94	0.05	0.05

TABLE III. PERFORMANCE COMPARISON BASED ON DATASET II

	Accuracy	Precision	Recall	F1 Score	FNR	FPR
CNN(1D)	0.89	0.89	0.70	0.78	0.12	0.11
CNN(2D)	0.90	0.90	0.76	0.82	0.09	0.10
AE	0.80	0.65	0.71	0.68	0.13	0.35
AECNN(1D)	0.88	0.77	0.83	0.80	0.07	0.23
AECNN(2D)	0.89	0.79	0.86	0.83	0.06	0.21

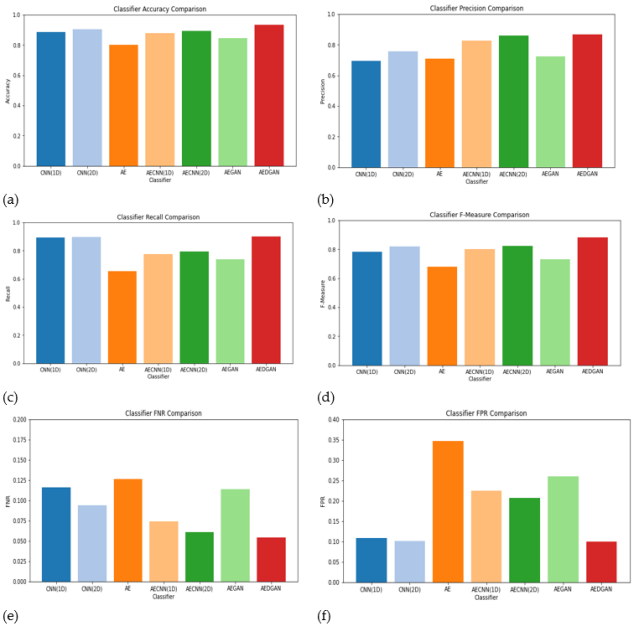

Fig. 7. Comparison of the detection performance (Dataset II) in terms of (a) Accuracy, (b) Precision, (c) Recall, (d) F-measure, (e) False negative rate, and (f) False positive rate.

VI. DISCUSSION

The results indicate that the autoencoder exhibited the poorest performance compared to the other models under study. This can be attributed to the possibility that the features learned by the autoencoder may not adequately represent benign samples, resulting in low detection accuracy, as indicated by the precision score for the AE model in Table 2. Furthermore, the output of the autoencoder requires additional analysis, and the detection relies on identifying an appropriate threshold for the constructed error. In contrast, the CNN models outperform the autoencoder model due to their capability to learn high-level features that effectively discriminate benign samples from malware samples.

In terms of the false alarm rate, the proposed model outperforms the others, achieving a low 5% rate for both false positives and false negatives. In contrast, the AE and AECNN models fail to strike a balance between false positives and false negatives, with high false positive rates due to the challenge of determining an appropriate threshold for distinguishing between benign and malware instances. The overlapping features of malware and benign samples, caused by the obfuscation nature of malware, hinder effective discrimination. Even with adversarial networks enhancing the representation of benign instances, the AEGAN still exhibits high false positives. Notably, the proposed AEDGAN substantially reduces the false positive rate to 5%, compared to 15%, 12%, 13%, and 21% for AEGAN, AECNN (2D), AECNN(1D), and AE models, respectively.

It can be observed from both Table II and Table III that the proposed model outperforms all other models studied for both datasets. However, the model's performance with Dataset II is inferior to its performance with Dataset I. The reason behind this discrepancy is that in Dataset I, the benign samples were extracted from the Windows 7 operating system, which exhibited distinguishable traits compared to the malware samples. On the other hand, the benign samples in Dataset II were derived from applications developed by a more diverse range of developers. Applications developed by Microsoft or integrated into the Windows OS by Microsoft may possess distinct API call sequences, especially in areas such as authentication and error handling, when compared to those developed by other software development firms.

Despite its promise, the proposed model has several limitations. One major challenge is the higher false positive rate (10%, as shown in Table II). This is because the second dataset contains a diverse set of malware samples from different families, leading to greater feature variability and overlap between benign and malicious applications. Such diversity makes it more difficult for the model to accurately distinguish between benign and malware instances, increasing the likelihood of false positives. Additionally, the model exhibits a lower detection rate for certain types of malwares, particularly those that employ obfuscation or evasive techniques, resulting in significant feature overlap with benign applications. This overlap makes it difficult for the model to reliably distinguish between malicious and non-malicious behavior. Moreover, while GAN-based data augmentation enhances generalization, the generated synthetic data may not fully capture the complexity of real-world benign applications, potentially introducing biases. The computational complexity of training GANs, autoencoders, and CNNs together also poses a challenge, making real-time malware detection in resource-constrained environments difficult. Furthermore, the model's effectiveness in practical, real-world scenarios remains uncertain, as it has not been extensively tested against evolving malware threats outside controlled environments. To address these issues, incorporating ensemble methods, leveraging diverse feature sets, and conducting real-world evaluations could further enhance the model's accuracy and robustness. Another key limitation is the dataset itself. The datasets used in this study may be quite obsolete (Windows 7), and based on our best knowledge, there is a lack of newly available datasets for malware detection. This limitation may affect the generalizability of our findings to more recent threats. In the future, we plan to collect datasets from newer versions of Windows to enhance the relevance and effectiveness of our detection methods.

VII. CONCLUSION

In this study, an anomaly-based zero-day anomaly-based malware detection model utilizing semi-supervised deep learning has been designed and developed. The model's development comprises three main phases: In the initial phase, we trained a Generative Adversarial Network (GAN) to acquire representations of benign applications, enabling the detection of malware and malicious applications. Given the relative stability of benign application behavior compared to malicious behavior, GAN-based data augmentation contributes to the generality and stability of the detection model. Furthermore, GAN is leveraged to generate a diverse set of synthetic data closely resembling real-world benign samples, thereby enhancing the model's capability to distinguish malware instances in subsequent learning stages. The second phase involved the development of an autoencoder, aimed at learning latent representations of benign samples and capturing essential features that characterize benign applications. In the third and final phase, we concatenated the latent representation with the last hidden layer of the GAN discriminator, representing them as an image. Subsequently, a Convolutional Neural Network (CNN) classifier was constructed to classify samples as either benign or malicious. This CNN model obviates the need for threshold selection to identify anomalous instances. The results indicate that the proposed model holds promise for detecting zero-day malware. In the worst-case scenario, it achieved an overall performance of 88% accuracy with a 10% false positive rate, surpassing the best existing solution by 5% in overall performance and reducing the false positive rate by 11%.

Despite its promise, the proposed model exhibits a lower detection rate and a higher false positive rate. The primary challenge lies in the inherent overlap between benign and malware features. The obfuscation and evasive characteristics of malware often lead to feature overlap between these classes. To address this challenge, we advocate for the use of a diverse set of features in the representation. Furthermore, we propose an ensemble approach involving anomaly detection models trained on diverse feature sets, incorporating both GAN and Autoencoder models, to enhance detection accuracy and mitigate false alarms.

Development and Evaluation of Accounting Information System and Shopee Open Application Programming Interface for a Small Business, Thailand

Kewalin Angkananon, Piyabud Ploadaksorn*
Business Information System Department-Management Sciences Faculty,
Suratthani Rajabhat University, Surat Thani, Thailand

***Abstract*—This research aimed to develop and evaluate an integrated Accounting Information System (AIS) with Shopee Open API for the Ban Huai Luek Agricultural Community Enterprise in Thailand, designed to enhance financial data management efficiency and optimize online marketing operations. The research employed a mixed-method approach, combining qualitative interviews with 30 stakeholders in three groups and quantitative assessments of system effectiveness with 388 consumers and 30 farmers. Interview findings revealed diverse stakeholder needs: Enterprise members prioritized financial management and operational costs, farmers emphasized security and technology access, while customers focused on e-commerce capabilities and market positioning. The developed AIS features 41 database tables and nine core functions, incorporating Shopee's e-commerce platform through Application Programming Interface (API) integration, enabling automated product listing, inventory management, and financial calculations. System evaluation demonstrated high user satisfaction across all groups. Consumer analysis showed an overall strong approval, with security and perceived benefits ranking highest, while performance efficiency scored lowest. Farmer assessments indicated high satisfaction, with ease of use and system accuracy rated highest, though security concerns emerged during initial technology adoption. Demographic factors, particularly age and income, significantly influenced user perceptions.**

Keywords*—*Accounting information system; e-commerce integration; agricultural community enterprise; shopee open API

I. Introduction

The digital transformation of agricultural community enterprises presents both opportunities and challenges in the contemporary business landscape. While e-commerce platforms and AIS have become instrumental in enhancing business competitiveness, many rural enterprises struggle with their implementation and integration [47]. Furthermore, the absence of systematic accounting practices presents substantial challenges in financial management and decision-making processes especially in Thailand [10]. Recent technological advances suggest integrating e-commerce platforms with accounting information systems could provide a comprehensive solution to these challenges. Contemporary research advocates for user-centric design approaches that incorporate integrated payment systems and address specific consumer needs [8]. The evolution of integration approaches, from basic API implementations to sophisticated platform-specific solutions, offers promising frameworks for development [13-15], [42]. Current research indicates that limited digital channel utilization and inadequate accounting systems significantly impact the operational efficiency and market reach of community enterprises [7]. The predominant reliance on personal social media platforms, such as Facebook and LINE applications, for product distribution reveals a critical gap in professional e-commerce implementation. Building on this foundation, this study addresses the critical gap between technological capability and practical implementation in rural agricultural settings.

Ban Huai Luek Agricultural Community Enterprise is a community-based organization focused on upland rice cultivation. In southern Thailand, particularly in Khian Sa District, Surat Thani Province, Thailand, farmers have innovatively integrated rice cultivation within rubber plantations. This agricultural practice is predominantly implemented in young rubber plantations, where trees are between 3-5 years old, as mature rubber trees create excessive shade unsuitable for rice growth [12]. The researcher empirical investigation reveals significant operational constraints within the enterprise, particularly in accounting practices and financial management. The enterprise's dependence on external governmental support for basic accounting functions, combined with limited transaction documentation and absence of formal financial statements, highlights the urgent need for systematic intervention. This situation is further complicated by inadequate cost calculation mechanisms throughout the supply chain, leading to unclear profit margins and missed opportunities for value-added product development. Therefore, this study examines the case of Ban Huai Luek Agricultural Community Enterprise, which exemplifies the challenges faced by traditional agricultural communities in adopting digital technologies. The theoretical framework for this study draws upon established models in technology adoption and consumer behavior. The Technology Acceptance Model (TAM) provides insights into user adoption patterns, while Online Consumer Behavior Theory emphasizes crucial roles of trust, security, and user experience in digital commerce [18]. These theoretical foundations are complemented by User Experience Design Principles [36] and Responsive Design concepts [24], ensuring comprehensive coverage of technical and user-centric aspects.

This research aimed to address these challenges through the development and implementation of an integrated AIS and Shopee Open API for the Ban Huai Luek Agricultural Community Enterprise, with particular emphasis on evaluating system usability from the user perspective. The study contributes to the existing literature by 1) Developing an integrated AIS and Shopee Open API for the Enterprise and 2) Evaluating the effectiveness of the AIS. This investigation not only addresses immediate practical challenges but also contributes to the broader understanding of digital transformation in rural enterprises in Thailand, potentially informing future policy and development initiatives in similar contexts.

This research makes a unique contribution to the field by developing and evaluating an integrated AIS with Shopee Open API specifically tailored for agricultural community enterprises in Thailand. Unlike previous studies that have focused on either general e-commerce development or basic accounting systems, our research bridges these domains through a platform-specific integration approach that addresses the challenges faced by rural agricultural businesses. This integrated approach not only solves immediate practical problems but also contributes to the broader understanding of technology adoption in rural enterprises, potentially informing future policy and development initiatives in similar contexts.

The content is structured into five main sections: Section I is Introduction, Section II is Literature review and relevant theoretical frameworks, Section III is Research methodology and data collection approaches, Section IV is System development results and efficiency evaluation, and Section V is Discussion and recommendations. Finally, the paper is concluded in Section VI. This research aims to demonstrate the value of digital technology integration in agricultural community enterprises and offers pathways for enhancing entrepreneurial capabilities in rural areas of Thailand.

