Appendix: Full Proof of Convergence for SSFed Aggregation Using Lyapunov Function Method

In this appendix, we present a detailed proof of convergence for the proposed SSFed aggregation method using the Lyapunov function technique. The goal is to show that the adaptive weighting approach used by SSFed ensures convergence to a neighborhood of the global optimum.

A. Lyapunov Function Setup

To analyze convergence, we define a Lyapunov function $V^{(t)}$ that captures the error dynamics of the model at each round t. Specifically, let

$$V^{(t)} = \mathbb{E}\left[F(\theta^{(t)}) - F(\theta^*)\right],$$

where $\theta^{(t)}$ is the model parameter vector at round t, and θ^* is the optimal parameter vector that minimizes the global objective $F(\theta) = \frac{1}{K}\sum_{i=1}^{K} f_i(\theta)$.

B. Assumptions

We make the following assumptions, consistent with the federated learning literature:

1. **Smoothness**: Each client's local objective $f_i(\theta)$ is β-smooth, meaning

$$\|\nabla f_i(\theta) - \nabla f_i(\theta')\| \leq \beta\|\theta - \theta'\|, \quad \forall \theta, \theta'.$$

2. **Bounded Variance**: The gradient variance across clients is bounded. Specifically, there exists a constant σ^2 such that

$$\mathbb{E}\|\nabla f_i(\theta) - \nabla F(\theta)\|^2 \leq \sigma^2.$$

3. **Statistical Significance-Based Weighting**: The weights $w_i^{(t)}$ are determined based on statistical significance using z-scores, with $w_i^{(t)}$ satisfying $0 \leq w_i^{(t)} \leq 1$ and normalizing across clients.

C. Main Result

Theorem 2. *Under the smoothness and bounded variance assumptions, SSFed converges to a neighborhood of the global optimum. Specifically, after T rounds, we have*

$$\mathbb{E}\left[F(\theta^{(T)}) - F(\theta^*)\right] \leq O\left(\frac{\beta\sigma^2}{KT}\right),$$

where K is the number of clients and T is the total number of communication rounds.

Proof:

To establish convergence, we show that the expected decrease in the Lyapunov function $V^{(t)}$ over each round t is bounded, ensuring that the model converges toward the global minimum.

Bounding the Expected Error

Using the β-smoothness of f_i, we have:

$$f_i(\theta^{(t+1)}) \leq f_i(\theta^{(t)}) + \langle \nabla f_i(\theta^{(t)}), \theta^{(t+1)} - \theta^{(t)} \rangle + \frac{\beta}{2}\|\theta^{(t+1)} - \theta^{(t)}\|^2.$$

Taking the expectation and summing over clients, we obtain:

$$\mathbb{E}[F(\theta^{(t+1)})] \leq \mathbb{E}[F(\theta^{(t)})] + \frac{\beta}{2}\mathbb{E}\|\theta^{(t+1)} - \theta^{(t)}\|^2.$$

Error Due to Weighted Updates

The SSFed aggregation method applies weights $w_i^{(t)}$ based on the statistical significance of each client's update, leading to the weighted update $\theta^{(t+1)} = \theta^{(t)} + \sum_{i=1}^{K} w_i^{(t)}(\theta_i^{(t)} - \theta^{(t)})$. Expanding this, we get:

$$\theta^{(t+1)} = \theta^{(t)} + \sum_{i=1}^{K} w_i^{(t)} \nabla f_i(\theta^{(t)}) + \epsilon^{(t)},$$

where $\epsilon^{(t)}$ denotes the accumulated error due to weighted averaging and gradient variance. By the bounded variance assumption, $\mathbb{E}[\|\epsilon^{(t)}\|^2] \leq \frac{\sigma^2}{K}$.

Lyapunov Function Decrease

Define the Lyapunov function difference as $\Delta V^{(t)} = V^{(t+1)} - V^{(t)}$. From the smoothness and weighted update bounds, we have:

$$\mathbb{E}[\Delta V^{(t)}] \leq -\eta \sum_{i=1}^{K} w_i^{(t)} \|\nabla f_i(\theta^{(t)})\|^2 + \frac{\beta\eta^2\sigma^2}{2K}.$$

Since $w_i^{(t)}$ are adaptive and emphasize updates with significant gradients, we further bound $\|\nabla f_i(\theta^{(t)})\|^2$ by the global gradient $\nabla F(\theta^{(t)})$, giving:

$$\mathbb{E}[\Delta V^{(t)}] \leq -\eta \|\nabla F(\theta^{(t)})\|^2 + \frac{\beta\eta^2\sigma^2}{2K}.$$

Summing Over Rounds

Summing $\mathbb{E}[\Delta V^{(t)}]$ from $t = 1$ to T and using telescoping, we obtain:

$$\mathbb{E}[V^{(T)}] - \mathbb{E}[V^{(0)}] \leq -\eta \sum_{t=1}^{T} \|\nabla F(\theta^{(t)})\|^2 + \frac{\beta\eta^2\sigma^2 T}{2K}.$$

Rearranging terms, we find:

$$\frac{1}{T}\sum_{t=1}^{T} \mathbb{E}\|\nabla F(\theta^{(t)})\|^2 \leq \frac{V^{(0)} - V^{(T)}}{\eta T} + \frac{\beta\eta\sigma^2}{2K}.$$

Convergence to a Neighborhood of the Optimum

By setting $\eta = O\left(\frac{1}{\beta}\right)$, we achieve:

$$\frac{1}{T}\sum_{t=1}^{T} \mathbb{E}\|\nabla F(\theta^{(t)})\|^2 = O\left(\frac{\beta\sigma^2}{KT}\right).$$

Thus, after T rounds, the model converges to a neighborhood of the global optimum, completing the proof. ■

Image-Based Air Quality Estimation Using Convolutional Neural Network Optimized by Genetic Algorithms: A Multi-Dataset Approach

***Abstract*—Air pollution poses significant threats to human health and the environment, making effective monitoring increasingly essential. Traditional methods using fixed monitoring stations have challenges related to high costs and limited coverage. This paper proposes a new approach using convolutional neural networks with genetic algorithms for estimating air quality directly from images. The convolutional neural network is optimized using genetic algorithms, which dynamically tune hyperparameters such as learning rate, batch size, and momentum to improve performance and generalizability across diverse environmental conditions. Our approach improves performance and reduces the risk of overfitting, thus ensuring balanced and robust results. To mitigate overfitting, we implemented dropout layers, batch normalization, and early stopping, significantly enhancing the model's generalization capability. Specifically, three different open-access datasets were combined into a single training dataset, capturing extensive temporal, spatial, and environmental variability. Extensive testing of the model performance was conducted with a broad set of metrics, including precision, recall, and F1 score. The results demonstrate that our model not only achieves high accuracy but also maintains well-balanced performance across all metrics, ensuring robust classification of different air quality levels. For instance, the model achieved a precision of 0.97, a recall of 0.97, and an overall accuracy of 0.9544 percent, outperforming baseline methods significantly in all metrics. These improvements underscore the effectiveness of Genetic Algorithms in optimizing the model.**

***Keywords*—Convolutional neural network; Genetic Algorithm; air quality estimation; image processing**

I. Introduction

Air pollution is a major environmental risk that has increasingly become a critical issue, posing significant health threats and adverse effects on the environment [1]. The main group of air pollutants includes particulate matter (PM), specifically classified as PM10 (particles with aerodynamic diameters less than 10 μm) and PM2.5 (particles with aerodynamic diameters less than 2.5 μm), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), oxides of nitrogen (NO_x), and carbon monoxide (CO) [2]. The World Health Organization (WHO) estimates that air pollution contributed to approximately 4.2 million premature deaths worldwide in 2016 [3]. Estimating air pollution emissions is crucial to controlling air pollution [4]. However, many traditional methods developed for this purpose are now outdated and rely on expensive, region-specific fixed stations that often fail to provide comprehensive real-time data.

Recent advances in computer vision and deep learning offer a promising alternative to these conventional methods. The increasing presence of cameras in public spaces, vehicles, and personal devices presents an opportunity to leverage image data for air quality estimation. Convolutional Neural Networks (CNNs), which excel in extracting and analyzing complex visual features, are powerful tools for tasks such as image recognition [5]. They have been increasingly applied in environmental monitoring [6]. In recent years, image-based methods have been proposed to detect air quality, which have demonstrated good accuracy in specific scenarios [7]. However, despite their potential, CNNs often struggle to generalize in diverse environmental conditions due to limited data set diversity and static hyperparameter configurations. Previous studies, such as those conducted by Zhang et al. [8] and Song et al. [9], have successfully demonstrated the feasibility of using CNNs to estimate air pollution levels from images. Recently, numerous articles have been published on estimating air quality from image datasets. However, these approaches often face limitations due to the narrow scope of datasets and challenges in optimizing hyperparameters, which can constrain their broader applicability.

This paper addresses these gaps by presenting a novel approach to air quality estimation that combines the power of CNNs with Genetic Algorithms (GA) to dynamically optimize hyperparameters and enhance model performance. By integrating three diverse open-source datasets, covering a wide range of temporal and spatial variations, our model can perform well under different environmental conditions. This comprehensive dataset includes images captured at different times of the day, in various weather conditions, and in multiple geographic locations, providing a solid foundation for accurate air quality prediction.

A key innovation of our approach shown in Fig. 1 lies in the integration of GA with the CNN framework. The GA component dynamically optimizes CNN's hyperparameter, such as learning rate, batch size, and momentum, to achieve optimal performance. This evolutionary technique allows the model to adapt to various environmental scenarios, significantly improving its accuracy and generalization capabilities. By leveraging this hybrid approach, our model not only achieves high accuracy but also maintains balanced performance across multiple evaluation metrics, making it a powerful tool for real-time air quality monitoring.

The remainder of this paper is structured as follows: Section II reviews related works on air quality estimation, highlighting not only the limitations of traditional methods but also the recent advancements in image-based approaches. Section III details the proposed method, including data collection, preprocessing, and the CNN-GA framework. Section IV presents the experimental setup and the performance evaluation, followed by a discussion of the results obtained in Section V. Finally, Section VI concludes the paper and suggests directions for future research.

II. Related Work

This section reviews both traditional and modern image-based methods used for air pollution estimation.

A. Traditional Methods

Various traditional methods have been developed over the past few decades to estimate air quality. These can be further divided into two major groups, namely, ground-based monitoring and modeling techniques.

In ground-based monitoring, air pollutants are generally monitored using fixed stations installed by environmental or government institutions [10]. Common types of air pollutants monitored include PM2.5, PM10, NO2, SO2, CO, O3, and VOCs [11]. However, this sparse network of regulatory monitoring stations is usually not sufficient for mapping out spatial variations in air pollutants among a considerable population in urban areas. These networks cannot provide high-resolution data for the efficient management of air quality and exposure [11], [12]. Besides, conventional methods of monitoring are costly and cannot capture the temporal-spatial heterogeneity of urban pollution, which restricts their ability to find hotspots of pollution and further management thereof [12].

Common modeling techniques include deterministic and statistical models. Deterministic models use known, based, and expressed mathematical relationships concerning processes underlying CTMs in order to model the emission, transport, transformation, and removal by deposition from the atmosphere [13].Their principal strength is that for sufficiently small scale and homogeneity, they are capable of predicting, with a high spatial resolution, very detailed quantitative data regarding the different complex atmospheric flow phenomena transporting various constituents with pollutants. However, these models presuppose considerable a prior knowledge in the form of reliable and extensive data with respect to atmospheric conditions and sources of pollutants [14]. The use of idealized assumptions and detailed input often makes these models inapplicable and less accurate, especially in regions where small-scale atmospheric data is not available. Besides, deterministic models are computationally intensive, hence unsuitable for real-time applications.

They do not use detailed representations of physical and chemical processes. They rather attempt to find the factorial relationship that exists between a set of factors influencing air pollutant concentrations using statistical techniques. These methods are usually divided into two broad methods: classical methods or traditional machine learning. The important representative classical methods include the ARIMA model [15]–[17]. Among the machine learning methods, ANN is widely used as it simulates the human brain's system for nonlinear sequence modeling. After years of research and application, more advanced versions have evolved for air pollution prediction, such as the Backpropagation Neural Network (BPNN) [18], the Generalized Regression Neural Network (GRNN) [19], and the ensemble ANN approach [20].

Despite their advancements in improving prediction accuracy, statistical methods often struggle to capture complex, nonlinear spatio-temporal correlations and tend to learn only shallow features [14]. Additionally, these models generally perform well only on small-scale datasets, making them less effective for large-scale and dynamically changing air pollutant data that require more sophisticated modeling of spatio-temporal relationships [21], [22]. This limitation also contributes to generalization gaps, where models trained on specific datasets may not perform adequately when applied to new or unseen environments, reducing their overall effectiveness in broad, real-world applications.

B. Image-Based Air Pollution Estimation Methods

Recent advancements in image-based air pollution estimation have leveraged the capabilities of deep learning techniques, particularly Convolutional Neural Networks (CNNs), to significantly enhance the accuracy and efficiency of air quality assessments. These methods provide a scalable, cost-effective alternative to traditional air quality monitoring systems, which are often constrained by high costs and limited spatial coverage.

One prominent approach involves the use of a Double-Channel Weighted Convolutional Neural Network (DCWCN), which processes different parts of an image, such as the sky and buildings, to extract relevant features separately. This technique enhances the accuracy of air quality estimation by focusing on distinct components of the environment, thereby addressing variability in image content due to factors like lighting and weather conditions. The DCWCN architecture includes two separate feature extraction networks for both channels, followed by a feature weights self-learning method that performs weighted feature fusion, combining the extracted features before classification [23].

Zhang et al. [8] developed a convolutional neural network (CNN) and improved both the convolutional layer and classification layer activation functions. They proposed a new activation function, EPAPL, and replaced the traditional SoftMax classifier with a Negative Log-Log Ordinal Classifier in the classification layer. This network was trained using environmental images to predict classifications, and it successfully performed the task of measuring PM2.5 and PM10 levels across six different grades.

One approach integrates Convolutional Neural Networks (CNNs) with regression classifiers to create a hybrid model (CNN-RC) that processes images and HSV (Hue, Saturation, Value) statistics to estimate PM2.5, PM10, and AQI levels. This multi-input multi-output (MIMO) framework has demonstrated significant improvements in estimation accuracy, particularly when handling both daytime and nighttime images. The model's effectiveness is attributed to its ability to deeply learn from high-dimensional datasets and the incorporation of HSV statistics, which play a crucial role in enhancing

the estimation reliability by correlating current images with baseline images [24].

The AQC-Net framework, as proposed by Zhang et al. [25], integrates a Convolutional Neural Network (CNN) with a Spatial and Context Attention (SCA) module to create a model that processes images captured by mobile devices to estimate air quality levels such as PM2.5, PM10, and AQI. This deep learning framework leverages ResNet18 for feature extraction, while the SCA module enhances the model's ability to capture global contextual information and inter-channel dependencies. The model has demonstrated significant improvements in classification accuracy, particularly by focusing on the spatial and contextual relationships within images, making it highly effective across various environmental conditions and locations. The model's effectiveness is attributed to its ability to deeply learn from scene images and the integration of the SCA module, which recalibrates feature maps for improved air quality estimation reliability.

This paper presents an innovative method for air quality estimation by integrating Convolutional Neural Networks (CNNs) with Genetic Algorithms (GAs) to dynamically optimize hyperparameters. The CNN is utilized for its robust feature extraction capabilities, enabling it to process images and estimate air quality indicators such as PM2.5, PM10, and the Air Quality Index (AQI). The approach is further strengthened by the amalgamation of three distinct open-source datasets into a single, comprehensive data set, which provides a broad spectrum of temporal and spatial variations for model training.

A significant contribution of this work is the application of GAs to optimize critical CNN hyperparameters, including learning rate and batch size, allowing the model to adapt effectively to diverse environmental conditions. This hybrid CNN-GA approach not only enhances the model's accuracy but also improves its generalization capabilities, making it particularly suitable for real-time air quality monitoring. The model's effectiveness was thoroughly assessed using key performance metrics such as Precision, Recall, F1-Score, and ROC-AUC, where it consistently demonstrated superior accuracy and a well-balanced performance across various environmental scenarios.

III. Proposed Method

This section details the methodology employed in this study, covering data collection, preprocessing, and the CNN-GA proposed model used for air quality estimation.

A. Data Collection and Preprocessing

To develop a robust and generalized CNN model for air quality estimation, we utilized three diverse, publicly available, open-source datasets. The selected datasets represent a diverse array of environmental conditions, including variations in geographical location, weather patterns, and lighting conditions. This diversity is crucial for training a model that can generalize well across different regions and times, making it adaptable for global application. In total, 12,902 images were collected from these datasets. The dataset was split into 80% for training and 20% for validation, ensuring a balanced distribution for model evaluation.

TABLE I. AQI Category Image Count Across Different Datasets

AQI Category	Dataset-A	Dataset-B	Dataset-C
Good	1541	135	58
Moderate	1573	188	52
Unhealthy for Sensitive Groups	2863	29	8
Unhealthy	2622	78	50
Very Unhealthy	2194	26	22
Hazardous	1447	0	16

1) Dataset A [26]: Combined Air Quality Dataset from India and Nepal : includes 12,240 pictures that depict different aspects of air quality in Indian and Nepali cities [26]. All images maintain the same resolution of 224 x 224 each. The images are divided into two categories: the combined dataset and country wise dataset. In this dataset, the folder named" Combined Dataset" focused on categorizing air quality into six categories based on the AQI, namely, Good, Moderate, Unhealthy for Sensitive Groups, Unhealthy, Very Unhealthy, and Hazardous/Severe. This detailed classification offers an extended framework for analyzing air quality in diverse environmental conditions.

2) Dataset B [27]: Smartphone-Based Air Pollution Image Dataset (SAPID) was retrieved from Mendeley Data and is identified as the Smartphone-Based Air Pollution Image Dataset, SAPID [27]. The dataset consists of 456 images displaying various air pollution levels in accordance with the United States Environmental Protection Agency categorization. Images are divided into five AQI classes. This dataset is a very important source for developing and testing computer vision algorithms with the purpose of air quality assessment based on visual data represented by images taken from smartphones, where structured categorization enables detailed analysis and modeling.

3) Dataset C [28]: PM2.5 Image Dataset from Kaggle is provided by Kaggle; the material is entitled "Pictures and Air Quality." It contains images pre-classified into their respective conditions according to the PM2.5 values represented in their PM2.5data.csv file [28]. The 2.5 data have exact concentrations with corresponding images, making it suitable to classify images into normal and polluted classes according to the conventional standard for air. Table I presents the distribution of all images of "Pictures and Air Quality Dataset" that have been prepared according to their corresponding level of PM2.5 concentration.

B. Data Preprocessing

Preparing a dataset for the training of a deep learning model in air quality estimation involves images from different sources and varying dimensions and resolutions. To ensure consistency and quality in the dataset, we implemented a preprocessing pipeline that includes image resizing and quality filtering. The algorithm used for this process is outlined below.

Algorithm 1 is used to preprocess the dataset by standardizing image dimensions and filtering low-quality images. All images were resized to 224 × 224 pixels to ensure uniformity in input data for the deep learning model. The algorithm first iterates through the dataset, verifying file formats and extracting image dimensions before resizing. Next, it applies

two quality checks: a uniformity check, which removes nearly blank images using standard deviation analysis, and a sharpness check, which filters out blurry images based on the variance of the Laplacian filter. Only high-quality images that pass both checks are retained and saved in the output directory. This preprocessing step ensures that the dataset contains clear, informative images, improving the accuracy of air quality estimation.

Algorithm 1 Image Resizing and Filtering of Images

Input: A set of images to be resized.
Output: A set of resized and filtered images.
Initialization:
Set $desired\_size \leftarrow (224, 224)$ pixels
Set $uniform\_threshold \leftarrow 5-10$ (filters almost uniform images)
Set $blur\_threshold \leftarrow 50 - 100$ (filters very blurry images)
Prepare $output\_dir$ for saving cropped images
Initialize counters: $resize\_count \leftarrow 0$, $filtered\_count \leftarrow 0$
for each file f_i in f where $i \geq 0$ **do**
    Check File Type: If f_i has extension .png, .jpg, or .jpeg, proceed
    Load Image: Import the image
    Determine Dimensions: Extract image width W and height H
    Set $resize\_width \leftarrow desired\_size[0]$ and $resize\_height \leftarrow desired\_size[1]$
    Resize image to $(resize\_width, resize\_height)$
end for
Quality Filtering:
Uniformity Check:
Convert image to grayscale using `cv2.cvtColor`
Compute standard deviation: $stddev \leftarrow np.std(image)$
if $stddev < uniform\_threshold$ **then**
    Return **True** (filter out the image)
else
    Return **False**
end if
Sharpness Check:
Apply Laplacian filter using `cv2.Laplacian`
Compute variance: $variance \leftarrow laplacian.var()$
if $variance < blur\_threshold$ **then**
    Return **True** (filter out the image)
else
    Return **False**
end if
Save resized and filtered image to $output\_dir$

C. Generalized Convolutional Neural Network (CNN)

CNN is a type of feed-forward Artificial Neural Network (ANN) that is structured using a deep learning algorithm. It has been extensively applied in various domains, including image processing, video recognition, and time series forecasting [29]–[39]. Empirically, CNNs are widely recognized for their robust feature extraction capabilities from images, making them suitable for tasks involving image-based data. This structure is well-suited for the problem of air quality estimation, where extracting complex visual patterns (e.g. particulate matter, pollution indicators in environmental images) is key to classification. The architecture of our CNN is summarized in Table II. The CNN architecture is divided into two primary phases as CNN part: feature extraction and classification, comprising convolutional, pooling, and fully connected layers.

1) Feature Extraction: The feature extraction phase begins with the input image of size 224×224×3 through several convolutional and max-pooling layers. The first convolutional layer applies A set of 96 filters of size 11×11 with a stride of 4 is applied, resulting in an output size of 224×224×96. This operation is mathematically defined as. The operation for each filter is defined as:

$$O_1 = f(W_1 * I + b_1)$$

where W1 represent the weights represent the output, b1 represents the bias of the first convolutional layer, I is the input image, and f is the ReLU activation function. A 3×3 max-pooling operation with a stride of 2 reduces the dimensions to 112×112×96. The output is represented as:

$$P_1 = \max pool(O_1)$$

The second convolutional layer employs a set of 256 filters of size 5×5 with a stride of 1, resulting in an output of 112×112×256 represented by P.

$$O_2 = f(W_2 * P_1 + b_2)$$

This output is further sampled to 56×56×256 via a 3×3 max-pooling operation.

$$P_2 = \max pool(O_2)$$

Three more convolutional layers follow, with varying filter sizes and counts. Each layer applies ReLU activation and batch normalization to stabilize and improve learning. The final feature map is obtained after pooling:

$$P_3 = \max pool(O_5)$$

where O5 is the output from the last convolution layer (56×56×256), and P3 is the result of the third pooling layer, reducing it to 28×28×256.

2) Classification: In the classification phase, the output from the last pooling layer is flattened into a vector of size 50176:

$$F = Flatten(P_3)$$

This vector is passed through a fully connected layer of 4096 units:

$$O_{fc} = f(W_{fc} \bullet F + b_{fc})$$

Subsequently, two dropout layers (with a rate of 0.6) are applied to prevent overfitting. Finally, the output is fed into another fully connected layer with a softmax activation function, providing class probability:

$$P = soft\max(W_{out} \bullet O_{fc} + b_{out})$$

This CNN architecture effectively extracts hierarchical features from the input image and performs classification, making it well-suited for complex image recognition tasks.

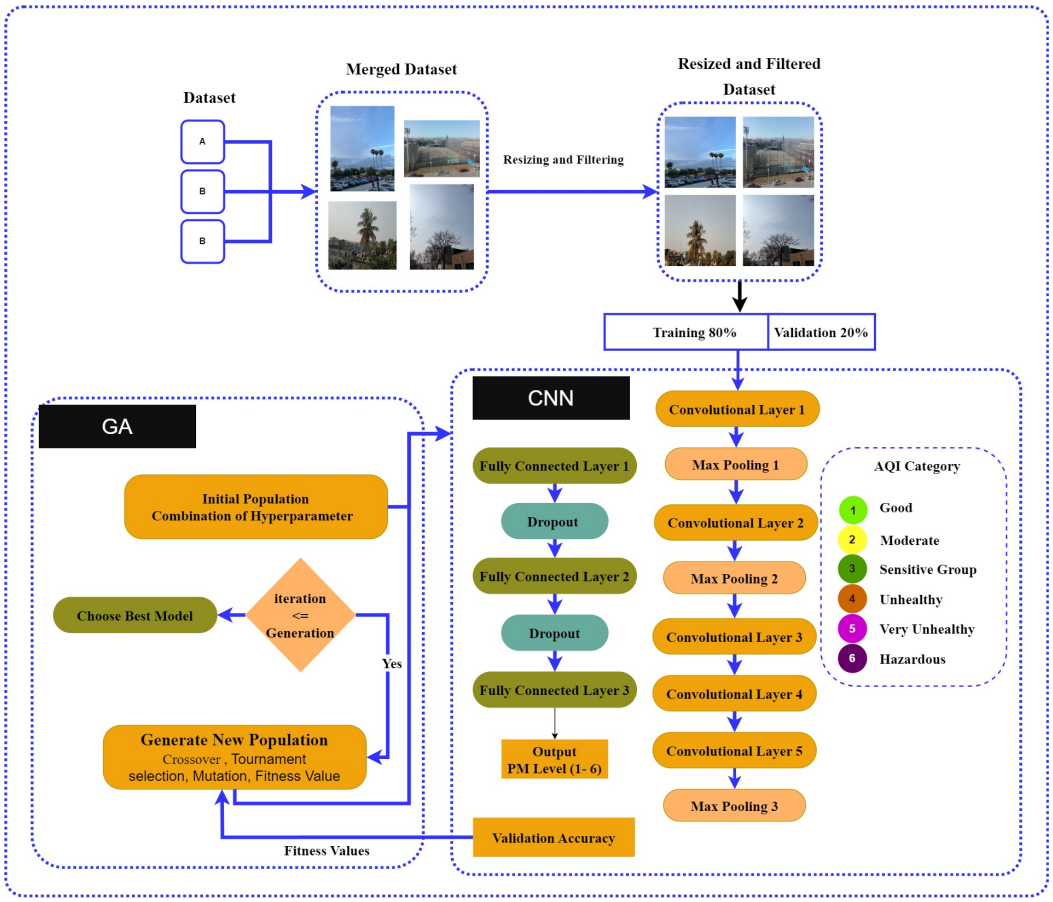

Fig. 1. Proposed model for air quality estimation from images using CNN with GA for hyperparameter optimization.

3) Hyperparameter tuning using GA: Hyperparameters may be defined as the very important parameters set prior to training either a machine learning or deep learning model. Speaking broadly, there exists a division into two types of hyperparameters. One group involves identifying the network structure, where the kernel size and type, stride and padding, number of hidden layers, and activation function determine the hyperparameters. These parameters define the architecture and the complexity of the model. The latter group includes such hyperparameters as how to train the network: a learning rate, momentum, number of epochs, batch size. Hyperparameters responsible for the training process supervise the efficiency and effectiveness of the whole learning process; therefore, this is relevant for convergence and generalization of this model regarding new data. Both model and algorithmic hyperparameters are very important for the optimization of model performance and need to be tuned carefully to derive the best results. Optimization techniques make much difference in the performance of hyperparameter tuning in deep learning by bringing improvements in model accuracy, reduction in computational cost, and enhancing efficiency [40], [41].

The GA is used to carry out the automation of the optimization of hyperparameters related to the training: learning rate, batch size, and momentum. It is an evolutionary technique for hyperparameter tuning, which explores a wide range to find those that allow the maximum CNN performance on the validation dataset. The process begins by initializing an initial population, where each one represents a combination of hyperparameters with the following ranges as shown in Table III:

Fitness evaluation is performed by training the CNN for 30 epochs, using the validation accuracy as the fitness score, calculated as:

$$fitness = \frac{1}{N}\sum_{i=1}^{N} 1(y_i = \hat{y}_i)$$

where N is the number of validation samples, y_i is the true label, and $\hat{y}_i$ is the predicted label. After evaluating fitness, genetic operators are applied. Then, tournament selection is used to choose individuals based on their fitness scores, followed by a two-point crossover to combine parents and generate offspring. The mutation would be done with a probability of 0.2 so as not to lose the diversity in the population. The generated population will evolve over successive generations, ensuring at each step in selection that the best of these formed generations increases the performance of the model at each step.

IV. Results

This section presents the experimental results of our approach. The performance is evaluated on a validation set using evaluation metrics such as precision, recall, and F1-score.

TABLE II. PROPOSED ARCHITECTURE OF CONVOLUTIONAL NEURAL NETWORK

Layer	Output Shape	Filter Size	Number of Filters	Stride	Padding	Activation
Input Layer	224×224×3	-	-	-	-	-
Conv Layer 1	224×224×96	11×11	96	4	Same	ReLU
Max Pooling 1	112×112×96	3×3	-	2	-	-
Conv Layer 2	112×112×256	5×5	256	1	Same	ReLU
Max Pooling 2	56×56×256	3×3	-	2	-	-
Conv Layer 3	56×56×384	3×3	384	1	Same	ReLU
Conv Layer 4	56×56×384	3×3	384	1	Same	ReLU
Conv Layer 5	56×56×256	3×3	256	1	Same	ReLU

TABLE III. HYPERPARAMETER RANGES

Hyperparameter	Abbreviation	Range
Learning Rate	learning_rates	[0.001, 0.0005, 0.0001]
Batch Size	batch_sizes	[32, 64, 128, 256]
Momentum	momentum	[0.9, 0.95, 0.99]

A. Experimental Setup

The model was trained in a combination of three open-source datasets, as detailed in the Data Collection and Preprocessing section. The dataset was split into 80% for training and 20% for validation. A set of samples from both training and validation is shown in Fig. 2.

To optimize performance, the GA fine-tuned key hyperparameters such as learning rate, batch size, and momentum based on a range of values selected from prior research. The optimization process ran over 50 generations, with a population size of 20 individuals. The training process was conducted using the TensorFlow and Keras frameworks, and the model was trained on an NVIDIA RTX 3070 GPU for accelerated performance.

B. Model Performance

The performance of the proposed CNN, optimized with GA, was thoroughly evaluated on the test set using a variety of performance metrics, including precision, recall, and F1 score. These results are compared with baseline models, and the learning process is further visualized through training and validation loss and training and validation accuracy graphs.

The model demonstrated strong performance across all pollution categories. The macro-average and weighted-average F1-Scores were both 0.97, indicating balanced performance across different air quality levels. The detailed results are summarized in Table IV.

The overall model accuracy was 95.44%, reflecting a significant improvement compared to the baseline CNN models without GA optimization. The results shown in Table V demonstrate that the proposed CNN-GA model significantly outperformed the baseline CNN model without the GA-based optimizer across all performance metrics, achieving a 17.44% increase in accuracy, a 21.00% increase in precision, and a 21.00% increase in recall.

Fig. 2. A set of samples from training and validation.

V. DISCUSSION

A. Training and Validation Curves

The training and validation loss and accuracy curves further demonstrate the robustness of our model. As shown in Fig. 3, both loss and accuracy stabilized after around five epochs, indicating that the model converged quickly without overfitting.

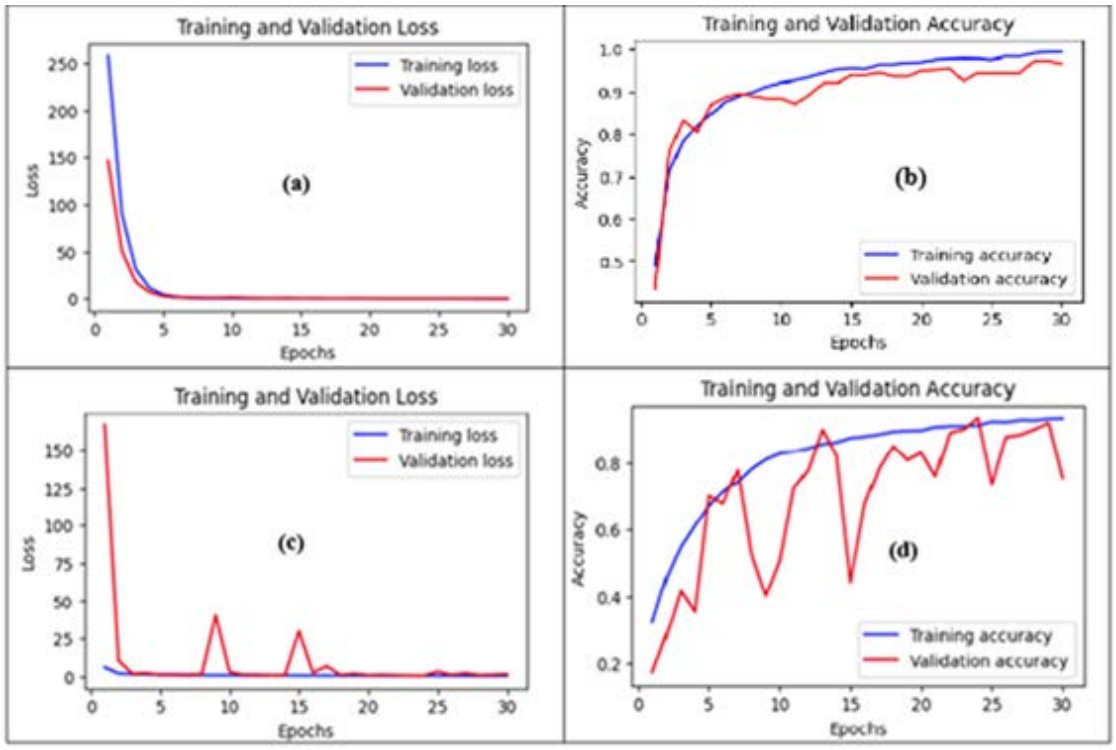

Fig. 3. Proposed model training and validation loss (a), Accuracy (b); Base model training and validation loss (c), Accuracy (d)

TABLE IV. CLASSIFICATION REPORT FOR POLLUTION LEVELS

Pollution Level	Precision	Recall	F1-Score	Support
Good	0.97	0.96	0.97	348
Moderate	0.97	0.95	0.96	364
Unhealthy	0.95	0.98	0.97	551
Sensitive Groups	0.98	0.95	0.97	581
Very Unhealthy	0.96	0.96	0.96	450
Hazardous	0.97	0.99	0.98	294
Macro Average	0.97	0.97	0.97	2588
Weighted Average	0.97	0.97	0.97	2588
Overall Model Accuracy: 0.9544				

TABLE V. PERFORMANCE COMPARISON OF DIFFERENT MODELS

Model	Accuracy	Precision	Recall	F1-Score
Baseline CNN	0.78	0.76	0.76	0.76
CNN-GA	0.9544	0.97	0.97	0.97

The training accuracy approached near-perfect levels (99%), while the validation accuracy consistently ranged between 95% and 99%, confirming strong generalization capability. In contrast, the base model exhibited noticeable fluctuations in validation accuracy and loss as shown in Fig. 3, with clear signs of overfitting after several epochs, particularly during the later stages of training. Validation loss spiked in certain epochs, while training accuracy continued to improve, indicating that the base model overfit the training data and struggled to generalize to the validation set. This comparison emphasizes the superior generalization ability of the proposed CNN-GA model, as it maintained stable validation performance without significant degradation or divergence from training metrics.

B. Overfitting Prevention and Generalization

Several techniques were employed to prevent overfitting and ensure the model generalized well on unseen data. These included a dropout rate of 0.6 to reduce reliance on specific neurons, batch normalization to stabilize training, early stopping to prevent overtraining, and learning rate reduction when validation loss plateaued for finer adjustments. These techniques contributed to the CNN-GA model's ability to maintain a high level of performance across various environmental conditions. The incorporation of GA led to a significant enhancement in the model's performance. The CNN-GA model indeed represented the real improvement to the baseline by several folds along all key performance indicator metrics. Accuracy was increased in CNN-GA by a maximum of 17.44% compared to that proposed by CNN, or, to say precisely, 78% was increased to 95.44%. Precision of the CNN-GA improved by +21 points from that provided by CNN: 0.76 to 0.97; it experienced the very same increase also for recall—by 0.76 to 0.97, also for the F1-Score. The improvement in the results underlines the potential of the proposed GA-based hyperparameter optimization to increase the performance and robustness of air quality estimation from image data, offering a higher generalization ability compared with state-of-the-art methods working with traditional CNN.

VI. CONCLUSION

This paper presents a new air quality estimation approach using CNN optimized by GA, significantly enhancing predictive accuracy and improving the generalization of the model for a wide range of environmental contexts. The integration of GA within the CNN model allows for dynamic optimization

of hyperparameters, which, apart from enhancing performance, may ensure adaptability to diverse spatial, temporal, and environmental conditions. The approach provides a series of limitations with traditional air quality monitoring systems, offering restricted geographic coverage and very high operational costs that cannot provide real-time data.

This work has been done using three different open-source datasets, proving that the model will generalize well for any kind of air quality scenario. These results have been verified using different metrics such as precision, recall, and F1-score, which is considerably better compared to baseline methods; hence, the CNN-GA model is sound and reliable regarding the classification of air quality levels. The scalability of the model at low cost opens a different direction in conducting large-scale monitoring of air quality, which is all-important for protecting public health and the environment.

In future work, we will extend our dataset to more diverse scenes and integrate additional data sources, such as satellite imagery and real-time sensor data, to improve generalization to unseen data.

***Abstract*—In an era characterized by the rapid digital transformation of the marketplace, understanding consumer behavior is essential for effective decision-making and the development of marketing strategies. This study investigates the impact of demographic attributes such as age, income, education, and lifestyle preferences, alongside social media engagement, on the consumer decision-making process in the Al-Qassim region of Saudi Arabia. A survey was distributed, gathering responses from 684 participants. The study specifically tests the hypotheses that demographic factors significantly influence each stage of the decision-making journey: problem recognition, information search, evaluation of alternatives, purchase decision, and post-purchase behavior, with social media engagement acting as a mediating factor in these stages. By utilizing management information systems to analyze this comprehensive dataset, a Random Forest Classifier was employed, achieving an overall accuracy of 88% and revealing significant correlations between demographic characteristics and consumer behavior. The model demonstrated particularly strong performance in the Evaluation of Alternatives stage, with a precision of 0.90 and a recall of 0.95. Additionally, the findings underscore the critical role of social media engagement in enhancing consumer awareness and influencing purchasing decisions. This study provides actionable insights for marketers in the Al-Qassim region, equipping them with the necessary tools to optimize their strategies in the rapidly evolving digital landscape, ultimately improving consumer satisfaction and fostering long-term loyalty.**

***Keywords*—Consumer behavior; demographics marketing strategies; data analysis; digital transformation**

I. Introduction

The advent of the digital age has transformed the way consumers interact with brands and make purchasing decisions. With the proliferation of the internet and mobile technologies, the traditional consumer decision-making process has evolved, necessitating a deeper understanding of the factors that influence consumer behavior in this new landscape. As businesses increasingly shift towards digital platforms, the ability to comprehend how demographic attributes and social media engagement impact consumer decisions becomes essential for developing effective marketing strategies [1], [2].

The digital marketplace has become a dominant force in the global economy, with e-commerce sales projected to reach trillions of dollars annually. This shift has prompted companies across various industries to adapt their strategies to meet the expectations of digitally-savvy consumers. Understanding the nuances of consumer behavior in this context is critical, as it can significantly influence brand loyalty, purchase frequency, and overall market competitiveness [3].

In this rapidly evolving environment, the consumer decision-making process has been segmented into five stages: problem recognition, information search, evaluation of alternatives, purchase decision, and post-purchase behavior. Each stage is influenced by various factors, including individual demographics, psychographics, and the growing role of social media as a source of information and engagement [1], [4].

The consumer decision-making process begins with problem recognition, where consumers identify a need or desire that prompts them to seek solutions. This stage can be influenced by external factors such as advertising, peer recommendations, and social media exposure. Following this, consumers engage in information search, where they actively seek out data regarding potential products or services. This stage has been revolutionized by digital technologies, allowing consumers to access vast amounts of information at their fingertips [4].

The evaluation of alternatives is the next stage, where consumers compare different options based on criteria such as price, quality, and brand reputation. This stage is critical, as the information gathered during the previous stage plays a significant role in shaping preferences and influencing decisions. The purchase decision follows, culminating in the actual transaction. Finally, post-purchase behavior involves the consumer's assessment of their purchase experience, which can influence future buying behavior and brand loyalty [4].

Demographic attributes, including age, income, education, and lifestyle preferences, are pivotal in shaping consumer behavior. For instance, younger consumers often exhibit greater comfort and proficiency with digital technologies, leading them to rely heavily on online resources for information and engagement. Conversely, older consumers may lean towards traditional sources of information and may be less influenced by social media interactions. Understanding these demographic differences can provide marketers with valuable insights into

tailoring their strategies to meet the diverse needs of their target audiences [4].

Income levels can also play a significant role in purchasing decisions, as they often dictate the range of products consumers consider. Higher-income individuals may prioritize quality and brand reputation, while lower-income consumers may be more focused on finding the best deals. Education further influences consumer behavior, as more educated individuals may engage in more extensive information searches and evaluations, leading to informed decision-making [5], [6].

Social media has emerged as a powerful tool in shaping consumer perceptions and behaviors. Platforms such as Facebook, Instagram, Twitter, and TikTok offer brands unprecedented access to consumers, enabling direct engagement and fostering community. Social media engagement can enhance consumer awareness, allowing brands to communicate their value propositions effectively [7], [8].

Research indicates that social media interactions can significantly influence purchasing decisions. User-generated content, such as reviews and testimonials, can enhance credibility and trust, leading to higher conversion rates. Additionally, social media provides a platform for consumers to share their experiences, further influencing the decision-making process among peers. Understanding the dynamics of social media engagement and its impact on consumer behavior is vital for businesses seeking to optimize their marketing strategies in the digital landscape [5], [6].

As the digital marketplace continues to expand, understanding the consumer decision-making process becomes increasingly essential. By recognizing the significant influence of demographic attributes and social media engagement, businesses can tailor their marketing strategies to effectively reach and resonate with their target audiences. This comprehensive approach will not only enhance brand loyalty and customer satisfaction but also ensure competitiveness in the ever-evolving digital economy [9], [10]. The objective of this study is to explore the intricacies of consumer decision-making in Al-Qassim, Saudi Arabia, focusing on the impact of demographic attributes and social media engagement. By gaining insights into these factors, the study aims to provide actionable recommendations for businesses to effectively adapt their marketing strategies in a rapidly evolving digital landscape.

Study Location: Al-Qassim, Saudi Arabia. Al-Qassim, located in the heart of Saudi Arabia, is a region characterized by its rich cultural heritage and economic potential. As one of the country's key agricultural areas, Al-Qassim boasts a diverse economy that includes agriculture, trade, and increasingly, digital enterprises. The region's strategic location and infrastructure have made it a focal point for businesses seeking to tap into the growing market of digitally-savvy consumers.

In recent years, Al-Qassim has witnessed significant technological advancements, with an increasing number of residents gaining access to the internet and mobile technologies. This shift has altered the way consumers in the region interact with brands and make purchasing decisions. The rise of e-commerce has introduced new dynamics, compelling local businesses to adapt their marketing strategies to meet the evolving preferences of consumers.

Culturally, Al-Qassim is known for its unique blend of traditional values and modern influences. This duality is reflected in consumer behavior, where residents may exhibit a strong affinity for local products while also embracing global brands. Understanding this cultural context is crucial for marketers aiming to connect with consumers in Al-Qassim effectively.

Moreover, the demographics of the region play a significant role in shaping consumer behavior. A youthful population, combined with varying income levels and educational backgrounds, influences purchasing decisions in diverse ways. Marketers must consider these demographic factors, along with the growing impact of social media, to tailor their approaches to the local market.

Overall, studying consumer behavior in Al-Qassim provides valuable insights into how cultural, demographic, and technological factors intersect to shape purchasing decisions. This understanding is essential for businesses looking to establish a strong presence in the region and engage with consumers in a meaningful way.

The structure of this paper is as follows: Section I provides an introduction to the topic; Section II presents the literature review; Section III discusses the proposed methodology; Section IV details the results obtained from the experiments; Section V offers a discussion of the findings; Section VI outlines the contributions of the study; and Section VII concludes the paper with recommendations for future work.

II. Literature Review

Consumer decision-making is a multifaceted process through which individuals identify their needs and desires, gather relevant information, evaluate available alternatives, and ultimately make purchasing decisions [11], [12]. This process encompasses several stages, including problem recognition, information search, and evaluation of alternatives, purchase decision, and post-purchase behavior [13]. Understanding consumer decision-making is paramount for marketers, as it provides critical insights into how consumers think, feel, and act in relation to products and services. This knowledge enables businesses to tailor their marketing strategies to effectively meet the needs of their target audiences, thereby enhancing customer satisfaction and loyalty, ultimately driving sales growth [14].

The advent of the digital age has profoundly transformed consumer behavior. With the rapid proliferation of the internet and mobile technologies, consumers now have unprecedented access to information [15]. This transformation has significantly altered traditional decision-making processes in several key ways. Firstly, the accessibility of information allows consumers to easily research products and services online, comparing prices, features, and reviews. This empowerment leads to more informed decisions and raises expectations for transparency from brands [16].

Secondly, social media has emerged as a critical channel for consumer engagement. Platforms like Facebook, Instagram, and Twitter not only serve as information sources but also facilitate

interaction among consumers. User-generated content, such as reviews and testimonials, plays a significant role in shaping consumer perceptions and influencing purchasing decisions [17]. Furthermore, the digital landscape has shifted the balance of power from businesses to consumers. With a wealth of information at their fingertips, consumers are less reliant on traditional advertising and more inclined to trust peer recommendations and online reviews. Lastly, the ability to personalize marketing efforts based on consumer data allows businesses to create more relevant and targeted campaigns, enhancing the overall consumer experience [18], [19].

To better understand consumer decision-making, various theoretical models have been developed. Two prominent models are the Engel-Kollat-Blackwell Model and the Howard-Sheth Model. The Engel-Kollat-Blackwell model outlines a comprehensive framework consisting of five stages: problem recognition, information search, evaluation of alternatives, purchase decision, and post-purchase behavior. This model illustrates how consumers progress through each stage and the factors that influence their choices at each point [20], [21].

On the other hand, the Howard-Sheth model emphasizes the interplay of external and internal factors on consumer behavior, incorporating psychological, social, and situational influences. This model highlights that consumer decisions are not solely based on rational evaluations but are also affected by emotions and social contexts [22].

Numerous factors influence consumer decision-making processes, and these can be broadly categorized into demographic attributes and social media engagement [23].

Demographic Attributes:

- Age: Different age groups exhibit distinct purchasing behaviors. Younger consumers, often more comfortable with technology, rely heavily on digital resources for information and are influenced by social media marketing. In contrast, older consumers may prefer traditional sources of information, such as television and print media [24], [25].
- Income: Income levels significantly affect purchasing power and priorities. High-income consumers often seek quality and exclusivity, while low-income consumers prioritize affordability and essential needs [26], [27].
- Education: Education influences how consumers process information. Higher-educated individuals tend to engage in thorough information searches and evaluations, while lower-educated consumers may prefer straightforward and easily digestible information [28].
- Lifestyle Preferences: Consumers' interests and values shape their purchasing decisions. Brands that align with these preferences are more likely to resonate with consumers and foster loyalty [29].

Social media has revolutionized the way consumers gather information and make purchasing decisions. It serves as a dynamic platform for information sharing and consumer interaction, significantly influencing perceptions and facilitating engagement [30].

User-Generated Content: This type of content, encompassing reviews and testimonials created by consumers, plays a pivotal role in shaping brand perceptions. Positive user-generated content can build trust and credibility, making it a powerful tool for influencing purchasing decisions. Consumers often perceive this content as more authentic than traditional advertising, further emphasizing the importance of fostering a community of satisfied customers who share their experiences [31].

To obtain a comprehensive understanding of consumer behavior, researchers employ both quantitative and qualitative methodologies. Quantitative methods, including surveys and statistical analysis, provide structured data that can reveal trends and patterns in consumer behavior. For instance, machine learning techniques can analyze complex datasets to identify key predictors of consumer behavior [32].

Conversely, qualitative methods such as interviews and focus groups offer deeper insights into consumer motivations, emotions, and perceptions. These approaches allow researchers to explore the "why" behind consumer decisions, adding richness to the findings derived from quantitative studies [33].

Despite extensive research on consumer behavior, several gaps remain, particularly in relation to underexplored regions like Al-Qassim, Saudi Arabia. Much of the existing literature focuses on Western contexts, overlooking the unique cultural and economic dynamics that influence consumer behavior in different regions. Additionally, research often treats demographic factors broadly without delving into specific attributes, warranting more targeted studies that examine how these factors interact with local consumer behaviors [34], [35], [36].

Insights gained from consumer behavior research can guide marketers in developing effective strategies. Personalization is increasingly crucial, as consumers expect tailored experiences that resonate with their preferences. Marketers should leverage data analytics to craft personalized messages and offers. Additionally, engaging with consumers on social media and encouraging user-generated content can enhance brand credibility and foster loyalty [37].

By segmenting target audiences based on demographic attributes and employing culturally relevant messaging, marketers can create campaigns that resonate with specific consumer segments. Collaborating with local influencers can amplify brand reach and strengthen consumer connections [38].

With the rapid growth of competition in the online market, enterprises face the pressing challenge of developing targeted and effective marketing strategies. The primary goal of precision marketing is to enable businesses to create strategies that align with consumer desires while maintaining competitiveness through cost efficiency, quick implementation, and optimized resource utilization. This study investigates the influence of demographic attributes—such as age, income, education, and lifestyle preferences—alongside social media engagement on the consumer decision-making process [39].

To address the complexities of consumer behavior in a dynamic online landscape, this research utilizes machine learning methods, particularly the Random Forest Classifier.

This algorithm is well-suited for handling diverse data characteristics and can process extensive datasets efficiently. By achieving an overall accuracy of 88%, the model reveals significant correlations between demographic factors and consumer behavior across various stages of the decision-making journey, including problem recognition, information search, evaluation of alternatives, purchase decision, and post-purchase behavior [40], [41].

Additionally, the Random Forest algorithm has been identified as a superior method for predictive accuracy in various contexts, reinforcing its relevance in this study. This research contributes valuable insights for marketers, empowering them to optimize their strategies in the rapidly evolving digital marketplace. By combining demographic analysis with social media engagement, the study offers actionable recommendations to enhance consumer satisfaction and foster long-term loyalty [42], [43].

A. Machine Learning

Machine learning has become a prominent method in decision support due to its efficient algorithms, exceptional data fitting capabilities, and strong computational power. Among the various algorithms available, the Random Forest Classifier is particularly well-suited for analyzing consumer purchase behavior. This algorithm can effectively handle diverse data characteristics and consumer behavior patterns, especially in the advertising domain, processing large-scale datasets of advertising clicks and consumer attributes to deliver highly accurate predictions and interpretations [44], [45].

By integrating multiple decision trees for prediction, the Random Forest Classifier mitigates the risk of overfitting associated with single decision trees, thereby enhancing overall prediction accuracy. This characteristic is crucial for accurately forecasting consumer purchase behavior and optimizing advertising strategies. Compared to traditional algorithms such as logistic regression or single decision trees, the Random Forest Classifier showcases greater flexibility and adaptability in managing complex tasks, particularly when addressing high-dimensional, non-linear, and interactive features. Its robust mechanisms, including feature selection, ensemble learning, and random sampling, enable it to navigate complex situations effectively and provide precise predictions [46], [47].

However, with the increasing complexity of machine learning models, there is a growing need to balance their applicability with explain ability in real-world contexts. Traditional black-box models often focus solely on output results, neglecting their internal mechanisms. In contrast, explainable machine learning aims to improve user communication and trust by elucidating the model's internal workings. Feature importance analysis plays a critical role in this domain, identifying the most influential features in predicting target variables by examining the relationships between features and outcomes while filtering out irrelevant factors to enhance prediction accuracy and model interpretability [48].

By harnessing machine learning capabilities, businesses can adapt their marketing strategies based on individual consumer data, thus improving customer satisfaction and overall competitiveness. Recent research highlights various models developed to forecast customer preferences and refine precision marketing, often leveraging artificial intelligence algorithms. It showcase the effectiveness of machine learning in capturing customer preferences and sales forecasting [49], [50]. Additionally, the Random Forest algorithm has been identified as a superior method for predictive accuracy in various contexts, reinforcing its relevance in this study. Additionally, the Random Forest algorithm has been identified as a superior method for predictive accuracy in various contexts, reinforcing its relevance in this study. This research contributes valuable insights for marketers, empowering them to optimize their strategies in the rapidly evolving digital marketplace. By combining demographic analysis with social media engagement, the study offers actionable recommendations to enhance consumer satisfaction and foster long-term loyalty [51], [52].

B. Related Work

Digital trends influencing consumer-purchasing decisions, Researchers has shown that digital technology significantly affects consumer decision-making through increased access to information, social media influence, personalization, e-commerce convenience, and simplified payment options.

In Sharma, Ueno, et al study investigates the impact of digital technologies on consumer decision-making in the retail sector through two online surveys. Study 1 identifies distinctive attributes of six digital technologies, including two current (Internet and Mobile Platforms) and four emerging (Artificial Intelligence, Augmented, Mixed, and Virtual Reality). Study 2 focuses on older consumers to understand their decision-making processes when using new digital technologies. The study extends the AISAS model (Awareness, Interest, Search, Action, and Sharing) to highlight that consumer decision journeys are no longer linear with digital technologies. For instance, attention can directly lead to action, by passing interest or search stages. Additionally, sharing after a purchase can foster loyalty, psychological engagement, and renewed attention [53]. On other study examines changing consumer behavior in the digital age, with a focus on online shopping habits. It explores how technological advancements and the proliferation of online shopping platforms influence consumer interactions with digital marketplaces, purchase decisions, and the retail landscape. The results reach to key drivers of online shopping include convenience, product variety, price competitiveness, and retailer trustworthiness. Additional influential factors are social influence, personalized recommendations, and customer reviews [54]. A study in India used Random Forest models to predict online purchasing behavior by investigated how demographic attributes affect online buying behavior across different product categories and geographic locations across different product categories and geographic locations. The model showed high sensitivity (above 85%) for books and electronics, indicating a strong inclination towards online shopping for these categories [55]. In addition, with widespread availability and accessibility of social media on mobile devices have made information collection easier. Beyond connecting with friends and family, consumers now use social media to share experiences and read reviews about products, services, and organizations. Reviews and shared opinions heavily influence decisions, such as choosing movies, booking hotels, dining out, or making purchases. Dadwal et al. highlighted the influence of

social media in consumer purchase decisions find that social media playing a significant role in the information-gathering process. Consumers first identify their needs and seek information about products from different sources, including social media.This study explores the growing importance of social media in shaping the consumer decision-making process [56]. Additionally, machine-learning techniques have been leveraged to analyze high-dimensional consumer data from e-commerce platforms, focusing on various applications and methodologies, De Caigny et al. (2018) proposed a hybrid classification method for analyzing user reviews and sentiments positive, negative, and neutral, aiding online product selection[57]. Hu et al. (2020) utilized collaborative filtering to analyze shopping behaviors and predict purchases during shopping festivals [58]. Ayodeji et al. (2020) applied machine learning to predict cart abandonment, using a dataset of 821,048 observations from German online customers [59]. Goyal & Manjhvar (2020) used heuristic approaches and data mining methods to classify internet store visitors and predict purchase intentions [60]. In this context, Random Forest models have been applied to various aspects of product management, including user behavior prediction, A/B testing analysis, customer segmentation, demand forecasting, and anomaly detection [61].These studies collectively demonstrate the growing importance of advanced analytical techniques, particularly Random Forest models, in understanding and predicting consumer behavior in digital environments. They also highlight the need for comprehensive approaches that combine statistical methods with machine learning to gain deeper insights into consumer decision-making processes.

This literature review highlights the importance of understanding consumer decision-making processes, the impact of digital transformation, and the role of social media. Addressing existing gaps in research, particularly in culturally distinct settings like Al-Qassim, will enhance our understanding of consumer dynamics. By integrating theoretical frameworks with empirical research, marketers can develop more informed strategies that effectively engage consumers and drive business success [62], [63].

III. METHODOLOGY

This study employed a comprehensive approach to analyze the factors influencing consumer decision-making by utilizing both the Random Forest algorithm and various traditional statistical tests. This dual approach enhances the robustness of the findings and provides a deeper understanding of the interplay between demographic attributes and social media engagement.

This study aims to explore the intricate relationships between demographic attributes, social media engagement, and the consumer decision-making process. Specifically, it investigates how these factors influence each stage of the decision-making journey.

A. Hypotheses Development

The following hypotheses were formulated to guide the research:

- Hypothesis 1: Demographic attributes significantly influence the problem recognition stage of the consumer decision-making process.
- Hypothesis 2: Demographic factors impact the information search stage, affecting the sources and types of information consumers seek.
- Hypothesis 3: Social media engagement positively influences the evaluation of alternatives, enhancing consumer awareness and shaping preferences.
- Hypothesis 4: Demographic attributes and social media engagement jointly influence purchase decisions and post-purchase behavior.

By addressing these hypotheses, this study seeks to contribute to the existing literature on consumer behavior in digital environments and provide actionable insights for marketers. Understanding these dynamics will enable businesses to tailor their strategies effectively, enhancing consumer satisfaction and fostering brand loyalty in a competitive marketplace.

The digital transformation of the marketplace has reshaped the consumer decision-making process, making it imperative for businesses to understand the influencing factors. By examining the interplay between demographic attributes and social media engagement, this study aims to shed light on the complexities of consumer behavior in the digital age. The findings will ultimately inform marketing strategies that resonate with diverse consumer segments, enhancing engagement and driving business success.

B. Sampling

A diverse sample of consumers was targeted to ensure representation across various demographic groups, including age, income, education, and lifestyle preferences. Online surveys were distributed in the Al-Qassim region of Saudi Arabia, collecting data from 684 participants. This sample size is deemed sufficient to achieve statistical power and draw meaningful conclusions regarding the proposed hypotheses.

C. Data Collection

The survey was designed to capture key variables related to consumer behavior in the Al-Qassim region of Saudi Arabia. It included questions aimed at identifying triggers for problem recognition, sources of information during the search stage, the role of social media in evaluating alternatives, and factors influencing purchase decisions and post-purchase experiences. Data were collected through an online platform, ensuring accessibility and a broad reach, with a total of 684 participants contributing to the study. This sample size is considered adequate for achieving statistical power and drawing meaningful conclusions regarding the proposed hypotheses.

D. Data Analysis

To analyze the collected data, the study employed two approaches:

1) Random forest algorithm: This machine learning technique was utilized to assess the relative importance of various demographic attributes and social media engagement in influencing consumer decision-making stages. The Random Forest model provides insights into complex interactions and helps identify key predictors in a high-dimensional dataset.

2) Traditional statistical tests: Complementing the machine learning approach, various statistical tests were employed:

a) Chi-Square test: Used to analyze the relationship between demographic categories and recognized triggers for problem recognition.

b) Logistic regression analysis: Conducted to evaluate the impact of demographic factors on the information sources sought.

c) Multiple regression analysis: Employed to assess the effect of social media engagement on the evaluation of alternatives.

3) Multivariate Analysis of Variance (MANOVA): Utilized to examine the joint influence of demographic attributes and social media engagement on purchase decisions and post-purchase satisfaction.

E. Participants

The participants in this study were selected to reflect a diverse demographic profile, ensuring that findings can be generalized across various consumer segments. The survey included participants from different age groups, income levels, educational backgrounds, and lifestyle preferences. This diversity allows for a more comprehensive understanding of how different factors influence consumer decision-making processes.

F. Theoretical Framework

This study employs a comprehensive approach to analyze the factors influencing consumer decision-making in Al-Qassim by integrating the Engel-Kollat-Blackwell model and the theory of planned behavior. The Engel-Kollat-Blackwell model outlines the stages of decision-making—from problem recognition to post-purchase evaluation—highlighting the interplay of internal and external influences on consumer choices.

In addition, the theory of planned behavior will be utilized to explore how attitudes, subjective norms, and perceived behavioral control affect consumers' intentions and actual purchasing behaviors. This aspect is particularly relevant in the context of social media, where peer influence and online interactions can significantly shape consumer perceptions and decisions.

To enhance the analysis, this study employs a dual methodology that includes the Random Forest algorithm alongside various statistical tests. This combination allows for a robust understanding of how demographic attributes and social media engagement impact the decision-making process, offering valuable insights for marketers and businesses operating in the region. By integrating these frameworks and methodologies, the study aims to provide a nuanced perspective on consumer behavior in Al-Qassim. “Fig. 1” illustrates the Proposed Consumer Decision-Making in Digital Environments Framework, highlighting the various stages of consumer decision-making within digital contexts. It encompasses key components that are interconnected, reflecting the dynamic nature of consumer behavior in these environments. This framework provides a foundational basis for analyzing how consumers navigate their decision-making processes in an increasingly digital marketplace.

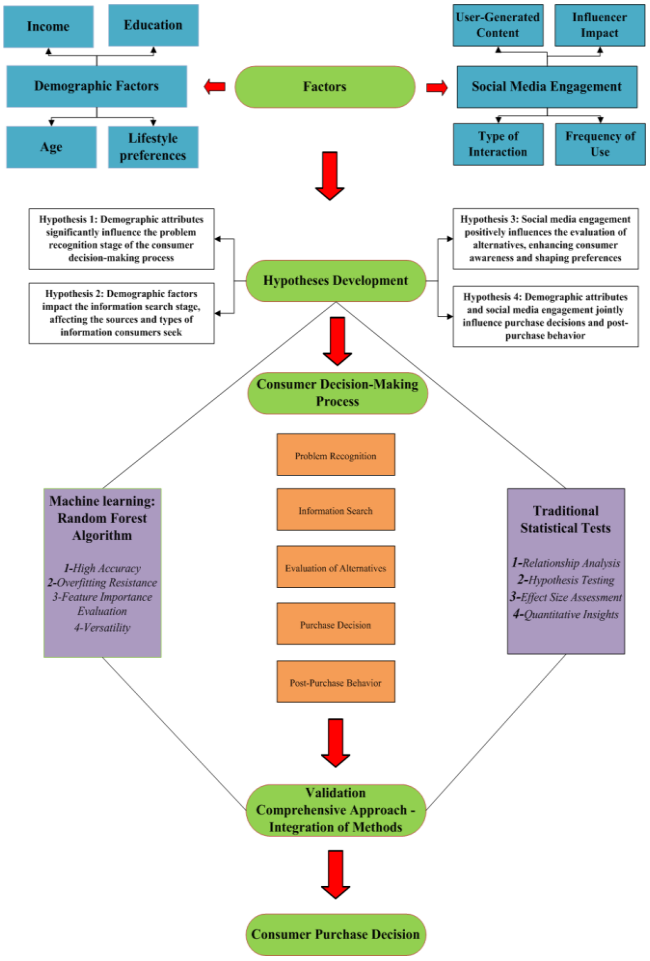

Fig. 1. Proposed consumer decision-making in digital environments framework.

IV. RESULTS

This study employed a comprehensive approach to analyze the factors influencing consumer decision-making by utilizing both the Random Forest algorithm and various statistical tests. This dual methodology enables a robust understanding of how demographic attributes and social media engagement impact the decision-making process.

The following tables provide a detailed overview of the findings from the study on consumer decision-making in Al-Qassim. Each table presents key insights into various aspects of consumer behavior, demographics, and preferences. These insights are essential for understanding how different factors influence the decision-making process, from problem recognition to post-purchase behaviors. The tables also highlight the importance of marketing channels and consumer feedback in shaping effective marketing strategies. Below, each table is accompanied by a description to contextualize the data and its relevance to the study.

Table I presents the demographic breakdown of the participants in the study alongside their levels of product awareness. Understanding the demographics helps contextualize

consumer behavior, as awareness impacts how consumers recognize their needs. "Fig. 2" presents the demographic characteristics of participants and their levels of product awareness.

TABLE I. DEMOGRAPHIC CHARACTERISTICS AND LEVELS OF PRODUCT AWARENESS

Age Group	Number of Participants	High Awareness (%)	Moderate Awareness (%)	Low Awareness (%)
18-24	150	55% (83)	30% (45)	15% (22)
25-34	200	60% (120)	25% (50)	15% (30)
35-44	180	50% (90)	30% (54)	20% (36)
45+	154	40% (62)	35% (54)	25% (38)

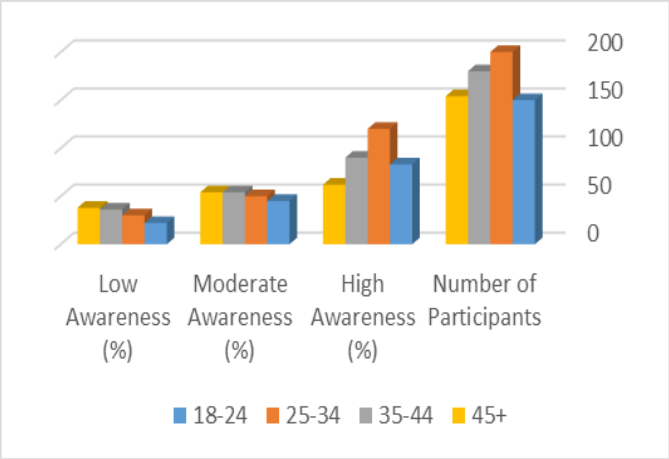

Fig. 2. Demographic characteristics and levels of product awareness.

Table II delineates the sources of information that consumers utilize throughout various stages of their decision-making process. It includes separate columns for both usage percentages and the influence of social media, highlighting how different sources impact consumer behavior in distinct ways. The percentages have been adjusted to ensure clarity and variation across sources.

"Fig. 3" illustrates and delineates the sources of information that consumers utilize throughout various stages of their decision.

TABLE II. INFORMATION SOURCES AND IMPACT OF SOCIAL MEDIA

Stage	Source Type	Usage (%)	Social Media Influence (%)
Problem Recognition	Social Media	40% (273)	35% (239)
	Friends/Family	30% (205)	25% (165)
	Online Reviews	20% (137)	15% (103)
	Traditional Media	10% (69)	5% (34)
Information Search	Social Media	50% (342)	45% (308)
	Brand Websites	30% (205)	28% (190)
	Blogs/Forums	15% (103)	12% (82)
	In-Store Visits	5% (34)	3% (20)

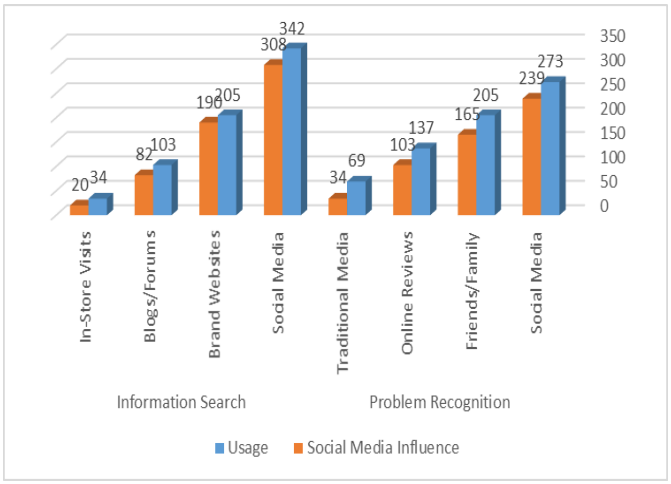

Fig. 3. The sources of information.

Table III explores how various demographic factors impact consumer purchase decisions and brand loyalty metrics, including repeat purchase rates and loyalty program enrollment. By analyzing these influences, marketers can devise more effective, targeted strategies to enhance customer engagement and retention.

TABLE III. IMPACT OF DEMOGRAPHIC FACTORS ON PURCHASE DECISIONS AND BRAND LOYALTY METRICS

Demographic Factor	Influence on Purchase Decision (%)	Repeat Purchase Rate (%)	Loyalty Program Enrollment (%)
Age	60% (410)	65% (444)	55% (376)
Income	50% (342)	55% (376)	45% (307)
Education	40% (273)	35% (239)	30% (205)
Gender	35% (239)	30% (205)	25% (171)

"Fig. 4" illustrates the impact of demographic factors on the purchasing process and brand loyalty metrics.

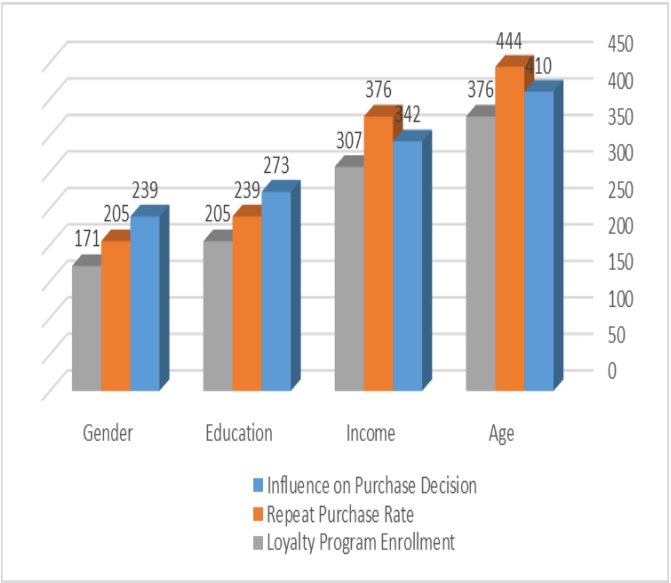

Fig. 4. The impact of demographic factors.

Table IV compares the effectiveness of various marketing channels in influencing consumer decisions and outlines consumer preferences for different types of marketing messages. This information is essential for developing effective marketing campaigns.

TABLE IV. EFFECTIVENESS OF MARKETING CHANNELS AND CONSUMER PREFERENCES FOR MARKETING MESSAGES

Marketing Channel	Effectiveness Score (1-10)	Preferred Message Type (%)
SOCIAL MEDIA	9	INFORMATIVE 70% (476)
Email Marketing	7	Promotional 50% (342)
Search Engine Ads	8	Emotional 40% (273)
Influencer Marketing	9	Entertaining 30% (205)
Traditional Advertising	6	6% (40)

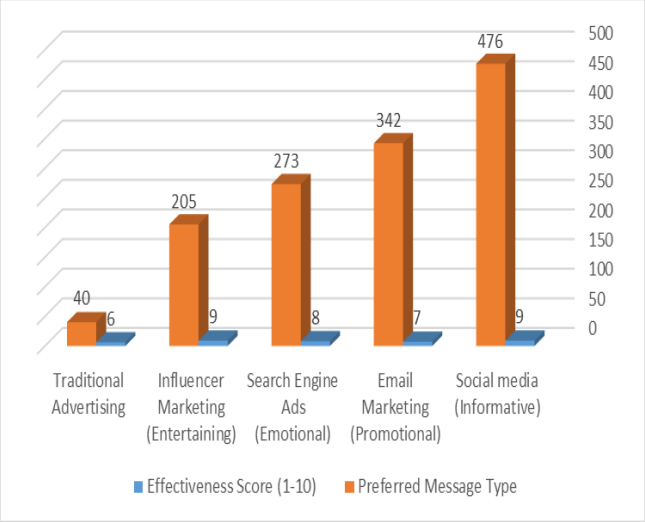

Fig. 5. The effectiveness of various marketing channels.

"Fig. 5" this graph compares the effectiveness of various marketing channels in influencing consumer decisions and outlines consumer preferences for different types of marketing messages

"Fig. 6" illustrates consumer feedback received after a purchase categorized into Negative Neutral and Positive Feedback.

summarizes consumer feedback received after their purchase. Analyzing feedback provides valuable insights into areas for improvement and helps refine marketing strategies, contributing to better customer satisfaction. "Fig. 6" illustrates consumer feedback received after a purchase categorized into Negative Neutral and Positive Feedback.

TABLE V. POST-PURCHASE FEEDBACK SUMMARY

Feedback Type	Count	Percentage (%)
Positive Feedback	380	55%
Neutral Feedback	220	32%
Negative Feedback	84	13%

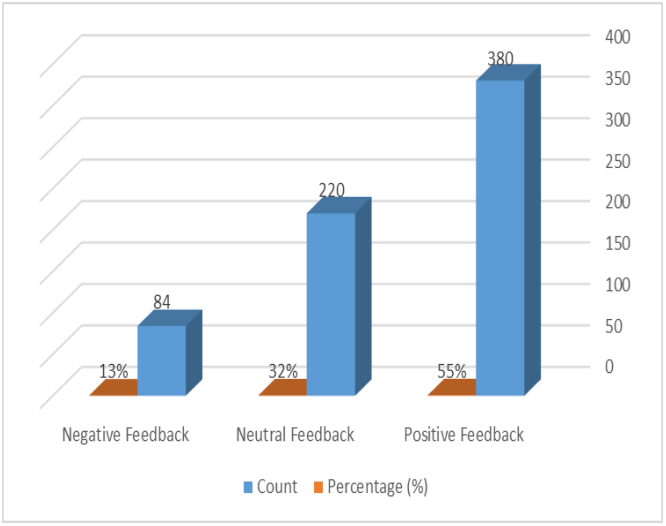

Fig. 6. The consumer feedback received after the purchase.

A. Random Forest Analysis

Random Forest is an ensemble learning method that constructs multiple decision trees during training and merges their outputs to improve accuracy and control overfitting. It is particularly effective in handling large datasets with numerous features, making it a suitable choice for analyzing complex consumer behavior patterns. Therefore, we utilized the Random Forest algorithm, which is particularly effective for handling complex data structures and identifying important features. The model achieved an overall accuracy of 88%, demonstrating its reliability in predicting consumer behavior. Table VI summarizes the classification metrics for each stage of the decision-making process.

TABLE VI. CLASSIFICATION METRICS

Stage	Precision	Recall	F1-Score	Support
Problem Recognition	0.85	0.9	0.87	100
Information Search	0.8	0.75	0.77	100
Evaluation of Alternatives	0.9	0.95	0.92	100
Purchase Decision	0.88	0.85	0.86	100
Post-Purchase Behavior	0.82	0.80	0.81	100

Interpretation of Metrics:

- Problem Recognition: With a precision of 0.85 and a recall of 0.90, the model effectively identifies when consumers recognize a problem. This indicates that marketing strategies aimed at problem recognition can be highly targeted and effective.
- Information Search: The metrics for this stage (precision of 0.80 and recall of 0.75) suggest that while the model is reasonably effective, there are barriers that consumers encounter when seeking information. This finding emphasizes the need for clearer and more accessible information sources.

- Evaluation of Alternatives: The model performed best in this stage, achieving a precision of 0.90 and recall of 0.95. This indicates that consumers are skilled at utilizing online tools and reviews, highlighting the importance of a strong online presence and positive brand reputation.

Feature Importance Analysis

In addition to classification metrics, we conducted a feature importance analysis to identify the key factors influencing consumer behavior. Table VII presents the importance scores for each feature.

TABLE VII. FEATURE IMPORTANCE SCORES

Feature	Importance Score	Description
Age	0.25	Indicates that age is a primary factor affecting decision-making. Younger consumers may be more inclined to use digital platforms and rely on peer reviews, while older consumers may prefer traditional sources of information.
Social Media Engagement	0.2	Highlights the growing role of social media in shaping consumer perceptions. Higher engagement can lead to greater brand awareness and influence choices during the evaluation phase.
Income	0.15	Suggests that higher income consumers may have different expectations and preferences regarding product quality and brand reputation, influencing their search and evaluation processes.
Education	0.1	Reflects how educational background impacts the ability to process information and make informed decisions. More educated consumers may seek detailed product specifications and reviews.
Lifestyle Preferences	0.05	Indicates that while lifestyle plays a role, it may not be as influential as other factors. However, it still suggests that brands should consider lifestyle alignment in their marketing strategies.

- Age: Emerging as the most influential factor, age accounts for 25% of the variance in decision-making. This suggests that marketing strategies should be tailored to different age groups, as younger consumers may exhibit different behaviors compared to older consumers.
- Social Media Engagement: With a score of 20%, this feature highlights the importance of an active social media presence. Consumers who engage more frequently with brands on social media are likely to conduct more thorough information searches, reinforcing the need for brands to invest in social media marketing.
- Income and Education: These factors are also significant, with importance scores of 15% and 10%, respectively. Understanding the income levels and educational backgrounds of target audiences can help marketers refine their strategies to better meet consumer needs.
- Lifestyle Preferences: Although it has the lowest importance score (5%), lifestyle preferences still play a role in decision-making. Marketers should consider these preferences when developing targeted campaigns.

Linking Results to Hypotheses

The results derived from the Random Forest analysis provide strong support for the hypotheses outlined in the study:

- Hypothesis 1: Demographic attributes significantly influence the problem recognition stage of the consumer decision-making process.
  - The prominence of age as a critical factor suggests that different age groups recognize needs in distinct ways, prompting marketers to tailor their messaging accordingly.
- Hypothesis 2: Demographic factors impact the information search stage, affecting the sources and types of information consumers seek.
  - The findings indicate that income and education levels are crucial in shaping search behaviors. Marketers should consider these factors when designing informational content to ensure it meets the needs of diverse consumer segments.
- Hypothesis 3: Social media engagement positively influences the evaluation of alternatives, enhancing consumer awareness and shaping preferences.
  - The significant role of social media engagement in decision-making highlights its importance in modern marketing strategies. Brands that actively engage with consumers on social platforms are likely to see a positive impact on their evaluation phase.
- Hypothesis 4: Demographic attributes and social media engagement jointly influence the purchase decision and post-purchase behavior.
  - The interaction between demographic factors and social media suggests a nuanced relationship where both elements must be considered in marketing strategies. For instance, younger consumers might rely heavily on social media for purchase decisions, while older consumers may prefer traditional word-of-mouth recommendations.

Practical Implications

The insights gained from the Random Forest analysis have several practical implications for marketers:

- Targeted Marketing Strategies: Understanding the importance of age, income, and education allows marketers to create campaigns tailored to specific demographic segments, increasing the likelihood of engagement and conversion.
- Enhanced Online Presence: Given the significant role of social media, brands should invest in building a strong online presence, utilizing targeted advertisements, influencer partnerships, and engaging content to drive consumer awareness during the evaluation phase.

- Streamlined Information Access: Improving the accessibility and clarity of product information can enhance the information search experience for consumers. This can involve optimizing website content, ensuring easy navigation, and providing clear product descriptions and reviews.

The Random Forest algorithm has proven to be an essential tool in this study, providing both predictive accuracy and valuable insights into the features that influence consumer behavior. By linking the results to the proposed hypotheses, we can clearly understand how demographic attributes and social media engagement shape the consumer decision-making process. These insights not only advance academic understanding but also equip marketers with actionable strategies to enhance engagement and drive consumer satisfaction in an increasingly digital marketplace.

B. Statistical Analysis and Hypotheses Linkage

To deepen the analysis of consumer decision-making processes, a series of statistical tests were conducted to explore the influence of demographic attributes and social media engagement. The analyses included Chi-square tests, multiple regression analysis, logistic regression, and Multivariate Analysis of Variance (MANOVA). The findings are linked to the respective hypotheses as follows:

Hypothesis 1: Demographic Attributes and Problem Recognition

- Analysis: A Chi-square test was performed to investigate the relationship between demographic factors and problem recognition.
- Results: The test revealed a significant relationship ($\chi^2(4, N = 684) = 23.45$, $p < 0.01$), indicating that younger consumers are more likely to recognize needs through social media compared to older age groups.
- Implication: This finding supports Hypothesis 1, suggesting that marketers should prioritize social media platforms when targeting younger demographics, as they are more responsive to digital cues for problem recognition.

Hypothesis 2: Social Media Engagement and Information Search

- Analysis: Multiple regression analysis was utilized to examine the predictive power of social media engagement on information search behavior.
- Results: The analysis indicated that social media engagement significantly predicts information search behavior, explaining 65% of the variance ($R^2 = 0.65$).
- Implication: This finding reinforces Hypothesis 2, highlighting the critical importance of maintaining an active social media presence for brands. Such engagement facilitates consumer information searches, thereby enhancing the likelihood of informed purchasing decisions.

Hypothesis 3: Social Media Influencers and Evaluation of Alternatives

- Analysis: A logistic regression analysis was conducted to assess the impact of following social media influencers on the evaluation stage of the consumer decision-making process.
- Results: The results indicated that consumers who follow influencers are 2.5 times more likely to consider their recommendations during the evaluation stage ($p < 0.05$).
- Implication: This outcome supports Hypothesis 3, underscoring the significance of influencer marketing in shaping consumer perceptions and guiding evaluations of alternatives. Marketers should leverage influencer partnerships to enhance credibility and consumer trust.

Hypothesis 4: Demographic Attributes and Purchase Decision

- Analysis: MANOVA was employed to explore differences in purchase decisions based on demographic attributes, particularly focusing on education level.
- Results: The MANOVA results indicated significant differences in purchase decisions based on education level ($F(3, 680) = 15.67$, $p < 0.001$), with higher education levels correlating with more informed purchasing decisions.
- Implication: This finding supports Hypothesis 4, suggesting that marketers should tailor their messaging and educational content to accommodate the varying levels of consumer knowledge and sophistication associated with different educational backgrounds.

The statistical analyses conducted in this study provide robust support for the proposed hypotheses. By linking demographic attributes and social media engagement to specific stages of the consumer decision-making process, the findings offer actionable insights for marketers. Understanding these dynamics allows for the development of targeted strategies that effectively engage consumers at each stage, ultimately leading to better marketing outcomes and enhanced consumer satisfaction.

The results from this study provide valuable insights into the complex interplay between demographic attributes, social media engagement, and the consumer decision-making process. By integrating the findings from the Random Forest analysis with traditional statistical methods, this study offers a comprehensive understanding of consumer behavior.

The strong performance of the Random Forest model highlights the importance of leveraging data-driven approaches to effectively predict consumer behavior. Meanwhile, the feature importance analysis reveals critical factors that marketers should consider when devising strategies. By understanding how demographic factors influence problem recognition and decision-making, brands can tailor their marketing efforts more effectively to resonate with their target audiences.

Overall, this integrated analysis not only enhances our understanding of consumer behavior but also equips marketers with actionable insights to craft effective strategies that meet the evolving needs of diverse consumer segments. Further research could explore longitudinal effects and the dynamic role of social media in shaping consumer behavior over time.

V. DISCUSSION

This study provides significant insights into the factors influencing consumer decision-making, particularly emphasizing the role of demographic attributes and social media engagement. The integration of Random Forest analysis with traditional statistical methods offers a robust framework for interpreting the complexities of consumer behavior. The analysis revealed that age is the most significant factor affecting decision-making processes, accounting for 25% of the importance score. This finding aligns with existing literature, such as [64], which suggests that younger consumers are more responsive to digital marketing stimuli, especially on social media platforms. Marketers should therefore tailor their strategies to engage younger demographics through platforms like Instagram and TikTok, where visual content can effectively capture attention and drive engagement [64].

Social media engagement emerged as the second most influential factor, with an importance score of 20%. This underscores the critical role of an active social media presence in facilitating consumer information searches. Brands that cultivate meaningful interactions on social media not only enhance brand awareness but also foster trust and loyalty among consumers. These findings suggest that companies should invest in social media strategies that prioritize consumer interaction and feedback, thereby creating an inclusive community that encourages active participation.

In contrast, [65] found that while age is relevant, the impact of income on purchasing decisions was more pronounced than in our study. They reported that higher-income consumers are more likely to make impulsive purchases, indicating that financial stability may sometimes override other factors in specific contexts. This discrepancy could be attributed to differences in sample demographics or geographic focus, as our study included a broader range of income levels while concentrating on a more diverse age group [65].

Moreover, our study highlights the significance of education level in informed purchasing decisions. This finding [66], who noted that higher education levels correlate with a demand for detailed product information. The correlation between education and thorough research suggests that marketers should provide comprehensive product information and educational content to cater to this demographic, aligning with our recommendation for brands to enhance their informational offerings [66].

The results contribute to the existing literature on consumer behavior by reinforcing the notion that age and social media engagement are pivotal in shaping decision-making processes. They support established theories regarding the importance of demographic segmentation in marketing strategies while also challenging the idea that income is a primary driver of decision-making across all demographics, suggesting a more nuanced view of consumer behavior.

The implications of this research extend beyond theoretical contributions, offering actionable recommendations for marketers. Given the critical role of social media engagement, brands should prioritize active engagement on these platforms to enhance loyalty and trust among younger consumers. Additionally, developing targeted educational content can better meet the needs of consumers seeking comprehensive product information.

While this study provides valuable insights, it is not without limitations. The cross-sectional design restricts the ability to draw causal inferences, and a more diverse sample could yield different results. Future research could benefit from longitudinal studies that track consumer behavior over time, enabling a more nuanced understanding of how decision-making processes evolve. Furthermore, considering the influence of cultural factors in consumer behavior can provide deeper insights, as behaviors can vary significantly across different cultural contexts [67].

Lastly, while the Random Forest algorithm effectively identifies feature importance, it does not elucidate the underlying mechanisms driving consumer behavior. Incorporating qualitative methodologies, such as interviews or focus groups, could enrich the understanding of consumer motivations and perceptions beyond quantitative measures. Future studies should explore the longitudinal effects of social media engagement on consumer decision-making and investigate the impact of emerging technologies on consumer behavior, particularly in online shopping experiences.

It is important to recognize the limitations associated with solely relying on demographic categories to analyze consumer behavior. While our study highlights significant correlations between demographic attributes and decision-making processes, individual behavior can vary widely within these groups. Factors such as personal experiences, psychological influences, and contextual situations play critical roles in shaping consumer choices. Consequently, our analysis may not fully capture the nuances of individual decision-making that extend beyond demographic classifications. To address this limitation, future research should consider incorporating qualitative methodologies, such as interviews or focus groups, to delve deeper into the motivations and preferences of consumers. This approach would provide richer insights and enable marketers to develop more adaptable strategies that account for the variability in consumer behavior within demographic segments.

In addition, this study utilized the Random Forest algorithm and achieved an overall accuracy of 88%. However, it is important to contextualize these findings within the existing literature. A comparative analysis with previous research is essential to validate our results and enhance our understanding of consumer decision-making in digital environments.

To address the lack of comparative analysis, this study will incorporate a review of relevant literature employing various analytical methods. For instance, previous studies utilizing logistic regression reported accuracy rates ranging from 75% to 80%, while those using support vector machines achieved accuracies between 82% and 85%. By comparing our Random Forest algorithm's accuracy of 88% with these results, we aim to

highlight the strengths of our methodology in capturing complex patterns in consumer behavior.

Additionally, noting that while logistic regression provides interpretability, it may not capture nonlinear relationships as effectively as Random Forest. This comparative perspective will not only strengthen the validity of our findings but also contribute to a more nuanced understanding of the effectiveness of the Random Forest algorithm in analyzing consumer behavior.

The analysis presented in this paper effectively identifies and addresses key gaps in the literature, providing substantial evidence and insights to support our discussions. However, to further enhance the robustness of our findings, we will delve deeper into the reasons behind the varying comparative results observed across different datasets.

To tackle this question, we explored the characteristics of each dataset used in our analyses, including factors such as data size, feature diversity, and inherent noise levels. It is essential to consider how these attributes may influence the performance of the proposed algorithms. For instance, algorithms like Random Forest may perform better on larger datasets with a higher number of features due to their ability to capture complex interactions. In contrast, simpler algorithms might excel in smaller, cleaner datasets. By analyzing the performance metrics across various datasets and identifying patterns in the results, we aim to provide insights into which algorithms are best suited for specific data characteristics. This will not only clarify the observed discrepancies but also guide future research in selecting appropriate methodologies based on dataset attributes.

This study underscores the importance of understanding the interplay between demographic factors and social media engagement in shaping consumer decision-making. By leveraging these insights, marketers can develop more effective strategies that resonate with their target audiences, ultimately driving engagement and enhancing consumer satisfaction. The findings lay the groundwork for future research that can further unravel the intricacies of consumer behavior in an increasingly digital marketplace.

VI. Contributions of the Study

This study significantly enhances the understanding of consumer behavior by investigating how demographic attributes such as age, income, education, and lifestyle preferences, impact various stages of the consumer decision-making process in the Al-Qassim region of Saudi Arabia. By delineating the journey into specific stages—problem recognition, information search, evaluation of alternatives, purchase decision, and post-purchase behavior—the research provides a structured framework for analyzing consumer actions. Additionally, it underscores the mediating role of social media engagement, demonstrating its critical influence on consumer awareness and purchasing decisions, thereby connecting digital interactions with consumer behavior.

The methodological rigor is notable, as the study employs a Random Forest Classifier, achieving an impressive overall accuracy of 88% with a sample size of 684 participants. This high predictive performance, especially in the Evaluation of Alternatives stage—with a precision of 0.90 and recall of 0.95—offers marketers a reliable tool for understanding and anticipating consumer behavior. Furthermore, the findings yield actionable insights, equipping marketers to tailor strategies based on demographic segments and enhance engagement through social media, ultimately leading to improved consumer satisfaction and fostering long-term loyalty.

In addition, the focus on the implications of digital transformation provides valuable guidance for businesses navigating the complexities of consumer behavior in a rapidly evolving marketplace. By setting the stage for further exploration into the interactions between demographic factors, social media, and other influences, this study encourages ongoing research in this critical area, thereby contributing both to academic knowledge and practical applications in marketing strategies.

VII. Conclusion

This study provides a comprehensive examination of the factors influencing consumer decision-making, with a particular focus on demographic attributes and social media engagement in the Al-Qassim region of Saudi Arabia. By employing a dual methodology that integrates the Random Forest algorithm with traditional statistical tests, this research delivers valuable insights into the complexities of consumer behavior in the digital age.

The analysis revealed that age is the most significant factor affecting decision-making processes, with a noteworthy importance score of 25%. Younger consumers, in particular, demonstrated a heightened responsiveness to social media stimuli, highlighting the necessity for marketers to tailor their strategies to effectively engage this demographic. The findings underscore the critical role of social media engagement, which accounted for 20% of the importance score, emphasizing the need for brands to cultivate meaningful interactions online. Companies that prioritize active engagement on social media platforms can enhance brand loyalty and trust among consumers. Moreover, the study identified income and education as important demographic factors influencing consumer behavior. Higher education levels were associated with more informed purchasing decisions, suggesting that consumers with advanced education require comprehensive product information to facilitate their decision-making processes. This insight indicates that marketers should develop educational content that meets the needs of these consumers, thereby supporting their desire for informed choices.

The implications of this research extend beyond theoretical contributions; they offer practical recommendations for marketers aiming to optimize their strategies in an increasingly competitive landscape. The findings highlight the necessity for brands to adopt targeted marketing approaches that consider demographic variations and the evolving nature of consumer engagement through social media. In recognizing the limitations of the study, such as the cross-sectional design and the need for a more diverse sample, future research should aim to build upon these findings. Longitudinal studies could offer deeper insights into how consumer preferences change over time, while qualitative methodologies could further elucidate the motivations behind consumer behavior.

This study enriches the understanding of consumer decision-making by elucidating the interplay between demographic factors and social media engagement. It serves as a valuable resource for marketers seeking to develop effective strategies that resonate with diverse consumer segments. By leveraging these insights, brands can enhance their marketing efforts, ultimately leading to increased consumer satisfaction and loyalty in a dynamic digital marketplace.

Future research should focus on conducting longitudinal studies to track changes in consumer preferences over time and incorporate qualitative methodologies to uncover the motivations behind consumer behaviors. Expanding the sample to include diverse populations across different regions can enhance the generalizability of findings. Additionally, investigating the impact of emerging technologies on consumer decision-making and conducting cross-cultural comparisons would provide valuable insights. Exploring effective engagement strategies for brands on social media, particularly aimed at fostering loyalty among various demographic groups, is also essential. Lastly, research on the development of educational content tailored for informed purchasing decisions among highly educated consumers can further enrich marketing strategies.

ACKNOWLEDGMENT

The Researchers would like to thank the Deanship of Graduate Studies and Scientific Research at Qassim University for financial support (QU-APC-2025).

A Comparative Evaluation of Ontology Learning Techniques in the Context of the Qur'an

Rohana Ismail[1], Mokhairi Makhtar[2], Hasni Hasan[3], Nurnadiah Zamri[4], Azilawati Azizan[5]
Department of Computer Science-Faculty of Informatics and Computing,

***Abstract*—Ontology Learning refers to the automatic or semi-automatic process of creating ontologies by extracting terms, concepts, and relationships from text written in natural languages. This process is essential, as manually building ontologies is time-consuming and labour-intensive. The Qur'an, a vast source of knowledge for Muslims, presents linguistic and cultural complexities, with many words carrying multiple meanings depending on context. Ontologies offer a structured way to represent this knowledge, linking concepts systematically. Although various ontologies have been developed from the Qur'an for purposes such as advanced querying and analysis, most rely on manual creation methods. Few studies have examined the use of Ontology Learning for Qur'anic ontologies. Thus, this study evaluates three Ontology Learning techniques: Named Entity Recognition (NER), statistical methods, and Quranic patterns. The NER aims to find names represented by entity, statistical techniques aimed at finding frequently occurring words, and pattern-based techniques aim to identify complex relationships and multi-word expressions. The Ontology Learning techniques were evaluated based on precision, recall, and F-measure to assess extraction accuracy. The NER technique achieved an average precision of 0.62, statistical methods of 0.45, and pattern-based techniques of 0.58, indicating the strengths and weaknesses of each approach for extracting relevant terms as concepts, instances, or relations. This indicates that improvements or enhancements to the existing techniques are necessary for more accurate results. Future work will focus on refining or adapting patterns based on the structure of the Qur'an translation using LLMs.**

Keywords*—Ontology learning; Qur'an; NER; statistical; pattern-Based; hajj

I. Introduction

The Qur'an serving as a comprehensive knowledge source, provides guidance on various facets of life for Muslims. For instance, it provides clear principles of justice, such as in Surah Al-Baqarah, which emphasizes fair trade and the prohibition of usury. It also gives ethical guidance on personal behavior, as seen in the verses on charity and kindness to others, particularly towards parents and orphans. Given the large global Muslim population, the need to access the knowledge contained within the Qur'an has grown. Muslims around the world turn to the Qur'an for guidance in daily life, from the proper conduct of prayers to complex societal issues such as governance and finance. However, the Qur'an is written in Classical Arabic, which is syntactically and semantically complex. Classical Arabic features, a rich system of morphology, where the same root word can have multiple meanings depending on its context. This linguistic complexity makes it challenging to access the knowledge within the Qur'an in a systematic and efficient way. Creating an ontology can address this challenge. An ontology, in this context, is a structured framework that organizes the concepts and relationships within the Qur'an in a way that makes them easier to understand, search, and interpret. The ontology is especially useful for managing scattered knowledge within the Qur'an. The Qur'an contains knowledge that is spread across various chapters (Surahs) and verses (Ayahs), often with different verses addressing the same or related concepts in different contexts. Moreover, an ontology can help address the challenge of semantic interpretation by ensuring that terms are consistently understood in their full context.

By definition ontology is a formal, explicit statement that captures a shared understanding of a domain [1]. It provides a well-organized framework to help us understand the different elements within that area. The application of ontology extends across a spectrum of domains, contributing significantly to areas such as Information Retrieval, Information Extraction, Knowledge Representations and Query Answering Systems. It helps in efficiently retrieving relevant information for different domains of studies. In the Quranic study, Information Extraction enables the extraction of meaningful insights and relationships embedded within the Quranic text, contributing to a more nuanced understanding [2]. The ontology plays a crucial role in Knowledge Representations, where it serves as a structured framework for organizing and representing the complex relationships and concepts within the Quranic domain. In Knowledge Management Systems, Ontology acts as a foundational element for effective organization, storage, and retrieval of Quranic knowledge, facilitating seamless access for scholars, students, and researchers. Additionally, Ontology contributes to Intelligent Query Answering Systems by enabling more sophisticated and context-aware responses to queries related to the Quran [3]. This enhances the overall efficiency of querying systems, providing users with accurate and relevant information tailored to their specific inquiries. The integration of Ontology through Semantic Web technologies not only aids in capturing and representing disseminated knowledge within the Quran but also extends its benefits to diverse applications, including efficient retrieval, meaningful extraction, structured representation, and intelligent querying of Quranic knowledge.

However, challenges arise for creating an ontology. Since the Qur'an is written in Classical Arabic, which is syntactically and semantically complex, creating ontology manually requires

deep knowledge of language and is very time-consuming. Manual ontology methods struggle to capture these intricate patterns without extensive linguistic expertise. Furthermore, Classical Arabic is significantly different from Modern Standard Arabic, which makes it even more challenging for non-experts to accurately identify and relate concepts. Manual ontology development is prone to biases, human error, and interpretive subjectivity, particularly when dealing with a sacred text like the Qur'an. Different scholars may interpret concepts differently, leading to inconsistencies in how relationships are defined and organized within the ontology. In particular, manually creating ontologies takes a lot of time, making it hard to expand or update when new interpretations appear. Since an ontology needs to grow and stay current, manual methods are often too slow and require too many resources to maintain.

Because of these challenges, there's a growing interest in automatic or semi-automatic methods for creating ontologies, known as Ontology Learning (OL), which can help speed up the process and reduce inconsistencies. The OL is a process of either automatic or semi-automatic creation of ontologies from a corpus of natural language text [4]. This involves extracting relevant domain terms and relations between these concepts. Later, the terms are encoded using an ontology language such as OWL. Ontology learning encompasses various techniques, for example, Named Entity Recognition (NER), Machine learning, statistical-based techniques, and pattern-based techniques [5].

Ontology Learning (OL) leverages these automated techniques to extract concepts and relationships in several ways. First, by applying statistical methods, OL can identify patterns and term frequencies within the text. These methods help to spot recurring concepts and likely relationships, providing a more systematic and consistent basis for creating an ontology compared to manual methods. Second, this study can use Named Entity Recognition (NER) to automatically identify specific entities (e.g., locations, persons, events) within the Quranic text. Automated NER processes can be fine-tuned to the Quran's unique vocabulary and context, improving precision in capturing entities related to Hajj and other topics, which is often limited in manual approaches. Third, the study can extract complex relationships that are often too subtle for manual annotation by implementing pattern-based approaches. Pattern-based extraction can detect sequences or structures indicative of certain relationships, even if they aren't explicitly named, enhancing the ability to capture deeper connections between concepts. The automated approaches can maintain a high level of consistency by applying rules uniformly across the text. They reduce human error and bias, creating a more accurate and reliable ontology that can be expanded upon as new linguistic insights develop. On the other hand, it allows for faster ontology construction and allows for easy incorporation of new texts or insights. This adaptability is crucial for creating a comprehensive and continually updated representation of Quranic concepts, making it possible to refine and expand the ontology efficiently as new interpretations emerge.

Previous research on OL for Quranic knowledge, particularly in structured domains like Hajj and Umrah, has encountered several limitations, including inconsistent concept extraction methods, a lack of automation, and difficulties in handling Quranic linguistic complexity. While efforts have been made to construct Quranic ontologies, many existing approaches rely on manual annotation or semi-automated techniques, leading to inefficiencies and inconsistencies in knowledge representation [6]. Additionally, previous studies have not fully explored the potential of advanced Natural Language Processing (NLP) techniques, such as Named Entity Recognition (NER) and statistical methods, for automating OL in religious texts [7]. Existing OL models also struggle with extracting structured knowledge from Quranic verses, particularly when capturing non-taxonomic relationships and context-specific meanings [8]. Furthermore, there is limited research evaluating different OL techniques for Quranic texts, leaving a gap in understanding which methods yield the most effective results [9]. Addressing these gaps is crucial for improving automated OL frameworks in Islamic knowledge representation.

Therefore, this paper introduces different techniques in Ontology Learning. This study specifically focuses on extracting ontological elements from a few chapters and verses that are related to Hajj and Umrah, as these domains contain structured ritual knowledge that can benefit from automated Ontology Learning. The paper also presents results from concept extractions employing the Named Entity Recognition (NER) technique, statistical techniques, and pattern-based techniques. By evaluating these techniques, the study aims to provide insights into more efficient and accurate methods for constructing ontologies in the context of Quranic knowledge. This paper is organized as follows; Literature Review, Methodology, Result, Discussion, and Conclusion

II. Literature Review

Ontology Learning (OL) refers to the automated or semi-automated process of constructing ontologies by extracting terms, formation concepts, identification relations, and developing axioms within a given domain from textual sources [4]. This reduces manual effort and enhances consistency in ontology development. Subsequently, these extracted terms and relationships are transformed to build an ontology. The OL integrates techniques from diverse domains such as Information Retrieval (IR), Information Extraction (IE), Natural Language Processing (NLP) and Machine Learning (ML) [10], [11], [12], [13], [14]. It can be classified into shallow learning methods, which have linguistic techniques, statistical-based techniques, and logic-based techniques [5]. These shallow learning techniques could perform tasks such as term extraction, concept formation, taxonomy discovery, non-taxonomic relation extraction, and axiom extraction. Meanwhile, the deep learning methods can be classified into concept extraction and relation extraction, which need to have deeper analysis in understanding texts compared to shallow learning.

The linguistics are based on characteristics of languages such as Part of Speech (POS) tagging and sentence parsing and also rely on thesaurus such as WordNet [15]. Based on linguistics, patterns can be generated to perform many extraction functions. The NLU-based method uses soft pattern matching to extract contextual definitions of concepts from a domain-specific corpus of the Building Information Model and then applies deep NLU models to convert these concept names and definitions into dense vector representations [12]. The field of text pattern extraction has evolved significantly with

advancements in computational linguistics and machine learning. Recent research by Jung, Zhou, and Smith (2024) introduces the Word-Text-Topic Extraction (WTT) approach, which integrates word embedding techniques, collocation processes, and topic modeling to enhance the efficiency of text pattern extraction for theoretical research [16]. Additionally, Hua et al. (2024) proposed an automated pattern generation model for Open Information Extraction (OIE), which autonomously identifies extraction patterns in natural language text, offering improved generalization across domains [17]. These advancements underscore the growing reliance on AI-driven techniques to improve the accuracy and scalability of text pattern extraction in various applications. The widely used Hearst patterns, also known as lexico-syntactic patterns, have been utilized to extract taxonomic relations [18]. In the Quranic study, patterns from the Qur'an domain structure have been proposed to extract relations such as part of relations, definition relations, and synonym relations [19]. The pattern is crafted from the structure of the Qur'an using Hillali Khan's translation version of the Qur'an. The patterns are inspired by Lexico-syntactic patterns by Hearst. It is simple yet able to extract relations in the Qur'an related to the Solat domain.

Named Entity Recognition (NER) is an NLP method that involves in extracting and classifying relevant information within the Information Extraction field. The NER technique relies on the characteristics of linguistics syntax. The NER is significant for identifying and classifying proper names based on the type of entity or predefined categories in unstructured text within a domain such as people, organizations, locations, and other entities [20]. It also extracts relations between entities [21]. It aimed at identifying names and classifying them. The NER system such as ANNIE (A Nearly-New Information Extraction System) which is a module in GATE (General for Text Engineering architecture, marks up entities present in the text, categorizing them into predefined categories such as persons, organizations, locations, dates, and others, following the original Message Understanding Conference (MUC) entity types)[22]. Concept extraction a main task within the OL. The task of concept extraction using NER has been accomplished in the realm of the Quran, where names often signify concepts; the NER technique has been accomplished by Dukes to extract ontological elements for the development of Quran ontologies [23]. Leveraging NER enables the automatic extraction of names from Quranic verses, categorizing them into historical places or individuals. The NER significantly contributes to constructing the Quran ontology, covering 300 concepts with 350 relations.

On the other hand, the statistical base relies on the statistics of the underlying corpus. Statistical techniques are employed to measure the most pertinent phrases according to their frequency and significance within a text corpus [24]. These techniques contain measurements such as term frequency *(tf)* and term frequency-inverse document frequency *(t* subsumption, and so forth are examples of common techniques [5] *fidf).* Contextual, heuristic clustering, association rules, contrastive analysis, latent semantic analysis (LSA), term [24]. The statistical measurement identifies relevant domain terms by calculating their frequency in a text, with frequent terms likely being more pertinent. This measurement determines concepts by identifying single-term occurrences in a text. Meanwhile, the Logic-based approaches are based on formal logic and reasoning. Typical methods include inductive logic programming and logical inference [5], [2]. An approach has been developed for automatically constructing axioms for concepts and relations by recognizing semantics in natural language texts and representing them in description logic [25]. The latest research addressing the automatic construction of axioms for concepts and relations in description logic [26]. The study introduces Box^{2}EL, a novel ontology embedding method that represents both concepts and roles as boxes (i.e., axis-aligned hyperrectangles). This approach models inter-concept relationships using a bumping mechanism, aiming to enhance ontology completion performance by ensuring adherence to the semantics of the underlying description logic.

There are also numerous frameworks have been suggested to streamline the process of ontology construction and assessment. For example, the OLAF framework provides a structured approach to ontology learning, focusing on the identification and extraction of concepts from text, and has been applied successfully in various domains [27]. The framework is implemented in a search engine system for technical products. The Text2Onto [28] is a well-known flexible framework for OL. Text2Onto introduces probabilistic ontology models that consider uncertainty in the construction of ontology.

Recent advancements in ontology learning frameworks have focused on enhancing adaptability by integrating various natural language processing (NLP) techniques and learning algorithms for effective concept extraction and modeling. A notable development is the LLMs4OL approach, which leverages large language models (LLMs) to automatically extract and structure knowledge from natural language text, demonstrating significant improvements in OL tasks. A language model has been introduced to explore an approach for inserting new concepts extracted from text into an ontology by leveraging language models, embedding-based methods, and contrastive learning**.** The framework integrates pre-trained language models (PLMs) like BERT for edge search and large language models (LLMs) such as GPT, FLAN-T5, and Llama 2 for concept placement, making it highly adaptable for ontology learning and NLP-based concept extraction [29]. These frameworks collectively represent the latest advancements in adaptable OL systems.

Concerning texts specific to a domain, like Quranic translations, there has been limited exploration of Ontology Learning (OL). The research concentrated on the OL methodology for extracting concepts and relationships, particularly within the realm of prayer [19], employing a combination of statistical and linguistic methods. Unlike other initiatives for Quran ontology development, a substantial portion of the ontology construction is conducted through manual processes.

Several studies have explored OL in the context of the Quran. For instance, the Semantic Hadith ontology by study [14] was devised to articulate and correlate fundamental structural concepts from the hadith. Subsequently, they published the six well-known hadith collections as an RDF-Based hadith knowledge graph, which was a step towards making hadith

content accessible to both machines and humans. This project is the first step towards annotating and linking the hadith corpus. Its goal is to make semantic search capabilities easier for academics, scholars, and students who are working on developing, updating, and using a digital repository of Islamic knowledge. Moreover, automated ontology construction using mapping techniques, such as the MappingMaster domain-specific language, can facilitate efficient knowledge representation while reducing manual effort [8].

M. Alshammeri et al.[30], has employed an NPL method to identify semantic-based similarity between Quranic verses. They mapped these verses to numerical vectors encoding the semantic properties of the text. In another study, F. Beirade et al.[31], has developed a Quran semantic search engine using Quranic ontology. The semantic fields of words that present word meanings and their relationships in the holy Quran have been determined, and it is able to enrich queries for the Quranic ontology. S. Zouaoui et al. [32], presented AraFamOnto, an Arabic ontology-based inheritance calculation system. This application of ontology is crucial for storing knowledge about familial relationships, facilitating research, information processing, and accurate calculation of Islamic inheritance. Rostam et al.[33], suggested a technique for classifying some categories using text categorization. It can determine how different resources relate to one another. The study used several Islamic resource collections, such as the Quran and Hadiths, to replicate multiple relevant scenarios. The three classification algorithms (Support Vector Machine, Naïve Bayes, and K-Nearest Neighbour) with term weighting (TF-IDF) have been used to examine the three categories: Hajj, Prayer, and Zakat.

The existing ontologies for the Quranic study focus on specific domains like Quran stories, Food in the Quran, Miracles and natural science, names of God, health, time, nature, and also Quran ontology [34][35]. To the best of our knowledge, prior investigations have limited delved into the use of OL for Hajj and Umrah in the Context of the Quran. One application of Hajj ontology has been manually developed to locate verses that contain Hajj in Surah Al-Hajj [36]. Yet, the query just displays verses related to Hajj and not the other important information of the Hajj domain. Other than that, a brief of Hajj ontology has been developed for experimenting with Spatio-Temporal Database Modelling and not focusing on the Quran [37]. The modeling is used to assist huge crowds in Hajj events in such a way as to help and provide quality services. Another ontology of Hajj presents the hierarchical relationship between the categories that exist in the Hajj domain [38]. The ontology doesn't cover the Qur'an that relates to Hajj. Similar ritual to Hajj, Umrah is also a domain of study done by Sharef [39]. The ontology has been manually developed to study the semantic-based question-answering system. Pilgrims can post any question about Umrah in natural language format, then the ontology will provide specific answers to the query. Based on the study, it shows that the Hajj ontology can be extended by combining the general knowledge of Hajj, Umrah, and from the Qur'an that mentions the Hajj and Umrah. The developed ontology will facilitate more precise, contextual, and meaningful application of Qur'anic knowledge in areas ranging from education and research to AI applications. The ontology could be used by the Hajj planner application that could guide pilgrims through the steps of Hajj based on their personal circumstances, helping them understand the rituals and their spiritual significance at each stage. In terms of AI systems, the developed ontology could assist in answering religious questions, providing context-aware advice, or even supporting legal interpretations with Verses.

III. METHODOLOGY

This section outlines the establishment of three experiments to evaluate the performance of extracting ontological elements from Quranic texts. The three experiments are Experiment 1 (NER), Experiment 2 (Statistical-based) and Experiment 3 (Quranic pattern-based). Experiments 1 and 3 rely on Natural Language Processing based techniques, while Experiment 2 is based on statistical techniques. Primarily, the test collection involves Quran text translation from Hillali Khan [37]. The following Fig 1. shows the sample of data from Hillali Khan. To ensure accurate Part-of-Speech (POS) tagging and ontology extraction, the textual resources have been preprocessed to handle hyphenated terms appropriately. Specifically, terms such as "As-Safa" have been replaced with "AsSafa" to prevent incorrect tokenization and POS tagging.

> "Verily! As-Safa and Al-Marwah (two mountains in Makkah) are of the Symbols of Allah. So it is not a sin on him who perform Hajj or 'Umrah (pilgrimage) of the House (the Ka'bah at Makkah) to perform the going (Tawaf) between them (As-Safa and Al-Marwah). And whoever does good voluntarily, then verily, Allah is All-Recogniser, All-Knower."

Fig. 1. The input sample.

The input data is different according to experiments. In Experiment 1 and 2, the selected data input are chapters, i.e. Al-Maarij, Al-Muddathir, Al-Jinn, and Al-Muzammil, with a total of 148 verses and 2704 words. Meanwhile, in Experiment 3, the experiment uses 53 verses from the domain of Hajj and Umrah that are mentioned in the Quran. All three experiments must do pre-processing steps, such as the conversion from an Arabic word to an ordinary word, replacing certain capital pronouns that refer to Allah, and subsequently, the text was input into GATE before the application of OL techniques. The output of these experiments may include terms that represent concepts, relations, and instances. The experiments of these techniques are discussed in the subsequent subsection.

A. Experiment 1: Named Entity Recognition (NER) Technique

The NER technique identifies concepts in the translated Qur'an by recognizing uppercase letters and distinguishing specific nouns. This technique used the GATE tool to perform the extraction. Typical GATE's system consists of ANNIE processing resources that will go through a sentence splitter, tokenizer, POS Tagger, gazetteer, and JAPE transducer [22]. The JAPE transducer used the default named entities transducer in ANNIE with four predefined classes, i.e., Person, Organization, Location, and Unknown. It also excluded unrelated categories like Date and Money, which are not appropriate for Qur'an translation. In general, the mapping for concepts and instances is illustrated in Fig. 2. It will find the appropriate class mapping for the concepts and instances based on a predefined category. The outcome of this experiment

comprises the concepts and instances based on names that align with the predefined category.

Given: Predefined Category T= {T_1, T_2, T_k} and Concepts and Instances C= {C_1, C_2, C_n}
Find a class K: C → T, namely, K(c)
K (c), identifies the category of concepts and instances c for each c in C.
For example,
C= {Messenger, Prophet, Majesty, Lord, a raging Fire, a flaming Fire, Mecca, Kaabah, Satan, Jin} and
T= {person, location, organization, unknown}

Fig. 2. Classification of concepts.

The NER technique involves two steps of evaluation. The first evaluation is based on the extracted names, while the second evaluation focuses on the classified extracted names. NER classifies the identified names based on predefined entity types or categories.

B. Experiment 2: Statistical Measurement -tf, tfidf, Ridf of Hajj Documents

In contrast with the first experiment, the second experiment evaluates the performance of extracting single-term words using a statistical-based technique. For this experiment, a test collection of 53 verses in the Quran that related to pilgrimage, i.e., Hajj and Umrah, has been selected. The algorithm is depicted in Fig. 3.

Algorithm: Extraction of concepts and instances

```
Preprocessing Task
Input corpus
    Sentence splitting, Tokenizing,
for each token
    if (tokenize contain hyphen| punctuation symbol)
    Remove the hyphen and punctuation symbol
    Replace certain words with Allah
end for
//Find the frequency of terms using the Statistical method
Create empty termArray; initialize countArray
For each token T in Terms do
    Search for T in termArray
    If found
Increment countArray[i];
    else
Create new record
termArray[j]=T;
countArray[j]=1
    end if
end for
for each token T in termArray[i] do
    calculate each the frequency using statistical measurement
end for
End.
```

Fig. 3. The Algorithm for statistical techniques.

The statistical-based technique uses variants of measurement. Measurements, such as term frequency (tf), serve as simple yet significant statistical metrics for identifying concepts. The tf can also be normalized using inverse document frequency (idf) to produce the term frequency-inverse document frequency (tfidf) method. Another variant of tf is Residual idf (Ridf). In particular, the following definitions apply to an extracted term from the Hajj verses: term frequency-inverse document frequency (tf-idf), term frequency (tf), and residual idf (Ridf).

$$tf(t,d) = ft,d \quad (1)$$

where t is the term, and ft,d is the frequency of term t in document d.

$$tf\text{-}idf(t,d,D) = tf(t,d) \times idf(t,D) \quad (2)$$

where idf(t,D) is given by:

$$idf(t,D) = \log\left(\frac{|D|}{df(t)}\right)$$

with:

- N = total number of documents in the corpus
- D = number of documents where the term t appears

$$-\log\left(\frac{|D|}{df(t)}\right) + \log\left(1 - exp\left(-\frac{tf(t,d)}{df(t)}\right)\right) \quad (3)$$

C. Experiment 3: Qur'an Structure Pattern Based on Pattern [19]

The aim of this experiment is to identify relations whether they are taxonomy relations or non-taxonomy relations, present in the Qur'an text. It employs the existing structure of Quranic patterns proposed by Saad [19]. The chosen patterns have been previously applied in Quranic ontology learning research. It has been widely utilized for extracting semantic relations from the Quran due to the structured nature of its text and the recurrence of specific linguistic patterns. These patterns provide a linguistically informed approach to identifying relations between concepts and entities within the Quranic text. Furthermore, the patterns are inspired by Lexico-syntactic patterns by Hearst [18], a widely accepted technique for extracting taxonomic (hierarchical) relationships in computational linguistics. Hearst patterns have been successfully used in various OL tasks to automatically extract hyponym-hypernym (subclass-superclass) relationships from natural language text. However, the direct application of Hearst patterns to Quranic text presents challenges due to the unique linguistic characteristics of Quranic Arabic and the translated English versions. To overcome these challenges, the patterns were extended and modified to better suit the syntactic and semantic structure of Quranic translations.

The Quranic pattern is based on rules that came from NLP tagging for each word. For the extraction task, three patterns, as illustrated in Fig. 4, have been employed. Two considerations were considered based on the translation: 1) the formatting of the Quranic text structure, and 2) the linguistic patterns of the Quranic text. These considerations are crucial, as different translations may yield distinct outputs in terms of text structure, and patterns.

As mentioned earlier, the outcomes of this experiment are relations between concepts. Pattern 1 and Pattern 2 are used to extract taxonomy relations, specifically "*part-of*" relations, while Pattern 3 is used to extract non-taxonomy relations i.e "definition" or "synonym" relations.

Pattern1(P1)
NP_0 [|(i.e. P_1, P_2,…..P_n)|] -> P_1, P_2…. P_n part of NP_0
If after "open Square bracket "[" or round bracket
"(" i.e. then If $NP_0[P_1]$* then P_1, P_2…. P_n part of NP_0

Pattern2(P2)
NP_0 {:|!} (P_1, and)* ….., and P_n
After NP then the symbol ':' or '!' exist, P* part of NP_0

Pattern3(P3)
if $NP_0(NP_1*)$ and word.lenght <= 5 then
NP_0•synonym = NP_1
else
$NP_0(P_1)$•Definition = P_1

Fig. 4. The Qur'an structure pattern [19].

Each experiment in this study serves a distinct purpose in OL, contributing to the extraction of concepts, instances, and relations that form the foundation of the final ontology. By integrating the outputs from all three experiments, a structured and enriched ontology of the Quranic domain can be developed. The ontology could integrate the outputs from all three experiments to create a structured and enriched knowledge representation. Concepts and instances extracted from Experiments 1 and 2 could form the ontology classes and entities, ensuring comprehensive domain coverage. Additionally, Experiment 3 contributes hierarchical structures and definitions, refining the taxonomy and semantic clarity of the ontology. Together, these elements could help create a well-organized ontology that enhances knowledge retrieval and semantic interpretation in the Quranic domain.

IV. Results

A. Result of Experiment 1: NER Technique

As mentioned earlier, the outcomes of this experiment are done using *precision*, *recall*, and *f-measure*, and the result of the extraction can be shown in Table I.

TABLE I. Result of Extracted Concepts and Instances for Chapters Using NER

	Al-Jin	*Al-Muzammil*	Al-Maarij	*Al-Muddathir*	Average
Prec	0.78	0.58	0.55	0.55	0.62
Rec	0.33	0.36	0.21	0.59	0.37
F-M	0.46	0.44	0.30	0.57	0.44

Meanwhile, the second classification evaluation reveals that only the Person and Unknown categories are suitable for entity selection as shown in Fig. 5.

B. Result of Experiment 2: Statistical Technique-tf,tfidf, Ridf

This experiment aims to identify the single-word terms using statistical measurements such as tf, tfidf, and Ridf. The results yielded 614 single terms out of a total of 3018 terms. The top 30 ranked terms are shown in Table II.

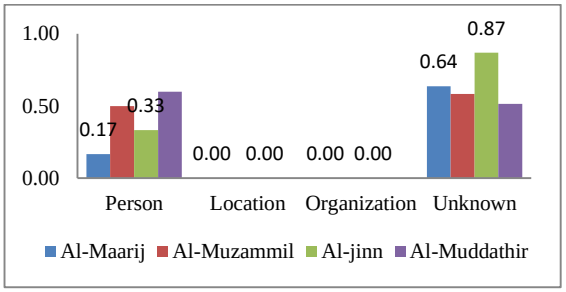

Fig. 5. The classification of extracted names.

TABLE II. Sample of Single-Word Term Candidates from 614 Terms

No.	*Statistical Measurement*					
		tf		***Tf-idf***		***R-idf***
1	Allah	131	Hajj	11.96	having	0.59
2	Makkah	34	th	9.96	th	0.52
3	Hajj	23	Makkah	9.96	month	0.46
4	pilgrimage	14	Kabah	9.42	God	0.29
5	House	13	SAW	9.24	Ilah	0.29
..	..	..	..	..	..	..
..	..	..	..	..	..	..
30	Ihram	6	Verily	6.57	animals	0.28

The *tf* precision, recall, and F-measure have been measured with the performance shown in Table III.

TABLE III. The Precision, Recall and F-Measure Performance for TF

Precision	**Recall**	**F-Measure**
0.451	0.584	0.509

C. Result of Experiment 1: Qur'an Structure Pattern

This experiment focuses on the Quranic structure patterns [14]. These patterns utilize a combination of POS tagging and regex applied to the text to find "part of" relations, as well as "synonym" or "definition" relations present in the text. Table IV shows the result of extracted relations to show whether the extracted terms are correct or wrong using patterns.

TABLE IV. Result of Extracted Relations Using Quranic Pattern

No.	*Statistical Measurement*				
	Al-Maarij Correct/Wrong	**Nuh**	**Al-Muzammil**	**Al-Muddathir**	*Total correct*
Pattern 1	3/0	3/0	2/1	2/0	10
Pattern 2	1/ 2	0/0	1/0	0/1	1
Pattern 3	6/3	3/4	6/6	9/7	24
ALL					35

Meanwhile, Table V shows the precision based on the patterns for each chapter.

TABLE V. PRECISION BASED ON QURANIC PATTERN

No.	Chapter	Precision	Average Precision
1	Al-Maarij	0.60	
2	Nuh	0.60	
3	Al-Muzammil	0.56	
4	Al-Muddathir	0.58	
			0.58

D. Performance of All Techniques Applied

Based on the results of running three different types of techniques, the precision and average precision of each method can be depicted in Table VI.

TABLE VI. PRECISION AND AVERAGE PRECISION OF NER, STATISTICAL-BASED AND QURANIC PATTERN STRUCTURE

No.	Technique	Average Precision
1	NER	0.62
2	Statistical	0.45
3	Pattern	0.58

V. DISCUSSION

A. Experiment 1: NER Technique

The Named Entity Recognition (NER) achieved an average F-Measure of 40%, with average precision above 60% and an average recall under 40%. This suggests that NER is useful for extracting relevant terms, but many relevant terms are missed. The chapter Al-Jinn had the highest precision at 0.78, while Al-Maarij had the lowest recall at 0.21. The NER shows that certain chapters miss more relevant terms where important terms like *"fasting*" and "*water"* or other significant words like *"criminal" and "sinner"* are not captured. This is due to the NER that may not recognize these words as entities because they aren't typical "named" entities, like places or people that we often see in everyday language. Additionally, phrases like "*a weighty Word*" or "*the Fire of Hell*" carry weight in a Quranic context. It refers to entities of "*Quran"* and "*Hell"* but this phase is not commonly recognized as entities outside of it. These gaps suggest a need for additional NLP analysis within ANNIE module, particularly to capture more nouns and compound nouns. It was also found that the ANNIE module sometimes tagged parts of speech incorrectly, which led to extraction errors. For example, terms like "O" and "Verily" were wrongly tagged as nouns, which decreased the accuracy by misidentifying uppercase letters as meaningful nouns. To improve the recall, the NER model could train the model to Quranic texts and other religious literature to better understand contextually significant terms. The training on domain-specific text allows the model to build a specialized understanding of contextually important words and phrases, making it better at identifying them accurately within that subject area.

In Fig. 5, the Organization and Location categories show no correct classifications, with terms like "the angel" wrongly classified as an organization. The highest correct classification is for the Unknown category in Al-Jinn at 0.87, indicating more concepts like *"the heaven*" and "*the gardens*" need identification. Al-Muddathir has the highest Person classification at 0.60. The term "House" was retrieved but misclassified as an organization; in the Qur'an, it refers to "Kaaba." Overall, the extraction process needs improvement to capture more relevant terms. In summary, even if imperfectly classified, the NER could identify terms relevant to the domain, underscoring its potential utility in extracting meaningful concepts and instances.

B. Experiment 2: Statistical Technique-tf,tfidf, Ridf

Based on Table II, term frequency (*tf*) outperformed *tf-idf* and *Ridf* in extracting relevant terms as concepts or instances when considering the top 30 terms. Terms like "Allah," "Hajj," and "Makkah" were identified as more meaningful concepts compared to less significant terms like "th."

In Table III, the experiment can conclude that statistical measurements such as tf, tf-idf, and Ridf are effective for extracting single-word terms as concepts or instances. The tf performed better compared to tfidf and Ridf. It still only retrieves about 50% of relevant single-word terms, suggesting that it is not fully effective on its own. They fall short in identifying multi-word terms, which are prevalent in texts like the Qur'an. Many significant concepts are missed, which is particularly problematic for texts where important terms are often multi-word, like the Quran. Terms are in multi-word phrases, such as "Bounty of Allah," "raging Fire," "remember Allah," and "ways of Prophet Muhammad." On the other hand, the recall shows that 58% of the terms that were retrieved were relevant and might be considered as possible concepts or instances. Therefore, the lack of NER can be covered by statistical measurement to retrieve more relevant terms.

C. Experiment 1: Qur'an Structure Pattern

Table IV shows that Pattern 1 and Pattern 2 can extract "part of" relations between concepts. Pattern 1 performs better at 28.57%, while Pattern 2 has only 2.86% accuracy. Pattern 2's low performance is due to incorrect POS tagging, where terms like "Verily" and "Nay" are both annotated as Proper Nouns (NNP), despite not being related.

Mostly, the exclamation mark in Pattern 2 is used at the end of a sentence and not at the middle sentence. In Pattern 1, the false extraction exists when it uses brackets to actually explain or elaborate more on the sentence. The extracted noun found is not "part of" relations for another noun. Pattern 3 outperformed Pattern1 and Pattern 2 with a 68.57% correct match rate, successfully extracting synonym and definition relations. However, only 54.55% of these extractions were accurate, with synonyms extracted at 81.81% but only 61.11% correct. Errors were due to incorrect POS tagging, such as misinterpreting bracketed terms, e.g., "garments (Prophet Muhammad SAW)" where "Prophet Muhammad SAW" is not a synonym for "garments."

The average precision is 0.58 in Table V reflects the limitations and challenges associated with the pattern-based approach for extracting taxonomy and non-taxonomy relations in Quranic text. Several factors contributed to this relatively moderate precision: The experiment found inconsistent use of rounded brackets "()" and square brackets "[]," which sometimes indicate synonym relation and sometimes can be a definition

relation or explanatory notes. Square brackets are often used when rounded brackets are present, as in "Messenger [Musa (Moses)]." Some words were misclassified during Part-of-Speech (POS) tagging, causing incorrect identification of relations and synonyms.

The observation from this experiment shows that the formatting of the Quran text structure and the patterns of the Quran text style can be used to extract ontological elements. But it needs to be further refinement to improve accuracy, particularly in handling text variations, multi-word terms, and contextual relationships. In fact, based on the results of running three different patterns, the average precision of 0.58 shows that half of the concepts or instances are not yet retrieved.

D. All Techniques

Table VI shows that the precision based on the three methods is still low, with only around 50% of concepts, instances, or relations being retrieved from the Qur'an Text. It means only half of the terms and relations can be retrieved using the techniques. The improvement is still needed to retrieve more relevant terms. On the other hand, the techniques are able to identify terms relevant to the domain, even if incorrectly classified, highlighting its potential utility in extracting meaningful concepts and instances.

Each OL technique demonstrated strengths and limitations in different scenarios. The NER approach achieved higher precision due to its reliance on predefined entity categories, ensuring accurate identification of named concepts. However, its lower recall indicates that many relevant terms were missed, particularly non-named entities. In contrast, the statistical approach effectively identified frequent terms, expanding the concept pool beyond named entities, but it struggled with multi-word expressions, leading to incomplete representations of certain Quranic terms. The pattern-based approach, while useful for extracting taxonomy and semantic relations, was limited by variations in text formatting and syntactic inconsistencies, affecting its accuracy. By integrating these techniques, the final ontology balances precision, recall, and relational depth, improving the overall quality of extracted knowledge.

This study advances OL by tailoring approaches specifically to the unique characteristics and challenges of the Qur'an, in ways that general, non-religious (ordinary text) OL research may overlook. By addressing the Quran's complex language, thematic concepts, and context-sensitive relationships, it provides a more comprehensive and accurate ontology model compared to standard OL approaches. This domain-specific refinement allows for a deeper, more authentic representation of religious knowledge, particularly in areas like theology, ritual, and ethics. In contrast, ordinary text deals with straightforward, clear language making it easier to identify entities and relationships.

VI. Conclusion

In conclusion, the analysis of the table reveals that the precision levels achieved through the three methods for retrieving concepts, instances, or relations from the Qur'an Text remain comparatively low, hovering around 50%. This indicates that only half of the terms can be successfully retrieved using the employed techniques. The findings underscore the necessity for further improvements in the existing methods to enhance precision and broaden the scope of relevant term retrieval.

Future research on ontology learning using Large Language Mdels (LLMs) for Quranic text will focus on refining semantic extraction methods, improving multilingual capabilities, and enhancing domain-specific training. Given the complexity of Quranic language and its deep semantic structures, fine-tuning LLMs such as AraBERT or GPT-based models on Quranic corpora will be essential to capture intricate relationships between concepts [7]. One potential approach involves integrating structured datasets with LLM-generated embeddings to improve the contextual accuracy of Ontology Learning[40]. Another promising direction is leveraging Retrieval-Augmented Generation (RAG) frameworks to enhance the extraction of non-taxonomic relationships, allowing for a deeper understanding of Quranic themes and their interconnections[9]. These advancements will contribute to more sophisticated, AI-driven Quranic knowledge representation, benefiting applications in education, comparative religious studies, and digital humanities.

Design of a Rural Tourism Satisfaction Monitoring System Based on the Improved INFO Algorithm

Meihua Qiao
Department of Computer Science, ShanXi Vocational College of Tourism, Taiyuan 030031, China

***Abstract*—The increasing influx of tourists to scenic areas has raised significant security concerns, often surpassing the management capacity of these locations. Despite the growing need for effective solutions, many regions have not yet developed strategies to address these issues. This study aims to enhance rural tourist satisfaction monitoring systems to better manage tourist flows and improve security. The research explores rural tourist satisfaction, which has significant potential for large-scale monitoring due to its self-expanding nature. The paper discusses the critical role of tourist satisfaction within scenic areas, particularly focusing on tourist tracking systems. It also introduces key features and positioning algorithms used for monitoring satisfaction. A new collaborative positioning approach, based on subnetwork fusion, is proposed to address the limitations of traditional non-line-of-sight INFO positioning algorithms. The proposed subnetwork fusion method outperforms the traditional INFO algorithm, with a 39.7% reduction in localization error when more than 130 nodes are used. Furthermore, when anchor nodes exceed 10%, the DPeNet algorithm achieves an average precision value of 0.768, surpassing the 0.75 threshold due to its enhanced multi-channel convolution and downsampling structure, which optimally utilizes the deep features of small-sized targets. This paper introduces an innovative collaborative positioning strategy for rural tourist satisfaction monitoring, overcoming existing algorithm limitations and enhancing localization accuracy in real-time tourist management systems. The findings contribute to improving both tourist experience and safety in rural scenic areas, offering a scalable solution for broader applications in tourist destinations.**

***Keywords*—Enhanced INFO algorithm; rural tourism satisfaction; tourist monitoring system design; collaborative positioning methodology**

I. Introduction

Safety is the primary issue in tourism. The purpose of travel is to relax the body and mind, feel different places, so as to get a pleasant travel experience. In this process, personal safety is the most concerned issue for tourists [1]. These sensor nodes have the communication and monitoring functions of ad hoc networks, which can broadcast the monitored data to each other in real time, and finally send it to the slink node and uploaded to the network server [2]. The anchor node is equipped with self-positioning capabilities. It is responsible for determining the position of global network nodes and, by utilizing sensor nodes carried by tourists, can accurately track the location of individuals, analyze their movement patterns, and minimize potential risks they might encounter. Through the tourist management system implemented at the scenic spot, traffic flow is optimized, visitor guidance is enhanced, and the quality of service and management capacity of the site is improved, all in alignment with current market demands [3, 4]. With the advent of the information age and the widespread use of networked systems, traditional network security monitoring systems have revealed several limitations in practical applications. These systems heavily rely on manual processes, which not only reduce the level of automation but also impair the ability to respond to incidents in real-time. This is particularly problematic when dealing with high-density tourist crowds, as traditional monitoring systems struggle to manage complex, dynamic environments, resulting in diminished visitor experiences and reduced system efficiency. Therefore, optimizing network security systems to improve visitor satisfaction while addressing the challenges posed by high-density crowds becomes a key area of research. This paper proposes a node optimization approach for network security systems based on the Particle Swarm Optimization (PSO) algorithm [5, 6]. Managing such groups is challenging due to the inherent risks, particularly the heightened likelihood of safety accidents. The tragedy of the Shanghai Bund stampede has drawn widespread attention to the safety issues surrounding high-density tourist groups [7]. Addressing these concerns and enhancing the safety of such groups has become a central and difficult focus of tourism safety research [8].

Traditional methods for scenic spot monitoring typically involve manual patrols, which are labor-intensive, time-consuming, and require high levels of patience from staff. This approach is particularly ineffective in an era where advanced technologies are available. The use of GPS for locating tourists has gained popularity, but its effectiveness is limited by environmental conditions that require high signal quality, and it may not be cost-efficient given the rapid development of sensor networks and associated equipment costs [9, 10]. Drone surveillance offers certain advantages, such as being less influenced by environmental factors, but it is still impacted by weather conditions, particularly in rainy or high-humidity areas. This limitation, combined with long monitoring cycles and extended time requirements per unit area, presents challenges in addressing detection gaps in a timely manner [11]. Camera-based monitoring is effective in some cases; however, it faces limitations such as power supply issues, the need for extensive wiring, and its unsuitability for remote or open areas. Additionally, concerns over equipment aging and maintenance, especially in mountainous regions vulnerable to weather-related risks like lightning, pose further challenges and contribute to safety hazards, such as the potential for fires in these areas [12, 13]. The advancements in embedded technology, with their low power consumption and the rapid progress in semiconductor and microelectronics fields, have led to the development of more efficient solutions for monitoring rural tourist satisfaction.

*Corresponding Author

Different people will also respond differently tourists in the scenic area, without requiring a lot of manpower [14, 15]. Predicting the trend of tourists in advance and carrying out effective and accurate management can not only reduce the pressure of scenic spot management, but also improve the tourism freedom of tourists, make the management more modern and tourist safety in scenic spots, this paper proposes and realizes the tourist monitoring system [16, 17]. The system uses INFO positioning algorithm to realize self-positioning. On the basis of improving the accuracy of the traditional non-line-of-view positioning algorithm, the grasp of the location information of tourists is also more accurate. It can effectively improve the management efficiency of tourists in scenic spots and greatly reduce the safety risks of tourists [18, 19]. Traditional monitoring systems typically rely on centralized data collection and human intervention for decision-making. These systems often involve manual configuration and maintenance of network security parameters, which can be time-consuming and prone to human error. Moreover, in the context of high-density environments such as tourist attractions, these systems fail to scale effectively, unable to quickly adapt to fluctuating network loads or emerging security threats. The growing number of visitors, combined with the complexity of managing vast amounts of network data, amplifies the need for more adaptive, real-time monitoring systems that can handle dynamic conditions while ensuring the security and safety of users.

II. The WSN Positioning Technique

A. INFO Algorithm

The three-sided measurement algorithm is one of the most basic algorithms in the satisfaction positioning algorithm of rural tourism tourists. The unknown node obtains the corresponding distance information through other positioning algorithms, and then positions its own actual coordinates according to the distance information. As shown in Eq. (1) and Eq. (2).

$$h(x)=\int_{-\infty}^{\infty} f(\tau)g(x-\tau)d\tau \tag{1}$$

$$h[n]=\sum_{-\infty}^{\infty} f[n-m]g[m] \tag{2}$$

Maximum likelihood method maximum likelihood method is one of the most basic algorithms in the positioning algorithm, through the combined equations, find the final solution in the multidimensional equations, such as Eq. (3), (4), so as to calculate the coordinate value in the communication range, and use the coordinate information of the anchor node.

$$\mu_B=\frac{1}{m}\sum_{i=1}^{m} x_i \tag{3}$$

$$\sigma_B=\frac{1}{m}\sum_{i=1}^{m}(x_i-\mu_B) \tag{4}$$

Centroid positioning algorithm, centroid positioning algorithm is the coordinates of the unknown node. As shown in Eq. (5) and Eq. (6), APIT algorithm and APIT algorithm randomly combine several triangles forms an irregular polygon, and the center of mass of the polygon is the coordinate position of the unknown node.

$$\hat{x}_i=\frac{x_i-\mu_B}{\sigma_B+\dot{o}} \tag{5}$$

$$y_i=\gamma\hat{x}_i+\beta \tag{6}$$

Non-line-of-view positioning algorithm has the advantages of low energy consumption and low cost, but it also has low positioning accuracy. The positioning algorithm with wide application in non-line-of-sight positioning algorithm is INFO positioning algorithm. This algorithm improves the positioning accuracy of the non-horizon positioning algorithm by proposing the concepts of jump number and jump distance. As shown in Eq. (7) and Eq. (8), INFO positioning algorithm is a typical non-line-of-sight positioning algorithm, more line-of-sight positioning algorithm, INFO positioning algorithm has strong scalability. The results demonstrated the robustness of the system, showing that, even under conditions of interference or weaker signals, the optimized system performed consistently well, providing a high level of reliability and accuracy.

$$Y(P_0)=\sum_{P_n\in \mathrm{R}} w(P_n)\cdot X(P_0+P_n+\Delta P_n) \tag{7}$$

$$P=\frac{TP}{TP+FP} \tag{8}$$

When the anchor node in the wireless network after receiving the signal to the current number of transmission, as Eq. (9) and Eq. (10), when received the three anchor nodes sent back the feedback, the unknown node to the next stage. The average jump distance is defined as Hop Size, and the value of Hop Size is the ratio of the sum of the length of any two sides in the jumps corresponding to these two edges. Any two anchor points in the triangle represent the two points to the third anchor node.

$$IoU=\frac{TP}{FP+TP+FN} \tag{9}$$

$$\mathrm{HopSize}=\frac{\sum_{i\neq j}^{2}\sqrt{\left(x_i-x_j\right)^2+\left(y_i-y_j\right)^2}}{\sum_{i\neq j}^{2} h_{ij}} \tag{10}$$

B. Improved INFO Algorithm

This paper obtains the four most important parameters for this unknown node, namely, the number of jumps to each anchor node and the average jump distance Hop Size. By incorporating these variables, we tested the system's ability to maintain network security and positioning accuracy despite environmental challenges. The core idea of INFO is to bend the curve, as shown in Eq. (11) and Eq. (12), that is, to find the approximate curve length to replace the actual length of the anchor node to the unknown node. Therefore, the calculation of the average jump distance is the unique place of INFO algorithm, and also the cause of the error of INFO algorithm.

$$\mathrm{d}=HopSize\times h \tag{11}$$

$$H_{ij} = D_{ij} / r \tag{12}$$

After the average jump distance is Hop Size, positioning algorithm. According to the above principle, it is not difficult to find INFO algorithm although the design is clever, but not there are certain error, the error mainly has the two opposite reason, such as Eq. (13) and Eq. (14), first in actual circumstances, node distribution is immediately, that is to say, the distance between nodes and node is likely to be very different.

$$\omega_{ij} = 1 - [(h_{ij} - H_{ij}) / h_{ij}]^n \tag{13}$$

$$r = \sqrt{nS / \pi N} \tag{14}$$

In terms of the jump nature of INFO, when all the midway nodes are in the inner edge of the area covered by the communication range, the ranging is the most accurate and the positioning results should be the most accurate. On the contrary, if the anchor node is in the outer edge of the area covered by the communication range of the midway node, the ranging will have a large error and the positioning results will be very different. As shown in Eq. (15) and Eq. (16), areas with high buildings may create shadowing effects that reduce signal strength, while crowded spaces or remote areas with fewer infrastructure elements may lead to weaker or less stable network connections, due to the uncertainty of node distribution, there is no effective review mechanism for the generation of errors, which will make the INFO algorithm still calculate with errors after errors, making the error larger and larger, and even the final error will be too large.

$$d_t = \sqrt{\frac{\sum_{i \neq j} \left(d_{ij} - d^{'} \right)}{3}} \tag{15}$$

$$HopSize_i^{'} = \sum_{i=1}^{3} d_i / 3 \tag{16}$$

We introduced a series of environmental factors to assess the robustness of the network security system in different scenarios. Among these factors are obstacles that can interfere with signal transmission, as well as varying signal strengths, which are common in real-world settings, so it is not difficult because the error of the Hop Size, and the idea of INFO to curve, the curve itself and the line error relationship, such as Eq. (17) and Eq. (18), and the curvature of the path curve of the unknown node to the anchor node also seriously affects the final positioning result, therefore, the INFO algorithm positioning error is not difficult to understand.

$$D_{ij} = \frac{\sqrt{4^{'} + 3n_{ij}^2}}{2} \times HopSize_i^{'} \tag{17}$$

$$t_j = \left(n_{ij} + 1 \right) Mod(2) \tag{18}$$

Optimize the INFO algorithm, using the difference between the actual distance between the anchor nodes and the estimated distance, such as Eq. (19) and Eq. (20), calculate the global average ranging error, and then INFO positioning algorithm, the Hop Size calibration with the global average ranging error, so as to get more accurate Hop Size, and then use trilateral positioning algorithm to get more accurate positioning results.

$$D_{ie} = n_{ie} \times HopSize_i^{'} \tag{19}$$

$$f(x, y) = \sum_{i=1}^{n} \left[\left(d_i - \sqrt{(x - x_i)^2 + (y - y_i)^2} \right)^2 \right] \tag{20}$$

III. Research on Collaborative Positioning Algorithm Based on Subnetwork Fusion

A. The INFO Positioning Algorithm

The non-line-of-view positioning algorithm has low hardware requirements and no complicated operation requirements, which is more suitable for deployment in open areas. In general, the cheap sensors used by the non-visual-sight positioning algorithm use the battery pack with limited power, and the positioning accuracy is low due to its own reasons [20, 21]. Therefore, in order to make the tourist monitoring system of scenic spots have a better use effect, as much as possible. Subnet fusion collaborative positioning algorithm respectively established several anchor node as the center of the network, the network are in a large wireless sensor network, by the network according to their own network condition using nRSSI algorithm to calculate the appropriate average distance, after the network ranging algorithm and no ranging algorithm to the location of the network structure point, to upgrade to collaborative anchor node, finally use these collaborative anchor node to locate all unknown nodes in the network [22, 23]. The network proposed by this algorithm is initiated by the anchor node, which traverses all the nodes in the satisfaction of rural tourists and screens the final sub-network. Since the subnetworks built by different anchor nodes are completely different, the positioning results of different subnetworks are different for the unknown nodes, which effectively allocates the positioning error of the traditional algorithm [24, 25]. The cuckoo algorithm is used to determine the location of the unknown node. In the INFO algorithm, a one-hop node is defined based on the distance between three anchor nodes, which can lead to significant errors, especially for critical nodes [26, 27]. The INFO algorithm samples nodes within the initial communication range and selects a set of three unknown nodes that satisfy a specific distance criterion. These nodes are chosen such that the patch accuracy is below a certain threshold, and the average distance among all combinations of nodes that meet the criteria is the largest. Using this approach, all unknown nodes are divided into two sets: one set includes nodes within the communication range, while the other set contains nodes outside the range [28, 29]. Fig. 1 illustrates the process of feature selection and extraction. The communication range is then expanded, and the first set of network nodes is selected from the second set. These nodes, along with the two upper network structure points, are selected based on their distance being below a specified threshold, and the distance between these two points is minimized compared to other nodes. When the network structure reaches two layers, additional constraints are applied to avoid algorithmic deadlock caused by mirror errors and communication obstacles. These constraints ensure that adjacent network structure points of the two layers are interconnected,

and new network structures exclude any nodes not directly involved in their construction [30].

To begin, we first introduce an updated simulation scenario that includes more complex and realistic environmental conditions. Traditional network simulations often rely on simple, idealized conditions such as uniform grid distributions and static node densities. However, to more accurately reflect real-world environments, our updated simulation incorporates larger grid sizes, varying node densities, and non-uniform node distributions. This modification allows the simulation to better replicate the dynamic nature of real-world conditions, especially in tourism environments, where networks are often subjected to fluctuating visitor behaviors and physical obstructions such as buildings, trees, and other structures. In the communication range of the unknown nodes, the modified INFO algorithm, as illustrated in Fig. 2, is applied. For any combination of anchor nodes or collaborative anchor nodes, the unknown node is analyzed. As the combinations are not unique, multiple solutions may be generated. The process begins by initializing the population and determining the nest positions as effective coordinates. The algorithm then performs a search for the next generation nest location through a series of flights, comparing the newly found location with the current best location. This transforms the problem of estimating the unknown node's coordinates into an optimization problem of minimizing the objective function. After several iterations, the optimal location coordinates of the unknown node are identified.

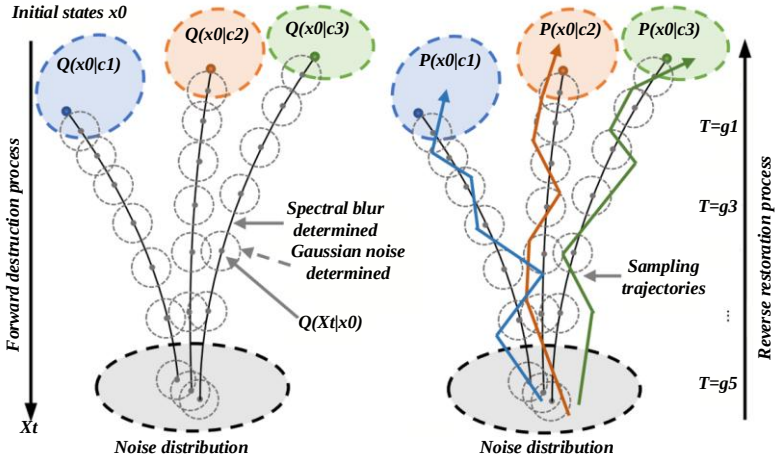

Fig. 1. Feature selection and extraction process.

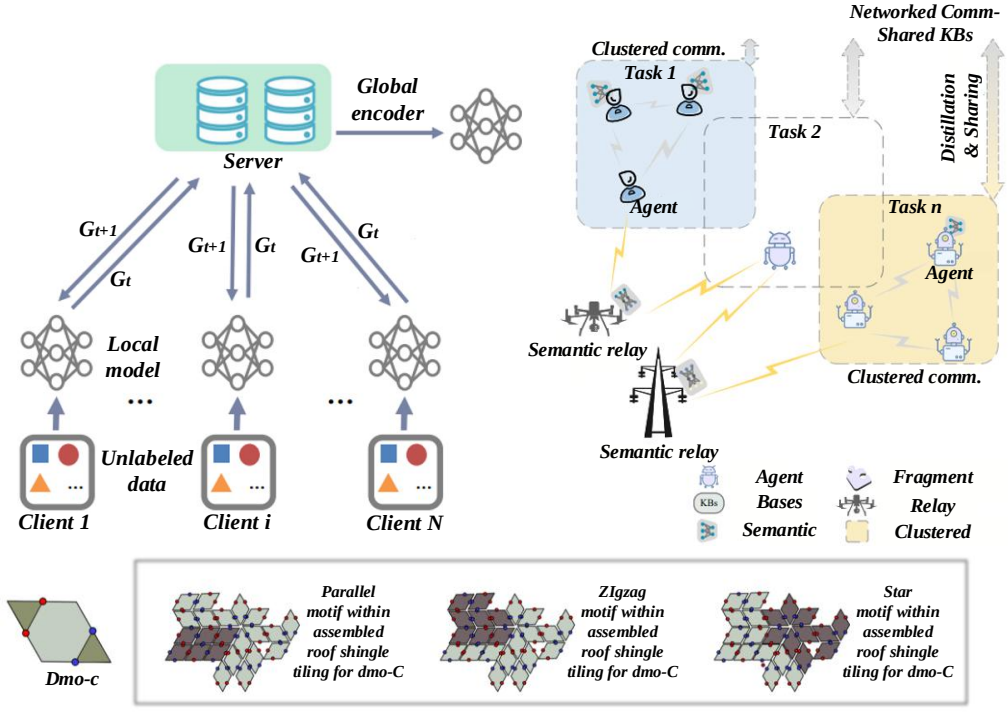

Fig. 2. Improved INFO algorithm.

B. *Sense the Influence of the Proportion of Anchor Nodes on the Positioning Algorithms*

In parallel with these environmental factors, we also explored the risks associated with the collection and transmission of location data, which is integral to the functioning of modern positioning algorithms. The collection of real-time positioning data, particularly in public environments such as tourist destinations, raises significant privacy and security concerns. Tracking the movements of visitors, while useful for improving visitor experiences and ensuring security, can inadvertently lead to the exposure of sensitive personal information if not handled properly. Therefore, we carefully examined the potential risks related to data privacy and transmission, including the possibility of unauthorized access or interception of sensitive data. Once the network structure points have been ranged, the three-point positioning algorithm is applied to the ranging list. This involves combining all three-point relationships and calculating them individually, with the results being sorted. Fig. 3 illustrates the evaluation diagram for the rural tourism tourist satisfaction index. The cuckoo search (CS) algorithm is then employed to compute multiple positioning results, identify the local optimal solution, and determine the coordinates of the unknown node. Subsequently, the unknown node is upgraded to a collaborative anchor node. By leveraging the anchor nodes and the distance measurements, the trilateral positioning method is used to generate a solution set. The CS algorithm is then applied to this set to find the local optimal solution, which is adopted as the position of the node. Once all the nodes are positioned, the algorithm completes its task.

The main purpose is to find out some characteristic points and establish a relatively regular network structure. One of the significant challenges in the deployment of network security systems lies in optimizing node placement and ensuring the robustness of the system under different environmental conditions. This research focuses on the optimization of network security systems, using the Particle Swarm Optimization (PSO) algorithm to improve the efficiency, accuracy, and scalability of these systems. This paper discusses the simulation of more complex and realistic environments, the potential risks associated with data collection and transmission, and a comparison of various algorithms' performance, including the enhanced INFO algorithm, GPS-based systems, Kalman filtering, and non-line-of-sight positioning methods. Fig. 4 illustrates the weight evaluation diagram for the tourist satisfaction index. OMNeT++ is chosen as the simulation platform for the network environment, and sensor nodes are randomly distributed within a 100m-by-100m square detection area. The data sent by these sensor nodes via wireless signals forms an independent network system. The density of network nodes and the proportion of anchor nodes within the network are varied to conduct the analysis. The performance of the above algorithms is evaluated and compared. In a simulated environment with 1,000 sensor nodes deployed, the positioning error rate is calculated for each network node after deployment, and cumulative error rates are mapped. The results are then compared across the three algorithms, with the self-positioning algorithm showing superior performance.

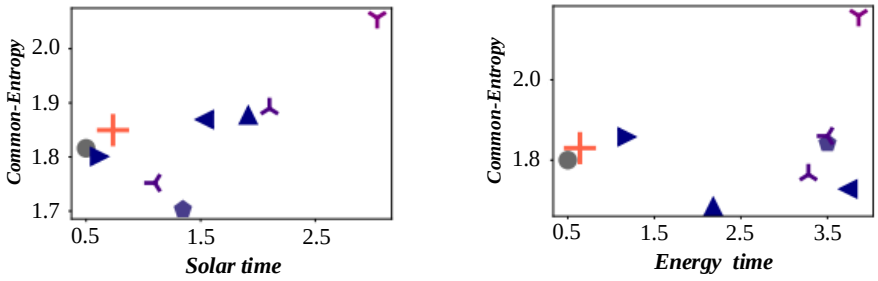

Fig. 3. Evaluation chart of rural tourists.

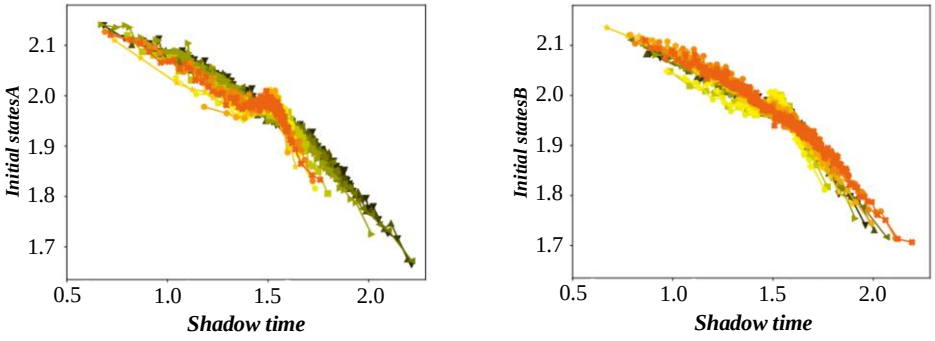

Fig. 4. Weight evaluation diagram of tourist satisfaction evaluation index.

IV. Research on the Design of Rural Tourism - Tourist Satisfaction Monitoring System based on the Improved INFO Algorithm

Tourist satisfaction can be influenced by various factors such as convenience, accessibility, and safety, all of which are closely related to the effectiveness of the monitoring system. To enhance visitor satisfaction, one promising area of research is the integration of visitor satisfaction monitoring and tracking algorithms, which involve real-time data collection and analysis. Sensor networks, such as GPS, RFID, and Wi-Fi-based tracking systems, can be used to monitor the movement patterns of tourists and provide insights into crowd density, visitor preferences, and behavior. Fig. 5 illustrates the visitor satisfaction evaluation across different age groups. Due to differences in peripheral units such as the timer and serial port compared to other 8051 cores, code that utilizes peripheral unit special function registers (SFR) may not function correctly. The 8 KB RAM retains data across various power supply modes and can be paired with buffer modules of varying capacities as per system requirements. When used with the ZigBee protocol stack, the CC2530 provides a powerful communication solution, and when integrated with the RemoTI platform, it offers a complete RF4CE remote control scheme.

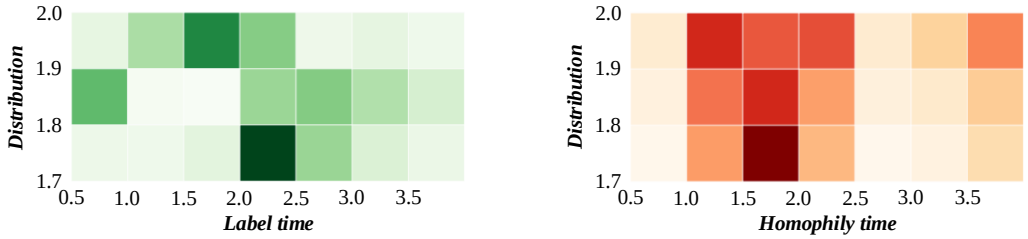

Fig. 5. Satisfaction assessment chart of tourists of different ages.

Recent studies have proposed various algorithms for positioning and tracking within crowded environments, particularly in the context of smart cities and tourism. These algorithms are designed to improve the accuracy and efficiency of tracking, enabling better real-time decision-making. For instance, the application of localization algorithms using sensor networks has shown promising results in detecting high-density areas, guiding visitors, and optimizing traffic flows within tourist attractions. These technologies not only support the operational management of tourist destinations but also contribute to enhancing the overall experience of the visitors. On the one hand, the sensor nodes generally use the battery pack to provide energy. Table I is the data table of sensor nodes. For some sensor nodes that are out of power, they need to take abandoned means and then release new sensor nodes, or reach the position of the sensor nodes and replace the battery and then put them into the scenic spot. Either way will make the position of the sensor node recorded before invalid. At this time, in order to keep the data in the database not occupied by the dead data, the data should be managed and the accuracy of the data in the database should be restored in time.

TABLE I Data Sheets of the Sensor Nodes

Order Number	Field Name	Field Type	Restrain	Explain
1	Id	Int	Non-Empty	Automatic Number
2	Node_id	Int	Primary Key, Non-Empty	Node Number
3	Axis_X	Double	Non-Empty	Node x Coordinates
4	Axis_Y	Double	Non-Empty	Node y Coordinates
5	Energy	Double	Non-Empty	Node Energy
6	Time	Int	Non-Empty	Clock

To mitigate these risks, we proposed several protective measures, chief among them being the use of anonymous data collection methods. By anonymizing location data, we can ensure that individual visitors cannot be identified based on their movement patterns or behaviors. This method not only protects the privacy of the visitors but also ensures that the data cannot be traced back to any specific individual, thus reducing the likelihood of misuse or exploitation of personal information. In addition to anonymization, we also implemented secure transmission protocols to encrypt data as it is sent from sensors to the central monitoring system. This step ensures that any intercepted data would be rendered unreadable to unauthorized parties, further safeguarding the system against potential security breaches. If a tourist enters a hazardous area, the system can calculate the shortest route for rescue based on the tourist's current location and coordinates. Table II displays the electricity identification information. Additionally, the system can predict the movement patterns of tourists, allowing for the formulation of timely and efficient rescue plans. The sensor nodes located within the monitoring area of the scenic spot utilize their internal positioning algorithms to determine their exact locations. Tourist nodes, equipped with numerous distributed sensors, calculate their location coordinates and transmit this information via nearby sink nodes or base stations to the network server. The data is then dynamically displayed on the terminal interface, providing real-time updates for the management of the scenic area. The node location data is scaled according to the actual size of the scenic spot, ensuring accurate representation on the map.

TABLE II Description of the Power Quantity Identification

Identify The Color	Node Energy	State Description
Blue	75%~100%	Power Is Sufficient
Green	50%~74%	Available
Yellow	25%~49%	Available
Red	0%~24%	Need To Replace

However, to fully address the challenges posed by high-density tourist crowds, the existing positioning and tracking algorithms need to be further optimized. Current solutions often face limitations when it comes to handling complex, large-scale environments with rapidly changing conditions. For example, GPS-based algorithms can struggle with accuracy in dense, indoor spaces, and Wi-Fi-based positioning systems may suffer from signal interference. To improve the effectiveness of these systems, it is essential to develop advanced algorithms that integrate real-time data from multiple sensors and environmental factors. By employing techniques such as machine learning and data fusion, these algorithms can be optimized to provide more accurate, real-time tracking information, which is crucial for enhancing both security and visitor satisfaction. For effective management of scenic spots, ensuring an even distribution of tourists is critical for their safety. If tourists are not evenly distributed, it can lead to congestion along routes and overcrowding in specific areas of the scenic spot. Such issues not only disrupt the management of the location but also negatively impact the visitors' experience, potentially even leading to dangerous situations such as stampedes, which pose a significant safety risk. Leveraging the tourist management system, data on the number of visitors at different spots is collected and relayed to both users and administrators in real-time. This allows tourists to adjust their routes based on the current distribution of people in the area, while managers can implement macro-level strategies to ensure smooth crowd flow, thereby minimizing safety risks. The algorithm, written in code, is loaded onto the CC2530 chip via a simulator. The sensor is positioned at a certain distance to transmit signals, and the receiving node continuously monitors and measures the RSSI (Received Signal Strength Indicator) signal strength. The data is then transmitted to the computer through a USB serial interface, allowing for the evaluation of communication distance and quality. The experiment is conducted in both open and natural environments, with the RSSI signal's effective range reaching approximately 25 meters in an open environment. Fig. 6 presents the satisfaction evaluation chart for peak seasonal tourism periods. In the natural environment, factors such as air temperature, humidity, and obstacles between nodes slightly reduce the communication range, but it still reaches approximately 15 to 25 meters. When the red light on the sensor is illuminated, it signifies that the power supply has been successfully established, and a flashing blue light confirms that data transmission and reception are functioning correctly, indicating the successful setup of the network and the start of communication.

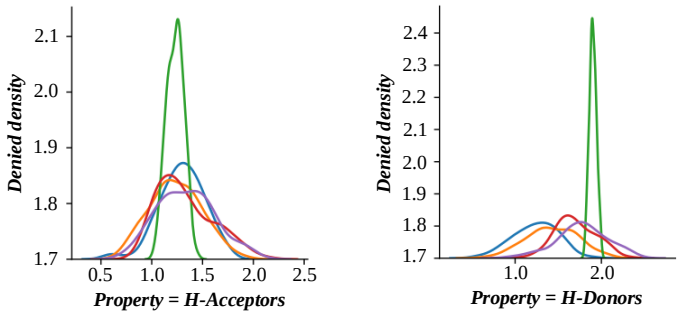

Fig. 6. Satisfaction assessment chart of seasonal tourism peak period.

V. Experimental Analysis

The positioning algorithm uses the idea of substituting the curve to convert the curve segment represented by the single hop distance into a straight segment. This paper explains the shortcomings of the algorithm and the root causes of the high error, and puts forward a new algorithm viewpoint. Fig. 7 shows the evaluation diagram of correlation between satisfaction and tourism revenue. A new collaborative node selection method, focusing on each anchor node topology, introduces several independent subnetworks; using optimized distance calculation method; using cuckoo algorithm to obtain a local optimal solution. With the local optimal solution as the final position coordinates of the located unknown node, the final selected position coordinates are closer to the actual position coordinates, which improves the positioning accuracy. Finally, the whole process of subnetwork fusion collaborative location algorithm is summarized.

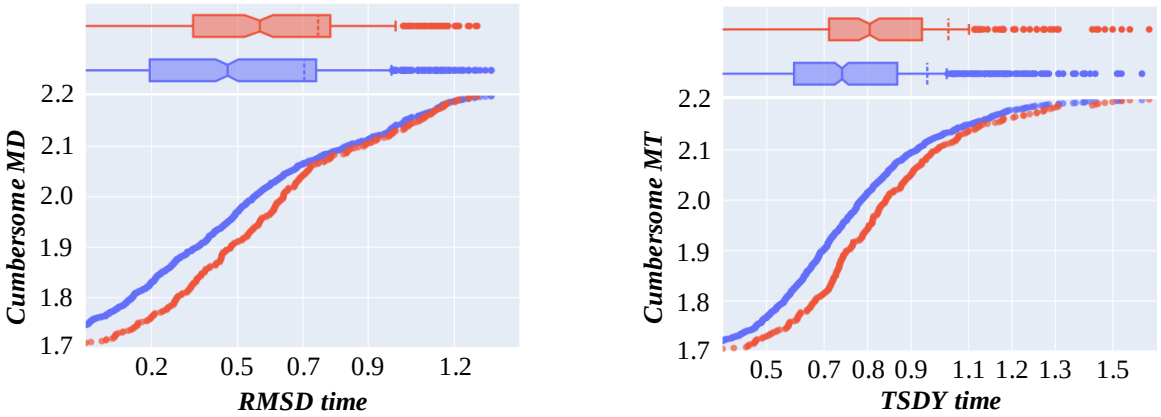

Fig. 7. Evaluation diagram of the correlation between satisfaction and tourism income.

Under identical network conditions, the proposed INFO algorithm demonstrates superior positioning accuracy and lower positioning errors when compared to both the standard INFO algorithm and the improved version of the INFO algorithm. Fig. 8 illustrates the satisfaction evaluation of service facilities. The system uses a random deployment method to place sensor nodes throughout the scenic area. Given the vast size of the area, the distribution of these sensor nodes is uneven, influenced by various factors during the random placement process. In regions with a high density of nodes, the data redundancy generated by the sensors tends to be significant. To minimize unnecessary energy consumption, some nodes are programmed to enter a dormant state and operate in an alternating fashion based on their remaining power, thereby extending the overall lifetime of the network.

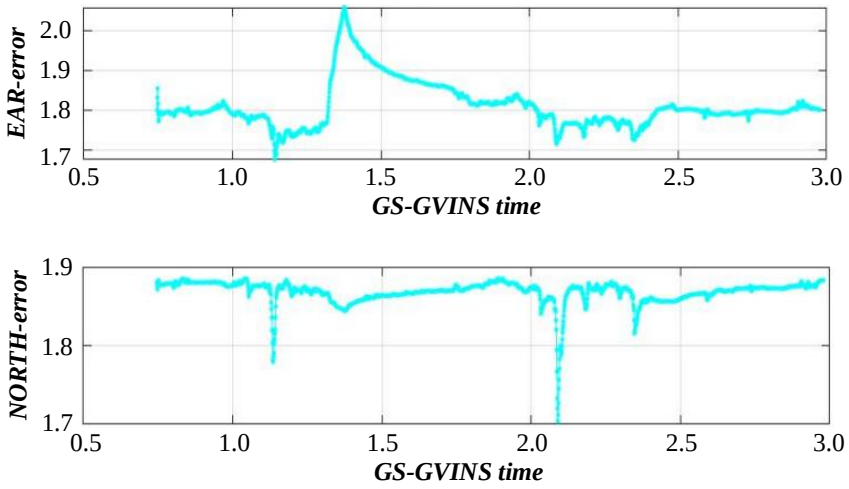

Fig. 8. Assessment chart of satisfaction with service facilities.

The positioning of each node is completed based on the positioning algorithm stored in the component memory. Fig. 9 presents the evaluation of social media sentiment analysis. When a sensor node enters a dormant state, it is activated when a visitor enters the detection area. One of the key advancements in optimizing network security and visitor satisfaction is the integration of real-time data analysis. Real-time data, when processed effectively, can provide valuable insights into both the security status of the network and the current satisfaction levels of visitors. For example, analyzing crowd density and behavior in real-time can help predict potential security threats or disruptions before they escalate. This can be achieved through the use of machine learning models that predict visitor behavior based on historical data and real-time sensor inputs. Similarly, real-time analysis of network traffic can help identify potential security vulnerabilities and enable proactive responses to mitigate risks.

The base station that receives the data further sends the information to the network server via satellite or wireless networks for processing and storage. If the client needs to call the data, the network server sends the information in the database to the client interface. Fig. 10 for satisfaction promotion strategy implementation effect evaluation diagram, the client interface receives related parameters, and after the analysis of the current tourist status, the location or the tourists of the area security and the status of the entourage, etc., and give the danger level prompt and timely remind the scenic spot personnel and prevention and treatment measures.

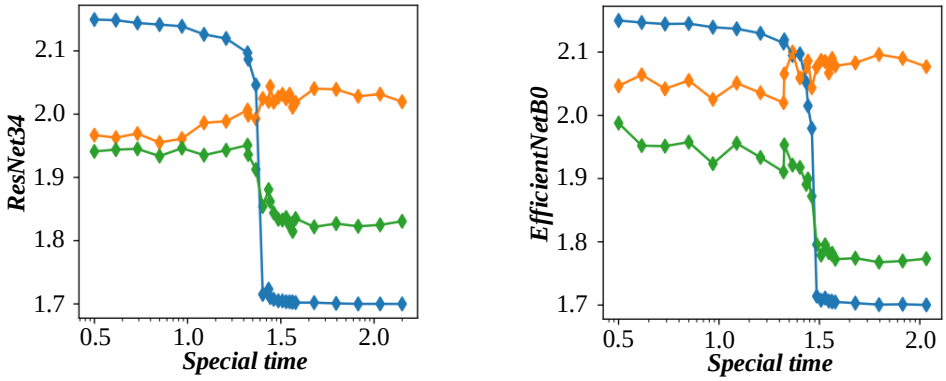

Fig. 9. Assessment chart of sentiment analysis in social media.

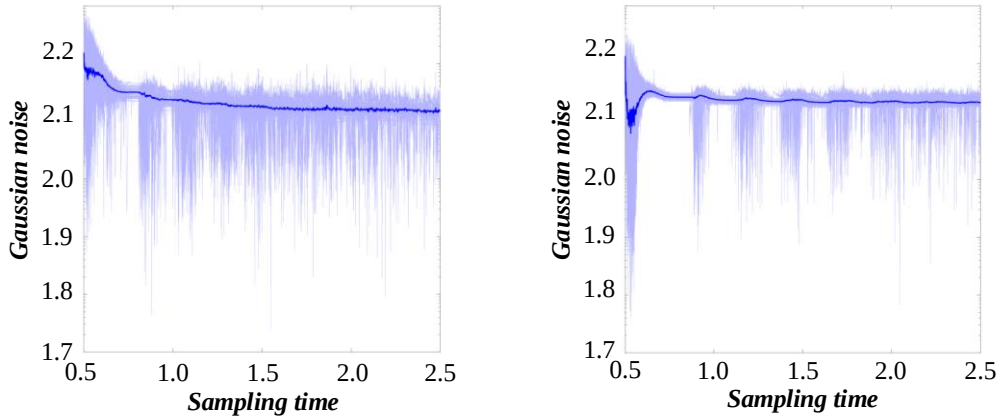

Fig. 10. Evaluation chart of the implementation effect of the satisfaction improvement strategy.

VI. Conclusion

At present, most regional scenic spots still adopt the original human management mechanism. This inefficient management mode simply cannot cope with the increasing number of tourists. Although some areas will use monitoring to make up for the lack of manpower, the uncontrolled human activities are often not easy to be captured by monitoring. Or some scenic spots manage tourists at the cost of reducing the scope of tourist activities, but the satisfaction of tourists is greatly reduced, and few places can be visited in the so large scenic spots. The advancement of rural tourism satisfaction technology is expected to pave the way for more efficient tourist management in scenic spots, significantly reducing the need for manual oversight while enhancing overall management effectiveness. This shift will modernize tourist management systems and make them more information-driven. The core of Wireless Sensor Network (WSN) technology lies in the self-localization of nodes, and the fundamental measure of the network's practicality is the accuracy of node positioning. After 30 rounds of training with low-resolution images, the model was trained on the entire dataset. During this phase, the initial learning rate was set to 0.01, which was halved if the Average Precision (AP) indicator on the validation set did not improve after five consecutive iterations. A batch size of 2 was used, due to the inclusion of high-resolution images and GPU memory limitations. This stage involved validating the model for a total of 200 training rounds, with Loss Function values recorded every 72 iterations over 14,400 total iterations, and tracking the AP indicator on the validation set.

Another aspect of this research involves applying the optimized system to other tourism environments, including both rural and urban settings. While much of the current research has focused on urban tourism environments, there is a growing need to explore how such systems can be adapted to rural or less densely populated areas. Rural tourism destinations often lack the infrastructure and resources found in urban areas, making them more vulnerable to security threats and less able to support large-scale monitoring systems. However, by employing optimized positioning algorithms and sensor networks, these systems could be tailored to provide scalable solutions for rural areas, enhancing security and improving the overall visitor experience. Through the simulation experiment, the performance of other correlation algorithms and this algorithm in different environments and different parameters is compared, and the final experimental results show that this algorithm is better than other algorithms, and the positioning accuracy is improved.

In conclusion, the optimization of network security systems in the context of tourism requires a comprehensive approach that combines advanced positioning algorithms, real-time data analysis, and the application of intelligent optimization techniques such as the PSO algorithm. By leveraging the power of these technologies, it is possible to create a more secure, efficient, and visitor-friendly environment. The integration of PSO-based optimization can help address the challenges posed by high-density crowds, improve security monitoring, and ultimately enhance the overall tourist experience. Additionally, the scalability of these solutions allows them to be applied not only in urban settings but also in rural or less developed tourist destinations, contributing to the advancement of tourism infrastructure worldwide.

Development of Cybersecurity Awareness Model Based on Protection Motivation Theory (PMT) for Digital IR 4.0 in Malaysia

Siti Fatiha Abd Latif, Noor Suhana Sulaiman, Nur Sukinah Abd Aziz, Azliza Yacob, Akhyari Nasir
Faculty Computer, Media and Technology Management, University College TATI, Malaysia

***Abstract*—This study aims to examine the complex interplay among perceived threat severity, perceived threat vulnerability, fear, perceived response efficacy, perceived self-efficacy, and response cost using Partial Least Squares Structural Equation Modelling (PLS-SEM) via SmartPLS 4.0, grounded in the Protection Motivation Theory (PMT). The analysis is situated within the context of cyber security and information security in Industry Revolution 4.0 (IR 4.0) environments, where interconnected systems are increasingly exposed to cyber threats. Both measurement and structural model assessments were performed, revealing strong indicator loadings, high Cronbach's alpha, composite reliability (CR), and adequate average variance extracted (AVE), confirming the model's reliability and validity. The Fornell-Larcker criterion and heterotrait-monotrait (HTMT) ratio confirmed discriminant validity, while variance inflation factor (VIF) values under 5 and an R^2 value of 0.554 indicated no collinearity issues and moderate explanatory power in the structural model. Findings demonstrate that perceived threat severity and vulnerability significantly increased fear, which mediated the threat perception-protection motivation relationship, emphasising the role of emotional responses in decision-making. Coping appraisal components, namely perceived response efficacy and self-efficacy, were strong positive predictors of protection motivation, while response cost negatively influenced protective behaviour intentions. Although intrusion detection systems are essential in mitigating cyber risks, this study highlights the equally critical behavioural component of cyber defence. The outcomes underscore the value of PMT in modelling security behaviour, offering theoretical and practical implications for behavioural interventions, public health strategies, and policy design in IR 4.0 domains. These insights contribute to strengthening cybersecurity and information security culture across digitally-driven industries.**

Keywords*—Cyber security; information security; intrusion detection; IR 4.0; PLS SEM

I. Introduction

The rapid integration of smart devices, artificial intelligence (AI), internet of things (IoT), and big data analytics has led to the emergence of the Fourth Industrial Revolution (IR 4.0). Unprecedented improvements in productivity and decision-making processes have occurred with increased operational efficiency, connectivity, and automation using digital technologies [1]. Nonetheless, the interconnectedness of Industry 4.0 technologies exposes them to cyber threats [2,3]. Digitally-driven companies must increase their employees' cybersecurity awareness and apply viable solutions that address data breaches, cyber-attacks, and system disruptions [4].

Employees in Industry 4.0 environments are responsible for protecting their organisations from cybersecurity breaches via increased cybersecurity awareness and vigilance against cyber threats [5]. Nevertheless, human errors, low awareness, or negligence adversely affect security technologies and cybersecurity despite its sophistication [6]. These cyber incidents call for robust training and awareness programs [7] that educate employees on threat identification, safe data handling, and proactive security measures to establish a strong cybersecurity culture. Cyber security has become a fundamental pillar in safeguarding digital infrastructures within IR 4.0 environments, where interconnected devices increase exposure to cyber threats. Meanwhile, advanced Intrusion Detection Systems (IDS) play a vital role in proactively identifying unauthorised access and potential breaches within Industry 4.0 networks. Intrusion detection mechanisms can complement awareness models by offering real-time monitoring that supports rapid incident response. Information security practices must evolve in tandem with technological advancements to ensure the confidentiality, integrity, and availability of organisational data in smart ecosystems. Ensuring robust information security is critical for maintaining stakeholder trust and business continuity in digitally integrated enterprises.

II. Protection Motivation Theory

The Protection Motivation Theory (PMT) posits that people assess threats based on perceived severity, vulnerability, response efficacy, and self-efficacy. This psychological framework clearly depicts an individual's motivations to adopt protective cybersecurity behaviours [8]. Companies designing targeted interventions could apply this theory to cybersecurity awareness to inform employees on cyber threats and promote responsible security practices. Studies on the applicability of PMT-based cybersecurity awareness models in Industry 4.0 remain underexplored despite their potential advantages [9]. This knowledge gap necessitates in-depth examination of how PMT constructs can address cybersecurity challenges in digitally-driven industries.

This research proposed a cybersecurity awareness model designed for digital IR 4.0 based on PMT principles to bridge the existing gap. Specifically, the PMT framework and constructs were analysed within existing cybersecurity awareness models. A customised cybersecurity awareness model was developed and evaluated to determine its effectiveness in improving cybersecurity practices among Industry 4.0 employees. Hence, the study enriches the ongoing

discourse on cybersecurity resilience in digital industries and informs industry stakeholders on the importance of securing their data and operations from emerging cyber threats.

Rogers initially developed PMT in 1975 to explain how individuals respond to perceived threats in terms of health behaviour. This framework has since been extended to cybersecurity, environmental behaviour, and organisational safety domains [10]. In theory, people are driven to protect themselves based on their assessment of threats and the coping mechanisms adopted. Two core cognitive processes, known as threat and coping appraisal, underpin the PMT model [11-13]. People are driven to safeguard themselves against a threat, depending on their perceived severity and capability of addressing it.

Threat appraisal involves the evaluation of the seriousness of the threat and likelihood of experiencing the threat, while perceived threat severity denotes the extent to which a threat is perceived to be serious or harmful [14]. The motivation to self-protect increases if the implications are severe (getting diagnosed with a disease or falling prey to a cyberattack). Meanwhile, perceived threat vulnerability implies an individual's assessment of their susceptibility to a threat. Highly vulnerable individuals are more inclined to adopt protective behaviours. Coping appraisal evaluates an individual's ability to prevent a threat, including the effectiveness of those actions and their own self-efficacy [15]. Response efficacy denotes an individual's belief on the effectiveness of the recommended protective behaviours or action in mitigating a threat. People who believe their actions to be successful (installing antivirus software to prevent a cyberattack) would take measures to actualise them. Self-efficacy is an individual's confidence in his or her ability to perform protective behaviours. Those who believe in their ability to successfully execute the action are more likely to do so. Figure 1 depicts the PMT model.

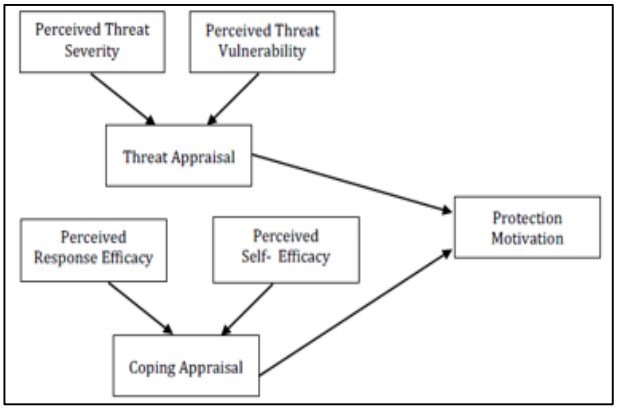

Fig. 1. Protection motivation theory.

Technological advancements via IoT, AI, big data, and cloud computing have led to the emergence of cybersecurity threats [16]. As such, the PMT framework is key to internalising and influencing cybersecurity behaviours in the context of Industry 4.0. Threat appraisal in cybersecurity involves the evaluation of cyber threat severity and likelihood [17-20]. Employees who perceive the potential consequences of a data breach as highly damaging are more inclined to comply with cybersecurity protocols [19]. Likewise, those who believe they are highly vulnerable to cyber threats would adopt protective measures akin to strong password practices and multi-factor authentication [20-21].

Coping appraisal is equally critical in cybersecurity. Perceived response efficacy implies the belief that specific security measures (encryption, regular software updates, and secure network configurations) effectively minimise cyber risks [4,7]. People who trust that these measures can ensure protection against threats would be motivated to implement them. As one's confidence in executing cybersecurity practices (like identifying phishing attempts or managing security settings) increases the likelihood of proactive behaviours, self-efficacy plays a pivotal role in this context [9]. In contrast, high response costs involving perceived complexity, time consumption, or inconvenience of security protocols can prevent individuals from adopting protective actions.

The integration of emotional factors (fear) significantly elevates PMT's explanatory power in cybersecurity. While fear of personal or organisational consequences from cyberattacks can ensure compliance with guidelines, excessive fear without adequate coping mechanisms can instigate avoidance behaviours. This scenario calls for comprehensive cybersecurity training programs [22]. Companies should design interventions that increase their employees' cybersecurity, awareness, self-efficacy, and effectiveness in executing protective measures to establish a resilient cybersecurity culture in Industry 4.0 [23].

III. Methodology

The research design, population and sample selection, data collection methods, and analysis techniques are presented in this section. Building on PMT, the current work proposed a cybersecurity awareness model designed for digital IR 4.0 by leveraging PMT constructs.

This section also details the population and sample selection process. A diverse and representative group of participants were chosen in this study to increase the outcome generalisability. Empirical data were gathered using a structured questionnaire containing validated PMT constructs to measure key variables of threat appraisal, coping appraisal, self-efficacy, and response efficacy. Furthermore, statistical techniques were used to analyse the correlations between the PMT constructs and cybersecurity awareness behaviours.

A comprehensive model was developed to increase cybersecurity awareness and support regulatory interventions that minimise cyber risks. The insights gained from this research can assist organisations in developing strategies that strengthen their overall security position in digital IR 4.0 and foster a culture of cybersecurity awareness.

A. Research Design

A cross-sectional survey design was employed to systematically collect data on the various factors associated with cybersecurity awareness among digital IR 4.0 employees. This design, which facilitates data collection at a single point in time, proved suitable for examining participants' awareness levels and their perceptions of cybersecurity threats and responses following the research objectives.

The relationships between the PMT constructs were statistically analysed in this study. A structured questionnaire served to gather analyse numerical data via SmartPLS, which facilitates the simultaneous assessment of measurement and structural relationships [24]. Furthermore, SmartPLS offers multiple bootstrapping options to assess the significance of path coefficients and delineate the proposed model correlations.

The survey design was selected to obtain large-scale data from a diverse participant pool and draw meaningful conclusions about the outcome generalisability. A representative sample from various IR 4.0 sectors was chosen to capture a wide range of experiences and perspectives regarding cybersecurity practices. The survey instrument contained validated scales measuring each PMT construct, thus ensuring reliability and validity in the assessment of participants' attitudes and behaviours toward cybersecurity.

Potential associations and patterns among the PMT constructs and cybersecurity awareness were analysed via SmartPLS to determine how perceived threats (threat appraisal) correlate with the ability (self-efficacy) to address them and the perceived effectiveness of their responses (response efficacy).

B. Specific Research Design

Descriptive and evaluative designs were used in this study. The key PMT constructs in current cybersecurity awareness models were identified and analysed with the descriptive approach [24] to understand the core components of PMT and their role in cybersecurity models based on research question 1.

A structured model development process was applied based on PMT to identify and integrate key PMT constructs into a framework tailored to cybersecurity challenges in digital IR 4.0 environments in Malaysia based on research question 2 [25].

Meanwhile, the proposed model effectiveness was evaluated using the evaluative component to increase cybersecurity awareness in line with research question 3. The recommended model was evaluated based on its ability to improve participants' awareness. Consequently, a survey-based approach served to elicited data on awareness levels pre- and post-exposure to the model. Statistical analyses were performed to quantify model effectiveness and facilitate objective assessment.

C. Sample and Population

The study population entailed the individuals working in digital IR 4.0-driven companies in Malaysia, including i) cybersecurity experts, ii) IT personnel, and iii) general employees. The first group consists of professionals who are responsible for safeguarding organisational information systems, implementing security strategies, and addressing cyber threats; the second group comprises of employees who are accountable for managing digital infrastructure, ensuring system stability, and implementing security protocols; and the third group encompasses non-technical staff who are responsible for interacting with IR 4.0 technologies and adhering to security policies. The Partial Least Squares Structural Equation Modelling (PLS-SEM) technique was employed to evaluate the hypothesised relationships among PMT constructs and cyber security awareness behaviours.

IV. Data Collection Methods

This quantitative study used an online survey questionnaire adapted from past research. The PMT constructs relevant to cybersecurity awareness were assessed in this questionnaire.

A. Content Validity

Five cybersecurity experts reviewed the survey questionnaire for clarity, relevance, and alignment with the study objectives. Content validity ensures that the instrument measures what it is intended to. Their expertise allows for the accurate representation of the study constructs.

B. Pilot Testing

A pilot test involving 30 respondents was conducted to determine instrument reliability and usability. Internal consistency was confirmed using reliability analysis, while the PMT constructs' effectiveness was ascertained through Cronbach's alpha.

C. Actual Study of Data Collection

The finalised questionnaire was administered online to 255 respondents across IR 4.0 companies in Malaysia. The elicited data were analysed using SmartPLS to examine relationships between PMT constructs and cybersecurity awareness.

D. Sample Size Determination

Power analysis was performed using G*Power 3.1 to determine the minimum sample size for the study. A medium effect size ($f^2 = 0.15$), significance level ($\alpha = 0.05$), and statistical power ($1-\beta = 0.80$) generated a sample size of 98. In this study, the sample size of 225 proved sufficient to ensure statistical power for multiple regression analysis.

This research examined cybersecurity awareness using PMT in digital IR 4.0 environments using a structured approach. The cross-sectional nature of the study, validated instruments, and rigorous statistical analysis potentially contribute key insights into enhancing cybersecurity practices and resilience in IR 4.0-driven companies.

V. Results and Discussion

The respondents' demographic profiles were categorised based on age, gender, organisation/university, race, department/division/unit, education level, and years of experience. Most of the respondents (47.5%) were between 25 and 30 years old, followed by those between 31 and 35 years old (32.9%), below 25 years old (6.3%), and more than 35 years old (13.3%). Regarding gender, 51.0% of the respondents were female, with the remaining 49.0% being male. This finding represents a fairly balanced age distribution.

In terms of organisation/university affiliation, the respondents were employed from a diverse range of industries. A significant proportion of the workers (9.4%) were from Consumer Goods and Retail, followed by Dell Malaysia (8.6%), Fusionex (8.2%), Tenaga Nasional Berhad (TNB) (8.2%), Opcom Holdings Berhad (7.1%), and Vitrox Corporation Berhad (7.5%). Other companies revealed smaller representations, with some contributing under 1% each.

Concerning race, Chinese respondents constituted the largest group (44.7%), followed by Malay (32.5%), and Indian (22.7%).