II. Literature Review

AIS serve as essential tools for transforming financial data into decision-making information through transaction processing modules [3], [32]. While high-quality accounting information is crucial for organizational performance [25], [29], research on AIS development methodologies remains limited. Ibrahim and Hassan [49] proposed a framework for implementing cloud-based accounting solutions for small agricultural enterprises, highlighting benefits in terms of cost-effectiveness and accessibility to modern technology. Various development approaches exist, including RAD, Waterfall, and Oracle [27], [38], with contemporary systems leveraging web services, mobile devices, cloud computing, and business intelligence capabilities [19], [46], [58], [61]. Darma and Wijaya [50] introduced innovative concepts for implementing blockchain technology in accounting information systems for agricultural supply chains, which enhances transparency and reliability of financial data. Concurrently, Patel and Sharma [51] presented a model integrating IoT technology with accounting information systems in smart farming contexts, enabling more precise and automated monitoring of production costs and efficiency.

E-commerce facilitates online business transactions through computer networks [1], [28], offering advantages in global market access, 24/7 operational capability, and cost-effectiveness through reduced overhead expenses [20]. E-commerce system development encompasses both front-end user interface design and back-end server functionality [20], with website design being crucial for consumer satisfaction and platform success [1], [48].

Chen et al. [52] examined factors influencing consumer trust in online agricultural marketplaces across Southeast Asian countries, finding that data security and product information transparency are critical factors in establishing confidence. This aligns with Wijaya and Rahmawati's [53] research, which demonstrated that digital marketing strategies significantly impact consumers' purchasing decisions for agricultural products, particularly through comprehensive information presentation and enhanced user experience.

The TAM, developed by study [11], predicts technology adoption through two variables: Perceived Usefulness (PU) and Perceived Ease of Use (PEOU). PU represents beliefs about performance enhancement, while PEOU reflects expected ease of system use. These factors influence user attitudes and system adoption behavior.

The UTAUT, developed by study [45], integrates eight theoretical models to explain technology acceptance and usage behavior. UTAUT comprises four core determinants: Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions, moderated by gender, age, experience, and voluntariness of use. In this research, UTAUT framework was applied to analyze how personal factors influence users' perceptions of website performance.

Table I shows a comparative analysis of existing integrated accounting and e-commerce systems with our proposed Ban Huai Luek AIS. As illustrated in the table, there is a clear progression from general API-based approaches [13-15], [42] to more specialized, platform-specific solutions. Each system contributes unique elements to the evolution of e-commerce and accounting integration. Previous implementations have focused primarily on general business contexts, with varying degrees of technical specificity and integration capabilities. For example, while some systems emphasize security features or sales management, others prioritize API generation or development efficiency. Our Ban Huai Luek AIS represents a more specialized implementation through focused Shopee platform integration specifically designed for agricultural community enterprises, addressing their unique operational requirements and technological constraints. The comprehensive nature of our implementation, utilizing 13 distinct development tools and multiple output formats, differentiates it from previous work that typically employed more limited technological approaches. This comparison highlights the unique contribution of our research in developing a tailored solution for agricultural community enterprises while building upon the strengths of existing systems.

TABLE I. DEVELOPMENT OF INTEGRATED ACCOUNTING INFORMATION SYSTEM AND E-COMMERCE

Aspect	Detail	[2]	[6]	[44]	Ban Huai Luek AIS
Production and Marketing Management	Key management components in Production management, Market management, Financial and accounting management			✓	
Online Marketing and Digital Presence	Focused on online business development for Website development, Search optimization, Facebook marketing, Content marketing through advertising articles, Influencer engagement				✓
Financial Management and Accounting Systems	Emphasize the importance of proper financial management: Both short-term and long-term financial planning; Systematic fund allocation and monitoring; Implementation of formal accounting systems			✓	
	Emphasize the importance of proper financial management: Accurate and systematic accounting practices enable better business planning; Improved accounting systems contribute to overall business operations	✓			
Business Development and Capacity Building	Improvements in community enterprises: Expanded distribution channels; Enhanced business knowledge among members; Improved online marketing capabilities; Development of systematic accounting practices	✓			
Digital Transformation	Emphasize the importance of digital tools, whether through comprehensive management systems or online marketing platforms		✓		
Systematic Management	Structured management approaches, particularly in financial and accounting systems, are crucial for success	✓		✓	
Capacity Development	Highlight the importance of building member capabilities, especially in business operations and digital skills	✓			✓
Multi-channel Marketing	A trend toward integrating traditional and online marketing channels	✓			✓

TABLE II. COMPARISON BETWEEN EXISTING STUDIES WITH OUR WORK

Aspect	[13]	[14]	[15]	[42]	Ban Huai Luek AIS
Primary Focus	API integration for accounting systems	Website-based sales accounting	API generation from open data	RESTful API for integrated accounting	E-commerce integrated accounting using API for integrated accounting from Shopee open data
Frame- work	Not specified	Laravel	Model-based approach	RESTful architecture	Laravel
Database	Not specified	MySQL	Open data sources	Not specified	MySQL
Impleme-ntation	Theoretical framework	Practical implement-ation	Automated generation	Agile development (3 sprints)	Practical implementation
Special Features	Security focus	Sales and inventory manageme-nt	Automated API generation	Development efficiency	Shopee integration
Development Tools	Not specified	Laravel, MySQL	Model-based tools	Not specified	Comprehensi-ve toolset (13 tools)
Integration Type	General API	Web-based system	Open data APIs	RESTful API	Shopee Open Platform
Target Users	General business	Trading companies	Developers	Companies	Agricultural community
Testing Methods	Not discussed	Not specified	Not specified	Black box testing	Postman, XAMPP, Black box testing
Output Formats	Not specified	Not specified	API endpoints	Not specified	Multiple (PDF, Excel, QR)

Table II shows a clear progression from general API-based approaches [2], [6], [44] to more specialized, platform-specific solutions. Each system contributes unique elements to the evolution of e-commerce and accounting integration, with AIS representing the most specialized implementation through focused integration with the Shopee platform [59-60].

Kumar and Singh [54] proposed a microservices and API Gateway integration framework for e-commerce platforms, enabling systems to achieve flexibility and scalability according to business requirements. Concurrently, Zhang et al. [55] developed API-based integration strategies for cross-platform e-commerce solutions, which reduce complexity in managing data across diverse sales channels. Supaporn and Chaisiri [56] investigated digital transformation of community enterprises in Northern Thailand, identifying critical success factors including member digital skill development, government agency support, and user-centered system design. These findings align with Thongpoon and Rakthai's [57] research, which revealed that organic agricultural product purchasing behavior through e-commerce platforms in Thailand depends on platform credibility, ease of use, and payment channel diversity.

III. METHODOLOGY

A Mixed method between quantitative and qualitative research was used as follows.

A. Research Participants

The study population comprised three groups: 12 enterprise members, 40 upland rice farmers in Khian Sa District, and upland rice consumers. For Objective 1, convenience sampling selected 30 participants (ten from each group: community enterprise members, upland rice farmers, and previous upland rice consumers) for interviews. For Objective 2, the sample consisted of 1) Ten community enterprise members and 2) 30 upland rice farmers, selected through purposive sampling (minimum one year of farming experience), following [39]

criteria. 3) 388 consumers with prior upland rice or health food purchasing history. The consumer sample size was determined using [39] recommendation of 384 participants for unknown population sizes. To account for potential non-responses, 400 questionnaires were distributed, yielding 388 completed returns.

B. Research Tool

The research employed two primary instruments: interview guides and system efficiency evaluation tools. The interview questions, focusing on Ban Huai Luek AIS development requirements, were validated by three accounting information technology experts, achieving an Index of Item-Objective Congruence (IOC) of 0.81. System efficiency evaluation utilized two quantitative instruments: a 29-item system usability assessment for upland rice farmers (Cronbach's alpha = 0.712) and a 27-item e-commerce efficiency evaluation for consumers (Cronbach's alpha = 0.9881). Both instruments demonstrated reliability above the 0.7 threshold established by [37], indicating strong internal consistency. The research protocol received approval from the Human Research Ethic Committee of Suratthani Rajabhat University (Ethic No. SRU-EC 2020/105) prior to data collection. Our evaluation metrics extend beyond the limited performance indicators used in previous systems [14-15]. While earlier implementations primarily measured technical performance or basic user satisfaction, our evaluation framework encompasses five distinct dimensions: functional accuracy, usability, performance efficiency, perceived benefits, and security. This multidimensional approach provides a more comprehensive assessment of both technical and user experience aspects, aligning with UTAUT principles [45] and offering greater insight into adoption factors.

C. Data Collection

A triangulation method validated findings. Data collection proceeded in two phases aligned with research objectives: Phase 1 (February 2021): In-depth interviews were conducted with three groups (ten participants each): the enterprise members, upland rice farmers, and upland rice consumers. Each interview lasted approximately 30 minutes. Phase 2 (August-September 2021): System evaluation utilized structured assessments from 30 upland rice farmers evaluating operational efficiency for famers; 388 consumers assessing e-commerce platform usability; and 12 enterprise members conducting Blackbox testing of the AIS. Each evaluation required 10-15 minutes for completion. The Blackbox testing focused on external software behavior [34-35], with 19 test cases selected based on specified requirements [24].

D. Data Analysis

The qualitative data analysis process involved systematic categorization of thematically similar data, followed by analysis and synthesis of interrelated and significant elements. The frequency of recurring themes was presented using percentage distributions. The quantitative analysis encompassed both descriptive statistics (Mean, S.D.) and advanced statistical methods, comprising t-test, f-test, pairwise comparisons utilizing the Least Significant Difference (LSD) method, and measures of distribution (skewness and kurtosis).

Unlike previous implementations [42] that evaluated systems primarily through technical testing, our approach includes comprehensive user testing across multiple stakeholder groups. This multi-stakeholder evaluation strategy captures the perspectives of all system participants—enterprise members, farmers, and consumers—providing a holistic view of system effectiveness throughout the entire agricultural value chain. This approach differs significantly from prior work that typically focused on either technical implementation [13] or single-user group perspectives [14], without considering the interconnected nature of agricultural community enterprises [41].

Data interpretation followed a five-point Likert Scale framework [23] with response options ranging from 5 (strongly agree) to 1 (strongly disagree).

E. Development Tools

Development tools include 1) Laravel Framework, a PHP language web application structure in MVC Shopee format. 2) Open Platform, a system helping applications connect with Shopee stores for data management. 3) Generate PDFs in Laravel with mPDF, which is a PHP library converting html files to PDF. 4) Excel exports and imports in Laravel. 5) PHP libraries for creating, editing, and composing images. 6) PHP QR-Code generator libraries. 7) XAMPP simulates a computer server to test programs on websites. 8) Composer manages PHP libraries to create order and safety for programs or systems developed. 9) Visual Studio Code, a free code editor for Windows and Macintosh operating systems. 10) iTerm, a command Line in MacOS operating system. 11) Git, a system platform to track, audit, and change Bitbucket source code: A service provider for storing files into the Git system via an online system. 12) Sequel Pro, a MySQL database management program for MacOS operating system. 13) Postman, a program for developing applications for testing web services, submitting a service request, and seeing the responses.

IV. Results

A. Interview Results of Members of the Enterprise

Based on interview findings from members of the Enterprise found that:

1) Financial management

a) The enterprise lacks a formal accounting system for group operations basis (Participant 1).

b) Sales are conducted on an order-by-order basis (Participant 2).

c) Individual income tracking exists for rice sales, but without cost and expense accounting (Participant 1).

d) Operational Costs.

e) No tracking of utilities and operational expenses as operations are based at group leader's residence (Participants 1, 4-5).

f) Group leader currently absorbs these costs (Participant 1).

g) Occasional member fundraising for exhibitions or investments (Participants 6-7).

h) Packaging costs are not calculated due to reliance on government-donated materials (Participants 8-10).

i) Technology Adoption.

j) 90% of members acknowledge accounting importance but lack expertise.

k) Strong interest in implementing user-friendly mobile accounting information system (Participants 4-5).

l) Participant 1 stated "we need a single point of entry that can seamlessly distribute information across our entire ecosystem." Participant 3 corroborated this view, adding: "The ability to synchronize product data automatically across platforms is crucial for our operational efficiency."

*m)*Participants 6-7 stated "we need a system that can integrate financial information across multiple online platforms - Facebook, Line, Shopee, and Lazada into one central platform."

B. Interview Results of Members of Upland Rice Farmers

Based on interviews with upland rice farmers: Key Technology Concerns: 80% express security concerns; 60% lack modern technology skills; 40% have limited access to equipment and internet connectivity. Resistance to Digital Adoption: Some farmers (Farmers 3-4, 6) prefer traditional paper-based methods; Consider digital systems less practical than manual record-keeping (Farmers 7-10).

C. Interview Results of Members of Upland Rice Farmers

Based on customer interviews regarding the upland rice of the Enterprise.