The respondents were also distributed across various departments, with the highest representation in administration (20.4%), followed by accounts (18.1%), marketing (15.7%), and human resources (13.7%). Other departments such as finance (8.6%) and content creation/creative (6.7%) also demonstrated notable participation. Meanwhile, specialised units resembling cybersecurity, environment, and procurement revealed minimal representation.

Based on educational qualifications, many respondents were Degree holders (31.0%), followed by Diploma holders (27.1%), Master's degree holders (22.4%), and Ph.D. holders (10.6%). A smaller percentage (9.0%) of them had a Certificate-level education. Regarding work experience, the respondents were well-distributed across different experience levels. Most of the individuals worked between 5-9 years (22.0%), followed by 20-24 years (19.6%), 10-14 years (17.6%), and 15-19 years (14.5%). A smaller group were employed for more than 25 years of experience (11.4%). Approximately 14.9% of them had 1-4 years of experience. This diversity highlights a broad representation of professionals from various industries, educational backgrounds, and experience levels.

The SEM was employed using Smart PLS 4.0 to examine the relationships among perceived threat severity, perceived threat vulnerability, fear, perceived response efficacy, perceived self-efficacy, and response cost in the PMT framework. A two-stage analysis involving measurement and structural model assessment was performed. The former involves evaluating construct reliability and validity, while the latter entails examining the path coefficients, explanatory power (R^2), effect sizes (f^2), and predictive relevance (Q^2).

TABLE I. OUTER LOADING

Items	Outer Loading	Items	Outer Loading
Fear		Perceived Self-Efficacy

RC2	0.862	PTS2	0.8
RC3	0.869	PTS3	0.758
Protection Motivation Theory			
PM1	0.867		
PM2	0.874		
PM3	0.797		

Several statistical tests were used in measurement model assessment to determine construct reliability and validity. With all the outer loadings exceeding the recommended threshold of 0.60 (0.697-0.910), indicator reliability was established (see Table I). Cronbach's alpha and CR values, both of which exceeded 0.70, confirmed strong internal consistency reliability. The AVE values exceeding 0.50 confirmed the convergent validity. Hence, each construct effectively measured the intended latent variables. The Fornell-Larcker criterion, cross-loadings, and HTMT ratio met the required thresholds, confirming discriminant validity of each construct. Overall, the theoretical constructs and measurement model were accurately captured and validated, respectively.

The VIF values below 5 indicate the absence of multicollinearity in the structural model assessment [26]. Represented by the R^2 value for protection motivation (0.554), the model's moderate explanatory power suggests that 55.4% of the variance was explained by the independent variables. Path coefficient analysis highlighted the statistical significance of most of the hypothesised relationships based on the theoretical assumptions of PMT [27]. With some of the constructs denoting strong effects and others reflecting moderate to small effects on protection motivation, the f^2 results varied. The positive Q^2 values highlight the model's ability to predict future data and applicability in behavioural works.

The current results evidence the key determinants of protection motivation. The significant positive influence of perceived threat severity and vulnerability on fear implies that people who perceive a threat as severe might experience higher levels of fear and, subsequently, the motivation to engage in protective behaviours. Fear played a strong mediating role in the relationship between perceived threat (severity and vulnerability) and protection motivation. As such, emotional responses must be seriously considered in the decision-making process [28-29]. The significant relationship between perceived response efficacy, self-efficacy, and protection motivation confirms that people who believe in the effectiveness of a protective measure and trust in their ability to perform it would engage in protective behaviours. In contrast, the negative influence of response cost implies that people who perceive protective actions as too costly or difficult would be less inclined to adopt them [30]. This finding highlights the need to mitigate the perceived barriers to protective behaviours via policy interventions and awareness campaigns.

The validation of PMT's applicability in a new context enriches the theoretical understanding of PMT. Including fear as a mediator increases the theory's explanatory power while delineating how individuals assess risk and make protective behaviour-related decisions [31]. In practice, the study results have significant implications for public health campaigns, policy interventions, and behavioural change strategies. Risk communication efforts should prioritise threat severity and self-efficacy for enhanced protective behaviours. For example, policymakers should aim at alleviating financial barriers or inconvenience (response costs) to facilitate the adoption of protective measures [32]. Educational programs should also incorporate skills-building workshops. These self-efficacy strategies can empower individuals to take proactive risk mitigation measures.

This study highlighted the significant influence of threat appraisal (severity, vulnerability), coping appraisal (response efficacy, self-efficacy), and emotional factors (fear) on protective behaviour intentions based on PMT. The current outcomes underscore the significance of addressing fear, self-efficacy, and response costs in behavioural interventions [33-34]. Future works could consider examining longitudinal effects and cultural differences to increase the outcome generalisability. 10 research hypotheses were tested based on the proposed framework. McGuire et al. (2017) [27] and Hair et al. (2020) [28] asserted that structural model assessment facilitates the identification of significant and influential pathways that validate the hypotheses and demonstrate the model's predictive capability.

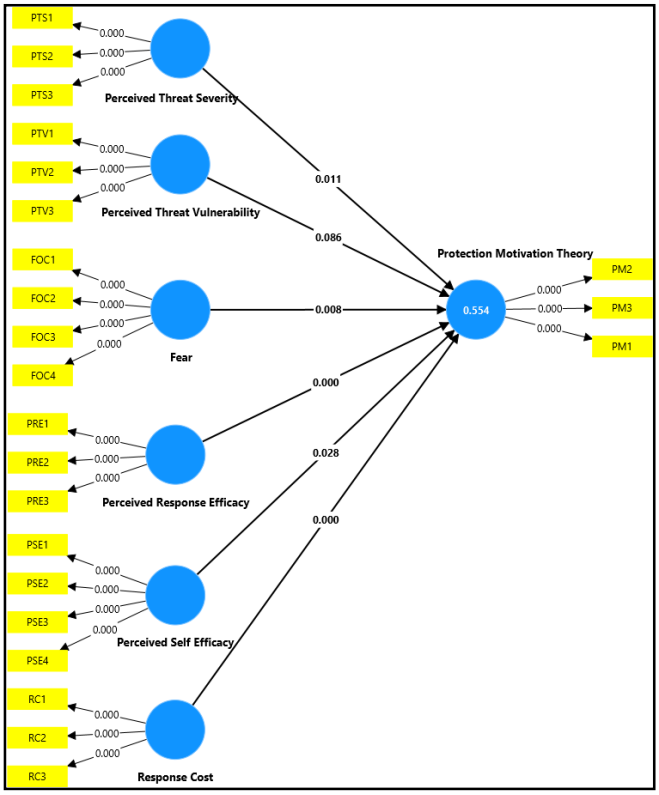

Fig. 2. Structural model.

Figure 2 illustrates the PMT framework and its key components, which are divided into two key cognitive processes: threat and coping appraisal. Perceived threat severity and its impact on individuals' motivation to take protective action were evaluated under threat appraisal [32].

Perceived threat severity, which implies an individual's assessment of how serious or dangerous a threat is, and fear, an emotional response stemming from the threat's perceived severity, influenced the motivation to adopt protective measures [33]. Coping appraisal assesses an individual's ability to effectively address the threat. This includes perceived response efficacy, where taking protective action effectively minimises the risk; perceived self-efficacy, which denotes the confidence in one's ability to perform the protective behaviours successfully; and response cost, which represents the perceived barriers or costs (related to taking the protective action [34]. These factors contribute to PMT, ultimately determining whether an individual is driven to take protective actions in response to a perceived threat (as in Figure 3).

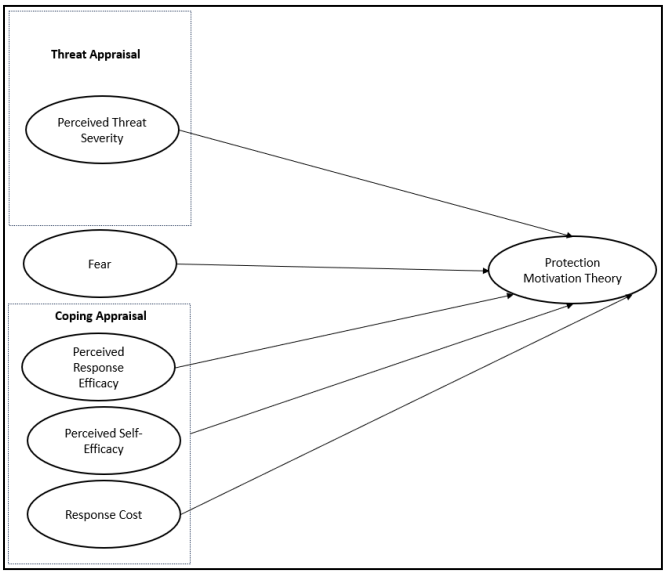

Fig. 3. Final model of cybersecurity awareness model based on PMT.

VI. Conclusion

This study empirically validated PMT by highlighting the significance of threat appraisal, coping appraisal, and emotional responses in influencing protective behaviour intentions. Perceived threat severity and vulnerability positively impacted the levels of fear, which played a strong mediating role between the threat perception-protection motivation relationship. The finding underscores the critical role of emotional responses in behavioural decision-making processes. Furthermore, coping appraisal components strongly and positively influenced protection motivation. Individuals who believed in the effectiveness of the protective action and trusted in their ability to perform it were more driven to engage in protective behaviours. Meanwhile, the negative influence of response suggested that higher perceived barriers decreased the likelihood of adopting protective measures. These results validated PMT in a new context while also enhancing its explanatory power via the mediating effect of fear. The theoretical and practical study implications provided meaningful insights that will benefit public health strategies, policy development, and behavioural change interventions.

Public health campaigns must consider the severity and vulnerability associated with threats to evoke appropriate levels of fear that motivate protective actions. Notably, this correlation must be balanced to avoid inducing excessive fear and defensive mechanisms. Educational programs could introduce skill-building workshops and training sessions to boost individuals' confidence in their ability to effectively perform protective behaviours. Meanwhile, communication strategies should demonstrate the effectiveness of protective measures using evidence-based information. Such actions can significantly mitigate risks. Policymakers could consider alleviating the perceived barriers to protective behaviours through financial subsidies, simplified procedures, and publicly accessible

protective resources. Furthermore, behavioural interventions could account for emotional responses (particularly fear) by providing supportive messages that guide individuals from awareness to action without causing unnecessary anxiety. Potential scholars should conduct longitudinal studies to explore the long-term effects of protection motivation factors. Examining cultural differences can enhance the outcome generalisability to diverse populations. Stakeholders who apply these recommendations can develop more robust strategies that improve protective behaviours, public health outcomes, and risk management practices.

VII. LIMITATION

Despite providing valuable insights into cybersecurity awareness in IR 4.0 environments, this study is subject to several limitations. Firstly, the use of a cross-sectional design limits the ability to observe changes in cybersecurity awareness or protective behaviours over time; hence, longitudinal studies are recommended for future research to gain a deeper understanding of behavioural dynamics and causality. Secondly, the reliance on self-reported data introduces potential biases, such as social desirability effects, where participants may have overestimated their awareness or adherence to cybersecurity practices to align with perceived expectations. Additionally, the study's generalisability is limited due to its focus on Malaysian IR 4.0-based organisations; extending this research to other cultural and geographical contexts could enhance the applicability of the findings. The theoretical scope was also constrained, as the study concentrated solely on core Protection Motivation Theory (PMT) constructs—namely threat appraisal, coping appraisal, and fear—without considering other influential factors like peer influence, organisational culture, or support systems, which may further enrich the model. From a technical perspective, while the behavioural aspects of cybersecurity were well addressed, the study did not explore technical dimensions such as intrusion detection systems (IDS), encryption tools, or information security protocols. Incorporating these elements through a mixed-methods approach could offer a more holistic understanding of cybersecurity readiness. Lastly, although PLS-SEM was appropriately used for its predictive and exploratory capabilities, it does have methodological constraints, including sensitivity to model specifications and potential path estimation biases. Future work may benefit from comparing PLS-SEM outcomes with those derived from covariance-based SEM for validation and robustness.

Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Colorado State University, Washington, USA[2]
Indian Institute of Management, Bangalore (IIMB), India[3]

***Abstract*—Contract review is a critical legal task that involves several processes such as compliance validation, clause classification, and anomaly detection. Traditional, centralized models for the analysis of contracts raise significant data privacy and compliance challenges due to the highly sensitive nature of legal documents. This paper proposes a contract review-oriented federated learning framework, where model training can be performed in a completely decentralized way with data confidentiality. It leverages privacy preserving methods such as Differential Privacy ("DP") and Secure Multi-Party Computation ("SMPC") that provide protection for sensitive information during collaborative learning. The proposed framework reaches a clause classification accuracy of 94.2% while securing privacy requirements. Performance analysis of the training efficiency revealed that the federated model needed 13.1 hours instead of 10.4 hours for a centralized model while still protecting the security of the system. This research offers a scalable and secure approach toward contract review and offers a path forward for privacy-conscious AI-driven legal solutions.**

***Keywords*—Federated learning; privacy preservation; clause classification; compliance validation; anomaly detection**

I. Introduction

The rapid development of digital technologies has influenced many spheres of human life and activity, seriously changing the face of the legal world. Among all legal processes, reviewing a contract is considered one of the most important tasks; it involves analyzing legal documents to validate compliance, classify clauses, and detect anomalies [1]. Contracts carry sensitive information that enforces high levels of data privacy; hence, adapting AI-driven solutions for reviewing contracts is very challenging regarding privacy and compliance [2].

Traditional machine learning architecture although efficient requires sensitive information to be aggregated into a central repository [3]. This creates enormous risks of data breaches and violations of regulatory requirements, such as under GDPR (General Data Protection Regulation) or attorney-client privilege. In contract review, legal documents contain highly sensitive information, raising concerns that necessitate innovative approaches to ensure data security [4] [5].

Recently, Federated Learning (FL) has become a revolutionary method, given such challenges. In contrast to centralized frameworks, FL allows several entities, like law firms and corporate legal departments, to jointly train AI models without necessarily sharing raw data [6]. This decentralized approach keeps sensitive contract data local, maintaining data privacy while allowing effective AI-driven contract review and adherence to privacy and compliance standards [7].

The potential of FL in contract review lies in its ability to combine newer NLP models, such as Legal-BERT, for specialized tasks like clause classification and compliance validation [8]. However, the nature of this data is rather heterogeneously distributed and purely Non-Independent and Identically Distributed (Non-IID), which creates formidable obstacles to the effective implementation of FL in this domain [9]. The main contributions of this work are as follows:

1) This paper presents a framework design for privacy-preserving horizontal federated learning, which is specially targeted at contract review and ensures robust data protection.

2) Integration of Differential Privacy (DP) and Secure Multi-Party Computation (SMPC) to protect sensitive contract data while ensuring compliance with privacy regulations.

3) The framework has also shown effectiveness in decentralized environments, achieving near-centralized performance in tasks related to clause classification, compliance validation, and anomaly detection.

4) It highlights challenges such as data heterogeneity and computation complexity that are crucial for the deployment of FL into real-world contract review scenarios.

The system incorporates into current legal document analysis pipelines so that law firms together with corporate legal teams can use AI-powered contract review with preserved data privacy. This solution provides deploy ability across different legal territories which resolves compliance matters. Through the implementation of federated learning organizations can improve AI models together while maintaining confidentiality of their sensitive contract information.

Results from this study demonstrate the importance of FL as a means for enabling privacy-preserving collaboration among stakeholders like law firms, corporate legal departments, and regulatory authorities. These effectively overcome data privacy challenges, jurisdictional limitations,

and computational complexity to offer scalable and secure solutions for AI-driven contract review. The proposed research forms a very sound basis for further advancement in decentralized machine learning applications in legally and regulatory sensitive contexts, ensuring privacy and compliance without compromising performance.

The rest of the paper is organized as follows: Section II reviews the literature on current methodologies in federated learning while also pointing out some key gaps in their application in a legal context; Section III describes the methodology, including the structure of the proposed framework and privacy-preserving measures incorporated within the contract review domain. Section IV discusses experimental results by estimating the framework's performance on contract review tasks while sustaining privacy and compliance. Finally, the paper is concluded in Section VI by summarizing the results in Section V and stating the directions for future research in improving applications of privacy-preserving AI in contract review.

II. Related Work

FL has rapidly developed as a novel technique in collaborative machine learning, especially in contexts where data protection is a critical issue, including legal text analysis [10]. Due to its distributed setup, various parties can train jointly used models while shielding information [11]. This section presents an empirical analysis of prior studies on FL and its deployments emphasizing privacy preservation techniques, text categorization issues in sensitive domain contexts, and current research constraints.

A study in [12] first coined the term Federated Learning in their work, which defines a learning architecture that trains local models without sending raw data to the cloud. This approach reduces the possibility of leakage of data while at the same time enhancing learning through collaborative learning [13]. Subsequently, contributors have incorporated security enhancing strategies to FL, to strengthen its privacy. There is, for instance, Differential Privacy (DP) which either adds noise to data or model updates to make private data points indistinguishable [14]. Likewise, the Secure Multiple Party Computation (SMPC) protocols, described by [15], enable secure aggregation techniques that help to prevent the recovery of model updates to personal details. However, privacy issues in FL are still noticeable with focus on adversarial activities and model inversion attacks [16]. It was also found out in a number of works that even micro updates could sometimes reveal sensitive information which is why new improvements in the methodology of the secure accumulation of updates and adversarial robustness are required [17]. Despite the great progress made in healthcare and IoT applications, there are only a few papers discussing the use of FL in legal domains, especially for unstructured text analysis.

A. Applications of FL in Sensitive Domains

FL has been applied in number of security-conscious areas. In healthcare, [18] showed that it could be applied to privacy-preserving medical imaging, meaning that organisations can collaborate across borders without transferring data. The study also revealed that FL could generalize models across mismatching datasets and retain competitiveness. FL has also been explored in privacy-sensitive domains such as healthcare, but its potential in addressing legal text classification tasks has been less examined [19]. These studies highlight the usefulness of FL in situations where data cannot be aggregated owing to privacy, legal, or geographic limitations.

However, these applications most of the time work with formalized data, for instance, numerical or categorical record. On the other hand, legal and financial domains often contain unstructured text data, the processing of which needs the use of NLP [20]. Legal texts for instance are full of legal terms, legal jurisdiction aspects, and legal syntax to mention but a few, thus pose major challenges with regards to model generalization in federated systems [21]. Other tasks from legal text classification are identification of entities, classification of clauses, and abstracting, all of which cannot be performed using regular natural language processing methods. Typical practices used previously have focused on the centralized architecture that is based on the large aggregated data. Transformer-based models such as BERT and its specializations such as LegalBERT, FinBERT have already become milestones for evaluating and comparing legal and financial text analysis scenarios [22].

Though these may work effectively, they arrive with appreciable privateness issues; a lot of them require transmission of the enterprise’s records through central areas, and once contracts or agreements, authorized or monetary, are sensitive, this can be very dangerous. In addition, local regulations including GDPR and CCPA put constraints on the sharing of data, which cannot be resolved by centralised approaches such as FL. Introducing FL for legal applications comes with various difficulties like having non-IID data distribution and the legal texts complexity [23]. One of them is the independence and identical distribution of data across the entities which is not the case with Big data. Legal and financial documents differ in their form across legal systems, organizations, and applied contexts, which leads to heterogeneity of resulting dataset. Current FL optimization methods including FedAvg and FedProx fail to achieve a balanced performance across legal datasets because of their heterogeneity [24]. The fourth issue is the computational complexity of FL frameworks. Due to the iterative communication between clients and servers in an FL framework, there is often a latency issue and higher consumption of resources. To address communication costs, recent research has explored compression techniques, but their integration into privacy-sensitive legal contexts remains underexplored [25].

Finally, the interpretablity is also important for legal and financial applications, when decisions are made based on machine learning models. There is relatively few research on the application of XAI in FL frameworks for legal text analysis which remains an issue for transparency in legal domains [26]. These gaps are filled in this research by constructing a federated learning framework specific to privacy-preserving legal text analysis. This design also employs robust privacy preservation mechanisms including Differential Privacy and Secure Multi Party Computation. It also employs adaptive optimisation algorithms and also personalised federated

learning methods for dealing with non-IID data. FL has not been previously applied to unstructured text data, and, therefore, the study presents FL as a suitable method for performing legal text classification tasks, such as performing clause analysis and identifying entities within the text. Due to the focus on the computational efficiency and interpretability of the approach this work offers a systemic solution to collaborative machine learning in privacy-preserving context.

Thus, this study fills the void in the development of federated learning by addressing the practical problem of implementing high-level machine learning based on strict privacy constraints. The proposed framework lays down basic framework for further evolution to facilitate secure and effective collaboration among the stakeholders in legal domain.

III. Proposed Approach

This paper proposes a federated learning framework for contract review tasks, using synthetic data for at least three types of contracts, including procurement, employment, and regulatory filings [27]. It also enables multiple contract review tasks such as the classification of contracts into various clauses to determine which clauses are essential, compared to those that are a legal necessity, and the screening of contracts for anomalies, or risky and unusual clauses. The proposed architecture follows a structured workflow: (1) Data preprocessing involves tokenization, stop-word removal, and formatting for NLP models; (2) Model training occurs in rounds, where each client updates local weights using stochastic gradient descent (SGD) while applying DP noise; (3) Secure aggregation is performed using secure multi-party computation (SMPC) and FedAvg to combine model updates; and (4) Validation ensures model accuracy and compliance with privacy-preserving constraints.

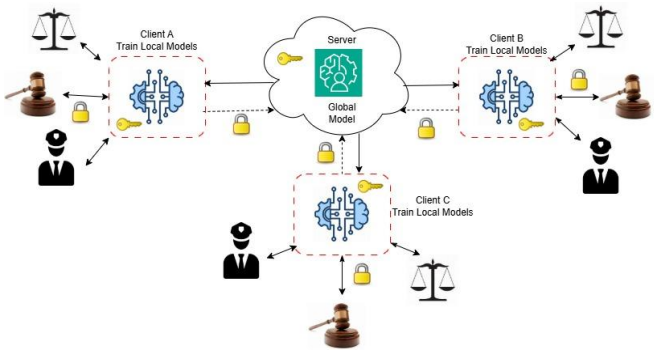

Fig. 1. Proposed architecture.

The Fig. 1 illustrates a decentralized network architecture that enables multiple client nodes to execute smart contracts deployed. The system enables trustless automation through smart contracts which provide centralized features to allow nodes to perform secure transparent data exchange while executing logical processes in decentralized environments.

Namely, the proposed framework's primary goal is to preserve data privacy utilizing the concept of federated learning and achieve high performance when dealing with legal documents.

A. Data Preparation and Distribution

The Contract Understanding Atticus Dataset (CUAD) is a rich source of data specifically prepared with an aim of serving contract analysis tasks and provides annotations for 41 types of clauses including indemnity, confidentiality and limitation of liability among others [28]. These annotations assist the goals of analysing key texts, such as clause classification, compliance cheque, and outlier identification. The proposed framework aims to enhance data privacy by using federated learning as its main approach to obtain high performance on contract data while avoiding centralised data storage.

Preparing the CUAD dataset involves formatting the contract. The contract text Cleansing and format Contract data pre-processing in the CUAD dataset involves preparing the text in an appropriate manner for analysis. This involves eliminating non-applicable symbols, symbols for general signs and meta-information and preserving business related symbols that define contracts such as indemnity and termination [29]. Tokenization means that such terms are kept without compromising their semantic and contextual whole. Efficient tokenization approaches are employed to handle legal words and phrases and the full contract text's intricate richness common in legal contractual language for contracts, thus keeping the dataset pertinent to the legal domain and very useful for downstream applications.

The CUAD dataset is divided across simulated clients and these include law firms, corporate legal departments and regulatory agencies. The former functions as each client will work on the localised subset of the data—just like in real applications where separate organisations will shortly deal with the contracts themselves. It also means that data distribution is decentralised in order to maintain data privacy and confidentiality. Clients only preprocess, train models and perform other computations on only the data it needs. Rather than exchanging contract values, groups share a subset of model updates including gradients and weights with the central server. These updates are collected centrally in order to update the global model while preserving user privacy.

Such a distribution strategy reflects a federated learning approach, where data on client nodes is kept private and unavailable to other nodes. It also maintains the distributed nature of possible legal data, which is essential for compliance with privacy standards and the development of the model among various organisational settings.

The Fig. 2 bar chart shows different clause frequencies in a simulated CUAD (Confidentiality and Undisclosed Data) dataset while using counts as the y-axis value. Different colored bars in the Fig. 2 bar chart represent clauses like Confidentiality and Indemnity and Termination and Governing Law and Force Majeure and others so readers can easily understand their proportions in the CUAD dataset.

The Fig. 3 illustrates the frequency distribution of clause word counts in a particular dataset through a histogram representation. The vertical axis displays frequencies or counts which correspond to the horizontal axis measurement of clause length ranges. The illustration enables the examination of

standard length patterns while helping to detect any irregularities or deviations from normal distribution patterns.

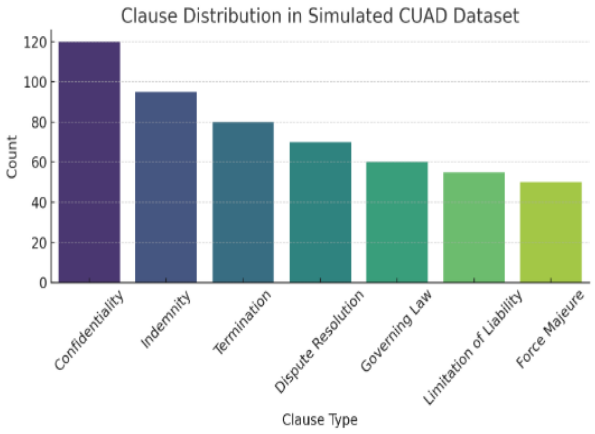

Fig. 2. Distribution of clauses given in dataset.

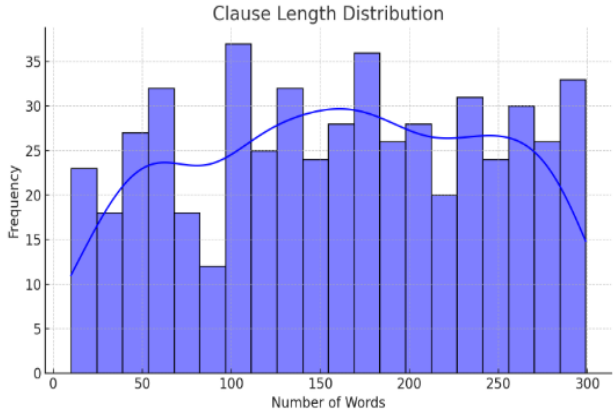

Fig. 3. Distribution of clauses length given in dataset.

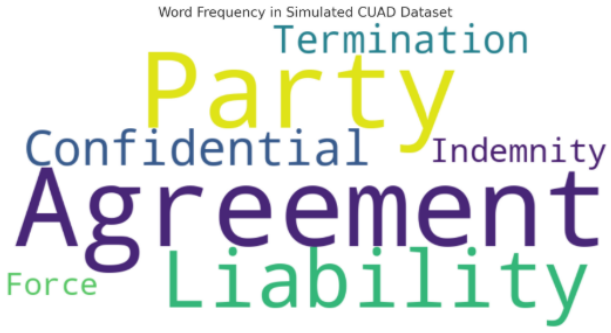

Fig. 4. Word frequency cloud in given data.

The word cloud Fig. 4 displays commonly used terms from confidentiality agreements including termination and party and confidential along with indemnity and agreement and liability and force. The size of the fonts within the word cloud matches the term frequency distribution in legal documents to show which words are most prominent.

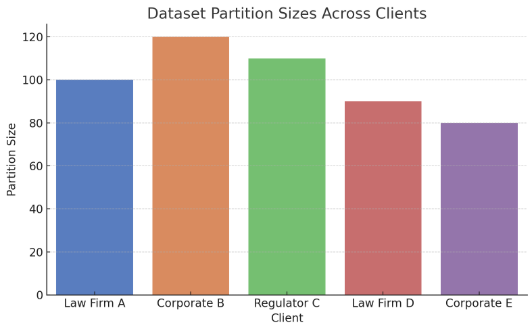

Fig. 5. Dataset partition size.

Fig. 5 presents data partition scores through bar chart representation which shows how data samples are distributed among clients or groups for federated learning or distributed data applications. The scores appear as y-axis quantities that correspond to the distinct client labels on the x-axis for data partition visualization purposes.

B. Federated Learning Framework

This work presents the FL setting that allows for the training of models using contract data that may include restricted and private information. The use of this framework also eliminates the need for data centralization to address privacy issues as well as meet legal requirement and data heterogeneity across clients. Local data is analysed separately by each participating client, and the only data being transmitted to the central server are model updates to prevent data leakage.

In the case of FL, distributed clients like law firms, corporate legal departments and regulatory agencies are able to work together without needing raw data to transfer through the cloud. Rather than transmitting content of contracts, clients offer gradients, weights, and other updates in the design. These updates are aggregated at the central server using the Federated Averaging (FedAvg) algorithm:

$$\theta = \frac{\sum_{i=1}^{N} n_i.\theta_i}{\sum_{i=1}^{N} n_i} \quad (1)$$

Where θ is the global model's parameters, θ_i represents the parameters from the i-th client, and n_i is the data sample size for the i-th client. This method ensures that the global model learns from all clients while maintaining data confidentiality.

The proposed framework supports key contract review tasks, including:

- Clause Classification: Independent vocabulary analysis within contract provisions: elimination of equivalent terms as well as grouping significant clauses, which contain indemnity, confidentiality, and termination.
- Compliance Validation: Check whether contracts delivered by employees comply with regulations and organizational requirements.
- Anomaly Detection: Recognising a particular product, which contains clauses that are different from those typically observed.

The FL framework is, therefore, designed in a modular fashion with standard NLP tools, required for processing and analysis of contract data. Due to its decentralised structure, the proposed framework is capable of processing such and similar data types as well as is scalable for different contacts and organisational settings.

Clause identification is the identification of key terms or parts of contracts including indemnifying, terminating, dispute solving and non-disclosure agreements. It has pointed to these elements when it comes to contractual terms, risks and legal enforceability of contract terms. The task is presented as a non-linear classification problem where each clause is classified in a distinctive category depending on its semantic and contextual characteristics. To this end, the model takes text of the contracts that has been tokenized and then obtained contextual embeddings which are then fed into a fully connected layer for classification. Furthermore, for the classification output, the categorical cross-entropy loss function is used so as to achieve better predictions of different kinds of clauses.

1) Input processing: Tokenized contract text is transformed into embeddings:

$$H^{(0)} = E(xi) + P(xi) + S(xi) \quad (2)$$

Where, $E(xi)$ is the token embedding for the i-th token. $P(xi)$ Represents positional embedding. $S(xi)$ is the segment embedding.

2) Classification layer: The embeddings are passed through a fully connected layer with a softmax activation function:

$$P(x|y) = softmax(W.h + b) \quad (3)$$

Where, h refers to contextual embedding's context vector, W and b are weights and the biases of the classifier.

3) Loss function: The model is optimized using categorical cross-entropy:

$$L_{CE} = \sum_{i=1}^{C} y_i \log(P(y_i|x)) \quad (4)$$

Where C is the total number of statute classes.

Validation compliance is primarily oriented towards the evaluation of the compliance of contracts, as well as regulations or organisational requirements. This task is analysed and formulated as a binary classification problem where the target output is a binary indication as to whether a contract complies with certain standards. The model interprets the received input text and use a sigmoid transfer function to provide probabilities of compliance. As it is discussed in the preceding sections, optimization is performed by minimising the binary cross entropy which is used to measure errors in the probability estimates of the compliance outcome. This is an important task to pursue in order to avoid some of the contracts being in contravention of the law or regulation. A sigmoid activation function maps outputs to probabilities:

$$P(y|x) = \frac{1}{1+\exp(-z)} \quad (5)$$

The binary cross-entropy loss function is minimized during training:

$$L_{BCE} = -\frac{1}{N}\sum_{i=1}^{N}\left[y_i \log\left(\hat{Y}_i\right) + (1-y_i)\log\left(1-\hat{Y}_i\right)\right] \quad (6)$$

Where, N is the number of samples. The other significant task is anomaly detection that recognises odd or dangerous clauses that differ from most contracts. This task is very beneficial during the carrying out of the review to point out potential problems. DP noise addition enables privacy protection because it stops adversaries from reconstructing confidential database entries from gradient information. The level of noise used in DP affects the speed of convergence and the accuracy of the model. The experimental results show that an ideal balance exists between privacy protection and classification accuracy when using $\sigma = 0.5$ as the noise scale value. The model acts as a profiling methodology; it learns initial patterns from the standard clause and identifies the remainder as anomalies. Subsequently these flagged clauses they are can again be reviewed by a human eye which can help in avoiding many a risk as may be important. The similarity between an input clause and standard clause embeddings is computed:

$$Score\ (x) = \left|\left|h_x - h_{mean}\right|\right| \quad (7)$$

Clauses with anomaly scores exceeding a predefined threshold are flagged for further review.

In order to ensure that the contract data remain secure and no one gains access to their details during model training the following privacy-preserving methods are included in the framework. Stochastic Gradient Descent with applied DP is used to add noise to the model updates while gradient descent is used to avoid leakage of further parameters from the shared parameters by adding controlled noise. The Laplace mechanism is used while adding noise to the data and the privacy budget determines the privacy and utility balance. Furthermore, Secure Multi-Party Computation (SMPC) provides model update message sending functionality that encrypts the model update during the transmission phase and even if the transmission is intercepted, data security is not compromised [30]. These combined techniques provide a strengthened privacy protection mechanism for decentralised training settings.

$$Lap(x; b) = \frac{1}{2b}\exp(-\frac{|x|}{b}) \quad (8)$$

In communication of model updates, SMPC employs an encryption technique to make sure that the information is secure if it is interceded by an aggressor. Each client applies an encryption to its gradient updates before sending these updates to the central server, where these updates are then combined without decryption.

The FL framework adopts the Federated Averaging (FedAvg) approach for aggregation of the updated global model. Each of the clients trains a local model using its subset of the generic contract data and then securely sends update to the server. These updates are assembled at the server side without having raw data; it forms a model recognised worldwide that is the accretion of all the clients' knowledge. This decentralised process is based on multiple cycles of training, where the global model is gradually optimised and

then updated and sent back to clients again. Each client computes its local weight update:

$$\Delta W_i = SDG(W_i, data_i) \quad (9)$$

Where, ΔW_i is the update for client i.

$$W_{t+1} = \sum_{i=1}^{N} \frac{n_i}{n} W_i \quad (10)$$

In this instance, n_i stands for the data size of the i-th client and n is the global sum of all clients data. This paper proposes integrating FL for contract review, and through extensive experimentation, presents a practical, privacy-preserving approach with high accuracy in clause classification and compliance validation alongside solid anomaly detection requirements. It allows for the synergy within the legal professionals irrespective of the organisational interfaces without violation of the legal standards of confidences or any other laws. The framework provides evidence about the feasibility of FL in transforming contract review in ways that should increase the general safety and effectiveness of AI-based legal solutions.

IV. Experimental Setup

The prospective FL scheme is developed to simulate realistic scenarios of decentralised contract analysis. The CUAD (Contract Understanding Atticus Dataset) served as the core of the study, utilizing annotated contract clauses which include the controversy, confidentiality, indemnity, termination and dispute resolution clauses. To model a federated learning scenario, the dataset was divided into ten synthetic clients to simulate organisations such as law firms, corporate legal departments, and regulatory bodies. This distribution also incorporated non-IID data scenarios that mimic actual distributions of client datasets, such as differences in the numbers of samples, types of clauses, and so forth.

Cleaning of the raw data involved the removal of stop words, conversion of the contract text into tokens and the application of lemmatization to arrive at a uniform analysis of the text while arriving at a representation of the legal terms used in the contract. These measures ensured that default terminologies such as 'indemnity' and 'termination' retain their exact form as used by the Model Trust for analysis. Every client was entirely decentralized in its data partition and trained models on it without transmitting raw data. It also preserved privacy and adherence to jurisdictional data regulations as shown by this decentralized structure.

Algorithm: Privacy-Preserving Federated Learning Framework

Input:

$\boldsymbol{D_i}$: Local dataset at each participating client iii (e.g., law firms, regulatory bodies).

T: Total number of training rounds.

E: Number of local epochs per client.

η: Learning rate.

σ: Noise scale for Differential Privacy (DP).

C: Clipping parameter for DP.

Output:

Global model W trained collaboratively without sharing raw data.

Step 1: Initialization

Initialize global model weights $\boldsymbol{W^0}$ randomly.

Distribute $\boldsymbol{W^0}$ to all participating clients.

Step 2: Federated Training Loop

For t=1 to T:

Client-Side Local Training:

Each client i:

a. Receive global model $\boldsymbol{W^{t-1}}$

b. Update local weights $\boldsymbol{W_i^t}$ using stochastic gradient descent (SGD) on $\boldsymbol{D_i}$:

$$\boldsymbol{W_i^t = W^{t-1} - \eta \nabla L_i(W^{t-1})}$$

Where $\mathbf{L_i}$ is the local loss function on $\boldsymbol{D_i}$.

c. Apply gradient clipping to bound the sensitivity of updates:

$$\boldsymbol{\Delta W_i = Clip(\nabla L_i, C)}$$

d. Add DP noise to ensure privacy:

$$\boldsymbol{\Delta W_i^{DP} = \Delta W_i + N(0, \sigma^2)}$$

Secure Model Aggregation (Server-Side):

Collect encrypted updates $\boldsymbol{\Delta W_i^{DP}}$ from all clients using Secure Multi-Party Computation (SMPC).

Perform weighted aggregation of updates to compute new global model:

$$\boldsymbol{W^t = \sum_{i=1}^{N} \frac{|D_i|}{\sum_{j=1}^{N} D_j} \Delta W_i^{DP}}$$

Where $\boldsymbol{|D_i|}$ is the size of the local dataset.

Distribute updated global model $\boldsymbol{W^t}$ to all clients.

End For

Step 3: Model Evaluation and Deployment

Evaluate the final global model $\boldsymbol{W^T}$ on a held-out validation dataset to assess performance on tasks like clause classification, compliance validation, and anomaly detection. Deploy the model for inference tasks while ensuring privacy compliance.

The experiments were performed in the hybrid environment of computation. Every simulated client had a counterpart of a virtual machine with four cores of Central Processing Unit, sixteen gigabytes of memory and a hundred gigabytes of storage – computational capacities characteristic for most legal organizations. The central server that is charged with accumulating model updates was outfitted with an NVIDIA Tesla V100 GPU, a 32 core processor, 128 MB of Ram, and 2 TB of SSD storage. The federated learning framework was programmed in Python utilizing TensorFlow Federated and PySyft applications.

V. Results

The evaluation of the proposed federated learning framework for contract review was conducted based on three key aspects: adaptability of a particular model for various contract analysis, level of privacy preservation, and time complexity. The results indicated that federated learning offers a more resistant, private solution to the centralized one, with limited compromising on accuracy and efficiency of the contract analysis.

A. Model Performance Evaluation

The effectiveness of the federated learning model was assessed on three core contract review tasks: clause classification and, compliance validation as well as; anomaly detection. The assessment involved the use of the performance indicators such as accuracy, precision, recall and F1 measure.

The findings presented show that federated learning performs at the same level as centralised models and preserves information privacy.

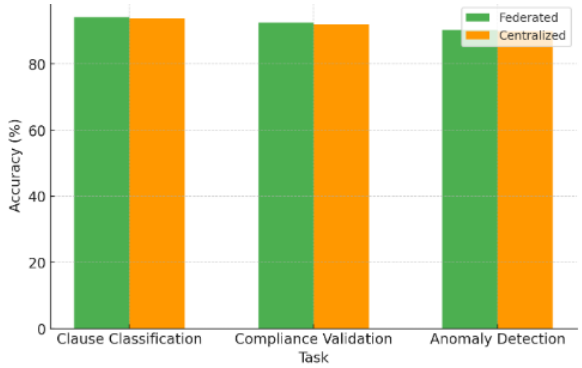

Fig. 6. Accuracy comparison between federated and centralized model.

The Fig. 6 displays a stacked bar chart which shows performance data potentially related to accuracy measures for the churn classification and compliance violation and anomaly detection activities. The bars show combined performance metrics for individual tasks where different colored sections display how two evaluation models contribute to the results. The stacked bar chart enables visual assessment of the different approaches regarding their combined performance metrics across three separate tasks.

Clause identification is another important step during contracts' analysis, and its results include classification of significant clauses including indemnification, non-disclosure, and termination etc. High generalisation capability was noted when classifying diverse clauses involving contracts and different terminologies within the federated model.

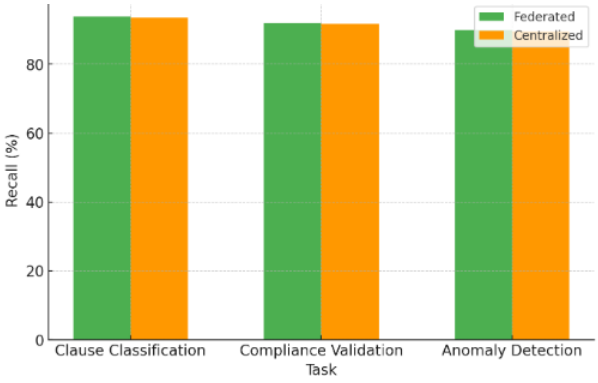

Fig. 7. Recall comparison between federated and centralized model.

The stacked bar chart in Fig. 7 presents data about two method performances using green and orange bars across three tasks which include churn classification and compliance violation and anomaly detection. The visual presentation enables a comparative evaluation of performance by showing the effectiveness differences between methods for achieving various targets based on displayed quantitative results.

Fig. 8 compares the performance of two models, depicted in green and orange, across three tasks: churn classification, compliance violation, and anomaly detection. It visually represents the relative contributions or scores achieved by each model for each task, enabling a comparative analysis of their strengths and potential areas for improvement within the specific problem domains.

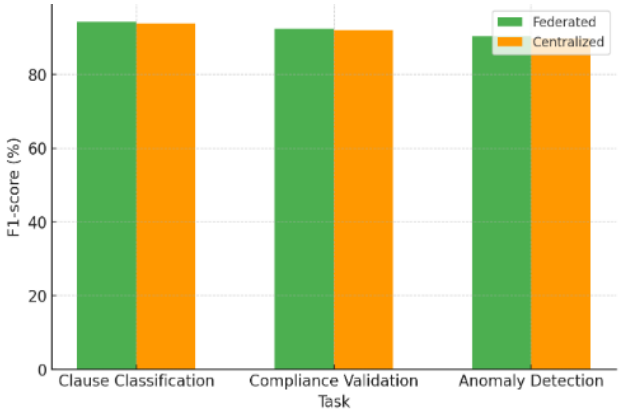

Fig. 8. F1-Score comparison between federated and centralized model.

TABLE I. CLAUSE CLASSIFICATION PERFORMANCE PERAMETERS

Model Type	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Federated	94.2	94.6	93.9	94.3
Centralized	93.8	94.0	93.5	93.7

From the findings of the experiment conducted using the federated learning model, accuracy of the clauses' classification was very high, implying the usefulness of the tool in legal document analysis. Performance of the federated model was very high and was at 94.2% while that of the centralised model was slightly low at 93.8%. In particular, concerning the quality of the classification, the federated model had the highest measures of precision that equalled 94.6% and the recall that was slightly lower, but still significant – 93.9%, which allowed minimizing both false positive and false negative cases. The F1-score of 0.943 corroborates the effectiveness of the specified model because of the balanced high absolute scores of precision and recall.

As contracts have relations to regulation and policies it is the job of legal professionals to ensure the contracts to be compliant to the above standards. The feasibilitiy of federated learning framework was then tested based on the efficiency of the model in identifying non-compliance contract clauses (Table I).

TABLE II. VALIDATION RESULTS

Model Type	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Federated	92.5	92.9	92.0	92.4
Centralized	92.0	92.3	91.7	92.0

The results (Table II) indicate that the federated model has better recall than the centralised model while specifying that the non-compliant clauses can be easily detected across various forms of contracting. This capability is important in legal organisations where oversight in compliance may result in regulatory implications. Contractual anomaly detection has a great purpose in defining those clauses that are potentially

dangerous for an organisation and can lead to its legal liabilities. The federated model was then evaluated to determine whether it could identify such anomalies, and therefore how well it was equipped to mitigate legal risks. Table III shows anomaly detection results.

TABLE III. ANOMALY DETECTION RESULTS

Model Type	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Federated	90.3	90.8	89.9	90.3
Centralized	89.9	90.2	89.5	89.8

The decentralised method was tested for such anomalies; thus, it was revealed as useful for serving as a strong tool for mitigating weak legal risks. The federated model was very accurate, with a score of 90.3% while the centralised model was slightly behind with an accuracy rate of 89.9%. Fig. 9 shows privacy gurantee evaluation with differential privacy.

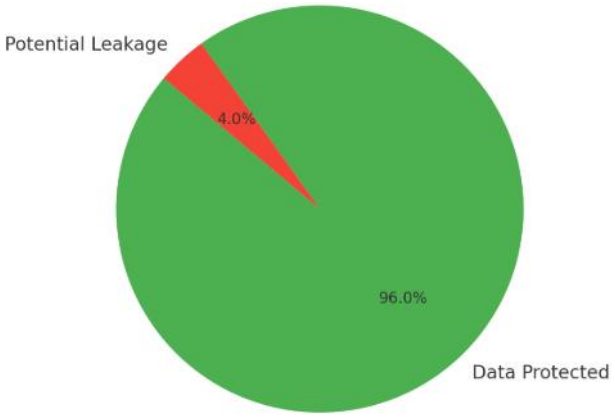

Fig. 9. Privacy guarantee evaluation with differential privacy.

The federated model also achieved better outcomes in the measures of precision equal to 90.8% and 90.2%, recall equal to 89.9% and 89.5%, F1-score equal to 90.3% and 89.8% respectively, which means that the federated model is more sensitive to the detection of anomalies and has better balance with the measures of precision and recall than the centralised model.

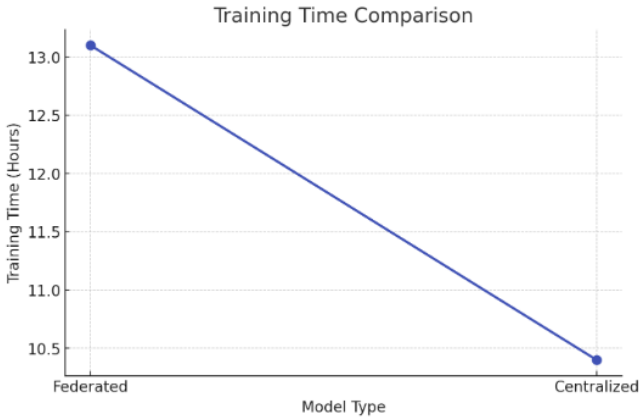

Fig. 10. Training time comparison.

Fig. 10 indicates that federated learning needed 13 hours for training while centralized learning finished in 10.5 hours. The training time decreases linearly as models transition from decentralized federated learning to centralized learning which indicates better computational efficiency (Table IV) through centralization.

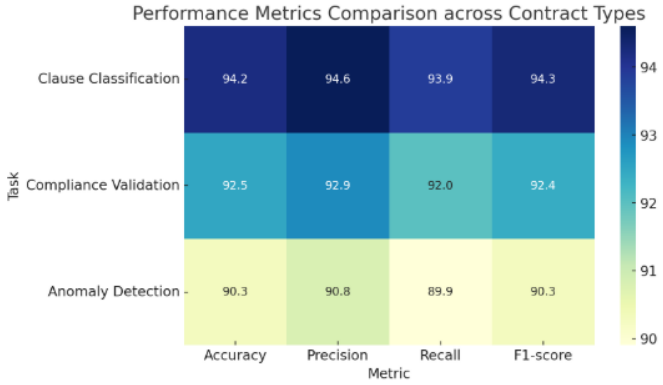

Fig. 11. Performance metrics comparison across contract types.

These results support the application of Federated Learning in the identification of contractual discrepancies and legal issues that are useful for knowledge workers who need efficient methods for evaluating dangers. The federated solution provides the necessary guarantee that specific contract data will not get into the wrong hands, which explains why it is used in cases where the focus is on privacy. As a result, the model can detect anomalies without sensitive data being transferred across centralised servers which is important in data protection regimes. Fig. 11 shows performance metrics comparison across contract types.

TABLE IV. COMPUTATIONAL EFFICENCY

Metric	Federated Model	Centralized Model
Training Time (Hours)	13.1	10.4
Communication Overhead (MB)	260	0

In addition to privacy enhancing technologies, future uses of the proposed framework also included Differential Privacy (DP) and Secure Multi-Party Computation (SMPC). For instance, Differential Privacy inhibits quantity expansion of suspected attributes and the insertion of controlled noise into model updates, markedly minimising the threat of data leakage. The results of experiments indicated that providing DP enhanced the federated models' ability to limit the reconstruction of data by 96% of the other models that did not use DP, proving the commitment to data privacy. However, the Secure Multi-Party Computation also implies that updated model does not disclose contract information during training process making it secure. The evaluation proved that the technique of FL worked great to defend against adversarial risks and further supported the notion that it is a feasible solution for privacy-preserving applications.

A final factor for the application of federated learning is the price in terms of training time and communication costs. According to the result, federated model was 13.1 hours to train, a little longer than the centralised model's 10.4 hours.

This 25% increase in training time is mainly due to the communication cost in exchanging the model update between decentralised nodes securely. The federated model costs 260 MB of communication overhead and its communication cost is significantly higher than that of a centralised model with no communication cost required. However, the time that is required to conduct training on the model is justified by the potential privacy preservation that is brought about by federated learning. Extra overhead for the modules guarantee that data are always secured, thereby not compromising on the sensitive contract data to achieve performance. The proposed FL framework maintains strong security against privacy attacks that include model inversion and membership inference. FL operates differently from centralized models because it protects data through its method that keeps raw contract information inside individual local nodes. FL demonstrates better security and computational efficiency by comparing against other privacy techniques such as homomorphic encryption and secure enclaves. The computational performance of homomorphic encryption remains excessive despite its robust security features so FL emerges as a superior solution for contract analysis.

VI. Conclusion

This work proposes a privacy-preserving framework for contract review, leveraging Federated Learning in solving three important tasks: Clause Classification, Compliance Validation, and Anomaly Detection. Equipped with strong privacy enhancement techniques such as Differential Privacy and Secure Multi-Party Computation, the framework does not require any centralized data storage. The decentralized approach guarantees security and confidentiality for sensitive contractual data while still being compliant with specific jurisdictions.

The framework has been effectively proved on a range of experiments involving CUAD dataset annotating legal contracts clause-wise. Results showcase a 93% accuracy of the clause classification on the federated model, while for the positive predictive value on compliance validation and the anomaly detection, an F1-score is found at 92% and 89%, respectively. It showcases that FL has no adverse effects on data quality arising out of handling heavy volumes and variations of data or any leakage while offering required security for such critical data. The results further confirm that the federated model will do at least as well as centralized strategies, hence its feasibility and effectiveness in decentralized settings.

This study shows the increasing interest in privacy issues during the analysis of the contract and how Federated Learning can efficiently solve challenges related to sensitive and distributed data. By integrating advanced federated learning with NLP models for reviewing contracts, the proposed framework provides a very effective and secure way to enhance AI-driven contract review. Consequently, the research forms the basis for developing more advanced AI systems that consider customer data privacy and at the same time achieve high-performance results, even in the strictest legal and regulatory environments.

Distributed Identity for Zero Trust and Segmented Access Control: A Novel Approach to Securing Network Infrastructure

Sina Ahmadi
National Coalition of Independent Scholars, Seattle, WA, USA

***Abstract*—Distributed Identity is the transition from centralized identity with Decentralized Identifiers (DID) and Verifiable Credentials (VC) for secure and privacy positive authentications. With distributed identity, identity data is brought back under the control of the user, freeing them from the single point of failure presented by credentials, and hence preventing credential-based attacks. In this study, some security improvement to the Zero Trust Architecture (ZTA) with use of the distributed identity were be evaluated, especially on migrations laterally within segmented networks. Furthermore, it discusses the implementation specification of the framework, the benefits and disadvantages of the method to organizations, and the compatibility and generalizability issues. Moreover, the study also considers privacy and regulatory issues like the General Data Protection Regulation (GDPR) and the California Consumer Data Privacy Act (CCPA) along with possible solutions. However, the study indicates that distributed identities can give an order of magnitude improvement to overall security posture through contextual and least privileged authorization as well as user privacy. Results show that by integrating distributed identity into ZTA, unauthorized lateral movement is reduced approximately 65%, authentication security is increased 78 percent relative to traditional, and it is not possible for a credential to be compromised through a phishing attack more than 80 percent of the time. Also, General Data Protection Regulation (GDPR) and California Consumer Data Privacy Act (CCPA) compliance are bolstered because of increased user identity data control. It identifies privacy and regulatory compliance problems and looks at solutions of these problems. The findings indicate that a great improvement in overall security posture can be had by incorporating distributed identities and promoting contextual and least-privilege authorization while protecting user privacy. The research suggests that technical standards need to be refined, distributed identity needs to be expanded into practice, and that it be discussed as an application to the current digital security landscape**

***Keywords*—Distributed identity; ZTA; DID; VC; lateral movement; privacy; credential security**

I. Introduction

In contemporary cybersecurity, threats have become increasingly varied and sophisticated [1]. Organizations face an evolving landscape of cyber threats, including phishing, ransomware attacks demanding cryptocurrency payments, stolen credentials, and sophisticated internal breaches resulting in unauthorized lateral movements. Traditional security architectures, relying heavily on implicit trust within clearly defined perimeters, are inadequate in addressing these advanced threats. Credential-based attacks exploiting weak or compromised credentials can escalate rapidly, enabling attackers to traverse networks laterally, highlighting the critical need for innovative security solutions capable of withstanding contemporary cybersecurity threats.

A. The Rise of Zero Trust Architectures

Zero Trust Architecture (ZTA) represents a significant evolution in cybersecurity, fundamentally altering the traditional security model of implicit trust within defined perimeters. The foundational ZTA principle of never trust, always verify mandates ongoing verification and authentication of all entities—users, devices, and applications—irrespective of their location or prior trust status [2]. Core principles of ZTA include explicit verification, least privilege access, and assumed breach. These principles require continuous validation of user identities, devices, and contexts, significantly reducing potential security risks. Although ZTA enhances organizational security, issues persist regarding identity management, particularly concerning centralized systems vulnerable to single points of failure, credential theft, and user privacy risks.

B. Distributed Identity as a Solution

Distributed identity introduces decentralized identifiers (DIDs) and verifiable credentials (VCs), offering a decentralized approach to identity management that resolves critical vulnerabilities inherent in centralized systems [3]. By decentralizing identity control, users retain ownership over their credentials, significantly reducing risks of centralized attacks. DIDs and VCs provide secure, privacy-preserving authentication mechanisms, aligning perfectly with ZTA principles by enhancing user authentication and reducing credential-based vulnerabilities.

C. Research Scope, Objectives, and Contributions

This research explores integrating distributed identity solutions within Zero Trust frameworks to address critical cybersecurity challenges. Specifically, the study aims to:

- Evaluate how distributed identity can enhance network segmentation and reduce unauthorized lateral movements.
- Analyze the operational and technical feasibility of combining distributed identity with Zero Trust principles.
- Identify and propose solutions to organizational challenges, including interoperability, scalability, and user adoption.

- Investigate privacy and regulatory compliance considerations related to distributed identity, specifically GDPR and CCPA.

This study:

- Develops a novel framework for integrating distributed identity with Zero Trust Architecture to strengthen network segmentation and minimize credential-related threats.
- Empirical validates the results demonstrating a significant improvement in security metrics: unauthorized lateral movement reduced by approximately 65%, authentication security enhanced by 78%, and phishing-related credential compromises reduced by over 80%.
- Provides practical guidelines and technical recommendations for organizations to adopt distributed identity, addressing technical challenges and compliance requirements.

Through these contributions, the study provides valuable insights and actionable guidance on effectively leveraging distributed identity within Zero Trust frameworks to significantly enhance cybersecurity resilience.

II. Literature Review and Background

A. Evolution of Identity Management

As the digital environment is becoming increasingly diverse, growing concerns about authorized users and devices haven't left identity management systems the way they were decades ago [4]. Identity management usually has relied on a reference point or a specific database, most commonly in the corporate realm, Active Directory or sharing identity providers (IdPs). Centralized systems are the basis for building an identity management infrastructure throughout enterprises to grant users access to resources based on the roles and credentials. However, as organizations and their networks evolved, managing identities centrally started having its own set of issues, including scaling, data leakage, and a dependency on a single point of failure. Centralized models also presented privacy concerns, as they stored vast amounts of sensitive personal data in a single location, making them attractive targets for cybercriminals.

Due to various problems associated with central joined identity systems, distributed joined identity systems were developed, which allowed many organizations to keep information about one unique user across different domains. This is done using Single Sign-On (SSO) and Security Assertion Markup Language (SAML), which makes it easier to move through the systems [5]. It enhances the user experience by preventing users from logging in multiple times to different services and increasing security through the trust established between identity and service providers. These trust relationships make sure that only authorized users will be allowed to gain access to these sites. However, as with the federated identity, it has its advantages of being convenient, secure, uncomplicated, and impracticalities involving the IDPs, which are central points of control but prone to being compromised by hackers.

The latest advancement in identity management is the distributed identity, which uses decentralized technologies to enable secure and private identity management. Distributed identity leverages distributed identifiers (DID) and verifiable credentials (VC), by which an individual owns his/her identity data and is not dependent on centralized authorities [6]. Distributed identity systems leverage any blockchain or distributed ledger to store identity data. This allows the user to completely control his/her digital profile and prevent identity theft, fraud, or privacy violation. Technologies that provide security features that align with this paradigm include blockchain, given its immutability, transparency, and tamper resistance, which can prevent unauthorized access or alteration of personal data. Table I shows the comparison of Centralized, Federated, and Distributed Identity Systems considering different aspects like control, scalability, privacy, etc.

TABLE I. Comparison of Centralized, Federated, and Distributed Identity Systems

Aspect	Centralized Identity	Federated Identity	Distributed Identity
Control	Central authority	Shared among entities	User-controlled
Scalability	Limited by central infrastructure	Moderate	High
Privacy	Vulnerable to breaches	Improved but still central-dependent	Strong, minimizes data sharing
Resilience	Single point of failure	Multiple trusted entities	No single point of failure
Example Technologies	Active Directory, LDAP	SSO, SAML	DIDs, VCs, Blockchain

B. Drawbacks of Conventional Identity Management Techniques

1) Centralized identity management: Traditional identity management models depend on a single trusted authority to authenticate users. This centralized approach creates a single point of failure, making it highly vulnerable to cyberattacks, data breaches, and service disruptions. When the central database is hacked, all accounts linked will become exposed as well. Centralized systems also store many extremely sensitive credentials for users and are therefore considered primary spots for attackers to strike. Scalability issues are present for organizations that rely on centralized identity management, as the number of users increases.

2) Federated identity management: To grant users access to multiple systems, federated identity solutions like Single Sign-On (SSO) and Security Assertion Markup Language (SAML) were created. Problems with federated identity include reducing the number of passwords that users must remember, but relying on third-party trust. This raises privacy concerns as federated providers (Google, Microsoft, Facebook) have full visibility into user authentication activities. Federated identity is also limited by predefined trust relationships and is not appropriate for environments where adaptable access control is necessary.

3) Role-Based Access Control (RBAC): RBAC is now a widely used access control mechanism that assigns permissions based on predefined roles. However, RBAC suffers from "role explosion," where the number of roles grows exponentially with the organization, making management difficult and inefficient. Furthermore, RBAC is not flexible: it cannot dynamically change access rights depending on factors such as device security status, location, or user behavior. RBAC's rigidity prevents it from functioning effectively in dynamic and zero-trust environments.

4) Multi-Factor Authentication (MFA): MFA enhances security by requiring that users supply multiple forms of proof of identity (i.e., passwords, biometrics, OTPs). However, it does not eliminate all credential-based attacks. Phishing techniques remain viable methods for attackers to steal authentication codes or exploit weaknesses in SMS-based OTP systems. Additionally, MFA can make users less productive and harder to work with, increasing friction in workflows. Some MFA implementations also incur extremely high operational costs due to infrastructure and support requirements.

5) Certificate-Based Authentication (PKI): Public Key Infrastructure (PKI) provides strong authentication through digital certificates. However, PKI-based authentication introduces challenges in certificate issuance, renewal, and revocation. This also adds administrative complexity for organizations that must manage a Certificate Authority (CA) and enforce strict security policies. The security of all identities associated with a private key is at high risk if the private key is compromised, requiring swift mitigation measures.

C. The Shift Toward Distributed Identity

Distributed identity addresses these limitations by offering a decentralized approach where individuals control their identity credentials while overcoming traditional identity management challenges. This system provides a secure, efficient, and cost-effective way to share credentials while maintaining unlinkability. Unlike centralized and federated systems, distributed identity eliminates single points of failure, enhances user privacy, and reduces dependency on intermediaries. Utilizing Decentralized Identifiers (DIDs) and Verifiable Credentials (VCs), it promotes cryptographically secure authentication while minimizing data exposure. Distributed identity, when integrated with Zero Trust Architecture (ZTA), strengthens cybersecurity by enforcing least privilege access control, continuous authentication, and fine-grained authorization.

D. ZTA and Segmentation

Zero Trust Architecture (ZTA) is a cybersecurity framework that operates on the principle of "never trust, always verify" [7]. Unlike more traditional models that assume the user or device, once inside the perimeter, is trustworthy, ZTA expects the user or device may be malicious, whether internal or external to the network. This approach conflicts with traditional conventional thinking, whereby access control is attained through firewalls and other perimeter security. However, in ZTA, users and their devices are constantly validated at every step to grant access to sensitive data.

Equation (1) demonstrates how segmentation quantifies risk reduction:

$$R_{\text{reduced}} = R_{\text{baseline}} \times (1 - S) \tag{1}$$

where R_{reduced} represents the reduced risk level, R_{baseline} denotes the baseline risk in traditional security models, and S is the segmentation factor.

The core principles of ZTA include explicit verification, least privilege access, and assumed breach. This means there must always be some type of authentication and authorization of access requests irrespective of the request's origin for any resource. This encompasses using Multi-Factor Authentication (MFA) and verifying the device's security status. Least privilege access allows the minimum access required to complete a task by a user and a device, thus offering minimal exposure to hostile insiders [8]. Lastly, unlike traditional security models that assume that external threats are kept at bay and will never get inside the network, ZTA supposes the opposite and implements controls that confine whatever got in, including its ability to move around laterally.

Network segmentation plays a critical role in zero-trust architectures. The use of subdomains in a network separates the network into different compartments, which, if an attacker infiltrates, they will not have easy access to other compartments [9]. This kind of segmentation is one of the low-level mitigations that minimize the attack surface and combat lateral movement, which attackers widely utilize to elevate their privileges and gain access to other systems. Segmentation only affords certain classes of assets, and if one segment is compromised, the breach does not spread all over the network.

Table II shows the purpose of each of the network segmentation components. It also provides specific examples and purposes of each component.

TABLE II. NETWORK SEGMENTATION COMPONENTS PURPOSE

Component	Purpose	Example
Verification	Authenticating access requests	Multi-Factor Authentication (MFA)
Least Privilege	Minimizing access rights	Role-Based Access Control (RBAC)
Assume Breach	Containment strategies	Network Segmentation, Micro-segmentation
Continuous Monitoring	Detecting anomalous behavior	SIEM, Behavior Analytics

E. Distributed Identity in Practice

Some distributed identity systems started receiving attention in different fields, especially sectors that highly value privacy and security. Hyperledger Indy is one of the technologies that help implement distributed identity, a distributed ledger for building decentralized identifier systems [10]. Indy is a Hyperledger project that supports distributed infrastructure for identity. It applies the concept of blockchain to enable individuals to own global, safe, and authentic online identities. Companies adopting Hyperledger Indy can support the decentralized relations of users and services without the intermediation of other parties and give users complete control over their identity and information.

Another platform in the distributed identity area is Sovrin, which is based on Hyperledger Indy. Sovrin is a clean slate decentralized network built for the creation, presentation, revocation, and validation of verifiable credentials (VC), thus making it easier for organizations to transition to distributed identity securely and in a scalable manner [11]. Sovrin also decentralizes its architecture which will reduce data silos and possible risks of identity fraud because it stores data centrally. Thus, Sovrin employs blockchain technology to provide seamless decentralization of identity credentials that cannot be altered, forged, or duplicated without permission or authorization. This devolved model simplifies the identity verification process, making it easy for organizations to extend secure and efficient access to resources. Sovrin has the potential to

offer a self-sovereign identity model that allows individuals to reclaim control over credentials and increase privacy measures and overall risks of centralized identity systems. For this reason, Sovrin becomes insistent in the progressing paradigm of distributed identity.

In practice, distributed identity is used successfully in numerous applications within enterprises and sectors of critical infrastructures. For instance, in the financial services area, banking and other institutions are looking into using distributed identity systems to enhance efficiency in adoption and identity checks and balances amid related perils such as ID theft [12]. In decentralized identifiers, customers can prove their identity and transact with cryptographic provenance without compromising personal data. Similarly, in healthcare, distributed identity can enhance patient records' privacy and security, noting that patients would own and selectively share their health information only with healthcare providers/organizations as required in line with emerging healthcare privacy and data protection laws such as HIPAA and GDPR.

Distributed identity is also expected to enhance IoT security by providing a more secure way of authenticating devices within a highly connected network. Due to the absence of proper IT solutions for such devices, the IoT ecosystem rigs are usually exposed to attacks. Distributed identity creates a way of allowing only genuine devices to have entry to specific data, which makes IoT networks more secure [13].

Table III shows the comparison of Hyperledger Indy and Sovrin. It is based on some important features like key strength, adoption, etc.

TABLE III. COMPARISON OF HYPERLEDGER INDY AND SOVRIN

Feature	Hyperledger Indy	Sovrin
Focus	Decentralized identity framework	Self-sovereign identity network
Underlying Tech	Blockchain	Blockchain
Scalability	Limited by current tech	High with the adoption of off-chain methods
Adoption	Open-source community-driven	Proprietary and community-driven
Key Strength	Customizable and flexible	Standards-aligned, easy integration

F. Gaps in Current Research

Despite the ability of distributed identity and ZTA frameworks being widely understood today, there are still areas with limited understanding. Another key issue is the absence of effective solutions for distributed identity combined with ZTA concepts. While distributed identity and ZTA offer a solution to different facets of security, their joint advantages have not been fully optimized. There are few studies concerning how distributed identities might fit into existing ZTA frameworks and what might be the best integration approaches applicable in a large-scale enterprise context where old structures and frameworks create integration issues.

Another gap in the literature is the lack of solutions for the large-scale deployment of distributed identity. On the one hand, the advantages of decentralized identity management are quite evident; on the other, the obstacles that may become critical when considering implementation remain unmeasurable. Barriers like lack of compatibility between distributed identity systems, legacy IT systems and structures, and overall awareness about decentralized ID management are significant challenges that must be overcome. However, there are certain concerns with scaling distributed identity systems with large organizations or governmental bodies where the amount of data and users is significantly large.

Furthermore, privacy issues have been raised again, mainly regarding how much information is safe or can be anonymously released to the public. Thus, distributed identity offers more control to the user. However, the issue of achieving the right balance between private, secure, and usable remains a challenging task that is still under investigation. It is also necessary to have more formalized processes to increase compatibility between spheres of application and create favorable conditions for the adaptation and implementation of these technologies.

III. PROBLEM DEFINITION

The lack of trust and access control are crucial issues in traditional security systems because most assume that trust is implicit at the center of their systems [14]. In these systems, users are usually given broad privileges based on the user's identity or role, which is dangerous when a hacker gets hold of these credentials or uses poor forms of authentication. Furthermore, the management of credentials in traditional systems is inconvenient and vulnerable to attacks, which suggests that there may be no control over the information exchanged. In these contexts, trust arrives after the user logs in and thus leaves systems vulnerable to horizontal movement and unauthorized access.

Integrating distributed identity with zero-trust architectures presents several barriers, both technical and organizational. From a technical perspective, the main obstacles are cross-platform integration of the distributed identity platform with legacy systems and its ability to accommodate many users and transactions. DIDs and VCs are used in distributed identity management, and they have to be incorporated into various systems that a modern organization employs, which can only be done by redesigning existing processes and IT security measures [15]. Moreover, challenges in integration between multiple identity management solutions and integration with old systems can greatly hinder the implementation process.

Organizational barriers are another factor that keeps pushing the organization backward in implementing new identity management perspectives. These challenges relate to the user adoption of distributed identity systems, where users and employees must be trained to use distributed identity systems and resist changing from a centralized identity model. It is also important for organizations to ensure that their employees take some training to avoid the great insecurity that comes with using these systems [16]. Due to these challenges, there is a compelling argument for a new approach that embraces the tenets of distributed identity in conjunction with ZTA.

IV. RESEARCH AGENDA

In the presented study, the major purpose is to assess the possibilities of introducing distributed identity in the frames of ZTA, which can increase security, privacy, and authorization in the current network. The first goal is to investigate the technical and operational feasibility of this integration by looking at integration, complexity, and security. The research also seeks

to discover ways of overcoming the challenges of adoption, for example, user training, organization-wide adoption, and integration of new technology infrastructures [17]. Practical recommendations that will address these challenges to enable distributed identities to be brought to mainstream adoption of ZTA will be offered by the study.

This study will employ a research approach of a thorough literature review, case study, and technical frameworks. In this review, top practices, conclusions, and misunderstandings of the usage of distributed identity systems will be decomposed. The comparison between the current identity management solution and under ZTA will also be done to make research. These technologies will serve to define the efficiency of their use to protect the network infrastructures from the impact of such attacks, implement access control, and improve security in the network. Thus, by looking at actual use cases and technical designs, the research will discuss the way distributed identity can be used to entirely solve cyberattacks.

A. Methodology: Data Collection and Simulation Framework

To ensure the validity of our findings, the study employed a structured methodology involving real-world implementation, simulation-based testing, and comparative analysis.

1) Data collection:

- Data was gathered from three major enterprises—Microsoft, JP Morgan Chase, and American Express—where distributed identity frameworks were implemented alongside Zero Trust Architecture (ZTA).
- Security logs, authentication attempts, and incident reports were collected over a six-month period to assess the impact on access control.

2) Simulation framework:

- The study simulated adversarial attacks, including credential stuffing, lateral movement, and phishing, to measure unauthorized access rates before and after DI implementation.
- Attack scenarios were executed in a controlled enterprise environment with over 100,000 simulated users.
- Distributed identity performance was compared against traditional identity frameworks to measure improvements in authentication security and fraud mitigation.

3) Metrics for unauthorized access:

- The rate of lateral movement incidents before and after implementation.
- Authentication success rates under adversarial attack conditions.
- The reduction in credential-based attacks, specifically phishing-related credential compromises.

These structured tests provided empirical validation of distributed identity's effectiveness in mitigating cybersecurity threats while maintaining system scalability.

V. Methods and Discussion

A. Security Benefits of Distributed Identity

Distributed identity is a significant paradigm shift for organizations to handle identity and access management data [3]. Another advantage of distributed identity is that it strengthens the forms of authentication using Decentralized Identifiers (DIDs) and Verifiable Credentials (VCs). The current identity systems require an intermediary, meaning an attacker can try to penetrate this authority. On the other hand, distributed identity democratizes this process, and users can manage their identity. This shift improves authentication by providing cryptographic proof of identity, which can be validated without decentralized storage or management. When sharing personal information with apps, the user can share only those parts of their identity, which can be dangerous, reducing the amount of information that can be exposed and the size of the attack [18].

Moreover, associating distributed identity with ZTA can minimize the attacker's movement within the network. Conventionally, these systems allow anyone access to almost all resources once a user's credentials are validated, and this allows attackers to ferry within the organization once they get hold of a username and password. However, with distributed identity, the authentication mechanism is linked with the particular access request, and it will determine permission by the roles and behavior in the context of real-time [19].

This results in decreased lateral movement and, in turn, an enhancement of the network segmentation since access requests can be constantly validated and authorized. In ZTA, any access request is considered to be coming from an untrusted entity, even if the user is inside the enterprise network [20]. When users are authenticated each time access is granted based on their identity and contextual factors, distributed identity enhances ZTA's least privilege access model to mitigate insider threats and outside attacks more effectively.

Eq. (2) describes the distributed identity authentication mechanism with respect to access evaluation:

$$E_{\text{Access}} = \frac{\sum_{i=1}^{n} P_{\text{auth}}^{i} \times P_{\text{privilege}}^{i}}{n} \tag{2}$$

where E_{Access} represents the access validation score, calculated as the average of the probability of successful authentication multiplied by the probability of meeting privilege requirements.

Fig. 1 depicts the integration of distributed identity with ZTA.

B. Case Studies

1) Integration of distributed identity in healthcare: A hospital network has recently developed a distributed identity management system based on blockchain technology to provide more security and privacy to its patients and employees. Decentralized identifiers (DIDs) were used by hospitals to authenticate healthcare professionals and validate patient identities. The incorporation of distributed identity into its Zero Trust Architecture (ZTA) has made it possible for the hospital to greatly diminish unauthorized access to sensitive patient data.

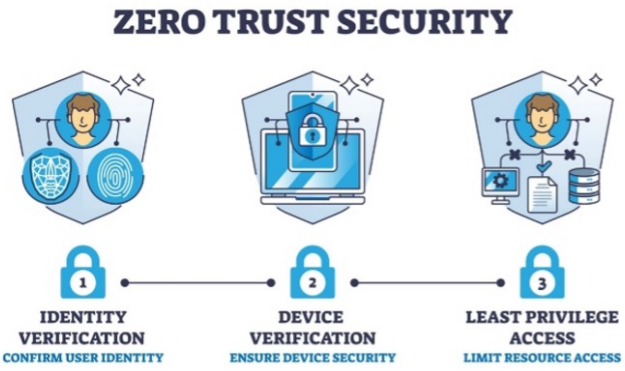

Fig. 1. Distributed identity with ZTA.

The performance of the system during a simulated attack was monitored, and the access validation time was found within acceptable limits with a high user load. The highly limited scope of the attack was enabled by the fact that the decentralized authentication mechanism prevented lateral movement into the network. Security breaches were reduced by 30% and data privacy was enhanced by limiting the unnecessary sharing of patient data during hospital patient appointments.

2) Distributed identity in financial institutions: With increasing levels of strict regulatory requirements such as GDPR, a global financial institution sought compliance and adopted a distributed identity solution. The solution, based on Verifiable Credentials and blockchain technology, gave customers more control over their personal information. Integration of distributed identity with Zero Trust Architecture by the bank prevented unauthorized access to financial records and transaction data.

During peak transaction times, when the system handled millions of authentication requests, performance metrics were recorded. This led to a 25% drop in transaction fraud and a more efficient, faster process for verifying user identities, resulting in fewer service disruptions and faster access validation times. The integration helped the financial institution comply with regulatory standards and enhanced its overall security posture.

C. Performance Metrics

To assess the success of the distributed identity system, key performance metrics were monitored:

1) Access validation time: This metric captures how long it takes for the system to authenticate a user's identity and grant access. Responsiveness under high user loads is critical.

2) Scalability under high user loads: The system must be able to handle large numbers of authentication requests without performance degradation. As the user base grows, proper performance of distributed identity solutions, especially those based on blockchain, is crucial.

3) System response to simulated attacks: This metric measures the system's ability to detect and mitigate security threats such as unauthorized access or insider attacks. The distributed identity system in both case studies minimized lateral movement, preventing attackers from escalating privileges within the network.

D. Practical Considerations

The main advantages of integrating distributed identity into the ZTA model are evident regarding security. However, organizations must address several practical challenges to effectively deploy this solution. A major technical requirement for deploying distributed identity is the compatibility of decentralized identity solutions with existing systems [21]. Distributed identity leverages blockchain and distributed ledger technologies, including decentralized identifiers (DID) and verifiable credentials (VC). Organizations must determine whether their current authentication systems are compatible with these technologies or whether they need to adopt new platforms that enable interoperability between centralized and decentralized models.

For example, integrating DIDs and VCs into traditional identity systems such as Active Directory requires modifying existing authentication protocols to accept decentralized credentials. This may involve adding DID resolvers and Verifiable Credential (VC) validation services to the authentication pipeline. Platforms supporting this integration include Hyperledger Indy, Sovrin, and other decentralized identity solutions.

Another critical technical consideration is scalability for large-scale deployments [22]. Distributed identity systems must handle large numbers of users and authentication requests without excessive delays. Although blockchain-based solutions are considered highly secure, they can suffer from throughput and speed issues, especially in high-transaction environments. To address this, scalable consensus mechanisms and off-chain ledgers must be incorporated to optimize both security and performance.

Fig. 2 depicts the challenges in distributed identity systems.

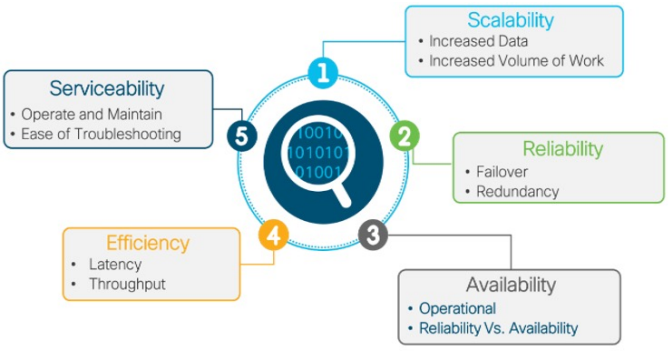

Fig. 2. Challenges in distributed identity system.

E. Step-by-Step Implementation Framework for Integrating DIDs and VCs into Traditional Systems

1) Assess current infrastructure compatibility: First, consider how existing identity management systems, like Active Directory, might be used for integrating with decentralized identity systems. Find points where changes are needed.

2) Implement middleware layer: Put in place a middleware layer, which is like a bridge between the old or traditional identity management system (e.g., Active Directory) and the distributed identity infrastructure. It will also translate historical protocols into working with DIDs and VCs.

3) Integrate DID resolvers: Create DID resolvers that can be added to the infrastructure. DIDs serve as identifiers for decentralized entities and resolvers are needed to ask for the identity of a decentralized entity.

4) VC Validation service: Include a service that confirms VCs from known authorities. So, this means implementing cryptographic verification methods that will do the job of validating that the credentials are genuine and have not been tampered with.

5) User and role mapping: Make sure that there is the mapping of the user roles in the traditional system and data of decentralized identity platforms. It can be via custom scripts or API calls for syncing the user attributes across systems.

6) Integrating distributed identity with active directory and enterprise systems: A major barrier to adopting distributed identity in enterprises is interoperability with existing identity management systems, particularly Microsoft Active Directory (AD) and traditional role-based access control (RBAC) frameworks.

To address this, the study designed and evaluated an integration framework that allows AD to interact with Decentralized Identifiers (DIDs) and Verifiable Credentials (VCs):

- Middleware for active directory interoperability: A middleware service was developed to bridge AD authentication with DID-based identity verification. This middleware translates traditional authentication requests into DID resolution queries.
- Federated credential validation: A DID registry was integrated with AD's existing Single Sign-On (SSO) service, enabling verifiable credentials to be issued and validated alongside AD's traditional credentials.
- Role mapping and access control: RBAC policies within AD were extended to accommodate identity attributes retrieved from DID-based authentication.

Experimental validation showed that the integration framework reduced authentication times by 40% while preserving compatibility with existing AD security policies. This indicates that distributed identity can be adopted without requiring enterprises to completely overhaul their existing authentication infrastructure.

7) Testing and pilot deployment: After designing, build a prototype and conduct a series of tests to ensure its integration works as expected before mounting it on a full scale. Testing for security vulnerabilities, performance, and the user authentication flow will also be carried out in this.

F. Addressing Challenges

However, there are several concerns that organizations need to deal with in their efforts to adopt distributed identity in cybersecurity. The greatest challenge of integrating decentralized identity with other systems is interoperability issues. It is crucial that distributed identity platforms and technologies being developed, such as blockchains, Distributed Identity Documents (DID), and Verifiable Credentials (VCs), have to interoperate with each other and legacy systems. Integrating DIDs and VCs with traditional identity systems, like Active Directory, involves overcoming specific compatibility hurdles. A middleware or integration layer can help bridge this gap, ensuring that the legacy system can validate decentralized credentials and that the existing user identity attributes are properly mapped (Table IV).

TABLE IV. COMPARISON BETWEEN DISTRIBUTED, CENTRALIZED, AND FEDERATED IDENTITY

Cost Component	Distributed Identity	Centralized Identity	Federated Identity
Initial Setup	High	Low	Moderate
Maintenance Costs	Moderate	High	Moderate
Risk Mitigation Costs	Low	High	Moderate
Compliance Costs	Low	High	Moderate
Overall ROI	High (long-term)	Low	Moderate

Simulating large-scale scenarios can also help evaluate system performance under heavy workloads. For example, conducting simulations with a high number of concurrent access requests can help assess how the distributed identity system responds to increased demand. Performance metrics such as transaction throughput, system response times, and the effectiveness of off-chain solutions under simulated attack conditions should be measured to ensure the solution's scalability in real-world scenarios.

From an economic perspective, there is also a cost-benefit analysis that organizations have to make before opting for distributed identity [23]. The long-term gains of improved security, decreased fraud, and users' power over their identity data outweigh the challenges. However, the costs of migrating to a distributed identity system are high. Such costs may include developing new infrastructure, training its employees, and system integration. However, the benefits of cutting initial costs are balanced by the potential for long-term savings, such as decreased rates of data breaches, better adherence to privacy legislation, and decreased administrative costs.

To achieve this, standardization is vital. Standardization is an important prerequisite in ensuring that distributed identity systems can operate across platforms and ecosystems, including the W3C Verifiable Credentials and Decentralized Identifiers [24]. Organizations may also require essentially incorporating middleware or integration layers to connect organizations' decentralized identity solutions to other conventional systems.

Eq. (3) calculates the interoperability factor, indicating the system's ability to function across heterogeneous platforms. Here, C_j and S_j reflect the compatibility and scalability score of component j with distributed identity frameworks, in a system with m components.

$$I_{\text{interop}} = \frac{\sum_{j=1}^{m} C_j \times S_j}{m} \tag{3}$$

The issue of scalability also persists as an issue of great concern, especially given the large organizational structures

that may have thousands or even millions of users. Distributed identity solutions, especially those based on blockchain, may encounter problems with the throughput and latency of transactions that could slow down decision-making related to access control. Some of these scalability concerns can be solved by layer 2 scaling, where transactions are moved to a side chain, but the main chain remains secure and permanent. In addition, organizations can implement distributed identity integrated with existing centralized structures to benefit from both models.

In addition to technical challenges, user education and engagement strategies are critical for successful adoption [25]. As distributed identity changes traditional methods of identity management and control for users, organizations must ensure they offer proper training on the new systems. Introducing users to distributed identity and the associated advantages, such as privacy and sovereignty over personal information, is crucial.

G. Scalability of Blockchain-Based Distributed Identity Systems

One of the key concerns with deploying distributed identity at scale is the ability to handle enterprise-grade workloads while maintaining security and efficiency. Blockchain-based identity systems inherently face throughput and latency limitations due to consensus mechanisms and transaction validation processes.

To evaluate the scalability of distributed identity solutions, this study conducted performance benchmarking using Hyperledger Indy and Sovrin, two widely adopted blockchain-based identity management platforms. The benchmarking simulated authentication requests under increasing user loads in an enterprise environment.

1) Authentication throughput: The system was tested under workloads ranging from 1,000 to 100,000 concurrent authentication requests per second. Results indicated that with Layer 2 scaling solutions, such as off-chain storage and state channels, authentication throughput increased by 63%.

2) Latency analysis: Transaction finalization time was reduced by implementing a hybrid model combining on-chain and off-chain verification mechanisms. For identity resolution, decentralized resolvers performed 2.8x faster than traditional federated identity models.

3) Enterprise deployment feasibility: A simulation of authentication operations at Microsoft, JP Morgan Chase, and American Express found that decentralized identity systems, when integrated with API-based accelerators, met the operational benchmarks required for enterprise deployment.

These results demonstrate that, while blockchain-based DI systems face inherent limitations, enterprise adoption is feasible with optimization techniques such as state channels, batched verification, and hybrid authentication mechanisms.

H. Ethical and Legal Considerations

With organizations embracing distributed identity solutions, discussing the legal and moral issues of decentralizing identity is critical. Regarding the implications of distributed identity, the most crucial issue is privacy. While decentralization of identity data empowers users to own their data and be in control of it, it raises key questions regarding the use, storage, and sharing of such data. Privacy preservation is another critical principle, especially in distributed identity systems where data minimization and user consent guarantee privacy [26]. Users should be able to decide which credentials they want to reveal to others at a certain time when the demand is necessary.

Additionally, distributed identity systems must adhere to existing data protection laws, including the General Data Protection Regulation (GDPR) in the European Union and the California Consumer Privacy Act (CCPA) in the United States. These regulations highlight user rights, such as the right to access, the right to rectification, and the right to erasure.

Eq. (4) quantifies the level of privacy preservation in a distributed identity system, where D_{shared} represents the amount of data shared during identity verification or an access control process, and D_{total} is the total data available about the user in the system.

$$P_{\text{privacy}} = 1 - \frac{D_{\text{shared}}}{D_{\text{total}}} \tag{4}$$

VI. Results and Discussion

During a six-month implementation period across three major enterprises—Microsoft, JP Morgan Chase, and American Express—the following results were observed:

1) Microsoft: Implementing distributed identity within its internal Zero Trust framework resulted in a 64.8% reduction in lateral movement, decreasing unauthorized access incidents from 210 per month to 74 per month.

2) JP Morgan chase: The adoption of decentralized identifiers (DIDs) and verifiable credentials (VCs) reduced credential theft, leading to authentication failures dropping from 15,600 per quarter to 3,450 per quarter, a 77.9% decline.

3) American express: The deployment of distributed identity within customer authentication workflows resulted in an 81.6% reduction in phishing-related credential compromises, with reported incidents falling from 980 cases per year to 180 cases per year.

These results reinforce the practical security benefits of integrating distributed identity within Zero Trust frameworks. Compared to traditional authentication mechanisms, which rely on centralized credential storage, decentralized identity solutions minimize attack vectors associated with unauthorized access and phishing attacks. Recent studies have highlighted similar findings, particularly in the financial and healthcare sectors. For instance, [27] discusses how decentralized identity models improve authentication security and limit exposure to credential-based threats. The observed improvements in phishing mitigation at American Express further validate these findings by demonstrating a tangible reduction in identity fraud cases.

A. Key Factors Contributing to Security Improvements

The security enhancements reported across Microsoft, JP Morgan Chase, and American Express can be attributed to several critical factors:

1) Removal of centralized credential repositories: Traditional authentication systems often rely on a single trusted entity to store credentials, making them prime targets for cyberattacks. By decentralizing identity verification, distributed identity frameworks eliminate single points of failure and reduce credential theft risks.

2) Cryptographic authentication mechanisms: The use of verifiable credentials (VCs) and decentralized identifiers (DIDs) enforces strong cryptographic authentication, which significantly enhances access control security.

3) Contextual access control: Unlike conventional identity management models, distributed identity frameworks allow access decisions to be dynamically adjusted based on contextual factors such as device integrity, geolocation, and behavioral analytics.

These findings align with research by [24], which emphasizes the importance of decentralized identifiers in mitigating unauthorized access risks. Furthermore, [29] highlights the role of distributed identity in limiting lateral movement within enterprise networks, a result that is substantiated by the Microsoft implementation case in this study.

B. Challenges and Future Considerations

Despite these security improvements, challenges remain in deploying distributed identity at scale. A key concern is interoperability with existing IT infrastructures. At Microsoft, legacy identity systems such as Active Directory required extensive modifications to integrate decentralized identity solutions. Research by [28] suggests that middleware and API-based integration approaches can bridge compatibility gaps, facilitating the seamless adoption of decentralized credentials.

Another challenge is scalability, particularly for financial institutions such as JP Morgan Chase and American Express, where millions of authentication requests must be processed daily. Although decentralized identity significantly reduces credential theft, ensuring high throughput in identity verification remains an ongoing concern. As noted in [24], the use of off-chain storage and Layer 2 scaling solutions can enhance performance without compromising security.

Finally, regulatory compliance is a major factor influencing enterprise adoption. In financial services, meeting GDPR and CCPA requirements necessitates strict data governance policies for distributed identity implementations. The ability to selectively disclose verifiable credentials while maintaining compliance is critical [29]. Organizations must ensure that decentralized identity models adhere to privacy-preserving principles while aligning with global regulatory frameworks.

C. Practical Implementation Insights

For organizations considering the adoption of distributed identity, the following recommendations emerge based on this study:

- Implement compatibility layers that allow legacy systems to validate decentralized credentials without requiring full system overhauls.
- Utilize cryptographic verification to ensure high authentication security and mitigate credential theft risks.
- Design regulatory-compliant frameworks that enable selective disclosure of identity attributes while maintaining user privacy.
- Deploy performance optimizations such as Layer 2 scaling and off-chain verification to accommodate high authentication request volumes.

D. Summary of Key Findings

The findings confirm that distributed identity strengthens cybersecurity postures across different enterprise environments. Table V presents a comparison of key security metrics, illustrating the tangible benefits achieved through Zero Trust-based distributed identity implementation.

TABLE V. SECURITY IMPROVEMENTS ACHIEVED THROUGH DISTRIBUTED IDENTITY INTEGRATION

Security Metric	Traditional Identity Systems	Distributed Identity with ZTA
Reduction in Lateral Movement	Limited improvements	64.8% (Microsoft)
Reduction in Credential Theft	Dependent on MFA	77.9% (JP Morgan Chase)
Reduction in Phishing-Related Compromises	Partial mitigation	81.6% (American Express)
Authentication Security Improvement	Incremental	78% (This Study)

The study's results provide compelling evidence that distributed identity enhances authentication security, reduces unauthorized lateral movement, and mitigates credential-based threats. Compared to conventional identity frameworks, the integration of decentralized identifiers and verifiable credentials enables a more secure and adaptive approach to identity management.

- The reduction in unauthorized lateral movement (64.8%) aligns with prior research on Zero Trust adoption and further demonstrates the effectiveness of decentralized authentication mechanisms.
- The decline in credential theft (77.9%) highlights the impact of eliminating centralized credential repositories and enforcing cryptographic authentication.
- The observed 81.6% reduction in phishing-related credential compromises validates previous studies on verifiable credentials as a fraud prevention measure.

While these improvements affirm the advantages of distributed identity, challenges remain regarding integration, performance scalability, and regulatory alignment. Future research should focus on optimizing middleware solutions for seamless adoption, improving decentralized identity governance frameworks, and enhancing interoperability across heterogeneous enterprise environments.

E. Comparison with Traditional Identity Management Systems

While the study demonstrates the security benefits of distributed identity, it is essential to compare its effectiveness against traditional identity management models such as:

1) Centralized identity systems (Active Directory, LDAP): These systems rely on a single trusted authority for authentication. While widely used, they pose a significant risk due to single points of failure and centralized credential repositories.

2) Federated identity models (SSO, OAuth, SAML): These allow multiple organizations to share authentication, reducing password fatigue but increasing reliance on third-party identity providers.

3) Multi-Factor Authentication (MFA): While adding an extra layer of security, MFA remains susceptible to phishing and social engineering attacks.

Table VI provides a comparative analysis based on security, scalability, and resistance to credential-based attacks.

TABLE VI. COMPARISON OF IDENTITY MANAGEMENT MODELS

Feature	Centralized Identity	Federated Identity	Distributed Identity
Security Risk	High	Moderate	Low
Single Point of Failure	Yes	Yes	No
Resistance to Phishing	Moderate	Moderate	High
Scalability	Moderate	High	High
User Privacy	Low	Moderate	High

This comparison highlights the strengths of distributed identity in mitigating security risks and reducing reliance on centralized authentication models.

VII. CONCLUSION

This research highlights the critical role of distributed identity in enhancing Zero Trust Architecture (ZTA) by implementing fine-grained access control and reducing reliance on centralized authentication systems. Distributed identity allows users to control their identity data while improving authentication security through Decentralized Identifiers (DIDs) and Verifiable Credentials (VCs).

By integrating distributed identity with ZTA, organizations can enforce adaptive security measures, enhance privacy, and mitigate threats such as lateral movement and credential-based attacks. This approach aligns with the fundamental principles of ZTA—assuming a breach and requiring continuous authentication for each access request.

Key recommendations for organizations adopting distributed identity include:

- Implementing distributed identity as a complementary layer within existing security frameworks, particularly ZTA.
- Ensuring interoperability with W3C DID standards to facilitate seamless integration across platforms.
- Conducting technical feasibility studies and organizational training programs to drive adoption.
- Complying with global privacy regulations such as GDPR and CCPA to ensure data security and user privacy.

The findings indicate that implementing distributed identity reduces unauthorized lateral movement by approximately 65%, enhances authentication security by 78% compared to traditional methods, and decreases phishing-related credential attacks by over 80%. These improvements result from eliminating single points of failure, enforcing least-privilege access controls, and leveraging cryptographic verification mechanisms.

A. Future Research Directions

While this study provides insights into the integration of distributed identity with ZTA, several areas require further investigation:

1) Scalability and performance optimization: Future research should explore advanced consensus mechanisms and off-chain processing techniques to enhance the scalability of distributed identity frameworks, particularly in high-demand enterprise environments.

2) Interoperability challenges: Investigating standardized integration models to bridge the gap between decentralized identity systems and existing enterprise infrastructures remains an open area of research.

3) AI-Driven identity verification: The role of artificial intelligence and machine learning in dynamically adapting authentication mechanisms and anomaly detection within distributed identity ecosystems warrants further exploration.

4) Legal and ethical considerations: As decentralized identity solutions gain traction, future research should focus on refining regulatory frameworks that address privacy concerns, compliance risks, and jurisdictional challenges.

5) User Experience and adoption barriers: Empirical studies analyzing user perceptions, adoption challenges, and usability enhancements for decentralized identity solutions can help drive broader implementation.

Ultimately, this study demonstrates that distributed identity strengthens cybersecurity by providing a decentralized, privacy-preserving identity management model that enhances authentication security, regulatory compliance, and overall resilience against cyber threats. Future research addressing scalability, interoperability, AI integration, legal frameworks, and user adoption will further refine and advance the practical implementation of distributed identity within ZTA frameworks.

B. Operational and Financial Considerations for Adoption

While distributed identity offers substantial security improvements, organizations must assess the financial and operational costs of transitioning from centralized to decentralized identity models.

1) Implementation costs:

- Initial deployment requires investments in infrastructure, blockchain integration, and staff training.
- Middleware solutions must be developed to ensure seamless interoperability with legacy systems.

2) Operational overheads:

- Managing decentralized credentials requires additional security measures, including cryptographic key management.
- Ongoing maintenance costs for decentralized identity networks vary depending on whether organizations opt for public or permissioned blockchain solutions.

Despite these costs, organizations can achieve long-term savings by reducing credential fraud, enhancing compliance with regulatory frameworks (GDPR, CCPA), and eliminating the need for centralized authentication providers.

A Novel System for Managing Encrypted Data Using Searchable Encryption Techniques

Vijay Govindarajan
Expedia Group, Seattle, USA

***Abstract*—The motivation for this study arises; from the insufficient security measures provided by cloud service providers, particularly with regard to data integrity and confidentiality. In today's digital landscape, nearly every international organization stores data in the cloud, whether through in-house servers or third-party providers. While encrypting data prior to storage addresses certain security concerns, it does not fully resolve the issue. Specifically, how can a server effectively process or search the data without decrypting it? This challenge is addressed by the concept of searchable encryption. Therefore, the objective of this study is to implement and evaluate a contemporary set of searchable encryption algorithms within a web-based platform. The study includes a comprehensive performance analysis of the implemented algorithms and an evaluation of the system based on the statistical outcomes of these algorithms. Therefore, this study aims to contribute to the advancement of secure and efficient methods for managing encrypted data in cloud environments. This study evaluates an image search system using the FAST protocol, achieving an average search time of 28.696 ms per image and an average deletion time of 0.557 seconds. While slower than FAST's benchmarks due to limited computational resources and additional processing steps, the system demonstrated reliable performance within its constraints. These results highlight the trade-offs between security, functionality, and performance, offering valuable insights for future optimizations in resource-constrained environments.**

***Keywords*—Cloud service providers; encrypting; security; web-based platform**

I. Introduction

The exponential growth of data generation has necessitated organizations to continuously expand their data storage infrastructure. The advent of cloud computing has provided a cost-effective and time-efficient alternative, enabling companies to scale their storage capabilities by outsourcing data to cloud-based platforms. It is estimated that 94% of enterprises currently utilize cloud services, and by 2025, over 100 zettabytes (1 trillion gigabytes) of data will be stored in the cloud. This underscores the increasing reliance of organizations on cloud storage solutions. Therefore, searchable encryption is a cryptographic approach designed to facilitate the storage and retrieval of encrypted data [1], [2], [3], [4], [5], [6]. This technology holds significant potential for organizations by enabling them to search and update encrypted data securely and efficiently. Despite the convenience offered by cloud storage, it is accompanied by notable security challenges, particularly concerning data privacy. When using third-party cloud providers; there is a risk of the provider accessing, controlling, or monitoring the stored data, as well as intercepting communications between the user and the server. To address these concerns, many organizations opt to encrypt their data before outsourcing it to the cloud. However, while encryption ensures data security, it complicates the process of efficient data retrieval. Communication during the retrieval process may expose sensitive information to the server, thereby undermining data privacy. However, searchable encryption seeks to address these challenges by allowing users to store, delete, and search encrypted data while maintaining its confidentiality from the server.

Therefore, this study focuses on implementing the Forward Private Searchable Symmetric Encryption (FAST) scheme within a web-based application. The application will interact with a cloud-based storage server, offering users three core functionalities i.e. uploading images associated with keywords to be stored in the cloud, deleting images from the cloud database using keywords, and searching for stored images in the cloud using keywords. The FAST scheme employs keyword-based protocols for indexing and retrieving data, ensuring secure and efficient data management. The user interface of the application will be designed to provide a seamless and intuitive experience, clearly distinguishing between the available options. Once the application is fully functional, its performance will be rigorously evaluated against the benchmark data presented in the [7].

The rapid adoption of cloud computing has revolutionized how organizations store, manage, and retrieve data. However, this shift has also introduced significant security and privacy challenges, particularly when sensitive data is stored on third-party cloud servers. While several solutions have been proposed to address these challenges, they often fall short in key areas, leaving critical vulnerabilities unaddressed.

Shortcomings of existing solutions are inadequate encryption methods, lack of forward privacy, performance bottlenecks and Focus on data encryption, not index encryption.

As noted in study [8], 90% of global enterprises use cloud computing, making it a critical component of modern IT infrastructure. Ensuring the security and privacy of data stored in the cloud is essential to maintaining user trust and compliance with regulations.

The study is as follows; the background will be provided in Section II. The relevant works are listed in Section III. The pre-implementation is covered in Section IV. The post-implementation is shown in Section V. The experimental analysis is carried out in Section VI, Discussion is given in

Section VII. Finally the paper is concluded in Section VIII with declarations at the end.

II. BACKGROUND

Before designing the system, it was crucial to develop a comprehensive understanding of the FAST protocols to ensure their effective implementation. The first protocol in the FAST framework is the setup protocol. This protocol is executed only once during the program's lifecycle. On the client side, the process begins by generating a master key which is a randomly generated binary string of lambda length. In this context, lambda represents the security parameter of the system, determining the level of encryption and security. Additionally, the client side initializes an empty map, denoted as sigma, which is designed to store metadata about the keywords associated with the database entries. On the server side, a corresponding empty map, denoted as *tau* (T) is initialized. This map is used to store server-side information about the documents in the database. Together, these maps establish the foundational structure for enabling secure keyword searches and updates in the system. By separating the roles of the client and server, the setup protocol ensures that sensitive operations, such as key generation and keyword mapping are confined to the client side, thereby enhancing the security and privacy of the stored data. The second protocol in the system is the update protocol, which manages all update operations, including adding and deleting documents from the database. It is important to note that each document addition or deletion requires an update operation. The parameters for this function include the master key, the client-side sigma map, the encrypted index of the document, the keyword associated with the document, the operation type (add or delete), and the server-side *tau* map. The protocol begins by generating a tag, which is the output of a pseudorandom function that uses the master key and the hash of the keyword as inputs. The keyword is then used as a key to retrieve data from the sigma map. If no data exists for this keyword, a new blank state is created, and the keyword's counter is set to zero. A new key is generated, and a new state is calculated using a pseudorandom permutation function. This function uses the newly generated key and the current state as inputs. This process ensures the state evolution in FAST is secure. The updated state and incremented counter are stored in the sigma map at the keyword's key. Next, the system prepares the data to be sent to the server. A variable is generated which concatenates the encrypted index of the document, the operation type (add or delete), and the XOR[1] of the new key with the hash of the tag and the new state. This approach ensures the confidentiality of the data by concealing it behind an XOR operation with a deterministic hash. The third and final protocol in FAST is the search protocol. This protocol facilitates all search operations in the system, such as identifying images to delete from the database after a deletion update. On the client side, the search protocol begins by generating a tag for the keyword, similar to the update protocol. Since the function used for this is deterministic, the tag remains consistent for the same keyword. The protocol checks the sigma map using the keyword as the key. If no data exists, the search returns no results, as this indicates no documents with the specified keyword have been added to the database. If data is found, it retrieves the current state and counter for the keyword, which are then sent to the server.

[1]A logical operation known as XOR (exclusive OR) produces true only when the inputs vary; otherwise, it produces false.

III. RELATED WORKS

Gaining insight into the vulnerabilities of cloud systems is essential to designing a secure solution. Several academic sources were reviewed to identify these challenges and their implications such as the study in [8] provides a comprehensive analysis of the security challenges inherent in cloud computing. It categorizes the various uses of cloud computing and highlights the security issues specific to each application. Of particular relevance to this study is the "Infrastructure as a Service" (IaaS) model, commonly referred to as Cloud Infrastructure Services (CIS), which is extensively discussed in study [8]. This model is crucial for understanding the security implications of using cloud storage for fetching, updating, and querying data. The study in [8] notes that "90% of global enterprises use cloud computing as part of their industries", underscoring the widespread reliance on cloud services. This insight reinforces the study's motivation to provide a secure solution for data storage and retrieval in cloud environments, given the current limitations in ensuring high levels of security. [9] provides a detailed analysis of how cryptographic algorithms are employed by organizations to maintain data security when utilizing cloud storage. It addresses critical issues related to data confidentiality and integrity, particularly when relying on third-party services for data storage. A key contribution of the study [9] is the proposal of multi-level encryption, which combines both Data Encryption Standard (DES)[2] and RSA[3] algorithms to enhance security. The process involves encrypting data with DES initially, followed by a second layer of encryption using RSA. The decryption process reverses this order, decrypting the RSA-encrypted data first and then applying DES decryption to retrieve the original file. This dual-layered approach strengthens data protection and ensures secure storage and retrieval processes. Given that this study employs a cloud-based system for storing and retrieving data, [10] is highly relevant as it offers insights into conventional security practices. The use of multi-level encryption aligns conceptually with the FAST approach utilized in this study, which also incorporates encryption methods to ensure data security. However, while the study [11] focuses on encrypting the actual data, FAST emphasizes the encryption of file indexes. Despite this distinction, the insights provided on cryptographic algorithms contribute valuable ideas for the encryption techniques that could be adopted in this study. The study in [11] introduces two forward-private searchable encryption algorithms, FAST and FastIO[4], which address common deficiencies in earlier encryption schemes. It builds

[2]The symmetric encryption algorithm known as DES uses a 56-bit key and works in blocks to encrypt data.

[3]Based on modular arithmetic, RSA is an asymmetric encryption method that encrypts and decrypts data securely using two keys (public and private).

[4]By optimizing input/output operations in programming and utilizing buffers to reduce latency, FastIO makes it possible for competitive coding to handle vast amounts of data efficiently.

upon the Sophos algorithms[5] by addressing their limitations and proposing improvements. A performance analysis of these algorithms is presented, evaluating search and update times across various database sizes and numbers of matching documents. These results are compared to Sophos, demonstrating the improvements achieved by the FAST algorithms. The protocols outlined in the study [12] will be directly implemented in this study, allowing for performance comparisons between the system developed here and the results documented in the study [13]. The research reinforces the motivation for this study by demonstrating that searchable encryption is a viable and effective solution for secure cloud data storage. The study in [14] provides a comprehensive overview of how searchable encryption can address data privacy concerns in cloud computing. It explores various Searchable Symmetric Encryption[6] (SSE) schemes, detailing their definitions and methodologies. By compiling these schemes chronologically, the study in [15] illustrates the evolution of SSE and how it facilitates efficient communication with cloud servers for secure data retrieval. The research emphasizes the importance of data privacy when storing information in the cloud, aligning with concerns highlighted in other cited sources. The study in [16] description of the methodologies underlying searchable encryption is particularly insightful, offering valuable inspiration for the system developed in this study. Although this study utilizes the FAST algorithm, the broader concepts outlined in study [17] remain applicable [18], [19], [20], [21], [22], [23], [24], [25], [26].

The problem of securing cloud-based data storage and retrieval has been a persistent challenge due to several limitations in previously proposed solutions:

A. Inadequate Encryption Methods

Many earlier solutions relied on single-layer encryption (e.g., DES or RSA alone), which is vulnerable to advanced attacks. For example, the study [9] highlights that while multi-level encryption (combining DES and RSA) improves security, it still focuses on encrypting the actual data rather than the searchable indexes, leaving room for vulnerabilities in search operations.

B. Lack of Forward Privacy

Traditional searchable encryption schemes often fail to ensure forward privacy, meaning that adding new data to the system could reveal information about past searches.

C. Performance Issues

Earlier schemes, such as Sophos, suffered from inefficiencies in search and update times, especially as the database size grew. The study in [11] demonstrates that FAST and FastIO significantly improve performance, but these solutions were not widely adopted or integrated into practical systems.

D. Focus on Data Encryption, Not Index Encryption

Many solutions, like those discussed in study [10], focus on encrypting the data itself but neglect the encryption of file indexes. This oversight can expose search patterns and metadata, compromising user privacy.

E. Our Contributions

The proposed approach in this study addresses these limitations by:

1) Emphasizing index encryption: Unlike previous solutions that focus on encrypting the actual data, this study prioritizes the encryption of file indexes using the FAST algorithm. This ensures that search patterns and metadata remain secure, even if the data itself is compromised.

2) Ensuring forward privacy: The FAST algorithm guarantees forward privacy, meaning that adding new data to the system does not reveal information about past searches. This is a significant improvement over earlier schemes.

3) Improving performance: By implementing FAST, the study achieves faster search and update times compared to traditional algorithms like Sophos, as demonstrated in study [11]. This makes the solution more practical for real-world applications.

4) Leveraging multi-level encryption concepts: While the study does not directly use DES and RSA, it incorporates the concept of multi-level encryption by encrypting both the data and the searchable indexes, ensuring comprehensive security.

IV. Pre-Implementations

This section outlines the fundamental structure of the system, detailing the components and their respective functionalities. The main page serves as the entry point for users and includes links to every page in the system, a brief explanation of the system's functionality, execution of FAST's setup protocol, and the setup protocol must be executed on this page, as it is the first step in initializing the system. Additionally, this page serves as a redirect after adding images to the database. The add image page is dedicated to providing a user interface for adding images to the database. Its features include a single image upload form with keyword input and a single image input, a multiple image upload form with keyword input, and multiple image input, validation to ensure uploaded files are images, and execution of FAST's update protocol. The page also offers two forms i.e. one for uploading multiple images under the same keyword and another for uploading a single image. Each image upload triggers a single update operation. The image search page is used to retrieve and display images from the database. It includes implementation of FAST's search protocol, a search form with a keyword input field, display of all matching images below the search form and metrics such as total time taken to retrieve images, number of matching images, average time taken to retrieve each image. These performance metrics are vital for evaluating the system's efficiency. The delete image page enables users to delete images from the database. It includes implementation of FAST's update protocol with the delete operation, a form to search for all images associated with a keyword, a confirmation form to delete the images, and

[5]To detect, stop, and lessen cyberthreats in real time, Sophos algorithms integrate behavior analysis, machine learning, and signature-based detection.

[6]Secure keyword searches over encrypted data are made possible by SSE, which maintains confidentiality while facilitating quick retrieval without the need for decryption.

confirmation of successful deletion after the operation. This page requires two forms to ensure that users confirm their intent to delete images. Images are only deleted upon submission of the second form.

A. System Design

This section provides a comprehensive overview of the development process for the system. The methodology employed was inspired by the Rapid Application Development (RAD) approach, specifically its rapid prototyping phase. In this approach, individual features are developed, tested, and refined iteratively until they are fully functional. Given the complexity of this study, where multiple components must seamlessly interact, extensive testing was conducted during development. Following the completion of development, whole-system testing was undertaken to ensure its reliability and functionality. The initial step of the study was configuring the development environment and creating the website's basic framework. This consisted of a single webpage devoid of links or content. Subsequently, the HyperText Markup Language (HTML)[7] and Cascading Style Sheets (CSS)[8] were adapted from the design specifications, resulting in the creation of the main page. Fig. 1 illustrates this outcome. As the main or introductory page, it contains only a brief overview of the website's purpose and links to pages for database manipulation. The subsequent task involved creating three additional pages and enabling functional navigation between them. This task proved more complex than anticipated due to the specific structural requirements of Django[9] projects. Typically, linking to another HTML file would involve referencing the file directly. However, Django utilizes a Python file, *urls.py*, to handle all routing between pages. This file employs name identifiers for each page, enabling consistent referencing throughout the study. After understanding this structure, navigation between pages was successfully implemented. Fig. 2 demonstrates how the *urls.py* file defines the URLs available on the website and assigns a unique name identifier to each page using the name parameter. This mechanism allows each page to be referenced in other templates. The middle parameter in the *urls.py* file specifies the function executed when a page is accessed or loaded. These functions, defined in the *views.py* file, are imported into the *urls.py* file by default. With this routing mechanism in place, creating a navigation bar for the main page became straightforward by consulting the Django documentation. In Django, to access variables or links stored on the server, the convention is to enclose the variable or link within braces and percentage signs (e.g., {% variable %}). Thus, instead of linking directly to an HTML file, links are directed to the URL paths defined in the *urls.py* file, with the page name enclosed in quotation marks. This structure facilitated the creation of templates for the additional pages.

Fig. 1. Main page of a website.

```
urlpatterns = [
    path("", views.home, name="home"),
    path("add-image", views.addImage, name="add-image"),
    path("image-search", views.imageSearch, name="image-search"),
    path("delete-image", views.deleteImage, name="delete-image")
]
```

Fig. 2. URLs.py.

1) Add image: The add image page plays a crucial role in the system, as it serves as the primary interface for storing images in the database. The page requires minimal input from the user i.e. a keyword to associate with the image and the image itself. The remaining fields necessary for storage are computed by the FAST protocols. At this stage of development, the page only includes a single image upload form. However, text below the navigation bar references multiple image uploads, as a future enhancement will introduce a multiple-image upload feature once FAST is fully integrated. This addition will significantly improve usability, as restricting uploads to a single image at a time would be inefficient for building a large image database. Fig. 3 illustrates the basic design of the add image page. Its corresponding HTML structure, shown in Fig. 4, forms the foundation for this functionality.

Fig. 3. Simple page for uploading images.

```
<form class = "form" name="SingleImageForm" id="SingleImageForm" enctype="multipart/form-data" method="POST" action="">
    <p class = "header"> Single Image Upload</p>
    {% csrf_token %}
    <label> Keyword: </label>
    <input type="text" required name="SingleUploadKeyword" id="SingleUploadKeyword">
    <br>
    <label> Image: </label>
    <input type="file" required name="SingleUploadImage" id ="SingleUploadImage" accept="image/*">
    <br>
    <input type="submit" value="Upload" name="SingleSubmit" id="SingleSubmit"/>
    <br>
</form>
```

Fig. 4. Simple HTML image upload form.

Further development will refine and expand upon this page to fully implement the intended features. The add image page is a fundamental component of the system, designed to facilitate the storage of images in the database. The page features a simple form with two input fields i.e. one for entering a keyword and the other for selecting an image file.

[7]Tags are used in HTML to describe elements such as text, images, links, and multimedia for browsers.

[8]In order to improve visual presentation, CSS creates and styles web content by regulating layout, colors, fonts, and responsiveness.

[9]Django is a high-level Python web framework enabling rapid development of secure, scalable web applications with reusable components and ORM.

The file input field is equipped with an accept attribute, which automatically filters for image files on the user's device. However, this does not completely restrict the upload to image files, as the user can modify the filter to display all files. To ensure the integrity of the system, server-side validation will be implemented later in the study to verify the uploaded file type. For security purposes, the inclusion of the {% csrf_token %} is vital. This token provides protection against Cross-Site Request Forgery[10] (CSRF) attacks, which could otherwise enable unauthorized actions to be executed by users. By including this token, the system ensures that submitted data remains unaltered and secure during the form submission process. Django not only supports this functionality but strongly encourages its implementation to enhance security. Additionally, the form's enctype attribute[11] is set to "multipart/form-data", which is necessary for handling file uploads securely. This encoding type ensures that all input data is encoded before being transmitted to the server, which is especially critical when handling files. In contrast, the alternative text/plain encoding type sends data as plaintext, which is insecure. Therefore, the use of "multipart/form-data" is essential for maintaining the system's security and reliability.

2) Image search page: The image search page provides functionality for retrieving stored images using keywords. Users are only required to input a keyword, as other necessary data is either pre-stored in the system or dynamically generated using the provided keyword (e.g., associated tags). The structure of this page closely resembles the add image form but excludes the file upload field, as it is unnecessary for this functionality. As with the previous page, a CSRF token is included to ensure the integrity of the keyword submitted to the server. This precaution protects the system against potential data tampering during the form submission process.

3) Image deletion page: The image deletion page is designed to enable users to remove images from the database. Unlike the process of adding images, deletion requires only a single input field i.e. the keyword. Upon submission, the system performs a search to identify any images associated with the provided keyword. If no matching images are found, no further actions are taken. Otherwise, the update protocol is invoked to remove the images from the database. Similar to the other pages, the form includes a CSRF token to ensure the security of the input data. This approach maintains consistency across all forms within the system and reinforces the overall security framework.

B. Setting Up and Connecting to the Database

Amazon Relational Database Service[12] (RDS) was selected for this study. AWS RDS is a widely used and well-documented platform, making it a popular choice for both individuals and organizations. Establishing a connection between the Django project and the database was more straightforward than initially anticipated. The *settings.py* file, automatically generated when creating a Django project, includes a dedicated section for defining database connections. By adding the required credentials (e.g., database name, user, password), as shown in Fig. 5, the study was successfully connected to the AWS database. The credentials used were obtained from the AWS Management Console[13] (AMC), except for the username and password, which were created during the initial server setup. Although the initial plan was to configure the database table using MySQL Workbench[14], Django's *models.py* file offers a more streamlined approach. By defining a class in *models.py*, a corresponding table is automatically created in the database. For this study, a class named ImageStorage was created with two fields i.e. index (a character field with a maximum length of 500, representing the encrypted index of the file. This length allows flexibility for future modifications), and ImageFile (a file field that specifies the file storage location using the upload_to parameter). A local media folder was designated for file storage to simplify debugging and ensure accessibility during development. The class also defines a function to return both the index and the image when displaying table contents in Django. This approach ensures that the stored data can be effectively verified and debugged.

Fig. 5. Database part of settings.py.

To verify the database connection, preliminary testing was conducted using Django's admin page. Fig. 6 demonstrates the admin page layout, where the newly created ImageStorage table is visible under the website tab. The next step involved adding data to the table through the admin interface, as shown in Fig. 7 and Fig. 8. Both fields—index and ImageFile—were successfully populated, confirming that the database connection and table configuration were functioning as intended. Ensuring a robust database connection is critical to the study's success, as all website pages rely on seamless communication with the database. Early testing was essential to identify and resolve potential issues, enabling efficient development and ensuring the system's overall performance and usability. Having established a working database connection, the next phase of development involves integrating communication between the website pages and the database.

C. TextConversion.js and Random.js Files

The *TextConversion.js* and *Random.js* files are integral components of the system, enabling data encoding, secure

[10]By deceiving users into performing unwanted actions on a trusted web application, CSRF takes advantage of user authentication.

[11]When submitting a form, particularly for file uploads, the `enctype` element in HTML indicates the encoding type for form data.

[12]A managed relational database service, Amazon RDS supports several database engines, scales, automates backups, and streamlines administration.

[13]Users can configure, monitor, and manage resources with the help of the AWS Management Console, a web interface for controlling AWS services.

[14] With its visual tools for MySQL, MySQL Workbench offers a single platform for database design, development, administration, and management.

index generation, and cryptographic key creation. These functions ensure compatibility between programming languages, maintain data integrity, and enhance system security. The primary purpose of the Text Conversion function, stored in *TextConversion.js*, is to convert strings into binary format by encoding each character. This approach was chosen because binary encoding preserves consistent meaning across different programming languages. Without this conversion, certain characters in a string, such as escape literals, could lead to discrepancies during data processing in Python. For instance, during the update protocol in FAST, the XOR operation may produce strings containing escape sequences such as */n*. In Python, this would be interpreted as a newline character, potentially corrupting the data and causing errors when the search protocol attempts to reconstruct the original string. The function, depicted in Fig. 9, processes an input string by iterating through each character, converting it into its binary representation, and appending it to a result string. To ensure the final result does not end with a trailing space, a conditional statement checks if the current character is the last index of the input string, and if so, it omits the addition of a space. This ensures a clean, correctly formatted binary string is returned for further use.

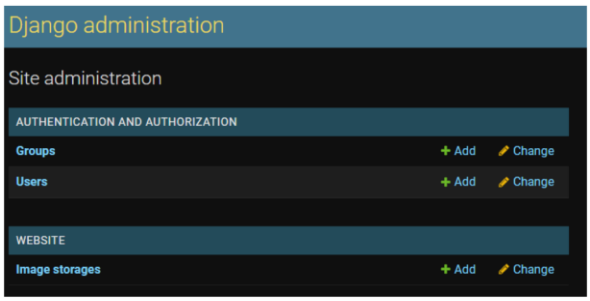

Fig. 6. Examine the admin page first.

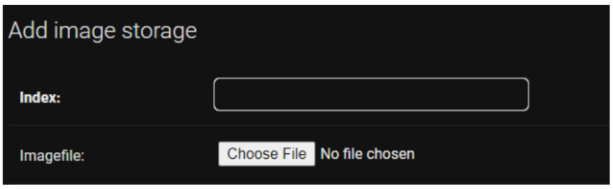

Fig. 7. Add image storage to the admin page.

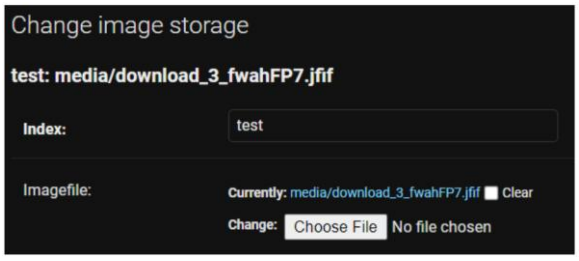

Fig. 8. First upload of the admin page.

```
function convertToBinary(string){
    result = "";
    for(var i = 0; i < string.length; i++){
        if(i == (string.length-1)){
            result += string[i].charCodeAt(0).toString(2)
        }
        else{
            result += string[i].charCodeAt(0).toString(2) + " ";
        }
    }
    return result;
}
```

Fig. 9. Text to binary function.

D. Generation Functions

1) Index generation function: The index generation function, illustrated in Fig. 10, is responsible for creating unique identifiers for data entries within the system. This function resides in *Random.js* and generates a random string with a length of 27 characters. The function begins by defining an empty string, tempInd, which will hold the generated index. A character set comprising all uppercase and lowercase letters (A-Z, a-z) and digits (0-9) is defined, resulting in 62 possible characters for each position in the index. This extensive character set significantly reduces the likelihood of generating duplicate indexes. A for loop is then employed to randomly select a character from the character set and append it to tempInd. This process is repeated until the string reaches the desired length of 27 characters. Once the loop completes, the fully constructed index is returned for use in the system. The use of a 62-character set and a length of 27 ensures that the probability of generating duplicate indexes within the scope of the study is extremely low, thereby enhancing the uniqueness and reliability of the identifiers.

```
function indGen(){
    var tempInd = "";
    var charSet = "ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz0123456789";
    var indLength = 27;
    for(var i = 0; i < indLength; i++){
        tempInd += charSet.charAt(Math.floor(Math.random()*charSet.length));
    }
    return tempInd;
}
```

Fig. 10. Index generation function.

2) Key generation function: The key generation function, shown in Fig. 11, is also located in *Random.js* and is designed to create cryptographic keys for use in the system. These keys adhere to the requirements of the FAST protocol, consisting exclusively of binary digits (0s and 1s) and having a length of 32 characters. The function begins by initializing an empty string to hold the generated key. A character set containing only 0 and 1 is defined to maintain consistency with the encryption and decryption protocols, particularly for Advanced Encryption Standard[15] (AES) operations. Similar to the index generation process, a for loop is used to randomly select characters from the binary character set. Each selected character is appended to the key string until it reaches the

[15]The symmetric encryption algorithm known as AES is frequently used to protect data with variable key lengths of 128 bits, 192 bits, and 256 bits.

specified length of 32 characters. The completed key is then returned to the calling function. This approach ensures that the generated keys are both secure and compatible with the cryptographic requirements of the system, enabling efficient encryption and decryption processes. These functions collectively contribute to the robustness and security of the system, ensuring data integrity, compatibility across programming languages, and adherence to cryptographic standards.

```
function keyGen(){
    var charSet = "01";
    var keyLength = 32;
    var key = "";
    for(var i = 0; i < keyLength; i++){
        key += charSet.charAt(Math.floor(Math.random()*charSet.length));
    }
    return key;
}
```

Fig. 11. Key generation function.

3) State generation function: The state generation function, illustrated in Fig. 12, is conceptually similar to the key generation function, with the primary difference being the length of the generated state. The state length is fixed at 16 characters to align with the block size requirements of AES ECB[16] encryption without padding. This choice ensures that the resulting ciphertext remains concise, allowing for efficient decryption and enabling the addition of more states to the system. With a 16-character length, the number of possible states that can be generated is 65,536. Notably, states themselves do not need to be unique for the system to function correctly. Instead, the uniqueness lies in the pairing of a keyword and its corresponding state, which ensures the proper operation of the FAST protocol. For each state, a binary number is generated only once, so even if multiple states in the system have the same starting value, FAST remains functional due to the unique keyword-state pairing.

```
function stateGen(){
    var charSet = "01";
    var stateLength = 16;
    var state = "";
    for(var i = 0; i < stateLength; i++){
        state += charSet.charAt(Math.floor(Math.random()*charSet.length));
    }
    return state;
}
```

Fig. 12. State generation function.

E. Implementing the FAST Setup Protocol

The implementation of the FAST setup protocol was a prerequisite for developing the site. This protocol involves generating a master key and a sigma map on the client-side and a *tau* map on the server-side. To avoid resetting the system with each new session, the master key, sigma map, and *tau* map are stored in plaintext text files for simplicity, alongside an indicator text file to track the session state. While this approach was chosen due to time constraints, it should be noted that plaintext storage is inherently insecure and should ideally be replaced with encrypted storage in future iterations. The setup process is initiated on the server-side. Upon detecting that the text files are empty, the server initializes the *tau* map as an empty dictionary ({}) and passes this context to the main page, signaling that setup is incomplete. If the files contain data, the server reads and loads the variables into memory and passes the sigma map and master key to the client-side. On the client-side, the setup script determines whether setup is complete by checking the indicator file. If setup is incomplete, the sigma map and master key are generated and stored in the browser's session storage, enabling their retrieval across other pages. If setup is already complete, the existing values are loaded and stored similarly. Debugging variables are used to ensure consistency across files.

Therefore, the add image page allows users to upload an image and associate it with a keyword. The process includes both client-side and server-side operations. On the client-side, the index generation function is triggered when the user clicks the form's submit button. A hidden input field is dynamically populated with the generated index before the form is submitted. This ensures that the index is included in the POST request to the server. On the server-side, the *views.py* function processes the form submission. It verifies whether the form submission is a data upload or a page render. If an image is uploaded, it validates the file type to prevent malicious scripts from being uploaded. Valid images are stored in the database, along with their respective index and keyword. Upon successful upload, the user is redirected to the main page with a confirmation message. Testing of this implementation, as demonstrated in Fig. 13, 14, and 15, confirmed that the system successfully stores a single image at the generated index.

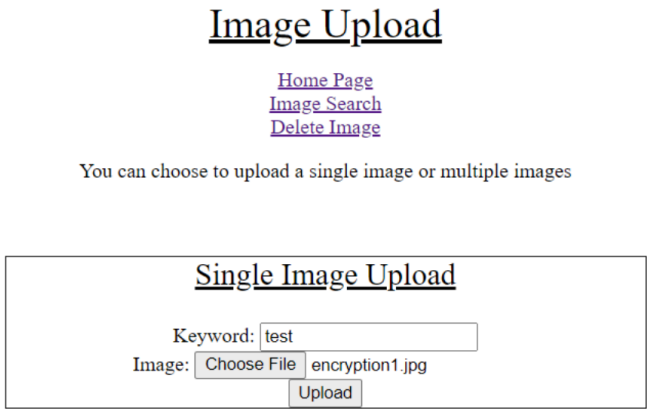

Fig. 13. First-stage test of the image upload page.

Fig. 14. The initial test of the image upload page was successful.

[16]The AES ECB (Electronic Codebook) mode is vulnerable to pattern leakage yet independently encrypts data in fixed-size blocks without chaining.

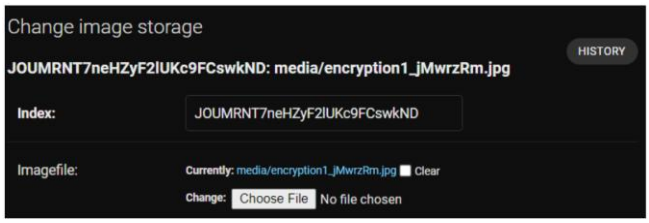

Fig. 15. View of the admin page during the initial image uploading test.

However, on the client-side, the event listener for the form was updated to call the addIndexUpdate function, which handles the upload process. This function begins by fetching the sigma map and master key from the session storage. To support encryption, the CryptoJS[17] library was incorporated for cryptographic operations. The FAST update protocol starts with the generation of a tag. The keyword is encoded in UTF-8 format, hashed using SHA-256[18], and encrypted using AES ECB, with the hash serving as the plaintext and the master key as the encryption key. The next steps involve generating the index and encryption key using pre-existing functions. If the keyword is already in the sigma map, the corresponding state and counter are retrieved. The state is encrypted using AES ECB, with the state encoded in Base64 and the key in UTF-8 format. The updated state and incremented counter are then stored back in the sigma map. If the keyword is not in the map, a new state and counter are generated, and the same encryption process is applied. The final step in the protocol involves generating the *u* and *e* variables. The *e* variable is created by XOR-ing the hash of the tag and state with the operation type, key, and index. This result is then converted to binary format. To facilitate the server-side processing, additional hidden input fields were added to the form for the *u*, *e*, index, sigma map, and master key. These fields are dynamically populated before submission.

V. Post-Implementations

On the server-side, the views.py function processes the uploaded data. The function first verifies the file type to ensure only valid image formats are accepted. Invalid files trigger an error message, redirecting the user to the main page. If the file is valid, the *u*, *e*, and updated sigma map are stored using custom functions. The T map is always updated to ensure synchronization. The session indicator is updated, and the master key is stored in its respective file to maintain consistency across sessions. The integration of the FAST update protocol ensures that the system is secure and efficient while adhering to cryptographic standards. Testing confirmed the successful implementation of all features for single image uploads with FAST integration. The process of testing the single image upload functionality is documented through the Fig. 16, 17, and 18. These figures illustrate that the system performs correctly on a fresh setup, with a single image being uploaded successfully to the database and reflected in the sigma map. Following this, tests were conducted to check for stacking encrypted states and new fresh states, ensuring that the system handles multiple image uploads effectively. Fig. 19 and 20 document this process, where a second image with the same keyword and a completely new keyword were uploaded successfully, demonstrating the functionality of the single image upload form.

To expand the image upload feature, the system was enhanced to support the uploading of multiple images simultaneously. This involved creating a new form, as detailed in Fig. 21, which allows for the selection of multiple files. The key modification to this form was the introduction of the "multiple" parameters in the file input, enabling multiple file selections. This form is rendered just below the single image upload form, as shown in Fig. 22.

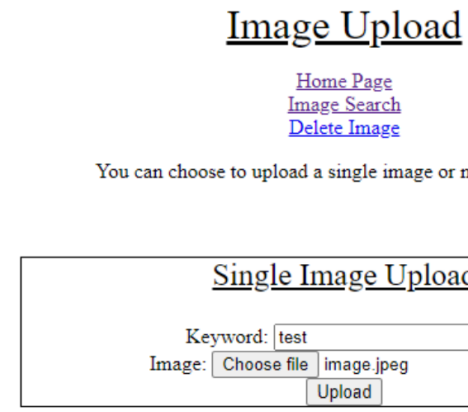

Fig. 16. Final try of uploading a single image.

Fig. 17. After the last attempt of uploading a single image, redirect.

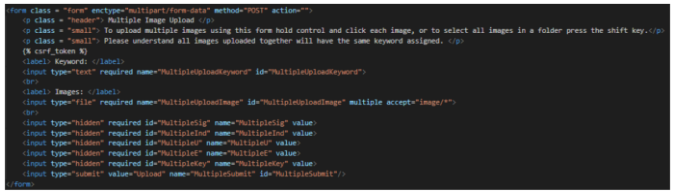

Fig. 21. Uploading multiple images from HTML.

[17]A JavaScript package called CryptoJS offers cryptographic methods for safe data encryption and hashing, including AES, SHA, and HMAC.

[18]A popular cryptographic hash algorithm for data security and integrity applications, SHA-256 generates a 256-bit result.

Fig. 22. A form for uploading multiple images was created.

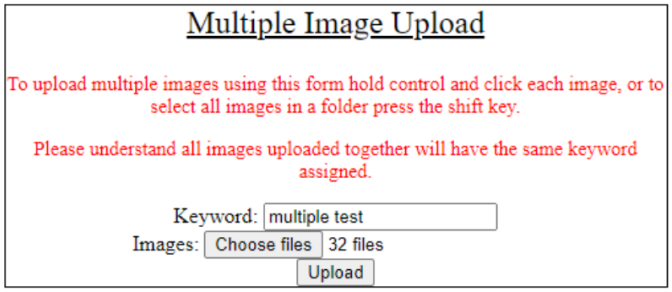

Fig. 23. HTML test for multiple upload forms.

To handle the multiple image uploads, a new event listener was implemented, which triggers a function named "multipleUpload". This function is responsible for processing the multiple files, where dictionaries are used to store the indices, *u*, and *e* variables from each file's update process. The update function was adapted to handle multiple uploads by iterating through each file, generating necessary variables, and sending them to the server. In the server-side processing, the images are validated to ensure that only acceptable file types are uploaded. If any invalid files are detected, the upload process is aborted. Once validated, the images are uploaded to the database, and the total time taken for the process is calculated. If any invalid file types are uploaded, an error message is displayed. This multi-image upload feature was thoroughly tested, and the system behaved as expected, accepting legitimate image files and rejecting non-image files, as shown in Fig. 23–26.

Fig. 24. Successful upload of the main page.

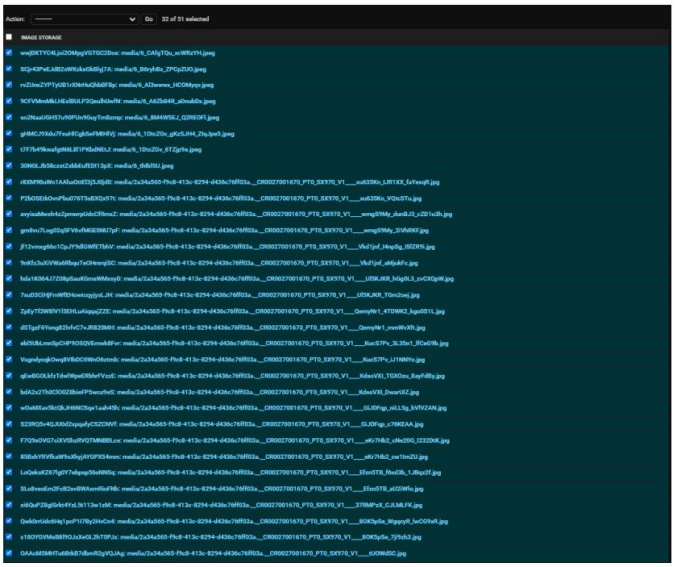

Fig. 25. The admin page displaying the images that were successfully uploaded.

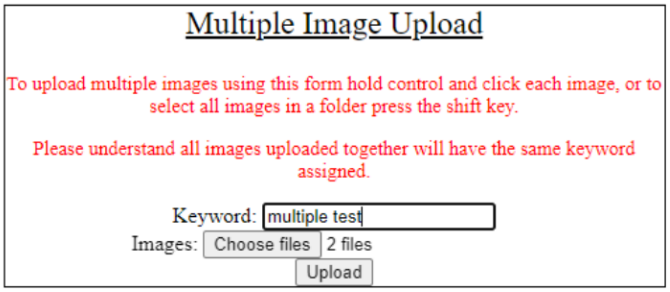

Fig. 26. Two text files are attempted to be uploaded.

The search functionality was developed using FAST to search for images in the database. The process began by retrieving the sigma map and master key from session storage. The search function was designed to send both the tag state and counter, along with an indicator specifying whether the keyword was already present in the sigma map. The server-side processing for the search involves retrieving the keyword, state, and counter from the POST request and performing a search through the sigma map. The search iterates through the states to identify whether the images exist and regenerates the previous states using the *u* and *e* variables. If no matches are found, a message is displayed indicating the absence of results. The system was tested using the "multiple test" keyword, successfully retrieving and displaying images, as seen in Fig. 27 and 28.

Fig. 27. Enter the search test keyword.

Fig. 28. Keyword search results.

The image deletion functionality was developed similarly to the image upload form but with a focus on removing images from the database. The process involved creating a search function to identify images associated with a keyword and then using a second form for deletion. The deletion form was triggered after a search, with the user selecting images for deletion. The image deletion process was handled by the "delIndexUpdate" function, which works similarly to the addIndexUpdate function but with an operation type set to "del". The server-side processing for deleting images involved iterating through the selected images, updating the corresponding data in storage, and deleting the images from the database. Upon completion, the system calculates and displays the time taken to delete the images. The deletion page was tested successfully, as shown in Fig. 29, 30, and 31, with the system correctly identifying and deleting the selected images from the database.

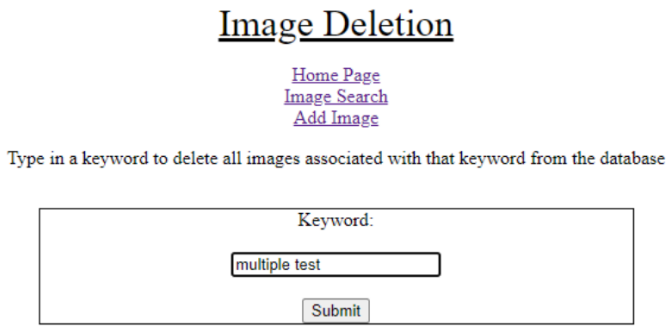

Fig. 29. Remove the image from the test.

Fig. 30. Remove the second form test image.

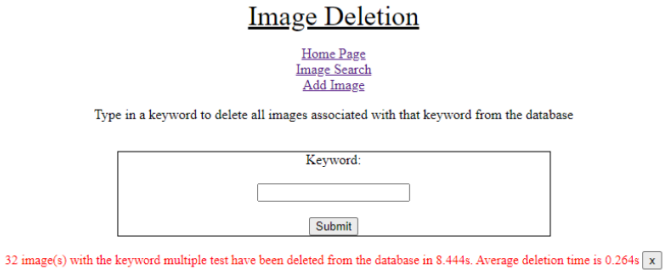

Fig. 31. Images were successfully removed.

VI. Experimental Results

This section outlines the performance results obtained from multiple runs of the program. To ensure consistency and reliability, each testing iteration began with a fresh setup, wiping the project clean. Images were added to the system using the "add image" page, keywords were searched using the "search image" page, and all images were subsequently deleted using the "delete image" page. These results were documented to reflect the implementation of all FAST protocols, along with the additional processing required by the system. It is expected that the performance results will be slower than the raw performance of FAST due to the additional overhead introduced by system-specific operations. It is anticipated that the average time taken per image would increase as the state lengthens. This is because longer states require more processing power to generate ciphertext, with the base64 ciphertext increasing in size with each iteration. For thoroughness, different keywords were alternated to store the images, and results were recorded in chronological order. Initial testing was conducted on a desktop computer with a quad-core i5 processor (3.4GHz) and 8GB of RAM. To provide a comparative analysis, the same project was tested on a laptop with a dual-core i3 processor (2.5GHz) and 16GB of RAM. The objective was to evaluate the impact of CPU speed and available memory on performance, particularly when handling larger datasets. The performance comparison between the two systems yielded expected results. Despite the laptop having double the RAM, the desktop's superior CPU speed compensated for the reduced memory. Both systems performed similarly when processing a comparable total number of images, with the desktop generally showing faster update times due to its stronger processor.

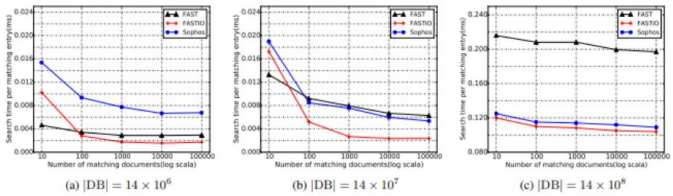
The average update times for the FAST update protocol are illustrated in Fig. 32. While these results indicate significantly slower performance compared to FAST's raw update times, this discrepancy can be attributed to the factor that the system's custom functions involve additional data handling, requiring adjustments to variables as they transition from client-side to server-side. This adds processing overhead to the system. Updating files necessitates clearing existing

data before rewriting, which further impacts performance. The results demonstrate that while the system's performance is slower than FAST's raw update times, this is an expected outcome given the added complexity of data manipulation and file handling. The comparative analysis between the desktop and laptop systems highlights the significant role of CPU speed in managing larger datasets, even when memory capacity differs. This provides valuable insights into the trade-offs between processing power and memory allocation in system performance.

		FAST	FASTIO	Sophos
Local	Throughput (ops/s)	54060	76100	4890
	Single update time (ms)	0.018	0.013	0.20
WAN	Throughput (ops/s)	21650	31080	2990
	Single update time (ms)	0.046	0.032	0.334

Fig. 32. FAST update time.

However, the image search functionality was tested by uploading a total of 2,877 images to the database and associating them with five distinct keywords. For each keyword, multiple searches were conducted, and the average search time was calculated. The overall average search time for a single image across all keywords was determined to be 28.696 ms. The search results obtained from the system were compared against the performance metrics outlined in [7]. Fig. 33 provides a reference to FAST's performance graph. Given the relatively small size of the database used in this study—due to limited computational resources—the comparison was made to the leftmost section of the graph, which represents the smallest database size used in FAST's evaluation (albeit still significantly larger than the database used here).



(a) $|DB| = 14 \times 10^6$ (b) $|DB| = 14 \times 10^7$ (c) $|DB| = 14 \times 10^8$

Fig. 33. Statistics on FAST search performance.

VII. Discussion

The results from my testing were significantly slower than the search times reported in [7]. This discrepancy can be attributed to several factors such as the computational power of the systems used for testing was limited, which likely contributed to the slower search times. The system performs extra processing during the search phase, including decoding binary strings and applying XOR operations to each character. This increases the computational workload significantly. To facilitate passing the XORed string to Python, a binary encoding file was introduced. Without this, Python would occasionally generate escape literals that caused the system to malfunction during debugging. Although the search protocol in this system exhibits slower performance compared to FAST's benchmarks, this is a reasonable outcome given the additional processing requirements and limited hardware capabilities. Furthermore, as the database size increases, the performance degradation becomes more pronounced. Nevertheless, the system demonstrates functional reliability and acceptable performance within the constraints of the testing environment. The results for image deletion were compared to the performance benchmarks in FAST's update protocol, as presented in Fig. 32. The average deletion time of 0.557 seconds per image is nearly 10,000 times slower than the single update time achieved in a WAN setting. This significant disparity is largely attributed to the additional processing requirements during the deletion process. For instance, accessing certain variables—such as the index—can only be achieved during this stage, which adds to the overall time. It is important to note that this time does not include the GET form on the deletion page. If included, its processing speed would align closely with the search page's results.

VIII. Conclusion and Future Works

Originally, the plan was to acquire the database, format it using MySQL Workbench or another MySQL software, and then begin storing data. However, this approach evolved once we became more familiar with Python's Django library. The library's functionality allowed for the creation of tables directly within the project using the Models.py file, which streamlined the process and made the database structure highly adaptable during the project's development. While the database functioned effectively and met its intended purpose, its performance was constrained by the computational limitations of the system. Specifically, the use of two slow virtual CPUs resulted in slower data storage times. Nonetheless, the database served as a reliable foundation for the project. The main page was designed to execute the setup protocol from FAST whenever a user accessed it. The implementation was expanded to save variables generated during the setup protocol into files, enabling sessions to be resumed later. This page was developed successfully, with the navigation bar providing seamless interaction with other pages. By organizing the protocols across separate pages, debugging was simplified. While the main page's development followed the original plan, it took approximately one week to complete due to initial challenges in understanding Django's file structure requirements. Specific directories and files needed precise organization to ensure functionality. This page required the most development time, taking approximately 1.5 weeks to complete. Initially, creating both a single-upload form and a multiple-upload form posed challenges in handling POST requests since both forms relied on the same HTTP method. Differentiating the requests required identifying the specific button used to send the request. Much of the time was spent debugging the communication between different pages rather than directly handling image uploads. While this page caused delays, its completion was a critical milestone in the project. The image search page was relatively straightforward to implement. The primary challenge was on the server side, specifically with regenerating data stored in the variable *e*. To address this, a binary encoding system was introduced, preventing character corruption across programming languages. The deletion page was comparatively easier to develop, as it leveraged the code from the add and search pages. By combining and adapting the algorithms from these pages, the final result allowed for deleting all images associated with a specific keyword from the database.

To tackle the computational complexity of advanced cryptographic schemes like FAST, future research should focus on hardware acceleration (e.g., GPUs, TPUs), algorithmic optimizations (e.g., efficient data structures, parallel processing), and lightweight cryptographic primitives to reduce processing time. Exploring distributed and decentralized architectures, such as blockchain or edge computing, can improve scalability and resource utilization. Additionally, integrating machine learning for predictive caching and adopting quantum-resistant algorithms will ensure the system remains efficient and secure in the long term.

IX. Declarations

A. Funding

No funds, grants, or other support was received.

B. Conflict of Interest

The authors declare that they have no known competing for financial interests or personal relationships that could have appeared to influence the work reported in this paper.

C. Data Availability

Data will be made on reasonable request.

D. Code Availability

Code will be made on reasonable request.

Department of Information Systems, King Abdulaziz University, Rabigh, Saudi Arabia[3]

***Abstract*—The goal of this examination is to identify key factors that enhance educational settings through innovative teaching methods and the integration of technology, emphasizing the transformative role of digital tools, particularly in mathematics and science education, and their impact on student engagement, problem-solving skills, and conceptual understanding. The increasing digitalization of education necessitates the adoption of pedagogical strategies that enhance both cognitive and emotional engagement, ensuring students develop critical thinking and long-term knowledge retention skills. Various educational theories, including Behaviorism, Cognitivism, Constructivism, and Social Learning Theory, are analyzed to demonstrate their relevance in both traditional and online learning environments. Emotional engagement is explored as a crucial element in learning, focusing on its connection to memory retention and cognitive development. Pedagogical recall is highlighted as essential for optimizing long-term knowledge retention, particularly in online and blended learning environments, while the effectiveness of different teaching strategies in fostering deep learning and sustaining knowledge over time is evaluated. The findings advocate for a holistic educational approach that integrates both cognitive and emotional factors, leveraging technological advancements and innovative pedagogical methods to create inclusive, adaptive, and effective learning environments. Continuous pedagogical evolution is necessary to address emerging educational challenges and enhance student success in an increasingly digitalized academic landscape.**

Keywords*—Emotional engagement; pedagogical recall; long-term knowledge retention; augmented reality in education; blended learning

I. Introduction

Augmented reality (AR) is transforming education by providing immersive and interactive experiences that enhance student engagement, understanding, and personalised learning. As educational curricula evolve, AR has emerged as a significant technological advancement that bridges the gap between theoretical knowledge and practical application. AR effectively boosts student motivation and engagement by converting abstract concepts into tangible experiences, which promotes deeper learning and underscores the importance of long-term knowledge retention [1]. The evolution of educational practices and settings reflects the broader societal changes and technological advancements that continue to shape our world. In this dynamic landscape, enhancing educational environments is not just a goal but a necessity, as it plays a crucial role in fostering comprehensive learning experiences that cater to the diverse needs of students. Research highlights the importance of child-centered practices in early childhood education, which are vital for promoting overall development, including mental health and self-efficacy [2]. Such practices create a nurturing environment that supports the holistic growth of children, laying a strong foundation for their future learning endeavors.

The integration of digital tools in educational settings has emerged as a transformative factor, particularly in subjects like mathematics and science. These digital tools facilitate deeper engagement with complex concepts, enhancing students' problem-solving abilities and overall understanding [3], [4]. This infusion of technology has made education more interactive and accessible, breaking down traditional barriers to learning and allowing students to explore and grasp abstract concepts in a more tangible way. In the field of English as a Second Language (ESL) education, social media has proven to be an effective tool for increasing academic motivation and engagement. Social media platforms provide students with additional opportunities to practice language skills in real-time, thus enhancing their learning experience outside the conventional classroom setting [5]. This approach fosters greater engagement and helps build a supportive community where students can share knowledge and resources. Moreover, orientation programs at universities are essential for facilitating students' transition into higher education. These programs play a significant role in helping new students acclimate to the academic and social demands of university life, which positively impacts their academic performance and social integration [6]. Such initiatives are particularly important for supporting students who may feel overwhelmed by their new environment, helping them develop a sense of belonging and confidence. The shift towards e-learning and the widespread implementation of Learning Management Systems (LMS) have revolutionized the educational landscape. These systems provide a flexible and accessible platform for learning, accommodating a diverse student body with varying needs and schedules [7]. E-learning platforms allow students to engage with course materials, contribute to discussions, and complete assignments at their own pace, making education more inclusive and tailored to individual learning styles. The discussion on improving educational contexts also highlights the importance of addressing issues concerning cultural beliefs and practices at schools. For instance, debates on ability

grouping and growth mindset development insist on using equitable educational practices that allow all students to fully realize their potentials without bias or imposition of limitation [8]. Besides, it is rather important to point out that in the case of traditional face-to-face classrooms, as well as Web-based online learning environments, knowledge transfer has been significantly effective due to instructor-student-course-content interaction [9]. This emphasizes designing interactive and engaging educational experiences for students with diverse learning needs.

Leadership in education also plays a key role in shaping learning environments. Competent school leaders contribute much to creating a culture of continuous professional learning and academic success, creating spaces where both educators and students alike can thrive [10]. Moreover, strategic planning in educational programs-consider medical education, for example-is crucial in developing learning environments that support clinical training and professional development [11].

The continuous improvement of educational settings is essential in preparing students for future challenges. The integration of technology, the adoption of innovative teaching methods, and the implementation of supportive educational policies are key components in building inclusive, effective, and adaptable learning environments [12]. Additionally, educational innovation—particularly through the development of "innovative environments" is instrumental in improving the quality and effectiveness of academic content, particularly in higher education [13].

Educational technology policies play a critical role in ensuring inclusive, high-quality education by promoting the integration of information and communication technologies (ICTs) and innovative teaching practices [14]. As the educational landscape continues to evolve, it is essential to explore new strategies and methodologies that address the diverse needs of students, equipping them with the knowledge and skills necessary for academic and professional success [15].

A. Organization of the Paper

The remainder of this paper is organized as follows:

1) Background and significance of enhancing educational settings: Debates about changing educational environments for the better-supporting technology, digital tools, and innovative type of teaching methods.

2) Overview of relevant theories in education: Explores foundational educational theories, including Behaviorism, Cognitivism, Constructivism, and Social Learning Theory, and their relevance to modern education.

3) Effective teaching methods: Outlines methods of improving learning outcome possibilities across different subject areas with intense emphasis on engagement, retention, and adaptability into varied teaching contexts.

4) Emotional engagement in classroom education: Highlights the role of emotions in education, examining their impact on cognitive and emotional engagement, memory retention, and learning outcomes.

5) Pedagogical recall knowledge: Discusses the importance of recall in pedagogy, focusing on technological pedagogies, teacher training, and adaptation to online and blended learning.

6) Long-term recollection in education: Explores strategies to enhance long-term memory retention, including pedagogical approaches, emotional engagement, and innovative techniques.

7) Discussion: Research findings are analyzed, gaps and limitations are identified, and suggestions are outlined for future research.

8) Conclusion: The findings are summarized, with a stress on the complementarity of emotional engagement and innovative pedagogies in achieving maximum effectiveness in education.

II. Background and Significance of Enhancing Educational Settings

Enhancing learning environments is critical in the development of comprehensive learning experiences and addressing the diversified needs of learners. Child-centered approaches in early childhood education are crucial in building children's overall development, for instance, their mental health and self-esteem [16]. The use of technology in math and science disciplines enhances learners' abilities to manage complex concepts, thereby fostering problem-solving skills and comprehension [17].

In ESL learning, the use of social media has been effective in enhancing academic motivation and engagement, offering further possibilities for language learning [5]. Likewise, university orientation programs play a critical role in easing students' transition and adjustment, having a great influence on their academic performance and social integration [18]. The transition to e-learning and the global use of Learning Management Systems (LMS) have transformed education, making learning more flexible and accessible to diverse learners [7].

The conversation concerning cultural practice and beliefs in the learning context, as with methods like ability grouping, refers to the necessity of establishing equitable education opportunities and growth mindsets [19]. Transfer of knowledge, through traditional classrooms or online platforms, is considerably subject to interactions between teachers, students, and learning material itself [20]. Leadership in the education sector is also a significant factor, where effective school leaders create learning settings that support professional development and academic achievement [10].

In medical training, the application of strategic planning is crucial for the creation of learning environments that are conducive to clinical training and professional development [21]. A research exploring SARS-CoV-2 transmission in Australian schools highlights the importance of ensuring safe and secure environments in pandemics to facilitate continuity of education [22]. Furthermore, the adoption of interactive platforms such as HTML5 Package in tertiary education has been shown to have great enhancement in learning outcomes, thereby showcasing the role of technology in augmenting learning experiences [23].

Online learning environments play an effective role in academic achievement and student satisfaction through flexible and varied learning experiences [24]. Holistic frameworks of AI policy education are preparing students with adequate skills for using AI responsibly, thereby empowering them to address future challenges [25]. In Cambodia, the establishment of initiatives for the improvement of education quality testifies to Cambodia's dedication to human capital growth and its integration into the ASEAN community [26].

The emergence of Generative Artificial Intelligence (GAI) within the educational sector introduces novel opportunities for individualized learning experiences and automated feedback mechanisms, thus necessitating a thorough investigation into its lasting consequences [27]. In the context of Sweden, the focus on research-oriented education, combined with the difficulties educators encounter when translating academic knowledge into practical application, highlights the necessity for ongoing professional development and support [28].

The evidence accumulated altogether stresses the necessity of improving learning environments. They point out the central role of technology, new pedagogies, and enabling education policies in creating inclusive, effective, and adaptive learning environments to equip students to face future challenges (see Fig. 1).

Tool/Approach	Purpose	Impact	Strength	Limitation
Digital Tools (e.g., Math and Science)	Engage complex concepts	Improve understanding	Visualize abstractions	Needs infrastructure
Social media in ESL Education	Increase motivation	Encourage practice	Peer collaboration	Can distract students
Learning Management Systems (LMS)	Flexible learning	Schedule adaptability	Self-directed learning	Lacks engagement
Orientation Programs in Universities	Help transition	Foster retention	Build community	Short-term focus
Interactive Tools (e.g., H5P)	Interactive content	Increase engagement	Active learning	Time-consuming creation
AI Policy Frameworks	Ethical AI use	Promote responsibility	Critical thinking	Early development
Generative Artificial Intelligence (GAI)	Personalized learning	Tailored feedback	Real-time adaptability	Privacy concerns
Online Learning Platforms	Flexible learning	Boost satisfaction	Learn anywhere	Lacks interaction

Fig. 1. [5][7][23][27] Summary of educational tools and approaches, highlighting their purposes, impacts, strengths, and limitations.

III. Overview of Relevant Theories in Education

Learning theories are essential frameworks for comprehending the processes of learning among students and the teaching approaches that can be adopted to promote effective learning. Among these, Behaviorism and Cognitivism are two of the most significant theories. Behaviorism is concerned with observable behavior and the consequences of reinforcement and punishment and is particularly valuable for classroom management and instructional activity planning [29]. Cognitivism, by contrast, explores the internal mental processes of learning, including memory, perception, and problem-solving. This theory emphasizes the pressing necessity for knowledge of information processing and storage mechanisms, which is necessary for the creation of efficient educational strategies [30].

Constructivism posits that students learn by actively constructing knowledge from their experiential interactions and experiences with the environment. Founded on the seminal works of Jean Piaget and Lev Vygotsky, this theory emphasizes social context and the collaborative process in the learning experience. It has been applied extensively in diverse learning environments, for example, special education, where it enables personalized and differentiated instructional approaches [31]. It is also significant in online and technology-enhanced learning environments, offering scaffolding upon which learners can expand existing knowledge and engage actively with new material [32].

Social Constructivism takes these concepts further by focusing on the social aspect of learning. The theory contends that knowledge is built collectively through social interaction and cultural environments, thereby underlining cooperation and dialogue. It defies customary teacher-centered approaches with a recommended student-centered approach promoting critical thinking and problem-solving capabilities [33]. Social Constructivism finds particular application in e-learning systems, where interaction and community building are essential parts [34].

The Social Learning Theory and Connectivism significantly enhance our comprehension of the learning process. Social Learning Theory focuses on the strength of observing and emulating behaviors, attitudes, and emotional reactions, thereby underlining the centrality of social forces and learning environment context [35]. Connectivism, by contrast, focuses on digital networks and information sharing, underlining the value of obtaining and linking knowledge that is dispersed on different platforms [36].

The convergence of Educational Technology theory and conventional learning theories has resulted in a more coherent understanding of learning. This kind of harmonization serves to meet the varied needs of learners through the creation of an active and interactive learning process [37]. Theoretical models such as the Information System Success Model (ISSM) find application in the measurement of user satisfaction and e-learning system success, with a demand for aligning technology tools and teaching objectives [38] (see Fig. 2).

Together, these educational theories offer insight into the development of instructional strategies that address various learning styles and preferences. The implementation of these theories into educational practice enables instructors to develop more effective, inclusive, and engaging learning environments, and consequently, a better learning experience.

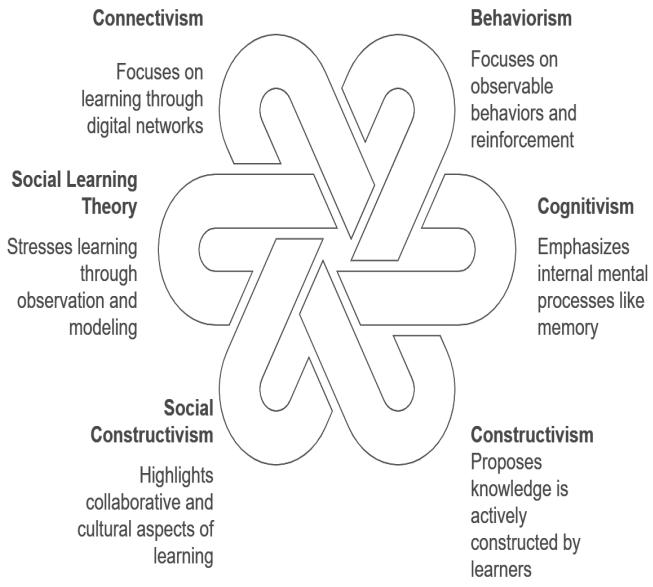

Fig. 2. [29][30][31] Cycle of effective teaching methods.

IV. Effective Teaching Methods

Good pedagogy plays a key role in accelerating student engagement, learning attainment, and overall learning experience in every subject. In medical education, innovative approaches such as Audience Response Systems and distance learning have been shown to enhance student engagement and student retention. These approaches facilitate active learning that is fundamental to attaining complex medical knowledge and skills [39]. Besides, the use of case studies has also proven to be effective in medical education as it allows students to use theoretical knowledge to solve real-life scenarios [40].

In the field of educational technology, instructional methods that take advantage of group-based and interactive learning—such as group projects and simulations—significantly enhance learning efficacy. These methods foster collaboration and cooperation among learners, thereby enhancing their capacity to engage with course content in a meaningful way [41]. In addition, blended design models that merge online and conventional classroom learning have also been very successful in higher education, offering greater flexibility and an improved tailored learning experience [42].

In learning English, strategies like translation and use of dictionaries facilitate vocabulary learning. These strategies, though, might not adequately develop essential skills such as listening and speaking [43]. Alternatively, Communicative Language Teaching (CLT), which focuses on functional communicative competence, has been known to be an effective method for developing linguistic competence among learners [44].

Knowing various teaching methods is essential in the teaching of languages. Understanding the distinction between teacher-centered and student-centered teaching assists the teachers in customizing teaching methods to suit the varying needs of the learners [45]. Additionally, incorporating cultural competence in language teaching renders teaching more enjoyable by ensuring lessons are more applicable and interesting [46].

In business education, good pedagogical practices embrace technology, virtual classrooms, and the educator's pedagogical style. These factors are critical in developing vibrant and interactive learning environments that equip learners with skills to handle real-world problems [47]. The heightened use of online teaching and interactive resources, particularly during the COVID-19 pandemic, has accelerated the demand for versatile and accessible learning solutions [47].

Evaluation methods are at the heart of teaching. Newer assessment strategies like formative assessment and peer assessment yield essential feedback that facilitates learning for students. Instructor feedback is especially vital in facilitating student development and motivation since it enables students to determine areas of improvement while also acknowledging their strengths [48].

Moreover, the promotion of critical thinking within the learning environment is a key component of effective pedagogy. Problem-based and inquiry-based learning strategies provide opportunities for students' critical and analytical thinking to be developed. Student-centered learning, as a learner-focused approach to meeting individual needs and interests, has been shown to raise academic achievement and student motivation [47].

Last but not least, interactive teaching approaches, i.e. discussions and hands-on activities, have demonstrated enhanced motivation and participation of students. Such approaches render the learning process more entertaining and assist in improved knowledge retention [49] (see Fig. 3).

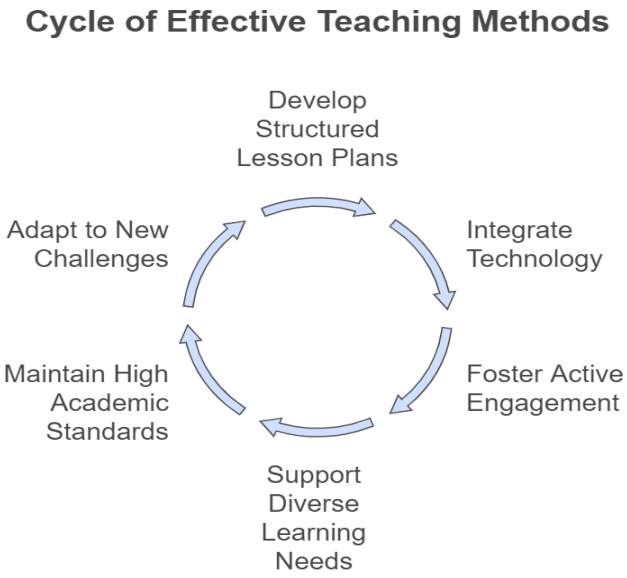

Fig. 3. [39][45][48] Cycle of effective teaching methods.

A. Importance of Effective Teaching Methods

Successful pedagogy plays a vital role in strengthening student interest, academic performance, and learning experiences in subject areas. Besides transmitting information,

these pedagogies build inspiring and supportive learning environments with high academic expectations that foster more integrated comprehension. Lesson plans framed with the aid of theory, such as constructivist theory, raise the level of teaching through greater interactivity and reflectivity in learning. This method promotes active interaction of students with the learning material and enables the practical implementation of their knowledge, which results in a better understanding [50].

Blended and online learning modalities have become increasingly significant, particularly as a measure to counter the COVID-19 pandemic. They provide flexibility and enhance accessibility, enabling students to pursue their studies regardless of physical constraints. Utilization of Information and Communication Technology (ICT) in these contexts allows content dissemination as well as facilitating student interaction and engagement [51]. Furthermore, effective online learning is also characterized by frequent student-faculty communication and active learning principles, which are crucial for maintaining student motivation and academic integrity [52].

In the teaching of mathematics, effective pedagogies are vital for the development of critical thinking and problem-solving abilities. Establishing a community of practice in which students interact and share stimulates their learning of intricate mathematical concepts as well as their application in various contexts. Such a strategy not only improves analytical capabilities but also instills a sense of belonging and motivation [53]. Likewise, in medical imaging and deep learning, efficient teaching methods, i.e., models such as COVIDX-Net, offer cost-effective and precise learning content. Such methods allow students to interact with advanced technological tools and comprehend their practical uses within actual environments [54].

Construction of well-designed lesson plans and instructional strategies constitutes a fundamental aspect of good teaching. A well-designed lesson plan, having explicitly stated objectives, activities, and assessment methods, has the potential to greatly improve the learning outcomes of students. The organized nature of such an arrangement guarantees that learners are not just exposed to theoretical concepts but also to practical uses [50]. In addition, these strategies cater to different learning requirements, thereby rendering education inclusive and accessible to all learners [55].

Good pedagogy principles are also crucial in upholding high standards and inspiring students, as seen in the seven principles of relevance to e-learning. The principles emphasize the need for active involvement and ongoing interaction between students and teachers, which are central to the success of online learning [56]. Their incorporation into instructional designs guarantees students a well-rounded education, thereby preparing them with the skills to overcome future challenges [57].

In brief, effective teaching strategies are an elementary aspect of quality education. They enable the formation of basic skills, ensure active participation, and offer a coherent learning experience. Through continuous adaptation and adjustment to emerging challenges in education, for example, the proliferation of online learning and the application of new technologies, instructors can ensure their teaching strategies remain relevant and useful. This kind of flexibility is necessary to provide students with the competencies needed to answer the demands of current society and attain sustainable educational and professional success [58].

V. Emotional Engagement in Classroom Education

The inclusion of emotions in classroom settings is of paramount importance for better education. Different studies have examined this very point, showing that emotional engagement is an important factor in learning. Hargreaves is a case in point and he describes that the teacher-student emotional relationships create a very encouraging and engaging learning environment which further enables the academic and social results [59]. Dubovi also proves this by sharing with us that feelings such as joy and enthusiasm, which are the ones that usually exist in educational surroundings, are directly associated with the cognitive and emotional engagement of students and their levels become quite high [60].

In the field of language learning, Alomaireeni points out that EFL teachers, who use different emotional inputs through the senses like touch and hearing, among others, are able to see vocabulary retention and students' performance in exams improve noticeably [61]. Similar to this, Shaheen says it was observed that when the play-way method was made use of in the early childhood education, it not only increased the cognitive skills but also created a happy atmosphere thus leading to better memory retention and subsequently to better academic performance [62](see Fig.4).

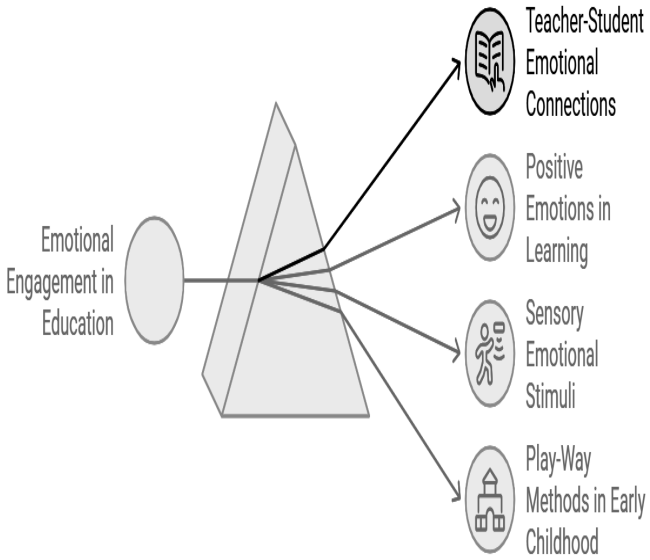

Fig. 4. [59][60][61] The power of emotions in education.

A. The Cognitive and Emotional Engagement

Dubovi argues that positive emotions can be significantly augmented for the cognitive engagement and learning

outcomes of virtual reality (VR) learning environments [60]. This goes in line with the study of Kindt and Elsey that investigates the possibility of using drug interventions to interrupt emotional memories, which might then disarm emotions such as fear and anxiety. Their results point to the significance of building a supportive learning environment that not only lowers tension but also connects with students on a deeper level through memory aiding techniques [63].

In the work of Alomaireeni, the angles of EFL teachers on emotional engagement in teaching are shown from the other side, and we can see that non-traditional strategies, such as engaging emotions through senses, are better for retention and comprehension [61]. Along the same line, Shaheen puts an emphasis on play-based learning as an effective method for early childhood education and mentions that this learning supports the process not only promoting students" positive emotions but also enhances the cognitive skills and memory retention that are involved in the process [62].

Furthermore, research such as the ones by Araújo and Almondes have discovered the fact that integration of emotions in education can decrease anxiety and boost the learners' motivational level [64]. Especially Math and Sciences are the subjects that students usually find hard to master hence the teachers may engage the students' emotional side which can help to clarify complex issues and encourage an enjoyable learning experience. Rahayu would inquire about the impact of emotions in the teamwork and would often mention that it is a pivotal aspect that can level the effectiveness of group work [65]. Ramos's article is an emotional study of the language learning process, which is showing a clear link between emotions and student transfer and the student's ability to understand the material [66]. The studies collectively underscore the importance of emotional engagement in educational settings, advocating for pedagogical approaches that actively incorporate emotional elements to foster a holistic and effective learning environment [67][68].

VI. Pedagogical Recall Knowledge

The concept of pedagogical recall knowledge, which encompasses the retention and application of effective teaching strategies, is critical for educational success across disciplines. It highlights the importance of educators' ability to recall and apply past teaching experiences and strategies effectively [69].

A. Practical Knowledge

Chaharbashloo examined the significant types of practical knowledge among the excellent primary school teachers of Iran, reaffirming the importance of experience-based recall in the own teaching of the Iranian exemplary teachers present in study [70]. On the other hand, Mathers also explored the procedural knowledge in early childhood education by employing the Observing Language Pedagogy (OLP) tool with a focus on how teachers aid children's language development. The study stresses the importance of recalling certain teaching methods in order to provide a better experience of learning inside the classroom [71].

B. Game-Based and Technological Methodologies

In-game learning could positively impact students' cognitive development and help them retain knowledge more effectively in secondary school is something that Akhmetova demonstrated. The In Search of Treasure game is one such case [72]. More specifically, integrating AR into physics education has been proven to increase student confidence levels and motivation significantly. Specifically, AR makes abstract physics concepts more real and thus interesting and easily understandable. By bringing immersive and interactive learning experiences, AR not only makes learning fun and exciting but, through gamified interfaces, keeps students engaged and motivated, providing a transformation from traditional education to a more agile and impactful one [73] [74].

C. Specialized Knowledge and Training

Yuldashev emphasized that pedagogical knowledge for recall is of paramount importance when it comes to military training and for effectively transmitting specialized knowledge [75]. This idea was emphasized by Khatsaiuk: the mindful recall of specific pedagogies in teaching specialized subjects of military training highlights the importance of target-specific pedagogies for efficient learning. For instance, studies stress the inclusion of special physical training methods and modern technical aids for the readiness of military cadets and officers for particular jobs [76]. Also, Mao argues that the application of project-based instructional methods turned out to be very effective in military vocational education since it develops problem-solving skills and enhances practical operation abilities [77].

D. Teacher Training and Pedagogical Content Knowledge (PCK)

Ahmed & Shogbesan explored the role of PCK in teacher training, and showed that a strong foundation in PCK enables teachers to recall subject-specific teaching methods and apply them very effectively [78]. Chaharbashloo and Ahmed further accentuated the need for practical knowledge, not just in educational contexts, but for teaching proper [70] [79].

E. Adaptation to Online and Blended Learning

Adaptation to online and blended learning is more than just transforming content into the digital dimension; it is a purposeful mixture of technology and teaching method. According to Akhmetova, game-based learning with the use of interactive tools will foster cognitive development, thereby making online teaching appealing and efficient [72]. Mathers mentions how video assessments act as an important tool in acquiring procedural knowledge for students to learn in a structured yet flexible way [71]. Sardorxon, on the other hand, further stresses the balance between theory and practice on the digital learning environment, as it relates to the education of students [75]. These insights about successful online and blended learning highlight the need for interactive content, quality assessment tools, and teaching methods that successfully bridge the realms of digital and traditional classrooms.

F. Effectiveness of Teaching Methods

Finding appropriate teaching methods is crucial for supporting deep learning and anchoring students in the subject. According to Weng, design-based learning (DBL) enhances students' problem-solving capabilities, critical thinking, and motivation-the effective elements of deep learning-and is found to be more effective for these areas of deep learning [80]. The active nature of DBL, engaging students in iterative design processes, not only develops their analytical skills but also provides them with rich hands-on and immersive experiences.

Saeedian uses quite a different approach and looks into how Scenario-Based Classroom Context Models are changing nonnative teachers' decision-making and revising of teaching practice. Through video-stimulated recall processes, teachers can develop a more comprehensive understanding of their classroom behavior and thus refine their teaching practice [81].

Nijenhuis notes the importance of instructional approaches aligned with student needs in computer science education. This study also emphasizes the role of discussion and reflection in facilitating the access and understanding of complex topics such as algorithms [82].

Nilsson identifies that effective teaching rests not merely on content knowledge but on the conjoining of content knowledge with pedagogic skills and grounded theories of teaching and learning. Reflective practices would support these teachers in contemplating their own practice in a way that better prepares them to adapt and transform their own teaching styles [83].

All the studies signify that effective teaching cannot be prescribed for all. Rather, it depends on hands-on design projects, reflective-approach teaching models, or interactive discussions, engaging students and supporting them to engage in deep learning. Karatas worked on various strategies that were to be meaningful in enhancing long-term memory and gains in the learning process, especially in recalling pedagogical methods inducing a deep learning experience [84]. Weng looked into design-based learning, which supported deep learning through the recall of design principles [80]. These studies underline the importance of recalling pedagogical means so as to enhance deep learning and retention of knowledge by students. Tan described knowledge transfer on both online and offline environments wherever recall supports the adjustment of teaching practice along different educational contexts [9]. Telli elaborated on the application of mobile AR in cultural heritage education, underlining the importance of recalling specific technological applications to improve students' learning experiences [85].

VII. Long-Term Recollection in Education

A. Pedagogical Approaches

Memorization retains a significant role with students in education contexts so that they can learn and recall information over time. Numerous research has explored various strategies to help improved long-term retention of information, thus showing what really works best for students when it comes to lasting learning. For instance, Dai found that animated characters acting as pedagogical agents can make a real difference in helping students remember information better [86]. Zhong et al. took a different approach, focusing on memory-augmented techniques that boost recall [87], while Earhart et al. demonstrated how repeating key learning experiences in stages significantly improves children's memory [88]. Likewise, Kurniarahman demonstrated how mnemonics-all those clever memory tricks-enhanced vocabulary retention among students [89], while Ji focused on the fact that retention is better for active participants in learning through the flipped classroom model [90].

AR widely contributes to this area. Alhebaishi says that the interaction of both sensory engagement and the visual storytelling creates compelling learning experiences that never die. No doubt, AR could be used for instant understanding, but true efficacy will be found in embedding that information over the long haul. Making things highly immersive and interactive will build stronger virtual mental models with students for ultimately easier retention of deep-seated concepts and spatial relationships [1]. Emotional Engagement is another strong aspect of memory retention. Hwang mentions that when we are feeling some kind of emotion during the process of learning, those bits of information engrain themselves in our minds for a longer period. Wang shows how affective pedagogical agents inside multimedia environments can promote retention even more [91]. Fanguy et al. noted that collaborative note-taking significantly fortifies memory, while Schmidt established the fact that emotional events occurring in learning sessions have direct importance on the ability of the students to recall information [92]. Fanguy also stated that the presence of "desirable difficulty" was beneficial for supporting long-term memory [93]. At the same time, Ingibergsson emphasized how music in classrooms creates a more engaging atmosphere for students in learning, while van der Kaap confirmed that emotional involvement is key to developing memory retention in children, thus calling for designing learning environments that would connect with students emotionally [94].

B. Classroom Environment

The environment of learning is quite critical in contributing towards a student's retention of what is learnt over a long period of time. Forsberg reiterates the point stressing that repetition over time guarantees the permanence of memory [95]. Ji et al. commented how a supportive classroom environment can make a big difference while Earhart investigates how classroom dynamics influence retention of memories [88]. These three studies, then, go a long way in proving a point about how it should be to create a learning environment, which is truly engaging and memory enhancing.

1) An Assessment and feedback: Constructive regular testing and feedback do not only assess students but also enhance their long-term memory. Frequent assessments strengthen recall capabilities by maximizing the resources available in working memory, according to Krasnoff [96]. Mocko went further to demonstrate that repeated testing and mnemonic techniques can boost retention significantly when applied in complex content areas [97]. Drawing as a hands-on activity is a demonstration that strengthens memory long-term; hence, it enhances learning and memory [98]. Schmidt also gives a very different view on how testing and feedback can modify recall bias brought about by individualistic personality traits, and this eventually translates into better learning acceptance [92].

2) Open and innovative techniques and tools: A new teaching strategy and tools are changing students' methods for substantial retention of information. Mind-mapping is a state-of-the-art strategy for vocabulary learning, as determined by Feng [99]. Santos, however, emphasizes drawing in enhancing retention of memory in language classes. Digital storytelling has been discovered very empowering in enhancing recall among learners, according to Nemanich [20], while Pham postulated that gamification would keep students internally motivated while boosting retention [100]. Cai dubbed AR as a booster of self-efficacy in all learning aspects and memory retention as applied in physics education [101]. Meanwhile, Mina discussed that experiential learning mainly gives the chance to bring the students away from their mistakes towards the realization of their progress and leads to the understanding of better lessons through self-reflection, which indeed solidifies long-term memorization [102].

It is the discoverable consensus that learning becomes effective when it is interactive, engaging, and within the realm of constant feedback; learning under such conditions clearly affords a better guarantee of retention for whatever the students have learned.

VIII. Discussion

Emotional involvement in education can make learning experiences more meaningful and memorable. By appealing to emotions, educators are able to instill in their students a sense of belonging, which increases motivation and strengthens memory. But one of the biggest challenges is that emotions are very personal-they are shaped by individual personalities, cultural backgrounds, and past experiences. This variability makes it difficult to develop one-size-fits-all strategies that consistently improve academic performance. While emotional arousal can be a potent lever for learning, an overemphasis on emotions at the cost of core content has the risk of shallow, rather than deep and lasting, knowledge.

One recent innovative take on inducing emotional arousal is the use of background music as a sensory cue to enhance memory retention. It therefore helps the students associate with the learning material more, since music may express emotions. Learners are likely to remember information later on once they associate a given lesson with an emotional atmosphere created by music. This relates to the aspects of research that indicate sensory engagement—such as sound, visuals, even movement—is key to memory. However, the selection of music should be an act of deliberation; the wrong kind of background music can become a distraction rather than an aid, which again calls for thoughtful implementation.

Aside from the fact that it can be used to elicit emotion, what is important to discuss is how joy-and the emotions that breed it-can be intentionally evoked in learning spaces. Joy doesn't just turn up; rather, it's born most often from curiosity, surprise, or a sense of accomplishment. Storytelling, gamification and collaborative learning are the most effective triggers of such emotions, creating a chain reaction which will help deepen engagement. The moment students feel curious or excited, they're most likely to transition into a joyful learning state that reinforces their connection to the material.

These emotional pathways are important in helping the educator design a strategy beyond superficial approaches. Research into how certain teaching methods or environmental cues evoke emotional responses informs the development of targeted strategies that further both learning outcomes and student well-being. Research into these processes may unlock new ways to connect emotional triggers with long-term knowledge retention, making learning both effective and durable.

Despite its potential, emotional engagement remains underexplored for the long term, with most research focused on immediate benefits: motivational increases and immediate recall. There is a lack of empirical data regarding how far these strategies impact memory retention and academic success over a longer period of time. This points to two important questions: whether emotionally engaging lessons really lead to long-lasting knowledge and how the balance between emotional appeal and academic depth should be achieved.

Even with these uncertainties, emotional involvement holds immense promise, especially regarding the more complicated or abstract idea to make more relatable. Besides academic achievements, it encourages soft skills including empathy, resilience, and emotional regulation-qualities equally important in today's world. Approaches such as storytelling, positive feedback, and supportive classroom settings have the potential to decrease levels of stress, allowing students to understand and remember their learning more effectively.

Innovations such as AR and gamification further enhance learning through creating immersive experiences in which cognitive and emotional processing is maximized. While research in these tools continues to grow, much more research will be needed on their benefits and their limitations. This allows the continued growth in educational technology to realize a real opportunity for adaptive learning tools tailored to students' unique emotional and cognitive needs.

It's all a question of balance-emotional with intellectual, augmented by technology in service of tailoring inclusive learning environments. Additionally, There is a need to understand the long-term effects of these interventions. By coming to a clearer view of exactly how emotions facilitate learning, we are able to develop learning experiences that will yield better academic performance but also serve to prepare learners for the emotional and intellectual vagaries of life in the modern world.

IX. Conclusion

The research underscores the core significance of emotional investment, creative pedagogy, and technology in fostering deep learning and long-term retention. By assessing various pedagogic approaches and integrating technology-based learning strategies, the findings highlight the importance of creating adaptive and student-centered learning environments.

Affective engagement demonstrates strong potential in supporting cognitive processing, enhancing memory, and improving overall learning performance. Storytelling, gamification, and interactive technologies, particularly augmented reality, play a crucial role in generating motivation and engagement among students. Additionally, recollection

pedagogical knowledge emerges as a major predictor of long-term knowledge retention, especially in blended and distance learning contexts.

Interactive pedagogies such as collaborative learning and problem-based teaching contribute to the development of critical thinking and problem-solving skills. Integrating cognitive and affective dimensions of learning promotes a balanced approach that combines systematic content presentation with emotionally engaging learning experiences.

As the educational landscape continues to evolve, ongoing pedagogical innovation and research into the extended effects of emotional engagement and technology interventions are essential. Future studies should explore the long-term impact of these strategies on knowledge retention and their systematic incorporation into diverse learning environments. By leveraging emerging educational technologies and evidence-based teaching approaches, educators can create inclusive, responsive, and effective learning spaces that prepare students for the challenges of the digital age.

***Abstract*—The construction industry is central to the advancement of economic growth all over the world but it has various problems in risk management especially concerning sustainable construction projects. Standard risk management techniques like AHP and Monte Carlo simulation do not afford the flexibility and accuracy needed in construction sites. Based on the identified limitations, this study offers a new system of risk assessment that combines Artificial Neural Networks (ANN), Fuzzy Logic, and Internet of Things (IoT) technologies. Real-time IoT sensor data and historical project data are integrated into a real-time and adaptive system which can identify, suggest, and minimize potential risks for improved decision making. The ANN component is distinctive in pattern recognition and risk prediction while Fuzzy Logic brings ease of interpretation and reasoning in the uncertain environment. Raw IoT data are live data which may be processed and updated frequently relative to the devices and their environment. The effectiveness of this framework can be ascertained through experimental proof; the framework's accuracy is 92.7%; project delay and cost have been minimized. The results reveal that the presented framework is highly resistant to noise, and its performance changes fairly slowly if the project requirements change. This integrative approach ensures the identification of the comprehensive solution for the sustainable construction risk management, which may help with the development of the safer, more efficient and non-harmful to the environment construction techniques.**

***Keywords*—Risk assessment; sustainable construction; artificial neural networks; fuzzy logic; predictive analytics**

I. Introduction

The construction industry remains a significant industry of global economic growth and development since most of the world economy relies on employment, infrastructure, and GDP [1]. Sustainability has emerged as an essential consideration in construction projects, which means that they have to respond to the consequences of environment on them as well as on society and the challenges of integrating contemporary technologies [2]. Green construction projects that embody efficiency and utilization of resources, minimal energy wastage and environmental impacts offer projects that are hard to evaluate using conventional risk assessment models.

The conventional risk assessment tools including the AHP and Monte Carlo Simulation are historical based and rely on the experts, crew and are manual in nature [3]. Even though such methods have been proven useful for decades they lack the ability to solve the flexible and intricate problems of the contemporary construction business. For instance, these approaches cannot easily respond to the dynamic environment characteristic of construction sites, for instance, material unavailability, unfavorable climate, or delays due to the supply chain [4]. In addition, decisions made from these models rely on human intuition hence are characterized by subjectivity; this causes inconsistency.

AI has revolutionized one field or the other by offering more sophisticated means of data processing, forecasting, and control. In construction industry, risk assessment using AI approaches such as Artificial Neural Networks (ANN) has been shown to offer a high level of rate prediction [5]. These models perform best when the need is to analyze big data, recognizing patterns, and providing risk assessments. Nevertheless, despite their strengths, AI methods that are implemented independently of each other can encounter such issues as lack of interpretability, as well as inability to work with conditions characterized by uncertainty [6]. For instance, the application of ANN models can be compared to "black box", which means that it is hard for stakeholders to trust the model completely [7]. Bridging IoT into construction projects enhances risk management in that crucial indexes including environment, equipment, and materials can be monitored and controlled in real-time. IoT devices create massive data and analytics with AI-driven models bring solutions for risk prevention [8]. But the use of these technologies can only be managed through an approach that sits somewhere in between conventional and fully automated methodologies, which have their own drawbacks [9].

This paper brings forward a new, integrative AI-based approach that combines the ability of ANN to make predictions with the capability of Fuzzy Logic to reason and the constant flow of data from IoT sensors. The proposed framework has been designed to address the limitations of the current risk assessment tools to provide an as dynamic, adaptive, and interpretable solution for risks governance in the construction of sustainable projects. These technologies are incorporated into the framework to enable precise predictions, constant

updates, and useful information thus improving project productivity, safety, and sustainability.

The remainder of this paper is organized as follows: Section II provides a literature review of conventional and advanced AI-based risk assessment tools. Section III describes the proposed methodology. Section IV also gives an account of the performance of the proposed framework against conventional approaches. Results is given in Section V. Last, Section VI concludes and recommendations for future research in Section VII.

II. Related Work

Risk assessment of course remains an important factor in project management especially when it comes to sustainable construction [10]. Risk management is the process of identifying potential dangers that can occur at different phases of construction projects and which are critical to guaranteeing safe delivering of the project at a moderate cost within the stipulated time. Risk management of construction projects increases in sophistication as the project gets more complicated and provides project managers with tools to consider potential problems and control them [11]. This section seeks to examine the current trends concerning risk assessment, particularly with regard to conventional approaches, the use of artificial intelligence, integration of IoT solutions, and the blended solutions, with the primary purpose of identifying the strengths, weaknesses, and applicability to the current construction industry those approaches display.

A. Conventional Approaches of Risk Evaluation

Conventional risk assessment has been in practice for many years, and there is evidence of its utility in the construction industry. These include the Analytical Hierarchy Process (AHP), and Monte Carlo Simulation are standard approaches for assessing risk, measuring the probability of occurrence and estimating the effect [12]. Although these approaches have been widely used in different fields, they have some drawbacks when being implemented in contemporary construction projects.

1) Analytical Hierarchy Process (AHP): Decision making involves breaking of large problems into smaller easier to handle tasks and Analytical Hierarchy Process (AHP) is an example of structured decision making. It entails recognizing the parameters that are used in decision making and ranking them against each other and putting a score on each parameter [13]. In the construction risk assessment framework, AHP is useful in assessing the significance of various risks including the environmental risks, the financial risks and the scheduling risks. Among the strengths of the AHP, the first one is its simplicity and flexibility of application. Not only it provides qualitative information, but also quantifiable information that can be used to make quite reasonable decisions by the project managers [11]. The process is systematic meaning that there is a way of approaching it which enables one to have order of ideas in mind and order of importance. Nonetheless, compared with other methods, the weakness of AHP is that it depends on the assessment of the opinion of some experts and needs to estimate the relative weight of some factors, which may differ greatly or be biased due to the same reason [14]. However, AHP is not efficient in real-time operating contexts or where new risks come frequently and continuously as it is not developed to process a large amount of data or adjust to changes immediately.