1) Market positioning

a) 80% of customers identify upland rice as a specialty product for health-conscious consumers.

b) Customers 1, 3-4 suggest targeting health-conscious demographic could increase revenue.

c) Customers 2, 5-7 recommend implementing online sales channels.

d) Digital Marketing Recommendations.

e) 100% of customers support developing online marketing channels.

f) Strong demand for diverse distribution channels (Customers 8-10).

g) Request for multiple payment options, particularly Cash on Delivery (COD) (Customers 1, 5-6).

h) Security.

i) Customer 5 stated "I need a secure payment system that protects my financial information when shopping online."

j) Customer 7 stated "I need a reliable customer support system."

k) Customer 9 stated "I need that system that a reliable transaction management system e.g., transaction tracking, refund monitoring, account management tools." Based on these interview findings, the system development scope will be defined according to the following key stakeholder requirements.

D. Development Results

The results of the development of the AIS consists of 1) Use case diagram (Fig. 1); 2) Information System Development; 3) Function Development; and 4) Black Box Testing. The result details are as follows: The AIS architecture integrates three key stakeholder groups: community enterprise members, farmers, and customers. The system's development employed an agile methodology [42], enabling iterative modifications throughout the development process to ensure optimal functionality and user requirements alignment. The AIS comprises frontend and backend interfaces. Frontend access available at https://khaorailanyai.com,requires user authentication through username/email and password credentials. Backend access available at https://khaorailanyai.com/app/login, features a dashboard displaying key metrics including Sales analytics, Order tracking, Rice purchase data, Monthly expense monitoring, Sales trend visualization, and Inventory status. The system incorporates geolocation functionality for plot management, enabling automated latitude/longitude capture with edit/delete capabilities. Core functionalities include: 1) Product management, 2) Order processing, 3) Expense tracking, 4) Customer relationship management, 5) Reporting, 6) Shopee integration, 7) Farmer management, and 8) E-commerce operations.

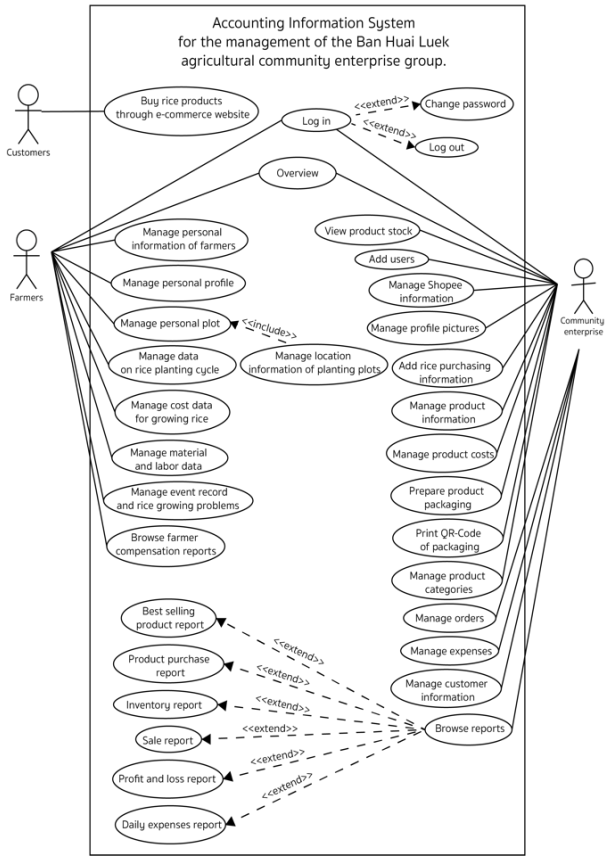

Fig. 1. Use case diagram.

A novel contribution of this research is the development of an integrated product management system facilitating seamless data synchronization between the web application and Shopee's e-commerce platform via Open API integration. This system enables automated sales data retrieval and financial analysis, including cost and profit calculations.

1) The product entry interface captures comprehensive product information including Product specifications: name,

type, details, image; Inventory metrics: price, stock quantity; Physical attributes: dimensions (width, length, height), weight; Logistics data: delivery time; Financial calculations: VAT percentage with automatic computation of pre-VAT price, VAT amount, and total price inclusive of VAT.

2) The system enables seamless product management through direct integration with Shopee's platform. Users can add products via the "Add Product" button, inputting product details and selecting appropriate categories. Product modifications and deletions are executed through dedicated edit and delete functions respectively.

3) Product cost management is facilitated through the edit function, where users can input individual cost details. Multiple cost entries can be added using the "Add cost" button, with changes confirmed via the "Save" function.

4) The packaging module facilitates product processing from raw materials through the following steps:

a) Production cycle initiation through the "Packaging" function.

b) Input of production parameters: production cycle details, production date, and rice species selection (system retrieves available inventory).

c) Product processing: product selection with automated maximum quantity calculation, multiple product processing capability, and product deletion option.

d) Quality control: QR code generation and printing for package tracking, automated inventory adjustment, and production list management.

The system maintains real-time inventory tracking and generates corresponding QR codes for product traceability.

5) Product types are managed through the "Add type" function, allowing input of type names with subsequent edit and delete capabilities.

Order management functionality comprises two key components:

- Order List Management:
  - Product processing: Product selection with automated maximum quantity calculation, multiple product processing capability, and product deletion option.
  - Features Shopee integration with automated order data synchronization.
  - Enables tracking number updates post-shipment.
- Order Creation:
  - Facilitates order processing for non-Shopee sales channels.
  - Allows manual order entry with contact channel specification.

The expense management module automates financial tracking through: Expense entry via "Add Expense" function; required data fields: expense type, notes, amount, payment date; Automated total calculation; Data confirmation through save function.

Customer list shows customer names, phone numbers, and modification date. The reporting module facilitates various financial and operational analyses through date-range queries: 1) inventory status, 2) daily expenses, 3) profit and loss statements, 4) sales analytics, 5) purchase history, and 6) best-selling products. Each report type is generated by specifying date parameters and utilizing the search function.

The system integrates with Shopee's Open API to manage product listings and order information across multiple sales channels [59], [60]. Through this integration, merchants can post products directly to their Shopee shops and retrieve order data, centralizing their sales management in one platform. To connect a Shopee store, users enter their Shopee-registered phone number and complete the authorization process by 1.Clicking "Log in" followed by "Other accounts"; 2.Confirming authorization; 3. Saving the configuration. Once authorized, the system displays the store's Shopee integration status. Users can:

- Update store information via the refresh function.
- Access their Shopee storefront through the "My Shop" button.
- Navigate to Shopee's seller platform via the "Seller Center" button.

This integration capability represents a key contribution of this research, enabling streamlined multi-channel commerce management. The AIS system's architecture comprises 41 database tables, adhering to established principles of database design [21]. The system implements nine core functions: 1) Shopee API Integration, Store Information Retrieval, 3) Performance Analytics Collection, 4) Data Array Transformation, 5) Product Management, 6) Packaging Management, 7) Inventory Control, 8) Returns Processing, and 9) Shopee Product Listing. These functions form an integrated framework for comprehensive e-commerce management through the Shopee platform.

E. E-Commerce

The e-commerce platform www.khaorailanyai.com facilitates upland rice product sales through a comprehensive user interface. As shown in Fig. 2, the platform features user authentication systems and a navigation menu comprising: Home, Blog, Store, Shopping Cart, Payment Notification, Reviews, FAQ, About Us, Sign-In, and Sign-Up functionalities.

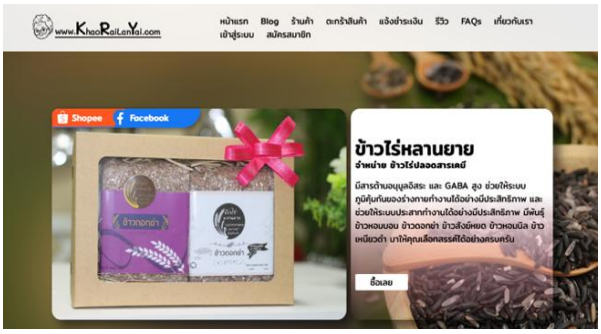

Fig. 2. E-commerce.

F. The AIS for Farmers

The AIS for farmers is a comprehensive web application comprising both frontend and backend components designed to facilitate rice cultivation management. The frontend interface is accessible to farmers via https://khaorailanyai.com, while the backend system can be accessed through https://khaorailanyai.com/app/login.The backend system incorporates six primary functionalities: 1) Dashboard visualization, 2) Farmer information management, 3) Rice cultivation cycle tracking, 3) Cost information monitoring, 4) Event logging, and 5) Report generation. Upon authentication, users are directed to a dashboard that presents consolidated metrics, including rice sales data, cost analysis, production volumes, and profit calculations. Through the farmer information module, users can maintain their personal profiles and manage plot-specific details. The system facilitates precise plot location documentation by enabling farmers to select locations on an interactive map interface and input specific latitude and longitude coordinates. The system facilitates comprehensive rice cultivation data management through an integrated interface. It enables farmers to track cultivation cycles, manage costs, and document critical production events. The platform features robust financial reporting capabilities in Excel format, incorporating detailed cost structures, production metrics, and sales analyses. A key innovation is the QR code functionality, allowing consumers to access authenticated farmer information and verify purchase data through a dual-verification system. This integration of data management and traceability mechanisms enhances operational efficiency throughout the cultivation and distribution process.

G. Evaluation Results

1) Functional testing results: The software system being tested is viewed as a "black box". The choice of test cases depends on the requirements or design specifications [33]. Functional testing focuses primarily on the external behavior [26], [31]. The results of Blackbox testing by all 12 members of the Enterprise found that all 19 functional functions passed the evaluation criteria (Table III).

2) Customer evaluation results: These results show the efficiency of the e-commerce from the consumer perspective.

a) Demographic information: A survey of 388 consumers revealed the following characteristics: Gender distribution: Most respondents were female (n=279, 71.91%), with males comprising 28.09% (n=109) of the sample. Age distribution: The predominant age group was 20-30 years (41%), followed by 31-40 years (27.06%). The least represented age group was over 60 years (0.77%). Marital status: The majority were single (77.58%), followed by married individuals (21.65%). Religious affiliation: Buddhism was the most prevalent religion (92.78%), followed by Islam (5.93%). A small proportion (1.29%) reported no religious affiliation. Educational attainment: The majority held a bachelor's degree (72.42%), followed by those with a master's degree (13.40%), and those with educational levels below a bachelor's degree (11.60%). Occupational distribution: Government officials and state enterprise employees constituted the largest group (45.10%), followed by those engaged in commerce or self-employed businesses (22.40%). The least represented occupational category was "other occupations" (1.30%). Monthly income: The most common income bracket was 30,001 - 40,000 baht (49.20%), followed by 20,001 - 30,000 baht (31.20%). The least represented income group was those earning 50,000 baht or more per month (5.20%). Analysis of consumer purchasing channels revealed that Shopee was the most frequently used platform (56.19%), followed closely by Lazada (52.84%). Line, primarily a messaging application, was utilized by 40.72% of consumers for shopping. Instagram and traditional websites were used by 33.76% and 31.96% of respondents, respectively. Facebook was the least popular among the major platforms, used by 30.41% of consumers for e-commerce activities as can be seen in Fig. 3.

TABLE III. FUNCTIONAL TESTING RESULTS

Functions	Test Results	Results
1. Login	A secure and reliable accounting system enhances user confidence.	Pass
2. Product management	The system offers comprehensive product management with operations and advanced search capabilities.	Pass
3. Product cost management	Self-managed product costing eliminates dependency on government assistance.	Pass
4. Packaging information management	It is much easier to manage packaging information than previously.	Pass
5. Product category management	Efficient and simplified product type administration.	Pass
6. Order management	Streamlined order management system with search, tracking, and shipping label printing capabilities.	Pass
7. Creating an order	Users can easily create orders.	Pass
8. Managing rice purchasing information	Accurate and efficient rice procurement management.	Pass
9. Expense management	Efficient and precise expense tracking system.	Pass
10. Managing customer lists	A database system enables quick customer contact and data management.	Pass
11. Managing farmer compensation reports	Efficient farmers return processing for cost analysis.	Pass
12. Inventory report management	Efficient inventory management with product traceability.	Pass
13. Managing daily expense account reports	Efficient management of daily expense accounts.	Pass
14. Managing profit and loss reports of the enterprise	Streamlined profit and loss management system for community enterprises.	Pass
15. Managing sales reports	Simplified sales report management.	Pass
16. Managing product purchase reports	Efficient and simplified purchase reporting.	Pass
17. Managing best-selling product reports	Simplified top-selling product reporting.	Pass
18. User management	The system provides secure user management with role-based access control.	Pass

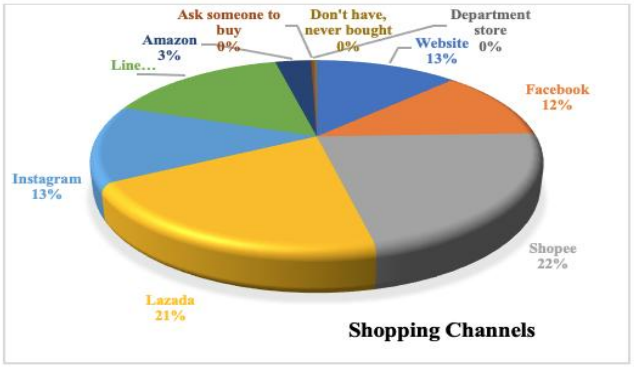

Fig. 3. The Pie chart of shopping channels.