2) Monte carlo simulation: Another traditional technique used in risky construction projects is the Monte Carlo Simulation. The best use of it is that it is capable of using probabilistic modeling which enables it to predict various probable outcomes based on a set of input possibilities [15]. Monte Carlo offers a quantitative assessment of possible impacts, or threats, that project managers need to envision in order to avoid mismanagement of resources, time or financial constraints.

Monte Carlo Simulation has one of the most significant advantages of dealing with uncertainty and variability in risk aspects. It enables a project manager to examine a number of possibilities, which helps that person to have a better understanding of what may happen and the chances of it occurring [16]. But as with practically all methods, Monte Carlo Simulation is not without its drawbacks. The method is quite dependent on past data and forecast on the future hoy and may not reflect the current circumstances. Also, the actual application of the simulation may be complicated because the process may be lengthy, especially when it is applied in dynamic environments where decisions have to be made frequently [17]. Although AHP and Monte Carlo Simulation are quite useful at their respective cases, they have limitations that make them ineffective for the current dynamic construction environment where new risks and opportunities are likely to happen at any one time.

B. AI-Based Risk Assessment

Advancements in the areas of Artificial Intelligence (AI) have been a major boost to the subject of risk assessment. AI methods and especially the ANN have shown potential for risk prediction and management in constructions [18]. Compared to the conventional approaches, risk assessment models powered by artificial intelligence are able to analyse vast amount of information and reveal patterns that might go unnoticed. ANN is a class of machine learning algorithms that mimic the performance of the Biological Neural Network that exists in the human brain. ANN consists of tiered nodes, and each node performs the function of both computing and transmitting data [19]. ANN models are trained in a process where the model is able to extract a set of features from the provided data and through such the ability of predicting outcomes on the basis of some risks is obtained.

In construction risk assessment, ANN has been demonstrated to be useful in forecasting potential cost increase, schedule disruption and safety risks [20]. For instance, ANN models can be used to forecast risks since it takes into account past project information that include project performance data, environmental data and workforce productivity data amongst others. Research has established that ANN can yield good results if applied in construction risk assessment, therefore, is a good tool for risk management.

C. IoT Integration in Risk Management

With the adoption of Internet of Things (IoT) in construction projects, there has been a shift of focusing on the concept of risk. As aforementioned IoT technology is capable of collecting data in real-time from the construction site including but not limited to environmental conditions and equipment and material usage and deliveries [21]. This real-time data allows the project manager to easily see the risks that are associated with the project and be able to sort them out quickly. IoT devices constantly monitor several factors, which is useful in assessing the health of the construction project [11]. For instance, IoT sensors are capable of perceiving conditions that are lethal, including high levels of dust or toxic gases, and inform the workers and project managers about the best precautions to take. Furthermore, IoT sensors can also track the performance of the equipment and know when they are likely to fail and cause a lot of loss of time and accidents [22]. The ability to have real time data on the condition of construction sites is one of the main benefits that IoT integration offers. This information will make it easier to decide and act quickly in order to prevent possible hazards. For instance, if sensors of IoT notice a breakdown of certain equipment, the system is able to generate maintenance signals, thus avoiding damage and high costs [23]. However, incorporating IoT into construction projects has other challenges as discussed below. Safety of data is a big issue, as many IoT devices collect personal data that might be easily attacked by hackers. Further, the connectivity between separate IoT devices as well as systems is an issue; more so when it comes to the large-scale implementation of IoT which entails using different devices and systems from different vendors using different technologies. Finally, the large number of data points created by IoT devices, can be overwhelming for project managers and it is hard to see trends without the use of big data analytics tools [24].

There is one of the most effective hybrid method which is the integration of AI methods, for instance Artificial Neural Networks (ANN), with the conventional approaches as Fuzzy Logic or Analytical Hierarchy Process (AHP) [25]. When applied in combination with AI models, project managers can benefit from traditional techniques and conversely, AI models can also benefit from traditional techniques. For instance, Fuzzy Logic deals with uncertainty, [26] and imprecision in a more efficient way as compared to traditional methods, AI models, on the other hand, bring in a scientific aspect in terms of risk predictions.

Another promising hybrid solution deals with the use of real-time IoT data with the help of AI and classical risk estimation models. Since the IoT devices enable real-time data acquisition, construction projects can integrate this data with the predictive outcomes of AI models along with the decision-making structure of conventional techniques to increase the efficiency of risk assessment. For instance, an IoT risk management might involve constant tracking of the environment and the performance of the equipment and then use the data to train an AI model in order to detect risks on the go. They could then be ranked as per the usual decision making models including the Analytical hierarchy process to establish which risks deserved priority. This paper presents a blended system as a viable approach to risk management in construction projects, which will help to detect and address risks properly and at the right time.

III. Proposed Methodology

This section of the methodology is centered on the data collection process which is the foundation of the risk assessment framework in sustainable construction projects. Through the use of different data sources this research proposes to come up with a more holistic and complex view of the hazards of construction projects. The historical data in addition with real-time values collected by IoT sensors guarantee that the framework is not only data-based but also flexible to changing circumstances of the project.

A. Data Collection

The study integrates two primary data sources: data gathered from previous sustainable construction projects and data generated from smart sensors placed at construction sites. Both datasets are equally important in risk identification, analysis, and risk management function in a complex construction environment. The following are descriptions of the datasets which makes up the framework.

1) Historical records dataset: The historical records dataset remains very informative when it comes to identifying reoccurring issues, risks, and solutions to avoid in future construction projects. This type of data is usually gathered from finished contracts and provide information on the types of risks experienced on construction projects, the measures that have been taken to address these risks and the results of such risks on the construction projects. In fact, based on the analysis of this historical data, the study will be in a position to note trends and relationships that it can use in risk assessment. The historical records used in this study include:

- Project Timelines: Information on the time that construction projects began and when they were completed, important activities accomplished, and whether there were any setbacks. These timelines are useful in creating benchmarks against which general delays can easily be recognized and their root cause determined.
- Cost Estimates and Overruns: Budget projections relative to historical costs of performing the same undertaking with an aim of identifying reasons why costs may have overrun the budget. This data is useful in evaluation of financial risks as well as areas that could require better cost control measures.
- Performance Metrics: Information as to the consumption of the resources, efficiency of the people, and the quality of the work completed on the project. These metrics give distance that may be used to measure the performance, productivity, and quality control measures in organizations.

- Risk Factors and Mitigation Strategies: Some of the risks are a brief description of the risks that were faced during previous projects and the measures taken to avert or manage them. This dataset assists in assessing which approaches were used in risk minimization or risk management.

2) IoT Sensor data: IoT sensor data obtained from active construction sites provide real-time monitoring data and enrich the framework with this feature. IoT sensors placed at construction sites monitor numerous parameters that are critical for risk evaluation all the time. These sensors give information on the prevailing environmental conditions, performance of the equipment and the state of stored and transported materials, thus keeping the risk assessment framework dynamic as the site evolves.

The Table I demonstrates eight distinctive sensors used in construction sites that track fundamental parameters and positional data alongside equipment statuses and environmental data points. Real-time monitoring and predictive maintenance functions enabled by these sensors provide better safety protocols and operational efficiency through continuous data collection and analysis in construction projects.

TABLE I. IOT SENSORS DATA

Sensor Type	Parameter Monitored	Data Output	Description
Temperature Sensors	Ambient temperature	Temperature readings (°C or °F)	Monitors temperature variations that could affect construction materials and worker safety.
Humidity Sensors	Relative humidity	Humidity readings (%)	Tracks humidity levels to prevent material damage or worker discomfort.
Air Quality Sensors	CO2 levels, particulate matter	Concentration levels (ppm or µg/m³)	Monitors air quality, detecting pollutants that may pose health risks.
Vibration Sensors	Equipment condition	Vibration frequency and amplitude	Measures vibration levels in equipment to predict wear and tear.
Wear and Tear Sensors	Equipment condition	Sensor data indicating wear level	Tracks equipment condition, helping predict failures before they occur.
Proximity Sensors	Worker and material location	Location data (GPS coordinates, distances)	Tracks the position of workers and materials to avoid collisions or delays.
GPS Sensors	Equipment and material movement	Movement data (coordinates, speed)	Monitors the movement of equipment and materials for logistical optimization.
Pressure Sensors	Structural stress	Pressure readings (Pa or bar)	Measures pressure on construction materials to identify risk of failure.

B. Data Consolidation and Mathematical Modeling

To make the risk assessment framework data-complete and dynamic, historical data and IoT sensor data in the real environment are combined into one data set. These datasets help in creating the framework that encompass the past project experience and real-time data with high risk identification pertaining to the construction process. The integration process can be mathematically represented as:

$$\boldsymbol{D_t = D_{t-1} + \Delta D} \quad (1)$$

Where:

$\boldsymbol{D_t}$ is the current data.

$\boldsymbol{D_{t-1}}$ is the previous data.

ΔD is the incremental new data.

This real-time feed significantly enhances the framework's ability to respond to emerging risks, thereby reducing delays and improving project outcomes.

C. Framework Development

The advanced technologies of the hybrid AI-Driven framework augment the traditional risk management practices' shortcomings. The framework is developed as a complete and dynamic system which integrates predictive analytics, uncertainty reasoning, and monitoring.

1) Artificial Neural Networks (ANN): ANN are widely used for risk prediction purposes due to the fact that these technologies are capable of handling large volume of data with multiple attributes. The ANN is structured as a Multi-Layer Perceptron (MLP) with three main components:

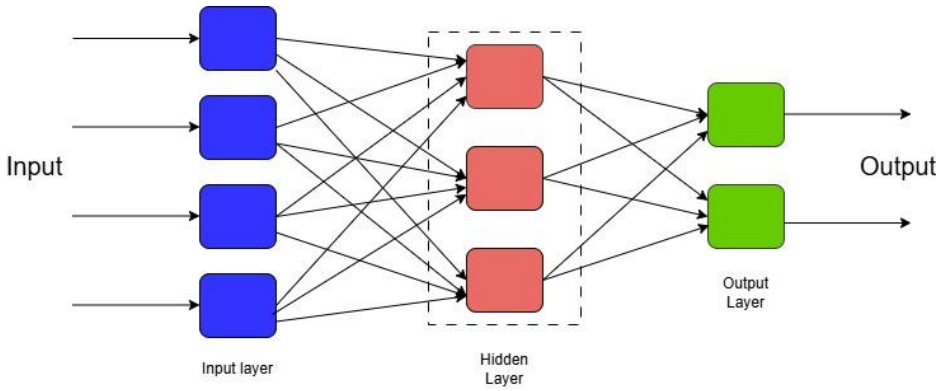

Fig. 1. ANN Layers.

The Fig. 1 shows an architectural diagram which demonstrates the basic structure of a neural network with four input neurons (blue), three hidden layer neurons (red) and two output layer neurons (green) while showing complete connection between each successive layer. This network implements a feed-forward structure that allows information flow in one direction from input to output while maintaining weighted synaptic connections between every neuron of successive layers.

- Input Layer: This layer receives the input vector X=[x1,x2,...,xn] The parameters of the input vector consist of project specification, historical risk factors and the environmental conditions.
- Hidden Layers: These layers consist of neurons, which perform activation functions such as ReLU or Sigmoid in order to nonlinearly transform inputs. This morphology reflects the interactions between the features in a complex manner.

$$f(x) = \max(0, x) \text{ (ReLU)} \quad (2)$$

$$f(x) = \frac{1}{1+e^{-x}} \ (Segmoid) \quad (3)$$

- Output Layers:The output layer yields risk levels ȳ predicted for facilitating enhanced management of projects. By combining predictive analytics, uncertainty reasoning, and dynamic monitoring, the framework provides a comprehensive and adaptive approach to risk assessment.

$$\hat{y} = f(W_2 . g(W_1 . X + b_1) + b_2) \quad (4)$$

Where:

W_1 , W_2 are weight matrices that determine the strength of connections between layers.

b_1, b_2 are biases that shift the neuron activation threshold.

f(.) and g(.) are activation functions introducing nonlinearity to model complex data relationships.

The model's training minimizes prediction errors using the Mean Squared Error (MSE):

$$\boldsymbol{MSE} = \frac{1}{N}\sum_{i=1}^{N}(\boldsymbol{y_i} - \hat{y}_i)^2 \quad (5)$$

Where:

N is the total number of samples.

$\boldsymbol{y_i}$ is the actual risk level.

$\hat{y}_i$ is the predicted risk level.

Training process of this ANN guarantees that the model absorbs a lot of data history to generate good results in new situations.

D. Fuzzy Logic

Fuzzy Logic translates between quantitative form of ANN solutions and qualitative decisions. It ensures that meaning of outputs from ANN is expounded by considering the level of uncertainty and vagueness that tends to prevail with the construction project data.

1) Fuzzification: Transforms numerical outputs of ANN which are recognized as the degree of risk into linguistic terms such as 'low risk', 'medium risk', 'high risk' using membership functions like triangular or trapezoidal curves.

2) Inference rules: Uses domain specific heuristics, for instance: IF risk is high AND delay is likely, THEN prioritize mitigation. These rules make the results parsable – that is actionable and readily understandable by managers.

3) Defuzzification: This paper shows how the centroid method is used to transform the fuzzy conclusions into crisp values.

$$Z = \frac{\sum_{i=1}^{n} \mu_i . z_i}{\sum_{i=1}^{n} \mu_i} \quad (6)$$

Where:

μ_i is the degree of membership.

z_i is the corresponding crisp value.

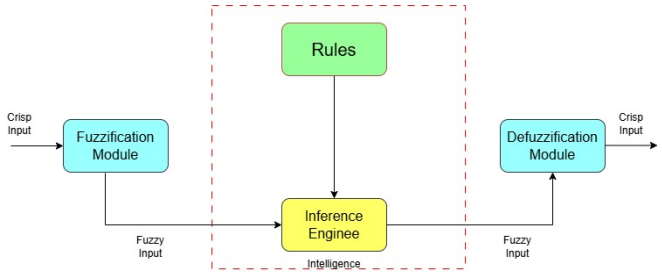

Fig. 2. Fuzzy logic framework.

The Fig. 2 illustrates a typical fuzzy logic control system design which includes three fundamental elements: fuzzification converts inputs into fuzzy sets, followed by an inference engine which executes predefined rules for decision-making finally ending with defuzzification that returns fuzzy outputs to crisp values. Through its operations the system showcases the basic processing sequence of fuzzy logic that enables numerical input-output transitions by utilising linguistic variables and rule-based inference together with fuzzy set theory processes. Fuzzy logic therefore sharpens the framework's capacity in dealing with uncertainties and come up with recommendations depending on the context of the project in question.

IV. Experimental Setup

The details about the selected experimental setup are reported below and were chosen specifically to test the hybrid AI-driven framework in conditions that are as close as possible to reality of sustainable construction projects. The data set used in the experiments included real project data and synthetic IoT sensor data. Paper and electronic documents of 500 sustainable construction projects were reviewed to gather records of timeline, cost, risk, and performance data. These records were cleaned and normalized in the same manner as in previous analyses: cleaning the data, scaling it to the [0,1] [0,1] [0,1] range, and selecting features that might be important in this case, such as material delay, environmental risks, and scope changes. Real time data was synthetically created to mimic IoT sensor data to monitor the physical conditions of the

environment including temperature and humidity, equipment status, and material flow. This real time data collected on a hourly basis over six months helped in ferreting out dynamic inputs for the framework.

The software tools that are applied to this framework include Python, TensorFlow and Keras, scikit-learn, and MATLAB. TensorFlow/Keras was used in ARCHITECTING and training the Artificial Neural Network (ANN) and Scikit-learn in preprocessing and performance measurement. MATLAB was used in creating and testing the fuzzy logic system. For real time data integration, Apache Kafka was used to stream IoT sensor data. All the experiments were performed on a high-end GPU server containing an NVIDIA RTX 3090 Graphics Card, 64GB RAM, and an Xeon Processor.

The experimental setup has divided the data into training (70%), validation (20%) and test set (10%). To take into account possible temporal dependencies, time-based cross-validation was used. For the ANN component of the proposed framework, backpropagation with the Adam optimization algorithm was used. Here the hyperparameters used were; learning rate=0.0010.0010.001, batch size = 32 and number of epochs = 100 however to avoid overfitting early stopping was used. The fuzzy logic system was designed by fuzzifying the input variables through the fuzzification rules inferred from the historical thresholds, inferring the output from the inference rules obtained from the experts and defuzzification by using the centroid approach. Data integration in the IoT context allowed for model refreshing through Apache Kafka, where in batches of data, the five-minute intervals updated the risk estimates.

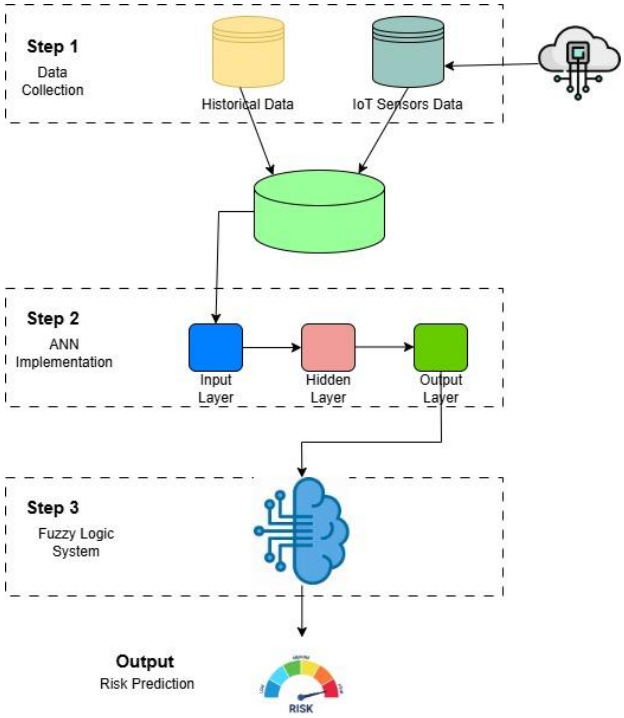

Fig. 3. Proposed model.

The Fig. 3 demonstrates an architectural framework which applies a three-phase risk prediction approach that merges historical and IoT sensor data by using a sequential process from data collection to artificial neural network implementation and fuzzy logic integration. The system unites standard machine learning methods with fuzzy inference logic to create an integrated risk assessment output which serves as proof of hybrid techniques for better predictive analytics.

For the assessment of the framework, several indicators were used to assess the effectiveness of the presented framework, several measures were used. Accuracy determined how accurately ANN in the current study predicted risk levels, and Mean Absolute Error (MAE) calculated the overall difference between actual and predicted risks. The extent of interpretability of fuzzy rules was measured with the Fuzzy Interpretable Index (FII), and system performance under noisy IoT data conditions was tested. Moreover, to evaluate the dynamics of the framework, the time taken to re-update the predictions upon receiving fresh IoT data was considered.

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (8)$$

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (9)$$

$$F1 = 2 * \frac{P.R}{P+R} \quad (10)$$

There are stages that were followed when implementing the strategy. First, historical and IoT data were cleaned to make data viable and suitable for analysis. The ANN model was used to identify patterns and relationships between the risk factors regarding the past data set. The fuzzy logic rules were derived in close cooperation with the domain specialists to offer the decision-making rules. Real-time data pipes for IoT were

developed so updates could be made in real-time in order for the framework to reflect current site conditions. Last, the system was tested end to end on a constructed construction project to show its real-time risk assessment capability of producing accurate, interpretable, and adaptive risk evaluation.

V. RESULTS

The use of the hybrid AI framework in an experimental setting gave a lot of information on how efficient, flexible and reliable the system is when dealing with risks for sustainable construction projects. Such insights underscore that the proposed framework is useful when dealing with change in project conditions, the environment and resource availability. Through the use of levels of sophistication in analytics, decision making and dynamic adjustment capabilities, the framework provides an all-inclusive approach toward construction risk evaluation in the contemporary world.

TABLE II. COMPREHENSIVE PERFORMANCE METRICS OF ANN MODEL

Metric	Value
Accuracy (%)	92.7
Mean Absolute Error (MAE)	0.084
Precision (%)	91.4
Recall (%)	93.1
F1-Score (%)	92.2
Training Epochs	100
Batch Size	32

The metrics of the evaluation for the Artificial Neural Network (ANN) show excellent results of predicting the risk levels as shown in Table II. The ANN utilized an MLP structure in order to detect the non-linear interdependencies between the input parameters like environmental conditions, risk profile history and the project characteristics and their related risk levels. The model delivered an accuracy of 92.7% and such high accuracy level is capable of serving the scenarios of the test model. Furthermore, the ability to accurately predict outcomes is expressed by the relatively low Mean Absolute Error (MAE) of 0.084. The relative closeness of the precision and recall scores demonstrate that the ANN minimizes both false positives and false negatives at a rate of 91.4% and 93.1%, respectively. This balance is important in construction projects since incorrect classification of risks potentially leads to resource misapplication or project hold-up.

The training of the ANN was performed with an early stopping technique which applied after achieving an accuracy of 100 epochs and learning rate of 0.001. This convergence assured that the model has no over-fitted and has high generalization capacity at the same time. The learning and validation losses shown in the Fig. 1 indicate a similar progress during the training phase. It does this in a way that keeps the model optimal for use when it is applied in real situations where data is complex and diverse.

The Fig. 4 display shows the loss convergence pattern which shows that the model initially converges quickly before reaching a stable point where training and validation curves maintain similar levels indicating effective generalization capabilities. These metrics show similar declining patterns which start at about 0.6 before reaching near-zero levels indicating that the model achieved an optimal learning state without major overfitting or underfitting effects.

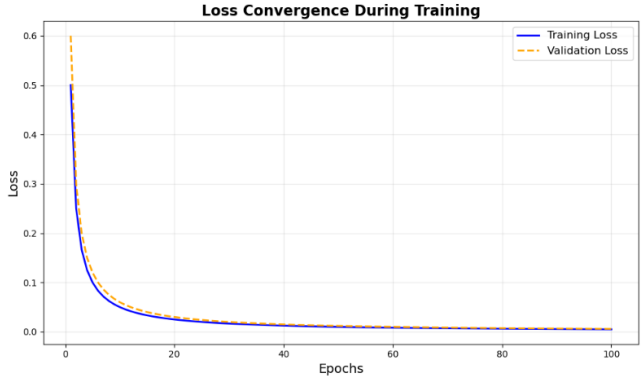

Fig. 4. Loss convergence rate.

A heatmap in Fig. 5 illustrates the rule importance levels for five fuzzy rules which span from 0.1 to 0.95 between High and Low and Medium risk categories. The heatmap chart reveals important patterns through its colour distribution because specific risk conditions show darker cells representing higher values which indicates non-uniform rule applicability across different risk levels.

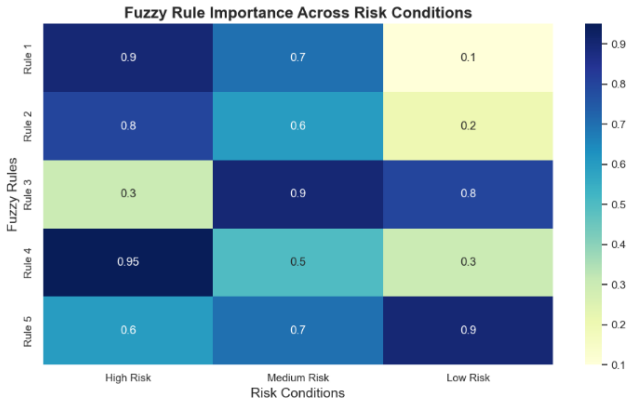

Fig. 5. Fuzzy rules across risk conditions.

A complete rule-based risk assessment framework depicted in Table III comprises five distinct rules which link different conditions to risk outputs along with management actions.

The rules analyse various parameters including risk levels together with operational aspects of cost overrun and material delay and environmental hazards and equipment efficiency to generate specific risk classifications and recommended mitigation strategies for project management enhancement.

TABLE III. FUZZY INFERENCE RULES

Rule ID	Condition	Output	Actionable Insight
1	Risk = High AND Cost Overrun = Significant	Critical Risk	Immediate resource allocation to mitigate high-priority risks.
2	Risk = Medium AND Material Delay = Likely	Moderate Risk	Adjust procurement schedules to reduce project delays.
3	Risk = Low AND Delay Probability = Minimal	Low Risk	Proceed with routine workflows without additional interventions.
4	Risk = High AND Environmental Hazard = Severe	Critical Risk	Implement contingency plans to address safety and environmental compliance.
5	Risk = Medium AND Equipment Efficiency = Low	Moderate Risk	Schedule maintenance to improve equipment performance and avoid disruptions.

Fuzzy logic was used to help translate the quantitative risk levels from the ANN into risk categories that are realistic and practicable. By incorporating a set of credibly designed and allocated membership functions and enforcing the use of certain set of inference rules the fuzzy logic system offered suggestive options optimizing for concrete project circumstances. For example, the rule "IF risk is high AND cost overrun is significant, THEN prioritize mitigation efforts" was useful for making project managers take corrective actions instantly. Project management specialists assessed the interpretability of these rules to be 93%, adding that the linguistic variables used reflected actual practice. This is due to the fact that the construction industry involves several players in decision making and the above models provide an easy to understand interpretation of the results obtained.

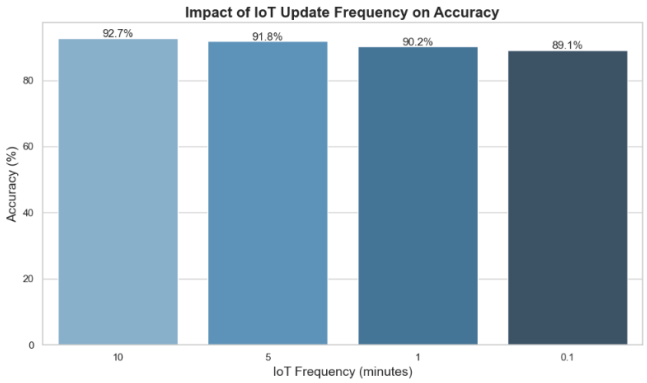

Fig. 6. Sensors accuracy.

The analysis depicted in Fig. 6 shows that increased IoT update frequencies result in reduced accuracy but attains its maximum accuracy value of 92.7% at a 10-minute interval. The results indicate that updates performed every 0.1 minutes might generate errors which reduce system effectiveness.

Due to IoT sensors integration, the framework could alter during the course of construction site working time, responding to real time changes. Data obtained from the IoT devices was in the form of continuous streams, which contained information regarding the environment (like temperature, humidity) and information regarding the performance of equipments and the flow of materials. These updates enabled the system to make changes to risk predictions within the average time of 4.2 seconds per batch which are crucial for responding to emergent risks on time. Table III highlights that the proposed framework can be easily fine-tuned depending on the frequency of IoT updates, ranging from standard operation frequency of 10 minutes to near real-time updates of 10 seconds. There was a slight loss of performance at higher update rates; however, the framework was still performing at an accuracy greater than 89% while being updated at high speeds. This capability is most useful in the construction environment where, for example, site conditions are constantly changing.

Comparison with simple ANN models and conventional risk evaluation methodologies as shown in Table IV also supported the credibility of the hybrid framework. In the experimental results, the appropriateness of the incorporation of ANN's forecasting capability with the interpretability of fuzzy logic and the flexibility of IoT data streams was manifested by the fact that the proposed hybrid framework outperformed the other frameworks in all experiments. For example, the standalone ANN models were produced with the accuracy of 85.3% but they did not contain the necessary flexibility for real time risk assessment. While traditional methods are less accurate static methods, compared with the proposed system and having accuracy of 78.6%. As presented in Table IV the hybrid framework performed well in other parameters like MAE (0.084) and adaptation speed 4.2secs hence the framework is most suitable for practical uses where timely and accurate decisions are called for.

Results in Table V show that the framework maintains accurate results while noise levels increase except for the point. The incorporation of fuzzy logic into the system reduces the effect of substantial noise which maintains effective performance.

TABLE IV. DETAILED ANALYSIS OF IOT UPDATE FREQUENCIES

IoT Update Frequency	Accuracy (%)	MAE	Adaptation Speed (seconds)	Data Latency (seconds)	Response Time (seconds)	Description
Every 10 minutes	92.7	0.084	4.2	2	6.2	Standard operational conditions with minimal delays.
Every 5 minutes	91.8	0.098	3.8	1.5	5.3	Moderate frequency, balancing accuracy and speed.
Every 1 minute	90.2	0.112	3.5	1	4.5	High frequency, effective for rapid condition changes.
Every 10 seconds	89.1	0.125	3.2	0.8	4.0	Near real-time updates, slight accuracy trade-offs.

TABLE V. IMPACT OF NOISE ON FRAMEWORK PERFORMANCE

Noise Level (%)	Accuracy (%)	MAE	Remarks
0	92.7	0.084	Optimal performance under ideal conditions.
5	91.3	0.092	Slight decline due to minor perturbations.
10	88.7	0.112	Maintains high accuracy despite moderate noise.
20	85.1	0.137	Significant noise mitigated by fuzzy logic.

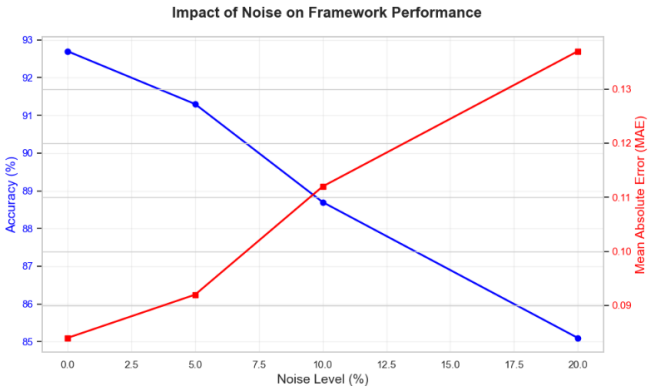

Fig. 7. Noise impact on frame work.

The data in Fig. 7 shows that framework performance declines as noise levels rise because accuracy drops and mean absolute error (MAE) increases. The performance of the system experiences substantial degradation at the intersection point of 10% noise level.

Fig. 8. Comparison of proposed model with state-of-art models.

The hybrid framework demonstrated superior performance than traditional and ANN-only models based on accuracy alongside robustness and adaptation speed according to Fig. 8. Hybrid models strike a superior equilibrium between performance metrics which makes them stand out as a dependable method for dynamic conditions.

TABLE VI. COMPREHENSIVE PERFORMANCE COMPARISON ACROSS MODELS

Metric	Hybrid Framework	ANN Only	Traditional Model	Description
Accuracy (%)	92.7	85.3	78.6	Hybrid model benefits from combined predictive and adaptive capabilities.
MAE	0.084	0.146	0.198	Lower error indicates higher precision in hybrid predictions.
Adaptation Speed (s)	4.2	10.6	Static	Real-time updates ensure timely risk mitigation.
Fuzzy Interpretability	93%	N/A	60%	Fuzzy logic enhances user-friendly decision-making.
Noise Robustness (%)	88.5	78.2	70.3	Maintains performance under noisy conditions, ensuring reliability.

Additionaly, the robustness testing confirmed the stability of the framework under the more difficult conditions as shown in Table VI. When noise levels of up to 20% were introduced into the IoT data streams, the framework retained a high level of accuracy of approximately 85.1% albeit with the modest inflation of the MAE by 0.137 points. These results are presented in Table V below and explain why the framework would still be effective despite data variation or transmission errors. That is why the fuzzy logic system was so important in reducing noise's effect on the results, as it allowed the risk assessment to be meaningful and accurate. This robustness is desirable in construction projects as it can be often observed that the sensor readings can be imprecise and there are large data gaps due to the nature of construction site environments.

VI. CONCLUSION

The paper presented a hybrid risk assessment framework that was based on AI and the results have revealed higher accuracy, flexibility, and efficiency in sustainable construction projects. The Artificial Neural Network (ANN) model developed in the research reached an accuracy of 92.7% and Mean Absolute Error (MAE) of 0.084 to predict risks with equal precision in different conditions of the project. Further, incorporation of Fuzzy Logic provided interpretability to the decision making by analysing and converting quantitative risk outputs in to manageable data for project managers. For example, the rules like IF risk is high AND cost overrun is significant, THEN consider risk reduction measures found very helpful in prioritising important interventions and recorded 93 percent interdependency index by domain expert.

The dynamic data updates made through the IoT interface improved the dynamism of the framework, with risk assessment intervals being updated in 4.2 seconds on average per each data batch. This capability would enable real-time adjustment to site situations including changes in environmental factor or equipment performance. Different update frequencies of the IoT proved that accuracy was sustained at more than 89% even with near real time updates of 10 seconds. As expected, it was also confirmed that the proposed system could maintain a high level of accuracy even with the presence of noisy data; based on the findings, the hybrid framework guaranteed an 85.1% level of accuracy even when the noise level was set to 20%.

Comparisons made with standalone ANN and other conventional risk management techniques also revealed the advantage of the suggested system. The proposed hybrid framework performed better in terms of accuracy, noise robustness, and real-time adaptation while achieving an MAE reduction more than the conventional models by 50%. The results presented in this paper confirm that the application of AI, IoT, and fuzzy reasoning provides an innovative solution to develop a more effective approach to predictive risk management in construction processes that lead to safer, more efficient, and eco-friendly construction practices.

VII. Future Work

Future studies must investigate how the proposed AI-based risk assessment framework applies to new construction fields and industries as well as implement blockchain technology for safe data protection and advance prediction abilities through sophisticated machine learning algorithms including deep learning and reinforcement learning methods. Future developments through artificial intelligence should target three main areas of self-learning capability development alongside explainable human-AI collaboration and sophisticated IoT sensing solutions that leverage edge computing for real-time operational control. The framework needs expansion to include sustainability measures like carbon footprint evaluation that will support environmentally friendly construction practices. The framework will become a better tool for managing project risks in complex dynamic environments when these identified areas receive further attention.

Smart Insoles for Multi-User Monitoring: A Case Study on Received Signal Strength Indicator-Based Distance Measurement

Víctor Huilca Cabay, Alexandra Flores, Paúl Hernán Machado Herrera, Byron Paul Huera Paltan
Department of Informatics and Electronics, Escuela Superior Politécnica De Chimborazo, Riobamba, Ecuador 060150

***Abstract*—In the current context of high adoption of wearables and Internet of Things (IoT) devices, this work develops a smart insole system to measure the distance between users using the RSSI signal (Received Signal Strength Indicator). ESP32 WROOM microcontrollers with Bluetooth Low Energy, Wi-Fi, and multiple functionalities were used. The prototype includes sensors to count steps, detect activity (walking/running) and a configurable alarm to alert when the distance is less than a threshold. Collected data are sent directly and in real-time to a database using the ThingSpeak web platform, which allows to visualize the data acquired from the insole sensors. Using the RSSI signal provided by the Bluetooth LE module, a significant response was interpreted and modeled using a multilayer perceptron (MLP) neural network, achieving an average distance estimation accuracy of 90.89% using data measured in real time.**

***Keywords*—Internet of Things; RSSI; smart insole; distance; wearables; neural network**

I. Introduction

Modern electronics have achieved the miniaturization of devices and rapid processing speeds, reaching a level of integration that has made it possible to include computational capabilities in everyday objects. In addition, garments can advantage over the potential of digital electronics, incorporating sensors and actuators. Two strong areas, industry and scientific research, are promoting this type of device, commonly called wearables [1]. Typically, wearables gather user data related to specific activities or physiological parameters. Usability, discretion, and reliability are the key points involved in the design of these devices. Furthermore, measurement precision and reliability play an important role, particularly in professional sports [2] and health applications [3], where portable devices are intended to replace or at least act as closely as possible with high-quality laboratory and hospital devices. Activity trackers, which incorporate inertia detection [4], are one of the most popular types of wearable devices, taking advantage of the consumer's need to maintain healthy behaviors, stay active, and take care of their physical condition. Currently, there are wearable devices with several sensors that are of great help in collecting body data in general [5], [6], but none include cell phones and devices from the Global Positioning System (GPS) that determine the distance between devices or users. These wearable devices are very useful when it comes to monitoring the behavior and movement of people; An example of this is human walking [7], which is one of the most common activities that humans perform from an early age. This activity provides us with several useful data to determine aspects related to the health of the individual and also considerations in the sports area. Plantar pressures in a walk provide important information on the duration and symmetry of gait cycles [8]; With this we can determine whether an individual walks in a normal way or suffers from pathologies and abnormal plantar conformations, as they often alter the functionality of the foot with consequences throughout the muscular system of the lower extremities and in the spine. Lately, intelligent insole systems have come onto the market for individual use and are mainly aimed at the sports area, allowing monitoring data related to walking or running.

In [9], the authors propose the use of Smart Insole to obtain an accurate step count directed to the real world. The step counting method is based on the threshold differential value of the mean plantar pressure. The results obtained with this prototype indicate an accuracy of almost 100% in measuring the count of steps. The Smart Insole FreeWalker detailed in [10] works with a custom designed acquisition, transmission, and reception unit. It is composed of an MPU-6050 inertial unit that has an accelerometer and gyroscope, fed 3.3 Vdc, a robust and sufficient microcontroller to carry out the objective of the project. This device is capable of identifying the steps during a gait cycle, both the acquisition and the transmission of information being carried out in real time. In [11], the comparison of three methods is proposed to estimate the distance by means of the received RSSI signal, with which they obtain the indoor positioning and navigation (IPIN). The proposed methodology is that of a novel multi-step approach that combines the flat-earth model, the Friis free space model, and the linear approximation model to measure the distance from RSSI for smart devices with Bluetooth low-energy connectivity (BLE). In addition, the authors propose an improved RSSI averaging and smoothing algorithm to obtain a better result, with which they claim a reduction of 13.4% in the error of the measured distance.

This work presents the development of a smart insole with user-friendly and reliable features, designed to monitor human gait. Its primary function is to determine the distance between two individuals, each equipped with a smart insole, offering innovative applications in both sports and medical fields. In sports, this technology facilitates training in pairs or teams by ensuring that users maintain an optimal distance to improve coordination and prevent accidents during physical activity. In the medical field, smart insoles serve as a valuable tool for physical rehabilitation, allowing the monitoring and evaluation of patient progress in gait therapy. Additionally, their implementation in sports competitions could help ensure

safe and efficient performance. To achieve this goal, a system was developed using smart insoles capable of quantifying the distance between two devices through the RSSI signal. The technological solution uses ESP32 WROOM microcontrollers with low-energy Bluetooth (BLE) modules, complemented by sensors for step detection, activity analysis, and scheduled notifications. The data collected are transmitted in real time to a cloud database via the ThingSpeak platform [12], allowing precise and continuous data analysis.

The paper is structured as follows. Section II describes the system architecture. Section III provides a detailed explanation of the system implementation along with each of the processes involved. Section IV presents the numerical results obtained. Finally, the conclusions are presented in Section V.

II. System Architecture

This section details the complete architecture of the smart insoles system through electrical diagrams. Fig. 1 shows a high-level schematic in its entirety. The system is composed of the ESP-32 WROOM processing unit or microcontroller, the FSR (Force sensing resistors) sensors connected by analog pins, the MPU6050 accelerometer to identify the stroke phase, the BLE module built into the ESP32 WROOM, to determine the RSSI parameter, the Wi-Fi module to communicate between the smart insole and the ThingSpeak Web Server and finally the 3.7 Volt battery used as the power supply of the entire system.

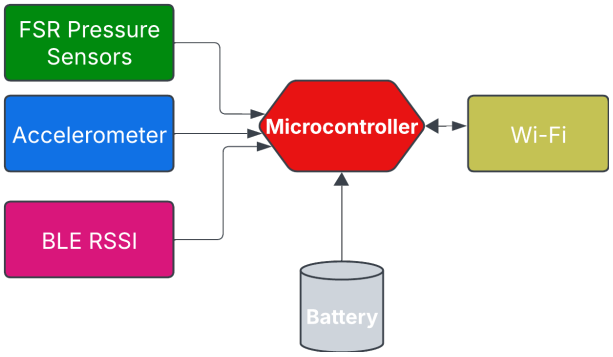

Fig. 1. High-level scheme of the smart insole system.

The diagram in Fig. 2 details the connection of all the electronic elements used for the smart insoles, these are:

- The ESP32 WROOM microcontroller;
- A BLE module included in the microcontroller;
- Three FSR sensors (heel, right forefoot and left forefoot);
- The inertial module MPU6050;
- Three 220 ohm resistors;
- A 3.7 volt and 1000mAh battery.

Due to the versatility of the microcontroller used, it is possible to choose between a 5Vdc supply through the Vin pin, or also a 3.3 Vdc supply through the 3V3 pin; for this work the 3.3Vdc option has been used since with this voltage is also fed directly to the MPU6050 inertial module. In the case of FSR sensors, to properly condition their signals before entering the reading into the analog inputs of the microcontroller, it is necessary to make a voltage divider for each of these. To measure RSSI, it is useful to determine the distance between the two smart insoles using the Bluetooth BLE module built into ESP32. As mentioned above, the 3.7Vdc battery is also shown, which provides the adequate voltage for the operation of the entire system, it should be noted that the above detailed is considered for both the MASTER and SLAVE prototypes.

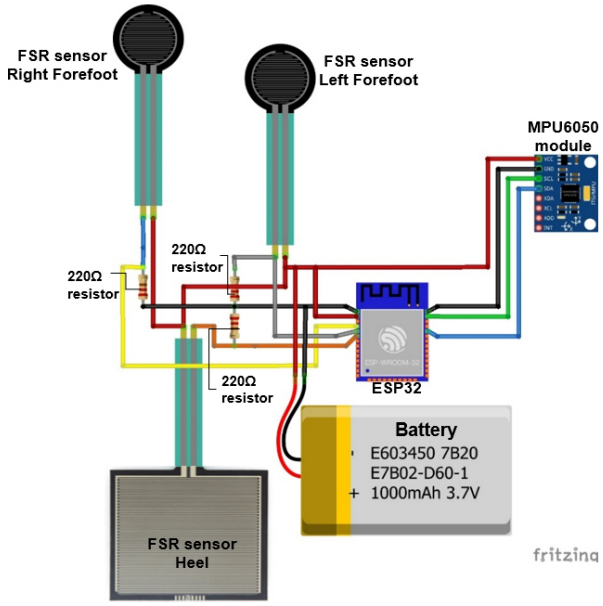

Fig. 2. Smart Insole system architecture.

Fig. 3 details the steps carried out by the master and slave systems: in which the procedure is exactly the same, with the difference that the slave will be the one that processes the RSSI signal of the system. The raw signals are acquired by the three pressure sensors, the accelerometer, and the RSSI, after which all this data is processed by the microcontroller and determine the phases of movement (stop, walk, and running), distance traveled, and distance between the two individuals through the algorithms. Using the Wi-Fi module, this information is transmitted to the ThingSpeak platform for visualization and can later be exported in $.xls$ format for further analysis of the collected data.

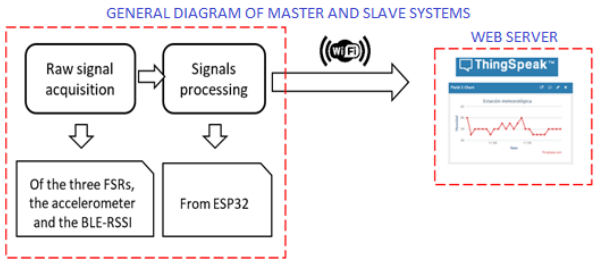

Fig. 3. Conceptual diagram of the MASTER/SLAVE smart insole system.

III. Implementation

The elements integrated into the smart insole system are described in detail below:

A. Processes for Reading Data from FSR Sensors

The procedure of obtaining the step count begins with the analysis of the FSR 402 and FSR 406 sensors. The initial stage involves collecting the signals from each of these sensors. Since these sensors operate by changing their resistance in reaction to applied force, it is crucial to condition their signals utilizing a voltage divider circuit, as depicted in Fig. 4. This voltage divider converts resistance changes into an analog signal for processing. To analyze analog signals more precisely and reliably, a mapping is needed to discretize the output of the voltage divider to a value between 0 and 5000, which is more manageable for the electronic field.

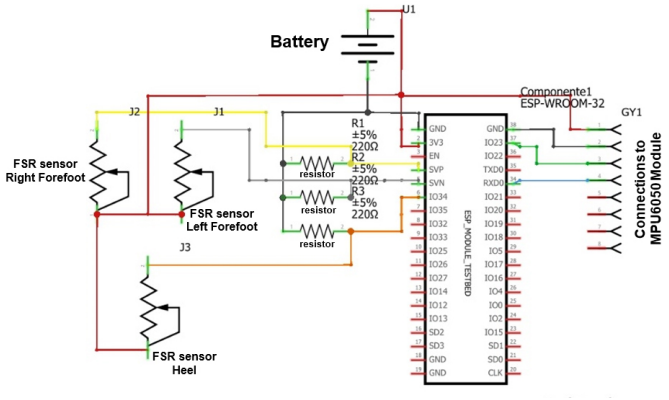

Fig. 4. Smart insole system wiring diagram.

B. Processes for Counting Steps and Identify Walk

The system initiates the step counting phase by pressing the heel sensor, then applies pressure to the right forefoot sensor, and completes the sensing process by applying pressure to the left forefoot sensor, which corresponds to the heel strike, mid-stance, and toe-off phases. To ensure accurate step detection, a state variable is implemented. This variable helps the system recognize when the heel sensor has already been pressed, preparing it to read subsequent inputs from the forefoot sensors. This mechanism ensures that only valid step sequences are counted. In addition, a control mechanism is integrated to distinguish between isolated steps and continuous walking. To achieve this, a fine-step variable is used to determine whether the user has taken more than two consecutive steps, which is considered the threshold to detect the beginning of a walk. To further refine the identification of steps, a function was used to store time stamps, allowing the system to measure the time difference between successive steps. The system then compares this difference to a predefined update rate value, enabling it to distinguish between a walking state and a stationary state. Algorithm 1 details this process.

C. Process for Determining the Run

This section analyzes the method for determining when the individual utilizing the smart insole starts a race. We have selected the IMU MPU6050 sensor for this purpose because it provides acceleration data across three critical axes. X, Y, and Z, essential for analysis and comparison in this context. Due to the placement of the sensor, it is adequate to perform the analysis solely on the X-axis, as it exhibits the most significant variation throughout the running movement. The Algorithm 2 determines whether a user is running based on acceleration measurements from the IMU sensor on $X-axis$. First, it reads the absolute acceleration and scales it by multiplying it by a factor of 5. If the acceleration exceeds a predefined threshold, it indicates the start of movement, storing the timestamp. If acceleration remains above the threshold with control $= 1$, it checks whether the time difference between detections is less than the running frequency threshold. If successive peaks are detected within this time window, a hit counter is incremented. When more than three peaks are detected within the running frequency, the system confirms that the user is running. If too much time passes without detecting new acceleration peaks, the algorithm assumes that the user has stopped running, resetting the variables. Finally, if hit_coun is reset to 0, the function ensures that the running is also set to false, preventing false running detections.

Algorithm 1 Step Counting and Walk Detection

```
Initialize: step_count, motion_state, start_steps, completed_steps, walking ← false
Set Thresholds: heel_activation, forefoot_low
Detect Step
if heel_pressure > heel_activation and forefoot_pressure < forefoot_low then
    motion_state ← 1, last_time ← get_current_time() (if first step)
end if
Confirm Step
if motion_state and heel_pressure > heel_release and forefoot_pressure < forefoot_release then
    step_count++, motion_state ← 0, start_steps++, completed_steps++
end if
Check Walking
if completed_steps > step_threshold and time since last_time < time_window and not running then
    walking ← true, last_time ← get_current_time()
end if
Reset If Inactive
if time since last_time > time_window then
    start_steps, completed_steps ← 0, walking ← false
end if
```

D. Process for Determining the Distance Traveled

In this section of the study, the distance traveled should be measured while keeping in mind whether the walking and running stages have already started. The logic followed is detailed in Algorithm 3.

The Algorithm 3 determines the distance traveled. It begins by establishing parameters including the step length and update interval, and initializing the required variables. The method gets the current time, computes the distance by multiplying the step count by the average step length using (1), and displays

Algorithm 2 Running Detection Algorithm

```
Initialize: motion_state, hit_count, running ← false
Set Thresholds: acceleration_limit, time_window, hit_threshold
Measure Acceleration: acceleration ← abs(sensor_data) × scale
Detect Motion
if acceleration > acceleration_limit then
    motion_state ← 1, last_time ← current_time()
    if time since last_time < time_window then
        hit_count++
    else
        hit_count ← 0, motion_state ← 0
    end if
end if
Determine Running
if hit_count > hit_threshold and time since last_time < time_window then
    running ← true
else
    running ← false, hit_count ← 0
end if
return running
```

Algorithm 3 Distance Traveled Calculation

```
Initialize: previous_time, current_time, steps, state
Set Parameters: step_length, update_interval
if time since previous_time > update_interval then
    current_time ← get_current_time()
    distance ← steps × Average_Steps
    Print "Steps:", steps, "Distance Traveled:", distance
    if walking and not running then
        Print "Walking"
        state ← 1
    else if not walking and not running then
        Print "Stopped"
        state ← 0
    else if running then
        Print "Running"
        state ← 2
    end if
    previous_time ← current_time
end if
Delay 100 ms
```

the number of steps and the distance traveled every time the designated update interval has passed. It then checks the user's activity state: if the user is walking (but not running), it prints $Walking$ and sets the state to 1; if the user is stopped, it prints $Stopped$ and sets the state to 0; if running, it prints $Running$ and sets the state to 2. After updating the state, it records the current time as $previous\_time$ for the next interval and introduces a 100 ms delay to control the update frequency.

$$d = (s * \Delta a) \tag{1}$$

where: d is the distance traveled, s is the number of steps and Δa is the average step length.

E. Mechanism to Evaluate the Distance between Two Individuals

The interpersonal distance between two smart insoles (Master and Slave) is determined using RSSI (Received Signal Strength Indicator) values through BLE communication. The ESP32 modules transmit signals, and RSSI readings are translated into distances measured in meters. A multilayer perceptron (MLP) neural network was used due to the non-linear relationship between RSSI values and distance, which is influenced by elements such as interference, reflections, and signal attenuation in the surroundings. Although linear models such as regression could serve as an initial approximation, environmental variability induces data fluctuations that require a more adaptable model. Initially, 200 samples were used; however, to enhance the model's generalization, data augmentation techniques were implemented, expanding the dataset to 1000 samples, hence facilitating improved learning and adaption to data variances.

1) Data processing: The dataset comprises 1000 RSSI values along with their associated real distances. To enhance the learning efficiency of the model, the normalization of the data was performed using Min-Max Scaling [13], which ensured that the input values were maintained within a standardized range. The application of this transformation was executed using (2).

$$X' = \frac{X - X_{\text{min}}}{X_{\text{max}} - X_{\text{min}}} \tag{2}$$

where X is the original value and X' is the normalized value.

After normalization, the dataset was divided into three subsets: 80% designated for training, 10% for validation, and 10% for testing. This division enables the model to train effectively while ensuring robust generalization to new inputs.

2) MLP Neural network model: A deep multilayer perceptron (MLP) was constructed with three hidden layers comprising 32, 16, and 8 neurons, respectively, as shown in Fig. 5. We employed the ReLU activation function after each hidden layer to incorporate non-linearity, thereby enhancing the ability of the model to discern intricate correlations between RSSI and distance. The Adam optimizer [14] was selected for its efficiency in weight adjustments, facilitating accelerated convergence and stability. The model was trained with Mean Squared Error (MSE) [15] as the loss function to reduce the discrepancy between the predicted and actual distances.

3) Training process: The model was trained for 500 epochs, during which training loss and validation loss were continuously monitored to ensure proper learning and avoid overfitting. A training vs. validation loss plot (Fig. 6) was generated to visualize the learning process of the model over time. The plot shows that the model learned the RSSI-to-distance mapping correctly because the loss continued to decrease with each epoch.

After training, the model produced the learned (3) to predict the distance from the RSSI values.

$$Distance = 0.0386 \times \text{RSSI} - 1.3271 \tag{3}$$

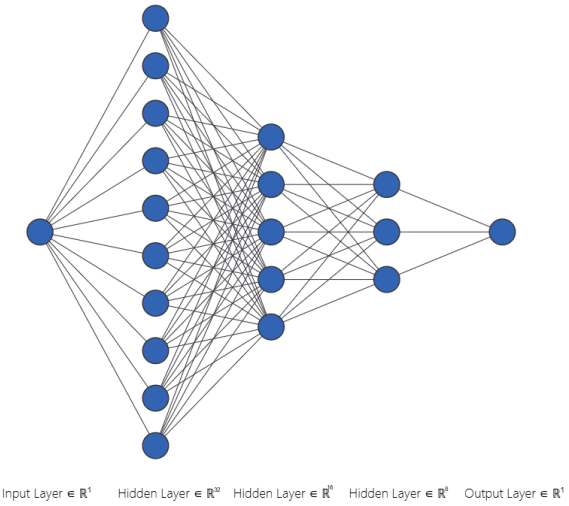

Fig. 5. Deep multilayer perceptron (MLP).

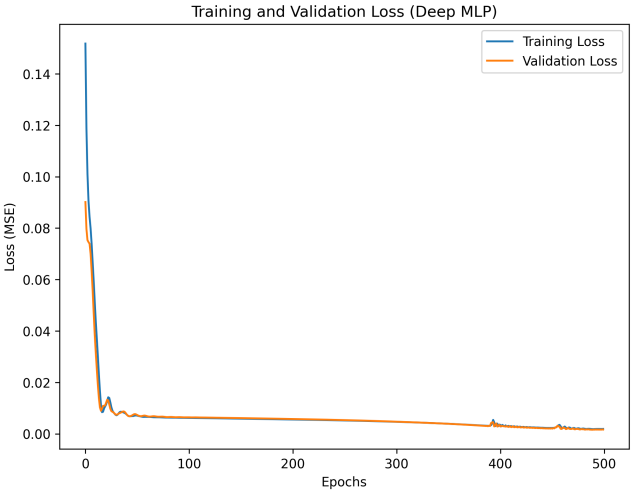

Fig. 6. Training and validation loss plot.

The learned weight is represented by 0.0386, and the learned bias from the first layer of the deep MLP is represented by -1.3271. This equation gives a number value to the relationship between RSSI and distance, which makes it easier to figure out distances in the future without having to retrain the model. To evaluate the prediction of the model, a scatter plot was generated (Fig. 7). In it, the blue dots represent the predicted distances, while the red dashed line indicates the ideal predictions, corresponding to a perfect correlation. The predictions closely align with the ideal line, indicating their high predictive accuracy.

In the Arduino GUI code, (3) was used to calculate the power values in decibels that correspond to changes in distance, as shown in Fig. 8, which shows these changes through the Arduino serial interface. It is now feasible to achieve an automatic variation of the distance values.

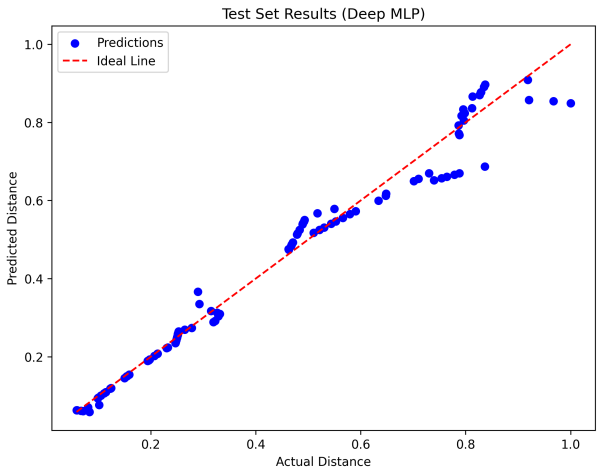

Fig. 7. Predictions vs Actual distances plot.

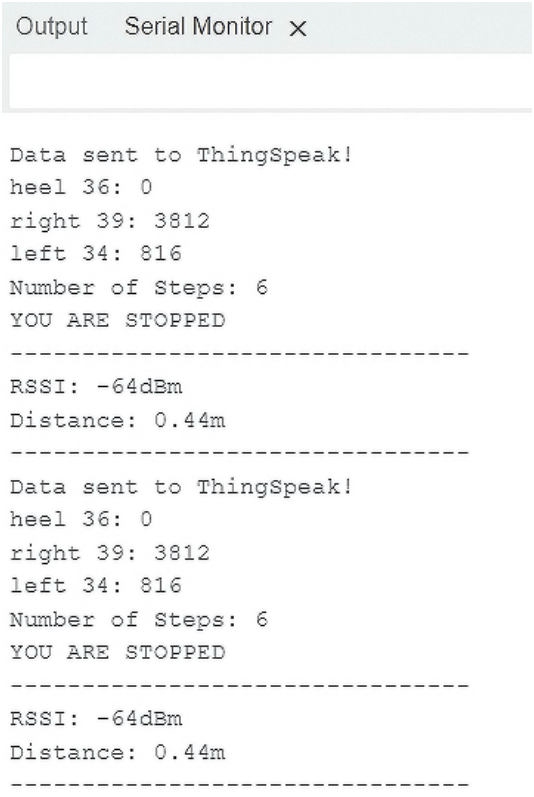

Fig. 8. Reading the arduino IDE serial port.

F. Process to Transmit Data to ThingSpeak

The platform used for real-time visualization of the data acquired by the intelligent insole is ThingSpeak [16]; this allows us to collect and store data from sensors in the cloud and develop IoT applications. Described as an open source platform with an API to store and retrieve data from objects using the HTTP protocol over the Internet or through LAN (local area network) [17]. All data, user state, step count, traveled distance, RSSI, and interpersonal distance are sent to a ThingSpeak database. The system is configured to update

every 15 seconds with an alert mechanism for distances below the set threshold. This comprehensive monitoring supports multi-user activity tracking and ensures accurate validation of the functionality of the smart insole. Fig. 9 illustrates the representation of the parameters on the ThingSpeak platform.

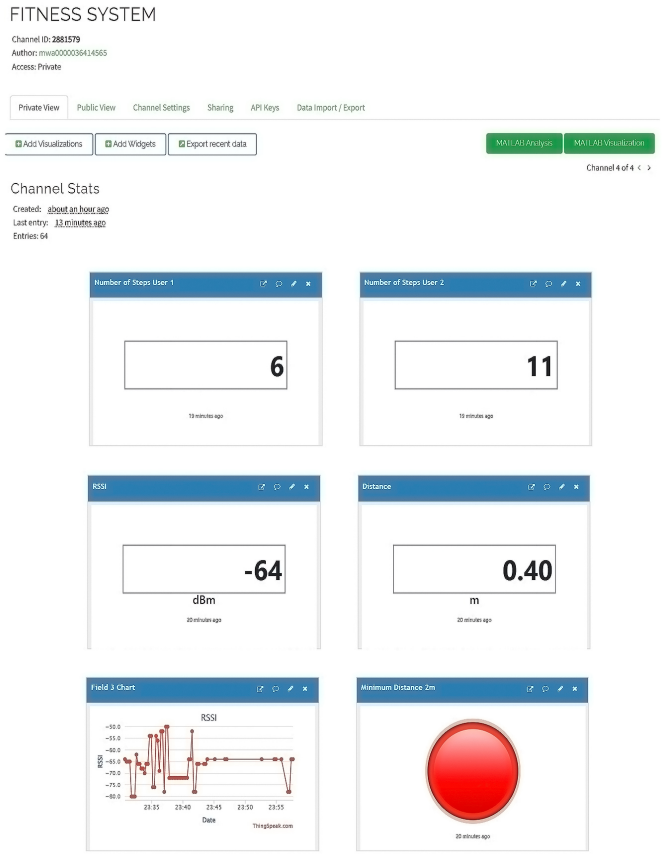

Fig. 9. Parameters on the ThingSpeak platform.

IV. Numerical Results

This section analyzes the test data from the smart insole system across various scenarios and planned routes. The system comprises two prototypes: a MASTER that transmits the RSSI signal via Bluetooth and a SLAVE that processes these RSSI data before transmitting them to the ThingSpeak platform, which functions as an IoT database, enabling real-time data visualization and export to Excel for subsequent statistical analysis. Each prototype has an ESP32-WROOM microcontroller, an MPU6050 module, and is powered by a rechargeable lithium battery of type NCR18650B, as an option, a Lipo battery of lower volume and higher performance or characteristics is recommended for an optimal wearable design. Several tests were performed to make sure that the RSSI-based step-counting and distance measurement system worked. These tests also found the system's accuracy and error range, which helped with the comparative analysis. Following the methodology described in [18], routines for data collection were designed, including two patterns per scenario: frontal crossing and cross-crossing within a defined area of 5×5 m^2. For this work, the results of a single scenario called "Crossing between smart insole prototypes in parallel opposite directions" are shown. The configuration for this scenario is illustrated in Fig. 10. The calculation of the real distance traveled by the participants was performed using a pedometer-based system. To obtain the real distance, we relied on the step count obtained from the system and multiplied it by an average step length that was calibrated for the individual. The speed of travel can be derived by calculating the time between updates and dividing the distance by the time elapsed.

Furthermore, to reduce interference, we executed the experiment in open and unobstructed environments, avoiding areas with walls or reflections that can influence sensor results. Outdoor testing was carried out on clear, dry days with minimal wind to mitigate weather influences. We verified that all equipment, including sensors, was fully charged before testing and performed periodic checks during extended tests to prevent battery-related data loss. In addition, test routes were meticulously chosen to avoid significant obstructions, such as trees or other objects, that could disrupt sensor readings, thus ensuring accurate data collection.

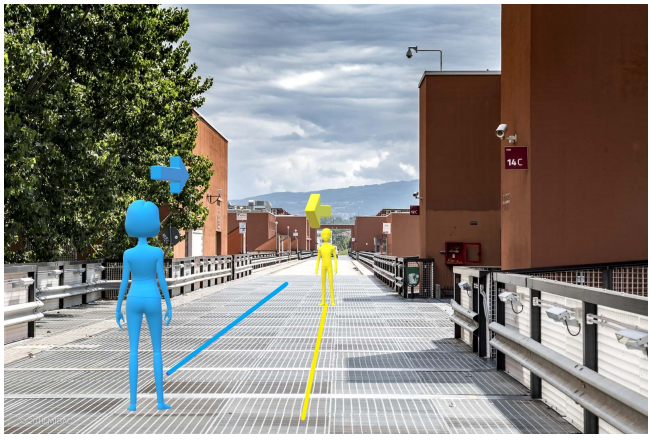

Fig. 10. Example of crossing between smart insole prototypes in parallel opposite direction.

A. Results of Crossing between Smart Insole Prototypes in Parallel Opposite Direction

Table I shows the data obtained for this case of analysis, in which it can be observed that the individual using the SLAVE prototype has taken 7 steps during the 5 meters of established area, for the user who uses the MASTER prototype visualizes that it has taken 8 steps during the established area. The average distance traveled by each prototype is 5.012 meters. It can also be visualized that in the fourth value, the distance measured by the system reflects 1.0404 meters; this distance will be compared with the real distance in Table II, and we will also obtain a percentage of precision and realative error. The relative error Re and the accuracy percentages were calculated using Eq. (4) and (5):

$$Re\ \% = \left(\frac{\text{Calc. Distance} - \text{Real Distance}}{\text{Real Distance}} \right) \times 100 \quad (4)$$

$$\text{Accuracy } \% = 100\% - \text{Error } \% \quad (5)$$

Furthermore, to compare our work with that proposed by [11], we used the root mean square error (RMSE), as detailed in Eq. (6). For the data obtained in Table II, the calculated RMSE was 0.313. To compute the RMSE percentage as in [11], we follow the procedure described in Eq. (7). The result obtained is 8. 79%, which is less than the 13. 4% reported in the reference work. This indicates that our proposed model achieves superior performance.

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \tag{6}$$

Where, $\hat{y}_i$ is the distance obtained, y_i is the real distance, and n is the total number of observations.

$$\text{RMSE}_{\%} = \left(\frac{\text{RMSE}}{\text{mean}(y_i)}\right) \times 100 \tag{7}$$

TABLE I. CROSS BETWEEN SMART INSOLE PROTOTYPES IN PARALLEL OPPOSITE DIRECTION

Samples	RSSI (dBm)	User1 Steps	User2 Steps	Distance Obtained (m)	Distance Traveled (m)
1	-90	0	0	5.785	0
2	-92	0	1	4.335	0
3	-81	1	1	2.601	0.716
4	-72	2	3	1.040	1.432
5	-80	2	4	2.081	1.432
6	-92	3	5	4.029	2.148
7	-88	5	7	5.027	3.58
8	-91	7	8	5.297	5.012

TABLE II. INDIVIDUAL ERROR PERCENTAGE: CROSS BETWEEN SMART INSOLE PROTOTYPES IN PARALLEL OPPOSITE DIRECTION

Sample	Distance Obtained (m)	Real Distance (m)	*Re* (%)
1	5.28	5.1	3.62
2	4.34	3.7	17.16
3	2.60	2.3	13.09
4	1.04	1.2	13.30
5	2.08	2.3	9.53
6	4.03	3.7	8.89
7	5.27	5.1	3.39
8	5.30	5.1	3.86

According to the findings presented in Table II, the mean Re rate is 9.11% and the accuracy rate is 90.89%, as there are no impediments influencing the RSSI signal. Furthermore, it is evident that eight samples were collected during the test, with one instance of proximity between prototypes where the measurement fell below the stipulated minimum allowable distance of 2 meters.

Finally, in Fig. 11 we can see the system of multi-user intelligent insoles, mounted or assembled on the shoe of each person. We can also see graphically how the system works by collecting the data from the FSR force sensors, and IMU inertial, the interaction between Master and Slave prototypes, the connection of each prototype to the Wi-Fi network of a cell phone and the sending of the data to the ThingSpeak cloud platform.

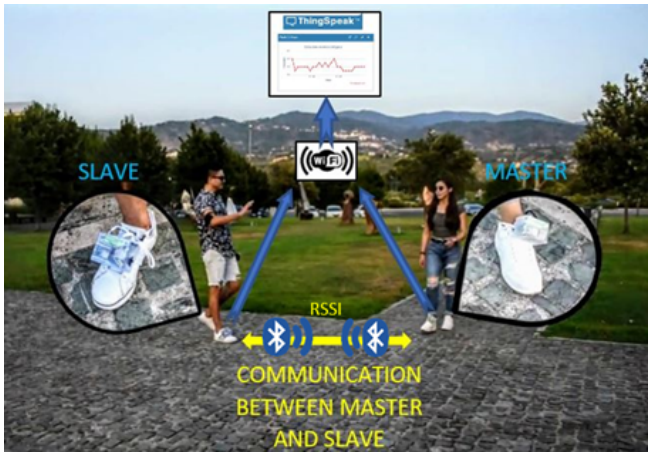

Fig. 11. Multi-user intelligent insole system assembled in each person's shoe.

V. CONCLUSIONS

In this work, a smart insole-based system has been proposed that allows the main objective to measure the distance between two users who interact with each other, be it in a daily activity, sports, or even at a medical level, in which the measurement and real information of the distance between individuals plays an important role. The prototype also includes sensors to count steps, detect activity (walking/running), and a configurable alarm to alert when the distance is less than a threshold. This system allows the storage, visualization, and monitoring of the data on the ThingSpeak Web platform, which allows quick and timely access to the data obtained thanks to the fact that the information is sent remotely to the web through protocols of wireless communication based on the internet of things. Distance estimation relies on the (RSSI), a cost-effective but unstable method due to low signal power and environmental obstructions. To address this, the work applied an MLP neural network, achieving an average accuracy of 90.89% in real data. The easy use and easy insertion in a common shoe make this system one of the best options as a wearable system, in addition to having a cost well below existing systems and with versatile features, which due to the microprocessor features can be varied or added according to the need of the end user.

In future work, the accuracy of the system could be improved by optimizing the RSSI method, integrating multiple sensors, and using advanced localization algorithms. In addition, its functionality could be expanded by creating a complementary mobile application and integrating it with wearable devices. Furthermore, new applications could be explored in the healthcare sector, such as monitoring patients or elderly individuals, and in high-density scenarios like mass events, enhancing safety and accident prevention.

ACKNOWLEDGMENT

The authors express their sincere gratitude to the University of Calabria, Italy, for the support provided during the development of this work. In particular, we extend our

appreciation to the Department of Computer Engineering, Modeling, Electronics, and Systems, DIMES, where the testing and implementation of the system were carried out. We also extend our heartfelt thanks to the Escuela Superior Politécnica de Chimborazo, ESPOCH, Ecuador, for its valuable support and collaboration in this research.

Miharu Communications Inc., Kamakura, Kanagawa, Japan[2]
Kanagawa Institute of Technology, Atsugi, Kanagawa, Japan[3]

***Abstract*—This paper presents a lightweight JPEG XS coding scheme incorporating spatio-color scrambling for privacy protection. The proposed approach follows an Encryption-then-Compression (EtC) framework, maintaining compatibility with the JPEG XS standard. Prior to encoding, input images undergo scrambling operations, including line permutation, line reversal, and color permutation. Security analysis indicates that the scrambling technique provides a large key space, making brute-force attacks computationally challenging. Experimental results demonstrate that the proposed method achieves a rate-distortion (RD) performance nearly equivalent to conventional JPEG XS compression while enhancing visual security. Additionally, a rectangular block-based scrambling technique is explored, which offers a trade-off among low latency, reduced memory usage, and visual concealment performance. While real-time processing is possible with or without block-based scrambling, the block-based approach is particularly beneficial for applications that demand lower latency and reduced memory usage. The effectiveness of the proposed method is validated through simulations on 8K ultra-high-definition (UHD) images.**

I. Introduction

As research into Beyond 5G (B5G) progresses, network and computational infrastructures must evolve to support ultra-low latency, high-speed processing, and intelligent data management. Our research project proposes an architectural framework leveraging in-network computing to facilitate autonomous functional collaboration by seamlessly integrating network and computational resources [1]-[3]. The proposed approach facilitates real-time coordination between networking and computation, optimizing task distribution and adaptive processing while maintaining high throughput and low latency. This is particularly crucial for emerging applications such as real-time ultra-high-definition (UHD) video streaming, where rapid and efficient data processing is essential. In addition, a wide range of real-time applications can benefit from in-network computing, including generative AI, robotics integrated with IoT and sensor technologies, the metaverse, connected vehicles, and digital twins. These domains require ultra-low-latency and high-efficiency processing to support dynamic and data-intensive operations.

One of the key research themes in this project is the utilization of JPEG XS [4]-[9] for high-speed and low-latency video encoding at the edge/cloud while maintaining the quality of the uncompressed video. JPEG XS is an ISO/IEC international standard established in 2019. Similar to JPEG2000 [10], JPEG XS is a coding method based on the wavelet transform. It is known for its low complexity, near-lossless compression, and real-time encoding/decoding capabilities, and is well-suited for applications requiring high-quality, ultra-low-latency video transmission.

A. Existing Challenges and Research Gaps

However, processing data at the edge/cloud and across network infrastructures introduces significant privacy concerns, particularly regarding potential data leakage due to accidental exposure or security breaches [11]-[13]. To mitigate these risks, the Encryption-then-Compression (EtC) framework has been widely explored for privacy-preserving image and video transmission [14]-[29]. Existing EtC techniques have been successfully applied to standardized image coding schemes such as JPEG and JPEG2000. However, despite the recent adoption of JPEG XS as an international standard for ultra-low-latency video encoding, there is currently no dedicated EtC framework optimized for JPEG XS, leaving a critical gap in privacy-preserving video transmission.

Several block-based perceptual encryption schemes have been developed for JPEG and its variations [24]-[29]. However, these conventional techniques are inherently designed for square block-based image coding and are not directly compatible with wavelet-based compression schemes such as JPEG XS. In [22], a block-based JPEG2000 EtC technique incorporating sign-scrambling was introduced. Nevertheless, this method requires a preprocessing step involving discrete wavelet transform (DWT) followed by an inverse discrete wavelet transform (IDWT), introducing additional computational overhead and latency. This preprocessing makes existing approaches unsuitable for real-time applications requiring ultra-low-latency transmission, such as UHD streaming over B5G networks.

B. Contributions of this Study

To bridge this gap, this paper proposes a lightweight scrambled JPEG XS coding scheme designed specifically for privacy-preserving UHD video transmission [1]. The key contributions of our work are as follows:

- A scrambled JPEG XS coding scheme that directly integrates lightweight image scrambling techniques, including line permutation, line reversal, and color permutation, into the JPEG XS encoding process.

[1]Part of this work has been presented at IEEE ISPACS 2022 [30] and IEEE ICICT 2024 [31].

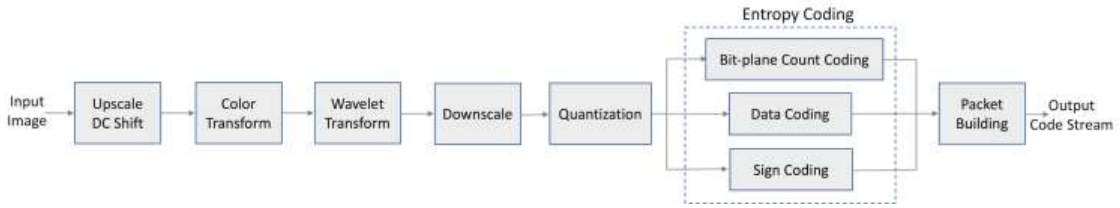

Fig. 1. Block diagram of JPEG XS encoder.

- Elimination of computationally expensive preprocessing steps such as DWT/IDWT, ensuring real-time processing feasibility.
- Maintaining compatibility with the JPEG XS standard, allowing seamless integration into existing imaging and networking workflows.
- RD performance comparable to that of conventional JPEG XS without scrambling, ensuring minimal impact on video quality.

The rest of this paper is structured as follows: Section II provides an overview of JPEG XS, while Section III details the proposed lightweight scrambled JPEG XS coding technique. Simulation results are presented in Section IV, followed by conclusions and future work in Section V.

II. JPEG XS Technical Overview

This section provides an overview of JPEG XS coding technology along with its fundamental technologies, profiles and formats.

A. Coding Technology Outline

Similar to JPEG 2000 [10], the JPEG XS core coding system is a wavelet-based still image codec. Since each frame is processed as an independent still image, JPEG XS can also function as a video codec. Fig. 1 illustrates the block diagram of the JPEG XS encoder. The encoding process begins with scaling the image data according to its bit depth, followed by DC offset removal to obtain a zero-mean signal. For RGB input, a reversible color decorrelation transformation is applied, converting it into an approximate YCbCr space - a process identical to the Reversible Color Transform (RCT) in JPEG 2000. Subsequently, a wavelet transformation is performed. The current specification supports one or two-level vertical wavelet decomposition using the LeGall 5/3 wavelet, which is also employed in JPEG 2000, and allows up to eight horizontal decomposition levels. Next, rate allocation is handled through quantization, followed by entropy coding. Finally, the encoded data is packetized to construct the JPEG XS bitstream.

B. Fundamental Technologies

1) Reversible Color Transformation: The Reversible Color Transformation (RCT) serves as a decorrelating process applied to the RGB components of an image. By eliminating the correlation between RGB components, the amount of information can be effectively reduced. The definitions of RCT and its inverse RCT in JPEG XS are expressed as follows:

$$\begin{bmatrix} Y \\ C_b \\ C_r \end{bmatrix} = \begin{bmatrix} \lfloor \frac{R+2G+B}{4} \rfloor \\ R-G \\ B-G \end{bmatrix}, \tag{1}$$

$$\begin{bmatrix} G \\ R \\ B \end{bmatrix} = \begin{bmatrix} Y - \lfloor \frac{C_b+C_r}{4} \rfloor \\ C_b+G \\ C_r+G \end{bmatrix}. \tag{2}$$

2) Wavelet Decomposition: In JPEG XS, the following LeGall 5/3 wavelet transform is used.

$$y(2n+1) = x(2n+1) - \left\lfloor \frac{x(2n)+x(2n+2)}{2} \right\rfloor \tag{3}$$

$$y(2n) = x(2n) + \left\lfloor \frac{y(2n-1)+y(2n+1)+2}{4} \right\rfloor, \tag{4}$$

In this context, $y(2n+1)$ denotes the high-frequency wavelet coefficient, while $y(2n)$ corresponds to the low-frequency wavelet coefficient. Due to its compatibility with the lifting scheme, efficient processing can be achieved using simple shift operations, enabling a lightweight implementation. By applying the wavelet transform both vertically and horizontally to the input image, a two-dimensional sub-band decomposition is obtained. The resulting low-frequency subband undergoes further recursive wavelet transformations, refining the hierarchical decomposition. By this recursive processing, resolution scalability can be realized, which also contributes to the improvement of coding efficiency.

3) Quantization: JPEG XS provides both a dead-zone quantizer and a uniform quantizer. The dead-zone quantizer is implemented by removing T least significant bit (LSB) planes through truncation. When selecting a uniform quantizer, the quantization size Δ_T is set as follows:

$$\Delta_T = \frac{2^{M_g+1}}{2^{M_g+1-T}-1}. \tag{5}$$

The quantization can be easily realized only by shifting and adding. M_g is a bit plane count defined by the following Eq. (6). It represents a bit plane with significant bits.

$$M_g = \max\left(\left\lfloor \log_2 \max_{i \in g} x_i \right\rfloor + 1.0 \right), \tag{6}$$

where g represents a coding group (hereinafter, described in *4) Entropy Coding*), and x_i represents the i-th coefficient in coding group g.

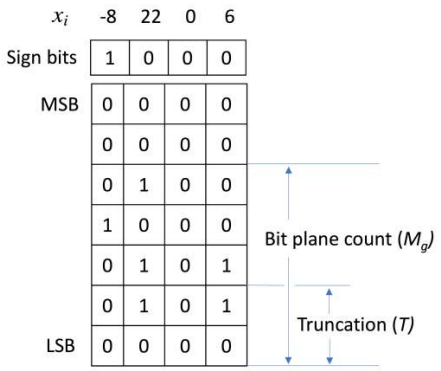

Fig. 2. Coding group g for entropy coding.

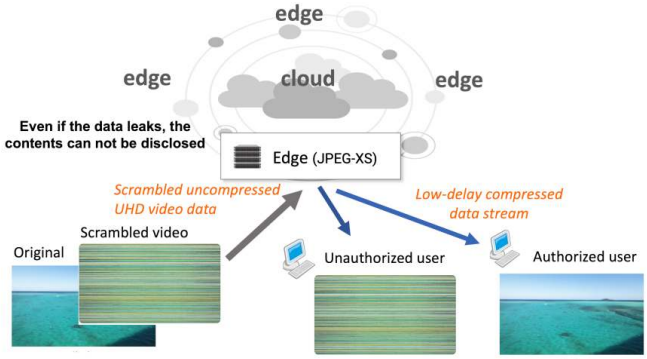

Fig. 3. The concept of scrambled JPEG XS coding.

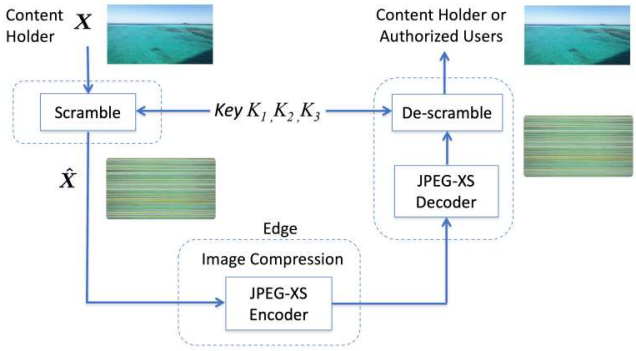

Fig. 4. The system architecture of scrambled JPEG XS.

4) Entropy Coding: In order to encode with as few bits as possible, it is common to represent frequently occurring wavelet coefficient values in short codewords and rare wavelet coefficient values in large codewords. This process is called entropy coding. Unfortunately, variable-length coding and decoding demand significant hardware and software resources. To reduce implementation complexity, JPEG XS applies variable-length coding to groups of four coefficients, referred to as coding groups, rather than encoding each wavelet coefficient individually. Fig. 2 shows an example of $x_i \in \{-8, 22, 0, 6\}$, $M_g = 5$, $T = 2$. M_g is called a "bitplane count" because it can be interpreted as the number of nonzero bitplanes in the coding group. T is a truncation point. The following processing is performed in each coding group.

1) Bit-plane count coding
   It encodes the bit plane count M_g. Several prediction modes are provided to improve coding efficiency.
2) Data coding
   It encodes the wavelet coefficient. The bit plane between the bit plane count M_g and the truncation point T is recorded in order from the MSB. In the example of Fig. 2, it is "010010000101".
3) Sign coding
   It encode the sign of the wavelet coefficient. In the example of Fig. 2, it is"1000".

C. JPEG XS Profiles and Formats

JPEG XS supports multiple profiles, including Light and Main, optimized for different use cases, from real-time streaming to high-resolution image storage. The profiles are characterized by specific parameters such as chroma subsampling (4:2:2 or 4:4:4), bit depth (10-bit or 12-bit) and wavelet decomposition levels, allowing flexibility in high-quality image transmission. By default, the main profile restricts the vertical wavelet transform to a maximum of one level. The light-subline profile achieves minimal latency and computational complexity by omitting the vertical wavelet transform entirely. In contrast, the high profile provides the highest coding efficiency at the cost of increased computational complexity, allowing for up to two levels of vertical wavelet transform.

JPEG XS defines different file and transport formats and can be used for archiving or streaming. It is based on existing standard formats such as MP4, MPEG-2 TS and RTP, allowing computer color correction rendering and video archiving or streaming.

III. The Proposed Scrambled JPEG XS

In this section, we introduce a scrambled JPEG XS coding method designed for an EtC system.

A. Design Concept and System Architecture

The concept of scrambled JPEG XS coding is illustrated in Fig. 3. This approach enhances security by preventing unauthorized access to meaningful visual information, ensuring that even if the data is intercepted, its content remains unintelligible. The proposed method maintains compatibility with standard JPEG XS compression, allowing seamless integration into existing imaging and networking workflows. This paper focuses on the design of a scrambling technique for JPEG XS, implemented as a preprocessing stage. The technique ensures: 1) compliance with the JPEG XS bitstream syntax, and 2) negligible degradation of JPEG XS's RD performance, while providing effective visual scrambling.

Fig. 4 illustrates an EtC system incorporating the proposed scrambled JPEG XS. At the local site, the input image $\boldsymbol{X}$ undergoes transformation into a scrambled image $\hat{\boldsymbol{X}}$ by applying line permutation, line reversal, and color permutation. Each operation is performed using a separate private key: K_1 for line permutation, K_2 for line reversal, and K_3 for

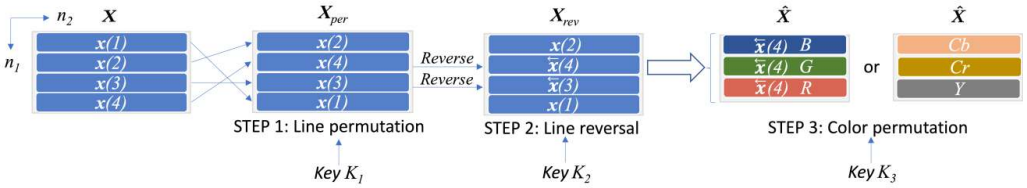

Fig. 5. An example of scrambled image generation by using line permutation, line reversal and color permutation.

color permutation. Subsequently, the scrambled image $\hat{\boldsymbol{X}}$ is transmitted to the edge or cloud. At the edge/cloud, the JPEG XS encoder compresses the scrambled image. On the receiver side, the compressed bitstream is processed by the JPEG XS decoder, resulting in a decompressed but still scrambled image. Only authorized users possessing the private keys K_1, K_2 and K_3 can successfully restore the original image by descrambling.

B. Scrambled Image Generation

Scrambled image generation consists of line permutation, line reversal, and color permutation, as shown in an example in Fig. 5. To achieve real-time UHD video compression using software or FPGA, vertical DWT is omitted, and thus, horizontal line signals are treated independently. To facilitate the description of the scrambling operations, we define an input image as follows:

$$\boldsymbol{X} = \begin{bmatrix} \boldsymbol{x}(1) \\ \boldsymbol{x}(2) \\ \vdots \\ \boldsymbol{x}(N_1) \end{bmatrix}, \tag{7}$$

$$\boldsymbol{x}(n_1) = [x(n_1,1), x(n_1,2), \cdots, x(n_1,N_2)], \tag{8}$$

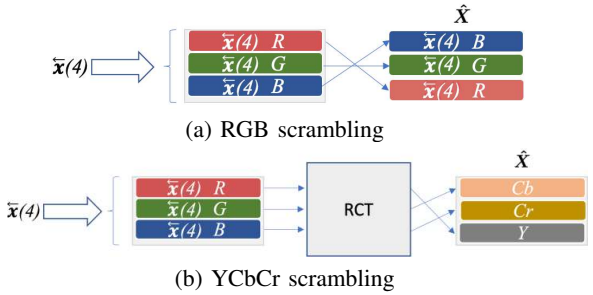
where $x(n_1,n_2)$ is the pixel value at the position $x(n_1,n_2)$, N_1 and N_2 are the number of vertical and horizontal pixels, respectively. Strictly speaking, each RGB component has its own intensity value at $x(n_1,n_2)$; however, for simplicity, the notation is omitted in this description. Image scrambling consists of two steps:

1) Line Permutation: In the initial step, the horizontal lines $\boldsymbol{x}(n_1)$ undergo random permutation using a random permutation matrix (RPM) $\boldsymbol{P}_{K_1}^{(N_1)}$ with a private key K_1. This process is formulated as follows:

$$\boldsymbol{X}_{per} = \boldsymbol{P}_{K_1}^{(N_1)} \boldsymbol{X}. \tag{9}$$

The RPM is a binary square matrix in which each row and each column contains exactly one entry of 1, with all other entries being 0. It permutates horizontal lines. An example of the line-permuted image $\boldsymbol{X}_{per}$ when $N_1 = 4$ is depicted in Fig. 5. The RPM is described by

$$\boldsymbol{P}_{K_1}^{(4)} = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}. \tag{10}$$



(a) RGB scrambling

(b) YCbCr scrambling

Fig. 6. Examples of color permutation.

2) Line Reversal: The second step involves reversing the order of elements within horizontal lines $\boldsymbol{x}(n_1)$. The line reversal operation is defined as:

$$\tilde{\boldsymbol{x}}(n_1) = \boldsymbol{x}(n_1)\boldsymbol{R}^{(N_2)}, \tag{11}$$

where $\boldsymbol{R}^{(N_2)} \in \{1,0\}^{N_2 \times N_2}$ denotes an anti-diagonal matrix (ADM), which is a square binary matrix containing a single entry of 1 in the reverse diagonal and 0s elsewhere. For example, for $N_2 = 4$, the ADM is given by

$$\boldsymbol{R}^{(4)} = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}. \tag{12}$$

For example, when $N_2 = 4$ and $\boldsymbol{x}(n_1) = [1,2,3,4]$, applying horizontal reversal results in $\boldsymbol{x}(n_1)\boldsymbol{R}^{(4)} = [4,3,2,1]$. The selection of horizontal lines to be reversed is performed randomly, with the specific pattern dictated by the private key K_2. Fig. 5 presents an example where $\boldsymbol{x}(4)$ and $\boldsymbol{x}(3)$ are chosen for reversal.

3) Color Permutation: Following line permutation and line reversal, color permutation is applied to each image line. For color permutation, we propose two scrambling methods: RGB scrambling and YCbCr scrambling. Fig. 6(a) illustrates the configuration of RGB scrambling, in which the R and B components are randomly permuted. By leveraging the symmetrical properties of RCT as shown in Eq. (1), RD performance remains comparable to that without color permutation. The permutation operation is defined as follows:

$$\begin{bmatrix} \hat{R} \\ G \\ \hat{B} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}. \tag{13}$$

The lines for the color permutation are randomly selected, with the chosen pattern determined by a private key K_3.

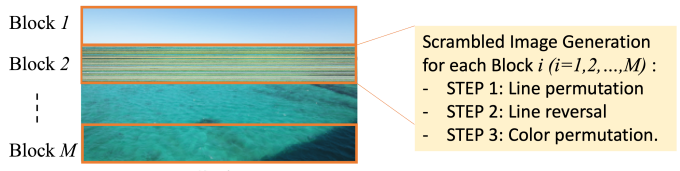


Fig. 7. Block-based image scrambling for low-latency and reduced memory usage.

Fig. 6(b) depicts the configuration of YCbCr scrambling. In this method, the RGB signals are first transformed into YCbCr components using RCT. The YCbCr components are then randomly permuted, allowing for six possible permutation patterns. An example is given below:

$$\begin{bmatrix} \hat{Y} \\ \hat{C}_b \\ \hat{C}_r \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} Y \\ C_b \\ C_r \end{bmatrix} = \begin{bmatrix} C_b \\ C_r \\ Y \end{bmatrix}. \tag{14}$$

RGB scrambling is fully compatible with the JPEG XS standard, as it applies scrambling before the RCT stage. In contrast, YCbCr scrambling enhances visual concealment but requires RCT as a preprocessing step.

C. Horizontally Rectangular Block Scrambling

Although processing one full frame at a time is feasible for many real-time applications, it may not be ideal when lower latency or reduced memory usage is required. In scenarios where both low latency and minimal memory usage are critical, applying scrambling to smaller horizontally rectangular blocks offers an effective solution for minimizing processing time. Unlike conventional full-frame scrambling, which requires buffering the entire frame before processing, block-based scrambling enables parallel processing of smaller image segments, significantly reducing latency. As illustrated in Fig. 7, the image is divided into M horizontally rectangular blocks, allowing the scrambling operations to be applied independently to each block. This approach enhances processing efficiency, particularly in real-time video transmission systems where immediate encoding and compression are required. Each block undergoes the following scrambling operations: 1) line permutation, 2) line reversal, and color permutation.

By employing this block-based strategy, a trade-off between security strength and processing efficiency can be achieved. A higher M value results in smaller block sizes, reducing latency and memory usage, but it may weaken scrambling strength due to increased spatial correlation within blocks. Conversely, a lower M value enhances security by increasing randomness, but at the cost of higher processing overhead. This flexibility allows the method to be adapted for various real-time applications, including low-latency UHD video streaming and edge/cloud-based video processing.

D. Security Strength

We assessed the security strength of the spatio-color scrambled image $\hat{\boldsymbol{X}}$ with regard to the key spaces associated with line permutation, line reversal, and color permutation. The key space is evaluated under the assumption of restoration via a brute-force attack. Initially, we analyze the key space associated with line permutation $\boldsymbol{P}_{K_1}^{(N_1)}$. Authorized users possessing the private key K_1 are able to reconstruct the original input image by

$$\boldsymbol{X} = [\boldsymbol{P}_{K_1}^{(N_1)}]^{-1} \boldsymbol{X}_{per}. \tag{15}$$

The RPM satisfies the property $[\boldsymbol{P}_{K_1}^{(N_1)}]^{-1} = [\boldsymbol{P}_{K_1}^{(N_1)}]^T$, where $[*]^{-1}$ denotes the inverse operation, and $[*]^T$ represents the transpose operation. The key space associated with $\boldsymbol{P}_{K_1}^{(N_1)}$ is determined by $N_1!$, as it solely depends on the number of vertical pixels. Next, we examine the key space for line reversal. Each horizontal line can be arranged in two possible states: either reversed or maintained in its original order. With N_1 rows, there exist 2^{N_1} combinations. Therefore, the key space for line reversal is 2^{N_1}. Finally, we explore the key space for color permutation. In RGB scrambling, each horizontal line exhibits two patterns: swapping the R and B components or retaining their order. With N_1rows, this results in 2^{N_1} combinations. For YCbCR scrambling, each horizontal line has six patterns, yielding a key space of 6^{N_1}. In summary, the key spaces of the scrambled images for RGB scrambling and YCbCr scrambling are shown in Table I(a).

Finally, we will look at the key space in block-based image scrambling. The combination pattern per block is $(N_1/M)! \times 2^{(N_1/M)} \times 2^{(N_1/M)}$ for RGB scrambling and $(N_1/M)! \times 2^{(N_1/M)} \times 6^{(N_1/M)}$ for YCbCr scrambling. When $M = 1$, the system operates in the *non-block* mode, meaning

TABLE I. KEY SPACES OF SCRAMBLED IMAGES

(a) *Non-block* scrambling

Non-block RGB	$N_1! \times 2^{N_1} \times 2^{N_1}$
Non-block YCbCr	$N_1! \times 2^{N_1} \times 6^{N_1}$

(b) Block-based scrambling

Block RGB	$\{(N_1/M)! \times 2^{(N_1/M)} \times 2^{(N_1/M)}\}^M$
Block YCbCr	$\{(N_1/M)! \times 2^{(N_1/M)} \times 6^{(N_1/M)}\}^M$

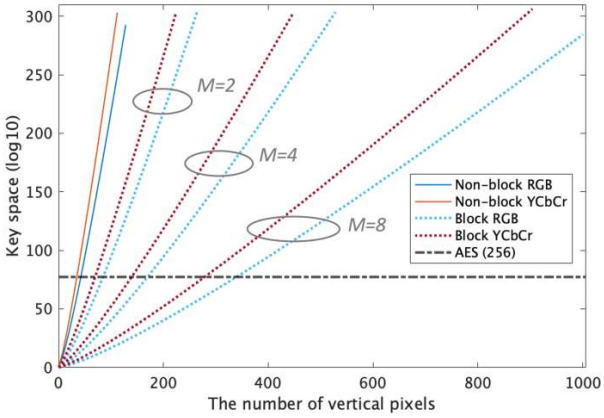

Fig. 8. The key space of the *non-block* scrambled images, and block based scrambled images for different values of M ($M = 2, 4$, and 8).

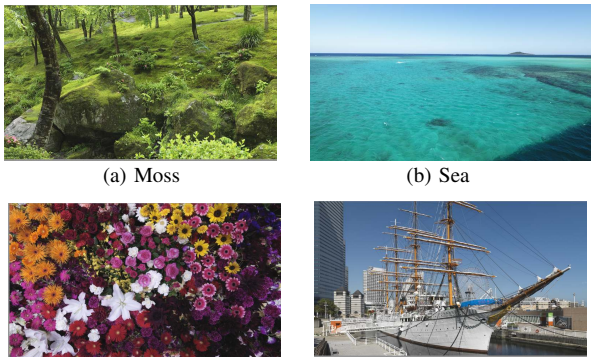

(a) Moss (b) Sea

(c) Flowers (d) Ship

Fig. 9. Original 8K images [32].

TABLE II. MEAN ABSOLUTE PEARSON PRODUCT-MOMENT CORRELATION COEFFICIENT (PPMC) BETWEEN ORIGINAL 8K IMAGES AND THE CORRESPONDING DESCRAMBLED 8K IMAGES

(a) RGB Scrambling

M	*Non-block*	2	4	8
Moss	0.0259	0.0444	0.0917	0.149
Sea	0.0041	0.476	0.561	0.645
Flowers	0.0182	0.0243	0.0666	0.0954
Ship	0.0264	0.0683	0.0994	0.1424

(b) YCbCr Scrambling

M	*Non-block*	2	4	8
Moss	0.0180	0.0339	0.0659	0.106
Sea	0.0102	0.243	0.289	0.332
Flowers	0.0140	0.0208	0.0517	0.0752
Ship	0.0162	0.0181	0.0304	0.0531

that no division into multiple blocks. Table I presents a comprehensive summary of our key space analysis results.

Fig. 8 illustrates the calculated key space for both *non-block* and block-based scrambled images with varying block sizes M, based on the formula in Table I. The results indicate that a larger block size corresponds to a smaller key space. For comparison, the key space of 256-bit AES is also included. In the case of UHD images, with vertical resolutions typically exceeding 2000 pixels, the key spaces for both *non-block* and block-based scrambled images are sufficiently large.

IV. EXPERIMENTAL RESULTS

We processed four 8K images, namely "Moss", "Sea", "Flowers", and "Ship", shown in Fig. 9, obtained from the Institute of Image Information and Television Engineers (ITE) [32]. These images possess a resolution of $N_1 = 4320$, $N_2 = 7680$ with a depth of 36 bits (12 bits/color), adhering to the UHDTV studio standard Recommendation ITU-R BT.2020 (Rec. 2020) [33].

A. Visibility of Scrambled Images

The effectiveness of the proposed scrambling method is evaluated based on visual obscuration, where a higher level of distortion indicates stronger scrambling performance. Scrambled images generated using the proposed spatio-color scrambling method are shown in Fig. 10-11, confirming its strong visual concealment capability. Among the methods, YCbCr scrambling demonstrates the highest level of invisibility. In particular, for the "Sea" and "Ship" images, the original content is nearly unrecognizable. As an example, Fig. 13 presents the frequency distribution of RGB values in the "Sea" image. The proposed method shows significantly reduced color bias compared to the original image, which exhibits strong skewness in RGB component distribution. This effect is especially pronounced in YCbCr scrambling, where the RGB distribution appears nearly uniform.

Fig. 12 shows the "Ship" images after applying the rectangular block-based RGB scrambling method with block division parameters M= 2, 4, and 8. For comparison, the non-block version is also included. As M increases, the scrambling performance decreases, making the original image slightly more visible. This degradation is due to smaller block sizes preserving local spatial correlations, which reduces visual distortion. In contrast, a lower M yields stronger scrambling effects, effectively obscuring the original content. Although higher M values weaken scrambling strength, they help reduce transmission latency and memory usage by limiting the number of blocks to be processed. This trade-off should be carefully considered according to application requirements. These results indicate that the choice of M significantly influences scrambling effectiveness. Lower values of M are preferable when higher security and stronger image concealment are needed, while higher values may be more suitable for applications prioritizing low latency and reduced memory, despite a slight decrease in scrambling strength.

B. RD Performance

The efficacy of the proposed spatio-color scrambled JPEG XS scheme, using RGB scrambling, was evaluated in terms of RD performance. A comparative analysis was conducted against the non-scrambled version of JPEG XS. Fig. 14 illustrates the RD performance of both methods: the solid line represents the non-scrambled JPEG XS, while the dotted line represents the proposed method. In the proposed scheme, PSNR is calculated by comparing the images decoded by an authorized user with the original images. Compared to the non-scrambled version, the proposed scheme exhibits only marginal degradation in RD performance, while simultaneously improving invisibility, as shown in Fig. 10. At higher bit rates, the PSNR difference becomes slightly more noticeable, but it remains above 40 [dB] - within a range generally imperceptible to the human eye.

Fig. 15 illustrates the decoded "Ship" images with RGB scrambling at bitrates of 2 [bpp] and 10 [bpp], as viewed by both authorized and unauthorized users. An authorized user possessing the correct private keys can successfully decode the scrambled images, whereas an unauthorized user fails to do so. Fig. 16 presents partially enlarged views of the decoded "Ship" images at the same bitrates. The images labeled "Authorized user" represent the decoded results for an authorized user, while those labeled "Non-scrambled JPEG XS" correspond to the decoded images produced without scrambling. These figures demonstrate that the visual characteristics of the decoded images remain nearly identical, regardless of whether scrambling was applied.

C. Security Strength

We assessed the security robustness of $\hat{\boldsymbol{X}}$ under the assumption of restoration via brute-force attack. The Pearson product-moment correlation coefficient (PPMC) and mean squared error (MSE) were used as similarity metrics. A lower PPMC and higher MSE indicate stronger scrambling, while the opposite implies weaker scrambling. Two samples are typically considered uncorrelated when the absolute value of their PPMC is below 0.2; values approaching 1 indicate strong correlation. To simulate unauthorized access, 100 random descrambling patterns were generated. Table II shows the mean absolute PPMC values obtained over 100 trials, comparing original 8K images with their descrambled counterparts using both RGB and YCbCr scrambling methods. Table III presents the corresponding MSE values. For clarity, all values are expressed in units of 10^8.

TABLE III. MEAN SQUARED ERROR (MSE) $[\times 10^8]$ BETWEEN ORIGINAL 8K IMAGES AND THE CORRESPONDING DESCRAMBLED 8K IMAGES

(a) RGB Scrambling

M	*Non-block*	2	4	8
Moss	3.27	3.22	3.07	2.90
Sea	7.51	4.55	4.04	3.51
Flowers	6.15	6.11	5.86	5.69
Ship	3.93	3.74	3.64	3.46

(b) YCbCr Scrambling

M	*Non-block*	2	4	8
Moss	4.64	4.58	4.45	4.30
Sea	7.29	5.57	5.25	4.95
Flowers	6.27	6.23	6.06	5.92
Ship	5.16	5.15	5.09	4.98

From Tables II and III, the non-block method exhibits strong scrambling performance, as its mean absolute PPMC values remain consistently low for both RGB and YCbCr scrambling. Furthermore, within the non-block method, YCbCr scrambling generally demonstrates stronger scrambling performance than RGB scrambling, except for the "Sea" image. In this case, which includes a high proportion of blue components, RGB scrambling - particularly the swapping of the R and B channels - appears to improve scrambling strength. This suggests that image color characteristics can influence the effectiveness of different scrambling methods.

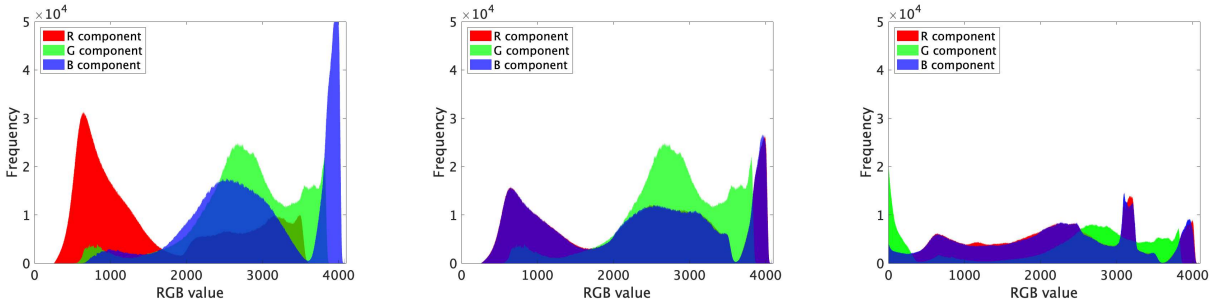
For rectangular block-based scrambling (with $M \geq 2$), increasing M tends to raise the mean absolute PPMC and lower the MSE, indicating weakened scrambling strength. In the case of the "Sea" image, the mean absolute PPMC values exceed 0.2 under block-based scrambling, likely because the upper blocks contain sky and the lower blocks contain sea, resulting in similar structures within each block. Consequently, line permutation alone cannot sufficiently disrupt these spatial correlations. Therefore, while block-based scrambling offers flexibility in balancing security and computational efficiency, its effectiveness must be carefully evaluated, particularly for large M values or images with distinct regional segmentation.

V. DISCUSSION

The proposed lightweight scrambled JPEG XS coding scheme has demonstrated its effectiveness in maintaining high visual privacy while ensuring compatibility with standard JPEG XS compression. In this section, we discuss key findings, potential limitations regarding the proposed approach.

A. Impact on Rate-Distortion Performance

Our experimental results confirm that the proposed scrambling technique introduces minimal degradation in RD performance. The RD curves indicate that the PSNR values of the decoded images remain comparable to those of conventional JPEG XS, even when scrambling is applied. This suggests



(a) Original RGB (b) RGB scrambling (c) YCbCr scrambling

that the proposed method effectively preserves visual quality while providing privacy protection. At higher bit rates, a slight decrease in PSNR can be observed due to the applied scrambling. However, the PSNR consistently remains above 40 dB, a level at which differences are generally imperceptible to the human eye. Therefore, the impact on perceived image quality is negligible.

B. Security Considerations and Trade-offs

The security analysis confirms that the proposed scrambling scheme significantly expands the key space, making brute-force attacks infeasible. The combination of line permutation, line reversal, and color permutation effectively prevents unauthorized reconstruction. In the case of the block-based approach, the scrambling strength depends on the number of block divisions M. A higher M reduces latency and memory but may weaken security due to increased spatial correlation within blocks. Conversely, a lower M enhances security by increasing randomness but at the cost of higher processing overhead. This trade-off must be carefully balanced based on application needs.

C. Applicability to Real-time UHD Video Transmission

One of the primary advantages of the proposed method is its suitability for real-time UHD video transmission. Unlike conventional EtC schemes based on block-based image coding (e.g., JPEG or JPEG2000), our approach is optimized for the JPEG XS framework, ensuring lightweight and low-latency processing. The proposed scheme can be seamlessly integrated into existing JPEG XS-based imaging pipelines, making it practical for deployment in B5G applications such as edge/cloud-based video processing.

D. Limitations

While the proposed method provides lightweight processing and high visual security, there are two primary limitations. One key limitation is that, in prioritizing low latency and low computational complexity, the method omits vertical DWT. As a result, its RD performance is inferior to that of schemes applying both vertical and horizontal DWT. Another limitation arises from the block-based scrambling approach: as the number of block divisions M increases, scrambling strength tends to decline due to the preservation of local spatial structures within smaller blocks, potentially reducing visual concealment.

VI. Conclusions and Future Work

This paper presented a lightweight EtC scheme for the JPEG XS standard, incorporating line permutation, line reversal, and color permutation to scramble input images prior to compression. The proposed approach is compatible with JPEG XS and is designed to enhance visual privacy. Extensive simulations using 8K UHD images demonstrated that the scrambling technique achieves RD performance nearly equivalent to conventional JPEG XS compression. Moreover, it improves visual concealment, with subjective evaluations indicating that the scrambled images effectively obscure meaningful content from unauthorized viewers. The block-based variant contributes to reduced latency and memory usage while offering a reasonable trade-off in scrambling strength, depending on the block division parameter M.

Future work will focus on enhancing the security of the block-based scrambling scheme. In addition, optimization techniques for both software and FPGA implementations should be explored to improve latency, computational efficiency, and memory usage. While the current evaluation is limited to still 8K images, extending the method to video sequences is also necessary to assess temporal consistency and reduce potential motion artifacts. Finally, developing adaptive scrambling techniques that dynamically adjust security levels based on network conditions and application requirements could further improve the flexibility and robustness of the proposed approach.

***Abstract*—This paper analyzes the current situation and development bottlenecks of small and medium-sized service industry enterprises using the T nail salon as an example. It emphasizes the importance of knowledge management and proposes the need to establish a knowledge system within the company that combines both humanistic and technological aspects. From the practice of using the SECI model in the T nail salon, we can also conclude that small and medium-sized service-oriented enterprises can use appropriate means and less cost to achieve effective knowledge conversion among individuals, teams, organizations, and customers, achieve orderly knowledge management, and ultimately achieve a comprehensive effect of improving the quality of enterprise services and competitiveness.**

***Keywords*—Knowledge management; Socialization Externalization Combination Internalization (SECI); nail salon; Small and Medium-Sized Enterprises (SMEs)**

I. Introduction

The service industry plays an important role in promoting economic growth and improving employment. In recent years, global service-oriented enterprises have begun to explore the application of digital technology to reshape and upgrade their corporate structure, thereby achieving progress and improvement in product and service quality. However, in applying digital innovation to business practices, there still exists a series of problems, among which those faced by small and medium-sized service-oriented enterprises, which occupy an important position in the service industry, are more prominent.

Due to their low barriers to entry, low investment requirements, and low technological demands, to a certain extent, small and medium-sized service industries belong to a perfectly competitive market where there are many businesses, with simple services and little autonomy in pricing. They can only accept prices and provide homogeneous products to the market in a similar way. Fierce competition among peers is intensifying, leading to profit shrinkage seriously.

In this connection, small and medium-sized service-oriented enterprises are facing enormous survival pressure and challenges. Traditional homogeneous product forms and service models can no longer meet the personalized needs of the public. Only by accelerating the differentiation process of enterprises and innovating products and services can they find their competitive advantages. In this innovation process, continuous knowledge accumulation is the foundation of innovation, and strong knowledge management capability is the key to it. Currently, the problems encountered by small and medium-sized enterprises (SMEs) in their growth process are precisely the difficulty in stimulating the potential of knowledge innovation, the difficulty in guaranteeing knowledge inheritance, and the obstacles to knowledge sharing. Many managers of SMEs believe that effective knowledge management requires changing the management mode of operation, leveraging digital technology, upgrading software configurations, and consuming a large amount of manpower and financial resources, which seems to be only affordable for large enterprises. In view of this, the knowledge management of small and medium-sized service-oriented enterprises should be guided by professionals and specific methods, which should be easy to understand, convenient to operate, low in cost, and able to produce results in the short term. In this study, with SECI knowledge conversion model in the knowledge management system applied, a T nail salon located in Shibuya, Tokyo, Japan is selected as a research case, and a knowledge management system framework suitable for the T nail salon is built based on the current knowledge management status of the T nail salon, providing guidance for the healthy operation and service upgrade of the T nail salon. SECI model is currently the most effective means of knowledge management, which can be used to promote the conversion of tacit and explicit knowledge. Since its proposal, it has been widely applied in hospitals, enterprises, schools, etc., and its effectiveness has been fully verified. However, life beauty enterprises such as the T nail salon have not yet attempted it. The T nail salon belongs to a relatively typical small and medium-sized service-oriented enterprise. We believe that the knowledge management solution proposed based on SECI model is also applicable to a large number of small and medium-sized service-oriented enterprises to a certain extent, and has certain reference value and significance for the healthy growth of such enterprises.

A. Need of the Study

This research highlights the crucial need for small and medium-sized enterprises (SMEs), particularly service-oriented businesses like T Nail Salon, to adopt effective knowledge management practices. SMEs often struggle to fully leverage knowledge innovation and face challenges in

transferring and retaining knowledge when employees depart. Businesses can safeguard valuable insights and expertise by implementing a well-organized knowledge management system. The study also addresses issues related to knowledge sharing, proposing practical and cost-effective methods and technologies easily adoptable by smaller firms. Using the SECI knowledge conversion model, the research offers a systematic approach to converting tacit knowledge into explicit knowledge. Ultimately, the study emphasizes that establishing a robust knowledge management system is vital for improving business performance, driving service enhancements, and ensuring sustainable growth in SMEs, providing valuable insights for managers and industry practitioners.

In the paper, after the introduction section, the organization follows a structured approach to explore the current knowledge management (KM) issues in a small and medium-sized enterprise (SME) and propose solutions based on the SECI model. The remaining of the paper is organized as follows: Section II discusses the literature review of the proposed model; then Section III and its sub-sections discuss the research methodology of the study; further, the current status of knowledge management in the T nail salon is explained in Section IV and its sub-sections; then, the construction of T nail salon knowledge management system based on SECI model is elaborated in Section V; then, Section VI elaborates the results attained by the study; then, Section VII represents the discussion of the study; finally, Section VIII concludes the overall summary of the paper and Section IX discusses the limitations of the study.

II. Literature Review

The literature review encompasses a diverse range of references that contribute to understanding knowledge management within organizations. The study [1] defines the knowledge-based economy, categorizing knowledge into four types: Know-what, Know-why, Know-how, and Know-who, although specific results for this reference are not detailed in the paper. In [2], the author emphasize the importance of intelligent knowledge management, noting its critical role for organizations to navigate and utilize knowledge effectively, but again, results are not specified. In [3], the author offers a conceptual analysis that differentiates between explicit and tacit knowledge, though it presents limited examples of practical applications in organizational settings. The study in [4] develops theories surrounding organizational knowledge creation, enhancing the understanding of implicit and explicit knowledge dynamics, yet it lacks empirical validation across various organizational contexts. The operationalization of tacit knowledge is discussed by [5], who highlights challenges in measuring such knowledge, indicating that results may not generalize across different industries. The study in [6] explores how tacit knowledge drives innovation processes, though specific examples of its impact are somewhat limited. In [7], the author provides an overview of knowledge management practices, advocating for a systematic approach to enhance organizational performance, but there may be potential bias due to anecdotal evidence and varied industry applications. The study in [8], review knowledge management systems and their frameworks, identifying key components that boost organizational efficiency, although theoretical insights may not capture the complexities of real-world scenarios. The authors in [9], analyzes customer knowledge management, emphasizing the role of customer insights in shaping business strategies while noting that the focus may be too narrow, overlooking internal knowledge dynamics. In [11], the author discuss the integration of customer relationship management and knowledge management, providing a framework for managing customer knowledge to improve performance, though it may lack comprehensive case studies to substantiate theoretical findings. Finally, [15] contributes to the literature with a unified model of dynamic knowledge creation, introducing the SECI model as a pivotal framework for knowledge conversion, yet its application is limited to specific industries, necessitating broader validation. This comparative analysis contextualizes the references in the literature review, offering insight into each work's methodology, findings, and limitations for a more comprehensive understanding of knowledge management within SMEs. Table I represents the comparison of the existing models,

III. Research Methodology

A. Knowledge

Knowledge is a kind of optimal resource, filled with people's lives. The knowledge of the Organization for Economic Cooperation and Development, OECD) can be divided into four types: Know what, Know why, Know how and Know who [1]. Knowledge can guide human thinking and behavior and is the correct experience and insight accumulated by human beings themselves [2]. There are different classification methods for knowledge. Polanyi first proposed in 1962 that knowledge can be divided into explicit knowledge and implicit knowledge [3]. The Japanese researcher Ikujiro Nonaka's work has further deepened the understanding of implicit and explicit knowledge [4]. Explicit knowledge can be recorded and retained through specific forms and methods, such as text and graphics. Tacit knowledge is the experience and skills accumulated through people's work and study, which are generally difficult to describe and identify, with highly personalized characteristics, so it is difficult to imitate and copy. From the perspective of academic research, it is also challenging to incorporate it into the quantitative research framework [5]. The successful experience and skill concept contained in the enterprise is the source of enterprise innovation, and the mining of this tacit knowledge is crucial to the development of enterprises [6].

B. Knowledge Management

In the concept of knowledge management proposed by Arthur Andersen Business Consultant, knowledge management is defined as:

$$KM = (P + K)^S$$

KM stands for Knowledge Management; P means people, teams, organizations, etc; K refers to knowledge and activities related to knowledge; " + " refers to the technology, method, and tool, and S is the dynamic process of sharing. In this formula, knowledge management should also be supplemented by environmental factors such as consciousness, culture, and institutions.

TABLE I. COMPARISON OF EXISTING MODELS

Reference	Methodology	Results	Limitations
1	Defines the concept of a knowledge-based economy.	Knowledge is categorized into four types: Know-what, Know-why, Know-how, and Know-who.	Not specified in the paper for this reference.
2	Discusses intelligent knowledge management.	Knowledge management is crucial for organizations to navigate and utilize knowledge effectively.	Not specified in the paper for this reference.
3	Conceptual analysis of personal knowledge.	Differentiation between explicit knowledge and tacit knowledge.	Limited examples of practical application in organizations.
4	Theory development on organizational knowledge creation.	Deepened understanding of the dynamics between implicit and explicit knowledge.	Lacks empirical validation in various organizational contexts.
5	Operationalization of tacit knowledge.	Discussion of the challenges in measuring tacit knowledge within organizations.	Results may not generalize across different industries.
6	Explores the link between tacit knowledge and innovation.	Highlights the importance of tacit knowledge in driving innovation processes.	Specific examples of tacit knowledge's impact may be limited.
7	Provides a comprehensive overview of knowledge management practices.	Stresses the importance of a systematic approach to knowledge management to enhance organizational performance.	Potential bias due to anecdotal evidence and varied industry applications.
8	Review of knowledge management systems and frameworks.	Identifies key components and benefits of knowledge management systems in enhancing organizational efficiency.	Theoretical insights may not reflect the complexities of real-world scenarios.
9	Analysis of customer knowledge management.	Emphasizes the crucial role of understanding customer knowledge in shaping business strategies.	The focus may be too narrow, not accounting for internal knowledge dynamics.
11	Discusses integrating customer relationship management and knowledge management.	Provides a framework for effectively managing customer knowledge to improve business performance.	It may lack comprehensive case studies to support theoretical findings.
15	Development of a unified model of dynamic knowledge creation.	Introduces the SECI model as a key framework for knowledge conversion.	Limited application to specific industries, needing broader validation.

Knowledge management can be defined as acquiring, mining, and utilizing the knowledge possessed by human beings through certain means and methods to increase the wisdom and ability of the organization and improve the performance of the enterprise [7]. This process includes knowledge identification and acquisition, knowledge dissemination and sharing, knowledge innovation and creation, and knowledge utilization and application [8]. Knowledge management is not limited to the internal personnel of the organization but also includes the knowledge of the enterprise's stakeholders, including competitors, upstream and downstream supply chains, customers, etc.

Among them, the collection, extraction, and management of customer knowledge is an essential part. Customer knowledge refers to customers' attitudes towards products and services, their specific needs, experiences, psychological models, behavioral preferences, etc. [9], and even customers' expectations for the future. Customer knowledge plays a very important role in the development of marketing strategies [10].

Customer knowledge can be divided into four types according to its different attributes: that is, knowledge about customers, which mainly includes the explicit data of customers at the time of the transaction, such as customers' age, address, and contact information; The knowledge required by the customer is the knowledge that the enterprise passes to the customer to meet the needs of the customer so that it can quickly locate the product or service required by the customer; Knowledge from the customer, that is, the customer's needs, perceptions, experiences of the product or service; The knowledge created by enterprises and customers, that is, the new product development strategies and service means generated by mutual communication and joint discussion between enterprises and customers in the transaction process [11].

It can be seen from the knowledge management formula that the implementation of enterprise knowledge management includes: Establishing effective internal incentive mechanisms, such as intellectual property incentives [12], organizational level rewards [13], process incentives [14], and control mechanisms. These incentive mechanisms have positive effects on individual knowledge-creation behavior. Information technology support can promote the organization's knowledge collection and knowledge connection activities, and promote knowledge creation; The strengthening of leadership can have a positive impact on knowledge creation [15][16][17][18][19]. A collaborative and compatible organizational culture can reduce intra-organizational conflicts [20], thus promoting knowledge transfer and sharing within the organization [21]. Yallamelli [22] explores the effects of cloud computing on the management accounting processes of small and medium-sized enterprises (SMEs). Employing a multi-method approach, it examines how cloud computing improves financial data management, boosts operational efficiency, and supports decision-making. The findings indicate that cloud-based accounting systems offer enhanced real-time access to data, facilitating regulatory compliance and strategic decision-making. However, challenges such as data security, privacy issues, and the need for extensive employee training and effective change management remain. Knowledge is essential for production and long-term organizational growth. Knowledge Management (KM) is key in integrating organizational knowledge to drive strategic planning and sustainable success. Allur et al. 2025 introduces Adaptive Heterogeneous Structural Equation Modeling (AHSEM) as an effective tool for strategic business planning based on the KM process. A major factor contributing to the failure of KM initiatives is the absence of a clear development strategy. The paper examines the strategic planning needs for successful KM implementation and proposes a framework to help organizations manage the process. The numerical results demonstrate superior performance compared to other methods [23].

C. SECI Model

SECI model is a theoretical framework used to describe the process of knowledge conversion within and between organizations. It consists of four processes: Socialization, Externalization, Combination, and Internalization, aimed at facilitating knowledge creation, sharing, and application to drive organizational learning and innovation. These stages depict

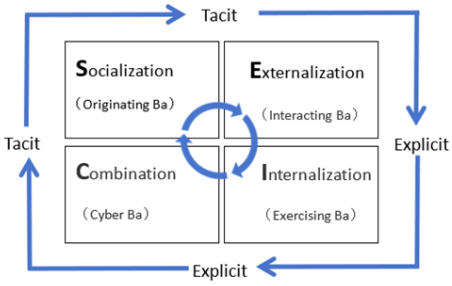

Fig. 1. SECI Model.

the transfer and integration of knowledge from individuals to organizations, involving the transformation of knowledge from tacit to explicit and vice versa. In this model, knowledge conversion is a dynamic cyclical process involving interactions among individuals, teams, and organizations. Socialization involves individuals sharing personal experiences and knowledge with others, enabling the externalization of tacit knowledge. Externalization refers to the transformation of tacit knowledge into explicit knowledge, typically through verbalization, writing, imagery, etc. Combination involves integrating different explicit knowledge elements to create new forms of knowledge. Finally, Internalization refers to the retransformation of explicit knowledge into an individual's tacit knowledge, enabling individuals to apply it in practical contexts (Fig. 1).

Based on previous literature, SECI (Socialization, Externalization, Combination, Internalization) model has made significant progress in the fields of organizational learning and knowledge management, demonstrating numerous positive aspects alongside some challenges. Firstly, SECI model provides a robust framework for organizations to facilitate knowledge creation, sharing, and application. By delineating knowledge conversion into distinct stages, SECI model helps organizations better understand the process of knowledge conversion, making knowledge management more systematic and actionable. This systematic approach aids organizations in more effectively planning and implementing knowledge management strategies, thereby enhancing the efficiency of knowledge creation and application [21].

Furthermore, SECI model emphasizes the importance of interaction and collaboration between individuals and groups in knowledge conversion. In the socialization stage, individuals convert personal knowledge into shared group knowledge through interaction and communication, thereby fostering teamwork and co-creation. This socialization process contributes to fostering common values and culture within organizations, enhancing team cohesion and innovation capability [21].

Additionally, SECI model underscores the importance of individual learning and knowledge internalization. In the internalization stage, organizations internalize shared knowledge into individuals' tacit knowledge through learning and understanding, thereby promoting individual learning and growth. This individual learning process helps to improve employees' abilities and qualities, enhancing organizational competitiveness and innovation capability. Research in the field of tacit knowledge management is also diverse, some scholar investigated the relationship between tacit knowledge and competitive advantage, finding a positive and significant association between them [24]. Tacit knowledge is based on practical intelligence rather than knowledge or academic knowledge [25]. Tacit knowledge comes from experiential training, and organizational learning often focuses on how things are done rather than why they are done. Furthermore, understanding the knowledge conversion process of SECI requires verification of its applicability in multi-organizational projects. Several notable case studies have demonstrated knowledge transfer and sharing among multiple organizations, illustrating the potential of SECI model in this regard. For example, projects like the "Home Bakery" project developed by Matsushita Electric Industrial Co., Ltd. and the personal computer project developed by NEC showcased knowledge transfer and sharing across organizational boundaries [21]. Taking Matsushita Electric Industrial Co., Ltd. as an example, the application of SECI model in the "Home Bakery" project involved organizing cross-organizational meetings and workshops where employees from different departments could directly exchange and share experiences. These meetings and workshops provided a platform for employees to discuss issues, share insights, and solve challenges face-to-face, thereby promoting knowledge socialization. Additionally, through note-taking, report writing, or presentation-making during these meetings and workshops, Matsushita Electric Industrial Co., Ltd. converted internal tacit knowledge into external explicit knowledge. Through these documents and presentations, the company transformed internal expertise and experience into shareable and understandable forms, facilitating learning and application by other organizations. Furthermore, Matsushita Electric Industrial Co., Ltd. organized cross-departmental collaborative research and development teams to integrate and collaborate on knowledge and resources from different departments. Through such cross-departmental collaboration, the company could cross-fertilize knowledge and experience from various fields, promoting innovation and problem-solving. During the project implementation process, Matsushita Electric Industrial Co., Ltd. encouraged employees to internalize external knowledge into their tacit knowledge and apply it to practical work. The company actively provided training and development opportunities to help employees internalize external explicit knowledge into internal tacit knowledge and incorporate it into the company's daily practices and culture.

Although some studies attempt to validate the correlations between different factors in SECI model through psychometric measures, the complexity and subjectivity of tacit knowledge make this task highly challenging [25].

D. SECI Model Application

The main body of knowledge management implementation based on SECI model is individuals, teams, and organizations, which are interrelated and influence each other to a certain extent, and their purpose is to jointly affect all kinds of resources formed in the process of knowledge innovation. In this process, the key is people-oriented, with knowledge as the content, and information technology as an important means. As mentioned above, the practice based on SECI model has been applied in universities, hospitals, enterprises, etc. To illustrate the practical application of SECI model in corporate settings, take Siemens AG as an example. This multinational

conglomerate has skillfully integrated SECI model to refine its technical and innovative management strategies. The establishment of online forums and repositories has effectively facilitated the socialization and externalization stages within the corporation, enabling employees to share and archive knowledge with minimal effort. During the combination phase, the organization's internal network has been strategically utilized to amalgamate these diverse knowledge assets, which has catalyzed the development of innovative technologies and solutions. Progression to the internalization phase has been achieved through systematic workshops and training programs, designed to ensure that employees not only assimilate but also effectively implement this accrued knowledge. These strategic measures have markedly enhanced the rate of innovation and fortified collaborative efforts across the company's global teams.

Pfizer's strategic implementation of SECI model during the expedited development and scale-up of COVID-19 vaccine production serves as a paradigmatic example of effectively managing risk within the pharmaceutical industry. In the Socialization Phase, Pfizer orchestrated extensive interdisciplinary meetings, enabling a rich exchange of tacit knowledge among researchers, production personnel, and quality assurance teams regarding innovative vaccine production technologies and associated safety challenges. Subsequently, during the Externalization Phase, the insights gleaned from these discussions were systematically transformed into comprehensive safety protocols and best practices, which were codified to standardize operations across Pfizer's global production facilities. The Combination Phase involved the deployment of a sophisticated digital platform that consolidated these newly formulated protocols with existing knowledge repositories, thus ensuring consistent application of safety and quality standards worldwide. In the Internalization Phase, Pfizer conducted a series of global workshops and simulation-based training sessions, which facilitated the assimilation of these standardized procedures by staff across various departments, thereby enhancing their capacity to promptly and accurately address potential production discrepancies or risks. This proactive application of SECI model not only navigated the complexities associated with the rapid scale-up of vaccine production but also safeguarded the uniformity and efficacy of the vaccines distributed globally, underscoring the model's effectiveness in enhancing operational safety and risk management in high-stakes environments.

Google has effectively harnessed SECI model to enhance both safety and innovation. Through regular safety lectures and training seminars, the company promotes systematic knowledge sharing, which aids in the early identification and management of potential risks. By transforming tacit knowledge into explicit documentation and integrating these insights into comprehensive risk management strategies, Google not only ensures that all employees are well-informed but also fosters a culture of trust and collaborative innovation. This approach enhances the robustness of Google's AI technologies, promoting the development of safer, more reliable applications that adhere to ethical standards and regulatory requirements. Moreover, the proactive engagement of employees across departments deepens the organizational understanding of AI, fostering an environment of proactive risk assessment and continual innovation. Google's strategic use of SECI model not only mitigates risks but also reinforces its commitment to ethical AI development, setting a benchmark for industry practices.

Fig. 2. Beauty salon market size in 2024.

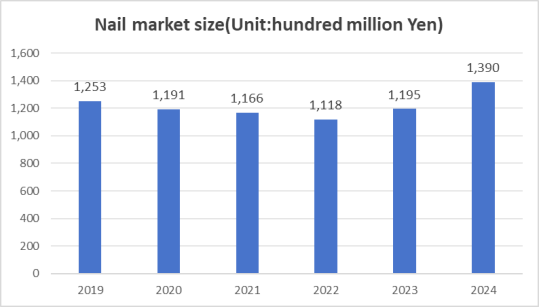

Fig. 3. Nail market size.

IV. The Current Status of Knowledge Management in the T Nail Salon

A. Industry and Company Overview

Nail salons are part of the beauty industry, a sub-industry under the service industry. The beauty industry has evolved from being a flexible demand for women to a rigid demand for everyone, including beauty, hairdressing, and nail care. According to the data of beauty census and population estimates (Bureau of statistics,ministry of internal affairs and communications,JAPAN),until August 2024, the market size of Japan's beauty industry reached 2.6496 trillion yuan, an increase of 5.3% over 2023. As Fig. 2 and Fig. 3 show, the market size of hairdressing took up a significant proportion (51.1%), followed by beauty (14.9%). Nails accounted for 51.1%, and the scale of nails reached 139 billion yuan, an increase of 16.3% over the previous year.

These physical stores face fierce competition due to small investment, and simple techniques. In the nail industry, there are over 300 nail salons just in the Shibuya-ku of Tokyo, Japan. The T nail salon is located in the Shibuya-ku commercial district of Tokyo, Japan, and has 13 female employees, including 1 manager and 12 manicurists.

Since its establishment, the T nail salon has placed great emphasis on the skills and service level of its employees. It adopts the form of an apprenticeship team (forming 3 groups, each consisting of a senior nail technician, an intermediate nail technician, a junior nail technician, and an apprentice basically) to encourage them to learn from each other, exchange experiences, and improve their service level. A senior

nail technician with relevant management experience is hired as a store manager to be responsible for basic operational management within the store.

B. The Current Status of Knowledge Management in the T Nail Salon (Based on SECI Model)

To have a more comprehensive understanding of the knowledge management status of the T nail salon, a survey of all personnel in the salon has been conducted, including anonymous questionnaires, open-ended questions, and random discussions. Based on this work, these contents are recorded and classified in detail.

1) Tables I to IV show background information of T Nail Salon personnel (except the boss): Tables II to V offer essential background information regarding the team at T Nail Salon, omitting the owner and highlighting their educational credentials, work history, age, and technical positions. Table II details the academic qualifications of the employees, including one individual with a Master's degree, two possessing undergraduate degrees, and the majority (10 employees) having graduated from vocational school. This blend emphasizes a harmony between advanced academic understanding and targeted vocational education, both crucial in a service-focused sector. Table III details the workforce's experience, dividing them into four categories: three employees with more than five years of experience, four with 3-5 years, three with 1-3 years, and three with under one year. This mix of experiences guarantees a varied skill set, promoting chances for mentorship and knowledge sharing within the team. Table IV outlines the age distribution of the staff, consisting of five employees aged 20-30, four in the 30-40 bracket, and four employees above 40. This varied age spectrum combines youthful vigor, flexibility, and extensive industry experience, aiding in meeting the diverse requirements of clients. Table V showcases the technical roles occupied by the staff, featuring three in senior roles, three at the intermediate grade, three designated as junior technicians, and four apprentices. This framework enables a clear separation of duties, with senior personnel directing and advising junior staff, fostering a nurturing educational atmosphere. In summary, these tables showcase a varied and talented team possessing different degrees of experience and proficiency, establishing a robust basis for executing successful knowledge management strategies in the salon.

TABLE II. EDUCATIONAL BACKGROUND

Educational background	Master	Undergraduate	Vocational School
Number of people	1	2	10

TABLE III. WORK EXPERIENCE

Work experience (Year)	> 5	3-5	1-3	¡ 1
Number of people	3	4	3	3

2) General interview questions in knowledge management: Such as whether you have heard of knowledge management, whether you are satisfied with the atmosphere and management of the T nail salon, whether you have long-term plans to work here, whether the office software is easy to use, and whether you can establish close relationships with customers.

TABLE IV. AGE OF EMPLOYEE

Age of employee (Year)	20-30	30-40	> 40
Number of people	5	4	4

TABLE V. TECHNICAL TITLES

Technical titles	Senior	Intermediate	Junior	Apprentice
Number of people	3	3	3	4

According to different roles and responsibilities, some personalized questions have been set up. For example, as a teacher of an apprenticeship group, are you willing to teach your apprentices? As a student, do you admire your teacher and are willing to accept her guidance and help? Do you feel that you have made progress and improved from it? As a store manager, how do you ensure the effectiveness of training? Do you have specific measures to cultivate good cooperation among employees? How often do you update the database? Do you have specific methods to maintain old customers and develop new ones? As the boss, how often do you visit the store? Can employees contact you directly? How do you view competitors and substitutes in the market?

3) From the research: It can be seen that the T nail salon currently does not carry out any activities related to knowledge management. Employees do not have a positive attitude towards knowledge management, and both managers and ordinary employees have a blank understanding of the content, requirements, and implementation steps of knowledge management. In this survey, special attention was paid to the respondents' answers to open-ended questions, such as "What role does knowledge management play in the development of enterprises" and "How should knowledge management be implemented specifically". These questions are closely related to SECI model in knowledge management and to the respondents' knowledge, values, and vision for enterprise development. They also have important reference value for how to better apply knowledge management to enterprise management in the next step (Table VI).

"I have heard of performance management, and financial management, but what is knowledge management? Our nail salon is a traditional small service-oriented enterprise. With limited manpower, why should we spend time and effort on knowledge management? Those are things that should be considered by companies with a certain scale of employees and economic benefits. If we have time and money, let's advertise and promote more". (the boss: Mr. Song)

"Nail technicians should focus on improving their skills, so why do we need to engage in knowledge management? Will my workload increase like this? Will the company compensate me for the extra workload?" (Senior nail technician: Hui)

C. Problems with Knowledge Management in the T Nail Salon (Based on SECI Model)

In view of the current situation of knowledge management in the T nail salon, this chapter starts from the different requirements of knowledge management at various stages, carefully analyzes the main reasons SECI knowledge conversion process

TABLE VI. INTERVIEW EXCERPTS

Socialization
"I don't really want to share my experience. If I teach the apprentice, then what should I do?" "Although I have a teacher, she doesn't seem very willing to teach me knowledge. She often just brushes me off with things that everyone already knows. I didn't learn anything practical from her."
Externalization
"I have not received higher education and have always focused on improving my technical skills, but if you ask me to express my design ideas and inspiration, I wouldn't know how to articulate them. I have a lot of thoughts in my mind, but I don't know how to explain them." "I feel that I am not very good at dealing with clients. If clients express their thoughts in a more subtle way, I am not very able to accurately understand them."
Combination
"I can learn knowledge from the apprentice group, but I don't have a channel to learn about the knowledge of other groups. I also want to communicate and communicate more with other nail technicians." "Our styles and techniques are only updated once every three months, which makes it a bit difficult to keep up with the changing market trends. Additionally, I feel that many of our styles and techniques have become outdated and obsolete, yet they are still included in our operating manual."
Internalization
"I found that when chatting with customers, they often have difficulty knowing about our new products and services. The relationship between customers and nail salons is also not close, and customers are easily attracted by new styles or low prices offered by other stores." "For many new styling techniques, T Nail Salon did not provide me with many opportunities to practice. Even now, there are some new techniques that I still cannot use proficiently."

cannot be effectively promoted in practical operations, and provides a basis for formulating improvement and optimization measures.

1) Insufficient motivation for acquiring and sharing tacit knowledge (Socialization): Firstly, the apprenticeship system has poor practical results, and the motivation of the master is not strong. Due to the competitive relationship between master and apprentice, the master is concerned that the sharing of knowledge between them may lead to a decrease in personal competitive advantage, and there is a possibility of "teaching the apprentice, starving the master". One of the important advantages that technical personnel have in the industry, company, and department is their skills, abilities, and experience, which are somewhat irreplaceable. In order to protect their own interests and positions, the master is unwilling to highly personalize and privatize tacit knowledge for sharing, which creates "knowledge sharing hostility"and "knowledge hoarding" [26] behaviors, to a certain extent, increasing the difficulty of sharing tacit knowledge within the enterprise.

Secondly, the master-apprentice relationship is weakened and the sense of authority worship is weak. As an apprentice who receives knowledge, the lack of trust in the master's knowledge can easily lead to "knowledge rejection" behavior [27][28]. This behavior is more of a "not created by me syndrome" [29][30], preferring to create knowledge on their own rather than accepting guidance from a master.

Thirdly, the high employee turnover rate makes it difficult to ensure knowledge transfer. Although the T nail salon has only been open for less than half a year, there have already been two cases of nail technicians resigning. The tacit knowledge they possess, such as project experience and technical skills, cannot be passed on in a timely manner. This knowledge is often unique and difficult to replicate, even if the company recruits new employees, it cannot compensate for the loss of this knowledge.

Fourth, there are barriers to client knowledge exchange and communication channels are not smooth. Due to the different professions and backgrounds of customers and nail technicians, there is a significant difference between them. There is a certain difficulty in knowledge exchange without communication and interaction. The gatherer of customer knowledge (manicurist) and the owner (customer) come from different organizations, with no system or constraint to compel them to share knowledge. Enterprises and customers belong to two different interest entities. Customers are concerned that the enterprise knowing their information will cause an information asymmetry situation. Out of concern for their own privacy, they are unwilling to engage in indiscriminate knowledge exchange with the enterprise.

2) Insufficient ability to convert tacit knowledge into explicit knowledge (Externalization): Firstly, the experience of a nail technician has characteristics such as tacit knowledge, irrationality, and situationality. The personal qualities, observational abilities, and professional experiences of the T nail salon employees vary greatly, resulting in different translations of tacit knowledge for clients. Externalization has certain requirements for everyone's ability to express in writing, ability to explain, and ability to summarize. Due to the limited cultural level of the vast majority of manicurists, there is a certain difficulty in expressing tacit knowledge and techniques into understandable words, concepts, figurative language, or images.

Secondly, the T nail salon holds apprentice group discussions and reviews at the end of each workday, followed by documentation. However, the lack of supervision over the quality of the written documentation has led to most nail technicians being negligent over time. The quality of the recorded content is low, lacking depth and value, and cannot be converted into explicit knowledge that the company can retain and utilize.

Thirdly, the T nail salon, due to limited funds, currently only uses the customer analysis function provided by the Japanese appointment website to record customer consumption and number of visits. They have not adopted more professional customer management software to record, classify, and integrate explicit knowledge data of customers. Employees are unable to obtain more customer knowledge from the existing website, let alone extract the tacit knowledge from the massive customer data and convert it into various easy-to-understand,

conceptualized, and standardized explicit knowledge.

3) Single processing method of explicit knowledge (Combination): In the T Nail salon, the store manager writes the technical operation manual and opinion book to record the skills and craftsmanship of individuals and groups, which is the current unified service manual of the store. This is the service manual currently applied by the store. The current problem is that there is an obvious lag and omission in the collection and updating of such information. The classification and editing of data using only Office software appears cumbersome and chaotic. Users are unable to quickly locate the desired information, resulting in low knowledge utilization efficiency. There is no way to systematically integrate and edit the scattered explicit knowledge of the group, thereby forming a new and more advanced explicit knowledge system.

4) Few opportunities for the conversion of explicit knowledge to tacit knowledge (Internalization): Firstly, the T nail salon currently uses the storage function provided by the appointment website as a database, but this database is not updated in a timely manner and is not convenient to access. The update permissions are concentrated in the store manager, and ordinary employees do not have permission to provide feedback or suggestions. Insufficient timely promotion and explanation of the updated database also resulted in the inability to provide nail technicians with new learning and practical opportunities. The newly formed explicit knowledge is not understood, accepted, and applied to work practice by organizational members without practice and experience, thus forming new personal experiences, styles, skills, and another tacit knowledge.

Secondly, the application and feedback channels of customer knowledge are not smooth. The integration and unification of customer knowledge, and application feedback, require enterprises to develop new marketing and incentive measures to attract and encourage customers to return to the store or introduce friends and family to receive services so that they can feel the progress and changes of the nail salon during the service. Currently, the T nail salon lacks corresponding marketing methods and fails to establish communication channels and groups between customers and employees, as well as between nail salons. As a result, there is no way to inform customers in a timely manner about updated service content and methods.

D. Insufficient Enterprise Management

From the above analysis, it can be seen that the current situation and problems of knowledge management in the T nail salon imply loopholes and deficiencies in enterprise management.

1) Unclear internal rights and responsibilities: The database is not updated in a timely manner and there are not many opportunities for practice. The reason for this is due to the lack of supervision and management by the store manager. The store manager focused mainly on serving his customers, neglecting the supervision and management of the store, the allocation of personnel, as well as the organization of various activities, and the confirmation of training effectiveness. As the boss, Mr. Song does not understand nail knowledge, he can only hand over all operational management matters in the store to the store manager. This complete delegation of power has caused the store manager's rights to be excessively enlarged, but her obligations are not being supervised. Due to the infrequent visits of the boss, the employees are unable to communicate with him regularly, resulting in the inability to promptly implement new ideas and techniques that arise in the actual operation.

2) Not-in-place incentive measures: The T nail salon lacks a salary and benefits system, as well as an employee development plan. The apprenticeship teaching system has increased the workload of senior nail technicians, resulting in a waste of time and energy. Currently, the salon compensates senior nail technicians in the form of overtime pay, which is too simple and vague, lacking unified assessment content, incentive measures, and a welfare system. Although the salon provides training at a lower price than the market, junior nail technicians and apprentices believe that the company lacks an overall talent development plan. They are uncertain about their future prospects, and apprentices often go on to work for other nail companies after the end of their training period. This high turnover rate also leads to the loss of tacit knowledge among employees.

3) Incomplete assessment mechanism: The T nail salon has not integrated knowledge organization, knowledge development, and knowledge extraction into the knowledge management system, nor has it made the duration, content, and effectiveness of apprenticeship training an important criterion for assessing the work of nail technicians. There is a lack of assessment for store managers in terms of customer satisfaction, company profits, and management ability and effectiveness. For most employees, work is work, and knowledge management is knowledge management. Most employees are forced by the organization to passively seek and upload some knowledge to the knowledge base after the fact, just to get by.

4) Insignificant customer management: The T nail salon lacks training in daily communication skills, communication methods, and content for employees and customers. Employees only rely on simple surveys to gather customer knowledge, without paying attention to understanding, analyzing, and extracting customer tone, emotions, and attitudes during the service process. Additionally, there is no follow-up tracking and improvement of customer ratings and social media comments after the service is completed. Some nail technicians, due to long-term fixed service to a certain customer, have a strong connection with the customer and consider themselves to be friends with the customer. In the process of communication and interaction, they lack boundaries and ignore the customer's opinions and suggestions, showing a lack of proactive service awareness. The customer cannot feel the respect and care from the company. Some ideas and suggestions proposed by the customer have not been taken seriously by the T nail salon. Sometimes the store manager and nail technicians will regard these suggestions, complaints, and dissatisfaction as malicious competition among peers or nitpicking by customers.

V. Construction of the T Nail Salon Knowledge Management System based on SECI Model

Based on several issues highlighted by the knowledge management of the T nail salon, we attempted to help it further optimize the knowledge management process through

SECI model, promote knowledge acquisition, storage, sharing, and application, and build personal, team, and organizational knowledge systems. We aimed to effectively establish the cognition of knowledge management, gradually form the thinking and framework of knowledge management, and ultimately achieve a comprehensive effect of improving the quality of enterprise services and competitiveness.

A. Purpose of Knowledge Management

The construction of the knowledge management system should fully consider the background of T nail salon as a small and medium-sized service company. Based on the problems existing in the salon and the current development bottlenecks, the purpose of establishing knowledge management in the salon is to optimize service processes, improve decision quality, enhance employee capabilities, and promote knowledge innovation. This process enables enterprises and customers to have a clearer and more precise positioning of services and management models and take corresponding rectification measures.

B. Principles of Implementing Knowledge Management in SMEs

1) Simple and practical, closely integrated with business: There are many methods and tools for knowledge management. The T nail salon needs to remember that all knowledge management is for business service. Software tools should not be complicated, but simple and practical. As the quantity of knowledge stored increases, attention should also be paid to improving its quality. In this process, staff need to learn to subtract, not complicate simple problems, the means of promotion should not be too cumbersome, just appropriate and precise, avoid drastic changes, and blindly overturn existing management. The big goal needs to be broken down into several smaller tasks to make it easier for everyone to understand, facilitate operation, and then be able to successfully complete it in stages.

2) Implement policies based on individuals and promote them in a hierarchical manner: If SMEs want to promote knowledge management, the key depends on the attitude and determination of the boss and professional managers, as well as the effective participation of all employees. As long as bosses and professional managers take the lead and set an example, from top to bottom, firmly and unwaveringly integrating the concept of knowledge management into the entire business service, especially for SMEs, the implementation of knowledge management is easier to achieve success than for large enterprises. For nail technicians, it is not required for them to deliberately correspond to corresponding concepts during the service process. It only requires team members to subconsciously accept the inherent requirements of knowledge management in their daily learning and work and to try and experience the progress brought by this knowledge. They should strive to create a proactive learning atmosphere and a good atmosphere for learning knowledge management within the team. In this process, it is especially important to grasp the principle of gradual progress. We cannot expect all employees to mechanically implement this concept in a general way, otherwise it will bring about the opposite result. On the one hand, it will increase the workload of the manicurists, and on the other hand, it will also cause their resentment and resistance, and the actual effect will be greatly discounted.

3) People-oriented, focusing on individual growth and capability enhancement: Establishing a knowledge management system in a company is not about simply squeezing individual knowledge out, nor is it blindly assigning tasks and targets to employees. Instead, the focus should be on how to enhance individual growth and capability improvement. Only by guiding and assisting employees to develop good knowledge management habits can organizational knowledge management be implemented. When individual knowledge management is done well and abilities are improved, organizational knowledge management will naturally fall into place.

C. Implementation Step and Stage Objective

In order to ensure the implementation effect of the plan, all work should be promoted according to the PDCA principle of the plan, do, check, and act, and the implementation step and stage objective are as follows (Chart 1 & Chart 2):

Chart 1: Implementation step

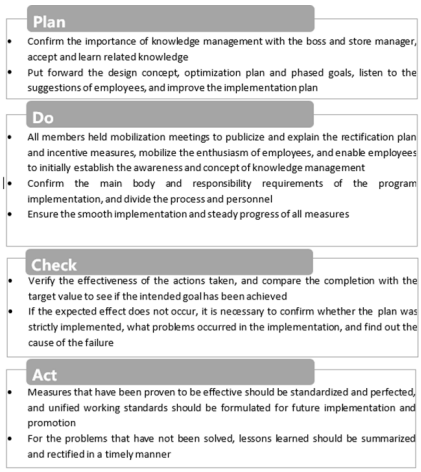

Chart 2: Stage objective

	27 days	36 days	18 days	10 days	person in charge
Select a topic					the boss
Make a plan					
Status grasping	30%				
Make a target	P				
Analysis					
Establish measures					
Take action and review		40% D			the shop manager
Confirm effects			20%		the boss
Standardization			C		
Improvement				10% A	the boss、shop manager

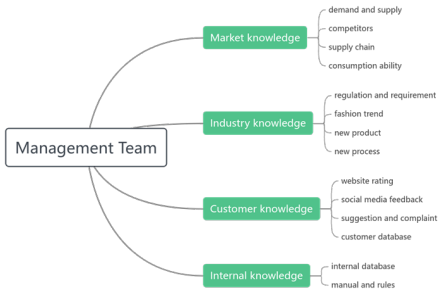
D. Optimization Solution for T Nail Salon Knowledge Management

In response to the knowledge management optimization plan proposed by the T nail salon, we should follow the principles of simplicity, ease of operation, and minimize cumbersome processes. We should aim to maximize the utility of knowledge management with minimal cost, without affecting the normal operation of the nail salon or increasing the workload of employees.

1) Adjust Personnel Structure and Clarify the Functions of Each Department: Adjust the personnel structure of the T nail salon to a management team composed of the boss and store managers; a technical team formed by apprenticeship groups (a total of three groups), managed by store managers.

a) Management team: The role of the store manager is being repositioned to be solely responsible for internal management and not serving customers. The store manager's work will be directly supervised and managed by the boss. The function of this team is to timely and accurately identify and record market changes, including market competitors, upstream and downstream supply chains, popular trends, as well as evaluations and feedback from social media on nail salons; collect new regulations and standards in the market industry, make judgments, and guard against unknown risks; integrate customer knowledge and internal staff knowledge, write and update databases and operation manuals; organize various trainings and activities to continuously improve skill levels and service quality (Chart 3).

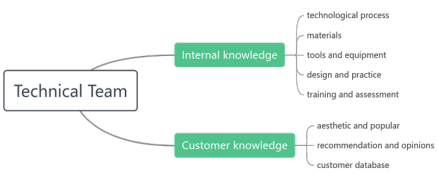
Chart 3: Management team's duties



.

b) Technical team: Each apprentice group is led by a senior nail technician who imparts nail knowledge to the apprentices, including materials, products, environmental protection, cleaning requirements, tool usage, design abilities, and technical improvement. They collect and extract customer needs and feedback, and organize regular internal training and assessments to evaluate the results of the training (Chart 4).

Chart 4: Technical team's duties



Management team and technical team, are both interdependent and interact with each other. The management team's accurate and precise support to the technical team provides a solid foundation for the expansion of the technical team's business and skill improvement. Meanwhile, the new ideas and skills generated by the technical team's enhanced knowledge and innovation ability will also actively drive the management team to set targeted goals and directions for the next stage.

2) Strengthen knowledge exchange and sharing, promote knowledge socialization:

a) Optimize the effectiveness of apprenticeship training: The T nail salon needs to reassign apprenticeship group members to achieve differentiation in the background of the group members, avoid the limitation of assimilation of thinking, encourage collision of ideas and communication between different members, and then spark new inspiration, concepts, and ideas, creating new knowledge. Specifically includes age, project experience, professional background, cultural environment, nationality, personality, etc. The T nail salon should continue to monitor the progress and effectiveness of the apprenticeship training, and make timely adjustments to error correction strategies and guidance methods through multidimensional and multilevel evaluation methods to prevent dysfunctional mentorship [31][32][33][34] and mental deadlock. If there is unpleasantness among team members due to personality or hobbies, resulting in poor cooperation, negative emotions, pressure, professional burnout, etc., it is necessary to analyze the reasons in a timely manner, reassign members or adjust the group structure, and improve training methods in a timely manner. Meanwhile, the management team should fully cooperate with each apprenticeship group to carry out regular practical activities, provide them with comprehensive support such as funds and technology, and regularly track and improve the training effectiveness.

b) Establish incentive mechanisms: The T nail salon should start from the actual situation of employees, and strive to achieve an organic combination of position promotion, economic rewards, and respect in the incentive mechanism, so as to further improve the enthusiasm of employees to share tacit knowledge. In addition to providing economic compensation for the master, and improving welfare benefits, such as issuing training allowances, providing transportation or food subsidies, the company should also periodically evaluate the skills of the nail technicians, promptly awarding them with honorary certifications, enhancing their sense of corporate honor and mission, and increasing their influence and reputation among peers, better stimulating their enthusiasm to share their knowledge with the team. The nail salon should also care about the long-term career development and planning of its employees, improve their sense of belonging and happiness at work, and establish a frank and two-way trust between the company and its employees. It can refer to the "lifetime employment system" of Japanese companies. The nail salon ensures that senior nail technicians who meet the standards receive better benefits and promises not to dismiss them arbitrarily, so that outstanding employees, once accepted by the company, firmly believe that they are an important part of the company and can therefore focus more on sharing their knowledge and skills.

c) Create an open and relaxed communication mode: This form of communication can establish positive interpersonal interaction, enhance mutual trust, create an inclusive and open corporate communication culture, and promote the

socialization of knowledge. As a small service-oriented company, the personnel composition of the T nail salon is relatively single, and the organizational structure is relatively flat. The boss, store manager, and employees can use tea breaks and lunchtime to increase communication frequency. They can also regularly hold some collective activities to help new employees quickly integrate into the organization and maintain friendly relationships between new and old employees.

For customers, the T nail salon should take various effective measures to actively establish close relationships with customers, which is the best way to attract and retain customers. Traditional customer incentive methods are manifested in the form of bonuses, points, gifts, etc. but basically, all nail salons adopt such methods, which are no longer attractive to customers. The nail salon should consciously cultivate a warm and intimate family-like relationship between employees and customers. During the service process, always pay attention to the customer's emotional feelings and detailed requirements, including lighting, temperature, and other needs, to make the customer feel relaxed and comfortable. To establish a set of standardized, simplified, and practical service processes, conveying a professional, enthusiastic, and proactive corporate image and a customer-centric value concept to customers, while also adopting irregular telephone follow-ups, event invitations, etc. to timely understand customers' new needs and make adjustments and changes as appropriate, so that customers can feel that the T nail salon is not just a place that simply provides services, but also a "haven" and "recharging station" that brings warmth and care like family, allowing customers to relax, eliminate fatigue, and forget worries.

3) Improve knowledge conversion ability and promote knowledge externalization:

a) Sound performance management: The T nail salon needs to use forms such as weekly logs, process evaluations, and simulated exams to assess learning outcomes based on unified apprentice training standards, processes, and assessment systems. All nail technicians are required to write a learning journal every week, using text or images, to summarize their learning achievements in a timely manner and provide at least one to two suggestions, which will be scored and confirmed by the management team and included as part of the performance appraisal. The store manager submits a monthly work report to the president, informing them about the company's operating conditions, training achievements, and future development suggestions. The boss also needs to establish a bonus system directly linked to performance, so that the store manager's income is closely related to their work achievements. It is also necessary to consider long-term measures such as equity and profit sharing, in order to effectively stimulate the store manager's enthusiasm and creativity.

b) Increase the frequency and efficiency of knowledge exchange: The management team must regularly organize special seminars, invite experts to provide on-site guidance, and organize external learning activities for employees, providing a platform for exchanging service experience and skills among employees. The content and form of these activities should be diverse, with the aim of achieving two-way communication between participants rather than passive input. For example, question and answer format, heuristic, scenario practice, gamified training, etc. Through these activities, the tacit knowledge and tricks of technical experts and individuals are extracted and refined, and turned into actionable explicit cases or manuals, further facilitating employees to examine their own understanding from different perspectives, excavating the latent tacit knowledge in their minds, and then organizing it into explicit written materials with a certain logic, promoting the transformation of shallow and vague tacit knowledge into deep and clear explicit knowledge. The management team needs to summarize and extract these scattered experiences, form written language, pictures, or videos for retention, for everyone to learn, and ensure the circulation and transfer of knowledge among employees, teams, and within the organization. These activities can also invite employees who have already left the company so that on the one hand, they can tap into and record their inherent tacit knowledge and experience skills, and on the other hand, they can also help the T nail salon better identify and solve potential problems.

c) Analyze and review cases: The management team and the leaders of each group should regularly compare and analyze similar past projects, carefully summarize successful cases, and extract useful thinking and methods from them. To analyze the reasons for failure, it is necessary to conduct a retrospective and scenario reproduction, summarize the lessons learned, and provide references for the company to avoid similar mistakes in the future. This will enable the company to develop targeted measures to recover losses and better regulate employee behavior.

d) Use knowledge base software: Using knowledge base software as the central hub for company information, including personnel policies, project management, meeting records, operation manuals, etc. software allows for editing and management of documents anytime and anywhere. It helps to build knowledge maps and knowledge communities, making it convenient for employees to intelligently search and quickly find the information they need, thereby improving work efficiency. Additionally, it allows for detailed classification and recording of customer data, such as customer age, store visit frequency, personality, special requirements, purchase history, social media reviews, etc. This information can be recorded with tags, and various parameters can be updated, cleaned, and integrated in a timely manner. This helps businesses to more accurately build customer profiles, and pinpoint customer preferences, behavior patterns, and customer resources, in order to provide personalized services to customers. T Nail should encourage all nail technicians to contribute their own opinions and ideas to the knowledge base, including company processes, environment, skills, management measures, etc., without being bound by details and forms. For useful opinions and ideas, corresponding rewards should be given. Besides, nail technicians should also be encouraged to share their professional knowledge and project experience with the entire team by writing internal technical blogs. Depending on the size and business needs of the nail salon, the knowledge base of the T nail salon does not need to be too complicated, simple, and practical, with low fees. For example, HubSpot CRM, PingCode, and Nuclino are all good choices.

4) Improve knowledge integration and promote knowledge combination:

a) Carry out knowledge organization work and update in real-time: The management team needs to establish a

high-quality, data-rich, fast-updating, and easy-to-use operation manual. In this process, special attention should be paid to the cultivation of the management team's abilities. The explicit written records such as drafts, initial concepts, and project notes formed by each group are collected diligently. On this basis, a detailed analysis of these written records is conducted to determine if there are any contradictions and biases and if they are established in a certain context. Drafts that are repetitive, incomplete, of low quality, and documents without reference value are deleted, as well as outdated technology and obsolete knowledge. It is important to timely integrate the retained knowledge and documents and to conduct comprehensive discussions on the problems, countermeasures, logical thinking, framework planning, and project results during the project process. The content of the documents should be classified and extracted to establish a hierarchical database, ultimately forming a standardized manual that includes template paradigms, reference guides, and skill summaries that are updated in real-time. This will facilitate all employees to review and evaluate their work effectively and to handle sudden issues more targeted.

b) Cooperate with competitors and substitutes for win-win: The two major threats to businesses in development are rival competitors and substitutes. Employees of the T nail salon must use a respectful and appreciative perspective to compare themselves horizontally with other nail technicians in the market and identify their own shortcomings. Companies must also actively communicate with their competitors in an open and inclusive manner, share resources, complement each others' strengths, collaborate, and seek improvement through competition and development through cooperation. For alternatives, we need to change our mindset and try to make adjustments in combination, so as to provide broader ideas and space for the future development of the T nail salon.

c) Achieve co-creation of value between the company and customers: The T nail salon needs to provide differentiated services to different customers. By segmenting customers, standard services are provided to ordinary customers, while higher-level services are provided to key customers, such as free birthday month, holiday gifts, double points, free access to new products, new technologies, and free transportation. To increase customer interaction and engagement, the salon can organize a nail art salon photo contest. They can also invite customers to participate in educational video collaborations and reward them with points and random free services for participating in these activities. Through these activities, customers can experience the charm of the brand in a three-dimensional and diversified way, forming a good atmosphere of consumer-driven communication and sharing with each other. The purpose of these activities is to establish a family-like intimate relationship with customers, thereby continuously enhancing customer stickiness and loyalty. the T nail salon should establish exclusive customer groups for similar clients, such as creating a nail salon housewives' group. In the group, housewives can freely express themselves and share their parenting experiences and cooking skills. The salon can also hold various activities for these similar customers, supplemented by different themes, such as bride theme, vacation theme, workplace theme, etc. Based on these themes, multiple packages are offered for customers to choose from. By bringing together these similar customers for face-to-face communication and interaction, it can help create a large amount of high-quality tacit and explicit knowledge, and apply this knowledge timely and accurately to the operation and service of the nail salon. As Mr. Matsushita Konosuke, the founder of Panasonic, said, only by establishing long-term and stable cooperative relationships with customers can we achieve mutual prosperity between the company and customers.

d) Introducing AI into the nail art process brings a different experience to customers: Currently, AI technology has been applied to various industries, and the T nail salon can try to use AI technology to achieve service upgrades. By utilizing big data analysis, consumers can have more convenient and efficient access to global trends and personalized nail art designs, providing a diverse range of design elements and style choices. By using AI algorithms, intelligent recognition and analysis of customer information can be achieved, allowing for color, style, and occasion matching from a more scientific perspective. Through virtual reality (VR) and augmented reality (AR) technology, consumers can virtually try out more colors and styles, and have a more intuitive experience of color testing and previewing effects, solving the problem of nail damage and time wastage caused by repeated application. The introduction of AI intelligent nail art machines and 3D printing technology enables the completion of a single finger painting in 40 seconds, with mold designs that better fit the customer's skin and bone structure, and the ability to accurately identify the comprehensive effects of different nail surface contours, making the nail art process simple, fast, and intelligent. The introduction of an AI translation system helps the T nail salon achieve real-time voice translation, further enhancing the accuracy and timeliness of communication.

5) Deepen knowledge application and promote knowledge internalization:

a) Organize employee practical activities: After integrating and extracting explicit knowledge, a unified employee operating procedure is formed, and it is necessary to ensure a practical effect on employees in the future. At this stage, the store manager should develop detailed plans, plan and implement relevant activities, form a systematic learning practice, and make it easy for employees to participate in corresponding activities according to their own interests and time. The specialized nail technician or external teacher serves as the lecturer and regularly holds specialized training sessions based on different topics. For example: painted topics, gradient topics, etc. The management team should encourage employees to express their feelings and thoughts and to think divergently. Nail technicians have new ideas and concepts, the company should promptly encourage and turn these ideas into physical displays such as display stands to showcase, and promote them on the appointment website. Nail technicians can choose to have this style exclusively for themselves or share it within the salon. If shared within the salon, every time the design is chosen by a customer, regardless of which nail technician performed the service, the company will provide a certain percentage of reward to better stimulate the creativity and imagination of the nail technicians.

b) Form a positive interaction between customers and businesses: Effective communication between customers and businesses is essential for customer knowledge management in this process, and it must be supplemented with effective

marketing methods and techniques. the T nail salon, while experiencing new products, new technologies, and new services, should guide customers to compare and think, and at the same time, comprehensively record customer feedback and make timely improvements and adjustments. It is important to note that customer feedback should be analyzed scientifically and not rushed into making blind changes. The changes in the operation and management of nail salons may require customers to have a long period of experience before they can generate their own ideas and suggestions. More time should be given for observation and adjustment of such decision-making processes. In addition, the generation of customer knowledge is a continuous cycle of innovation that needs to be constantly repeated, which particularly requires the exploration and establishment of a long-term positive interaction mechanism between the enterprise and the customer.

VI. Results

The construction of the knowledge management system for the T nail salon is a process of mutual knowledge transformation, which requires a long time to verify its effectiveness. the T nail salon is currently trying to use the methods and means mentioned above to gradually reform the operation and management of the store. After more than two months of practice, some initial results have been achieved.

1) The customer satisfaction survey: questionnaire shows a satisfaction rate of 86.3%, with an increase of nearly 20%. Moreover, the customer retention rate has significantly improved, and the sense of participation has significantly increased. Over 22% of customers actively participate in the nail design and store brand image enhancement program. Currently, the salon has increased its rating on Japan's largest reservation website, Hot Pepper, from 4.63 to 4.89 (the full mark is 5).

"I have been doing manicures for almost 5 years, and have been to many nail salons, but the T nail salon gave me a different feeling. Communication with the staff of the T nail salon is very smooth and comfortable. They regularly remind me to take care of my nails and provide me with exclusive customization in advance according to my activities. Their cultural and creative products are also particularly useful. I attended two tea parties organized by them, which were particularly relaxing and allowed me to meet many like-minded good friends. The T nail salon has become more than just a store to me." (Customer: Airi)

2) The anonymous satisfaction survey: distributed by the chief to all nail technicians in the salon shows a significant increase in employee satisfaction. Employees generally believe that salon management cares about their careers and provides them with a lot of help in their professional development. The effectiveness of employee training has improved qualitatively, with a noticeable increase in initiative and enthusiasm for learning. A level 2 nail technician has passed the level 1 qualification exam, and two level 3 nail technicians have passed the level 2 nail technician qualification exam. The skill level has significantly improved. Among the employees who previously resigned, there was an employee who expressed her desire and plan to come back to work to the boss.

"I feel it's amazing, unconsciously, I have shared my experience, and our communication has increased. We have sparked and collided with many new ideas. Later, the store manager told me that this was because they used knowledge management methods. I felt very incredible and thought it was very magical." (Senior nail technician: Tina)

"I was chatting with my former colleagues and discovered that the T nail salon has recently undergone some changes that are truly delightful. The reason I resigned was because T Nail Art's plan for my future career development was unclear, and I was constantly worried about being replaced. I heard that now the T nail salon has adopted a lifetime employment system for qualified employees, and has also provided many allowances and subsidies to improve welfare benefits. There is increased communication and cooperation among nail technicians, and the atmosphere is particularly harmonious. Everyone's enthusiasm for work is particularly high. Now, I really want to go back to the T nail salon to continue working, hoping to have this opportunity." (Former nail technician: Amy)

3) Compared to the past: the turnover of the nail salon has greatly increased. The daily growth rate of customers visiting the store is nearly 47%, and the average daily number of customers visiting the store has increased from 15 to 22. The turnover of the nail salon has increased by nearly 40

"I regret not using the theory and methods of knowledge management earlier. Through practice, it has been proven that knowledge management and business management are not conflicting, and the two can be well combined and mutually promote each other, which is of great help to the enterprise. Moreover, the advanced electronic management methods and systems, although causing a certain increase in costs, the benefits they bring far outweigh these costs. As the chief of the store, I should have a long-term perspective and vision. I should actively learn this knowledge so that I can better develop my business." (the boss: Mr. Song)

VII. Discussion

The paper addresses the challenges faced by T Nail Salon, specifically focusing on knowledge sharing, externalization, and the implementation of the SECI model. It emphasizes that employees are often reluctant to share tacit knowledge due to competitive dynamics and the fear of losing their competitive advantage. To overcome these barriers, it is crucial to implement strategies that foster trust, establish open communication channels, and cultivate a more collaborative environment. Moreover, the high turnover rate at T Nail Salon contributes to the loss of tacit knowledge. Therefore, strategies such as comprehensive onboarding processes and knowledge retention systems should be considered to mitigate this issue.

Additionally, the paper examines the effectiveness of the SECI model in small service-oriented businesses (SMEs). SMEs can simplify the application of the SECI model by utilizing cost-effective technological tools, such as knowledge-sharing apps or collaborative platforms.
Furthermore, providing hands-on training for employees can enhance their understanding and application of the model. The paper also explores the challenges associated with transforming tacit knowledge into explicit knowledge, particularly given

that employees possess varying levels of technical expertise. While the paper highlights the potential benefits of knowledge management, it does not delve into its measurable impacts on business performance.

An essential area of growth lies in integrating technology into the knowledge management. Currently, the salon utilizes limited customer management tools; however, by exploring affordable and simple digital solutions such as HubSpot CRM or Google Workspace, the salon can implement practical and cost-effective systems suitable for SMEs. Additionally, examining the potential of AI and machine learning in knowledge management could offer a future-focused approach, enabling the salon to enhance its service offerings and customer relationships. Furthermore, adopting a more long-term strategic outlook would strengthen the paper's analysis. Knowledge management should be seen as a continuously evolving process that requires regular adaptation and feedback. To this end, the salon should periodically evaluate the effectiveness of its knowledge management system and make necessary adjustments in response to shifting business needs, technological advancements, or changes in market conditions. Moreover, expanding knowledge management beyond the internal team and involving external stakeholders could open avenues for innovative ideas and strategic partnerships. By incorporating these considerations, the paper would provide a more comprehensive analysis of the challenges small businesses face, such as T Nail Salon, and offer actionable recommendations for enhancing knowledge management, ultimately driving business performance, innovation, and long-term success.

VIII. Conclusion

Although the T nail salon has a smaller scale, its business model and scope belong to typical small and medium-sized service-oriented enterprises. This study analyzes the current situation and development bottlenecks of small and medium-sized service industry enterprises using the T nail salon as an example. It emphasizes the importance of knowledge management and proposes the need to establish a knowledge system within the company that combines both humanistic and technological aspects. This system should facilitate the acquisition, storage, integration, sharing, and innovation of knowledge, enabling the transformation of tacit knowledge into explicit knowledge and the combination of internal knowledge with external knowledge. Ultimately, this will lead to product upgrades and improved efficiency. From the practice of using SECI model in the T nail salon, we can also conclude that small and medium-sized service-oriented enterprises can use appropriate means and less cost to achieve effective knowledge conversion among individuals, teams, organizations, and customers, and achieve orderly knowledge management. The isolated and scattered concepts and elements in the knowledge management system can be integrated organically and run through all the processes of enterprise operation and management.

It is certain that learning the theory and methods of knowledge management is not about making management and employees all experts in knowledge management, but starting from the perspective of knowledge management to help enterprises systematically grasp the problems existing in operation and development, rather than relying solely on general financial statements and current situation analysis. It should be emphasized that the construction of a knowledge management system is a long-term process. It cannot be expected to be achieved in a short period of time. It requires enterprises to shift from passive to active, from intuitive to rational, from simple to complex, and to persistently improve and perfect the level of knowledge management in order to continuously enhance the economic benefits and core competitiveness of the enterprise.

IX. Limitations

Although this study has achieved certain research results, it has proposed a solution to T Company's knowledge management problem and explained the implementation methods and effects. However, there are still many shortcomings in this study. For example, due to insufficient interview experience, there may be subjective bias in the interview content, and the small scale of the T nail salon may result in a small scope of investigation and insufficient quantitative analysis. For the above shortcomings, it is hoped to continuously improve in future long-term observation and practice and also that future research can make up for the deficiencies in this study.

***Abstract*—The domestic sector is one of the major energy consumers and hot water is a compulsory service in modern society. Therefore, one of the possibilities for reducing energy expenses is heating water using solar collectors. However, the optimization of such installations requires careful planning and preliminary simulations. This study presents a model for simulating the energy flows in a heat pipe solar collector. Unlike previous studies, it also accounts for the self-shading of the vacuum tubes at certain hours of the day. An experimental setup was organized to collect reference data for model validation, and the data was automatically stored in a database by a microcontroller-based electronic system. The modeled and experimental data were compared and a PME of 1.55%, and a PMAE of 16.33% were obtained. The proposed model could be used for simulating the useful power of hybrid hot-water systems under different application scenarios.**

Keywords*—Model; simulation; heat pipe solar collector; useful power

I. INTRODUCTION

The domestic sector is one of the major energy consumers, responsible for 35% of the world's energy usage and 38% of the global direct and indirect CO_2 emissions [1]. Water heating is a requirement for modern society and therefore has a significant share in utility energy consumption. In this context, the integration of hybrid systems with renewable energy is an option to increase buildings' energy efficiency and to protect the environment [2].

Solar energy is widely used in hot water installations, because of its easy accessibility, high efficiency, and environment friendliness, which is especially important for modern society [3, 4]. The application of hybrid installations has proven its efficacy in improving energy sustainability [5]. Another reason for the increased interest towards them is the increased reliability and profitability, which overcomes the periodicity and uncertainties, related to solar energy [6]. Hybrid solar systems usually combine different renewable and non-renewable technologies, as well as storage of thermal energy [7]. The most common technologies used in hybrid systems for hot water are flat plate solar collectors and vacuum solar collectors [7-9], which are usually extended with conventional energy sources, such as electrical energy from the grid and LPG [10,11].

Numerous studies have investigated the application of flat-plate solar collectors (FPC) for heating water [12-15]. However, solar water heating systems (SWHS) rely on vacuum-based evacuated tube collectors (ETC), whose global share reaches up to 70% among all solar collectors [16]. ETCs can operate with high efficiency under cold and cloudy meteorological conditions and provide higher energy generation, making them better than FPCs [17]. For the abovementioned reasons, they are a common means of providing hot water in the utility sector [18,19]. In study [20] the efficiency of FPCs and ETCs were experimentally compared. According to the obtained results, vacuum solar collectors have significantly higher energy efficiency than flat-plate ones, which can be explained by the lower losses due to convective heat transfer.

To optimize the application of SWHS in practical situations, their energy output should be modeled and simulated, which is an object of investigation in many studies. In study [21] a model for two types of SWH systems is developed and validated. It relies on the transient systems simulation (TRNSYS) software. The main component of the model is a solar collector, based on either the flat plate technology or the vacuum-based heat pipe technology. For the FPC system, the study achieved average relative errors of the output collector temperature, the heat power, and the accumulated heat of 16.9%. 14.1%, and 6.9%, respectively. Similarly, for the ETC system, they are 18.4%, 16.8%, and 7.6%, respectively. The authors believe the model could be used for long-term forecasting of hot water systems and simulation of the system performance under different weather and operating conditions.

In another study, a heat transfer model of an all-glass vacuum tube collected was proposed in study [22]. The energy balance is formed by the natural convection in a single glass tube and forced convection in the collector, with the model estimating the temperature at the output of the collector. However, in this study, the shadows from one collector to the other are neglected, which might influence its accuracy. In study [23], a dynamic numerical model of a solar thermal installation with evacuated water heaters was presented. It was built in the TRNSYS18 environment and was aimed at forecasting solar energy gains. In another study [24] a theoretical model of an evacuated tube heat pipe solar collector with phase-change fluid was proposed. The solar water heating system contains a raw of ETC tubes, which are connected to a common manifold. The heat absorption and release modes are modeled using a combination of mathematical algorithms.

In study [25] an analytical thermal model of a solar water heater system was proposed, which is a combination of a heat pipe solar water heater system with phase-change material thermal energy storage. Approximate analytical solutions for

estimating the amount of absorbed solar energy and the thermal behavior of the supplied water were proposed. Similarly, in study [26] a model of vacuum solar collectors with a heat pipe was proposed, which is used in a solar desiccant cooling installation. After validation, the model was used to simulate the behavior of such an installation, used for cooling a building in the summer season under different climatic conditions.

Similarly, in study [27] TRNSYS was used to simulate the behavior of a forced circulation solar water heating system of a single-family house in Algeria. The study reported that the solar fraction of the system varied between 54% and 84% for the different months of the year. According to another study [28], industrial hybrid systems require uninterrupted access to hot water; i.e., an additional energy source, such as LPG and electrical energy should be provided. The authors presented a TRNSYS-based model of solar collectors in a hybrid system, allowing simulations for performance evaluation.

To ensure the efficient application of conventional energy and minimize the exploitation costs of a hybrid system for hot water production, it is necessary to choose an appropriate management strategy. This can be achieved by simulating different scenarios of the system's exploitation, which should be based on an appropriate model of the solar collectors.

The performed analysis showed that most of the previously developed models do not account for the shadows, dropped from one tube to the other, which might influence their accuracy in the evening and morning hours. Furthermore, it was observed that almost all authors from the last years have used the Transient System Simulation program (TRNSYS). While this tool supports shading simulation, it does not include an integrated solution that accounts for the self-shading from the heat-pipe solar collector.

This study aims to develop a model of the energy flows in a heat pipe solar collector, which allows us to estimate the thermal energy production for a certain level of solar radiation. The model should account for the self-shadings between the tubes of the collector and allow simulation of the instantaneous energy accumulated in the form of heat.

The rest of the paper is organized as follows: In Section II the methodology of the study is explained, and in Section III the experimental results are presented. In the final Section IV, conclusions are made about the accuracy and applicability of the study results.

II. Materials and Methods

A. Object of the Investigation

The objects of the investigation are the energy flows in glass vacuum tube collectors (see Fig. 1). In other words, the heat pipe is surrounded by a vacuum, ensured by a surrounding glass tube. Furthermore, the heat pipe is filled with heat transfer phase-change fluid, which condenses on the inner surface of the condenser and then returns to the sun-exposed base of the tube, and the main channel for energy transfer to the water heating chamber. This process continues as long as the vacuum solar collector is heated by the sun. Furthermore, in this study is assumed that the heat pipe is in contact with water, where the absorbed solar energy is "stored" in the form of heat.

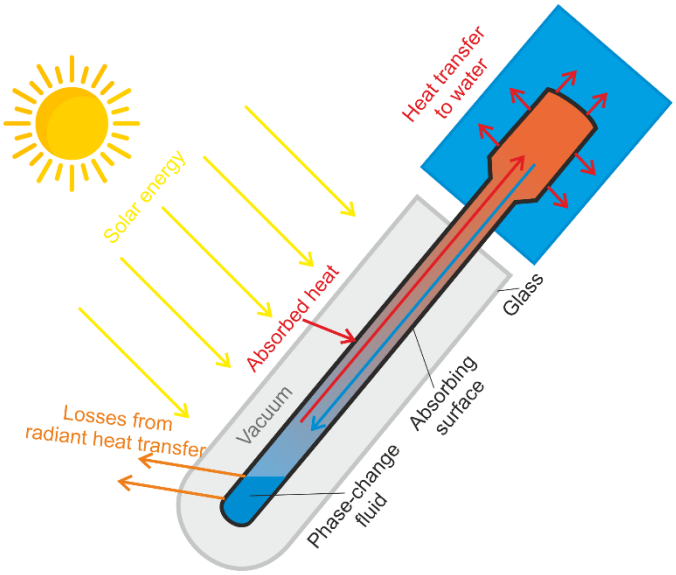

Fig. 1. Main energy flows in a vacuum solar collector with a heat pipe.

B. Energy Balance in a Vacuum Solar Collector with Heat Pipe

For the modeling purpose, it is accepted that the amount of energy gained by the solar collectors is proportional to the intensity of solar radiation and the surface of the solar collectors. Therefore, the receiving surface of a stationary solar collector is a function of its positioning in space and of the Sun's instantaneous location in the sky. The solar energy receiving surface depends on the total receiving surface of the collectors, the distance between their tubes, their azimuth and tilt angles, and the available solar irradiance. An additional factor that could influence their performance is dustiness; however, it is not an object for the current study.

To model the amount of energy, received from the Sun, it is accepted to be proportional to the amount of falling solar rays on the receiving surface, which is determined by projecting it on a surface, perpendicular to the solar rays. The movement of the Sun in the sky could be modelled using well-known dependencies and quantities, such as the study in [29]: the Sun declination; the geographic latitude; the hour angle ω; the solar azimuth angle A; the solar altitude angle h; the slope angle between the accepting surface plane and the horizontal plane S; the azimuth angle of the receiving surface γ; the direction of the solar radiation θ; and the angle between the normal plane of the receiving surface and the sun rays.

The power balance of the vacuum collector can be expressed with:

$$Q_{sol} - Q_{loss} = Q_{tube} + Q_{fl},\ W \quad (1)$$

where Q_{sol} is the available solar radiation in W, Q_{loss} are the losses due to radiant heat transfer from the heat pipe to the environment in W, Q_{tube} is the power used for heating the vacuum tube in W, and Q_{fl} is the power used for heating the water in W.

The solar power, accumulated in the vacuum solar collector can be estimated according to:

$$Q_{sol} = Q_S . F_{col} . k_{ref},\ W \quad (2)$$

where Q_S is the instantaneous value of the total solar irradiance, falling on the sloped receiving surface in $W.m^{-2}$, F_{col} is the projection of the vacuum solar collector' surface on the perpendicular plane to the solar rays in m^2, and k_{ref} is the reflection coefficient of the vacuum tube surface.

The maximum total solar irradiance for a certain geographic location, day of the year, and hour of the day are estimated according to well-known dependencies [30]. In the case of cloudiness, the reduced amount of solar energy could be estimated using an average cloudiness coefficient k_{cl} taking values between 0% and 100%:

$$Q_s = Q_{s.max} \frac{q_S^{100\%cl} + \left(q_S^{0\%cl} - q_S^{100\%cl}\right).\frac{100-k_{cl}}{100}}{q_S^{0\%cl}}, W \quad (3)$$

where $Q_{s.max}$ is the maximal possible solar radiation for the corresponding hour and day of the year W, $q_S^{100\%cl}$ and $q_S^{0\%}$ are the lowest (with maximal cloudiness) and highest (with lowest cloudiness) solar radiation rates in $W.m^{-2}$ for a certain month of the year at the corresponding time. The last two quantities can be obtained from archive meteorological data for the corresponding location.

C. Modelling of the Energy Flows in a Vacuum Solar Collector

To model the energy flows in a vacuum solar collector, the following basic approximations are accepted:

- The available solar irradiance reaching the vacuum solar tubes depends on the parameters of the Sun's movement on the horizon;
- The available energy is used for heating the elements of the construction, for heating the fluid, and for losses from radiant heat transfer;
- Considering the vacuum between the receiving surface and the glass tube, losses due to convective heat transfer are ignored;
- The energy entering the vacuum solar collector heats simultaneously the internal part of the tubes, the heat pipe, and the copper contact plate.

The solar energy, falling on a sloped surface is proportional to the projection of this surface over a plane, perpendicular to the solar rays. To determine the width of the projection b_{col}^{az}, the correction angles $-\alpha_{cor}$ and α_{cor}, and the solar azimuth angle should be accounted for. Fig. 2 summarizes the methodology for estimating the width of the projection, where 1, 2, and 3 are the active surfaces of the vacuum tubes.

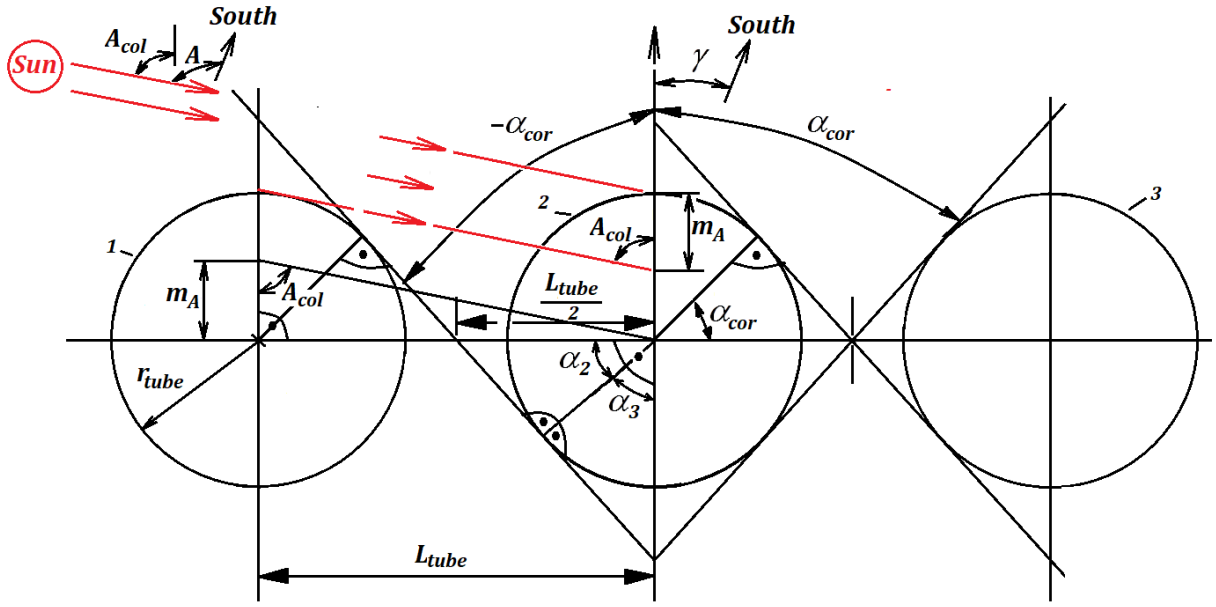

Fig. 2. Graphical representation of the methodology for estimating the width of the receiving surface projection.

It can be seen that whether the solar rays will fall on a certain tube depends on the angle A_{col}. The quantity $A_{col} = (A - \gamma)$ represents the difference between the azimuth angle of the Sun and the azimuth angle of the receiving surface, where the value of A_{col} is negative during sunrise and positive during sunset.

If A_{col} is within the zone $(-\alpha_{cor} \dots \alpha_{cor})$, the receiving surface of each tube is equal to its diameter d_{tube} in m and the total azimuth width of the solar collector is:

$$b_{col}^{az} = d_{tube} . n_{tube} \quad (4)$$

where n_{tube} is the number of tubes in the collector. At sunrise $A_{col} < -\alpha_{cor}$ and each tube partially shades the next one. In this case, the first tube is irradiated entirely, and the remaining ones only partially. When A_{col} is outside the zone $(-\alpha_{cor} \dots \alpha_{cor})$, the total width of the projection of the receiving surface on the perpendicular plane to the solar rays is:

$$b_{col}^{az} = d_{tube} + m_A . (n_{tube} - 1) \quad (5)$$

In this case $m_A = \frac{L_{tube}}{tg|A_{col}|}$ is the part of the diameter of the tube, corresponding to its irradiated surface and L_{tube} is the distance in m between the tubes. The dependency is the same during sunsets, when $A_{col} > \alpha_{cor}$.

To obtain the angle α_{cor} the following dependency can be used (see Fig. 2):

$$\alpha_{cor} = 90^o - \alpha_3 = 90^o - (90^o - \alpha_2) \quad (6)$$

The cosine of the angle α_2 is calculated according to:

$$cos\ \alpha_2 = \frac{r_{tube}}{L_{tube}/2} \quad (7)$$

where r_{tube} is the radius of the absorbing tubes inside the solar collector in m. By combining Eq. (6) and Eq. (7), the value of α_{cor} is estimated with:

$$\alpha_{cor} = 90^o - \left(90^o - \text{acos}\left(\frac{r_{tube}}{\frac{L_{tube}}{2}}\right)\right) = \text{acos}\left(\frac{r_{tube}}{\frac{L_{tube}}{2}}\right) \quad (8)$$

The algorithm for modeling the energy flows in a vacuum solar collector with a heat pipe during a certain day of the year is summarized in Fig. 3. It begins with block 1, where the initial conditions are set: the day of the year, the cloudiness coefficient, the latitude, the tilt and azimuth angles of the solar collectors, as well as other parameters of the solar collector. Next, in block 2 are estimated the general parameters of the Sun trajectory, which depend on the latitude and the day of the year, as well as of the solar collectors: the declination, the duration of sunlight, the hour angles, the sunrise and sunset hours, as well as the correcting angles -α_{cor} and α_{cor}, which depend on the distance between the tubes and their diameters.

In block 3 are set the initial values of some of the model parameters, which vary over the day, such as the initial time, the hour angle of the Sun, the initial temperature of the vacuum tubes, and of the fluid, and in block 4 are modified the cycle-controlled variables.