H. Consumer Evaluation Results

Consumers expressed high levels ($\bar{x}$ = 4.41) of agreement across all five dimensions of the e-commerce website usability. Security received the highest rating ($\bar{x}$ = 4.44), followed by website benefits ($\bar{x}$ = 4.41). Functional accuracy and ease of use were equally rated ($\bar{x}$ = 4.40), while performance efficiency received the lowest, yet still high, rating ($\bar{x}$ = 4.38). These results indicate a generally positive perception of the website's usability, with a particular emphasis on security features as can be seen in Fig. 4.

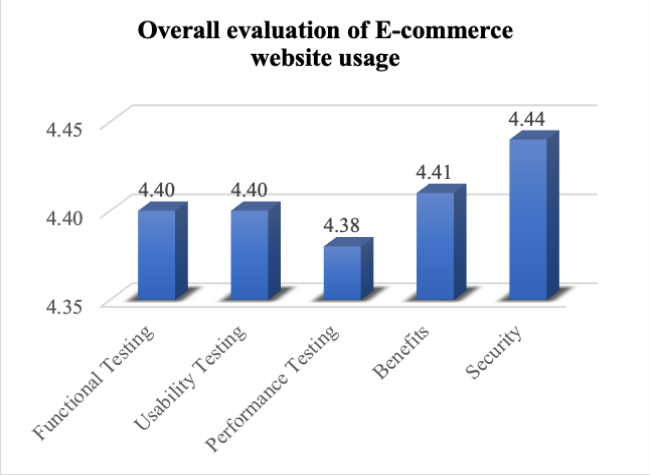

Fig. 4. Overall evaluation of E-commerce website usage.

I. Functional Testing

Table IV illustrates consumer perceptions regarding the functional accuracy of the e-commerce. An overall opinion of functional testing found average score at a high level of opinion ($\bar{x}$ = 4.40). All scores were at a high level. Question 4 had the highest scores ($\bar{x}$ = 4.47), followed by question 2 ($\bar{x}$ = 4.40), and the least were questions 1 and 3. ($\bar{x}$ = 4.37).

J. Usability Testing

Table V illustrates consumer perceptions regarding the usability of the E-Commerce. An overall opinion of Usability Testing found average score at a high level ($\bar{x}$ = 4.40). It was found that all scores were at a high level. Question 4 had the highest scores ($\bar{x}$ = 4.44), followed by question 2 ($\bar{x}$ = 4.43), and the least were questions 1 and 8. ($\bar{x}$ = 4.37).

K. Performance Testing

Table VI illustrates consumer perceptions regarding the performance of the e-commerce. An overall opinion of performance testing found average score at a high level ($\bar{x}$ = 4.38). It was found that all scores were at a high level. Question 3 had the highest scores ($\bar{x}$ = 4.43), followed by question 5 ($\bar{x}$ = 4.42), and the least were question 2 ($\bar{x}$ = 4.31).

TABLE IV. CONSUMER PERCEPTIONS OF E-COMMERCE FUNCTIONAL ACCURACY

Questions	$\bar{x}$	S.D.	Level of Agreement
1. Reports on best-selling and popular products facilitate easier purchasing decisions	4.37	0.67	High
2. Responsiveness through chat messaging increases purchase confidence	4.40	0.67	High
3. Display of remaining stock quantity expedites purchase decisions	4.37	0.71	High
4. Customer review information accelerates purchase decisions	4.47	0.65	High
Overall	**4.40**	**0.67**	**High**

TABLE V. CONSUMER PERCEPTIONS OF E-COMMERCE USABILITY

Questions	$\bar{x}$	S.D.	Level of Agreement
1. Ease of registration and E-Commerce access	4.37	0.62	High
2. Clarity of on-screen images	4.43	0.65	High
3. Readability and clarity of font size and style	4.41	0.65	High
4. Appropriateness of background color for text readability	4.44	0.63	High
5. Effectiveness of vocabulary and terminology	4.43	0.67	High
6. Ease of data input	4.41	0.68	High
7. User-friendliness of buttons, menus, and navigation	4.39	0.68	High
8. Availability of system usage instructions	4.37	0.71	High
9. Stability of marketing channels	4.38	0.68	High
Overall	**4.40**	**0.66**	**High**

TABLE VI. CONSUMER PERCEPTIONS OF E-COMMERCE PERFORMANCE

Questions	$\bar{x}$	S.D.	Level of Agreement
1. Accuracy of button and menu functionality	4.36	0.67	High
2. Presence of error notifications	4.31	0.69	High
3. Correct integration with online marketplaces	4.43	0.68	High
4. Accuracy of customer interaction data transmission	4.38	0.71	High
5. Accuracy of order calculation and payment processing	4.42	0.70	High
Overall	**4.38**	**0.69**	High

L. Benefits

Table VII illustrates consumer perceptions regarding the benefits of the e-commerce. An overall opinion of benefits

found average score at a high level ($\bar{x}$ = 4.41). It was found that all scores were at a high level. Question 3 had the highest scores ($\bar{x}$ = 4.45), followed by question 5 ($\bar{x}$ = 4.43), and the least were question 1 ($\bar{x}$ = 4.36).

TABLE VII. CONSUMER PERCEPTIONS OF E-COMMERCE BENEFITS

Questions	$\bar{x}$	S.D.	Level of Agreement
1. Comprehensiveness of product details	4.36	0.67	High
2. Facilitation of information access for decision-making	4.39	0.69	High
3. Diversity and efficiency of payment options	4.45	0.65	High
4. Rapid dissemination of store news and promotions	4.41	0.68	High
5. Simplification of the purchasing process	4.43	0.67	High
Overall	**4.41**	**0.67**	**High**

M. Security

Table VIII illustrates consumer perceptions regarding the security of the e-commerce. An overall opinion of e-commerce security found average score at a high ($\bar{x}$ = 4.44). It was found that all scores were at a high level. Question 3 had the highest scores ($\bar{x}$ = 4.46), followed by question 2 ($\bar{x}$ = 4.44), and the least were question 1 ($\bar{x}$ = 4.42). The assessment of skewness and kurtosis yielded values within the range of -1.96 to +1.96, indicating that the data conforms to a normal distribution.

TABLE VIII. CONSUMER PERCEPTIONS OF E-COMMERCE SECURITY

Questions	$\bar{x}$	S.D.	Level of Agreement
1. Implementation of user authentication system	4.42	0.62	High
2. Presence of login error notifications	4.44	0.62	High
3. Provision of secure payment channels	4.46	0.64	High
Overall	**4.44**	**0.63**	**High**

N. Testing for Differences Between Personal Factors and Perceptions

Table IX elucidates the differences in perceptions across personal factors with respect to various aspects of the e-commerce, including: functional accuracy, usability, performance efficiency, perceived benefits, and security. This analysis examines how individual demographic characteristics influence users' evaluations of these key website attributes.

1) Impact of differential personal factors on perceptions of e-commerce functional accuracy: Analysis of variance revealed that certain personal factors significantly influence perceptions of the e-commerce's functional accuracy at the .01 level of statistical significance. Specifically, age group and average monthly income emerged as significant factors. Beyond these two factors, other personal characteristics did not exhibit significant differences. Pairwise comparisons using the Least Significant Difference (LSD) method revealed the following results: a) Significant differences in perceptions were observed across various age groups: The 20-30 age group differed significantly from the 31-40 age group (p = .002). The 20-30 age group showed significant differences from the 41-50 age group (p = .014). The 20-30 age group exhibited significant differences from the 51-60 age group (p = .005). b) Significant differences in perceptions were observed across various income brackets: Consumers with monthly incomes between 10,001 - 20,000 baht differed significantly from those earning 30,001 - 40,000 baht (p = .002). The 30,001 - 40,000-baht income group showed significant differences from those earning more than 50,000 baht (p = .021). These findings indicate that income disparities result in statistically significant variations in perceptions regarding the functional accuracy of the information system. The differences were significant at the .01 and .05 levels, respectively.

TABLE IX. ANALYSIS OF VARIANCE BETWEEN PERSONAL FACTORS AND PERCEPTIONS

Personal Factors		Gender	Age	Marital Status	Religious Affiliation	Educational Attainment	Occupation	Income
SAT1	**T/F test**	-1.791	3.895	1.070	0.685	0.236	0.713	3.441

2) Impact of differential personal factors on perceptions of usability: Analysis of variance revealed that certain personal factors significantly influence perceptions of e-commerce website usability. Specifically, age group and average monthly income emerged as significant factors, with differences observed at the .05 and .01 levels of statistical significance, respectively. Other personal factors did not demonstrate significant differences. Pairwise comparisons using the Least

Significant Difference (LSD) method yielded the following results: a) Significant differences in perceptions of usability were observed across various age groups: The 20-30 age group differed significantly from the 31-40 age group ($p = .019$). The 18-30 age group showed significant differences from the 41-50 age group ($p = .028$). The 18-30 age group exhibited significant differences from the 51-60 age group ($p = .014$). b) Significant differences in perceptions of usability were observed across various income brackets: Consumers with monthly incomes between 10,001 - 20,000 baht differed significantly from those earning 30,001 - 40,000 baht ($p = .001$). The 30,001 - 40,000-baht income group showed significant differences from those earning more than 50,000 baht ($p = .018$). The 20,001 - 30,000-baht income group exhibited significant differences from those earning more than 50,000 baht ($p = .044$). These findings indicate that income disparities result in statistically significant variations in perceptions of usability. The differences were significant at the .01 and .05 levels, respectively.

O. Impact of Differential Personal Factors on Perceptions of E-Commerce Performance

Analysis of variance revealed that certain personal factors significantly influence perceptions of the information system's performance. Specifically, age group and average monthly income emerged as significant factors, with differences observed at the .05 and .01 levels of statistical significance, respectively. Other personal factors did not demonstrate significant differences. Pairwise comparisons using the Least Significant Difference (LSD) method yielded the following results:

1) Significant differences in perceptions of information system performance were observed across age groups: The 20-30 age group differed significantly from the 31-40 age group ($p = .015$). The 18-30 age group exhibited significant differences from the 51-60 age group ($p = .009$). These findings indicate that age differences result in statistically significant variations in perceptions of information system performance at the .05 and .01 levels of significance, respectively.

2) Significant differences in perceptions of e-commerce performance were observed across various income brackets: Consumers with monthly incomes between 10,001 - 20,000 baht differed significantly from those earning 30,001 - 40,000 baht ($p < .001$). The 10,001 - 20,000 baht income group showed significant differences from the 20,001 - 30,000 baht group ($p = .035$). The 30,001 - 40,000 baht income group exhibited significant differences from those earning more than 50,000 baht ($p = .023$).

P. Impact of Differential Personal Factors on Perceptions of E-Commerce Benefits

Analysis of variance revealed certain personal factors significantly influence perceptions of e-commerce benefits. Specifically, age group and average monthly income emerged as significant factors, with differences observed at the $p < .05$ and $p < .01$ levels of statistical significance, respectively. Other personal factors did not demonstrate significant differences. Pairwise comparisons using the Least Significant Difference (LSD) method yielded the following results:

1) Significant differences in perceptions of information system benefits were observed across age groups: The 18-30 age group differed significantly from the 31-40 age group ($p = .002$). The 20-30 age group exhibited significant differences from the 41-50 age group ($p = .014$). The 20-30 age group showed significant differences from the 51-60 age group ($p = .005$).

2) Significant differences in perceptions of information system benefits were observed across various income brackets: Consumers with monthly incomes between 10,001 - 20,000 baht differed significantly from those earning 30,001 - 420,000 baht ($p < .001$). The 10,001 - 20,000-baht income group showed significant differences from the 20,001 - 30,000-baht group ($p = .048$). The 30,001 - 40,000-baht income group exhibited significant differences from those earning more than 50,000 baht ($p = .008$). The 20,001 - 30,000-baht income group differed significantly from those earning more than 50,000 baht ($p = .039$). These findings indicate that income disparities result in statistically significant variations in perceptions of information system benefits at the .01 and .05 levels of significance.

Q. Impact of Differential Personal Factors on Perceptions of Security

Analysis of variance revealed that average monthly income significantly influences perceptions of security at the .05 level of statistical significance. Other personal factors did not demonstrate significant differences. Pairwise comparisons using the Least Significant Difference (LSD) method yielded the following results: Significant differences in perceptions of security were observed across various income brackets: Consumers with monthly incomes between 10,001 - 20,000 baht differed significantly from those earning 30,001 - 40,000 baht ($p = .004$). The 30,001 - 40,000 baht income group exhibited significant differences from those earning more than 50,000 baht ($p = .018$). These findings indicate that income disparities result in statistically significant variations in perceptions of security at the .01 and .05 levels of significance, respectively.

R. Farmers' Opinions on the Information System for Farmers

Farmer's opinion on the use of innovations for managing the Enterprise across all aspects, with an overall high level of agreement ($\bar{x} = 4.04$). The highest opinion on the ease of use ($\bar{x} = 4.11$), followed by the accuracy ($\bar{x} = 4.07$), performance and benefits are equal with $\bar{x} = 4.03$ and least satisfied were security with ($\bar{x} = 3.97$). The details of satisfaction in each aspect are shown below.

1) Accuracy in the operation of the information system (Functional Testing): Table X shows the farmers' opinions on the accuracy of the information system for the management of the Enterprise. Overall opinions at a high level ($\bar{x} = 4.07$), while the highest score was the system provided accurate information ($\bar{x} = 4.37$), followed by the efficient use of the information system functions ($\bar{x} = 4.13$), and conditional

information searches could be performed correctly ($\bar{x}$ = 4.10), respectively.

TABLE X. OPINIONS ON THE ACCURACY OF THE INFORMATION SYSTEM

System properties	$\bar{x}$	S.D.	Level of Agreement
1. Providing information correctly	4.37	0.61	High
2. Using the information system's functions can be done efficiently.	4.13	0.51	High
3. Conditional data search is performed correctly.	4.10	0.48	High
4. Accurate display of important data reports	3.93	0.45	High
5. The interaction is efficient.	3.80	0.55	High
Overall	**4.07**	**0.52**	**High**

2) The ease of use of the information system: Table XI shows the results of evaluating farmers' opinions on the ease of use of the information system. It was found that farmers generally expressed a high level of satisfaction overall ($\bar{x}$ = 4.11). The highest score of satisfaction was the appropriateness of the background color, which made the text easy to read and clear ($\bar{x}$ = 4.37). This was followed by the readability and clarity of the font size and style ($\bar{x}$ = 4.20). The visibility of images on the screen and the efficiency of vocabulary and terminology were equally rated at $\bar{x}$ = 4.17. The lowest-rated aspect was the ease of using buttons, menus, and navigation features ($\bar{x}$ = 3.93).

TABLE XI. SATISFACTION WITH THE EASE OF USE OF THE INFORMATION SYSTEM

System properties	$\bar{x}$	S.D.	Level of Agreement
1. Registration and login are easy.	3.97	0.41	High
2. The image displayed on the screen is clearly visible.	4.17	0.59	High
3. Readability and clarity of font size and style	4.20	0.41	High
4. The appropriateness of background color for text readability	4.37	0.49	High
5. The efficiency of vocabulary and terminology	4.17	0.53	High
6. Simplicity of data entry	4.10	0.61	High
7. Ease of use of buttons, menus, and navigation	3.93	0.25	High
8. Accessibility of system instructions	4.00	0.00	High
Overall	**4.11**	**0.41**	**High**

3) Performance testing: Table XII shows farmers' satisfaction with the efficiency of the information system for the management of the Enterprise. The research results found that the overall efficiency of the system was highly satisfactory ($\bar{x}$ = 4.03).While the highest score was an ability to work at full efficiency even after long-term use ($\bar{x}$ = 4.20), followed by the speed of the system response ($\bar{x}$ = 4.17).

4) Benefits of using the information system: Table XIII shows the satisfaction of farmers with the benefits of using the information system for the management of the Enterprise. It was found that overall Farmers' satisfaction was at a high-level score ($\bar{x}$ = 4.03). The highest score was with the information system that helped check the location of the planting plot ($\bar{x}$ = 4.13), followed by the information system that helped search for the desired information according to the stored categories ($\bar{x}$ = 4.07), and the information system that helped increase the convenience of recording rice planting accounts ($\bar{x}$ = 4.00), respectively.

TABLE XII. SATISFACTION WITH THE EFFICIENCY OF THE INFORMATION SYSTEM

Questions	$\bar{x}$	S.D.	Level of Agreement
1. The information system is capable of responding quickly to tasks.	4.17	0.38	High
2. The information system is stable and ready to handle errors.	3.93	0..25	High
3. The information system operates efficiently even after extended periods of use	4.20	0.41	High
4. The information system can be connected to other information systems.	3.93	0.25	High
5. The information system can support usage on the Internet network well.	3.93	0.25	High
Overall	**4.03**	**0.31**	High

TABLE XIII. SYSTEM SATISFACTION WITH BENEFITS OF USING THE INFORMATION SYSTEM

Questions	$\bar{x}$	S.D.	Level of Agreement
1. Information systems help to easily collect data on rice plantations.	3.97	0.18	High
2. Information system helps increase convenience in accounting for rice cultivation.	4.00	0.37	High
3. Information systems make it possible to search for desired information according to storage categories.	4.07	0.25	High
4. The information system helps to check the location of the plantation.	4.13	0.35	High
5. The information system can display reports on costs, profits, and sales of rice cultivation.	3.97	0.18	High
Overall	**4.03**	**0.27**	**High**

5) Security: Table XIV presents the farmers satisfaction on the security of the information system for the management of the AIS. An overall satisfaction of security of the information system shows a high-level score at $\bar{x}$ = 3.97. The highest score of farmer satisfaction was information system had a user code and password for access ($\bar{x}$ = 4.13), followed by the information system had divided user levels for access ($\bar{x}$ = 3.90), and the information system had a warning when an error occurred in entering the information system ($\bar{x}$ = 3.87), respectively.

TABLE XIV. SATISFACTION WITH INFORMATION SYSTEM SECURITY

Questions	$\bar{x}$	S.D.	Level of Agreement
1. The information system has specified user IDs and passwords for use.	4.13	0.35	High
2. The information system has user-level permissions for access.	3.90	0.31	High
3. There is a notification when there is an error in entering the information system.	3.87	3.87	High
Overall	**3.97**	**0.33**	**High**

V. DISCUSSION

A. The Development of the AIS

The development of the AIS used an agile software development method because researchers can edit the program at any time when they find errors during development. This results in no wasted time developing software and for completeness of software. This is in line with [43], stating that the agile software development method can go back and modify the system development at any time in the development. The AIS had been validated and reviewed from three experts considering the suitability of the software in terms of content, accuracy in using functions, and the difficulty of use before developing the information system for users to check completeness of information. This is consistent with [21] who said that in developing information systems, good database system design is required at different levels. The AIS uses PHP language for the management, using MySQL and phpMyAdmin to develop database management. It is in line with [6] who developed the system that can manage news, public relations, product information, accounting system, and member information. It is also associated with [44] who studied the management model of the silk product community enterprise , Buriram. It was found that the results of developing the management model included: 1) production management; 2) Market management; and 3) Financial and accounting management. The AIS development process consists of 1) product management; 2) order management; 3) expense management; 4) customer list; 5) report, 6) Shopee Access Permissions, 7) famer management, and 8) e-commerce. It is similar to the development of [17] which comprise of Information recognition, information recording, analysis of information and information report. Our development approach aligns with Ibrahim and Hassan's [49] framework for cloud-based accounting solutions for small agricultural enterprises, emphasizing cost-effectiveness and technology accessibility. The system's comprehensive architecture incorporating 41 database tables and nine core functions represents a more sophisticated implementation compared to previous systems, providing advanced integration capabilities specifically designed for agricultural community enterprises [41]. This comprehensive approach is consistent with Kumar and Singh's [54] microservices and API Gateway integration framework, enabling system flexibility and scalability according to business requirements. Furthermore, our implementation of Shopee's Open API for e-commerce integration aligns with Zhang et al.'s [55] API-based integration strategies for cross-platform e-commerce solutions, which reduce complexity in managing data across diverse sales channels.

B. Customers' Perception

Consumers expressed highly positive perceptions across all aspects of the e-commerce usability, with security emerging as the most critical factor. This finding aligns with [4], who identified security as a crucial determinant of trust in electronic commerce. The implementation of the internationally recognized Omise payment system corroborates the concept of [22], that reliable payment systems directly influence consumers' perceptions of security. The high importance consumers attribute to website benefits aligns with the TAM proposed by [11], which posits that PU is a critical factor in the adoption of new technologies. Furthermore, the emphasis on functional accuracy reflects the system quality, which [9] identified as one of the key determinants influencing online purchasing behavior. The research findings indicating that usability is equally important as benefits and functional accuracy align with [34] emphasizing the significance of user-friendly website design. Furthermore, these results corroborate [11], identifying PEOU as another critical factor in technology adoption. Although consumers rated performance efficiency as the least important factor, it still received a high overall score, indicating its significant role aligning with [45], which posits that Performance Expectancy is one of the key determinants influencing technology acceptance and use.

The positive consumer perceptions regarding security and system benefits align with Chen et al.'s [52] findings on factors influencing consumer trust in online agricultural marketplaces across Southeast Asia, which identified data security and product information transparency as critical factors in establishing consumer confidence. The high ratings for both usability and functional accuracy also correspond with Wijaya and Rahmawati's [53] research demonstrating that comprehensive information presentation and enhanced user experience significantly impact consumers' purchasing decisions for agricultural products. Our findings regarding the importance of diverse payment options and secure transaction systems validate Thongpoon and Rakthai's [57] research, which revealed that organic agricultural product purchasing behavior through e-commerce platforms in Thailand depends significantly on platform credibility, ease of use, and payment channel diversity.

Analysis of variance revealed differences in personal factors, specifically age group and average monthly income, significantly influence perceptions of e-commerce functional accuracy at the .01 level of statistical significance: aligning with the research of [45], that age affects technology acceptance. Furthermore, the observed impact of income differences on perceptions corresponds with [16], highlighting the influence of socioeconomic factors on Internet usage and digital technology adoption. Analysis of variance revealed that differences in personal factors, specifically age group and average monthly income, significantly influence perceptions of usability at the .05 and .01 levels of statistical significance, respectively: aligning with [11], identifying PEOU as a critical factor. Users of different ages and income levels may possess varying technological skills and experiences, potentially leading to divergent perspectives on usability. Analysis of variance revealed that differences in personal factors, specifically age group [30] and average monthly income, significantly influence

perceptions of e-commerce performance at the .05 and .01 levels of statistical significance, respectively. The difference in how people view technology fits with the UTAUT, a model developed by [45], which posits that Performance Expectancy is a crucial factor in technology acceptance. Users of different ages and income levels may have varying expectations regarding system performance, potentially leading to divergent perceptions of the e-commerce's efficiency. Analysis of variance revealed that differences in personal factors, specifically age group and average monthly income, significantly influence perceptions of information system benefits at $p < .05$ and $p < .01$ levels of statistical significance, respectively. These findings align with both [11] and [45], the UTAUT emphasize the importance of perceived usefulness. Users of different ages and income levels may have divergent perspectives and needs, potentially leading to varied perceptions of system benefits. Analysis of variance revealed that differences in average monthly income significantly influence perceptions of security at the .05 level of statistical significance: aligning with [4], highlighting security as a crucial factor in establishing trust in electronic commerce. Users with varying income levels may exhibit different degrees of concern regarding financial security.

C. Farmers' Perception

The research results found that farmers expressed positive opinions regarding the use of information systems for managing the Ban Huai Luek Agricultural Community Enterprise. This aligns with TAM [11], which suggests that perceived usefulness and perceived ease of use are important factors affecting technology acceptance. The research found that farmers had favorable opinions about both the ease of use and the benefits of using the information system. Additionally, the results were consistent with the Unified Theory of Acceptance and Use of Technology (UTAUT) [45], which states that performance expectancy and effort expectancy are important factors affecting technology acceptance. However, the results revealed that farmers had the lowest opinions regarding system security. This finding aligns with the study by [5], which found that concerns about data security were one of the major barriers to digital technology adoption among small-scale farmers. Therefore, future system development should focus on enhancing system security and building user confidence. Farmers' concerns about initial technology use are consistent with Rogers' [40] concept of diffusion of innovations, which states that the adoption of new technologies is a process that takes time and progresses through various stages. Therefore, the development of user manuals and provision of continuous training are essential to support farmers in using the system effectively.