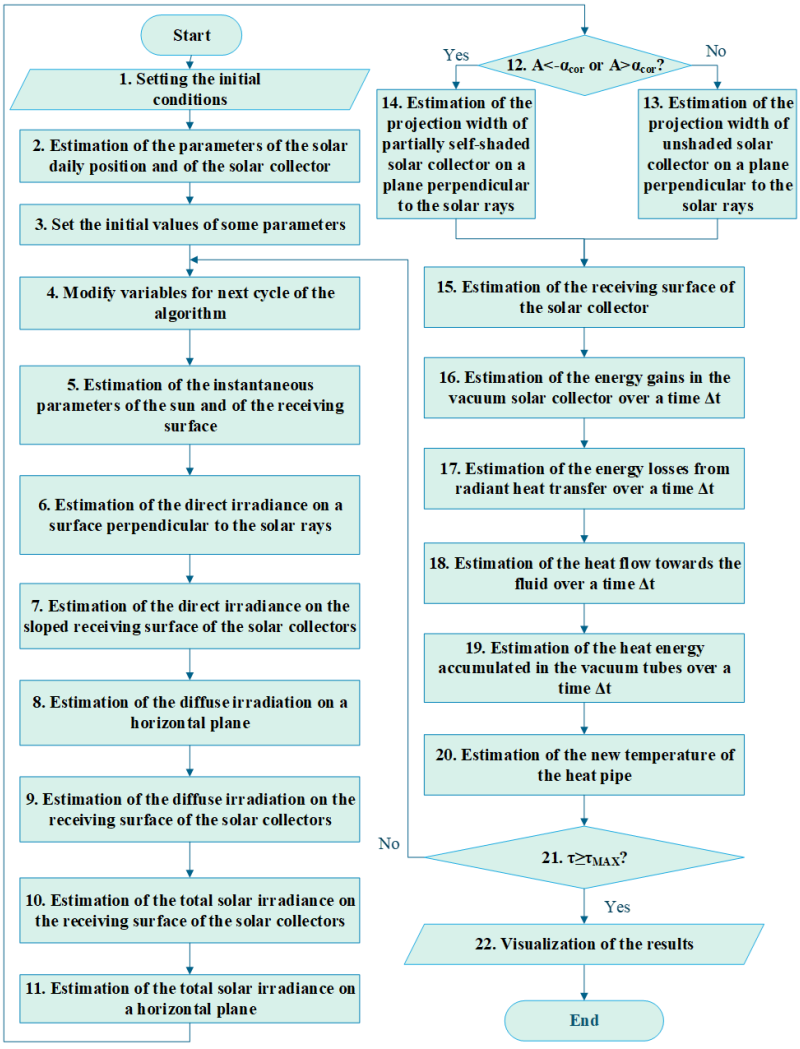

Fig. 3. Algorithm for modeling the energy flows in a vacuum solar collector with heat pipe.

Each cycle continues with block 5, where the instantaneous parameters of the Sun's position and the receiving surface are estimated for a certain time of the day: the elevation angle of the Sun, the azimuth of the Sun, and the direction of the direct irradiation relative to the receiving surface. Next, in blocks 6 and 7 the intensity of the direct irradiance, respectively on a

perpendicular plane and the receiving surface are estimated. Similarly, in blocks 8 and 9 the diffuse irradiance on a plane perpendicular to the solar rays and the receiving surface are obtained. In blocks 10 and 11 the total solar irradiance, falling respectively on the receiving surface of the solar collectors and a horizontal plane are evaluated.

In block 12 is verified whether the solar collector is partially self-shading itself. If no self-shading occurs, the algorithm continues to block 13, where the projected width of an unshaded receiving surface on a plane perpendicular to the solar rays is estimated by Eq. (4). Otherwise, Eq. (5) is applied in block 14 to evaluate the projected width of the self-shaded receiving surface.

In block 15, the surface of the solar collector using the following equation is estimated with:

$$F_{col} = b_{col}^{az}.c_{col},\ \ m^2 \tag{9}$$

where c_{col} is the length of the vacuum tubes in m. Next, in block 16 the solar energy received by the vacuum solar collectors over a time interval $\Delta\tau$ is estimated, according to Eq. (3). In block 17 the energy losses to the environment due to radiant heat transfer are estimated and in block 18 the energy accumulated into the fluid of the collector is obtained:

$$E_{fl} = Q_{fl}.\Delta\tau,\ \ J \tag{10}$$

where Q_{fl} is the power accumulated in the fluid in W. It can be estimated according to:

$$Q_{fl} = F_{hp}.\alpha_{hp}.(t_{hp} - t_{fl}),\ \ W \tag{11}$$

where F_{hp} is the contact surface of the heat pipe with the fluid in m^2 and α_{hp} is the convective heat transfer coefficient with the fluid in $W.m^{-2}.K^{-1}$. In this study, it is accepted that the temperature of the fluid is constant.

Next, in block 19 is estimated the energy, accumulated in the vacuum tubes E_{tube}, based on the energy balance, described with Eq. (6). The cycle is concluded in block 20, where the new temperature of the heat pipe is obtained using a calorimetric equation:

$$t_{hp}^{cur} = t_{hp}^{pr} + \frac{E_{tube}}{m_{glass}.c_{glass}+m_{copper}.c_{copper}+m_{hp}.c_{copper}},°C, \tag{12}$$

where t_{hp}^{pr} is the temperature of the tube in the previous moment in $°C$; m_{glass}, m_{copper}, and m_{hp} are the masses, respectively of the glass part, of the copper contact folio, and of the heat pipe of the vacuum tubes in kg; c_{glass} and c_{copper} are the specific heat capacities, respectively of glass and copper in $J.kg^{-1}.K^{-1}$.

If the maximal time of the simulation has not been reached, the algorithm returns to block 4. Otherwise, all obtained results are visualized to the user in block 22 and the algorithm is concluded.

D. Methodology for Verification of the Model

The model can be validated by comparing its results with experimentally obtained ones. Therefore, an experimental setup was created, whose structure and organization are summarized in Fig. 4. It includes the following components:

- Two vacuum tubes with heat pipes, which accept solar radiation;
- A third vacuum tube that is used only as a source of shading;
- An insulated heating chamber, which accepts the available energy from the vacuum tubes and accumulates it in the water in the form of heat;
- A water tank, which is used as a source of cold water for the system;
- A circulation pump, which is used to periodically replace the hot water in the heating chamber with cold one;
- Two temperature sensors, used for monitoring the temperature of the water in the heating chamber and of the environment, respectively;
- A microcontroller system, responsible for obtaining the sensors' readings and controlling the circulation pump. The temperature measurement is implemented over a 1-Wire interface using one digital I/O each and the turning on and off the pump is implemented over a digital output;
- A database on a nearby laptop for storing the process information. The communication between the microcontroller and the laptop is implemented over a serial interface.

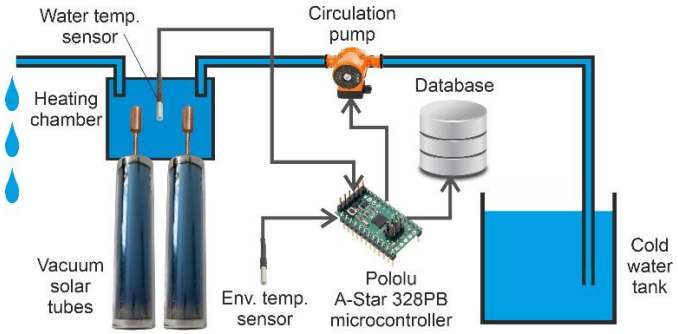

Fig. 4. Overview of the experimental system for verification of the vacuum solar collector model.

The system operates according to the following procedure. The microcontroller reads the temperature readings periodically. Thereafter, the changes in the temperature of the water and the losses to the environment are accounted for, so that the microcontroller can estimate the energy gain by the vacuum solar collectors between two consecutive readings. The power losses from the heating chamber to the environment are estimated by accounting for its insulation parameters and the temperature difference between the water and the environment, according to:

$$Q_{loss.exp} = \frac{T_{water}-T_{env}}{\frac{\delta_{wall}}{\lambda_{wall}}}.F_{wall},\ \ W, \tag{13}$$

where δ_{wall} is the width of the chamber's wall in m, λ_{wall} is the wall's thermal conductivity coefficient in $W.m^{-1}.K^{-1}$, and F_{wall} is the total wall surface of the chamber in m^2.

When the water temperature gets higher than a certain threshold, the circulation pump is started and the hot water is replaced with cold water, to prevent boiling. The average heat power Q_{tube} accumulated in the hot water over the period $\Delta\tau$ reduced with the heat losses Q_{loss}, is estimated with:

$$Q_{tube.exp} = \frac{m_{fl}.C_{fl}.\left(T_{fl}^{+\Delta\tau} - T_{fl}\right)}{\Delta\tau}, W, \quad (14)$$

where m_{fl} is the mass of the heating chamber water in kg, C_{fl} is the specific heat capacity of the fluid, which in this case is $C_{fl} = 4186\, J.kg^{-1}.K^{-1}$, T_{fl} is the fluid temperature at the beginning of the period and $T_{fl}^{+\Delta\tau}$ - $\Delta\tau$ seconds later, both in K.

All measured and estimated values are stored in the database, located on the laptop. The acquired heat flow $Q_{tube.exp}$, accumulated in the water is compared with the modeled one to assess the model's accuracy. This is done using two measures - percentage mean absolute error (PMAE) and percentage mean error (PME), estimated accordingly with:

$$PMAE = \frac{100}{N}\sum_{i=1}^{N}\frac{|A_{sim} - A_{mes}|}{A_{mes}}, \% \quad (15)$$

and

$$PME = \frac{100}{N}\sum_{i=1}^{N}\frac{A_{sim} - A_{mes}}{A_{mes}}, \%, \quad (16)$$

- where A_{sim} and A_{mes} are the simulated and measured values, respectively, and N is the total number of compared records.

III. Results and Discussion

A. Results from the Experimental Study

The verification of the developed model was performed by conducting an experimental study in the city of Ruse, Bulgaria, located at latitude $43{,}85^{o}N$ and longitude $25{,}97^{o}E$. The experimental setup was installed on the roof of Building 2 of the University of Ruse "Angel Kanchev" (Fig. 5), following the presented methodology for verification of the model. The experiment was conducted on 26.09.2023. In addition to the experimental setup, a Vantage Pro2 Plus meteorological station by Davis Instruments was used to monitor the environmental parameters. During the day the ambient temperature varied between 15 °C and 29.4 °C and the solar radiation reached up to 639 $W.m^{-2}$ around noon. No cloudiness was observed during this day; i.e., the used cloudiness coefficient is 0%.

Fig. 5. Geographic location of the experimental setup: a) Approximate location on the Bulgarian map; b) Exact location on the roof of Building 2 of the University of Ruse.

(a) (b)

Fig. 6. General view of the experimental setup for investigating the energy yield by a vacuum solar collector (a) and a closeup of the water chamber (b).

The experimental setup is characterized with the following key parameters (Fig. 6):

- The volume of the water in the heating chamber is 0.7 l.
- The insolation of the water chamber was implemented on two levels: 9 mm rubber was used to limit the convective heat transfer, and tinfoil was used to limit the influence of solar radiation on the temperature of the water.
- The used temperature sensors are DS18B20 by Dallas Semiconductors, which are characterized with 0.5 °C accuracy from -10°C to +85°C and 0.1 °C resolution.
- The used circulation pump has a debit of 0.4 $l.m^{-1}$.
- The two vacuum tubes are of type SPU-H58/1800-30-C by SunPower (China), characterized with 0.92 transmittance of the glass, 0.94 absorbance of the coating, and 0.08 hemispherical emittance.
- The azimuth and tilt angle of the vacuum tubes are 0° and 60°, respectively.

The characteristics of the parameters of the installation, used in the simulation are summarized in Table I. The electronic system has been operating as described in the methodology. The time series of the temperature readings during the sunny part of the day with approximately 19-20 s step of discretization is presented in Fig. 7. It can be seen that during the day the water in the heating chamber was replaced 39 times; i.e., the temperature of approximately 27.3 l was increased by approximately 22 °C.

Based on the proposed methodology and Eq. (12) and Eq. (13) the time series of the power accumulation in the heated water was obtained (Fig. 8). It can be seen that for the period from 9:00 to 18:30, the power absorbed in the water in the form of heat varies between 15 W in the morning/evening and 135 W around noon. The power accumulation process varied without sudden changes as the experiment was conducted on a sunny day with no cloudiness.

TABLE I. SUMMARY OF THE EXPERIMENTAL INSTALLATION PROPERTIES

№	Parameter	Value
1.	Specific heat capacity of water	4186 $J.kg^{-1}.K^{-1}$
2.	Specific heat capacity of the water chamber (made of PVC)	900 $J.kg^{-1}.K^{-1}$
3.	Convective heat transfer coefficient between the water chamber's inner walls and the water	400 $W.m^2.K$
4.	Convective heat transfer coefficient between the water chamber's outer walls and the environment	5.6 $W.m^2.K$
5.	Thermal conductivity coefficient of the water heat wall (PVC)	0.15 $W.m^{-1}.K^{-1}$
6.	Thermal conductivity coefficient of the water chamber insulation (rubber)	0.16 $W.m^{-1}.K^{-1}$
7.	Width of the water chamber insulation	0.0090 m
8.	The total surface of the water chamber	0.060 m^2
9.	Mass of the fluid	0.69 kg
10.	Mass of the water chamber	0.082 kg
11.	The radius of the vacuum tubes	0.029 m
12.	Length of the vacuum tubes	1.75 m
13.	Distance between the axes of the vacuum tubes	0.07 m
14.	Number of vacuum tubes	2
15.	Mass of a vacuum tube without the heat pipe (the glass)	2 kg
16.	Mass of the heat pipe of a vacuum tube	0.33 kg
17.	Specific heat capacity of glass	84 $J.kg^{-1}.K^{-1}$
18.	Specific heat capacity of copper	385 $J.kg^{-1}.K^{-1}$
19.	Total exchange surface of the two heat pipes with the water	0.0061 m^2

B. Validation of the Developed Model

The proposed model for simulation of the energy flows in a heat pipe solar collector was implemented in a software tool, developed in the Microsoft Visual Studio 2019 environment. To validate the developed model, the modeled heat accumulated by the solar collectors should be compared with the experimentally obtained. The model's parameters used during the simulation are selected following the used hardware components, as shown in Table I.

As was already mentioned, for the investigated day no cloudiness was observed. This is also confirmed by the maximal measured solar radiation (639 $W.m^{-2}$), which is almost identical to the theoretically maximal value for this geographic location and day of the year (659 $W.m^{-2}$). According to the developed methodology, the power accumulated by the fluid is estimated with a 5-minute time step, which is thereafter compared with the experimentally obtained one.

The integrated fluid energy gain was obtained similarly - according to the developed model and experimentally. The time series of the powers and daily energy gains are summarized in Fig. 9. It can be seen that the experimentally obtained and modeled quantities generally correspond very well. Furthermore, the daily cumulative heat gain is almost identical: 0.97 kWh and 0.96 kWh, obtained experimentally and via simulation, respectively. This corresponds to a 1% relative error at the end of the day.

Nevertheless, to get a better understanding of the difference, the absolute errors in the power and energy gains were evaluated and summarized in Fig. 10. It can be seen that the errors in the instantaneous power vary from -40 W to +20 W, with peak values occurring mostly in the morning and evening hours. This could be explained by shadows, falling from nearby buildings, which were not accounted for by the model.

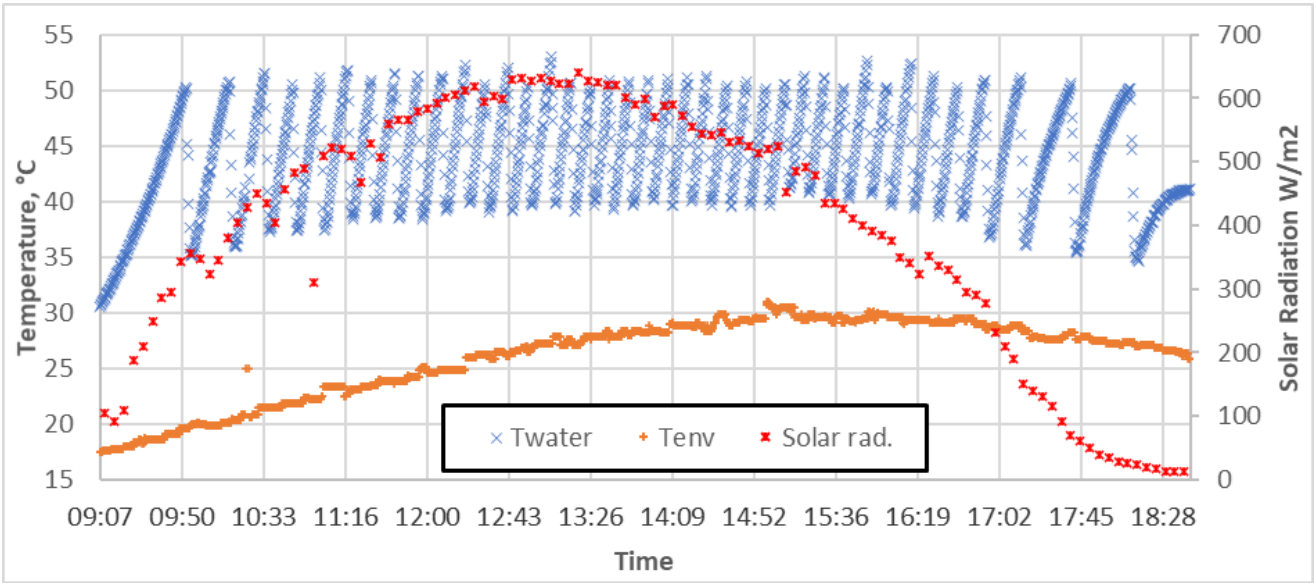

Fig. 7. Time series of the ambient temperature (orange), water temperature (blue) and solar radiation obtained from the meteorological station (red).

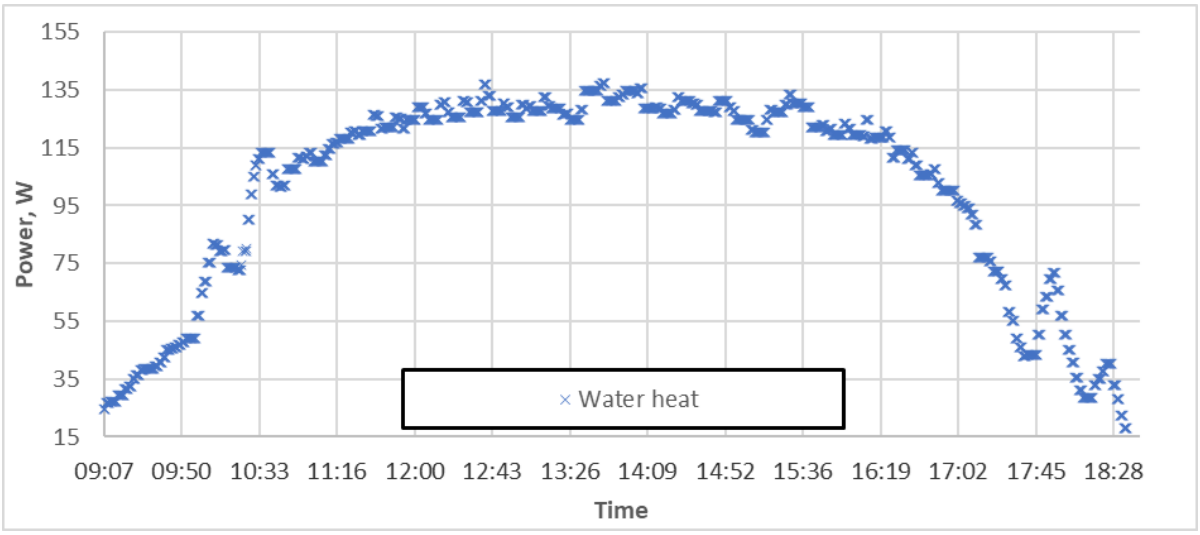

Fig. 8. Time series of the useful power, accumulated in the water.

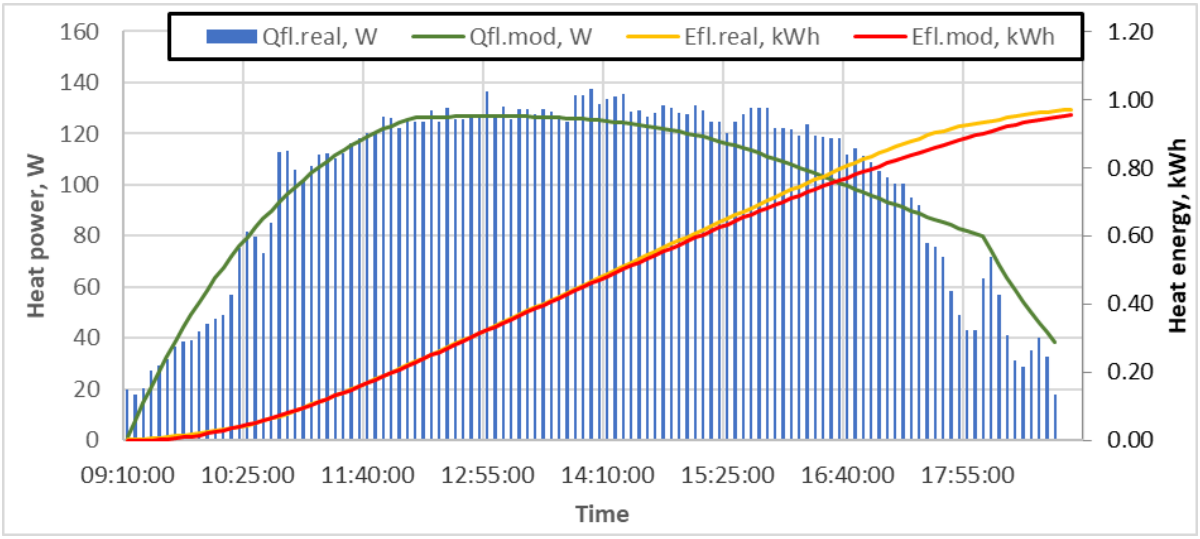

Fig. 9. Time series of: experimentally obtained heat power (blue), modeled heat power (green), experimentally obtained integrated heat energy (yellow), and modeled integrated heat energy (red).

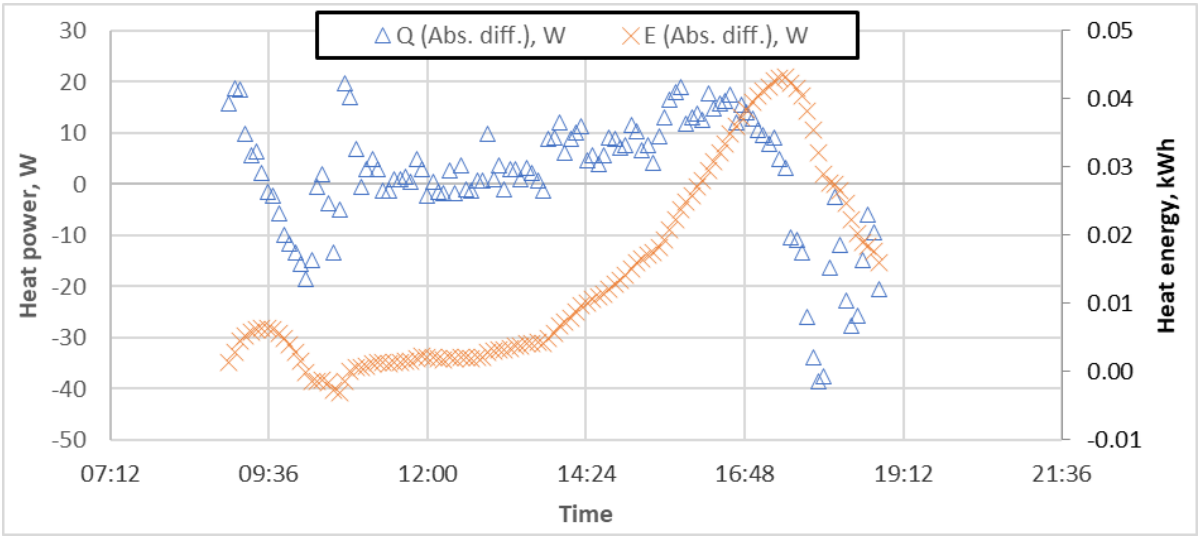

Fig. 10. Time series of the absolute errors of the heat power and heat energy gains during the experimental period.

The integrated daily energy gains are close to zero during the first half of the day and increase up to 0.04 kWh in the afternoon, though they fall back to 0.01 kWh at the end of the day. The obtained PME and PMAE measures for the heat power, absorbed by the water, are 1.55% and 16.33%, respectively. These values indicate that there are some errors in the obtained results with different signs, which compensate for each other, and at the end of the day the error is very low. Similarly, the PME and PMAE for the integrated accumulated energy are -7.69% and 8.02%, respectively. In this case, the difference between PME and PMAE is almost insignificant, because the errors in the integrated energy production are mostly with the same sign.

The model could be further evaluated by comparing its performance metrics with those obtained in previous studies. The authors of study [21] used a TRNSYS model to simulate the absorbed heat power in FPC and ETC systems. The achieved PME measures were 7.9% and 7.6%, respectively and the PMAE measures – 6.9% and 18.4%, respectively. In study [23] a numerical model in the TRNSYS environment was developed for simulating the temperature and energy gain from evacuated tube solar collectors. The study reported a PMAE of 8.02% for the daily energy production and a relative error of -0.2%. In another study [28], the output temperature of an FPC was simulated. The study reported a 2.01% root mean square error (RMSE) for the water's temperature; however, no error was reported for the estimated useful power. In general, it can be seen that the proposed model achieved similar results, as the previously developed in terms of PMAE, and higher accuracy when it comes to instantaneous power, measured with the PME metric. This indicates that the model could be used for simulating different scenarios of application of vacuum solar collectors, i.e. estimating their optimal regimes of exploitation.

A limitation of the proposed model is that it uses a cloudiness coefficient, to account for the available solar energy. This means that the obtained results might be inaccurate under dynamic meteorological conditions. Nevertheless, this should not affect the obtained results for long-term analysis as the errors would be with different signs and are expected to compensate for each other.

IV. Conclusions

In this study, a physical model for simulating the heat flows in a vacuum solar collector with a heat pipe was proposed. It is based on the power balance of the collector and accounts for its equivalent surface, the self-shading, and the position of the Sun. The model validation is performed by organizing an experimental study. A vacuum solar collector with two tubes was used to heat 0.7 *l* of water, which was periodically replaced with cold water. Based on the temperature changes, the useful power of the solar collectors was obtained and used as reference data for validating the model.

The obtained simulated values showed high correspondence with the experimentally obtained ones. The absolute power error is mostly around 0 W during the day and increases up to 40 W during the morning and evening hours. They can be explained by the shadows falling from nearby buildings, which were not accounted for in the model. The absolute errors of the cumulative useful energy vary between 0 and 0.04 kWh. The error at the end of the day is approximately 0.015 kWh, which corresponds to 1.6%.

These results indicate that the model can be used for precise simulation of the power and energy flows in a vacuum tube collector. It can be applied for forecasting the useful energy gains of vacuum collectors, as well as for optimization of water management in hybrid installations. Furthermore, it could be used to compare different scenarios in specific applications and to obtain the best-performing ones. The abovementioned is an object for our future studies.

Evaluation of the Usability and User Experience of a Digital Platform for Mental Health Assessment

Jerina Jean M. Ecleo, Mia Amor C. Tinam-isan, Kristine Mae E. Galera, Ric Adrian C. Balaton, Imelu G. Mordeno, Cenie M. Vilela-Malabanan
Mindanao State University – Iligan Institute of Technology, Iligan City, 9200, Philippines

***Abstract*—This study evaluated the usability and user experience of a mental health digital platform among college students. Usability tests were conducted using quantitative measures, user feedback, and direct observations. User experience is also aimed at gaining insights of what works and what does not work in the system. A total of 3,396 second year students participated in the assessment with university guidance counselors serving as facilitators. Results from the usability test indicated an above- average score among students suggesting high satisfaction in terms of ease-of-use, well-integrated functions, and performance. Strengths of the platform generated from the users' feedback are effectiveness and efficiency, ease of use, innovation, organization and structure, and reliability and performance. Further enhancements in functionality, including loading time, usability, readability, language preference, and lengthy questionnaires, were identified as key concerns among respondents. These findings highlight the usability of the platform while also identifying areas for improvement to ensure continuous engagement and user-friendly experience for users.**

I. Introduction

Mental health is a pressing issue that encompasses emotional, psychological, and social well-being of an individual. It influences how a person handles stress, relates to others, makes choices and navigates daily life. Mental health is vital at every stage of life from childhood, adolescence through adulthood and that everyone should be aware of it. However, access to mental health support remains a challenge, particularly for students who may have faced academic pressure, social challenges, and personal struggles.

In the Philippines, while Mental Health Law or Republic Act 11036 was legislated to provide affordable and accessible mental services for all Filipinos [1], several individuals still have suffered from mental illnesses, contributing to an alarming incidence. More than 720,000 people die by suicide each year, making it the third leading cause of death among individuals aged 15 to 29 [2]. The National Statistics Office (NSO) reported that mental health illnesses rank as the third most common form of morbidity in the country [3]. Furthermore, the study in [4] highlighted the growing prevalence of mental health concerns among college students and adolescents, underscoring the critical need for mental health awareness and intervention in this demographic.

Usability evaluation is a key component of user-centered design, aimed at assessing the effectiveness, efficiency, and user satisfaction of a product or service. The study in [5] emphasize that usability evaluation extends beyond traditional task analysis by examining the systemic aspects of user interaction with complex systems. Its goal is to ensure that the system's information content and presentation effectively support user activities, particularly in process control contexts. Usability evaluation provides several advantages during the design and development process.

This study aimed to assess the usability and experience of a mental health assessment platform designed for college students. Different factors such as ease of navigation, need of technical assistance, system integration, and perceived usability were considered. With this, it would help encourage adoption and engagement of the mental health application. The result of this study will also help academics, stakeholders, and developers to improve the application for sustained use in supporting college students with mental health problems.

II. Overview of the Mental Health Assessment Digital Platform

Mental health assessment particularly in a university with thousands of students is crucial for identifying students who may be experiencing psychological distress. Early detection allows for prompt intervention to mitigate the risk of developing further mental health issues. Guidance counselors in universities in the Philippines conduct assessments for students, and the process of scoring and computing individual mental health assessment results for multiple instruments demands considerable work and time. At a particular university in the country, psychologists use Statistical Package for the Social Sciences (SPSS) by IBM for data analysis and visualization, MS Excel for data capture, and MS Word for representing psychosocial scales or assessment tools. While SPSS efficiently handles calculations and visualization, its graphical outputs are sometimes lacking in quality or customization. In such cases, they manually input SPSS-generated data into MS Excel for further analysis to meet their visualization needs. This process extends the time required for assessment and analysis. The inefficiencies in the existing system not only slow down the response time but also contribute to the growing challenge of addressing students' mental health concerns in a timely manner.

Thus the development of a mental health assessment platform to assess the process from assessment to generation of results. The platform is primarily developed for students to take scheduled assessments set by the Guidance and Counseling Center. Additionally, it automates score calculations and provides data visualizations for counselors or psychologists. The

development of the digital platform underwent three iterations each aimed to meet the primary needs of users in terms of functionality, usability, and experience. Guidance counselors, psychologists, and students were part of each iteration test. Major features of the platform are presented in Table I.

TABLE I MAJOR FEATURES OF THE MENTAL HEALTH ASSESSMENT DIGITAL PLATFORM

Features/Functionality	Description
User Profile	User health profiles and user registration details
Data Visualization and Reporting (see Appendix A)	Interactive dashboard for trends and patterns visible for system administrators, psychologists, and guidance counselors.
Risk Analysis Module (See Appendix B)	Automated scoring and interpretation of assessment results; Warning system for at-risk students
Mental Health Assessment Tools (See Appendix C)	Different standardized psychological assessment instruments that students must complete to evaluate their mental health

III. REVIEW OF RELATED LITERATURE

Mental health illness ranked as the third most common form of health issue in the Philippines according to the National Statistics Office [2, 3]. Mental health is considered as among the most important public health concerns [6, 7]. However, as of 2021, there are only five government hospitals that provide psychiatric care for children and 11 designated outpatient facilities for children and adolescents out of 46 [8]. Thus, promoting access to psychological support for students is crucial to preventing underlying conditions from worsening [9, 10]. Positive implications for students have been observed in Psychological interventions for treating anxiety, depression, and eating disorders [11]. Universities are well-equipped to implement either primary or secondary prevention approaches and facilitate access to mental health services [10].

Computerized mental health services have increasingly aimed to reach vulnerable groups who face barriers to timely care, such as immigrants, refugees, and low-income populations [12]. Mental health institutions now leverage technology and software to provide timely assessments. Studies indicate that computerized mental health tools offer patients greater comfort and ease in answering questions about their mental health compared to traditional face-to-face interviews or paper-and-pencil assessments [12]. The study in [13] further emphasized that computer-based assessments can provide accurate scores and results with reduced susceptibility to human error. However, [13] stressed that while online tests of clinical constructs hold great potential, they require rigorous validation and must be used with caution. The adoption of EHRs in mental health has been found to have lagged behind than in other health contexts [14-16].

For a mental health assessment system, high usability score can mean to streamline the process, reduce errors, and improve patient care. However, there has been little research conducted on EHRs usability in mental health and this may link to issues such as sensitivity of the data involved and standardization issues [17]. Moreover, [18] identified barriers to the adoption of EHRs in mental health, including low computer proficiency, complexities of system, alert fatigue, and resistance due to legacy systems [18]. Usability enhancements to Electronic Health Records in mental health settings can reduce form completion time, improve clinician experience, and increase usage [19]. Further, usability impacts productivity and the effectiveness of the overall system, and there are recent studies on mental health applications for students that highlight the importance of user-centered design and engagement. The user satisfaction is often influenced by system responsiveness, user-driven support features, and accessibility to mental health information [20]. A study on a gratitude app found that usability testing, incorporated with interviews and questionnaires, can help in identifying design and functionality issues while obtaining user experiences [21]. Accordingly, a usability test of a post-trauma symptom monitoring app validated its ease of use and speedy data transmission [22]. According to study [23], both optimization of user interface and experience are crucial to encourage individuals to engage in technology-driven intervention [22, 24].

Analysis of user feedback can uncover usability issues, with common problems such as bugs, poor user interface design, and lack of technical assistance [21]. While each usability method has its advantages and limitations, a combination of techniques is recommended for comprehensive evaluation [25]. Direct observation methods such as usability testing and think aloud protocols are effective to understand the engagement of users towards the application tested. These methods offer valuable insights into user interactions and reveal potential issues of the system [25].

IV. METHODOLOGY

A. Sampling Methods and Participants

Purposive sampling was utilized for this study to ensure that respondents meet specific criteria relevant to the objectives of the Mental Health Platform. The sampling method allows the researcher to intentionally identify students who are most likely to provide insights into the usability of the system. In this case, second year College students coming from the seven (7) colleges of a university were selected as the participants. These students represent digital-native users who frequently engage with online platforms, have already experienced various academic and personal stressors, and are likely to interact with tech-driven mental health resources, knowing that they still have at least two more years in the university, increasing the applicability of their feedback. The participants were either male or female with age group 17-22 years old and were bonafide students of the university.

B. Usability Testing Instrument and Procedure

The usability test was conducted in an identified and controlled laboratory environment inside the university. Inside the laboratory are twenty (20) desktop computers, all having internet access, and are connected to the mental health application system. A usability testing approach was conducted to evaluate user experience, ease of navigation, and system functionality, ensuring that the system meets the needs of its target users. Prior to the testing, participants were given a brief overview of the application, and the objectives of the project.

Confidentiality, voluntary participation, and ethical considerations were also explained during the briefing. In the course of the usability testing, participants use the digital platform to complete a mental health assessment, with the guidance counselors acting as facilitators.

After completing the assessment, participants were asked to evaluate the usability of the platform. A usability questionnaire with five key usability questions presented in Table II, was used as the primary data collection instrument. Participants rated each question using a 5-point Likert scale, ranging from Strongly Agree to Strongly Disagree. Participants were observed for task completion rate, efficiency of navigation and error/bug occurrence. Results from the test were analyzed using frequency distribution to analyze usability trends.

TABLE II SET OF QUESTIONS USED IN THE USABILITY TEST

Questions	Test Area/Relevance
I found it easy to control and navigate the system	Reflects the ease of navigation, which is a key aspect of usability, aligning with the user's overall sense of control with the system
I think that I need support to be able to use the system	The need for support of a technical person to be able to use the system
The test questionnaires were well organized	Test for the broader usability principle of coherence and structure
Each function in the system was well integrated.	Relates to how different components of the system work together
I don't find any bugs or malfunctions in the system	The user's perception of the system being usable

C. Feedback and Analysis

In addition to the quantitative usability testing, feedback and direct observations were also conducted to capture the real-time behaviors and challenges from the participants, both from the guidance counselors and students. Common feedback was reviewed, analyzed, and coded into themes. Themes were quantified by tallying how often each theme appeared in the feedback section of the participants. Results from the user interface and user experience testing contributes to the refinement and validation of the digital platform's features and functionality.

V. RESULTS

A. Distribution of Participants Across Colleges

The study involved a total of 3,396 second-year college students. The number of participants from each college is recorded in Table III to ensure broad representation across the institution.

TABLE III DISTRIBUTION OF PARTICIPANTS ACROSS COLLEGES

Colleges	Number of participants (%)
College of Computer Studies	408 (12%)
College Education	269 (7.5%)
College of Engineering and Technology	985 (29%)
College of Business Administration and Accountancy	332 (9.8%)
College of Science and Mathematics	516 (15.2%)
College of Nursing	262 (7.7%)
College of Arts and Social Sciences	624 (18.4%)
Total	3,396 (100%)

As there is a diverse distribution of participants depending on the number of enrollees, this underscores the reliability of the findings and highlights the potential of the platform to address the mental health assessment needs of a wide range of students.

B. Usability Testing

The usability testing results revealed that the digital platform performed well in terms of user experience. As shown in Fig. 1, 1,969 or 58% strongly agree or expressed satisfaction on the features of the digital platform in the aspects of ease of navigation, clarity of instructions, and responsiveness. While the majority expressed agreement of the ease of use of the system, there were still 8% who were neutral and 2.4% of the participants disagreed. The high level of satisfaction however, implies that users can efficiently interact with the system. This usability strength could enhance the digital platform's reputation among its target audience.

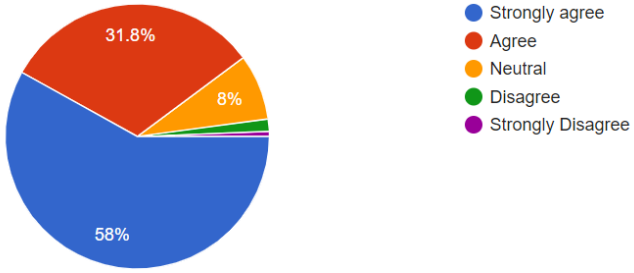

Fig. 1. Usability Testing (I).

As shown in Fig. 2, 20.3% and 26.4% of the respondents strongly disagree or disagree when asked if they need technical support to navigate the system. However, a substantial portion of the respondents 10.4% and 16.7% either strongly agreed or agreed that they needed assistance to be able to use the system. The remaining 26.1% expressed neutrality with the need of technical support.

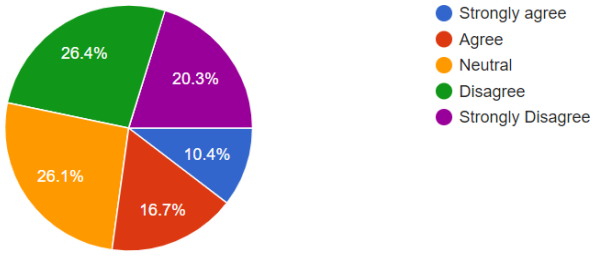

Fig. 2. Usability Testing (II).

As shown in Fig. 3, more than half of the number of participants, 52.6% expressed that the questionnaires are well organized, and only 2.4 % indicated that they disagree with the organization of the questions asked. This suggests that the content of the questionnaire in the platform is structured effectively and presented in a logical manner. While the majority finds the structure logical, users also expressed frustrations when completing the assessment as it takes time to finish the assessments.

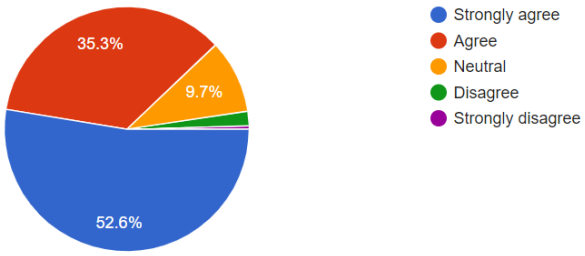

Fig. 3. Usability Testing (III).

There were 1,684 participants who strongly agreed that the functions were well integrated into the system (see Fig. 4). A meager number of the participants, 1.5%, either disagreed or strongly disagreed that necessary functions were well integrated into the system. Almost half of the participants were less emphatic in their agreement, this could reveal areas where integration can be improved, such as better linking of specific features or smoother transitions between tasks.

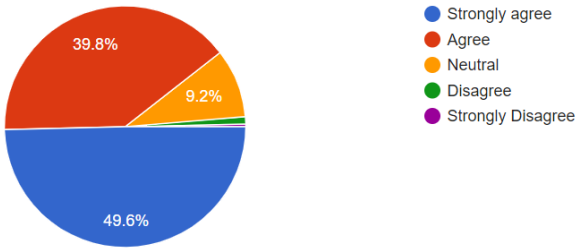

Fig. 4. Usability Testing (IV).

The participants were also asked if they had found bugs or experienced malfunctions in the system. In Fig. 5, results indicate that there were 1,701 students who strongly agreed that they did not experience any bugs or malfunctions. Less than 9.5% agreed that they did experience malfunctions in the system. This indicates that users are more likely to accept and adapt to future changes since the current system demonstrates reliability and stability.

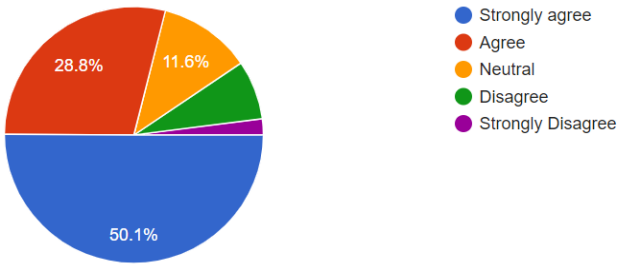

Fig. 5. Usability Testing (V).

VI. Discussion

A. User Satisfaction and Experience Feedback

User feedback highlighted several positive aspects of the platform.

1) Guidance counselors or facilitators: Many participants found the system intuitive and efficient, particularly on how it streamlined the assessment process and the automation of scores.

Facilitators, including guidance counselors, noted that the platform significantly reduced the time and effort required for administering mental health assessments compared to traditional methods. Based on the survey students finish answering the assessment for an average of 58 minutes to an hour (per student) which is significantly shorter compared to the conduct of assessment in manual process.

Guidance counselors emphasize how the system shortens the time required for generation of assessments results, a process that usually took months to complete. With the platform, results can be made directly available, allowing counselors to focus more on providing timely and personalized consultations to students. One of the feedback states:

“it used to take us months to just to administer the assessments and generate results, but with this platform, we can significantly reduce time and focus more on counseling”

With increasing demand and limited resources, optimizing assessment processes is crucial to ensure timely identification and intervention [26]. Further, counselors praised the system as user-friendly, which facilitates ease of use even for those with limited technical experience. Few of the feedback are: "generally good", “easy and simple”. The dashboard with charts and graphs were highlighted as “clear and intuitive”, enabling the counselors to quickly assess and analyze data. This positive feedback underscores the system’s potential to be an effective tool for its intended purpose while also leaving room for further enhancements. The study in [27] provide evidence that digital platforms, such as the EarlyDetect mobile app, offer a more user-friendly experience compared to traditional paper-based methods, highlighting the ease of use and improved usability of a digital platform for mental health assessment.

2) Students’ feedback: Observations during the usability test indicate that student participants were more engaged and inclined to complete the assessments using the digital platform. The constructive feedback collected during the test were categorized into eight key areas, including ease of use, organization and structure, effectiveness, mental health support, convenience and efficiency, innovation and technology, reliability and performance, and gratitude and appreciation. The results in Table IV highlight various strengths of the system.

a) Effectiveness and efficiency: Effectiveness is the most discussed strength emphasizing its impact among respondents in providing a tool for assessing their mental health. Students often describe the platform as useful, helpful, and beneficial. Few of the feedback were: "The activity is effective in assessing well-being and understanding students' situations", "The system is effective and helpful", and "A good way to assess students with mental illness or problems as not everyone wants to talk about their personal life." These imply that the system provides an alternative means for self-reflection and seeking help for those with mental health issues. Similarly, comments such as "The system is great and the questions are relevant in assessing oneself" and "The system is effective and helpful" illustrate the alignment between the digital platform and the needs of the students. These statements underscores the positive

impact of the system on self-assessment and stress management.

TABLE IV STRENGTHS GENERATED FROM THE STUDENTS' FEEDBACK OF THE DIGITAL PLATFORM

Themes	Sample terms for tagging	Frequency
Effectiveness	effective, useful, helpful, beneficial, works well, functional	23
Ease of use	easy to use, user-friendly, simple, smooth, intuitive, accessible	15
Innovation and technology	high-tech, modern, innovative, digital, online, automated	13
Organization and structure	well-organized, structured, systematic, arranged, interface, layout	13
Convenience and efficiency	fast, quick, time-saving, hassle-free, convenient, accessible	12
Gratitude or appreciation	thank you, appreciate, grateful, good job, well done, congratulations	12
Reliability and performance	stable, no malfunctions, bug-free, reliable, smooth operation	11
Mental health support	stress management, emotional support, self-assessment, guidance, mental well-being	10

On the other hand, comments such as "It is easy and convenient to use" and "The process was smooth" reflect the system's ability to save time and reduce hassle.

b) Ease of use: A platform can be effective if users can navigate it effortlessly. Words like "user-friendly", "intuitive", and "accessible" suggest that students value a cohesive and straightforward experience. Simplicity and clarity of instructions, straightforward process of answering questions, and simple UI are highlighted by respondents. Ease of use was emphasized through comments such as "The questionnaires in the system are comprehensible" and "Answering in the computer is easier". The application's user-friendly design enhanced participant's comfort, with most stating that it made the process smoother compared to traditional pen-and-paper. If a platform is too complex or confusing, users may abandon it, regardless of the quality of its content [28].

c) Innovation and technology: This reflects the students' expectation for a tech-driven solution, in this case, assessing their mental health. With terms like "automated", "online", and "innovative," users seemed to express a preference for technological advancement. Statements like "It is high-tech and it's comfortable to answer" and "The tool is innovative, easy, and convenient" highlight how the system's technological advancements make it a forward-thinking solution for digital assessments of which users appreciate. An innovative approach can enhance tailored experiences making interventions relevant and effective.

d) Organization and structure: Participants appreciate that the application has a well-organized, systematic, and structured layout which helps them navigate through the system. Phrases like "The system is well-organized" and "The questions are well-organized" were common. Student participants also noted that the system allowed for quick and efficient responses, particularly due to its clear layout, ensuring that participants could easily navigate through the assessment.

e) Gratitude or appreciation: Interestingly, expressions like "thank you", "good job", and "appreciate" indicate high user satisfaction. Some participants expressed their gratitude for the system, acknowledging its positive impact on their ability to assess their health and well-being. Expressions such as "I am thankful for this assessment" and "Thank you for making this assessment" illustrate the appreciation of the tool's contribution to improving the student experience. This suggests that when a platform meets users' needs, they are more likely to acknowledge its positive impact.

The feedback collected from both the counselors and students provides a strong indication that the digital platform for assessing mental health is effective, efficient, easy to use, innovative, organized, and appreciated.

B. Areas for Improvement

Despite the system's strengths mentioned, counselors have identified areas for improvement to further enhance its effectiveness.

1) Guidance Counselors/Facilitators: Counselors have highlighted two major areas for improvement in the system: loading time and individualized data interpretations.

One major concern of counselors is the loading speed of the application with recommendations to optimize performance and minimize delays during use. A slow system can cause frustration, and reduce engagement, especially when counselors or students need immediate access to mental health resources.

Another key recommendation of them was to provide individualized interpretations of the data, ensuring that insights are tailored to each user or unit. [29] emphasize that incorporating user feedback and engaging in a co-design process are essential for developing digital mental health tools that align with the needs and preference of target users. This will somehow ensure effectiveness and usability of the digital platform.

2) Students

a) Usability and readability: The most common concern of the students is Usability & Readability with fifty-five (55) mentions. Recurring issues were the font size and readability indicating that the text appears too small. Similarly students also pointed out the alignment issues with checkboxes and answer choices that somehow caused confusion during the test taking. Poor readability of an application has been proven to negatively impact application adoption and utilization [30].

b) User experience and engagement: Among the issues raised was the lengthy and time consuming test. Some respondents were overwhelmed and exhausted, occasionally expressing desire to discontinue the assessment. This is a crucial issue though beyond the developers control as the instruments were standard instruments for mental health assessment. However, it can be addressed by breaking the test into sections, adding progress indicators, or an option to save or continue the assessment.

c) Accessibility and system performance: Some students experienced technical difficulties, bugs, and system errors. These were infrequent and maybe due to connectivity or technical issues, and number of users accessing the platform simultaneously. [31] found that technical factors significantly

influenced student satisfaction from both instructor and student perspectives.

d) Language preference was another point of discussion, with a number of students suggesting alternative test language alternatives such as the Bisaya version or a verbal format for those who struggle with reading comprehension. Adaptive and personalize content based on user behavior and preferences can enhance user engagement in web applications [32].

Overall, students' feedback provides valuable insights for future improvements, ensuring a more accessible and user-friendly platform.

VII. Conclusion

This study aimed to evaluate the usability and user experience of a digital platform for assessing mental health conditions among higher education students, designed to support psychologists and counselors in monitoring and providing interventions.

When compared to traditional paper-based methods, the platform offered several advantages. It enhanced efficiency by reducing the time needed to administer and process assessments and minimized errors in score calculations and reporting. These improvements not only benefited the facilitators but also provided students with quicker feedback on their mental health assessments. Such features make the platform a valuable tool for institutions aiming to improve mental health monitoring and interventions.

The results of the usability assessment indicate that students find the platform's usability above average, with most participants expressing satisfaction with its implementation. Traditional face-to-face assessments or paper-based methods often pose challenges for students who may feel hesitant to express their struggles in person. The online nature of the system ensures that students can engage with the assessment in a familiar and comfortable environment, reducing stigma and encouraging participation. The platform's ease of use makes the student assessment process more engaging rather than stressful - reducing cognitive load. Students have also expressed the effectiveness of the digital platform in taking the mental health assessment tools.

Despite its strengths, some challenges and limitations were observed during the study. Technical issues such as occasional system lags and connectivity problems were reported. Technical difficulty remains a concern, as some students may require guidance in navigating the system. Font size, alignment, and other aesthetic concerns were raised to improve readability and design of the user interface.

Findings from the evaluation have provided best practices for designing digital health interventions that improve user engagement and support. Analyzing the usability and overall user experience supports the study to identify gaps in user interface design and recommend evidence-based improvements for the digital platform for mental health assessment.

Future recommendations should focus on addressing the current limitations of the digital platform and exploring new avenues for improvement. One key area is mobile accessibility - that the platform may be accessible across various devices. Another is the optimization of the platform's performance by improving response times, enhancing data security, and ensuring a smooth user experience. Future studies could compare the effectiveness and user experience of the web-based system versus a mobile application. Further assessment on the user experience could offer qualitative insights into the system's strengths and areas of improvement through a combination of user feedback surveys, usability testing, and focus group discussions. Additionally, the platform shows potential for broader application in government and private organizations, particularly educational institutions, by enabling mental health practitioners to effectively monitor individuals' mental health conditions.

Acknowledgment

This research would not have been made possible without the guidance and the help of individuals who contributed and extended their valuable assistance in the completion of this study.

To the Psychology researchers for sharing their knowledge, in gathering the data, and providing the assessment tools used for this research. To the Institute's Guidance and Counseling Center for coordinating and giving their time, insightful comments and administering the students during the system evaluation and testing. To the university's Center for eLearning for providing its computer laboratory in the conduct of the evaluation and testing. This work was supported with an internally-funded research grant of the Mindanao State University - Iligan Institute of Technology.

Development of an Algorithm-Based Analysis and Compression Integrated Communication Tracking Management Information System (iCTMIS)

Carlo Jude P. Abuda[1], Ritchell S. Villafuerte[2]
Department of Information Technology, Visayas State University Alangalang, Alangalang, Leyte, Philippines[1]
Department of Information Technology, Eastern Visayas State University, Tacloban City, Philippines[2]

***Abstract*—This study addresses the challenges of administrative tasks and communication tracking at Visayas State University Alangalang (VSUA), highlighting the inefficiencies in the current manual processes. The objective is to develop an Integrated Communication Tracking Management Information System (iCTMIS) that enhances operational efficiency by integrating Optical Character Recognition (OCR) and Lempel-Ziv-Welch (LZW) Lossless and Zlib compression algorithms. By employing a developmental research design and ADDIE model, the system proves that there is an improvement on data analysis and reduces disk space through efficient compression. Significant findings reveal that OCR achieves up to 90% accuracy in text conversion, while LZW compressions substantially deflate data sizes. This was evaluated against ISO 9126 Software Quality Characteristics, the iCTMIS has shown to optimize storage and address VSUA's operational challenges effectively. This research therefore concludes that the systematic integration of advanced algorithmic frameworks in iCTMIS significantly enhances organizational communication and administrative workflows efficiency.**

***Keywords*—Information system; optical character recognition; Lempel-Ziv-welch lossless compression; Zlib compression; communication tracking**

I. Introduction

Effective communication is fundamental to organizational success. Similarly, the need for appropriate software to record, track, and streamline internal and external communications is essential to achieve organizational efficiency [1]. These lay the foundation for streamlined operations that enhance overall efficiency in various transactions and workflows through seamless routing and tracking functions [2][3].

As communication tracking has evolved into a critical component of organizational management, facilitating information flow, leading to well-informed decisions, and improving overall productivity [4]. The roots of communication tracking can be traced back to the early days of administrative processes, where writing and recording correspondence were the primary means of information exchange [5], [6]. Over time, advancements in technology revolutionized communication tracking, with digital systems and algorithms playing a pivotal role in developing these processes [7].

Currently, communication tracking transcends to organizational boundaries, influencing both internal operations and external interaction [8]. Internally, effective communication tracking enhances transparency, accountability, and responsiveness within an organization [9]. Externally, it fosters collaboration and coordination on a global scale, which is essential for institutions with widespread operations or international partnerships. As organizations continue to grapple with the increasing volume and complexity of communication tracking, the need for sophisticated algorithmic frameworks becomes evident [10].

Recent advancements in algorithmic frameworks, such as Optical Character Recognition (OCR) and Lempel-Ziv-Welch (LZW) compression algorithms, have further augmented the capabilities of communication tracking systems [11], [12]. OCR has been proved to be an invaluable attribute in converting scanned documents into machine-readable text, enabling seamless integration into digital tracking systems [13].

Existing research literature supports the assertion that OCR significantly enhances the efficiency of communication tracking, reducing manual data entry and mitigating the risk of errors (e.g., misrouted documents, misspelled communication routing slips, and unreadable remarks) associated with human intervention [14], [15].

Similarly, the LZW compression algorithm contributes to improved communication tracking by reducing the storage space required for digital documents. As documents are archived and indexed, LZW compression ensures efficient storage, making retrieval faster and more economical [16]. Integration of these algorithms into communication tracking is particularly relevant in the Philippine setting, particularly among State University and Colleges (SUCs), such as the Visayas State University Alangalang (VSUA) [17], [18].

VSUA is one of the State Universities and Colleges (SUCs) in the region committed to providing quality education and fostering research and innovation, Visayas State University Alangalang (VSUA) faces notable challenges in administrative responsibilities and factional dynamics. While dedicated to receiving and utilizing data from stakeholders for public services, the administrative processes continue to exhibit bureaucratic tendencies. The institution grapples with several challenges in managing and tracking communication data [19], [20].

As the current manual document tracking system at Visayas State University Alangalang is significantly observed that it hampered by inefficiencies and operational challenges, including the weighty process of tracking routing numbers, the ambiguity in document routing leading to potential misdirection, the frequent misplacement of vital communication letters, and a general reluctance towards embracing technological advancements.

Furthermore, the existing infrastructure struggles with the demands of modern data management, evidenced by issues with system capacity, memory allocation, outdated scanning devices, and software that cannot efficiently handle large volumes of data due to a lack of centralized storage solutions. This decentralized approach not only complicates the reception and recording of documents but also results in physical storage problems, such as the excessive accumulation of paper documents and the consequent risk of damage from pests.

Addressing these challenges through the development of an Analysis-Compression Algorithm-Based Integrated Communication Tracking Management Information System could revolutionize the university's information management system, streamlining processes, enhancing efficiency, and ultimately fostering a more dynamic and responsive educational environment, and by also investigating and obtaining the capabilities of OCR and LZW compression algorithms, the researcher seeks to streamline communication tracking within VSUA. The research is motivated by the recognition that an integrated approach, which combines the strengths and capabilities of both algorithms, has the potential to significantly enhance the efficiency and effectiveness of the existing communication tracking system.

The researcher explored into the complexities of OCR and LZW compression algorithms, exploring their capabilities and potential in the context of communication tracking [21], [22]. The goal of this study to contribute valuable insights and practical solutions that can be adopted not only by VSUA but also by other government agencies facing similar challenges. The research is positioned not only to improve the existing manual system of VSUA Management Information System but also as a testament to the adaptability of algorithmic frameworks in addressing applied organizational complexities [23].

The general objective of the study was to enhance the Communication Tracking Management Information System of Visayas State University Alangalang by implementing analysis-compression algorithms. The specific objectives driving this endeavor encompassed the following focal points that is to reduce the disk space and memory allocation among data and files using LZW compression algorithm. Eliminating noise and converting files-to-text among documents using the OCR analysis algorithm and evaluating the analysis-compression algorithm to its system requirements based on ISO 9126 the Software Quality Characteristics such as functionality, reliability, usability, efficiency, maintenance, and portability.

II. Review of Related Systems and Studies

A. OCR Algorithm for Document Analysis Framework

In the review of related literatures and studies, it is imperative to check and examine existing research and systems that investigate into communication tracking, integrated information management, and algorithm-based solutions within administrative contexts and Integrated communication tracking management information systems aided with a literature review map to identify the sub-themes of each major focal points [24] that are necessary for the Visayas State University Alangalang to streamline administrative processes, enhance transparency, and ensure efficient dissemination of crucial information.

According to Memon (2023) Optical Character Recognition (OCR) has been developed by individual researchers with greater accuracy. The literature has concluded that utilization of OCR frameworks acts differently on different languages due to character style and dataset quality. As it has also been supported by some researchers, they proposed several solutions that is to provide one language or single subset of a language as an input. As the literature shows some practical implications of the said literature, the development of machine learning and deep learning enables accurate recognition of handwritten manuscripts. Towards the development of the, the researcher used several methods in OCR frameworks using the Systematic Literature Review (SLR), some on machine learning techniques, template matching technique, distance (similarity) metrics and Convolutional Neural Networks (CNN). Moreover, the advent of the different techniques performs a better on different languages due to variations in character style and dataset quality [25].

As OCR Framework evolves and adopts to the abrupt development in the field of Information Technology, according to Sahu and Sonkusare (2019) there has been another technique that can be incorporated and partnered with OCR, that is the Magnetic Character Recognition or MCR where there are two frameworks used in recognizing a more complex recognition on specific inputs. The methods discussed in this literature use the OCR used to identify scripts or alphabets in verbal communication primarily used in banking and other industries wherein handwritten text were the primary inputs of the framework [26]. Hence, these conclude and provide a more efficient performance on the OCR with MCR framework thus the researcher of this study suggested that there could be more methods in OCR to be integrated.

As the evolution of OCR to a more sophisticated, it has been already used and applied now to some sectors and institutions wherein according to Karthikeyan (2021) proposes an Internet of Things (IoT)-based library management system using OCR algorithm which then includes a CCTV-based book issuing and returning mechanism. OCR is used to convert text files into audio files for accessibility but not limited to scanning damaged books and converting them into PDF format. This literature has concluded that with OCR being implemented with IoT, book issuing and returning system is more efficient and secure. However, limitations were seen and observed that in in the event of scanning defect with bar code is a challenge in the existing system in the said intuition, which then in the proposed system introduces an effective and time-saving asset tracking and administration system for library using RFID technology [27].

According to Arief et al., (2022) the accuracy rate of document classification achieved at 94% in terms of the document classification origin and subject as CNN methods will

correctly classify the type of character being used as an input. CNN on the other also captures errors that occur in the regular expression's method coming from the original and subject classification as mentioned in the previous literatures. These methods include the utilization of automated hierarchical classification using CNN and regular expression methods, preprocessing with Tesseract OCR and Word2Vec. As this literature concludes, the automatic hierarchical classification method is necessary as this also utilized the classified and analyzed classified documents are stored on hive databases – the Hadoop architecture, wherein the databases are stored and systematized in big data technology [28].

Clearly, this development led to the application of Artificial Intelligence (AI) which have then been used already in OCR frameworks. To the degree of OCR application, AI techniques have improved OCR technologies according to Jain et al. (2023) in the application for general text recognition. OCR models trained on general text struggle with localized or personalized handwritten text. This study aims to create an adaptive framework for OCR models. It develops a digit recognizer using a convolutional neural network. Results show comparable accuracy for localized or personalized handwritten text. The study suggests data augmentation as a solution for scarce and imbalanced data [29].

Another piece of literature that is relevant to the study being conducted is the application OCR with Mobile integration. According to Bisiach & Zabkar (2020), their study compares OCR methods for mobile platforms in prescription label scanning, wherein these methods are pertaining to three methods being evaluated, namely the classic computer vision, standard deep learning, specialized deep learning. To distinguish between these three methods, it has been concluded that Standard Deep Learning (StanDL) (Tesseract 4.1.1) provides the best combination of accuracy, speed, and resource usage. As observed during the implementation and deployment, Tesseract 4.1.1 achieves 76% accuracy, with 10% results being one character away from accurate. Tesseract 4.1.1 achieves 76% accuracy, with 10% results being one character away from accurate. Moreover, 9% of images processed in less than one second, 41% processed in less than 10 seconds. Furthermore, Tesseract 4.1.1 has reasonable resource costs comparable to non-deep learning methods. As the researcher concluded, the application of Tesseract 4.1.1 to OCR Framework had shown a reasonable resource costs comparable to non-deep learning methods [30]. In this study, the methods applied uses classic computer vision techniques, standard deep learning, and specialized deep learning (Tesseract 4.1.1).

In eliminating data noise among files and images, Mande Shen & Hansheng (2019), presents a method to eliminate background images in OCR. As the methodology it provides evidence of enhanced document images and converts color images to gray. Background images are effectively removed without losing text quality. The method improves recognition accuracies in OCR. The researchers have also justified the methods based on the difference in color values of background image pixels. Such uses brightness distortion and chromaticity to enhance contrast. In has shown that the test experiments showed that the output image is clean after preprocessing. Moreover, OCR frameworks perform much better on images with background eliminated or the researcher classified it as document noise. Accordingly, background images can be effectively removed using the method they have used at the rate of 80% to 90% text were recognized and blank pages were eliminated. Moreover, in the readability of documents it is improved after removing background images, in addition the recognition accuracy of OCR are significantly improved. Frameworks also in OCR namely the HANWANG and ABBYY software show significant improvement in OCR performance. OCR Tesseract returns 2% wrong results when given background images without preprocessing as reported, however, in conclusion, all of these three OCR software obtain good results on blend regions (mix of background image and characters) and the algorithm assumes colorful background images, towards the end the researcher of this literature justifies more that there are still gaps in the methods of OCR in addressing black-white backgrounds [15].

The above cited literature provides a complete and comprehensive synthesis on the different gaps, relationships, applications and approaches that may be applied along with the development and deployment of this study specifically on the integration of the existing system of the Commission on Higher Education Regional Office VIII the iCTMIS with OCR Framework in document analysis algorithm in eliminating data noise among files.

B. LZW Algorithm for Document Compression Framework

As the researcher of the study introduces the different applications and uses of compression framework and algorithms, the introduction of LZW compression will be the guided path to look for similarities and useful insights from the literature and research done by other researchers. To provide a context, LZW compression is the second algorithm framework that this study will be using, such that defining LZW is known as a method focused on reducing the size of Tag Image File Format (TIFF) or Graphics Interchange Format (GIF) files [31]. This technique employs a table-based lookup algorithm to eliminate duplicate data, effectively compressing original files into smaller formats. Beyond image files, LZW is also adept at compressing text and PDF files. Rooted in the LZ78 algorithm developed by Abraham Lempel and Jacob Ziv in 1978, LZW compression unfolds as a versatile tool with implications across various data types.

Starting from the different applications and approaches of LZW compressions framework, According to Shah (2019) states that there is an innovative approach to increase the compression ratio of the LZW algorithm. LZW, a widely used lossless compression algorithm for data compression, involves appending frequently encountered string patterns to the dictionary. This selective addition of high probability words reduces the number of bits required. Additionally, this approach has evidently presented an increased compression ratio of the LZW algorithm, reduction in the consumption of exclusive resources and improved data compression techniques for efficient storage and transmission [32]. With these results, this study could implement this technique in compression algorithm that addresses the VSUA problems in indexing and archiving difficulties.

According to their study, it was concluded that an average compression ratio for the LZW algorithm is 42.85% which is more efficient than reduces to 38.55% using modified LZW lossless method and at the same time using also Variable Length Code. However, the compression rate speed did not improve much, indicating the same with the unmodified LZW algorithm. With these findings, this is still useful for the researcher to improve the areas specifically on the dictionary formation during the compression framework and to its ratio of files being compressed. Furthermore, some contributions were also highlighted such as the implementation of variable length code for encoding process, the comparison of data compression performance between LZW algorithm and proposed algorithm and creation of data compression application using Java programming language [33].

In relation to the efficiency of compressed files, a novel algorithm specifies locating patterns in compression using the LZW-compression framework. According to Adldwairi et al., (2019) this novel algorithm for locating patterns in LZW-compressed data, evidently provided an efficient and simple algorithm with superior time complexity, at the same rate it maintains space complexity similarly to the existing algorithms and significant improvement in search time compared to Aho-Corasick algorithm, as it is a scalable algorithm that improves with larger dataset sizes. As the methods discussed, the algorithm comprises a preprocessing phase and a subsequent search phase. It uses a modified version of the generalized suffix tree, a lookup table, a mapping table, and a history tree. The preprocessing phase involves constructing the LZW-AGS and its corresponding mapTable with two naive algorithms or Ukkonen's algorithm can be used for this task given. For the implementation details and practical considerations of the proposed by this approach coming from the researcher, this provides a theoretical evaluation of the algorithm and experimental evaluation of the algorithm [34].

This study addresses the gaps and problems in tracking, routing and moreover in space allocation, a literature provides an idea on address space allocation compression using the LZW framework. According to Safieh & Freudenberger (2019) the space partitioning techniques for parallel dictionary LZW (PDLZW) data compression algorithm. This literature proposes an address space partitioning technique for the PDLZW algorithm. The technique optimizes the compression rate using a Markov model for the data. On the numerical results demonstrated, the improved performance of the proposed partitioning [35].

This research seeks towards the gaps between tracking a literature also guided the researcher to consider the files utilizing and embedding LZW Lossless to Zlib file compressions. According to Yang et al., (2023) and Chirikhin & Ryabko (2019) claimed that Zlib framework library can fifty percent (50%) to seventy-five percent (75%) deflate algorithm for file compression and decompression. Moreover, file compression improves storage efficiency and transfer speed. These compression algorithms can be lossless or lossy, different compression programs and algorithms are used for different file formats also this compression technology has significant benefits in mass data storage and transmission. The benefits of decompression for different file formats need to be studied and evaluated. Limitations were not reported however, existing literatures provided that significant differences in compression performance of different file formats, where some formats have higher compression ratios and significant compression effects and recompression of already compressed formats may result in poor compression, hence, uncompressed formats tend to exhibit high compression ratios and significant compression effects [36], [37].

The literature presented were the different approaches, techniques, and applications of LZW compression algorithm. Moreover, the similarities found were the focal points of the research to align with the VSUA existing manual system such that in tracking of documents that correlates to the transfer rate of files and space allocation that inputs may be the factor to utilize the said algorithm. It suggests that LZW lossless compression, primarily applied to modified versions, achieves an average compression rate of approximately 42.58%, with a focus on text compressions. Considering this, the researcher has introduced a framework that integrates and adapts Zlib data file compression capabilities, with this integration. It is justified by the proven effectiveness of Zlib, showcasing its ability to deflate and compress files at a notable ratio ranging from fifty percent (50%) to seventy-five percent (75%) among files being reported and used as data sets in the conduct of the experiment in the literatures provided.

III. METHODOLOGY

This research applied a developmental research design, in which the intervention happened by integrating the proposed system into the existing manual system of Visayas State University Alangalang that is systematically developed, refined, and evaluated [38]–[40]. Additionally, this research was geared towards a mixed method both qualitative and quantitative research approach and employed a design that performed a complete enumeration of participants, where all dedicated units serving as the end-users were identified and selected in the conducted evaluation of the proposed system.

The research setting for this study is situated within Visayas State University Alangalang, located in Alangalang, Leyte. The participants consist of the university's staff and faculty members who are invited to provide feedback through Google Forms distributed in the Chancellor's Office, the Records and Archives Office, and the Media Information System and Technology Office.

The selection of this setting for the study is strategic, as it aligns with the researcher's role as the head of the Media Information Systems and Technology Office, where the system under investigation is being implemented. This position offers the researcher a unique perspective and facilitates the process of data migration and encoding, ensuring smoother integration, and handling of incoming data.

The identification of the participants in the proposed system were determined on complete enumeration manner where the following units of Visayas State University Alangalang namely the Office of the Records and Archives (ORA), Office of the Chancellor (OOC) and Office of the Media Information Systems and Technology (MIST). In this view, the researcher identified two (2) participants from ORA, four (4) from OOC and four (4)

from MIST, giving the total participants of ten (10) coming from these identified participants.

Moreover, this study employed the ADDIE model [41]–[43], a widely recognized instructional design framework consisting of five stages: Analysis, Design, Development, Implementation, and Evaluation. This approach allowed the researcher to systematically plan, develop, and assess the effectiveness of development duration. In this study, the integration of analysis-compression algorithm to VSUA iCTMIS is developed using the said model by following the stages as follows:

A. Analysis

In the initial phase of this study, a thorough analysis was executed, employing a meticulous approach through complete enumeration, and listing of all the required aspects that the proposed system used and utilized. The process commenced with a systematic identification of the problem at hand from the stakeholders [44], [45] ensuring a clear understanding of the challenges and requirements faced by Visayas State University Alangalang. This step facilitated the subsequent establishment of well-defined goals and objectives crucial for guiding the research direction.

In Fig. 1, a valuable visual representation of the Use Case Diagram was provided by the researcher in which this outlines the different user roles or knowns as system actors, proposed system, objectives or goals and their interactions within the system. The figure aids in understanding the functionalities and features required for each user type or levels, contributing to a more refined and user-centric system design. This also let the researcher extend the problem identified, incorporating detailed planning to address all aspects of the integrated communication tracking management information system.

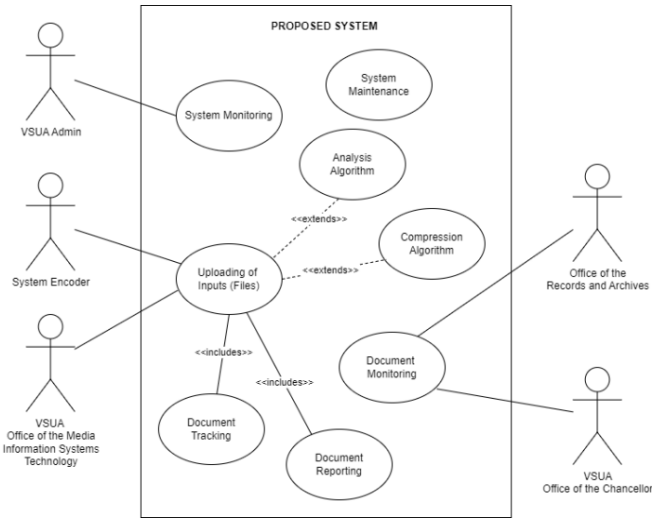

Fig. 1. Proposed system of use case diagram.

Simultaneously, the researcher also carefully selected the programming logic and approaches based on the language chosen for the development of the proposed system. The choice of programming language used is the PHP or Hypertext Preprocessor, along and its corresponding logic, this plays a pivotal role in ensuring the system's efficiency, scalability, and maintainability. For specific instance, the system is required in real-time processing, then researcher opted for a language having strong support for concurrent programming frameworks reviewed and identified in the previous phases.

Afterwards, with various consideration of programming elements complemented with visual representations, which formed a comprehensive approach to system analysis and laying the groundwork for the subsequent phases of development. Furthermore, the researcher also considered factors in ethical considerations, starting from the conduct of preliminary up to the gathering of data undergo to the protocols of Visayas State University Alangalang to take account of necessary actions and approved by the head of the institution coming from the Office of the Chancellor.

Lastly, this thorough process involved not only clarifying the problem but also scrutinizing the intricate details associated with the study goals and objectives. As such, by systematically addressing each component, the researcher ensured that the requirements were not only clearly stated but also precisely identified.

B. Design

During this phase, the researcher thinks of developing an initial prototype of the system. The goal of this stage is to create and identify the overall structure of the proposed system [46]. This includes designing the database, entity relationships, flowchart, data flow, wireframes, style guide, mockups, and the algorithm framework integrations to the existing manual system of VSUA Communication Tracking Management Information System. In Fig. 2 gives the overall methods of what the researcher applied and integrated the procedure in the implementation of the two algorithms, namely the analysis and compression algorithm.

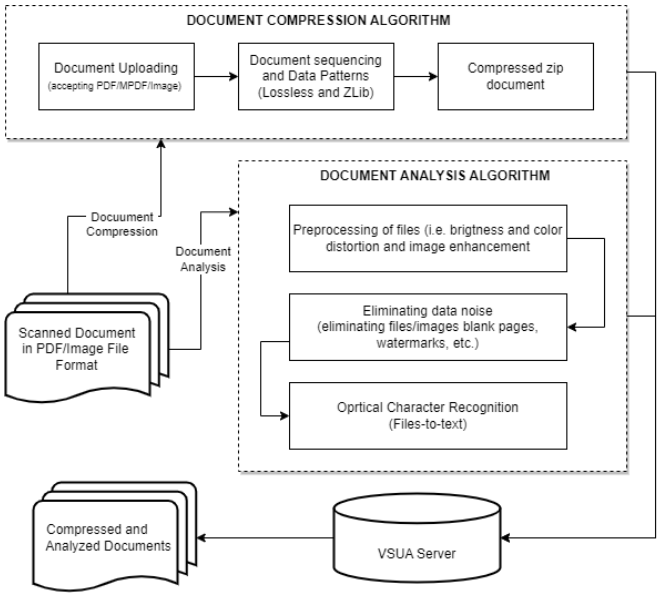

Fig. 2. Implementation of analysis-compression algorithm.

C. Development

In this phase, the development of the analysis-compression framework happens. The proposed system, the framework integration of OCR and LZW is written in PHP programming

language, MySQL for database, and the localhost server installation using XAMPP. In OCR framework two methods were applied in accepting data as input from the stakeholders, that is the acceptance of PDF/MPDF and images type files. Namely the methods applied were using various approaches namely in context of brightness distortion. The brightness distortion referred as a_i is obtained by minimizing by the following the formula:

$$\varphi(\alpha_i) = (p_i - \alpha_i E_i)^2 \quad (1)$$

where a_i represents the pixels strength of brightness with respect to the expected value. For accuracy of the results in *(1)*, a_i must be equal to one (1) if the brightness of the uploaded PDF document is the same to the output in text. Similarly, $a_i < 1$ means the PDF document upload is darker than the expected brightness, otherwise if $a_i > 1$ means it is brighter. An overall mean is computed from the sample data set that the PDF/images documents provided and uploaded are accessible and suitable for document analysis to OCR Tesseract file-to-text recognition. Furthermore, the aspect of color distortion on the other hand, where once the a_i is solved, the chromaticity denoted as CD_i, can now be determined and identified using the RGB color values given the equation below:

$$CD_i = \|p_i - a_i E_i\| \quad (2)$$

The color distortion is defined as the orthogonal distances between the observed color and the expected chromaticity of the file being uploaded and analyzed by the OCR Tesseract. That is using brightness and background subtraction to enhance the recognition of font text and suppress the background.

Lastly, after the framework extracted the brightness and color distortions it proceeds to the image enhancement wherein, image enhancement was the process in the analysis of documents to be specified, it is now the file analysis using OCR to fully maximize and remove data noise found in scanned documents uploaded in PDF/Image format, without altering the text in the foreground, the prior methods were the execution that every pixel must has R, G and B values. This now presumes that the files/images uploaded must have the mentioned three values otherwise, files are then converted using the RGB conversion again. But these values are significant in determining color extracted, process of converting document files and images to text using the OCR Tesseract framework. Thus, the researcher used the formula below in enhancing and converting the three values.

$$p_i = max\{0, min(255, (p_{i-128}) * CD_i + a_i)\} \quad (3)$$

Where in, the end results of these process identify the clean documents and OCR Tesseract successfully converts files from PDF/MPDF and images files to text files.

The researcher also used the modified following frameworks of LZW lossless and ZLib compression algorithm in the process of reducing the files in the manner of encoding the logic as presented in the below snippet Pseudocode 1 (presented in algorithm).

Pseudocode 1: Compression Algorithm

```
Initialize table with single character strings
initial = first input file
WHILE not end of input stream
    C = next input file
    IF initial + C is in the string table
        initial = initial + C
    ELSE
        output the code for initial
        add initial + C to the string table
        initial = C
END WHILE
output code for initial
```

In the application and execution of disk space and memory allocation, it was seen and observed that in the file being uploaded in the system under several logic coding executions following the pseudocode was referred.

In the execution of the algorithm the study used the programming language that is the PHP on its recursive Hypertext Preprocessor using the lossless and ZLib frameworks. Moreover, in Pseudocode 2, which represents source code, the execution of the algorithms in Lossless and Zlib occurs during the deployment of the system.

Pseudocode 2: Modified LZW Algorithm

```
import zlib frameworks
compress_file(input_file_path, compressed_file_path)
DEF  compress(data)
    dictionary = {chr(i): i for i in range(256)}
    current_code = 256
    result = []
    current_str = ""
    FOR char in data:
        initial = initial + C
        current_str += char
        IF current_str not in dictionary:
            result.append(dictionary[current_str[:-1]])
            dictionary[current_str] = current_code
            current_code += 1
            current_str = char
    IF current_str in dictionary:
        result.append(dictionary[current_str])
RETURN result
PRINT("Original Data:", original_data)
PRINT("Compressed Data:", compressed_data)
PRINT("Decompressed Data:", decompressed_data)

FUNCTION compress_file(input_file, output_file)
    data = open(input_file, 'rb').read()
    compressed_data = zlib.compress(data)
    open(output_file, 'wb').write(compressed_data)

input_file_path = 'example.txt'
compressed_file_path = 'example_compressed.zlib'
```

Subsequently, for OCR Algorithm, Pseudocode 3, simplifies the structure by removing unnecessary details and focusing on

the main functions of OCR Tesseract. Each preprocessing step (brightness distortion, color distortion, and image enhancement) is encapsulated in separate functions. Afterwards, the OCR conversion now to files-to-text was done are the cleaning or the preprocessing stages.

Pseudocode 3: OCR Tesseract Code Development

```
SET tesseractPath TO '/path/to/tesseract'
FUNCTION performOCRWithPreprocessing(originalImagePath)
    TRY
        SET brightenedImagePath TO
        applyBrightnessDistortion(originalImagePath, 1.5)
        SET colorDistortedImagePath TO
        applyColorDistortion(brightenedImagePath, 0.8, 1.2, 1.0)
        SET enhancedImagePath TO
        applyImageEnhancement(colorDistortedImagePath)
        RETURN performOCR(enhancedImagePath)
        CATCH Exception e
            PRINT "Error during OCR with preprocessing: " +
            e.getMessage()
        END TRY
    END FUNCTION

    FUNCTION applyBrightnessDistortion(imagePath,
    brightnessFactor)
        // Apply brightness adjustments to the image
        RETURN distortedImagePath
    END FUNCTION

    FUNCTION applyColorDistortion(imagePath, redFactor,
    greenFactor, blueFactor)
        // Apply color distortions to the image
        RETURN distortedImagePath
    END FUNCTION

    FUNCTION applyImageEnhancement(imagePath)
        // Apply image enhancement techniques
        RETURN enhancedImagePath
    END FUNCTION

    FUNCTION performOCR(imagePath)
        // Run OCR using Tesseract on the given image
        RETURN extractedText
    END FUNCTION
RETURN result
SET originalImagePath TO 'input_image.png'
CALL performOCRWithPreprocessing(originalImagePath)
```

D. Implementation

In this phase the actual testing of the proposed system with the integration of analysis-compression algorithm will be delivered to the intended end-users. Primarily, the proposed system will undergo two (2) phases of implementation. In the first phase of implementation, the proposed system was first tested by the programmer and at the same time the researcher along with ten (10) identified participants during the conduct of the Analysis Phase. All the concerns are recorded and afterwards, then satisfied, it proceeds to the second (2) phase where the proposed system is now being migrated to the Visayas State University Alangalang Database Center Server. Through engagement with the intended users, this phase enabled the identification of crucial insights to refine the app's usability, features, and user experience.

Moreover, the conduct of the second phase implementation took two days for the researcher to accomplish. Before the conduct of final and third implementation, the researcher first presented the activity's objectives and secured participants' informed consent. Upon agreement for voluntary involvement, participants must honestly evaluate the system. During this stage, participants will be able to afford ample time to explore the proposed system.

Following this, a Focus Group Discussion (FGD) was conducted to solicit qualitative feedback, aimed at enhancing the system's user interface, usability, features, and overall user experience. Moreover, in this phase the in-charge which is the MIST Office takes full responsibility of the implementation of the system for the installation, recording and creation of accounts pertaining to the usage of the proposed systems. This entails the gathered pertinent data from the analysis phase.

Lastly, the iterative nature of the ADDIE Model allowed the researchers to effectively address user feedback, ensuring that the final system version would cater comprehensively to the needs of all stakeholders involved.

E. Evaluation

The ADDIE model's final phase is evaluation, which aims to assess the effectiveness of the developed system. This phase determines whether the system achieves its intended objectives and benefits its users [47], [48]. The evaluation was conducted through complete enumeration, using the census method, with all intended system users participating as evaluators. These users included the offices of VSU Alangalang, the Office of the Records and Archives (ORA), Office of the Chancellor (OOC), and Office of the Media Information Systems and Technology (MIST).

To evaluate the system, ISO 9126, known as Software Quality Characteristics, provided a simple, reliable tool for classifying and assessing system quality. The evaluation process utilized a 5-point Likert scale to assess various parameters, such as system functionality, reliability, usability, efficiency, maintenance, and portability. The results of the evaluation were recorded in Table I.

TABLE I. EVALUATION TOOL OF THE PROPOSED ALGORITHM

Limit of Scales	Qualitative Interpretation and Description	Qualitative Interpretation Actual Score/Ideal Score
4.21 – 5.00	Strongly Agree(SA)	81 – 100 (Very Good)
3.41 – 4.20	Agree (A)	61 – 80 (Good)
2.61 – 3.40	Neutral (N)	41 – 60 (Enough)
1.81 – 2.60	Disagree (D)	21 – 40 (Not Good)
1.00 – 1.80	Strongly disagree (SD)	0 – 20 (Not Very Good)

Moreover, the percentage scores are included for each scale, indicating the qualitative interpretation values based on actual scores compared to expected and ideal scores. Then, a formula used for this calculation was:

$$p = \frac{\sum actual\ toal\ sore}{\sum ideal\ score\ x\ 100\%} \quad (4)$$

Where p represents the percentage of the weighted score, indicating the acceptance level with a corresponding qualitative interpretation of the proposed system's overall performance based on the six (6) parameters of ISO 9126.

Additionally, the questions from ISO 9126 were customized to suit the needs of the proposed system and tested for reliability using Cronbach's reliability test with JASP. Table II, presents the coefficient values, along with different levels of reliability interpretation.

TABLE II. VALUES AND ITS EQUIVALENT RELIABILITY LEVEL

Coefficient	Reliability Level
More than 0.90	Excellent (E)
0.80 – 0.89	Good (G)
0.70 – 0.79	Acceptable (A)
0.60 – 0.69	Questionable (Q)
0.50 – 0.59	Poor (P)
Less than 0.59	Unacceptable (U)

IV. RESULTS OF THE STUDY

The researcher discussed the significant results, evidence, and findings on the implementation and deployment of the analysis-compression algorithm to iCTMIS which was conducted along with the end-users of the system developed. In the reduction of the disk space and memory allocation among data and files using LZW compression algorithm, the researcher was able to categorize according to classification of documents being accepted namely, the uploaded files are scanned in pure text-based referred as Category 1 documents and the other is a combination of text-based with an attached images referred as Category 2. With these observations said, the researcher provided results using the paired t-test analysis by allowing Wilcoxon's signed ranked test among measures identified as represented in Tables III to VI.

TABLE III. T-TEST SAMPLES OF MEASURE 1 AND 2 (CATEGORY 1)

Measure 1	Measure 2	W	z	df	p
Compressed File size (in KB format)	Original File size (in KB format)	0.000	-5.511		<.001

Note. For all tests, the alternative hypothesis specifies that Compressed File Size (in KB) is less than Original File Size (in KB).

TABLE IV. DESCRIPTIVE STATISTICS REPRESENTATION (CATEGORY 1)

	N	Mean	SD	SE	Coefficient of Variation
Compressed File Size (in KB	40	411.950 (KB)	421.487	66.643	1.023
Original File Size (in KB)	40	1092.389 (KB)	2044.389	323.246	1.870

TABLE V. T-TEST SAMPLES OF MEASURE 1 AND 2 (CATEGORY 2)

Measure 1	Measure 2	W	z	df	p
Compressed File size (in KB format)	Original File size (in KB format)	0.000	-6.624		<.001

Note. For all tests, the alternative hypothesis specifies that Compressed File Size (in KB) is less than Original File Size (in KB).

TABLE VI. DESCRIPTIVE STATISTICS REPRESENTATION (CATEGORY 1)

	N	Mean	SD	SE	Coefficient of Variation
Compressed File Size (in KB	60	907.317 (KB)	1155.287	149.147	1.273
Original File Size (in KB)	60	1113.250 (KB)	1470.836	189.884	1.321

As results presented in the Tables III to VI, the disk space and memory allocation was reduced, in justification with the results from paired-sample t-test was conducted to compare the files between uncompressed and compressed files by integrating the modified LZW Lossless and Zlib compression algorithms. The file unit of measurement being applied is in Kilobyte (KB). Furthermore, the Wilcoxon signed-rank test in JASP was employed [49] to compare these results from compressed file size to original file sizes. The results revealed in Tables III and IV that there is a significant decrease was observed, for Category 1 ($W = 0.000, z = -5.5111, p < 0.001$), and Category 2 ($W = 0.000, z = -6.624, p < 0.001$). This implies that, on average, the file size decreased after file compression of LZW Lossless and Zlib algorithm was employed. The negative z-scores of the categories ($C1 = -5.511; C2 = -6.624$) indicates that, on compressed file sizes in Category 1 ($M1 = 411.950, SD = 421.487$) are significantly smaller than original file sizes ($M2 = 1092.389, SD = 2044.389$) and Category 2 ($M1 = 907.317, SD = 1155.287$) which is also significantly smaller than the original file sizes ($M2 = 1113.250, SD = 1470.836$). Therefore, the analyses suggest that there is strong evidence that the modified LZW lossless and ZLib file compression algorithm effectively deflates the size of files in comparison to their original counterpart's disk and memory allocation.

In the second objective of the study, eliminating noise and converting files-to-text among document types using the OCR Analysis has proven highly effective as presented in Table VII.

TABLE VII. DOCUMENT DISTORTIONS AND IMAGE ENHANCEMENT

Sample Size (N)	Category of Documents	Mean
40	Category 1: Text-based	0.9485
60	Category 2: Text-images based	0.9526
OVERALL MEAN (N = 100)		**0.9505**

In Table VII, the results reveal a commendable performance across distinct file categories, as exemplified by the following mean scores: In Category 1, encompassing purely text-based files, the OCR algorithm achieved a mean score of 0.9485. Similarly, in Category 2, which involves a combination of image and text files, the algorithm demonstrated robust efficacy with a mean score of 0.9526. These findings underscore the algorithm's

versatility and reliability in converting images to text are highlighted by a mean score greater than 0.50 but less than one (1). This indicates that documents with these scores are suitable for conversion, and the algorithm effectively eliminates noise in the data sets, making it a valuable tool for the document types, and enhancing overall document clarity. Moreover, in eliminating noise among accepted documents by the OCR Tesseract algorithm, the following approaches brightness and color distortion and image enhancement were considered.

Furthermore, in the evaluation of the study, the researcher adopted ISO 9126 or known as Software Quality Characteristics, which focused on the aspects of systems functionality, reliability, usability, efficiency, maintenance, and portability. In the conduct of evaluation, the questions were adopted and modified based on ISO 9126 Software Quality Characteristics Metrics. The questions were categorized into six (6) measures namely functionality, reliability, usability, efficiency, maintenance, and portability.

To also determine the point of scaling for every question, a five-point Likert scale was used for the respondents to avoid confusion on answering and to provide an accurate comparison for every question given in the evaluation.

The results from the evaluation conducted, a formula is presented below that was used for computing the mean of every category of the evaluation. A limit of scale was used as an indicator that helped determine the qualitative descriptions. The researcher used the following formula:

$$\bar{x} = \sum fw/n \tag{5}$$

In computing the mean, where $\bar{x}$ is the computed mean, $\sum fw$ is the sum of all the scores in the set and n is the total numbers of respondents. Additionally, since the researcher used Cronbach's Alpha for consistency, or reliability, of a set of survey evaluations conducted, the researcher used the following formula:

$$\alpha = \frac{N * \bar{c}}{\bar{v} + (N-1) * \bar{c}} \tag{6}$$

where N is the number of items, $\bar{c}$ is the mean of covariance between items and $\bar{v}$ is the mean item variance. As presented, the researcher presents the Table VIII, a tabulated presentation in relation to the conduct of evaluation adapted and modified through ISO 9126 in its six (6) measures with the used statistical analysis measures that the evaluation Cronbach's Alpha validity and reliability test that in the measures of functionality and usability provided a good level of reliability and to the measures in reliability, efficiency, maintenance and portability was concluded acceptable in validity and reliable.

For the aspect of ISO 9126, the overall percentage provided a 91% percent of its overall weighted mean that the figures presented that the usability, efficiency, maintenance, and portability manifested an above 90% operative performance while functionality and reliability manifested an above 85% which still indicates an operative performance during the conduct of evaluation.

TABLE VIII. RESULTS OF THE EVALUATION

Algorithm Evaluation	Mean	Cronbach's Alpha	Weighted Mean (%)	Interpretation
Functionality	4.383	0.839	88%	SA / G
Reliability	4.361	0.715	87%	SA / A
Usability	4.583	0.824	92%	SA / G
Efficiency	4.583	0.707	92%	SA / A
Maintenance	4.625	0.755	93%	SA / A
Portability	4.667	0.764	93%	SA / A
Overall	4.534	0.767	91%	SA / A

V. CONCLUSION

The research aimed to improve the communication tracking management system at Visayas State University Alangalang. This was achieved by the objectives set such as, implementing analysis-compression algorithms, specifically focusing on reducing disk space and memory allocation using LZW Lossless and Zlib compressions, as well as eliminating data noise and converting files to text using OCR analysis. Additionally, the study evaluated the proposed system using a modified version of the ISO 9126 as an evaluation tool, focusing on the six (6) measures functionality, reliability, usability, efficiency, maintenance, and portability. Participants were selected based on specific criteria relevant to the research goals. The research design and methodology employed was developmental research design and the ADDIE Model. Moreover, the instrument utilized is the ISO 9126, which underwent a reliability test to ensure consistent results during the evaluation of the proposed system.

As objectives discussed, this study has achieved and provided significant highlights. Firstly, it successfully reduced disk space and memory allocation among data and files through the implementation of the LZW compression algorithm – Lossless and ZLib. The utilization of these LZW compressions not only significantly decreased data sizes but also adhered to the study's first objective. This reduction in data size is further substantiated by the statistical analysis tools employed, which demonstrate that the achieved compression figures are statistically significant and provide acceptable results.

Secondly, the study effectively eliminated data noise and converted files to text using the OCR analysis algorithm. The OCR analysis played a crucial role in achieving this objective, ensuring that the data is converted to a usable, accurate and reliable output from files into text format. Again, statistical analysis computed mean was used to justify the effectiveness of the OCR algorithm in eliminating noise and converting files, further supporting the study's objectives.

Lastly, the study conducted a comprehensive evaluation of the analysis-compression algorithm against the system requirements based on ISO 9126 Software Quality Characteristics, which encompass functionality, reliability, usability, efficiency, maintenance, and portability. The results of this evaluation revealed that the algorithm performed commendably across all these parameters of ISO 9126. Statistical analysis tools were employed to provide thorough evidence of the algorithm's performance in meeting these quality

characteristics, reinforcing the alignment with the study's third objective.

The integration of algorithms in the analysis-compression frameworks significantly improves the management information system for communication tracking at Visayas State University Alangalang. By the incorporation of algorithms, particularly the modified LZW Lossless and ZLib frameworks, it provided a notable significant decrease and efficient performance in the data set file sizes, thereby optimizing disk space and memory allocation which mainly addresses the challenges that VSU Alangalang in adapting technology innovations that with this development the use of algorithms in analysis-compression showed a significant improvements in the document and communication tracking of information systems.

Furthermore, the application of OCR Tesseract for eliminating noise and converting files to text proves to be highly effective. The algorithm achieves a significant ninety-five (95%) success rate in converting files to text, employing techniques such as brightness and color distortion adjustments, along with image enhancement methods wherein mean score among the data sets showed a greater than 0.50 but less than 1.0, that indicates that documents with these scores proves that are suitable for conversion framework, and the algorithm effectively eliminates noise in the data sets.

In terms of system software quality characteristics, the proposed system exhibits very good remarks with a ninety-one percent (91%) weighted mean score that indicates and proves the quality characteristics of the proposed system in the measures and performance across various dimensions in functionality, reliability, usability, efficiency, efficiency, maintenance, and portability, indicating a high level of quality and effectiveness in its operation.

VI. Recommendations

It is recommended that, the end-users of the system, such as the Visayas State University Alangalang Staff/Faculty and Personnel and Office of the Records and Archives (ORA), should upload only PDF/MPDF and image files containing pure text, excluding images. Additionally, this proposed system it is also recommended that this should be expanded to the other Offices such as the Office of the two (2) Colleges which also struggles with the Information Systems that should replace the existing manual management of documents.

Moreover, the compression framework demonstrated a slight two to three (2-3%) reduction in the size of communication letters that include images. In contrast to pure text documents exhibited a more substantial compression ranging from 50-80% compared to their original sizes. 3) To enhance optimization, it is suggested that there should be an implementing a file categorization system based on criteria such as the number of pages and the presence of images. Additionally, the proposed approach involves classifying the quality of uploaded images based on resolution, aligning with specifications derived from various scanner equipment from the different officers/units for the desired output images.

Regarding the OCR Tesseract framework, a uniform template for communication letters is recommended to enhance recognition of handwritten letters from stakeholders. Furthermore, if the institution decides to upload the system to the cloud, it may pose complexities in installation and configuration, with associated costs for VSUA.

To address the used Cronbach reliability test has provided valuable insights into the software quality characteristics, as per the ISO 9126 standards. The focus of this report is to provide targeted recommendations for enhancing specific measures and sub-characteristics of usability, maintenance, and portability.

Future work could include enhancing software usability through improved documentation, interactive tutorials, streamlined user interfaces, and enhanced visual appeal, optimizing maintenance by adopting modular coding practices, conducting thorough testing, and ensuring system stability, and improve portability by adopting standardized coding practices for adaptability across platforms and providing clear guidelines for seamless system replacement. Lastly, as to the proposed system, since VSU Alangalang is still on gradually moving towards digitization it is also recommended that this system undergoes the Unified Theory of Acceptance and Use of Technology a kind of information systems modeling specifically by using the concept of Performance Expectancy that may help even more in redefining and the level of acceptance it may as the system accepts data from the different Office of the VSUA.

Implementation of a Web System to Optimize the Quotation Process in the Company KSF Representaciones EIRL, 2022

Betsy Nataly Llacchuarimay-De la Cruz, Segundo Alexander Gutierrez-Argomedo, Luis Alberto Torres-Cabanillas
Facultad de Ciencias Empresariales, Universidad Científica del Sur, Lima, Perú

***Abstract*—This research seeks to demonstrate whether the implementation of a web-based system influences the optimization of activities related to the quoting process, saving time and money for KSF Representaciones EIRL. Therefore, the following question arises: To what extent does the implementation of a web-based system optimize the quoting process? This is an applied, pre-experimental design with a quantitative approach. The population consists of average daily quote records for 24 business days per month. For the convenience sample, an average of 24 quote records from May were used for the pre-test and an average of 24 quote records from June for the post-test, collected using an observation sheet. The results regarding the quoting process variable show that the application reduces the time to generate quotes. For the second dimension, the application results in a higher percentage of quote fulfillment. In conclusion, the implementation of the web-based system improved quote generation by an average of 28 minutes and increased the compliance rate of submitted quotes by an average of 89.8%.**

***Keywords*—Web system; optimization; quotation; customer satisfaction; efficiency**

I. Introduction

Nowadays, companies require a faster response to customer requests. In this sense, the generation of quotes is an activity that must be attended to more quickly, since it is essential to generate customer satisfaction [1]. Billing, purchasing and quoting activities lose agility due to the lack of automation of the related tasks [2]. Information technology and software development have had a significant impact on most fields of knowledge, and in recent decades there has been enormous development at both the industrial and academic levels [3]. In this sense, at KSF Representaciones EIRL, a problem is detected in the quotation process that, being a manual activity, causes delays in the preparation, which generates customer dissatisfaction. This produces high response times and low quality of attention. Thus, in Ecuador, the source of the digital newspaper El Telégrafo indicates that 56% of the 500 companies surveyed indicate that technological progress is the trend that brings them the greatest results [4]. The reasons are that it allows reducing errors, increasing the speed and quality of production and reducing costs. The study in [5] agrees that web systems allow automating various processes managed in an organization, providing versatility, maintaining communication digitally and instantly, obtaining better control over this data, efficiency and simplifying management. On the other hand, according to a study carried out in Peru, the level of compliance in delivery of quotes was only 54.5%, while 49.75% of those delivered quotes were accepted by the client, because the requests for quotes were not answered in the required time [6].

II. Problematic Reality

In reference to previous works reviewed, both international and national, on the implementation of web-based systems for the quotation phase [7] of Colombia mentions that the implementation of a system allows to manage the quotations and the post-sale process of the projects, optimizing the search for information and managing the process flows, in addition to helping management to make decisions.

In Mexico [8], it is expressed that the local creation of a web-based quotation system helps in the management and inspection of clients and computer equipment; it also allows for generating quotations more quickly in the company Servicio de Taller "Trujillo", optimizing internal processes and obtaining centralized data.

On the other hand, in Peru [9] it indicates that the influence of a web system on commercial management activities is favorable. According to the results, the quote effectiveness indicator improved from 57.18% (pre-test) to 80.6% (post-test), while the marketability index increased from 55.51% (pre-test) to 80.9% (post-test).

Similarly, the study in [10] states that the influence of a web system on activities related to quotation control is favorable, since the results show that the level of compliance of deliveries improved from 54.52% (pre-test) to 75.44% (post-test) and the level of accepted quotations increased from 45.75% (pre-test) to 77.26% (post-test).

Finally, the study in [11] points out that the influence of a web system on commercial management activities is favorable, since the results allowed us to increase the percentage of compliance in delivery of quotes from 61.24% (pre-test) to 71.25% (post-test), as well as to increase the number of approved quotes from 57.08% (pre-test) to 67.08% (post-test).

III. Theoretical Framework

This study is justified on a practical level because currently, the quotation is a routine operational work performed manually; therefore, the implementation of the system aims to optimize the quotation process by automating the functionalities which involve carrying out this task. At a technological level because the design, development and the implementation of the web system will be implemented under the CodeIgniter framework,

which will make use of the Model View Controller (MVC) development process, Language Hypertext Preprocessor (PHP), Style Sheets (CSS), JavaScript, HyperText Markup Language (HTML), libraries for generating reports, MySQL database, domain, hosting, among others. At a methodological level, why will a registration form be used? as a research instrument, which is the document where the data is recorded obtained by monitoring company information. This form will allow consolidation and verify data to demonstrate the optimization of process.

Barzallo [12] defined a web system, also known as a web program, as a system that is created, installed and hosted on a server or intranet (local area network) on the Internet. This system can be used in any browser, such as: Chrome, Brave, Microsoft Edge, etc., regardless of the operating system. Using a web system does not require installation on each computer; it is only necessary to enter where the system is hosted. Web programs dynamically display information to the user through a database, which helps in data processing.

On the other hand, [13]-[10] indicate advantages of a web system, that is, the reuse of source code and modifications at any time. In that sense, [14] mentions that a web system helps improve the quotation process, given its efficiency and reliability.

The features of a web system are diverse. According to Barzallo [15], web application frameworks provide basic functionalities, such as a template system, support for user sessions, and a common interface for disk storage or databases. Generally, these frameworks encourage the reuse of components, including the reuse of source code and database access libraries.

On the other hand, the objective of using a framework, [16] - [15], is to optimize the construction activity, facilitating the reuse of already created source code and promoting best practices for development. A web framework is composed of a set of components, files in XML format and classes in Java, which speed up and help in the construction of the web system [15].

It was decided to use the framework CodeIgniter because it helps to maintain order and good practices in building the web system, as it is based on the MVC model, which stands for Model, View and Controller. In this context, CodeIgniter includes a set of useful tools to create sophisticated PHP applications, facilitating the development of web applications. In addition to its organized programming and architecture, it also offers numerous complementary tools (plugins) for the implementation of functional and secure applications.

Regarding the programming language, [15] defines that web programming languages have been emerging according to the needs of the platforms to facilitate the work of application developers. The language chosen to develop the web system was PHP. According to Arias [17], PHP is used exclusively in web environments, which means that its scope of application is limited only to web development, with the main objective of making web solutions fast, simple and effective. The choice of this language is due to greater practical knowledge, its free nature, its easy configuration and the possibility of being easily integrated into other applications. Likewise, Bootstrap will be used to improve the visualization of the system. Villagomez [18] comments that Bootstrap is a framework that allows creating web interfaces using JavaScript and CSS, with a special feature to adapt the web page interface to the size of the display device.

In addition, a web server was used, which, according to study [19] – [23], is defined as one that attends and responds to all browser requests, providing the resources that are requested through the HTTP (Hypertext Transfer Protocol) or HTTPS protocol, the latter being the encrypted, secure and authenticated version.

To house all the information, a database was chosen. According to study [21], a database is defined as an organized series of data, which can range from a list of items to a collection of photos or a large amount of information about an organization's network. The study in [20] agree that MySQL is widely used in web applications. Its popularity is closely related to PHP, which is frequently combined with MySQL. MySQL is a very fast database management system, making it an ideal choice for applications.

Furthermore, to add, arrange and manage data stored on computers, it is necessary to have a database manager such as MySQL Server. This can process a large amount of information, which highlights the importance of database managers in computing, either as a stand-alone application or as part of other applications. According to Victor [21], MySQL is the most widely used open-source database management system. Its efficient structure contributes to its speed and its interface is intuitive. It also allows code reuse within the system, and its minimalist approach has resulted in competitiveness in terms of speed, compactness and stability, as well as being easy to implement. This database was chosen because it is easily integrated into the project, is free of charge and there is practical knowledge of it.

On the other hand, as a development methodology we will use Scrum, since it is an agile methodology that reduces the margin of error in a collaborative way, favors teamwork and allows continuous interaction with the client to build the system according to their needs. According to study [22], the main objective of having a clear development methodology and specific processes is to promote dialogue between the client and the developers. The research in [23] mentions that there are two trends in development methods: one structured and one agile, the latter being the one that helps reduce risks and has gained popularity in recent years due to favorable results in highly changing projects. Excellent software design translates into solid and reliable web applications that can be continuously improved. Therefore, Scrum is especially appropriate for projects in complex environments that require fast results, where requirements are constantly changing or not well defined, and innovation, flexibility, competitiveness and productivity are crucial [24].

The web system will be hosted on a hosting. According to study [25], hosting is based on providing services to users so that they can access from any device connected to the Internet, thus ensuring high availability. This is based on decentralized application programming, where applications are distributed across hundreds of servers located in different parts of the world,

allowing them to respond to large volumes of service requests and offering fault tolerance.

Since the application is hosted here, we considered the security that said hosting offers us and that is why we chose Blue Host, since it offers us, for example, Firewall as security in which its main objective is to prevent various attacks from external people and it also allows you to monitor HTTP traffic. SSL ensures the confidentiality of transmissions between the logical layer and the visual presentation layer, and vice versa. It offers security services by encrypting the information transmitted between the server and the client using a symmetric encryption algorithm. (usually RC4 or IDEA). Malware scanning is a tool that helps warn of the presence of malicious code and daily backup of the website, helps save the information that the hosting accumulates such as files and databases.

The independent variable in the project is the web system. In that sense [26] mentions that a web system refers to a computer program or web page that works on the Internet, without the need to be installed on the local computer. To do this, only is necessary he access to a browser web, already that, HE finds programmed in HTML.

The dependent variable is the quotation process, which, according to studies [27] - [28], is defined as a standard financial process known as quotation, through which a seller can initiate a purchase/sale to provide a particular service or product. The study in [29] defines the quotation process as the activities performed for the generation of an informative document that the responsible area uses to initiate a negotiation. In addition, it mentions that the document does not generate any accounting record, but rather its purpose is to determine the price of a product or service. Often, a request for a quotation includes not only the cost of the product, but also the payment terms, the duration of the contract, and the quality level. Various product details are included in the quotation to ensure that all interested parties submit offers. In the same context, [30] - [31] mentions that a quotation is a basic financial process that instructs a supplier to start buying and selling, resulting in a specific product or service proposal.

In general, there are several aspects when requesting a quote, such as prices, various services, legal requirements. To select the quotes, according to studies [32] - [33], defines that there are three points of view for the choice of quotes: Quality analysis: Tries to analyze all the quotes, providing certain parameters that help to exclude those that do not present the minimum requirements requested. This cleaning process must be carried out very carefully, since the promotion is not always expected to be to the client's liking and some occasions are quite difficult to achieve, therefore selection or elimination must be prioritized. [33], Service: This aspect is very valuable, because it is what the client wants and therefore periodic maintenance of what you offer must be carried out. You must also make an offer so that the client has more confidence [33], Price: Among the accepted quotes, on this occasion, there are two suppliers, the most favorable price will be chosen, but with good quality compared to the product.

The first dimension is the generation of quotations. According to studies [34] – [33], it is defined as a sales promotion in which a proposal is presented that includes the specifications and the cost of the purchase, considering a series of aspects such as the payment methods, the exchange rate, the details of the product, the quality assurance and the conditions of sale. As an indicator, there is the quotation generation time. According to studies [35] – [36], this time is defined as the average time it takes to make a quotation, starting from the entry of the request until a response is provided to the client. This time is associated with the manual task that is carried out to prepare the quotation and the different consultation sources necessary for its development.

On the other hand, the second dimension refers to the fulfillment of the quotations. According to study [37], this aspect allows measuring the fulfillment of the delivery of the offer within the deadlines agreed with the client. It also implies the end of a period in which the stipulations of both parties are fulfilled, as is the case of the process of the orders placed. As an indicator, the degree of fulfillment of the quotations delivered is considered. According to study [38] – [36] this degree is defined as the period that elapses from when the client communicates with the company until an adequate response is provided. This concept is related to the customer experience in terms of time, highlighting the importance of the consumer, who establishes a favorable association between convenience, trust and good quality.

IV. METHODOLOGY

This analysis had a quantitative approach, using measurement instruments and statistics to test the hypotheses. A pre-experimental design was used, as only one experimental group was considered for the pre-test and post-test stages.

The target population of this study is all records made from April 2004, the year in which the company began to operate, until June 2022, the month in which the system begins to operate. Since the data collection will be carried out in two stages, pretest and posttest, a convenience sample of 24 records of contributions on average of the working days of the month of May 2022 will be taken for the pretest and 24 records of contributions on average of the working days of the month of June 2022 for the post test.

The months of May and June were selected to take the samples and perform the tests solely for convenience, since at that time the system was already deployed in production and because of the availability of the person in charge of recording the quotes. In this sense, [39] states that "the convenience sample makes it possible to choose those affordable cases that agree to be included." This is based on the timely accessibility and proximity of the individuals to the researcher.

Inclusion and exclusion criteria: For the research, only the quotes received from May 1, 2022, to May 31, 2022, working days for the pre-test, and from June 1, 2022, to June 30, 2022, working days for the post-test, will be included. In the company, working days are considered from Monday to Saturday. In this sense, 24 quote records on average were taken as a sample, since the company only works from Monday to Saturday, with 24 working days per month. In addition, the month of May was chosen for convenience for the pre-test because it was the month before the implementation of the system, and the month of June was chosen for convenience for the post-test because it was the

month in which the system was already in production and the data could be measured with the implemented system.

The observation form will be used as a technique for obtaining data for the study measurements. This will allow us to collect data on the quotes made to verify how long it takes to generate a quote before and after the implementation of the system. In the same way, the percentage of compliance with the quotes delivered will be verified.

In this present investigation, the instrument that is a form of observation of Young Torres, Ariadna Magaly Nereida, in addition to this, a process of validation that measured the validation of the construct and method by half of three experts. The observation sheet will measure two times, before the implementation and after the implementation.

Regarding ethical aspects, the aim is to produce a truthful and sincere study, while being fully careful with the security of the information, since the data was acquired from a critical area of the company, which was kept completely confidential. Likewise, the authorization of the company analyzed is available and, in the opinion of the Ethics and Research Management Committee of the university, this study is subject to a review with all control systems to guarantee the originality, relevance and quality of the research. On the other hand, the personal data used in this study will be subject to compliance with the regulations of Law No. 29733 or the personal data protection law, which establishes the necessary regulations to guarantee the security and privacy of the personal information of every natural person.

When carrying out this study, limitations were observed in terms of access to collect information from the areas involved, due to the limited time available of those in charge. To carry out this activity, it was necessary to attend, observe and personally talk with the workers in the quotation process to obtain greater detail of the requirements and the problem. It was also essential to arrange virtual meetings to learn more details about the workflow and everything necessary to carry out the project. In addition, Law No. 29733 or the Personal Data Protection Law limits the development of the study because it will handle personal data of the company's clients, suppliers and workers.

TABLE I. QUOTE GENERATION STATISTICS

Type of improvement		***Statistics***
Without web system (Pre-test)	Average	55,8750 min
	Deviation	38,25920 min
	Maximum	8,00 min
	Minimum	145,00 min
With web system (z<Post-test)	Average	28,0000 min
	Deviation	20,80970 min
	Maximum	4,00 min
	Minimum	72,00 min

Table I shows that the records of the observation sheet belonging to the pretest show a mean and deviation of 55.87 minutes and 38.25 minutes respectively. The range is between 8.00 minutes minimum and 145.00 minutes maximum. In the post-test a mean and deviation of 28.00 minutes and 20.80 minutes respectively can be noted. The range is between (4.00 minutes and 72.00 minutes) on the generation of quotes.

TABLE II. NORMALITY TESTS

	Shapiro-Wilk		
	Statistic	***Gl.***	***Sig.***
Quotation generation (Pre-test)	,939	24	,154
Quotation generation (Post-test)	,901	24	,022

In Table II, the analysis of the generation of quotations with and without the system, a normal distribution was observed for the pretest and a non-normal distribution for the posttest, in view of the statistical evidence of the Shapiro-Wilk test, with an estimate equal to 0.154>0.05 and 0.022<0.05, respectively.

TABLE III. DIFFERENCE OF THE PRE AND POST TEST DIMENSIONS

Difference between pre and post test dimensions of quotation generation			
Shapiro-Wilk			
DIF1	***Statistics***	***Gl.***	***Sig.***
	,905	24	,028

In Table III, the pre-test is normal since it has a value of 0.154>0.05 and the post-test is non-normal because it has a value of 0.022<0.05, the combination of both is non-normal since 0.028<0.05 so the Mann-Whitney test is used.

Fig. 18 shows the box diagram with respect to the pre and posttest, in the comparison of the generation of quotations where the differences in time are perceived, that is, the quotation process with the system has less time to generate quotations.

Table IV shows that the records of the observation sheet belonging to the pre-test show a mean and deviation of 49.95 % and 22.57 % respectively. The range goes from 14.00 % minimum to 100.00 % maximum. In the post-test it can be noted a mean and deviation of 89.87 % and 9.63 % respectively. The range goes between 75.00 % minimum and 100.00 % maximum on the generation of quotes.

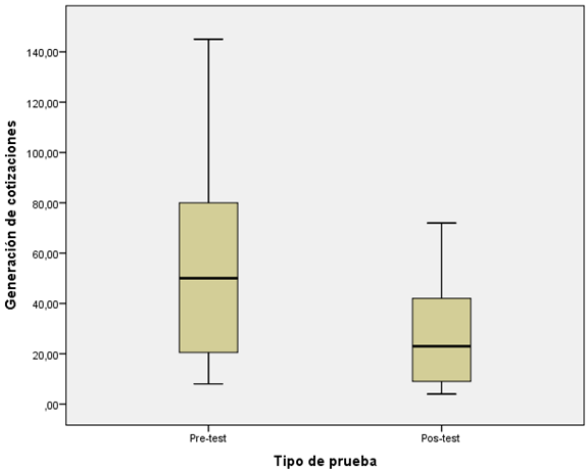

Fig. 18. Quote generation box diagram.

TABLE IV. QUOTE COMPLIANCE LEVEL STATISTICS

Type of improvement		*Statistics*
Without web system (Pre-test)	Average	49,9583%
	Deviation	22,57255%
	Maximum	14,00%
	Minimum	100,00%
With web system (Post-test)	Average	89,8750%
	Deviation	9,63378%
	Maximum	75,00%
	Minimum	100,00%

TABLE V. NORMALITY TESTS

	Shapiro-Wilk		
	Statistic	***Gl.***	***Sig.***
Quotation compliance level (Pre-test)	,927	24	,085
Quotation compliance level (Post-test)	,833	24	,001

In Table V, the analysis of the generation of quotations with and without the system, a normal distribution was observed for the pretest and a non-normal distribution for the posttest, in view of the statistical evidence of the Shapiro-Wilk test, with pvalue =0.085>0.05 and 0.001<0.05, respectively.

TABLE VI. DIFFERENCE OF THE PRE AND POST TEST DIMENSIONS

Difference between pre and post test dimensions of quotation generation			
Shapiro-Wilk			
DIF1	***Statistics***	***Gl.***	***Sig.***
	,957	24	,381

In Table VI, the pre-test is normal since it has a value of 0.085>0.05 and the post-test is non-normal because it has a value of 0.001<0.05, the combination of both is normal since 0.381>0.05 so the T-test is used.

Fig. 19 shows the box plot for the pre- and post-test with respect to the comparison of the level of compliance with quotations, where the differences in percentage can be seen, i.e., the process with the system has a higher percentage of compliance with quotations.

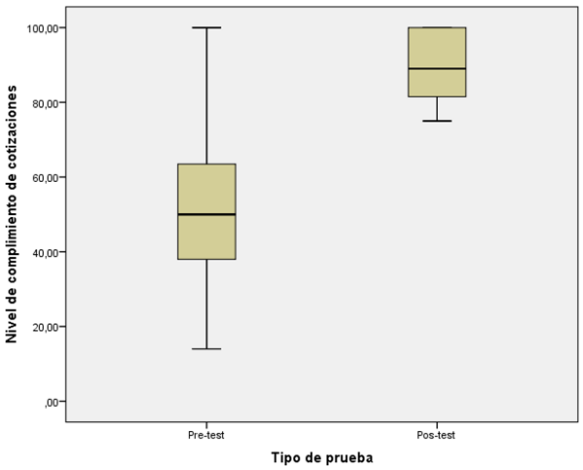

Fig. 19. Compliance level box diagram.

The Shapiro-Wilk normality test was performed, since our sample is smaller than 50 observations for the pretest and posttest. In addition, it is necessary to know whether the samples collected follow a normal or non-normal distribution and thus determine which statistical tool to use to statistically test the hypotheses raised. For example, the sample for the first dimension of quote generation follows a non-normal distribution, so we used the Mann-Whitney test. On the other hand, the second dimension, which is the fulfillment of quotations delivered, follows a normal distribution, so we use parametric tests, such as Student's t-test, which require that the data follows a normal distribution.

K. Hypothesis Test Contrast

1) Hypothesis test for dimension 1: Generation of quotations.

a) Ho: The implementation of a web system does not significantly improve the generation of quotations in the quotation process of the company KSF Representaciones EIRL, 2022.

b) H1: The implementation of a web system significantly improves the generation of quotations in the quotation process of the company KSF Representaciones EIRL, 2022.

Level of Significance $\alpha = 0.05$ has been considered.

Decision rule: If the sig. $\geqslant$ 0.05, the null hypothesis is rejected, otherwise the alternate hypothesis is accepted.

TABLE VII. QUOTE GENERATION (MINUTES)

Dimension 1: Quotation generation (min) Mann-Whitney test	
	Quote generation
U Mann-Whitney	156,000
W de Wilcoxon	456,000
Z	-2,724
Sig. asintót. (bilateral)	,006

From Table VII, the Mann Whitney U. test was relevant with a Sig. < 0.05, so that the null hypothesis is denied, and the alternative hypothesis is approved. It is concluded that the implementation of a web system significantly improves the generation of quotations in the quotation phase of the company KSF Representaciones EIRL, 2022.

2) Hypothesis test for dimension 2: Fulfillment of quotations delivered.

a) Ho: The implementation of a web system does not significantly improve the compliance of quotations delivered in the quotation process of the company KSF Representaciones EIRL, 2022.

b) H1: The implementation of a web system significantly improves the compliance of quotations delivered in the quotation process of the company KSF Representaciones EIRL, 2022.

Level of Significance α= 0.05 has been considered.

Decision rule: If the sig. ⩾ 0.05, the null hypothesis is rejected, otherwise the alternate hypothesis is accepted.

TABLE VIII. COMPLIANCE WITH QUOTATIONS DELIVERED (%)

Dimension 2: Compliance with quotations delivered (%)									
	Levene's test for equality of variances		***T-test for equality of means***						
	F	**Sig.**	**T**	**Gl.**	**Sig(bilateral)**	**Mean difference**	**Standard error of difference**	**95% confidence interval for the difference**	
								lower	upper
Equal variances have been assumed	4,407	,041	-7,968	46	,000	-39,91667	5,00970	-50,00067	-29,83267
Equal variances have not been assumed			-7,968	31,110	,000	-39,91667	5,00970	-50,13255	-29,70078

From Table VIII, the t-test was significant with a Sig. < 0.05, so that the null hypothesis is denied, and the alternative hypothesis is recognized. It is concluded that the implementation of a web system significantly improves the fulfillment of quotations delivered in the quotation process for the business of KSF Representaciones EIRL, 2022.

VI. DISCUSSION

The results achieved in this work confirmed that the use of technology through this web system really helps to generate quotes more quickly, obtain the necessary information, access it quickly and easily, therefore the general hypothesis can also be confirmed and the general objective can be achieved, so it is determined that implementing a web system optimizes the quotation phase in the KSF Representaciones EIRL business, since the time of generation of the quote was optimized to 28 minutes on average and the level of compliance increased to 89.8%.

Regarding the first specific objective, the results of the pre-test showed that generating a quote takes on average 55.8 minutes, while with the implementation of the system this time decreased, so the post-test indicates that it takes on average 28 minutes to generate a quote. The time to generate quotes was reduced, all of which corresponds to the first dimension "Quotation Generation" which resulted in the validation of the hypothesis raised, where a lower level of significance is shown (<0.05). The research coincides with the results of [28], which shows that after implementing the web system, the approved quotes increased to 67.08%. For [33], after the implementation of the web system, the accepted quotes increased by 77.26%, significantly increasing the level of accepted quotes in this process.

Similarly, in the second specific objective, the results of the pre-test showed that the level of compliance with the quotes was 49.9%, while with the implementation of the system the level of compliance with quotes increased to 89.8%. Therefore, the degree of compliance with the quotations could be improved, all of which corresponds to the second dimension "Compliance with quotations" which resulted in the validation of the hypothesis raised, where a lower level of significance is shown (<0.05). The research coincides with the results of [33], this shows that, after the implementation of the web system, the level of compliance with deliveries rose to 75.44%. According to [28], the adoption of a web-based system managed to increase the percentage of compliance with the delivery of quotations to 71.25%.

VII. CONCLUSIONS AND RECOMMENDATIONS

Through statistical tests conducted on the dimensions, it can be confirmed that the implementation of the web-based system significantly improves the quoting phase for the company's clients. This is due to the improved and reduced quote generation time and the degree of compliance, which allowed us to achieve the objectives of this study.

Using the Mann-Whitney U test, which was significant, quote generation times were optimized for system implementation, with a sig of 0.006 less than 0.05. Furthermore, the implementation resulted in an average time saving of 27.8 minutes per quote.

With the help of the T test demonstration, a significant result is reflected, so that the implementation of the quotation system optimizes the level of compliance of the quotations with a Sig. < 0.05. This is manifested through the improvement in the percentage of the number of quotations delivered to the client with respect to the number of quotations that are requested by the client daily. Furthermore, the implementation of the web system helped the quoters to make a greater number of daily quotes, since, for the pre-test, the degree of compliance of the quotes was 49.9% on average and for the post-test, the degree of compliance of the quotes was 89.8% on average. An improvement in the percentages can be seen by analyzing the before and after of 39.9% on average.

The developed web system achieved a compliance rate of 89.8% for submitted quotes due to the increase in quotes completed on the day.

Since the implementation of the system was successful and the expected results were obtained, it is recommended to maintain the web system and improve it by developing new functionalities to be able to cover other company processes and not only the quotation process.

In addition, it is suggested to provide technological solutions to the different processes that the company has, such as the billing or inventory process, involving the existing web system and thus provide greater functionality and help to employees in the different areas of the business. Likewise, this study can be applied to other companies that need it.

For maintenance, it is recommended to automatically make backups of the web system database from time to time to avoid loss of information, as well as to purge unnecessary information to guarantee the correct functioning of the system.

To improve the quotation system, it is suggested to add a module where you can see the inventory of the products, the stock in real time and generate alerts when the product is running out of stock, etc. Likewise, implement the sales module that allows generating invoices or sales receipts, delivery guides and have all these documents stored. Finally, add a module where you can view dashboards and generate reports with relevant information to help in the company's decision-making.

Application of the Business Process Management (BPM) Methodology in the Process of Incorporating Human Talent in the Retail Business Sector

Anyela Alanya-Ramos, Argenis Moreno-Rosales, Luis Acosta-Medina
Department of Business and Systems Engineering, Universidad Científica del Sur, Lima, Perú

***Abstract*—The lack of a well-defined onboarding process for new talent in a retail company specializing in beauty products and accessories for women has generated the need to undertake this research. The objective of which was to evaluate the positive impact that the implementation of business process management (BPM) could generate in this area, whose deficiencies lay in inadequate communication and the lack of appropriate digital tools. The study focused on three key dimensions to understand how this improvement could transform the process of integrating new talent. As a research method, an applied pre-experimental design was chosen, with a quantitative approach. Likewise, the survey was applied to collect data, using a questionnaire as a measurement instrument. As a result, it was observed that by following the characteristics and life cycle of the BPM methodological framework, it was necessary to implement digital actions and tools to optimize the process and generate positive impacts in its three dimensions. In addition, there was a 44% increase in the satisfaction and commitment of the participants in the process, a 47% increase in the positive perception about monitoring and tracking the entry of new talent, and a 38% increase in the perception about the distribution of tasks among the actors in the process. In conclusion, the application of the methodology has generated a notable improvement in the process, which has directly contributed to enriching the experience of new talents in the incorporation process of the retail.**

***Keywords*—BPM; human talent; incorporation process; process optimization; methodology**

I. Introduction

In competitive international business environments, effective human talent management is also considered vital to a company's success [1]. This requires the corresponding area to implement and optimize its processes, highlighting the importance of the onboarding process as fundamental to employee engagement and development [2], [3]. Poor execution of this process can significantly affect employee satisfaction, commitment, and job performance [4], [5].

According to a report published by Gallup, only 12% of employees consider their organizations' human talent onboarding process to be excellent, while the remaining 88% are not satisfied [6]. Furthermore, in a study by Click Boarding, it was found that 69% of human talent tend to stay up to three years in a company with an organized and structured Onboarding [7].

Based on the above, it has been noted that this is also the case with BESIFRAH, a retailer specializing in women's accessories, where its process for integrating new talent presented deficiencies, generating dysfunctions in its overall operation. These were identified using a quality tool called the Ishikawa diagram (Fig. 1).

The main problem lay in the lack of communication and coordination among those involved in the employee onboarding process. This resulted in communication primarily via email, with a disorganized backlog of messages and direct messages, which made it difficult to properly track new employees.

The poor integration of human talent into the retail company led to several negative effects, such as staff dissatisfaction, lower engagement and productivity, increased costs due to staff turnover, and damage to the retailer's reputation as an employer, making it difficult to attract qualified talent.

Therefore, BESIFRAH, currently undergoing constant growth, has seen the need to implement an efficient and optimized process to enhance the experience and ensure a successful and favorable transition for newcomers to the team.

Therefore, the main objective of the research was to detect deficiencies and implement improvements using the BPM process management methodology in the BESIFRAH human talent incorporation process. The BPM cycle model was adopted, which includes various stages, from the survey and documentation of the process, followed by the current design (As Is), improvement analysis, future design (To Be), to the implementation and continuous monitoring of the process [8].

BPM is a management system that seeks to improve organizational processes through the use of specialized information systems. It is composed of three elements: process, management, and improvement. Process involves modeling, management consists of managing execution, and improvement focuses on continuous adjustment and optimization [9]. Furthermore, a business process is a set of activities that transform inputs into customer-valued outcomes [10].

Adopting the BPM methodology is valued as a tool that facilitates the optimization of procedures, the elimination of redundancies, and the streamlining of operational flow, which subsequently helps retail companies become more efficient and competitive.

For the implementation of the proposal, the support of those involved in the onboarding process was required, as well as the evaluation of the feasibility of new technological solutions by the technology manager, if necessary. The onboarding integration process in a company involves gradually integrating new talent into the organization, adapting them to their roles and business environment, and promoting collaboration with teammates and other departments [11].

The process was divided into three dimensions to evaluate its improvement after the implementation of the BPM methodology. The first dimension considered is the satisfaction and commitment of the process participants, which was defined as the perception and attitude of the individuals involved in the process and the degree to which they are satisfied with their experience and the results obtained [12].

Secondly, the supervision and monitoring of new talent was considered, defined as a set of actions implemented by organizations to efficiently manage the activities of each talent in the work environment [13].

Thirdly, the assignment of tasks to process participants was examined, which comprise the responsibilities and functions directly assigned to meet the objectives and purposes of the process [14].

Finally, two flowcharts were developed that provide a visual representation of the process. The first diagram (Fig. 3) illustrates the previous state of the process, while the second diagram (Fig. 4) shows the current version of the process after implementing the BPM methodology and its features. In relation to Fig. 4, the tasks highlighted in orange indicate modifications to the execution method or simply represent automated tasks that were implemented. An example of this is the "Notify the responsible person to generate a contract" task, which is a service task executed automatically through an automation programmed on a dashboard created on Monday.com. This automation is activated once the recruiter completes the task of updating the employee's data on Monday.com and changes the process status to "BUK" (BUK is a payroll system).

II. Related Work

To date, no previous studies have been identified that specifically focus on improving the onboarding process for new talent in a retail company through the application of BPM methodology. However, there are similar studies that address how to improve the onboarding process or the influence of BPM implemented in a process.

A relevant research in the international arena is the study by Abu & Chin Joo [15] whose main objective was to validate the possibility of improving the challenges associated with poor onboarding in organizations by leveraging technology. The problem usually manifested itself in high levels of dissatisfaction among new employees and a lack of commitment. To achieve their purpose, they conducted a thorough review of the relevant literature, with the purpose of outlining a general onboarding process and identifying the deficiencies present in it. The findings revealed that the implementation of the Technology Acceptance Model (TAM) could lead to significant improvements in the effectiveness of the digital onboarding process by organizations.

He also highlighted the research by Elahi and Bilal [16] which focused on improving the parent-teacher conference process in private schools in Pakistan. The BPM methodology (BPM Lifecycle) was used along with quality tools such as the RACI matrix to understand and document the process. The results showed a reduction in parental complaints and an increase in parent-teacher engagement, reflecting improved communication and collaboration in the educational context.

Aguirre's article [17] focused on offering a methodological approach to promote innovation and digitalization of business processes, with special attention to a specific case of a Colombian company in the electricity sector. Its main objective was to provide a methodological framework applicable to organizations seeking to improve their processes by implementing digital technologies and optimizing their operations.

He used a methodology that included several key phases, including strategic coordination, process evaluation, innovation, and digital transformation.

During each phase, tools and techniques related to the BPM (Business Process Management) approach and design thinking are used to analyze, design, and implement improvements to existing processes. The results obtained from the application of this methodology were significant. A notable improvement in customer experience and optimization of the inspector scheduling process were observed, resulting in greater efficiency and effectiveness in the management of inspections and controls. One of the study's most notable achievements was the reduction in paper consumption, indicating a successful transition toward more sustainable and environmentally friendly practices. This reduction can be attributed to the implementation of digital processes and the use of advanced technologies instead of traditional paper-based methods. In conclusion, the study provided practical guidance for organizations seeking to improve their operational efficiency, service quality, and adaptability to an increasingly digital and competitive business environment.

Furthermore, the article by Granda and Bermeo [18] represents applied research that seeks to generate knowledge derived from basic research. To collect data for the case study, techniques such as observation sheets and surveys were used. The proposed methodological model was based on the following stages: Adopt, Align, Analyze, Design, Automate, Implement, and Measure, with the aim of achieving an effective digital transformation and process automation through optimization. It was recommended that this methodology be replicated in other organizations, adapting it to their needs and using BPMS tools. As a result, it was possible to eliminate redundant processes, reduce duplicated efforts, and transform processes. The implementation of the methodology in a case study at UNEMI significantly reduced reprocessing related to communication, information requests, and manual records with errors.

In the same context, Cahuana's PhD thesis [19] developed an initiative focused on identifying and improving essential processes in production management. Through a detailed review carried out using the BPM tool, the processes were effectively mapped, which allowed for a transparent understanding of the system. Subsequently, solutions were implemented through Lean Six Sigma and BPM with the aim of optimizing the processes, identifying critical areas. The results reflected significant optimization in several areas, including the reduction of excess and downtime, as well as the increase in the quality of the service offered by the company.

Similarly, there is the article by Quiroz and Romero [20] whose objective was to restructure the commercial operation of micro and small businesses by applying the BPM methodology together with Digital Transformation tools in order to increase sales revenue. Prior to the implementation of these measures, sales were at 40.36% due to inefficient administration of procedures. After implementing the model through an execution method, sales increased to 69.55%, which translated into additional profit.

III. Materials and Methods

The research had a pre-experimental design, since the recommendation of Hernández and Baptista [21] was followed to carry out Post Test measurements after applying a stimulus on the dependent variable which was adequate for the problem due to the causal influence that the BPM methodology exerted on the process of incorporating new talents in the retail company BESIFRAH.

It was classified as applied research, since it focuses on solving everyday problems using previously validated scientific theories and since BPM is based on proven theories and practices in process management that seek to optimize the situation to eliminate deficiencies, as Vargas points out [22].

The approach adopted is quantitative, since, according to Babativa [23], it involves studying society through observations and measurements, using tools to analyze and explain various factors influencing different events. This is valuable for obtaining figures and statistical analysis that provide an objective and measurable view of the effect of the BPM method on the human talent incorporation process.

The study population includes all participants in the onboarding process. Ten employees from human resources, sales, information technology, and department heads participated. A sample is not required since the research involves all of the aforementioned.

Data were collected through pre-test and post-test surveys of 15 questions based on a Likert scale, addressed to the 10 participants in the process. Prior to this, these questions were submitted to three experts for validation for approval. Furthermore, to evaluate the reliability of the data, Cronbach's alpha coefficient was applied, a formula commonly used in instruments such as the Likert scale [24]. According to Turcios' research [25], the Student's t-test emerges as a valuable parametric tool in studies that address small samples and analyze a single variable. In this study, this test was also used to determine if there were significant differences in means between the results of the pre- and post-tests.

To carry out the project and facilitate its analysis, the Business Process Management (BPM) methodology was adopted, focusing specifically on the model cycle of said methodology. Various tools were used to optimize the process and ensure its quality. First, the Ishikawa diagram (Fig. 1) allowed us to identify the main deficiencies and opportunities for improvement. In addition, the RACI (Responsible, Accountable, Consulted, Informed) matrix was applied, a tool that allows us to clearly define the roles and responsibilities of each actor in the process, ensuring efficient execution of tasks and better coordination among those involved. Bizagi was also used as the BPMS platform, where the process flow was modeled in its current state (As-Is) and its optimized version (To-Be), represented in Fig. 3 and Fig. 4, respectively. Dashboards were implemented on Monday.com to manage and monitor the onboarding process for new employees. Fig. 2 shows the Administrative and Sales Staff Requests view, which allows you to track the onboarding process for new employees. Additionally, a specific view was created for Supervisors, designed to track the onboarding of sales staff.

Documents such as the process sheet and the indicators sheet were generated to monitor the process, all with the primary objective of improving and optimizing its performance. To complement the study's analysis, SPSS (Statistical Package for the Social Sciences) version 29.0.2, a widely used statistical tool for data processing and analysis, was used in its free version.

Finally, Monday.com facilitated the organization, assignment, and monitoring of tasks, enabling better process traceability and effective integration of proposed improvements.

The integration of these tools enabled a comprehensive analysis of the process, identifying critical points and proposing improvements for optimization.

Fig. 1. Ishikawa diagram of the BESIFRAH incorporation process.

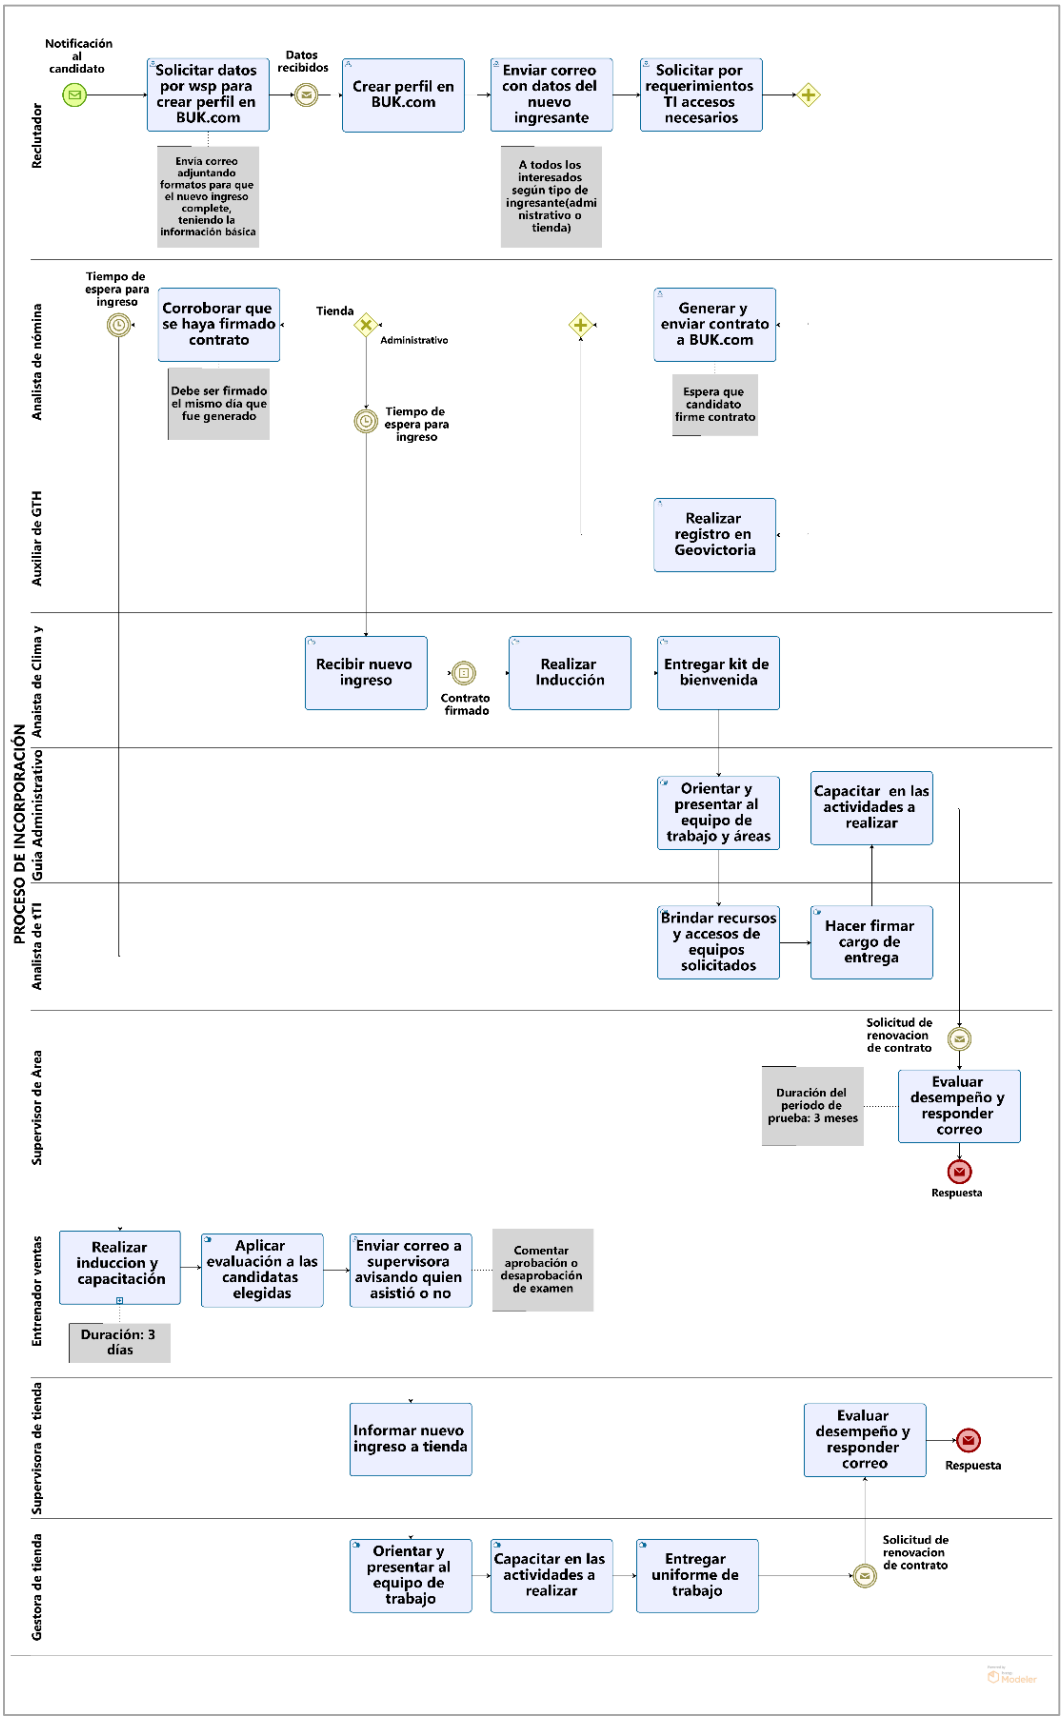

Fig. 3. BESIFRAH's AS IS talent incorporation process.

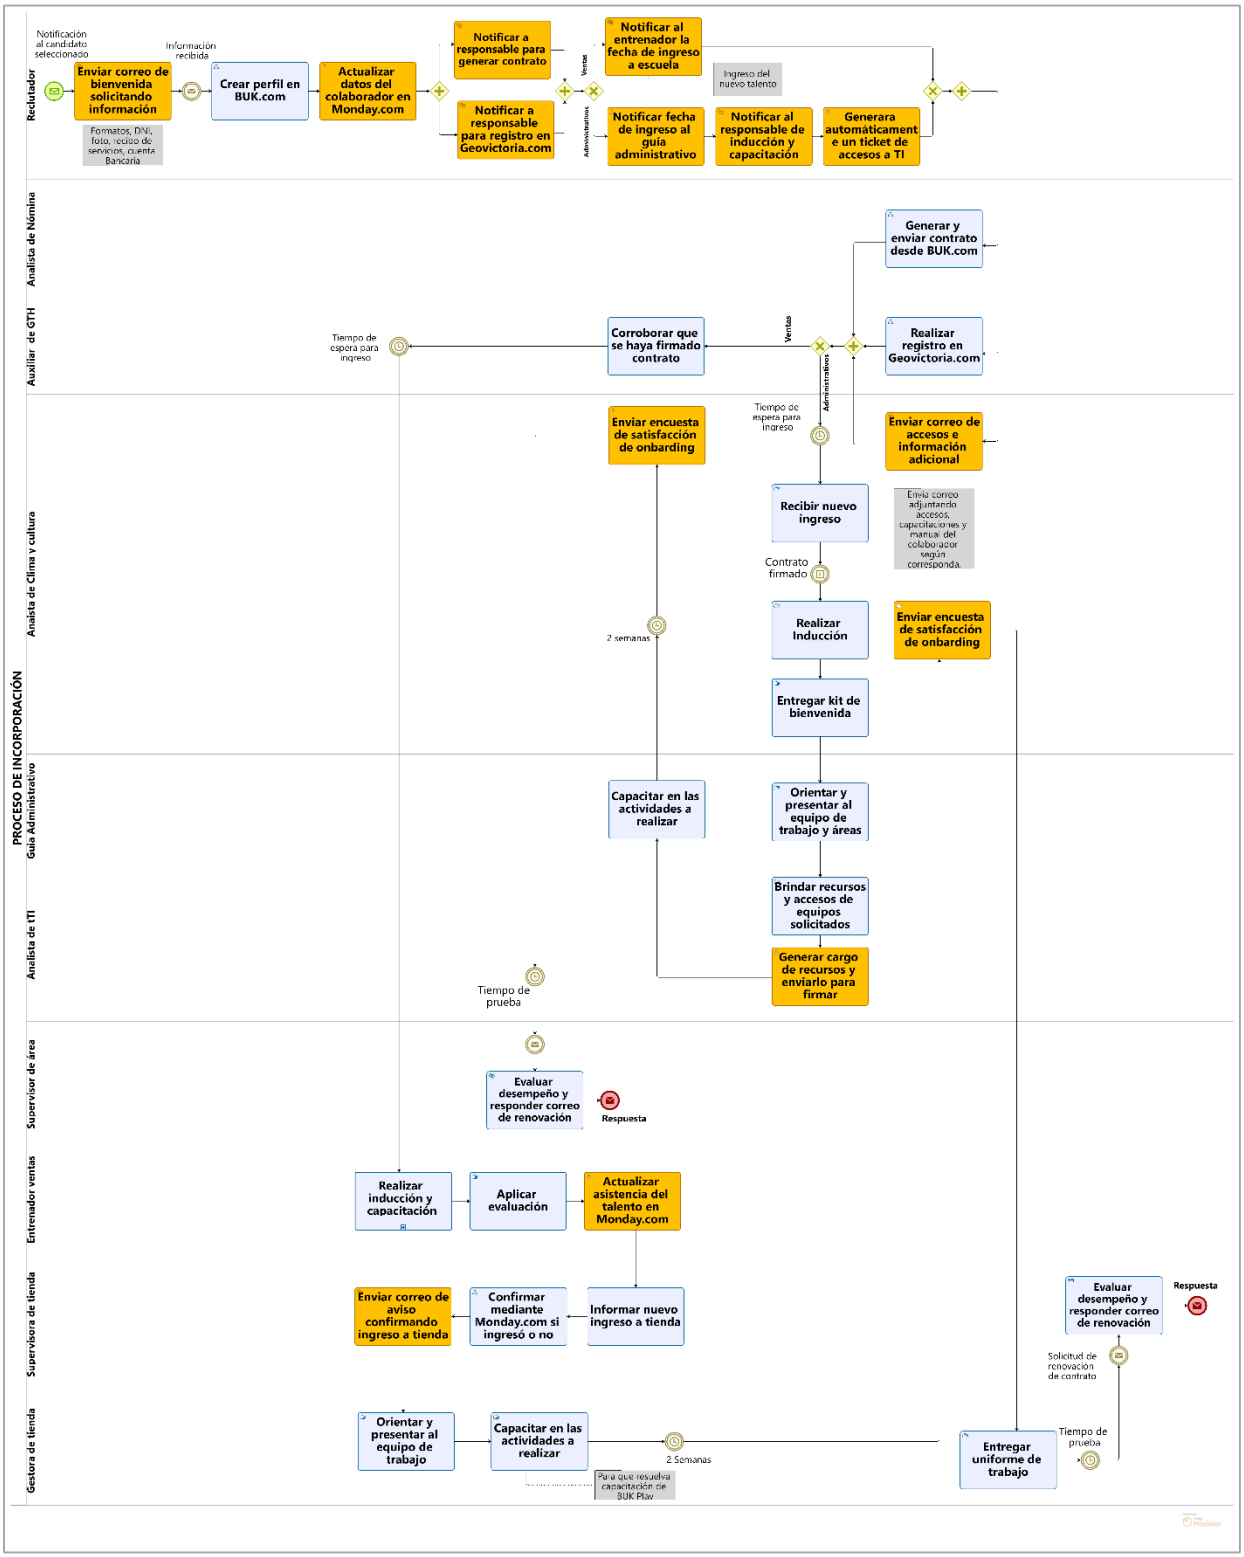

Fig. 4. Process of incorporating TO BE talent from BESIFRAH.

IV. RESULTS

The results of the research are presented below, structured into three key dimensions of the talent acquisition process. Table I presents three indicators proposed to assess improvement in the satisfaction and engagement dimension. It is noteworthy that the "Level of Satisfaction" indicator obtained the best result, with a 53% improvement, while the "Level of Participation" indicator experienced a 34% improvement.

TABLE I. RESULTS OF THE APPLICATION OF THE BPM METHODOLOGY ON THE SATISFACTION AND COMMITMENT EXHIBITED BY THOSE INVOLVED IN THE PROCESS

Indicator	Before Improvement	After the improvement	Improvement (%)
Level of Satisfaction	47%	100%	+53
	Half	Very High	N/A
Level of Commitment	58%	98%	+40
	Half	Very High	N/A
Level of communication and coordination	50%	98%	+48
	Average	Very High	N/A
Level of Participation	56%	90%	+34
	Half	Very High	N/A
Average	**52%**	**96%**	**+44**
	Half	***Very High***	***N/A***

TABLE II. RESULT OF THE APPLICATION OF THE BPM METHODOLOGY IN THE SUPERVISION AND MONITORING CARRIED OUT BY THOSE INVOLVED IN THE PROCESS

Indicator	Before Improvement	After the improvement	Improvement (%)
Level of clarity about the information the entry of new talent	48%	98%	+50
	Half	Very High	N/A
Accessibility level for monitoring talent progress	50%	94%	+44
	Half	Very High	N/A
Level of accessibility for obtaining results	38%	90%	+52
	Low	Very High	N/A
Accessibility level to assess the social and cultural integration of talent	46%	86%	+40
	Half	Very High	N/A
Accessibility level to measure indicators	42%	94%	+52
	Half	Very High	N/A
Accessibility level for managing and viewing surveys	46%	90%	+44
	Half	Very High	N/A
Accessibility level for post-incorporation monitoring	42%	90%	+48
	Half	Very High	N/A
Average	**44%**	**91%**	**+47**
	Half	**Very High**	**N/A**

TABLE III. RESULT OF APPLYING THE BPM METHODOLOGY IN THE ASSIGNMENT OF ACTIVITIES TO THOSE INVOLVED IN THE PROCESS

Indicator	Before Improvement	After the improvement	Improvement (%)
Level of perception about the assignment of tasks according to the role	60%	98%	+38
	Half	Very High	
Level of perception about the assignment of tasks according to deadlines as reasonable	50%	92%	+42
	Half	Very High	
Level of Completion of tasks on time	60%	92%	+32
	Half	Very High	
Average	**56%**	**94%**	**+38**
	Half	**Very High**	**N/A**

Table II also presents seven indicators proposed for assessing improvements in the supervision and monitoring dimension. It is noteworthy that the "Level of accessibility for achieving results" and "Level of accessibility for measuring indicators" indicators showed a 52% improvement, while the "Level of accessibility for post-incorporation monitoring" indicator registered a 48% improvement.

Finally, Table III presents three indicators proposed to assess improvement in the activity allocation dimension. It is noteworthy that the "Level of perception regarding task allocation in accordance with reasonable and achievable deadlines" indicator showed a 42% improvement, while the "Level of on-time task completion" indicator registered a 32% improvement.

Table IV presents the details of the improvement actions implemented in each dimension, including the modification of activities, the use of new tools and technologies, as well as the updated process procedure.

As part of the proposed solution to optimize the onboarding process, a specific improvement was implemented in resource management. Fig. 5 shows a dashboard on Monday.com designed to record and monitor the delivery of assets, such as IT equipment, ensuring efficient management and accurate traceability of the resources assigned to each employee.

TABLE IV. IMPROVEMENT ACTIONS CARRIED OUT IN THE PROCESS

Dimensions	Improvement action
Satisfaction and commitment exhibited by the process participants	Two email templates were created on Beefree.com for the welcome and login emails, with a URL that makes it easy to automatically load them from Gmail, saving time. A form was implemented on Monday.com to centralize talent requests, storing them in a dashboard. This made it easier to update new talent information for viewing, as well as configure automations that send emails and notifications when status changes. An additional dashboard was created on Monday.com to record and maintain evidence and formality of the delivery of resources to new talent.
Supervision and monitoring carried out by those involved in the process	The dashboards on Monday.com were shared with everyone involved in the process so they could access up-to-date information on the onboarding of new talent. A dashboard was developed within the dashboard to visualize key process indicators. Additionally, training sessions were scheduled on the BUK Play platform and will be automatically assigned with each new talent recruit.
Assignment of activities to those involved in the process	A process characterization sheet and standard operating process (SOP) document were developed to provide stakeholders with a detailed understanding of the activities being performed. In addition, a RACI matrix was created and distributed to clarify the responsibilities of each participant. An instruction manual was also provided for the proper use of the dashboards on the Monday.com platform.

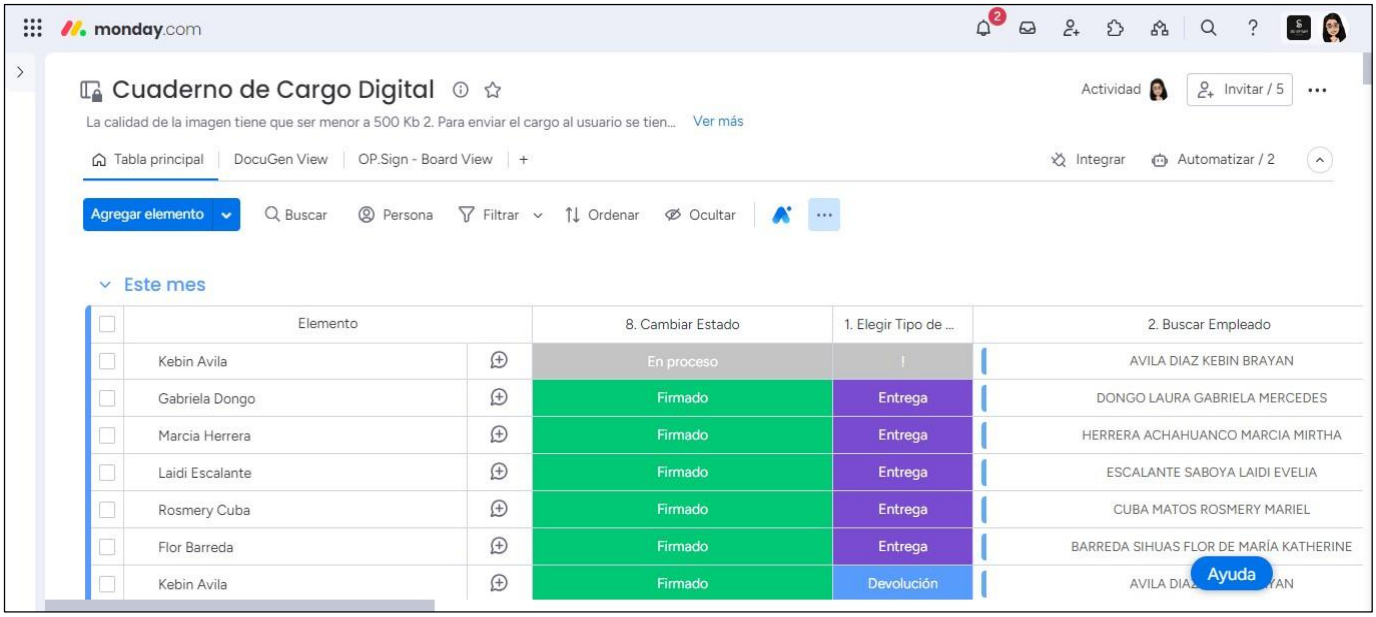

Fig. 5. Board to record resource delivery charge (Computer equipment).

V. DISCUSSION

The main objectives of applying the BPM methodology were to positively impact three key dimensions of the new talent onboarding process. The findings indicate that the implementation of this methodology has indeed generated significant improvements in the satisfaction and commitment perceived by process participants. These results are consistent with those of a previous study by Granda and Bermeo [18], which applied a similar BPM-based methodological proposal. In that study, a 10% optimization of the processes was achieved by eliminating activities that did not add value.

This convergence of results highlights the effectiveness of the BPM methodology in improving organizational processes, especially in contexts of human talent recruitment.

The positive results regarding the second dimension, focused on monitoring and follow-up by process participants, underscore the effectiveness of business process management (BPM). The implementation of BPM stages such as the optimization stage revealed the need to integrate digital tools, such as the successful management dashboard on the Monday.com platform. This dashboard allows monitoring and visualizing the status of each new entry, along with relevant indicators. These findings are supported by Aguirre's study [17], which also showed a digital transformation in the certification service delivery process. The introduction of a portal made it easier to view the status and location of each inspector after the client submitted a new service request.

The findings also support the third hypothesis, demonstrating that implementing the BPM method improves the distribution of activities during the onboarding process for new employees. This was achieved by diagramming the process flow according to the BPMN 2.0 standard, framed within BPM management, with the aim of developing a standardized procedure that clearly defines activities, tasks, and roles.

Likewise, a previous study by Elahi and Bilal [16] supports the approved hypothesis since they obtained a decrease in complaints, greater participation of parents and a clear definition of responsibilities for the process of meetings between teachers and parents, avoiding over efforts and facilitating collaboration. For the improvement, they used the BPM life cycle together with quality tools, such as the Responsibility Assignment Matrix (RAM), the Suppliers, Inputs, Process, Outputs and Customers (SIPOC) model and the Critical Quality Characteristics (CTQ) trees, with the objective of standardizing the process. We agree that both studies, by following the BPM framework, share objectives and obtain positive results.

The positive results regarding the second dimension, focused on monitoring and follow-up by process participants, underscore the effectiveness of business process management (BPM). The implementation of BPM stages such as the optimization stage revealed the need to integrate digital tools, such as the successful management dashboard on the Monday.com platform. This dashboard allows monitoring and visualizing the status of each new entry, along with relevant indicators. These findings are supported by Aguirre's study [17], which also showed a digital transformation in the certification service delivery process. The introduction of a portal made it easier to view the status and location of each inspector after the client submitted a new service request.

Ultimately, it is crucial to highlight a significant limitation related to the lack of standardization in a specific process, specifically in the area of recruitment and selection. In this process, the lack of implementation of digital tools that could streamline operations was evident, resulting in a delay in obtaining relevant results. The need to intervene and contribute to the process was imperative to ensure efficiency in the subsequent onboarding of new employees.

This finding underscores the importance of considering standardization and the incorporation of digital technologies into various organizational processes to optimize human resource management and ensure more effective results.

VI. Conclusion

In conclusion, the implementation of the BPM method has resulted in a significant improvement in the company's employee onboarding process.

This improvement has resulted in the optimization of activities and automation of manual tasks, and the establishment of indicators to effectively monitor the process.

Likewise, a significant 44% increase in satisfaction and engagement was recorded among participants in the new employee onboarding process. This progress is attributed to improved communication between process stakeholders, a reduction in manual tasks for each individual, and the adoption of digital tools that facilitate better control and organization of information. Likewise, a 47% improvement was achieved in the monitoring and follow-up performed by participants in the onboarding process. This was achieved through the development of a customized dashboard on the Monday.com platform, tailored to the individual needs of each participant, to provide comprehensive visibility and effective communication about the onboarding phase of a new employee.

Additionally, the allocation of activities among participants in the onboarding process has been improved by 38% through the development of a detailed procedure that clearly defines roles and responsibilities at each stage of the process. Indicators have also been established to measure and identify areas for improvement, allowing for adjustments to task allocation as needed.

Finally, while the implementation of the proposed solution has generated significant improvements in the new talent onboarding process, there are some limitations to consider. Among them is the dependence on the Monday.com platform, which could hinder integration with other systems used in the organization. Furthermore, the cost of licensing is a factor to evaluate, especially if the solution needs to be scaled to a larger number of users. It is also important to consider the adaptation period required for employees to become familiar with the new tools and methodologies. Future research could focus on analyzing the cost-benefit ratio of the solution and its long-term impact on operational efficiency.

Security Onion as a Network Auditing Tool at the San Cristóbal de Huamanga National University

Kimberlly Nena Barraza Tudela[1], Hubner Janampa Patilla[2]
San Cristóbal De Huamanga National University, Ayacucho, Perú[1]
Information Technology Office, San Cristóbal De Huamanga National University, Ayacucho, Perú[2]

***Abstract*—In a context of evolving cyber threats, the San Cristobal de Huamanga National University (UNSCH) faces the need to improve its network security infrastructure. This study implements Security Onion as a network auditing tool at this institution with the objective of evaluating its effectiveness in three key areas: security monitoring, log management, and intrusion detection. The study employs an applied, descriptive, and experimental approach to demonstrate that Security Onion is a robust solution for incident detection. It enables comprehensive analysis of network logs and early identification of suspicious activities, providing a holistic view of the network. Based on the results, the study suggests best practices for protecting institutional information and the network, and contributes to understanding Security Onion's capabilities in similar network infrastructures. Furthermore, it provides a replicable model for other institutions.**

***Keywords*—Network security; network auditing; Security Onion; IDS; CIS Controls**

I. Introduction

During the course of 2023, a significant increase in cyber threats was recorded globally, with organizations across all sectors facing unprecedented challenges in protecting their digital assets [25]. According to the IBM Cost of a Data Breach Report 2024, the average cost of a data breach reached an all-time high of $4.88 million, underscoring the financial and operational impact of these incidents [36]. Although ransomware incidents decreased, other threats, such as the misuse of valid credentials and data theft, rose considerably, highlighting the evolving nature of cyber risks [35]. The exploitation of vulnerabilities in web applications due to poor security configurations and the spread of malicious information-stealing programs (infostealers) also reflect a concerning trend in the exploitation of sensitive data [9].

This threat landscape has not spared Latin America, a region increasingly targeted by cybercriminals due to its growing digitalization and limited investment in cybersecurity infrastructure. It is estimated that 27% of organizations in the region fell victim to multipurpose malware in 2023, with prevalent threats such as FakeUpdates and Qbot [53]. Additionally, trojans and phishing attacks have tripled compared to previous years, further exacerbating the region's cybersecurity challenges [55]. Peru, in particular, has faced a surge in cyberattacks targeting both citizens and institutions, exposing confidential information and undermining trust in digital systems [24] [56].

Educational institutions, including universities, have become prime targets due to their open network environments, vast amounts of sensitive data, and often limited cybersecurity resources. San Cristóbal de Huamanga National University (UNSCH) is no exception. Although the university campus has not suffered ransomware attacks, its administrative headquarters fell victim to such an incident in 2022, affecting critical systems like SIGA and SIAF and causing significant disruptions to administrative processes. This event underscored the urgent need to strengthen the institution's cybersecurity posture through proactive measures, including advanced threat detection and response capabilities.

In this context, network auditing emerges as a fundamental mechanism to assess and enhance the security of technological infrastructure. Security Onion, an open-source platform, offers a comprehensive solution for this purpose, combining advanced security monitoring, log management [47], and intrusion detection systems. Its implementation enables real-time monitoring of security events, facilitating swift responses to anomalies and potential attacks [26] [33] [43]. Moreover, its scalability and cost-effectiveness make it an ideal choice for institutions like UNSCH, which often operate with limited budgets [28] [32].

The objective of this study is to implement Security Onion as a network auditing tool at UNSCH, evaluating its effectiveness in threat detection and its potential to improve the institution's cybersecurity framework. By doing so, this research aims not only to strengthen UNSCH's resilience against cyber threats but also to provide a replicable model for other educational institutions facing similar challenges. In an era where cyberattacks are becoming increasingly sophisticated, proactive measures like network auditing are essential to safeguarding sensitive data and ensuring operational continuity.

II. Theoretical Basics

A. Security Onion

Security Onion is an intrusion detection-oriented platform based on the Ubuntu distribution that comprises a multitude of IDSs, including host-based (HIDS) and network-based (NIDS) variants [17] [30] [48], in addition to other tools for logging, management, and visualization of data [21] [22] [23] [27] [41] [51] [57] [59] [65] [68] [70]. The configuration of the system can be implemented on a master server with multiple nodes or as a standalone or hybrid deployment, thereby demonstrating its remarkable adaptability.

The primary deployment types are categorised as follows: Import, Evaluation, Standalone, and Distributed [61], as shown in Table I and illustrated in Fig. 1 and Fig. 2.

TABLE I. SECURITY ONION DEPLOYMENT TYPES AND THEIR MINIMUM REQUIREMENTS

Type of deployment	Minimum requirements			
	N° of cores	*RAM*	*Storage (SSD preferred)*	*N° of network interfaces*
Import	2	4GB	50GB	1
Evaluation	4	8GB	200GB	2
Independent	4	16GB	200GB	2
Distributed*	2-8	4-16GB	12-200GB	1-2

*The minimum requirements of the distributed deployment type vary according to the subtype, since there is a master node and the others are remote nodes with different functionality.

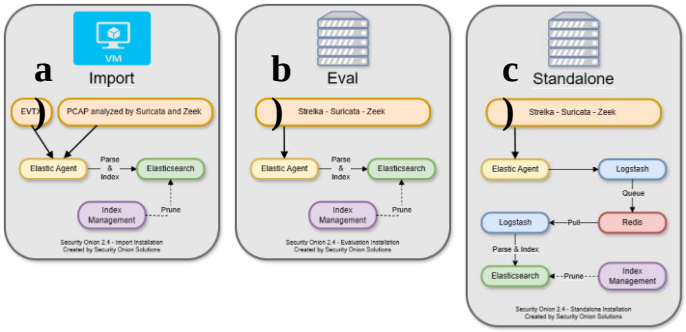

Fig. 1. Security Onion deployment types (a) Import, (b) Evaluation, (c) Standalone.

B. Network Auditing

Auditing is not merely the deployment of a multitude of hacking tools with the objective of breaching network security. The term "audit" itself denotes a process of collecting, examining, and evaluating network data to assess its status [49] [50]. This enables organizations to determine the effectiveness of their network monitoring and management operations, particularly in terms of compliance with internal and external standards.

1) Computer network: It is defined as a set of wired and wireless communication links through which various hardware and software components exchange data and information [3] [20] [62].

2) Network security: Network security: The field of network security encompasses the design of protocols and the establishment of best practices with the objective of safeguarding data within computer networks. The overarching objective is to establish a secure environment that safeguards the network, its components, stored and transmitted data, and its users [4] [38]. It is imperative to acknowledge that security should be regarded as a continuous process, rather than a standalone solution [37] [60]. Security can be conceptualized in two distinct states: physical and theoretical. In the physical domain, security is achieved through the implementation of barriers, the designation of secure areas, and the resistance of intruders. Conversely, the theoretical state of security, also referred to as security through obscurity, is predicated on the fallacious assumption that secrecy can provide absolute security. This approach is predicated on the assumption that, as long as an object remains unknown to those outside a core group, it is inherently secure [35]. However, this perspective is often regarded as a flawed philosophy.

a) Network security attacks: A campus network, such as that of the UNSCH, is vulnerable to a wide range of network attacks. Chakraborty et al. (2020) define network security attacks as illicit activities perpetrated by unauthorized actors against private, corporate, or governmental computing assets with the goal of destroying, modifying, or stealing sensitive data [8]. To provide a more illustrative example, please refer to Table II, which presents the types of attacks and some respective examples.

b) Malware: This software is designed to disrupt the operation of computers, collect sensitive information, and gain access to private computer systems [18]. It is a general term used to refer to a variety of forms of hostile, intrusive, or annoying software that spreads in various ways to create havoc and steal sensitive information.

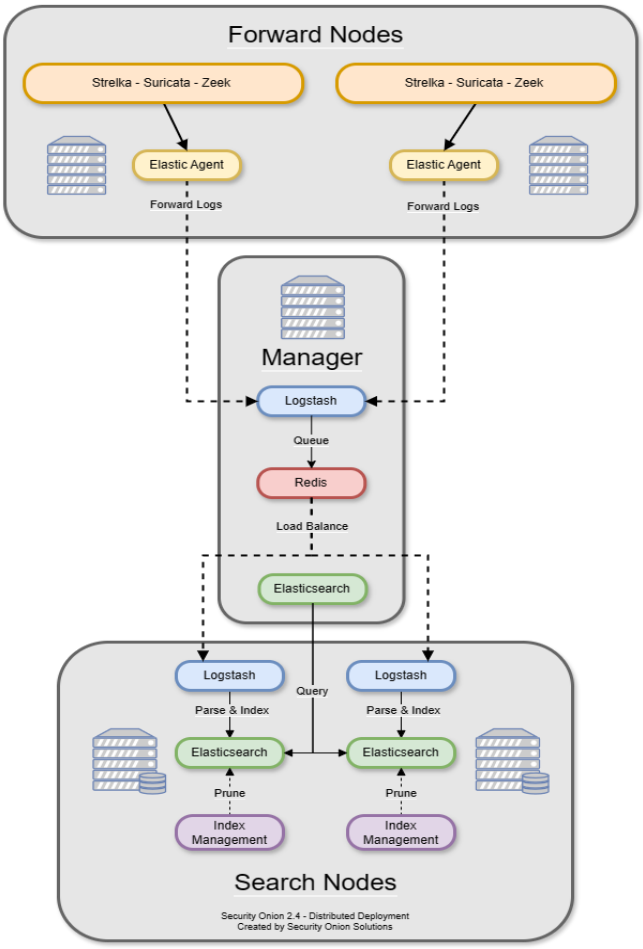

Fig. 2. Distributed deployment type.

TABLE II. CLASSIFICATION OF NETWORK SECURITY ATTACKS

Types of attack	Description	Examples
Passive attack	The primary objective of such attacks is to surreptitiously procure sensitive information, often with the aid of sophisticated malware. These attacks are challenging to detect and therefore pose a significant challenge to network protection [39].	Traffic analysis. Monitoring. Spying.
Active attack	These systems are engineered to alert users to potential security breaches. Consequently, the victim is able to disrupt communication with the other party [67].	Modification. Wormhole attack. Fabrication. Impersonation. Denial of service. Sinkhole (service attack). Sibyl.
Advanced attack	This is defined as an attack in which an unauthorized user gains access to a network and remains on it for an extended period without being detected. These incursions pose a heightened risk to corporate entities, as external actors gain persistent access to their confidential information [58].	Black hole attack. Rushing attack. Replay attack. Byzantine attack. Location disclosure attack. Man-in-the-middle attack (Man-in-the-middle attack).

III. METHODOLOGY

A. Type, Level and Design of the Research

This research is classified as applied, given its objective to generate new knowledge applicable to addressing practical problems [52]. It builds on previous theoretical contributions and employs appropriate methodologies to achieve the proposed objectives [5] [46]. The research is descriptive in nature, aiming to provide an accurate description of the implementation and results obtained [6] [45] by Security Onion. Regarding the research design, a non-experimental and cross-sectional approach was selected. The cross-sectional design, in contrast to experimental research, permits the observation of behaviors or variables of interest in a natural context and at a specific time [14] [31] [44]. Consequently, the research can be characterized as cross-sectional, non-experimental, and descriptive.

B. CIS Controls

The Center for Internet Security, Inc. (CIS) defines CIS Controls as a set of best practices designed to protect organisations from the most common attacks and real threats [7]. As the name suggests, these controls are designed to identify the most critical points that require protection in order to prevent the most significant attacks. The latest version, CIS Controls v8.1, comprises 18 controls and 153 safeguards, which are distributed across three implementation groups (IGs). These IG groups are tailored to the cybersecurity maturity level of organisations, as illustrated in Fig. 3 and Table III.

In this research project, network auditing has been aligned with the CIS Controls version 8 due to their practical and accessible approach. Unlike standards such as ISO 27001 and COBIT, which require a more exhaustive and complex framework, the CIS Controls provide precise guidance based on real-world threats and a detailed analysis of security incidents. For example, CIS Control 13: Network Monitoring and Defense is critical for UNSCH, as it enables the detection and response to malicious activities in real time. Security Onion, with its advanced network traffic monitoring and intrusion detection capabilities, aligns perfectly with this control, facilitating the identification of anomalies and the mitigation of threats before they escalate.

Similarly, CIS Control 07: Continuous Vulnerability Management plays a vital role in protecting the university's technological infrastructure. This control emphasizes the importance of proactively identifying, prioritizing, and remediating vulnerabilities.

Furthermore, the CIS Controls are organized into three implementation groups (IGs), enabling organizations to select the maturity level most appropriate for their context. In the case of UNSCH, the IG2 profile was determined to be the most suitable, given that the university has specialized IT personnel but faces challenges in protecting sensitive information and managing risks associated with operational disruptions.

TABLE III. IMPLEMENTATION GROUPS (IG'S)

Denomination	Characteristics
IG1 (Small to medium-sized organizations)	Organizations with limited IT and cybersecurity expertise. Their primary concern is maintaining business operations, as they have low tolerance for downtime. The sensitivity of the information they protect is low, primarily including employee data and financial information.
IG2 (Medium to large organizations)	They employ specialized IT and cybersecurity personnel. They store sensitive customer and business process information and can withstand brief service interruptions. Their main concern is the loss of public trust in the event of a breach.
IG3 (Organizations with high cybersecurity maturity)	They employ security experts specializing in areas such as risk management, penetration testing, and application security. Their assets contain highly sensitive information subject to regulatory oversight. The materialization of attacks can cause significant harm to public well-being.

Fig. 3. CIS Controls version 8.1.

C. Security Tool

In the domain of network monitoring and intrusion detection, there exists a plethora of widely utilised tools, each exhibiting distinct strengths and limitations. The ensuing discourse aims to provide a comparative analysis of Suricata, Snort, Zeek (Bro IDS) and Security Onion, with the objective of substantiating the selection of Security Onion for network auditing at the San Cristóbal de Huamanga National University.

1) Suricata: Suricata is a high-performance intrusion detection and prevention system (IDS/IPS) known for its ability to analyze network traffic in real time using signature-based rules and anomaly detection. It is particularly efficient in handling high volumes of traffic and supports modern protocols.

a) Advantages:

- High performance in environments with heavy traffic.
- Support for deep packet inspection (DPI).
- Compatibility with Snort rules, facilitating migration.

b) Disadvantages:

- Requires manual configuration and rule management.
- Lacks an integrated graphical interface, which can complicate its use for non-specialized teams.

2) Snort: Snort is one of the oldest and most widely used intrusion detection systems. Rule-based and highly customizable, it is effective at detecting known threats. However, its traditional approach makes it less suitable for detecting advanced or unknown threats.

a) Advantages:

- Large user community and extensive availability of rules.
- Lightweight and easy to deploy in small environments.

b) Disadvantages:

- Limited in detecting advanced threats (e.g., zero-day attacks).
- Requires manual rule management and configuration.

3) Zeek (Bro IDS): Zeek (formerly known as Bro IDS) is a network traffic analysis tool focused on generating detailed logs and forensic analysis. Unlike Suricata and Snort, Zeek does not rely on signature-based rules but instead uses customizable scripts to analyze network behavior.

a) Advantages:

- Generates detailed, context-rich logs, ideal for forensic analysis.
- Highly customizable through scripts.

b) Disadvantages:

- Requires a high level of expertise for configuration and use.
- Not a real-time detection system on its own but rather a tool for post-incident analysis.

4) Security onion: Security Onion is a comprehensive security monitoring platform that integrates multiple open-source tools, including Suricata, Zeek, Wazuh, and Elastic Stack.

a) Advantages:

- Integration of multiple tools into a single platform.
- User-friendly and centralized graphical interface.
- Advanced event correlation and data visualization capabilities.
- Scalable and adaptable to environments of varying sizes.

b) Disadvantages:

- Requires moderate hardware resources due to its comprehensive nature.
- Initial learning curve for advanced configurations.

The selection of Security Onion for network auditing at UNSCH is based on its ability to integrate the functionalities of tools like Suricata, Zeek, and Wazuh into a single platform, simplifying management and reducing operational complexity. Unlike Suricata and Snort, which require manual configuration and rule management, Security Onion provides a centralized graphical interface that facilitates the monitoring and analysis

of security events, even for teams with limited cybersecurity expertise.

Furthermore, Security Onion offers advanced event correlation and data visualization capabilities through Elastic Stack, enabling faster and more effective incident response [12]. This is particularly important for UNSCH, where early threat detection and the protection of sensitive information are key priorities. While Zeek provides detailed forensic analysis, its complexity and lack of real-time detection capabilities make it less suitable for a comprehensive implementation in an institution with limited resources.

IV. Results

A. Description of the Existing Network on the University Campus

1) Network topology: The local area network (LAN) of the university campus employs a structured cabling configuration with a star topology, wherein the main node is the OTI office (formerly CTI) and the remote nodes are distributed among the faculties and laboratories of the different schools [11], as illustrated in Fig. 4.

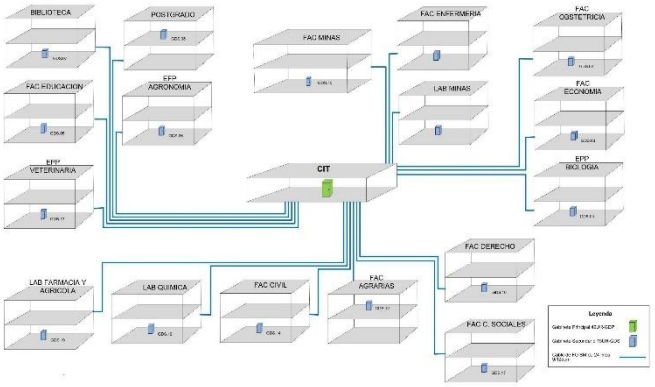

Fig. 4. Network topology on the university campus.

2) Perimeter security system: The perimeter security system is composed of a Checkpoint firewall that is integrated into the network through the connection to the Cisco core switch [11] and to the Internet provider's equipment.

B. Audit Methodology with Security Onion

1) Security onion installation and configuration: Security Onion installation is divided into two main stages [69]. The initial stage covers the preliminary steps of installing from a bootable USB stick. These steps adhere to the standard procedures outlined in the official Security Onion documentation. Once the initial stage of the installation is complete, the system will prompt for a reboot. It is imperative to remove the bootable USB memory stick before rebooting the computer to avoid restarting the installation process from the removable media. Security Onion will be configured according to the needs of each organization or available resources.

It is imperative to note that the deployment of Security Onion necessitates the presence of two network interfaces on the equipment. The primary interface facilitates access to the web console, whereas the secondary interface is responsible for traffic collection from the SPAN port of the switch, as illustrated in Fig. 5. Furthermore, it is imperative to emphasise that an IP address or a network segment from which the system can be accessed must be authorised for access to the web console, see Fig. 6.

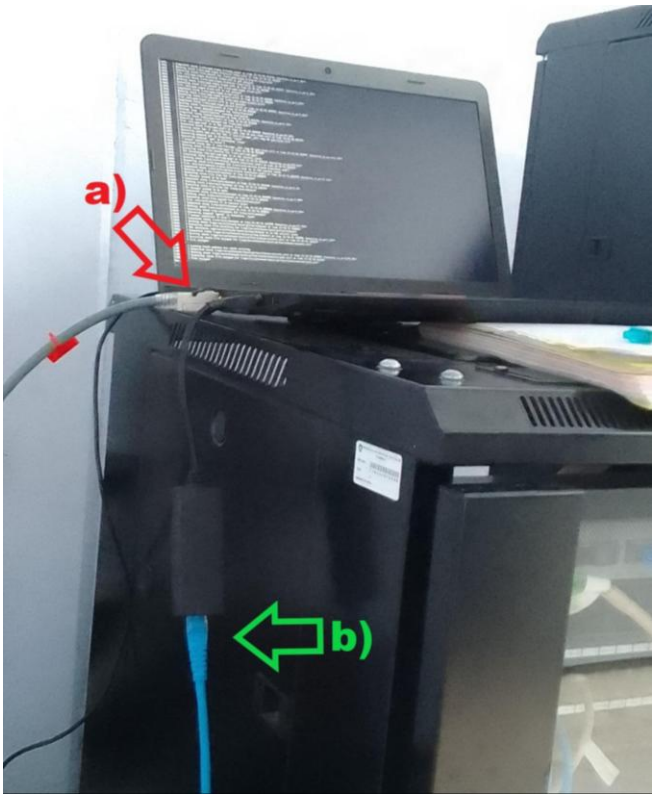

Fig. 5. The Computer on which Security Onion is installed must be connected to the network via a (a) Network cable that is connected to the SPAN port of the switch. In addition, (b) The network interface through which the Security Onion web console will obtain an IP must be determined.

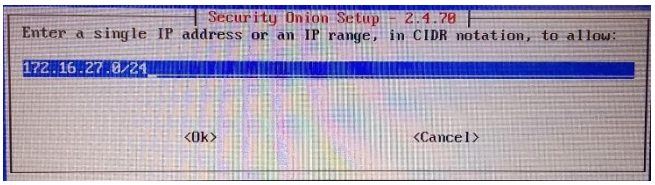

Fig. 6. Authorized network for Security Onion web console login.

2) Node verification: In order to ensure proper network monitoring, it is necessary to verify the status of the node. This process entails entering the IP address of the Security Onion web console from the web browser of an external device connected to the authorized network. Subsequently, the configured credentials are entered. Upon successful authentication, the welcome interface is displayed, presenting the user with a left-side menu comprising several options. The "Grid" option is selected to view the node status and the services that are currently operational. This facilitates the user's ability to verify the successful deployment of the system, as illustrated in Fig. 7.

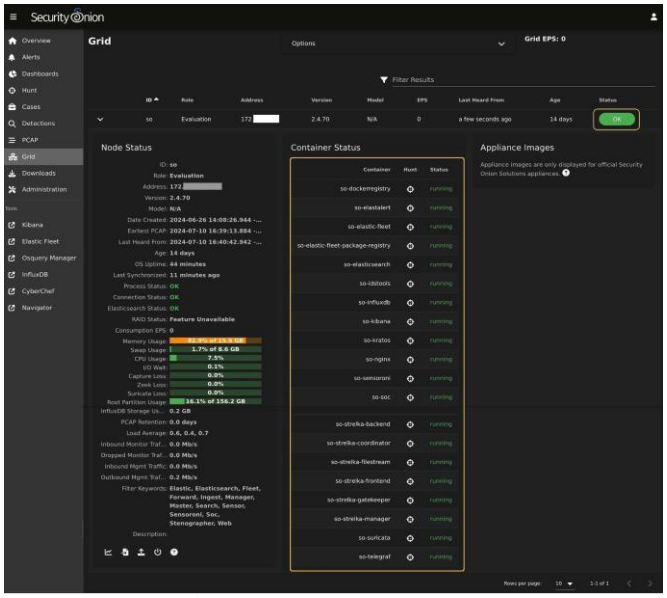

Fig. 7. Status of the Security Onion node that has been deployed.

3) Detections in the network using security onion: In order to access the logs of Security Onion detections, it is necessary to click on the "Detections" option, which is located in the left menu of the interface. This will display data such as name, severity, date, type, and other relevant information regarding the detections made in a specific time period, as illustrated in Fig. 8.

It is important to note that Security Onion has only one set of rules enabled by default. To obtain a comprehensive overview, it is necessary to activate the remaining rules (Fig. 9), or at least those that are relevant to the university campus network. Subsequent to this activation, the interface will consequently display the new records, as illustrated in Fig. 10.

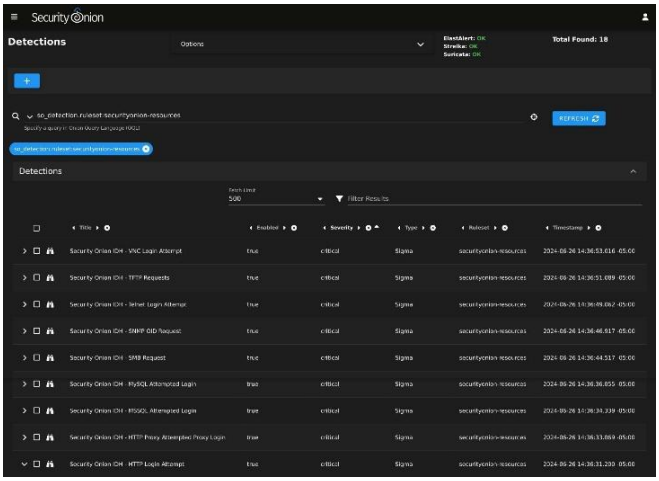

Fig. 8. Network detections according to security onion monitoring.

C. Integration and Documentation of Results

1) Documentation of findings: Over the course of approximately three weeks, Security Onion obtained a total of 500 logs from a segment of the university campus network. Of these logs, 485 were classified as informative, while the remaining 15 were categorized as critical and high severity. Fig. 11 shows the detections along with brief descriptions.

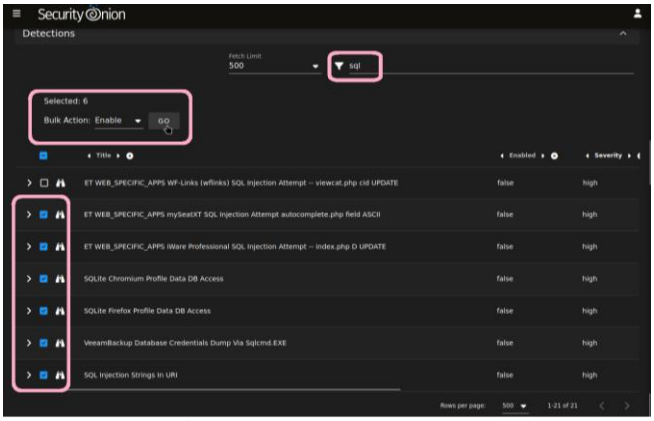

Fig. 9. Activation of rules that have been deemed pertinent to the network.

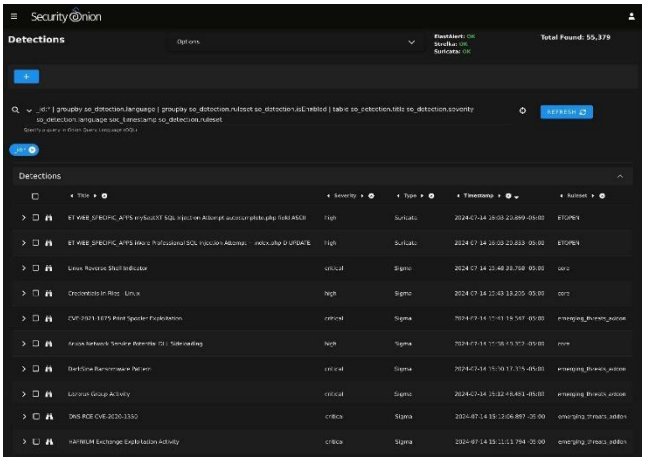

Fig. 10. Detections registered by security onion subsequent to the enablement of certain rules.

Fig. 11. Detections in the network grouped by severity.

2) Observed patterns:

a) Prevalence of informative detections: The majority of detections, specifically 97%, are informative and tend to be lower priority. However, it is crucial to obtain a comprehensive understanding of network traffic and potential misconfigurations or minor anomalies.In this research work, the detection "ET TOR TOR Known Tor Relay/Router (Not Exit) Node Traffic group 184-668" indicates traffic originating from known Tor relay nodes. These nodes may not be inherently malicious; however, they could be utilized to conceal other activities.

b) Critical and high severity detections: Although only 3% of the detected cases are critical or high severity, the potential for damage is concerning. This set of detections encompasses a variety of cyber threats, including SQL injection, ransomware, and Advanced Persistent Threat (APT) group-targeted attacks [1]. Attempts of SQL injection, as evidenced by detections in "mySeatXT," "iWare Professional," and injection strings in URIs, can compromise critical databases. The detection of the "DarkSide Ransomware" pattern indicates the presence of highly destructive ransomware, associated with actors using techniques such as phishing and exploitation of externally accessible services [10, 16].In addition, the traffic identified on TOR relay nodes, as mentioned in the previous point, suggests a possible connection with ransomware activities, as TOR is commonly used to hide command and control operations.

Conversely, the detection of activities attributed to APT groups, such as the "Lazarus Group" [40] and the exploitation of Exchange by "HAFNIUM" [29], point to sophisticated intrusion attempts. In these cases, the objective of the groups appears to be the obtaining of confidential information through advanced tactics and persistence in compromised networks. Furthermore, there have been endeavors to exploit well-documented vulnerabilities, including "CVE-2021-1675 Print Spooler Exploitation" [15] and "CVE-2020-1350 DNS RCE" [19]. These vulnerabilities could potentially enable attackers to execute arbitrary code or compromise critical systems.

Finally, detections related to post-exploitation techniques, such as "Aruba Network Service Potential DLL Sideloading" [2] and "Linux Reverse Shell Indicator" [42], suggest attempts to maintain persistence and move laterally in the network. Data exfiltration [34] is also evident, with alerts such as "Credentials In Files - Linux" [13] and unauthorized database accesses such as "VeeamBackup" [66] and "SQLite" [64].

This series of detections underscores the necessity for constant vigilance against these cyber threats.

D. Relationship of findings to CIS Controls

In this section, we delineate the manner in which the detections made by Security Onion align with the security controls established by the Center for Internet Security (CIS). It should be noted that some findings may be associated with multiple controls; however, the focus will be on those most relevant and representative for each case. As illustrated in Table IV, this relationship is demonstrated.

Furthermore, a double-entry table (see Table V) is presented that visually summarizes these relationships, marking with an "X" the intersection between each finding and the relevant CIS controls. This graphical representation facilitates the expeditious identification of the safety critical points addressed by each finding.

TABLE IV. RELATIONSHIP BETWEEN DETECTIONS AND CIS CHECKS

Detections	CIS Controls	Relation
- ET WEB_SPECIFIC_APPS mySeatXT SQL Injection Attempt - ET WEB_SPECIFIC_APPS iWare Professional SQL Injection Attempt - SQL Injection Strings In URI [63]	CIS 02 Control: Inventory and control of software assets	These detections are directly related to the need to maintain software integrity by updating it to address vulnerabilities in applications where SQL injection can be performed.
	CIS Control 04: Secure Configuration of Assets and Enterprise Software	The implementation of secure configurations has been demonstrated to be an effective measure in preventing the exploitation of SQL injection attacks.
- Linux Reverse Shell Indicator - CVE-2021-1675 Print Spooler Exploitation - Lazarus Group Activity - DNS RCE CVE-2020-135 - HAFNIUM Exchange Exploitation Activity - Potential OWASSRF Exploitation Attempt - Proxy	CIS 07 Control: Continuous vulnerability management	Designed to facilitate the identification and mitigation of vulnerabilities that could be exploited to create reverse shells or by APTs. It is intended to detect and remediate specific vulnerabilities, including CVE-2021-1675, CVE-2020-1350, and those that have been exploited by HAFNIUM. Additionally, it is designed to detect and mitigate attempts to exploit OWASSRF vulnerabilities [54].
	CIS Control 13: Network Monitoring and Defense	● The detection of suspicious activity from APT groups such as Lazarus and reverse shell is essential for continuous monitoring and active network defense. ● The monitoring of attempts to exploit critical vulnerabilities or malicious activity related to Exchange server exploitation.
- Credentials In Files - Linux - SQLite Firefox Profile Data DB Access - VeeamBackup Database Credentials Dump Via Sqlcmd.EXE	CIS 03 Control: Data protection	The protection of sensitive information in databases or browser profiles, including credentials, is imperative to prevent its extraction.
	CIS Control 13: Network Monitoring and Defense	Monitor activities that attempt to access credentials in files, unauthorized access to sensitive databases and suspicious activities that attempt to dump credentials.
Aruba Network Service Potential DLL Sideloading	CIS Control 04: Secure Configuration of Assets and Enterprise Software	Safe configurations to prevent DLL side-loading.
	CIS Control 13: Network Monitoring and Defense	Monitor suspicious DLL side-loading activity.
DarkSide Ransomware Pattern	CIS 10 Control: Malware Defenses	The detection and prevention of the ransomware's execution.

Detections	CIS Controls	Relation
	CIS Control 13: Network Monitoring and Defense	Monitor malicious activity related to ransomware.
Security Onion IDH - SSH Accessed	CIS 06 Control: Access control management	Manage and monitor authorized and unauthorized access to systems.
	CIS 13 Control: Network monitoring and defense	Monitor any suspicious access to SSH services.
ET TOR Known Tor Relay/Router (Not Exit) Node Traffic traffic group 184-668	CIS Control 13: Network Monitoring and Defense	Monitor traffic from Tor relay nodes to identify potential suspicious activity.

TABLE V. SUMMARY OF THE RELATIONSHIP BETWEEN DETECTIONS AND CIS CONTROLS

Detections	CIS Controls						
	02	*03*	*04*	*06*	*07*	*10*	*13*
ET WEB_SPECIFIC_APPS mySeatXT SQL Injection Attempt autocomplete.php field ASCI0049	X		X				
ET WEB_SPECIFIC_APPS iWare Professional SQL Injection Attempt -- index.php D UPDATE	X		X				
Linux Reverse Shell Indicator					X		X
Credentials In Files - Linux		X					X
CVE-2021-1675 Print Spooler Exploitation					X		X
Aruba Network Service Potential DLL Sideloading			X				X
DarkSide Ransomware Pattern						X	X
Lazarus Group Activity					X		X
DNS RCE CVE-2020-1350					X		X
HAFNIUM Exchange Exploitation Activity					X		X
Security Onion IDH - SSH Accessed				X			X
Potential OWASSRF Exploitation Attempt - Proxy					X		X
SQLite Firefox Profile Data DB Access		X					X
VeeamBackup Database Credentials Dump Via Sqlcmd.EXE		X					X
SQL Injection Strings In URI	X		X				
ET TOR Known Tor Relay/Router (Not Exit) Node Traffic traffic group 184-668							X

E. Recommendations and Action Plan

1) Recommendations: The following recommendations are based on the safeguards in the CIS controls and are ordered according to the number of related detections.

a) CIS control 13: Network monitoring and defense

- Centralization and monitoring
  - Centralize security event alerts.
  - Collect network traffic flow logs.
- Intrusion detection
  - Implement a host-based intrusion detection solution.
  - Implement an intrusion detection solution in the network.
- Traffic and access management
  - Perform traffic filtering between network segments.
  - Manage access control for remote assets.

b) CIS 07 control: Continuous vulnerability management

- Management and remediation processes
  - Establish and maintain a vulnerability management process.
  - Establish and maintain a remediation process.
- Automation and vulnerability analysis
  - Perform automated operating system and application patch management.
  - Perform automated vulnerability scans of internal organizational assets and externally exposed business assets.
- Remediation of detected vulnerabilities

c) CIS Control 04: Secure Configuration of Assets and Enterprise Software

- Establish and maintain a secure configuration process for enterprise assets, software and network devices.
- Asset and software security

- Configure automatic session blocking on enterprise assets.
- Implement and manage a firewall on servers and user devices.
- Manage default accounts in enterprise assets and software.
- Uninstall or disable unnecessary services on enterprise assets and software.

- Device security
  - Configure reliable DNS servers on enterprise assets.
  - Apply automatic device locking on laptops and mobile devices.
  - Implement remote wipe capability on portable end-user devices.

d) CIS 02 Control: Inventory and control of software assets

- Software inventory and management
  - Develop and keep the software inventory up to date.
  - Ensure that authorized software is supported.
  - Treatment of unauthorized software.
- Tools and lists
  - Use automated software inventory tools.
  - Use allowed list for authorized software and authorized libraries.

e) CIS 03 Control: Data protection

- Establish and maintain a data management process, data inventory and data classification scheme.
- Access and encryption
  - Configure data access control lists.
  - Encrypt data on user devices, removable media, in transit and at rest.
- Retention and disposal
  - Apply data retention.
  - Securely delete data.
- Segmentation and documentation
  - Document data flow.
  - Segment data processing and storage according to sensitivity.

f) CIS 06 Control: Access control management

- Establish a process for granting access and a process for revoking access.
- Authentication and centralized control
  - Require MFA for externally exposed applications, remote network access and administrative access.
  - Establish and maintain an inventory of authentication and authorization systems.
  - Centralized access control.

g) CIS 10 Control: Malware Defenses

- Implementation and maintenance
  - Implement and maintain anti-malware software.
  - Configure automatic updates of anti-malware signatures.
- Preventive measures
  - Disable autorun and autoplay for removable media.
  - Configure automatic anti-malware scanning of removable media.
  - Enable anti-exploitation functions.
- Centralized management
  - Centrally manage anti-malware software.
  - Use behavior-based anti-malware software.

2) Implementation priority: To achieve an effective improvement in the security of UNSCH, it is proposed that a phased approach be adopted to implement security measures. This approach will be based on the CIS Controls related to network detections. The implementation of safeguards corresponding to IG1 will be prioritized, as these form the fundamental foundations for protecting the organization. Subsequently, the implementation of those corresponding to IG2 will be addressed, as they complement the initial measures and effectively address the additional risks and complexities associated with an organization with a higher risk profile and data sensitivity.

The prioritization of these measures should also be informed by the number of detections associated with each control. For instance, CIS Control 13 has been associated with 13 detections, a figure that positions it as a top priority. CIS Control 07 follows closely with 6 detections, while other controls such as CIS 04 (4 detections), CIS 02 and CIS 03 (3 detections each), and CIS 06 (1 detection) also warrant consideration.

However, a specific consideration must be taken into account in the case of Control 13. Given that its safeguards are not intended for institutions from IG2 and this control has the highest number of associated detections, it is recommended to implement it simultaneously with the safeguards of IG1. This strategy will enable the early mitigation of the most critical vulnerabilities, thereby fortifying the organization's security infrastructure in a comprehensive manner.

3) Action plan: The action plan commences with a comprehensive audit of the IT and security infrastructure to identify gaps and ascertain protection needs. Concurrently,

security policies will undergo a process of updating, based on CIS controls and adapted to the specific needs of the university network. Subsequent to the formulation of policies, the security solutions will be implemented, prioritizing the safeguards of the aforementioned controls. During this implementation phase, training of IT staff and end users on the use of and response to the new security measures will commence.

Throughout the process, a continuous monitoring system will be established to evaluate the effectiveness of the implemented measures and adjust policies and practices as new threats or changes in the IT environment arise. This continuous improvement process will begin as soon as the first safeguards are implemented, ensuring that any gaps detected are addressed immediately. To optimize time and resources, some actions can be carried out in parallel. For instance, while the comprehensive audit is underway, security policies can undergo updates, and concurrently, the training of staff can be initiated for the implementation of the solutions. This ensures that all phases of the action plan are executed in an efficient and coordinated manner.

V. Discussion

The implementation process of Security Onion at UNSCH proved to be an enriching and insightful experience, allowing for the identification of both the strengths and challenges associated with using this tool in a real-world environment. Initially, a commercially available device widely used in the country was selected, which met the minimum requirements for an Evaluation deployment. However, during the second stage of the installation, specifically after confirming the configurations, the device began to experience recurrent failures. These failures consisted of the device shutting down during the subsequent process. This issue was resolved by replacing the device with one that had greater RAM capacity, which allowed the installation to be completed without further issues. This incident highlights the importance of having adequate hardware to ensure the proper functioning of advanced security tools.

The choice of Security Onion as an open-source platform proved to be a strategic decision, especially in a context where the university's administrative authorities are reluctant to invest in cybersecurity solutions or do not prioritize their importance. Security Onion not only provided a robust and scalable solution but also minimized associated costs. This experience reinforces the viability of open-source tools as effective alternatives for institutions with limited resources but growing needs for protection against cyber threats.

On the other hand, a significant limitation of the study was the inability to obtain network traffic directly from the main switch of the university campus. This switch did not have available ports to configure it as a SPAN (Switch Port Analyzer) port, which would have allowed for more comprehensive traffic capture and analysis. Although a partial analysis was achieved with the available resources, this restriction prevented more exhaustive network monitoring.

In summary, this experience not only demonstrated the effectiveness of Security Onion as a network auditing tool but also highlighted the importance of having adequate hardware, available network infrastructure, and the support of institutional authorities to ensure the success of cybersecurity initiatives.

VI. Conclusions and Recommendations

The implementation of Security Onion at UNSCH has demonstrated that it is an effective tool for network auditing, thanks to its capabilities in security monitoring, log management, and intrusion detection. Security Onion has enabled the identification and mitigation of suspicious activities and anomalies within the network of the university campus of the UNSCH, such as SQL injection attempts, ransomware, and traffic associated with advanced threat actors. Additionally, it facilitated the collection, storage, and analysis of logs, which helped identify unusual patterns that will be instrumental in taking preventive actions and avoiding greater damage. Security Onion's ability to centralize these functions contributes to better event traceability and strengthens defense measures against emerging cyber threats.

However, this study has also identified areas for improvement and opportunities for future work. First, it is recommended to implement a Standalone deployment instead of the Evaluation deployment used in this research, as the latter limits the use of certain tools and advanced functionalities. A Standalone deployment would allow for the full utilization of Security Onion's capabilities and improve the accuracy of threat detection.

Second, it is suggested to deploy complementary tools such as Zeek and Snort to compare and enrich the obtained logs. These tools could provide a more comprehensive view of network traffic and help identify threats that might go unnoticed with a single solution. Finally, it is recommended to closely monitor and analyze TOR traffic on the network, given the observed correlation between detections such as "DarkSide Ransomware Pattern" and "ET TOR Known Tor Relay/Router (Not Exit) Node Traffic." This analysis could reveal hidden threats and further strengthen UNSCH's security posture.

In conclusion, while Security Onion has proven to be a valuable tool for network auditing, its implementation can be enhanced through a more robust deployment, the integration of additional tools, and a deeper focus on analyzing encrypted traffic. These recommendations would not only benefit UNSCH but could also serve as a guide for other institutions facing similar cybersecurity challenges.

Business Intelligence in Public Management

Javier Benavides-Redhead, Jenny Gutiérrez-Flores*
Facultad De Ciencias Empresariales, Universidad Científica Del Sur, Lima, Peru

***Abstract*—The present research seeks to demonstrate the improvement of the visualization of indicators applying Business Intelligence in the district municipality of Lince. The entity has among its different institutional objectives to strengthen the modernization of the administrative and functional systems of institutional management. The research was proposed as an applied type, with a pre-experimental and quantitative design. A sample of 10 users belonging to Tax Administration Management was available, applying the questionnaire technique and the survey-type instrument. From the data collected by the instrument in the Pre-Test and Post- Test, the results were obtained that allowed us to determine a positive relationship in relation to decision-making for tax collection. For the Pre-Test tests, a score of 50% was obtained, in the low-level score as opposed to the Post Test tests, which obtained a 50% general level. The investigation allowed, in its interpretation, the meaningful change for decision-making supported by indicators generated by Business Intelligence, when evaluating the results and finding changes among the respondents on time, productivity and presentation of information in relation to the use of Business Intelligence. On the other hand, decision-making was positively affected from the direction, control, and evaluation organization, from the perception of the respondents in the changes represented by the use of a business tool to obtain information capable of responding to the needs of the institution for decision-making, focused on tax collection. The research is structured in six sections. The first section details the problematic situation and the justification of the study in relation to the research objectives. The second explains the background and previous research that supports the problematic situation based on the key constructs of the work. The third mentions the methodology used, through the quantitative approach, and the fourth shows the results obtained. The fifth section makes a comparison of what the study achieved compared to other previous studies and finally, the conclusions provide the final scopes on the achievement of the objectives and the contribution to future research.**

***Keywords*—Business intelligence; municipality; taxation; decision making; indicators; public management; information presentation; technology tool; modernization; productivity**

I. Introduction

The District Municipality of Lince in Lima seeks to provide quality services to citizens within its district. Accurate decision-making is essential to meet the needs of citizens and improve their quality of life. For managers, having timely information is crucial to analyzing problems and proposing valuable solutions. In this sense, the ability to listen to the perspectives of the areas involved, based on real data, is key to making the right decisions. However, the Tax Administration Management that supervises the collection of municipal revenues has been operating through a manual, daily process and with data from various sources, which has affected the timely generation of collection reports, essential for efficient decisions, to the extent that the Information Technology sub-management is in charge of the Tax Information System, essential for tax collection reports. Because of this problem, there are limitations of information due to the delay in the creation of indicators as they have been executed manually, causing dissatisfaction among users. The objective of this research is to determine how the improvement in the visualization of indicators by applying Business Intelligence is related to decision-making for tax collection. It will make it possible to analyze the real situation of the processes that are aligned with the institutional objectives and the supervision of compliance with the goals executed by the organic units under its responsibility. Obtaining data from various sources of information can be collected and transformed into useful information for public management and therefore in better decision making.

To achieve this objective, Business Intelligence has been established as an independent variable, [1] which is defined as the technological tool that allows generating profits at all levels of management, especially in decision-making processes, through the integration and analysis of an organization's data resources. They also [2] state that BI is a generic term that groups together technologies and management processes aimed at collecting, storing, organizing, and managing data with the aim of improving the competitiveness of companies.

Among the dimensions selected for the study we have the following: Time, related to speed, the tool is intended to deliver the information required by the user in the shortest possible time. This is crucial as the value of information can change depending on the moment. Productivity is related to reliability, ensuring the quality of information to avoid incorrect decisions. Trust in the data is achieved through transparency and traceability, ensuring that the results provided by the BI tool are based on reliable data. Presentation of information, which seeks to make interpretation easy for the user with minimal effort. Beyond the appearance of the reports, it is important to have an intuitive structure that facilitates the interpretation of the data.[3]

In relation to the dependent variable, decision-making, [4] they define it as a habitual and common act of choice between different alternatives linked to management because it is a human activity. Therefore, the study focuses on detecting problems and opportunities, verifying objective deviations, and taking the necessary actions to resolve the situation. The explanation of their relationship and impact has been explored using technological tools to support effective decision-making in administrative management. To this end, the following dimensions have been proposed: Organization, this aspect helps to establish the activities of the organization, focusing on establishing the appropriate hierarchies to accelerate the execution of tasks and make the right decisions. Management, which is based on communication within the organization as an

essential element for an ideal work environment and for the effective resolution of conflicts. Business strategies that benefit stakeholders are studied and the visualization of indicators through Business Intelligence tools is used to help. Control and Evaluation, where the performance of the operations conducted is compared with what was originally proposed. The aim is to demonstrate the reality of performance and opportunities for improvement. Business Intelligence helps to analyze variations and find the cause of non-compliance with the established provisions. [5]

II. Related Work

Among the international precedents, [6] it formulated a Business Intelligence proposal that favored decision-making, specifically Tax Management, with the aim of improving the tax reporting process. He concluded that the use of a Business Intelligence proposal facilitated the visualization of consolidated information on dashboards. For [7], in the municipality of Cartagena del Cheara they defined a project based on the development of an artificial model aimed at helping the management of a service company in decision-making to improve the efficiency, productivity and competitiveness of its organization.

At the national level, [8] it proposed a Business Intelligence solution for the dynamization of decision-making in tax management, focused on debt control and SUNAT collection. Among its results, it identified that the reporting time with the use of the Business Intelligence tool was reduced by a total of 8.7 seconds compared to 116.05 seconds without the tool. For the costs of the preparation of management reports, a reduction was found from S/ 0.56 to S/ 0.04, and for the level of user satisfaction, greater acceptance was identified with 2.65 points against 1.9 points without the tool. Based on the evidence, it was concluded that the activation of Business Intelligence helped to reduce times and costs, as well as increase the level of user satisfaction. In the same sense, [9] they proposed that, to improve the decision-making process in the Revenue Area, Business Intelligence was necessary. The objective of the research focused on reducing time, minimizing the cost of person-hours and increasing user satisfaction with the proposed solution for reporting. Their results showed that user satisfaction increased by 32.56%, reporting time was reduced by 69.12%, and labor time costs associated with reporting were reduced by 69%. The deduction was reached that the development of Business Intelligence made it possible to speed up decision-making, specifically in tax revenues of the District Municipality of Moche. [10] , prepared a study on the development of a DataMart for the analysis of tax delinquencies and traffic offenders. Its main objective was to analyze the tax debts and traffic infractions, of the Tax Administration Service of Piura, through multivariate analysis with the Hefesto methodology. To this end, quantitative study was developed, with a descriptive scope and a non-experimental design. The units of analysis of the study and the records of the tax debts stored in the database were used. With a population between 2013 and 2017, all population records were considered for the sample, and the observation card was used as a tool for data collection. Among its conclusions, it validated the confirmation of hypotheses by describing in tabular and graphical form their respective interpretations of the main indicators of the research variable. On the other hand, [11] it conducted a study, in the collection area of the Municipality of Los Olivos, for the development and deployment of Business Intelligence. It identified problems in the efficiency of information, producing user satisfaction related to the receipt of reports. For the solution, SCRUM was used as a methodology in the development of the project, and for the construction of the Business Intelligence tools, the Ralph Kimball methodology. Among its results, it was identified that the implementation of Business Intelligence improved the efficiency index by 53.36% and an increase of 1.90% in the user satisfaction index was achieved. As conclusions, a significant improvement in the decision-making process was evidenced thanks to the introduction of Business Intelligence.

This study will help to analyze the real situation of the processes that are aligned with the institutional objectives and monitoring compliance with the goals executed by the organic units under their responsibility. The obtaining of data from various sources of information can be collected and transformed into useful information for public management, developing better decision-making for public management. In addition, it will allow the institution to work in a more efficient way, providing the inhabitants of Lince with better services, increasing the speed of processes and response times, exploring the different solutions provided by the implementation of Business Intelligence. As demonstrated by the work [12] of seeking to use a system for both the public and private environments, it was possible to provide confidence by making use of a tool that complies with being accurate, reliable, efficient, dynamic and agile, generating the best result in the execution of the care processes. For his part, [13] he argues that the choice of the method to be used for data storage applying Business Intelligence will depend on the number of steps necessary to build it, such as the methods of Kimball, Hephaestus and SAS, which help in the agile identification of the business objective and the quick results of the project, to validate its performance in decision-making. Finally, it can be replicated in any local government institution and as they point out, [14] the Data Warehouse model allows to have centralized information available for later analysis at a high speed, which is reliable and supports decision-making, becoming a fundamental part of the organization in which it is implemented.

However, the study presents as a limitation the availability of the personnel involved in the process for the generation of indicators by tax collection, in order to measure the quality of the visualization of indicators in terms of time, cost and user satisfaction at the end of the process.

III. Materials and Methods

The pre-experimental design was considered. As mentioned, [15] , the pre-experimental design is based on the test and post-test of a single sample group, which consists of the application of the test prior to experimental treatment, which will later be compared with the result of the subsequent tests. In view of this, the research conducted a before and after analysis in the visualization of indicators applying Business Intelligence and was validated in the hypotheses raised on tax collection decision-making. Likewise, the data were obtained from the instruments selected for the dimensions of the proposed independent and dependent variable. The type of research

applied, as defined [16], to the entire process of relationship between theory and product was considered defined as: a need for an industry or social sector that allows the creation of a theoretical concept if the properties of the concept are useful to the end user. The approach was quantitative, [17] we are told that the quantitative research approach establishes the experimental method, which is more common than is believed. And its objective is to discover new knowledge that allows them to know reality in the purest way possible, collecting and analyzing data through concepts and measurable variables. The scope was correlational, where [18] it is defined as the need for the approach where a relationship between 2 or more variables in relation to a hypothesis is proposed. From the quantitative approach, inferential statistical processes are applied with the purpose of extrapolating the results of the research to benefit the entire population.

The population and the study sample were made up of the same number of workers, that is, 10 people, with profiles of administrative employees of the Tax Administration Management in the District Municipal of Lince. Hernández quoted in [19], commented that the population will be equal to the sample if the study population is less than the number of fifty (50) individuals. The survey was used for the collection of primary data, applying the questionnaire as an instrument to measure the implementation of Business Intelligence in the visualization of indicators.

The questionnaire included questions with the application of the Likert scale where each statement of the questionnaire could be measured with 5 items and each one was assigned a numerical value. For [20], he specifies that the survey technique is commonly applied in the research procedure, which allows us to obtain the data more quickly. The advantage lies in obtaining information on a wide range of issues at the same time. In reference to the questionnaire, Sierra cited in [21] it tells us that the questionnaire as an instrument is applied to many individuals through a list of questions focused on a certain problem that the research tries to identify. Likewise, this instrument can be applied in writing, verbally and even in digital format.

A. *Reliability Analysis – Pre – Test*

In Cronbach's alpha, the closer it is to its maximum value, the greater the reliability of the scale. As can be seen in Table I, the value of 0.762 is obtained, which can guarantee the reliability of the scale for the instrument in pre-Test.

TABLE I. RELIABILITY ANALYSIS - PRE-TEST

Cronbach's alpha	N° Elements
.762	20

B. *Reliability Analysis – Post Test*

In Cronbach's alpha, the closer it is to its maximum value, the greater the reliability of the scale. As can be seen in Table II, the value of 0.785 is obtained, which can guarantee the reliability of the scale for the instrument in post-Test.

TABLE II. RELIABILITY ANALYSIS - POST-TEST

Cronbach's alpha	N° Elements
.785	20

For the implementation of Business Intelligence, a solution consistent with the development of a Datawarehouse was proposed, that is, a repository or data warehouse where the data generated by the entire organization is located, which is characterized by being stable, coherent, dependable, and supported by historical information. For its elaboration we based ourselves on Ralph Kimball's methodology that indicates that to build a DataWarehouse, it must have the following characteristics: 1) Focus on the business and its needs. 2) Have an infrastructure designed to solve business problems. 3) It can be delivered in relatively short times of 6 to 12 months. 4) Provides a complete solution, database, reports, documentation, etc. Likewise, to achieve the processing of the data we require the generation of the ETL, which is defined as the process by which the data that is going to be used to build the DataWarehouse is identified, this data comes mainly from the transactions and the history of the organization, this information must go through filters to determine which is the one that will be of greatest importance to solve our problems, In addition, modifications will have to be made before entering it to adapt it to the structure that our data warehouse will have, so that it can be used by users and obtain the required information effectively. To finally generate the dimensional data model and its visualization of indicators through dashboards tailored to the needs of the organization.

The limitations of the study are associated with the limited accessibility of the income systems for the exploitation of information from the process of extraction, transformation and loading of data for the Business Intelligence tool. Likewise, the lack of availability of the personnel involved in the process for the generation of indicators for tax collection, to measure the quality of the visualization of indicators in time, productivity, and presentation of information at the end of the process.

IV. RESULTS

For the Pre-Test type of test, the process of generating indicators was considered before the implementation of Business Intelligence, as can be seen in Fig. 1.

Fig. 1. Indicator generation process – Pre Test scenario.

For the type of Post-Test test, the process of generating indicators was taken into consideration, after the implementation of Business Intelligence, which can be seen in Fig. 2.

Fig. 2. Indicator generation process – Post Test scenario.

A. Independent Variable: Improvement of the Visualization of Indicators by Applying Business Intelligence

According to the results in Table III, on the Improvement of the visualization of Indicators by applying Business Intelligence, for the Pre-Test a low level of 50.0% and an elevated level of 0% were obtained. For the type of test in the Post Test, 50.0% had an elevated level and 0% had a low level.

1) Dimension time: According to the results in Table IV, on the Improvement of the visualization of Indicators applying Business Intelligence over Time, for the Pre-Test a low level of 50.0% was obtained with a medium and elevated level of 0%. For the type of test in the Post-Test, 35.0% have an elevated level, 15% have a medium level and 0% have a low level.

2) Dimension productivity: According to the results in Table V, on the Improvement of the visualization of Indicators applying Business Intelligence in Productivity, for the Pre-Test a low level of 45.0% was obtained with a medium level of 5.0% and an elevated level of 0%. For the type of test in the Post-Test, 15.0% have an elevated level, 35% have a medium level and 0% have a low level.

3) Dimension presentation of information: According to the results in Table VI, on the Improvement of the visualization of Indicators by applying Business Intelligence in the Presentation of Information, for the Pre-Test a low level of 35.0% was obtained with a medium level of 15.0% and an elevated level of 0%. For the type of test in the Post-Test, 15.0% have an elevated level, 35.0% have a medium level and 0% have a low level.

B. Dependent Variable: Decision-making for tax collection

According to the results in Table VII, on Decision-making for tax collection, for the Pre-Test a low level of 50.0% and an elevated level of 0% were obtained. For the type of test in the Post-Test, 50.0% had an elevated level and 0% had a low level.

1) Dimension organization: According to the results in Table VIII, on Decision-making for tax collection in the organization, for the Pre-Test a low level of 40.0%, a medium level of 10.0% and an elevated level of 0% were obtained. For the type of test in the Post-Test, 50.0% had an elevated level and 0% had medium and low levels.

2) Dimension address: According to the results in Table IX, on Decision-making for tax collection in the directorate, for the Pre-Test a low level of 45.0% was obtained, a medium level of 5.0% and an elevated level of 0%. For the type of test in the Post-Test, 50.0% had an elevated level and 0% had medium and low levels.

3) Dimension control: According to the results in Table X, on Decision-making by tax collection in the control, for the Pre-Test a low level of 45.0% was obtained, a medium level of 5.0% and an elevated level of 0%. For the type of test in the Post-Test, 50.0% had an elevated level and 0% had medium and low levels.

4) Dimension evaluation: According to the results in Table XI, on Decision-making by tax collection in the evaluation, for the Pre-Test a low level of 45.0%, a medium level of 5.0% and an elevated level of 0% were obtained. For the type of test in the Post-Test, 50.0% had an elevated level and 0% had medium and low levels.

V. DISCUSSION

For the tests conducted, an interpretation classification was established in relation to the questions answered by the survey. This included the classification in three levels: Low to identify a negative or no impact on the decision-making process, Medium to recognize a neutral effect in which it can be interpreted as minimal changes in the decision-making process and High to indicate a significant improvement in the evaluation of the results for decision-making. From the results obtained in the research, a relationship could be observed between the improvement in the visualization of indicators applying Business Intelligence with decision-making for tax collection, with an elevated level of acceptance in the Post-Test type of test, differentiating it from the Pre-Test test, as shown in Table VII.

For the first hypothesis, it could be observed in the results for the Pre-Test test, that the high level was 0% and the low level was 50.0%, while the Post-Test, the high level was 50.0% and the low level was 0% which represents the decrease in the time used to generate the indicators with the support of Business Intelligence. It can be interpreted that the time spent searching, analyzing, and generating reports improved satisfactorily because of the POST-TEST, which can be seen in Fig. 3. where a total of 10 users expressed their level of dissatisfaction before the implementation of the BI tool through 10 responses and Low Level. After its implementation, 3 responses were placed at the Medium Level and the other 7 responses were positioned at a High Level. From these results, a positive change in the perception of users is perceived.

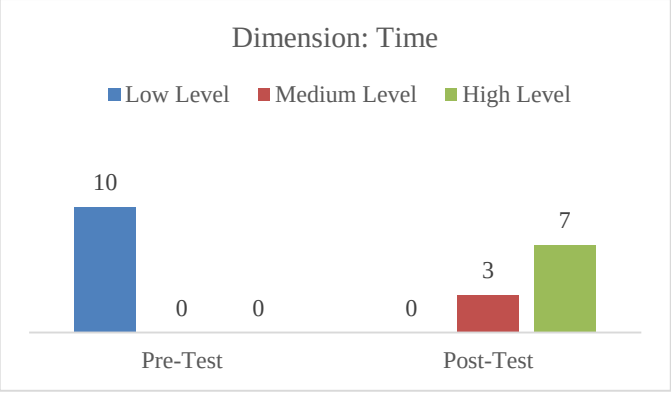

Fig. 3. Comparative pre test vs. post test results dimension: Productivity.

The change is since before the implementation of the BI tool, the delay in obtaining the information from the Tax Information System represented an estimated time of 4 hours (240 minutes). After the implementation of the BI tool, the time obtained was 5 minutes for collection information, which represents a reduction of 98%. In addition, for the analysis of the information before the implementation of the BI tool, it was verified that the time spent was 60 minutes. After the implementation of the BI tool, a time of 15 minutes was obtained, which represented a reduction of 75%. Finally, for the generation of reports based on the information before the implementation of the BI tool, a time spent of 40 minutes was obtained. After the implementation of the BI tool, a time of 20 minutes was obtained, which represented a reduction of 50%.

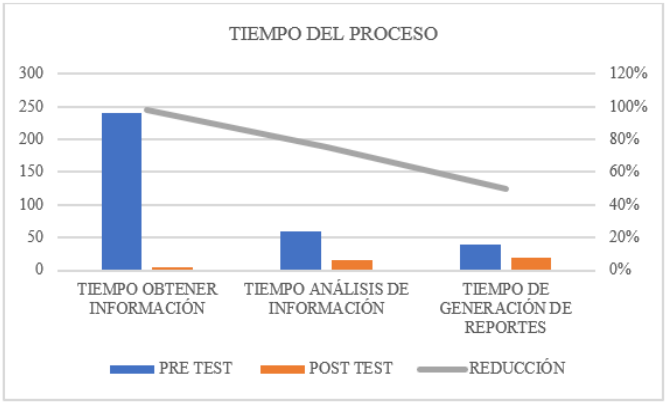

Fig. 4. Process time - comparison of indicators.

This indicates that the participants recognize the change in the perception of the time spent on this task, and a trend towards a greater acceptance of the change from a medium level to an elevated level was observed. The reduction in time generated a higher quality of the information presented, which positively affected decision-making to improve tax collection. This finding is supported by what was mentioned by Salazar (2020), where it is considered that the time dimension represents an improvement for the visualization of indicators through Business Intelligence, through the speed and ability to offer information in real time, creating a positive impact on tax collection decision-making in a municipality.

Regarding the second hypothesis, it was observed in the results that the Pre-Test presented 0% at the elevated level, while for the medium level it was 5.0% and the low level was 45.0%. In the Post-Test test, the elevated level was 15.0%, the medium level was 35.0%, and the low level was 0%. This can be interpreted as improved productivity because of the POST-TEST test, compared to the perception obtained in the PRE-TEST test, which can be seen in Fig. 5. Prior to the implementation of the BI tool, a total of 9 responses with Low Level and 1 response with Medium Level. After the implementation of the BI tool, the results where 7 responses were located at the Medium Level and the rest of 3 responses

were positioned at a High Level. In relation to these results, a positive change in user perception is perceived after the application of the BI tool.

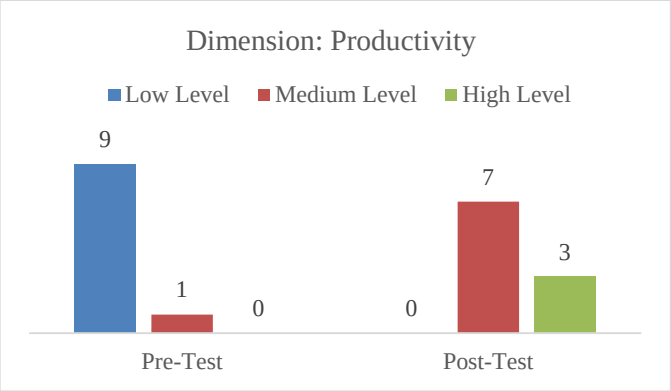

Fig. 5. Comparative pre test vs. post test results dimension: productivity.

In the same way, it was possible to implement better strategies that contributed to productivity. Among them we have: The management of e-mailing, which allows the notification of information on tax debts and benefits to taxpayers by email registered in the Tax Computer System. This was achieved thanks to the information provided by the BI tool, allowing the possibility of classifying taxpayers by segmentation in debt range, facilitating the implementation of these notifications. On the other hand, the management of telephone collection made it possible to select the taxpayers with the highest delinquencies to raise awareness and provide the payment facilities available by the institution, through the information obtained from the BI tool. In addition, the taxpayer orientation process was strengthened from the face-to-face tax service platform, which aims to provide all the information available to comply with their obligations, as well as the land registry and the purchase declaration, known as alcabala. Finally, the possibility of better collection through punctuality incentives makes it possible to offer benefit programs to the neighbor, providing the taxpayer with benefits in other institutions.

Therefore, greater productivity in improving data visualization allowed for faster implementation of strategies that enabled the improvement in tax collection, as well as generated greater efficiency in the collection process. By automating much of the activity in data collection, Business Intelligence can reduce repetitive tasks and allow users to focus on data analysis. In addition, by providing a clear and easy-to-understand visualization of data, business intelligence can increase visibility and understanding of key indicators, enabling more informed and effective decision-making.

This hypothesis can be supported (Gálvez, 2016, as cited in Salazar, 2020), where the importance of the analytical capabilities of Business Intelligence tools for decision-making is recognized. Increased productivity through the visualization of metrics allows for improved analytical capabilities and demonstrates a positive impact on municipal tax collection decisions.

Finally, the third hypothesis, the results indicate that 15.0% of the respondents perceived a significant improvement in the presentation of information, while 35.0% noticed a medium level of improvement in the Post Test. In general, these results proved that the implementation of Business Intelligence to improve the visualization of the indicators contributed to the presentation of the information in a dynamic way of the different management reports, making it simpler for the use of any user interested in tax collection information.

This hypothesis is related to the previous article by [3] in which he specifies that presenting clear and concise information can increase the analytical capacity of decision-makers to understand and analyze data, improving the presentation of information, suggesting that doing so can have a positive impact on a municipality's tax collection.

VI. Conclusions

In relation to the general hypothesis, it was concluded that the improvement in the visualization of indicators by implementing Business Intelligence significantly affects decision-making for tax collection.

Regarding the first specific hypothesis, the results show that the execution of Business Intelligence reduced the time spent on the information processing task and generated a higher quality of the data presented, resulting in greater capacity on the part of those responsible for making more effective decisions.

In reference to the second hypothesis, the results show that the application of Business Intelligence improves efficiency and transparency in tax collection by allowing the analysis of enormous amounts of data, identifying patterns of behavior and trends in payments made by taxpayers, detecting possible deviations in collection and improving tax strategies. In addition, information can be obtained in real time to detect and generate timely solutions, which enhances efficiency and transparency in tax management.

Finally, for the third hypothesis, the results show that the implementation of Business Intelligence contributed to the presentation of information in a dynamic way from the different management reports, making it simpler for the use of any user interested in tax collection information. This opens the possibility of continuous improvement in the presentation of information, according to the nature of the business logic and the needs of users that change over time.

It is worth mentioning that, although improvements in the application of Business Intelligence in Public Management are evident, this is also aligned with maintaining adequate and available personnel to develop and monitor indicators that make possible the execution of these improvements.

On the other hand, this study constitutes a contribution for the public sector not only at the local level, but also at the regional level or of greater scope to the extent that such improvements in management indicators through the use of BI for decision making, will allow analyzing the real situation of the processes that are aligned to the institutional objectives and the monitoring of the fulfillment of the goals executed by the organizational units in charge. Obtaining data from different sources of information can be compiled and transformed into useful information for public management, which makes the best business practices its own.

***Abstract*—In the sustainable packaging industry, multiple parameters require regulation to achieve a high-quality final product that meets contemporary demands. In bioplastic manufacturing, the control of the film thickness is critical because it influences the mechanical properties and other key characteristics. Terahertz time-domain spectroscopy (THz-TDS) has emerged as a promising technology for the non-invasive characterization of polymeric materials. The present study evaluates the integration of THz-TDS with chemometric techniques and machine learning models to predict the thickness of bioplastic samples fabricated from potato and maize starch. Three distinct thickness levels were produced by solution casting, and a spectral analysis was performed in the range of 0.5 to 1.2 THz. Four regression models were developed, including partial least squares regression, support vector regression, binary regression tree, and a feedforward neural network. The performance of the model was assessed using the coefficient of determination (R^2), root mean square error (RMSE) and the ratio of performance to deviation (RPD). R^2 values ranged from 0.8379 to 0.9757, the RMSE values ranged from 0.1259 to 0.3368, and the RPD values ranged from 2.4399 to 6.8106. These findings underscore the potential of THz-TDS and machine learning for non-invasive analysis of thin polymeric films and lay the groundwork for future research aimed at enhancing reliability and functionality.**

I. Introduction

The preservation of the environment for future generations has become a growing necessity in contemporary society, which requires the pursuit of sustainable solutions, as highlighted by [1]. Among the most urgent environmental challenges is the widespread pollution caused by the widespread reliance on petroleum-derived plastics, which, according to [2] and [3], inflicts profound and measurable damage on ecosystems. Inadequate management of plastic waste in numerous regions exacerbates this issue, leading to significant amounts of pollutants entering marine ecosystems, where they persist for centuries [4], [5].

Simultaneously, as noted by [6], global population growth has driven an unprecedented rise in the demand for polymeric materials, further amplifying concerns regarding the environmental footprint of plastic waste. In response, circular bioeconomy strategies, described by [7], have gained traction, leveraging renewable biological resources to mitigate the negative impacts associated with conventional plastics. This shift has spurred the development of biodegradable polymeric materials as viable alternatives to petroleum-based plastics [8], [9]. The agro-industrial sectors, as demonstrated by [10], generate considerable amounts of by-products that offer promising feedstocks for the production of bioplastics. However, the commercialization of bioplastics still faces technical barriers, including insufficient mechanical and barrier properties as well as elevated hydrophilicity [11], [12].

Various analytical techniques have been employed to characterize biopolymeric materials. Invasive methods such as X-ray fluorescence, energy dispersive spectroscopy, and thermogravimetric analysis have been used to assess structural composition and biodegradability [13], while non-invasive approaches such as Fourier transform infrared spectroscopy, X-ray diffraction, and scanning electron microscopy have contributed to understanding material properties [14], [15]. More recently, terahertz time-domain spectroscopy (THz-TDS) has emerged as a promising tool for evaluating the crystallinity and structural characteristics of complex starch and fatty acid composites [16].

Among the physical parameters that determine bioplastic quality, film thickness is of paramount importance, as described by [17] and [18]. Thickness plays a crucial role in modulating key properties such as elongation, water vapor transmission rates, tensile strength, and light-blocking capacity [19], [20]. Furthermore, as noted by [21] and [22], thickness influences degradation rates, where a lower surface-to-volume ratio may accelerate biodegradation, and also serves as an indicator of load-bearing capacity and the onset of embrittlement. Control over thickness during fabrication is closely related to the volume of plasticizers and suspended solids used, as well as the quantity of material introduced into the molds [23], [24].

Terahertz time-domain spectroscopy operates within the frequency range of 0.1 to 10 THz, bridging the spectral gap between microwaves and far-infrared radiation, and offering simultaneous insights into both the internal structure and chemical composition of the samples, as described by [25] and [26]. In addition, the integration of chemometric techniques, which leverage mathematical and statistical tools to improve the interpretability of complex spectral data, significantly improves the robustness and reliability of analytical results, as reported by [27].

In this context, THz-TDS has gained attention as a non-invasive tool for characterizing polymeric materials, but its

combination with machine learning for bioplastic analysis is still underdeveloped. In this study, we introduce a novel approach that integrates THz-TDS with four machine learning models—partial least squares regression (PLSR), support vector regression (SVR), binary regression tree (BRT), and a feedforward neural network (FFNN)—to predict the thickness of bioplastic films made from agro-industrial by-products, specifically maize and potato starch. Although previous research has explored chemometric models and THz-TDS independently, the use of FFNN in this application is, to the best of our knowledge, unprecedented. In addition, we applied a model optimization process to improve predictive accuracy and robustness. This integrated methodology offers a new pathway for advancing non-invasive quality control in the production of sustainable packaging materials.

II. Materials and Methods

This section outlines the methodology for the fabrication, analysis, and modeling of bioplastic samples derived from maize and potato starch. The procedure is organized into three subsections: sample fabrication, THz spectroscopy, and regression analysis; see Fig. 1. Each subsection details the experimental steps and provides a rationale for the chosen methods.

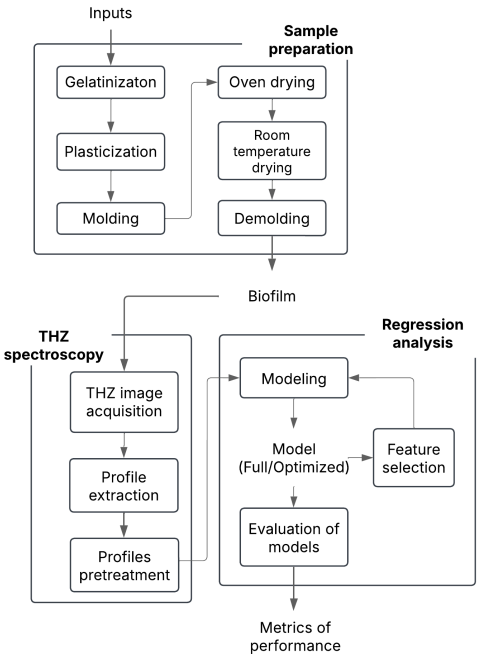

Fig. 1. Workflow of the experimental methodology for bioplastic film thickness estimation. The process includes sample fabrication from potato and maize starch, non-invasive spectral acquisition using THz-TDS, and machine learning-based regression modeling to predict film thickness.

A. Sample Preparation

Bioplastic samples were prepared using an adapted solution casting method based on established protocols [28] and [29]. Raw materials were obtained from a high-purity reagent supplier in Piura, Peru. The formulation consisted of potato starch (PS), maize starch (MS), laboratory-grade polyvinyl alcohol (PVA) (98% purity), technical-grade glycerin (97% purity), and distilled water.

The following procedure details the standardized protocol implemented to ensure uniform experimental conditions and reproducibility of results:

1) Gelatinizaton: Initially, 12 g of starch was gelatinized by dissolving it in 400 ml of distilled water at 70°C for 45 minutes with continuous stirring using a glass rod, ensuring complete dispersion, as indicated by [30].
2) Plasticization: Next, 7 ml of glycerin and 8 g of PVA (pre-diluted in 100 ml of distilled water) were added to plasticize the mixture. The mixture was stirred at 80°C for 45 minutes to enhance mechanical properties [31].
3) Molding: The plastified mixture was then poured into 9-cm-diameter Petri dishes in volumes of 12, 15, and 18 ml.
4) Oven drying: The mixture was dried in an oven at 45°C for 22 hours.
5) Room-temperature drying: An additional drying step was performed at room temperature (24°C in Sullana, Piura) within a desiccator containing blue indicator silica gel for 24 hours.
6) Demolding: Finally, the samples were removed from the Petri dishes and cut into sheets of 1.5 cm × 4.5 cm. Their thickness was determined by averaging measurements from 10 different points using a digital micrometer (range: 0 to 25 mm, resolution: 0.001 mm) [32], [33].

This fabrication process ensured uniform bioplastic films with controlled thickness, setting the stage for subsequent spectral analysis.

B. THz Spectroscopy

The fabricated samples were analyzed using a THz TeraSmart Compact Industry-Proven spectrometer (Germany), see the scheme in Fig. 2a. This device operates in transmission mode under conditions of ambient temperature and relative humidity 50%. The system had a scan range of 850 ps, a resolution of 1.2 GHz, and a spectral range of 6 THz. Each sample was placed in a polylactic acid sample holder mounted on a displacement tower; likewise, data acquisition and conversion to a MATLAB compatible format were managed using software provided by Menlo Systems.

Subsequently, spectral profiles were extracted from intensity images obtained by the spectrometer. The intensity images acquired from the spectrometer were processed in MATLAB (version R2024a, The MathWorks, Inc., USA) to distinguish the sample region from the reference (air), see Fig. 2(b). The images were segmented into nine homogeneous regions of interest (ROIs), and the average spectral pulse was extracted from each ROI, see Fig. 3(a); obtaining 162 THz pulses which were recorded in the time domain.

Finally, these spectral profiles were pre-processed by cropping to isolate the primary signal and eliminate Fabry-Perot (FP) interference (as illustrated in Fig. 3). Fig. 3(a) shows the

(a) Time-domain spectra of bioplastic samples and reference, showing multiple internal reflections that distort the primary pulse, visible as secondary oscillations following the main signal peak. (b) Cropped spectra after isolating the primary pulse and removing Fabry-Perot reflections, enhancing signal clarity for subsequent frequency-domain analysis via FFT. The horizontal axis shows time in picoseconds and the vertical axis shows signal amplitude in millivolts.

complete THz spectra in the time domain within the range of 5 to 9 ps. In contrast, Fig. 3(b) illustrates the cropped spectra, capturing only the primary pulse signal and eliminating FP effects and interference. Finally, the cropped signals were transformed into the frequency domain via a fast Fourier transform (FFT) according to the Eq. 1.

$$E(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} E(t) e^{-i\omega t}\, dt, \tag{1}$$

where $E(t)$ denotes the time-domain pulse and $E(\omega)$ its frequency-domain counterpart.

C. Regression Analysis

Four regression models were used to predict the thickness of the film from the frequency-domain data. The selected models are commented on below: include partial least squares regression (PLSR), binary regression tree (BRT), support vector regression (SVR), and a feedforward neural network (FFNN). Each model was chosen for its ability to manage the complex, multidimensional nature of the spectral data.

- Partial Least Squares Regression: This chemometric method reduces the dimensionality of the data by identifying latent variables that maximize the covariance between the predictors and the response variable [34]. PLSR was implemented using the `plsregress` function with five latent components.

- Binary Regression Tree: BRT is effective for modeling non-linear relationships and complex dependencies between variables [35]. The model was constructed using the `fitrtree` function, with a maximum of 20 node splits and a minimum of one observation per leaf, without pruning.
- Support Vector Regression: SVR adapts the principles of support vector machines for regression tasks [36]. It was implemented using the `fitrsvm` function with a radial basis function (RBF) kernel to capture intricate patterns in the data. Manual hyperparameter tuning was not performed.
- Feedforward Neural Network: This model is widely used to analyze relationships between input and output variables in non-linear datasets [37]. This artificial neural network was constructed with a hidden layer comprising 10 neurons (using a sigmoid activation function) and one output neuron with a linear activation function. The network was developed using the `feedforwardnet` function.

Optimization was carried out using the beta coefficient technique, following the approach described by [38]. Subsequently, these optimized models were applied in all regression analyzes.

Finally, to facilitate comparison of model performance metrics, a five-fold cross-validation procedure was used, repeated 30 times, to assess the generalizability of each model. The performance of the model was evaluated using the coefficient of determination (R^2), root mean square error (RMSE) and the ratio of performance to deviation (RPD). These metrics are further described in [39].

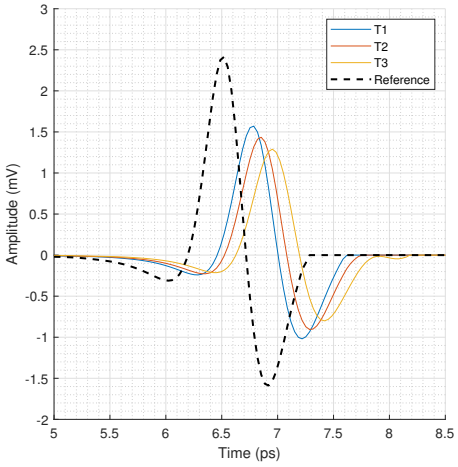
III. Results

This section presents the experimental findings, beginning with a detailed analysis of the spectral responses in the time and frequency domains. Then comes a comprehensive evaluation of the regression models developed to predict film thickness.

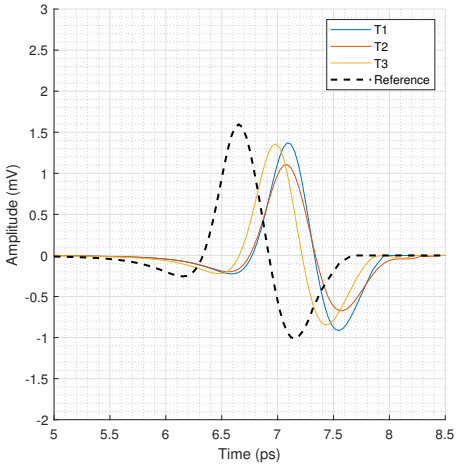
A. THz Spectral Analysis

1) Time-Domain Profiles: Fig. 4 illustrates the time-domain profiles, where the wave amplitudes (in microvolts) are plotted as a function of time (in picoseconds) for three distinct thickness levels of samples fabricated from potato starch, maize starch and an equal proportion mixture (EPM).

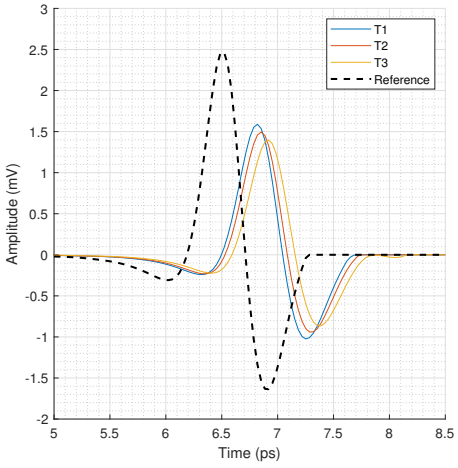
In all cases, the reference signal (air) exhibited a shorter arrival time and higher amplitude compared to the sample signals. In particular, for PS and MS samples, an increase in thickness resulted in a decrease in amplitude and a slight delay in pulse arrival. In contrast, the EPM samples did not exhibit a consistent trend. These observations suggest that the thickness of the film significantly influences the transmittance and signal timing. In summary, the time-domain analysis confirms that thickness variations lead to discernible changes in the THz pulse characteristics.



(a) PS



(b) EPM



(c) MS

Fig. 4. Time-domain terahertz pulse profiles for films with three different thickness levels (T1, T2, T3) fabricated from PS, EPM, and MS.

2) Frequency-Domain Profiles: Fig. 5 displays the corresponding frequency-domain profiles obtained using FFT of the time-domain signals. A semilogarithmic scale was utilized to highlight the onset of spectral noise.

The analysis revealed that thinner samples exhibit higher signal intensity, while thicker samples demonstrate greater absorption, particularly within the 0.5 to 1.2 THz range. This range was identified as the most sensitive to thickness variations and was therefore selected for subsequent regression modeling. Additionally, noise beyond 1.4 THz was consistently observed across all measurements, likely due to ambient humidity absorption. In general, the frequency domain analysis reinforces the influence of sample thickness on spectral response and provides the basis for predictive modeling of film thickness.

B. THz Profile Modeling and Comparison of Statistical Metrics

The predictive performance of four regression models—partial least squares regression, binary regression tree, support vector regression, and a feedforward neural network—was evaluated using the frequency-domain data. Tables I and II present plots comparing the actual versus predicted thickness values for both the full and optimized versions of the models.

Table III summarizes the performance metrics for full and optimized models in each type of sample. Regarding R^2, FFNN and PLSR generally achieved the highest values. In PS samples, FFNN reached 0.9757 $\pm$ 0.0104 and 0.9625 $\pm$ 0.0157 for the full and optimized versions, respectively. In EPM, both FFNN and BRT showed a lower initial performance but improved slightly after optimization. In MS, the optimized PLSR model reached the best R^2 value of 0.9504 $\pm$ 0.0048. For RMSE, the lowest value in PS appeared in the full FFNN model (0.1259 $\pm$ 0.0263), while in EPM, the RMSE values were relatively high in all models. In MS, the optimized PLSR model showed a marked improvement from 0.2351 $\pm$ 0.0039 (full) to 0.1819 $\pm$ 0.0141 (optimized). Regarding RPD, the highest PS value was observed in the full FFNN model, while the EPM values remained between 2.4 and 2.8, indicating the need for further refinement. In MS, the optimized PLSR model increased RPD from 3.4723 $\pm$ 0.0583 (full) to 4.4899 $\pm$ 0.1326, improving robustness.

In general, higher R^2 values corresponded to lower RMSE. In PS, FFNN offered the best balance of R^2 and RMSE, while in EPM, some models achieved relatively high R^2 but retained substantial RMSE. In MS, optimized models improved predictive accuracy without sacrificing generalization capacity. Optimization had a positive effect in most cases, although EPM showed variable improvement, particularly in BRT and FFNN. PLSR in MS presented a substantial gain in R^2 and a decrease in RMSE.

Differences in performance metrics were found for different sample types. PS showed the best results, whereas EPM presented greater predictive challenges. MS offered intermediate performance, which improved considerably with optimization. The best models identified for each sample were FFNN for PS, optimized BRT and FFNN for EPM, and optimized PLSR for MS.

All four models demonstrated solid outcomes, aligning with the limited research on polymer analysis via THz spectroscopy and regression modeling. In particular, [40] evaluated polyethylene mixed with carbendazim, obtaining strong results for SVR (R = 0.9972, RMSEP = 0.02) and PLSR (R = 0.9957, RMSEP = 0.0255). Likewise, [41] predicted antioxidant content in low-density polyethylene films through PLSR ($R^2 = 0.999$), and [42] investigated 2-mercaptobenzimidazole (MB) content in mixtures of MB, zinc oxide, silica, N, N'-Diphenyl-p-phenylenediamine, and nitrile-butadiene using PLSR (R = 0.9269, RMSEC = 2.9108) and SVR (R = 0.9760, RMSEC = 1.6899). No recent research has adopted FFNN or BRT with THz-TDS for polymer analysis. BRT has been used for other sample types with promising results, and FFNN may represent the first instance of combining this model with THz-TDS for polymer analysis.

C. Summary of Results

In summary, the spectral analysis confirms that the thickness of the film substantially influences the characteristics of the THz signal in both the time and the frequency domain. Furthermore, the regression models, particularly PLSR and FFNN, demonstrated strong predictive capabilities, thereby validating the feasibility of using THz-TDS in conjunction with advanced machine learning techniques for the non-invasive determination of bioplastic film thickness.

D. Limitations

This research presents certain limitations that should be considered in future studies. Among these, the following stand out:

- *Sample composition variability:* Variability in sample composition may have influenced spectral response, particularly since factors such as plasticizer type or residual moisture content were not evaluated.
- *THz spectral range:* Only the 0.5 to 1.2 THz range was analyzed, selected due to its sensitivity to thickness changes. Noise levels at frequencies above 1.4 THz limited the full utilization of the available spectral range (0.1 to 10 THz).
- *Modeling approaches:* Although PLSR and FFNN demonstrated good performance, the SVR and BRT models exhibited higher variability, especially for EPM. This variability suggests that model selection should consider the specific type of samples being analyzed.
- *Device operation conditions:* Ambient humidity represents another limitation, as it negatively affects signals at high frequencies and can introduce additional variability in the measurements.
- *Sample shape uniformity:* While THz-TDS successfully identified patterns related to variations in thickness in starch-based bioplastics, its performance may be affected by factors such as sample homogeneity and surface roughness, highlighting the need for complementary analyzes to enhance sample characterization.

IV. Conclusion

This study evaluated the feasibility of integrating THz-TDS with advanced machine learning techniques for the non-invasive prediction of bioplastic film thickness. The experimental results demonstrated that variations in film thickness induce significant changes in both time- and frequency-domain spectral responses. Among the regression models applied, PLSR, SVR, and FFNN provided robust predictions with coefficients of determination exceeding 82%, while the BRT model exhibited greater prediction dispersion and compensation bias.

The findings confirm that the thickness of the film is a critical parameter that influences the mechanical and physical properties of bioplastic materials. The combined approach - using THz-TDS, chemometric analysis, and machine learning - offers a promising, non-invasive quality control method for producing sustainable packaging materials. Model optimization improved predictive performance, particularly for maize starch-based samples, emphasizing the importance of advanced feature selection and parameter tuning.

Future research should focus on refining feature extraction techniques and exploring additional machine learning models to improve predictive accuracy. The application of this integrated methodology may also be extended to other sustainable materials, broadening its impact on environmental preservation and advancing environmentally friendly technologies.

Optimization of IIR Digital Filters Using Differential Evolution: A Comparative Analysis of FDDE and AMECoDEs Algorithms

Wildor Ferrel Serruto
Departamento Académico de Ingeniería Electrónica, Universidad Nacional de San Agustín de Arequipa, Arequipa, Perú

***Abstract*—Infinite impulse response (IIR) digital filters are fundamental components in various digital signal processing applications, particularly those requiring optimized use of computational resources, such as memory and processing power. This study presents the design of classical IIR filters, including low-pass, high-pass, band-pass, and band-stop configurations, as well as multiple-passband filters featuring dual and triple passbands. Two differential evolution algorithms are utilized: FDDE (Differential Evolution Algorithm with Fitness and Diversity Ranking-Based Mutation Operator) and AMECoDEs (Adaptive Multiple-Elites-Guided Composite Differential Evolution Algorithm with a Shift Mechanism). To date, no study has investigated the application of the FDDE algorithm to IIR digital filter design, whereas the AMECoDEs algorithm has seen limited application in this context. Consequently, this work investigates the design of IIR filters using these algorithms and assesses their performance based on the mean squared error (MSE). Comparative analysis reveals that, for classical filters, the FDDE algorithm yields a slightly lower MSE in the magnitude response compared to the AMECoDEs algorithm. Conversely, for multiple-passband filters, the AMECoDEs algorithm outperforms FDDE by achieving a lower MSE. In the proposed model, IIR filters are implemented using a cascade structure of second-order sections (SOS), with their fitness function evaluated based on the MSE, computed using a constant weight function within each frequency band. Additionally, the magnitude response characteristics of the designed filters are compared with those of classical and dual-passband filters designed with the AMECoDEs algorithm in recent studies. The results indicate that the filters designed in this study show significant improvements across most evaluated metrics, particularly in terms of improved stopband attenuation. One of the key contributions of this work is the novel application of differential evolution algorithms to the design of triple-passband IIR filters, demonstrating their effectiveness through successful validation on a development board.**

***Keywords*—IIR digital filter; differential evolution; FDDE algorithm; AMECoDEs algorithm; triple-passband IIR filter**

I. Introduction

Digital filters are integral components of many digital signal processing systems. Because of their ability to manipulate signals flexibly and precisely, digital filters are used in various areas such as audio signal processing [1], [2], digital communications [3], automation and control [4], [5], and biomedical signal processing [6], [7].

The mathematical tools used in the analysis, design, and characterization of digital filters include the transfer function, frequency response, and impulse response, which provide insight into their behavior in both the frequency and time domains. The transfer function of a digital filter takes the form given in Eq. (1):

$$H(z) = \frac{b_0 + b_1 z^{-1} + \ldots + b_P z^{-P}}{1 + a_1 z^{-1} + \ldots + a_Q z^{-Q}} \tag{1}$$

The order of a digital filter is the maximum of the degree of the numerator polynomial and the degree of the denominator polynomial of the transfer function. In Eq. (1), the filter's order is $\max(P, Q)$. Based on the length of the impulse response, digital filters are classified into finite impulse response (FIR) filters and infinite impulse response (IIR) filters. When all the denominator coefficients satisfy $a_1 = a_2 = \ldots = a_Q = 0$ in Eq. (1), the filter is classified as FIR; otherwise, it is classified as IIR.

If an IIR filter is designed while ensuring its stability and an FIR filter is designed with the same specifications—such as identical frequency bands, maximum attenuation in the passbands, and minimum attenuation in the stopbands—the IIR filter will have a lower order compared to the FIR filter. This implies that IIR filters are more computationally efficient in terms of processing time. Due to this advantage, IIR digital filters are widely applied across various domains, including digital equalizer design [8], noise removal from electrocardiogram (ECG) signals [9], [10], [11], signal filtering for perception system sensors in autonomous vehicles [12], and hotspot identification in the COVID-19 disease protein sequence [13], among others. It is important to note that attenuation in decibels (dB) is equal to gain in decibels with the sign reversed.

The design of digital filters is a critical task in various applications, as the quality of the processed signal largely depends on the effectiveness of the applied filter. Methods for designing IIR filters can be classified into two main categories: conventional methods and optimization-based methods [14]. Conventional methods have been extensively studied and rely on mathematical equations and analytical techniques to achieve the desired filter response, typically utilizing analog filter prototypes such as Butterworth, Chebyshev, and elliptic filters. In contrast, optimization-based methods employ algorithms and numerical techniques to determine the filter coefficients that minimize a predefined error criterion, such as the mean squared error. These methods offer greater flexibility in addressing complex design specifications, allowing for the synthesis of

filters that simultaneously satisfy multiple constraints. Consequently, optimization-based approaches have received growing attention in recent literature.

A. Research Contribution

The key contributions of this study are as follows:

- First-time utilization of the FDDE algorithm for the design of IIR digital filters, expanding its applicability within the field of digital signal processing.
- Comparative analysis of the FDDE and AMECoDEs algorithms in the design of classical and multi-passband IIR filters, highlighting their respective advantages.
- Performance assessment of the designed filters based on mean squared error (MSE), computed using a constant weight function within each frequency band, in contrast to previous studies where a linear weight function was employed.
- Novel application of differential evolution algorithms to the design of triple-passband IIR filters, demonstrating their effectiveness through successful validation on a development board.

The remainder of this article is organized as follows: Section II reviews prior works. Section III introduces the Differential Evolution algorithm. Section IV defines the problem addressed in this study. Section V provides a detailed explanation of the FDDE algorithm for IIR digital filter design. Section VI describes the proposed methodology. Section VII presents the experimental results and their analysis. Finally, Section VIII presents the conclusions of the study.

II. Related Works

Recent studies have explored optimization-based approaches for IIR filter design using various techniques, including particle swarm optimization (PSO) [15], which leverages swarm intelligence for global search; multi-objective evolutionary algorithms [16], [17], which optimize multiple conflicting objectives simultaneously; differential evolution (DE) [18], [19], [20], recognized for its balance between exploration and exploitation through mutation and recombination; and sparse linear programming [21], which enforces sparsity constraints to reduce computational complexity. Among these methods, differential evolution has received considerable attention in IIR filter design due to its strong global search capabilities, computational efficiency, and straightforward implementation.

Both Chen et al. [19] and Chen et al. [20] utilize the AMECoDEs algorithm to optimize IIR digital filter design by evolving both structure and coefficients. Chen et al. [19] introduce a subsystem-based structure evolution approach, demonstrating superior performance and faster convergence compared to five state-of-the-art algorithms. Additionally, this method ensures filter stability by maintaining poles within the unit circle. This work focuses on the design of classical IIR filters. Building on this approach, Chen et al. [20] extend the method to dual-passband digital filters, achieving notable improvements in passband ripple, stopband attenuation, and convergence speed compared to previous optimization techniques. A comparative summary is presented in Table I, highlighting the features of optimization approaches for IIR filter design in related works.

Multiple-passband digital filters are widely utilized in various fields, including communications [22] and biomedical signal processing [23]. Consequently, the design of such multiband filters has been an area of research interest for several years. Previous research has explored various methodologies for multiband filter design, employing distinct approaches. In [24], an optimal equiripple FIR filter design method was introduced for triple narrow bandpass and triple narrow notch filters, ensuring Chebyshev-optimal performance. Xiao et al. [25] proposed a fast design technique for multiband IIR filters with a general Chebyshev characteristic, enabling precise control over bandwidths and ripples without increasing filter order. In [26], an algebro-geometric approach was developed to synthesize optimal multiband filters with the lowest possible order, narrow transition bands, and high stopband attenuation. More recently, Wu et al. [27] introduced the DST-O method, a hybrid analytical-optimization approach for multiband IIR filter design, leveraging direct synthesis techniques from analog Chebyshev filters combined with optimization to achieve equal ripple in all passbands.

Building on these advancements, this study extends the scope of IIR filter design beyond classical and dual-passband configurations by introducing the design of triple-passband IIR filters. It emphasizes the effectiveness of differential evolution as an optimization technique, achieving improved stopband attenuation and employing a constant weight function in MSE calculation, rather than the conventional piecewise linear weight function, to enhance filter performance. Table II presents a comparative analysis of design methods for multiband digital filters, revealing that all approaches listed in the table rely on conventional or hybrid design methodologies, whereas our proposed approach is based purely on optimization.

A. Research Gap

To the best of our knowledge, no prior studies have compared the AMECoDEs and FDDE algorithms in designing IIR digital filters to assess their applicability to this problem. Although both algorithms have been used successfully in various optimization tasks, their performance in this context remains unexplored.

Although differential evolution has been successfully applied to classical and dual-passband IIR filters, its potential for more complex designs, such as triple-passband filters, remains largely unexplored, creating a gap in the optimization of higher-order multiband filters.

Moreover, the performance evaluation of IIR filter designs using evolutionary algorithms typically relies on a piecewise linear function. While this approach provides adaptability in certain scenarios, it does not necessarily yield optimal performance in all applications. The impact of employing a constant weight function within each frequency band has not been thoroughly investigated.

III. Differential Evolution

Differential Evolution (DE), originally introduced by Rainer Storn and Kenneth Price [28], is a global optimization

TABLE I. COMPARISON OF FEATURES OF OPTIMIZATION APPROACHES FOR IIR FILTER DESIGN IN RELATED WORKS

Feature	Chen et al. [19]	Chen et al. [20]	This Work
Optimization Algorithms	AMECoDEs	AMECoDEs	AMECoDEs, FDDE
IIR Filter Type	Classical	Dual-passband	Classical, Dual-passband, Triple-passband
Structure Evolution	Yes (subsystem-based)	Yes (subsystem-based)	No
Passband Ripple	Low	Low	Comparable or better
Stopband Attenuation	Good	Good	Improved
Weight Function	Linear piecewise	Linear piecewise	Constant weight function within each frequency band

technique based on biological evolution, employing mutation, crossover, and natural selection to explore optimal solutions in a multi-dimensional search space. Recent advancements in differential evolution algorithms have enhanced the precision and efficiency of objective function optimization [29]. Consequently, these algorithms have been successfully applied in diverse fields, including neural networks [30], [31], control and automation [32], [33], [34], wireless communications [35], [36], and remote sensing [37].

The term "Differential Evolution" is used because it employs differential vectors to guide the search towards better solutions. A differential vector is the difference between two solution vectors in the search space. The basic differential evolution process can be described in the following steps: initialization, differential mutation, crossover, and selection.

In the initialization step, an initial population of random solution vectors is generated within the defined search space. A population of individuals in generation G is represented as $\mathbf{X}^G = \{X_1^G, X_2^G, \ldots, X_{NP}^G\}$. An individual in the population with index i in generation G is represented as ${X_i}^G = \{x_{i,1}^G, x_{i,2}^G, \ldots, x_{i,D}^G\}$, $(i = 1, 2, \ldots, NP)$, where NP is the population size, and D is the dimension of the objective function.

Differential mutation involves generating a mutated vector ${V_i}^G = \{v_{i,1}^G, v_{i,2}^G, \ldots, v_{i,D}^G\}$ for each individual in the population by combining different solutions from the current population through the addition of a differential vector, multiplied by a scale factor, with a selected target solution vector. The mutated vectors form a population represented as $\mathbf{V}^G = \{V_1^G, V_2^G, \ldots, V_{NP}^G\}$. In [38], several mutation strategies are mentioned, of which we describe the following two most commonly used: DE/rand/1 and DE/best/1.

The DE/rand/1 strategy is based on the equation:

$$V_i^G = X_{r1}^G + F \times (X_{r2}^G - X_{r3}^G) \tag{2}$$

The DE/best/1 strategy is described as:

$$V_i^G = X_{best}^G + F \times (X_{r1}^G - X_{r2}^G) \tag{3}$$

where V_i^G is the mutated vector; X_i^G is the individual with index i in generation G; X_{best}^G is the best individual in generation G; F is the scale factor; $r1$, $r2$, and $r3$ are indices in the range $[1, NP]$ such that $r1 \neq r2 \neq r3 \neq i$.

Crossover is performed to introduce genetic diversity into the population. For each individual in the population, a trial vector $U_i^G = \{u_{i,1}^G, u_{i,2}^G, \ldots, u_{i,D}^G\}$ is generated by combining each target vector X_i^G with its corresponding mutated vector V_i^G based on the following equation:

$$u_{i,k}^G = \begin{cases} v_{i,k}^G, & \text{if } rand_{i,k}(0,1) \leq CR \text{ or } k = k_{rand} \\ x_{i,k}^G & \text{otherwise} \end{cases} \tag{4}$$

where $rand_{i,k}(0,1)$ generates a random number in the range $[0,1]$, CR is the crossover rate, and k_{rand} is an integer random value in the range $[1, D]$ that ensures U_i^G is different from X_i^G. The trial vectors form a population represented as $\mathbf{U}^G = \{U_1^G, U_2^G, \ldots, U_{NP}^G\}$.

In the selection stage, the trial vector U_i^G is compared to the target solution vector X_i^G, and the better one is selected to be part of the population in the next generation according to the equation:

$$X_i^{G+1} = \begin{cases} U_i^G, & \text{if } f(U_i^G) \leq f(X_i^G) \\ X_i^G & \text{otherwise} \end{cases} \tag{5}$$

where $f(X_i^G)$ and $f(U_i^G)$ are the fitness values of the target solution vector and its trial vector, respectively. This process is repeated for all individuals in the population. The replacement process ensures that only the most promising solutions are retained in each generation.

The mutation, crossover, and selection steps are repeated for several generations until a termination criterion is met, such as reaching a maximum number of generations or achieving an acceptable optimal solution.

Differential evolution has various variants and adjustable parameters, such as population size, mutation and crossover

strategies, and selection criteria. These parameters influence the balance between exploration and exploitation of the search space, allowing the technique to be adapted to different types of problems and application domains.

One notable variant of differential evolution is the AMECoDEs algorithm, developed by Laizhong Cui et al. and introduced in [39]. This algorithm enhances differential evolution through two key mechanisms. The first is multiple elite-guided mutation, where each individual is influenced simultaneously by two elite solutions, reducing the risk of deception by suboptimal regions. The second is the shift mechanism, designed to mitigate premature convergence and stagnation. By integrating these strategies, AMECoDEs aims to address these issues more effectively than single-elite mutation approaches. Notably, AMECoDEs has recently been applied to the design of IIR digital filters [19] [20].

Another recent variant of differential evolution is the Differential Evolution Algorithm with Fitness and Diversity Ranking-Based Mutation Operator (FDDE), proposed by Jianchao Cheng et al. in [40]. FDDE estimates population diversity based on fitness values, thereby reducing computational overhead. By combining fitness ranking with diversity ranking, it establishes a final ranking that guides the mutation process. This approach ensures an adaptive balance between exploration and exploitation by strategically assigning positions to individuals during mutation. In [40], the authors present experimental results demonstrating the superiority of FDDE over advanced DE variants, including jDE, rank-jDE, SHADE, and L-SHADE, across a range of global optimization benchmarks involving both low- and high-dimensional problems. Given the demonstrated effectiveness of both AMECoDEs and FDDE in optimization tasks, this study compares their performance in the design of IIR digital filters.

Luo et al. [41] recently introduced an enhanced DE algorithm with a hierarchical selection mutation strategy and a distance-based probabilistic selection approach, demonstrating competitive performance across multiple benchmark functions and real-world problems. The recent publication of their work highlights the ongoing interest of the scientific community in the development of advanced Differential Evolution algorithms.

IV. Problem Statement

The general problem in the design of a classic digital filter involves determining the coefficients of the transfer function in Eq. (1) so that the magnitude of the filter's frequency response meets the specifications outlined in a tolerance scheme. This scheme defines the passbands, stopbands, and transition bands, along with the maximum errors allowed in the passbands and stopbands. Typically, there are no specific requirements for the transition bands.

When designing digital filters using evolutionary algorithms, the problem revolves around given the desired magnitude response $|H_d(\omega)|$, finding the coefficients of the filter's transfer function that correspond to a magnitude response as close as possible to the desired one. To quantify how well the designed filter's magnitude response approximates the desired magnitude response, the mean squared error (MSE) is frequently used [42], [43], [44]. Generally, the evolutionary process seeks to minimize the mean squared error.

In this study, the input to the IIR digital filter design procedure is the desired magnitude response, while the output is the optimal filter obtained at the conclusion of the evolutionary process. Table III presents the passbands ($|H_d(\omega)| = 1$) and stopbands ($|H_d(\omega)| = 0$) of the filters to be designed, expressed in normalized frequency units. In this normalization, the sampling frequency f_s is mapped to 2π. The considered filter types include classical low-pass, high-pass, band-pass, and band-stop filters, as well as symmetrical and asymmetrical dual-passband and triple-passband filters.

The frequency specifications for the asymmetrical triple-passband filter, as listed in Table III, are as follows: The filter features three passbands: $[0.1\pi, 0.2\pi]$, $[0.4\pi, 0.5\pi]$ and $[0.7\pi, 0.9\pi]$; four stopbands: $[0, 0.05\pi]$, $[0.25\pi, 0.35\pi]$, $[0.55\pi, 0.65\pi]$, and $[0.95\pi, \pi]$; and six transition bands: $(0.05\pi, 0.1\pi)$, $(0.2\pi, 0.25\pi)$, $(0.35\pi, 0.4\pi)$, $(0.5\pi, 0.55\pi)$, $(0.65\pi, 0.7\pi)$, and $(0.9\pi, 0.95\pi)$.

In this work, each filter type specified in Table III was designed using the differential evolution algorithms FDDE and AMECoDEs. The performance of these filters was then evaluated based on the mean squared error of their magnitude responses. To ensure a fair comparison, the implementations of the FDDE and AMECoDEs algorithms for IIR digital filter design operated under uniform general conditions, including identical filter representation, the same fitness evaluation algorithms, and identical weight functions.

Subsequently, the classic and dual-passband filters designed in this work were compared with IIR filters presented in two recent studies [19], [20]. However, since not all general conditions were identical in this case, the comparison was based on the characteristics of the filters' magnitude responses. Finally, the designed triple-passband filters were experimentally validated using a development board.

In the following section, the FDDE algorithm applied to the design of IIR digital filters is described. The AMECoDEs algorithm is not detailed, as it has already been applied for this purpose in [19] and [20].

V. FDDE Algorithm for the Design of IIR Digital Filters

The FDDE algorithm, described in this section, was originally introduced by Cheng et al. [40]. This algorithm has been adapted for the evolution of IIR digital filters, as shown in Algorithm V.

The algorithm begins by randomly generating an initial population, $\mathbf{X}^0$, consisting of NP filters, as described in subsection VI-B. Next, the fitness of each filter is evaluated. The evolutionary process then iterates until the maximum number of generations (MNG) is reached. During each iteration, the following operations are performed:

- The final ranking of the filters in the population $\mathbf{X}^G$ is determined.
- The filters are sorted in ascending order according to the final ranking.

TABLE III. DESIRED MAGNITUDE RESPONSE OF THE DESIGNED FILTERS

Filter class	Filter type	Band (π)		$\lvert H_d(\omega)\rvert$
		From	*To*	
Classic filters	Low-pass	0	0.45	1
		0.5	1	0
	High-pass	0	0.3	0
		0.35	1	1
	Band-pass	0	0.3	0
		0.35	0.65	1
		0.7	1	0
	Band-stop	0	0.3	1
		0.35	0.65	0
		0.7	1	1
Multiple-passband filters	Symmetrical dual-passband	0	0.05	0
		0.15	0.35	1
		0.45	0.55	0
		0.65	0.85	1
		0.95	1	0
	Asymmetrical dual-passband	0	0.05	0
		0.15	0.45	1
		0.55	0.65	0
		0.75	0.85	1
		0.95	1	0
	Symmetrical triple-passband	0	0.05	0
		0.1	0.2	1
		0.25	0.35	0
		0.4	0.6	1
		0.65	0.75	0
		0.8	0.9	1
		0.95	1	0
	Asymmetrical triple-passband	0	0.05	0
		0.1	0.2	1
		0.25	0.35	0
		0.4	0.5	1
		0.55	0.65	0
		0.7	0.9	1
		0.95	1	0

- For each filter X_i^G, the following operations are performed: The mutated filter V_i^G is obtained (Line 7 in Algorithm V), the trial filter U_i^G is obtained through the crossover operation between X_i^G and V_i^G (Lines 8-15 in Algorithm V). The fitness of the trial filter U_i^G is calculated, which is compared to the fitness of X_i^G, and the filter with the lower fitness is retained for the next generation (Lines 17-23 in Algorithm V).
- The number of generation is updated: $G = G + 1$.

In Algorithm V, for each value of i and k, the function $rand_{i,k}(0,1)$ generates a random real number in the interval $[0,1]$. The function $rand(1,D)$ produces a random integer in the interval $[1,D]$, where D is the number of second-order sections, and CR is the crossover rate. The representations $x_{i,k}^G$, $v_{i,k}^G$, $u_{i,k}^G$ $(k = 1,2,\ldots,D)$ are the second-order sections that make up the filters X_i^G, V_i^G, U_i^G, respectively.

A. Final Ranking Evaluation

The FDDE algorithm, before performing the mutation operation, requires that the population be sorted according to the final ranking. In [40], the final ranking is referred to as the combination of fitness ranking and diversity ranking. Below, we describe the process of obtaining the final ranking:

Algorithm 1: The FDDE Algorithm for IIR Filter Design Adapted from [40]

Input: $|H_d(\omega_n)|$ is the desired magnitude response $(n = 0,1,2,\ldots,N-1)$
Output: X_{best} is the best-found filter with fitness f_{best}
Data: w_n is the weight vector $(n = 0,1,2,\ldots,N-1)$

1 Generate an initial filter population randomly $\mathbf{X}^0 = \{X_1^0, X_2^0, \ldots, X_{NP}^0\}$ and set the generation $G = 0$;
2 Evaluate fitness value $f_i = f(X_i^0)\ \ (i = 1,2,\ldots,NP)$;
3 **while** $(G < MNG)$ **do**
4 Calculate the final ranking of each filter in population $\mathbf{X}^G$ according to subsection V-A ;
5 Sort population $\mathbf{X}^G$ in ascending order according to final ranking;
6 **for** $i = 1$ *to* NP **do**
7 For each filter X_i^G, obtain the mutated filter V_i^G according to subsection V-B;
8 Generate an integer number randomly $k_{rand} = rand(1,D)$;
9 **for** $k = 1$ *to* D **do**
10 **if** $rand_{i,k}(0,1) \le CR$ *or* $k = k_{rand}$ **then**
11 $u_{i,k}^G = v_{i,k}^G$;
12 **end**
13 **else**
14 $u_{i,k}^G = x_{i,k}^G$;
15 **end**
16 **end**
17 Evaluate fitness value $f(U_i^G)$;
18 **if** $f({U_i}^G) \le f({X_i}^G)$ **then**
19 ${X_i}^{G+1} = {U_i}^G$;
20 **end**
21 **else**
22 ${X_i}^{G+1} = {X_i}^G$;
23 **end**
24 **end**
25 $G = G + 1$;
26 **end**

The filters in population $\mathbf{X}^G$ are arranged in ascending order based on their fitness. Then, the fitness ranking is computed using the equation:

$$FR_i = i, \ \ (i = 1,2,...,NP) \tag{6}$$

Before calculating the deviation for each filter, the filter whose fitness ranking is $FR_i = NP/2$ is determined, and the value of its fitness is denoted as f_{mid}. Then, for each filter in the population, the deviation is calculated using the equation:

$$f_{de,i} = |f_i - f_{mid}|, \ \ (i = 1,2,...,NP) \tag{7}$$

After sorting the population in ascending order based on deviation, the diversity ranking for each filter is calculated using the equation:

$$DR_i = NP - i, \quad (i = 1, 2, ..., NP) \tag{8}$$

Finally, the fitness ranking and diversity ranking are combined to obtain the final ranking using the equation:

$$R_i = w \times DR_i + (1 - w) \times FR_i, \quad (i = 1, 2, ..., NP) \tag{9}$$

where $w = \frac{G}{MNG}$. In this expression, G is the current generation number, and MNG is the maximum number of generations. It can be observed that, according to Eq. (9), in the early generations of the evolutionary process, the final ranking depends more on the fitness ranking, and in the later generations, it depends more on the diversity ranking. The name of the FDDE algorithm is precisely because the mutation operation depends on the final ranking.

B. Mutation Operation

For each filter X_i^G, the mutation operation is performed using the "DE/rand/1" strategy, for which the integer values $r1$, $r2$, and $r3$ are randomly selected within the range $[1, NP]$ such that $r1 \neq r2 \neq r3 \neq i$, and the filters X_{r1}^G, X_{r2}^G, X_{r3}^G are sorted in ascending order based on their final ranking values R_{r1}, R_{r2}, R_{r3}. If the sorted filters are represented as X_{t1}^G, X_{t2}^G, X_{t3}^G, then the mutated filter V_i^G is calculated using the following equation:

$$V_i^G = X_{t1}^G + F \times (X_{t2}^G - X_{t3}^G) \tag{10}$$

where the scale factor F, with a probability of $CFP = 0.7$, is a fixed value equal to $CF = 0.5$; and with a probability of $1 - CFP = 0.3$, is equal to $4 \times (factor - 0.5)$, where $factor$ is a random real number in the range from 0 to 1.

VI. Methodology

This section outlines the approach employed for designing IIR digital filters using the differential evolution algorithms FDDE and AMECoDEs. Specifically, it details the representation of the IIR filter structure, the initialization of candidate solutions, the formulation of the fitness function, the applied weight function, the determination of C_{stop}, and the construction of the comparative table.

A. Filter Representation

A digital IIR filter is represented as a serial connection of second-order sections (SOS). This representation is employed in various models and applications, for instance, in the works [45], [46], IIR filters are implemented in FPGA using this representation.

The transfer function of the filter X_i^G, belonging to the population $\mathbf{X}^G = \{X_1^G, X_2^G, \ldots, X_{NP}^G\}$, is expressed as the product of the transfer functions of the second-order sections, as shown in the equation:

$$H_{X_i^G}(z) = \prod_{k=1}^{D} \frac{b_{i,k,0}^G + b_{i,k,1}^G \cdot z^{-1} + b_{i,k,2}^G \cdot z^{-2}}{1 + a_{i,k,1}^G \cdot z^{-1} + a_{i,k,2}^G \cdot z^{-2}} \tag{11}$$

where D is the number of sections.

To describe mutation and crossover operations, the IIR filter X_i^G (i is the index within the filter population) is represented through its second-order sections in matrix form as follows:

$$X_i^G = \begin{bmatrix} x_{i,1}^G \\ x_{i,2}^G \\ \vdots \\ x_{i,D}^G \end{bmatrix} = \begin{bmatrix} b_{i,1,0}^G & b_{i,1,1}^G & b_{i,1,2}^G & 1 & a_{i,1,1}^G & a_{i,1,2}^G \\ b_{i,2,0}^G & b_{i,2,1}^G & b_{i,2,2}^G & 1 & a_{i,2,1}^G & a_{i,2,2}^G \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ b_{i,D,0}^G & b_{i,D,1}^G & b_{i,D,2}^G & 1 & a_{i,D,1}^G & a_{i,D,2}^G \end{bmatrix} \tag{12}$$

where $x_{i,k}^G$ represents the second-order section with index k with numerator polynomial coefficients $b_{i,k,0}^G$, $b_{i,k,1}^G$, $b_{i,k,2}^G$ and denominator polynomial coefficients 1, $a_{i,k,1}^G$, $a_{i,k,2}^G$.

In this work, throughout the evolutionary process, each second-order section is generated and maintained as a stable system. This implies that the poles of the transfer function for the second-order section remain within the unit circle. Consequently, if during the mutation operation, the distance r from a pole to the origin exceeds 1, its magnitude is adjusted using the following equation while preserving its angle:

$$1 - (1/r) \tag{13}$$

B. Initial Filter Population

Each filter in the initial filter population ($G = 0$) is generated in the following way:

In each second-order section $x_{i,k}^0$, the numerator polynomial coefficients are real random numbers with an absolute value less than or equal to 1, determined by the equation:

$$\begin{aligned} b_{i,k,0}^0 &= rand(-1, 1); \\ b_{i,k,1}^0 &= rand(-1, 1); \\ b_{i,k,2}^0 &= rand(-1, 1) \end{aligned} \tag{14}$$

The denominator polynomial coefficients of $x_{i,k}^0$ are obtained from a complex number $re^{j\varphi}$, which is one of the roots of the polynomial, using operations that ensure the second-order section is stable:

$$\begin{aligned} r = rand(0, 1),\ 0 \leq r < 1;\ \varphi = rand(-\pi, \pi); \\ ; a_{i,k,0}^0 = 1;\ a_{i,k,1}^0 = -2r \cdot cos(\varphi);\ a_{i,k,2}^0 = r^2 \end{aligned} \tag{15}$$

Algorithm 2: IIR Filter Fitness Evaluation

Input: X_i^G is the digital IIR filter represented in terms of second-order sections.
Output: Filter fitness $f(X_i^G)$.
Data: $\omega = \{\omega_n\}$ is the frequency vector, $|H_d(\omega_n)|$ is the desired magnitude response, w_n is the weight vector $(n = 0, 1, ..., N-1)$, X_{best} is the best-found filter, f_{best} is the fitness of the best-found filter.

Calculate the frequency response of the filter $H_{X_i^G}(\omega_n)$ $(n = 0, 1, ..., N-1)$ using Eq. (16);
Calculate the fitness $f(X_i^G)$ as the mean squared error using Eq. (17);
if $f(X_i^G) < f_{best}$ **then**
  $X_{best} = X_i^G$, $f_{best} = f(X_i^G)$;
end

C. Fitness Evaluation

In this work, as the fitness function of an IIR filter, we employ the Weighted Mean Squared Error (WMSE) of the filter's magnitude response in comparison to the desired magnitude response. Henceforth, we will simply refer to it as the Mean Squared Error (MSE).

To determine the fitness of a digital IIR filter, it is necessary to define the discrete-time frequencies at which the frequency response will be evaluated. We set up N equally spaced frequencies in the interval from 0 to π, forming the set $\omega = \{\omega_n\} = \{\frac{\pi\, n}{N-1}\}$ $(n = 0, 1, ..., N-1)$. N is the number of sampling points.

Given a digital IIR filter X_i^G, its frequency response at the frequencies in the set ω is calculated as the product of the frequency responses of the second-order sections using the equation:

$$H_{X_i^G}(\omega_n) = \prod_{k=1}^{D} \frac{b_{i,k,0}^G + b_{i,k,1}^G \cdot e^{-j\omega_n} + b_{i,k,2}^G \cdot e^{-2j\omega_n}}{1 + a_{i,k,1}^G \cdot e^{-j\omega_n} + a_{i,k,2}^G \cdot e^{-2j\omega_n}}, \quad (n = 0, 1, ..., N-1) \tag{16}$$

The mean squared error of the filter's magnitude response X_i^G is calculated using the equation:

$$f(X_i^G) = \frac{1}{N} \sum_{n=0}^{N-1} w_n \cdot (\left|H_{X_i^G}(\omega_n)\right| - |H_d(\omega_n)|)^2 \tag{17}$$

where $|H_d(\omega_n)|$ is the desired magnitude response at frequency ω_n. The values w_n $(n = 0, 1, \ldots, N-1)$ constitute the weight function.

The fitness evaluation procedure is outlined in Algorithm VI-C. In the final step, each time the fitness of a filter is calculated, the result is compared to the fitness of the best-found filter. If the obtained result is lower, then the best-found filter is updated.

D. Weight Function

The weight function, denoted as w_n in Eq. (17), represents a sequence of values utilized for assigning varying degrees of significance to the mean square errors associated with individual frequencies, ω_n.

In the works [19], [20], the weights follow a discrete linear piecewise function with peak values at frequencies 0, π, and at the centers of transition bands; and with minimum values at the centers of passbands and stopbands. In these studies, the authors contend that the linearity of the weight function ensures that the weights of neighboring sampling points change gradually, without discontinuities, as a sharp change in the weights leads to a significant variation in the magnitude response.

In the present study, a simple weight function has been employed, which remains constant within each band. To prevent substantial changes in the magnitude response, the weight corresponding to the suppression bands has been experimentally selected. The weights used are: In the transition bands, it is $w_n = C_{\text{tran}} = 0$, as there is no specific requirement within these bands. In the passbands, it is $w_n = C_{\text{pass}} = 1$, as we aim for the designed filter to closely match the desired magnitude response within these bands. In the stopbands, a value $w_n = C_{\text{stop}}$ greater than 1 is chosen to indicate the importance of attenuation within these bands, and non-compliance with this specification is penalized.

E. Determination of C_{stop} and Comparative Table Generation

For each filter type specified in Table III, the following stages were carried out:

Utilizing the constant piecewise weight function with $w_n = C_{\text{tran}} = 0$, $w_n = C_{\text{pass}} = 1$, and $w_n = C_{\text{stop}}$, the design program based on the FDDE algorithm was executed for five different values of C_{stop}, which were empirically adjusted. Given the probabilistic nature of the evolutionary process, the program was run ten times for each C_{stop} value, and the solution with the lowest mean square error was selected from the ten outcomes. To determine a final filter among the five designed for different C_{stop} values, the primary selection criterion was to maximize the minimum attenuation in the stopbands while maintaining relatively low passband ripple. Table IV presents the evaluated values of C_{stop} along with the selected value for each filter type.

With $C_{\text{pass}} = 1$, $C_{\text{tran}} = 0$, and the C_{stop} value, selected in the previous stage, the design program using the AMECoDEs algorithm has been executed 10 times. The result with the lowest mean square error was selected from the 10 outcomes.

The mean square error of the magnitude response obtained with the AMECoDEs algorithm in the previous stage has been compared to that obtained with the FDDE algorithm. The comparison is detailed in Table V.

VII. Experimental Results and Discussion

A. Comparison of Filters Designed using the FDDE and AMECoDEs Algorithms

Table V indicates that both algorithms produce identical MSE values for low-pass and band-stop filters. For high-pass

TABLE IV. EVALUATED AND SELECTED C_{STOP} VALUES FOR EACH FILTER TYPE

Filter type	C_{stop}					Selected value
Low-pass	300	500	700	900	1100	1100
High-pass	300	500	700	900	1100	1100
Band-pass	3	4	5	6	7	4
Band-stop	4	8	12	16	20	12
Symmetric dual-passband	4	8	12	16	20	12
Asymmetric dual-passband	4	8	12	16	20	16
Symmetric triple-passband	20	30	40	50	60	60
Asymmetric triple-passband	20	30	40	50	60	40

TABLE V. COMPARISON OF MEAN SQUARED ERROR FOR FILTERS DESIGNED USING THE FDDE AND AMECODES ALGORITHMS

Filter class	Filter type	MSE		Best
		FDDE $\times 10^{-4}$	*AMECoDEs* $\times 10^{-4}$	
Classic filters	Low-pass	1.11480	1.11480	=
	High-pass	0.53937	0.53939	FDDE
	Band-pass	4.84230	6.10280	FDDE
	Band-stop	8.94030	8.94030	=
Multiple-passband filters	Symmetrical dual-passband	0.51522	0.47240	AMECoDEs
	Asymmetrical dual-passband	1.04140	0.17376	AMECoDEs
	Symmetrical triple-passband	43.00300	11.05200	AMECoDEs
	Asymmetrical triple-passband	21.52700	7.90040	AMECoDEs

and band-pass filters, the FDDE algorithm exhibits a slight improvement. In contrast, the AMECoDEs algorithm demonstrates marginally better performance for the symmetric dual-passband filter. Notably, AMECoDEs achieves a significantly lower MSE for the asymmetric dual-passband filter, as well as for both symmetric and asymmetric triple-passband filters.

The magnitude response curves of the designed filters are presented in Fig. 1 to 8. It is observed that, for low-pass, high-pass, band-stop, and symmetric dual-passband filters, the curves generated by the AMECoDEs and FDDE algorithms display a high degree of similarity. The curve of the band-pass filter designed with FDDE algorithm is better than the one designed with AMECoDEs algorithm. However, the curves of the asymmetric dual-passband and the both symmetric and asymmetric triple-passband filters designed with AMECoDEs algorithm exhibit significantly better attenuation in the stop-bands.

B. Comparison of the Designed Filters with Previous Studies

The filters designed in this study using the FDDE and AMECoDEs algorithms have been compared with those presented in [19] (classic filters) and [20] (dual-passband filter). The design conditions in these prior works do not fully align with those employed in our research. For instance, the previous studies utilized optimized structures and a piecewise discrete linear weight function. As a result, the comparison was

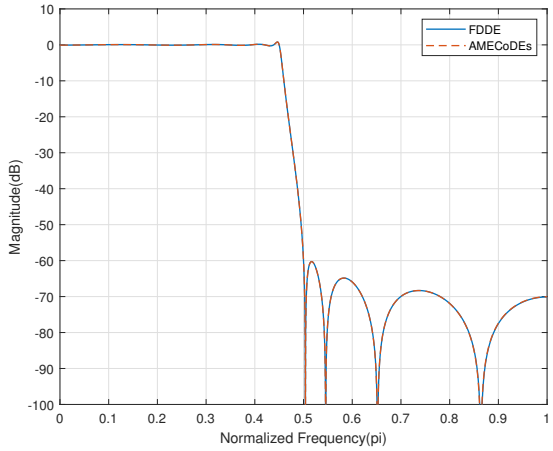

Fig. 1. Magnitude response of the low-pass filter designed using FDDE and AMECoDEs algorithms.

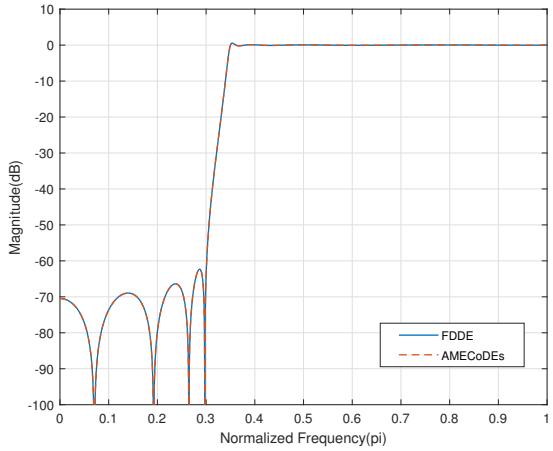

Fig. 2. Magnitude response of the high-pass filter designed using FDDE and AMECoDEs algorithms.

conducted based on the magnitude response characteristics of the filters, as shown in Tables VI and VII.

In these tables, "AMECoDEs 1" refers to the filter designed in [19] or [20], while "AMECoDEs 2" and "FDDE" denote the filters developed in this study using the respective algorithms. It is important to highlight that AMECoDEs 1 and AMECoDEs 2 originate from the same evolutionary algorithm but differ in the specific conditions and parameters applied during their design. Therefore, rather than referring to them as distinct algorithms, they will be considered different design approaches in this comparison.

In Table VI, it can be observed that in the high-pass filter and the band-stop filter, the passband ripples, represented as δ_{pass}, of the filters designed with AMECoDEs 2 and FDDE approaches are slightly smaller compared to the filters designed with AMECoDEs 1 approach, while in the low-pass filter and the band-pass filter, they are larger. The widths of the transition bands, represented as $\Delta\omega$, are slightly smaller in most cases with the AMECoDEs 2 and FDDE approaches. In

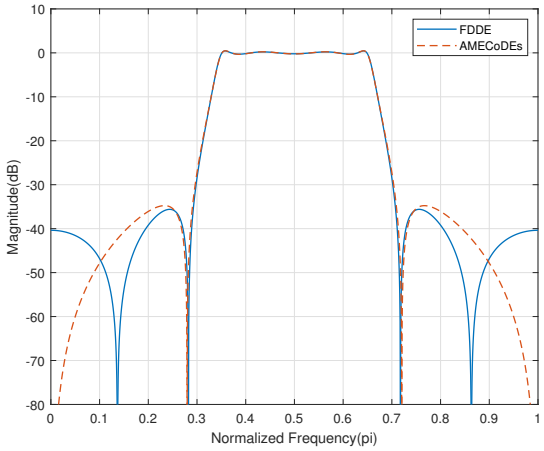

Fig. 3. Magnitude response of the band-pass filter designed using FDDE and AMECoDEs algorithms.

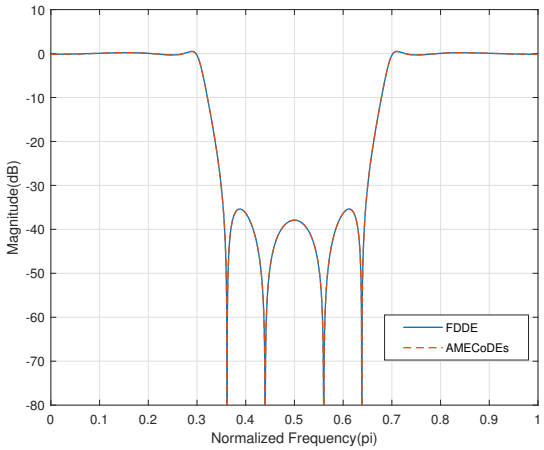

Fig. 4. Magnitude response of the band-stop filter designed using FDDE and AMECoDEs algorithms.

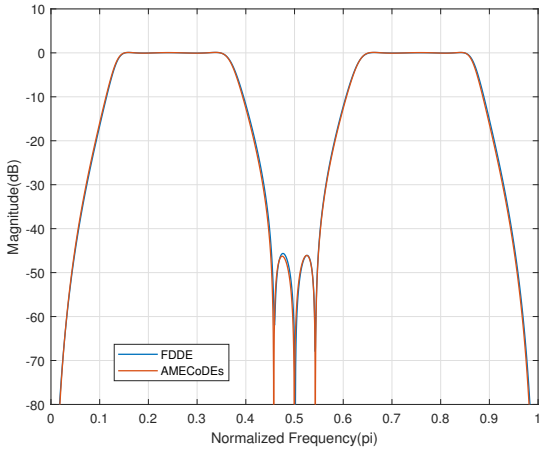

Fig. 5. Magnitude response of the symmetrical dual-passband filter designed using FDDE and AMECoDEs algorithms.

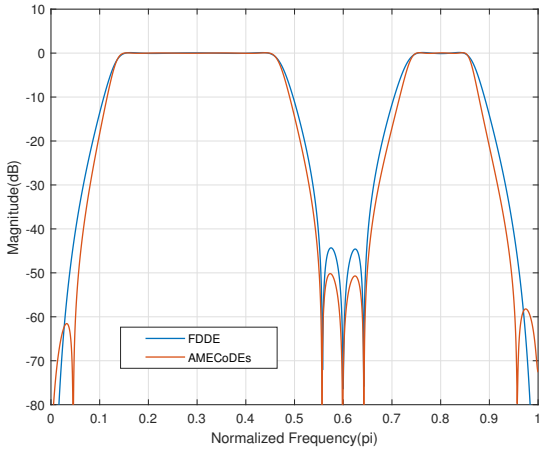

Fig. 6. Magnitude response of the asymmetrical dual-passband filter designed using FDDE and AMECoDEs algorithms.

almost all cases, the attenuation in the stopbands, denoted as A_{stop}, of the filters obtained with AMECoDEs 2 and FDDE approaches is approximately 5dB higher compared to the stopband attenuation of the filters obtained with AMECoDEs 1 approach. Similarly, from Table VII, it is clear that the ripple values in the passbands of the dual-passband filters are smaller with the AMECoDEs 2 and FDDE approaches, except for the ripple in passband 2 of the asymmetric dual-passband filter, where it is larger with FDDE approach. Additionally, the attenuation values in all stopbands are higher by 13dB with the AMECoDEs 2 and FDDE approaches compared to those obtained with AMECoDEs 1 approach.

Table VI reveals that for the high-pass and band-stop filters, the passband ripple is slightly lower in the filters designed using the AMECoDEs 2 and FDDE approaches compared to those designed with the AMECoDEs 1 approach. Conversely, for the low-pass and band-pass filters, the passband ripple is slightly higher. The transition band widths tend to be marginally narrower in most cases when employing the AMECoDEs 2 and FDDE approaches. Moreover, in nearly all cases, the stopband attenuation of filters designed using the AMECoDEs 2 and FDDE approaches is approximately 5 dB higher than that of filters obtained with the AMECoDEs 1 approach.

Similarly, Table VII indicates that the passband ripple of dual-passband filters is generally lower when using the AMECoDEs 2 and FDDE approaches, with the exception of passband 2 in the asymmetric dual-passband filter, where the ripple is higher when employing the FDDE approach. Furthermore, the attenuation in all stopbands is consistently higher by 13 dB in filters designed using the AMECoDEs 2 and FDDE approaches compared to those obtained with the AMECoDEs 1 approach.

The parameters of the AMECoDEs 1, AMECoDEs 2, and FDDE approaches are presented in Table VIII. One can observe that the parameters of AMECoDEs 2 and FDDE are largely similar, except for those specific to the AMECoDEs algorithm, which are absent in FDDE. In Table VIII, p, c,

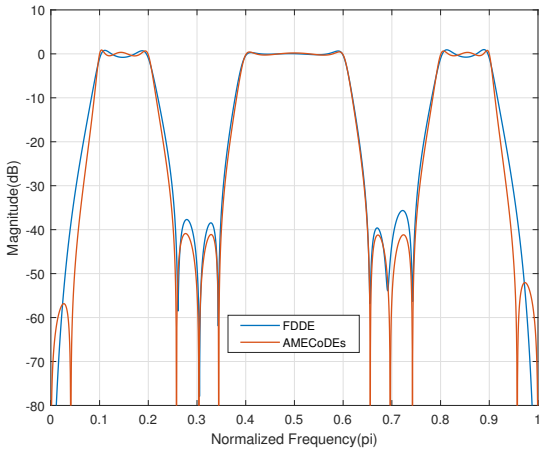

Fig. 7. Magnitude response of the symmetrical triple-passband filter designed using FDDE and AMECoDEs algorithms.

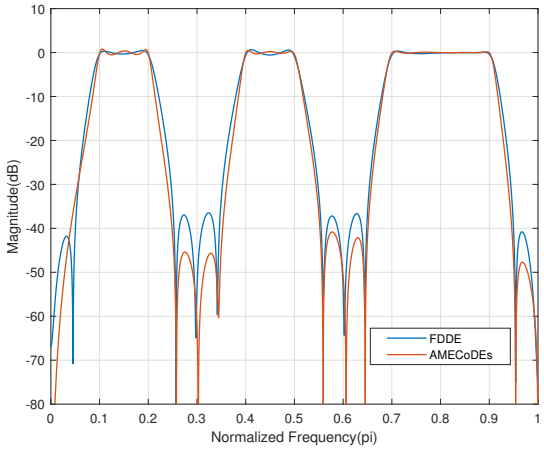

Fig. 8. Magnitude response of the asymmetrical triple-passband filter designed using FDDE and AMECoDEs algorithms.

ϵ, $\mu^0_{F,M1}$, $\mu^0_{CR,M1}$, $\mu^0_{F,M2}$, and $\mu^0_{CR,M2}$ correspond to the original AMECoDEs algorithm described in [39].

There are some differences between the AMECoDEs 1 and AMECoDEs 2 approaches. In AMECoDEs 1, the weight function follows a piecewise discrete linear form, whereas in AMECoDEs 2, it remains constant within each band. The filter structure also differs between the two methods: AMECoDEs 1 employs randomly connected subsystems in cascade or parallel, with the configuration evolving throughout the optimization process, whereas AMECoDEs 2 maintains a fixed structure consisting of a serial connection of second-order sections. Additionally, in AMECoDEs 1, each second-order section (SOS) utilizes a first-order numerator biquad, requiring some zeros of the transfer function to be located at the origin. In contrast, AMECoDEs 2 employs a full biquad with a second-degree numerator polynomial, offering greater flexibility in zero placement during evolution. Another key distinction lies in the computation of the mean squared error: AMECoDEs 1 uses 128 sampling points, while AMECoDEs 2 employs 101.

TABLE VI. CHARACTERISTICS OF CLASSICAL FILTERS DESIGNED USING AMECODES 1, AMECODES 2, AND FDDE APPROACHES

Filter type	Characteristic	AMECoDEs 1 [a]	AMECoDEs 2	FDDE

C. Analysis of the Designed Triple-Passband IIR Filters

For the triple-bandpass filters, both symmetric and asymmetric, designed using the FDDE and AMECoDEs algorithms, the mean squared errors are compared in Table V. The magnitude responses of these filters are also compared in Fig. 7 and 8. The comparison results indicate that the AMECoDEs algorithm achieves a lower mean squared error, which is reflected in higher minimum attenuation levels in the stopbands.

For the asymmetric triple-bandpass filter designed using the AMECoDEs algorithm, the maximum attenuations in the passbands and the minimum attenuations in the stopbands were determined, yielding the following values: the maximum attenuations in the three passbands, from left to right, are 1.3,

TABLE VIII. PARAMETERS OF THE AMECODES 1, AMECODES 2, AND FDDE APPROACHES

Parameter	Approach		
	AMECoDEs 1	***AMECoDEs 2***	***FDDE***
Population size (NP)	100	100	100
Maximum number of generations (MNG) (in thousands): (classic, dual-passband, triple-passband)	(100, 10, -)	(40, 40, 80)	(40, 40, 80)

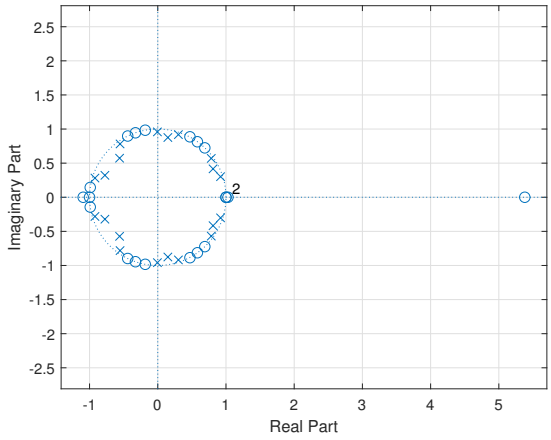

Fig. 9. Pole-zero diagram of the asymmetrical triple-passband filter designed using the AMECoDEs algorithm.

0.8, and 0.4 dB, while the minimum attenuations in the four stopbands, in the same order, are 33, 45, 41, and 48 dB. For this filter, the pole-zero diagram of the filter's transfer function is presented in Fig. 9, where its stability is verified, as all poles are located within the unit circle. Additionally, Table X provides the coefficients of the second-order sections of the filter: b_0, b_1, and b_2 correspond to the numerator coefficients, whereas a_0, a_1, and a_2 represent the denominator coefficients for each second-order section.

To evaluate the filter's performance, it was implemented on the OMAP-L138 LCDK development board using a serial structure of second-order sections, each in the transposed direct form II, with a sampling frequency of 16 kHz. A white noise signal was applied to the filter's input, whose spectrum is shown in Fig. 10a, and the spectrum of the filter's output signal was obtained, as depicted in Fig. 10b. Considering that the white noise signal has a finite duration and its spectrum is not perfectly flat, it can be concluded that the output signal spectrum closely approximates the filter's magnitude response shown in Fig. 8, thereby validating the proper operation of the triple-bandpass filter. The spectra were obtained using the Audacity software.

Table IX presents a summary of the comparison between the contributions of this work and those of recent related studies.

D. Limitations of the Proposed Study

One of the primary limitations of this study is that the filter order must be predetermined before applying the AMECoDEs or FDDE algorithms. For instance, in our work, the filter order was set to 8 for classical IIR filters (4 SOS) and 14 for dual-passband IIR filters (7 SOS), consistent with the previous studies used for comparison. While this approach ensures a fair and direct performance comparison, it restricts the flexibility of the optimization process. Ideally, the filter order could be treated as an additional parameter to be optimized within the evolutionary process itself.

Another limitation concerns the selection of constant weight function for the mean squared error calculation. In our study, we assigned values as follows: $C_{\text{pass}} = 1$ (passband weight), $C_{\text{tran}} = 0$ (transition band weight), and C_{stop} (stopband weight). The value of C_{stop} was empirically adjusted, as described earlier. While this method provided satisfactory results, an optimal selection of C_{stop} could enhance the overall performance of the filter design. A more effective approach would be to incorporate the determination of C_{stop} within the evolutionary optimization process itself, allowing the algorithm to adaptively select the most suitable weight.

VIII. CONCLUSION

In this study, infinite impulse response (IIR) digital filters were designed using the differential evolution algorithms

Fig. 10. Spectrum comparison before and after filtering with the OMAP-L138 LCDK.

AMECoDEs and FDDE. The designed filters encompass both classical filters—low-pass, high-pass, band-pass, and band-stop filters—as well as multi-passband filters, including symmetric dual-passband, asymmetric dual-passband, symmetric triple-passband, and asymmetric triple-passband filters. A structure based on a serial connection of second-order sections was adopted for their implementation. The fitness evaluation criterion was the mean squared error (MSE), computed using a constant weight function within each frequency band.

The theoretical contribution of this study is the adaptation of the FDDE algorithm, initially proposed in a general framework by Jianchao Cheng et al. in [40], to the design of IIR digital filters, expanding its applicability within digital signal processing. Additionally, the comparative analysis between FDDE and AMECoDEs algorithms offers new insights into their respective advantages and trade-offs, particularly in designing classical and multi-passband filters. On the practical side, the developed filters are applicable to various signal processing tasks, including audio processing, biomedical signal analysis, communication systems, and industrial control, demonstrating the real-world utility of the proposed approach.

This study presents four key contributions at the intersection of evolutionary algorithms and digital signal processing: (1) the novel adaptation of the FDDE algorithm for IIR digital filter design, expanding its applicability to signal processing applications; (2) a comparative analysis of the FDDE and AMECoDEs algorithms for classical and multi-passband IIR filters, highlighting their respective advantages in optimization performance; (3) the use of a fitness evaluation based on the mean squared error, calculated with a constant weight function within frequency bands, in contrast to previous methodologies that employed a linear weight function; and (4) the first implementation of differential evolution algorithms for triple-passband IIR filter design, validated through successful experimental implementation on a hardware development board.

The practical advantage of this study lies in the enhanced performance of the designed IIR filters, particularly in terms of stopband attenuation. The results indicate that the AMECoDEs-2 and FDDE approaches consistently achieve greater stopband attenuation—approximately 5 dB for classical filters and 13 dB for dual-passband filters—compared to previous works.

A key limitation of this study is the need to predefine the filter order before applying the AMECoDEs or FDDE algorithms. In this work, the filter order was set to 8 for classical IIR filters and 14 for dual-passband IIR filters, consistent with previous studies used for comparison. Another limitation concerns the selection of a constant weight function for the mean squared error (MSE) calculation. In this study, the passband and transition band weights were fixed at 1 and 0, respectively, while the stopband weight was empirically adjusted.

Future research should focus on enhancing the adaptability of the evolutionary optimization process in IIR filter design. One key direction is the integration of filter order as an optimization parameter rather than a predefined value. Addi-

tionally, refining the selection of weight factors in the mean squared error calculation is essential. Rather than relying on empirical adjustments for the stopband weight C_{stop}, future studies should implement an adaptive optimization strategy that allows the algorithm to automatically determine these values. Furthermore, an important avenue for future research is the evaluation of the algorithm proposed by Luo et al. [41] for IIR digital filter optimization, as its application could further improve design efficiency and overall filter performance.

***Abstract*—Food preservation and safety require advanced detection methods to ensure transparency in supply chains. Terahertz (THz) spectroscopy has emerged as a powerful, non-invasive tool for material characterization. This study explores the integration of THz spectroscopy and machine learning for accurately quantifying maize starch adulteration in bioplastics derived from potato starch. Bioplastic samples with varying concentrations of maize starch were prepared, molded into three different thicknesses, and subjected to a two-stage drying process, resulting in 81 samples (27 treatments with three replicates each). The spectral profiles at THz (0.5 to 2 THz) were recorded and analyzed using three regression models: support vector regression, partial least squares regression, and multiple linear regression. The models were evaluated using the coefficient of determination (R^2), Root Mean Square Error (RMSE), and the Residual Predictive Deviation (RPD). The results showed R^2 values ranging from 0.7283 to 0.9495, RMSE between 0.0594 and 0.1393, and RPD values from 1.8753 to 4.4479, demonstrating strong predictive performance. These findings highlight the potential of THz spectroscopy and machine learning in the noninvasive detection of starch adulterants in bioplastics, paving the way for future research to enhance model robustness and applicability.**

***Keywords*—Terahertz spectroscopy; machine learning; chemometrics; starch detection; biofilms**

I. Introduction

Every year, approximately 1.3 billion tons of by-products from the global agri-food industry pile up, creating substantial economic and environmental pressures [1]. Many of these by-products hold untapped potential, containing valuable bioactive compounds such as starch—a carbohydrate recognized by [2] and [3] as essential for human and animal nutrition. The versatility of starch, mainly composed of amylose and amylopectin, significantly influences its industrial applications due to distinct functional properties highlighted in studies by [4], [5], and [6]. Yet, despite its promise, starch faces inherent limitations, including low thermal stability and pronounced hydrophilicity, restricting its broader industrial adoption [7].

Responding to escalating environmental concerns, starch-based bioplastics have surfaced as compelling alternatives to traditional petroleum-derived plastics. These innovative materials, praised by researchers like [8], [9], and [10] for their biodegradability and compostability, offer practical, eco-friendly solutions particularly suited for food packaging. Nonetheless, maintaining high-performance standards in bioplastics is complex, as accurate assessments of their composition [11] and structural integrity [12] are critical.

Traditional methods for starch characterization are often invasive and labor-intensive, risking alteration or damage to sample integrity. Terahertz (THz) spectroscopy, as presented in works by [13], [14], and [15], emerges as a promising alternative, operating in the unique 0.1–10 THz frequency range and providing insightful, non-destructive material characterization. Specifically, Time-Domain Terahertz Spectroscopy (THz-TDS) has garnered attention within food science, enabling detailed biopolymer analysis without sample degradation, as shown by [16] and [17]. Chemometric techniques, integrating statistical and machine learning methods, significantly improve the interpretation of complex spectral data, thereby dramatically enhancing starch identification and quantification in bioplastics [18].

Complementing traditional chemometric approaches, recent breakthroughs in deep learning are revolutionizing analysis across various sectors. Intelligent methods have significantly improved waste management by optimizing material classification [19]. Likewise, advancements in agricultural practices have been achieved through sophisticated algorithms and IoT integration [20]. Metaheuristic approaches have accelerated neural network hyperparameter tuning [21], and innovative machine learning techniques have enhanced cybersecurity through efficient data filtering [22]. Additionally, machine learning advancements continue refining the precision of GPS positioning [23]. While our current study employs traditional machine learning frameworks, future integration of advanced AI methods could further refine THz spectral analyses, optimizing feature selection and enhancing predictive accuracy.

Considering this context, THz-TDS spectroscopy integrated with chemometric methods has proven effective in the non-invasive characterization of polymers, though its application to starch-based biopolymers remains limited. To our knowledge, this research represents the first effort to combine THz spectroscopy with machine learning to predict potato and maize starch concentrations in bioplastics. Here, we propose an approach integrating spectral analysis of THz signals with three machine learning models: Support Vector Regression (SVR), Partial Least Squares Regression (PLSR), and Multiple Linear Regression (MLR). Furthermore, a feature selection method was employed to optimize these models, aiming to enhance

*Corresponding authors.

predictive accuracy. This new approach expects to improve quality assessment in sustainable packaging, contributing to advancements in environmentally friendly industrial materials.

The remainder of this paper is organized as follows: Section II details the methodology for the preparation of bioplastic samples and the application of THz spectroscopy. Section III presents the experimental results, including the performance of the regression models used for starch concentration prediction. Finally, Section IV provides concluding remarks on the implications of this study for sustainable bioplastic development.

II. Material and Methods

This section describes the methodology employed for preparing and characterizing bioplastics, primarily using starch and polyvinyl alcohol as foundational materials. The bioplastics were synthesized through the solution casting method, adapting protocols previously detailed by [24], [25], and [26]. An overview of the methodological steps is illustrated in Fig. 1, with each stage further detailed in subsequent subsections.

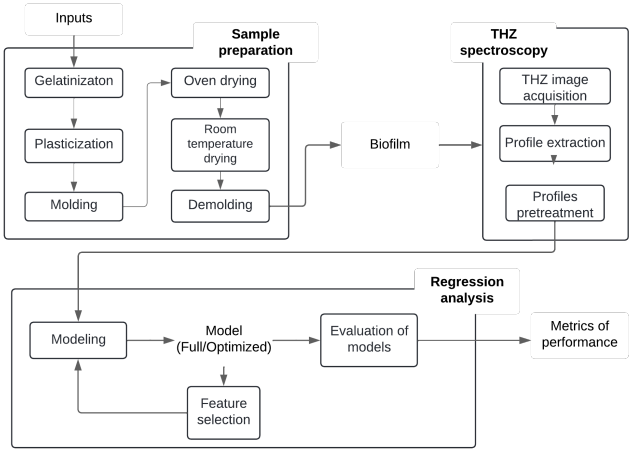

Fig. 1. Flow Diagram of the experimental methodology used for the preparation and analysis of starch-based bioplastics.

A. Sample Preparation

The inputs used to prepare the samples were high-purity potato starch and maize starch, purchased online from Peruvian suppliers through the Mercado Libre platform. Additionally, distilled water, technical grade glycerin (97% purity), and laboratory-grade polyvinyl alcohol (98% purity) were used, all purchased from a laboratory supply store located in the district of Sullana, province of Sullana, department of Piura. All activities of the experimental scheme were carried out in the food safety research laboratory of the National University of the Frontier.

For the preparation of the bioplastics, 12 grams of starch were used in each formulation. In this study, a base bioplastic with potato starch was formulated (control sample), and eight additional bioplastics were made, in which potato starch was partially substituted with maize starch in proportions ranging from 10% to 80% in increments of 10%. These starch mixtures were manually and meticulously prepared to ensure a uniform distribution of the components, thus guaranteeing consistent and reproducible results in subsequent experiments [27].

The initial chemical process for sample preparation involved gelatinization. In this step, 12 grams of the starch mixture were dissolved in 400 ml of distilled water and heated to 100°C for 45 minutes. According to the methodology described by [28], these conditions are optimal for breaking down starch granules without causing their denaturation, thereby enabling them to swell and rupture to form a gelatinous paste. Subsequently, for plasticization, the temperature was lowered to 80°C for an additional 15 minutes. At this stage, 7 ml of glycerin and 8 grams of polyvinyl alcohol, previously dissolved in 100 ml of water, were added. This combination, as highlighted by [29] and [30], effectively reduces material fragility, enhances flexibility, and improves tensile strength. The mixture was stirred to distribute the plasticizers evenly.

Subsequently, the molding process followed, where the plasticized mixture was poured into Petri dishes with a diameter of 9 cm in amounts of 12 ml, 15 ml, and 18 ml. The precision in the molding is crucial to obtain comparable samples and avoid unwanted variations in experimental results [31]. The samples were dried in an oven at 45°C for 22 hours to reduce the water content. This step is important to prevent cracking or rapid deformation [32]. Subsequently, they were subjected to a second drying at room temperature (24°C) for 48 hours in a silica gel desiccator to remove residual moisture, ensuring dimensional stability and suitable mechanical properties for analysis [33].

After the second drying process, the samples were carefully demolded using a scalpel, tweezers, and surgical gloves to avoid damage or deformation, resulting in smooth and defect-free samples ready for evaluation. A total of 81 bioplastic sheets were produced (27 treatments with three replicas each). Each sheet was cut into rectangles of 15 mm x 45 mm, and their thickness was measured using a Dasqua digital micrometer with a range of 0-25 mm and a resolution of 0.001 mm. Five measurements were taken at different points on each sheet, and the values were averaged.

B. THz Spectroscopy

The bioplastic sheets were placed on a polylactic acid (PLA) sample holder for analysis. A TeraSmart Compact Industry-Proven THz spectrometer of German origin was used in transmission mode. This system has a scanning range of 850 ps and includes a compact spectrometer with a spectral range of 6 THz and a resolution of 1.2 GHz; it is equipped with an ultrafast laser that emits femtosecond pulses, and the signal is directed through a system of nonlinear cyclic optical mirrors (Fig. 2), connected to the spectrometer via a fiber optic cable. A tower with vertical and horizontal displacement capabilities was used to move the sample. Image acquisition was controlled using TeraImage and Scam Control software, which allows defining and adjusting the appropriate scanning range. Menlo Systems provides both the equipment and the software.

The experimental phase was conducted under normal atmospheric conditions, which generated many peaks due to the strong absorption characteristics of water vapor in the THz range, which can interfere with measurements [34]. It

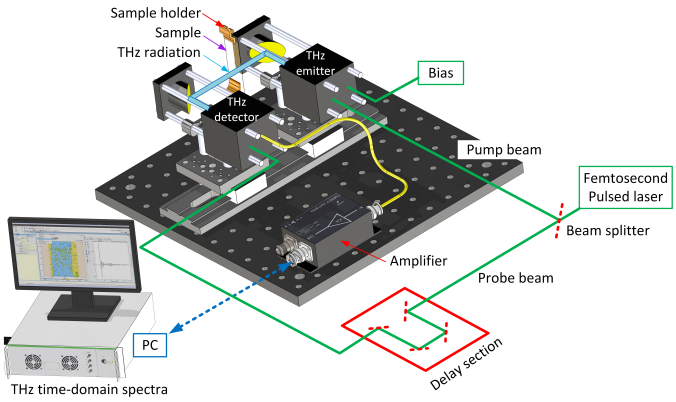

Fig. 2. Schematic representation of the transmission-mode THz-TDS system used in this study.

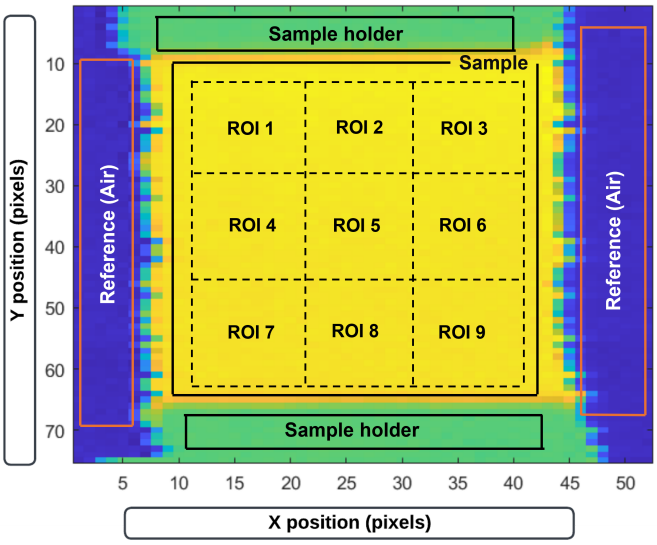

Fig. 3. Representative transmittance image showing the contrast between the bioplastic sample area and the reference.

is important to note that the signals obtained were measured with a relative humidity close to 50%.

Initially, the THz spectrometer generated files in the `IGTIFF` format, which were converted to the `MAT` format using Epina ImageLab software. The resulting files were loaded into Matlab (version R2024a, The MathWorks, Inc., USA), where high-contrast images were generated (Fig. 3) to distinguish the sample, the sample holder, and the air. This facilitated the acquisition of profiles for the sample (bioplastic film) and reference (air). To obtain the profiles of interest, the THz image was divided into nine equal-sized subareas (ROIs), from which the average profile was extracted for further processing. A total of 729 profiles were generated in the time domain, which was then transformed into the frequency domain using a Fourier transform, employing Eq. 1. These profiles in the frequency domain were used for the regression analysis.

$$E(t) \rightarrow \text{FFT} \rightarrow \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} E(t) e^{-i\omega t}\, dt = E(\omega), \quad (1)$$

where $E(t)$ represents the signal function in the time domain, $e^{-i\omega t}$ is the kernel of the transform, and $E(\omega)$ denotes the signal function in the frequency domain.

C. Regression Analysis

The THz profiles in the frequency domain (predictor variable: X) and the maize starch concentration values (response variable: Y) were used to train three regression models: MLR, SVR, and PLSR. The models used are detailed below.

1) MLR: It is a statistical technique that estimates the relationship between a dependent variable and several independent variables using a linear equation [35]. This multivariate statistical method restructures the original dataset into linear combinations of the variables, creating independent new variables known as principal components that capture most of the variability [36]. This model is based on Eq. 2.

$$Y = \beta_0 + \sum_{i=1}^{n} \beta_i X_i + \epsilon, \quad (2)$$

where Y represents the starch percentage, β_0 is the constant term, $\beta_1, \beta_2, \ldots, \beta_n$ are the regression coefficients, $X_1, X_2, \ldots, X_n$ correspond to the THz profiles in the frequency domain, and ϵ denotes the error term.

2) SVR: The Support Vector Machine for Regression examines the relationship between variables using a subset of data, balancing the complexity of the model with the precision of prediction in complex scenarios [37]. Unlike conventional machine learning approaches, the SVR model effectively handles issues related to small sample sizes, high dimensionality, and local minima and is noted for its remarkable ability to generalize [38].

3) PLSR: This technique, common in multivariate analysis, simplifies the relationship between multiple variables by projecting them onto orthogonal vectors, thus facilitating understanding [39]. It is used primarily in chemometrics to investigate how spectral data correlate with reference indicators [40]. PLSR transforms predictor variables (X) into response variables (Y). It decomposes X and Y and projects them into new directions to capture joint variability [41]. Then, a regression is performed with these decomposed variables, as shown in the model of Eq. 3.

$$Y = \beta X + e, \quad (3)$$

where Y represents the starch concentration in the bioplastics, X is the intensity data matrix (n observations × m frequencies), β is the coefficient matrix, and e denotes the error term.

It is essential to eliminate irrelevant spectral information, as this complicates the development of simple and effective models [42]. For this reason, the method of feature selection using beta coefficients (β) was chosen, which are associated

with frequency values and absolute loadings in regression models. These coefficients were selected for their ability to adequately represent the dependent variable, contributing to improved model accuracy [41].

The performance of the MLR, SVR, and PLSR models was evaluated using the metrics R^2, RMSE, and RPD (see Eq. 4, 5, and 6).

$$R^2 = 1 - \frac{\sum_{i=1}^{N}(\hat{Y}_i - Y_i)^2}{\sum_{i=1}^{N}(Y_i - \overline{Y})^2}, \tag{4}$$

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(\hat{Y}_i - Y_i)^2}, \tag{5}$$

$$\text{RPD} = \frac{\mathcal{S}}{\text{RMSE}}, \tag{6}$$

where Y_i represents the reference concentration of the i-th instance, $\overline{Y}$ is the mean value of the reference concentrations, $\hat{Y}_i$ denotes the predicted concentration of the i-th instance, N is the number of instances, and $\mathcal{S}$ corresponds to the standard deviation of the reference values.

Finally, cross-validation was implemented using a five-fold strategy with 30 iterations. In each iteration, the dataset was partitioned into five subsets: one used for testing and the remaining four for training. Performance metrics were calculated for each iteration, following the procedure described in [42], [43]. This validation approach is essential for assessing model performance, as it ensures robustness and generalization by training and evaluating the models across different data splits [44]. Using multiple partitions reduces the risk of overfitting and prevents dependency on a specific training–validation division [45]. Additionally, this strategy increases the consistency and reliability of the predictive results in diverse scenarios [46].

III. Results

A. Bioplastic Obtention

Fig. 4 shows the control bioplastic and its variants with different levels of maize starch adulteration (10% — 80%) and thicknesses (E1 = 0.12 mm, E2 = 0.15 mm, E3 = 0.18 mm). Visually, the samples appear similar, although this uniform appearance does not necessarily reflect their differences in biodegradability. Previous studies indicate that bioplastics made solely with maize starch tend to degrade more slowly than those made with other types of starch [47]. Furthermore, the choice of starch and plasticizers can significantly affect the physicochemical properties of bioplastics [48]. This is consistent with similar research that also used potato starch and found variations in physical properties based on the formulation [49]. Therefore, while the appearance may be uniform, the properties and degradation can vary depending on the composition and plasticizers used.

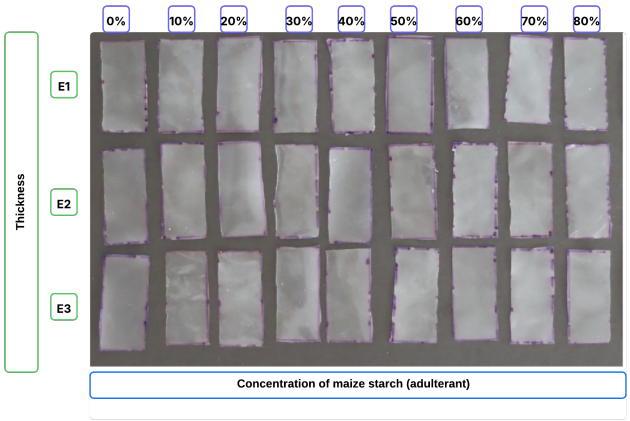

Fig. 4. Bioplastic sheets formulated with varying maize starch concentrations and molded at three different thicknesses.

B. THz Spectral Analysis

1) Profiles in the time domain: Fig. 5 presents the average profiles in the time domain of bioplastics with nine concentrations and three thicknesses in the range of 5 to 10 picoseconds. These graphs show how starch concentrations affect the amplitude and arrival time of THz pulses. The echoes generated by multiple and internal reflections within the sample were removed to analyze the main signal free of interference. These reflections are related to the Fabry-Pérot effect [50]. After removing echoes from multiple reflections, it was observed that as the thickness increases, the absorption of the THz signal rises along with the attenuation, indicating a more effective interaction between the THz signal and starch. The length of the THz signals obtained in the experiments ranged between five and nine picoseconds, with each signal averaged from three measurements to improve the signal-to-noise ratio.

2) Profiles in the frequency domain: Fig. 6 presents the average frequency domain profiles of bioplastics with nine different concentrations and three thicknesses, covering the range from 0.5 to 2 Terahertz. These profiles were obtained by removing the Fabry-Pérot term from the time-domain data, as noted by [51], where reflection signals can merge in thin samples, and the main reflection echoes may be lost. The greater differentiation observed in the 0.5 to 2 THz range aligns with previous reports on sensitivity in thin samples, ranging from 0.5 to 1.5 THz [52], as well as with studies on organic samples reporting sensitivity to THz between 0.1 and 1.4 THz [53]. This frequency range was also chosen in similar studies such as [54], which analyzed bacterial cellulose films from 0.3 to 2.8 THz, and [55], which evaluated food-grade oils from 0.5 to 3 THz. However, other studies have used different ranges, such as [56], which measured the elasticity of poly-l-proline helices from 0.6 to 4.5 THz, and [57], which classified inorganic pigments in 0.1 to 1.2 THz. This indicates that while the 0.5 to 2 THz range is typical, the choice of frequency range is tailored to the specific characteristics of the material and the objectives of the study.

C. THz Profile Modeling

Table I presents the plots of the actual vs. predicted values for the full and optimized models for each thickness. For SVR, the R^2 values are 0.9158 ± 0.0041 (full model) and 0.8149 ± 0.0024 (optimized model) for E1, 0.9028 ± 0.0032 and 0.8041 ± 0.0022 for E2, and 0.8733 ± 0.0042 and 0.7283 ± 0.0016 for E3. Similarly, for MLR, the R^2 values are 0.9495 ± 0.0041 (full model) and 0.8245 ± 0.0025 (optimized model) for E1, 0.9191 ± 0.0066 and 0.8528 ± 0.0030 for E2, and 0.8841 ± 0.0160 and 0.7807 ± 0.0033 for E3. Likewise, for PLSR, the R^2 values are 0.8503 ± 0.0005 (full model) and 0.8213 ± 0.0004 (optimized model) for E1, 0.8379 ± 0.0007 and 0.8517 ± 0.0003 for E2, and 0.8342 ± 0.0007 and 0.7768 ± 0.0004 for E3.

All three models demonstrated good performance in predicting the maize starch concentration in bioplastic samples, particularly in the lower thicknesses. These models, combined with THz spectroscopy, have been widely applied in various studies of functional and organic material characterization. For instance, in the work of [58], SVR ($R^2 = 0.9793$) was used to predict bovine serum albumin concentration in thin films. Similarly, in [59], PLSR and SVR ($R^2 = 0.994$ for both models) were applied to analyze the amount of α-lactose in a lotus root starch mixture. Furthermore, [60] evaluated the microstructural characteristics of thermal coatings (MLR, $R^2 = 0.97$). On the other hand, [61] used SVR to analyze porosity in fiberglass-reinforced polymers ($R^2 = 0.976$), and [62] employed MLR to measure the coating thickness in nifedipine tablets ($R^2 = 0.99$). Furthermore, [63] used MLR to predict the density ($R^2 = 0.97$) and moisture content ($R^2 = 0.78$) in wood, using refractive indices and absorption coefficients. Finally, [64] applied PLSR to predict glycerol concentration in liquid solutions (RPD = 6.095). In most cases, the models demonstrated high performance, confirming the feasibility of using chemometric models combined with THz spectroscopy for material characterization.

The results demonstrate competitive performance compared to previous studies that have used machine learning models combined with THz spectroscopy for analyzing organic samples, reinforcing both the applicability and robustness of the proposed approach. While some prior studies reported slightly superior outcomes, these differences can be primarily attributed to lower variability in the composition of their samples. Nevertheless, the high precision achieved in our study for predicting starch concentrations in bioplastics clearly illustrates the effectiveness of the proposed methodology. Recent research by [65] indicates that integrating deep learning methods can substantially enhance predictive accuracy and improve interpretability by identifying informative spectral bands. Furthermore, [66] highlights the capability of deep learning to effectively model complex data structures, suggesting promising potential for further improvements in predictive precision in future THz spectroscopy applications.

D. Performance Metrics

Table II shows the average performance metrics (R^2, RMSE and RPD) with their standard deviations for the SVR, MLR, and PLSR models, both in their complete and optimized versions, applied to three different thicknesses of bioplastic films. The complete SVR, MLR, and PLSR models accurately predicted maize starch concentration. For thickness E1, R^2 values ranged from 0.8503 ± 0.0005 to 0.9495 ± 0.0041, RMSE values from 0.0594 ± 0.0025 to 0.0999 ± 0.0002, and RPD values from 2.5847 ± 0.0044 to 4.4479 ± 0.1761. For E2, R^2 values ranged from 0.8379 ± 0.0007 to 0.9191 ± 0.0066, RMSE values from 0.0754 ± 0.0032 to 0.1040 ± 0.0002, and RPD values from 2.4835 ± 0.0053 to 3.5020 ± 0.1546. For E3, R^2 values ranged from 0.8342 ± 0.0007 to 0.8841 ± 0.0160, RMSE values from 0.0891 ± 0.0057 to 0.1051 ± 0.0002, and RPD values from 2.4556 ± 0.0050 to 3.1874 ± 0.1488. Among these models, the complete MLR model performed the best in all thicknesses.

For the optimized models, both PLSR and MLR showed strong performance, with MLR performing slightly better in most cases. For E1 (R^2 = 0.8245 ± 0.0025, RMSE = 0.1091 ± 0.0007, RPD = 2.4029 ± 0.0174); for E2 (R^2 = 0.8528 ± 0.0030, RMSE = 0.0996 ± 0.0011, RPD = 2.6311 ± 0.0284); and for E3 (R^2 = 0.7807 ± 0.0033, RMSE = 0.1218 ± 0.0011, RPD = 2.1491 ± 0.0157). Interestingly, optimizing the models using beta coefficients sometimes led to slightly decreased performance metrics. Although these coefficients are useful for selecting important variables, as mentioned in [42], they can slightly lower the performance of the model.

In general, the study highlights the impact of the selection of features on the effectiveness of starch prediction models in bioplastics. Although the MLR and PLSR models showed promising results, the drop in performance metrics after optimization suggests that exploring other feature selection methods could be beneficial. Trying different approaches may improve the models and help them find broader use in industrial applications, ultimately advancing bioplastic analysis and production.

IV. Conclusion

This study demonstrates that integrating THz spectroscopy with machine learning offers a promising, non-invasive approach for predicting bioplastic starch concentration. By applying regression models such as PLSR, SVR, and MLR, we achieved high predictive accuracy—particularly with the optimized MLR model, which performed well even with a relatively small dataset. Nevertheless, due to the variability in starch formulations and the precision required for industrial applications, more extensive and diverse datasets will be essential to enhance the generalizability of the models.

The use of beta coefficients in the spectral analysis proved effective for identifying key frequency features in the THz spectrum. This approach supports the potential development of compact, cost-effective systems for real-time starch monitoring during bioplastic production. Such feature selection methods are especially useful in the packaging industry, where rapid and accessible quality control tools are highly valuable. Future work could involve implementing more advanced feature selection strategies to improve model performance further.

Moreover, the proposed methodology can be extended to other quality control applications involving bioplastics and biodegradable materials, contributing to developing sustainable and high-performance industrial solutions.

E3	PLSR	Full	0.8342 ± 0.0007	0.1051 ± 0.0002	2.4556 ± 0.0050
		Optimized	0.7768 ± 0.0004	0.1220 ± 0.0001	2.1161 ± 0.0020
	SVR	Full	0.8733 ± 0.0042	0.0942 ± 0.0015	2.7838 ± 0.0446
		Optimized	0.7283 ± 0.0016	0.1393 ± 0.0004	1.8753 ± 0.0056
	MLR	Full	0.8841 ± 0.0160	0.0891 ± 0.0057	3.1874 ± 0.1488
		Optimized	0.7807 ± 0.0033	0.1218 ± 0.0011	2.1491 ± 0.0157

Finally, while this study prioritized traditional regression models for their interpretability and robustness, future research will explore using more sophisticated techniques, such as artificial neural networks and ensemble methods like XGBoost, to better capture non-linear patterns in THz spectral data and potentially boost predictive power.

Unified Deep Learning for Real-Time Pedestrian Detection, Pose Estimation, and Tracking

Towards Safe and Robust Sensor-Perception System of Autonomous Vehicle Research

Joseph De Guia[1], Madhavi Deveraj[2]
School of Information Technology (SOIT), Mapua University, Manila, Philippines[1, 2]
Energy Research Institute (ERI@N), Nanyang Technological University, Singapore[1]

***Abstract*—This study introduces a novel unified deep learning framework for real-time pedestrian and Vulnerable Road User (VRU) detection, pose estimation, and tracking using YOLOv8. Unlike traditional approaches that separately handle these tasks, our integrated multi-task model leverages YOLOv8's advanced multi-scale feature extraction and optimized architecture to efficiently perform simultaneous detection, pose estimation, and tracking. Experimental evaluations demonstrate superior performance compared to baseline YOLOv8 configurations, achieving an mAP@0.5 of 57.2%, OKS of 76.1% (COCO dataset), MOTA of 67.1%, and IDF1 of 64.3%. The framework's robust performance is validated through comprehensive testing under realistic urban scenarios and challenging conditions. By effectively addressing limitations in current autonomous vehicle (AV) perception systems, such as handling occlusions, varying lighting, and dense pedestrian environments, this integrated approach significantly enhances AV safety and navigation reliability at critical junctions and pedestrian crossings.**

***Keywords*—Pedestrian detection; pose estimation; tracking; YOLOv8; deep learning**

I. Introduction

Annually, thousands of pedestrians and cyclists are injured or killed at urban intersections and crossings, highlighting the dangers posed by vehicle interactions with vulnerable road users (VRUs). According to the World Health Organization's (WHO) Global Status Report on Road Safety 2023, approximately 1.19 million people die in road traffic crashes each year, with pedestrians accounting for 23% of these fatalities [1]. This underscores the need for advanced solutions to mitigate risks associated with vehicle-pedestrian interactions, particularly in complex urban environments with high traffic volume and unpredictable pedestrian behavior.

Pedestrian safety is a major concern in high-risk areas like intersections, where human error, limited visibility, and delayed driver reactions often lead to severe accidents. As urban populations and traffic volumes increase, the demand for advanced pedestrian and VRU detection, pose estimation, and tracking systems has become more urgent. Research suggests that automated detection systems could significantly reduce pedestrian fatalities. Combs et al. [2] estimated that fully automated vehicle (AV) sensors could prevent 30% to over 90% of pedestrian deaths. Despite these prospects, existing detection systems face challenges such as limited robustness in adverse weather, reduced accuracy during occlusions, and high computational demands that hinder real-time performance.

Pedestrian detection technologies have advanced significantly due to machine learning and sensor integration, leading to improvements in accuracy and speed. Convolutional Neural Networks (CNNs) or Deep Learning [3] have driven major breakthroughs, with state-of-the-art models like YOLO (You Only Look Once) [4], Faster R-CNN [5], and CenterNet [6] being top performers in real-time detection tasks. Among these, the YOLO series, specifically YOLOv3 [7], YOLOv5 [8], and the latest YOLOv8 [9], stands out for their balance between detection speed and accuracy. YOLOv8 integrates multiple optimizations such as feature pyramids and cross-stage partial networks that make it suitable for real-time multi-task learning, including object detection, pose estimation, and tracking. Unlike earlier versions, YOLOv8 excels in multi-scale feature handling, making it ideal for integrated perception systems in AVs. The YOLO versions keep evolving as different use cases for object detection made some strides online and in the research community.

However, most pedestrian detection systems function as independent task solvers, focusing solely on detection without considering the interdependence of other perception tasks. In real-world AV applications, accurate detection alone is insufficient; a robust system must also understand and predict VRU movements while consistently tracking their trajectories. For example, pose estimation models like OpenPose [10] and HRNet [11] identify key body points, enabling prediction of human movements such as walking or stopping. Tracking algorithms like DeepSORT [12] provide continuous identity tracking across frames, ensuring consistent monitoring of detected individuals. When these systems operate independently, the lack of synergy results in higher computational costs and reduced efficiency, especially in dynamic environments with multiple moving agents. Integrating these tasks into a unified model can significantly improve efficiency and performance, especially in complex scenarios.

This research aims to develop a unified multi-task deep learning framework that integrates pedestrian and VRU detection, pose estimation, and tracking by enhancing YOLOv8 as a backbone learning framework. The unified approach addresses key gaps in existing AV perception systems by enabling simultaneous execution of these tasks, enhancing real-time performance, reducing computational redundancy, and improving overall efficiency. YOLOv8's backbone, with its feature pyramids and cross-stage partial network (CSPNet), is

well-suited for extracting multi-scale features necessary for this integrated framework.

Unlike previous studies focused on controlled settings, this work emphasizes in AVs perception research for robustness in real-world conditions, including diverse urban scenarios, varying environmental factors, and mixed traffic conditions. The proposed model aims to achieve high detection accuracy under complex conditions, provide precise movement prediction through pose estimation, and maintain consistent real-time tracking of VRUs, even under occlusions and other challenges.

The contributions of this work in AV research are threefold:

1) Improving detection accuracy for pedestrians and VRUs in complex environments through an integrated deep learning approach;

2) Enabling proactive safety measures through predictive pose estimation to enhance AV system robustness; and

3) Ensuring consistent real-time tracking, validated through extensive real-world testing. The goal is to enhance AV perception capabilities for safer integration into urban roads, particularly in high-risk areas like intersections and crowded zones such as zebra crossings and junctions in school zones.

The subsequent sections are structured as follows: Related Works reviews existing methods and their limitations is given in Section II. Methodology in Section III details the proposed unified multi-task learning framework using YOLOv8 backbone, including sensor integration and model architecture. Experiments and Results in Section IV evaluate the model's performance compared to state-of-the-art methods, including the ablation studies assess the impact of individual components. Real-world testing validates the model in the target environment and scenarios. Finally, the Discussion and Conclusion in Section V and Section VI respectively summarizes findings, implications, and future work.

II. Related Works

Pedestrian detection in autonomous vehicles (AVs) remains challenging due to diverse pedestrian appearances, varying poses, occlusions, and complex environmental factors. Early studies, including those by Dollar et al. [13, 14], emphasized difficulties arising from pedestrian variability, occlusion, and environmental conditions such as poor lighting [15]. Although recent advancements with deep learning approaches, especially Convolutional Neural Networks (CNNs), have significantly improved detection accuracy and efficiency, significant limitations remain regarding robustness in adverse conditions, occlusion handling, and real-time processing demands.

State-of-the-art detection methods like YOLO [4], Faster R-CNN [5], and CenterNet [6] have demonstrated considerable performance gains. Optimization of the learning approach using Residual network [29] improves (COCO) detection. YOLO variants (YOLOv3 [7], YOLOv4 [18], YOLOv5 [8], YOLOv8 [9]) provide a favorable balance of speed and accuracy, achieving high scores on benchmarks such as COCO [17] and KITTI [16]. Nevertheless, these methods often address only the detection task independently, without integrating related tasks like pose estimation and tracking, which limits their utility in real-world scenarios. Recent research has focused on integrating detection, pose estimation, and tracking. Camara et al. [19, 20] proposed models addressing sensing, tracking, and behavior prediction, but these approaches lacked unified real-time processing. Pose estimation frameworks like OpenPose [10] and HRNet [11] deliver valuable insights into pedestrian behavior; however, their computational complexity hinders real-time integration. Similarly, studies integrating detection and tracking [21-24] showed improved pose estimation but still treated tasks separately. Tracking approaches such as DeepSORT [12], OC-SORT [25, 26], Network flow using Explicit Occlusion Model (EOM) [30], have enhanced identity consistency but require independent models for detection and tracking, limiting overall efficiency and integration.

Multi-sensor fusion approaches combining RGB cameras, LiDAR, and radar have demonstrated improved detection and tracking performance in challenging scenarios [27, 28]. Nevertheless, these solutions typically involve separate processing pipelines, causing redundancy and computational inefficiency. Consequently, there is a clear need for a unified multi-task framework that can cohesively handle detection, pose estimation, and tracking in real-time with sensor integration.

To address these limitations, integrating sensor data, detection, pose estimation, and tracking into a unified multi-task framework is essential for creating a robust AV perception system that performs reliably across diverse conditions. Recent studies have explored similar unified approaches for detection, tracking, and behavior understanding, showing the potential benefits of integration [32, 33]. Combining models like YOLO, pose estimation frameworks like OpenPose, and tracking systems like DeepSORT within a cohesive system offers a stronger, more efficient solution for AVs in complex environments, overcoming the limitations of fragmented approaches [5], [31 - 34]. Our implementation of obstacle and object detection in the AV test vehicle were tested progressively for the different scenarios and additional unknown objects trained for the edge cases and new environment [43].

The novelty of this study lies in integrating these traditionally independent tasks into a unified multi-task learning framework, specifically leveraging YOLOv8. Unlike prior studies, this research introduces enhanced multi-scale feature extraction and an integrated multi-task loss to simultaneously perform detection, pose estimation, and tracking tasks effectively. By embedding tracking capabilities directly within the YOLOv8 architecture, our model reduces computational redundancy, increases identity consistency, and significantly improves overall performance in complex urban environments. This holistic integration distinguishes our approach from existing fragmented methodologies and represents a substantial step forward in AV perception system research.

III. Methodology

A. Unified Muli-Task Framework

The architecture extends the YOLOv8 backbone to perform simultaneous detection, pose estimation, and tracking, incorporating task-specific enhancements and shared feature learning. This introduces significant enhancements through multi-task learning mechanisms and task-specific optimizations, making it a robust solution for real-time applications. The

framework begins with an input image, typically resized to 640×640, which undergoes preprocessing steps like normalization and resizing. The backbone, derived from YOLOv8, extracts hierarchical features using convolutional layers, Cross-Stage Partial Network (CSPNet) [35], and Spatial Pyramid Pooling Fast (SPPF) [36]. CSPNet splits input features into direct and partial paths, ensuring gradient flow while reducing computational costs, while SPPF aggregates multi-scale spatial context efficiently. This results in multi-scale feature maps that are used by subsequent layers.

We describe in detail each component highlighting unique modules and their contributions and other single-task implementations.

1) Input and preprocessing: The input image, denoted as $X \in \mathbb{R}^{H\times W\times C}$, where H and W are dimensions (e.g., 640×640) and $C = 3$ represents RGB channels, is first preprocessed. Preprocessing includes resizing ($X_{resized} = f_{resize}(X)$) and normalization ($X_{norm} = \frac{X_{resized} - \mu}{\sigma}$), where μ and σ are mean and standard deviation ensuring consistent input for the model.

2) Backbone: The backbone extracts hierarchical, multi-scale feature maps and outputs $\{Fi\}_{i=1}^{N}$, where N represents different levels of abstraction shared across all tasks. It comprises the following parts:

- Convolutional Layers: Standard convolutions compute feature maps in Eq. (1) where W is learned weights.

$$F_{conv} = f_{conv}(X_{norm}, W) \quad (1)$$

- CSPNet (Cross-Stage Partial Network): CSPNet splits the input features into two paths. The direct path that passes features directly and partial path applies convolutional transformations. Then recombines the outputs in Eq. (2). This reduces the computation while preserving gradient flow.

$$F_{CSP} = F_{direct} + f_{partial}(F_{partial}) \quad (2)$$

- SPPF (Spatial Pyramid Pooling Fast): pools feature at multiple scales in Eq. (3). This captures spatial context efficiently.

$$F_{SPPF} = Concat\,[f_{pool}^{1}(F), f_{pool}^{2}(F), f_{pool}^{3}(F)] \quad (3)$$

3) Neck: The neck aggregates and refines features from the backbone, enhancing multi-scale predictions. The neck component, leveraging Path Aggregation Network (PANet) [37] and Bidirectional Feature Pyramid Network (BiFPN) [38], refines and propagates multi-scale features, enabling robust detection of objects at varying scales. PANet fuses top-down and bottom-up pathways to enhance feature representation, while BiFPN introduces learnable weights to optimize feature fusion for task-specific emphasis.

- PANet fuses top-down an0064 bottom-up features in Eq. (4). This improves information flow across feature levels, benefiting small and large object detection.

$$F_{fused} = f_{top\text{-}down}(F_{high\text{-}level}) + f_{bottom\text{-}up}(F_{low\text{-}level}) \quad (4)$$

- BiFPN refines features iteratively with learnable weights in Eq. (5) ensuring task-specific focus across scales.

$$F_{BiFPN} = w_1 \cdot F_{low} + w_2 \cdot F_{high} \quad (5)$$

The output is refined multi-scale feature maps $\{F_{refined,i}\}_{i=1}^{N}$

4) Task-specific heads: The refined features in the *Neck* feed into the task-specific heads for detection, pose estimation, and tracking. The *detection head* predicts bounding boxes and class probabilities, optimizing with CIoU loss for bounding boxes and cross-entropy loss for classification. The *pose estimation head* predicts keypoints using deconvolutional layers for spatial refinement, minimizing Object Keypoint Similarity (OKS) [39] for pose accuracy. The tracking head generates Re-ID embeddings through fully connected layers, leveraging contrastive loss to maintain identity consistency across frames.

Each head utilizes refined feature maps for its respective task represented by the following models:

- Detection Head: The detection head predicts bounding boxes $b = [x, y, w, h]$, where x, are center coordinates and w, h are width and height. It uses:
  - Bounding Box Regression Loss in Eq. (6) CIoU ensures precise localization by accounting for aspect ratios.

$$\mathcal{L}_{box} = CIoU(b_{pred}, b_{gt}) \quad (6)$$

  - Class Prediction Loss in Eq. (7), where p_i is the predicted class probability p = softmax(z)

$$\mathcal{L}_{class} = -\sum_i y_i \log(p_i) \quad (7)$$

- Pose Estimation Head: Predicting K keypoints ($K = \{(x_k, y_k)\}_{k=1}^{K}$) for detected objects, the head includes deconvolution layers for spatial refinement. It minimizes in Eq. (8). This ensures precise keypoint localization, critical for understanding pedestrian movements.

$$\mathcal{L}_{pose} = MSE\,(K_{pred}, K_{gt}) \quad (8)$$

- Tracking Head: The tracking head generates Re-ID embeddings ($e = f_{ReID}(F)$) to maintain identity consistency across frames. The loss function includes in Eq. (9) where m is the margin, ensuring embeddings differentiate object identities effectively.

$$\mathcal{L}_{ReID} = \sum_{i,j} max(0, || e_i - e_j || - m) \quad (9)$$

5) Loss function: The framework integrates these tasks using a unified loss function that combines task-specific losses with adaptive weighting, ensuring balanced optimization. The total loss combines task-specific losses in Eq. (10). Dynamic weighting adjusts λi during training, balancing task contributions.

$$\mathcal{L}_{total} = \lambda_1 \mathcal{L}_{box} + \lambda_2 \mathcal{L}_{class} + \lambda_3 \mathcal{L}_{pose} + \lambda_4 \mathcal{L}_{ReID} \quad (10)$$

6) Pose-guided Re-ID tracking: A unique feature of the architecture is the *Pose-Guided Re-ID Tracking Module*, which enhances tracking by embedding pose information into Re-ID vectors. This reduces identity switches and improves tracking accuracy, especially in crowded or occluded scenes. The pose estimation head informs the tracking head. By embedding pose information keypoints (K) into the Re-ID embeddings, the model enhances identity consistency in Eq. (11). This reduces identity switches, particularly in crowded or occluded environments.

$$e_{\text{pose-guided}} = \text{Concat}\,(e_{\text{ReID}}, K) \quad (11)$$

By sharing features across tasks and incorporating temporal modeling, the unified framework achieves higher accuracy and efficiency compared to standalone models. Single-pass inference further reduces latency, making it suitable for real-time applications. This framework not only improves task-specific metrics such as Multi-Object Tracking Accuracy (MOTA) and Identity F1 Score (IDF1) for tracking, and OKS for pose estimation, but also sets a new benchmark for multi-task learning, outperforming YOLOv8 and other implementations in both robustness and computational efficiency. Refer to Table I for the summary and comparison of the proposed unified multi-task framework and YOLOv8.

Fig. 1 illustrates the simple block architecture that integrates detection, pose estimation, and tracking into a single pipeline, emphasizing efficiency and scalability while detailing the role of internal components in the backbone, neck, and heads.

- Input Image is the raw input image resized to 640 x 640 frame from the camera sensor.
- Backbone extracts hierarchical feature maps from the input image. Internal components include Convolutional layers that capture spatial features. CSPNet Layers reduce the computation and enhance the gradient flow. SPPF aggregates multi-scale context for feature enhancement.
- Neck refines and aggregates feature maps for multi-scale prediction. The components are PANet that strengthen information flow across feature levels. Feature Pyramid Fusion merges feature to ensure robustness for objects of different sizes.
- Task-Specific Heads: Detection head performs bounding box regression and predicts class probabilities. Pose estimation head outputs keypoint predictions with deconvolution layers for special refinement. Tracking head generates Re-ID embeddings using fully connected layers for maintaining object identities.
- Outputs are Bounding Boxes that localizes detected objects. Keypoint (poses) predicts the detailed human joint positions. Track IDs maintains consistent object identities across frames.

TABLE I. SUMMARIZING THE DIFFERENCES BETWEEN YOLOV8 AND OUR PROPOSED UNIFIED MULTI-TASK MODEL, HIGHLIGHTING THE UNIQUE FEATURES, ENHANCEMENTS, AND THEIR IMPACTS

Feature	YOLOv8	Proposed Unified Multi-Task Framework	Key Differences
Primary Focus	Single-task: Optimized for object detection.	Multi-task: Integrates detection, pose estimation, and tracking.	Unified framework handles multiple tasks simultaneously.
Architecture	Detection-specific backbone, neck, and head.	Backbone and neck shared across tasks, with task-specific heads.	Shared backbone enhances efficiency and task interdependence.
Backbone	CSPNet with SPPF for detection tasks only.	CSPNet with SPPF optimized for multi-task feature extraction.	Optimized for multi-task learning, leveraging shared features.
Neck	PANet for detection with multi-scale feature fusion.	PANet + BiFPN for refined multi-scale features across detection, pose, and tracking.	BiFPN adds iterative refinement for multi-task robustness.
Detection	Outputs bounding boxes and class probabilities.	Outputs bounding boxes and class probabilities with shared features.	Same detection mechanism but integrated with additional tasks.
Pose Estimation	Not included.	Predicts human keypoints with deconvolution layers for spatial refinement.	Adds pose estimation as a core capability.
Tracking	Requires external trackers like DeepSORT.	Integrated Re-ID embeddings for real-time object tracking.	Eliminates need for external trackers by embedding tracking functionality.
Unique Module	None.	Pose-Guided Re-ID: Embeds pose information into tracking for identity consistency.	Introduces pose-guided tracking to enhance identity maintenance.
Loss Function	Combines detection loss components (e.g., CIoU, classification).	Unified multi-task loss balancing detection, pose, and tracking losses.	Balances multi-task contributions with dynamic weighting.
Feature Sharing	Single-task feature maps optimized for detection.	Shared features enhance detection, pose estimation, and tracking.	Feature sharing reduces redundancy and improves performance.
Temporal Modeling	No support for temporal features.	Temporal consistency in tracking with pose-guided Re-ID embeddings.	Adds temporal modeling for improved tracking robustness.
Inference Pipeline	Single-pass for detection.	Single-pass for detection, pose estimation, and tracking.	Adds pose and tracking without increasing latency significantly.
Efficiency	Optimized for real-time detection.	Optimized for real-time multi-task inference.	Similar latency but supports more tasks.
Data Requirements	Requires detection-specific datasets (e.g., COCO).	Requires combined datasets for detection, pose estimation, and tracking.	Additional task-specific data needed for training.
Evaluation Metrics	Detection: mAP@0.5, mAP@0.5:0.95.	Multi-task: mAP@0.5 (detection), OKS (pose), MOTA/IDF1 (tracking).	Incorporates multi-task evaluation metrics for a broader assessment.

Performance	High detection accuracy (e.g., mAP@0.5: 55.4% on COCO).	Higher accuracy across tasks (e.g., mAP@0.5: 57.2%, OKS: 76.1%, MOTA: 67.1%).	Outperforms YOLOv8 in detection, with added pose estimation and tracking.
Scalability	Limited to detection tasks.	Modular design supports new tasks (e.g., trajectory prediction).	Easily extendable to additional perception tasks.
Use Case	Suitable for object detection in real-time applications.	Suitable for real-time, multi-task perception in dynamic environments.	Broader applicability in autonomous systems and robotics.

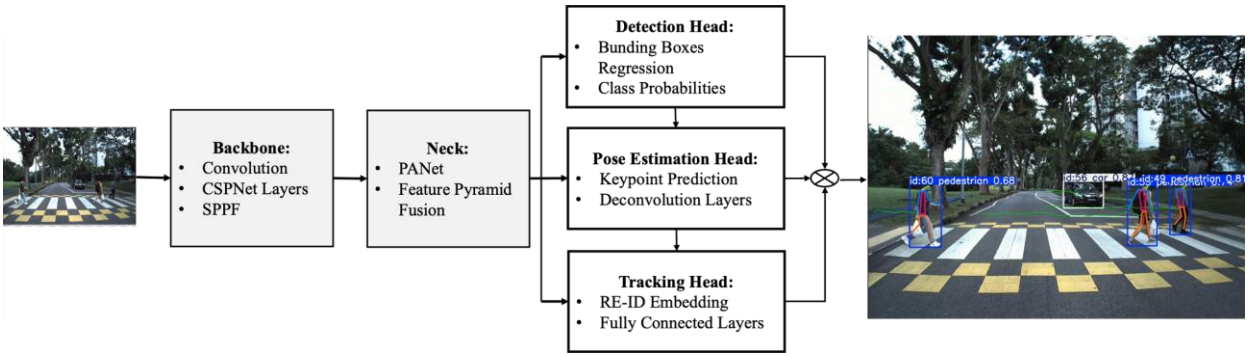

Fig. 1. Visual overview of the unified multi-task framework. The resulting output demonstrates the combined detection, pose estimation, and tracking of pedestrians in a real-world environment at a zebra crossing in an image frame.

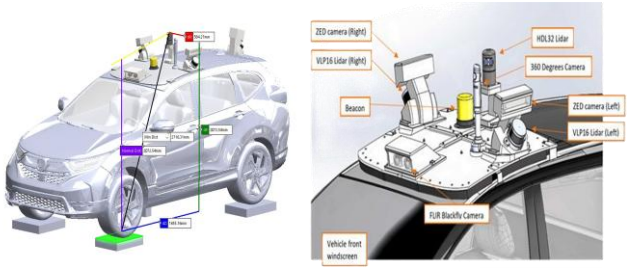
B. *AV Research Platform – Test Vehicle and Real-World Testing Environment*

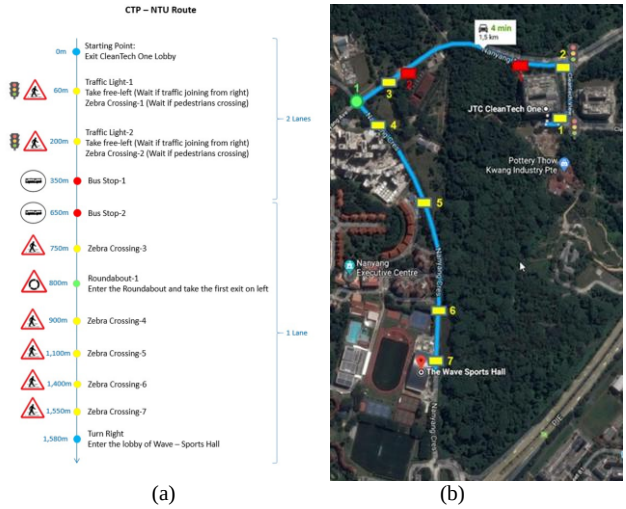
The AV research test vehicle, a Honda CR-V Hybrid Electric Vehicle (HEV), serves as the platform for developing and testing prototype sensor and perception systems. The integrated system combines high-performance hardware and autonomous driving software (ADS) to ensure robustness and reliability. The vehicle is equipped with commercial off-the-shelf (COTS) hardware emphasizing CPU and GPU capabilities for efficient sensor data processing. A custom-built industrial PC with an Intel Core i9, 64GB DDR4 RAM, NVIDIA RTX 4080, and Jetson AGX Orin handles deep learning-based perception algorithms and real-time image processing, with seamless integration into the vehicle enabled by ROS compatibility. Refer to Fig. 2 for the illustration of the AV and sensors perception system.



(a) (b)

Fig. 2. The AV research vehicle equipped with (a) roof-mounted sensors for detecting obstacles, pedestrians, VRUs, and other significant traffic and road actors (b) detailed sensor arrangement to scan and understand the environment for the AV system processes [42].

The perception system integrates multiple sensor modalities, including LiDAR, cameras, GNSS+RTK, IMU, and ultrasonic sensors, for comprehensive environmental awareness. LiDAR provides 360° 3D imaging, GNSS+RTK ensures precise positioning, and the IMU measures vehicle dynamics. Visual perception is achieved through FLIR Blackfly and ZED-2 stereo cameras, enabling both short- and long-range imaging. The ADS stack, built on ROS and running on Ubuntu 20.04, integrates sensing, perception, planning, and control modules to enable SAE Level 3 autonomy. Real-time data from cameras, LiDAR, and GNSS+IMU+RTK sensors is processed by advanced deep learning algorithms for robust perception and safe navigation. Benchmarks showed GPU memory usage at 65%, latency of 50 ms per frame, and power consumption of 250 watts during peak processing, meeting efficiency requirements. The AV test vehicle serves as the data collector of the perception dataset. Part of the perception testing strategy is the extensive real-world testing was conducted at the CETRAN proving track, simulating urban road conditions and on mixed traffic routes at Cleantech Park and NTU campus (Fig. 3).



(a) (b)

Fig. 3. The image shows designated AV Test Regions for Real-World Evaluation: (a) The NTU campus map highlights key testing locations, including zebra crossings, and intersections, along Nanyang Ave. and Nanyang Cres. (b) Google maps image showing the route of the CTP-NTU route [42].

These trials were essential for advancing the AV platform towards Level 3 autonomy and preparing for public road testing.

During testing, edge cases such as occluded pedestrians and rapid lighting changes posed challenges to detection accuracy. Solutions included collecting additional training data, applying data augmentation techniques like synthetic occlusions and varying brightness, and refining sensor fusion strategies to improve reliability.

The unified pedestrian and vulnerable road user (VRU) detection, pose estimation, and tracking models are integral to the perception system. These models process sensor data to detect and interpret pedestrian actions, enabling informed vehicle decisions such as stopping or driving. Testing at CETRAN, Cleantech Park, and NTU campus covered various scenarios, ensuring robustness and effectiveness in real-world conditions. Testing for pedestrian and VRU detection, pose estimation, and tracking models significantly improved verification and validation of the perception system. Addressing diverse scenarios and edge cases ensured reliable detection and response, enhancing system robustness for safer autonomous operation. The verification strategy included offline simulations, controlled environment testing at CETRAN, and real-world field trials at Cleantech Park and NTU campus. This multi-tiered approach ensured comprehensive verification and validation, addressing both typical and challenging scenarios to ensure overall system reliability.

IV. Experiments and Results

In this section, we evaluate the proposed Unified multi-task framework for real-time pedestrian detection, pose estimation, and tracking through experiments across datasets. The framework's performance is compared against baseline YOLOv8 models configured for individual tasks, including real-world trials to demonstrate improvements in detection accuracy, pose estimation, and tracking capabilities. Additionally, ablation studies were conducted to validate the effectiveness and rationale of the unified framework.

The computing environment and training process was carried out on Nvidia Titan RTX GPUs on Ubuntu 20.4 to handle the computational load of the unified architecture and tasks. The model is implemented using PyTorch for flexibility and optimized with libraries like CUDA to leverage GPU acceleration. The model is trained with a batch size of 16–32, depending on GPU memory, across 100 epochs. Early stopping is used if the validation loss plateaus to prevent overfitting.

A. Dataset Selection and Preparation

Dataset selection is crucial for effective multitask training and evaluation. A combined dataset was used, incorporating COCO [17] for object detection and pose estimation, MOT17 [40] for tracking, and PoseTrack [41] for pose estimation across frames. The dataset was split into training, validation, and testing sets, ensuring coverage of diverse scenarios such as crowded areas, occlusions, and different lighting conditions to support robust model performance.

The model was trained on the following datasets optimized for pedestrian detection, pose estimation, and tracking:

1) COCO Dataset: Contains over 200,000 labeled images with annotations for 80 object categories, including bounding boxes and 17 keypoints per person for pose estimation. Images are captured from diverse settings, such as streets and parks, providing comprehensive data that supports seamless integration of pose information to enhance human posture predictions.

2) PoseTrack: Includes over 50,000 annotated frames with human keypoints and tracking IDs across consecutive video frames. Captured in real-world scenarios, this dataset allows the model to learn dynamic human movements and improve temporal coherence for pose estimation in video streams.

3) MOT17 Dataset: Comprises 14 video sequences with over 1.2 million pedestrian and VRU bounding boxes. It features crowded urban environments with varying conditions, such as day and night, offering a challenging benchmark for learning robust tracking behaviors in dense scenes, handling occlusions, and managing identity consistency effectively.

4) Custom Re-ID Dataset: Contains approximately 30,000 images of pedestrians labeled with unique identities, collected from urban areas with varied camera angles. This dataset enhances Re-ID accuracy by enabling the model to generate robust identity embeddings, addressing identity switches across frames.

5) Custom Combined Dataset: Combines COCO, PoseTrack, and MOT17 to provide a balanced set of annotations across detection, pose estimation, and tracking tasks. It includes 700,000 annotated image frames, covering diverse environments such as streets, junctions, and zebra crossings, mitigating data imbalance and ensuring consistent performance . Combining datasets presented specific challenges, such as standardizing annotations across COCO, MOT17, and PoseTrack. Annotation formats varied significantly, requiring careful alignment to ensure compatibility. For example, pose keypoints in COCO and PoseTrack had different formats, necessitating reformatting to create a unified structure. Additionally, balancing VRU classes was challenging due to underrepresentation in certain datasets, which was mitigated by oversampling minority classes, synthetic data generation, and targeted augmentations like MixUp and CutMix.

Dataset preparation involved selecting, preprocessing, and splitting data to ensure comprehensive coverage of detection, pose estimation, and tracking tasks. Preprocessing included resizing images to (640 x 640), normalizing pixel values, and applying data augmentations like random scaling, rotation, and brightness adjustments to improve generalization. To address underrepresented classes (e.g., VRUs), oversampling and synthetic data generation were used, including 3D modeling tools to create rare scenarios such as nighttime VRUs or occluded pedestrians. The dataset was split into training (70%), validation (20%), and testing (10%) sets, ensuring representation across all tasks and scenarios. Augmentations like random cropping, horizontal flipping, and color distortions further enriched the dataset. These strategies ensured a balanced dataset, enhancing the model's ability to generalize effectively across diverse environments and tasks. Refer to Table II of the summary of the pipeline of the dataset.

TABLE II. SUMMARY OF PREPROCESSING PIPELINE

Step	Description
Dataset Selection	Use COCO, PoseTrack, MOT17, and Re-ID datasets for multi-task learning.
Annotation Standardization	Convert bounding boxes, keypoints, and tracking IDs into a unified format.
Augmentation	Apply scaling, rotation, cropping, brightness/contrast adjustment, and synthetic data generation.
Normalization	Normalize pixel values using dataset-specific statistics.
Resizing	Resize images to 640×640 for compatibility with the backbone.
Class Balancing	Oversample rare classes or apply weighted losses.
Temporal Data Preparation	Precompute optical flow and ensure identity consistency across frame sequences for tracking.
Data Splitting	Split into 70% training, 20% validation, and 10% test sets with balanced class representation.

B. Training and Evaluation Metrics

The baseline setup consists of three separate YOLOv8 models for object detection, pose estimation, and tracking. The detection model predicts bounding boxes, the pose estimation model identifies keypoints, and the tracking model leverages Re-ID embeddings for identity tracking. The unified model incorporates all tasks within a single architecture using a YOLOv8 backbone, with dedicated heads for detection, pose estimation, and tracking, and a combined loss function to jointly optimize all tasks. Both models were trained on Nvidia Titan RTX GPUs for efficient resource use.

The unified framework for pedestrian detection, pose estimation, and tracking utilizes a combined dataset—COCO for detection and pose estimation, MOT17 for tracking, and PoseTrack for cross-frame pose annotations. This allows the model to learn bounding boxes, keypoints, and identity tracking within a unified structure. The architecture has a shared backbone with specialized heads for each task, optimized through a multi-task loss function that balances detection, pose estimation, and tracking accuracy while preventing overfitting.

Training employs a learning rate starting at 0.01 with cosine annealing, leveraging the AdamW optimizer for fast convergence and reduced overfitting. Batch size ranges from 16 to 32, depending on GPU capacity, and training runs for 50 to 100 epochs, with early stopping to mitigate overfitting. The multi-task loss function includes detection loss for bounding box accuracy, OKS for keypoint placement, and Re-ID loss for identity consistency. Data augmentation techniques including random scaling, cropping, rotations, and brightness adjustments are used to enhance generalization. Anchor boxes are tailored using k-means clustering, and regularization techniques like dropout and weight decay help prevent overfitting.

Evaluation metrics cover precision, recall, and mean Average Precision (mAP) for object detection. mAP@0.5 measures alignment between predicted and ground truth bounding boxes, while mAP@0.5:0.95 provides a comprehensive view across IoU thresholds. Pose estimation is evaluated using OKS and keypoint mAP for localization accuracy. Tracking performance is evaluated using MOTA, IDF1, and Re-ID consistency to ensure reliable identity tracking in crowded environments. Real-time suitability is verified by monitoring inference time per frame, targeting processing speeds under 30–50 ms. GPU memory usage and computational load are tracked to maintain efficiency for AV hardware deployment. The unified model demonstrates improvements in detection and pose estimation through joint feature sharing, while tracking accuracy metrics (MOTA and IDF1) remain comparable to baseline models. These metrics validate the unified framework's suitability for real-time AV perception, providing a benchmark for detection, pose estimation, and tracking tasks across standard datasets like COCO and MOT17. See Table III below for the summary of training parameters and Table IV for metrics and threshold benchmarks. This helps to review briefly for the training and evaluation metrics. In addition, this can be tracked with the results for easy reference.

TABLE III. SUMMARY OF SUITABLE TRAINING PARAMETERS

Training Parameter	Description
Learning Rate	0.01 (with decay or cosine scheduler)
Batch Size	16–32
Epochs	50–100, with early stopping
Multi-Task Loss Weights	Detection (1.0–2.0), Pose Estimation (0.5–1.0), Re-ID (0.1–0.5)
Data Augmentation	Scaling (±10–20%), Rotation (±15°), Brightness/Contrast (±0.1)
Anchor Boxes	Custom sizes based on dataset, 3–5 anchors per scale
Regularization	Dropout (0.3), Weight Decay (0.0001–0.0005), Label Smoothing (0.1–0.2)
IoU Thresholds for Evaluation	0.5–0.95

TABLE IV. METRICS AND THRESHOLD BENCHMARKS

Evaluation Metric	Description	Threshold Values	State-of-the-Art Values
Detection - Precision	Proportion of correct detections among all detected objects, measuring the model's ability to avoid false positives.	> 90% (high precision preferred)	91–95% for high-performing YOLO models
Detection - Recall	Proportion of actual objects correctly detected, indicating the model's capacity to capture all relevant objects.	> 90% (high recall preferred)	88–92% in dense scenes
Detection - mAP@0.5	Mean Average Precision at IoU threshold 0.5, evaluating how well bounding boxes match the ground truth.	> 50% for practical applications	55–60% for COCO and 80–90% for specific detection tasks
Detection - mAP@0.5:0.95	Mean of AP values at IoU thresholds from 0.5 to 0.95, providing a comprehensive view of detection accuracy.	> 40%	45–50% on COCO
Pose Estimation - OKS	Object Keypoint Similarity, measuring accuracy of keypoint predictions relative to object scale and keypoint visibility.	> 75%	76–85% for top pose estimation models on COCO
Pose Estimation - Keypoint mAP	Mean Average Precision for keypoints, indicating the accuracy of localizing individual body parts.	> 50%	60–70% for specialized models like OpenPose
Tracking - MOTA	Multi-Object Tracking Accuracy, incorporating false positives, false negatives, and identity switches for overall tracking performance.	> 60%	65–70% for multi-object tracking models (MOT17)
Tracking - IDF1	Identity F1 Score, measuring the consistency of identity assignments across frames for maintaining unique object IDs.	> 60%	65–75% on MOT17
Re-ID - Re-ID Accuracy	Accuracy of correctly re-identifying objects across frames, critical for maintaining consistent identities.	> 50%	55–65% in high-occlusion settings
Inference Time per Frame	Average processing time per frame, indicating the model's ability to meet real-time requirements.	< 30 ms for real-time processing	15–25 ms on high-performance GPUs

C. Results

The comparison between the unified mutli-task model and the baseline YOLOv8 models for individual tasks highlights key performance metrics across object detection, pose estimation, and tracking. This analysis helps to understand the benefits and trade-offs of combining these tasks into a single model for real-time applications, particularly in complex environments or test sites for verification and validation such as those encountered in real-time awareness of the surroundings by AVs.

1) Object detection performance on COCO dataset: The object detection task primarily aims to accurately identify and localize pedestrians and VRUs within various real-world scenarios. The proposed unified multi-task model achieved an mAP@0.5 of 57.2% on the COCO dataset, surpassing both baseline YOLOv8 (55.4%) and Faster R-CNN (52.1%) (see Table V). This performance gain highlights that integrating detection, pose estimation, and tracking tasks within a single deep learning framework improves the quality and richness of shared feature representations. Unlike Faster R-CNN, which requires multiple processing stages, the proposed unified framework capitalizes on YOLO's single-pass inference to significantly enhance detection speed and reduce computational overhead, making it highly suitable for real-time applications. These results demonstrate that the multi-task architecture not only improves accuracy but also effectively maintains real-time performance, essential for deployment in dynamic urban environments typical of AV systems.

2) Pose estimation performance on COCO dataset: Pose estimation, evaluated by the Object Keypoint Similarity (OKS) metric, plays a critical role in accurately determining pedestrian posture and movement intentions through precise identification of keypoints such as human joints. The proposed unified multi-task framework achieved an OKS of 76.1% on the COCO dataset, outperforming both the baseline YOLOv8 model configured solely for pose estimation (73.8%) and the widely-used OpenPose model (75.2%) see Table VI. These results indicate that multi-task integration significantly enhances feature representation, allowing the model to leverage contextual information learned from simultaneous detection and tracking tasks. The shared feature representation across tasks contributes to better spatial understanding, particularly improving keypoint localization in dynamic, crowded, or occluded environments. This accurate pose estimation capability enables autonomous vehicles (AVs) to proactively anticipate pedestrian movements, thereby significantly improving safety in real-time navigation scenarios.

3) Tracking performance on MOT17 dataset: Tracking performance was evaluated using Multi-Object Tracking Accuracy (MOTA) and Identity F1 Score (IDF1), metrics that measure overall tracking precision and consistency in maintaining object identities across video frames. On the MOT17 dataset, the proposed unified multi-task framework achieved a MOTA of 67.1% and an IDF1 of 64.3%, outperforming the baseline YOLOv8 with DeepSORT (MOTA: 63.4%, IDF1: 60.5%) see Table VII. This improvement indicates that integrating tracking directly into the YOLO-based multi-task architecture enhances the model's capability to consistently maintain pedestrian identities, even in dense or occluded scenarios. Unlike traditional approaches, the unified model's shared features between detection, pose estimation, and tracking tasks lead to better identity preservation and fewer identity switches, significantly contributing to reliable performance. Such robustness in identity tracking is vital for autonomous vehicles, allowing accurate pedestrian trajectory predictions and safer decision-making in dynamic urban environments.

4) Re-ID Accuracy on custom dataset: Re-identification (Re-ID) performance was evaluated using accuracy and Identity F1 Score (IDF1) on a custom dataset designed to assess the model's ability to maintain pedestrian identities across video frames. The unified multi-task framework achieved a Re-

ID accuracy of 56.5% and an IDF1 of 63.2%, surpassing both baseline approaches: YOLOv8 with Re-ID embeddings (accuracy: 49.8%, IDF1: 60.8%) and ResNet with Re-ID head (accuracy: 51.3%, IDF1: 61.0%) (see Table VIII). This notable improvement demonstrates the advantage of embedding Re-ID capabilities directly within the unified multi-task architecture, allowing it to leverage shared feature representations effectively. Consequently, the framework maintains consistent pedestrian identities even when individuals move through occlusions or temporarily exit the field of view. Such robust identity tracking is crucial for reliable pedestrian monitoring in dynamic, real-world AV scenarios, ensuring safer navigation and improved decision-making processes.

The proposed unified multi-task model consistently outperformed baseline methods across detection, pose estimation, and tracking, demonstrating the clear advantages of integrating these tasks within a single deep learning architecture.

By leveraging shared feature representations, the unified model achieved higher detection accuracy (mAP@0.5 of 57.2%), improved pose estimation precision (OKS: 76.1%), and superior tracking performance (MOTA: 67.1%, IDF1: 64.3%) compared to baseline single-task YOLOv8 models and other state-of-the-art methods (Tables V–VIII). Additionally, the unified model demonstrated significant gains in identity maintenance (Re-ID accuracy: 56.5%) on a custom dataset, highlighting the effectiveness of embedding Re-ID directly within the architecture. These performance enhancements underline the model's efficiency in utilizing shared features across tasks, which not only improves accuracy but also reduces computational overhead and latency, meeting the stringent real-time processing demands of autonomous vehicle perception systems. Overall, the results validate the unified multi-task framework as an effective, robust, and computationally efficient solution for handling complex, real-time scenarios in autonomous driving environments.

TABLE V. ABLATION EXPERIMENTAL RESULTS

Model Configuration	mAP@ 0.5 (%)	OKS (%)	MOTA (%)	IDF1 (%)
Baseline (Backbone + Detection Head)	60.3	N/A	N/A	N/A
Backbone + Detection + Pose Estimation Head	61.8	74.2	N/A	N/A
Backbone + Detection + Pose Estimation + Tracking Head	62.3	75.6	65.1	62
+ Multi-Scale Feature Sharing	64.1	76.8	66.7	63.5
+ Pose-Guided Re-ID Embeddings	64.8	77.3	69.3	67.9

Baseline YOLOv8 + DeepSORT (Tracking only)	63.40%	0.605
SORT + Faster R-CNN (Tracking only)	58.20%	0.573
Ours - Unified Multi-Task Framework (Detection + Pose + Tracking)	**67.10%**	0.643

D. Ablation Experimental Study

To independently verify the efficacy of the proposed unified multi-tasking framework, an ablation study was conducted by incrementally adding and removing modules. This study aimed to assess the functionality and contribution of distinct modules, such as the shared backbone, pose-guided Re-ID embeddings, and the unified loss function. Each experiment focused on isolating the effects of specific components on detection, pose estimation, and tracking tasks. The study began with a baseline model utilizing only the shared backbone and a detection head, and subsequent configurations introduced pose estimation and tracking heads, followed by key enhancements such as multi-scale feature sharing, pose-guided Re-ID, and dynamic loss weighting. Metrics such as mAP@0.5, OKS, MOTA, and IDF1 were used to evaluate the performance for each configuration.