Our findings regarding farmers' security concerns align with Darma and Wijaya's [50] research on blockchain technology implementation in agricultural supply chains, which emphasizes the importance of data security and transaction reliability. The generally positive perception of the system's functionality and benefits corresponds with Patel and Sharma's [51] model integrating IoT technology with accounting information systems in smart farming contexts, which highlights the value of precise and automated production cost monitoring. Furthermore, the observed importance of ease of use and system accuracy in farmer assessments aligns with Supaporn and Chaisiri's [56] investigation into digital transformation of community enterprises in Northern Thailand, which identified member digital skill development and user-centered system design as critical success factors for technology adoption. The implementation of geolocation functionality and QR code traceability in our system addresses the needs for enhanced transparency and reliability in agricultural information systems as identified by both Darma and Wijaya [50] and Supaporn and Chaisiri [56].

This research presents several limitations: 1) The system development is confined to the Shopee platform, as it is the only platform providing accessible API integration capabilities, which may not encompass other online marketing channels utilized by farmers; 2) The constrained evaluation timeframe precludes comprehensive assessment of long-term impacts on business sustainability; and 3) Digital infrastructure challenges prevalent in rural areas may adversely affect system performance in real-world operational environments [62-64].

VI. CONCLUSION

Based on stakeholder interviews, key requirements for the AIS development emerged across three groups: 1) the Enterprises' members, Upland rice farmers, and Consumers informed the development of the integrated AIS that balances operational efficiency with user accessibility while maintaining robust security measures. The development of the AIS consists of 41 tables and nine main functions: 1) Connecting with Shopee; 2) Function to retrieve store information from Shopee; 3) Shopee store performance data retrieval function; 4) Function to convert data form into Array format; 5) Product recording function; 6) Packaging function; 7) Product stock cutting function; 8) Product return function and; 9) Product listing function in Shopee. This is considered as a new contribution of the research, especially the function of placing products information in Shopee stores through the developed web application. The information can pull from the Shopee platform to calculate costs and profits through Shopee Open API. The development of the information system for farmers comprises key functional areas: farmer data management, rice cultivation cycle management, cost data management, event logging, and report processing.

The customer analysis of the e-commerce, based on 388 consumer responses, revealed high satisfaction across all dimensions, with security and perceived benefits as primary concerns. The findings align with the TAM, demonstrating that demographic factors, particularly age and income, significantly influence consumer perceptions. These insights contribute to understanding rural e-commerce behavior and emphasize the importance of security measures and user benefits in website development strategies. The evaluation of 30 farmers revealed high satisfaction with the accounting information system, particularly in usability and functionality aspects. Though initial security concerns existed, these were addressed through comprehensive user documentation to support system implementation.

Future research should focus on developing an advanced Analytics Module that would enable community enterprises to monitor and analyze consumer behavior more effectively. The development of mobile applications with offline functionality would address digital infrastructure challenges in rural areas.

Additionally, comparative longitudinal studies between community enterprises that implement the system and those that do not would provide deeper insights into the economic and social impacts of such technological integration.

ACKNOWLEDGMENT

The authors gratefully acknowledge the financial of Office of the Higher Education Fund, Thailand. Thanks to the Ethics committee of the Suratthani Rajabhat University that approved this research. Thank you to all participants, experts and others who sacrificed their time to provide information for this research.

***Abstract*—Steel Plate Shear Walls (SPSWs) are a significant structural system because they can dissipate energy and have a very high lateral stiffness. However, the discovery and elimination of vital structural vulnerabilities, mainly in multi-cavity configurations, is still a major challenge. This study utilizes developments in the deep learning era to improve the identification and representation of such vulnerabilities. An improved DNN architecture was employed to analyze the effectiveness of multi-cavity SPSWs under different loading conditions. The proposed method combines hybrid information extraction techniques with various geometries and materials to ensure a reliable prediction of structural element failures. The tests have shown highly positive results, with the enhanced DNN outperforming conventional procedures by achieving higher accuracy, lower false-positive rates, and superior generalization across various test cases. This work demonstrates a new way to detect weaknesses in a structure, thereby developing an effective tool for engineers to prevent the sustainability and safety of SPSWs in critical infrastructure.**

***Keywords*—Structural vulnerabilities; deep neural networks; steel plate shear walls; seismic design; machine learning**

I. Introduction

Steel Plate Shear Walls (SPSWs) have established themselves as important parts of modern structural engineering, especially in places that are exposed to seismic activity. The major reason for their presence, which is the ability to offer lateral resistance and energy dissipation, makes them a source of strength and enables the buildings to encounter a disaster efficiently [1]. SPSWs consist basically of flat thin steel plates put inside a structural frame, and their design has been adapted in time to cater to more and more complex requests. The most innovative is the multi-cavity system where the steel plate gets divided into several smaller subregions or cavities which saves weight and also helps with improved seismic performance. Despite advancements, mainstream methods for detecting vulnerabilities in SPSWs, particularly in multi- cavity designs, remain a major challenge [2-3].

In traditional SPSW systems, structural weaknesses cause premature failure when subjected to seismic loading [4]. The weaknesses may result from defects in the design, differences in the material used, or even a lack of understanding of how the interactions among various structural components must occur. The biggest hindrance in locating the final susceptible zones in multi-cavity SPSWs which had complicated stress distribution systems is simply the complexity of those real-life conditions. Conventional methods, such as finite element analysis (FEA) and experimental testing, are the most widely used techniques to analyze the SPSW system behavior [5-6]. Although valuable, these techniques have significant shortcomings, including high costs, long processing times, and limited adaptability to various scenarios. This leads to the emergence of innovative solutions for detecting and assessing vulnerabilities.

In recent years, ML and AI technologies have gained novel applications for major engineering initiatives that require solving very complex problems, including structural engineering. Deep neural networks (DNNs) are one of the various ML techniques that have been used extensively in the past due to their ability to process large datasets and identify the correlations present in them. Success in domains like damage detection, material property prediction, and structural health monitoring are all examples of the successful application of DNNs [7]. However, if any research has been conducted on their applicability in SPSW, especially the multi-cavity configurations, it would appear to be very limited [8-10]. The study of DNN's application to those issues is used in this case as a kind of guarantee that the conventional work constraints will be eliminated and that the accuracy and efficacy of the deficiency detection will be greatly enhanced.

The research is devoted to developing an enhanced DNN-based framework that can be utilized to identify and classify potential failures occurring in multi-cavity SPSWs. The proposed procedure in this study addresses critical challenges, including accurate representation of complex structural shapes, integration of diverse data sources, and mitigation of overfitting [11-12]. Using good practices gained from complex DNN architectures and training techniques, the work's goal is a solution to the outstanding difficulties in a very difficult real-world application: examining the vulnerability of SPSWs. This is achieved mainly by integrating geometric and material properties, both of which are input features in which the detailed study of different conditions in terms of structural performance is done [13-14].

An important feature of this study is the insistence on hybrid methods of feature extraction. Unlike classical techniques that solely involve either a geometric parameter or a property of the material, the new method merges both. This

increases the model's capability for a more complete appreciation of the structural processes governing SPSWs. In addition, the procedure of training employs advanced optimization and regularization approaches thus transmitting the ability of the model to the novel situations which the DNN is to solve [15-16]. This ensures that the DNN can handle diverse test cases, including previously unexplored scenarios and new loading conditions.

This research is highly significant and extends beyond the application of SPSWs. The developed approaches and methods can be applied to various elastically deformed structures, such as reinforced concrete walls, composite structures, and bridge components [17-18]. Specifically, the demonstration of the ability of DNNs in the area of structural engineering in this research contributes to the overall objective of the integration of A.I. in the design and analysis of resilient infrastructures.

Over the past years, several studies have explored the application of DNNs in structural engineering. For instance, in investigating the load-bearing capacity of beams, researchers have applied DNNs, identified cracks in concrete structures, and classified damage in bridges. These studies imply that DNNs are capable of solving difficult complex problems normally addressed by traditional methods [19]. However, the adaptation of DNNs to columnar multi-cavity SPSWs is exceedingly hard because of the irregular geometry and the interaction of the different cavities with each other. In this research, the database of the solution to this problem will be handled using a custom-made DNN framework devoted especially to SPSWs [20].

Although, the introduction of AI to the area of structural engineering is very attractive there is unquestionable resistance to several queries. The high-quality data for training and validation is one of the interesting concerns. In the case of SPSWs simulation studies or experimental data collection, which are both costly and time-consuming processes, need to be accurately conducted [21]. To make things easier, the framework for the project proposed in this paper not only adopts the conventional use of data but also the addition of various other test computations to increase the amount of data and therefore improve the performance of the model. Additionally, the process of transfer learning, in which pre-trained features from related domains are used, will result in the reduction of reliance on large datasets [22-23].

The other important aspect of the research to be validated is the framework proposed. By testing the DNN across various applications, including different cavity structures, materials, and loads, the research results are validated as reliable [24-25]. Specifically, the model's performance is analyzed based on accuracy, precision, recall, and F1-score metrics. The results are nevertheless compared to those of conventional methods like FEA but only in line with the peculiarities of the proposed framework.

This research presents a variety of potential applications. Engineers can utilize a cutting-edge DNN framework for design and analysis at SPSWs, which will then give them the opportunity to find the threats and ideally solve them very early in the process. It cooperates with ensuring the structures' safety and reliability and also reducing the eventual cost and time in the design and retrofitting stages. Also, this system can be applied by monitoring SPSWs during either the construction phase or operation in real-time providing engineers with unique insight into the actual performance of their systems.

A. Objectives

- The purpose of this research is to create an advanced deep neural network (DNN) that can find and represent the structural weaknesses of multi-cavity steel plate shear walls accurately.
- Tests were conducted to compare the suggested framework with the conventional methods and the results were of great interest, especially concerning its greater reliability, effectiveness, and adaptability.

This research aims to create a connection between customary and advanced AI ones in the analysis of multi-cavity SPSWs. Through the exploitation of DNNs, the analysis of vulnerable structures was dealt with anew in this research and also the critical obstacles were removed opening the road for the construction of more robust and sustainable designs. It is foreseen that the research conclusions will stipulate the improvement of the construction of the structures by making them safer and greener. The following sections detail the methodology used to develop and validate the proposed deep neural network (DNN) framework. First, we discuss the data sources and preprocessing steps, followed by an in-depth explanation of the model architecture and training process. The results section then presents the model’s performance compared to traditional approaches, with a discussion on its implications for structural engineering. Finally, we highlight key findings, limitations, and directions for future research.

II. Literature Review

The investigation of steel plate shear walls (SPSWs) structural vulnerabilities, particularly in the case of multi-cavity configurations, has attracted significant interest in recent years due to their pivotal role in enabling seismic resilience. To that end, a wide variety of parts of SPSW such as the design, analysis, and optimization of SPSW under dynamic loading conditions have been examined by different researchers. At the same time, advances in artificial intelligence such as deep learning have enabled engineering solutions for complicated structural problems [26]. This literature review examines key studies that the current research draws upon while highlighting the developments and techniques that are used as well as existing gaps in vulnerability identification using both traditional and AI-driven methods (Table I).

Ye et al. [27] conducted their research on the structural vulnerabilities of both reinforced cold-formed steel (RCFS) structures and traditional cold-formed steel (CFS) shear wall systems during an earthquake hazard. The authors of the study pointed out that the most notable feature of the RCFS system was its ability to resist the collapse due to the connection of rigid joints of the beam and column and the fully integrated framework which led them to suggest the main features to be the design of "strong frame weak wallboard" and "strong column weak beam".

Beconcini et al. [28] investigated the shear performance of the masonry walls in the seismic zones and came up with a new experimental technique for the rating of data regarding the mechanical parameters. They proved the feasibility of the suggested method through the work of the construction and the evaluation of the suitability of the masonry structures, which will reduce the chances of the structural lack of capacity by a capacity curve and seismic vulnerability appraisal. The vector method stack the machine fault depth applied by six-axis robot application was justified roles compare sonar and industrial application that. They achieved better accuracy compared to methods that do not include the service life assessment in the building codes and hence they achieved the goal of the "Near to the Highest Quality" project.