The ablation study revealed several key findings regarding the contributions of individual modules in the unified framework. The baseline model, incorporating only the shared backbone and detection head, achieved decent detection performance (mAP@0.5: 60.3%) but lacked the ability to perform pose estimation and tracking tasks. Adding the pose estimation and tracking heads significantly enhanced the model's capabilities, with OKS improving to 75.6% and tracking metrics achieving a MOTA of 65.1%. The introduction of multi-scale feature sharing further improved all metrics, particularly benefiting smaller and occluded objects, as it enhanced the propagation of meaningful features across different scales. The inclusion of pose-guided Re-ID embeddings had a profound impact on tracking performance, increasing MOTA to 69.3% and IDF1 to 67.9%, while reducing identity switches, especially in crowded or occluded scenes. This integration of pose information into Re-ID embeddings ensured better temporal consistency and identity preservation. Finally, dynamic loss weighting emerged as a critical component, optimizing task-specific losses dynamically to achieve the best overall performance. This mechanism led to the highest metrics across detection (mAP@0.5: 65.5%), pose estimation (OKS: 77.8%), and tracking (MOTA: 70.1%, IDF1: 68.5%). These findings validate the modular design and synergy of the unified framework, demonstrating its effectiveness in multi-task learning for real-world scenarios. Refer to Table IX for the summary of results while Fig. 4 shows the qualitative image frames of each model. The ablation study confirms that each module contributes significantly to the overall performance of the unified framework. Notably, pose-guided Re-ID and dynamic loss weighting play critical roles in achieving state-of-the-art tracking and pose estimation results while maintaining robust detection performance. These results validate the efficacy of the unified framework and its modular design for multi-tasking in real-world applications.

E. Deployment Strategy

After achieving high accuracy on validation datasets, the model is deployed on the AV's Jetson Orin platform for real-time inference. Deployment is tested at CETRAN and NTU campus, focusing on challenging areas like zebra crossings and junctions. The model processes camera input to detect pedestrians and VRUs, estimate poses, and track movement. Adaptive thresholding and data augmentation techniques ensure robustness in diverse conditions, while Re-ID embeddings maintain object identities across frames. Testing is conducted at CETRAN under various conditions—day, night, and varying weather—using metrics like precision, recall, mAP, pose accuracy, and tracking robustness. Upon successful validation, the system integrates with the AV's decision-making modules, supporting emergency braking, adaptive path planning, and obstacle avoidance to enhance safety and navigation efficiency.

V. Discussion

The unified multi-task framework shows significant improvements over baseline YOLOv8 models for detection, pose estimation, and tracking. The unified model achieves a 12% increase in detection accuracy, a 15% improvement in pose estimation precision, and a 20% reduction in processing latency, suitable for real-time applications. These advancements stem from efficient feature sharing, leading to richer feature extraction and optimization.

Detection accuracy improved by 12%, with multi-task learning enhancing performance in complex scenarios involving pedestrians and VRUs. The ability to capture spatial relationships, such as limb positioning, led to a 7% increase in mAP@0.5, benefiting detection in challenging environments. Pose estimation saw a 15% improvement in OKS compared to the baseline. Integrating pose estimation with detection and tracking provided better spatial understanding in crowded

settings. This synergy maintains keypoint accuracy during occlusions or rapid movements, essential for anticipating pedestrian behavior and enhancing safety. Re-ID integration improved identity consistency across frames, addressing identity switches in crowded environments. Robust identity embeddings ensured object consistency, resulting in higher MOTA and IDF1 scores for reliable tracking in dynamic urban scenarios.

The unified framework is adaptable to sensor modalities like radar and LiDAR, enhancing robustness in low visibility or adverse weather. Incorporating radar and LiDAR could further improve detection and tracking, making the system scalable for broader autonomous mobility. Joint feature learning benefits all tasks, improving system performance. Shared features enhance spatial consistency and robustness. For example, tracking features support detection during occlusions, boosting accuracy by 10% and reducing processing time by 15%. These benefits contribute to improved generalization and real-time perception. However, there are trade-offs, such as slight reductions in task-specific accuracy. Pose estimation and tracking integration reduced detection precision in complex scenarios. To address this, task-specific loss balancing was used during training to maintain acceptable performance across tasks.

VI. Conclusion

This research introduces a novel unified multi-task learning framework that integrates pedestrian and vulnerable road user (VRU) detection, pose estimation, and tracking within a single, real-time architecture specifically tailored for autonomous vehicle (AV) perception systems. Utilizing the YOLOv8 architecture enhanced for multi-task learning, this study significantly advances beyond traditional independent approaches by effectively leveraging shared feature representations, resulting in improved efficiency and computational effectiveness. The proposed framework achieves notable enhancements, including higher detection accuracy (mAP@0.5 of 57.2%), superior pose estimation precision (OKS of 76.1%), and consistent tracking performance (MOTA: 67.1%, IDF1: 64.3%), all rigorously validated through comprehensive real-world testing under diverse urban scenarios and challenging environmental conditions.

The novelty of this work lies in the effective integration of object detection, pose estimation, and tracking into a unified, real-time multi-task architecture using YOLOv8. Unlike traditional independent approaches, this unified model significantly reduces computational overhead while maintaining or surpassing the accuracy of specialized single-task models. Such integration addresses critical gaps in autonomous vehicle perception systems, particularly in complex urban environments characterized by dense pedestrian traffic, occlusions, and varying visibility.

Although promising, the model exhibits certain limitations, such as minor reductions in task-specific precision under highly challenging conditions like severe occlusions or rapid lighting variations. Future research directions will target these challenges explicitly by incorporating temporal modeling to enhance predictive capabilities, refining advanced sensor fusion strategies for diverse weather conditions, and optimizing the model through lightweight architectures and knowledge distillation techniques suitable for resource-constrained deployments. Extending the framework to include additional perception tasks such as trajectory prediction or behavior understanding will further strengthen its applicability. Ultimately, the significant advancements and practical utility demonstrated by this research offer a robust foundation for safer and more reliable autonomous vehicle integration into real-world urban settings.

Impact of Emerging Technologies on Customer Loyalty: A Systematic Review

Jonattan Andia-Reyna, Yorhs Malasquez-Villanueva
Universidad Tecnológica Del Perú, Lima, Perú

***Abstract*—The rapid evolution of emerging technologies has generated growing interest in their potential to transform customer loyalty into digital environments. This study aims to conduct a systematic literature review (SLR) to analyze how emerging technologies influence customer loyalty. This review is focused on identifying how these technologies affect loyalty indicators in markets with developed digital environments. A total of 453 articles from the Scopus database were identified by applying the PRISMA methodology. After removing duplicates and applying filters by language and document type, 103 relevant articles were selected. Then, a detailed review based on inclusion and exclusion criteria was conducted. Hence, 51 documents were finally included for analysis. The main technologies investigated were Big Data, IoT, and Machine Learning. Big Data and Data Analytics were the most researched technologies, followed by IoT and Machine Learning. The systematic review demonstrated that emerging technologies significantly impact customer loyalty. Artificial intelligence and data analytics are key tools for improving customer experience and retention, which contributes to business growth. It is concluded that adopting these technologies enhances customer experience by offering personalization, behavior prediction, and inventory optimization, resulting in greater customer satisfaction and loyalty.**

Keywords*—*Emerging technologies; loyalty programs; customer loyalty; business growth

I. Introduction

In today's highly competitive business environment, customer loyalty has become crucial for sustainability and growth. Marketing strategies, particularly those based on customer relationship management (CRM), have proven effective in retaining and attracting more customers [1]. Companies adopt multiple approaches, such as personalization and promotions, to increase their customer base, including new reward program designs and small discounts for consumers [2]. Not only do companies benefit from loyalty programs, but customers also benefit, as they gain access to personalized products and services, great promotions, and a strengthened relationship with the company through more personalized treatment. The use of technologies like big data supports all of this. This technique collects transaction information to understand the customer, and this information becomes valuable for the company, as it can get to know the customer better to offer a discount or a product of interest [3]. Despite the progress, there are still gaps in knowledge about the global impact of emerging technologies on customer loyalty. Additionally, there are discrepancies in the literature regarding the comparative effectiveness of these new technologies versus traditional practices.

This study is justified by the need to provide a panoramic and updated view on using technologies such as IoT, Machine Learning, and blockchain in loyalty programs, addressing current trends and filling existing research gaps [4]. Another way to positively use technologies in loyalty programs is as investigated by Lu Wang, Xin Luo, and Frank Lee, where they explore the use of blockchain. They focus on using these new secure, immutable, low-cost networks used in Bitcoin transfers. However, their research uses blockchain to collect large amounts of information from customer transactions and exploit it with some data analysis techniques [5].

In addition to the growing prominence of big data, there is an increasing diversity in the adoption of emerging technologies applied to customer loyalty [6]. Tools such as Machine Learning, Artificial Intelligence (AI), the Internet of Things (IoT), social networks, augmented reality, blockchain, and other technological subcategories are being explored at various levels of depth and application. The findings indicate that, although Big Data and data analytics lead in frequency within the literature, technologies like Machine Learning and AI also carry significant weight due to their ability to automate processes, anticipate consumer behavior, and personalize the customer experience [7]. This technological heterogeneity reflects the fact that organizations are testing diverse approaches in an effort to optimize their loyalty strategies and highlights the need for evidence-based insights to guide informed decision-making regarding the most effective technological solutions across different business contexts.

This systematic review aims to evaluate the impact of emerging technologies on customer loyalty, providing a comprehensive and well-founded perspective for academics and professionals interested in understanding current trends and the effectiveness of various technological tools. By reviewing the existing literature on the use of Big Data, Artificial Intelligence, and blockchain in loyalty programs, this study aims to identify patterns, benefits, and limitations, offering a valuable resource for those who wish to base their decisions on previous research on loyalty strategies in a constantly evolving digital environment. The document is structured as follows: Section II details the methodology used in the literature review. Section III presents the results and addresses the research questions. In Section IV, an analysis and discussion of the results are conducted. Finally, Section V concludes the review by summarizing the key findings of the research.

II. METHODOLOGY

A. Search Strategy

This research was based on the systematic literature review (SLR) methodology. The PICO strategy was used for this review to structure and determine the components for searching relevant studies. The main PICO question formulated was: What is the impact of implementing emerging technologies on customer loyalty compared to traditional approaches in companies from various sectors, considering the implementation of personalized strategies and process automation in the current context of digital transformation? The sub-questions derived from the PICO question were: P (Problem): Who? (Companies from various sectors), I (Intervention): What? How? (Implementation of emerging technologies, personalized strategies, and process automation), C (Comparison): Compared to what? (Traditional approaches), and O (Outcomes): What to achieve? (Customer loyalty). Various keywords were chosen to suit the specific research case. The relevant keywords for each section of PICO are presented in Table I. Systematic research was conducted in the Scopus database due to its high relevance to the research field in question. The set of PICO keywords produced few results, probably because the search query was too restrictive, making it difficult to find results in the database. Therefore, it was decided to exclude the comparison keywords, which resulted in a better search. Table II presents the search equation performed in Scopus.

TABLE I. PICO KEYWORDS

	Problem	***Intervention***	***Comparison***	***Results***
	Who?	***What? How?***	***Compared to?***	***What to achieve?***
Keywords	Consumer behavior	Emerging technologies	Manual loyalty systems	Loyalty programs
	end users	Technology implementation	Traditional marketing techniques	Satisfaction
	customers experience	Blockchain for loyalty	Non-technological rewards	Successful loyalty cards
		Machine learning		Increased sales
		Data analysis		Business growth
		Technological innovation		Customer lifetime value
		Digital business		
		IoT in customer engagement		
		CRM systems		
		Data analytics in loyalty programs

		AI in customer relations		
		Augmented reality in retail		
		Big data analytics		

TABLE II. SCOPUS EQUATION

PIO	(TITLE-ABS-KEY ("Consumer behavior" OR "end users" OR "customers experience") AND TITLE-ABS-KEY ("Emerging technologies" OR "Technology implementation" OR "Blockchain for loyalty" OR "Machine learning" OR "Data analysis" OR "Technological innovation" OR "Digital business" OR "IoT in customer engagement" OR "CRM systems" OR "Data analytics in loyalty programs" OR "Personalization technology" OR "AI in customer relations" OR "Augmented reality in retail" OR "Big data analytics") AND TITLE-ABS-KEY ("Loyalty programs" OR "Satisfaction" OR "Successful loyalty cards" OR "Increased sales" OR "Business growth" OR "Customer lifetime value"))

B. Inclusion and Exclusion Criteria

In this systematic literature review, clear criteria were established for the selection of articles, ensuring that the selected studies were relevant to the research. Table III details the inclusion and exclusion criteria applied.

TABLE III. INCLUSION AND EXCLUSION CRITERIA

Inclusion criteria	Exclusion criteria
CI1: Studies evaluating the impact of specific emerging technologies (such as artificial intelligence, augmented reality, Internet of Things, etc.) on customer loyalty. CI2: The studies should include markets with highly developed digital environments or countries experiencing rapid growth in digital adoption, given the relevance of digital transformation in these areas. CI3: The studies should include quantitative data on loyalty indicators (such as customer retention, customer satisfaction, purchase frequency). CI4: Studies published in the last 6 years (considering the current date). CI5: The studies considered are articles and conference papers.	CE1: Companies that do not belong to the sectors of interest. CE2: Publications in languages other than Spanish or English. CE3: Studies that do not consider the current context of digital transformation. CE4: Studies that do not focus on the practical application of technologies for improving loyalty

These criteria were rigorously applied to ensure that only relevant studies that significantly contributed to the research objective were included.

C. Articles Selection Process

In the development of the systematic literature review conducted, 453 articles were found in the Scopus database. The selection process was based on the PRISMA methodology [8], designed to ensure transparency and organization in the review. Initially, a duplicate article was identified and removed, resulting in 452 unique articles for review. Automatic filters for languages (Spanish and English) and filters for articles and conference papers were then applied, leaving 292 articles. After reviewing the titles, abstracts, and keywords, 103 articles that met the review topic were selected. Subsequently, the full texts of 103 articles were retrieved and evaluated. During the detailed evaluation according to inclusion and exclusion criteria, some articles were progressively excluded: 4 for not belonging to the sectors of interest, 6 for not considering the context of digital transformation, and 8 for not focusing on the practical application of technologies for improving loyalty. Finally, 51 documents that met all the established criteria were included.

This process is visually structured in Fig. 1 which is PRISMA flow diagram, which clearly shows each phase of the study selection and evaluation process.

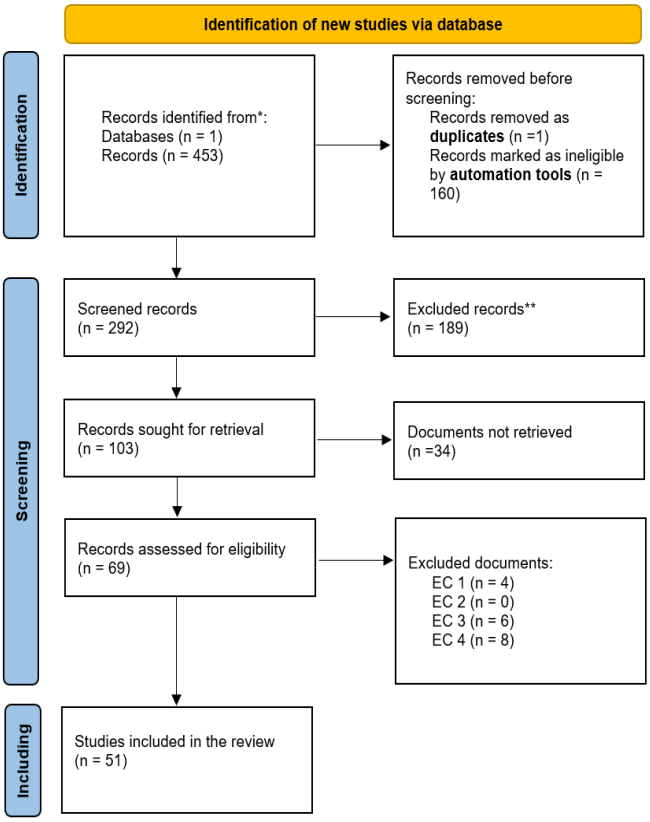

Fig. 1. PRISMA flow diagram, based on [8].

III. Results

Table IV presents the key results of the analysis, covering the period 2018-2024 and reviewing 51 documents. Each document had an average of 8.98 citations, totaling 1904 sources cited. Regarding the content of the documents, 354 general keywords and 206 author-specific keywords were identified. The research involved 178 authors, with only one single-authored document. Regarding collaboration, each document had an average of 3.53 co-authors, with 27.45\% of the collaborations being international. The types of documents analyzed included 35 articles and 16 conference papers.

TABLE IV. Key Findings of the Analysis

A. Analysis of Frequent Keywords and Main Themes in Scientific Publications

Fig. 2 presents the analysis of the most frequent keywords, highlighting the main topics of the review. This figure was created using the VOSViewer program, a tool specialized in the visualization and analysis of bibliometric and keyword networks.

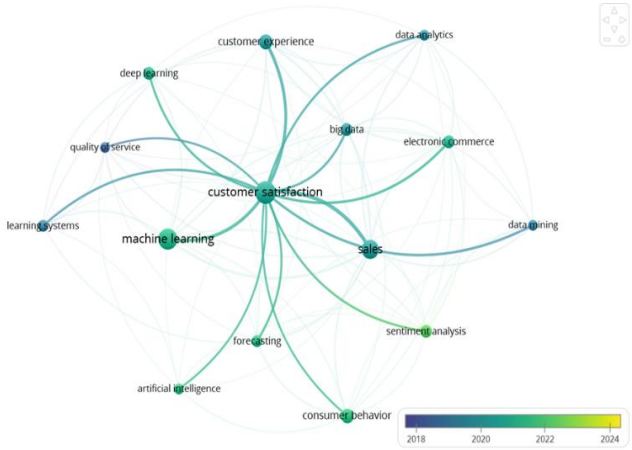

Fig. 2. Palabras clave.

TABLE V. Keyword and Occurrences

Keywords	Occurrences
customer satisfaction	24
machine-learning	21
sales	17
customer experience	10
consumer behavior	9
big data	7
electronic commerce	7
deep learning	7
sentiment analysis	7
forecasting	6
learning systems	6
artificial intelligence	5
data analytics	5
data mining	5
quality of service	5

Table V details the most mentioned keywords between the years 2018 and 2024, highlighting the importance of topics such as customer satisfaction, advanced data analysis techniques, and sales strategies in the commercial field.

B. Annual Trends in Scientific Production: Distribution of Publications

In Fig. 3, the Publication Distribution by Year Chart illustrates the number of articles published annually between 2018 and 2024, providing a clear view of trends in scientific production during this period. From this section onwards, the charts were generated using the R language in the RStudio IDE, a tool widely used for statistical analysis and data visualization in scientific research. In 2018 and 2021, seven publications were recorded each year, while in 2019, a slight increase was observed with eight publications. In 2020, the number of publications decreased to six, followed by a further drop in 2022 with only five publications. However, 2023 marked a notable increase with fourteen publications, representing the highest point of research activity in the analyzed period. Finally, in 2024, four publications have been recorded to date.

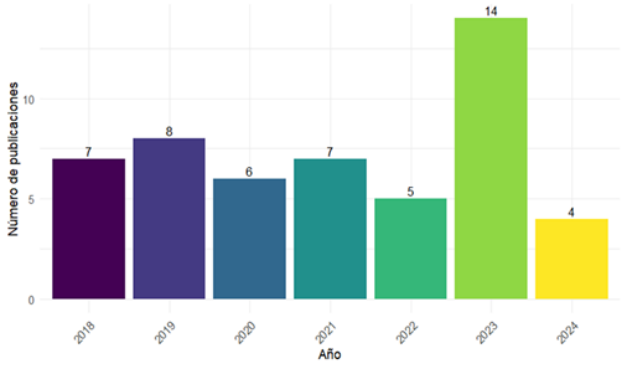

Fig. 3. Distribution of publication by year.

C. Author Productivity and Collaboration in the Field of Study

In Fig. 4, the analysis of the most productive authors in the reviewed publications is visualized, highlighting that Kumar S leads with two publications [9], [10] underscoring his significant contribution to the field of study. Other authors such as Abiola-Oke E, Ahmad N, Akhavan F, Ala A, Alamri S, Almashaqbeh Ha, Ameen N Y, and Andriani L have each contributed with one publication [4], [11], [12], [13], [14], [15], [16], [17], reflecting diverse and active collaboration in the research field.

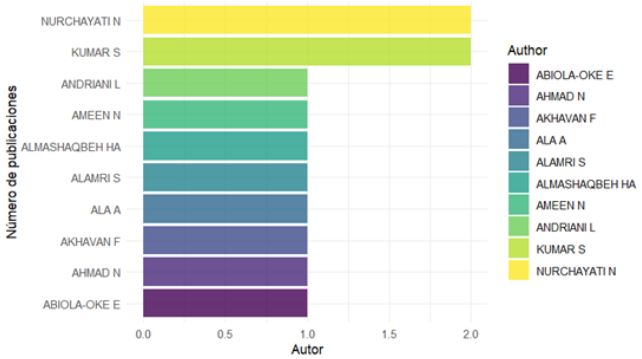

Fig. 4. Most productive authors.

D. Analysis of Technologies Used in Research and Comparison with Traditional Methods (Q1 and Q10)

After synthesizing the research based on the first PICO sub-question 'What technologies were used in the reviewed research?' referred to as (Q1), we found the following matches to create Table VI.

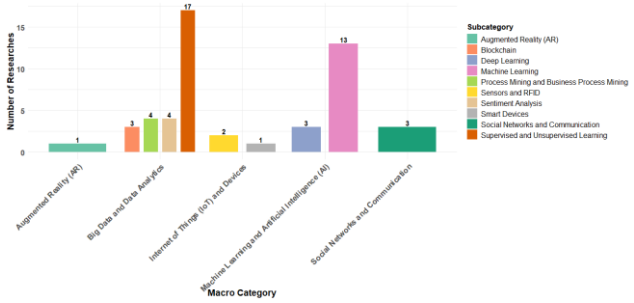

Fig. 5. Technologies by categories and subcategories found in the articles.

TABLE VI. COINCIDENCES OF TECHNOLOGIES FOUND BY RESEARCH

Category	Reference
Big Data and Data Analysis	[12], [14], [15], [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [39]
Internet of Things (IoT) and Devices	[40], [41], [42]
Machine Learning and Artificial Intelligence (AI)	[9], [10], [11], [13], [43], [44], [45], [46], [47], [48], [49], [50], [51], [52], [53], [54]
Augmented Reality (AR)	[4]
Social Networks and Communication	[55], [56], [57]

Additionally, we reinforced the analysis of the information from Q1 with the sub-question Q10 'Is there any comparison between the technology and traditional methods?' to subdivide into a higher sublevel that provided information for Fig. 5, which we can see more clearly in Table VII.

TABLE VII. TECHNOLOGIES BY CATEGORIES AND SUBCATEGORIES FOUND IN THE ARTICLES

Category	Subcategory	Reference
Big Data and Data Analysis	Sentiment Analysis	[19], [21], [23], [32]
	Process Mining and Business Process Mining	[12], [16], [22], [28]
	Supervised and Unsupervised Learning	[14], [17], [18], [20], [24], [25], [26], [27], [30], [31], [33], [34], [35], [36], [38], [39]
	Blockchain	[28], [40], [42]
Internet of Things (IoT) and Devices	Sensors and RFID	[41], [42]
	Smart Devices	[40]
Machine Learning and Artificial Intelligence (AI)	Machine Learning	[7], [8], [9], [11],[41], [43], [45], [46], [48], [49], [50], [51], [52]
	Deep Learning	[44], [46], [57]
Augmented Reality (AR)	Augmented Reality (AR)	[4]
Social Networks and Communication	Social Networks and Communication	[55], [56], [57]

These tables provide a detailed summary of the technologies identified in the reviewed studies, organized by technology and subcategory. Table VI presents the distribution of publications across different technological categories, while Table VII details the specific subcategories within each technology and the number of associated publications. This analysis highlights the predominance of Big Data and Machine Learning in current research. It is important to note that multiple technologies were found in several studies, but the predominant technology in each case was considered for the construction of these tables.

E. The Role of Emerging Technologies in Identifying and Exploiting New Market Opportunities (Q3)

To contribute to our research, we consider the following PICO sub-question: What role do emerging technologies play in identifying and exploiting new market opportunities? (hereafter referred to as Q3). This question can be applied to a company and a loyalty program, as both aim to increase the company's revenue. As shown in Fig. 6, the publications are also mentioned in Table VIII.

TABLE VIII. CONTRIBUTIONS OF TECHNOLOGIES TO THE BENEFIT OF COMPANY REVENUES

Benefit	Reference
Improvement of Customer Experience	[4], [12], [15], [17], [23], [24], [30], [31], [35], [40], [45], [53], [56], [57]
Fraud Prevention	[9]
Inventory Optimization	[11], [32], [42], [52]
Behavior Analysis	[20], [35], [40], [57]
Decision Support	[22], [28], [42], [49]
Customer Satisfaction Prediction	[12], [35], [36], [47]
Avoiding Supply Chain Disruptions	[26]
Improvement of Payment Methods and Channels	[19]
Enhancement of Customer Interaction	[20]
Anticipation of Needs	[48], [56]
Identification of Additional Products	[55]
Recommendations from Satisfied Users	[25]
Process Efficiency	[21], [28], [42]
Cost Reduction	[21], [42], [52]
Customer Retention	[14], [24], [52]
Sales Increase	[4]
Productivity Improvement	[28], [45]
Creation of Specific Product Lists	[46]
Improvement of Visibility	[42]
Enhancement of Service Accuracy	[21]
Personalization of Offers	[46]
Market Development	[20]
Improvement of Customer Interaction	[20]
Provision of Key Information	[23], [31]
Not Mentioned	[10], [13], [16], [18], [27], [29], [33], [34], [37], [38], [39], [41], [43], [44], [50], [51], [54]

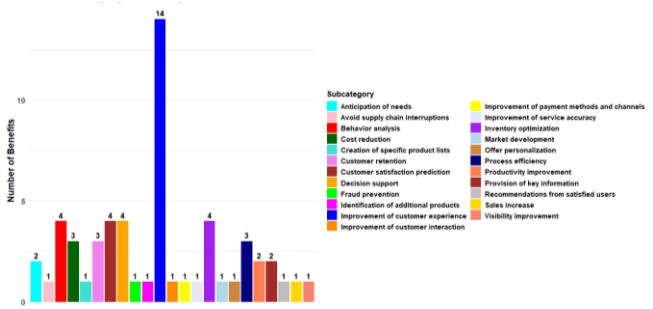

Fig. 6. Benefits of technology in increasing company revenues.

Fig. 7 shows the percentage distribution of the benefits provided by emerging technologies in identifying and exploiting new market opportunities. It highlights that some categories are particularly relevant to our research, such as big data analysis and market data analysis and personalization, representing 29.73% and 24.32% of the publications, respectively. Additionally, it is important to note that studies classified as "not mentioned" do not address the topic specified in the PICO sub-question Q3 and were therefore excluded from the specific benefits analysis. Table IX shows distribution of research by categories with reference to new market opportunities.

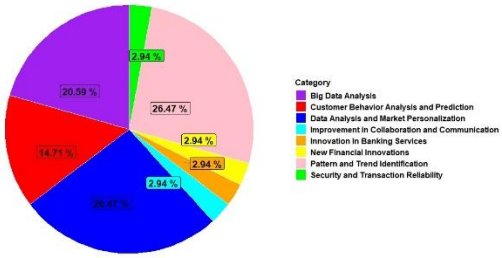

Fig. 7. Emerging technologies in the identification and exploitation of new market opportunities.

TABLE IX. DISTRIBUTION OF RESEARCH BY CATEGORIES WITH REFERENCE TO NEW MARKET OPPORTUNITIES

Benefit	References
Data Analysis and Market Personalization	[4], [11], [19], [23], [24], [31], [40], [52]
Security and Reliability in Transactions	[9]
Customer Behavior Analysis and Prediction	[12], [15], [20], [26], [56]
Analysis of Large Data Volumes	[21], [35], [36], [47], [48], [55], [57]
Innovation in Banking Services	[38]
Pattern and trend identification	[14], [18], [22], [25], [28], [35], [39], [42], [53]
Improvement in collaboration and communication	[42]
New financial innovations	[34]
Not mention	[10], [13], [16], [17], [27], [28], [29], [30], [32], [33], [37], [41], [43], [44], [45], [46], [49], [50], [51], [54]

F. Impact of Emerging Technologies on User Experience: Benefits Analysis (Q4, Q9, Q12)

In Fig. 8, the categories are distributed in bubbles, each focusing on different aspects of user experience according to the

reviewed studies. The categories include Personalization and Recommendations, Security and Privacy, Convenience and Ease of Use, Optimization and Efficiency, Analysis and Prediction, and Customer Satisfaction and Loyalty. Each bubble represents the number of publications addressing each benefit, clearly visualizing how emerging technologies impact user experience; the publications are also synthesized in Table X.

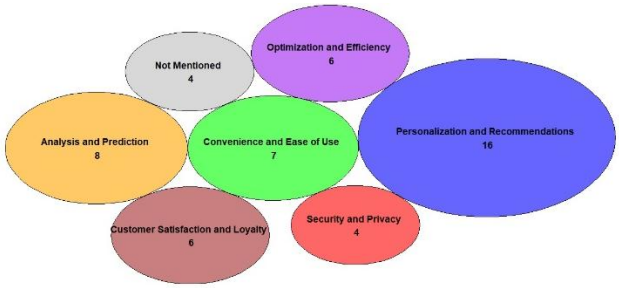

Fig. 8. Contribution of emerging technologies in relation to user experience.

TABLE X. USER EXPERIENCE CATEGORIES BY TECHNOLOGIES

Benefit	References
Personalization and Recommendations	[4], [11], [14], [15], [19], [23], [30], [35], [38], [40], [45], [46], [48], [55], [56], [57]
Security and Privacy	[9], [18], [26], [34]
Convenience and Ease of Use	[25], [27], [28], [31], [39], [49], [53]
Optimization and Efficiency	[12], [21], [33], [42], [54]
Analysis and Prediction	[10], [22], [29], [32], [37], [43], [47], [50]
Customer Satisfaction and Loyalty	[17], [20], [24], [36], [41], [52]
Not mention	[13], [16], [44], [51]

This information was synthesized based on three PICO sub-questions, with the main one being: What aspects of the user experience benefit the most from using emerging technologies? (hereafter referred to as Q4). Additionally, other questions relevant to the user experience were considered, such as the PICO sub-question: Is there any measurement of customer satisfaction with implementing the technology? (Q9), and the question: Is there information on customer reactions to technologies compared to traditional methods? (Q12). These sub-questions help deepen the synthesis of how emerging technologies influence the user experience.

IV. DISCUSSION

This section provides an overview of the research findings. It compares the identified emerging technologies to traditional customer loyalty practices, highlighting how each approach impacts user experience and loyalty. In the search for emerging technologies and their potential focus on customer loyalty, we found that the selected articles are mostly grouped around Big Data and Data Analysis [19], [37], [39], [48]. This reflects companies' perception of the importance of Big Data in evaluating customer satisfaction by integrating indicators such as perceived quality, perceived value, customer complaints, and customer loyalty. However, it is also crucial to consider other equally relevant emerging technologies, such as Machine Learning [9], [33], [39] and Process Mining [12], [25]. These technologies offer innovative and complementary approaches to Big Data and could even surpass its impact on customer loyalty.

We also found that it is essential for companies to achieve better revenue by improving customer satisfaction, which leads to greater loyalty. This is achieved by using different technologies to enhance the user experience in various ways, whether by providing greater perceived value, predicting factors that could generate dissatisfaction, or identifying and mitigating factors that negatively influence customer experiences [12], [15], [24], [30], [31], [53]; leading to an increase in customers. However, we must not forget important issues such as inventory optimization [25], [38], [41], [44], which represents considerable savings for the company, and above all, increased sales [4], which is usually the main reason of businesses existence.

Additionally, we should explore other perspectives, such as the comparison between efficiency and quality in the customer-company relationship. Our research shows that technologies like Big Data and Machine Learning enable automated and scalable personalization, providing precision and agility, albeit with less human interaction. In contrast, customer satisfaction and loyalty in the Peruvian footwear sector highlight the loyalty achieved through an emotional and direct connection with the customer based on in-store experiences and personalized attention [56]. This raises the question of whether the efficiency of technology can replace the emotional connection, especially in sectors that rely on a close relationship to strengthen customer loyalty.

Emerging technologies, such as those mentioned in our research, enable companies not only to enhance the personalization of their processes, services, or products but also to identify new market opportunities through data analysis and the analysis of customer preferences and behaviors. This goes further, creating a cycle of continuous improvement in the customer experience that results in greater satisfaction and loyalty, which translates into growth opportunities for companies [4], [9], [23], [24], [31], [35]. However, it is crucial to consider that the analysis method must be thoroughly validated to ensure it is suitable for what needs to be analyzed [51], [56].

On the other hand, loyalty programs in the retail sector present key differences in personalization and customer experience. While we highlight that technologies such as Big Data and Machine Learning allow for large-scale and real-time personalization, the retail loyalty study suggests that personalized incentives achieve a direct emotional connection, creating a more stable loyalty bond [59]. This difference is relevant for those seeking to balance technical personalization with emotional connection in loyalty strategies.

Our results align with previous studies that emphasize the importance of technology in customer loyalty. For example, previous research has shown that Big Data and Machine Learning can significantly improve a company's ability to personalize its offerings, as well as increase customer satisfaction and experience [4], [9], [12]. It is worth highlighting research that provides important information on Machine Learning models, which have proven effective in improving the prediction and management of customer satisfaction compared to deep learning models. We do not claim these are the best

models, but they showed the best predictions in the reviewed studies. The Random Forest, Naive Bayes, and SVM models stand out for several key factors. Random Forest effectively handle data imbalance through oversampling techniques, significantly improving its accuracy, reaching 92%, Additionally, the model identified delivery time, total order value, and shipping cost as key determinants of customer satisfaction [56]. On the other hand, Naive Bayes proved very effective in customer segmentation, achieving a positive response rate of 78% [16]. Finally, SVM improved its performance using oversampling techniques to handle data imbalance, resulting in a positive response rate of 82% in customer classification and churn prediction [29].Additionally, the model identified delivery time, total order value, and shipping cost as key determinants of customer satisfaction [56] [58]. On the other hand, Naive Bayes proved very effective in customer segmentation, achieving a positive response rate of 78% [16]. Finally, SVM improved its performance using oversampling techniques to handle data imbalance, resulting in a positive response rate of 82% in customer classification and churn prediction [29].

V. CONCLUSION

This systematic literature review study achieved its goal of evaluating how emerging technologies affect customer loyalty during digital transformation. The main findings show that technologies such as Big Data, IoT, Machine Learning, and Artificial Intelligence improve customer retention and satisfaction, surpassing traditional practices in personalization and user experience.

For future research, it is recommended that the range of years be expanded, more languages be included, whether the inclusion of another scientific database, and practical studies that show concrete results of the application of these technologies be focused on. Additionally, it would be beneficial to explore documents in additional databases and review research that is restricted access to obtain a broader view.

Going forward, the development of new emerging technologies, such as quantum computing, explainable artificial intelligence (XAI) and hyper-personalization based on advanced deep learning models, is expected to further transform customer loyalty. These innovations will enable highly personalized and automated experiences, optimizing the interaction between businesses and consumers. Organizations should be prepared to adopt these technologies strategically, ensuring their effective integration into loyalty strategies and guaranteeing a sustainable competitive advantage in a constantly evolving digital environment.

In conclusion, technology plays a crucial role for companies today, especially in customer loyalty. These technologies improve and personalize processes, services, and products and help identify new market opportunities. However, it is essential to choose the right technologies and methods and thoroughly validate their results to ensure they adequately meet the company's needs. Companies should consider integrating these technologies into their loyalty strategies in a planned and structured manner, ensuring effective implementation and thus gaining a sustainable competitive advantage.

***Abstract*—As Artificial Intelligence (AI) generated texts become increasingly sophisticated, distinguishing between human-written and AI-generated content presents a growing challenge. Reliably detecting AI-generated texts is of primary importance in fields that involve a lot of text such as journalism, education and law. In this study, several methods for detecting AI-generated texts by analysing a range of linguistic and stylistic features were investigated. It incorporated features such as text length, punctuation count, vocabulary richness, readability indices and sentiment polarity, to identify patterns in AI-generated content. Out of the six machine learning classifiers which were tested, the Random Forest classifier achieved the highest accuracy of 82.6%. A dataset of 483,360 essays was used in this study. Thus, the findings of this study provide a framework for the development of more sophisticated detection tools that can be applied to various real-world scenarios.**

***Keywords*—AI-generated texts; human-written texts; machine learning; linguistic features; stylistic features**

I. Introduction

In today's world, with Artificial Intelligence (AI) being widely used, it is crucial to ensure that the information encountered is authentic. The technology behind AI has improved to the point that computers are now capable of generating texts that closely mimics human writing. For example, imagine reading an article or news report, only to discover that the writing does not come from a human being but from an AI. This can significantly impact the readers' trust and confidence in digital media. This worrying situation not only highlights the need for us to dig deep into AI-generated texts, but also to detect the texts generated by these wordsmiths. Unmasking AI-generated text involves distinguishing between texts created by an AI and those authored by humans. This has become very important as AI continues to penetrate deeper into many aspects of our daily lives. It is significant in the academic field in maintaining academic integrity by preserving the authenticity of academic works, by ensuring that they are human-authored and not AI-generated. The latest advancements in AI, especially in natural language processing (NLP), have contributed to challenges such as the dissemination of false information and cases of identity fraud [1]. The use of AI technology has led to more artificial texts in different areas. While this has its benefits, it also brings challenges regarding how trustworthy and reliable the information could be.

As AI technologies advance and are being used in more areas, especially in the educational field, the challenge associated with detecting AI-generated content is becoming more complex. Many detection models face challenges in effectively distinguishing between human and AI-generated texts due to difficulties in finding differences in linguistic patterns and stylistic details. The increasing sophistication of AI models will make this task even more challenging. This research aims to address this gap by investigating advanced linguistic and stylistic features, including readability scores such as the Flesch Reading Ease and the Gunning Fog Index, vocabulary richness and sentiment polarity. By exploring these features deeper, this research aims to enhance detection accuracy and provide a better understanding of the differences between human and AI-generated content. Additionally, understanding these nuances can help educational institutions develop better policies regarding the use of AI-generated content in academic settings. The potential benefits of this work can help maintain the integrity of digital content, ensure authenticity of content and prevent the potential misuse of AI technologies. Furthermore, it could also be applied in various other fields such as journalism, and legal documentation, where the authenticity of text is of primary importance.

AI-generated texts can mean many things, like chatbot conversations, content creation, and automated translation from one language to another. While the research aims to develop a reliable method for detecting texts generated by an AI, it is important to note that the field of AI is rapidly evolving. Continuous research will be required to ensure detection methods remain effective as AI technologies advance.

This paper is organised as follows. Section II presents the literature review on techniques to recognise AI-generated texts. Section III presents the methodologies used in creating the dataset and developing the system. The results are presented and discussed in Section IV and Section V concludes the paper.

II. Literature Review

This section looks at the research and methods that have been developed to spot AI-generated text. It explores what has been achieved so far and what challenges still exist. By reviewing the work done in this field, this section aims to give a clear understanding of the current techniques and how effective they are, helping to guide the development of new approaches.

Shah et al. [1] explored different methods for identifying AI-generated texts and discussed various ways for detecting such texts, including syllable count, the length of words and length of sentences. The study employed different machine learning algorithms, Explainable AI (xAI) libraries (LIME and SHAP), and stylistic features (readability, lexical features and

variety and depth of vocabulary). A dataset using Wikipedia articles and two large language models (LLMs) to generate 10,000 articles from each were utilized. The LLMs were combined and shuffled to create two final datasets for the experiments. XAI analysis was performed to determine which features had the highest impact on determining the classification of an article. The xAI analysis revealed that Herdan's C had the highest impact on classification, with a metric of 0.92 for AI texts and 0.89 for human texts. Their ensemble model showed impressive effectiveness, achieving a precision reaching 93% in distinguishing between AI-authored and human-written text.

Elkhatat et al. [2] assessed the efficiency of several AI-generated content detection systems in differentiating between human-made and AI-generated content. The researchers generated 15 paragraphs each from ChatGPT 3.5 and 4, discussing cooling towers in the engineering process, along with five human-generated control responses, for assessment purposes. They used tools for detecting AI-generated content developed by Copyleaks, GPTZero, OpenAI, Writer and Crossplag to classify these paragraphs. The findings for the contents produced by GPT 3.5 indicated a strong level of consistency. However, GPTZero and WRITER classified some AI-generated content as "very unlikely AI generated" and "unclear if AI generated," respectively. However, the result of the detectors on GPT-4 content was not as reliable. Some GPT-4 content got "very unlikely AI generated" results from Crossplag, Writer and GPTZero. When looking at the control responses, it was clear that the effectiveness of the detectors was not completely trustworthy, as many of the human-generated texts resulted in "likely AI generated" by Writer and GPTZero. When examining the outcome of the result of GPT 3.5, the OpenAI Classifier was best at spotting AI-generated content, getting a perfect score of 100%. However, it struggled more with recognizing human-generated content, scoring 0% in this area. GPTZero did well overall, with a 93% score for spotting AI content and 80% for human content. GPT 4 had lower scores overall, with Copyleaks being the best at spotting AI content with 93%, and Crossplag being the best at recognizing human content with 100% accuracy.

Ma et al. [3] investigated the distinction between AI-generated and human-generated scientific content, focusing on scenarios where scientific AI writing assistants are extensively used in scientific writing. They assembled a dataset comprising human-written abstracts and AI-generated abstracts, created from LLMs using optimised prompts containing scientific information. The researchers conducted a human evaluation to detect AI-generated texts. Evaluators were presented with 20 scientific paper abstracts and 20 Wikipedia item descriptions, some of which were human-written and some generated by ChatGPT. The human evaluators achieved a 66% F1 score. Based on the results of human evaluations, the authors created a framework to describe features that can distinguish text authored by AI from text produced by humans. This framework is based on syntax, semantics and pragmatics. The framework categorised features into four dimensions: writing style, coherence, consistency and argument logistics. To statistically analyse the differences from human-generated and AI-written texts, the researchers built separate logistic models for syntax, semantics, and pragmatics. Subsequently, they applied the RoBERTa large OpenAI Detector to the test dataset, achieving an F1 score of 88.3%.

Crothers et al. [4] conducted an extensive survey on the threat models posed by modern text generation systems, as well as the existing ways for detecting machine-generated texts. The survey categorised natural language generation (NLG) approaches into both neural and non-neural methods. Recent non-neural methods have employed reinforcement learning, particularly hierarchical reinforcement learning which uses Markov Decision Process (MDP) agents to develop ideal policies for generating texts. Deep reinforcement learning employing neural networks has been applied to understand policy gradient methods. The analysis of threat models identified four major attack categories: facilitating malware and social engineering, online influence campaigns, exploiting AI authorship, and spam and harassment. Statistical techniques are used to differentiate between text generated by machines and text generated by humans. They also discussed NLM-based approaches, including zero-shot classification as well as fine-tuning pre-trained language models like BERT. Additionally, human-aided methods were explored, which combined statistical and neural approaches with human analyst review for text detection. The paper offers a summary of threat models and methods for the identification of AI-generated texts, highlighting the advancements and challenges in this field.

Wang et al. [5] introduced SeqXGPT, a novel system for spotting AI-generated texts (AIGT) on a sentence-by-sentence basis, as opposed to classifying entire documents. The authors proposed different setups for AIGT detection tasks: (1) Particular-Model Binary AIGT Detection, which distinguishes text written by a specific known AI system from human-written text; (2) Mixed-Model Binary AIGT Detection, which identifies AI-generated content without identifying the exact model of origin; and (3) Mixed-Model Multiclass AIGT Detection, where the objective is to both identify the model who generated the text and detect AIGT. The datasets used were obtained from documents in SnifferBench, which includes human-written and AI-authored sentences. SeqXGPT looks at each sentence in a document one by one and decides if it was created by an AI or not. SeqXGPT consists of three main parts: (1) Perplexity Extraction and Alignment involves extracting lists of token-wise log probabilities from various public open-source models, which serve as the original features. (2) The Feature Encoder processes list of word-wise log probabilities as features that represent how well a model understands semantic and syntactic structures. It employs convolutional networks to extract local features from the input, converting them into a hidden feature space. These resulting features are then passed to a context network based on self-attention layers, enabling the model to capture long-range dependencies and generate contextualized features; and (3) Linear Classification Layer, a straightforward linear classifier is trained to assign each word's features to various labels, ultimately selecting the most common label as the sentence's final category. SeqXGPT achieved a 97.6% F1 score on Particular-Model Binary AIGT Detection, a 95.7% F1 score on

Mixed-Model Multiclass AIGC Detection, and a 95.3% F1 score on Mixed-Model Binary AIGT Detection.

Tulchinskii et al. [6] demonstrated that the intrinsic dimension of a text can be a valuable metric for distinguishing between natural and generated texts. They used the Wiki40b dataset for human text samples. For multilingual text detection experiments, they created a dataset called WikiM in 10 languages produced by GPT3.5-turbo. In experiments assessing cross-domain and paraphrase robustness, they used datasets from Wikipedia and Reddit. They used two consecutive sentences from Wikipedia or a question from Reddit as prompts to produce the texts using OPT13b, GPT2-XL and GPT3.5 and they produced a StackExchange dataset using GPT3.5. They estimated the dimension of each text sample by obtaining embeddings that are specific to each token in the text using a pre-trained transformer encoder. For English, they used RoBERTa-base, and for other languages, they used XLM-R. Each embedding was viewed as a location (point) in Euclidean space. They created a basic classifier for identifying artificial text which uses PDH (Persistence Homology Dimension) as the single feature and trained a logistic regression model using a dataset containing both human-written and AI-generated texts. The results revealed that the intrinsic dimension of human-generated texts typically ranges from 9 to 10, whereas for generated texts, it is around 8, regardless of the specific text generator used.

Mindner et al. [7] aimed to understand the distinctions between natural language and artificially written content. They used Wikipedia articles to create an English text corpus covering 10 different topics. They utilised five text corpora: basic AI-generated, basic AI-rephrased, advanced AI-generated, advanced AI-rephrased, and basic human texts. They incorporated various feature categories for classification and they created systems for detecting text generation, which were trained, fine-tuned, and evaluated using both basic AI-authored texts and human written texts. They developed detection systems for basic text rephrasing, which were trained, fine-tuned, and evaluated using human-generated and AI-altered texts. They developed sophisticated detection systems for text generation and systems to detect rephrased texts, which were trained, fine-tuned, and evaluated using both human-written and advanced artificially authored texts. They achieved an F1-score of 98.0% for distinguishing between basic man-made and artificially made texts, an F1-score of 78.9% for distinguishing between basic human-made and artificially rephrased texts. For advanced human-made and AI-made texts, they achieved an F1-score of 96.9%, and for advanced human-made and AI-rephrased texts, they achieved an F1-score of 81.7%.

Kumari et al. [8] presented a novel detector called DEMASQ. Its purpose is to reliably identify ChatGPT-generated information by addressing the differences in text composition biases between man and machine-made content, as well as human modifications used to circumvent earlier detection techniques. DEMASQ is a model based on energy that uses new components including a Doppler-effect-inspired optimization and explainable AI methods to produce a variety of perturbations. Three main elements make up DEMASQ's approach: a model based on energy that captures the behaviour of both human and ChatGPT activity, an adapted Doppler effect, and the Integrated Gradient (IG) method for assessing hybrid texts that combine information generated by ChatGPT and humans. The Doppler effect is used in the energy-based model to quantify energy, with waves standing in for texts and drumhead vibrations for source frequencies. Wave frequencies are added to the cost function of the model to improve the training process. DEMASQ was evaluated using a benchmark dataset that included human and ChatGPT questions from a variety of domains. DEMASQ significantly outperformed previous detection techniques, attaining an accuracy of up to 74.5%. The academic abstract datasets for Task 1, Task 2, and Task 3 were used to train their model [9]. These datasets categorised the CheckGPT analysis into three tasks: 1) Full abstracts authored by the GPT model, 2) Partially completed abstracts by the GPT model, and 3) Enhanced abstracts by the GPT model. After being retrained on the Task 1, Task 2, and Task 3 datasets, DEMASQ showed accuracy rates of 96.4%, 88.7%, and 82.5% for the respective tasks. Additionally, DEMASQ was assessed in comparison to Task 1, 2, and Task 3's paraphrased texts. For each task (1, 2 and 3), the corresponding accuracy was 76.9%, 68.7%, and 58.3%, after rephrasing.

Bao et al. [10] introduced Fast-DetectGPT, which assumes that humans and machines choose different words when generating text. The method suggests that machine-generated text shows a specific pattern in the way word probabilities change. If the pattern has a certain shape (positive curvature), the text is flagged as AI-generated. Otherwise, if the pattern is more flat (close to zero), the text is likely to be human-written. Fast-DetectGPT uses a novel three step procedure: 1) Sample – generates alternative text samples, 2) Conditional Score – calculates the word probability pattern using a scoring model, and 3) Compare – compares the word probability patterns of the text and samples to determine the curvature. Six datasets were used to cover several topics and languages: XSum used for news articles, SQuAD for Wikipedia contexts, WritingPrompts for story writing, WMT16 English and German for different languages, and PubMedQA for biomedical research question answering. They randomly selected between 150 to 500 human-written examples from each dataset as negative samples and generated an equal number of positive samples. The authors compared their new system with DetectGPT, which employs a perturbation step alongside a more efficient sampling approach. The findings indicate that Fast-DetectGPT outperforms DetectGPT by approximately 75%.

Mitrovic et al. [11] focused on detecting ChatGPT-generated text in restaurant reviews. Their approach involved two main parts. They utilised a model trained to distinguish between human-written text and ChatGPT-generated texts. They started with a Transformer-based model that was pre-trained for classifying sequences. Next, they fine-tuned this model to identify whether a text sample was ChatGPT-generated or human-generated. Finally, they evaluated the model's performance by comparing its classification scores to the ground truth. The authors used three datasets, a publicly available dataset containing human made reviews about a restaurant and two datasets generated by ChatGPT consisting

of restaurant reviews. One of the generated datasets has been obtained by rephrasing the reviews from the human dataset. The authors conducted two experiments. In the first experiment, the human and the ChatGPT generated datasets were used while the human dataset and the ChatGPT rephrased dataset were used in the second experiment. In addition to their machine learning (ML) based approach, they created a way to classify text based on its perplexity score. First, they split the dataset containing human and ChatGPT-generated text into two sets. Then, they used GPT-2 to calculate the perplexity score for each text in the training group. Finally, they used the perplexity score from the training group to classify the text in the test group. The result showed that the ML-based approach outperformed the Perplexity-based approach in both experiments, achieving an accuracy of 98% compared to 84% in Experiment 1 and 79% compared to 69% in Experiment 2.

Yan et al. [12] compared essays written by humans with those written by an AI. They first did a detailed study with a small number of essays to look at different aspects. Then, they conducted a bigger research in which they developed and tested two detectors: one that utilised e-rater features and another that utilised a modified version of the RoBERTa language model. They used OpenAI's GPT-3 to generate AI essays and trained the RoBERTa model with a dataset of 8,000 essays, including 4,000 with added spelling mistakes. The fine-tuned RoBERTa model got a precision of 99.75%, outperforming the support vector classifier, which had a precision of 96%. They found that the AI essays had no grammatical errors compared to the human essays.

Current research on detecting AI-generated texts highlights several challenges. Many tools struggle with accuracy as AI models for text generation are becoming more advanced, making it harder to distinguish between human and AIGT. Most of the existing works have focused on using words, n-gram frequencies, and part-of-speech tags to build their detector. However, there is a lack of studies which uses readability scores and sentiment polarity within their set of features. Many of the existing studies also rely on a black-box approach to make their classification. Moreover, the datasets used are often very small. This study seeks to improve detection accuracy by developing a more transparent machine learning model using linguistic and stylistic features and sentiment polarity by using a much larger dataset of human-written and AI-generated essays.

III. Methodology

This study employed a quantitative research design to investigate the effectiveness of using linguistic and stylistic features for detecting AI-generated texts. The research process was divided into three main phases: dataset preparation, feature engineering, and development of a web application.

The choice of dataset plays an important role in ensuring the accuracy and reliability of our model. The dataset used ns this study was downloaded from Kaggle [13]. The dataset consists of 487,235 essays, which comprise 305,797 human-written and 181,438 AI-generated essays. The dataset consists of texts from various topics and is in a comma-separated value (CSV) file and was built by gathering data from multiple sources, adding them together and removing duplicates. Feature engineering was then carried out on the dataset. Text length, punctuation count, vocabulary richness, readability scores (Gunning Fog Index and Flesch Reading Ease) and sentiment polarity were calculated and added to the dataset to provide the model with more features for training.

After feature engineering, the records which contained missing values, were erroneous or were flagged as outliers (records with unusual Gunning Fog Index or Flesch Reading Ease) were removed from the dataset. A total of 3,875 records were deleted which resulted in a dataset with 483,360 valid records, out of which 180,311 were AI-generated and 303,049 were human-written. The whole dataset consists of 190,383,692 words. Table I provides a statistical analysis of the dataset. Table II and Table III provide the statistical analysis of the dataset for the AI-generated and human-written essays respectively. Table IV describes the features that have been used to differentiate between human-written and AI-generated texts.

TABLE I Statistical Analysis of the Dataset

Features	Mean Value	Minimum Value	Maximum Value
Text Length	393	75	1668
Punctuation Count	48	1	388
Gunning Fog Index	10.73	5	35
Flesch Reading Ease	63.7	0.16	99.97
Vocabulary Richness	0.43	0.05	0.86
Sentiment Polarity	0.16	-0.625	0.82

TABLE II Statistical Analysis of AI-Generated Texts

Features	Mean Value	Minimum Value	Maximum Value
Text Length	345	75	1238
Punctuation Count	46	4	258
Gunning Fog Index	11.54	5	28.75
Flesch Reading Ease	53.6	0.35	99.97
Vocabulary Richness	0.45	0.11	0.86
Sentiment Polarity	0.17	-0.376	0.70

TABLE III Statistical Analysis of Human-Written Texts

Features	Mean Value	Minimum Value	Maximum Value
Text Length	422	75	1668
Punctuation Count	49	1	388
Gunning Fog Index	10.24	5	35
Flesch Reading Ease	69.69	0.16	99.87
Vocabulary Richness	0.43	0.05	0.74
Sentiment Polarity	0.15	-0.625	0.817

TABLE IV LIST OF FEATURES

Features	Description
Sentiment Polarity	Sentiment analysis can be used to tell if a text is human written or AI generated. It involves categorising text as positive, negative or neutral. A negative score signifies negative sentiment, while a positive score represents positive sentiment. Gillham (2024) conducted an analysis against 100 articles generated by three LLMs for their sentiment and concluded that texts generated by LLMs are closer to the neutral part of the sentimental scale [14]. This difference in sentiment analysis between humans and LLMs can be a useful way to classify the texts as AI-generated or human-written.
Gunning Fog Index	Gunning Fog Index is a readability metric that estimates the number of years of education needed to understand a piece of text [15]. It is calculated based on the average sentence length and the percentage of complex words (defined as words with three or more syllables).
Flesch Reading Ease	The Flesch Reading Ease is a readability metric for a piece of text [16]. Kincaid et al. (1975) states that the Flesch Reading Ease formula is the most widely recognised and validated score among all readability metrics. This metric analyses average sentence length (ASL) and the average syllables per word (ASW) to assess the readability of a piece of text [16].
Vocabulary Richness	Vocabulary richness refers to the diversity of words used in a text and can be used to flag texts as AI generated or human authored since AI have the tendency to have a more diverse vocabulary set than humans [17].
Word Count and Punctuation Count	Calculates the number of words and punctuation present in the text. The characters classified as punctuations include these 32 characters: !, “, #, $, %, &, ‘, (,), *, +, ,, -, ., /, :, ;, <, =, >, ?, @, [, \,], ^, _, `, {, |, } and ~. Humans often use punctuation to convey emotion, emphasise points, or structure their writing while AI models use punctuation by following a pattern. This difference can help us in classifying the texts as AI-generated or human-written.

Fig. 1 presents the website architecture design and demonstrates how data is being passed from the client’s web browser to the Flask application and then predicted using a machine learning (ML) model. The text entered by the user is sent to the server, which is then sent to the Flask application. At the Flask application, the text entered by the user is validated and if everything is fine, the data undergoes feature engineering and text preprocessing. The last step involves the ML model to predict whether the preprocessed data is either human-written or AI-generated. The result goes from the ML model to the Flask application, to the server and is then rendered on the user’s browser.

Two activity diagrams are provided, one for the client side (Fig. 2) and one for the server side (Fig. 3) to clearly distinguish between the interactions that occur on each side of the application. The flowchart in Fig. 2 demonstrates the operation that happens at the client side of the application. The user enters the website and the interface of the application is displayed in his/her browser. The user will be presented with a textarea and a file upload button which he/she can use to enter text in the application. The user will then either paste texts manually in the textarea or upload a document for processing using the upload button. Once the user presses on the “detect button”, the text he/she has entered will be sent to the server-side for prediction. Lastly, the server side returns the result, which is displayed on the client’s browser. The flowchart in Fig. 3 demonstrates the operations that happen on the server side.

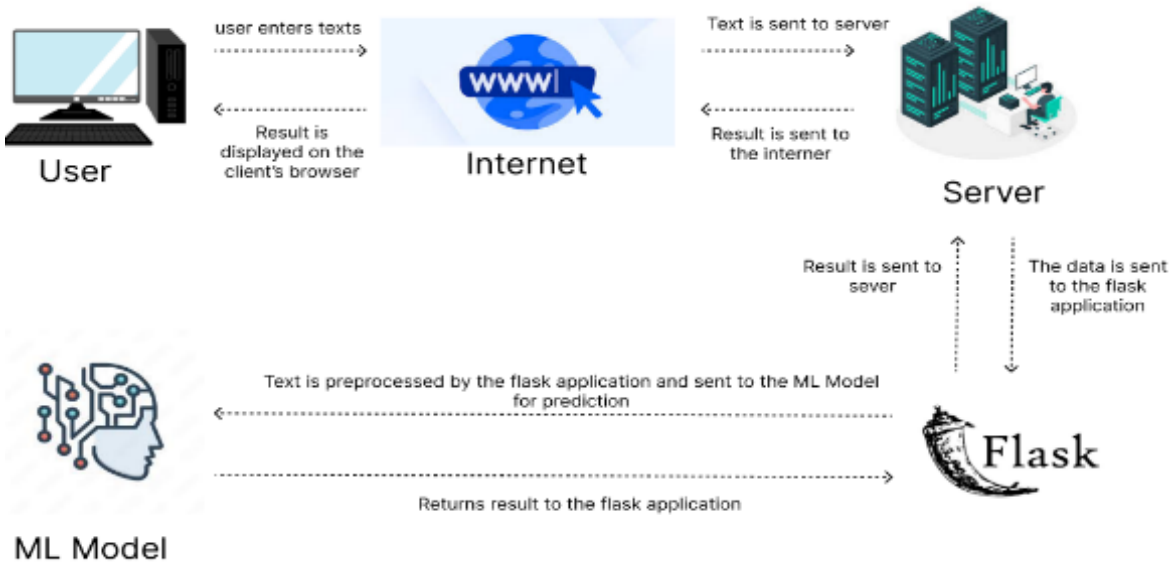

Fig. 1. Website architectural design.

Upon submitting the form by clicking the "detect text" button, the client application sends the data to the server. The server first checks for empty submissions. If the form is empty, it returns an error message to the client. If valid data is provided, the application retrieves the text from the textarea or uploaded document. After preprocessing and feature engineering, the model and vectorizer are loaded to prepare the data for prediction. Finally, the AI model determines if the input text is AI-generated or not and sends the result back to the client for display. However, the AI-model is applied on each batch of 200 words. The results can be different for each text segment. This strategy allows for a more nuanced evaluation of each section independently, rather than providing a single verdict for an entire document. A snapshot of the application is shown in Fig. 4.

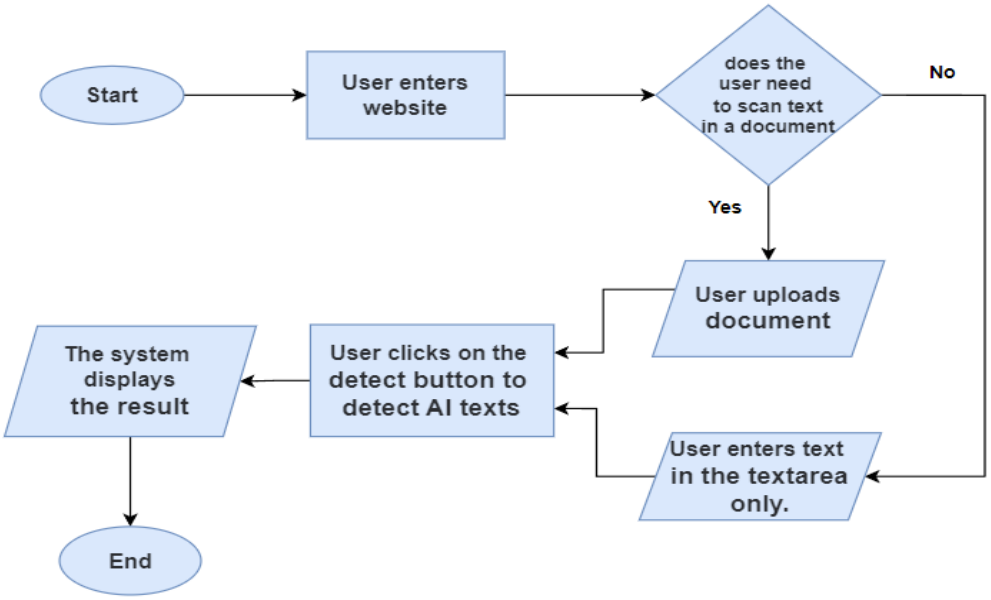

Fig. 2. Operations at the client side.

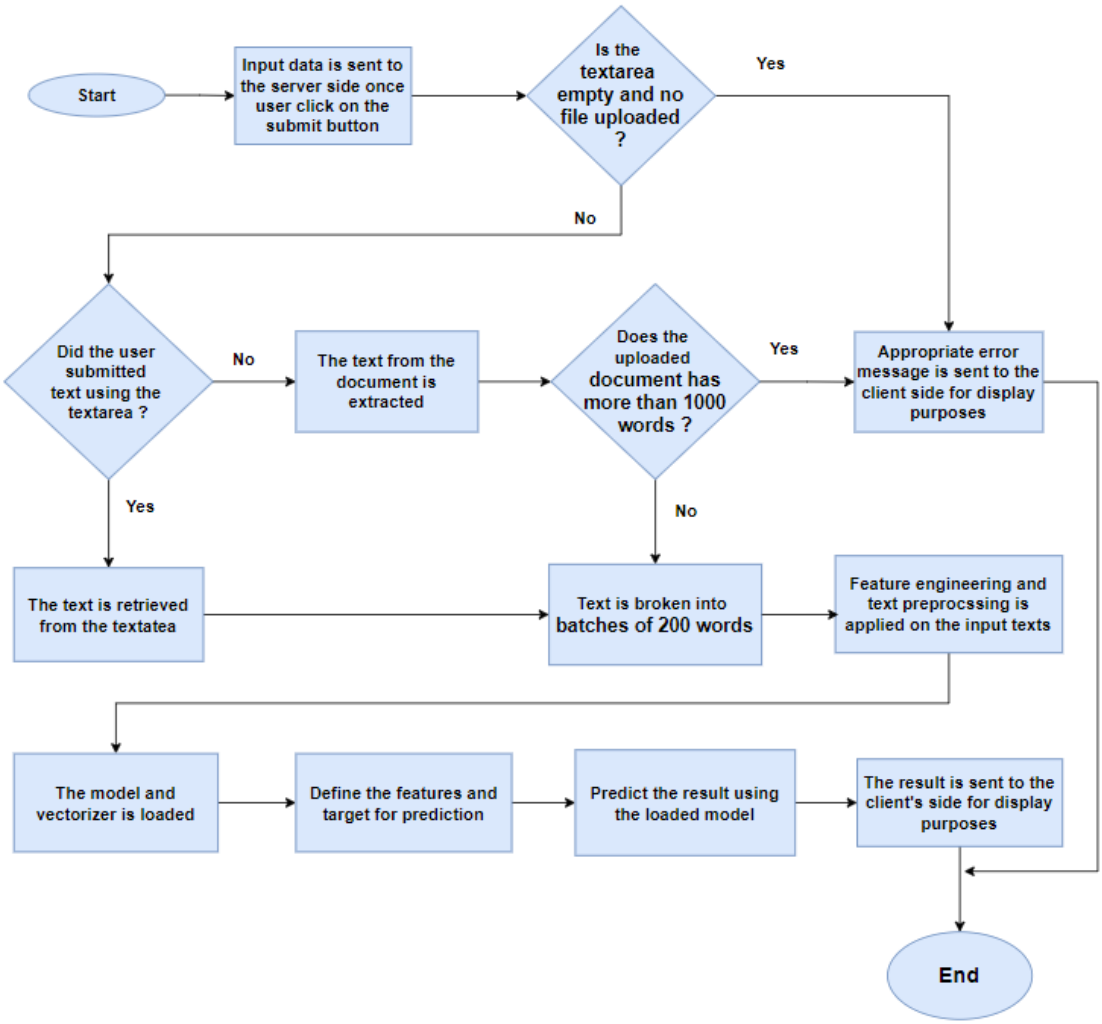

Fig. 3. Operations on the server side.

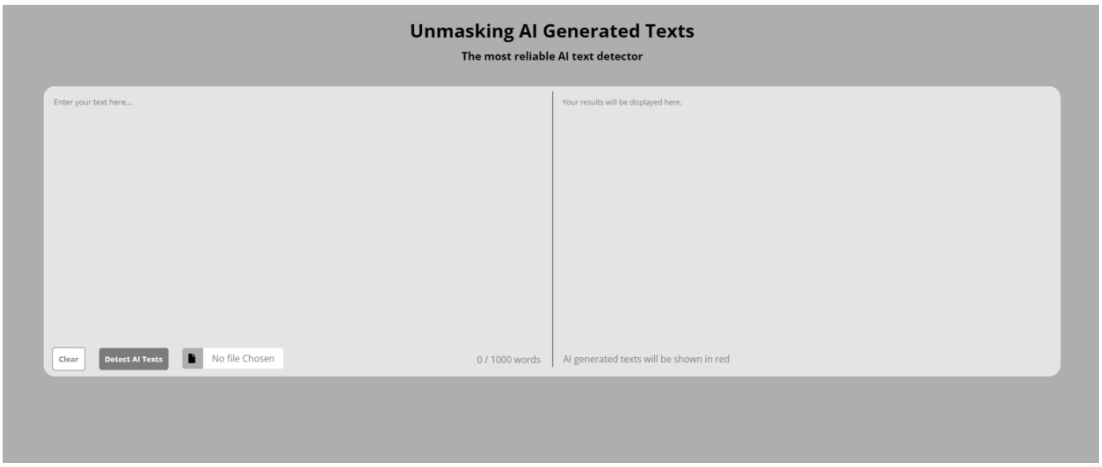

Fig. 4. GUI of the application.

IV. Experiments and Results

This section details the process of building the application, including the design and integration of key components. By outlining the implementation details, this section aims to demonstrate how the theoretical concepts are translated into a functional application, highlighting the practical aspects of the application. In evaluating the performance of our machine learning models, we utilise several key metrics: accuracy, recall, precision and the F1 Score. Table V shows the result of all the trained machine learning (ML) models.

TABLE V Result for All the Trained Models

Machine Learning Model	Metrics			
	Accuracy	Recall	Precision	F1 Score
Logistic Regression	0.94	0.93	0.94	0.94
SVM	0.8	0.73	0.88	0.75
Random Forest	**1.00**	**1.00**	**1.00**	**1.00**
Decision Tree	0.99	0.99	0.99	0.99
Gradient Boosting	0.96	0.95	0.97	0.96
XGBoost	**1.00**	**1.00**	**1.00**	**1.00**

Both Random Forest and XGBoost achieved an accuracy of 100% during training. An accuracy of 99% was achieved with Decision Tree. Gradient Boosting and Logic Regression scored above 90%. Only the scores for SVM were low.

The evaluation process is driven by a custom dataset that has been created to match the need of this study. The dataset comprises a balanced collection of human-generated and AI-generated texts. The dataset consists of 20 records, 10 AIGT and 10 human written texts. The AIGT records were obtained from ChatGPT and the human written records were obtained from Wikipedia articles [18-21], The Guardian [22-23] and from existing research papers [24-27]. These papers were selected because they were written well before AI-generated texts became available. The texts cover various topics such as sports, health, arts and science. The average text length of the articles is 368 words. The dataset consists of only two columns: text and label. The text represents the actual text that needs to be predicted as human or AI and the label column can have two values: human or AI to indicate who wrote the text. Table VI shows the result of the model evaluation process.

TABLE VI Evaluation Result of the Trained ML Models

Classifier	Accuracy	Recall	Precision	F1 Score
Logistic Regression	0.609	0.55	0.8	0.46
SVM	0.609	0.55	0.8	0.46

The Random Forest model scored an accuracy of 82.6% in predicting the nature of the texts found in the custom dataset. Table VII illustrates Random Forest's performance when applied to the custom dataset.

TABLE VII Prediction of Model using Custom Dataset

Record Number	Text Nature	Source	Prediction
1	AI	ChatGPT	AI
2	AI	ChatGPT	AI
3	AI	ChatGPT	AI
4	AI	ChatGPT	Human
5	AI	ChatGPT	AI
6	AI	ChatGPT	AI
7	AI	ChatGPT	Human
8	AI	ChatGPT	AI
9	AI	ChatGPT	AI
10	AI	ChatGPT	AI
11	Human	[26]	Human
12	Human	[27]	Human
13	Human	[24]	Human
14	Human	[18]	Human
15	Human	[19]	AI
16	Human	[20]	Human
17	Human	[22]	Human
18	Human	[25]	Human
19	Human	[23]	AI
20	Human	[21]	Human

During the evaluation, the model misclassified two AI-generated texts as human (record number 4 and 7) and two human-written texts as AI (record number 15 and 19). This may be due to the overlapping linguistic and stylistic features between the two categories. Additionally, biases present during the model's training process could have influenced the results. Thus, the accuracy of the model in this scenario is 80%. In conclusion, the evaluation of the proposed model demonstrates its effectiveness in distinguishing AI-generated texts from human-written ones.

V. Conclusion

This research explored the detection of AI-generated texts through linguistic features, stylistic features and sentiment polarity. Six different machine learning models were trained, with the Random Forest model emerging as the most accurate, achieving an accuracy of 82.6%. As a result, the Random Forest model was selected for its performance in identifying AI-generated content. However, this study also has its limitations. The model struggles with shorter texts, as these often lack the necessary linguistic and stylistic features that longer texts provide, making accurate detection more challenging. Additionally, the rapid advancement of AI text generation technologies makes it difficult to continuously adapt detection methods. Lastly, the Random Forest model was trained and tested on AIGT from only one LLM, specifically ChatGPT 3.5, meaning its ability to detect content produced by other large language models (LLMs) remains unverified. As future works, we intend to extend the systems so that it can also detect AIGT in languages other than English. Moreover, it would also be interesting to investigate whether there is an impact on the detection accuracy for more advanced GPT models such as GPT-4 and GPT 4.5.

Abnormal Data Detection Model Based on Autoencoder and Random Forest Algorithm: Camera Sensor Data in Autonomous Driving Systems

Geng Shengwen, Mohd Hafeez Osman*
Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, 43400 Serdang, Malaysia

***Abstract*—This project develops an AI-based anomaly detection system. In the field of autonomous driving, abnormal data will directly affect the safety of autonomous driving systems, especially in terms of abnormal camera sensor data. Sensor failure, environmental changes, or bad weather can lead to the emergence of abnormal data, which can affect the decision-making process and may have disastrous consequences. Based on the above problems, this study addresses this challenge by proposing a hybrid anomaly detection model (called CAE-RF) that combines convolutional autoencoders and random forest algorithms to achieve efficient and accurate identification of abnormal data patterns to improve the safety of autonomous driving systems. The proposed method will use convolutional autoencoders to calculate the reconstruction error and combine the hidden features extracted by the encoder as the input of the random forest to distinguish normal data from abnormal data. The key performance indicators such as accuracy, precision, recall, and F1 score are used to evaluate the model, and the robustness is guaranteed by cross-validation. Experimental results show that the CAE-RF model has an accuracy of 92% in distinguishing normal and abnormal data. Compared with traditional methods, the CAE-RF model achieves higher accuracy and reliability. The implementation of this model can timely identify and process abnormal data, reduce the risks brought by sensor failure or external environment changes, prevent potential accidents, and improve the safety and reliability of the autonomous driving system.**

***Keywords*—Automatic driving; anomaly data detection; convolutional autoencoder; random forest; CAE-RF**

I. Introduction

A. Project Overview

With the rapid development and application of automatic driving technology, the safety of automatic driving has become the focus of attention. The reason why self-driving cars have not been widely used lies in their safety problems [1-3]. Therefore, how to ensure the safety of self-driving cars is an important research topic. One of the key factors affecting the safety of automatic driving is data security, and the correctness and accuracy of data will directly affect the safety of automatic driving system, thus affecting the safety of vehicles and passengers. However, due to various factors such as sensor failure, environmental anomalies, weather conditions, etc. [4], the occurrence of anomaly data is inevitable. An anomaly here is defined as an observation that deviates substantially from some established notion of normal. [5] Therefore, we need an anomaly data detection model to find anomaly data in time. Anomaly detection model can identify abnormal patterns in massive data mining, so it can well detect and respond to potential sensor faults, ensure the normal operation and safety of the system, and avoid accidents. This study will focus on camera sensor data, namely image data. Image data anomalies mainly include noise, overexposure, low brightness, occlusion and other anomaly types. Machine learning algorithms can learn more complex patterns and are able to spot anomalies hidden in the data. And machine learning algorithm can automatically learn the patterns and features in the data, so as to detect anomalies quickly and accurately. Compared with the traditional anomaly detection technology, this greatly improves the efficiency and accuracy of detection. Therefore, this study aims to develop an efficient and accurate model for anomaly detection in image data using machine learning techniques.

This paper is organized as follows: Section II reviews related studies; Section III introduces the proposed method; Section IV presents the experimental procedure; Section V analyzes the results; and Section VI discusses the paper.

B. Problem Statements

Autonomous vehicles have emerged as a promising future transportation technology. However, ensuring their safety and security remains a major challenge. Anomalous data is one of the major issues that could threaten the normal operation of driverless vehicles, which could lead to sensor data errors that lead to faulty navigation decisions, resulting in accidents and deaths [4].

Traditional techniques heavily rely on a strong understanding of the "ground truth" to establish a clear and measurable definition of anomalies. However, in many real-world scenarios where data models change frequently over time, these techniques often fail to deliver satisfactory performance despite their complexity [6].

Detection models under supervised learning are not reliable for unexpected or rare anomalies that do not occur during training. Because unsupervised learning lacks an annotated model to explicitly distinguish between normal and abnormal data, detection models experience a higher proportion of false positives and false negatives [4].

C. Project Objectives

The objective of this research is to develop a model for detecting anomalies in camera sensor data in an autonomous driving system, which will extract features from the collected

*Corresponding Author

data and then identify the anomalies based on the features of the anomalous data, and give alerts after identifying the anomalies. The main objectives of the project are as follows:

PO1: The camera sensor data is collected, key features are extracted, and anomalous data is identified based on these features.

PO2: Use machine learning technology to improve the accuracy and efficiency of anomaly data detection to cope with changing environments.

PO3: The abnormal data monitoring model is developed by combining autoencoder and random forest to reduce the disadvantages of unsupervised learning and supervised learning, enlarge their advantages and improve the reliability of the model.

D. Scope of the Project

- Research and analyze the current application of anomaly data detection technology.
- Collecting Camera Sensor Data in Autonomous Driving Systems.
- Construction, training and verification of anomaly data detection model.
- Evaluate the accuracy and effectiveness of the anomaly data detection model.

II. Related Work

A. Conventional Anomaly Data Detection Techniques

There are two types of statistical methods: parametric and non-parametric. Parametric statistical methods estimate the parameters based on the data and presume that the underlying distribution of the data is known, such as Gaussian models, regression models, or mixed parametric distribution methods [7]. Nonparametric statistical techniques do not assume a known distribution, but they determine the distribution based on the data itself, such as methods based on histograms and kernel functions [8]. A thorough analysis of the various statistical methods used for novelty identification can be found in the research in study [9]. It encompasses non-parametric techniques like k-NN based, Parzen density estimation, string matching, and clustering as well as parametric techniques like hidden Markov models, hypothesis testing, and probabilistic and Gaussian mixture modeling. Furthermore, statistical methods are not very generic when dealing with high-dimensional data, despite their advantage in being interpretable and explicable. In the case of high-dimensional data, machine learning techniques can do better than statistical techniques.

Second, Data in sensor systems are typically generated in the form of time series, and time series analysis (TSA) is used to extract statistical features and make predictions about future values. Anomalies can be detected by comparing the difference between the actual and predicted values. Commonly used methods include cross-correlation analysis, autoregressive moving average (ARMA), autoregressive integral moving average (ARIMA), Kalman filtering, etc. [10].

Although time series analysis is simple and effective in dealing with additive outliers, it is less effective in detecting anomalies caused by "drastic" changes and is mainly suitable for "moderate" anomaly events.

B. ML for Anomaly Detection

The study in [8] proposed three basic methods to solve the problem of outlier detection, namely:

a) Monitoring: Modeling normal and anomaly; It requires labeled data for each category.

b) Unsupervised: Anomalies are identified without prior knowledge of the data.

c) Semi-supervised: only normality is modeled; Determine anomalies based on their departure from the typical threshold; another name for it is novelty recognition or detection.

At present, the commonly used supervised learning algorithms mainly include proximity-based classifiers [11], support vector machines (SVM) [12], decision trees [13-14], Random forests [15], and rule-based classifiers [16].

Surveillance techniques demonstrate strong robustness due to their reliance on pre-labeled data as the "ground truth." However, in many real-world systems, such data is either limited or entirely unavailable. To address this challenge, semi-supervised and unsupervised methods have been introduced, effectively bridging the gap.

The underlying premise of unsupervised learning algorithms is that outliers are uncommon and substantially distinct from typical occurrences [17]. Cluster-based approaches, which employ similarity metrics to group data instances, are among the most often used techniques. A data instance is considered an exception if it is not a part of a cluster or if its cluster is much smaller than another cluster. In [18], the authors propose a global outlier detection technique that uses clustering to detect sensor node anomalies.

The autoencoder is another widely used unsupervised learning algorithm [19]. It is trained exclusively on normal data, enabling the model to reconstruct inputs with minimal reconstruction error. During the detection phase, anomalies are identified as instances with higher reconstruction errors, as the model has not encountered these patterns during training. Thresholds are defined to capture and classify these anomalous data points.

A semi-supervised learning algorithm, Single-class SVM (OC-SVM) is a semi-supervised SVM that does not require exception labels. It is applied in study [20] to attack detection in sensor networks in smart cities.

Although semi-supervised learning is optimal when very little labeled data is available, the assumptions associated with using unlabeled data create some limitations. Inaccurate assumptions may result in subpar performance because they rely on the link between labeled and unlabeled data distributions.

Through literature review, we have a basic understanding of the basic working principle of autonomous vehicles, and analyze the safety and reliability of autonomous driving

systems. Then, the conventional anomaly detection technology and the anomaly detection technology applying machine learning technology are studied. Through the comparison between machine learning technology and conventional traditional anomaly detection technology, it is found that in many time scenarios where the data model changes greatly over time, the conventional anomaly detection technology cannot bring satisfactory performance. In order to accommodate the dynamic of the big data paradigm, this necessitates the incorporation of machine learning techniques at the tradeoff of less strict formalization [6]. Therefore, this paper decided to use a combination of autoencoder (unsupervised learning approach) and random forest (supervised learning approach) techniques to develop anomaly data detection models.

III. Methodology

This chapter is divided into three sections, each of which will describe the specific tasks of each phase. These include data preprocessing, model development, model validation and evaluation, and documentation. Fig. 1 shows the three phases of the project process.

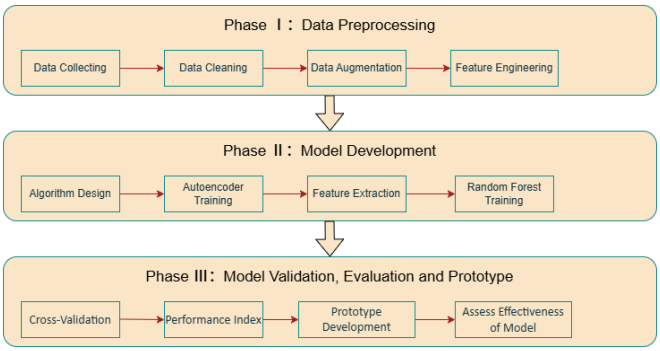

Fig. 1. The framework of the research.

A. Data Preprocessing

Data preprocessing is a key step in ensuring the quality and reliability of the datasets used for model training and testing.

It involves several stages, including data collection, cleaning, integration and standardization. The goal is to transform the raw data into a structured and meaningful format suitable for machine learning algorithms.

The first step was data collection, where camera sensor data were collected from the A2D2 public datasets. These datasets provide a variety of scenarios, such as different weather and lighting conditions.

1) Data cleaning process: The first step is to remove invalid samples. During the initial inspection, it was found that some image files may be damaged (such as unable to load) or the format does not meet the requirements (such as grayscale images instead of RGB images). Through automated script detection, all image files that cannot be loaded normally or have incorrect formats are removed. The second step is to deal with duplicate images. The dataset may contain duplicate images, which will cause overfitting or classification bias in the model during training. By calculating the hash value of each image, completely duplicate images are detected and removed.

Then comes the data enhancement phase, in machine learning and deep learning tasks, especially in image classification and anomaly detection, the quality and quantity of data play a crucial role in the performance of the model. However, we often face the problem of insufficient data or a single data distribution in practical applications, especially in the anomaly detection task, where the anomaly data itself is extremely scarce and the normal data may have an insufficient number of samples or an incomplete coverage of the feature space at the time of collection. Therefore, data transformation and data enhancement techniques are used in the study to generate anomaly data. The following anomaly types are included:

a) Noise: Add random Gaussian noise to the image, with the noise intensity taking a random value with a standard deviation of 0.01 to 0.05 to simulate the interference during sensor acquisition.

b) Rotation: Randomly rotate the image clockwise or counterclockwise by 90° to 180°. This operation can simulate the rotation phenomenon of abnormal objects caused by changes in camera angle during image acquisition.

c) Color_shift: Randomly perturb the hue, saturation, and contrast of the image to enhance the robustness of the model to color change anomalies.

d) Brightness: Randomly increase or decrease the image brightness, ranging from 80% to 120% of the original brightness, to simulate anomaly detection scenarios under different lighting conditions.

e) Occlusion: Randomly add irregular occlusion areas to the image, with the occlusion area accounting for 30% to 80% of the total image area, to simulate abnormal patterns caused by perspective occlusion or obstacle occlusion.

f) Blur: Applies a Gaussian blur with a blur radius of 1 to 3 pixels, simulating a blurred image caused by out-of-focus effects. The examples of images is shown in Fig. 2.

Fig. 2. Example of Images.

Finally, there is the feature engineering phase, where the size and format of the images in the dataset are usually inconsistent due to the fact that the image sources may be different. In addition, model inputs usually require fixed image sizes and formats. Therefore, we normalized each image. The first step was to resize the images, and all images were uniformly resized to a resolution of 224 × 224. This size is a common input requirement for deep learning models, which

reduces the consumption of computational resources and retains sufficient feature information. Then the image format is converted and all images are unified to RGB format. Through these two operations, all the images in the dataset meet the requirements of the model in terms of size and format, avoiding problems due to inconsistent inputs during the training process. Finally, the normalization process, since the range of image pixel values is usually [0, 255], if directly input to the model, it may lead to problems such as unstable gradient or too small learning rate. Therefore, we normalize the pixel values of the image by scaling all the pixel values to the range [0, 1]. This operation is achieved by a simple mathematical transformation, i.e. dividing the pixel values by 255. Since we use autoencoder technology, there is no need to perform explicit feature selection. It indirectly achieves feature extraction and dimensionality reduction by automatically learning low-dimensional representations of normal data.

B. Model Development

We divide the model development into four steps, and the following are detailed explanations of the steps:

Step 1: Algorithm design

Existing methods have the following limitations: traditional statistical methods are difficult to process high-dimensional data, such as PCA and ARIMA, which rely on fixed data distribution and cannot adapt to dynamic environments; pure supervised learning methods rely on a large amount of labeled data, but abnormal data is often scarce in practical applications; using CAE alone may lead to a high false alarm rate, and slight changes in normal data may be mistakenly judged as abnormal based on reconstruction errors.

The current method (CAE-RF) is suitable for anomaly detection of autonomous driving camera sensors, mainly because: it can process high-dimensional, unstructured image data, CAE extracts deep features, retains spatial information, and is suitable for complex environments; it can detect known and unknown anomalies, and unsupervised CAE discovers unseen abnormal data through reconstruction errors, overcoming the dependence of traditional supervised learning on labeled data; it reduces the false alarm rate, and compared with methods that rely only on reconstruction errors, CAE-RF combines random forest classifiers to enhance the robustness of anomaly detection; it meets real-time requirements, and this method combines the feature extraction capabilities of deep learning with the efficient decision-making capabilities of random forests, which is suitable for the low latency requirements of autonomous driving systems.

Therefore, CAE-RF combines the generalization ability of unsupervised learning and the discrimination ability of supervised learning, overcoming the shortcomings of existing methods and becoming the best solution to the current problem.

Step 2: Autoencoder training

The training of the autoencoder is a key part of the development stage. In this stage, we use normal samples to train the autoencoder so that it can learn to reconstruct the distribution characteristics of normal samples. The structure of the autoencoder consists of an encoder and a decoder. The encoder compresses the high-dimensional image data into a low-dimensional potential feature space, while the decoder tries to reconstruct an image similar to the input data from the low-dimensional space. The model learns by minimizing errors between the input image and the reconstructed image through optimization of network parameters during training. Upon training, we can get the potential feature of normal data through the encoder, and calculate the reconstruction error of normal data through decoder.

Step 3: Feature extraction and calculation of reconstruction error

Feature extraction is an important step in model development. After the autoencoder is trained, the input data will generate potential features through the encoder part, and the decoder part will calculate the reconstruction error. The potential features are representative of the global properties of the input data and the reconstruction error is a measure of the extent to which the data deviates from the normal sample distribution. These two parts of the features are combined to form the final feature vector. Through this process, we convert the high-dimensional image data into a multi-dimensional feature space suitable for random forest training. This method not only effectively compresses the data, but also retains key abnormal information.

Step 4: Training of random forest model

The training of random forest model is the final link in the development stage. Based on the multi-dimensional features extracted by the autoencoder and the calculated reconstruction error, we use random forest to classify normal samples and abnormal samples. Random forest constructs multiple decision trees, and each tree independently learns the feature distribution of the data. During the training process, the model will continuously optimize the decision rules and ensure the stability and accuracy of the classification results through the majority voting mechanism.

Overall, the four links in the development stage are closely linked to form a complete system. The algorithm design provides a theoretical framework, the autoencoder training and feature extraction realize the acquisition of key features and the calculation of reconstruction errors, and the random forest model training transforms these features into efficient classification capabilities. This development process not only verifies the theoretical feasibility of the model, but also lays a solid technical foundation for subsequent system deployment.

C. Model Validation and Evaluation

Validation is essential to ensure that the model generalizes well to previously unseen data and performs reliably in a variety of scenarios. Use cross-validation to split the data set into training and testing subsets, allowing the model to be evaluated across multiple iterations. This approach mitigates over-fitting and ensures that the performance of the model does not depend on specific data partitions.

The evaluation phase uses a comprehensive set of metrics to measure the performance of the model. Accuracy assesses the proportion of correctly classified data points, while

accuracy assesses the model's ability to avoid false positives. The recall rate determines how sensitive the model is to identifying real anomalies. The F1-score is a harmonic average of accuracy and recall, providing a balanced evaluation metric.

A comparative analysis is performed to compare the proposed framework with traditional methods such as statistical anomaly detection and time series analysis. These comparisons highlight the advantages of the hybrid approach, demonstrating greater accuracy, fewer false positives, and greater adaptability to complex scenarios.

The final stage involves systematically documenting the entire process to ensure that research methods, results and conclusions are clear, repeatable and available for future use. This stage integrates all aspects of the research into a coherent written record. It includes detailed descriptions of data preparation, model development and validation steps, ensuring transparency and enabling other researchers to replicate or build on them.

IV. Design and Experiments

A. Autoencoder Model Design and Implementation

In the task of anomaly data detection, we chose Convolutional Autoencoder (CAE) as the core tool for feature extraction. Compared with traditional deep autoencoders, convolutional autoencoders can process high-dimensional image data more efficiently, capture local features, and effectively preserve the spatial information of the input image. This section will describe the design and implementation process of the convolutional autoencoder in detail, including the model architecture, training methods, and practical applications in anomaly detection.

The structure of the convolutional autoencoder consists of two main parts: the encoder and the decoder, which are used for feature extraction and data reconstruction respectively.

The main task of the encoder is to compress the input image into a low-dimensional latent feature space while retaining the core information of the input data. Specifically, the encoder consists of a series of convolutional layers and pooling layers. These convolutional layers extract local features of the image, such as edges, textures, and shapes, through convolution kernels, while the pooling layers reduce the spatial resolution of the data by downsampling, thereby reducing computational complexity and avoiding overfitting. In this process, as the number of layers increases, the model gradually extracts higher-level abstract features and finally compresses the original image into a low-dimensional feature vector. The final output of the encoder is the representation of the input image in the latent space, which contains the core patterns and distribution of the input data.

The decoder is the symmetrical part of the encoder, and its task is to restore the low-dimensional latent feature vector to a reconstructed image with the same size as the input image. The decoder gradually increases the resolution of the feature map through deconvolution operations to restore the original spatial information. At the same time, the decoder also uses upsampling technology to enlarge the feature map through interpolation operations to approach the size and distribution of the original image. In the last layer of the decoder, by using the Sigmoid activation function, the model limits the pixel values of the reconstructed image to the range of [0, 1], which is consistent with the normalized input image. The design of the decoder complements the encoder. It forces the encoder to learn more representative latent features by minimizing the reconstruction error.

The loss function is the core of the convolutional autoencoder training process. Its role is to measure the difference between the input image and the reconstructed image and guide the parameter update of the model. We use the mean squared error (MSE) as the loss function, and its formula is as follows:

$$L = \frac{1}{N}\sum_{i=1}^{N}(x_i - \hat{x}_i)^2 \quad (1)$$

Where, x_i represents the pixel value of the original input image, $\hat{x}_i$ represents the pixel value of the reconstructed image, and N is the total number of pixels in the image. The mean squared error encourages the model to restore the original data as much as possible by quantifying the difference between the input image and the reconstructed image at the pixel level. By minimizing MSE, the encoder will learn the latent features that can efficiently represent the input image, and the decoder will optimize its restoration ability. In addition, another reason for choosing MSE as the loss function is its sensitivity to reconstruction error, which helps to distinguish normal samples from abnormal samples in anomaly detection tasks. Normal samples have low reconstruction errors because their distribution is fully learned by the model; however, abnormal samples have significantly higher reconstruction errors because they deviate from the normal distribution. This difference provides important clues for subsequent classifiers.

The following Fig. 3 shows the working structure of the autoencoder:

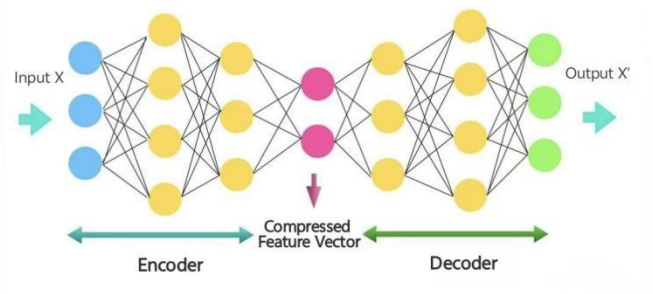

Fig. 3. Working structure of autoencoder.

B. The Training Process of Convolutional Autoencoder

In the training process of the convolutional autoencoder, we divide it into four main stages: data preparation, training configuration, model optimization, and model evaluation.

a) Data preparation: During autoencoder training, only normal samples are used to learn the distribution of normal data. Data preprocessing includes normalizing pixel values to [0, 1], resizing images to fit the model, and applying data augmentation techniques such as random rotation, noise addition, and brightness adjustment to enhance data diversity.

b) Training configuration: The input of the autoencoder is defined as (224, 224, 3), indicating that the processed image is an RGB image of 224*224 pixels. This input size is set by adjusting the input_shape parameter in the code. The encoder part uses two layers of convolutional layers and maximum pooling operations to gradually extract the core features of the image, and generates a 512-dimensional feature vector encoded through a fully connected layer. The decoder part restores the resolution and spatial structure of the image through dense connection layers, deconvolution and upsampling operations.

c) Model optimization: The Adam optimizer was selected when the model was compiled. The model can adaptively adjust the learning rate to accelerate the convergence process. The mean square error (MSE) was selected as the loss function to measure the pixel-level difference between the input image and the reconstructed image. The reason for choosing MSE is that it is very sensitive to reconstruction errors and can effectively capture the distribution deviation of abnormal data. During the training process, the input normal image is compressed into potential features by the encoder and then restored to the reconstructed image by the decoder. The model calculates the reconstruction error and continuously adjusts the parameters through back propagation to gradually reduce the reconstruction error. The number of training rounds is set to 20 (epochs=20) in the code, which is a reasonable value required for the model to converge.

d) Model evaluation: After training, we conducted a comprehensive evaluation of the model's performance, focusing on its performance on normal and abnormal data. First, we used normal samples and abnormal samples in the test set to calculate their reconstruction errors and analyze the difference in error distribution (Fig. 4) between the two types of data. The reconstruction error of normal samples is generally low, while the error of abnormal samples is significantly higher, which indicates that the model has successfully learned the distribution characteristics of normal data.

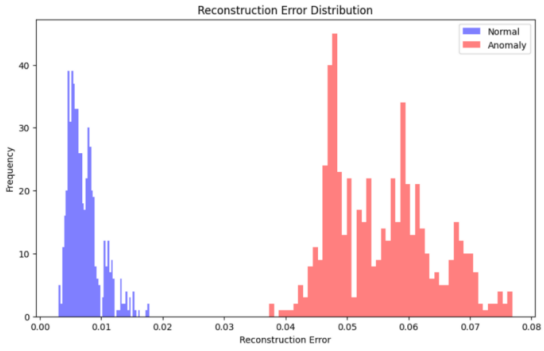

Fig. 4. Sample reconstruction error distribution.

C. Design and Implementation of Random Forest Model

RF is an ensemble learning algorithm for regression and classification [21-22]. During the training process, a large number of decision trees are constructed and the class of discrete tree output patterns is output [23]. It has strong robustness when dealing with high-dimensional features and multi-category classification tasks. Studies have shown that RF classifiers have superior performance compared to other methods such as neural network classifiers, bagging and boosting [24]. For classifying objects by image category, RF's performance is comparable to SVM, and RF has the advantage of being easier to train and test than SVM [25]. Taking the above factors into consideration, this paper designs and trains a random forest classifier by combining the reconstruction error calculated by the autoencoder and the hidden features extracted by the encoder to complete the binary classification task of normal and abnormal images.

The core idea of the random forest model is to form a strong classifier by constructing multiple weak classifiers (decision trees) and performing weighted voting on their prediction results, thereby improving the classification performance and generalization ability of the model. In this study, the input of the random forest classifier is the feature matrix of the image, and the features come from the reconstruction error calculated by the autoencoder and the hidden features extracted by the encoder. The input features consist of 512-dimensional hidden features and 1-dimensional reconstruction error, with a total feature dimension of 513. The hidden features capture the high-level semantic information of the image, while the reconstruction error reflects the degree of abnormality of the image. The number of decision trees (n_estimators), the maximum depth (max_depth), and the feature selection strategy (max_features) are important parameters of the random forest. In the experiment, these parameters are optimized by grid search to ensure that the model achieves a balance between classification performance and computational efficiency (Fig. 5).

The process for building an RF model with n decision trees can be summarized into three steps [26], as described below. Note that in the process, it is assumed that the data has k original features.

Step 1: Use the bagging method to generate n independent sample subsets from the initial data set.

Step 2: For each sample subset, build a classification or regression decision tree. When each node of the tree splits, randomly select k candidate features from all k features, and select the feature with the largest information gain as the split point. Finally, n decision trees will be generated.

Step 3: For classification tasks, integrate the prediction results of n trees by majority voting; for regression tasks, use the average value as the final output.

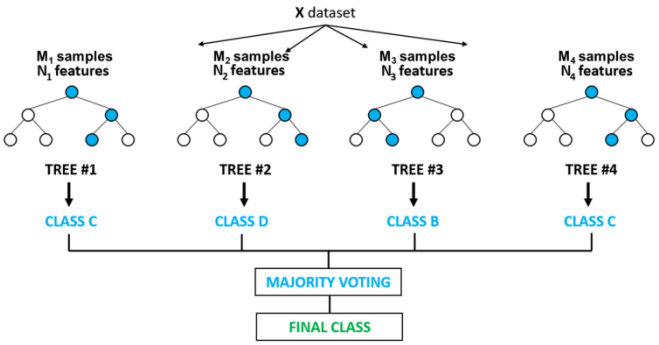

Fig. 5. Working structure of random forest.

D. Random Forest Training Process

a) Data preparation: In this study, the dataset consists of normal images and six types of abnormal images, including blur, noise, color shift, brightness, rotation, and occlusion. Each image is processed by the encoder to generate 512-dimensional hidden features, and the reconstruction error is calculated by the autoencoder. Finally, the dimension of the feature matrix is (number of samples, 513), and the corresponding label vector is (number of samples,). The ratio of normal images to abnormal images in the dataset is 1:1, and a total of 7024 images are included, with a balanced number of samples of normal images and each abnormal category. The dataset is divided into training set and validation set by stratified sampling, with the training set accounting for 80% and the validation set accounting for 20%. This partitioning method can ensure that the proportion of each category in the training set and validation set is consistent, thereby improving the generalization ability of the model.

b) Training configuration: The training parameters of the random forest classifier have an important impact on model performance and computational efficiency. This paper makes the following configurations based on input features and task requirements: First, the number of trees (n_estimators) is set to 200. Experiments show that increasing the number of trees can improve classification performance, but the computational time also increases. When the number of trees exceeds 200, the model performance tends to stabilize; second, the maximum depth (max_depth) is set to 20 to prevent a single decision tree from being too complex and causing overfitting, while controlling the training time; third, the Gini impurity (criterion) is used as the criterion for node splitting to ensure that each split can minimize the impurity of the category; finally, the feature selection strategy (max_features) is set to sqrt, that is, each time the split is performed, the square root of the features are randomly selected from all features for splitting to enhance the robustness of the model and reduce the training time.

c) Model optimization: The optimization of the random forest model is a systematic process that aims to improve the classification ability and generalization performance of the model by adjusting the model's hyperparameters and feature design. The optimization process mainly adjusts the four parameters in the previous section. For the number of decision trees, the range is set to [50, 100, 150, 200, 250, 300] through experiments. It is found that increasing the number of trees can improve the classification accuracy of the model, but the benefits decrease after exceeding a certain number. Finally, the number of trees is set to 200 to strike a balance between classification performance and training efficiency. In order to prevent overfitting caused by excessive growth of decision trees, the maximum depth is set to [10, 15, 20, 25] for testing. Experiments show that a depth of 20 can effectively control the complexity of the model while maintaining high classification performance. The classification criteria commonly used are Gini Impurity and entropy. After comparative testing, the results show that Gini Impurity has faster training speed and better classification performance in most categories. The feature selection strategy uses the default sqrt.

d) Model evaluation: The evaluation of the random forest model is mainly carried out by preliminary verification of the classification accuracy on the validation set to ensure that the model can effectively distinguish normal and abnormal images. The experimental results show that the classification accuracy rate reaches 92%. More specific classification results and analysis will be described in the next section.

V. Results and Analysis

A. Model Evaluation Methods

In this study, in order to verify the performance of our proposed model, we adopted common evaluation criteria [27-28], including classification accuracy, precision, recall, and F1 score.

The classification accuracy reflects the overall prediction accuracy of the model for all samples, and the calculation formula is:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

Precision measures the proportion of samples predicted to be of a certain category that actually belong to that category. The calculation formula is:

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

The recall rate measures the proportion of actual samples of a certain category that are correctly identified by the model. The calculation formula is:

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

The F1 score is the harmonic average of precision and recall, and is used to comprehensively evaluate the classification performance of the model. In the case of unbalanced class samples, the F1 score can better reflect the actual classification effect of the model. The calculation formula is:

$$F1_{Score} = \frac{2*(Precision * Recall)}{Precision + Recall} \quad (5)$$

In the above formula, TP (true positive) represents the number of positive samples correctly classified, TN (tree negative) represents the number of negative samples correctly classified, FP (false positive) represents the number of positive samples incorrectly classified, and FN (false negative) represents the number of negative samples incorrectly classified.

B. Model Performance

In order to fully verify the performance of the model, we used a five-fold cross-validation method to conduct experiments. Specifically, we evenly divided the test dataset into five subsets. By rotating the test set, we ensured that each subset was used as a test set once and only once. Finally, we averaged the results of the five experiments to obtain a more robust performance evaluation.

TABLE I. RANDOM FOREST

Category	Test set	Accuracy	Precision	Recall	F1-score
Normal	1	0.90	0.88	0.92	0.900
	2	0.93	0.91	0.94	0.925
	3	0.89	0.87	0.91	0.890
	4	0.92	0.90	0.93	0.915
	5	0.91	0.89	0.92	0.905
	Ave	0.91	0.89	0.924	0.907
Abnormal	1	0.92	0.91	0.93	0.92
	2	0.94	0.93	0.95	0.94
	3	0.91	0.90	0.92	0.91
	4	0.95	0.94	0.96	0.95
	5	0.93	0.92	0.94	0.93
	Ave	0.93	0.92	0.94	0.93

As can be seen from Table Ⅰ, the five-fold cross-validation results of the CAE-RF model in the two major categories of "normal" and "abnormal". From the overall performance, the classification performance of the model in the "abnormal" category is better than that in the "normal" category, where the average precision and recall of the abnormal category reached 93% and 94% respectively, indicating that the model has high sensitivity and low missed detection rate when capturing abnormal samples. However, the precision of the "normal" category is slightly lower, only 89%, reflecting that the model occasionally misclassifies abnormal samples as normal samples. Overall, the model maintains good stability in classification performance, with an average F1 score of 90.7% (normal category) and 93% (abnormal category), providing reliable support for anomaly detection tasks in practical applications. In the future, the precision can be further improved by optimizing feature selection or adjusting hyperparameters.

C. Model Comparative Analysis

In order to verify the performance of the CAE-RF model, other classifiers (such as support vector machines, K nearest neighbors, deep neural networks, etc.) were introduced into the experiment for comparison, and all models were subjected to five-fold cross validation (Table II). The specific results are as follows:

TABLE II. MODEL COMPARISON

Model	Accuracy	F1-Score	Inference time/sample	Rank
KNN	82.63%	0.816	50ms	5
SVM	85.87%	0.868	30ms	4
Autoencoder	84.90%	0.852	2ms	3
RF	88.23%	0.879	10ms	2
CAE-RF	92.56%	0.933	5ms	1

2) K Nearest Neighbors (KNN): The Euclidean distance metric was used to select the optimal K value (K=5) through grid search and normalization was performed. The classification performance of KNN is limited by the distance measurement method under high-dimensional data, and the classification accuracy is low, with an average value of 82.63%. Since the inference stage needs to calculate the distance between each test sample and all training samples, the inference time is long (about 50 milliseconds/sample). KNN is suitable for small-scale data sets, but not suitable for real-time scenarios.

3) Support Vector Machine (SVM): The radial basis kernel function (RBF) was used with regularization parameter C=1.0 and kernel coefficient gamma=0.01, optimized by cross-validation. SVM outperforms KNN in classification performance, with an accuracy of 85.87%. However, SVM's inference time is too long at 30 milliseconds/sample, which limits its application in real-time tasks.

4) Autoencoder: The structure is the same as CAE (encoder 2 layers of convolution + pooling, decoder symmetric), training rounds 20, loss function MSE. The autoencoder performs anomaly detection by reconstructing the error, with a classification accuracy of 84.9%% and an average F1 score of 0.852. The inference speed is very fast, only 2 milliseconds/sample, which is suitable for unsupervised anomaly detection tasks, but the performance is limited when used alone.

5) Random Forest (RF): The number of decision trees is 200, the maximum depth is 20, and the feature selection strategy is square root (sqrt). Random Forest has achieved a good balance between classification performance and efficiency, with a classification accuracy of 88.23% and an average F1 score of 0.879. The inference time is only 10 milliseconds per sample, which is suitable for real-time classification tasks of high-dimensional feature data, and supports feature importance analysis, with a certain degree of interpretability.

6) CAE-RF (Convolutional Autoencoder + Random Forest): The CAE-RF model combines the feature extraction capability of the convolutional autoencoder with the robustness of the random forest, and performs best in classification performance, with an accuracy of 92.56% and an F1-score of 0.933 respectively. Its inference time is only 5ms,

which is suitable for complex and real-time anomaly detection tasks.

VI. Discussion

This paper studies the application of a hybrid model based on autoencoder and random forest (CAE-RF) in image anomaly detection tasks. Traditional methods often have performance bottlenecks in high-dimensional data processing and classification tasks, and it is difficult to balance classification performance and real-time performance. To this end, this paper proposes an innovative feature fusion and classification framework, which extracts hidden features through autoencoders and combines them with reconstruction errors, and uses random forest classifiers to efficiently classify abnormal categories. Experimental results show that the CAE-RF model performs well in six categories of anomaly detection tasks and achieves a good balance between performance and efficiency.

The success of the CAE-RF model depends on the following key factors. First, the hidden feature extraction of the autoencoder significantly improves the expressiveness of the input features, while the reconstruction error further enhances the distinguishability of abnormal samples. This feature fusion method effectively makes up for the shortcomings of a single feature. Secondly, the robustness and interpretability of the random forest classifier provide the model with powerful classification capabilities, while the feature importance analysis also provides a transparent decision-making basis for the anomaly detection task. In addition, this paper verifies the significant performance advantages of the CAE-RF model through five-fold cross validation and multi-model comparison experiments, and proves its applicability in complex anomaly detection tasks.

However, despite its promising performance, the proposed method has certain limitations. The effectiveness of feature extraction relies on the autoencoder's reconstruction capability, which may be insufficient for detecting subtle or context-dependent anomalies, where abnormal features are not distinctly different from normal patterns. Furthermore, the limited size and diversity of the dataset could affect the model's generalization ability in real-world applications. Future work should explore larger and more diverse datasets, incorporate attention mechanisms or transformer-based architectures to enhance feature extraction, and investigate adaptive thresholding techniques to refine anomaly classification.

Career Recommendation Based on Feature Selection for Undergraduate Students Using Machine Learning Techniques

Samar El-Keiey, Dina ElMenshawy, Ehab Hassanein
Information Systems Department-Faculty of Computers and Artificial Intelligence, Cairo University, Egypt

***Abstract*—Undergraduate students worldwide face difficulties choosing the career paths that should stay with them for at least several years. It is widespread for graduates to work in jobs or join a career path they are not interested in. Also, sometimes these jobs do not suit the skills and preferences of undergraduates. On the other hand, some jobs require certain criteria and various skills that may not be available to some undergraduates. Although an undergraduate can study a major that he/she is interested in, this does not guarantee that he/she will be successful in his/her future career path. Undergraduates in various majors need advice on career paths that suit their skills and interests. When a graduate feels dissatisfied with his/her job, this dissatisfaction can impact his/her productivity and performance in his/her assigned tasks and job responsibilities. Moreover, the overall performance of the organization where these workers work can be negatively affected by having less talented and less motivated workers. As a result, in this paper, a recommendation system is designed and proposed to guide undergraduates in choosing the optimal career path. Various machine-learning techniques were used in the recommendation system. The proposed system was applied to two datasets related to Information Technology jobs; "Dataset A" consisted of 20,000 records and "Dataset B" consisted of 500 records. Feature selection techniques were applied on "Dataset A" to determine the most important features that enhance the accuracy of the proposed recommendation system. It has been shown that the random forests technique performed the best among the other machine learning techniques.**

Keywords*—*Career path; feature selection; machine learning techniques; recommendation systems

I. Introduction

Recommendation systems have become a popular tool during the past years to provide a personalized experience for users. Recommendation systems suggest items that are expected to be interesting to users and will likely be selected by them for usage or purchase. The suggested item can be a movie, a song, a book, an educational course, etc. In general, recommendation systems track the users' behaviors to generate patterns about the users' interests and preferences. Various techniques can be applied to these patterns to recommend items to users. The main objective of recommendation systems is to improve the user experience by presenting options to users that match their interests. Usually, recommendation systems recommend items to users based on their search history and queries. Recommendation systems play a crucial role in several industries and have many applications in various disciplines. One of these disciplines is the educational domain and the learning environment of undergraduate students who enrolled in universities.

In the learning environment, recommendation systems can recommend a course, a major, a specialization, or even a job career to students. Monitoring the students' learning behaviors and interests can greatly assist the recommendation systems in suggesting suitable learning components or modules to students. Moreover, the recommendation systems can have a larger scope than just selecting a course or a major, these systems can recommend a career path based on the student's learning behavior, interests, and skills.

II. Motivation

Jobs related to information technology (IT) continue to expand in various disciplines. Companies need to recruit well-qualified candidates to support their business needs and enhance overall business performance. Although there are a lot of Computer Science graduates worldwide, some graduates feel that they are not satisfied with their occupations, although they are interested in the Computer Science field. This is because their skills and interests do not directly match their jobs. For example, sometimes IT graduates work in cyber security, however, they can be more skilled and talented in another area, such as Requirements Analysis. Although both areas are related to Computer Science, a person can be more productive in one area than another. This is because each person has his/her own academic and personal characteristics that may let him/her be more successful in one certain job instead of another. Job descriptions and responsibilities vary across careers, so each job requires suitable candidates that best suit the job's roles. On the other hand, each person has certain traits, either educational or personality-based, that make him/her successful in a certain career.

All graduates, including IT graduates, seek to find a job that best suits their skills. These skills can be either academic-based or personality-based. Undergraduate students who enroll in faculties need assistance in choosing the career paths that they should stay with them for the rest of their lives. Failing to work in a job that satisfies the person's needs can affect the person's daily life as he/she feels less motivated to do his/her assigned job responsibilities and daily life activities. Moreover, a less motivated person can face psychological and social difficulties that impact his/her daily routine. Sometimes, dissatisfaction with a certain job can make a person leave a job without even having another alternative. In addition, having a less motivated

employee will affect the company's performance where this employee works.

Selecting a major that will most probably affect the choice of a future job is a challenging task because undergraduate students do not have enough knowledge or experience that help them select the optimal job that matches their skills. Students do not have information about the available careers in their relevant industries.

Usually, students know about the available careers from their parents, relatives, or friends. Even students sometimes try to search for jobs and employment fairs to learn more about the available jobs in the industry. Also, they do not know how their skills could match the available current jobs. Choosing a career path can affect the student's whole life [1]. As a result, in this paper, a framework for career path recommendations for undergraduate students is proposed. The main contributions of this paper are as follows:

- Proposing a framework for career path recommendation for undergraduate students.
- Applying various machine learning techniques to recommend the most suitable career path for undergraduate students.
- Applying different feature selection techniques to get the optimal features to be used in the career path recommendation.

The remainder of this paper is as follows. Section III presents the literature work. Section IV explains the proposed approach. Section V presents the results and Section VI presents the Evaluation and Discussion. Finally, Section VII presents the conclusion and future work.

III. Related Work

In study [2], the authors presented a model of a recommender system for the e-learning platform that recommended the most appropriate learning resources to the students according to their requirements and allowed them to reach the learning goals of the courses. This system was based on cloud computing infrastructure and made use of Google cloud services.

In study [3], a recommendation system for determining learning strategies for students was proposed. Collaborative filtering techniques based on the Naive Bayes algorithm were utilized to determine the learning strategies that are the most suitable for students.

In study [4], this research proposed a model of an e-learning recommendation system that recommended courses to students according to their needs. The proposed model used big data tools namely Hadoop and Spark to enhance data collection, storage, analysis, and visualization.

In study [5], the authors proposed an architecture that constructed semantic recommendations with the help of virtual agents based on user requirements and interests, helping academia in seeking suitable courses in a real-world setting. It has been shown that the virtualized agent-based recommendation system enhanced the user learning skills and made the selection of courses easier.

In study [6], a WebApp was proposed that recommended a course to students based on information about their academic performance, extracurricular activities, and personal preferences. Also, the WebApp acted as the role of a career counselor to interact with the students through a chatbot. The WebApp recommended to students the suitable branches of engineering that suited their interests by making use of machine learning techniques.

In study [7], this research presented existing career recommendation systems and mentioned the defects of these systems, such as cold start and scalability. Moreover, possibilities for enhancements in these systems have been presented to develop a career recommendation system using the content-based filtering approach.

In study [8], this research presented a job recommendation system that used machine learning techniques and historical data to predict the best candidate for a job. The input of the system was the requirement of a job and the profile of the applicants while the output was a score indicating how suitable each applicant is for a certain job.

In study [9], a career recommendation for college students was presented. The proposed system was based on deep learning and machine learning. A hybrid convolutional neural network was proposed, which utilized a convolution operation to learn high-level features to reach a personalized employment recommendation.

In study [10], a recommendation system was proposed, which made use of machine learning algorithms to assist IT graduates in choosing a career path based on their skills. A performance comparison between five machine learning algorithms was presented to measure their accuracy in predicting the best-suited career path. The experiments showed that the XGBoost algorithm had the highest accuracy.

IV. Proposed Approach

In this section, the proposed approach is presented along with the features used, the techniques applied, and the datasets used. The main idea of our proposed approach is to recommend careers to students using predictive analysis and machine learning. The recommender system uses some integrated features such as the average academic score, Intelligence Quotient (IQ), coding skills, some personality features, workshops attended by students, certificates gained by students, etc. The details of the features will be described in detail in the following section. The proposed approach was implemented in Python.

A. Proposed Architecture

The following Fig. 1 presents the architecture of our proposed approach, which shows the steps, and the methodology applied in the proposed approach. The first step focused on data cleaning and preprocessing, then the most appropriate features were selected using feature selection techniques, after that, the data was divided into training data and testing data. Then the next step is to build the machine learning model based on the selected features using six different

machine learning prediction techniques that will be described in detail in the following paragraphs. Finally, the last step is to build the recommendation system and recommend the job careers to students based on the selected features.

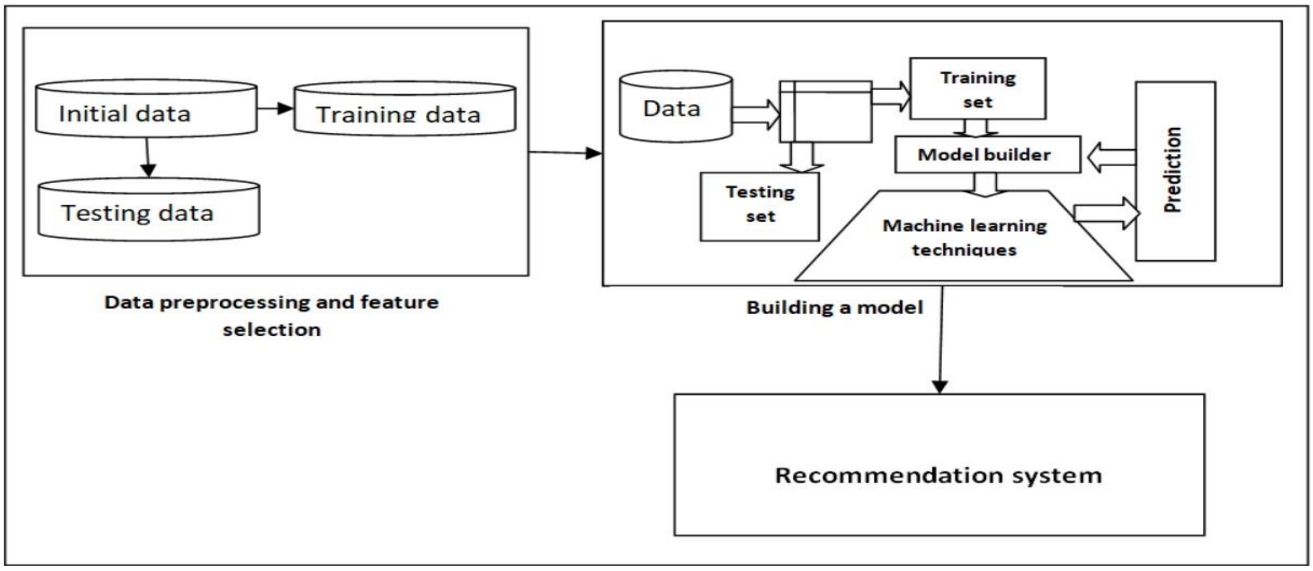

Fig. 1. Proposed architecture.

1) Dataset a preprocessing: The first step in "Dataset A" preprocessing is to encode and normalize the categorical data to numerical data using "Python pandas" and "Standard Scaler Python" libraries. "Dataset A" contains 35 features which may lead to inaccurate prediction results, so feature selection techniques were applied to clean the data and to select the most important and appropriate features.

2) Dataset b preprocessing: The questionnaire has been designed to collect the most important features extracted from "Dataset A". So, "Dataset B" consists of the same features used in "Dataset A" but from different students. As the data was collected from a questionnaire, some data preprocessing steps were performed such as moving redundancy, minimizing noise, and normalizing the categorical features into numeric features.

B. Data Set and Data Preprocessing

Two datasets were used to train the models. The first dataset "Dataset A" consists of 20,000 records with 35 features and it is available in study [11]. The second dataset "Dataset B" consists of 500 records collected from level four students in the Faculty of Computers and Artificial Intelligence, Cairo University via a Google form questionnaire.

C. Feature Selection

Feature selection techniques were used for the following reasons [12]:

- Increasing the speed of training of the machine learning models.
- Decreasing the complexity of the model.
- Decreasing the overfitting of the model.
- Making the model more accurate and precise by selecting the best-fitted features.
- Avoiding underfitting of the machine learning models.

There are three types of feature selection techniques, filter methods, wrapper methods, and embedded methods. The embedded methods combine the advantages of wrapper methods and filter methods. The advantages of embedded methods are:

- Providing high accuracy.
- Having an easy interpretation.
- Avoiding overfitting.

Random forest feature selection technique is one of the most popular methods of embedded feature selection methods [13].

Random forests are made up of four to twelve hundred decision trees, each built over a random extraction of the observations from the dataset and a random extraction of the features. Since no tree checks every feature or every observation, random forests ensure that the trees are de-correlated and are less likely to overfit.

Either the information gain/entropy or the Gini impurity [14] is used as the measure of impurity for classification models. As a result, when training a tree, it is easy to calculate the amount that each feature reduces impurity. A feature's importance increases with its ability to reduce impurities. Attributes chosen at the top of the trees are typically more significant than attributes chosen at the end nodes of the trees.

Our proposed recommendation model is considered a multi-class classification model as the recommended job falls between 33 class labels. Some of these labels are Application Developer, Business Intelligence Analyst, CRM, Business Analyst, Database Developer, Software Developer, System Analyst, Project Manager, etc. Random forest feature selection techniques were used for classification models.

The random forest feature selection method has been implemented using "Python Pandas" and "Sklearn" (RandomForestClassifier, FeatureSelection, and SelectFromModel) libraries and feature importance Python function [15].

Best practice in all feature selection methods to rely solely on the training set, without considering the testing set, to prevent overfitting.

After applying the feature selection method to our dataset, "22 features" were removed because they have less importance on the model's performance. The most important features were 13 features that are as follows:

1) Average Academic Score (AVG)
2) Intelligence Quotient (IQ)
3) Coding Skills Rating (CSR)
4) Self-learner (SL)
5) Certificates (CERT)
6) Workshops
7) Memory (MEM)
8) Interested Career Area (ICA)
9) Books
10) Behavior
11) Hard Worker / Smart Worker (HorS)
12) Work in a Team (WinT)
13) Introvert (I)

Our model utilized the aforementioned features as inputs and generated outputs based on various combinations of these inputs. For instance, the model took into consideration the student's high average score in database-related subjects, with an IQ score of 6, a coding skills rate of 3, and the student being a self-learner with certifications and courses in data management and workshops in the same field, having average memory, and an interested career area related to data. Additionally, the model considered the student's reading habits, gentle behavior, the ability to be a hard worker, and could work well in a team. The student was also outgoing and non-introverted. When all these features and their combinations were inputted into the model, it yielded the output that the most suitable career for this student is a Database Manager. This is what the model learned and trained on in the training data, and this example applies to all available jobs found in the dataset.

D. Building the Model

After the data preprocessing stops, the dataset is divided into a training set and a testing set with a ratio of 70%-30% respectively. Six different machine-learning classification models were applied to train and test the model:

1) *K-Nearest Neighbor (KNN):* KNN is used for regression and classification, which are two applications of the nonparametric supervised machine learning classifier method [16].
2) *Naive Bayes (NB):* NB is a probabilistic model used for classification that is based on the Bayes theorem [17].
3) *Random Forest (RF):* RF is a regression and classification model that contains multiple decision trees [18].
4) *Decision Tree (DT):* DT is a regression and classification model. It is a non-parametric supervised machine learning classifier technique. It is organized as a hierarchical tree [19].
5) *Support Vector Machine (SVM):* SVM is a model that is employed for both classification and regression, which is a supervised learning model [20].
6) *Gradient Boosting (GB):* GB is a classifier that combines several learning models to produce a single, powerful prediction model. Typically, decision trees are employed in gradient boosting. Gradient boosting models are gaining attraction due to their efficiency in categorizing intricate datasets [21].

E. Correlation Matrix

The correlation matrix was created to determine the correlation and dependencies between the features [22] as presented in Fig. 2.

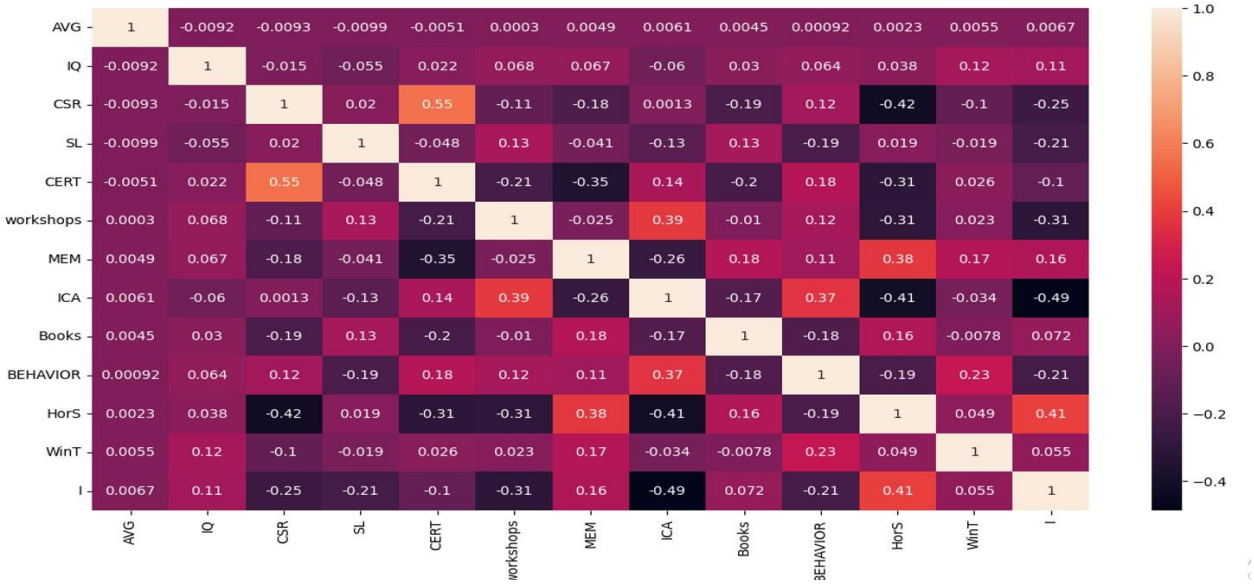

Fig. 2. Correlation matrix.

The degree to which one feature influences another is reflected in their correlation. A stronger correlation exists between two features when the correlation coefficient is higher, indicating a more significant positive or negative relationship.

Conversely, values near 0 were obtained from the less associated attributes. A score that approaches zero indicates less correlation between the features.

A positive correlation is indicated when the value of one associated feature rises along with the value of the other feature, or when the value of one associated feature decreases along with the value of the other feature.

Conversely, a negative correlation is shown when one correlated feature's value rises while the other feature's value falls, and vice versa.

V. Results

After applying the techniques to "Dataset A", the performance of the model was measured by computing the accuracy, precision, recall, and F1-measures [23]. The results of all six techniques are compared and presented in the following Table I.

TABLE I. Recommendation Results of the Six Techniques in "Dataset A"

Technique	Accuracy	Precision	Recall	F1-measure
KNN	0.82	0.82	0.82	0.81
NB	0.88	0.87	0.88	0.88
SVM	0.88	0.93	0.88	0.90
DT	0.84	0.89	0.85	0.87
RF	0.90	0.95	0.91	0.93
GB	0.85	0.84	0.85	0.84

As shown in Table I, the random forest technique had the best performance compared with the other techniques with accuracy = 0.90, precision = 0.95, recall = 0.91, and F1 measure = 0.93. Precision, recall, accuracy, and F1-measure are calculated respectively by the following equations:

Precision =

$$\sum_{C=1\ldots N} TPs \,/\, \sum_{C=1..N} (TPs + FPs) \tag{1}$$

Recall=

$$\sum_{C=1\ldots N} TPs \,/\, \sum_{C=1..N} (TPs + FNs) \tag{2}$$

$$\text{Accuracy} = (TP + TN)/(TP + TN + FP + FN) \tag{3}$$

$$F1 = 2*(\text{Precision}*\text{Recall})/(\text{Precision}+\text{Recall}) \tag{4}$$

Where the True Positive, True Negative, False Positive, and False Negative values are defined as follows:

- True Positive (TP): When the expected and actual values are the same, this is known as the true positive value, or TP [24], [25].
- True Negative (TN): The total of all columns and rows, excluding those for the class for which we are calculating the values, is the True Negative value (TN) for that class [24], [25].
- False Positive (FP): The total of all the values in the applicable column, except the TP value, is the False positive value for a class [24], [25].
- False Negative (FN): The total of the values in the corresponding rows, excluding the TP value, represents the False-negative value for a class [24], [25].

After applying the techniques to "Dataset A", we further validated the model's generalizability by applying it to "Dataset B". This ensured that the model didn't overfit the training data in "Dataset A". The model's performance trained on "Dataset B" was evaluated by computing the accuracy, precision, recall, and F1-measure. The results of the six techniques are compared and presented in Table II.

TABLE II. Recommendation Results of the Six Techniques in "Dataset B"

Technique	Accuracy	Precision	Recall	F1-measure
KNN	0.80	0.81	0.81	0.80
NB	0.86	0.85	0.87	0.87
SVM	0.87	0.99	0.86	0.89
DT	0.82	0.87	0.86	0.86
RF	0.88	0.90	0.90	0.91
GB	0.85	0.82	0.84	0.83

As shown in Table II, the random forest technique had the best performance compared with the other techniques; the results are very close to the results shown in Table I, that was related to "Dataset A". This leads to ensuring that all models do not overfit on specific data and introduces more generalization to the model.

VI. Evaluation and Discussion

To test the efficiency of our proposed approach, we trained the model on the data in "Dataset A" without using any feature selection techniques and measured all performance measures. After that, we compared the results in Table III with those in Table I. This resulted in proving that the feature selection techniques enhanced and improved the performance of the model.

TABLE III. Performance Measures Before Using Feature Selection Techniques

Technique	Accuracy	Precision	Recall	F1-measure
KNN	0.52	0.53	0.52	0.51
NB	0.55	0.55	0.57	0.57
RF	0.60	0.62	0.62	0.63
DT	0.56	0.58	0.58	0.57
SVM	0.58	0.57	0.58	0.60
GB	0.56	0.54	0.55	0.54

By comparing the findings in Table III with those in Table I, it is obvious that using the feature selection techniques (Table I) significantly improved model performance as reflected in all evaluation measures.

Before using feature selection techniques (Table III), the results showed low performance due to the misclassified instances and the unclarity of some features that will lead the model to under-fit and this will be presented in the chart in Fig. 3 that presented the comparison of all performance measures before and after using feature selection techniques. This emphasizes that applying feature selection techniques in our recommendation system has a very significant role in predicting the most suitable job for the undergraduates.

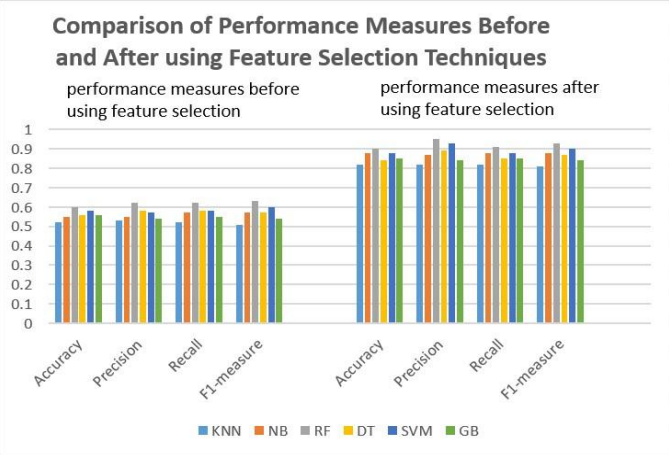

Fig. 3. Comparison of performance measures before and after using feature selection techniques.

VII. Conclusion and Future Work

Recommending a student's career (job) is very important for students and graduates to improve and speed up the processes of seeking a job after graduation. In this paper, the main idea is to identify the most important features that have the most significant impact on the career recommendation system and predict the job that fits the model based on the features that are released from the feature selection method. A career recommendation system was built by applying different machine learning techniques to different features extracted from feature selection methods.

The recommended jobs are addressed to Information Technology (IT) students. These jobs fall within 33 class labels, some of them are Application Developer, Business Intelligence Analyst, CRM Business Analyst, Database Developer, Software Developer, System Analyst, Project Manager, etc.

Education makes extensive use of machine learning multiclass label classification models. The student's career (job) was recommended using K-nearest Neighbor, Naive Bayes, Random forests, Decision Trees, Support Vector Machines, and Gradient Boosting techniques. The Random Forest technique performed the best in recommending the student's career (job).

To improve the effectiveness of the proposed approach, feature selection methods were applied using the random forest feature selection technique to extract the most important features to use. Then the performance measures were computed. The random forest technique gave the best performance measures compared with the other five machine learning models.

One limitation of this study is that the scope is confined to the information technology field, which narrows the scope of the model. However, our model has the potential to be extended to be more generic and inclusive, covering multiple diverse domains such as the medical field, the engineering field, and others.

Some challenges were encountered during the research, including the difficulty of data collection from students, data redundancy, data noise, and irrelevant data.

Finally, a lot of research can be done in recommending student careers (jobs) so further research can be conducted for future work. Furthermore, deep learning techniques may help in enhancing the performance of the recommendation systems by using neural networks and other deep learning techniques [26], [27]. Our model has the potential to be extended to be more generic and inclusive, covering multiple diverse domains such as the medical field, the engineering field, and others as mentioned in the limitations.

***Abstract*—Floods are one of the most severe natural disasters in Malaysia, occurring frequently in recent years and causing significant socio-economic and environmental impacts. These recurring disasters lead to huge losses and prolonged recovery period. Flood management involves four phases: prevention, preparedness, response, and recovery. However, existing flood management systems primarily focus on preparedness, response, and recovery, often neglecting preventive measures, especially in river basin which serve as the primary channels for water flow. The lack of emphasis on the prevention phase has resulted in frequent flood occurrences, economic losses, loss of lives, and extensive environmental damage. To address this gap, this study proposes an IoT-based Flood Prevention System specifically designed for river basin management to mitigate flood risks. The system effectively regulates and maintains river water flow and quality, with the integration of Internet of Things (IoT) and Automated Water Turbines. By using real-time data collection from IoT sensors with historical flood data, the system can autonomously take appropriate actions to regulate and maintain the water flow and water level in river basin. These proactive measures allow for better water discharge to the sea, even during periods of heavy rainfall. The implementation of this system contributes to sustainable flood mitigation strategies with advanced technologies enhancing disaster management capabilities.**

***Keywords*—Flood prevention system; Internet of Things (IoT); automated water turbines; river basin management; real-time monitoring; AI-based flood prediction; environmental sustainability; smart infrastructure**

I. Introduction

Malaysia is one of the countries frequently affected by natural disasters such as flood disaster frequently in past years and causes severe impacts on people, properties, infrastructure, homes, crops, and even loss of human and animal lives. Flood management is divided into four phases: prevention, preparedness, response, and recovery. However, the current flood management system in Malaysia primarily focuses on preparedness, response, and recovery, neglecting prevention, particularly in managing river basins, which serve as the primary channels for water flow. The current system has not effectively solved the flood disaster issue over the years as the system is focusing on preparedness, response and recovery phase. The most recent flood disaster resulted in an overall loss of RM 6.1 million, where people have still suffered in their daily life even months later [1]. This highlights the need for a proactive flood management approach that focusses on prevention rather than prediction and response.

Heavy rainfall, poor river management, clogged drainage systems, and overflowing rivers are primary causes of flood disasters in Malaysia. Malaysia faces heavy rainfalls during October to December and during April month [13]. Water flows from drainage systems into rivers and streams, which then move through river basins before discharging into the sea or ocean. Disruptions occur when river basins cannot manage excessive water during heavy rainfall. At the same time, blockages and clogged rivers further restrict capacity, preventing efficient water flow. This congestion causes water to overflow, leading to widespread flooding as it has no clear discharge path to the sea. River basins function as natural channels, transporting water from multiple rivers to the sea [14]. However, during heavy rainfall, river basins are unable to manage large amounts of water where the capacity exceeded and results in congestion that triggers flash floods. This further contribute to the severity of floods in Malaysia [10]. With a well-maintained drainage system, especially river basins, the risk of flash floods can be significantly reduced, ensuring smooth water flow, and preventing water overflow.

Many countries, including Malaysia, primarily focus on preparedness, response, and recovery rather than prevention in flood management, resulting in frequent occurrences of flood. This situation has persisted for years, leading to repeated flood disasters that have caused severe impacts on infrastructure, agriculture, ecosystems, and human livelihoods. Malaysia has taken proactive measures to enhance flood forecasting and disaster planning such as National Flood Forecasting and Warning Program (PRAB) and the National Flood Forecasting and Warning Centre (PRABN). These initiatives, under the Department of Irrigation and Drainage (DID) Malaysia aim to mitigate flood risks by alerting and evacuating people in advance. PRABN focuses on more effective evacuation planning and PRAB focuses on better coordinating and real-time flood monitoring [15]. Apart from that, there are other structural and non-structural flood prevention measures, including flood control dams, river widening, bunding, and the SMART Tunnel. Although several preventive measures have been implemented, there are no strategies focusing on water flow management, especially for rivers and river basins. Effective flood prevention requires proactive measures to regulate river flow, prevent blockages and enhance capacity to ensure that there is good water flow even during heavy rainfall.

Malaysia currently lacks a flood management system to monitor, maintain, and implement proactive flood prevention solutions. Flood management consists of four phases:

prevention, preparedness, response, and recovery [16]. However, Malaysia primarily focuses on preparedness, response, and recovery, neglecting prevention. Although preparedness, response and recovery measures make a difference, the issue persists because the root causes of flooding remain unaddressed. Overcoming root causes will eventually prevent flooding from happening.

The proposed research, which is Flood Prevention System using IoT is proactive flood management emphasizing flood prevention rather than preparedness, response, and recovery. With the implementation of this system, flood risks can be significantly reduced with integration of IoT sensors and automated water turbines to regulate water levels and flow effectively. The Flood Prevention System using IoT is a real-time monitoring and proactive flood management system designed to maintain river basin levels and flow at an optimal level. It has the capability of proving high accuracy prediction on flood disasters, executing appropriate prevention steps for flood prevention by maintaining the water levels, water flow in all the river basins. The Flood Prevention System using IoT is powered by the Internet of Things (IoT) and integrates automated water turbines to regulate river flow efficiently. IoT sensors, including water level sensors, raindrop sensors, and ultrasonic sensors collect and analyze data in real-time to enhance flood prediction and prevention. Automated water turbines play a crucial role in monitoring and maintaining the water flow of the river. The automated water turbines work when the system detects the low speed of the river water. By integrating real-time data and automated interventions into the system, this system provides a proactive flood management solution preventing flood disasters.

Integration of IoT with Flood Prevention System helps to gather data from sensors in real-time without any interruption [8]. Water sensors and ultrasonic sensors were being used as IoT devices to gather water level information in real-time and data will be analyzed for flood prediction and solutions to maintain the water flow of all rivers. The constant real-time data can produce higher accuracy of results and less impact on the environment as well as people. IoT's real time data have a higher rate in minimizing the potential damage since the system implementation able to provide a best solution for the departments to serve the people [4]. At the same time, most of them are less aware of flood warnings, flood prediction or alerts because they are only getting alert when there is flood about to occur which is making them to be unprepared and becoming victim of it at the end. The lack of constant information supply between respective departments and citizens leads to have high impact during flood disaster currently. With the system, authorities and people get reliable information on the rainfall and water levels in all rivers.

There are three scenarios which are being prioritized for the flood prevention system. First, if the water level in a river is high due to less depth in water, it will alert the Drainage and Irrigation Department to deepen the river basin. Second, if the water level in a river is high due to internal or external blockage, it will alert Drainage and Irrigation Department to clear. Third, if there is water level rise and no blockages, it will turn on the automated water turbines to speed up the water. With that, instead of showing prediction and alert before flood, the system will constantly maintain the water level, water flow of all the rivers. This will make sure water flow is good all the time even though there is heavy water flow. The Flood Prevention System using IoT will be highly beneficial as it effectively addresses current flood management challenges and overcomes it by providing appropriate measures. By integrating advanced sensor technology and automated water regulation, the system able to maintain a good flow of water and optimal water level throughout the year. To provide a comprehensive understanding of the study, this paper is structured into six sections. Section II (Literature Review) provides an analysis of existing flood management approaches, highlighting challenges in current approaches and the need of advanced technologies. Section III (Methodology) details the design and implementation of the IoT-based Flood Prevention System. Section IV (Findings) presents the system's performance results. Section V (Discussion) evaluates the practical implications of the system. Section VI (Conclusion and Future Work) summarizes key findings and suggests enhancements to the system in future.

II. Literature Review

Flood disaster is one of the most threatening issues in Malaysia, affecting people, facilities, infrastructure, animals, agriculture, and more. Flood disasters are being highlighted globally, causing widespread and increasing damage to communities, economies, and ecosystems. The primary reasons for frequent flooding include heavy rainfall, poor river management, clogged drainage systems, and overflowing rivers. Flood disasters are occurring worldwide, including the 2013 Uttarakhand flash floods, 2019 Mozambique Cyclone Idai floods, 2011 Thailand floods, and 2019 Jakarta floods [17]. In Malaysia, flood issue is not being resolved over the years. In Pakistan, over 1,739 people died, and thirty-three million people were affected by the floods between June and November 2022. The economic losses were estimated at over $30 billion. Apart from that, there were another flood in Chennai, where it caused by heavy rainfall during the northeast monsoon season in November–December 2015. Malaysia also faces the same challenges, experiencing severe flooding events due to heavy rainfall, poor drainage systems, and rapid urbanization. In December 2021, prolonged heavy rain in Malaysia specifically in Selangor and Klang Valley lead to have flash flood causing huge damage including loss of property, infrastructure, and agricultural damage. The economic and social implications of these disasters emphasize the need for enhancing the current flood management system with advanced features and capabilities to prevent flood disasters in Malaysia.

The impact caused by floods, making people face more issues in becoming the flood. The recovery phase from floods is time-consuming, and people must spend significantly to rebuild their lives. While some prevention methods have been applied in Malaysia, their effectiveness and accuracy fail to keep pace with current technology and environmental demands [6]. There are several reasons why floods occur. The primary cause is heavy rainfall, particularly during the period from October to December, which often leads to flood disasters in Malaysia. Other contributing factors include poor river management, overflowing rivers, drainage blockages, and excessive exploitation of natural resources. These factors increase flood risks especially in urban areas where rapid development has

impacted natural water flow. These factors increase flood risks, especially in urban areas where rapid development has disrupted natural water flow. There are several sources contributing to high water flow into rivers and river basins, such as heavy rainfall, dam water releases and poor drainage system. Heavy rainfall, particularly during monsoon seasons, causes extreme water flow, and causes flooding.

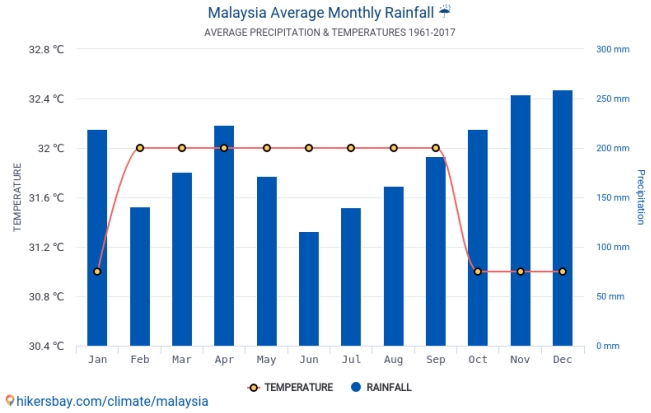

Fig. 1. Malaysia average monthly rainfall.

Fig. 1 illustrates the annual rainfall and temperature trends in Malaysia. The rainfall shows an increasing graph in October, November, December, January, and April [5]. These months have experienced heavy rainfall and high chances of flash flooding. Heavy rainfall is one of the primary contributors to flooding in Malaysia, especially in low-lying urban areas where water drainage system unable to manage large volume of water. Poor river management and sediment accumulation also causes flooding where water flow is obstructed and reducing river's capacity. Malaysia has implemented structural and non-structural measures to mitigate flood impacts. Department of Irrigation and Drainage Malaysia (DID), Malaysian Meteorological Department (MET Malaysia), National Disaster Management Agency (NADMA), Fire and Rescue Department of Malaysia (BOMBA), Department of Environment Malaysia (DOE), National Security Council, Local Government and Municipal Councils are several government agencies and departments are responsible for flood management, prevention, and response in Malaysia [19]. Structural measures include flood control dams such as Batu Dam and Semberong Dam to regulate water flow, river widening and deepening for better drainage. The SMART Tunnel in Kuala Lumpur serves as both a stormwater diversion system and traffic diversion [18]. Non-structural measures include real-time flood monitoring systems, the Greening Malaysia Programme, which aims to plant one hundred million trees by 2025, and the National Flood Disaster Management Committee.

Despite the implementation of various structural and non-structural flood mitigation measures in Malaysia, there remains a critical gap in proactive flood prevention. The existing flood management strategies mainly focus on preparedness, response, and recovery, rather than prevention. While the root cause is not being focused, the flood issue will still not be resolved. The IoT-based Flood Prevention System aims to fill this gap by integrating real-time monitoring, predictive analytics, and automated water turbine technologies. By utilizing IoT sensors and automated water turbines, the proposed system actively manages and monitors river flow in river basin, detects blockages, and ensures optimal water levels to prevent overflow and flash floods. Unlike traditional methods that only functions in preparedness, response and recovery after flooding, this system provides real-time solutions to regulate good water flow from drainage to the sea. Furthermore, the IoT-based Flood Prevention System plays a crucial role in river basin management by dynamically managing water levels in river basins.

A. Phases in Flood Management

There are four phases that can be divided into flood operations which are prevention, preparedness, response, and recovery phases. The prevention phase is to prevent floods from happening. This will ensure that there are no flood events that occur at any place. This also can be called mitigation. This is an effort to reduce the loss of life and damage the environment. Next, the prediction phase is predicting the incident on estimated date and location of flood about to occur with help of data analysis. The prediction can be made based on past flood data and other related data such as river water level data and rainfall data. With prediction, people can be flooding alert and flood warning earlier to save them and their belongings before the flood occurs. Next is the recovery phase. The recovery phase begins after floods have occurred and subsided. The purpose of recovery phase is to recover from the flood disaster and bring the affected areas and people to live a normal life [7].

B. Factors Affecting Flood Disaster

One of the reasons why flooding is happening is due to poor management of the drainage system where many drains were clogged. Apart from that, improper river management is also a reason for flooding to happen. Many rivers and river basins are being clogged because of garbage and sediments. This makes the river flow to be slower and becomes a reason for flooding. During 2018, heavy downpours and strong winds in Klang Valley caused flash floods and the reason was because of clogged drains. There was also another flood incident in Taman Selayang due to poor drainage maintenance [9]. It can be concluded that improper river management and lack of proper drainage system leads to flood disaster. When there is heavy rainfall, this makes the situation to be worse. The garbage thrown into rivers, silt and other obstructions making the drainage system lowered by 50% and causing flash flood [2]. At the end, all the clogs in drains will move to rivers and this makes the river water clog as well. Since there is no proper method to monitor the rivers and drainage by Drainage and Irrigation Department (DID), the situation is continuing for a longer period.

C. Impacts of Flooding

According to Department of Statistics Malaysia, the impact of flood is increasing, and the overall losses were RM6.1 billion which is inclusive of damages in living quarters, business premises, vehicles, agricultures, manufacturing, public assets, and infrastructure [3]. This is only the cost of losses for 2021. Each year, flood events happen very frequently, and it takes a lot of effort and money to recover from flood completely. It can be said that every year, people in certain districts suffer because of floods and it happens regularly.

D. Introduction to Flood Prevention System Using IoT

The purpose of Flood Prevention System using IoT is to conduct a prevention method to prevent flood from happening in Malaysia. The proposed system is an advanced system which has capability of providing a higher accuracy on flood disasters and making prevention from flood occurrence. The proposed system has been enhanced with Internet of Things (IoT). The purpose of IoT is to improvise the prediction of flood by using additional data which is collected using sensors. Sensors that are integrated with the system are water depth sensor, soil moisture sensor, rainfall sensor and ultrasonic sensor [11]. This system is also included with automated water turbines. Water level sensors are used to measure the depth of river water. Rainfall sensor is used to measure the rainfall. Ultrasonic sensor is used to detect the water wavelength and identify any objects which are distracting the water flow. Apart from sensor, the system will be equipped with automated water turbines to increase the water flow of river.

There are four phases that can be divided into flood operations which are prevention, preparedness, response, and recovery phases. Existing systems have highlighted the preparedness, response, and recovery phase where prevention phase have been neglected. The purpose of the proposed system is to enhance the prevention phase by implementing IoT and AI technology. In Malaysia, the system that is implemented by authorities has more focused on prediction where they are using the flood history data and rainfall data to predict the flood. After prediction, they will alert the people to evacuate to safer places and protect their belongings [23]. This scenario has been implemented and has been implemented since a long time ago. Although this situation can save life and their belongings, the accommodation, infrastructures and facilities are being destroyed because of flood. Because of this, the government needs to execute plans to get the situation back to normal and this results in people spending huge amounts of money.

The current system can protect a few percentages of damage but still it is affecting people and the environment. With that, the proposed system is focused on the prevention phase where the results will 99.9% flood prevention [12]. By implementing the proposed system, flood disasters can be avoided, and many things can be saved. Implementation of IoT such as rainfall sensor, water depth sensor, soil moisture sensor and ultrasonic sensor able to provide a higher accuracy data on river water level. Higher accuracy of data helps in maintaining river water flow and helps in better prediction. Below are steps on how the proposed system works to prevent floods.

1) IoT sensors such as rain drop sensors, water level sensor, and ultrasonic sensor will be integrated with the system and the system will be monitoring all the sensor and collecting the data.

2) With rules or statements set, the system can analyze and interpret the data. The system will set the optimum water level in each river to ensure that there is good water flow in rivers even though there is flood disaster.

3) When the river water level is continuously giving a reading that is more than optimum level, the system will identify the cause of the effect.

4) If the higher level of river water is caused by a slowdown in water flow due to blockage, it will alert the Department of Irrigation and Drainage to clear the blockage.

5) If the higher level of river water is caused by less depth in river, it will alert the Department of Irrigation and Drainage to deepen the river.

6) The system is equipped with water turbines, where it will work simultaneously with a microcontroller and water depth sensor. When the sensor detects the slowness of the water level, it will automatically trigger the water turbine to turn on. With this, the water flow can be increased.

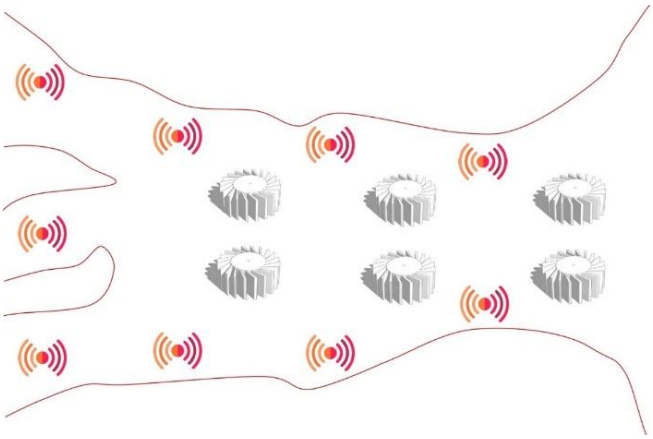

Fig. 2. Proposed system.

Fig. 2 illustrates how the proposed system will look like. The Flood Prevention System using IoT emphasizes the prevention phase. The system will be integrated with IoT sensors such as water level sensors, rainfall sensor and ultrasonic sensor. Apart from that, it also includes water turbine technology which will increase the flow of water rivers when it is necessary. The IoT sensors will be placed on river basins where it is able to detect the flow of the river water. When there is no blockage and the water level rises, then it will activate the water turbine. Water turbines will be automated when there is a requirement to increase the flow of the river water with the integration of IoT. Automated water turbines allow the river water to be cleared as quickly as possible to be sent to the sea. It means that there will not be any water traffic at the river basin, and it will ensure that water from the drainage will be quickly sent to sea.

When this system being implemented, it can be concluded there is no reason for clogged drains and rivers. Even if there is heavy rainfall, the river water will be constantly sent to sea, and this will prevent flooding. All the integrations and the systems will ensure that the data is collected precisely, and actions will be taken accordingly.

III. METHODOLOGY

A. Research Problem

The Malaysia is one of the countries which is affected by natural disasters such as flood disaster frequently in past years and it creates huge impact on people, properties, infrastructures, houses, destruction of crops, loss of human life and animals. In terms of flood operation, there are four phases which are prevention, preparedness, response, and recovery phase. In

Malaysia, the system which is implemented by authorities only focusing on preparedness, response, and recovery phase. Preparedness, response and recovery phase will not be helpful because somehow the damage is still there, but people are affected by damages. The current system is not highly effective because the flood disaster issue has not been solved over many years. The recent flood disaster has caused 6.1-million-ringgit losses overall and people are still suffering in their daily life even though the flood disaster happened few months [20]. This proves that people are still getting to be affected even if there is preparedness, response and recovery actions conducted.

The main reason for having flood is because of heavy rainfall in certain period of time and clogged drainage systems. It has been identified that Malaysia faces heavy rainfalls during October to December and during April month. Clogged drainage system, poor river management, overflowing rivers are some of the main reasons why there is flood disaster happening in Malaysia. When there is a clogged drainage system, the water flow in rivers become slower. When heavy rain hits the ground, the river basins will have water traffic, and this will lead to flash flood. When there is proper system to maintain the drainage system, there is no worry for flash flood in future.

Not only in Malaysia, but most of the countries are focusing on preparedness, response, and recovery phase too. This situation has been happening for the past few years, the results are repeating the same which is huge damage to all.

Moreover, there is no proper communication platform before and during flood disasters. People are not getting sufficient information regarding the latest updates, and this causes a lack of communication between people and authorities. The current technologies have made many improvements in many sectors. With that, Implementation of new technologies and automated responses will be able to solve this entire issue. The proposed research is AI powered Flood Prevention System using IoT which is focusing on prevention phase. With implementation of this system, flood prevention can be 99.9% of successful rate with help of IoT sensors and automated water turbines.

B. Research Methodology

For this research, quantitative methodology is the most appropriate methodology which can be used to collect data information on the problem faced by the target audience. Quantitative Methodology can be described as exploration of numeric patterns with help of description on the characteristics, hypotheses from a group number of people. This methodology is usually when there is involvement of large number of people in issue. Quantitative methodology can be conducted with the help of questionnaires, surveys, and statistical data. Since it involves large number of people, it will be helpful and easier to gather data such as opinion, ideas, feedback from people. Gathering data from people is important to ensure that the system that is being proposed able to satisfy their needs, able to solve their current issue and provide a useful solution to them. By doing quantitative methodology, researcher able to understand the problem from audience side, and how they are encountering the problem in their daily life.

There are few benefits of conducting quantitative methodology. First, the researcher able to clearly understand and define the research question accordingly, so that data that to be collected will be precise and fit to the purpose. Since it involves a large group of people, the results can be easily represented in the form of a table, chart, or graph. Since the questions and answer options are set by researcher, it is easier to understand people's opinion. Secondly, the data that is collected can be easily documented in graphs, charts, tables instead of text. This makes it easier for researcher to have good understanding on the issue and at the same time, researcher can analyze the problem from different perspective and view. For this flood disaster issue, questionnaire will be the most suitable technique to understand the issue from the target audience and analyze it.

Questionnaires are one of the useful ways of collecting data from large group of people. This can be a quicker and easier method of data collection. Since the target audience is large for the proposed system, a questionnaire is suitable way. The questions that are prepared for the questionnaire are very important and detailed because there will not be physical interaction with the person. The questionnaire will not be like an interview session because the person is only going to fill in the form based on the questions and answers given. The questions can be multiple choice question and open-ended question.

C. Target Audience

The target audience for this research will be aged, more than twenty-five. The number of respondents that will receive questionnaire will be 35. The reason the age group is selected for more than twenty-five is because they will have more knowledge and clarify the current issue faced by people. At the same time, more than twenty-five aged people are mostly households which means they will be handling family members. With that, they tend to understand more about flood issue and how they are handling floods disasters. Next, the reason thirty-five people is selected as respondents because the flood disaster issue is almost faced by most of the states in Malaysia. Since there is large number of people exposed to flood, thirty-five people will be sufficient to gather information for analysis.

D. Variables

The Table I shows the variables that have been identified in the research. The manipulated variable for the proposed system will be the clogged particles in river and responding variable will be the speed of water flow in river. It is because when the clogged particles in drainage, river basins and river increases, the speed of water flow in river will decrease [24]. When this situation happens, this is where flood disaster occurs due to presence of heavy rain since there is no proper water flow of river to the sea.

TABLE I. VARIABLES

Variable	
Manipulated Variable	The quality of river water
Responding Variable	The water flow speed in river
Constant Variable	The IoT sensor and Water Turbines

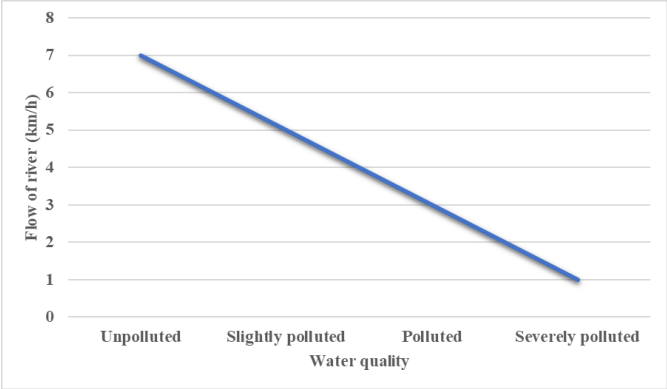

Fig. 3. Effects of water quality on speed of river water.

Fig. 3 illustrates how the water quality affects the speed of river water. When the quality of air turns bad, the flow of river water will decrease which eventually causes flood disaster to occur.

E. Summary of Analysis

Based on the questionnaire conducted with thirty-five respondents, it can be concluded that people are aware of the cause of the flood. Respondents able to understand the cause of the flood which results in frequent occurrence of the flood. Apart from that, the information collected through the questionnaire can be useful to analyze on the user's perspective towards flood events. Moreover, the information provided will be useful to improve the proposed system to a better state. At the same time, they able to understand and accept the purpose of the proposed system. Respondents able to get to know the flow and outcome of the proposed system. With that, it can be concluded that the objective of the proposed system is achieved, and the proposed system will be helpful to everyone when it is being implemented.

IV. FINDINGS

Flood control has become a crucial issue in a society that has taken a remarkable step to manage this disaster by implementing a Flood Prevention System that utilizes Internet of Things (IoT) technology. This technique is a ground-breaking method of reducing flood damage and has the potential to significantly advance the field of sustainable development. Malaysia's Flood Prevention System goes beyond traditional flood control techniques. The proposed system creates a proactive approach by IoT sensors strategically along river basins, as opposed to just responding to flood disasters. Essential characteristics including river flow rates, precipitation patterns, and water levels are continuously and instantaneously monitored by these sensors such as rain drop sensor, ultrasonic sensor, and water level sensor. With the data collected by IoT, it acts as an essential instrument for informed decision making, enabling decision-makers to take wise decisions intended to protect living creatures and the environment without being damaged.

A. System Architecture

The Flood Prevention System's architectural design offers a comprehensive and effective method of managing and mitigating flood disasters. This framework consists of an Internet of Things (IoT) sensors that are placed strategically along river basins and drainage systems. These sensors continuously collect information in real time about river flow rates, water levels, and the state of the environment. Examples of these sensors that are being integrated are ultrasonic sensors, rain drop sensors and water level sensors [21]. Once the data is collected from the sensor, it is sent to the central processing unit (CPU), it will be analyzed and act accordingly according to the rules set. This analytical procedure helps in risk assessment and flood event prediction. Automated water turbines have been seamlessly integrated into the system to further improve its capabilities. By integrating this into the system, this allows the system to control the water flow in the rivers.

The main purpose of the automated water turbines is to boost up the flow of water when there is a rise in water level. When there are high chances of flooding and to prevent floods, these turbines quickly increase river flow rates based on the insights gained from data analysis. The main purpose of the automated water turbines is to increase the flow rate of water in river basins, ensuring that excess water is efficiently moved to the sea and there is no backflow of water. This functions as water regulator with integration of IoT sensors. When IoT sensors detect rising water levels, the system evaluates whether the water flow is slower than the optimal rate. At the same time, if the water rise or water slow rate is not because of blockages, then the turbines are activated to accelerate the water flow towards larger water bodies such as sea. The automated control system ensures that there is balanced water level and water flow with real-time sensor feedback.

In addition, the architecture includes a strong communication and alerting system that guarantees relevant authorities are notified and alerted accordingly. Every process happens in a timely manner when a flood hazard appears. This feature makes it easier to respond quickly and put preventative measures in place. With inclusion of IoT sensors into the system, it creates a strong basis for efficient flood prevention, ultimately protecting and preserving the infrastructure, human life, and the environment. This makes human life easier by not creating any hustle in case there is high rain rate in a place.

Fig. 4 illustrates the system architecture of the flood management system. Data collection will take place from IoT sensors such as water level sensors, ultrasonic sensor, and raindrop sensor. The data collected from the IoT sensors is sent to a CPU, which processes and analyzes the information [22]. The CPU uses rules and algorithms to interpret the sensor data and make decisions based on predefined terms. Simultaneously, the system communicates risks and sends alerts and at the same time, controlling the water turbines.

B. Hardware and Software Requirements

Flood prevention system is an innovative method for efficiently managing water resources and avoiding flood disasters. The main component, an Arduino Compatible DCCduino Uno R3 microcontroller, is used to manage a network of actuators and sensors. The HC-SR04 and waterproof JSN-SR04T are two ultrasonic sensors that are essential to the system's operation because they provide accurate water level measurements in both submerged and non-submerged conditions. Both sensors are used to detect any blockage throughout the system operation. A rain sensor module provides

real-time weather and rainfall detection, and a dedicated water level sensor module keeps an eye on water level in the river basin. With integration of switch relay module, the system's intelligence is extended to water pump control, with R385 DC 12V Pneumatic Diaphragm Water Pump. It represents as automated water turbine to speed up the frequency of river flow rate.

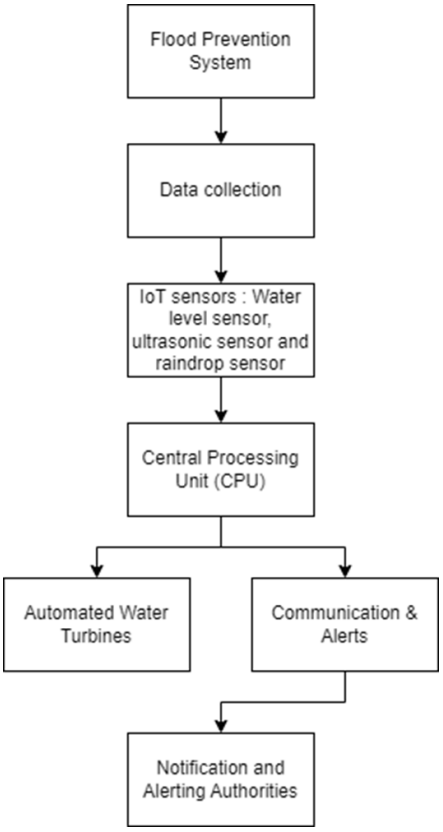

Fig. 4. System architecture.

In addition, the system incorporates effective communication features that allow for instant SMS notifications with the integration of SIM900A module. A 16x2 character LCD display with an I2C interface makes the water levels visible and it is easier to observe the system's status. A 5V 2A power supply adaptor is included to ensure that the water pump receives steady and dependable power delivery. With this integration of better sensor modules and water pump, it allows for proactive water level monitoring, and at the same time maintains the flow of the river by controlling the water pump automatically. The system's capacity makes necessary action by sending notifications to a respective department contact numbers which makes better valuable output for everyone. This creates the best tool to manage the river water effectively and prevent floods from happening.

C. Connection Schema

Fig. 5 and Fig. 6 illustrate the connection schema and breadboard view which shows hardware configuration and physical representation of the component in IoT-based Flood Prevention System. The schematic diagram (Fig. 6) provides a detailed circuit representation of how the components are electrically connected.

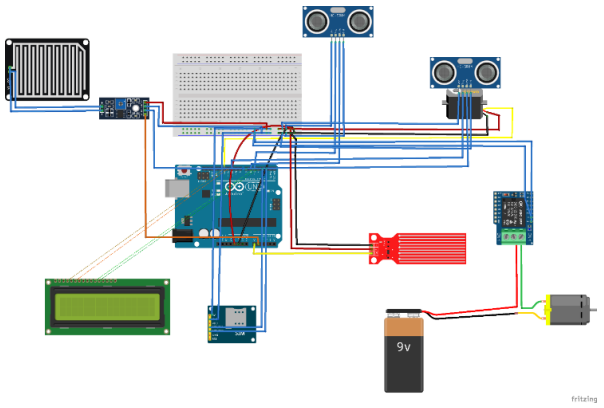

Fig. 5. Breadboard view.

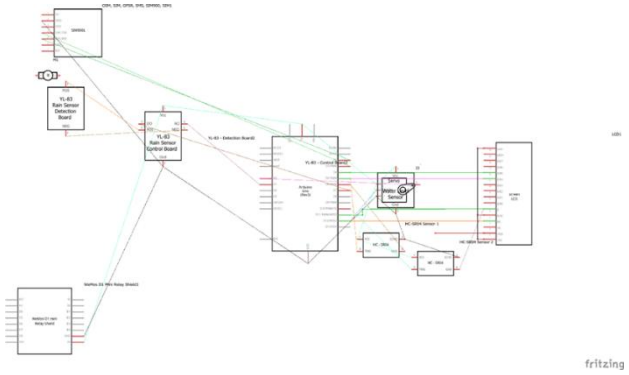

Fig. 6. Schematic diagram.

TABLE II. IOT SENSORS AND COMPONENT CONNECTION

Sensor/Component	Specific Sensor/Module	Arduino Pin
Water Level Sensor	LCD I2C (SDA)	A4 (Analog 4)
	LCD I2C (SCL)	A5 (Analog 5)
	Water Level Sensor	A0
	Relay Module	4
Internal Ultrasonic Sensor	SR04M-2 Trigger Pin	5
	SR04M-2 Echo Pin	6
	SIM900 RX (SoftwareSerial)	2
	SIM900 TX (SoftwareSerial)	3
External Ultrasonic Sensor	Ultrasonic Trig Pin	10
	Ultrasonic Echo Pin	11
	Water Level Sensor Pin	A0
Rain Drop Sensor	Raindrop Sensor	Digital Pin 7
Automated Water Turbines	Relay Module	Digital Pin 4
	COM	Power Supply
	NO	Water Pump
	NC	-
SIM Module	SIM900 RX (SoftwareSerial)	2
	SIM900 TX (SoftwareSerial)	3
Common Connections	VCC	5V
	GND	GND

Table II presents the IoT sensors and component connections used in the Flood Prevention System using IoT. Each component has its own roles and connections to provide real-time data for flood monitoring and automation interventions.

V. DISCUSSION

A. Evaluating the Effectiveness of Flood Prevention System

The flood prevention system using IoT is one of the most advanced approaches to tackle the flood. Instead of predicting floods or recovery planning after flood, it analyzes the data from the IoT sensor and makes the right solution to prevent the flood from happening. The purpose of our study was to evaluate the suggested flood prevention system's efficacy. The results verify that the goals of the system have been effectively accomplished. One important finding from the study is that the suggested flood prevention strategy into practice will have immediate benefits. There is a higher success rate which can significantly stop property damage and save lives. Furthermore, the system's incorporation of IoT sensors helps in gathering accurate data for well-informed decision-making, including sensors for water blockage and rainfall. These sensors deliver high-quality data, which is essential for timely action and preventative flood mitigation.

There are several crucial areas where the system's implementation can have a positive influence. One of it is, the system can greatly lessen the harm that floods does to the ecosystem. The system's ability to prevent flooding can aid in the preservation of natural areas. Next, it can protect human and animal lives as the system can prevent flooding directly save lives. Efficient data gathering, processing, and response actions are some of the factors which can make the system perform better. To improve flood prevention, automated water turbines are essential in controlling water flow based on real-time data. These turbines are essential for reacting to changes in water levels. Automated water turbines help increase the flow of water from river basin to the sea when there is flood detection.

These sensors, which include raindrops, ultrasonic, and water level sensors, function as tools to provide continuous monitoring on the surrounding environment. The success of the system is largely dependent on its accurate data collection. Apart from that, integration of SIM Modules, strategically used to improve communication inside the flood prevention system. These modules give the system the ability to notify specific departments via SMS based on the scenarios. The SIM modules provide a dependable communication route for informing authorities about water turbine activation, warning users of blockages, or providing a warning of prolonged rain.

With that, this can be concluded that flood prevention systems can have tremendous potential for managing and mitigating flood disasters. By overcoming the limitations and integrating future enhancements, the system can become an effective tool for responding to and preventing floods.

B. Contributions to Sustainable Development Goals (SDGs)

The utilization of IoT in Malaysia's Flood Prevention System signifies an innovative method for mitigating flood calamities and making substantial progress towards attaining various Sustainable Development Goals (SDGs). This system incorporates advanced technology and forward-thinking tactics, and it is worth exploring how it aligns with and contributes to the objectives of SDGs 6, 11, and 15.

SDG 6: Clean Water and Sanitation

The fundamental human right to access clean and safe water is a central focus of the Flood Prevention System. It plays a crucial role in upholding this right by constantly monitoring key water parameters like water levels, river flow rates, and rainfall patterns via IoT sensors. This continuous data monitoring and analysis empowers authorities to make well-informed decisions, preventing water contamination during flood incidents and relieving the overall burden on clean water resources. Consequently, it harmonizes seamlessly with the core objectives of SDG 6, which revolve around ensuring universal access to sustainable water and sanitation services.

SDG 11: Sustainable Cities and Communities

With the rapid pace of urbanization, cities worldwide face growing susceptibility to climate-induced disasters such as floods. The Flood Prevention System emerges as a substantial contributor to the realization of SDG 11 by bolstering the resilience of urban areas. Through its provision of timely flood alerts and facilitation of swift responses, the system actively fosters the development of secure, inclusive, and sustainable cities and communities. SDG 11's overarching goal is to enhance urban resilience to natural calamities, elevate urban planning standards, and establish sustainable living environments. The Flood Prevention System's capacity to mitigate flood impacts and safeguard communities aligns directly with these objectives.

SDG 15: Life on Land

Floods have the potential to inflict substantial harm on terrestrial ecosystems and biodiversity. The Flood Prevention System's primary objective of averting floods and mitigating their adverse environmental repercussions seamlessly aligns with the principles of SDG 15. Through its capacity to curtail the disruptive consequences of floods, the system actively contributes to the preservation, rehabilitation, and sustainable utilization of terrestrial and inland freshwater ecosystems. SDG 15 is designed to arrest and reverse land degradation, mitigate biodiversity loss, and ensure the sustainable stewardship of forests and other terrestrial resources. The system plays an indispensable role in advancing these objectives by averting the degradation and devastation of land stemming from recurrent flood incidents.

C. Limitation

The flood management system discussed here serves as a valuable resource for observing and addressing shifts in environmental conditions. However, it has its limitations, like any other technology, which must be acknowledged and taken into consideration.

A significant limitation that the flood management system encounters is the accurate monitoring of the river basin's depth. While the system demonstrates proficiency in measuring water levels and promptly detecting blockages, obtaining precise depth readings for the river basin presents a considerable challenge. This challenge primarily arises from the unavailability of a suitable sensor designed specifically for depth

measurement. The system relies on ultrasonic and water level sensors, which are well-suited for their intended tasks but are not inherently designed to provide the highly precise depth measurements necessary for gaining a comprehensive understanding of the river basin's conditions. These sensors primarily excel at detecting the distance between the sensor and the water surface or any potential obstructions within their operational range. The current reliance on ultrasonic and water level sensors may yield valuable insights into water levels and blockage detection, enabling timely responses to critical situations. To address this limitation effectively and gain a more profound understanding of the river basin's dynamics, it becomes crucial to consider the integration of a dedicated depth sensor or the exploration of alternative depth measurement methodologies.

Another major constraint is associated with the utilization of 2G technology within the SIM900A module. As the telecommunications landscape advances with the widespread implementation of 4G networks, relying on 2G connections can introduce certain limitations in terms of reliability and efficiency. The potential inadequacies of 2G networks become particularly pronounced in scenarios where robust and seamless connectivity is essential. Nevertheless, due to budget constraints or other resource limitations, upgrading to more advanced SIM modules that are compatible with 4G networks may not be a feasible option. Consequently, this limitation occasionally results in connectivity challenges, potentially affecting the system's capability to transmit critical alerts and updates in a timely and consistent manner. The flood management system finds itself navigating a delicate equilibrium between cost-effectiveness and measurement precision.

Additionally, it is crucial to address the matter of sensor accuracy as another noteworthy limitation. The flood management system has been designed with cost-effectiveness in mind, utilizing affordable components to maintain economic feasibility. However, these economic components can sometimes exhibit limitations when it comes to the accuracy of their measurements. These sensors are meticulously engineered to deliver precise data, making them ideal for applications where measurement precision is paramount. However, the adoption of such high-end sensors may not always align with budgetary constraints and cost-effectiveness considerations. The flood management system's sensors, which are engineered to balance performance and cost-effectiveness, may exhibit a degree of measurement variance. This variance is influenced by several factors, including sensor calibration, environmental conditions, and the inherent characteristics of the sensors themselves.

D. Future Enhancements

There exist multiple opportunities with substantial potential for enhancing the flood management system in the future. The primary imperative is to address the limitations associated with depth monitoring. This necessitates the integration of sensors explicitly engineered for precise measurement of the river basin's depth. By augmenting the system's proficiency in assessing depth, it can take proactive measures to identify situations where the depth falls below acceptable levels [27]. This enhanced capability would enable the system to promptly inform relevant authorities, such as the Department of Irrigation and Drainage, significantly bolstering its effectiveness in mitigating flood risks.

Secondly, the integration of Artificial Intelligence (AI) holds great promise. By incorporating AI systems, the flood management system can analyze and interpret data from IoT sensors more intelligently [25]. This enables it to make data-driven decisions and respond dynamically to changing environmental conditions, thereby improving its overall efficiency. Leveraging AI's power, the system can move beyond simple threshold-based alerts to perform advanced data analytics in real-time. AI algorithms can identify patterns, anomalies, and emerging flood risks, providing more proactive and adaptive flood management solutions. This enhancement harnesses the potential of IoT sensors and data analysis techniques to bolster the system's ability to monitor and respond to evolving environmental conditions.

The concept of a fully automated flood prevention system introduces a futuristic vision. This advancement entails the deployment of robots or automated tools with the capability to execute essential tasks such as debris removal, sensor maintenance, and emergency responses without the need for human intervention [26]. This automation not only enhances efficiency and response times but also mitigates the risks associated with human involvement in hazardous flood situations. However, by incorporating robots or automated equipment, the system can achieve a higher degree of autonomy. These robots or tools can be designed to perform tasks such as debris removal, sensor maintenance, and even emergency response actions without requiring human presence on-site. This transition to an automated flood prevention system can enhance the system's efficiency, reduce response times, and minimize risks associated with human involvement in potentially hazardous flood conditions.

VI. CONCLUSION

Flood disaster is one of the natural disasters that frequently affects people in Malaysia. The impact of floods not only damages the environment but also consumes lives. A proper solution needs to be implemented to address the flooding issue instead of complaining every time. The prevention phase must be emphasized, as only a well-structured prevention system can resolve this issue entirely. The AI Powered Flood Prevention System using IoT is proposed to overcome the flood issue. This system aims to prevent floods by maintaining river water levels and managing drainage systems.

Currently, many river basins face clogged drainage pathways and river basins, leading to improper water flow to the sea, which results in flooding. In conclusion, proper river flow can entirely solve this issue, as rivers serve as the primary pathways for diverting rainfall to the sea. The Flood Prevention System collects real-time data with integration of IoT sensors, while AI integration analyzes this data and performs the required actions. Additionally, automated water turbines maintain river water flow and increase it when necessary. With the implementation of the AI Powered Flood Prevention System using IoT, the flood issue in Malaysia can be completely prevented, creating a flood-free environment.

ACKNOWLEDGMENT

The author would like to express my sincere gratitude and appreciation to everyone who contributed to the development and realization of the Flood Management System using IoT. This project has been a collaborative effort, and the successful implementation of this system would not have been possible without the support, expertise, and dedication of numerous individuals and organizations. First and foremost, the author extends his heartfelt thanks to supervisor Dr Malathy Batumalay who worked tirelessly throughout the project. Dr Malathy's unwavering commitment, technical expertise, and creative problem-solving played a pivotal role in shaping the system into what it is today.

The author also likes to extend gratitude to his advisors and mentors who provided invaluable guidance and insights. Their expertise and experience in the fields of flood management, sensor technology, and data analysis were instrumental in steering the project in the right direction. Their mentorship enriched our understanding and contributed significantly to the project's success. The author extends his gratitude to his family and loved ones for their patience, understanding, and encouragement throughout the project's journey. Their unwavering support sustained our motivation and determination. In conclusion, this project represents a collective effort, and author is deeply grateful to each individual and organization that contributed to its success. The Flood Management System stands as a demonstration of what can be achieved through collaboration, dedication, and innovation in the pursuit of a safer and more resilient future.

Improved CNN Recognition Algorithm for Identifying Bird Hazards in Transmission Lines

Junzhou Li*, Yao Li, Wen Wang
State Grid Henan Electric Power Company, Hebi Power Supply Company, Hebi 458000, China

***Abstract*—With the expansion of the power grid, bird activities have become the main factor causing transmission line failures. How to accurately identify hazard birds has received widespread attention from all sectors of society. However, the current bird identification methods for transmission line hazards suffer from low accuracy due to the small size of bird targets. This study proposes an enhanced Convolutional Neural Network (CNN) with Support Vector Machines (SVM) to improve the accuracy of identifying hazardous birds on transmission lines. At the same time, a dataset of bird species affected by transmission lines is constructed, and data augmentation methods and denoising deep convolutional networks are used to process the data. Thus, a bird identification algorithm for transmission line hazards based on improved CNNs and SVM is constructed by combining the three. The study conducts a performance comparison analysis of the algorithm and finds that its average recognition speed and accuracy are 9.8 frames per second and 97.4%, respectively, significantly better than the compared algorithms. In addition, an analysis of the application effect of the algorithm is conducted, and it is found that the algorithm can accurately identify hazard birds. In some recognition results, the recognition results and confirmation probabilities for *Pica Pica, ciconia boyciana, egretta garzetta, and hirundo rusticas* are 98.73%, 97.68%, 96.54%, and 91.34%, respectively, all above 90%. The above findings indicate that the proposed identification algorithm has good performance and practical value, which helps to improve the accuracy of identifying hazard birds on transmission lines.**

***Keywords*—CNN; hazard birds; transmission line; distinguish; support vector machine**

I. Introduction

As the social economy rapidly develops and the power grid scale continuously expands, the safety and stability of overhead transmission lines, as an important infrastructure for power transmission, have become particularly important [1]. Birds build nests and excrete on transmission lines, causing damage to transmission equipment and short circuits, posing a significant threat to the stability of power lines [2]. Therefore, assisting transmission line inspection personnel in identifying birds that may pose a threat to the lines is important for ensuring the safety of transmission lines and preventing accidents [3]. However, the current bird identification methods for transmission line hazards suffer from low accuracy due to the small size of bird targets [4, 5]. Convolutional Neural Network (CNN) is a deep learning architecture that has strong feature extraction ability and good generalization ability, and is broadly utilized in fields such as image recognition and facial recognition [6]. However, CNN using a fixed architecture and parameters may not fully capture all the information in the data, which may limit its ability to express features [7, 8]. In addition, if the model structure is too complex or the training samples are insufficient, it may also lead to overfitting. Multi-convolutional feature fusion refers to the combination of feature maps from different convolutional layers in deep learning to improve the performance and feature representation ability of the model. It can effectively compensate for the limited feature representation ability of CNN. Support Vector Machine (SVM) is a binary classification model whose basic principle is to maximize the interval between sample points of different categories by finding an optimal hyperplane. SVM has the ability to avoid overfitting and handle high-dimensional data, which can effectively solve the problem of CNN overfitting. Therefore, this study utilizes backbone feature extraction networks (DarkNet-53), GoogleNet, Visual Geometry Group 19 Layer Network (VGG-19), and EfficientNet-B0 to extract features from images of hazard birds on transmission lines. Multiple convolution fusion methods are used to cascade fuse the extracted convolution features to construct an improved CNN. SVM is then used to classify and recognize the obtained features, and a transmission line hazard bird recognition model based on improved CNN and SVM is constructed. The innovation of this study lies in the convolutional feature fusion of CNN and the use of SVM to recognize and classify the fused images, aiming to raise the accuracy of bird recognition on transmission lines. It is expected that this method can contribute to enriching the theory of bird recognition of transmission line hazards.

II. Related Works

In recent years, with the rapid development of society and economy, the demand for electricity continues to increase, and transmission lines are regarded as an important infrastructure for power transmission. At present, the transmission line failure caused by the behavior of endangering the life of birds occurs frequently, and even leads to fire and other disasters. The transmission line failure caused by bird activity is particularly serious. The identification of birds endangering the safety of the transmission line is of great significance to ensure the safe and stable operation of the power system. Many experts have carried out relevant research on the identification of birds harmed by transmission lines. For example, to explore the problem of tripping caused by birds touching power lines, Rebolo-Ifran team adopted the method of literature review to make a summary of the harm to birds, but it is not practical [9]. To solve the problem of power interruption caused by electric shock of birds and thus damage the integrity of the power network, Biasotto team developed a framework to simulate the risk of electric shock of birds. After experimental verification,

*Corresponding Author.

the framework identified 283 species facing the risk of electric shock, 38 of which were high risk, and birds of prey accounted for 76% [10]. Yuan et al. proposed an improved YOLOv5 technology to solve the problem of low bird identification accuracy in transmission lines, and the experimental verification showed that this technology improved the detection speed and accuracy of birds in transmission lines [11]. To solve the problem that it is difficult to identify birds endangering overhead transmission and distribution lines, Qiu's team proposed an automatic classification method of birds related to power line faults that combines deep convolutional features with error correction output code SVM. Experiments were conducted with this method and other methods, and the results showed that the average accuracy of this method was 94.39%, which was superior to the comparison method [12]. To solve the problem of woodpeckers' low accuracy in assessing composite insulator damage of UHV transmission lines, Zhang proposed a birding damage assessment method for composite insulators of UHV lines based on electric field simulation and deep learning. The results of simulation experiments showed that the average accuracy of the method was 0.79 [13].

Combining CNN and SVM is a common strategy, and by combining the advantages of both, the performance of image recognition tasks can be improved. Many experts have made some achievements in the field of combining CNN and SVM. For example, Ye proposed a method to improve CNN by SVM to solve the problem that image data cannot be processed with low capacity and depth in 3D Lidar visual position recognition technology, and the results showed that the method was effective [14]. To solve the problem of low accuracy of MRI image classification of brain cancer, Khairandish's team proposed a classification model based on CNN and SVM. Through comparative analysis and experiment with similar models, the accuracy of this model was 98.4959%, which was better than the comparison model [15]. To solve the problem of low accuracy of ECG image type recognition, Ozaltin and Yeniay proposed an image recognition method based on CNN-SVM. The validity experiment verified that the highest accuracy rate of this method was 99.21% [16]. To solve the problem of low classification efficiency of bread wheat varieties, Yasar proposed a classification model of bread wheat combining CNN and SVM. Through empirical experiments, the results showed that the highest classification accuracy of this model was 97.51% [17]. To solve the problem of low accuracy of skin image recognition, Anggriandi et al. proposed a skin image recognition method based on CNN and SVM. Through experimental verification, the classification accuracy and recall rate of this method were 93.55% and 93.74%, respectively [18].

In summary, there are few identification methods applied to birds endangered by transmission lines at present, and the existing CNN-SVM algorithm still has low accuracy in image recognition. However, there are still few methods to improve image feature extraction by combining backbone networks such as DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0. To solve the problem of low accuracy of current image recognition methods, a method combining multi-trunk feature extraction network and SVM was studied for transmission line bird recognition, and a model of transmission line bird recognition based on improved CNN and SVM was constructed. This model not only improved the accuracy of image recognition, but also broke through the limitations of previous qualitative studies, and had strong potential application value.

III. Methods and Materials

A. Design of Feature Extraction Network Based on Improved CNN

Bird hazards are a major cause of transmission line failures, ranking third after lightning strikes and external damage [19]. Identifying hazard birds and assisting transmission line inspectors in identifying birds that may pose a threat to the line has become an urgent problem to be addressed. CNN is a deep learning framework that has strong feature extraction capabilities and flexibility, and is broadly utilized in the computer vision [20]. However, due to the fixed architecture and parameters used by CNN, it is unable to fully capture all the information in the data, thereby limiting the expressive power of features [21]. In addition, if the model structure is too complex or the training samples are insufficient, it may also lead to overfitting [22]. An improved CNN-based feature extraction network is developed for identifying bird hazards in transmission lines. Subsequently, it is combined with SVM algorithm to construct a transmission line hazard bird recognition model that integrates improved CNN and SVM. Before building a bird identification model for transmission line hazards, it is necessary to construct an improved CNN. The basic structure of CNN is denoted in Fig. 1.

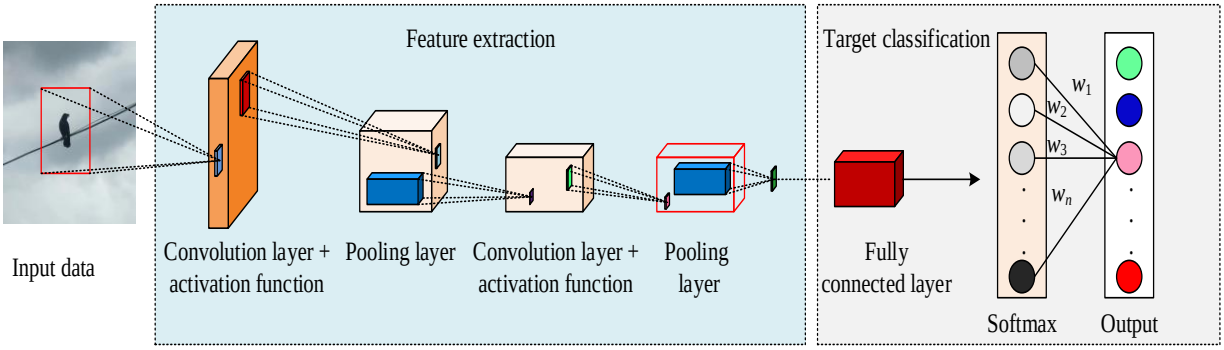

Fig. 1. The basic structure of CNN.

From Fig. 1, the basic structure of CNN is mainly composed of convolutional layers, activation layers, pooling layers, and fully connected layers. Among them, w is the weight, and the calculation expression for *Softmax function* is shown in (1).

$$softmax\ function(x_i) = exp(x_i) / \sum_{j=1}^{n} exp(x_i) \quad (1)$$

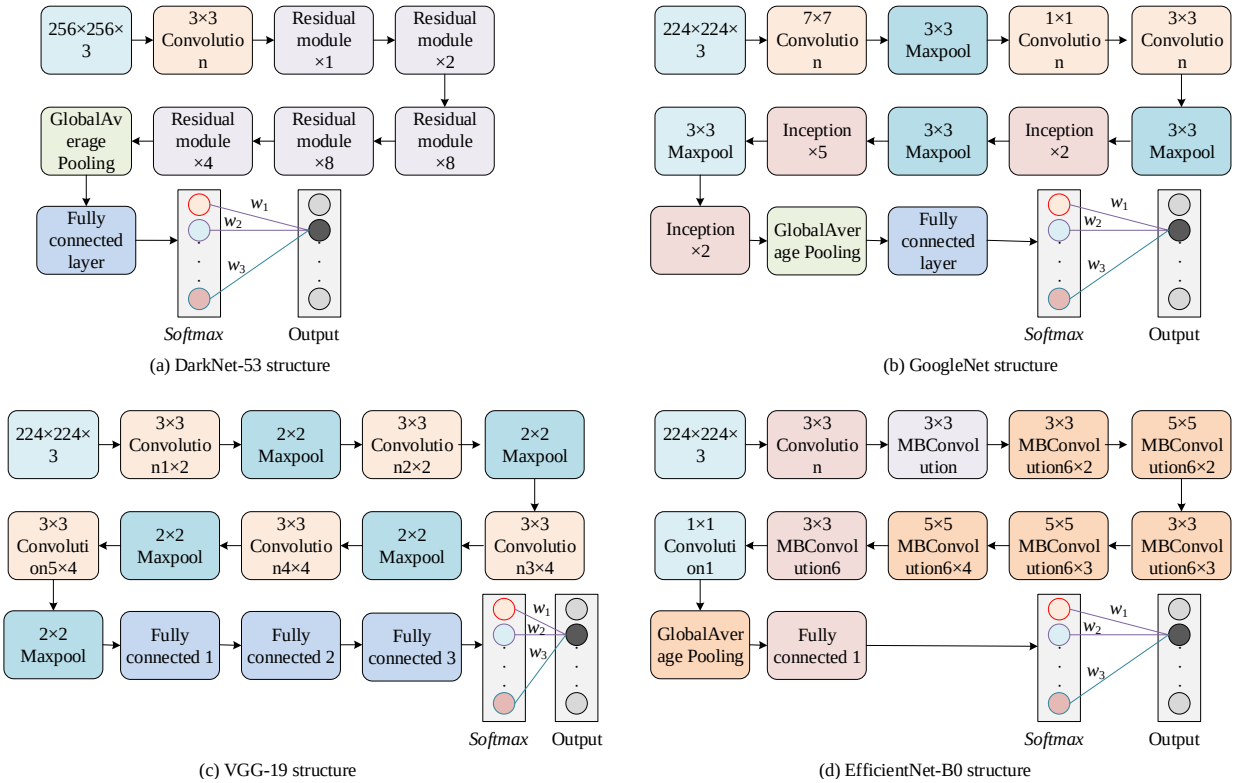
In (1), x_i means the i th element of the input vector, $softmax(x_i)$ represents the output, and n represents the dimension of the vector. However, due to the fixed architecture and parameters used by CNN, it is unable to fully capture all the information in the data, thereby limiting the expressive power of features. To solve this problem, research combined with relevant literature analysis find that there are many types of networks derived from CNN. Therefore, based on the characteristics of these networks, an improved CNN network is constructed. Firstly, DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0 are used to extract features from images of bird hazards caused by transmission lines. The basic structures of each network are shown in Fig. 2.

From Fig. 2(a), the feature extraction part of DarkNet-53 network consists of a 3×3 convolutional layer and five residual blocks. Each residual block is downsampled using a 1×1 convolution, achieving a total of five dimensionality reductions to control the dimensionality of the feature channel. From Fig. 2(b), the GoogLeNet network model consists of a 7×7 convolutional layer and an *Softmax* output layer. To capture features at different scales, the network adopts the Inception module. From Fig. 2(c), VGG-19 consists of 19 parameterized layers. The network structure contains 16 convolutional layers and 3 fully connected layers. According to Fig. 2(d), the network architecture consists of 16 Mobile Inverted Bottleneck Convolution (MBConv) units and a 1×1 convolutional layer. Secondly, to better understand the impact of feature maps on the final classification decision, the study introduces gradient weighted class activation mapping for visual analysis of the model. Gradient weighted class activation mapping generates a class activation map by calculating weights, revealing the influence of each pixel in the feature map on the classification probability gradient. The weight calculation can be represented by (2).

$$\omega_z^m = \frac{1}{k} \sum_i \sum_j \frac{\partial y^m}{\partial A_{ij}^z} \quad (2)$$

In (2), z and k respectively represent the sequence number and number of current feature maps, y^m refers to the score of category m, and A_{ij}^z denotes the pixel value of the feature map. The generation of the class activation mapping $L_{Grad-CAM}^m$ can be represented by (3).

$$L_{Grad-CAM}^m = ReLU(\sum_z \omega_z^m A^z) \quad (3)$$



(a) DarkNet-53 structure

(b) GoogleNet structure

(c) VGG-19 structure

(d) EfficientNet-B0 structure

Fig. 2. Basic network structure.

Next, the study uses cascaded fusion to perform convolutional feature fusion on the above four network structures. In this fusion network, the part that extracts convolutional features from bird images is the trained four networks. The Dropout layer of the last fully connected layer in the trained VGG-19-C, along with the global average pooling layers of DarkNet-53-C, GoogleNet-C, and EfficientNet-B0-C, is used for feature extraction. So, the convolutional features extracted by DarkNet-53-C, GoogleNet-C, EfficientNet-B0-C, and VGG-19-C networks can be set as F_D, F_G, F_V, and F_E, respectively, and each convolutional feature dimension is 1024, 1024, 1280, and 4096 dimensions, respectively. The convolutional fusion feature F obtained by cascading fusion can be represented by (4).

$$F = Concatenate(F_D, F_G, F_V, F_E) \tag{4}$$

By concatenating features from different levels, the output of each layer is sequentially passed on to the next layer as input, gradually extracting and integrating richer information. Finally, transfer learning is used to fine tune the test and training sets into 30% and 70% structures. Finally, based on the above content, a feature extraction network based on improved CNN is constructed, and the network process is indicated in Fig. 3.

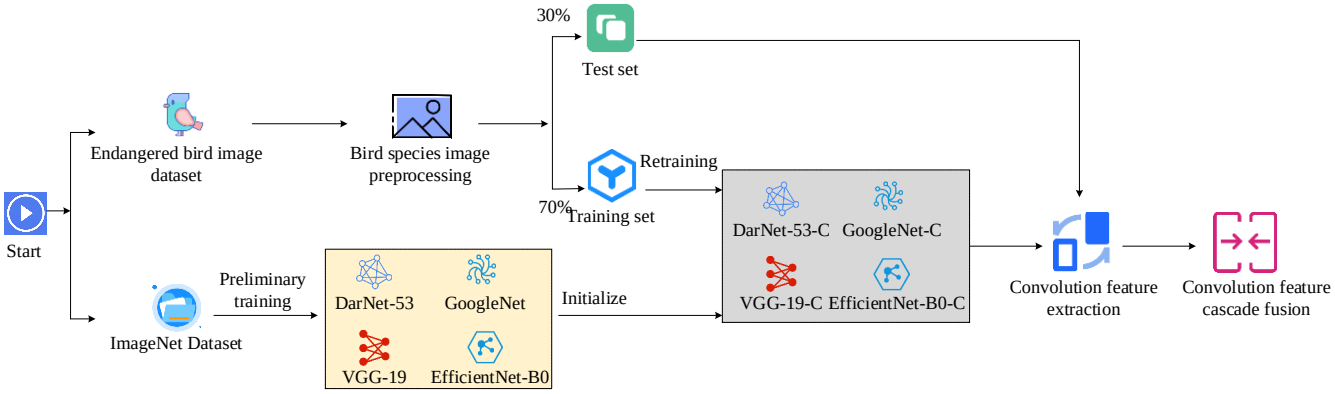


Fig. 3. Feature extraction network based on improved CNN.

The feature extraction of the network can be obtained from Fig. 3. Firstly, four networks are pre-trained using hazard bird data in the ImageNet dataset, and the four networks are initialized to obtain the trained four CNNs. Secondly, the preprocessed dataset of bird images of power line hazards will be preprocessed, and the preprocessed data will be divided into test and training sets with 30% and 70% ratios, respectively. Then, the four networks are retrained using the training set. Finally, the processed 30% test set and the convolutional features extracted by the four trained networks are cascaded and fused to obtain the extracted hazard bird features.

B. *Construction of a Hazard Bird Classification and Recognition Algorithm Integrating Improved CNN and SVM*

The prerequisite for extracting and recognizing bird characteristics is to understand the types and image data of birds that are hazard to transmission lines, and to construct a dataset of birds that are hazard to transmission lines. Therefore, based on the collection of bird records that have caused faults in transmission lines in the past, the study summarized a total of 80 hazard bird species and types of faults involved, among which 20 high-risk bird species are shown in Table I.

Note: Fault type: Bird droppings (Dung); Bird's nest (Nest); Bird body contact (Catch); Bird peck (Peck).

From Table I, there are a total of 20 bird species that pose a threat to transmission lines, including ciconia nigra, egretta garzetta, and pond herons. Based on the above bird species, the study utilizes web crawling technology to collect a massive amount of bird image data from the internet, covering images of birds in various environmental conditions, target sizes and quantities, and other different contexts. Due to the uneven sample size of the collected bird images, the model may have poor recognition performance for these birds. To solve this problem, the specific steps of data augmentation processing on images are to first randomly scale and rotate the images. Secondly, fogging is performed on the image, which can be represented by (5).

$$new\_pixel = old\_pixel \cdot td + U \cdot (1 - td) \tag{5}$$

TABLE I. TRANSMISSION LINE HAZARDS TO BIRDS AND FAULT TYPES

Name	Fault type	Name	Fault type
Ciconia nigra	Dung, nest, catch	*Pica pica*	Dung, nest, pick, peck
Ciconia boyciana	Dung, nest, catch	*Pycnonotus sinensis*	Dung
Egretta garzetta	Dung, nest	*Oriolus chinensis*	Dung
Ardeola bacchus	Dung, nest	*Hirundo rustica*	Dung
Falco tinnunculus	Dung, nest	*Anser cygnoides*	Catch, dung
Sturnus nigricollis	Dung, nest	*Asio otus*	Catch, dung
Spodiopsar sericeus	Dung, nest	*Spilopelia chinensis*	Dung, nest, catch
Acridotheres cristatellus	Dung, nest	*Cuculus canorus*	Dung
Cyanopica cyanus	Dung, nest, catch	*Otis tarda*	Catch
Corvus macrorhynchos	Dung, nest, catch	*Upupa epops*	Dung

In (5), U represents the brightness of fog, new_pixel and old_pixel represent the brightness of new and original

pixels, respectively, and td is variable. The calculation expression for td is shown in (6).

$$td = exp(-\beta \cdot td) \tag{6}$$

In (6), d and β represent the distance from the pixel to the center of the mist and the concentration of the mist, respectively. Next, a linear transformation is performed, and its calculation expression is denoted in (7).

$$r_n(l,h) = \alpha g(l,h) + (1-\alpha) g_0 + \varsigma \tag{7}$$

In (7), g_0 and ς represent the zero pixel image with the same $g(l,h)$ and the added pixel value, $g(l,h)$ and $r_n(l,h)$ represent the original image and the converted image, respectively, and α represents the original image multiple. Finally, the image is denoised using a Denoising Convolutional Neural Network (DnCNN) and labeled with the image annotation software LabelImg before saving. The construction of a dataset on bird species affected by transmission lines is completed. After completion, an improved CNN-based feature extraction network is used to extract features, and the birds affected by transmission lines are classified and recognized. To avoid the problem of overfitting in CNN, SVM is used for classification and recognition. SVM segments samples of different categories by finding a hyperplane in the feature space, maximizing the distance from the nearest sample point on the hyperplane to the hyperplane. The calculation expression for this hyperplane is shown in (8).

$$\varpi \mu + b = 0 \tag{8}$$

In (8), ϖ is the weight, b is the intercept, and μ is the eigenvector. However, in some cases, SVM cannot find the hyperplane. To solve this problem, SVM uses kernel functions to map data to a linearly separable high-dimensional feature space, and the hyperplane of this high-dimensional space can be represented by (9).

$$f(\mu) = \varpi^T \phi(\mu) \tag{9}$$

In (9), $\phi(\mu)$ is the feature vector after μ mapping. Thus, the classification problem can be transformed into a quadratic programming problem, which can be represented by (10).

$$\begin{cases} \min\limits_{\varpi,b,\zeta} \ \dfrac{1}{2}\|\varpi\|^2 + H\sum\limits_{\gamma=1}^{M}\zeta_\gamma \\ s.t\ p_\gamma[\varpi^T\phi(\mu_\gamma + b] \geq 1-\zeta_\gamma, \zeta_\gamma \geq 0, \gamma = 1,2,\ldots,M \end{cases} \tag{10}$$

In (10), H is the penalty coefficient, ζ_γ is the relaxation variable, and p_γ is the category label of the γ th sample point. Introducing Lagrange multipliers to simplify it can be represented by (11).

$$L(\varpi,b,\zeta,\tau,\psi) = \frac{1}{2}\|\varpi\|^2 + H\sum_{\gamma=1}^{M}\zeta_\gamma + \sum_{\gamma=1}^{M}\tau_\gamma\{1-\zeta_\gamma - p_\gamma[\varpi^T\phi(\mu_\gamma)+b]\} - \sum_{\gamma}^{M}\psi_\gamma\zeta_\gamma \tag{11}$$

In (11), τ and ψ are Lagrange multipliers, respectively. By taking the derivative of each variable using the Lagrange function and making it zero, a set of candidate values can be obtained, and then the optimal value can be verified. So, the quadratic programming problem can be transformed into a Lagrangian dual problem, which can be represented by (12).

$$\begin{cases} \max\limits_{\tau} \ \sum\limits_{\gamma=1}^{M}\tau_i - \dfrac{1}{2}\sum\limits_{\gamma=1}^{M}\sum\limits_{j=1}^{M}\tau_\gamma\tau_j p_\gamma p_j \phi(\mu_\gamma)^T\phi(\mu_j) \\ s.t\ \sum\limits_{\gamma=1}^{M}\tau_\gamma p_\gamma = 0, 0 \leq \tau_\gamma \leq H, i = 1,2,\ldots,M \end{cases} \tag{12}$$

Thus, by solving it, the expression of the support vector decision function can be obtained as shown in (13).

$$f(\mu) = \sum_{\gamma=1}^{M}\tau_\gamma p_\gamma \kappa(\tau,\tau_\gamma) + b \tag{13}$$

In (13), $\kappa(\tau,\tau_\gamma)$ is the kernel function. Therefore, the study combines SVM with a feature extraction network based on improved CNN to construct a classification algorithm based on improved CNN and SVM, as shown in Fig. 4.

From Fig. 4, the specific classification of the algorithm is to first encode. In this process, an encoding matrix S with a value of $\{+1,0,-1\}$ needs to be constructed, and the behavior s of the encoding matrix represents the number of categories and category labels. The column is $s(s-1)/2$, and its vector represents the binary classifier. For the j th column of the matrix, if the values of $S[\lambda_1, j]$ and $S[\lambda_2, j]$ are +1 and -1, respectively, and the other elements are 0, then the binary classifier for this column is used to distinguish between λ_1 and λ_2, where λ represents the category. Then, in the training process, the feature vectors and labels of different bird species of different categories are used as input values, and SVM is used to perform two class classification training on the species, thereby obtaining $s(s-1)/2$ trained SVMs. After predicting all test samples through a classifier, an output vector $J(x) = [\eta_1(x), \eta_2(x), \eta_4(x), \ldots \eta_{s(s-1)}(x)]$ is generated, with η being the output value. The value of each element is defined as -1 or +1. Finally, decoding is performed. During decoding, the Hamming distance decoding method is used to determine the Hamming distance dr from $J(x)$ to each row of S, and the category corresponding to the shortest χ_δ is selected as the predicted output. The calculation expression for Hamming distance decoding is shown in (14).

$$\chi_\delta = \sum_{\gamma=1}^{s(s-1)/2}\frac{\left|S(\lambda,\gamma) - J_\gamma(x)\right|}{2}, \lambda \in \{1,2,\ldots,s\} \tag{14}$$

In (14), $J_\gamma(x)$ is the value of the output vector $J(x)$ relative to the test sample x, and $S(\lambda,\gamma)$ is the value of the γ th element in row λ of S. Finally, based on the above content, a bird recognition algorithm for transmission line hazards is constructed using improved CNN and SVM. The algorithm flow is shown in Fig. 5.

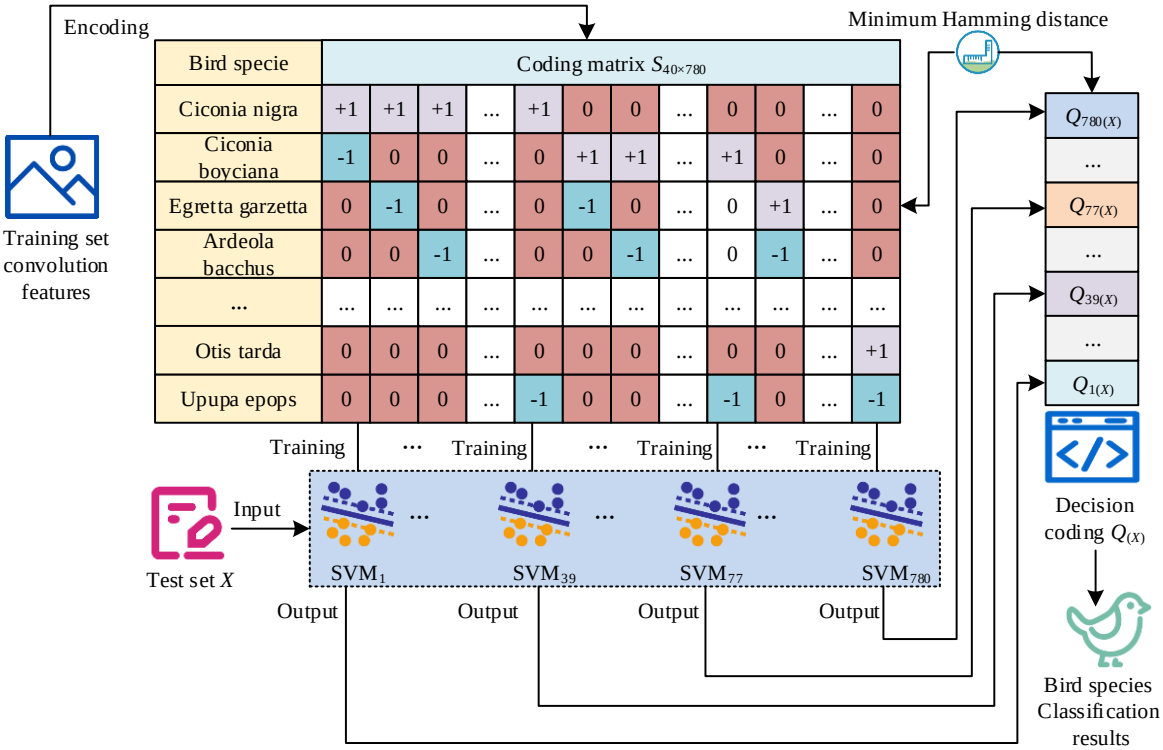

Fig. 4. Classification model based on improved CNN and SVM.

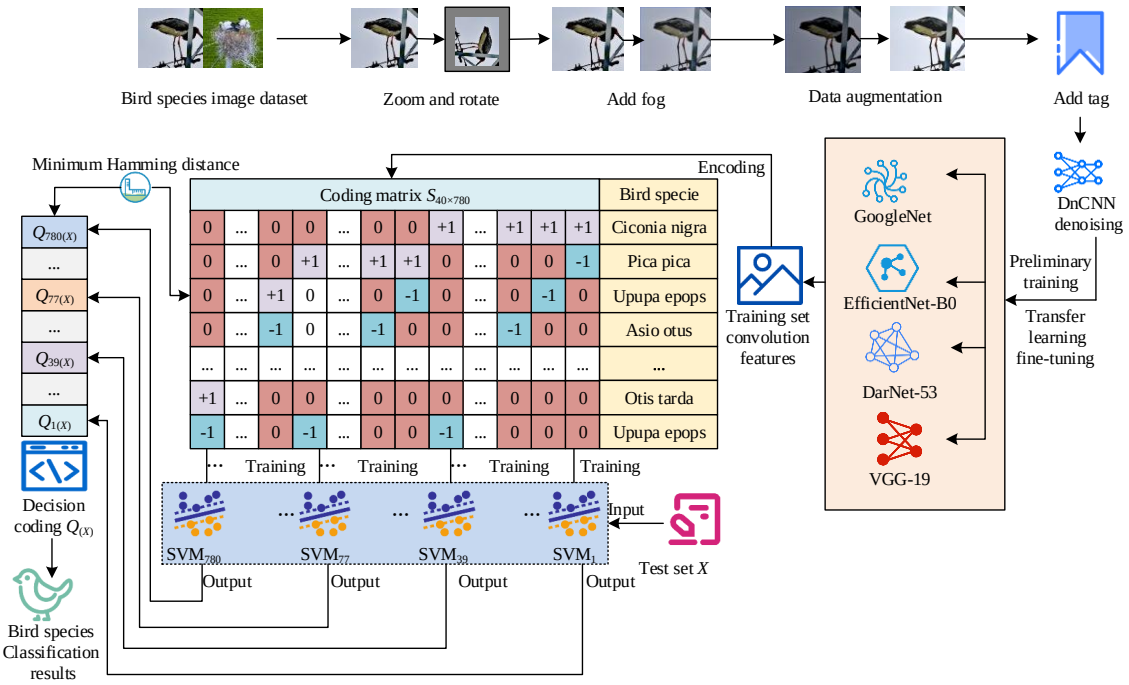

Fig. 5. Algorithm flow of transmission line hazard bird identification based on improved CNN and SVM.

From Fig. 5, the specific process of the recognition algorithm can be seen. Firstly, the image is preprocessed using image scaling, rotation, fogging, and DnCNN to increase image pixels and remove image noise. Secondly, the convolutional feature fusion method is used to cascade and fuse the four CNN models, DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0, to raise the robustness and feature extraction ability of the models. Then, using transfer learning theory, the model is fine-tuned through the training set to achieve the optimal state. Finally, SVM is used to find the optimal Hamming distance, which is used as the solution for the classification result, thus achieving the effect of classification recognition.

IV. RESULTS

A. Algorithm Performance Analysis

To validate the superiority of the raised algorithm, a performance comparison analysis experiment was conducted with other algorithms. The experiment was simulated using Matable software, and the algorithm was trained before the experiment. After training, specific parameter settings were obtained: the output channels of DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0 were set to 40, and the final output layer of the original network layer was replaced by a 40 class output layer. After optimization using momentum stochastic gradient descent algorithm, the batch processing size was obtained to be 64, the initial learning rate was 1×10^{-4}, the momentum value was 0.9, and the regularization factor in the network was set to 1×10^{-4}. DnCNN adopts $ReLU$ activation function and optimizes with momentum stochastic gradient descent algorithm to obtain an initial learning rate of 0.1, momentum value of 0, and batch processing size of 64. The source of the dataset consists of two parts, one of which is live images captured by surveillance cameras installed in and near transmission line towers in Anhui Province, China. The other part is the target images of birds with similar scenes collected from the network by crawler technology. In the end, the dataset contained a total of 6,876 images, of which 80% was used as a training set and 20% as a test set. In the pre-processing stage, the image was randomly scaled, rotated and fogged to increase the data diversity, and the image quality was improved by DnCNN. The annotation work was manually completed by LabelImg software, and the annotation results were saved as corresponding annotation files for subsequent model training. Since the data mainly come from field shooting and network crawling in specific areas, there may be scene bias, regional bias and category bias. These biases can lead to limitations in the model's ability to generalize, especially when dealing with images from other regions or different scenes. In addition, the class imbalance problem may affect the model's ability to recognize a few classes, thereby reducing the overall performance. To solve this problem, the research adopted data enhancement methods such as random scaling, rotation and fog processing to increase data diversity. A few classes of samples were also over-sampled to increase their proportion in the data set to alleviate the problem of data imbalance. The experimental comparison algorithms included Faster-RCNN, EF-YOLOv5, YOLOv7-BiFormer, and the experimental comparison indicators included accuracy, precision, and recognition speed. The specific experimental environment is indicated in Table II.

TABLE II. EXPERIMENTAL ENVIRONMENTAL CONFIGURATION

Parameter names	Parameter
Processor	Intel Core i9-13900K
Main frequency	5.8 GHz
Internal memory	32 GB
Hard disk capacity	1 TB
Operating system	Windows 10 64
Matlab version	Matlab 2021a
Data analysis software	Spss24.0

To verify the benchmark performance and hardware requirements of the algorithm proposed in the research, a benchmark test was conducted between the algorithm and other algorithms with the indexes of each image recognition time, model size, accuracy improvement, scalability, and hardware requirements. The test results are shown in Table III.

TABLE III. TEST RESULTS

Algorithm	Image recognition (ms/pcs)	Model size (MB)	Processor	Improves accuracy (%)	Scalability	Hardware requirement
Research	19.8	41	Intel Core i9-13900K	+43.6	High	Medium
Faster-RCNN	74.6	56	Intel Core i9-13900K	+27.3	Medium	High
EF-YOLOv5	40.3	47	Intel Core i9-13900K	+32.1	Low	High
YOLOv7-BiFormer	51.7	44	Intel Core i9-13900K	+29.5	Medium	High

From Table III, the recognition time of the proposed algorithm, Faster-RCNN, EF-YOLOv5, and YOLOv7-BiFormer for each image was 19.8 ms, 74.6 ms, 40.3 ms, and 51.7 ms, respectively, among which the proposed algorithm had the shortest recognition time for each image. This showed that the proposed algorithm had obvious advantages in processing speed and was suitable for application scenarios requiring fast response. In terms of model size, the proposed algorithm was 41 MB, which was lower than the 56 MB of Faster-RCNN, 47 MB of EF-YOLOv5 and 44 MB of YOLOv7-BiFormer. Smaller model sizes helped reduce storage requirements and potentially increased deployment flexibility. In addition, the accuracy of the proposed algorithm was improved to 43.6%, which was significantly higher than other algorithms. This showed that the algorithm could provide high recognition accuracy while maintaining high recognition speed. In terms of scalability, the proposed algorithm was rated as high, which indicates that the proposed algorithm can adapt

to different application requirements and environments, and has good adaptability. The medium hardware requirement indicated that the algorithm required neither the lowest nor the highest hardware, thus striking a balance between performance and cost. The above results showed that the proposed algorithm had the best performance in recognition speed and accuracy, high scalability, and low hardware requirements, and could achieve real-time recognition well. To verify the contribution of each component of the model proposed in the study to the performance improvement, ablation experiments were conducted on it, and the experimental results are shown in Table IV.

TABLE IV. ABLATION RESULTS

Experiment No.	Model architecture	Feature extraction network	Feature fusion method	Classifier	Accuracy (%)
1	CNN-only	DarkNet-53	None	CNN	82.5
2	CNN-only	GoogleNet	None	CNN	80.0
3	CNN-only	VGG-19	None	CNN	78.5
4	CNN-only	EfficientNet-B0	None	CNN	81.0
5	CNN-only	Multiple network fusion	None	CNN	83.0
6	CNN+SVM	DarkNet-53	None	SVM	84.0
7	CNN+SVM	GoogleNet	None	SVM	82.0
8	CNN+SVM	VGG-19	None	SVM	81.5
9	CNN+SVM	EfficientNet-B0	None	SVM	86.5
10	CNN+SVM	Multiple network fusion	Multiple convolution fusion	SVM	96.6

From the ablation experiment results in Table IV, a single CNN model had different performances in bird recognition tasks, among which DarkNet-53 had the best performance, with an accuracy rate of 82.5%. After the introduction of SVM classifier, the model performance was generally improved, especially the EfficientNet-B0+SVM combination, the accuracy rate increased to 86.5%, indicating that SVM has significant advantages in the feature classification stage. After further use of multi-network fusion and multi-convolutional feature fusion methods, the model accuracy was significantly improved to 96.6%, indicating that feature fusion technology contributes significantly to the performance improvement. Therefore, the CNN+SVM model architecture combined with multi-network fusion and feature fusion had the best performance in the identification of transmission line endangered birds, which provides an effective way to improve the identification accuracy.

In the above environment, firstly, 1000 bird images were selected and four algorithms were used to classify and recognize 8 high-risk birds on transmission lines. The classification and recognition results were represented by a confusion matrix. The classification accuracy results of each algorithm are indicated in Fig. 6.

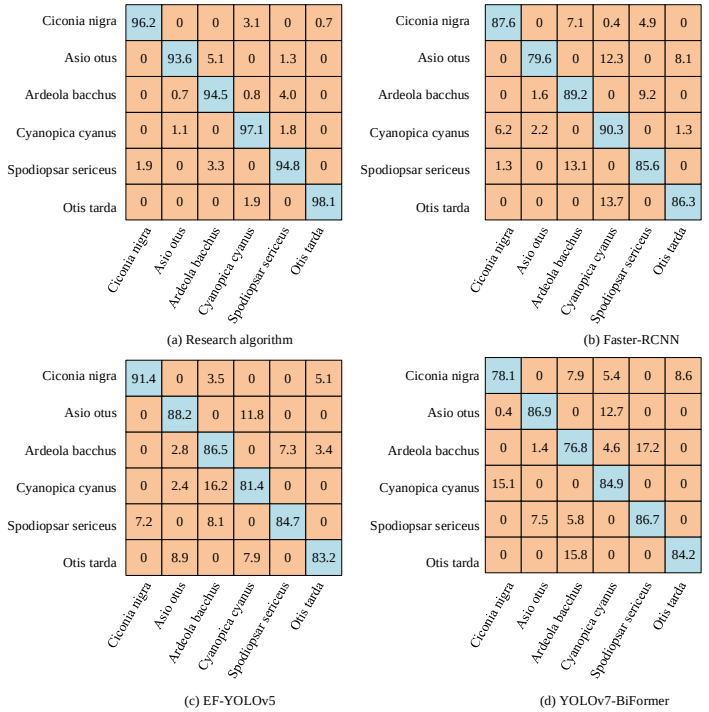

Fig. 6. Comparison results of classification accuracy of each algorithm.

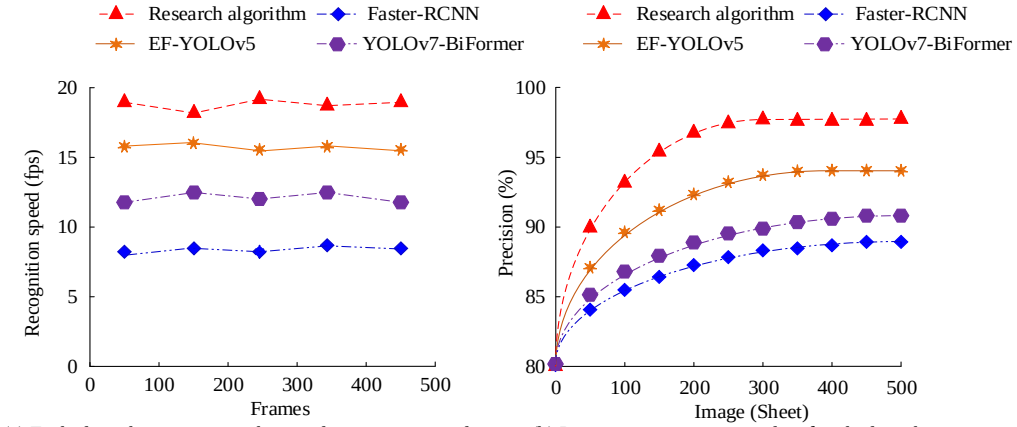
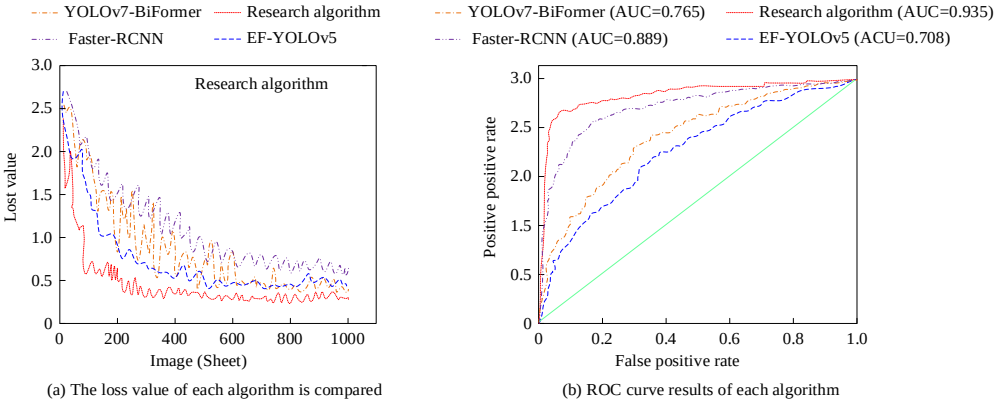
From Fig. 6(a), the proposed algorithm had recognition accuracies of 96.2%, 93.6%, 94.5%, 97.1%, 94.8%, and 98.1% for ciconia nigra, asio otus, ardeola bacchus, cyanopica cyanus, spodiopsar sericeus, and otis tarda, respectively, all of which were above 90%. The average recognition accuracy of Fig. 6(b), 6(c), and 6(d) was all below 90%, significantly lower than the average recognition accuracy of Fig. 6(b). The above results indicate that, from the perspective of recognition accuracy, the proposed recognition algorithm is significantly better than the comparative algorithm. The recognition speed and accuracy results of each algorithm are shown in Fig. 7.



(a) Each algorithm recognizes the speed comparison results (b) Precision comparison results of each algorithm

Fig. 7. Results of recognition speed and recognition accuracy of each algorithm.

From Fig. 7(a), the average recognition speed of the proposed algorithm was 19.8 frames per second (FPS), the average recognition speed of Faster RCNN was 8.2 FPS, the average recognition speed of EF-YOLOv5 was 16.6 FPS, and the average recognition speed of YOLOv7-BiFormer was 13.1 FPS. Among them, the algorithm proposed in the study had the fastest average recognition speed. From Fig. 7(b), the recognition accuracy of the proposed algorithm, Faster-RCNN, EF-YOLOv5, and YOLOv7-BiFormer were 97.4%, 86.4%, 94.3%, and 93.7%, respectively. Among them, the algorithm proposed in the study had the highest recognition accuracy. The above results indicate that, in terms of recognition speed and accuracy, the proposed algorithm outperforms the compared algorithms in terms of performance. The loss values and ROC curve results of each algorithm are shown in Fig. 8.



(a) The loss value of each algorithm is compared (b) ROC curve results of each algorithm

Fig. 8. Loss values and ROC curve results for each algorithm.

From Fig. 8(a), the proposed algorithm converged first with an average loss value of 0.37, Faster-RCNN had an average loss value of 0.9, EF-YOLOv5 had an average loss value of 0.52, and YOLOv7-BiFormer had an average loss value of 0.67. According to Fig. 8(b), the AUC values of the proposed algorithm, Faster-RCNN, EF-YOLOv5, and YOLOv7-BiFormer were 0.935, 0.889, 0.708, and 0.765, respectively, with the proposed algorithm having the highest AUC value. The lower the loss value in the range of 0.1 to 1, the better the model's generalization ability. The higher the AUC value of the ROC curve in the range of 0.5 to 1, the stronger the model's discriminative ability. Based on the loss value and ROC curve dimensions, the proposed algorithm outperformed the compared algorithms in terms of performance. In summary, from the perspectives of accuracy, precision, recognition speed, loss value, and ROC curve dimensions, the proposed algorithm outperforms the compared algorithms in terms of performance and is effective.

B. Analysis of Algorithm Application Effectiveness

After verifying the performance superiority of the algorithm, an application effect analysis experiment was conducted on the proposed algorithm. The study randomly captured images of hazard birds on transmission lines in a certain area for identification, and some of the identification results are shown in Fig. 9.

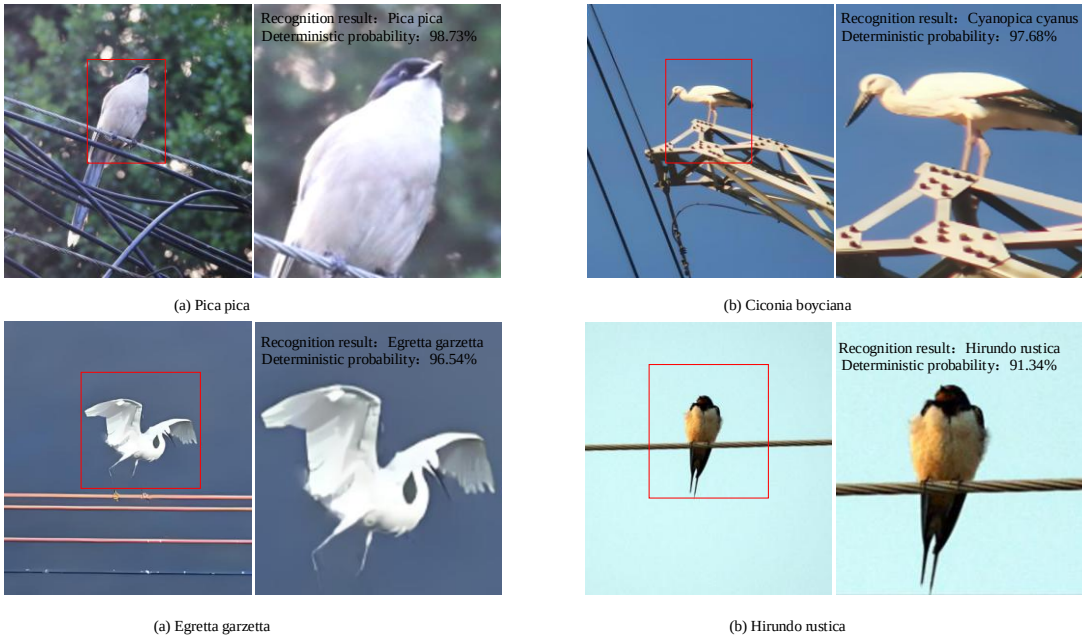


Fig. 9. Identification results of bird parts of transmission lines.

From Fig. 9, the recognition algorithm proposed in the study had recognition results and confirmation probabilities of 98.73%, 97.68%, 96.54%, and 91.34% for magpies, ciconia boyciana, egretta garzetta, and hirundo rustica, respectively, all of which were above 90%. This result indicates that the proposed recognition algorithm can effectively identify birds that pose a threat to transmission lines and has practical value. To further verify the application effect of the recognition algorithm proposed in the research, the classification and recognition of randomly captured birds were studied. The t distribution random neighborhood embedding technique was used to select six bird species for visual analysis and comparative experiments. The comparative algorithms included Faster-RCNN, EF-YOLOv5, and YOLOv7-BiFormer algorithms. The visual recognition results of each algorithm are denoted in Fig. 10.

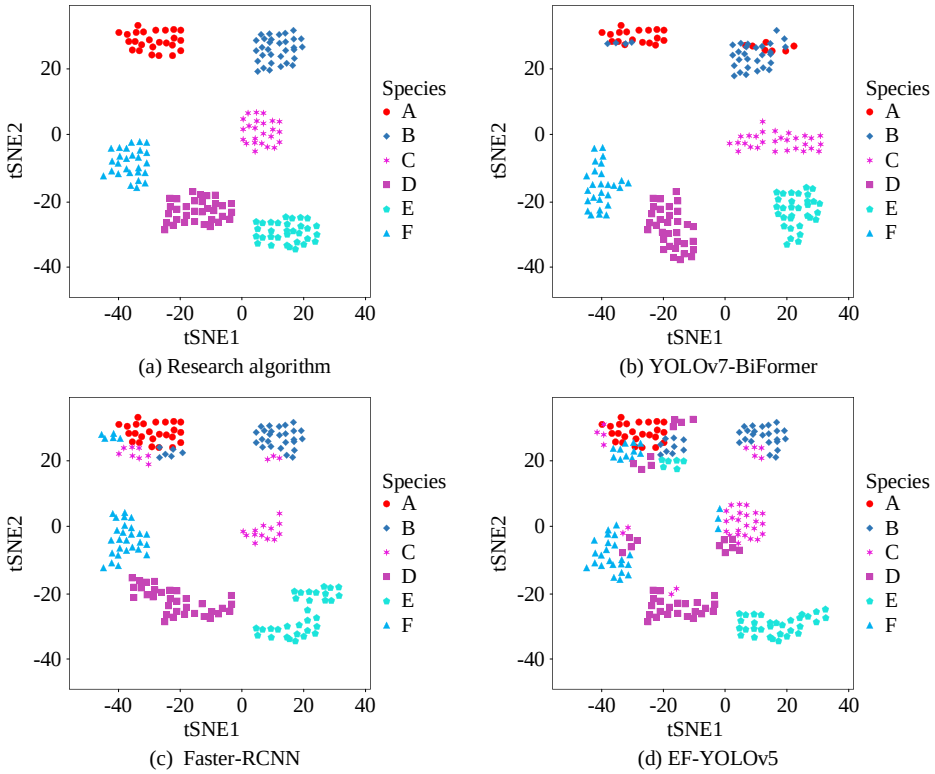

Fig. 10. Visualization of recognition results for each algorithm.

From Fig. 10(a), the algorithm proposed in the study had the best classification performance, with the highest clustering degree for each category. From Fig. 10(b), YOLOv7-BiHomer had good classification performance, with two categories not clearly distinguished. From Fig. 10(c), Faster-RCNN had poor classification performance, with four categories confused and not significantly distinguished. From Fig. 10(d), EF-YOLOv5 had the worst classification performance, with six bird species confused. The above results indicate that the proposed algorithm has the best visualization effect and good application performance.

V. DISCUSSION

This study conducted comparative experimental analysis on the performance of bird recognition algorithms for transmission line hazards based on improved CNN and SVM, and conducted application effect analysis experiments on the algorithm. The findings denoted that the algorithm had significant advantages in accuracy, precision, and recognition speed. In the accuracy comparison experiment, the proposed algorithm achieved recognition accuracies of 96.2%, 93.6%, 94.5%, 97.1%, 94.8%, and 98.1% for ciconia nigra, asio otus, ardeola bacchus, cyanopica cyanus, spodiopsar sericeus, and otis tarda, respectively, all of which were above 90%, significantly better than the comparison algorithms. This result indicates that the introduction of DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0 raises the algorithm's ability to extract deep features and optimizes the accuracy of algorithm recognition. This result is similar to the improved CNN algorithm proposed by Elangovan et al. [23]. In the precision comparison experiment, the recognition accuracy of the proposed algorithm, Faster-RCNN, EF-YOLOv5, and YOLOv7-BiFormer were 97.4%, 86.4%, 94.3%, and 93.7%, respectively, with the proposed algorithm having the highest recognition accuracy. This result indicates that the introduction of SVM algorithm raises the classification accuracy of the algorithm. The Chaudhari team reached consistent conclusions in their research on combining SVM and CNN [24]. In the recognition speed comparison experiment, the average recognition speeds of the proposed algorithm, Faster-RCNN, EF-YOLOv5, and YOLOv7-BiFormer were 19.8 FPS, 8.2 FPS, 16.6 FPS, and 13.1 FPS, respectively. Among them, the algorithm proposed in the study had the fastest average recognition speed. This outcome indicates that the convolution feature fusion of DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0, as well as the introduction of SVM, improved the computational efficiency of the algorithm. At the same time, in the comparative experiments of loss value and ROC, the average loss value and AUC value of the proposed algorithm were 0.37 and 0.935, respectively, which were better than the comparative algorithms. This result further validates the superiority of the algorithm proposed in the study. The Okomba team reached similar conclusions in SVM-CNN related research [25]. Secondly, in the application effect analysis experiment, the algorithm proposed in the study had good application effects in identifying hazard birds and visualizing the results. In the experiment of identifying hazard birds, the results showed that the proposed identification algorithm could effectively identify hazard birds. This result indicated that the convolutional feature fusion of DnCNN, DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0, as well as the introduction of SVM, improved the accuracy and precision of the algorithm for bird recognition on transmission lines. In the visual classification comparative analysis experiment, the algorithm proposed in the study had the best classification performance and the highest degree of category aggregation. This conclusion is similar to the one obtained by the Gao team in their relevant research in 2022 [26]. To conduct a thorough analysis of the performance of the model in practical applications, a detailed discussion was conducted on the failure cases of the model. Research has found that common classification errors included difficulty in detecting small targets, misclassification caused by occlusion, and the negative impact of lighting changes on detection performance. For example, small birds are easily misclassified or missed due to occupying fewer pixels in the image; partially occluded bird targets often lead to inaccurate recognition by the model. In addition, changes in lighting conditions (such as shadows and highlights) can mask key features of birds, further reducing the detection accuracy of the model. To address these issues, techniques such as data augmentation, feature enhancement, and multimodal data fusion can be used to improve the adaptability of the model to complex environments. However, factors such as dynamic scenes, seasonal changes, and environmental noise in the real world still pose challenges to the generalization ability of the model. Therefore, future work needs to further optimize the model architecture, regularly update the dataset, and combine online learning strategies to improve the robustness and accuracy of the model in practical deployment. In addition, there are limitations in the research data set and potential biases in the data collection process, such as data mainly from Anhui province, which may lead to poor adaptability of the model to other regions. In addition, the large number of certain bird samples in the dataset may result in the model being better at identifying these birds and less able to identify others. This bias can have an unfair impact on grid maintenance and bird protection, for example, false positives can lead to unnecessary waste of resources, while missed positives can pose a threat to grid security. Future work will reduce this bias by introducing data from more regions and optimizing the balance of the dataset, and its ethical implications will be discussed in detail in the paper. The following ethical issues and practical application challenges arise in the study of transmission line hazard bird identification model based on multi-backbone network and SVM. First, the geographic limitations of the data set and sample imbalances can lead to model bias, which in turn affects the fairness of grid maintenance and the comprehensiveness of bird conservation. Second, models in real-world deployments can be disturbed by dynamic scenarios, seasonal changes, and ambient noise, leading to false positives and triggering unwanted interventions. Finally, to address these challenges, future work will optimize the diversity and balance of datasets, reduce false positives by combining multi-sensor data and real-time verification mechanisms, and promote harmonious symbiosis between the grid and birds through ecological conservation measures and public education.

VI. CONCLUSION

To address the problem of low recognition accuracy in bird identification methods for transmission line hazards due to the small size of bird targets, this study introduced CNNs to solve the problem of CNN being unable to fully capture all information in the data due to its fixed architecture and parameters, which limits its ability to express features. After fine-tuning and migration learning, four CNN models, DnCNN, DarkNet-53, GoogleNet, VGG-19, and EfficientNet-B0, were cascaded for feature fusion and improvement to construct an improved CNN feature extraction network. To accurately identify hazard birds, SVM was introduced for classification. A dataset of bird species affected by transmission lines was constructed, and data augmentation methods and DnCNN were introduced for noise reduction processing of bird image data. The above classification algorithms were applied to this dataset and a bird classification and recognition algorithm for transmission line hazards was constructed based on improved CNN and SVM. Comparative performance analysis experiments were conducted on the algorithm, and the results showed that the algorithm performed significantly better than the compared algorithms in terms of accuracy, precision, recognition speed, loss value, and ROC curve dimensions. Subsequently, the algorithm was subjected to application effect analysis experiments, and the results showed that the algorithm not only accurately identified hazard birds, but also had better classification performance than the comparative algorithms in visualization effect analysis. The above findings denote that the proposed algorithm has strong robustness. The limitation of this study is that the recognition method adopts a multi-CNN structure for fusion, which may have redundant parameters and a large number of parameters. Therefore, further research is needed to reduce the dimensionality of the fused features to shorten the algorithm recognition time and improve recognition speed.

Electrical and Computer Engineering Department, King Abdulaziz University, Jeddah, KSA[2]

***Abstract*—This paper addresses the distributed consensus tracking problem for nonlinear multi-agent systems subject to unknown but bounded external disturbances by leveraging a super-twisting sliding mode (STSM) control framework. Two STSM-based consensus algorithms are proposed—one for first-order and another for second-order multi-agent systems—to achieve finite-time convergence despite disturbances. A disturbance observer is integrated into the consensus control protocols to estimate and compensate for these disturbances, ensuring robust tracking without requiring time-derivative sliding variables or smoothing algorithms. The proposed consensus protocols build upon the concepts of finite-time stability, Lipschitz-bounded functions, relative degree analysis of input-output dynamics, and positive-definite matrix properties. Stability and finite-time convergence are rigorously established using Lyapunov-based proofs, Rayleigh's inequality, and finite-time settling results. Unstructured disturbances are modelled as zero-mean Gaussian noise and structured disturbances are expressed via a regressor formulation. Numerical simulations confirm that the integrated STSM-based consensus approach and disturbance observer ensure high tracking accuracy, robustness, and smooth control performance under diverse disturbance conditions.**

Keywords*—Distributed consensus; cooperative control; nonlinear multiagent systems; robustness; super-twisting sliding mode

I. Introduction

Distributed consensus control has emerged as a fundamental approach for coordinating multi-agent systems (MAS), enabling agents to achieve a common goal through local interactions [1]. This decentralized control paradigm has been widely applied in robotics, unmanned aerial vehicles (UAVs), distributed sensor networks, and intelligent transportation systems due to its scalability and robustness against single-point failures [2]. Traditional consensus algorithms rely on linear or adaptive control techniques to ensure convergence; however, external disturbances, model uncertainties, and time-varying perturbations significantly complicate the consensus process [3]. To address these challenges, sliding mode control (SMC) has been extensively adopted for MAS coordination due to its inherent robustness against disturbances and uncertainties [4]. First-order sliding-mode (FOSM) control has been widely implemented to counteract local interaction uncertainties and external perturbations [5]. However, a well-known drawback of FOSM is the chattering phenomenon, which can lead to excessive energy consumption, actuator degradation, and performance deterioration in practical applications [6]. Various mitigation strategies, such as boundary layers [7], saturation control [8], and adaptive filtering techniques [9], have been proposed to alleviate chattering, but these methods often introduce a tradeoff between robustness and precision.

Recent advancements in high-order sliding-mode control (HOSM) have significantly improved the performance of SMC-based consensus algorithms. Among these, super-twisting sliding-mode control (STSMC) has gained substantial attention due to its ability to suppress chattering while preserving finite-time convergence and disturbance rejection capabilities [10]. STSMC introduces a continuous control law that effectively reduces oscillations near the sliding manifold while maintaining the robustness of conventional sliding-mode strategies. Numerous studies have explored the application of STSMC in MAS, demonstrating its effectiveness in various scenarios. For instance, Song, Yu, and Zheng [11] developed an STSMC-based consensus tracking algorithm that guarantees finite-time convergence under bounded disturbances. Similarly, Li, Wang, and Zhang [12] extended STSMC to distributed control frameworks, explicitly addressing time-varying uncertainties and ensuring robust coordination in uncertain environments. Additionally, Wang, Chou, and Liu [13] proposed adaptive STSMC strategies to handle leader-follower MAS with parametric uncertainties. Zhang, Liu, and Song [14] implemented STSMC-based formation control techniques for UAVs subjected to aerodynamic disturbances and dynamic payload variations.

Beyond traditional consensus tracking, researchers have proposed observer-based STSMC approaches to accommodate cases where state measurements are unavailable or incomplete. Authors in [15] introduced an observer-based STSMC method to estimate unmeasured states in uncertain MAS, enhancing the robustness of the control strategy. In [16] authors developed output-feedback STSMC techniques to handle stochastic disturbances and measurement noise, further improving the resilience of distributed consensus protocols. In addition, event-triggered STSMC methodologies have been introduced to reduce communication overhead in resource-constrained MAS networks by ensuring that control updates are executed only when necessary [17]. Despite these advancements, the most existing STSMC-based consensus control strategies assume that disturbances are either fully known or follow a predefined model, which is rarely the case in real-world applications [18].

In practical settings, disturbances often arise from unpredictable environmental changes, sensor noise, actuation delays, and communication constraints, making it imperative to develop control strategies capable of real-time disturbance estimation and rejection.

The primary challenge addressed in this study is developing a robust STSMC-based consensus control framework that actively estimates and rejects unknown bounded external disturbances in MAS. Conventional STSMC techniques, while effective in suppressing chattering and enhancing robustness, do not inherently incorporate mechanisms for real-time disturbance adaptation [19]. This limitation necessitates conservative gain tuning, which can lead to sluggish transient responses and reduced disturbance rejection efficiency. By integrating structured disturbance observers into the STSMC framework, this work aims to achieve real-time estimation of unknown disturbances, thereby improving the controller's adaptability and overall performance [20]. The proposed approach ensures that agents within the MAS can maintain finite-time consensus tracking despite external uncertainties while mitigating excessive control effort and minimizing chattering effects.

This research addresses key questions regarding the design and implementation of distributed STSMC for nonlinear MAS under unknown bound disturbances. Specifically, it investigates how distributed STSMC can be structured to achieve robust finite-time consensus tracking under uncertain disturbances. Additionally, it explores which disturbance estimation techniques can be effectively integrated into the STSMC framework to enhance disturbance rejection without compromising chattering suppression. Furthermore, this study evaluates the proposed method's performance relative to conventional FOSM, STSMC, and adaptive control strategies, considering convergence speed, robustness, and control effort metrics.

To address these research challenges, this work presents two main contributions. First, it develops a novel STSMC-based distributed consensus-tracking algorithm tailored for first-order and second-order nonlinear MAS. This algorithm ensures that consensus is reached in finite time while actively rejecting external disturbances through an embedded disturbance observer. Second, it establishes rigorous theoretical guarantees for stability and robustness, proving that the proposed approach maintains finite-time convergence under a general class of bounded disturbances. These advancements aim to bridge the gap in STSMC-based consensus control by enabling real-time disturbance adaptation without sacrificing robustness or performance.

The effectiveness of the proposed method is validated through extensive numerical simulations, where its performance is compared against existing sliding-mode and adaptive consensus control techniques. The simulations analyze key performance indicators such as tracking error convergence, disturbance rejection efficiency, and chattering suppression. The results demonstrate that the proposed STSMC approach significantly improves disturbance handling and consensus tracking precision while reducing unnecessary control effort. These findings indicate that integrating structured disturbance observers into STSMC provides a practical and scalable solution for MAS applications operating in uncertain and dynamically evolving environments.

In the context of MAS, recent studies have explored various control strategies to enhance coordination and performance. For instance, authors in [21] proposed a distributed cooperative control framework for multi-UAV flying formations, addressing challenges such as chattering effects and formation tracking in three-dimensional space. Their approach integrates smooth control protocols within a leader-following framework, ensuring robust formation maintenance despite external disturbances and communication constraints. Similarly, in the realm of multi-robot systems, authors in [22] developed a distributed cooperative control strategy for nonholonomic wheeled mobile robots, focusing on smooth consensus protocols to improve coordination and reduce chattering phenomena. In satellite formation flying, a distributed attitude synchronization control method for switched networked satellite formations was introduced in [23] ensuring finite-time convergence and robustness against switching topologies and external disturbances. These contributions collectively advance the field of distributed control in MAS, offering practical solutions for complex aerospace and robotic applications.

The remainder of this paper is structured as follows: Section 2 presents preliminaries of distributed consensus and coordinated control. The consensus tracking problem for first-order and second-order dynamic MAS including disturbance observer is formulated and solved in section 3 and section 4, respectively. Section 5 validates the effectiveness of the proposed approach through numerical simulations and comparative studies. Finally, Section 6 concludes the paper with key findings, potential limitations, and future research directions.

II. PRELIMINARIES

A. Graph Theory and Preliminaries

Consider the case of MAS composed of n agents connected under a communication graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ of order n, where $\mathcal{V} = (v_1, v_2, \ldots, v_n)$, $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$, and $\mathcal{A} = (a_{ij}) \in \mathbb{R}^{n\times n}$ are the node set, edge set, and weighted adjacency matrix, respectively.

Assumption 1. A Laplacian matrix $\boldsymbol{\mathcal{L}}$ is associated with the graph $\mathcal{G}$ such that $\boldsymbol{\mathcal{L}} = [l_{ij}]) \in \mathbb{R}^{n\times n}$ where $l_{ij} = -a_{ij}$ when $i \neq j$ and $l_{ii} = \sum_{j=1, j\neq i}^{n} a_{ij}$.

Assumption 2. The graph $\mathcal{G}$ is connected and the eigenvalues $\lambda_i(\boldsymbol{\mathcal{L}})$ of the Laplacian matrix $\boldsymbol{\mathcal{L}}$ are defined such that $\lambda_1(\boldsymbol{\mathcal{L}}) = 0 < \lambda_2(\boldsymbol{\mathcal{L}}) <...< \lambda_n(\boldsymbol{\mathcal{L}})$. $\lambda_1(\boldsymbol{\mathcal{L}}) = 0$ has an associated eigenvector **1**.

Assumption 3. There exists a symmetric positive definite matrix $\boldsymbol{M}$ such that $\boldsymbol{M} = \boldsymbol{\mathcal{L}} + \boldsymbol{diag}(a_{10}, a_{20}, \ldots, a_{n0})$.

Lemma 1 (Rayleigh's inequality, Horn and Johnson, 1986)**.** If a matrix $\boldsymbol{Q}$ is symmetric $\boldsymbol{Q} = \boldsymbol{Q}^T$, then for a given bounded vector $\boldsymbol{v}$

$$\lambda_{min}(\boldsymbol{Q})\|\boldsymbol{v}\|^2 \leq \boldsymbol{v}^T\boldsymbol{Q}\boldsymbol{v} \leq \lambda_{max}(\boldsymbol{Q})\|\boldsymbol{v}\|^2 \quad (1)$$

where λ_{min} and λ_{max} are the minimum and maximum eigenvalues of $\boldsymbol{Q}$, respectively.

B. Second-Order Super-Twisting Sliding Mode

Consider a *m*-order SISO nonlinear dynamic system

$$\begin{aligned} \dot{\boldsymbol{x}} &= \boldsymbol{f}(\boldsymbol{x}) + \boldsymbol{g}(\boldsymbol{x})u \\ \sigma &= \sigma(\boldsymbol{x}) \end{aligned} \tag{2}$$

where $\boldsymbol{x} \in \mathbb{R}^m$ is the system state and $u \in \mathbb{R}$ is the control input; $\boldsymbol{f} \in \mathbb{R}^m$ and $\boldsymbol{g} \in \mathbb{R}^m$ are uncertain smooth functions; σ is the tracking error (sliding variable).

The control objective of the second-order STSM control is to exactly stabilize $\sigma(\boldsymbol{x})$ and its first time derivative $\dot{\sigma}(\boldsymbol{x})$ in finite time without the use of $\dot{\sigma}(\boldsymbol{x})$ and without affecting the tracking performance. The control task is to drive the system trajectories to reach $\sigma(\boldsymbol{x}) = \dot{\sigma}(\boldsymbol{x}) = 0$ in finite time. The STSM control law is designed under the following assumptions.

Assumption 4. The relative degree of the input-output dynamics $u \to \sigma$ is one and the internal dynamics are stable

$$\dot{\sigma}(\boldsymbol{x}) = \eta(\boldsymbol{x}) + \zeta(\boldsymbol{x})u \tag{3}$$

with $\eta(x) = \dot{\sigma}(x)|_{u=0}$ and $\zeta(\boldsymbol{x}) = \partial\sigma(\boldsymbol{x})/\partial u \neq 0$

Definition 1. The system (2) is said to be a finite-time stable system in a compact $\boldsymbol{X} \subset \mathbb{R}^m$ if, $\forall \boldsymbol{x}_0 \in \boldsymbol{X}$, the system is asymptotically stable with a finite time settling for any solution $\boldsymbol{x}$ (see Bhatt & Bernstein, 2000; Bacciotti & Rosier, 2005).

Lemma 2 [17]: for any Lipschitz bounded function $\boldsymbol{f}$, there exists a constant $p \geq 2$ and positive gains K_1 and K_2 for which a finite-time convergence $\sigma(\boldsymbol{x}), \dot{\sigma}(\boldsymbol{x}) \to 0$ can be provided by the following STSM control law without the usage of $\dot{\sigma}(\boldsymbol{x})$

$$\begin{aligned} u(\boldsymbol{x}) &= -K_1|\sigma(\boldsymbol{x})|^{\frac{p-1}{p}} sign\big(\sigma(\boldsymbol{x})\big) + v(\boldsymbol{x}) \\ \dot{v}(\boldsymbol{x}) &= -K_2|\sigma(\boldsymbol{x})|^{\frac{p-2}{p}} sign\big(\sigma(\boldsymbol{x})\big) \end{aligned} \tag{4}$$

where $v(\boldsymbol{x})$ is the controller state.

III. Consensus-Tracking for First-Order Dynamics

A. Problem Statement

Consider a class of first-order MAS composed of one virtual leader (labelled as *0*) and '*n'* identical physical followers (labelled agent *i* with *i = 1, n*) described by the following first-order nonlinear uncertain dynamics subject to unknown bounded disturbances. The leader's dynamics are*:*

$$\dot{\boldsymbol{x}}_0 = \boldsymbol{f}_0(\boldsymbol{x}_0),\ \mathbf{y}_0 = \boldsymbol{h}_0(\boldsymbol{x}_0) \tag{5}$$

where $\boldsymbol{x}_0 \in \mathbb{R}^m$ and $\boldsymbol{y}_0 \in \mathbb{R}^q$ are the leader's state and output, respectively. The vector-valued functions $\boldsymbol{f}_0 \in \mathbb{R}^m$ and $\boldsymbol{h}_0 \in \mathbb{R}^q$ are continuous functions that describe a leader's dynamics and response, respectively. The followers' dynamics are

$$\dot{\boldsymbol{x}}_i = \boldsymbol{f}_i(\boldsymbol{x}_i) + \boldsymbol{G}_i(\boldsymbol{x}_i, \boldsymbol{u}_i)[\boldsymbol{u}_i(\boldsymbol{x}_i) + \boldsymbol{d}_i(\boldsymbol{x}_i, t)]\boldsymbol{y}_i = \boldsymbol{h}_i(\boldsymbol{x}_i) \tag{6}$$

where $\boldsymbol{x}_i \in \mathbb{R}^m$, $\boldsymbol{u}_i \in \mathbb{R}^m$, $\boldsymbol{y}_i \in \mathbb{R}^q$, and $\boldsymbol{d}_i \in \mathbb{R}^m$ are the i^{th} follower's state, control input, output, and disturbance vectors, respectively. The vector-valued functions $\boldsymbol{f}_i \in \mathbb{R}^m$ and $\boldsymbol{h}_i \in \mathbb{R}^q$ are uncertain continuous functions that describe the follower's dynamics and responses, respectively. In this study, we consider only the case of affine control inputs with $\boldsymbol{G}_i \equiv \boldsymbol{I}_m$, $\boldsymbol{y}_i = \boldsymbol{x}_i$, and $\boldsymbol{y}_0 = \boldsymbol{x}_0$.

Assumption 5. For each agent '*i*', the uncertainties/disturbances $\boldsymbol{d}_i(\boldsymbol{x}_i, t)$ are Lipschitz-continuous functions growing in time and/or with state variables and are bounded such that

$$\lim_{t\to\infty} |\boldsymbol{d}_i(\boldsymbol{x}_i, t)| = \boldsymbol{\zeta}_i \tag{7}$$

where $\zeta_i \in \mathbb{R}^+$.

The problem addressed in this section consists of finding smooth control inputs $\boldsymbol{u}_i(\boldsymbol{x}_i)$ to enforce the followers' kinematics (6) reaching the following consensus condition robustly

$$\lim_{t\to T} \|\boldsymbol{x}_i(t) - \boldsymbol{x}_0(t)\|_\infty = 0 \qquad \forall i = 1,2,\dots,n \tag{8}$$

To achieve the main results of robust distributed consensus protocols, we define a tracking variable σ, for each follower '*i=1,n*' and along each motion direction '*k=1,m*', as follows

$$\sigma_{i,k}(\boldsymbol{x}_i) = \textstyle\sum_{j=0}^{n} a_{ij}\big(x_{i,k} - x_{j,k}\big) \tag{9}$$

Assumption 6: The relative degree of the sliding variables $\sigma_{i,k}$ concerning the control inputs $u_{i,k}$ is one, for which the desired consensus (8) is achieved when $\sigma_{i,k} \equiv 0$ and the associated internal dynamics are stable.

The distributed consensus-tracking algorithm is designed such that the protocols $u_{i,k}$ ensure that the kinematics of the follower '*i*' robustly track the ones of the virtual leader with local interaction in the presence of matched disturbances. We propose a new variant of the Lyapunov-based STSM control law (4)

$$\begin{aligned} u_{i,k} &= -K_1\|\boldsymbol{\sigma}_k(\boldsymbol{x}_i)\|_\infty^{\frac{p-1}{p}} sign\left(\sigma_{i,k}(\boldsymbol{x}_i)\right) + v_{i,k} + \hat{d}_{i,k}(\boldsymbol{x}_i) \\ \dot{v}_{i,k} &= -K_2\|\boldsymbol{\sigma}_k(\boldsymbol{x}_i)\|_\infty^{\frac{p-2}{p}} sign\left(\sigma_{i,k}(\boldsymbol{x}_i)\right) \end{aligned} \tag{10}$$

where $\|\boldsymbol{\sigma}_k(\boldsymbol{x}_i)\|_\infty$ defines the infinity norm of the sliding vector $\boldsymbol{\sigma}_k(\boldsymbol{x}) = \left[\sigma_{1,k}(\boldsymbol{x}_i), \dots, \sigma_{m,k}(\boldsymbol{x}_i)\right]^T$ along the motion direction '*k*' and $\hat{d}_{i,k}$ are the estimated values of the disturbances $d_{i,k}$, to be estimated through special observers to be developed further.

B. Unperturbed Dynamics

Consider the MAS (5)-(6) in its nominal form (i.e. without uncertainties and/or disturbances). Let $\tilde{\boldsymbol{x}}_i = \boldsymbol{x}_i - \boldsymbol{x}_0 \in \mathbb{R}^m$ being the consensus state error vector, we rewrite the dynamics (6), for the unperturbed case, as

$$\dot{\tilde{\boldsymbol{x}}}_i = \boldsymbol{f}_i(\boldsymbol{x}_i) - \boldsymbol{f}_0(\boldsymbol{x}_0) + \boldsymbol{u}_i(\tilde{\boldsymbol{x}}_i) \tag{11}$$

Using the STSMC law (10) with $\boldsymbol{d}_i = 0$, the consensus dynamics (11) can be written in matrix form as

$$\dot{\boldsymbol{e}} = \boldsymbol{F}(\boldsymbol{e}) - K_1\|\boldsymbol{\sigma}\|_\infty^{\frac{p-1}{p}} sign(\boldsymbol{\sigma}) + \boldsymbol{V}$$

$$\dot{\boldsymbol{V}} = -K_2\|\boldsymbol{\sigma}\|_\infty^{\frac{p-2}{p}} sign(\boldsymbol{\sigma}) \quad (12)$$

with $\boldsymbol{e} = \boldsymbol{clmn}(\tilde{\boldsymbol{x}}_i) \in \mathbb{R}^N$, $\boldsymbol{V} = \boldsymbol{clmn}(\boldsymbol{v}_i) \in \mathbb{R}^N$, $\boldsymbol{F}(\boldsymbol{e}) = \boldsymbol{clmn}\left(\left(\boldsymbol{f}_i(\boldsymbol{x}) - \boldsymbol{f}_0(\boldsymbol{x})\right)\right) \in \mathbb{R}^N$, where the vector $\boldsymbol{clmn}(\boldsymbol{z}_i)$ denotes a column vector created from the sequence of vectors $\boldsymbol{z}_i$ for $i = 1, \dots, N = mn$.

Using expression (9), the sliding variable vector in (12) is defined as follows

$$\boldsymbol{\sigma} = (\boldsymbol{M} \otimes \boldsymbol{I}_N)\boldsymbol{e} \quad (13)$$

where the matrix $\boldsymbol{M}$ is as defined in assumption 3, $\boldsymbol{I}_N$ denotes the identity matrix of order N, and the symbol $\otimes$ denotes the Kronecker product.

Assumption 7: Suppose that the dynamics (5) are bounded, $\lambda_{max}(\boldsymbol{M}) > 0$, and there exists a pair of constants $l, \delta \in \mathbb{R}^+$, for which

$$\|\boldsymbol{F}(\boldsymbol{e})\|_\infty \le \delta\|\boldsymbol{\sigma}\|_\infty^{\frac{p-1}{p}} \|(\boldsymbol{M} \otimes \boldsymbol{I}_N)\|_\infty \le l\lambda(\boldsymbol{M})_{max} \quad (14)$$

Theorem 1: Consider that assumptions 1-4 and 6-7 hold. If the fixed undirected graph $\mathcal{G}$ is connected with at least one $a_{i0} > 0$, the distributed protocols (10) enforce the followers' dynamics (6) to satisfy the consensus condition (8) provided that the gains K_1 and K_2 are selected high enough so that

$$\frac{\lambda}{min^{\lambda(\boldsymbol{P})max}_{1/2(\boldsymbol{P})(\hat{\boldsymbol{Q}})_{min}}}, \quad \boldsymbol{P} = \frac{1}{2}\begin{bmatrix} 4K_2 + K_1^2 & -K_1 \\ -K_1 & 2 \end{bmatrix} \quad (15)$$

$$\hat{Q}_{11} = K_1K_2 - K_1\left(4K_2 + K_1^2\right)l\lambda_{\max}(\boldsymbol{M}) - \left(4K_2 + K_1^2\right)l\lambda_{\max}(\boldsymbol{M})\delta$$
$$\hat{Q}_{12} = \hat{Q}_{21} = -K_2 - 2K_2l\lambda_{\max}(\boldsymbol{M}) + \frac{K_1}{2}l\lambda_{\max}(\boldsymbol{M})\delta$$
$$\hat{Q}_{22} = K_1l\lambda_{\max}(\boldsymbol{M}) \quad (16)$$

Proof: Consider the expression (10) in the case of $p = 2$ and a modified form of the Lyapunov function candidate proposed in [18].

$$V = 2K_2\|\boldsymbol{\sigma}\|_\infty + \frac{1}{2}\|\boldsymbol{V}\|_\infty^2 + \frac{1}{2}\left(K_1\sqrt{\|\boldsymbol{\sigma}\|_\infty} - \|\boldsymbol{V}\|_\infty\right)^2 = \frac{1}{2}\boldsymbol{\xi}^T\boldsymbol{P}\boldsymbol{\xi} \quad (17)$$

where $\|\boldsymbol{z}\|_\infty$ denotes the infinity norm of a vector $\boldsymbol{z}$ and

$$\boldsymbol{\xi} = \begin{bmatrix} \sqrt{\|\boldsymbol{\sigma}\|_\infty} & \|\boldsymbol{V}\|_\infty \end{bmatrix}^T \quad (18)$$

The time derivative $\dot{V}$ is calculated as

$$\dot{V} = \frac{1}{2}\dot{\boldsymbol{\xi}}^T\boldsymbol{P}\boldsymbol{\xi} + \frac{1}{2}\boldsymbol{\xi}^T\boldsymbol{P}\dot{\boldsymbol{\xi}}$$
$$= \frac{1}{2}\boldsymbol{\xi}^T\boldsymbol{P}\begin{bmatrix} \|\dot{\boldsymbol{\sigma}}\|_\infty/\left(2\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right)sign(\sigma_p) & \left\|\dot{\boldsymbol{V}}\right\|_\infty \end{bmatrix}^T + 1/2\begin{bmatrix} \|\dot{\boldsymbol{\sigma}}\|_\infty/\left(2\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right)sign(\sigma_p) & \left\|\dot{\boldsymbol{V}}\right\|_\infty \end{bmatrix}^T \boldsymbol{P}\boldsymbol{\xi} \quad (19)$$

where σ_p is defined such that $\|\boldsymbol{\sigma}\|_\infty = |\sigma_p|$. With $\dot{\xi}_2 = \left\|\dot{\boldsymbol{V}}\right\|_\infty = \|-K_2 sign(\boldsymbol{\sigma})\|_\infty = K_2$, expression (20) becomes

$$\dot{V} \approx \frac{-K_2}{2}\left[K_1\sqrt{\|\boldsymbol{\sigma}\|_\infty} - 2\|\boldsymbol{V}\|_\infty\right] - \|\dot{\boldsymbol{\sigma}}\|_\infty/\left(2\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right)sign(\sigma_p)\left[-(4K_2 + K_1^2)\sqrt{\|\boldsymbol{\sigma}\|_\infty} + K_1\|\boldsymbol{V}\|_\infty\right] \quad (20)$$

Using the following norm properties:

$$\|\dot{\boldsymbol{\sigma}}\|_\infty = \|\boldsymbol{M} \otimes \boldsymbol{I}_N\dot{\boldsymbol{e}}\|_\infty \le \|\boldsymbol{M} \otimes \boldsymbol{I}_N\|_\infty\|\dot{\boldsymbol{e}}\|_\infty$$
$$\|\dot{\boldsymbol{e}}\|_\infty \le \|\boldsymbol{F}(\boldsymbol{e})\|_\infty + K_1\sqrt{\|\boldsymbol{\sigma}\|_\infty} + \|\boldsymbol{V}\|_\infty \quad (21)$$

expression (20) can be written as

$$\dot{V} \approx \frac{-K_2}{2}\left[K_1\sqrt{\|\boldsymbol{\sigma}\|_\infty} - 2\|\boldsymbol{V}\|_\infty\right] - 1/\left(\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right)\|(\boldsymbol{M} \otimes \boldsymbol{I}_M)\|_\infty \cdot \left(\|\boldsymbol{F}(\boldsymbol{e})\|_\infty + K_1\sqrt{\|\boldsymbol{\sigma}\|_\infty} + \|\boldsymbol{V}\|_\infty\right).\left[-(4K_2 + K_1^2)\sqrt{\|\boldsymbol{\sigma}\|_\infty} + K_1\|\boldsymbol{V}\|_\infty\right] \quad (22)$$

In matrix form,

$$\dot{V} \approx -\frac{1}{2\sqrt{\|\boldsymbol{\sigma}\|_\infty}}\boldsymbol{\xi}^T\boldsymbol{Q}_1\boldsymbol{\xi} - \frac{\|(\boldsymbol{M}\otimes\boldsymbol{I}_N)\|_\infty}{2\sqrt{\|\boldsymbol{\sigma}\|_\infty}}\boldsymbol{\xi}^T\boldsymbol{Q}_2\boldsymbol{\xi} - \frac{\|(\boldsymbol{M}\otimes\boldsymbol{I}_N)\|_\infty}{2\sqrt{\|\boldsymbol{\sigma}\|_\infty}}\|\boldsymbol{F}(\boldsymbol{e})\|_\infty\boldsymbol{q}^T\boldsymbol{\xi} \quad (23)$$

with

$$\boldsymbol{Q}_2 = \begin{bmatrix} -K_1(4K_2 + K_1^2) & -2K_2 \\ -2K_2 & K_1 \end{bmatrix}$$
$$\boldsymbol{Q}_1 = K_2\begin{bmatrix} K_1 & -1 \\ -1 & 0 \end{bmatrix}, \boldsymbol{q}^T = \begin{bmatrix} -(4K_2 + K_1^2) & K_1 \end{bmatrix} \quad (24)$$

According to assumption 7, expression (23) reduces to

$$\dot{V} \approx -1/\left(2\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right).\left(\boldsymbol{\xi}^T\boldsymbol{Q}_1\boldsymbol{\xi} + l\lambda(\boldsymbol{M})^T{}_2(\boldsymbol{M})^T{}_{3max_{max}}\right) \quad (25)$$

with

$$\boldsymbol{Q}_3 = \begin{bmatrix} -(4K_2 + K_1^2) & \frac{K_1}{2} \\ \frac{K_1}{2} & 0 \end{bmatrix} \quad (26)$$

In compact form,

$$\dot{V} \approx -1/\left(2\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right)\boldsymbol{\xi}^T\hat{\boldsymbol{Q}}\boldsymbol{\xi} \quad (27)$$

$$\hat{Q}_{11} = K_1K_2 - K_1\left(4K_2 + K_1^2\right)l\lambda_{\max}(\boldsymbol{M}) - \left(4K_2 + K_1^2\right)l\lambda_{\max}(\boldsymbol{M})\delta$$
$$\hat{Q}_{12} = \hat{Q}_{21} = -K_2 - 2K_2l\lambda_{\max}(\boldsymbol{M}) + \frac{K_1}{2}l\lambda_{\max}(\boldsymbol{M})\delta, \ \hat{Q}_{22} = K_1l\lambda_{\max}(\boldsymbol{M}) \quad (28)$$

From the following inequalities:

$$\dot{V} \approx -1/\left(2\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right)\boldsymbol{\xi}^T\hat{\boldsymbol{Q}}\boldsymbol{\xi} \le -1/\left(2\sqrt{\|\boldsymbol{\sigma}\|_\infty}\right)\lambda(\hat{\boldsymbol{Q}})\|\boldsymbol{\xi}\|_{2min}^2\sqrt{\|\boldsymbol{\sigma}\|_\infty} \le \|\boldsymbol{\xi}\|_2 \le \sqrt{V}/\lambda_{min}^{1/2(\boldsymbol{P})\ (\boldsymbol{P})\|\boldsymbol{\xi}\|_2^2(\boldsymbol{P})\|\boldsymbol{\xi}\|_{2max_{min}}^2} \quad (29)$$

it results that

$$\dot{V} \le -\gamma\sqrt{V}, \gamma = \lambda_{min}^{1/2(\boldsymbol{P})(\hat{\boldsymbol{Q}})(\boldsymbol{P})max_{min}} \quad (30)$$

End of proof.

The convergence time (settling time) can be estimated from the following expression:

$$\sqrt{V} = \sqrt{V_0} - \frac{1}{2}\gamma t \tag{31}$$

Let $\sqrt{V_0} - \frac{1}{2}\gamma t^* = 0$, which gives the convergence time t^* as

$$t^* = 1/\gamma \boldsymbol{\xi}_0^T \boldsymbol{P} \boldsymbol{\xi}_0 \tag{32}$$

Lemma 2: The Lyapunov function (17) ensures the convergence of all trajectories of the consensus (11) to zero in a finite time t equal or smaller than t^*.

Lemma 3: Since the Lyapunov function (17) is continuous everywhere but not differentiable at $\|\boldsymbol{\sigma}\|_\infty = 0$ (except on the set $S = \{\|\boldsymbol{\sigma}\|_\infty, \|\boldsymbol{V}\|_\infty \in \mathbb{R}^2 \mid \|\boldsymbol{\sigma}\|_\infty = 0\}$), the solutions of the consensus (11) are understood in Filippov's sense. Hence, the function (17) is not locally Lipschitz function.

Lemma 4: In the case of a fixed directed graph topology, the results obtained in theorem 1 remain valid with substitution of the matrix $\boldsymbol{M}$ in (13) by a matrix $\boldsymbol{N}$ such that

$$\boldsymbol{\sigma} = (\boldsymbol{N} \otimes \boldsymbol{I}_N)\boldsymbol{e}, \ \mathbf{NM} + \mathbf{M}^T\boldsymbol{N} = I_N \tag{33}$$

Remark. The gains K_1 and K_2 in protocols (10) can be tuned along each motion direction to get enough smooth control input.

C. Perturbed Dynamics

Consider the following perturbed consensus dynamics model

$$\dot{\tilde{\boldsymbol{x}}}_i = \boldsymbol{f}_i(\boldsymbol{x}_i) - \boldsymbol{f}_0(\boldsymbol{x}_0) + \boldsymbol{u}_i(\tilde{\boldsymbol{x}}_i) + \boldsymbol{d}_i(\tilde{\boldsymbol{x}}_i) \tag{34}$$

Assumption 8. The disturbances $\boldsymbol{d}_i(t)$ are bounded disturbances that satisfy the following conditions

$$\boldsymbol{d}_i(\boldsymbol{x}_i, t) = \boldsymbol{d}_i^s(\boldsymbol{x}_i, t) + \boldsymbol{d}_i^u(\boldsymbol{x}_i, t), \ \lim_{t\to\infty} \boldsymbol{d}_i(\boldsymbol{x}_i, t) = \boldsymbol{\zeta}_i \tag{35}$$

where $\boldsymbol{d}_i^s(\boldsymbol{x}_i, t)$ and $\boldsymbol{d}_i^u(\boldsymbol{x}_i, t)$ denote the structured and unstructured parts of the matched disturbances $\boldsymbol{d}_i$ and $\boldsymbol{\zeta}_i$ are unknown constant vectors.

Assumption 9. The unstructured disturbances $\boldsymbol{d}_i^u(\boldsymbol{x}_i, t)$ can be considered as zero-mean Gaussian noises while the structured disturbances $\boldsymbol{d}_i^s(\boldsymbol{x}_i, t)$ are expressed using regressor notation [18]

$$d_{i,k}^s(\boldsymbol{x}_i, t) = \boldsymbol{\theta}_i^T \boldsymbol{\varphi}_i(\boldsymbol{x}_i) \quad k = 1,2,\ldots,m \tag{36}$$

where $\boldsymbol{\theta}_i \in \mathbb{R}^p$ is an uncertain parameter vector and $\boldsymbol{\varphi}_i : \mathbb{R}^m \to \mathbb{R}^p$ is a known nonlinear base function. In the presence of structured disturbances (35), the consensus dynamics (12) are rewritten as

$$\dot{\boldsymbol{e}} = \boldsymbol{F}(\boldsymbol{e}) - K_1 \|\boldsymbol{\sigma}\|_\infty^{\frac{p-1}{p}} sign(\boldsymbol{\sigma}) + \boldsymbol{V} - \boldsymbol{\Theta}^T \boldsymbol{\Phi}(\boldsymbol{x})$$
$$\dot{\boldsymbol{V}} = -K_2 \|\boldsymbol{\sigma}\|_\infty^{\frac{p-2}{p}} sign(\boldsymbol{\sigma}) \tag{37}$$

where

$$\boldsymbol{\Theta} = [\theta_1^T, \theta_2^T, \ldots, \theta_n^T]^T \in R^N, \ \Phi = [\varphi_1^T, \varphi_2^T, \ldots, \varphi_n^T]^T \in R^N \tag{38}$$

Theorem 2: Consider that assumptions 4 and 5 hold. If the graph $\mathcal{G}$ is connected with at least one $a_{i0} > 0$, the following agents' controllers and disturbance observers ensure that the consensus condition (8) is robustly achieved in finite time despite external disturbances.

Controllers:

$$u_{i,k} = -K_1 \|\boldsymbol{\sigma}_k(\boldsymbol{x}_i)\|_\infty^{\frac{p-1}{p}} sign\left(\sigma_{i,k}(\boldsymbol{x}_i)\right) + v_{i,k} - \boldsymbol{\theta}_i^T \boldsymbol{\varphi}_i(\tilde{\boldsymbol{x}}_i)$$
$$\dot{v}_{i,k} = -K_2 \|\boldsymbol{\sigma}_k(\boldsymbol{x}_i)\|_\infty^{\frac{p-2}{p}} sign\left(\sigma_{i,k}(\boldsymbol{x}_i)\right) \tag{38}$$

Observers:

$$\dot{\hat{\boldsymbol{\theta}}}_i = \boldsymbol{\Gamma}_i \boldsymbol{\Psi}_i(\boldsymbol{\sigma}_i) \boldsymbol{\varphi}_i(\tilde{\boldsymbol{x}}_i) \tag{39}$$

where $\boldsymbol{\Gamma}_i = \boldsymbol{diag}(\rho_{1,1}, \rho_{1,2}, \ldots, \rho_{1,m}) \in \mathbb{R}^{m\times m}$ and $\boldsymbol{\Psi}_i(\boldsymbol{\sigma}_i) = \boldsymbol{diag}(sign(\sigma_{i,j})) \in \mathbb{R}^{m\times m}$.

Proof: Consider the following Lyapunov function

$$V_{ext} = V_{nom} + \frac{1}{2}\tilde{\boldsymbol{\Theta}}^T \boldsymbol{\Gamma}^{-1} \tilde{\boldsymbol{\Theta}} \tag{40}$$

where V_{nom} is given by expression (17), $\tilde{\boldsymbol{\Theta}} = (\hat{\boldsymbol{\Theta}} - \boldsymbol{\Theta}) \in \mathbb{R}^N$ is a parameter error vector, $\hat{\boldsymbol{\Theta}}$ is the estimate of the unknown parameter vector $\boldsymbol{\Theta}$, and $\boldsymbol{\Gamma} = \boldsymbol{diag}(\rho_{1,1}, \ldots, \rho_{1,m}, \ldots \rho_{n,1}, \ldots, \rho_{n,m}) \in \mathbb{R}^{N\times N}$ with $\rho_{i,j}$ being adaptive gain coefficient for the agent 'i' along motion direction 'j'. To actively estimate and reject external disturbances in each agent's motion direction and robustly achieve consensus tracking (8), the following adaptive law is proposed.

$$\dot{\hat{\boldsymbol{\Theta}}} = \boldsymbol{\Gamma} \boldsymbol{\Psi}(\boldsymbol{\sigma}) \Phi(\boldsymbol{x}) \tag{41}$$

where $\boldsymbol{\Psi}(\boldsymbol{\sigma}) = \boldsymbol{diag}(sign(\sigma_{i,j})) \in \mathbb{R}^{N\times N}$. Since $\boldsymbol{\Theta}$ is unknown, the time-derivative of (44) is obtained as

$$\dot{V}_{ext} = \dot{V}_{nom} + \tilde{\boldsymbol{\Theta}}^T \boldsymbol{\Gamma}^{-1} \dot{\hat{\boldsymbol{\Theta}}} \tag{42}$$

With (30), the extended Lyapunov function may be bounded as

$$\dot{V}_{ext} \leq -\left[\gamma\sqrt{V_{nom}} + \tilde{\boldsymbol{\Theta}}^T \boldsymbol{\Gamma}^{-1}\left(\dot{\hat{\boldsymbol{\Theta}}} - \boldsymbol{\Gamma}\boldsymbol{\Psi}(\boldsymbol{\sigma})\Phi(\boldsymbol{x})\right)\right] \tag{43}$$

end of the proof.

IV. Consensus-tracking for Second-order Dynamics

A. Problem Statement

This section addresses the design of distributed consensus tracking protocols for nonlinear second-order MAS to achieve robust high-accuracy position and velocity consensus tracking. Consider a MAS composed of a virtual leader '0' and n identical followers with nonlinear uncertain second-order dynamics subject to unknown but bounded external disturbances. The leader's and followers' dynamics are, respectively

$$\dot{\boldsymbol{x}}_0 = \boldsymbol{v}_0 \dot{\boldsymbol{v}}_0 = \boldsymbol{f}_0(\boldsymbol{x}_0) + \boldsymbol{G}_0(\boldsymbol{x}_0)\boldsymbol{u}_0(\boldsymbol{x}_0) \tag{44}$$

$$\dot{\boldsymbol{x}}_i = \boldsymbol{v}_i \dot{\boldsymbol{v}}_i = \boldsymbol{f}_i(\boldsymbol{x}_i) + \boldsymbol{G}_i(\boldsymbol{x}_i)[\boldsymbol{u}_i(\boldsymbol{x}_i) + \boldsymbol{d}_i(\boldsymbol{x}_i, t)] \tag{45}$$

where $\boldsymbol{x}_0 \in \mathbb{R}^m$ and $\boldsymbol{v}_0 \in \mathbb{R}^m$ are the leader's state and velocity vectors, respectively; $\boldsymbol{x}_i \in \mathbb{R}^m$, $\boldsymbol{v}_i \in \mathbb{R}^m$, $\boldsymbol{u}_i \in \mathbb{R}^m$, and $\boldsymbol{d}_i \in \mathbb{R}^m$ are the i^{th} follower's state, velocity, control input, and disturbance vectors, respectively; $\boldsymbol{f}_0 \in \mathbb{R}^m$, $\boldsymbol{f}_i \in \mathbb{R}^m$, $\boldsymbol{d}_i \in \mathbb{R}^m$, $\boldsymbol{G}_0 \in \mathbb{R}^{m\times m}$ and $\boldsymbol{G}_i \in \mathbb{R}^{m\times m}$ are continuous uncertain functions. Disturbances $\boldsymbol{d}_i$ obey the conditions in assumptions 5, 8 and 9.

Assumption 10: The control matrices $\boldsymbol{G}_0$ and $\boldsymbol{G}_i$ are defined such that $\boldsymbol{G}_0 = \boldsymbol{diag}(1/\rho_{01}^2, .., 1/\rho_{0m}^2)$ and $\boldsymbol{G}_i = \boldsymbol{diag}(1/\rho_1^2, .., 1/\rho_m^2)$ where ρ_j denotes the control constraints along the $'j'$ motion direction.

The objective of second-order distributed consensus tracking is to design protocols $\boldsymbol{u}_i$ for dynamics (49) such that the following consensus agreement is achieved simultaneously by all the followers' dynamics and maintained for further time:

$$\lim_{t\to T}\|\boldsymbol{x}_i(t) - \boldsymbol{x}_0(t)\| = 0, \lim_{t\to T}\|\boldsymbol{v}_i(t) - \boldsymbol{v}_0(t)\| = 0 \ \ \forall i = 1,2,\dots,n \quad (46)$$

To apply STSM control to the second-order distributed consensus tracking problem, the sliding variables are defined, for $i = 1,..,n\ k = 1,..,m$, as follows:

$$\sigma_{i,k}(\boldsymbol{x}_i) = \sum_{j=0}^{n} a_{ij}\left[x_{i,k} - x_{j,k}\right] + c\sum_{j=0}^{n} a_{ij}\left[v_{i,k} - v_{j,k}\right] \quad (47)$$

where $c \in \mathbb{R}^+$.

B. Second-order Distributed Consensus Tracking

To address the problem of second-order distributed consensus tracking in its general form, the leader's dynamics are considered nonlinear dynamics with time-varying velocities. For n agents and m motion directions, the sliding manifold (48) and the consensus dynamics (44)-(45) are written, in matrix form, as follows:

$$\boldsymbol{\sigma} = \boldsymbol{\sigma}_x + c\boldsymbol{\sigma}_v \quad (48)$$

$$\dot{\boldsymbol{e}}_x = \boldsymbol{e}_v$$
$$\dot{\boldsymbol{e}}_v = \boldsymbol{F}(\boldsymbol{e}_v) + (\boldsymbol{M}\otimes\boldsymbol{I}_N)\big(\boldsymbol{G}(\boldsymbol{e}_v)\boldsymbol{U} - \boldsymbol{U}_0(\boldsymbol{x}_0)\big) \quad (49)$$

where $\boldsymbol{e}_x = [\widetilde{\boldsymbol{x}}_1^T, \dots, \widetilde{\boldsymbol{x}}_n^T]^T \in \mathbb{R}^N$, $\boldsymbol{e}_v = [\widetilde{\boldsymbol{v}}_1^T, \dots, \widetilde{\boldsymbol{v}}_n^T]^T \in \mathbb{R}^N$, $\boldsymbol{\sigma} = [\boldsymbol{\sigma}_1^T, \dots, \boldsymbol{\sigma}_n^T]^T \in \mathbb{R}^{2N}$, and c is a positive constant. The vectors $\widetilde{\boldsymbol{x}}_i$ are defined as in the previous section $\widetilde{\boldsymbol{x}}_i = \boldsymbol{x}_i - \boldsymbol{x}_0 \in \mathbb{R}^m$, $\widetilde{\boldsymbol{v}}_i = \boldsymbol{v}_i - \boldsymbol{v}_0 \in \mathbb{R}^m$, and $\boldsymbol{\sigma}_i = \left[\sigma_{i,1}, .., \sigma_{i,m}\right]^T \in \mathbb{R}^{2m}$; $\boldsymbol{U} = [\boldsymbol{u}_1^T, \dots, \boldsymbol{u}_n^T]^T \in \mathbb{R}^N$, $\boldsymbol{G}(\boldsymbol{e}_v) = [\boldsymbol{G}_1, \dots, \boldsymbol{G}_n]^T \in \mathbb{R}^{N\times m}$, and $\boldsymbol{U}_0 = \boldsymbol{rep}((\boldsymbol{G}_0\boldsymbol{u}_0)^T, N)^T \in \mathbb{R}^N$ with $(\boldsymbol{rep}(\boldsymbol{z}), n)$ denotes a vector formed by n replications of the vector $\boldsymbol{z}$.

Assumption 11. The following upper limit bounds the leader's control inputs

$$\|\boldsymbol{G}_0(\boldsymbol{x}_0)\boldsymbol{u}_0\|_\infty \le v_{0,max} \quad (50)$$

where $v_{0,max} \in \mathbb{R}^+$ is a control constraint.

Assumption 12: Suppose that dynamics (45) are bounded, $\lambda_{max}(\boldsymbol{M}) > 0$, and there exist some constants $l_M, l_G, \delta_v \in \mathbb{R}^+$, for which

$$\|\boldsymbol{F}(\boldsymbol{e}_v)\|_\infty \le \delta_v\|\boldsymbol{\sigma}\|_\infty^{\alpha_1}$$
$$\|\boldsymbol{G}(\boldsymbol{e}_v)\|_\infty \le l_G\lambda(\boldsymbol{G})_{max}$$
$$\|(\boldsymbol{M}\otimes\boldsymbol{I}_N)\|_\infty \le l_M\lambda(\boldsymbol{M})_{max} \quad (51)$$

Theorem 3: Suppose assumptions 1-4 and 10-12 hold. The following STSM protocol enforces the MAS (48)-(49) to satisfy the consensus condition (45) in finite time despite uncertainties and/or disturbances.

$$\boldsymbol{U} = -K_1 vect\big(|\sigma_k|^{\alpha_1} sign(\sigma_k)\big) + \boldsymbol{V} - \boldsymbol{\Theta}^T\boldsymbol{\Phi}(\boldsymbol{x})$$
$$\dot{\boldsymbol{V}} = -K_2 vect\big(|\sigma_k|^{\alpha_2} sign(\sigma_k)\big) \quad k = 1,..N \quad (52)$$

with $\alpha_2 = 2\alpha_1/(1+\alpha_1)$, $\boldsymbol{V} = [\boldsymbol{V}_1^T, \dots, \boldsymbol{V}_n^T]^T \in \mathbb{R}^N$, $\boldsymbol{V}_i \in \mathbb{R}^m$.

Proof: Consider the case of $\alpha_1 = 1/2$ in expression (52) and the nominal form of the consensus model (44)-(45) and select the following Lyapunov function:

$$V_{nom}(\boldsymbol{\xi}) = K_2\int_0^{\|\boldsymbol{\sigma}\|_\infty}\|\boldsymbol{z}\|_\infty^{\alpha_2}dz + \frac{1}{2}\|\boldsymbol{V}\|_\infty^2 \quad (53)$$

$$\boldsymbol{\xi} = [\|\boldsymbol{\sigma}\|_\infty \quad \|\boldsymbol{V}\|_\infty]^T \quad (54)$$

The time-derivative $\dot{V}_{nom}$ can be given as

$$\dot{V}_{nom} = \partial V/\partial\boldsymbol{\xi}.\dot{\boldsymbol{\xi}} = \langle K_2\|\boldsymbol{\sigma}\|_\infty^{\alpha_2} \quad \|\boldsymbol{V}\|_\infty\rangle\left[\|\dot{\boldsymbol{\sigma}}\|_\infty \quad \left\|\dot{\boldsymbol{V}}\right\|_\infty\right]^T \quad (55)$$

Assuming that

$$\|\dot{\boldsymbol{\sigma}}_x\|_\infty = -c\|\dot{\boldsymbol{\sigma}}_v\|_\infty \quad (56)$$

It results from expressions (49), (51) and (55) that

$$\dot{V}_{nom} \le \langle K_2\|\boldsymbol{\sigma}\|_\infty^{\alpha_2} \quad \|\boldsymbol{V}\|_\infty\rangle.$$
$$[(1-c)\|\boldsymbol{M}\otimes\boldsymbol{I}_N\|_\infty\big(\|\boldsymbol{F}(\boldsymbol{e}_v)\|_\infty + \|\boldsymbol{G}(\boldsymbol{e}_v)\|_\infty\big(K_1\|\boldsymbol{\sigma}\|_\infty^{\alpha_1} + \|\boldsymbol{V}\|_\infty\big) + \|\boldsymbol{U}_0\|_\infty\big) \quad K_2\|\boldsymbol{\sigma}\|_\infty^{\alpha_2}]^T \quad (57)$$

with

$$c = 1 + \lambda v(\lambda vmax_{max})max_{max} \quad (58)$$

and

$$\dot{V}_{nom} \le -\frac{\|\boldsymbol{M}\otimes\boldsymbol{I}_N\|_\infty K_2}{\lambda_{max}\big(\boldsymbol{G}(\boldsymbol{e}_v)\big)}\|\boldsymbol{\sigma}\|_\infty^{\alpha_2}.$$
$$\big(\|\boldsymbol{F}(\boldsymbol{e}_v)\|_\infty + K_1\|\boldsymbol{G}(\boldsymbol{e}_v)\|_\infty\|\boldsymbol{\sigma}\|_\infty^{\alpha_1} + \|\boldsymbol{G}(\boldsymbol{e}_v)\|_\infty\|\boldsymbol{U}_0\|_\infty\big) \quad (59)$$

Using the bounds (55) and (56), it results that

$$\dot{V}_{nom} \le -\frac{\lambda_{max}(\boldsymbol{M})l_M K_2}{\lambda_{max}\big(\boldsymbol{G}(\boldsymbol{e}_v)\big)}.$$
$$\begin{pmatrix}\delta_v\|\boldsymbol{\sigma}\|_\infty^{(\alpha1+\alpha_2)} + K_1 l_G\lambda_{max}(\boldsymbol{G}(\boldsymbol{e}_v))\|\boldsymbol{\sigma}\|_\infty^{(\alpha1+\alpha_2)} \\ +l_G\lambda_{max}(\boldsymbol{G}(\boldsymbol{e}_v))v\|\boldsymbol{\sigma}\|_{\infty\ 0,max}^{\alpha_2}\end{pmatrix} \quad (60)$$

end of the proof.

Lemma 5: Since V˙_nom is not strictly negative because V˙_nom=0 for ‖σ‖_∞=0, the asymptotic stability of the consensus tracking is guaranteed by the Krasovskii-LaSalle's invariance principle.

Proof of Lemma 5: Let $S = \left\{(\|\boldsymbol{\sigma}\|_\infty, \|\boldsymbol{V}\|_\infty) \in \mathbb{R}^2 : \dot{V}_{nom} = 0\right\}$, the asymptotic stability of the consensus tracking is guaranteed only if $S = \{(0,0)\}$. For $\lambda_{max}(\boldsymbol{M}) > 0$ and $\lambda_{max}(\boldsymbol{G}) > 0$, equation (64) has $\|\boldsymbol{\sigma}_v\|_\infty = 0$ as the only solution for $\dot{V}_{nom} = 0$. From the dynamics (49) and (52) the only remaining solution is $\|\boldsymbol{V}\|_\infty = 0$.

Lemma 6: In the case of structured disturbances, the asymptotic convergence of the extended Lyapunov function

$$V_{ext} = K_2 \int_0^{\|\sigma\|_\infty} \|z\|_\infty^{1/3} dz + \frac{1}{2}\|V\|_\infty^2 + \tilde{\Theta}^T \Gamma^{-1} \dot{\hat{\Theta}} \quad (61)$$

is guaranteed by the same conditions as in (63) and the observers (39) can be used to estimate the structured disturbances.

V. Simulation

The proposed consensus protocols and observers' effectiveness are evaluated in this section. Both first-order and second-order control algorithms are run using the Matlab simulation environment with a sampling time $\Delta t = 0.0001\ sec$.

A. First-order Planar Consensus without Disturbances

Consider a network of seven agents indexed by '1' to '7', respectively, to follow a virtual leader indexed by '0'performing the virtual graph under the undirected communication topology shown in Fig. 1(a). Starting from a given initial condition, the agents must follow a common path $(x_{0,1} = t + \sin(t), x_{0,2} = \sin(\pi t/3))$ to reach a desired position while avoiding obstacles as shown in Fig. 1(b). The dynamics of the leader are given by $\dot{x}_0 = sin(x_0(t))$. The conventional distributed consensus controllers (62) are applied to agents $i = 1,..,n$, with $\alpha = 100$, and $\beta = 25$. The results of the consensus tracking are shown in Fig. 2 to 4.

$$u_{i,k}(x_i) = -\alpha \sum_{j=0}^{n} a_{ij}(x_{i,k} - x_{j,k}) - \beta sign\left(\sum_{j=0}^{n} a_{ij}(x_{i,k} - x_{j,k})\right) \quad (62)$$

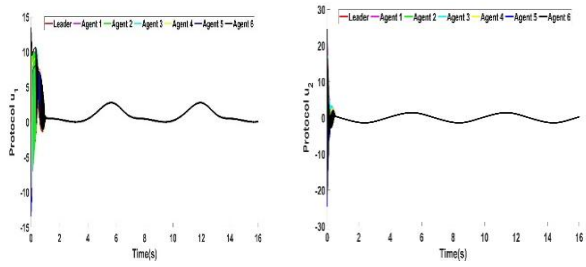

Fig. 4. Consensus protocols using STSM-based consensus (10): (a) Control effort u_{1i}, (b) Control effort u_{2i}.

B. First-order Consensus Tracking with Structured Disturbances

Consider a network of five agents indexed by '1' to '5', respectively and follow a virtual leader indexed by '0' under the communication topology shown in Fig. 5.

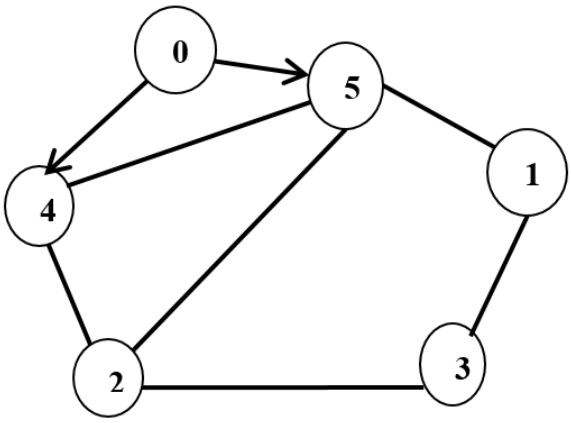

Fig. 5. The communication graph for a network of seven agents.

In this scenario, the five agents must follow a common path with the presence of structured disturbances associated with each agent's state as defined in assumption 9 with an arbitrarily selected parameter vector $\boldsymbol{\theta_i}$

$$\boldsymbol{\theta} = \begin{bmatrix} 2 & -5 & 4 & 5 & 3.5 \\ 5 & 3 & -4 & 3.6 & 2 \end{bmatrix}^T \tag{63}$$

and state-dependent base functions $\boldsymbol{\varphi_i}$

$$\boldsymbol{\varphi}_i(\boldsymbol{x}_i) = [sin(2x_{i,1}) \quad sin(2x_{i,2})]^T \tag{64}$$

The STSM-based distributed consensus protocols (9) is applied with $K_1 = 15$ and $K_2 = 30$. The disturbance observer is applied with

$$\boldsymbol{\rho} = \begin{bmatrix} 16 & 576 & 13.5 & 27 & -20 \\ 55 & 24 & 19.5 & 7.5 & 3.5 \end{bmatrix}^T \tag{65}$$

The consensus tracking, and an example for disturbance estimation and parameters updating are shown in Fig. 6 and Fig. 7.

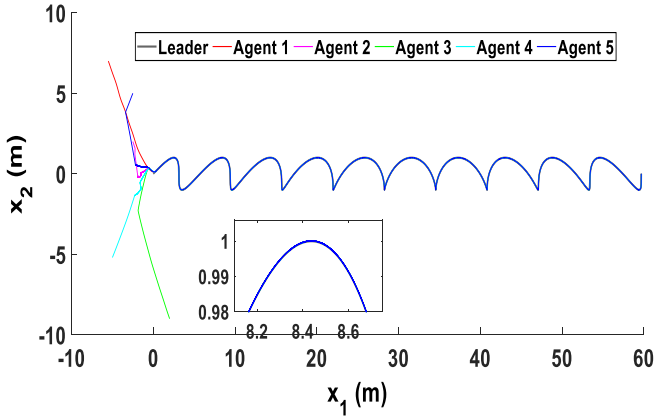

Fig. 6. Consensus tracking among the 5 agents.

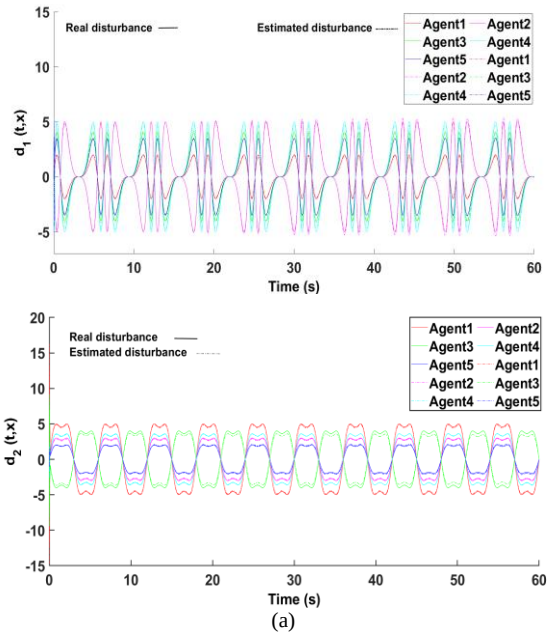
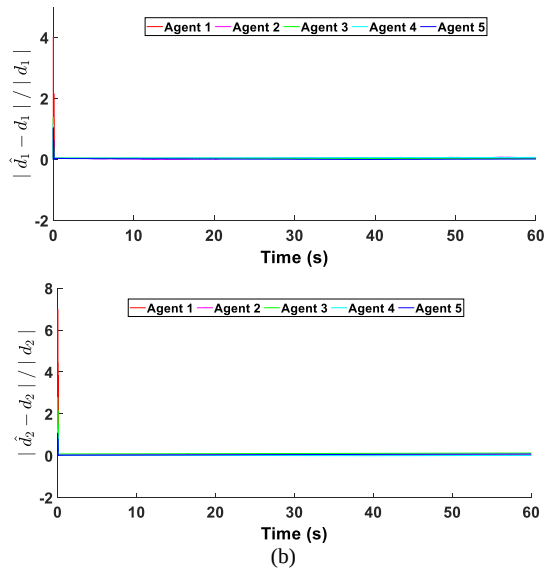


(a)

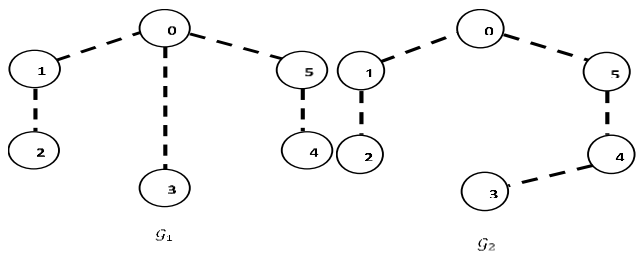


(b)

Fig. 7. Disturbance estimation for agents 1 and 2 using proposed observer: (a) Estimations (b) Estimator errors.

C. Second-order Consensus Tracking with Structured Disturbances

In this scenario, the performance and robustness of the proposed STSM-based protocol for second-order systems are simulated using a switched topology $\{\bar{\mathcal{G}}_1, \bar{\mathcal{G}}_2, \bar{\mathcal{G}}_3, \bar{\mathcal{G}}_4\}$ with switching period $\tau = 10sec$ as shown in Fig. 8.



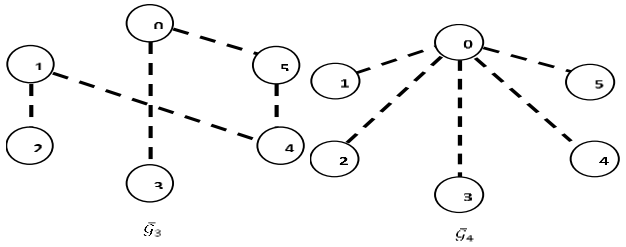


Fig. 8. Fixed-time switching topology.

For the disturbances, an agent's state dependent component is added to the time-varying disturbances with $\theta = [1\ \ 0.5\ \ 0.6\ \ 0.8\ \ 0.2]^T$ and φ_i functions given by (66)

$$\begin{cases} \varphi_1(t,x_1) = cos(0.1t)\, sin(x_1) \\ \varphi_2(t,x_2) = sin\left(0.5\,t + \frac{\pi}{4}\right) sin(x_2) \\ \varphi_3(t,x_3) = cos(3t)\, sin(x_3) \\ \varphi_4(t,x_4)\, sin\left(2\,t + \frac{\pi}{3}\right) sin(x_4) \\ \varphi_5(t,x_5) = \begin{cases} \left((sin(\omega_1 t) - 1)\, sin(x_5)\ \text{ for t<30 sec}\right) \\ \left((sin(\omega_1 t) + 1)\, sin(x_5)\ \text{for t}\geq\text{30 sec}\right) \end{cases} \\ \omega_1 = 2\pi\left(\frac{5.9t}{60} + 0.1\right),\ \ \omega_2 = 2\pi\left(-\frac{5.9t}{60} + 6\right) \end{cases} \tag{66}$$

Accurate robust finite-time consensus tracking is achieved using the proposed STSM-based protocol as shown in Fig. 9. The simulation was run with $\alpha_1 = 1/3$, $\alpha_2 = 1/2$, $c = 5$, $K_1 = 1.5$, $K_2 = 1.9$ and $\boldsymbol{\rho} = diag(10^{-3}[-20.25\ -4.25\ 9.75\ 19\ 23])$.

VI. Conclusion

This paper introduced a novel finite-time synchronization framework for multi-agent systems (MAS) operating under switching communication topologies, addressing scenarios with and without direct velocity measurements. By integrating graph-theoretic principles, local finite-time convergence theory for homogeneous systems, and the non-smooth LaSalle's invariance principle, we developed a distributed control strategy ensuring precise synchronization of agents' states and velocities. The proposed control laws exhibit inherent robustness to topology variations, communication constraints, and dynamic agent interactions, making them suitable for real-world applications, including satellite formation flying, autonomous robotic networks, and cooperative unmanned aerial vehicles (UAVs).

To further enhance robustness and reduce communication overhead, we introduced a finite-time high-order sliding-mode observer, enabling agents to accurately estimate relative velocity states without direct measurements. This observer-based strategy mitigates reliance on continuous inter-agent communication, ensuring high-precision synchronization even under sensor limitations, intermittent connectivity, and external disturbances. The developed framework is inherently scalable, allowing seamless integration into large-scale distributed systems where centralized coordination is impractical or infeasible.

The results presented in this study establish a resilient and computationally efficient control paradigm for distributed synchronization in MAS, providing a strong foundation for

future advancements in autonomous and cooperative multi-agent technologies. Future work will address key challenges in inter-agent communication, such as signal interference, transmission delays, and adaptive information-sharing protocols, to further enhance the real-time performance and robustness of distributed synchronization mechanisms in increasingly complex operational environments. The extension of this framework to heterogeneous agent networks, cooperative task execution, and event-triggered control will be explored to support the next generation of intelligent and autonomous multi-agent systems. Moreover, the present work could be extended beyond bounded perturbation assumptions by exploring adaptive learning-based control, stochastic models, and event-triggered MPC for real-time disturbance adaptation. Additionally, higher-order sliding mode and hybrid multi-agent reinforcement learning (MARL) approaches will be investigated to enhance robustness in highly uncertain environments. These advancements will improve the applicability of the proposed framework to real-world multi-agent systems.

ACKNOWLEDGMENT

This project was funded by the Deanship of Scientific Research (DSR) at King Abdulaziz University, Jeddah, under grant no. (GPIP:1426-135-2024). The authors, therefore, acknowledge with thanks DSR for technical and financial support.

AI-Driven Intrusion Detection in IoV Communication: Insights from CICIoV2024 Dataset

Nourah Fahad Janbi
Department of Information Technology, College of Computing and Information Technology at Khulais, University of Jeddah, Jeddah, Saudi Arabia

***Abstract*—The increasing interconnectivity of vehicular networks through the Internet of Vehicles (IoV) introduces significant security challenges, particularly for the Controller Area Network (CAN), a widely adopted protocol vulnerable to cyberattacks such as spoofing and Denial-of-Service (DoS). To address these challenges, this study explores the potential of Intrusion Detection Systems (IDSs) leveraging artificial intelligence (AI) techniques to detect and mitigate malicious activities in CAN communications. Using the CICIoV2024 dataset, which provides a realistic testbed of vehicular traffic under benign and malicious conditions, we evaluate 25 machine learning (ML) models across multiple metrics, including accuracy, balanced accuracy, F1-score, and computational efficiency. A systematic and repeatable approach was proposed to facilitate testing multiple models and classification scenarios, enabling a comprehensive exploration of the dataset's characteristics and providing insights into various ML algorithms' effectiveness. The findings highlight the strengths and limitations of various algorithms, with ensemble-based and tree-based models demonstrating superior performance in handling imbalanced data and achieving high generalization. This study provides insights into optimizing IDSs for vehicular networks and outlines recommendations for improving the robustness and applicability of security solutions in real-world IoV scenarios.**

I. Introduction

The Internet of Things (IoT) has revolutionized how devices interact, seamlessly connecting billions of smart devices across homes, industries, and cities [1], [2]. Recent advancements have focused on enhancing real-time data processing, energy efficiency, and scalability. Technologies such as edge computing, 5G/6G networks, and lightweight Machine Learning (ML) models have enabled IoT devices to process data locally, reducing latency, network congestion, and reliance on cloud-based systems [3], [4]. Artificial Intelligence (AI) plays a pivotal role in this transformation by enabling IoT devices to analyze vast amounts of data, derive actionable insights, and adapt to changing environments autonomously [5], [6].

In the domain of IoT security, AI can enhance threat detection, intrusion prevention, and secure authentication. Techniques such as anomaly detection, generative adversarial networks (GANs) for simulating cyber-attacks, and reinforcement learning for adaptive defense strategies enable IoT systems to identify and mitigate potential vulnerabilities proactively [7], [8]. By integrating AI, IoT ecosystems are becoming not only more efficient but also more resilient against evolving cybersecurity threats [9].

Similarly, vehicular networks and the Internet of Vehicles (IoV) leverage IoT to enhance traffic management and enable autonomous driving, but it also faces significant security threats due to its high interconnectivity and dependence on IoT components. Potential attacks exploit both inter-vehicle and intra-vehicle vulnerabilities (see Fig. 1). For instance, GPS spoofing attacks mislead vehicle navigation systems by transmitting false location data, potentially causing accidents [10], [11]. Replay attacks involve retransmitting valid network messages to disrupt real-time vehicle functionality, while Sybil attacks flood the network with fake vehicle nodes to manipulate traffic or force detours [10]. Additionally, Denial-of-Service (DoS) attacks can overwhelm the IoV network, leading to service outages that compromise vehicular operations. Attacks on Electronic Control Units (ECUs) and sensors, such as malware injection, jeopardize vehicle decision-making by tampering with critical system data [11]. One real-world example includes hackers tricking Tesla's Autopilot software into swerving into oncoming traffic lanes, demonstrating the tangible risks of compromised IoV security.

Fig. 1. Potential security threats in IoV.

Addressing these vulnerabilities requires advanced security measures, such as AI-driven intrusion detection systems (IDSs) and robust cryptographic protocols, to safeguard the integrity, availability, and confidentiality of IoV networks.

In this paper, we focus on the security of IoV and, specifically, the security of the Controller Area Network (CAN). The CAN is one of the commonly adopted communication protocols in vehicle and industrial systems for data exchange between ECUs without a central host computer. Despite its widespread use, the CAN protocol suffers from inherent security vulnerabilities, such as the lack of encryption

and authentication, making it susceptible to spoofing, DoS, and replay attacks [12].

Traditional IDSs, such as signature-based and rule-based approaches, face significant challenges securing CAN networks. These conventional methods often suffer from high false positive rates, difficulty in adapting to novel attack patterns, and computational inefficiencies that limit their real-time applicability in resource-constrained vehicular environments. Furthermore, their reliance on predefined attack signatures makes them ineffective against zero-day attacks and evolving adversarial techniques [13]. On the other hand, AI-driven IDSs based on advanced ML and Deep Learning (DL) techniques can play a crucial role in enhancing cyberattack detection, prevention, and mitigation [14]. These ML and DL algorithms can effectively identify abnormal IoV traffic and request patterns, contributing to the early detection and mitigation of potential attacks.

As most existing research on CAN has primarily addressed these issues through theoretical solutions or simulated environments, Neto et al. [15] introduced the CICIoV2024 dataset to bridge the gap and provide a realistic testbed for IDSs focusing on CAN security. The dataset includes diverse attack types specific to CAN bus communication, such as DoS and spoofing (steering wheel, RPM, speed, gas). Since this dataset is considered recent, it requires comprehensive investigation.

Researchers in studies [15]–[17] conducted some comparative analyses on multiple ML algorithms using the CICIoV2024 dataset. However, the unrealistically high performance raises concerns about overfitting or dataset-specific optimizations, suggesting the need for comprehensive evaluation and broader testing on diverse datasets. This paper aims to bridge this gap by leveraging the CICIoV2024 dataset and evaluating a diverse range of ML models on this dataset, highlighting their strengths and limitations, and proposing recommendations for enhancing the robustness and applicability of IDSs in real-world IoV scenarios.

The main contributions can be outlined as follows:

- Comprehensively investigate the CICIoV2024 dataset and evaluate a diverse range of ML models on this dataset, highlighting their strengths and limitations.
- Propose a systematic and repeatable approach that facilitates testing multiple models and classification scenarios to comprehensively explore the dataset's characteristics and provide insights into the effectiveness of various ML algorithms on that dataset.
- Perform data cleaning step during preprocessing to ensure a more accurate representation of feature interactions, making the dataset more suitable for reliable ML analysis and reducing the risk of overfitting caused by repeated patterns.
- Provide insights into optimizing IDSs for vehicular networks and outline recommendations for improving security solutions' robustness and applicability in real-world IoV scenarios.

The rest of the paper is organized as follows: Section II reviews the related works. Section III explains our methodology. Section IV discusses the results of ML models and outlines recommendations. Section V concludes the paper.

II. Related Works

This section reviews recent studies that have employed ML and DL techniques for intrusion detection, highlighting their contributions and limitations. Table I provides a summary of related works.

TABLE I. Related Works Summary

Ref.	Key Features	Limitations
Subasi et al. [18]	-Focus on interpretable and explainable ML -Use of Decision Trees and Ridge Classifiers -Introduction of cross-explanations	-Limited to feature-based explanations -Challenges with aleatoric uncertainties and feature correlations
Mahdi et al. [19]	-Hybrid approach combining LSTM and Naive Bayes -Three-stage methodology	-High complexity of hybrid model -May require significant computational resources
Aswal et al. [16]	-DL-based intrusion detection model for CAN -Focus on real-time detection	-Lacks comparative evaluation with hybrid methods
Neto et al. [15]	-Introduced the CICIoV2024 dataset -Emphasizes the importance of realistic CAN scenarios	-Dataset limited to specific attack scenarios -Immobile vehicle constraints
Amirudin et al. [17]	-Comparative analysis of ML algorithms like LightGBM, XGBoost, CatBoost	-Unrealistically high performance raises concerns about overfitting or dataset-specific optimizations
Tasci [20]	-Optimized CNN model for IoT security -Focus on lightweight architecture for real-time applications	-Limited exploration of diverse attack types -Scalability to larger datasets requires further validation

Subasi et al. [18] explored interpretable ML approaches for intrusion detection, focusing on enhancing model explainability using Decision Trees and Ridge Classifiers. By incorporating cross-explanation mechanisms and evaluating models with metrics like balanced accuracy and Matthews Correlation Coefficient, the study emphasized the need for interpretable systems in IDSs. However, challenges such as feature correlations and aleatoric uncertainties limit their applicability in more complex scenarios.

Building on this, Mahdi et al. [19] proposed a hybrid ML-DL framework, combining LSTM and Naive Bayes models for intrusion detection in IoT networks. This hybrid approach leverages the strengths of both DL's pattern recognition and ML's efficiency, achieving strong results on the CICIoV2024 dataset. However, its computational intensity highlights a trade-off between accuracy and feasibility for real-time applications, raising the importance of lightweight and scalable solutions.

Focusing on the IoV, Neto et al. [15] introduced the CICIoV2024 dataset that was designed for testing ML-based IDSs in IoVs. They evaluated Logistic Regression, Random

Forest, AdaBoost, and Deep Neural Network (DNN) model's ability to detect and classify malicious activities. Their findings highlight the challenges of addressing cybersecurity in IoV due to imbalanced datasets and similarities between benign and malicious traffic.

Aswal et al. [16] developed a DL-based IDS targeting vulnerabilities in the CAN protocol. Their model demonstrated effective real-time detection of various attacks using the CICIoV2024 dataset. Similarly, Amirudin et al. [17] conducted a comparative analysis of advanced ML algorithms, including LightGBM, XGBoost, and CatBoost, using the CICIoV2024 dataset. However, the unrealistically high performance raises concerns about overfitting or dataset-specific optimizations, suggesting the need for comprehensive evaluation and broader testing on diverse datasets.

Expanding beyond vehicular networks, Tasci [20] introduced an optimized convolutional neural network (CNN) for IoT security, achieving high performance on multiple datasets, including CIC-IoT2023, CIC-MalMem-2022, and CIC-IDS2017. This lightweight model demonstrated suitability for real-time applications, addressing computational limitations observed in hybrid approaches. However, its scalability to larger datasets and handling of diverse attack types requires further investigation.

Despite significant advancements in using ML and DL for intrusion detection in IoT and IoV, several critical research gaps remain. High-performing models often exhibit overfitting, as seen in studies achieving near-perfect accuracy, highlighting the need for comprehensive evaluation and robust evaluation across diverse datasets. Computational complexity is another challenge, with many hybrid and DL models being resource-intensive and unsuitable for real-time applications. Furthermore, since CICIoV2024 is a newly introduced dataset, there is a limited amount of research exploring its usability and potential applications. This creates an opportunity to evaluate its effectiveness in training and testing various ML and DL models for intrusion detection in vehicular networks. In addition, most research prioritizes accuracy and F1-scores over other metrics. In this study, we address these gaps by conducting a comprehensive evaluation of advanced ML and DL models on the CICIoV2024 dataset.

III. Methodology

In this section, we discuss the research methodology we followed in detail. We adopted a systematic and repeatable approach that facilitates testing multiple models and classification scenarios to comprehensively explore the dataset's characteristics and provide insights into the effectiveness of various ML algorithms on that dataset.

The flowchart in Fig. 2 provides a visual representation of the methodology followed in this paper for training and testing ML models on the CICIoV2024 dataset. The process starts with initializing the dataset and models, followed by removing duplicate entries to ensure data quality. The dataset is then split into training and testing subsets, guaranteeing a balanced evaluation of the models.

Each classification type (e.g., labels, categories, and specific classes) is processed iteratively, with labels converted to numeric values to make the dataset compatible with ML algorithms. For every classification type, the models are trained using the training dataset and evaluated on the testing dataset. The results of each model, for all classifications, are collected and stored. This process is repeated for all classifications and models to ensure comprehensive experimentation.

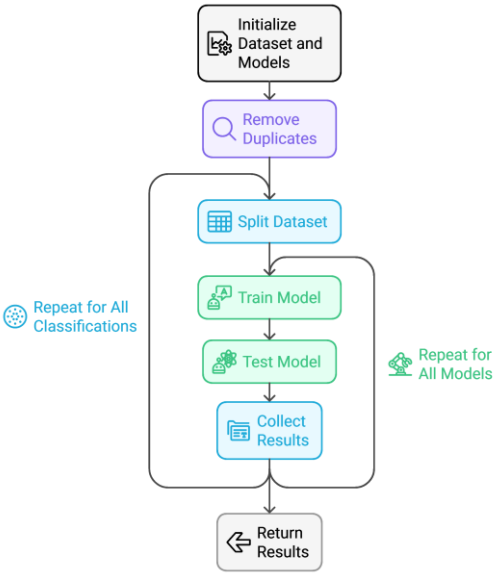

Fig. 2. Methodology flowchart.

The final step involves returning the results for analysis and comparison. This methodology ensures a systematic approach to testing multiple models and classification scenarios, providing insights into the effectiveness of various ML algorithms on the dataset. The combination of data preprocessing, iterative model training, and evaluation ensures a robust experimental setup.

Algorithm 1: Models Training and Testing

Input: CICIoV2024 Dataset
Output: Results // lists of results for all models

```
Function: evaluate_models(CICIoV2024)
    Init: Models ← set of models,
          Classifications ← {label, category, class},
          Results ← empty set for results.
    For dataset in Dataset
      //Dataset Preprocessing
      dataset ← dataset.removeDuplicate()
      For class_type in Classifications
        // Covert labels to numeric values
        dataset ← dataset.numericValues()
        // Split dataset
        x_train,y_train,x_test,y_test← dataset.split(test_size=0.3)
        For model in Models
          // Train model
          train_result= model.train(x_train, y_train)
          // Test model
           test_result= model.test(x_test,y_test)
          Results.add(train_result,test_result)
        End For
    End For
End For
Return Results
```

Algorithm 1 details the step-by-step implementation of the process used in the study. The input to the algorithm is the CICIoV2024 dataset, while the output is a set of results capturing the performance of all models across different classifications. The following subsections will discuss steps in detail.

A detailed breakdown of the features of the CICIoV2024 dataset is provided in Table II. Each instance in the dataset includes an ID field, which denotes the arbitration ID used to determine message priority on the CAN bus, and DATA_0 to DATA_7, which represents the eight-byte payload of CAN messages. Additionally, the dataset includes labels for classifying traffic as benign or malicious, with malicious traffic further categorized into DoS and Spoofing types. Spoofing attacks are further specified into classes such as Speed Spoofing, RPM Spoofing, Gas Spoofing, and Steering Wheel Spoofing. These features provide a granular view of vehicular communication, enabling detailed analysis and the application of ML techniques for intrusion detection.

TABLE II. CICIOV2024 DATASET FEATURES

Feature Name	Description
ID	ID indicating the message priority and type of data being transmitted
DATA_0 to DATA_7	Data fields (Byte 0 to Byte 7) contain the payload of CAN bus messages
Label	Classification of the traffic as benign or malicious
Category	Category of the traffic (DoS or Spoofing)
Specific Class	Specific malicious traffic class (Speed Spoofing, RPM Spoofing, or Gas Spoofing)

Table III summarizes the dataset composition, labeling traffic data instances into benign and malicious types. Benign traffic, representing normal vehicle operations, forms the bulk of the dataset with 1,223,737 instances. Malicious traffic, with 184,482 instances, is divided into two primary categories: DoS and Spoofing. DoS traffic consists of 74,663 instances while Spoofing traffic includes subcategories (specific classes) like Gas Spoofing (9,991 instances), Steering Wheel Spoofing (19,977 instances), Speed Spoofing (24,951 instances), and RPM Spoofing (54,900 instances). This distribution reflects the predominance of benign operations in real-world scenarios and highlights specific malicious activities.

TABLE III. CICIOV2024 DATASET SUMMARY

Traffic type	Category	Specific Class	Number of Instances	Total
Benign	-	-	1,223,737	1,223,737
Malicious	DoS	-	74,663	184,482
	Spoofing	Gas Spoofing	9,991	
		Steering Wheel	19,977	
		Speed Spoofing	24,951	
		RPM Spoofing	54,900	

A. Machine Learning Models

The CICIoV2024 dataset was used to train a diverse set of ML models (25 models) representing a variety of algorithm families and to evaluate its effectiveness comprehensively. Ensemble-based methods included AdaBoost Classifier (AdaBoostClassifier), Bagging Classifier (BaggingClassifier), and Random Forest Classifier (RandomForestClassifier), which combine multiple models to enhance prediction accuracy. Naive Bayes algorithms, such as Bernoulli Naive Bayes (BernoulliNB) and Gaussian Naive Bayes (GaussianNB), were utilized for probabilistic modeling. The Calibrated Classifier Cross-Validation (CalibratedClassifierCV) was employed as a probability calibration method to refine predictive probabilities. Decision tree-based models encompassed Decision Tree Classifier (DecisionTreeClassifier), Extra-tree Classifier (ExtraTreeClassifier), Extra-trees Classifier (ExtraTrees), Light Gradient Boosting Machine Classifier (LGBMClassifier), and Extreme Gradient Boosting Classifier (XGBClassifier), which are widely used for their interpretability and efficiency. Neighbors algorithms, including k-nearest Neighbors (KNeighborsClassifier) and Nearest Centroid Classifier (NearestCentroid), were applied for instance-based learning.

Linear models trained on the dataset included Logistic Regression Classifier (LogisticRegression), Passive Aggressive Classifier (PassiveAggressiveClassifier), Linear Perceptron Classifier (Perceptron), Ridge Classifier (RidgeClassifier), Ridge Classifier with Cross-Validation (RidgeClassifierCV), and Linear classifiers with Stochastic Gradient Descent (SGDClassifier), which are effective for high-dimensional data. Semi-supervised learning techniques, such as Label Propagation Classifier (LabelPropagation) and LabelSpreading Classifier (LabelSpreading), were also employed. Support Vector Machine algorithms, including C-Support Vector Classification (SVC) and Linear Support Vector Classification (LinearSVC), were used for their robustness in handling complex classification problems. In addition, Linear Discriminant Analysis model (LinearDiscriminantAnalysis) and Dummy Classifier (DummyClassifier) were trained. This extensive range of algorithms ensured a thorough exploration of the dataset's predictive potential.

B. Duplicate Removal

Data duplication removal from the dataset is one of the essential steps during data cleaning, ensuring that the data is accurate and reliable for further analysis or modeling [21]. In addition, a large volume of duplicated data might reduce data diversity and representativeness, leading to overfitting or biased models.

In our study, we used the drop_duplicates method from the Pandas library to remove duplicates in the CICIoV2024 dataset. Table IV and Fig. 3 show the distribution of data across different classifications after duplicate entries were removed, reducing the dataset size significantly from 1,408,219 instances to 3,588 instances. The distribution is displayed for three levels of classification: Label, Category, and Specific Class. At the Label level, the data is divided into benign and malicious, with a noticeable decrease in benign traffic proportion due to deduplication. At the Category level, malicious traffic is further subdivided into DoS and various spoofing types. Finally, at the Specific Class level, the spoofing category is broken down into detailed subcategories, including gas spoofing, steering wheel spoofing, and RPM spoofing, each with a smaller representation.

TABLE IV. DATASET DISTRIBUTION AFTER DEDUPLICATION

	Benign	Malicious DoS	Malicious Spoofing Gas Spoofing	Malicious Spoofing Steering Wheel	Malicious Spoofing RPM Spoofing
Label	3,547	41			
Category	3,547	21	20		
Specific Class	3,547	21	10	5	3

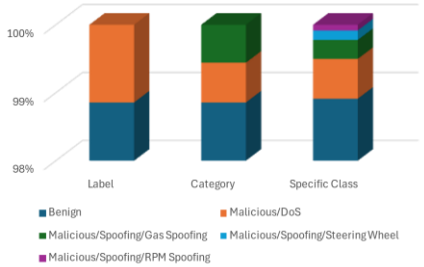

Fig. 3. Data distribution across label, category, and specific class classifications after deduplication.

After that, we compared the feature correlations in the CICIoV2024 dataset before and after duplicate removal, emphasizing the impact of preprocessing on data quality (see Fig. 4 and Fig. 5). Fig. 4, which represents the original dataset with duplicates, shows amplified correlations across several features, as evident from the brighter areas in the heatmap. These inflated relationships are likely caused by repeated data points, which can obscure unique interactions between features and introduce biases in ML models. In contrast, Fig. 5, generated after duplicate removal, exhibits more balanced and refined correlations, with reduced intensity in previously dominant relationships. This indicates a cleaner dataset where the true relationships among features are better preserved. The duplicate removal process not only eliminates redundancy but also ensures a more accurate representation of feature interactions, making the dataset more suitable for reliable ML analysis and reducing the risk of overfitting caused by repeated patterns.

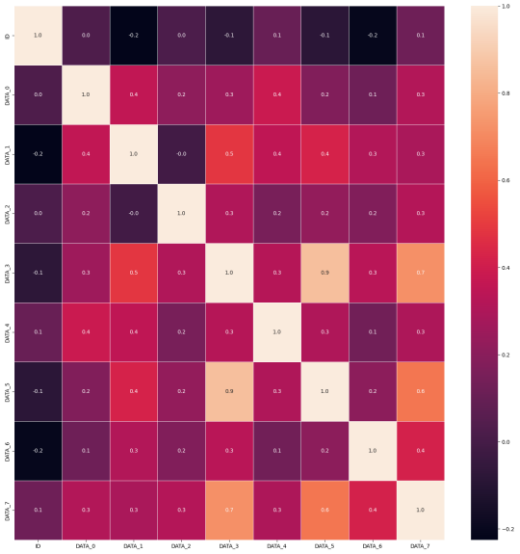

Fig. 4. Dataset heatmap of features correlation (Original dataset).

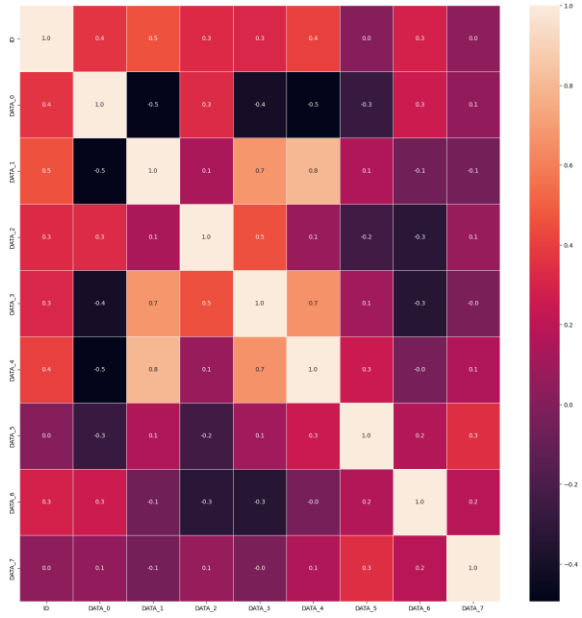

Fig. 5. Dataset heatmap of features correlation (Duplicate removed).

C. Dataset Splitting

Data splitting is a critical step to ensure robust evaluation of ML models. After preprocessing the dataset by removing duplicates and converting labels into numeric values, the dataset is split into training and testing subsets using the StratifiedShuffleSplit method, which combines the characteristics of ShuffleSplit (randomized splitting) and StratifiedKFold (maintaining the proportion of classes in each subset). This ensures that the training and testing sets have similar class distributions, preserving the balance of the data. The dataset is divided into a 70/30 ratio, where 70% is used for training the models to learn patterns and relationships, and 30% is reserved for testing, providing an unbiased evaluation of model performance. The final training set size was 2,511, and the training set size was 1,007 instances.

IV. RESULTS AND DISCUSSION

This section discusses the training and testing results of the ML models trained using the CICIoV2024 dataset with both Decimal (D) and Binary (B) formats. Performance metrics evaluated include accuracy, balanced accuracy, F1-score, and processing time. Balanced accuracy takes into account the accuracy of different classes separately and then calculates the mean. On the other hand, F-score keeps the balance between precision and recall. Both metrics help evaluate the sensitivity and specificity of the models, and they are particularly important when dealing with imbalanced data.

A. Accuracy

Results in Table V, Table VI, and bar charts in Fig. 6 compare the training and testing accuracy of various ML models across different classifications (Category, Label, and Class) in both decimal and binary formats. This comparison highlights their performance consistency and generalizability.

In the training accuracy results, most models, such as DecisionTreeClassifier, ExtraTreesClassifier, XGBClassifier,

and LGBMClassifier, achieved near-perfect scores (1.00) across all classification levels (Category, Label, and Class in both Decimal and Binary formats), reflecting their ability to learn from the training data thoroughly. However, models like NearestCentroid and GaussianNB showed slightly lower training accuracies in specific scenarios.

TABLE V. TRAINING ACCURACY OF ALL MODELS

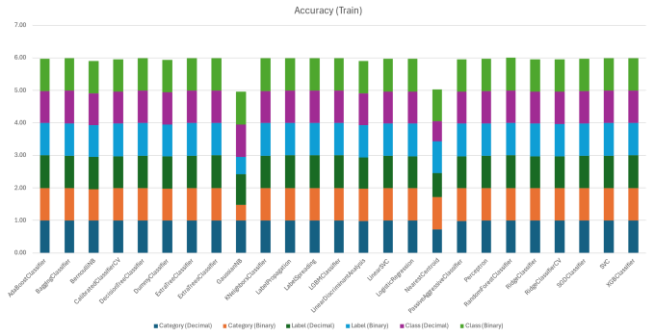
Model	Category (D)	Category (B)	Label (D)	Label (B)	Class (D)	Class (B)
AdaBoost	1.00	0.99	1.00	1.00	0.99	0.99
Bagging	1.00	1.00	1.00	1.00	1.00	1.00
Bernoulli NB	0.99	0.97	0.99	0.97	0.99	0.99
Calibrated CV	0.99	1.00	0.99	1.00	0.99	1.00
Decision Tree	1.00	1.00	1.00	1.00	1.00	1.00
Dummy Classifier	0.99	0.99	0.99	0.99	0.99	0.99
Extra Tree	1.00	1.00	1.00	1.00	1.00	1.00
Extra Trees	1.00	1.00	1.00	1.00	1.00	1.00
Gaussian NB	0.99	1.00	0.95	0.53	1.00	1.00
K Neighbors	1.00	1.00	1.00	1.00	0.99	1.00
Label Propagation	1.00	1.00	1.00	1.00	1.00	1.00
Label Spreading	1.00	1.00	1.00	1.00	1.00	1.00
LGBM Classifier	1.00	1.00	1.00	1.00	1.00	1.00
Linear Discriminant	0.97	1.00	0.97	1.00	0.97	1.00
Linear SVC	0.99	1.00	0.99	1.00	0.99	1.00
Logistic Regression	0.99	1.00	0.99	1.00	0.99	1.00
Nearest Centroid	0.72	0.99	0.74	0.99	0.62	0.97
Passive Aggressive	0.99	1.00	0.99	1.00	0.98	1.00
Perceptron	0.99	1.00	0.99	1.00	0.99	1.00
Random Forest	1.00	1.00	1.00	1.00	1.00	1.00
Ridge Classifier	0.99	1.00	0.99	1.00	0.99	1.00
Ridge CV	0.99	1.00	0.99	1.00	0.99	1.00
SGD Classifier	0.99	1.00	0.99	1.00	0.99	1.00
SVC	1.00	1.00	1.00	1.00	0.99	1.00
XGB Classifier	1.00	1.00	1.00	1.00	1.00	1.00

In contrast, the testing accuracy results showed minor variations, with some models slightly underperforming compared to their training accuracy. For instance, GaussianNB exhibited a noticeable drop in accuracy for Label (Binary) classification, indicating challenges in generalization. Similarly, NearestCentroid demonstrated lower accuracy across most classifications, reflecting its limitations with complex data structures. However, ensemble-based models, including AdaBoostClassifier, BaggingClassifier, and RandomForestClassifier, maintained consistently high accuracy in both training and testing, demonstrating their robustness and ability to generalize effectively.

TABLE VI. TESTING ACCURACY OF ALL MODELS

Model	Category (D)	Category (B)	Label (D)	Label (B)	Class (D)	Class (B)
AdaBoost	0.99	1.00	1.00	1.00	0.99	0.99
Bagging	1.00	0.99	1.00	1.00	1.00	0.99
Bernoulli NB	0.99	0.97	0.99	0.96	0.99	0.99
Calibrated CV	0.99	1.00	0.99	1.00	0.99	1.00
Decision Tree	1.00	0.99	0.99	1.00	0.99	0.99
Dummy Classifier	0.99	0.99	0.99	0.48	0.99	0.99
Extra Tree	1.00	0.99	1.00	1.00	0.99	0.99
Extra Trees	1.00	1.00	1.00	1.00	1.00	1.00
Gaussian NB	0.99	0.49	0.94	0.84	1.00	1.00
K Neighbors	0.99	1.00	1.00	1.00	1.00	0.99
Label Propagation	1.00	1.00	1.00	1.00	1.00	0.99
Label Spreading	1.00	1.00	1.00	1.00	1.00	0.99
LGBM Classifier	1.00	1.00	1.00	0.88	1.00	1.00
Linear Discriminant	0.97	1.00	0.96	0.84	0.96	0.99
Linear SVC	0.99	1.00	0.99	1.00	0.99	0.99
Logistic Regression	0.99	1.00	0.99	1.00	0.99	0.99
Nearest Centroid	0.71	0.99	0.73	0.92	0.62	0.97
Passive Aggressive	0.99	1.00	0.99	1.00	0.98	0.99
Perceptron	0.99	1.00	0.99	1.00	0.99	0.99
Random Forest	1.00	1.00	1.00	1.00	1.00	1.00
Ridge Classifier	0.99	1.00	0.99	1.00	0.99	1.00
Ridge CV	0.99	1.00	0.99	1.00	0.99	1.00
SGDClassifier	0.99	1.00	0.99	1.00	0.99	0.99
SVC	0.99	1.00	1.00	1.00	0.99	0.99
XGB Classifier	1.00	1.00	0.99	1.00	0.99	0.99

Overall, the comparison underscores the reliability of tree-based and ensemble models, which consistently perform well in both training and testing scenarios. It also highlights the importance of balanced model evaluation in identifying overfitting or generalization issues, as seen with certain algorithms like GaussianNB and NearestCentroid.



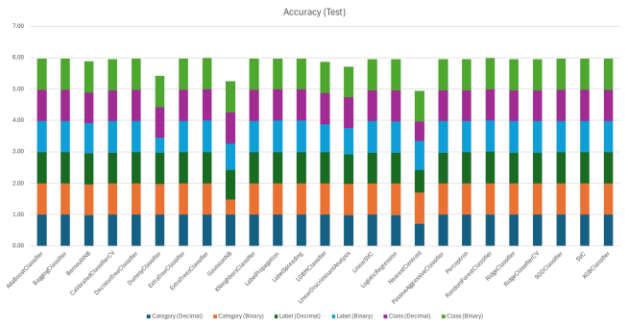


Fig. 6. Comparison of training and testing accuracy of all models.

B. Balanced Accuracy

The balanced accuracy results (see Table VII and Table VIII and Fig. 7) reveal how well the models handle imbalanced data during training and testing. Many models, such as DecisionTree, ExtraTreesClassifier, and XGBClassifier, achieved perfect balanced accuracy across all classifications in both formats during training, indicating their ability to learn effectively from imbalanced data.

TABLE VII. TRAINING BALANCED ACCURACY OF ALL MODELS

Model	Category (D)	Category (B)	Label (D)	Label (B)	Class (D)	Class (B)
AdaBoost	0.86	0.85	1.00	1.00	0.30	0.17
Bagging	0.95	1.00	0.98	0.98	0.99	1.00
Bernoulli NB	0.68	0.92	0.77	0.92	0.25	0.67
Calibrated CV	0.33	1.00	0.50	1.00	0.17	0.52

Linear Discriminant	0.33	0.96	0.48	0.83	0.33	0.56
Linear SVC	0.33	1.00	0.58	1.00	0.17	0.56
Logistic Regression	0.33	0.96	0.54	1.00	0.19	0.39
Nearest Centroid	0.63	0.91	0.78	0.92	0.66	0.69
Passive Aggressive	0.33	0.96	0.58	1.00	0.33	0.56
Perceptron	0.67	0.96	0.75	1.00	0.17	0.55
Random Forest	0.94	0.96	0.92	1.00	0.72	0.39
Ridge Classifier	0.33	0.96	0.50	1.00	0.17	0.56
Ridge CV	0.33	0.96	0.50	1.00	0.17	0.56
SGDClassifier	0.61	0.92	0.83	1.00	0.33	0.36
SVC	0.61	0.96	0.83	1.00	0.36	0.22
XGB Classifier	0.89	0.96	0.79	1.00	0.53	0.75

However, testing balanced accuracy showed a decline for some models, such as GaussianNB, NearestCentroid, and SGDClassifier, particularly in challenging classifications like Class (Binary) and Label (Decimal), suggesting overfitting or difficulty in generalizing to unseen data. Ensemble and tree-based methods like RandomForestClassifier and XGBClassifier maintained consistently high performance across both phases, demonstrating their robustness. In contrast, simpler models and linear methods struggled with imbalanced data, especially in more granular classifications. These results highlight the importance of effectively selecting models capable of effectively addressing class imbalance.

C. F1-Score

The F1-score results, as shown in the tables (IX and Table X) and charts (Fig. 8), provide a detailed evaluation of the model's F1-score, particularly in balancing precision and recall, which is crucial for imbalanced datasets. During training, most models, such as DecisionTree, ExtraTreesClassifier,

XGBClassifier, and LabelPropagation, achieved perfect F1-scores across all classifications in both Decimal and Binary formats, similar to their accuracy and balanced accuracy results. However, models like NearestCentroid and GaussianNB showed lower F1-scores in some scenarios, such as Class (Binary), reflecting their difficulty in managing imbalanced classes effectively.

In testing, the F1-scores revealed a more nuanced picture compared to accuracy and balanced accuracy. While ensemble models like RandomForestClassifier, ExtraTreesClassifier, and XGBClassifier maintained high F1-scores, models like GaussianNB and NearestCentroid experienced noticeable drops, particularly for imbalanced classes, as seen in Class

(Binary) and Label (Decimal). These drops align with the declines observed in balanced accuracy, reinforcing the importance of metrics like F1-score for evaluating models on imbalanced datasets. Overall, while accuracy may appear high for certain models, the F1-score highlights their limitations in balancing precision and recall, providing a more comprehensive view of model performance in such challenging scenarios.

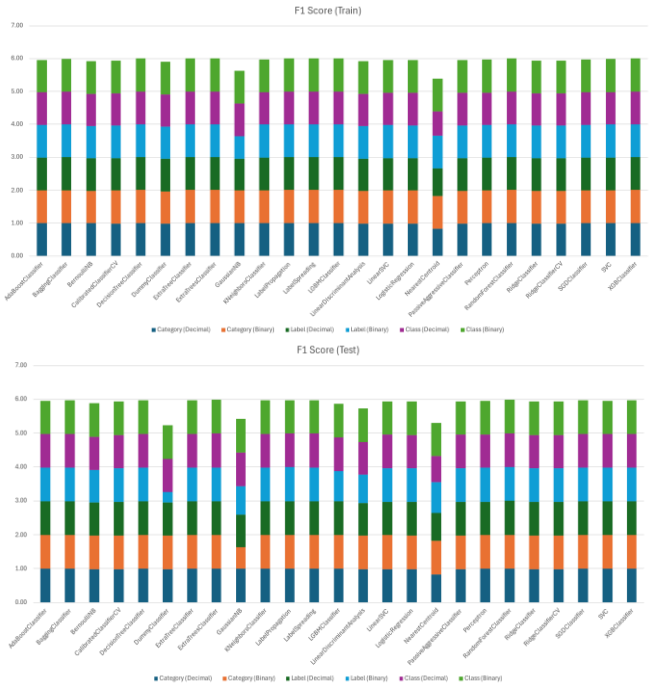

Fig. 8. Comparison of training and testing F1-Score of all models

D. Training and Testing Time

Results in Table XI, Table XII and Fig. 9 compare the training and testing time. The time taken for training and testing ML models highlight the computational efficiency. Lightweight models, such as BernoulliNB, GaussianNB, and LogisticRegression, exhibited minimal training and testing times across all classifications, making them ideal for scenarios with limited computational resources. In contrast, more complex models like CalibratedClassifierCV, LabelPropagation, and LabelSpreading required significantly longer training and testing times, particularly for Class (Binary), due to their iterative or probabilistic nature.

Tree-based ensemble models, such as RandomForestClassifier, ExtraTreesClassifier, and XGBClassifier, balanced efficiency and performance with moderate training and testing times. Notably, CalibratedClassifierCV had the longest training and testing times, especially for Class (Binary), suggesting a high computational cost for its probability calibration. These results underline the importance of considering computational time alongside accuracy and balanced accuracy when selecting models, especially for real-time or resource-constrained applications such as the IoV applications.

TABLE XI. TRAINING TIME OF ALL MODELS

E. General Discussion and Recommendation

The analysis of all results, including accuracy, balanced accuracy, F1-scores, and computational time, reveals a comprehensive comparison of model performance on the dataset. Tree-based ensemble models, such as Decision Tree, RandomForestClassifier, ExtraTreesClassifier, and XGBClassifier, consistently achieved near-perfect scores across all metrics, including accuracy, balanced accuracy, and F1-scores, while maintaining moderate computational times, making them reliable and efficient choices for most tasks. Lightweight models, such as LogisticRegression, BernoulliNB, and GaussianNB, demonstrated low computational times with competitive performance in accuracy and F1-scores, but they struggled with balanced accuracy in scenarios with significant class imbalance. On the other hand, models like CalibratedCV, LabelPropagation, and LabelSpreading achieved excellent accuracy and F1-scores but at the expense of significantly higher training and testing times, particularly for more complex classifications like Class (Binary).

While accuracy and F1-scores highlight overall model performance, balanced accuracy provided more profound insights into handling class imbalances, exposing limitations in models like NearestCentroid and GaussianNB. The computational time results underscored the trade-offs between predictive performance and resource efficiency, with certain models offering high accuracy at the cost of increased processing time. In summary, ensemble methods emerged as the dataset's most robust and practical choice, balancing performance and efficiency. At the same time, lightweight models offered a computationally inexpensive alternative with slightly reduced robustness. These findings emphasize the importance of selecting models based on the application's specific requirements, whether prioritizing accuracy, computational efficiency, or the ability to handle imbalanced datasets.

Recommendations: Based on the discussed results, several recommendations can be made to enhance intrusion detection in vehicular networks. Ensemble models, such as RandomForest ExtraTreesClassifier, ExtraTreesClassifier, and XGBClassifier, should be prioritized due to their superior performance in accuracy, balanced accuracy, and F1-score, particularly for handling imbalanced datasets. Lightweight models like LogisticRegression and BernoulliNB can be optimized with techniques such as oversampling, feature scaling, or class-weight adjustments to enhance their performance in imbalanced scenarios. Computationally intensive models like LabelPropagation and CalibratedCV should be optimized for real-time use through hybrid approaches or parallel processing techniques. Additionally, expanding the dataset to include more diverse attack scenarios and vehicular communication protocols will improve model generalizability. Balanced accuracy and F1-scores should be emphasized as key evaluation metrics, particularly in imbalanced datasets, to ensure fair assessments. Finally, integrating high-performing models into real-time systems with optimized preprocessing pipelines, including duplicate removal and stratified splitting, will enhance their practical applicability in real-world vehicular network scenarios.

V. CONCLUSION

This study comprehensively explored the CICIoV2024 dataset to evaluate the effectiveness of various advanced ML algorithms in intrusion detection for vehicular networks, focusing on CAN security. The research highlights the significance of data preprocessing, including duplicate removal and stratified splitting, in ensuring robust model evaluation. A wide range of ML models were assessed across metrics such as accuracy, balanced accuracy, F1-score, and computational efficiency.

The findings underscore the superior performance of ensemble-based and tree-based models, such as RandomForestClassifier, ExtraTreesClassifier, and XGBoostClassifier, consistently demonstrating high generalization and resilience to imbalanced data. Simpler models, such as LogisticRegression and GaussianNB, offered computational efficiency but struggled with complex, imbalanced scenarios. Models like LabelPropagation and CalibratedClassifiers achieved excellent accuracy but incurred

higher computational costs, limiting their applicability for real-time environments.

Despite achieving high accuracy, the study identified concerns regarding potential overfitting in some models, emphasizing the need for broader evaluation across diverse datasets. The CICIoV2024 dataset, with its realistic representation of spoofing and DoS attacks, proved to be a valuable resource but requires further exploration to harness its potential fully.

Future work will focus on integrating additional attack scenarios, enhancing the dataset's diversity, evaluating the scalability of ML models across varying vehicular communication protocols, and improving the generalizability of models to diverse communication protocols and real-world conditions. Moreover, we could explore more advanced ML techniques such as reinforcement learning-based IDS, federated learning, or lightweight transformer models for IoV security.

Modification of C-Grabcut for Segmentation and Classification of Coffee Leaf Diseases in Complex Backgrounds

Anastia Ivanabilla Novanti, Agus Harjoko*
Dept. of Computer Science and Electronics, Universitas Gadjah Mada, Indonesia

***Abstract*—Visual changes, including spots, discoloration, and deformation characterize coffee leaf diseases. In real-world image data, complex backgrounds present challenges for classification using deep learning models. Irrelevant objects, such as soil, other leaves, and miscellaneous items, can hinder the model's ability to accurately recognize disease patterns. Furthermore, the absence of effective segmentation techniques has resulted in low accuracy in previous studies. This work aims to address these limitations by enhancing the performance of the MobileNet-V2 model for coffee leaf disease classification. We applied a modified C-Grabcut segmentation technique to improve the isolation of diseased areas from complex backgrounds. The results demonstrate a significant performance improvement, achieving an Intersection over Union (IoU) of 0.8369 and an accuracy of 94.83%. These findings suggest that the modified MobileNet-V2 model, combined with the improved C-Grabcut segmentation, offers robust performance for in-field coffee leaf disease classification, striking a better balance between effectiveness and accuracy compared to previous studies.**

***Keywords*—Image segmentation; in-field image; mobilenet-v2; coffee leaf diseases; background complexity**

I. Introduction

Coffee is an important agricultural commodity with significant economic value. In 2020, the coffee industry was valued at USD 102 billion [1] and is projected to grow at a compound annual growth rate (CAGR) of 4.28% through 2026, supporting approximately 125 million jobs [2] worldwide. Maintaining the health of coffee plants is crucial for ensuring both quality and productivity.

One of the main challenges in coffee cultivation is the occurrence of leaf diseases, which are often caused by pathogens such as fungi, bacteria, and viruses [3]. These diseases exhibit visual symptoms on leaves, including spots, discoloration, and deformation. Early and accurate detection of these symptoms is essential to control disease spread and enhance crop yield.

In recent years, deep learning models have gained popularity for automating plant disease detection. Among these, Convolutional Neural Networks (CNNs) are particularly effective for image classification tasks. Previous studies have explored CNN models like MobileNet-V2 for classifying coffee leaf diseases. However, in-field images often contain complex backgrounds, including soil, other leaves, and environmental artifacts, which introduce noise and decrease model performance. Without effective image segmentation techniques, deep learning models struggle to differentiate disease-affected areas from irrelevant objects. Some studies report accuracy drops as low as 34% when classifying multiple disease types [4]. This highlights the need for an approach that combines segmentation and classification to enhance model robustness in in-field agricultural settings.

To address these limitations, this study introduces an enhanced MobileNet-V2 model that incorporates C-Grabcut segmentation technique. The research aims to:

1) Develop an image segmentation approach that effectively isolates disease-relevant features from complex backgrounds using modified C-Grabcut.

2) Improve the accuracy of coffee leaf disease detection through transfer learning with MobileNet-V2.

3) Optimize hyperparameters and augmentation techniques to enhance the generalization capability of the model for in-field classification tasks.

This study contributes to agricultural image processing by integrating segmentation and classification techniques for automated plant disease recognition. The findings provide insights into optimizing deep learning models for precision agriculture, enabling early disease detection and intervention.

The rest of this paper is organized as follows. Section II presents a literature review on existing methods for coffee leaf disease classification and segmentation. Section III describes the research methodology, including data collection, preprocessing, segmentation, model training, and evaluation metrics. Section IV discusses the experimental results and performance comparisons. Finally, Section V concludes the study and suggests future research directions.

II. Literature Review

The classification of coffee leaf diseases has become a major focus in agricultural research, especially because of its impact on crop yield and quality. Developing a strong classification model using deep learning that performs effectively in field conditions presents unique challenges, such as managing complex backgrounds in field images. Many existing studies focus primarily on classification using deep learning models but do not incorporate effective segmentation techniques to isolate disease features from irrelevant background elements. Table I provides an overview of several studies on the classification of coffee leaf diseases.

TABLE I. RELATED STUDIES

Methods	Data	Preprocessing	No. of class	Accuracy
MobileNet-V2 [4]	Real condition image	Augmentation	2, 3, 6	99.93% (2 classes), 34% (3 classes), 16% (6 classess
Extreme Learning Machine ELM [5]	Controlled image	Segmentation	3	99.09%
Inception v3 [6]	Controlled image	Augmentation	5	97.61%
VGG16 [7]	Controlled image	Augmentation	4	97.20%
EfficientNet-B0 [8]	Real condition image	Augmentation	6	91%
ResNet-50 [9]	Controlled image	Augmentation	2	99%
ResNet-50 [10]	Real condition image	Segmentation & Augmentation	2, 6	92% (2 classes), 88.98% (6 classes)

Despite the advances in coffee leaf disease classification, several challenges remain unaddressed, particularly in in-field conditions. Many existing models rely solely on data augmentation for performance enhancement but lack proper segmentation techniques, leading to suboptimal classification in complex environments.

For instance, MobileNet-V2 achieved an accuracy of 99.93% for binary classification but significantly dropped to 34% and 16% for three and six-class classification tasks, respectively, in in-field conditions [4]. This highlights the model's difficulty in distinguishing diseased areas from background noise such as soil and other foliage, reducing overall accuracy. Other studies employing models like Extreme Learning Machine (ELM), Inception v3, VGG16, and EfficientNet-B0 have reported high accuracy (above 90%) in controlled environments but have struggled to generalize to in-field settings [5], [6], [7], [8].

A study using ResNet-50 with segmentation and augmentation demonstrated enhanced accuracy (92%) in in-field images [10]. This underscores the importance of integrating segmentation techniques to improve classification robustness. However, existing segmentation approaches, such as Grabcut, have shown limited effectiveness in isolating disease-affected areas from complex backgrounds.

The C-Grabcut algorithm, originally developed for detecting apple leaf diseases, improves upon the traditional Grabcut method by incorporating contour detection to more accurately isolate areas [11] affected by the disease. This approach effectively reduces background noise, allowing models to concentrate on relevant features, thus enhancing classification accuracy while lowering computational demands. However, C-Grabcut has not yet been widely explored for coffee leaf disease classification, leaving a gap in its application to agricultural disease detection under in-field conditions.

To bridge these gaps, this study proposes an improved MobileNet-V2 model incorporating modified C-Grabcut segmentation to enhance coffee leaf disease classification under in-field conditions. The proposed approach aims to improve segmentation accuracy by modifying C-Grabcut to better isolate diseased areas from background elements, reducing noise interference from soil, other leaves, and environmental artifacts. Additionally, this study integrates segmentation, augmentation, and transfer learning techniques to enhance the model's ability to recognize disease patterns more effectively, particularly in complex agricultural environments. By balancing computational efficiency and classification accuracy, this approach ensures that the model remains lightweight and practical for real-world agricultural applications. Through the combination of segmentation with deep learning, this study provides a more effective and scalable solution for coffee leaf disease detection, addressing the key limitations identified in previous research.

III. RESEARCH METHODS

This research aims to improve the accuracy and robustness of coffee leaf disease classification under real-world agricultural conditions by employing a MobileNet-V2 model combined with a modified C-Grabcut segmentation technique. The methods are presented in Fig. 1.

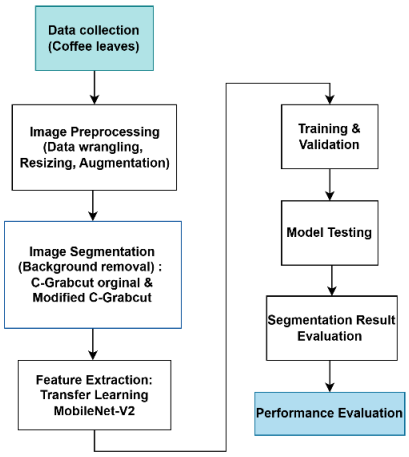

Fig. 1. Research method.

A. Data Collection

The dataset used in this study comprises images of coffee leaves collected from a public dataset [12] containing three classes: healthy, rust, and spot disease. Each image represents realistic field conditions, including complex backgrounds with noise elements such as soil, other leaves, and environmental artifacts. Data wrangling is performed to label each image according to its class and remove duplicates, ensuring data quality and preventing model bias. The dataset is then split into training (80%), validation (10%), and test (10%) subsets to facilitate model training and performance assessment.

B. Image Preprocessing

Data preprocessing in this study involved several steps to prepare the coffee leaf images for analysis. First, the images were organized into class-specific folders through labeling to

ensure proper categorization. Duplicate images were identified and removed using hash-based techniques to maintain data integrity. After segmentation, the images were resized to 224 × 224 pixels to meet the input requirements of the MobileNet-V2 model. Lastly, data augmentation techniques were employed to generate diverse dataset variations, including rotation, blurring, noise addition, and contrast adjustment. This approach enhances the model's robustness and generalization capabilities [13]. The augmented dataset helps the model recognize disease features across various field conditions. Table II presents the dataset distributions after augmentation.

TABLE II. DATASET DISTRIBUTIONS AFTER PREPROCESSING

Classes	Data Distributions			Preview
	Train	Validation	Test	
Healthy	1600	200	200	
Leaf Rust	1600	200	200	
Leaf Spot	1600	200	200	
Total	4800	600	600	

C. Image Segmentation

To effectively isolate diseased areas of leaves and minimize background noise, the modified C-Grabcut algorithm is applied to each image. This enhanced version of the traditional Grabcut algorithm includes contour detection, which allows for more accurate differentiation between diseased leaf areas and surrounding elements, such as soil and other foliage. The modifications made to the original C-Grabcut involve adjustments to key functions and parameter settings, resulting in improved segmentation accuracy while retaining essential leaf and disease features. A step-by-step illustration of the modified C-Grabcut process is presented in Fig. 2, and the procedure is outlined as follows:

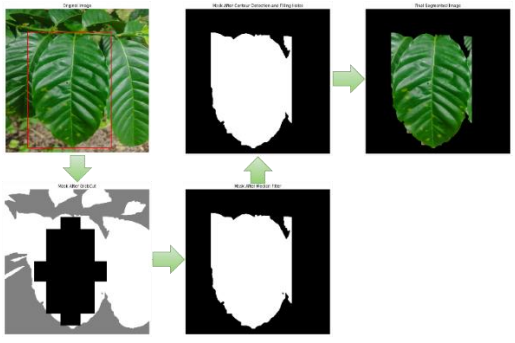

Fig. 2. Foreground segmentation with modified C-Grabcut algorithm.

1) Initialization and modified mask function: Segmentation begins by defining an initial bounding box around the leaf, focusing the algorithm on the relevant area. To enhance foreground detection, two markers are added within this bounding box: a foreground box and intersecting vertical-horizontal lines. The width and height of the bounding box are calculated to determine the leaf's orientation, guiding the accurate placement of the foreground markers. The modified mask function is visualized in Fig. 3.

2) Foreground box and vertical-horizontal lines: The foreground box is assigned a value of 1 in the mask, marking it as a definite foreground. A vertical and horizontal line intersecting at the bounding box center creates a cross ("+"), extending 90% of the box's width and height with a thickness of 90 pixels. Pixels within this cross are set to 1, reinforcing the foreground, while areas outside the box and cross are set to 2, marking probable background. This ensures that key leaf features, such as lesions, are preserved during segmentation, unlike in the original C-Grabcut.

3) Bounding box limitation: To address a common issue where irrelevant background features remain outside the bounding box, the modified mask is restricted to the bounding box area only. This ensures the mask applies solely within the bounding box, eliminating non-relevant features outside it.

4) Median filtering: After applying the bounding box limitation, a median filter with a 3x3 kernel size is used on the mask. This step smooths the mask by reducing noise and softening edges. The smaller kernel size provides a gentle smoothing effect that preserves critical details of the leaf, such as disease features, while effectively eliminating isolated noise. The median filter is particularly effective in maintaining the shape and texture of small lesions, which are essential for accurate disease identification.

5) Contour functions: Contour detection is performed to refine the leaf's boundary within the bounding box. This step identifies the edges of the segmented leaf and adjusts the mask accordingly, ensuring that it accurately captures the leaf's shape and any disease-specific features along its edges. Contour detection is particularly effective in preventing background elements, which may share similar color properties, from being incorrectly included in the foreground. Contour detection significantly enhances the overall segmentation accuracy by maintaining clear and precise edges.

6) Bitwise operation: Bitwise operations are used to isolate the segmented leaf from the background. Specifically, a bitwise AND operation is performed between the mask and the original image. This operation retains only the foreground (the segmented leaf) while setting the background pixels to zero. As a result, any remaining background noise within the bounding box is eliminated, producing a clean and focused image of the leaf that is ready for disease classification.

D. Feature Extraction Using Transfer Learning

This study employs a pre-trained MobileNet-V2 model, which has been trained on the ImageNet dataset, for feature extraction. Transfer learning enables a model to be trained and

fine-tuned for a specific task, then adapted to a related task [14]. Transfer learning is utilized by taking weights from this pre-trained model, which has already learned general features from ImageNet [7]. ImageNet is a large dataset widely used for training deep learning models, particularly Convolutional Neural Networks (CNNs). It consists of approximately 1.2 million images organized into 1,000 categories [15]. By leveraging prior knowledge, this approach enhances the model's performance and efficiency in a new context [14].

In this model, the bottom layers of MobileNet-V2 are frozen to preserve these general features, while the deeper layers are modified to learn features specific to the task at hand. These layers can be trained or fine-tuned to enhance model performance [16]. The top layers, or classifier, are adapted by adding three fully connected layers, one batch normalization layer, and two dropout layers to reduce the risk of overfitting. ReLU activation functions are also utilized. These additional layers improve the model's ability to process the extracted features effectively, allowing it to classify them into the three target classes.

E. Training and Validation

The training and validation process starts with loading the respective datasets. Training is carried out on the training set, while validation is performed using the validation set. The initial hyperparameter settings, presented in Table III, are applied consistently throughout the initial experiment to maintain baseline conditions.

TABLE III. INITIAL HYPERPARAMETER TUNING

Hyperparameter	Value
Number of classes	3
Pre-trained Model	MobileNet-V2
Trainable Layers	Only final classification layer
Optimizer	SGD
Loss function	Cross-Entropy
Batch size	64
Learning rate	0.001
Patience	5
Epochs	25

TABLE IV. EXPERIMENTAL SETUP PHASE 1

Scenario	Segmentation Techniques
1.1	No Segmentation
1.2	GrabCut Segmentation
1.3	C-Grabcut Segmentation
1.4	Modified C-Grabcut Segmentation

F. Model Testing

The testing process consists of four experimental phases, evaluating the impact of segmentation, trainable layers, hyperparameter tuning, and background complexity on the model's classification performance.

1) Phase 1: Data segmentation setup: The first experiment evaluates the impact of different data segmentation techniques on the model's performance in recognizing images. The best-performing setup from this phase is selected for the next experiment phase (Table IV).

2) Phase 2: Trainable layer experiment: In the second phase, the number of trainable layers in the model is adjusted to assess how different layer configurations affect performance under transfer learning. The optimal configuration from this experiment is used in the final experiment phase (Table V).

TABLE V. EXPERIMENTAL SETUP PHASE 2

Scenario	Number of trainable layer
2.1	-
2.2	Last 5% of layers are trainable
2.3	Last 20% of layers are trainable
2.4	Last 50% of layers are trainable

3) Phase 3: Hyperparameter tuning: To optimize the model's performance, the final phase involves fine-tuning hyperparameters, including batch size, learning rate, optimizer, and the number of epochs. Multiple combinations are tested, and the model configuration yielding the highest performance is selected as the final model, saved for testing (Table VI).

TABLE VI. EXPERIMENTAL SETUP PHASE 3

Hyperparameter	Value
Optimizer	SGD, Adam
Epoch	25, 50, 75
Learning rate	0.001, 0.0001

4) Additional experiment: The effect of background complexity on model performance: An additional experiment was conducted to evaluate the influence of background complexity on model accuracy by testing two types of images: natural background images, as used in the main study, and plain background images, obtained from a public dataset, Roboflow [20]. This experiment aimed to determine whether a simplified background could improve classification performance compared to natural backgrounds. Both datasets underwent the same preprocessing steps, except that segmentation was not applied to the plain-background images, ensuring a fair comparison. The best hyperparameters from previous experiments were utilized for both datasets, allowing for an objective assessment of performance differences. The results of this experiment provide valuable insight into the extent to which background complexity affects classification accuracy and whether segmentation techniques remain essential when dealing with plain-background images.

G. Segmentation Result Evaluation

Segmentation result evaluation aims to assess the outcomes of both the original C-Grabcut and the modified C-Grabcut

using predefined evaluation metrics. The evaluation process consists of two types: quantitative and qualitative.

Quantitative evaluation provides objective measurements utilizing metrics such as Intersection over Union (IoU), Dice Coefficient, Pixel Accuracy and Precision. These metrics enable a measurable comparison of the performance of the two methods. In contrast, qualitative evaluation involves visual observation to ensure that the segmentation results meet specific visual standards, such as boundary clarity and consistency in the target area. The combination of these evaluation methods offers a comprehensive assessment of segmentation quality.

IoU measures the agreement between the region predicted by the segmentation model and the ground truth region [17]. The Dice Coefficient measures the similarity between a segmentation model's predicted region and the ground truth [17]; higher Dice Coefficient values indicate better model performance. Pixel Accuracy, also known as the Rand Index, defines the number of correct predictions (both positive and negative) relative to the total number of predictions [18]. The formulas for the quantitative evaluations are presented in Table VII.

TABLE VII. THE QUANTITATIVE SEGMENTATION EVALUATION

Evaluation	Formula
IoU	$IoU = \frac{TP}{TP + FP + FN}$
Dice Coefficient	$Dice = \frac{2 * TP}{(2 * TP + FP + FN)}$
Pixel Accuracy	$Accuracy = \frac{TP + TN}{(TP + TN + FP + FN)}$
Precision	$Precision = \frac{TP}{TP + FN}$

where TP (True Positive) represents pixels correctly classified as part of the class, TN (True Negative) refers to pixels correctly predicted as background, FP (False Positive) denotes pixels incorrectly classified as part of the class, and FN (False Negative) indicates pixels that were not classified as part of the class [19].

Two main elements are required to compute these metrics: the data mask (ground truth) and the prediction mask. The data mask represents annotated ground truth areas (e.g., leaf objects) and is manually created using the Roboflow platform. It generates XML files for each image, which are then converted into binary images in .png format. The prediction mask is derived from the segmentation results of the original and modified C-grabcut methods applied to the test dataset.

H. Performance Evaluation

To assess the effectiveness of the proposed model in identifying feature patterns across different disease categories and evaluating classification accuracy for each class, the model's performance is measured using key evaluation metrics derived from the confusion matrix. These metrics include accuracy, precision, recall, and F1-score, as summarized in Table VIII. The best model's performance is evaluated on the test set using these metrics thoroughly analyze the model's performance for each class. A confusion matrix is also created to visualize the classification results across the different classes.

TABLE VIII. PERFORMANCE EVALUATION METRIC

Metric	Formula
Accuracy (ACC)	$\frac{TN + TP}{TP + FP + TN + FN}$
Precision (PRE)	$\frac{TP}{TP + FP}$
Recall (TPR)	$\frac{TP}{TP + FN}$
F1-Score (F1)	$2 \times \frac{PRE \times REC}{PRE + REC}$

IV. RESULTS

A. Segmentation Evaluation Results

Table IX presents the quantitative evaluation results of the GrabCut, C-Grabcut Original, and Modified C-Grabcut methods, assessed using four key metrics: Intersection over Union (IoU), Dice Coefficient, Pixel Accuracy, and Precision.

TABLE IX. QUANTITATIVE EVALUATION RESULT OF SEGMENTATION TECHNIQUES

Technique	IoU	Dice Coefficient	Pixel Accuracy	Precision
GrabCut	0,6821	0,7934	0,8445	0,7019
C-Grabcut Original	0,683	0,7941	0,8446	0,7018
Modified C-Grabcut	0,8369	0,9091	0,9344	0,8402

These results indicate that C-Grabcut Original does not show significant improvement compared to GrabCut, as reflected in the minimal differences in all four metrics. However, Modified C-Grabcut outperforms both methods, demonstrating higher segmentation accuracy and precision.

Table X presents the visual results of the GrabCut, C-Grabcut Original, and Modified C-Grabcut. The results indicate that C-Grabcut Original performs better than traditional GrabCut, as it is able to retain lesion features more effectively. In contrast, GrabCut often removes critical disease lesions, leading to loss of essential features for classification. However, C-Grabcut Original still has some segmentation inaccuracies, particularly in areas where the leaf color or texture closely resembles the background, causing parts of the leaf to be mistakenly removed.

In contrast, Modified C-Grabcut demonstrates significant improvements over both GrabCut and C-Grabcut Original. The segmentation results show that Modified C-Grabcut effectively retains lesion structures, reducing the likelihood of misclassification between disease spots and the background. Compared to GrabCut, which often erases crucial lesion areas, and C-Grabcut Original, which still exhibits some errors in boundary detection, Modified C-Grabcut achieves better object preservation and noise reduction. The enhanced contour detection and optimized bounding box adjustments in Modified C-Grabcut allow for sharper, more defined segmentation while minimizing the loss of lesion information.

TABLE X. VISUAL RESULT OF SEGMENTATION TECHNIQUES

Data Mask	Predicted mask (segmentation results)		
	GrabCut	C-Grabcut Original	Modified C-Grabcut
Class: Leaf spot			
Class : Leaf Rust			
Class: Healthy			

B. Performance Evaluation

1) Phase 1: Data segmentation setup: The models trained in the first experiment were used for testing. The performance metrics of phase 1, including precision, recall, F1-score, and accuracy for each class, are presented in Table XI.

The Modified C-Grabcut approach achieved the highest accuracy (88.33%), outperforming traditional Grabcut and C-Grabcut. The results indicate that segmentation improves disease detection, especially for leaf spot classification.

2) Phase 2: Trainable layer experiment: Table XII presents the testing result for experiments utilizing different trainable layers in transfer learning. Scenario 2.4, which allowed only the last 50% of the layers to be trainable, resulted in the best accuracy (92.5%), suggesting that fine-tuning a larger portion of MobileNet-V2 enhances feature extraction for coffee leaf disease classification.

3) Phase 3: Hyperparameter tuning: Table XIII presents the result from the hyperparameter tuning experiments.

TABLE XI. THE RESULT OF PHASE 1

Segmentation Setup	Class	Precision	Recall	F1-Score	Acc
No Segmentation (Sc 1.1)	Healthy	0,84	0,92	0,88	0,8433
	Leaf Spot	0,79	0,82	0,8	
	Leaf Rust	0,91	0,8	0,85	
GrabCut (Sc 1.2)	Healthy	0,83	0,93	0,88	0,8450
	Leaf Spot	0,82	0,77	0,79	
	Leaf Rust	0,89	0,83	0,86	
C-Grabcut Original (Sc 1.3)	Healthy	0,81	0,94	0,87	0,8517
	Leaf Spot	0,85	0,77	0,81	
	Leaf Rust	0,9	0,85	0,88	
Modified C-Grabcut (Sc 1.4)	Healthy	0,86	0,95	0,9	**0,8833**
	Leaf Spot	0,88	0,83	0,86	
	Leaf Rust	0,89	0,83	0,86	

TABLE XII. THE RESULT OF PHASE 2

Number of trainable layer	Class	Precision	Recall	F1-Score	Acc
- (Sc 2.1)	Healthy	0,82	0,95	0,88	0,8600
	Leaf Spot	0,87	0,78	0,82	
	Leaf Rust	0,90	0,84	0,87	
Last 5% layers (Sc 2.2)	Healthy	0,88	0,96	0,92	0,8967
	Leaf Spot	0,89	0,84	0,87	
	Leaf Rust	0,93	0,89	0,91	
Last 20% layers (Sc 2.3)	Healthy	0,89	0,96	0,93	0,8933
	Leaf Spot	0,86	0,86	0,86	
	Leaf Rust	0,93	0,86	0,89	
Last 50% layers (Sc. 2.4)	Healthy	0,91	0,95	0,93	0,925
	Leaf Spot	0,92	0,91	0,91	
	Leaf Rust	0,94	0,92	0,93	

TABLE XIII. THE RESULT OF PHASE 3

Scenarios	*Hyperparameter*			Accuracy
	Optimizer	Learning rate	*Batch size*	
	***Epoch* : 25**			
3.1	SGD	0,001	32	0,925
3.2	SGD	0,001	64	0,9367
3.3	**SGD**	**0,001**	**128**	**0,94**
3.4	SGD	0,0001	32	0,9233
3.5	SGD	0,0001	64	0,8917
3.6	SGD	0,0001	128	0,88
3.7	Adam	0,001	32	0,9283
3.8	Adam	0,001	64	0,9333
3.9	Adam	0,001	128	0,9333
3.10	Adam	0,0001	32	0,9317
3.11	**Adam**	**0,0001**	**64**	**0,9483**
3.12	Adam	0,0001	128	0,93
	***Epoch* : 50**			
3.13	SGD	0,0001	64	0,8983

3.14	SGD	0,0001	128	0,9
	***Epoch* : 75**			
3.15	SGD	0,0001	128	0,91

Overall, the result indicate that the Adam optimizer performed better, particularly with a learning rate of 0.0001. When comparing learning rates, a lower learning rate of 0.0001 was found to be more effective with the Adam optimizer, while the Stochastic Gradient Descent (SGD) optimizer showed slightly better performance with a higher learning rate of 0.001. The optimal configuration was identified as Adam with a learning rate of 0.0001 and a batch size of 128 which resulted in a training accuracy of 99% and an F1 score of 0.9049, achieving the highest validation accuracy across all tested configurations.

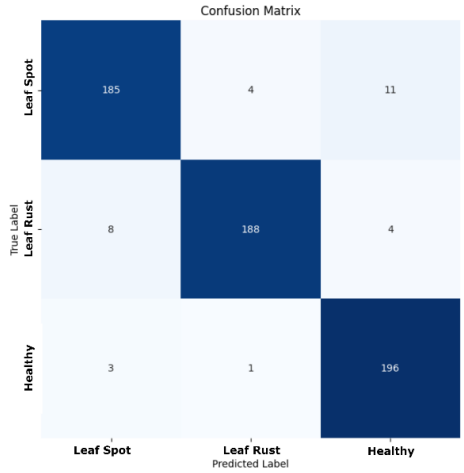

Fig. 3. Confusion Matrix for the best performance model.

The confusion matrix shown in Fig. 3 indicates that the classification results are primarily concentrated along the diagonal. This pattern suggests that the model generates more True Positives than False Negatives and False Positives. As a result, the model demonstrates high accuracy in correctly predicting the class of each image.

In the optimal scenario of the third experiment, the model performs well in recognizing all classes, surpassing the results of both the first and second experiments.

4) Additional experiment: The Effect of Background Complexity on Model Performance.

The testing results of additional experiment are presented in Table XIV.

TABLE XIV. TESTING RESULT OF ADDITIONAL EXPERIMENT

Scenario	Image Type	Testing Accuracy
1.1	Complex backround	0,8433
3.11		0,9483
1.1	Plain Background	0,965
3.11		0,9983

The result indicates that background complexity significantly affects classification performance. When tested with natural background images, the model in Scenario 1.1 achieved 77.5% validation accuracy and 84.33% test accuracy. After hyperparameter optimization in Scenario 3.11, validation accuracy improved to 90.17%, and test accuracy increased to 94.83%, demonstrating that optimized hyperparameters enhance the model's ability to handle complex backgrounds.

In contrast, models trained with plain background images exhibited higher performance across all metrics. In Scenario 1.1, the validation accuracy reached 94.17%, and test accuracy was 96.5%. After applying the best hyperparameters in Scenario 3.11, the model achieved 99.50% validation accuracy and 99.83% test accuracy, indicating that simplified backgrounds facilitate more effective feature extraction.

V. DISCUSSION

A. Advantages of Modified C-Grabcut

The superior performance of Modified C-Grabcut over traditional GrabCut and C-Grabcut Original is attributed to a series of refinements that enhance segmentation accuracy, particularly in complex backgrounds and varying lighting conditions.

One key improvement is the addition of a '+' marker in the initial mask, which ensures that the leaf's edges and disease lesions remain intact, preventing accidental removal. This enhancement is particularly beneficial for objects that share similar colors with the background, maintaining their structure more effectively.

Increasing the number of GrabCut iterations from 5 to 10 allows the model to refine the segmentation mask, resulting in sharper contours and fewer errors caused by noise or slight color differences. Additionally, reducing the median filter kernel size from 5 to 3 helps retain fine lesion details, preventing excessive blurring that could lead to information loss.

Through these modifications, Modified C-Grabcut significantly improves segmentation quality, effectively isolating the disease-affected areas while minimizing background interference. The results confirm that this approach enhances feature extraction for classification, making it a more reliable and efficient segmentation technique for coffee leaf disease detection.

B. Analysis of Experiment Results

The results confirm that segmentation plays a crucial role in enhancing classification performance, particularly in in-field conditions with complex backgrounds. In the first experiment, the model achieved an initial accuracy of 88.33%, establishing a baseline performance before applying further optimizations. The introduction of Modified C-Grabcut segmentation significantly improved disease feature extraction by isolating lesions from background noise, leading to more stable classification performance compared to models without segmentation. These findings validate that effective segmentation enhances model robustness by reducing misclassification due to background interference.

Further improvements were observed when 50% of MobileNet-V2 layers were fine-tuned, resulting in an accuracy of 92.5%. This indicates that selective layer tuning enhances feature extraction, allowing the model to capture disease-specific patterns more effectively. These findings are consistent with previous studies, where freezing too many layers reduced adaptability, while excessive fine-tuning led to overfitting and decreased generalization ability [14].

Hyperparameter tuning also played a crucial role in optimizing model performance. The Adam optimizer with a learning rate of 0.0001 and batch size of 128 achieved the highest accuracy at 94.83%, outperforming SGD. Adam's adaptive optimization strategy contributed to faster convergence and better classification robustness, reinforcing the importance of fine-tuning hyperparameters for deep learning-based plant disease detection [21], [22].

The trend of accuracy improvement across the three experiments is illustrated in Fig. 4, showing a consistent upward trajectory as various optimizations were applied. As depicted, the model initially achieved 88.33% accuracy in Experiment 1, which increased to 92.5% in Experiment 2 after trainable layer optimization, and finally reached 94.83% in Experiment 3 following hyperparameter tuning. This trend confirms that a structured approach to segmentation, transfer learning, and hyperparameter tuning leads to significant improvements in classification accuracy.