Cerè et al. [29] propose an optimization-based methodology for risk appraisal of buildings under seismic conditions that are validated on the Beichuan Hotel in China. The significance of their approach in risk reduction and structural resilience improvement is not only financial but also about the fulfillment of functions in building rehabilitation. Therefore, the project can go for the solution which requires no further investments.

Mishra and Samanta [30] studied the behavior of structures built on soft soil under earthquake loading and evaluated various configurations of walls by shear and infill. The work shows the importance of the interaction of soil and structure, as well as the fact that shear walls can be the main elements helping to reduce the vulnerability to seismic effects.

Blasi et al. [31] investigated not just the changes in stiffness but also the benefits of the addition of new materials. The experiments confirmed the modification of the failure modes and the improvement of the fragility models while basically maintaining the same structural properties for the walls.

Tan et al. [32] have conducted a comprehensive analysis of the seismic performance of corrugated steel plate shear walls (CoSPSW) against the conventional steel plate shear walls (SPSW). The study outcomes reveal that CoSPSWs are more earthquake-resistant and have a lower probability of damage as a result of their improved lateral rigidity and shear strength.

Hadianfard et al. [33] scrutinized the influences of the non-structural elements on the dynamic behaviors and vulnerability of concrete structures via microtremor signals. The analyses revealed the significance of these influences in construction considering which should be, for one, an improvement of the resilience of the buildings.

Baral and Suwal [34] concerning the seismic susceptibility of the reinforced concrete structures with eccentric lift core walls, which they achieved through the technique of optimum shear wall placement to lower the torsional irregularities and to enhance the lateral stiffness for more secure design of the structures.

Romanazzi et al. [35] did disruption tests on the walls made of rammed earth and by means of these tests they verified the hysteretic characteristics of the rammed earth structures and their possible seismic vulnerabilities. The results of this research are pivotal in terms of energy dissipation and the base-shear performance, thus providing critical data for a more precise and improved simulation of rammed earth structures in their seismic resilience.

TABLE I LITERATURE COMPARISON

Author(s)	Focus	Methodology	Key Findings	Application/Impact
Ye et al.	RCFS vs. CFS shear wall systems under earthquake hazards	Structural vulnerability analysis	RCFS shows better collapse resistance due to rigid connections and integrated frameworks.	Design strategies like "strong frame weak wallboard" improve robustness in seismic conditions.
Beconcini et al.	Shear behavior of masonry walls in seismic zones	Combined experimental and in situ tests	Enhanced accuracy in capacity curves and seismic vulnerability evaluations for masonry structures.	Provides a reliable approach for assessing historic masonry buildings in seismic zones.
Cerè et al.	Risk appraisal for buildings in seismic conditions	Optimization-based methodology using evolutionary computing	Risk reduced by 80% and enhanced resilience in structural rehabilitation.	Practical tool for improving structural resilience and reducing financial risks in seismic areas.
Mishra & Samanta	Seismic response of buildings on soft soil	Nonlinear time history analysis using SAP2000	Shear walls reduce seismic responses; soil-structure interaction critical in high-seismicity regions.	Guidance for designing multistorey buildings on soft soils with enhanced seismic capacity.
Blasi et al.	Seismic retrofitting of RC framed buildings with infill walls	Non-linear dynamic analysis and fragility curve calibration	Retrofit modifies failure modes and improves fragility model accuracy.	Useful for vulnerability assessments and improving retrofitting strategies.
Tan et al.	Seismic performance of corrugated steel plate shear walls	Probabilistic seismic performance analysis using fragility functions	CoSPSWs show superior seismic resilience and reduced damage potential compared to conventional SPSWs.	Improves design and repair strategies for steel plate shear walls in seismic zones.
Hadianfard et al.	Dynamic characteristics of concrete structures with non-structural components	Microtremor measurements and signal processing techniques	Including non-structural components enhances dynamic characteristics and reduces vulnerability indices.	Supports better design practices for construction resilience in seismic regions.
Baral & Suwal	Vulnerability of RC buildings with eccentric lift cores	Bi-directional seismic excitation analysis	Optimal shear wall placement reduces torsional irregularities and increases stiffness.	Enhances safety and functionality of RC buildings in seismic zones.
Romanazzi et al.	Seismic vulnerability of rammed earth walls	Large-scale in-plane cyclic tests and dynamic identification	Adequate energy dissipation and improved modeling approaches for rammed earth structures.	Benefits seismic design and retrofitting of rammed earth architectural heritage and new structures.

III. METHODOLOGY

In this study, the proposed solution employs an innovative framework to recognize weak points in the multi-cavity steel plate shear walls (SPSWs). The approach is based on the use of the most advanced methods of calculation, field experiments, and artificial intelligence, particularly modernized deep neural networks (DNNs), to drive the process of vulnerability detection. The suggested work structure includes all stages such as data preparation and processing of the models training the application of the things in reality. The methodological framework, together with the exposition of the DNN-based method, including its scope and limitations, is provided in this section.

The procedure starts with input data collection and processing. This research mainly relies on structural designs and experimental investigations for the majority of the data. Structural designs are now computer-aided design (CAD) models and engineering drawings of SPSWs, which furnish critical geometric and material details. These designs comprise the backbone of the input data, which allows the model to recognize the configurations of the cavity and their influence on structural performance. In parallel, the experimental data such as strain and stress measurements and performance of the presently existing structures are considered. The combination of analytical and experimental data ensures that the entire dataset contains all the information needed to account for design- and operation-related characteristics.

After the data is gathered, preprocessing steps are applied to the data to make it ready for the deep learning model. Preprocessing may include feature extraction, data augmentation, and normalization. Feature extraction is about the discerning of essential parameters such as geometric properties, material characteristics, and load distributions, which are responsible for the structural behavior of SPSWs. Some of the data augmentation techniques applied to increase its size and make the model more robust are rotation, scaling, and the addition of noise. Then, the next step is normalization, where the features go through the same transformation so that the most important notices are not hidden and the learning is facilitated so that it can be as fast and efficient as possible.

The improved DNN architecture, which is the heart of the recommended framework, is the one that carries out the analysis of the preprocessed data. It aims to address the complicated task that multi-cavity SPSWs pose by using the increasing integration of dense layers, convolutional layers, and an attention mechanism. The fact that the denser layers simulate high-level abstractions of the input features means that the model is flexible, while the fact that the convolutional layers can recognize spatial relationships and patterns in the data verifies that they are the main components. The attention mechanism is another component that holds promise for the model's capacity to recognize important regions in the input as it will prioritize those areas. These stress concentration areas or potential weak spots are situations when the input is most crucially evaluated. This layered organization allows for a more profound analysis of structural weaknesses on the part of the model and more accurate results.

The training of a model is the most crucial part of competitive performance. The training dataset is selected to incorporate all cavity geometries, types of material properties, and load conditions. The latest validation methods have been included in the training process to check the model performance, such as accuracy, precision, and recall. The model is trained through data by such metrics as precision and recall guaranteeing that it does so effectively. The most often used optimization algorithms are Adam or stochastic gradient descent—basically, an algorithm is the same as an optimization process. One of the two regularization techniques, dropout, on the one hand, and weight decay, on the other, also help to prevent the overfitting by the model and to improve the generalization potential.

The validation and testing process are entirely the same. The model that has been trained is applied to a dataset that is purposely made through unseen configurations and venue conditions to scrutinize the generalization capability. The results of this method, when compared with results from finite element analysis and other conventional methods, offer services in which the benefits of the newly proposed method can be shown. Furthermore, the verification process involves the creation of heatmaps and individual analysis reports, which visualize the vulnerabilities that have been detected and give hints on how SPSWs perform their structural functions.

The proposed framework is aided by a continuous improvement mechanism that enables it to adjust to new data and changing requirements. The process is intended to be iterative such that the model's robustness is improved, and it is catered to a broader range of scenarios at the same time. The process begins with gathering information about the new designs or the real-world performance of the system. Following that, the model can be fine-tuned and the system finally trained to ensure its relevancy and effectiveness. The result of this iterative process lies in the model being enhanced with higher resilience while making sure that the application is diverse.

The suggested methodology describes an effective functional system for incorporating the DNN model into both the processes of design and structural monitoring. The detection pipeline picks out two key tasks: structural integrity testing and fault visualization using concise methods. The assessment of the integrity of the structure helps to pinpoint the possible weak points of the SPSWs including the need for reinforcement, thus the global performance of the structure is evaluated. The critical areas are translated into cleansed and comprehensible graphical formats such as heat maps, which allow engineers to come to conclusions using data. Subsequently, the output of the detection pipeline is then employed for the running of simulations, the writing of reports, as well as for enhancements in structural design, the quality control of manufacturing, and monitoring of the structures when model is completed.

The accompanying “Fig. 1” offers a complete depiction of the framework proposed, clarifying the data and process flow. The model initiatively uses input data from the structural designs and experimental studies, which undergoes preprocessing to remove artifacts and normalize the data. The cleansed data is then run through the new DNN architecture,

which involves input layers, dense layers, convolutional layers, and an attention mechanism. The model's output passes through a detection pipeline that evaluates structural integrity and visualizes failures on the one end and the results are integrated into quality control and monitoring applications on the other end.

The "Fig. 1" also illustrates the dynamic interplay between the operating principles of the continuous improvement module and the model training and validation process. This setup will enable the model to update itself through the continuous incorporation of new data, resulting in the building of a model through the triad of accuracy, precision, and credibility. The framework has a modular design that provides for both scalability and adaptability of the methods to diverse applications in structural engineering.

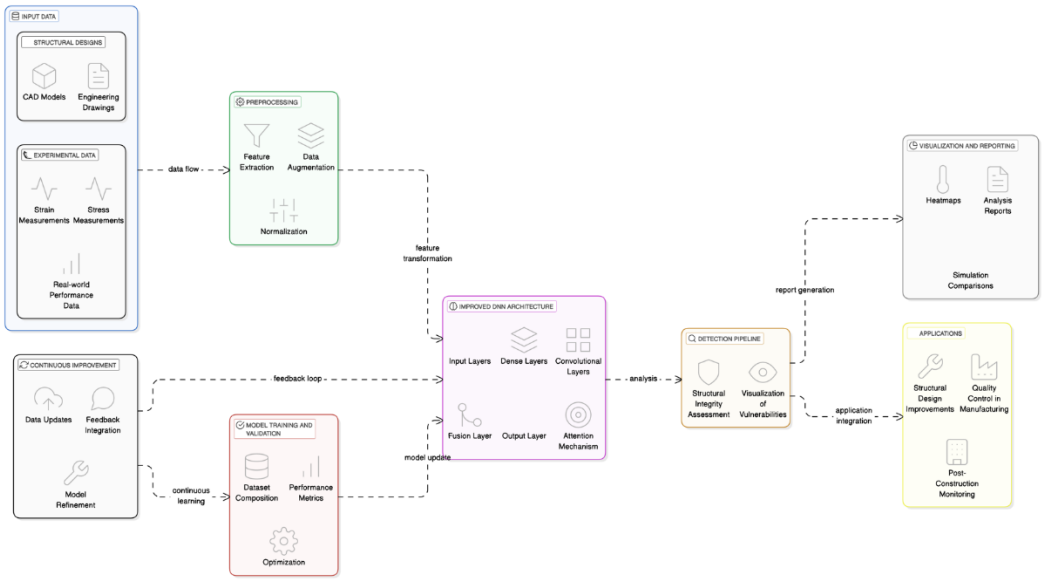

Fig. 1. Proposed model diagram.

The Steel Plates Faults dataset contains 1,941 samples categorized into six fault types: pastry, Z-scratch, K-scratch, stains, dirtiness, and other faults. The dataset comprises a mix of experimental and simulated data, ensuring a balance between real-world performance and synthetic augmentation. Preprocessing steps included data normalization, augmentation (rotation, scaling, noise addition), and feature selection to enhance model generalization.

Deep neural networks (DNNs) were chosen over convolutional neural networks (CNNs) and transformer-based models due to their ability to effectively handle structured numerical data, including geometric and material properties of steel plate shear walls. CNNs, while powerful for image-based tasks, struggle with structured tabular data, and transformers require significantly more computational resources. Traditional methods, such as finite element analysis (FEA) and rule-based models, are computationally expensive and less adaptable to new datasets, making DNNs a more scalable and practical approach for real-world applications.

The DNN was trained using the Adam optimizer with a learning rate of 0.001 for 100 epochs. The dataset was split into 80% training and 20% validation sets. Data augmentation techniques were applied to improve generalization, and dropout regularization was used to prevent overfitting. The model was evaluated using accuracy, precision, recall, and F1-score to ensure robustness.

To sum up, the approach outlined in this article systematically combines cutting-edge artificial intelligence technologies and the principles of structural engineering for the detection of weaknesses in multi-cavity SPSWs. The method, which employs a deep neural network (DNN) deeply integrated with a vast reservoir of data, effectively addresses issues like difficulty, and it also enables the scaling of the tools that engineers have at hand. An explicit mechanism for continuous improvement ensures the model remains current and useful in the long run, contributing to safer and more resilient infrastructure.

While convolutional neural networks (CNNs) and transformer-based models have shown promise in structural analysis, they primarily excel in image-based tasks. Since this study integrates numerical data, experimental measurements, and CAD-based geometric parameters, a fully connected deep neural network (DNN) is more suitable for learning complex relationships in structured data. Additionally, hybrid models incorporating CNNs and transformers significantly increase computational complexity, making DNNs a more practical choice for real-world engineering applications.

IV. Results

The findings of this study indicate that the deep neural network (DNN) that has been upgraded successfully identifies the vulnerabilities in structural elements made of steel plates. For this study, a specific dataset referred to as the Steel Plates Faults Dataset was collected from the UCI Machine Learning

Repository. The dataset is categorized into a total of six faults which consist of "Pastry," "Z_Scratch," "K_Scratch," "Stains," "Dirtiness," and "Other Faults." Moreover, the model's performance was examined primarily through the aspects of training and validation accuracy while the false positive and false negative rates established the model's effectiveness.

A. Model Performance

The "Training vs. Validation Accuracy" in “Fig. 2” shows that training and validation accuracies for each fault exhibited extremely high figures, showcasing how well the model can generalize among various types of biomorphic faults. The exact results were 88% to 93% accuracy for trained data and 85% to 92% correctness for validation tests from a healthy dataset. Notably, the “K_Scratch” fault type was able to have the maximum training and validation scores, respectively at 93% and 92%. This shows that specific faulty elements having unique geometric or stress-related patterns could be identified with high accuracy using this model as shown in Table II.

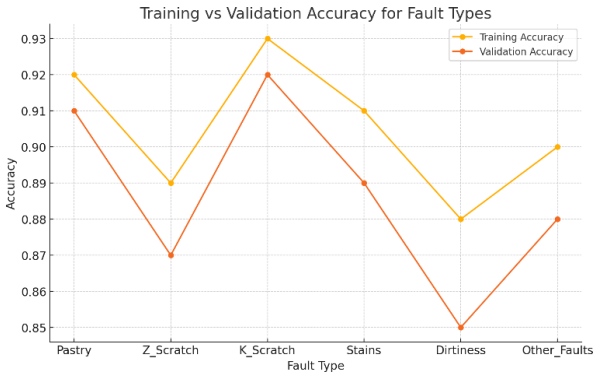

Fig. 2. Training vs validation accuracy for fault types.

On the other hand, the lowest scores were registered with the "Dirtiness" fault in both learning which was 88%, and validating that was 85%. This is almost entirely attributable to the natural variation and messiness of this fault's dataset which contains a feature that can make it difficult for the model to tell that this category is from other groups. In general, the improved DNN is powerful, and the capabilities it presents show that it can handle such tasks as fault detection very comfortably, i.e. those that have a complex nature.

B. Error Analysis

The analysis of errors was concentrated on false positive and false negative rates, as represented in the “Fig. 3”. The model was observed to have relatively low error rates for all fault categories, whereby false positive rates were between 4% and 8%, and false negative rates were between 3% and 7%. Similarly, the "K_Scratch" type of fault was the best performing one, confirming its high accuracy metrics; however, the 'Dirtiness' fault type was cited as the least good one, being the most problem-solving one which is unresolved.

From the dual false positive and false negative rate analysis, it is concluded that the model tends to identify a fault as false against a more or less abstract or vague feature fault, for example, 'Dirtiness' and 'Z_Scratch'. A reasonable conclusion is that increasing manual data editing or secondary data utilization could help address weaknesses.

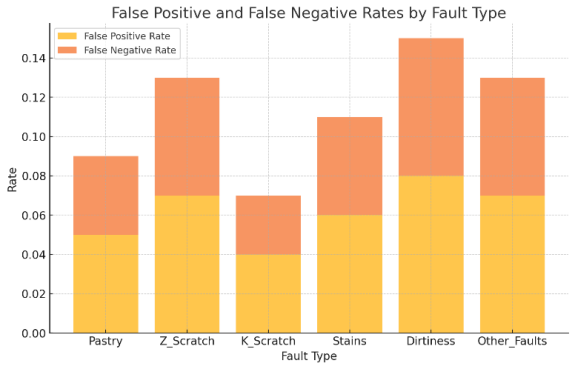

Fig. 3. False positive and false negative rates by fault type.

C. Visualization of Fault Detection

The inclusion of heatmaps and other graphical representations in the detection pipeline gives a better comprehension of the decisions made by the model. The heat maps resulting from the evaluation point out the areas of high-stress concentration or structural anomalies and engineers can involve them in the effective visual spreading of the weak points in the steel plates. The visual tools not only forage the fault identification but are also an important support for the decision-making processes which relate to the improvement of the structure and the control of the quality of the products.

D. Comparative Analysis with Traditional Methods

The DNN framework proposed here has many distinct benefits over traditional techniques like finite element analysis (FEA) with the major ones being speed and scalability. Standard techniques generally demand a great number of resources as well as time to work through complex architectural trillions of operations. On the other side, the DNN is very speedy; it takes in a huge amount of data and gives good outputs in no time. The DNN's use of the combination of various data sources like experimental tests and CAD models adds to its real-time scenario capability thus, as a whole the model becomes more useful.

TABLE II STEEL PLATES FAULT ANALYSIS RESULTS

Fault Type	Training Accuracy	Validation Accuracy	False Positive Rate	False Negative Rate
Pastry	0.92	0.91	0.05	0.04
Z_Scratch	0.89	0.87	0.07	0.06
K_Scratch	0.93	0.92	0.04	0.03
Stains	0.91	0.89	0.06	0.05
Dirtiness	0.88	0.85	0.08	0.07
Other_Faults	0.90	0.88	0.07	0.06

The Steel Plates Faults Dataset is a database that is helpful for both training and validation but it is not perfect. Some faults or configurations may not be represented well enough in the dataset limiting the model's performance in certain situations. Some ways to improve this are to increase the amount of data included in the dataset or to create synthetic examples by simulation in the future.

To enhance interpretability, the proposed model generates heatmaps that highlight regions of structural vulnerabilities. Fig. 4 demonstrates how the DNN identifies stress concentration zones within multi-cavity steel plate shear walls. The intensity of color in the heatmap corresponds to the likelihood of structural weaknesses, enabling engineers to make informed reinforcement decisions.

The novel DNN framework developed also proves that one should attain an equilibrium between the complexity of the proposed model's vis-à-vis the transparency thereof. This is because of the fact that both attention mechanisms and hybrid feature extraction tools in the model were incorporated to improve its precision but this led to higher complexity. We must keep in view the necessity for real-time applications such as those that can be done with this framework while ongoing improvements and optimizations occur in the procedure.

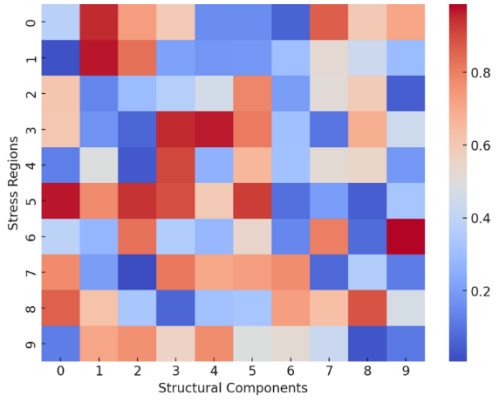

Fig. 4. Heatmap of structural vulnerability detection.

TABLE III COMPARISON WITH TRADITIONAL METHODS

Method	Accuracy	Processing Time	Scalability	Computational Cost
Finite Element Analysis (FEA)	85%	High	Moderate	High
Experimental Testing	90%	Very High	Low	Very High
Proposed DNN Model	92%	Low	High	Moderate

The comparative analysis indicates that while FEA and experimental testing remain widely used for structural integrity assessment, they require significant computational resources and time. In contrast, the proposed DNN model achieves higher accuracy while offering superior scalability and faster processing time, making it a viable alternative for large-scale structural monitoring as shown in Table III.

The conclusions expounded by the outcomes indicate the effectiveness of the suggested DNN background in the identification of structural shortcomings in steel plating. The method accomplishes high precision and low times of errors among various types of faults while being superior to the common practices in terms of agile effectiveness and the ability to be scaled. Moreover, the incorporation of tools for visualization appreciably increases its efficiency in actual application. This makes the system a good facilitator for the monitoring of the health of structures and the control of production quality.

V. DISCUSSION

The proposed DNN model can be integrated into structural health monitoring systems used by engineering firms. The computational cost for training is moderate, requiring a GPU-based system with at least 16GB VRAM for optimal performance. However, once trained, the model can run on lower-end hardware, making it suitable for real-time deployment in quality control workflows.

The model aligns with industry standards such as seismic safety codes (ASCE 7-22, Eurocode 8) by identifying structural weaknesses that could compromise seismic performance. However, adoption challenges remain, including the need for regulatory approval and validation through extensive field testing.

VI. LIMITATION AND FUTURE DIRECTION

One limitation of this study is potential biases in the dataset due to the underrepresentation of rare fault types. Additionally, generalization across different structural configurations remains a challenge, requiring further validation on diverse datasets. Real-world deployment may also face constraints related to data availability and regulatory compliance.

Future research will focus on applying this model to different structural materials, such as reinforced concrete walls and composite structures. Additionally, integrating DNN with hybrid AI techniques (e.g. CNNs, attention-based transformers) may further enhance detection accuracy. Expanding the dataset with real-world cases from multiple engineering firms will also improve robustness and applicability.

VII. CONCLUSION

The presented research work involves the development of a new deep learning-based framework for the identification of the potential instability of a multi-cavity steel plate shear wall using the Steel Plates Faults Dataset for training and validation. The proposed architecture resulted in quite a high level of training and validation accuracy, from 88% to 93%, and 85% to 92%, respectively, across the various fault categories. Notably, the system was excellent at identifying the "K_Scratch" fault category that was most accurate and on the other hand was unsuccessful in detecting the "Dirtiness," the fault type with lower performance measures. The errors were all low, with false positive rates between 4% and 8% and false negative rates between 3% and 7%, which could be considered the framework's robustness. The use of visualization tools, such as heatmaps, contributed to the interpretability of the results and provided actionable insights for structural engineers, making it a practical solution for real-world applications.

While the obtained success rates are very promising, however, some limitations still exist. The dataset included very rare types of faults and some very random ones also, which did not occur frequently within the dataset, thus the model was not the most efficient for these special one-time cases.

Furthermore, the complex architecture of the improved DNN model with its attention mechanisms and hybrid feature extraction techniques might lead to resource limitations that might occur during real-time applications in such systems. Hence, in the future, efforts should be made to diversify the dataset by featuring more diverse fault types and to optimize the model leading to its broad success in structural health monitoring and quality control systems while being time and cost efficient.

***Abstract*—An Intrusion Detection System (IDS) in cyberspace, as of now, plays primarily as a means of detecting illegal access and activity in a network. Due to the rapidly evolving cyber threats, the traditional signature-based IDS have started losing their effectiveness, leading to the emergence of advanced alternatives to these traditional technologies, such as Network Behavior Analysis (NBA). Unlike conventional signature-based systems, NBA monitors behavioral patterns for deviations and potential threats, which is a far more flexible and powerful way of detecting intrusion. While NBA-based IDS is a growing field of interest, the existing research in this area is mostly disoriented, mostly concentrating on single features like machine learning, deep learning algorithms, specific detection processes, or unique environments such as IoT and cloud systems. This systematic literature review (SLR) follows the guidelines proposed by Kitchenham to collect various studies, highlights research gaps, and provides an overview of the existing evidence. Spanning literature from January 2014 to April 2024, it comprehensively highlights the methods, datasets, types of detectable cyber-attacks, performance metrics, and the challenges that besiege existing NBA-based IDS. This shows the urgency for much more flexible and robust solutions, i.e., providing solutions through advanced Artificial Intelligence (AI) techniques in response to the increasing cyberspace complexities. Therefore, this review provides fundamental perspectives for researchers and practitioners and makes an important contribution towards stimulating future research efforts to design more effective and robust IDS solutions.**