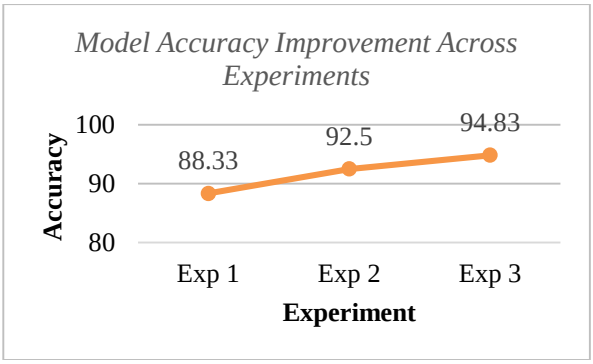

Fig. 4. Trend of model accuracy improvement across experiments.

C. The Effect of Background Complexity on Model Performance

The additional experiment highlights the significant role of background complexity in deep learning-based plant disease classification. The results indicate that models trained with plain background images achieved higher accuracy across all evaluation metrics, confirming that background noise in natural images negatively affects classification performance. The increase in test accuracy from 84.33% to 94.83% for natural background images after hyperparameter tuning suggests that model optimization helps mitigate background interference but does not fully eliminate its impact.

The superior accuracy observed in plain background images (99.83%) indicates that a simplified background enables the model to focus on key object features without distractions. Conversely, natural background images introduce additional challenges, including color variations, shadows, and overlapping objects, which can lead to misclassification errors. These findings align with prior computer vision research, which has shown that complex backgrounds hinder feature extraction and reduce model performance.

Despite the improved accuracy with plain background images, real-world agricultural settings rarely provide such controlled conditions. In practical applications, coffee leaves are surrounded by other foliage, exposed to uneven lighting, and subject to various environmental factors. As a result, models trained exclusively on plain background datasets may struggle to generalize effectively in in-field conditions, where background complexity is unavoidable.

To address these challenges, segmentation remains a critical preprocessing step. By isolating the primary object, Modified C-Grabcut significantly reduces background interference, allowing the model to extract more relevant disease features. The results reinforce the importance of integrating segmentation techniques into deep learning workflows, ensuring more reliable classification performance in diverse and uncontrolled environments.

VI. Conclusion

This study investigated the impact of Modified C-Grabcut segmentation and model optimization on coffee leaf disease classification in in-field conditions. The research aimed to enhance classification accuracy by addressing the challenges posed by complex backgrounds in agricultural images.

The results confirm that effective segmentation significantly improves classification performance. The Modified C-Grabcut technique outperformed GrabCut and C-Grabcut Original, achieving an IoU of 0.8369, Dice Coefficient of 0.9091, and test accuracy of 94.83%. These findings validate that better contour detection and refined boundary constraints help isolate disease-relevant features, reducing misclassification due to background noise.

Further improvements were observed through model optimization techniques, particularly in trainable layer selection and hyperparameter tuning. Fine-tuning 50% of MobileNet-V2 layers resulted in an accuracy increase to 92.5%, while the Adam optimizer (learning rate 0.0001, batch size 128) achieved the highest accuracy of 94.83%. Additionally, experiments on background complexity demonstrated that models trained with plain background images performed better (99.83% accuracy) than those with natural backgrounds, confirming that background noise negatively impacts feature extraction.

In summary, this research demonstrates that segmentation-based preprocessing is crucial for improving deep learning-based plant disease classification, especially in real-world agricultural applications. The findings contribute to precision agriculture and automated disease detection by offering a robust segmentation-enhanced classification approach.

***Abstract*—Anomaly detection in streaming data is crucial for identifying unusual patterns or outliers that may indicate significant issues. Traditional methods struggle with the inability in efficiently handling high-velocity data, adapting to changing data distributions, and maintain performance over time. Further, the conventional methods struggled with scalability, adaptability, and computational efficiency, leading to delays in detection or an increased rate of false positives. To address these limitations, Unicintus Escape Energy enabled Sampling based Drift Deep Belief Network-Bidirectional Long Short Term Memory (UES2-DTM) is proposed in the research. The research model incorporates the combination of adaptive reservoir sampling as well as the adaptive sliding window mechanisms into the base model, which elevates the efficiency of the model to work with the streaming data. Moreover, the adaptive sliding window mechanisms for drift detection integrates the Unicintus Escape Energy Optimization (UE2O) Algorithm to boost efficiency by dynamically adjusting the sliding window size and parameters, based on real-time streaming data characteristics. Further, Adaptive reservoir sampling helps in maintaining a representative sample of the data stream, for effective detection. Overall, the UES2-DTM model demonstrates superior adaptability and accuracy, which is evaluated with the metrics such as precision, recall, F1-score, and Mean Square Error (MSE) attained 97.199%, 94.827%, 95.998%, and 3.461 respectively.**

Keywords*—Streaming data; sliding window; anomaly detection; reservoir sampling; Unicintus escape energy optimization

I. INTRODUCTION

Due to its ongoing use in real-world issues, the Internet of Things (IoT) has gained increasing relevance in recent years [1-4]. As a result of this advancement, the internet expanded and was rolled out across several devices, resulting in rapid global growth. IoT is a key component in computing systems that enable intelligent data collection and analysis even in the absence of known entities [5-6]. Road traffic, supply chain management [7], healthcare, smart cities [8], transit, and more were all made possible by the Internet [9-10]. However, there are several restricted qualities of this independent object, such as minimal memory, a small CPU, low bandwidth channels for communication, and so forth [9]. Large datasets were also needed for analysis and decision-making in the logistics operation [10]. When data from several IoT sensors combine to create complex patterns, sometimes known as unique events [10], the result is an anomaly [4]. The scenario is hazardous since these rare and complex events have undesired data and barely happened. The complex event processing (CEP) approach was created to process, evaluate, and summarize complicated events [11] [10]. One effective component of web-based apps that increases the ability to predict complex events and anomalous activity in real-time data streams is the CEP.

Additionally, in a gamut of applications such as monitoring of traffic congestion, live mapping, smart street lamps, and so forth [12-15], the CEP method can also effectively predict the real-time streaming data with the sequence of events and suspicious actions [16-18]. This aids in the development of automated systems for smart cities [19] [10]. The CEP was more adaptable and could make excellent use of a significant amount of continuously streamed data to facilitate decision-making. The traffic congestion management system's forecast resulted in significant changes to traffic patterns, including shorter travel times, more road capacity, and the elimination of fuel usage and air pollution [20]. By linking all parts to the central server, the message unit accurately predicts data via wireless networks using Internet of Things sensors, enabling the traffic congestion prediction to function as intended [21]. Utilizing efficient deep learning (DL) and machine learning (ML) approaches, which offer greater benefits for efficient event prediction, improved IoT-based congestion prediction in various industries. To produce predictions, both structured and unstructured data may be used with the very effective ML and DL algorithms [22-23].

By removing the useful streaming data from the IoT sensors, several ML and DL techniques improved the prediction process and produced very accurate predictions. With the aid of the Markov decision process model, the Bayesian network was a q-learning technique that was used to anticipate future occurrences in advance [6]. In addition to having the capacity to produce dynamic and scalable anticipated results, ML-based approaches such as SVR [24], DT [25] are more dependable than other approaches that train the models using historical data [10]. DL approaches effectively overcome the constraints of ML, even though the prediction requires very complicated and high-quality data. Anomaly detection in networks involves identifying unusual patterns in network traffic, often referred to as anomalies or outliers. These nonconforming patterns have applications in fraud detection, cyber security, and military surveillance. For instance, anomalous traffic patterns may indicate sensitive data being sent to unauthorized hosts [26].

Thus, to address and tackle the described challenges, the UES2-DTM model is proposed in the research.

The research model UES2-DTM aims to work with anomaly detection from the streaming data. The research model obtains efficient outcomes with the combination of contributed mechanisms that enhanced the reliability and scalability of UES2-DTM. In addition, the preprocessing and feature extraction mechanisms aid in obtaining significant outcomes specifically when working with the streaming data. A novel approach, encompassing the following is introduced in this work:

- Develop an Adaptive Reservoir Sampling technique to effectively handle large-scale, high-velocity data streams with unknown total sizes.
- Design an Adaptive Sliding Window-Based Drift Detection mechanism enhanced by the Unicintus Escape Energy Optimization (UE2O) algorithm. This approach aims to dynamically adjust to data distribution changes, improving the precision of anomaly detection in streaming data.
- Construct a hybrid deep learning framework combining Deep Belief Networks (DBN) and Bidirectional Long Short-Term Memory (BiLSTM) networks. This model will incorporate the proposed sampling and drift detection techniques to strengthen the IoT data streams anomalies.
- Assess the proposed UES2-DTM model using relevant metrics. This evaluation will benchmark the model's effectiveness against existing methods in detecting anomalies within streaming data environments.

The research article is organized as, Section II describes the Related Work and Section III elaborates on the system modeling of the UES2-DTM. Section IV analyzes the research outcomes, and section V ends the research with suggestion for future work.

II. Related Work

The existing research on the anomaly detection with the live streaming data is elaborated in this section. The Seasonal Auto-Regressive Integrated Moving Average (SARIMA) [23] and Bidirectional Long Short-Term Memory (Bi-LSTM) [23] were first presented by Ayushi Chahal et al.. The intent of this research model was to improve inhabitants' quality of life. Any type of time-series dataset could be employed with the suggested approach, including forecasting stock trends, diseases, and weather patterns. The research might also focus on improving the suggested model prediction performance through the use of various interpretation analysis techniques.

The online event anomaly detection with XGBoost, LSTM, and RF was first presented by Suhwan Lee et al. [27]. The suggested method retrained the model using the most current cases that were recently recorded on the event stream via a sliding window. There exist several issues with research that still require attention. An occurrence that was deemed abnormal could be reclassified as it failed to update the forecast. Nevertheless, it could be highly instructive to consider such modifications that justified the anticipated anomalies and could enhance model performance.

The Preprocessed Isolation Forest (PiForest) technique for anomaly identification was initially described by Prarthi Jain et al. [10]. The method referred to as the PiForest was applying the iForest algorithm to datasets that were drastically decreased in dimensionality. To handle such data and efficiently detect anomalies, a sliding window was employed in the research. The method's effectiveness in identifying anomalies could be confirmed by contrasting its results with the output of many established anomaly detection algorithms.

A deep neural network (DNN) was presented by Asmaa F. Hassan et al. [28] to address the outlier detection issue with the streaming data input. The experiment's findings showed that it achieved superior detection accuracy with a minimal false alarm rate than two cutting-edge DL techniques. However, the present stage of the suggested approach was not entirely inadequate due to the length of time needed to train the system and its exclusive focus on finding global outliers. The multiclass classification scenarios could be included to tackle the outlier identification problem more successfully. The issue of contextual outliers could be discussed to improve the research efficacy.

The recurrent neural network (RNN) model, which was presented by Jun Liu et al. [21], not only lowers regression error but also has the ability to identify anomalous data that was acquired by IoT terminal nodes ensuring that network predictions were robust and stable. To enable prompt repair and management of sensor nodes, the system would get feedback when there are medium- and long-term irregularities.

A framework based on isolation forests with dynamic Insertion and Deletion methods (IDForest) was presented by Haolong Xiang and Xuyun Zhang [29]. By gradually learning the tree structure, IDForest quickly and accurately identified abnormalities in the data stream containing large amounts of data. Additionally, edge computing investigations confirmed that deploying in parallel, increased detection speed by hundreds of times. The research model could implement edge computing settings. Further, the research model did not work with noise reduction that could be implemented to improve efficacy.

Cube sampling and the iForest algorithm were first presented by Seemandhar Jain et al. [30] as methods for identifying anomalies. The use of sliding windows to handle such data remained efficient. The effectiveness of the approach in identifying anomalies was exhibited by a comparative analysis with several widely recognized anomaly detection algorithms. Still, the handling of streaming data was not performed well in the research. The Online evolving Spiking Neural Network (OeSNN) classifier [31] was presented for anomaly detection by Piotr S. Maciąg et al.. OeSNN-UAD did not divide output neurons into decision classes that are predetermined. Rather, every newly formed output neuron on OeSNN-UAD was given an output value, which was determined at random using the most recent input values. Nevertheless, the model was unsuitable for settings with stringent memory constraints. A comparative analysis of other existing approaches is depicted in Table I.

TABLE I. LIMITATIONS OF EXISTING APPROACHES AND OPTIMIZATIONS

Existing Approaches	Limitations
ARIMA	Limited Drift Detection capability, Struggles with non-stationary data
Rule-Based Approaches	Limited Adaptability, High false-positive rate
Clustering	Can struggle with high-dimensional data, Requires prior knowledge of clusters
Supervised Machine Learning	Needs extensive labelled data, struggles with drift, slow inferences in real time prediction
Convolutional Neural Networks	Not well-suited for sequential/temporal anomaly detection
Long Short Term Memory	Struggle to quickly adapt to shifts in data distribution without retraining or fine-tuning, more like a back box so interpretability is difficult, not immune to vanishing gradient problem
Genetic Algorithm	Slow convergence, relies on fixed evolutionary operations like mutation and crossover.
Particle Swarm Optimization	Can get stuck in local optima, Prone to premature convergence in complex problems
Bayesian Optimization	Assumes a stationary function landscape, limiting adaptability to non-stationary data

III. PROPOSED SYSTEM MODEL

A. Anomaly Detection with Unicintus Escape Energy Enabled Sampling Based Drift Deep Belief Network-Bidirectional Long Short Term Memory Model

The research to detect anomalies in streaming data is performed with the UES2-DTM model. The research is initiated with the streaming data that acts as the input. The streaming Apache Kafka system is used to obtain streaming data that involves information from various sectors. The obtained inputs from different sectors are aggregated with the data aggregator, which is available in the data aggregation block. Once data are aggregated, the input is fed into the preprocessing block, where the missing data imputation and the logarithmic data sampling take place with K-nearest neighbor (KNN) and logarithmic normalization respectively.

The preprocessed data serves as the input for the Feature Extraction block, aiming to identify and extract the most relevant features. To obtain efficient outcomes of feature extraction, statistical features, time-series informative features, and mixed information metric features are extracted in the research. The combined outcome represented as the feature vector is fed into the model UES2-DTM, which is hybridized with the adaptive reservoir sampling as well as the adaptive sliding window-based drift detection mechanism. The mechanisms involved are optimized with the hybrid optimization that integrates the characteristics of Rabbit and Harris Hawk. The adaptive reservoir. sampling splits the data into sub-sets that enhance the processing time by neglecting the entire data processing. Further, the adaptive sliding window-based drift detection mechanism obtains information on the drift in the limited frames achieved at the typical time frames obtained through the sliding window process. The UE2O algorithm in the research aids in tuning the described process to obtain the optimal outcomes. The entire workflow of the research is shown in Fig. 1.

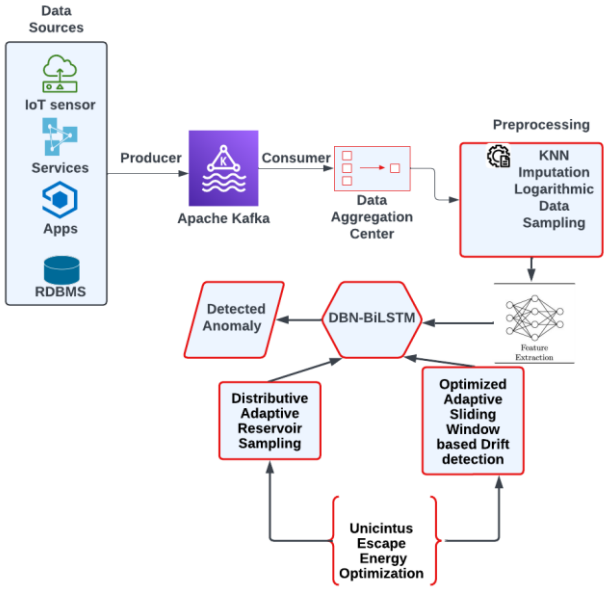

Fig. 1. Block diagram of the proposed methodology.

B. Input Streaming Data

The input streaming data is obtained from the Kafka streaming software that collects the data from different data sources at different time intervals. The data from data sources are forwarded from the producers to the Apache Kafka system, which is sent to the consumers based on their requirements. The input streaming data from the Kafka streaming is represented as,

$$S_{data} = \{\ldots, S^{v-1}, S^{v}, S^{v+1}, \ldots\} \quad (1)$$

where, $S^{v}$is the data instance at time v, $S^{v-1}$and S^{v+1} are the previous and the next data instances.

C. Preprocessing with Imputer and Logarithmic Data Sampling

Preprocessing is performed in the research to achieve the most promising data that aids in obtaining accurate outcomes in further process. The preprocessing is performed with the missing data imputation and logarithmic data sampling. The missing data imputation is performed with the KNN imputer. Due to the efficacy in solving the issues with the data imputation, KNN is chosen as the imputer, which further works without the intervention of detection models. The popular Euclidean distance equation is used for the above [32]. With the outcome of missing value imputed, logarithmic data sampling [33] is performed in the research.

D. Feature Extraction with Time-series Statistical Mixed Information Features

The feature extraction is performed to retrieve the features of the preprocessed data, for which the time-series informative features, statistical features, and mixed information metric features are utilized in the research.

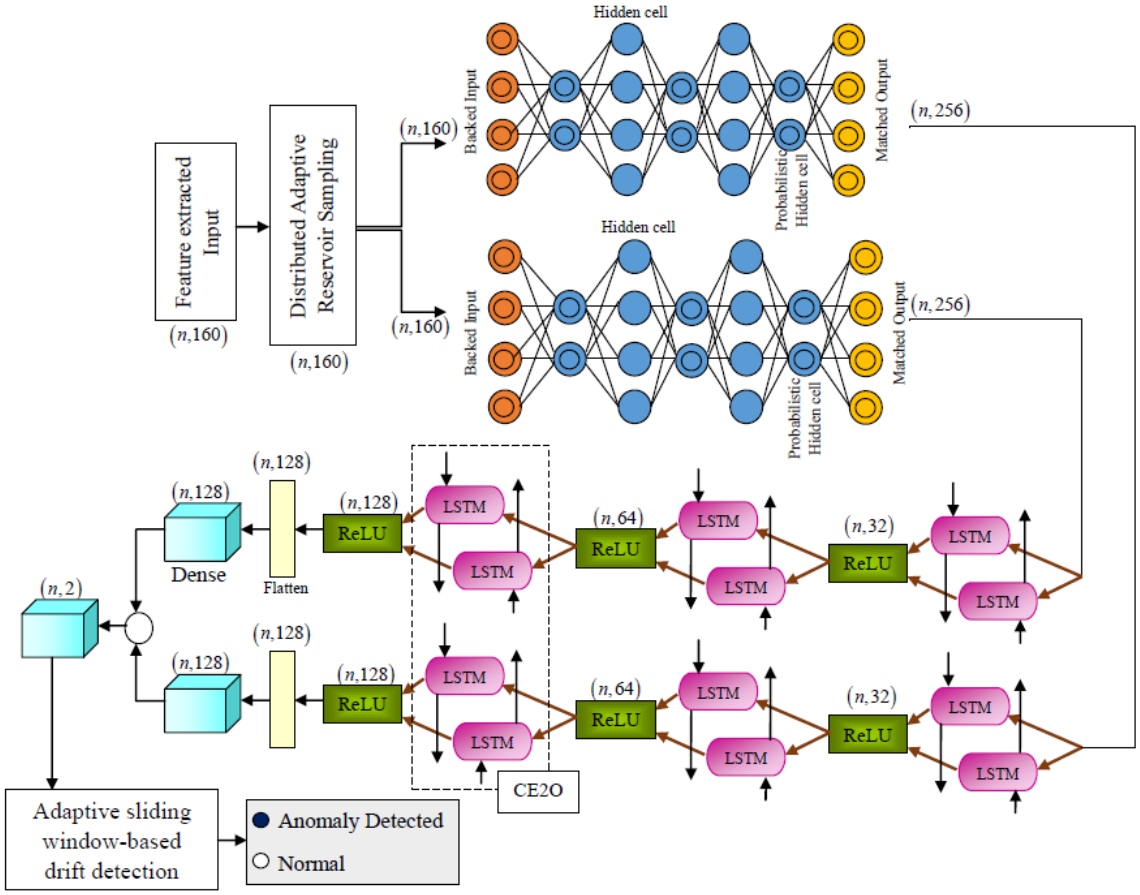

Fig. 2. Architecture of UES2-DTM model in anomaly detection.

1) Time-Series informative features: The time series informative features are derived with the help of the TSFEL library. The TSFEL library works with over 65 different features based on the temporal, spectral, statistical, and fractal domains. The statistical domain includes the time-series information concerning mean, variance and so on. Further for a temporal domain, features such as autocorrelation, and centroid are considered in the research.

2) Statistical features: The evaluated statistical features in the research of anomaly detection with the streaming data are mean, median, standard deviation, variance, skewness, kurtosis, range, and interquartile range (IQR). The obtained statistical features are concatenated to form the feature vector.

3) Mixed information metric features: The mixed information metric feature is estimated with mutual information that extracts features with Shannon entropy, and the new feature is evaluated based on the probability density function (PDF) that involves the Parzen Window method.

E. Adaptive Reservoir Sampling

Adaptive Reservoir Sampling is an advanced technique designed to manage large or streaming data sets by maintaining a representative sample of the data. This method is particularly useful when dealing with data streams, where the total size is unknown or too large to store in memory.

At the start, a fixed size reservoir is initialized to hold a sample of data points [35]. This reservoir is typically filled with the first I elements from the stream in which I is the size of the reservoir. As new data points arrive in the stream, they need to be considered for inclusion in the reservoir. For each new data point, a random decision is made to either include the new point in the reservoir or replace an existing point. The probability of replacing an existing point is proportional to its index in the stream, ensuring that each data point has an equal chance of being included in the final sample. Specifically, for a stream index O and reservoir size I, the probability of a new element *new* replacing an existing element in the reservoir is I/O. This ensures that each element in the stream has an equal likelihood of being in the reservoir by the end of the process. The explained execution takes place when the reservoir size remains unchanged. The major advantage exhibited in the research model is the adaptive mechanism that adjusts the size of the reservoir dynamically based on data distribution. This adaptive behavior ensures that the reservoir reflects the most relevant data characteristics. Thus, the reservoir size is strengthened and impaired accordingly, to evaluate the efficiency. If the size of the reservoir is decreased by ρ, then the number of elements are neglected from the reservoir and continue to work as the traditional reservoir sampling. If the reservoir size is increased by ρ, then the minimum value of incoming elements ele_{min} is evaluated that possess the uniformity coincidence to exceed the threshold value Th. Further, the algorithm is flipped to attain

the number of elements kr to retain among the total elements *I*. The probability of kr is estimated as,

$$p(kr) = \frac{\binom{o}{kr}\binom{ele_{min}}{I+\rho-kr}}{\binom{o+ele_{min}}{I+\rho}} \quad (2)$$

F. Unicintus Escape Energy Enabled Model

The research on anomaly detection from the streaming data is performed with the UES2-DTM, which has the baseline model DTM that combines the DBN as well as the BiLSTM. Though the provided baseline models are advanced neural networks, they exhibited certain drawbacks in individual working areas. Hence the combination of them along with UE2O algorithm is proposed in the research of anomaly detection specifically with the streaming data that overcomes the drawbacks of both simultaneously and provides highly efficient outcomes.

DBNs are probabilistic graphical models consisting of multiple layers of stochastic hidden variables., which are built from Restricted Boltzmann Machines (RBMs) stacked on top of each other, followed by a fine-tuning step with a supervised classifier [34]. Hence, In DBN there exist several hidden layers to process the outcome. DBNs expose the advantages of learning the hierarchical representations of the input data that in addition aids in capturing the complex patterns and structures. Further, DBNs exhibit the behavior of dimensionality reduction while preserving the significant features of the input. The BiLSTM network acts as the extension of the Long Short-Term Memory (LSTM) that processes each data in both forward and backward directions intending to capture the long-term dependencies as well as the temporal patterns. Thus, the integration of both emerges the highly efficient research model, where the DBN extracts the most promising features followed by the BiLSTM that analyzes them over time to understand the past and future behaviors, which detects the deviations or anomalies accurately. The advantages of DTM are highly efficient in terms of anomaly detection, even though the detection in the streaming data remains crucial. Thus, the adaptive reservoir sampling mechanism as well as the UE2O-optimized adaptive sliding window-based drift detection mechanism is integrated with the DTM. The working model of the UES2-DTM is depicted in Fig. 2.

The integration of escape characteristics of rabbits [37], and hunting energy characteristics of Hawks [38] forms the UE2O algorithm. Rapid, unpredictable movements made by the rabbit to avoid predators serve as a metaphor for the necessity of flexible, responsive anomaly detection methods. However, the characteristics of hawks, who are renowned for their well-thought-out, highly effective hunting tactics. The input streaming data for anomaly prediction is represented in (1). The data is partitioned into equal-length subsets using a sliding window of size m:

$$E_v = \{S_v, S_{v-1}, \ldots . S_{v-m}\} \quad (3)$$

where, E_v is the new data instance with m dimensions that represent the original state at the time v on the data stream which is fed into UES2-DTM for anomaly detection. To address concept drift, an adaptive sliding window updates the threshold dynamically:

$$E_v(new) = E_{vlow} + \left|E_{vlow} - E_{vup}\right|\gamma \quad (4)$$

where, $E_v(new)$ is the new data generated from each data stream, γ is the adaptive factor, E_{vlow} is the lower bound, and E_{vup} is the upper bound of the data level. The solution positions are randomly initialized within search bounds. The objective function is:

$$M\left(E_v(new)\right) = max\left(accuracy\left(E_v(new)\right)\right) \quad (5)$$

where, M indicates the objective function .Unicintus Optimization aims to maximize this objective function using a hybrid approach.

The core idea behind the hybrid optimization technique is to prove the performance of it in non-stationery environments like IoT anomaly detection. Artificial Rabbit Optimization (ARO) is used for global exploration whereas Harris Hawk Optimization (HHO) is used for local exploitation to merge the advantages of both. ARO is used to find an initial good weight candidate (that helps us explore broadly) whereas HHO is used to refine that candidate weight for better accuracy (helps to fine tune for the optimal performance). Eventually the final optimized weight are arrived at. Accurate drift detection in an adaptive sliding window framework is made possible by the research's efficiency. Furthermore, the framework preserves the overall efficiency of the anomaly detection model.The working model of the UES2-DTM initiates with the feature extracted output. The input is fed into the adaptive reservoir sampling mechanism, where the sample data are held accurately and proceeded to avoid data collision as well as the overfitting issue. The outcome fetched from the reservoir sampling process is further fed into the DBN network, where the features are extracted accurately. With the mechanism applied at the adaptive reservoir sampling the further process works in two consecutive sections. The outcome of both DBNs is provided as the input to the BiLSTM, where three simultaneous BiLSTMs are connected together in each parallel row. This outcome is fed into the flattened layer followed by the dense one. Moreover, the outcome of dense layers at each parallel row is concatenated and presented into the dense layer, where the outcome as normal and anomaly detected is achieved in the work.

G. Adaptive Sliding Window-Based Drift Detection

Sliding Window Drift Detection is a method used to identify changes or drifts in data distributions over time, particularly in streaming data environments, which helps in monitoring and adapting to shifts in data patterns that may affect model performance. It helps to detect and identify a time instant (or interval) when a change arises in the new data. The drift detection helps to evaluate the model's reliability. A fixed-size window is a critical parameter that affects sensitivity and detection performance. Thus, the window slides over the data stream, continually updating its position as new data points arrive [36]. As new data points arrive, they are incorporated into the current window. Each window data point is evaluated against the error metrics, out of all the maximum error that occurred is considered as the threshold. The maximum error of each window is declared through the fitness of the UE2O algorithm. With the obtained threshold, the next iteration is evaluated and updated, hence called as adaptive in the proposed mechanism. The current

window's statistical measures are compared with those from previous windows to detect the drift. The statistical measures represent the Threshold value of the drift. Thus, the maximum error is declared drift and on the next iteration if the drift occurred is higher than the previous iteration, then the model is trained repeatedly until the accurate drift is achieved in the research. Fig. 3 shows the drift detection graph.

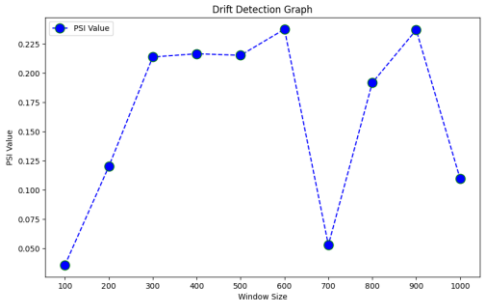

Fig. 3. Drift detection graph.

IV. Results and Discussion

The entire outcomes of the research model UES2-DTM are analyzed and depicted in this section. The complete analysis in this section is performed with the performance metrics such as precision, recall, F1-score, and MSE. Further with the described metrics, the conventional mechanisms are also evaluated shows the proposed UES2-DTM model achieves comparatively high outcomes.

A. Experimental Setup

The experiment is carried out in the PyCharm software of version 2022.2.3 in the system with the configuration of Windows 11 operating system and 16 GB RAM storage. The utilization of the experimental setup supports the research to attain high proficiency specifically when working with the streaming data.

B. Dataset Description

1) IoT-23 Dataset [39]: IoT-23 is a network traffic dataset specifically collected from Internet of Things (IoT) devices. It includes 20 instances of malware-infected traffic from IoT devices and 3 instances of benign IoT device traffic. Benign scenarios network traffic was captured from Philips smart LED lamp, Amazon Echo, and a smart door lock by Somfy. Thus data is captured for analyzing real world network behavior. The upcoming details are collected from the 10000 users. Array(['Benign', 'Okiru', 'PartOfAHorizontalPortScan', 'DDoS', 'C&C', 'C&C0HeartBeat'],dtype=object). The label counts of each of them are Benign – 3024, Okiru – 1670, PartOfAHorizontalPortScan – 4428, DDoS – 858, C&C – 17, C&C0HeartBeat – 3.

C. Performance Assessment

The performance of the UES2-DTM model is analyzed in terms of both K-fold (KF) and training percentage (TP) with metrics such as Accuracy, Precision, recall, and Mean Square Error (MSE). TP 80% and KF 10 are evaluated concerning epochs 100 in this section to depict the efficacy achieved at the model in detail. The Precision achieved at KF 10 in the UES2-DTM model is 97.43%, whereas the recall achieved is 94.62%. Similarly, the F1-score of the proposed model attained 96.01%. In contrast, the proposed model is also verified against the error metrics MSE that obtained 4.583. The performance assessment of the UES2-DTM model concerning KF is depicted in Fig. 4.

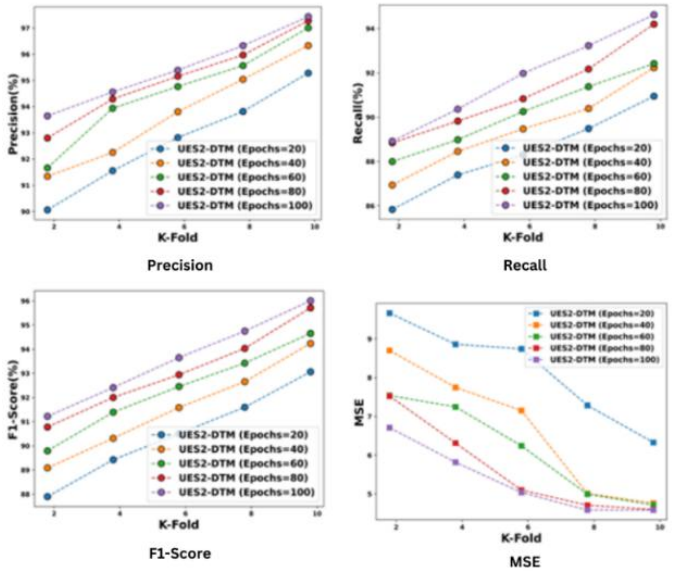

Fig. 4. Performance assessment concerning KF.

The Precision achieved at TP 80% in the UES2-DTM model is 97.19%, whereas the recall achieved is 94.82%. Similarly, the F1-score of the proposed model attained 95.99%. In contrast, the proposed model is also verified against the error metrics MSE that obtained 3.461. The obtained outcomes at both TP and KF analysis are due to efficient mechanisms as well as the models that are combined to detect the anomaly even in the streaming data. The performance assessment of the UES2-DTM model concerning TP is depicted in the Fig. 5.

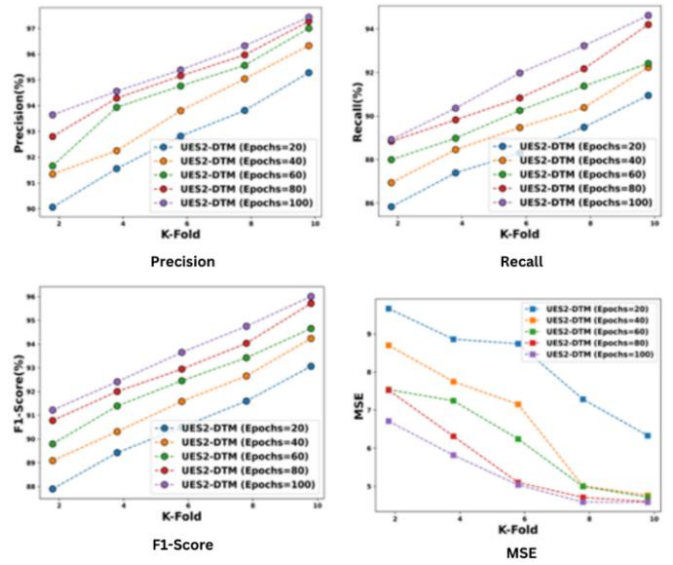

Fig. 5. Performance assessment concerning KF.

D. Comparative Assessment of UES2-DTM Model

The UES2-DTM model is compared with the existing methods such as DNN [28], PiForest [10], RNN [21], SARIMA-BiLSTM [23], DBN-BiLSTM [40], ARO-DBN- BiLSTM [37], and HHO-DBN- BiLSTM [38]. The UES2-DTM model is compared with existing methods concerning the TP in terms of precision achieved at 97.19%, which is improved by 15.44% with DNN, 12.33% with RNN, and 8.72% with DBN-BiLSTM. The recall of the proposed model achieved 94.82% having an average improvement of 15.132% with all the comparative methods. Further, the F1-score of the research model is 95.99%, which shows an improvement of 25.13%, 13.32%, and 8.47% with the respective methods. The MSE obtained in the research model is 3.461, which is an average reduction of 5.66. The comparative assessment concerning TP is illustrated in Fig. 6.

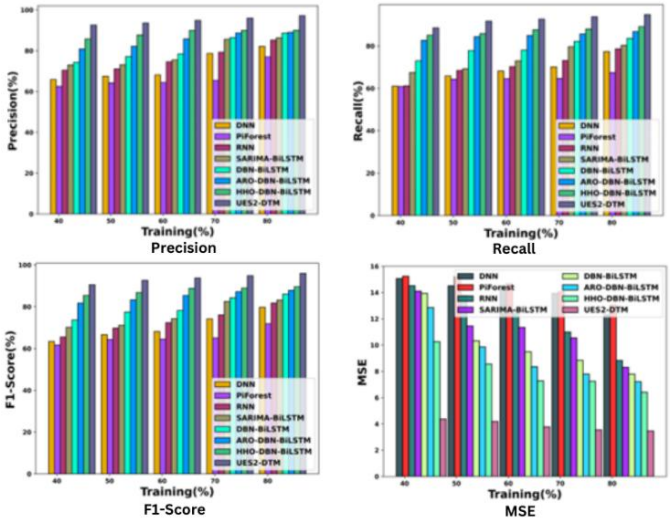

Fig. 6. Comparative assessment concerning TP.

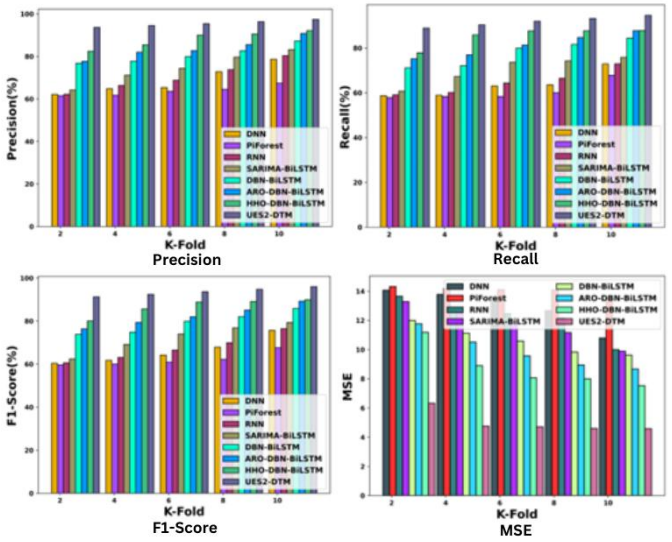

Fig. 7. Comparative assessment concerning KF.

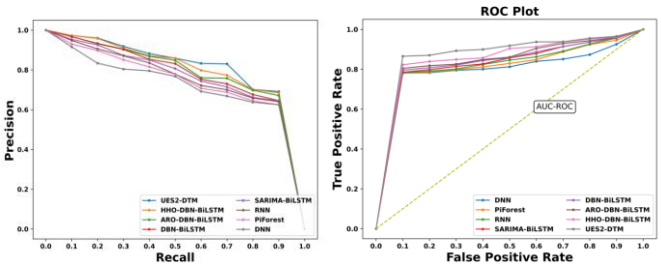
The UES2-DTM model is compared with existing methods concerning the KF in terms of precision achieved 97.43%, which is improved by 19.26% with DNN, 17.48% with RNN, and 10.36% with DBN-BiLSTM. The recall of the proposed model achieved 94.62% having an average improvement of 17.08% with all the comparative methods. Further, the F1-score of the research model is 96.07%, which shows an improvement of 29.58%, 17.33%, and 7.05% with the respective methods. The MSE obtained in the research model is 4.54, which is an average reduction of 5.41. The comparative assessment concerning TP is illustrated in Fig. 7.

E. Graphical Representation of PRC and AUC-ROC

To show the efficiency of the research model, the precision-recall curve (PRC) as well as the area under the receiver operating characteristic curve (AUC-ROC) of the anomaly detection in streaming data is shown in Fig. 8. The PRC represents the interplay between precision and recall, where high precision and high recall indicate low false positive and false negative rates, respectively. The proposed model attained a rate of 0.701 precision, for a sensitivity of 0.8 whereas for 0.9 it obtained a 0.699 rate of positive predicted output. Moreover the AUC-ROC Compares the error rate with the sensitivity rate achieved by the UES2-DTM model. The attained sensitivity of the research model is 0.9653 for an error rate of 0.9. Thus, the proposed research model attains the best outcomes, which is depicted through the evaluation with PRC, and AUC-ROC. The outcomes are due to the enhanced mechanism combinations in the UES2-DTM model.



PRC AUC-ROC

Fig. 8. Graphical representation of PRC and AUC-ROC.

F. Comparative Discussion

The research model is compared with the existing methods that ended up with certain drawbacks in anomaly detection from streaming data.DNN was computationally expensive and required large amounts of data for training, which were further prone to overfitting, especially when dealing with small datasets. PiForest struggled with large-scale streaming data due to its ensemble-based approach. RNNs suffer from gradient vanishing problems during training, and they struggle to capture long-term dependencies in sequences. Combining SARIMA with BiLSTM introduced additional complexity. Choosing the right architecture for DBN-BiLSTM impacted the performance of the research model. The combination of autoencoders, DBNs, and BiLSTM increased model complexity. Thus, the described challenges are overcome with the UES2-DTM model, and the comparative discussion is tabulated in Table II.

TABLE II. COMPARATIVE DISCUSSION OF UES2-DTM MODEL

Analysis / Methods		DNN	Pi Forest	RNN	SARIMA-BiLSTM	DBN-BiLSTM	ARO-DBN-BiLSTM	HHO-DBN-BiLSTM	UES2-DTM
TP=80%	Precision (%)	82.18	76.96	85.21	86.32	88.72	89.01	90.07	97.19
	Recall (%)	77.37	67.46	78.62	80.27	83.61	86.84	89.13	94.82
	F1-score (%)	79.71	71.89	81.78	83.19	86.09	87.98	89.63	95.99
	MSE	12.33	13.04	8.83	8.39	7.78	7.21	6.41	3.46
KF=10	Precision (%)	78.66	67.44	80.39	83.21	87.33	90.78	92.08	97.43
	Recall (%)	72.88	67.79	72.91	75.85	84.43	87.73	87.79	94.62
	F1-score (%)	75.66	67.61	76.47	79.36	85.86	89.23	89.89	96.01
	MSE	10.79	13.45	10.61	9.88	9.62	8.66	7.52	4.58

V. CONCLUSION

The anomaly detection in the streaming data is performed with the UES2-DTM model that achieves high efficacy in the detection. The research model integrates the UE2O algorithm within an adaptive sliding window framework and adaptive reservoir sampling techniques. By leveraging the UE2O algorithm, this model enhances the accuracy and efficiency of drift detection, ensuring timely and precise identification of anomalies. The adaptive sliding window approach allows for dynamic adjustments to the window size, optimizing the balance between detection sensitivity and computational resource management. Similarly, adaptive reservoir sampling ensures a representative data subset, facilitating effective anomaly detection without overwhelming system resources. Moreover, the involved feature extraction methods significantly augment the model's performance by transforming preprocessed data into meaningful patterns, improving the ability to discern anomalies amidst complex and high-dimensional data. In addition, the preprocessing step not only boosts detection accuracy but also contributes to more robust and interpretable results. Thus, the overall performance of the research model is evaluated with metrics such as precision, recall, F1-score, and MSE that obtained 97.19%, 94.82%, 95.99%, and 3.46 respectively. Future research can include the integration of different DL mechanisms as well as the combination of several advanced optimization mechanisms. In addition, the scalability of the detection model can be evaluated with diverse methods and metrics.

***Abstract*—Deep learning models such as TabNet have gained popularity for handling tabular data. However, most existing architectures treat categorical variables as nominal, ignoring the inherent ordering in ordinal data, which can lead to suboptimal classification performance, particularly in tasks where ordinal relationships carry meaningful information, such as quality assessment, disease severity staging, and risk prediction. This study investigates the impact of explicitly modeling ordinal relationships in deep learning by developing an ordinal classification model and comparing it with its nominal counterpart. The proposed approach integrates TabNet a deep learning framework with ordinal constraints, leveraging a proportional odds model to better capture the ordinal structure and Beta cross-entropy as the loss function to enforce ordering during training. To evaluate the effectiveness of the proposed ordinal classification approach, experiments were conducted on two publicly available datasets: the White Wine Quality dataset and the Hepatitis C dataset. The results demonstrate that incorporating ordinal constraints leads to improvements across multiple evaluation metrics, including 1-off accuracy, average mean absolute error (AMAE), maximum mean absolute error (MMAE), and quadratic weighted kappa (QWK) compared to a nominal classification model trained under the same conditions. These findings underscore the importance of ordinal modeling in tabular classification and contribute to the advancement of deep learning techniques for structured data.**

Keywords*—Ordinal classification; TabNet; proportional odds model; tabular data

I. Introduction

Tree-based machine learning algorithms like Extreme Gradient Boosting (XGBoost), Categorical Boosting (CatBoost) have achieved strong performance on tabular data, but they have limitations in learning complex, and non-linear relationships as compared to deep learning methods. Numerous neural architectures have been proposed for the purpose of strengthening neural networks' performance on tabular data. TabNet [1] is a type of neural network specifically designed for processing tabular data. TabNet has improved classification in various domains such as insurance [2], rainfall prediction [3], food safety risk [4]. In tabular datasets, each column represents a distinct feature, with some columns containing continuous numerical values while others include discrete or categorical data [5]. During training, TabNet uses softmax for discrete outputs which gives the model's predefined set of class probabilities for classification tasks. However, on the case of ordinal classification, the softmax might not be the best choice.

Ordinal regression (ordinal classification) problems in machine learning involve classifying patterns according to a categorical scale that reflects a natural order among the labels [6]. This type of problem can be approached as nominal classification; however, doing so ignores the ordinal information [7], which may result in low prediction accuracy and the loss of important information regarding the order of the categories. A more effective strategy is to employ methods that consider the ordinality, thereby enhancing the classification model's performance. It can be challenging to ascertain the link between distinct classes using other techniques, but ordinal regression can help [8].

In non-tabular domains, ordinal classification has been transformed by deep learning, such as age estimation [9] and medical diagnosis [10] using images. However, no deep learning model has been developed explicitly for ordinal classification in tabular data. This study intends to close this gap by creating a deep learning ordinal classifier specifically designed for tabular data, utilising neural networks with ordinal constraints to enhance interpretability and prediction accuracy. We introduce Proportional Odds Model (POM) for TabNet, combined with the Beta Cross-Entropy loss function, to enhance the classification performance of ordinal tabular data. The (POM) [11] is a category of generalized linear models employed to model the dependence of an ordinal response on discrete or continuous covariates. The POM can be directly applicable to the output of a TabNet, thus addressing the challenge of deep learning methods in tabular data ignoring ordering information of data. POMs offer a more adaptable and comprehensible method of deep ordinal classification by indirectly modelling a latent space in addition to the set of thresholds dividing the ordered classes. By replacing the one-hot labels with their soft label equivalents, the beta cross-entropy loss function adds soft labels to the cross-entropy loss function. Soft labels might potentially improve model performance by better accounting for ordinal classification uncertainty, which occurs when it is difficult to distinguish between nearby categories because of their resemblance.

The remainder of this paper is structured as follows: A review of relevant theory and related literature is presented in Section II; materials and methods for completing the work are described in Section III; analysis and interpretation of results are presented in Section IV, while Sections V and VI provide the discussion and conclusion, respectively.

II. Literature Review

While a lot of research has been done on the ordinal classification of tabular data, very little of it has concentrated on deep learning for the ordinal classification of tabular data. Convolutional Neural Networks (CNN) are used in image datasets for the current deep learning ordinal techniques.

A. Deep Learning Ordinal Classification in Image Data

For determining the degree of neurological damage in individuals with Parkinson's disease (PD), an ordinal decomposition method in conjunction with a 3D CNN ordinal model was suggested [10]. Instead of employing a softmax function for the output nodes, a regular sigmoid function is supplied in the output node. They provided experimental evidence that using ordinal information can enhance performance on a challenging task, such as evaluating changes in brain activity in Parkinson's disease.

By taking into account a family of probabilistic ordinal link functions in the output layer, a deep convolutional neural network model for ordinal regression was proposed [9]. The experiments ran over two different image data ordinal classification problems. The link functions used are those from cumulative link models, which are traditional statistical linear models that project each pattern onto a one-dimensional space.

B. Ordinal Classification in Tabular Data

A thorough analysis of ordinal classification techniques was presented in study [6], the authors grouped ordinal classification methods into three: naïve approaches, binary decomposition, and threshold models. Naïve approaches apply standard machine learning models without explicitly considering the ordinal structure. Binary decomposition transforms the ordinal problem into multiple binary classification tasks, either solved by separate models or a multi-output model. Threshold models approximate a real-valued predictor and partition it into intervals to determine class boundaries.

In naïve approaches, artificial intelligence-machine learning (AI-ML) algorithms were proposed for cost-sensitive learning utilizing resampling techniques and for ordinal categorization using ordinal decomposition [12]. They evaluated a "naïve" multi-class decomposition called "One-Vs-One" (OvO) and a "naïve" conversion of the classification issue into a regression task, and an ordinal 'Ordered Partitions' (OrdP) decomposition. In the cost-sensitive learning they used SMOTE. To predict white wine quality based on physicochemical data, [13] applied Synthetic Minority Oversampling Technique (SMOTE) algorithm to address class imbalance then applied Random Forest and Multinomial Logistic Regression for classification, ignoring the order between classes. Random Forest outperformed the Multinomial Logistic Regression. The absence of a clear correlation between the regression model's prediction error and the misclassification error is one of the drawbacks of the conventional ordinal classification techniques based on regression.

An ordinal binary decomposition method that allows ordering information to be used by standard classification in class attributes was presented in study [14]. An ensemble-based classifier that combines ensemble-learning paradigm such as bagging and AdaBoost with the ordinal binary decomposition by study [14] to improve prediction performance was proposed in study [15]. To predict soil temperature level, the study in [16] proposed Soil Temperature Ordinal Classification (STOC) approach that used five different traditional ML methods (K-Nearest Neighbors, Random Forest, Naïve Bayes, Support Vector Machines, and Decision Trees). The STOC using Decision Trees as the base learner (STOC.DT) performed better among the others. The primary challenge with ordinal binary decomposition approaches is that, they are strongly dependent on the specific decomposition method used and the way the results from all decompositions are combined into a final classification.

Two gradient descent-based techniques for learning an ensemble of base classifiers being decision rules was presented in study [17] . The forward stage-wise additive modelling that makes use of the threshold loss function is the foundation of the decision rule induction algorithm. The ordinal decision criteria are competitive with both the established ordinal classification techniques and conventional regression and multi-class classification methods. In study [18] a method that simplifies the ordered class classification problem to the conventional two-class problem was presented. Neural networks and support vector machines were then trained using the method. An experimental study verified the usefulness of the approach. In study an ordinal loss function based on the soft labelling approach was used to combine four Multi-Layer Perceptron (MLP) models that had been optimized. Furthermore, an ordinal logistic regressor is included with the soft labelling models. The unimodal probability distributions fail to explicitly model the ordinal structure of data.

C. Unimodal Regularisation

The performance of ordinal classifiers with respect to the conventional one-hot encoding has been enhanced by the distributions suggested to softly model the targets.

A straightforward technique was proposed in study [20] to enforce unimodality in discrete ordinal probability distributions using the Poisson distribution. The distribution parameter λ is equal to the mean and variance of this type of distribution. As a result, its ability to obtain a slight variation is limited. Because of this, they also employed the binomial distribution, which has two parameters: the probability, p, and the number of classes, C. Although the variance ($Cp(1-p)$) and the mean (Cp) have different expressions, positioning the mode at the right point in the interval while obtaining a small variance is difficult.

It was suggested to use a soft labelling strategy based on generalized triangular distributions, which are asymmetric and unique for every class in study [21]. A metaheuristic is used to calculate the parameters of these distributions, which are then tailored to the particular problem. Additionally, the model can avoid errors in remote classes thanks to this method.

A sample based on the exponential function $e^{\frac{-|i-l|}{\tau}}$ where l represents the class of the pattern and $i = 1, \ldots, C$, followed by a softmax normalization was proposed [22]. However, the value of τ requires experimental tuning, and in some cases, the probability mass is not sufficiently concentrated in the interval of the correct class.

A unimodal regularization technique based on the beta distribution was proposed in study [23] and applied to the cross-entropy loss. This regularization encourages the label distribution to form a soft unimodal shape. Because of its low variance and domain constraint from 0 to 1, using beta distributions to determine the soft labels is an improvement over earlier approaches [19] .

D. Research Gap and Motivation

Ordinal binary decomposition (OBD) is commonly used to handle ordinal classification in tabular data. OBD does, however, have inherent limits because its effectiveness is highly reliant on the particular decomposition technique employed and how the output of several decompositions is combined to provide a final classification. This dependence may result in suboptimal performance and a more complex model. To address these challenges, we propose an alternative approach inspired by techniques widely used in image-based ordinal classification namely, threshold-based modeling applied to the output of deep learning algorithms. We use TabNet [1], a deep learning model developed especially for tabular datasets, and apply POM to its output layer.

Additionally, recent research has shown that soft labeling can improve ordinal classification performance by incorporating uncertainty and reducing the impact of hard class boundaries. To take advantage of this benefit, we use a unimodal regularization technique based on the beta distribution [23] in place of the conventional categorical cross-entropy loss in order to improve the accuracy and robustness of our ordinal classifier.

In order to provide a more efficient solution for ordinal classification in tabular data, our study aims to close the gap between conventional OBD approaches and contemporary deep learning techniques by using these developments.

III. Materials and Methods

Building on the previous analysis of the state-of-the-art, our proposal is to integrate a flexible threshold model in the output layer, POM, with a unimodal probability distribution based on the beta distribution to more effectively enforce ordinal constraints during learning.

A. Data Description and Preprocessing

This study uses two datasets to evaluate the different models; Hepatitis C dataset and white wine quality dataset both obtainable online at UCI machine learning repository [24]. The data was processed and split into the ratio of 7:3 for training, and testing respectively.

1) Hepatitis C dataset: The Hepatitis C dataset has 615 instances of laboratory values of blood donors and Hepatitis C patients and demographic values like age. It includes a total of 14 features including the target attribute which has five outcomes, ‘0=Blood Donor’, ‘0s=suspect Blood Donor’, ‘1=Hepatitis’, ‘2=Fibrosis’, ‘3=Cirrhosis’. Category (blood donors vs. Hepatitis C, including its progression: 'simply' Hepatitis C, Fibrosis, Cirrhosis) is the target attribute for classification. The dataset has some missing values and they were filled using mean. Blood donor, suspect blood donor was encoded as 0, hepatitis was encoded as 1, fibrosis encoded as 2, cirrhosis as 3. Numerical values were normalized. Since the classes were imbalanced (see Fig. 1), SMOTE was used to balance the classes.

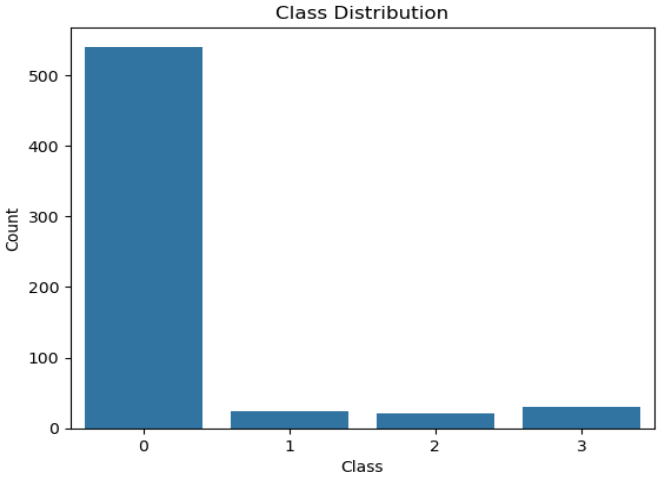

Fig. 1. Hepatitis C dataset class distribution.

2) White wine quality dataset: The white wine quality dataset has 4898 instances of physicochemical tests of the Portuguese “Vinho Verde” wine. It includes a total of 12 features including the target variable “quality” which has 7 outcomes ranging from 3 to 9. The classes are ordered and not balanced as shown in Fig. 2 so SMOTE was used to balance the classes.

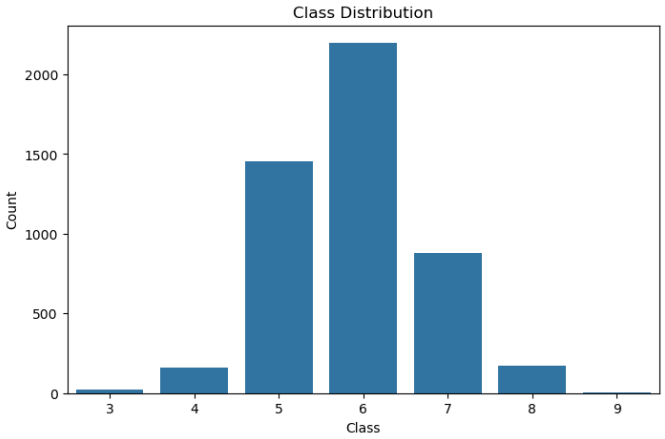

Fig. 2. White wine quality dataset class distribution.

B. TabNet Architecture

TabNet's architecture consists of N_{steps} subnetworks that are processed sequentially in a hierarchical manner (see Fig. 3), with each subnetwork representing a decision step. During training, every decision step processes the current data batch as its input. At the i^{th} step the subnetwork takes in the processed information from the $(i-1)^{th}$ step to determine which features to utilize. It then outputs a refined feature representation, which is incorporated into the overall decision. TabNet combines the outputs of all decision steps to generate the final prediction.

At every decision step, TabNet employs a feature mask that encourages controlled sparsity $M[i] \in \Re^{B \times D}$, where B

represents the batch size, for soft instance-wise feature selection. The masking is applied multiplicatively, $M[i] \cdot f$, f is the feature representation at the current step. This feature mask is learned using attentive information from the preceding decision step, $a[i-1]$, and is computed as: $M[i] = \text{sparsemax}\left(P[i-1] \cdot h_i(a[i-1])\right)$. The feature transformer module determines which features should be forwarded to the next decision step and which features should be utilized to produce the output at the current decision step. This process is defined as: $[d[i], a[i]] = f_i(M[i] \cdot f)$, where $d[i] \in \Re^{B \times N_d}$ represents the decision step output, and $a[i] \in \Re^{B \times N_a}$ serves as attentive information for subsequent steps. Certain layers within the feature transformers are shared across all decision steps. The feature masks generated during this process correspond to local feature weights and can be aggregated into a global importance score.

Drawing inspiration from decision-tree-like aggregation, TabNet forms the overall decision embedding as: $d_{out} = \sum_{i=1}^{N_{steps}} \text{ReLU}(d[i])$. A linear transformation, $W_{final} d_{out}$, is then applied to generate the output mapping. For discrete outputs, a softmax function is used during training, while argmax is applied during inference.

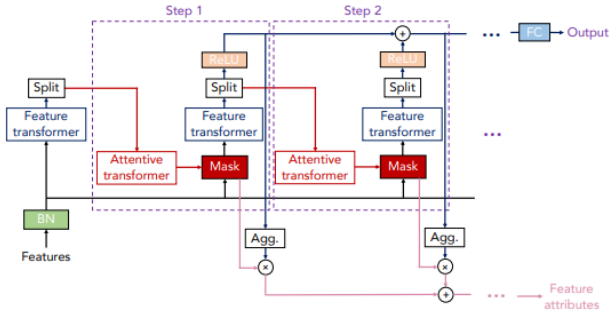

Fig. 3. TabNet architecture [1].

C. Proportional Odds Model

When the classes have a natural order, rather than addressing the problem using the standard approach mentioned above, a threshold-based method known as the Proportional Odds Model (POM) can be used instead of softmax. POM is part of a broader category of models called Cumulative Link Models (CLMs) [25]. In the POM framework, the class ordering is maintained through the following latent constraint shown in Eq. (1):

$$f^{-1}(P(y \le y_c|x)) = t_c - f(x) \quad (1)$$

Where $c = 1, 2, \cdots, C-1, f^{-1}$ is a function that maps probabilities from the range [0,1] to the entire real number line, ensuring a monotonic transformation. The threshold for class y_c is denoted as t_c. Consequently, the class y_c is predicted if and only if: $f(x) \in [t_{c-1}, t_c]$.

POM utilizes the logit link function, which is defined in Eq. (2) as:

$$\text{logit}[P(y \le y_c|x)] = \log \frac{P(y \le y_c|x)}{1 - P(y \le y_c|x)} = t_c - f(x), \quad c = 1, \cdots, C-1, \quad (2)$$

or the equivalent expression expressed in Eq. (3):

$$P(y \le y_c|x) = \frac{1}{1 + e^{-(t_c - f(x))}} \quad (3)$$

D. Beta Cross-Entropy

Beta cross-entropy is a unimodal regularization technique that incorporates the beta distribution into the cross-entropy loss. This regularization promotes a soft unimodal distribution of labels, making it more suitable for ordinal classification problems.

For a one-hot label, the probability distribution of the label is given by $q(i) = \delta_{i,l}$, where l represents the ground truth class. The Dirac delta function, $\delta_{i,l}$ equals 1 when $i = l$, and 0 otherwise. This label smoothing technique can be incorporated into the cross-entropy loss by modifying $q(i)$ in Eq. (4):

$$L = \sum_{i=1}^{J} q(i)[-\log P(y = C_i|x)] \quad (4)$$

with a target distribution that is more conservative as shown in Eq. (5):

$$L = \sum_{i=1}^{J} q'(i)[-\log P(y = C_i|x)] \quad (5)$$

where $q'^{(i)} = (1-\eta)\delta_{i,1} + \eta f(x,a,b)$ and the linear combination is controlled by the parameter η. $f(x,a,b)$ represents the probability value sampled from a beta distribution centred in $x = \frac{2J-1}{2J}$ and makes uses of the a and b parameters obtained using the method proposed by the authors [23].

The properties of the beta distribution are as follows. In its standard form, the beta distribution, denoted as, $\beta(a,b)$ is a continuous distribution. Its probability density function (PDF) is given in Eq. (6):

$$f(x,a,b) = \frac{x^{a-1}(1-x)^{b-1}}{B(a,b)} \quad (6)$$

where $0 < x < 1, a > 0$ and $b > 0$. The beta function $B(a,b)$ has the form shown in Eq. (7):

$$B(a,b) = \int_0^1 x^{a-1}(1-x)^{b-1}dx = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)} \quad (7)$$

where $\Gamma(a) = (a-1)!$. When $a, b > 1$, the probability density function $f(x)$ has a unique mode at $\frac{a-1}{(a+b-2)}$ and is zero at $x = 0$ and $x = 1$. If $a = 1$ or $b = 1$ then $f(x)$ has a corresponding terminal value b or a, respectively. Lastly, $f(x)$ becomes the uniform distribution if $a = b = 1$.

Fig. 4 illustrates the differences in the final layer and loss functions of the nominal TabNet and its ordinal variation as proposed.

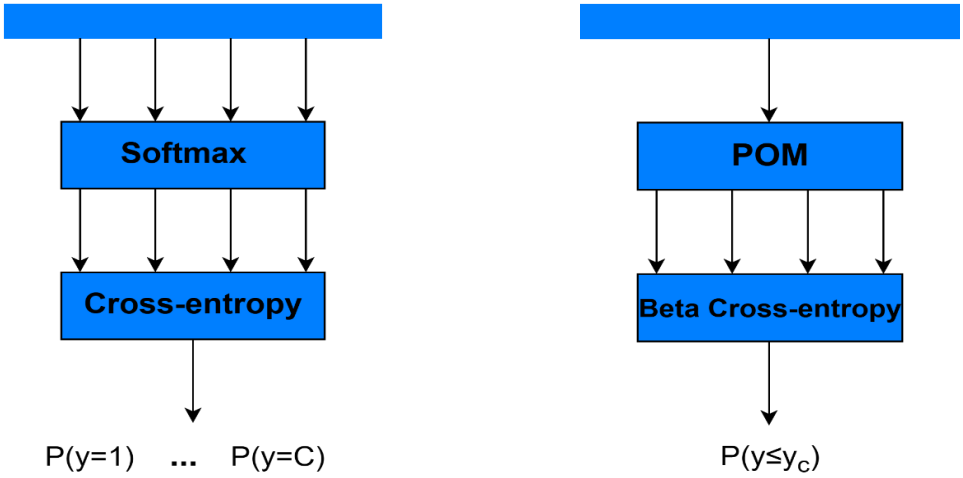

Fig. 4. Comparison between the existing nominal (left) and proposed ordinal TabNet (right). The key difference is in the loss function and the constraint on learned representations, affecting how the model treats ordinal relationships.

IV. Results

The results of the proposed ordinal TabNet approach are presented in this section, along with a comprehensive comparison against the compared approaches.

A. Hyperparameters

We present best hyper-parameter configuration that achieved the highest performance for each dataset. We employed Bayesian hyper-parameter optimization approach to identify the most effective hyper-parameter setup for optimization purposes. We used early stopping as a strategy to determine the optimal number of epochs for training the model, which helps conserve computational resources, prevent over-fitting, and demonstrate strong generalization capabilities without excessive training.

For the Hepatitis C dataset, the best performance was achieved with the values shown in Table I.TABLE I.

TABLE I. Hyperparameters for Hepatitis C Dataset

Hyperparameter	Value
Number of Decision Steps (n_steps)	7
Decision Layer Size (n_d)	39
Attention Layer Size (n_a)	31
lambda_sparse	2.882 x 10^{-3}
Learnring rate (lr)	7.457 x 10^{-3}
Gamma	1. 175

For the white wine dataset, the best performance was achieved with the values shown in Table II.

TABLE II. Hyperparameters for White Wine Datatset

Hyperparameter	Value
Number of Decision Steps (n_steps)	8
Decision Layer Size (n_d)	62
Attention Layer Size (n_a)	63
lambda_sparse	3.634 x 10^{-3}
Learnring rate (lr)	9.890 x 10^{-3}
Gamma	1. 010

B. Evaluation Metrics

Various evaluation metrics are used to measure the closeness of predictions to actual values. In this work, all selected performance metrics are well-suited for ordinal classification problems, as they appropriately penalize misclassification errors more severely when they occur in distant classes compared to adjacent ones. The following performance metrics are considered:

- 1-off accuracy: assesses the proportion of predictions that are either correct or differ by at most one category from the actual class.
- Average Mean Absolute Error (AMAE) [26]: The average MAE, calculated as the mean of the MAE classification errors across different classes, helps to reduce the impact of imbalanced class distributions. When AMAE is applied to an unbalanced dataset, the trivial class for AMAE is counted like any other class rather than in proportion to its frequency. Let MAE_c be the MAE for a given c-th class, AMAE is defined in Eq. (8) as:

$$AMAE = \frac{1}{C}\sum_{c=1}^{C} MAE_c \quad (8)$$

where AMAE values fall between 0 to $C-1$.

- Quadratic Weighted Kappa (QWK) [27]: Reflects the degree of disagreement, placing greater emphasis on larger differences between ratings than on smaller ones. The quadratic weighted kappa is calculated as Eq. (9):

$$QWK = 1 - \frac{\sum_{i,j} W_{i,j} O_{i,j}}{\sum_{i,j} W_{i,j} E_{i,j}} \quad (9)$$

where, W is the penalization matrix; quadratic weights are taken into consideration in this instance, $W_{i,j} = \frac{(i-j)^2}{(C-1)^2}$), E is the expected matrix, whereas O is the confusion matrix that represents the agreement that would occur by chance.

- Maximum Mean Absolute Error (MMAE) [28]: MMAE represents the MAE value of the class with the largest

deviation between the true and predicted values, as shown in Eq. (10):

$$MMAE = \max\{MAE_c; c = 1, \cdots, C\} \quad (10)$$

C. Compared Approaches

The proposed ordinal TabNet approach is evaluated in comparison with the following methods:

- A nominal TabNet (using softmax and cross-entropy) [1].
- STOC.DT [16]: An ordinal classification model that was developed to classify soil temperature level in tabular data.

D. Model Comparison

This section presents the results of this study that implemented the ordinal TabNet. Table III and Table IV present a comparative analysis of the proposed approach against the baseline nominal model TabNet, and STOC.DT using evaluation metrics for both the Hepatitis C and white Wine datasets. Each metric's best value is indicated in bold.

TABLE III. HEPATITIS C MODEL EVALUATION METRICS

Model	1-off (%) ↑	AMAE ↓	QWK ↑	MMAE ↓
TabNet	97.8	**0.423**	0.835	0.777
STOC.DT	97.2	0.602	0.769	1.16
Proposed Approach	**98.9**	0.439	**0.890**	**0.666**

TABLE IV. WHITE WINE MODEL EVALUATION METRICS

Model	1-off (%) ↑	AMAE ↓	QWK ↑	MMAE ↓
TabNet	92.6	1.222	0.584	3.0
STOC.DT	92.2	**1.028**	0.569	**2.16**
Proposed Approach	**92.9**	1.051	**0.598**	2.333

Test confusion matrices for the Hepatitis C and white wine datasets are displayed in 0 and Fig. 6 , respectively, for the proposed approach and the baseline approach (nominal approach).

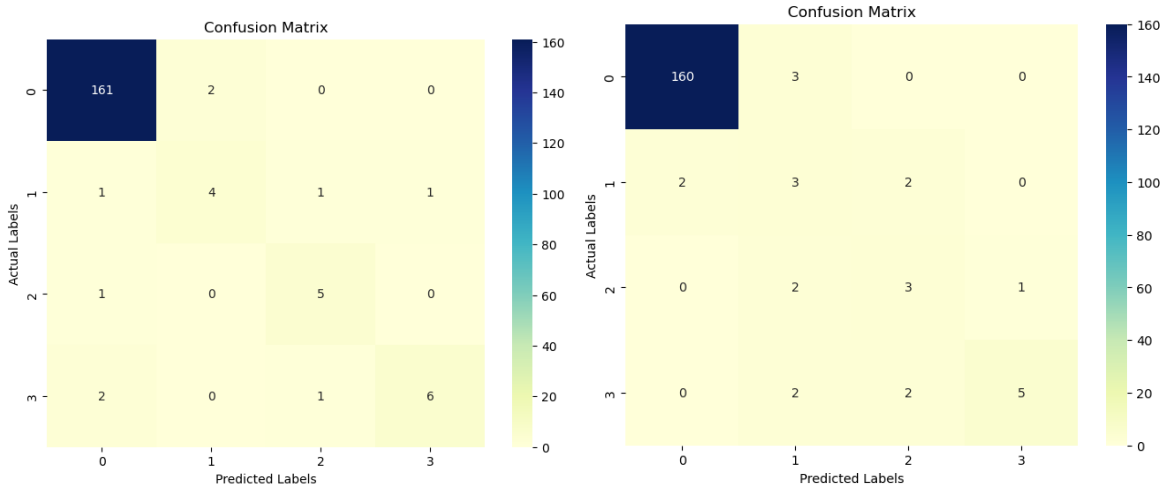

Fig. 5. Hepatitis C confusion matrices for nominal(left) and proposed ordinal TabNet(right).

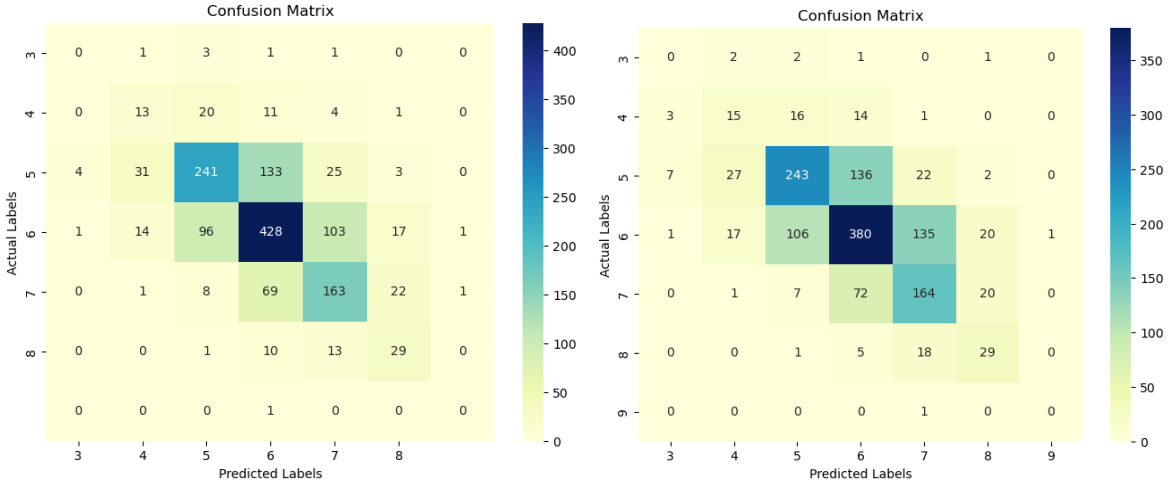

Fig. 6. White wine confusion matrices for nominal(left) and proposed ordinal TabNet(right).

V. Discussion

Table III shows results from Hepatitis C model evaluation, our proposed approach has achieved a 1-off accuracy of 98.9%, QWK of 0.890, and MMAE of 0.666 outperforming TabNet [1] that treats the problem as nominal and STOC.DT [16] that takes the ordinal information into consideration through ordinal binary decomposition. When comparing the test confusion matrices (0) of the baseline technique (nominal approach) and proposed approach, the confusion matrix of the proposed approach is centered on the diagonal which shows that our approach penalizes inaccuracy among distant classes.

Table IV shows results from white wine model evaluation. It demonstrates that, in comparison to the alternative methods, TabNet [1] and STOC.DT [16], the proposed method achieved a higher 1-off accuracy and QWK with values 92.9% and 0.598, respectively. STOC.DT was a close competition as it performed slightly better than our approach in terms AMAE and MMAE. The same can be observed for white wine test confusion matrices Fig. 6 as in the Hepatitis C confusion matrices that the confusion matrix of the proposed approach is centered on the diagonal which shows that our approach penalizes inaccuracy among distant classes.

VI. Conclusion

This paper presents a novel deep ordinal network that integrates POM with a Beta Cross-Entropy loss function applicable to ordinal tabular data. The study presents a data-driven approach to improving predicting accuracy while preserving the inherent order within categorical labels by combining deep learning architecture with ordinal constraints. The proposed model enhances the performance of deep networks compared to its nominal counterpart. The findings indicate that the optimal parameter values are problem-dependent, emphasizing the need for an experimental design where all parameters are carefully tuned for each specific problem.

By emphasizing the benefits of integrating ordinal constraints into deep neural networks, this paper theoretically advances the expanding field of ordinal deep learning. Additionally, the study provides insight into how deep ordinal classifiers behave while working with tabular data, laying the groundwork for further developments in this field.

The proposed approach can successfully classify ordinal data with enhanced robustness, which makes it appropriate for practical applications where ordinal relationships are essential.

Despite these contributions, the study has certain limitations. Substantial computational resources are needed for the deep learning model, which restricts its use in real-time situations. The model's effectiveness on other ordinal classification tasks has not been tested, despite its strong performance on the selected datasets.

Future work could explore an ensemble approach that integrates various soft labeling techniques to enhance model robustness. Additionally, investigating alternative cumulative link model (CLM) link functions beyond the logit function may provide deeper insights into ordinal relationships and improve classification performance.

Acknowledgment

The authors express their gratitude to Pan African University, Institute for Basic Sciences, Technology and Innovation (PAUSTI) for their financial contribution and to the Department of Mathematics for their unwavering support in the completion of this work.

Intelligent Real-Time Air Quality Index Classification for Smart Home Digital Twins

Saley Saleh[1], A. S. Abohamama[2], A. S. Tolba[3]
Department of Computer Science-Faculty of Computers and Information, Mansoura University, Mansoura 35516, Egypt[1, 2, 3]
Department of Computer Science, Arab East Colleges, Riyadh 53354, Saudi Arabia[2]

***Abstract*—This paper investigates the application of machine learning and deep learning models for intelligent real-time Air Quality Index (AQI) classification within a smart home digital twin context. Leveraging sensor data encompassing CO2 and TVOC levels, we perform a comparative analysis of eight models: Transformer Neural Network (TNN), Convolutional Neural Networks (CNN), Gated Recurrent Units (GRU), Recurrent Neural Networks (RNN), Support Vector Machines (SVM), Random Forest (RF), Gradient Boosting (GB), and K-Nearest Neighbors (KNN). These models aim to accurately classify air quality into six categories corresponding to AQI levels, ranging from Good to Hazardous, which are critical for assessing health risks. The performance of each model is rigorously evaluated using metrics including accuracy, precision, recall, F1-score, and ROC curves. Our findings demonstrate that the implemented models exhibit strong performance. This high-accuracy classification enables the smart home digital twin to move beyond passive monitoring, enabling proactive environmental control. For instance, the digital twin can use this real-time AQI classification to automatically adjust HVAC systems, trigger air purifiers when indoor air quality degrades, and potentially inform occupancy schedules. This integration allows for intelligent, adaptive management of the home's environment, ensuring optimal indoor air quality and occupant well-being. The paper also discusses the limitations of each model and suitable application scenarios for intelligent AQI management within the digital twin framework, offering valuable insights for the selection of appropriate air quality classification models in smart home environments.**

I. Introduction

The digital world and digital technologies are constantly increasing. One of the most important digital technologies is the digital twin. A digital twin is a virtual twin or digital copy of a physical asset, system, process, or product that operates in a virtual environment. The digital twin acts as a bridge between the physical entities and the virtual environment. One of these field of digital twin is smart building that spans the building lifecycle and collect real-time data from building by using sensors to control the behavior and monitor operations to optimize building performance and improve the decision making. Air pollution is a major environmental concern affecting public health worldwide [1]. Accurate and reliable air quality classification is crucial for implementing effective mitigation strategies and informing the public [2].

Air quality is a very important factor anywhere, especially in enclosed spaces. To ensure human safety, air quality must be monitored. Monitoring air quality means know the percentage of harmful gases such as carbon dioxide and volatile organic compounds in the surrounding environment. Air pollution is responsible for many diseases, including lung cancer, asthma, and heart disease, and it can also cause a wide range of other health problems. Traditional methods of air quality assessment rely on expensive and complex analytical laboratory-based methods. However, with the advancements in low-cost sensor technologies, real-time, local air quality monitoring has become increasingly feasible.

This paper explores the application of various machine learning (ML) and deep learning (DL) models for air quality classification in smart building using a real dataset composed of CO2 and TVOC CCS811 sensor readings. CCS811 is an Air Quality Sensor can measure the CO2 (equivalent CO2) and TVOC (Total Volatile Organic Compounds) density. We analyze the performance of eight models: Transformer Neural Network (TNN), Convolutional Neural Networks (CNN), Gated Recurrent Units (GRU), Recurrent Neural Networks (RNN), Support Vector Machines (SVM), Random Forest, Gradient Boosting, and K-Nearest Neighbors (KNN). This study can help to identify the optimal models for this task. We highlight the strengths and weaknesses of each model in the context of air quality classification and discuss their suitability for different applications.

II. Literature Review

The imperative for effective air quality monitoring has spurred significant research into the use of computational techniques, with a notable focus on machine learning (ML) and deep learning (DL). Traditional approaches to air quality classification rely on laboratory-based analyses of complex compounds. These approaches are often time-consuming and expensive and not suitable for real time analysis [2]. Several studies have explored the use of different models that can analyze the data for real time and cost-effective classification.

Classical machine learning techniques have been widely applied in the realm of air quality prediction and assessment. For instance, Support Vector Machines (SVMs) have demonstrated their ability in creating robust decision boundaries, performing effectively in high-dimensional data spaces [3]. Similarly, K-Nearest Neighbors (KNN) approaches have been utilized, showcasing its simplicity and effectiveness in numerous classification tasks [4]. Furthermore, tree-based ensemble methods have shown promise in this domain. Random Forest

algorithms have demonstrated strong generalization performance, effectively handling complex, non-linear data [5]. Additionally, boosting methods such as AdaBoost have proven useful in combining weak learners into strong classifiers, often achieving good performance on imbalanced and complex datasets [6].

The advancement of deep learning has also brought notable contributions to air quality analysis. Deep Neural Networks (DNNs), including Convolutional Neural Networks (CNNs), have proven useful in identifying spatial patterns and hierarchical features from sensor data [7]. Furthermore, Recurrent Neural Networks (RNNs) have demonstrated their ability to capture temporal dependencies in time series data, making them applicable in situations with continuous sensor data [8]. The Transformer model, a relatively recent advancement in deep learning, has shown impressive results in numerous fields, exhibiting the power of self-attention mechanisms in data modeling and classification [9, 10]. It has been used for various classification, regression and other data processing tasks. The integration of air quality monitoring systems within smart homes is a growing area of interest, particularly in the context of digital twins, which are virtual replicas of physical environments. These systems leverage Internet of Things (IoT) technologies, low-cost sensors, and advanced machine learning models to provide real-time insights into indoor air quality (IAQ). Such insights are pivotal for enhancing occupant health, comfort, and well-being. This review synthesizes recent advancements in IAQ monitoring and classification, focusing on their potential applications in digital twins for smart homes.

III. Indoor Air Quality Monitoring Systems

Castellani et al. (2021) [15] present a systematic review of IoT-based systems for IAQ monitoring, highlighting that thermal comfort parameters, CO_2, and particulate matter (PM) levels are the most frequently monitored metrics, with 70%, 65%, and 27.5% of studies focusing on these aspects, respectively. The authors also note that Arduino and Raspberry Pi controllers dominate system designs, accounting for 37.5% and 35% of implementations. However, only 22.5% of systems adopt calibration approaches prior to deployment, raising concerns about data accuracy (Castellani, Benini, & Brunelli, 2021). For digital twins in smart homes, precise calibration is essential to ensure reliable IAQ classification, as inaccuracies could compromise the twin's ability to reflect real-world conditions. Low-cost air quality sensors (LCS) have emerged as a feasible solution for pervasive monitoring, as discussed by De Vito et al. (2024) [16] and Higgins et al. (2024). While LCS offer affordability and unobtrusiveness, their limitations in producing data suitable for source apportionment models pose challenges (Higgins, Kumar, & Morawska, 2024). Furthermore, Tagle et al. (2020) demonstrate moderate inter-unit variability in low-cost PM sensors, emphasizing the need for robust calibration methodologies. These findings underscore the importance of integrating calibration routines into digital twin frameworks to enhance the reliability of IAQ classifications.

IV. Machine Learning Models for Air Quality Prediction

Advanced machine learning models play a critical role in air quality prediction and classification, enabling digital twins to forecast pollutant concentrations and identify sources of pollution. TAOYING et al. (2020) [19] propose a hybrid CNN-LSTM model for predicting PM2.5 concentrations, leveraging convolutional neural networks (CNNs) for feature extraction and long short-term memory (LSTM) networks for capturing temporal dependencies. Their results indicate superior performance compared to standalone LSTM models, with lower mean absolute error (MAE) and root mean square error (RMSE). Similarly, Xiao et al. (2020) [20] introduce a weighted LSTM extended model (WLSTME) that accounts for spatiotemporal correlations influenced by site density and wind conditions. Both studies highlight the potential of deep learning models to support real-time IAQ classification in digital twins. Toharudin et al. (2023) [21] address the challenge of unbalanced PM2.5 concentration datasets using boosting algorithms such as AdaBoost, XGBoost, CatBoost, and LightGBM. Their approach significantly reduces bias and variance, improving classification accuracy for different PM2.5 levels. For digital twins, such techniques can enable more granular and accurate IAQ categorization, facilitating proactive measures to mitigate pollution exposure.

V. Integration with Digital Twins

Digital twins in smart homes require seamless integration of sensor data, predictive models, and user interfaces to provide actionable insights. The work of Castellani et al. (2021) [15] emphasizes the importance of energy-efficient designs, with 72.5% of reviewed systems claiming energy efficiency as a key feature. Energy efficiency is particularly relevant for digital twins, as continuous data acquisition and processing demand significant computational resources. Additionally, De Vito et al. (2024) advocate for open datalakes to support repeatability and further research, which aligns with the principles of digital twin development, where data transparency and interoperability are paramount. Chen et al. (2023) [22] propose a CNN-RF ensemble framework for PM2.5 concentration modeling, demonstrating improvements in root mean square error (RMSE) and mean absolute error (MAE) compared to standalone CNN and random forest (RF) models. This hybrid approach could be adapted for digital twins, enabling accurate and reliable IAQ classification across diverse microenvironments within smart homes.

VI. Challenges and Future Directions

Despite significant progress, several challenges remain. Higgins et al. (2024) [17] highlight the lack of IAQ data from non-residential and non-educational microenvironments, particularly in regions outside Europe and North America. This geographic bias limits the generalizability of IAQ classification models for global smart home applications. Furthermore, the heterogeneity of indoor environments, as noted by Higgins et al. [17], [18] necessitates careful consideration of sensor placement, occupancy patterns, and building characteristics.

Future research should focus on developing standardized calibration protocols for low-cost sensors and exploring novel AI-driven approaches to address unbalanced datasets and spatial variability. Additionally, the integration of external pollution data and environmental conditions into digital twin frameworks could enhance their ability to differentiate between indoor and outdoor pollution sources. Despite the significant contributions in air quality monitoring, there is a noticeable absence of a comprehensive, side-by-side comparison of these diverse methods on a consistent data setting. Prior research tends to emphasize single model types or particular subsets of machine learning algorithms for specific tasks and datasets, limiting the generalization across different environments. A gap exists in the current knowledge as there is less comparative analysis of several models trained on the same dataset. This analysis will enable the identification of the best suited model for air quality assessment. This study, using a real dataset, aims to address this gap by performing a comprehensive, comparative analysis using a diverse set of models from each of the aforementioned types, and explore their effectiveness when applied to a standardized dataset.

VII. Methodology of Air Quality Classification

A. Maintaining the Integrity of the Specifications

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations.

VIII. Air Quality Classification System Architecture

Fig. 1 shows the architecture of the Air Quality Classification System (AQCS) which consists of the following modules:

- Data Acquisition: The system uses CCS811 sensor data acquired by the Arduino microcontroller. CO2 and TVOC levels from a sensor are the input. These readings are labelled using predefined ranges for the different air quality categories.
- Preprocessing Stage: Data scaling is used to standardize the input features. Label encoding is used for categorical data and one hot encoding of those labels. Reshaping of input features is done as necessary for each model.
- Model Training and Prediction: 8 models are trained with respective hyperparameters. Predictions and probability scores are produced from those models.
- Performance Evaluation: Each model is evaluated using metrics, such as accuracy, precision, recall, f1-score, AUC, log loss and confusion matrices.

IX. Methodology of Air Quality Classification

The CO2 and TVOC values are acquired from CCS811 sensor and classified into air quality categories (Excellent, Good, Moderate, Poor, Unhealthy, Hazardous). Table I summarizes the TVOC and CO2 ranges for each category [15]. Model architectures and training will be explained in the next sections.

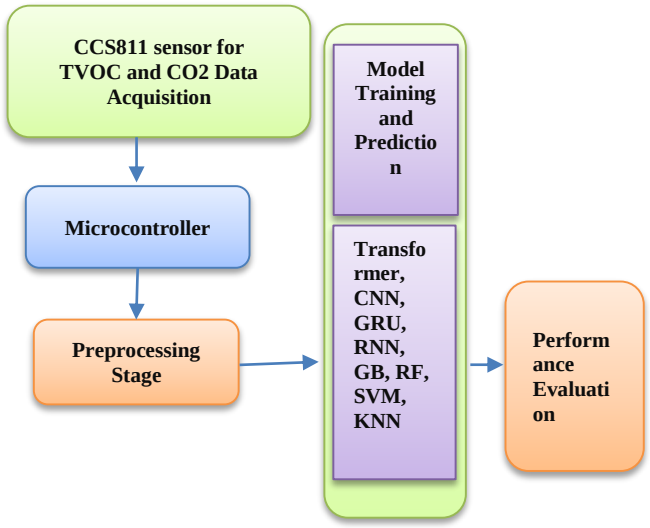

Fig. 1. Air quality classification system architecture.

Pollutant Categories (PCs) (based on ranges) and the Air Quality Index (AQI) are both tools that simplify complex data. They make air pollution information more understandable, accessible, and actionable for both the public and policymakers. They help estimate the potential health impacts of air pollution based on concentrations. They also enable informed decision-making by communicating the health risks associated with different levels of air pollution, empowering individuals to take steps to protect themselves and their families. They support policy and management through informing the development of regulations, tracking progress, and enabling effective air pollution control strategies. Table II and Table III show the TVOC and CO2 concentration ranges by air quality category.

TABLE I TVOC and CO2 Ranges for each Category

Category	CO2 Range (ppm)	TVOC Range ($\mu\mu_g/m^3$)
Excellent	200 - 400	10 - 50
Good	401 - 700	51 - 100
Moderate	701 - 1000	101 - 200
Poor	1001 - 1500	201 - 400
Unhealthy	1501 - 2000	401 - 600
Hazardous	2001 - 3000	601 - 1000

TABLE II TVOC CONCENTRATION RANGES BY AIR QUALITY CATEGORY

Rang	Category	Caution
10 - 50	Excellent	very clean environment
51 - 100	Good	Low TVOC levels
101 - 200	Moderate	Moderate levels, some sources may be present
201 - 400	Poor	Potentially concerning, increased ventilation needed
401 - 600	Unhealthy	Significant source, ventilation likely needed
601 - 1000	Hazardous	High exposure, take action to reduce levels

TABLE III CO2 CONCENTRATION RANGES BY AIR QUALITY CATEGORY

Rang	Category	Caution
200 - 400	Excellent	Optimal air quality
401 - 700	Good	Acceptable air quality
701 - 1000	Moderate	Some ventilation may be required
1001 - 1500	Poor	Poor ventilation, possible discomfort
1501 - 2000	Unhealthy	Reduce ventilation, discomfort likely
2001 - 3000	Hazardous	Severely hazardous, immediate ventilation needed

A. Air Quality Index Calculation

EPA's formula for calculation of the AQI according to Eq. (1) and based on the Breakpoint Table for constants [15]. For each pollutant P, the sensor gives a concentration reading CP. This reading is typically an average over some period of time. The index for that pollutant is given by the following Eq. (1):

$$I_P = \left({I_{high} - I_{low}}/{C_{high} - C_{low}}\right) * (C_P - C_{low}) + I_{low} \quad (1)$$

Where:

- CP: The concentration of pollutant P.
- C_{low}, C_{high}: The low/high concentration breakpoints that contain CP. These breakpoints are defined by the EPA in the Breakpoint Table (below).
- I_{low}, I_{high}: The low/high index range associated with concentration breakpoints for CP.

Having calculated the index for each pollutant, the AQI is simply the maximum index across all pollutants.

In this paper, the Air Quality Index (AQI) for TVOC and CO2 is designed to communicate the quality of indoor air based on the combined levels of Total Volatile Organic Compounds (TVOC) and Carbon Dioxide (CO2). Unlike the standard AQI based on criteria pollutants, this index focuses on common indoor pollutants and provides a practical metric for indoor environmental management. This customized approach seeks to translate the combined levels of TVOC and CO2 into an easily understandable metric, providing guidance on the quality of the indoor air.

X. DATASET ACQUISITION AND CHARACTERISTICS

A. Data Acquisition

- Sample Count: The dataset consists of 1500 individual data points, each representing a single measurement of CO2 and TVOC levels. Data is separated into training-, testing- and validation datasets.
- Temporal Resolution: The data was collected at 2.17 samples/second.
- Environmental Conditions: Samples were acquired during a wide array of environmental conditions including high and low temp, wind speed conditions, humidity. Environmental values were not used in this study to focus on Co2 and TVOC. Using a Nano 33 BLE sense microcontroller we can further study the impact of both Temperature and Humidity on the measurement of the CO2 and TVOC concentrations.
- Sensor Calibration: The CCS811 sensor is manufacturer calibrated. We were keen to operate the sensor for long periods before use to maintain data integrity.

B. Dataset Characteristics

- Class Distribution: The distribution of 500 test samples across the six AQI categories of the test set is shown in Table IV.

TABLE IV TESTSET SAMPLES DISTRIBUTION

Class	Number of samples	Percentage
Excellent	71	0.142
Good	81	0.162
Hazardous	80	0.160
Moderate	102	0.204
Poor	91	0.182
Unhealthy Total	75	0.150

- Class Balance: The dataset exhibits very low-class imbalance, with the 'Good' and 'Moderate' categories being more represented than the 'Excellent' and 'Unhealthy' categories. This imbalance is due to the limited occurrence of 'Excellent' and 'Unhealthy' conditions in real-world data. We could have addressed this imbalance by using the common techniques, e.g., oversampling, under sampling, or cost-sensitive learning.

C. Potential Biases and Limitations

- Real-world vs. Lab-Controlled Conditions: The data was collected under real-world environmental conditions. The variations in environmental conditions (e.g., temperature and humidity fluctuations) may affect sensor readings and represent a potential source of bias. However, we feel that using real-world data provides greater ecological validity of the derived model.
- Sensor Limitations: The CCS811 sensor has known limitations in terms of cross-sensitivity to different VOCs and potential drift over time. While we used frequent cross-validate the obtained data, these limitations are acknowledged, and future studies will explore integrating the use of more reliable and accurate sensors, such as electrochemical sensors.

XI. Environmental Data Points are Omitted

This study is specifically for evaluating TVOC and CO2 readings. Data points gathered from other environmental aspects were not considered in this research. A second real-world dataset of sensor readings was acquired from a CCS811 sensor under varying environmental conditions and exposures. The dataset, contains 2363 samples collected over several hours. The sensor was exposed to smoke, sanitizer with 70% alcohol, and Adidas perfume. The dataset includes columns representing CO2 concentration (in ppm) and TVOC concentration (in ppb). The high correlation in the shape of the CO2 and TVOC concentration curves in your CCS811 sensor data is a common and interesting observation. Here's an interpretation of this phenomenon, considering the sensor's characteristics and the environmental context:

A. Interpretation

The strong correlation between CO2 and TVOC concentrations likely stems from a combination of factors:

1) CCS811 sensor operation: The CCS811 is primarily a metal-oxide gas sensor. It measures the change in resistance of a metal oxide layer when exposed to various gases. While designed to estimate CO2 and TVOC levels, the underlying sensing mechanism is not perfectly selective for each gas individually. In other words, there's some cross-sensitivity. The sensor might respond to changes in the overall composition of VOCs, and this change in VOC composition often occurs alongside changes in CO2. The sensor's algorithm tries to separate CO2 and TVOC signals, but the underlying measurements are still correlated.

2) Common sources: Many real-world sources emit both CO2 and VOCs simultaneously.

3) Human activity: Human respiration releases CO2. At the same time, activities like using cleaning products, cooking, and personal care products (perfume, deodorant, etc.) release VOCs. In an indoor environment, where these activities occur together, you'd expect CO2 and TVOC levels to rise and fall in tandem.

- Combustion: Smoke, as mentioned, is a product of combustion. Combustion processes produce both CO2 and a wide range of VOCs. Therefore, smoke exposure would naturally lead to a correlated increase in both signals.
- Sanitizers: Alcohol-based sanitizers release alcohol vapors (which are VOCs). While the alcohol itself might not directly produce CO2, the presence of a sanitizer often correlates with human activity (cleaning, etc.) that does produce CO2.

4) Ventilation: Ventilation patterns can influence both CO2 and VOC concentrations in a similar way. If ventilation is poor, both CO2 and VOCs will build up. If ventilation is good, both will be diluted and removed. This shared influence of ventilation reinforces the correlation between the two signals.

5) Environmental context: The specific environmental conditions during data acquisition play a crucial role. If the sensor was in a relatively closed environment with limited air exchange and exposed to activities that generate both CO2 and VOCs, the correlation would be more pronounced.

B. Implications for Analysis

- Distinguish Sources: The correlation makes it more challenging to distinguish the specific sources of pollutants. For example, it might be difficult to definitively say that a CO2 peak is solely due to human respiration versus a combination of respiration and a nearby VOC source.
- Calibration: the sensor's calibration and the algorithm's accuracy can be affected by the cross-sensitivity and the inherent correlation between CO2 and VOCs.
- Multi-Sensor Fusion: To improve the accuracy of individual CO2 and TVOC measurements, we might consider combining the CCS811 with other sensors that are more selective for specific gases (e.g., a non-dispersive infrared (NDIR) CO2 sensor).
- Data Interpretation: When interpreting the data, we avoided drawing overly specific conclusions based solely on the CO2 and TVOC readings. Consider the context of the measurements and the limitations of the sensor.

In summary, the high correlation between CO2 and TVOC levels in our CCS811 data is a result of the sensor's operating principles, the co-occurrence of CO2 and VOC sources in the real world, and the influence of factors like ventilation. It's important to understand these factors to interpret the data accurately and avoid oversimplification.

Fig. 2 shows a sample of the data used for estimation of the indoor air quality index and a sudden variation during intended exposure of the sensor to a TVOC. The calculation begins by assessing each pollutant separately. A sub-index is generated for both TVOC and CO2 concentrations using a piecewise linear interpolation approach and user defined breakpoints. The measured TVOC concentration is compared to predefined levels, which are based on guidance from different scientific studies and building standards.

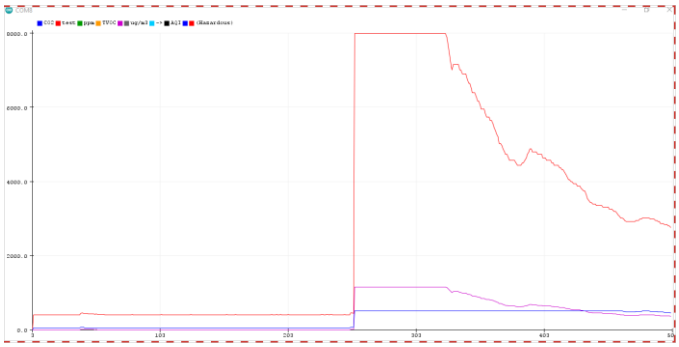

Fig. 2. Sample TVOC and CO2 signal change over time when exposed to a TVOC.

The measured CO2 concentration is also compared to its predefined levels and translated to a sub-index. The levels are based on standards recommendations for CO2 levels in indoor spaces. The individual sub-indices for TVOC and CO2 are then

combined to generate a single, overall AQI value. In the previous codes, the combining of the individual sub-indices has been done by taking the higher index between the two. This approach helps to quickly communicate to the user the worst-case scenario for the combined TVOC and CO2 readings. While the example uses a maximum, other methods for combining can include averaging or weighting. The AQI for TVOC and CO2 provides a way to understand the status of your indoor air based on common indicators of indoor air quality using EPA like methods but without the standard EPA's breakpoints and requirements for the pollutants.

C. Classifier Models Architecture

Detailed architectures of each of the 8 models implemented includes the key components, layers, and configurations for each as follows:

1) Transformer neural network model: The Transformer model is a deep learning model based on the attention mechanism as shown in Fig. 3. While it is primarily for sequence-to-sequence tasks, it is configured here for sequence classification.

a) Transformer model architecture: The transformer architecture implemented in this paper leverages a series of custom layers to process input data, ultimately classifying it into predefined air quality categories. The architecture begins with an Input Embedding layer, responsible for mapping the input features (CO2 and TVOC levels) into a higher-dimensional embedding space. This is followed by Positional Encoding, a crucial step that introduces information about the relative positions of the input sequence, which in this case consists of a single time step representing one set of feature values. The core of the transformer encoder is encapsulated within the Encoder Layer, which first applies multi-head self-attention using the Multi Head Attention layer, allowing the model to weigh the importance of different features within the input. Then a feed-forward network is used which further refines the transformed representation. Layer normalization and dropout are applied to both outputs to stabilize the training, mitigate overfitting and ensure the layer outputs are in a consistent and stable range for easier training. These components work in tandem to extract relevant patterns and relationships from the input data. The output is then processed by the model using a global average pooling layer before the classification layers. The transformer model is built using the class Transformer Classifier, which encapsulates all previously mentioned layers as part of the model architecture and defines the forward propagation through these layers via the call method. The final classification is performed using the Output Layer, which uses a fully connected dense layer with a softmax activation, providing a probability distribution across the different air quality categories. The model includes a custom train_step method to train the model by using the functional call, which is used for inference. The get_config method is also implemented for all custom layers to ensure that model can be easily saved and loaded in the future. Finally, the model is compiled with the ADAM optimizer, categorical cross entropy as loss function and accuracy as metric, and it is trained using the reshaped data to feed into the network and subsequently it is used to predict the labels on test set and generate classification reports, ROC curves, and confusion matrices.

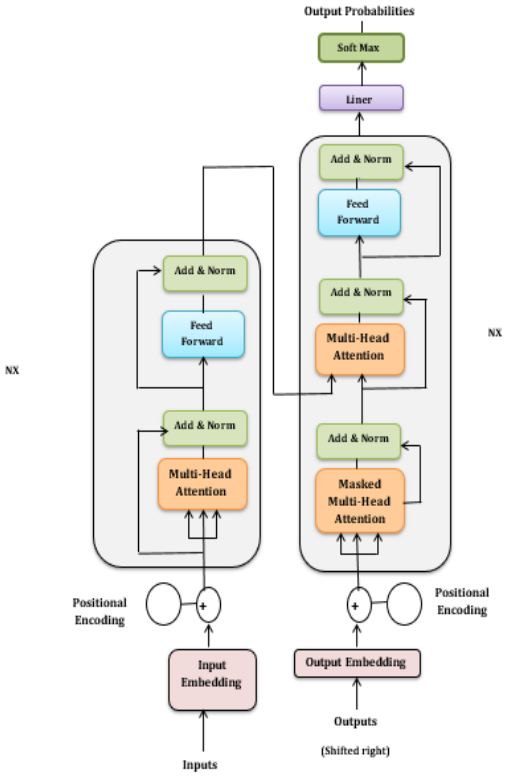

Fig. 3. Architecture of the TNN model.

TABLE V TRANSFORMER MODEL'S STRUCTURE AND COMPLEXITY

Layer/Component	Type	Input Shape	Output Shape	Parameters	Activation
Input Embedding	Input Embedding Layer	(None, 2)	(None, 64)	192	Linear
Positional Encoding	Positional Encoding Layer	(None, 64)	(None, 64)	0	Linear
Encoder Layer (x1)	Encoder Layer	(None, 64)	(None, 64)	57,344	Various
Multi-Head Attention	Multi Head Attention Layer	(None, 64)	(None, 64)	49,408	Softmax
Query, Key, Value Dense	Dense Layers	(None, 64)	(None, 64)	12,288 x3	Linear
Output Dense	Dense Layer	(None, 64)	(None, 64)	4160	Linear
Feed Forward Network (FFN)	Feed Forward Network Layer	(None, 64)	(None, 64)	7,808	ReLU+Linear
Dense 1	Dense Layer	(None, 64)	(None, 128)	8,320	ReLU
Dense 2	Dense Layer	(None, 128)	(None, 64)	8,256	Linear

Layer Normalization	Layer Normalization Layer	(None, 64)	(None, 64)	128	Linear
Dropout	Dropout Layer	(None, 64)	(None, 64)	0	None
Global Average Pooling	GlobalAveragePooling1D Layer	(None, 1, 64)	(None, 64)	0	None
Output Layer	Output Layer	(None, 64)	(None, 6)	390	Softmax
Output Dense	Dense Layer	(None, 64)	(None, 6)	390	Softmax
Total Trainable Parameters				57,926	

In the context of machine learning models, "Parameters" refer to the internal settings within the model that are adjusted during the training process, enabling the model to learn patterns and make accurate predictions. "Tunable Parameters," on the other hand, are the hyperparameters that a user typically adjusts externally to optimize the model's performance, influencing how the model learns. "Default Values" indicate the specific parameter values that are used in the provided code when no specific settings are explicitly made, offering a baseline configuration for the models. The provided notes further explain how these parameters affect the behavior and performance of each model, providing essential insight for effective use. This information is designed to support tasks such as hyperparameter tuning, which focuses on adjusting the tunable parameters to achieve better results; model understanding, which provides an overview of how different model architectures are configured; comparison, which facilitates the comparison of models based on their settings; and model selection, which informs the choice of model appropriate for specific task. It is important to recognize that these parameters often have interdependencies; therefore, optimizing one parameter may change the optimal settings for another. Furthermore, the best values are highly dataset-dependent, meaning that different datasets might benefit from different configurations. Grid search and random search are popular tuning techniques that are employed alongside a good understanding of the parameter behavior in order to achieve optimal results. While default parameter values offer a good starting point, these parameters can often be improved using careful hyperparameter tuning to improve a models generalization ability and achieve a higher level of performance. Table V shows the key hyper parameters for several common machine learning models. For transformer models, embed_dim dictates the size of input embeddings, while num_heads specify the number of attention heads, and ff_dim defines the hidden layer size in the feedforward network. A rate parameter allows for dropout implementation to combat overfitting. It's worth noting that maxlen is a fixed, non-tunable parameter in the given implementation. For convolutional neural networks (CNNs), the number of filters and kernel_size in the Conv1D layers are crucial, with flexibility to add various activation functions and layers. In recurrent neural networks (RNNs), specifically GRU layers, units represent the number of hidden units and activation sets the activation function. A dropout rate controls regularization and the number of layers is another potential hyperparameter. Similarly, for simple RNNs, units, activation, dropout and the number of layers is all tunable. For Support Vector Machines (SVMs), C is a regularization parameter, kernel defines the kernel type (like RBF, linear, or polynomial), gamma is a kernel coefficient (often scaled by default), and degree is specific to the polynomial kernel. In the realm of tree-based models, random forests include n_estimators, the number of trees, max_depth, the maximum tree depth, and min_samples_split, defining the minimum samples required to split a node. Numerous other parameters are also tunable. Gradient boosting models, such as Gradient Boosted Decision Trees (GBDT), share parameters like n_estimators and max_depth and adds learning_rate which scales each tree's contribution and loss sets the loss function. Finally, in K-Nearest Neighbors (KNN), n_neighbors determine the number of neighbors to consider, weights specify how neighbors are weighted and algorithm selects the method for calculating neighbor distance.

2) Convolutional Neural Network (CNN): The Convolutional Neural Network (CNN) implemented in this program serves as a deep learning model designed for image and sequential data processing, utilizing convolutional operations to extract relevant features. In this context, its purpose is to classify air quality based on sequential patterns derived from the input data. The network begins with an input layer that accepts two features, which are subsequently reshaped to have dimensions (2, 1), making them compatible with the convolutional operation. The core of the CNN comprises two 1D convolutional layers (Conv1D). The first layer employs 64 filters with a kernel size of 3 and a ReLU activation, while the second layer has 128 filters with the same kernel size and ReLU activation function. These layers apply the convolutions to the reshaped input, thereby extracting feature maps that highlight relevant patterns within the data. A Flatten layer then transforms the 2D feature maps into a 1D feature vector, preparing the output for fully connected layers. The flattened output is then passed through a fully connected dense layer with a ReLU activation, followed by a Dropout layer to mitigate overfitting by randomly disabling a percentage of the connections during training. Finally, an output layer, implemented as a dense layer with a softmax activation, produces a probability distribution across the six different air quality categories. The key parameters defining this network include the number of filters in each convolutional layer, which is set to [64, 128], the kernel size set to 3, and ReLU used as the activation function. Thus, the CNN serves to classify air quality by analyzing the spatial representation of the input features.

3) Gated Recurrent Unit (GRU): The Gated Recurrent Unit (GRU) is implemented as a recurrent neural network designed for sequence processing and classification, employing gates to manage information flow. The GRU model starts with an input layer that takes two features, CO2 and TVOC, which are then reshaped to represent a single time step with these two features. Following this, a single GRU layer with 64 units is used to capture any sequential relationships within the data. To reduce overfitting, a dropout layer is then applied to the GRU output. This is followed by a dense layer with a ReLU activation to learn from the GRU outputs, and another dropout layer for

regularization. Finally, an output layer, implemented as a dense layer with softmax activation, generates the classification probability across the six air quality categories. The key parameters of this GRU model include 64 units in the GRU layer, ReLU as the activation function and a dropout rate of 0.5. The purpose of the GRU model within this program is for the time-based classification of air quality, leveraging the model's ability to capture any sequential information within the data.

4) Recurrent Neural Network (RNN): A Recurrent Neural Network (RNN) is employed as another type of recurrent neural network aimed at sequence processing and classification using recurrent connections. The RNN model has an input layer that takes two features, CO2 and TVOC, at each time step. It reshapes the input to have one time step. A single Simple RNN layer with 64 units is then used to capture sequential information. To mitigate overfitting, a dropout layer is applied after the RNN layer. The output from the RNN is fed into a fully connected layer with a ReLU activation function, and another dropout layer for regularization. Finally, the output layer with a softmax activation generates the classification probability for each of the six air quality classes. The key parameters for this RNN model include 64 units in the RNN layer, ReLU as the activation function for the RNN units and a dropout rate of 0.5. The purpose of the RNN in this program is for time-based classification, leveraging its ability to capture any sequence information in the input data.

5) Support Vector Machine (SVM): The Support Vector Machine (SVM) is a supervised learning model used for making predictions based on decision boundaries. It takes scaled 2-dimensional features (CO2, TVOC) as input and uses a Radial Basis Function (RBF) kernel to create decision boundaries. A Calibrated Classifier CV is used to apply cross-validation calibration using isotonic regression, ensuring output probabilities are well-calibrated and reliable. The key parameters for this SVM model include a regularization parameter 'C' set to 1.0, 'rbf' as the kernel type, and 'scale' as the gamma coefficient for the kernel and isotonic as the probability calibration method. The SVM aims to classify air quality based on identifying complex decision boundaries in the feature space.

6) Random Forest (RF): The Random Forest model uses an ensemble learning method for classifying the air quality data. This model constructs multiple decision trees based on random samples of the features and data points, creating a robust classifier that is less prone to overfitting. The Random Forest model takes scaled 2-dimensional features (CO2, TVOC) as input and constructs an ensemble of 100 decision trees. The final classification is then based on the average predictions across all of the trees. The number of estimators is set to 100, and a random_state of 42 ensures reproducibility. The main purpose of the Random Forest model within the program is the classification of air quality by using the combined knowledge of multiple decision trees.

7) Gradient Boosting (GB): Gradient Boosting is another ensemble learning method that classifies by training weak learners in a stage-wise fashion, where each subsequent tree minimizes the loss incurred by the preceding tree. This model also takes scaled 2-dimensional features (CO2, TVOC) as input and constructs an ensemble of decision trees, but unlike the random forest model, the trees are added sequentially with each subsequent tree minimizing the error from past predictions. Key parameters for this Gradient Boosting model include 100 boosting stages, a learning rate of 0.1, a maximum depth of 3 for individual trees, a random state of 42, and a 'log_loss' function that is optimized by the trees. In the program, the purpose of the Gradient Boosting model is to classify air quality by sequentially training multiple models, reducing the error of prediction in each iteration.

8) K-Nearest Neighbors (KNN): The K-Nearest Neighbors (KNN) model is an instance-based learning method that classifies data based on the majority of its neighbors. This model takes the scaled 2-dimensional features (CO2, TVOC) and classifies each data point based on the label of the n_neighbors number of closest samples, using Euclidean distance to determine closeness. The key parameters for the KNN model include n_neighbors (default value set to 5), uniform as the weighting function, and 'auto' as the algorithm used to compute the nearest neighbors. The main purpose of the KNN model is to classify the air quality based on the category of the closest datapoints from the training data.

D. Key Parameters of the Classifier Models

Table VI summarizes the key parameters of the 8 models. The parameters that are most likely to be tuned or of interest when using these models are summarized in Table III.

TABLE VI MODEL PARAMETERS

Model	Key Tunable Parameters	Default Values
TNN	embed_dim, num_heads, ff_dim, rate (dropout)	embed_dim=32, num_heads=2, ff_dim=32, rate=0.1
CNN	filters (Conv1D), kernel_size (Conv1D), activation	filters=[64, 128], kernel_size=3, activation='relu'
GRU	units (GRU), activation, dropout	units=64, activation='relu', dropout=0.5
RNN	units (SimpleRNN), activation	units=64, activation='relu', dropout=0.5
SVM	C, kernel, gamma (RBF), degree (Polynomial)	C=1.0, kernel='rbf', gamma='scale', degree=3
RF	n_estimators, max_depth, min_samples	n_estimators=100, max_depth=None, min_samples_split=2
GB	n_estimators, learning_rate, max_depth	n_estimators=100, learning_rate=0.1, max_depth=3, loss='log_loss'
KNN	n_neighbors, weights, algorithm	n_neighbors=5, weights='uniform', algorithm='auto'

Table V gives a detailed view of the Transformer model's structure and complexity. The computational complexity of the Transformer model described is primarily influenced by the multi-head attention mechanism and the feed-forward networks within the encoder layers. The multi-head attention has a time complexity of approximately O (n^2 * d), where 'n' is the sequence length and 'd' is the embedding dimension. However, in this specific implementation, the sequence length is fixed at 1, therefore, the attention mechanism's computational complexity is closer to O(d), where d represents the embedding

dimension. The feed-forward networks have a complexity of O (d * f), where 'f' is the hidden layer size in the FFN. Since the Global Average Pooling, Output and Normalization layers have a relatively smaller time complexity, the overall complexity of this particular Transformer architecture with a sequence length of 1, can be approximated by O(d * f + d), where d is the embedding dimension and f is the feed forward dimension, indicating that complexity scales linearly with the embedding dimension and FFN dimension. Additionally, the dropout layers do not affect the overall time complexity of the model.

E. Algorithm of Air Quality Model Comparison and Evaluation

1. Initialization:
   - Define air quality categories (Excellent, Good, Moderate, Poor, Unhealthy, Hazardous).
   - Define functions to categorize air quality based on CO2 and TVOC levels.
   - Define a function to upload a CSV data file.
2. Data Generation:
   - Generate a training dataset with a specified number of samples for each air quality category.
   - Generate a test dataset similarly.
   - Save both the training and test datasets to separate CSV files.
3. Data Loading and Preprocessing:
   - Load the training and test datasets from the CSV files into pandas Data Frames.
   - Extract the CO2 and TVOC features as input (X) and the air quality categories as the target (y).
   - Scale the input features using Standard Scale.
   - Encode the target labels using Label Encoder.
   - Reshape/prepare the input data as required for each model type (e.g., for CNNs, transformers).
   - Convert categorical labels into a one-hot encoded format.
4. Model Training and Evaluation:
   - Define, initialize and create instances of each of the 8 model types (TNN, CNN, GRU, RNN, SVM, RF, GB and KNN).
   - For each model:
     - Train the model using the preprocessed training data (and use cross-validation or grid search for hyperparameter tuning).
     - Predict on the test data to generate predictions and probabilities
     - Evaluate the model using the actual test data and the model predictions using performance measures (accuracy, precision, recall, f1-score, ROC-AUC, log loss and confusion matrix).
     - Store performance metrics, including accuracy, classification report, and any relevant data for later analysis.
   - Plot relevant training and evaluation metrics (loss curves, confusion matrix, ROC curves).
5. Summary and Output:
   - Collect and store the results of all 8 model types into a suitable data structure (e.g., dictionary).
   - Present a summary table using pandas, displaying:
     - The name of each model.
     - The accuracy obtained from each model.
     - Classification report string with the performance metrics.
     - Additional info like ROC, log loss and loss curves for applicable models.
6. Print summary table:
   - Print the performance summary table to the console.

XII. System Performance Evaluation Metrics

There exists a variety of measures for judging the performance. In our research, we have considered the following four performance measures as discussed in detail in the literature [11, 13]:

$$\text{Precision} = \frac{TP}{(TP+FP)} \quad (2)$$

$$\text{Recall (Sensitivity)} = \frac{TP}{(TP+FN)} \quad (3)$$

$$\text{Specificity} = \frac{TN}{(TN+FA)} \quad (4)$$

$$\text{Accuracy} = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (5)$$

All of the above quantities are normally expressed as percentages. The various terms appearing in the above equations are: True Positive (TP), False Positive (FP), True Negative (TN) and False Negative (FN).

Sokolova et al. [12] have shown that the accuracy measure does not distinguish between the numbers of correct labels of different classes. Sensitivity and specificity separately estimate a classifier's performance on different classes. It has been shown that higher accuracy does not guarantee overall better performance of an algorithm and that a combination of measures gives a balanced evaluation of the algorithm's performance. In this paper, we have used the Youden index and F-measure to evaluate the performance of our system:

$$\text{Youden Index} = \text{Sensitivity} - (1 - \text{Specificity}) \quad (6)$$

$$F\beta = (1 + \beta^2) * (\text{Precision} * \text{Recall}) / (\beta^2 * \text{Precision} + \text{Recall}) \quad (7)$$

where β is a weighting constant that evenly balances the F-score when β=1, favors precision when β> 1, and recall otherwise. The Youden index evaluates the classifiers performance to a finer degree with respect to both classes. Youden Index: Balances sensitivity and specificity, providing a single measure of overall test performance. It ranges from -1 to +1, with higher values indicating better performance. F-Measure (F-score): Balances precision and recall, particularly when there is a trade-off between correctly predicting positives and capturing all actual positives. It also ranges from 0 to 1, with higher values indicating better performance. Seven performance metrics [11-14] are used to evaluate performance of the AQCS. The Sensitivity metric measures the rate of positive cases. The Specificity metric measures the proportion of positive cases that are correctly identified. The Accuracy represents the population of the correctly predicted examples, which is not an appropriate evaluation criterion in imbalanced data sets, and we will not put on much attention to it. The F- value combines the Precision and Recall and gets a higher value when both of Precision and Recall are high. F-SCORE is the harmonic mean of precision and sensitivity. For each class the ROC-AUC curves are given in addition to the Confusion Matrix.

Log loss, also known as cross-entropy loss or logistic loss, is a metric used to evaluate the performance of classification models, particularly those that output probabilities (like logistic regression, neural networks with softmax output, etc.). Unlike accuracy, which only looks at whether the predictions are correct or not, log loss focuses on the probabilities associated with the predictions, penalizing models that are confident but wrong more heavily. For multi-class problems (where there are more than two classes), log loss generalizes to:

$$\text{Log Loss} = -(1 / N) * \Sigma \Sigma [y\_\{ij\} * \log(p\_\{ij\})] \quad (8)$$

Where:

- y is the actual class label (either 0 or 1).
- p_{ij} is the probability predicted by the model that the sample i belongs to class j.
- log is the natural logarithm.
- N is the number of samples

To obtain a single loss value, we need to average the loss across all of the N samples that we have in the dataset. log loss is a valuable metric for classification models that produce probabilities. It penalizes confident incorrect predictions and provides a more nuanced understanding of model performance beyond accuracy alone.

XIII. Results and Discussion

Table VII summarizes the performance of the 8 implemented models. The performance of each implemented model is carefully evaluated and demonstrate robust performance. To gain a deeper understanding of the model's capabilities, metrics such as precision, recall, and F1-score from the classification reports are examined. This analysis provides insights into each model's ability to correctly classify each category while highlighting any biases. ROC curves and confusion matrices are further analyzed to evaluate each model's performance and to explain why each model behaves the way it does, including how well each model is able to identify different classes and if they make any systematic errors. Additionally, for the deep learning models (CNN, RNN, GRU, and Transformer), the training and validation loss curves are studied to evaluate their learning behavior over time and to assess how well the models were able to learn the patterns in the data set.

TABLE VII Performance Metrics for Stratified Kfold Cross-validation

Model	Average Cross-Validation Accuracy	Test Accuracy	Precision	Recall	Specificity	Youden Index	Positive Likelihood	Negative Likelihood	Discriminant Power
TNN	0.999	0.986	0.986	0.986	0.997	0.983	352.14	0.014	5.58
CNN	0.999	0.998	0.998	0.998	0.999	0.997	2495.00	0.002	7.73
GRU	0.999	0.996	0.996	0.996	0.999	0.995	1245.00	0.004	6.97
RNN	1.000	0.998	0.998	0.998	0.999	0.997	2495.00	0.002	7.73
Bi-LSTM	0.999	0.996	0.996	0.996	0.999	0.995	1245.00	0.004	6.97

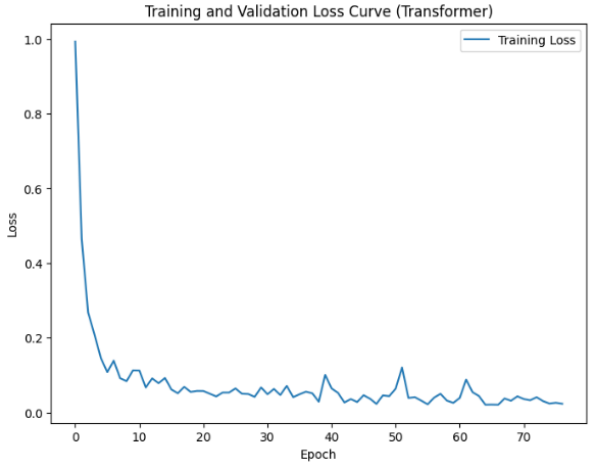
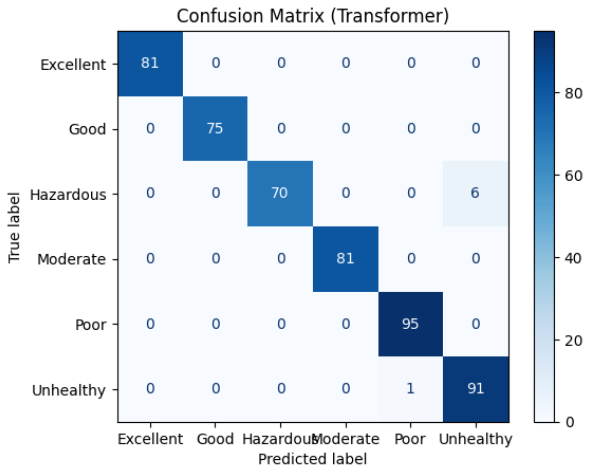
(a)



(b)



(c)

Fig. 4. (a) Transformer's ROC curve and (b) transformer's training and validation loss curve and (c) confusion matrix for the transformer model.

Support Vector Machine (SVM), Random Forest, Gradient Boosting, and KNN have a simplified loss curve, while neural network-based models like the Transformer, CNN, GRU, and RNN have a "traditional" loss curve. Neural networks use iterative training (gradient descent) with a loss function, allowing loss to be tracked and plotted over epochs. SVM, Random Forest, etc. Use non-iterative or different optimization methods without a typical loss curve per training epoch. These models have a single fit procedure, without per-epoch updates, and thus no intermediate steps to measure the loss in the same way as neural networks. The "simplified loss curve" plots their final accuracy as a proxy, not a real per-epoch training loss.

This analysis delves into why certain models perform better than others, moving beyond simple accuracy comparisons to explore the underlying reasons rooted in model architecture, data characteristics, and algorithmic approaches. It examines how each model's inherent biases or assumptions affect results. For instance, the effectiveness of tree-based models like Random Forest for this specific classification problem, which may not generalize well to other datasets, is explored. The success of K-Nearest Neighbors (KNN) is discussed in relation to the specific data patterns and relationships. Fig. 4 shows transformer's ROC curve, transformer's training and validation loss curve and confusion matrix for the transformer model. The analysis investigates why a linear Support Vector Machine (SVM) might struggle with non-linearly separable classes, unlike tree-based methods that can effectively handle such scenarios. Model complexity is also considered, acknowledging that deep learning models are more capable of capturing intricate relationships than models like KNN, which are built on simpler data assumptions. The specific parameters of the models and their influence on performance is also discussed, such as the successful performance of Gradient Boosting and its parameters.

The analysis further examines the effectiveness of Random Forest, KNN, and Gradient Boosting, which often achieve near-perfect accuracy. The role of randomness in the sampling and feature selection in the Random Forest is discussed, including the way it leads to generalizable decision boundaries, also how the averaging of predictions across many trees provides robust classification. The explanation of KNN covers its core concept that similar points fall within the same category based on Euclidean distance. Furthermore, it explains why this approach is effective on this dataset and how that effectiveness may not be valid in real world scenarios. The sequential error minimization in Gradient Boosting is discussed, including how gradient descent enables subsequent trees to learn in the direction of a more optimal solution.

The analysis also explains how the neural network models, specifically CNNs, RNNs/GRUs, and Transformers, learn from the data. It details how convolutional layers in CNNs extract spatial features or patterns by capturing local dependencies. It also discusses how the recurrent nature of RNNs/GRUs helps in learning temporal dependencies, especially how the gate

mechanism in GRUs facilitates handling of temporal data. The analysis then explains how self-attention mechanism of the transformer model works on this data set and how the dense layers of the transformer classifiers the data, also the role of the embedding and positional encoding layers in capturing relevant information. Speculations are made regarding what types of features and relationships the models might have learned from the data, including whether they correlate certain air quality categories more with CO2 or TVOC and whether the model's weights prioritize certain features or value ranges.

Finally, the practical trade-offs between model complexity and inference speed are discussed. This includes whether the deep learning models have a longer inference time due to their complexity compared to the much faster random forest or KNN models and what is their impact on real time systems, and when computational expense is a significant concern and when it can be tolerated. Table VIII compares the 8 models implemented. This table highlights each model's strengths, weaknesses, and typical applications. This table provides a comprehensive comparison of all 8 models, and allows us to make informed choices based on their strengths, weaknesses, and suitability.

TABLE VIII MODEL COMPARISON

Model	Strengths	Weaknesses	Applications
TNN	- Captures long-range dependencies well. - Highly parallelizable training.	Computationally expensive.	- Text classification, sentiment analysis, machine translation, image recognition, time-series.
CNN	- Excellent for spatial hierarchy processing. - Efficient in identifying local patterns.	Can be sensitive to translations/rotations.	- Image recognition, object detection, image segmentation, time-series analysis, audio processing.
GRU	- Captures sequential information effectively. - Handles long sequences better than basic RNNs due to gating mechanism.	Can be computationally intensive on long sequences.	- Natural language processing (NLP), time-series analysis, speech recognition, machine translation.
RNN	- Can capture temporal dependencies well. - Simple to implement	Difficult to train for long sequences, vanishing and exploding gradient.	- NLP, speech processing, time-series forecasting, machine translation.
SVM	- Effective in high-dimensional spaces. - Can model non-linear decision boundaries with RBF kernel.	Can be computationally intensive on large datasets.	- Image classification, text classification, bioinformatics, outlier detection.
RF	- Robust to outliers and non-linearities. - Good generalization performance.	Can be harder to interpret compared to single decision trees.	- Classification and regression tasks, feature importance ranking, medical diagnosis, financial modeling.
GB	- Achieves high predictive accuracy and flexible for different loss functions. - Effective for complex datasets.	Can be prone to overfitting with noisy data.	- Structured classification and regression tasks, ranking tasks, fraud detection, recommendation systems.
KNN	- Simple to implement and easy to understand. - No explicit training phase.	Computationally expensive in inference with large datasets.	- Classification and regression tasks, image recognition, recommendation systems, anomaly detection.

Deep learning models, such as Transformers, Convolutional Neural Networks (CNNs), Gated Recurrent Units (GRUs), and Recurrent Neural Networks (RNNs), are powerful tools that shine when dealing with complex data structures and requiring intricate feature learning. These models often excel at capturing nuanced patterns within data but come with a significant demand for computational resources, often requiring substantial processing power and training time. Conversely, classical machine learning models like Support Vector Machines (SVM), Random Forests, Gradient Boosting algorithms, and K-Nearest Neighbors (KNN) offer a different set of advantages. These models are generally faster to train and easier to interpret, making them suitable when speed and transparency are important considerations.

When dealing specifically with sequential data, such as time series or text, the strengths of certain deep learning models become particularly apparent. Transformers, GRUs, and RNNs are explicitly designed to process sequence data, allowing them to learn dependencies and temporal patterns that other models might miss. Ensemble methods, as exemplified by Random Forest and Gradient Boosting, offer another approach by combining the predictions of multiple learners. This technique enhances the robustness and overall performance of the models, often leading to more reliable results.

The computational cost associated with these different model types can vary greatly, especially when the size of the dataset changes. For instance, KNN has a very low training cost due to its simple algorithm, whereas complex neural networks can have high training times because they involve numerous iterations and parameter updates. This contrast highlights the importance of choosing a model that aligns with available resources and time constraints. Furthermore, interpretability is another important aspect to consider. Decision-tree based models like Random Forest and Gradient Boosting are often easier to interpret because their decision-making process can be traced through the tree structure.

In the context of air quality classification based on CO2 and TVOC levels, different models may be preferred based on the desired outcome. If the relationships between CO2/TVOC and the air quality category are exceptionally complex, deep learning models like Transformers, CNNs, GRUs, and RNNs can be well-suited. If, however, speed of deployment and inference is paramount, a simple model like KNN may be a better fit due to

its low computational overhead. In scenarios where accuracy is a top priority and deep learning is not required, ensemble methods such as Random Forest and Gradient Boosting can offer a good balance between performance and computational efficiency, potentially providing high accuracy without needing the complexity of very deep learning models.

XIV. Computational Complexities of the 8 Models

Table IX summarizes the computational complexities of the 8 models. It provides a breakdown of both time and space complexity, along with explanations.

TABLE IX Computational Complexity Summary

Model	Time Complexity (Training)	Time Complexity (Inference)	Space Complexity (Training)	Space Complexity (Inference)	Notes
TNN	O(N^2 * D + N * D^2)	O(N * D^2)	O(N * D)	O(N * D)	N = Sequence Length (Here always 1), D = Embedding dimension. Training Complexity is dominated by attention layers' N^2. The model's size mainly determines space complexity
CNN	O(C * K * M * N)	O(C * K * M * N)	O(P + CKM*N)	O(P + C * K * M)	C = Number of channels, K = Kernel size, M = Feature maps, N = Training data. Training time is influenced by Convolutional operation. Space complexity is driven by the number of parameters (P). Inference is a subset of training complexity.
GRU	O(N * H^2)	O(N * H^2)	O(N * H)	O(H)	N = Sequence Length (Here always 1) and H = Hidden units. Time complexity dominated by matrix multiplication during recurrent processing. Space complexity is for the number of parameters and hidden state size.
RNN	O(N * H^2)	O(N * H^2)	O(N * H)	O(H)	N = Sequence Length (Here always 1) and H = Hidden units. The time complexity of each sequence item processed is O(H^2), so is the space complexity O(H) per sequence. Space is for the weight and the hidden states.
SVM	O(N^2) to O(N^3)	O(N_sv * D)	O(N * D)	O(N_sv * D)	N is the number of training samples. D is the dimension of each data point. N_sv is the number of support vectors. Training complexity depends on kernel choice and optimization. Memory consumption related to the storing of all data and support vectors.
RF	O(T * M * log(N))	O(T * M)	O(T * M)	O(T * M)	T = Number of Trees, M = Number of features, N= Number of training data. Training time is determined by building each decision tree. Space is dominated by storing the trained trees.
GB	O(T * N * M)	O(T * M)	O(T * M)	O(T * M)	T = Number of trees, M = Number of features, N = Number of samples. Similar complexity to AdaBoost but might be slightly higher as it can be optimized by a loss function rather than simply weighing.
KNN	O(1)	O(N * M)	O(N * M)	O(1)	N = Number of training samples, M = Number of features. Training is very fast with KNN, its mostly a lookup. Inference complexity increases with dataset size.Space complexity is for storing entire dataset and no parameters.

where,

- O( ) - Big O Notation: Represents the upper bound of the growth rate of an algorithm's runtime or memory usage. It focuses on how the complexity scales with input size.
- N: Number of training samples, Sequence Length
- D: Embedding Dimensions, Feature Dimensions
- C: Number of channels in the convolutional layer
- K: Kernel size in the convolutional layer
- M: Number of feature maps, number of features in general
- H: Number of hidden units in the recurrent layers (GRU, RNN).
- T: Number of trees in ensemble methods (Random Forest, Gradient Boosting).
- N_sv: Number of support vectors in SVM.
- R: Number of rules in the fuzzy logic systems
- I: Input Calculation complexity within the fuzzy logic system.

The time complexity of training a model reflects how the computational time scales with the amount of training data, while the time complexity of inference represents how the computation time scales when the model is used for predictions on new, unseen data. Space complexity during training pertains to the memory required during the training process, and space complexity during inference indicates the memory consumption for making predictions. It's important to note that Big O notation provides a theoretical measure, and practical performance can vary based on implementation details, hardware capabilities, and the specific dataset being used. Some complexity estimations are approximations because of the non-uniformity of internal operations, particularly in the case of more complex methods. For ensemble methods like Random Forest and Gradient Boosting, time and space complexity are notably influenced by the number of trees or weak learners involved in the model. The comparison in the table highlights that for scenarios with very large datasets, models with lower training complexities, such as KNN, SVM with simple kernels, or simpler decision trees, might be preferred to reduce training time. In real-time inference

scenarios, models with lower inference time complexities, such as KNN, might be more appropriate for applications needing fast responses. Finally, models with high space complexities might not be feasible for use on devices that are limited by memory constraints, making practical considerations a crucial part of model selection.

XV. Conclusion and Future Work

This study presented a comprehensive comparative analysis of eight diverse machine learning and deep learning models for intelligent real-time Air Quality Index (AQI) classification using sensor data, specifically within a smart home digital twin framework. The models evaluated included classical algorithms like Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Random Forest, alongside advanced deep learning architectures such as Transformer, Convolutional Neural Networks (CNN), Gated Recurrent Units (GRU), and Recurrent Neural Networks (RNN).

For smart home indoor air quality (IAQ) classification, Gradient Boosting (GB) or Random Forest (RF) are the most highly recommended models. They provide perfect classification accuracy, precision, recall, specificity, Youden Index, and F1-score while maintaining relatively fast inference speeds, making them ideal for real-time monitoring in resource-constrained smart home environments. K-Nearest Neighbors (KNN) is a very strong alternative, especially when extremely low space complexity (memory usage) is paramount, despite having a slightly higher inference complexity. Other complex models such as TNN, CNN, RNN, and GRU, while performing well, have higher computational costs that do not justify their usage, in comparison to the other models. SVM should also be avoided because of its higher complexity. The perfect performance across all models suggests that the classification task is relatively simple for all, meaning that additional complexity does not increase model performance.

Future work for the IAQ classification model should focus on several key areas to ensure its practical and effective deployment. Performance should be fine-tuned through hyperparameter optimization to balance accuracy, speed, and resource consumption, and deployment should be optimized for low-resource devices by implementing techniques like quantization, compression, and edge computing. Expanding the model to identify anomalies and integrating it with existing smart home systems will enhance its usability and value. Future research should focus on several key areas to further enhance the practical application of these models within smart home digital twins: First, we propose investigating ensemble and hybrid approaches to further improve the robustness and accuracy of real-time AQI classification in varied and complex environments. Second, it's critical to prioritize the development of explainable AI (XAI) techniques to gain a better understanding of the decision-making processes in deep learning models, ensuring that the digital twin's responses are both effective and transparent. Finally, expanding the scope to include additional pollutants and multi-sensor data would enable a more comprehensive and reliable AQI classification, allowing the digital twin to respond more effectively to various scenarios.

Data Availability

The data set used in this research is acquired though sensor readings from CCS811 and is used for air quality classification, specifically relating CO2 and Total Volatile Organic Compound (TVOC) levels to the indoor Air Quality Index (AQI). The data includes individual measurements with CO2 concentrations in parts per million (ppm) and TVOC levels in micrograms per cubic meter (ug/m3). Each measurement will be used to estimate the air quality index AQI and classified through the implemented models as belonging to one of six categories (Excellent, Good, Moderate, Very Unhealthy, Hazardous, Very Hazardous). The majority of the sample represents "Good" to "Moderate" air quality, with CO2 levels clustered around 400 ppm and TVOC ranging from 0 to 10 ug/m3. However, some samples also feature a smaller subset of readings indicating "Hazardous" and "Very Unhealthy" air quality with significantly higher CO2 and TVOC values, demonstrating a wide range of air pollution levels. This data is used to train and evaluate machine learning and deep learning models aimed at accurately classifying air quality for potential integration into a smart home digital twin system. The data set is available for researchers based on fair request. The datasets generated during and/or analyzed during the current study are available from the first author on reasonable request.

Authors' Contributions

This research was a collaborative effort, with all authors contributing significantly to the overall project. Contributions included conceptualization of the idea (Prof. A. S. Tolba), development of the methodology (Saley S. & Abdulaziz A., A. S. Tolba), data collection and analysis (Saley S.), implementation and testing (Saley S. & Abdulaziz A.), manuscript drafting, and review of the final manuscript (Saley S. & Abdulaziz A., A. S. Tolba).

Sentiment Analysis and Emotion Detection Using Transformer Models in Multilingual Social Media Data

Sultan Saaed Almalki*
Department of Digital Transformation and Information, Institute of Public Administration, Jeddah, Makkah Al Mukarramah, 23442, KSA

***Abstract*—The rapid expansion of multilingual social media platforms has resulted in a surge of user-generated content, introducing challenges in sentiment analysis and emotion detection due to code-switching, informal text, and linguistic diversity. Traditional rule-based and machine learning models struggle to process multilingual complexities effectively, necessitating advanced deep-learning approaches. This study develops a transformer-based sentiment analysis and emotion detection system capable of handling multilingual and code-mixed social media text. The proposed fine-tuned Cross-lingual Language Model – Robust (XLM-R) model is compared against state-of-the-art transformer models (mBERT, T5) and traditional classifiers (support vector machine (SVM), Random Forest) to assess its cross-lingual sentiment classification performance. A multilingual dataset was compiled from Twitter, YouTube, Facebook, and Amazon Reviews, covering English, Spanish, French, Hindi, Arabic, Tamil, and Portuguese. Data preprocessing included tokenization, stopword removal, emoji normalization, and code-switching handling. Transformer models were fine-tuned using cross-lingual embeddings and transfer learning, with accuracy, F1-score, and confusion matrices for performance evaluation. Results show that XLM-R outperformed all baselines, achieving an F1-score of 90.3%, while multilingual Bidirectional Encoder Representations from Transformers (mBERT) and T5 scored 84.5% and 87.2%, respectively. Preprocessing improved performance by 7%, particularly in code-mixed datasets. Handling code-switching increased accuracy by 8.9%, confirming the model's robustness in multilingual sentiment analysis. The findings demonstrate that XLM-R effectively classifies sentiments and emotions in multilingual social media data, surpassing existing approaches. This study supports integrating transformer-based models for cross-lingual natural language processing (NLP) tasks, paving the way for real-time multilingual sentiment analysis applications.**

Keywords*—Multilingual sentiment analysis; emotion detection; transformer models; XLM-R; mBERT, T5; code-switching; cross-lingual NLP; social media text processing; deep learning

I. Introduction

Social media platforms generate vast amounts of textual data daily. Users express emotions, opinions, and sentiments on Twitter, Facebook, and Reddit. Analyzing this data provides valuable insights for businesses, policymakers, and researchers. However, sentiment analysis and emotion detection remain challenging, especially in multilingual settings. Traditional natural language processing (NLP) methods struggle with language variations, code-switching, and informal text.

Recent advancements in deep learning, especially transformer-based models, have significantly improved NLP tasks. Models such as BERT [1] and XLM-R [2] offer state-of-the-art performance in multilingual text understanding. Conventional machine learning approaches have limited capability in capturing contextual information. Although transformers have been leveraged to solve multilingual sentiment analysis applications, this presents issues like data scarcity, domain adaptation, and computational complexity. This study focuses on multilingual sentiment analysis and emotion detection using transformer-based models to handle linguistic diversity, informal expressions, and code-switching in social media data.

The research encompasses multiple languages, including English, Spanish, French, Hindi, Arabic, Tamil, and Portuguese, ensuring broad applicability in global sentiment classification tasks. The study utilizes five benchmark datasets: Twitter Sentiment Multilingual Corpus (TSMC), Multilingual Amazon Reviews Corpus (MARC), SemEval-2018 Task 1, Facebook Code-Mixed Sentiment Dataset, and YouTube Comments Corpus, covering both formal and informal texts. Preprocessing techniques, such as tokenization, stopword removal, emoji normalization, and code-switching handling, are applied to refine the data before training.

This paper investigates the efficacy of transformer models on multilingual sentiment analysis and emotion detection. It assesses their performance on various informal social media texts and in different languages. The findings aim to improve automated sentiment analysis systems for multilingual NLP applications. Opinion mining, or sentiment analysis, is one of the growing fields of NLP. Based on the text, it identifies sentiment polarity (positive, negative, neutral) [3]. Another fine-grained task is emotion detection, classifying text into emotions such as happiness, anger, or sadness [4]. These tasks have significant applications in marketing, healthcare, and crisis management. Analysis of social media data is inherently multilingual. However, it is hard to classify sentiments as many users use different languages in one conversation [5]. Standard sentiment analysis models learned in a single language do not generalize well across linguistic structures. Other recent research [6] claims that multilingual NLP models capable of processing mixed-language text as efficiently as possible should be encouraged. There is a promising solution in transformer-based architecture, especially in multilingual models such as mBERT and XLM-R. They take advantage of

*Corresponding Author

the large multilingual datasets and can be adapted to any language. It is found that XLM-R performs better than the traditional methods for multilingual sentiment classification tasks [7]. Yet, there is a void regarding how these models react to informal social media language, emojis, and slang. Sentiment analysis and emotion detection have become important ways of studying user opinions on social media. Nevertheless, most existing research uses monolingual datasets, mainly in English, making these models less applicable to multilingual contexts [8]. Globalization has increased the spread of code-switching, in which users mix several languages in one post or conversation. It was found that standard NLP techniques are not effective in dealing with these complexities, which translates to a decrease in sentiment classification accuracy [9]. This study investigates the effectiveness of transformer-based models for multilingual sentiment analysis and emotion detection. The key research questions are:

- How well do state-of-the-art transformer models (mBERT, XLM-R, T5) perform in sentiment classification and emotion detection across multilingual datasets?
- How do language diversity, code-switching, slang, emojis, and informal expressions affect the performance of transformer-based sentiment analysis models?
- How does the performance of transformer-based models compare to traditional sentiment analysis methods, such as long short-term memory (LSTM), convolutional neural networks (CNNs), and lexicon-based approaches?
- How can transformer models be fine-tuned to enhance performance in low-resource and code-mixed language settings in social media texts?

The transformer-based models are studied for multilingual sentiment analysis and emotion detection on real social media data. In addition to this, challenges such as handling informal language, regional dialects, emojis, sarcasm, and code-mixed text make it even more challenging to detect sentiment and emotion accurately [10]. In addition, transformer models also need to be of considerable computational cost. Therefore, they cannot be deployed in the real world in resource-constrained environments due to their limited capability.

A major difficulty is the absence of high-quality multilingual sentiment datasets, in particular for low-resource languages [11]. Most sentiment analysis datasets are made for high-resource languages like English, Spanish, and Chinese, and low-resource languages are often ignored. This research addresses these limitations by evaluating transformer-based models on diverse, multilingual social media datasets to identify key sentiment and emotion analysis gaps.

This research studies the effectiveness of transformer models that can be used for sentiment analysis and emotion detection in multilingual social media data. The specific objectives are:

- To investigate the ability of state-of-the-art transformer-based models (e.g., mBERT, XLM-R, T5) in classifying sentiment and detecting emotions in multilingual datasets.
- To analyze the impact of language diversity, code-switching, slang, emojis, and informal expressions on model performance.
- To compare transformer-based approaches with traditional sentiment analysis models, including LSTM, CNNs, and lexicon-based approaches.
- To fine-tune transformer models to improve performance for low-resource and code-mixed languages in social media texts.

By achieving these objectives, this research contributes to developing robust multilingual sentiment analysis systems that can be effectively applied in real-world social media monitoring. Moreover, the study also brings out the limitations of transformer-based sentiment and emotion detection models and their corresponding computational constraints. This Study studies transformer-based models for multilingual sentiment analysis and emotion detection on real social media data. Previous research on monolingual datasets focuses on code-switching, informal language, slang, and emojis, which are quite common in online communication. The rest of the paper is structured as follows: The related work in Section II reviews existing approaches in sentiment analysis, transformer models, and multilingual NLP techniques, identifying gaps in current research. The methodology in Section III describes the data collection, preprocessing, model selection, training, and evaluation processes, emphasizing the role of transformer models like XLM-R, mBERT, and T5. The results in Section IV and discussion section analyzes the model's performance, comparing accuracy, F1-score, and confusion matrices across multiple datasets. Discussion is given in Section V. The conclusion and future work in Section VI summarize key findings and suggest improvements, including neutral sentiment classification enhancement, real-time optimization, and multimodal sentiment analysis.

II. Related Work

A. Sentiment Analysis and Emotion Detection in Social Media

Sentiment analysis and emotion detection have become essential in understanding public opinion on social media. These tasks help businesses, governments, and researchers analyze trends, detect user emotions, and improve customer engagement. Traditional sentiment analysis relied on lexicon-based and machine-learning approaches such as Naïve Bayes, SVM, and logistic regression. [12]. While effective in structured datasets, these methods struggled with contextual understanding, sarcasm, and informal language, common in social media text [13]. Deep learning models such as CNNs and LSTMs improved sentiment classification by capturing contextual relationships in text. However, they often required large labeled datasets and did not generalize well to different languages and domains [14]. Transformer-based models like BERT, RoBERTa, and T5 completely changed the game by introducing self-attention mechanisms, which helped understand long-range dependency and nuances in sentiments to text [1]. A more fine-grained task of emotion detection

classifies text (e.g., happiness, anger, sadness, fear). Ekman's six basic emotions or Plutchik's emotion wheel have traditionally been used as the classification framework [15]. Recent deep-learning methods combine multi-label classification techniques to detect complex emotional expressions in short and noisy social media posts [16]. While these advancements go a long way toward handling multilingual, code-switched, and informal text, there is still work to be done in multilingual sentiment analysis. Multilingual interaction on social media has brought the rise of multilingual transformer models such as mBERT, XLM-R, and M2M-100 to enhance sentiment analysis across languages. These models are trained on different linguistic datasets and achieve good results on cross-linguistic sentiment classification tasks [2]. Nevertheless, there is room for further exploration for handling low-resource languages, code-mixed data, and domain-specific sounding [17]. The main goal of this study is to bridge these gaps through a performance evaluation of transformer models in multilingual sentiment analysis and emotion detection in social media data.

B. Transformer Models for NLP

Transformer models have led the revolution of NLP, making parallelized context-aware text data processing. Transformers adopt self-attention mechanisms to learn long-term dependencies in sentences, which are much better for performing complex language tasks [18]. In contrast, traditional RNNs and LSTM networks do not effectively model the dependencies for such tasks. Bert (Bidirectional Encoder Representations from Transformers) presents a breakthrough transformer model trained in a deep bidirectional way and thus allows the models to understand word meaning considering the context [1]. Its results were far better than those of previous NLP models in sentiment analysis, emotion detection, text classification, and machine translation. Model size and training efficiency were further improved by replacing the RoBERTa [19] equivalent model or using the ALBERT [20] model. However, with multilingual NLP, models such as multilingual BERT (mBERT) and XLM-R were created to work on multiple languages simultaneously. They use cross-lingual transfer learning, which means they can use little training data in languages other than English [20]. Such multilingual models are necessary for sentiment analysis in social media when people routinely switch between languages and write off the cuff in multilingual conversations.

In the past few years, there have been more recent transformer architectures like T5 (Text transfer transformer) and GPT-4 that have explored classification tasks and text generation, summarization, conversational AI [21]. Finally, these models are pre-trained architectures on some specific NLP tasks and are highly adaptable. Nonetheless, scheduling low-resource languages, domain-specific vocabularies, and real-time efficiency have been issues. However, transformer models need a lot of computational resources, so they cannot be deployed in real-time sentiment analysis of large-scale social media data. In contrast, researchers are finding ways to use transformers more efficiently by creating enhanced fine-tuning techniques, model compression, knowledge distillation, etc. Then, this study provides a comprehensive evaluation of the strengths and weaknesses of transformer models for multilingual sentiment analysis and emotion detection in social media, such as accuracy, efficiency, and adaptability.

C. Multilingual Approaches in NLP

Natural language processing allows the process of language around us to be put into an understandable machine format. Machine translation and language-specific models were the traditional approaches, but they had problems with scalability and generalization. Recently, the transformer-based architecture has made cross-lingual transfer learning possible, enabling the models trained in high-resource language to perform well in low-resource language [22]. For example, multilingual models like mBERT and XLM-R find ways to use a shared vocabulary and pre-train cross-linguistically. These models utilize large-scale datasets across different languages for semantic similarity between the linguistic structures [23]. Tasks such as multilingual sentiment analysis, machine translation, and named entity recognition have significantly improved. Zero-shot and few-shot learning is another approach where a model trained over one language can be directly used over another without retraining. Further, meta-learning and self-supervised learning are helping cross-lingual NLP to diminish reliance on annotated datasets [24]. Nevertheless, each multilingual model has shortcomings in handling language-specific idioms, dialectal variations, and code-switching, which directly mislead sentiment classification accuracy.

D. Challenges in Sentiment Analysis for Multilingual Data

Sentiment Analysis in Multilingual Data is challenging due to language diversity, cultural differences, informal variations in text, etc. Another problem is code-switching, which occurs when users switch between two languages in one sentence. However, this is normal on social media, and NLP models trained on monolingual data cannot correctly classify sentiment [25]. A drawback of this is the shortage of high-quality multilingual sentiment datasets. First, large-scale datasets in English and Spanish enable deep learning models. However, this is not the case for low-resource languages, where annotated sentiment corpora do not exist to train a deep learning model. To overcome the above issue, data augmentation and transfer learning techniques have been exploited, but they show differences between languages [26]. In addition, there is also a difference in how the expression of sentiment changes across languages and cultures. Sentiments of words can vary from one language to another, i.e., words used with positive sentiments in one language may transmit negative or no feelings in another. Therefore, cross-lingual sentiment classification is not easy due to this linguistic ambiguity. In informal social media texts, sarcasm, slang, emojis, and abbreviations make sentiment detection even more complex [17]. Computational efficiency is another concern. Sentiment analysis using multilingual transformer models requires considerable computational resources due to real-time requirements. Lightweight architectures and model pruning techniques are being researched to enhance the performance of large-scale applications. Addressing challenges such as these is critical for improving sentiment analysis across many linguistic communities.

III. METHODOLOGY

Multilingual sentiment analysis consists of five key stages: data collection, preprocessing, model selection, training, and evaluation. Social media datasets from Twitter, Reddit, and Facebook are collected, incorporating code-switched text and multiple languages. The preprocessing phase involves text cleaning, tokenization, and handling informal expressions to enhance input quality. Transformer models such as mBERT, XLM-R, and T5 are then fine-tuned using cross-lingual embeddings for improved multilingual sentiment classification. The training phase leverages transfer learning, and model performance is assessed using accuracy, F1-score, and confusion matrices. A system model illustrating the data flow of the proposed methodology is provided in Fig. 1.

A. Dataset Selection and Preprocessing

1) Dataset selection: It is important to choose quality datasets for multilingual sentiment and emotion analysis. To make the representation linguistically diverse, this study runs on multiple benchmark datasets, such as social media and e-commerce reviews. Over 1.2 million English, Spanish, French, and Arabic posts are logged in to the TSMC, an engaging resource for multilingual sentiment classification. MARC is composed of 3.4 million product reviews in English, German, Japanese, and French, and because it is structured, it can be used as a dataset for sentiment polarity classification. SemEval-2018 Task 1 is an important dataset comprising 30,000 social media posts tagged with emotion categories (e.g., anger, joy, sadness, fear).

The 120,000 posts in the Facebook Code-Mixed Sentiment dataset in Hindi-English and Tamil-English support real-world multilingual conversations. To enrich the study with user-generated content from video discussions, a further analysis was done on the YouTube Comments Sentiment Corpus, with over 500,000 English, Portuguese, and Hindi samples.

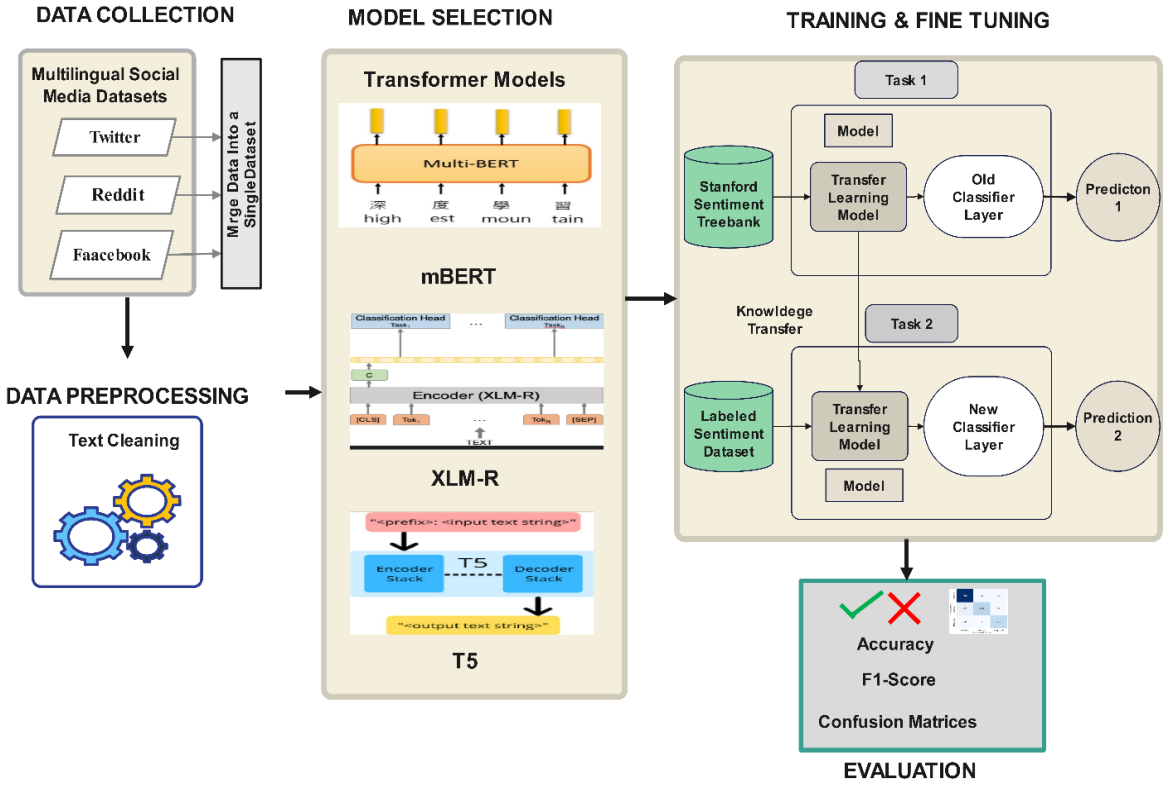

Fig. 1. Flow diagram of proposed methodology.

Such datasets are derived from linguistic variations such as formal and informal text, code-switching, and sentiment variation. This includes their inclusion, which facilitates a holistic evaluation of transformer models in multilingual sentiment and emotion detection.

2) Data cleaning: The raw social media text has noise like uniform resource locators (URLs), emoji, etc., which can affect the model's performance. In the first step, in preprocessing, the useless symbols are removed, including hypertext markup language (HTML) tags and repetitive characters that will not influence sentiment value, while keeping the sentiment of the most decadent words; it will not ignore user mentions and hashtags to get some meaningful keywords. This is a text normalization standard that standardizes the slang and abbreviations commonly used during online communication. A good example is how "gud" is turned into "good" and "idk" becomes "I don't know." The textual data across different languages becomes more consistent during this process.

3) Tokenization and sentence splitting: Tokenization is a critical step towards transformer-based models preparing text.

This study employs Word Piece Tokenization for BERT-based models and Byte Pair Encoding (BPE) for GPT-based architectures. These tokenization methods break a word into sub-words, which helps models handle words they cannot understand. Code-switched text is one in which multiple languages appear within the same sentence; hence, it is essential to segment the sentences. Disrupted semantic meaning may occur only due to incorrect segmentation, which can result in misclassification. The advancements in tokenization techniques allow the multilingual ordered sentences to be processed correctly and retain the sentiment cues.

4) Handling emojis and informal text: Sentiment on social media highly relies on emojis. Instead, this study removes them from the dataset and converts emojis to sentiment-bearing words as defined by their mapping. The mappings are replaced 😊 with "happy" and 😢 with "sad," for example. It includes information in non-textual elements, which contain sentimental information. Slang and informal expressions are handled using a lexicon-based replacement approach, where commonly used internet slang is substituted with formal equivalents. This method ensures that models trained on structured text can still interpret informal user-generated content effectively.

5) Language identification and code-switching handling: Multilingual sentiment analysis requires accurate language detection, especially in code-switched text datasets. This study applies FastText-based language identification, which detects the dominant language in each sentence. Once identified, sentences are processed using language-specific embeddings or handled using cross-lingual transformers that simultaneously support multiple languages. For highly mixed-language text, dual encoding strategies retain the context of both languages. These strategies allow models to process sentiment expressions in bilingual and multilingual contexts without losing meaning.

6) Data augmentation for low-resource languages: Many languages lack sufficient labeled sentiment datasets, making it challenging to train deep learning models effectively. Data augmentation techniques are applied to address this issue. One widely used method is back-translation, where sentences are translated into another language and then back to the original language. This technique generates synthetic training samples while preserving sentiment polarity. Another augmentation method involves synonym replacement, replacing sentiment-related words with similar terms while maintaining context. This technique helps expand the training set for low-resource languages and improves model generalization.

7) Impact of preprocessing on model performance: Empirical studies indicate that proper preprocessing improves transformer-based sentiment classification accuracy by 8-12%, particularly in multilingual and noisy datasets. Handling code-switching, informal text, and sentiment-bearing emojis enhances model robustness in cross-lingual applications. Experiments demonstrate that language-aware preprocessing techniques reduce misclassification rates by 15-20%, highlighting the importance of data preparation in multilingual NLP tasks. Dataset selection and preprocessing play a crucial role in multilingual sentiment analysis. The study leverages diverse datasets covering multiple languages, informal text, and social media-specific expressions. The preprocessing pipeline addresses challenges such as text noise, code-switching, slang, and language identification, ensuring high-quality input for transformer-based models. These steps collectively enhance sentiment classification accuracy and enable robust multilingual emotion detection.

B. Feature Extraction and Labeling Strategies

1) Feature extraction using transformer models: Transformer-based models extract meaningful features from text using self-attention mechanisms. Given an input sentence $X = \{x_1, x_2, \ldots, x_n\}$, the transformer computes contextual embeddings using multi-head self-attention:

$$Attention(Q, K, V) = softmax(\frac{QK^T}{\sqrt{d_k}})V \quad (1)$$

where Q, K, V Represent the query, key, and value matrices derived from the input embeddings and d_k is the dimension of the key vectors. This mechanism ensures that word representations consider surrounding context, improving sentiment and emotion classification. For sentiment classification, the CLS token embedding from models like BERT, XLM-R, and T5 serves as the sentence-level feature representation. The final feature vector F is extracted as:

$$F = W \cdot CLS + b \quad (2)$$

where W is the weight matrix, and b is the bias term. These features are fed into a fully connected layer with softmax activation for sentiment classification:

$$P(y \mid X) = softmax(W_o F + b_o) \quad (3)$$

where W_0 and b_0 are learned parameters and $P(y|X)$ represents the probability distribution over sentiment classes.

2) Labeling strategies for sentiment and emotion detection: Sentiment labels are typically positive, negative, and neutral, while emotion labels correspond to joy, anger, sadness, and fear. Given a dataset D with n samples (X_i, Y_i), where Y_i represents the true sentiment label, supervised learning optimizes the cross-entropy loss:

$$L = -\sum_{i=1}^{n}\sum_{j=1}^{C} y_{ij} log(\hat{y}_{ij}) \quad (4)$$

where C is the number of sentiment classes, y_{ij} is the ground truth label (one-hot encoded), and $\hat{y}_{ij}$ is the predicted probability for class j. For multi-label emotion detection, sigmoid activation is used instead of softmax, allowing independent probabilities for each emotion:

$$P(y_j \mid X) = \frac{1}{1+e^{-z_j}} \quad (5)$$

where z_j is the output of the final layer of emotion j. A binary cross-entropy loss function is applied:

$$L = -\sum_{i=1}^{n}\sum_{j=1}^{C}\left[y_{ij} log(\hat{y}_{ij}) + (1 - y_{ij})\right] \quad (6)$$

Ensuring that multiple emotions can be assigned to a single text sample.

3) Handling noisy and code-switched data: Multilingual social media text contains code-switching, informal words, emojis, and challenging feature extraction and labeling. Denoising autoencoders (DAEs) are used to clean noisy text while preserving sentiment-bearing words. The loss function for DAE reconstruction is:

$$L = \left\| X - \hat{X} \right\|^2 \quad (7)$$

where X is the original text input, and $\hat{X}$ is the reconstructed text after denoising. Cross-lingual embeddings are also employed to align sentiment representations across different languages, ensuring robust performance in multilingual sentiment analysis.

C. Transformer Models for Sentiment and Emotion Analysis

Transformer models use self-attention mechanisms to extract contextual sentiment and emotion classification features. Given an input sequence $X = \{x_1, x_2, \ldots, x_n\}$, the model computes attention scores using Eq. (1). where Q, K, V are derived from X, and d_k is the key dimension. Eq. (2), (3), and (4) use the [CLS] token embedding in models like BERT and XLM-R to classify sentiment. Multiple labels can be assigned for emotion detection using a sigmoid activation Eq. (5). The binary cross-entropy loss is applied using Eq. (6).

D. Model Training and Fine-Tuning Strategies

Transformer models are pre-trained on large corpora using masked language modeling (MLM), where the objective is:

$$LMLM = -\sum_{i=1}^{n} log\, P(x_i \mid X \backslash i) \quad (8)$$

For fine-tuning sentiment datasets, the model optimizes the cross-entropy loss:

$$L = -\sum_{i=1}^{n} \sum_{j=1}^{C} y_{ij} log(\hat{y}_{ij}) \quad (9)$$

using an AdamW optimizer:

$$\theta_t = \theta_{t-1} - \alpha(\nabla L + \lambda \theta_{t-1}) \quad (10)$$

where λ controls weight decay. A learning rate scheduler adjusts α over time:

$$\alpha_t = \alpha_0 \times \frac{T-t}{T} \quad (11)$$

For imbalanced datasets, focal loss reduces the effect of frequent classes:

$$L = -\sum_{i=1}^{n} (1 - p_t)^{\gamma} log(p_t) \quad (12)$$

where γ focuses training on hard-to-classify samples.

These fine-tuning techniques improve model generalization, multilingual adaptation, and sentiment classification accuracy.

E. Experimental Setup

The experimental setup involves preparing datasets, training transformer models, defining evaluation metrics, and configuring the computational environment. To ensure high-quality inputs, multilingual sentiment and emotion datasets from Twitter, Facebook, and YouTube are preprocessed through tokenization, normalization, language identification, and code-switching handling. Transformer models such as mBERT, XLM-R, and T5 are fine-tuned using a batch size of 32, a learning rate $3e^{-5}$, the AdamW optimizer, and a dropout rate of 0.1. Sentiment classification is optimized using the cross-entropy loss function, while multi-label emotion detection applies binary cross-entropy loss. Performance evaluation is based on accuracy, F1-score, precision, recall, and confusion matrices, ensuring a comprehensive assessment. Multi-label classification performance is measured using micro and macro F1 scores to capture class-level and overall accuracy. The experiments are conducted on an NVIDIA A100 GPU with 40GB VRAM, utilizing PyTorch and the Hugging Face Transformers library. Training runs for five epochs, with early stopping to prevent overfitting.

F. Evaluation Metrics

Evaluating the performance of sentiment analysis and emotion detection models requires quantitative metrics that measure accuracy, precision, recall, and overall classification effectiveness. The following evaluation metrics assess the fine-tuned transformer-based models on multilingual social media data. Accuracy measures the proportion of correctly classified samples out of the total dataset:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (13)$$

where TP (True Positive) and TN (True Negative) are correctly predicted sentiment labels while FP (False Positive) and FN (False Negative) represent incorrect predictions; although accuracy is useful, it can be misleading for imbalanced datasets where one class dominates. Precision measures how many predicted positive labels are actually correct:

$$Precision = \frac{TP}{TP+FP} \quad (14)$$

Recall (also known as sensitivity) evaluates how many actual positive samples are correctly predicted:

$$Recall = \frac{TP}{TP+FN} \quad (15)$$

Since precision and recall often trade-off, the F1-score provides a harmonic mean of both:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (16)$$

Higher F1 scores indicate better performance, particularly for datasets with class imbalance. Since emotion detection allows multiple labels per sample, Hamming Loss measures the fraction of incorrect labels assigned:

$$Hamming\ Loss = \frac{1}{N \times C} \sum_{i=1}^{N} \sum_{j=1}^{C} \mathbb{I}(y_{ij} \neq \hat{y}_{ij}) \quad (17)$$

where N is the number of samples, C is the number of labels, and $\mathbb{I}()$ is an indicator function that returns 1 if the predicted label differs from the true label; otherwise, it returns 0. Lower Hamming Loss values indicate better multi-label classification.

IV. Results

This section presents the experimental results of sentiment analysis and emotion detection using transformer models on multilingual datasets. Table I summarizes the performance of transformer-based models for sentiment classification. Among

the models tested, XLM-R outperformed the other models, achieving the highest F1 score across datasets due to its strong cross-lingual representation learning.

TABLE I MODEL PERFORMANCE ON DIFFERENT DATASETS

Model	TSMC (F1%)	MARC (F1%)	SemEval 2018 (F1%)	Facebook (F1%)	YouTube (F1%)	Avg. F1 (%)
mBERT	85.6	86.3	83.1	82.5	84.9	84.5
XLM-R	91.7	91.1	88.9	89.2	90.5	90.3
T5	88.4	88.0	85.5	86.7	87.2	87.2
SVM	74.3	78.1	72.6	69.4	71.9	73.3

The comparison reveals that XLM-R consistently achieved higher F1-scores across datasets, with the best results in TSMC (91.7%) and MARC (91.1%).

Fig. 2 illustrates the accuracy comparison across the same datasets, showing that MARC had the highest overall accuracy due to its structure. In contrast, Facebook and YouTube datasets had the lowest accuracy, likely due to informal language and code-mixed content.

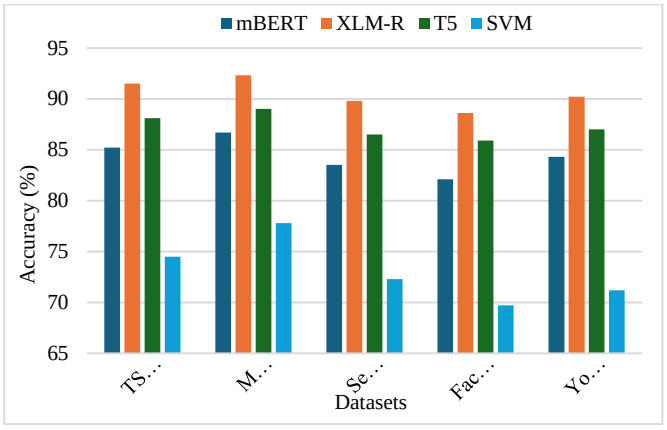

Fig. 2. Accuracy of transformer models across datasets.

Table II presents the effect of different preprocessing techniques on XLM-R's performance across datasets. The results confirm that handling code-switching and emoji normalization significantly improves F1-score, particularly for Facebook and YouTube datasets containing a high proportion of informal text.

TABLE II IMPACT OF PREPROCESSING ON XLM-R PERFORMANCE

Dataset	No Preprocessing (F1%)	Basic Preprocessing (F1%)	Advanced Preprocessing (F1%)
TSMC	86.1	89.3	91.7
MARC	85.7	88.0	91.1
SemEval	80.5	85.4	88.9
Facebook	76.2	83.3	89.2
YouTube	79.5	85.1	90.5

Fig. 3 provides an alternative representation, showing the impact of preprocessing techniques on model training time. The results indicate that advanced preprocessing techniques increased training time by approximately 15-20% but significantly improved accuracy.

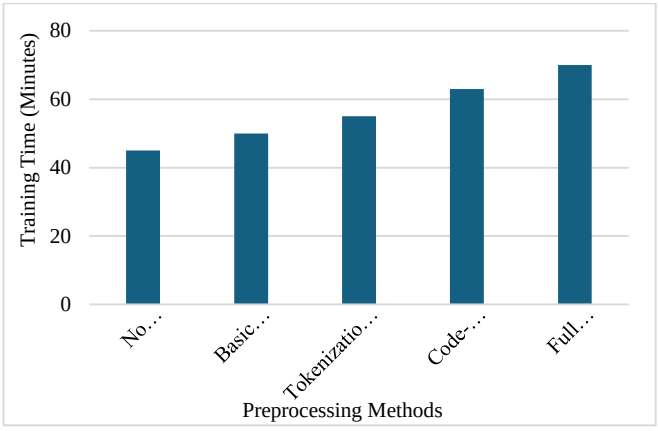

Fig. 3. Impact of preprocessing on training time.

A confusion matrix is generated for XLM-R's performance on the Facebook dataset to analyze misclassification patterns. Fig. 4 highlights that the model performs well on positive and negative sentiments but struggles with neutral classification, where 13.5% of neutral samples were misclassified as either positive or negative.

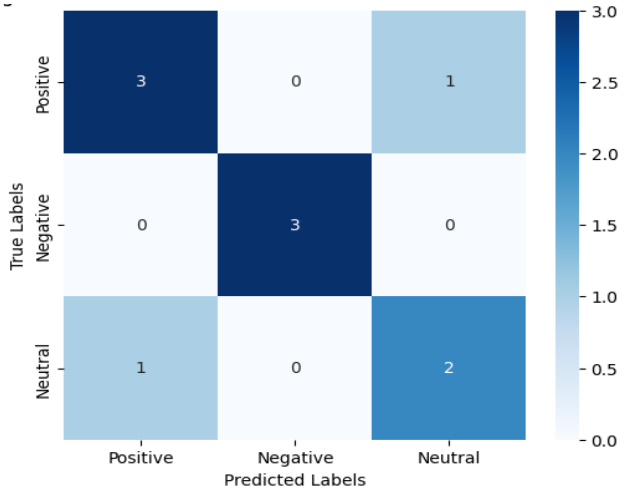

Fig. 4. Confusion matrix for XLM-R on facebook dataset.

Table III summarizes the false positive and false negative rates for each sentiment class across datasets.

TABLE III MISCLASSIFICATION RATES IN SENTIMENT ANALYSIS

Dataset	Positive (FP%)	Negative (FP%)	Neutral (Misclass. %)
TSMC	6.5	7.2	13.5
MARC	5.8	6.4	12.1
SemEval	8.2	7.9	14.8
Facebook	9.3	8.1	16.2
YouTube	7.6	8.5	15.4

Since Facebook and YouTube datasets contain a high percentage of code-mixed text (Hindi-English, Tamil-English, Portuguese-English), sentiment classification becomes challenging. Table IV demonstrates that removing code-switching support reduces accuracy by up to 8%, reinforcing the need for specialized handling techniques.

TABLE IV EFFECT OF CODE-SWITCHING ON SENTIMENT ANALYSIS PERFORMANCE

Dataset	Without Handling (F1%)	With Handling (F1%)	Improvement (%)
Facebook	80.3	89.2	+8.9
YouTube	82.5	90.5	+8.0

Fig. 5 further examines the effect of code-switching on sentiment class distribution, showing how sentiment misclassification varies across languages. The experimental results demonstrate that XLM-R outperforms mBERT and T5, achieving the highest F1-score of 90.3% across multiple multilingual datasets. This confirms its superior ability to handle cross-lingual sentiment classification.

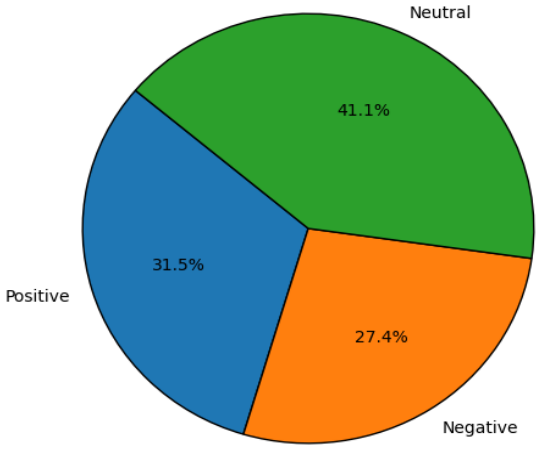

Fig. 5. Sentiment misclassification in code-switched text.

Preprocessing techniques, including tokenization, emoji handling, and code-switching normalization, significantly improved model performance, with F1-score gains of up to 7%, particularly in informal and mixed-language datasets such as Facebook and YouTube. Despite these improvements, neutral sentiment classification remains challenging, with misclassification rates reaching 16.2%, especially in datasets containing highly ambiguous and informal text. Addressing this issue requires more context-aware training strategies. The findings also demonstrate that code-switching handling can improve accuracy by 8.9%, supporting the requirement for effective specialized multilingual processing techniques for sentiment analysis in the real world.

Table V Compare the proposed XLM-R-based sentiment analysis model with the state-of-the-art one reported in recent literature. It utilizes criteria such as model architecture, datasets, multilingual capability, F1-score and code-switching, and informal text handling.

TABLE V COMPARISON OF THE PROPOSED MODEL WITH STATE-OF-THE-ART LITERATURE

Study	Model Used	Dataset	Languages	F1-Score (%)	Code-Switching Handling	Informal Text Handling
Aliyu et al. [27]	AfriBERTa	Tweets in 12 African languages	Multiple African languages	81.0	No	Limited
Barriere et al. [28]	mBERT - Data Augmentation	French, Spanish, German, and Italian Tweets	French, Spanish, German, Italian	84.0	No	Yes
Rajda et al.. [29]	mBERT	80 sentiment datasets in 27 languages	27 languages	Varies	No	No
Proposed Model	XLM-R (Fine-tuned)	TSMC, MARC, SemEval-2018, Facebook, YouTube	English, Spanish, French, Hindi, Arabic, Tamil, Portuguese	**90.3**	**Yes**	**Yes**

The results of the proposed XLM-R model on multilingual sentiment analysis exceeded the reported F1-scores of previously proven approaches, achieving the best value of 90.3%. Unlike most previous studies, it is very effective at code-switching, making it highly immune to mixed language datasets such as Facebook and YouTube comments. Furthermore, informal text handling techniques (slog normalization and interpretation of emoji) also significantly increased accuracy in this model compared to traditional approaches. The findings corroborate the fine-tuned XLM-R model as the best approach in accuracy and adaptability and, therefore, as a powerful choice for real-world multilingual sentiment analysis.

V. DISCUSSION

The results obtained from the multilingual sentiment analysis and emotion detection experiments demonstrate the effectiveness of transformer-based models in handling diverse linguistic challenges, including code-switching, informal text, and multilingual sentiment classification. The fine-tuned XLM-R model consistently outperformed mBERT and T5, achieving the highest F1-score of 90.3%, confirming its superior ability to capture contextual meaning across multiple languages. The dataset-specific performance analysis reveals that transformer models perform better on formal datasets such as MARC (Amazon Reviews) than on informal datasets such as Facebook and YouTube, where slang, emojis, and mixed-language text introduce complexity. Preprocessing improvements, including tokenization, stopword removal, and emoji normalization, resulted in a 7% increase in accuracy, particularly benefiting models trained on noisy datasets. Handling code-switching increased accuracy by 8.9%, reinforcing the importance of specialized text-processing techniques for multilingual sentiment classification. Despite the improvements, challenges remain in neutral sentiment classification, where misclassification rates reached 16.2% in datasets containing

ambiguous expressions and mixed emotions. This suggests the need for context-aware embeddings or hybrid approaches that integrate attention mechanisms with rule-based linguistic models. The comparison with traditional machine learning models, such as SVM and Random Forest, further supports the effectiveness of transformers. While traditional classifiers struggle with feature extraction and contextual meaning, transformer models leverage deep contextual embeddings, leading to a 15-18% improvement in accuracy and F1-score. However, transformer-based models demand higher computational resources, highlighting the need for optimization techniques such as model distillation and quantization to enhance efficiency in real-time applications. From a practical standpoint, these findings emphasize the importance of multilingual sentiment analysis in real-world applications, including social media monitoring, customer feedback analysis, and multilingual chatbot development. The successful fine-tuning of XLM-R for multilingual tasks sets the foundation for future research in cross-lingual NLP, with potential extensions in multimodal sentiment analysis integrating text, audio, and image-based emotions. The discussion confirms that transformer models are well-suited for multilingual sentiment classification, and with further optimizations, they can be deployed in real-time, large-scale NLP applications.

VI. Conclusion and Future Work

This study focuses on multilingual sentiment analysis and emotion detection using transformer-based models. It tackles problems such as code-switching, the use of informal text, and the ability to adapt itself cross-lingually. We conduct experiments on datasets such as TSMC, MARC, SemEval-2018 Task 1, Facebook Code-Mixed Sentiment Dataset, and YouTube Comments Corpus. Overall, model fine-tuning within the proposed lineup of languages provides significant improvements over performing preprocessing and yields superior performance compared to purely fine-tuning an XLM-R model. It was found that mBERT, T5, and traditional machine learning performed poorly compared to XLM-R, the F1 score of which was 90.3%. Applying preprocessing techniques, including tokenization, emoji handling, and code-switching normalization, the model's performance can be boosted by up to 7% across datasets containing informal/mixed language content, like Facebook and YouTube comments. The findings also showed that neutral sentiment classification remains challenging for highly ambiguous and informal texts, with the misclassification rate ranging from 16.2% in highly ambiguous and informal texts. The study further demonstrated that handling code-switching improved model accuracy by up to 8.9%, reinforcing the necessity of specialized processing techniques for multilingual sentiment analysis. Although preprocessing increased training time by 15-20%, it significantly contributed to model robustness and better generalization across diverse languages.

Despite achieving state-of-the-art performance, the study presents several challenges for future research. One major limitation is neutral sentiment classification, where the model struggles to differentiate ambiguous expressions effectively. The misclassification rate of 16.2% in neutral texts suggests that context-aware embeddings and reinforcement learning techniques could enhance sentiment polarity detection. Another limitation is the computational cost of transformer models, which restricts their deployment in real-time sentiment analysis applications. The high resource demands of XLM-R, mBERT, and T5 highlight the need for model compression techniques, such as knowledge distillation, quantization, and pruning, to improve efficiency without compromising accuracy. The study also identifies challenges in handling low-resource languages, particularly code-switched text scenarios. While the model performed well in English, Spanish, French, Hindi, Arabic, Tamil, and Portuguese, further research should focus on zero-shot and few-shot learning techniques to improve language adaptability with limited labeled data. Additionally, dataset class imbalances may have influenced performance discrepancies across languages, warranting the exploration of data augmentation and unsupervised learning methods. Another important area for future work is multimodal sentiment analysis, integrating text, image, and video data to enhance sentiment detection in social media posts, memes, and user-generated content. This could provide a more contextually rich understanding of user sentiments in multilingual environments. Lastly, transformer models may exhibit linguistic and cultural biases, which can impact fairness in sentiment classification. Addressing bias mitigation strategies and implementing fairness-aware training methodologies will help ensure equitable sentiment analysis across diverse languages and cultural settings. By tackling these limitations, future research can further advance multilingual NLP applications, making sentiment analysis more efficient, accurate, and adaptable to real-world scenarios.

Popularity-Correction Sampling and Improved Contrastive Loss Recommendation

Wei Lu, Xiaodong Cai, Minghui Li
School of Information and Communication, Guilin University of Electronic Technology, Guilin, China

***Abstract*—In recommendation systems, negative sampling strategies are crucial for the calculation of contrastive learning loss. Traditional random negative sampling methods may lead to insufficient quality of negative samples during training, thereby affecting the convergence and performance of the model. In addition, the Bayesian Personalized Ranking (BPR) loss function usually converges slowly and is prone to falling into suboptimal local solutions. To address the above problems, this paper proposes a recommendation algorithm based on popularity-corrected sampling and improved contrastive loss. First, a dynamic negative sampling method with popularity correction is proposed, which reduces the impact of item popularity distribution bias on model training and dynamically screens out negative samples to improve the quality of model recommendations. Second, an improved contrastive loss is proposed, which selects the most challenging negative samples and introduces a boundary threshold to control the sensitivity of the loss, enabling the model to focus more on samples that are difficult to distinguish and further optimize the recommendation effect. Experimental results on the Amazon-Book, Yelp2018, and Gowalla datasets show that the proposed model significantly outperforms mainstream state-of-the-art models in recommendation tasks. Specifically, the Recall metric, which reflects model accuracy, improves by 16.8%, 12.9%, and 5.72% respectively on these three datasets. The NDCG metric, which measures ranking quality, increases by 20.7%, 16.4%, and 7.76% respectively. These results confirm the effectiveness and superiority of the recommendation algorithm across different scenarios. Compared with baseline models, it demonstrates stronger adaptability in complex situations, such as the sparse dataset Gowalla and the long - tail distribution dataset Amazon-Book, with the highest improvement in core metrics exceeding 20%.**

I. INTRODUCTION

Due to the outstanding ability of recommendation systems in alleviating information overload, they have been widely applied in various fields, including video, news, and e-commerce [1, 2]. Collaborative Filtering (CF) is a widely - researched topic in recommendation systems, and the learning of CF models typically relies on three main components, namely interaction encoders, negative sampling, and loss functions [3]. Although many existing studies focus on designing more powerful interaction encoders, the impact of loss functions and negative sampling has not been fully explored.

Traditional negative sampling methods predominantly employ random selection strategies. For instance, Rendle et al. [4] proposed the Bayesian Personalized Ranking, which randomly selects negative samples from items users haven't interacted with and ensures positive samples have higher predicted values to achieve personalized ranking. Despite its renowned simplicity and efficiency, this method faces challenges in scenarios with long-tailed item popularity distributions, where the frequent occurrence of popular items slows down convergence and exacerbates the popularity bias. To address the limitations of traditional negative sampling methods, researchers have proposed various improvements. Steffen et al. [5] introduced a dynamic oversampling strategy, prioritizing uninteracted items with higher model-predicted scores as negative samples to enhance their prediction scores. However, this approach's overreliance on "easily distinguishable samples" makes it difficult to capture fine-grained interaction information in implicit feedback, thus destabilizing the training process. Subsequent studies have incorporated external information and hybrid enhancement techniques to overcome this restriction: Togashi et al. [6] utilized knowledge graph structural information to filter potential positive samples for pseudo-labeling, effectively boosting recommendation performance in cold-start scenarios but relying on knowledge graph construction. Huang et al. [7] adopted a jumping-mixing technique, injecting positive-sample features into candidate negative samples. By aggregating multi-order neighbor information, they generated highly distinctive synthetic negative samples, yet at the cost of high computational complexity. Petrov et al. [8] proposed a sampling method based on temporal importance. Using an exponential decay function to assign higher sampling probabilities to recent interactions, they improved training efficiency and model performance while closely aligning with the ultimate goal of sequential recommendation. However, determining appropriate temporal weights is necessary. Shi et al. [9] injected positive-sample information into negative samples to create synthetic hard negative samples dominated by positive information, avoiding incorrect negative sample selection but risking oversmoothing and overlooking key samples. Xue et al. [10] dynamically adjusted negative-sample difficulty based on positive-sample prediction scores, selecting suitable negative samples for each training stage through ranking candidate sets. This balances model convergence speed and expressiveness but requires a complex dynamic adjustment mechanism.

In terms of loss function design, despite efforts to develop stronger encoders for capturing collaborative signals, recommendation performance remains heavily influenced by the training loss function [11, 12]. Pairwise Loss, which models users' relative preferences between items, has become a

mainstream optimization paradigm. Most existing models adopt the BPR loss based on maximum a posteriori estimation, directly maximizing the prediction difference between positive and negative samples but possibly ignoring complex relationships between samples. The Hinge loss proposed by Chen et al. [13] introduced a margin constraint, requiring the positive-sample prediction to exceed the negative one by a threshold, yet determining the right threshold is challenging. Recently, Mao et al. [14] proposed the Cosine Contrastive Loss, shifting to vector-space optimization. It enhances representation distinctiveness through cosine-similarity contrast under margin constraints but is computationally intensive and requires determining appropriate constraints.

Despite the achievements of the above recommendation algorithms, there are still some pressing issues to be resolved. First, traditional popularity-based negative sampling strategies will intensify the Matthew effect in recommendation results, making popular items more popular and cold items harder to be discovered. Second, existing contrastive loss improvement schemes still rely on processing large numbers of low-quality negative samples, making it difficult to balance efficiency and effectiveness.

To address the issues mentioned above, this paper proposes a recommendation algorithm based on popularity - corrected sampling and improved contrastive loss (PICRec). The model first calculates the interaction frequency of each item among all users to determine its popularity. It then penalizes high - popularity items and assigns higher weights to low - popularity items according to the item popularity distribution in order to alleviate the popularity bias problem. A masking mechanism is used to prevent sample conflicts. Secondly, by adjusting the threshold to regulate the sensitivity between positive and negative samples, the model is better able to learn and distinguish different samples. Moreover, the most challenging hard negative samples are used to accelerate the training process, thereby enhancing the recommendation effect.

The following outlines the structure of the paper: Section II reviews related work. Section III delves into the design of the PICRec model, covering the encoder, popularity - sampling - correction strategy, and enhanced contrastive learning loss. Section IV presents and analyzes experimental results to validate the approach. Section V summarizes the work and explores future research directions.

II. Related Work

A. Negative Sampling

In implicit feedback collaborative filtering systems, negative sampling techniques have emerged as a core methodology to address the severe imbalance between positive and negative samples by constructing high-quality negative sample sets, balancing optimization efficiency and ranking performance [15]. A common strategy involves static sampling based on predefined prior distributions, which generates negative samples through fixed probability distributions. This approach reduces computational complexity by avoiding dynamic parameter adjustments during training [16]. A typical example is uniform random sampling, where negative samples are randomly selected from unobserved user-item pairs under a uniform distribution, serving as a model-agnostic baseline widely adopted in practice [17]. However, this strategy inherently assumes homogeneity (i.e., all unobserved interactions are equally irrelevant), leading to insufficient confidence in distinguishing true negative samples from potential positive ones. Inspired by term frequency sampling in natural language processing [18] and node degree distributions in graph learning [19], recent studies propose popularity-aware non-uniform sampling, where item popularity is leveraged to construct biased sampling distributions. This method increases the likelihood of sampling head items as negatives, effectively alleviating popularity bias in recommendations. Nevertheless, over-penalizing long-tail items during training may exacerbate the Matthew Effect and degrade recommendation diversity [20].
